The Fort Frances load meeting capability is limited to 82 MW inclusive of approximately 3 MW of 98th percentile winter dependable hydro generation output from Fort Frances GS. This load meeting capability is the maximum total amount of load that can be served at Fort Frances MTS, Burleigh DS, and a new hypothetical load directly served on the Fort Frances TS 115 kV bus. It does not include load served on K6F. To achieve this load meeting capability, two new 25 MVar capacitor banks are assumed to be installed on the Fort Frances TS 115 kV bus to manage pre-contingency voltages. The load meeting capability is limited by post-contingency voltage decline on the Fort Frances TS 115 kV bus following the loss of F25A as shown in Table 6-5. The F25A contingency has a significant impact on 115 kV bus voltages because it removes one of the Fort Frances TS transformers (and the existing capacitor bank on its tertiary winding) by configuration. Note that for the purpose of deriving a conservative load meeting capability, a constant MVA load model was used as opposed to a voltage dependent load model.

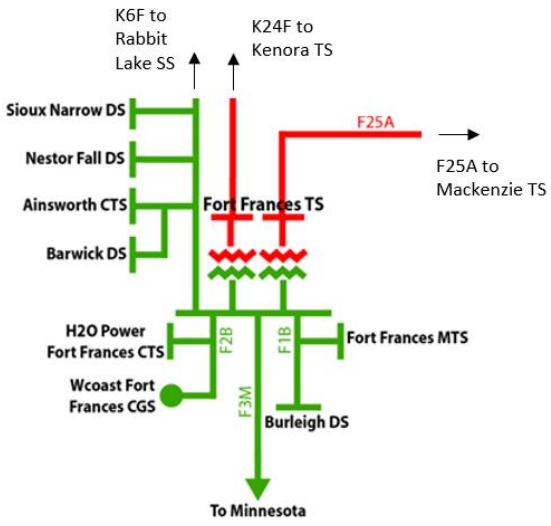

Figure 6-12 | Fort Frances Subsystem

Figure 6-13 below shows the Fort Frances subsystem winter peak demand forecast and associated load meeting capability.

Table 6-5 | Post-Contingency (F25A N-1) Voltage Change (82 MW Fort Frances Subsystem Total Demand)

Station/Bus	Pre-Cont Voltage	Post-Cont Pre-ULTC Voltage	Post-Cont Post-ULTC Voltage
Fort Frances TS (230 kV)	240 kV	234 kV	228 kV
Fort Frances TS (115 kV)	123 kV	110 kV (10% decline)	116 kV

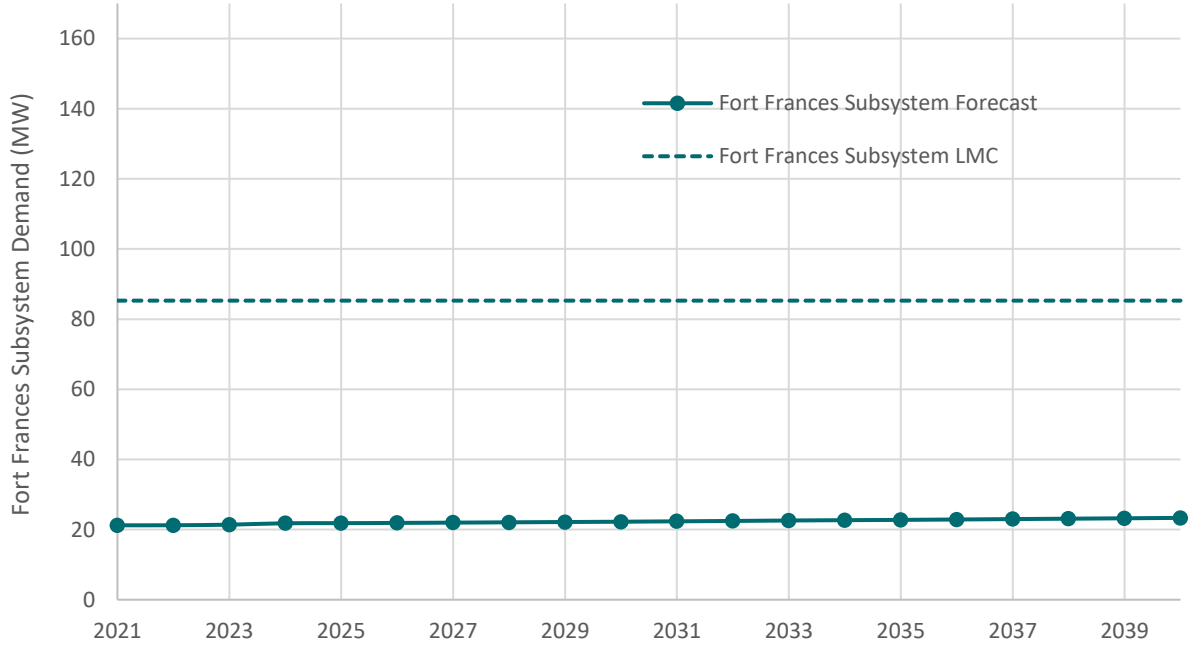

Figure 6-13 | Fort Frances Subsystem Load Meeting Capability and Demand Forecast

7. Options Considered and Recommendations

This section describes the options considered and recommendations to address the near- to medium-term needs identified in section 6. This section is organized as follows:

Section 7.1 describes the options considered for the Margach DS, Crilly DS, and Kenora MTS station capacity needs. This includes a discussion of how each station capacity need was screened for non-wires alternative suitability and, where there were promising non-wires opportunities, the options considered and financial analysis.

Section 7.2 explores configuration options to improve customer reliability at Fort Frances TS. These options will inform the Regional Infrastructure Plan where a final configuration will be chosen.

Note that the recommendation for the E1C operations and high voltage need can be found in Section 6.2.3 and will not be further discussed in this section.

7.1 Options and Recommendations for Station Capacity Needs

7.1.1 Methodology and Options Considered

There are two approaches for addressing station capacity needs:

- Build new infrastructure to increase station capacity. This is commonly referred to as a "wires" option and typically entails upsizing the existing station (e.g., replacing transformers with higher rated transformers or adding additional transformers) or building a new station to supply incremental demand growth. Wires options may also include modifications to or the addition of other power system equipment such as voltage regulation devices, switches, or breakers.

- Install or implement measures to reduce net peak demand to maintain loading within existing station capacity. This is commonly referred to as a "non-wires" alternative and can include options like energy storage, local distributed generation, demand response, conservation and demand management, or any combination of the above. Note that centrally delivered energy efficiency measures under the 2021-2024 Conservation and Demand Management framework are already included in the load forecast, as discussed in Section 5.2.2. Additional conservation and demand management can be considered as a non-wires alternative.

While wires options typically provide a step-change increase in capacity and are available in all hours, non-wires alternatives are more targeted and must account for the frequency and duration of the capacity need in addition to its magnitude. Therefore, identifying suitable technology types, sizing options, and simulating their discounted cash flows are significantly more complex for non-wires alternatives than wires options.

Non-wires alternatives are not suitable for all station capacity needs and there are often qualitative factors that rule out the use of non-wires alternatives. Before carrying out options analysis, a screening process is first applied to determine the suitability of non-wires alternatives for each need that considers the characteristics of the demand growth, the technical feasibility of non-wires alternatives to address the limiting phenomena, and any additional factors that would complicate or facilitate the implementation of non-wires alternatives. For stations where non-wires alternatives are suitable, the IRRP carries out options analysis as described below.

High-level cost estimates for wires options are usually provided by the transmitter. In contrast, cost estimates for generation and other non-wires alternatives are based on benchmark capital and operating cost characteristics for each resource type and size. Note that the error margin in cost estimates is significant at the planning stage (-50% to +100%); they are only intended to enable comparison between options during the IRRP. Material and labour costs have increased rapidly over the COVID-19 period and there is a high degree of uncertainty in future costs. Wires option costs can be reviewed in the Regional Infrastructure Plan before implementation work begins and the Working Group will revisit recommendations if cost estimates differ significantly. Actual non-wires alternative costs can also vary significantly from the benchmark estimates used in the IRRP depending on local market constraints at the time of implementation. The entity responsible for implementing the non-wires alternative (for station capacity needs, this will typically be the local distribution company) will only implement the alternative if it remains cost effective. Subsequent regional planning activities will be triggered if future costs differ significantly from those in the current IRRP.

For non-wires options, upfront capital and operating costs are compiled to calculate the levelized unit energy cost ($/MW-year). Similarly, an annual revenue requirement ($/year) is compiled for wires options. For each option, a discounted cash flow model is created which includes the levelized unit energy cost or annual revenue requirement as well as bulk system energy and capacity costs where applicable. Note that, in order to enable an apples-to-apples comparison, the discounted cash flow for the non-wires options includes a credit for the bulk system capacity value it provides. The discounted cash flow model for all options is compiled over the lifespan of the longest option considered (typically 70 years for wires options). The net present value (in 2021 CAD dollars) of these cash flows are the primary basis through which options are compared.

A list of the assumptions made in the economic analysis can be found in Appendix E.

7.1.2 Options and Recommendation for Crilly DS

Crilly DS is expected to reach capacity in 2027. Crilly DS is a small (LTR of ~2.2 MW) station supplied from a bus shared with Sturgeon Falls CGS, a small hydroelectric plant approximately 50 km west of Atikokan. This is a non-standard supply arrangement that results in annual outages to Crilly DS when the generator is undergoing maintenance. Diesel generation is currently used for backup power whenever Sturgeon Falls is on outage. Furthermore, the existing station equipment will reach end-of-life over the next ~10 years and space constraints limit in situ refurbishment options.

Non-wires alternatives are not suitable for Crilly DS due to three factors. First, non-wires alternatives will not be able to eliminate nor reduce existing reliance on backup generation. Load modifying non-wires alternatives (e.g., energy efficiency measures or demand response) could potentially reduce peak demand and overall energy consumption but, when transmission supply is interrupted due to Sturgeon Falls outages, they cannot replace the need for backup generation. Similarly, distributed energy resources can reduce peak demand below the station LTR but, during outages, the distribution system served by Crilly DS must still rely on backup diesel generation. Frequent reliance on backup diesel generation results in poor reliability and is technically challenging due to difficulties in staying connected and maintaining power quality when supplying loads on a long single-phase distribution line. The long-term solution for Crilly DS station capacity should ideally provide reliability on par with other single circuit supply stations (where regular supply interruptions are not required for generator maintenance outages).

Second, structures and equipment at Crilly DS are approaching end-of-life in the near future. While the specific end-of-life dates vary based on asset conditions, existing structures and equipment are expected to require refurbishment/replacement over the next 10 years. Even if non-wires alternatives can address overloads due to incremental growth above the current station capacity, the station must still be rebuilt/refurbished at end-of-life.

Third, Crilly DS serves a small pool of customers (approximately 500 homes and businesses) in a remote location. This customer pool is too small to cost-effectively target energy efficiency or demand response measures since the overhead costs will likely be prohibitive compared to the potential savings in deferred or upsized infrastructure. Furthermore, while voluntary energy efficiency and demand response programs can produce predictable results when applied over large populations, the demand savings when targeted to a small group of customers is unreliable.

Since non-wires alternatives are not suitable for Crilly DS, Hydro One Distribution is considering the follow wires options:

- Refurbish Crilly DS at its current location (and continue to rely on backup power during outages),

- Rebuild Crilly DS at a different location as a 115/25 kV HVDS (close to the existing station/supply point),
- Rebuild Crilly DS at a different location as a 230/25 kV HVDS (connected to F25A closer to the community served by Crilly DS), or
- Replace Crilly DS with 115:25 kV padmount transformer (transformer enclosed in a grounded cabinet that can be accommodated outside the existing station fence).

The cost of these wires options ranges from $7.5-15M (including line work required for connection) and will address both the station capacity and end-of-life needs. Refurbishing Crilly DS at its current location is likely the least costly option but is undesirable due to the continued reliance on backup power. Furthermore, the incremental capacity that can be accommodated at the existing location may be limited due to the space constraints. Rebuilding Crilly DS as a full HVDS (either at 115 kV or 230 kV) would offer the best reliability and performance but also at the greatest cost. Replacing Crilly DS with a padmount transformer may be a more cost-effective option but there are still technical hurdles to be further investigated such as the ability for 115 kV protections to be accommodated within a padmount configuration.

Since non-wires alternatives are not suitable and there are no upstream supply capacity needs that require further regional coordination, the IRRP recommends that Hydro One Distribution conduct local planning, in coordination with the Regional Infrastructure Plan, to refine refurbishment/new station options identified in the IRRP with the goal of balancing reliability improvements and cost.

7.1.3 Options and Recommendation for Margach DS

Margach DS is expected to reach capacity in 2023 due to a large existing industrial customer seeking to be resupplied from a nearby CTS. Margach DS is approximately 10 km east of Kenora.

Non-wires alternatives are not suitable for addressing the Margach DS station capacity need due to the timing and magnitude of the demand increase. Resupplying the large industrial customer causes the forecast demand at Margach DS to jump by 40% from 2022 to 2023. Energy efficiency measures are typically only feasible if the demand exceeding station capacity is a small percentage of the total demand in each year. Similarly, historical zonal demand response auction data indicates that demand response is only feasible to reduce peak demand levels by single digit percentages. While distributed generation can technically be sized to accommodate any demand growth (within station short circuit and thermal limitations) this would functionally be the same as the new customer self-generating rather than seeking grid supply and is unlikely to be cost effective. The near-term timing of the demand growth is also problematic for implementing non-wires alternatives since many of the technical and regulatory barriers for implementing non-wires alternatives are still being tested.

The IRRP recommends that Hydro One Distribution install transformer fan monitoring which will increase the station capacity above forecast demand levels. Installing fan monitoring is an inexpensive method to increase the station LTR by enabling the use of higher thermal ratings on the existing transformers. The cost of installing fan monitoring is in the range of $1-1.5M compared to the cost of adding a new transformer which would be greater than $3M. Fan monitoring will increase the station capacity from approximately 10 MW today to 16 MW.

If additional capacity needs arise, a second transformer at the station which currently acts as a spare can be brought into service, but no recommendation beyond the fan monitoring is required based on the current forecast.

7.1.4 Options and Recommendations for Kenora MTS

Kenora MTS serves the City of Kenora and is expected to reach capacity in 2029 with a moderate annual growth rate of 1.25%. The station has an LTR of 23.4 MW and demand will exceed the LTR by approximately 4 MW by the end of the forecast horizon (2040).

Non-wires alternatives are promising for addressing the Kenora MTS station capacity need. The magnitude of the need relative to the total demand is moderate which makes targeting load modifying non-wires alternatives like energy efficiency and demand response feasible. The timing of the need is in the mid-term, so the forecast confidence is reasonably high while still having adequate lead time to demonstrate the efficacy of relatively untested non-wires alternatives and navigate technical and regulatory barriers. The timing of the need also means that lessons learned from the IESO's York Region Non-Wires Alternative Demonstration Project can be leveraged for implementing non-wires alternatives for Kenora MTS.

The following subsections discuss the wires options for Kenora MTS, non-wires alternatives, and recommendations.

7.1.4.1 Wires Options

There are two high-level wires options:

- Expand Kenora MTS with an additional transformer and associated protections, control, and structures at a cost of approximately $5M. This can be accommodated on existing land owned by the distributor, Synergy North, within the station. This option assumes that feeder loads can be rebalanced and servicing these loads on existing distribution system infrastructure is possible.

- Construct a new substation located across the city from the existing station at a cost of approximately $30M. The new station would be supplied from Rabbit Lake SS.

The existing Kenora MTS station is located on the northern edge of the city. The proposed new substation would be located on the far west side of the city and, in addition to addressing station capacity needs, would provide substantial distribution system benefits by reducing the length of feeders required to reach customers and improving voltage and frequency regulation. The long feeders to the western parts of the system currently experience voltage and frequency issues especially during outages requiring parts of the distribution system to be resupplied from alternate feeders. Synergy North is also aware of significant development interest along the western outskirts of the city, but no formal agreements have been finalized. A new station would provide a supply point close to these customers and improve distribution system performance.

A new station would also provide a redundant transmission supply point that is connected to a different bus/breaker at Rabbit Lake SS than the existing station. If a new station is built, the distribution system could be designed with tie points and reclosers to enhance the overall reliability across Kenora.

The distribution system benefits above have only been qualitatively described in the IRRP. As discussed in the following subsections, the cost effectiveness of the non-wires alternatives may hinge on whether they can provide similar distribution system benefits as a new station. Future analysis by Synergy North should further quantify the value of these benefits.

7.1.4.2 Non-wires Alternatives

Three non-wires alternatives for Kenora MTS were identified and sized according to the characteristics of the hourly demand profile described in Section 5.6:

- A 4 MW gas generation facility (aero engine). The cost estimate for gas generation is based on the IESO's internal benchmark cost reports. To estimate its contribution to provincial system adequacy, its effective capacity was assumed to be 93% of its installed capacity, which is the lesser of its unforced capacity and the zonal capacity maximums reported in the 2021 IESO Annual Planning Outlook.[22]

- A 6-hour 4 MW (24 MWh) battery. The cost estimate for battery storage is based on data from the National Renewable Energy Laboratory. Note that local generation (e.g., wind or solar) was not required to complement the battery due to the relatively low energy requirement (i.e., the battery can be recharged from existing grid power when it is not needed).

[22] The 2021 Annual Planning Outlook is available on the IESO's Planning and Forecasting webpage.

- A combination of energy efficiency measures and demand response. The availability and cost of incremental energy efficiency measures (i.e., in addition to the conservation and demand management programs already included in the demand forecast) are based on the IESO's 2019 Conservation Achievable Potential Study[23]. The 2019 Achievable Potential Study and incremental energy efficiency savings for Kenora MTS are further described in Appendix E. Demand response costs are estimated from average capacity auction values from 2018-2021 for the Northwest zone.

The net present value (NPV) of each wires and non-wires alternative's cost is shown in Table 7-1. The NPV includes the levelized unit energy cost as well as bulk system energy and capacity costs and benefits associated with each option over a 45-year asset life (which is typical for station equipment).

Table 7-1 | Kenora MTS Wires and Non-wires Alternative Costs

Option	Cost NPV ($2021 Real)
Expand Kenora MTS	$4 M
New Station	$25 M
4 MW Gas Generation	$22 M[24]
24 MWh Battery Storage	$10 M[24]
Combination of Energy Efficiency and Demand Response	$1-9 M[25]

7.1.4.3 Recommendation

The cost of the non-wires alternatives generally falls between the cost of expanding the existing station and a new station (which also improves reliability and performance on the distribution system). Therefore, the decision to pursue non-wires alternatives versus traditional wires options rests on distribution system benefits that can be realized by each option. For example, battery storage can be sited on the distribution system such that it improves voltage regulation along lengthy feeders. If the value of the distribution system benefits is greater than the cost difference between the battery and station expansion, the battery may be the most cost-effective solution for ratepayers overall.

[23] The 2019 Conservation Achievable Potential Study can be found on the IESO's website.
[24] Assumes full (unforced capacity) credit for system capacity value. Actual cost could be higher depending on the deliverability of the NWA resource.
[25] Cost ranges from $1-9 M depending on whether the energy efficiency measures are part of provincially cost-effective CDM (i.e implemented through the IESO's Local Initiative Program) or if they are incremental to provincially cost-effective CDM.

The technologies, regulatory framework, and protocols required to implement dispatchable non-wires alternatives (e.g., batteries, gas generation, or demand response) for the purpose of meeting local capacity needs are still being tested. The IESO's York Region Non-Wires Alternative Demonstration Project[26] is currently exploring market-based approaches to secure energy and capacity services from distributed energy resources (DERs) for local needs. There is a window of opportunity between today and 2029 when the Kenora MTS capacity need arises to leverage learnings from the York Region Pilot and further refine the procurement and operation of non-wires alternatives for Kenora MTS.

Since there are no upstream constraints on the transmission system requiring further regional coordination, the IRRP recommends that Synergy North lead further NWA analysis and refinement as part of local planning. Synergy North should monitor load growth at Kenora MTS to determine when a firm commitment for additional capacity is required and implement non-wires alternatives if they remain feasible and cost-effective. Furthermore, the IESO will consider Kenora MTS as a potential focus area for the Local Initiatives Program[27] under the 2021-2024 Conservation and Demand Management Framework. The IESO will collaborate with Synergy North in 2023 as further details for the next round of the Local Initiatives Program become available. In addition to the energy efficiency measures that may result from the IESO's Local Initiative Program, Synergy North may also use the Ontario Energy Board's Conservation and Demand Management Guidelines[28] to leverage distribution rates for non-wires alternatives.

7.2 Options for Improving Customer Reliability at Fort Frances TS

As discussed in Section 2.1.4, the IRRP will not make a specific recommendation for improving customer reliability since Fort Frances Power's roadmap for Fort Frances MTS is still under development. However, this section will document the options considered during the IRRP process and the IRRP recommends that Fort Frances Power and Hydro One continue to collaborate and select a preferred option in local planning.

The Fort Frances TS 115 kV station layout and connection to Fort Frances MTS is shown in Figure 7-1. The 115 kV side of Fort Frances TS is comprised of a 6-breaker ring bus with connections to the station's two autotransformers and circuits K6F, F3M, F2B, and F1B. Fort Frances MTS is currently connected to the L1-bus (which connects to F1B) and is physically located immediately adjacent to Fort Frances TS. Transmission outages to F1B and the L1 bus have accounted for 90% of Fort Frances Power's customer interruptions over the last 10 years. Therefore, Hydro One has proposed reconfiguration options with the goal of reducing Fort Frances MTS' exposure to transmission outages.

---

[26] For more information on the pilot and latest developments, please see the York Region Non Wires Alternatives Demonstration Project engagement webpage.

[27] For more information on the Local Initiatives Program, please see the Save ON Energy Local Initiatives webpage and the 2021-2024 Conservation and Demand Management Framework webpage.

[28] More information about the Conservation and Demand Management Guidelines is available on the OEB's website (link).

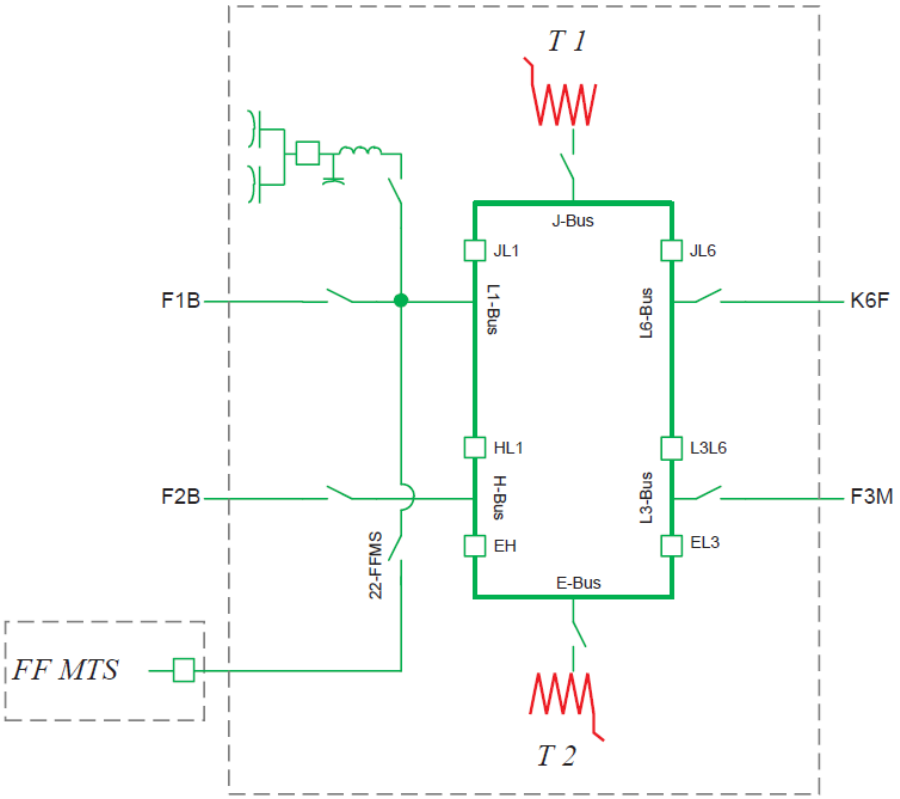

Figure 7-1 | Fort Frances TS 115 kV Single Line Diagram

The following options, in order of increasing complexity and cost, were contemplated:

- Replace the existing 22-FFMS air-break switch with an interrupter switch (still connected to F1B) and install a second interrupter switch to connect Fort Frances MTS to F2B. One of the two switches would be operated normally open, but the switches would allow Fort Frances MTS to be transferred between F1B and F2B to avoid any supply interruptions during planned outages on either of the two circuits or buses.
- Install a new 115 kV breaker on the L1 bus and move the Fort Frances MTS termination between this new breaker and the HL1 breaker. This would form a 7-breaker ring bus and Fort Frances MTS would have its own position separate from any other circuit.

- Install a second breaker at Fort Frances MTS and connect it to the H-bus via a new air-break switch. Since Fort Frances MTS already has two transformers, if both Fort Frances MTS breakers are normally closed, this configuration could provide fully redundant transmission supply. However, the feasibility of having both supply points normally closed is still being reviewed; a normally open point may be required to manage short circuit levels. If either the L1-bus or H-bus supply points needs to be operated normally open, this option would be functionally the same as the first option (but more expensive).

8. Supply to the Ring of Fire

The Ring of Fire is a remote area covering 5000 km^2 located 500 km north of Thunder Bay with rich deposits of critical minerals.[29] There is strong interest in developing mining activities in this area, however as it is located far from established infrastructure, it is currently without all-season road access or grid power supply. Transmission supply to the Ring of Fire was contemplated in the 2015 cycle of regional planning for Northwest Ontario. With renewed interest in developing the Ring of Fire from both government and mining companies, the IESO is updating its Supply to the Ring of Fire study in parallel with the ongoing Northwest IRRP. This report provides an update on preliminary findings as of Q4 2022 including:

- Transmission supply options and high-level cost estimates;
- Key opportunities for alignment that should be considered in the decision to pursue transmission supply to the Ring of Fire as well as its routing and connection point;
- Avoided diesel system costs from connecting remote communities to the grid via a transmission line to the Ring of Fire; and
- Greenhouse gas reductions associated with connecting remote communities and Ring of Fire mines to the grid, as opposed to self generation.

Note that the decision to pursue transmission supply to the Ring of Fire ultimately lies with mining companies and remote communities as the direct beneficiaries of such a project, and with the provincial and federal governments to advance broader policy objectives. The purpose of the renewed Supply to the Ring of Fire study is to help inform government policy and potential customers seeking connection.

8.1 Background

A map of the Ring of Fire area and nearby features of interest are shown in Figure 8-1. Interest in developing the Ring of Fire has varied over the years and there is a high degree of uncertainty in the eventual mining sector electrical demand that may materialize. However, with the current focus on developing critical minerals to support decarbonisation, interest in developing the Ring of Fire area is growing.

[29] Ontario's critical mineral list can be found in the 2022-2027 Critical Mineral Strategy is available on Ontario's Mining and Minerals website.

In addition to potential mining loads, there are five off-grid Matawa First Nation communities in the vicinity of the Ring of Fire. These communities rely on diesel generation systems that are expensive to operate, produce environmental pollutants, and may constrain the communities' growth. Enabling grid supply for these communities is an important factor contributing to the overall rationale for transmission supply to the Ring of Fire. The transmission supply routing and connection point to the existing electricity system should also consider the significant potential for hydro generation in the area which may be able to connect to the grid via the transmission line to the Ring of Fire.

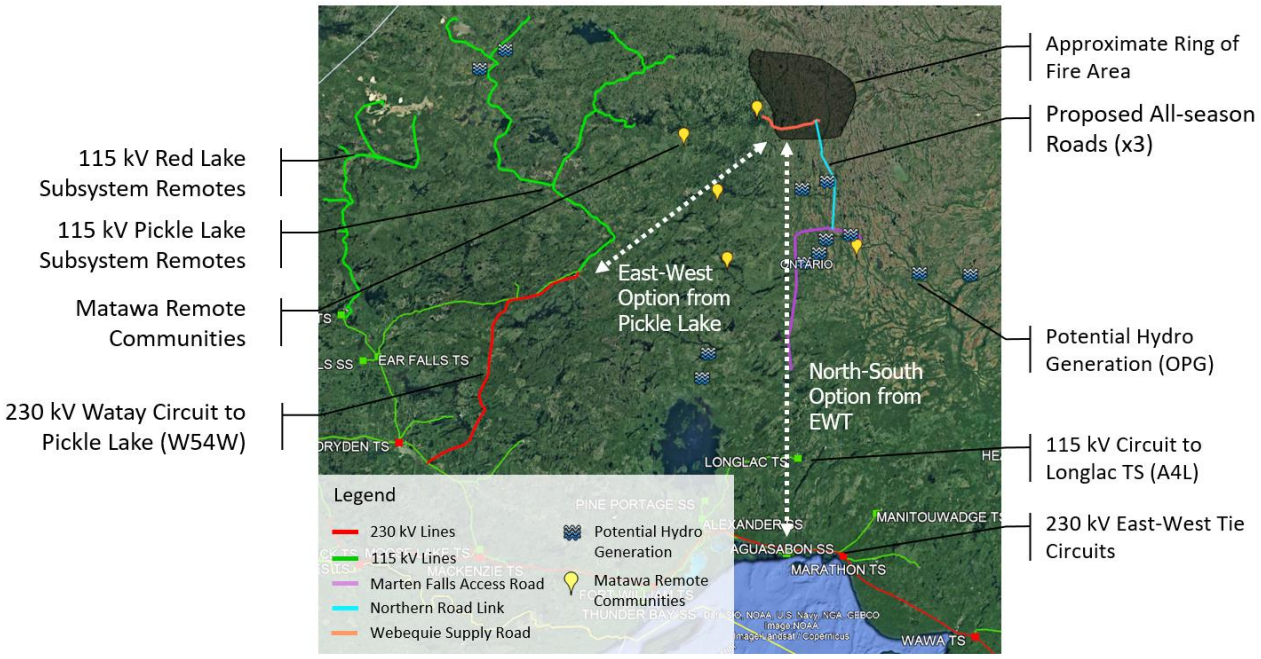

Figure 8-1 | Ring of Fire and Surrounding Area Map

Transmission supply to the Ring of Fire was contemplated in the 2015 North of Dryden IRRP and the 2016 Greenstone-Marathon IRRP. The North of Dryden IRRP outlined potential transmission supply options with the goal of connecting remote communities as well as serving mining electricity demand at the Ring of Fire if it were to materialize. This plan contemplated reinforcing the existing transmission system from the Dryden area to Pickle Lake and building a new transmission line from Pickle Lake to the Ring of Fire. The North of Dryden IRRP, in conjunction with the 2014 Remote Connection Plan, culminated in the indigenous-led Wataynikaneyap Transmission Project.

The Wataynikaneyap Transmission Project includes a new 230 kV line from Dinorwic Junction (near Dryden) to Pickle Lake as well as 115 kV transmission lines extending north of Pickle Lake and Red Lake to connect remote communities. The Matawa area remote communities chose not to participate in the Wataynikaneyap Transmission Project and no transmission lines were built from Pickle Lake to the Matawa communities or the Ring of Fire. This transmission supply option to the Ring of Fire is referred to as the East-West option in Figure 8-1.

The Greenstone-Marathon IRRP extended this analysis to consider potential cost optimization opportunities between new customers in the Greenstone area and remote communities/mines at the Ring of Fire. This entailed a North-South transmission supply option extending from the existing East-West Tie circuits northwards through Greenstone (which is electrically supplied from Longlac TS) and onwards to the Ring of Fire. The largest new customer in the Greenstone area at the time choose to self-generate instead of pursuing transmission supply and the North-South transmission supply option did not proceed.

To date, there have been no firm commitments from customers seeking transmission connection in the Ring of Fire area.

8.2 Policy Drivers and Demand Forecast

Enabling development in the Ring of Fire area is an important policy objective for the provincial government. Ontario's Critical Mining Strategy[30] identifies the Ring of Fire as a "priority project" and a "transformative opportunity for unlocking multi-generational development of critical minerals." The strategy also highlights the importance of Ontario's relatively clean electricity system for enabling development of lower-emissions mining compared to other jurisdictions.

The province has also expressed support for a "Corridor to Prosperity" comprised of three proposed all-season roads led by First Nations partners that connects to the existing highway system and extends northwards towards the Ring of Fire. These proposed roads include the Marten Falls Community Access Road, Webequie Supply Road, and Northern Road Link. The proposed roads are at various stages in their provincial and federal Environmental and Impact Assessments. Taken together, they would provide a continuous all-season transportation corridor to the Ring of Fire that would be necessary to facilitate mining development. Ontario has committed $1 billion to support these road infrastructure projects on the basis that federal contributions will match provincial commitments.

There is a high degree of uncertainty in terms of both the magnitude and timing of mining electricity demand at the Ring of Fire. The IESO's latest mining demand forecast includes approximately 30 MW of electricity demand associated with two proposed mining projects. The 2015/6 IRRP forecasts included up to 70 MW of demand at the Ring of Fire but some proponents have since walked away from their development plans. If transmission and

[30] The 2022-2027 Critical Mineral Strategy is available on Ontario's Mining and Minerals website.

transportation infrastructure were developed, mining demand would almost certainly be much higher than currently forecast. As of January 2022, there are approximately 26,000 active mining claims held by 15 companies in the Ring of Fire. The IESO will continue monitoring development plans and intends to update the mining forecast in Q1 2023 to better capture Ring of Fire growth scenarios.

The five Matawa area remote communities have a total demand of approximately 4 MW today and are forecast to grow at 4% per year.[31] This forecast was last updated in 2019 and will be updated as new information becomes available.

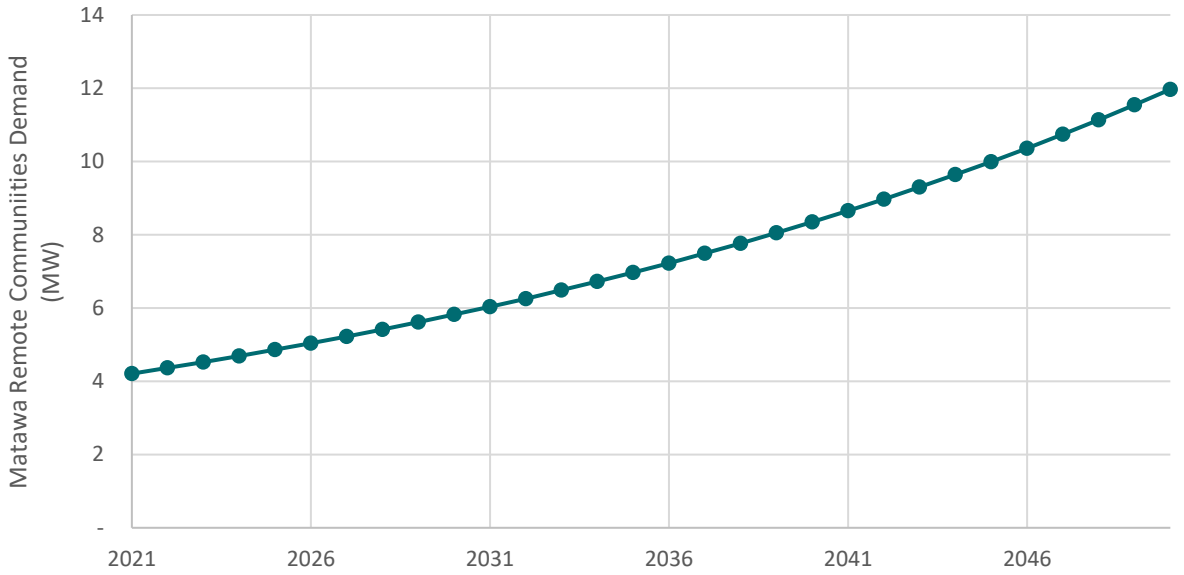

Figure 8-2 | Matawa Remote Communities Demand Forecast

[31]The forecast 4% growth rate reflects potential demand growth if the remote communities are grid connected and no longer constrained by diesel supply capacity.

8.3 Transmission Supply Options and Cost Estimates

As discussed in Section 8.1, at a high level, there are two transmission supply options to the Ring of Fire that could be pursued: a North-South option connecting to the East-West Tie circuits between Marathon and Thunder bay and an East-West option connecting to the new Wataynikaneyap TS near Pickle Lake. The conceptual electrical elements of each option are listed in Table 8-1. Note that at this stage, no detailed engineering design or routing work has been performed. The transmission options are presented here for discussion purposes and to facilitate high-level cost estimation (-50% to +100%).

The North-South option is estimated to cost between $860M and $1.08B while the East-West option is estimated to cost between $600M and $780M ($2022 real, overnight capital cost). The cost ranges reflect uncertainty in the final station configurations as well as in the per unit (km) cost of transmission lines which can vary depending on the technology type and geography. These cost estimates are not inclusive of step-down transformer stations at the loads themselves nor reactive compensation devices which will depend on the magnitude of the demand. Note that material and labour costs have increased rapidly over the COVID-19 period and there is a high degree of uncertainty in future costs.

Table 8-1 | Ring of Fire Transmission Option Conceptual Elements

Transmission Supply Option	Element #	Description	Length (km)	Cost ($2022 real)
North-South	1	230 kV single circuit line from East-West Tie circuits to Longlac	120	$170-215M
	2	New stations at East-West Tie connection point[32] and Longlac (to enable connection to A4L);	N/A	$115-125M
	3	230 kV single circuit line from Longlac to McFaulds Lake; roughly parallel to proposed roads	410	$575-740M
East-West	1	230 kV single circuit line from Wataynikaneyap TS near Pickle Lake to McFaulds Lake; roughly along route envisioned in the 2014 Remote Connection Plan	370	$580-745M
	2	Wataynikaneyap TS modifications	N/A	$20-30M

[32] Connecting the Ring of Fire line directly to East-West Tie lines between Lakehead TS and Marathon TS minimizes costs since it is the closest 230 kV supply point to the Ring of Fire. However, connecting to only one (or any subset) of the four parallel East-West Tie lines will unbalance flows between Marathon TS and Lakehead TS and may decrease the overall transfer capability of the East-West Tie. Future studies should weigh the costs and benefits of connecting to either Lakehead TS or Marathon TS versus a new junction and/or switching station on the East-West Tie.

While the East-West option is less expensive than the North-South option, it would provide less incremental capacity to supply load and would also increase exposure to outages. The load meeting capability for a radial expansion of the transmission system like the Ring of Fire is typically constrained by thermal, voltage, and load security limits. The thermal rating of a 230 kV single circuit line is unlikely to be constraining; as an example, a single East-West Tie circuit has a continuous rating of approximately 320 MW in the summer and 390 MW in the winter. This far exceeds the current known mining and remote community demand forecast. Voltage limits can be managed by installing voltage regulation devices at the loads and can be sized according to the expected demand, however this would add incremental cost and operational complexity. Load security limits, however, may become the most limiting factor depending on future mining developments.

Ontario Resource and Transmission Assessment Criteria (ORTAC) Section 7.1 load security criteria specifies the maximum amount of load that can be interrupted after certain contingencies. For the loss of a single element (i.e. single circuit supply to the Ring of Fire), no more than 150 MW may be interrupted. This limits the total load served on the North-South option to 150 MW. The East-West option is connected downstream of the new single circuit Wataynikaneyap line (W54W). The total load served by W54W is also limited to 150 MW including the all existing loads and their growth, new mining customers along W54W, and the Ring of Fire and Matawa communities. Existing load served on W54W totals approximately 45 MW today and is expected to grow to 80 MW by 2040. While the remaining room is sufficient for serving the currently forecast demand at the Ring of Fire (30 MW mining plus Matawa area communities), it leaves relatively little room to accommodate additional development. Furthermore, the IESO is aware of several additional mining projects potentially seeking connection along W54W. While these projects are not yet certain enough to be included in the IRRP reference forecast, they could significantly reduce the available capacity for growth at the Ring of Fire.

While not addressed by ORTAC criteria, another consideration is the level of exposure to outages. The East-West option would involve connecting the Ring of Fire and Matawa communities to a radial system that already spans several hundred kilometers of transmission lines (W54W and D26A). Each time any part of this system is faulted (e.g., in an electrical storm or fire), the whole system is removed from service until the fault can be addressed. By comparison, the North-South option can be connected to the East-West Tie (or nearby station) which are more robust and has redundant supply.

Due to the uncertainty in future mining developments, it is too early to rule out the East-West option at this time. However, the potential capacity constraints and customer reliability impacts related to the East-West option should be considered when selecting a preferred transmission option. The next section discusses opportunities for alignment and further considerations that may impact the preferred transmission option.

8.4 Opportunities for Alignment

A decision to pursue transmission supply to the Ring of Fire, and decisions on its preferred routing, should consider alignment with four opportunities in addition to supplying mining demand at the Ring of Fire:

- Supplying Matawa Remote Communities
- Enabling potential hydro generation
- Improving supply to Longlac
- Co-locating with transportation corridor

These opportunities for alignment are discussed in turn below.

8.4.1 Supplying Matawa Remote Communities

There are five Matawa indigenous remote communities in the vicinity of the Ring of Fire:

- Webequie
- Nibinamik
- Neskantaga
- Marten Falls
- Eabametoong

These communities were previously identified as economic for grid connection in the 2014 Remote Connection Plan but elected not to participate in the Wataynikaneyap Transmission Project. The 2014 Remote Connection Plan found that it was more cost-effective to supply the communities via a single circuit 115 kV transmission line (either from Pickle Lake or the East-West Tie circuits) than continued reliance on off-grid diesel generation systems. Transmission supply to the Ring of Fire could also enable connection of the Matawa remote communities. Both the North-South and East-West transmission options would serve this purpose. Updated potential avoided diesel generation system costs are discussed in Section 8.4.2.

Note that the decision to pursuing grid connection is up to the communities. The IESO will continue to engage with the Matawa communities to inform future studies. Furthermore, grid connection of remote communities does not preclude local energy projects such as the installation of distributed generation and storage. The IESO continues to support broad equitable participation in Ontario's energy sector through its Energy Support Programs including

the Indigenous Energy Projects (IEP) Program[33] which provides funding support to First Nation and Metis communities to assess and develop energy projects and partnerships.

8.4.2 Enabling Hydro Generation

In Jan 2022, the Ontario government asked Ontario Power Generation to examine opportunities for new hydroelectric development in northern Ontario. New hydroelectric generation could address the growing long-term electricity needs forecast for the province, with the potential for economic benefits for local and Indigenous communities in the north. Ontario Power Generation has shared this work with the Ministry of Energy and the IESO so that it can be considered as part of the IESO's work towards developing an achievable pathway to zero emissions in the electricity sector. Development of transmission supply to the Ring of Fire should consider the connection of potential hydro generation in the area.

There is significant hydroelectric generation potential in the vicinity of the Ring of Fire. Due to the geographic distribution of these potential generation facilities, the North-South transmission option is better suited than the East-West option to connect these facilities on the way to the Ring of Fire. Furthermore, the North-South option connects to a more robust point in the bulk transmission system which may result in fewer deliverability constraints and lower overall losses. The Ring of Fire North-South transmission line is not necessarily the optimal connection point for potential hydro generation near the Ring of Fire. Other connection options, to Pinard TS for example, may reduce the overall bulk system reinforcements needed to deliver the hydro generation capacity to southern Ontario. However, connecting to the Ring of Fire transmission line could significantly reduce the length of connection lines required for these potential hydro generators and future studies should consider the synergies between Ring of Fire transmission supply and enabling the connection of potential hydro generation.

8.4.3 Improving Supply to Longlac

The existing radial 115 kV circuit, A4L, to Longlac TS is near capacity and customers have expressed concern about poor reliability due to long and frequent outages. While no firm growth plans or new customer connection requests were received during this IRRP, there continues to be a high degree of interest for mining and industrial developments in the Greenstone and Geraldton areas supplied by A4L. There are also existing customers along A4L who have elected to self-generate rather than connect to the transmission system due to capacity constraints.

A4L refurbishment is underway and distance-to-fault relays have been installed which should decrease the frequency of outages and improve restoration times. However, these improvements do not increase the load meeting capability on A4L and, as with many other areas in the Northwest region, growth can materialize quickly.

[33] For more information, please visit the Indigenous Energy Projects Program webpage.

The North-South transmission option passes directly by Longlac TS and could help increase capacity and provide a secondary supply path to further improve reliability. The North-South option conceptual elements in Table 8-1 includes a 230/115 kV transformer station at Longlac for this purpose. Note that the East-West option is not suitable for reinforcing Longlac.

8.4.4 Co-locating with Transportation Corridor

The proposed Marten Falls Community Access Road, Webequie Supply Road, and Northern Road Link will provide a continuous all-season transportation corridor to the Ring of Fire. While detailed routing has not yet been performed, the North-South transmission option is well aligned with the proposed roads. The line length determined for the North-South option in Table 8-1 assumes that the transmission corridor runs parallel to the proposed roads wherever possible but the potential cost savings associate with colocation has not been factored into the transmission cost estimate yet. This likely overestimates the cost of the North-South transmission option compared to the East-West option; future studies should conduct more detailed engineering design and routing analysis to better quantify the benefits of colocation.

Co-locating linear infrastructure is consistent with provincial policy as articulated in Section 1.6.8 of the 2020 Provincial Policy Statement[34] and may help reduce environmental impacts. The roads would also provide easier access to the transmission line which could simplify construction as well ongoing operation and maintenance. Note that there are no proposed all-season roads along the East-West option route.

8.5 Avoided Matawa Communities Diesel System Costs

The Matawa remote communities are currently supplied by remote on-site diesel generation which is costly to operate. Up to 70% of the fuel must be flown in when winter roads are not available contributing to high costs and increased emissions from fuel transport. The costs of supplying electricity from remote diesel generation systems versus the grid over the first 20 years of transmission connection are shown in Figure 8-3. The net present value of remote diesel generation costs is estimated to be $446M over this period, while serving the same load from the provincial grid is estimated to be roughly $35M.[35] These net present values are expressed in real dollars in the year when transmission connection is hypothetically brought in-service. For the purpose of this assessment, it was assumed that transmission connection occurs in 2030 given the typical 7-year lead time of new transmission projects.

[34] The 2020 Provincial Policy Statement can be found on the Ontario government's Land Use Planning webpage.

[35] The cost of serving loads on the provincial grid is solely based on the system's marginal cost of energy. It does not include cost of transmission connection itself. Connecting remote communities is one of multiple potential benefits (other benefits include supplying mining loads and enabling hydro generation) that contribute towards a rationale for transmission supply. The cost of transmission supply should be compared against this full suite of benefits.

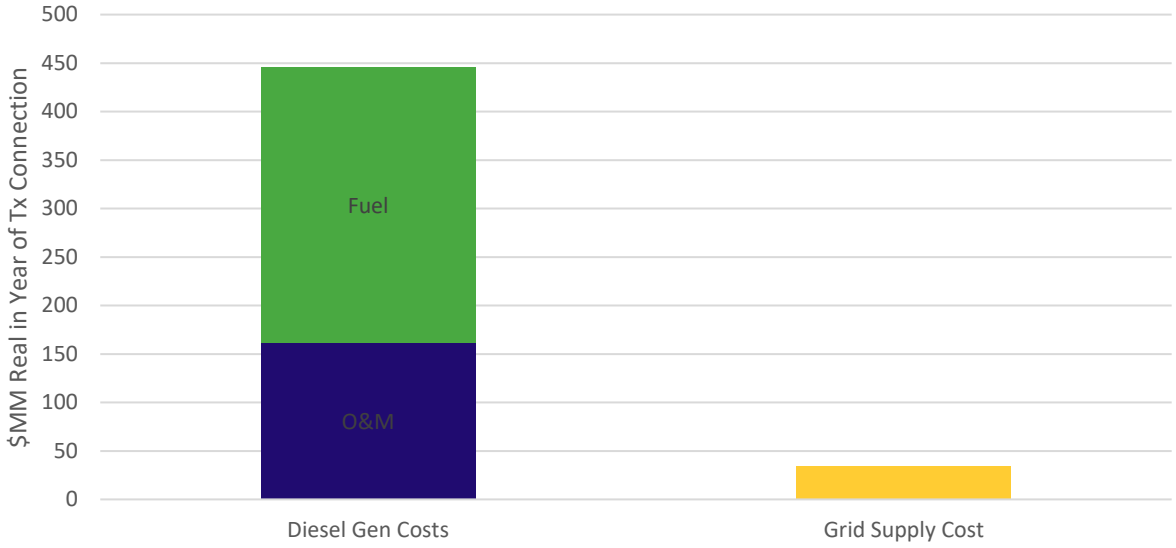

Figure 8-3 | NPV of Electricity Supply Costs from Diesel Generation versus the Provincial Grid for Matawa Remote Communities over the First 20 Years of Grid Connection

The cost of continuing to supply electricity to the remote Matawa communities by local diesel generation was estimated using the IESO's internal fuel forecast and aggregated cost data for remote communities served by Hydro One Remote Communities.[36] Generally speaking, economic and cost assumptions were consistent with the 2014 Remote Connection Plan adjusted for inflation. The cost of supplying electricity from local diesel generation is comprised of two components:

- Fuel costs including the cost for the fuel itself, winter road/air transportation, and the cost of carbon;
- Operating and maintenance costs estimated from historical revenue requirement and rate application regulatory submissions as a percentage of fuel costs.

[36] Not all Matawa communities are served by Hydro One Remote Communities. For communities served by Independent Power Authorities for which cost data was not directly available, system costs were estimated based the size of their load and Hydro One Remote Communities' system costs.

Of the $446M net present value, $284M is associated with fuel costs and $162M with operating and maintenance costs. Note that this cost estimate does not include the capital costs associated with expanding existing diesel systems to meet future capacity growth. This enables an apples-to-apples comparison with the cost of grid electricity which also did not include the incremental resource capacity cost of serving the newly connected remote communities. Furthermore, since the incremental capacity requirement is dependent on the year in which transmission connection occurs and the system needs/market conditions in the period following grid connection, capital costs associated with this capacity cannot be accurately calculated today. Future studies should refine the consideration of capacity costs when there is more certainty on when transmission supply will proceed.

The cost of serving Matawa remote communities should they be connected to the provincial electricity grid was based on the system marginal cost forecast in the 2021 Annual Planning Outlook.

8.6 Avoided Greenhouse Gas (GHG) Emissions

Avoided GHG emissions was estimated for the Matawa communities and the future mining load through the comparison of emissions on the electricity system (consistent with the 2021 Annual Planning Outlook emission rate per MWh) versus diesel generation for remote communities and natural gas generation for mining loads.[37]

The GHG reduction associated with connecting Matawa communities depends on the forecast demand levels and growth rate when transmission connection occurs. Consistent with the diesel system cost savings estimates in the previous section, transmission connection was assumed to occur in 2030. On average, over the first 20 years of transmission connection (i.e. 2030-2049), GHG reductions are expected to be approximately 27,000 tCO2e per year.

The GHG reduction associated with mining loads depends on the amount of demand that materializes. As discussed in Section 8.2, there is a high degree of uncertainty in terms of both the magnitude and timing of this demand. For illustrative purposes, if 30 MW of demand materializes (consistent with demand from known projects), GHG reductions would total 68,000 tCO2e per year. If 70 MW of demand materializes (consistent with demand from the 2015 IRRP forecasts), GHG reductions would total 160,000 tCO2e per year. The true avoided GHG emissions associated with connecting mining loads instead of on-site generation could be much higher given the large number of active mining claims in the Ring of Fire.

[37] The natural gas generation was assumed to be a combined cycle gas turbine (CCGT) facility with a heat rate of 7.265 MW/MMbtu and a natural gas emission intensity of 53.157 kgCO2e/MMbtu. For diesel generation emissions, the Hydro One Remote Communities fleet average generator efficiency and a diesel emission intensity of 75.22 kgCO2e/MMbtu was assumed.

8.7 Next Steps

The sections above provide an overview of preliminary findings to date of the Supply to the Ring of Fire Study and highlights some areas of uncertainty that will require further investigation. The IESO will continue the Supply to the Ring of Fire Study in 2023. The scope, timing, and engagement process will evolve with government policy direction. The IESO will share updates with the Working Group to inform upcoming regional planning activities such as the Regional Infrastructure Plan.

9. Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and preferences of communities to be considered in the development of the plan and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the activities undertaken for this Northwest IRRP.

9.1 Engagement Principles

The IESO's engagement principles[38] help ensure that all interested parties are aware of and can contribute to the development of this IRRP. The IESO uses these principles to ensure inclusiveness, sincerity, respect, and fairness in its engagements, striving to build trusting relationships as a result.

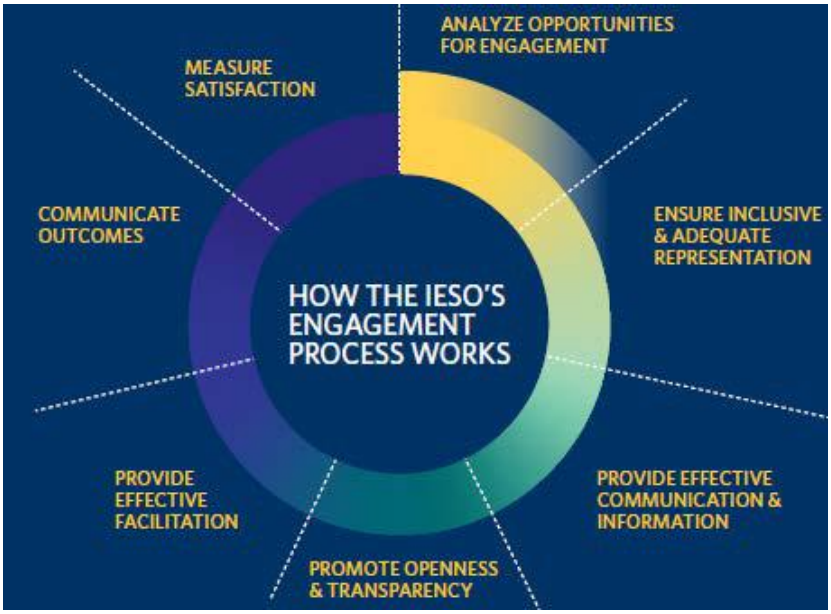

Figure 9-1 | IESO's Engagement Principles

[38] https://www.ieso.ca/en/sector-participants/engagement-initiatives/overview/engagement-principles

9.2 Creating an Engagement Approach for the Northwest

The first step in ensuring that any IRRP reflects the needs of community members and interested stakeholders is to create an engagement plan to ensure that all interested parties understand the scope of the IRRP and are adequately informed about the background and issues to provide meaningful input on the development of the IRRP for the region.

Creating the engagement plan for this IRRP involved:

- Targeted discussions to help inform the engagement approach for this planning cycle;
- Communications and other engagement tactics to enable broad participation, using multiple channels to reach audiences; and
- Identifying specific stakeholders and communities who may have a direct impact in this initiative and that should be targeted for further one-on-one consultation, based on identified and specific needs in the region.

As a result, the engagement plan for this IRRP included:

- A dedicated webpage[39] on the IESO website to post all meeting materials, feedback received and IESO responses to the feedback throughout the engagement process;
- Regular communication with interested communities and stakeholders by email and through the IESO weekly Bulletin;
- Public webinars;
- Targeted discussions sessions;
- Face-to-face meetings; and
- One-on-one outreach with specific communities and stakeholders to ensure that their identified needs are considered (see Sections 9.4 and 9.5).

[39] https://www.ieso.ca/en/Sector-Participants/Engagement-Initiatives/Engagements/Regional-Electricity-Planning-Northwest-Ontario

9.3 Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for this round of planning, leveraging existing relationships built through the previous planning cycle. This started with the Scoping Assessment Outcome Report for the Northwest region. An invitation was sent to targeted municipalities, Indigenous communities, and those with an identified interest in regional issues to announce the commencement of a new regional planning cycle and invite interested parties to provide input on the Northwest Scoping Assessment Report before it was finalized.

Feedback was received and focused on the need to ensure that municipal energy planning, including the need to recognize climate change priorities, as well as economic development and industrial growth (including forestry and mining) were in scope of the development of the IRRP. In addition, reliability remained a paramount concern within this region. Along with a response to the feedback received, the final Scoping Assessment was posted on January 13, 2021, which identified the need for a coordinated regional planning approach across the Northwest region – particularly important since the previous planning cycle targeted regional plans within five identified sub-regions.

Following the finalization of the Scoping Assessment, outreach then began with targeted municipalities to inform early discussions for the development of the IRRP including the IESO's approach to engagement. The launch of a broader engagement initiative followed with an invitation to IESO subscribers of the Northwest planning region as well as all identified municipalities and Indigenous communities to ensure that all interested parties were made aware of this opportunity for input. Four public webinars were held at key stages during the IRRP development to give interested parties an opportunity to hear about progress and provide comments on various components of the plan.

All these engagement sessions received strong participation with a cross-representation from stakeholders and community representatives. Feedback was received as a result each engagement meeting which was considered in each of the stages in the IRRP development.

The public webinars invited input on:

1. The draft engagement plan, the electricity demand forecast and the early identified needs to set the foundation of this planning work.

2. The defined electricity needs for the region and potential options to meet the identified needs.

3. The analysis of options and draft IRRP recommendations.

In addition, three targeted discussions were held virtually to uncover specific feedback from communities and stakeholders on the following three topics:

1. Customer Reliability Concerns
2. Emerging Local Initiatives
3. Emerging Electricity Needs in the North of Dryden Area

Comments received during this engagement focused on the following major themes:

- Given the large geographic area for this planning region, consideration throughout the engagement should be given to targeted discussions to address local reliability and priorities. Education and support should be available to enable purposeful engagement for all interested parties
- Consideration in the demand forecast should be given to local developments, growth plans and climate change goals (i.e., electrification) – particularly in communities where capacity may be limited
- Non-wires alternatives should be considered to meet needs and, in particular, climate change priorities; existing resources in the region should be considered where contracts are due to expire
- Due consideration should be given to providing capacity for new commercial and industrial (mining and forestry) growth as well as electrification of existing industry
- Opportunities for future proponents to leverage existing partnerships or create new relationships among local and Indigenous communities to have due consideration of priorities and provide business prospects, where possible

Feedback received during the written comment periods for these webinars helped to guide further discussion throughout the development of this IRRP as well as add due consideration to the final recommendations.

All interested parties were kept informed throughout this engagement initiative via email to Northwest region subscribers, municipalities, and Indigenous communities as well as the members of the Northwest Regional Electricity Network.

Based on the discussions through the Northwest IRRP engagement initiative and broader network dialogue, there is a clear interest to further discuss the potential for development of the mining sector in this region and to look for alternative energy solutions to meet local needs, particularly as communities and industries shift towards electrification. This insight has been valuable to the IESO and will help to inform future discussions to examine and consider these types of initiatives and the opportunities that they may present in future planning efforts. To that end, ongoing discussions will continue through the IESO's Northwest Regional Electricity Network to keep interested parties engaged in a two-way dialogue on local developments, priorities, and planning initiatives to prepare for the next planning cycle.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's Northwest IRRP engagement webpage.

9.4 Bringing Municipalities to the Table

The IESO held meetings with municipalities to seek input on their own planning and priorities to ensure that these plans were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings were held with targeted municipalities in the region to discuss: key issues of concern, including forecast regional electricity needs; options for meeting the region's future needs; reliability concerns; and broader community engagement. These meetings helped to inform the municipal/community electricity needs and priorities and provided opportunities to strengthen this relationship for ongoing dialogue beyond this IRRP process.

9.5 Engaging with Indigenous Communities

The IESO remains committed to an ongoing, effective dialogue with communities to help shape long-term planning across Ontario. To raise awareness about the regional planning cycle in Northwest Ontario and provide opportunities to provide input, the IESO invited Indigenous communities located in or near the Northwest region to participate in webinars that were held on:

- December 8, 2020
- May 20, 2021
- September 27, 2021
- November 2, 18, 29, 2021
- April 25 and 26, 2022
- November 3, 2022

The First Nation communities that were invited to the webinars were:

- Animakee Wa Zhing No. 37
- Animbiigoo Zaagi'igan Anishinaabek
- Anishinaabeg of Naongashiing (Big Island)
- Anishinabe of Wauzhushk Onigum
- Aroland
- Bearskin Lake
- Big Grassy River (Mishkosiminiziibiing)
- Biinjitiwaabik Zaaging Anishinaabek
- Bingwi Neyaashi Anishinaabek
- Cat Lake
- Constance Lake
- Couchiching
- Deer Lake
- Eabametoong
- Eagle Lake
- Fort William
- Grassy Narrows
- Iskatewizaagegan No. 39
- Kasabonika Lake
- Keewaywin
- Kiashke Zaaging Anishinaabek
- Kingfisher Lake
- Kitchenuhmaykoosib Inninuwug
- Lac des Mille Lacs
- Lac La Croix

- Lac Seul
- Long Lake No. 58
- Marten Falls
- McDowell Lake
- Michipicoten
- Mishkeegogamang
- Mitaanjigamiing
- Muskrat Dam Lake
- Naicatchewenin
- Namaygoosisagagun
- Naotkamegwanning
- Neskantaga
- Netmizaaggamig Nishnaabeg (Pic Mobert)
- Nibinamik
- Nigigoonsiminikaaning
- Niisaachewan Anishinaabe Nation
- North Caribou Lake
- North Spirit Lake
- Northwest Angle No. 33
- Ojibway Nation of Saugeen
- Ojibways of Onigaming
- Pays Plat
- Pikangikum
- Poplar Hill
- Rainy River
- Red Rock Indian Band
- Sachigo Lake
- Sandy Lake
- Seine River
- Shoal Lake No. 40
- Slate Falls
- Wabaseemoong
- Wabauskang
- Wabigoon Lake
- Wapekeka
- Washagamis Bay (Obashkaandagaang)
- Wawakapewin
- Webequie
- Whitesand
- Wunnumin Lake

The Métis communities that were invited to the webinars were:

- MNO Atikokan Métis Council
- MNO Greenstone Métis Council
- MNO Kenora Métis Council
- MNO Northwest Métis Council (Dryden)
- MNO Sunset Country Métis Council (Fort Frances)
- MNO Superior North Shore Métis Council (Terrace Bay)
- MNO Thunder Bay Métis Council
- Red Sky Independent Métis Nation

9.5.1 Information about Indigenous Participation and Engagement in Transmission Development

By conducting regional planning, the IESO determines the most reliable and cost-effective options after it has engaged with stakeholders and Indigenous communities and publishes recommendations in the applicable regional or bulk planning report. Where the IESO determines that the lead time required to implement the recommended solutions requires immediate action, the IESO may provide those recommendations ahead of the publication of a planning report.

In instances where transmission is the recommended option, a proponent applies for applicable regulatory approvals, including an Environmental Assessment that is overseen by the Ministry of Environment, Conservation and Parks (MECP). This process includes, where applicable, consultation regarding Aboriginal and treaty rights, with any approval including steps to avoid or mitigate impacts to said rights. MECP oversees the consultation process generally but may delegate the procedural aspects of consultation to the proponent. Following development work, the proponent will then apply to the OEB for approval through a Leave to Construct hearing and, only if approval is granted, can it proceed with the project. In consultation with MECP, project proponents are encouraged to engage with Indigenous communities on ways to enable participation in these projects.

There are no new transmission projects recommended as a result of this Northwest planning initiative.

10. Conclusion

The Northwest IRRP identifies electricity needs in the region over the 20-year period from 2021-2040, recommends a plan to address immediate and near-term needs, and lays out actions to monitor long-term needs. The IESO will continue to participate in the Working Group during the next phase of regional planning, the Regional Infrastructure Plan, to provide input and ensure a coordinated approach with bulk system planning where such linkages are identified in the IRRP.

In the near term, the IRRP recommends new and/or upgraded stations to address station capacity needs at Crilly DS and Margach DS, further refinement of non-wires alternatives at Kenora MTS, reconfiguration of Fort Frances TS to improve customer reliability at Fort Frances MTS, and additional reactors at or near Pickle Lake SS to manage high voltages so that E1C can be operated normally open. Responsibility for these actions has been assigned to the appropriate members of the Technical Working Group.

The IRRP recommends that the Working Group monitor growth, particularly in the Red Lake and Fort Frances areas. The IRRP studied high growth sensitivities to establish load meeting capabilities in these areas against which growth should be monitored to determine when future regional planning activities should be triggered. The IESO will update its mining sector demand forecast in early 2023 and provide updates to the Working Group. Electricity demand at White Dog DS and Marathon DS should also be monitored to confirm the timing of station capacity needs emerging in the 2030's. No firm recommendations are required for these potential long-term needs at this time.

The IESO will continue the Supply to the Ring of Fire Study in 2023. The scope and timing will evolve with government policy direction and the IESO will share updates with the Working Group to inform upcoming regional planning activities.

The Working Group will meet at regular intervals to monitor developments and track progress toward plan deliverables. If underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the OEB.

REGIONAL INFRASTRUCTURE PLAN REPORT

Northwest Ontario

Regional Infrastructure Plan Report

[Northwest Ontario]

[Date: August 4, 2023]

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

Northwest Ontario Technical working group

Page intentionally left blank

Disclaimer

This Regional Infrastructure Plan (RIP) Report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group (TWG).

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Technical Working Group.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	Northwest Ontario Region (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")
START DATE: February 9, 2023	**END DATE:** August 4, 2023

1. INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process for the Northwest Region, preceded by, the publication of Needs Assessment (NA) report in July 2020 by Hydro One, followed by the Scoping Assessment (SA) in January 2021 & Integrated Regional Resource Plan (IRRP) in January 2023 published by the IESO respectively.

Hydro One as the lead transmitter undertakes the development of a RIP with input from the TWG for the region and publishes a RIP report. The RIP report includes a common discussion of all the options and recommended plans and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs.

2. OBJECTIVES AND SCOPE

Objectives:

- Provide a comprehensive summary of needs and wires plans to address the needs for the Northwest Ontario region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

Scope:

- A consolidated summary of needs and recommended plans for the region over a study period of 2023-2043 based on available information.
- A consolidated report of the needs and relevant wires plans to address near and medium-term needs identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs and wires plans in the near and medium-term to address these needs based on new and/or updated information.

- Consideration of long-term needs identified in the Northwest Ontario IRRP, Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

This section provides a detailed overview of the various steps followed during different phases of Regional Planning Process and their outcomes starting with the Needs Assessment, Scoping Assessment, Local Plan, Integrated Regional Resource Plan and finally details the Regional Infrastructure plan Methodology.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

This section provides a general overview of the Geographical boundaries, Circuit connections and Stations located in the Northwest Ontario region though a regional planning area map and a single line diagram. The Northwest region includes the area roughly bounded by Lake Superior to the south, the Marathon area to the east, and the Manitoba border to the west. It includes the districts of Kenora, Rainy River, and Thunder Bay. The region is comprised of 230kV circuits from the Manitoba interties in the west to Marathon TS in the east and 115kV sub-systems in between.

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR UNDERWAY

This section provides a summary and brief description of all the projects completed in the past ten years or are currently underway.

I. Following Major projects were completed during the last ten years:

1. **Manitouwadge TS (2016)** – The 115/44kV, 5/7MVA T1 transformer was replaced with new 115/44kV 25/33/41.7 MVA unit.
2. **Dryden TS (2018)** – Five 115kV breakers and two 115/44kV, 11/15MVA transformers were replaced with new 115/44 kV 25/33/42MVA units.
3. **Lakehead TS (2017)** – Two 230/115kV autotransformers were replaced with new 230/115kV 150/200/250MVA units.
4. **Birch TS (2015)** – One 115/25kV transformer was replaced with a new 115/25kV 25/33/42MVA unit.
5. **Ear Falls TS (2022)** – Four 115kV breakers and one 115/13.2kV transformer was replaced with a new 115/13.2 kV 7.5/10/12.5MVA unit.
6. **East West Tie (2022)** – A 450 km, double-circuit, 230kV transmission line from Wawa TS to Lakehead TS was built with a connection approximately mid-way at Marathon TS.
7. **Wataynikaneyap Power Project Phase 1 (2022)** – A 300 km, single circuit, 230kV transmission line from Dinorwic to Pickle Lake, Ontario was built with a 230/115kV autotransformer, related switching facilities and necessary voltage control devices.

II. Following Major projects are underway:

1. **Rabbit Lake SS (2024-2027)** – Replace 115kV circuit breakers and associated equipment.
2. **Whitedog Falls SS (2025-2028)** – Replace 115kV circuit breakers and associated equipment.

3. **Mackenzie TS (2026-2029)** – Replace 230kV circuit breakers and associated equipment.
4. **Wawa TS (2026-2029)** – Replace two existing 230/115kV autotransformers with two new units; replace four 230kV and four 115kV circuit breakers.
5. **Wataynikaneyap Power Project Phase 2 (2022-2024 and beyond)** – Construct approximately 1438 km of 115kV, 44kV and 25kV transmission lines and twenty substations to connect 16 First Nations in two transmission subsystems.

Note: The planned in-service year for the above projects is tentative and is subject to change.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

During the study period, the load in the Northwest Ontario Region is expected to grow at an average annual rate of approximately 2% in winter from 2023 to 2033. The Region is winter peaking so this assessment is based on winter peak loads.

The following other assumptions are made in this report.

- The study period for the RIP assessments covers near and medium-term. However, a longer term forecast up to 2043 is provided to identify long-term needs and align with the Northwest Ontario region IRRPs.
- LDCs reconfirmed load forecasts up to 2033. A longer term forecast up to 2040 is adopted with IRRP load forecast. The additional three years of forecasts were extrapolated based on growth rate as a reasonable position to complete the 20 years period.
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR); or winter 10-day LTR if undergoing a winter season analysis.
- Bulk transmission line and auto-transformation capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Adequacy assessment is conducted as per ORTAC.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying the Northwest Ontario Region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway are completed.

I. **Needs identified in the region**

a. **Asset Renewal for Major HV Transmission Equipment (Replace equipment identified in deterioration and technical obsolescence)**

- Rabbit Lake SS
- Whitedog Falls SS
- Mackenzie TS
- Wawa TS
- Marathon TS
- Lakehead TS
- Lakehead TS C8 Condenser
- Fort Frances TS
- Kenora TS

b. **Station Capacity**

- Margach DS
- Crilly DS
- White Dog DS
- White River DS
- Kenora MTS

c. **Transmission Line Capacity**

- E2R and E4D
- M2W

d. **System Reliability, Operation and Load restoration**

- Fort France MTS - Planned outages considering station single supply configuration
- E1C - Operation and High Voltage under a Normally-open configuration

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the Northwest Ontario region. The needs include those previously identified in the NA and IRRP for the Northwest Ontario region as well as any new needs identified during the RIP phase.

9. CONCLUSION AND RECOMMENDATIONS

The major infrastructure investments recommended by the TWG in the Northwest Ontario region is given below:

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Asset Renewal Needs				
Rabbit Lake SS	Replacement of the 115kV switchyard and its associated equipment	Hydro One Transmission	2024-2027	35.2
Whitedog Falls SS	Replacement of three 115kV breakers, DC station services and associated equipment	Hydro One Transmission	2025-2028	8.5
Mackenzie TS	Replacement of one 230/115kV autotransformer, five 230kV breakers, four switches, the AC station services and associated equipment	Hydro One Transmission	2025-2028	54.6
Wawa TS	Replacement of two 230/115kV autotransformer, associated breakers and equipment and station services	Hydro One Transmission	2026-2029	43.8
Marathon TS	Replacement of 230kV and 115kV breakers and associated equipment	Hydro One Transmission	2026-2029	14.6
Lakehead TS	Replacement of 230kV and 115kV breakers, the station services and associated equipment	Hydro One Transmission	2028-2031	41.5
Lakehead TS Condenser C8 Replacement	Replacement of the condenser C8 with a +60/- 40 MVAR STATCOM	Hydro One Transmission	2027	40.6
Fort Frances TS	Replacement of the 230kV breakers, associated equipment, and the station services	Hydro One Transmission	2029-2032	20.3
Kenora TS	Replacement of 230kV breakers, associated equipment, and the station services	Hydro One Transmission	2030-2033	17
Station Capacity Needs				
Margach DS	To be monitored and implemented in investment plan in 2025	Hydro One Distribution	2025	1

Crilly DS	To further assess the Alternative 1 and Alternative 2 from this RIP	Hydro One Distribution	NA	NA
White Dog DS	To be monitored and reviewed in next planning cycle	Hydro One Distribution	NA	NA
White River DS	To be monitored and reviewed in the next planning cycle	Hydro One Distribution	NA	NA
Kenora MTS	To further assess the alternatives from this RIP; To be monitored and reviewed in next planning cycle	Synergy North	NA	NA
Transmission Line Capacity Needs				
E2R and E4D	To further evaluate the four alternatives based on mining customers' requests	Hydro One Transmission and Proponent	TBD	125-375
M2W	To further evaluate the two alternatives based on mining customers' requests	Hydro One Transmission and Proponent	TBD	TBD
System Reliability, Operation and Load restoration Needs				
Fort Frances MTS	Installation of a second breaker and switch in Fort Frances MTS to create a second supply to the MTS	Fort Frances Power	2026-2027	0.85
E1C Operation	To open E1C end at Ear Falls TS and installation of a 10 – 15 MVAR shunt reactor at Pickle Lake SS	Hydro One Transmission	2026-2027	20
Other Planning Considerations				
Fort Williams TS Shunt Capacitor Banks Replacement	Replacement of temporary capacitor banks with permanent units	Hydro One Transmission	2026-2027	6
Greenstone-Marathon Area System Needs	Further evaluation of the alternatives presented in the past IRRPs and RIP upon customers' requests	Hydro One Transmission and Proponent	TBD	TBD
Supply to the Ring of Fire	IESO to update Supply to the Ring of Fire study	IESO	TBD	TBD

1. INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process where, Hydro One as the lead transmitter undertakes the development of a RIP with input from the TWG for the region and publishes a RIP report. The second cycle of the Regional Planning process for the Northwest Ontario Region was initiated with the publication of Needs Assessment (NA) report in July 2020 by Hydro One, followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) in January 2021 and in January 2023 published by the IESO respectively.

The RIP report includes a common discussion of all the options and recommended plans and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs.

This report was prepared by the Northwest Ontario Technical Working Group ("TWG"), led by Hydro One Networks Inc. (Transmission). The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC"), the Municipalities, the transmitters, and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: Northwest Ontario Region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Networks Inc. (Distribution)
2	Independent Electricity System Operator ("IESO")
3	Atikokan Hydro Inc.
4	Fort Frances Power Corporation
5	Sioux Lookout Hydro Inc.
6	Synergy North
7	Wataynikaneyap Power LP
8	NextBridge Infrastructure LP
9	Hydro One Networks Inc. (Transmission)

2. OBJECTIVES AND SCOPE OF REGIONAL INFRASTRUCTURE PLAN

This RIP report examines the needs in the Northwest Ontario Region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs for the Northwest Ontario region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major high voltage transmission equipment, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs and wires plans in the near and medium-term to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the Northwest Ontario IRRP, Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

3.1 Overview

Bulk System Planning, Regional Planning and Distribution Planning are the three levels of planning for the electricity system in Ontario. Bulk system planning typically looks at issues that impact the system on a provincial level and requires longer lead time and larger investments. Comparatively, planning at the regional and distribution levels look at issues on a more regional or localized level. Typically, the most

essential and effective regional planning horizon is the near- to medium-term (1- 10 years), whereas long-term (10-20 years) regional planning mostly provides a future outlook with little details about investments because the needs and other factors may vary over time. On the other hand, Bulk System plans are developed for the long term because of the larger magnitude of the investments.

The regional planning process begins with a Needs Assessment (NA) which is led by the transmitter to identify, assess, and document which of the needs

a) can be addressed directly between the customer and transmitter along with a recommended plan, and;
b) that require further regional coordination and identification of Local Distribution Companies (LDCs) to be involved in further regional planning activities for the region.

At the end of the NA, a decision is made by the Technical Working Group (TWG) as to whether further regional coordination is necessary to address some or all the regional needs. If no further regional coordination is required, recommendations to implement the recommended option and any necessary investments are planned directly by the LDCs (or customers) and the transmitter. The Region's TWG can also recommend to the transmitter and LDCs to undertake a local planning process for further assessment when needs

a) are local in nature,
b) require limited investments in wires (transmission or distribution) solutions, and;
c) do not require upstream transmission investments.

If coordination at the regional or sub-regional levels is required for identified regional needs, then the Independent Electricity System Operator (IESO) initiates the Scoping Assessment (SA) phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires or resource alternatives, e.g., Conservation and Demand Management (CDM), Distributed Generation (DG), etc., in order to make a decision on the most appropriate regional planning approach including Local Plan (LP), Integrated Regional Resource Plan (IRRP) and/or Regional Infrastructure Plan (RIP).

The primary purpose of the IRRP is to identify and assess both resource and wires options at a higher or macro level, but sufficient to permit a comparison of resource options vs. wire infrastructure to address the needs. Worth noting, the LDCs' CDM targets as well as contracted DG plans provided by IESO and LDCs are reviewed and considered at each step in the regional planning process.

If and when an IRRP identifies that resource and/or wires options may be most appropriate to meet a need, resource/wires planning can be initiated in parallel with the IRRP or in the RIP phase to undertake a more detailed assessment, develop specific resource/wires alternatives, and recommend a preferred wires solution.

The RIP phase is the final phase of the regional planning process and involves: discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and, development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive and consolidated report of a wires plan for the

region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

The various phases of Regional Planning Process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome are shown below in figure 1.

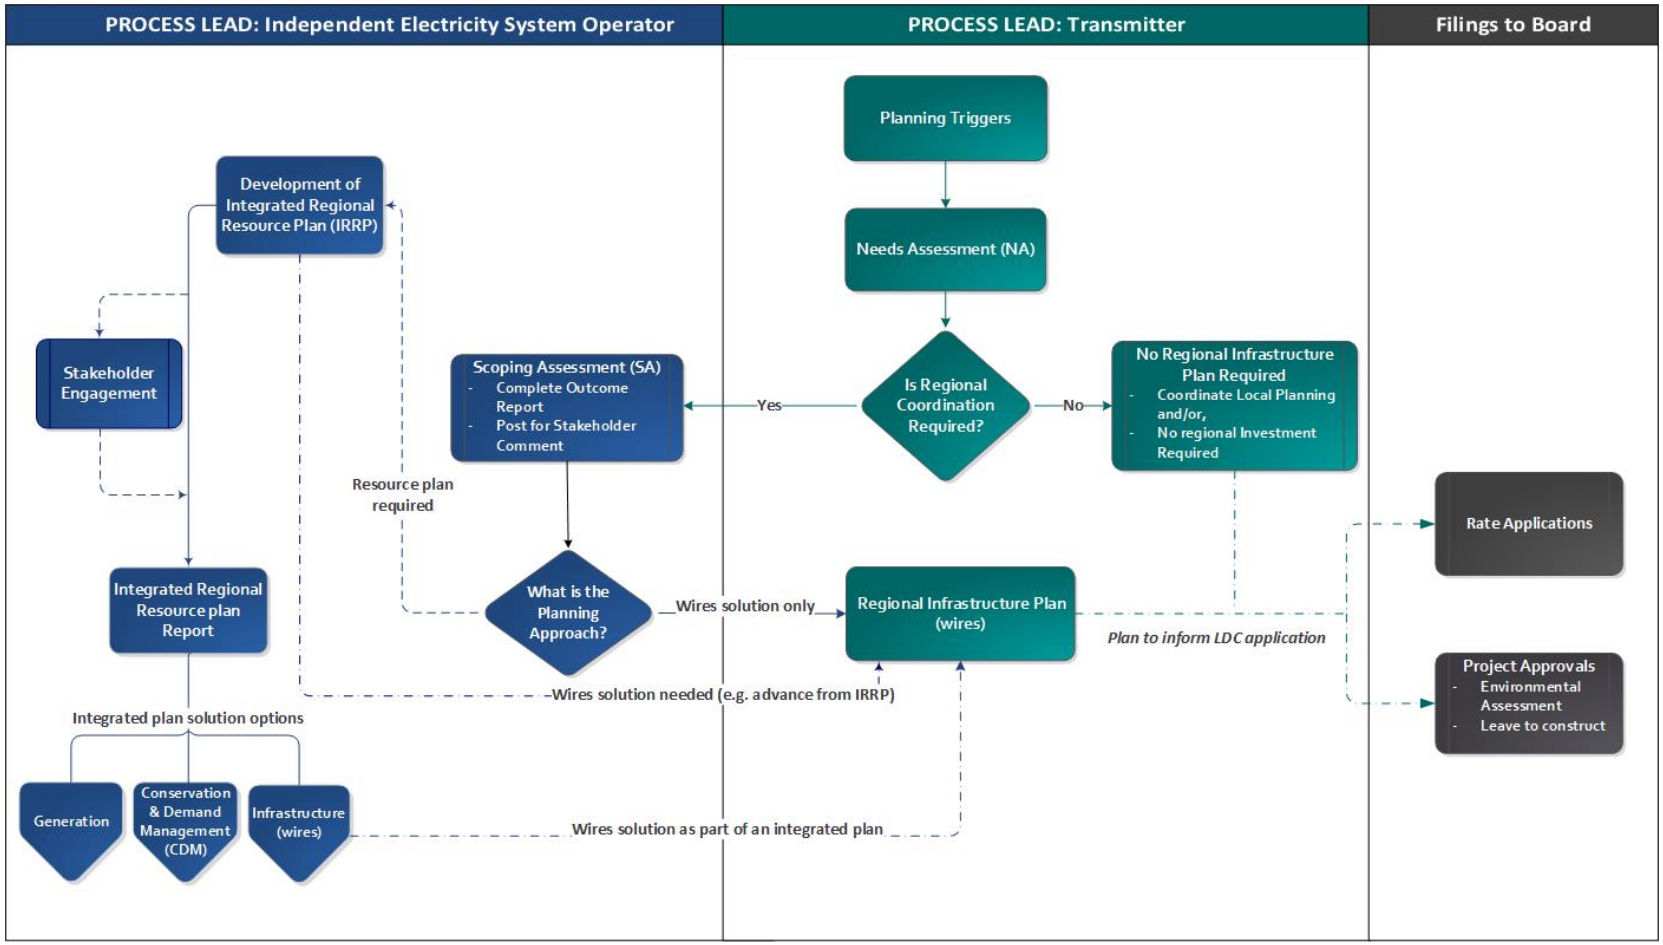

Figure 1: Regional Planning Process Flowchart

3.2 Regional Infrastructure Plan Methodology

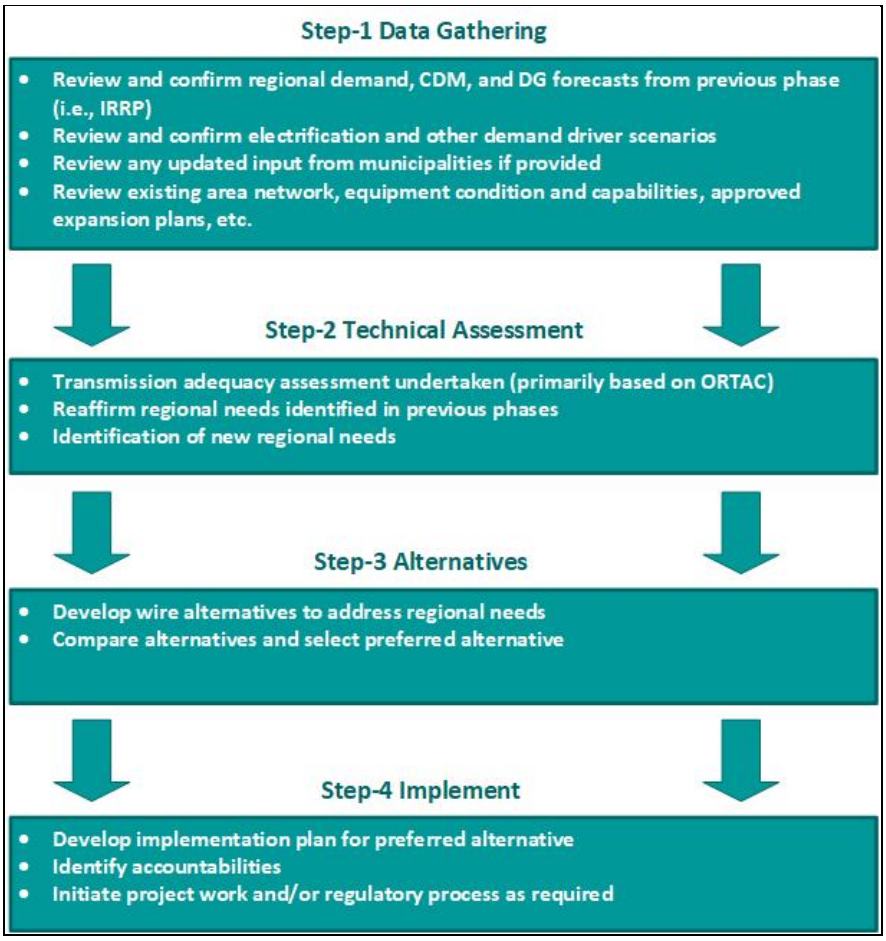

Figure 2: Regional Infrastructure Plan Methodology

Figure 2 above represents the four-step process of the Regional Infrastructure Plan which are described below:

3.2.1. Data Gathering:

The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the technical working group (TWG) to reconfirm or update the information as required. The data collected includes:

- Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs. As agreed by TWG members, the load forecast from the IRRP was used for this RIP.

- Review and confirm electrification and other growth scenarios which effects the projects recommended in in previous stages and also update the inputs provided by the Municipalities.
- Existing area network and capabilities including any bulk system power flow assumptions.
- Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

3.2.2. Technical Assessment:

The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3.2.3. Alternative Development:

The third step is the development of wires options to address the needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

3.2.4. Implementation Plan:

The fourth and last step is the development of the implementation plan for the preferred alternative, identifying accountabilities and initiate project work or obtain permissions from Regulatory Commission if any.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

Northwest Ontario Region is roughly boarded by west of Hudson Bay and James Bay, North and West of the Lake Superior, and East of the Canadian province of Manitoba. The region consists of the districts of Thunder Bay, Kenora and Rainy River. Almost 54 percent of Region's entire population lives in Thunder Bay. The region accounts for approximately 60 percent of land area of the province and about two percent of Ontario's total population.

The geographical boundaries of the Northwest Ontario region are shown in Figure 3 below.

Figure 3: Map of Northwest Ontario Regional Planning Area

Bulk electrical supply to the Northwest Ontario region is provided through a combination of local generation stations connected to the 230kV and 115kV network, the East-West Tie transmission corridor and future Waasigan transmission line.

The Local Distribution Companies ("LDCs") that serve the electricity demands for the Northwest Ontario are Hydro One Networks Inc. (Distribution), Atikokan Hydro Inc., Synergy North, Sioux Lookout Hydro Inc., and Fort Frances Power Corporation. The LDCs receive power at the step-down transformer stations and distribute it to the end users – industrial, commercial and residential customers.

In the first cycle of regional planning, the region was divided into four sub-regions, each with its own IRRP. The January 2015 Integrated Regional Integrated Regional Resource Plan ("IRRP") report for North of Dryden Sub-Region, the June 2016 IRRP report for Greenstone-Marathon Sub-Region, the July 2016 IRRP report for West of Thunder Bay Sub-Region, and the December 2016 IRRP report for Thunder Bay Sub-Region focused on northern, eastern, western, and central parts, respectively, of the Region. All IRRP reports were prepared by the IESO in conjunction with Hydro One and the LDCs. The January 2021 Northwest Region second cycle SA report prepared by IESO recommended a single IRRP covering the entire Northwest region. Subsequently, the January 2023 Northwest Ontario Region IRRP prepared by IESO considered the region as a whole.

4.1 North of Dryden Sub-Region

A radial single-circuit 115kV transmission line (“E4D”) and a new 230kV transmission line ("W54W”) supply electricity to the customers in the North of Dryden sub-region. The major supply stations for this sub-region are Dryden TS and Pickle Lake CTS, where the voltage is stepped down from the 230kV to 115kV at both stations, to serve local and industrial customers. Two of Wataynikaneyap Power’s 115kV transmission lines (WBC and WPQ) will supply two remote subsystems, north of Pickle Lake and Red Lake. Electricity demand in the North of Dryden sub-region is generally supplied by local hydroelectric generation.

The circuits and stations of the area are summarized in the Table 2 below:

Table 2: Transmission Station and Circuits in the North of Dryden Sub-Region

115kV circuits	230kV circuits	Transformation Stations	Generation Stations
• E4D • E2R • E1C • M1M • M3E • C3W • C2M • WBC** • WPQ**	• W54W	• Red Lake TS • Cat Lake MTS • Pickle Lake CTS* • Slate Falls DS • Perrault Falls DS • Crow River DS • Pickle Lake SS • Ear Falls TS • CTS1 • CTS2 • CTS3*	• Ear Falls GS (18.6MW) • Manitou Falls GS (72MW) • Lac Seul GS (12.5MW)

*Stations with Autotransformers installed

** Multiple Wataynikaneyap Power circuits and transformer stations are supplied radially from WBC (which connects to Pickle Lake CTS) and WPQ (which connects to E2R). See Appendices B & C for details.

4.2 Greenstone-Marathon Sub-Region

Electrical supply to the customers in the Greenstone-Marathon Sub-Region comprises of Marathon TS and Alexander Switching Station (“SS”). Located in the town of Marathon, Marathon TS connects the Northwest electrical system to the East Lake Superior electrical system at Wawa TS, with four 230kV lines - W21M, W22M, W35M and W36M. Marathon TS steps down 230kV to 115kV and supplies customers in the Town of Marathon, White River and Manitouwadge through a 115kV single circuit - M2W. Three circuits A5A, A1B, and T1M - in series connect Marathon TS to Alexander SS in Thunder Bay Sub-Region.

The circuits and stations of the area are summarized in the Table 3 below:

Table 3: Transmission Station and Circuits in the Greenstone-Marathon Sub-Region

115kV circuits	230kV circuits	Transformation Stations	Generation Stations
• A1B • A5A • A4L • T1M • M2W	• W21M • W22M • W35M • W36M • M23L • M24L • M37L • M38L	• Marathon TS* • Longlac TS • Manitouwadge TS • Beardmore DS #2 • Jellicoe DS #3 • Manitouwadge DS #1 • Marathon DS • Pic DS • Schreiber Winnipeg DS • White River DS • CTS1 • CTS2 • CTS3 • CTS4 • CTS5	• CGS1 • CGS2 • CGS3 • CGS4 • CGS5 • CGS6

*Stations with Autotransformers installed

4.3 West of Thunder Bay Sub-Region

Supply to this Sub-Region is provided from a 230kV transmission system consisting of Kenora TS, Fort Frances TS, Dryden TS, and Mackenzie TS. Kenora TS steps down 230kV to 115kV and supplies customers in the City of Kenora and surrounding areas. In addition, it also connects Ontario to Manitoba's electrical system through two 230kV transmission lines, K21W and K22W. Fort Frances TS steps down 230kV to 115kV and supplies customers in the City of Fort Frances and surrounding areas. It also connects Ontario to Minnesota's electrical system through a 115kV transmission line, F3M. Dryden TS steps down 230kV to 115kV and supplies customers in the City of Dryden and surrounding areas. It also connects West of Thunder Bay to North of Dryden Sub-Region. Mackenzie TS steps down 230kV to 115kV and supplies customers in Atikokan and surrounding areas. It also connects West of Thunder Bay to the Thunder Bay Sub-Region. The West of Thunder Bay Sub-Region is also supplied by many local hydroelectric generation facilities.

The circuits and stations of the area are summarized in the Table 4 below:

Table 4:Transmission Station and Circuits in the West of Thunder Bay Sub-Region

4.4 Thunder Bay Sub-Region

Thunder Bay Sub-Region consists of the Lakehead TS as the 230kV step-down transformation facility which steps down 230kV to 115kV and supplies customers in the City of Thunder Bay and surrounding areas. The area is served primarily at 115kV by three step-down transformer stations – Birch TS, Fort William TS, and

Port Arthur TS #1. Two parallel circuits A7L and A8L connect Lakehead TS to Alexander SS, which then interconnect Alexander Generating Station ("GS"), Cameron Falls GS, and Pine Portage GS together.

The circuits and stations of the area are summarized in the Table 5 below:

Table 5: Transmission Station and Circuits in the Thunder Bay Sub-Region

*Stations with Autotransformers installed

The single line diagram of the Transmission Network of Northwest Ontario region is shown in Figure 4 below.

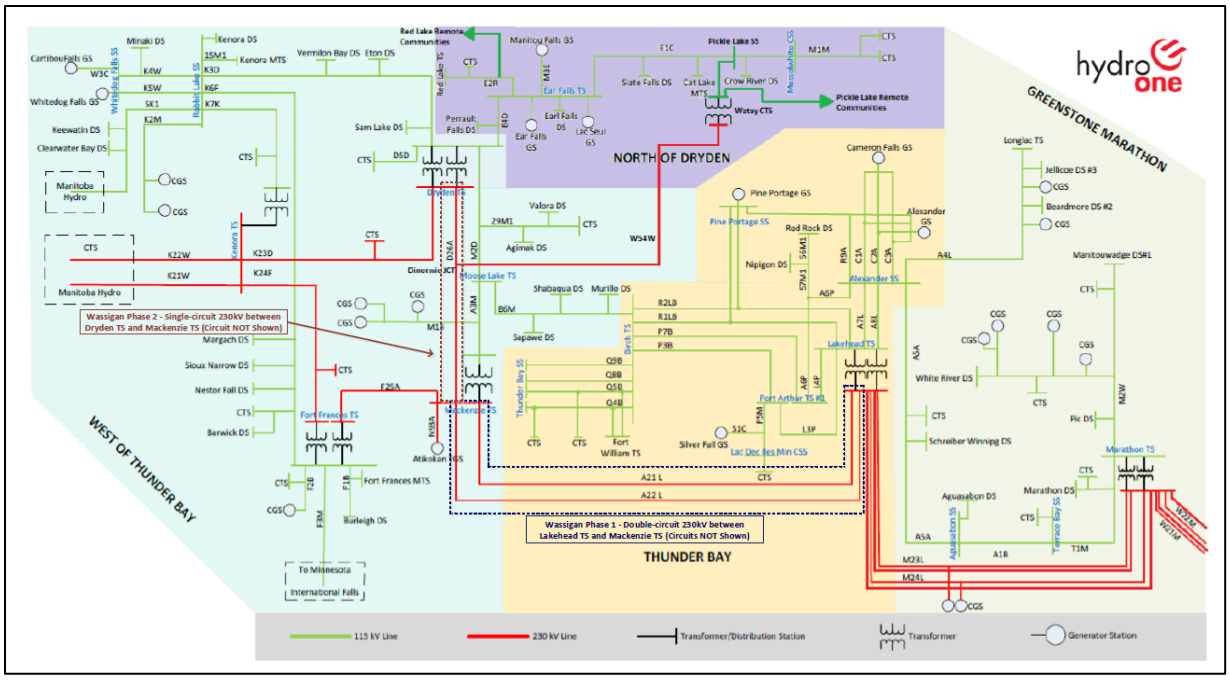

Figure 4: Northwest Ontario Transmission Single Line Diagram

4.5 New/Ongoing Transmission Line Projects Connect Sub-Regions

Below three recent/ongoing transmission projects in the Northwest regions reinforce the transmission corridors of the four sub-regions:

- East-West Tie Reinforcement
  - New double circuit 230kV line from Wawa TS to Lakehead TS in the Municipality of Shuniah, near Thunder Bay, Ontario, with a connection approximately mid-way at the Marathon TS.
- Waasigan Transmission Line Project
  - Phase 1 – New double circuit 230kV line from Lakehead TS to Mackenzie TS;
  - Phase 2 – New single circuit 230kV line from Mackenzie TS to Dryden TS.
- Wataynikaneyap Transmission Project
  - New single circuit 230kV line from Dinorwic Junction near Dryden to Pickle Lake CTS near Pickle Lake;
  - 115kV Remote connection subsystems north of Pickle Lake and Red Lake.

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR ARE UNDERWAY

In this section, all projects that have been completed in the past ten years or currently are underway is provided and their scope of work is briefly discussed. As a part of this or previous Regional Planning Cycle(s), several "Major HV Transmission Projects" were recommended in the Northwest Region to improve the supply capability and reliability.

Hydro One, Next Bridge Infrastructure and Wataynikaneyap Power, three Transmission Asset Owners (TAO) in the region have undertaken execution of the projects recommended in the past ten years. A summary and brief description of all the projects completed or are currently underway is given below:

I. Following Major projects were completed during the last ten years:

- **Manitouwadge TS (2016)** – The 115/44kV, 5/7 MVA T1 transformer was replaced with new 115/44kV 25/33/41.7 MVA unit.
- **Dryden TS (2018)** –Two 115/44kV, 11/15 MVA transformers were replaced with new 25/33/42 MVA units in addition to replacement of five 115kV breakers.
- **Lakehead TS (2017)** – Two 230/115kV autotransformers were replaced with new 230/115kV 150/200/250MVA units.
- **Birch TS (2015)** – One 115/25kV transformer was replaced with a new 115/25kV 25/33/42MVA unit.
- **Ear Falls TS (2022)** – One 115/13.2 kV transformer was replaced with a new 115/13.2 kV 7.5/10/12.5MVA unit in addition to replacement of four 115kV breakers.
- **East West Tie Reinforcement (2022)** – A 450 km, double-circuit, 230kV transmission line from Wawa TS to Lakehead TS was built with a connection approximately mid-way at Marathon TS.
- **Wataynikaneyap Power Project Phase 1 (2022)** – A 300 km, single circuit, 230kV transmission line from Dinorwic to Pickle Lake, Ontario was built with a 230/115kV autotransformer, related switching facilities and the necessary voltage control devices.

II. Following Major projects are underway:

- **Rabbit Lake SS (2024-2027)** –This investment will replace the station equipment identified as in poor condition and at high risk of failure. Hydro One will replace identified 115kV circuit breakers, associated disconnect switches, instrument transformers and equipment protections. The scope of work also involves installing new AC station service, DC battery and PCT building.
- **Whitedog Falls SS (2025-2028)** – This investment will replace the station equipment identified as in poor condition and at high risk of failure. Hydro One will replace identified 115kV circuit

breakers and associated switches. The scope of work also involves replacing and upgrading DC station supply system.

- **Mackenzie TS (2025-2028)** – This investment will replace the station equipment identified as in poor condition and at high risk of failure. Hydro One will replace 230kV circuit breakers, select protections, and AC/DC station service systems. A new 115/44kV load facility at Mackenzie TS to replace the one at Moose Lake TS.

- **Wawa TS (2026-2029)** – This investment will replace the station equipment identified as in poor condition and at high risk of failure. Hydro One will replace two autotransformers rated 75/100/125MVA, 230/115kV, four 230kV circuit breakers, and four 115kV circuit breakers. The scope of work also includes replacing associated disconnect switches, protection equipment and the station service system.

- **Wataynikaneyap Power Project Phase 2 (2022-2024 and beyond)** – This investment, led by Wataynikaneyap Power, will construct approximately 1438 km of overhead 115kV, 44kV and 25 kV transmission lines and twenty substations to connect 16 First Nations in two transmission subsystems by 2024 (10 north of Pickle Lake and 6 north of Red Lake). The Red Lake subsystem is designed to connect a seventh First Nation beyond 2024.

Note: The planned in-service year for the above projects is tentative and is subject to change.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

6.1. Load Forecast

After verification from the TWG participants, and as no material changes were identified, the Northwest Region IRRP Load Forecasts were used in development of this Report. TWG participants, including representatives from LDC's, Wataynikaneyap Power, IESO and Hydro One, provided information and input for the IRRP Load forecast, which also includes the inputs from the Municipal Energy Plans (MEP) and/or Community Energy Plans (CEP).

During the study period, the load in the Northwest Ontario Region is expected to grow at an average annual rate of approximately 2% in winter from 2023-2033. The Region is winter peaking, so this assessment is based on winter peak loads.

Figure 5 shows the Northwest Region median winter weather net non-coincident load forecast from 2023-2033. Note that the non-coincident forecast is typically 10-15% higher than the coincident

forecast in the Northwest region. This assessment is based on non-coincident forecast. In the event that non-coincident load forecast identifies network element needs, a sensitivity study will be performed utilizing coincident load forecast. The load forecasts from the Northwest Ontario Region were adopted as agreed to by the TWG. The load forecast shown is the regional non-coincident forecast, representing the sum of the load in the area for the step-down transformer stations.

The main factor contributing to the deviation between the load forecasts in the IRRP and the RIP is the mining sector forecast. In the IRRP, the mining forecast was considered final as of the end of 2021. However, after the completion of IRRP, IESO has provided an updated reference scenario for the mining forecast, accounting for potential future mining projects. As a result, this updated mining forecast contributes to the variation between the load forecasts in the IRRP and RIP beyond 2026.

Non-coincident forecast for the individual stations in the region is available in Appendix A and is used to determine any need for station capacity relief in the region.

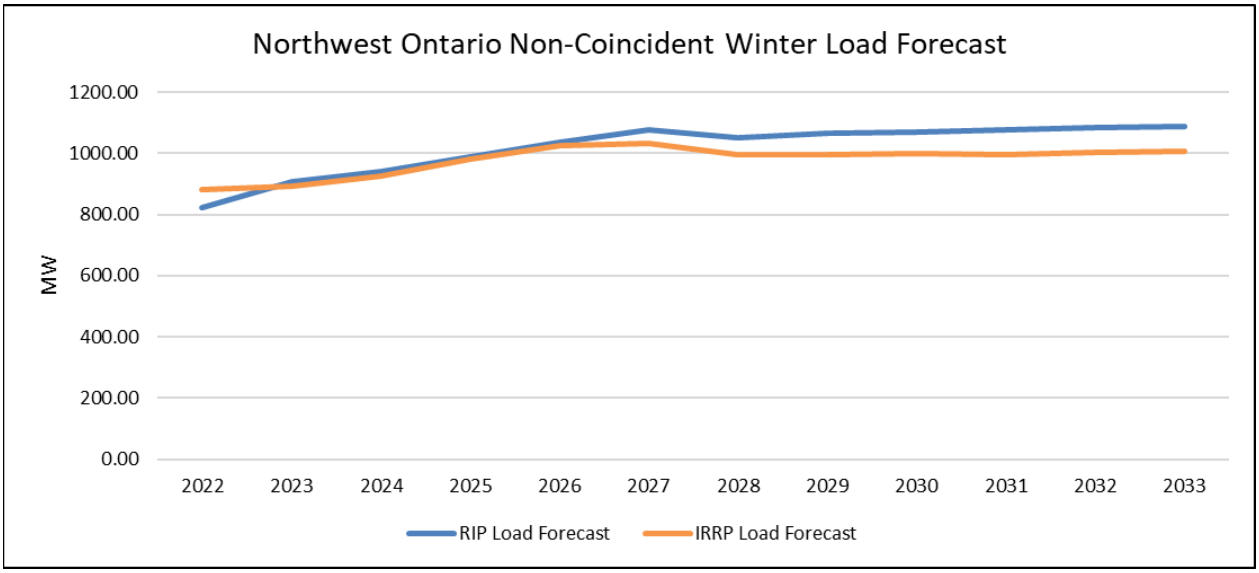

Figure 5: Northwest Ontario Region Winter Non-Coincident Net Peak Load Forecast

6.2. Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2023-2033. However, a longer term forecast up to 2040 is provided to identify long-term needs and align with the Northwest region IRRPs.

- LDCs reconfirmed load forecasts up to 2033. A longer term forecast up to 2040 is adopted with IRRP load forecast. The additional three years of forecasts were extrapolated based on growth rate as a reasonable position to complete the 20 years period.
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- This region is winter peaking, so this assessment is based on winter peak loads. However, since summer transmission line ratings are more constrained, Section 7.3 Transmission Line Capacity Needs is based on potential summer peak load demands.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR) or by using the winter 10-day LTR if performing a winter season assessment.
- Bulk transmission line and auto-transformation capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Adequacy assessment is conducted as per ORTAC.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying the Northwest Region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway, listed in **"Section 5"** are completed.

In current regional planning cycle, the following regional assessments were completed, and their findings were used as inputs to this RIP report:

- Northwest Region Second Cycle Needs Assessment Report completed in July 2020 by Hydro One
- Northwest Region Second Cycle Scoping Assessment Report completed in January 2021 by the IESO
- Northwest Region Second Cycle Integrated Regional Resource Plan Report completed in January 2023 by the IESO

The Technical Working Group identified several regional needs based on the forecasted load demand over the near to mid-term period in the reports mentioned above. The results of the Adequacy Assessment to define the needs are discussed in sub-sections "7.1 to 7.4" and a detailed description and status of plans to meet these needs are given in **"Section 8"** of this report.

7.1. Asset Renewal Needs for Major HV Transmission Equipment

In addition to the asset renewal needs identified in previous regional planning cycle, Hydro One and TWG has also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the Northwest Region. The complete list of major HV transmission equipment requiring replacement in the Northwest Region is provided in table 6 in this sub-section. Hydro One, Next Bridge Infrastructure and Wataynikaneyap Power are the Transmission Asset Owners (TAO) in the Region.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
  replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

Table 6: Major HV Transmission Asset assessed for Replacement in the region

Station/Circuit	Need Description	Planned ISD
Rabbit Lake SS	Replace equipment identified in deterioration and technical obsolescence	2024-2027
Whitedog Falls SS	Replace equipment identified in deterioration, technical obsolescence and lack of spare parts availability and no manufacturer support	2025-2028
Mackenzie TS	Replace equipment identified in deterioration and technical obsolescence	2025-2028
Wawa TS	Replace Equipment deterioration due to aging infrastructure	2026-2029
Marathon TS	Replace equipment identified in deterioration and technical obsolescence	2026-2029

Lakehead TS	Replace equipment identified in deterioration and technical obsolescence	2028-2031
Lakehead TS	Replace Condenser C8 identified in deterioration and technical obsolescence	2027
Fort Frances TS	Replace equipment identified in deterioration and technical obsolescence	2029-2032
Kenora TS	Replace equipment identified in deterioration, technical obsolescence and lack of spare parts availability and no manufacturer support	2030-2033

Note: The planned in-service year for the above projects is tentative and is subject to change.

7.2. Station Capacity Needs

Over the study period 2023-2033 RIP reviewed the capacity of all the 230kV, 115kV Transforming stations and 115kV step down Distribution stations within the Northwest Ontario Region. The NA and IRRP studies had previously indicated that the following stations require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast, the stations which require capacity relief during the study period are shown in Table 7 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (winter) Limited Time ratings.

Table 7: Northwest Ontario Region Station Capacity Needs in the study period

Sr.no.	Station Name	Capacity (MVA)	2023 Historical Loading (MW)	Station 10 day LTR (MW)	Need Date
1	Margach DS	11.60	10.07	10.44	2023
2	Crilly DS	2.40	2.28	2.16	2027
3	White Dog DS	3.20	2.37	2.88	2027
4	White River DS	15.60	12.02	14.04	2029
5	Sam Lake DS	24.00	23.34	21.06	Now
6	Kenora MTS	26.00	19.13	23.40	2030

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.3. Transmission Line Capacity Needs

Over the study period 2023-2033 RIP reviewed the capacity of all the 230kV and 115kV Transmission lines within the Northwest Region. The NA and IRRP studies had previously indicated that the following Transmission lines potentially require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast and following contingencies, the Transmission lines which require capacity relief during the study period are shown in Table 8 below. The mining sector load materialization timing drives the need timeframe. It defines when the peak load forecast exceeds the most limiting seasonal (summer) Limited Time ratings.

Table 8: Northwest Ontario Region Transmission Line Capacity Needs in the study period

Sr.no.	Name of Circuit	Name of Section	Contingency	LTE Line Rating (Amps)	Need Date
1	E2R	Ear Falls TS – Red Lake TS	NA	421	TBD
2	E4D	Dryden TS – Ear Falls TS	NA	410	TBD
3	M2W	Pic JCT – Manitouwadge JCT	NA	290	TBD

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.4. System Reliability, Operational and Load restoration Needs

Load security and load restoration needs were reviewed as part of the current study. The ORTAC Section 7 requires that no more than 600 MW of load be lost as a result of loss of 2 transmission elements.

Furthermore, loads are to be restored in the restoration times[1] specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

The IRRP studies had previously indicated that the following stations and transmission line require actions on system reliability and operational improvement. The RIP further confirms those needs with regards to System Reliability and Operation requirements.

[1] These approximate restoration times are intended for locations that are near staffed centers. In more remote locations, restoration times should be commensurate with travel times and accessibility.

Table 9: Northwest Ontario Region System Reliability and Operational Needs in the study period

Station/Circuit	Need Description
Fort France MTS	Planned outages considering station single supply configuration
E1C	Operation and high voltage under a normally open configuration

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the Northwest Ontario region. These needs include those previously identified in the NA and IRRP for the Northwest Ontario as well as any new needs identified during the RIP phase. All references to costs included in the alternative analysis are considered as planning allowances[2] and are used for comparative purposes only and may vary. The Needs in the region are summarized below in Table 10 below:

Table 10: Near/Mid-term Needs Identified in the region

Station/Circuit Name	Description of Need	Need Date	RIP Report Section
Asset Renewal Needs			
Rabbit Lake SS	Replace equipment identified in deterioration and technical obsolescence	2024-2027	8.1.1
Whitedog Falls SS	Replace equipment identified in deterioration, technical obsolescence and lack of spare parts availability and no manufacturer support	2025-2028	8.1.2
Mackenzie TS	Replace equipment identified in deterioration and technical obsolescence	2025-2028	8.1.3
Wawa TS	Replace Equipment deterioration due to aging infrastructure	2026-2029	8.1.4

[2] Allowances do not include real estate costs, environmental impacts and other costs not directly associated with the electrical infrastructure.

Marathon TS	Replace equipment identified in deterioration and technical obsolescence	2026-2029	8.1.5
Lakehead TS	Replace equipment identified in deterioration and technical obsolescence	2028-2031	8.1.6
Lakehead TS	Replace Condenser C8 identified in deterioration and technical obsolescence	2027	8.1.6
Fort Frances TS	Replace equipment identified in deterioration and technical obsolescence	2029-2032	8.1.7
Kenora TS	Replace equipment identified in deterioration, technical obsolescence and lack of spare parts availability and no manufacturer support	2030-2033	8.1.8
Station Capacity Needs			
Margach DS	Station Capacity Needs	2023	8.2.1
Crilly DS	Station Capacity Needs	2027	8.2.2
White Dog DS	Station Capacity Needs	2027	8.2.3
White River DS	Station Capacity Needs	2029	8.2.4
Sam Lake DS	Station Capacity Needs	Now	8.2.5
Kenora MTS	Station Capacity Needs	2030	8.2.6
Transmission Line Capacity Needs			
E2R	Capacity Needs of Section Ear Falls TS – Red Lake TS	TBD	8.3.1
E4D	Capacity Needs of Section Dryden TS – Ear Falls TS	TBD	8.3.1
M2W	Capacity Needs of Section Pic JCT – Manitouwadge JCT	TBD	8.3.2
System Reliability, Operational and Load restoration Needs			
Fort France MTS	The planned transmission outage caused customer interruptions due to the station's single supply configuration.	2023	8.4.1
E1C Operation and High Voltage	Supply capacity limitations with E1C operated normally closed; high voltage issues with E1C operated normally open	2023	8.4.2

Other Planning Considerations			
Fort William TS Shunt Capacitor Banks Replacement	Temporary capacitor banks to be replaced with permanent units	2026-2027	8.5.1

8.1 Asset Renewal Needs for Major HV Transmission Equipment

The Asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement)
- Replacing equipment with higher ratings and built to current standards

From Hydro One's perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

8.1.1. Rabbit Lake SS

Rabbit Lake SS, a North American Electric Reliability Corporation (NERC) Bulk Electrical System station, was originally built in 1956 and is located within the city limits of Kenora, Ontario. The switching station has six 115kV transmission lines connecting to three customer generating stations (CGSs) as well as Whitedog Falls SS, Kenora TS, Fort Frances TS, Dryden TS, and the interconnection with Manitoba Hydro. There are six 115kV oil circuit breakers and two 115kV SF6 circuit breakers in the yard.

Hydro One has plans to replace equipment identified in deterioration due to aging infrastructure and technical obsolescence due to outdated design. The scope of work involves replacing 115kV circuit breakers, associated disconnect switches, instrument transformers and equipment protections. A New AC station service, DC battery and PCT building will also be installed.

This investment will help maintain the reliability of supply to area customers and reduce the risk of interruptions caused by station equipment failure. The project is currently planned to be completed in 2024-2027.

8.1.2. Whitedog Falls SS

Whitedog Falls Switching Station (SS) located approximately 80 km northwest of the City of Kenora, containing three 115kV circuits that terminate at the station with four circuit breakers, connecting to Rabbit Lake SS, Caribou Falls GS, and Whitedog Falls GS.

Hydro One has plans to replace equipment identified in deterioration due to aging infrastructure and technical obsolescence with little or no spare parts and manufacturer support. The scope of work involves replacing 115kV circuit breakers and associated disconnect switches. Replacement and upgrades of the DC station supply system will also be part of this investment,

This investment will help maintain the reliability of supply to area customers and reduce the risk of interruptions caused by station equipment failure. The project is currently planned to be completed in 2025-2028.

8.1.3. Mackenzie TS

Mackenzie TS is a 230/115kV station is located approximately 200 km west of Thunder Bay, Ontario. Mackenzie TS has six 230kV breakers which are about 46 years old. The station is a major station for Waasigan transmission line reinforcement project.

Hydro One has plans to replace station equipment identified in deterioration due to aging infrastructure and technical obsolescence with minimal spare parts and manufacturer support. The scope of work involves replacing the existing 230/115kV 75/125 MVA autotransformer with new 230/115kV 75/100/125 MVA. The project will also replace 230kV circuit breakers, select protections, and AC/DC station service systems. Hydro One has also planned to install a new 115/44 kV load facility at the station to replace the one at Moose Lake TS, optimizing the area supply configuration.

This investment will help maintain the reliability of supply to Atikokan Hydro customers and reduce the risk of interruptions caused by station equipment failure. This project is currently planned to be completed in 2025-2028.

8.1.4. Wawa TS

Wawa TS is a 230/115kV transformer station, located southeast of the township of Wawa in northern Ontario. It was put in-service in 1969. The station is a major hub for connecting the Northeast, Northwest and Hydro One Sault Ste. Marie transmission systems. The existing autotransformers, oil circuit breakers, disconnect switches, protection and control, station service, and other ancillary facilities are in poor condition and in deterioration that require replacement to maintain the operability and reliability of the station.

Hydro One has plans to replace all deteriorated equipment at the station. The scope of work involves replacing two 239-121/13.9kV 75/100/125 MVA autotransformers, four 230kV circuit breakers, and four 115kV circuit breakers. In addition, the scope of work also includes replacing associated disconnect switches, protection equipment and station service system.

This investment will improve transmission system reliability and reduce the risk of interruptions caused by station equipment failure. This project is currently planned to be completed in 2026-2029.

8.1.5. Marathon TS

Marathon TS is a 230/115kV transformer station, located in the City of Marathon in northern Ontario. It was put in-service in 1970. The station is critical to the transmission system of the Northwest and a major hub for East-West power transfer. All four 115kV oil circuit breakers at the station are about 40 years old, and three 230kV circuit breaker at the station are about 48 years old.

Hydro One has plans to replace station equipment identified in deterioration due to aging infrastructure to ensure the reliability of the transmission system and supply to customers. The scope of work involves replacing three 230kV circuit breakers with new SF6 breakers, and four 115kV circuit breakers with new SF6 breakers. The replacement of disconnect switches, protection equipment, and AC station service system will also be part of this investment.

In addition to component replacement. this project will separate and re-terminate two branches of 115kV circuit M2W. M2W is a radial transmission line consisting of two independent branches that merge into 1 switching position at the entry point of Marathon TS. To unbundle, Hydro One will install one additional 115kV circuit breaker with associated protections in order to create a new switching position at Marathon TS 115kV bus.

This investment at Marathon TS will improve transmission system reliability performance and reduce the risk of interruptions caused by station equipment failure. This project is currently planned to be completed in 2026-2029.

8.1.6. Lakehead TS

Lakehead TS is a 230/115kV transformer station which was put in-service in 1955, located northeast of the city of Thunder Bay in norther Ontario. The station is critical to the transmission system of the Northwest, a major hub for East-West power transfer, and a major station for Waasigan transmission line reinforcement project. The station is classified as Bulk Electric System (BES) under NERC standards.

8.1.6.1 HV Component Replacement

Hydro One has plans to replace all station equipment identified in deterioration due to aging infrastructure to ensure the reliability of the transmission system and supply to the customers. The scope of work involves replacing high voltage circuit breakers with new SF6 breakers, replacing eight 115kV circuit breakers with new SF6 breakers, replacing protection equipment associated with 115kV facilities and the synchronous condenser, replacing select switches, and replacing/upgrading AC station service system.

This investment will improve transmission system reliability and reduce the risk of interruptions caused by station equipment failure. This project is currently planned to be completed in 2028-2031.

8.1.6.1 Condenser C8 Replacement

The transformers T7 and T8 at Lakehead TS are 239/121/13.9 kV 250 MVA autotransformers with primary and secondary windings connecting to the 230kV and 115kV systems, respectively. The tertiary windings of T7 and T8 are rated at 60MVA. In 2009, a -40/+60Mvar SVC replaced a poor condition condenser connected at T7 tertiary bus. The SVC consists of a 100Mvar TCR and a 60Mvar filter. A recent condition assessment has highlighted the poor condition and high risk of failure associated with C8, a synchronous condenser connected to T8's tertiary bus. To address this issue, Hydro One consulted with IESO to explore the options of maintaining the status quo, removing the condenser, or replacing it with appropriately sized equipment. The consideration of the need for condenser inertia was also part of the assessment.

Following discussions between IESO and Hydro One, it has been recognized that replacing C8 with a static synchronous compensator (STATCOM) is the preferred solution. To ensure optimal controller coordination, the recommended replacement strategy involves sourcing the STATCOM from the same vendor as the existing SVC. By installing a STATCOM with the same capacity and connecting it to the 13.8kV tertiary winding of transformer T8, effective voltage control of the 230kV bus at Lakehead can be achieved in coordination with the existing SVC at T7. This asset and infrastructure replacement will effectively mitigate the risks associated with equipment failure and enhance the overall reliability of the system. It's important to note that IESO is currently conducting further studies to assess the reactive power needs in northern Ontario.

8.1.7. Fort Frances TS

Fort Frances TS is in the Town of Fort Frances and was put in-service in 1947. Hydro One has plans to replace equipment identified in deterioration due to aging infrastructure and technical obsolescence. The scope of work involves replacing high voltage circuit breakers, replacing/upgrading AC/DC station service systems and protection equipment.

This investment will improve transmission system reliability and reduce the risk of interruptions caused by station equipment failure. This project is currently planned to be completed in 2029-2032.

8.1.8. Kenora TS

Kenora TS is a 230/115kV station in-service since 1972 and located in east side of Kenora City, Ontario. The station is critical to supply of the city of Kenora and the interconnection with the province of Manitoba.

Hydro One has plans to replace station equipment identified in deterioration due to aging infrastructure and technical obsolescence with minimal spare parts and manufacturer support. The scope of work involves replacing high voltage circuit breakers, protection equipment and replacing/upgrading AC/DC station service systems.

This investment will improve transmission system reliability and reduce the risk of interruptions caused by station equipment failure. This project is currently planned to be completed in 2030-2033.

8.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2023-2033 for the 230kV ,115kV Transformer stations and 115kV step down Distribution stations in the Northwest Ontario Region using either the summer or winter peak load forecasts that were provided by the study team. Based on the results, the following Station capacity needs have been identified in the during the study period:

8.2.1 Margach DS– 115kV – Distribution Station Step-Down Transformer Capacity Needs (2023)

Margach DS is approximately 10 km east of Kenora. Margach DS presently has two 115/ 26.5kV 7.5MVA transformers (T1/T2) with a winter LTR of 10.4MW. The historical demand at Margach DS has remained stable, consistently just below 10 MW. The station will exceed its normal supply capacity in 2023.

Table 11: Margach DS Load Forecast

Station	LTR (MW)	Load Forecast (MW)										
		2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
Margach DS	10.4	10.50	10.48	10.47	10.48	10.51	10.53	10.53	10.53	10.55	10.55	10.58

The following alternatives were considered to address Margach DS capacity need.

Alternative 1: Install Transformer Fan Monitoring.

Installing transformer fan monitoring is a relatively inexpensive solution to increase the station LTR by enabling the use of higher thermal ratings on the existing transformers.

Alternative 2: Maintain Status Quo

Considering that the peak loading in 2022 was 9.96 MW and there is only anticipated natural residential load growth, maintaining the status quo is also considered a viable solution.

The LDC- Hydro One Distribution recommends alternative 2 as the preferred solution at the time of this RIP. Regarding alternative 1, the LDC has incorporated it into its investment plan with an anticipated implementation date in 2025. Given the gradual growth in station loading and the existing plan in place, the LDC will closely monitor the station's load and take necessary actions if required before 2025, ensuring a smooth transition to Alternative 1.

8.2.2 Crilly DS– 115kV – Distribution Station Step-Down Transformer Capacity Needs (2027)

Crilly DS is a small (~2.2 MW LTR) station supplied from 115kV transmission circuit M1S and has a 6.6 kV bus shared with Sturgeon Falls CGS, a small hydroelectric plant located approximately 50 km west of Atikokan. This legacy non-standard supply arrangement results in annual outages at Crilly DS during maintenance periods of the generator. Backup power from diesel generation is utilized when Sturgeon Falls is offline. Moreover, the station equipment is approaching its end-of-life, and limited space constraints limit refurbishment options on-site.

Crilly DS is expected to exceed its capacity in 2027 due to incremental growth in the community.

Table 12: Crilly DS Load Forecast

Station	LTR (MW)	Load Forecast (MW)										
		2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
Crilly DS	2.16	2.14	2.14	2.15	2.16	2.18	2.19	2.20	2.21	2.23	2.24	2.25

To address this capacity issue, the TWG has identified the following alternatives for consideration:

Alternative 1: Refurbish Crilly DS at the current location

This alternative is likely the least costly solution, but Crilly DS will still rely on backup power from diesel generation during outages at Sturgeon Falls CGS.

Alternative 2: Rebuild Crilly DS at a different location as a 115/25 kV HVDS

This alternative entails rebuilding Crilly DS at a different location, operating as a 115/25 kV HVDS station. The new site would be situated closer to the existing station and supplied by the 115kV transmission circuit M1S.

Alternative 3: Rebuild Crilly DS at a different location as a 230/25 kV TS (connected to F25A closer to the community served by Crilly DS)

This alternative will rebuild the station and operate it as a 230/25kV Transformer Station (TS).

Alternative 4: Replace Crilly DS with 115:25kV padmount transformer (transformer enclosed in a grounded cabinet that can be accommodated outside the existing station fence)

This alternative requires further investigations on the feasibility of configuring the station with a padmount transformer.

Hydro One Distribution are considering all 4 alternatives. Due to the radial supply nature of M1S, reliability concerns can only be partially addressed by upgrading station assets at Crilly DS. Considering the timeline and the need for further assessment, the LDC has indicated that additional studies and investigations are required to evaluate the cost and benefits of all four alternatives before determining the preferred solution to address the station capacity needs projected for 2027. In the interim, the LDC will closely monitor the loading of Crilly DS and take appropriate actions if the load grows faster than forecasted. This

proactive approach will ensure that any capacity challenges are promptly addressed. By conducting thorough analyses and closely managing the station's loading, the LDC aims to make informed decisions and select the most suitable alternative to meet the future capacity requirements of Crilly DS.

8.2.3 Whitedog DS – 115kV - Distribution Station Step Down Transformer Capacity Need (2027)

Whitedog DS is a distribution station that receives its supply from the OPG Whitedog GS 13.8kV bus. The station is comprised of three 0.667MVA single-phase transformers, with an additional single-phase transformer serving as a spare. All the single-phase transformers in the station are 75 years old. Currently, Whitedog DS is connected to a single feeder (12.48kV) that supplies the Whitedog First Nation community.

Whitedog DS is expected to exceed its capacity in 2027 due to incremental growth in the community. Recently, the Whitedog First Nation also expressed plans for growth and expansion within their community and it is at the preliminary stage of development. To support this potential load growth, the capacity of the Whitedog DS station would need to be increased. In addition, OPG is planning system renewal work on this 13.8 kV bus and needs to coordinate scope and cost with the LDC if the connection is to be maintained.

Table 13: Whitedog DS Load Forecast

Station	LTR (MW)	Load Forecast (MW)										
		2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
Whitedog DS	2.88	2.80	2.82	2.85	2.87	2.92	2.95	2.99	3.01	3.05	3.07	3.11

To address this capacity issue, the TWG has identified the following tentative alternatives for consideration:

Alternative 1: Replace the existing transformers with a larger size

This alternative will allow Whitedog DS to remain connected to the OPG bus. But it involves expanding the existing site to accommodate larger-size transformers, which need OPG's approval since OPG owns the land. Additionally, OPG is in the process of refurbishing the Whitedog GS switchgear; if the DS is to remain connected to OPG, the scope of work is subject to coordination with OPG.

Alternative 2: Relocate Whitedog DS as a 115/12.48 kV DS

This alternative will relocate Whitedog DS with a larger size transformer to the Hydro One Whitedog Switching Station, connecting it to the transmission 115kV bus. This solution may require a small site expansion, which would necessitate approval from OPG.

Alternative 3: Maintain Status Quo

This alternative will not take action at this point and continue monitoring if the forecasted load growth materializes. This alternative requires the LDC to work with the generator to land on an amicable solution for the generator's system renewal work.

The LDC – Hydro One Distribution recommends alternative 3 maintaining the status quo for now. While the Whitedog First Nation has expressed plans for future growth, they are currently in the preliminary stage, indicating that the load demand increase might not materialize in the immediate future. Maintaining the status quo allows the LDC to closely monitor the actual load growth and assess its sustainability before committing to significant infrastructure changes. If the projected increase materializes, appropriate corrective actions will be taken. This approach ensures that the LDC can respond effectively to the evolving needs of the Whitedog First Nation while maintaining a reliable power supply to the community.

8.2.4 White River DS – 115kV - Distribution Station Step Down Transformer Capacity Need (2029)

White River DS is a 115/26.8 kV step down distribution station supplying the Town of White River. The station has two 7.5/10MVA transformers both in service serving the load with a LTR of 14.04MW. However, the station is lacking the provision of a spare transformer as a backup in the event of a failure. Currently, if one of the transformers fails, the load can be transferred to the remaining operational unit. With the projected load growth, White River DS's contingency capacity to fully restore the load following a contingency will be compromised, specifically, in the event of one transformer failure, the failed transformer's load cannot be offloaded to the other transformer at the station due to overloading as the load grows in the area. Hence, the station is expected to exceed the contingency capacity in 2029.

Table 14: White River DS Load Forecast

Station	LTR (MW)	Load Forecast (MW)										
		2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
White River DS	14.04	13.42	13.51	13.69	13.80	13.91	14.00	14.09	14.18	14.27	14.35	14.44

To address this capacity issue, the TWG has identified the following tentative alternatives for consideration:

Alternative 1: Maintain Status Quo

This alternative will not take action at this point and continue monitoring if the forecasted load growth materializes.

Alternative 2: Install a MUS Facility

There is a tentative plan for the LDC to look into installing a MUS facility at the station; in such case, the station contingency capacity can be increased with the additional MUS facility. It is also recognized as the most cost-effective solution to address the need.

The LDC – Hydro One Distribution recommends alternative 1 to maintain the status quo as the preferred solution. Based on the load forecasts, White River DS will exceed contingency capacity in 2029. The next

cycle of regional planning will commence in 2025. It will allow the working group to reevaluate this need and confirm if the capacity needs at White River DS still holds in 2028. Should this be the case, the study group at that moment will decide the best course of action to fill this need.

8.2.5 Sam Lake DS – 115kV -Distribution Station Step Down Transformer Capacity Need (Now)

Sam Lake DS is a Hydro One Distribution owned 115/25kV High Voltage Distribution Station (HVDS) supplied from 115kV circuit K3D. The station is the sole supply for Sioux Lookout Hydro LDC. It contains two 115kV/25kV 15/20/25MVA transformers (T1 and T2) and only one of the transformers is in-service at any given time. The station is projected to exceed its normal supply capacity this year. A Local planning study[3]was conducted and was published in January 2023 with a TWG[4] recommended solution to address the need.

Station	LTR (MW)	Load Forecast (MW)										
		2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
Sam Lake DS	21.6	28.22	28.47	28.67	28.70	28.72	28.74	28.74	28.74	28.78	28.81	28.87

The following alternatives were considered by the TWG in the Local Planning study:

Alternative 1 – T1 and T2 Transformer both in service at Sam Lake DS

Currently, only one of the transformers is on load, while the other is a hot spare in case of a transformer contingency. Therefore, the additional capacity can be made available if both T1 and T2 are in service.

Alternative 2 – Install fan monitoring on T1 and T2 at Sam Lake DS

As discussed in section 2, T1 and T2 transformers at Sam Lake DS are currently equipped with unmonitored fans, and it is not reliable to load the transformers at the maximum fan-cooled rating without a fan monitoring system. Therefore, installing fan monitoring can increase the station capacity at Sam Lake DS.

Alternative 3 – Install an additional (3rd) transformer at Sam Lake DS

An additional transformer at Sam Lake DS can also increase the capacity at Sam Lake DS.

Alternative 4 – Construct a new 115kV/25kV station supplied from Hydro One's K3D Circuit

A new High Voltage Distribution Station (HVDS) can be built to increase the capacity of the area.

Alternative 5 – Construct a new 230kV/25kV station supplied from Wataynikaneyap transmission system

[3] Local Planning – Report (Sam Lake DS)
[4] Local Planning Technical Working Group Members: Hydro One Inc. (Transmission), Hydro One Inc. (Distribution) and Sioux Lookout Hydro.

A new station can be built and supplied from the new Wataynikaneyap 230kV system, which would bring in a new transmission supply and significantly improve the load supply diversity at the Sam Lake DS area in case of a K3D outage.

The TWG have conducted a coordinated review and evaluation of all the alternatives to address the local capacity need. The TWG recommended Alternative 2 – Install fan monitoring on T1 and T2 at Sam Lake DS. This alternative allows Hydro One Distribution and Sioux Lookout Hydro to address the capacity need in the timeframe required (based on the winter conservative load forecast) and maintain supply reliability to the Sam Lake area customers. This alternative is the lowest cost option and achieves the best balance between cost versus local system benefits.

8.2.6 Kenora MTS – 115kV - Transmission Station Capacity Need (2030)

Kenora MTS is currently equipped with 115/12.5 KV transformers T1, T2 and T4. T1 and T4 have a rating of 9/12 MVA, while T2 has a rating of 10/13/14 MVA. The station's total planning winter LTR is 23.4MW. Therefore, this station will exceed its normal supply capacity in 2030.

Table 15: Kenora MTS Load Forecast

Station	LTR (MW)	Load Forecast (MW)										
		2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
Kenora MTS	23.4	21.4	21.7	21.9	22.1	22.5	22.9	23.2	23.5	23.8	24.1	24.4

Synergy North has received inquiries from potential customers seeking new connections, but formal agreements still need to be finalized. Although these new connection loads have not been incorporated into the forecast, an annual growth rate of 1.25% has been applied to account for the significant level of development interest. The following wires and non-wires alternative solutions are considered:

Alternative 1: Expand Kenora MTS with an Additional Transformer

Install an additional transformer and associated protections, control, and structures with an expansion of the existing station.

Alternative 2: Construct a new substation across the city from the existing station

The proposed new substation will be located on the city's west side. In addition to increasing the supply capacity, this solution will provide substantial distribution system benefits by reducing the feeder length required to reach the customers and improving the distribution system performance.

Alternative 3: Non-Wires Solutions

IRRP recommends three non-wire alternatives. A 4MW gas generation facility, a 6-hour 4MW (24MWh) battery, or a combination of energy efficiency measures and demand response are feasible options. This alternative will provide potential distribution benefits to the end customers.

Alternative 4: Maintain Status Quo

This alternative is considered based on the long-term horizon of the need. Kenora MTS will exceed station capacity in 2030 based on the load forecasts provided by the LDC. The next cycle of regional planning will commence in 2025 and will allow the working group to reevaluate this need and confirm if the station capacity need still holds true in 2028. Should this be the case, the TWG at that moment will decide the best course of actions to address this need.

The TWG recommends Alternative 4 as the preferred solution at this RIP. Considering the long-term outlook of the need, the LDC intends to move forward by retaining the services of a consultant to assist in understanding the pricing of each of the proposed alternatives. Prior to determining the preferred alternative an investigation of the total costs and benefits of each solution will be completed. The LDC does not intend to engage in any material investments prior to 2028 to mitigate the challenge of Kenora MTS reaching its thermal capacity, instead continued study and monitoring of load growth and customer connections is anticipated to trigger investment. To fully understand the preferred alternative and investment benefits, the LDC intends to incorporate and quantify the benefits of grid scale and behind-the-meter (BTM) energy storage solutions that may allow for access to many different services reducing the cost of reliable service to the City of Kenora.

Furthermore, the LDC recognizes that non-wires alternative could be developed in stages to reduce cost and align with the load growth as compared to a traditional wires investment (e.g., new substation.) This offers enhanced reliability for radially supplied customers that would otherwise not have effective options to improve their reliability, particularly for momentary outages.

The roadmap below has been prepared to ensure that the LDC remains well positioned to address the challenge with sufficient time for deployment and with the most cost-effective solution for its customers.

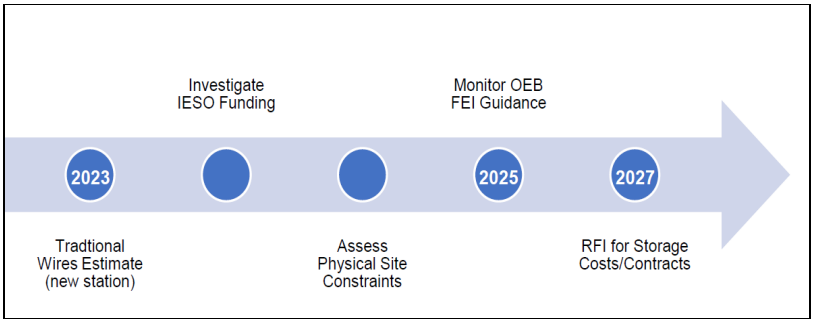

Figure 6: Kenora MTS Strategy Roadmap

8.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission

Lines Capacity Assessment was performed over the study period 2023-2033 for the 230kV and 115kV Transmission line circuits in the Northwest Region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater this need. Based on the results, the Northwest region currently does not have a firm supply capacity need. But it is important to consider the potential impact of large mining and industrial developments that can quickly consume the remaining supply capacity with minimal lead time. After engaging with development proponents and stakeholders during the IRRP phase, the Technical Working Group (TWG) identified three potential transmission circuits, E4D, M2W and E2R, that may require additional supply capacity if all proposed projects materialize.

8.3.1 E4D and E2R – 115kV – Capacity Needs under Mining Sector Development

The E4D circuit supplies the Ear Falls and Red Lake area, while the E2R circuit serves the Red Lake area north of Dryden. The E4D circuit has a continuous summer rating of 410 A, equivalent to approximately 72 MW. Additionally, there is a combined 18 MW of dependable hydro generation output from three hydroelectric power stations. Considering the thermal capability and hydro generation, the load capability of the E4D circuit is approximately 90 MW during the summer. It is worth noting that the winter load meeting capability is expected to be higher due to the circuit's higher thermal rating and increased hydro generation output.

As for the E2R circuit, it has a continuous summer rating of 421 A, translating to a load meeting capability of approximately 74 MW. The E2R circuit's continuous winter rating is 528 A, resulting in a load meeting capability of approximately 93 MW due to pre-contingency thermal and voltage limitations, meaning a load of 93 MW also causes pre-contingency voltage declines at Red Lake TS.

The IRRP forecasts the summer peak demand of the E4D circuit to reach 67 MW in 2032, and the summer peak demand of the E2R circuit to reach 61 MW in the same year.

The system area map is shown below in Figure 7:

Figure 7: Dryden - Ear Falls - Red Lake Map

Considering the potential combined area load growth from mining and Wataynikaneyap Power customer connections, which could increase by 50-115 MW by 2028, a few mining and industrial customers are actively engaging with IESO and Hydro One Transmission to explore potential options to accommodate this load increase. As shown on Figures 8-11, four transmission alternatives have been proposed to address the capacity needs in the area. These options also require the installation of appropriately sized voltage devices to mitigate voltage performance criteria.

- Alternative 1 - Upgrade 115kV Circuit E4D and E2R:

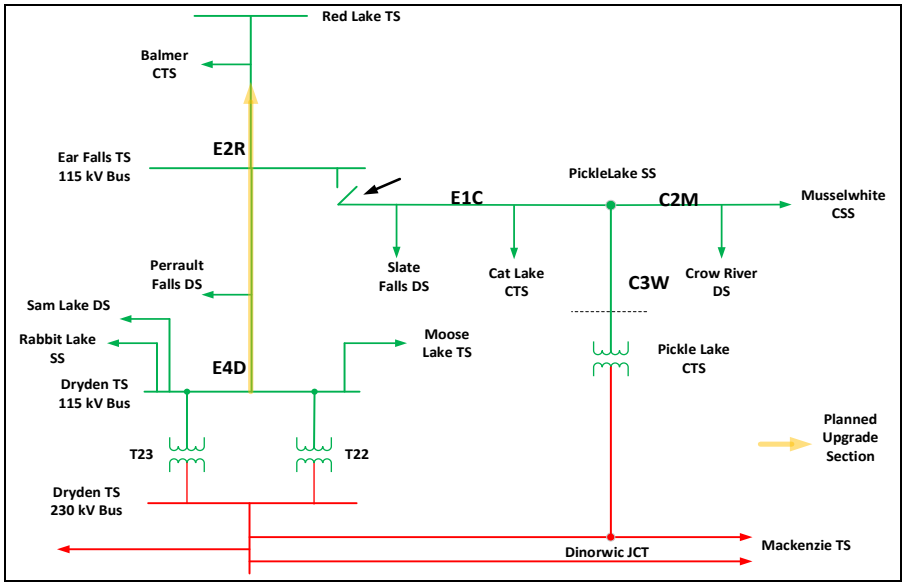

Figure 8: Alternative 1 Single Line Diagram - Upgrades on Existing Infrastructure

- Alternative 2 – Building a new 115kV Single Transmission Line from Dryden TS to Red Lake TS:

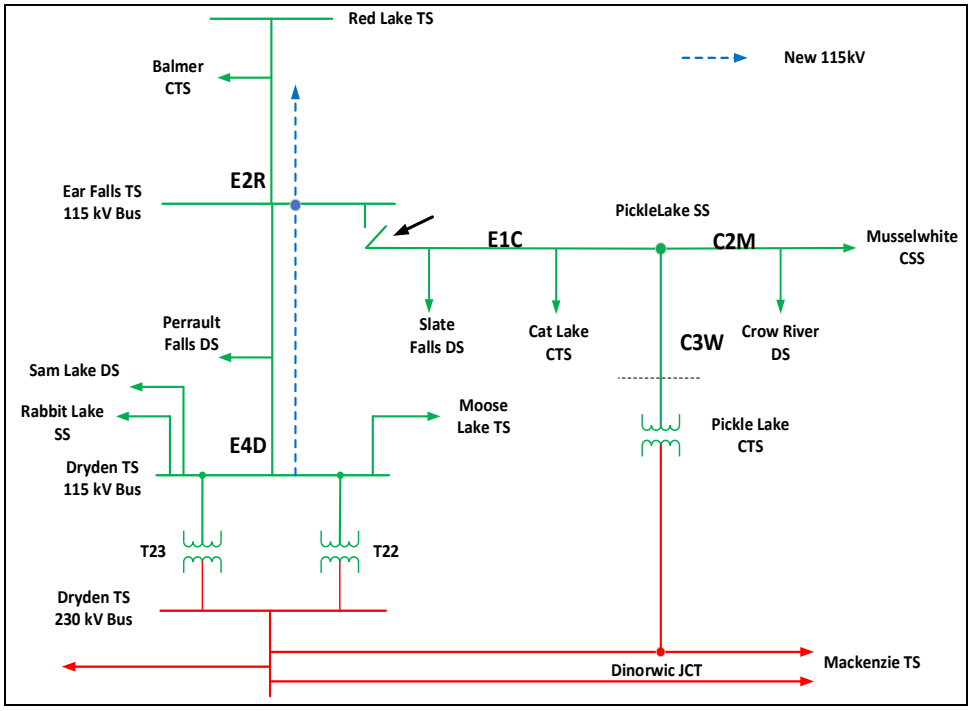

Figure 9: Alternative 2 Single Line Diagram – Building New 115kV Infrastructure

- Alternative 3 – Building a new 115kV Single Transmission Line from Ear Falls TS to Red Lake TS with E4D Upgrades:

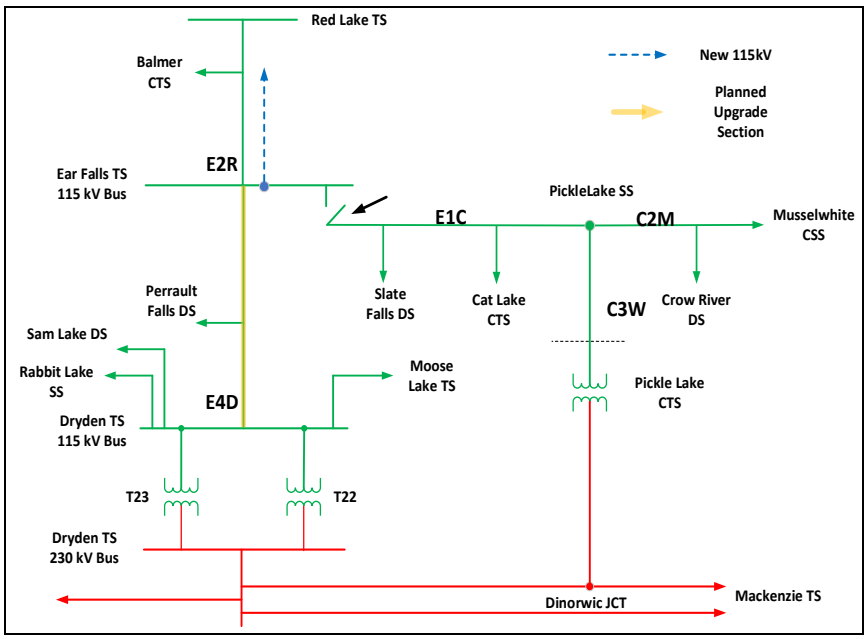

Figure 10: Alternative 3 Single Line Diagram - Building New 115kV Infrastructure and Upgrades on Existing Infrastructure

- Alternative 4 – Building a new 230kV Single Transmission Line from Dryden TS to Red Lake TS:

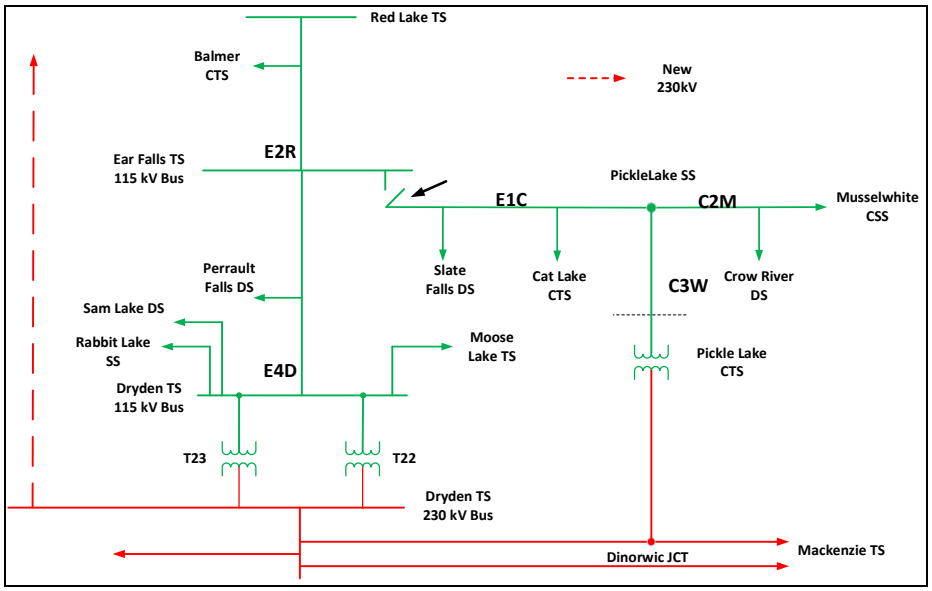

Figure 11: Alternative 4 Single Line Diagram - Building New 230kV Infrastructure

These options require the installation of appropriately sized voltage devices to mitigate pre-contingency voltage limitations. The planning allowance for these alternatives ranges from $125M to $375M, depending on the materialized load and the required infrastructure.

To determine the most cost-effective and beneficial solution to increase the area's load meeting capability, one of the project proponents has taken the lead in initiating a technical feasibility study with IESO and a physical feasibility study with Hydro One. These studies aim to thoroughly investigate the proposed alternatives and assess their economic viability and overall benefits. The goal is to identify the optimal solution that not only meets the area's increasing load demands but also ensures long-term reliability and system stability.

By conducting a detailed analysis and leveraging the expertise of Hydro One and IESO, it is expected to identify the most suitable course of action that maximizes cost-effectiveness and delivers significant value to all stakeholders in the area. The findings of this study will contribute to the decision-making process, enabling the selection of a preferred solution that aligns with the region's future growth plans.

8.3.2 M2W – 115kV – Capacity Needs under Mining Sector Development

The M2W circuit is a radial transmission line supplied from Marathon TS, consisting of two independent branches. One branch extends approximately 70 km in the north-east direction to Manitouwadge DS, while the other branch stretches eastward for about 100 km to White River DS.

There is a possible growing capacity need on the branch that leads towards Manitouwadge DS flagged by a customer connection application after the 2023 Northwest Ontario IRRP The section from Pic JCT to Manitouwadge JCT is the most constrained, with a continuous summer rating of 290 A, equivalent to approximately 57 MW. Recently, there has been significant interest from mining customers, with an anticipated growth of 30-80 MW by 2028. The 2022 summer peak demand on the M2W branch was 6.1 MW. Additionally, an industrial customer is planning a mining project of 50.9 MW by 2025-2026 on this branch. If the mining project proceeds as planned, the branch will start to experience capacity issues.

To address the potential need for additional capacity, the following alternatives are being considered:

- Alternative 1 - Upgrade the conductor and structures on the existing M2W circuit
- Alternative 2 - Building a new parallel 115kV circuit supplied from Marathon TS

Since the anticipated increase in mining sector load has not yet materialized, further assessment of the above alternatives for reinforcing the M2W circuit will be conducted to determine their cost and feasibility. These assessments will be undertaken in the event of a request from customers for additional load and upon reaching an agreement with them.

8.4 System Reliability, Operational and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. A study has

been performed, considering the net coincident load forecast and the loss of one element over the study period 2023-2033 to cater this need**.** Based on the results, the following system reliability and operation needs have been identified for this Region.

8.4.1 Fort Frances MTS Customer Reliability Need

Fort Frances MTS, a step-down transformer station that supplies LDC loads in Fort Frances, is supplied from the nearby Fort Frances TS via a single circuit 115kV line F1B. Line F1B extends approximately 20 km to the east of Fort Frances to also supply rural Hydro One LDC loads. The single circuit supply configuration results in Fort Frances MTS supply interruptions during certain transmission outages (planned and unplanned). Over the past 10 years, 90% of Fort Frances Power's customer interruptions is a due to transmission supply losses as reported by the Ontario Energy Board (OEB). Fort Frances LDC has indicated a reliability need due to the single circuit supply configuration as planned and unplanned outages causes community-wide power outages. Outage durations ranges from 4 to 8 hours with a total of 16MW load interrupted. Despite meeting the ORTAC criteria, the current supply configuration of the Fort Frances MTS remains highly disruptive for customers. However, considering the close proximity of Fort Frances MTS to Fort Frances TS, there is potential for cost-effective improvement solutions.

The two stations are located across the street from each other. Most of the Fort Frances MTS station equipment has exceeded their manufacture life span and will need to be replaced within the next 10-15 years. The current Fort Frances MTS station configuration also does not allow for any primary 115kV components to be isolated for maintenance purposes; therefore, the entire station must be de-energized to allow for primary components to be serviced or repaired. Considering all above, reconfiguration of the station will improve the supply interruptions for Fort Frances MTS.

The Fort Frances TS 115kV station layout and connection to Fort Frances MTS is shown in Figure 12. Fort Frances TS 115kV side is comprised of a six-breaker ring bus with connections to the station's two autotransformers and circuits K6F, F3M, F2B and F1B. Fort Frances MTS is currently connected to the F1B circuit which connects to L1 bus. Hydro One has proposed reconfiguration options with the goal of reducing Fort Frances MTS' exposure to transmission outages.

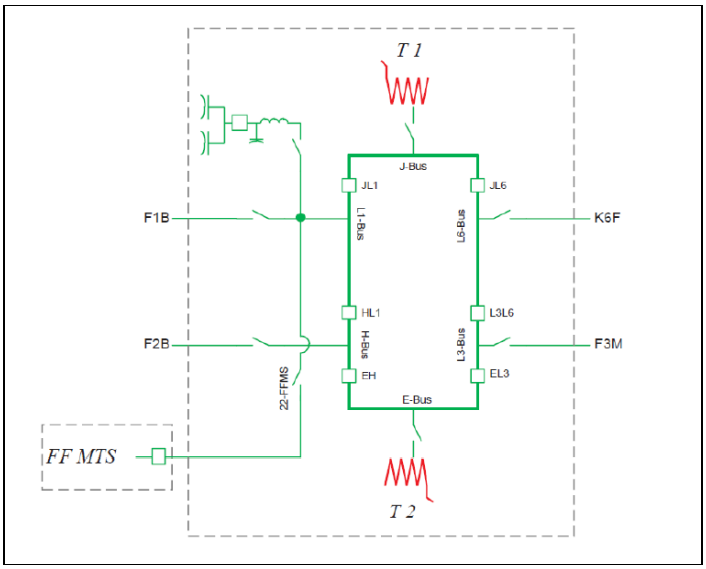

Figure 12: Fort France TS Single Line Diagram

Alternative 1:

Replace the existing 22-FFMS air-break switch with an interrupter switch (still connected to F1B) and install a second interrupter switch to connect Fort Frances MTS to F2B. One of the two switches would be operated normally open, but the switches would allow Fort Frances MTS to be transferred between F1B and F2B to avoid any supply interruptions during planned outages on either of the two circuits or buses.

Alternative 2:

Install a new 115kV breaker on the L1 bus and move the Fort Frances MTS termination between this new breaker and the HL1 breaker. This would form a 7-breaker ring bus and Fort Frances MTS would have its own position separate from any other circuit. This would still have the MTS on a single supply.

Alternative 3:

Install a second breaker at Fort Frances MTS and connect it to the H-bus via a new air-break switch. Since Fort Frances MTS already has two transformers, if both Fort Frances MTS breakers are normally closed, this configuration could provide fully redundant transmission supply. However, the feasibility of having both supply points normally closed is still being reviewed; a normally open point may be required to manage short circuit levels and loop flows. If either the L1-bus or H-bus supply points needs to be operated normally open, this option would be functionally the same as the first option (but more expensive).

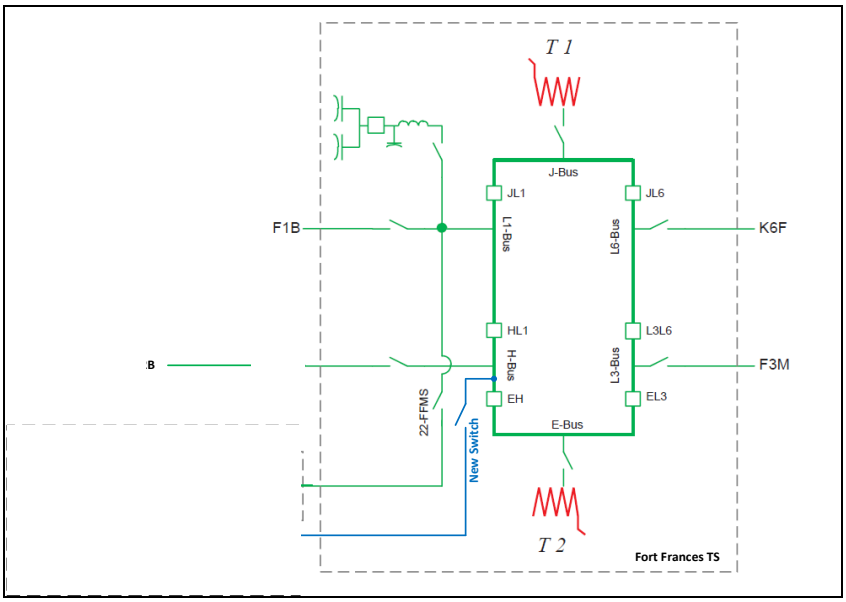

Figure 13: Fort Frances MTS Need Alternative 3

Alternative 4:

Install a second breaker and switch at Fort Frances MTS on the 115kV side, connecting it to 115kV circuit F2B via a drop feed. This creates a second supply for Fort Frances MTS, achieving full redundancy while tapping at a different location comparing to Alternative 3

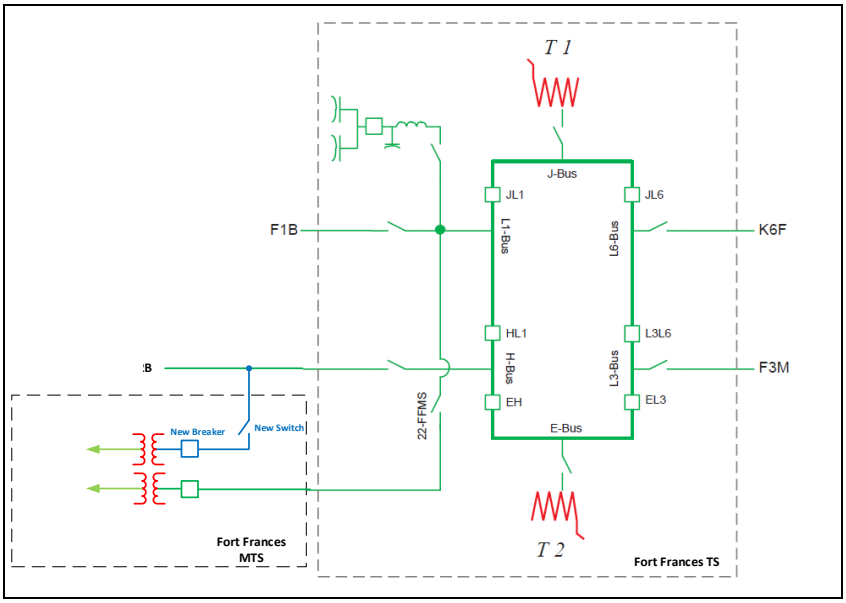

Figure 14: Fort Frances MTS Need Alternative 4

The LDC Fort Frances Power recommends alternative 4 as the optimal alternative for addressing the need. The interruptions caused by planned transmission supply outages can be effectively mitigated with the dual supply. This alternative also provides FFPC with the capability to isolate any primary station components for maintenance purposes without requiring a station-wide outage. Alternative 4 offers a robust station supply configuration that enhances reliability for current customers and accommodates potential significant load growth from industrial customers and electrification of the community. Fort Frances Power has started the preparation of the IESO SIA application package at the time of this RIP, and the project is planned for execution in the year 2026-2027. Additionally, the implementation of Alternative 4 will serve as a building block for the forthcoming Fort Frances MTS End-of-Life replacement project, contributing to its seamless execution.

8.4.2 E1C Operation and High Voltage Need

The Integrated Regional Resource Plan (IRRP), published in January 2023, identified operational challenges concerning the 115kV E1C transmission line. This line plays a critical role in the Pickle Lake area system, and its operational state significantly affects the system's overall performance. Two main challenges have been identified in the E1C operation. Limitations on supply capacity when E1C operates in a normally closed state and high voltage issues when it operates in a normally open state. A single line diagram of the area is presented in Figure 15.

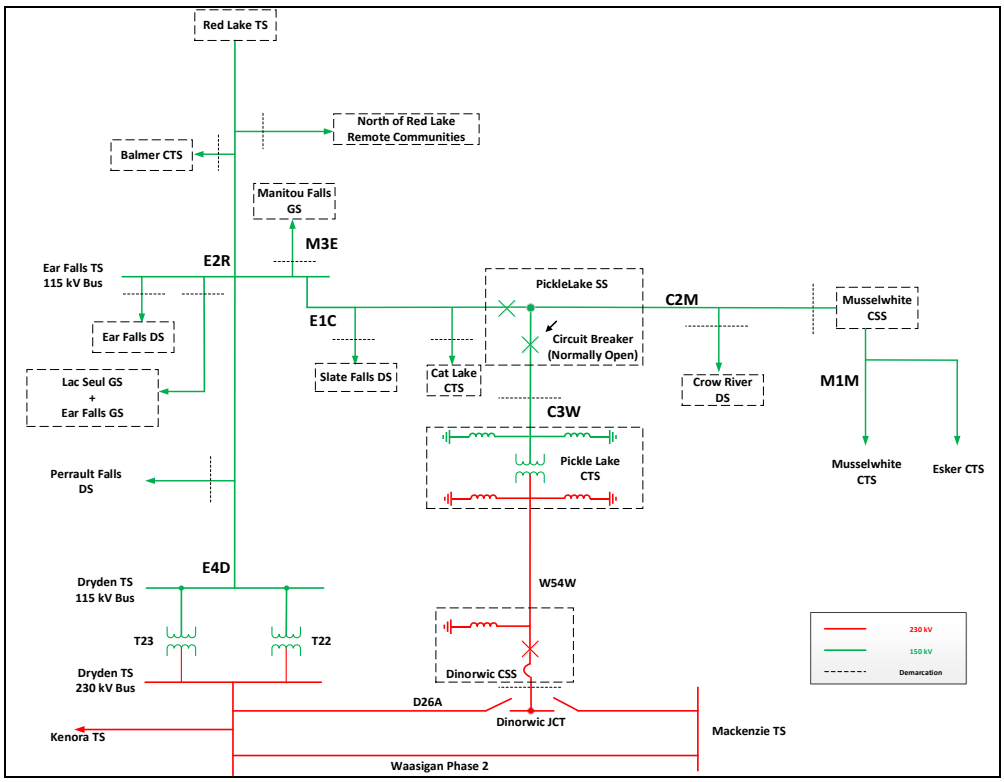

Figure 15: Dryden - Pickle Lake - Ear Falls - Red Lake Area Single Line Diagram

Operating the E1C in a closed state results in a loop configuration that restricts transfer capability through E4D and W54W, thereby limiting the area's overall potential for load increase. This limitation could potentially impact local business expansion. Moreover, if E4D were to fail, the local generations at Ear Falls TS would remain connected, potentially causing transient instability. To maintain system adequacy and meet forecast demand in the Ear Falls, Red Lake, and Pickle Lake areas, it is crucial to introduce a normally open point on the E1C line end. This change would offload E4D and shift the loading on the Pickle Lake area to the newly installed 230kV transmission line W54W. However, operating E1C in an open state would lead to high voltage issues under light load conditions, regardless of the E1C end that is opened. To resolve this problem, the following alternatives are being considered.

Alternative 1: Installation of a Remote-Controlled Switch at a Mid-Point of E1C and Operate E1C Normally Open at the New Switch Location

While opening E1C mid-point reduces most high-voltage issues and provides for more capacity on the E4D by shifting load supply to W54W, it would require an upgraded or newly installed isolation switch capable of being remotely operated from the control center. Closing the switch may be required at times under light load conditions and with unexpected events, involving failure of transmission equipment in the Pickle Lake or Ear Falls areas, could trigger the need to revert to the operating configuration in the Pickle Lake area as illustrated in Figure 15. This involves closing the switch and opening the circuit breaker at Pickle Lake SS. While using an existing switch (with no remote-control capability and no on-load switching capability) will be implemented as an interim solution; this alternative, as a permanent solution, is associated with a planning allowance of approx. $6M and the effectiveness and reliability of communications to this very remote site is low. In addition, sourcing independent and reliable AC and DC supplies for the switch will be challenging and expensive. Therefore, this alternative is considered and rejected as a permanent solution.

Alternative 2: Opening E1C on the Pickle Lake SS Line End with Reactor Installations at Cat Lake MTS or Ear Falls TS

This alternative was discussed with the TWG and was compared with alternative 3.

Opening E1C at the Pickle Lake SS end leads to a voltage as high as 132 kV on the E1C line end near Pickle Lake SS under a light load pre-contingency condition. It also results in multiple post-contingency violations. Consequently, a 10-15 Mvar shunt reactor would need to be installed near Cat Lake MTS or Ear Falls TS to implement this solution. The Ear Falls location would require site expansion. It is unknown at this time the physical feasibility of installing a high voltage shunt reactor at the MTS. As the short circuit level at the MTS is low, at least two reactor installations would be required to comply with the 4% voltage change criteria when switching a reactive device. Planning allowance is approximated to be $20M for an Ear Falls installation.

Alternative 3: Opening E1C on the Ear Falls TS Line End with Reactor Installations at Pickle Lake SS

This alternative mirrors alternative 2 but opens the other end of E1C. High voltage violations are less severe in this configuration, with pre-contingency voltages in the area staying within the ORTAC limit. The most critical contingency is the loss of one of the existing 20 Mvar reactors at Pickle Lake CTS. The TWG

has confirmed that installing an additional 10 - 15 Mvar reactor at Pickle Lake SS would address the high voltage violation. Space is available at Pickle Lake SS for a reactor installation and the short circuit levels are sufficient at this station to require 1 reactive device in lieu of two smaller ones. Planning allowance is approximated to be $20M.

The TWG recommends Alternative 3 as the most effective solution. This approach only experiences high voltage violations under post-contingency scenarios, and the addition of a 10 -15 Mvar reactor can effectively mitigate these violations. Once this reactor is installed at Pickle Lake SS, the interim normally open point on E1C (mid-point) will be closed and the new normally open point made to be at Ear Falls TS; refer to Figure 16 for the recommended solution. Once the project is initiated, the TWG will investigate and refine the automatic reactor switching scheme recommended in IRRP.

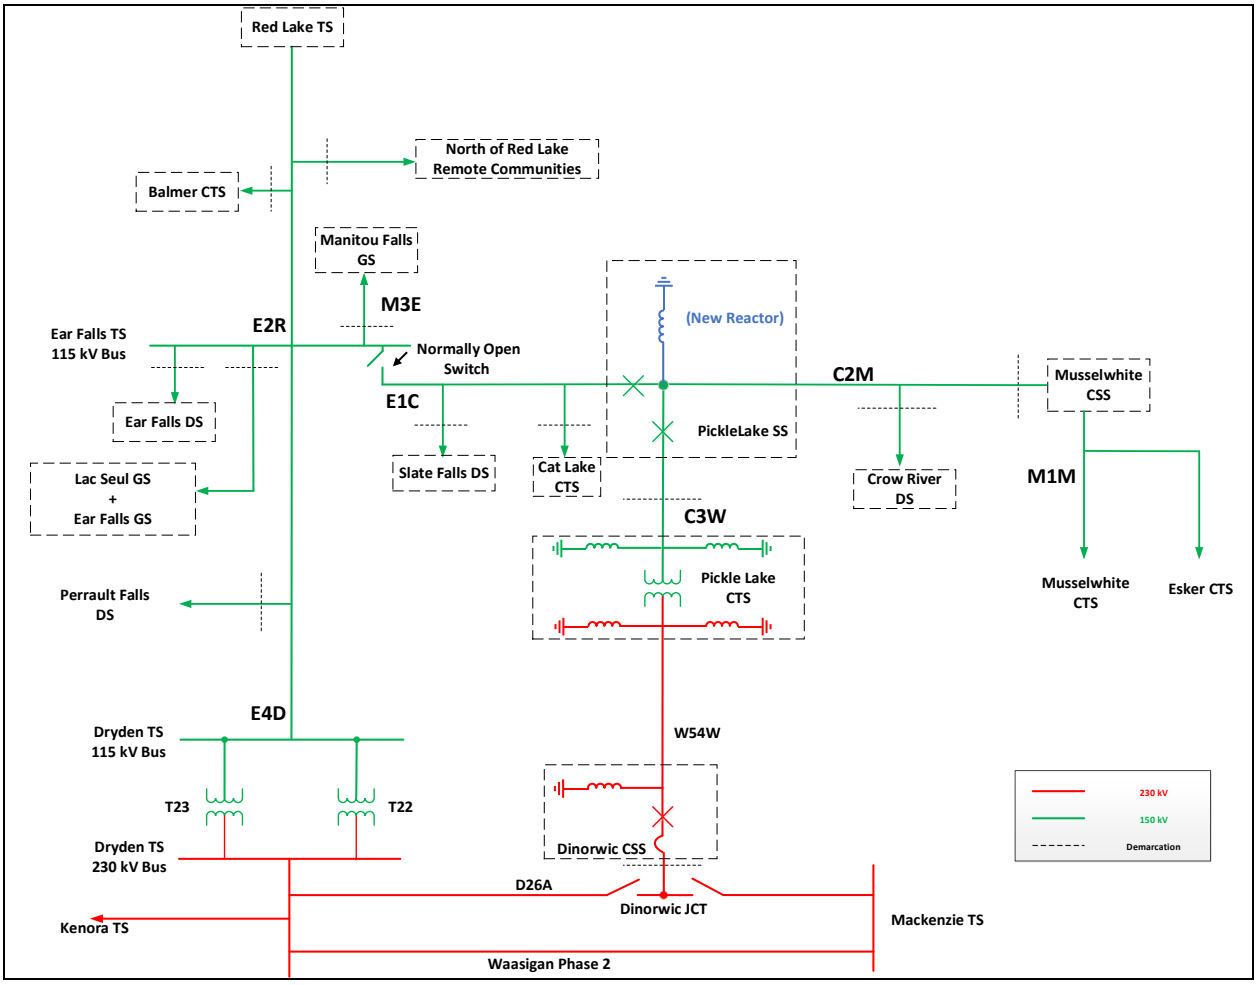

Figure 16: E1C Operation Recommended Solution

8.5 Other Planning Considerations

8.5.1 Fort William TS Shunt Capacitor Banks Replacement

Fort William TS, a step-down station in southeastern Thunder Bay, is supplied by 115kV transmission circuits B5 and B15, providing power to the suburban area. The station comprises of two 115/25 kV transformers with capacities of 50/66.6/83.3 MVA each. Additionally, Fort William TS relies on temporary capacitors on trailers, namely SC1 and SC2, which have been in service for a considerable period. SC1 and SC2 are rated at 14.88 Mvar and 15.77 Mvar respectively, operating at 25 kV. However, both capacitor banks have been assessed in poor conditions and as obsolete.

Presently, SC1 is scheduled for maintenance ensuring that SC1 remains available for service when needed. SC2 is in a significantly deteriorated condition, requiring extensive repairs both in terms of time and costs. It is crucial to address the concerns for supporting local loads and satisfying IESO's contingency planning criteria for both capacitor banks. Therefore, the following alternatives have been considered in this RIP:

Alternative 1: Maintain Status Quo

This alternative was considered and rejected as it does not address the deteriorated condition and the reliance on temporary mobile units, which could reduce supply reliability for customers.

Alternative 2: Refurbish the Existing Units

This alternative was considered and rejected due to the asset condition. SC2 has suffered damage with parts stolen and missing, making refurbishment a significant and non-economic investment with higher future maintenance requirements.

Alternative 3: Replacement for Both Units.

This alternative will provide new permanent shunt capacitors which are appropriately configured to ensure reliable supply to customers and fulfill system contingency planning criteria.

The TWG recommends alternative 3 as the preferred and cost-effective solution. Given the asset condition, refurbishing SC2 is not deemed worthwhile compared to the effort required for replacement. Recognizing the criticality of these units for local system reliability, Hydro One is initiating a project, with a planning allowance of $6M, to replace both units with similar equipment. Simultaneously, SC1 is scheduled for maintenance to ensure its functional operation until replacement.

By implementing alternative 3, Fort William TS will address the significant deteriorated assets issue, meet contingency planning criteria, and maintain a reliable power supply to customers.

8.5.2 Greenstone - Marathon Area System Needs

In Northwest Ontario, there continues to be interest in additional loads and generation connections in the Greenstone-Marathon sub-region. Alternatives presented in the past IRRPs, and RIPs remain valid. Further assessment of those alternatives for reinforcing the area will be conducted to determine their cost and feasibility. These assessments will be undertaken in the event of a request from customers for additional load and upon reaching an agreement with them.

8.5.3 Supply to the Ring of Fire

The Ring of Fire is a remote area approximately 500 km north of Thunder Bay rich in critical minerals but without grid power supply. As per the 2023 Northwest Ontario IRRP, there are a few options to energize the Ring of Fire area. With renewed interest in developing the Ring of Fire from both government and mining companies, the IESO is updating its Supply to the Ring of Fire study to help inform government policy and potential customers seeking connection. Preliminary findings were included in the 2023 Northwest IRRP. The scope and timing of the IESO's ongoing study will evolve with government policy direction.

9. CONCLUSION AND RECOMMENDATION

This section concludes the Regional Infrastructure Plan report for Northwest Ontario region. The Major infrastructure investments recommended by the TWG in the near and mid-term planning horizon 2023-2033 are provided in Table 16 below, along with their planned in-service dates (ISD) and budgetary estimates for planning purposes.

Table 16: Recommended Plans over the next 10 Years

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Asset Renewal Needs				
Rabbit Lake SS	Replacement 115kV switchyard and associated equipment	Hydro One Transmission	2024-2027	$35.2M
Whitedog Falls SS	Replacement three 115kV breakers, DC station services and associated equipment	Hydro One Transmission	2025-2028	$8.5M
Mackenzie TS	Replacement of one 230/115kV autotransformer, five 230kV breakers, four switches, AC station services and associated equipment	Hydro One Transmission	2025-2028	$54.6M
Wawa TS	Replacement of one 230/115kV autotransformer, associated breakers and equipment and station services	Hydro One Transmission	2026-2029	$43.8M
Marathon TS	Replacement of 230kV and 115kV breakers and associated equipment	Hydro One Transmission	2026-2029	$14.6M
Lakehead TS	Replacement of 230kV and 115kV breakers, station services and associated equipment	Hydro One Transmission	2028-2031	$41.5M
Lakehead TS Condenser C8 Replacement	Replace Condenser C8 with a +60/-40 Mvar STATCOM	Hydro One Transmission	2027	$40.6M
Fort Frances TS	Replacement of 230kV breakers, associated equipment, and station services	Hydro One Transmission	2029-2032	$20.3M
Kenora TS	Replacement of 230kV breakers, associated equipment, and station services	Hydro One Transmission	2030-2033	$17M

Station Capacity Needs				
Margach DS	Monitor and implement investment plan in 2025	Hydro One Distribution	2025	$1M
Crilly DS	Further assess the Alternative 1 and Alternative 2 from this RIP	Hydro One Distribution	NA	NA
White Dog DS	Monitor and review in next planning cycle	Hydro One Distribution	NA	NA
White River DS	Monitor and review in next planning cycle	Hydro One Distribution	NA	NA
Kenora MTS	Further assess the alternatives from this RIP; monitor and review in next planning cycle	Synergy North	NA	NA
Sam Lake DS	Install fan monitoring – Refer to Local Planning for more detail	Hydro One Distribution and Sioux Lookout Hydro	2023	$1.5M
Transmission Line Capacity Needs				
E2R and E4D	Further evaluation on the four alternatives based on mining customers' requests	Hydro One Transmission and Proponent	TBD	$125M-375M
M2W	Further evaluation on the 2 alternatives based on mining customers' requests	Hydro One Transmission and Proponent	TBD	TBD
System Reliability, Operation and Load restoration Needs				
Fort Frances MTS	Install a second breaker and switch in Fort Frances MTS to create a second supply to the MTS	Fort Frances Power	2026-2027	$0.85M
E1C Operation	Open E1C end at Ear Falls TS and install a 10 – 15 MVAR shunt reactor at Pickle Lake SS	Hydro One Transmission	2026-2027	$20M
Other Planning Considerations				
Fort Williams TS Shunt Capacitor	Temporary capacitors to be replaced with permanent units	Hydro One Transmission	2026-2027	$6M

Banks Replacement				
Greenstone-Marathon Area System Needs	Further evaluation of the alternatives presented in the past IRRPs and RIP upon customers' requests	Hydro One Transmission and Proponent	TBD	TBD
Supply to the Ring of Fire	IESO to update Supply to the Ring of Fire study	IESO	TBD	TBD

Note:

a) The planned in-service dates are tentative and subject to change
b) Costs are based on budgetary planning estimates/allowance and excludes the cost for distribution infrastructure (if required)

This Integrated Regional Resource Plan (IRRP) Addendum was prepared by the Independent Electricity System Operator (IESO) pursuant to the terms of its Ontario Energy Boardlicence , EI-2013- 0066.

This IRRP Addendum Report was prepared on behalf of the Technical Working Group (Working Group) of the North of Dryden sub-region which included the following members:

Independent Electricity System Operator (IESO)

Wataynikaneyap Power

Hydro One Networks Inc. (Hydro One Transmission)

Hydro One Networks Inc. (Hydro One Distribution)

Atikokan Hydro Inc.

Fort Frances Power Corporation

The Working Group assessed the reliability of electricity supply to customers in the North of Dryden sub-region over a 25-year period beginning in 2025; developed a plan that considers opportunities for regional coordination in anticipation of potential demand growth and varying supply conditions in the region; and developed an implementation plan for the recommended options while maintaining flexibility to accommodate changes in key conditions over time.

The North of Dryden Working Group members agree with the IRRP's Addendum recommendations and support the implementation of the plan, subject to obtaining necessary regulatory approvals and appropriate community consultations.

Executive Summary

The Northwest Integrated Regional Resource Plan (IRRP) Addendum addresses electricity system needs in the North of Dryden sub-region over a 25-year horizon, from 2025 to 2050. While the 2023 Northwest IRRP did not identify firm electricity needs in this sub-region, it acknowledged that new needs could emerge if growth in the mining sector materialized. In 2024, the IESO received further information indicating significant potential load growth tied to mining developments in the region. In response, the IESO initiated this Addendum study ahead of the standard five-year planning cycle to proactively assess system adequacy and ensure reliable electricity supply.

The North of Dryden sub-region includes Dryden, Ear Falls, Red Lake, and Pickle Lake, and encompasses 21 remote First Nation communities connected via the Wataynikaneyap transmission system. Electricity planning for the region is carried out by a Technical Working Group (TWG), which includes the Independent Electricity System Operator (IESO), licensed transmitters, and local distribution companies. In this sub-region, the TWG includes Hydro One Networks Inc. and Wataynikaneyap Power, who together support the development of coordinated solutions to meet emerging electricity needs.

Electricity demand in the region is forecasted to grow significantly, with peak demand increasing from approximately 120 MW in 2023 to over 420 MW under the reference scenario and up to 750 MW under extreme growth by 2050. This growth is primarily driven by mining sector expansion and community growth. The IRRP developed three demand scenarios; Reference, High, and Extreme to test system robustness and inform planning decisions.

The Addendum identifies near-, medium-, and long-term electricity system needs in the sub-region. The primary need in the sub-region is in the Red Lake area, where electricity demand is expected to exceed available supply capacity by 2028 due to thermal constraints on the existing 115 kV transmission corridors (E4D and E2R). These constraints are driven by sustained load growth, particularly from mining developments. In the Pickle Lake area, which is supplied by the 230 kV circuit W54W, the existing infrastructure has sufficient capacity to accommodate forecasted load growth under the reference scenario. However, additional voltage support will be required toward the end of the planning horizon to maintain system reliability and ensure compliance with planning criteria. This includes the installation of reactive compensation to address emerging voltage constraints and support future connections.

To address these needs, the TWG recommends reinforcing the existing 115 kV transmission corridor in the area. This includes two new 230 kV double-circuit transmission lines, one from Dryden TS to Ear Falls TS and the other from Ear Falls TS to Red Lake SS, along with four new 230/115 kV autotransformers and reactive compensation at Red Lake SS, Ear Falls TS, and Pickle Lake TS. The existing 115 kV circuits E4D and E2R will be reconfigured to operate normally open, providing backup supply during outages. This option meets all applicable planning criteria, addresses imminent connection needs in the Red Lake area, and reinforces the transmission system to support long-term growth and enable economic development across the North of Dryden sub-region. This option:

- Supports regional electricity needs through 2050 and beyond, across reference, high, and extreme demand scenarios.
- Enhances reliability and reduces the risk of load interruptions in the North of Dryden sub-region.
- Facilitates the connection of new resources including hydroelectric, biomass, and other generation by lowering connection costs and enabling power transfers to the broader grid.
- Strengthens system resilience and robustness while meeting all applicable planning criteria.
- Offers long-term cost efficiency, as building a double-circuit line upfront is significantly more economical than adding a parallel single-circuit line later.
- Minimizes environmental and land-use impacts by leveraging existing rights-of-way where feasible.

Non-wires alternatives (NWAs) were also evaluated, including natural gas, biomass, solar, wind, and battery energy storage systems. While some options offer system benefits, they face limitations in reliability and/or land use. Natural gas, while cost-competitive, presents challenges related to fuel supply, regulatory compliance, and community acceptance. Hybrid renewable options require extensive land and cannot serve all hourly load requirements. Ultimately, NWAs were deemed unsuitable as standalone solutions for the Red Lake area's long-term needs but may complement transmission investments in future planning cycles.

Extensive engagement was conducted with municipalities, Indigenous communities, industry stakeholders, and the public. Feedback emphasized support for the recommended transmission solution, concerns about transmission lead times, interest in enabling economic development, and the importance of respecting Indigenous land rights and ensuring meaningful participation. These insights were incorporated throughout the planning process.

In conclusion, the IRRP Addendum recommends Transmission Option 3 – Double Circuit as the preferred solution to meet electricity needs in the North of Dryden sub-region. This option supports regional growth and reliability through 2050 and beyond, aligns with planning criteria and stakeholder expectations, and enables future resource development and community expansion. The TWG will continue to monitor demand growth, particularly in Pickle Lake, and initiate further reinforcements as needed. The next cycle of regional planning for Northwest Ontario began in Q3 2025 and will build upon the findings of this Addendum.

1. Introduction

This Northwest Integrated Regional Resource Plan (IRRP) Addendum Study ("the Study") builds on the Independent Electricity System Operator's (IESO) 2023 Northwest IRRP, published in January 2023. This addendum study was initiated by the Technical Working Group (TWG) earlier than the mandated five-year cycle of regional planning to address emerging electricity needs in the North of Dryden sub-region, where growing demand is anticipated due to mining developments and community expansion. Its objective is to ensure that the transmission system can continue to reliably support future electricity requirements in this rapidly growing area.

The North of Dryden sub-region encompasses a large geographic area extending north from Dryden through Ear Falls, Red Lake, and Pickle Lake, reaching as far as Sachigo Lake in the northwest and Big Trout Lake in the northeast. It includes the recently completed Wataynikaneyap transmission system, which connects 17 remote First Nation communities. This sub-region spans parts of the Robinson-Superior Treaty area, First Nation Treaty areas 3, 5, and 9, as well as Regions 1 and 2 of the Métis Nation of Ontario (MNO), and includes a total of 21 remote communities.

For planning purposes, the region is defined by its electrical infrastructure rather than geographic boundaries. It is supplied by 230 kV and 115 kV circuits extending east from Kenora and north from Atikokan, and includes the 230/115 kV systems located north of Dryden. A geographic map and single line diagram illustrating the sub-region's infrastructure are provided in Figure 1.1 and Figure 1.2 respectively.

Four local distribution companies (LDCs) serve the area: Hydro One Networks Inc., Atikokan Hydro Inc., and Fort Frances Power Corporation. Transmission assets in the region are owned by two licensed transmitters: Hydro One Networks Inc. and Wataynikaneyap Power. This IRRP Addendum was prepared by the IESO on behalf of a Working Group composed of these LDCs and transmitters.

This Addendum follows from the previous regional planning cycle, where Hydro One published its Needs Assessment in July 2020[1] and the IESO issued the Scoping Assessment Outcome Report in January 2021[2]. The Northwest IRRP was released in January 2023[3] and the Northwest Regional Infrastructure Plan (RIP)[4] was published in August 2023. This Addendum supplements the 2023 Northwest IRRP and does not replace or supersede its findings.

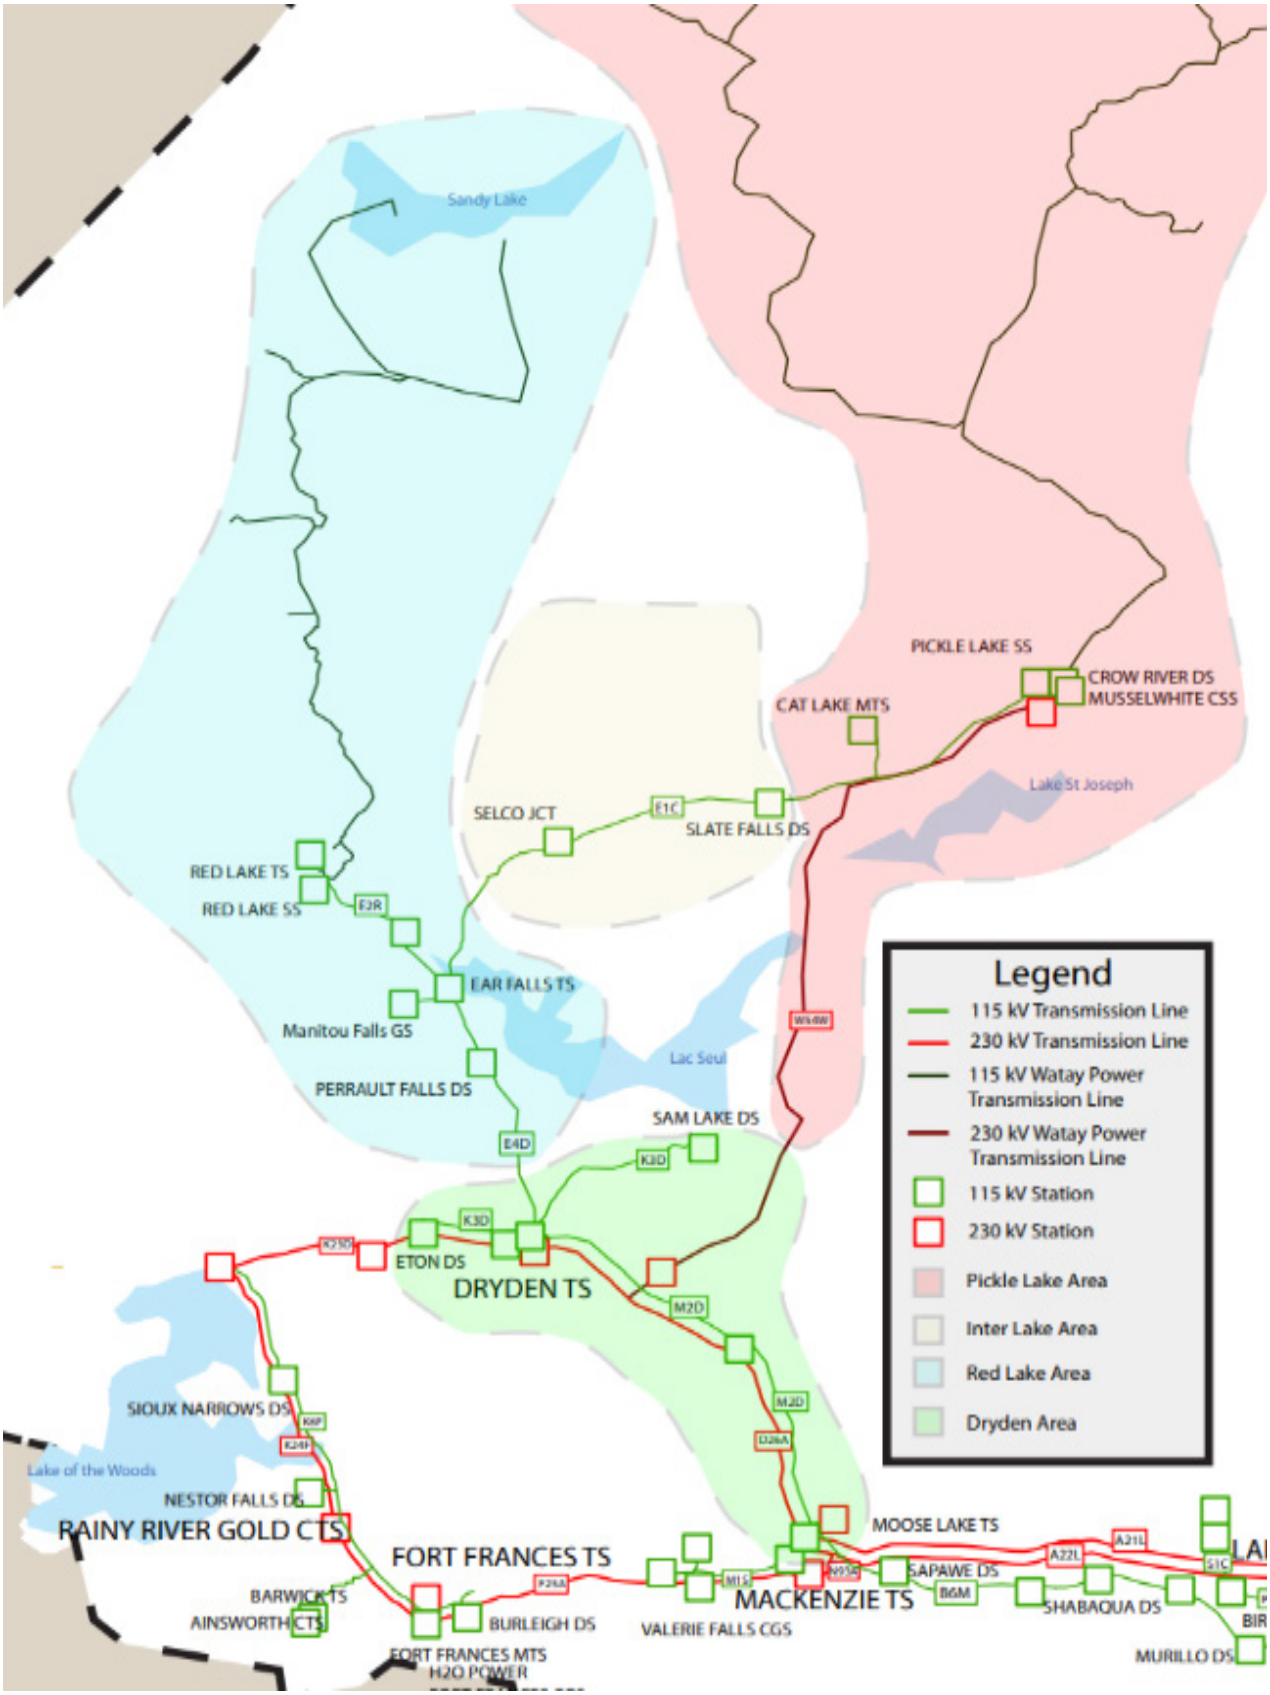

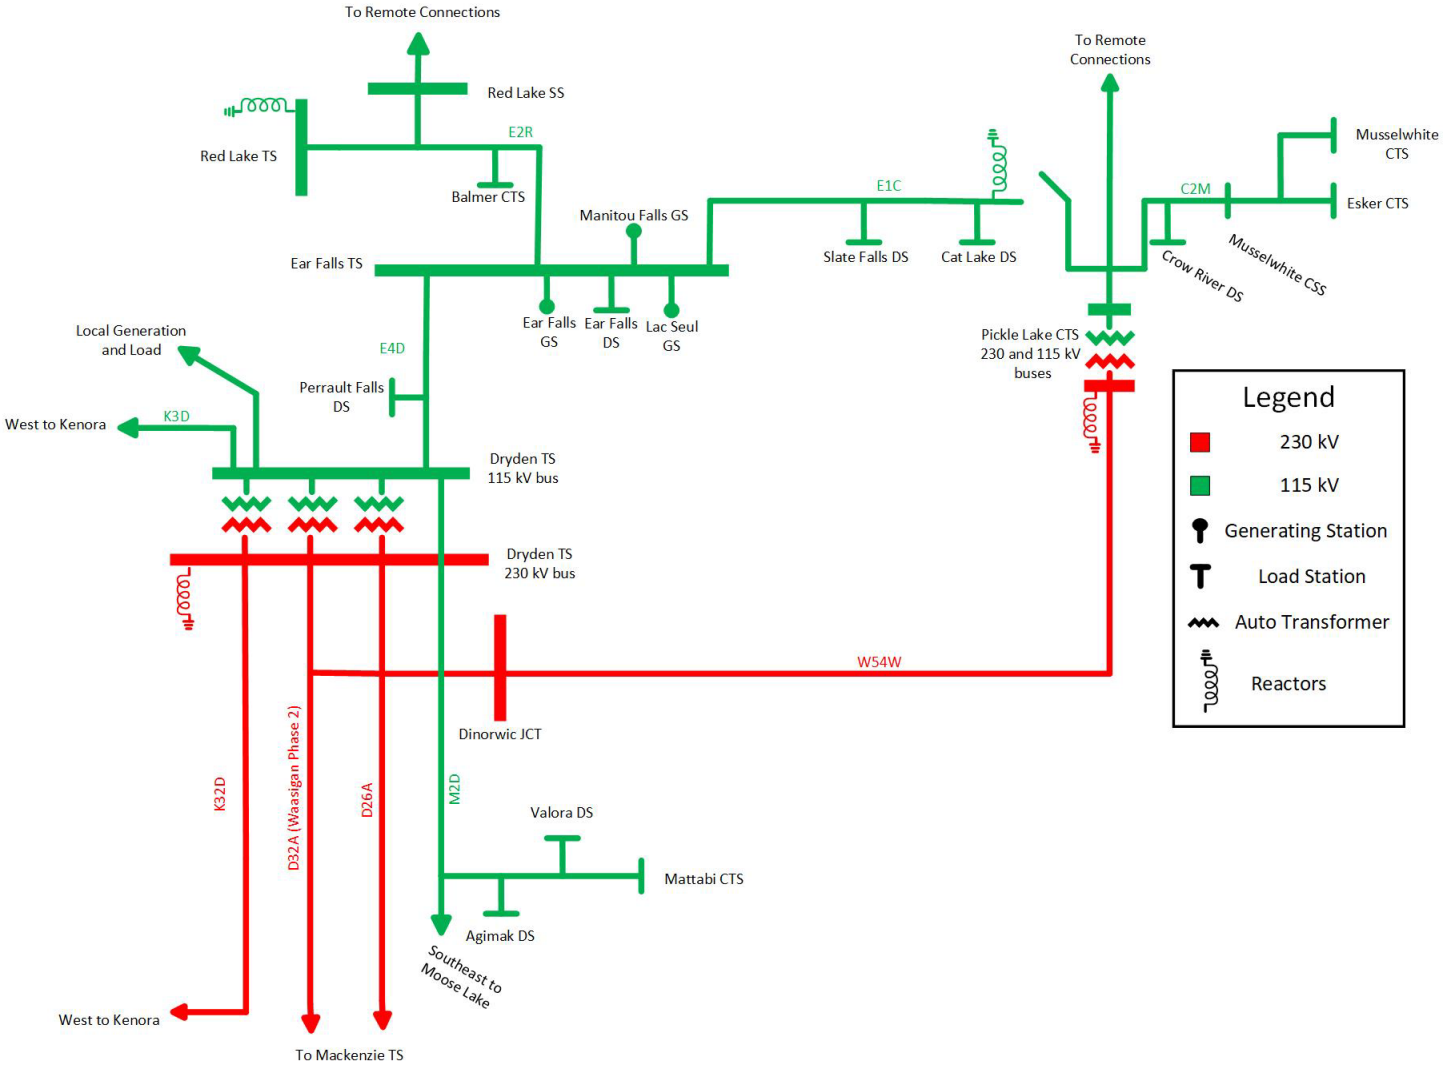

Figure 1.2 | Current Electricity Infrastructure in the North of Dryden Sub-Region

2. The Integrated Regional Resource Plan Addendum

This IRRP Addendum outlines recommended actions to address the electricity needs of the North of Dryden sub-region over the next 25 years. These recommendations are informed by projected electricity demand growth and assessed against the capabilities of the existing transmission infrastructure. The analysis is guided by the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards established by the North American Electric Reliability Corporation (NERC). Each recommendation has been evaluated based on system reliability, cost-effectiveness, technical feasibility, optimal use of existing infrastructure where practical, and stakeholder input.

Several major transmission reinforcement projects in the Northwest region are foundational to enabling future development in the North of Dryden sub-region:

- **East-West Tie Reinforcement:** A new double-circuit 230 kV transmission line from Wawa TS to Marathon TS and from Marathon TS to Lakehead TS. In service since 2022.
- Waasigan Transmission Line Project:
    - *Phase 1* – A new double-circuit 230 kV line from Lakehead TS to Mackenzie TS (under construction; expected in-service December 2025).
    - *Phase 2* – A new single-circuit 230 kV line from Mackenzie TS to Dryden TS (expected in-service December 2027).
- **Wataynikaneyap Transmission Project:** A new single-circuit 230 kV line from Dinorwic Junction (near Dryden) to Wataynikaneyap TS (near Pickle Lake), along with associated 115 kV circuits connecting remote communities north of Pickle Lake and Red Lake. In service as of 2025.
- **Pickle Lake Shunt Reactor Project:** Installation of a 115 kV line shunt reactor at Pickle Lake SS to moderate voltage and enable a normally open point on circuit E1C. Expected in-service October 2026.

With the East-West Tie and Wataynikaneyap projects already in service, and the Waasigan Transmission Line progressing toward completion, these reinforcements collectively strengthen the 230 kV backbone across the Northwest. These upstream enhancements position the system to accommodate targeted investments within the North of Dryden sub-region, supporting future load growth tied to industrial and community expansion.

Electricity demand in the sub-region is expected to increase significantly, primarily driven by mining and industrial activity. These developments can result in large, step-changes in demand with relatively short lead times, presenting challenges for long-term transmission planning. To address this, the IRRP considered high-growth demand scenarios to test the robustness and adaptability of the plan under more aggressive assumptions.

This plan is organized into two components:

- **Near- and Medium-Term Recommendations:** Actions and studies to be undertaken by Working Group members within specified timeframes. These actions address needs with high forecast certainty and require committed action during this planning cycle.
- **Ongoing Monitoring:** Activities to track long-term or potential needs that may emerge under high-growth scenarios but remain uncertain in the current forecast. These include monitoring electrification trends, energy efficiency performance, and updates to industrial or mining development plans.

This phased approach ensures that immediate system needs are addressed while maintaining flexibility to adapt as new information becomes available.

2.1 Near- and Medium-Term Recommendations

This section summarizes the electricity system needs identified in the Study and the recommended actions to address them.

2.1.1 Red Lake Area Supply Capacity Need

Electricity demand in the Red Lake area is expected to exceed available supply capacity by 2028, driven by sustained growth. Under the reference forecast, capacity needs are projected to rise from 40 MW in 2028 to 115 MW by 2050. The current system is constrained during summer conditions due to pre-contingency thermal limits on the 115 kV circuits E4D (Dryden to Ear Falls) and E2R (Ear Falls to Red Lake). Load forecasts for the Red Lake Area under reference, high-growth, and extreme-growth scenarios are provided in Figure 6.5. These recommendations are based on the reference forecast.

Transmission reinforcement options were assessed, ranging from targeted upgrades along the Dryden–Ear Falls–Red Lake corridor (estimated capital cost: $800–$1,000 million) to broader incremental reinforcements extending through the Dryden–Pickle Lake–Ear Falls corridor (estimated cost: $2,500 million), which would also enhance supply capacity for the Pickle Lake area. These options and their benefits are discussed further in Section 7.

Several non-wires alternatives (NWAs) were evaluated, including:

- 130 MW natural gas fired generating resource
- 130 MW biomass fired generating resource
- A hybrid resource consisting of 400 MW battery storage, 4,000 MW solar, and 150 MW wind

However, these NWA were found unsuitable as stand-alone solutions due to technical and reliability constraints:

1. The 115 kV network's ~80 MW capacity limits the ability to host large, centralized resources, requiring fragmented siting and connections.
2. The single-circuit configuration of transmission lines introduces unacceptable reliability risks under ORTAC load security criteria, particularly as demand approaches 150 MW by 2040 under the reference scenario which could occur earlier if mining developments materialize sooner.

Therefore, to address the supply capacity needs in the Red Lake area, the IRRP recommends the following transmission investments:

- Hydro One Transmission to:
- Construct two new double-circuit 230 kV transmission lines: one from Dryden TS to Ear Falls TS, and another from Ear Falls TS to Red Lake SS.
- Install two new 250 MVA 230/115 kV autotransformers at Ear Falls TS.
- Reconfigure existing 115 kV circuits E4D and E2R to operate normally open, allowing them to serve as backup supply during outages.
- Wataynikaneyap Power to:
- Install two new 250 MVA 230/115 kV autotransformers at Red Lake SS.

While NWAs are not viable as primary solutions, they may offer supply diversity and resilience. The IRRP therefore recommends that the IESO explore cost-effective supply resources to complement these transmission reinforcements during the next Northwest Ontario IRRP cycle, expected to begin later this year.

2.1.2 Pickle Lake Area Supply Capacity Need

The current load meeting capability (LMC) of the Pickle Lake area is approximately 125 MW, constrained by pre-contingency voltage limits as defined by ORTAC. Voltage sensitivity analysis under the reference load growth scenario indicates that these criteria will be violated at Pickle Lake TS by 2043, limiting the area to supply further demand. To address this, capacitive compensation will be required to support future load connections.

However, rather than waiting until 2043, the IRRP recommends advancing the installation of a 40 MVar capacitor bank at Pickle Lake TS. This proactive step will not only mitigate the anticipated voltage deficiencies but also deliver near-term benefits by improving operability during outages and supporting load restoration efforts. The region currently faces reliability challenges due to limited remote operational capability and the absence of backup supply, which increases restoration time and complexity. The capacitor bank will help alleviate these issues by enhancing voltage stability and reactive support under contingency conditions.

Under N-1 conditions, ORTAC load security criteria limit interruptible load to 150 MW. While the reference scenario remains within this threshold, the high-growth scenario exceeds it by 2030. Load forecasts under reference, high-growth, and extreme-growth scenarios are shown in Figure 6-2-2. Recommendations in this section are based on the reference scenario.

Looking ahead, the plan recommends that the TWG continue to monitor demand growth and explore reinforcement options for the corridor between Pickle Lake and Red Lake. This would further improve backup supply capability and overall reliability in the region.

Near- and medium-term recommendations are summarized in Table 2.1 and discussed further in Section 7.

Table 2.1 | Summary of Near- and Medium-Term Recommendations

Need/Subsystem	Recommendation	Lead Responsibility	Implementation
Red Lake Area Supply Capacity	Reinforce the existing 115 kV E2R and E4D transmission corridors. Hydro One Transmission will construct two new double-circuit 230 kV transmission lines: one from Dryden TS to Ear Falls TS, and another from Ear Falls TS to Red Lake SS. Hydro One will install two new 250 MVA 230/115 kV autotransformers at Ear Falls TS, and Wataynikaneyap Power will install two new 250 MVA 230/115 kV autotransformers at Red Lake SS. Upon completion, the existing 115 kV circuits E4D and E2R will operate in a normally open configuration and serve as backup supply during outages. Hydro One and IESO will collaborate to refine location of open points.	Hydro One; Watay Power	Hydro One to determine in-service date reflecting urgency of 2028 need date.
Pickle Lake Area Supply Capacity	Install a 40 MVar capacitor at Pickle Lake TS to address voltage concerns. Monitor demand growth and trigger planning to evaluate reinforcing the corridor between Pickle Lake and Red Lake to ensure adequate backup supply and system resilience.	Hydro One; Watay Power	2030

3. Development of the Plan

3.1 Regional Planning Process

In Ontario, electricity planning at the regional level is carried out through a structured regional planning process. This process assesses the interconnected electricity needs of a region, defined by shared supply infrastructure over the near, medium, and long term, and results in a coordinated plan to ensure reliable and cost-effective electricity supply.

A regional plan considers existing infrastructure, forecast growth, and customer reliability expectations. It evaluates potential solutions and recommends actions to address identified needs.

The current regional planning framework was formalized by the Ontario Energy Board (OEB) in 2013 and operates on a five-year cycle for each of the province's 21 defined planning regions. The process is carried out by the IESO in collaboration with licensed transmitters and local distribution companies (LDCs) within each region. It consists of four key components:

1. **Needs Assessment** – Led by the region's lead transmitter, this initial screening identifies electricity needs and determines whether regional coordination is required.
2. **Scoping Assessment** – Led by the IESO, this step defines the appropriate planning approach and the scope of any recommended planning activities.
3. **Integrated Regional Resource Plan (IRRP)** – Led by the IESO, the IRRP proposes coordinated solutions to meet identified needs.
4. **Regional Infrastructure Plan (RIP)** – Led by the lead transmitter, the RIP provides further detail on recommended wires solutions.

Additional information on the regional planning process and the IESO's planning approach is available in Appendix A of the 2023 Northwest IRRP.

Regional planning is one of several planning activities in Ontario's electricity sector. Bulk system planning, led by the IESO, and distribution system planning, led by LDCs, also play key roles. While each planning level has distinct objectives, there are natural overlaps among them, particularly in areas where infrastructure and customer needs intersect.

3.2 The Northwest Region and IRRP Addendum Development

The Northwest IRRP was initiated in January 2021, following Hydro One's Needs Assessment in July 2020 and the IESO's Scoping Assessment Outcome Report in January 2021. In alignment with the standard 18-month IRRP timeline, the original publication was scheduled for July 13, 2022. However, in April 2022, the IESO requested a six-month extension from the OEB to incorporate key developments in the region. This extension allowed for more comprehensive engagement, consideration of additional growth scenarios, and improved coordination with ongoing bulk system studies across both the Northwest and Northeast.

As part of the IRRP, the IESO identified several sub-regions for continued monitoring, including the North of Dryden area. In response to significant load growth and new developments in this sub-region, the IESO initiated an IRRP Addendum in August 2024 to evaluate options for maintaining reliable electricity supply.

4. Background and Study Scope

During the first cycle of regional planning, the Northwest region was divided into four sub-regions, each with its own Integrated Regional Resource Plan (IRRP):

- **North of Dryden** (published January 2015)[5]
- **Greenstone-Marathon** (published June 2016)[6]
- **West of Thunder Bay** (published July 2016)[7]
- **Thunder Bay** (published December 2016)[8]

In the second cycle, these sub-regions were considered collectively within the broader context of Northwestern Ontario, culminating in the publication of the 2023 Northwest IRRP. The third cycle of regional planning for the Northwest region commenced in Q3 2025.

4.1 Study Scope

This IRRP Addendum addresses emerging electricity needs in the North of Dryden sub-region and evaluates supply options to meet these needs, identifying the most effective solution. The plan was developed by the IESO in collaboration with the Technical Working Group (TWG) and incorporates:

- Forecast electricity demand growth
- Conservation and demand management (CDM)
- Distributed generation (DG)
- Transmission and distribution system capabilities
- Relevant community plans
- Equipment end-of-life considerations
- Developments in the bulk transmission system

[5] North of Dryden IRRP can be found on IESO's North of Dryden regional planning engagement website.
[6] Greenstone-Marathon IRRP can be found on IESO's Greenstone-Marathon regional planning engagement website.
[7] West of Thunder Bay IRRP can be found on IESO's West of Thunder Bay regional planning engagement website.
[8] Thunder Bay IRRP can be found on IESO's Thunder Bay regional planning engagement website.

The IRRP Addendum was guided by the following planning steps:

- Developing a 25-year electricity demand forecast and identifying system needs over that horizon
- Assessing the load meeting capability (LMC) and reliability of the existing transmission system, including facility ratings, transformer performance, local generation, and reactive power devices
- Applying contingency-based assessments and reliability standards from ORTAC, NERC, and NPCC (where applicable)
- Confirming end-of-life asset replacement needs and timing with transmitters and LDCs
- Identifying and evaluating alternatives to address system needs, including generation, transmission, distribution, and non-wires solutions such as CDM
- Conducting sensitivity analyses for areas with high growth potential to test the robustness and flexibility of proposed solutions
- Engaging with communities to understand needs and explore alternatives
- Evaluating options to address near- and long-term needs
- Communicating findings, conclusions, and recommendations in a comprehensive plan

4.1.1 Scope of Regional Planning regarding New Connections

Growth in the North of Dryden sub-region is primarily driven by industrial customers, particularly in the mining sector. While many of these customers are not yet connected to the electricity grid but have expressed interest in doing so. This Study also incorporates the latest demand growth forecasts from the municipalities and Indigenous communities and enables future growth. This Study used the best available information to simulate potential future connection configurations.

Rather than evaluating the capability to supply each individual project, the Study focused on assessing the overall adequacy of regional infrastructure to meet projected demand. Local connection requirements for specific projects were only considered where they aligned with broader regional needs[9].

4.2 Parallel Planning Activities

Several planning initiatives are underway in parallel with this IRRP Addendum, including the Northern Ontario Bulk Study and the Northern Ontario Connection Study (NOCS). These efforts are expected to inform and complement regional planning activities.

[9] Participation in the IRRP does not replace the formal connection processes required for new customers, including Customer Impact Assessments (CIA) and System Impact Assessments (SIA). Additionally, the absence of identified regional reliability needs in a specific area through the IRRP does not guarantee approval of future connection requests through CIA or SIA processes.

4.2.1 Northern Ontario Bulk Study

The IESO initiated the Northern Ontario Bulk Study to address several key objectives:

- Responding to increasing electricity demand in Northern Ontario, driven by mining developments, electrification of metal production, and broader industrial electrification
- Supporting province-wide demand growth, which requires new supply resources and expanded transmission capacity to enable bulk transfers across Ontario
- Advancing the Government of Ontario's Critical Minerals Strategy and Powering Ontario's Growth report by unlocking economic opportunities and enabling resource development in Northern Ontario

The study is evaluating transmission options to reinforce the supply corridor between southern and northern Ontario and exploring new supply resources in the North to meet higher demand growth.

4.2.2 Northern Ontario Connection Study

The IESO is conducting the Northern Ontario Connection Study in response to a request from the Government of Ontario to develop supply options in Northwest Ontario that will:

- Connect remote First Nations communities currently reliant on diesel generation
- Improve reliability for grid-connected First Nations communities
- Support critical minerals mining development
- Enable new hydro and renewable resource development

Further engagement for NOCS is planned for late spring/summer 2025, with the study expected to conclude in Q3 2025.

5. Electricity Demand Forecast

This section outlines the development of the demand forecast for the North of Dryden sub-region. While IRRPs typically use a 20-year planning horizon, a 25-year forecast was developed for this Addendum to capture the full impact of anticipated mining activity in the area.

The forecast consists of three components: distribution-connected demand, transmission-connected demand, and a focused mining sector forecast. The mining sector forecast is integrated within the transmission-connected category but also presented separately to highlight future incremental demand.

- **Distribution-connected**: The distribution-connected forecast reflects demand served on the distribution systems in the North of Dryden sub-region and is based on information submitted by local distribution companies (LDC). The regional planning process relies on LDCs to consider municipal and regional official plans and First Nations development plans and translate them into electrical demand forecasts. Distributors have a better understanding of future local demand growth and drivers than the IESO, since they have the most direct involvement with their customers, connection applicants, and the municipalities they serve.
- **Transmission-connected**: The transmission-connected forecast reflects demand served directly from the transmission system. This typically consists of large industrial customers that have their own transformation station. The transmission-connected forecast is informed by direct engagement with customers.
- **Mining Sector**: The mining sector forecast captures electricity demand from both existing grid-connected and known future mining projects that are not yet grid-connected. The mining sector forecast is informed by data from government, industry publications, and engagement with individual project proponents, municipal energy committees, and task forces (i.e., Northwestern Ontario Municipal Association [NOMA]). Note that electricity demand from existing mining projects is also reflected in the above transmission- and distribution-connected forecast components. When the mining sector component is layered on top of the distribution-connected and transmission-connected components, only the contribution of new mining projects is shown to avoid double counting

All forecasts in this section refer to non-coincident peak demand, meaning the sum of each station's individual peak demand. Each component is described in further detail below.

5.1 Historical Demand

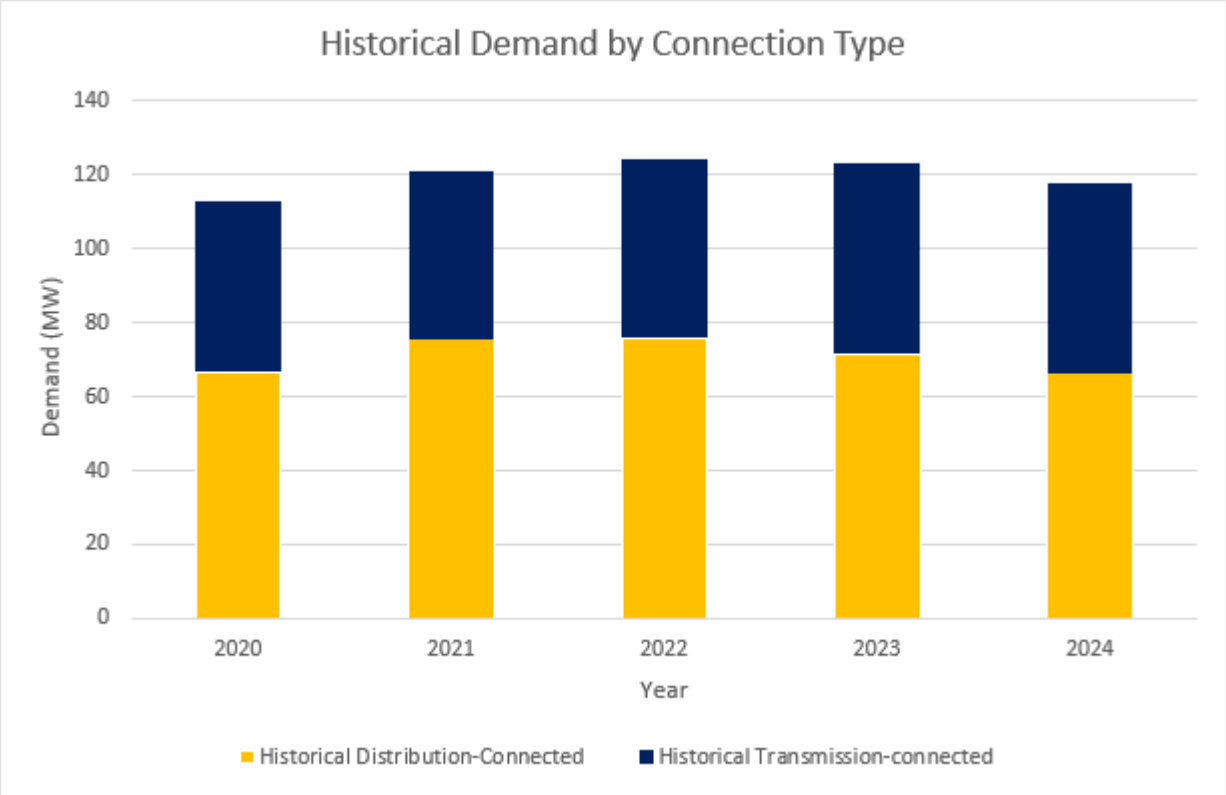

Figure 5.1 illustrates net and gross historical demand over the past five years in the North of Dryden sub-region. Historically, distribution-connected customers have accounted for approximately 60% of peak demand, with the remainder served through transmission connections.

Demand growth was steady through 2022, tapering slightly into 2024, with an average annual growth rate of 0.9%. Peak demand in the sub-region has hovered just above 120 MW from 2021 to 2023.

The North of Dryden sub-region is winter peaking, with annual peak demand typically occurring on winter evenings between 7:00 p.m. and 8:00 p.m.

Distributed generation has historically contributed about 10–15 MW during peak conditions. This contribution was added to the net demand forecast to derive the gross demand forecast. The 2020 gross demand was used as the starting point for the forecast, with station-level adjustments made where anomalous conditions were identified.

Figure 5.1 | 2020–2024 Historical Demand

5.2 Distribution-connected Forecast

To develop the distribution-connected forecast, each LDC prepared a gross station-level demand forecast for its service territory (see Section 5.2.1). These forecasts were then adjusted to reflect:

- The impact of provincial conservation targets
- Distributed generation contracted through programs such as FIT and microFIT.[10]

[10] More information about the Feed-in Tariff can be found on the IESO's website.

- Extreme weather conditions

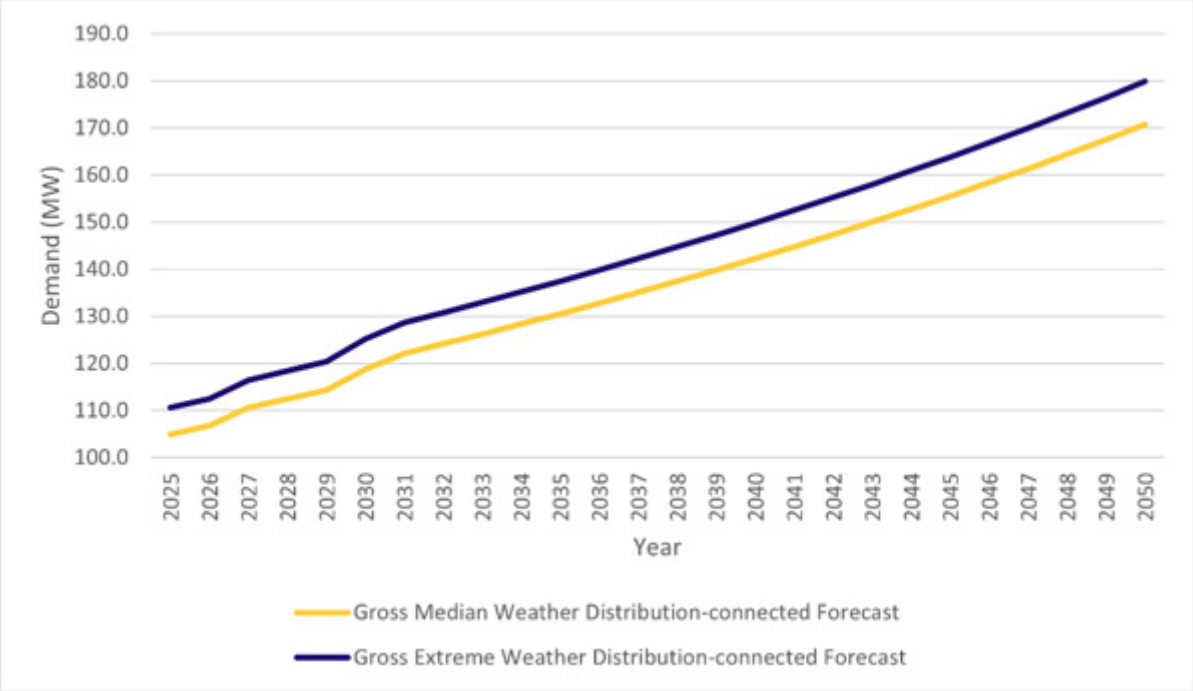
The result is a reference scenario forecast that accounts for expected peak demand under typical operating conditions.

5.2.1 Gross Local Distribution Company Forecast

Each participating LDC developed gross demand forecasts at the station level, or at the station bus level for multi-bus stations, based on their understanding of local development plans and customer engagement. These forecasts incorporate anticipated changes in consumer demand due to efficiency improvements and rising electricity prices (i.e., "natural conservation"), but exclude impacts from future distributed generation or new conservation measures, which are accounted for separately by the IESO.

From these forecasts, demand growth from new developments and known connection applications was identified. The compiled distribution-connected forecasts were then adjusted for extreme weather conditions, as shown in Figure 5.2. This gross forecast includes residential loads and distribution-connected mining loads under the reference scenario.

Figure 5.2 | Total Gross Median and Extreme Weather Distribution-connected Forecast



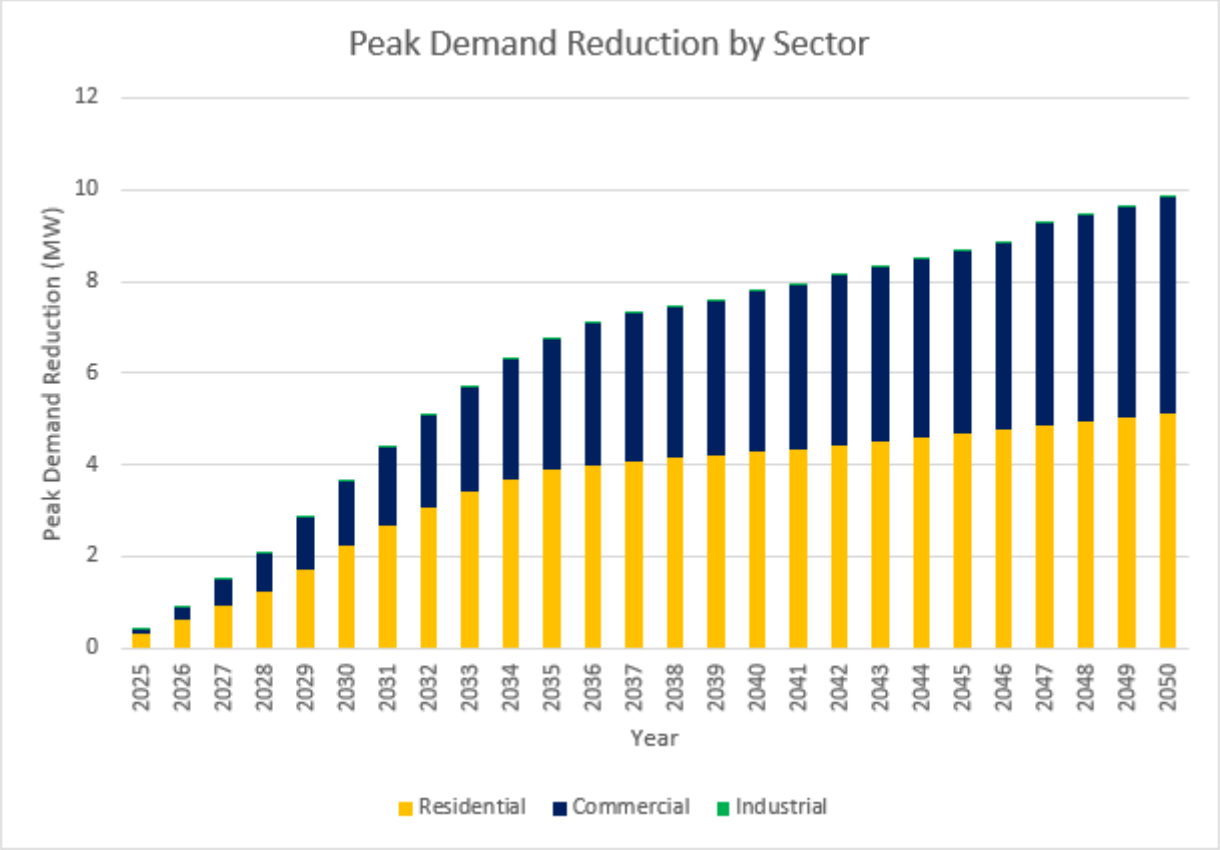


Figure 5.3 | Contribution of Conservation to Forecast

5.2.2 Contribution of Conservation to the Forecast

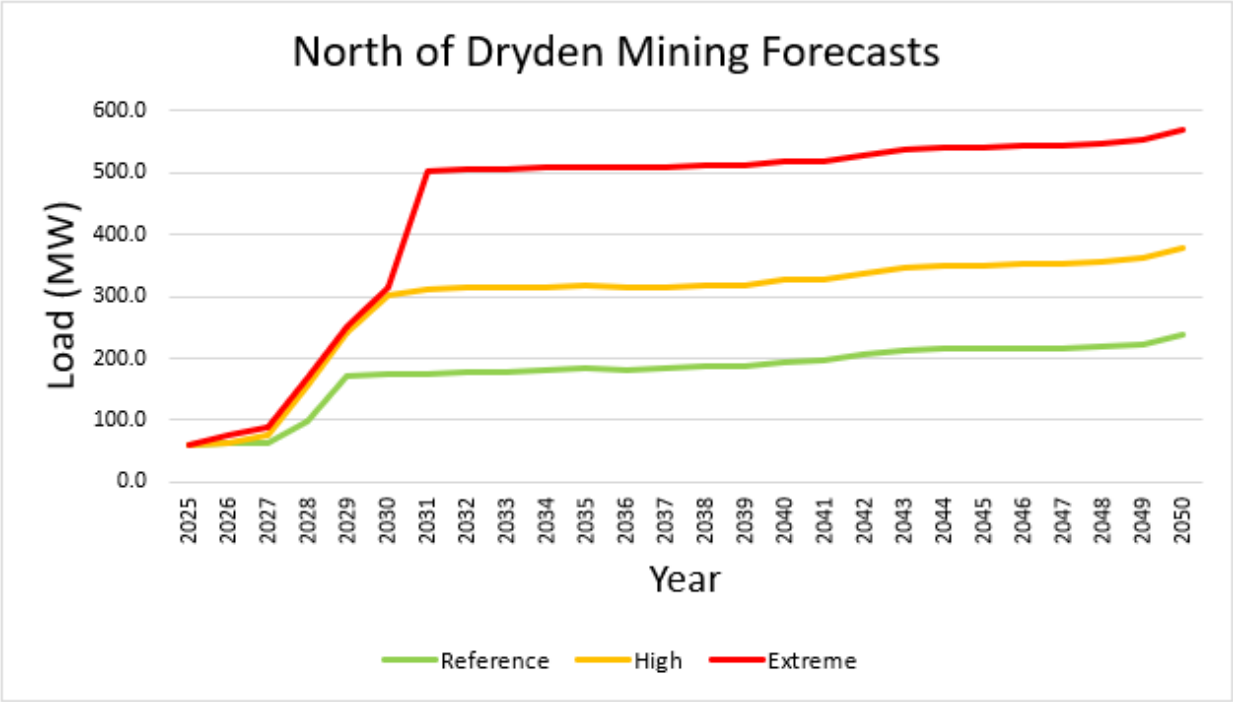
Electricity Demand-Side Management (eDSM), previously known as Conservation and Demand Management (CDM), is a clean and cost-effective resource that helps meet the province's electricity needs. The 2025–2036 Electricity Demand-Side Management (eDSM) Framework, which expands on the foundation laid by the 2021–2024 Conservation and Demand Management (CDM) Framework, is a large initiative led by the IESO that aims to reduce electricity demand and improve system efficiency. Electricity Demand-Side Management is achieved through the delivery of programs and collaboration with local distribution companies and partners which contributes to electricity savings in Ontario. This framework enables the IESO to optimize the full value of demand-side management in a variety of ways allowing consumers on a province-wide basis to save on energy costs in their homes, businesses, institutions, and industrial facilities and add more flexibility to regional tailoring and innovation to respond to evolving grid needs.

Figure 5.3 shows the total contribution of conservation to the forecast and is divided into three sectors such as residential, commercial, and industrial.

5.3 Transmission-connected Forecast

The North of Dryden sub-region includes several customer transformer stations (CTS) that directly serve large industrial customers connected to the high-voltage transmission system, such as mining operations. Expansion of existing mines and the development of new projects are expected to be the primary drivers of electricity demand growth in the sub-region.

To support planning, the IESO developed a mining sector forecast that incorporates multiple potential future mining projects at various stages of development. This forecast is based on information gathered from project proponents, industry publications, stakeholders, utilities, and government sources. Unlike the distribution-connected forecast, the mining forecast was not adjusted for extreme weather, as industrial demand in this sub-region is generally not sensitive to weather.



The mining forecast is presented across three scenarios, Reference, High, and Extreme to reflect varying levels of project certainty. The likelihood of a project materializing is informed by factors such as data reliability, project development stage, and expected in-service dates. The IESO also consulted with the Ministry of Energy and Mines and incorporated feedback from the Northwestern Ontario Municipal Association, which recommended removing likelihood-based discounting to better reflect worst-case planning scenarios. NOMA's mining forecast was also used to update the IESO's internal projections.

Table 5.1 | Mining Forecast Scenario Descriptions

Scenario	Description
Reference	• Includes all active mining projects, as well as those classified as committe and are most likely to connect • Established from mining forecasts and other commitment indicators/factc such as commodity outlook and prospective in-service dates of projects reported from System Impact Assessments (SIA) and Technical Feasibilit Studies (TFS) • Aligned with 2025 Annual Planning Outlook Reference scenario
High	Reference Scenario plus: • Mining projects that have more uncertainty in timing.
Extreme	High Scenario plus: • Mining projects that have the greatest uncertainty in timing.

Figure 5.4 illustrates the mining demand forecast under all three scenarios. The high and extreme cases show significantly higher MW values compared to the reference scenario. The figure includes demand from both new and existing mines but does not include distribution-connected demand.

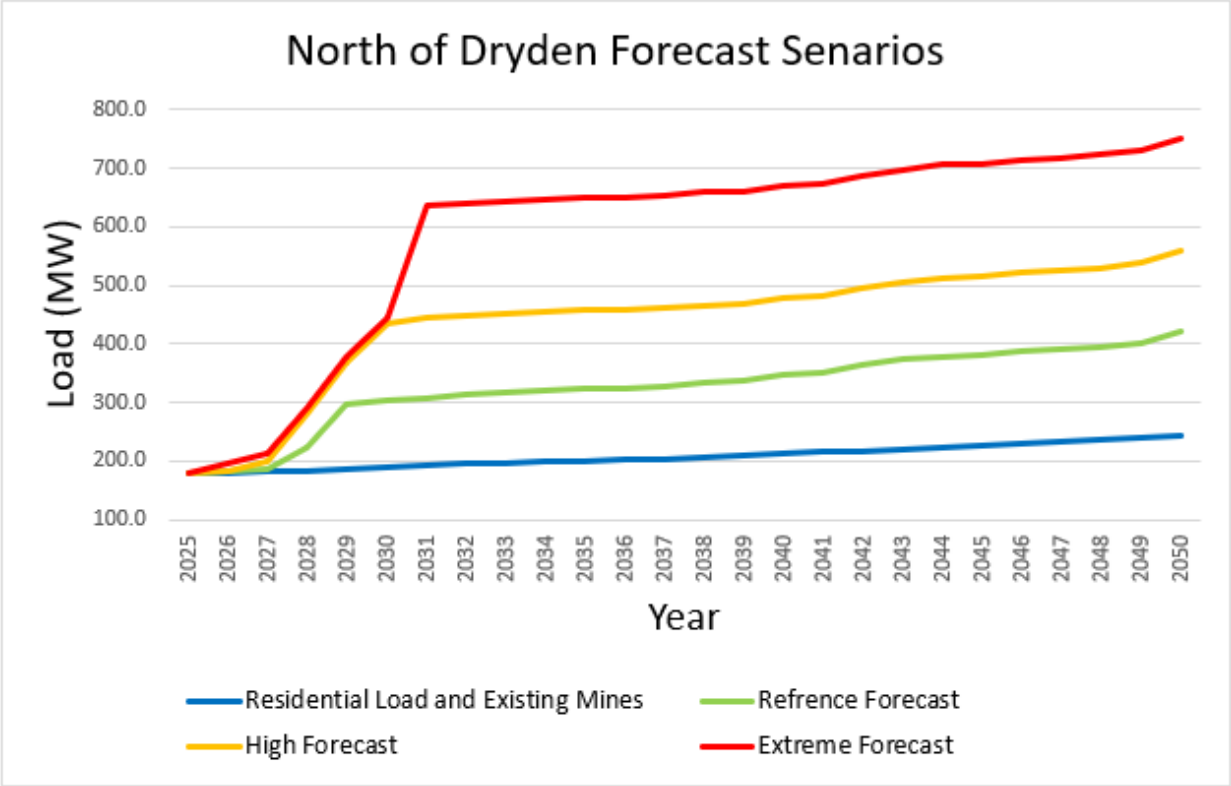


Figure 5.4 | Mining Demand Forecast

5.4 Total North of Dryden Demand Forecast Scenarios

Figure 5.5 presents the total non-coincident demand forecast for the North of Dryden sub-region. The forecast shows a marked increase in demand beginning in 2027, driven primarily by industrial and mining sector growth.

Figure 5.5 | Total North of Dryden Demand Forecast

5.5 Demand Profile – Red Lake, Pickle Lake, and Dryden

In addition to annual peak forecasts, hourly demand profiles were developed for the Red Lake, Pickle Lake, and Dryden areas, regions where non-wires alternatives (NWAs) were evaluated. These profiles span 8,760 hours per year and are used over the 25-year forecast horizon to characterize demand at one or more stations with identified needs.

Hourly profiles are developed using a multiple linear regression model based on historical data. The model is applied under various weather and calendar conditions to simulate a range of future hourly demand scenarios. These profiles are then ranked by median energy values, and the median profile is scaled to match the annual peak forecast for each year. This approach supports the evaluation of NWAs by estimating energy requirements and informing technology selection.

It is important to note that these profiles are not intended to deterministically define hourly energy needs for NWAs. Instead, they provide a reasonable approximation of energy requirements for planning purposes, including estimating operating costs and selecting appropriate technologies. As consumer behaviour evolves, new businesses emerge, and electrification trends accelerate, demand patterns may shift significantly. The Technical Working Group will continue to monitor these developments as part of the ongoing planning process.

Details on the demand profiling methodology can be found in Appendix D.1 of the 2023 NW IRRP.

6. Needs

This section outlines the transmission system needs identified for the North of Dryden sub-region. These needs focus on localized supply and reliability concerns in key areas, including Dryden, Red Lake, and Pickle Lake. While the IRRP is primarily concerned with regional infrastructure and reliability, it also considers committed transmission projects identified through bulk system planning such as the Waasigan Transmission Line Project where relevant. Although bulk system needs are outside the scope of the IRRP, this report highlights potential interactions between regional and bulk system developments.

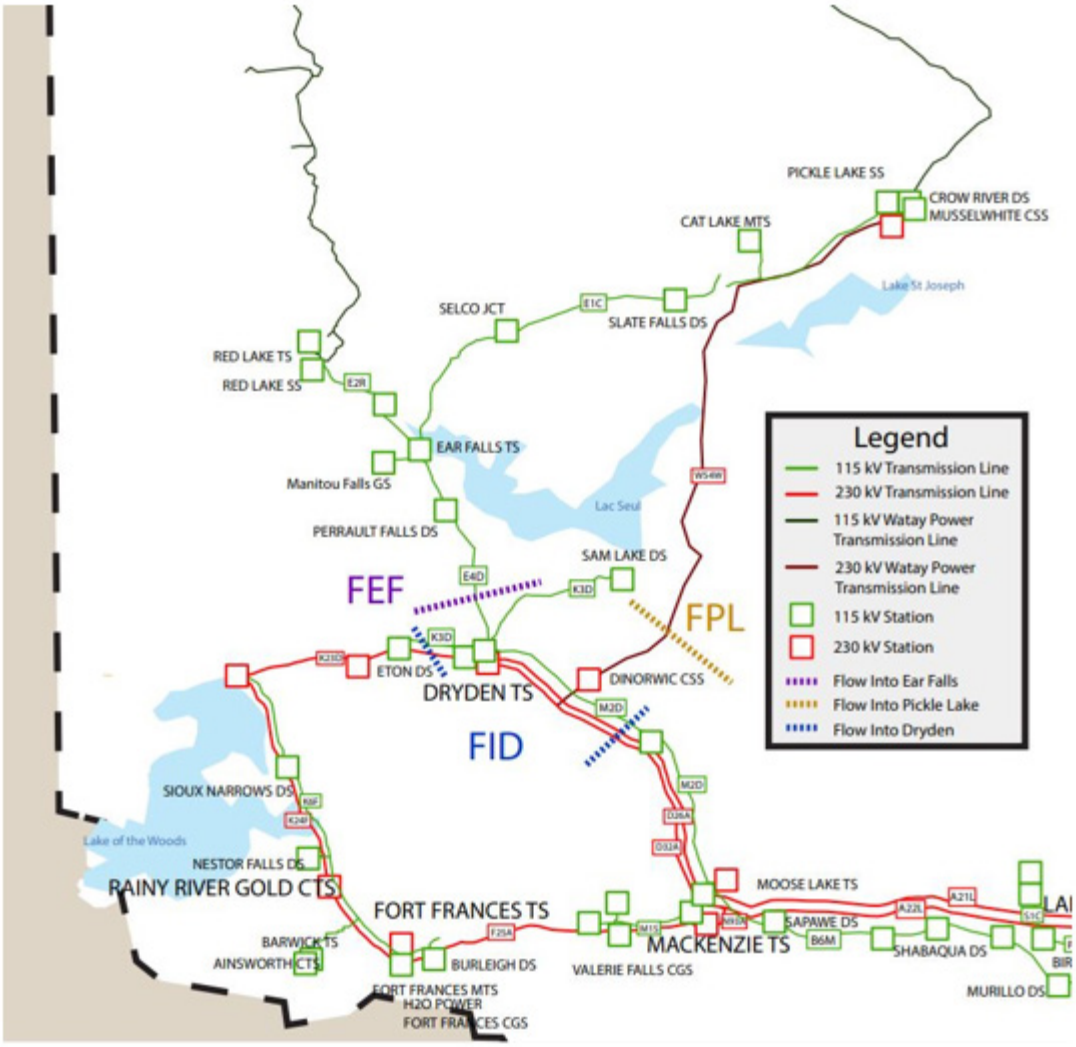
This section is organized as follows:

- **Section 6.1** – Methodology for identifying system needs
- **Section 6.2** – Firm station capacity and local operational needs under the reference forecast
- **Section 6.3** – Potential needs under higher-than-forecast growth scenarios.

6.1 Needs Assessment Methodology

Based on the reference demand forecast (net demand under extreme weather conditions), system capability, transmitter-identified end-of-life asset replacement plans, and the application of ORTAC and NERC/NPCC standards, the Working Group identified electricity system needs in the following categories:

- **Station Capacity Needs**
  These arise when forecast demand exceeds the ability of regional step-down transformer stations to deliver power to the local distribution network during peak periods. A station's capacity rating is typically based on the 10-day Limited Time Rating (LTR) of its smallest transformer, assuming the largest transformer is out of service. Capacity may also be constrained by downstream or upstream equipment (e.g., breakers, disconnect switches, low-voltage bus, or transmission circuits) that are undersized relative to the transformer rating.
- **Supply Capacity Needs**
  These refer to the transmission system's ability to continuously supply electricity to a local area at peak demand. Supply capacity is determined by the Load Meeting Capability (LMC), which accounts for transmission element limitations under contingency conditions, as defined by ORTAC and NERC/NPCC standards. LMC studies are conducted using power system simulation tools.
- **End-of-life Asset Refurbishment Needs**
  These are identified by transmitters based on asset age, expected service life, condition, and risk of failure. Near-term and early mid-term replacement needs are typically condition-based, while medium- to long-term needs are often based on expected service life.



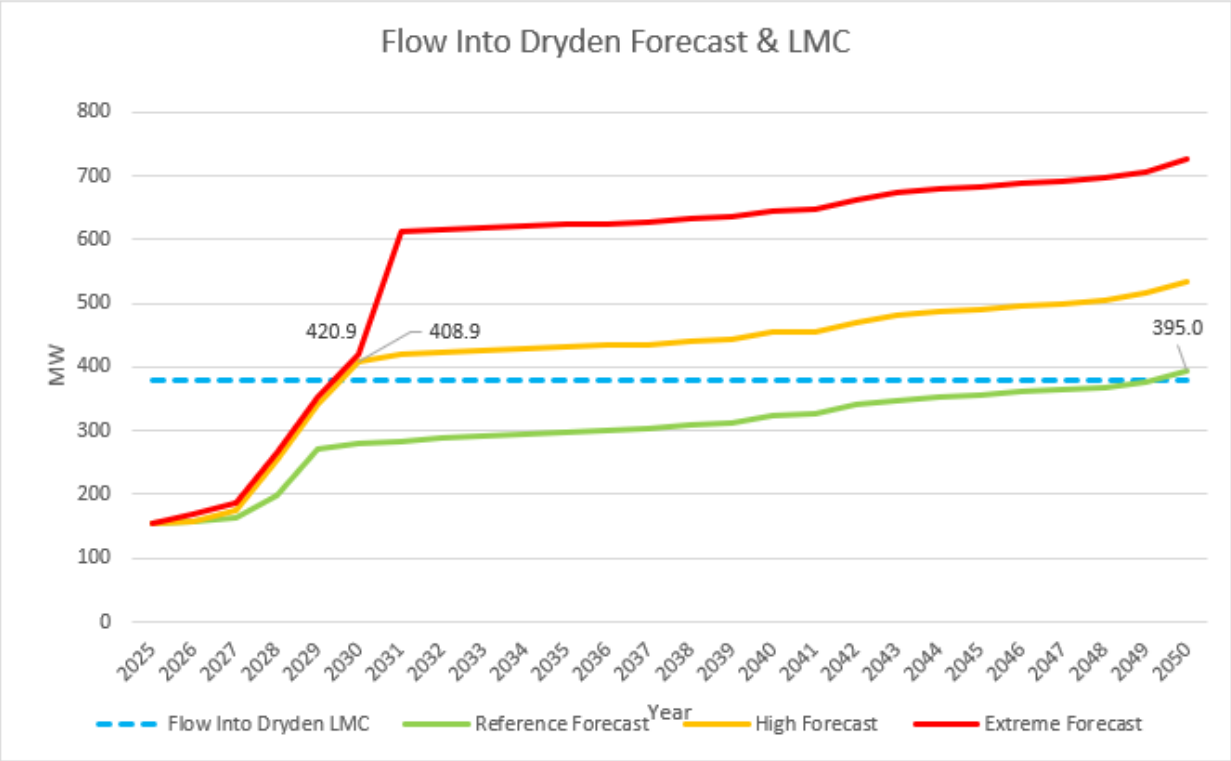
- **Load Security and Restoration Needs**
  These describe the system's ability to minimize the impact of major transmission outages and restore service within reasonable timeframes. Load security refers to the amount of supply interrupted during an outage (e.g., loss of both circuits on a double-circuit tower line), while load restoration refers to the system's ability to recover supply. Requirements are defined in Section 7 of ORTAC.

6.2 Needs Identified

To assess transmission reliability and identify emerging needs in the North of Dryden sub-region, the Study analyzed power flows across key interfaces that define how electricity is delivered into major areas. Specifically, the analysis focused on flows into the Ear Falls, Pickle Lake, and Dryden areas, each representing distinct supply paths. These interfaces form the basis for evaluating system capacity and determining when reinforcements may be required.

The geographic extent of each interface is illustrated in Figure 6.1.

Figure 6.1 | North of Dryden Interfaces



6.2.1 Flow into Dryden

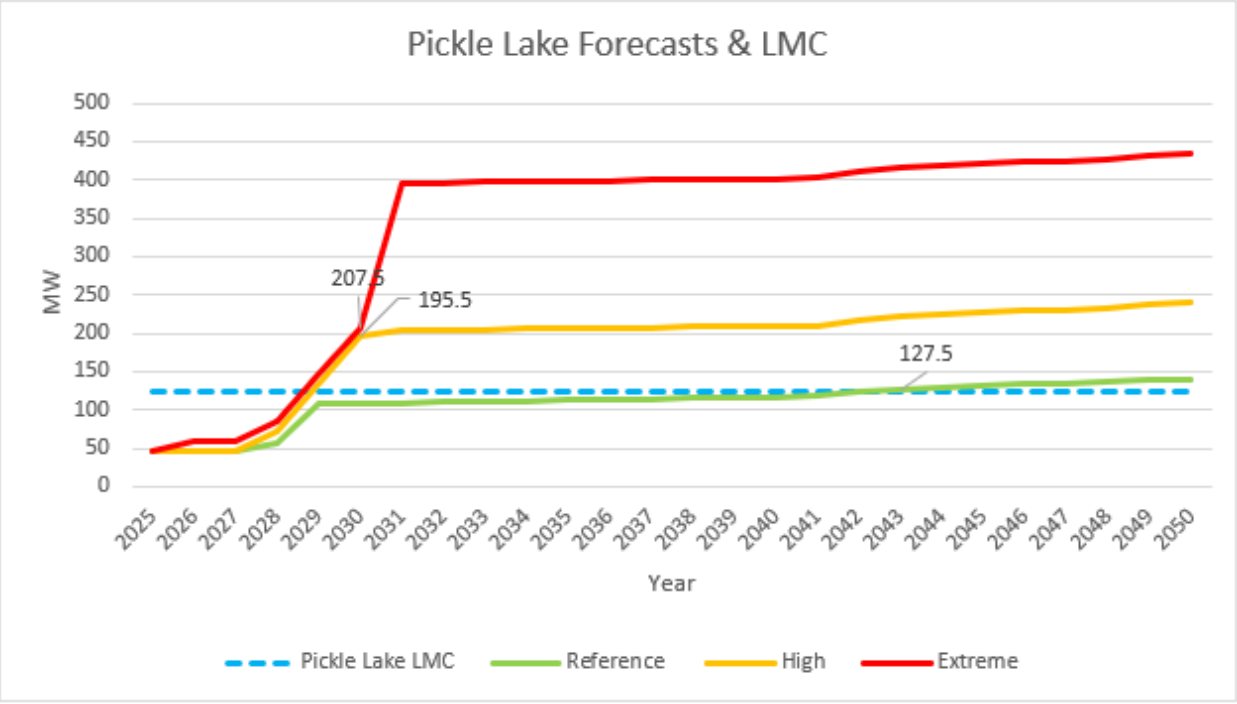
The Flow into Dryden (FID) interface is defined by the transfer of electricity into the Dryden area via:

- 230 kV circuits D26A and D32A from Mackenzie (once Waasigan Phase 2 is in service)
- Circuits K23D and M2D from Kenora and Moose Lake

The LMC of this interface is 380 MW, limited by summer thermal constraints under single-element outage conditions. In the event of a contingency on D32A, the remaining D26A circuit reaches its thermal limit when demand north of Dryden exceeds 380 MW. Figure 6.2 shows forecast demand across the FID interface relative to its LMC. Under the Reference scenario, demand remains within limits until approximately 2049, after which exceedances begin to appear. However, under high and extreme growth scenarios, constraints could emerge earlier, highlighting the need for continued evaluation. Further analysis will be conducted in the next regional planning cycle for Northwestern Ontario, commencing in 2025.

Figure 6.2 | Flow into Dryden Load Meeting Capability and Forecast Scenarios

6.2.2 Flow into Pickle Lake



The Flow into Pickle Lake (FPL) interface is defined by the radial supply via circuit W45W, with circuit E1C providing a partial backup path through the Red Lake system. The current load meeting capability (LMC) of the Pickle Lake area is approximately 125 MW, constrained by pre-contingency voltage limits as defined by ORTAC. Voltage sensitivity analysis under the reference load growth scenario indicates that these criteria will be violated at Pickle Lake TS by 2043, limiting the area to supply further demand.

To address this, 40 MVar of capacitive compensation will be required to support future load connections. However, rather than waiting until 2043, the IRRP recommends advancing the installation of a 40 MVar capacitor bank at Pickle Lake TS. This proactive step will not only mitigate the anticipated voltage deficiencies but also deliver near-term benefits by improving operability during outages and supporting load restoration efforts. The region currently faces reliability challenges due to limited remote operational capability and the absence of backup supply, which increases restoration time and complexity. The capacitor bank will help alleviate these issues by enhancing voltage stability and reactive support under contingency conditions.

The capacitor bank addresses the voltage violations in the Pickle Lake area and enables the system to support load levels exceeding 300 MW. However, under N-1 conditions, ORTAC load security criteria limit interruptible load to 150 MW. While the reference scenario remains within this threshold, the high-growth scenario exceeds it by 2030. Load forecasts under reference, high-growth, and extreme-growth scenarios are shown in Figure 6.3. Recommendations in this section are based on the reference scenario.

Looking ahead, the plan recommends that the TWG continue to monitor demand growth and explore reinforcement options for the corridor between Pickle Lake and Red Lake. This would further improve backup supply capability and overall reliability in the region.

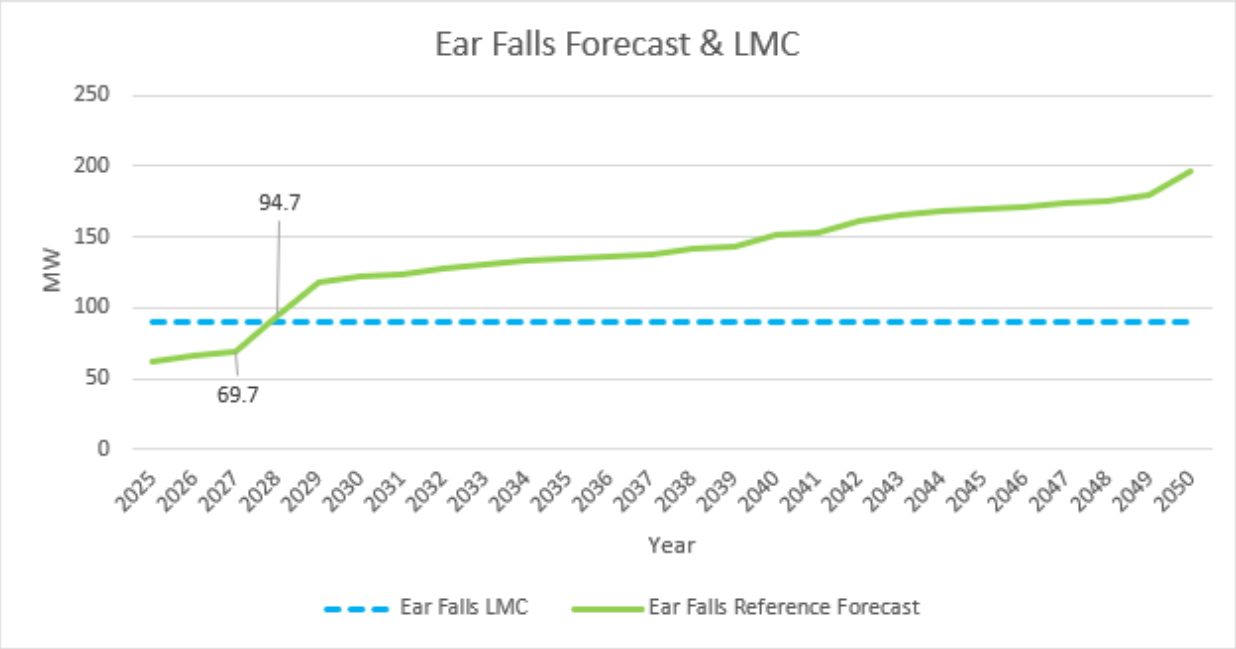


Figure 6.3 | Flow into Pickle Lake Load Meeting Capability and Forecast Scenarios

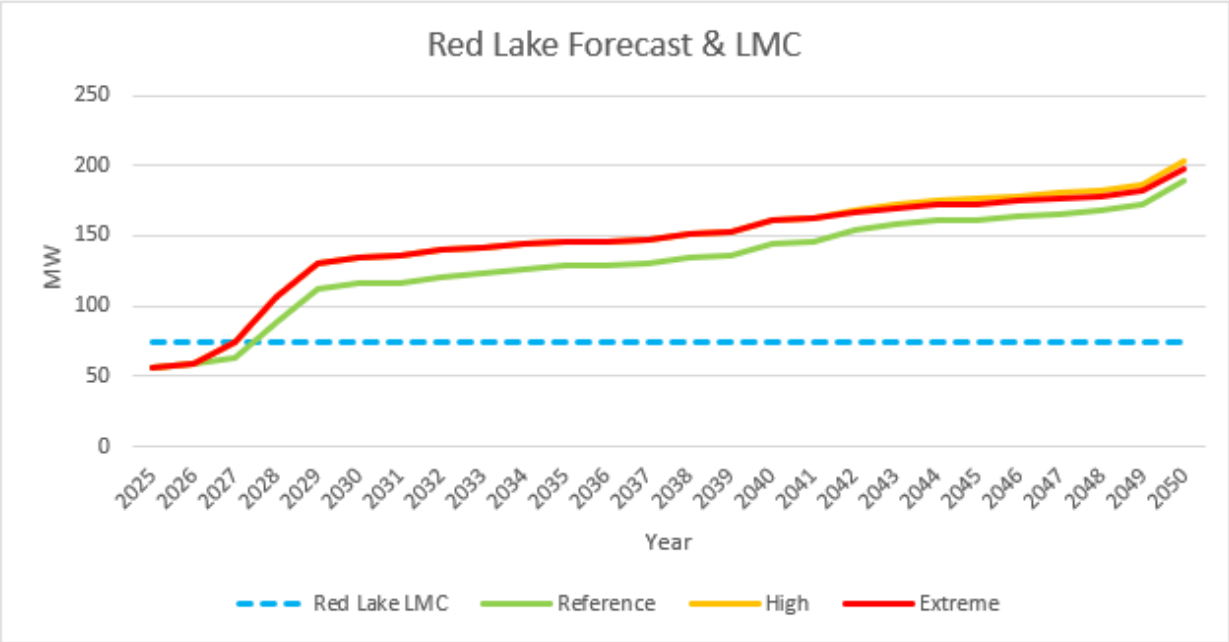
6.2.3 Flow into Ear Falls



The Flow into Ear Falls (FEF) interface is defined by radial supply via circuit E4D, with circuit E1C offering potential backup. The current LMC for this interface is 90 MW, limited by the summer thermal rating of E4D. Figure 6.4 shows forecasted demand across the FEF interface relative to this threshold. Under the reference forecast, demand exceeds the LMC by 2028.

Figure 6.4 | Flow into Ear Falls Load Meeting Capability and Forecast Scenarios

Within the broader Ear Falls area, the Red Lake subsystem is of particular interest. It is radially supplied via circuit E2R, with a summer LMC of 74 MW based on E2R's continuous thermal rating. Figure 6.5 shows forecasted demand across E2R relative to its thermal capacity. The subsystem is nearing its capacity, with thermal limitations on both E2R and E4D constraining supply under pre-contingency summer conditions.

Figure 6.5 | Red Lake Load Meeting Capability and Forecast Scenarios

In winter, the LMC increases to approximately 93 MW, though it remains limited by both thermal and voltage constraints on E2R. According to System Impact Assessment (SIA) 2022–730, the connection of the 13 MW Great Bear Resources Mine would require additional reactive compensation and would nearly exhaust the available capacity of the Ear Falls–Red Lake corridor. Any further load additions in the Red Lake area would exceed the current system capability and require transmission reinforcements.

System operators have also raised concerns about the lack of operational flexibility between the Pickle Lake and Red Lake subsystems, particularly given rising demand and the diminishing effectiveness of the Patricia Islanding scheme. Hydro One is currently addressing this issue.

Given that the reference forecast exceeds the FEF and Red Lake LMCs by 2028, reinforcement is required not only at the Ear Falls interface but also within the Red Lake supply corridor. While the high and extreme scenarios do not present immediate thermal constraints, they will require additional reactive support to maintain voltage performance under higher loading conditions.

6.2.4 E1C Operation and End-of-Life

The most recent cycle of regional planning identified operational challenges associated with the 115 kV E1C transmission line, which plays a critical role in supporting the Pickle Lake and Interlake area system. Its operational configuration has a significant impact on overall system performance. Two key issues were noted: limited supply capacity when E1C operates in a normally closed state, and high voltage levels under light load conditions when operated in a normally open state.

To maintain system adequacy and meet forecasted demand in the Ear Falls, Red Lake, and Pickle Lake areas, it is necessary to introduce a normally open point at the Ear Falls TS end of E1C. This adjustment would relieve loading on E4D and shift demand in the Pickle Lake area to the newly commissioned 230 kV W54W transmission line. However, operating E1C in an open configuration introduces high voltage concerns during periods of low demand.

As outlined in the 2023 Northwest Regional Infrastructure Plan, the Technical Working Group (TWG) recommended opening E1C at the Ear Falls TS end and installing reactors at Pickle Lake SS to mitigate voltage issues.

Currently, E1C has approximately 30 MW of available supply capacity. However, with potential mining developments in the Interlakes area, this remaining capacity may be insufficient under higher growth scenarios. Additionally, Hydro One has identified E1C as reaching end-of-life, with approximately 70% of pole replacements already completed.

Table 6.1 summarizes the firm transmission needs identified in this Addendum.

Table 6.1 | Summary of Near-Term and Medium- Term Needs

Subsystem	Need	Timing
Red Lake	The Flow into Red Lake LMC is expected to reach capacity in 2028. Voltage deficiencies due to load growth are also expected to occur by 2028. Reliability in this area is low due to inadequate remote load restoration and backup supply.	2028
Pickle Lake	Voltage deficiencies due to load growth are expected to occur by 2043. Reliability in this area is low due to inadequate remote load restoration and backup supply	2043
Ear Falls	E1C is reaching end-of-life and the Hydro One sustainment program is underway to replace the conductor like-for-like	Ongoing

6.3 Long-Term Needs under High Growth Scenario

Electricity demand in the North of Dryden sub-region is primarily driven by the mining sector, which tends to introduce large, incremental blocks of load with short lead times. This can create constraints on the existing transmission system.

To ensure flexibility, high-growth scenarios were studied for the Dryden, Red Lake, and Pickle Lake areas. The goal was to test the robustness and scalability of the transmission solutions developed for the reference scenario. This was achieved by simulating new projects at proposed connection points or nearby transformer stations and applying planning criteria outlined in Section 2.

By quantifying system limitations under high-growth conditions, planners can more effectively monitor demand and initiate timely reinforcements if required. Sensitivity studies show that extensive transmission reinforcement and/or resource procurement will be needed to support forecasted load growth in each area.

Table 6.2 | Summary of Long-Term Needs

Subsystem	Need	Timing
Dryden	The Flow in Dryden LMC is expected to reach capacity in 2049. This need advances significantly under high and extreme growth scenarios and will trigger additional supply capacity needs on the FID interface and additional reactive compensation.	2049
Pickle Lake	The Flow in Pickle Lake LMC is expected to reach capacity in 2042. This need advances significantly under high and extreme growth scenarios and will trigger additional supply capacity needs on the FPL interface and additional reactive compensation.	2042

7. Options Analysis and Recommendations

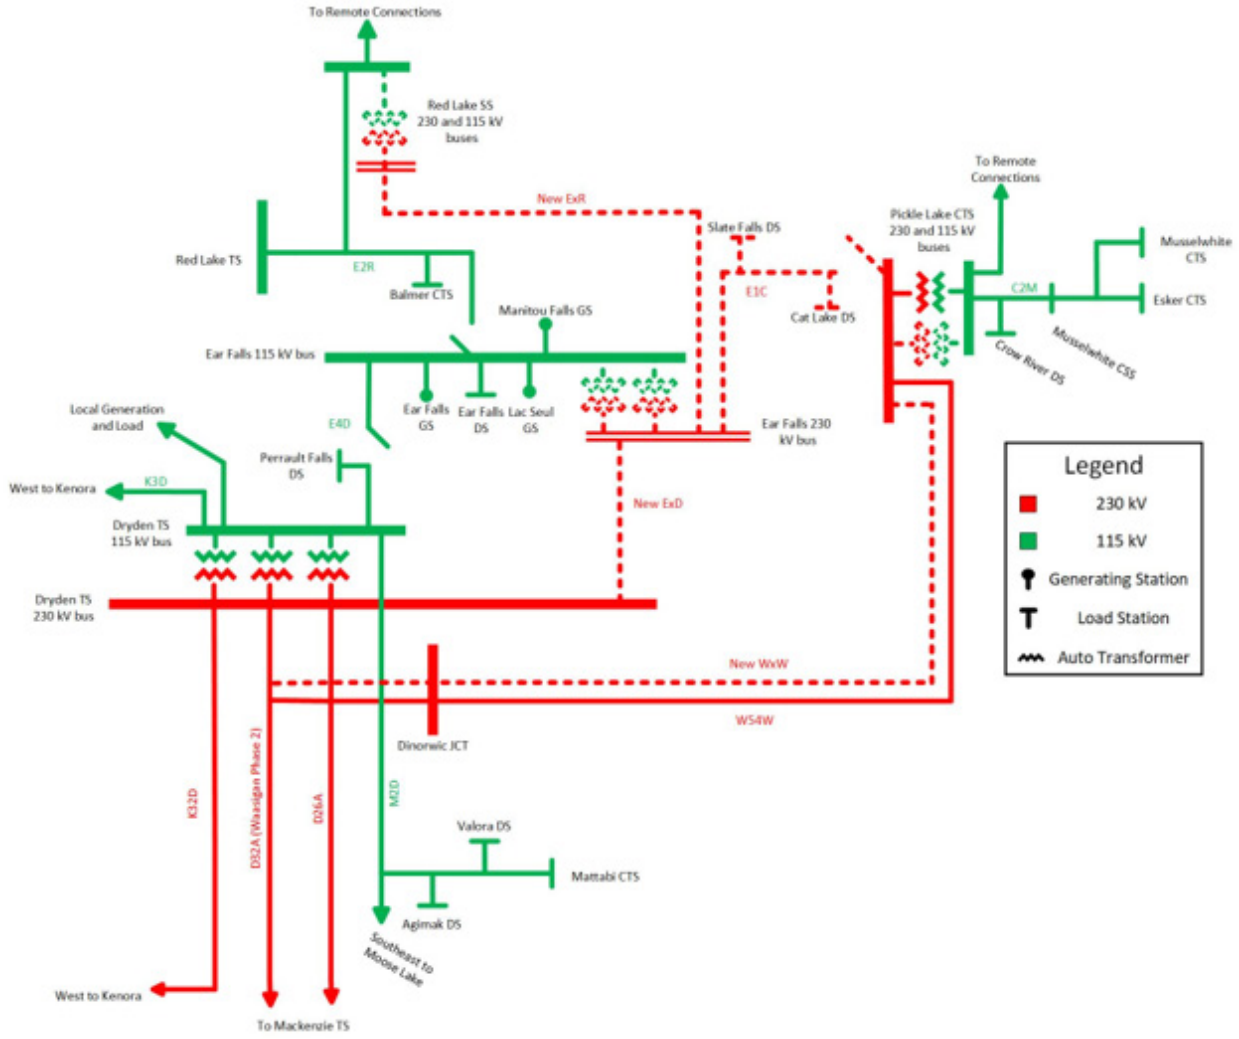
This section summarizes the transmission and non-wires options evaluated to address electricity system needs in the North of Dryden sub-region. The analysis includes:

- Section 7.1 – Transmission and non-wires options considered for near- to medium-term needs
- Section 7.2 – Comparison of transmission options
- Section 7.3 – Non-wires alternatives analysis.
- Section 7.4 – Recommendation

7.1 Transmission Options

To address the identified electricity needs, three primary transmission options were evaluated, along with a fourth variation involving double-circuiting. These options were informed by Hydro One's technical assessments, IESO planning studies, and feedback from local communities.

7.1.1 Option 1



This option includes:

- A new 230 kV transmission line from Dryden to Ear Falls (100 km)
- A new 230 kV transmission line from Ear Falls to Red Lake (62 km)
- A new 230 kV transmission line from Ear Falls to Pickle Lake (260 km)
- A new 230 kV transmission line from Dinorwic Junction to Pickle Lake (302 km)

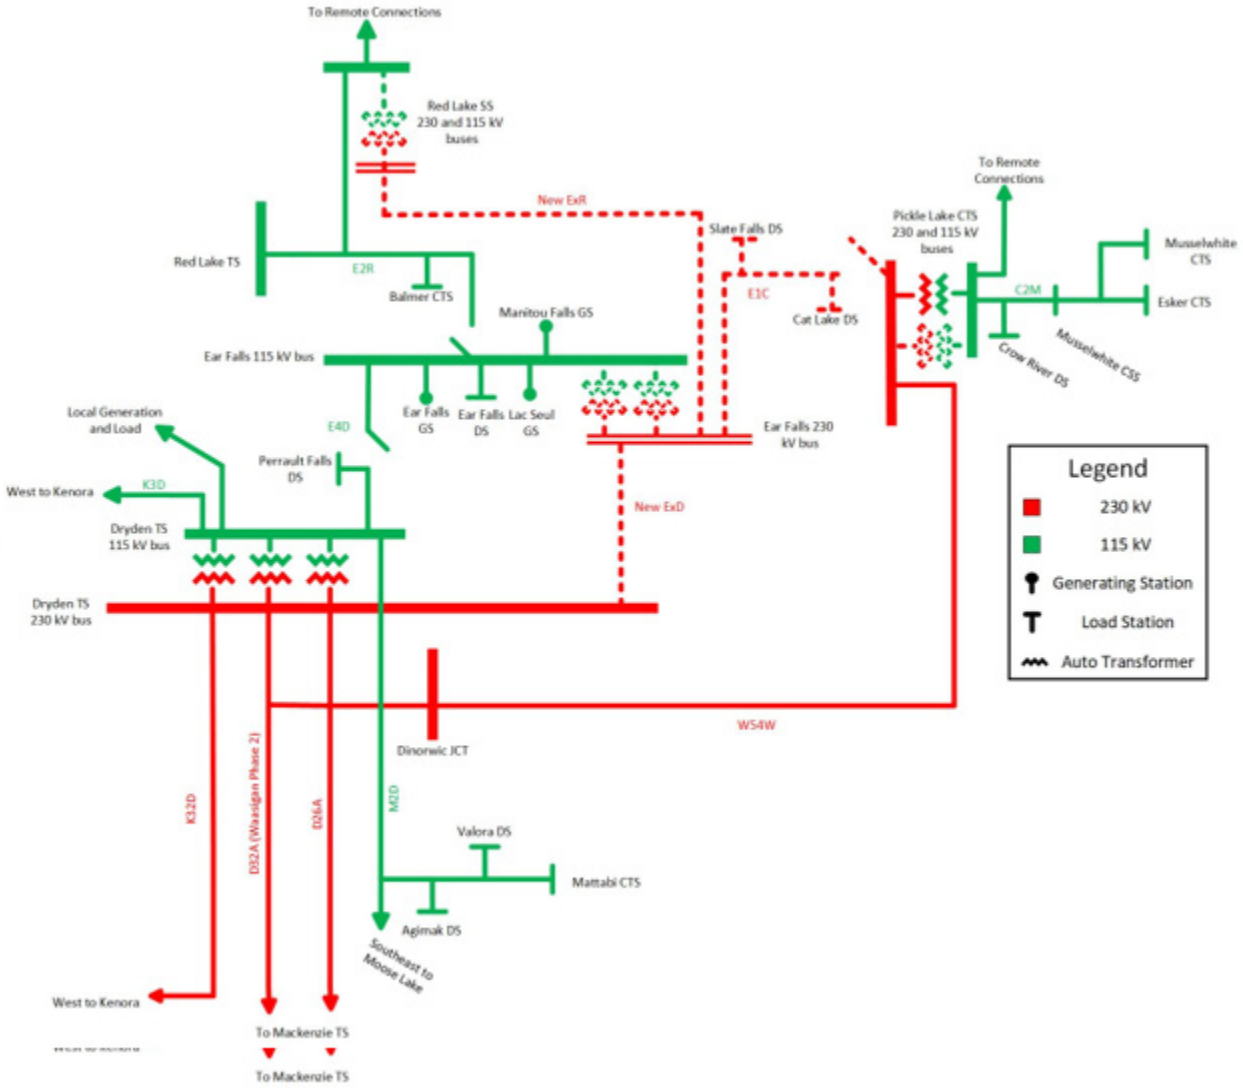
Supporting infrastructure includes:

- Two 230/115 kV autotransformers at Ear Falls TS
- One 230/115 kV autotransformer at Red Lake SS
- One 230/115 kV autotransformer at Pickle Lake CTS
- Replacement of step-down transformers at Perrault Falls, Slate Falls, and Cat Lake MTS with 230/12.5 or 25 kV units
- A new switching station with a 230 kV ring bus at Dinorwic TS
- Decommissioning of existing 115 kV E1C
- Reactive compensation for voltage support

Figure 7.1 | Transmission Option 1

7.1.2 Option 2

This option includes:



- A new 230 kV transmission line from Dryden to Ear Falls (100 km)
- A new 230 kV transmission line from Ear Falls to Red Lake parallel to E2R (62 km)
- A new 230 kV transmission line from Ear Falls to Pickle Lake (260 km)

Supporting infrastructure includes:

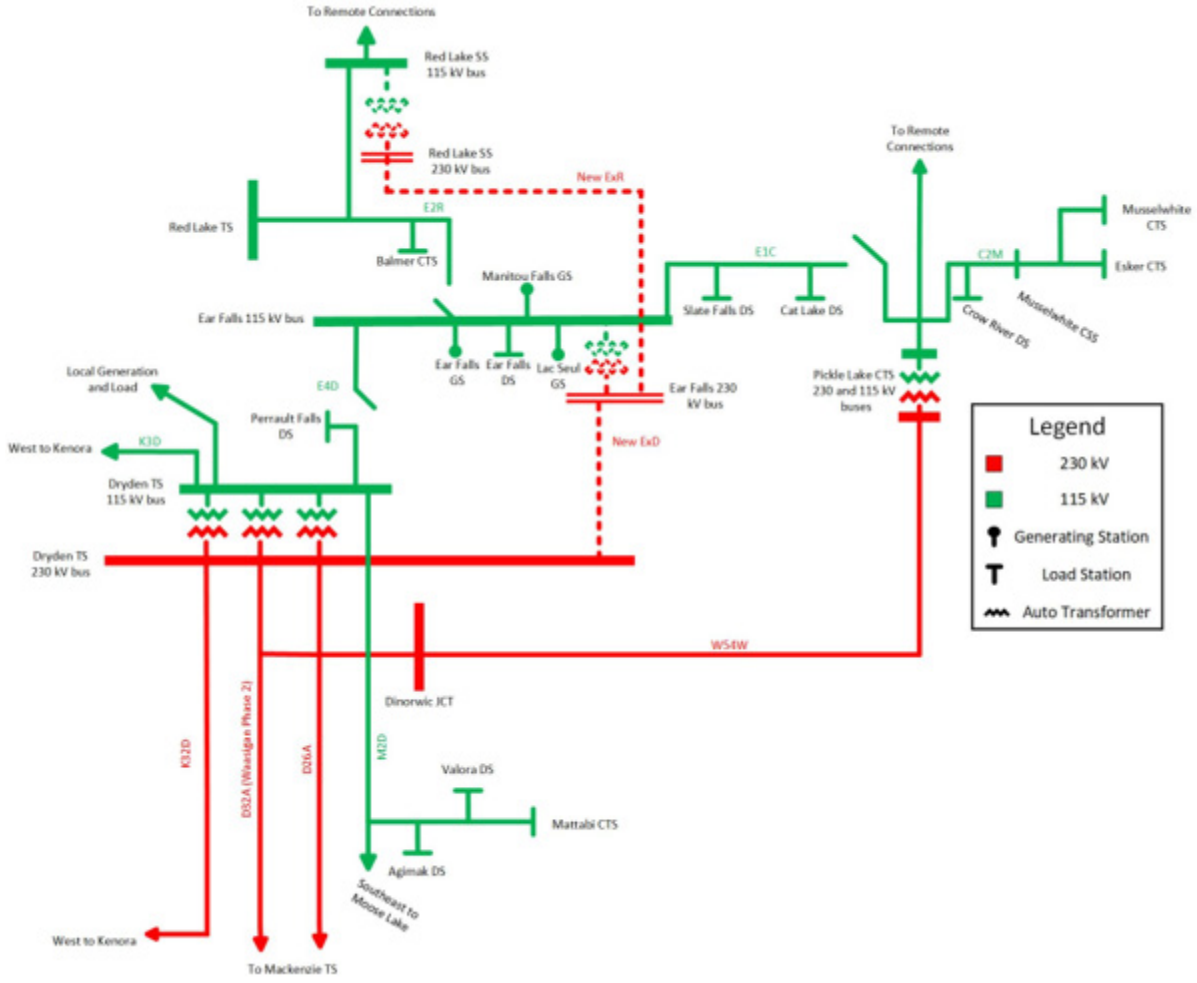
- Two 230/115 kV autotransformers at Ear Falls TS
- One 230/11 kV autotransformer at Red Lake SS
- One 230/115 kV autotransformer at Pickle Lake CTS

- Replacement of step-down transformers at Perrault Falls, Slate Falls, and Cat Lake MTS with 230/12.5 or 25 kV units
- Decommissioning of existing 115 kV E1C
- Reactive compensation for voltage support

Figure 7.2 | Transmission Option 2

7.1.3 Option 3

This option includes:



- A new 230 kV transmission line from Dryden to Ear Falls (100 km long)
- A new 230 kV transmission line from Ear Falls to Red Lake (62 km long)

Supporting infrastructure includes:

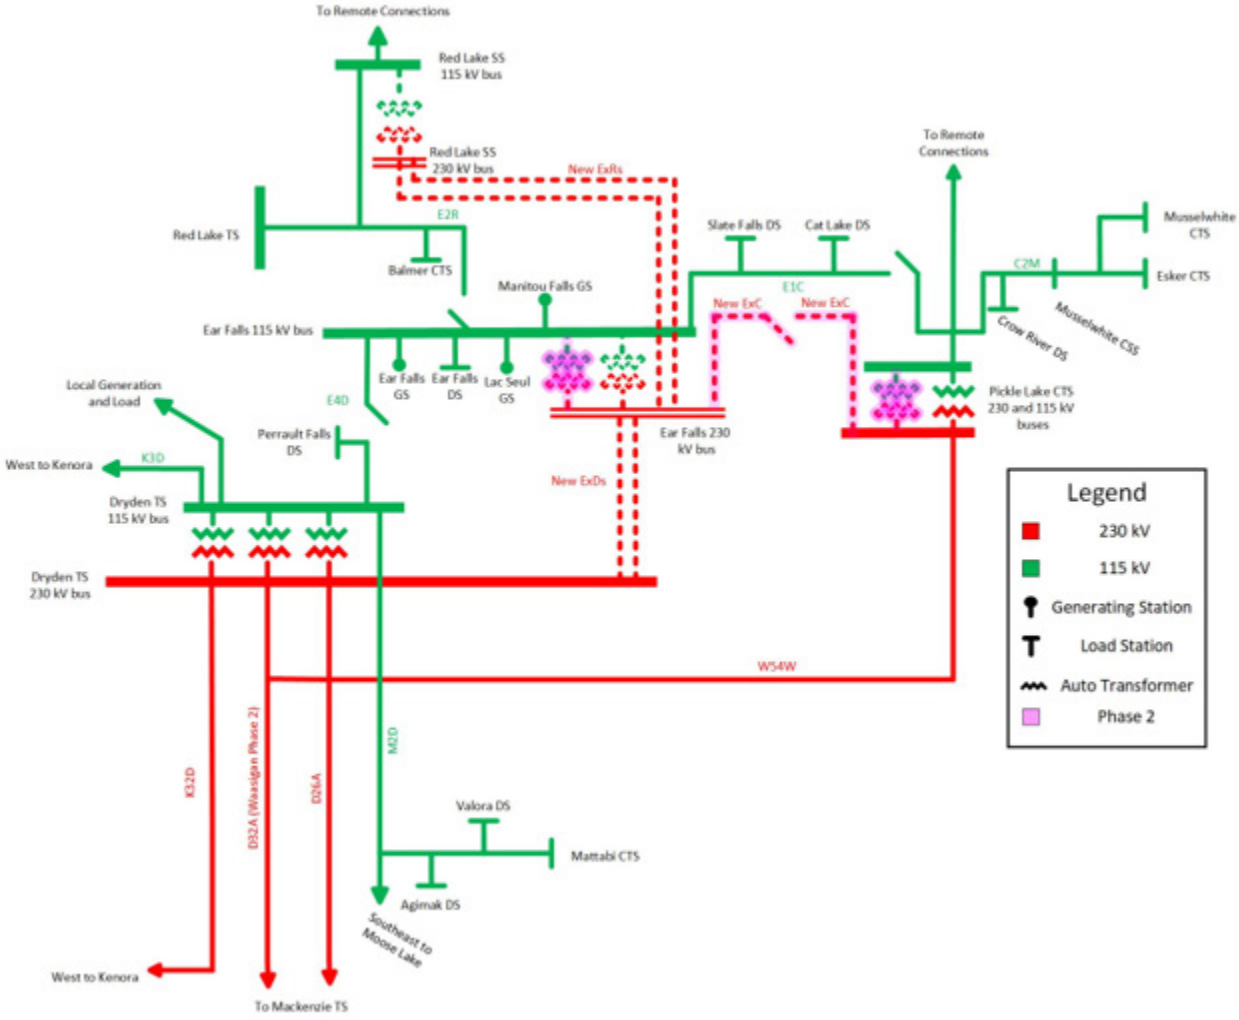
- One 230/115 kV auto-transformer at Ear Falls TS
- One 230/115 kV auto-transformer at Red Lake SS.
- Reconfiguration of existing 115 kV circuits E4D and E2R to operate normally open
- Reactive compensation for voltage support

A single line diagram of this transmission option can be found in Figure 7.3.

Figure 7.3 | Transmission Option 3

All three options involve a single-circuit supply to Red Lake and Pickle Lake. While the transmission lines can technically supply the demand forecast meeting thermal and voltage criteria, this configuration does not meet ORTAC load security criteria, which limits the amount of interrupted load following a contingency to 150 MW. Load growth beyond this threshold would require exemptions or additional infrastructure. Single-circuit supply also limits system reliability and resiliency, particularly during outages.

7.1.4 Option 3 – Double-circuit



To enhance reliability and resiliency, a variation of Option 3 was studied that involved an upgraded double-circuit 230 kV line Dryden to Red Lake and reinforced supply to Pickle Lake. The following transmission upgrades summarize the scope of work needed for this option:

- A new 230 kV double-circuit transmission line from Dryden to Ear Falls (100 km long)
- A new 230 kV double-circuit transmission line from Ear Falls to Red Lake (62 km long)
- Reconfiguration of existing 115 kV circuits E4D and E2R to operate normally open

Supporting infrastructure includes:

- Two 230/115 kV auto-transformers at Ear Falls TS
- Two 230/115 kV auto-transformers at Red Lake SS
- Reactive compensation for voltage support

Figure 7.4 | Transmission Option 3 Double Circuit

7.2 Options Comparison

Each transmission option was assessed against the applicable planning criteria under all-in service, N-1, and N-1-1 configurations, as detailed in Section 2.

7.2.1 Options Load Meeting Capability Comparison

Table 7.1 | Option Load Meeting Capabilities

Transmission Option	LMC Flow into Dryden (MW)	LMC Flow into Pickle Lake (MW)	LMC Flow into Ear Falls (MW)
Option 1	381	404	150 or 355 (with criteria exemption)
Option 2	381	150 or 307 (with criteria exemption)	150 or 355 (with criteria exemption)
Option 3	381	150 or 307 (with criteria exemption)	150 or 355 (with criteria exemption)
Option 3 (double circuit)	381	150 or 307 (with criteria exemption)	437

Constructing a double-circuit transmission line upfront is generally more cost-effective than staging and building two separate single-circuit lines over time. In addition to the economic advantages, this approach also reduces the overall footprint of transmission infrastructure, minimizing environmental impact and land use. This principle informed the evaluation of Option 3 (Double-Circuit) as a more efficient and sustainable solution.

For Options 1 and 2, the LMCs for Dryden and Ear Falls are identical due to the shared 230 kV upgrade from Dryden to Red Lake. However, achieving these LMCs requires exemptions from ORTAC load security criteria, which limit the maximum amount of interruptible load to 150 MW for the loss of a single element. In contrast, Option 3 (Double Circuit) complies fully with ORTAC without requiring exemptions, offering a more resilient and standards-compliant solution.

The higher LMC for Pickle Lake in Option 1 is due to the inclusion of the new line parallel to the existing 230 kV transmission line W54W from Dinorwic JCT to Pickle Lake TS. This configuration meets all planning criteria without exemptions but comes at a significantly higher cost compared to Option 3 (Double Circuit) with a 230 kV E1C upgrade, as discussed in Section 7.2.2.

Additionally, the 115 kV circuits E4D and E2R (Dryden–Ear Falls and Ear Falls–Red Lake) are approaching end-of-life within the next 20 years. The IESO has studied these circuits as potential backup supply paths. Preliminary analysis suggests that uprating these circuits may be economically viable to enhance backup capability. The IESO will continue to monitor load growth in the Red Lake and Ear Falls areas to determine appropriate replacement strategies, which will be further explored in the next regional planning cycle beginning in Q3 2025.

7.2.2 Options Cost Comparison

Table 7.2 summarizes the cost of the three options, including the cost of double-circuit configuration for Option 3.

Table 7.2 | Option Cost Comparison

Transmission Option	Estimated Capital Cost ($M)	New Circuit kms	Meets Red Lake area Reference Load Need Until	Meets Red Lake area High Load Growth Need Until
Option 1	2,490	724	2040	2034
Option 2	1,560	422	2040	2034
Option 3	720	262	2040	2034
Option 3-dbl	830	424	2050 and beyond	2050 and beyond

7.2.3 E1C upgrade and new customer connection point

As discussed in Section 6.2.4, circuit E1C is undergoing end-of-life replacement. It is recommended that Hydro One replace the conductor with a 411 kcmil conductor or better, which has a continuous rating of100 MVA. This upgrade will increase supply capacity and enable a proposed industrial customer to connect to E1C instead of their previously proposed location. This connection would be approximately 90 km shorter, resulting in a $150–$200 million reduction in transmission costs for the project. To support this connection, an additional 55 MVar shunt capacitor will be required at the new E1C connection point.

Following the customer connection, E1C should be operated normally open at Pickle Lake, consistent with recommendations in the 2023 Northwest IRRP. The upgraded conductor will also enhance E1C's ability to back up at least 50 MW of additional load in both Pickle Lake and Red Lake during contingencies, which provides system benefit.

To further improve reliability in the Pickle Lake and Red Lake areas, especially under high-growth scenarios, it may be necessary to reinforce the connection between these areas via the existing E1C corridor or by constructing a new 230 kV line parallel to the Wataynikaneyap W54W line. If E1C is upgraded to 230 kV, it could serve as a parallel supply path to Pickle Lake, complementing the Option 3 (Double-Circuit) transmission line from Dryden to Red Lake.

This configuration would allow the entire Pickle Lake area load to be backed up during outages. Additional reactive support (capacitive compensation) will be required at Pickle Lake TS, Ear Falls TS, and downstream corridors to enable full backup capability.

7.2.4 Transmission Options Conclusion

For the remainder of the analysis, Options 1, 2, and 3 were no longer considered, as they do not meet the demand in the long term, making them less resilient and cost-effective compared to Option 3 (Double Circuit), which meets all criteria and supports long-term growth through 2050 and beyond.

7.3 Non-Wires Alternatives (NWA)

In addition to evaluating transmission solutions for the North of Dryden sub-region, non-wires alternatives (NWAs) were also considered. The assessment focused on three sub-systems: Red Lake, Pickle Lake, and Dryden.

In the Red Lake area, forecasted load growth is expected to exceed the region's Load Meeting Capability (LMC) of 74 MW, creating a significant supply gap. While new Electricity Demand Side Management (eDSM) measures have been considered, their impact is relatively modest and provides only 5 MW of capacity savings by 2050. This limited contribution highlights the challenge of addressing the area's growing energy needs through demand-side solutions alone. As a result, there remains a substantial net requirement of 127 MW (755,995 MWh) by 2050, much of which is driven by expanding mining activity. Mining loads typically have a flat demand profile, requiring consistent supply across all hours and seasons, with peak demand occurring during winter months.

Various resource options were considered to create a range of NWA costs for North of Dryden. The following NWA economic assessments were studied:

1. Natural gas
2. Biomass
3. Solar + Wind + BESS
4. Wind +BESS
5. Solar + BESS

Although the NWA options 4 and 5 were studied, not every load requirement of every hour (8760 hourly needs) would be served. As a result, these two options were ruled out from the NWA analysis.

Some assumptions were also made during the economic assessment which include:

- Various emitting and non-emitting resource options were considered creating a range of costs for Non-Wire Alternative's (NWA's).

- Emitting resources considered included Combine Cycle Gas Turbine (CCGT) and Biomass facilities, with overnight capital costs, fixed operating and maintenance (FOM), biomass fuel and variable operating and maintenance (VOM) sourced from 2024 Annual Technology Baseline (ATB) data by The National Renewable Energy Laboratory (NREL).
- Natural gas fuel costs and carbon costs assumptions from 2025 Annual Planning Outlook (APO).
- NWA emitting and non-emitting levelized costs are based on 2024 ATB data from NREL whereby the values are converted to Canadian (CAD) 2025$.
- System benefits based on the 2025 APO Capital Expansion (CapEx) portfolio https://www.ieso.ca/-/media/Files/IESO/Document-Library/planning-forecasts/apo/2025/APO-2025-Marginal-Energy-Costs-and-Capacity-Costs.xlsx
- All dollar figures are $2025 Real, the inflation rate is assumed to be 2% per year, and the social discount rate is 4% Real.
- Net present value (NPV) is considered from 2026 to 2102, with the transmission option commencing in 2033 for 70 yrs and the NWA aligning with this transmission timeline. The transmission costs consist of the Red Lake portion of the transmission options.

Further details on assumptions made for NWA can be found in Appendix D.

Table 7.3 presents a comparative economic analysis of various supply options for meeting future electricity needs in the Red Lake area. It includes both transmission and non-wires alternatives (NWAs), evaluating each option across several key dimensions: total utility cost, system benefit, net impact to ratepayers, land requirements, and the percentage of need and load served.

A key metric in this analysis is System Benefit, which refers to the option's contribution to Ontario's overall resource adequacy and energy requirements. In other words, it reflects how much the resource helps meet provincial-level electricity demand not just local needs. This is particularly important when considering NWAs, as some options may offer broader system value beyond the immediate region.

Table 7.3 | Economic Assessment for Wires and Non-Wires Alternatives

Options	Total Cost (Utility)	System Benefits	Net Benefit/Cost to Ratepayer	Land Requirement	% of Need Served	% of Load Served
Transmission Option 3	$647 M	$0 M	-$647 M	~500–1000 hectares/5–10 km^2	100.0%	100.0%
Natural Gas	$1,378 M	$1,378 M	$0 M	~20–40 hectares/0.2 - 0.4 km^2	100.0%	100.0%
Biomass	$2,755 M	$1,585 M	-$1,170 M	~20–40 hectares/0.2 - 0.4 km^2	100.0%	100.0%
Solar + Wind + BESS	$3,295 M	$2,923 M	-$372 M	~6,572 hectares/65.7 km^2	99.2%	99.7%
Wind + BESS	$11,118 M	$10,092 M	-$1,026 M	~48,895 hectares/ 489 km^2	99.0%	99.6%
Solar + BESS	$6,035 M	$5,193 M	- $842 M	~4,344 hectares/ 43.4 km^2	97.6%	98.9%

Note: All values are Net Present Values (NPVs), from 2026 to 2102, at a 4% social discount rate, in $2025 CAD.

Based on Table 7.3, transmission option 3 (as a single circuit) has the least transmission cost to ratepayers ($647 M). However, natural gas net cost has the least cost option for the Red Lake area of $0 M based on the 2024 National Renewable Energy Laboratory's (NREL) cost for a Combine Cycle Gas Turbine (CCGT) facility. Due to the later introduction of Option 3 built as a double circuit, a full economic assessment was not completed. However, it would be expected to have higher costs (of approximately 25%) than the single circuit option with a similar distribution of costs to benefits (i.e., no system benefits). Natural gas overnight capital cost from NREL is likely understated as these costs do not capture incremental costs associated with locating in the northwest region of Ontario. In addition, the natural gas supply needs for a 127 MW gas plant may not be feasible, since Red Lake is supplied by a gas distribution lateral off the TransCanada Energy Mainline. Further analysis is required to assess the true feasibility of implementing this option. In contrast, the biomass option has the highest cost to ratepayers in comparison to all the listed options, with a net benefit of $1.2 B.

Within the non-emitting NWA options, Wind + Solar + BESS has the least net benefit cost of $372 M, which is a lower net cost relative to the transmission option 3 of $647 M. This option would require about 65.7km^2 of land, which would need to be discussed with the local area community to assess for siting feasibility and acceptance. The options Wind + BESS and Solar + BESS are also provided to illustrate the possible land requirement range. Nonetheless, these options will not be able to meet 100% of the hours of the sub-region, which is an important factor to consider.

Overall, when evaluating non-wires alternatives, a natural gas generator presents comparable initial utility costs to those of transmission option 3. While the generator may offer certain system benefits, it also raises several significant concerns that make the transmission alternative a more attractive and viable recommendation. Key issues include the challenges of load restoration during generator outages, unserved load risks, and the absence of interconnection for backup supply between the Pickle Lake and Red Lake area. Further uncertainty exists regarding the exact location of the proposed plant, construction risks, the alignment of pipeline infrastructure, and the level of community acceptance. Additionally, reliance on a gas plant would not resolve the broader transmission limitations, as it only addresses the needs of the Red Lake area under the reference scenario. In the high-demand scenario, a generator of the size considered in this study would be insufficient to meet the projected capacity requirements. Finally, reliance on natural gas generation to meet demand, on a continuous basis, would not be compliant with the Clean Electricity Regulations (CER) enacted under the Canadian Environmental Protection Act. These regulations establish a performance standard of 30 tonnes of CO2 emissions per gigawatt-hour (T/GWh). Should additional needs arise in both the Pickle Lake and Red Lake areas, further reinforcement, either through transmission expansion or an additional generation facility in the Pickle Lake area, would be necessary. Although both options have strong stakeholder support, the transmission alternative remains the more favourable option due to these unresolved concerns associated with the natural gas option.

7.4 Recommendation

The transmission options were evaluated based on several key metrics, including:

- Cost to ratepayers
- Ability to serve forecasted load
- Compatibility with existing infrastructure
- Potential for future expansion
- System reliability and resilience

Option 3, when built as a single-circuit transmission line, is capable of meeting the reference load forecast up to the medium term. However, under this configuration, nearly all load in the Red Lake and Ear Falls areas would be radially supplied via a single circuit. In the event of a contingency, this load would be interrupted, and while circuit E4D could provide backup, it is insufficient to restore full supply. Over the long-term, this configuration violates ORTAC load security criteria, which limits the amount of interrupted load following a contingency to 150 MW.

Recommended Solution: Option 3 – Double-Circuit

To address these concerns, the IRRP recommends Option 3 built to a double-circuit transmission line, consisting of the following elements:

- Construct a double-circuit 230 kV transmission line from Dryden TS to Ear Falls TS (100 km)
- Construct a double-circuit 230 kV transmission line from Ear Falls TS to Red Lake SS (62 km)
- Install two new 230/115 kV autotransformer at Ear Falls TS
- Install two new 230/115 kV autotransformer at Red Lake SS
- Reconfigure existing 115 kV circuits E4D and E2R to operate normally open
- Install 40 MVar shunt capacitors at:
- Red Lake SS
- Ear Falls TS
- 230 kV side of Pickle Lake TS

The proposed 230 kV transmission line does not align well with the Transmitter Selection Framework (TSF) due to the urgent need to increase supply capacity in the Red Lake area. The TSF best suits projects with longer lead times (≥ 6 years) to accommodate a competitive procurement process. Given the time-sensitive nature of this project, proceeding outside the TSF would better support timely delivery, system reliability and support economic development.

Benefits of the Recommended Option

This option:

- Meets regional electricity needs through 2050 and beyond, under reference, high, and extreme demand scenarios
- Improves reliability and reduces load interruptions in the North of Dryden sub-region
- Supports connection of new resources, including hydroelectric, biomass, and other generation, by reducing connection costs and enabling power transfer to the broader grid
- Enhances system robustness and resilience, while remaining compliant with planning criteria
- Reduces long-term costs, as the incremental cost of building a double-circuit line is significantly lower than constructing a parallel single-circuit line later
- Leverages existing rights-of-way, where feasible, to minimize environmental and land-use impacts.

Considering the construction challenges in Northern Ontario and the incremental cost advantages, the double-circuit configuration provides enhanced reliability for municipalities, remote communities, and industrial customers. It also prepares the transmission system for future expansion to accommodate high and extreme load growth in the Pickle Lake area.

8. Community and Stakeholder Engagement

Engagement is critical in the development of an Addendum. Providing opportunities for input in the regional planning process ensures that the views and perspectives of Indigenous communities, municipalities, stakeholders, communities, market participants, customers, and the general public, are considered in the development of the Plan, helping to lay the foundation for successful implementation. This section outlines the engagement principles and activities undertaken to date for the North of Dryden Addendum.

8.1 Engagement Principles

The IESO's External Relations Engagement Framework and the Indigenous Engagement Framework are built on a series of key principles that respond to the needs of the electricity sector, communities and the broader economy. These principles ensure that diverse and unique perspectives are valued in the IESO's processes and decision-making. We are committed to engaging with purpose with external audiences to foster trust and build understanding as the energy transition continues.

Figure 8.1 | IESO'S Engagement Principles

The IESO's engagement principles[11] help to ensure that all interested parties are aware of and can contribute to the development of this Plan. The IESO uses these principles to ensure inclusiveness, sincerity, respect, and fairness in its engagements, striving to build trusting relationships as a result.

8.2 Engagement Approach

To ensure that the Plan reflects the needs of Indigenous communities, market participants, municipalities, stakeholders, communities, customers and the general public, engagement involved:

- Leveraging the North of Dryden engagement webpage to post updated information, engagement opportunities, meeting materials, input received and the IESO responses to feedback,
- Holding targeted discussions with municipalities, associations and mining industry to help inform the engagement approach for this planning cycle and to understand feedback and perspectives at key milestones,
- Hosting a series of public webinars at major junctions in the Plan's development to share plan details, understand feedback and answer questions
- Carrying out communications and other engagement tactics to enable broad participation through email and IESO's weekly Bulletin updates.

As a result, the engagement for the North of Dryden Addendum included:

- A dedicated webpage[12] on the IESO website to post all webinar materials, feedback received and IESO responses to the feedback throughout the engagement process,
- Regular communication with interested communities and stakeholders by email or through the IESO weekly Bulletin,
- Hosting public webinars at major milestones in the plan development to share plan details, understand feedback, and answer questions,
- Targeted one-on-one outreach with Indigenous communities, municipalities, and stakeholders to ensure that their identified needs are addressed.

8.3 Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for this round of planning, leveraging existing relationships built through the previous planning cycle. This started with an email to impacted municipalities, Indigenous communities, industry stakeholders, and municipal associations to announce the commencement of the development of an Addendum to the 2023 Northwest Integrated Regional Resource Plan.

[11] https://www.ieso.ca/en/sector-participants/engagement-initiatives/overview/engagement-principles

[12] https://www.ieso.ca/Sector-Participants/Engagement-Initiatives/Engagements/Regional-Electricity-Planning-North-of-Dryden-Sub-Region

An invitation was sent to targeted municipalities to discuss the draft demand forecast and electricity needs in the region. A virtual meeting was held early in the process and feedback was received, which centered on the need to ensure that municipal energy planning, economic development and industrial growth (mining) were included in the development of the Addendums demand forecast. In addition, reliability remained a paramount concern within this region. The IESO had further engagement with the Northwest Energy Task Force (NW-ETF) to help further inform the Addendum demand forecast.

A second in-person meeting was held with elected officials and municipal staff from impacted municipalities to provide an update on the progress of the Addendum. During the meeting, the IESO shared the demand forecast, electricity needs, and preliminary options screening results.

The launch of a broader engagement initiative followed with an invitation to IESO subscribers of the Northwest planning region as well as all identified municipalities and Indigenous communities to ensure that all interested parties were made aware of this opportunity for input.

A third virtual meeting was held with elected officials and municipal staff from impacted municipalities, as well as the NW-ETF, to provide an update on the options evaluation and draft recommendations and seek feedback. Municipalities and the NW-ETF were supportive of the draft recommendations for the Addendum and what the Plan means for the growth in their communities and economic development. NW-ETF noted how pleased they were with how collaborative the regional plan was. The Municipality of Red Lake and the NW-ETF shared concerns that long lead times for transmission infrastructure may not align with the timing of planned industrial projects.

Two public webinars were held at key stages during the Plan's development to give interested parties an opportunity to hear about progress and provide feedback to each component of the Plan. The first public webinar was held on May 7, 2025 to share the draft demand forecasts, needs, and options screening. The webinar, attended by a cross-representation of community representatives, municipalities, associations, businesses, and other stakeholders, and written feedback was collected over an approximately two-week comment period after the webinar, also sought feedback from interested stakeholders and community representatives.

A second public webinar was held on July 30, 2025 to share the options analysis and draft recommendations, and sought feedback from interested stakeholders and community representatives. The webinar was attended by a cross-representation of community representatives, municipalities, associations, businesses, and other stakeholders, and written feedback was collected over an approximately two-week comment period after the webinar.

The public webinars invited input on:

1. The electricity demand forecasts, the electricity needs for the region and potential options to meet the identified needs.
2. The analysis of options and draft Addendum recommendations.

Comments received during this engagement focused on the following major themes:

- Cost allocation methodology for new transmission infrastructure.
- Consideration of local developments, growth plans and reliability concerns in demand forecasts particularly in communities with limited capacity.
- Consideration of non-wire alternatives to meet needs, as well as existing resources in the region where contracts are due to expire.
- Concern about long lead times for transmission infrastructure and the resulting impacts on planned industrial project timelines, along with feedback that the Addendum should address interim needs as new transmission is developed.
- General support for the draft Option 3 Double Circuit recommendation.
- Request that government declare Addendum recommendation a priority project to expediate the new transmission line.

Each engagement session received strong participation and interest with a cross-representation from stakeholders and community representatives. Feedback received as a result of each engagement meeting and webinar was considered throughout the development of each milestone of the Addendum.

All interested parties were kept informed throughout this engagement initiative via email to Northwest region subscribers, municipalities, and Indigenous communities, in addition to webpage updates. All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's North of Dryden Addendum engagement webpage.

Discussions during the Addendum engagement showed strong interest in further exploring the potential development of the mining sector, opportunities to unlock regional economic growth, and alternative energy solutions to meet local needs—particularly as communities and industries face capacity constraints or transition toward electrification. This insight has been valuable to the IESO and will help to inform future discussions to examine and consider these types of initiatives and the opportunities that they may present in future planning efforts, including an upcoming Northwest Integrated Regional Resource Plan.

8.4 Involving Municipalities in the Plan

The IESO held meetings with municipalities to seek input on their own planning and priorities to ensure that these plans were taken into consideration in the development of this Addendum. At major milestones in the Addendum process, meetings were held with targeted municipalities in the region to discuss key issues of concern, including forecasts, regional electricity needs, options for meeting the region's future needs, reliability concerns, and broader community engagement. These meetings helped to inform the municipal/community electricity needs and priorities and provided opportunities to strengthen this relationship for ongoing dialogue beyond this Addendum process.

Throughout these discussions valuable feedback was received concerning anticipated growth in the mining industry and local communities, including:

- Municipality of Red Lake is preparing a Red Lake Gap Analysis Study that could be used as an input to better understand the residential and commercial growth expected in the next 3–5 years, due to enhanced transportation infrastructure that would connect neighboring communities.
- Northwest Energy Task Force shared their demand forecast for the region to be used as an input into the finalization of the Addendums demand forecast.
- Advocacy that more electricity infrastructure was needed in the Northwestern region to support current and future residential and industrial growth.

These insights have been invaluable to the IESO, as they support an understanding of local growth and accurate electricity demand forecast scenarios, the determination of needs, and the recommendation of solutions to ensure adequate and reliable long-term supply. To that end, ongoing discussions will continue to keep interested parties engaged in a two-way dialogue on local developments, priorities, and initiatives to prepare for the next planning cycle.

8.5 Engaging with Indigenous Communities

The IESO remains committed to ongoing, effective dialogue with Indigenous communities to help shape long-term planning across Ontario. To raise awareness about the regional planning cycle in Northwest Ontario and provide opportunities to provide input, the IESO invited Indigenous communities that may be potentially impacted or may have an interest based on treaty territory, traditional territory or traditional land use to participate in webinars that were held on:

- Addendum Letter of Commencement November 29, 2024
- May 7, 2025
- July 30, 2025

The following First Nations communities were invited to the webinars:

- Animakee Wa Zhing No. 37
- Animbiigoo Zaagi'igan Anishinaabek
- Anishinaabeg of Naongashiing (Big Island)
- Anishinabe of Wauzhushk Onigum
- Aroland
- Asubpeeschoseewagong First Nation
- Bearskin Lake
- Big Grassy River (Mishkosiminiziibiing)
- Biigtigong Nishnaabeg
- Biinjitiwaabik Zaaging Anishinaabek
- Bingwi Neyaashi Anishinaabek
- Cat Lake
- Constance Lake
- Deer Lake
- Eabametoong
- Eagle Lake
- Fort Severn
- Gakijiwanong Anishinaabe Nation
- Ginoogaming First Nation
- Gull Bay First Nation
- Iskatewizaagegan No. 39
- Kasabonika Lake
- Keewaywin
- Kiashke Zaaging Anishinaabek
- Kingfisher Lake
- Kitchenuhmaykoosib Inninuwug
- Koocheching First Nation
- Lac des Mille Lacs
- Lac Seul
- Long Lake No. 58
- Marten Falls
- McDowell Lake
- Michipicoten
- Mishkeegogamang
- Missanabie Cree
- Muskrat Dam Lake
- Namaygoosisagagun
- Naotkamegwanning
- Neskantaga
- Netmizaaggamig Nishnaabeg (Pic Mobert)
- Nibinamik
- Niisaachewan Anishinaabe Nation
- North Caribou Lake
- North Spirit Lake

- Northwest Angle No. 33
- Ojibway Nation of Saugeen
- Ojibways of Onigaming
- Pays Plat
- Pikangikum
- Poplar Hill
- Rainy River
- Sachigo Lake
- Sandy Lake
- Shoal Lake No. 40
- Slate Falls
- Wabaseemoong
- Wabauskang
- Wabigoon Lake
- Wapekeka
- Washagamis Bay (Obashkaandagaang)
- Wawakapewin
- Webequie
- Weenusk
- Whitesand
- Whitewater Lake
- Wunnumin Lake

The following Tribal Councils and Provincial Territorial Organizations (PTOs) were invited to the webinars:

- Anishinabek Nation, Union of Ontario Indians
- Chiefs of Ontario
- Grand Council Treaty #3
- Independent First Nations Alliance (IFNA)
- Keewaytinook Okimakanak/Northern Chiefs Council
- Matawa First Nations Management
- Matawa First Nations Tribal Council
- Nishnawbe Aski Nation
- Shibogama First Nations Council
- Windigo First Nations Council

The following Métis communities were invited to the webinars:

- Métis Nation of Ontario
- Red Sky Independent Métis Nation

The IESO also had one-on-one meetings with Indigenous communities for opportunities to provide input on their own planning and priorities to ensure that these plans were taken into consideration in the development of this Addendum.

Feedback on IESO engagement efforts from Indigenous communities included:

- Support for the construction of a new 230kV line from Dryden to Red Lake, as the recommended option due to risks that First Nation communities north and south of Red Lake will face development restrictions in a time when new housing, community infrastructure, and services are badly needed.
- Projects will require the consent and meaningful participation of First Nations to move forward with construction. Hydro One is best positioned to develop the Project and has committed to meaningful First Nations participation under its "First Nation Equity Partnership Model."
- Land rights and ownership need to be respected and Manito Aki Inaakonigewin (MAI), the "Great Earth Law," needs to be followed and adhered to for all proposed activities and projects occurring in Treaty #3. The options did not show the potential negative environmental footprint on the land itself. The environmental impacts need to be discussed and addressed prior to new transmission going ahead.

8.5.1 Information about Indigenous Participation and Engagement in Transmission Development

By conducting regional planning, the IESO determines the most reliable and cost-effective options after it has engaged with stakeholders and Indigenous communities and publishes recommendations in the applicable regional or bulk planning report. Where the IESO determines that the lead time required to implement the recommended solutions requires immediate action, the IESO may provide those recommendations ahead of the publication of a planning report.

In instances where transmission is the recommended option, a proponent applies for applicable regulatory approvals, including an Environmental Assessment that is overseen by the Ministry of Environment, Conservation and Parks (MECP). This process includes, where applicable, consultation regarding Aboriginal and treaty rights, with any approval including steps to avoid or mitigate impacts to said rights. MECP oversees the consultation process generally but may delegate the procedural aspects of consultation to the proponent. Following development work, the proponent will then apply to the OEB for approval through a Leave to Construct hearing and, only if approval is granted, can it proceed with the project. In consultation with MECP, project proponents are encouraged to engage with Indigenous communities on ways to enable participation in these projects.

9. Conclusion

The Northwest IRRP Addendum identifies electricity system needs in the North of Dryden sub-region over a 25-year planning horizon from 2025 to 2050. It examines near-, medium-, and long-term requirements.

Based on the analysis, the IESO recommends the development of Transmission Option 3, constructed to a double-circuit standard with appropriate reactive support. This solution balances cost-effectiveness with reliability and scalability, ensuring the system can adapt to future growth.

The Study also recommends that the Working Group continue to monitor demand growth, particularly in the Pickle Lake areas, and triggering planning for further reinforcements from Ear Falls towards Pickle Lake as load materializes under high-growth scenarios. Sensitivity analyses conducted in this Addendum have established load meeting capability thresholds that should be used to trigger future regional planning activities.

The IESO will continue to plan for high-growth scenarios in the next cycle of regional planning for Northwest Ontario, which commenced in Q3 2025. This upcoming cycle will explore transmission options aligned with ongoing bulk system studies and assess the feasibility of non-wires alternatives.

The Working Group will meet regularly to monitor developments and track progress toward plan deliverables. If underlying assumptions change significantly, the plan may be revisited through an amendment or by initiating a new regional planning cycle ahead of the standard five-year schedule mandated by the Ontario Energy Board (OEB).

Appendix A – 2023 Northwest IRRP

This Addendum is built on the 2023 Northwest Integrated Regional Resource Plan ("2023 NW IRRP"). The 2023 NW IRRP, Appendices, and Data Tables can be found on IESO's Northwest regional planning engagement website.

Appendix B – Additional Figures

B.1 Single Line Diagrams

Figure B.1 | Option 1

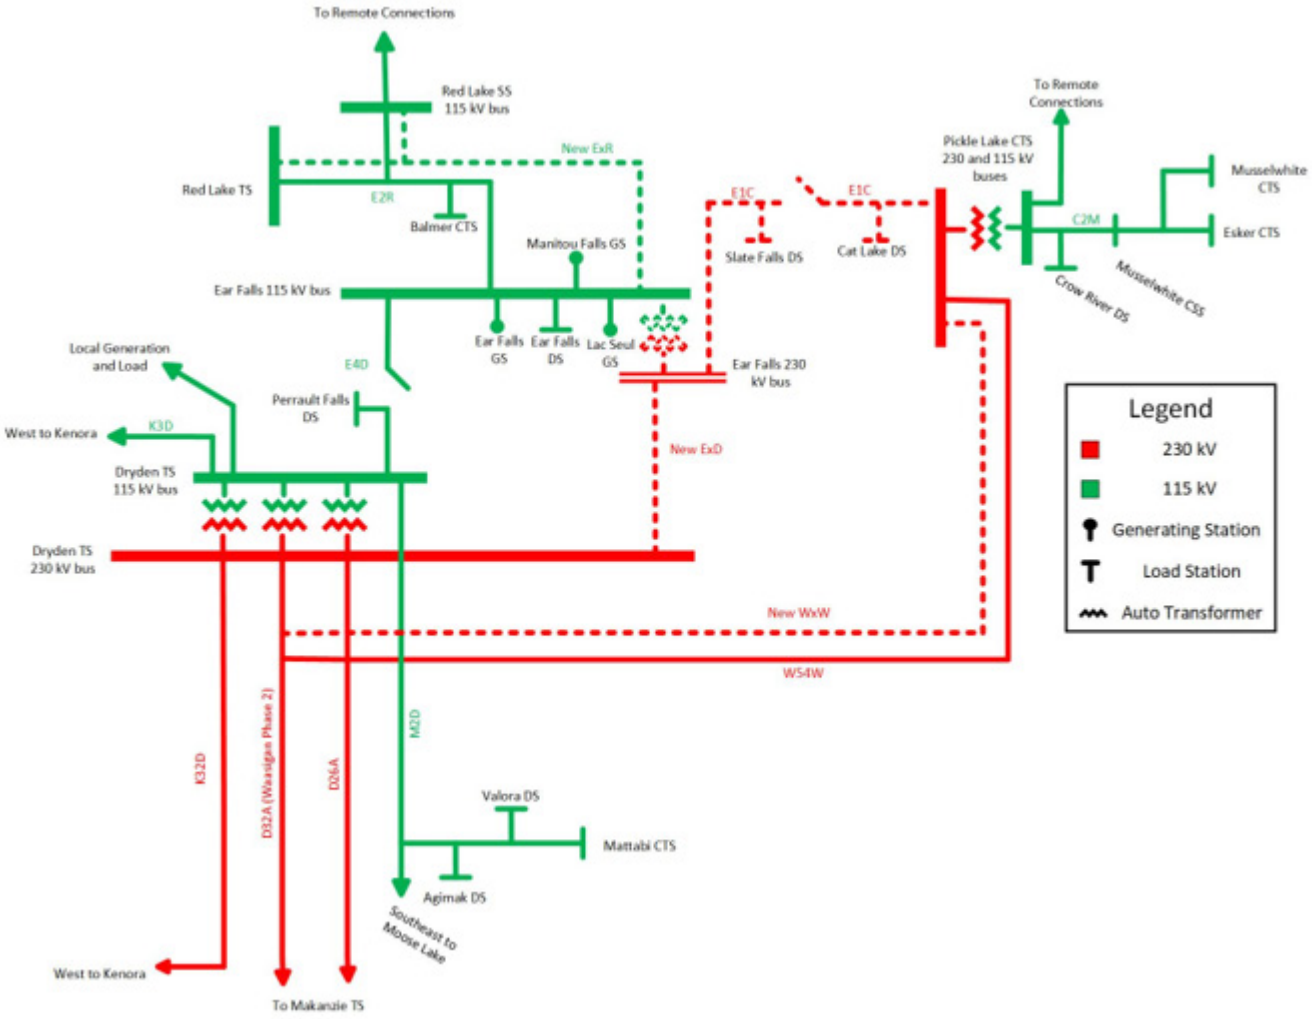


Figure B.2 | Option 2

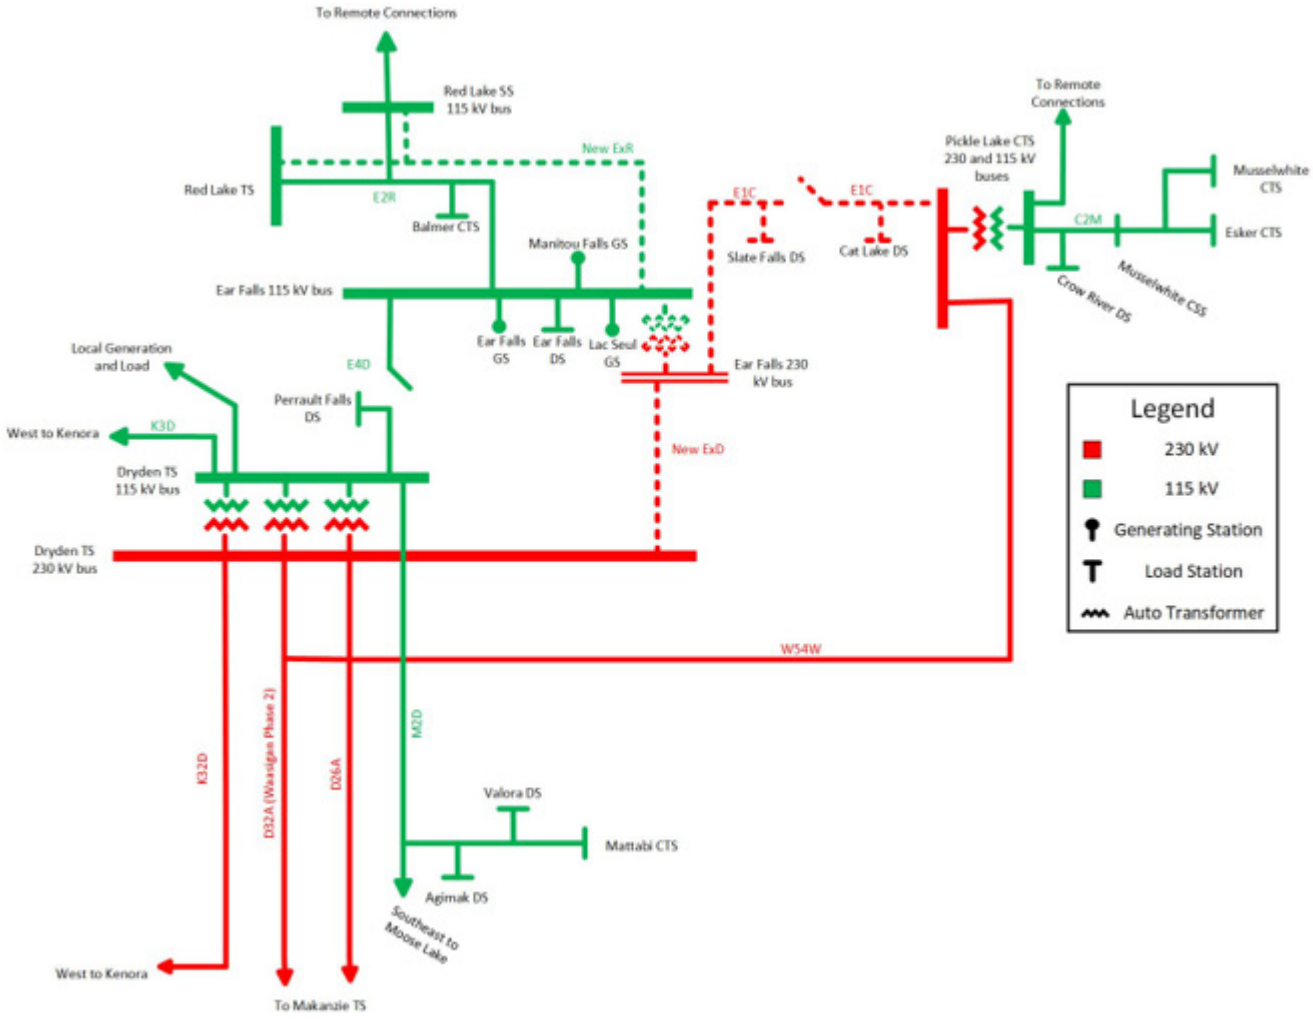

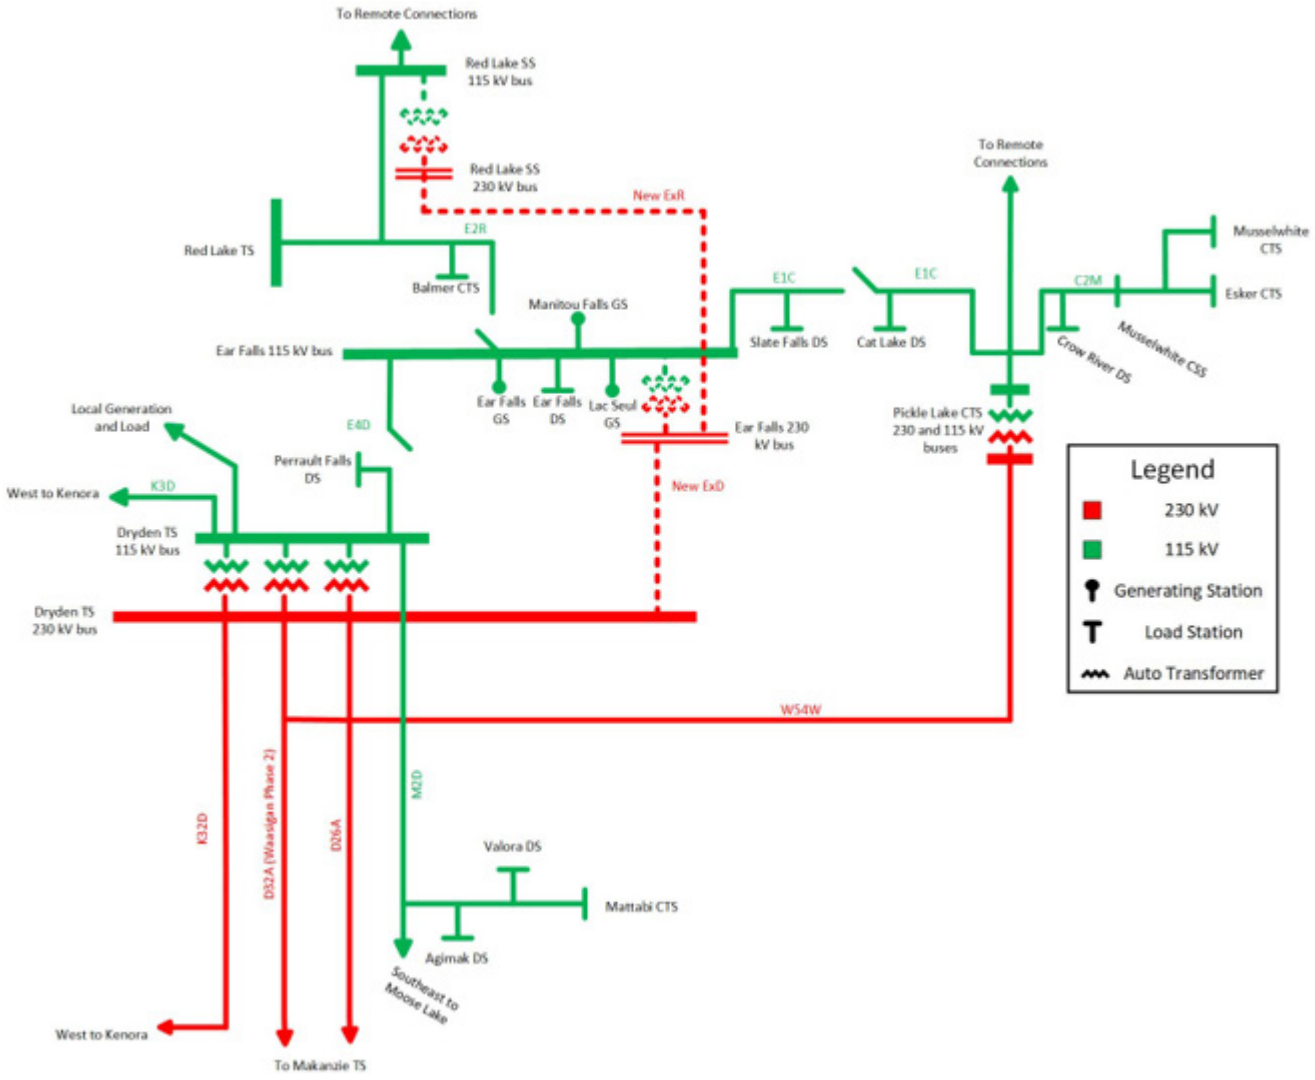

Figure B.3 | Option 3

Appendix C – Options Reactive Support Requirements

It should be noted that these reactive support requirements are in addition to reactive support recommended at the connection point of certain industrial customers. In particular the 60 MW customer that is connecting in the interlakes area will require 55 Mvar of reactive support, and the 23 MW customer connecting in the Watay Power operated Red Lake area will require 10 Mvar of reactive support. This support is needed to maintain transfer capability in these regions, as large industrial loads can negatively affect voltages, particularly in weaker parts of the system.

C.1 Option 1

The reactive support requirements for option 1 for the reference load case are as follows:

- 40 Mvar @ 220kV capacitor at Red Lake SS
- 40 Mvar @ 220kV capacitor at Ear Falls TS
- 40 Mvar @ 220kV capacitor at Pickle Lake TS 230 kV

The IESO recommends that the transmitter avoid procuring single switchable shunts with over 40 Mvar of support to respect voltage change criteria.

The reactive support requirements for option 1 for the high load case are as follows:

- 40 Mvar at Ear Falls TS
- 40 Mvar at Dinorwic CSS
- 100 Mvar at Pickle Lake TS 230 kV
- 200 Mvar at Wawa TS 230 kV

The IESO recommends that the transmitter avoid procuring single switchable shunts with over 40 Mvar and STATCOMS with over 100 Mvar of reactive support to respect voltage change criteria.

C.2 Option 2

The reactive support requirements for option 2 for the reference load case are as follows:

- 40 Mvar at Red Lake SS
- 40 Mvar at Ear Falls TS
- 40 Mvar at Pickle Lake TS 230 kV

The IESO recommends that the transmitter avoid procuring single switchable shunts with over 40 Mvar of support to respect voltage change criteria.

The reactive support requirements for option 2 for the high load case are as follows:

- 40 Mvar at Ear Falls TS
- 40 Mvar at Dinorwic CSS
- 100 Mvar at Pickle Lake TS 230 kV
- 200 Mvar at Wawa TS 230 kV

The IESO recommends that the transmitter avoid procuring single switchable shunts with over 40 Mvar and STATCOMS with over 100 Mvar of reactive support to respect voltage change criteria.

C.3 Option 3

The reactive support requirements for option 3 for the reference load case are as follows:

- 40 Mvar at Red Lake SS
- 40 Mvar at Ear Falls TS
- 40 Mvar at Pickle Lake TS 230 kV

The IESO recommends that the transmitter avoid procuring single switchable shunts with over 40 Mvar of support to respect voltage change criteria.

The reactive support requirements for option 3 for the high load case are as follows:

- 40 Mvar at Ear Falls TS
- 100 Mvar at Dinorwic CSS
- 100 Mvar at Pickle Lake TS 230 kV
- 200 Mvar at Wawa TS 230 kV

The IESO recommends that the transmitter avoid procuring single switchable shunts with over 40 Mvar and STATCOMS with over 100 Mvar of reactive support to respect voltage change criteria.

Appendix D – Non-Wires Alternatives Economic Assessment Assumptions

The following assumptions were made for the Non-Wires Alternatives Analysis:

- Various emitting and non-emitting resource options were considered creating a range of costs for Non-Wire Alternatives (NWAs)
- Emitting resources that were considered included: Combine Cycle Gas Turbine (CCGT) and Biomass facilities, overnight capital costs, fixed operating and maintenance (FOM), biomass fuel and variable operating and maintenance (VOM) sourced from 2024 Annual Technology Baseline (ATB) data by the National Renewable Energy Laboratory (NREL).
- Natural gas fuel costs and carbon costs assumptions from 2025 Annual Planning Outlook (APO)
- NWA emitting and non-emitting levelized costs are based on 2024 ATB data from NREL whereby the values are converted to Canadian (CAD) 2025$
- System benefits are based on the 2025 APO Capital Expansion (CapEx) portfolio
- All dollar figures are $2025 CAD Real, the inflation rate is assumed to be 2% per year, and the social discount rate is 4% Real
- Net present value (NPV) is considered from 2026 to 2102, with the Transmission (Tx) option commencing in 2033 for 70 yrs and the NWA aligning with this Tx timeline
- Land Requirements Supplemental Information:
    - Land area of Red Lake is 600 km^2
    - 1 Hectares = 0.01 km^2
    - Wind Land Requirement = 34 Hectares/MW[13]
    - Solar Land Requirement = 3.04 Hectares/MW[14]
    - Battery Land Requirements = 0.65 Hectares/200MWh (or 0.003 Hectares/MWh)[15]
    - Natural Gas Requirements = According to Natural Gas Association, the average natural gas plant requires between 20 and 40 acres of land
    - Biomass facility land requirement is assumed to equal the natural gas land requirement provided above

Disclaimer

This Needs Assessment ("NA") Report was prepared for the purpose of identifying potential needs in the Northwest and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the NA phase and b) require further assessment and regional coordination. The results reported in this NA are based on the input and information provided by the Technical Working Group ("TWG") for this region at the time. Updates may be made based on the best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Summary

This is the 3rd cycle of Regional Planning for the Northwest Region. The previous Regional Planning cycle was completed in August 2023 with the publication of the Regional Infrastructure Plan ("RIP") report. The Technical Working Group ("TWG") consists of Atikokan Hydro Inc., Fort Frances Power Corp., Hydro One Transmission & Distribution, Independent Electricity System Operator, NextEra Energy Canada, Sioux Lookout Hydro, Synergy North, and Wataynikaneyap Power.

Based on load forecasts provided by Local Distribution Companies ("LDC"), existing directly connected customers, recent customer connection applications, information provided by regional municipalities, proactive groups, and existing government initiatives and strategies, the TWG recommends a comprehensive electrical plan for the region. In recognition of the distinctive, urgent and ever evolving demands of customers in the Northwest region – such as mining operation, data centers, forestry companies and large industrial manufacturers, and in accordance with the Transmission System Code ("TSC"), the TWG has agreed to begin the Scoping Assessment ("SA") phase promptly, which will then lead into development of the Integrated Regional Resource Plan ("IRRP") and finally completing the regional planning cycle with a RIP. To support this, the LDCs have already provided their respective 20-year forecast.

Broadly speaking, the needs are capacity and reliability in nature for all Northwest sub-regions. The IRRP will review the results of Waasigan Phase 1 & 2 against future system needs and will decide if further bulk studies are needed. The IRRP will also analyze wires and non-wires alternatives such as transmission, distribution, traditional generation, new energy resource technologies including Battery Energy Storage System ("BESS"), and demand side management strategies to meet the capacity and reliability needs in the region.

In summary, by starting the Scoping Assessment and advancing toward the IRRP, the TWG is taking critical, coordinated steps to ensure that the Northwest region's growing and evolving energy needs are met with reliable, sustainable, and forward-looking solutions.

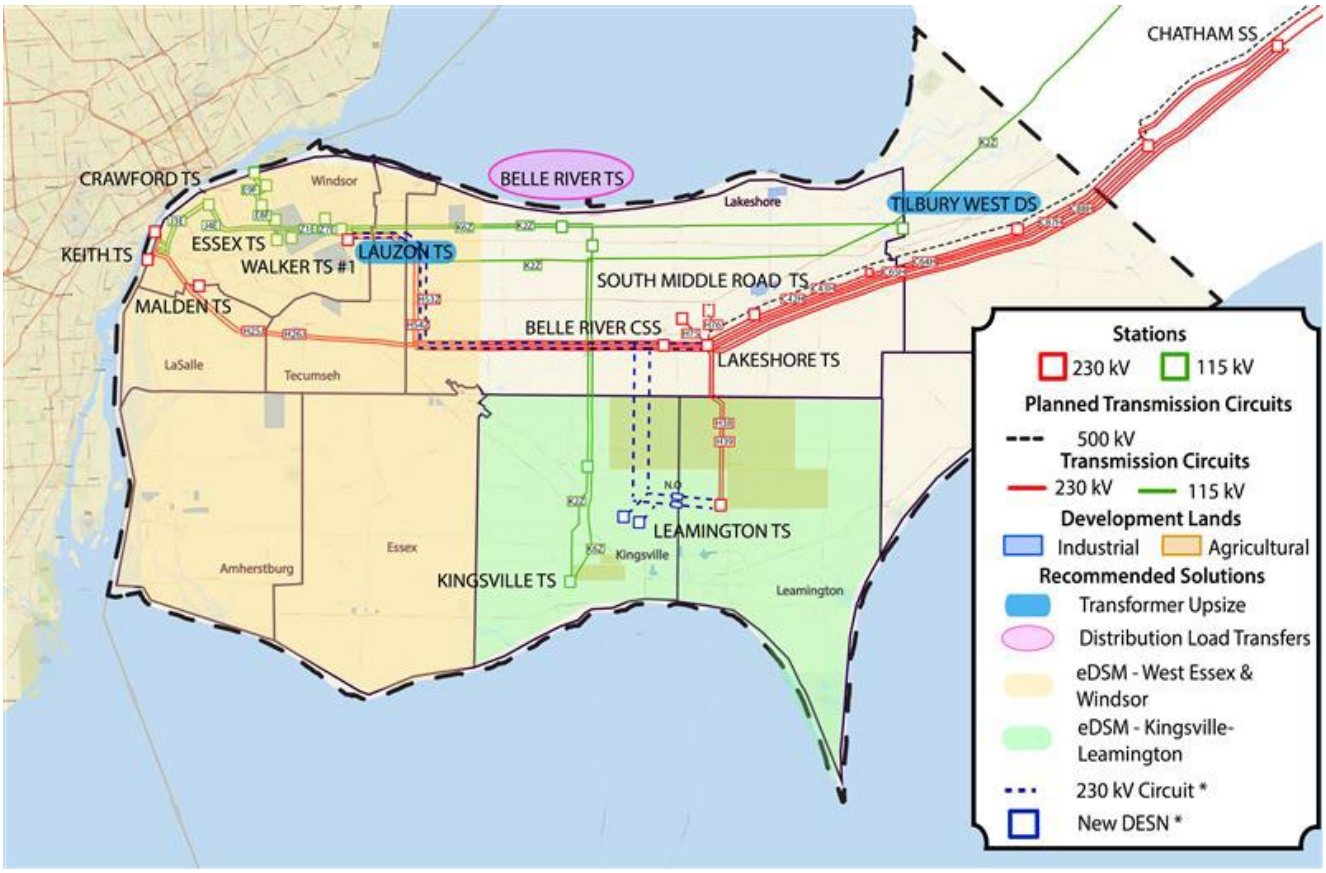
UVLS	Under Voltage Load Shedding

Executive Summary

The Windsor-Essex Integrated Regional Resource Plan (IRRP) addresses electricity needs in the region over the twenty-year period from 2024 to 2043. The Windsor-Essex region is located in southwest Ontario, east of the Chatham-Kent/Lambton/Sarnia region. It includes the City of Windsor, Town of Amherstburg, Town of Essex, Town of Kingsville, Town of Lakeshore, Town of LaSalle, Municipality of Leamington, Town of Tecumseh, Township of Pelee Island, and the western portion of the Municipality of Chatham-Kent.

Due to the rapidly growing agricultural sector and more recent economic developments, regional electricity planning in southwestern Ontario has been occurring on a continuum since 2019 rather than the typical five-year cycle, with no signs of slowing down. From 2018 to 2022, winter net electricity demand in the region has increased by approximately 370 megawatts (MW) and the region is projected to be winter peaking going forward. Successful electricity resources implemented in the region include 857 MW of generation procurements since 2020, the construction of a new double-circuit transmission line into the region, the completion of Lakeshore Transmission Station (TS), and the completion of South Middle Road Dual-Element Spot Network (DESN) #1, with construction of South Middle Road DESN #2 underway to be completed in 2025. In 2023 there were 3 MW of verified electricity Demand-Side Management (eDSM) savings in the region. This IRRP builds upon those previous regional and bulk plans to continue to ensure reliable electricity supply across the region.

The IESO conducted extensive engagement and outreach throughout the planning process through targeted discussions, webinars and communications to seek input and ensure that key local information about growth and development and energy-related initiatives were taken into consideration in the development of this IRRP. In response to sustained growth driven by municipal and housing developments, greenhouse development, industrial development, and electrification initiatives in the West Essex and Windsor sub-system as well as Lakeshore/Tilbury sub-system, the Technical Working Group recommends:



- Considering potential targeted eDSM programs for the West Essex and Windsor sub-system;
- Constructing a new double-circuit 230 kV transmission line from Lakeshore TS to Lauzon TS, to increase the supply capacity into the area, as well as enable potential electricity supply resource connections;
- Exploring the potential scope and value of a corridor study to identify future transmission paths into the West Essex and Windsor sub-system;
- Upsizing the transformers at Lauzon TS DESN 2, to address multiple station capacity needs and enable the forecast load growth at Lauzon TS and load from Belle River TS, after load transfers; and
- Upsizing the transformers at Tilbury West DS, to address the local station capacity need.

To address continued growth in the agriculture sector, the Technical Working Group reinforces the recommendations from the 2022 Windsor-Essex Addendum for:

- Continuing targeted eDSM programs for the Kingsville-Leamington sub-system (e.g., continuing the targeted greenhouse sector incentives supporting Light Emitting Diode – or LED – conversions and advanced lighting controls).
- Constructing two new DESNs with a connecting double-circuit 230 kV transmission line from Lakeshore TS, to increase the station and supply capacity in Kingsville-Leamington; and
- Constructing a double-circuit 230 kV transmission line connecting the new lines to H38/H39 with normally open breakers to provide load restoration capability.

Figure 1 visually depicts the IRRP recommendations across the Windsor-Essex region.

Figure 1 | Overview of Recommended Solutions for Windsor-Essex IRRP

The Technical Working Group will continue to monitor growth across the region to determine if or when further reinforcements will be needed. This includes monitoring any future community energy plans, electrification trends, customer connection queues, and changes to local generation. In the interim, operational measures can be used to support growth in the region through use of operating ratings and improving the redundancy of the Lakeshore Remedial Action Scheme (RAS).[1]

[1] A Remedial Action Scheme – or RAS – is a set of pre-planned operating actions that are initiated under select contingencies to ensure the reliability and stability of the electricity grid. In particular, the Lakeshore RAS monitors the 230 kV circuits in the region and may reject load or generation depending on the contingency observed.

Engagement is critical in the development of an IRRP. It provides opportunities for input in the regional planning process enables the views and perspectives of the public, Indigenous communities, market participants, municipalities, stakeholders, communities, and customers to be considered in the development of the plan. Furthermore, engagement helps lay the foundation for successful implementation of the IRRP.

The Technical Working Group will continue to meet to develop the Regional Infrastructure Plan (RIP) and annually thereafter to monitor developments and track progress toward plan deliverables. If underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the Ontario Energy Board.

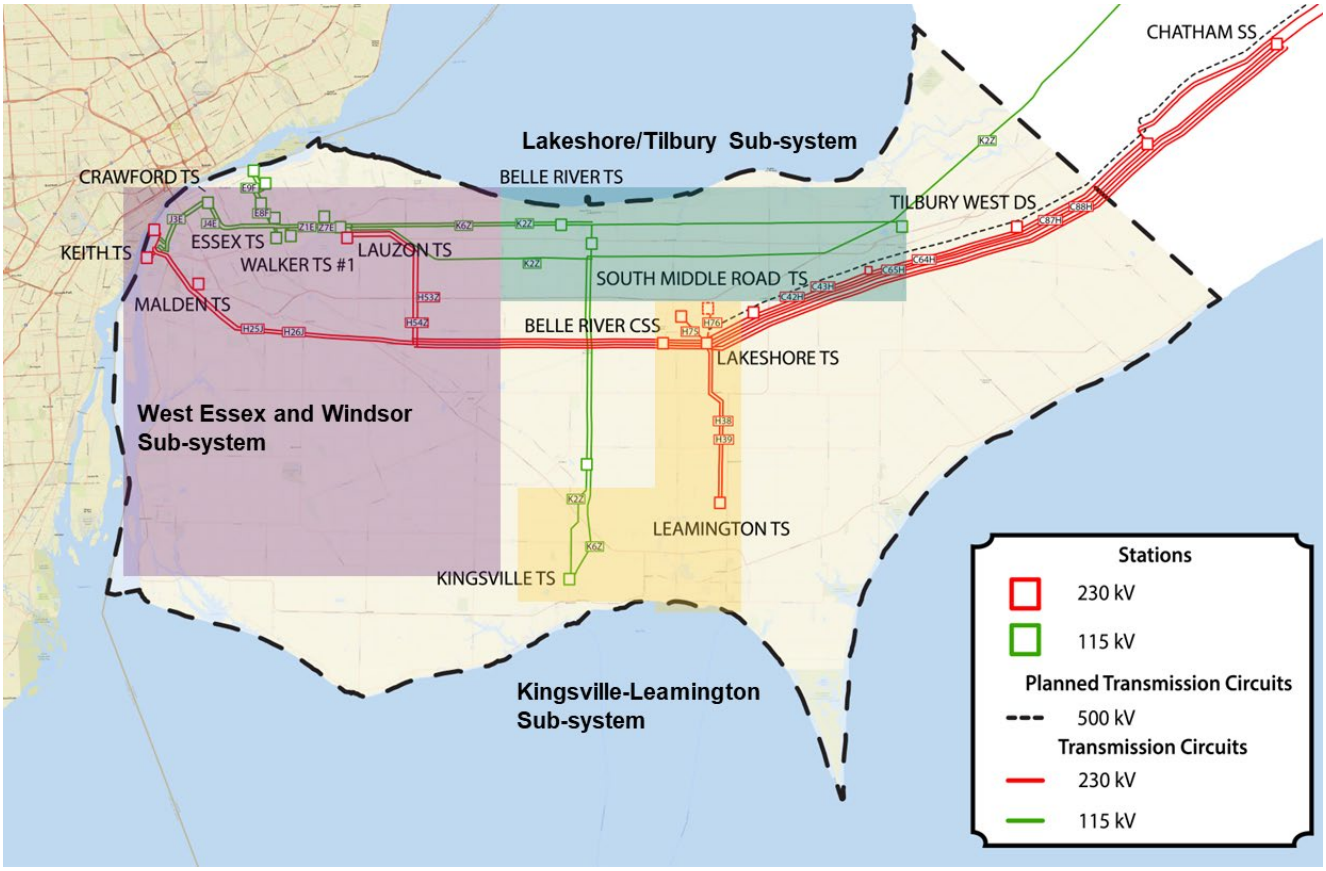
1. Introduction

This IRRP addresses the electricity needs of the Windsor-Essex region over the 20-year period from 2024 to 2043. The Windsor-Essex region is located in southwest Ontario, east of the Chatham-Kent/Lambton/Sarnia region. It includes the City of Windsor, Town of Amherstburg, Town of Essex, Town of Kingsville, Town of Lakeshore, Town of LaSalle, Municipality of Leamington, Town of Tecumseh, Township of Pelee Island, and the western portion of the Municipality of Chatham-Kent.

Several Indigenous communities are located in or near the region, including: Aamjiwnaang First Nation, Caldwell First Nation, Chippewas of Kettle and Stony Point First Nation, Chippewas of the Thames First Nation, Eelŭnaapéewi Lahkéewiit Delaware Nation, Munsee-Delaware Nation, Oneida Nation of the Thames, and Walpole Island First Nation.

The region's electricity is delivered by five Local Distribution Companies (LDCs): ENWIN Utilities Ltd. ("ENWIN"), Essex Powerlines Corporation ("Essex Powerlines"), E.L.K Energy Inc. ("E.L.K."), Entegrus Powerlines Inc. ("Entegrus"), and Hydro One Networks Inc. ("Hydro One Distribution"). Hydro One Networks Inc. ("Hydro One Transmission") is the primary transmission asset owner. This IRRP report was prepared by the Independent Electricity System Operator (IESO) on behalf of a Technical Working Group, composed of the LDCs, Hydro One Transmission, and the IESO.

Figure 2 depicts the electrical transmission infrastructure for the Windsor-Essex region. Power is transmitted into the region via 230 kV transmission lines from Chatham Switching Station (SS) east of the region to Lakeshore TS, which supplies Leamington TS and South Middle Rd TS. The 230 kV corridor continues west with two circuits toward Lauzon TS and two circuits toward Keith TS via Malden TS. Keith TS provides an interconnection with the Michigan system via 230 kV circuit J5D.



Historically, the region was supplied by four 230 kV circuits along with local generation resources; however, as of December 2024, two additional 230 kV circuits from Chatham SS to Lakeshore TS were completed.

For the purposes of regional planning, the Windsor-Essex region has been divided into three sub-systems, as shown in Figure 2:

- The **West Essex and Windsor sub-system** in the west of the region, electrically defined by the load and generation connected to and downstream of the H53Z, H54Z, H25J, and H26J 230 kV circuits west of Lakeshore TS. In Windsor, Keith TS and Lauzon TS connect the region's 115 kV network to the 230 kV transmission system via two autotransformers at each station. These supply the 115 kV transmission lines that connect to Belle River TS, Crawford TS, Essex TS, Kingsville TS, Lauzon TS, Tilbury West DS, Walker Municipal Transformer Station (MTS) #2, and Walker TS #1. Keith TS has one DESN and Lauzon TS has two DESNs (in addition to the autotransformers). Malden TS and NextStar TS are also connected to the 230 kV lines in this sub-system.
- The **Kingsville-Leamington sub-system** in the south-east of the region, electrically defined by the load and generation connected to Kingsville TS, the H38 and H39 230 kV radial circuits south of Lakeshore TS, and the H75 and H76 radial circuits north of Lakeshore TS.

- The **Lakeshore/Tilbury sub-system** in the north-east of the region, electrically defined by the load and generation connected to the K2Z and K6Z 115 kV circuits downstream of Lauzon TS, inclusive of Belle River TS and Tilbury West DS but excluding Kingsville TS.

Figure 2 | Map of the Windsor-Essex Region and Defined Sub-systems

There are seven transmission-connected customers in the region served by Customer Transformer Stations (CTSs). There are also several transmission-connected generation resources in the region, primarily gas and wind generation, some solar generation, as well as some battery storage facilities under development. The distribution-connected resources or distributed generation (DG) in the region includes natural gas combined heat and power (CHP), solar and wind resources, and a small amount of biogas.

This report describes the culmination of the Windsor-Essex IRRP, which was initiated in May 2023 following the publication of the Needs Assessment Report in February 2023 by Hydro One and the Scoping Assessment Outcome Report in May 2023 by the IESO. The Scoping Assessment identified needs requiring further assessment through an IRRP. The Technical Working Group was then formed to gather data, identify near- to long-term needs in the region, and develop the recommended actions included in this IRRP.

This report is organized as follows:

- A summary of the recommended plan for the region is provided in Section 2;
- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the region and the study scope are discussed in Section 4;
- Demand forecast scenarios, eDSM contributions, and DG assumptions are described in Section 5;
- Electricity needs in the region are presented in Section 6;
- Alternatives and recommendations for meeting needs are addressed in Section 7;
- A summary of engagement activities is provided in Section 8; and
- The conclusion is provided in Section 9.

2. The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of the Windsor-Essex region over the twenty-year period from 2024 to 2043. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system, as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by the North American Electric Reliability Corporation (NERC). The IRRP's recommendations are informed by an evaluation of different options to meet the needs, considering reliability, cost, technical feasibility, maximizing the use of the existing electricity system (where economic), and feedback from stakeholders.

The Windsor-Essex electricity demand forecast, provided by the LDCs, anticipates sustained growth driven by municipal and housing developments, industrial development, expansion of the agriculture industry, and electrification initiatives. The decreased reliance on emitting generation and resources coming off contract in the region are also major drivers of the electricity supply needs into and within the region.

The IRRP recommendations below are organized under near-term, medium-term, and other ongoing or long-term initiatives to address needs in the three sub-systems identified: West Essex and Windsor, Kingsville-Leamington, and Lakeshore/Tilbury. This distinction reflects the different levels of forecast certainty, lead time for development, and planning commitment required over these time horizons. This approach ensures that the IRRP provides clear direction on investments needed in the near and medium term, while retaining flexibility over the long term as electrification, energy efficiency, and development plans evolve.

2.1. Status of Ongoing Work

Following the previous cycle of region planning and various bulk plans, several projects were recommended which have now been completed or are presently underway. The plans implemented a multi-pronged approach of both wires and non-wires solutions to address electricity needs across the region. The status of these projects is summarized in Table 1.

Table 1 | Summary of Ongoing and Recently Completed Projects

Project	Expected In-Service Date
Conduct IESO Grid Innovation Fund targeted call for indoor agriculture projects	Complete
Upsize Keith TS end-of-life 230/115 kV autotransformers T11/T12	Complete
Decommission Keith TS end-of-life T1 (115 kV/27.6 kV) transformer	Complete

Project	Expected In-Service Date
Build a new switching station at the Leamington Junction[2]	Complete
Acquire 550 MW of new or existing local resources[3]	Complete
Begin bilateral negotiations for Brighton Beach Generating Station	Complete[4]
Build a new supply station, South Middle Road DESN 1	Complete
Build a new 230 kV double-circuit transmission line from Chatham SS to Lakeshore TS	Complete
Carry out Greenhouse-specific Light Emitting Diode (LED) Incentive, Save On Energy incentives in the Southwest zone, and Advanced Lighting Controls	Ongoing
Build a second new supply station, South Middle Road DESN 2	2025
Upsize Lauzon TS DESN 1 end-of-life step-down transformers	2026
Replace the phase-shifting transformer at Keith TS ("PSR5")[5]	2028
Build a new 230 kV double-circuit transmission line from Lambton TS southwards to Chatham SS (the "St. Clair line")	2028
Build a single-circuit 500 kV transmission line from Longwood TS to Lakeshore TS	2030
Build two new 230 kV DESNs and double-circuit connection lines from Lakeshore TS, including the option for a new 230 kV line between Leamington TS and the new DESNs, and transfer Kingsville TS load to the new DESNs	On hold – recommended again in this IRRP

[2] This was ultimately put into service as Lakeshore TS.
[3] Approximately 857 MW of generation was procured in Windsor-Essex since 2020.
[4] The negotiations for Brighton Beach Generating Station are also complete, with a contract term from July 16, 2024 to July 15, 2034.
[5] This recommendation is a result of a joint intertie study completed by the IESO and the Midcontinent Independent System Operator, rather than a regional planning or bulk planning initiative. The purpose of this project is to address end-of-life concerns and increase the capability of the device to improve control of scheduled intertie flows between the two jurisdictions.

2.2. Near- to Medium-Term Plan

The Technical Working Group recommends the near- to medium-term plans, including several recommendations to accommodate load growth, maintain reliability, and optimize asset replacement. Where possible, needs are grouped to align with integrated sets of solutions. The following subsections discuss these near- to medium-term plans.

2.2.1. Targeted Electricity Demand Side Management

The Kingsville-Leamington and West Essex and Windsor areas are experiencing sustained growth, driven by greenhouse lighting, industrial development, municipal and housing growth, and electrification initiatives. For this reason, a combination of non-wires alternatives (NWAs) and wires options is required to address the needs in these two sub-systems. The Technical Working Group recommends the continuation of energy efficiency programs targeted to the greenhouse sector, as well as exploring opportunities to leverage provincial eDSM programs for the local area.

2.2.2. Supply Stations and Connection Lines in Kingsville-Leamington

An integrated solution is recommended to address the capacity needs and load restoration needs in Kingsville-Leamington. The Technical Working Group recommends two new 230 kV load supply stations in the Kingsville-Leamington area to address the forecast capacity requirements starting in 2027. The new supply stations also have the potential to offload a portion of Kingsville TS. These stations are to be supplied via a new 230 kV double-circuit line from Lakeshore TS. A new 230 kV double-circuit line between the new supply stations and Leamington TS should also be built to address the sub-system's load restoration needs. The new DESNs and supply lines will enable the connection of both new load and generation resources, and the load restoration lines will improve reliability in the area.

Depending on the subsequent design and environmental assessment phases, there may be an opportunity to integrate the recommended double-circuit 230 kV transmission line from Lakeshore TS to the new Kingsville-Leamington supply stations with the transmission pathway for the new double-circuit 230 kV transmission line recommended from Lakeshore TS to Lauzon TS (see Section 2.2.5). There could be a portion of transmission line shared between these two recommendations west of Lakeshore TS, which would split into two separate paths– one toward Kingsville-Leamington and one toward Lauzon TS. The combined solution would optimize the use of the transmission infrastructure and provide further integration in the Windsor-Essex region.

2.2.3. Load Transfer from Belle River TS

Belle River TS is forecast to immediately exceed its station capacity by 1 MW, with the need increasing slowly over the 20-year study period to 17 MW in 2043. Given the magnitude of this need and the available capacity on the nearby Lauzon TS once DESN 1 and DESN 2 are both upsized in 2025 and 2029 respectively, the Technical Working Group recommends load transfers from Belle River TS to Lauzon TS DESNs 1 and 2 (see Section 2.2.4). In the interim, operational measures, such as using operational ratings, can be used to manage this need until the wires solution is in place.

2.2.4. Upsize Lauzon TS DESN 2

Lauzon TS DESN 2 has an asset replacement need in 2029, as well as a station capacity need starting in 2032. The Technical Working Group recommends upsizing the transformers at Lauzon TS DESN 2 to address these two needs, and to help address the Belle River TS capacity need.

2.2.5. New Transmission into West Essex and Windsor

To ensure continued supply to the West Essex and Windsor sub-system, the Technical Working Group recommends a new 230 kV double-circuit line from Lakeshore TS to Lauzon TS to meet the supply capacity need in 2032. This will increase the transfer capability into the sub-system, allow for additional connections, and improve the resource deliverability along this transmission path. As noted in Section 2.2.2, there is potential for this solution to integrate with the recommendation for Kingsville-Leamington capacity need.

2.2.6. Summary of Near- to Medium-Term Plans

Table 2 summarizes these near- to medium-term plans for Windsor-Essex.

Table 2 | Summary of the Near- to Medium-Term Plans for the Windsor-Essex IRRP

Need(s)	Technical Working Group Recommendation	Lead Responsibility	Expected In-Service Date
West Essex and Windsor supply capacity need	Leverage targeted eDSM programs to support growth in West Essex and Windsor[6]	IESO	N/A
Kingsville-Leamington load security and operational concerns	Explore options to make the design of the Lakeshore Remedial Action Scheme (RAS)[7] redundant	Hydro One Transmission	N/A
Kingsville-Leamington station and supply capacity needs	Continue existing eDSM programs to manage demand across and the sub-system[6]	IESO	N/A

[6] Whereas eDSM programs are recommended in the near-term, they are also expected to contribute to the long-term growth and reliable electricity supply in the region.

[7] A Remedial Action Scheme – or RAS – is a set of pre-planned operating actions that are initiated under select contingencies to ensure the reliability and stability of the electricity grid. In particular, the Lakeshore RAS monitors the 230 kV circuits in the region and may reject load or generation depending on the contingency observed.

Need(s)	Technical Working Group Recommendation	Lead Responsibility	Expected In-Service Date
Kingsville-Leamington station capacity, supply capacity, and load restoration needs	Construct two new supply stations in the Kingsville-Leamington area with two 230 kV circuits from Lakeshore TS Connect the two new 230 kV circuits to Leamington TS via two additional 230 kV circuits	Hydro One Transmission	2027–2029
Belle River TS station capacity need	Transfer load from Belle River TS to the upsized Lauzon TS DESN 1 and 2	Hydro One Distribution	2026–2031
Lauzon TS DESN2 station capacity need	Upsize transformers	Hydro One Transmission	2029
West Essex and Windsor supply capacity need	Build a new 230 kV double-circuit line from Lakeshore TS to Lauzon TS	Hydro One Transmission	2032

2.3. Long-Term Plan and Ongoing Initiatives

In the long term, the Windsor-Essex region's electricity demand is projected to continue to grow. This IRRP sets out recommended actions required to ensure that options remain available to address future needs in the most efficient and cost-effective way, if and when they ultimately arise.

2.3.1. Upsize Tilbury West DS

Tilbury West DS is forecast to exceed its peak station capacity in 2036. The recommendation to upsize the transformers at Tilbury West DS can be implemented in three to five years. Given the timing of this need, the Technical Working Group recommends monitoring growth and triggering the upsizing of transformers at Tilbury West DS as needed, or revisiting this need in the next cycle of regional planning.

2.3.2. West Essex and Windsor Corridor Study

The High Forecast for West Essex and Windsor indicates the need for further supply in this sub-system; however, there are land restrictions due to conservation areas, an airport, and flooding risks. Thus, the Technical Working Group recommends the scope and value of a corridor study be explored to identify additional paths for transmission supply into West Essex and Windsor, to prepare for a quicker response when higher growth materializes.

2.3.3. Monitor Load Growth

Load in this region is projected to increase and is expected to advance under the High Forecast. Given the uncertainty of the High Forecast, a firm recommendation addressing this level of growth is not required at this time. The Technical Working Group will continue to monitor load growth across the region – in particular, the agricultural sector in Kingsville-Leamington and industrial sector in West Essex and Windsor – and revisit these needs in the next cycle of regional planning. As part of broader monitoring, the Technical Working Group should also monitor and participate in any future community energy plans developed by municipalities in the Windsor-Essex region, as well as the status of bulk system transmission and resource developments.

2.3.4. Summary of Long-Term Plan

Table 3 summarizes the long-term recommendations beyond the ten-year horizon and ongoing initiatives.

Table 3 | Summary of Long-Term Plan for the Windsor-Essex IRRP

Need(s)	Technical Working Group Recommendation	Lead Responsibility	Expected In-Service Date
Tilbury West DS station capacity	Upsize transformers	Hydro One Distribution	2036
West Essex and Windsor High Forecast supply capacity	Conduct a corridor study to identify additional paths for transmission supply west of Lakeshore TS	IESO	N/A
Windsor-Essex region growth	Monitor load growth across the region, transmission projects, and changes in generation across the region	IESO	N/A

3. Development of the Plan

3.1. The Regional Planning Process

In Ontario, preparing to meet the electricity needs of customers at a regional level is achieved through regional planning. Regional planning assesses the interrelated needs of a region – defined by common electricity supply infrastructure – over the near, medium, and long term, and results in a plan to ensure cost-effective and reliable electricity supply. A regional plan considers the existing electricity infrastructure in an area, forecasts growth and customer reliability, evaluates options for addressing needs, and recommends actions.

The current regional planning process was formalized by the Ontario Energy Board in 2013 and is performed on a five-year cycle for each of the 21 planning regions in the province. The process is carried out by the IESO, in collaboration with the transmitters and LDCs in each region. The process consists of four main components:

1. A Needs Assessment, led by the transmitter, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;
2. A Scoping Assessment, led by the IESO, which identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities;
3. An IRRP, led by the IESO, which proposes recommendations to meet the identified needs requiring coordinated planning; and/or
4. A RIP, led by the transmitter, which provides further details on recommended wires solutions.

Regional planning is not the only type of electricity planning in Ontario. Other types include bulk system planning and distribution system planning. There are inherent overlaps in all three levels of electricity infrastructure planning. Further details on the regional planning process and the IESO's approach to it can be found in Appendix A.

The IESO has recently completed a review of the regional planning process, following the completion of the first cycle of regional planning for all 21 regions. Additional information on the Regional Planning Process Review, along with the final report, is posted on the IESO's website.

3.2. Windsor-Essex and IRRP Development

The process to develop the Windsor-Essex IRRP was initiated in May 2023, following the publication of the Needs Assessment report in February 2023 by Hydro One and the Scoping Assessment Outcome Report in May 2023 by the IESO. The Scoping Assessment recommended that the needs identified for the Windsor-Essex region be considered through an IRRP in a coordinated regional approach, supported with public engagement. The Technical Working Group was then formed to develop the terms of reference for this IRRP, gather data, identify needs, develop options, and recommend solutions for the region.

4. Background and Study Scope

This is the third cycle of regional planning for the Windsor-Essex region. Electricity planning in Ontario typically occurs on a cyclical basis. However, due to the rapidly growing agricultural sector and more recent economic developments, planning in southwestern Ontario has been occurring on a continuum over the last five years, with no signs of slowing down. The 2019 Windsor-Essex bulk study occurred in parallel with the 2019 Windsor-Essex IRRP, followed by the 2020 Windsor-Essex Regional Infrastructure Plan and the 2021 West of London bulk plan that considered a broader area that encompassed this region[8]. In tandem, the 2022 Windsor-Essex Addendum was undertaken to address remaining local needs in Kingsville and Leamington.

The previous regional and bulk recommendations and subsequent plans are summarized in the sections below.

4.1. Previous Regional Planning Cycle

The previous cycle of regional planning for the Windsor-Essex region was completed in 2019, which implemented a multi-pronged approach of both wires and non-wires solutions to address electricity needs across the region. Subsequently, an Addendum was completed in 2021 to assess remaining local reliability issues in the Kingsville and Leamington areas: capacity needs to enable new distribution-level customers to connect, as well as load restoration needs. Recommendations from this planning cycle are summarized below.

2019 Windsor-Essex IRRP

- IESO Grid Innovation Fund targeted call for indoor agriculture projects – two projects contracted within Kingsville-Leamington, with support provided between 2020 and 2023.
- Greenhouse-specific LED Incentive, Save On Energy incentives in the Southwest zone, and Advanced Lighting Controls – implemented under the 2021–2024 Conservation and Demand Management Framework and continuing under the 2025–2036 eDSM Framework. In 2023, there were 3 MW of verified eDSM savings in the region.
- Upsize Keith TS end-of-life 230/115 kV autotransformers T11/T12 from 125 MVA to 250 MVA– completed in 2023.
- Upsize Lauzon TS DESN 1 end-of-life step-down transformers T5/T6 – expected to be in-service by 2026.
- Decommission Keith TS end-of-life T1 (115 kV/27.6 kV) transformer – completed.

[8] The West of London bulk plan considered the area from outside the western edge of the City of London, to the City of Sarnia in the northwest, and to the City of Windsor in the west.

2020 Windsor-Essex Regional Infrastructure Plan

- Build a new supply station, South Middle Road DESN 1, connected to Lakeshore TS – completed in 2022.
- Build a second new supply station, South Middle Road DESN 2, connected to Lakeshore TS – work underway, expected to be in-service in 2025.

2022 Windsor-Essex Addendum

- Build two new 230 kV DESNs and double-circuit connection lines from Lakeshore TS, including a new 230 kV line between Leamington TS and the new DESNs – on hold pending customer commitment and is being recommended again in this IRRP.
- Transfer load in excess of the Kingsville TS station load meeting capability to the new DESNs once in-service – on hold until DESNs proceed and is being recommended again in this IRRP.
- Initiate engagement with customers to determine cost-justified measures to mitigate the load restoration need – on hold until DESNs proceed.

4.2. Bulk Planning and Other Developments

In addition to historical regional planning activities, the Windsor-Essex region has been the subject of bulk planning initiatives and other developments. The 2019 Windsor-Essex bulk plan focused on increasing the overall transfer capability of the bulk transmission system west of Chatham to reliably supply the forecast load growth in the Kingsville-Leamington area and Windsor-Essex region. The 2021 West of London bulk plan. This plan looked to address remaining bulk transmission system constraints east of Chatham and ensure adequate supply to the West of London area. In addition, given the expiry of generation contracts in the area, it intended to identify any transmission constraints limiting the ability of supply resources and imports within West of London to meet provincial needs.

2019 Windsor-Essex Bulk Plan

- Build a new switching station at the Leamington Junction (Lakeshore TS) – completed in 2022.
- Build a new 230 kV double-circuit transmission line from the existing Chatham SS to the new switching station at the Leamington Junction (Lakeshore TS) – completed in 2024 (one year earlier than planned).

2021 West of London Bulk Plan

- Build a new 230 kV double-circuit transmission line from Lambton TS southward to Chatham SS (the "St. Clair line") and associated station facility expansions or upgrades required at the terminal stations – development underway and regulatory approval received, expected to be in-service in 2028.

- Begin bilateral negotiations for Brighton Beach Generating Station, to support the area's needs in the near-term until the Lambton-to-Chatham transmission line is in-service – completed.[9]
- Build a single-circuit 500 kV transmission line from Longwood TS to Lakeshore TS – development underway, expected to be in-service in 2030.
- Acquire 550 MW of new or existing local resources – secured through completed procurements, expected to be in-service earlier than the 2030 to 2035 need.

2024 Central-West Bulk Plan

- Reconstruct the M31W circuit between Buchanan TS and the tap line for the planned Centennial TS with higher capacity double-circuit towers, strung with one circuit but capable of accommodating a second circuit in the future – development underway, expected to be in-service in 2027.
- Monitor load growth across the Central-West area and be prepared to implement dynamic voltage devices as demand grows, including Ingersoll TS.

Ongoing South and Central Bulk Planning

A new South and Central Bulk Plan is underway to address known bottlenecks in the transmission system, including between northern and southern Ontario, within the Greater Toronto Area, and along the Windsor-to-Hamilton corridor. The objectives of the study are to unlock opportunities for generation connections, enable phase-out of emitting resources, and support future growth and economic development. The study will determine the transmission reinforcements and/or network expansion required to enable reliable:

- Reliable supply under scenarios for decommissioning greenhouse gas (GHG) emitting resources; and
- Long-term, high-growth scenarios within key areas of the South-Central system, such as the Windsor-to-Hamilton corridor.

Other Developments

In 2022, a governmental directive declared that three of the transmission lines recommended in the regional and bulk plans above are priority projects, specifically:

- The Chatham-to-Lakeshore double-circuit 230 kV line (completed in 2024);
- The double-circuit 230 kV St. Clair line; and
- One single-circuit 500 kV line from Longwood TS to Lakeshore TS.

This would streamline the Ontario Energy Board's regulatory approval process and designate Hydro One Transmission as the transmitter for the priority projects. In the Order in Council the government also asked Hydro One Transmission to undertake development work and seek approvals for two future projects:

[9] The negotiations for Brighton Beach Generating Station are also complete, with a contract term from July 16, 2024 to July 15, 2034.

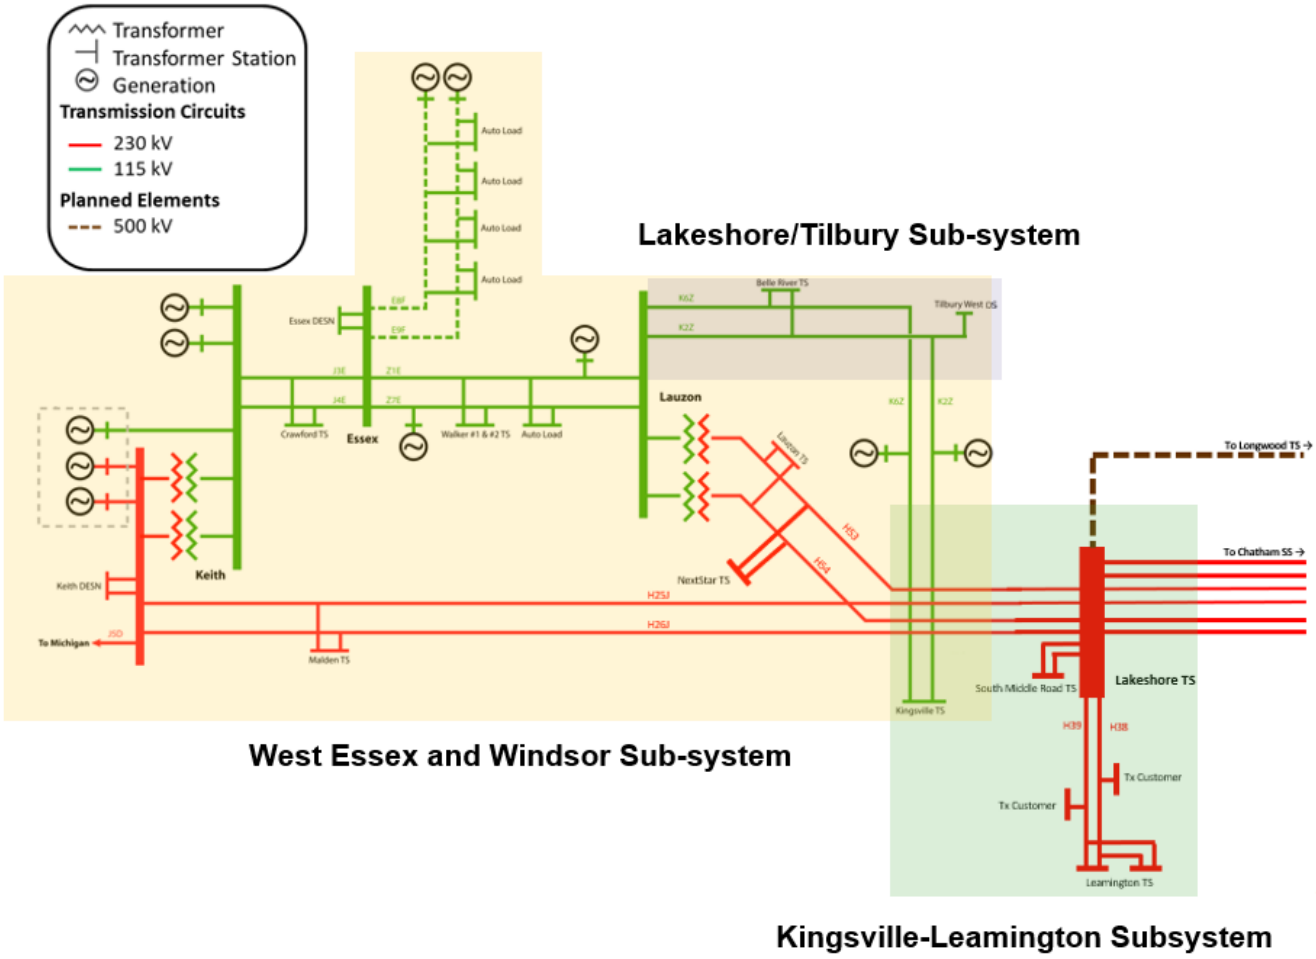
This had the effect of streamlining the Ontario Energy Board's leave to construct process for these projects. Further, in 2020 and 2022, the Minister of Energy issued Directives requiring Hydro One Transmission to develop these projects, including their associated station facility upgrades, along with two new projects:

- A new 230 kV line that would run from Lakeshore TS to the Windsor area; and
- A second 500 kV transmission line from Longwood TS to Lakeshore TS

4.3. Current Cycle of Regional Planning

The current cycle of regional planning began in 2023, with the publication of the Needs Assessment, in which several needs requiring further regional coordination were identified. The 2023 Scoping Assessment recommended an IRRP for the entire region to address needs in a coordinated manner. This report presents an integrated regional electricity plan over a 20-year period from 2024 to 2043.

This IRRP develops and recommends options to meet the electricity needs of the Windsor-Essex region in the near, medium, and long term. The plan was prepared by the IESO on behalf of the Technical Working Group, and includes consideration of forecast electricity demand growth, eDSM, DG, transmission and distribution system capability, relevant community plans, condition of transmission assets, and developments on the bulk transmission system.



The following transmission facilities were included in the scope of this study:

- Transformer stations: Belle River TS, Crawford TS, Essex TS, Keith TS, Kingsville TS, Lauzon TS, Leamington TS, Malden TS, South Middle Road TS, Tilbury West DS, Walker MTS #2, Walker TS #1, and eight CTS.
- 115 kV transmission circuits: J3E, J4E, E8F, E9F, Z1E, Z7E, K6Z, and K2Z.
- 230 kV transmission circuits: H25J, H26J, H53Z, H54Z, H38, H39, H75, and H76.

The single line diagram of the Windsor-Essex region is shown in Figure 3. Note that the bulk system transfer capabilities into the region[10] are not within the scope of the IRRP, but are encompassed in the ongoing South and Central Bulk study. The schedule of bulk planning activities is identified through the IESO's Annual Planning Outlook.

[10] Includes flow into Lakeshore from the six 230 kV circuits from Chatham SS and the recommended 500 kV circuit from Longwood TS under development.

Figure 3 | Single Line Diagram of the Windsor-Essex Region

The Windsor-Essex IRRP was developed by completing the following steps:

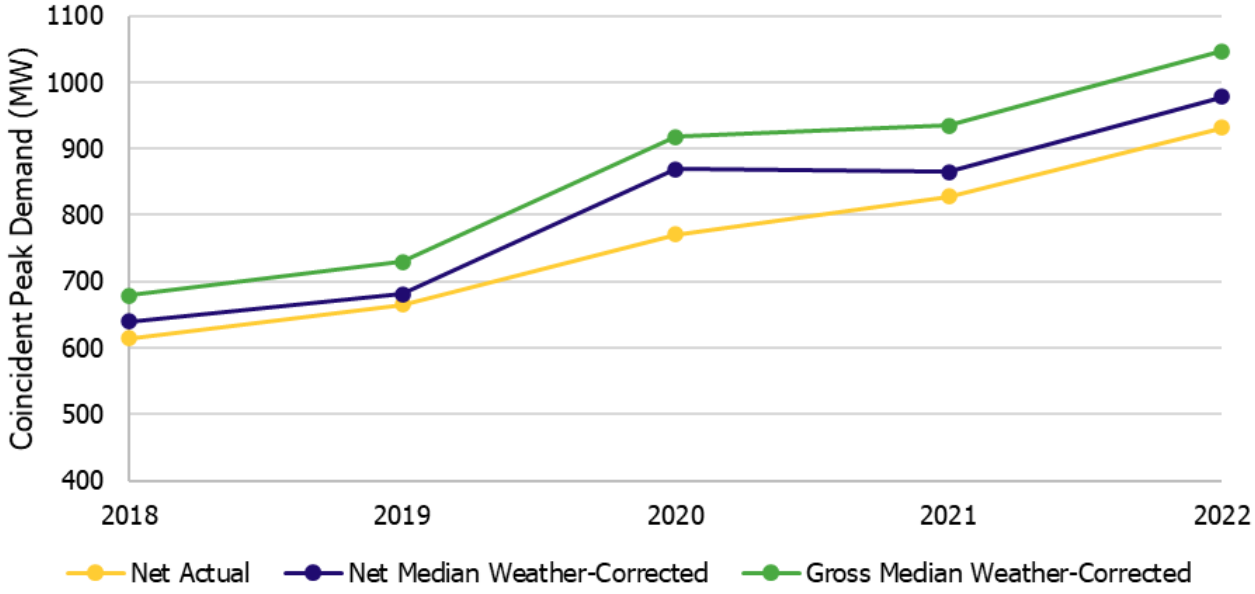
- Establishing alternatives to address system needs, including, where feasible and applicable, generation, transmission and/or distribution, and other approaches such as non-wires alternatives, including eDSM.
- Engaging with the community on needs and possible alternatives.
- Evaluating alternatives to address near- and long-term needs.
- Considering the impact of the High Forecast as a sensitivity of the flexibility and optionality of the potential alternatives.
- Communicating findings, conclusions, and recommendations within a detailed plan.

5. Electricity Demand Forecast

Regional planning in Ontario is driven by having to meet peak electricity demand requirements in the region. This section describes the development of the demand forecast for the Windsor-Essex region. It highlights the assumptions made for peak demand forecasts, including weather correction, the contribution of eDSM and DG, and the development of a High Forecast scenario. The "Planning Scenario" was derived based on firm loads (current and planned), organic growth, residential, electrification, community energy plans, greenhouse growth, and industrial growth as described in more detail in Appendix B. The "Planning Forecast" is the result of "Planning Forecast" presented net of existing DG and eDSM, and corrected for extreme weather. The Planning Forecast is used in assessing the electricity needs of the area over the planning horizon.

The "High Scenario" incorporates potential demand growth that is less certain, in terms of timelines, magnitude and location, into the Planning Scenario. The "High Forecast" is also the result of the High Scenario adjusted to be net of existing DG and eDSM, and corrected for extreme weather. The High Forecast used as the basis for a sensitivity analysis as described further in Section 5.7.2.

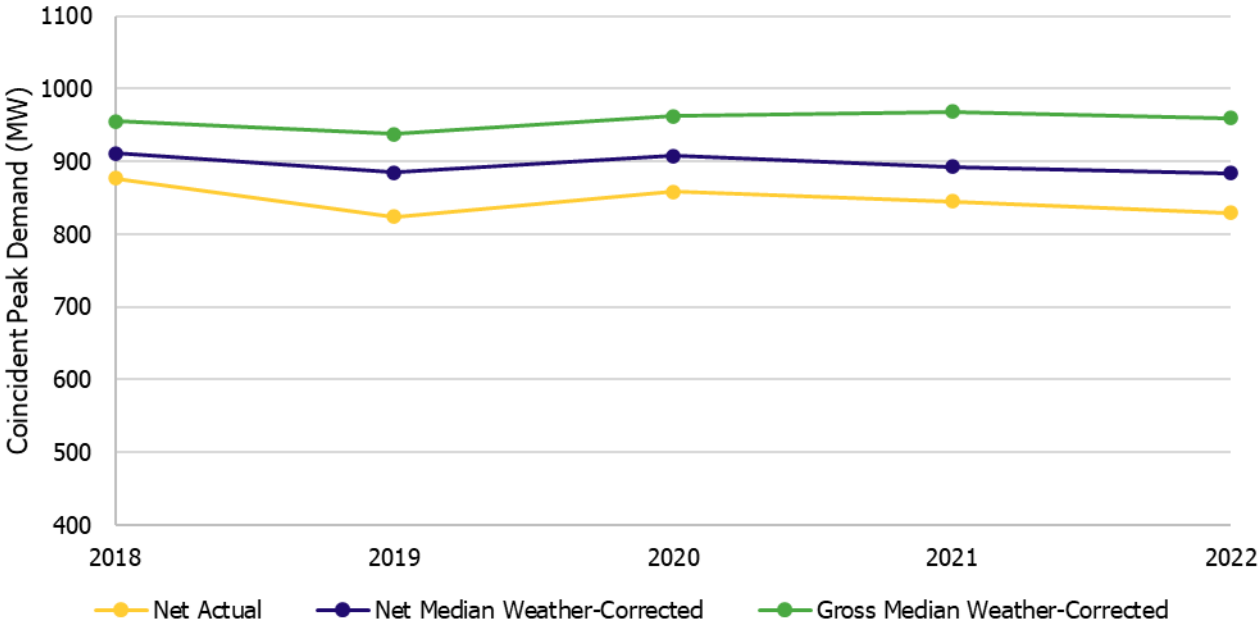
To evaluate the reliability of the electricity system, the regional planning process is typically concerned with the coincident peak demand for a given area. This is the demand observed at each station for the hour of the year in which overall demand in the study area is at its maximum. This differs from a non-coincident peak, which refers to each station's individual peak, regardless of whether these peaks occur at different times. In the past, the Windsor-Essex region peak loading has historically occurred in the summer. However, with the recent and projected growth of the greenhouse sector, the region is now winter peaking.



5.1. Historical Demand

The Windsor-Essex region is winter peaking mainly due to increased greenhouse load for lighting during winter months. From 2018 to 2022, electrical demand[11] grew by nearly 370 MW, peaking between approximately 9 AM to 6 PM. Figure 4 shows the historical winter peak demand as measured three different ways:

1. Coincident net actual, as observed at the metering point;
2. Net median weather-corrected (adjusted to reflect median weather conditions); and
3. Gross median weather-corrected historical demand with contributions of DG removed.



[11] Gross median weather-corrected demand.

Figure 4 | Historical Winter Peak Demand in the Windsor-Essex Region

Summer peak electricity demand within the Windsor-Essex region has remained stable in the five years prior to this planning cycle. Figure 5 shows the summer coincident net actual, net median weather-corrected, and gross median weather-corrected historical demand. The summer gross median weather-corrected demand has averaged 960 MW over the past five years, with the peak demand hour for each year occurring between approximately 2 PM to 5 PM.

Figure 5 | Historical Summer Peak Demand in the Windsor-Essex Region

Since the forecast was developed in 2023, the 2022 summer and winter gross median weather-corrected peaks at each station in the Windsor-Essex region were used as the starting points for the forecast.

5.2. Current Drivers of Load Growth

Electricity demand in the Windsor-Essex region is growing at a rapid pace due to residential and commercial growth, continued expansion of the agricultural and industrial sectors, and electrification. Agriculture has been driving electricity demand growth and needs in the region over the last several years, especially in winter, and continues to be an important driver going forward. Broader economic development across the region, electrification, and local climate action plans are also expected to be key factors for future electricity needs. These factors identified as drivers of growth are used to inform the forecasts developed for the region and are discussed in more detail in the following subsections.

5.2.1. Community Load Growth

The population of the Windsor-Essex region is approximately 420,000 people, with close to 10,000 new residents welcomed between 2021 and 2022, according to the latest census. The Provincial Housing Commitment is anticipated to result in the development of 13,000 new homes over the next ten years in the Windsor-Essex region. This residential development will be accompanied by population growth, and Windsor expects a need will arise to expand its infrastructure to support this growth. The region also anticipates that new residences will employ electric heating and that existing residences will convert to electric heating, with the lowest expected conversion rate being 60 per cent. In addition to electric heating, electric vehicle uptake is expected to increase in the area, in accordance with forward looking projections from Statistics Canada and the regulated targets for zero-emission vehicles within the Electric Vehicle Availability Standard implemented by the Government of Canada in 2023. Electric vehicle uptake is expected by both municipal fleets and more broadly by community members.

Further, the region anticipates climate change and resulting extreme weather will have an impact on electricity demand. Windsor-Essex experiences hotter summers than other areas of Ontario because of its southern geography, which results in more days requiring electric cooling. The City of Windsor and County of Essex are surrounded on three of four sides by large bodies of water, and there are a number of shoreline and low-lying areas in the region that are vulnerable to flooding.[12]

The communities of the Windsor-Essex region anticipate steady population growth accompanied by necessary residential development. The City of Windsor, Municipality of Leamington, Town of LaSalle, Town of Tecumseh, and Municipality of Chatham-Kent each expect a population increase near to or greater than 6,000 individuals over a ten-year period, as informed by their Development Charges Background Studies.

Communities have identified large development projects that will increase electricity demand; these include the Howard-Bouffard Secondary Plan in the Town of LaSalle, the Tecumseh Hamlet Secondary Plan, Oldcastle Hamlet Development plan and Manning Road Secondary Plan in Tecumseh, the Settlements Areas for Employment Lands plan in the Town of Essex, and the Sewage Treatment Facility expansion in the Town of Kingsville. Moreover, some communities have identified objectives for reducing electricity demand through Energy Management plans like the City of Windsor and the Town of Lakeshore.

[12] Based on the City of Windsor East Riverside Flood Risk Assessment and Essex Region Conservation Authority website.

5.2.2. Agricultural Sector

The Kingsville-Leamington area within the Windsor-Essex region is home to North America's largest concentration of greenhouse vegetable production. Growth in the agricultural sector has been driven by strong indoor agricultural growth, mainly vegetable greenhouses, as well as, in part, cannabis, specifically through existing greenhouses switching to lit indoor facilities, expansion of greenhouse facilities, and supplemental load to support the sector. There are also early indications of expansion to include berries and propagation.

Indoor agriculture loads are significantly different from other industrial, commercial, and residential loads in the province. The concentration of indoor agriculture in Windsor-Essex owes much to the region's natural advantages. Its proximity to the Windsor-Detroit border crossing is ideal for supplying both the Canadian and U.S. markets, and its southern latitude and climate provide optimal conditions for agricultural activities. Windsor-Essex also hosts an established ecosystem of support industries and partners, including agriculture research and greenhouse fabrication facilities, which further encourage greenhouse growth in the area.

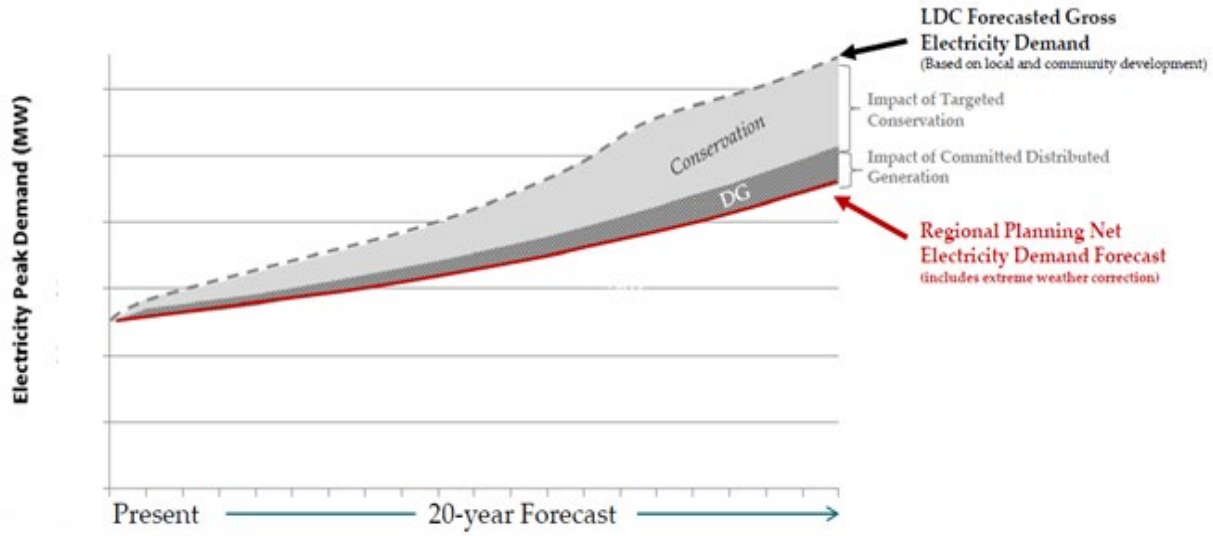
Since the last cycle of regional planning, the greenhouse sector continues to grow. Both transmission-connected greenhouse loads, and the recommended supply stations (South Middle Rd DESNs 1 and 2) have connected or are under development. In the future, agricultural growth may concentrate in the southern portion of Chatham-Kent, between Wheatly and Port Alma.

5.2.3. Industrial Sector

Windsor-Essex remains the country's manufacturing and automotive powerhouse, with significant recent investments in electric vehicle battery manufacturing. Windsor-Essex is home to more than 1,000 manufacturers, with more than 90 parts manufacturers, including two original equipment manufacturers, over 250 machine, tool, die and mould manufacturers, and more than 500 automation-related firms.[13]

In April 2024, the Ontario government announced that it will offer support to four companies in the automotive and food processing industries (DS Actimo Canada, Kautex Textron, Integrity Tool & Mold Inc. and Highbury Canco Corp.) to expand their manufacturing capacity in the area. The government anticipates that these companies will invest around $215 million, and create around 153 new local jobs.[14] In October 2024, NextStar Energy (a joint venture between Stellantis and LG Energy Solution) started production in their new electric vehicle battery plant in Windsor. At full production, the plant is expected to employ 2,500 workers and produce enough battery cells to power 450,000 vehicles annually. In addition, the Ontario government announced that it would invest over $9 million to train approximately 2,300 manufacturing and construction sector workers in Windsor.[15]

5.3. Demand Forecast Methodology



The steps taken to develop a 20-year IRRP peak demand forecast are depicted in Figure 6. Gross demand forecasts, which assume the weather conditions of an average year based on historical

[13] https://www.investwindsoressex.com/industries/advanced-manufacturing/#:~:text=Industry%20profile,Automate%20Canada
[14] https://news.ontario.ca/en/release/1004431/ontario-welcomes-125-million-manufacturing-boost-in-southwestern-ontario
[15] https://news.ontario.ca/en/release/1005049/ontario-investing-over-9-million-to-train-2300-workers-in-windsor

weather conditions (referred to as "normal weather"), were developed by the LDCs. These forecasts were then modified to reflect the peak demand impacts of provincial conservation targets and DG contracted through previous provincial programs, such as Feed-In Tariff (FIT) and microFIT, and adjusted to reflect extreme weather conditions in order to produce a Planning Forecast for planning assessments. This net forecast was then used to assess the electricity needs in the region.

Additional details related to the development of the demand forecast are provided in Appendix B. The Ontario Energy Board has also published a Load Forecast Guideline for regional planning, through the Regional Planning Process Advisory Group.

Figure 6 | Illustrative Development of Demand Forecast

5.4. Gross LDC Forecasts

Each participating LDC in the Windsor-Essex region prepared gross demand forecasts at the station level, or at the station bus level for multi-bus stations. These gross demand forecasts account for increases in demand from new or intensified development, plus known connection applications. The LDCs cited alignment with municipal and regional official plans and credited them as a source for input data. LDCs were also expected to account for changes in consumer demand resulting from typical efficiency improvements and in response to increasing electricity prices ("natural conservation"), but not for the impact of future DG or new conservation measures (such as codes and standards and eDSM programs), which are accounted for by the IESO (discussed in Section 5.5). The gross LDC forecasts assume median on-peak weather conditions and loading that is coincident to each station.

Figure 7 and Figure 8 show the gross non-coincident demand forecasts provided by the LDCs for the Windsor-Essex region under the Planning Scenario and High Scenario for summer and winter peak demand.

Figure 7 | Total Summer Gross Non-Coincident Demand Forecasts Provided by LDCs (Median Weather)[16]

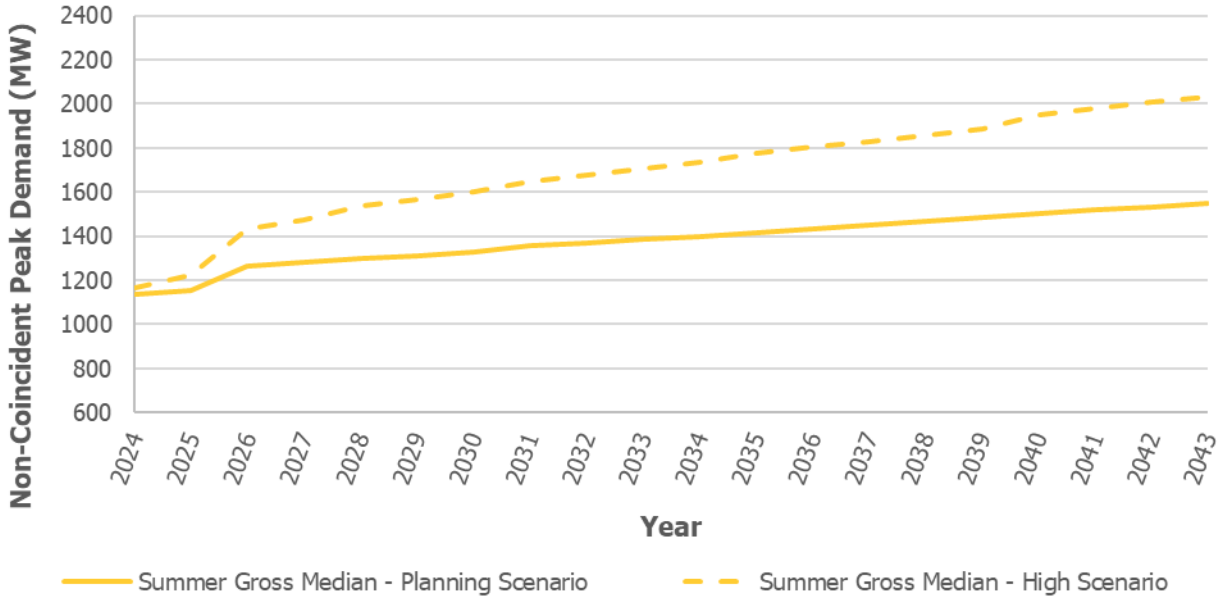


Figure 8 | Total Winter Gross Non-Coincident Demand Forecasts Provided by LDCs (Median Weather)[17]

[16] Excludes existing transmission-connected industrial customers in the Windsor-Essex region (historically contributing an average of 75 MW to the summer non-coincident peak demand), as well as forecasted greenhouse and industrial sector growth not assigned to specific LDCs.

[17] Excludes existing transmission-connected industrial customers in the Windsor-Essex region (historically contributing an average of 63 MW to the winter non-coincident peak demand), as well as forecasted greenhouse and industrial sector growth not assigned to specific LDCs.

LDCs have a better understanding of future local demand growth and drivers than the IESO, since they have the most direct involvement with their customers, connection applicants, and the municipalities and communities that they serve. The IESO typically carries out demand forecasting at the provincial level. More details on LDC load forecast assumptions can be found in Appendix B.2 to B.6.

5.5. Contribution of Energy Efficiency to the Forecast

Energy efficiency is a clean and cost-effective resource that helps meet Ontario's electricity needs and has been an integral component of provincial and regional planning. Energy efficiency is achieved through a mix of codes and standards amendments, as well as eDSM program-related activities. These approaches complement each other to maximize conservation results.

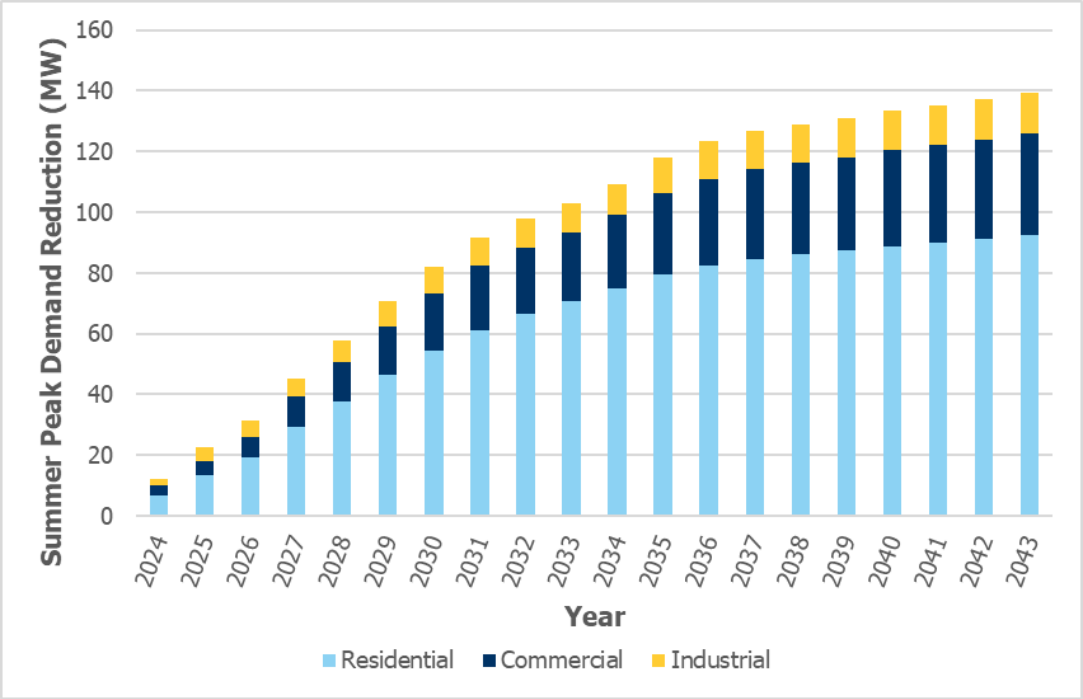
The estimate of demand reduction due to codes and standards are based on expected improvement in the codes for new and renovated buildings, and regulation of minimum efficiency standards for equipment used by specified categories of consumers (i.e., residential, commercial and industrial consumers).

The estimates of demand reduction due to eDSM program-related activities account for the 2021–2024 Conservation and Demand Framework, federal programs that result in electricity savings in Ontario, and forecasted long-term energy efficiency programs. Under the 2021–2024 Conservation and Demand Management Framework, the IESO centrally delivered programs on a province-wide basis to serve business and residential customers, as well as Indigenous communities.

The demand forecast was finalized before approval of the new 2025–2036 eDSM framework and its savings targets, and assumes that programs continue at 2021–2024 Conservation and Demand Framework levels, with adjustments for gross demand growth. The increased targets under the new framework may impact the exact scale and timing of needs.

Figure 9 and Figure 10 show the estimated total yearly reduction to the demand forecast due to energy efficiency (from codes, standards, and eDSM programs) for each of the residential, commercial, and industrial consumers. Additional details are provided in Appendix B.8 and Appendix E.

Figure 9 | Total Summer Forecast Peak Demand Reduction (Codes, Standards, and eDSM Programs)



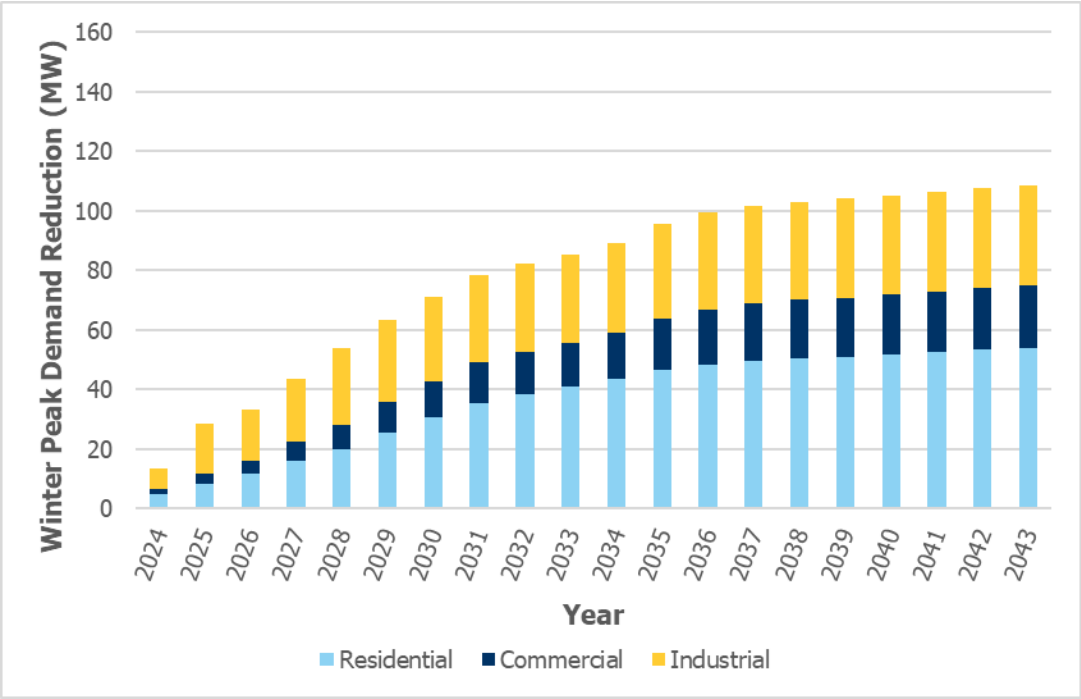


Figure 10 | Total Winter Forecast Peak Demand Reduction (Codes, Standards, and eDSM Programs)

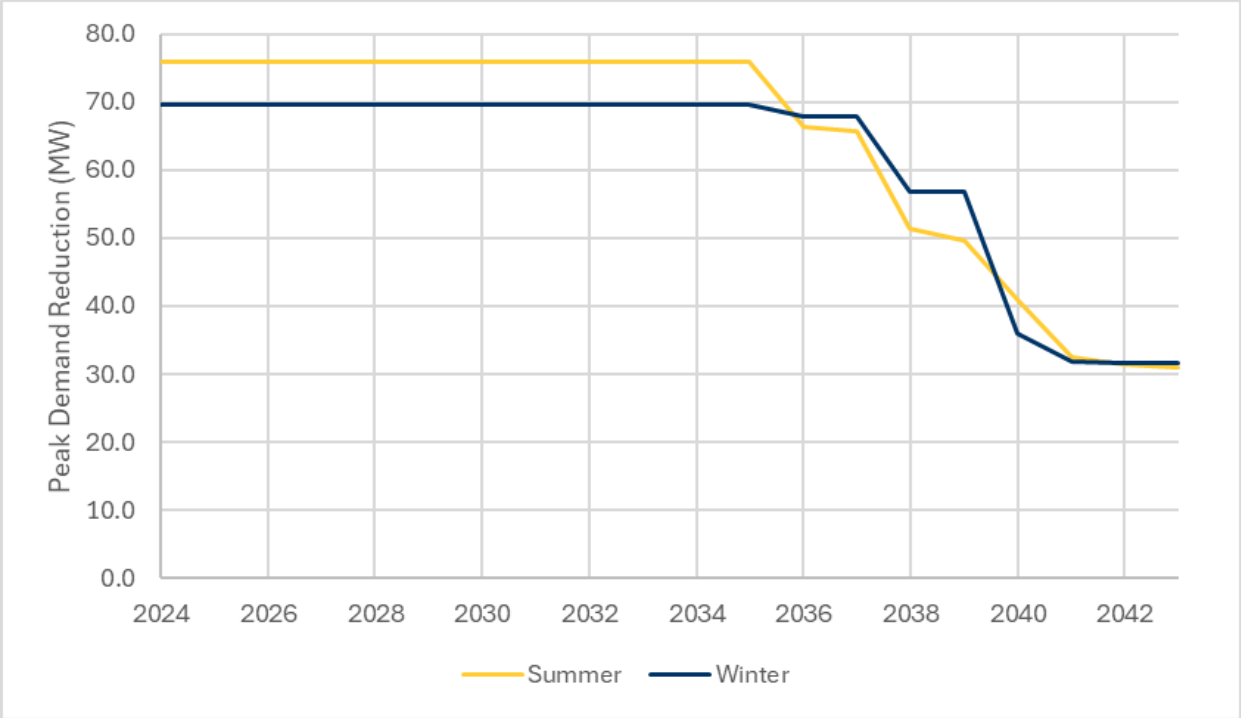


5.6. Contribution of Distributed Generation to the Forecast

In addition to energy efficiency, DG in the Windsor-Essex region is also forecast to offset peak demand requirements. The introduction of Ontario's FIT Program increased the significance of distributed renewable generation which, while intermittent, contributes to meeting the province's electricity demands. The installed DG capacity by fuel type and contribution factor assumptions can be found in Tables 3 and 4 of the accompanying IRRP data tables (provided as a separate Excel file). Most of the total installed DG capacity in the Windsor-Essex region is wind and solar, with the remainder being natural gas (CHP) and biogas facilities.

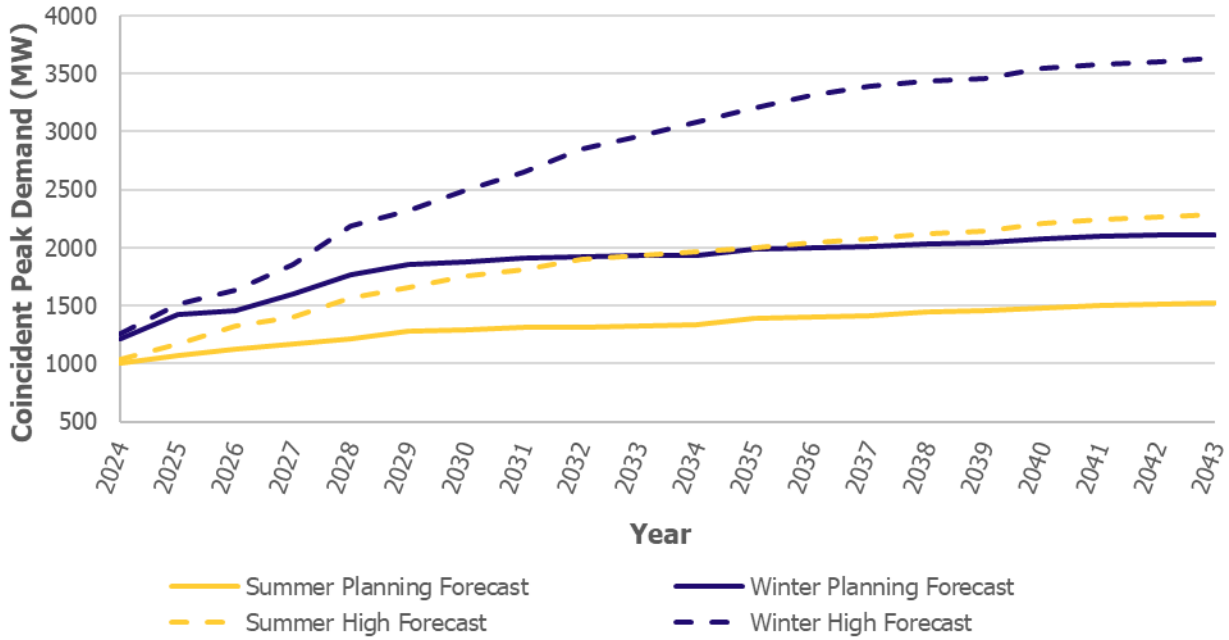
After reducing the demand forecast due to energy efficiency (as described in Section 5.5) the forecast is further reduced by the expected contribution from contracted DG. Figure 11 shows the impact of DG on reducing the Windsor-Essex region demand forecasts. Note that facilities without a contract with the IESO were not included in the DG peak demand reduction forecast, except for DG facility information provided directly by the LDCs.

Figure 11 | Peak Demand Reduction Due to DG

A decision was made within the Technical Working Group to consider the expected lifespan of each DG facility based on resource type, rather than assuming that facilities will not be re-contracted past their current contract end date. In alignment with the IESO 2024 Annual Planning Outlook, the assumption for resource expected lifespans was 25 years for solar, and 30 years for wind, natural gas and biogas. A total of 76 MW of summer peak contribution is identified for the Windsor-Essex region in 2024, reducing to 30 MW by 2044. This reduction is reflected in the planning forecasts as discussed in the next section.

5.7. Planning Forecasts

After taking into consideration the combined impacts of energy efficiency and DG, a 20-year net demand forecast was produced for the Windsor-Essex region considering the Planning Scenario and High Scenario. The following subsections describe the implementation of weather correction to create the Planning Forecast and High Forecast, the total demand outlook for the region, and the specific demand outlooks for the agricultural and industrial forecasts (which represent significant and unique portions of the overall load growth).



5.7.1. Net Extreme Weather Planning Forecast

The net extreme weather forecast is created by adjusting the net median weather forecast (the gross demand forecast including the forecast DG and eDSM impacts) for extreme weather conditions. The weather correction methodology is described in Appendix B.1. The Planning Forecast results from the net extreme-weather forecast applied to the Planning Scenario.

Note that this Planning Forecast is coincident, meaning that each station forecast reflects its expected contribution to the regional peak demand level. This supports the identification of need dates for regional needs that are driven by more than one station. For station-specific needs, the non-coincident forecast is calculated by applying a non-coincidence factor. The factor is based on the historical non-coincident peaks of each station compared to the station's contribution to the region's coincident peaks over the past five years.

The coincident net extreme weather forecast for the Windsor-Essex region is shown in Figure 12 Figure 12: both the Planning Forecast and High Forecast representing peak summer and winter demand.

Figure 12 | Net Extreme Weather Planning Forecast and High Forecast for the Windsor-Essex Region

5.7.2. High Forecast Scenario

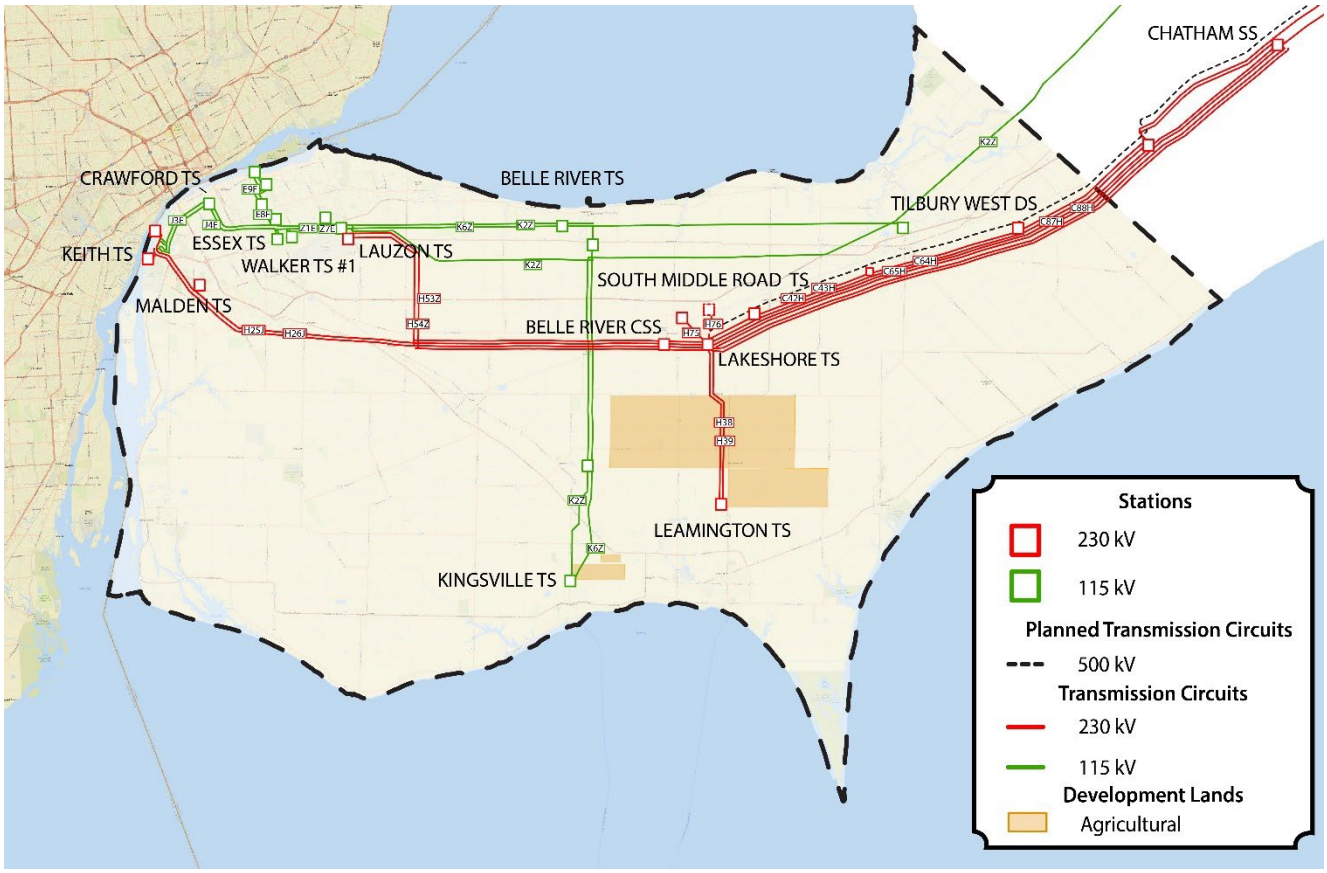
The Technical Working Group developed a High Forecast sensitivity scenario for the Windsor-Essex region, which is also shown in Figure 12. The High Forecast is meant to quantify prospective development in the Windsor-Essex region that is not yet committed. This higher demand scenario is driven by significant growth potential in the agricultural and industrial sectors, as described in detail in Sections 5.7.3 and 5.7.4.

The High Forecast can be used as a proxy for a variety of factors that could drive demand higher over the next 20 years, including, but not limited to:

- Electric vehicle charging;
- Electrified space and water heating;
- A faster pace of residential development;
- Unanticipated new industrial customers of growth among existing industrial customers; and
- Higher growth in the agricultural sector.

The higher demand scenario was not used to drive any firm recommendations for this IRRP; however, it was used to help the Technical Working Group identify where the future electricity concerns may be and when they could materialize. This information can also be useful for communities conducting community energy plans, for the Technical Working Group in determining areas to monitor in future planning cycles, and for communities and stakeholders to consider when planning various projects in the region. Moreover, while developing this IRRP, the Technical Working Group also considered the flexibility of evaluated options to accommodate greater long-term growth. This is later described in Section 7.

5.7.3. Agricultural Forecast



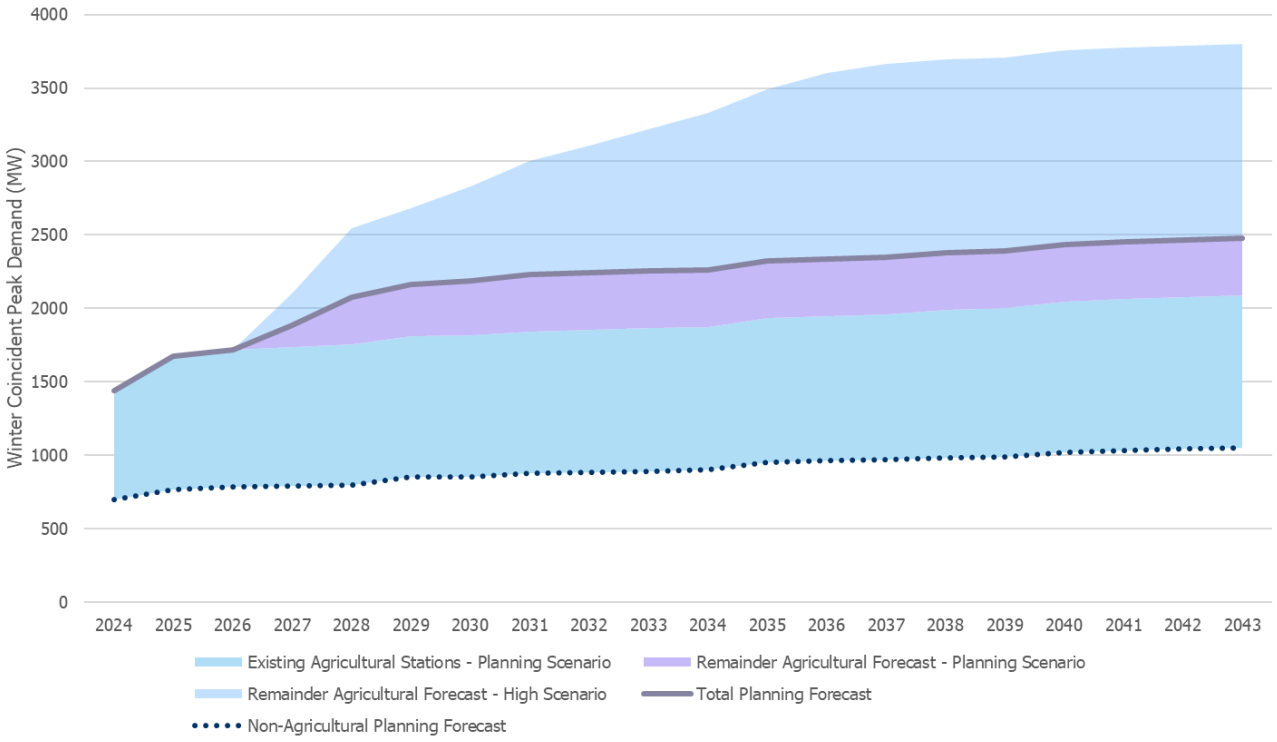
The agricultural forecast was developed to capture the future growth of the agricultural sector, including greenhouses, in both the Planning Forecast and High Forecast scenarios. The forecast incorporates the anticipated greenhouse developments that were known at the time it was produced. The greenhouse sector continues to expand – the previous IRRP projected a five per cent annual growth rate, which has been realized in the near term. Future growth in the Planning Forecast is expected to be four per cent for the sector, with High Forecast growth of seven per cent. Increasing construction and operational costs contribute to growth levels projected to be slower than the 2019 IRRP forecast.

The Ontario agricultural market is increasingly looking for local greenhouse food as a reliable and secure alternative to importing from traditional suppliers. As a result, Ontario greenhouse growers are expanding their operations, changing their propagation practices, and modifying the items they grow. The sector is shifting from propagating plants in fields to propagation within the greenhouse, to reduce insect contamination and other impurities. Vegetable growers are also starting to expand into berry production, which requires chilled warehouses and more packing space.

To develop the agricultural forecast, engagement was conducted with Indigenous communities, market participants, municipalities, stakeholders, communities, customers and the general public. Public webinars allowed stakeholders to provide their inputs into the planning process and issue public comments on the load forecast, needs, and recommendations. In particular, information on the geographic locations of agricultural growth in Windsor-Essex was provided by municipalities in

the region and Ontario Greenhouse Vegetable Growers (OGVG). Greenhouse development remains concentrated in the Leamington and Kingsville areas of Windsor-Essex. This geographic information was used as an approximation to map the agricultural forecast load for the purpose of conducting the needs and options studies, as shown in Figure 13.

Figure 13 | Geographic Locations of Agricultural Growth in the Windsor-Essex Region



After the forecast was finalized, there were early indications of greenhouse load potential in the area between Wheatly toward Chatham-Kent, along Lake Erie. This pocket of growth is likely to be located in the Chatham-Kent/Lambton/Sarnia planning region outside of the geographic/electrical boundaries shown in Figure 13. It is not expected that this growth will detract from the forecast growth in Windsor-Essex.

Greenhouse developments are subject to a variety of factors, including land availability, municipal support, and water supply. The availability of water supply is a key constraint, with some growers digging their own wells and capturing rainwater to be processed and used to overcome the limitations of municipal/county water supplies.

Peak demand for the agricultural forecast is seen in the winter when greenhouses use grow lights to support their crop production. As greenhouses shift to LED lights (including under an IESO-administered eDSM program), peak demand per acre drops, allowing greenhouses to produce more for the same electricity usage. Grow lights tend to be used between October to April, but growers consider September, October, March, and April to be shoulder months. Electricity demand for greenhouses persists year-round as production continues; however, grow lights are not typically

required during summer months. Figure 14 depicts the winter agricultural peak demand forecasts for the Planning and High scenarios.

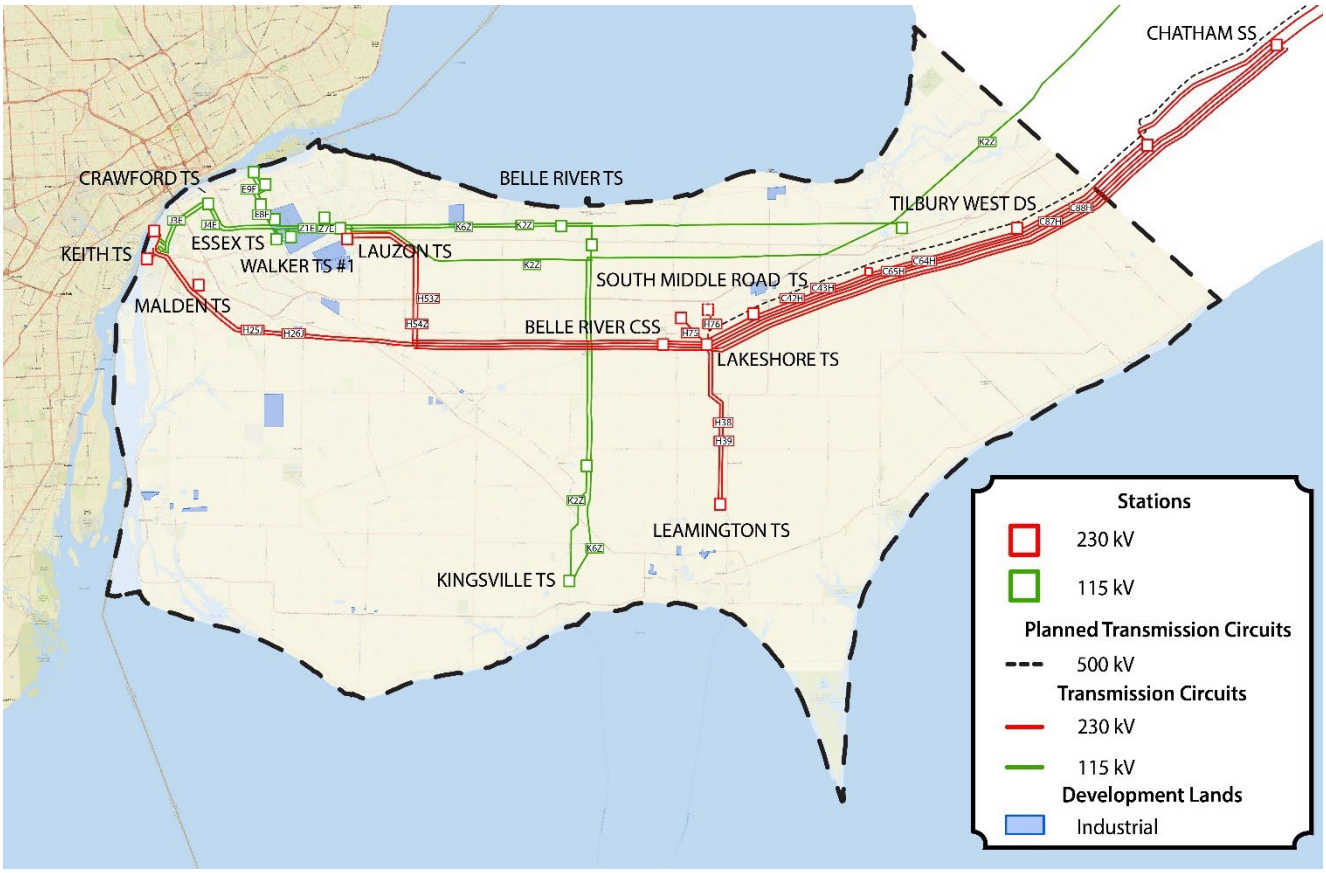


Figure 14 | Agricultural Winter Forecast

5.7.4. Industrial Forecast

Information on potential industrial development lands in the Windsor-Essex region was provided from the County of Essex and Invest WindsorEssex – the not-for-profit organization supported by the City of Windsor and County of Essex responsible for advancing economic development in the region. As shown in Figure 15, industrial development lands are primarily concentrated in the West Essex and Windsor area. The municipalities supplied information on potential industrial land developments, and in some cases, industrial expansion forecasts used in the Planning Scenario and High Scenario. Across the Windsor-Essex region, approximately 800 new acres have been allocated for industrial development, with construction started in 2024.

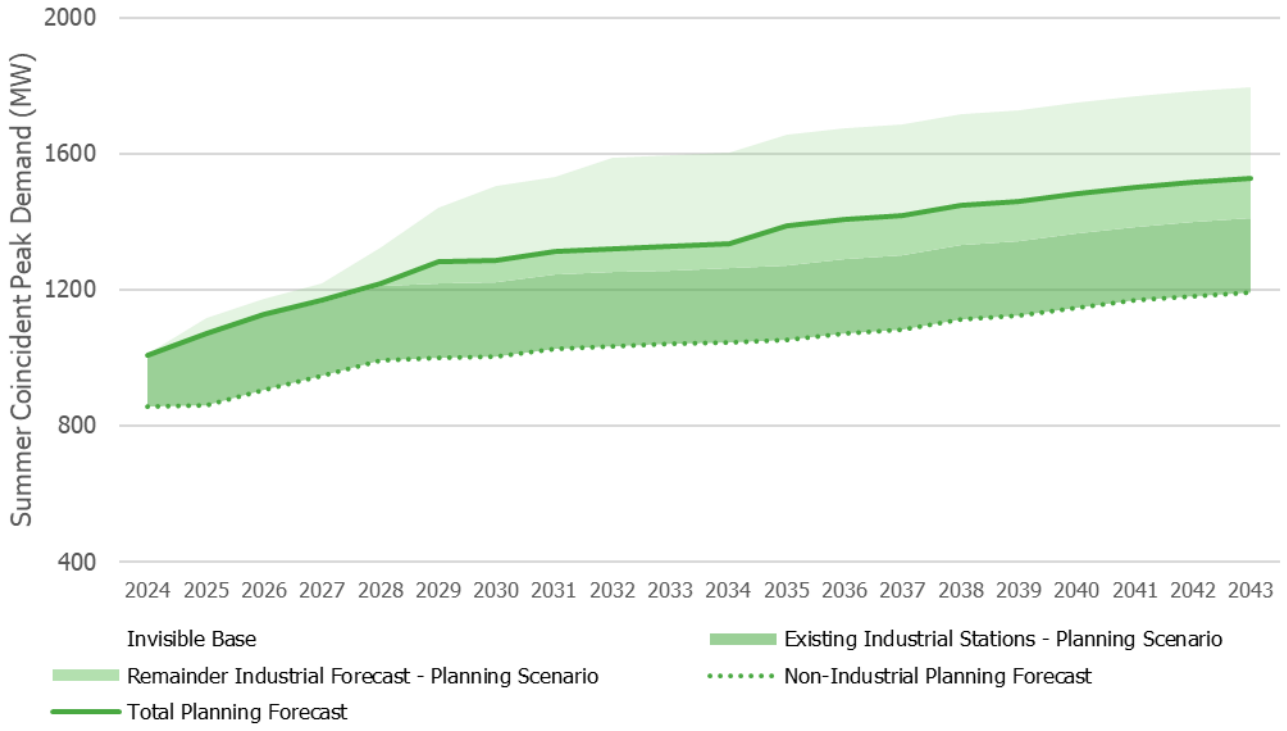

Figure 15 | Geographic Locations of Industrial Growth in the Windsor-Essex Region

The information provided by Invest WindsorEssex identifies approximately 20 new projects in the area requiring significant electrical supply. In addition, anticipated development in the Town of LaSalle could require approximately three gigawatts of power to service business parks and natural environment developments.

The Planning Forecast considered firm and reasonably expected industrial loads, while the High Forecast also incorporated less certain industrial load potential based on municipal and stakeholder input. Figure 16 shows the contributions of the industrial loads to the forecast under the Planning and High Forecasts, relative to the loads at existing stations, and particularly the existing industrial loads in the region. The demand captured in the industrial forecast is relatively constant throughout the year, as industrial loads generally have no relationship with weather conditions.

Figure 16 | Industrial Contribution to Summer Forecast

5.8. Hourly Forecast Profiles

In addition to the annual peak forecast, hourly load profiles (8,760 hours per year over the 20-year forecast horizon) for station(s) included in identified needs were developed to characterize the needs with finer granularity. The profiles were based on historical load data, adjusted for variables that impact demand, such as calendar day (i.e., holidays and weekends) and weather. The profiles were then scaled to match the IRRP peak Planning Forecast for each year. As described later in Section 7, these profiles were used to quantify the magnitude, frequency, and duration of needs to better evaluate the suitability of generation and distributed energy resource options.

Additional load profile details, including hourly heat maps for needs where non-wires alternatives other than eDSM were assessed, can be found in Appendix D. Note that this data is used to roughly inform the overall energy requirements needed to develop and evaluate alternatives; it cannot be used to deterministically specify the precise hourly energy requirements. Real-time loading is subject to various factors, like actual weather, customer operation strategies, and future customer segmentation. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification are more widely adopted. Hence, these hourly forecasts are only used to select suitable technology types and roughly estimate costs for the needs and options studied in the IRRP. The Technical Working Group will continue to monitor forecast changes as part of the implementation of the plan.

6. Needs

6.1. Needs Assessment Methodology

Based on the planning demand forecast, system capability, the transmitter's identified asset replacement plans, and the application of ORTAC, NERC TPL-001-5.1, and Northeast Power Coordinating Council (NPCC) Directory #1 standards, the Technical Working Group identified electricity needs in the near-, medium- and long-term timeframes. These needs can be categorized according to the following:

- **Station Capacity Needs** describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations during peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day Limited Time Rating (LTR) of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be more limited by downstream or upstream equipment (i.e., breakers, disconnect switches, low-voltage bus, or high voltage circuits) or by voltage drop limitations, which are independent of thermal ratings.
- **Supply Capacity Needs** describe the electricity system's inability to provide continuous supply to a local area during peak demand. This is referred to as the load meeting capability (LMC) of the transmission supply. The LMC is determined by evaluating the maximum demand that can be supplied to an area after accounting for limitations of the transmission elements (i.e., a transmission line, group of lines, or autotransformer), when subjected to contingencies and criteria prescribed by ORTAC, TPL-001-5.1, and NPCC Directory #1. LMC studies are conducted using power system simulation analyses.
- **Asset Replacement Needs** are identified by the transmitter by an asset condition assessment, which is based on a range of considerations, such as equipment deterioration due to aging infrastructure or other factors; technical obsolescence due to outdated design; lack of spare parts availability or manufacturer support; and/or potential health and safety hazards, etc. Replacement needs identified in the near- and early medium-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium- to long-term needs should reflect the potential for the need date to change as condition information is routinely updated.
- **Load Security and Restoration Needs** describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage

within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC.

Technical study results for the Windsor-Essex IRRP can be found in Appendix G. The needs identified are discussed in Sections 6.2 to 6.7.1 for the most limiting season for each of the three sub-systems.

6.2. West Essex and Windsor Sub-system Needs

There is an asset replacement need at Lauzon TS DESN 2 that, when combined with the station capacity need under the Planning Forecast, was assessed for the opportunity to consider an integrated solution. There is also a supply capacity need on transmission path into the West Essex and Windsor sub-system, which consists of the four 230 kV supply circuits going west from Lakeshore TS: two circuits to Lauzon TS (H53Z and H54Z) and two circuits to Keith TS (H25J and H26J). Table 4 summarizes the needs for the West Essex and Windsor sub-system under the Planning Forecast.

Table 4 | Summary of West Essex and Windsor Sub-system Planning Needs

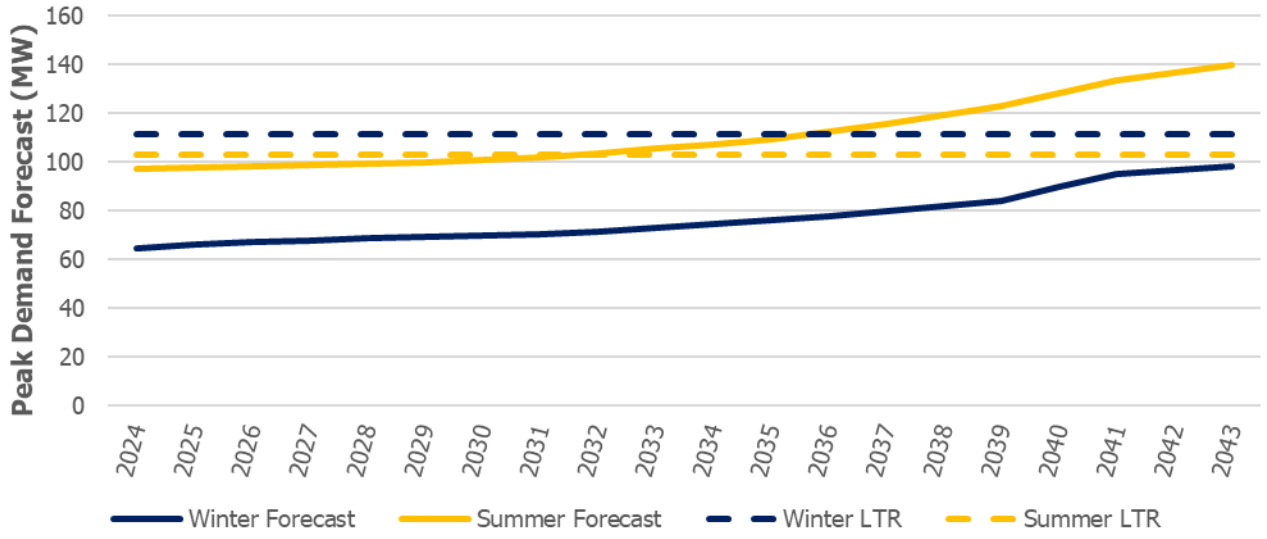
Need	Need Date	Need by 2043 (MW)
Lauzon DESN 2 (T7/T8) end-of-life	2029	n/a
Lauzon DESN 2 (T7/T8) station capacity	2032	37
West Essex and Windsor supply capacity	2032	230

6.2.1. Asset Replacement Needs

The asset replacement need for Lauzon TS DESN 2 was included within the scope of the Windsor-Essex IRRP for its potential integration with the station's capacity need.

6.2.1.1. Lauzon DESN 2 End-of-Life Needs

Lauzon TS DESN 2 transformers were identified as requiring replacement based on asset condition and were originally scheduled to be replaced with like-for-like 115/27.6 kV 83 megavolt ampere (MVA) units by 2032. The IRRP 20-year demand forecast identified station capacity needs at Lauzon TS DESN 2, necessitating the need to reconsider the like-for-like replacement plan.



6.2.2. Station and Supply Capacity Needs

The station capacity needs are driven by industrial loads that cannot be accommodated at the existing supply stations due to the magnitude and uncertainty of their location, as well as load growth at Lauzon TS.

6.2.2.1. Lauzon DESN 2 Station Capacity Needs

Supplying customers in West Essex and Windsor, Lauzon TS DESN 2 is forecast to reach its summer station capacity limit in 2032 and grow to a 37 MW need by 2043. The station consists of two 115 kV/27.6 kV transformers with an LTR of 103 MW.

Figure 17 | Lauzon TS DESN 2 Station Capacity Need

6.2.3. West Essex and Windsor Supply Capacity Need

The load in the West Essex and Windsor sub-system is supplied through 230 kV transmission lines from Lakeshore TS (near Comber) to Lauzon TS and to Keith TS (both in Windsor). The 230/115 kV autotransformers at Lauzon TS and Keith TS supply the 115 kV network in West Essex and Windsor. The area is also served by local generation in the Windsor area. The LMC of the sub-system is limited to 840 MW based on the thermal capability of the circuits going to Lauzon TS under the various planning scenarios and applicable contingencies to the circuits along the Lakeshore to Lauzon TS/Keith TS corridor. Considering the forecast growth in the sub-system – including the industrial forecast presented in Section 5.7.4 – this sub-system has a supply capacity need starting in 2032 with 65 MW, which increases to 230 MW in 2043.

6.2.4. High Forecast Needs

Considering the High Forecast, the West Essex and Windsor supply capacity need increases to 840 MW and is advanced by seven years – to 2025 from 2032 under the Planning Forecast. This illustrates the potential impact on the need year, if a portion of the High Forecast materializes. Considering station capacity needs, the Lauzon TS DESN 2 need is advanced to the near-term and two new station capacity needs are identified at Malden TS and Keith TS, as summarized in Table 5.

Table 5 | Summary of New/Updated West Essex and Windsor Sub-system High Forecast Needs

Need	Need Date[18]	2043 Need (MW)
Lauzon DESN 2 (T7/T8) station capacity	2025	120
West Essex and Windsor supply capacity	2025	790
Keith TS station capacity	2033	42
Malden TS station capacity	2040	45

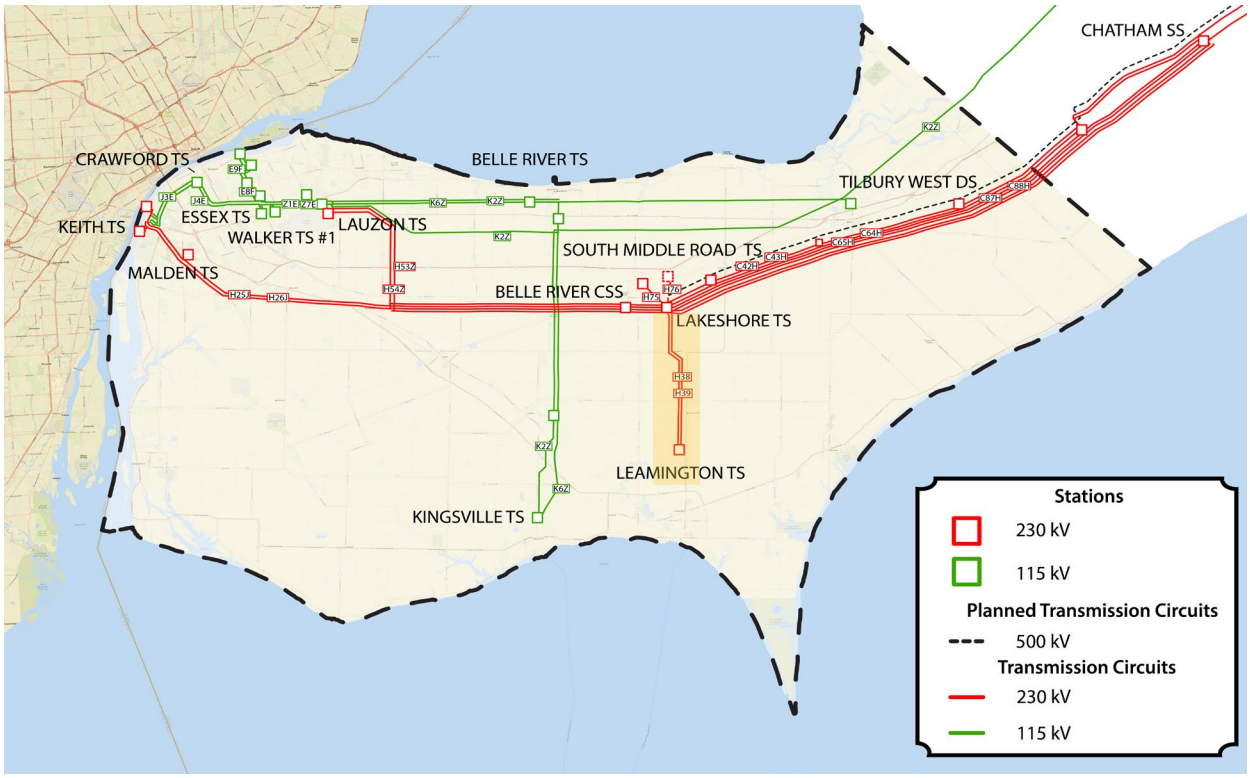
6.3. Kingsville-Leamington Sub-system Needs

The Kingsville-Leamington sub-system continues to experience rapid electricity demand growth from greenhouse loads. Due to the nature of the load growth, the sub-system is expected to be winter peaking and has a unique load profile relative to the rest of the region. Thus, all loading and capacity values in this section refer to the non-coincident winter peak. There are restoration needs, as well as station and supply capacity needs that have been identified, which will be discussed in the following subsections. Table 6 summarizes the Kingsville-Leamington sub-system needs.

Table 6 | Summary of Kingsville-Leamington Sub-system Needs

Need	Need Date[19]	2043 Need (MW)
Leamington TS load restoration	Immediate	320
Kingsville-Leamington Greenhouse station and supply capacity	2027	390

6.3.1. Planning Load Security and Restoration Needs



6.3.1.1. Leamington TS Supply (H38/H39 circuits)

The load restoration need on the twelve kilometre, 230 kV double-circuit line from Lakeshore TS to Leamington TS was identified in the 2022 Windsor-Essex Addendum. Leamington TS DESN 1 and DESN 2, as well as two transmission-connected customers south of Lakeshore TS, are supplied radially through these circuits. Figure 18 depicts this portion of the transmission system in the Windsor-Essex region.

[18] Based on non-coincident station forecasts for station capacity needs and coincident station forecasts for supply capacity needs, as explained in Section 0.

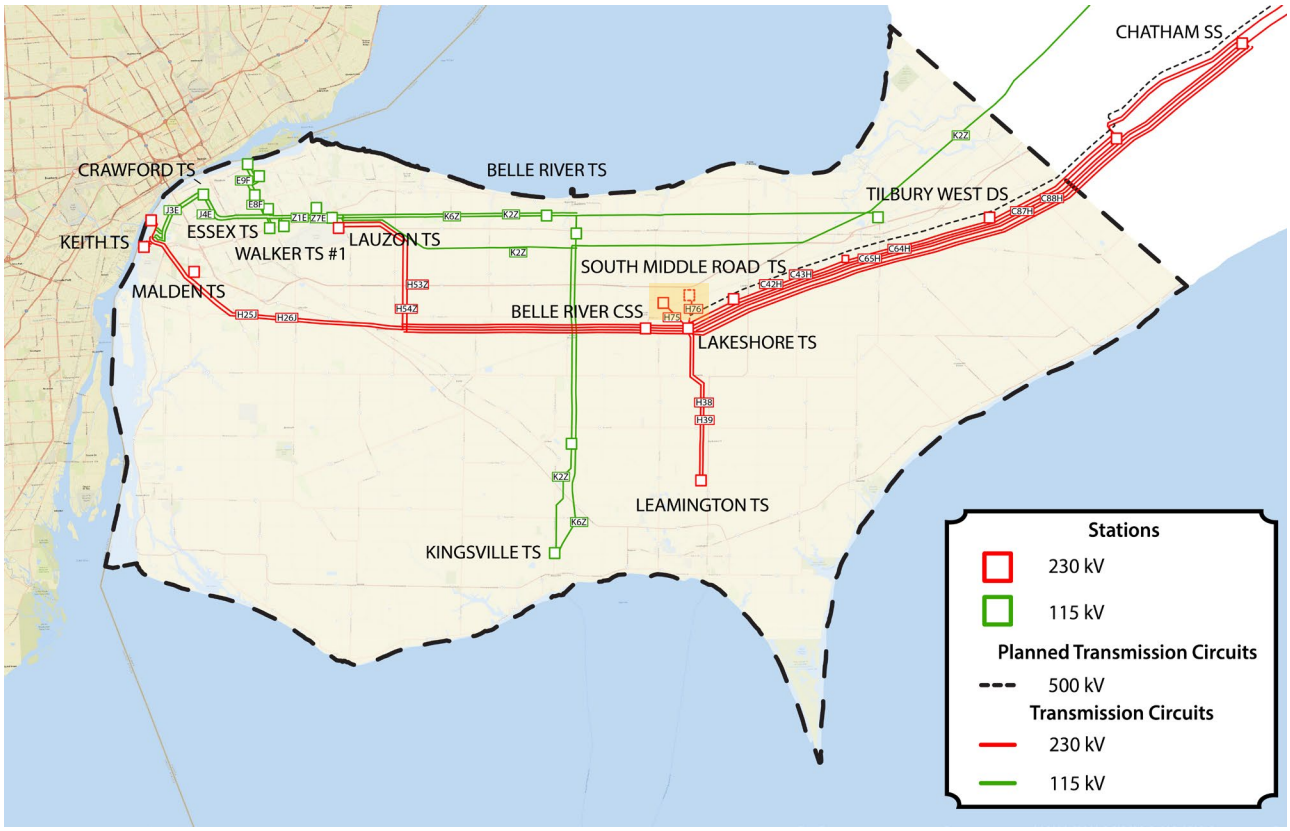
[19] Based on non-coincident station forecasts.

Figure 18 | Map of Leamington TS Transmission (Highlighted Yellow)

As per ORTAC Section 7.1, no more than 150 MW is allowed to be interrupted by configuration following a single-element contingency, and a total of 600 MW (by configuration, load curtailment or load rejection) following a two-element contingency. The current system has a RAS, whereby up to 170 MW would be lost following the loss of either radial supply circuit. With all recommended bulk reinforcements in-service, it is expected that the RAS will no longer be needed, such that the load security need is addressed.

By the end of the study period, approximately 490 MW would be interrupted following an outage to both circuits, H38 and H39, by configuration. Of this 490 MW, Hydro One Transmission has indicated that only 30 MW of the load could be restored within four hours through a load transfer to Kingsville TS. Thus, the restoration targets of load in excess of 250 MW cannot be restored within 30 minutes, nor can load in excess of 150 MW be restored within four hours. This is in violation of load restoration planning requirements (ORTAC Section 7.2), and is summarized in Table 7.

Table 7 | Load Restoration Planning Requirements on the Leamington Supply Lines



Time Post-Contingency	ORTAC Requirement: Restoration Target	Peak Load to be Restored	Achievable Based on the Current and Planned Transmission System?
Within 30 minutes	Load in excess of 250 MW	240 MW	No
Within four hours	Load in excess of 150 MW	340 MW	No, 30 MW is achievable
Within eight hours	All load	490 MW	Yes – the circuits are assumed to be restored by the transmitter within eight hours

6.3.1.2. South Middle Rd Supply (H75/H76)

A load restoration need on the one kilometre, 230 kV double-circuit line from Lakeshore TS to South Middle Rd TS (H75 and H76) was identified in the Needs Assessment. South Middle Rd TS DESN 1 and DESN 2 are supplied radially through these circuits. Figure 19 provides an overview of this portion of the transmission system in the Windsor-Essex region. Since these circuits are one kilometre or less in length, the loss of H75 and H76 is not a respected double contingency per planning criteria. Thus, there are no load restoration violations identified.

As per ORTAC criteria, no more than 150 MW is allowed to be interrupted by configuration following a single contingency. Under the current configuration and RAS, 120 MW of load would be lost following the loss of H75 or H76, which falls within the load security criteria. Thus, no load security concerns have been identified.

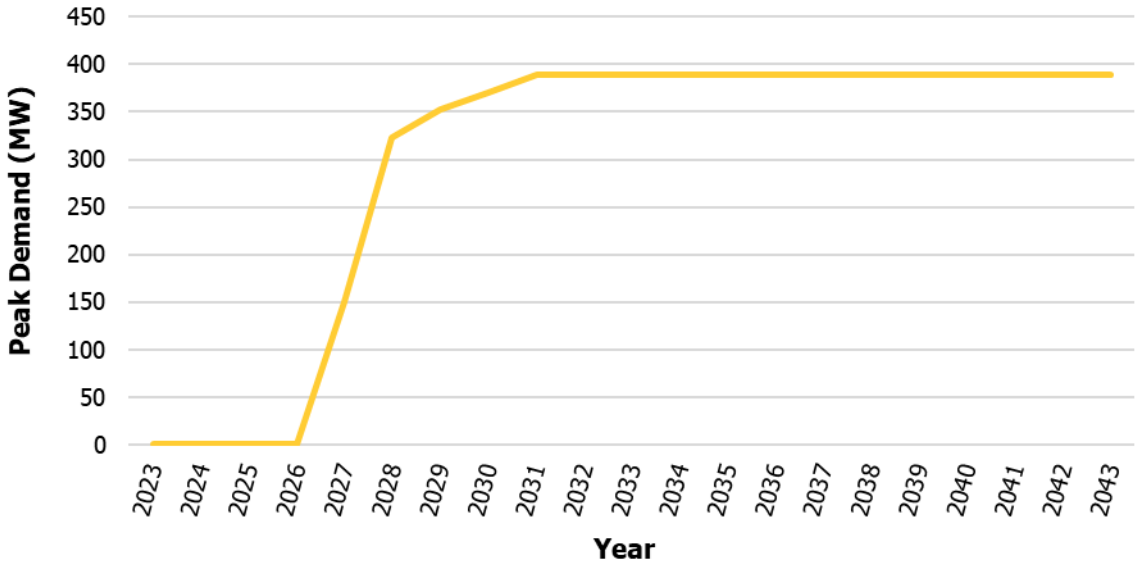


Figure 19 | Map of South Middle Rd Transmission Supply (Highlighted Yellow)

6.3.2. Station and Supply Capacity Needs

The Kingsville-Leamington capacity need is driven by load growth and new greenhouse developments that cannot be accommodated at the existing supply stations. The capacity need starts at 150 MW in 2027 and quickly reaches 390 MW by 2031.

Figure 20 | Kingsville-Leamington Greenhouse Developments Capacity Need

The supply capacity in the Leamington area is measured by the LMC on the Leamington tap – the 230 kV circuits identified as H38 and H39. The current system is limited to 380 MW due to the maximum allowable voltage drop.[20] There is sufficient capacity to supply the existing loads on these circuits, but it is unable to accommodate the 390 MW in additional greenhouse demand.

The supply capacity in the South Middle Rd area, measured by the LMC on the South Middle Rd tap, is limited to 455 MW, also based on maximum allowable voltage drop, assuming the voltage dependent load model. This is limited to 417 MW, based on the station capacity. This is sufficient to supply the two DESN stations at South Middle Rd TS, approximately 410 MW combined for the 2043 winter peak.

6.3.3. High Forecast Needs

Under the High Forecast, the magnitude of the load increases significantly among the total loads in the Kingsville-Leamington area – consisting of Kingsville TS, Leamington TS, South Middle Rd TS, and the new greenhouse developments. Considering the non-coincident peaks of theses loads, the electricity demand forecast increases from 1,400 MW in the Planning Forecast to 2,400 MW.

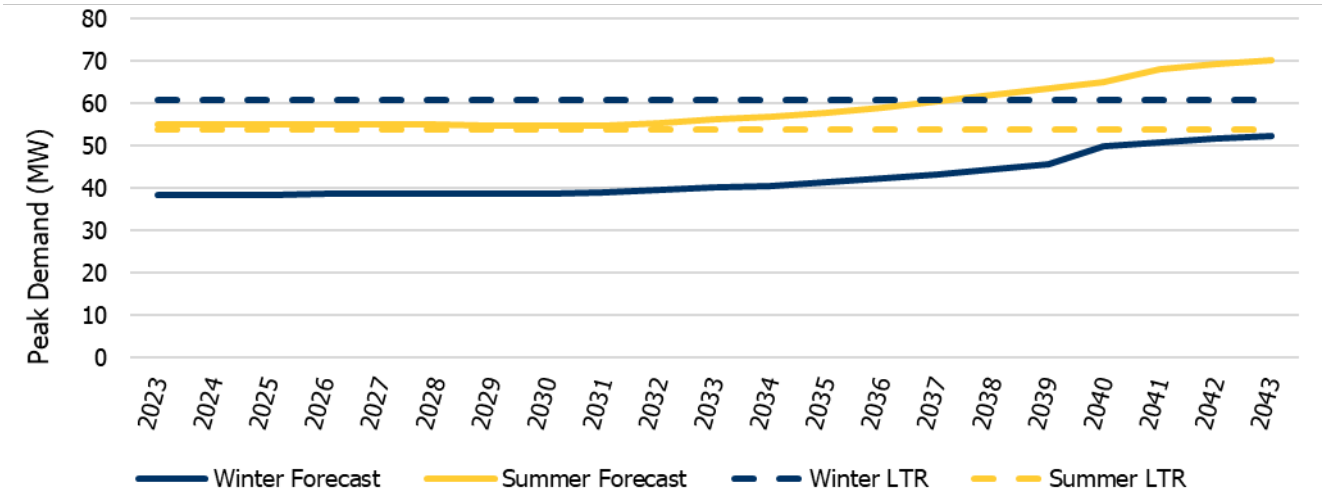
6.4. Lakeshore/Tilbury Sub-system Needs

There are immediate summer station capacity needs at Belle River TS. In the longer term, there are station capacity needs at Tilbury West DS, which emerge in 2036 due to a summer need, but the magnitude of need in 2043 is driven by a winter need. Table 8 summarizes needs for the Lakeshore/Tilbury sub-system.

Table 8 | Summary of Lakeshore/Tilbury Sub-system Needs

Need	Need Date	2043 Need (MW)
Belle River TS station capacity	Immediate	16
Tilbury West DS station capacity[21]	2036	13

6.4.1. Station Capacity Needs



6.4.1.1. Belle River TS Station Capacity Needs

Belle River TS has an immediate summer station capacity need of one megawatt in 2024. Over the forecast period, the summer need increases to 16 MW by 2043. There is no winter need over the forecast period. Figure 21 shows the peak demand forecast relative to the summer and winter LTR values for Belle River TS.

[20] With all elements in service, ORTAC Section 4.3 limits the percentage voltage drop change following a contingency on the transmission system to 10 per cent before tap changer action and 10 per cent after tap changer action.

[21] Need date is driven by summer need but size of need is driven by winter need.

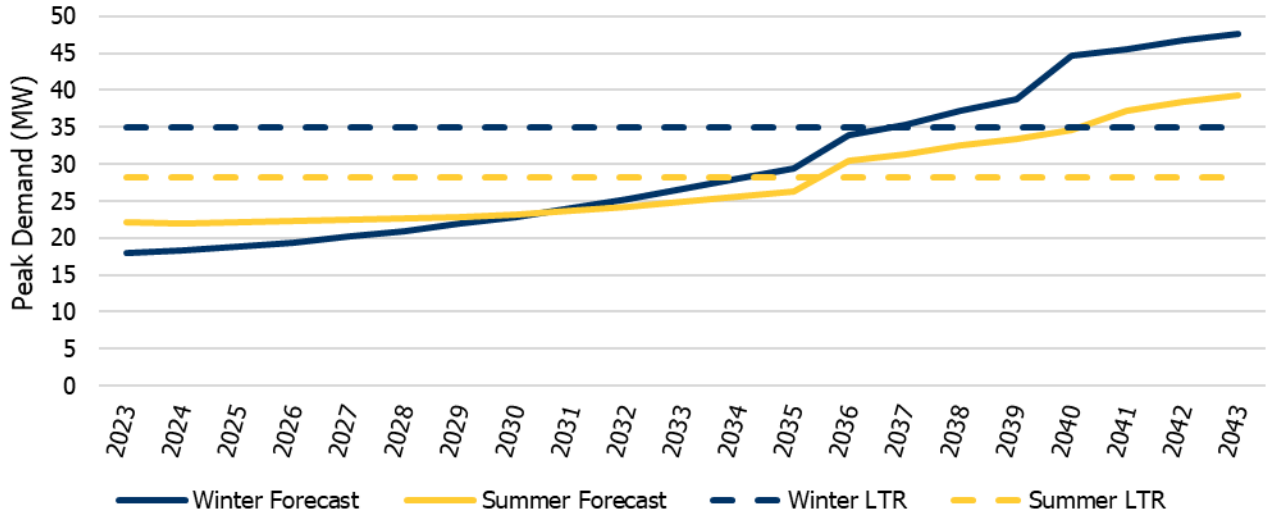


Figure 21 | Belle River TS Station Capacity Need

6.4.1.2. Tilbury West DS Station Capacity Needs

Tilbury West DS has a station capacity need of three megawatts in summer 2036, which increases to 13 MW by winter 2043. Figure 22 shows the Tilbury West DS demand forecast in relation to the summer and winter LTR values.

Figure 22 | Tilbury West DS Demand Forecast

6.5. Operational Issues

Operational issues are not defined as planning needs; however, they affect the reliability and operability of the region. As a result, the Technical Working Group investigates the potential for addressing operational issues using solutions already being considered to meet planning needs, where opportunity for overlap exists. The following operational issues were identified by the Technical Working Group:

- **Kingsville-Leamington Sub-system Load Security:** There is a temporary RAS in place for the Kingsville-Leamington sub-system, known as the Lakeshore RAS. This scheme allows for load connections in advance of the recommended transmission reinforcements coming into service, to continue to enable growth in the interim. However, the RAS impacts reliability in the Kingsville-Leamington sub-system. It is also operationally complex, due to the lack of redundancy and interaction with the Windsor RAS.
- **Lakeshore TS Station Configuration:** There is an operational concern at Lakeshore TS, where a contingency can that introduce low voltage concerns on the downstream circuits. in
- **Lauzon TS Station Configuration:** There is an operational concern at Lauzon TS., where a contingency can result in low voltage concerns, in the area.
- **Lakeshore/Tilbury sub-system Load Security:** There is an under voltage load shedding (UVLS) scheme in place for the Lakeshore/Tilbury sub-system. This sub-system is radially supplied from Lauzon TS, resulting in post-contingency voltage concerns., which is mitigated through the UVLS. As load increases in this sub-system, the reliance on this scheme may increase.

6.6. Supply into Windsor-Essex

The focus of regional planning is to ensure reliable supply within a region. While supply into the region is out of scope of this IRRP, the High Forecast indicates a potential need for additional transmission reinforcement into the Windsor-Essex region in the mid-2030s. The ongoing South and Central Bulk Plan will assess this potential need, while considering the transmission reinforcements and/or network expansion required to support economic development, reduce reliance on emitting resources and enable reliable long-term supply.

6.7. Summary of Identified Needs

6.7.1. Planning Needs

Table 9 provides an overview of all the Planning needs identified in this IRRP.

Table 9 | Summary of Planning Needs in the Windsor-Essex Region

Sub-System	Need	Need Date	2043 Need (MW)
West Essex and Windsor	Lauzon DESN 2 end-of-life	2029	n/a
West Essex and Windsor	Lauzon DESN 2 (T7/T8) station capacity	2032	37
West Essex and Windsor	West Essex and Windsor supply capacity	2032	230
Kingsville-Leamington	Leamington TS load restoration	Immediate	320
Kingsville-Leamington	Kingsville-Leamington Greenhouse Development station and supply capacity	2027	390
Lakeshore/Tilbury	Belle River TS station capacity	Immediate	16
Lakeshore/Tilbury	Tilbury West DS station capacity	2036	13

7. Plan Options and Recommendations

This section describes the options considered and recommendations to address the needs in the Windsor-Essex region. In developing the plan, the Technical Working Group considered a range of integrated options. Considerations in assessing alternatives included maximizing use of existing infrastructure, provincial electricity policy, federal regulations, technical feasibility, cost effectiveness, lead time, local preferences, and consistency with longer-term needs in the area.

Generally speaking, there are two approaches for addressing regional needs:

- Build new transmission or distribution infrastructure. These are commonly referred to as "wire" options and can include things like new transmission lines, autotransformers, step-down transformer stations, voltage control devices, upgrades to existing infrastructure, or distribution-level load transfers. Wire options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate certain reliability concerns.
- Install or implement measures to reduce the net peak demand to maintain loading within the system's existing capability. These are commonly referred to as "Non-Wire" Alternatives (NWAs) and can include things like local utility-scale generation or storage, distributed energy resources (including distribution-connected generation and demand response), or eDSM.

Section 7.1 provides a more in-depth overview of all option types considered in IRRPs. Section 7.2 describes the screening approach used to assess which needs would be best suited for a more detailed assessment for non-wires options. Subsequently, Section 7.3 to Section 7.5 present the options that were ultimately developed and evaluated (including a cost comparison) before the Technical Working Group made a recommendation.

7.1. Non-Wires Analysis Process in IRRPs

Wires options are always considered in regional planning, and while they are always viable options for regional needs, NWAs may be more suitable for specific need types and characteristics. To select and appropriately size non-wire options like generation or battery storage, additional work is required – including the creation of an hourly load profile, as described in Section 5.8. The most suitable technology type and capacity is chosen by examining the "unserved energy" profile, which is the hourly demand above the existing station or system capability The profile indicates the duration, frequency, magnitude, and total energy associated with each need. More details on the NWA process and analysis are provided in Appendix C.

7.1.1. Needs Screening

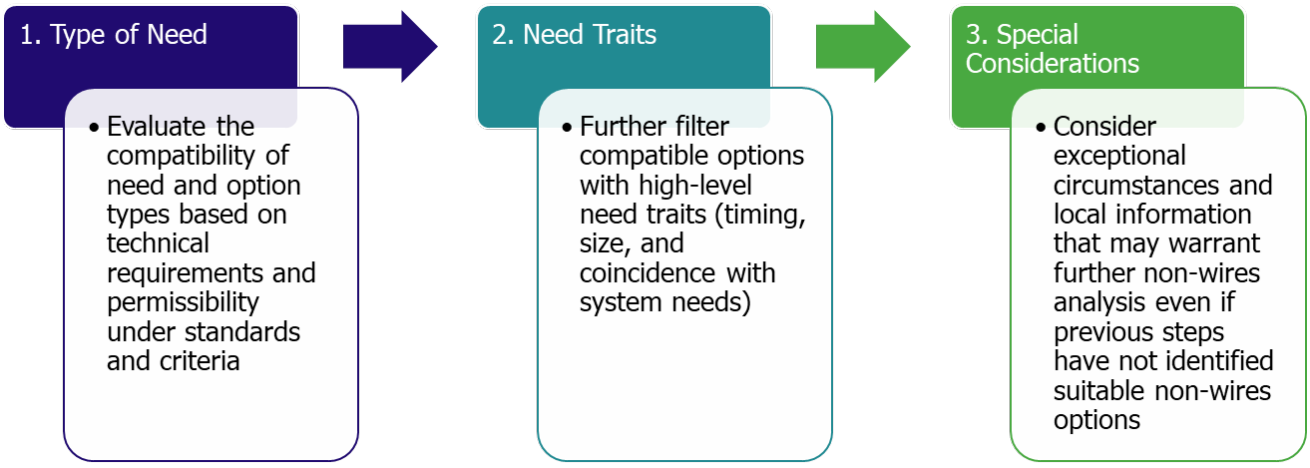
While traditional wires infrastructure is always a viable option for regional needs, NWAs are suitable for specific types of needs, as described in the Integrated Regional Resource Plans: Guide to Assessing Non-Wires Alternatives. An initial screening step is performed to identify which NWAs may be suitable for the type of need addressed.

High-level cost estimates for wire options are based on input provided by the transmitter and transmission benchmark costs. Similarly, cost estimates for non-wire options are based on benchmark capital and operating cost characteristics for each resource type and size. The complete list of assumptions used in the needs screening and options analysis is provided in Appendix F.

New eDSM measures can also help decrease the net electricity demand. Centrally delivered energy efficiency measures under the 2021–2024 Conservation and Demand Management Framework and Save on Energy brand are already included in the load forecast, as discussed in Section 5.5. As part of this framework, the IESO was directed to deliver a new program to address regional and/or local system needs. The Local Initiative Program is now one tool that is available to target the delivery of additional eDSM savings at specific areas of the province with identified system needs. LDCs can also use the Ontario Energy Board's Non-Wires Solutions Guidelines for Electricity Distributors to leverage distribution rates to help address distribution and transmission system needs using NWAs. Generally, incremental eDSM measures are suitable for needs where growth is slow and the magnitude of the overload relative to the total demand is very small (i.e., on the order of few per cent per year). These considerations are discussed further in Section 7.2, as part of the screening of options that was conducted.

Where NWAs are screened in and determined to be feasible, the upfront capital and operating costs for both wire options and NWAs are compiled to generate levelized annual capacity costs (measured in dollars per kW per year). In this scenario, the cash flow of the levelized costs for the options are compared over the lifespan of the wire option and the net present value of these levelized costs is the primary basis through which feasible options are compared. Where NWAs are screened out or determined to be infeasible for meeting the need, overnight capital costs for wire options are used instead.

NWAs are subject to uncertainties in the procurement in terms of both the resource costs bid my proponents and the overall success of the procurement. Pilot or demonstration projects can be explored in cases where other barriers (e.g., regulatory frameworks for cost-sharing and recovery, or operationalization to meet local reliability constraints) impede the adoption of some of these cost-effective options following the completion of the IRRP.



It is important to recognize that there is a significant error margin around cost estimates at the planning stage (from minus 50 per cent on the low side to plus 100 per cent on the high side), as they are only intended to enable comparison between options during the IRRP. The transmitter-led RIP (which is conducted after the IRRP) performs additional detailed analysis and allows the opportunity to refine cost estimates of wire options before implementation work begins. The IESO continues to participate in the Technical Working Group during the RIP and revisits these recommendations if cost estimates differ significantly.

7.2. NWA Screening Results

As explained in Section 7.1, an array of options can be developed to meet local needs during an IRRP, but options are ultimately evaluated to recommend the most cost-effective and technically feasible solution that aligns with stakeholder needs and preferences.

Screening occurs early in the IRRP study after local reliability needs are known but before options analysis. It helps direct time-intensive aspects of detailed NWA analysis (hourly need characterization, options development, financial analysis, and engagement) toward the most promising options. The three-step, high-level approach is shown in Figure 23.

Figure 23 | IRRP Screening Mechanism

The results of the application of the screening mechanism to the Windsor-Essex IRRP needs are summarized in Table 10 and then further described in the sections below. More details on the steps and inputs used in the screening mechanism can be found in Appendix C. The list of assumptions made in the needs screening and option analysis can be found in Appendix F.

Table 10 | Results of the Windsor-Essex IRRP Screening

Sub-system	Need	Options Screened In	Options Screened Out[22]
West Essex and Windsor	Lauzon TS DESN 2 end-of-life and station capacity	Wires options	All NWA options
West Essex and Windsor	West Essex and Windsor supply capacity	Wires options Energy efficiency Transmission-connected generation	Distributed generation Demand response

[22] Since the IESO is mandated to centrally deliver provincial eDSM programs, the incremental eDSM potential is estimated for each need regardless of its ability to meet the need.

Sub-system	Need	Options Screened In	Options Screened Out[22]
Kingsville-Leamington	Kingsville-Leamington Greenhouse Developments station and supply capacity	Wires options Demand response Energy efficiency	Distributed generation Transmission-connected generation
Kingsville-Leamington	Kingsville-Leamington load restoration	Wires options	All NWA Options
Lakeshore/ Tilbury	Belle River TS station capacity	Wires options Energy efficiency Distributed generation	Transmission-connected generation Demand response
Lakeshore/ Tilbury	Tilbury West DS station capacity	Wires options Energy efficiency Distributed generation	Transmission-connected generation Demand response

7.3. West Essex and Windsor Sub-system Evaluation

This section evaluates options to address the asset replacement need and station capacity need at Lauzon DESN 2, and the supply capacity need into the sub-system.

7.3.1. Lauzon TS Asset Replacement and Supply Capacity Needs

As described in Section 6.2, an asset replacement and station capacity need were identified at Lauzon TS DESN 2. These needs at Lauzon TS are evaluated together in this section to consider integrated solutions.

Wires Options

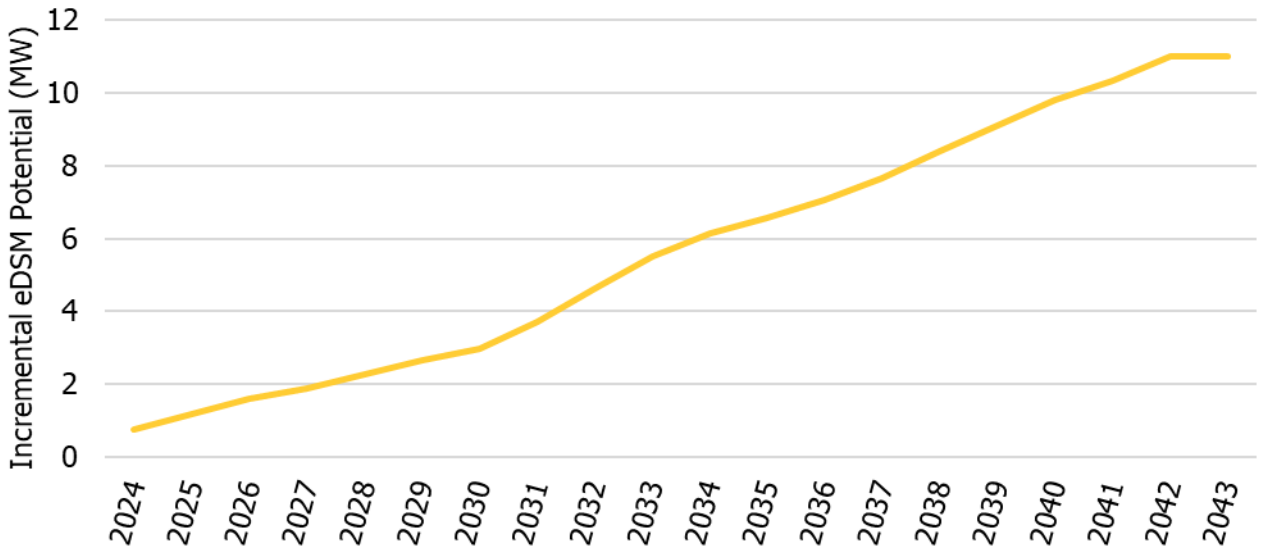
The wires options assessed were:

1. Upsizing the existing transformers at Lauzon TS DESN 2; and
2. Constructing a new DESN at Lauzon TS or connected to the circuits between Lauzon TS and Lakeshore TS.

Out of the two wires options, only option one – upsizing the existing transformers at Lauzon TS DESN 2 – addresses both the asset replacement and station capacity needs at Lauzon TS. In addition, upsizing the DESN from its current LTR of 100 MW to 180 MW would supply the need at Lauzon TS DESN 2 while also facilitating up to 15 MW of load transfers from Belle River TS (see Section 7.5.1). The remainder of the incremental capacity could be used to supply a portion of additional West Essex and Windsor load, depending on where the future loads materialize. The incremental cost of upsizing the transformers at Lauzon DESN 2, relative to a like-for-like replacement, is estimated to be between $15–30M.

Option two could address the Lauzon TS DESN 2 station capacity need by providing 180 MW of additional capacity but would not address the asset replacement need. The estimated cost of option

two is $60M, which is substantially higher than option one, since it does not take advantage of the end-of-life sustainment.



Non-wires Options

Since a cost-effective, integrated solution to address both needs is possible, all NWAs were screened out. However, since energy efficiency is important in managing demand in Ontario, the incremental eDSM potential for Lauzon TS DESN 2 was estimated. EDSM plays a key role in maximizing the useful life of existing infrastructure and maintaining reliable supply. The IESO is mandated to centrally deliver province-wide eDSM programs for Ontario that target businesses, residential customers, and First Nations communities. The IESO offers incentives and rebates to electricity customers through a suite of Save On Energy programs, which provide a valuable and cost-effective system resource that helps customers better manage their energy costs.

While eDSM does not address the asset replacement need, it could be used to meet approximately 11 MW of the 40 MW need at Lauzon TS, as shown in Figure 24. The eDSM can be targeted to Lauzon TS DESN 2 customers using regional adders to encourage uptake in areas where transmission constraints exist, as well as targeted local programming, both of which are delivered by the IESO through the Save On Energy brand. The cost of eDSM is estimated to be $50M; however, this was assumed to be cost-effective to the system, meaning that there is a net benefit when comparing the program investment (cost) against the provincial average avoided costs of providing electricity (benefit).

There are other potential benefits to NWAs, such as customer cost savings, maximizing the utilization of the existing electricity system, and reducing GHG emissions. As some of these other objectives may align with municipal energy plans in the region, this may be useful input for identifying the potential for projects and strategies at the local level, while identifying where electrical system benefits and infrastructure deferral value may also exist.

Figure 24 | Estimated Incremental eDSM Potential for Lauzon TS DESN 2

Long-term Considerations

Going forward, the need for additional transformation at Lauzon TS should be monitored. Under the High Forecast, other stations in the West Essex and Windsor sub-system – namely Keith TS and Malden TS – are forecast to develop station capacity needs. Monitoring load growth and implementing eDSM programs across the West Essex and Windsor sub-system will help to ensure that the electricity system is able to reliably meet future needs.

Recommendations

Based on the Technical Working Group's analysis of the options to address the Planning Forecast, it is recommended to upsize the transformers at Lauzon TS DESN 2 to 180 MW LTR to meet both the asset replacement need and station capacity need at Lauzon TS.

This solution also facilitates load transfers from Belle River TS and can be used to serve new industrial developments in the area. The Technical Working Group should also monitor load growth across other stations in the sub-system.

7.3.2. West Essex and Windsor Supply Capacity Need

As presented in Section 6.2, there is a supply capacity need to the West Essex and Windsor sub-system.

Wires Options

To address the supply capacity needs of the West Essex and Windsor sub-system, transmission expansion options were evaluated. Two electrical pathways for additional transmission into the sub-system were considered: Lakeshore TS to Lauzon TS and Lakeshore TS to Keith TS. Transmission options focused on the path from Lakeshore TS to Lauzon TS, based on the location of the thermal limitation identified. The length of this transmission path is 32 km. This path is also identified in the non-wires options analysis as limiting the ability to connect large amounts of generation. Thus, options to reinforce this path would address the supply capacity need and improve deliverability at the same time. The option of reinforcing the existing transmission line to Lauzon TS, instead of constructing a new line, was also considered, but this option was ultimately rejected, since it would not provide sufficient capacity to meet the need.

The following wires options were evaluated:

1. A single-circuit 230 kV line from Lakeshore TS to Lauzon TS;
2. A double-circuit 230 kV line from Lakeshore TS to Lauzon TS; and
3. A single-circuit 500 kV line from Lakeshore TS to Lauzon TS.

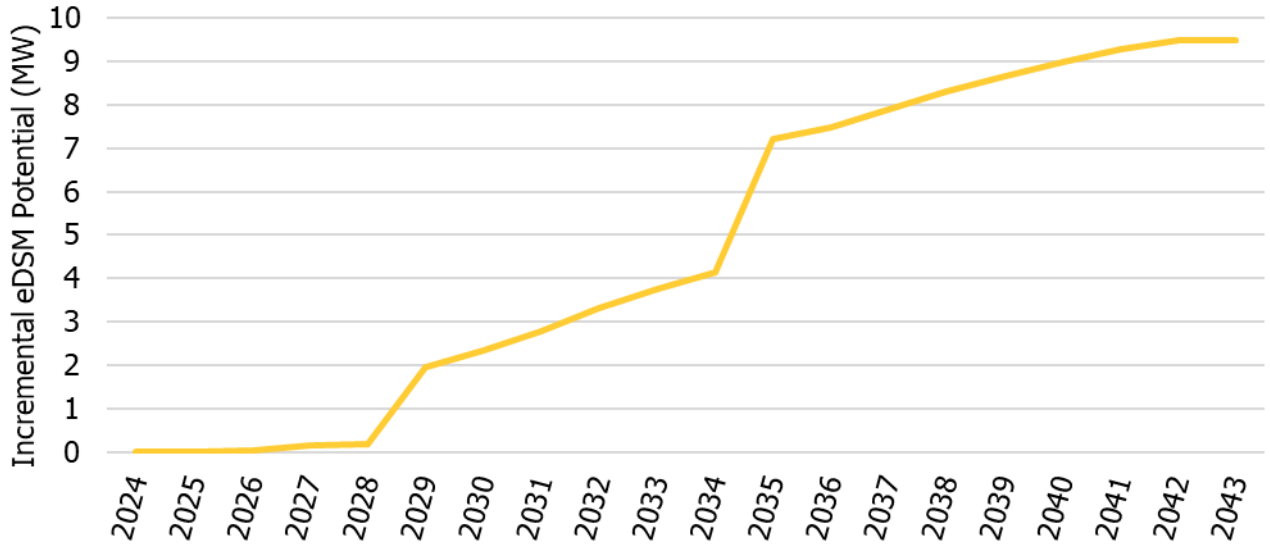
For option one, the single-circuit 230 kV transmission line would increase the transfer capability by 360 MW, which can address the Planning Forecast need and account for changes in generation supply. Based on preliminary estimates, this option is expected to cost $120M. This option falls within the scope of the Minister of Energy's existing direction that Hydro One Transmission (Order in Council 875/2022) develop and seek approvals for "a new 230 kV transmission line that connects the

Windsor area to the Lakeshore Transformer Station, including associated station facility expansions or upgrades required at the terminal stations.". In addition, it can facilitate more connections at Lauzon TS and along the entire transmission corridor from Lakeshore TS.

For option two, the double-circuit 230 kV line increases the transfer capability by 510 MW, which addresses the Planning Forecast need and would help to serve additional loads beyond the Planning Forecast (e.g., if the High Forecast were to materialize). This option would also fall under the scope of existing direction to Hydro One Transmission (Order in Council 875/2022). This option is expected to cost between $235M but has additional benefits on top of the higher supply capability. The double-circuit option has the added benefit of providing improved redundancy and reliability, by allowing for outages to occur while still having one of the two circuits in-service to maintain supply. In addition, the connection of a double-circuit line at Lauzon TS would provide the opportunity to strategically locate the two termination points at the station to address some of the existing operational concerns at Lauzon TS identified in Section 6.5.

For option three, the 500 kV transmission line provides a comparable amount of transfer capability as option two, but is more expensive – estimated to cost between $350M. This is driven by the cost of higher voltage equipment, as well as the need to build a new 500 kV station with new autotransformers. Option three also limits new load connections to Lauzon TS instead of facilitating the growth along the entire corridor. Since the 500 kV transmission network is the backbone of the electricity system, the ability to connect directly to it is restricted. In addition, this option would essentially lock-in further load growth as needing to connect to Lauzon TS, limiting the location of economic development across the West Essex and Windsor sub-system. This option would also be beyond the scope of Order in Council 875/2022, potentially compounding the longer lead times assumed for a 500 kV transmission project.

Non-wires Options



Due to the large magnitude of the West Essex and Windsor supply capacity, eDSM, demand response, and DG were not found to be adequate to resolve the needs. However, eDSM was considered as a cost-effective way to address near-term load growth. Thus, for the West Essex and Windsor supply capacity need, the following non-wires options were assessed:

1. eDSM; and
2. Transmission-connected generation at Lauzon TS.

As shown in Figure 25, eDSM can only provide 9 MW of the 230 MW need but can be used to support growth across the West Essex and Windsor sub-system at a cost of $35M, which is cost effective relative to system benefits. The IESO recently received an increased level of funding to support industrial energy efficiency.[23] The eDSM can be targeted to West Essex and Windsor customers using regional adders to encourage uptake in areas where transmission constraints exist, as well as targeted local programming delivered by the IESO through the Save On Energy brand.

[23] IESO Receives Natural Resources Canada Funding for Industrial Energy Efficiency

Figure 25 | Estimated Incremental eDSM Potential for West Essex and Windsor Industrial Developments

Transmission-connected generation options were sized to meet the need profile of 230 MW peak demand, 20 hours of maximum continuous energy, and 100,000 megawatt-hours (MWh) of maximum continuous energy. The following generation options were identified as meeting the need profile:

- 1,000 MW of wind with 270 MW / 2,700 MWh of Battery Energy Storage System (BESS); and
- 400 MW of solar with 220 MW / 1200 MWh of BESS.

A solar-only option was considered but did not meet the adequacy criteria to be able to meet the duration of the need from 2040 onwards. A wind-only solution was screened out due to the size of the summer need, a BESS-only solution was screened out due to the duration of the need, and implementation of a small modular reactor was screened out based on the size of the need and load characteristics. The combination of wind, solar, and BESS was considered, but this combination did not require any wind generation to meet the need.

Given the size of the resources needed to meet the need profile, all three transmission-connected generation options exceeded the connection capacity of the H53Z and H54Z circuits, and were, therefore, technically infeasible. They also require significant land-use in an urban area (ranging from 1,400 to 34,000 hectares), which would also limit space for economic development.

Long-term Considerations

The High Forecast indicates the need for additional supply into the West Essex and Windsor sub-region. If additional transmission is required, the termination of the transmission supply would depend on the location of economic development in the area. Options include expanding to existing stations in the area (Lauzon TS or Keith TS), or building a new station optimally located to supply multiple pockets of growth.

Options were considered to adapt the 230 kV wires options (options one or two), so that additional supply capacity could be available along the same infrastructure. One way would be to construct the

option with 500 kV towers, so that the circuit(s) could be converted to the higher voltage in future, by replacing the conductors and insulators. However, this would restrict where load growth in West Essex and Windsor could occur, by concentrating supply transfer at Lauzon TS. Another possibility would be to construct half of the 230 kV wires option with 500 kV equipment, but operate it at the lower voltage until the optimal termination of the 500 kV circuit within West Essex and Windsor could be determined. However, these variations are cost prohibitive. In addition, it will be difficult to convert the line from 230 kV to 500 kV after it is in-service. The conversion would take an extended period of time, which would interrupt supply to a significant portion of existing loads in West Essex and Windsor for an unacceptable amount of time. This introduces the risk of increasing the upfront cost, overbuilding, and stranding assets in the future.

Future growth in the area beyond the Planning Forecast could be supported by additional transmission supply, but would need to consider any potential land limitations. The West Essex and Windsor sub-system – and the City of Windsor in particular – is prone to flooding and severe weather events. Surrounded by three bodies of water – Lake Erie, Lake St. Clair, and the Detroit River – the City of Windsor is known as one of Ontario's most flood-prone areas. Over the past decade, the city's low flood plain, along with an increase in the frequency of severe weather events, has contributed to a spike in major water damage for the region. These issues are expected to exacerbate further due to climate change. There is value in conducting a corridor study to consider diversification of supply, enable load and generation resources in the region, and provide redundancy between transmission pathways and station locations.

Recommendations

To meet the supply capacity need and support future growth in the area, it is recommended to build a new double-circuit 230 kV line from Lakeshore TS to Lauzon TS. Depending on the design and environmental assessment process, there may be an opportunity to integrate this solution with the recommendation for the Kingsville-Leamington sub-system. Furthermore, additional eDSM programs targeting the West Essex and Windsor sub-system are recommended.

According to the High Forecast, further transmission line reinforcements or local generation in West Essex and Windsor may be needed to enable additional industrial load growth. Due to land restrictions and uncertainty of load growth locations, a corridor study could help identify potential paths for transmission supply into the West Essex and Windsor area that best supply growth across the sub-system.

The Technical Working Group also recommends that a corridor study should be conducted to identify potential transmission paths into the sub-system to position the system to more quickly respond when higher growth materializes.

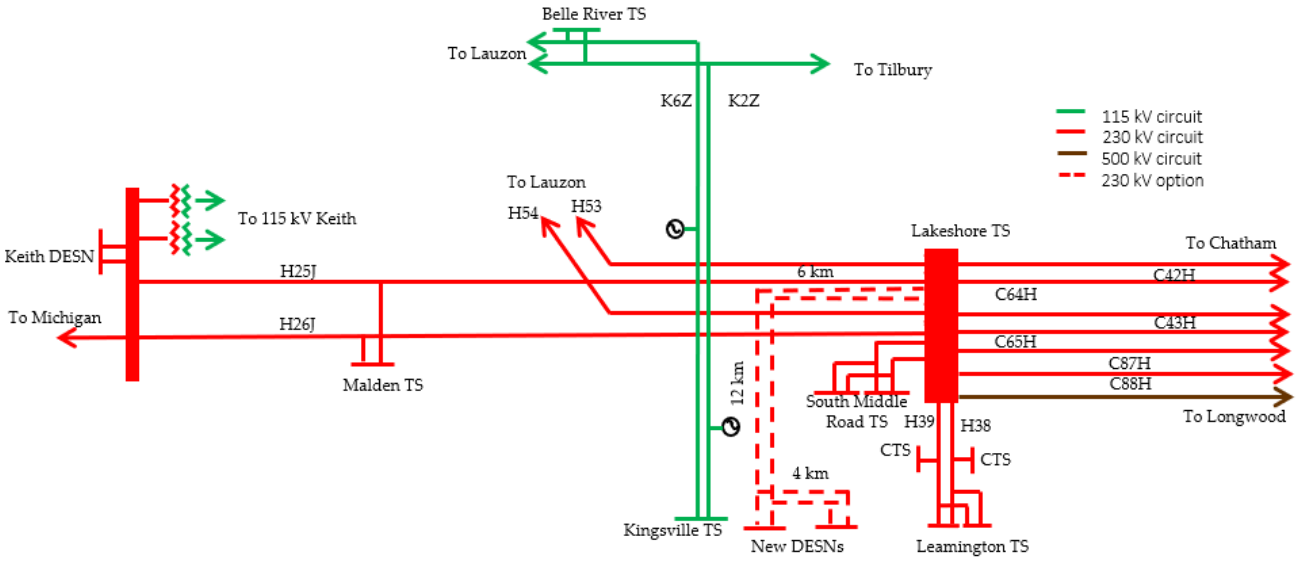
7.4. Kingsville-Leamington Sub-system Evaluation

This section evaluates options to address the station capacity, supply capacity and load restoration needs in the sub-system.

7.4.1. Kingsville-Leamington Greenhouse Development Station and Supply Capacity Needs

As described in Section 6.3, station and supply capacity needs were identified for the Kingsville-Leamington greenhouse loads. Options to address these needs are evaluated together in this section.

Interim Solution – Operational Measures



As discussed in Section 6.3.1.1, capacity needs are being addressed using the Lakeshore RAS in the interim, until the previously recommended bulk transmission reinforcements come in-service. Once the transmission reinforcements come into service over the 2028 to 2030 period, the Lakeshore RAS will no longer be needed to address the load security needs. By making the Lakeshore RAS redundant in the interim, the magnitude of loads potentially subject to the lower level of reliability is reduced.

As an interim solution, it is recommended that Hydro One Transmission explore options to modify the design of the Lakeshore RAS to make this operational measure more redundant and improve the near-term reliability in the Kingsville-Leamington sub-system.

Wires Options

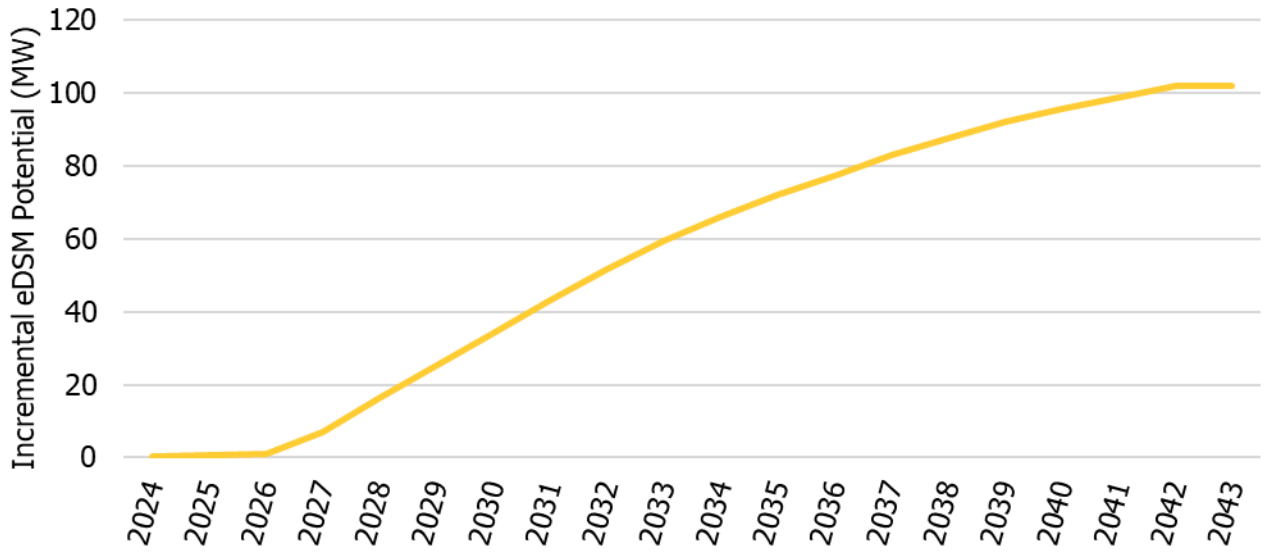
The Technical Working Group evaluated the transmission wire option, which was previously recommended in the 2022 Windsor-Essex Addendum – to construct a new radial double-circuit 230 kV line from Lakeshore TS, connecting to two new DESNs. The locations of the DESNs have been estimated based on best available information from Hydro One Distribution, which may be updated during the RIP or subsequent design and environmental assessment work. Thus, the assumed length of the radial line is 22 km, comprising 18 km to the first DESN and 4 km to the second DESN. Figure 26 depicts the single line diagram of this option.

Figure 26 | Configuration of Option for New 230 kV TS and Connection Lines

This option fully addresses the sub-system's station capacity and supply capacity needs. It is expected to cost $210M, with an estimated implementation time between four and five years. This option facilitates both load and generation connections in the Kingsville-Leamington sub-system and allows offloading of the existing Kingsville TS.

This option also provides integration with other needs across the region. It will allow for Kingsville TS to be offloaded via distribution transfers, relieving the 115 kV network limitation discussed in Section 7.5. It provides additional connection capacity for greenhouse load, broader growth in the area and DG, which is otherwise limited in the sub-system. The wires option also enables the load restoration solution, as described in Section 7.4.2. Finally, it is possible that a portion of the transmission pathway for this option can be integrated with the recommended solution for addressing the West Essex and Windsor supply capacity (see Section 7.3.2). Depending on the subsequent design and environmental assessment process, there could be a portion of transmission line shared between these two recommendations west of Lakeshore TS, which would split into two separate paths– one toward Kingsville-Leamington and one toward Lauzon TS. The combined solution would optimize the use of the transmission infrastructure and provide further integration in the Windsor-Essex region.

The Technical Working Group also evaluated the possibility of using the existing radial supply lines to serve the load. However, the remaining capacity on these circuits is insufficient to meet the Planning Forecast. This approach would also exacerbate the existing load restoration concerns and would be limited by the length of the H75/H76 tap, as well as the physical constraints for expansion on the H38/H39 tap.



Non-wires Options

As presented in Section 7.2, the following non-wires options were screened in:

1. Energy efficiency (eDSM); and
2. Demand response.

Under the existing eDSM framework and programs primarily targeting greenhouses, up to 100 MW of the total 390 MW winter need can be addressed. The expected cost of achieving the full 100 MW of peak demand savings is $330M. As covered in Section 7.3, eDSM is important for managing demand in Ontario and plays a key role in maximizing the useful life of existing infrastructure and maintaining reliable supply. In the Kingsville-Leamington area, eDSM savings are primarily achieved through programs targeting greenhouse grow lights and greenhouse envelope improvements, which have a substantial impact in winter months (see Appendix E for more details).

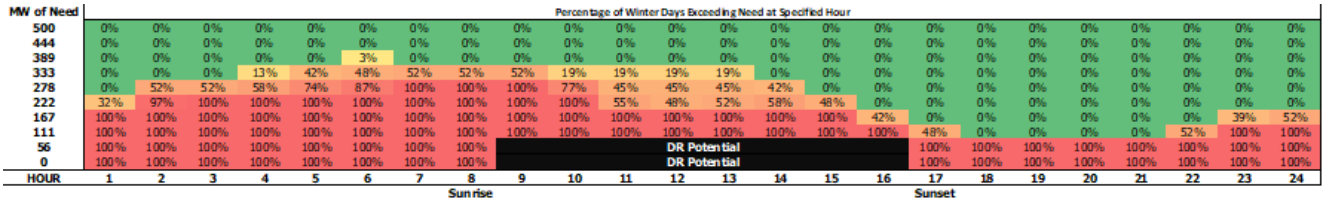


Figure 27 | Estimated Incremental eDSM Potential of Kingsville-Leamington Greenhouse Loads

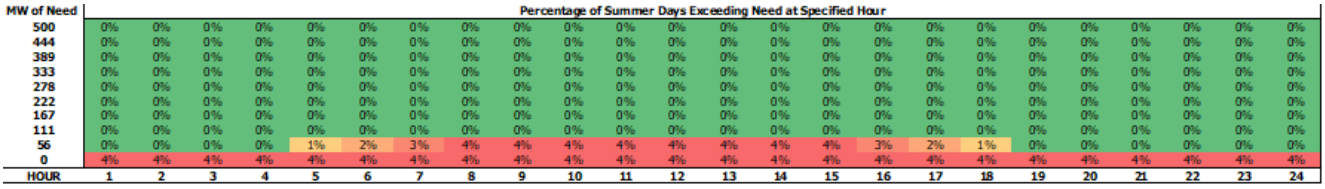
Demand response is an option to address the Kingsville-Leamington station capacity and supply capacity needs. However, a new local program would be required, since the local need profile is not aligned with the design of the provincial procurement. This would require its own procurement process and a unique, local activation system. It is expected that such a program would take two to three years to implement. While there are no cost benchmarks for this type of solution, it is expected that a demand response solution would be more expensive than leveraging the existing eDSM framework and programs in the area.



Demand response among the greenhouse loads in the Kingsville-Leamington sub-system would be feasible through use of a third-party aggregator to allow participation of all the loads in the area. Greenhouses could participate in demand response by reducing the use of grow lights during the daytime in winter months. Based on information provided by OGVG, the potential greenhouse peak demand reduction is in the order of tens of megawatts during winter daytime periods. Figure 28 shows the heat map of the hourly winter need for December 2043, overlaid with the expected magnitude and timing of demand response ("DR Potential"). Figure 29 shows the 2043 hourly summer need, represented by July. No greenhouse demand response was indicated to be possible in the summer.

As shown in these heat maps, the winter need peaks between 5 AM and 6 AM, whereas the demand response potential is available between 8 AM and 4 PM. Furthermore, the winter need persists 24 hours per day, which does not align with a demand response program's ability to deliver short-term capacity relief. Finally, while the magnitude of need in the Kingsville-Leamington sub-system is greatest in winter, a summer need persists which would not be addressed by the demand response option.

Long-term Considerations

The High Forecast indicates additional station capacity needs in the Kingsville-Leamington sub-system, if agricultural load growth in the region accelerates. Up to six additional supply stations would be required to meet the 930 MW of additional greenhouse growth in the High Forecast. The placement of these supply stations would be sited depending on the location of the growth. It is also possible that some of the growth materializes within southwestern Ontario but would be situated outside of the Windsor-Essex region. Should higher growth occur within the Windsor-Essex region, supply connection lines to the upstream 230 kV corridor, as well as connections between the existing supply stations, will be required to enable this capacity. The Technical Working Group will continue to monitor growth to enable the required supply stations and connections as required.

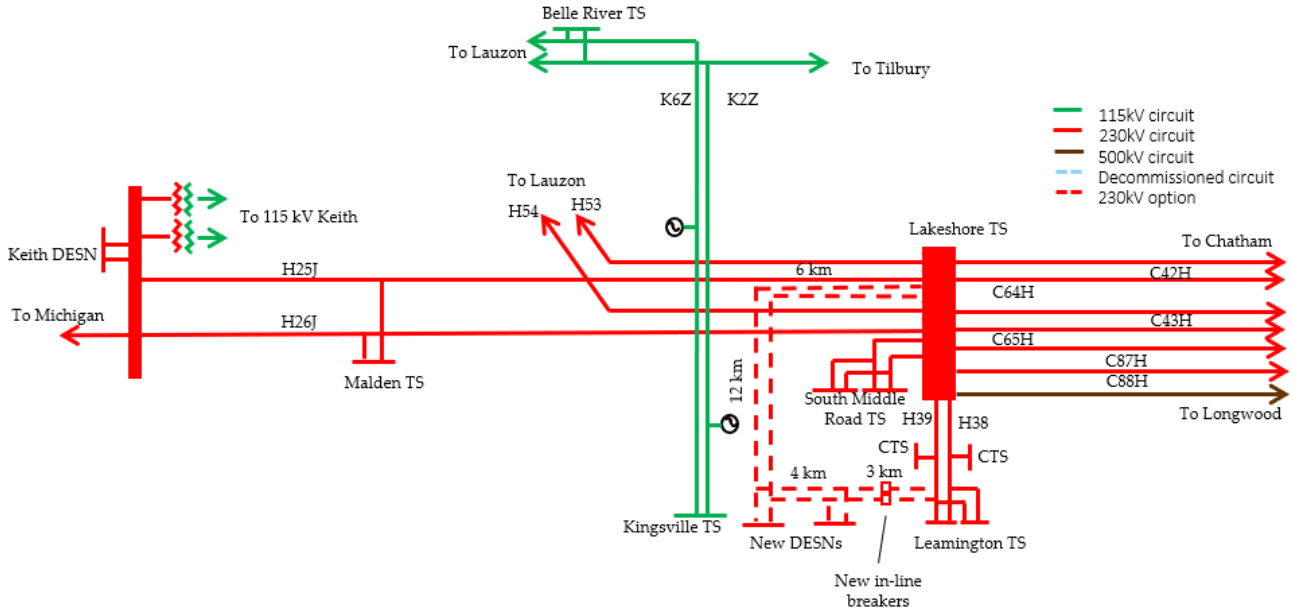
Recommendations

The recommended option to address the station capacity, supply capacity, and load restoration is the integrated wires option of a 22 km double-circuit 230 kV transmission line from Lakeshore TS serving two new transformer stations in the Kingsville-Leamington area.

This solution is depicted in Figure 26. Depending on the design and environmental assessment process, there may be an opportunity to integrate this solution with the recommendation for the West Essex and Windsor sub-system.

It is recommended to continue the existing eDSM programs in the Kingsville-Leamington area to increase capacity in the sub-system and provide broader system benefits.

Considering the uncertainty among the forecast drivers in the region and the potential for increased eDSM targets under the new 2025-2036 eDSM Framework, the Technical Working Group will continue to monitor growth in the region to determine whether sector trends and connection requests indicate a need for development beyond the Planning Forecast.



7.4.2. Leamington TS Load Restoration and Security Needs

The load restoration need for the supply circuits toward Leamington TS is evaluated in this section. As discussed in Section 6.3.1.1, load security will be addressed by ongoing transmission reinforcements in the area; thus, no load security needs are identified in this sub-system.

Wires Options

Figure 30 shows the integrated wires option to address the load restoration need – a double-circuit 230 kV transmission line connecting the existing H39/H39 circuits with the wires solution to address the station capacity and supply capacity needs in the sub-system. Under the Planning Forecast scenario, in-line breakers would be required in a normally open position to operate the load restoration lines. This provides a benefit to the broader Kingsville-Leamington sub-system, since the solution provides improved flexibility to restore supply to loads under a variety of outages and contingencies. However, under specific outage scenarios (e.g., peak winter load), not all customers will be restored. Since the specific loads that can be restored cannot be guaranteed, there is a broader benefit to this option for all load in the sub-system.

Figure 30 | Integrated Solution to Address Kingsville-Leamington Station Capacity, Supply Capacity, and Load Restoration Needs

The pathway and length of the load restoration lines are subject to future design work and the environmental assessment process. Based on best available information from Hydro One Distribution regarding the expected location of new DESNs, the load restoration lines are estimated to be three kilometres long. The portion of the integrated solution addressing the load restoration needs in the Kingsville-Leamington sub-system is expected to cost $30M.

Non-wires Options

Due to the nature of planning criteria outlined in ORTAC 7.2, non-wires options such as eDSM, demand response, and DG cannot be applied to load restoration needs because they do not restore the connection of loads to the bulk transmission system. Thus, non-wires options are infeasible for load restoration needs. However, as noted in the 2022 Windsor-Essex IRRP Addendum study, there may be value in pilot projects or other demonstration projects to help meet the sub-systems load restoration needs using NWAs – in addition to constructing the load restoration line.

Long-term Considerations

The projected load flows under the Planning Forecast require that the load restoration lines are operated with normally open in-line breakers. However, the High Forecast indicates the potential need for additional supply stations and lines in the Kingsville-Leamington sub-system. In this scenario, the optimal configuration would be to convert the radial supply lines into a transmission loop. This would require unique connections to the upstream transmission system on either end of the supply lines (i.e., at Lakeshore TS and another supply station west or east of Lakeshore TS, depending on the location of additional growth in this area). This would support new supply stations, allow for redundant supply, and address the load restoration needs. There may be opportunities to integrate this with the High Forecast transmission options for the West Essex and Windsor sub-system, if both paths are aligned.

Recommendations

The recommended option to address the load restoration need is the integrated wires option: the 3 km double-circuit 230 kV transmission line connecting the existing H39/H39 circuits to the new supply stations and connection lines recommended in the previous section, as shown in Figure 30.

7.5. Lakeshore/Tilbury Sub-system Evaluation

The station capacity needs at Belle River TS and Tilbury West DS are evaluated in this section.

7.5.1. Belle River TS Station Capacity Need

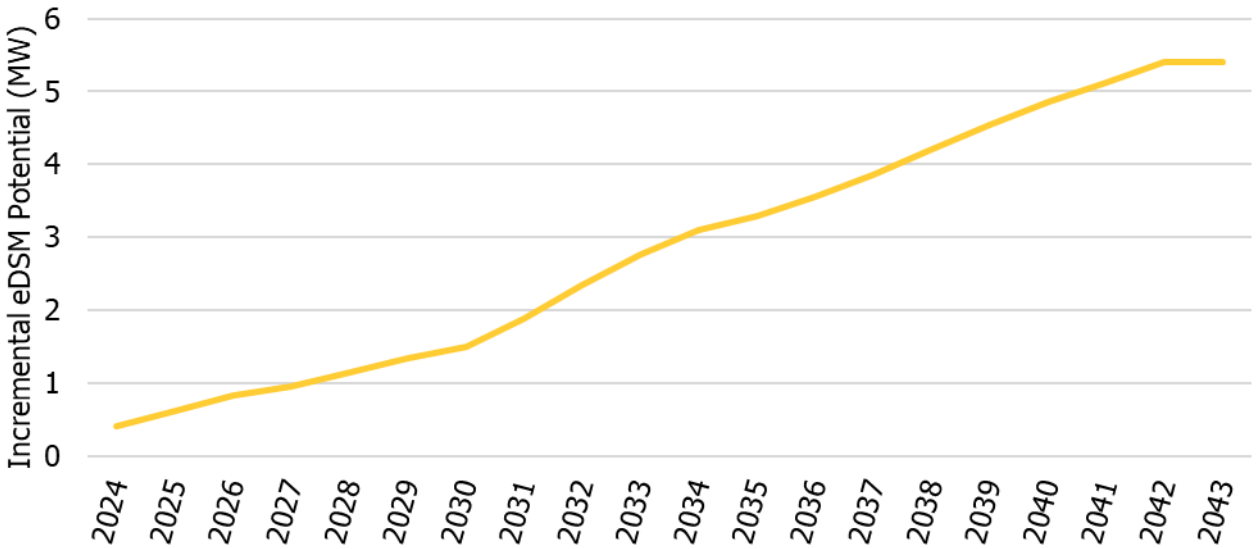
As described in Section 6.4.1, a station capacity need was identified at Belle River TS. This section evaluates the wires and non-wires options to address that need.

Wires Options

For the Belle River TS station capacity need, the following wires options were evaluated:

1. Load transfers on the distribution system;
2. Upsize transformers at Belle River TS; and
3. New DESN at Belle River TS.

Option one is to leverage capacity on the existing transmission system to transfer load from Belle River TS to nearby stations, namely Lauzon TS DESN 1 and DESN 2. The planned upsizing of Lauzon TS DESN 1 from 100 MW to 180 MW LTR in 2025 will enable load transfers on the distribution system from Belle River TS to Lauzon DESN 1 to meet some of the station capacity need. Similarly, the recommended solution to address the end-of-life and station capacity need of Lauzon TS DESN 2 will also result in upsized transformers, which will enable additional load transfers on the distribution system to fully meet the Belle River TS station capacity need. This solution is expected to cost between $10M and $15M to implement. The load transfers are expected to take place between 2026 and 2031, considering the timing of upsizing Lauzon DESN 1 in 2025 and Lauzon DESN 2 in 2029.



Option two is to upsize the DESN at Belle River TS from 53 MW LTR to 100 MW LTR, which is estimated to cost between $15M and $30M. Option three is to construct a new 100 MW LTR DESN at Belle River TS, which is estimated to cost $60M. Both options two and three are expected to take between three and five years. These options also provide additional capacity beyond the Belle River TS need; however, this capacity cannot be utilized due to upstream capacity limitations.

Non-wires Options

New eDSM programs in the area could meet 5 MW of the 17 MW need over the 20-year period, as illustrated in Figure 31. The estimated cost of achieving these eDSM savings is $18M, which is considered cost effective to the system. However, previous eDSM programs targeting loads at Belle River TS have had less than expected impact, reflecting challenges targeting programs to relatively

small areas and predominantly residential load composition. Consequently, there is a higher level of uncertainty with this option.

Figure 31 | Estimated Incremental eDSM Potential for Belle River TS

Long-term Considerations

Load growth beyond the Planning Forecast may require additional supply to the Lakeshore/Tilbury 115 kV sub-system. Options for increasing future supply in the region include new 115 kV circuits, a 230 kV conversion, or new 230 kV supply, depending on the level of growth anticipated and the cost effectiveness of these solutions to meet the projected need. Long-term considerations in the Lakeshore/Tilbury sub-system are also interrelated with options to supply the Kingsville-Leamington sub-system, since options to offload Kingsville TS loads onto the 230 kV system could alleviate supply concerns on the 115 kV system.

Recommendations

In the interim, operational measures, such as loading the transformer beyond its LTR, can be used to manage this need until the wires solution is in place.

In the near term, the recommendation to address the Belle River TS station capacity need is to transfer load through the distribution system to the upsized Lauzon TS DESN1 and DESN2 by 2031. This work may commence after Lauzon TS DESN1 has been upsized in 2025, but is expected to take an additional one to two years to complete after Lauzon TS DESN2 has been upsized in 2029.

7.5.2. Tilbury West DS Station Capacity Need

As described in Section 6.4.1, a station capacity need was identified at Tilbury West DS. This section evaluates the wires and non-wires options to address that need.

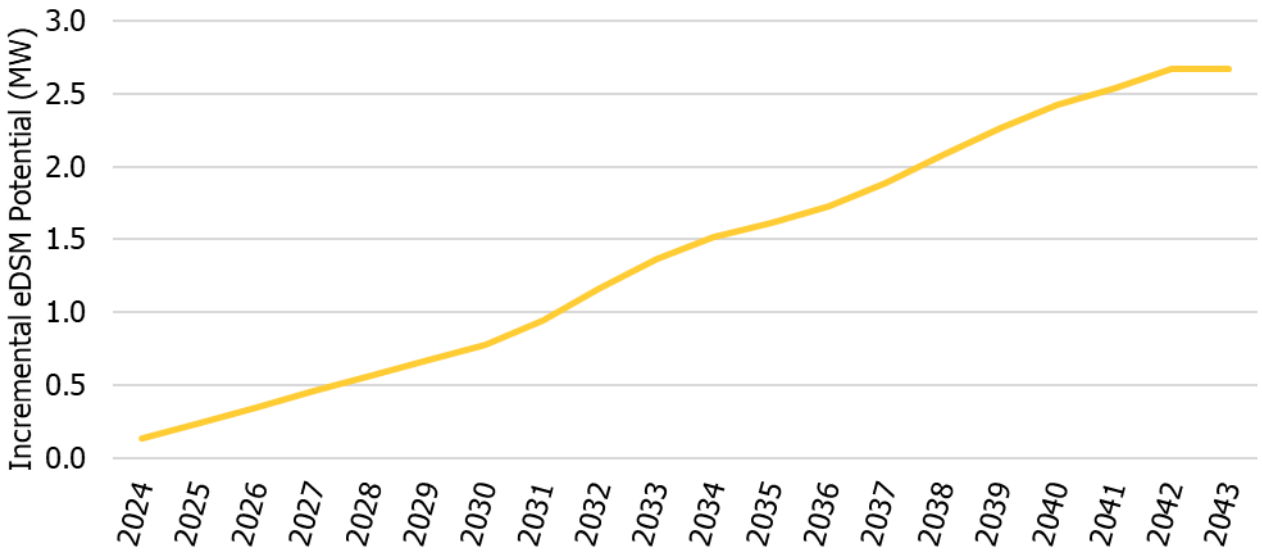
Wires Options

To meet the Tilbury West DS station capacity need, load transfers are not feasible since load could only be transferred to Belle River TS, which already has a capacity need. The remaining wires options assessed are:

1. Upsize transformers at Tilbury West DS; and
2. New DESN at Tilbury West DS.

For option one, upsizing the transformers at Tilbury West DS would increase the summer LTR from 28 MW to 53 MW. This is estimated to cost between $15M and $30M and take three to five years to implement. This option also improves reliability and resiliency in the area by increasing the capability to transfer load on the distribution system in the event of an outage.

Option two is a new 100 MW LTR DESN. This is more expensive than option one. It is estimated to cost $60M and would take the same amount of time as option one to implement. This option was determined to be infeasible, since upstream limitations would mean that this capacity cannot be fully utilized and would be a stranded asset.



Non-wires Options

For Tilbury West DS, the following non-wires options were assessed:

1. eDSM; and
2. DG.

eDSM programs targeting load supplied by Tilbury West DS could meet 3 MW of the 13 MW need over the 20-year period, as illustrated in Figure 32. The eDSM can be targeted to Tilbury West DS customers using regional adders to encourage uptake in areas where transmission constraints exist, as well as targeted local programming delivered by the IESO through the Save On Energy brand. The estimated cost of achieving these eDSM savings is $8M, which is considered cost effective to the system.

Figure 32 | Estimated Incremental eDSM Potential for Tilbury West DS

By 2043, the need profile for Tilbury West DS peaks at 13 MW, requires 91 hours of maximum continuous demand, and approximately 600 MWh of maximum continuous energy supplied. Based on the characterization of the need, the following DG solutions were screened in:

- Combined wind and BESS solution;
- Combined solar and BESS solution; and
- Combined solar, wind, and BESS solution.

Wind as a standalone option was screened out due to the land requirements combined with the maximum continuous hours of need. Solar as a standalone option was screened out since it could not meet the winter and overnight needs. BESS as a standalone solution was screened out based on the continuous hours of the need and magnitude of energy for these hours. Small modular reactors were screened out, since the need size does not warrant this type of technology.

Among the screened-in generation options, the following solutions were sized to meet the need:

- 22 MW of wind and 26 MW / 250 MWh of BESS;
- 60 MW of solar and 26 MW / 250 MWh of BESS; and
- 20 MW of wind, 8 MW of solar, and 24 MW / 230 MWh of BESS.

All three DG options exceed the DG connection capacity at Tilbury West DS, which currently has a thermal capacity limit of 19 MW. Furthermore, there are connection restrictions downstream of the 115 kV K2Z circuit due to inverter-based resource limitations, as well as the fact that this circuit has a limited ability to deliver resources to the rest of the province. In particular, Tilbury West DS has a low short-circuit ratio, which limits its capability to connect new inverter-based resources. In addition, these options have a large land requirement of between 200 and 770 hectares. If these solutions were feasible, they would be expected to take between four to six years to implement.

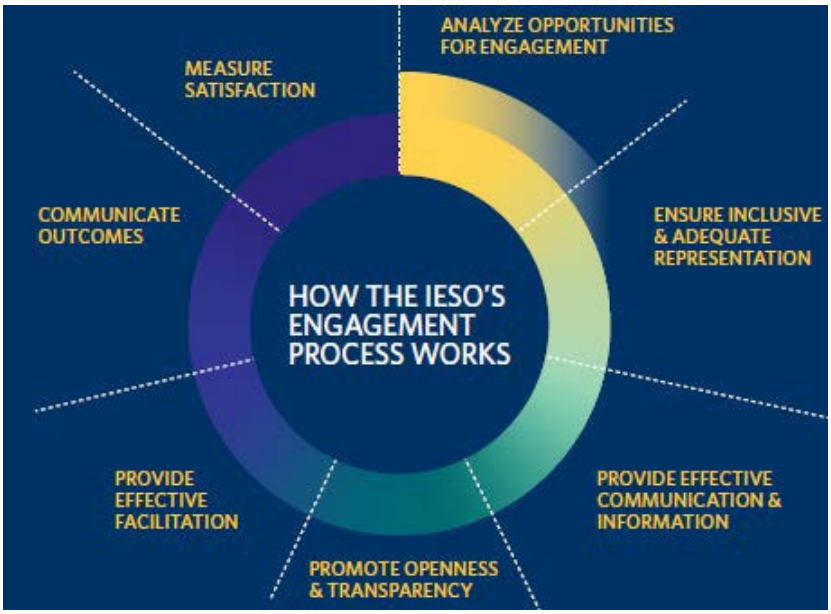
Long-term Considerations

Long-term considerations for this need are discussed in Section 7.5.1.

Recommendations

The recommendation to address the Tilbury West DS station capacity need is to upsize transformers at Tilbury West DS to 25/41.7 MVA (rated for 53 MW LTR) to meet the need by 2036.

Given that this option would take three to five years to implement, while the need emerges in 2036, the Technical Working Group recommends load monitoring. This way, upsizing the transformer can be triggered when needed, or revisited in the next cycle of regional planning.



8. Community and Stakeholder Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and perspectives of the public, which for these purposes, refers to Indigenous communities, market participants, municipalities, stakeholders, communities, customers and the general public, to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the activities undertaken to date for the Windsor-Essex IRRP.

8.1. Engagement Principles

The IESO's External Relations Engagement Framework and the Indigenous Engagement Framework is built on a series of key principles that respond to the needs of the electricity sector, communities and the broader economy. These principles ensure that diverse and unique perspectives are valued in the IESO's processes and decision-making. We are committed to engaging with purpose with external audiences to foster trust and build understanding as the energy transition continues.

Figure 33 | The IESO's Engagement Principles

8.2. Engagement Approach

To ensure that the Plan reflects the needs of Indigenous communities, market participants, municipalities, stakeholders, communities, customers and the general public, engagement involved:

- Leveraging the Windsor-Essex engagement webpage to post updated information, engagement opportunities, meeting materials, input received and IESO responses to feedback,
- Targeted discussions with municipalities and associations to help inform the engagement approach for this planning cycle and to understand feedback and perspectives at key milestones,
- Hosted a series of public webinars at major junctions in the plan development to share plan details, understand feedback and answer questions, and
- Communications and other engagement tactics to enable a broad participation through email and IESO's weekly Bulletin updates.

As a result, the engagement plan for this IRRP included:

- A dedicated webpage on the IESO website to post all meeting materials, feedback received and IESO responses to the feedback throughout the engagement process,
- Regular communication with interested communities and stakeholders by email or through the IESO weekly Bulletin,
- Public webinars, and

- Targeted one-on-one outreach with specific communities and stakeholders to ensure that their identified needs are addressed (see Section 8.4).

8.3. Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for this round of planning, and to continue to build relationships and dialogue in this region from past engagements. This started with the Scoping Assessment Outcome Report for the Windsor-Essex region. An invitation was sent to targeted Indigenous communities, municipalities, and those with an identified interest in regional issues, to announce the commencement of a new planning cycle and invite interested parties to provide input on the Windsor-Essex region Scoping Assessment Report finalization. A public webinar was held in April 2023 to provide an overview of the regional electricity planning process and seek input on the high-level needs identified and proposed approach. The final Scoping Assessment was posted later in May 2023, identifying the need for a coordinated regional planning approach and an IRRP.

Following finalizing the Scoping Assessment, several targeted outreach meetings began with municipalities and associations in the region to inform early discussions for development of the IRRP, including the IESO's approach to engagement and to ensure growth, electrification, and development plans have been accurately captured in the Technical Working Group's draft demand forecast scenarios. The launch of a broader engagement initiative followed, with an invitation to IESO subscribers of the Windsor-Essex region to ensure that all interested parties were made aware of this opportunity for input. Three public webinars were held at major stages during the IRRP development to give interested parties an opportunity to hear about its progress and provide comments on key components of the plan. These webinars were attended by a cross-representation of community representatives, municipalities, associations, businesses, and other stakeholders, and written feedback was collected over an approximately three-week comment period after each webinar.

The three stages of engagement at which input was invited:

1. The draft engagement plan, and electricity demand forecast scenarios – to set the foundation of this planning work.
2. The defined electricity needs for the region and high-level screening of potential options to meet the identified needs.
3. The analysis of options and draft IRRP recommendations.

Comments received during this engagement were primarily focused on:

- Ensuring key areas of growth in specific pockets in the Windsor-Essex region (including lands designated for industrial developments and planned agricultural developments) have been considered and accounted for in the IRRP work;
- Ensuring infrastructure development matches future potential growth; and
- Keeping lines of communication following the plan completion to share information and updates.

Feedback received during the written comment periods for these webinars helped to guide further discussions throughout the development of this IRRP, as well as add due consideration to the final recommendations.

All interested parties were kept informed throughout this engagement initiative via email to Windsor-Essex region subscribers, municipalities, and Indigenous communities.

Based on the discussions through this engagement initiative, a key priority was to ensure the IRRP, and recommended actions aligned with strong forecast growth and development both within specific municipalities and the region more broadly (e.g., future urban expansion and employment areas as outlined in the updated Windsor-Essex region Official Plan). This insight has been valuable to the IESO – it supported an understanding of local growth and accurate electricity demand forecast scenarios, the determination of needs, and the recommendation of solutions to ensure adequate and reliable long-term supply. To that end, ongoing discussions will continue to keep interested parties engaged in a two-way dialogue on local developments, priorities, and initiatives to prepare for the next planning cycle.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's Windsor-Essex IRRP engagement webpage.

8.4. Bringing Municipalities and Associations to the Table

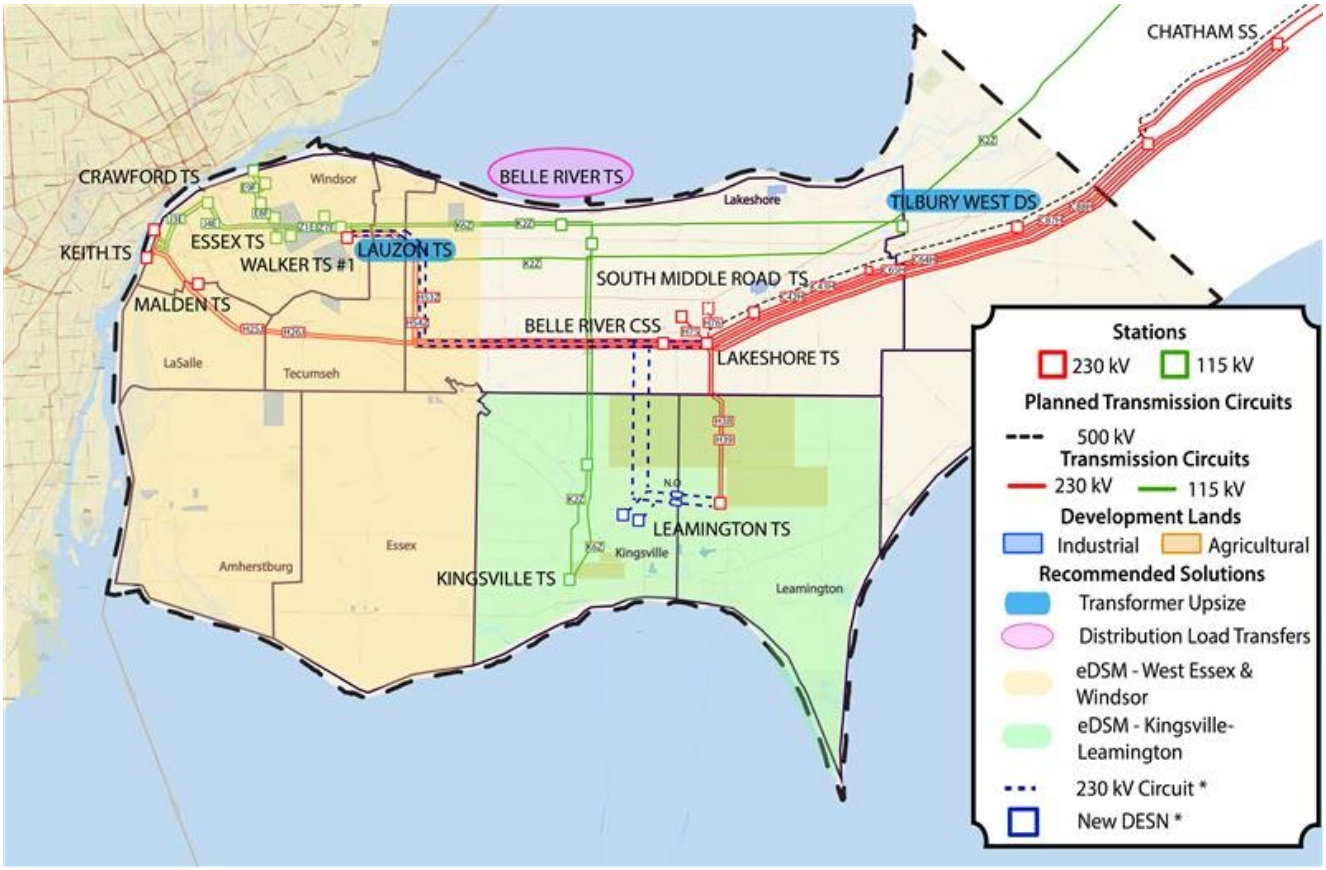
The IESO held meetings with municipalities and association to seek input on their planning and to ensure that key local information about growth and development and energy-related initiatives were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings were held with the upper- and lower-tier municipalities, and associations in the region to discuss key issues of concern, including ensuring infrastructure development matches growth, options for meeting the region's future needs, and broader community engagement. These meetings helped to inform the development of the forecast scenarios, municipal/community electricity needs and priorities, establish new relationships, and provided opportunities for ongoing dialogue beyond this IRRP process.

Through these discussions, valuable feedback was received around strong anticipated growth in major growth centres in the region, including, but not limited to the following feedback:

- Strong population growth across the Windsor-Essex region based on 2051 growth projections and in some areas above and beyond the regional forecast.
- The County of Essex zoning plans for residential and employment lands.
- Residential growth in the Town of LaSalle due to new residential development.
- The City of Windsor plans for residential development, energy conservation, and industrial expansion.
- The Municipality of Leamington's expected residential growth and indications of greenhouse developments in the region.
- The Town of Amherstburg's residential growth forecasts and industrial development lands.

- The Town of Essex's residential growth forecast and employment lands for industrial development.
- The Town of Kingsville's planning applications for residential units, municipal infrastructure plans, greenhouse development expectations, and expected trend for electricity demand.
- The Town of Lakeshore's residential growth forecast, industrial developments, and agricultural development lands.
- The Town of Tecumseh's residential development plans.
- New development and growth projects identified by Invest WindsorEssex.
- Expected growth rate in the greenhouse sector based on Ontario Greenhouse Vegetable Growers.

8.5. Engaging with Indigenous Communities



To raise awareness and share information about the regional planning activities underway and invite participation in the engagement process, regular outreach including extending the opportunity to meet one-on-one was made to Indigenous communities within the Windsor-Essex region throughout the development of the plan. This includes the communities of the Aamjiwnaang First Nation, Caldwell First Nation, Chippewas of Kettle and Stony Point First Nation, Chippewas of the Thames First Nation, Eelŭnaapéewi Lahkéewiit Delaware Nation, Munsee-Delaware Nation, Oneida Nation of the Thames, Walpole Island First Nation.

The IESO remains committed to an ongoing, effective dialogue with communities to help shape long-term planning in regions all across Ontario.

9. Conclusion

The Windsor-Essex IRRP identifies electricity needs in the region over the 20-year period from 2024 to 2043, recommends a plan to address immediate and near-term needs, and lays out actions to monitor long-term needs. Figure 34 visually depicts these recommendations across the region.

Figure 34 | Overview of Recommended Solutions for the Windsor-Essex IRRP

In the interim, operational measures can be used to support growth in the region through the use of operating ratings and improving the redundancy of the Lakeshore RAS. The Technical Working Group also recommends targeting eDSM programs in the Kingsville-Leamington and West Essex and Windsor sub-systems to support both near-term and long-term growth.

In the near term, the Technical Working Group recommends upsizing the transformers at Lauzon TS DESN 2 and transferring loads on the distribution system from Belle River TS to Lauzon TS. The Technical Working Group also recommends constructing two new transformer stations in the Kingsville-Leamington sub-system with a double-circuit 230 kV transmission line connection from Lakeshore TS, along with a double-circuit 230 kV transmission line linking the new connection lines to H38/H39 with normally open breakers for load restoration.

In the medium-term, a new double-circuit 230 kV transmission line from Lakeshore TS to Lauzon TS is recommended to support growth in the West Essex and Windsor sub-system. Depending on the

subsequent design and environmental assessment process, there may be an opportunity to integrate this recommendation with the 230 kV double-circuit line into Kingsville-Leamington recommended in the near term.

In the long term, the Technical Working Group recommends upsizing the transformers at Tilbury West DS. Finally, the Technical Working Group recommends exploring the scope and value of a corridor study to identify future transmission paths into the West Essex and Windsor sub-system.

The IESO will continue to participate in the Technical Working Group during the next phase of regional planning, the RIP, to provide input and ensure a coordinated approach. The Technical Working Group will continue to monitor growth across the region to determine if or when further reinforcements will be needed. This includes any future community energy plans, electrification trends, customer connection queues, changes to local generation, and changes to eDSM programs. The Technical Working Group will meet at regular intervals to monitor developments and track progress toward plan deliverables. If underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the Ontario Energy Board.

REGIONAL INFRASTRUCTURE PLAN REPORT

WINDSOR-ESSEX

Regional Infrastructure Plan Report

Windsor-Essex

October 20, 2025

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

Windsor-Essex Technical Working Group

Page intentionally left blank

Disclaimer

This Regional Infrastructure Plan (RIP) Report for the Windsor - Essex region was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group (TWG).

The preferred solution(s) that have been recommended in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP TWG at the time.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	**Windsor-Essex** (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")
START DATE: April 24, 2025	**END DATE:** October 20, 2025

1. INTRODUCTION

Hydro One as the lead transmitter undertakes the development of a RIP with input from the TWG for the region and publishes a RIP report. The RIP report includes discussion of all the options, recommended plans, and preferred wire infrastructure investments identified in the phases to address the needs over the study period.

2. OBJECTIVES AND SCOPE

Objectives:

- Provide a comprehensive summary of needs and wires plans to address the needs for the Windsor-Essex region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

Scope:

- A consolidated report of the needs and relevant wires plans to address near- and medium-term (2024-2033) needs identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the 2024-2033 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term (2034-2043) needs identified in the Windsor-Essex IRRP, Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

This section provides a detailed overview of the various steps followed during different phases of Regional Planning Process and their outcomes starting with the Needs Assessment, Scoping Assessment, Local Plan, Integrated Regional Resource Plan and finally details the Regional Infrastructure plan Methodology.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

This section provides a general overview of the geographical boundaries, circuit connections and stations located in the Windsor-Essex region through a regional planning area map and a single line diagram.

The Windsor-Essex region consists of the City of Windsor, the Municipality of Leamington, the Towns of Amherstburg, Essex, Kingsville, Lakeshore, LaSalle, Tecumseh, and the Township of Pelee, as well as the western portion of the Municipality of Chatham-Kent. The region also includes a number of Indigenous communities including Aamjiwnaang First Nation, Caldwell First Nation, Chippewas of the Thames, Haudenosaunee Confederacy Chiefs Council (HCCC)/Haudenosaunee Development Institute (HDI), Oneida Nation of the Thames, Six Nations of the Grand River and Walpole Island First Nation (Bkejwanong Territory).

The Windsor-Essex region is divided into three sub-systems, each with some transmission facility, for regional planning purposes: the West Essex and Windsor sub-system in the west of the region; the Kingsville-Leamington sub-system in the south-east of the region; and the Lakeshore/Tilbury sub-system in the north-east of the region.

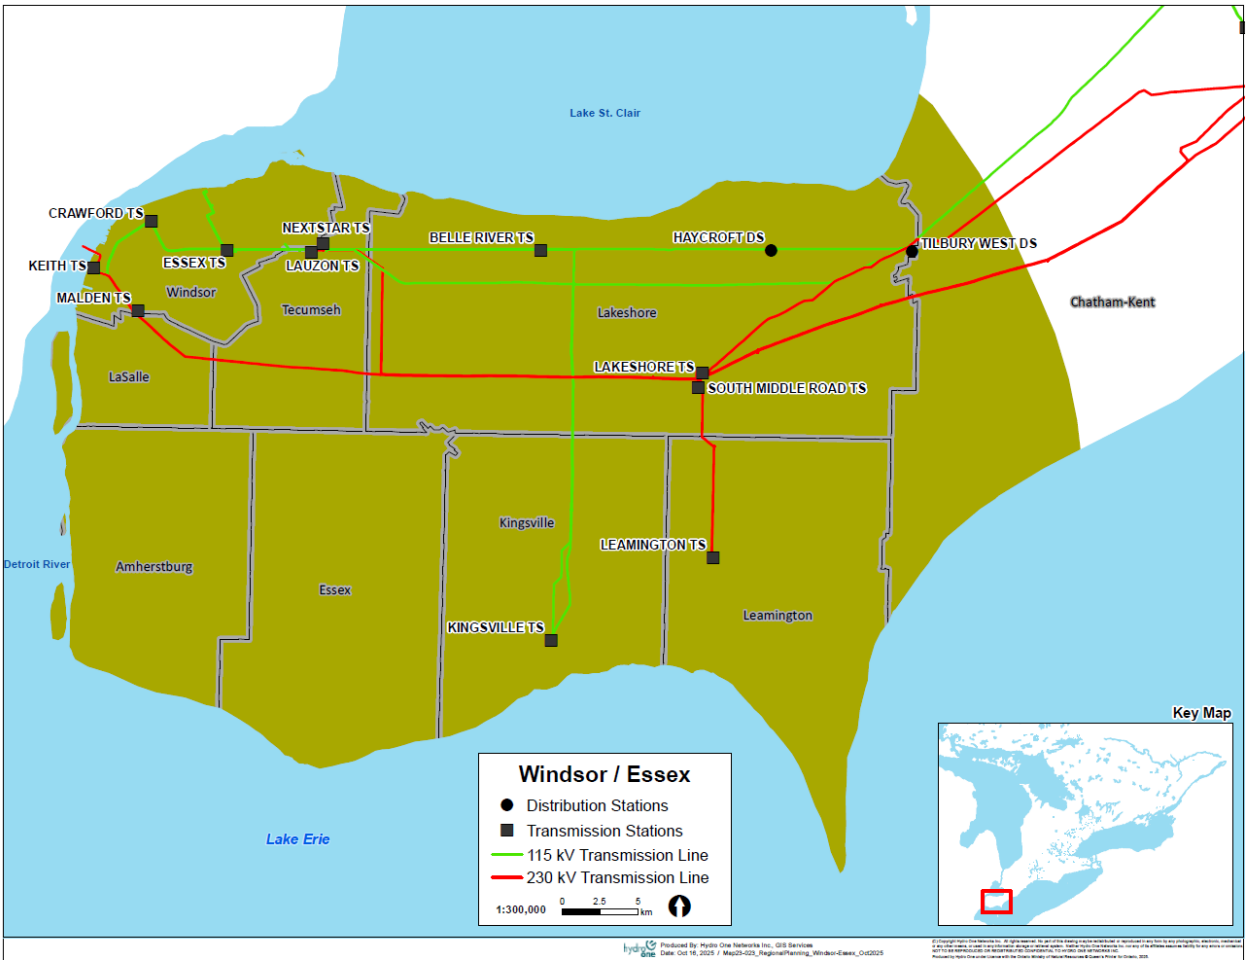


Figure 1-1: Windsor-Essex Region Map

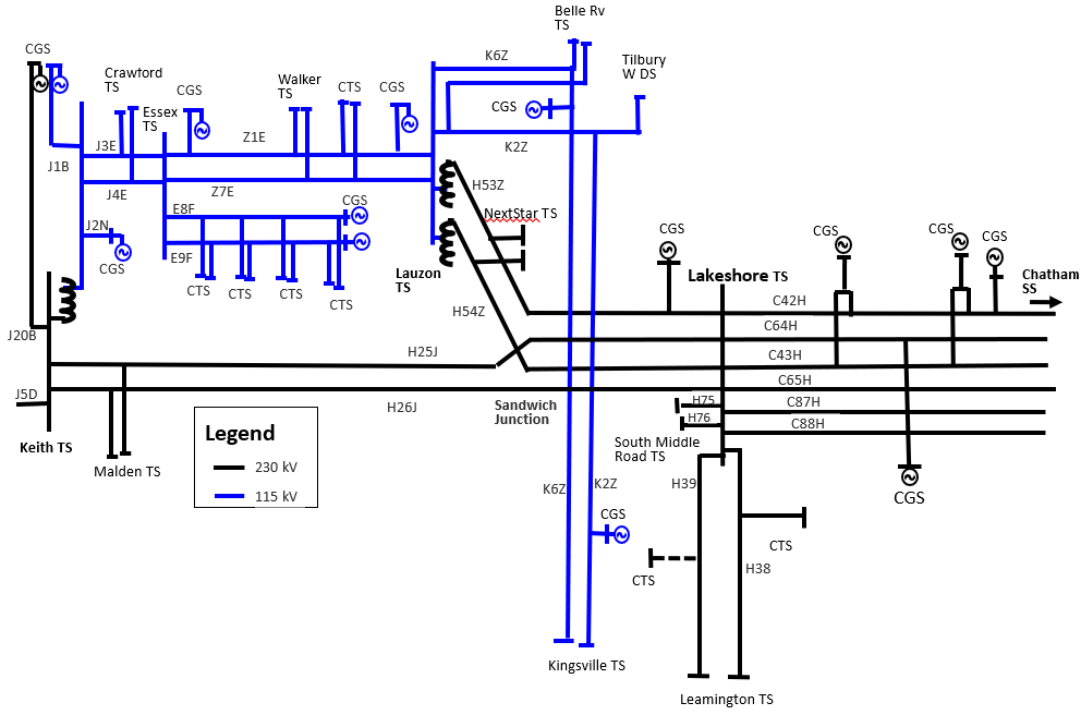

Figure 1-2: Single Line Diagram Windsor-Essex Region's Existing Transmission System

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR UNDERWAY

This section provides a summary and brief description of all the projects completed in the past ten years or are currently underway.

I. Following Major projects were completed in the region during the last ten years:

1. Keith TS breakers replacement: the following breakers were replaced SC11K, SC11SC, SC1B, T11P, T12P, and SC2Y (I/S 2015); HT11K, HT12K, L1P and T1L3 renamed L3K (I/S 2024); L2P and L3P (I/S 2025).
2. Crawford TS transformer T3 replacement and neutral grounding reactors installation on T3 and T4 (I/S 2017).
3. Malden TS breakers replacement: two 27.6 kV feeder breakers were replaced (I/S 2018).
4. Supply to Essex County Transmission Reinforcement: A new 13 km double-circuit 230 kV transmission line to Leamington area tapped to previous C21J/C22J (Chatham SS x Keith TS) circuits, and new 75/100/125 MVA Leamington TS DESN1 (I/S 2018).
5. Reconfiguration of 230 kV and 115 kV circuits and 27.6 kV feeders at Keith TS to accommodate the construction of Gordie Howe International Bridge (I/S 2018).
6. Leamington TS expansion: Installation of 75/100/125 MVA Leamington TS DESN2 (I/S 2019).
7. Kingsville TS 25/42 MVA transformers (T1, T2, T3, T4) replacement with 50/83 MVA units T5, T6 (I/S 2022).
8. Keith TS 115 MVA autotransformers replacement with 150/200/250 MVA units (I/S 2023).

9. Tilbury TS decommissioned (2019).
10. Keith TS transformer T1 decommissioned (2021).
11. Built new switching station (Lakeshore TS) at Leamington Junction (I/S 2022).
12. Built new 75/100/125 MVA South Middle Road TS DESN1 (I/S 2022).
13. Build Chatham SS x Lakeshore TS 2-cct 230 kV line (I/S 2024).
14. Built new 75/100/125 MVA South Middle Road TS DESN2 (I/S 2025).

II. Following Major projects are underway in the region:

1. Keith TS 300/500 MVA phase angle regulator PSR5 replacement (expected I/S 2028).
2. Lauzon DESN1 50/83 MVA transformers T5 and T6 asset renewal with 75/125 MVA units (expected I/S 2026).
3. Development of Chatham SS x Lambton TS 2-cct 230 kV line* (expected I/S 2028).
4. Development of Longwood TS x Lakeshore TS 1-cct 500 kV line (expected I/S 2030).

Note: The planned in-service year for the above projects is tentative and is subject to change.

* The Chatham SS x Lambton line is outside the Windsor-Essex region but will improve power transfer into the region.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

During the study period, the load in the Windsor-Essex region is expected to grow at a compound annual rate of approximately 2% in winter and 1.3% in the summer from 2024 to 2043. (Based on the high load forecast, the rates would be 6.7% in winter and 3.6% in the summer.) The Region has become winter peaking, hence this assessment considers both summer and winter peak loads.

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2024-2043.
- LDCs reconfirmed load forecasts up to 2043 in the area are the same as the IRRP, except for the addition of new load in the Coatsworth area for the greenhouse sector and the modification of the eDSM to be in line with the IESO 2025 Annual Planning Outlook.
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- The Region is winter peaking, so this assessment is based on both winter and summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR) based on 35°C ambient temperature for summer peaking stations, and winter 10-day Limited Time Rating (LTR) based on 10°C ambient temperature for winter peaking stations.

- Bulk transmission line capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Adequacy assessment is conducted as per ORTAC.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying the Windsor-Essex region to meet the needs in the region and lists the facilities that require reinforcement over the study period. The adequacy assessment assumes that all the projects that are currently underway are completed.

I. Needs identified in the region

a. Asset Renewal for Major HV Transmission Equipment

- Lauzon TS DESN2 transformers T7 and T8

b. Station Capacity

- Lauzon TS DESN2 transformers T7 and T8
- Tilbury West DS
- Belle River TS
- Keith TS and Malden TS
- Kingsville-Leamington Greenhouse Supply Stations
- New Coatsworth Area Greenhouse Supply Stations

c. Transmission Supply Capacity

- West Essex and Windsor Sub-system Supply Capacity
- Kingsville-Leamington Sub-system Supply Capacity
- Coatsworth Area Supply Capacity

d. System Reliability, Operation and Load Restoration

- Kingsville-Leamington Sub-system Load Restoration

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the preferred wires solutions for the Windsor-Essex Region. The needs include those previously identified in the NA and IRRP for the Windsor-Essex Region as well as any new needs identified during the RIP phase.

9. CONCLUSION AND RECOMMENDATIONS

The major infrastructure investments recommended by the TWG in the Windsor-Essex region, in the near and medium terms, are given below:

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Asset Renewal Needs				
Lauzon TS DESN2 transformers (T7/ T8)	Replace 50/83 MVA units with 75/125 MVA units	Hydro One Transmission	2032	$76M
Station Capacity Needs				
Lauzon TS DESN2 transformers (T7/ T8)	Replace 50/83 MVA units with 75/125 MVA units.	Hydro One Transmission	2032	$76M
Belle River TS	Load transfer to Lauzon TS DESN1/2	Hydro One Distribution	2026	$15M
Kingsville-Leamington Greenhouse supply stations	Leamington DESN5/6 (230/27.6 kV 75/125 MVA)	Hydro One Transmission	2029	$120M
Coatsworth Greenhouse supply station	Coatsworth DESN1 (230/27.6 kV 75/125 MVA)	Hydro One Transmission	2029	$60M
Transmission Line Capacity Needs				
230 kV supply line to West Essex and Windsor sub-system*	Establish: (a) a new double-circuit 230 kV Lakeshore TS x Lauzon line; (b) Lauzon 230 kV switchyard.	Hydro One Transmission	2032	$300M
230 kV supply line to Kingsville-Leamington sub-system	Establish a new double-circuit 230 kV from Lakeshore TS into the Leamington/Kingsville area	Hydro One Transmission	2029	$176M
230 kV supply line to Coatsworth area	Establish a new 230 kV line tap from Chatham SS x Lakeshore TS line to Coatsworth DESN1	Hydro One Transmission	2029	$96M
System Reliability, Operation and Load restoration Needs				

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Operational complexity of Lakeshore RAS	Installation of dual batteries at Leamington TS and South Middle Road TS	Hydro One Transmission	2027	$9M
Low voltage concern about loss of Lauzon TS HV capacitor bank with autotransformer	Development of 230 kV switching at Lauzon TS will mitigate this risk.	Hydro One Transmission	2032	Nil**
Restoration in Kingsville-Leamington sub-system	Establish a new double-circuit 230 kV from Leamington DESN5/6 to H38/H39 for restoration of loads connected to these lines.	Hydro One Transmission	2030	$60M

Note:

a) The planned in-service dates are tentative and subject to change.
b) Costs are based on planning estimates may exclude the cost for distribution infrastructure (if required).
c) * Development work for the recommended Lakeshore TS x Lauzon line has commenced.
d) ** The mitigation of low voltage concern is an incidental benefit of the Lauzon 230 kV switching facility development for the 230 kV supply line to West Essex and Windsor sub-system
e) Switchyard reconfiguration is not planned for Lakeshore TS hence an opportunity does not exist to alleviate the operational low voltage concern due to the loss of a high voltage capacitor bank.

The long-term needs which have been identified are to be monitored to enable timely commencement of appropriate work.

Tilbury West DS: capacity need identified in 2037.

1. INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process. Hydro One as the lead transmitter undertakes the development of a RIP with input from the Technical Working Group (TWG) for the region and publishes a RIP report. The third cycle of the Regional Planning process for the Windsor-Essex region was initiated with the publication of Needs Assessment (NA) and the report was published in February 2023 by Hydro One. This was followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) which were published in May 2023 and in April 2025 respectively, by the Independent Electricity System Operator (IESO).

The RIP report includes a common discussion of all the options and recommended plans and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs.

This report was prepared by the Windsor-Essex TWG, led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC"), the Municipalities and the IESO. Participants of the TWG are listed below in Table 1.

Table 1: Windsor-Essex region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Networks Inc. (Transmission)
2	Independent Electricity System Operator (IESO)
3	Enwin Utilities Ltd (Enwin)
4	Hydro One Networks Inc. (Distribution)
5	Essex Powerlines Corporation (Essex Powerlines)
6	E.L.K Energy Inc. (E.L.K. Energy)
7	Entegrus Powerlines Inc. (Entegrus)

2. OBJECTIVES AND SCOPE OF REGIONAL INFRASTRUCTURE PLAN

This RIP report examines the needs in the Windsor-Essex region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs for the Windsor-Essex region.

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major high voltage transmission equipment, transmission and distribution system capability along with any updates with respect to local plans, conservation and electricity Demand Side Management ("eDSM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs 2024-2033 identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the 2024-2033 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the Windsor-Essex IRRP, Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

3.1 Overview

Bulk System Planning, Regional Planning and Distribution Planning are the three levels of planning for the electricity system in Ontario. Bulk system planning typically looks at issues that impact the system on a provincial level and requires longer lead time and larger investments. Comparatively, planning at the regional and distribution levels looks at issues on a more regional or localized level. Typically, the most essential and effective regional planning horizon is the near to medium term (1 – 10 years), whereas long-term (10 – 20 years) regional planning mostly provides a future outlook with little details about investments because the needs and other factors may vary over time. On the other hand, bulk system plans are developed for the long term because of the larger magnitude of the investments.

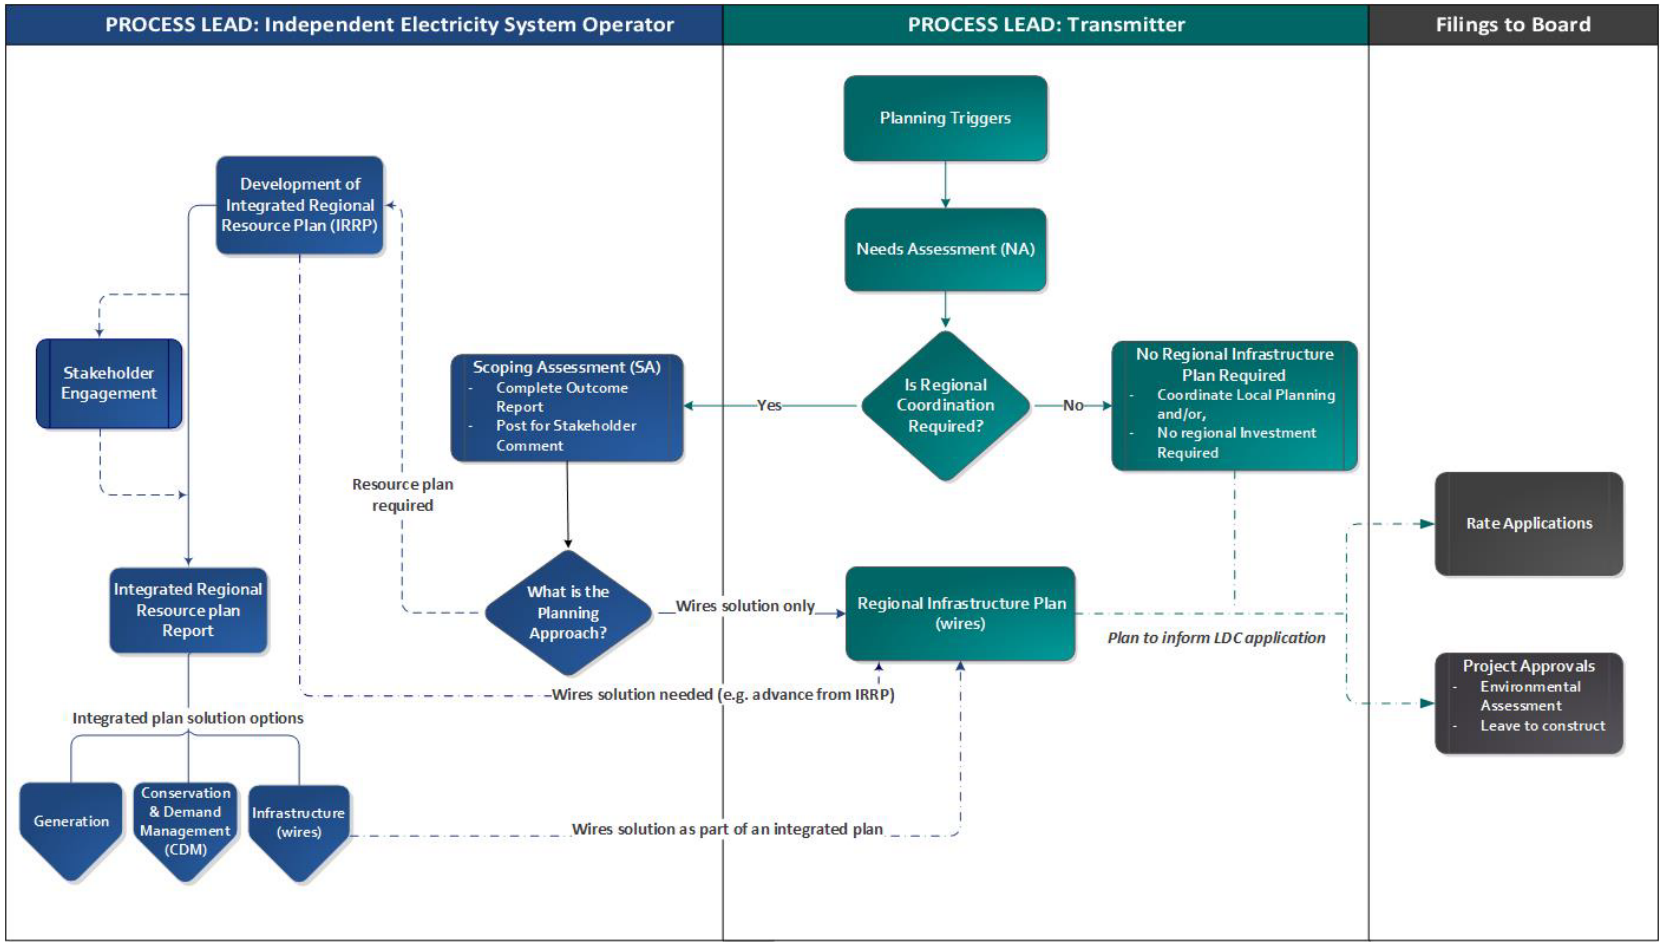
The regional planning process begins with a Needs Assessment which is led by the transmitter to identify, assess, and document which of the needs that,

a) can be addressed directly between the customer and transmitter along with a recommended plan, and;
b) require further regional coordination and identification of Local Distribution Companies (LDCs) to be involved in further regional planning activities for the region.

At the end of the NA, a decision is made by the TWG as to whether further regional coordination is necessary to address some or all the regional needs. If no further regional coordination is required, recommendation to implement the recommended option and any necessary investments are planned directly by the LDCs (or customers) and the transmitter. The region's TWG can also recommend to the transmitter and LDCs to undertake a local planning process for further assessment when needs

a) are local in nature,
b) require limited investments in wires (transmission or distribution) solutions, and;
c) do not require upstream transmission investments.

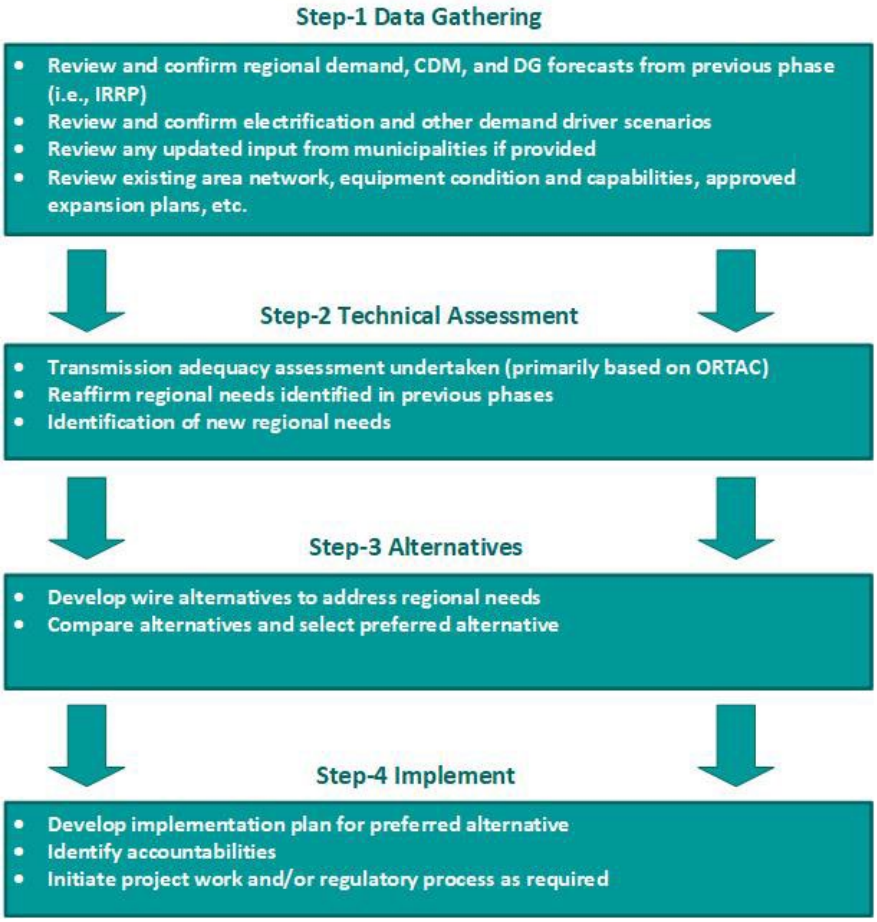
If coordination at the regional or sub-regional levels is required for identified regional needs, then the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires or resource alternatives, e.g., electricity Demand Side Management (eDSM), Distributed Generation (DG), etc., in order to make a decision on the most appropriate regional planning approach including Local Plan (LP), IRRP and/or RIP.



The primary purpose of the IRRP is to identify and assess both resource and wires options at a higher or macro level, but sufficient to permit a comparison of resource options vs. wire infrastructure to address the needs. Worth noting, IESO's foreast eDSM contributions as well as contracted DG plans provided by IESO and LDCs are reviewed and considered at each step in the regional planning process.

If and when an IRRP identifies that resource and/or wires options may be most appropriate to meet a need, resource/wires planning can be initiated in parallel with the IRRP or in the RIP phase to undertake a more detailed assessment, develop specific resource/wires alternatives, and recommend a preferred wires solution.

The RIP phase is the final phase of the regional planning process and involves: discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and, development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive and consolidated report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.



The various phases of Regional Planning Process (NA, SA, IRRP and RIP) and their respective phase trigger, lead, and outcome are shown below in figure-1.

Figure-1 Regional Planning Process Flowchart

3.2 Regional Infrastructure Plan Methodology

Figure-2 Regional Infrastructure Plan Methodology

Regional Infrastructure Plan phase is a four-step process which are described below:

3.2.1. Data Gathering:

The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the TWG to reconfirm or update the information as required. The data collected includes:

- Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and electricity demand management programs. The load forecast from the IRRP was used for this RIP, except for the addition of new load in the Coatsworth area for the greenhouse sector and the modification of the eDSM to be in line with the IESO 2025 Annual Planning Outlook.

- Review and confirm electrification and other growth scenarios which affects the projects recommended in previous stages.
- Existing area network and capabilities including any bulk system power flow assumptions.
- Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

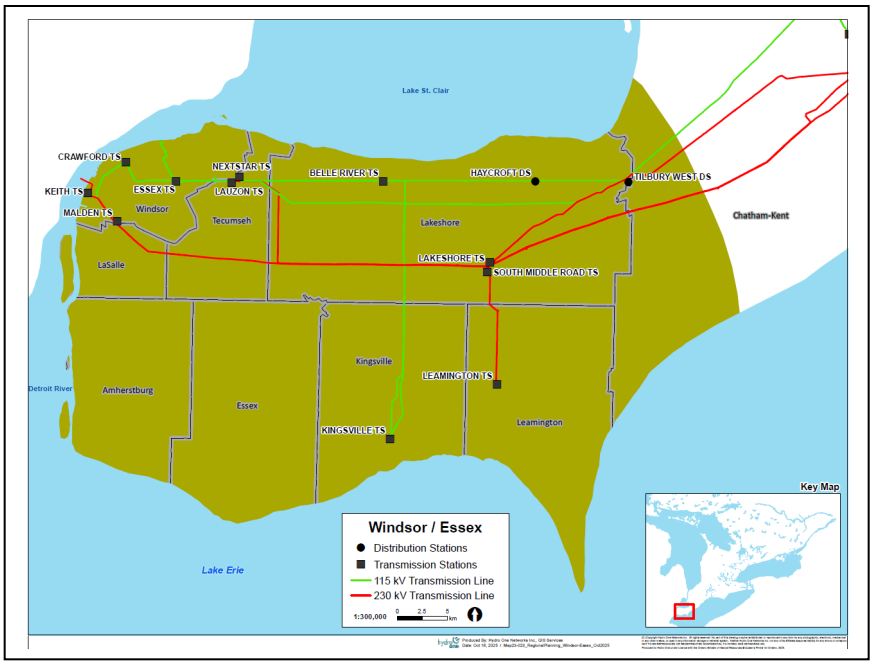
3.2.2. Technical Assessment:

The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3.2.3. Alternative Development:

The third step is the development of wires options to address the needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

3.2.4. Implementation Plan:



The fourth and last step is the development of the implementation plan for the preferred alternative, identifying accountabilities and initiate project work or obtain permissions from Regulatory Commission if any.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The Windsor-Essex region consists of the City of Windsor, the Municipality of Leamington, the Towns of Amherstburg, Essex, Kingsville, Lakeshore, LaSalle, Tecumseh, and the Township of Pelee, as well as the western portion of the Municipality of Chatham-Kent. The region also includes several Indigenous communities including Aamjiwnaang First Nation, Caldwell First Nation, Chippewas of the Thames First Nation, Chippewas of Kettle and Stony Point First Nation, Oneida Nation of the Thames, and Walpole Island First Nation. For electricity planning purposes, the region is defined by electricity infrastructure boundaries, not municipal boundaries. It is one of seven planning regions in Southwest Ontario, adjacent to the Chatham-Kent/Lambton/Sarnia region to the east.

The geographical boundaries of the Windsor-Essex region are shown in Figure 3 below.

Figure 3: Map of Windsor-Essex Regional Planning Area

The region's 230 kV transmission include: Chatham SS x Lakeshore TS circuits (C42H, C43H, C64H, C65H, C87H, C88H), Lakeshore TS x Keith TS circuits (H25J, H26J), Lakeshore TS x Lauzon TS circuits (H53Z, H54Z), Lakeshore TS x Leamington TS circuits (H38, H39), Lakeshore TS x South Middle Road TS circuits (H75, H76), Brighton Beach CGS x Keith TS circuit (J20B) and the Keith TS x Michigan interconnection J5D. The regions 115 kV transmission include: Keith TS x Essex TS circuits (J3E, J4E), Essex TS x Lauzon TS circuits (Z1E, Z7E), Essex TS x E. Windsor CGS circuits (E8F, E9F), Brighton Beach CGS x Keith TS circuit (J1B) and W. Windsor Power CGS x Keith TS circuit (J2N). The 115 kV network connects to the 230 kV system via auto transformers at Keith TS and Lauzon TS. The major transmission stations in the region are Lakeshore TS, Keith TS and Lauzon TS.

The region has remedial action schemes (RAS) for managing risks of thermal overloads and voltage decline: the Lakeshore RAS and the Windsor Area RAS.

This region is served by five LDCs: Enwin, Essex Powerlines, E.L.K. Energy, Entegrus, and Hydro One Distribution. Enwin and Hydro One Distribution are directly connected to the transmission system, while the three other LDCs have connections to Hydro One distribution feeders. The region is now winter peaking with some stations peaking in the winter and others in the summer.

Electricity demand in the region is growing at a rapid pace due to residential and commercial development, and continued expansion of the agricultural and industrial sectors. Agriculture has been driving electricity demand growth and needs in the region over the last several years, especially in winter, and continues to be an important driver going forward. Broader economic development across the region,

electrification, and local climate action plans are also expected to be key factors for future electricity needs. These factors identified as drivers of growth are used to inform the forecasts developed for the region.

The circuits and stations of the area are summarized in Table 2 below:

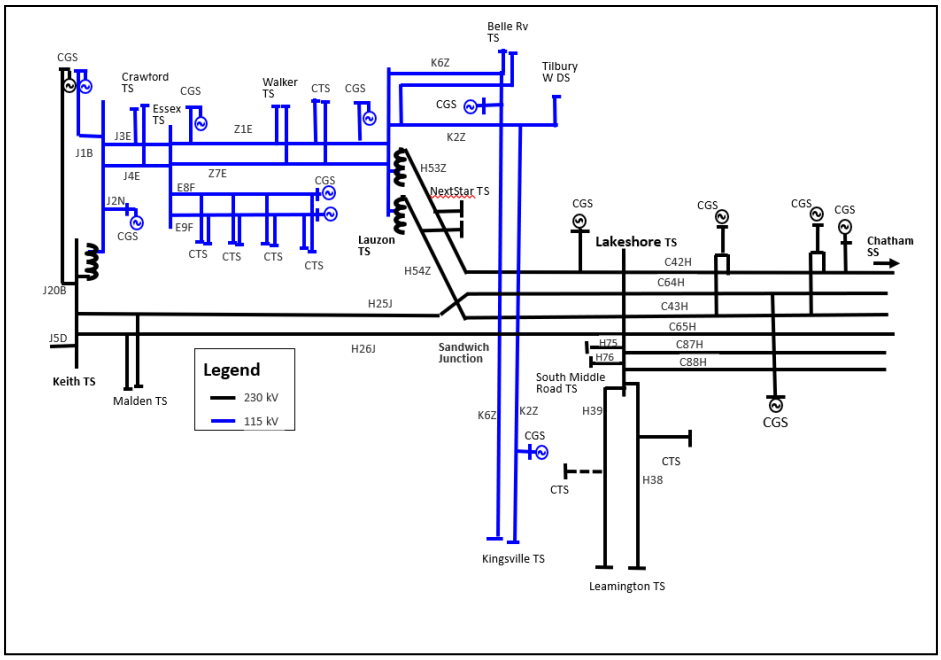


Table 2: Transmission Station and Circuits in the Windsor-Essex region

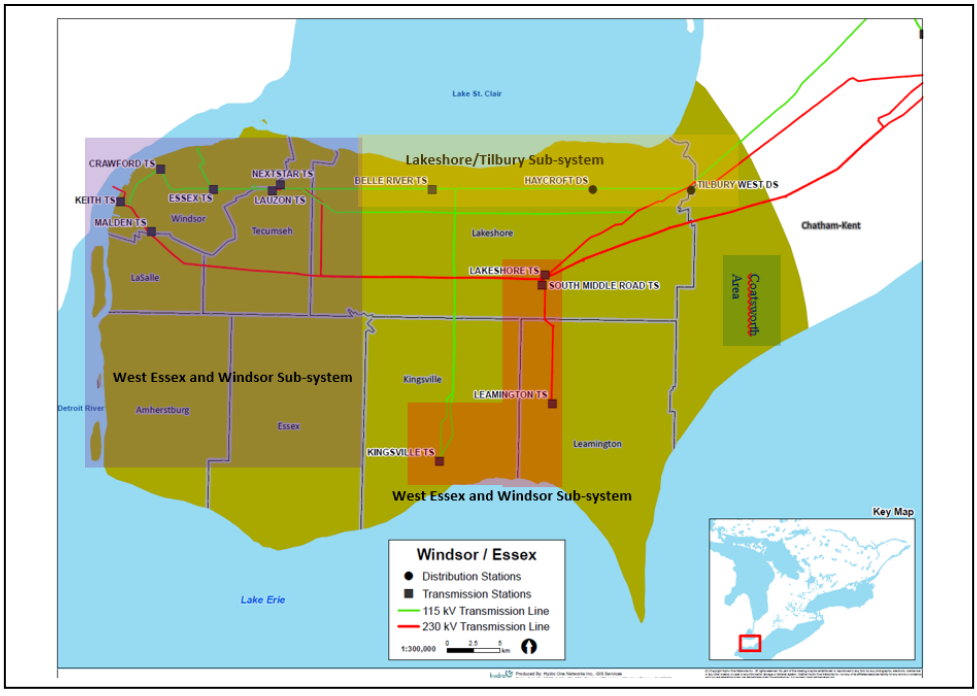
115kV circuits	230kV circuits	Hydro One Transformer Stations	Generation Stations
J3E, J4E, Z1E, Z7E, E8F, E9F, J1B, J2N, K2Z, K6Z, N5K	C42H, C43H, C64H, C65H, C87H, C88H, H25J, H26J, H53Z, H54Z, H38, H39, H75, H76, J20B, J5D	Lakeshore TS, Keith TS*, Lauzon TS*, Malden TS, NextStar TS, Leamington TS, South Middle Road TS, Kingsville TS, Belle River TS, Crawford TS, Essex TS, Walker TS #1, Tilbury West DS, Walker MTS#2, CTS1, CTS2, CTS3, CTS4, CTS5, CTS6, CTS7	Total 13 CGS, 1723 MW Total 1 BESS, 87 MW

*Stations with autotransformers installed



The single line diagram of the Transmission Network of Windsor-Essex region is shown in Figure 4 below.

Figure 4: Windsor-Essex Transmission Single Line Diagram

The region is divided into three sub-systems, each with some transmission facility, for regional planning purposes (Figure 5):

Figure 5: Sub-systems in Windsor-Essex Region

- The **West Essex and Windsor sub-system** in the west of the region, electrically defined by the load and generation connected to and downstream of the H53Z, H54Z, H25J, and H26J 230 kV circuits west of Lakeshore TS. In Windsor, Keith TS and Lauzon TS connect the region's 115 kV network to the 230 kV transmission system via two autotransformers at each station. These supply the 115 kV transmission lines that connect to Belle River TS, Crawford TS, Essex TS, Kingsville TS, Lauzon TS, Tilbury West DS, Walker MTS #2, and Walker TS #1.
- The **Kingsville-Leamington sub-system** in the south-east of the region, electrically defined by the load and generation connected to Kingsville TS, the H38 and H39 230 kV radial circuits south of Lakeshore TS, and the H75 and H76 radial circuits north of Lakeshore TS. The stations in this sub-region are winter peaking on account of the greenhouse sector and their large uptake of artificial crop lighting.
- The **Lakeshore/Tilbury sub-system** in the north-east of the region, electrically defined by the load and generation connected to the K2Z and K6Z 115 kV circuits downstream of Lauzon TS, inclusive of Belle River TS and Tilbury West DS but excluding Kingsville TS.

The **Coatsworth area**, located in the south-east of the region, where there is expectation of significant greenhouse development is outside of the three subsystems because there is currently no transmission facility in the area.

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR ARE UNDERWAY

In this section a complete list of all the projects that are completed in past ten years or are currently underway is provided and are briefly discussed in the sub-sections. As a part of this or previous Regional Planning Cycle(s), several "Major HV Transmission Projects" were recommended in the **Windsor-Essex region** to improve the supply capability and reliability.

Hydro One, being the Transmission Asset Owner (TAO) in the region, has undertaken the execution of the projects recommended in the past ten years. A summary and brief description of all the projects completed or are currently underway is given below:

I. The following Major projects were completed during the last ten years:

1. Keith TS breakers replacement: the following breakers were replaced SC11K, SC11SC, SC1B, T11P, T12P, and SC2Y (I/S 2015); HT11K, HT12K, L1P, T1L3, renamed L3K (I/S 2024); L2P and L3P (I/S 2025).
2. Crawford TS transformer T3 replacement and neutral grounding reactors installation on T3 and T4 (I/S 2017).
3. Malden TS breakers replacement: two 27.6 kV feeder breakers were replaced (I/S 2018).

4. Supply to Essex County Transmission Reinforcement: A new 13 km double-circuit 230 kV transmission line to Leamington area tapped to the previous C21J/C22J (Chatham SS x Keith TS) circuits, and new 75/100/125 MVA Leamington TS DESN1 (I/S 2018).
5. Reconfiguration of 230 kV and 115 kV circuits and 27.6 kV feeders at Keith TS to accommodate the construction of Gordie Howe International Bridge (I/S 2018).
6. Leamington TS expansion: Installation of 75/100/125 MVA Leamington TS DESN2 (I/S 2019).
7. Kingsville TS 25/42 MVA transformers (T1, T2, T3, T4) replacement with 50/83 MVA units T5, T6 (I/S 2022).
8. Keith TS 115 MVA autotransformers replacement with 150/200/250 MVA units (I/S 2023).
9. Tilbury TS decommissioned (2019).
10. Keith TS transformer T1 decommissioned (2021).
11. Built new switching station (Lakeshore TS) at Leamington Junction (I/S 2022).
12. Built new 75/100/125 MVA South Middle Road TS DESN1 (I/S 2022).
13. Build Chatham SS x Lakeshore TS 2-cct 230 kV line (I/S 2024).
14. Built new 75/100/125 MVA South Middle Road TS DESN2 (I/S 2025).

II. Following Major projects are underway:

Note: The planned in-service year for the above projects is tentative and is subject to change.

1. Keith TS 300/500 MVA phase angle regulator PSR5 replacement (expected I/S 2026).
2. Lauzon TS 50/83 MVA transformers T5 and T6 replacement with 75/125 MVA units (expected I/S 2026).
3. Development of Chatham SS x Lambton TS 2-cct 230 kV line (expected I/S 2028). This project, while outside the Windsor-Essex region, will improve transfers into the region.
4. Development of Longwood TS x Lakeshore TS 1-cct 500 kV line (expected I/S 2030).

6. LOAD FORECAST AND STUDY ASSUMPTIONS

6.1. Load Forecast

After verification from the TWG participants, the following two updates were provided and the W-E IRRP Load Forecasts were modified accordingly for the development of this Report:

(a) the addition of new load in the Coatsworth area due to expected significant development of the greenhouse sector in the area (as provided by Hydro One Distribution), and

(b) eDSM update based on the IESO 2025 Annual Planning Outlook (as provided by the IESO).

TWG participants, including representatives from LDC's, IESO and Hydro One provided information and input for the IRRP Load forecast. The municipalities were contacted as part of IRRP stakeholder

engagement process to get their insight on the future load growth and was considered during IRRP load forecast development.
The study considers a reference planning forecast and a high forecast, both based on extreme weather. The reference planning forecast is based on relatively firm assumptions: firm loads, organic growth, electrification, community energy plans, residential growth, greenhouse growth, and industrial growth. The high forecast is a proxy for a variety of factors which could result in higher demand over the next 20 years, such as electrification, higher growth in the agricultural sector and development that is not yet committed. The reference forecast is used to recommend near- to medium-term plans and action plans to monitor long-term needs, while the high forecast is used to identify where future needs may arise and recommend actions to ensure options would be available to address these needs if they arise.

During the study period (2024 to 2043), the load in the Windsor-Essex region is expected to grow at a compound annual rate of approximately 2% in winter and 1.3% in the summer. Based on the high load forecast, the rates would be 6.7% in winter and 3.6% in the summer. The Region is now winter peaking.

Figures 5 & 6 show the Windsor-Essex region extreme summer and winter weather net coincident and non-coincident load forecasts from 2024 to 2043. The regional coincident forecast is the demand observed at each station for the hour of the year in which the overall demand in the region is maximum. The regional non-coincident forecast represents the peak demand at each station in the region regardless of the time of occurrence in the season. Non-coincident and coincident forecast for the individual stations in the region is available in Appendix A. The non-coincident forecast is used to determine the need for station capacity relief at each station, while the coincident forecast is used to determine the need for supply capacity in an area.

Figure 6: Windsor-Essex region summer/winter coincident Net Peak Reference Load Forecasts

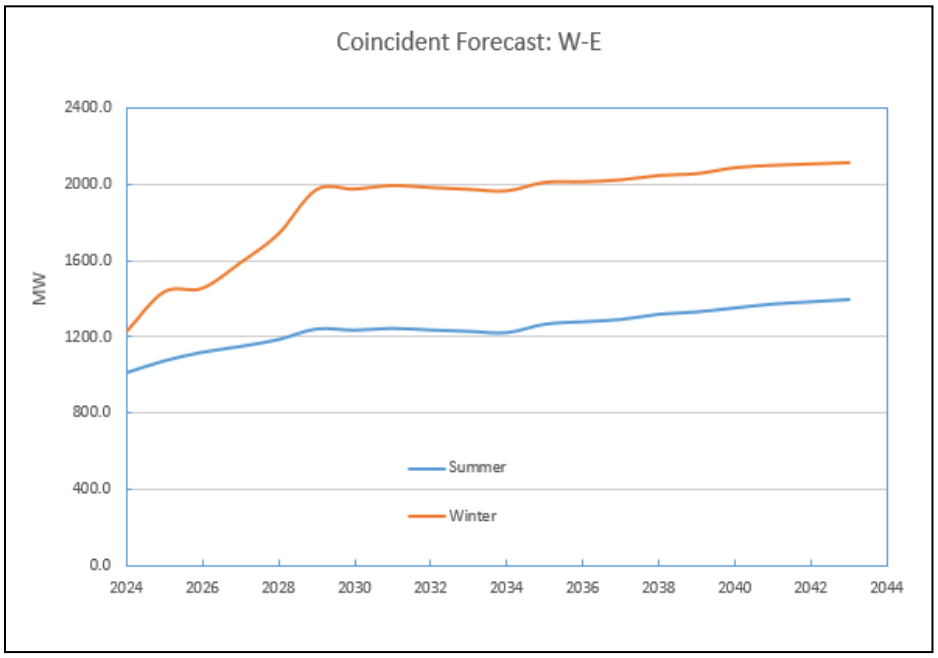


Figure 7: Windsor-Essex region summer/winter Non-coincident Net Peak Reference Load Forecasts

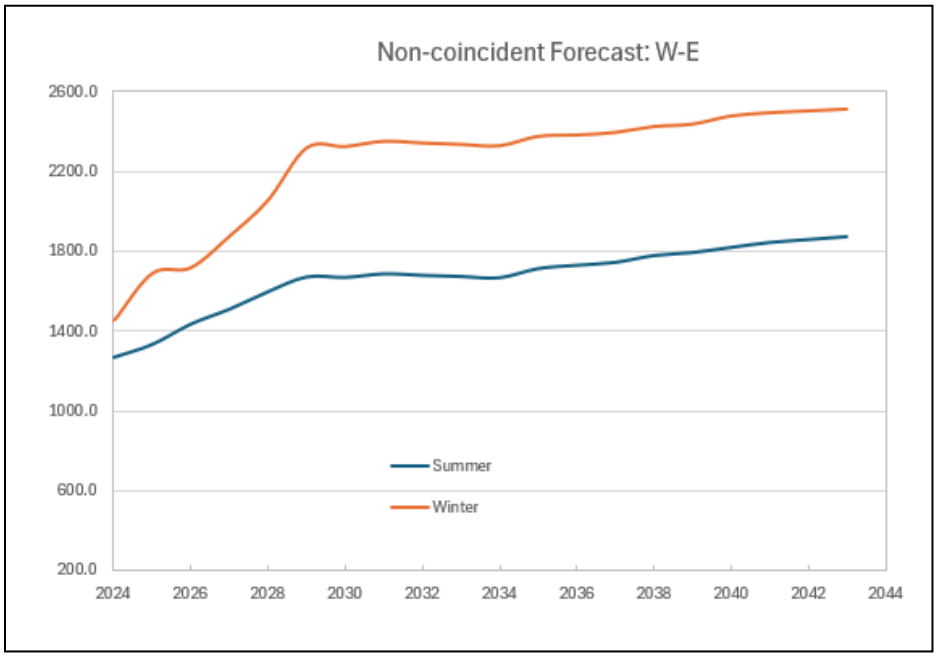

Figure 8: Windsor-Essex region summer/winter coincident Net Peak High Load Forecasts

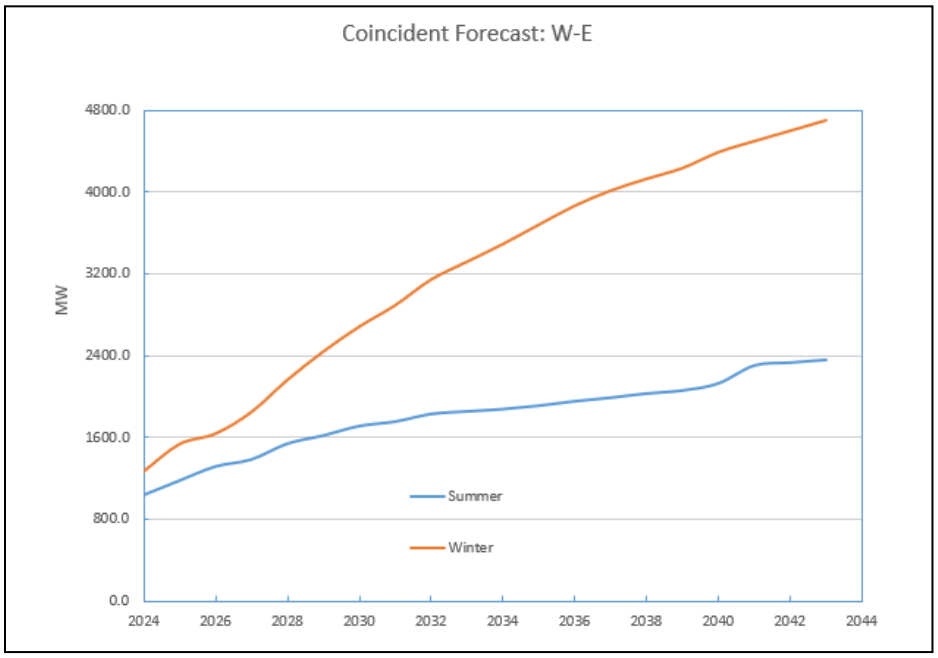

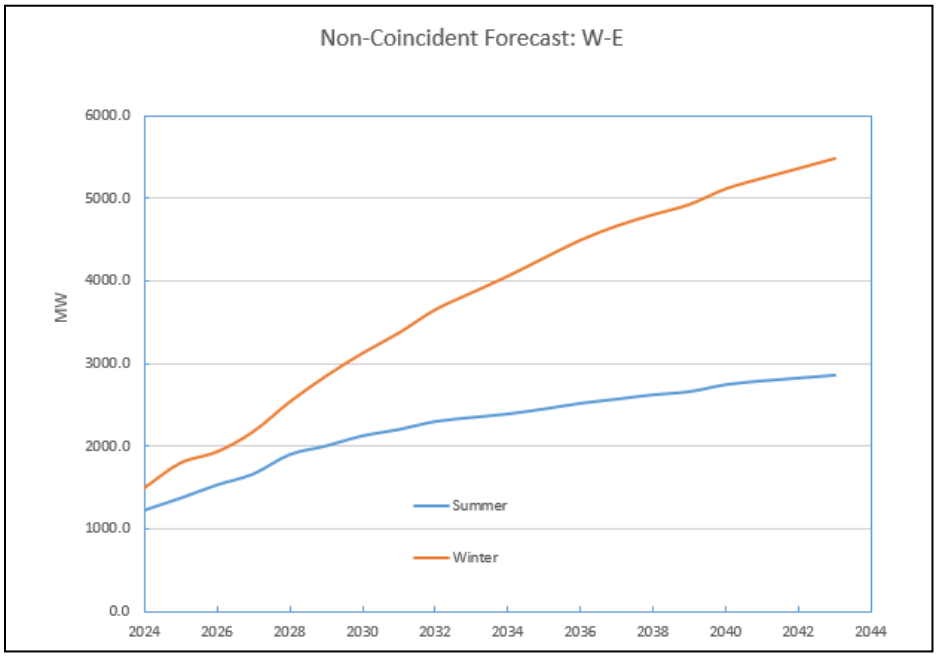

Figure 9: Windsor-Essex region summer/winter Non-coincident Net Peak High Load Forecasts

6.2. Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2024 – 2043, the same as the IRRP.
- All planned facilities for each project which has been initiated and listed in section 4 are assumed to be in-service as of the planned project in-service year.
- The Region is winter peaking, so this assessment considers both summer and winter peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR) based on 35°C ambient temperature.
- Bulk transmission line capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Adequacy assessment is conducted as per ORTAC.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying the Windsor-Essex region and lists the facilities requiring reinforcement over the near- and mid-term periods. The adequacy assessment assumes that all the projects that are listed in **"Section 5"** are completed.

In the current regional planning cycle, the following regional assessments were completed, and their findings were used as inputs to this RIP report:

- Windsor-Essex region Second cycle Needs Assessment Report, Completed in February 2023 by Hydro One.
- Windsor-Essex region Second cycle Scoping Assessment Report, Completed in May 2023 by the IESO.
- Windsor-Essex region Second cycle Integrated Regional Resource Plan Report, Completed in April 2025 by the IESO.

The Technical Working Group identified several regional needs based on the load demand forecast over the study period in the reports mentioned above. The results of the Adequacy Assessment to define the needs are discussed in sub-sections "7.1 to 7.4" and a detailed description and status of plans to meet these needs are given in **"Section 8"** of this report.

7.1. Asset Renewal Needs for Major HV Transmission Equipment

In addition to the asset renewal needs identified in previous regional planning cycle, Hydro One and TWG has also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the 2024 -2033 period in the Windsor-Essex region. The complete list of major HV transmission equipment requiring replacement in the Windsor-Essex region is provided in table 3 in this sub-section. Hydro One and Enwin are the only Transmission Asset Owners (TAO) in the Region.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
    - replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

Table 3: Major HV Transmission Asset assessed for Replacement in the region planned in next 10 years

Station/Circuit	Need Description	Planned ISD
Lauzon TS DESN2 transformers (T7/T8)	Units built in 1972 and due for replacement in 2029. (Station capacity exceedance: 0.6 MW in summer 2035.)	2032
Lauzon TS DESN2 transformers (T5/T6)	50/83 MVA transformers T5 and T6 replacement with 75/125 MVA units	2026
Keith TS Phase shifters	300/500 MVA phase angle regulator PSR5 replacement	2026

Note: The planned in-service year above is tentative and is subject to change.

7.2. Station Capacity Needs

Over the study period 2024-2043 RIP reviewed the capacity of all the 230kV and 115kV transformer stations within the Windsor-Essex region. The NA and IRRP studies had previously indicated that the following stations require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast and identifies the need for station capacity to support new load in the Coatsworth area due to greenhouse development in the area. The stations which require capacity relief during the study period are shown in Table 4 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer or winter) Limited Time ratings.

Table 4: Windsor-Essex region Station Capacity Needs in the study period

Sr.no.	Station Name	Station LTR (MW) (Summer/Winter)	2023 Loading (MW) (Summer/Winter)	Need Date
1	Lauzon TS DESN2 (T7/T8)	103.2/111.5	96.9/63.5	2035 (2025)[1]
2	Belle River TS	53.7/60.8	55.1/38.4	Immediate
3	Tilbury W DS	22.5/22.5	22.1/17.9	2037 (2036)[1]
4	Keith TS	104.8/112.0	65.3/62.7	(2034)[1]
5	Malden TS	183.4/194.8	102.2/80.5	(2040)[1]
6	Leamington DESN5/6*	183.4/194.8	-/-	2027
7	Coatsworth DESN1*	183.4/194.8	-/-	2029

[1] Need year in brackets based on high load forecast.

* Station to be developed as per need date, the listed LTR is expected.

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.3. Transmission Line Capacity Needs

Over the study period 2024-2043 RIP reviewed the capacity of all the 230kV and 115kV Transmission lines within the Windsor-Essex region. The IRRP indicated the need to increase transmission supply capacity into the West Essex and Windsor sub-system due to new load, and further showed that a supply circuit (H54Z) to the sub-system would require capacity relief with all elements in service within the study period; and the need for transmission supply capacity for the Kingsville-Leamington sub-system to support new load stations (Leamington DESN5/6). The RIP has confirmed these needs based on the load forecast and identifies the need for transmission supply capacity to support a new load station in the Coatsworth area. The transmission line capacity needs are summarized in Table 5 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer or winter) Limited Time ratings.

Table 5: Windsor-Essex region Transmission Line Capacity Needs in the study period

Sr.no.	Name of Circuit	Name of Section	Maximum Capacity (LTE)	2024 Loading	Need Date
1	H54Z	Lakeshore TS x Sandwich Jct	1047 A	463 A	2032 (2025)[1]
2	New 230 kV supply line to Kingsville x Leamington sub-system	Lakeshore TS x Leamington DESN5/6	-	-	2027 (2027)[1]
3	New 230 kV supply line to Coatsworth area	Chatham SS x Lakeshore x Coatsworth	-	-	2029 (2029)[1]

[1] Need year in brackets based on high load forecast.

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.4. System Reliability, Operation and Load Restoration Needs

The following operational issues were identified:

- Operational complexity of the Lakeshore RAS due to its lack of redundancy.
- Operational low voltage concerns at Lakeshore TS which may result from the loss of a high voltage capacitor bank and a supply circuit due to station configuration.
- Operational low voltage concerns and at Lauzon TS which may result from the loss of a high voltage capacitor bank and a 230/115 kV autotransformer due to the station configuration.

Load security and load restoration needs were reviewed as part of the current study. ORTAC Section 2.4.10 requires that no more than 600 MW of load be lost as a result of a double circuit contingency.

Further, loads are to be restored in the restoration times[1] specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.

[1] These approximate restoration times are intended for locations that are near staffed centers. In more remote locations, restoration times should be commensurate with travel times and accessibility

- Load interrupted in excess of 250 MW must be restored within 30 minutes.

The IRRP identified restoration needs in the Leamington-Kingsville sub-system and the RIP further confirms this.

The above 30-minute and 4-hour restoration requirements cannot be met for loads supplied by the radial two-circuit line H38/H39 (Leamington DESN1/DESN2, and two customer transformer stations). However, all loads can be restored within 8 hours, and 30 MW of Leamington TS DESN1/DESN2 load can be restored by transfer to Kingsville TS.

For loads at Leamington DESN1/DESN2 and two customer transformer stations which are supplied by the radial two-circuit line H38/H39 from Lakeshore TS, all can be restored within 8 hours while 30 MW of Leamington DESN load can be restored by transfer to Kingsville TS within 4 hours. Hence, the above 30-minute and 4-hour restoration requirements cannot be met. For the new Leamington DESN5 and DESN6 which are needed for the Kingsville-Leamington Greenhouse Development, all loads can be restored within 8 hours, but the 30-minute and 4-hour restoration requirements cannot be met. There is need for a solution to address these restoration requirements.

Restoration Need Table

Circuits Supplying Load	30-minute restoration (need date)	4-hour restoration (need date)
H38/H39	192 MW (immediate) 210 MW (2043)	262 MW (immediate) 280 MW (2043)
Kingsville-Leamington Greenhouse line	66 MW (2028) 105 MW (2043)	166 MW (2028) 205 MW (2043)

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the Windsor-Essex Region. These needs include those previously identified in the NA and IRRP for the Windsor-Essex Region as well as any new needs identified during the RIP phase. All estimated costs included in the alternative analysis are considered as planning estimates and are used for comparative purposes only and may vary. The needs in the region are summarized in Table 6 below:

Table 6: Needs Identified in the region

Station/Circuit Name	Description of Need	Need Date	RIP Report Section
Asset Renewal Needs			
Lauzon DESN 2 T7/T8 transformers	Replacement based on asset condition assessment	2032	8.1.1

Station Capacity Needs			
Lauzon DESN 2	Existing station capacity exceeded	2035 (2025)[1]	8.2.1
Belle River TS	Existing station capacity exceeded	2024	8.2.2
Tilbury West DS	Existing station capacity exceeded	2037 (2036)[1]	8.2.3
Kingsville-Leamington Greenhouse Supply Stations	New DESNs are needed for new load due to greenhouse development	2027	8.2.4
Coatsworth Area Greenhouse Supply Stations	New DESN is needed for new load due to greenhouse development	2029	8.2.5
Keith TS DESN	Station capacity exceedance based on high load forecast	(2034)[1]	8.2.6
Malden TS	Station capacity exceedance based on high load forecast	(2040)[1]	8.2.6
Transmission Line Capacity Needs			
230 kV Supply line to West Essex and Windsor sub-system	New supply line to West Essex and Windsor sub-system due to significant increase in demand from municipal growth, industrial development and electrification initiatives.	2032 (2025)[1]	8.3.1
230 kV Supply line to Kingsville-Leamington sub-system	New double-circuit 230 kV line needed to supply new DESN stations	2027 (2027)[1]	8.3.2
230 kV Supply line to Coatsworth Area	New double-circuit 230 kV line needed to supply a new DESN station	2029 (2029)[1]	8.3.3
System Reliability, Operation and Load restoration Needs			
Operational Issue	Operational complexity of the Lakeshore RAS due to lack of redundancy.	2024	8.4.1
Operational Issue	Low voltage may result from the loss of a high-voltage capacitor bank and another element at Lakeshore TS and Lauzon TS.	2024	8.4.1
Restoration line in Kingsville-Leamington sub-system	A 230 kV line is needed to meet the 30-minute and 4-hour ORTAC restoration requirements.	2024	8.4.2

[1] Need year in brackets based on high load forecast.

8.1 Asset Renewal Needs for Major HV Transmission Equipment

The Asset renewal assessment considers the following options for “right sizing” the equipment:

- Maintaining the status quo;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities;
- Eliminating equipment by transferring all the load to other existing facilities;
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement);
- Replacing equipment with higher ratings and built to current standards.

From Hydro One's perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

8.1.1 Lauzon TS – DESN2 T7/T8 Transformers

T7/T8 50/83 MVA 230/27.6 kV power transformers were built in 1972 and based on asset condition assessment, are identified for replacement in 2032. A like-for-like replacement of these units would be adequate in meeting the load up to 2035. However, as discussed in Sect 8.2, there are station capacity needs in the medium term which require upsizing the transformers.

8.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2024-2043 for the 230kV and 115kV Transforming stations in the Windsor-Essex region using either the summer or winter peak load forecasts. Based on the results, the following station capacity needs have been identified over the study period:

8.2.1 Lauzon TS DESN2 (T7/T8 50/83 MVA 230/27.6 kV)

Lauzon TS is located in the eastern part of the City of Windsor, and includes 230/115 kV autotransformers (T1, T2), as well as two 230/27.6 kV DESNs (T5/T6 and T7/T8). Lauzon TS is connected to the 230 kV circuits H53Z/H54Z, and to 115 kV circuits Z1E/Z7E and K2Z/K6Z. Lauzon DESN 1 T5/T6 units are in the process of being replaced with larger units.

Lauzon TS DESN 2 is summer peaking. Based on the reference forecast, the capacity of the DESN is expected to be reached by 2035 due to municipal growth, industrial development and electrification initiatives in the West-Essex and Windsor sub-system. It would exceed this capacity by 37 MW in 2043. Considering a high load forecast scenario, the DESN capacity would be reached by 2025, and by 2043 would be exceeded by 120 MW.

Alternatives and Recommended Plan

The following alternatives were considered to accommodate excess load at the station.

- Alternative 1: Electricity demand side management program
  Electricity demand side management (eDSM) targeted at the station customers may be used to achieve about 11 MW of load reduction by about 2043, at a cost of $50M. This option does not fully address the need.

- Alternative 2: Construct a new DESN in the vicinity of Lauzon TS
  Constructing a new 50/83 MVA 230/27.6 kV DESN at Lauzon TS would be at an estimated cost of $60M.

- Alternative 3: Upsize existing units
  Replacing the existing 50/83 MVA power transformers with 75/125 MVA units at an estimated incremental cost, relative to like-for-like replacement, of $15 - $30M.

Replacing T7 and T8 transformers with the larger 75/125 MVA units in 2032 is the preferred wires option being the least cost option. This upsizing would also provide for the transfer of load from Belle River TS which is forecast to be marginally over its station capacity in the near term (2 MW in 2025), increasing slowly over the 20-year study period to 13 MW in 2043.

8.2.2 Belle River TS (T1/T2 25/42 MVA 115/27.6 kV)

Belle River TS is located the Municipality of Lakeshore, and connected to 115 kV circuits K2Z and K6Z. This is a summer peaking station, and its capacity is currently exceeded, and by 2043 the exceedance would be 17 MW. The transformers were built in 2005 and are not due for replacement until 2065. The following alternatives were considered to accommodate the excess load at the station.

- Alternative 1: Electricity demand side management program
  New eDSM programs targeted at the station customers may be used to achieve about 5 MW of the need by 2043 at a cost of $18M. This alternative would not fully meet the need.

- Alternative 2: Construct a new DESN at Belle River TS
  Constructing a new 50/83 MVA 115/27.6 kV DESN at Belle River TS would be at an estimated cost of $60M. This option would provide additional capacity beyond the need of the station. However, this additional capacity would not be realisable because of limitations in the 115 kV network.

- Alternative 3: Advance and upsize the replacement of T1/T2
  Advancing the replacement of the existing units with upsized units would be at an estimated incremental cost of $15 - $30M relative to like-for-like replacement, plus advancement cost. This option would provide additional capacity beyond the need of the station. However, this additional capacity would not be realisable because of limitations in the 115 kV network.

- Alternative 4: Load transfer
  The excess load from Belle River TS could be transferred to the upsized Lauzon DESN1/2 via the distribution system at an estimated cost of $15M.

Transferring load from Belle River TS to Lauzon DESN1/2 is the preferred wires option.

8.2.3 Tilbury West DS (T1/T2 15/25 MVA 115/27.6 kV)

Tilbury West DS is located in the Municipality of Lakeshore, and it is supplied from 115 kV circuit K2Z. This is currently a summer peaking station, and based on the reference forecast it is expected to become winter peaking by 2031, and by 2025 on the based on the high forecast. The station summer capacity would be marginally exceeded in 2037 and by 8 MW in 2043; the winter capacity would be marginally exceeded in 2039 and by 9 MW in 2043. Considering a high load forecast scenario, the DESN capacity would be marginally exceeded by 2036, and by 15 MW in 2043. The transformers were built in 1988 and are not due for replacement until 2048. The following alternatives were considered to accommodate the excess load at the station.

- Alternative 1: Electricity demand side management program
  New eDSM programs may be used to achieve about 3 MW of the need by 2043 at a cost of $8M.

- Alternative 2: Construct a new DESN at Tilbury West
  Constructing a new 50/83.3 MVA 115/27.6 kV station at Tilbury West DS would be at an estimated cost of $60M. This option would provide station summer capacity of 92 MW. However, the additional capacity beyond the need of the station would not be realisable because of limitations in the 115 kV network.

- Alternative 3: Advance and upsize the replacement
  Advancing the replacement of the existing units with upsized 25/42 MVA units would be at an estimated incremental cost of $15 - $30M relative to like-for-like replacement, plus advancement cost. This option would provide additional capacity beyond the need of the station.

Advancing the replacement of existing units with upsized 25/42 MVA units is the preferred wires option.

8.2.4 Kingsville-Leamington Greenhouse Supply Stations

New greenhouse development is expected to continue in the Kingsville-Leamington sub-system resulting in rapid load growth in the area. By 2027 there would be need for 150 MW of station capacity and this need would grow to 390 MW by 2031 under the reference forecast. Under the high forecast the need would be 930 MW by 2043. As the station capacity need cannot be met by existing stations, the following alternatives were considered to meet this need.

- Alternative 1: Electricity demand side management program
  The potential peak demand reduction through the reduction of grow lights in the winter daytime periods is expected to be in the order of tens of MWs in the winter and nothing in the summer. eDSM targeting greenhouses is expected to achieve about 20 MW by 2028 and about 100 MW by 2043 at a cost of about $330M. Hence these non-wires options cannot meet the need.

- Alternative 2: Construct new DESN stations
  The wires option to meet the need of the reference forecast is the establishment of two new 75/125 MVA 230/27.6 -27.6 kV DESN stations (Leamington DESN 5 and 6). (The high forecast need of 930 MW by 2043 would require six similarly sized DESNs.) The location(s) of the stations would depend on customer input. Given the four to five-year timeline to establish a new facility, the earliest in-service date for these stations is 2028. The cost estimate for the two DESN stations is about $120M. The DESNs would need to be supplied by a new 22 km double-circuit 230 kV line from Lakeshore TS.

  The recommended option is the construction of new DESNs. The location of the stations would depend on customer input. The existing need to transfer some load off Kingsville TS for the relief of the 115 kV network, can be met with the transfer of some Kingsville TS load to the new DESNs following their establishment.

8.2.5 Coatsworth Area Greenhouse Supply Station

The Coatsworth area is located in the south-west of the Municipality of Chatham-Kent. There are indications of very significant new greenhouse development in this area which would result in 190 MW of new load in 2029 and remaining flat under the reference forecast. Under the high load forecast the need would steadily increase to 1400 MW by 2043, requiring seven new DESN stations. The nearest transmission supply station to the area is Leamington TS about 20 km to the west. As the station capacity need cannot be met by existing stations, the following alternatives were considered to meet this need.

- Alternative 1: Electricity demand side management program
  The application of eDSM targeting greenhouses is not a viable alternative without transmission connection of the greenhouses.

- Alternative 2: Construct new DESN station
  The wires option to meet the need of the reference forecast is the establishment of a new 75/125 MVA 230/27.6 -27.6 kV DESN station (Coatsworth DESN 1). The high forecast need of 1440 MW by 2043 would require seven similarly sized DESNs. The location(s) of the stations would depend on customer input. The cost estimate for the new DESN station is about $60M. The DESN would need to be supplied by a new double-circuit 230 kV line.

The recommended option is the construction of a new DESN.

8.2.6 Keith TS and Malden TS

There is no station capacity need at Keith TS and Malden TS over the study period based on the reference forecast. However, the high load forecast indicates station capacity need in 2043 of 37 MW at Keith TS and of 39 MW at Malden TS.

Given that these needs are based on the high forecast and arise in the long term, targeting eDSM programs at the stations' customers while monitoring load growth is recommended to ensure that the electricity system can reliably meet future needs.

8.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. In the process of regional planning, Transmission Lines Capacity Assessment was performed over the study period 2024-2043 for the 230kV and 115kV Transmission line circuits in the Windsor-Essex region by assessing thermal limits of the circuit and the voltage range as per ORTAC. Based on the results, the following line capacity needs have been identified in region:

8.3.1 230 kV Supply Line to West Essex and Windsor sub-system

The Lakeshore TS x Lauzon TS (34 km) double-circuit 230 kV line comprise circuits H53Z and H54Z. H54Z is strung with 795 kcmil ACSR (26/7) conductor over the Lakeshore TS x Sandwich Jct section, but with 1192.5 kcmil ACSR (54/19) conductor over the balance of the circuit. The companion circuit, H53Z, is strung with 1192.5 kcmil ACSR (54/19) conductor the entire length. Based on the reference summer forecast, H54Z would be thermally overloaded in year 2032 following the loss of double-circuit H53Z/H25J. By 2036 the loss of H53Z + H25J or H54Z + H26J would result in voltage collapse of Lauzon 230 kV. Under the high forecast scenario, the thermal overload would occur in 2024. The thermal overload of H54Z and the voltage collapse of Lauzon 230 kV have both resulted in the need to increase the supply capacity into the West Essex and Windsor sub-system. Under the reference summer forecast, the need would be 65 MW in 2032 increasing to 230 MW in 2043. Under the high load forecast, the need would arise in 2025 and increase to 840 MW in 2043. The following alternatives were considered to meet the need under the reference forecast.

Alternative1: New Lakeshore TS x Lauzon 1-cct 230 kV line

- Lakeshore TS x Lauzon 1-circuit 230 kV line which would provide 360 MW of additional transfer capability to meet the 2043 capacity need at a cost of $250M. This option would require the development of 230 kV switching facilities at Lauzon TS.

Alternative 2: New Lakeshore TS x Lauzon 2-cct 230 kV line

- Lakeshore TS x Lauzon double-circuit 230 kV line which would provide 510 MW of additional transfer capability at a cost of $300M. This option would require the development of 230 kV switching facilities at Lauzon TS.

Alternative 3: New Lakeshore TS x Lauzon 1-cct 500 kV line

- Lakeshore TS x Lauzon 1-circuit 500 kV line which would provide about 500 MW of additional transfer capability at a cost of $350M. This option would require the development of 500 kV and 230 kV switching facilities at Lauzon TS.

The recommended alternative is the development of the Lakeshore TS x Lauzon new double-circuit 230 kV 34 km line. This option is within the scope of the Order in Council Directive 875/2022 requiring Hydro One Networks to expand the transmission system. This would require a new right-of-way between Lakeshore TS and Sandwich Junction. The existing right-of-way between Lauzon TS and Sandwich Junction in which the existing double-circuit H53Z/H54Z line is located can accommodate two additional circuits, however final transmission line routing will be established through the Environmental Assessment process. A new 230 kV switchyard will be required for appropriate termination and switching for the new and existing 230 kV elements. This will partially address operational voltage concern at the station resulting from the coincident loss of the station 115 kV capacitor bank, a 230/115 kV autotransformer and 230 kV circuit H54Z due to the station configuration. It is to be noted that development for this recommended alternative has commenced.

8.3.2 230 kV Supply Line to Kingsville-Leamington Sub-system

Leamington DESN5/6 cannot be supported by the existing transmission hence there is need, in 2027, to increase the transmission supply capacity into the sub-region. The viable wires option to meet this need is the construction of a double-circuit 230 kV line from Lakeshore TS into the sub-region to connect the two DESNs. The new line would require a new right-of-way. The locations of the stations would inform the length of the new line. Currently, it is assumed that a 22 km line would be needed for the two DESNs. This would require four to five years to develop at an estimated cost of $176M.

The recommended wires option is to build the double-circuit 230 kV line to supply the DESNs. There is an opportunity to coordinate the development of this line with the recommended Lakeshore TS x Lauzon TS double-circuit line to leverage benefits. By having the supply line to Kingsville-Leamington tap off the Lakeshore TS x Lauzon TS line, its length would be reduced to about 16 km for a cost saving of about $48M.

8.3.3 230 kV Supply Line to Coatsworth Area

There is currently no transmission line facility in the Coatsworth area. The viable wires option to meet the need to supply Coatsworth DESN1 is the construction of a double-circuit 12 km 230 kV line. The line would be tapped off the Chatham SS x Lakeshore 230 kV line at about 18 km from Lakeshore TS and would require a new right-of-way. The length of the line and the location of the tap to the Chatham SS x

Lakeshore line would depend on the location of the DESN. This would require four to five years to develop at an estimated cost of $96M.

The recommended wires option is to build the double-circuit 230 kV line to supply the DESN.

8.4 System Reliability, Operation and Restoration Needs

Issues which relate to system operability, system general reliability and restoration were considered by the Woking Group, and the feasibility of leveraging solutions developed to address regional needs to also address operational needs was considered.

8.4.1 Operational Issues

The following issues were identified: operational complexity of the Lakeshore RAS due to its lack of redundancy; operational low voltage concerns at Lakeshore TS which may result from the loss of a high voltage capacitor bank and a supply circuit; and at Lauzon TS from the loss of high voltage capacitor bank and a 230/115 kV autotransformer due to the station configuration.

- It is recommended to mitigate the operational complexity of the Lakeshore RAS by installing dual batteries at Leamington TS and at South Middle Road TS. This will take about two years to develop at an estimated cost of about $9M.
- The development of a new Lakeshore TS x Lauzon TS line would provide the opportunity to reconfigure Lauzon TS to alleviate the voltage concern at the station resulting from the coincident loss of the station 115 kV capacitor bank and a 230/115 kV autotransformer due to the station configuration (Sect 8.3.1).
- Switchyard reconfiguration is not planned for Lakeshore TS hence an opportunity does not exist to alleviate the operational low voltage concern associated with the simultaneous loss of a high voltage capacitor bank and a supply circuit.

8.4.2 Restoration Needs in Kingsville-Leamington Sub-system

All loads supplied by the radial two-circuit line H38/H39 (Leamington DESN1/DESN2, and two customer transformer stations) can be restored within 8 hours following a permanent fault on the line; similarly for all loads to be supplied by the new 230 kV line to the Kingsville-Leamington Sub-system (Leamington DESN5 and DESN6) following a permanent fault.

However, the 30-minute and 4-hour restoration requirements cannot be met for loads supplied by these lines, as only 30 MW of Leamington DESN load can be restored by transfer to Kingsville TS within 4 hours. The restoration needs are summarized below.

Circuits Supplying Load	30-minute restoration need (date)	4-hour restoration need (date)
H38/H39	192 MW (immediate) 210 MW (2043)	262 MW (immediate) 280MW (2043)
Kingsville-Leamington Greenhouse line	66 MW (2028) 105 MW (2043)	166 MW (2028) 205 MW (2043)

The load restoration requirement can be achieved by developing a new double-circuit 230 kV 3 km restoration line to link the new supply line to the Kingsville-Leamington sub-system (Sect 8.3.2) to circuits H38/H39 with normally open breakers at Leamington TS. The breakers would be closed for load restoration, as needed. A normally closed 230 kV disconnect switch would be installed on each circuit immediately north of the first supply station from Lakeshore TS. The switches are intended to be used for isolating the permanently faulted section to enable restoration to proceed. This will take about two years to develop at an estimated cost of $60M. The extent to which need is met would depend on the location of the outage and the loading conditions.

It is recommended to construct the 3 km double-circuit 230 kV restoration line for restoration of loads supplied from circuits H38/H39 and the proposed supply line to the Kingsville-Leamington sub-system.

9. CONCLUSION AND RECOMMENDATION

This section concludes the Regional Infrastructure plan Report for Windsor-Essex region. The Major Infrastructure investments recommended by the TWG in the near and mid-term planning horizon 2024-2033 are provided in Table 7 below, along with their planned in-service dates (ISD) and planning cost estimates.

The Windsor-Essex RIP identifies electricity needs in the region over the 20-year period from 2024 to 2043, recommends a plan to address near- and mid-term reference needs, and lays out actions to monitor long-term reference needs.

Table 7: Recommended Plans over the next 10 Years

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Asset Renewal Needs				
Lauzon DESN2 (T7/T8)	Existing T7/T8 50/83 MVA transformers to be replaced with 75/125 MVA units plus associated station upgrade	Hydro One Transmission	2032	$76M

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Station Capacity Needs				
Lauzon DESN2 (T7/T8)	Transformer replacement with upsized units plus associated station upgrade	Hydro One Transmission	2032	$76M
Belle River TS	Load transfer to Lauzon DESN1/2 following upsizing of transformers. Operational measures would be used to manage capacity overload until the transfer.	Hydro One Distribution	2025	$15M
Kingsville-Leamington Greenhouse Supply Stations	Develop two new 75/125 MVA 230/27.6 -27.6 kV DESN stations (Leamington DESN 5 and 6).	Hydro One Transmission	2027	$120M
Coatsworth Area Greenhouse Supply Station	Develop Coatsworth Area 75/125 MVA 230/27.6 -27.6 kV DESN1	Hydro One Transmission	2029	$60M
Transmission Line Capacity Needs				
230 kV supply line to West Essex and Windsor sub-system*	[1]Develop a new 34 km double-circuit 230 kV Lakeshore TS x Lauzon TS line plus associated Lauzon 230 kV switching facility.	Hydro One Transmission	2032	$300M
230 kV supply line to Kingsville-Leamington sub-system	[1]Develop a new 22 km double-circuit 230 kV from Lakeshore TS to supply the new Leamington DESN 5 and 6.	Hydro One Transmission	2029	$176M
230 kV supply line to Coatsworth Area	Develop a new 12 km double-circuit 230 kV from Chatham SS x Lakeshore TS corridor to supply the new Coatsworth Area DESN1	Hydro One Transmission	2029	$96M
System Reliability, Operation and Load restoration Needs				
Operational complexity of the Lakeshore RAS	Installation of dual batteries at Leamington TS and South Middle Road TS.	Hydro One Transmission	2027	$9M
Low voltage concern about loss of Lauzon TS HV capacitor bank with autotransformer	Development of an appropriate 230 kV switching at Lauzon TS will mitigate this concern.	Hydro One Transmission	2032	Nil**

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Restoration in Kingsville-Leamington Sub-system	Development of 2-circuit230 kV line linking the new Kingsville-Leamington supply line to Leamington TS.	Hydro One Transmission	2030	$60M

Notes:

a) The planned in-service dates are tentative and subject to change

b) Costs are based on planning estimates and excludes the cost for distribution infrastructure (if required)

c) * Development work for the recommended Lakeshore TS x Lauzon line has commenced.

d) ** The mitigation of low voltage concern is an incidental benefit of the Lauzon 230 kV switching facility development for the 230 kV supply line to West Essex and Windsor sub-system.

e) [1] Coordinated development of these two projects is recommended. This will enable the Kingsville-Leamington supply line to tap off the supply line to West Essex and Windsor sub-system for a cost saving of about $48M.

f) Switchyard reconfiguration is not planned for Lakeshore TS hence an opportunity does not exist to mitigate the risk of operational low voltage associated with the loss of a high voltage capacitor bank.

The following need, which has been identified to arise beyond 10 years, is to be monitored to enable timely commencement of the alternative identified in Section 8.

- **Tilbury West DS: capacity need identified in 2037**. The station summer capacity would be marginally exceeded in 2037 and by 8 MW in 2043; the winter capacity would be marginally exceeded in 2039 and by 9 MW in 2043. The transformers were built in 1988 and are not due for replacement until 2048. The preferred plan is replacement of the existing units with upsized 25/42 MVA units.

Hydro One Networks Inc. (Lead Transmitter)

Disclaimer

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Study Team.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Study Team.

Study Team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

Executive Summary

This Regional Infrastructure Plan ("RIP") was prepared by Hydro One with support from the RIP Study Team in accordance to the Ontario Transmission System Code requirements. It identifies investments in transmission facilities, distribution facilities, or both, that should be developed and implemented to meet the electricity infrastructure needs within the London Area.

The participants of the Regional Infrastructure Plan ("RIP") Study Team included members from the following organizations:

- Entegrus Power Lines Inc.
- ERTH Power Inc.
- Hydro One Networks Inc. (Distribution)
- London Hydro Inc
- Tillsonburg Hydro Inc.
- Independent Electricity System Operator
- Hydro One Networks Inc. (Transmission)

This RIP is the final phase of the second cycle of the London Area regional planning process, which follows the completion of the London Area Needs Assessment in May 2020 [5] and the Greater London Sub-region Restoration Local Planning Report in October 2021 [6]. Scoping Assessment and Integrated Regional Resource Plan was not carried out in this cycle. This RIP provides a consolidated summary of the needs and recommended plans for London Area Region over the planning horizon (10 years). No new need had been identified at this time.

This RIP discusses needs identified in the previous regional planning cycle, the Needs Assessment and Local Planning reports for this cycle, and wires solutions recommended to address these needs. Implementation plans to address some of these needs are already completed or are underway. Since the previous regional planning cycle, the following projects have commenced and/or completed:

- Aylmer TS transformers and low-voltage switchyard replacement project competed in 2017.
- Strathroy TS failed transformer T1 and low-voltage switchyard replacement project completed in 2019.
- Wonderland TS failed transformer T6 was replaced in 2019.
- St. Thomas TS was decommissioned and 115 kV circuit W14 re-termination work was completed in 2020.
- Sarnia Scott TS to Buchanan TS 230 kV circuits N21W/N22W tower structures refurbishment project was completed in 2021.
- Nelson TS station refurbishment project will be completed in 2022.
- Tillsonburg TS new low-voltage capacitor banks installed in 2021 and switchyard component replacement project to be completed in 2022.
- Longwood TS protection and control replacement project to be completed in 2023.
- Edgeware TS protection and control replacement project to be completed in 2024.

The major infrastructure investments planned for the London Area over the near and mid-term planning horizon are provided in the Table 1 below, along with the planned in-service dates.

TABLE 1 - RECOMMENDED PLANS FOR LONDON AREA OVER THE NEXT 10 YEARS

Need	Stations / Lines	Recommended Action Plan	In-service
Station capacity	Talbot TS	No action required	--
Greater London sub-region restoration need	W36/W37	No action required	--
End-of-life equipment replacement	Buchanan TS	Replacement of autotransformers and associated equipment	2028
	Clarke TS	Replacement of step-down transformers, associated disconnect switches, low-voltage switchyard components	2028
	Talbot TS	Replacement of step-down transformers (T3/T4), associated disconnect switches, low-voltage switchyard components	2028
	Wonderland TS	Low-voltage switchyard components replacement	2026
	M31W/ M32W (Salford Junction x Ingersoll)	London Area East Optical Ground Wire (OPGW) Infrastructure	2027
	W36/W37/W5 NL/W6NL/W2S/ N21W	London Area West Telecom Optical Ground Wire (OPGW) Infrastructure Installation	2029

The Study Team recommends Hydro One to continue with the implementation of infrastructure investments listed in Table 1 above.

In accordance with the Regional Planning process, the RIP should be reviewed and/or updated at least every five years. The London Area Region will continue to be monitored and should there be a need that emerges earlier due to a change in load forecast or any other reason, the next regional planning cycle will be triggered in advance of the five-year timeline.

1. Introduction

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE LONDON AREA REGION BETWEEN 2021 AND 2031.

The report was prepared by Hydro One Networks Inc. (Transmission) ("Hydro One") on behalf of the Study Team that consists of Entegrus Power Lines Inc., ERTH Power Inc., London Hydro Inc., Tillsonburg Hydro Inc., Hydro One Networks Inc. (Distribution), and the Independent Electricity System Operator ("IESO"), in accordance with the new Regional Planning process established by the Ontario Energy Board in 2013.

The London Area includes the municipalities of Oxford County (comprising Township of Blandford-Blenheim, Township of East Zorra-Tavistock, Town of Ingersoll, Township of Norwich, Township of South-West Oxford, Town of Tillsonburg, Township of Zorra), City of Woodstock, Middlesex County (comprising Municipality of Adelaide Metcalfe , Municipality of Lucan Biddulph, Municipality of Middlesex Centre, Municipality of North Middlesex, Municipality of Southwest Middlesex, Municipality of Strathroy-Caradoc, Municipality of Thames Centre, Village of Newbury), City of London, Elgin County (comprising Municipality of Town of Aylmer, Municipality of Bayham, Municipality of Central Elgin, Municipality of West Elgin, Municipality of Dutton/Dunwich, Township of Malahide, Township of Southwold), and the City of St. Thomas. In addition, the facilities located in the London Region supply part of Norfolk County. The boundaries of the London Area are shown below in Figure 1-1.

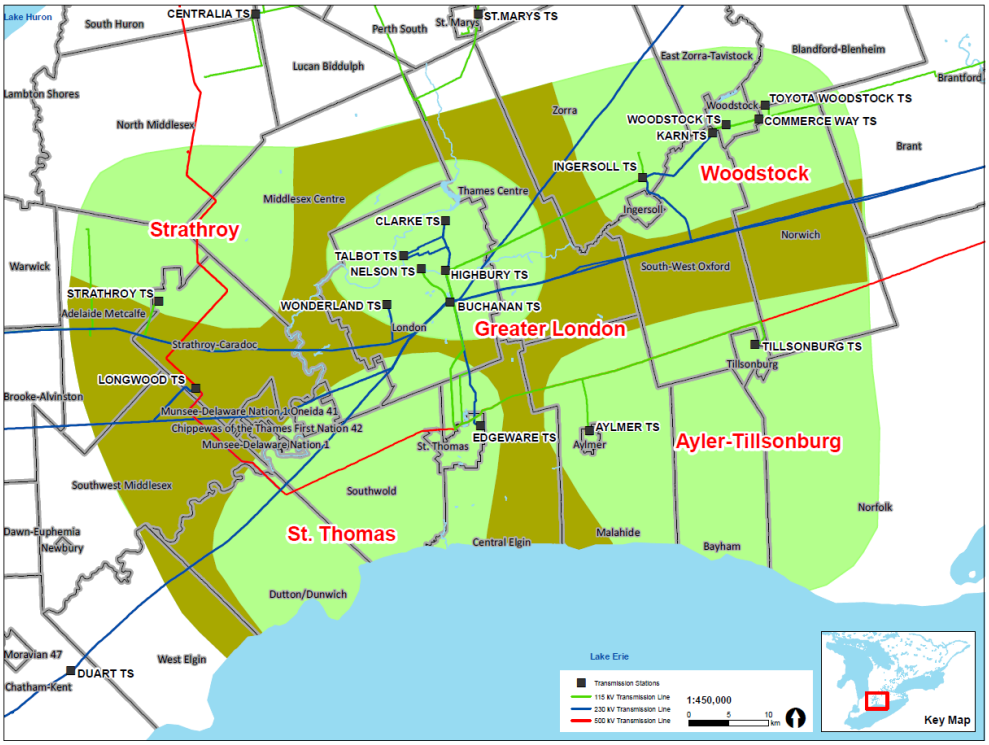

FIGURE 1-1: LONDON AREA REGION MAP

1.1. Objectives and Scope

The RIP report examines the needs in the London Area Region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs;
- Identify any new needs that may have emerged since previous planning phases i.e., Needs Assessment and Local Planning;
- Assess and develop a wires plan to address these needs; and
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, major high voltage sustainment needs emerging over the near and medium term horizon, transmission and distribution system capability along with any updates to local plans, conservation and demand management ("CDM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the relevant wires plans to address near and medium-term needs identified in previous planning phases;
- Discussion of any other major transmission infrastructure investment plans over the planning horizon;
- Identification of any new needs and a wires plan to address these needs based on new and/or updated information;
- Develop a plan to address any longer term needs identified by the Study Team.

1.2. Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the regional characteristics.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 discusses the needs and provides the alternatives and preferred solutions.
- Section 7 provides the conclusion and next steps.

2. Regional Planning Process

2.1. Overview

Planning for the electricity system in Ontario takes place at three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning focuses on assessing supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2. Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Study Team determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (non-wires alternatives) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO.

[1] Also referred to as Needs Screening

The IRRP phase also includes IESO led stakeholder engagement with municipalities, Indigenous communities, business sectors and other interested stakeholders in the region.

The RIP phase is the fourth and final phase of the regional planning process and involves discussion of previously identified needs and plans, identification of any new needs that may have emerged since the start of the planning cycle, and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and/or LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region;
- Working and planning for connection capacity requirements with the LDCs and transmission connected customers.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

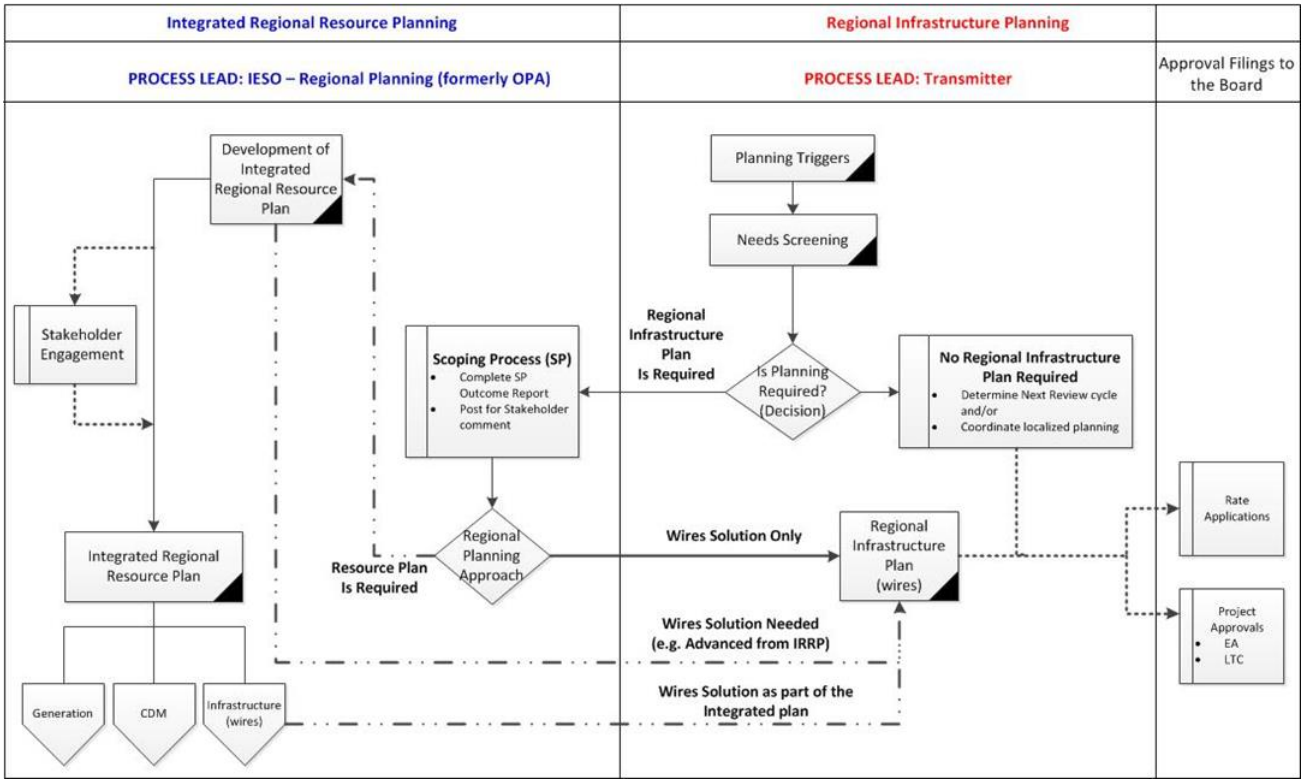

FIGURE 2-2: REGIONAL PLANNING PROCESS FLOWCHART

Upon the conclusion of Needs Assessment, the Study Team agreed that the need in the region (i.e., Greater London sub-region restoration need) was local in nature and no further regional coordination was required. Subsequently, a Local Planning report was completed to specifically address the restoration need. Therefore, Scoping Assessment and Integrated Regional Resource Plan was not carried out for London Area in this cycle.

2.3. RIP Methodology

The RIP phase consists of a four step process (see Figure 2-3) as follows:

1) Data Gathering: The first step of the process is the review of planning assessment data collected in the previous phase of the regional planning process. Hydro One collects this information and reviews it with the Study Team to reconfirm or update the information as required. The data collected includes:

   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.

2) Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Depending upon the changes to load forecast or other relevant information, regional technical assessment may or may not be required or be limited to specific issue only. Additional near and mid-term needs may be identified in this phase.
3) Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4) Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

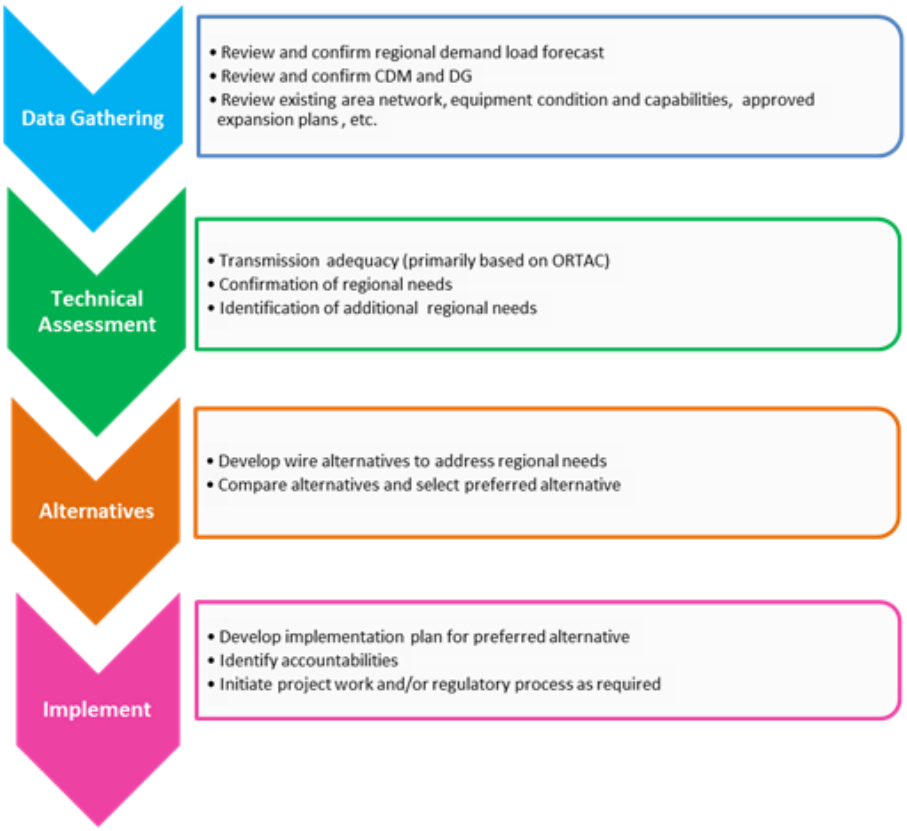

FIGURE 2-3: RIP METHODOLOGY

3. Transmission System Supplying London Area

The hub of the electrical system in London Area is Longwood Transformer Station ("TS"). Longwood TS provides the single connection to the 500 kV system in this area, through which provides majority of the resources to meet the demand in the London Area and rest of southwestern Ontario. The 500 kV system is part of the bulk power system and although it is not studied as part of this RIP, it should be noted that in 2021, the IESO identified a need to expand the 500 kV bulk system to supply the load growth in the Leamington area by 2030. The IESO recommended a new 500 kV single-circuit line connecting Longwood TS and Lakeshore TS and two 500/230 kV autotransformers to be constructed at Lakeshore TS.

London Area is supplied by a network of 230 kV and 115 kV circuits which is connected to Longwood TS through five 500/230 kV autotransformers. Autotransformers at Buchanan TS and Karn TS provide the necessary 230/115 kV autotransformation. Step-down transformer stations are connected to both 230 kV and 115 kV systems to bring the power to distribution level of 27.6 kV to serve the area. There are fourteen Hydro One step-down TS's, three transmission connected industrial load customers and three transmission connected generators in the London Area. The London Area Region summer coincident peak demand in 2021 was about 1152 MW, adjusted to extreme weather.

The existing facilities in the London Area are summarized below and depicted in the single line diagram shown in Figure 3-4:

- Fourteen step-down transformer stations supply the London Area load: Aylmer TS, Buchanan TS, Clarke TS, Commerce Way TS, Edgeware TS, Highbury TS, Ingersoll TS, Longwood TS, Nelson TS, Strathroy TS, Talbot TS (two Dual Element Spot Networks, DESN 1 and DESN 2), Tillsonburg TS, Wonderland TS, and Woodstock TS.
- Three directly connected industrial customer loads are connected in the London Area: Enbridge Keyser CTS, Lafarge Woodstock CTS and Toyota Woodstock TS.
- There are three existing transmission-connected generating stations in the London Area as follows:
    - Suncor Adelaide GS is a 40 MW wind farm connected to 115 kV circuit west of Strathroy TS
    - Port Burwell GS is a 99 MW wind farm connected to 115 kV circuit near Tillsonburg TS
    - Silver Creek GS is a 10 MW solar generator connected to 115 kV circuit near Aylmer TS

Although depicted, Duart TS is not included in the London Area study and will be studied as part of the Chatham-Kent/Lambton/Sarnia (CKLS) Area Regional Planning.

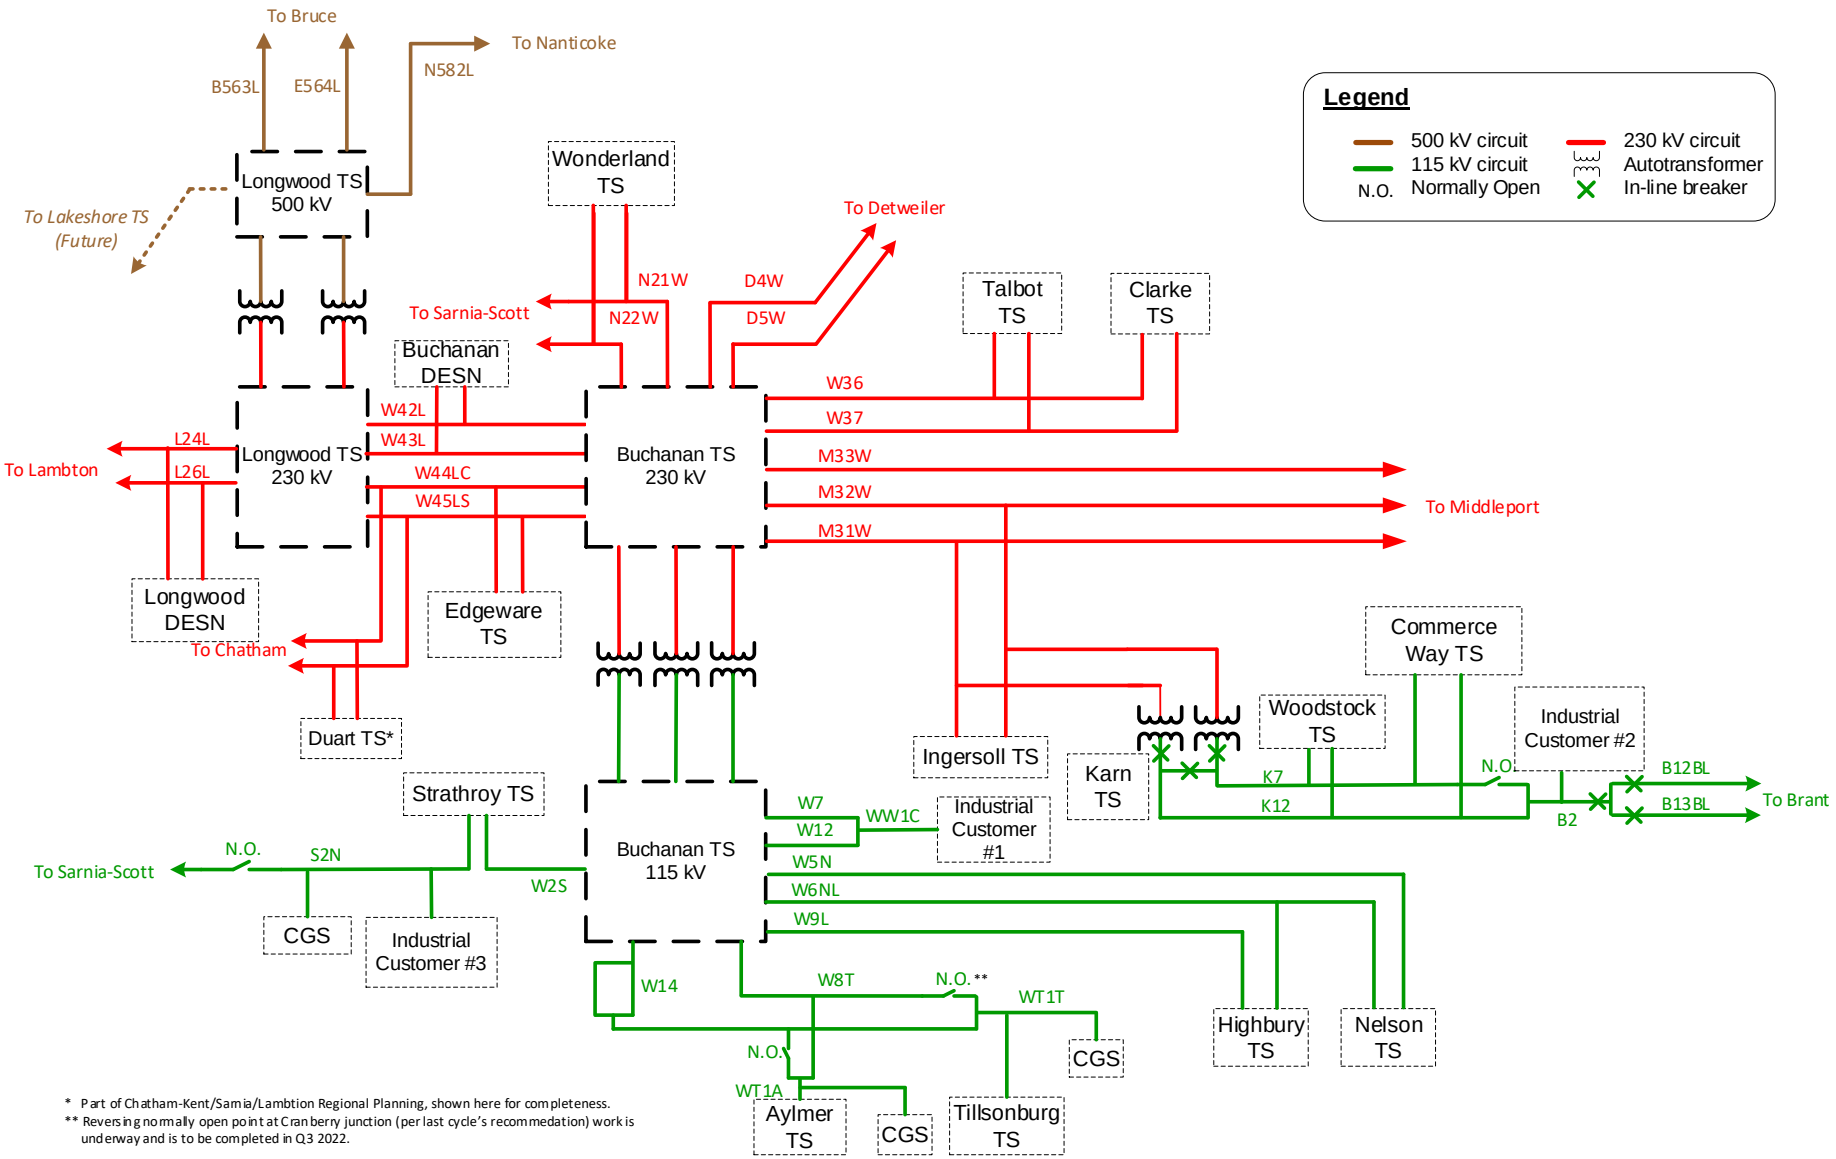

FIGURE 3-4: SIMPLIFIED SINGLE LINE DIAGRAM OF THE LONDON AREA REGION'S TRANSMISSION NETWORK

4. Transmission Projects Completed and/or Underway Over the Last Ten Years

OVER THE LAST TEN YEARS, A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND UNDERTAKEN BY HYDRO ONE AIMED TO MAINTAIN THE RELIABILITY AND ADEQUACY OF ELECTRICITY SUPPLY IN THE LONDON AREA REGION.

A summary and description of the major projects completed and/or currently underway over the last ten years is provided below.

- Strathroy TS like-for-like replacement of 25/42 MVA 115/27.6 kV transformer T2 due to failure completed in 2012.
- Ingersoll TS like-for-like replacement of 75/125 MVA 230/27.6 kV transformers T5 & T6 that were approximately 35 years old. The transformers were identified to have a design weakness and were replaced to mitigate the risk of failures, improve restoration time and maintain system performance completed in 2012.
- Woodstock TS 50/83 MVA 115/27.6 kV transformers T1 & T2 that were approximately 50 years old and were deemed end-of-life were replace like-for-like in 2014.
- Aylmer TS transformers and low-voltage switchyard replacement project competed in 2017.
- Strathroy TS failed transformer T1 and low-voltage switchyard replacement project completed in 2019.
- Wonderland TS failed transformer T6 was replaced in 2019.
- St. Thomas TS was decommissioned and 115 kV circuit W14 re-termination work was completed in 2020.
- Sarnia Scott TS to Buchanan TS 230 kV circuits N21W/N22W tower structures refurbishment project was completed in 2021.
- Nelson TS station refurbishment project will be completed in 2022.
- Tillsonburg TS new low-voltage capacitor banks installed in 2021 and switchyard component replacement project to be completed in 2022.
- Longwood TS protection and control replacement project to be completed in 2023.
- Edgeware TS protection and control replacement project to be completed in 2024.

5. London Area Demand

5.1. Load Forecast

The electricity demand in the London Area Region is anticipated to grow at an average rate of 1% over the next ten years. The London Area Region has been historically a summer-peaking region. Figure 5-5 shows the London Area Region's summer coincident peak load forecast for the 2022 – 2031 study period (extreme weather corrected peak) developed during the RIP phase. The load forecast prepared for the RIP phase is approximately 5% lower than the Needs Assessment load forecast due to higher forecasted contributions from CDM and DG.

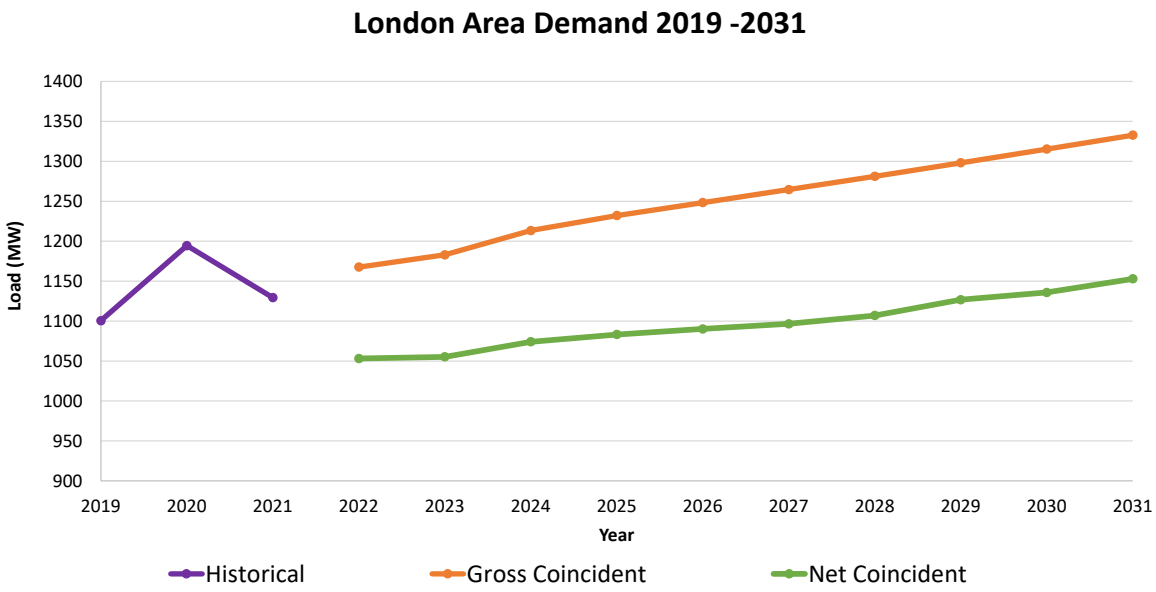

FIGURE 5-5: LONDON AREA REGION LOAD FORECAST

The load forecast shows that the region peak summer load increases from 1053 MW in 2022 to 1153 MW by 2031. The corresponding non-coincident summer peak loads increase from 1159 MW to about 1250 MW over the same period. The non-coincident and coincident net load forecasts for the individual stations in the London Area Region are given in Appendix D, Table D-1 and Table D-2.

LDCs in this region emphasized that impact of electrification have not been factored into the current RIP load forecasts. Should initiatives such as gas furnace conversion and continued electric vehicle adoption accelerate, transmission system adequacy will have to be re-assessed.

5.2. Forecast Assumptions

The following assumptions are made:

- The study period for the RIP assessment is 2022 – 2031.
- The 2021 summer station peak load is considered as a reference point and was adjusted for extreme weather impact (2.12% in 2021). Growth rates were extrapolated from LDCs' load forecasts via linear regression and are applied onto to the reference point to develop a gross load forecast.
- Distributed generation ("DG") refers to small-scale power generation connected in the distribution system which is located close to where the electricity is consumed. Both conservation & demand management ("CDM") as well as DG can reduce the amount of load that needs to be supplied and their contributions, as provided by the IESO, are directly net against the gross load forecast to develop a net load station forecast. A non-coincident version of the net load forecast was used to assess the station capacity.
- Load data for transmission-connected industrial customers in the region was assumed to be consistent with historical peak loads.
- All facilities that are identified in Section 4 and that are planned to be placed in-service within the study period are assumed to be in-service.
- Normal planning supply capacity for transformer stations is determined by the summer 10-day Limited Time Rating ("LTR"), assuming a 90% lagging power factor.

6. Regional Needs and Plans

THIS SECTION DISCUSSES ELECTRICAL INFRASTRUCTURE NEEDS IN THE LONDON AREA AND SUMMARIZES THE PLANS DEVELOPED TO ADDRESS THESE NEEDS.

This section outlines and discusses electrical infrastructure needs in the London Area and plans to address these needs for the study period of 2022 – 2031.

Based on the gross regional non-coincident load forecast, Clarke TS is forecasted to exceed its 10-Day LTR in 2023 and Highbury TS and Tillsonburg TS will also exceed station LTR in the medium term. However, these stations are expected to be adequate to meet the net load forecast for the remainder of the study period as planned CDM targets and DG contributions continue to offset the load growth. Overall, as the net load forecast prepared for the RIP phase is approximately 5% lower than the Needs Assessment load forecast, no new need was identified.

During the development of this RIP, issue about available capacity was raised at a number of stations, most notably Strathroy TS and Tillsonburg TS. Available capacity and its allocation among LDCs are governed by OEB's Transmission System Code and are separate from the regional planning process. Hydro One Transmission will continue to engage with its customers following the conclusion of this RIP.

Table 6-2 provides a summary of the needs identified in this cycle and the corresponding sub-sections where recommendations and plans are discussed. The planned in-service dates are tentative and will be finalized closer to project commencement in coordination with impacted LDCs.

TABLE 6-2: IDENTIFIED NEAR AND MID-TERM NEEDS IN LONDON AREA REGION

No.	Need	Need Date	Section
1	Talbot TS station capacity	Today	6.1
2	Greater London sub-region restoration need	Today	6.2
3	End-of-life equipment replacement	Vary	6.3

6.1. Talbot TS

6.1.1. Sustainment Need

The existing Talbot TS comprises two 230 kV/27.6 kV DESNs (T1/T2 and T3/T4) and supplies electricity to London Hydro customers. It is supplied by two 230 kV circuits W36 and W37. Step-down transformers T3 and T4 have been in-service from 1979 and are in poor condition and approaching end-of-life. A number of 27.6 kV breakers and protection equipment have also been identified for replacement.

6.1.2. Station Capacity Need

The station capacity for T1/T2 and T3/T4 are 113 MW and 161 MW respectively. The summer regional non-coincident peak load of the two DESNs in 2021 are 119 MW and 168 MW. According

to the regional non-coincident net load forecast in the study period, Talbot TS T1/T2 DESN is expected to exceed its station capacity throughout the study period and Talbot TS T3/T4 DESN will exceed its capacity in 2029.

6.1.3. Recommendation

The station capacity need was first identified in the 2020 Needs Assessment and was primarily driven by temporary load transfer from neighbouring station (Nelson TS). As noted in Section 4, Nelson TS underwent refurbishment which includes converting the low-voltage supply from 13.8 kV to 27.6 kV. During the construction period, significant portion of the load that was originally supplied by this station was transferred to Clarke TS and Talbot TS. The newly refurbished Nelson TS was placed in-service in December 2018 and as more 27.6 kV distribution feeders becomes available in downtown London, London Hydro confirmed load will be transferred back to Nelson TS and additional transformation capacity is not required at this time.

The Study Team recommends Hydro One to proceed with like-for-like replacement of T3 and T4 at Talbot TS. Project is expected to be completed in 2028. In addition, Hydro One will look for opportunities to coordinate this project with London Hydro for the metalclad switchgear replacement.

6.2. Greater London Sub-region Restoration Need

6.2.1. Description

The 230 kV double-circuit line,W36 and W37, emanates from Buchanan TS and supplies Talbot TS (both DESNs) and Clarke TS. Should the simultaneous loss of W36/W37 occurs, all of the loads supplied by the Clarke TS and Talbot TS, which amounts to over 340 MW[2], would be interrupted by configuration. The potential load loss exceeds the ORTAC 30-minute restoration criteria.

6.2.2. Recommendation

This need was first reported in the first cycle of regional planning for the London Area Region in 2015. The 2017 IRRP working group recommended installing switching devices and feeder extensions on the distribution system. The IRRP working group also acknowledged while these measures will not fully address the restoration need, they will substantially improve the restoration capability in a cost-effective manner.

The restoration need persists in the current regional planning cycle and was further re-assessed with London Hydro via the Local Planning process. The Study Team noted a significant portion of the interrupted load could be restored by a neighbouring unaffected station, Highbury TS, if its station capacity limit is lifted. This option was not pursued further at this time as work required will be extensive and cost prohibitive. Hydro One undertook a detailed historical equipment performance review to assess the probability of common-mode failure that would lead to simultaneous loss of W36 and W37. It was concluded that the only common-mode failure that may result in the simultaneous loss of both W36/W37 is the failure of the steel poles that carry

[2] 2021 historical coincident peak load.

the two circuits and probability of this event is very low. Therefore, the Study Team recommends no action is required at this time.

6.3. End-of-Life Equipment Replacement

6.3.1. Buchanan TS

6.3.1.1. Description

Buchanan TS is a major 230/115 kV transformer station in the area that supplies load stations in London Area. The station houses three 230/115 kV auto-transformers, three 230 kV capacitor banks, one 115 kV capacitor bank and two 230/27.6 kV step-down transformers. There are sixteen 230 kV oil breakers and nine SF6 circuit breakers in the 230 kV switchyard; seventeen oil circuit and three SF6 circuit breakers in the 115 kV switchyard.

Two of the 3 auto-transformers T2 and T3 are 48 and 54 years old respectively, are in poor condition, and approaching the end of life.

6.3.1.2. Recommendation

To address poor equipment performance of deteriorating equipment, Hydro One plans to replace two 230kV autotransformers, spill containment pits, AC and DC station service equipment, as well as some obsolete protection, controls and telecom equipment.

6.3.2. Clarke TS

6.3.2.1. Description

Clarke TS is a DESN station located in the northern part of the London Area. The station is supplied by two 230 kV circuits W36 and W37. The station supplies electricity to London Hydro and Hydro One Distribution customers.

The two 230/27.6 kV 50/83 MVA transformers T3 and T4 are 55 years old, in poor condition, and approaching end of life. Some of the protection equipment is also found to be obsolete.

6.3.2.2. Recommendation

To address the assets in poor condition and end-of-life, Hydro One plans to replace step-down transformers like-for-like, associated disconnect switches, 27.6 kV switchyard components including breakers, station services, capacitors and protections. Replacement plan will be closely coordinated with affected LDCs and the expected completion date is 2028.

6.3.3. Wonderland TS

6.3.3.1. Description

Wonderland TS is a DESN station located in the western part of the London Area. The station is supplied by two 230 kV circuits N21W and N22W. The station supplies electricity to London Hydro and Hydro One Distribution customers.

The Wonderland T5/T6 DESN facility was originally built in the 1960s and its equipment is degrading in condition. The 50/83 MVA T6 power transformer was replaced in 2004 due to failure. The companion transformer, T5, failed in July 2019 and was subsequently replaced. The existing air insulated 27.6 kV switchgear, majority of which are original installations have reached end-of-life due to deteriorated condition and has limited availability of parts for ongoing support and maintenance. All site protection and control equipment, consisting of first generation electro-mechanical relaying are deemed end-of-life, obsolete and require replacement. During the early project development phase, London Hydro and Hydro One Distribution were consulted to assess if there is a capacity need to replace the 50/83 MVA transformers with 75/125 MVA and it was concluded there is no such need at the time.

6.3.3.2. Recommendation

To address the end-of-life need, Hydro One plans to replace the Wonderland 27.6 kV switchyard. Replacement plan will be closely coordinated with affected LDCs and the expected completion date is 2026.

6.3.4. London Area East OPGW Infrastructure

6.3.4.1. Description

M31W and M32W are 230 kV network circuits that connect Buchanan TS and Middleport Port TS. Ingersoll TS and Karn TS are tapped off M31W/M32W at Salford Junction. High voltage 230/115 kV autotransformers are located at Karn TS provide the necessary transformation from the 230 kV system to the Woodstock and Commerce Way 115 kV system.

6.3.4.2. Recommendation

To improve the reliability of power system telecom network, Hydro One plans to install 9km of OPGW fibre from Salford Junction to Ingersoll TS and remove the existing licensed microwave link connects Ingersoll TS to Buchanan TS. Project is expected to be completed in 2027.

6.3.5. London Area West OPGW Infrastructure

6.3.5.1. Description

Several transmission lines in the London area that emanate from Buchanan TS currently rely on leased legacy dedicated metallic cable infrastructure for DC remote trip protections. These include 230kV circuits W36/W37 that connect to Talbot TS and Clarke TS, 115 kV circuits W5N/W6NL that connect to Nelson TS and Highbury TS, 115 kV circuit W2S that connects to Strathroy TS and 230kV circuit N21W connecting to Sarnia Scott TS.

6.3.5.2. Recommendation

To improve the reliability of power system telecom network, Hydro One plans to establish a geographically diverse and fully redundant fibre optic network for protection and SCADA applications. A combination of Hydro One's existing and new OPGW-based fibre and two leased third-party fibre links would be utilized. The existing metallic cable will be removed and the project is expected to be completed in 2029.

7. Conclusions and Next Steps

THIS REGIONAL INFRASTRUCTURE PLAN CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE LONDON AREA REGION.

The major infrastructure investments recommended by the Study Team in the near and mid-term planning horizon are provided in Table 7-3 below are all end of life needs, along with their planned in-service date. The planned in-service dates are tentative and will be finalized closer to project commencement in coordination with impacted LDCs.

TABLE 7-3: RECOMMENDED PLANS IN LONDON AREA REGION OVER THE NEXT 10 YEARS

Stations / Lines	Scope	In-service
Buchanan TS	Replacement of autotransformers and associated equipment	2028
Clarke TS	Replacement of step-down transformers, associated disconnect switches, low-voltage switchyard components	2028
Talbot TS	Replacement of step-down transformers (T3/T4), associated disconnect switches, low-voltage switchyard components	2028
Wonderland TS	Low-voltage switchyard components replacement	2026
M31W/ M32W (Salford Junction x Ingersoll)	London Area East OPGW Infrastructure	2027
W36/W37/W5 NL/W6NL/W2S/ N21W	London Area West Telecom OPGW Infrastructure Installation	2029

The Study Team recommends Hydro One to continue with the implementation of infrastructure investments listed in Table 7-3.

In accordance with the Regional Planning process, the RIP should be reviewed and/or updated at least every five years. The Region will continue to be monitored and should there be a need that emerges earlier due to a change in load forecast or any other reason, the next regional planning cycle will be triggered in advance of the five-year timeline.

NEEDS ASSESSMENT REPORT

London Area

November 26, 2024

Needs Assessment Report

London Area

- November 26, 2024 -

Lead Transmitter:

Hydro One Networks Inc.

Prepared by: London Area Technical Working Group

Page intentionally left blank

Disclaimer

This Needs Assessment (NA) Report was prepared for the purpose of identifying potential needs in the London Area and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the NA phase and b) require further assessment and regional coordination. The results reported in this NA are based on the input and information provided by the Technical Working Group (TWG) for this region at the time. Updates may be made based on best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	London Area Region (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")
START DATE: July 29, 2024	**END DATE:** November 26, 2024

1. INTRODUCTION

The 2nd Regional Planning cycle for the London Area Region was completed in August 2022 with the publication of the Regional Infrastructure Plan ("RIP") report. This is the 3rd cycle of Regional Planning for the region.

The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten (10) years.

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. Considering these timelines, the 3rd Regional Planning cycle was triggered in July 2024 for the London Area Region. Due to significant load growth in the region, the Technical Working Group ("TWG") decided that the 3rd Regional Planning cycle be triggered one year in advance of the five-year period.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the London Area Region NA and includes:

a) Review and reaffirm needs/plans identified in the previous regional planning cycle RIP (as applicable),
b) Identify any new needs resulting from this assessment,
c) Recommend which need(s) require further assessment and regional coordination in the next phases of the regional planning cycle; and,
d) Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), and RIP, based on updated information available at that time. The planning horizon for this NA is ten (10) years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The London Region includes the municipalities of Oxford County (comprising Township of Blandford-Blenheim, Township of East Zorra-Tavistock, Town of Ingersoll, Township of Norwich, Township of South-West Oxford, Town of Tillsonburg, Township of Zorra), City of Woodstock, Middlesex County (comprising Municipality of Adelaide Metcalfe , Municipality of Lucan Biddulph, Municipality of Middlesex Centre, Municipality of North Middlesex, Municipality of Southwest Middlesex, Municipality of Strathroy-Caradoc, Municipality of Thames Centre, Village of Newbury), City of London, Elgin County (comprising Municipality of Town of Aylmer, Municipality of Bayham, Municipality of Central Elgin, Municipality of West Elgin, Municipality of Dutton/Dunwich, Township of Malahide, Township of Southwold), and City of St. Thomas. In addition, the transmission facilities in this region also supply part of Norfolk County.

5. INPUTS/DATA

The TWG comprises of representatives from Local Distribution Companies ("LDC"), the Independent Electricity System Operator ("IESO"), and Hydro One and provides input and relevant information for the London Area Region regarding capacity needs, reliability needs, operational issues, and major high-voltage (HV) transmission assets requiring replacement over the planning horizon. The LDCs also capture input from municipalities in the development of their ten-year load forecast.

In accordance with the regional planning process, stakeholder engagement takes place during the SA and IRRP phase.

6. ASSESSMENT METHODOLOGY

The assessment's primary objective is to identify the electrical infrastructure needs in the Region over the ten-year planning horizon. The assessment methodology includes a review of planning information such as load forecast (which factors various demand drivers and consideration of MEPs and/or CEPs where available), conservation and demand management ("CDM") forecast, distributed generation ("DG") forecast, system reliability and operation, and major HV transmission assets requiring replacement.

A technical assessment of needs is undertaken based on:

a) Current and future station capacity and transmission adequacy;

b) System reliability needs and operational concerns;

c) Major HV transmission equipment requiring replacement with consideration to "right-sizing"; and,

d) Sensitivity analysis to capture uncertainty in the load forecast as well as variability of demand drivers such as electrification.

7. NEEDS

I. Updates on needs identified during the previous regional planning cycle

The following needs and projects have been recently completed:

- Edgeware TS PCT and component replacement (completed in 2024)
- Reversing of the normally open point at Cranberry Junction, per the Aylmer-Tillsonburg Reinforcement project (completed in 2024)
- Tillsonburg TS component replacement (completed in 2023)
- Nelson TS station refurbishment (completed in 2022)
- Tillsonburg TS low voltage capacitor banks installation (completed in 2021)
- Sarnia Scott TS x Buchanan TS 230 kV N21W/N22W circuits tower structures refurbishment (completed in 2021)
- St. Thomas TS decommissioning and 115 kV W14 circuit re-termination work (completed in 2020)
- Strathroy TS T1 and component replacement (completed in 2019)
- Wonderland TS T6 replacement (completed in 2019)

The needs and projects discussed in the London Area 2nd cycle RIP report for the London Area Region are as follows:

- Talbot TS Station Capacity: According to the net load forecast in the study period, Talbot TS T1/T2 DESN and Talbot T3/T4 DESN was expected to exceed its station capacity throughout the study period
- Talbot TS transformers T3 and T4, associated disconnect switches, and low-voltage switchyard components replacement need: Replacement that will allow for maintaining reliability (2032)
- Greater London Sub-Region Restoration Need: The 230 kV double-circuit line, W36 and W37, emanates from Buchanan TS and supplies Talbot TS (both DESNs) and Clarke TS. Should the simultaneous loss of W36/W37 occur, all loads supplied by the Clarke TS and Talbot TS would be interrupted by configuration. The potential load loss would exceed the ORTAC load restoration criteria.
- Buchanan TS Autotransformer T2 and T3 and associated equipment replacement need: Replacement that will allow for maintaining reliability (beyond planning horizon)
- Clarke TS Transformer T3 and T4, associated disconnect switches, and low-voltage switchyard components replacement need: Replacement that will allow for maintaining reliability (beyond planning horizon)

II. Newly identified needs in the region

The following are new needs that were identified as part of this assessment:

a) Asset Renewal for Major HV Transmission Equipment

- No new Asset Renewal Needs

b) Transformation Capacity

- New Transformation Capacity needs were identified at the following stations:
  - Aylmer TS
  - Clarke TS
  - Edgeware TS
  - Nelson TS
  - Strathroy TS
  - Tillsonburg TS
  - Woodstock TS
  - Wonderland TS

c) Transmission System Capacity

- Thermal limitations were observed on 230 kV W44LC/W45LS for the loss of companion circuit
- Thermal limitations were observed on the 115 kV WT1T to Tillsonburg TS, in pre-contingency

d) System Reliability, Operation and Load restoration

- Load restoration limitations on 230 kV M31W/M32W and 115 kV K7/K12/B2 circuits for a single tower contingency caused by the loss of double-circuit line M31W and M32W or for a double contingency with the loss of both autotransformers at Karn TS
- Load restoration limitations on 230 kV M31W/M33W circuits for a single tower contingency
- Load restoration limitations on 230 kV W44LC/W45LS circuits for a single tower contingency

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

The impact of the sensitivity analysis for the high and low growth scenarios was considered relatively minor to near-term need dates for station and line capacity needs.

9. RECOMMENDATIONS

The TWG recommendations are as follows:

I. Needs that require further assessment and regional coordination

These needs may have broader regional impacts and require further assessment and coordination during the next phases[1] of the regional planning cycle. A list of these needs are as follows:

a. Transmission System Capacity

- Thermal limitations on 230 kV W44LC/W45LS for the loss of companion circuit
- Thermal limitations on the 115 kV WT1T to Tillsonburg TS pre-contingency

b. System Reliability, Operation and Load Restoration

- Load restoration limitations on 230 kV M31W/M32W and 115 kV K7/K12/B2 circuits for a single tower contingency causing the loss of double-circuit line M31W and M32W or for a double contingency with the loss of both autotransformers at Karn TS
- Load restoration limitations on 230 kV M31W/M33W circuits for a single tower contingency
- Load restoration limitations on 230 kV W36/W37 circuits for a single tower contingency
- Load restoration limitations on 230 kV W44LC/W45LS circuits for a single tower contingency

c. Transformation Capacity Needs:

- Aylmer TS
- Edgeware TS
- Clarke TS
- Nelson TS
- Strathroy TS
- Talbot T1/T2
- Talbot T3/T4
- Tillsonburg TS
- Wonderland TS
- Woodstock TS

II. Needs that do not require further regional coordination

The TWG recommends reviewing all needs in the region, identified in this needs assessment, proceed to the next phases of this regional planning cycle for further assessment.

[1] Non-wires options are further considered (i.e. incremental to CDM and DG that is considered in this NA) as potential options in addressing these needs during the IRRP phase.

List of LDC(s) to be involved in further regional planning phases:

- Entegrus Powerlines Inc.
- ERTH Power Inc.
- Hydro One Distribution
- London Hydro Inc.
- Tillsonburg Hydro Inc.

List of LDC(s) which are not required to be involved in further regional planning phases:

- N/A

1. INTRODUCTION

The second cycle of the Regional Planning process for the London Area Region was completed in August 2022 with the publication of the Regional Infrastructure Plan ("RIP") report. The RIP report included a common discussion of all the options and recommended plans for preferred wire infrastructure investments to address the near- and medium-term needs.

This Needs Assessment initiates the third regional planning cycle for the London Area Region. The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:

i) require further assessment and regional coordination (and hence, proceed to the next phases of regional planning); and,

ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years. A flow chart of the Regional Planning Process is shown in Figure 1 below.

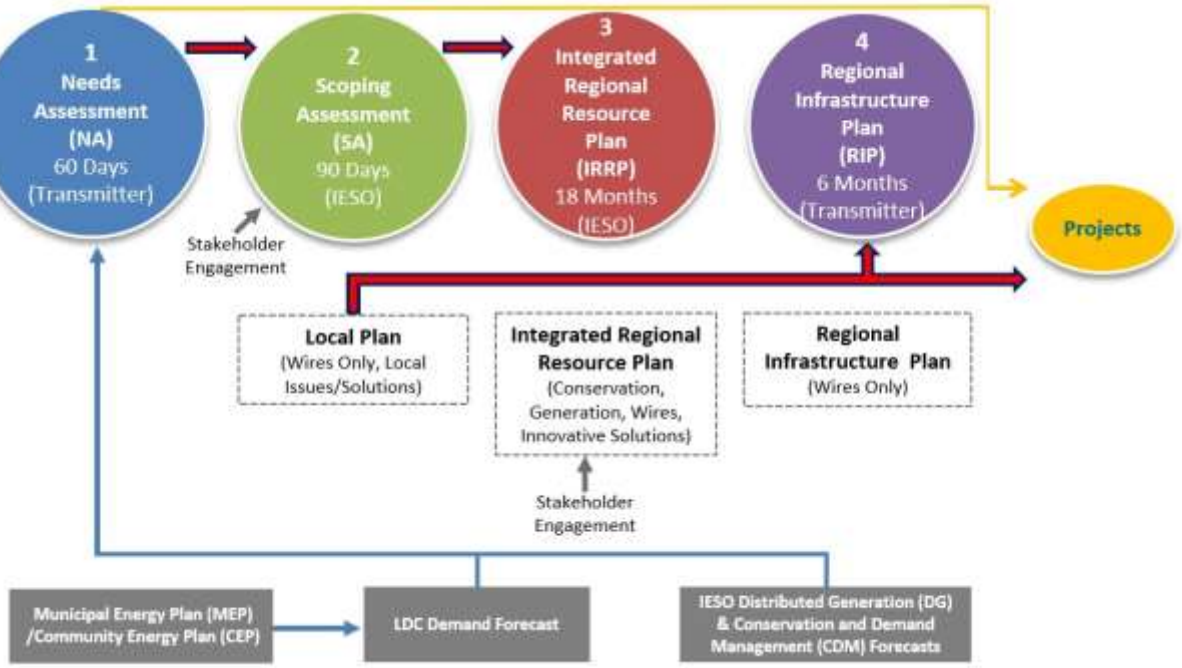

Figure 1: Regional Planning Process

This report was prepared by the London Area Technical Working Group ("TWG"), led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC") and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: London Area Region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Networks Inc. (Transmission) – Transmitter
2	Independent Electricity System Operator (IESO) – System Operator
3	Entegrus Powerlines Inc. – LDC
4	ERTH Power Inc. – LDC
5	Hydro One Networks Inc. (Distribution) – LDC
6	London Hydro Inc. – LDC
7	Tillsonburg Hydro Inc. – LDC

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. As such, the 3rd Regional Planning cycle was triggered for the London Area region. Due to significant load growth in the region, the Technical Working Group ("TWG") decided that the 3rd Regional Planning cycle be triggered one year in advance of the five-year requirement.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this NA covers the London Area region and includes:

- Review and reaffirm needs/plans identified in the previous cycle RIP (as applicable),
- Identify any new needs resulting from this assessment,
- Recommend which need(s) require further assessment and regional coordination in the next phases of the regional planning cycle; and,

- Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), Local plan (LP) and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is 10 years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The geographical boundaries of the London Area region are shown in Figure 2 below. The London Region includes the municipalities of Oxford County (comprising Township of Blandford-Blenheim, Township of East Zorra-Tavistock, Town of Ingersoll, Township of Norwich, Township of South-West Oxford, Town of Tillsonburg, Township of Zorra), City of Woodstock, Middlesex County (comprising Municipality of Adelaide Metcalfe , Municipality of Lucan Biddulph, Municipality of Middlesex Centre, Municipality of North Middlesex, Municipality of Southwest Middlesex, Municipality of Strathroy-Caradoc, Municipality of Thames Centre, Village of Newbury), City of London, Elgin County (comprising Municipality of Town of Aylmer, Municipality of Bayham, Municipality of Central Elgin, Municipality of West Elgin, Municipality of Dutton/Dunwich, Township of Malahide, Township of Southwold), City of St. Thomas. In addition, the transmission facilities in this region also supply part of Norfolk County.

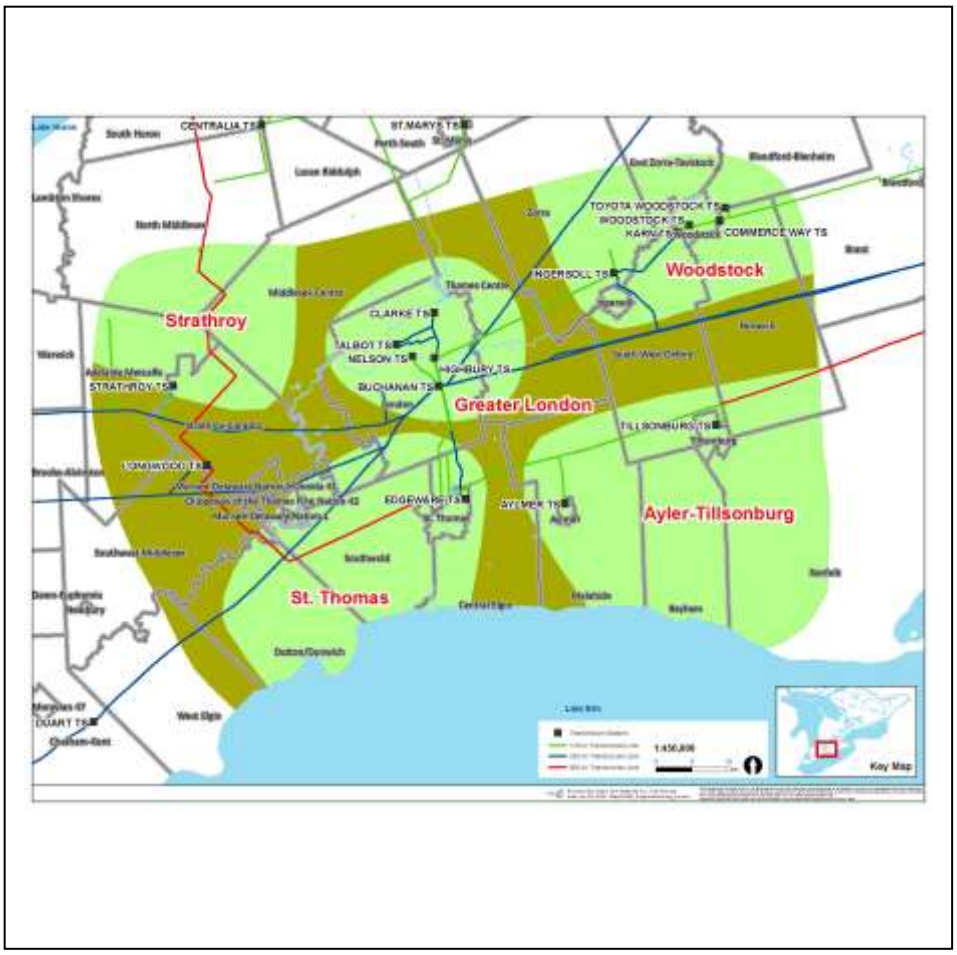

Figure 2: Map of London Area Regional Planning Area

The Bulk Electrical Supply Network in the London Area consists of 500/230kV autotransformers at Longwood TS that supplies a network of 230kV and 115kV circuits. There are 230/115kV autotransformers at Buchanan TS and Karn TS.

London Area transmission system is a network of 230 kV and 115 kV circuits and is connected to Longwood TS through five 500/230 kV autotransformers. Autotransformers at Buchanan TS and Karn TS provide the necessary 230/115 kV auto-transformation. Step-down transformer stations are connected to both 230 kV and 115 kV systems to bring the power to distribution level of 27.6 kV to serve the area. There are fourteen Hydro One step-down TS's, three transmission connected industrial load customers and three transmission connected generators in the London Area.

The existing facilities in the London Area are summarized below and depicted in the single line diagram shown in Figure 3:

- Fourteen step-down transformer stations currently supply the London Area load: Aylmer TS, Buchanan TS, Clarke TS, Commerce Way TS, Edgeware TS, Highbury TS, Ingersoll TS, Longwood TS, Nelson TS, Strathroy TS, Talbot TS (Dual Element Spot Network or DESN 1 and DESN 2), Tillsonburg TS, Wonderland TS, and Woodstock TS.
- One new step-down transformer station is planned to be in-service in 2026/2027: Centennial TS.
- Three directly connected industrial customer loads are connected in the London Area.
- Three existing transmission-connected generating stations in the London Area.

Although depicted, Duart TS is not included in the London Area study and will be studied as part of the Chatham-Kent/Lambton/Sarnia (CKLS) Area Regional Planning.

The single line diagram of the Transmission Network of London Area region is shown in Figure 3 below.

5. INPUTS AND DATA

TWG participants, including representatives from LDCs, IESO, and Hydro One provided information and input for the London Area NA. With respect to the load forecast information, the OEB Regional Planning Process Advisory Group (RPPAG) recently published a document called "Load Forecast Guideline for Ontario" in October 2022. The objective of this document is to provide guidance to the TWG in the development of the load forecasts used in the various phases of the regional planning process with a focus on the NA and the IRRP. One of the inputs into the LDC's load forecast that is called for in this guideline is information from Municipal Energy Plans ("MEPs") and/or Community Energy Plans ("CEPs"). The list of all the Municipalities falling under the geographical boundaries of the region are given in Appendix E.

The information provided includes the following:

- London Area 10-year Load Forecast for all supply stations inclusive of the inputs provided by the municipalities (e.g. through their MEPs & CEPs).

- Known capacity and reliability needs, operating issues, and/or major assets requiring replacement/ refurbishment; and
- Planned/foreseen transmission and distribution investments that are relevant to Regional Planning for the London Area.
- Captured uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

6. ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in development of this Needs Assessment:

6.1 Technical Assessments and Study Assumptions

The technical assessment of needs was undertaken based on:

- Current and future station capacity and transmission adequacy;
- System reliability and operational considerations;
- Asset renewal for major high voltage transmission equipment requiring replacement with consideration to "right-sizing"; and,
- Load forecast data was requested from industrial customers in the region, and
- This assessment is based on summer peak loads. Three load forecasts were developed i.e. Normal Growth scenario, High & low Growth scenario. The High and low Growth scenario load forecast was developed to conduct a sensitivity analysis to cover unforeseen developments such as, fuel switching, Government policies, higher than expected EV charging trend during peak load conditions, etc.

The following other assumptions are made in this report.

- The study period for this Needs Assessment is 2024-2033.
- The Region is summer peaking, so this assessment is based on summer peak loads.
- Line capacity adequacy is assessed by using coincident peak loads in the area.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
- Normal planning supply capacity for transformer stations is determined by the Hydro One summer 10-Day Limited Time Rating (LTR) of a single transformer at that station.
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).

6.2 Information Gathering process

6.2.1. Load forecast:

The LDCs provided their historical peaks, starting points with considerations for load transfers, and load forecasts without weather normalization, for all the stations supplying their loads in the London Area region for the 10-year study period including the inputs from the Municipalities such as MEPs and CEPs. The IESO provided a Conservation and Demand Management ("CDM") and Distributed Generation ("DG") forecast for the London Area region. The region's extreme summer non-coincident peak gross load forecasts for each station were prepared by applying the LDC load forecast growth rates to the actual 2023 summer peak corrected for load transfers and extreme weather. The extreme summer weather correction factor for 2023 was provided by Hydro One. The net extreme summer weather load forecasts were produced by reducing the gross load forecasts for each station by the percentage CDM and then by the amount of effective DG capacity provided by the IESO for that station. It is to be noted that as contracts for existing DG resources in the region begin to expire, at which point the load forecast has a decreasing contribution from local DG resources, and an increase in net demand. This extreme summer weather corrected net load forecast for the individual stations in the London Area region is given in Appendix A.

The CDM savings is estimated based on existing and planned CDM programs, as well as Building Codes & Equipment Standards. The estimated CDM forecasts will be further refined in the next phases of Regional Planning.

Distributed generation is accounted for through values provided by the IESO, based on the known contracted resources.

6.2.2. Sensitivity Analysis:

A sensitivity analysis was undertaken by the TWG to capture uncertainty in the load forecast as well as variability of drivers such as electrification. Hence, the NA recommendations are not necessarily linked to sensitivity scenarios; but rather are used to identify any emerging needs for consideration in developing recommendations. The impact of sensitivity analysis for the high and low growth scenarios are provided in section 8 of this report.

6.2.3. Asset renewal Needs for Major HV Equipment:

List of major HV transmission equipment planned and/or identified to be refurbished and/or replaced based on asset condition assessment, relevant for Regional Planning purposes**.** This includes HV transformers, autotransformers, HV Breakers, HV underground cables and overhead lines. The scope of equipment considered is given in section 7.1.

6.2.4. System Reliability and Operational Issues:

The IESO will identify any known system reliability and operational issues for the London Area region.

7. NEEDS

This section describes emerging new needs identified in the London Area Region and/or updates on previously identified needs since the completion of Previous Regional Planning cycle.

Needs that were identified and discussed in the previous regional planning cycle with associated projects that were recently completed and reaffirmed needs that are underway and are briefly described below with relevant updates. These projects include:

1. W36/W37 Load Restoration: This need was reported in the previous Regional Planning cycles and the impacted LDC, London Hydro, and Hydro One undertook further planning and analysis as part of Local Planning process. A detailed historical equipment performance review was performed to assess the probability of common-mode failure that would lead to simultaneous loss of W36 and W37. It was concluded that the only common-mode failure that may result in the simultaneous loss of both W36/W37 is the failure of the steel poles that carry the two circuits and probability of this event is very low.

All near, and mid-term needs that are discussed as a part of this report are summarized in Table 3 below.

Table 3: Near/Mid-term Needs Identified in Previous RIP and/or this NA

Need Description	Recommended Plan/Update	Previous RIP Report Section	NA Report Section
Asset Renewal Needs			
Talbot TS	Talbot TS Transformers T3 and T4 and associated switchyard equipment replacement	6.1.1	7.1.1
Buchanan TS	Buchanan TS Autotransformers T2 and T3 and associated switchyard equipment replacement	6.3.1	N/A*
Clarke TS	Clarke TS Transformer T3 and T4 and associated switchyard equipment replacement	6.3.2	N/A*
Station Capacity Needs			
Aylmer TS	The load forecast exceeds the station supply capacity in the near term	N/A	7.2.1
Clarke TS	The load forecast exceeds the station supply capacity in the near term	N/A	7.2.2
Edgeware TS	The load forecast exceeds the station supply capacity in the near term	N/A	7.2.3
Strathroy TS	The load forecast exceeds the station supply capacity in the near term	N/A	7.2.4
Nelson TS	The load forecast exceeds the station supply capacity in the medium term	N/A	7.2.5

Talbot T1/T2	The load forecast exceeds the station supply capacity in the near term	6.1.2	7.2.6
Talbot T3/T4	The load forecast exceeds the station supply capacity in the near term	6.1.2	7.2.7
Tillsonburg TS	The load forecast exceeds the station supply capacity in the near term	N/A	7.2.8

Transmission Line Capacity Needs			
W44LC/W45LS	Transmission Line Capacity limitation on 230 kV W44LC/W45LS for the loss of companion circuit in the medium term	N/A	7.3.1
WT1T/W14	Transmission Line Capacity limitation on the 115 kV WT1T to Tillsonburg TS pre-contingency in the near term	N/A	7.3.2
System Reliability, Operation and Load restoration Needs			
M31W/M32W K7/K12/B2	Load restoration limitation on 230 kV M31W/M32W and 115 kV K7/K12/B2 circuits for a single tower contingency causing the loss of double-circuit line M31W and M32W or for a double contingency with the loss of both autotransformers at Karn TS	N/A	7.4.1
M31W/M33W	Load restoration limitation on 230 kV M31W/M33W circuits for a single tower contingency	N/A	7.4.2
W36/W37	Load restoration limitation on 230 kV W36/W37 circuits for a single tower contingency	6.2	7.4.3
W44LC/W45LS	Load restoration limitation on 230 kV W44LC/W45LS circuits for a single tower contingency.	N/A	7.4.4
Voltage Performance			
N/A	N/A		

*Current planned date of replacement beyond the planning horizon of this Needs Assessment

7.1 Asset Renewal Needs for Major HV Transmission Equipment

In addition to the previously identified asset renewal needs from the second regional planning cycle, Hydro One and TWG has also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the London Area Region. The complete list of major HV transmission equipment requiring replacement in the London Area Region is provided in table 4 in this section. Hydro One is the only Transmission Asset Owner (TAO) in the Region.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
  replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

The Asset renewal assessment considers the following options for “right sizing” the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., “like-for-like” replacement)
- Replacing equipment with higher ratings and built to current standards

From Hydro One’s perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages. Hydro One will continue to assess asset priorities based on recent operational performance to determine the appropriate timing for replacement.

Table 4: Major HV Transmission Asset assessed for Replacement in the region

Station/Circuit	Need Description	Planned ISD
Talbot TS	Talbot TS Transformer T3 and T4 and associated switchyard equipment replacement	2032

7.1.1 Talbot TS (T3/T4)

The existing Talbot TS comprises two 230 kV/27.6 kV DESNs (T1/T2 and T3/T4) and supplies electricity to London Hydro customers. It is supplied by two 230 kV circuits W36 and W37. Step-down transformers T3 and T4 have been in-service from 1979 and as per asset condition assessment, are identified for replacement. In recent years, Talbot TS has experienced several failures with the breakers in the medium-voltage switchyard. Hydro One will continue to assess asset priorities based on recent operational performance to determine the appropriate timing for replacement. A station capacity need has also been identified for the Talbot T3/T4 DESN (Section 7.2.7)

7.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period **2024-2033** for the 230kV and 115kV Transforming stations in the **London Area** Region using the summer non-coincident peak load forecasts that were provided by the Technical Working Group. Based on the results, the following Station capacity needs have been identified in the during the study period

7.2.1 Aylmer TS – 115/27.6 kV

Aylmer TS is a DESN station located in Aylmer-Tillsonburg. The station is supplied by the 115 kV circuit W8T and supplies electricity to ERTH Power and Hydro One Distribution customers. The station had a 2023 non-coincident summer peak of 30.2 MW. The station forecast exceeds the station LTR of 43.0 MW within the near term (within 5 years).

7.2.2 Clarke TS – 230/27.6 kV

Clarke TS is a DESN station located in the northern part of London. The station is supplied by two 230 kV circuits W36 and W37 and supplies electricity to London Hydro and Hydro One Distribution customers. The station had a 2023 non-coincident summer peak of 101.7 MW. The station forecast exceeds the station LTR of 109.7 MW within the near term (within 5 years).

7.2.3 Edgeware TS – 230/27.6 kV

Edgeware TS is a DESN station located in the St. Thomas area. The station is supplied by the 230 kV circuits W44LC and W45LS and supplies electricity to Entegrus, Hydro One Distribution, and London Hydro customers. The station had a 2023 non-coincident summer peak of 100.9 MW. The station forecast exceeds the station LTR of 180.9 MW within the near term (within 5 years).

7.2.4 Nelson TS – 115/27.6 kV

Nelson TS is a DESN station located in London. The station is supplied by the 115 kV circuits W5N and W6NL and supplies electricity to London Hydro customers. The station had a 2023 non-coincident summer peak of 57 MW. The station forecast exceeds the station LTR of 107 MW in the medium term (5-10 years).

7.2.5 Strathroy TS – 115/27.6 kV

Strathroy TS is a DESN station located in Strathroy. The station is supplied by the 115 kV circuits S2N and W2S and supplies electricity to Entegrus and Hydro One Distribution customers. The station had a 2023 non-coincident summer peak of 38.1 MW. The station forecast exceeds the station LTR of 61.1 MW within the near term (within 5 years).

7.2.6 Talbot T1/T2 DESN – 230/27.6 kV

Talbot TS comprises of two 230 kV/27.6 kV DESNs (T1/T2 and T3/T4) and supplies electricity to London Hydro customers. The Talbot T1/T2 DESN is supplied by two 230 kV circuits W36 and W37. The station is supplied by the 230 kV circuits S2N and W2S. The station supplies electricity to London Hydro customers. The station had a 2023 non-coincident summer peak of 115.5 MW. The station forecast exceeds the station LTR of 113.5 MW within the near term (within 5 years).

7.2.7 Talbot T3/T4 DESN – 230/27.6 kV

Talbot TS comprises of two 230 kV/27.6 kV DESNs (T1/T2 and T3/T4) and supplies electricity to London Hydro customers. The Talbot T3/T4 DESN is supplied by two 230 kV circuits W36 and W37. The station is supplied by the 230 kV circuits S2N and W2S. The station supplies electricity to London Hydro customers. The station had a 2023 non-coincident summer peak of 163.4 MW. The station forecast exceeds the station LTR of 161.6 MW within the near term (within 5 years).

7.2.8 Tillsonburg TS – 115/27.6 kV

Tillsonburg TS is a DESN station located in Tillsonburg. The station is supplied by the 115 kV WT1T (tapped from W14) and supplies electricity to Hydro One Distribution and Tillsonburg Hydro customers. The station had a 2023 non-coincident summer peak of 93.4 MW. The station forecast exceeds the station LTR of 108.9 MW within the near term (within 5 years).

7.2.9 Wonderland TS – 230/27.6 kV

Wonderland TS is a DESN station located in the southwest part of London. The station is supplied by the 230 kV circuits N21W/N22W and supplies electricity to London Hydro and Hydro One Distribution customers. The station had a 2023 non-coincident summer peak of 115.9 MW. The station forecast exceeds the station LTR of 122.4 MW within the near term (within 5 years).

7.2.10 Woodstock TS – 115/27.6 kV

Woodstock TS is a DESN station located in Tillsonburg. The station is supplied by the 115 kV circuits K7/K12/B2 and supplies electricity to Hydro One Distribution customers. The station had a 2023 non-coincident summer peak of 60.8 MW. The station forecast exceeds the station LTR of 86.3 MW within the near term (within 5 years).

7.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period 2024-2033 for the 230kV and 115kV Transmission line circuits in the London Area Region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater this need. Based on the results, the following line capacity needs have been identified in the during the study period:

7.3.1 W44LC/W45LS – 230 kV – Thermal Limits

The W44LC/W45LS double circuit line, of which the portion from Buchanan JCT to Edgeware TS is about 16 km and supplies Edgeware TS and will supply the future Centennial TS. For the loss of one of the W44LC or W45LS, the loading on the Buchanan JCT to Edgeware TS section exceeds its post-contingency rating in the Medium-Term.

7.3.2 WT1T/W14 – 115 kV – Thermal Limits

The WT1T radial circuit is about 3.5 km tapped from the W14 circuit. The loading on the Cranberry JCT to ESWF JCT and the ESWF JCT to Tillsonburg JCT exceeds its pre-contingency rating in the Near-Term.

7.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. A study has been performed, considering the net coincident load forecast and the loss of one element over the study period 2024-2033 to cater this need**.** Based on the results, some system reliability, operating and restoring issues have been identified for this Region.

As per the load security criteria (ORTAC Section 7.1), with one element out of service, planned load curtailment or load rejection is permissible only to account for local generation outages; and not more than 150MW of load may be interrupted by configuration, planned load curtailment or rejection. With two elements out of service, not more than 600 MW of load may be interrupted by configuration, planned load curtailment or rejection.

As per the load restoration criteria (ORTAC Section 7.2), interrupted load must be restored within the following timelines:

- Load above 250 MW, within 30 minutes;
- Load above 150 MW, within 4 hours; and
- All load, within 8 hours.

7.4.1 M31W/M32W 230 kV – K7/K12/B2 115 kV – Load Restoration

Based on the net coincident load forecast at Ingersoll TS and stations connected along the 115 kV circuits K7/K12/B2, the load interrupted by configuration may reach up to 267 MW for the loss of double-circuit line M31W and M32W or loss of both autotransformers at Karn TS. Ingersoll TS up to 95 MW, Woodstock TS up to 92 MW, Commerce Way TS up to 68 MW and Toyota Woodstock CTS up to 20 MW.

In accordance with ORTAC, the system is required to restore 17 MW within 30 mins, 100 MW within 4 hours and the remaining 150 MW within 8 hours. This need was identified in previous Regional Planning cycles and remains in this cycle.

Approximately 20 MW of load can be transferred to the B2 circuit from Brant TS.

7.4.2 M31W/M33W– 230 kV – Load Restoration

Based on the load forecast at the new Centennial TS, the load interrupted by configuration will reach approximately 189 MW in 2027 for the loss of double-circuit line M31W and M33W.

In accordance with ORTAC, the system is required to restore 39 MW within 4 hours and the remaining 150 MW within 8 hours.

7.4.3 W36/W37 – 230 kV – Load Restoration

Based on the net coincident load forecast at Clarke TS, Talbot T1/T2 and Talbot T3/T4, the load interrupted by configuration will reach up to 414 MW in 2033 for the loss of double-circuit line W36 and W37. Clarke TS up to 126 MW, Talbot T1/T2 up to 119 MW and Talbot T3/T4 up to 166 MW.

In accordance with ORTAC, the system is required to restore 164 MW within 30 minute, 100 MW within 4 hours and the remaining 150 MW within 8 hours. This need was reported in the previous Regional Planning cycles and the impacted LDC, London Hydro, and Hydro One undertook further planning and analysis as part of Local Planning process. A detailed historical equipment performance review was performed to assess the probability of common-mode failure that would lead to simultaneous loss of W36 and W37. It was concluded that the only common-mode failure that may result in the simultaneous loss of both W36/W37 is the failure of the steel poles that carry the two circuits and probability of this event is very low.

7.4.4 W44LC/W45LS – 230 kV – Load Restoration

Based on the net coincident load forecast at Edgeware TS, Duart TS and the future Centennial TS, the load interrupted by configuration will reach up to 486 MW in 2033 for the loss of double-circuit line W44LC and W45LS. Edgeware TS area up to 247 MW, Duart TS approximately 50 MW, and the future Centennial TS approximately 189 MW.

The simultaneous loss of double-circuit line W44LC and W45LS will interrupt approximately 486 MW of load at Edgeware TS, Duart TS and the new Centennial TS by configuration.

In accordance with ORTAC, the system is required to restore 236 MW within 30 minute, 100 MW within 4 hours and the remaining 150 MW within 8 hours.

Approximately 50 MW of load can be transferred from Duart TS.

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments. The TWG determined that the key electric demand driver in the London Area region to be considered in this sensitivity analysis is electric vehicle (EV) penetration and unforeseen electrification which would cause the load to increase at a faster rate than shown in the forecast; or the potential delay in some projects which could result in less demand than anticipated.

The TWG reviewed EV scenarios and any unforeseen electrification needs to develop high demand growth forecasts by applying 50% additional growth to the growth rate on the extreme summer corrected Normal Growth net load forecasts. The low growth scenario was obtained by reducing the growth rate by 50%.

The normal and high growth forecasts are shown in Tables A.1, A.2, A.3 and A.4 in Appendix A.

The impact of sensitivity analysis for the high and low growth scenario identified the following updates or new Station/Line capacity needs:

Table 5: Impact of Sensitivity Analysis on Station/Line capacity needs in the region

Sr.no.	Need Identified	Normal Growth Scenario	High Growth Scenario	Low Growth Scenario
1	Aylmer TS Station Capacity	2025	2025	Long Term
2	Clarke TS Station Capacity	2026	2025	2027
3	Edgeware TS Station Capacity	2025	2025	2033
4	Nelson TS Station Capacity	2030	2028	Long Term
5	Strathroy TS Station Capacity	2028	2024	Long Term
6	Talbot T1/T2 DESN Station Capacity	2024	2024	2024
7	Talbot T3/T4 DESN Station Capacity	2024	2024	2024
8	Tillsonburg TS Station Capacity	2024	2024	2027
9	Wonderland TS Station Capacity	2027	2026	Long Term
10	Woodstock TS Station Capacity	2025	2025	Long Term

11	W44LC/W45LS Transmission Line Capacity	2029	2029	2029
12	WT1T Transmission Line Capacity	2025	2025	2025
13	M31W/M32W/K7/K12/B2 Load Restoration	Ongoing	Ongoing	Ongoing
14	M31W/M33W Load Restoration	2027	2027	2027
15	W36/W37 Load Restoration	Ongoing	Ongoing	Ongoing
16	W44LC/W45LS Load Restoration	Ongoing	Ongoing	Ongoing

9. CONCLUSION AND RECOMMENDATION

The Technical Working Group's recommendations to address the needs identified are as follows:

Table 7: Needs which require further regional coordination

Sr.no.	Need	Recommendation
1	Talbot T3/T4 DESN Asset Renewal	To be considered in addition to capacity needs in the next Regional Planning phases.
2	Aylmer TS Station Capacity	To be further assessed in the next Regional Planning phases.
3	Clarke TS Station Capacity	To be further assessed in the next Regional Planning phases.
4	Edgeware TS Station Capacity	To be further assessed in the next Regional Planning phases.
5	Nelson TS Station Capacity	To be further assessed in the next Regional Planning phases.
6	Strathroy TS Station Capacity	To be further assessed in the next Regional Planning phases.
7	Talbot T1/T2 Station Capacity	To be further assessed in the next Regional Planning phases.
8	Talbot T3/T4 Station Capacity	To be further assessed in the next Regional Planning phases.
9	Tillsonburg TS Station Capacity	To be further assessed in the next Regional Planning phases.
10	Wonderland TS Station Capacity	To be further assessed in the next Regional Planning phases.
11	Woodstock TS Station Capacity	To be further assessed in the next Regional Planning phases.
12	W44LC/W45LS post-contingency capacity limitation (Buchanan JCT x Edgeware JCT)	To be further assessed in the next Regional Planning phases.
13	WT1T/W14 pre-contingency capacity limitation (Cranberry JCT x ESWF JCT and ESWF JCT x Tillsonburg JCT)	To be further assessed in the next Regional Planning phases.
14	Load restoration limitation – M31W/M32W / K7/K12/B2 due to	To be further assessed in the next Regional Planning phases.

	the loss of double-circuit line M31W and M32W or for a double contingency with the loss of both autotransformers at Karn TS	
15	Load restoration limitation – M31W/M33W for a single tower contingency	To be further assessed in the next Regional Planning phases.
16	Load restoration limitation – W36/W37 for a single tower contingency	To be reassessed in the next Regional Planning phases.
17	Load restoration limitation – W44LC/W45LS for a single tower contingency	To be further assessed in the next Regional Planning phases.

List of LDC(s) to be involved in further regional planning phases:

- Entegrus Powerlines Inc.
- ERTH Power Inc.
- Hydro One Distribution
- London Hydro Inc.
- Tillsonburg Hydro Inc.

List of LDC(s) which are not required to be involved in further regional planning phases:

- N/A

Working Group	Technical Working Group of the Peterborough to Kingston Region

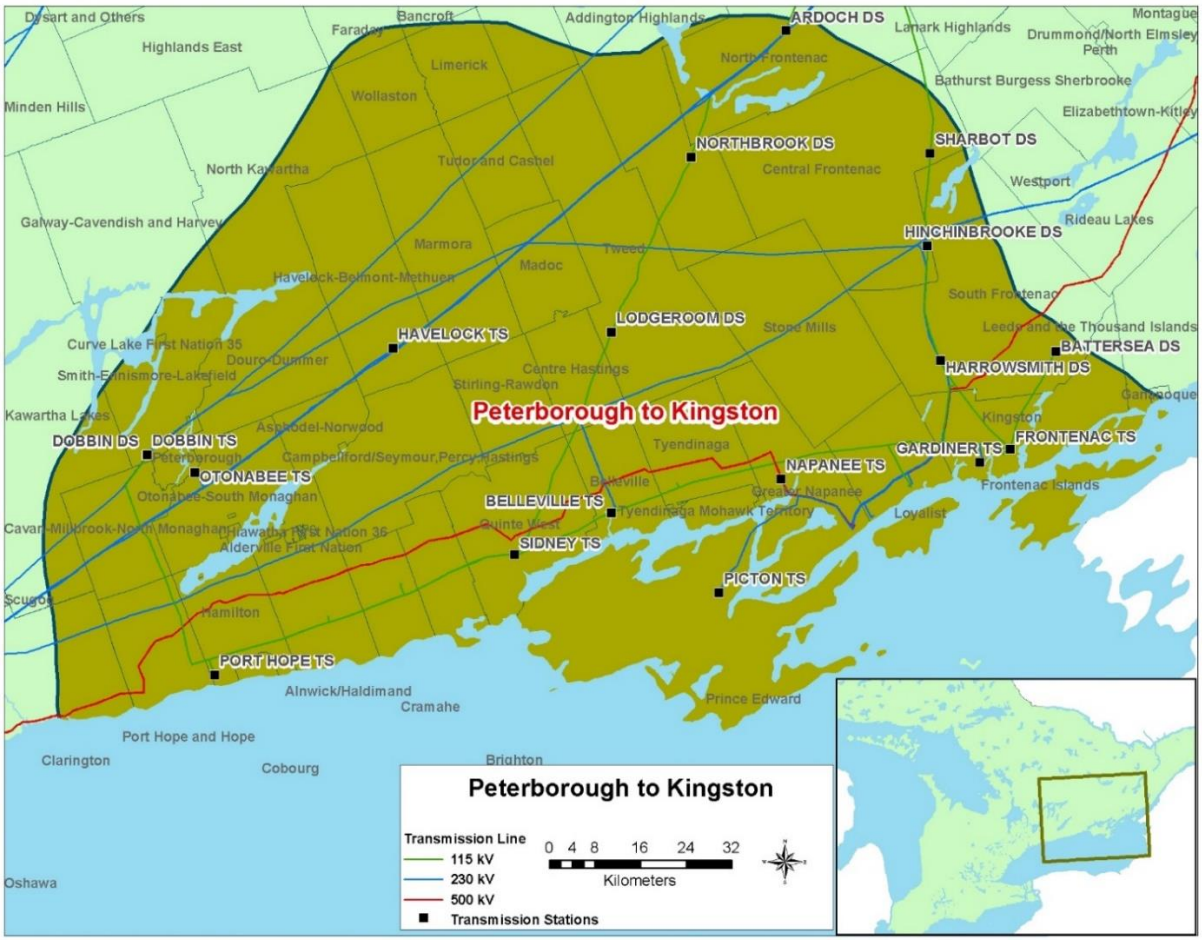
This Integrated Regional Resource Plan (IRRP) was prepared by the Independent Electricity System Operator pursuant to the terms of its Ontario Energy Board licence, EI-2013-0066.

This IRRP was prepared on behalf of the Technical Working Group (Working Group) of the Peterborough to Kingston region, which is composed of the following licensed transmitters and licensed distributors:

- Elexicon Energy Inc. (Elexicon)
- Hydro One Networks Inc. (Distribution) (Hydro One (Distribution))
- Hydro One Networks Inc. (Transmission) (Hydro One (Transmission))
- Independent Electricity System Operator (IESO)
- Lakefront Utilities Inc. (Lakefront Utilities)
- Utilities Kingston
- Eastern Ontario Power

The Working Group assessed the adequacy of electricity supply to customers in the Peterborough to Kingston region over a 20-year period beginning in 2019; developed a plan that considers opportunities for coordination in anticipation of potential demand growth and varying supply conditions in the region; and developed an implementation plan for the recommended options, while maintaining flexibility in order to accommodate changes in key conditions over time.

The Working Group developed a plan that considers the potential for long-term electricity demand growth in the region and maintains the flexibility to accommodate changes to key conditions over time.



The Working Group members agree with the IRRP's recommendations and support implementation of the plan, subject to obtaining necessary regulatory approvals and appropriate community engagement and consultations.

1 Introduction

The Peterborough to Kingston region is located in eastern Ontario as shown in

Figure 1-1. It includes Frontenac County, Hastings County, Northumberland County, Peterborough County, Prince Edward County, parts of Lennox and Addington County, and related municipalities. Peterborough, Belleville and Kingston are the three largest population centres in the region. The region also comprises several Indigenous communities including Alderville First Nation, Hiawatha First Nation, Curve Lake First Nation, Mohawks of the Bay of Quinte, Tyendinaga Mohawk, Kawartha Nishnawbe and the traditional territory of the Huron Wendat.

Figure 1-1 | Overview of the Peterborough to Kingston Region and Transmission System

The region is supplied by the following local distribution companies:

- Elexicon which serves Port Hope and Belleville;
- Eastern Ontario Power, which is embedded to Hydro One Distribution, serves over 3,500 distribution customers in Gananoque, Ontario;
- Lakefront Utilities, embedded to Hydro One Distribution, serves 10,000 distribution customers across the Town of Cobourg and the Village of Colborne;

- Kingston Utilities serves 28,000 distribution customers in Central Kingston; and
- Hydro One Distribution[1], which supplies distribution customers in the surrounding areas of the region.

These LDCs receive power at the step-down transformer stations and distribute it to end users, i.e., industrial, commercial and residential customers.

In Ontario, planning to meet the electrical supply and reliability needs of a large area or region is conducted through regional electricity planning, a process that was formalized by the Ontario Energy Board (OEB) in 2013. In accordance with this process, transmitters, distributors and the IESO are required to carry out regional planning activities for each of the province's 21 electricity planning regions, including the Peterborough to Kingston region, at least once every five years.

This IRRP identifies needs pertaining to power system capacity, reliability requirements, and end-of-life asset replacement and coordinates options to meet customer needs in the area over a 20-year period. Given forecast uncertainty, the longer development lead time and the potential for technological change, the plan does not recommend specific investments or projects to meet mid- and long-term needs, but maintains the flexibility to evolve in step with emerging developments. Instead, this IRRP focuses both on recommendations to meet near-term needs, and on the near-term actions required to lay the groundwork for determining options to meet mid- and long-term needs.

The focus of this IRRP is providing an adequate reliable supply to support community growth. A key consideration in this analysis is whether near-term actions maintain, or act as a barrier to, long-term options. The recommended near-term actions are intended to be completed before the next IRRP cycle, scheduled for 2025, or sooner, depending on demand growth or other factors. In some cases, the scope of near-term actions includes the continuation of defined planning activities coordinated among key stakeholders to develop and complete recommendations within a specific time period. The completion of these actions will inform decisions for the next scheduled planning cycle, or sooner, particularly around integrated solutions that address multiple needs, as well as demand-side options and capabilities for which sufficient information is not currently available.

This report is organized as follows:

- A summary of the recommended plan for the Peterborough to Kingston region is provided in Section 2;
- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the Peterborough to Kingston region and the study scope are discussed in Section 4;
- The demand outlook scenarios, and energy efficiency and distributed energy resource (DER) assumptions, are described in Section 5;
- Electricity needs in the Peterborough to Kingston region are presented in Section 6;
- Alternatives and recommendations for addressing the needs are described in Section 7;
- A summary of engagement activities to date and moving forward, is provided in Section 8; and
- A conclusion is provided in Section 9.

[1] Includes former Peterborough Distribution which was sold to Hydro One Distribution serves distribution customers in Peterborough, Lakefield, and Norwood.

2 The Integrated Regional Resource Plan

This Integrated Regional Resource Plan (IRRP) provides recommendations to address the electricity needs of the Peterborough to Kingston region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC)[2] and reliability standards governed by the North American Electric Reliability Corporation (NERC).

This IRRP identifies three planning horizons: from the base-year (2019)[3] through the near term (up to 2024), medium term (year 6 to 10, through to 2029), and longer term (year 11 to 20, or through to 2038). These planning horizons reflect the inverse relationship between the length of time and demand certainty (in that the longer the outlook, the less certain it is), lead time for electricity resource development, and planning commitment required.

This IRRP identifies and recommends specific projects for implementation in the near term. This is necessary to ensure that they are in-service in time to address the area's more urgent needs, respecting the lead-time for development of the recommended projects or actions. This IRRP also identifies possible long-term electricity needs, some of which may advance to the near or medium term for a high growth scenario. However, as these needs are forecast to arise in the future, it is not necessary, nor would it be prudent given forecast uncertainty and the potential for technological change, to commit specific projects at this time. Instead, near-term actions are identified to gather information and lay the groundwork for future options. These actions are intended to be completed before the next IRRP cycle so that their results can inform further discussion at that time or so the Working Group can respond in a timely manner, if a high growth scenario were to materialize.

2.1 Near- to Medium-Term Plan

The plan to meet the near-and medium-term needs of electricity customers in the Peterborough to Kingston region was developed to maximize the use of the existing electricity system in consideration of planning criteria such as reliability, cost, and feasibility. The near-term plan was also developed to be consistent with the long-term development of the region's electricity system.

The Working Group's recommendations for the near- and medium-term plan focus on addressing both station capacity needs in Belleville and Kingston and supply capacity needs on pockets of the 115 kV system. The area's near-term supply capacity needs in the Peterborough and Quinte West area are impacted by ongoing bulk system planning activities in the area. Further planning studies to assess bulk system impacts are also identified. The recommendations are summarized below.

Recommended Actions

1. **Build a new 230 kV Dual Element Spot Network (DESN) transformer station at Belleville TS**

[2] Refer to ORTAC for details: http://www.ieso.ca/-/media/files/ieso/Document%20Library/Market-Rules-and-Manuals-Library/market-manuals/market-administration/IMO-REQ-0041-TransmissionAssessmentCriteria.pdf

[3] To be consistent with Regional Plan's Needs Assessment, the 2019 was used as a base year

To address today's station capacity need at Belleville TS, as well as to serve the growing electricity demand in the region, Elexicon will work with Hydro One (Transmission) to initiate the development of a new Dual Element Spot Network (DESN) transformer station at Belleville, with an expected in-service date of 2025. This will increase the supply capacity to the region and will resolve the capacity need at Belleville TS until the end of the planning horizon.

2. Hydro One Distribution load transfer – Gardiner TS DESN #1 to Gardiner TS DESN #2

There is an immediate need for new capacity at Gardiner TS DESN #1. As a first step, performing a load transfer of 11 MW between Gardiner TS DESN #1 and Gardiner TS DESN #2 by 2022 is the cost-effective way to reduce load at Gardiner TS DESN #1. Although, a second load transfer of 11 MW can be performed, it comes with a high cost. Therefore, instead of performing a second load transfer, the next part of the solution is recommended action #3 - to advance end-of-life replacement of transformers at Gardiner TS DESN #1. After implementing first load transfer and recommended action #3, the Working Group will continue to monitor load at Gardiner TS DESN #1 and, evaluate if a second 11 MW load transfer is needed.

3. Hydro One Transmission to advance end-of-life replacement of transformers at Gardiner TS DESN #1

The station transformers at Gardiner TS DESN #1 are reaching end-of-life in the mid-2020s. Replacement of these transformers with units of a higher limited time emergency rating (LTR) is recommended as soon as possible (2024-2025), as the need is imminent. Advancing the replacement date, combined with the load transfer in recommended action #2, will address the Gardiner TS DESN #1 capacity need for the duration of the planning horizon for the reference load forecast and for the mid-term horizon for the high growth load forecast

4. Monitor load growth and initiate development and siting work to build a new 230 kV DESN transformer station in Kingston when needed

Building a new 230 kV station in Kingston will address the local need for station capacity at both Frontenac TS and Gardiner TS over the long term and for multiple growth scenarios. Due to the uncertainty in the forecast, the timing of the need for the new station could be in the near- to medium term or as late as 2029. Hence, Hydro One Distribution and Utilities Kingston will work together to monitor the load growth in their service areas, and work with Hydro One Transmission to commence the development work and subsequent construction of a new 230 kV station and required line connection, either transmitter or distributor owned, when it is deemed to be appropriate.

5. Address implementation and cost allocation barriers to cost-effectively deploying non-wires alternatives to defer needs

The development of a non-wire alternative, specifically additional energy efficiency or a local storage solution, could defer the new station ultimately required to accommodate load growth in the City of Kingston. This is cost-effective, under the reference load growth scenario, if cost-allocation can reflect the system benefits the non-wires alternative would provide. Additional barriers to implementation also exist around who would implement the solution and how they would seek cost-recovery, particularly if the transmitter or both benefiting LDCs were to implement a part of the solution. The IESO will work with the impacted transmitter and LDCs between regional planning cycles to address these barriers to implementation and cost allocation for a non-wires alternative, in tandem with developing plans for a new transformer station.

6. Complete the ongoing Gatineau Corridor End-of-Life Study and implement recommendations

The outcomes of the Gatineau Corridor End-of-Life Study will improve the supply capability in the Peterborough to Kingston region. Namely, addressing the identified supply capacity need to the Peterborough and Quinte West area. By implementing the recommendations of the Gatineau Corridor End-of-Life study this need should be addressed.

7. Upgrade Cataraqui autotransformers' secondary conductors and reassess as part of the Lennox to St. Lawrence bulk system study

Upgrading the autotransformers' secondary conductors will increase the thermal capacity of these autotransformers from 250 MW to 285 MW and will resolve the thermal violation after losing one of the autotransformers. A future Lennox to St. Lawrence bulk system study will reassess the need with this solution in place and study if additional capacity is required.

8. Replace Port Hope TS T3/T4 with the closest available standard size transformers

Port Hope TS T3/T4 are reaching end-of-life and there are no opportunities for end-of-life optimization at this time. This IRRP recommends like-for-like replacements with the closest available standard size transformers of equal or greater capacity.

2.2 Long-Term Plan

A number of alternatives are possible to meet the region's long-term needs. While specific solutions do not need to be committed today, it is appropriate to begin work now to gather information, monitor developments, engage the community, and develop alternatives to support decision making in the next iteration of the IRRP. This IRRP sets out near-term actions required to ensure that options remain available to address future needs, if and when they arise.

Recommended Actions

1. Implement Conservation

The implementation of provincial conservation targets is a key near-term action of the Peterborough to Kingston region's long-term plan. In developing the demand forecast, peak demand impacts associated with meeting provincial targets were assumed before identifying the residual needs.

Meeting provincial conservation targets amounts to approximately 73 MW, or 5% of the total forecast demand growth, by the end of the study period.

To ensure these savings materialize, it is recommended that conservation efforts be focused as much as possible on measures that will contribute to meeting program energy targets while also maximizing peak demand reductions. The monitoring of conservation success will lay the foundation for the long-term plan by evaluating the performance of specific conservation measures in the sub-region and assessing potential for additional conservation.

2. Study the potential bulk system impact of future supply reinforcement to Belleville TS

After building a new 230 kV station at Belleville, the transmission system supply into Belleville is expected to meet the load growth over the 20-year planning horizon. However, beyond this time horizon, the system supply capability will be limited due to excessive voltage change violations during contingency conditions. To solve this issue, transmission reinforcement to Belleville might be necessary. Before the next planning cycle, the bulk system impact of transmission reinforcement to Belleville TS should be included in the scope of a relevant individual bulk planning study for the area.

3. Monitor the Peterborough to Quinte West 115 kV system voltage performance following the recommendations of the Gatineau corridor end-of-life study

Low voltage violations are observed during contingency conditions in the long-term planning horizon on the 115 kV system in the Peterborough to Quinte West area. These violations may naturally be resolved by the outcome of recommendations in the forthcoming Gatineau corridor end-of-life study; therefore, this need will be monitored and re-assessed during the next planning cycle.

4. Monitor demand growth, conservation achievement and distributed generation uptake

On an annual basis, the IESO, with the Working Group, will review CDM achievement, the uptake of provincial DG projects, and actual demand growth in the Peterborough to Kingston Region. This information will be used to determine when decisions on the long-term plan are required, and to inform the next cycle of regional planning for the area. Information on CDM and DG is also a useful input into the ongoing development of non-wires alternatives as potential long-term solutions.

5. Initiate the next regional planning cycle early, if needed

Along with the indices outlined above, the Working Group will monitor changes in growth targets, progress in electrification in the region, and any significant changes in forecast growth. If monitoring activities determine that the region's growth is exceeding the load forecast (the high demand forecast in Belleville and Kingston, or the reference demand forecast in the remainder of the region), it may be necessary to initiate the next iteration of the regional planning process earlier than 2025 given the lead time for the long-term supply options.

3 Development of the Plan

3.1 The Regional Planning Process

In Ontario, planning to meet an area's electricity needs at a regional level is completed through the regional planning process, which assesses regional needs over the near, medium, and long term, and develops a plan to ensure cost-effective, reliable electricity supply. A regional plan considers the existing transmission electricity infrastructure, local supply resources, forecast growth and area reliability; evaluates options for addressing needs; and recommends actions to be undertaken.

The current regional planning process was formalized by the OEB in 2013, and is conducted for each of the province's 21 electricity planning regions by the IESO, transmitters and local distribution companies (LDCs) on a five-year cycle.

The process consists of four main components:

1) A Needs Assessment, led by the transmitter, which completes an initial screening of a region's electricity needs;
2) A Scoping Assessment, led by the IESO, which identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities;
3) An IRRP, led by the IESO, which identifies recommendations to meet needs requiring coordinated planning; and
4) A Regional Infrastructure Plan (RIP) led by the transmitter, which provides further details on recommended wires solutions.

More information on the regional planning process and the IESO's approach to regional planning can be found in Appendix B - Development of the Plan.

In addition to regional planning process, there are bulk planning and distribution planning processes. Distribution system planning is for system at 44 kV and lower, while bulk and regional planning are for higher voltages. Furthermore, regional planning focuses more on a particular, local part of the grid, while bulk planning reviews electricity transfers across the province. There are inherent overlaps in all three levels of electricity infrastructure planning.

The IESO has recently completed a review of the regional planning process following the completion of the first cycle of regional planning for all 21 regions. Additional information on the Regional Planning Process Review along with the final report is posted on the IESO's website.

3.2 Peterborough to Kingston IRRP Development

Development of the Peterborough to Kingston IRRP was initiated in 2020 with the release of the Needs Assessment report. This product was prepared by Hydro One (Transmission) with participation from the IESO, Elexicon Energy, Hydro One (Distribution), Lakefront Utilities, Eastern Ontario Power, and Utilities Kingston. Screening for needs was carried out to identify needs that may require coordinated regional planning. The subsequent Scoping Assessment Outcome Report, which was prepared by the IESO, recommended that an IRRP should be developed to address previously identified and new needs in this region due to the potential for coordinated solutions.

In 2020, the Working Group was formed to develop finalize Terms of Reference for this IRRP, gather data, identify near- to long-term needs in the region, and recommend actions to address them.

4 Background and Study Scope

This is the second cycle of regional planning for the Peterborough to Kingston region. During the first cycle of regional planning, a Needs Assessment[4] was conducted for the Peterborough to Kingston region in February 2015 that was led by Hydro One Networks Inc. Transmission, and included representatives from the IESO, the former Veridian Connections Inc., Kingston Hydro, and the former Peterborough Distribution Inc. and Hydro One Networks Inc. Distribution. After reviewing the needs identified in the report, the participants recommended that further regional coordination was not required, and instead the needs would be addressed through a local study.

This cycle of regional planning identified a number of needs requiring further regional coordination and recommended an IRRP be initiated. This report presents an integrated regional electricity plan for the next 20-year period starting from 2019[5].

4.1 Study Scope

This IRRP, prepared by the IESO on behalf of the Working Group, recommends options to meet the electricity needs of Peterborough to Kingston region over near- to medium-term timeframe and sets out near-term actions required to ensure that options remain available to address long-term needs. Guided by the principle of maintaining an adequate level of reliability performance as per the Ontario Resource and Transmission Assessment Criteria (ORTAC)[6], this IRRP reviews needs identified and discussed as part of the Scoping Assessment, with the focus on:

- Providing an adequate, reliable supply to support community growth;
- Minimizing the impact of supply interruptions; and
- Coordinating and aligning end-of-life asset replacements with evolving needs.

Given that parts of the Peterborough to Kingston region's 230 kV and 115 kV transmission networks also serve as major pathways for the flow of power to and from adjacent regions (Greater Toronto Area and Ottawa) and the connection of large generation facilities, the IRRP assesses the Peterborough to Kingston region 230 kV and 115 kV networks under certain system conditions. A detailed assessment of the bulk electricity system examining various bulk system conditions is typically undertaken through a separate planning process, as described in section 4.2, and is beyond the scope of this IRRP.

The following transmission facilities were included in the scope of this study:

230 kV connected stations: Belleville TS, Dobbin TS, Gardiner TS, Havelock TS, Napanee TS, Otonabee TS, Picton TS and a customer owned station.

115 kV connected stations: Ardoch DS, Battersea DS, Dobbin DS, Frontenac TS, Harrowsmith DS, Hinchinbrooke DS, Lodgeroom DS, Northbrook DS, Port Hope TS, Sharbot DS, Sidney TS, and four customer owned stations.

[4] The 2015 Needs Assessment Report for the Peterborough to Kingston Region is available on the Hydro One website (link)

[5] To be consistent with Regional Plan's Needs Assessment, the 2019 was used as a base year

[6] The Ontario Resource and Transmission Assessment Criteria is available on the IESO website (link)

230 kV transmission lines: C27P, H23B, H27H, P15C, T22C, T25B, T31H, T32H, X1H, X1P, X21, X22, X2H, X3H and X4H.

115 kV transmission lines: B1S, B5QK, P3S, P4S, Q3K, Q3M6, Q6S and S1K.

230/115 kV autotransformers: Dobbin T1, T2[7], T5 and Cataraqui T1 & T2.

Electricity to the Peterborough to Kingston region is supplied primarily through the 500 kV station Lennox TS, located in Lennox and Addington County, in conjunction with a number of 230 kV transmission lines from Clarington TS and Cherrywood TS, both located in the GTA East area. A large portion of the load in the Peterborough to Kingston region is connected to a regional 115 kV system, supplied by the 230 kV transmission system through five (5)[7] 230-115 kV autotransformers located at Dobbin TS and Cataraqui TS.

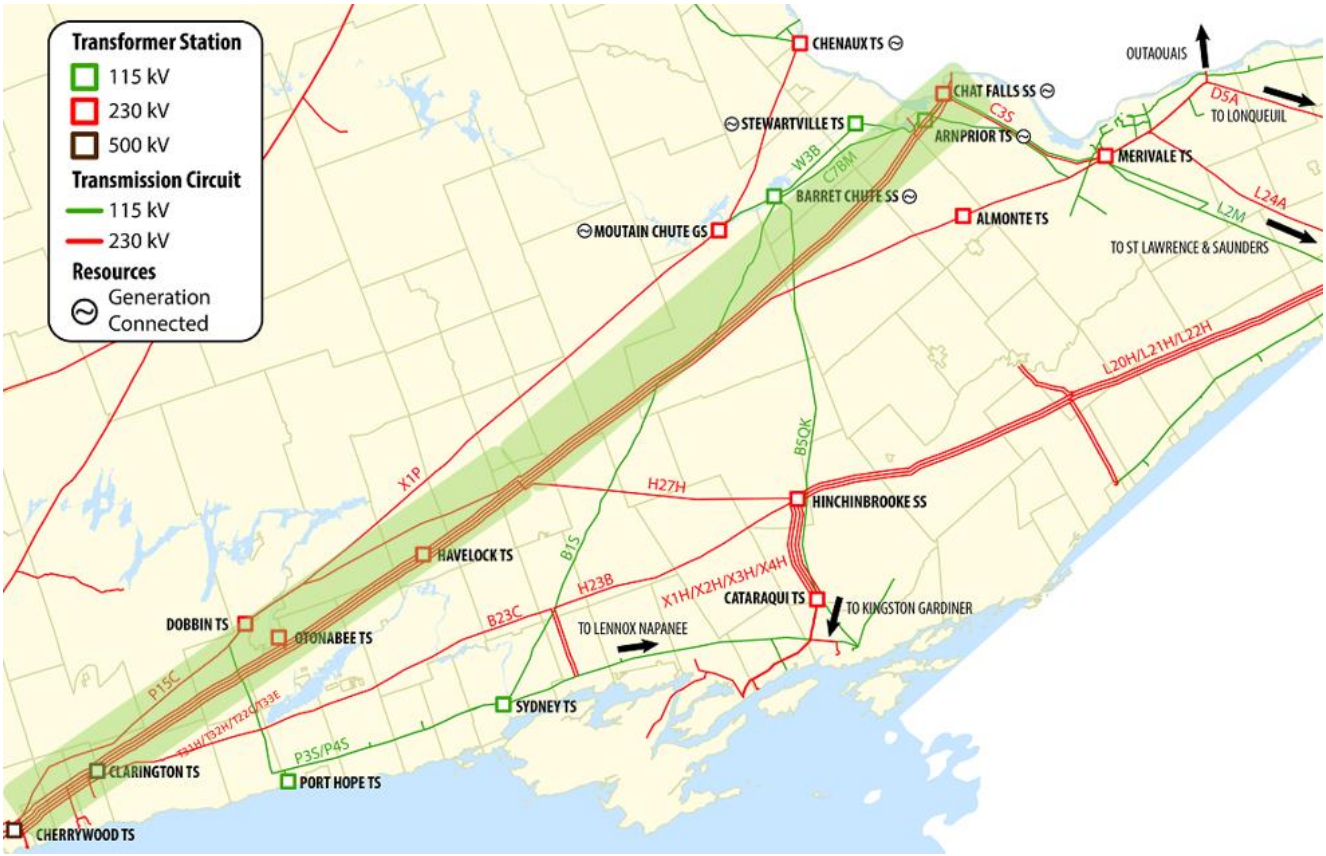
The Peterborough to Kingston region can be broken out into a number of sub-systems or areas with common supply points/limitations, which includes Peterborough, Port Hope to Quinte West, Belleville, and Kingston.

- The Peterborough area is supplied by two step-down transformer stations, Dobbin TS and Otonabee TS. Power is delivered into this area through the 230 kV transmission circuits P15C, C27P, T22C and T31H running between GTA East and the Ottawa area.
- The Port Hope to Quinte West area is supplied by two step-down transformer stations, Port Hope TS and Sidney TS which are both served by the regional 115 kV system.
- The Belleville area is supplied by one step-down transformer station, Belleville TS which is supplied via the 230 kV transmission circuits T25B and H23B.
- Lastly, the Kingston area is supplied by three step down transformer stations, Frontenac TS, Gardiner TS #1 and Gardiner TS #2. Frontenac TS is supplied by the regional 115 kV system, whereas Gardiner TS (#1 & #2) are supplied by the 230 kV transmission circuits X2H and X4H.
- Together, the Peterborough area and the Port Hope to Quinte West area, form part of a larger electrical sub-system within the Peterborough to Kingston region, referred to as the Peterborough to Quinte West sub-system or area.

The Peterborough to Kingston IRRP was developed by completing the following steps:

- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe;
- Examining the load meeting capability (LMC) and reliability of the existing transmission system, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC and NERC planning criteria;
- Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO-controlled grid as described in Section 7 of ORTAC;
- Confirming identified end-of-life asset replacement needs and timing with LDCs;
- Establishing alternatives to address system needs, including, where feasible and applicable, possible energy efficiency, generation, transmission and/or distribution, and other approaches such as non-wires alternatives;

[7] Normally, Dobbin T2 is operated out of service



- Engaging with the community on needs, findings, and possible alternatives;
- Evaluating alternatives to address near- and long-term needs; and
- Communicating findings, conclusions, and recommendations within a detailed plan.

4.2 Related Bulk System Planning Studies

Gatineau Corridor End-of-Life Study

As shown in Figure 4-1, the Gatineau corridor consists of five (5) 230 kV transmission circuits stretching between GTA East and Ottawa area. As shown, these circuits form a major pathway on the bulk transmission system and provide or support supply to Ottawa and Peterborough, connection of Chats Falls area generation and imports from Quebec. The study assesses transmission equipment end-of-life needs forecast to arise over the next five to ten years, in addition to forecast reliability needs in the areas of Ottawa and Peterborough to Quinte West.

Figure 4-1 | Gatineau Corridor

The Gatineau corridor circuits are critical in supporting the regional 115 kV supply system, and in some cases directly supply step-down transformer stations (Dobbin TS and Otonabee TS). The options being assessed as part of the study have a direct impact on the supply to the Peterborough to Kingston region. Forecast needs between the Gatineau Corridor End-of-Life study and the Peterborough to Kingston regional planning studies have been coordinated, seeking opportunities for integrated solutions addressing both bulk and regional needs. The IESO's participation on the Working Group in the next stage of regional planning, the RIP, will help ensure recommendations are aligned with the latest bulk system information.

5 Electricity Demand Forecast

Regional planning in Ontario is driven by the need to meet peak electricity demand requirements in the region. In order for the Working Group to plan for the future electricity needs of the region, a 20-year planning demand forecast was developed. This section outlines the demand forecast methodology, discusses historical electricity demand trends, development of the planning demand forecasts (both coincident and non-coincident) as well as the expected contributions of CDM and DG towards reducing the peak demand in the region. By taking all of these factors into consideration the planning demand forecast is developed and it is used to plan the transmission grid such that the grid can operate reliably and economically in the long term.

Furthermore, high growth forecast scenarios were developed to provide insight into the system's capability when faced with higher load than projected by the reference planning demand forecast. Two demand forecast sensitivity scenarios have been established and outlined in sections 5.9 and 5.10: a scenario where DG resources were expected to be out of service following their contract expiration, and a scenario to account for increased load growth, particularly in Kingston and Belleville, due to electrification.

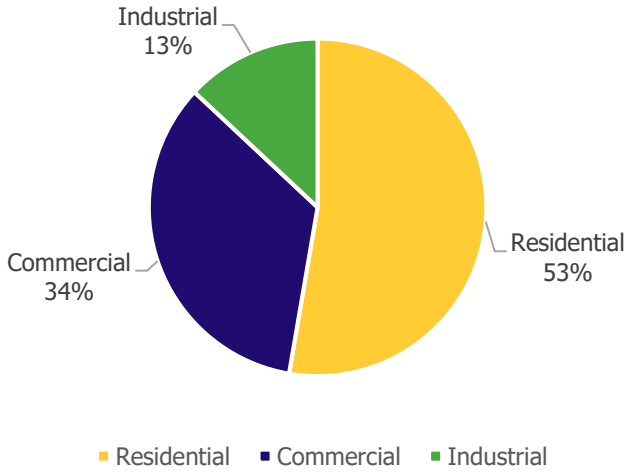
5.1 Demand Forecast Methodology

For the purpose of the IRRP, a 20-year planning forecast was developed to assess electricity supply and reliability needs. Transmission infrastructure supplying an area is sized to meet peak-demand requirements (rather than energy demand requirements). Peak demand requirements are first determined at the station or DESN[8] level, allowing capability in pockets where there is load growth, or where existing equipment has been historically close to its load supply capability, to be more accurately assessed. These forecasts are then aggregated to understand the limits of the transmission system and identify overall regional electricity needs during regional coincident peak times.

The planning forecast is divided notionally into four time horizons: present day, near, medium, and long term. The near term (one to five years) has the highest degree of certainty; any near-term needs are typically met using regional transmission or distribution solutions. Other methods (i.e., conservation and demand management (CDM) or DG) are considered in the near- to mid-term (six to 10 years), since lead times to develop and incorporate these options depend on the size of the need.

The long-term forecast covers the 10- to 20-year period and has the lowest degree of certainty. It is used to identify potential longer-term needs, and for the consideration and development of integrated solutions, including CDM, DG, and major transmission upgrades. Early identification of potential needs and possible solutions enables engagement with the local community and all levels of government long before the need is triggered, maximizes opportunities for input to inform decision-making, and helps ensure local planning can account for new infrastructure.

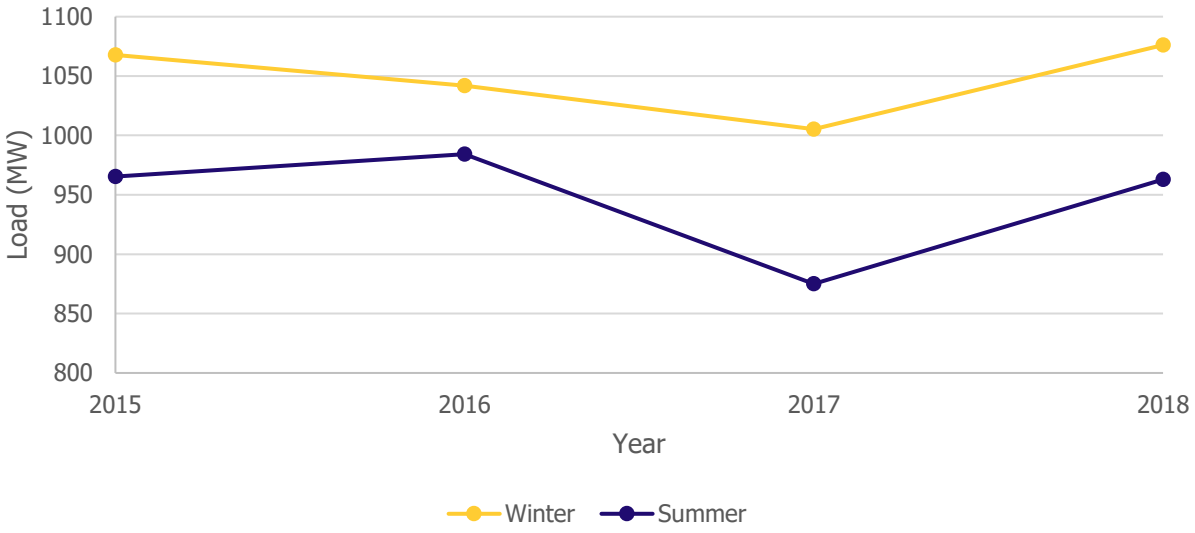
[8] A dual-element spot network, or DESN, refers to a standard station layout used throughout the province, where two supply transformers are configured in parallel to supply one or two low-voltage switchgear which the distributor uses to supply load customers. This paralleled dual supply ensures a standard level of reliability where one supply transformer can be lost due to an outage or planned maintenance but supply to the customer can be maintained. A single local transformer station can have one, two, or more individual DESNs.



To address the long-term uncertainty in the electricity demand outlook, the robustness of the existing system was assessed to determine the capability of the existing system and its ability to supply customers, given possible outages and system states (e.g., contingencies).

Additional details on the demand outlook assumptions can be found in Appendix A - Methodology and Assumptions for Demand Forecast. The demand outlook was used to assess any growth-related electricity needs in the region.

5.2 Historical Electricity Demand



The Peterborough to Kingston region electricity demand is a mix of residential, commercial and industrial loads, encompassing diverse economic activities ranging from educational institutions to large business parks. As seen in Figure 5-1, the region's residential sector is the largest consumer of electricity accounting for approximately 50% of the peak load. The commercial and industrial sectors also have impactful contributions to the region's peak load, accounting for approximately 35% and 15% respectively. Peak demand can also be influenced by extreme weather conditions, with peaks in demand typically occurring after several days of extreme temperatures. In addition to weather, factors affecting commercial and industrial energy demand, such as increased economic activity, improvements in energy efficiency, and on-site generation development have impacts on the regional peak.

Figure 5-1 | Regional Sector Segmentation Data (Winter)

The regional historical loading data from 2015 to 2018 shows that the electricity system in the region has typically been winter-peaking. As shown in Figure 5-2, the coincident net peak demand in the region has been around 950 MW and 1050 MW in the summer and winter respectively. Upon review of the data, the Working Group determined that 2018 loading data would prove to be the most effective base year to use for the purposes of developing the planning load forecast. The regional peak in 2018 was approximately 1080 MW in the winter and 960 MW in the summer.

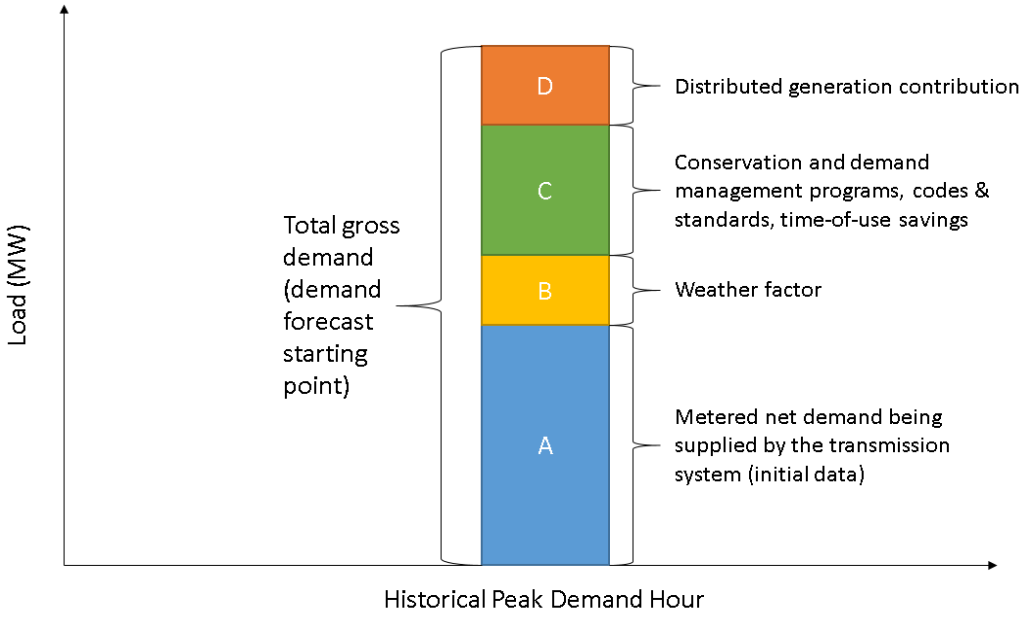


Figure 5-2 | Historical Net Peak Demand in the Peterborough to Kingston Region

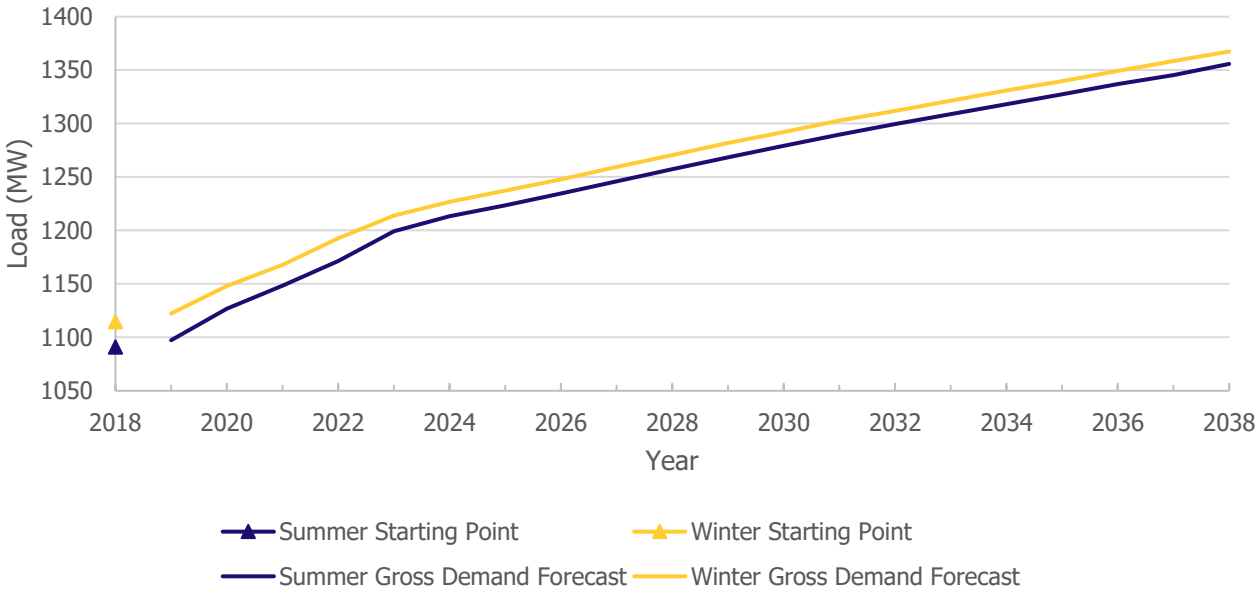
5.3 Gross Demand Forecast Starting Point

To develop a forecast starting point, a net metered load data was obtained for all LDCs at each station within the region for both the summer and winter peak hours of 2018. The historical metered data is not a satisfactory representation of the true demand in the region as it does not account for the impacts of DG, CDM, and the effects of weather during a particular year. In order to account for the aforementioned factors, through a procedure known as the "unbundling" process, the Working Group established a new starting point to reflect the actual gross demand under median weather conditions. Having a gross demand starting point allows the LDCs to forecast growth from a starting point which represents the actual demand in the region, as opposed to simultaneously forecasting net load growth, DG, and CDM savings. This approach is summarized in Figure 5-3. Note that for the Peterborough to Kingston region, unbundling gross load was achieved to the extent for which the necessary data was available. For a more detailed look at the weather correction methodology see Appendix A.1 - Method for Accounting for Weather Impact on Demand.

Figure 5-3 | Normal/Extreme Weather Corrected Coincident Net and Gross Peak Demand in the Peterborough to Kingston Region



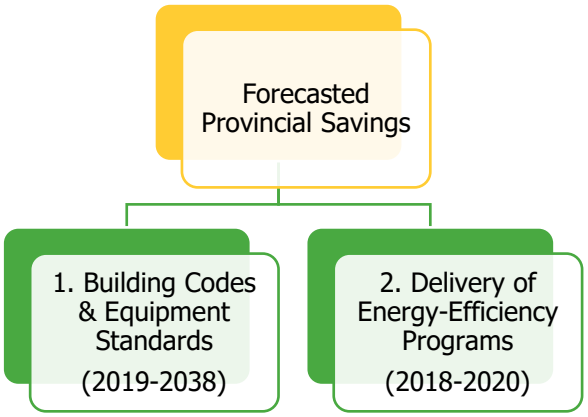
5.4 Gross Demand Forecast

Utilizing the established gross demand, median weather starting points, the LDCs provided 20-year forecasts at a station level. LDCs are tasked with the development of their own gross load forecasts at each station. This is due to the fact that LDCs have strong insights into customer and regional growth expectations over the planning horizon due to their direct relationship with customers. This insight includes known connection applications and knowledge regarding typical electrical demand for various types of customer groups.

The LDC forecasts account for increases in demand due to various factors such as new or intensified development, economic growth, population growth, changes in consumer behaviour, etc. It is noted that the gross demand forecast that was developed did not account for future DG or new conservation measures, such as codes and standards and demand response programs. These components were accounted for in later portions of the demand forecasting process as described in section 5.1. Most LDCs cited alignment with municipal and regional official plans as a primary source for input data. Other common considerations included known connection applications and typical electrical demand for similar customer types. For a more detailed look into each LDCs forecast methodology see Appendix A - Methodology and Assumptions for Demand Forecast.

Both the summer and winter median weather, gross demand forecasts are depicted in Figure 5-4.

Figure 5-4 | Coincident, Median Weather, Gross Demand Forecasts



5.5 Contribution of Conservation to the Forecast

Conservation and Demand Management (CDM) is a clean and cost effective resource for helping to meet Ontario's electricity needs and has played an integral part in ensuring the development of a reliable and sustainable electricity system through provincial and regional planning. CDM is achieved through a mix of program-related activities, and mandated efficiencies from building codes and equipment standards. It plays a key role in maximizing the use of existing assets and maintaining reliable supply by offsetting a portion of a region's demand growth, and helping to ensure it does not exceed equipment capability.

Future CDM savings for the Peterborough to Kingston region have been projected out over the course of the 20-year planning horizon to take into account both policy-driven conservation through the provincial CDM Framework, as well as expected peak demand impacts due to building codes and equipment standards for the duration of the forecast.

To estimate the peak-demand impact of existing and committed CDM savings in the region, the forecast for provincial savings were divided into two main categories, as shown in Figure 5-5.

Figure 5-5 | Categories of Conservation & Demand Management Savings

For the Peterborough to Kingston region, the IESO worked with the LDCs to identify the breakdown of load per customer sector on a station level. The breakdown of load was divided into three categories: residential, commercial and industrial. This provided higher resolution when forecasting energy efficiency, as energy efficiency potential estimates vary by sector due to differing energy consumption characteristics and applicable measures.

The estimated impact of existing or committed CDM programs and codes and standards for the Peterborough to Kingston region have been applied to the gross demand extreme weather forecast, along with DG (as described in Section 5.7), to determine the net peak demand for the region. Additional details are provided in Appendix A - Methodology and Assumptions for Demand Forecast.

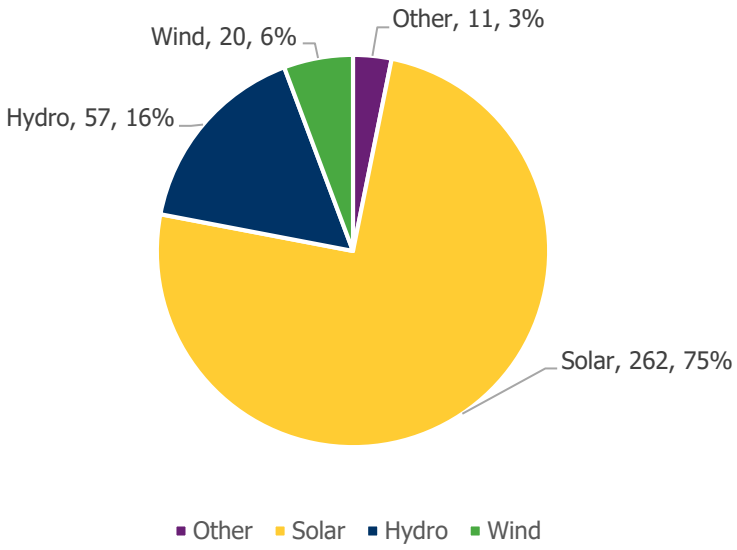


Table 5-1 | Reduction to Summer Demand Forecast due to Conservation

Year	2020	2022	2024	2026	2028	2030	2032	2034	2036	2038
Savings (MW)	15	35	61	74	80	82	80	75	72	72

5.6 Contribution of Distributed Generation to the Forecast

The IESO has contracts with several distributed generators in the Peterborough to Kingston region. For the purposes of the planning demand forecast only IESO contracted DG and significant behind the meter resources noted by the LDCs have been included when accounting for the DG resources in the region. A breakdown by fuel type of distributed generation resources in the region for the year 2019 is shown in Figure 5-6.

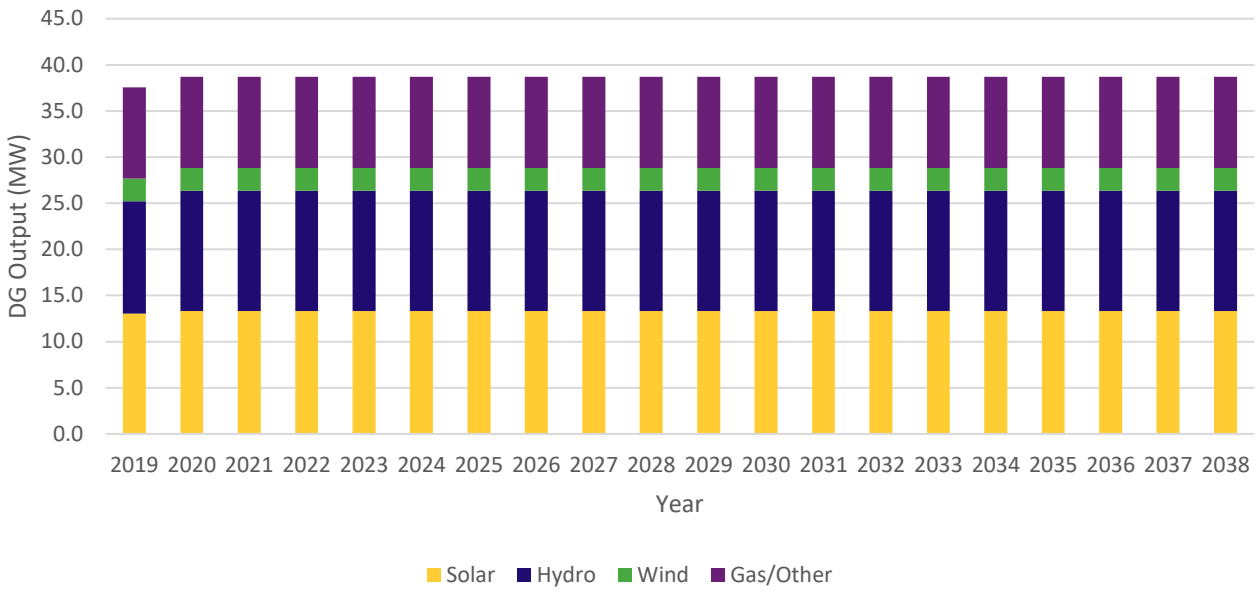

Figure 5-6 | Installed DG Capacity (MW,%) in the Peterborough to Kingston Region (2019) by Resource Type

The resources that were included in the DG forecast were comprised of a mix of solar, wind, hydroelectric and other (biogas, landfill gas and natural gas) projects. The majority of distributed generation in the region consists of solar resources (75% of total contracted installed DG capacity in 2019). Specific capacity contribution factors were attributed to each resource type in order to estimate the effective capacity that would be available to shave load during the regional peak hours. Upon applying the associated capacity contribution factors to each resource in the DG list, the data was then aggregated on a station level in order to put together a forecast specifying the estimated peak load reduction due to DG output. Figure 5-7 shows the contribution of DG output at the time of region's peak in the Peterborough to Kingston region by Resource Type.

Various DG contracts that have been administered by the IESO are set to expire during the 20-year planning horizon with the majority of those that will expire coming off contract in the final five years of the forecast period. For the purposes of the planning demand forecast, the Working Group decided to assume that contracts coming to the end of their terms will be reacquired by the IESO. Thus, the planning demand forecast assumed that all contracts will persist throughout the planning horizon. However, it was also deemed beneficial to create a sensitivity forecast scenario to explore how the needs identified through the technical study would evolve if all contracts did truly expire and behind the meter generation was not accounted for in the planning forecast. The sensitivity forecast is outlined in section 5.9.

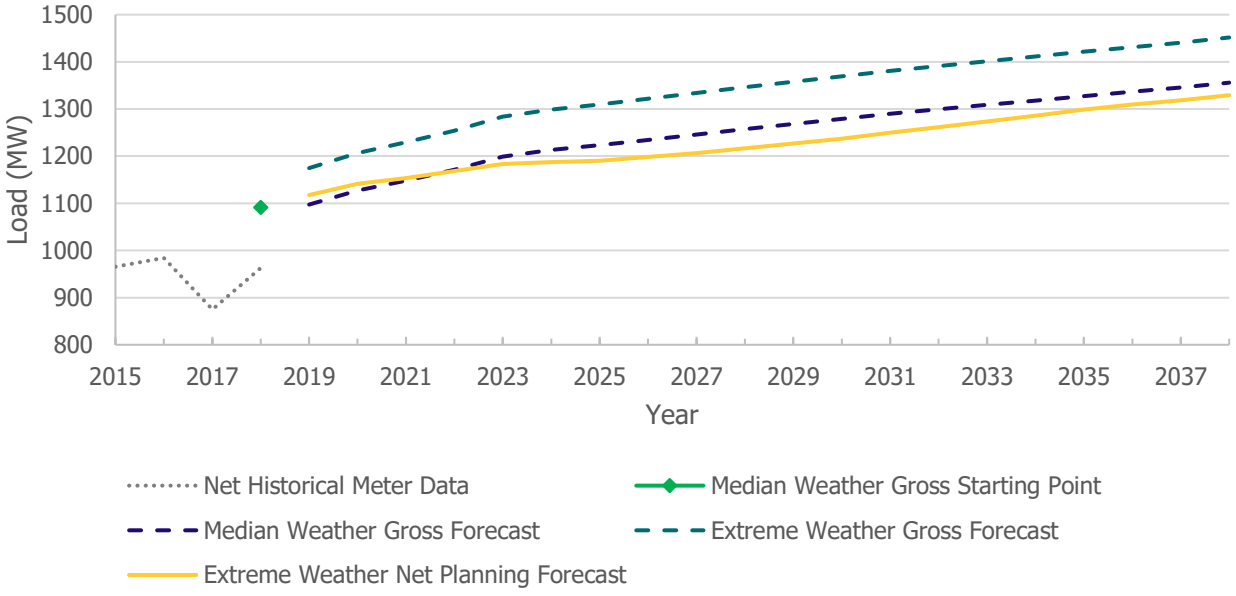
Figure 5-7 | Contribution of DG output at the time of region's peak in the Peterborough to Kingston Region by Resource Type

5.7 Planning Demand Forecast

The final planning demand forecast was used to carry out system studies, and was the primary input for identifying potential needs. It was prepared by first taking the gross median weather demand forecasts prepared by LDCs and adjusting them to account for the expected impact of extreme weather conditions (as described in section 5.5), thereby increasing demand. Furthermore, the impacts of CDM savings and DG were added (as described in the sections 5.6 and 5.7), which resulted in reducing the demand. The outcome of these steps results in the final planning demand forecast, which is an extreme weather net demand forecast. For a more detailed look into each LDCs forecast methodology see Appendix A - Methodology and Assumptions for Demand Forecast.

Figure 5-8 and Figure 5-9 shows the summer and winter planning demand forecast, aggregated for the entire Peterborough to Kingston region. For comparison, the figure also shows the net metered historical peaks from 2015-2018, the 2018 median weather corrected starting point, the gross median weather forecast and the gross extreme weather forecast.

Figure 5-8 | Summer, Extreme Weather, Net Demand Forecast



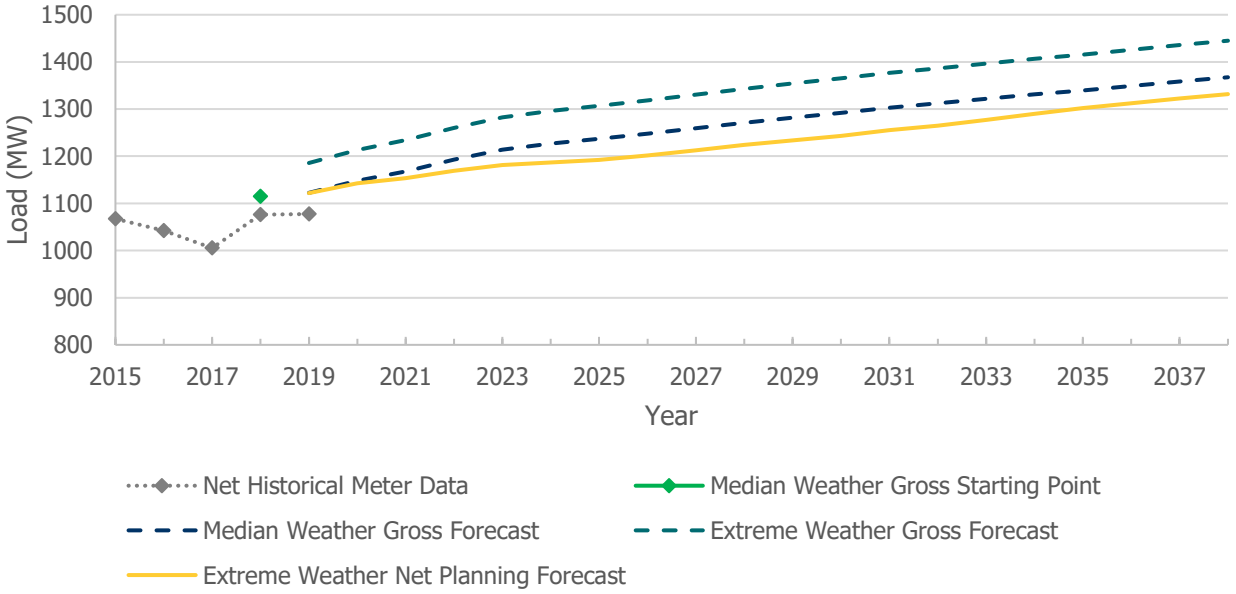


Figure 5-9 | Winter, Extreme Weather, Net Demand Forecast

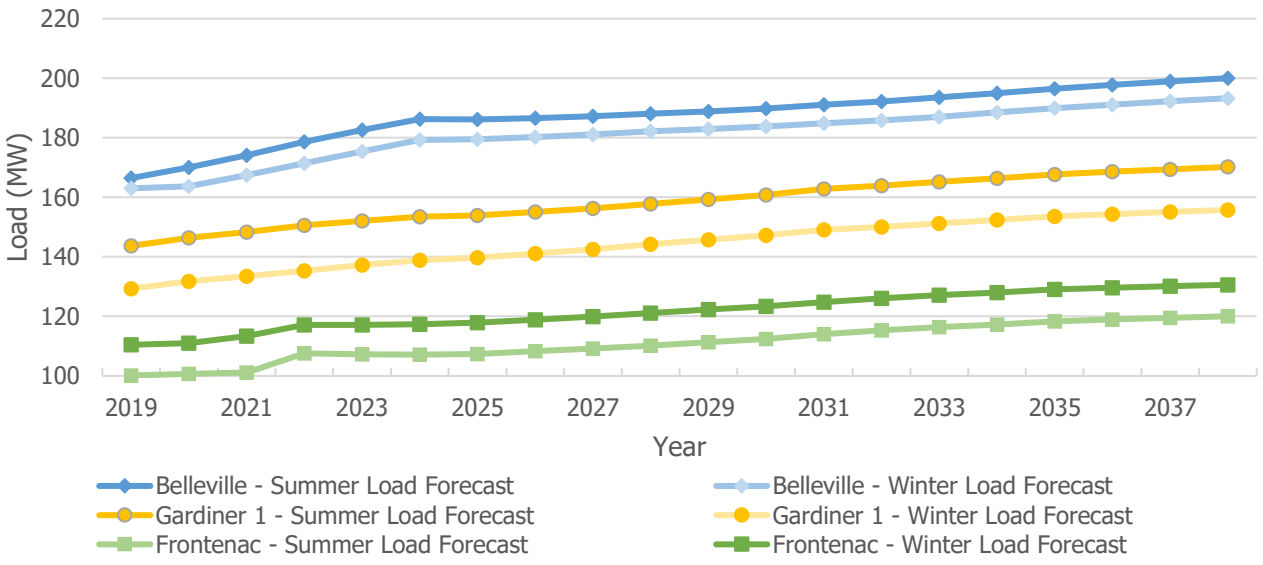


5.8 Non-Coincident Station Forecasts

To evaluate the adequacy of the electric system, the regional planning process involves measuring the demand observed at each station for the hour of the year when overall demand in the study area is at a maximum, also called the coincident peak demand. This differs from a non-coincident peak, which refers to each station's individual peak, regardless of whether the stations' peaks occur at different times. Apart from assessing the adequacy of the electrical grid, the adequacy of each station is assessed as part of the regional planning process. For this assessment, non-coincident forecasts is created, as shown in Figure 5-10. If a station's non-coincident forecast loading exceeds the capability of each transformer at the station, this is indication of a station capacity need.

The Scoping Assessment completed prior to the start of the IRRP had identified three stations which were likely to have station capacity needs over the course of the planning horizon; Belleville TS, Frontenac TS and Gardiner TS DESN #1. A further screening was completed by the Working Group during the IRRP to establish these needs.

Figure 5-10 | Summer and Winter Non-coincident Station level Planning Demand Forecast

5.9 Sensitivity Scenario: Retirement of Distributed Generation Resources

The development of the planning demand forecast assumed that contracts coming to the end of their terms will be reacquired by the IESO. The Working Group identified the need to look at the other bookend scenario; i.e., creating a sensitivity forecast which assumes that all DG resources are taken out of service following the expiry of their contracts. This scenario also assumed that non-IESO contracted behind the meter generators, accounted for by LDCs in the planning forecast, would not contribute towards reducing the gross demand forecast. This was due to the fact that there was little to no certainty with regards to the operation of these resources during times of regional peak.

With the assumption that expired contracts will retire, it was determined that it will not have a significant impact to region's demand as the DG contribution at the time of region's peak is approximately 40 MW as shown in Figure 5-7.

5.10 Sensitivity Scenario: High Growth Forecasts

The Working Group, in consultation with key customers, developed a high demand scenario. While the scenario developed is most impacted by the incorporation of potential impacts of electrification in the Kingston area (identified through stakeholder feedback), the rest of the region was also reviewed by the applicable LDCs to capture any relevant long-terms growth plans or any currently foreseeable electrification impacts for their areas.

The City of Kingston had many stakeholders who were able to provide input into high growth forecast scenarios. This included projects ranging from electric vehicle charging infrastructure to electrified space heating installations. High growth forecasts for the City of Kingston thus added considerable load to the reference forecast.

Two high growth scenarios were developed, with high growth scenario 1 representing a more moderate impact from electric heating than high growth scenario 2. To develop the high growth scenario 2 winter demand scenario, the rated output of existing natural gas heating appliances (BTUh) was converted to the equivalent electric resistive heating demand (kW). For the high growth scenario 1 winter demand scenario the electric resistive heating demand of high growth scenario 2 was converted to an equivalent electric heat pump demand. Since the differentiating factor between high growth scenario 1 and 2 was the assumption on the efficiency of conversion to electric space heating, only one high growth scenario (scenario 1) was developed for summer demand. Further details of the input to both forecast scenarios are presented in Appendix A.

Stakeholders serviced from Belleville TS were not able to provide detailed load growth information pertaining to electrification projects. As such, industry reports and data pertaining to electric vehicle demand as well as city growth statistics were used to create a high growth forecast resulting in an increase of another 3 MW by the year 2038. Further details on the high growth scenario for Belleville TS can also be found in Appendix A.

Table 5-2 | Different Forecast Scenarios - Summer

Summer Load Forecast	2020	2030	2038
Belleville - Reference Forecast	170	190	200
Belleville - High Growth Forecast	170	191	203
Kingston - Reference Forecast	247	273	290
Kingston - High Growth 1 Forecast	247	297	332

Table 5-3 | Different Forecast Scenarios - Winter

Winter Load Forecast	2020	2030	2038
Belleville - Reference Forecast	164	184	193
Belleville - High Growth Forecast	164	185	196
Kingston - Reference Forecast	243	270	287
Kingston - High Growth 1 Forecast	243	296	329
Kingston - High Growth 2 Forecast	243	347	415

5.11 Load Profiling

In addition to the annual peak forecast, hourly load profiles (8,760 hours per year over the 20 year forecast horizon) for certain stations or group of stations with identified needs were developed to characterize their needs with finer granularity. The profiles are based on historical data adjusted for variables that impact demand such as calendar day (e.g. holidays and weekends) and weather (e.g. extreme weather events like ice storms or heat waves) impacts. The profiles are then scaled to match the annual peak forecast for each year. As described in section 7.1, these profiles are used to quantify the magnitude, frequency, and duration of needs to better evaluate the suitability of generation and distributed energy resource options.

Note that this data is used to roughly inform the overall energy requirements that a non-wire alternative would need to meet for the purposes of evaluating alternatives; the intent in this application is not to deterministically specify the precise hourly energy requirements. Further, the purpose of this data is to enable the selection of suitable technology types and roughly estimate operating costs. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification achieve greater adoption. The Working Group will continue to monitor these changes as part of plan implementation.

6 Power System Needs

Based on the demand outlook, system capability, application of provincial planning criteria, and the transmitter's identified end-of-life asset replacement needs, the Peterborough to Kingston IRRP Working Group determined electricity needs in the near, medium, and long term. This section describes end-of-life, capacity, and reliability needs in the Peterborough to Kingston region.

6.1 Needs Assessment Methodology

Based on the application of ORTAC[9] and North American Electric Reliability Corporation (NERC) TPL 001-4 Standard[10], the Working Group identified electricity needs local or regional reliability requirements for the following categories:

- **Station Capacity Needs** describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations at peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day LTR of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be limited when downstream or upstream equipment, e.g., breakers, disconnect switches, low-voltage bus or high voltage circuits, is undersized relative to the transformer rating.
- **Supply Capacity Needs** describe the electricity system's inability to provide continuous supply to a local area at peak demand. This is limited by the LMC of the transmission supply to an area. The LMC is determined by evaluating the maximum demand that can be supplied to an area accounting for limitations of the transmission elements, e.g., a transmission line, group of lines, or autotransformer, when subjected to contingencies and criteria prescribed by ORTAC and TPL 001-4. LMC studies are conducted using power system simulations analysis.
- **End-of-life Asset Replacement Needs** are identified by the transmitter with consideration to a variety of factors such as asset age, the asset's expected service life, risk associated with the failure of the asset, and its condition. Replacement needs identified in the near- and early mid-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium- to long-term needs should reflect the potential for the need date to change as condition information is routinely updated.

[9] https://www.ieso.ca/-/media/Files/IESO/Document-Library/Market-Rules-and-Manuals-Library/market-manuals/connecting/IMO-REQ-0041-TransmissionAssessmentCriteria.pdf

[10] https://www.nerc.com/files/TPL-001-4.pdf

- **Load Security and Restoration Needs** describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC. No load security and restoration needs were identified as part of this IRRP.

6.2 Near/Medium-Term Needs

Station Capacity Needs

Station capacity needs have been identified for Belleville TS, Frontenac TS and Gardiner TS DESN #1 in the near or medium term. The following sections describe these capacity needs, along with the sensitivity of the need date to high growth forecasts (as described in section 5.10).

Belleville TS Station Capacity Need

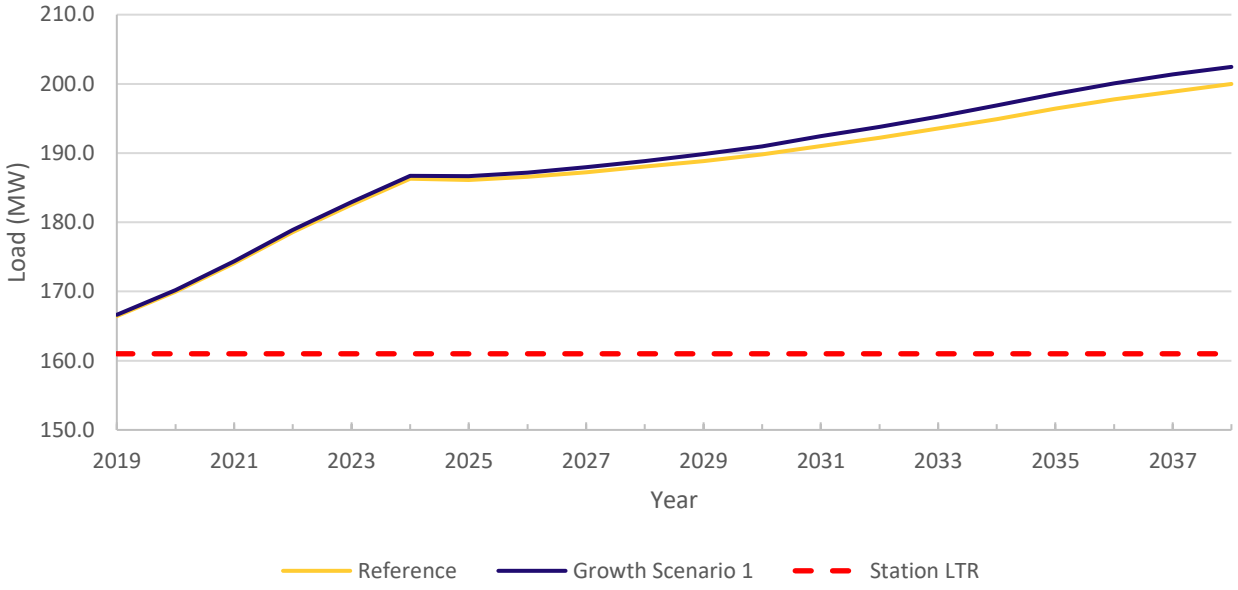
Belleville TS consists of one DESN connected to the 230 kV system. The station has a summer capacity of 130 to 161 MW[11], depending on the load composition when transmission circuit H23B and the companion transformer are both lost. Currently, the station has reached the capability of the existing station transformers, be it 130 MW or 161 MW. Furthermore, the station's load is similar in summer and winter seasons, however, the transformer's summer ratings are lower than winter.

While the Belleville TS transformers are currently undergoing an end-of-life replacement, targeted in-service 2022, this refurbishment is not expected to result in a material improvement to the station's capacity. Based on historical and forecast demand, there is a capacity need at Belleville TS today.

Another 30 MW of load is forecast to connect to Belleville TS over the next 20 years. Figure 6-1 and Figure 6-2 show the various non-coincident forecast scenarios that were developed for Belleville TS for the summer and winter, respectively, along with the current capacity of the station. If a high growth scenario materializes, this capacity need would worsen.

[11] The 130 MW is a voltage limitation, while the 161 MW is a thermal limitation, and which one becomes more limiting is subject to the load composition.

Figure 6-1 | Summer Non-Coincident Demand Forecast Scenarios for Belleville TS



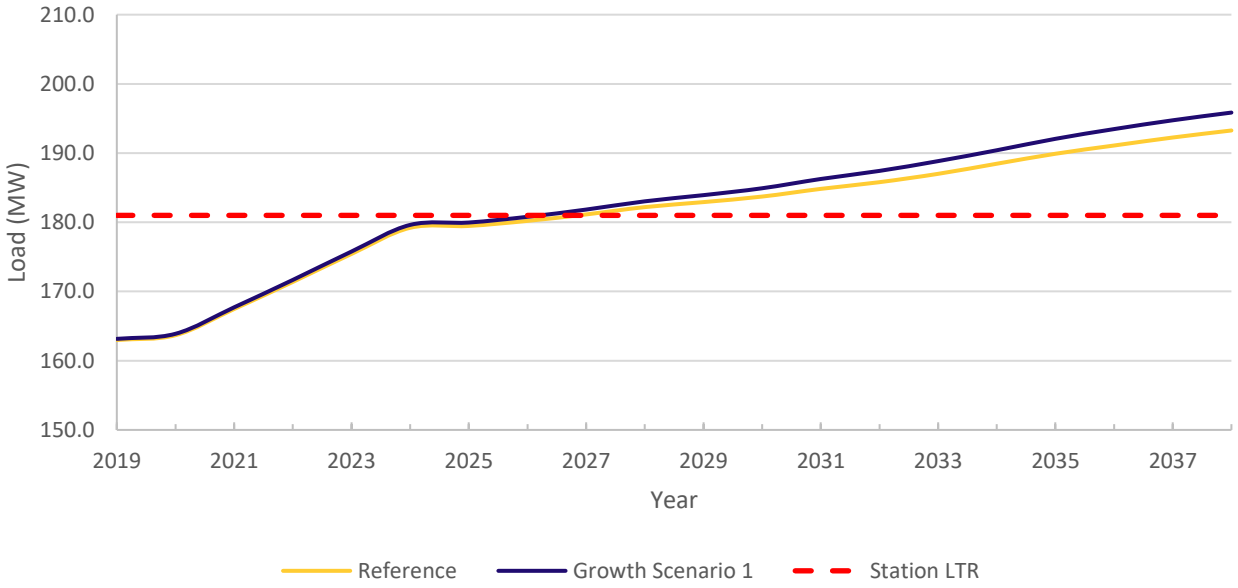


Figure 6-2 | Winter Non-Coincident Demand Forecast Scenarios for Belleville TS

Station Capacity Needs in the Kingston area

The City of Kingston is supplied by two station sites, Frontenac TS and Gardiner TS (which contains two DESNs, #1 and #2). These stations have overlapping service territories, and so, capacity needs in the region should be looked at holistically. There is significant growth forecast within the City of Kingston over the 20 year planning horizon, however, the magnitude varies considerably based on the forecast scenario considered – reference, high growth 1, and high growth 2. As can be expected, the station capacity needs can arise earlier under the high growth scenarios than for the reference forecast. The next two sections provide further details on the Frontenac TS and Gardiner TS station capacity needs.

Frontenac TS Station Capacity Need

The Kingston area distribution system is divided into two territories supplied by two different LDCs. The central area that contains the Kingston downtown core is supplied by Utilities Kingston while the remaining area to the west of Kingston's downtown core, as well as area the developments east of the Cataraqui River, are supplied by Hydro One (Distribution).

While the load growth is distributed throughout the area, the system is electrically supplied from two separate paths:

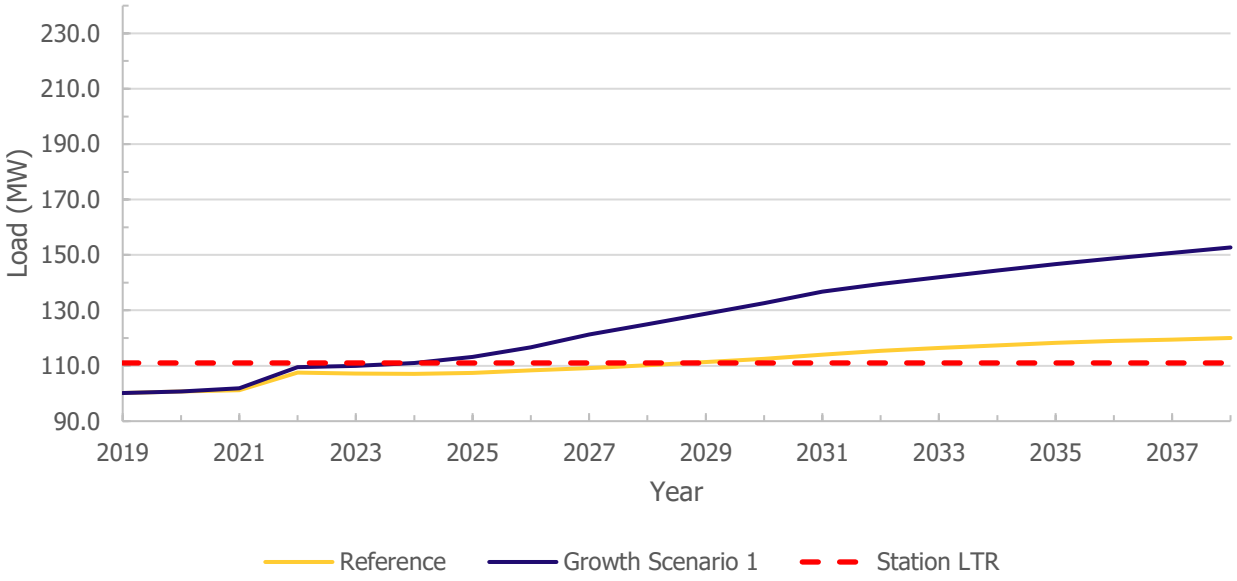
(1) Frontenac TS is supplied from the 115 kV circuits B5QK and Q3K; and
(2) Gardiners TS DESN #1 and #2 are supplied from the 230 kV circuits X2H and X4H.

The forecast load for Frontenac TS and Gardiner TS DESN #1 are both expected to exceed the stations' respective LTR in the near to mid term. The configuration of the distribution system in Kingston is such that there are frequent load transfers between Frontenac and Gardiner TS DESN #1 via 44 kV feeder ties which allow for added reliability during planned and emergency work. This flexibility will become more rigid if either Frontenac TS or Gardiner TS DESN #1 are loaded to their maximum capability. As a result, the reliability benefits of timely load restoration, the operational benefits for outage planning, and the identified capacity needs have to be balanced when planning an adequate system for the long term.

Throughout the planning process it became evident that the potential for rapid load growth is a risk for the area as a whole. High growth scenarios were developed which include the impact of future electrification programs such as electrification of fleet vehicles, thermal heat pumps, and fuel switching incentives. These high growth scenarios advance and amplify the two major capacity needs in the area.

Frontenac TS is supplied by two transformers with a total summer capacity of 111 MW. Figure 6-3 and Figure 6-4 show the various non-coincident demand forecast growth scenarios developed for Frontenac TS for the summer and winter seasons, respectively. The station's capacity (LTR) is included in the figure to identify the need. The figures illustrate the area is anticipated to exceed the current capacity by between 10 to 110 MW by 2038, depending on the forecast scenario. The station capacity need is anticipated to materialize as late as 2029 or as early as 2022, depending on the forecast scenario.

Figure 6-3 | Summer Non-Coincident Demand Forecast Scenarios for Frontenac TS



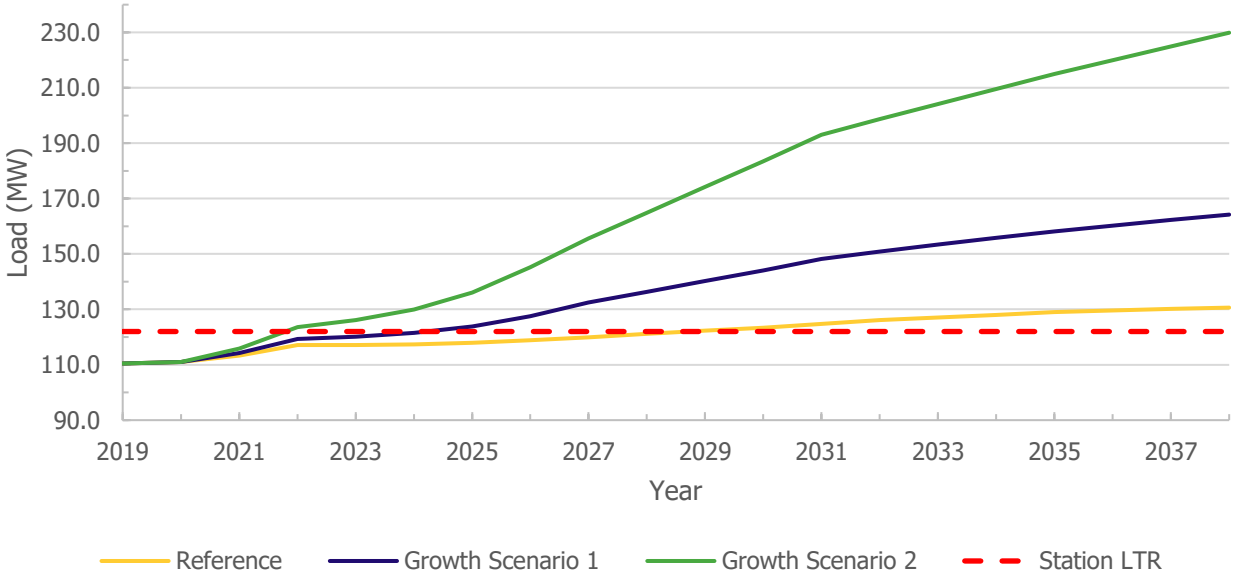


Figure 6-4 | Winter Non-Coincident Demand Forecast Scenarios for Frontenac TS

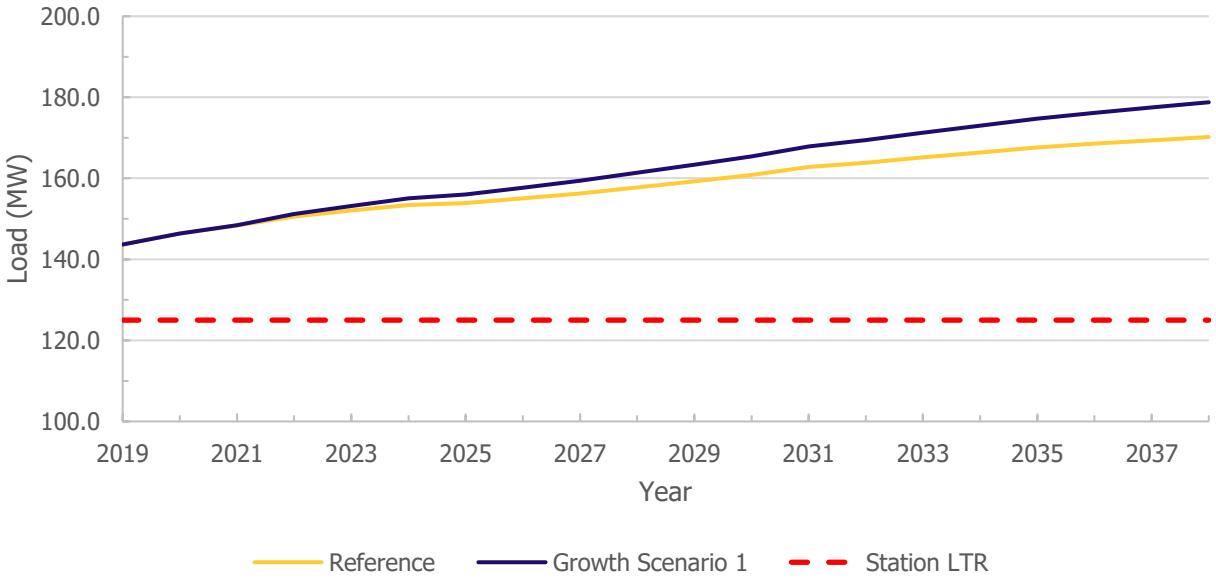
Gardiner TS (DESN #1) Station Capacity Need

A local capacity need was identified at the Gardiner TS DESN #1 within the Peterborough to Kingston region. Gardiner TS currently consists of two DESNs connected to the 230 kV system. The T1/T2 DESN (#1) has a summer capacity of 125 MW, while the T3/T4 DESN (#2) has a summer capacity of 85 MW. Gardiner TS DESN #2 is the newer of the two DESNs and has ample station capacity, while Gardiner TS DESN #1 has reached its capacity. Another 25 to 50 MW of load growth is forecast for Gardiner TS DESN #1, depending on the forecast scenario. Figure 6-5 and Figure 6-6 show the various forecast scenarios developed for Gardiner TS DESN #1 for the summer and winter, respectively. The station's capacity (LTR) is included in the figure to identify the need. It is also to be noted that Hydro One Transmission has identified that Gardiner TS DESN #1 is approaching end-of-life.

The figures illustrate that Gardiner TS DESN #1 has a summer capacity need today, and the magnitude of need increases for the high growth scenarios.

Figure 6-5 | Summer Non-Coincident Demand Forecast Scenarios for Gardiner TS DESN#1



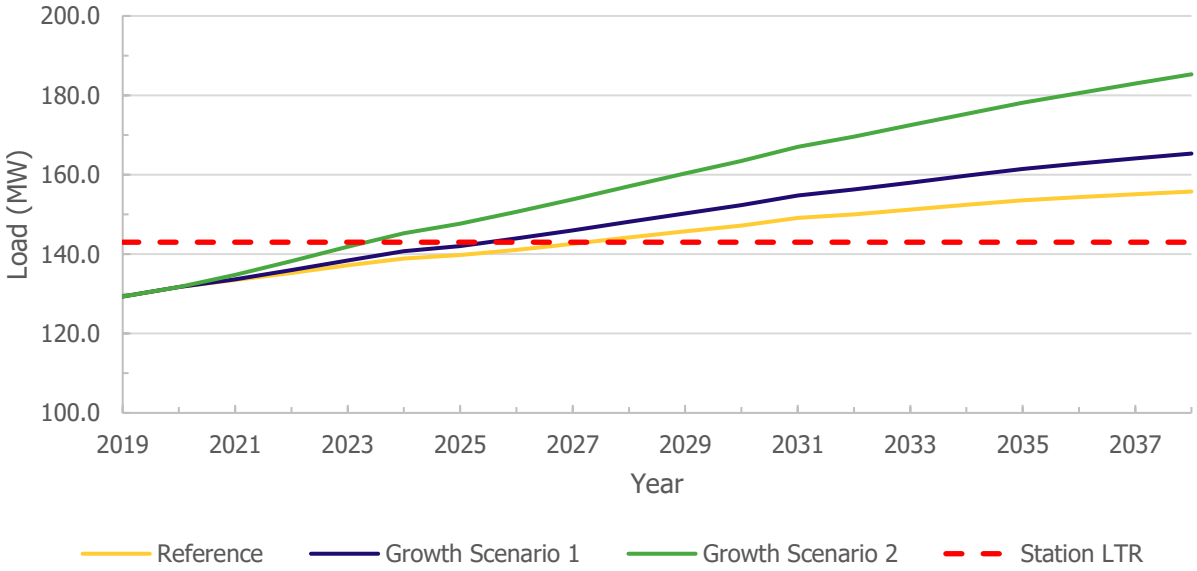


Figure 6-6 | Winter Non-Coincident Demand Forecast Scenarios for Gardiner TS DESN#1

Supply Capacity Needs

The Peterborough to Kingston region's electricity demand growth affects the 230 kV transmission supply capability to serve the 115 kV local area. While load growth is distributed throughout the area, two bulk supply capacity needs were observed, these are:

1. Supply lines affecting Peterborough to Quinte West load

2. Cataraqui autotransformer capability to support Frontenac and other 115 kV loads

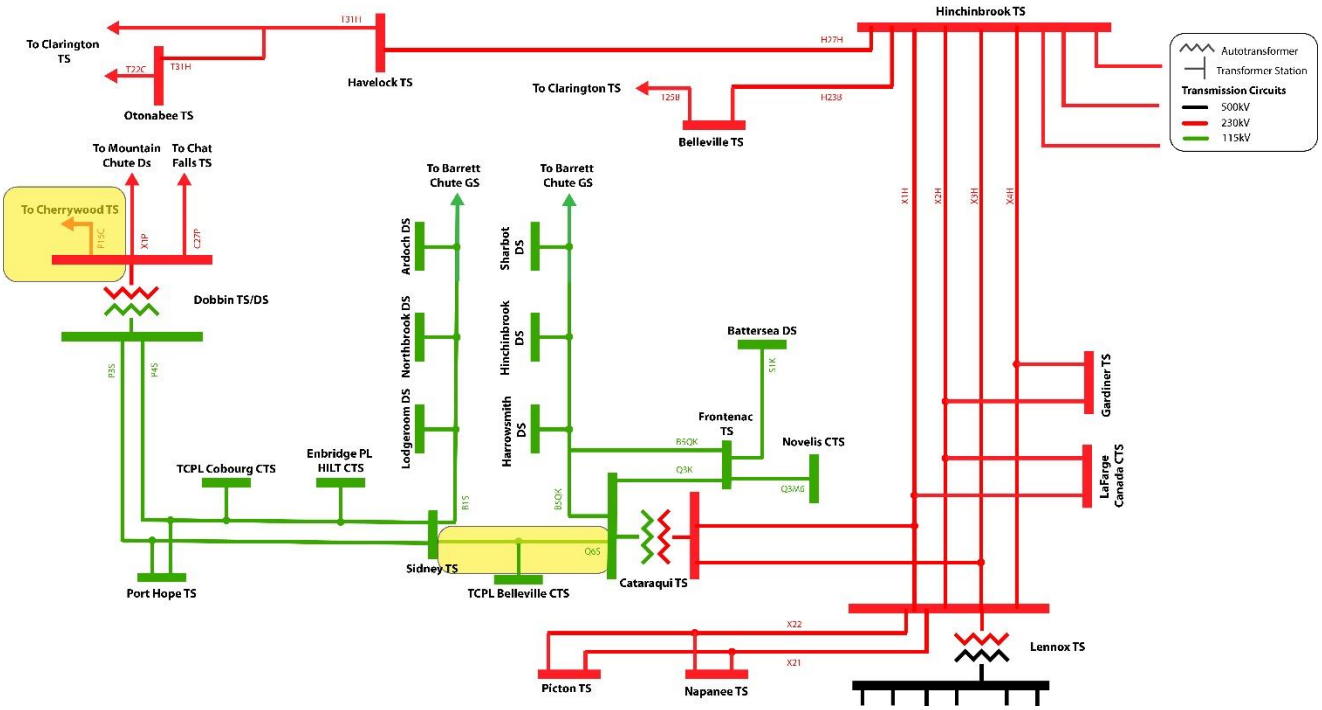
These two bulk supply needs observed are described next. The impact of DG retirement is negligible as the region's demand increases slightly – ~40 MW.

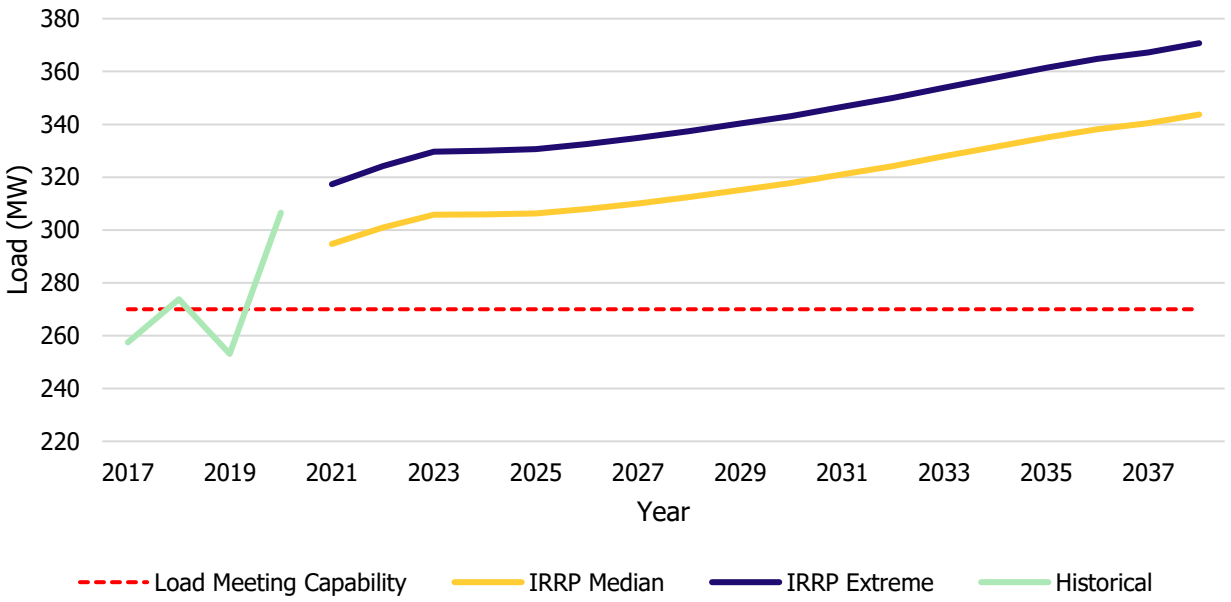
Peterborough to Quinte West Supply Capacity needs

The load growth in the Peterborough to Quinte West sub-system is expected to introduce supply capacity needs in the area. There are 230 kV and 115 kV supply lines that serve load in that pocket. Specifically, P15C, a 230 kV single circuit from Cherrywood TS to Dobbin TS, and Q6S, a 115 kV single circuit supplying Sidney TS from Cataraqui TS, are two critical circuits supplying this load pocket. The limitation on these two circuits dictates a Load Meeting Capability (LMC) of 270 MW for the sub-system, shown on Figure 6-8. As shown in this figure, the sub-system load is expected to increase by approximately 60 MW over the 20-year planning horizon.

This need is being coordinated with bulk planning system study activities in the area to ensure impacts from the broader system are considered when reviewing and resolving this need.

Figure 6-7 | Critical Supply to Dobbin by Sidney (P15C and Q6S)





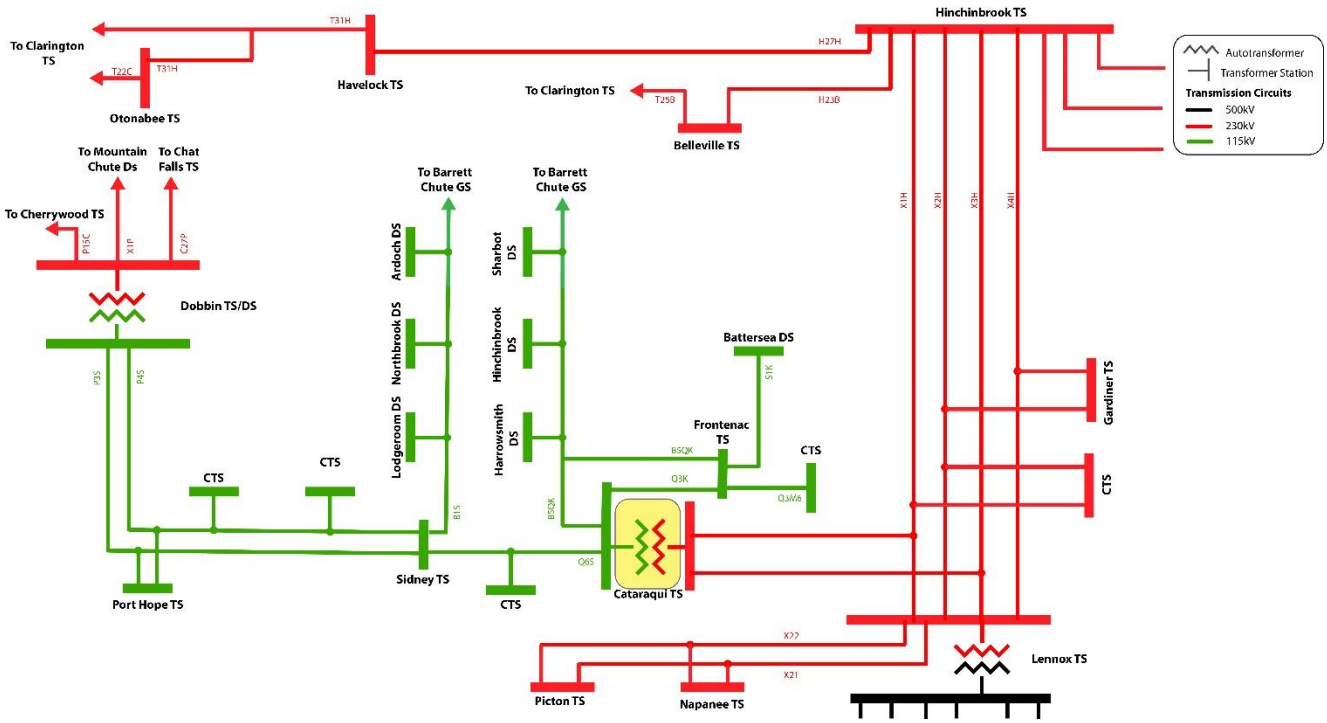


Figure 6-8 | Peterborough to Quinte West Forecast and LMC

Cataraqui Autotransformers Supply Capacity Need

The load growth at Frontenac TS and other 115 kV supply stations is expected to result in a supply capacity need at Cataraqui TS in 2023. The load is expected to continue to increase over the 20-year planning horizon.

Figure 6-9 | Cataraqui Autotransformers

End-of-Life Refurbishment Needs

The transmitter identified some end-of-life asset replacement needs for the Peterborough to Kingston region, with several needs arising in the near to medium term. These consisted of station transformer replacement needs. Based on the outcomes of the Needs Assessment and the Scoping Assessment, only one end-of-life need was identified as requiring further coordinated planning in the IRRP. Port Hope TS T3/T4 transformer replacement, currently expected to be needed in 2025 based on the latest asset condition information, was included in the IRRP. The end-of-life needs are based on the best available asset condition information at the time of each stage of the planning cycle, timing of asset needs can change as new information becomes available.

Summary of Near/Medium-Term Needs

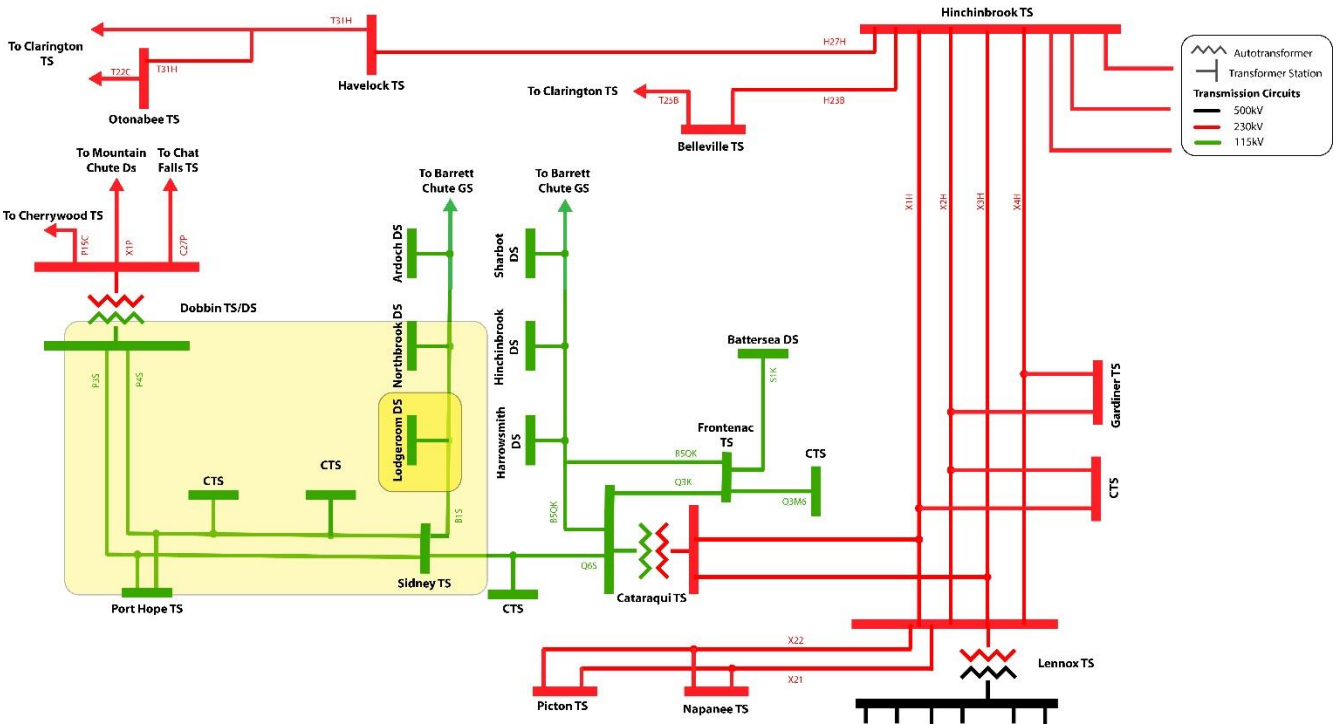
	Needs	Location	Need Date[12]
1	Station Capacity	Belleville TS	Today
2	Station Capacity & End-of-Life Refurbishment	Gardiner TS DESN #1	Today
3	Supply Capacity	Peterborough to Quinte West	Today
4	Supply Capacity	Cataraqui Autos	2023
5	End-of-Life Refurbishment	Port Hope TS	2025
6	Station Capacity	Frontenac TS	2029

6.3 Long-Term Needs

Supply Capacity Needs

The long-term load growth for the Peterborough to Kingston region results in supply capacity needs on the 115 kV system. While load growth is distributed throughout the area, the sub-system is electrically supplied from two separate paths:

1. 115 kV circuits supplying the Port Hope, Sidney, Lodgeroom DS area
2. B5QK circuit supplying the Frontenac TS area.



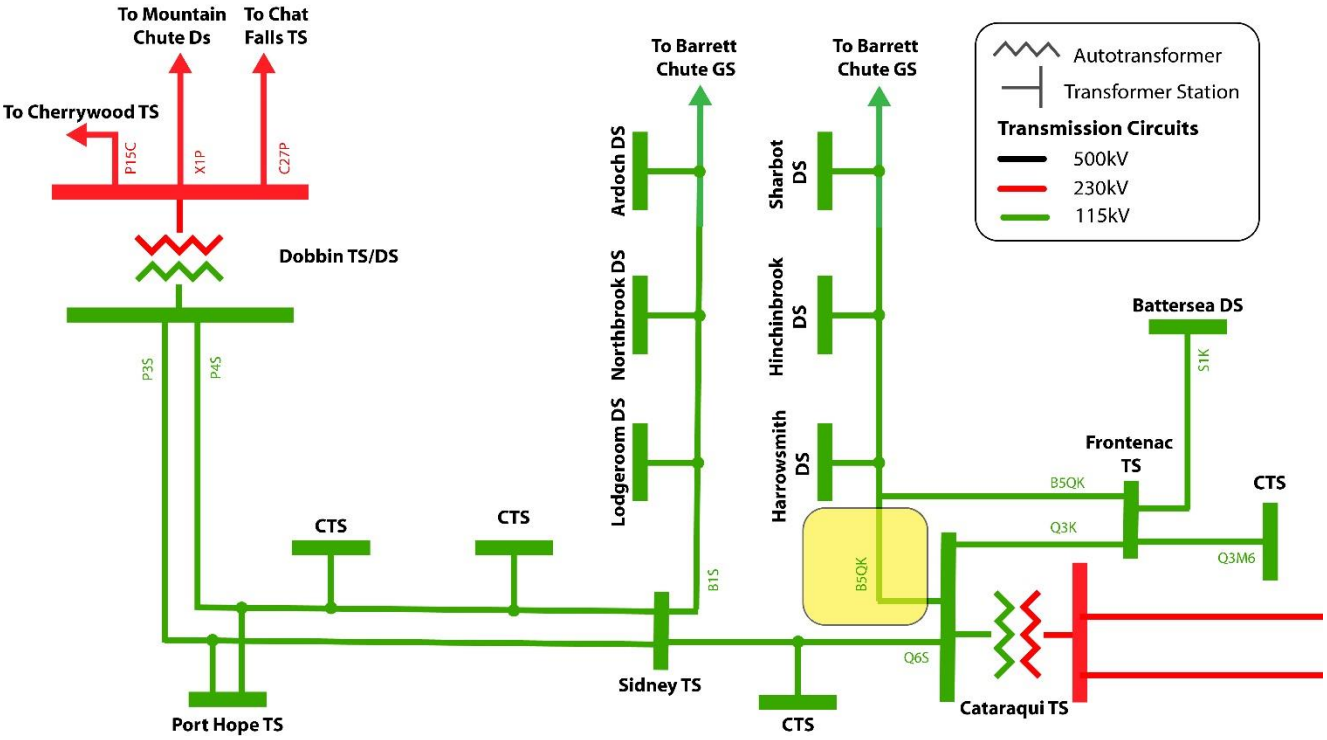
The local supply needs observed are described next. The impact of DG retirement is negligible as the region's demand increases slightly ~40 MW.

[12] Based on reference forecast. Impact of high growth is discussed within the relevant section.

Peterborough to Quinte West Voltage Need

The load on the 115 kV system is expected to grow by 60 MW over the 20 year planning horizon. It is expected to introduce voltage criteria violations in the area. During a pre-existing outage on circuit C27P, the loss of circuit P15C will result in under-voltage violations starting in 2033 at Lodgeroom DS. These conditions worsen and appear at additional stations on the 115 kV system in later years as load continues to grow, as depicted in Figure 6-10.

Figure 6-10 | 115 kV Pocket Voltage Need



Kingston Transmission Supply Capacity Needs

The forecast load growth in Kingston, specifically at Frontenac TS, is expected to introduce supply capacity needs in the area. There are two upstream 115 kV supply lines serving Frontenac TS and one of them – B5QK[13] highlighted on Figure 6-11– is forecast to exceed its capacity in the long term as the load grows by 27 MW to 165 MW[14]. This limit isn't expected to be exceeded until the end of the planning horizon for the reference forecast, but a need can emerge as early as 2027 or 2025, for high growth scenarios 1 and 2, respectively.

Figure 6-11 | B5QK overloaded section

Summary of Long-Term Needs

	Needs	Location	Need Date[12]
1	Supply Capacity	Peterborough to Quinte West	2033
2	Supply Capacity	Kingston Area	2038

6.4 Needs Summary

The majority of the needs in the region are near- and medium-term station and supply capacity needs. Station capacity needs occur in the Belleville and Kingston areas and the supply capacity needs present on multiple portions of the 115 kV system in the region. The table below provides an overview of the needs considered in the development of options for the plan.

Table 6-1 | Summary of Needs

Area/Facility	Need	Description	Need Date[12]
Belleville TS	Station Capacity	An existing capacity need was identified for Belleville TS, limited by voltage issues for the loss of one transmission supply as well as transformer capacity.	Today
Gardiner TS	Station Capacity & End-of-Life Refurbishment	An existing transformer capacity need was identified for DESN #1 (T1/T2) as well as an End-of-Life refurbishment need	Today
Peterborough to Quinte West	Supply Capacity	The load meeting capability of the system is currently exceeded. The outcomes of the Gatineau Corridor End-of-Life Study are forecast to address this need.	Today
Cataraqui TS	Supply Capacity	The autotransformers at Cataraqui is currently forecast to be exceeded.	2023
Port Hope TS	End-of-life	The station transformers at Port Hope TS have been identified as reaching end-of-life in 2025 and requiring replacement.	2025
Frontenac TS	Station Capacity	The transformers at Frontenac TS are forecast to exceed their capability.	2029
Peterborough to Quinte West	Supply Capacity	The load meeting capability of the system is currently exceeded. The outcomes of the Gatineau Corridor End-of-Life Study are forecast to address this need.	2033
Kingston Area	Supply Capacity	The thermal capability of B5QK, which supplies Frontenac TS, is forecast to be exceeded.	2038

7 Plan Options and Recommendations

In developing the plan, the Working Group considered a range of integrated options. Considerations in assessing alternatives included maximizing use of existing infrastructure, provincial electricity policy, feasibility, cost, and consistency with longer-term needs in the area.

Generally speaking, there are two approaches for addressing regional needs that arise as electricity demand increases:

1. Build new infrastructure to increase the load meeting capability of the area. These are commonly referred to as "wires" options and can include things like new transmission lines, autotransformers, step-down transformer stations, voltage control devices or upgrades to existing infrastructure. Wires options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate certain reliability concerns.
2. Install or implement measures to reduce the net peak demand to maintain loading within the system's existing load meeting capability. These are commonly referred to as "non-wires" alternatives and can include things like local utility scale generation, distributed energy resources, or conservation and demand management.

The IESO utilized a screening approach for assessing which needs would be best suited to undergoing a detailed assessment for non-wires alternatives, including CDM. The initial screening exercise examined the duration, frequency, timing, and magnitude of the need, as well as cost of traditional wires solutions, for each identified need.

Through this initial screening exercise, it was determined that non-wires alternatives should be assessed for the Frontenac TS capacity need.

7.1 Options for Meeting Near- to Medium-Term Needs

Options for Meeting Station Capacity Needs

Options for Meeting the Belleville TS Station Capacity Need

The options that were considered for Belleville included but were not limited to the following:

1. An addition of a third transformer and station bus at Belleville TS,
2. A new Dual Element Spot Network (DESN) transformer station at Belleville, or
3. Load Transfers

Since Belleville TS does not currently have any distribution load transfer capability, due to a lack of adjacent stations, distribution load transfers were not explored further.

Each of the first two options are estimated to cost approximately $30-35 M. For a similar cost, option 2 provides more long-term capability and would also perform better under outage conditions.

The high-level cost estimates for wires options are provided by the transmitter, Hydro One. The intention of these high-level (or "planning") estimates are to enable comparison between options and are typically within an accuracy of +100%/-50%. The Regional Infrastructure Plan (RIP) following the IRRP will perform additional detailed analysis and refine these cost estimates before implementation work begins. The IESO will continue to participate in the Working Group during the RIP and revisit these recommendations if costs estimates differ significantly.

Installing a second DESN at Belleville TS will resolve the need until the end of the planning horizon (20 years). To fully utilize the additional capacity beyond the planning horizon, new supply lines into Belleville would be required. A reinforcement option considered beyond the 20 year planning horizon is to extend X21/X22 (radial lines to Picton/Napanee from Lennox) to Belleville. An initial network study was performed to assess the feasibility of this option and the results of the preliminary study showed that the new station's capacity can be fully utilized following this reinforcement. However, there might be upstream bulk system impacts with this option, therefore a full bulk planning study is needed to identify any impacts.

Options to Meet the Kingston Area Station Capacity Needs

The Working Group has determined that the limitations of the existing supply to the area poses a risk to accommodating future load growth in the Kingston area. There is a risk that load will materialize sooner than expected as the Working Group is aware of several electrification initiatives on the horizon, identified by both the City and the LDCs for the area. There is also a risk that some of these initiatives may not take place or that they may not have as large an impact as forecast. In either scenario, there is a need for additional capacity at Gardiner TS DESN #1 and Frontenac TS.

Many options and combinations of options were explored by the Working Group and the most relevant ones will be described here.

- Non-wires alternatives: Simple Cycle Gas Turbine (SCGT) generator, Battery Storage
- Distribution load transfers - Permanent load transfers to a station with available capacity
- Increase capacity of the existing station(s) – through asset refurbishment and/or uprates
- A new station (new or existing site)

The capacity at Gardiner TS DESN #1 has already been exceeded today. However, Gardiner TS DESN #2 is adjacent to the station which allows for less complicated load transfers. It is important to note that Gardiner TS DESN #2 is a new transformer station, built in the last 15 years, and has capacity available on the order of 40 MW. The option of load transfers is usually the first avenue pursued as it is preferable to building additional transmission assets.

Hydro One Distribution has identified two load transfer options from Gardiner TS DESN #1 to Gardiner TS DESN #2, each transferring up to 11 MW of load. The first is relatively simple and low in cost while the second load transfer would require a new feeder position, increasing the relative cost.

Hydro One Transmission has identified a replacement plan for Gardiner TS DESN #1 as it is approaching end-of-life. The transformers will be replaced for a like to like replacement with new transformers however, the new transformer units will have a higher LTR and as such, will increase the capacity at the Gardiner TS DESN #1. The simpler 11 MW load transfer, paired with an uprate resulting from a "like-for-like" replacement of the station at Gardiner TS DESN #1, would completely address the reference forecast need over the 20-year planning horizon. With the second 11 MW load transfer the high growth forecast need can be met as well.

Turning to the need at Frontenac TS, the load transfer options available would be to transfer load from Frontenac TS to either Gardiner TS DESN #1 to Gardiner TS DESN #2. Currently, the distribution system in Kingston is operated in such a way that temporary load transfers between stations, ranging from 5 to 20 MW, are regularly utilized as a part of planned and emergency work. Performing a 10 MW load transfer to alleviate the need at Frontenac TS would compromise this flexibility and reduce the reliability of the system. Furthermore, net present value analysis suggests the load transfer would have to delay the need for a new transmission station by at least four years in order for this option to be economically favourable. Therefore, load transfer is an unfavorable option.

This IRRP maintains the long-term flexibility to respond to changes in demand for electricity in the future using cost-effective solutions, such as non-wires alternatives. In particular, smaller scale initiatives could have the potential to cost-effectively defer the need for a conventional solution (i.e. "wires" options), especially when paired with other measures such as energy efficiency. These cost-effective solutions can also be deployed to help delay or reduce large capital investments in transmission and distribution infrastructure. Value is created by delaying the date at which transmission and distribution equipment needs to be expanded, providing optionality. Timing permitting, optionality value allows more time to understand load growth and emerging trends prior to making significant infrastructure investments which reduces the risk of underutilized and/or stranded assets.

The Working Group also examined the feasibility of implementing non-wires resources to reduce the forecast demand in the area and defer the need for a new station or existing station expansion. These potential resources were considered both on an individual basis and as a package of solutions. Figure 7-1 shows that a capacity need exists at all times in the year 2038 at Frontenac station which means the solution will need to address a large scale need.

Figure 7-1 | Need Characterization Heat Map Frontenac 2038

The analysis for non-wires alternatives identified that an SCGT, battery storage, and energy efficiency as viable solutions for the reference scenario need at Frontenac station. In the year 2038, there is a 10 MW need at Frontenac station under reference forecast, and the station capacity need starts to arise in the year 2029.

Cost estimates for generation and other non-wires alternatives are based on benchmark capital and operating cost characteristics for each resource type and size. Generally speaking, the most cost-effective transmission-connected options for meeting local needs in this region are resources with performance and costs on par with SCGT generators, depending on the relative size of the capacity versus energy requirements. New natural gas-fired generation was considered in the economic analysis for illustrative purposes to represent the cost of new generation. In some cases, battery storage such as lithium nickel manganese cobalt oxide (NMC) batteries are also becoming competitive due to declining technology costs and the expectation of carbon prices increasing in line with federal policy. Other distributed energy resources, which are typically distribution-connected are also considered. The most cost-effective distributed options are typically a combination of smaller-scale storage and demand response. For each of the above options, the system capacity value is "credited" back to arrive at the net cost to meet local reliability needs. This is done to ensure a level playing field comparison between resources that provide capacity and wires options that address the local need but do not provide system capacity benefits.

Both the upfront and operating cost of the wires options, generation, and distributed energy resources are compiled to generate levelized annual capacity costs ($/kW-yr) over the lifespan of the asset in question for each option. The net present value (NPV) of these levelized costs are the primarily basis through which options are compared.

The costs to implement an SCGT (10 MW) is on the order of $20 M and would defer the need by 10 years, if implemented in 2029. A battery storage solution (10 MW) could defer the need by 10 years as well at an estimated cost of $7 M[15]. After which, a new station is needed. Further, results show that targeted incremental energy efficiency in the area could provide upwards of 15 MW of peak capacity savings by 2030. The costs mentioned here are inclusive of system benefits and present the net value and cost.

To evaluate the combination of these alternatives to delay larger investments, the Working Group considered costs, in terms of NPV. The outcome, in order of highest cost to lowest cost of the combinations are as follows: SCGT [2029] & Station [2038] ($42M), Station [2029] ($30M), Battery [2029] and Station [2038] ($28M). Non-wires solutions for the reference scenario may be useful in addressing the mid-term need and delaying the need for a station, however, barriers exist to both implementation and appropriate allocation of costs to ensure these solutions are cost effective for the local area.

The discussion above only applies to the reference scenario and if a higher growth scenario were to occur then the individual non-wires solutions would no longer be sufficient to meet the need. For the high growth scenarios, the SCGT option was screened out due to high costs. Two different approaches were considered for the high growth scenario in terms of battery solutions: the longest possible deferral of need and the maximised ratio between cost and time of deferral. The order according to cost, from highest to lowest, for combinations of options is: 26 MW Battery [2025] and Station [2032] ($50M), 10 MW Battery [2025] and Station [2027] ($43M), and Station [2025] ($35M).

The Working Group acknowledges that the deferment benefit that a non-wires alternative could provide is highly dependent on how load growth materializes. For the reference forecast, the non-wires alternatives are close in cost to the traditional wires option but if a high growth scenario materializes overall cost would then increase.

[15] After accounting for system benefit achieve by providing support to meet system adequacy/capacity needs

The Working Group next considered some high level review of how a new transformer station should be supplied. In the vicinity, there are two stations – Frontenac TS supplied from the 115 kV system and Gardiner TS supplied from the 230 kV. Frontenac TS is supplied by two 115 kV circuits on separate tower lines. Frontenac TS supplies the Central downtown Kingston area south of Highway 401 as well as the area north of Highway 401 and East of the Cataraqui River. Gardiner TS (DESN #1 & #2) is supplied by the 230 kV system via a double circuit tower line. Gardiner TS supplies the area east of Cataraqui River as well as the area north of Highway 401 and west of the Cataraqui River.

When assessing the options for a new 115 kV supplied station versus a new 230 kV supplied station the analysis showed the 230 kV station to be more favourable for the following reasons. First, in order to build a 115 kV station the two circuits would need to be reinforced in order to meet transmission criteria and ensure load can be supplied during a contingency event. Second, due to upstream constraints on the 115 kV system, it would not be possible to supply the load of an uprated Frontenac TS or a new 115 kV station without considerable upgrades to the Cataraqui autotransformers. Third, building a new 230 kV station in close proximity to the existing 230 kV double circuit tower line may require less additional transmission line work than the 115kV system and also, the 230 kV system can fully supply a new station, without capacity constraints.

The Working Group has confirmed that a new 230 kV station site west of Frontenac TS appears to be the most cost effective option that could help meet the identified needs into the long term, however this option will require Hydro One Distribution to build long feeders to supply customers east of the Cataraqui River. The Working Group has also confirmed that a new 230 kV station east of Frontenac TS would be preferable from a distribution upgrade perspective, however this option has high cost of transmission line extensions within the urban area of Kingston. The Working Group acknowledges that the citing of a new station requires a consideration to balance the cost required to extend 230 kV transmission lines to supply the station versus extending distribution lines required to serve the load. The timing and citing of the station is to be coordinated between the transmitter and the LDCs at which point the trade offs, which could include consideration of how to distribute load between the new and existing stations to manage overall distribution costs, will be considered.

Options for Addressing Supply Capacity Needs

Options for Addressing the Peterborough to Quinte West Supply Capacity Need

The IRRP considered a number of options to address the Peterborough to Quinte West supply capacity need that included and were not limited to the following:

1. Building new transmission supply capacity supplying Dobbin TS
2. Building new transmission supply capacity supplying Sidney TS
3. Siting a new generating resource at Sidney TS

However, this need requires a coordination with the Gatineau Corridor End-of-Life Study to ensure the broader system is considered when reviewing and resolving this need and will be addressed through that study.

Options for Addressing the Cataraqui Autotransformers Supply Capacity Need

The Cataraqui autotransformers have a summer long-term emergency rating of 250 MW. This rating is currently limited by the transformer secondary conductors. A cost effective way to increase the thermal ratings on these autotransformers is to upgrade the transformer secondary conductors, improving the long-term emergency rating without having to upgrade the autotransformers. Upgrading the transformer secondary conductor increases the long-term emergency rating to 285 MW for an estimated cost of $0.5M.

Non-wires alternatives were screened out at an early stage due to the low cost and low impact of the identified secondary conductor replacement solution. Therefore, this IRRP recommends upgrading the transformer secondary conductors and reassessing whether additional capacity will be required as part of the Lennox to St. Lawrence bulk system study.

End-of-Life Refurbishment Options and Recommendations

Port Hope TS is supplied by the 115 kV system between Dobbin TS and Frontenac TS. Port Hope TS is reaching end-of-life in 2025. Generally, options considered for end-of-life replacements include:

- Replacement of the assets "like-for-like" or with the closest available standard;
- Reconfiguration of the existing assets to "right-size" the replacement option based on: the forecast load growth, changes to the use of the asset since it was originally installed, and reliability or other system benefits that an alternate configuration may provide; or
- Retirement of a facility, considering the impact on load supply and reliability.

Working Group assessments indicated that there are no opportunities for end-of-life optimization at this time and like-for-like replacements with the closest available standard can best address the End-of-Life need at Port Hope TS Recommended Near- to Medium-Term Plan

To address the needs identified, the Working Group recommends the actions described below to meet the near-and medium-term electricity needs of the Peterborough to Kingston region. Successful implementation of these actions, in addition to achievement of existing targeted conservation measures, is expected to address the region's electricity needs until the late 2020s /early 2030s under the reference forecast.

Build a new 230 kV DESN transformer station at Belleville TS and monitor load growth

To address today's station capacity need at Belleville TS, as well as serve the growing electricity demand in the region, Elexicon and Hydro One (Transmission) are to initiate the development of a new DESN transformer station at Belleville, with an expected in-service date of 2025. This will increase the supply capacity to the region and will resolve the capacity need at Belleville TS until the end of the planning horizon.

Between planning cycles, the Working Group will continue to monitor the load growth at Belleville TS and re-visit the capacity need in the next regional planning cycle, in order to re-assess whether/when a re-enforcement to Belleville is required. Non-wires alternative such as energy efficiency can delay the implementation, and will be reviewed as part of the next regional planning cycle.

Furthermore, before the next planning cycle, the IESO should assess the bulk system impact of transmission reinforcement to Belleville TS should be included in the scope of a relevant individual bulk planning study for the area.

Hydro One (Distribution) load transfer and advance end-of-life replacement at Gardiner TS DESN #1

To address the near-term capacity need at Gardiner TS DESN #1, Hydro One (Distribution) will complete a relatively low cost and low lead-time load transfer of 11 MW between Gardiner TS DESN #1 and Gardiner TS DESN #2 by 2022 as a first step.

In addition, Hydro One will explore advancing the end-of-life replacement of Gardiner TS DESN #1 transformers to increase the station capacity. Advancing the replacement date, combined with the load transfer, will address the Gardiner TS DESN #1 capacity need for the duration of the planning horizon for the reference load forecast.

The Working Group will continue to monitor load growth in the area to evaluate if a second 11 MW load transfer to Gardiner TS DESN #2 is required.

Monitor load growth and initiate development and siting work to build a new 230 kV DESN transformer station in Kingston when needed

Building a new 230 kV station in Kingston, supplied by 230 kV circuits X2H and X4H, will address the local need for station capacity at both Frontenac TS and Gardiner TS over the long term and for multiple growth scenarios. Due to the uncertainty in the forecast, the timing of the need for the new station could be in the near to medium term, as late as 2029. Hence, Hydro One Distribution and Utilities Kingston will work together to monitor the load growth in the area, and trigger the development work, and ultimately the construction, of a new 230 kV supply station when there is sufficient certainty in the timing of new demand materializing.

Address implementation and cost allocation barriers to cost-effectively deploying non-wires alternatives to defer needs

The development of a non-wire alternative, specifically additional energy efficiency or a local storage solution, could defer the new station ultimately required to accommodate load growth in the City of Kingston. This is cost-effective, under the reference load growth scenario, if cost-allocation can reflect the system benefits the non-wires alternative would provide. Additional barriers to implementation also exist around who would implement the solution and how they would seek cost-recovery, particularly if both benefiting LDCs were to implement a part of the solution. The IESO will work with impacted LDCs between regional planning cycles to address these barriers to implementation and cost allocation for a non-wires alternative, in tandem with developing plans for a new transformer station.

Complete the ongoing Gatineau Corridor End-of-Life Study and implement recommendations

The outcomes of the Gatineau Corridor End-of-Life Study will improve the supply capability in the Peterborough to Kingston region. Namely, addressing the identified supply capacity need to Peterborough and Quinte West. By implementing the recommendations of the Gatineau Corridor End-of-Life study this need should be addressed.

Upgrade Cataraqui autotransformers' secondary conductors and reassess as part of the Lennox to St. Lawrence bulk system study

Upgrading the autotransformers' secondary conductors will increase the thermal capacity of these autotransformers from 250 MW to 285 MW and will resolve the thermal violation after losing one of the autotransformers. A future Lennox to St. Lawrence bulk system study will reassess the need with this solution in place and study if additional capacity is required.

Replace Port Hope TS T3/T4 with the closest available standard size transformers

Port Hope TS T3/T4 are reaching end-of-life and there are no opportunities for end-of-life optimization at this time. This IRRP recommends like-for-like replacements with the closest available standard size transformers of equal or greater capacity.

7.2 Options for Meeting Long-Term Needs

For needs appearing in the long term, there is an opportunity to develop and explore options, as specific projects do not need to be committed immediately. This approach is designed to: maintain flexibility; avoid committing ratepayers to investments before they are needed; provide adequate time to assess the success of current and future potential conservation measures in the study area; test emerging technologies; engage with communities and stakeholders; and lay the foundation for informed decisions in the future.

Option for Meeting Supply Capacity Needs

Options for Meeting the Peterborough to Quinte West Supply Capacity Needs

Similar to the Cataraqui autotransformers need, the Peterborough to Quinte West pocket voltage need relates to the Peterborough to Quinte West supply need where it is expected that any reinforcement made to the Peterborough to Quinte West area supply, such as those contemplated in the Gatineau Corridor End-of-Life Study, will naturally resolve the under voltage violations observed in this pocket.

Options for Meeting the Kingston Transmission Supply Capacity Needs

Since this need starts to substantiate beyond the planning horizon following the reference forecast, early development work for a transmission line upgrade is not required at this time.

There may be opportunities for the Working Group to work with communities and local utilities to manage future electricity demand through the development of community-based solutions under the IESO's new CDM Framework or other mechanisms or opportunities that may evolve between planning cycles.

7.3 Recommended Long-Term Plan

A number of alternatives are possible to meet the region's long-term needs. While specific solutions do not need to be committed to today, it is appropriate to begin work now to gather information, monitor developments, engage the community, and develop alternatives to support decision making in the next iteration of the IRRP. The long-term plan sets out the near-term actions required to ensure that options remain available to address future needs if and when they arise.

The recommended actions for the long-term plan are outlined below.

Monitor the Peterborough to Quinte West 115 kV system voltage performance following the recommendations of the Gatineau Corridor End-of-Life Study

Low voltage violations are observed in the long-term planning horizon in the Peterborough to Quinte West 115 kV pocket. These violations may naturally be resolved by the outcome of the Gatineau Corridor End-of-Life Study; therefore, this need will be monitored and re-assessed following the Gatineau Corridor End-of-Life Study plan during the next planning cycle.

Monitor Kingston Area Transmission Supply Capacity Needs

The IESO should re-evaluate the capacity need on B5QK periodically and explore non-wire solutions with the Working Group and communities as appropriate.

Monitor demand growth, conservation achievement and distributed generation uptake

On an annual basis, the IESO, with the Working Group, will review CDM achievement, the uptake of provincial distributed generation (DG) projects, and actual demand growth in the Peterborough to Kingston Region. This information will be used to determine when decisions on the long-term plan are required, and to inform the next cycle of regional planning for the area. Information on CDM and DG is also a useful input into the ongoing development of non-wires alternatives as potential long-term solutions.

Initiate the next regional planning cycle early, if needed

Along with the indices outlined above, the Working Group will monitor changes in growth targets, progress in electrification in the region, and any significant changes in forecast growth. If monitoring activities determine that the region's growth is exceeding the load forecast (the high demand forecast in Belleville and Kingston, or the reference demand forecast in the remainder of the region), it may be necessary to initiate the next iteration of the regional planning process earlier than 2024 given the lead time for the long-term supply options.

7.4 Summary of Recommended Actions and Next Steps

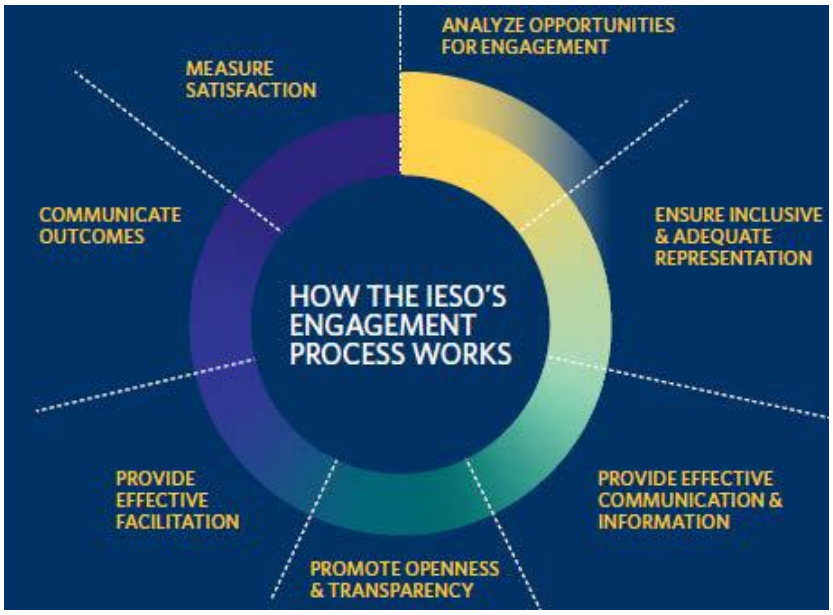
Table 7-1, below, summarizes the specific recommendations that should be implemented immediately to address the most imminent electricity supply needs in the Peterborough to Kingston region.

Table 7-1 | Summary of 2021 Peterborough to Kingston IRRP Recommendations

Need	Recommendation	Lead Responsibility	Estimated Cost	Timeline
Belleville Station Capacity	Build a new Dual Element Spot Network (DESN) transformer station at Belleville	Elexicon and Hydro One Transmission	~$30-35M	Beginning in 2021
Kingston Area Station Capacity – Frontenac TS	Monitor load and trigger development work, and ultimately construction, for a new 230 kV transformer station, when required. Continue development of energy efficiency programs for the area	Utilities Kingston, Hydro One Distribution, Hydro One Transmission IESO	~$30-35M	Station needed between 2025 and 2029 depending on forecast scenario.
Kingston Area Station Capacity – Gardiner TS DESN #1	Perform permanent 11 MW load transfer to Gardiner TS DESN #2. Hydro One transmission to perform end-of-life refurbishment of the station, therby increasing LTR. LDCs to monitor load and evaluate the second 11 MW load transfer, if required, as it has a high cost ($5.5M), which is not included in the estimate).	Hydro One Distribution, Hydro One Transmission	~$0.5M	First Load transfer: 2022 Refurbishment: as soon as possible (2024-2025) Second Load Transfer: explore it, if required
Port Hope TS	Replace Port Hope TS T3/T4 with the closest available standard size transformers	Hydro One Transmission	Cost of refurbishment incurred by Hydro One Transmission	Beginning in 2025
Cataraqui Autos Supply Capacity	Upgrade Cataraqui Autotransformers' secondary conductors	Hydro One Transmission	~$0.5M	Early 2024

The Working Group has also identified the following additional planning activities to address ongoing regional planning needs

Need	Recommendation	Lead Responsibility	Timeline
Peterborough to Quinte West Area	Complete the ongoing Gatineau Corridor End-of-Life Study and implement recommendations	IESO	Early 2022
Cataraqui Autos Supply Capacity	Following the conductor upgrade, review this need in further detail as part of Lennox to St. Lawrence bulk study.	IESO	2023



8 Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and preferences of communities to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the activities undertaken to date for the Peterborough to Kingston IRRP.

8.1 Engagement Principles

The IESO's engagement principles[16] help ensure that all interested parties are aware of and can contribute to the development of this IRRP. The IESO uses these principles to ensure inclusiveness, sincerity, respect and fairness in its engagements, striving to build trusting relationships as a result.

Figure 8-1 | The IESO's Engagement Principles

8.2 Creating an Engagement Approach for Peterborough to Kingston

The first step in ensuring that any IRRP reflects the needs of community members and interested stakeholders is to create an engagement plan to ensure that all interested parties understand the scope of the IRRP and are adequately informed about the background and issues in order to provide meaningful input on the development of the IRRP for the region. Creating the engagement plan for this IRRP involved:

- Discussions to help inform the engagement approach for the planning cycle;
- Communications and other engagement tactics to enable a broad participation, using multiple channels to reach audiences; and

[16] https://www.ieso.ca/en/sector-participants/engagement-initiatives/overview/engagement-principles

- Identifying specific stakeholders and communities who may have a direct impact on this initiative and that should be targeted for further one-on-one consultation, based on identified and specific needs in the region

As a result, the engagement plan[17] for this IRRP included:

- A dedicated webpage[18] on the IESO website to post all meeting materials, feedback received and IESO responses to the feedback throughout the engagement process;
- Regular communication with interested communities, rights-holders and stakeholders by email or through the IESO weekly Bulletin;
- Public webinars;
- Web-conferencing meetings; and
- One-on-one outreach with specific stakeholders to ensure that their identified needs are addressed (see Section 8.4 Bringing Municipalities to the Table).

8.3 Engage Early and Often

Early communication and engagement activities began with invitations to all subscribers, municipalities, Indigenous communities and rights-holders in the Peterborough to Kingston Region to learn about and provide comments on the draft Scoping Assessment Outcome Report. The IESO also held preliminary discussions to help inform the engagement approach for this first active cycle of formal regional planning. This started with an invitation to targeted municipalities, Indigenous communities, rights-holders and those with an identified interest in regional issues to help inform the engagement approach and. learn more about how to provide comments on the Peterborough to Kingston Scoping Assessment Report before it was finalized.

Feedback was received and focused on the need to consider local economic development and impacts to service when undertaking planning activities as part of implementation of recommended work. Feedback in early discussions also emphasized the importance of aligning community energy and climate action plans, electrification targets and other planning initiatives in the development of the IRRP. Along with a response to the feedback received, the final Scoping Assessment was posted in May 2020 which identified the need for a coordinated regional planning approach done through an IRRP for the Peterborough to Kingston Region. The final Scoping Assessment, identified the need for an IRRP for the Peterborough to Kingston Region. Following a written comment window, the final Scoping Assessment Outcome Report was published in May 2020.

[17] https://www.ieso.ca/-/media/Files/IESO/Document-Library/engage/KWCG-Region/KWCG-Engagement-Plan.ashx

[18] https://www.ieso.ca/en/Sector-Participants/Engagement-Initiatives/Engagements/Integrated-Regional-Resource-Plan-Kitchener-Waterloo-Cambridge-Guelph

Outreach then began with targeted communities to inform early discussions for the development of the IRRP including the IESO's approach to engagement. The launch of a broader engagement initiative followed with an invitation to subscribers of the Peterborough to Kingston region to ensure that all interested parties were made aware of this opportunity for input. Three public webinars were held at critical stages during the IRRP development to give interested parties an opportunity to hear about progress and provide comments on key components of the plan. All webinars received strong participation with cross-representation of stakeholders and community representatives attending the webinar, and submitting written feedback during a 21-day comment period.

The three stages of engagement invited input on:

1. The draft engagement plan, the electricity demand forecast and the early identified needs to set the foundation of this planning work.

2. The defined electricity needs for the region and potential options to meet the identified needs.

3. The analysis of options and draft IRRP recommendations.

Comments received during this engagement focused on the following major themes:

• Consideration should be given to local developments and growth plans

• Alignment and coordination is needed with other community planning and projects in the region. Future infrastructure and/or electricity supply should consider the priorities of energy and climate action plans and, in particular, plans for fuel switching in the municipal, commercial and residential sector, as well as vehicle electrification

• Incorporate shifting economies into planning assumptions and cost benefit analysis

• Integrated options that provide both local and broader provincial system benefit should be considered

• Recommendations for the near and mid term should be based on a high demand growth scenario, and provide flexibility for the long term should additional increased demand materialize as a result of electrification plans

Feedback received during the written comment periods for these webinars helped to guide further discussion throughout the development of this IRRP as well as add due consideration to the final recommendations. This includes using a high-demand forecast scenario to shape the development of the IRRP as a result of community feedback on local plans for electrification.

All interested parties were kept informed throughout this engagement initiative via email to Peterborough to Kingston region subscribers, municipalities and communities as well as the members of the East Regional Electricity Network.

Based on the discussions both through the Peterborough to Kingston IRRP engagement initiative and broader network dialogue, it is clear that there is broad interest in several East Ontario communities to further discuss the potential for alternative energy solutions. The near- to medium-term nature of the Peterborough to Kingston region's future electricity needs presents a valuable opportunity for communities to mobilize projects and initiatives to meet local growth targets and energy priorities. To that end, ongoing discussions will continue through the IESO's East Regional Electricity Network to keep interested parties engaged on local developments, priorities and planning initiatives.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's Peterborough to Kingston IRRP engagement web page.

8.4 Bringing Municipalities to the Table

The IESO held meetings with municipalities to seek input on their planning priorities and to ensure that these plans were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings were held with municipalities in the region to discuss: key issues of concern, including forecast regional electricity needs; community energy and climate action plans, options for meeting the region's future needs; and, broader community engagement. These meetings helped to inform the municipal/community electricity needs and priorities and provided opportunities to strengthen this relationship for ongoing dialogue beyond this IRRP process.

8.5 Engaging with Indigenous Communities

To raise awareness about the regional planning activities underway and invite participation in the engagement process, regular outreach was made to Indigenous communities and rights-holders within the Peterborough to Kingston electricity planning region throughout the development of the plan. This includes the communities of Alderville First Nation, Hiawatha First Nation, Curve Lake First Nation, Mohawks of the Bay of Quinte, Tyendinaga Mohawk, Kawartha Nishnawbe and the traditional territory of the Huron Wendat.

The IESO remains committed to an ongoing, effective dialogue with communities and First Nation rights-holders to help shape long-term planning in regions all across Ontario.

9 Conclusion

This report documents an IRRP that has been developed for the Peterborough to Kingston region, and identifies regional electricity needs and opportunities to preserve or enhance electricity system reliability for the next 20 years. The IRRP makes recommendations to address near- to medium-term issues, and lays out actions to monitor, defer, and address long-term needs.

To support the development of the plan, this IRRP includes recommendations with respect to developing alternatives, and monitoring load growth and efficiency achievements. Responsibility for these actions will be undertaken by the appropriate members of the Working Group.

The Working Group will continue to meet at regular intervals to monitor developments and track progress toward plan deliverables. In the event that underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the OEB.

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all needs identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group ("TWG").

The preferred solution(s) that have been identified in this report may be re-evaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP TWG.

TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE RIP TECHNICAL WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE PETERBOROUGH TO KINGSTON REGION.

The participants of the RIP Technical Working Group (TWG) included members from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Eastern Ontario Power Inc.
- Elexicon Energy Inc.
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator
- Kingston Hydro
- Lakefront Utilities Inc.

This RIP is the final phase of the second cycle of the Peterborough to Kingston regional planning process. It follows the completion of the Peterborough to Kingston Integrated Regional Resource Plan ("IRRP") in November 2021 and the Peterborough to Kingston Needs Assessment ("NA") in February 2020.

The Peterborough to Kingston RIP provides a consolidated summary of the needs and recommended plans for the region based on available information. It discusses the needs identified in the previous and current regional planning cycle, , any new needs identified as part of this RIP phase, and wires solutions recommended to address these needs. Implementation plans to address some of these needs are already completed or are underway from the previous planning cycle, including:

- Load transfer from Gardiner TS DESN 1 to Gardiner TS DESN 2 to provide transformation capacity relief at Gardiner TS DESN 1 (completed in 2019)

The major infrastructure investments recommended by the TWG in the near and mid-term planning horizon are provided in Table 1-1 below, along with their planned in-service date and budgetary cost estimate for planning purposes.

Table 1-1: Recommended Plans in Peterborough to Kingston over the Next 10 Years.

Stations/Lines Project	Details	In-Service Timeframe	Budgetary Cost Estimate[1] ($Million)
Cataraqui TS: Upgrade secondary conductor	Upgrade existing copper conductor on secondary side of auto transformers	2023	$0.5
Gardiner TS DESN1: Station Capacity and Transformers T1/T2 Asset Renewal	Replace the end-of-life transformers with similar type and size equipment as per current standard[2]	2028*	$30
	Load transfer from DESN1 to DESN2	2022	$0.5
Frontenac TS: Station Capacity	Develop plan to build new 230kV 75/125 MVA DESN station in the area, as needed	2025-2029	$30-$35
Otonabee TS 44kV: Station Capacity	Transfer 8MW of load from Otonabee 44kV bus to Dobbin TS	2022	$0.1
Port Hope TS: Transformers T3/T4 Asset Renewal	Replace the end-of-life transformers with similar type and size equipment as per current standard	2026	$25
Belleville TS: Build new DESN	Build a new 230 kV 75/125 MVA DESN with associated capacitor banks at the existing Belleville TS site	2026	$35-$40
Picton TS: Transformers T1/T2 Asset Renewal	Replace the end-of-life transformers with similar type and size equipment as per current standard	2025	$14.5
Dobbin TS: T1/T2/T5 Auto Transformer Asset Renewal	Replace the end-of-life auto transformers with two new 150/250 MVA unit and switchyard refurbishment	2029	$100

*Hydro One is exploring whether Gardiner TS T1/T2 transformers replacement date can be advanced to help address the station capacity need at Gardiner TS DESN 1 described in section 6.4

The Study Team recommends that:

- Hydro One and LDCs to continue with the implementation of infrastructure investments listed in Table 1-1 above while keeping the Technical Working Group apprised of project status;
- All the other identified needs/options in the long-term will be further reviewed by the Study Team in the next regional planning cycle.

[1] Planning estimates are provided for Hydro One's portion of the work based on 2020 costs and are subject to change in the future

[2] The new standard units are expected to have a higher LTR of about 160 MW

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE PETERBOROUGH TO KINGSTON REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") on behalf of the Technical Working Group (TWG) that consists of Hydro One Inc. (Transmission), Eastern Ontario Power Inc., Elexicon Energy Inc. ("Elexicon"), Hydro One Inc. (Distribution), Independent Electricity System Operator ("IESO"), Kingston Hydro, and Lakefront Utilities Inc., in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The Peterborough to Kingston region is comprised of the area bordered approximately by Clarington on the West, North Frontenac county on the North, Frontenac County on the East and Lake Ontario on the South. The boundaries of the Region are shown in Figure 1-1 below.

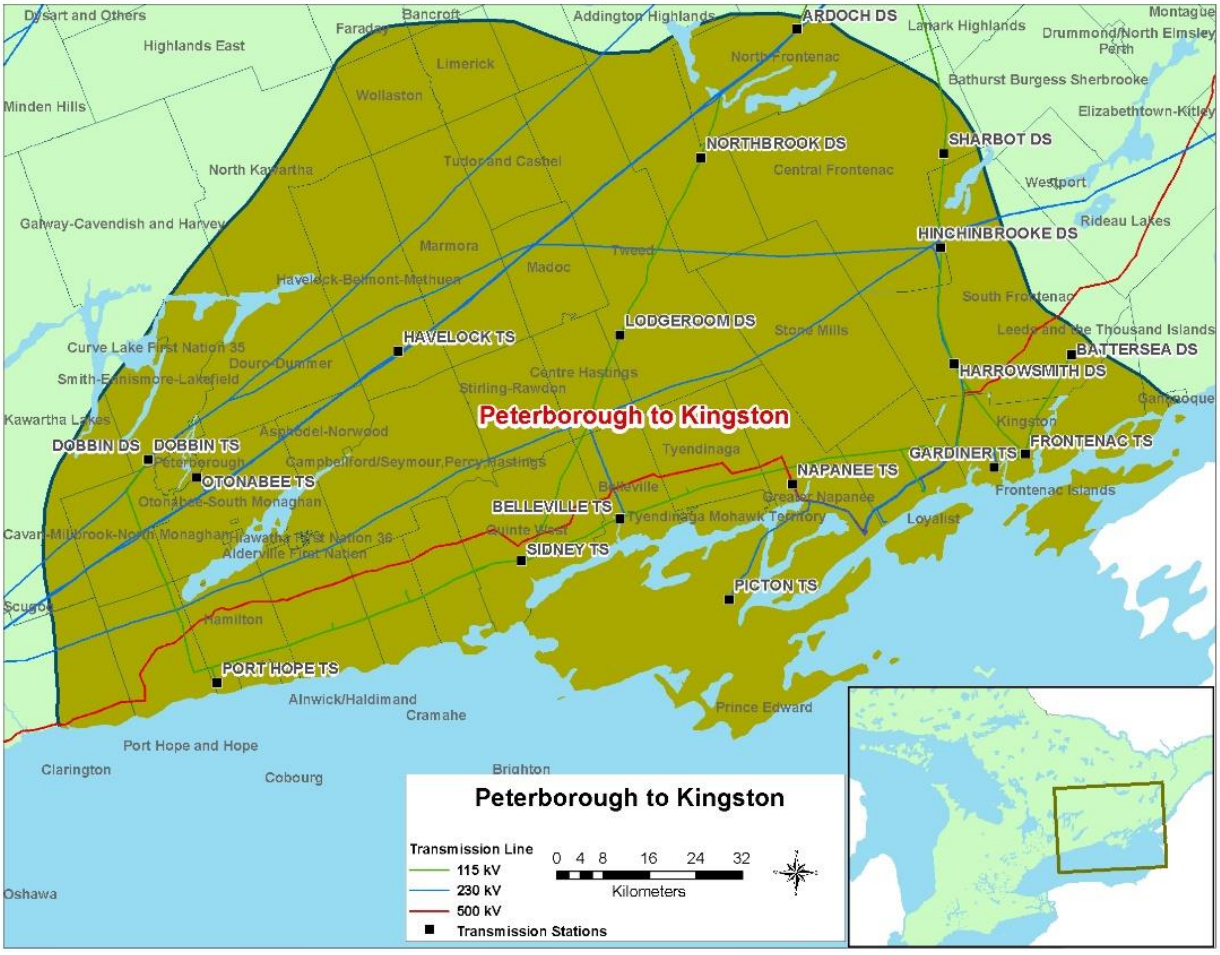

Figure 1-1: Peterborough to Kingston Region

1.1. Objectives and Scope

This RIP report examines the needs in the Peterborough to Kingston Region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs;
- Identify any new needs that may have emerged since previous planning phases e.g., Needs Assessment ("NA"), Scoping Assessment ("SA"), and/or Integrated Regional Resource Plan ("IRRP");
- Assess and develop a wires plan to address these needs; and,
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major high voltage transmission equipment , transmission and distribution system capability along with any updates to local plans, conservation and demand management ("CDM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant plans to address near and medium-term needs identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan, and Integrated Regional Resource Plan).
- Identification of any new needs over the planning horizon and wires plans to address them
- Consideration of long-term needs identified in the Peterborough to Kingston IRRP or identified by the TWG.

1.1. Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the regional characteristics.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the adequacy of the transmission facilities in the region over the study period.
- Section 7 discusses the needs and provides the alternatives and preferred solutions.
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [3] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the TWG determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO and where further regional coordination is required. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess

[3] Also referred to as Needs Screening

the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities, Indigenous communities, business sectors and other interested stakeholders in the region.

The RIP phase is the fourth and final phase of the regional planning process and involves: discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and/or LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, LP, and IRRP phases of regional planning;
- Planning for connection capacity requirements with the LDCs and transmission connected customers.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

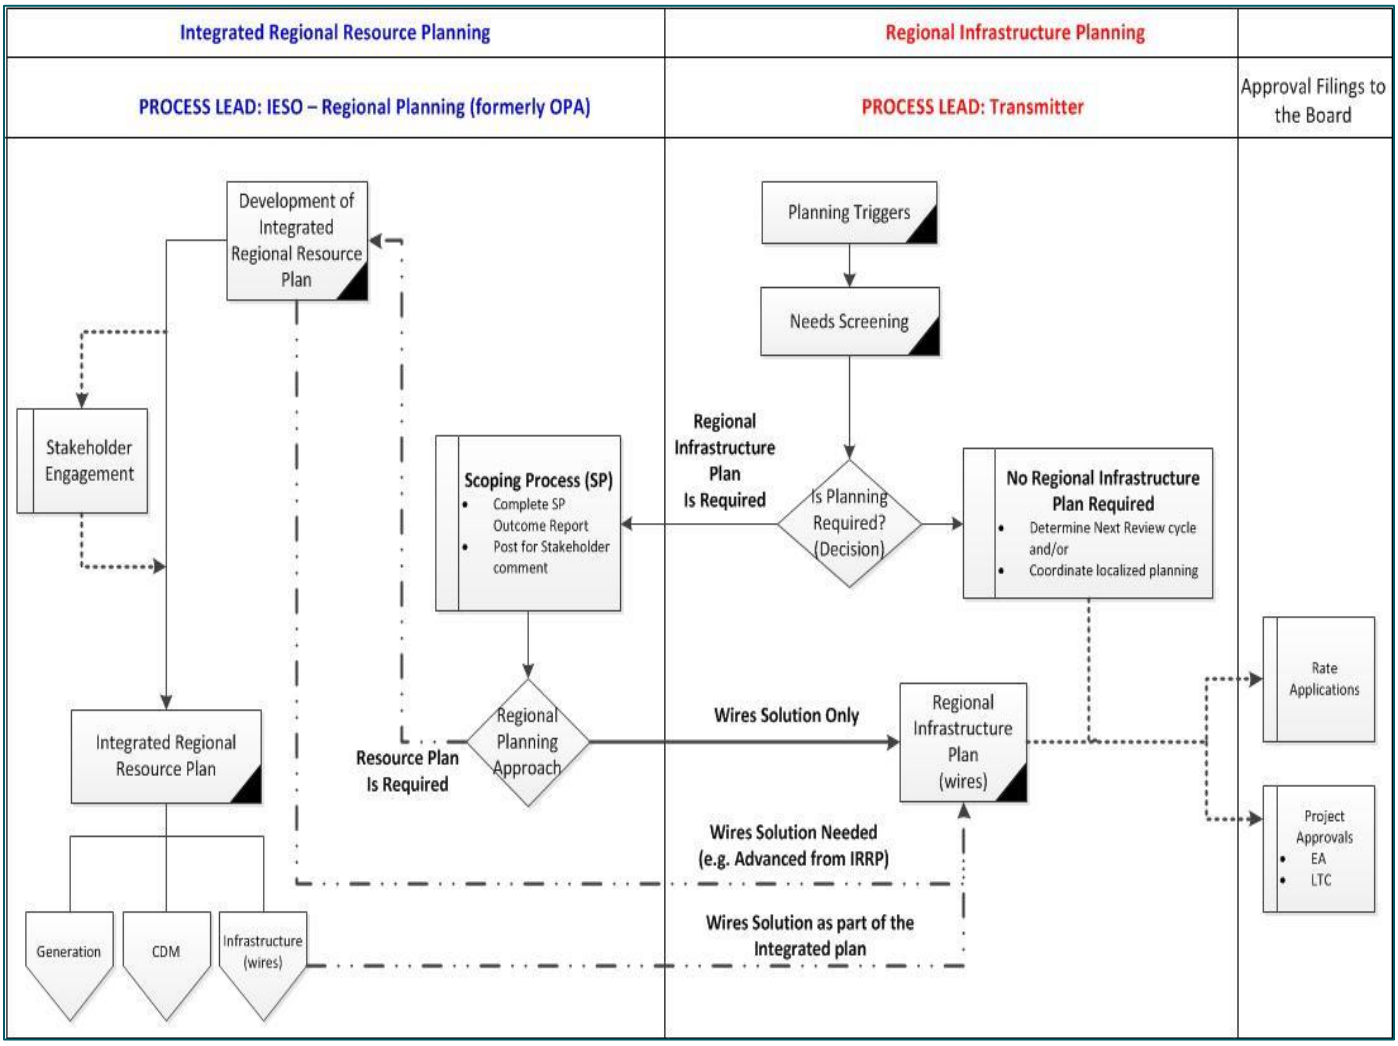

Figure 1: Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous phases of the regional planning process. Hydro One collects this information and reviews it with the TWG to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs. As agreed by TWG members, the load forecast from the IRRP was used for this RIP.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Depending upon any changes to load forecast or other relevant information, regional technical assessment may or may not be required or be limited to a specific issue(s) only. Additional needs may be identified in this phase.

3. Alternative Development: The third step is the development of wires options to address the needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.

4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

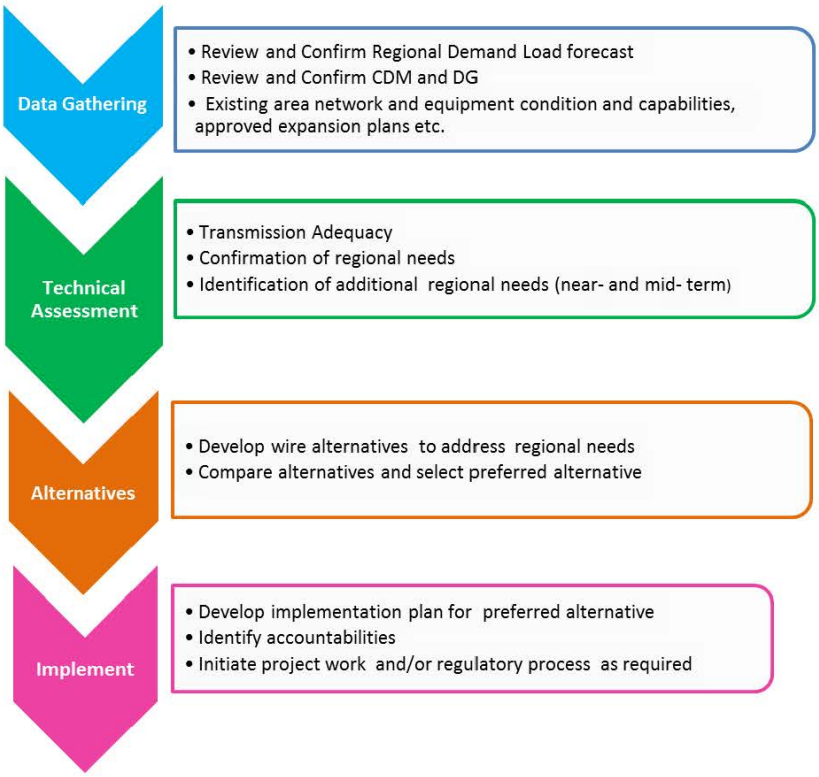

Figure 2-2: RIP Methodology

3. REGIONAL CHARACTERISTICS

THE PETERBOROUGH TO KINGSTON REGION IS COMPRISED OF THE AREA ROUGHLY BORDERED GEOGRAPHICALLY BY THE MUNICIPALITY OF CLARINGTON ON THE WEST, NORTH FRONTENAC COUNTY ON THE NORTH, FRONTENAC COUNTY ON THE EAST, AND LAKE ONTARIO ON THE SOUTH. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM TEN STEP-DOWN TRANSFORMER STATIONS AND EIGHT HIGH VOLTAGE DISTRIBUTION STATIONS.

Electrical supply to the region is provided through 500/230kV autotransformers at Lennox TS and 230/115kV autotransformers at Cataraqui TS and Dobbin TS, and a 230kV and 115kV transmission network supplying the various step-down TS's and HVDS's in the region. The main generation facility in the region is the 2000 MW Lennox Generation Station connected to Lennox TS.

The Local Distribution Customers (LDC) in the Peterborough to Kingston Region are Hydro One Distribution, Eastern Ontario Power, Elexicon, Kingston Hydro, and Lakefront Utilities. The high-voltage system in this Region also provides supply to five other direct transmission connected load customers.

The existing facilities in the Region are summarized below and depicted in the single line diagram shown in Figure 3-1. The 500kV system is part of the bulk power system and is not studied as part of this Needs Assessment:

- Lennox TS is the major transmission station that connects the 500kV network to the 230kV system via two 500/230 kV autotransformers.

- Cataraqui TS and Dobbin TS are the transmission stations that connect the 230kV network to the 115kV system via 230/115 kV autotransformers.

- Ten step-down transformer stations supply the Peterborough to Kingston load: Dobbin TS, Port Hope TS, Sidney TS, Picton TS, Otonabee TS, Havelock TS, Belleville TS, Napanee TS, Gardiner TS, and Frontenac TS. There are also eight HVDS that supply load in the Region: Dobbin DS, Ardoch DS, Northbrook DS, Lodgeroom DS, Hinchinbrooke DS, Harrowsmith DS, Sharbot DS, and Battersea DS

- Five Customer Transformer Stations (CTS) are supplied in the Region
- There are 7 existing Transmission connected generating stations in the Region as follows:
    - NPIF Kingston GS is a 130 MW gas-fired cogeneration facility that connects to 230 kV circuits X1H and X2H near Lennox TS
    - Lennox GS is a 2000 MW natural gas-fired station connected to Lennox TS
    - Wolfe Island GS is a 198 MW wind farm connected to circuit X4H near Gardiner TS
    - Napanee GS is a 910 MW gas-fired plant connected to Lennox TS at the 500 kV system

- Kingston Solar CGS is a 100 MW solar generation facility connected to 230 kV circuit X2H
- Stone Mills CGS is a 60 MW solar generation facility connected to 230 kV circuit H23B
- Amherst Island CGS is a 76 MW wind farm connected to 115kV circuit Q6S

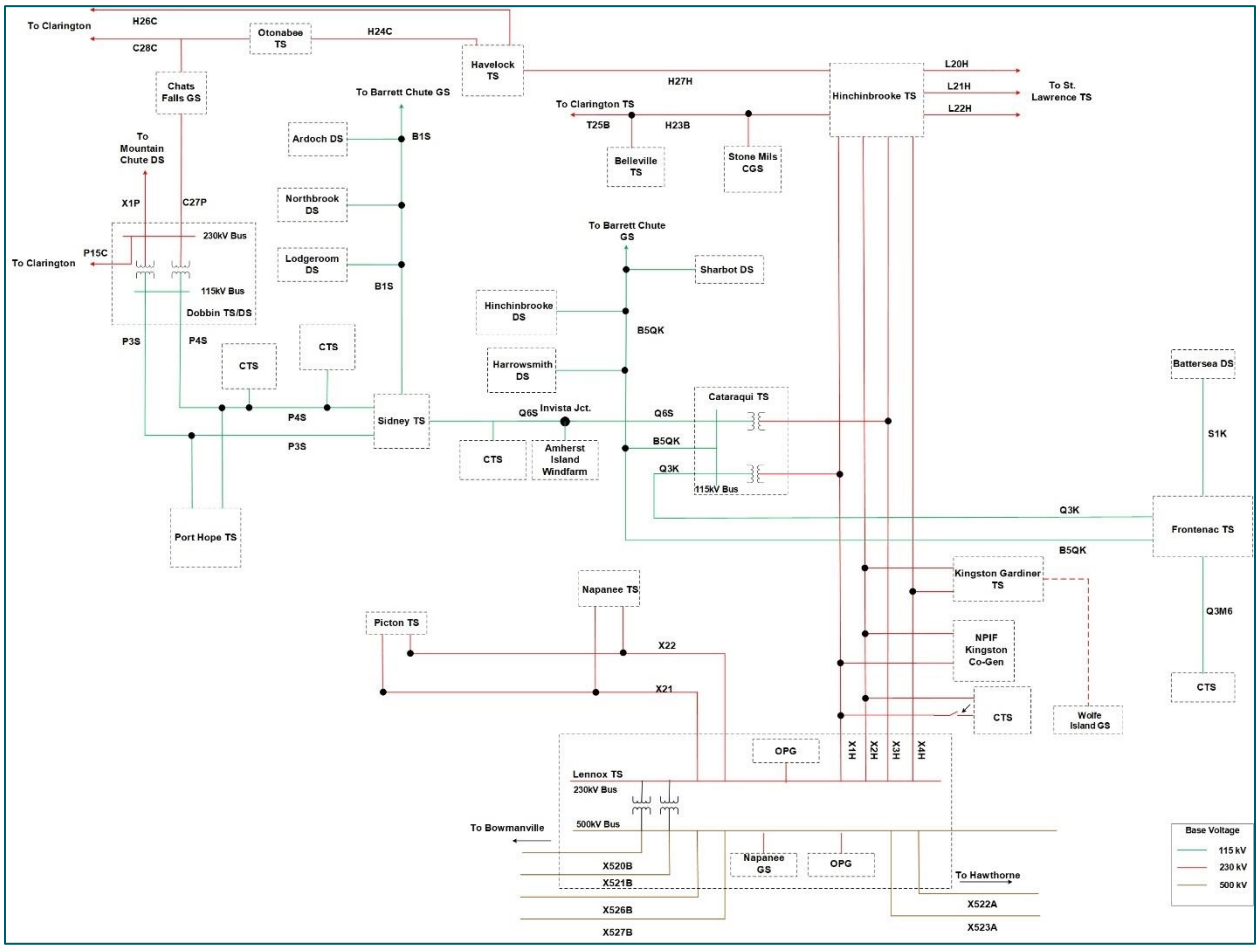

Figure 3-1: Single Line Diagram of Peterborough to Kingston's Transmission Network

4. TRANSMISSION FACILITIES/PROJECTS COMPLETED AND/OR UNDERWAY OVER THE LAST TEN YEARS

OVER THE LAST TEN YEARS, A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND UNDERTAKEN BY HYDRO ONE AIMED TO MAINTAIN THE RELIABILITY AND ADEQUACY OF ELECTRICITY SUPPLY TO THE PETERBOROUGH TO KINGSTON REGION.

A summary and description of the major projects completed over the last 10 years is provided below:

- Connect Napanee GS (2017) – A 910 MW gas turbine (Napanee GS) was connected to the 500 kV bus in the Lennox TS switchyard

- Transformation capacity relief at Gardiner TS DESN 1 (2019) – Gardiner TS DESN 1 load exceeded its normal supply capacity. Hydro One Distribution transferred load from Gardiner TS DESN 1 to Gardiner TS DESN 2.

The following projects are currently underway:

- Lennox TS 230kV & 500kV Breaker Replacement (2026/27)
- Belleville TS T1/T2 Transformer Replacement (2022)

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The electricity demand in the Peterborough to Kingston Region is anticipated to grow about .8% annually from 2021 to 2031.

Figure 5-1 shows the Peterborough to Kingston Region's extreme weather coincident peak net load forecast ("load forecast") for summer and winter. The load forecast for the individual stations in the Peterborough to Kingston Region is given in Appendix D.

As per the new regional planning process requirement, the load forecast used in the RIP is same as the IRRP phase unless there is a material change or if a LDC(s) member of the TWG requests to update their load forecast.

In the case of the Peterborough to Kingston Region, the TWG decided to use the load forecast in the recently completed Peterborough to Kingston Region IRRP (Nov. 2021) for the purposes of the RIP load forecast. Note that the TWG reviewed the extreme summer non-coincident peak net load forecast from the IRRP against the actual historical peak load observed in 2020 for the stations that have been identified to have a capacity need, namely Belleville TS, Frontenac TS, Gardiner TS DESN 1, and Otonabee TS (discussed in Section 6.4). Although, the actual 2020 peak load for these stations is slightly lower than what was forecasted in the IRRP, the TWG decided to proceed with the IRRP 2020 forecasted load since it does not materially change the planning outcome. The need dates will continue to be monitored throughout the regional planning process.

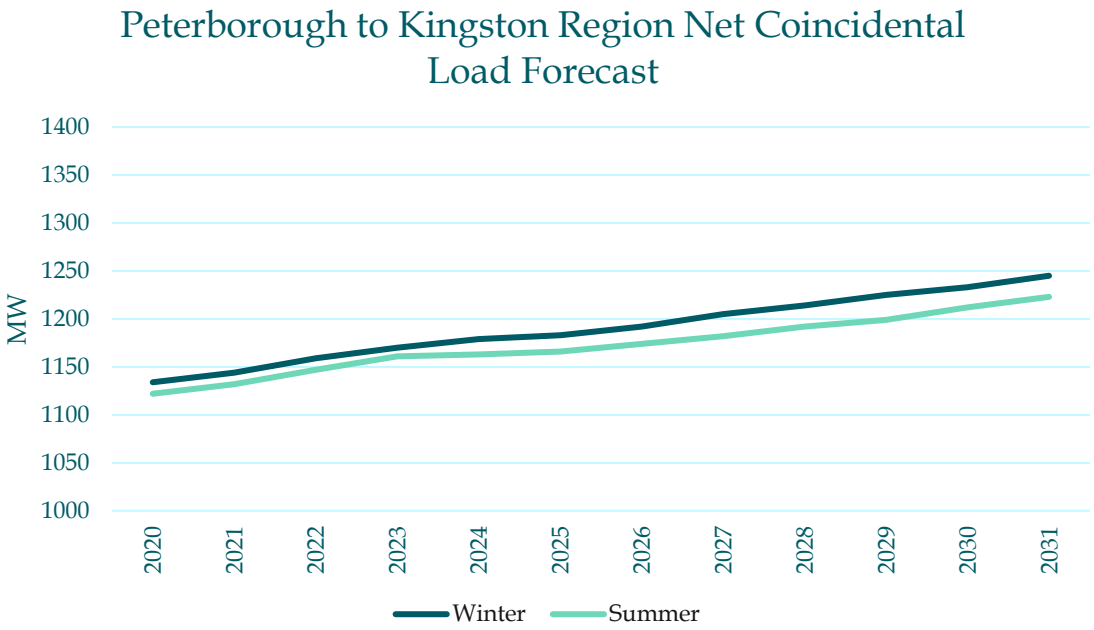

Figure 5-1: Peterborough to Kingston Region Load Forecast

5.2 Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP adequacy assessment is 2020-2031.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for all stations for stations having no low voltage capacitor banks and .95% lagging power factor for stations having low voltage capacitor banks
- Normal planning supply capacity for transformer stations is determined by the summer 10-Day Limited Time Rating (LTR).
- Line capacity adequacy is assessed using peak loads in the area.
- Output of generating stations in the area is based on 98% dependable generation availability for transmission connected run of river hydro-electric stations as per Ontario Resource Transmission Assessment Criteria (ORTAC) criteria.
- Adequacy assessment is conducted as per ORTAC and using the load forecast described in section 5.1.

6. ADEQUACY OF EXISTING FACILITIES

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND TRANSFORMER STATION FACILITIES SUPPLYING THE PETERBOROUGH TO KINGSTON REGION OVER THE PLANNING PERIOD (2021-2031).

Within the current regional planning cycle, three regional planning reports have been completed for the Peterborough to Kingston Region. The findings of these reports are inputs to this Regional Infrastructure Plan. These reports are:

- 2020 Peterborough to Kingston Region Needs Assessment ("NA") Report;
- 2020 Peterborough to Kingston Region Scoping Assessment ("SA") Report; and,
- 2021 Peterborough to Kingston Region Integrated Regional Resource Plan ("IRRP")

This section provides a review of the adequacy of the transmission lines and stations in the Peterborough to Kingston Region. The adequacy is assessed using the latest regional load forecast provided in Appendix D and assumes all projects currently underway (described in section 4) are in-service. Sections 6.1 to 6.5 present the results of this review. Asset renewal needs for major HV transmission equipment were identified in previous phases of this regional planning cycle and are also addressed in Section 7 of this RIP report.

6.1 230/115 kV Autotransformers

Bulk power supply to the Peterborough to Kingston Region is provided by Hydro One's 500kV/230kV and 230 kV/115kV autotransformers. The number and location of these autotransformers are as follows:

a) Two 500/230 kV autotransformers at Lennox TS
b) Two 230/115 kV autotransformers at Cataraqui TS
c) Three 230/115 kV autotransformers at Dobbin TS

The 500/230 kV autotransformers at Lennox TS are part of the bulk system and outside the scope of this RIP.

Based on the RIP load forecast, the load growth at Frontenac TS and other 115kV supply stations is expected to result in a supply capacity need at Cataraqui TS in 2023. The load is expected to increase over the long-term.

The 230/115 kV autotransformers at Dobbin TS are expected to be adequate over the study period.

6.2 230 kV Transmission Lines

All 230 kV transmission circuits, with the exception of circuits X21 and X22 in the Peterborough to Kingston Region are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the rest of the Ontario's transmission system and to the load centers in the Greater Ottawa regions. These circuits are as follows:

- 230kV circuits: C27P, H23B, H27H, P15C, T22C, T25B, T31H, T32H, X1H, X1P, X2H, X3H and X4H.

These 230kV transmission lines can be divided into the main corridors as summarized below:

a) Clarington TS to Otonabee TS, Havelock TS, Chats Falls SS 230kV circuits T22C, T31H, T32H
   - Supplies Otonabee TS, Havelock TS
b) Clarington TS to Hinchinbrooke SS 230kV circuits T25B and H23B
   - Supplies Belleville TS
c) Lennox TS to Hinchinbrooke SS 230 kV circuits, X1H, X2H, X3H, X4H
   - Supplies Gardiner TS and a Customer CTS
d) Cherrywood TS to Dobbin TS, Chat Falls SS 230kV circuits P15C and C27P

From the circuits listed above, P15C is the limiting circuit for supply capacity needs in the region during low water conditions with a contingency on circuits X1P or C27P. This supply capacity need is being assessed as part of the bulk system planning.

6.3 115 kV Transmission Lines

The Peterborough to Kingston Region consists of several 115 kV lines. This 115 kV network serves local area load. The 115 kV transmission facilities can be divided into the main corridors as summarized below:

a) Dobbin TS to Sidney TS 115kV transmission circuits P3S/P4S
   - Supplies Port Hope TS, Sidney TS, and two Customer CTS

b) Sidney TS to Cataraqui TS 115kV transmission circuit Q6S
   - Supplies Sidney TS and a Customer CTS

c) Cataraqui TS to Frontenac TS 115kV transmission circuits Q3K/B5QK
   - Supplies Sharbot DS, Hinchinbrooke DS, Harrowsmith DS, and Frontenac TS

d) Barrett Chute GS to Sidney TS 115kV transmission circuit B1S
   - Supplies Ardoch DS, Northbrook DS, Lodgeroom DS

From the circuits listed above, Q6S is the limiting circuit for supply capacity needs in the region during low water conditions with a contingency on circuits 230kV circuits X1P, C27P, or P15C.

This supply capacity need is being assessed as part of the bulk system. The remaining 115 kV circuits are within their thermal limits and within the voltage range as per ORTAC for the loss of a single 115 kV circuit in the Region.

6.4 230 kV and 115 kV Connection Facilities

There is a total of ten step-down transformer stations and eight high voltage distribution stations that supply the Peterborough to Kingston load as shown in Table 6-1 below:

Table 6-1: Step-Down Transformer Stations and High Voltage Distribution Stations

Dobbin TS	Port Hope TS	Sidney TS	Picton TS
Otonabee TS	Havelock TS	Belleville TS	Napanee TS
Gardiner TS	Frontenac TS	Dobbin DS	Ardoch DS
Northbrook DS	Lodgeroom DS	Hinchinbrooke DS	Harrowsmith DS
Sharbot DS	Battersea DS		

A station capacity assessment was performed over the study period for the above stations in the Region using either the summer or winter station peak load forecasts as appropriate. The results are as follows:

6.4.1 Belleville TS T1/T2 Station Capacity Need

The 2020 extreme summer weather non-coincident peak net load at Belleville TS was forecasted to be 170 MW[4]. The Summer 10-Day LTR of Belleville TS is about 161 MW.

Based on the RIP load forecast, Belleville TS is exceeding its Summer 10-Day LTR today and the magnitude of the need increases in the near and mid-term. In addition to normal load growth in the area, Elexicon has recently received approximately 30 MW of new load connection inquiries to be connected at Belleville TS.

6.4.2 Frontenac TS T3/T4 Station Capacity Need

The 2020 extreme summer weather non-coincident peak net load at Frontenac TS is 101 MW[5]. The Summer 10-Day LTR of Frontenac TS is about 111 MW.

Based on the RIP load forecast, Frontenac TS is expected to reach its Summer 10-Day LTR by 2029.

[4] The 2020 extreme summer weather non-coincident peak net load at Belleville TS is based on the 2021 Peterborough to Kingston Region IRRP load forecast, which has been adopted by the TWG for use in this RIP. The actual, weather corrected 2020 summer peak load at Belleville TS was 157 MW, but still forecasted to exceed the 161MW LTR in 2022.

[5] The 2020 extreme summer weather non-coincident peak net load at Frontenac TS is based on the 2021 Peterborough to Kingston Region IRRP load forecast, which has been adopted by the TWG for use in this RIP. The actual 2020 summer peak load at Frontenac TS was 104 MW.

6.4.2 Gardiner TS DESN 1 (T1/T2) Station Capacity Need

The 2020 extreme summer weather non-coincident peak net load at Gardiner TS DESN 1 was forecasted to be 146 MW[6]. The Summer 10-Day LTR of Gardiner TS DESN 1 and DESN 2 is about 125 MW and 85 MW, respectively.

Based on the RIP load forecast, the loading on Gardiner TS DESN 1 is exceeding its Summer 10-Day LTR today and the magnitude of the need increases in the near and mid-term.

6.4.3 Otonabee TS (T1/T2) 44kV Capacity Need

The 2020 extreme summer weather non-coincident peak net load at Otonabee TS 44 kV bus was 103 MW . The Summer 10-Day LTR of Otonabee TS 44kV is 97 MW.

Based on the 2020 net loading and load forecast, the loading on Otonabee TS 44kV is exceeding its Summer 10-Day LTR today and the magnitude of the need increases in the near and mid-term.

6.4.4 Other TSs and HVDSs in the Region

Based on the RIP load forecast, all the other TSs and HVDSs in the Region are expected to be within their normal supply capacity during the study period. Therefore, any capacity needs for these TSs and HVDSs will be reviewed in the next regional planning cycle.

Table 6-2: Adequacy of the Step-Down Transformation Facilities

Station	Summer 10-Day LTR Capacity (MW)	2020 Summer Peak Net Forecast (MW)	Need Date
Belleville TS T1/T2	161	170	Today
Frontenac TS T3/T4	111	101	2029
Gardiner TS DESN 1 (T1/T2)	125	146	Today
Otonabee TS 44kV Bus	97	103	Today

[6] The 2020 extreme summer weather non-coincident peak net load at Gardiner TS DESN 1 is based on the 2021 Peterborough to Kingston Region IRRP load forecast, which has been adopted by the TWG for use in this RIP. The actual 2020 summer peak load at Gardner TS DESN 1 was 130 MW.

6.5 System Reliability and Load Restoration

In case of contingencies on the transmission system, ORTAC provides the load restoration requirements relative to the amount of load affected. Planned system configuration must not exceed 600 MW of load curtailment/rejection. In all other cases, the following restoration times are provided for load to be restored for the outages caused by design contingencies.

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

No new significant system reliability and operating issues identified for this Region. Based on the net coincident load forecast, the loss of one element will not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period.

6.6 Other Needs

6.6.1 Asset Renewal Needs for Major HV Transmission Equipment

Hydro One has identified asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the Peterborough to Kingston Region. Hydro One is the only Transmission Asset Owner (TAO) in the Region.

These needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as equipment deterioration due to aging infrastructure or other factors; technical obsolescence due to outdated design; lack of spare parts availability or manufacturer support; and/or potential health and safety hazards, etc. Asset replacement work planned over the study period in the region is summarized in Table 6-3.

Table 6-3: Peterborough to Kingston Region – Planned Asset Replacement Work

No.	Station	Description	in-service Timing
1	Picton TS	T1/T2 Replacement	2025
2	Port Hope TS	T3/T4 Replacement	2026
3	Lennox TS	230kV & 500kV Breaker Replacement. Part of Bulk system	2026/27
4	Dobbin TS	Auto Transformers T1/T2/T5 Replacement	2029
5	Gardiner TS DESN 1	T1/T2 Replacement	2028*

*Hydro One is exploring whether Gardiner TS T1/T2 transformers replacement date can be advanced to help address the station capacity need at Gardiner TS DESN 1 described in section 6.4

7. REGIONAL PLANS

THIS SECTION DISCUSSES ELECTRICAL INFRASTRUCTURE NEEDS IN THE PETERBOROUGH TO KINGSTON REGION AND PRESENTS WIRES ALTERNATIVES AND PREFERRED WIRES SOLUTIONS FOR ADDRESSING THESE NEEDS. TABLE 7-1 LISTS NEEDS PREVIOUSLY IDENTIFIED IN THE NA AND IRRP FOR THE PETERBOROUGH TO KINGSTON REGION AS WELL AS THE ADEQUACY ASSESSMENT CARRIED OUT AS PART OF THIS RIP REPORT.

The electrical infrastructure near and mid-term needs in the Peterborough to Kingston Region are summarized below in Table 7-1 and Table 7-2.

Table 7-4: Identified Near and Mid-Term Needs in Peterborough to Kingston Region

Need Type	Section	Station/Circuit/Area	In-service Timing
Supply Capacity	7.1	Peterborough to Quinte West	Today
	7.2	Cataraqui TS Autotransformers	2023
Station Capacity	7.3	Belleville TS	Today
	7.4	Frontenac TS	2029
Station Capacity	7.5	Gardiner TS DESN 1 (T1/T2)	Today
Station Capacity	7.6	Otonabee TS 44kV Bus	Today

Table 7-5: Major Asset Renewal Needs in Peterborough to Kingston Region

Need Type	Section	Station/Circuit/Area	In-Service Timing
Asset Renewal for Major HV Transmission Equipment	7.7	Picton TS T1/T2 transformers	2025
	7.8	Port Hope TS T3/T4 transformers	2025
	7.9	Gardiner TS T1/T2 (DESN 1) transformers	2028*
	7.10	Dobbin Auto Transformers T1/T2/T5	2029

*Hydro One is exploring if and how Gardiner TS T1/T2 transformers replacement date can be advanced to help address the station capacity need at Gardiner TS DESN 1 described in section 6.4

Maintaining status quo is not an option for any of the end of life autotransformers or station transformers due to risk of equipment failure and would result in increased maintenance cost and prolonged customer outages and interruptions. These transformers will be replaced with standard units.

No other lines or HV station equipment in the Peterborough to Kingston region than listed above, have been identified for major replacement/refurbishment at this time.

7.1 Supply Capacity – Peterborough to Quinte West

7.1.1 Description

The Peterborough to Quinte West sub region mainly consists of Port Hope TS and Sidney TS. The area is supplied from Dobbin TS to the North West, Cataraqui TS from the East, and Barrett Chute SS to the North East. During low water conditions and contingency situations, the thermal capacity on circuits P15C and Q6S can be exceeded.

7.1.2 Alternatives and Recommendation

IESO is currently undertaking a bulk study of the area and the recommendations from the study is expected to resolve the thermal loading limits of P15C and Q6S.

7.2 Supply Capacity – Cataraqui TS Autotransformers

7.2.1 Description

Cataraqui TS supplies the 115kV stations in the Eastern sub region of the region through two 230/115kV auto transformers. It is forecasted that in 2023 the coincidental loading of the stations in the sub region will reach the supply capacity of the Cataraqui TS auto transformers.

7.2.2 Alternatives and Recommendation

The current limitation of the Cataraqui TS auto transformers are due to a short span of copper conductors connected the secondary side of the auto transformers within the station. Upgrading the conductors will allow the long term emergency to increase by 35 MW and resolve this need in the near term.

7.3 Station Capacity – Belleville TS

7.3.1 Description

Belleville TS consists of one DESN supplied by 230kV circuits, H23B and T25B. The station has a summer 10-Day LTR of 161 MW. The station is also limited by voltage drop limitations when transmission circuit H23B is lost along with the companion transformer by configuration and the maximum loading can be as low as 130 MW, depending on the load composition at the station.

Based on the 2020 net load forecast, the station will exceed its capacity in 2022. In addition, Elexicon has also recently received approximately 30 MW of load connection inquiries to be connected at Belleville TS, but not including in the current load forecast. Hence, there is an immediate need for additional transformation capacity at Belleville TS today.

While the Belleville TS T1/T2 transformer replacement is currently underway, with an expected in-service date of 2022, this refurbishment is not expected to result in any significant improvement to the station's capacity and does not solve the voltage limitation issue.

7.3.2 Alternatives and Recommendation

The following alternatives were considered to address the Belleville TS station capacity need:

1. **Alternative 1 – Install a new DESN with two 75/125 MVA transformers with two 32 MVAR Capacitor banks and assess transmission line capacity**: Installing a second DESN at Belleville TS with two 32 MVAR capacitor banks will help mitigate the voltage drop at the Belleville TS LV bus and will resolve the station capacity need over the long-term (20 years) based on the current load forecast. Belleville TS switchyard also has space for a second DESN. The estimated cost for this option is approximately $35-40 M. However, it should be noted that preliminary studies indicate that there will be voltage constraints on the transmission lines supplying Belleville TS for a H23B contingency, which will restrict the full utilization of the additional station capacity in the long term as the total load at Belleville TS DESN1 and the new Belleville TS DESN2 is expected to be limited to 210 MW total, but should be sufficient capacity to meet the forecasted demand in the next 20 years. To fully utilize the capacity of the second DESN and increase the capacity beyond 210 MW, new supply lines into Belleville will be required to alleviate the voltage drop limits at Belleville TS. A possible reinforcement option is to extend X21/X22 from Napanee TS to Belleville TS along an existing Q6S Right of Way. There may also be upstream bulk system impacts with this option, therefore a full bulk planning study is needed to identify any impacts when looking beyond 20 years.

2. **Alternative 2 – Install an additional third 75/125 MVA transformer at Belleville TS and assess transmission line capacity**: Installing a third transformer at Belleville TS would resolve the need over the study period, however it is not a long term solution as compared to alternative 1 as it does not provide reliability of a full DESN, will significantly increase short circuit level at the 44kV bus, and does not alleviate the current voltage limitation. The estimated cost for this option is also similar to alternative 1 at approximately $30-35 M.

3. **Alternative 3 – Load transfers:** Since Belleville TS does not currently have any distribution load transfer capability, due to a lack of adjacent stations, distribution load transfers was not recommended by the TWG.

Considering the above alternatives, the TWG recommends Alternative 1. To address today's station capacity need at Belleville TS, as well as the growing electricity demand in the region,

Hydro One (Transmission and Distribution) and Elexicon have started development of a new DESN transformer station at Belleville, with an expected in-service date of 2026. This will increase the supply capacity to the region and will resolve the capacity need at Belleville TS in the near and mid term.

The TWG will continue to monitor the load growth at Belleville TS and revisit the capacity need in the next regional planning cycle in order to re-assess whether/when a transmission line reinforcement to Belleville is required in the long term. In case of a H25B contingency where voltage violations are exceeded, operational measures will be taken to resolve the issue. Furthermore, IESO will undertake any necessary bulk system studies regarding the transmission reinforcement to Belleville TS.

7.4 Station Capacity – Frontenac TS

7.4.1 Description

Frontenac TS consists of one DESN supplied by 115kV circuits, Q3K and B5QK. The Summer 10-Day LTR of Frontenac TS is about 111 MW.

Based on the 2020 net load forecast, Frontenac TS is expected to exceed its Summer 10-Day LTR by 2029 but can be as early as 2022 for a high growth scenario. As there is limited load transfer capability between Frontenac TS and Gardiner TS DESN1 and excess load in Eastern Kingston area may not be able to supply from Gardiner TS DESN1, there is a need for additional transformation capacity at Frontenac TS in the mid-term.

7.4.2 Alternatives and Recommendation

The following alternatives were considered to address the Frontenac TS station capacity need:

1. **Alternative 1 – Upgrade Frontenac T3/T4 transformers**: The transformers at Frontenac TS are already the largest size for a 115/44kV DESN and therefore upgrading these transformers is not feasible.

2. **Alternative 2 – Install a new DESN with 50/83MVA transformers at Frontenac TS**: As the 115kV circuits supplying Frontenac TS have little thermal capacity, adding a second DESN at Frontenac TS will require significant upgrades to the existing 115kV transmission circuits. In addition, the cost of converting 115 kV transmission line to 230 kV is large and has been a deterrent due to low load growth in the area.

3. **Alternative 3 – Extend 230kV circuits X2H and X4H 13 km to the East of St. Lawrence River and install a new 75/125 MVA DESN**
   This option was assessed and reject due to the high cost and many environmental and real estate issues with the line extension.

4. **Alternative 4 –Build a new 230kV 75/125 MVA DESN near Gardiner TS**
   Load transfer capability exists between Frontenac TS and Gardiner TS DESN 1 via 44kV feeder ties but is limited and for operation measures and is not be suitable for permanent new loads forecasted in Eastern Kingston. Building a new 230 kV DESN near the current X2H/X4H corridor can alleviate this constraint by supplying new load in the area as well as providing an extra station where load can be transferred from Frontenac TS to the new DESN, as needed.

Considering the above alternatives, the TWG recommends Alternative 4. Hydro One transmission will work with Kingston Hydro and Hydro One Distribution to undertake development work for a new station in the area in the near term, which may be built by the Transmitter or the LDC.

The development of additional energy efficiency, could defer the new station ultimately required to accommodate load growth in the City of Kingston. This is cost-effective, under the reference load growth scenario, if cost-allocation can reflect the system benefits the non-wires alternative would provide. Additional barriers to implementation also exist around who would implement the solution and how they would seek cost-recovery, particularly if the transmitter or both benefiting LDCs were to implement a part of the solution. The IESO will work with the impacted transmitter and LDCs between regional planning cycles to address these barriers to implementation and cost allocation for a non-wires alternative, in tandem with developing plans for a new transformer station

7.5 Station Capacity – Gardiner TS DESN 1 (T1/T2)

7.5.1 Description

Gardiner TS DESN 1 is supplied by 230 kV circuits X2H and X4H. The Summer 10-Day LTR of Gardiner TS DESN1 is 125 MW.

Based on the 2020 net load forecast, Gardiner TS has exceeded its Summer 10-Day LTR. Hence, there is a need for additional transformation capacity at Gardiner TS DESN1 in the near term.

7.5.2 Alternatives and Recommendation

The following alternatives were considered to address the Gardiner TS DESN1 station capacity need:

1. **Alternative 1 – Expedite Gardiner TS DESN1 refurbishment**:
   As the current transformers 10 Day LTR is 125 MW, replacing it with new standard 75/125 MVA transformers will increase the LTR to about 160 MW. This will provide enough capacity to meet the load growth at DESN 1 until 2033.

2. **Alternative 2 – Load Transfer from Gardiner TS DESN1 to Gardiner TS DESN2**:
   Gardiner TS DESN2 was built within the last 15 years and has a 10 day LTR of 85 MW. DESN2 has available capacity at the station to supply additional loading. Hydro One distribution has confirmed that an permanent additional 11 MW load transfer from Gardiner TS DESN1 to Gardiner TS DESN2 is possible by reconfiguring its distribution system.

Considering the above alternatives the TWG recommends to proceed with both Alternatives 1 and 2. As the cost of the distribution load transfer is low and the load transfer work is much faster than the Gardiner TS DESN1 refurbishment, Hydro One Distribution can proceed with the work to alleviate the immediate loading constraint on Gardiner TS DESN1 with an expected completion date end of 2022, while Hydro One Transmission will explore opportunity to accelerate the Gardiner TS DESN1 refurbishment. The combination of these two options will address the current capacity limit at Gardiner TS DESN1. Hydro One Transmission will provide an update to the Technical Working Group for Gardiner TS DESN1 refurbishment in Q3 2022.

7.6 Station Capacity – Otonabee TS 44kV bus (T1/T2)

7.6.1 Description

The 2020 non-coincident peak net load at Otonabee TS 44 kV bus was 103 MW . The Summer 10-Day LTR of Otonabee TS 44kV winding is 97 MW.

Based on the 2020 net load forecast, the loading on Otonabee TS 44kV is exceeding its Summer 10-Day LTR today. Hence, there is a need for additional transformation capacity at Otonabee TS 44 kV bus in the near term.

7.6.2 Alternatives and Recommendation

The following alternatives were considered to address the Otonabee TS 44kV station capacity need:

1. **Alternative 1 – Transfer load from Otonabee TS 44kV to Dobbin TS**:
   Dobbin TS is nearby station that have over 50MW of remaining capacity and is not expected to reach its LTR of 160 MW in the long term. The secondary voltage is also 44kV, which allows load transfer between the two stations. Although there is an existing plan to transfer 4 MW of load from Otonabee TS 44kV bus to Dobbin TS, that is not enough to alleviate the capacity limits at Otonabee TS 44kV bus. Hydro One Distribution has confirmed that an additional 8 MW of load can be transfer from

Otonabee TS 44kV to Dobbin TS. This will provide enough capacity to meet the load growth forecast at Otonabee TS 44 kV bus until 2030.

2. **Alternative 2 – Transfer load from Otonabee TS 44kV to Otonabee 27.5kV**: As the voltage levels are different between the 2 low voltage winding of the bus, transferring the load between the different voltages is extremely difficult, costly, and time consuming as it requires all the downstream DS's to be converted to 27.6kV, and in many cases due to distance is not feasible.

The TWG recommends that Hydro One Distribution proceed with the above work in Alternative 1 to ensure continued supply reliability to customers at Otonabee TS 44 kV. Otonabee TS 44kV bus will be monitored after the load transfer and plans should be made if more load transfer from Otonabee TS 44kV bus to Dobbin TS is needed in the long term.

7.6 Asset Renewal Need – Picton TS T1/T2 Transformer Replacement

7.6.1 Description

Picton TS is a 230/44kV transformer station serving Hydro One Distribution. The station comprises two 50/83MVA transformers, T1/T2. The station's 2020 actual peak load was 59 MW and it has a Summer 10-Day LTR of approximately 78MW.

Transformers T1 and T2 are currently about 60 years old and are planned for similar standard units based on their asset condition assessment and taking "right sizing" into consideration. The tentative in-service date is expected in 2025.

The TWG recommends that Hydro One proceed with the above work to ensure continued supply reliability to customers.

7.6.2 Alternatives and Recommendation

1. Alternative 1 - Maintain Status Quo: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.

2. Alternative 2 - Like-for-like replacement with similar equipment: Proceed with these end of life asset replacement as per the existing refurbishment plan for the transformers at Picton TS T1/T2. This alternative would address the end-of-life assets need and would maintain reliable supply to the customers in the area.

7.7 Asset Renewal Need – Port Hope TS T3/T4 Transformer

7.7.1 Description

Port Hope TS is located in the city of Port Hope, Ontario and supplies Hydro One Distribution and Elexicon loads. Port Hope TS T3/T4 are 50/83 MVA transformers with a 10 day LTR of 104 MW. T3/T4 currently supplies about 70 MW of load and the long term forecast is well within the current LTR.

The T3/T4 transformers were built in 1959 and have been identified as has reached the end of service life and requiring replacement. The scope of this project is to replace T3/T4 step-down transformers, associated spill containment structure and majority of assets within 44 kV BY switchyard. The targeted in-service is in year 2025.

The Study Team has assessed right sizing approach to downsizing and/or upsizing these transformers based on needs. The Working Group concluded that reducing the size of these transformers is not an option as the load in the area is not decreasing. Upsizing is also not an option as the long term forecast does not justify upgrade. Accordingly, it is recommended to replace these transformers with similar size.

7.7.2 Alternatives and Recommendation

1. Alternative 1 - Maintain Status Quo:
This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.

2. Alternative 2 - Like-for-like replacement with similar equipment:
Proceed with these end of life asset replacement as per the existing refurbishment plan for the transformers at Port Hope TS T3/T4. This alternative would address the end-of-life assets need and would maintain reliable supply to the customers in the area.

7.8 Asset Renewal Need – Gardiner TS T1/T2 (DESN 1) Transformer

7.8.1 Description

Gardiner TS is located in the city of Kingston, Ontario and supplies Hydro One Distribution and Kingston Hydro loads. Gardiner TS DESN1 T1/T2 are 75/125 MVA transformers with a 10 day LTR of 125 MW. The current loading on T1/T2 have exceeded its 10 day LTR.

The T1/T2 transformers were built in mid 1970s and has reached the end of service life requiring replacement in the previous planning cycle. Following recent inspections of the transformers, the conditions of the transformers were found to be acceptable and the plan to replace the transformers were deferred to 2028.

The Study Team has assessed downsizing and/or upsizing need for these transformers. As the 10 day LTR of the current transformers are substandard, the Working Group concluded that replacing the current transformers which new standard 75/125 MVA units will increase the supply capacity to about 160 MW and alleviate the current overloading at DESN1. Reducing the size of these transformers is not an option as the load in the area is increasing. Upsizing is also not an option as the current units are already the largest size for a 230/44kV step-down transformers.

7.8.2 Alternatives and Recommendation

1. Alternative 1 - Maintain Status Quo:
This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.

2. Alternative 2 - Like-for-like replacement with similar equipment:
Expedite this end of life asset replacement as the current transformers are already overloaded. This alternative would address the end-of-life assets need and would maintain reliable supply to the customers in the area.

7.9 Asset Renewal Need – Dobbin TS T1/T2/T5 Auto Transformers

7.9.1 Description

Dobbin TS is located near the city of Peterborough, Ontario and supplies Peterborough to Quinte loads. Dobbin TS consists of three 230/115 kV auto transformers. T1 is rated at 150/250 MVA and T5 is rated at 115 MVA. T2 is rated at 36/78 MVA and currently out of service.

During the previous planning cycle, T2 and T5 were planned to be replaced with one 150/250 MVA unit. However, as T1 has also reached the end of service life, it would be more efficient and cost effective to replace all three transformers with two 150/250 MVA units.

7.9.2 Alternatives and Recommendation

1. Alternative 1 - Maintain Status Quo:
This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.

2. Alternative 2 – Replace three existing autotransformers with two units:
Proceed with these end of life asset replacement as per the existing refurbishment plan for the transformers at Dobbin TS. This alternative would address the end-of-life assets need and would maintain reliable supply to the customers in the area.

8. CONCLUSION AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE PETERBOROUGH TO KINGSTON REGION.

This RIP report addresses near term and mid-term regional needs identified in the earlier phases of the Regional Planning process and during the RIP phase. The major infrastructure investments recommended by the TWG in the near and mid-term planning horizon are provided in Table 8-1 below. As the industry is currently witnessing supply chain issues and delays in procurement of equipments, it can impact the near term planning horizon if left unresolved.

Investments to address the mid-term needs, for cases where there is time to make a decision, will be reviewed and finalized in the next regional planning cycle. These needs are summarized in Table 8-1.

Table 8-1: Recommended Plans in Peterborough to Kingston Region over the Next 10 Years.

Stations/Lines Project	Details	In-Service Timeframe	Budgetary Cost Estimate[7] ($Million)
Cataraqui TS: Upgrade secondary conductor	Upgrade existing copper conductor on secondary side of auto transformers	2023	$0.5
Gardiner TS DESN1: Station Capacity and Transformers T1/T2 Asset Renewal	Replace the end-of-life transformers with similar type and size equipment as per current standard[8]	2028*	$30
	Load transfer from DESN1 to DESN2	2022	$0.5
Frontenac TS: Station Capacity	Develop plan to build new 230kV 75/125 MVA DESN station in the area, as needed	2025-2029	$30-$35
Otonabee TS 44kV: Station Capacity	Transfer 8MW of load from Otonabee 44kV bus to Dobbin TS	2022	$0.1
Port Hope TS: Transformers T3/T4 Asset Renewal	Replace the end-of-life transformers with similar type and size equipment as per current standard	2026	$25
Belleville TS: Build new DESN	Build a new 230 kV 75/125 MVA DESN with associated capacitor banks at the existing Belleville TS site	2026	$35-$40
Picton TS: Transformers T1/T2 Asset Renewal	Replace the end-of-life transformers with similar type and size equipment as per current standard	2025	$14.5
Dobbin TS: T1/T2/T5 Auto Transformer Asset Renewal	Replace the end-of-life auto transformers with two new 150/250 MVA unit and switchyard refurbishment	2029	$100

*Hydro One is exploring whether Gardiner TS T1/T2 transformers replacement date can be advanced to help address the station capacity need at Gardiner TS DESN 1 described in section 6.4

The Study Team recommends that:

- Hydro One and LDCs to continue with the implementation of infrastructure investments listed in Table 8-1 above while keeping the Study Team apprised of project status;
- All the other identified needs/options in the long-term will be further reviewed by the Study Team in the next regional planning cycle.

[7] Planning estimates are provided for Hydro One's portion of the work based on 2020 costs and are subject to change in the future

[8] The new standard units are expected to have a higher LTR of about 160 MW

APPENDIX E: LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

NEEDS ASSESSMENT REPORT

Peterborough to Kingston Region

Date: December 20, 2024

Needs Assessment Report

Peterborough to Kingston

December 20, 2024

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

Prepared by: Peterborough to Kingston Technical Working Group

Page intentionally left blank.

Disclaimer

This Needs Assessment (NA) Report was prepared for the purpose of identifying potential needs in the Peterborough to Kingston (the "region") and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the NA phase and b) require further assessment and regional coordination. The results reported in this NA are based on the input and information provided by the Technical Working Group (TWG) for this region at the time. Updates may be made based on best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	Peterborough to Kingston Region (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")

START DATE: September 05, 2024 **END DATE:** December 20, 2024

1. INTRODUCTION

The second Regional Planning cycle for the Peterborough to Kingston Region was completed in May 2022 with the publication of the Regional Infrastructure Plan ("RIP") report. This is the third cycle of Regional Planning for the region.

The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years.

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. Due to an increase in load growth in the region, the Technical Working Group ("TWG") decided that the 3rd Regional Planning cycle be triggered in advance of the five-year period in September 2024.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the region NA and includes:

a) Review and reaffirm needs/plans identified in the previous regional planning cycle RIP (as applicable),
b) Identify any new needs resulting from this assessment,
c) Recommend which need(s) require further assessment and regional coordination in the next phases of the regional planning cycle to develop a preferred plan; and,
d) Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is ten years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The region is comprised of the area roughly bordered geographically by the municipality of Clarington on the West, North Frontenac County on the North, and Lake Ontario on the South. Electrical supply to this region is provided by 3 "Three" major Transmission Stations with Autotransformers that feeds, 10 "Ten" step-down Transformer Stations, 8 "Eight" HV Distribution Stations and 5 "Five" Customer transformer Stations.

5. INPUTS/DATA

The TWG comprises of representatives from Local Distribution Companies ("LDC"), the Independent Electricity System Operator ("IESO"), and Hydro One and provides input and relevant information for the region regarding capacity needs, reliability needs, operational issues, and major high-voltage (HV) transmission assets requiring replacement over the planning horizon. The LDCs also capture input from municipalities in the development of their 10-year summer and winter load forecasts.

In accordance with the regional planning process, stakeholder engagement takes place during the IRRP phase.

6. ASSESSMENT METHODOLOGY

The needs assessment's primary objective is to identify the electrical infrastructure needs in the Region over the 10-year planning horizon. A 20-year planning assessment is undertaken in the next phases of regional planning, i.e., IRRP and RIP phases. The assessment methodology includes a review of planning information such as load forecast (which factors various demand drivers and consideration of MEPs and/or CEPs where available), conservation and demand management ("CDM") forecast, distributed generation ("DG") forecast, system reliability and operation, and major HV transmission assets requiring replacement.

A technical assessment of needs is undertaken based on:

a) Current and future station capacity and transmission adequacy;

b) System reliability needs and operational concerns;

c) Major HV transmission equipment requiring replacement with consideration to "right-sizing;" and,

d) Sensitivity analysis to capture uncertainty in the load forecast as well as variability of demand drivers such as electrification.

7. NEEDS

I. Updates on needs identified during the previous regional planning cycle.

The following needs and projects discussed in the region's second cycle RIP have been completed:

- Gardiner TS (Station Capacity) – Load transfer (~10MW) from DESN1 to DESN2 was completed in 2024.
- Belleville TS (Asset Renewal) – T1/T2 transformer were replaced by similar 75/100/125 MVA standard step-down transformers in 2021/2022.

- Cataraqui TS (Supply Capacity) – It was recommended to upgrade the existing copper conductor on secondary side of auto transformers. However, in an assessment the conductor was found to be sufficient and an update to this recommendation was suggested, which will be discussed in this RP cycle.

The following needs and projects discussed in the region's second cycle RIP are currently underway:

- Otonabee TS 44kV (Station Capacity) – 8 MW of load transfer will be transferred to Dobbin TS in 2025.
- Belleville TS (Station Capacity) – Build new Belleville DESN #2 with two 75/100/125 MVA transformers at the existing Belleville TS site. The new DESN is planned to be in service in end of 2026.
- Frontenac TS (Station Capacity) – Frontenac TS currently supplies Central Kingston and East Kingston but the existing 115kV lines and upstream autotransformers at Cataraqui TS that supply Frontenac TS have reached capacity. As recommended in second cycle RIP, Hydro One Transmission is working with Utilities Kingston to plan a new 230kV-44kV station in the West Kingston area in the near term, which may be built by the Transmitter or Utilities Kingston. This station capacity need will be further assessed in the next phases of this Regional Planning cycle.
- Gardiner TS DESN1 (Asset Renewal) – T1/T2 transformer will be replaced by like for like 75/100/125 MVA standard step-down transformers. Planned in-service year for T1 is 2026 and T2 is 2027.
- Port Hope TS (Asset Renewal) – T3/T4 transformer will be replaced by like for like 50/67/83 MVA standard step-down transformers. Planned in-service year is 2033.
- Picton TS (Asset Renewal) – T1/T2 transformer will be replaced by like for like 50/67/83 MVA standard step-down transformers. Planned in-service year is 2026.
- Dobbin TS (Asset Renewal and decommissioning) - T1 and T2 autotransformers are to be replaced by two new 150/250MVA units and decommissioning of T5 autotransformer with an expected in-service date in end of 2028.
- Lennox TS (Asset Renewal) – Ten (10) existing 230kV ABCB & oil breakers to be replaced by new SF6 breakers. Planned in-service year is 2026.
- Peterborough to Quinte West (P15C 230kV & Q6S 115kV Supply Capacity) - Hydro One have started the project to build a new 230kV double circuit line from Clarington TS to Dobbin TS as recommended in Gatineau Corridor End-of-Life Study published in December 2022. Planned in-service year is end of 2029.
- B5QK (Long-term Capacity need in 2038) – As recommended in the previous cycle IRRP, IESO will re-evaluate this capacity need in next phases of this Regional Planning cycle, when 20 year load forecast will be developed.

II. Newly identified needs in the region

The following are new needs that were identified as part of this assessment:

a) Asset Renewal for Major HV Transmission Equipment

- Cataraqui TS (T1/T2)

b) Transmission Station Capacity

- Dobbin TS
- Gardiner TS
- Napanee TS
- Belleville TS
- Cataraqui TS
- Picton TS
- Hinchinbrooke DS
- Frontenac TS

c) Transmission Line Capacity

- 115 kV B1S line under Q6S contingency

d) System Reliability, Operation and Load restoration

- No new System Reliability, Operation and Load restoration needs identified in this NA.

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

The impact of the sensitivity analysis for the high and low growth scenarios identified the following updates to new station capacity needs:

- Sidney TS (2031), Otonabee TS 27.6kV (2026), Otonabee TS 44kV (2028) and 115kV P4S (2031).

These needs will be assessed again during the next phases of this Regional Planning cycle.

9. RECOMMENDATIONS

The Technical Working Group's recommendations to address the needs identified are as follows:

Needs that do not require further assessment and regional coordination: These needs are local in nature and do not have a regional impact. They can be addressed by a straightforward transmission and/or distribution wires solution. They do not require investment in any upstream transmission facility or require Leave to Construct (i.e., Section 92) approvals. These needs generally impact a limited number of LDCs and can be addressed directly between Hydro One and the LDC(s) to develop a preferred local plan. A list of these needs are as follows:

Needs which do not require further regional coordination.

Need location	Need description
Asset Renewal Needs	
Cataraqui TS	T1/T2 renewal based on asset condition assessment.
Station Capacity Needs	
Dobbin TS (T3/T4)	Projected to reach capacity in 2032
Cataraqui TS	Update on need identified in previous cycle RIP
Picton TS	Projected to reach capacity in 2026
Hinchinbrooke DS	Projected to reach capacity in 2028

Needs that require further assessment and regional coordination: These needs may have broader regional impacts and require further assessment and coordination during the next phases[1] of the regional planning cycle. A list of these needs are as follows:

Needs which require further regional coordination.

Need location	Need description
Station Capacity Needs	
Gardiner TS (T1/T2)	Projected to reach capacity now and 2028
Napanee TS (T1/T2)	Projected to reach capacity in 2026
Belleville TS	Capacity limitation due to transmission voltage restrictions
Frontenac TS	Further assess the capacity need in the next phases of this Regional Planning cycle
Transmission Lines Capacity Needs	
115 kV B1S line	Projected to reach capacity in 2028, under Q6S contingency with high hydro generation

List of LDC(s) to be involved in further regional planning phases:

- Hydro One Distribution
- Elexicon Energy Inc.
- Kingston Hydro Corporation
- Lakefront Utilities Inc.
- Eastern Ontario Power Inc.

List of LDC(s) which are not required to be involved in further regional planning phases:

- None

[1] Non-wires options are further considered (i.e. incremental to CDM and DG that is considered in this NA as potential options in addressing these needs during the IRRP phase.

1. INTRODUCTION

The second cycle of the Regional Planning process for the Peterborough to Kingston (P to K) Region was completed in May 2022 with the publication of the Regional Infrastructure Plan ("RIP") report. The RIP report included a common discussion of all the options and recommended plans for preferred wire infrastructure investments to address the near- and medium-term needs.

This Needs Assessment initiates the third regional planning cycle for the P to K Region. The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years. A flow chart of the Regional Planning Process is shown in Figure 1 below.

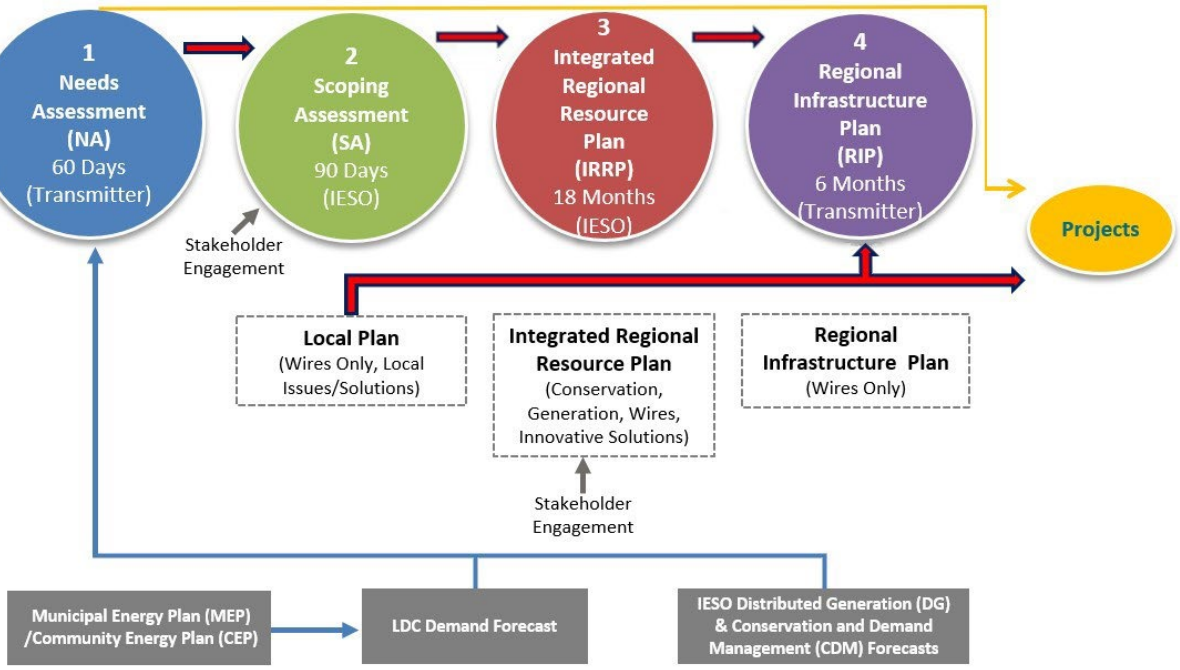

Figure 1: Regional Planning Process

This report was prepared by the Peterborough to Kingston region Technical Working Group("TWG"), led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC") and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: Peterborough to Kingston Region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Transmission (Lead Transmitter)
2	Independent Electricity System Operator
3	Hydro One Distribution
4	Elexicon Energy Inc.
5	Kingston Hydro Corporation
6	Lakefront Utilities Inc.
7	Eastern Ontario Power Inc.

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. Due to an increase in load growth in the region, the Technical Working Group ("TWG") decided that the 3rd Regional Planning cycle be triggered in advance of the five-year period in September 2024.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this NA covers the Peterborough to Kingston region and includes:

- Review and reaffirm needs/plans identified in the previous cycle RIP (as applicable),
- Identify any new needs resulting from this assessment,
- Recommend which need(s) require further assessment and regional coordination in the next phases of the regional planning cycle to develop a preferred plan; and,
- Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no

regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), Local plan (LP) and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is 10 years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The Peterborough to Kingston (P to K) region is comprised of the area roughly bordered geographically by the municipality of Clarington on the West, North Frontenac County on the North, and Lake Ontario on the South. The region includes Frontenac County, City of Kingston, Hasting County, Northumberland County, Peterborough County, and Prince Edward County. The geographical boundaries of the P to K region are shown in Figure 2 below.

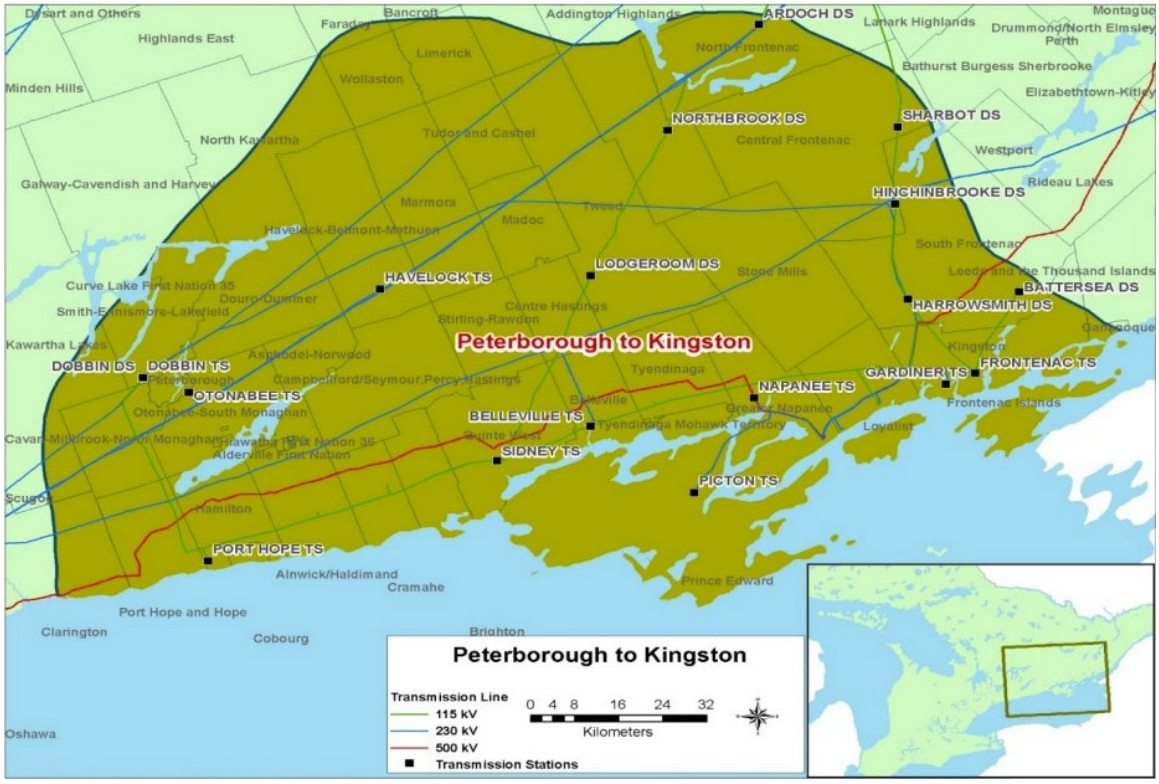

Figure 2: Map of P to K Regional Planning Area

Electrical supply to all five (5) Local Distribution Customers (LDC) listed in table -1 and five (5) Customer Transformer Stations (CTS) in the P to K region is provided by 500/230kV autotransformers at Lennox TS and 230/115kV autotransformers at Cataraqui TS and Dobbin TS through a 230kV and 115kV transmission lines network. There are seven (7) Generation Stations that generates a total of 3474 MW. The 500kV system is part of the bulk power system and is not studied as part of this Needs Assessment.

The details of existing facilities in the region are summarized below and depicted in the single line diagram shown in figure 3.

- 500/230kV Autotransformer: Lennox TS is the major transmission station that connects the 500kV network to the 230kV system via two autotransformers.
- 230/115kV Autotransformer: Cataraqui TS and Dobbin TS are the two (2) transmission stations that connect the 230kV network to the 115kV system via 230/115 kV autotransformers.
- Ten (10) step-down transformer stations and eight (8) High Voltage Distribution Stations (HVDS) are connected to 230 and 115 kV lines that supply load in the Region.
- Five Customer Transformer Stations (CTS) are supplied in the Region.
- Seven Generating stations are also connected.

The circuits and stations names are summarized in the Table 2 below:

Table 2: Transmission Station and Circuits in the P to K Region

115kV circuits	230kV circuits	Hydro One Transformer Stations	Generation Stations
P3S, P4S, Q6S, B1S, Q3K & B5QK.	X1H, X2H, X3H, X4H, X21, X22, H23B, H27H, X1P, C27P, T32H, C25H, T22C, P15C & T25B.	Dobbin TS*, Cataraqui TS*, Lennox TS*, Belleville TS, Dobbin TS, Frontenac TS, Gardiner TS, Havelock TS, Napanee TS, Otonabee TS, Picton TS, Sidney TS, Port Hope TS, CTS -1, CTS-2, CTS-3, CTS-4 & CTS-5.	Seven (7) Generating Stations with total capacity of 3474 MW.

*Stations with Autotransformers installed

The single line diagram of the Transmission Network of P to K region is shown in Figure 3 below.

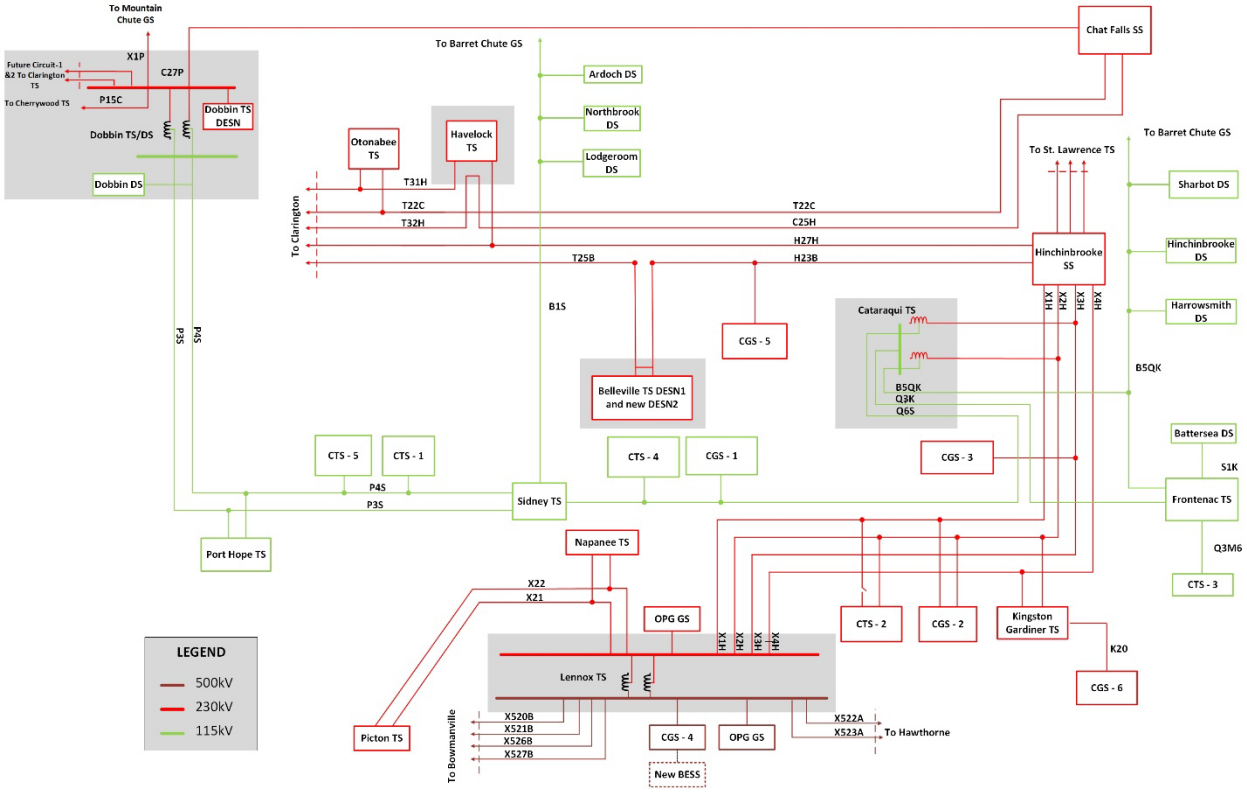

Figure 3: P to K region Transmission Single Line Diagram

5. INPUTS AND DATA

TWG participants, including representatives from LDCs, IESO, and Hydro One provided information and input for the P to K NA. With respect to the load forecast information, the OEB Regional Planning Process Advisory Group (RPPAG) recently published a document called “Load Forecast Guideline for Ontario” in Oct. 2022. The objective of this document is to provide guidance to the TWG in the development of the load forecasts used in the various phases of the regional planning process with a focus on the NA and the IRRP. One of the inputs into the LDC’s load forecast that is called for in this guideline is information from Municipal Energy Plans (MEP) and/or Community Energy Plans (CEP). The list of all the Municipalities falling under the geographical boundaries of the region are given in Appendix-E.

The information provided includes the following:

- P to K 10-year summer and winter Load Forecasts for all supply stations inclusive of the inputs provided by the municipalities (e.g., through their MEPs & CEPs).
- Known capacity and reliability need, operating issues, and/or major assets requiring replacement/ refurbishment; and

- Planned/foreseen transmission and distribution investments that are relevant to Regional Planning for the P to K region.
- Captured uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

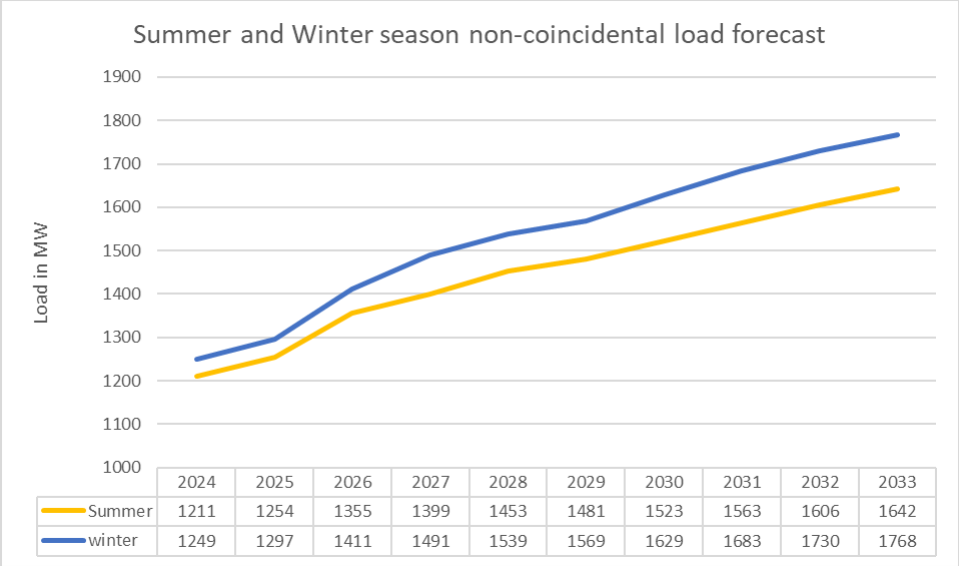
6. ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in development of this Needs Assessment:

6.1 Technical Assessments and Study Assumptions

The technical assessment of needs was undertaken based on:

- Current and future station capacity and transmission adequacy;
- System reliability and operational considerations;
- Asset renewal for major high voltage transmission equipment requiring replacement with consideration to "right-sizing;" and,
- Load forecast data was requested from industrial customers in the region, and
- This assessment is based on summer and winter peak loads. Three load forecasts were developed i.e., Normal Growth scenario, High and Low Growth scenarios. The High and Low Growth scenarios were developed to conduct a sensitivity analysis to cover unforeseen developments such as, fuel switching, Government policies, higher than expected EV charging trend during peak load conditions, etc.



The following other assumptions are made in this report.

- The study period for this Needs Assessment is 2024-2033.
- The Region is winter peaking, but station LTRs are more limiting during the summer season. So, this assessment is based on both summer and winter peak loads.
- Line capacity adequacy is assessed by using coincident peak loads in the area.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
- Normal planning supply capacity for transformer stations is determined by the Hydro One summer 10-Day Limited Time Rating (LTR) of a single transformer at that station.
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).

6.2 Information Gathering Process

6.2.1. Load forecast:

The LDCs provided their load forecasts for summer and winter for all the stations supplying their loads in the P to K region for the 10-year study period including the inputs from the Municipalities such as MEPs and CEPs. The IESO provided a Conservation and Demand Management ("CDM"), and Distributed Generation ("DG") forecast for the P to K region. The region's extreme summer and winter non-coincident peak gross load forecasts for each station were prepared by applying the LDC load forecast growth rates to the weather corrected forecast starting point. The overall 10-year load forecast growth rate for summer season is 3.6% and 4.2% for winter season. The extreme summer and winter weather correction factors were provided by Hydro One. The net extreme summer weather load forecasts were produced by reducing the gross load forecasts for each station by the percentage CDM and then by the amount of effective DG capacity provided by the IESO for that station. It is to be noted that as contracts for existing DG resources in the region begin to expire, at which point the load forecast has a decreasing contribution from local DG resources, and an increase in net demand. This extreme summer and winter weather corrected net load forecast for the individual stations in the P to K region is given in Appendix A. The graphical representation of the regional net non-coincidental load growth for both summer and winter season over the study period is shown in figure 4 below.

	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
Summer	1211	1254	1355	1399	1453	1481	1523	1563	1606	1642
winter	1249	1297	1411	1491	1539	1569	1629	1683	1730	1768

Figure 4: P to K region net summer and winter season non-coincidental load

6.2.2. Sensitivity Analysis:

A sensitivity analysis was undertaken by the TWG to capture uncertainty in the load forecast as well as variability of drivers such as electrification. Hence, the NA recommendations are not

necessarily linked to sensitivity scenarios; but rather are used to identify any emerging needs for consideration in developing recommendations. The impact of sensitivity analysis for the high and low growth scenarios are provided in section 8 of this report.

6.2.3. Asset Renewal Needs for Major HV Equipment:

List of major HV transmission equipment planned and/or identified to be refurbished and/or replaced based on asset condition assessment, relevant for Regional Planning purposes. This includes HV transformers, autotransformers, HV Breakers, HV underground cables and overhead lines. The scope of equipment considered is given in section 7.1.

6.2.4. System Reliability and Operational Issues:

IESO will perform more detailed study to identify system reliability and operational issues in the region during next phases of regional planning.

7. NEEDS

This section describes emerging new needs identified in the P to K Region and/or updates on previously identified needs since the completion of Previous Regional Planning cycle.

Needs that were identified and discussed in the previous regional planning cycle (Regional Infrastructure Plan ("RIP") report) with associated projects that were recently completed and reaffirmed needs that are underway and are briefly described below with relevant updates and will not be discussed further in the report. These projects include:

1. Gardiner TS (Station Capacity) – Load transfer (~10MW) from DESN1 to DESN2 was completed in 2024.
2. Belleville TS (Asset Renewal) – T1/T2 transformer were replaced by similar 75/100/125 MVA standard step-down transformers in 2021/2022.
3. Cataraqui TS (Supply Capacity) – It was recommended to upgrade the existing copper conductor on secondary side of auto transformers. However, in an assessment the conductor was found to be sufficient and an update to this recommendation was suggested, which will be discussed in this RP cycle. This station capacity need should be further assessed in conjunction with Frontenac TS in the next phases of this Regional Planning cycle.
4. Belleville TS (Station Capacity) – Build new Belleville DESN #2 with two 75/100/125 MVA transformers at the existing Belleville TS site. The new DESN is planned to be in service in end of 2026.
5. Frontenac TS (Station Capacity) – Frontenac TS currently supplies Central Kingston and East Kingston but the existing 115kV lines and upstream autotransformers at Cataraqui TS that supply Frontenac TS have reached capacity. As recommended in second cycle RIP, Hydro One

Transmission is working with Utilities Kingston to plan a new 230kV-44kV station in the West Kingston area in the near term, which may be built by the Transmitter or Utilities Kingston. This station capacity need will be further assessed in the next phases of this Regional Planning cycle.

6. Gardiner TS DESN1 (Asset Renewal) – T1/T2 transformer will be replaced by like for like 75/100/125 MVA standard step-down transformers. Planned in-service year for T1 is 2026 and T2 is 2027.
7. Port Hope TS (Asset Renewal) – T3/T4 transformer will be replaced by like for like 50/67/83 MVA standard step-down transformers. Planned in-service year is 2033.
8. Picton TS (Asset Renewal) – T1/T2 transformer will be replaced by like for like 50/67/83 MVA standard step-down transformers. Planned in-service year is 2026.
9. Dobbin TS (Asset Renewal and decommissioning) - T1 and T2 autotransformers are to be replaced by new 150/250MVA units and decommissioning of T5 autotransformer with an expected in-service date in end of 2028.
10. Lennox TS (Asset Renewal) – Ten (10) existing 230kV ABCB & oil breakers to be replaced by new SF6 breakers. Planned in-service year is 2026.
11. Peterborough to Quinte West (P15C 230kV & Q6S 115kV Supply Capacity) - Hydro One have started the project to build a new 230kV double circuit line from Clarington TS to Dobbin TS as recommended in Gatineau Corridor End-of-Life Study published in December 2022. Planned in-service year is end of 2029.
12. B5QK (Long-term Capacity need in 2038) – As recommended in the second cycle IRRP, IESO will re-evaluate this capacity need in next phases of current Regional Planning cycle, when 20 year load forecast will be developed.

Note: The planned in-service year for the above projects is tentative and is subject to change.

All near, and mid-term needs that are discussed as a part of this report are summarized in Table 3 below.

Table 3: Near/Mid-term Needs Identified in this NA and/or are updated from previous RIP

Need location	Need description/Update	Previous RIP Report Section	NA Report Section
Asset Renewal Needs			
Cataraqui TS	T1/T2 renewal based on asset condition assessment.	7.2	7.1.1
Transmission Station Capacity Needs			
Dobbin TS (T3/T4)	Projected to reach capacity in 2032	New	7.2.1
Gardiner TS (T1/T2)	Projected to reach capacity now and 2028	7.5 & 7.8	7.2.2
Napanee TS (T1/T2)	Projected to reach capacity in 2026	New	7.2.3
Cataraqui TS	Update on need identified in previous cycle RIP	7.2	7.2.4

Picton TS	Projected to reach capacity in 2026	7.6	7.2.5
Hinchinbrooke DS	Projected to reach capacity in 2028	New	7.2.6
Belleville TS	Capacity limitation due to transmission voltage restrictions	7.3	7.2.7
Frontenac TS	Further assess the capacity need in the next phases of this Regional Planning cycle	7.4	7.2.8
Transmission Line Capacity Needs			
115 kV B1S line	Projected to reach capacity in 2028, under Q6S contingency, high hydro output	New	7.3.1
System Reliability, Operation and Load restoration Needs			
No new system Reliability, Operation and Load restoration need is identified in this NA.			

7.1 Asset Renewal Needs for Major HV Transmission Equipment

In addition to the previously identified asset renewal needs from the second regional planning cycle, Hydro One and TWG has also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the P to K Region. The complete list of major HV transmission equipment requiring replacement in the P to K Region is provided in table 4 in this section. Hydro One is the only Transmission Asset Owner (TAO) in the Region.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
- replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
- Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
- Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

The Asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement)
- Replacing equipment with higher ratings and built to current standards

From Hydro One's perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

Table 4: Major HV Transmission Asset assessed for Replacement in the region

Station/Circuit	Need Description	Planned ISD*
Gardiner TS	T1/T2 replacement with like for like 75/100/125 MVA units.	2027
Port Hope	T3/T4 replacement with like for like 50/67/83 MVA units.	2033
Picton TS	T1/T2 replacement with like for like 50/67/83 MVA units.	2026
Dobbin TS	T1/T2 Autotransformers to be replaced by two bigger 150/250MVA units and decommissioning existing T5.	2028
Lennox TS	Ten (10) 230kV ABCB & Oil breakers to be replaced by new SF6 breakers.	2026
Cataraqui TS	T1 and T2 230/115kV Autotransformers to be replaced with 150/200/250 MVA units.	2034

* The planned in-service year for the above projects is tentative and is subject to change.

7.1.1 Cataraqui TS – T1/T2 Autotransformers

The existing T1/T2, 230/115 kV, 150/200/250 MVA autotransformers were built in 1968 and are identified to be replaced based on asset condition assessment. The existing autotransformers have substandard rating due to internal limitations and will be replaced by similar size modern units which is expected to have a higher LTR. This replacement will also help resolve the station capacity need identified in previous cycle RIP and is discussed in section 7.2.4 of this report. The planned in-service date is 2034.

7.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2024-2033 for the 230kV and 115kV Transforming stations in the P to K Region using the summer and winter non-coincidental peak net load forecasts that were provided by the Technical Working Group. Based on the results, the following Station[2] capacity needs have been identified in the during the study period:

7.2.1 Dobbin TS (T3/T4)

Dobbin TS is located near the city of Peterborough, Ontario, and supplies load to Hydro One Distribution through its two 75/100/125MVA, T3/T4 step down transformers. The 2032 non-coincident peak net load is expected to exceed its summer and winter LTRs of 156 MW and 177 MW, respectively.

While the need for additional capacity is projected toward the end of the study period, it depends on several factors, including whether the load increases as anticipated. There is a possibility that this overload could be managed through load transfers to nearby stations. It is recommended that Hydro One Transmission and Distribution collaborate to address this potential issue, and no regional planning coordination is required at this time.

7.2.2 Gardiner TS (T1/T2)

Gardiner TS DESN 1 is located in city of Kingston, Ontario, and is supplied by 230kV, X2H/X4H circuits and supplies load to Hydro One Distribution and Kingston Hydro Corporation (embedded) currently through its two 75/100/125 MVA, T1/T2 step down transformers. These transformers were identified for replacement in previous regional planning cycle and are planned to be replaced in 2027 and will have a better LTR (~170MW). The non-coincident peak net load summer load at this station is exceeding its LTR of 121 MW now.

Kingston Hydro Corporation has projected significant load growth in 2026, driven by an industrial development project, and again in 2032, due to a customer transitioning from a conventional gas heating system to geothermal heating. These new contributions will lead to exceed the new transformer to exceed its LTRs by 2028. It is recommended that a solution for this additional capacity be identified in the next phase of the regional planning cycle.

7.2.3 Napanee TS (T1/T2)

Napanee TS is located in Greater Napanee area, Ontario, and is supplied by 230kV, X21/X22 circuits and supplies Hydro One Distribution load through its 50/67/83 MVA T1/T2 step down transformers. The 2026 non-coincident peak net load is expected to exceed its summer and winter LTRs of 101.7 MW and 116.9 MW, respectively.

Hydro One Distribution has projected significant load growth in 2026, driven by two large customers. These new loads are expected to exceed the new transformer LTRs by 2026. However, as these load

[2] Belleville TS and Frontenac TS capacity needs were already identified in the 2nd cycle RP and there are no changes to the recommendations made in the RIP by TWG. Updates to all previously identified needs is provided in beginning of section-7 of this report.

forecasts are not committed load, the station capacity need may be shifted accordingly. It is recommended the load growth shall be monitored and a solution for this additional capacity be identified in the next phase of the regional planning cycle.

7.2.4 Cataraqui TS

Cataraqui TS is a 230/115kV autotransformer station that supplies the 115kV stations in the Eastern sub region of the P to k region. It was recommended upgrade the existing copper conductor on secondary side of auto transformers. However, in an assessment performed by Hydro One, the conductor in the 115kV yard was found to be sufficient. T1/T2, 230/115 kV, 150/200/250 MVA autotransformers will be replaced with similar size units in 2034. The new autotransformers are expected have higher LTRs and will further address the issue of overload at the station. The replacement of existing autotransformers is based on asset condition assessment and hence it is recommended that no further regional planning coordination is required at this time.

7.2.5 Picton TS

Picton TS is located in Picton area, Ontario, between Bay of Quinte and Prince Edward Bay, and is supplied by 230kV, X21/X22 circuits and supplies Hydro One Distribution load through its 50/67/83 MVA T1/T2 step down transformers. The 2026 non-coincident peak net load is expected to exceed its summer and winter LTRs of 75 MW and 89 MW, respectively.

The existing T1/T2 transformers have been identified for replacement based on asset condition assessments. The replacement units will be of similar size but will have higher LTRs (~100MW) due to modern designs, which will be enough to supply the load throughout the study period. It is recommended that no further regional planning coordination is required at this time.

7.2.6 Hinchinbrooke DS

Hinchinbrooke DS is located in Central Frontenac area, Ontario and is supplied by 115kV B5QK circuit and supplies Hydro One Distribution Load through its 115/13.2 kV T1 transformer. The 2028 non-coincident peak net load is expected to exceed its winter LTRs of 8.4 MW. The load growth in the area is not significant and can be monitored and addressed within Hydro One Transmission and Distribution. No further regional planning coordination is recommended at this time.

7.2.7 Belleville TS

Belleville TS is located in Belleville area and is supplied by two 230 kV T25B and H23B lines and supplies load to Hydro One Distribution and Elexicon Energy Inc. through its DESN1 two 75/100/125 MVA, 230/44kV, T1/T2 step down transformers. A new Belleville TS DESN2 will be in service by the end of 2026 to address the supply capacity need in the region. Based on the load forecast, and the existing voltage constraints on the transmission lines supplying Belleville TS for a H23B contingency at the Belleville TS, limiting the total loading by the year 2028-2031, depending on the load and LV configuration at Belleville TS DESN2. This undervoltage cannot be mitigated without a partial loss of load at DESN2 post 2028 loading. Therefore, it is recommended to conduct a comprehensive assessment in the next phases of the regional planning cycle to manage this need as well as a full bulk planning study as identified in the previous regional planning cycle.

7.2.8 Frontenac TS

Frontenac TS is located in Kingston area and is supplied by two 115kV B5QK and Q3K lines and supplies Hydro One Distribution, Utilities Kingston, and Eastern Ontario Power Inc. load through its two 50/67/83 MVA, 230/44kV, T3/T4 stepdown transformers. As recommended in second cycle RIP, Hydro One Transmission is working with Utilities Kingston to plan a new station in the area in the near term, which may be built by the Transmitter or the LDC. The Frontenac station capacity need should be further assessed in the next phases of this Regional Planning cycle.

7.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period 2024-2033 for the 230kV and 115kV Transmission line circuits in the P to K Region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater this need. Based on the results, the following line capacity needs have been identified in the during the study period:

7.3.1 115kV B1S

B1S is a long 145km 115kV single-circuit radial line which extends between Barrett Chute GS and Sidney TS and serving Ardoch DS, Northbrook DS and Lodgeroom DS in between. The supply capacity of the line could exceed its continuous rating in in the near to medium timeline following a contingency on Q6S line and high hydro output from generators in the region. The B1S line is limited by a low sag temperature which is the main reason of this line could be overloaded. Hydro One Transmission will perform an internal assessment to see if there is room for improving the sag temperature to address the issue in near time, but it is also recommended to do a full assessment during the next phases of this regional planning cycle.

7.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. A study has been performed, considering the net coincident load forecast and the loss of one element over the study period 2024-2033 to cater this need**.** Based on the results, no new significant system reliability, operating and restoring issues have been identified for this Region.

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments. The TWG determined that the key electric demand driver in the P to K region

to be considered in this sensitivity analysis is the new Industrial load and expansion of urban areas from municipalities, electric vehicle (EV) penetration, and unforeseen electrification which would cause the load to increase at a faster rate than shown in the forecast; or the potential delay in some projects which could result in less demand than anticipated.

The TWG reviewed the new Industrial load and expansion of urban areas from municipalities, EV scenarios, and any unforeseen electrification needs to develop high demand growth forecasts by applying 50% additional growth to the growth rate on the extreme summer and winter corrected Normal Growth net load forecasts. The low growth scenario was obtained by reducing the growth rate by 50%.

The normal and high growth forecasts are shown in Appendix A.

The impact of sensitivity analysis for the high and low growth scenario identified the following updates or new station capacity needs:

Table 5: Impact of Sensitivity Analysis on Station/Line capacity needs in the region

Sr.no.	Need Identified	Normal Growth Scenario	High Growth Scenario	Low Growth Scenario
1	Dobbin TS (T3/T4)	2032	2029	2032
2	Gardiner TS (T1/T2)	Current and 2028	Current	Current and 2033
3	Gardiner (T3/T4)	NA	NA	NA
4	Napanee TS (T1/T2)	2026	2026	NA
5	Picton TS	2026	2026	NA
6	Hinchinbrooke DS	2028	2027	NA
7	Sydney TS	NA	2031	NA
8	Otonabee TS 25.6kV	NA	2026	NA
9	Otonabee TS 44kV	NA	2028	NA
10	B1S	2028	2028	2028
11	P4S	NA	2031	NA
12	Belleville TS (undervoltage)	2028	2027	NA
13	Frontenac TS	2027	2026	2030

In addition, the radial tap from 230kV circuits X2H and X4H serving Kingston through Gardiner TS DESN1 and DESN2 have a summer Long Term Emergency (LTE) rating of about 395 MW. Current normal summer loading forecast for Gardiner TS DESN1 and DESN2 total 293 MW by 2033, leaving about 102 MW of

thermal capacity remaining. If the area experiences a higher load growth as per the scenario above and/or large transmission customer connection up to 100 MWs, there will be capacity need in this area.

The sensitivity analysis identified the additional capacity needs at towards the end of the study period. The sensitivity analysis and these needs will be assessed again during the next phases of this Regional Planning cycle.

9. CONCLUSION AND RECOMMENDATION

The Technical Working Group's recommendations to address the needs identified are as follows:

Needs that do not require further assessment and regional coordination: These needs are local in nature and do not have a regional impact. They can be addressed by a straightforward transmission and/or distribution wires solution. They do not require investment in any upstream transmission facility or require Leave to Construct (i.e., Section 92) approvals. These needs generally impact a limited number of LDCs and can be addressed directly between Hydro One and the LDC(s) to develop a preferred local plan. A list of these needs are as follows:

Table 7: Needs which do not require further regional coordination

Need location	Need description
Asset Renewal Needs	
Cataraqui TS	T1/T2 renewal based on asset condition assessment.
Station Capacity Needs	
Dobbin TS (T3/T4)	Projected to reach capacity in 2032
Cataraqui TS	Update on need identified in previous cycle RIP
Picton TS	Projected to reach capacity in 2026
Hinchinbrooke DS	Projected to reach capacity in 2028

Needs that require further assessment and regional coordination: These needs may have broader regional impacts and require further assessment and coordination during the next phases[3] of the regional planning cycle. A list of these needs are as follows:

Table 8: Needs which require further regional coordination

Need location	Need description
Station Capacity Needs	
Gardiner TS (T1/T2)	Projected to reach capacity now and 2028

[3] Non-wires options are further considered (i.e. incremental to CDM and DG that is considered in this NA) as potential options in addressing these needs during the IRRP phase.

Napanee TS (T1/T2)	Projected to reach capacity in 2026
Belleville TS	Capacity limitation due to transmission voltage restrictions
Frontenac TS	Further assess the capacity need in the next phases of this Regional Planning cycle
Transmission Lines Capacity Needs	
115 kV B1S line	Projected to reach capacity in 2028, under Q6S contingency with high hydro generation

List of LDC(s) to be involved in further regional planning phases:

- Hydro One Distribution
- Elexicon Energy Inc.
- Kingston Hydro Corporation
- Lakefront Utilities Inc.
- Eastern Ontario Power Inc.

List of LDC(s) which are not required to be involved in further regional planning phases:

- None

1. Executive Summary

The Gatineau Corridor End-of-Life Study examines transmission equipment reaching end-of-life (EOL) in the Gatineau transmission corridor along with forecast reliability concerns in the areas supplied by those transmission circuits, Ottawa and Peterborough to Quinte West. Consideration of replacement options for significant EOL transmission facilities through an IESO-led integrated planning process can ensure assets are renewed in a cost-effective manner that aligns with the evolution of the electricity system (e.g. decarbonisation of the electricity sector and the economy) and reflects potential new or emerging needs that have arisen in an area since the assets were first installed. The reliability issues identified through the study include:

- Approximately 800 km of the 230 kV circuits on the Gatineau Corridor (Oshawa to Ottawa) are expected to reach end-of-life over the next 5 to 10 years
- The Load Meeting Capability (LMC) for the Ottawa area is forecast to be exceeded in the mid 2020's
- The LMC for the Peterborough to Quinte West area is insufficient today

To minimize cost, minimize land-use impacts, mitigate forecast risk, preserve options to increase system capability in the future and due to lack of cost effective stand-alone resource or energy efficiency alternatives, the following integrated solution package is recommended to address the transmission equipment EOL needs and accommodate the demand forecast for the Ottawa and the Peterborough to Quinte West areas over the long-term:

- Refurbish all 800 km of 230 kV circuits on the Gatineau Corridor identified as nearing EOL
- Build a new double circuit 230 kV transmission line into Dobbin TS (in Peterborough) from either Cherrywood TS (in Pickering) or Clarington TS (in Oshawa) with a planned in-service of 2029
- Pursue up to 230 MW of additional system cost-effective energy efficiency in the Ottawa area over the 20 year planning horizon, while monitoring demand growth and resource acquisition activities in the Ottawa zone
- Update and expand the use of remedial action schemes (RAS) in the Peterborough and Ottawa areas to meet planning standards and further improve both areas' LMCs

This solution package represents the lowest cost option, with transmission reinforcements estimated to cost approximately $650 M. The transmission reinforcements ensure reliability in the Peterborough to Quinte West area is sufficient for the next 20 years and reliability in the Ottawa area is sufficient until 2037. If the 230 MW of additional energy efficiency is implemented, Ottawa area's reliability would also be sufficient over the 20 year planning horizon. The solution package maintains the capacity of the existing circuits being refurbished and avoids the need to address localized issues that would result from retiring the circuits (i.e. reconfiguration of stations and short line builds in the Ottawa area).

2. Introduction

2.1 Power System Planning in Ontario

The Independent Electricity System Operator (IESO) is responsible for conducting independent planning for electricity generation, demand management, conservation and transmission in the Province of Ontario. In carrying out this mandate, the IESO undertakes planning activities to ensure that the province has, and will continue to have, an adequate and reliable supply of resources and transmission to meet Ontario's electricity needs.

The IESO's planning generally consists of regional planning and bulk system planning. These are two separate but inter-related planning activities. Regional planning is carried out according to a regional planning process endorsed by the Ontario Energy Board (OEB). Regional planning produces plans that address system issues that are local in nature, within 21 planning regions covering the province. Bulk System Planning is carried out by the IESO to address system issues which are more provincial in nature, such as the province-wide need for generation capacity, and transmission system solutions to enable transporting power reliably and economically across the province. Also covered are regulatory compliance studies and reporting requirements, such as required by the North American Electric Reliability Corporation (NERC) reliability standards and the Northeast Power Coordinating Council (NPCC) criteria.

2.2 Gatineau Corridor End-of-Life Study

The Gatineau Corridor End-of-Life Study examines transmission equipment reaching end-of-life (EOL) in the Gatineau transmission corridor along with forecast reliability concerns in the areas of Ottawa and Peterborough to Quinte West which are supplied by the circuits located within the corridor. Consideration of replacement options for EOL transmission facilities through an integrated planning process can ensure assets are renewed in a cost-effective manner that aligns with the evolution of the electricity system (e.g. decarbonisation of the electricity sector and the economy) and new or emerging issues that have arisen in an area since the assets were originally constructed.

2.3 Gatineau Corridor and Key Areas of Interest

Gatineau Corridor

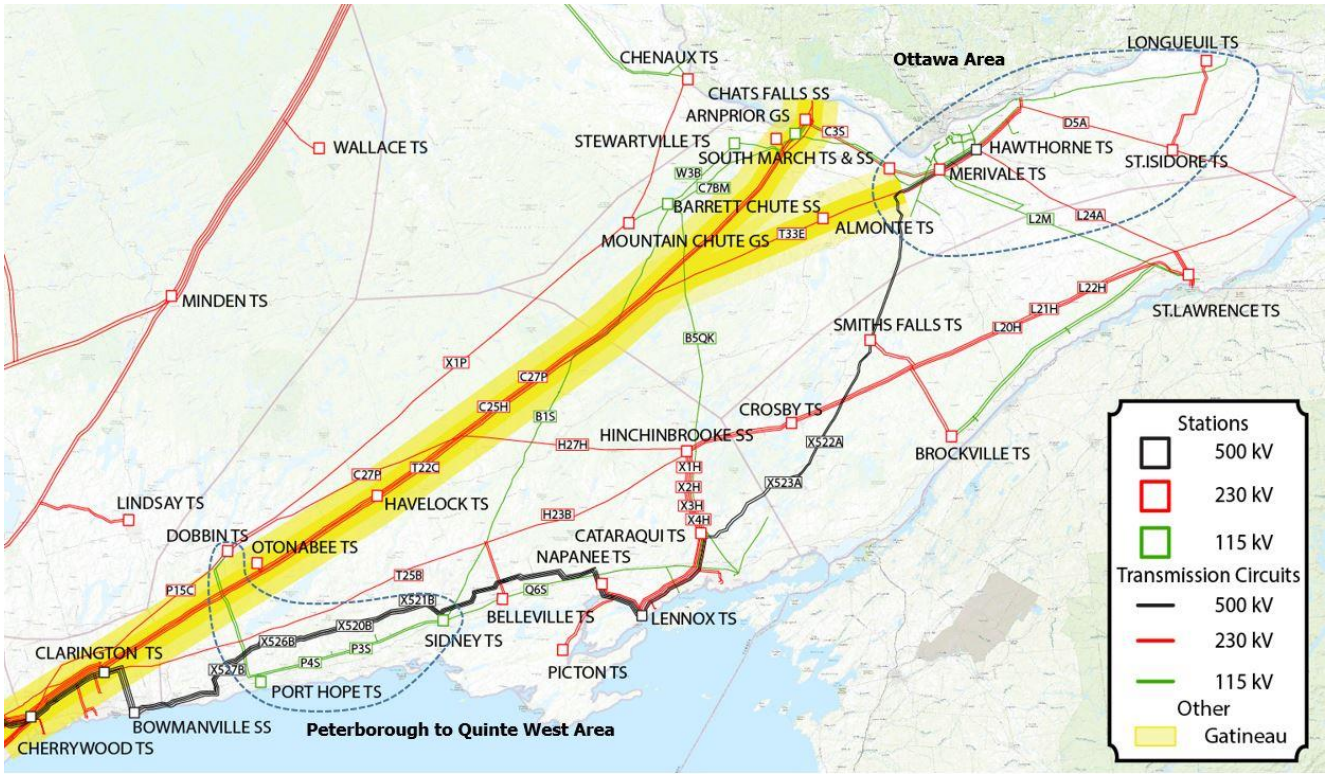
The Gatineau corridor is a 300 km long transmission corridor that runs from Durham region to Peterborough and onto Ottawa. The Gatineau corridor was originally constructed in the late 1920's to early 1930's primarily to transfer power from hydro electric facilities in eastern Ontario and Quebec to the Toronto load centre. The Gatineau corridor consists of five (5) 230 kV transmission lines (P15C/C27P, T22C, T32H/C25H, T33E/E34M, and T31H/H27H), and have a combined length of 1,300 line-kms. Today, the corridor serves a number of purposes which include facilitating generation, transferring bulk system flows across eastern Ontario, and supplying loads in the Peterborough to Quinte West and Ottawa areas.

Peterborough to Quinte West Area

The Peterborough to Quinte West area is located in eastern Ontario and includes Peterborough County, Northumberland County, Prince Edward County, and the City of Quinte West. The electricity demand of this area is a mix of residential, commercial and industrial loads, encompassing diverse economic activities ranging from educational institutions, large business parks, health care, national defence bases, manufacturing and industrial processes.

This area is supplied by a number of 230 and 115 kV transmission lines coming from the directions of Durham region and the County of Lennox and Addington. The area is served by four supply stations which include Otonabee TS, Dobbin TS, Port Hope TS, and Sidney TS. While Otonabee TS is in close proximity to Dobbin TS which is the other supply station in Peterborough, the upstream electricity system serving Otonabee TS is distinct from the system serving the other three stations. When describing system capability and demand forecasts in this report, the definition of the Peterborough to Quinte West area excludes Otonabee TS.

Electricity demand in this summer peaking Peterborough to Quinte West area has been fairly constant and has historically reached approximately 310 MW. There is approximately 300 MW of transmission connected hydro-electric generation located in the Greater Madawaska and Renfrew areas supporting the load in Peterborough to Quinte West.



Ottawa Area

The City of Ottawa is the second largest city in Ontario with a population of approximately 1 million people. The city has seen its population grow steadily by approximately 1.5% annually since 2015, and with that has also seen a steady growth of its developed lands. This development is primarily focused in five areas: the downtown core, Nepean & Riverside South, South Kanata & Stittsville, the Village of Richmond, and Orleans. This growth is primarily being seen through the development of new mixed commercial/residential communities, intensification of existing communities, and major projects like the Ottawa Light Rail Transit system. In rural Ottawa, the economy contributes over $1 billion to the GDP. Rural economic activity includes such things as agriculture, retail sales, construction, forestry and mining (aggregates), tourism, manufacturing, personal and business services, and transportation.

Ottawa is supplied by a number of 500, 230 and 115 kV transmission lines coming from the directions of Peterborough County and the County of Lennox and Addington. Electricity demand in this summer peaking area has been steadily growing and has historically reached approximately 1,800 MW. There are a number of different electricity supply resources in the surrounding area that help support the Ottawa load, including approximately 600 MW of hydro-electric generation located on the Madawaska and Ottawa rivers, 70 MW of gas generation located in the city, and three interties with Quebec system.

A map of the area highlighting the Gatineau corridor and the areas of Peterborough to Quinte West and Ottawa are shown in Figure 1.

Figure 1 | Map of Gatineau Corridor, Highlighting Areas of Interest

3. Planning for Transmission Asset End-of-Life in the Gatineau Corridor

3.1 Transmission Asset End-of-Life

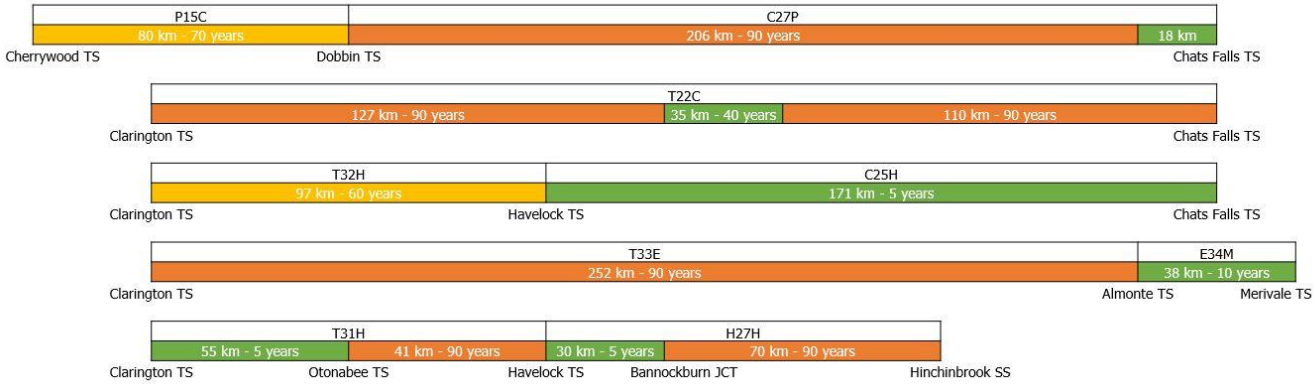
Consideration of end-of-life (EOL) transmission asset replacement needs is an integral part of transmission planning. When an asset reaches EOL, a decision must be made to either replace it ("like-for-like" or "right-size") or, in some cases, decommission it to meet safety, reliability, environmental, and customer requirements. While the length of time varies, many transmission assets remain in use and deliver value for 40 years or more. Over such a long period of time, the functional requirements of the transmission system could change, as customer needs, system conditions, sector trends, and government policy evolve. Coordination of transmission asset replacement needs with other forecast reliability and security needs over the long-term is critical to maximizing the benefits and value of transmission system investments.

End-of-Life

EOL represents the state of having a high likelihood of failure, or loss of an asset's ability to provide the intended functionality, wherein the failure or loss of functionality would cause unacceptable consequences. EOL is determined by the asset owner's risk-based assessments, taking into account such factors as reliability, loss of load, environmental considerations, and safety.

EOL is different from the "useful life" of asset which is an accounting estimate of the number of years it is likely to remain in service considering factors such as manufacturer guidelines, and historical asset performance, failure and retirement data.

As assets age and begin to approach their "useful life", assessments are carried out to determine their overall condition by examining asset-specific health metrics, along with performance history. Based on the results, equipment is scheduled to be replaced when it reaches EOL.



3.2 Gatineau Corridor Transmission Asset End-of-Life

The Gatineau Corridor was originally constructed in the late 1920's to early 1930's. At over 90 years since its original construction, large portions of corridor and specifically the transmission line conductors are nearing EOL, and in some instances have already been partially refurbished to maintain safety and reliability of the transmission system.

Transmission line conductors have a "useful life" of approximately 90 years. The facility owner, Hydro One Networks Inc. (HONI) has identified that the conductors on transmission lines C27P, T22C and T33E are nearing EOL based on asset condition assessments and require replacement before 2028. A decision to either refurbish the EOL facilities "like-for-like" or decommission and replace them with new cost effective facilities that provide additional value must be made now, as new transmission lines typically take 7 years to design, approve and construct.

While HONI has only identified the three transmission lines (C27P, T22C and T33E) as nearing EOL, other transmission lines in the corridor were examined in this study to identify potential candidates for right-sizing or decommissioning. Asset demographic age information for the Gatineau corridor transmission lines are illustrated in Figure 2.

Figure 2 | Age of Gatineau Corridor Transmission Line Conductors

GREEN Recently refurbished, the plan assumes continued service

YELLOW Intermediate age

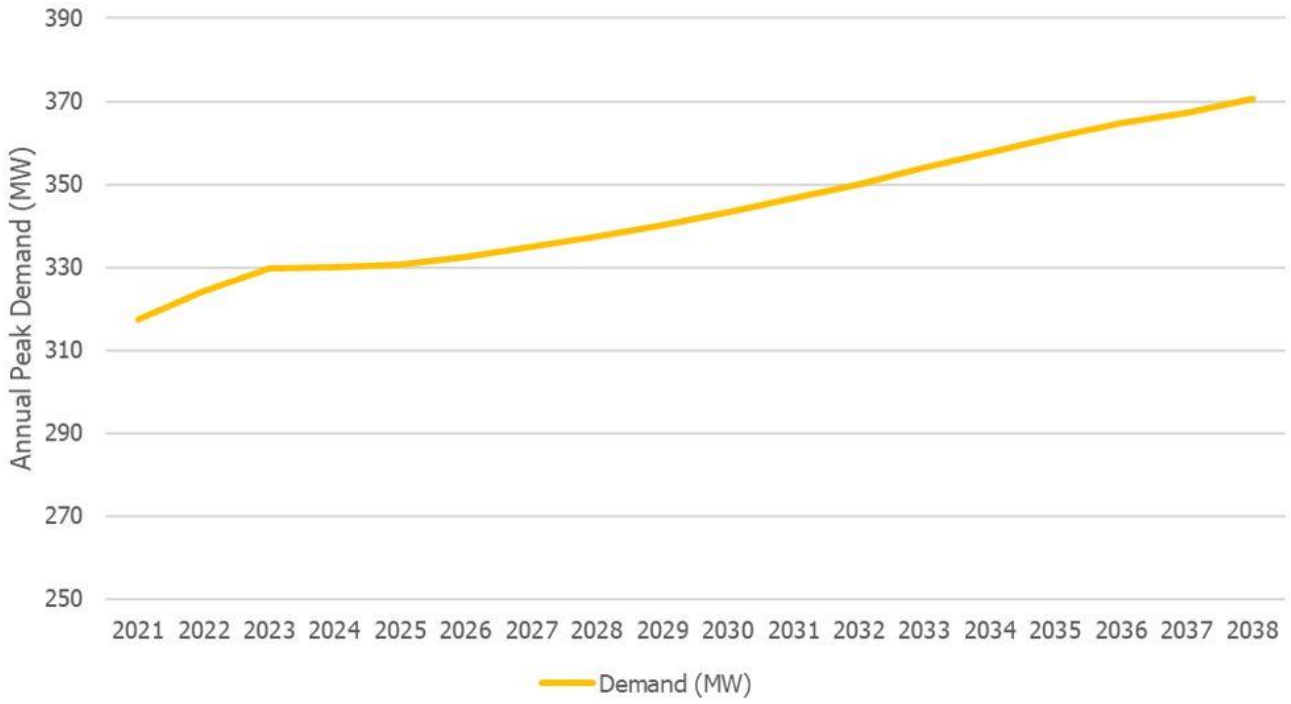
ORANGE Sections that are ~90 years old total 806 km

3.3 Potential Opportunities for Right-sizing or Decommissioning

As noted earlier, while HONI has only identified the three transmission lines, C27P, T22C and T33E as nearing EOL, all transmission lines in the corridor were screened to identify potential candidates for right-sizing or decommissioning. The screening considered various qualitative factors such as the criticality of the facility on reliability, stranding recently refurbished facilities, and potential for other cost effective alternatives. The screening identified transmission lines T22C and T33E as potential candidates for decommissioning, as alternatives exist that are potentially more cost effective and/or provides greater system value. The transmission lines C27P, T32H, T31H, and H27H are recommended to be refurbished when they reach EOL as cost effective alternatives are not evident. The last remaining circuit in the corridor P15C, is essential to supplying Peterborough to Quinte West and also the eastern Ontario system. For this reason, the circuit P15C can either be refurbished or upgraded to help accommodate the forecast demand for Peterborough to Quinte West and Ottawa areas. A summary of the considerations for each transmission line is provided in

Table 1.

Table 1 | Opportunities for Right-sizing or Decommissioning in the Gatineau Corridor



Transmission Line	Considerations	Opportunity for Right-sizing or Decommissioning
P15C/C27P	• The transmission lines P15C and C27P are critical supply circuits for the Peterborough to Quinte West area, P15C is a limiting constraint for the area's load meeting capability, as well as an upstream constraint for Ottawa's load meeting capability • The transmission line P15C runs between Pickering and Peterborough, passing by northern part of Durham region where load growth is expected most in the future • The transmission line C27P provides transmission connection for the 85 MW hydro-electric Arnprior Generating Station; if C27P were to be decommissioned, a portion of C27P would still need to maintained (~15 km) • The vast majority of the C27P transmission line is approaching its "useful life" or has been identified as nearing EOL	P15C: Opportunity for upgrading C27P: No
T22C	• The transmission line T22C is critical in supporting the Ottawa area during certain transmission outage conditions • The transmission line T22C provides transmission connection for Otonabee TS; if T22C were to be decommissioned, supply to Otonabee TS would need to reconfigured to one of the remaining circuits in the corridor • The majority of the transmission line has been identified as nearing EOL	T22C: Opportunity for decommissioning and replacing with a new transmission line that can offer additional system value
T32H/C25H	• The transmission line T32H/C25H is critical in supporting the Ottawa area during certain transmission outage conditions • The transmission lines T32H/C25H are critical supply circuits for Havelock • A portion of the transmission line (60%) was recently refurbished, and the remaining portion of the transmission line still has 30 years before reaching its average "useful life".	T32H/C25H: No
T33E/E34M	• The transmission line T33E/E34M is critical in supporting the Ottawa area during certain transmission outage conditions • The transmission lines T33E/E34M supply Almonte TS, Terry Fox TS, and Cambrian MTS; if T33E were to be decommissioned, a portion of T33E would still need to be maintained (~55km) and reconnected to one of the remaining circuits in the corridor • The entire T33E has been identified as nearing EOL	T33E: Opportunity for decommissioning and replacing with a new transmission line that can offer additional system value E34M: No
T31H/H27H	• The transmission line T31H/H27H helps support the loads in the areas of Lennox and Addington county, City of Kingston and Hinchinbrooke Township during certain transmission outage conditions • The transmission lines T31H/H27H are critical supply circuits for Havelock • A portion of the transmission line (40%) was recently refurbished, and the remaining portion of the transmission line has been identified as nearing EOL	T31H: No H27H: No

4. Demand Forecasts

4.1 Peterborough to Quinte West Area Demand

The Peterborough to Quinte West electricity demand is a mix of residential, commercial and industrial loads, encompassing diverse economic activities including educational institutions, large business parks, manufacturing and Canadian Forces bases. As shown in Figure 3, loads in this summer-peaking area are forecast to grow from 310 MW to 370 MW over the next 20 years.

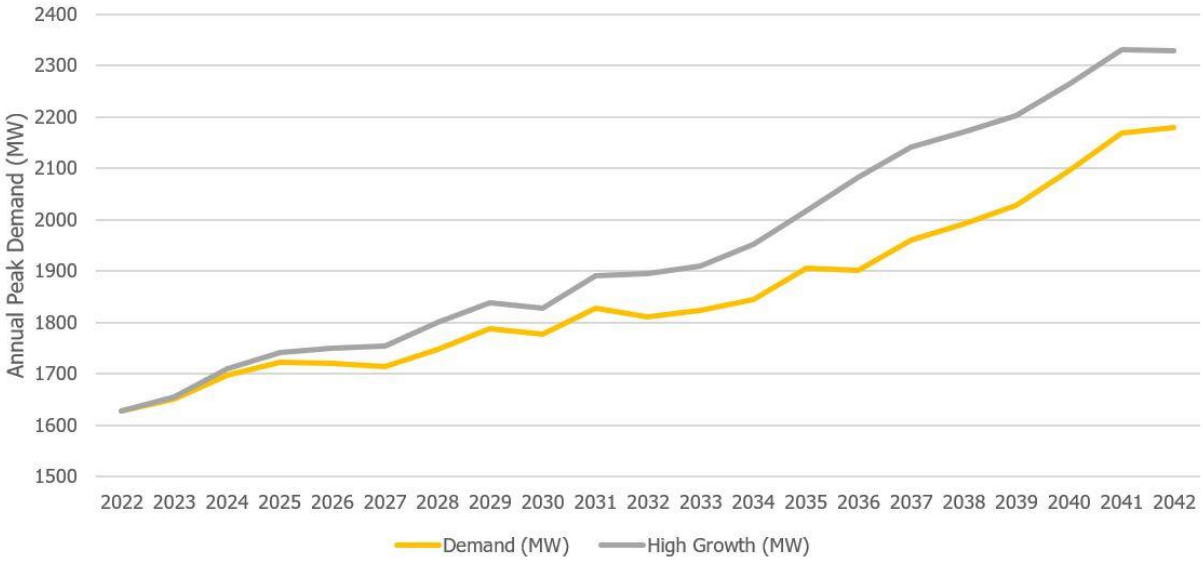


Figure 3 | Peterborough to Quinte West Demand Forecast

4.2 Ottawa Area Demand

The Ottawa electricity load growth is primarily being seen through the development of new mixed commercial/residential communities, intensification of existing communities, and major projects like the Ottawa Light Rail Transit system. As shown in Figure 4, loads in this summer-peaking area are forecast to grow from approximately 1650 MW to 2200 MW and 2350 MW over the next 20 years under the reference forecast and high growth scenario respectively.

Figure 4 | Ottawa Demand Forecast

Energy Evolution - Ottawa's Community Energy Transition Strategy

Energy Evolution[1] is the action plan for how Ottawa will meet its targets to reduce greenhouse gas emissions to zero by 2040 within the corporation, and by 2050 Ottawa-wide. Its vision is to transform Ottawa into a thriving city powered by clean, renewable energy. To achieve Ottawa's emission reduction targets will require:

- Significantly reduce energy demand for existing end-uses
- Phase out fossil fuels
- Increase use of renewable resources

Some of the identified actions to help achieve these targets will have an interdependency with planning the electricity system supplying the City of Ottawa, such as electrification of personal and commercial vehicles, electrification of heating, and new renewable resources.

The Energy Evolution strategy was approved by Ottawa's City Council on October 28, 2020. The impact of Energy Evolution on the peak electricity demand has yet to be quantified and is not included in the demand forecast shown in Figure 4. The IESO will work with the City of Ottawa and the Greater Ottawa regional planning working group during the next cycle of regional planning for Greater Ottawa (expected to commence in Q4 2022), to determine the how the strategy would impact the development of planning forecasts and scenarios, and what additional planning activities are necessary to support the City of Ottawa's Energy Evolution strategy. It's anticipated that to achieve energy evolution targets, Ottawa demand would grow beyond the high growth scenario and this uncertainty was considered when evaluating options.

[1] More information regarding Energy Evolution is available on the City of Ottawa's website (link)

5. Supply Capability to Focus Areas

Supply capability to the areas of Peterborough to Quinte West and Ottawa is provided by a number of internal generation resources, as well as external resources accessed through the 500 kV and 230 kV transmission system (connecting the area to the rest of the Ontario)[2].

Planning of the transmission system focuses on ensuring that the system will operate reliably over a broad spectrum of system conditions and following a wide range of probable system contingencies. These planning events and performance requirements are established through a number of planning criteria and standards by the North American Electric Reliability Corporation (NERC), the Northeast Power Coordinating Council (NPCC), and the IESO. The planning events examined are aimed to stress the transmission system (i.e. adjusting hydro-electric generation output for drought conditions, adjusting the load forecast for extreme weather, loss of one or more transmission and/or generation elements, etc.), and the performance requirements are intended to set a baseline for designing the electricity system.

As Ontario's electricity grid is made up of a variety of different energy resource types, it's important to note that the capability of each resource type at the time of peak loading conditions will vary. Variable generators such as wind and solar are modelled to historical output coincident with the time of peak. Hydro-electric generators are modelled to their historical output available during drought conditions.

5.1 Peterborough to Quinte West Supply

5.1.1 Peterborough to Quinte West Internal Resources

Transmission-connected resources currently comprise of mostly hydro-electric generation along the Madawaska and Ottawa rivers. These resources represent a combined total of 300 MW of installed generation capacity[3], however the generation output is expected to be closer to 40 MW during drought conditions.

5.1.2 Peterborough to Quinte West Load Meeting Capability

Supply to Peterborough to Quinte West is also provided through the Flow into Dobbin and Sidney (FIDS) transmission interface which is bounded by two 115 kV circuits from Cataraqui TS (Q6S) and from Barrett Chute TS (B1S), and two 230 kV circuits in the Gatineau Corridor (P15C and C27P), providing supply from broader provincial resources.

[2] The mixture of resources used to supply the region's and the province's energy needs at any time is determined by the real-time energy market.

[3] The region also has a significant number of distribution connected resources, mainly solar. The impact of these distributed resources has been considered as part of the reference load forecast.

The FIDS interface is thermally limited by 230 kV circuit P15C from Cherrywood TS to Dobbin TS in the summer. Generally, losing one or more of the interface circuits will lead to overloads of the remaining circuit(s). In the existing system, the load meeting capability of Peterborough to Quinte west area is limited to 270 MW today, the limiting phenomena is illustrated in Table 2.

Table 2 | Peterborough to Quinte West Load Meeting Capability

Transmission Equipment Out of Service	Phenomena	Peterborough to Quinte West LMC
Q6S	Thermal overload on P15C	270 MW
P15C	Thermal overload on Q6S	280 MW

5.2 Ottawa Supply

5.2.1 Ottawa Internal Resources

Transmission-connected resources currently comprise of a significant amount of hydro-electric generation along the Madawaska and Ottawa rivers, one natural-gas generation plant in the City of Ottawa, and one wind generator to the east of the city. These resources represent a combined total of 800 MW of installed generation capacity[4]. Over the next 20 years, contracts for the natural gas-fired and wind generators are expected to expire, which needs to be considered when identifying local supply needs.

5.2.2 Ottawa Load Meeting Capability

Supply to Ottawa is also provided through the Flow into Ottawa (FIO) transmission interface, defined as two 500 kV circuits from Lennox TS (X522A, X523A), and four 230 kV transmission circuits from Beauharnois (B5D), St. Lawrence TS (L24A), Chats Falls TS (C3S) and Almonte TS (E34M), providing supply from broader provincial resources.

Under normal operating conditions, the Ottawa load is primarily supplied by the two 500 kV circuits from Lennox TS. However, when these two primary supply circuits are unavailable, the Ottawa load relies on the 230 kV electricity system to supply the load. The FIO interface is thermally limited by the 230 kV circuit L24A from St. Lawrence TS to Hawthorne TS, and the upstream 230 kV circuit P15C from Cherrywood TS to Dobbin TS. In the existing system, the load meeting capability of Ottawa is limited to 1700 MW today due to thermal limitations. While not the most limiting, Ottawa's load meeting capability is also limited by voltage instability. Information regarding Ottawa's load meeting capability and limiting phenomena is shown in Table 3.

[4] The region also has a significant number of distribution connected resources, mainly hydro-electric and solar. The impact of these distributed resources has been considered as part of the reference load forecast.

Ottawa is also interconnected with Quebec through three (3) 230 kV interconnections and three (3) 115 kV interconnections. The six interties facilitate mostly economic energy transactions between Ontario and Quebec through the Ontario electricity market. The current interties between Quebec and Ontario have a combined capacity of 2,775 MW; however, transmission constraints in Ontario limit the available transfer capability between the two areas[5]. Real-time transactions with Quebec have reached a maximum of about 1,800 MW.

Table 3 | Ottawa Load Meeting Capability

Transmission Equipment Out of Service	Phenomena	Ottawa LMC
Loss of X522A & X523A	Thermal overload on P15C	1700
Loss of X522A & X523A	Voltage Instability	1800

[5] More information about the Ontario-Quebec interconnection is available in the IESO's 2017 report – "Ontario-Quebec Interconnection Capability: A Technical Review" (link)

6. Need for Additional Supply

The IESO has conducted an assessment of the system's capability to supply the areas of Peterborough to Quinte West and Ottawa. Planning criteria were applied in accordance with North American Electric Reliability Corporation standards and the Northeast Power Coordinating Council reliability directories to determine system capacity needs. In the context of the bulk system, adequacy is defined as the ability to supply regional demand, while respecting transfer capability limits across the bulk system and interconnections.

This assessment considered both the contribution of existing internal generation and resources external to the area.

6.1 Capacity Requirement

A deterministic approach was used to evaluate the need for additional capacity behind the Flow into Dobbin and Sidney, and Flow into Ottawa interfaces. A need was identified where the annual coincident load forecast exceeded the interface transfer limits and the total capacity of internal transmission-connected generation.

6.1.1 Flow into Dobbin and Sidney

Based on this assessment, to supply Peterborough to Quinte West there is a capacity need of 100 MW in the summer by 2035. The capacity need is an existing issue, that arises during periods of high demand coinciding with low water conditions. The annual capacity requirement for FIDS is shown in Figure 5.

In addition to the annual capacity shortfall, the estimated frequency, duration, and magnitude of unserved energy events were also investigated and used to inform options development. Figure 6 contains heat maps to visually demonstrate these characteristics. Each cell in the heat map indicates the expected frequency, of all hours of unserved energy, that may occur in that specific hour or month. By 2035, unserved energy is expected to occur mostly in the months of April through October, with the largest impact observed during the summer peaks.

There is a significant amount of distribution connected solar generation within the Peterborough to Quinte West area. The effects of the solar generation can be seen in the heat maps, as the solar generation helps offset the demand during the hours of 8:00 AM to 5:00 PM and reduces the energy needs during those hours.

Hour Ending

6.1.2 Flow into Ottawa

Based on this assessment, a capacity need first emerges in 2025 and grows to 475 MW in the summer by 2042 under the reference scenario. Under the high growth scenario, the capacity need increases to 625 MW by 2042. When considering generation coming off contract, the capacity need becomes 550 MW and 700 MW respectively (approximately 75 MW of transmission connected generation coming off contract during the 20 year planning horizon). The annual capacity requirement is shown in Figure 7. In addition to the annual capacity shortfall, the estimated frequency, duration, and magnitude of unserved energy events were also investigated and used to inform options development. Figure 8 contains heat maps to visually demonstrate these characteristics. While Ottawa is a summer peaking area today, its expected that Ottawa will gradually shift to being winter peaking over the next 20 years due to decarbonisation efforts.

7. Analysis of Alternatives

This study compares alternatives to meeting the identified near-, mid-, to long-term supply capacity requirements for the areas of Peterborough to Quinte West and Ottawa. The alternatives considered include both traditional transmission wires type reinforcements aimed at improving the FIDS and FIO interface transfer limits as well as non-wire alternatives (NWAs) such as generation, battery energy storage systems (BESS), demand response, etc.

Non-wire Alternatives

For each need where NWAs are potentially suitable, the demand profiling methodology is used to characterize the need and inform options analysis. The development of NWAs takes into consideration a number of factors, such as:

- Maximizing the use of existing infrastructure and resources in the region (e.g., merchant generation, generators with expiring contracts, etc.) to defer transmission and/or generation investment.
- New generation and/or storage with the attributes that most closely meet the need, or integrated solutions in combination with demand response or energy efficiency measures.
- New transmission facilities to deliver provincial resources.

NWA selection is based on capacity (MW) and energy requirements (MWh). The need characteristics are quantified by capacity factors and the energy-not-served (ENS) profile which is the forecast hourly demand above the load meeting capability that can be served by the existing power system in a specified area. The ENS profile is not static over the planning horizon, allowing NWAs to be installed in modular and discrete blocks as demand grows. Transmission solutions and non-energy-limited resources can primarily be sized based on the power capacity requirements alone, however energy-limited resources must also consider the energy requirement and temporal patterns. For example, BESS must be sized such that the energy reservoir has enough storage capability to withdraw enough energy overnight, and inject it the next day with enough capacity to meet demand.

The capacity and energy requirements evolve as demand grows and influences the feasibility and economics of various NWAs. In general, potential options that are known to satisfy technical requirements and have the lowest cost tend to be screened for suitability first. The NWA should aim to cost-effectively meet the need on an equivalent dollar and reliability basis. Calculating the levelized unit capacity cost provides a means of assessing alternative options for planning purposes and is generally used as a screening tool to shortlist resources for more detailed analysis. The calculation considers factors such as overnight capital costs, fixed operating, maintenance and administrative (OM&A) costs, variable OM&A costs, etc.) amortized across the NWAs lifetime.

Cost estimates for NWAs are based on benchmark capital and operating cost characteristics for each resource type and size. Generally speaking, the most cost-effective transmission-connected options for meeting local needs are resources with costs on par with simple cycle gas turbines (SCGT) generators or BESS, depending on the relative size of the facility and the capacity factor. New natural gas-fired generation was considered in the economic analysis for illustrative purposes to represent the cost of new generation. BESS are also becoming cost competitive due to declining technology costs and the expectation of carbon prices increasing in line with federal policy.

NWAs also provide bulk system capacity and energy benefits and are taken into consideration as part of the cost analysis. Bulk system capacity benefits are considered in each year capacity is required and is based on the capacity auction reference price. The reference price is the estimated Net Cost of New Entry (Net CONE) of the anticipated lowest cost marginal resource in Ontario that would be developed when new generation is required. Bulk system energy benefits are considered for any instance where the NWA displaces higher marginal cost resources.

Energy Efficiency

Energy efficiency is a low cost resource that offers tremendous benefits for individuals, businesses and the power system as a whole. Energy-efficiency programs help reduce the need for new investments in power plants and transmission lines.

The IESO offers a number of Conservation and Demand Management (CDM) programs as part of the 2021-2024 CDM Framework under the Save on Energy brand. In order to address regional and local system needs, the IESO can also assess the potential for savings opportunities incremental to these current initiatives that are cost effective based on system benefits and can be leveraged to help defer or compliment wires infrastructure and ensure system reliability.

As described in Section 6, a capacity requirement exists in Peterborough to Quinte West area today and is forecast to appear in the Ottawa area by 2025. As the timing of the needs are in the near-term and with the magnitude of the needs being substantial (upwards of 100 MW within the first 10 years), incremental energy efficiency was considered in this assessment as a potential compliment to other solutions, not as a stand-alone solution.

7.1 Alternatives Considered

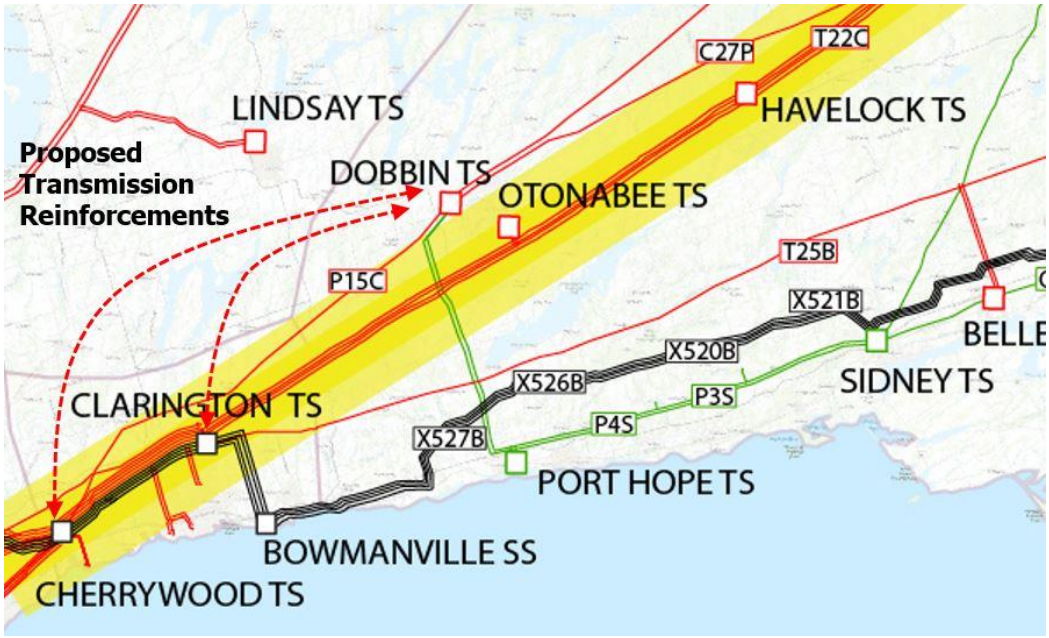
In total there were six packages of solutions put together to form the basis of the alternatives considered. Each package comprises of a combination of solutions described in this report. The packages are shown in Table 4**Error! Reference source not found.**.

Table 4 | Gatineau Corridor EOL Study Solution Packages

	T22C & T33E	Peterborough to Quinte West Area Improvements	Peterborough to Quinte West LMC	Ottawa Area Improvements	Ottawa LMC	Cost (2021 $M)
1	Refurbish	Two 230 kV circuits from Dobbin TS to Clarington TS/Cherrywood TS	440 MW	Pursue targeted energy efficiency	1950 MW	$600M-$650M
2	Retire	Two 230 kV circuits from Dobbin TS to Clarington TS/Cherrywood TS	440 MW	Two 230 kV circuits from St. Lawrence TS to Merivale TS Pursue targeted energy efficiency	2050 MW	$725M-$775M
3	Retire	Two 230 kV circuits from Dobbin TS to Clarington TS/Cherrywood TS	440 MW	One 500 kV circuit from St. Lawrence TS to Hawthorne TS	2150 MW	$875M-$925M
4	Refurbish	175 MW resource at/near Dobbin TS	390 MW	Pursue targeted energy efficiency	1950 MW	$1,150M-$2,000M
5	Retire	Two 230 kV circuits from Dobbin TS to Clarington TS/Cherrywood TS	440 MW	480 MW resource at/near Hawthorne TS	2180 MW	$875M-$1,725M
6	Retire	225 MW resource at/near Dobbin TS	390 MW	480 MW resource at/near Hawthorne TS	2180 MW	$2,150M-$4,150M

Transmission Reinforcement into Peterborough

Transmission reinforcement into Peterborough involves a new transmission line between Dobbin TS in Peterborough and either Cherrywood TS in Pickering or Clarington TS in Oshawa. With four (4) 230 kV transmission circuits interconnecting Cherrywood TS and Clarington TS, and the presence of 500-230 kV auto-transformation at both stations, the two stations are quite similar from an electrical supply perspective.



There are different variations to how this transmission reinforcement could be achieved. Each variation comparably increases the Peterborough to Quinte West LMC to approximately 440 MW. This improved capability sufficiently accommodates the 20-year planning forecast which reaches a maximum of 370 MW. As such, in addition to accommodating the planning forecast, the transmission reinforcement alternative provides additional flexibility and resiliency in meeting future changes in demand. The transmission reinforcement into Peterborough also mitigates the upstream thermal constraints limiting Ottawa for the duration of the 20-year planning forecast.

The variations of this transmission reinforcement include:

- Rebuild an existing single circuit 230 kV line from Cherrywood TS (Pickering) to Dobbin TS (Peterborough) into a double circuit 230 kV line
- Build a new double circuit 230 kV transmission line from Cherrywood (Pickering) TS to Dobbin TS
- Build a new double circuit 230 kV transmission line from Clarington TS (Oshawa) to Dobbin TS

A map showing the transmission reinforcement to Peterborough is shown in Figure 9.

Figure 9 | Map of Proposed Transmission Reinforcement Options into Peterborough

As the variations are currently comparable from a cost, scope[6], and capability perspective, each variation should be further examined during the project development and project approval stages led by the transmitter[7] in order to select the preferred variation.

Resource in Peterborough to Quinte West

A new resource located in the Peterborough to Quinte West area was considered as a NWA to the transmission reinforcement into Peterborough. The resource requirements can range depending on whether the transmission lines T22C and T33E are refurbished or decommissioned. Decommissioning the transmission lines will increase the flows from GTA east to Ottawa and through the P15C and C27P transmission lines. The analysis identified a SCGT facility (175 MW) as the most feasible non-wire alternative if T22C/T33E are refurbished. Alternatively, the analysis identified a CCGT (225 MW) as the most feasible non-wire alternative if T22C/T33E are decommissioned. Additional alternatives involving hybrid BESS and wind were also examined. A BESS solution would be deployed modularly in discrete blocks as demand grows.

Refurbishment of T22C and T33E into Ottawa

This option involves refurbishing the EOL transmission lines T22C from Clarington TS to Chats Falls TS, and T33E from Clarington TS to Almonte TS. While this option appears to maintain the existing transmission supply to Ottawa, the LMC for Ottawa is improved to 1950 MW through the addition of a new RAS, and the mitigation of the upstream thermal limitations on P15C through either the transmission reinforcement into Peterborough or a new resource in the Peterborough to Quinte West area. A new LMC of 1950 MW accommodates the forecast demand in Ottawa up to year 2037 based on the reference forecast.

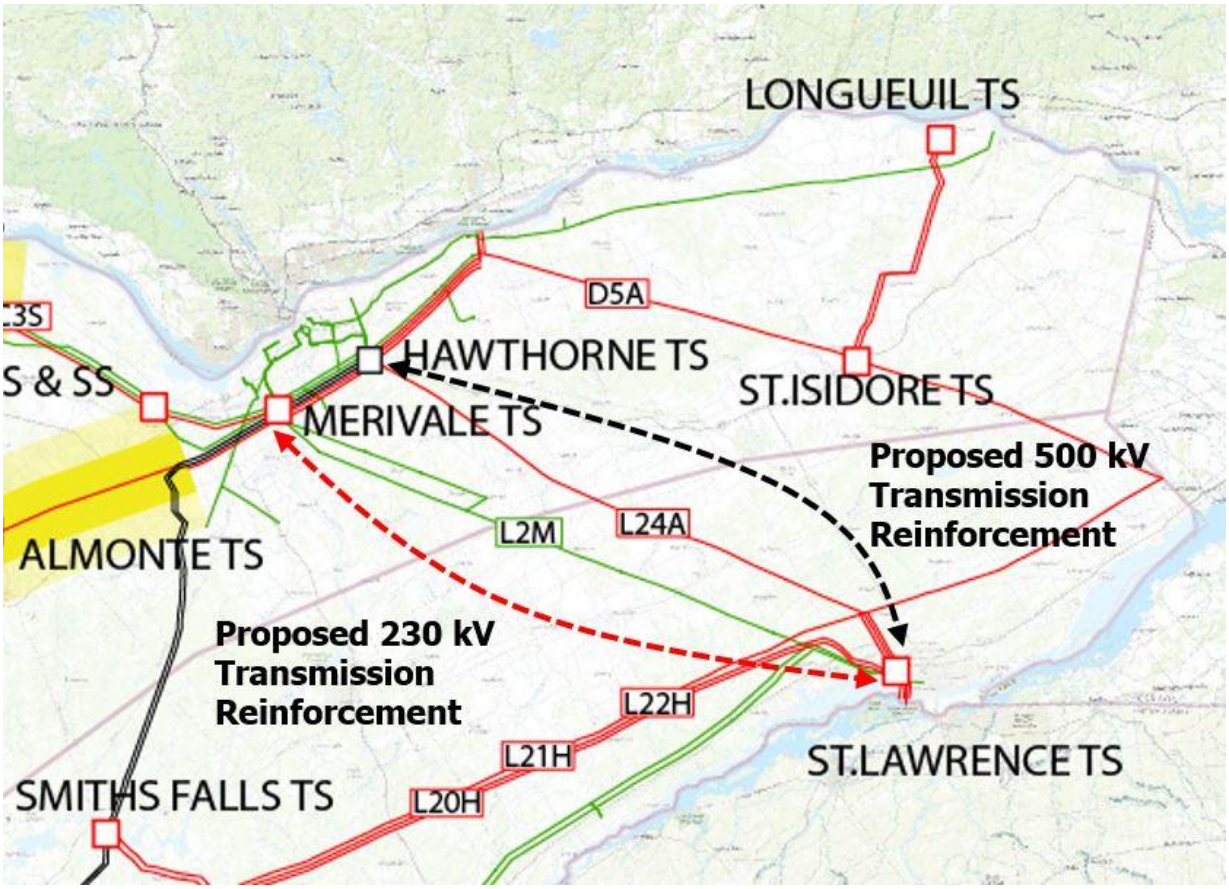
Transmission Reinforcement into Ottawa

The transmission reinforcement into Ottawa involves a new transmission line between St. Lawrence TS in Cornwall and either Merivale TS (230 kV transmission line) or Hawthorne TS (500 kV transmission line) which are both in Ottawa. The two variations to how this transmission reinforcement can be achieved are comparable as they both strengthen the tie between the Ottawa area and the Cornwall area which has a sizeable amount of hydro-electric generation. The variations of this transmission reinforcement include:

- Build a new double circuit 230 kV transmission line from St. Lawrence TS (Cornwall) to Merivale TS (Ottawa)
- Build a new single circuit 500 kV transmission line from St. Lawrence TS (Cornwall) to Hawthorne TS (Ottawa)

---

[6] A new transmission line originating from Cherrywood TS is assumed to repurpose existing breaker positions at Cherrywood TS currently serving Pickering GS which is planned for retirement between 2024-2026.



[7] New transmission lines in Ontario are subject to the Environmental Assessments ("EA") Process where line routing will be assessed and evaluated, interested parties will have an opportunity to provide input on line routing to the transmitter as part of the EA (Ontario Government Website link)

Both variations enable the opportunity for decommissioning the two EOL transmission lines T22C and T33E. The variations are quite comparable to each other, the 500 kV transmission line option offers an incremental capacity improvement of 100 MW at an incremental cost of approximately $150M.

A new 230 kV transmission line into Merivale TS will increase the Ottawa LMC to 2050 MW which will accommodate the forecasted demand in Ottawa up to year 2039, while a new 500 kV transmission line into Hawthorne TS increases the Ottawa LMC to 2150 MW which will accommodate the forecasted demand in Ottawa up to year 2041.

A map showing the Ottawa transmission reinforcements is shown in Figure 10.

Figure 10 | Map of Transmission Reinforcement Options for Ottawa

Resource in Ottawa

A new resource located in the Ottawa area was considered as a NWA to the refurbishment of T22C/T33E or the transmission reinforcement into Ottawa. The analysis identified a SCGT facility (480 MW) as the most feasible non-wire alternative. Additional alternatives involving hybrid BESS and wind were also examined. A BESS solution would be deployed modularly in discrete blocks as demand grows.

Remedial Action Schemes

For all solution packages, a Remedial Action Scheme (RAS) will be relied upon to help accommodate the forecasted demand. RASs (formerly named Special Protection Systems) are utilized to expand the capability of the transmission system and maximize the benefits of the transmission system equipment. The use of RAS's are governed by applicable planning criteria[8]. The two RASs identified, one for Peterborough to Quinte West and another for Ottawa, are both load rejection based schemes that will disconnect up to 150 MW when two or more power system elements are out of service (i.e. two transmission circuits are unavailable). Load rejection or load shedding schemes exists in both areas today, however the schemes will require modifications/updates to accommodate the forecasted demand.

7.2 Energy Efficiency

As discussed earlier, incremental energy efficiency was considered in this assessment as a compliment to other solutions. This section aims to quantify the energy efficiency opportunities in Ottawa.

In 2019, the IESO and the Ontario Energy Board completed the first integrated electricity and natural gas achievable potential study in Ontario (2019 APS)[9]. The main objective of the APS was to identify and quantify energy savings (electricity and natural gas) potential, GHG emission reductions and associated costs from demand side resources for the period from 2019-2038. The study shows a significant and sustained potential for energy efficiency across all sectors and is used to inform:

- future energy efficiency policy and/or frameworks;
- program design and implementation; and
- assessments of Conservation and Demand Management (CDM) non-wires potential in regional planning.

The APS study is used to determine an estimate of the remaining system cost-effective energy efficiency potential for planning study areas when accounting for existing provincial programs, federal program and savings from codes and standards.

In order to determine which needs should be evaluated for the use of energy efficiency as a solution, a screening mechanism was applied, in accordance with the IESO's standard criteria which includes consideration of factors such as the timing and magnitude of the need, its size relative to total forecasted demand, and coincidence with provincial system peak. The potential for energy efficiency to help address the identified needs was assessed for the Ottawa area supply capacity need, but not the Peterborough to Quinte West need, due to the timing and magnitude of the need identified.

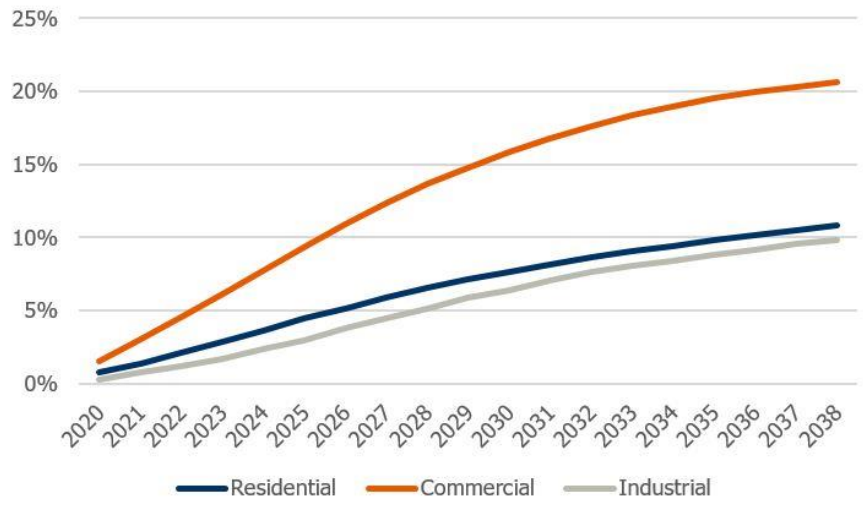
[8] Usage of RAS is governed by IESO's Ontario Resource Transmission Assessment Criteria (link), NERC's Transmission System Planning Performance Requirements – (link), and NPCC's Directory # 1 Design and Operation of the Bulk Power System (link).
[9] More information about the 2019 Conservation Achievable Potential Study is available on the IESO website (link)

7.2.1 Energy Efficiency Potential in Ottawa

As part of the analysis developed for the 2020 Integrated Regional Resource Plan for the Ottawa sub-region, the IESO estimated that energy efficiency has the potential to reduce demand by approximate 1% per year on average in the Ottawa zone based on the 2019 APS results. These opportunities are reduced in the near term by existing CDM commitments while new opportunities increase in the medium term, following conclusion of the 2021-2024 CDM framework. The cumulative maximum achievable potential savings is shown in Figure 11 and Figure 12.

Note that the portion of the maximum achievable potential that is committed is included in the planning forecast shown in Figure 4.

Figure 11 | Cumulative Maximum Achievable Zonal Potential as a Share of Consumption



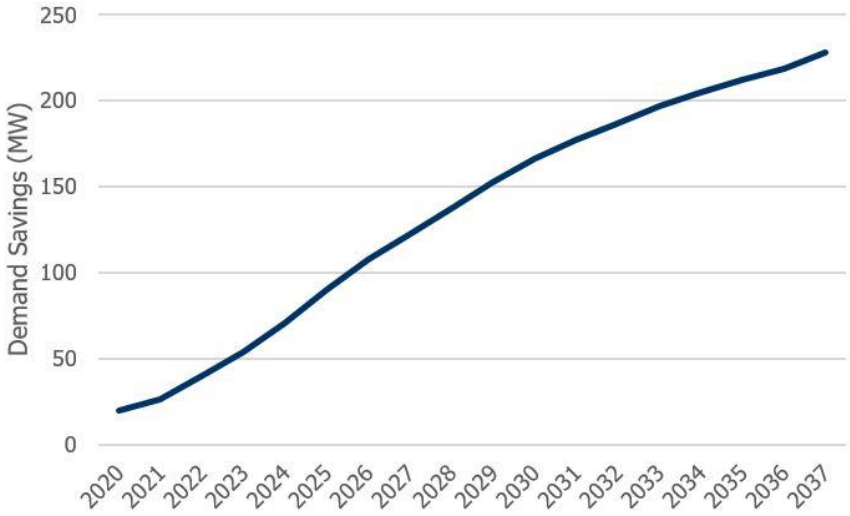


Figure 12 | Cumulative Maximum Achievable Zonal Potential as a Share of Consumption Net of Committed Savings

Uncommitted cumulative CDM potential that is cost effective based on avoided provincial system energy and capacity costs for stations within the FIO interface is presented in Figure 13. The estimated cost to deliver these savings is $587 million dollars over the forecast period.

Figure 13 | Uncommitted CDM Potential in Ottawa

Ongoing Energy Efficiency Activities in Ottawa

The IESO is currently delivering province-wide Save on Energy-branded CDM programs in the Ottawa area as part of the 2021-2024 CDM Framework to encourage the adoption of energy efficiency process and technologies in businesses and communities.

Additionally, as part of the 2021-2024 CDM Framework,[10] the IESO was directed to deliver a new competitive program to target additional CDM incremental to the province-wide programs to address regional and/or local system needs. The Local Initiative Program,[11] is now one tool that is available to target the delivery of additional CDM savings at specific areas of the province with identified system needs. The IESO is currently working with Hydro Ottawa to develop a Local Initiative Program procurement in order to begin targeting incremental savings opportunities described above and previously highlighted in the 2020 Ottawa IRRP.

As part of the 2021-2024 CDM Framework Mid-Term Review[12] published in December 2022, the IESO reviewed the scale of the opportunity for CDM to be targeted to address regional or local needs, available tools for targeting CDM, and the opportunities for LDCs to building on IESO CDM programs where they can add value to the distribution system. Based on accelerated findings, the Minister of Energy approved a number of IESO recommendations in October 2022, including Local Initiative Program enhancements to reduce barriers to participation and to add flexibility for incentives for DER solutions. The IESO should continue to explore opportunities to target savings in the Ottawa and Peterborough to Quinte regions in order to help address these emerging bulk and regional system needs.

[10] More information about the 2021-2024 CDM Framework is available on the IESO website (link).
[11] More information about the Local Initiative Program is available on the IESO website (link).
[12] More information about the 2021-2024 CDM Framework Mid-Term Review is available on the IESO website (link).

7.3 Comparison of Alternatives

7.3.1 Technical Comparison

A transmission reinforcement to Dobbin TS in Peterborough, regardless of whether the transmission line comes from Cherrywood TS in Pickering or Clarington TS in Oshawa, accommodates the 20-year long-term forecast for Peterborough to Quinte West. In addition, the transmission reinforcement provides an additional 70 MW of supply capacity for the area beyond the current demand forecast. This margin will allow for additional growth beyond the forecast and enables the area to better respond to demand forecast changes (i.e. greater penetration of electrification, industrial/manufacturing growth).

Furthermore, the current limiting constraint to Ottawa's LMC is the upstream thermal overload of P15C. The transmission reinforcement to Dobbin TS in Peterborough not only addresses the Peterborough to Quinte West need, but also addresses this upstream thermal limitation for Ottawa.

Lastly, if the proposed transmission reinforcement originates from Cherrywood TS in Pickering, the new transmission line may potentially benefit new load connections in the northern areas of Pickering, Whitby, and Oshawa around and north of highway 407 further into the future.

In comparison, the resource alternative to address this upstream thermal overload will require a resource between 175 and 225 MW, which will need to run frequently (30% of hours by year 10 of the forecast and 80% of hours by year 20 of the forecast). The analysis considered a CCGT facility and hybrid storage facility (BESS with wind) as the most feasible NWA alternatives due to the energy requirements.

With the upstream thermal overload of P15C resolved, either by the transmission reinforcement to Dobbin TS or the resource alternative, the focus becomes addressing the voltage instability issue and the forecast capacity requirements in Ottawa. Refurbishing the EOL transmission lines T22C and T33E mostly maintains the status quo. The improvement in the LMC to 1950 MW is mostly attributed to mitigating the upstream thermal overload of P15C and the addition of a load rejection RAS in Ottawa.

The second transmission alternative, building a new double circuit 230 kV transmission line from St. Lawrence TS in Cornwall to Merivale TS in Ottawa provides a small improvement to the voltage instability issue and increases the Ottawa LMC to 2050 MW. While this alternative introduces a new 230 kV supply into west Ottawa which would help in the resiliency of supplying west Ottawa loads, by not refurbishing T22C and T33E, part of that improvement is counteracted by the decommissioning.

The third transmission alternative, building a new single circuit 500 kV transmission line from St. Lawrence TS in Cornwall to Hawthorne TS in Ottawa, provides another small improvement to the voltage instability issue and increases the Ottawa LMC to 2150 MW.

The three transmission alternatives result in varying Ottawa LMCs of 1950, 2050, and 2150 MW. With the three alternatives, the improvement in LMC will be able to accommodate the reference Ottawa demand forecast up to year 2037, 2039, and 2041 respectively. While the alternative to refurbish T22C and T33E results in the lowest Ottawa LMC out of the three, maintaining the status quo helps preserve the capacity that T22C and T33E provides to Ottawa, which in the future can be combined with a new transmission line reinforcing Ottawa that may be needed in the future to accommodate a high growth scenario (i.e. such as electrification).

The resource alternative is sized to meet the demand forecast. Depending on the technology, if a BESS were implemented, the resource could also be installed in modules as the demand grows.

7.3.2 Cost Comparison

The IESO compared the net present value (NPV 2021$) of total costs and benefits for various alternatives required to address the Peterborough to Quinte West and Ottawa supply capacity requirements.

This economic evaluation was based on available cost estimates for similar sized resources and planning estimates for the proposed transmission facilities constructed based on similar past projects. The costs for each solution package are summarized in Table 4. More information regarding cost assumptions is described in Appendix D.

The three transmission only packages (1 through 3) are very comparable in cost, with incremental steps in cost resulting in incremental steps in supply capacity for Ottawa.

The three other packages (4 through 6) represent a hybrid comprising of both transmission and resources (SCGT/CCGT, BESS, and wind) and also an all resources based solution (SCGT/CCGT, BESS, and wind). The wide range in costs shown here reflects the cost difference between a SCGT/CCGT and a BESS and wind combination.

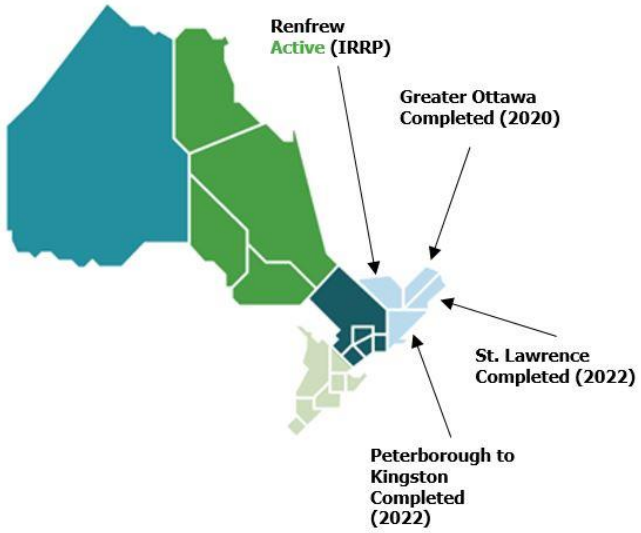
As mentioned earlier, both NWSs and EE provide bulk system capacity and energy benefits and have been taken into consideration as part of the cost analysis.

Based on the technical and cost comparison presented in this section, the IESO recommends solution package #1 to address the EOL needs in the Gatineau corridor and the supply capacity needs in Peterborough to Quinte West and Ottawa. This is further described in section 10 of the report.

8. Linkages with Regional Planning

Bulk system planning as shown in Figure 14 is just one form of electricity planning that is undertaken in Ontario, with the others being regional planning and distribution planning.

Figure 14 | Electricity Planning in Ontario



Planning at the bulk system level typically considers the 230 kV and 500 kV network and examines province-wide system issues. In addition to considering major transmission facilities or "wires," bulk system planning assesses the resources needed to adequately supply the province. This type of planning is typically carried out by the IESO pursuant to government policy. Distribution planning, which is carried out by local distribution companies (LDCs), considers specific investments in an LDC's territory at distribution-level voltages.

Regional planning can overlap with bulk system planning and with the distribution planning of LDCs. For example, overlaps can occur at interface points where there may be regional resource options to address a bulk system issue or when a distribution solution addresses the needs of the broader local area or region, making it important for regional planning to be coordinated with both bulk and distribution system planning.

By recognizing the linkages between bulk, regional and distribution system planning, and coordinating the multiple needs identified over the long term, a comprehensive assessment of electricity needs can be carried out to develop integrated solutions that can address multiple needs.

As a result of the Gatineau corridor being approximately 350 km long, it has linkages with a number of different regions in southern Ontario including Greater Toronto Area East, Peterborough to Kingston, Renfrew, and Ottawa. In this section, key linkages to some of these regions are described. A map illustrating the 21 planning regions in Ontario is shown in Figure 15, with the regions in the east highlighted.

Figure 15 | Planning Regions in Eastern Ontario

8.1 Peterborough to Kingston Region

Regional planning for Peterborough to Kingston was most recently completed in May 2022. This was the first cycle of regional planning for Peterborough to Kingston to reach the integrated regional resource planning and regional infrastructure planning stage where a more in depth examination of power system needs was carried out.

The regional studies identified transmission system issues that have linkages with the upstream transmission system and specifically the Gatineau Corridor EOL Study. The recommended option also addresses the voltage issues on the 115 kV system identified in the 2021 Peterborough to Kingston IRRP[13].

In addition to the coordinated approach to issue identification, the regional planning activities allowed the IESO to obtain very detailed load forecasts that were developed by the Peterborough to Kingston regional planning working group along with valuable insight from the local distributors. The Peterborough to Kingston regional planning load forecast directly informed the load forecast used for the Peterborough to Quinte West area in the Gatineau Corridor End-of-Life study.

8.2 Greater Ottawa Region

Regional planning for Greater Ottawa was most recently completed in December 2020. Through those regional studies, capacity issues with the bulk transmission supply to the Ottawa 115 kV system were identified. This led to a series of near-term actions being recommended through the Ottawa Area IRRP which included:

[13]More information about these transmission issues are available in section 6 of the Peterborough to Kingston IRRP (link).

- Advancing the EOL replacement of the 230-115 kV auto-transformer T22 at Merivale TS which will result in a slightly higher supply capacity
- Triggering of a broader Ottawa 115 kV System Study to be carried out by the IESO (study ongoing)
- Pursue system cost effective energy efficiency in the Ottawa 115 kV system area

In recent months, through discussion with the Greater Ottawa regional planning working group, the IESO was informed of substantial load growth emerging in various areas across the City of Ottawa. The size and aggressive timing of the load growth resulted in the working group's decision to trigger the next cycle of regional planning early (expected to commence in Q4 2022).

Through the next cycle of regional planning, a new detailed 20-year planning forecast will be developed to assess transmission system supplying Greater Ottawa. Further, as described earlier in section 4.2, Ottawa's city council approved the Energy Evolution strategy on October 28, 2020. The impact of Energy Evolution on the peak electricity demand has yet to be quantified and has not been incorporated into the various bulk or regional planning forecasts. The impacts of Energy Evolution on electricity demand will be further explored as part of this next cycle of regional planning.

Depending on the outcomes of regional planning, additional reinforcements to the bulk transmission system may need to be triggered earlier then currently forecast.

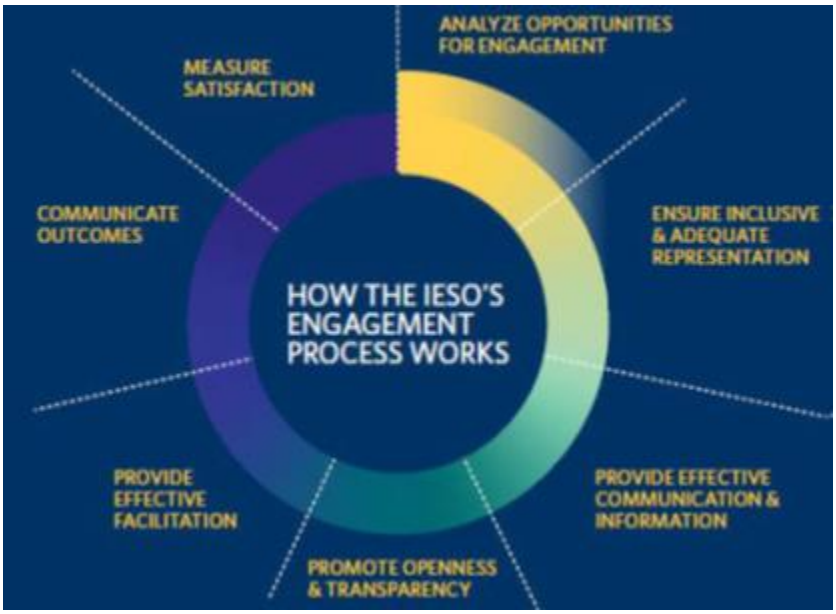
8.3 Greater Toronto Area East

One of the alternatives to addressing the supply capacity issues for Peterborough to Quinte West involves a new transmission line between Dobbin TS in Peterborough and either Cherrywood TS in Pickering or Clarington TS in Oshawa. As indicated in section 7.3.1 the two stations Clarington TS and Cherrywood TS are electrically quite similar in terms of their ability to provide capacity improvements to the Peterborough to Quinte West areas.

However, the option to terminate at Cherrywood TS may have the added benefit of improving the load meeting capability of the local area, namely northern Pickering and Whitby. Based on recent discussion between the IESO and Elexicon Energy, the LDC for this area, updated growth forecasts may trigger the need for additional supply meeting capability in the mid term.

Although growth rates and preferred alternatives for meeting any ensuing needs have not been established through the regional planning process, the Cherrywood connection option offers additional flexibility by accommodating a greater range of future load growth scenarios.

The IESO will continue discussions with the GTA East regional working group members to determine if there is need to trigger the next cycle of regional planning early.



9. Engagement

The IESO has developed and is transitioning to a formalized process[14] for bulk system planning to enhance transparency and opportunities for purposeful engagement and input. As part of that work, defining how stakeholders can participate in the electricity planning process and be kept informed has been identified as a critical component of the process design. Providing opportunities for input in the transmission planning process enables the views and preferences of communities and stakeholders to be considered in the development of the plan, and helps lay the foundation for successful implementation. The IESO has endeavored to encompass those principles throughout the Gatineau Corridor EOL study work. This section outlines the engagement principles as well as the activities

9.1 Engagement Principles

The IESO's engagement principles[15] help ensure that all interested parties are kept informed and enables opportunities for purposeful engagement to contribute to electricity planning initiatives such as the development of this Gatineau Corridor EOL planning study. The IESO adheres to these principles to ensure inclusiveness, sincerity, respect and fairness in its engagements, striving to build trusting relationships as a result.

Figure 16 | The IESO's Engagement Principles

[14] More information about the bulk planning process is available on the IESO website (link).
[15] More information about the IESO's engagement principles are available on the IESO website (link).

9.2 Engagement Approach

To ensure that the bulk plan reflects the needs of Indigenous communities, community members and interested stakeholders, engagement involved:

- Leveraging the East Ontario Bulk Planning Initiatives[16] engagement webpage on the IESO website to post updated information, engagement opportunities, meeting materials, input received and IESO responses to the feedback;
- Regular communication with communities, stakeholders and interested parties through email, East Ontario Electricity Network updates[17], and IESO weekly Bulletin;
- Public webinars; and
- Targeted outreach throughout plan development with municipalities, customers, Indigenous communities and rights-holders, and those with an identified interest in the Gatineau Corridor area.

The Gatineau Corridor EOL study was initiated prior to the IESO implementing a formalized bulk planning process. However, as part of implementation of the new process, three public webinars (two targeting all interested parties and one specifically targeting Indigenous Communities) were held at the remaining major junctures of plan development to give interested parties an opportunity to understand the scope of the study and provide comments on the proposed recommendations.

The webinars received strong participation with cross-representation of stakeholders and municipal and Indigenous community representatives in attendance, and submitting written feedback during a 21-day comment period.

Comments received during this engagement focused on the following major themes:

- **Forecast Risk in Ottawa:** Interest was expressed in better understanding how the study will ensure that Ottawa is positioned to meet emerging electricity needs, in particular needs driven by the City's decarbonisation plans.
- **Resource Cost Assumptions:** Feedback received indicated that updated market information should be incorporated into the study's cost assumptions. A suggestion was provided that the upcoming procurements may allow the IESO to gain a better sense of the current cost of storage for use in future assessments.
- **Scope of Transmission Alternatives:** Questions from engagement participants indicated a general desire to better understand the scoping of the study, and the associated options analysis. In particular, interested parties wanted to understand why the IESO did not consider various wires and non-wire alternative transmission options as part of the study.
- **Consideration of Emerging Growth in GTA East:** Targeted outreach with Elexicon and Durham Region identified emerging load growth in north Whitby that may trigger new load station development.

Based on the engagement discussions and feedback received, it is clear that interested parties want to ensure that the IESO is incorporating the best available information into the study analysis and

[16] More information about East Ontario Bulk Planning Initiatives is available on the IESO website (link).
[17] More information about the East Ontario Electricity Network is available on the IESO website (link).

recommendation so that the final recommendation meets Ontario's future electricity needs and priorities. Section 7 of the report includes the analysis of alternatives.

The bulk planning process is continuing to evolve. The IESO will work to increase transparency and cost discovery around transmission versus generation decision making as resource acquisition mechanisms continue to mature. Outcomes of this engagement will also be incorporated in other related electricity planning work and regional planning processes, such as the next GTA East regional planning cycle.

All background information, including engagement meeting presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's East Ontario Bulk Planning Initiatives engagement webpage.

9.3 Bringing Communities to the Table

The IESO held meetings with communities to seek input on local planning priorities and initiatives that should be taken into consideration in the development of this bulk plan. At major milestones in the study development process, targeted discussions were held with the upper- and lower-tier municipalities both in the East Ontario planning regions as well as in the adjacent GTA East planning area to discuss study recommendations. These meetings helped to inform electricity needs at the municipal/community-level, develop options and recommended solutions, and further build and strengthen local relationships for ongoing dialogue beyond this bulk process.

9.4 Engaging with Indigenous Communities

As part of the engagement process, the IESO reached out to Indigenous communities in and near the Eastern Ontario planning area throughout the development of the plan. Those invited to participate included: Alderville; Algonquins of Ontario (AOO Consultation Office); Algonquins of Pikwakanagan; Association of Iroquois and Allied Indians; Beausoleil; Chippewas of Georgina Island; Chippewas of Rama; Curve Lake; Haudenosaunee Confederacy Chiefs Council; Haudenosaunee Development Institute; Hiawatha; Huron-Wendat Nation; Mississaugas of Scugog Island; Mohawk Council of Akwesasne; Mohawks of the Bay of Quinte; Ogemawahj Tribal Council; MNO High Land Waters Métis Council; MNO Oshawa and Durham Region Métis Council; MNO Ottawa Region Métis Council; and MNO Peterborough and District Wapiti Métis Council.

A webinar for Indigenous communities was held on April 13, 2022. To ensure the invited communities had ample opportunity to participate, after the webinar concluded the presentation deck was emailed to them along with an invitation and registration information for a general webinar that was held on April 14, 2022. Feedback was received from the Haudenosaunee Development Institute which was posted along with the other received feedback on the IESO's engagement page for Bulk Electricity Planning - East Ontario under the entry for May 5, 2022. A general webinar was held on August 11, 2022, an invitation email was sent to the communities on July 19. A link to the materials for East Ontario planning was included and communities were informed that a feedback/comment period would be open until September 1, 2022.

The IESO remains committed to an ongoing, effective dialogue with communities to help shape long-term planning in regions in Ontario.

10. Conclusions and Recommendations

To minimize cost, minimize land-use impacts, mitigate forecast risk, preserve options to increase system capability in the future and due to lack of cost effective stand-alone resource or energy efficiency alternatives, the solution package #1 from Table 4 is recommended to address the transmission equipment EOL needs and accommodate the demand forecast for the Ottawa and the Peterborough to Quinte West areas over the long-term. Solution package #1 includes:

- Refurbish all 800 km of 230 kV circuits on the Gatineau Corridor identified as nearing EOL
- Build a new double circuit 230 kV transmission line into Dobbin TS (in Peterborough) from either Cherrywood TS (in Pickering) or Clarington TS (in Oshawa) with a planned in-service of 2029
- Pursue up to 230 MW of additional system cost-effective energy efficiency in the Ottawa area over the 20 year planning horizon, while monitoring demand growth and resource acquisition activities in the Ottawa zone
- Update and expand the use of remedial action schemes (RAS) in the Peterborough and Ottawa areas to meet planning standards and further improve both areas' LMCs

This solution package represents the lowest cost option, with transmission reinforcements estimated to cost approximately $650 M. The transmission reinforcements ensure reliability in the Peterborough to Quinte West area is sufficient for the next 20 years and reliability in the Ottawa area is sufficient until 2037. If the 230 MW of additional energy efficiency is implemented, the Ottawa area's reliability would also be sufficient over the long-term. By refurbishing the existing Gatineau transmission lines and maintaining the supply capacity these lines provide Ottawa, this preserves the ability to further expand the LMC of Ottawa in the future with new transmission from Cornwall, when required. While there exists some load forecast uncertainties (high growth scenarios such as electrification of vehicles, heating, etc.) that, if materialized, can result in the need for additional improvements in the Ottawa area, this solution package lays the foundation to build on. Transmission planning in Ottawa will continue with the next cycle of regional planning scheduled to begin in Q4 2022.

Beyond monitoring load growth to trigger future system reinforcements when they are required, there are additional options with shorter lead times which could contribute to meeting Ottawa's supply capacity needs should they arise under a high growth scenario, including use of imports from Quebec, local demand response, BESS, and targeting additional energy efficiency in Ottawa.

Lastly, as presented in this report, the new transmission line into Dobbin TS can originate from either Cherrywood TS in Pickering or Clarington TS in Oshawa. While both routes are comparable in terms of addressing the needs for Peterborough to Quinte West and Ottawa, a new transmission line originating from Cherrywood TS may provide additional benefits for potential load connections in the Pickering and Whitby areas. Regional planning for the GTA East region is currently in-between planning cycles (in-active), however the working group members remain engaged in discussion to help inform the final line routing decision.

Appendix A – Planning Assessment Criteria

In developing this bulk plan, the IESO followed a number of steps including:

- Data gathering, including development of electricity demand forecasts;
- Conducting technical studies to determine electricity needs and the timing of these needs;
- Developing potential options; and
- Preparing a recommended plan including actions for the near and longer term.

Throughout this process, engagement was carried out with stakeholders interested in the area, in the form of public webinars and targeted discussions with the affected communities, local distribution companies and transmitters.

This bulk report documents the inputs, findings and recommendations developed through the process described above and provides recommended actions for the various entities responsible for plan implementation. The report helps ensure that recommendations to address near-term needs are implemented, while maintaining the flexibility to accommodate changing long-term conditions.

The overall objectives of planning are consistent among both regional and bulk planning, which are the following:

- Ensure reliability and service quality;
- Enable economic efficiency; and
- Support sector policy and decision making.

There are various reliability standards which, as the electricity system planner and operator, the IESO is obliged to meet. NERC and NPCC membership requires the bulk system be planned to consider specific operating conditions, such as peak and light load, and a set of contingencies to ensure the bulk system is planned reliably and meets standards. Additionally, the IESO is required to demonstrate its adherence to these standards through compliance reporting.

Reliability standards require the IESO to define its own performance criteria to meet under the conditions and contingencies specified. The Ontario Resource and Transmission Assessment Criteria (ORTAC) define the planning performance criteria for Ontario which are more specific and/or more stringent standards than NERC/NPCC. The IESO also considers operational issues and solutions that simultaneously consider bulk system reliability needs, regional needs, and assets reaching end of life, as appropriate.

The study used the planning criteria in accordance with events and performance as detailed by:

- NERC TPL-001 "Transmission System Planning Performance Requirements" (TPL-001),
- NPCC Regional Reliability Reference Directory #1 "Design and Operation of the Bulk Power System" (Directory #1), and
- IESO Ontario Resource and Transmission Assessment Criteria (ORTAC).

In addition to meeting established criteria and standards, the IESO also seeks to enable economic efficiency and support sector policy. Bulk system planning has a role in ensuring policy objectives can be incorporated with maximum benefit to ratepayers, and in identifying opportunities for improving overall system economics, especially in a competitive environment. This includes seeking economic opportunities, such as reducing losses, congestion, or other service costs, facilitate intertie/trade requirements, and providing timely and relevant information to market participants to enhance their participation and decision making leading to greater market efficiency and competition. It also includes supporting policy implementation affecting the power grid, such as sensitivity analysis of the economic impact of carbon pricing policies on congestion costs, as well as considering community energy plans and goals.

Appendix B – Load Forecast and Supply Need Data

The following datasets are included in this section and are also available in the excel file provided:

- Ottawa peak demand forecasts
  - Table 4 & 5: Total coincident reference and high growth scenarios for summer and winter seasons
- Peterborough to Quinte West peak demand forecasts
  - Table 6: Total coincident reference scenario for summer season

Refer to the excel file provided for the following datasets:

- Table 7: Forecast Ottawa Hourly Load (2022 to 2042)
- Table 8: Forecast Peterborough to Quinte West Hourly Load (2019 to 2037)
- Table 9: Forecast Ottawa Hourly Capacity Need (2022 to 2042)
- Table 10: Forecast Peterborough to Quinte West Hourly Capacity Need (2019 to 2037)

Notes:

The planning forecast for the Ottawa area is aligned with the Ottawa Zone demand forecast from the 2021 Annual Planning Outlook (Ottawa planning area aligns with definition of the Ottawa Zone)[18]

The planning forecast for the Peterborough to Quinte West area is aligned with the Peterborough to Kingston Integrated Regional Resource Plan demand forecast (Peterborough to Quinte West need is more local in nature comprising of a small number of stations)[19]

[18] The 2021 Annual Planning Outlook is available on the IESO website (link).
[19] The 2021 Peterborough to Kingston IRRP is available on the IESO website (link).

Appendix C – Assessment of Supply

The IESO assessed supply capacity requirements for Peterborough to Quinte West and Ottawa areas based on the details in the following sections.

Capacity Assessment

A deterministic approach was used to evaluate the need to improve the load meeting capability of the Peterborough to Quinte West and Ottawa areas. A need was identified where the annual coincident load forecast exceeded the total installed capacity of transmission-connected gas generation in winter or summer (discounted by seasonal derates) and the transmission interface transfer limits (FIDS and FIO).

For example, in the Ottawa supply capacity need is identified when the Ottawa demand is larger than the internal generation resources (70 MW, less derates and contract expiry) plus the transmission capacity into the Ottawa area (i.e., on the FIO interface).

The assessment considered the installed capacity of transmission-connected gas generation in winter or summer (discounted by seasonal derates). To be conservative, imports were not considered as part of this assessment (nor exports). The capability of hydro-electric generation is impacted by water levels which varies based on rainfall and snowmelt. The assessment considered the hydro-electric generation at output levels available during 98% of the time historically (i.e. dry conditions).

Appendix D – Economic Assessment Assumptions

The following is a list of the assumptions made in the economic analysis:

1. The NPV of the cash flows is expressed in 2021$ CAD.
2. The USD/CAD exchange rate was assumed to be 0.76.
3. Natural gas price forecast is as per Sproule Outlook @ Dawn used in the 2021 Annual Planning Outlook (APO).
4. The NPV analysis was conducted using a 4% real social discount rate. Sensitivities at 6% and 8% were performed. An annual inflation rate of 2% is assumed.
5. The life of the station upgrades was assumed to be 45 years; the life of the line was assumed to be 70 years; and the life of the generators and BESS was assumed to be 30 years and 15 years respectively. The life of the BESS was based on 3600 cycles, which is assumed to be used to serve the local need first, and then global energy and ancillary services for the rest of the year. Cost of asset replacement were included where necessary to ensure the same NPV study period.
6. Development timelines for transmission was assumed to be 7 years; development timelines for generation and BESS were assumed to be 3 years.
7. A SCGT and CCGT were identified as one of the lowest-cost gas generation resource alternatives, based on escalating values from a previous study independently conducted for the IESO.[20] A sensitivity of +/- 25% was assessed.
8. A BESS was identified as one of the lowest-cost resource alternatives. Total energy storage system costs are composed of capacity and energy costs (i.e. energy storage devices are constrained by their energy reservoir). Costs were based on escalating values from the 2022 NREL Electricity Annual Technology Baseline (ATB)[21]. A sensitivity of +/- 25% was assessed.
9. Sizing of the storage solution was based on meeting the peak capacity and peak energy requirements for the local reliability need, such that the reservoir size is capable of using existing gas resources to sufficiently charge to meet the hours of unserved energy.
10. System capacity value was $570/MW-day (2021$ CAD) based on the estimated Net Cost of New Entry (Net CONE) of the anticipated lowest cost marginal resource that would be developed in Ontario when new generation is required. A sensitivity of +/- 25% assessed.
11. Production costs were determined based on energy requirements to serve the local reliability need, assuming the fixed and variable operating & maintenance costs for the resource.

[20] New natural gas-fired generation was considered in the economic analysis for illustrative purposes to represent the lowest option of new generation.

[21] https://data.openei.org/submissions/4129

12. Carbon pricing assumptions are based on the Ontario Emissions Performance Standards (EPS) program, from $50/t in 2022 to $170/t by 2030, and applied to a new facility's production. A sensitivity of +100% was assessed.
13. The assessment was performed from an electricity consumer perspective and included all costs incurred by project developers, which were assumed to be passed on to consumers.
14. Planning estimates for the various transmission facilities assessed were constructed based on similar past projects with assistance from Hydro One. Transmission line refurbishment for a single circuit transmission line costs were assumed at $500k/km and new transmission line costs were assumed at roughly $3-4M/km.

Appendix E – Sizing Battery Energy Storage Systems

To determine the size requirements of BESS that could serve this local need, the dynamics of the need were investigated in detail to ensure that the potential BESS is able to sequentially charge/inject within the local limitations. The system was sized such that the reservoir would have enough storage capability to charge enough energy (MWh) overnight and inject it the next day, with enough capacity (MW) to shave the peak such that it never exceeds the transmission limit.

To accomplish this, a methodology was derived to size BESS for local needs. In general, the model inputs are the local load profile, local transmission limits to avoid, and local energy available for charging the BESS. These inputs are at the hourly granularity, and typically projected for many future years. The first step of the algorithm is to determine the largest peak power capacity requirement (i.e. the single hour where the local load is highest above the transmission limit) and the largest peak energy requirement (i.e. the largest amount of energy required to shave the biggest peak) for the year.

This Integrated Regional Resource Plan (IRRP) was prepared by the Independent Electricity System Operator (IESO) pursuant to the terms of its Ontario Energy Board licence, EI-2013- 0066.

This IRRP was prepared on behalf of the Technical Working Group of the Parry Sound/Muskoka sub-region which included the following members:

- Independent Electricity System Operator
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Alectra Utilities
- Elexicon Energy
- Lakeland Power
- EPCOR Electricity Distribution Ontario Inc.
- Newmarket-Tay Power Distribution Ltd.

The Technical Working Group assessed the reliability of electricity supply to customers in the Parry Sound/Muskoka sub-region over a 20-year period beginning in 2021; developed a plan that considers opportunities for regional coordination in anticipation of potential demand growth and varying supply conditions in the region; and developed an implementation plan for the recommended options, while maintaining flexibility in order to accommodate changes in key conditions over time.

The Parry Sound/Muskoka Technical Working Group members agree with the IRRP's recommendations and support implementation of the plan, subject to obtaining necessary regulatory approvals and appropriate community engagement and consultations. The Parry Sounds/Muskoka Technical Working Group members do not commit to any capital expenditures and must still obtain all necessary regulatory and other approvals to implement recommended actions.

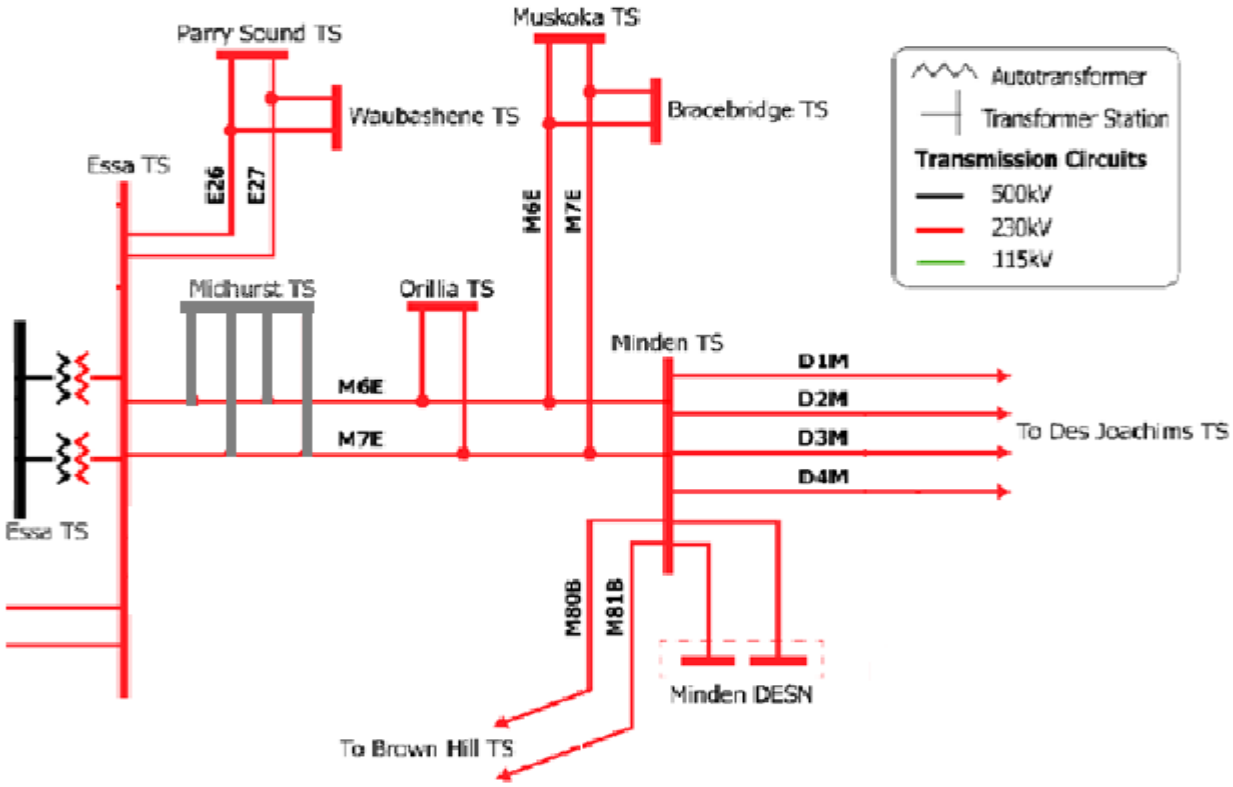
1. Introduction

This IRRP addresses the electricity needs of the Parry Sound/Muskoka sub-region over the next 20 years from 2021 to 2040. The Parry Sound/Muskoka sub-region is located in the South Georgian Bay Muskoka region and it encompasses the Districts of Muskoka and Parry Sounds and the northern part of Simcoe County.

The Parry Sound/Muskoka sub-region is winter peaking. Electrical supply to the sub-region is provided through the autotransformers at Essa TS (near Barrie) and Minden TS and the 230 kV transmission lines and step-down transformers as shown in Figure 1. Generation in the area includes the Des Joachims Hydroelectric Generating Station (GS) and the Henvey Inlet Wind Inlet GS.

The electricity within the sub-region is supplied by six local distribution companies (LDCs): Hydro One Networks, Alectra Utilities, Elexicon Energy, Lakeland Power, EPCOR Electricity Distribution Ontario Inc. and Newmarket-Tay Power Distribution Ltd. The transmission asset owner is Hydro One Networks. This IRRP report was prepared by the IESO on behalf of the Technical Working Group composed of the six LDCs and transmitter.

In Ontario, planning to meet the electrical supply and reliability needs of a large area or region is conducted through regional electricity planning, a process that was formalized by the Ontario Energy Board (OEB) in 2013. In accordance with this process, transmitters, distributors and the IESO are required to carry out regional planning activities for each of the province's 21 electricity planning regions, including the South Georgian Bay Muskoka region, at least once every five years.



This is the second cycle of regional planning for the Parry Sound/Muskoka sub-region. This cycle began in 2020 with the publication of the South Georgian Bay Muskoka Needs Assessment Report. This was followed by a Scoping Assessment which identified needs that should be addressed through the IRRP process and recommended two IRRPs; one for Parry Sound/Muskoka sub-region and another for Barrie/Innisfil sub-region. A Technical Working Group was then formed to gather data, identify electricity needs in the region and developed recommendations included in this Parry Sound/Muskoka IRRP.

This IRRP report is organized as follows:

- A summary of the recommended plan for the Parry Sound/Muskoka sub-region is provided in Section 2;
- The process and methodology used to develop the plan is discussed in Section 3;
- The context for electricity planning in the Parry Sound/Muskoka sub-region and the study scope are discussed in Section 4;
- The demand forecast and conservation and demand management (CDM) and distributed generation (DG) assumptions are described in section 5;
- Electricity needs in the Parry Sound/Muskoka sub-region are presented in Section 6;
- Alternatives and recommendations to address electricity needs are addressed in Section 7;

- A summary of engagement activities is provided in section 8; and
- The plan conclusion is provided in Section 9.

Figure 1| Parry Sound/ Muskoka Electricity System

2. The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of the Parry Sound/Muskoka sub-region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by North American Electric Reliability Corporation (NERC). The IRRP's recommendations are informed by an evaluation of options, representing alternative ways to meet the needs, that considers: reliability, cost, technical feasibility, maximizing the use of the existing electricity system (where economic), and feedback from stakeholders.

The following sections provide details of the needs identified and the recommendations to address these needs. The needs were identified over two main planning horizons, i) 7 to 10 years as near to medium-term and ii) beyond 10 years as longer-term. These planning horizons are distinguished in the IRRP to reflect the different levels of forecast certainty, lead time for development, and planning commitment required over these time horizons.

2.1 Needs in the Near to Medium-Term Horizon and Recommendations

The summary of recommendations for the needs in the near to medium-term horizon is listed in the table below.

Table 1 | Summary of Near/Medium-term Plan for Parry Sound/Muskoka IRRP

Need Description	Recommendation	Lead Responsibility	Required by
Waubaushene TS over its summer 10-day Limited Time Rating (LTR)	Consider incremental, cost-effective CDM to defer the need arising in 2027 until the transformers are replaced for end-of-life. If by 2024 there are no commitments for incremental, cost-effective CDM, implement alternative solution such as advancing the end-of-life replacement of the transformers. The Regional Infrastructure Plan (RIP) will further explore this backstop solution	Technical Working Group Hydro One	2024 2027
Sections of M6E/M7E circuits to reach end-of-life	Like for like replacement	Hydro One	2024

Need Description	Recommendation	Lead Responsibility	Required by
Sections of D1M/D2M circuits to reach end-of-life	Like for like replacement	Hydro One	2028

2.1.1 Consider Incremental Cost Effective CDM at Waubaushene TS

Waubaushene TS peak demand forecast will exceed its 10-day LTR rating by 2027 and the existing transformers are reaching end-of-life in 2030. Assessments as part of this IRRP indicate that incremental, cost-effective CDM is a good candidate for deferring this need until the transformers can be replaced as part of their planned sustainment and is the recommended action. However, no provincial framework for CDM programs in 2027 currently exists, and, therefore, the TWG will continue to monitor these developments following plan completion and explore various pathways for incremental cost-effective CDM. If this CDM cannot be committed by 2024[1], the TWG recommends that a backstop solution be implemented, such as advancement of the end-of-life transformers. The backstop solution will be further explored in the Hydro One led RIP.

2.1.2 Like for Like Replacement for sections of 230 kV circuits M6E/M7E and D1M/D2M

Sections of 230 kV circuits M6E/M7E and D1M/D2M will reach end-of-life by 2024 and 2028 respectively. A like-for-like approach is recommended for the replacement of these assets.

2.2 Needs in Longer-Term Horizon and Recommendations

In the longer-term horizon, minor station capacity needs have been identified at Minden TS starting in 2038. A longer-term supply capacity need has also been identified on 230 kV circuit M6E for a Minden HL7 Breaker Failure (BKF).

While this need is expected to arise in the longer-term, potential options were contemplated to inform future plans. The analysis showed that incremental, cost-effective CDM is potentially a good candidate to defer this need, when considering the need characteristics. Given the time of the need, no firm recommendation is required at this time; however, it is recommended to continue to consider incremental, cost-effective CDM as an option in between planning cycles and bring these insights into the next cycle of regional planning for the region.

2.2.1 Supporting Community Energy Plans and Monitoring Energy Efficiency and Electrification Trends

Three main plans in the sub-region have been identified when pertaining to energy and climate change in communities. These include:

[1] This year has been selected on the basis of the lead-time for the backstop solution, i.e., to advance the end-of-life transformers.

- The Integrated Community Energy Climate Action Plans (ICECAP) for the townships for the Archipelago, Carling, Georgian Bay, McKellar, Seguin, Georgian Bay; the Town Parry Sound; Municipality of McDougall; Chimnissing/Beausoleil, Dokis, Henvey Inlet, Magnetawan, Moose Deer Point, Sawanaga, Wahta Mohawk and Wasauksing First Nations; and Wiikwemkoong Unceded Territory
- Sustainable Seven Sound (SSS) supported by seven municipalities in the County of Simcoe and the district Municipality of Muskoka including the Towns of Midland and Penetanguishene and the Township of Georgian Bay, Severn, Oro-Medonte, Tiny and Tay
- Energy Management Plan for Village of Sundridge and Township of Joly and Strong

The scope varies by municipality and plan but the general aim is to improve energy efficiency, building greater resiliency, lower greenhouse gas emissions, and invest in the local economy.

While the IRRP seeks to align with these plans where possible, not all of the objectives fall within the scope of the regional planning nor the IESO's mandate. For example, absent of provincial government policy, the IESO is technology agnostic and will generally choose the most economic option that adequately resolves the need and meets applicable reliability standards. Greenhouse gas emissions are considered in the IRRP's options analysis by accounting for the carbon price associated with emitting resources, but the IESO does not have emission reduction targets unless directed by government policy. Furthermore, while regional planning is responsible for ensuring electricity ratepayer value and minimizing electricity costs, the IESO relies on government policy for broader socioeconomic considerations.

There are three climate energy plan (CEP) objectives that the IESO and regional planning can play a role in supporting. First, the IESO recognizes that distributed energy resources (DER) are becoming increasingly prevalent and features prominently in many CEPs. DERs can provide benefits to both customers as well as the distribution and transmission systems. By enabling DERs to provide wholesale services, system costs can be reduced and opportunities for customers and investors can be increased. The IESO's Enabling Resources Program (ERP) will produce a 5-10 year plan to enable resources to provide services they cannot or cannot fully currently provide. The ERP has identified storage, hybrids, and DERs as high-priority opportunities. The IESO developed a DER roadmap in the fall of 2021 to provide clarity on IESO objectives, initiatives, and timing for DER integration and is completing a DER Potential Study by June 2022. More information can be found on the Distributed Energy Resource Roadmap engagement page.

Second, the Technical Working Group will continue to support and monitor energy efficiency uptake. Conservation expected to be achieved through codes, standards, and program delivery has already been included in the planning forecast as described in Section 5.4. On September 30, 2020, the IESO received a Ministerial directive to implement a new 2021-2024 CDM Framework. The new CDM Framework will contribute to lowering the net demand as seen on the transmission system and ensures energy efficiency can continue to play a role in meeting the region's needs. The Technical Working Group will monitor uptake of the CDM framework as well as energy efficiency initiatives in CEPs and assess the impact of these additional savings on the timing of local reliability needs.

Finally, the Technical Working Group will monitor electrification trends and their impact on the demand forecast. The Technical Working Group recognizes that many CEPs are calling for ambitious electrification targets as a means to achieve carbon emission reductions. It is not yet clear how impactful electrification will be to the load forecast in the near-term but it could drive significantly higher demand in the long term that will necessitate new electricity supply into the area. While it is still difficult to establish when firm investments or infrastructure reinforcements will be needed, it is prudent to prepare for a future where electricity demand could potentially be significantly higher than forecast.

3. Development of the IRRP

3.1 The Regional Planning Process

In 2013, the OEB created a formal process for regional planning which is carried out by the IESO, in collaboration with the transmitters and LDCs in each planning region. The regional planning formal process sets out 21 different electricity planning regions for the province. Regional planning assesses the interrelated needs of a region over the near, medium, and long term and develops a plan to ensure cost-effective, reliable electricity supply. Regional plans consider the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluate options for addressing needs, and recommend actions to be undertaken.

The process consists of four main components:

1. A Needs Assessment, led by the largest transmitter in the region, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;

2. A Scoping Assessment, led by the IESO, which identifies the most appropriate planning approach to address identified needs;

3. An IRRP, also led by the IESO, which proposes recommendations to meet the identified needs requiring coordinated planning; and/or

4. A RIP, led by the transmitter, which provides further details on recommended wires solutions.

Further details on the components of the regional planning process in Ontario and the IESO's approach to regional planning can be found in Appendix A.

In addition to regional planning, there are also bulk system planning and distribution network system planning processes. Bulk system planning typically considers the 230 kV and 500 kV network and examines province-wide system issues whereas distribution network planning considers the supply of electricity within an LDC's system. Regional planning is the intersection of those two.

A review of the regional planning process was finalized in 2021 following the completion of the first cycle of regional planning for all 21 regions. The Regional Planning Process Review Final Report is published on the IESO's website.

3.2 Parry Sound/Muskoka and IRRP Development

The process to develop the Parry Sound/Muskoka IRRP was initiated following the publication of Hydro One's South Georgian Bay Muskoka Needs Assessment report in April 2020 and the IESO's Scoping Assessment report in November 2020. The Scoping Assessment report recommended that the needs identified for the Parry Sound/Muskoka sub-region be considered through an IRRP in a coordinated regional approach. The Technical Working Group was then formed to develop the terms

of reference for this IRRP, gather data, identify needs, develop options and recommend solutions in the sub-region.

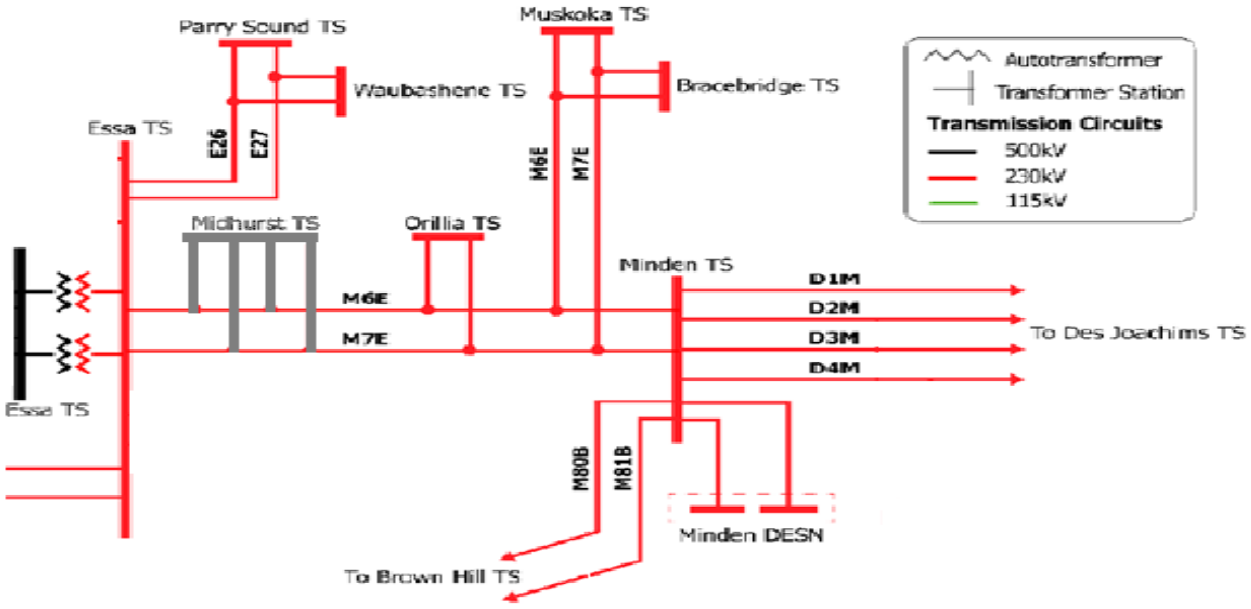
4. Background and Study Scope

This is the second cycle of regional planning for the Parry Sound/Muskoka sub-region. During the first cycle of regional planning, a Needs Assessment was conducted for the South Georgian Bay Muskoka Region in March 2015 that was led by Hydro One Networks Inc. Transmission. After reviewing the needs identified in the report, the Technical Working Group recommended that further regional coordination should be considered and a Scoping Assessment was published in June 2015 which recommended coordinated planning through an IRRP. Subsequently, the IRRP for Parry Sound/Muskoka was published in December 2016 and the RIP was published in August 2017.

This cycle of regional planning started with a Needs Assessment published by Hydro One in April 2020 which identified a number of needs requiring further regional coordination. This was followed by a Scoping Assessment which was published in November 2020. This report recommended an IRRP be initiated. This report presents an integrated regional electricity plan for the next 20-year period starting from 2021.

4.1 Study Scope

This IRRP was prepared by the IESO on behalf of the Technical Working Group and recommends options to meet the electricity needs of the Parry Sound/Muskoka sub region for the study period with a focus on providing an adequate, reliable supply to support community growth. The plan includes consideration of forecast electricity demand growth, conservation and demand management (CDM), distributed generation (DG), transmission and distribution system capability, relevant community plans, condition of transmission assets and developments on the bulk transmission system.



The following transmission facilities were included in the scope of this study:

Step-down transformer stations: Parry Sound TS, Waubaushene TS, Orillia TS, Bracebridge TS, Muskoka TS and Minden TS.

Transmission lines: D1M, D2M, D3M, D4M, E26, E27, M6E, M7E, M80B, M81B

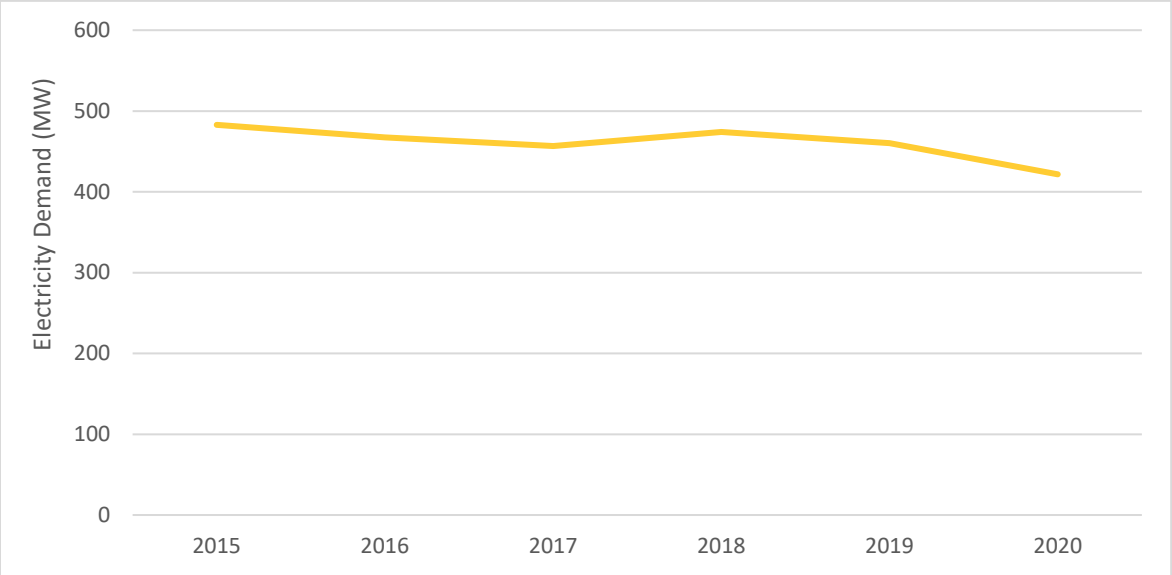
The single line diagram of the Parry Sound Muskoka sub-region is shown in Figure 2 below. Note that Midhurst and Essa are not within the scope of the this IRRP.

Figure 2 | Single Line Diagram of Parry Sound/ Muskoka Sub-Region

The Parry Sound/ Muskoka IRRP was developed by completing the following steps:

- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe;
- Examining the Load Meeting Capability (LMC) and reliability of the existing transmission system, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC and NERC planning criteria;
- Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO controlled grid as described in section 7 of ORTAC;
- Confirming identified end-of-life asset replacement needs and timing with LDCs;
- Establishing alternatives to address system needs, including, where feasible and applicable, possible energy efficiency, generation, transmission and/or distribution, and other approaches such as non-wires alternatives;
- Engaging with the community on needs, findings and possible alternatives;
- Evaluating alternatives to address near and long-term needs; and
- Communicating findings, conclusions and recommendation within a detailed plan.

5. Electricity Demand Forecast



Regional planning in Ontario is driven by the need to meet peak electricity demand requirements in the region under study. This section describes the specific details of the development of the demand forecast for the Parry Sound/Muskoka sub-region. It highlights the assumptions made for peak demand forecasts including the contribution of CDM and distributed generation to reducing peak demand. The resulting net demand forecast, termed the planning forecast, is used in assessing the electricity needs of the area over the planning horizon.

To evaluate the reliability of the electricity system, the regional planning process is typically concerned with the coincident peak demand for a given area. This is the demand observed at each station for the hour of the year in which overall demand in the study area is at a maximum. This differs from a non-coincident peak, which refers to each station's individual peak, regardless of whether these peaks occur at different times. Within the Parry Sound/Muskoka sub-region, the peak loading hour for each year occurs in the winter.

5.1 Historical Electricity Demand

Electricity demand in the Parry Sound/Muskoka sub-region is primarily driven by residential and commercial customers and demand typically peaks during the winter months. However, station capacity needs arise in the summer as the ratings are lower then. The historical demand is shown below in Figure 3. The technical Working Group determined 2020 to be the base year to be used for developing the planning load forecast. The historical peak demand has decreased from 480 MW in 2015 to 420 in 2020.

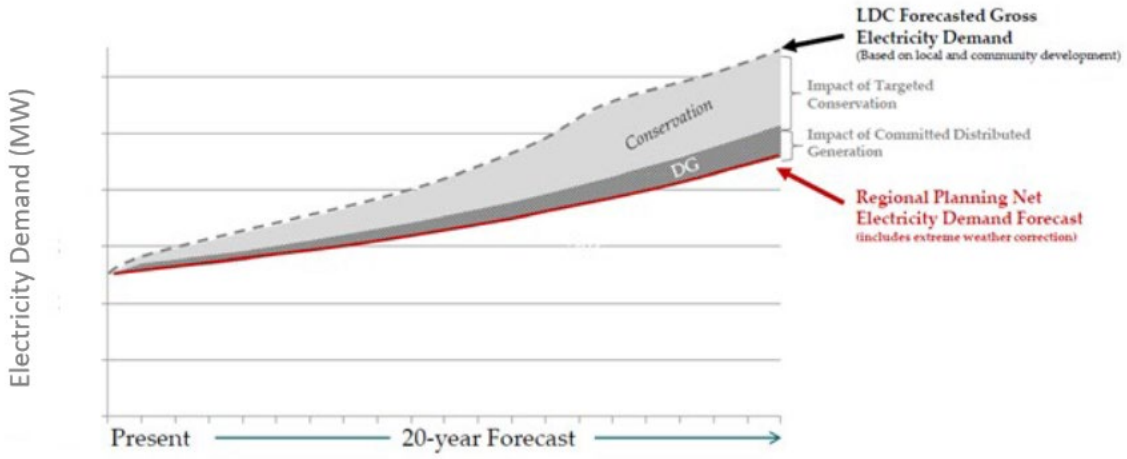


Figure 3 | Historical Winter Peak Demand – Parry Sound/ Muskoka Sub-Region

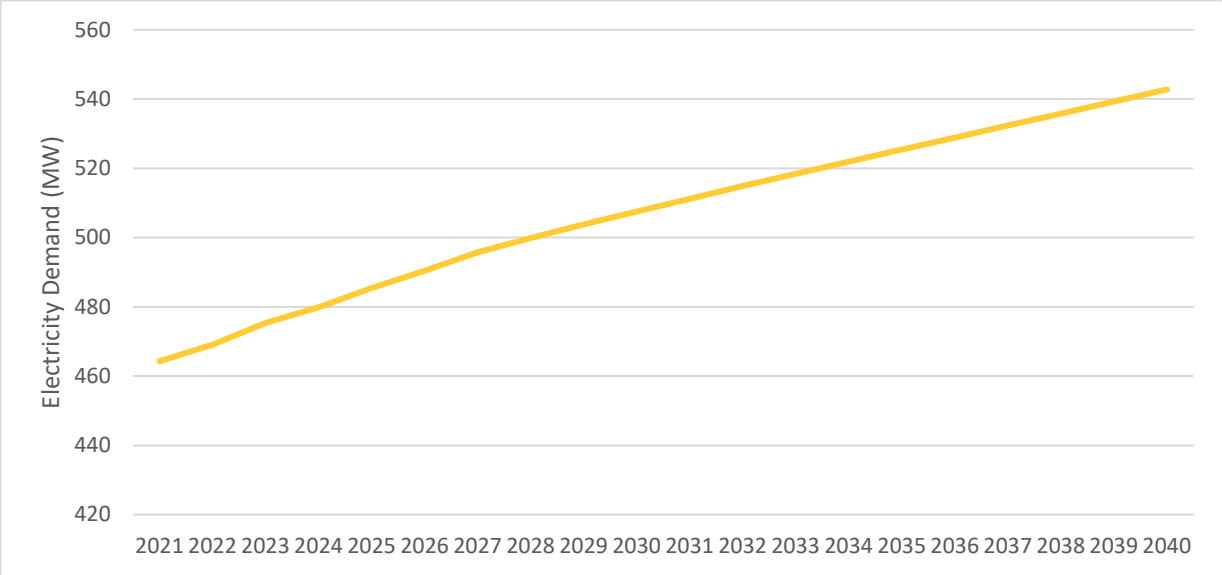
5.2 Demand Forecast Methodology

A 20-year regional peak demand forecast was developed to assess reliability needs for the Parry Sound/Muskoka sub-region; Figure 4 shows the steps taken to develop this. Gross demand forecasts, which assume the weather conditions of an average year based on historical weather conditions i.e., normal weather, were provided by the LDCs. These forecasts were then modified to reflect the peak demand impacts of provincial conservation savings and DG contracted through previous provincial programs such as FIT and microFIT. The forecasts were then adjusted to reflect extreme weather conditions in order to produce a reference forecast for planning assessments to assess the electricity needs in the region. Additional details related to the development of the demand forecast are provided in Appendix B.

Figure 4 | Illustrative Development of the Demand Forecast



5.3 Gross Demand Forecast

Gross demand forecasts were submitted by each participating LDC in the Parry Sound/Muskoka sub-region. This is because LDCs have better insights of future local demand growth and drivers due to their direct involvement with their customers. This insight includes future connection applications and knowledge regarding typical electrical demand for different types of customer groups. Through engagement for the Parry Sound/Muskoka sub-region, it was communicated that Seguin Township submitted a Minister Zoning Order (MZO) in January 2022 to rezone land along the southern border of the town of Parry Sound for future housing development. The municipality of Parry Sound opposed the MZO application and listed four studies Seguin need to provide before the municipality of Parry Sound can partner with Seguin Township on the project. Also mentioned as part of engagement, was growth of a Parry Sound industrial park. Since these developments had not been committed yet, they were not considered in the gross demand forecasts submitted by the LDCs. These developments will be monitored in between regional planning cycles.

The LDC gross demand forecasts account for increases in demand due to new or intensified development, economic growth, population growth, changes in consumer behaviour, etc. Most LDCs cited alignment with municipal and regional official plans and credited them as a primary source for input data. LDCs are also expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices, i.e., "natural conservation", but not for the impact of future DG or new conservation measures, such as codes and standards and CDM programs, which are accounted for by the IESO as discussed in Section 5.4 below. The gross LDC forecast assumes median on-peak weather conditions.

More details on the LDCs' load forecast methodology can be found in Appendix B. Figure 5 below shows the total gross coincident LDC forecast for both summer and winter weather.

Figure 5 | LDC Coincident Gross Winter Demand Forecast – Median Weather

5.4 Contribution of Conservation to the Demand Forecast

CDM helps in meeting Ontario's electricity needs by reducing demand. This is achieved through a mix of codes and equipment standards amendments as well as CDM program-related activities.

Demand reduction due to codes and standards are based on expected improvement in the codes for new and renovated buildings and through regulation of minimum efficiency standards for equipment used by specified categories of consumers. Program-related activities include Save on Energy programs, as well as those that are being implemented as part of the 2021-2024 CDM framework.

CDM savings have been applied for the Parry Sound/Muskoka sub-region gross peak demand forecast for median weather, along with DG (as described in section 5.5) to determine the net peak demand for the sub-region. This takes into account both policy-driven conservation through the provincial CDM Framework, as well as expected peak demand impacts due to building codes and equipment standards for the duration of the forecast.

The final estimated conservation peak demand reductions applied to the gross demand forecast is shown in Table 2 for a selection of the forecast years. Additional details are provided on Appendix B.

Table 2 | MW Savings from Conservation and Demand Management

Year	2022	2024	2026	2028	2030	2032	2034	2036	2038	2040
Winter Savings (MW)	7	14	17	19	22	24	24	24	24	24

5.5 Contribution of Distributed Generation to Demand Forecast

Distributed Generation is also factored in to offset the Parry Sound/Muskoka sub-region gross peak demand forecast for median weather. No assumptions were made regarding DG growth as in the long-term, the contribution of DG is expected to diminish as contracts expire. The resources that were included in the DG forecast were comprised of a mix of solar and hydroelectric projects. Specific capacity contribution factors were attributed to each resource type in order to estimate the effective capacity that would be available to shave load during the regional peak hours. Upon applying the associated capacity contribution factors to each resource in the DG list, the data was then aggregated on a station level in order to put together a forecast specifying the estimated peak load reduction due to DG output.

The DGs included in this IRRP are distributed connected from the following sites:

- Minden TS
- Muskoka TS
- Orillia TS
- Parry Sound TS
- Waubaushene TS

Effective winter capacity totaled 29 MW in 2022. The expected annual peak demand contribution of contracted DG in the Parry Sound/Muskoka sub-region and capacity contribution factors can be found in Appendix B.

5.6 Net Extreme Weather Planning Forecast

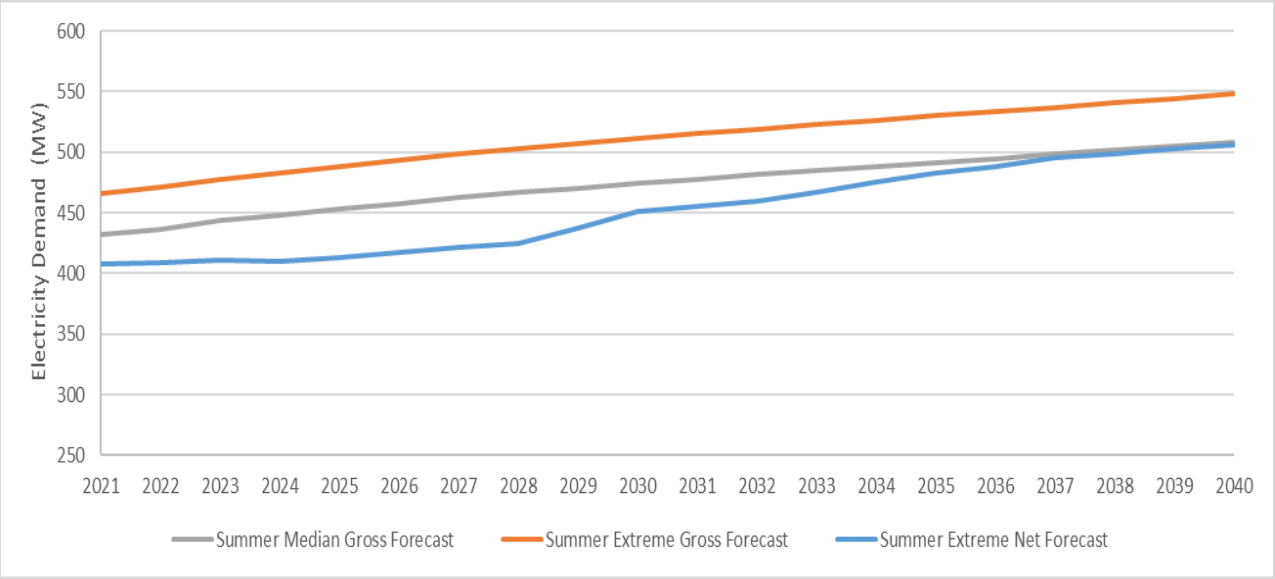
The net extreme weather planning forecast, also known as the "planning" forecast, is the coincident peak demand forecast for the sub-region and is used to carry out system studies for identifying potential needs in the Parry Sound/Muskoka sub-region. This forecast is created in three steps:

1. The gross median weather forecast, provided by the LDCs, is adjusted to extreme weather conditions, according to the methodology described in Appendix B. The result is the gross extreme weather forecast.
2. The impacts of forecast CDM savings and DGs output are added to the gross extreme weather forecast which results in a net extreme weather forecast, or planning forecast.

3. A coincidence factor is applied to convert the forecast to non-coincident. The coincidence factor is based on the contribution of each station to the group's coincident peak over the past five years. Non-coincident station forecasts are utilized for assessing the capacity adequacy of each transformer station in the sub-region.

The net extreme weather forecasts for the Parry Sound/Muskoka sub-region are shown in Figure 6 and Figure 7 below for summer and winter. For comparison, the figures also show the median gross weather forecast and the extreme gross forecast.

Figure 6 | Summer Net Extreme Weather Demand Forecast



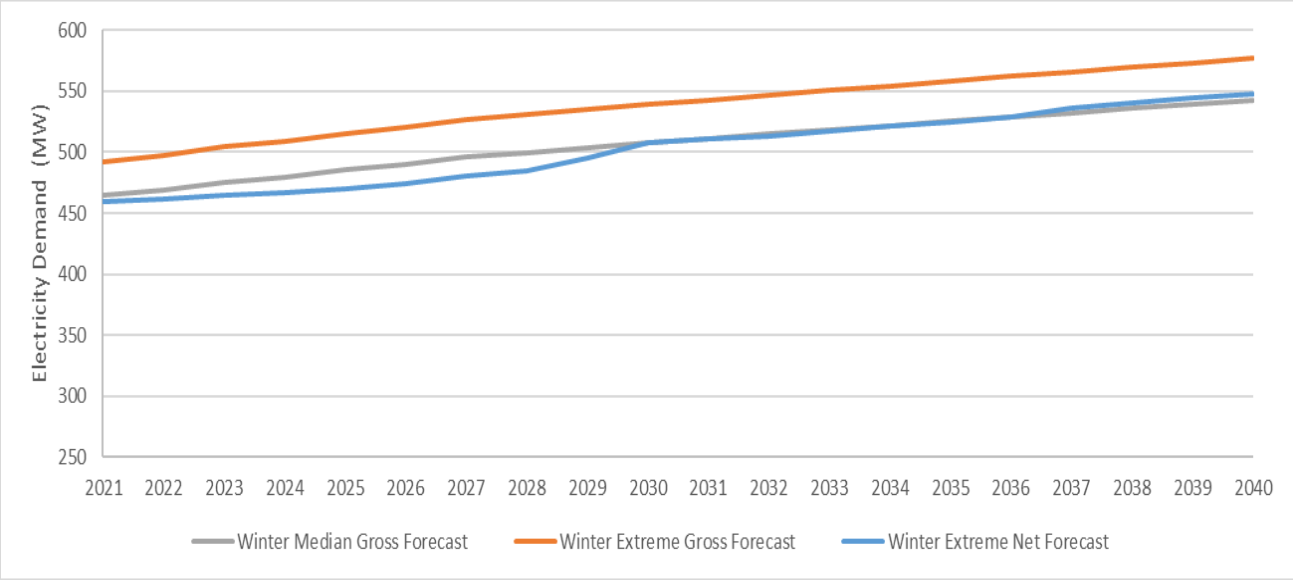


Figure 7 | Winter Net Extreme Weather Demand Forecast

5.7 Load Profiling

In addition to the annual peak demand forecast, hourly load profiles (8,760 hours per year over 20 year forecast horizon) for a number of stations or group of stations with identified needs were developed to characterize their needs with finer granularity. The profiles are based on historical data adjusted for variables that impact demand such as calendar day (e.g. holidays and weekends) and weather (e.g. extreme weather events like ice storms or heat waves) impacts. The profiles are then scaled to match the annual peak forecast for each year. These profiles are used to quantify the magnitude, frequency and duration of needs to better evaluate the suitability of Non-Wires Alternatives (NWA) options.

Additional load profile details including summary tables and hourly heat maps for each need can be found in Appendix B.

5.8 Sensitivity Scenario

A sensitivity scenario was performed for higher demand. This higher demand scenario is to take into account a variety of factors that could drive demand higher; these include but are not limited electric vehicles charging infrastructure and electrified space heating installations in the sub-region. For this, a growth factor of 5% was applied equally to each LDC's station in the sub-region to determine the impact this would have on the need dates identified in system studies.

The higher demand scenario will not be used to drive any firm recommendations for this IRRP; however, it will help the Technical Working Group identify where the future pinch points may be and when they could materialize. This information can be useful for communities conducting Community Energy Plans, for the TWG in determining areas to monitor in future cycles of regional planning, and for communities and stakeholders as they think about various projects in the sub-region.

6. Electricity System Needs

6.1 Needs Assessment Methodology

Based on the net extreme weather planning demand forecast, the transmitter's identified end-of-life asset replacement plans and the application of ORTAC and North American Electric Reliability Corporation (NERC) TPL-001-4 Standard, the Technical Working Group identified electricity needs for the following categories:

- **Station Capacity Needs** describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations at peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day LTR of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be limited when downstream or upstream equipment, e.g., breakers, disconnect switches, low-voltage bus or high voltage circuits, is undersized relative to the transformer rating.
- **Supply Capacity Needs** describe the electricity system's inability to provide continuous supply to a local area at peak demand. This is limited by the LMC of the transmission supply to an area. The LMC is determined by evaluating the maximum demand that can be supplied to an area accounting for limitations of the transmission elements, e.g., a transmission line, group of lines, or autotransformer, when subjected to contingencies and criteria prescribed by ORTAC and TPL-001-4. LMC studies are conducted using power system simulations analysis.
- **End-of-life Asset Refurbishment Needs** describe the needs identified by the transmitter with consideration to a variety of factors such as asset age, the asset's expected service life, risk associated with the failure of the asset and its condition. Replacement needs identified in the near-and early mid-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium-to long-term needs should reflect the potential for the need date to change as condition information is routinely updated.
- **Load Security and Restoration Needs** describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC.

Technical study results can be found in Appendix D. The needs identified are discussed in the section below.

6.2 Needs Identified

Table 3 below summarizes the needs identified by the Parry Sound/Muskoka IRRP.

Table 3 | Summary of Needs for Parry Sound/Muskoka IRRP

No.	Need	Need Description	Need Date
1	Waubaushene Station Capacity	Waubaushene TS demand forecast is over its summer 10-day LTR	2027
2	End-of-Life refurbishment	M6E/M7E section[2]	2024
3	End-of-Life refurbishment	D1M/D2M section	2028
4	M6E/M7E Supply Capacity	After a loss of either M6E or M7E, the remaining circuit will exceed its Long Term Emergency (LTE) rating	2034
5	Minden Station Capacity	Minden TS demand forecast will exceed its summer 10-day LTR	2038

The summary of the location of the needs identified in the Parry Sound/Muskoka sub-region are shown in Figure 8.

Figure 8 | Summary of Location of Needs

[2] Note that the sections of M6E and M7E that are at end-of-life are different than the thermally limited sections

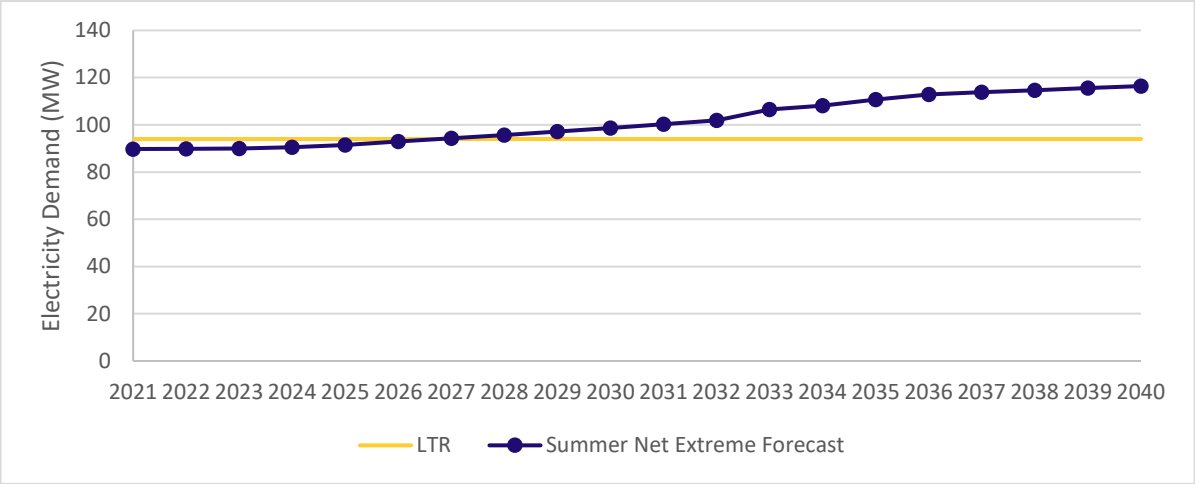
6.2.1 Station Capacity Needs

Table 4 below shows that there are station capacity needs for the Parry Sound/Muskoka sub-region according to the planning forecast. In the near to medium-term, there are station capacity needs at Waubaushene TS. The summer demand forecast for Waubaushene TS exceeds its 10-day LTR by 2027 as seen in Figure 9. In the longer-term, there are capacity needs for Minden TS arising in 2038 as its summer demand forecast exceeds Minden TS 10-day LTR as seen in Figure 10.

Table 4 | Step-down Station Summer Capacity Needs

Station	10-day LTR Rating (MW)	2022 (MW)	2025 (MW)	2030 (MW)	2040 (MW)
Minden TS	52	44.3	44.2	45.8	52.8
Waubaushene TS	94	89.9	91.5	98.6	116.4

Figure 9 | Waubaushene TS Capacity Needs



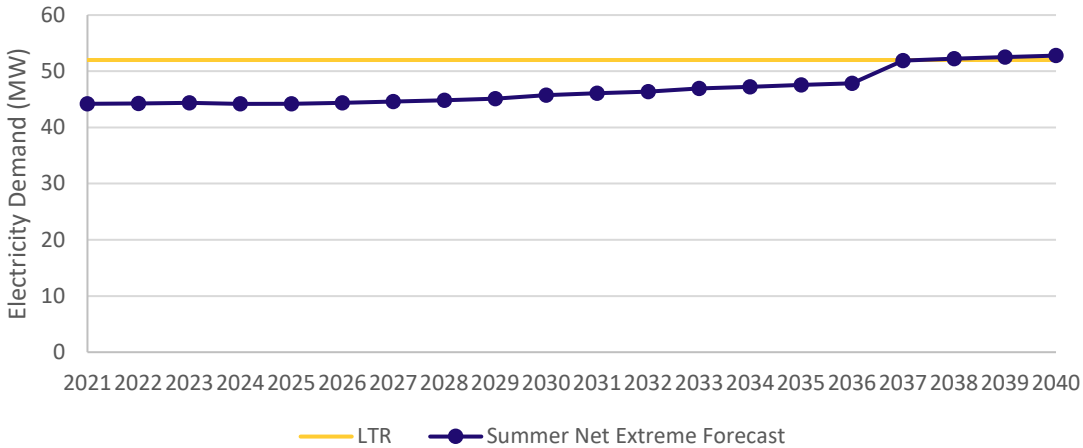


Figure 10 | Minden TS Capacity Needs

In the higher demand sensitivity scenario, the station capacity need is advanced to 2022 for Waubaushene TS and to 2037 for Minden TS.

Besides the station capacity needs identified above, Hydro One's Needs Assessment also identified station capacity need at Parry Sound TS which was identified in the previous cycle of regional planning. The transformers were also assessed at being end-of-life. In order to address the station capacity and end-of-life needs, Hydro One is installing new 230/44 kV 83 MVA transformers which are scheduled to be in service by 2024. The LTRs of the new transformers were applied in the IRRP's assessment of station capacity needs and no further station capacity needs were identified.

6.2.2 Supply Capacity Needs

The circuits M6E and M7E form a 230 kV double circuit from Essa TS to Minden TS. These circuits provide supply to Midhurst, Orillia, Bracebridge and Muskoka. This need occurs for section Minden TS to Cooper Falls JCT (51 km in length) which belongs to the Parry Sound/Muskoka sub-region. M6E section Minden TS to Cooper Falls JCT TS will exceed its LTE rating for a failure of breaker HL7 at Minden HL7 starting in 2038. Also, with M7E already out of service, for loss of Essa T3, M6E is at 133% of its LTE in 2040. Note that in the higher demand sensitivity scenario, this supply capacity need is advanced by two years.

6.2.3 End-of-Life Refurbishment Needs

As per information provided by Hydro One, sections of 230 kV circuits M6E/M7E and D1M/D3M are reaching end-of-life. The in service dates will be 2024 for M6E/M7E and 2028 for D1M/D3M. The end-of-life section includes 25 km from Orillia TS to Cooper Falls JCT for M6E/M7E and 62 km from Minden TS to Otter Creek TS for D1M/D3M.

6.2.4 Load Security and Restoration Needs

There are no load security or restoration needs identified for Parry Sound/Muskoka sub-region for the time frame.

7. Plan Options and Recommendations

In developing the plan, the Technical Working Group considered a range of integrated options. Considerations in assessing alternatives included maximizing use of existing infrastructure, provincial electricity policy, feasibility, cost, and consistency with longer-term needs in the area.

Generally speaking, there are two approaches for addressing regional needs that arise as electricity demand increases:

1. Build new infrastructure to increase the load meeting capability of the area. These are commonly referred to as "wires" options and can include things like new transmission lines, autotransformers, step-down transformer stations, voltage control devices or upgrades to existing infrastructure. Wires options may also include control actions or protection schemes that influence how the system is operated to avoid or to mitigate certain reliability concerns.

2. Install or implement measures to reduce the net peak demand to maintain loading within the system's existing load meeting capability. These are commonly referred to as NWA and can include things like local utility scale generation, distributed energy resources, or conservation and demand management.

The IESO utilized a screening approach for assessing which needs would be best suited to undergoing a detailed assessment for non-wires alternatives, including CDM. The initial screening exercise examined the duration, frequency, timing, and magnitude of the need, as well as cost of traditional wires solutions, for each identified need.

The screening process resulted in NWA being considered for all of the near/medium-term needs to be addressed by the IRRP, except the end-of-life needs. Needs characterization was completed for the Waubaushene TS station capacity need. While the supply capacity need arising on the M6E/M7E circuits is in the longer-term, needs characterization was completed for this need to inform future options.

7.1 Options and Recommendations for Meeting Near/Medium-Term Needs

7.1.1 Waubaushene TS Station Capacity Need

Waubaushene TS will reach end-of-life (EOL) in 2030 and was planned for replacement at this time; however, current needs show an earlier replacement is required. Waubaushene will be over its 10-day summer LTR in 2027.

In terms of non-wires options, the Technical Working Group first reviewed the findings of the Local Achievable Potential (LAP) Study for the Parry Sound and Waubaushene TS service area that was recommended in the last Parry Sound/Muskoka IRRP, and subsequently completed between cycles.

The LAP study was to determine the cost and feasibility of using distributed energy resources (DER) and CDM options to defer needs requiring major capital investments. The LAP explored needs at Parry Sound and Waubaushene and determined that:

1. Dispatchable DERs are required to meet the characteristics of the needs; and
2. There are limited opportunities for dispatchable DER in the area

As part of the development of this IRRP, the Technical Working Group updated the analysis of NWA to ensure it captures the latest information related to option screening, informed by the needs characterization, and options costs. Based on the characteristics of the need, the non-wires alternatives assessment for Waubaushene indicated incremental CDM to be a good candidate for a non-wires solution.

In terms of wires options, the transformers replacement can be advanced and upgraded to larger units to meet the need. However, this requires a lead time of 2-3 years. Another non-wires option considered was energy storage as it is the least cost of the distributed resource options and serves as a benchmark that can be compared with the transformers replacement option.

The table below summarizes the options considered and the net present value of their levelized cost for the Waubaushene station capacity needs.

Table 5 | Options for Waubaushene TS Station Capacity Needs and Costs

	Option	Cost NPV
Wires	Station replacement/upgrade. Transformers are scheduled for replacement in 2030 but this can be advanced and upgraded to larger units. There is an opportunity to align the station capacity needs with EOL replacement; however, a 2-3 year lead time is required	$5 M
Non-wires - Storage	29 MW of storage	$30 M
Non-wires- CDM	Incremental cost effective CDM in the area served by the station	-

It is recommended to consider incremental, cost-effective CDM to defer the need arising in 2027 until the transformers are replaced for end-of-life. If by 2024 there are no commitments for incremental, cost-effective CDM, implement alternative solution such as advancing the end-of-life replacement of the transformers. The RIP will further explore this backstop solution.

7.1.2 D1M/D2M & M6E/M7E (Orillia x Copper) End-of-Life Needs

When equipment reaches the end of its life and requires replacement, a number of options can be considered.

- Replacement of the equipment with "like-for-like" or closest available standard;
- Reconfiguration of existing equipment to "right-size" the replacement option based on:
    - Demand forecast,
    - Changes to the use of the equipment since it was originally installed,
    - Reliability or other system benefits that an alternate configuration may provide; and
- Retirement of equipment, considering the impact on load supply and reliability.

Since no violations were identified for the identified circuits in system studies, a like-for-like replacement with the closest available standard is appropriate and can best address the end-of-life needs at sections of D1M/D2M and M6E/M7E.

7.2 Options and Recommendations for Meeting Longer-Term Needs

For needs appearing in the long term, there is an opportunity to develop and explore options, as specific projects do not need to be committed immediately. This approach is designed to: maintain flexibility; avoid committing ratepayers to investments before they are needed; provide adequate time to assess the success of current and future potential conservation measures in the study area; test emerging technologies; engage with communities and stakeholders; and lay the foundation for informed decisions in the future.

Additionally; the Working Group will monitor changes in growth targets, progress in electrification in the region, and any significant changes in forecast growth. If monitoring activities determine that the region's growth is exceeding the load forecast, it may be necessary to initiate the next iteration of the regional planning process earlier.

7.2.1 Minden Station Capacity Needs

Minden TS is expected to have station capacity needs by 2038. Given the timing of the need, no firm recommendation is required at this time. It is advised to monitor the load growth in the areas and provide enough lead time to capture changes into the next cycle of regional planning where these needs can be revisited.

7.2.2 M6E/M7E (Minden x Copper) System Capacity Need

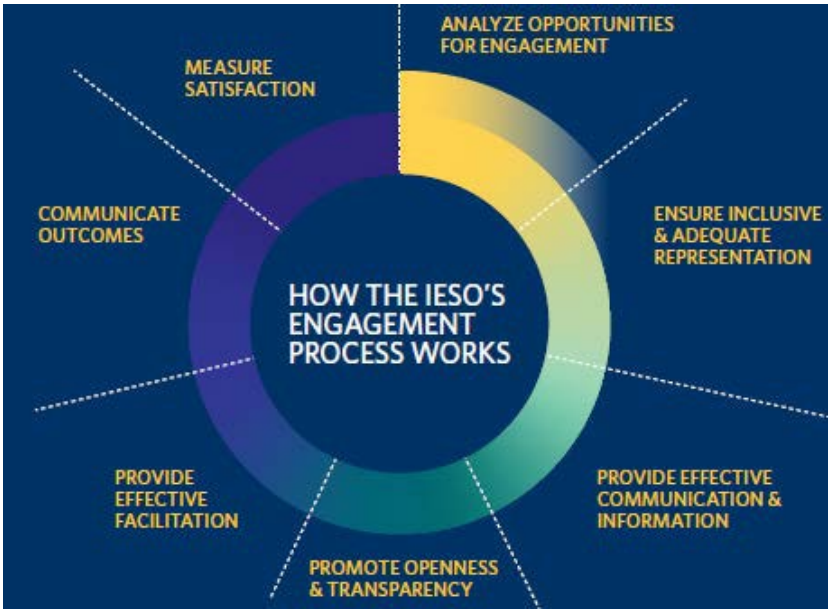
The IRRP considered a number of options including incremental cost-effective CDM and storage, even though this is a longer-term need. This analysis showed that incremental cost-effective CDM is a potentially well-suited for deferring this need. As such, the Technical Working Group should continue to consider incremental, cost-effective CDM in between cycles and in the next cycle of regional planning in the region.

7.3 Summary of Recommended Actions and Next Steps

Table 6, below, summarizes the specific recommendations that should be implemented to address the electricity supply needs in the Parry Sound/Muskoka sub-region.

Table 6 | Summary of Parry Sound/Muskoka IRRP Recommendations

Need Description	Recommendation	Lead Responsibility	Timeline
Minden TS to reach its summer 10-day LTR	Monitor load growth to ensure load supplying capability is maintained; consider in the next cycle of regional planning	Technical Working Group	2038
Waubaushene TS to reach its summer 10-day LTR	Consider incremental, cost-effective CDM to defer the need arising in 2027 until the transformers are replaced for end-of-life. If by 2024 there are no commitments for incremental, cost-effective CDM, implement alternative solution such as advancing the end-of-life replacement of the transformers. The RIP will further explore this backstop solution	Hydro One	2024/2027
M6E/M7E (Minden TS x Cooper Fls JCT) supply capacity	Monitor demand growth in the area; consider CDM option on next cycle of regional planning as a means of deferring transmission upgrade	Hydro One	2034
Sections of D1M/D2M circuits to reach end-of-life	Like-for-like replacement approach	Hydro One	2028
Sections of M6E/M7E Orillia to Cooper to reach end-of-life	Like-for-like replacement approach	Hydro One	2024



8. Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and preferences of communities to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the activities undertaken for the IRRP.

8.1 Engagement Principles

The IESO's engagement principles help ensure that all interested parties are aware of and can contribute to the development of this IRRP. The IESO uses these principles to ensure inclusiveness, sincerity, respect and fairness in its engagements, striving to build trusting relationships as a result.

Figure 11 | The IESO's Engagement Principles

8.2 Creating an Engagement Approach for Parry Sound/Muskoka

The first step in ensuring that any IRRP reflects the needs of community members and interested stakeholders is to create an engagement plan to ensure that all interested parties understand the scope of the IRRP and are adequately informed about the background and issues in order to provide meaningful input on the development of the IRRP for the region.

- Creating the engagement plan for this IRRP involved:
- Discussions to help inform the engagement approach for the planning cycle;

- Developing and implementing engagement tactics to allow for the widest communication of the IESO's planning messages, using multiple channels to reach audiences; and
- Identifying specific stakeholders and communities that should be targeted for one-on-one consultation, based on identified and specific needs.

As a result, the engagement plan for this IRRP included:

- A dedicated webpage on the IESO website to post all meeting materials, feedback received and IESO responses to the feedback throughout the engagement process;
- Regular communication with interested communities and stakeholders by email or through the IESO weekly Bulletin;
- Public webinars;
- Targeted individual and small group meetings; and
- One-on-one outreach with specific stakeholders to ensure that their identified needs are addressed (see Section 8.3).

8.3 Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for this new round of planning and establish new relationships with communities and stakeholders in the region.

An invitation was sent to targeted municipalities, Indigenous communities and those with an identified interest in regional issues to announce the commencement of a new regional planning cycle and invite interested parties to provide input on the draft South Georgian Bay/Muskoka Scoping Assessment Outcome Greater before it was finalized. Feedback received encouraged the IESO to consider renewable technologies to help reduce local demand.

Following a written comment window, the final Scoping Assessment Outcome Report was published in November 2020 that identified the need for a coordinated planning approach done through two sub-regional IRRP: Barrie/Innisfil and Parry Sound/Muskoka.

Following these initial discussions and finalization of the Scoping Assessment, the launch of a broader engagement initiative followed with an invitation to subscribers of the South Georgian Bay/Muskoka region to ensure that all interested parties were made aware of this opportunity for input.

Three public webinars were held at major junctures during IRRP development to give interested parties an opportunity to hear about its progress and provide comments on key components. The webinars received cross-representation of stakeholders and community representatives attending the webinar and submitting written feedback during a 21-day comment period.

The three stages of engagement invited input on:

1. The draft engagement plan, the electricity demand forecast and the early identified needs to set the foundation of this planning work.
2. The defined electricity needs for the region and potential options to meet the identified needs.

3. The analysis of options and draft IRRP recommendations.

All interested parties were kept informed throughout this engagement initiative via email to South Georgian Bay/Muskoka region subscribers, municipalities and communities as well as the members of the GTA/Central Regional Electricity Network.

Based on the discussions both through the Parry Sound/Muskoka IRRP outreach activities and broader network dialogue, there appears to be significant community growth planned in more rural area requiring new infrastructure, and broad interest in electrification, renewable energy solutions, net-zero development, and decarbonisation of electricity supply. To that end, ongoing discussions will continue through the IESO's GTA Central Regional Electricity Network to keep interested parties engaged on local developments, priorities and planning initiatives.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the dedicated IRRP engagement webpage.

8.4 Bringing Municipalities to the Table

The IESO held meetings with municipalities to seek input on their planning and to ensure that these plans were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings with the upper- and lower-tier municipalities in the region were held to discuss: key issues of concern, including forecast regional electricity needs; options for meeting the region's future needs; and, broader community engagement. These meetings helped to inform the municipal/community electricity needs and provided opportunities to strengthen this relationship for ongoing dialogue beyond this IRRP process.

8.5 Engaging with Indigenous Communities

To raise awareness about the regional planning activities underway and invite participation in the engagement process, regular outreach was made to Indigenous communities within the Southern Huron-Perth electricity planning sub-region or that may have interests in the sub-region throughout the development of the plan. This includes the First Nation communities of Alderville, Beausoleil, Chippewas of Georgina Island, Chippewas of Rama, Curve Lake, Henvey Inlet, Hiawatha, Huron-Wendat Nation, Magnetawan, Mississaugas of Scugog Island, Moose Deer Point, Shawanaga, Wahta Mohawks and Wasauksing as well as the Métis Nation Ontario communities of Barrie South-Simcoe Métis Council, Georgian Bay Métis Council and Moon River Métis Council

9. Conclusion

The Parry Sound/Muskoka IRRP identifies electricity needs in the sub-region and opportunities to preserve or enhance system reliability for the next 20 years. This report makes recommendations to address near- to medium-term issues, and lays out actions to monitor, defer, and address long-term needs. The IESO will continue to participate in the Working Group during the next phase of regional planning, the Regional Infrastructure Plan, to provide input and ensure a coordinated approach with bulk system planning where such linkages are identified in the IRRP.

To support the development of the plan, this IRRP includes recommendations with respect to developing alternatives, and monitoring load growth and efficiency achievements. Responsibility for these actions has been assigned to the appropriate members of the Technical Working Group.

The Technical Working Group will meet at regular intervals to monitor developments and track progress toward plan deliverables. In the event that underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the OEB.

REGIONAL INFRASTRUCTURE PLAN

December 16, 2022

[This page is intentionally left blank]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Independent Electricity System Operator (IESO)
Alectra Utilities Corporation (Alectra)
Hydro One Networks Inc. (Distribution)
InnPower
Orangeville Hydro
Elexicon Energy
Lakeland Power
Epcor Electricity Distribution Ontario Inc
Newmarket-Tay Power Distribution Ltd
Wasaga Distribution Inc.

Disclaimer

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Technical Working Group.

Technical Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE TECHNICAL WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE SOUTH GEORGIAN BAY-MUSKOKA REGION.

The participants of the South Georgian Bay-Muskoka Regional Infrastructure Plan ("RIP") Technical Working Group ("TWG") included members from the following organizations:

- Independent Electricity System Operator ("IESO")
- Alectra Utilities Corporation ("Alectra")
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- InnPower
- Orangevile Hydro
- Lakeland Power
- EPCOR Electricity Distribution Ontario Inc.
- Newmarket-Tay Power Distribution Ltd.
- Wasaga Distribution Inc.

This RIP is the final phase of the second cycle of the South Georgian Bay-Muskoka Regional Planning (RP) process. It follows the completion of the South Georgian Bay-Muskoka Integrated Regional Resource Plan ("IRRP") which was subdivided into two sub-regions; Barrie Innisfil and Parry Sound/Muskoka both completed in May 2022. This also follows completion of the South Georgian Bay-Muskoka Needs Assessment ("NA") and Scoping Assessment ("SA") in April 2020 and November 2020, respectively.

The South Georgian Bay-Muskoka RIP provides a consolidated summary of needs and recommended plans for the region over a 10-year planning horizon (2022-2032) based on available information. The load forecast for the 2033-2042 period is provided to show the longer term needs and trend. All needs for this long-term horizon will be reviewed again and confirmed in future regional planning cycles.

The first cycle of Regional Planning process was completed in August 2017 with the publication of the South Georgian Bay-Muskoka RIP report, which provided a description of needs and recommendations of preferred wires plans to address near-term needs.

I. Update on the needs identified during the previous regional planning cycle

The following needs and projects identified in the previous regional planning cycle have been completed:

- Orillia TS M6E/M7E Switches (2021) - Hydro One installed new 230kV motorized disconnect switches on the M6E and M7E circuits (at Orillia TS) to improve load restoration time.

- Minden TS (2021) – Replacement of end-of-life (EOL) 230/44kV 42MVA (T1/T2) transformers with new 230/44kV 83MVA units.

The following needs and projects identified in the previous regional planning cycle are currently underway:

- Parry Sound TS (2023) - Replace existing 230/44kV 42MVA transformers (T1/T2) with new 230/44kV 83MVA units and replace station protection and station service equipment.

- Barrie TS (2023) Replace and upgrade existing 115/44kV 83MVA transformers (T1/T2) with new 230kV/44kV 125MVA transformers. Remove Essa TS T1/T2 autotransformers and convert Barrie TS supply circuits (E3B/E4B) from 115kV to 230kV.

- Orangeville TS (2023)- Replace existing T1/T2 230/44/27.6 kV 75/125 MVA transformers with two 230/27.6 kV 50/83 MVA units and reconfigure the dual voltage switchyard to a standard DESN that would supply the 27.6 kV load. Also replace and upgrade T3/T4 230/44 kV 50/83 MVA transformers with two 230/44 kV 75/125 MVA units to accommodate additional capacity.

II. Newly Identified needs:

The major infrastructure investments in this 2nd cycle recommended by the TWG in the South Georgian Bay-Muskoka Region over the near and medium-term (2022-2032) period are given in Table 1 below, along with their planned in-service date and budgetary estimate for planning purposes.

Table 1. South Georgian Bay-Muskoka Region - Recommended Plans over the 2022-2032 Study Period

Need	Station / Circuit	Investment Description	Lead	Planned In-Service Date[1]	Cost ($M)[2]
Station Capacity	Everett TS	Modify current transformer (CT) ratio setting the low voltage 44kV transformer breakers	HONI	2023	0.5
	Barrie TS	Construct new 230/27.6kV 83MVA transformer station and connect to 230kV E28B/E29B circuits	HONI / Inn Power	2027	44
	Waubaushene TS	Replace and upgrade existing 230/44kV 83MVA transformers (T5/T6) with new 230/44kV 125MVA units.	HONI / Hydro One Dx	2027	20
Asset Renewal - Transmission Line	M6E / M7E (Orillia TS x Coopers Fls)	Replace end- f-life (EOL) transmission line conductor (25km)	HONI	2026	30
	E8V / E9V (Orangeville TS x Essa JCT)	Replace EOL transmission line conductor and associated assets (56km)	HONI	2027	70
	D1M / D2M (Minden TS x Otter Creek JCT)	Replace EOL transmission line conductor and associated assets (62 km)	HONI	2028	70
Asset Renewal - Transmission Station	Wallace TS	Replace existing EOL 230/44kV 42MVA transformers (T3/T4) with new 230/44kV 42MVA units	HONI	2025	25
	Midhurst TS	Replace existing 230/44kV 125MVA EOL transformer (T4) with a new 230/44kV 125MVA unit	HONI	2026	12
	Orillia TS	Replace existing EOL 230/44kV 125MVA transformer (T2) with new 230/44kV 125MVA unit	HONI	2025	12
	Bracebridge TS	Replace existing EOL 230/44kV 83MVA transformer (T1) with new 230/44kV 83MVA unit	HONI	2026	10
	Alliston TS	Replace existing EOL 230/44kV 83MVA transformer (T3/T4) with new 230/44kV 83MVA units	HONI	2030	16

The South Georgian Bay-Muskoka TWG recommends that Hydro One and LDCs continue with the implementation of infrastructure investments listed in Table 1 while keeping the TWG apprised of project status.

[1] Planned in-service dates are tentative and subject to change

[2] Costs are based on budgetary planning estimates and excludes the cost for distribution infrastructure (if required).

The next regional planning cycle for the South Georgian Bay-Muskoka Region must be triggered within five years, beginning with the Needs Assessment ("NA") phase. It is expected that the next NA will start in Q2 2025. However, the next regional planning cycle can be started earlier if required to address any emerging needs.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE SOUTH GEORGIAN BAY-MUSKOKA REGION.

The report was prepared by Hydro One Networks Inc. (Transmission) ("Hydro One") on behalf of the Technical Working Group ("TWG") in accordance with the regional planning process established by the Ontario Energy Board ("OEB") in 2013. The TWG included members from the following organizations:

- Independent Electricity System Operator ("IESO")
- Alectra Utilities Corporation ("Alectra")
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- InnPower
- Orangeville Hydro
- Lakeland Power
- EPCOR Electricity Distribution Ontario Inc.
- Newmarket-Tay Power Distribution Ltd.
- Wasaga Distribution Inc.

Electrical supply to the South Georgian Bay-Muskoka region is provided through two (2) 500/230kV auto-transformers at Essa TS, the 230kV transmission lines connecting Minden TS to Des Joachims TS, the 230kV circuits E8V and E9V coming from Orangeville TS, and the single 115kV circuit S2S connecting to Owen Sound TS. There are sixteen (16) Hydro One step-down transformer stations in the region, most of which are supplied by circuits radiating out from Essa TS, and the majority of the distribution system is at 44kV, except for Orangeville TS which has 27.6kV and 44kV feeders. Figure 1-1 represents the South Georgian Bay-Muskoka Region Map.

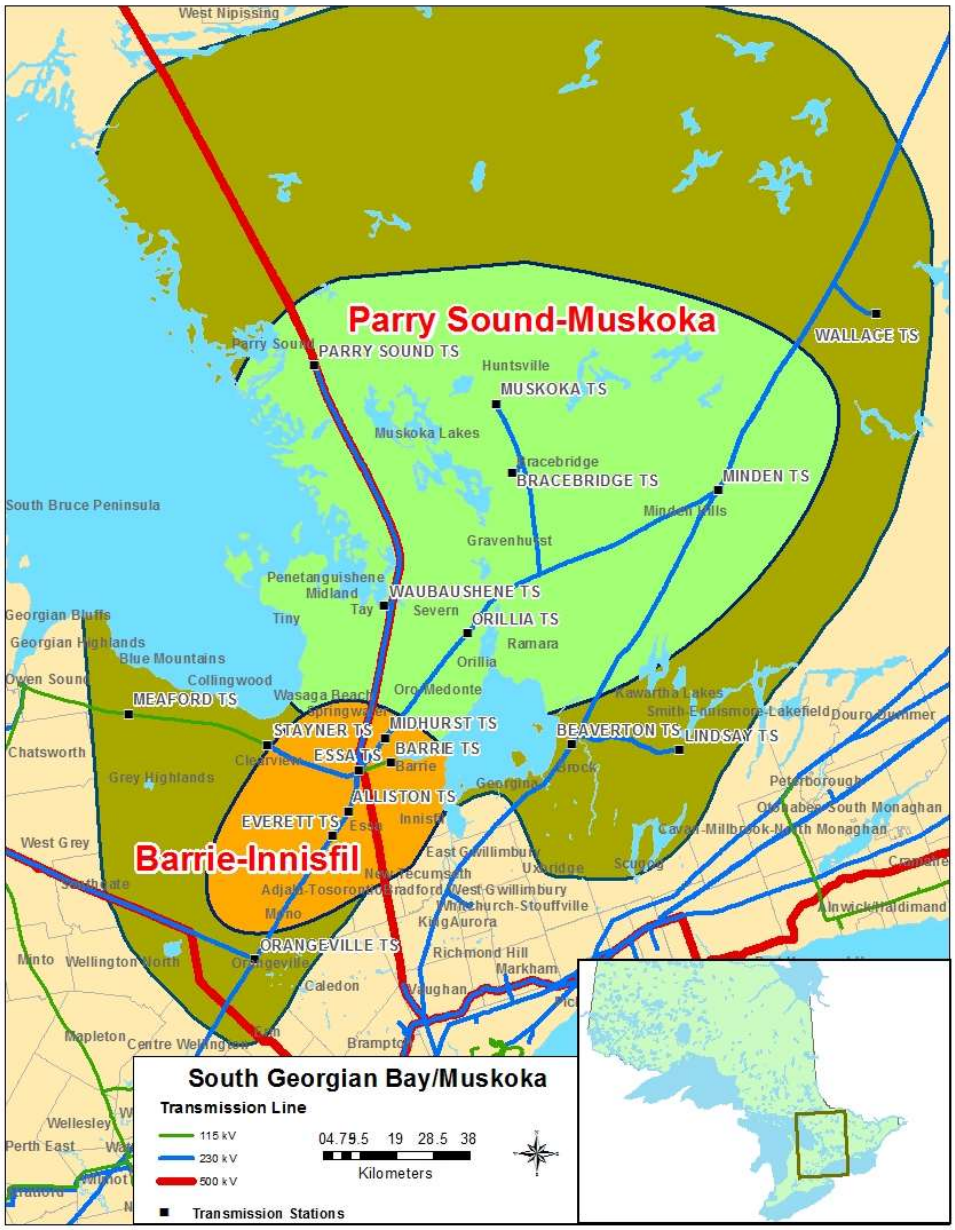

Figure 1-1 South Georgian Bay-Muskoka Region Map

1.1 Objectives and Scope

This RIP report examines the needs in the South Georgian Bay-Muskoka Region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs for the region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major high voltage transmission equipment, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs (2022-2032) identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the 2022-2032 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the South Georgian Bay-Muskoka IRRP or identified by the TWG.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process;
- Section 3 describes the regional characteristics;
- Section 4 describes the transmission work completed over the last ten years;
- Section 5 describes the load forecast and study assumptions used in this assessment;
- Section 6 describes the results of the adequacy assessment of the transmission facilities in the region over the study period and identifies the needs;
- Section 7 discusses the needs, provides alternatives to address each need, and recommends a preferred solutions; and,
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: The Needs Assessment ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Technical Working Group (TWG) determines whether further regional coordination is necessary to address them. If no further regional coordination is required to address the need(s), further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer to develop a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straightforward wires solution. The TWG considers various factors in determining that a LP is the appropriate planning approach.

In situations where identified needs require further coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the TWG, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and decides on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities, Indigenous communities, business sectors and other interested stakeholders and establishes a Local Advisory Committee (LAC) in the region or sub-region.

The RIP phase is the final phase of the regional planning process and involves: discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and, development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive and consolidated report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the regional planning process taking effect.
- The NA, SA, IRRP and LP phases of regional planning.
- Conducting wires planning as part of the RIP for the region or sub-region.
- Planning for connection capacity requirements with the LDCs and transmission connected customers.

Figure 2 -1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

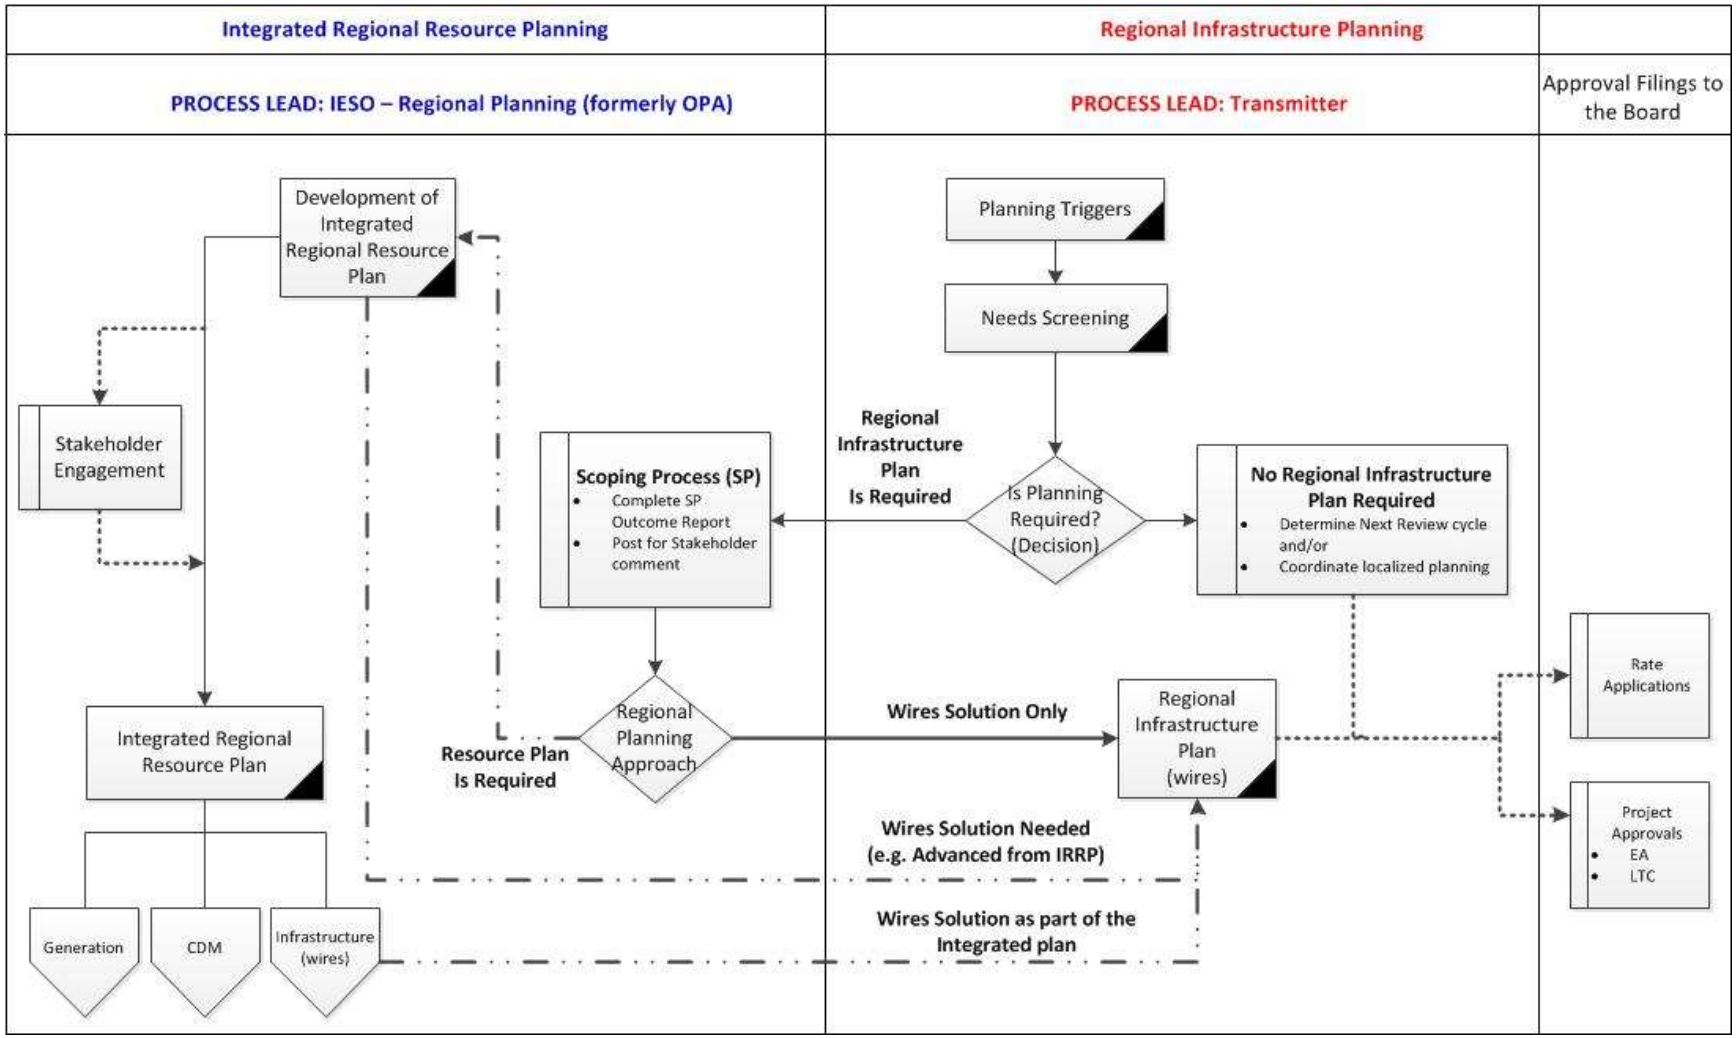

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the technical working group (TWG) to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs. As agreed by TWG members, the load forecast from the IRRP was used for this RIP.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3. Alternative Development: The third step is the development of wires options to address the needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

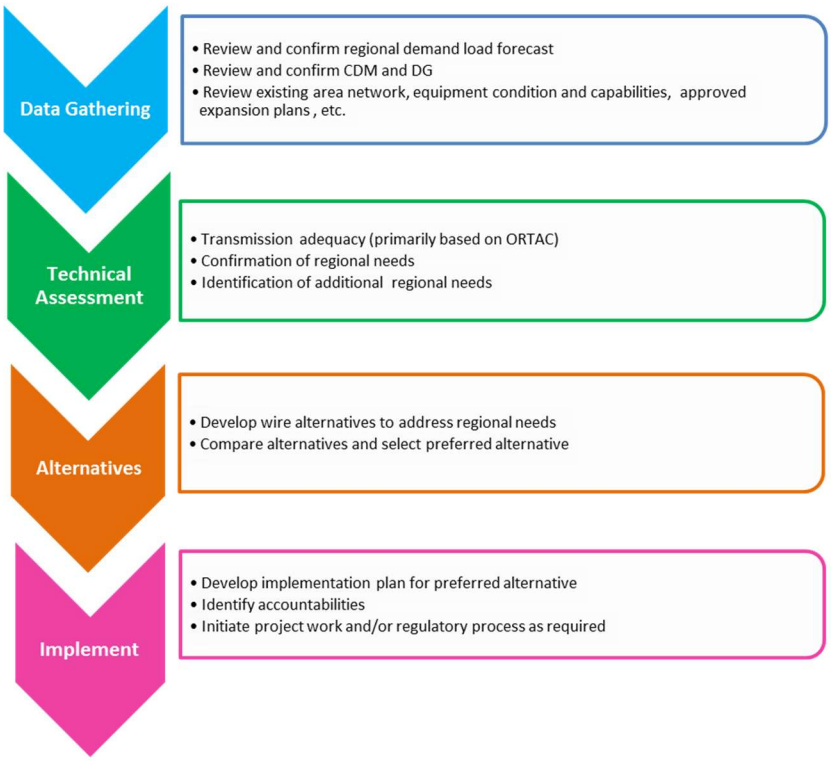

Figure 2-2 RIP Methodology

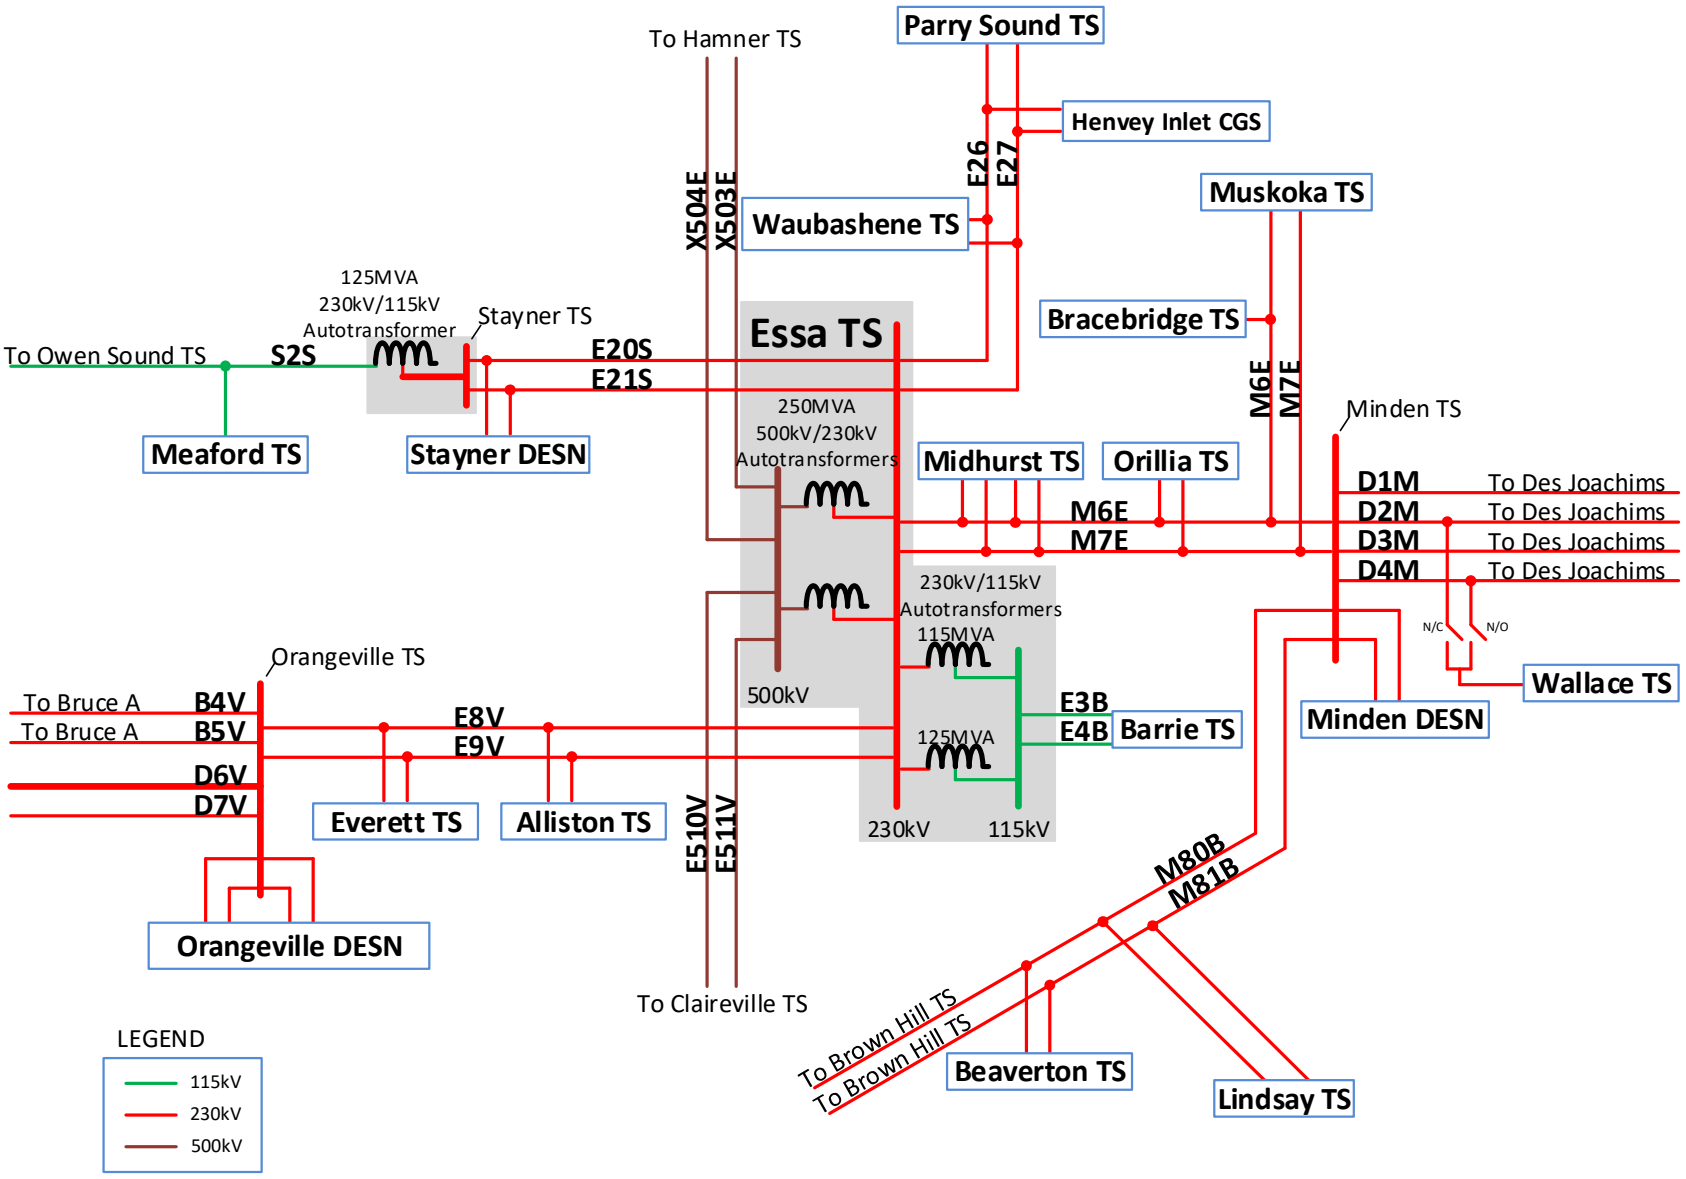
3. REGIONAL CHARACTERISTICS

THE SOUTH GEORGIAN BAY/MUSKOKA REGION IS COMPRISED OF THE BARRIE/INNISFIL AND THE PARRY SOUND/MUSKOKA SUB-REGIONS. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM TWO AUTO-TRANSFORMERS AT ESSA TS, THE 230KV TRANSMISSION LINES D1M, D2M, D3M AND D4M CONNECTING MINDEN TS TO DES JOACHIMS TS, THE 230KV CIRCUITS E8V AND E9V COMING FROM ORANGEVILLE TS AND THE SINGLE 115KV CIRCUIT S2S CONNECTING TO OWEN SOUND TS.

The existing facilities in the Region are summarized below and depicted in the single line diagram shown in Figure 3-1. The 500kV system is part of the bulk power system and is not studied as part of this report.



There are sixteen (16) HONI step-down transformer stations in the Region, most of which are supplied by circuits radiating out from Essa TS, and the majority of the distribution system is at 44kV, except for Orangeville TS which has 27.6kV and 44kV feeders.

The April 2020 South Georgian Bay/Muskoka Region second cycle NA report, prepared by Hydro One, considered the South Georgian Bay/Muskoka as a whole. Subsequently as a result of the Scoping Assessment, the South Georgian Bay/Muskoka Region was divided into two sub-regions, Barrie/Innisfil Sub-Region and Parry Sound-Muskoka Sub-Region.

The Barrie/Innisfil Sub-Region roughly encompasses the City of Barrie and the towns of Innisfil, New Tecumseth and Bradford West Gwillimbury. It includes the townships of Essa, Springwater, Clearview and Mulmur, Adjala-Tosorontio. The Barrie/Innisfil Sub-Region includes the areas supplied by Midhurst TS, Barrie TS, Everett TS, and Alliston TS, and transmission circuits E8V/E9V, E3B/E4B, and M6E/M7E.

This Parry Sound/Muskoka sub-region roughly encompasses the Districts of Muskoka and Parry Sound, and the northern part of Simcoe County. The Parry Sound/Muskoka Sub-Region includes the areas supplied by Parry Sound TS, Waubaushene TS, Orillia TS, Bracebridge TS, Muskoka TS, Minden TS, and transmission circuits M6E/M7E and E26/E27.
The following circuits are not included in the South Georgian Bay/Muskoka Region:

- The 230kV circuits, B4V and B5V, and all stations which they supply. These circuits and stations are included in the Greater Bruce/Huron Region.
- The 230kV circuits, D6V and D7V, and all stations which they supply. These circuits and stations are included in the Kitchener/Waterloo/Cambridge/Guelph Region.

Note: BATU project will convert E3B/E4B to 230kV and connect Barrie TS directly to Essa TS 230kV bus (In-Service 2023)

Figure 3-1 South Georgian Bay-Muskoka Region Single Line Diagram

4. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR UNDERWAY

OVER THE LAST TEN YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED BY HYDRO ONE, OR ARE CURRENTLY UNDERWAY, AIMED AT IMPROVING THE SUPPLY CAPABILITY AND RELIABILITY IN THE SOUTH GEORGIAN BAY-MUSKOKA REGION.

A summary and brief description of the major projects completed and/or currently underway over the last ten years is provided below:

- Midhurst TS and Orillia TS Capacitor Banks (2012) – Installation of four (4) 44kV, 32.4 MVAr capacitor banks at Midhurst TS and Orillia TS (two banks at each station) to minimize post-contingency voltage decline on the low voltage buses at both stations and defer the overload on circuit M6E.

  Meaford TS Transformer Replacement (2015) – The 115/44 kV, 25/42 MVA T1/T2 transformers were at end-of-life (EOL) and replaced like-for-like.

- Orillia TS M6E/M7E Switches (2021) – Loss of M6E and M7E resulted in violation of ORTAC load restoration criteria based on the peak load forecast. Hydro One installed new 230kV motorized disconnect switches on the M6E and M7E circuits (at Orillia TS) to improve load restoration time.

- Minden TS Transformer Replacement (2021) – The 230/44kV, 42MVA T1/T2 transformers were at EOL and replaced with new 230/44kV 83MVA units.

The following projects are underway:

- Barrie TS (2023) – This investment will convert the existing 115kV E3B/E4B circuits to 230kV and connect directly to the Essa 230kV bus. Barrie TS will be rebuilt with new 230/44kV 75/125MVA transformers and connect to the new 230kV E28/E29B circuits. The 230/115kV autotransformers at Essa TS will also be removed as part of this investment.

- Orangeville (2023) – Based on asset condition assessment the existing T3/T4 230/44kV 83MVA transformers will be replaced with new 125MVA units and also, the existing nonstandard three winding 230/44/27.6 125MVA transformers (T1/T2) be replaced with new dual winding 230/27.6, 83MVA units. This investment also involves reconfiguration of low voltage equipment and transfering existing 44kV feeders from T1/T2 DESN to the T3/T4 DESN.

- Parry Sound TS (2023) - Parry Sound TS transformer supply capacity has been exceeded, and transformers have also been assessed at being end of life and in need of replacement due to their asset conditions. Hydro One will be installing new 230/44kV 83MVA transformers units to address both end of life and capacity needs at this station.

5. FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

During the study period, the load in the South Georgian Bay-Muskoka Region is expected to grow at an average annual rate of approximately 2% (summer) and 1.8% (winter) from 2022 to 2032.

Figure 5-1 shows the South Georgian Bay-Muskoka Region extreme summer weather net load forecast from 2022 to 2042. The load forecasts from the Barrie Innisfil sub-region IRRP and Parry Sound/Muskoka sub-region IRRP were adopted as agreed to by the TWG. The load forecast shown is the regional non-coincident forecast, representing the sum of the load in the area for the step-down transformer stations.
Non-coincident forecast for the individual stations in the region is available in Appendix D and is used to determine any need for station capacity relief.

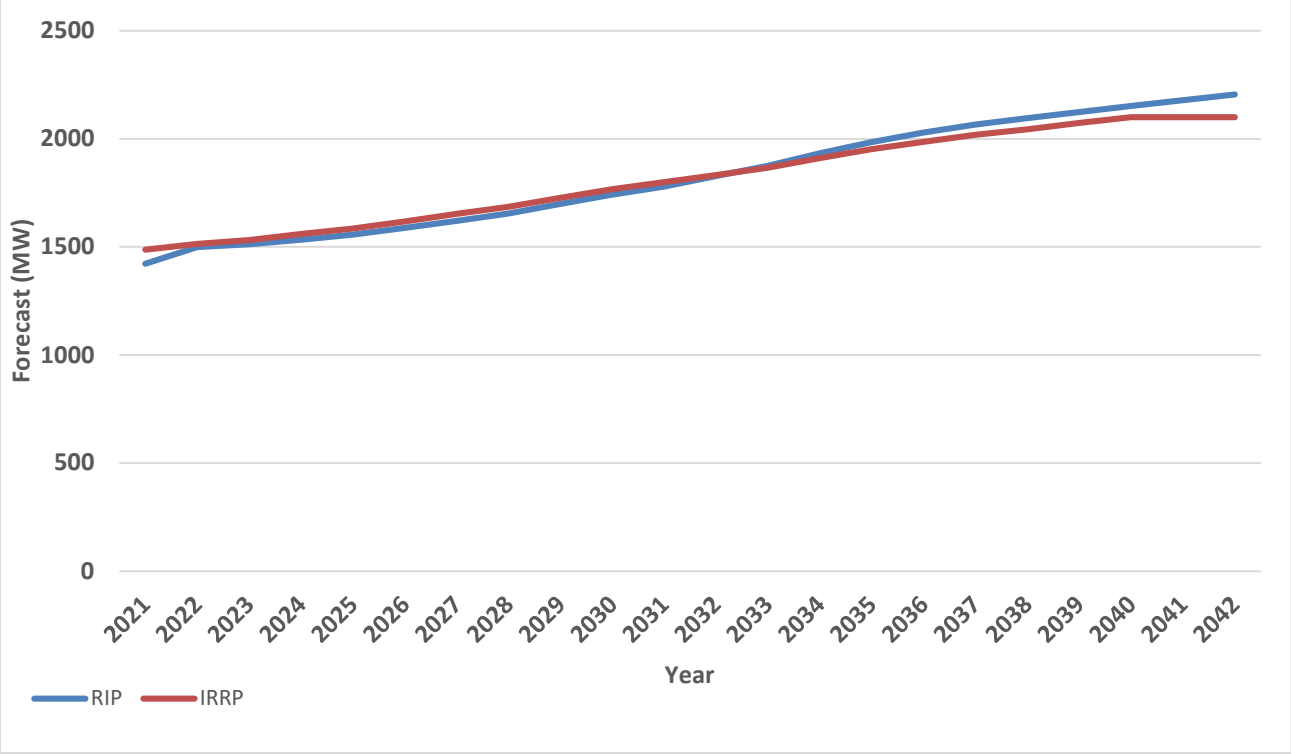


Figure 5-1 South Georgian Bay-Muskoka Region Non–Coincident Net Summer Peak Load Forecast

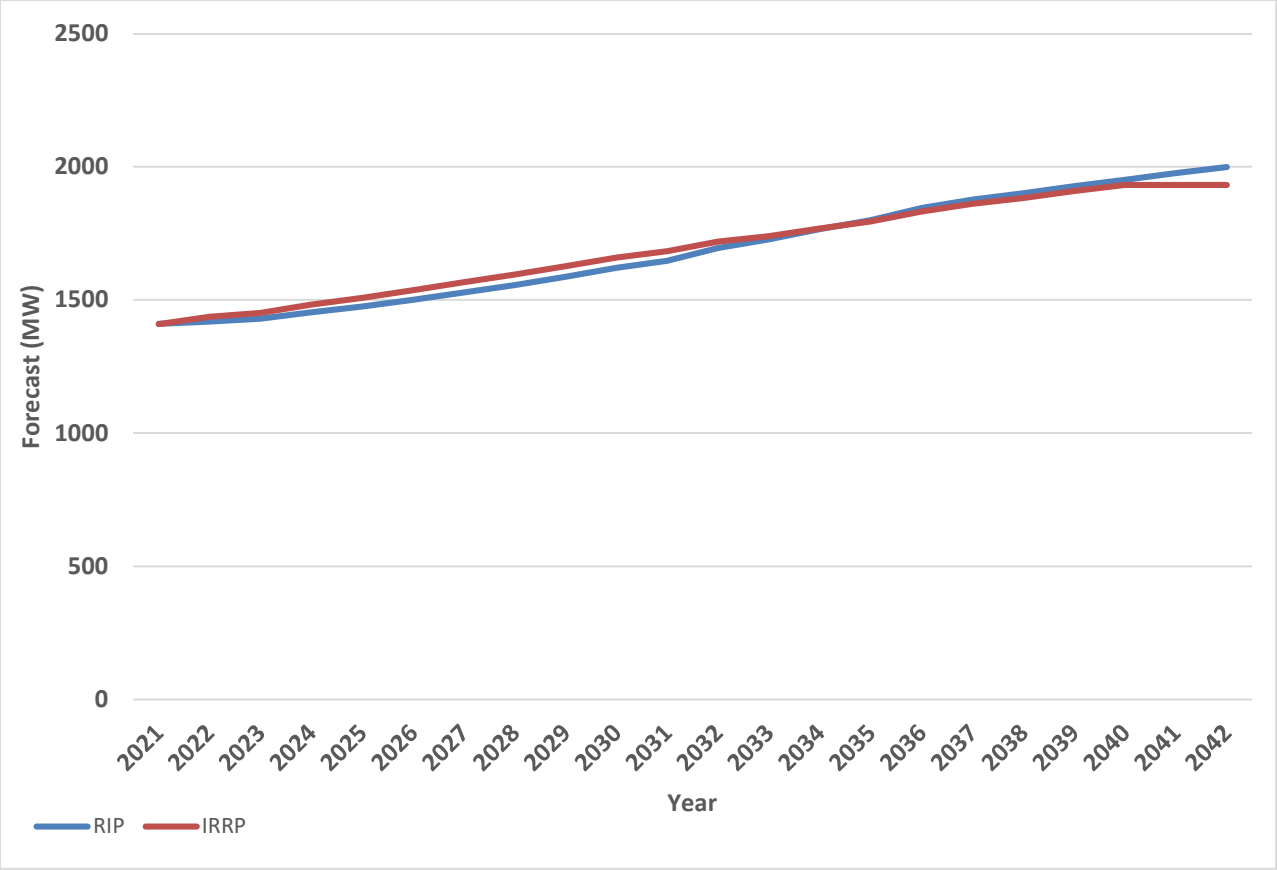

Figure 5-2 South Georgian Bay-Muskoka Region Non–Coincident Net Winter Peak Load Forecast

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2022-2032. However, a longer term forecast up to 2042 is provided to identify long-term needs and align with the IESO's Barrie Innisfil sub-region and Parry Sound/Muskoka sub-region IRRPs.
- LDCs reconfirmed load forecasts up to 2040. The additional two years of forecasts were extrapolated based on growth rate as a reasonable position to complete the 20 years period.
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- Both summer and winter loads were considered to assess line and transformer loadings.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR).
- Bulk transmission line capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Adequacy assessment is conducted as per ORTAC.

6. ADEQUACY OF EXISTING FACILITIES AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND TRANSFORMER STATION FACILITIES SUPPLYING THE SOUTH GEORGIAN BAY-MUSKOKA REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM PERIOD.

Within the current regional planning cycle, four regional assessments have been conducted for the South Georgian Bay-Muskoka Region. The findings of these assessments are inputs to this RIP. These assessments are:

1) South Georgian Bay-Muskoka Region second cycle Needs Assessment (NA) Report, April 2020
2) South Georgian Bay/Muskoka second cycle Scoping Assessment Outcome Report, November 2020
3) Barrie/Innisfil sub-region second cycle Integrated Regional Resource Planning (IRRP), May 2022
4) Parry Sound/Muskoka sub-region second cycle Integrated Regional Resource Planning (IRRP), May 2022

The NA and IRRP reports identified several regional needs based on the forecasted load demand over the near to mid-term period. A detailed description and status of plans to meet these needs is given in Section 7.

This section provides a review of the adequacy of the transmission lines and stations in the South Georgian Bay/Muskoka Region. The adequacy is assessed using the load forecasts provided in Appendices D. The assessment assumes all projects currently underway (described in section 4) are in-service and specifically, the Barrie Area Transmission Reinforcement project and Orangeville/Parry Sound transformer replacements are in-service by 2023.

Sections 6.1- 6.3 present the results of the adequacy assessment and Table 6-1 lists the region's near, mid, and long-term needs identified in both the IRRP and RIP phases.

6.1 500 kV and 230 kV Transmission Facilities

All 500 kV and 230 kV transmission circuits in the South Georgian Bay-Muskoka Region are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the rest of Ontario's transmission system. The 230 kV circuits also serve local area stations within the region and the power flow on these circuits vary depending on the bulk system transfers as well as the local area loads.

6.1.1 500/230 kV Transformation Facilities

Bulk power supply to the South Georgian Bay-Muskoka Region is provided by 500/230 kV autotransformers at Essa TS which serves as a hub for major power flows between Hanmer TS (Sudbury) and Clairville TS (Toronto). Additional support for the region is provided from the 230 kV generation facilities (Des Joachims GS, Henvey Inlet CGS)

6.1.2 230 & 115 kV Transmission Circuits

The 230kV circuits in the region are as follows;

- E20S/E21S (Essa TS x Stayner TS)
- E26/E27 (Essa TS x Parry Sound TS)
- M6E/M7E (Essa TS x Minden TS)
- D1M/D2M/D3M/D4M (Minden TS x Des Joachims)
- 115 kV - S2S (Stayner TS x Owen Sound TS)

Table 6-1 below highlights the line section(s) and violations identified in the IRRP and reaffirmed in this RIP.

Table 6-1 South Georgian Bay-Muskoka Region - Lines Sections Exceeding ratings

No.	Line	Section	Contingency	Year Line Rating exceeded
1	M6E/M7E	Essa TS x Midhurst TS	N-1[1]	2034
2	M6E	Minden x Coopers Fls JCT	N-1[2]	2038
3	M6E	Minden x Coopers Fls JCT	N-1-1[3]	2040

[1] Loss of one of either M6E or M7E will result in overload of the companion circuit.
[2] Minden TS HL7 breaker fail.
[3] M7E O/S followed by loss of Essa TS T3

The options and preferred solutions to address these needs are discussed further in Section 7 of the report.

6.2 Step-Down Transformation Facilities

There are sixteen (16) step-down transformer stations in the South Georgian Bay-Muskoka Region as listed in Table 6-2.

Table 6-2 South Georgian Bay-Muskoka Region - Step-Down Transformer Stations

Alliston TS	Everett TS	Minden TS	Parry Sound TS
Barrie TS	Lindsay TS	Muskoka TS	Stayner TS
Beaverton TS	Meaford TS	Orangeville TS	Wallace TS
Bracebridge TS	Midhurst TS	Orillia TS	Waubaushene TS

This RIP reviewed the step-down transformation capacity for the stations within the South Georgian Bay-Muskoka Region. The NA and IRRP studies had previously indicated that the following stations require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast, the stations which require capacity relief during the 2022-2032 study period are shown in Table 6-3 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer or winter) 10-day LTR.

Table 6-3 South Georgian Bay-Muskoka Region - Stations Requiring Relief in the study period (2022-2032)

Station	Capacity (MW)	2022 Loading (MW)	Need Date
Everett TS	86	85	Immediate
Barrie TS	162[3]	98	2027
Waubaushene TS	94	90	2027

Further, based on the load forecast, the stations requiring relief beyond the study period are listed below:

- Midhurst TS (T1/T2) – 2033
- Midhurst TS (T3/T4) – 2034

6.3 Asset Renewal for Major HV Transmission Equipment

A number of Hydro One facilities in the South Georgian Bay-Muskoka Region will require replacement over the 2022-2032 study period as listed in Table 6-4 below.

Asset renewal needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as (but not limited to):

- Equipment deterioration;
- Technical obsolescence due to outdated design;
- Lack of spare parts availability or manufacturer support; and/or,
- Potential health and safety hazards, etc.

The major high voltage equipment considered includes the following:

1. 230/115kV autotransformers;
2. 230 and 115kV load serving step-down transformers;
3. 230 and 115kV breakers where:
    - replacement of six breakers or more than 50% of station breakers, the lesser of the two
4. 230 and 115kV transmission lines requiring refurbishment where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
5. 230 and 115kV underground cable requiring replacement where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

*The planned in-service dates are tentative and subject to change.

6.4 Load Security and Load Restoration

Load security and load restoration needs were reviewed as part of the current study. The ORTAC Section 7 requires that no more than 600 MW of load be lost as a result of a double circuit contingency.

Further, loads are to be restored in the restoration times[4] specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interruped in excess of 250 MW must be restored within 30 minutes.

This RIP further confirms there are no identified load security and restoration violations within the study period. The technical working group does not recommend any further action.

[4] These approximate restoration times are intended for locations that are near staffed centres. In more remote locations, restoration times should be commensurate with travel times and accessibility

7. REGIONAL PLANS

THIS SECTION DISCUSSES NEEDS, PRESENTS WIRES ALTERNATIVES AND THE PREFERRED WIRES SOLUTIONS FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS FOR THE SOUTH GEORGIAN BAY-MUSKOKA REGION.

The electrical infrastructure needs for the South Georgian Bay-Muskoka Region are summarized in Table 7-1. These needs include those previously identified in the NA for the South Georgian Bay-Muskoka Region and IRRPs for the Barrie/Innisfil and the Parry Sound/Muskoka Sub-Regions as well as any new needs identified during the RIP phase. All estimated costs included in the altnerative analysis are considered as planning budgetary estimates and are used for comparative purposes only.

Table 7-1 South Georgian Bay-Muskoka Region – Near, Medium and Long Term Needs

Type	Section	Needs	Timing
Station Capacity	7.1	Everett TS	2023
		Barrie TS	2027
		Waubaushene	2027
		Midhurst TS	2033/2034
		Minden TS	2036
Supply Capacity	7.2	M6E/M7E (Essa x Midhurst)	2034
		M6E/M7E (Minden x Coopers Fls)	2038
Asset Renewal for Major HV Transmission Equipment	7.3.1	M6E/M7E (Orillia x Coopers Fls)	2026
		E8V/E9V (Orangeville TS x Essa Jct)	2027

		Alliston TS (T3/T4)	2030
Load Security/Restoration	7.4	None Identified in this planning cycle	-

7.1 Station Capacity Needs

7.1.1 Everett TS

Everett TS is 230/44kV 50/83MVA transformer station with a summer and winter 10-Day LTR of 86MW. Load at this station is forecasted to increase up to 105MW by the end of 2032. Supply capacity is presently limited by a current transformer (CT) ratio setting on the transformer breaker bushing, thereby restricting the ability to utilize the full supply capability of the transformers.

Table 7-2 Everett TS Load Forecast

Station	LTR (MW)		Load Forecast									
		2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032
Everett TS	86	85	86	87	88	90	92	93	95	97	100	105

The following alternatives were considered to address Everett TS capacity need:

Alternative 1 - Maintain Status Quo: This alternative was considered and rejected as it does not provide supply capacity to area customers during the study period. Under this scenario load cannot be increased at this station.

Alternative 2 – Replace and upgrade T1/T2 with new 75/125MVA units: Under this alternative the existing T1/T2 transformers will be replaced with new 75/125MVA transformers. This was considered and rejected as this would result in additional cost of approximately $10M and prematurely retire the T1/T2 transformers. These transformers remain in acceptable condition are not scheduled to be replaced by Hydro One within the study period.

Alternative 3 – Modify the CT Ratio: This alternative would require modifying the CT ratio of the low voltage transformer breaker CTs to realize the full supply capacity of the transformers.

The TWG recommends Alternative 3 as the preferred and cost effective alternative for addressing the need. CT ratios are established based on expected loading at a station and typically lower when transformer stations are initially constructed. As the load increases these ratios must be adjusted to ensure protection, control and metering continue to operate as intended. This solution utilizes existing assets without incurring additional high capital expenditures and will allow the station LTR to increase to 108MW (summer) and 177MW (winter) once completed. The budgetary cost for this alternative is expected to be $0.5M

7.1.2 Barrie TS

The Barrie Area Transmission Upgrade (BATU) project is presently underway and scheduled to be in-service in 2023. Barrie TS will be upgraded to a new 230/44kV 125MVA transformer station with 8 feeder positions (six for Alectra Utilities and two for Hydro One Distribution with InnPower as an embedded customer).

Barrie TS will have a 10-Day LTR of 162MW and the forecasted load will exceed its normal supply capacity in 2028 based on the summer demand forecast (see Table 7-3 below). Coincident with the station capacity violation, Hydro One distribution and its embedded LDC (InnPower) will also see a supply capacity constraint on their two 44kV feeders in 2028. Minor capacity increases can be accommodated on the 44kV system, but only on an emergency basis and cannot be used as a permanent supply solution for increased load growth. InnPower will

need new supply capacity into the Innisfil service territory to service its load growth beyond the 2-feeder capacity that Barrie TS can supply.

An Innisfil supply study was completed to evaluate supply options for InnPower and consequently help to offload demand from Barrie TS. Results of this study are described in the alternatives below.

Table 7-3 Barrie TS Load Forecast

Station	LTR (MW)		Load Forecast									
		2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032
Barrie TS	162	98	119	128	141	154	161	163	164	167	170	174

Alternative 1 - Maintain Status Quo:

This alternative was considered and rejected as it does not address future station capacity restrictions at Barrie TS, nor does it provide InnPower with the mid-term supply capacity required for load growth in their service territory.

Alternative 2 – Inn Power to connect to existing Alectra Feeder as embedded customer:

This solution was initially discussed by the TWG in the first planning cycle to provide increased supply to InnPower without additional station work at Barrie TS. Spare feeder capacity is not available and thus, this alternative fails to meet the full supply needs within the study period and will need to be combined with alternate solutions. This alternative was rejected on this basis, and thus costs have not been explored further.

Alternative 3 – Install an Additional 44kV feeder position from Barrie TS:

This solution was discussed with the TWG and closely relates to Alternative 2. A new dedicated feeder position for InnPower will provide up to 25MW supply capacity, however this solution would still fail to meet the full supply needs of InnPower within the study period, and the increased load will still be seen at Barrie TS triggering a capacity need in 2028. This solution will need to be combined with alternate solutions to relieve Barrie TS.
The combined transmission and distribution costs to install and construct a new distribution line from Barrie TS is estimated to cost $20M, however this alternative is rejected as it does address capacity needs at Barrie TS.

Alternative 4 – Load existing 44kV supply feeders beyond normal capacity

This alternative was explored by the TWG to increase supply on the two 44kV feeders from Barrie TS beyond the normal supply capacity. This solution requires increased voltage support on the distribution system along the feeders and will provide up to 20MW increased supply capacity (10MW/feeder). Distribution costs to facilitate increased feeder loading is estimated to cost $8M, however this alternative is rejected as it still does address Capacity needs at Barrie TS.

Alternative 5 – Provide 230kV tap connection to Innisfil service territory for new transformer station

This alternative involves construction of a 230/27.6kV 50/83MVA transformer station in Innisfil to supply the increased load demand forecast. This station will connect directly to the 230kV E28B/E29B circuits which will be completed in 2023 as part of the Barrie Area Transmission Upgrade project. A new 9km double circuit 230kV transmission line will be constructed to connect this new transformer station.

This alternative will provide increased supply capacity for InnPower within the study period and allow for load growth in the future. This alternative can be utilized as a standalone solution to meet the needs without additional interim investments or in conjunction with other alternatives presented above. This solution also allows InnPower to transfer load to this station which would otherwise be connected to Alliston TS. This transfer of load helps to mitigate a capacity need during the study period which would see an additional expenditure to increase supply capacity on the T3/T4 DESN at Alliston TS.
The estimated cost for this investment is expected to be $44M which is comprised of $14M for transmission line construction and $30M for a new transformer station.

The TWG recommends proceeding with Alternative 5. This alternative provides a robust transmission solution to meet InnPower's demand forecast and will also allow for future load growth beyond the study period. This solution will also help to relieve Barrie TS which will see a capacity need in 2028. Based on findings in the Needs Assessment and IRRP, Hydro One and InnPower have commenced development work on this alternative to meet the 2028 need date and TWG recommends continuing with this work.

7.1.3 Waubaushene TS

Waubaushene TS presently has 230/44 83MVA transformers (T5/T6) with a summer LTR of 94MW. This station will exceed its normal supply capacity in 2028 (see Table 7-4 below).

Summer overloading at this station continues to be of concern and the TWG agrees that a solution is required to address this need. Hydro One Distribution has permanently transferred 10MW of load from Waubaushene TS to Midhurst TS to help with recent summer loading concerns, however a solution is required to further address the upcoming supply capacity need.

Table 7-4 Waubaushene TS Load Forecast

Station	LTR (MW)	Load Forecast										
		2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032
Waubaushene TS	94	90	90	91	92	93	94	96	97	99	100	102

Alternative 1 - Maintain Status Quo: This solution is not recommended as it does not address the supply capacity need at the station. This solution will prevent load growth at this station beyond 2027.

Alternative 2 – Load Transfer to neighboring stations

This solution was explored during the NA and IRRP phase. Hydro One distribution assessed transfer capability to other stations and determined that a maximum of 10MW of load could be transferred, and this was completed in Q1 2022. Further transfers are not feasible without significant distribution construction costs and regulators on the low voltage network estimated to be $ 5-10 M depending on feeder construction and voltage regulation.

Alternative 3 – Replace End-of-Life Waubaushene TS T5/T6 transformers with upgraded 125MVA units.

Replace and upgrade existing T5/T6 transformers with larger 75/125MVA units. This solution will increase supply capacity to allow load to continue to grow as per the demand forecast.

The TWG recommends Alternative 3 as the preferred and cost-effective alternative for addressing the need. The existing T5/T6 transformers at Waubaushene TS have been identified by Hydro One as requiring replacement based on their asset condition and is planned for replacement in 2027. This date coincides with the supply capacity need timing as shown in Table 7.4 and thus the TWG agrees this is the ideal scenario to address the capacity need and right size the transformers. The budgetary cost for the replacement and upgrade of the transformers is expected to be $20M. Hydro One will follow Ontario Energy Board (OEB) approved procedures to determine appropriate cost allocation as this project addresses both a sustainment and capacity upgrade need.

7.1.4 Midhurst TS and Minden TS

As identified in Table 7-1, the stations listed below will require capacity relief beyond 2032. Based on the long-term horizon of these needs the load at these stations will be reviewed in the next regional planning cycle. The timing for capacity relief of these stations is shown below:

- Midhurst TS T1/T2: 2033 and Midhurst TS T3/T4: 2034
- Minden TS T3/T4: 2036

7.2 Supply Capacity Needs

The M6E/M7E circuits are a 230kV double circuit transmission line forming a critical path between Essa TS and Minden TS. These circuits are approximately 120 km long and serve to provide connection to load serving stations and provide a path for network flows. Based on the coincident load forecast of the stations in the region, sections of this line will start to experience supply capacity violations at the end of the study period and will require mitigating solutions to allow for increased flows. The two circuit sections are described below:

1. Essa TS x Midhurst TS (10km) – For the loss of M6E or M7E, the companion circuit will exceed its Long-Term Emergency (LTE) rating as early as 2034 based on theload forecast.

2. Minden TS x Coopers Falls JCT (51km) – This section of transmission line will experience Long-Term Emergency (LTE) rating violations as early as 2038 for a Minden TS HL7 breaker failure, and Essa T3 contingency with M7E out of service.

Based on the long-term horizon of these needs solutions to address them will be further explored in the next regional planning cycle. Flows on this line and its violations are heavily influenced by area resource assumptions and demand forecast of the transformer stations connected to this circuits. IESO has also identified that incremental cost effective CDM, storage and other non-wires alternatives will be explored to address this need. The TWG will review this need in the next regionalplanning cycle and initiate an investment should this violation be advanced due to changing system conditions.

7.3 Asset Renewal Needs for Major HV Transmission Equipment

A number of Hydro One facilities in the South Georgian Bay-Muskoka Region will require replacement over the 2022-2032 study period. Hydro One is the only Transmission Asset Owner (TAO) in the Region.

The asset renewal assessment considers options for right sizing the equipment such as:

- Maintaining the status quo;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities;
- Eliminating equipment by transferring all the load to other existing facilities;
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement); and,
- Replacing equipment with higher ratings and built to current standards.

7.3.1 Transmission Line Refurbishment

The following transmission line sections were identified by Hydro One as requiring refurbishment over the study period based on asset condition assessment:

1. M6E/M7E Orillia x Coopers Fls – This is a 50km 230kV line section that was in-serviced in 1950. Based on asset condition assessment, this line section requires like for like refurbishment to ensure supply reliability and safety is maintained. The planned in-service date for this investment is 2026.

2. E8V / E9V Orangeville TS X Essa JCT – This is a 112km 230kV line section that was in-serviced in 1950. Based on asset condition assessment, this line section requires like for like refurbishment to ensure supply reliability and safety is maintained. The planned in-service date for this investment is 2027.

3. D1M / D2M Otter Creek JCT x Minden TS – This is a 124km 230kV line section that was in-serviced in 1950. Based on asset condition assessment, this line section requires like for like refurbishment to ensure supply reliability and safety is maintained. The planned in-service date for this investment is 2028.

7.3.2 Transmission Station Refurbishment

Hydro One identified a number of step-down transformers as requiring replacement over the study period based on asset condition assessment. Details of the planned work as recommended by the TWG are given in Table 7-5 below.

Table 7-5 Asset Renewal Plan-Transmission Stations

No.	Station	Planned In-Service Date*
	In Execution/Construction	
1	Barrie TS Replace and upgrade existing 115/44kV 83MVA transformers (T1/T2) with new 230kV/44kV 125MVA transformers. Remove Essa TS T1/T2 autotransformers and convert Barrie TS supply circuits (E3B/E4B) from 115kV to 230kV. This investment is also known as Barrie Area Transmission Upgrade (BATU) and will include replacement of end of life equipment at Essa TS, in addition to increasing both station and supply capacity to the area.	2023
2	Orangeville TS Replace and upgrade existing 230/44kV 83MVA transformers (T3/T4) with new 230/44kV 125MVA units. Replace and upgrade existing nonstandard three winding 230/44/27.6 125MVA transformers (T1/T2) with new dual winding 230/27.6 83MVA units. Reconfigure low voltage equipment and transfer existing 44kV feeders from T1/T2 DESN to the T3/T4 DESN. This replacement plan will decrease the risk of equipment failure and contribute to maintaining supply reliability to Orangeville Hydro and Hydro One Distribution customers in the Orangeville area.	2023
3	Parry Sound TS Replace existing 230/44kV 42MVA transformers (T1/T2) with new 230/44kV 83MVA units and replace station protection and station service equipment. Replacement of these power transformers will help to maintain the reliability of supply and provide increased supply capacity to customers in the area by right sizing to 83MVA units.	2024
	In Development	
4	Wallace TS Replace existing 230/44kV 42MVA transformers (T3/T4) with new 230/44kV 42MVA units. Replacement of Oil circuit breakers will also be part of this investment. This investment will help maintaining reliability of supply to Hydro One Distribution customers and reduce the risk of interruptions caused by station equipment failure.	2025

5	Midhurst TS Replace existing 230/44kV 125MVA T4 transformer with a new like-for-like unit. The T3/T4 DESN presently supplies load to Alectra though 8 x 44kV feeders. T4 is the sole unit that has been identified as requiring replacement due to poor asset condition. This investment will help maintain reliability of supply to area customers and reduce the risk of interruptions caused by transformer asset failure. Load growth in the area will be reviewed in the next regional planning cycle. The TWG will ensure solutions to increase supply capacity in the region are explored in advance of the need date.	2026
6	Orillia TS Replace existing 230/44kV 125MVA T2 transformer with a new like-for-like 230/44kV 125MVA unit. The T1 transformer was replaced in 2015 after failure and does not require replacement during this study period. This investment will help maintain reliability of supply to Hydro One Distribution customersand decrease the risk of interruptions caused by failure of transformer T2.	2025
7	Bracebridge TS Replace existing 230/44kV 83MVA transformer (T1) with new like-for-like 230/44kV 83MVA unit. Bracebridge TS presently has one transformer (T1) and is used to supply 2 x 44kV feeders and a backup for industrial pipeline operation. The load at this station is not expected to trigger installation of a second transformer and thus like-for-like replacement of T1 will be sufficient during the study period. This investment will help maintain reliability of supply to area customers and reduce the risk of interruptions caused by transformer asset failure.	2026
8	Waubaushene TS Replace existing 230/44 83MVA transformers (T5/T6) with new 125MVA units. This investment will help to maintain reliability of supply to area customers and provide increased supply capacity to meet demand forecast.	2027
9	Alliston TS Replace existing 230/44kV 83MVA transformers (T3/T4) with new like-for-like 230/44kV 83MVA units.	2030

	This investment will help maintain reliability of supply to area customers and reduce the risk of interruptions caused by transformer asset failure and removal of legacy obsolete equipment.	

*The planned in-service year is tentative and is subject to change.

The above asset replacement plans have taken "right sizing" into consideration. All transformer replacements in the development phase are planned to be replacewith like-for-like units based on the load forecast in the study period and Hydro One standard equipment. The TWG recommends that Hydro One proceed with the above station sustainment work to ensure system reliability is maintained.

7.4 Load Security / Restoration

As indicated in section 6.4 there are no load security or restoration violations in the SGB-Muskoka region over the study period. The TWG will continue to monitor and take corrective action as needed.

7.5 Long Term Considerations

Like many other regions in Ontario, load growth in the SGB-Muskoka region will be directly impacted by new energy programs specifically those which help drive electrification. In addition, it is anticipated large market participants will also have incentive programs to modify operations/technologies to reduce greenhouse emissions. Details of how future programs will impact demand is unknown at this time thus the TWG will continue to monitor these trends throughout planning cycles to identify areas in need of investment.

8. CONCLUSION AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE SOUTH GEORGIAN BAY-MUSKOKA REGION.

The major infrastructure investments recommended by the Technical Working Group (TWG) in the near and medium-term planning horizon (2022-2032) are provided in Table 8-1 below, along with their planned in-service dates and budgetary estimates for planning purposes.

Table 8-1 Recommended Plans in Region over the Next 10 Years

Need	Station / Circuit	Investment Description	Lead	Planned In-Service Date[5]	Cost ($M)[6]
Station Capacity	Everett TS	Modify current transformer (CT) ratio setting the low voltage 44kV transformer breakers	HONI	2023	0.5
	Barrie TS	Construct new 230/27.6kV 83MVA transformer station and extend and connect to 230kV E28B/E29B circuits	HONI / Inn Power	2027	44
	Waubaushene TS	Replace and upgrade existing end-of-life 230/44kV 83MVA transformers (T5/T6) with new 230/44kV 125MVA units.	HONI / Hydro One Dx	2027	20
Asset Renewal Needs for Major HV Transmission Equipment	M6E / M7E (Orillia TS x Coopers Fls)	Replace transmission line conductor and associated assets. (25km)	HONI	2026	30
	E8V / E9V (Orangeville TS x Essa JCT)	Replace transmission line conductor and associated assets. (56km)	HONI	2027	70
	D1M / D2M (Minden TS x Otter Creek JCT)	Replace transmission line conductor and associated assets. (62km)	HONI	2028	70
	Wallace TS	Replace existing 230/44kV 42MVA transformers (T3/T4) with new 230/44kV 42MVA units.	HONI	2030	25
	Midhurst TS	Replace existing 230/44kV 125MVA transformer (T4) with a new 230/44kV 125MVA unit.	HONI	2026	12
	Orillia TS	Replace existing 230/44kV 125MVA transformer (T2) with new 230/44kV 125MVA unit	HONI	2025	12
	Bracebridge TS	Replace existing 230/44kV 83MVA transformer (T1) with new 230/44kV 83MVA unit	HONI	2026	10
	Alliston TS	Replace existing 230/44kV 83MVA transformer (T3/T4) with new 230/44kV 83MVA units	HONI	2030	16

[5] The planned in-service dates are tentative and subject to change.

[6] Costs are based on budgetary planning estimates and excludes the cost for distribution infrastructure (if required).

The South Georgian Bay-Muskoka TWG recommends Hydro One and LDCs continue with the implementation of infrastructure investments listed in Table 8-1. All the other identified needs/options in the long-term will be further reviewed by the TWG in the next regional planning cycle.

APPENDIX E. LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
GS	Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DER	Distributed Energy Resource
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

NEEDS ASSESSMENT REPORT

South Georgian Bay - Muskoka

Date: August 27, 2025

Needs Assessment Report

South Georgian Bay - Muskoka

August 27, 2025

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

Prepared by: South Georgian Bay-Muskoka Technical Working Group

Page intentionally left blank

Disclaimer

This Needs Assessment (NA) Report was prepared for the purpose of identifying potential needs in the South Georgian Bay - Muskoka and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the NA phase and b) require further assessment and regional coordination. The results reported in this NA are based on the input and information provided by the Technical Working Group (TWG) for this region. Updates may be made based on the best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	**South Georgian Bay - Muskoka** Region (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")

START DATE: April 29, 2025 **END DATE:** August 27, 2025

The second Regional Planning cycle for the **South Georgian Bay - Muskoka** Region was completed December 6, 2022 with the publication of the Regional Infrastructure Plan ("RIP") report - South Georgian Bay-Muskoka Regional Infrastructure Plan (RIP).

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. Considering these timelines, the 3rd Regional Planning cycle was triggered in **April 2025** for this Region. The planning horizon for this Needs Assessment ("NA") is ten years. A 20-year planning assessment is undertaken in the next phase of regional planning, i.e., IRRP and RIP phases.

The purpose and scope of the NA is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group (TWG) comprises of representatives from Local Distribution Companies ("LDC"), the Independent Electricity System Operator ("IESO"), and Hydro One Transmission. They provide input and relevant information for the region and undertake a technical assessment to identify the electrical infrastructure needs in the region. They collaborate to develop both summer and winter gross and net peak electricity demand forecasts (including input from municipalities), which form the basis for the technical assessment. The following are key considerations of the technical assessment:

a) Current and future station capacity and transmission adequacy.
b) System reliability needs and operational concerns.
c) Major HV transmission equipment requiring replacement with consideration to "right-sizing"; and,
d) Sensitivity analysis to capture uncertainty in the load forecast as well as variability of demand drivers such as electrification.

In this Needs Assessment, TWG has identified the following regional needs and recommendations:

Needs that require further regional coordination.

#	Need Location	Need Description
1	M6E/M7E (Supply Capacity)	Supply Capacity need identified on (Essa x Midhurst, Minden x Coopers Fls JCT). Further coordination is required to reaffirm need, solution and timing.
2	Alliston T3/T4 (Supply Capacity)	Alliston TS (T3/T4) is a 230-44kV 83MVA transformer station and will exceed its normal supply capacity within the study period. Further coordination is required to reaffirm need, solution and timing.
3	Everett T1/T2 (Supply Capacity)	Everett TS (T3/T4) is a 230-44kV 83MVA transformer station and will exceed its normal supply capacity within the study period. Further coordination is required to reaffirm need, solution and timing.
4	Midhurst T1/T2, T3/T4 (Supply Capacity)	Midhurst TS (T1/T2) and (T3/T4) are 230-44kV 125MVA transformer stations and will both exceed their normal supply capacity within the study period. Further coordination is required to reaffirm need, solution and timing.
5	Claireville Area North and Flow North	Operational issues identified, will be studied in Bulk System Plan

Needs that do not require further regional coordination.

#	Need Location	Need Description
6	E8V/E9V (Asset Renewal + Supply Capacity)	Essa TS x Orangeville TS line section will be upgraded as per Ministry of Energy's – Energy for Generations report. This upgrade planned for 2029 will resolve supply capacity needs identified on section (Essa x Alliston JCT) and asset renewal needs. Further coordination is not required.

List of LDC(s) to be involved in further regional planning phases:

- Alectra Utilities Corporation (Alectra)
- Hydro One Distribution
- InnPower
- Orangeville Hydro
- Elexicon Energy
- Lakeland Power
- EPCOR Electricity Distribution Ontario Inc
- NT Power Distribution
- Wasaga Distribution Inc.

List of LDC(s) which are not required to be involved in further regional planning phases:

- n/a

1. INTRODUCTION

The second cycle of the Regional Planning process for the South Georgian Bay - Muskoka Region was completed in December 2022 with the publication of the South Georgian Bay-Muskoka Regional Infrastructure Plan (RIP). The RIP report included a common discussion of all the options and recommended plans for preferred wire infrastructure investments to address the near- and medium-term needs.

This Needs Assessment initiates the third regional planning cycle for the South Georgian Bay - Muskoka Region. The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years. A flow chart of the Regional Planning Process is shown in Figure 1 below.

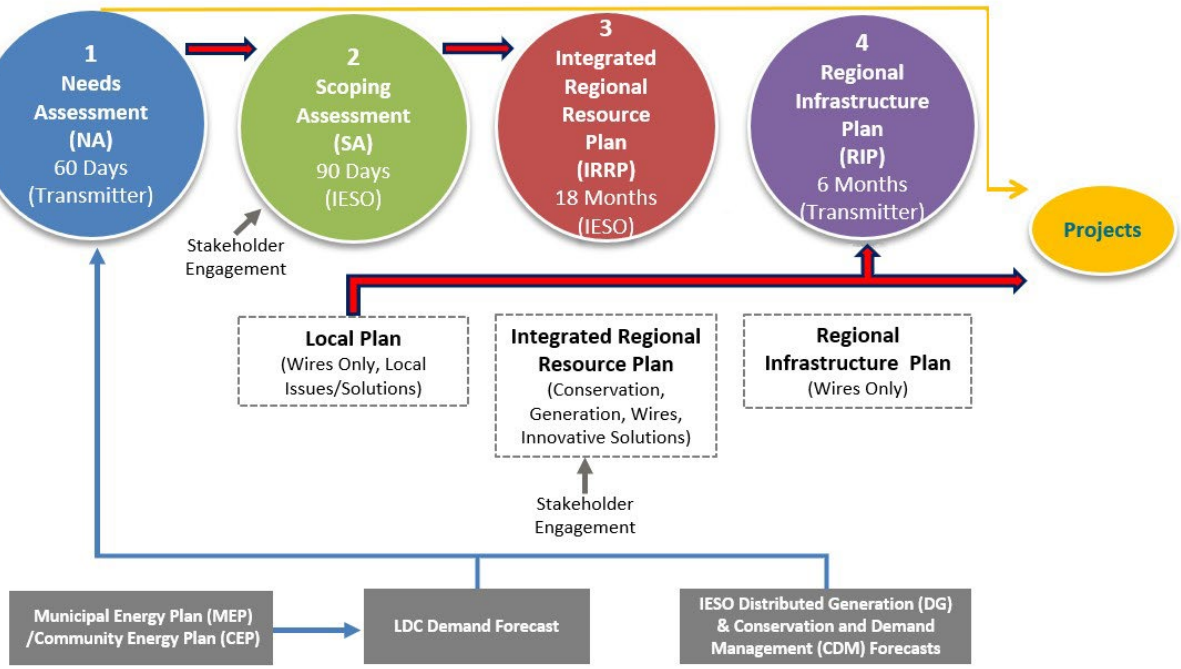

Figure 1: Regional Planning Process

This report was prepared by the South Georgian Bay - Muskoka Technical Working Group("TWG"), led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC") and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: South Georgian Bay - Muskoka Region TWG Participants

Sr. no.	Name of TWG Participants
1	Independent Electricity System Operator (IESO)
2	Alectra Utilities Corporation (Alectra)
3	Hydro One Networks Inc. (Transmission & Distribution)
4	InnPower
5	Orangeville Hydro
6	Elexicon Energy
7	Lakeland Power
8	EPCOR Electricity Distribution Ontario Inc
9	NT Power Distribution
10	Wasaga Distribution Inc.

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. As such, the 3rd Regional Planning cycle was triggered for the South Georgian Bay - Muskoka region.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this NA covers the South Georgian Bay - Muskoka region and includes:

- Review and reaffirm needs/plans identified in the previous cycle RIP (as applicable),
- Identify any new needs resulting from this assessment,
- Recommend which need(s) require further assessment and regional coordination in the next phase of the regional planning cycle to develop a preferred plan; and,
- Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), Local plan (LP) and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is 10 years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

Electrical supply to the South Georgian Bay-Muskoka region is provided through two (2) 500/230kV auto-transformers at Essa TS, the 230kV transmission lines connecting Minden TS to Des Joachims TS, the 230kV circuits E8V and E9V coming from Orangeville TS, and the single 115kV circuit S2S connecting to Owen Sound TS. There are sixteen (16) Hydro One step-down transformer stations in the region, most of which are supplied by circuits radiating out from Essa TS, and the majority of the distribution system is at 44kV, except for Orangeville TS which has 27.6kV and 44kV feeders.

The geographical boundaries of the South Georgian Bay - Muskoka region is shown in Figure 2 below.

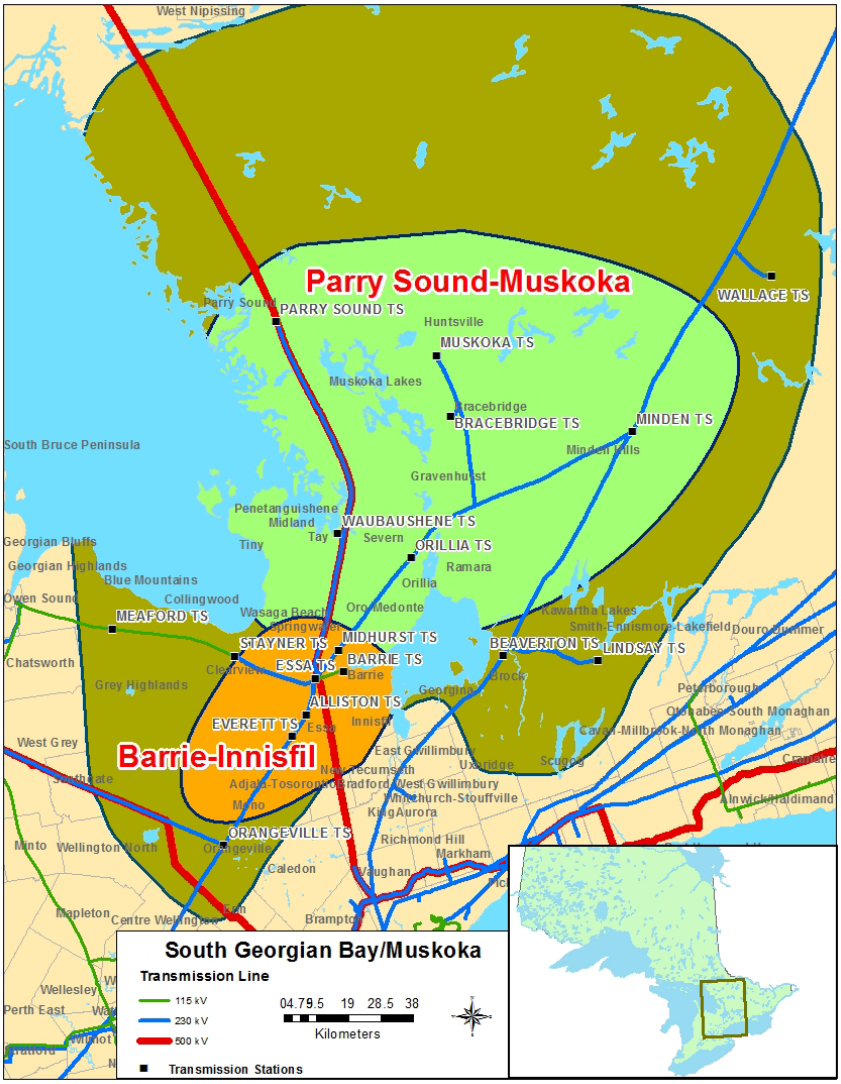

Figure 2: Map of South Georgian Bay - Muskoka Regional Planning Area

The circuits and stations of the area are summarized in the Table 2 below:

Table 2: Transmission Station and Circuits in the South Georgian Bay - Muskoka Region

115kV circuits	230kV circuits	Hydro One Transformer Stations		Generation Stations
S2S	D1M / D2M D3M / D4M E8V / E9V E20S / E21S E26 / E27 E28 / E29 M6E / M7E M80B / M81B	Alliston TS Barrie TS Beaverton TS Bracebridge TS Essa TS * Everett TS Lindsay TS Meaford TS Midhurst TS	Minden TS Muskoka TS Orangeville TS Orillia TS Parry Sound TS Stayner TS* Wallace TS Waubaushene TS	Henvey Inlet North /South) 700MW

*Stations with Autotransformers installed

The single line diagram of the Transmission Network of South Georgian Bay - Muskoka region is shown in Figure 3 below.

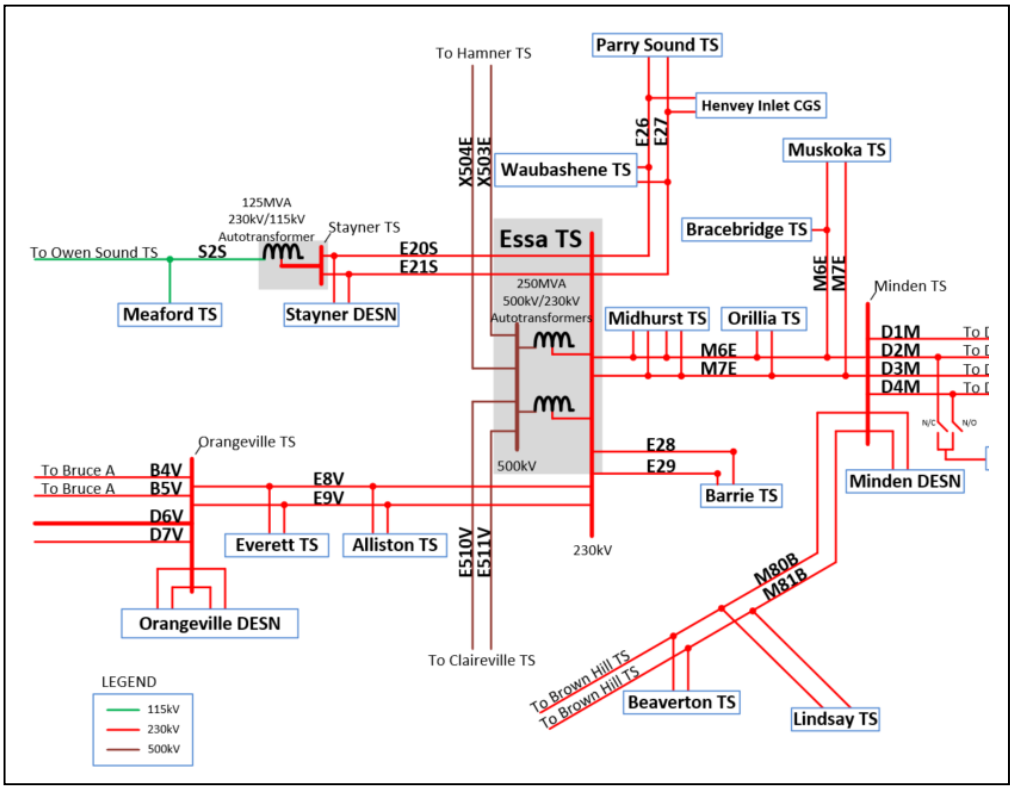

Figure 3: South Georgian Bay - Muskoka Transmission Single Line Diagram

5. INPUTS AND DATA

TWG participants, including representatives from LDCs, IESO, and Hydro One provided information and input for the **South Georgian Bay - Muskoka** NA. With respect to the load forecast information, the OEB Regional Planning Process Advisory Group (RPPAG) recently published a document called "Load Forecast Guideline for Ontario" in Oct. 2022. The objective of this document is to provide guidance to the TWG in the development of the load forecasts used in the various phases of the regional planning process with a focus on the NA and the IRRP. One of the inputs into the LDC's load forecast that is called for in this guideline is information from Municipal Energy Plans (MEP) and/or Community Energy Plans (CEP). The list of all the Municipalities falling under the geographical boundaries of the region are given in Appendix-E.

The information provided includes the following:

- **South Georgian Bay - Muskoka** 10-year summer and winter Load Forecasts for all supply stations inclusive of the inputs provided by the municipalities (e.g. through their MEPs & CEPs).
- Known capacity and reliability needs, operating issues, and/or major assets requiring replacement/ refurbishment; and
- Planned/foreseen transmission and distribution investments that are relevant to Regional Planning for the **South Georgian Bay - Muskoka**.
- Captured uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments

6. ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in development of this Needs Assessment:

6.1 Technical Assessments and Study Assumptions

The technical assessment of needs was undertaken based on:

- Current and future station capacity and transmission adequacy.
- System reliability and operational considerations.
- Asset renewal for major high voltage transmission equipment requiring replacement with consideration to "right-sizing"; and,
- Load forecast data was requested from industrial customers in the region, and
- This assessment is based on both summer and winter peak loads. Three load forecasts were developed i.e. Normal Growth scenario, High and Low Growth scenarios. The High and Low Growth scenario was developed to conduct a sensitivity analysis to cover unforeseen

developments such as fuel switching, Government policies, higher than expected EV charging trend during peak load conditions, etc.

- Consideration of existing or planned distributed energy resources

The following other assumptions are made in this report.

- The study period for this Needs Assessment is 2024-2034.
- The Region is marginally winter peaking; however, the assessment was done on both summer and winter peak loads due to summer equipment ratings being lower.
- Network line and auto-transformation capacity adequacy is assessed by using coincidence peak loads in the area.
- Load-serving station and radial line capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
- Normal planning supply capacity for Hydro One transformer stations is determined by the seasonal 10-Day Limited Time Rating (LTR) of a single transformer at that station.
- Normal planning supply capacity for LDC transformer stations is in accordance with LDC methodology.
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).
- Transmission-connected Resources (e.g. Generators) were set to historical generation output of 98% and 85% availability for the seasons under study, information provided by the IESO.

6.2 Information Gathering Process

6.2.1. Load forecast:

The LDCs provided their load forecasts for summer and winter for all the stations supplying their loads in the South Georgian Bay - Muskoka region for the 10-year study period including the inputs from the Municipalities such as MEPs and CEPs. The IESO provided a Conservation and Demand Management ("CDM") and Distributed Generation ("DG") forecast for the South Georgian Bay - Muskoka region. The region's extreme summer/winter non-coincident peak gross load forecasts for each station were prepared by applying the LDC load forecast growth rates to the actual 2024 summer peak extreme weather corrected loads. The extreme summer/winter weather correction factors were provided by Hydro One. The net extreme summer weather forecasts were produced by reducing the gross load forecasts for each station by the percentage CDM and then by the amount of effective DG capacity provided by the IESO for that station. It is to be noted that as contracts for existing DG resources in the region begin to expire, at which point the load forecast has a decreasing contribution from local DG resources, and an increase in net demand. This

extreme summer/winter weather corrected net load forecast for the individual stations in the South Georgian Bay - Muskoka region is given in Appendix A.

6.2.2. Sensitivity Analysis:

A sensitivity analysis was undertaken by the TWG to capture uncertainty in the load forecast as well as variability of drivers such as electrification. Hence, the NA recommendations are not necessarily linked to sensitivity scenarios; but rather these scenarios are used to identify any emerging needs for consideration in developing recommendations. The impact of sensitivity analysis for the high and low growth scenarios are provided in section 8 of this report.

6.2.3. Asset Renewal Needs for Major HV Equipment:

List of major HV transmission equipment planned and/or identified to be refurbished and/or replaced based on asset condition assessment, relevant for Regional Planning purposes. This includes HV transformers, autotransformers, HV Breakers, HV underground cables and overhead lines. The scope of equipment considered is given in section 7.1.

6.2.4. System Reliability and Operational Issues:

Relevant information regarding system reliability and operational issues in the region as feedback provided by the IESO and Hydro One operation teams during the NA phase.

7. NEEDS

This section describes emerging new needs identified in the South Georgian Bay - Muskoka Region and/or updates on previously identified needs since the completion of Previous Regional Planning (RP) cycle.

Needs that were identified in the previous regional planning cycle with associated projects that were recently completed and reaffirmed needs that are underway are briefly described below with relevant updates and will not be discussed further in this report.

1. **Everett TS Station Capacity** - CT ratio of the low voltage transformer breaker CTs were modified in 2024. However, additional capacity needs are identified and will be studied in this cycle.
2. **Barrie TS Station Capacity** - Construct new 230/27.6kV 83MVA Innpower MTS and extend 230kV E28B/E29B circuits to connect. The planned in-service year is 2029.
3. **Waubaushene TS Station Capacity** – Replacing and upgrading existing 230/44kV 83MVA T5/T6 transformers with 125MVA units. The planned in-service year is 2028.
4. **M6E/M7E (Orillia TS x Coopers FLS JCT) Asset Replacement** – Updated condition assessments have confirmed that the conductor and key components remain in acceptable asset condition, as a result, this need has been postponed beyond the study period of this RP cycle. A new capacity need, however, has been identified and will be studied in this RP cycle.
5. **E8V/E9V (Orangeville TS x Essa JCT) Asset Replacement** – Updated condition assessments have confirmed that the conductor and key components remain in acceptable asset condition, as a result, this need was postponed to 2035 i.e., beyond the study period of this RP cycle. However, IESO has identified a capacity need via the Central & South Bulk study and System Impact Assessments, which will be discussed in this RP cycle.
6. **D1M/D2M (Minden TS x Otter Creek JCT)** – Updated condition assessments have confirmed that the conductor and key components remain in acceptable asset condition, as a result, this need has been postponed beyond the study period of this RP cycle.
7. **Wallace TS Asset Replacement** – T3/T4 transformers will be replaced with like for like 230/44kV 42MVA standard step-down transformer. The planned in-service year is in 2034.
8. **Midhurst TS Asset Replacement** – T4 transformer will be replaced with like for like 230/44kV 125MVA standard step-down transformer. The planned in-service year is in 2034.
9. **Orillia TS Asset Replacement** – T2 transformer will be replaced with like for like 230/44kV 125MVA standard step-down transformer. The planned in-service year is in 2026.
10. **Bracebridge TS Asset Replacement** – T1 transformer will be replaced with like for like 230/44kV 83MVA standard step-down transformer. The planned in-service year is in 2026.
11. **Alliston TS Asset Replacement** – T3/T4 transformers will be replaced with like for like 230/44kV 83MVA standard step-down transformers. The planned in-service year is in 2040. However, a new capacity need has been identified and will be studied in this RP cycle.

Note: The planned in-service year for the above projects is tentative and is subject to change.

All near, and mid-term needs that are discussed as a part of this report are summarized in Table 3 below.

Table 3: Near/Mid-term Needs Identified in this NA and/or Updated from Previous RIP

Need Location	Need Description/Update	NA Report Section
Asset Renewal Needs		
No new Asset Renewal needs identified in this Regional Planning Cycle.		
Station Capacity Needs		
Alliston TS (T3/T4)	Projected to reach capacity in 2032	7.2.1
Everett TS (T1/T2)	Projected to reach capacity in 2030	7.2.2
Midhurst TS (T1/T2)	Projected to reach capacity in 2030	7.2.3
Midhurst TS (T3/T4)	Projected to reach capacity in 2029	7.2.4
Transmission Line Capacity Needs		
230kV M6E/M7E	Projected to reach capacity in mid-term	7.3.1
230kV E8V/E9V	Need identified by IESO in Central & South Bulk study and System Impact Assessments	7.3.2
System Reliability, Operation and Load restoration Needs		
Claireville Area North and Flow North	Operational issues identified, will be studied in the area Bulk System Plan	7.4

7.1 Asset Renewal Needs for Major HV Transmission Equipment

In addition to the previously identified asset renewal needs from the second regional planning cycle, Hydro One and the TWG identified new asset renewal needs for major HV transmission equipment over the next 10 years in the **South Georgian Bay - Muskoka** Region. They are listed in Table 4 below. Hydro One is the only Transmission Asset Owner (TAO) in the Region

Asset renewal needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
  replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

The asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement)
- Replacing equipment with higher ratings and built to current standards

From Hydro One's perspective as a facility owner and operator of its transmission equipment, doing nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance costs and longer duration of customer outages.

Table 4: Major HV Transmission Assets Requiring Replacement in the SGB Muskoka Region

Station/Circuit	Need Description	Planned ISD
Orillia TS	T2 transformer will be replaced with new like for like 230/44kV 125MVA standard step-down transformers	2026
Bracebridge TS	T1 transformer will be replaced with new like for like 230/44kV 83MVA standard step-down transformers	2026
Wallace TS	T3/T4 transformers will be replaced with new like for like 230/44kV 42MVA standard step-down transformers	2034
Midhurst TS	T4 transformer will be replaced with new like for like 230/44kV 125MVA standard step-down transformers	2034

7.1.1 E8V/E9V (Orangeville TS x Essa JCT)

This double circuit 230kV transmission line was in-serviced in 1950. Based on asset condition assessment, this line section requires conductor refurbishment at the end of the study period (2035) to ensure supply reliability and safety is maintained. In conjunction with the existing asset renewal need, these circuits were identified to have a capacity need via the Central & South Bulk study and System Impact Assessments by IESO and recently announced in the *Energy For Generations*[1] report issued by the Ministry of Energy and Mines (June 2025) as a key investment to facilitate growth in the province and strengthen the north-south electricity corridor (more information in section 7.3.2). The in-service date requested in the report precedes the asset renewal upgrade timeline and the upgrade will naturally replace existing components installed on the line. It is recommended this need requires further coordination. The expected in-service date is 2029.

7.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2024-2034 for the 230kV and 115kV Transforming stations in the **South Georgian Bay - Muskoka** Region using the summer and winter peak load forecasts that were provided by the Technical Working Group. Based on the results, the following Station capacity needs have been identified during the study period:

7.2.1 Alliston TS (T3/T4)

Alliston TS (T3/T4) is a 230-44kV 50-83MVA Step Down transformer station supplied by the E8V/E9V circuits. This station presently has a summer 10-day LTR of 100MW and will exceed its normal supply capacity in 2032 based on the summer demand forecast.

Previous regional planning cycle identified these transformers would be replaced in 2030, however Hydro One has since revised its assessment on the condition of these units and delayed the replacement outside of the study period to 2040.

It is recommended the capacity need be assessed and reaffirmed in the next phase of this regional planning cycle.

7.2.2 Everett TS (T1/T2)

Everett TS (T1/T2) is a 230-44kV 50-83MVA Step Down transformer station supplied by the E8V/E9V circuits. This station presently has a 10-day LTR of 107MW (sum) and 115MW (win) and will exceed its normal supply capacity in 2030 and 2033 respectively.

As a result of the findings in the previous cycle RIP, Hydro One modified the CT ratio of the low voltage transformer breaker CTs to increase the station capacity. This was completed in 2024 and helped to defer

[1] https://www.ontario.ca/page/energy-generations

a capacity need identified in the previous cycle. Everett TS load forecast continues to grow and irrespective of the recent modifications, station capacity needs continue to exist within the study period.

It is recommended this need be assessed and reaffirmed in the next phase of this regional planning cycle.

7.2.3 Midhurst TS (T1/T2)

Midhurst TS (T1/T2) is a 230-44kV 75-125MVA Step Down transformer station supplied by the M6E/M7E circuits. This station presently has a 10-day LTR of 162MW (sum) and will exceed its normal supply capacity in 2030 based on the summer demand forecast.

It is recommended this need be assessed and reaffirmed in the next phase of this regional planning cycle.

7.2.4 Midhurst TS (T3/T4)

Midhurst TS (T3/T4) is a 230-44kV 75-125MVA Step Down transformer station supplied by the M6E/M7E circuits. This station presently has a 10-day LTR of 149MW (sum) and will exceed its normal supply capacity in 2029 based on the summer demand forecast.

It is recommended this need be assessed and reaffirmed in the next phase of this regional planning cycle.

7.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period 2025-2034 for the 230kV and 115kV Transmission line circuits in the South Georgian Bay - Muskoka Region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater this need. Based on the results, the following line capacity needs have been identified during the study period:

7.3.1 230kV - M6E/M7E

The M6E/M7E circuits are 230kV transmission lines forming a critical path between Essa TS and Minden TS. Two sections of this circuit (Essa x Midhurst) and (Coopers Fls JCT x Minden) both exceed their Long Term Emergency (LTE) supply capacity during the study period and will require mitigating solutions to allow for increased flow. These needs were also documented in the previous cycle of regional planning and the TWG recommended to continue to monitor loading. Flows on this path are heavily influenced by area load and generation both within and outside of the SGB-Muskoka region.

It is recommended this need to be further explored in the next phase of this regional planning cycle.

7.3.2 230 kV - E8V/E9V

E8V/E9V circuits are 230kV transmission lines forming a critical path between Essa TS and Orangeville TS. These circuits supply customer transformer stations, carry system flows, and are incorporated into the FETT (Flow East Toward Toronto) interface limits. Based on the coincident load forecast, the Essa TS x Alliston JCT line section will exceed its supply capacity during the study period and will require mitigating solutions to allow for increased flows. This finding incorporates a higher growth scenario with the prospect of large industrial connected loads to be connected on the circuits.

In conjunction with the identified capacity need, these circuits were recently announced in the *Energy For Generations*[2] report issued by the Ministry of Energy and Mines (June 2025) as a key investment to facilitate growth in the province and strengthen the north-south electricity corridor. Also based on asset condition assessment, this line section requires conductor refurbishment at the end of the study period (2035) to ensure supply reliability and safety is maintained.

This investment to upgrade these circuits is presently underway with an in-service date planned for 2029. This investment will address the supply capacity needs identified above, including asset replacement. No further regional coordination is required.

7.3.3 115kV Circuits

No Supply capacity needs on 115kV circuit were identified during the study period.

[2] https://www.ontario.ca/page/energy-generations

7.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service.

Operational needs presented to the TWG consisted of two legacy concerns: Load restoration (M6E/M7E) and Long Term Emergency (LTE) overloading (M6E/M7E)

Load Restoration criteria continue to be respected in the region and were recently addressed by the installation of 230kV motorized in-line switches on the M6E/M7E circuits. Thermal overloading has also been reaffirmed in this Needs Assessment and will be further studied in future stages of regional planning.

Additional operational concerns on area interface limits on the CLAN (Claireville Area North) and FN (Flow North) limits were identified. The TWG acknowledges that increased flows in the overall area impact operational limits, however this will be further assessed in bulk area studies outside of regional planning.

Given the above needs have either already been identified or will be studied outside of this process, no other new significant system reliability, operating and restoring issues have been identified for this Region.

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments. The TWG determined that the key electric demand driver in the South Georgian Bay - Muskoka region to be considered in this sensitivity analysis is electric vehicle (EV) penetration and unforeseen electrification which would cause the load to increase at a faster rate than shown in the forecast; or the potential delay in some projects which could result in less demand than anticipated.

The TWG reviewed EV scenarios, and any unforeseen electrification needs to develop high demand growth forecasts by applying 50% additional growth to the growth rate on the extreme summer/winter corrected Normal Growth net load forecasts. The low growth scenario was obtained by reducing the growth rate by 50%.

Table 5: Impact of Sensitivity Analysis on Station/Line capacity Needs in the Region

		Summer Growth Scenario			Winter Growth Scenario		
Sr.no.	Need Identified	Low	Normal	High	Low	Normal	High
1	Alliston (T3/T4)	-	2032	2028	-	-	2033
2	Alliston (T2)	-	-	-	-	-	-
3	Barrie (T3/T4)	-	2031	2028	-	-	-
4	Beaverton (T3/T4)	-	-	-	-	-	-
5	Bracebridge (T1)	-	-	-	-	-	-
6	Everett (T1/T2)	-	2030	2027	-	2033	2029
7	Lindsay (T1/T2)	-	-	2034	-	-	2032
8	Meaford (T1/T2)	-	-	-	-	-	
9	Midhurst (T1/T2)	-	2030	2028	-	-	2032
10	Midhurst (T3/T4)	-	2029	2027	-	-	-
11	Minden (T1/T2)	-	-	-	-	-	-
12	Muskoka (T1/T2)	-	-	2030	-	-	2031
13	Orangeville (T1/T2)	-	-	2030	-	-	2034
14	Orangeville (T3/T4)	-	-	-	-	-	-
15	Orillia (T1/T2)	-	-	-	-	-	-
16	Parry Sound (T1/T2)	-	-	-	-	-	-
17	Stayner (T3/T4)	-	-	-	-	-	-
18	Wallace (T3/T4)	-	-	2029	-	-	2030
19	Waubashene (T5/T6)	2030	2028	2026	2034	2028	2028

The sensitivity analysis identified the additional capacity needs at the end of the study period. High growth scenario forecasts introduce additional supply capacity needs at Lindsay TS, Midhurst TS, Muskoka TS, and Wallace TS. These needs will be assessed again during the next phase of this Regional Planning cycle.

9. CONCLUSION AND RECOMMENDATION

The Technical Working Group's recommendations to address the needs identified are as follows:

Table 6: Needs that Require Further Regional Coordination

#	Need Location	Need Description
1	M6E/M7E (Supply Capacity)	Supply Capacity need identified on (Essa x Midhurst, Minden x Coopers Fls JCT). Further coordination is required to reaffirm need, solution and timing.
2	Alliston T3/T4 (Supply Capacity)	Alliston TS (T3/T4) is a 230-44kV 83MVA transformer station and will exceed its normal supply capacity within the study period. Further coordination is required to reaffirm need, solution and timing.
3	Everett T1/T2 (Supply Capacity)	Everett TS (T3/T4) is a 230-44kV 83MVA transformer station and will exceed its normal supply capacity within the study period. Further coordination is required to reaffirm need, solution and timing.
4	Midhurst T1/T2, T3/T4 (Supply Capacity)	Midhurst TS (T1/T2) and (T3/T4) are 230-44kV 125MVA transformer stations and will both exceed their normal supply capacity within the study period. Further coordination is required to reaffirm need, solution and timing.
5	Claireville Area North and Flow North	Operational issues identified, will be studied in Bulk System Plan

Table 7: Needs that Do Not Require Further Regional Coordination

#	Need Location	Need Description
6	E8V/E9V (Asset Renewal + Supply Capacity)	Essa TS x Orangeville TS line section will be upgraded as per Ministry of Energy's – Energy for Generations report. This upgrade planned for 2029 will resolve supply capacity need identified on section (Essa x Alliston JCT) and asset renewal needs. Further coordination is not required.

List of LDC(s) to be involved in further regional planning phases:

- Alectra Utilities Corporation (Alectra)
- Hydro One Distribution
- InnPower
- Orangeville Hydro
- Elexicon Energy
- Lakeland Power
- EPCOR Electricity Distribution Ontario Inc
- NT Power Distribution
- Wasaga Distribution Inc.

List of LDC(s) which are not required to be involved in further regional planning phases:

- n/a

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CEP	Community Energy Plan
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CSS	Customer Switching Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DS	Distribution Station
GS	Generating Station
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	KiloVolt
LDC	Local Distribution Company
LP	Local Plan

Disclaimer

This Regional Infrastructure Plan (RIP) report is an electricity infrastructure plan that identifies and addresses near and mid-term needs based on information provided and/or collected by the Study Team.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the Study Team.

Study Team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN (RIP) WAS PREPARED BY HYDRO ONE WITH PARTICIPATION AND INPUT FROM THE RIP STUDY TEAM IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE PLANNED, DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE SUDBURY/ALGOMA REGION.

The participants of the Regional Planning activities for the Sudbury/Algoma region ('the Study Team')included members from the following organizations:

- Greater Sudbury Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- North Bay Hydro (Embedded LDC)
- Independent Electricity System Operator (IESO)
- Hydro One Networks Inc. (Lead Transmitter)

The last regional planning cycle for the Sudbury/Algoma region was completed in June 2016 with the publication of the RIP report.

This RIP is the final phase of the 2nd regional planning cycle and follows the 2nd Cycle Sudbury/Algoma region's Needs Assessment (NA) completed in August 2020. Based on the findings of the NA, the Study Team recommended no further regional coordination is required at this time. Hence, this RIP is based on the data collected during the NA phase and the findings and recommendations of the NA report. A new Energy Efficiency framework was announced by the Ontario Government since the completion of the NA of the Sudbury/Algoma region. Resulting impacts of the newly announced framework are not reflected in the present RIP.

This RIP provides a consolidated summary of the outcome of the needs and recommended plans for the Sudbury/Algoma region as identified by the regional planning study team. The RIP also discusses needs identified in the previous regional planning cycle and the NA report for this cycle; and the projects developed to address these needs. Implementation plans to address some of these needs are already completed or are underway. Since the initiation of the previous regional planning cycle, the following project has been completed:

- **Espanola TS**: Replace 115/44 kV 15MVA (T1) and 42MVA (T2) transformers with new 115/44 kV 42 MVA units. These transformers were assessed at being at their end-of-life and in need of replacement due to the assets'condition. This project was successfully carried out and in serviced in Q4 2016.

- **Larchwood TS** – Replace 110/44 kV 20 MVA (T2) transformer with a new 115/44kV 42MVA unit. This project was successfully completed and in serviced in Q4 2015.

The major infrastructure investments identified and supported by the Study Team over the near- and mid-term planning horizon are provided in Table 1 below, along with their planned in service dates and budgetary allowances for planning purpose.

Table 1: Recommended Plans in Sudbury/Algoma region over the Next 10 Years

No.	Needs	Plans	Planned I/S Date	Budgetary Allowance ($M)
1	Manitoulin TS Capacity Constraint	Change limiting CT ratio	2021	0.02
2	Under peak load conditions, the loss of two Martindale 230/115kV transformers may result in the overload of the third Martindale transformer	Martindale autotransformers T21/T23 Replacement project	2022[1]	76
3	With either X25S or X26S is out of service, the loss of the companion circuit may result in voltage declines at Martindale 230kV and 115kV buses below acceptable limits set out in the Ontario Ressources and Transmission Assessement Criteria(ORTAC) document	Unbundle X25S/X26S	2023	8
4	Elliot Lake TS end-of-life (EOL) Power Transformer Replacement	Right-sizing that station by replacing 115/44 kV 42 MVA (T1) power transformer with new 115/44kV 42 MVA unit. Remove 115/44 kV 19 MVA (T2) 8autotransformer. Upon completion of this project, the station will remain with 2 – 115/44kV 42 MVA (T1/T3) power transformers.	2025	23
5	Algoma TS end-of-life (EOL) autotransformer replacement	Replace 230/115kV 195 MVA and 115 MVA autotransformers (respectively T5 and T6) with new 230/115kV 125 MVA transformers.	2025	23
6	Clarabelle TS end-of-llife (EOL) Power transformer Replacement	Replace 230/44kV 125 MVA (T1/T2) power transformers with new 230/44kV 125 MVA units.	2027	19
7	Martindale TS end-of-life (EOL) Power Transformer Replacement	Replace 230/44 kV 125 MVA (T1/T2) power transformers with new 230/44 kV 125 MVA units.	2028	19
8	Martindale TS Supply Capacity Constraint	Maintain the status quo and reassess station supply needs during the next Regional Planning Cycle	2028	N/A

The Study Team recommends the continuation of the investments listed in Table 1. Hydro One transmission will coordinate with affected LDCs to implement these undertakings.

[1] Earlier Regional Planning documents indicate 2020 as the planned in service date for this project. Needs reprioritization as well as current pandemic conditions resulted in pushing the targeted completion date for this undertaking to 2022.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE SUDBURY/ALGOMA REGION BETWEEN 2020 AND 2029.

The report was prepared by Hydro One Networks Inc. (HONI) with input from Study Team members during the Needs Assessement (NA) phase and documents the results of the NA and recommended plan. The Study Team included representative from Greater Sudbury Hydro Inc, North Bay Hydro, HONI(Transmission and Distribution) and the Independent Electricity System Operator (IESO) in accordance with the Regional Planning process established by the Ontario Energy Board (OEB) in 2013.

The Sudbury to Algoma Region includes Greater Sudbury Area, Manitoulin Island, and townships of Verner, Warren, Elliot Lake, Blind River and Walden. The boundaries of the Sudbury to Algoma Region are shown below in Figure 1.

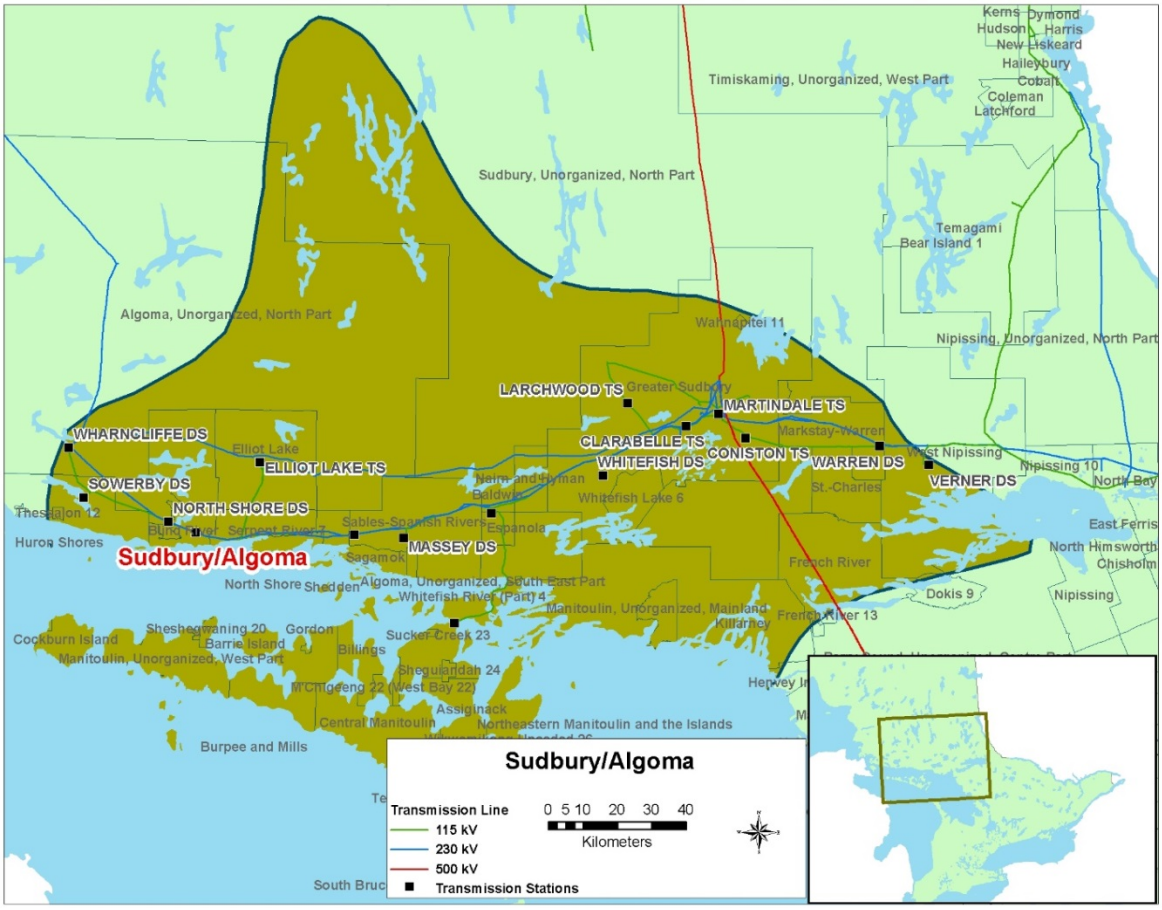

Figure 1-1: Sudbury/Algoma region

Electrical supply to the Sudbury/Algoma region is provided through a network of 230kV and 115kV transmission circuits supplied by autotransformers at Hanmer TS, Algoma TS and Martindale TS. This area is further reinforced through the 500kV circuits (P502X and X504/503E) connecting Hanmer TS

(Sudbury) to both Porcupine TS (Timmins) and Essa TS (Barrie). It is also connected to northwest Ontario through Mississagi TS

1.1 Objective and Scope

The RIP report examines the needs in the Sudbury/Algoma region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs;
- Identify any new needs that may have emerged since previous planning phases e.g., NA and/or Integrated Regional Resource Plan(IRRP);
- Assess and develop a wires plan to address these new needs; and
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, major high voltage sustainment issues emerging over the near, mid and long-term, transmission and distribution system capability along with any updates with respect to local plans, Conservation and Demand Management (CDM), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration. A new Energy Efficiency framework was announced by the Ontario Government since the completion of the NA of the Sudbury/Algoma region. This RIP does not take into account the resulting impact of the newly announced CDM framework.

The scope of this RIP is as follows:

- Discussion of any other major transmission infrastructure investment plans over the near, mid and long-term (0-20 years)
- Identification of any new needs and a wires plan to address these needs based on new and/or updated information, if any.

As mentioned this particular RIP is based on the information collected and recommendations from the NA phase of regional planning because no further regional coordination or assessments were required.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the regional characteristics.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies needs.
- Section 7 discusses the needs and provides the alternatives and preferred solutions.
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board (OEB) in 2013 through amendments to the Transmission System Code (TSC) and Distribution System Code (DSC). The process consists of four phases: the Needs Assessment [2] (NA), the Scoping Assessment (SA), the Integrated Regional Resource Plan (IRRP), and the Regional Infrastructure Plan (RIP).

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Study Team determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company (LDC) or customer and develops a Local Plan (LP) to address them.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then

[2] Also referred to as Needs Screening

further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region.

The RIP phase is the fourth and final phase of the regional planning process and involves: discussion and reconfirmation of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and/or LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect.
- The NA, SA, and LP phases of regional planning.
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.
- Working and planning for connection capacity requirements with the LDCs and transmission connected customers.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

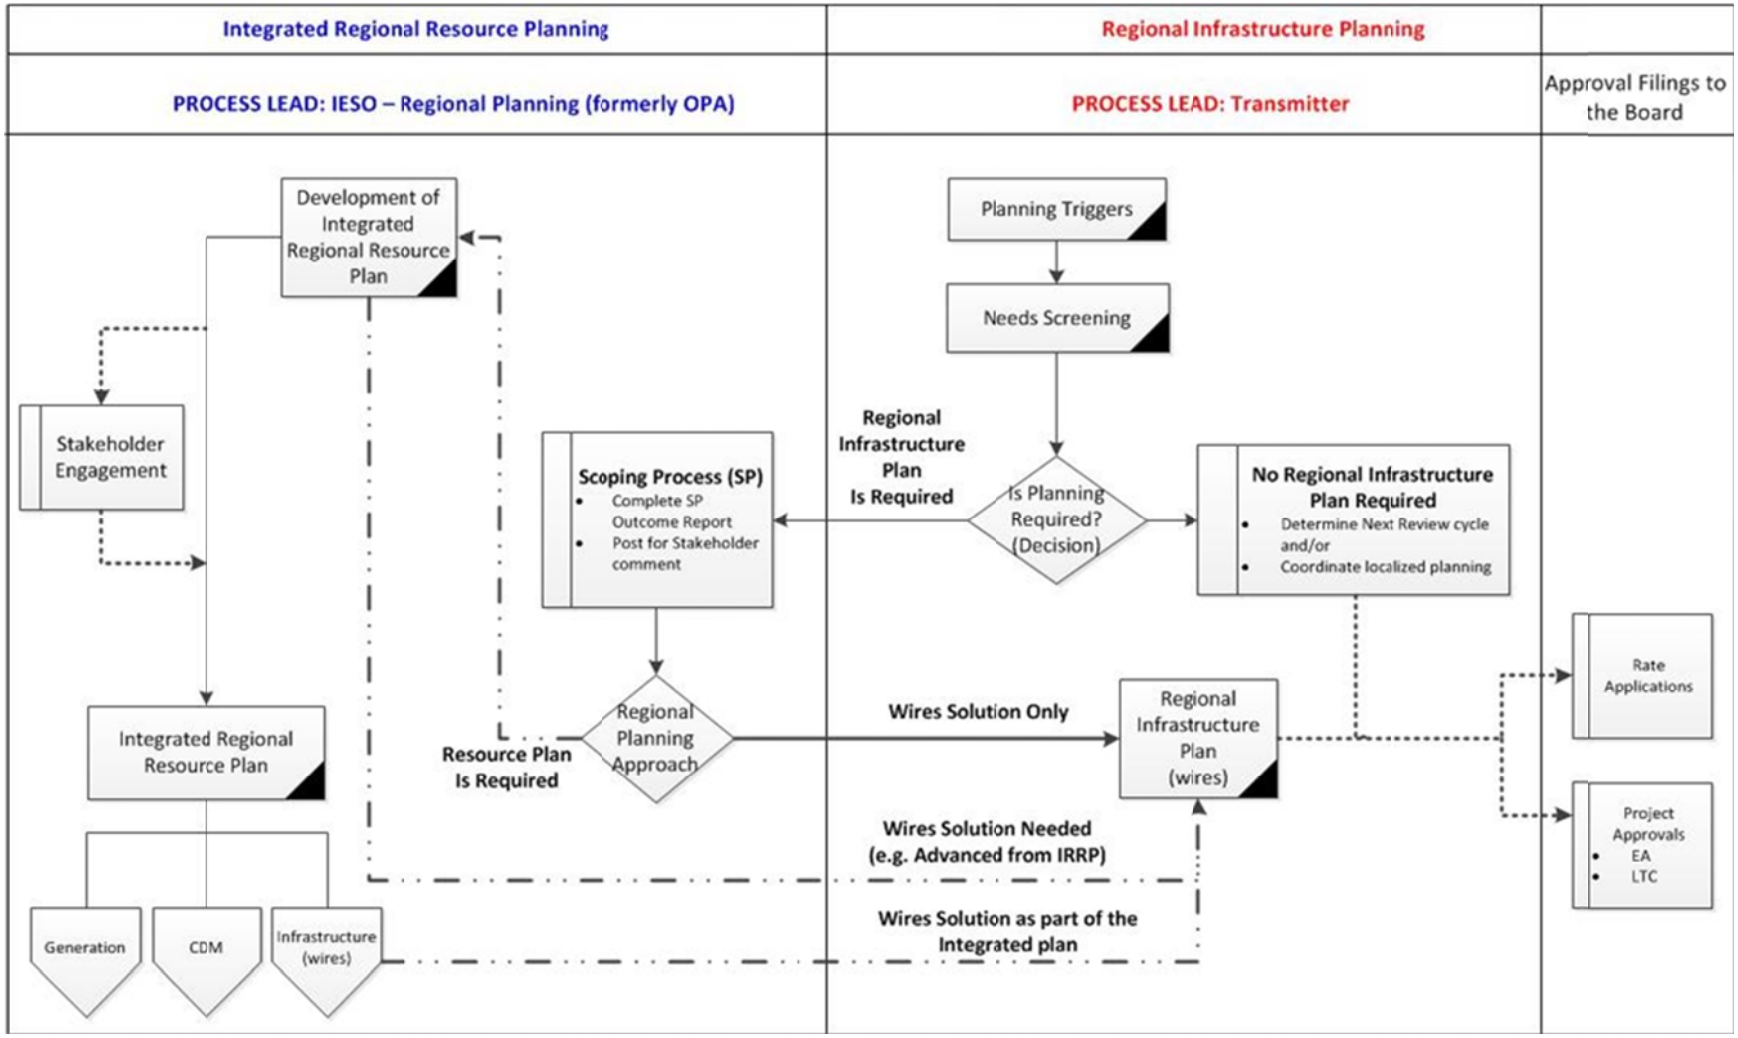

Figure 2-1: Regional Planning Process Flowchart

For the Sudbury/Algoma region, no need was identified that requires regional coordination. Hence,the Regional Planning process for the region moved directly to its RIP phase following the completion of the NA phase.

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous phase of the regional planning process. Hydro One collects this information and reviews it with the Study Team to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Depending upon the changes to load forecast or other relevant information, regional technical assessment may or may not be required or be limited to specific issue only. Additional near and mid-term needs may be identified in this phase.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

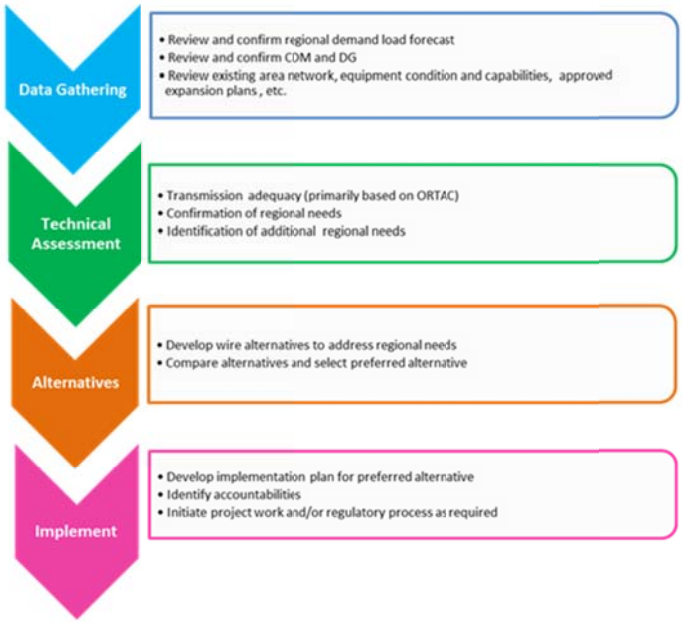

Figure 2-2: RIP Methodology

3. REGIONAL CHARACTERISTICS

THE SUDBURY/ALGOMA REGION IS COMPRISED OF THE GREATER SUBDURY AREA, MANITOULIN ISLAND AND THE TOWNSHIPS OF VERNER, WARREN, ELLIOT LAKE AND WALDEN. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED THROUGH A NETWORK OF 230KV AND 115KV CIRCUITS SUPPLIED FROM AUTOTRANSFORMERS AT HANMER TS, ALGOMA TS AND MARTINDALE TS.

Bulk electrical supply to the Sudbury/Algoma region is currently provided through Hanmer TS, Algoma TS and Martindale TS, three (3) major autotransformers station in the region. This area is further reinforced through the 500 kV circuits (P502X and X503/504E) connecting Hanmer TS (in Sudbury) to Porcupine TS (in Timmins) and Essa TS (in Barrie). The area is also connected to the north western Ontario through Mississagi TS.

This region has the following two transmission-connected local distribution companies (LDC):

- Greater Sudbury Hydro Inc.
- Hydro One Networks Inc. (Distribution)

North Bay Hydro is a third LDC in this region embedded into the Hydro One Disribution system. Although invited to participate directly in the NA process, the data related to this LDC as well as their operational concerns was communicated through their host LDC Hydro One Distribution.

Tranmission connected industrial/commercial loads in the Sudbury to Algoma region form a large percentage (approximately 50%) of the overall demand. Although these customers are not explicitly participating in the regional planning process, Hydro One will consider their impact in the RIP of this region.

Below is a description of the major assets in the region:

- Hanmer TS is the major transmission station that connects the 500kV network to the 230kV system via two 500/230 kV autotransformers.
- Algoma TS (230 kV) and Martindale TS (230 kV) are the transmission stations that connect the 230kV network to the 115kV system via 230/115 kV autotransformers.
- Eight (8) step-down transformer stations supply the Sudbury/Algoma load Algoma TS (115 kV), Martindale TS (115 kV), Coniston TS[3], Larchwood TS, Manitoulin TS, Espanola TS, Clarabelle TS, Elliot Lake TS. There are also nine HVDS that supply load in the Region: Sowerby DS, Wharncliffe DS, North Shore DS, Striker DS, Spanish DS, Massey DS, Whitefish DS, Warren DS and Verner DS.

[3] Coniston TS in its entirety is being decommissioned and removed.The load previously supplied from Coniston TS will be transferred onto Martindale TS DESN. The targeted completion date falls between now and the next Regional Planning Cycle for this region.

- Nine (9) Customer Transformer Stations (CTS) are supplied in the Region: Carmeuse Lime CTS, Sudbury Smelter CTS, Falconbridge CTS, Nickel Rim CTS, Eacom Nairn CTS, Onaping Area M&M CTS, Milman Foundry CTS, Vale Copper #4 CTS and Vale Frood Stbe #2 CTS.
- There are four (4) existing transmission connected generating stations (GS) in the region as follows:
    - Red Rock GS is a 40 MW hydro electric generation plant connected to circuit T1B
    - Rayner GS is a 42MW hydro electric generation plant connected to circuit T1B
    - McLean's Mountain Wind is a 60 MW wind farm connected to circuit S2B. It is located at the North end of the Manitoulin Island.
    - Aux Sables GS is a 5 MW hydro electric generation plant connected to 115kV circuit S2B
    - Serpent GS is a 8 MW hydro electric generation facility connected to 115kV circuit S2B

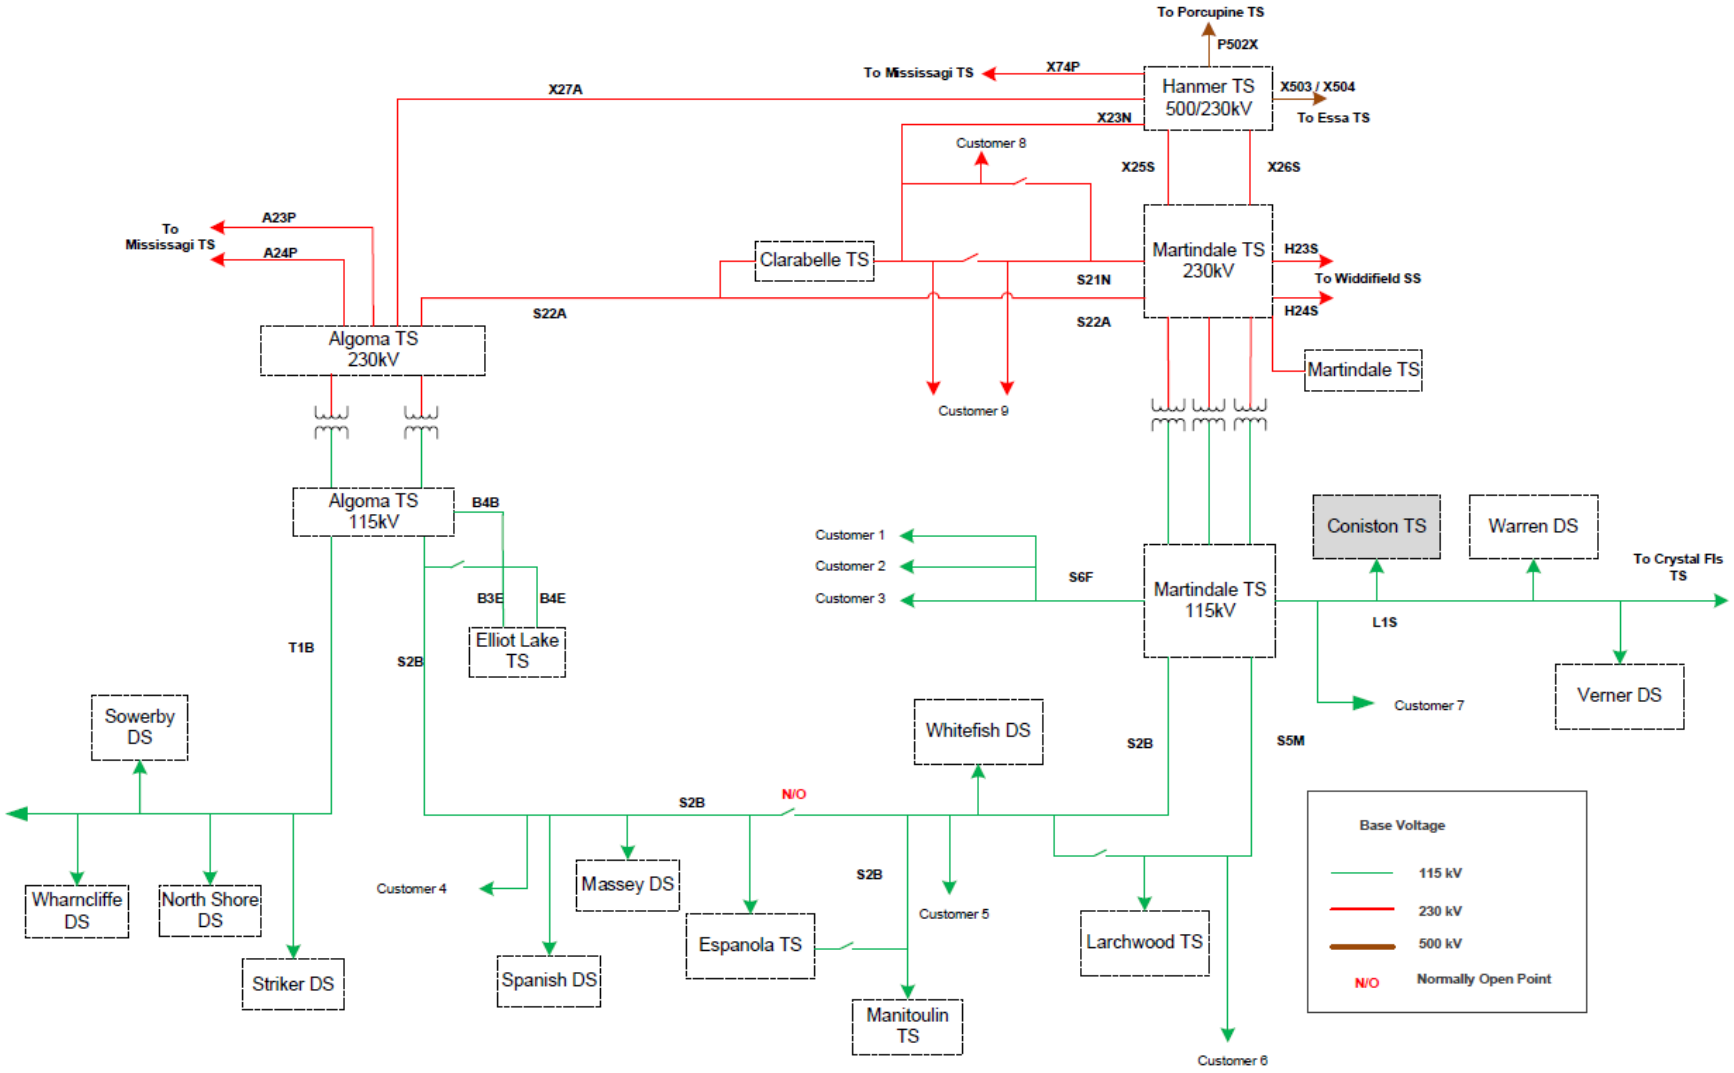

Figure 3-3: Single Line Diagram of Sudbury/Algoma Region

4. TRANSMISSION PROJECTS COMPLETED OVER LAST TEN YEARS

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, IN CONSULTATION WITH THE LDCs AND/OR THE IESO, AIMED TO MAINTAIN OR IMPROVE THE RELIABILITY AND ADEQUACY OF SUPPLY IN THE SUDBURY/ALGOMA REGION.

A summary and description of the major projects completed and/or currently underway over the last ten years is provided below:

i. **Espanola TS**: Replace 115/44 kV 15MVA (T1) and 42MVA (T2) transformers with new 115/44 kV 42 MVA units. These transformers were assessed at being at their end-of-life and in need of replacement due to the assets'condition. This project was successfully carried out and in serviced in Q4 2016.

ii. **Larchwood TS** – Replace 110/44 kV 20 MVA (T2) transformer with a new 115/44kV 42MVA unit. This project was successfully completed and in serviced in Q4 2015.

iii. **Coniston TS** - The previous Regional Planning cycle Needs Assessment makes mention of the removal of the Coniston TS and its load being transferred to a newly built Hanmer TS DESN. Due to customers's changing system needs, this plan was reviewed and it evolved into the removal of the station in concurrence with the conversion of the legacy 22kV loads to 27.6kV and their transfer onto one of the feeders originating from Martindale TS. Current pandemic conditions have slowed down the progression of this project. The project is currently planned to be completed in Q3 2021.

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The LDCs provided load forecasts for all the stations supplying their loads in the Sudbury/Algoma region for the 10 year study period. The IESO provided a CDM and Distributed Generation (DG) forecast for the Sudbury/Algoma region. The region's extreme winter non-coincident peak gross load forecast for each station was prepared by applying the LDC gross load forecast growth rates to the actual 2019/20 winter peak load corrected for extreme weather. The extreme weather correction factors were provided by Hydro One. The net extreme weather corrected winter load forecast was produced by reducing the gross load forecast for each station by the percentage CDM and by the amount of effective DG capacity provided by the IESO for that station. It is to be noted that in the mid-term (5 to 10 year) time frame, contracts for existing DG resources in the region begin to expire, at which point the load forecast indicates a decreasing contribution from local DG resources, and thus an increase in net demand. These load forecasts for the individual stations in region are given in Appendix A. While the non-coincident load forecast was used to determine the need for station capacity, the coincident load forecast was used to assess the need for autotransformation and transmission line capacity in the region.

5.2 Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2020-2029.
- All transmission facilities listed in Section 3 are in service.
- Where forecasts were not available, industrial loads were assumed based on historical information.
- Winter is the critical period with respect to line and transformer loadings. The assessment is therefore based on winter peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low voltage capacitor banks and 95% lagging power factor for stations having low voltage capacitor banks.
- Line capacity adequacy is assessed by using coincident peak loads.
- Autotransformers capacity adequacy is assessed by using coincident peak loads.
- Normal planning supply capacity for transformer stations in this sub-region is determined by the Hydro One summer 10-Day Limited Time Rating (LTR).
- Adequacy assessment is conducted as per the Ontario Resource Transmission Assessment Criteria (ORTAC).

6. ADEQUACY OF FACILITIES

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND DELIVERY STATION FACILITIES SUPPLYING THE SUDBURY/ALGOMA REGION OVER THE 2020-2029 PERIOD.

Within the current regional planning cycle one regional assessment have been conducted for the Sudbury/Algoma region. The study is presented below:

The NA report principally identified two (2) needs within the study period and reaffirmed existing needs arising from EOL asset issues. A review of the loading on the transmission lines and stations in the Sudbury/Algoma region was also carried out as part of this RIP report using the latest regional load forecast as given in Appendix D. Sections 6.1 to 6.5 present the results of this review. Further description of assessments, alternatives and preferred plan along with status is provided in Section 7.

All the identified needs in the first cycle of the Regional Planning of the Sudbury/Algoma have been addressed. The low voltage at Manitoulin TS stems from the station being at the end of a long radial circuit under normal operating conditions. The power transformers at Manitoulin TS are equipped with under load tap changers with wide regulation bands (+/-20%) to maintain the LV side voltage within acceptable voltage limits. As such, Hydro One and the affected LDC are assured that the low voltage incidence at the Manitoulin TS high side connection point has no material impact on the system or its connected customers. Hydro One will continue to monitor the voltage performance at the Manitoulin TS high side connection point and will take the appropriate remedial actions if and when this low voltage incidence is deemed adversely impactive to customers and system reliability.

6.1 230/115 kV Autotransformers

The 230/115 kV autotransformers (Algoma TS and Martindale TS) supplying the Region are within their thermal limits and within the voltage range as per Ontario Resource and Transmission Assessment Criteria (ORTAC) over the study period for the loss of a single 230/115 kV autotransformer in the Region.

6.2 230 kV Transmission Lines

The 230 kV circuits supplying the Region are within their thermal limits as per ORTAC over the study period for the loss of a single 230 kV circuit in the Region.

6.3 115kV Transmission Lines

The 115 kV circuits supplying the Region are within the thermal limits of the circuits as per ORTAC over the study period adequate over the study period for the loss of a single 115 kV circuit in the Region.

6.4 230 kV and 115 kV Connection Facilities

A station capacity and voltage assessment was performed over the study period for the 230 kV and 115 kV TS's in the Region using the winter station peak load forecasts that were provided by the study team. The results are as follows:

6.4.1 Clarabelle TS

The 2019 actual non-coincident winter peak load at Clarabelle TS was 121 MW which is below the its 10-day winter LTR of 184 MW. Based on demand forecast Clarabelle TS will not be loaded above its 10-day LTR during the assessed planning horizon.

6.4.2 Elliot Lake TS

The 2019 actual non-coincident winter peak load on Elliot Lake TS was 20 MW which is below its 10-day winter LTR of 66 MW. Based on demand forecast, Elliot Lake TS will not be loaded above its 10-day LTR during the assessed planning horizon.

6.4.3 Espanola TS

The 2019 actual non-coincident winter peak for Espanola TS was 13 MW which is below the station 10-day winter LTR of 61 MW. As per the demand forecast, the loading at Espanola TS will not exceed the station 10-day winter LTR within the assessed planning horizon.

6.4.4 Larchwood TS

The 2019 actual non-coincident winter peak for Larchwood TS was 13 MW which is below the station 10-day winter LTR of 37 MW. Based on the submitted load forecast, the loading on Larchwoord TS will not exceed the station 10-day winter LTR within the assessed planning horizon.

6.4.5 Manitoulin TS

Manitoulin TS has a summer and winter 10-day LTR of 37 MW. The station loading - the weather adjusted winter peak loading of 37.8 MW - is already above the station LTR. The station supply capability is limited by a Current Transformer (CT) ratio setting on the low voltage bus of the station, thereby restricting the ability to utilize the full supply capability of the transformers. It should be noted

that the station low voltage bus configuration is such that the loss of one of the transformers will remove half of the load by configuration[4]. Therefore, the loss of one of the transformers during station peaking conditions will not result in a thermal overload of the remaining transformer. That being said, adequate supply capability at the station should be maintained to pick up the dropped load in the occurrence of such an event. Given its geographical location, this station cannot rely on any other nearby station for capacity relief via load transfer. Plans are already in place to address this need. These plans are further detailed in section 7 of this report.

IESO has expressed concerns on the voltage performance at the 115kV connection point of circuit S2B at Manitoulin TS. During system conditions where the nearby McCleans Mountain wind farm is unavailable, voltages on the 115kV side of the station can be as low as 108 kV which is below ORTAC voltage limit of 113kV. This low voltage incidence has previously been well documented and studied and was further reiterated in 2015 during the first cycle of the Sudbury/Algoma Needs Assessment. Circuit S2B is normally operated open, leaving Manitoulin TS, McCleans Mountain wind farm, one industrial customer and Whitefish DS on the Martindale TS side of the circuit. The low voltage at Manitoulin TS stems from the station being at the end of a long radial circuit under normal operating conditions. The power transformers at Manitoulin TS are equipped with under load tap changers with wide regulation bands (+/- 20%) to maintain the LV side voltage within acceptable voltage limits. As such, Hydro One is assured that the low voltage incidence at the Manitoulin TS high side connection point has no material impact on the system or its connected customers. Hydro One will continue to monitor the voltage performance at the Manitoulin TS high side connection point and will take the appropriate remedial actions if and when this low voltage incidence is deemed adversely impactive to customers and system reliability.

6.5 End-of-life (EOL) Equipment Needs

Hydro One and LDCs have provided high voltage asset information under the following categories that have been identified at this time and are likely to be replaced over the next 10 years:

- Autotransformers
- Power transformers
- HV breakers
- Transmission line requiring refurbishment where an uprating is being considered for planning needs and require Leave to Construct (i.e., Section 92) application and approval
- HV underground cables where an uprating is being considered for planning needs and require EA and Leave to Construct (i.e., Section 92) application and approval

The end-of-life assessment for the above high voltage equipment typically included consideration of the following options:

[4] Discussion between the Transmitter and the LDC have confirmed that the existing configuration continues to provide an acceptable level of reliability.

1. Replacing equipment with similar equipment and built to current standards (i.e., “like-for-like” replacement);
2. Replacing equipment with similar equipment of higher / lower ratings i.e. “right sizing” opportunity and built to current standards;
3. Replacing equipment with lower ratings and built to current standards by transferring some load to other existing facilities;
4. Eliminating equipment by transferring all of the load to other existing facilities;

In addition, from Hydro One’s perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

Accordingly, major high voltage equipment has been identified as approaching its end-of-life over the next 10 years and assessed for right sizing opportunity in section 7. At this time, end-of-life driven sustainement needs have been identified at the following stations in the region:

- Algoma TS,
- Clarabelle TS,
- Elliot Lake TS and
- Martindale TS

6.6 System Reliability and Load Restoration

In case of contingencies on the transmission system, ORTAC provides the load restoration requirements relative to the amount of load affected. Planned system configuration must not exceed 600 MW of load curtailment/rejection. In all other cases, the following restoration times are provided for load to be restored for the outages caused by design contingencies.

a. All loads must be restored within 8 hours.
b. Load interrupted in excess of 150 MW must be restored within 4 hours.
c. Load interrupted in excess of 250 MW must be restored within 30 minutes.

No new significant system reliability and operating issues were identified for the Sudbury/Algoma region.

The IESO has expressed the need for additional voltage control flexibility at Algoma TS and this is being addressed as part of the autotransformer replacement project planned at the station. The new autotransformers being procured are equipped with Under Load Tap Changers that will provide the required voltage control flexibility.

Based on the net coincident load forecast, the loss of one element will not result in load interruption greater than 150 MW as per ORTAC. The maximum load interrupted by configuration due to the loss of two elements is below the ORTAC limit of 600MW by the end of the 10-year study period.

6.7 Longer Term Outlook (2029-2040)

Consistent with the NA, the RIP is based on on the 2020-2029 period, a further looking assessment was conducted and looked into the loading between 2029 and 2039. Appendix E presents the winter load forecast used for this assessement. The long-term load forecast was obtained from extrapolation of the near and medium term load forecast into 2039 using the station specific load growth factors.

No long-term needs for the Sudbury/Algoma region was identified beyond the already identified additional capacity needs at Manitoulin TS (starting 2020) and Martindale TS (starting 2028). Recommendations have been made and agreed upon by the Study Team on how to best address these needs. The study group recommend an on-going monitoring of additional load connection requests as they materialize themselves.

Municipalities in region may develop their community energy plans with a primary focus to reduce their energy consumption by local initiatives over next 25 to 30 years. With respect to electricity, these communities may plan for an increased reliance on community energy sources such as distributed generation, generation behind the meters like rooftop solar systems and local energy battery storage systems to reduce cost and for improved reliability of electricity supply.

Some of the communities in Ontario are working towards self-sufficiency by improving efficiencies of existing local energy systems i.e. reducing energy consumption and losses by means of utilizing smarter buildings, houses, efficient heating, cooling, appliances, equipment, and processes for all community needs. Ultimately, the objective of these energy plans in the region is to be a net zero carbon community over the next 25 to 30 years.

Community energy plans may have potential to supplement and/or defer future transmission infrastructure development needs. The Study Team therefore recommends LDCs to review their respective regional community energy plans and provide updates to the working group of any potential projects that may affect future load forecasts in the next cycle of regional planning.

7. REGIONAL NEEDS & PLANS

THIS SECTION DISCUSSES ELECTRICAL INFRASTRUCTURE NEEDS IDENTIFIED IN THE PREVIOUS REGIONAL PLANNING CYCLE, THE NEEDS ASSESSMENT REPORT FOR THIS CYCLE; AND SUMMARIZES THE PLANS DEVELOPED TO ADDRESS THESE NEEDS.

This section outlines and discusses infrastructure needs and plans to address these needs for the near-term (up to 5 years) and the mid- term (5 to 10 years) and the expected planned in service facilities to address these needs.

Current development and sustainment plans are further discussed below.

7.1 Martindale TS Supply Capacity

Martindale TS has a winter 10-day LTR of 164 MW. Based on current load growth projections at the station and considering expiration of generating contracts, the station net load will surpass the station winter 10-day LTR starting in 2028. This is the first iteration of the NA that shows a potential supply capacity need at the station. Given the anticipated timing of the need, there is time to re-evaluate this need in the next cycle of regional planning and once there is additional information on the IESO's resource adequacy framework, scheduled to take place no later than in 2025. Should the need materialize sooner than anticipated at Martindale TS, a station specific needs assessment can be carried out at that time so as to determine the best course of action for meeting the station supply capacity needs.

The following alternatives were considered to address the Martindale TS Supply Capacity need:

1. **Alternative 1 - Maintain Status Quo (Recommended)**: Martindale TS will exceed supply capacity in 2028 based on the load forecasts provided by area customers. The next cycle of regional planning will commence no later than in 2025 and will allow the working group to reevaluate this need and confirm whether or not the occurrence of the supply capacity congestion at Martindale still holds true in 2028. Should this be the case, the study group at that moment will decide the best course of actions to fill this need.

2. **Alternative 2– Add a low voltage capacitor bank for power factor correction:** Studies show that an additional 10 MW of supply capacity can be enabled by the the addition of a capacitor bank on the low voltage bus of this station. The addition of the capacitor bank will improve the station load power factor and draw less reactive power through the power transformers, enabling more active power flow on the units. This solution will provide capacity relief at Martindale TS beyond the study period and defer the need for additional transformation capacity. This alternative was considered but rejected due to how far in the future the need is ought to materialize itself. The next Regional Planning cycle of the region is to reevalute the station supply capacity needs and decide the optimal approach to address the need should it still exist.

7.2 Manitoulin TS Supply Capacity

Manitoulin TS has a summer and winter 10-day LTR of 37 MW. The station loading – the extreme weather adjusted winter peak loading of 37.8 MW - is already above the station LTR .The station supply capability is limited by a Current Transformer(CT) ratio setting on the low voltage bus of the station, thereby restricting the ability to utilize the full supply capability of the transformers. It should be noted that the station low voltage bus configuration is such that the loss of one of the transformers will remove half of the load by configuration[5]. That being said, adequate supply capability at the station should be maintained to pick up the dropped load in the occurrence of such an event. Given its geographical location, this station cannot rely on any other nearby station for capacity relief via load transfer. This need must be adressed as soon as practically feasible to allow full utilization of the station transformers capacity.

The following alternatives were considered to address the Manitoulin TS Supply Capacity need:

1. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected due to the fact that the station winter peak load is already above the station LTR. The absence of neighboring load supply stations that can provide capacity relief to Manitoulin TS should one of the power transformer be unavailable makes this alternative even more unacceptable.

2. **Alternative 2 - Change the CT ratio(Recommended):** A Preliminary assessement has identified that the existing limitation can be removed by changing the CT ratio. Hydro One Networks Inc. is coordinating the implementation of this alternative with the affected LDC. This alternative is currently planned to be implemented in 2021.

7.3 Martindale TS – Hanmer TS Corridor Unbundling

With either X25S or X26S is out of service, the loss of the companion circuit may result in voltage declines at Martindale 230kV and 115kV buses below acceptable ORTAC. The scope of this project aims to decouple one of the two circuits (X25S or X26S) into its own position at both Hanmer TS and Martindale TS. Hydro One Networks initiated this project as per the IESO's recommendation provided via a letter dated October 19th, 2018 addressed to Hydro One Transmission Planning Division. The targeted in service date is in year 2023.

7.4 Martindale TS EOL Autotransformer Replacement

Martindale TS is a 230/115kV BES classified station which also includes a 230kV/44kV Dual Element Spot Network (DESN) station located in Sudbury. The station is comprised of two (2) – 230/115 kV 125 MVA autotransformers (T21, T22) and one (1) 230/115 kV 115 MVA autotransformer (T23).

[5] Discussion between the Transmitter and the LDC have confirmed that the existing configuration continues to provide an acceptable level of reliability.

Autotransformers T21 and T23 as well as five (5) – 230kV breakers and select disconnect switches have been identified as EOL based on asset condition. Under peak load conditions, the loss of the two 125 MVA Martindale 230/115kV autransformers may result in the overload of the third smaller autransformer. The completion of this project will see the station equipped with three (3) 125MVA 230/115kV autotransformers.

The following alternatives where considered to remedie the T23 thermal overload and address EOL assets needs at Martindale TS:

1. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition, would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.

2. **Alternative 2 - Like-for-like replacement with similar equipment (Recommended):** Proceed with like for like replacement of the identifield EOL equipment within the station except for T23 where a larger unit matching the other two autotransformers is to be procured to replace the existing smaller unit. This alternative would address the end-of-life assets need and would alleviate the risk of overloading T23 should the other two larger transformer become simulatenously unavailable. This project is ongoing and planned to be in serviced in 2022.

7.5 Martindale TS EOL Power Transformer Replacement

Martindale TS, as mentioned above, also features a DESN station that supply both LDCs identified in the Sudbury/Algoma region. The DESN station is comprised of two(2) – 125 MVA 230/44kV power transformers. These power transformers as well as select 44 kV equipment are scheduled to be replaced in 2028 to address end-of-life needs. The identified EOL equipment will be replaced with Hydro One standard equipement of similar size and capabilities. These are the largest standard 230/44kV transformers Hydro One uses. The scope of this project as presently planned does not aim at increasing the Martindale TS supply capacity beyond what exists today nor does it deviate from Hydro One's standard transformer size and procurement practices.

The following alternatives were considered to address Martindale TS DESN station EOL assets need:

1. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.

2. **Alternative 2 - Like-for-like replacement with similar equipment (Recommended):** Proceed with these end-of-life asset replacement as per the existing refurbishment plan for the EOL equipment at Martindale TS DESN. This alternative would address the end-of-life assets need and would maintain reliable supply to the customers in the area.

.

7.6 Algoma TS EOL Autotransformer Replacement

Algoma TS is a BES autotransformation station located west of Sudbury in the Algoma area. The station serves at termination point to four (4) circuits – X27A, S22A and A23/24P – and features two 230/115kV autotransformers that supply the underlying 115kV transmission system. The autotransformer are respectively 195MVA (T5) and 115MVA (T6). The autotransformers are scheduled to be replaced with two 230/115kV 125 MVA units by the end of 2022. The new units are being procured with Under Load Tap Changers (ULTC) as a mean to provide better operational flexibility.

The following alternatives were considered to address Algoma TS station EOL assets need:

1. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.

2. **Alternative 2 – Like-for-Like replacement with similar equipment**: This alternative was considered and rejected. The station supply need has been assessed and as a result, standard 125 MVA units are sufficient to adequately supply the forecasted region electricity need. Pursueing with this alternative will involve the procurement of two(2) non standard sized transformers and will continue to deviate Hydro One asset fleet with its standard equipement procurement standards.

3. **Alternative 3 – Like for like replacement with similar equipement and right sizing of T5 and T6 autotransformers (Recommended)**: Proceed with the end-of-life asset replacement and transformer right sizing plans as per the existing plans at Algoma TS. This alternative would address the end-of-life assets need, maintain reliable and adequate supply to the customers in the area while better aligning Hydro One asset fleet with its standard equipment procurement practices.

7.7 Clarabelle TS EOL Power Transformer Replacement

Clarabelle TS is a 230/44kV transformer station located in the Sudbury/Algoma region. The station features two 230/44kV 125 MVA step down transformers that supply both identified LDCs in the Sudbury/Algoma region. The power transformer at Clarabelle TS are scheduled to be replaced in 2027 alongside select station equipment to address EOL needs.
The following alternatives were considered to address Clarabelle TS station EOL assets need:

1. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.

2. **Alternative 2 - Like-for-like replacement with similar equipment (Recommended):** Proceed with these end-of-life asset replacement as per the existing refurbishment plan for the power

transformers and identified EOL equipment at Clarabelle TS. This alternative would address the end-of-life assets need and would maintain reliable supply to the customers in the area.

7.8 Elliot Lake TS EOL Power Transformer Replacement

Elliot Lake TS is a Hydro One transformer station located west of Sudbury. The station consists of two(2) 115/44kV 42 MVA transformers (T1 and T3) alongside one 115kv/44kV 19 MVA transformer (T2). A station asset assessement has identified T1 and T2 as candidate for replacement within the mid-term horizon. Concurently, recent supply need assessement at the station has deemed T2 no longer necessary to maintain supply reliability and adequacy at the station. The LDC supplied from Elliot Lake TS further concurred that T2 can be removed from Elliot Lake TS without impacting their supply reliability and adequacy . As such, this project will see the like-for-like replacement of T1 transformer, the removal of T2 transformer and the reconfiguration of the station to a near standard Jones DESN design.

The following alternatives were considered to address Elliot Lake TS station EOL assets need:

4. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.

5. **Alternative 2 – Like-for-Like replacement with similar equipment**: This alternative was considered and rejected. The station supply need has been assessed and as a result, T2 transformer was deemed no longer necessary. Pursueing with this alternative will involve the procurement of an additional transformer that is no longer needed in addition of continueing to maintain non standard station configuration.

6. **Alternative 3 - Like for like replacement with similar equipement and removal of T2(Recommended)**: Proceed with the end-of-life asset replacement and station reconfiguration plans as per the existing station refurbishement and reconfiguration plans at Elliot Lake TS. This alternative would address the end-of-life assets need, maintain reliable supply to the customers in the area while avoiding the need to procure and maintain an asset that is deemed no longer necessary.

8. CONCLUSION AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN (RIP) REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE SUDBURY/ALGOMA REGION.

The Study Team reaffirms the recommendations from NA to the continue with infrastructure investments presented in section 7. Hydro One and the affected LDCs are to jointly coordinate the implementation of these undertakings while keeping the Study Team apprised of project status. Below is a summary of the near and mid-term planned projects along with their respective planned in service dates and planning allowances:

1. Hanmner TS to Martindale TS corridor Unbundling – Estimated at $8M and planned to be in service in 2023,
2. Martindale TS autotransformer replacement - Estimated at $76M and planned to be in service in 2022
3. Martindale TS EOL Power transformer replacement – Estimated at $19M and planned to be in service in 2028
4. Manitoulin TS supply capacity – Estimated at $20,000 and planned to be in serviced in 2021
5. Algoma TS EOL autotransformer replacement – Estimated at $23M and planned to be in service in 2023
6. Clarabelle TS EOL Power transformer replacement – Estimated at $19M and planned to be in service in 2027
7. Elliot Lake TS EOL Power transformer replacement – Estimated at $23M and planned to be in service in 2025

Needs Assessment Report

Sudbury Algoma Region

October 24, 2025

Lead Transmitter:

Hydro One Networks Inc.

Prepared by: Sudbury Algoma Technical Working Group

Page intentionally left blank

Disclaimer

This Needs Assessment (NA) Report was prepared for the purpose of identifying potential needs in the Sudbury Algoma region and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the NA phase and b) require further assessment and regional coordination. The results reported in this NA are based on the input and information provided by the Technical Working Group (TWG) for this region. Updates may be made based on the best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	**Sudbury Algoma** Region (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")

START DATE: June 27, 2025 **END DATE:** October 24, 2025

The second Regional Planning cycle for the Sudbury Algoma Region was completed in December 2020 with the publication of the Regional Infrastructure Plan ("RIP") report – Sudbury Algoma Regional Infrastructure Plan (RIP).

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. Considering these timelines, the 3rd Regional Planning cycle was triggered in **June 2025** for this Region. The planning horizon for this Needs Assessment ("NA") is ten years. A 20-year planning assessment is undertaken in the next phases of regional planning, i.e., IRRP and RIP phases.

The purpose and scope of the NA is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group (TWG) comprises representatives from Local Distribution Companies ("LDC"), the Independent Electricity System Operator ("IESO"), and Hydro One Transmission. They provide input and relevant information for the region and undertake a technical assessment to identify the electrical infrastructure needs in the region. They collaborate to develop both summer and winter gross and net peak electricity demand forecasts (including input from municipalities), which form the basis for the technical assessment. The following are key considerations of the technical assessment:

a) Current and future station capacity and transmission adequacy.
b) System reliability needs and operational concerns.
c) Major HV transmission equipment requiring replacement with consideration to "right-sizing"; and,
d) Sensitivity analysis to capture uncertainty in the load forecast as well as variability of demand drivers such as electrification.

In this Needs Assessment, TWG has identified the following regional needs and recommendations:

Needs that require further regional coordination.

#	Need Location	Need Description
1	**Martindale TS 230/44 kV step-down transformers (T25 & T26)**	Capacity Need: The load exceeds the 10-day LTR of the step-down transformers, T25 and T26, based on winter demand forecast at the station by 2034.
2	**Martindale TS 230/115 kV Autotransformers (T21, T22, & T23)**	Capacity Need: With one autotransformer out-of-service and subsequent failure of another unit, the third autotransformer will exceed its winter 10-day LTR. The Martindale TS autotransformers supply the local 115 kV system serving LDCs and industrial customers. Based on the winter coincident forecast, this need is expected to materialize in 2030.
3	**Manitoulin TS 115 kV Voltage**	Voltage violation: The 115 kV bus at Manitoulin TS experiences low voltage under peak demand conditions at the station.

Needs that do not require further regional coordination.

#	Need Location	Need Description
1	**Martindale TS 230/44 kV step-down transformers (T25 & T26)**	Asset Renewal Need: T25 and T26 are approaching End of Life (EOL) based on their condition assessment. The transformers are planned for like-for-like replacement in 2032.

List of LDC(s) to be involved in further regional planning phases:

- Greater Sudbury Hydro
- North Bay Hydro (Embedded LDC)
- Hydro One Distribution

List of LDC(s) which are not required to be involved in further regional planning phases:

- N/A

1. INTRODUCTION

The second cycle of the Regional Planning process for the Sudbury Algoma Region was completed in December 2020 with the publication of the Sudbury Algoma Regional Infrastructure Plan (RIP). The RIP report included a common discussion of all the options and recommended plans for preferred wire infrastructure investments to address the near- and medium-term needs.

This Needs Assessment initiates the third regional planning cycle for the Sudbury Algoma Region. The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years. A flow chart of the Regional Planning Process is shown in Figure 1 below.

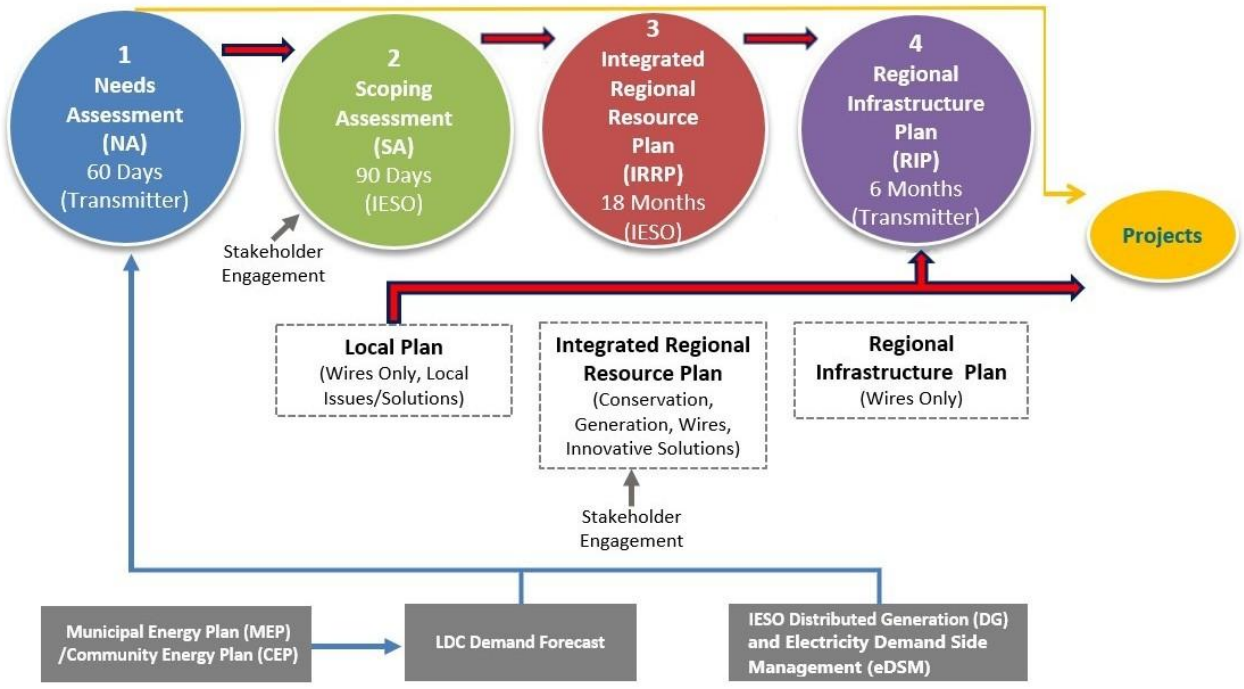

Figure 1: Regional Planning Process

This report was prepared by the Sudbury Algoma Technical Working Group ("TWG"), led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC") and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: Sudbury Algoma Region TWG Participants

Sr. no.	Name of TWG Participants
1	Independent Electricity System Operator (IESO)
2	Hydro One Networks Inc. (Transmission & Distribution)
3	Greater Sudbury Hydro
4	North Bay Hydro (Embedded LDC)

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. As such, the 3rd Regional Planning cycle was triggered for the Sudbury Algoma region.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this NA covers the Sudbury Algoma region and includes:

- Review and reaffirm needs/plans identified in the previous cycle RIP (as applicable),
- Identify any new needs resulting from this assessment,
- Recommend which need(s) require further assessment and regional coordination in the next phases of the regional planning cycle to develop a preferred plan; and,
- Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), Local plan (LP) and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is 10 years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

Electrical supply to the Sudbury Algoma Region is provided through a network of 230kV and 115kV transmission circuits supplied by autotransformers at Hanmer TS, Algoma TS and Martindale TS. This area is further reinforced through the 500kV circuits (P502X and X504/503E) connecting Hanmer TS (Sudbury) to both Porcupine TS (Timmins) and Essa TS (Barrie). It is also connected to Northwest Ontario through Mississagi TS.

The geographical boundaries of the Sudbury Algoma region are shown in Figure 2 below.

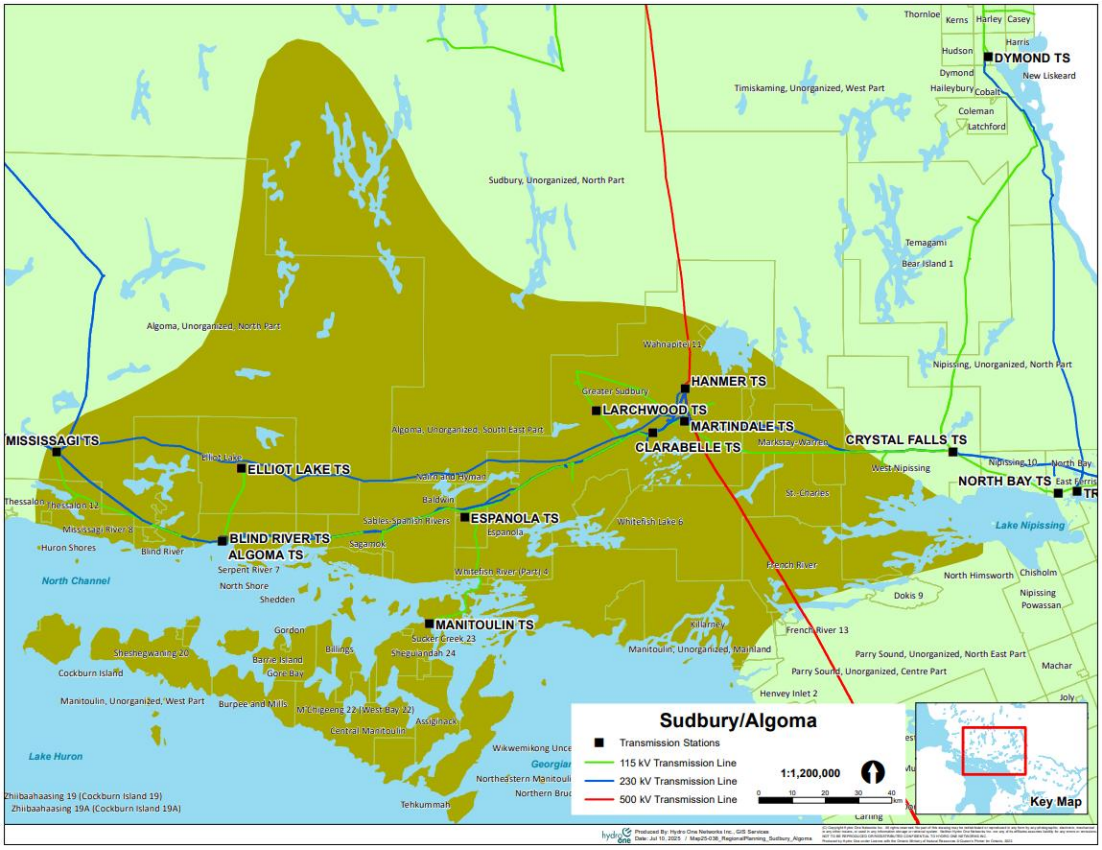

Figure 2: Map of Sudbury Algoma Regional Planning Area

The circuits and stations of the area are summarized in Table 2 below:

Table 2: Transmission Stations and Circuits in the Sudbury Algoma Region

115kV circuits	230kV circuits	Hydro One Transformer Stations	Generation Stations
• S6F • S5M • S2B • B4B • T1B • B3E • B4E • L1S	• X74P • X27A • A23P • A24P • X23N • S21N • X25S • X26S • X29S • S22A	• Algoma TS* • Martindale TS* • Hanmer TS* • Clarabelle TS • Elliot Lake TS • Espanola TS • Larchwood TS • Manitoulin TS • Mississagi TS	• Red Rock GS • Rayner GS • McLean Mountain WGS • Aux Sable GS • Serpent River CGS

*Stations with autotransformers installed

The single line diagram of the Transmission Network of Sudbury Algoma region is shown in Figure 3 below.

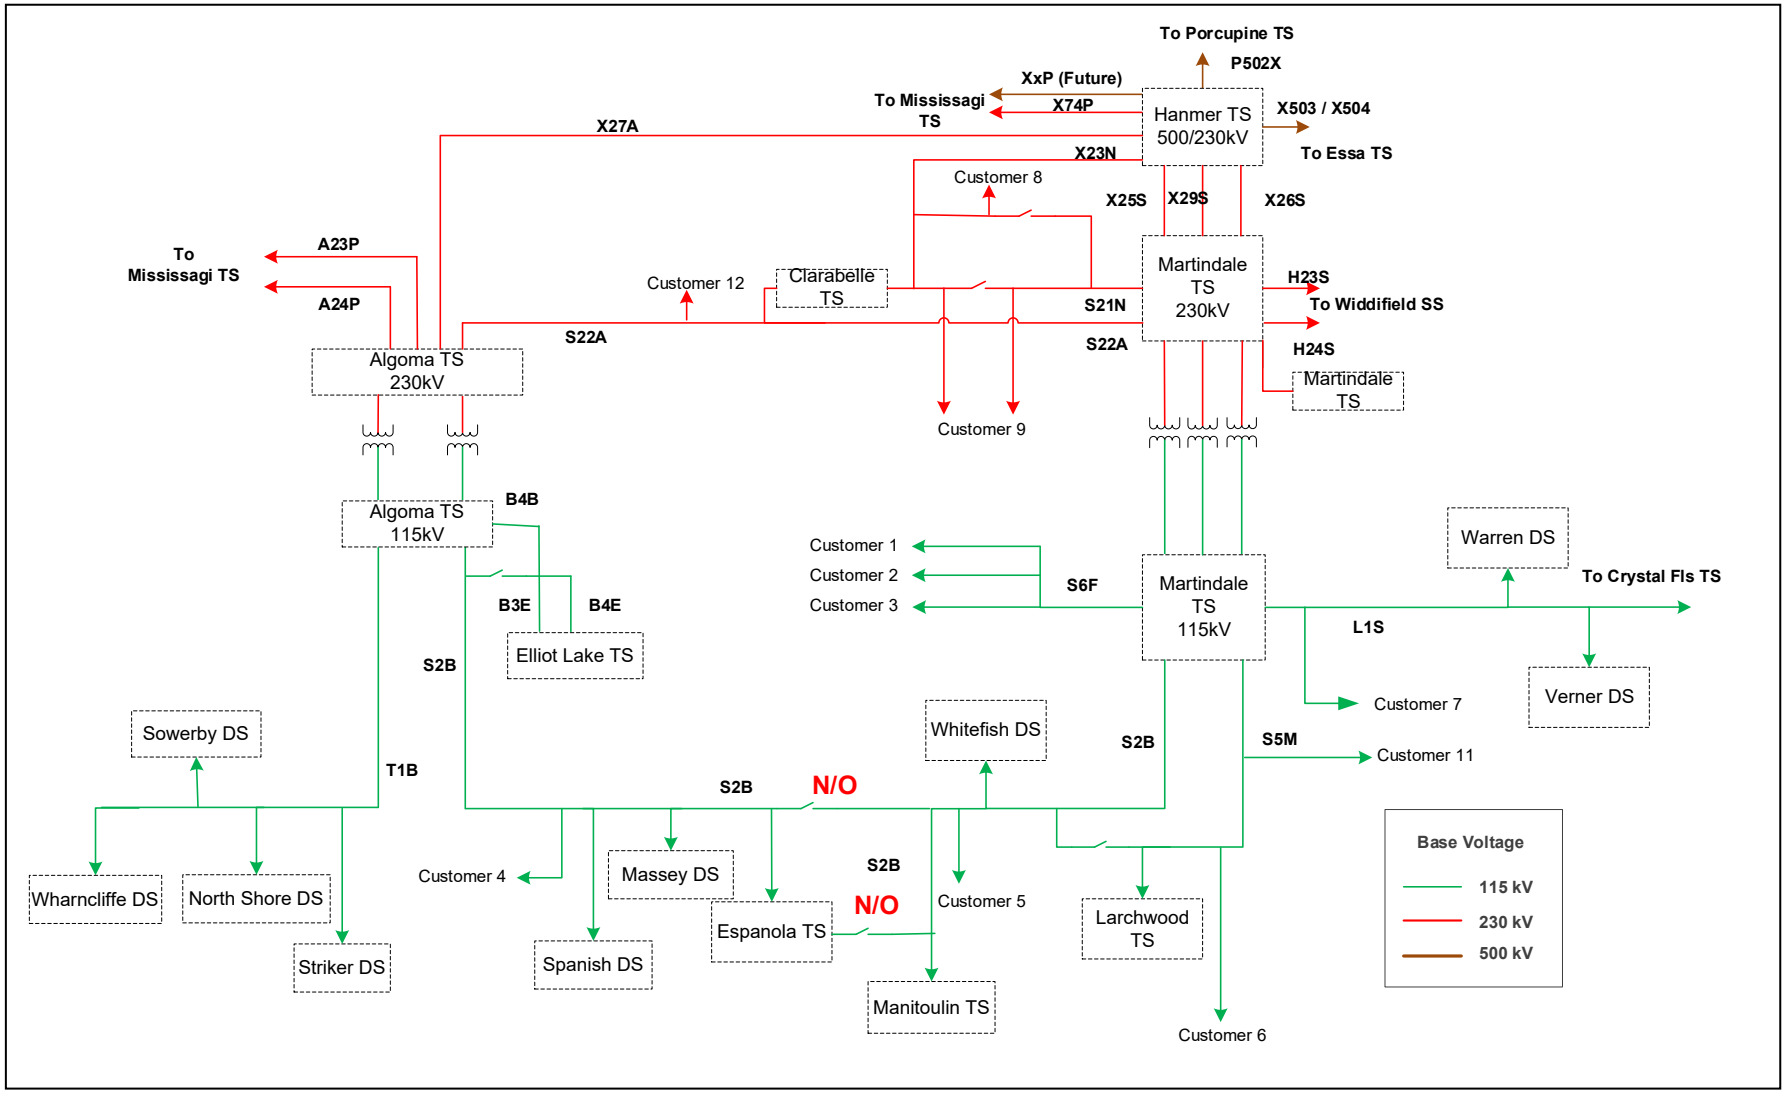

Figure 3: Sudbury Algoma Transmission Single Line Diagram

5. INPUTS AND DATA

TWG participants, including representatives from LDCs, IESO, and Hydro One provided information and input for the **Sudbury Algoma NA**. With respect to the load forecast information, the OEB Regional Planning Process Advisory Group (RPPAG) recently published a document called "Load Forecast Guideline for Ontario" in Oct. 2022. The objective of this document is to provide guidance to the TWG in the development of the load forecasts used in the various phases of the regional planning process with a focus on the NA and the IRRP. The list of all the Municipalities falling under the geographical boundaries of the region is given in Appendix-E.

The information provided includes the following:

- **Sudbury Algoma** 10-year summer and winter Load Forecasts for all supply stations inclusive of the inputs provided by the municipalities (e.g. through their MEPs & CEPs).
- Known capacity and reliability needs, operating issues, and/or major assets requiring replacement/ refurbishment.
- Planned/foreseen transmission and distribution investments that are relevant to Regional Planning for the **Sudbury Algoma region**.
- Captured uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

6. ASSESSMENT METHODOLOGY

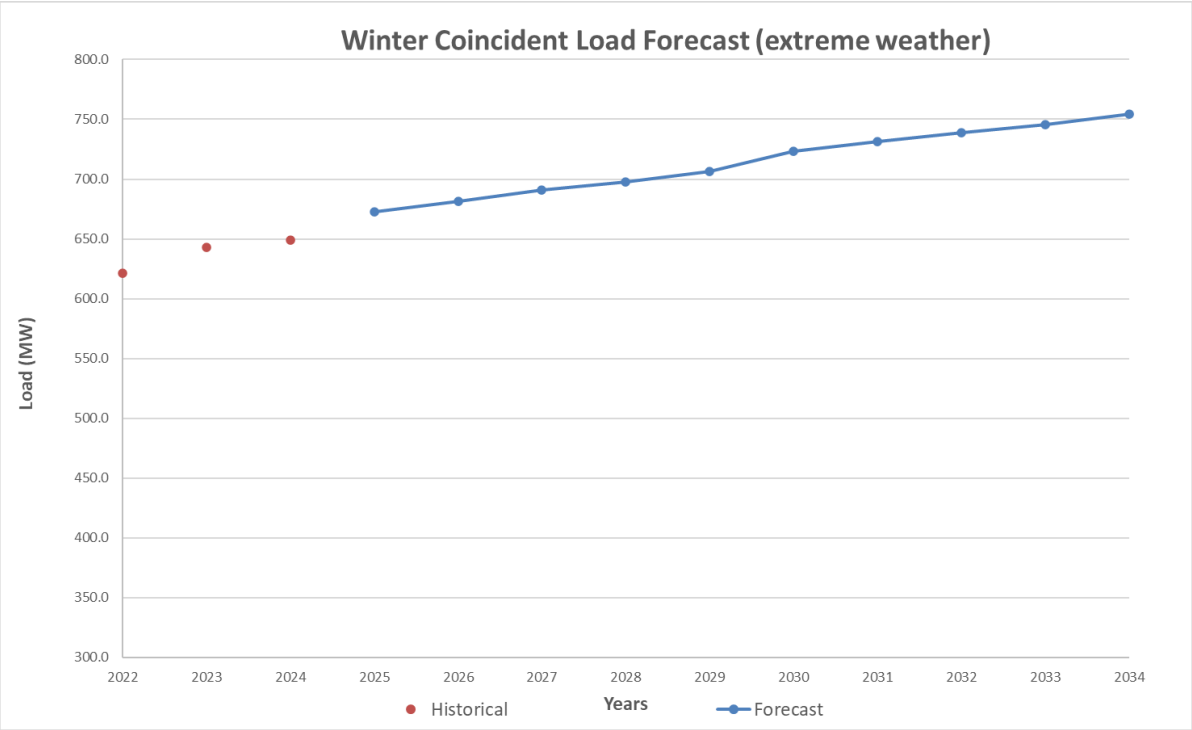
The following methodology and assumptions are made in development of this Needs Assessment:

6.1 Technical Assessments and Study Assumptions

The technical assessment of needs was undertaken based on:

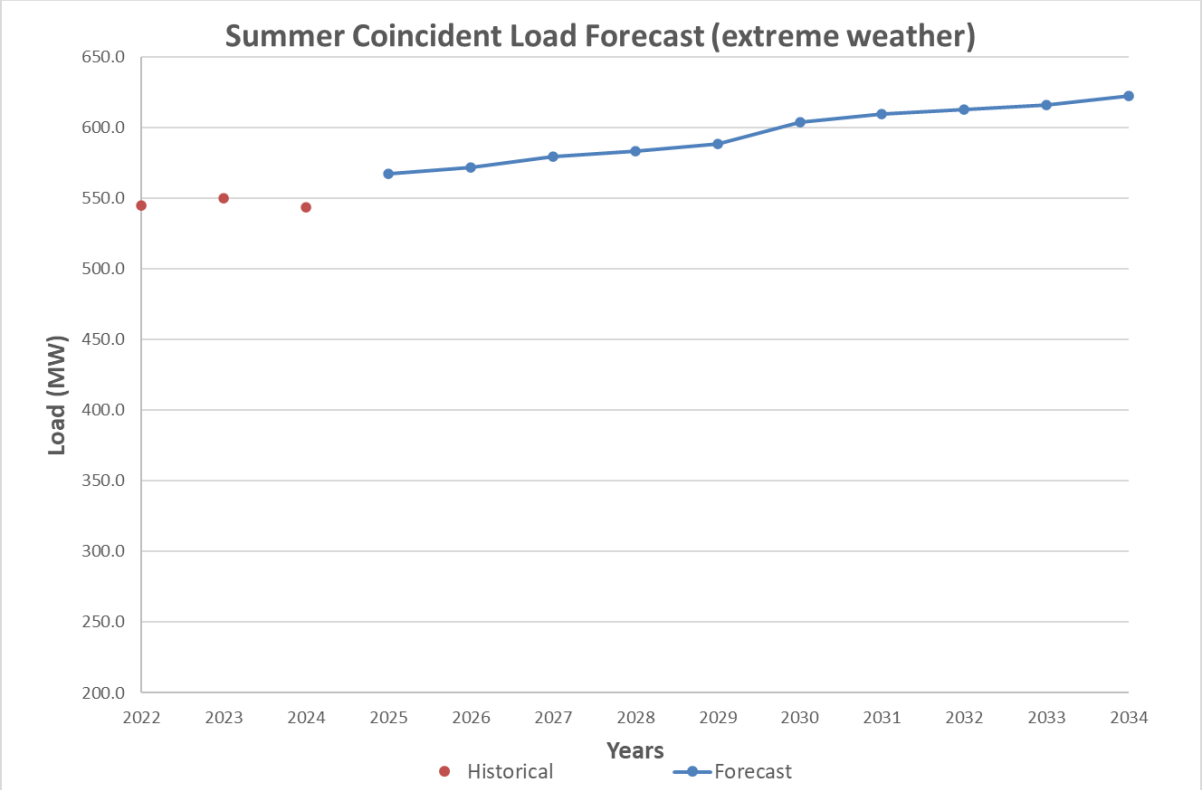
- Current and future station capacity and transmission adequacy.
- System reliability and operational considerations.
- Asset renewal for major high voltage transmission equipment requiring replacement with consideration to "right-sizing".
- Load forecast data requested from industrial customers in the region.
- This assessment is based on both summer and winter peak loads. Three load forecasts were developed, i.e. Normal Growth scenario, High and Low Growth scenarios. The High and Low Growth scenarios were developed to conduct a sensitivity analysis to cover unforeseen developments such as fuel switching, Government policies, higher than expected EV charging trend during peak load conditions, etc.
- Consideration of existing or planned distributed energy resources.

The following other assumptions are made in this report.



- The study period for this Needs Assessment is 2025-2034.
- While the Region is currently winter peaking, this assessment covers both summer and winter peak loads in the area.
- Line capacity adequacy is assessed by using coincidence peak loads in the area.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
- Normal planning supply capacity for transformer stations is determined by the Hydro One summer and winter 10-Day Limited Time Rating (LTR) of a single transformer at that station.
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).

6.2 Information Gathering Process



6.2.1. Load forecast:

The LDCs provided their load forecasts for summer and winter for all the stations supplying their loads in the Sudbury Algoma region for the 10-year study period including the inputs from the Municipalities such as MEPs and CEPs. The IESO provided an Electricity Demand Side Management ("eDSM"), and Distributed Generation ("DG") forecast for the Sudbury Algoma region. The region's extreme summer and winter non-coincident peak gross load forecasts for each station were prepared by applying the LDC load forecast growth rates to the actual 2024 summer peak extreme weather corrected loads. The extreme summer and winter weather correction factors were provided by Hydro One. The net extreme summer weather load forecasts were produced by reducing the gross load forecasts for each station by the percentage CDM and by the amount of effective DG capacity provided by the IESO for that station. It is to be noted that as contracts for existing DG resources in the region begin to expire, at which point the load forecast has a decreasing contribution from local DG resources, and an increase in net demand. This extreme summer and winter weather corrected net load forecast for the individual stations in the Sudbury Algoma region is given in Appendix A. Note, the industrial loads have not been shown in the tables in Appendix A. The winter and summer coincident load forecast are shown in graphs below, which include industrial loads in the region. The Sudbury Algoma region is winter peaking and the winter coincident load is expected to grow from 650 MW in 2024 to 755 MW by 2034. The summer coincident peak load is expected to grow from 543 MW in 2024 to 623 MW by 2034. Graphs 1 and 2 show the winter and summer coincident load forecasts over the study period.

Graph 1: Winter Coincident Forecast in Sudbury Algoma Region

Graph 2: Summer Coincident Forecast in Sudbury Algoma Region

6.2.2. Sensitivity Analysis:

A sensitivity analysis was undertaken by the TWG to capture uncertainty in the load forecast as well as variability of drivers such as electrification. Hence, the NA recommendations are not necessarily linked to sensitivity scenarios; but rather are used to identify any emerging needs for consideration in developing recommendations. The impact of sensitivity analysis on the high growth scenarios is provided in section 8 of this report.

6.2.3. Asset Renewal Needs for Major HV Equipment:

List of major HV transmission equipment planned and/or identified to be refurbished and/or replaced based on asset condition assessment, relevant for Regional Planning purposes. This includes HV transformers, autotransformers, HV Breakers, HV underground cables and overhead lines. The scope of equipment considered is given in section 7.1.

6.2.4. System Reliability and Operational Issues:

Relevant information regarding system reliability and operational issues in the region as feedback provided by the IESO and Hydro One Operation teams during the NA phase.

7. NEEDS

This section describes emerging needs identified in the Sudbury Algoma Region and/or updates on previously identified needs since the completion of the previous Regional Planning cycle.

Needs that were identified in the previous regional planning cycle with associated projects that were recently completed and reaffirmed needs that are underway are briefly described below with relevant updates and will not be discussed further in this report.

1. **Algoma TS - 230/115kV Autotransformer Replacement:** Replaced T5 and T6 autotransformers with new 230/115kV, 125 MVA transformers. The new replacement units have Under Load Tap Changer (ULTCs) for better operational flexibility. New T5 was placed in-service in 2021 and updated nomenclature to T7. New T6 was placed in-service in 2025 and updated nomenclature to T8.
2. **Clarabelle TS - 230/44kV Step-down transformer replacement:** The replacement of 230/44kV, 125 MVA step-down transformers T1 and T2 has been deferred to late 2030s based on their recent condition assessment.
3. **Coniston TS – Station Decommissioning:** The decommissioning of Coniston TS was completed in 2021.
4. **Elliot Lake TS – Station Refurbishment:** Right sizing the station by replacing EOL 115/44 kV, 42 MVA (T1) autotransformer with new 115/44kV 42 MVA unit and removal of autotransformer T2. Upon completion of this project, the station will remain with 2 – 115/44kV 42 MVA (T1/T3) auto transformers and a DESN. The project is expected to be completed in 2026.
5. **Hanmer TS to Martindale TS corridor unbundling:** Circuit X25S was unbundled and new circuit X29S was connected to the terminal stations. The project was completed in 2023.

6. **Martindale TS – 230/115kV Autotransformer Replacement:** Autotransformers T21 and T23 were replaced with 125 MVA unit in 2018.
7. **Martindale TS – 230/44kV Step-down transformer Replacement:** Transformers T25 and T26 were also identified for replacement in the previous regional planning cycle based on asset condition with planned completion in 2028. However, based on recent condition assessment the replacement of the transformers has been deferred to 2032.

Note: The planned in-service year for the above projects is tentative and is subject to change.

All near and mid-term needs that are discussed as part of this report are summarized in Table 3 below.

Table 3: Near/Mid-term Needs Identified in this NA and/or Updated from Previous RIP

Need Location	Need Description/Update
Asset Renewal Needs	
Martindale TS 230/44 kV step-down transformers (T25 & T26)	Transformers T25 and T26 are approaching EOL based on their condition assessment. The transformers are planned for like-for-like replacement in 2032.
Station Capacity Needs	
Martindale TS 230/44 kV step-down transformers (T25 & T26)	The load exceeds the 10-day LTR rating of the transformers based on winter demand forecast at the station by 2034.
Martindale TS 230/115 kV Autotransformers (T21, T22, & T23)	With one autotransformer out-of-service and subsequent failure of another unit, the third autotransformer will exceed its winter 10-day LTR. The Martindale TS autotransformers supply the local 115 kV system serving LDCs and industrial customers. Based on the winter coincident forecast, this need is expected to materialize in 2030.
Transmission Line Capacity Needs	
None Identified	None Identified
Voltage Performance	
Manitoulin TS 115 kV voltage	The 115 kV bus at Manitoulin TS experiences low voltage under peak demand conditions at the station.
System Reliability, Operation and Load restoration Needs	
None Identified	None Identified

7.1 Asset Renewal Needs for Major HV Transmission Equipment

Apart from the asset renewal needs identified during the second regional planning cycle, Hydro One and the TWG did not identify any new asset renewal requirements for major high-voltage transmission equipment over the next 10 years in the **Sudbury Algoma Region**. Hydro One remains the sole Transmission Asset Owner (TAO) in the Region.

Asset renewal needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
  replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

The asset renewal assessment considers the following options for “right sizing” the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., “like-for-like” replacement)
- Replacing equipment with higher ratings and built to current standards

From Hydro One’s perspective as a facility owner and operator of its transmission equipment, doing nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance costs and longer duration of customer outages.

Table 4: Major HV Transmission Assets Requiring Replacement in Sudbury Algoma Region

Station/Circuit	Need Description	Planned ISD
Martindale TS	Existing T25 and T26 are 230/44 kV, 125 MVA step-down transformers at Martindale TS. These are the largest standard 230/44 kV units in Hydro One fleet. As per recent condition assessment, the units are approaching EOL. and need replacement. The transformers are currently planned for like-for-like replacement.	**2032**

7.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2025-2034 for the 230kV and 115kV Transforming stations in the **Sudbury Algoma** Region using the summer and winter peak load forecasts that were provided by the Technical Working Group. Based on the results, the following Station capacity needs have been identified during the study period:

7.2.1 Martindale TS (T25/T26)

T25 and T26 are 230/44 kV, 125 MVA step-down transformers supplying the DESN load at Martindale TS. For each season, the supply capacity of the DESN is determined by the winter and summer 10-day LTR of the most limiting transformer. The load at the DESN was expected to exceed its winter 10-day LTR of 164 MW by 2028 in the previous regional planning cycle. However, based on the latest load forecast developed in this Needs Assessment, the peak winter load is expected to exceed the winter 10-day LTR by 2034. The peak summer load at the station is lower and well within the summer 10-day LTR of the transformers.

It is recommended that the capacity need of the step-down transformers be studied in the next phase of regional planning. Note, the capacity need of T25/T26 may be impacted by the asset renewal need of the same units if the 10-day LTR of the future units is greater than existing values.

7.2.2 Martindale TS (T21/T22/T23)

T21, T22 and T23 are 230/115 kV, 125 MVA autotransformers responsible for supplying the local 115 kV system which serves LDCs and industrial customers via 115 kV circuits. Under peak winter coincident load, the loss of two autotransformers will result in marginally overloading the third autotransformer above its 10-day LTR of 173 MW. This overload is expected to materialize in 2030 for transformer T23 with the least LTR (173 MW). The overload will be experienced on the other two units by 2034.

Similarly, autotransformer T22 reaches its 10-day LTR under a breaker fail contingency at Martindale TS which results in simultaneous loss of autotransformers T21 and T23. The 10-day LTR of T22 is slightly higher at 178 MW and the need is expected to materialize in 2034.

It is recommended that the capacity need of the autotransformers be further studied in the next phase of regional planning.

7.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings.

A Transmission Lines Capacity Assessment was performed over the study period 2025-2034 for the 230kV and 115kV Transmission line circuits in the **Sudbury Algoma** Region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater this need. Based on the results, in the Sudbury Algoma region there are no transmission lines capacity needs.

7.4 Voltage Performance

Voltage performance was assessed for the Sudbury Algoma region for all elements in-service and post system contingencies.

7.4.1 Manitoulin TS

The 115 kV bus experiences low voltage under peak load conditions at Manitoulin TS. Under system conditions when Mclean Mountain wind farm is unavailable and peak load conditions at Manitoulin TS, the 115 kV bus at the station is below the ORTAC limit of 113 kV. The ULTCs of the step-down transformers have a wide range and are able to maintain the 44 kV bus voltage within the ORTAC limits. This need was reaffirmed in the previous regional planning cycle. No mitigation was recommended since there was no material impact to customers connected on the 44 kV bus. Hydro One has monitored and will continue to monitor the performance of the 115 kV and 44 kV buses at the station.

It is recognized that voltage violation at Manitoulin TS 115 kV bus has no material impact to connected customers. Though mitigation is not necessary, the TWG recommends exploring potential wires and non-wires solutions in the next phase of regional planning that can also alleviate other needs in the region.

7.5 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. This section assesses the Load Security and Load Restoration criteria for the region over the study period.

7.5.1 Load Security

As per ORTAC load security criteria:

Criteria 1: With all transmission facilities in service, equipment loading must be within continuous ratings, voltages must be within normal ranges and transfers must be within applicable normal condition stability limits. This must be satisfied coincident with an outage to the largest local generation unit.

Low voltage is observed on the 115 kV bus at Manitoulin TS under peak load conditions as described in the needs above.

An outage of the largest generator in the region, Rayner G1/G2, resulted in all equipment loading to be within continuous rating and voltages to be in normal ranges.

Criteria 2: With any one element out of service, equipment loading must be within applicable long-term emergency ratings, voltages must be within applicable emergency ranges, and transfers must be within applicable normal condition stability limits. Planned load curtailment or load rejection, excluding voluntary demand management, is permissible only to account for local generation outages. Not more than 150 MW of load may be interrupted by configuration and by planned load curtailment or load rejection, excluding voluntary demand management.

For all n-1 contingencies in the Sudbury Algoma region, this criterion is satisfied.

Criteria 3: With any two elements out of service, voltages must be within applicable emergency ranges, equipment loading must be within applicable short-term emergency ratings and transfers must be within applicable emergency condition stability limits. Equipment loading must be reduced to the applicable long-term emergency ratings in the time afforded by the short-time ratings. Planned load curtailment or load rejection exceeding 150 MW is permissible only to account for local generation outages. Not more than 600 MW of load may be interrupted by configuration and by planned load curtailment or load rejection, excluding voluntary demand management.

Martindale TS autotransformers:

- If an autotransformer experiences unplanned outage at Martindale TS, the operating practice is to transfer load to another station to prepare for the loss of another autotransformer. This is achieved by transferring Martindale TS supplied section of circuit S2B to Algoma TS. The load transfer will prevent the remaining autotransformer from exceeding its 10-day LTR should a second autotransformer fail.
- Planned outages of autotransformers are scheduled during off peak seasons when the load in the 115 kV subsystem is low. Additionally, Martindale supplied section of circuit S2B is transferred to Algoma, if necessary. The low loading on 115 kV subsystem and/or load transfer will prevent the remaining autotransformer from exceeding its 10-day LTR should an autotransformer fail.
- Under the breaker fail contingency described in section 7.2.2, the breaker in question is equipped with motor operated disconnect switches. Hydro One control room can isolate the breaker by opening the motor operated disconnect switches and re-energizing the autotransformers within the time afforded by the short-term rating of the units.

This criterion is satisfied with any two elements out of service in the Sudbury Algoma region.

7.5.2 Load Restoration

The transmission system is planned with design criteria in a way to ensure that the affected loads can be restored within restoration time provided.

- All loads must be restored within approximately 8 hours.
- Load interruption greater than 150 MW, the excess amount of load greater than 150 MW needs to be restored within approximately 4 hours.
- Load interruption greater than 250 MW, the excess amount of load greater than 250 MW needs to be restored within approximately 30 minutes.

In the Sudbury Algoma region, there are radial circuits and loads that are supplied by single transformers, with limited transfer capability. Planned outages are taken by transferring load (where possible) and in coordination with any impacted customers. Unplanned outages may require investigation by operators and field crews to identify and replace faulted equipment in the system to restore power to impacted customers. Though there can be instances where load may not be restored within 8 hours as per ORTAC, all reasonable efforts are made to achieve the criterion.

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments. The TWG determined that the key electric demand driver in the Sudbury Algoma region to be considered in this sensitivity analysis is electric vehicle (EV) penetration and unforeseen electrification which would cause the load to increase at a faster rate than shown in the forecast; or the potential delay in some projects which could result in less demand than anticipated.

The TWG reviewed any unforeseen electrification needs to develop high demand growth forecasts by applying 50% additional growth to the growth rate on the extreme summer and winter load forecast for all LDC serving stations. A 75% additional growth was used for Martindale TS and Clarabelle TS to reflect greater interest in connecting to these stations from proponents. Industrial customer load was not increased. Instead, a fictitious new load of 40 MW was connected to the 115 kV system at Martindale TS, and another 40 MW load was connected to 115 kV circuit S2B emanating from Algoma TS.

No new needs were identified as part of the sensitivity analysis. Table 5 below lists the impact on capacity needs at Martindale TS. Note, it is understood that adding the 40 MW load on section of S2B supplied by Martindale TS would exacerbate the existing voltage concerns at Manitoulin TS 115 kV bus and was not discussed further.

Table 5: Impact of Sensitivity Analysis on Needs in the region

#	Need Identified	Winter Growth Scenario	
		Normal Growth Scenario	High Growth Scenario
1	**Martindale TS 230/44 Step-down Transformer overload**	2034	2030
2	**Martindale TS 230/115 Autotransformer overload**	2030	Imminent

9. CONCLUSION AND RECOMMENDATION

The Technical Working Group's recommendations to address the needs identified are as follows:

Table 7: Needs that Do Not Require Further Regional Coordination

#	Need Location	Need Description
1	**Martindale TS 230/44 kV step-down transformers (T25 & T26)**	Asset Renewal Need: T25 and T26 are approaching End of Life (EOL) based on their condition assessment. The transformers are planned for like-for-like replacement in 2032.

Table 8: Needs that Require Further Regional Coordination

#	Need Location	Need Description
1	**Martindale TS 230/44 kV step-down transformers (T25 & T26)**	Capacity Need: The load exceeds the 10-day LTR of the step-down transformers, T25 and T26, based on winter demand forecast at the station by 2034.
2	**Martindale TS 230/115 kV Autotransformers (T21, T22, & T23)**	Capacity Need: With one autotransformer out-of-service and subsequent failure of another unit, the third autotransformer will exceed its winter 10-day LTR. The Martindale TS autotransformers supply the local 115 kV system serving LDCs and industrial customers. Based on the winter coincident forecast, this need is expected to materialize in 2030.
3	**Manitoulin TS 115 kV Voltage**	Voltage violation: The 115 kV bus at Manitoulin TS experiences low voltage under peak demand conditions at the station.

List of LDC(s) to be involved in further regional planning phases:

- Greater Sudbury Hydro
- North Bay Hydro (Embedded LDC)
- Hydro One Distribution

List of LDC(s) which are not required to be involved in further regional planning phases:

- N/A

Disclaimer

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs (2021-2030) identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be re-evaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

Executive Summary

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE PLANNED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE CHATHAM-KENT / LAMBTON / SARNIA (CKLS) REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Bluewater Power Distribution Corporation
- Entegrus Power Lines Inc.
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator

In the first cycle of the Regional Planning ("RP") process for the CKLS Region, a Needs Assessment ("NA") was published in June 2016 and recommended that an Integrated Regional Resource Plan ("IRRP") was not required. The first cycle of the RP process was completed in August 2017 with the publication of the Regional Infrastructure Plan ("RIP") which provided a description of needs and recommendations of preferred wires plans to address near-term needs.

This RIP is the final phase of the second cycle of the regional planning process for the CKLS Region, which follows the completion of the Chatham-Kent/Lambton/Sarnia Region Scoping Assessment Outcome Report in December 2021 and the CKLS Needs Assessment in September 2021. This report provides a consolidated summary of needs and recommended plans for the Chatham-Kent/Lambton/Sarnia Region for the near-term (up to 5 years) and mid-term (5 to 10 years).

Investments planned for the CKLS Region over the near and mid-term, identified in the various phases of the regional planning process, are given in the table below.

No.	Project	In-Service Date	Cost
1	Construct new Lambton-by-Chatham double-circuit line (St. Clair Transmission Line)	2028	$210-290M[1]
2	Build new Dresden TS supplied by LxC corridor	2028	$40M
3	St. Andrews TS refurbishment	2025	$40-50M

[1] Letter: IESO Letter to Hydro One re Transmission Line from Lambton to Chatham [4]

In accordance with the Regional Planning process, the RIP should be reviewed and/or updated at least every five years. The Region will continue to be monitored and should there be a need that emerges earlier due to a change in load forecast or any other reason, the next regional planning cycle will be started to address the need.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN (“RIP”) TO ADDRESS THE ELECTRICITY NEEDS OF THE CHATHAM-KENT / LAMBTON / SARNIA REGION.

The report was prepared by Hydro One Networks Inc. (“Hydro One”) and documents the results of the joint study carried out by Hydro One, Entegrus Power Lines Inc., Bluewater Power Distribution Corporation, Hydro One Distribution, and the Independent Electricity System Operator (“IESO”), in accordance with the Regional Planning process established by the Ontario Energy Board (“OEB”) in 2013.

The CKLS Region includes the municipalities of Lambton Shores and Chatham-Kent, as well as the townships of Petrolia, Plympton-Wyoming, Brooke-Alvinston, Dawn-Euphemia, Enniskillen, St. Clair, Warwick, and Villages of Oil Springs and Point Edward. The area is bordered by the London area to the east and Windsor-Essex to the southwest. The boundaries of the Region are highlighted in Figure 1-1 below.

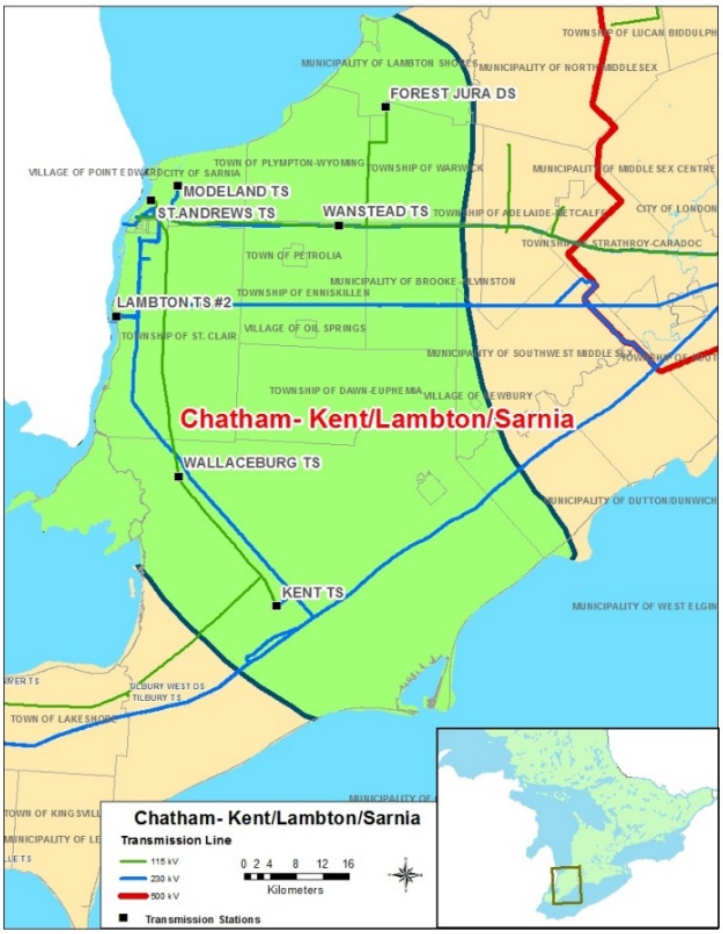

Figure 1-1. Chatham-Kent/Lambton/Sarnia Region

1.1 Objective and Scope

This RIP report examines the needs in the CKLS Region. Its objectives are:

- To develop a wires plan to address needs identified in previous planning phases for which a wires-only alternative was recommended by the Working Group
- To identify new supply needs that may have emerged since previous planning phases (e.g. Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan)
- To provide the status of wires planning currently underway or completed for specific needs
- To identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region

The RIP reviewed factors such as the load forecast, major high voltage sustainment work, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management (CDM), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of all the needs and relevant plans to address near and mid-term needs (2021-2030) identified in previous planning phases (Needs Assessment or Local Plan)
- Identification of any new needs over the 2021-2030 period
- Develop a plan to address any longer term needs identified by the Working Group

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process
- Section 3 describes the Region
- Section 4 describes the transmission work completed over the last ten years
- Section 5 describes the load forecast and study assumptions used in this assessment
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies needs
- Section 7 summarizes the Regional Plan to address the needs
- Section 8 provides the conclusion and next steps

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013, through amendments to the Transmission System Code ("TSC") and the Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment ("NA"), the Scoping Assessment ('SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight-forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource options (e.g. CDM, generation and Distributed Energy Resources ("DER")) at a higher or more macro level but sufficient to permit a comparison of options. If the IRRP process identifies that infrastructure

options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend the preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution was determined to be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timeliness provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and/or LDCs for the CKLS Region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect.
- The NA, IRRP, and LP phases of regional planning.
- Working and planning for connection capacity requirements with the LDCs and transmission connected customers

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

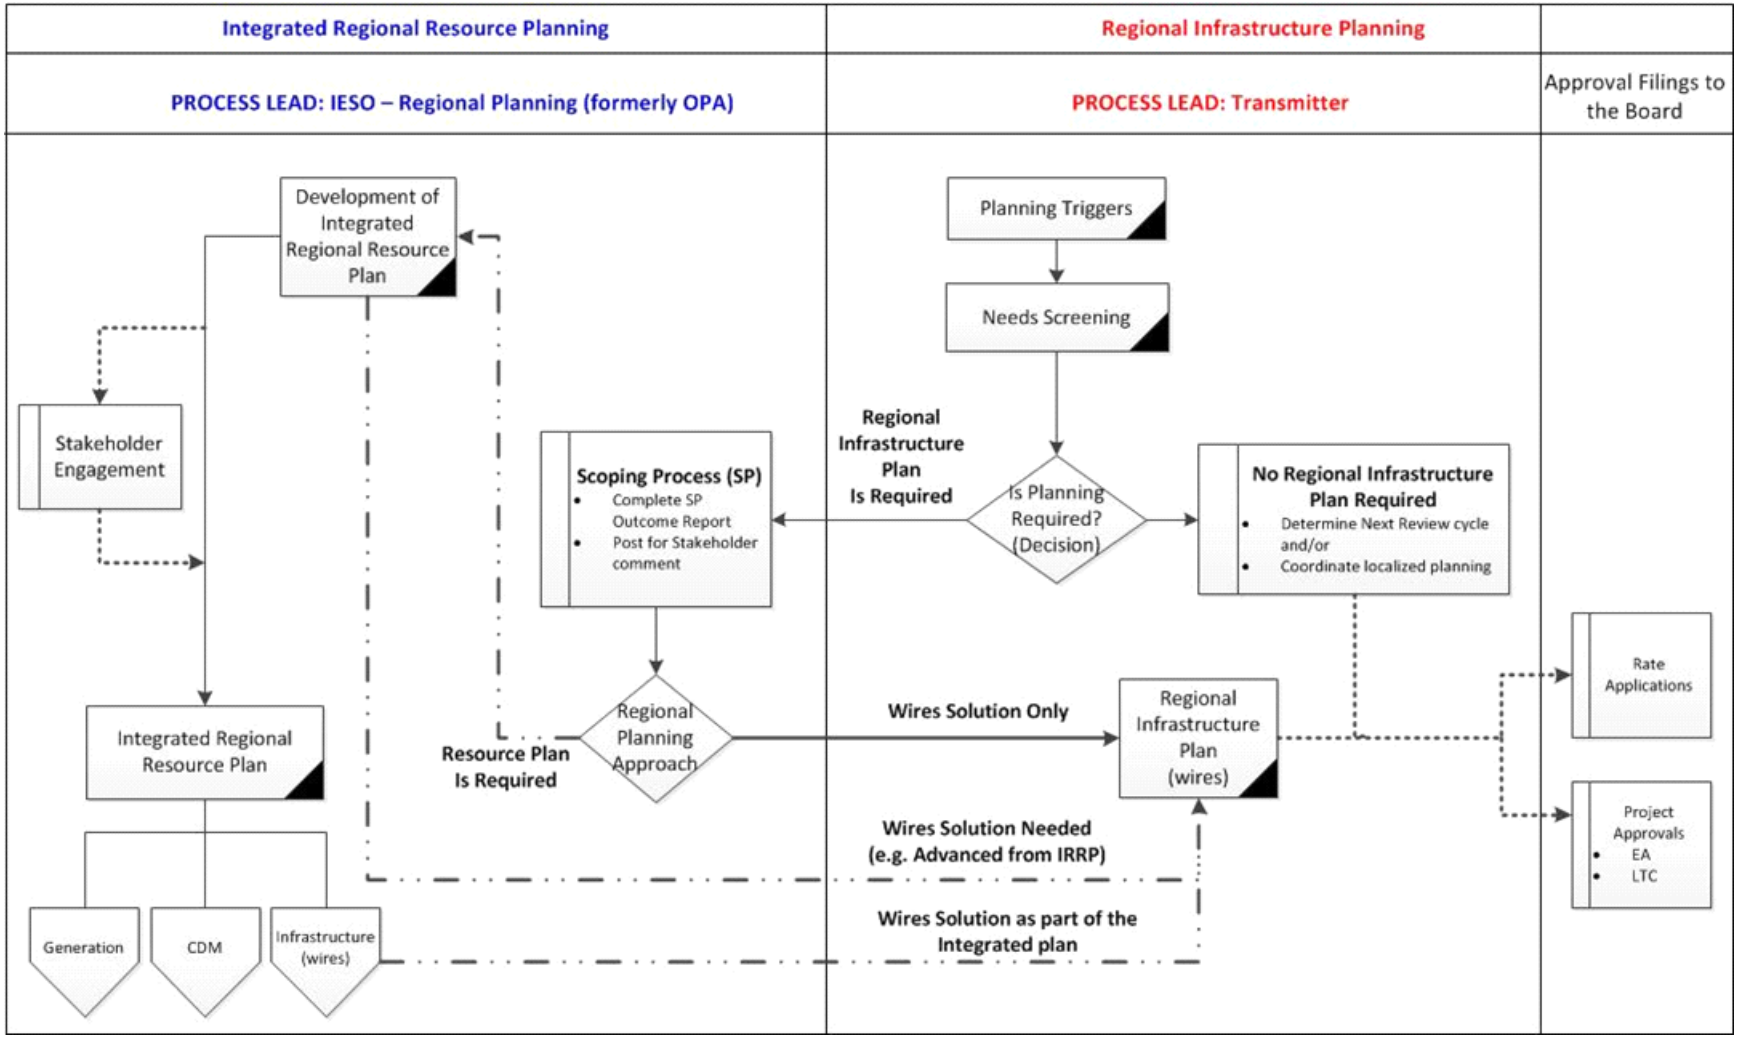

Figure 2-1. Regional Planning Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1. Data Gathering: The first step of the RIP phase is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Gross and net peak demand forecast at the transformer station level. This includes the effect of any distributed generation and/or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

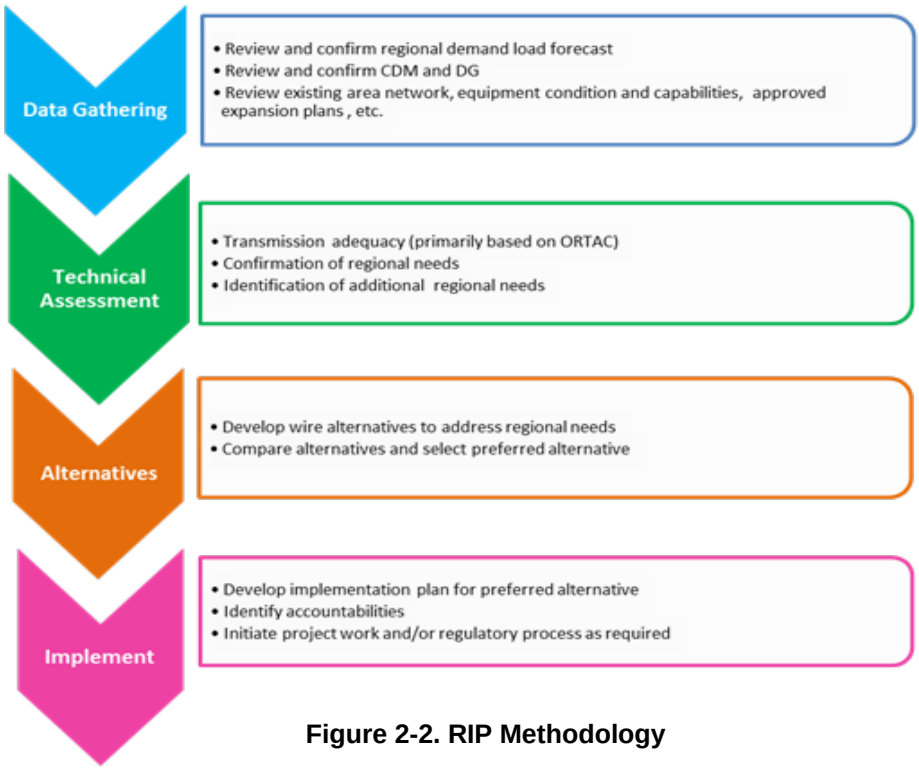

Figure 2-2. RIP Methodology

3. REGIONAL CHARACTERISTICS

THE CHATHAM-KENT / LAMBTON / SARNIA REGION COMPRISES THE MUNICIPALITIES OF LAMBTON SHORES AND CHATHAM-KENT, AS WELL AS THE TOWNSHIPS OF PETROLIA, PLYMPTON-WYOMING, BROOKE-ALVINSTON, DAWN-EUPHEMIA, ENNISKILLEN, ST. CLAIR, WARWICK, AND VILLAGES OF OIL SPRINGS AND POINT EDWARD. THE AREA IS BORDERED BY THE LONDON AREA TO THE EAST AND WINDSOR-ESSEX TO THE SOUTHWEST AS SHOWN IN FIGURE 1-1.

Electricity supply for the Region is provided through a network of 230 kV and 115 kV transmission lines. The bulk of the electrical supply is transmitted through 230 kV circuits (N21W, N22W, L24L, L26L, W44LC and W45LS) between Longwood TS and Buchanan TS and Lambton TS/Scott TS/Chatham SS, and 230 kV circuits L28C and L29C towards Chatham SS. This Region also contains a number of interconnections with neighboring Michigan State (B3N, L4D and L51D).

Within the Region, electricity is delivered to the end users of LDCs and direct-connected industrial customers by eight Hydro One step-down transformation stations, as well as nine customer-owned transformer or distribution stations supplied directly from the transmission system. Large gas-fired generators in the region include: Greenfield Energy Centre CGS, TransAlta Sarnia CGS, St. Clair Power CGS, North Kent 1 CGS, and Greenfield South Power Corporation (GSPC) CGS. Appendix A lists all step-down transformer stations in the Region. Appendix B lists all transmission circuits and Appendix C lists LDCs in the Region. The Single Line Diagram for the CKLS Region transmission system facilities is shown below in Figure 3-1.

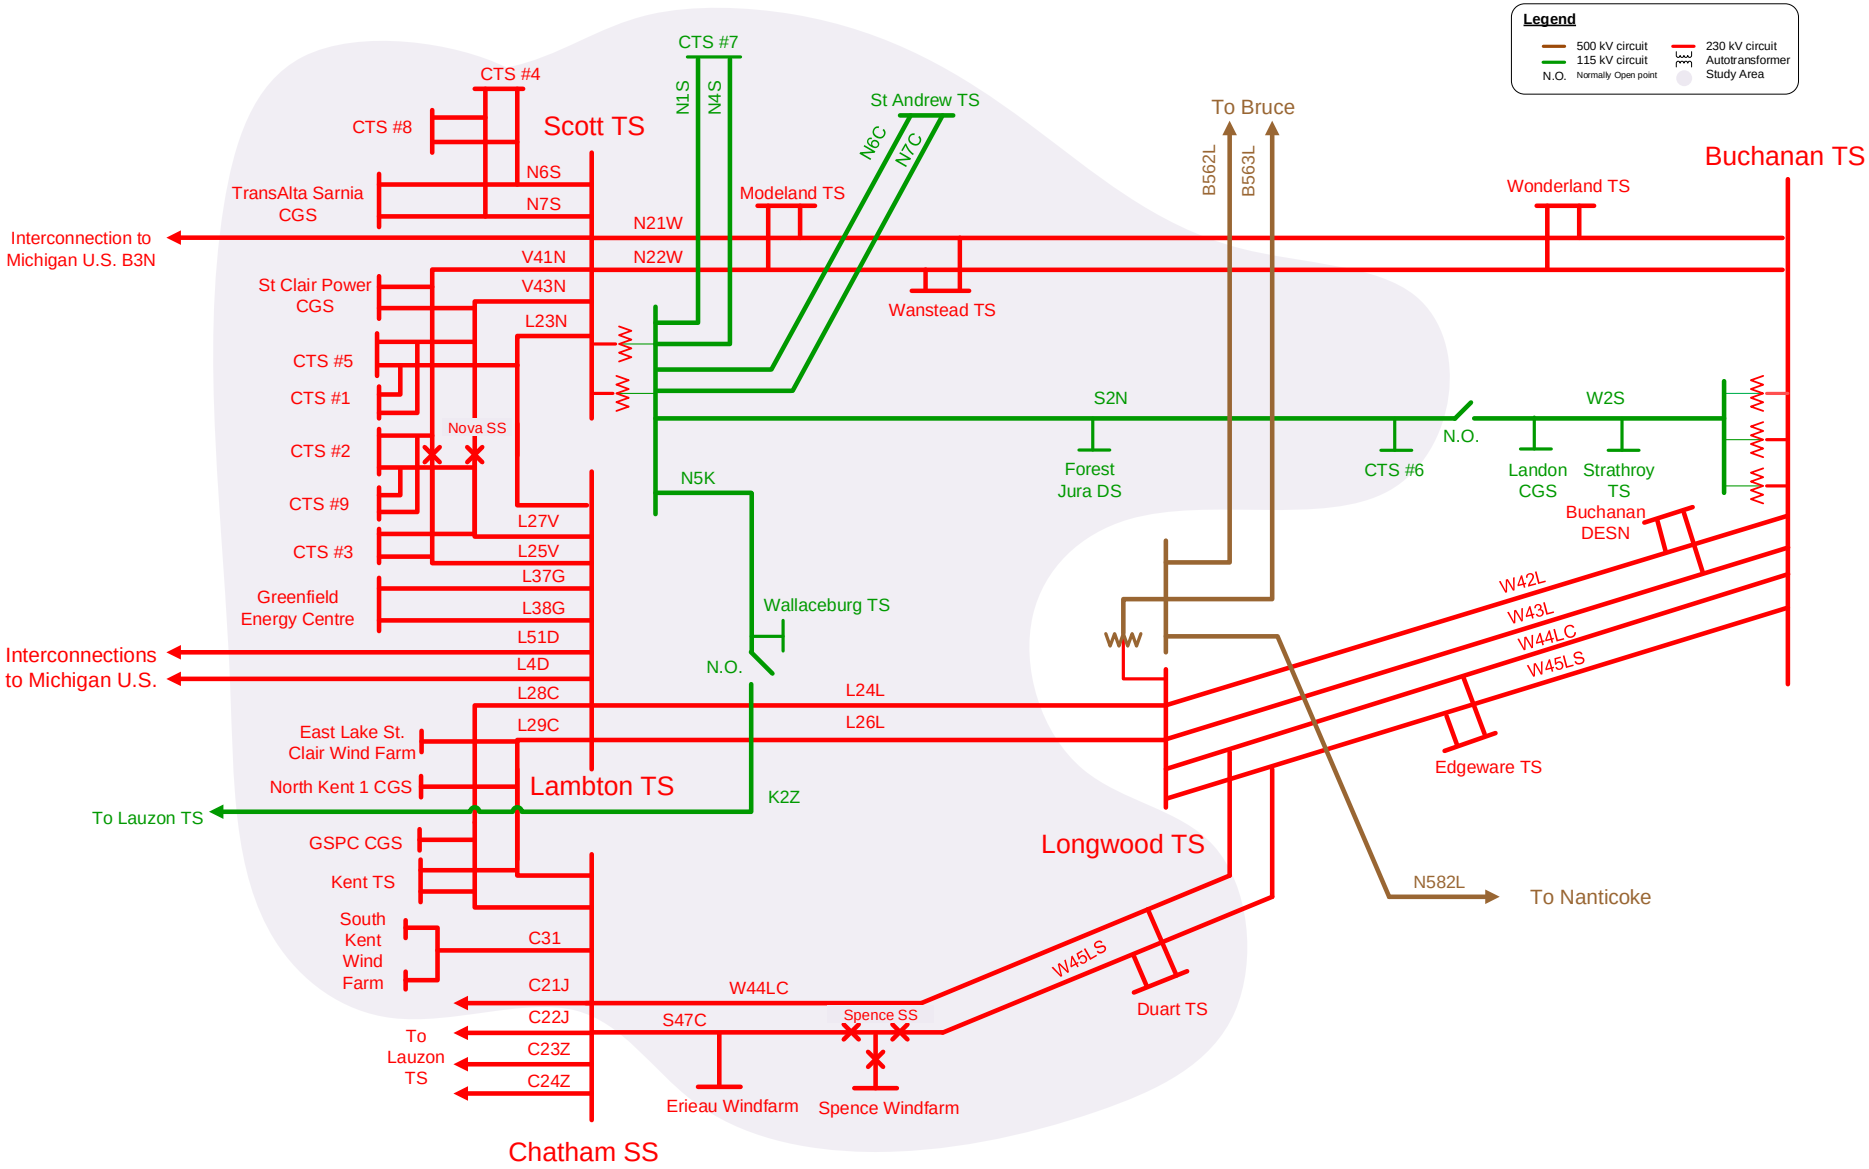

Figure 3-1. Chatham-Kent / Lambton / Sarnia Region Single-Line Diagram

4. TRANSMISSION FACILITIES COMPLETED OVER LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE CHATHAM-KENT / LAMBTON / SARNIA REGION.

In addition to Hydro One's ongoing transmission station and line sustainment programs, specific projects were identified as a result of joint planning studies undertaken by Hydro One, IESO and the LDCs; or initiated to meet the needs of the LDCs; and/or to meet Provincial Government policies. A brief listing of the completed projects is given below.

For bulk power system transfer needs:

- 230 kV Capacitor Bank replacement at Chatham SS in 2020

For major station refurbishment needs based on asset condition assessment:

- Wanstead TS in 2018

For renewable generation connection needs:

- 230 kV North Kent 1 Wind Farm onto circuit L29C in 2017
- 230 kV East Lake St. Clair Wind Farm onto L29C in 2012
- 230 kV Erieau Wind Farm onto circuit S47C in 2012

The following projects are underway:

- Lambton TS switchyard is currently undergoing major station refurbishment work with a projected in-servicing by 2023
- Scott TS switchyard is currently undergoing major station refurbishment work with a projected in-servicing by 2024
- New Lambton by Chatham transmission line is currently under development with a projected in-servicing by 2028

5. LOAD FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the CKLS Region is forecast to increase annually between 2021 and 2030. The growth rate varies across the Region with most of the growth concentrated in the Municipality of Chatham-Kent and more specifically in the Dresden area. The Region's 2022 RIP load forecasts, including the Dresden Area forecast, are provided in Appendix D and were prepared by the Working Group upon initiation of the RIP phase. The RIP forecasts are identical to the Needs Assessment forecast except as otherwise noted in Appendix D.

As per the load forecasts in Appendix D, the winter *gross* coincident load in the Region is expected to grow at an average rate of approximately 2.7% annually from 2021-2030 and the summer *gross* coincident load in the Region is expected to grow at an average rate of approximately 2.4% from 2021-2030.

As per the load forecasts in Appendix D, the winter *net* coincident load in the Region is expected to grow at an average rate of approximately 2.5% annually from 2021-2030 and the summer *net* coincident load in the Region is expected to grow at an average rate of approximately 2.2% from 2021-2030.

For both winter and summer coincident load, the strongest growth is expected between 2021 and 2025, tapering off to an average of 1% annual growth over the last 5 years of the study period.

Figure 5-1 shows the Region's gross and net *winter* coincident forecasts while Figure 5-2 shows the Region's gross and net *summer* coincident forecasts. The regional-coincident (at the same time) forecast represents the total peak load of all 18 step-down transformer stations in the Region.

Based on historical load and on the coincident load forecasts, the Region's summer coincident peak load is larger than its winter coincident peak load. Based on historical load and the non-coincident load forecasts, the Region contains most stations that are summer peaking and a few that are winter peaking. Equipment ratings are normally higher in winter than summer due to ambient temperature. Based on these factors, assessment for this Region was conducted for summer peak load.

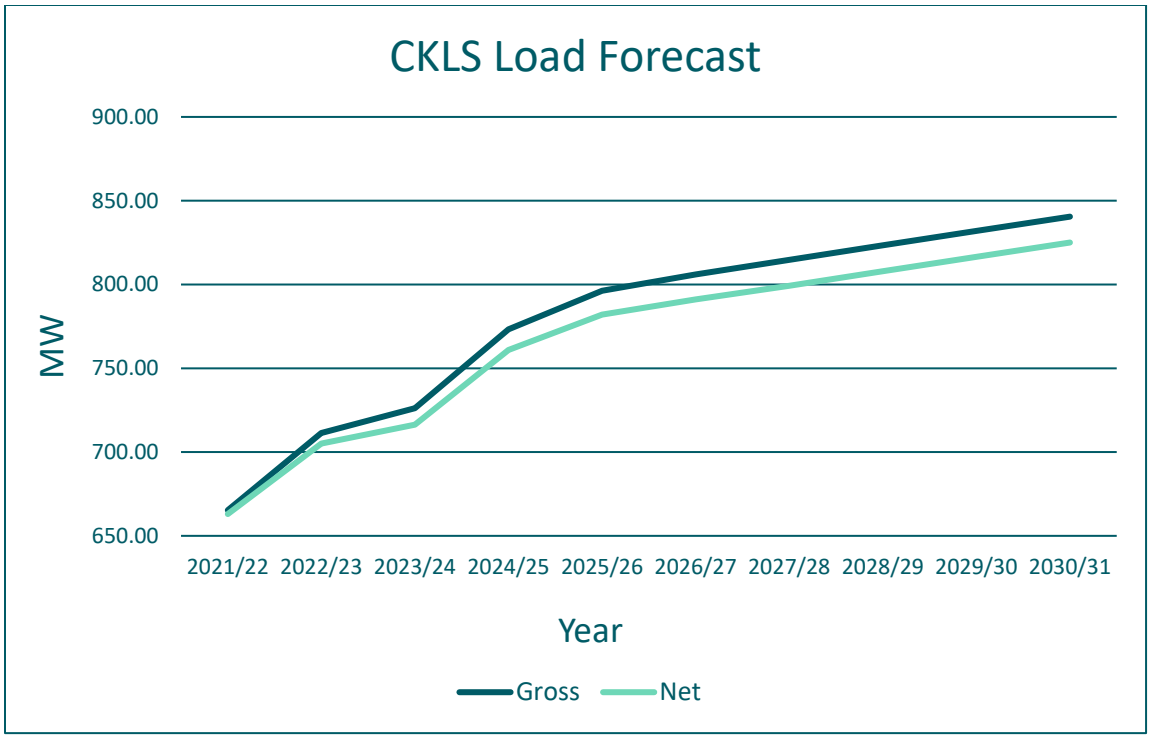

Figure 5-1. Chatham-Kent/Lambton/Sarnia Region Winter Coincident Forecast

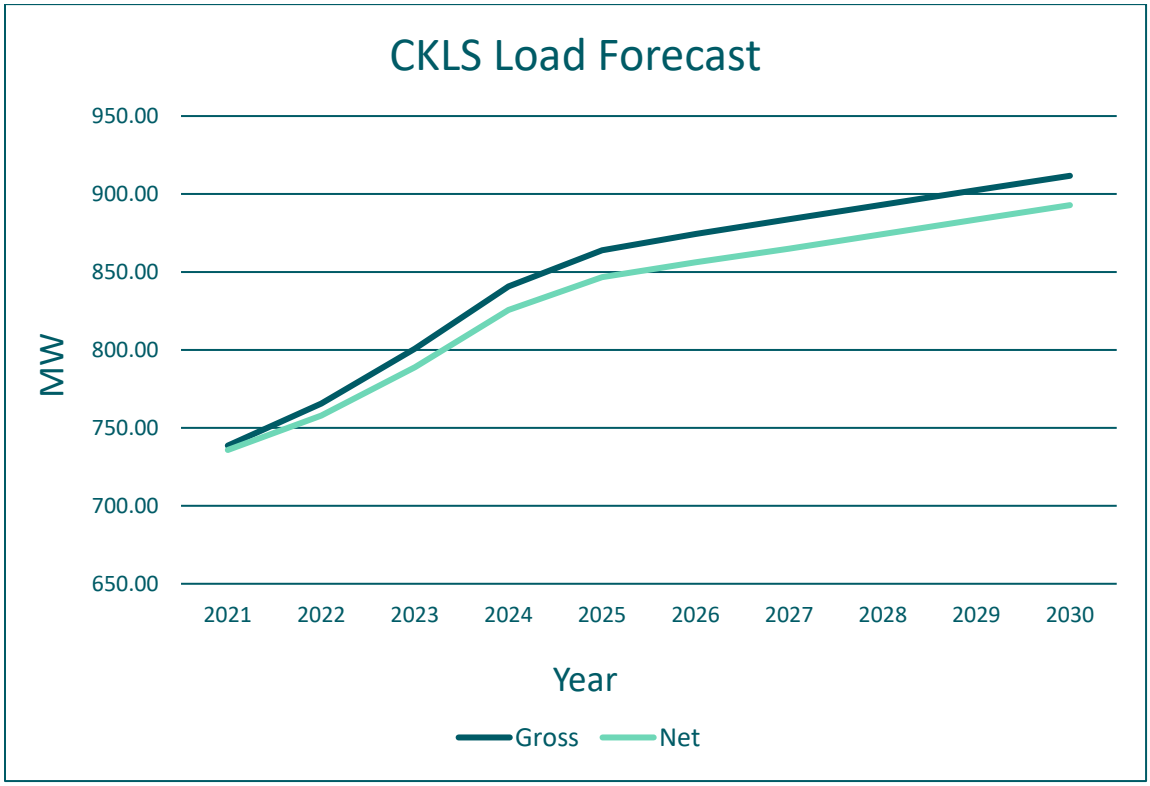

Figure 5-2. Chatham-Kent/Lambton/Sarnia Region Summer Coincident Forecast

5.2 Study Assumptions

The following assumptions are made in this report.

1) The study period for the RIP assessments is 2021-2030.

2) The Region contains most stations that are summer peaking and some that are winter peaking. The assessment is therefore based on summer peak loads.

3) Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity by assuming a 90% lagging power factor for stations without low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer and winter 10-Day Limited Time Rating (LTR), as appropriate.

4) Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).

6. ADEQUACY OF FACILITIES AND REGIONAL NEEDS OVER THE 2021-2030 PERIOD

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND STEP-DOWN TRANFORMATION STATION FACILITIES SUPPLYING THE CHATHAM-KENT / LAMBTON / SARNIA REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM.

Within the current regional planning cycle, two regional assessments have been conducted for the Chatham-Kent/Lambton/Sarnia Region. The findings of these studies are input to the RIP. The studies are:

1) Needs Assessment Report – Chatham-Kent/Lambton/Sarnia Region, September 2021
2) Chatham-Kent/Lambton/Sarnia Region Scoping Assessment Report, December 2021

This RIP reviewed the loading on transmission lines and stations in the Chatham-Kent/Lambton/Sarnia Region based on the RIP load forecast. Sections 6.1-6.5 presents the results of this review and Table 6-1 lists the Region's needs identified in both the Needs Assessment and the SA phases.

In addition, this RIP reviewed an updated list of Hydro One transmission lines and station major sustainment work over the next several years to determine if there are opportunities to consolidate with any emerging development needs within the Region. Section 7.5 presents the results of this review.

Table 6-1: Near and Mid-term Regional Needs

Type	Section	Needs	Timing
Needs and Timing Identified in the Needs Assessment Report and the Scoping Assessment [1]			
Transmission Circuit Capacity	6.2.2	Post-contingency overload and voltage violations on L28C/L29C due to strong load growth in neighbouring Windsor-Essex region	Medium-Term
Transformation Capacity	6.2.3	Transformation capacity need in the Wallaceburg TS and Kent TS area (Dresden area) due to new load connection requests	Short- to Medium-Term
		St. Andrews TS	2024
		Forest Jura HVDS	2030

*subject to final routing selection for the Lambton by Chatham (St. Clair) transmission line [5]

6.1 230 kV Transmission Facilities

Half of the 230 kV transmission circuits in the CKLS Region are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the rest of Ontario's transmission system and are also part of the transmission path from generation in Southwestern Ontario to the load centers in the London and Windsor-Essex areas. These circuits also serve local area stations within the Region and the power flow on them depends on the bulk system transfer as well as local area loads. These circuits are as follows (refer to Figure 3-2):

1) Scott TS to Buchanan TS 230kV transmission circuits N21W/N22W – supplies Modeland TS, Wanstead TS, and Wonderland TS (London Area)
2) Lambton TS to Longwood TS 230kV transmission circuits L24L/L26L
3) Chatham SS to Buchanan TS 230kV transmission circuits W44LC/W44LS/S47C – supplies Duart TS, and generation connections for Erieau Wind Farm and Spence Wind Farm
4) Lambton TS to Chatham SS 230kV transmission circuits L28C/L29C – supplies Kent TS, and generation connections for East Lake St. Clair Wind Farm, North Kent 1 CGS, and GSPC CGS

The RIP review shows that, based on current forecast station loadings, bulk transfers, and IESO's West of London Bulk Study [3], 230 kV circuits L28C/L29C are expected to exceed their post-contingency thermal limits and experience voltage violations over the study period. Supply capacity of all other 230kV transmission circuits is adequate over the study period.

6.2 230/115 kV Transformation Facilities

Bulk power supply to the CKLS Region is provided by Hydro One's 230 kV to 115 kV and 230kV to 345kV autotransformers. The number and location of these autotransformers are as follows:

1) Two (2) 230/115kV autotransformers at Scott TS
2) Two (2) 230/345kV autotransformers at Lambton TS (interconnection to Michigan)

The RIP review shows that based on current forecast station loadings and bulk transfers, the auto-transformation supply capacity is adequate over the study period.

6.3 Supply Capacity of the 115 kV Network

The CKLS Region contains two (2) double-circuit and two (2) single circuit 115 kV lines. These 115 kV circuits radially supply local area load. These circuits are as follows (see Figure 3-2):

1) Scott TS TS to CTS #7 115 kV double-circuit transmission line N1S/N4S – radially supplies CTS
2) Scott TS TS to St. Andrews TS 115 kV double-circuit transmission line N6C/N7C – radially supplies St. Andrews TS
3) Scott TS to Adelaide JCT 115 kV transmission circuit S2N – radially supplies Forest Jura HVDS and CTS #6
4) Scott TS to Kent TS TS 115 kV transmission circuit N5K with normally-open point at Wallaceburg TS – radially supplies Wallaceburg TS

The RIP review shows that based on current forecast station loadings, the supply capacity of the 115 kV network is adequate over the study period.

6.4 Step-down Transformer Stations

There are 18 step-down transformer stations within the CKLS Region. Nine supply electricity to LDCs and nine are transmission-connected industrial customer stations. These stations are listed in Appendix C. One of the 18 stations is owned and operated by an LDC.

As part of the Needs Assessment, as well as this RIP, step-down transformation station capacity was reviewed. Since the September 2021 Needs Assessment, the load forecasts at stations in the region remained unchanged; refer to Appendix D for the forecasts. Based on new customer connection requests, there is a potentially strong capacity need in the Dresden area, which is currently supplied by Kent TS and Wallaceburg TS. If the need materializes, additional capacity would be required in the next 3-6 years. The analysis also showed that the net load forecast at St. Andrews will reach the station's summer LTR in 2024, however, the planned like-for-like replacement of the transformers and switchyard (2025) will increase the station capacity and address the capacity need. Likewise, the net load forecast at Forest Jura HVDS is expected to reach the stations summer LTR in 2030 – the station owner, Hydro One Distribution, will continue to monitor the station loading and develop a plan to address the capacity need that is forecasted towards the end of the study period. The gross load forecast at all remaining stations can be accommodated over the study period.

6.5 Other Items Identified During Regional Planning

6.5.1 End-Of-Life Equipment Replacement Needs

Lambton TS – T7/T8, T5/T6 and Component Replacement

Lambton TS has two 230kV/345 kV 600MVA auto-transformers (T7/T8) that facilitate the interconnection to Michigan and two 230kV/27.6kV 56/75/93MVA step-down transformers (T5/T6) that supply Hydro One Distribution via six 27.6 kV feeders.

The current scope of this project is to replace the T7/T8 transformers with a single 1000MVA auto-transformer, the T5/T6 transformers like-for-similar with 50/83MVA capacity, the 27.6kV switchyard and associated equipment.

Based on the load forecast, similar equipment ratings are required for the EOL replacement. The new step-down transformers will increase the capacity of the station by 20 MVA. This project is underway and the planned in-service date for the project is in year 2023.

Scott TS – T5 and 115kV Switchyard Replacement

Scott TS has two 230kV/115kV 150/200/250 MVA auto-transformers (T5/T6) that supply the 115kV system in the CKLS region. Transformer T5 has been in service since 1958 as well as the 115 kV switchyard.

The current scope of this project included the like-for-like replacement of the T5 auto-transformer and the 115kV switchyard including associated equipment.

Based on the load forecast, similar equipment ratings are required for EOL replacement. The planned in-service date for the project is in year 2024.

St. Andrews TS – T3/T4 and Component Replacement

St. Andrews TS is transformer station that was built in 1964. The station consists of two 115kV/27.6 kV 56/74/93 MVA step-down transformers (T3/T4) supplied radially by 115 kV circuits N6C/N7C. The station supplies Bluewater Power Distribution Corporation via six feeders and an industrial customer via two feeders.

The current scope of this project is to replace T3/T4 transformers like-for-similar with 50/83MVA capacity and the 27.6kV switchyard along with associated equipment.

Based on the load forecast for the station, similar equipment ratings are required for EOL replacement of all equipment discussed above. The new transformers will increase the capacity of the station by 20MVA. The planned in-service date for the project is in year 2025.

Kent TS – T2 and Component Replacement

Kent TS consists of two 230kV/27.6 kV, 75/100/125 MVA step-down transformers (T1/T2) supplied by 230 kV circuits L28C/L29C (Lambton x Chatham). The station supplies Hydro One Distribution and Entegrus Powerlines Inc. T1 was replaced on demand due to a transformer failure in 2020.

The scope of this project includes the like-for-like replacement of transformer T2 along with the 27.6kV switchyard and associated equipment.

Based on the load forecast, similar equipment ratings are required for EOL replacement. Once T2 is replaced, the capacity of the station will increase by 35-40MVA. The planned in-service date for the project is in year 2027.

N1S/N4S – Transmission Line Refurbishment

End-of-life refurbishment of 115kV double-circuit transmission line is planned for the section between Scott TS and Vidal JCT and is expected to be completed in 2027.

N6C/N7C – Transmission Line Refurbishment

End-of-life refurbishment of 115kV double-circuit transmission line is planned for the section between Scott TS and St. Andrews TS, and is expected to be completed in 2027.

S2N – Transmission Line Refurbishment

End-of-life refurbishment of 115kV transmission line is planned for the section between Scott TS and Adelaide JCT and is expected to be completed in 2025.

N5K – Transmission Line Refurbishment

End-of-life refurbishment of 115kV transmission line is planned for the section between Scott TS and Kent TS and is expected to be completed in 2027. Depending on the route selection for the new Lambton-by-Chatham transmission line (referred to as the St. Clair Transmission Line project), this refurbishment may not be required as the N5K circuit may be decommissioned.

7. REGIONAL PLANS

THIS SECTION DESCRIBES THE NEEDS FROM TABLE 6-1 AND SUMMARIZES THE REGIONAL PLANS FOR ADDRESSING THE NEEDS.

7.1 Transmission Circuit Capacity

7.1.1 Circuits L28C/L29C

The L28C/L29C double-circuit transmission line will start to experience capacity issues and voltage violations in the medium term due to significant capacity needs in the neighbouring Windsor-Essex region as well as the demand for potential new connections in Dresden Area. The need for reinforcement of this corridor was documented in IESO's West of London Bulk System Study which recommended the construction of a new 230kV double-circuit transmission line between Lambton and Chatham.

Recommended Plan and Current Status

To address the potential need for additional capacity and improved voltage performance along this corridor, Hydro One has agreed with IESO's recommendation to construct the new 230kV double-circuit transmission line which is expected to be in-serviced in 2028. Three of the five routes that are currently under study involve the decommissioning of circuit N5K and a voltage conversion of Wallaceburg TS from 115kV to 230kV. The selection of the preferred route for the new double-circuit line is anticipated in Q2 2023.

7.2 Transformation Capacity

7.2.1 Wallaceburg TS and Kent TS Area (Dresden Area)

There is potentially a strong need for capacity in the Dresden Area which is currently supplied by Wallaceburg TS and Kent TS. The demand for new customer connections in the area has the potential of exceeding 100 MW by 2025 and upwards of 130 MW by the end of the study period – a capacity need that cannot be wholly supplied by the available capacities at Wallaceburg TS and Kent TS. Wallaceburg TS has approximately 5-10 MW of available capacity, whereas the existing Kent TS (T1/T2) has about 30-35 MW of spare capacity which will increase to roughly 65 MW once T2 is replaced in 2027, and the need for new capacity in this area remains in high demand. This need was also documented in IESO's Dresden Load Connection Study (included in Appendix 3 of the CKLS Scoping Assessment Outcome Report [2]) which recommended the construction of a new station supplied by the 230kV Lambton by Chatham corridor. If Wallaceburg TS is converted to 230kV supply as a result of the new Lambton by Chatham transmission line routing, additional transformation capacity of 30-40 MW would become available.

Recommended Plan and Current Status

Subject to the confirmation of the load materializing in the Dresden Area, Hydro One would move forward with IESO's recommendation of constructing a new station (proposed to be named Dresden TS) on the Lambton by Chatham corridor. Due to the existing limitations on the L28C/L29C circuits the construction of the new Dresden TS would be aligned with the construction of the new Lambton by Chatham transmission line with the intention of being ready connect new customers at the same time that the new double-circuit line is complete, in 2028. The immediate capacity needs of new customers can be supplied by the limited capacities available at Kent TS (T1/T2 DESN) and Wallaceburg TS until the proposed Dresden TS is placed in service. The need for Dresden TS may possibly be delayed if the Lambton by Chatham routing results in additional capacity becoming available at Wallaceburg TS.

7.2.2 St. Andrews TS

St. Andrews TS will reach its LTR in 2024, from which point it will continue to grow at an average rate of less than 0.5% towards the end of the study period. As the station is expected to slowly start exceeding its LTR, additional capacity is required.

Recommended Plan and Current Status

To address the capacity need at St. Andrews, it is recommended that Hydro One proceed with the sustainment plan to replace the end-of-life transformers and switchyard which will increase the LTR of the station by 20 MVA and provide sufficient capacity for the long-term. The replacement of the EOL assets is expected to be completed in 2025. Capital contribution from customers is not anticipated at this time as this a like-for-like sustainment project.

Additionally, if more capacity is requested in the local area of St. Andrews TS, the nearby Modeland TS will still have approximately 30MVA of spare capacity by the end of the study period. The existing Modeland TS also has the potential for future expansion should capacity need arise in the area.

7.2.3 Forest Jura HVDS

Forest Jura HVDS, a station owned by Hydro One Distribution, is expected to reach its LTR in 2030, with and average growth rate of 1.2% over the study period. If the forecast materializes as expected, additional capacity will be required in the long-term.

Recommended Plan and Current Status

To address the potential capacity need at Forest Jura HVDS, Hydro One Distribution will monitor the loading and determine a plan to ensure the station can meet the capacity demand.

7.3 Voltage Performance

7.3.1 Circuit N5K

Assuming a large load growth at Wallaceburg TS in the absence of the proposed Dresden TS, there would be voltage violations on the 115kV N5K circuit. This violation is mitigated with the new Dresden TS in place and Wallaceburg loaded within its LTR. Also, if the Lambton by Chatham line routing results in the decommissioning of N5K and Wallaceburg TS being supplied at 230kV, the violation is mitigated.

Recommended Plan and Current Status

It is recommended to maintain loading at Wallaceburg within its capacity limit and wait for the Lambton by Chatham line routing to be established, anticipated in Q2 2023, which will determine if the supply voltage to Wallaceburg TS is increased to 230kV. The line routing selection will also help determine the urgency in constructing the new Dresden TS.

7.4 Bulk System Performance

7.4.1 Circuits L28C/L29C

Based on the study assumptions listed in Section 5.2, and accounting for needs in neighbouring Windsor-Essex Region, there is a bulk system need to reinforce the 230kV corridor between Lambton and Chatham. There are a number of large-scale combined-cycle gas plants in the Sarnia-Lambton area and gas-fired generation output could vary depending on broader system conditions such as expected load growth in the province or availability of other generation resources. Moreover, the Chatham-Kent/Lambton/Sarnia Region is connected to the US market through interconnections in Sarnia and Lambton. Import and export generation levels on the interties have a significant impact on the bulk transmission system. Generation output and import/export levels were parameters considered for the bulk system performance for this Region as well as to serve the growing needs in neighbouring regions (Windsor-Essex region and Chatham-Kent area). The IESO undertook a study to assess the bulk system adequacy for the West of London area, under different system conditions. As a result, the need to reinforce the Lambton-by-Chatham corridor was identified to increase supply capacity into Windsor-Essex region and Chatham-Kent area to meet the mid-term capacity need, and improve the deliverability of resources in Lambton-Sarnia.

Recommended Plan and Current Status

As recommended in IESO's West of London Bulk System Study, Hydro One will proceed with the construction a new double-circuit transmission line between Lambton and Chatham to address bulk system reinforcement needs. The project is expected to be completed in 2028.

7.5 Transmission Sustainment Plans

As part of Hydro One's transmitter requirements, Hydro One continues to ensure a reliable transmission system by carrying out maintenance programs as well as periodic replacement of equipment based on their condition. Table 7-1 lists Hydro One's major transmission sustainment *projects* in the Region that are currently planned or underway. Maintenance *programs* such as insulator, shield wire, structure replacements will continue to be carried out in the Region as required based on equipment/asset condition assessments.

Table 7-1: Hydro One Transmission Major Sustainment Initiatives[2]

Station/Lines	General Description of Work	Planning In-Service Date
Lambton TS	• Replacement of T7/T8 auto-transformers and associated switches • Replacement of T5/T6 DESN transformers and associated switches • Replacement 27.6kV switchyard and associated equipment	2023
Scott TS	• Replacement of T5 auto-transformer • Replacement of 115kV switchyard and associated equipment	2024
St. Andrews TS	• Replacement of T3/T4 DESN transformers and associated switches • Replacement of 27.6kV switchyard and associated equipment	2025
Kent TS	• Replacement of T2 DESN transformers and associated switch • Replacement of 27.6kV switchyard and associated equipment	2027
N1S/N4S	• Refurbishment of circuit section between Scott TS and Vidal JCT	2027
N6C/N7C	• Refurbishment of circuit section between Scott TS and St. Andrews TS	2027
S2N	• Refurbishment of circuit section between Scott TS and Adelaide JCT	2025
N5K	• Refurbishment of circuit section between Scott TS and Kent TS*	2027

*subject to final routing selection for the Lambton by Chatham (St. Clair) transmission line

[2] Scope and dates as of August 2022 and are subject to change

Based on the needs identified in the region thus far and the transmission sustainment plans listed in Table 7-1, consolidation of sustainment and development needs is not necessary at this time.

8. CONCLUSION

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE CHATHAM-KENT / LAMBTON / SARNIA REGION.

Six near and mid-term needs were identified for the CKLS Region. They are:

I. Transmission Circuit Capacity on Lambton by Chatham Corridor (mid-term)

II. Transformation Capacity in Dresden Area (mid-term)

III. Transformation Capacity at St. Andrews TS (short- to mid-term)

IV. Transformation Capacity at Forest Jura HVDS (mid-term)

V. Voltage Performance on N5K (mid-term)

VI. Bulk System Performance on Lambton by Chatham Corridor (mid-term)

This RIP report addresses six needs and has concluded that regional plans are required. Next Steps, Lead Responsibility, and Timeframes for implementing the regional plans to address needs I through VI are summarized in the Table 8-1 below.

Table 8-1: Regional Plans – Next Steps, Lead Responsibility and Plan In-Service Dates

No.	Project	Next Steps	Lead Responsibility	In-Service Date	Cost	Needs Mitigated
1	Construct new Lambton by Chatham double-circuit line (St. Clair Transmission Line)	Project Under Development	Hydro One Transmission	2028	$210-290M	I,VI
2	Build new Dresden TS supplied by Lambton by Chatham corridor	Initiate project	Hydro One Transmission	2028*	$40M	II,V
3	St. Andrews TS Refurbishment	Detailed Estimate	Hydro One Transmission	2025	$40-50M	III
4	Monitor growth at Forest Jura HVDS	Monitor & Determine Plan	Hydro One Distribution	--	--	IV

*may be delayed if Lambton by Chatham route selection results in additional capacity available at Wallaceburg TS

In accordance with the Regional Planning process, the Regional Plan should be reviewed and/or updated at least every five years. The region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

APPENDIX E: LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CSS	Customer Switching Station
CTS	Customer Transformer Station
DCF	Discounted Cash Flow
DER	Distributed Energy Resources
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GATR	Guelph Area Transmission Reinforcement
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

Disclaimer

This Regional Infrastructure Plan ("RIP") Report for Greater Bruce/Huron ("GBH") region was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group ("TWG").

The preferred solution(s) that have been recommended in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP TWG at the time.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	**Greater Bruce/Huron region** (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")
START DATE: October 20, 2024	**END DATE:** April 11, 2025

1. INTRODUCTION

The Regional Infrastructure Plan ("RIP") is the final step of Regional Planning ("RP") process for the Greater Bruce/Huron ("GBH") region, preceded by, the publication of Needs Assessment ("NA") report in September 2024 by Hydro One. At the end of NA phase, the Technical Working Group ("TWG") decided that there is no need for Scoping Assessment ("SA") and/or Integrated Regional Resource Plan ("IRRP") phases to meet the identified needs in this cycle; therefore, the TWG proceeded directly to the RIP phase.

Hydro One as the lead transmitter undertakes the development of a RIP with input from the TWG for the region and publishes a RIP report. The RIP report includes a common discussion of all the options and recommended plans, and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs.

2. OBJECTIVES AND SCOPE

Objectives:

- Provide a comprehensive summary of needs and wires plans to address the needs for the GBH region.
- Identify new supply needs that may have emerged since Needs Assessment phase.
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

Scope:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs 2024-2033 identified in Needs Assessment.
- Identification of any new needs over the 2024-2033 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the GBH as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

This section provides a detailed overview of the various steps followed during different phases of the Regional Planning Process and their outcomes and details of the Regional Infrastructure plan Methodology.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

This section provides a general overview of the Geographical boundaries, Circuit connections and Stations located in the GBH region though a regional planning area map and a Single Line diagram ("SLD").

The GBH region comprises of the counties of Bruce, Huron, and Perth, as well as portions of Grey, Wellington, Waterloo, Oxford, and Middlesex counties.

Electricity supply for the GBH region is provided through a network of 230 kV and 115 kV transmission lines supplied mainly by generation from the Bruce Nuclear Generating Station and local renewable generation facilities in the region. These circuits connect the region to the adjacent South Georgian Bay/Muskoka region and the adjacent Kitchener-Waterloo-Cambridge-Guelph ("KWCG") region.

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR UNDERWAY

This section provides a summary and brief description of all the projects completed in the past ten (10) years or are currently underway.

I. The following Major projects were completed during the last ten years:

1. Goderich TS – Transformers T1, T2 and T3 Removal, Transformer T5 Installation and station Reconfiguration. This project was completed in 2017.
2. Centralia TS – Transformers T1 and T2 Replacement, Transformer T3 Removal and station Reconfiguration. This project was completed in 2018.
3. Palmerston TS – Transformers T1 and T2 Replacement, Transformer T3 Removal and station Reconfiguration. This project was completed in 2019.
4. Bruce A TS – 230kV ABCB ("Air-Blast Circuit Breaker") Station Refurbishment. This project was completed in 2022.
5. Stratford TS – Transformer T1 Replacement. This project was completed in 2022.
6. Hanover TS – Transformer T2 Replacement. This project was completed in 2022.
7. 115 kV L7S Circuit – Capacity Increase and Clearance Improvement between Seaforth TS and Kirkton JCT. This project was completed between 2022 to 2023.
8. Wingham TS – Transformers T1 and T2 Replacement. This project was completed in 2024.

II. Following Major projects are underway:

1. Seaforth TS – Transformers T1, T2, T5 and T6 Replacement. This project is planned to be completed by Q1 2027.

Note: The planned in-service years for the above projects are tentative and subject to change.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

During the study period, the summer *net* and *gross* coincident load in the region is expected to grow at an average rate of approximately 1.4% and the winter *net* and *gross* coincident load in the region is expected to grow at an average rate of approximately 0.8%.

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2024-2033.
- LDCs reconfirmed load forecasts up to 2033 in the area are the same as their load forecasts in NA phase.
- All planned facilities for which work has been initiated and are listed in section 5 are assumed to be in-service.
- Some of the stations in this region are summer peaking and others are winter peaking, so this assessment is based on summer and winter peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating ("LTR") based on 35°C ambient temperature.
- Bulk transmission line capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Adequacy assessment is conducted as per Ontario Resource and Transmission Assessment Criteria ("ORTAC").

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing transmission systems and transformer station facilities supplying the GBH region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway are completed.

I. Needs identified in the region

a. Asset Renewal for Major HV Transmission Equipment

- Owen Sound TS – T5 Replacement: Like-for-Like replacement of transformer T5 to maintain supply reliability to the LDCs in the area. This project is planned to be completed by 2032.

b. Station Capacity

- During the study period, no station capacity needs were identified.

c. Transmission Line Capacity

- During the study period, no transmission system capacity needs were identified.

d. System Reliability, Operation and Load restoration

- 115 kV L7S Circuit – System reliability and performance issues due to line galloping and line component failures.
- Operational issue with supply capacity at Hanover TS under outage conditions.
- Operational issue with supply capacity on D10H when load is transferred between Detweiler TS in KWCG region and Hanover TS in the GBH region.

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred solutions for the GBH region. The needs include those previously identified in the NA for the GBH region as well as any new needs identified during the RIP phase.

9. CONCLUSION AND RECOMMENDATIONS

The major infrastructure investments recommended by the TWG in the Greater Bruce/Huron region are given below:

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Asset Renewal Needs				
Seaforth TS	T1, T2, T5 and T6 Transformer Replacement	Hydro One Transmission	Q1 2027	$76M
Owen Sound TS	T5 Transformer Replacement	Hydro One Transmission	Q2 2032	$25M
System Reliability, Operation and Load restoration Needs				
115 kV L7S Circuit Capacity Increase	Monitoring the performance of this circuit and proceeding with corrective plan as required in the next phase of the Regional Planning cycle	Hydro One Transmission	On Going	N/A
Operational issue with supply capacity at Hanover TS, under outage conditions	Monitor and review in next regional planning cycle	Hydro One Transmission	Next Regional Planning Cycle	N/A
Operational issue with supply capacity on D10H, during load transfer between Detweiler TS and Hanover TS	Monitor and review in next regional planning cycle	Hydro One Transmission	Next Regional Planning Cycle	N/A

Notes:

a) The planned in-service dates are tentative and subject to change.
b) Costs are based on budgetary planning estimates exclude the cost for distribution infrastructure (if required)

1. INTRODUCTION

The Regional Infrastructure Plan ("RIP") is the final step of Regional Planning Process. Hydro One as the lead transmitter undertake the development of a RIP with input from the Technical Working Group ("TWG") for the region and publishes a RIP report. The third cycle of the Regional Planning process for the Greater Bruce/Huron ("GBH") region was initiated with the publication of Needs Assessment ("NA") and the report was published in September 2024 by Hydro One.

At the end of the NA phase, the TWG decided that there is no need for Scoping Assessment ("SA") and Integrated Regional Resource Plan ("IRRP") phases to meet the identified regional needs, and all identified system operational needs in this cycle will be revisited in the next Regional Planning Cycle. The TWG decided that there is no need for integrated regional planning to meet the identified needs in this cycle and that planning can proceed directly to the RIP.

The RIP report includes a common discussion of all the options and recommended plans, and preferred wire infrastructure investments identified in NA phase to address the near- and medium-term needs.

This report was prepared by the GBH region TWG, led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by Hydro One, the Local Distribution Companies ("LDC"), the Municipalities and the IESO. Participants of the TWG are listed below in Table 1.

Table 1: **GBH** region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Networks Inc. (Lead Transmitter)
2	Hydro One Networks Inc. (Distribution)
3	Independent Electricity System Operator (IESO)
4	ERTH Power Corporation
5	Festival Hydro
6	Westario Power Inc.
7	Entegrus Powerline Inc.
8	Wellington North Power

2. OBJECTIVES AND SCOPE OF REGIONAL INFRASTRUCTURE PLAN

This RIP report examines the needs in the GBH region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs for the GBH region.
- Identify new supply needs that may have emerged since the Needs Assessment ("NA") phase.
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and/or distribution facilities that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major High Voltage ("HV") transmission equipment, transmission and distribution system capability along with any updates with respect to local plans, electricity Demand Side Management ("eDSM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration. The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs 2024-2033 identified in previous planning phase, the NA phase in this cycle.
- Identification of any new needs over the 2024-2033 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the GBH region Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

3.1 Overview

Bulk System Planning, Regional Planning and Distribution Planning are the three levels of planning for the electricity system in Ontario. Bulk system planning typically looks at issues that impact the system on a provincial level and requires longer lead time and larger investments. Comparatively, planning at the regional and distribution levels looks at issues on a more regional or localized level. Typically, the most essential and effective regional planning horizon is the near- to medium-term (1- 10 years), whereas long-term (10-20 years) regional planning mostly provides a future outlook with little details about investments because the needs and other factors may vary over time. On the other hand, bulk system plans are developed for the long term because of the larger magnitude of the investments.

The regional planning process begins with a Needs Assessment which is led by the transmitter to identify, assess, and document which of the needs that,

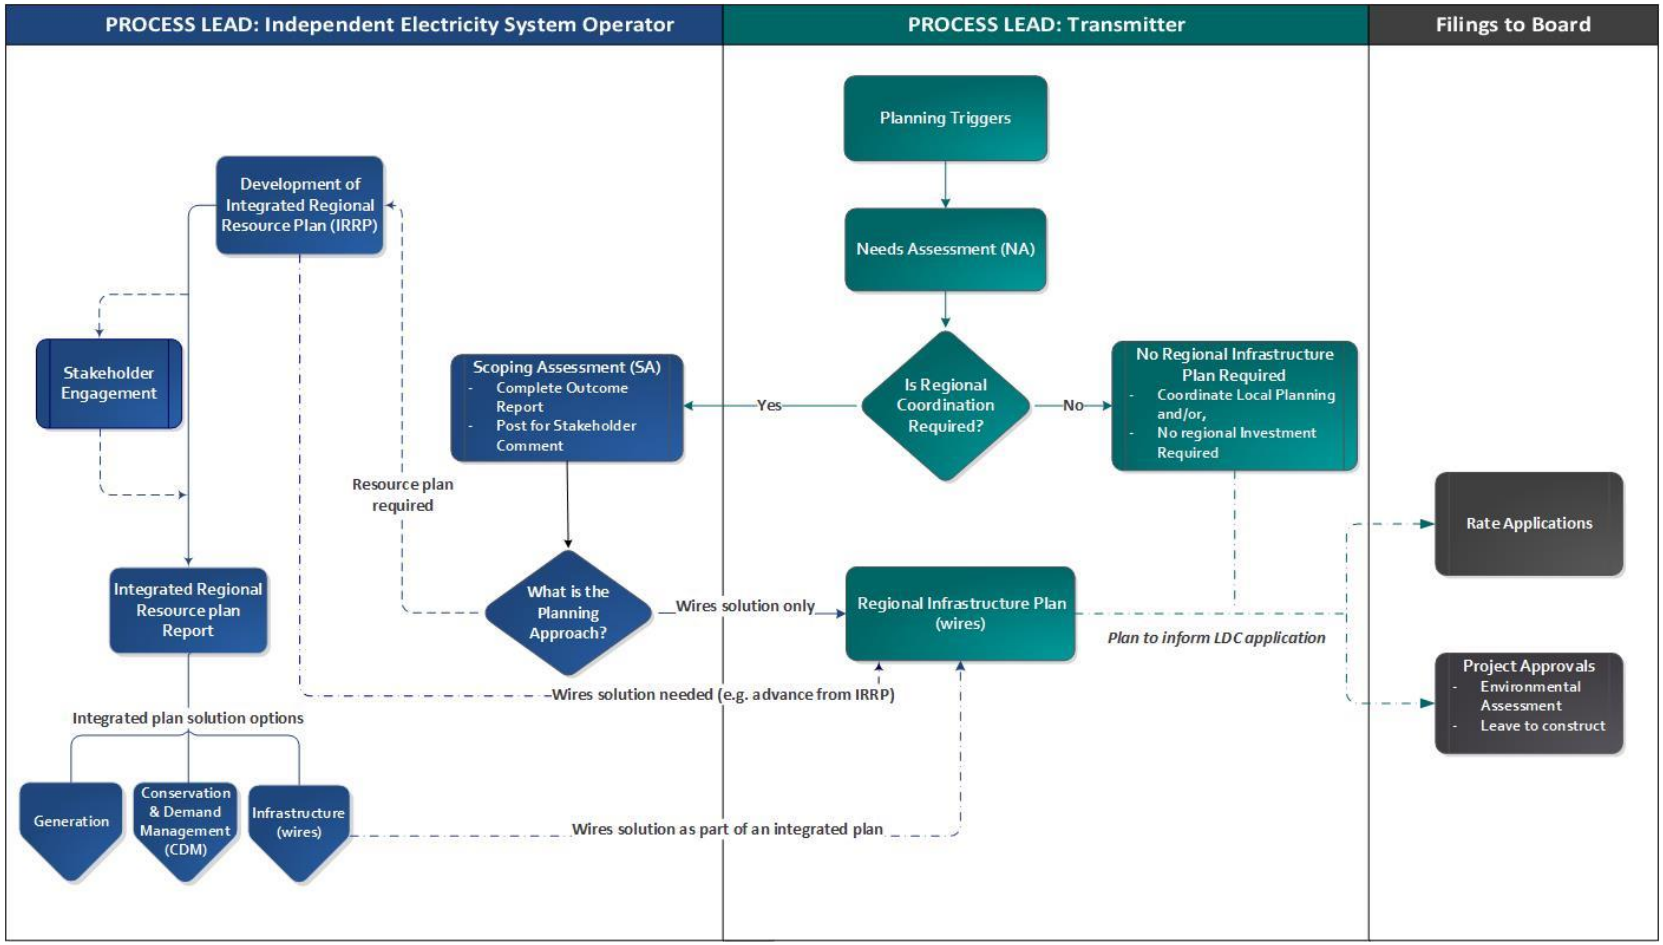
a) can be addressed directly between the customer and transmitter along with a recommended plan, and;

b) require further regional coordination and identification of Local Distribution Companies ("LDCs") to be involved in further regional planning activities for the region.

At the end of the NA, a decision is made by the TWG as to whether further regional coordination is necessary to address some or all the regional needs. If no further regional coordination is required, recommendation to implement the recommended option and any necessary investments are planned directly by the LDCs (or customers) and the transmitter. The region's TWG can also recommend to the transmitter and LDCs to undertake a local planning process for further assessment when needs

a) are local in nature,
b) require limited investments in wires (transmission or distribution) solutions and;
c) do not require upstream transmission investments.

If coordination at the regional or sub-regional levels is required for identified regional needs, then the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires or resource alternatives, e.g., electricity Demand Side Management ("eDSM"), supply resources, etc., in order to make a decision on the most appropriate regional planning approach including Local Plan (LP), IRRP and/or RIP.



The purpose of the IRRP is to coordinate regional wires and non-wires options to create an integrated plan considering feasibility, cost, reliability, government policy directives, environmental performances, and community preferences to address the need. Worth noting, the LDCs' eDSM targets as well as contracted Supply Resource plans provided by IESO and LDCs are reviewed and considered at each step in the regional planning process.

If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution (planning can be initiated in parallel to IRRP). Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led community and stakeholder engagement with municipalities in the region or sub-region.

The RIP phase is the final phase of the regional planning process and involves discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive and consolidated report of a wires plan for the region. Once completed, the RIP report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

The various phases of Regional Planning Process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome are shown below in Figure 1.

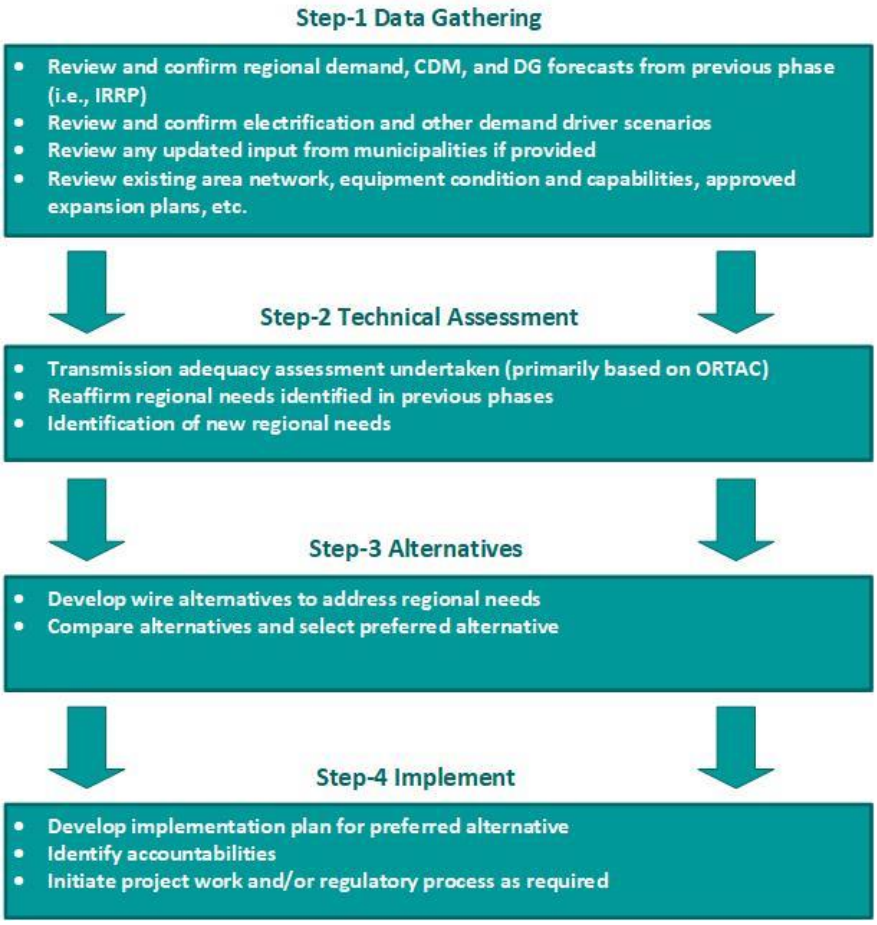


Figure 1: Regional Planning Process Flowchart

3.2 Regional Infrastructure Plan Methodology

Regional Infrastructure Plan phase is a four-step process as shown in Figure 2. These phases are described in the following sub-sections:

Figure 2: Regional Infrastructure Plan Methodology

3.2.1. Data Gathering:

The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the TWG to reconfirm or update the information as required. The data collected includes:

- Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs. As it was confirmed by the TWG, there was no major change to the NA phase load forecast; therefore, the load forecast from the NA phase was used for this RIP.

- Review and confirm electrification and other growth scenarios which affect the projects recommended in previous stages.
- Existing area network and capabilities including any bulk system power flow assumptions.
- Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

3.2.2. Technical Assessment:

The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3.2.3. Alternative Development:

The third step is the development of wires options to address the needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

3.2.4. Implementation Plan:

The fourth and last step is the development of the implementation plan for the preferred alternative, identifying accountabilities and initiate project work or obtaining permissions from Regulatory Commission if any.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The GBH region comprises of the counties of Bruce, Huron, and Perth, as well as portions of Grey, Wellington, Waterloo, Oxford, and Middlesex counties.

The geographical boundaries of the GBH region is shown in Figure 3 below.

Figure 3: Map of GBH Regional Planning Area

Electricity supply for the GBH region is provided through a network of 230 kV and 115 kV transmission lines supplied mainly by generation from the Bruce Nuclear Generating Station ("NGS") and local renewable generation facilities in the Region. Majority of the electrical supply in the region is transmitted through 230 kV circuits (B4V, B5V, B22D, B23D, B27S and B28S) radiating out from Bruce A TS.

These circuits connect the GBH region to the adjacent South Georgian Bay/Muskoka region and the adjacent Kitchener-Waterloo-Cambridge-Guelph ("KWCG") region. Within this region, electricity is delivered to the end users of LDCs and directly connected industrial customers by eleven (11) Hydro One step-down transformation stations, as well as seven (7) customer-owned transformer or distribution

stations supplied directly from the transmission system. Appendix B lists all step-down transformer and distribution stations in the Region. Appendix C lists all transmission circuits and Appendix D lists LDCs in the Region. The circuits and stations of the area are summarized in Table 2 below:

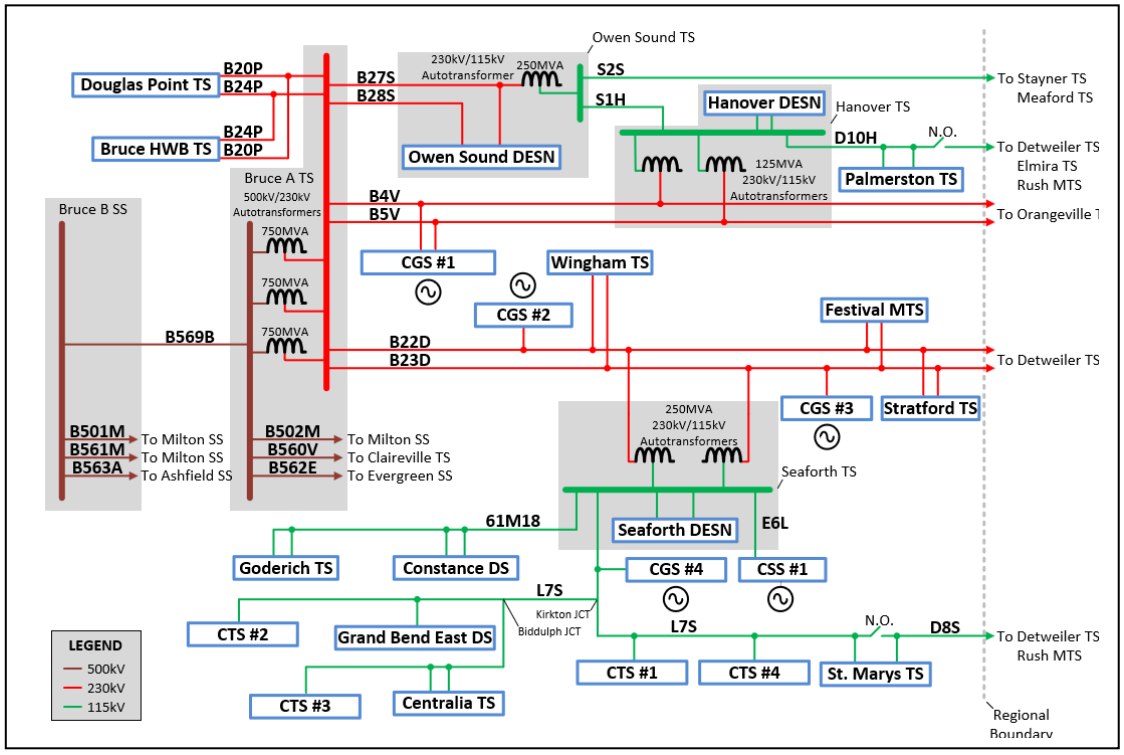

Table 2: Transmission Station and Circuits in the GBH region

115kV circuits	230kV circuits	Hydro One Transformer/Distribution Stations		Generation Stations
S2S	B4V	Bruce A TS *	Goderich TS	Bruce A NGS
S1H	B5V	Bruce B SS	Constance DS	Bruce B NGS
D10H-North	B22D	Bruce HWP B TS	St. Marys TS	CGS #1

The single line diagram of the Transmission Network of GBH region is shown in Figure 4 below.

Figure 4: GBH region Transmission Single Line Diagram

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR ARE UNDERWAY

In this section a complete list of all the projects that have been completed in the past ten (10) years or are currently underway is provided and are briefly discussed in the sub-sections. As a part of this or previous Regional Planning Cycle(s), several "Major HV Transmission Projects" were recommended in the GBH region to improve the supply capability and reliability.

Hydro One, being the only Transmission Asset Owner ("TAO") in the region, has undertaken the execution of the projects recommended in the past ten years. A summary and brief description of all the projects completed or are currently underway is given below:

I. The following Major projects were completed during the last ten years:

1. Goderich TS – T1, T2, T3 Removal, T5 Installation and station Reconfiguration: Removal of 15/20/25MVA 115-27kV T1 transformer, removal of 11/15MVA 115-27kV T2 and T3 transformers, and installation of a new 50/67/83MVA 115-27kV T5 transformer to address thermal capacity issues at this station. Under this project, the station was reconfigured following DESN arrangement standards. This project was completed in 2017.

2. Centralia TS – T1 and T2 Replacement, T3 Removal and station Reconfiguration: Replacement of 11/15/19MVA 115-28kV T1 and T2 transformers with new 25/33.3/41.7MVA 115-28kV units, removal of 11/15/19MVA 115-28kV T3 transformer and reconfiguration of the station as per DESN arrangement standards. This project was completed in 2018.

3. Palmerston TS – T1 and T2 Replacement, T3 Removal and station Reconfiguration: Replacement of 42MVA 115-44kV T1 and T2 transformers with new 50/66.7/83.3MVA units, removal of 42MVA 115-44kV T3 transformer, and reconfiguration of the non-standard three (3) transformer arrangement station to two (2) transformer DESN station arrangement as per the standard. This project was completed in 2019.

4. Bruce A TS – 230kV ABCB Station Refurbishment: Replacement of sixteen (16) 230kV Air-Blast Circuit Breakers ("ABCB") with SF6 type to maintain station supply reliability to the customers in the area. This project was completed in 2022.

5. Stratford TS – T1 and Component Replacement: Replacement of 50/67/83MVA 230-27.6kV T1 transformer and associated equipment to maintain station supply reliability to Festival Hydro Inc., Hydro One Distribution as well as other embedded LDCs in the area. The project was completed in 2022.

6. Hanover TS – T2 and Component Replacement: Replacement of the 115-44kV transformer T2 with a new 50/66.7/83.3MVA 110-44kV unit to maintain station supply reliability to Hydro One Distribution and embedded LDCs in the area. The project was completed in 2022.

7. 115 kV L7S Circuit – Capacity increase and clearance Improvement: Between year 2022 to 2023, sub-standard clearances of the limiting section of L7S were addressed to increase their sag temperature from 83°C to 125°C and improve the capacity of this circuit. Furthermore, Hydro One undertook a complete condition assessment of L7S and identified a variety of deficiencies that have been addressed.

8. Wingham TS – T1 and T2 Replacement: Replacement of 50/83MVA 230-44kV T1 and T2 transformers with new 50/66.7/83MVA 230-44kV units to maintain station reliability to the customers in the area. This project was completed in 2024.

II. Following Major projects are underway:

1. Seaforth TS – T1, T2, T5 and T6 Replacement: Replacement of 25/33.3/41.7MVA 115-28kV T1 and T2 step-down transformers with 25/33.3/41.7MVA 110-28kV units and replacement of 150/200/250MVA 230-115kV T5 and T6 autotransformers with 150/200/250MVA 239-121-13.9kV units. This project will maintain station reliability and ensure continued supply reliability to Hydro One Distribution and embedded LDCs in the area. The project is planned to be completed by Q1 2027.

Note: The planned in-service years for the above projects are tentative and subject to change.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

6.1. Load Forecast

After verification from the TWG participants, as no material changes were identified in the GBH region, NA Load Forecasts were used in the development of this Report. TWG participants, including representatives from LDCs, IESO and Hydro One provided information and input for the load forecast. The municipalities were contacted as part of the stakeholder engagement process to get their insight into the future load growth and was considered during the load forecast development.

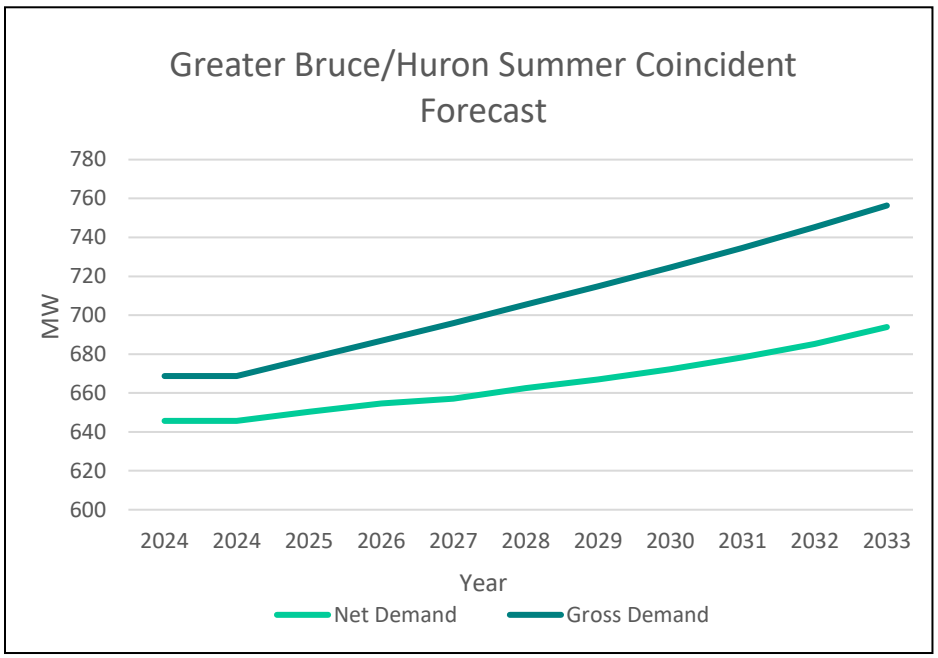
As per the load forecasts for the study period from 2024 to 2033, the summer net and gross coincident load in the region is expected to grow at an average rate of approximately 1.4% annually and the winter net and gross coincident load in the region is expected to grow at an average rate of approximately 0.8% annually.

Figures 5 & 6 shows the GBH region summer and winter weather net and gross coincident load forecast from 2024 to 2033. The load forecast from the GBH region was adopted as agreed to by the TWG.

Based on historical load and the non-coincident load forecasts, the Greater Bruce/Huron region contains some stations that are summer peaking and others that are winter peaking. Equipment ratings are normally lower in the summer than in winter due to ambient temperature. Based on these factors, assessment for this region was conducted for both summer and winter peak load.

Non-coincident and coincident forecast for the individual stations in the region is available in Appendix A and is used to determine any need for station capacity relief in the region.

Figure 5: GBH Region Summer Coincident Net and Gross Load Forecast



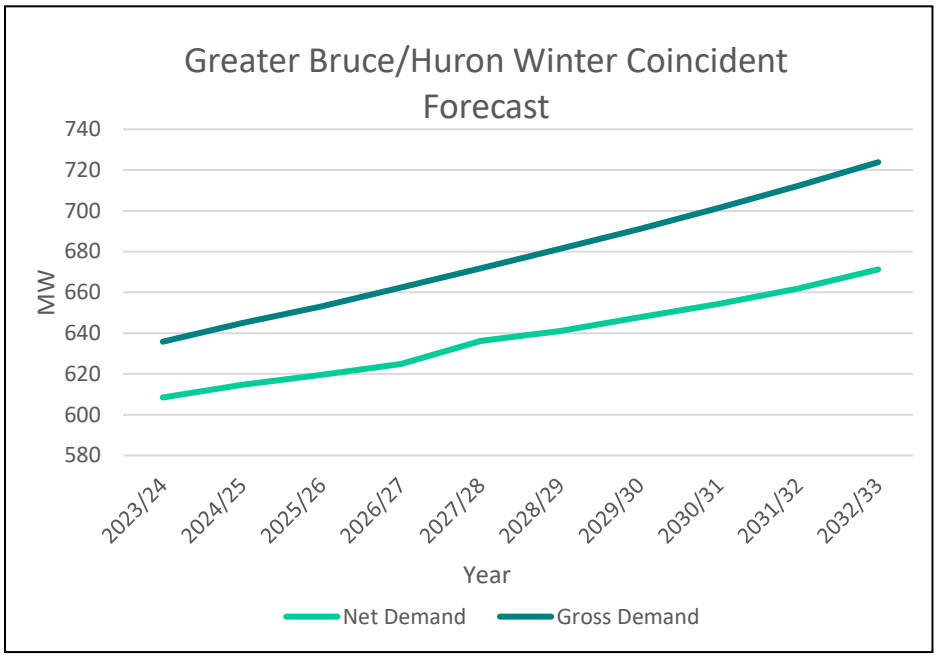


Figure 6: GBH Region Winter Coincident Net and Gross Load Forecast

6.2. Other Study Assumptions

The following other assumptions are made in this report:

- The study period for the RIP assessments is 2024-2033.
- LDCs reconfirmed load forecasts up to 2033 in the area are the same as the NA phase.
- All planned facilities for which work has been initiated and are listed in section 5 are assumed to be in-service.
- Some of the stations in this region are summer peaking and others are winter peaking, so this assessment is based on summer and winter peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating ("LTR") based on 35°C ambient temperature.
- Bulk transmission line capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Adequacy assessment is conducted as per ORTAC.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing transmission systems and transformer station facilities supplying the GBH region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway, listed in section 5 are completed.

In the current regional planning cycle, the following regional assessments were completed, and their findings were used as inputs to this RIP report:

- GBH region Third cycle Needs Assessment report, Completed in September 2024 by Hydro One

The TWG identified several regional needs based on the forecasted load demand over the near to mid-term period in the reports mentioned above. The results of the Adequacy Assessment to define the needs are discussed in sub-sections 7.1 to 7.4 and a detailed description and status of plans to meet these needs are given in section 8 of this report.

7.1. Asset Renewal Needs for Major HV Transmission Equipment

In addition to the asset renewal needs identified in previous regional planning cycle, Hydro One and TWG have also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next ten (10) years in the GBH region.
The complete list of major HV transmission equipment requiring replacement in the GBH region is provided in table 3 in this sub-section. Hydro One is the only Transmission Asset Owner (“TAO”) in the GBH region.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major HV equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
    - replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

- 230 and 115kV underground cable requiring replacement where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

Table 3 below contains the new asset replacement needs identified during the RIP study period:

Table 3: Major HV Transmission Asset assessed for Replacement in the region

Station/Circuit	Need Description	Planned ISD
Owen Sound TS	T5 Transformer Replacement	Q2 2032

Note: The planned in-service year for the above projects is tentative and subject to change.

7.2. Station Capacity Needs

Over the study period 2024-2033 RIP reviewed the capacity of all the 230kV and 115kV transforming stations within the GBH region. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer and winter) Limited Time ratings.

The NA study previously found no station capacity needs in the GBH region. This RIP, aligned with the latest load forecast, confirms that all stations remain within their LTR limits throughout the study period, with no capacity need identified at this time.

7.3. Transmission Line Capacity Needs

Over the study period 2024-2033 RIP reviewed the capacity of all the 230kV and 115kV transmission lines within the GBH region. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer and winter) Limited Time ratings.

The NA study previously found no transmission line capacity needs in the GBH region. This RIP, aligned with the latest load forecast and assessed contingencies, confirms that all Tx lines remain within their LTR limits throughout the study period, with no capacity need identified at this time.

7.4. System Reliability, Operation and Load Restoration Needs

Load security and load restoration needs were reviewed as part of the current study. The ORTAC Section 7 requires that no more than 600 MW of load be lost as a result of a double circuit contingency. Further, loads are to be restored in the restoration times[1] specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

Following the assessment done in GBH region, below system reliability need has been identified:

- 115kV L7S circuit:
  There have been some reports regarding system operation and performance of this circuit. Majority of issues reported were due to line galloping and line component failures.

  To increase the line capacity on this circuit, Hydro One addressed sub-standard clearances on sections on L7S between Seaforth TS and Kirkton JCT in 2022-2023. During the same time, Hydro One replaced deficient line components on various sections of this circuit to improve the delivery point performance. Hydro One will continue monitoring the performance of the remaining sections of this circuit and will proceed with corrective plans as required.

During both NA and RIP phases, TWG identified the following system operational issues in this region:

- Operational difficulties regarding transferring load between Detweiler TS in Kitchener-Waterloo-Cambridge-Guelph Region and Hanover TS in GBH. This is a concern in the operational timeframe when there are autotransformers out of service Detweiler TS and Hanover TS, due to increasing load on the 115kV circuit D10H.

- System operational issues during post-contingency load supply at Hanover TS. This is seen when there is one autotransformer out of service, and operators need to prepare for the loss of the remaining transformers.

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the GBH region. These needs include those previously identified in the NA for the GBH region as well as any new needs identified during

[1] These approximate restoration times are intended for locations that are near staffed centers. In more remote locations, restoration times should be commensurate with travel times and accessibility.

the RIP phase. All estimated costs included in the alternative analysis are considered as planning budgetary estimates and are used for comparative purposes only and may vary.

The needs in the region are summarized below in Table 4 below:

Table 4: Near/Mid-term Needs Identified in the region

Station/Circuit Name	Description of Need	Planned ISD	COST ($M)
Asset Renewal Needs			
Seaforth TS	T1, T2, T5, T6 Transformer Replacement	Q1 2027	$76M
Owen Sound TS	T5 Transformer Replacement	Q2 2032	$25M
System Reliability, Operation and Load restoration Needs			
115 kV L7S Circuit Capacity Increase	Monitoring the performance of this circuit and proceeding with corrective plan as required in the next phase of the Regional Planning cycle	On Going	N/A
Operational issue with supply capacity at Hanover TS, under outage conditions	Monitor and review in next regional planning cycle	Next Regional Planning Cycle	N/A
Operational issue with supply capacity on D10H, during load transfer between Detweiler TS and Hanover TS	Monitor and review in next regional planning cycle	Next Regional Planning Cycle	N/A

Note: The planned in-service year for the above projects is tentative and subject to change.

8.1 Asset Renewal Needs for Major HV Transmission Equipment

The asset renewal assessment considers the following options for “right sizing” the equipment:

- Maintaining the status quo;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities;
- Eliminating equipment by transferring all the load to other existing facilities;
- Replacing equipment with similar equipment and built to current standards (i.e., “like-for-like” replacement);
- Replacing equipment with higher ratings and built to current standards.

From Hydro One's perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance costs and longer duration of customer outages.

8.1.1. Seaforth TS – T1, T2, T5 and T6 Transformers Replacement

Seaforth TS is a major station and consists of two (2) 150/200/250MVA 115-27.6kV autotransformers supplied by 230kV circuits B22D and B23D (Bruce x Detweiler). The 115kV yard from Seaforth TS supplies nearly 200km of single circuit supply along the circuits L7S,61M18 and E6L. Seaforth TS also consists of two (2) 25/33/42MVA 115-27.6kV step-down transformers and supplies Hydro One Distribution and embedded LDCs via four 27.6kV feeders.

Following the asset condition assessment, the current scope of this project is to replace 230-115kV autotransformers T5 and T6, and step-down transformers T1 and T2 with like-for-like units which will be sufficient units based on the current load forecast.

Operations has identified the need for refined voltage control on the 115kV system. Therefore, the new autotransformers T5 and T6 at Seaforth TS will be equipped with Under Load Tap Changers ("ULTC") to meet this need. The planned in-service date for the project is Q1 2027.

8.1.2. Owen Sound TS – T5 Transformer Replacement

Owen Sound TS is supplied by two (2) 230kV circuits B27S and B28S and consists of two (2) 75/100/125MVA 230-44kV transformers T3 and T4 feeding its 44kV Dual Element Spot Network ("DESN"). This station also consists of a 150/200/250MVA 230-115kV autotransformer T5 which feeds 115kV circuits S2S and S1H.

Based on asset condition assessment, autotransformer T5 is expected to reach its end of life during the study period. It is planned to replace T5 with a like-for-like unit. The planned in-service date for the project is Q2 2032.

8.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2024-2033 for the 230kV and 115kV transforming stations in the GBH region using the summer and winter peak load forecasts that were provided by the study team. Based on the results, all stations are within their LTR limits and there is no need for station capacity upgrades at this time.

8.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings.

A Transmission Lines Capacity Assessment was performed over the study period 2024-2033 for the 230kV and 115kV Transmission line circuits in the GBH region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater for this need. Based on the results, no new transmission system capacity needs were identified.

8.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. A study has been performed, considering the net coincident load forecast and the loss of one element over the study period 2024-2033 to cater to this need**.**

Following the assessment done, below need have been identified for this Region:

- 115kV L7S circuit:
  There have been some reports regarding system reliability and the performance of this circuit. Majority of issues reported were due to line galloping and line component failures.

  To address the line capacity on this circuit, Hydro One increased sub-standard clearances on sections on L7S between Seaforth TS and Kirkton JCT in 2022-2023. During the same time, Hydro One replaced deficient line components on various sections of this circuit to improve the delivery point performance. Hydro One will continue monitoring the performance of the remaining sections of this circuit and will proceed with corrective plans as required.

The TWG has identified below system operational issues related to current load supply concerns under certain operational conditions:

- Operational issue with supply capacity at Hanover TS under outage conditions:
  There have been reports of operational difficulties transferring load between Detweiler TS in KWCG region and Hanover TS in GBH region. This is a concern in the operational timeframe when there are autotransformers out of service at Detweiler TS and Hanover TS, due to increasing load on the 115kV circuit D10H.
- Operational issue with supply capacity on D10H when load is transferred between Detweiler TS in KWCG region and Hanover TS in the GBH region:
  Thia issue is regarding post-contingency load supply concerns at Hanover TS when there is one autotransformer out of service, and operators need to prepare for the loss of the remaining transformer.

The TWG recognizes that the operational conditions experienced in real-time may not always align with the planning timeframe considerations applied in this RIP but are indicative of potential concerns as load continues to grow. Thus, TWG agrees that no further action is required at this time. However, the TWG will monitor these concerns and investigate this need further in the next cycle of regional planning.

9. CONCLUSION AND RECOMMENDATION

This section concludes the Regional Infrastructure Plan ("RIP") report for GBH region. The Major Infrastructure investments recommended by the TWG in the near and mid-term planning horizon 2024-2033 are provided in Table 5 below, along with their planned in-service dates ("ISD") and budgetary estimates for planning purposes.

Table 5: Recommended Plans over the next 10 Years/Long Term

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Asset Renewal Needs				
Seaforth TS	T1, T2, T5 and T6 Transformer Replacement	Hydro One Transmission	Q1 2027	$76M
Owen Sound TS	T5 Transformer Replacement	Hydro One Transmission	Q2 2032	$27M
System Reliability, Operation and Load restoration Needs				
115 kV L7S Circuit Capacity Increase	Monitoring the performance of this circuit and proceeding with corrective plan as required in the next phase of the Regional Planning cycle	Hydro One Transmission	On Going	N/A
Operational issue with supply capacity at Hanover TS, under outage conditions	Monitor and review in next regional planning cycle	Hydro One Transmission	Next Regional Planning Cycle	N/A
Operational issue with supply capacity on D10H, during load transfer between Detweiler TS and Hanover TS	Monitor and review in next regional planning cycle	Hydro One Transmission	Next Regional Planning Cycle	N/A

Note:

a) The planned in-service dates are tentative and subject to change.
b) Costs are based on budgetary planning estimates and excludes the cost for distribution infrastructure (if required).

Appendix C: Lists of Transmission Circuits

Sr. No.	Connecting Stations	Circuit ID	Voltage (kV)
1	Bruce A TS – Orangeville TS	B4V/B5V	230 kV
2	Bruce A TS – Detweiler TS	B22D/ B23D	230 kV
3	Bruce A TS – Owen Sound TS	B27S/B28S	230 kV
4	Bruce A TS – Douglas Point TS	B20P/B24P	230 kV
5	Hanover TS – Palmerston TS	D10H-North	115 kV
6	Seaforth TS – Goderich TS	61M18	115 kV
7	Seaforth TS – St. Marys TS	L7S	115 kV
8	Owen Sound TS – Hanover TS	S1H	115 kV
9	Seaforth TS – Edmondville CSS	E6L	115 kV

Appendix D: List of LDC's

Sr. no.	Name of LDC
1	Hydro One Networks Inc. (Distribution)
2	ERTH Power Corporation
3	Festival Hydro
4	Westario Power Inc.
5	Entegrus Powerline Inc.
6	Wellington North Power

Appendix E: List of Municipalities in the region

Sr. no.	Name of Municipality
1	Bruce county
2	Huron county
3	Perth county
4	Portion of Grey county
5	Portion of Wellington county
6	Portion of Waterloo county
7	Portion of Oxford county
8	Portion of Middlesex county

Appendix E: Acronyms

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CEP	Community Energy Plan
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CSS	Customer Switching Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DS	Distribution Station
eDSM	electricity Demand Side Management
GBH	Greater Bruce/Huron
GS	Generating Station
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
KWCG	Kitchener-Waterloo-Cambridge-Guelph
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MEP	Municipal Energy Plan
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board

ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
RIP	Regional Infrastructure Plan
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
STG	Steam Turbine Generator
TS	Transformer Station
TWG	Technical Working Group
ULTC	Under Load Tap Changers

List of Figures **4**

List of Tables **6**

List of Acronyms **7**

1. Introduction **10**

2. The Integrated Regional Resource Plan **13**

2.1 Near-/Mid-Term Plan 13

2.2 Ongoing Initiatives 16

3. Development of the Plan **18**

3.1 The Regional Planning Process 18

3.2 Niagara and IRRP Development 18

4. Background and Study Scope **19**

5. Electricity Demand Forecast **21**

5.1 Historical Demand 21

5.2 Demand Forecast Methodology 22

5.3 Gross LDC Forecast 22

5.4 Contribution of Conservation to the Forecast 23

5.5 Contribution of Distributed Generation to the Forecast 24

5.6 Net Extreme Weather ("Planning") Forecast 25

5.7 High Forecast Scenario 26

5.8 Hourly Forecast Profiles 27

6. Needs **29**

6.1 Needs Assessment Methodology 29

6.2 Station Capacity Needs 30

6.3 Supply Capacity Needs 34

6.4 Asset Replacement Needs 35

6.5 Load Security Needs 35

6.6 Summary of Identified Needs 36

7. Plan Options and Recommendations 38

7.1 Options Considered in IRRPs 38

7.2 Screening Options 39

7.3 Options and Recommendations for Meeting the Beamsville TS, Niagara West MTS, and Vineland DS Needs 43

7.4 Options and Recommendations for Meeting the Crowland TS, Load Security, and Niagara 115 kV Sub-System Needs 45

7.5 Summary of Recommended Actions and Next Steps 48

8. Community and Stakeholder Engagement 51

8.1 Engagement Principles 51

8.2 Creating an Engagement Approach for Niagara Region 51

8.3 Engage Early and Often 52

8.4 Bringing Municipalities to the Table 53

8.5 Engaging with Indigenous Communities 54

9. Conclusion 55

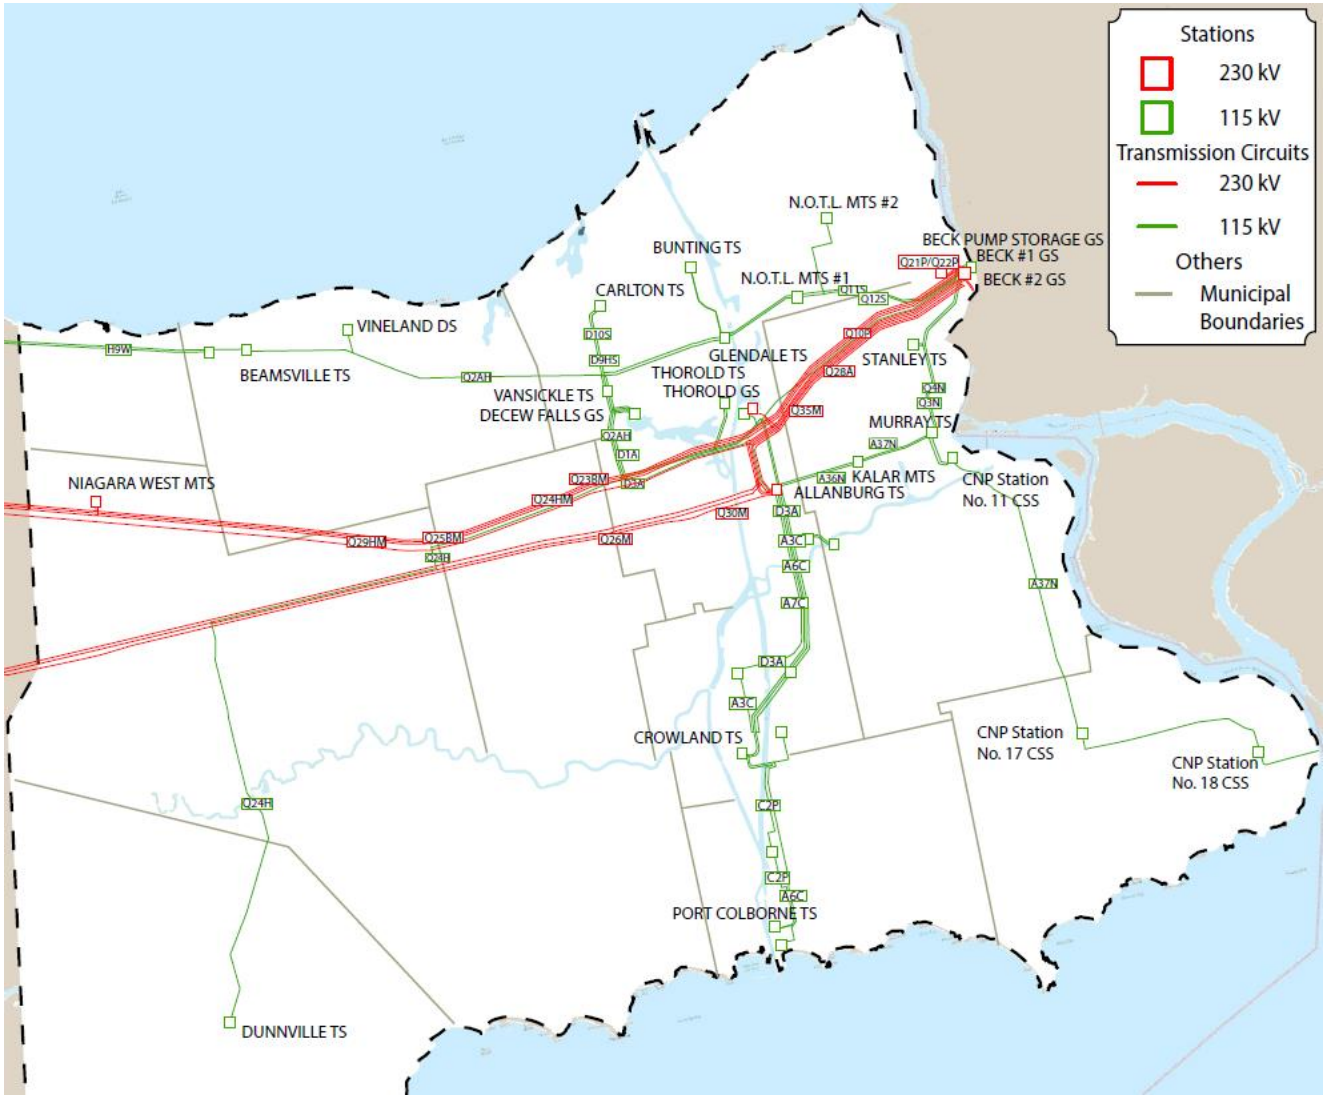
ORTAC	Ontario Resource and Transmission Assessment Criteria
RIP	Regional Infrastructure Plan
TS	Transformer Station

1. Introduction



This Integrated Regional Resource Plan ("IRRP") addresses the electricity needs of the Niagara Region over the next 20 years, from 2022 to 2041. The Niagara Region is located between Lake Ontario and Lake Erie, and includes one upper-tier municipality (Regional Municipality of Niagara) and 12 lower-tier municipalities: Fort Erie, Grimsby, Lincoln, Niagara Falls, Niagara-on-the-Lake, Pelham, Port Colborne, St. Catharines, Thorold, Wainfleet, Welland, and West Lincoln.

This region also includes the following First Nations and Métis Nation of Ontario councils:

- Mississaugas of the New Credit
- Oneida Nation of the Thames
- Six Nations of the Grand River (Six Nations Elected Council and Haudenosaunee Confederacy Chiefs Council)
- Métis Nation of Ontario Niagara Region Métis Council

The Niagara Region is summer-peaking and, over the last five years, peak electrical demand has remained steady at an average of 810 MW. Electrical supply is provided primarily through 230/115 kilovolt ("kV") autotransformers at Allanburg Transformer Station ("TS"), and is generally served by 230 kV and 115 kV transmission lines and step-down transformation facilities as shown in Figure 1. The region is defined electrically by the 230 kV transmission circuits that connect Sir Adam Beck Generating Station ("GS") #2 in the east to Burlington TS and Middleport in the west. Other large transmission-connected generating facilities include Sir Adam Beck GS #1 and Decew Falls GS connecting to the 115 kV system, and Thorold GS connecting to the 230 kV system.

Figure 1 | Overview of the Niagara Region

The region's electricity is delivered by six local distribution companies ("LDCs"): Alectra Utilities, Canadian Niagara Power Inc. ("CNPI"), Grimsby Power Inc., Hydro One Networks Inc. (Distribution), Niagara on the Lake Hydro Inc., Niagara Peninsula Energy Inc. ("NPEI"), and Welland Hydro Electric System Corp. Hydro One Networks Inc. (Transmission) is the primary transmission asset owner. This IRRP report was prepared by the Independent Electricity System Operator ("IESO") on behalf of a Technical Working Group, composed of the LDCs, Hydro One, and the IESO.

Development of the Niagara IRRP was initiated in August 2021, following the publications of the Needs Assessment report in May 2021 by Hydro One and the Scoping Assessment Outcome Report in August 2021 by the IESO. The Scoping Assessment identified needs for further assessment through an IRRP. The Technical Working Group was then formed to gather data, identify near- to long-term needs in the region, and develop the recommended actions included in this IRRP.

This report is organized as follows:

- A summary of the recommended plan for the region is provided in Section 2;

- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the region and the study scope are discussed in Section 4;
- Demand forecast scenarios, and conservation and demand management and distributed generation assumptions, are described in Section 5;
- Electricity needs in the region are presented in Section 6;
- Alternatives and recommendations for meeting needs are addressed in Section 7;
- A summary of engagement activities is provided in Section 8; and
- The conclusion is provided in Section 9.

2. The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of the Niagara Region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system, as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC") and reliability standards governed by the North American Electric Reliability Corporation ("NERC"). The IRRP's recommendations are informed by an evaluation of different options to meet the needs and consider: reliability, cost, technical feasibility, maximizing the use of the existing electricity system (where economic), and feedback from stakeholders.

The Niagara electricity demand forecast, provided by the LDCs, projects sustained growth driven by community area, employment area, and rural settlement expansions. This growth spans multiple municipalities, including (but is not limited to): Lincoln, West Lincoln, Welland, Thorold, and Niagara Falls.

The IRRP recommendations below are organized under a near-/medium-term plan and other ongoing or long-term initiatives. This distinction reflects the different levels of forecast certainty, lead time for development, and planning commitment required over these time horizons. This approach ensures that the IRRP provides clear direction on investments needed in the near and medium term, while retaining flexibility over the long term, as electrification, energy efficiency, and development plans evolve.

2.1 Near-/Mid-Term Plan

The near- and mid-term plan comprises several recommendations to accommodate load growth, maintain reliability, and optimize asset replacement. Where possible, needs are grouped to align with integrated sets of solutions. These recommendations are summarized in Table 1 and further discussed below.

Table 1 | Summary of the Near/Mid-Term Plan for the Niagara IRRP

Need(s)	Lead Responsibility	Technical Working Group Recommendation	Expected In-Service Date
• Beamsville TS station capacity	• Grimsby Power • NPEI • Hydro One Distribution	• Coordinate load transfers to offload Beamsville TS to Niagara West MTS in the near-term	• 2023

Need(s)	Lead Responsibility	Technical Working Group Recommendation	Expected In-Service Date
• Beamsville TS, Niagara West Municipal Transformer Station ("MTS"), and Vineland Distribution System ("DS") station capacity • Niagara 115 kV sub-system supply capacity	• Grimsby Power • NPEI • Hydro One Distribution • Hydro One Transmission	• Initiate development of a new 230 kV station supplied from Q23BM and Q25BM, or an expansion of Niagara West MTS	• 2026-2027
• Beamsville TS, Niagara West MTS, and Vineland DS station capacity	• Grimsby Power • NPEI • Hydro One Distribution	• Monitor load growth between regional planning cycles	• Ongoing
• Beamsville TS and Vineland DS station capacity	• Technical Working Group	• Investigate opportunities to target incremental conservation and demand management ("CDM") to Beamsville TS and Vineland DS	• Ongoing
• Crowland TS station capacity and asset replacement • A6C/A7C load security • Niagara 115 kV sub-system supply capacity	• Hydro One Transmission	• Initiate development for the replacement of Crowland TS with a new 230 kV station, supplied by new 230 kV double-circuit lines from Q24HM and Q29HM	• 2028
• Niagara 115 kV sub-system supply capacity	• Hydro One Transmission	• Develop and implement a new 115 kV sub-system load rejection scheme	• 2024

Need(s)	Lead Responsibility	Technical Working Group Recommendation	Expected In-Service Date
• Niagara 115 kV sub-system supply capacity	• Hydro One Transmission	• Uprate Q28A	• 2024
• Niagara 115 kV sub-system supply capacity	• Technical Working Group	• Monitor load growth between regional planning cycles	• Ongoing
• Niagara 115 kV sub-system supply capacity	• Technical Working Group	• Investigate opportunities to target incremental CDM to the 115 kV sub-system	• Ongoing
• Murray TS (T11/T12) station capacity	• NPEI • Hydro One Transmission	• Monitor load growth and transfer load in excess of the station limit to Murray TS transformer 13 and 14 (T13/T14)	• 2023

2.1.1 Load Transfers from Beamsville TS and a New or Expanded 230 kV Station

Stations limits are typically dictated by the lowest rated transformer. Beamsville TS is fully utilized today and there is no remaining capacity for growth. Nearby stations Niagara West MTS and Vineland DS are also forecast to reach their capacity limits by 2026 and 2030, respectively.

The IRRP considered the merits of a portfolio of "non-wires" (non-transmission) options as well as integrated "wires" (transmission) options. Based on planning-level cost estimates and its ability to address capacity shortfalls at the three stations, the Technical Working Group recommends that a new 230 kV station supplied by Q23BM and Q25BM is built. This could be accomplished by expanding the existing Niagara West MTS. Development and implementation for additional capacity should begin as soon as possible for a targeted in-service date of 2026-2027. The next stage of regional planning, the Regional Infrastructure Plan ("RIP") led by Hydro One, should confirm the party who will lead development work (i.e., Grimsby Power, NPEI, or Hydro One).

In the meantime, the IRRP recommends that the local distributors (Grimsby Power, NPEI, Hydro One Distribution), in conjunction with Hydro One Transmission where appropriate, develop a plan to transfer load from Beamsville TS to the other nearby stations (Niagara West MTS, Vineland DS) to manage the urgent Beamsville TS need until the new station is in-service.

2.1.2 Major High Voltage Equipment Replacement of Crowland TS, New 230 kV Transmission Lines, Q28A Upgrade, and Control Actions

The existing T5 and T6 transformers at Crowland TS will require major high voltage ("HV") equipment replacement in 2026, and are forecast to be fully utilized in 2022. Crowland TS, as well as other stations supplied by the A6C/A7C circuits, are also impacted by a load security need that exists today. Moreover, Crowland TS is included in the broader Niagara 115 kV sub-system whose supply capacity need exists today and continues to grow by the end of the planning horizon.

The IRRP developed and evaluated portfolios of non-wires options, standalone generation, and wires alternatives for the multiple needs in this area. Ultimately, the most feasible and cost-effective solution at this time requires wires reinforcements: the upgrade of Q28A, the replacement of 115 kV Crowland TS with a larger 230 kV station supplied by new 230 kV transmission lines from Q24HM and Q29HM, and a new load rejection scheme developed to manage the Niagara 115 kV sub-system load. The IRRP recommends that Hydro One should begin implementation as soon as possible for a targeted in-service dates of 2024, 2024, and 2028 for the load rejection scheme, Q28A upgrade, and new 230 kV station and lines, respectively. Measures to manage the HV equipment replacement infrastructure at Crowland TS should be implemented by Hydro One until the station replacement is in-service.

2.1.3 Load Transfers from Murray TS (T11/T12)

Murray TS (T11/T12) is forecast to be beyond capacity in 2022 during its station peak. Given the small magnitude of this need and the available capacity on the other set of transformers at Murray TS (T13/T14), the IRRP recommends that some load is re-allocated to T13/T14 and growth continues to be monitored.

2.2 Ongoing Initiatives

In addition to the near- and mid-term plan above, two ongoing actions were identified to manage needs expected in the long-term.

2.2.1 Monitor Load Growth

Carlton TS and Kalar MTS are expected to reach capacity in 2028 and 2030, respectively. In the case of Carlton TS, distribution-level load transfers to Bunting TS have been indicated as an option. Given the timing, no firm recommendation is required at this time for either need; the Technical Working Group will continue to monitor load growth and revisit these needs in the next cycle of regional planning. As part of broader monitoring, the Technical Working Group should also keep apprised of and participate in any future Community Energy Plans developed by municipalities of the Niagara Region.

2.2.2 Explore Opportunities for Targeted CDM

In addition to monitoring how the forecast demand materializes, the IRRP recommends continuing to consider opportunities for targeted CDM. During the options analyses, the benefits and potential of incremental, cost-effective CDM were identified – particularly if targeted to manage near-term needs until transmission reinforcements are in-service (as is the case for the Beamsville TS/Vineland DS/Niagara West MTS area, as well as the 115 kV sub-system), or to defer long-term needs (such as at Kalar MTS). The Technical Working Group should continue to support and monitor CDM uptake, and bring these insights into the next cycle of regional planning for the Niagara Region.

3. Development of the Plan

3.1 The Regional Planning Process

In Ontario, preparing to meet the electricity needs of customers at a regional level is achieved through regional planning. Regional planning assesses the interrelated needs of a region – defined by common electricity supply infrastructure – over the near, medium, and long-term, and results in a plan to ensure cost-effective and reliable electricity supply. A regional plan considers the existing electricity infrastructure in an area, forecasts growth and customer reliability, evaluates options for addressing needs, and recommends actions.

The current regional planning process was formalized by the Ontario Energy Board in 2013 and is performed on a five-year cycle for each of the 21 planning regions in the province. The process is carried out by the IESO, in collaboration with the transmitters and LDCs in each region. The process consists of four main components:

1. A Needs Assessment, led by the transmitter, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;
2. A Scoping Assessment, led by the IESO, which identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities;
3. An IRRP, led by the IESO, which proposes recommendations to meet the identified needs requiring coordinated planning; and/or
4. A RIP, led by the transmitter, which provides further details on recommended wires solutions.

Regional planning is not the only type of electricity planning in Ontario. Other types include bulk system planning and distribution system planning. There are inherent overlaps in all three levels of electricity infrastructure planning. Further details on the regional planning process and the IESO's approach to it can be found in Appendix A.

The IESO has recently completed a review of the regional planning process, following the completion of the first cycle of regional planning for all 21 regions. Additional information on the Regional Planning Process Review, along with the final report is posted on the IESO's website.

3.2 Niagara and IRRP Development

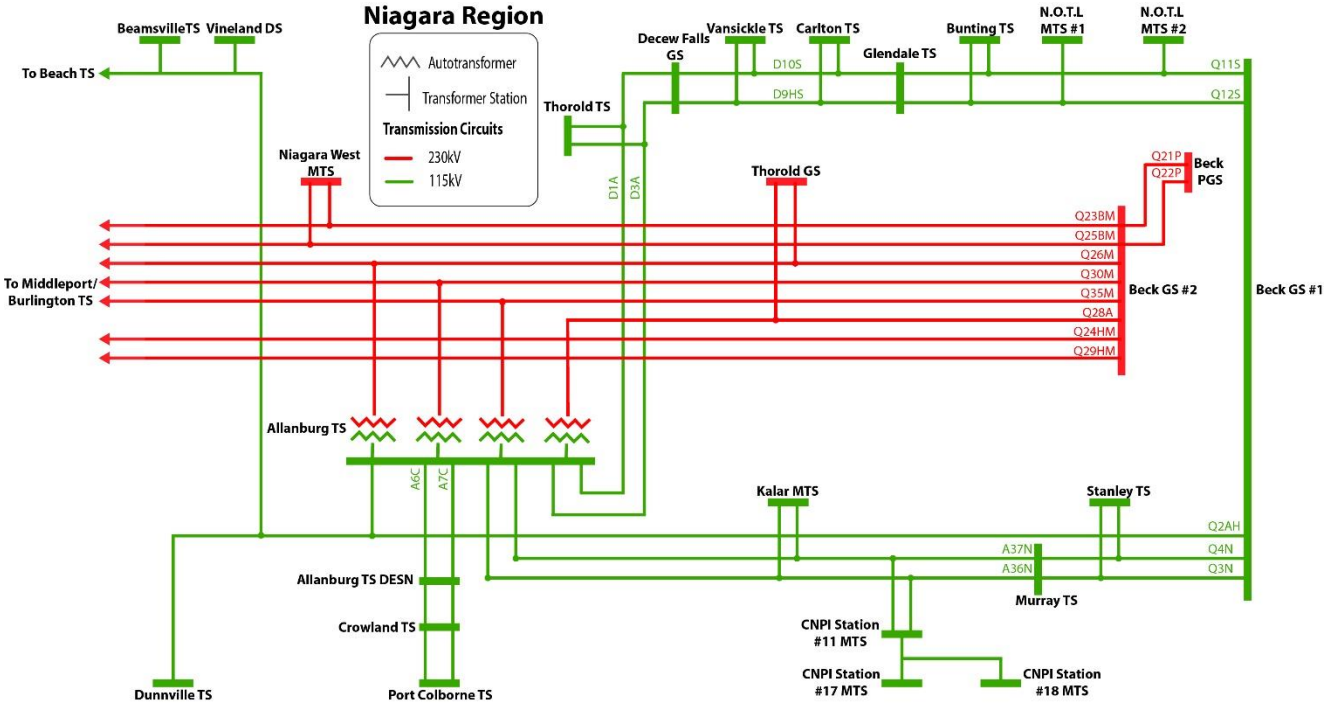
The process to develop the Niagara IRRP initiated in August 2021, following the publication of the Needs Assessment report in May 2021 by Hydro One and the Scoping Assessment Outcome Report in August 2021 by the IESO. The Scoping Assessment recommended that the needs identified for the Niagara Region be considered through an IRRP in a coordinated regional approach, supported with public engagement. The Technical Working Group was then formed to develop the terms of reference for this IRRP, gather data, identify needs, develop options, and recommend solutions for the region.

4. Background and Study Scope

This is the second cycle of regional planning for the Niagara Region. This region roughly encompasses the municipalities Fort Erie, Grimsby, Lincoln, Niagara Falls, Niagara-on-the-Lake, Pelham, Port Colborne, St. Catharines, Thorold, Wainfleet, Welland, and West Lincoln. This region also includes the following First Nations and Métis Nation of Ontario Councils: Mississaugas of the New Credit, Oneida Nation of the Thames, Six Nations of the Grand River (Six Nations Elected Council and Haudenosaunee Confederacy Chiefs Council), and the Métis Nation of Ontario Niagara Region Métis Council. Following a Needs Assessment and Scoping Assessment in 2016, a RIP was initiated by Hydro One and subsequently published in 2017, concluding the first planning cycle for the Niagara Region. An IRRP was not developed, as two electricity needs were identified in 2016, but no further regional coordination was required.

The current cycle of regional planning began in 2021 with the publication of the Needs Assessment Report, where several needs requiring further regional coordination were identified. The 2021 Niagara Scoping Assessment recommended an IRRP for the entire region to address needs in a coordinated manner. This report presents an integrated regional electricity plan for the next 20-year period starting from 2022.

This IRRP develops and recommends options to meet the electricity needs of the Niagara Region in the near, medium, and long term. The plan was prepared by the IESO on behalf of the Technical Working Group, and includes consideration of forecast electricity demand growth, CDM, distributed generation ("DG"), transmission and distribution system capability, relevant community plans, condition of transmission assets, and developments on the bulk transmission system.



The following transmission facilities were included in the scope of this study:

- Transformer stations: Allanburg TS, Beamsville TS, Bunting TS, Carlton TS, Crowland TS, Dunnville TS, Glendale TS, Kalar MTS, Murray TS, Niagara West MTS, Niagara-on-the-Lake ("NOTL") York MTS, NOTL #2 MTS, Port Colborne TS, Stanley TS, Thorold TS, Vansickle TS, Vineland DS, CNPI #11 MTS, CNPI #17 MTS, CNPI #18 MTS. Except for Niagara West MTS, all stations are supplied from 115 kV transmission circuits.
- 115 kV transmission circuits: Q3N/Q4N, Q11S/Q12S, Q2AH, A36N/A37N, A6C/A7C, D1A/D3A, D9HS/D10S.
- 230 kV transmission circuits: Q23BM, Q24HM, Q25BM, Q26M, Q28A, Q29HM, Q30M, Q35M.

The single line diagram of the Niagara Region is shown in Figure 2 below. Note that the bulk system transfer capabilities on the Queenston Flow West interface[1] through the region is not within the scope of the IRRP and would be separately studied in a bulk transmission plan, as required. The schedule of bulk planning activities is identified through the IESO's Annual Planning Outlook.

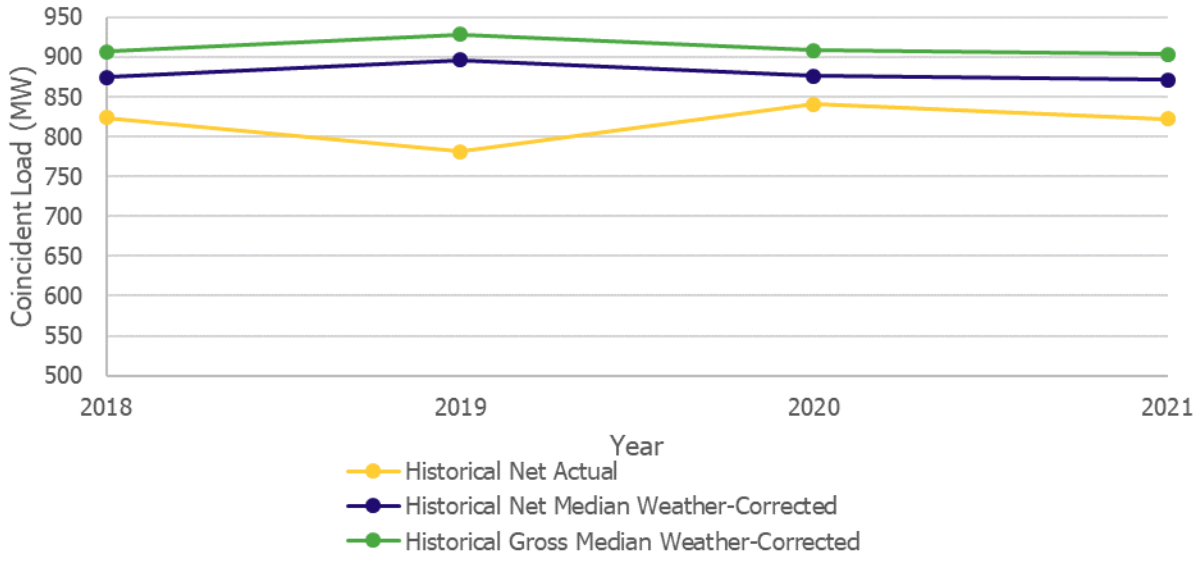
[1] Includes flow out at Beck (Q25BM + Q23BM + Q24HM + Q29HM) and flow in at Middleport (Q30M + Q26M + Q35M).

Figure 2 | Single Line Diagram of the Niagara Region

The Niagara IRRP was developed by completing the following steps:

- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe (as described in the following steps);
  - Examining the load meeting capability ("LMC") and reliability of the existing transmission system, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC and NERC criteria;
  - Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO-controlled grid;
  - Confirming identified asset replacement needs and timing with the transmitter and LDCs;
- Establishing alternatives to address system needs including, where feasible and applicable, generation, transmission and/or distribution, and other approaches such as non-wires alternatives including CDM;
- Engaging with the community on needs and possible alternatives;
- Evaluating alternatives to address near- and long-term needs; and
- Communicating findings, conclusions, and recommendations within a detailed plan.

5. Electricity Demand Forecast



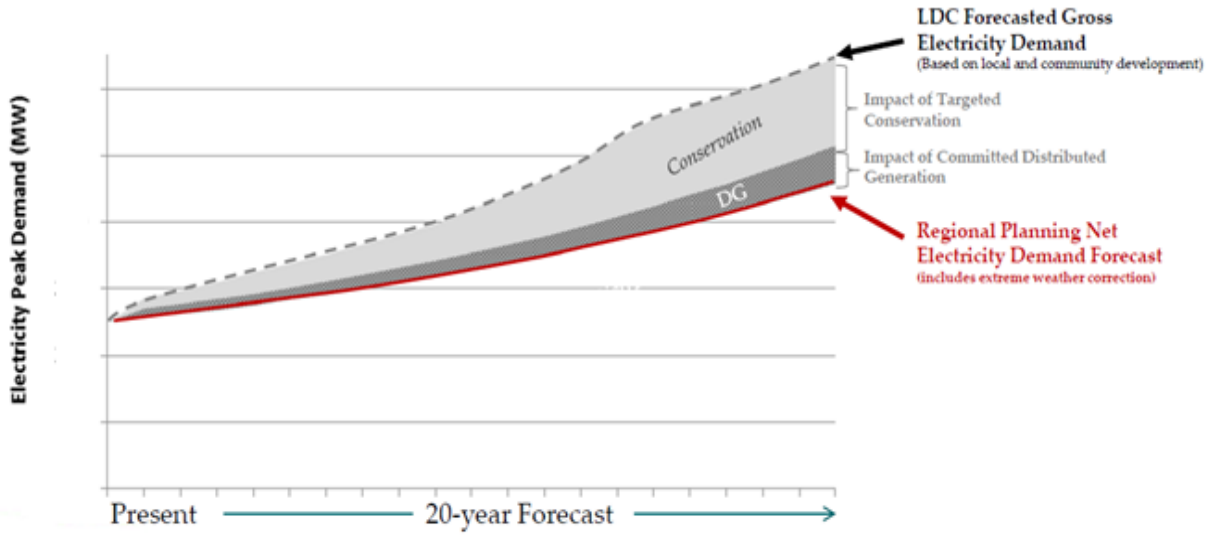
Regional planning in Ontario is driven by having to meet peak electricity demand requirements in the region. This section describes the development of the demand forecast for the Niagara Region. It highlights the assumptions made for peak demand forecasts, including weather correction, the contribution of CDM and DG, and the development of a high growth scenario. The reference net extreme weather demand forecast is used in assessing the electricity needs of the area over the planning horizon; the high forecast scenario, used as the basis for a sensitivity analysis, is described further in Section 5.7.

To evaluate the reliability of the electricity system, the regional planning process is typically concerned with the coincident peak demand for a given area. This is the demand observed at each station for the hour of the year in which overall demand in the study area is at its maximum. This differs from a non-coincident peak, which refers to each station's individual peak, regardless of whether these peaks occur at different times. Within the Niagara Region, the peak loading hour for each year has historically occurred in the summer.

5.1 Historical Demand

Peak electricity demand within the Niagara Region has been steady over the last four years. Figure 3 below shows the coincident net actual (as observed at the metering point), net median weather-corrected (adjusted to reflect median weather conditions), and gross median weather-corrected (contribution of DG removed) historical demand. The gross median weather-corrected demand has averaged 910 megawatts ("MW") over the past four years, with the peak demand hour for each year occurring consistently in the summer between approximately 4 PM to 7 PM. The 2021 gross median weather-corrected peak at each station in the Niagara Region was used as the starting point for the forecast.

Figure 3 | Historical Demand in the Niagara Region

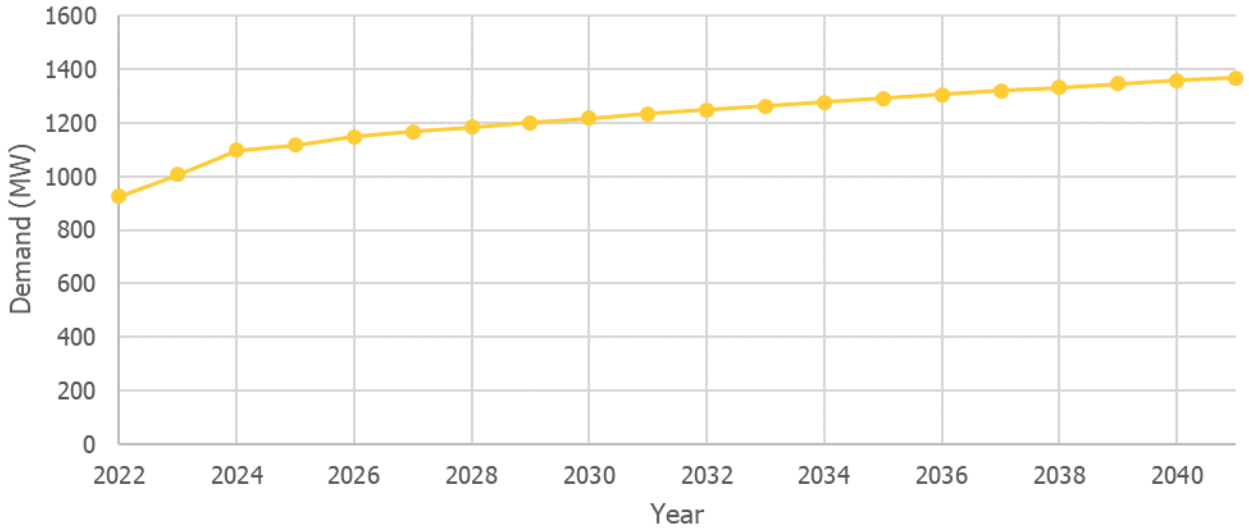


5.2 Demand Forecast Methodology

The steps taken to develop a 20-year IRRP peak demand forecast are depicted in Figure 4. Gross demand forecasts, which assume the weather conditions of an average year based on historical weather conditions (referred to as "normal weather"), were developed by the LDCs. These forecasts were then modified to reflect the peak demand impacts of provincial conservation targets and DG contracted through previous provincial programs such as Feed-In Tariff ("FIT") and microFIT, and adjusted to reflect extreme weather conditions in order to produce a reference forecast for planning assessments. This net forecast was then used to assess the electricity needs in the region.

Additional details related to the development of the demand forecast are provided in Appendix B. Though the Niagara IRRP forecast was created prior to October 2022, the Ontario Energy Board also since published a Load Forecast Guideline for regional planning, through the Regional Planning Process Advisory Group.

Figure 4 | Illustrative Development of Demand Forecast



5.3 Gross LDC Forecast

Each participating LDC in the Niagara Region prepared gross demand forecasts at the station level, or at the station bus level for multi-bus stations. These gross demand forecasts account for increases in demand from new or intensified development, plus known connection applications. The LDCs cited alignment with municipal and regional official plans, and credited them as a source for input data. LDCs were also expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices ("natural conservation"), but not for the impact of future DG or new conservation measures (such as codes and standards and CDM programs), which are accounted for by the IESO (discussed in Section 5.4). The gross LDC forecast assumes median on-peak weather conditions, and station loading that is coincident to the region.

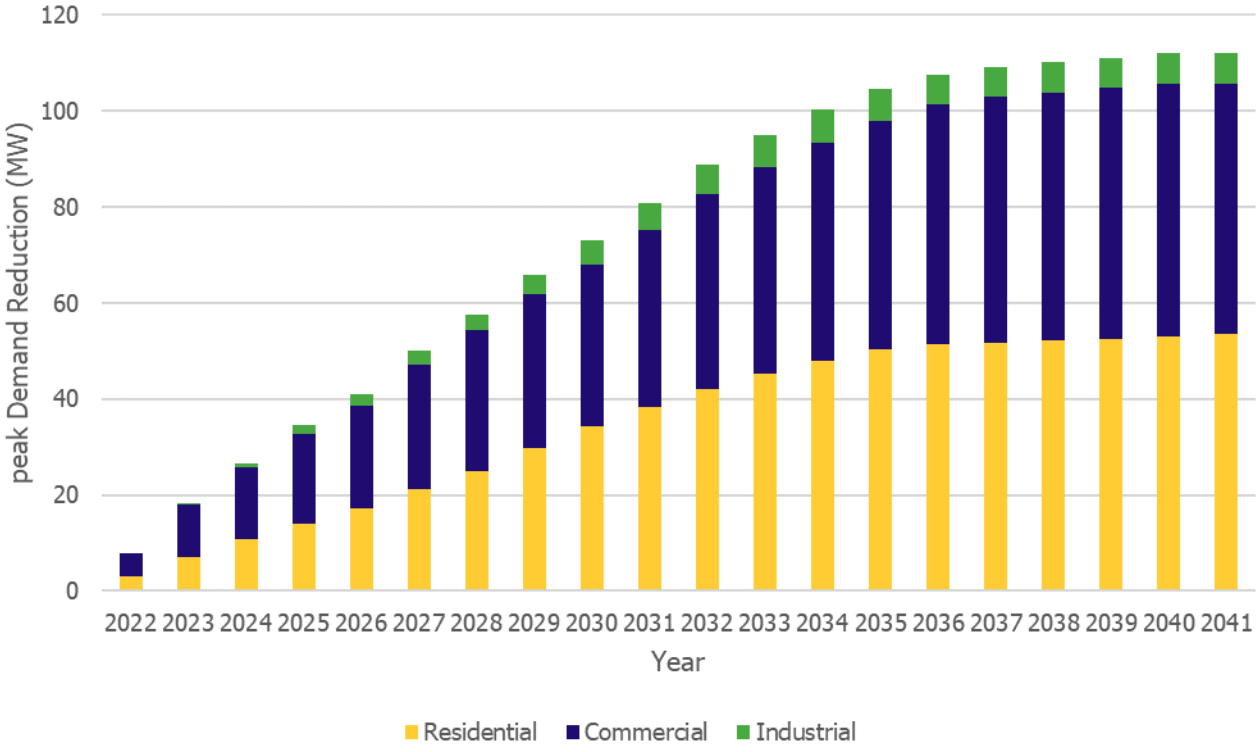
LDCs have a better understanding of future local demand growth and drivers than the IESO, since they have the most direct involvement with their customers, connection applicants, and municipalities and communities which they serve. The IESO typically carries out demand forecasting at the

provincial level. More details on the LDCs' load forecast assumptions can be found in Appendix B.2 to B.8. Figure 5 below shows the total gross demand forecast provided by the LDCs for the Niagara Region.

Figure 5 | Total Gross Demand Forecast Provided by LDCs (Median Weather)[2]

5.4 Contribution of Conservation to the Forecast

Conservation and demand management is a clean and cost-effective resource that helps meet Ontario's electricity needs, and has been an integral component of provincial and regional planning. Conservation is achieved through a mix of codes and standards amendments, as well as CDM program-related activities. These approaches complement each other to maximize conservation results.



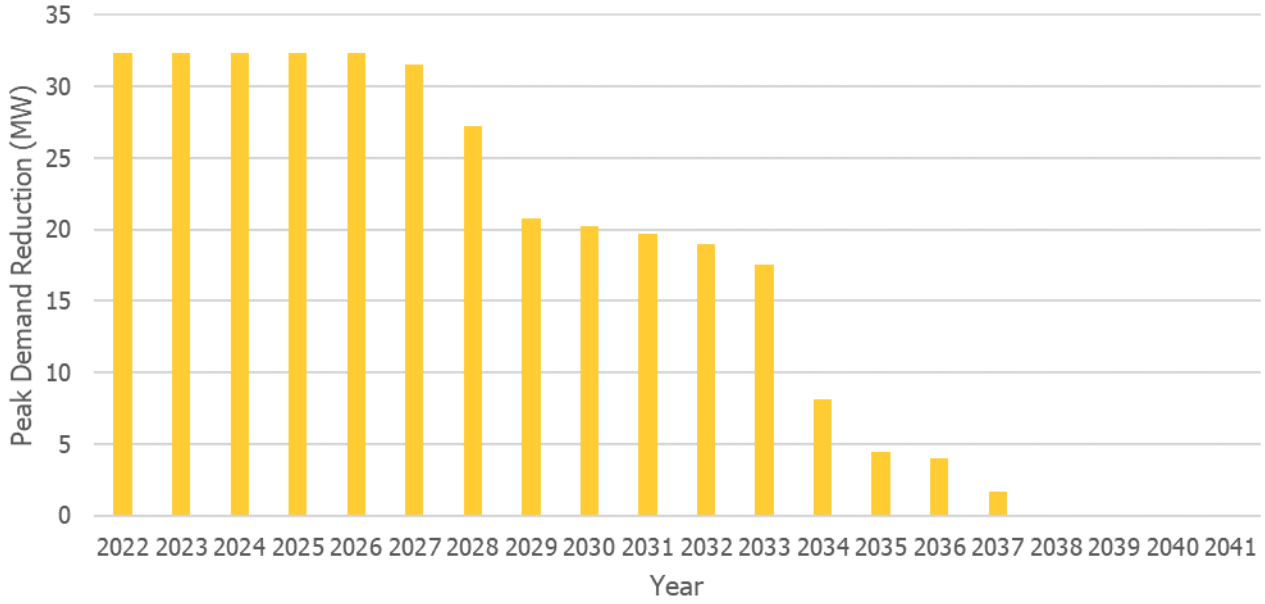
The estimate of demand reduction due to codes and standards are based on expected improvement in the codes for new and renovated buildings, and through regulation of minimum efficiency standards for equipment used by specified categories of consumers (i.e., residential, commercial and industrial consumers).

The estimates of demand reduction due to program-related activities account for the 2021-2024 CDM Framework, federal programs that result in electricity savings in Ontario, and forecasted long-term energy efficiency programs. The 2021 – 2024 CDM Framework is the main piece, in which the IESO centrally delivers programs on a province-wide basis to serve business and low-income customers, as well as Indigenous communities.

Figure 6 shows the estimated total yearly reduction to the demand forecast due to conservation (from codes, standards, and CDM programs) for each of the residential, commercial, and industrial consumers. Additional details are provided in Appendix B.9.

[2] Excludes existing transmission-connected industrial customers in the Niagara Region (historically contributing an average of 15 MW to the coincident peak demand).

Figure 6 | Total Forecast Peak Demand Reduction (Codes, Standards, and CDM Programs)



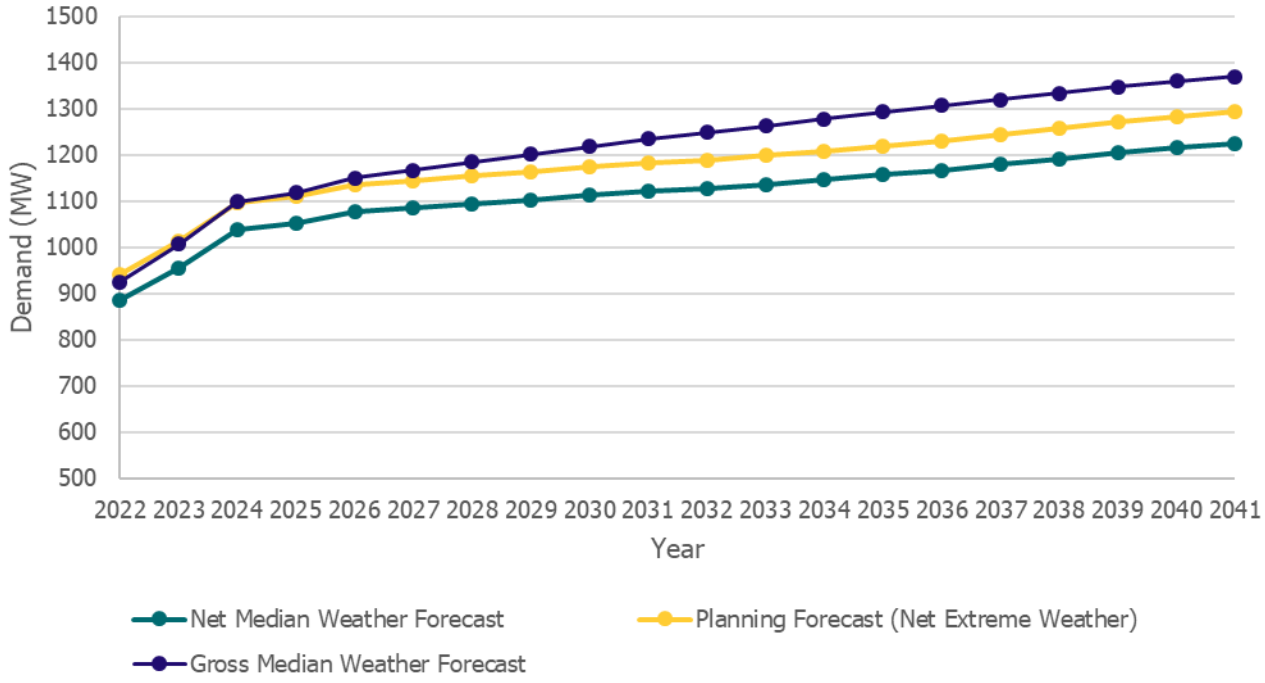
5.5 Contribution of Distributed Generation to the Forecast

In addition to conservation resources, DG in the Niagara Region is also forecast to offset peak-demand requirements. The introduction of Ontario's FIT Program increased the significance of distributed renewable generation which, while intermittent, contributes to meeting the province's electricity demands. The installed DG capacity by fuel type and contribution factor assumptions can be found in Appendix B.10. Most of the total contracted installed DG capacity in the Niagara Region is solar, wind, and waterpower, with some biogas, landfill gas, and natural gas facilities.

After reducing the demand forecast due to conservation, as described in Section 5.4, the forecast is further reduced by the expected contribution from contracted DG. Figure 7 shows the impact of DG on reducing the Niagara Region demand forecast. Note that any facilities without a contract with the IESO are not currently included in the DG peak demand reduction forecast.

Figure 7 | Peak Demand Reduction to Demand Forecast, Due to DG

In the long term, the contribution of DG is expected to diminish as their contracts expire. A total of 32 MW of peak contribution is identified for the Niagara Region in 2022, reducing throughout the 2030s to 0 MW by 2038. This reduction is reflected in the high forecast scenario (see Section 5.7 for more details on its development and assumptions), but not the reference forecast. Rather, the reference Niagara IRRP forecast assumes a constant contribution of approximately 32 MW each year for the entire study period. This aligns with the Technical Working Group decision to assume that already-existing DG facilities with expired contracts will continue to offset demand.



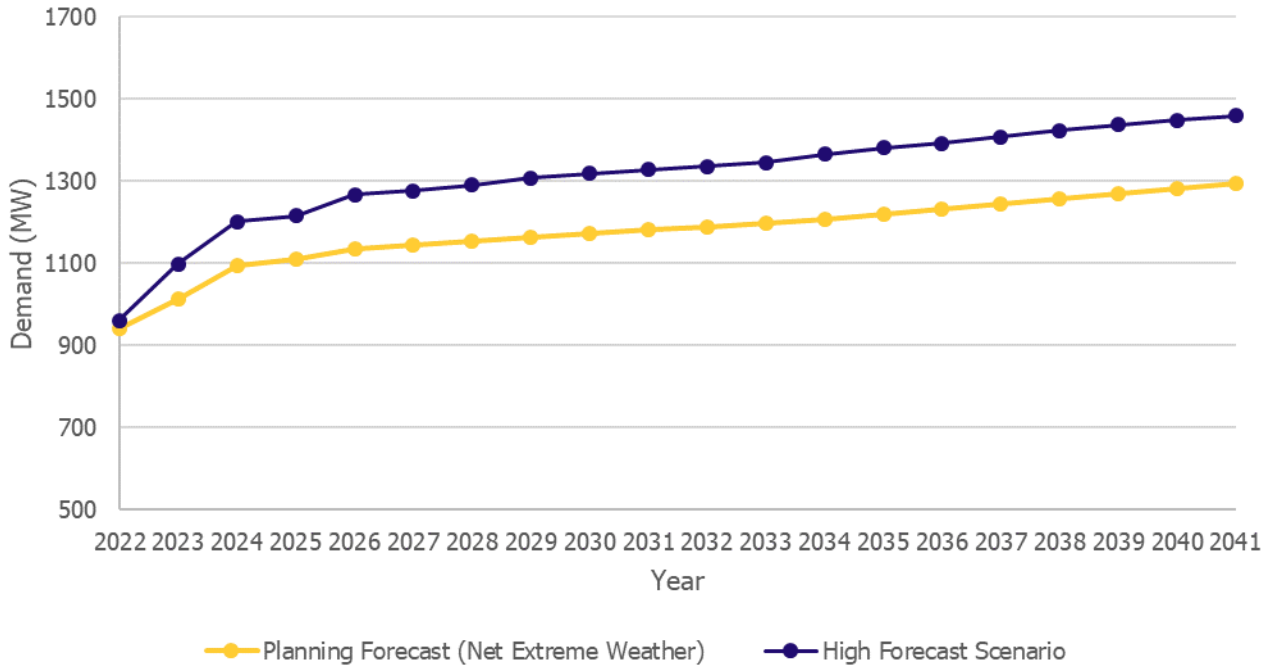
5.6 Net Extreme Weather ("Planning") Forecast

The net extreme weather forecast, also known as the "planning" forecast, is created by adjusting the net median weather forecast (the gross demand forecast, plus the forecast DG and conservation impacts as described above) for extreme weather conditions. The weather correction methodology is described in Appendix B.1.

Note that this planning forecast is coincident, meaning that each station forecast reflects its expected contribution to the regional peak demand level. This supports the identification of need dates for regional needs that are driven by more than one station. For station-specific needs, the non-coincident forecast is calculated by applying a non-coincidence factor. The factor is based on the historical non-coincident peaks of each station compared to the station's contribution to the region's coincident peaks over the past six years.

The coincident net extreme weather forecast for the Niagara Region is shown in Figure 8 below.

Figure 8 | Net Extreme Weather ("Planning") Forecast for the Niagara Region[3]



5.7 High Forecast Scenario

The Technical Working Group opted to develop a high forecast sensitivity scenario for the Niagara Region. This higher demand scenario is to take into account a variety of factors that could drive demand higher over the next 20 years, including but not limited to: electric vehicle charging infrastructure, electrified space heating installations, unanticipated new industrial customers, or general higher-than-expected growth. However, the Technical Working Group did not have specific end-use data available to develop the high forecast. Instead, the DG contribution to peak (as described in Section 5.5) was removed according to contract expiries, resulting in approximately 3% higher total regional load by 2041 when compared to the reference planning forecast. The impact on stations with greater contracted DG is higher.

The high forecast also included several large industrial customers whose connection was uncertain at the time of finalizing the reference forecast. These include customers that members of the Technical Working Group were aware of and liaising with, as well as customers that initiated a System Impact Assessment with the IESO during the Niagara IRRP development. In total, another 132 MW was added due to this assumption, when compared to the reference planning forecast. This is shown in Figure 9.

[3] See footnote 2.

Figure 9 | High Forecast Scenario for the Niagara Region[4]

The higher demand scenario was not used to drive any firm recommendations for this IRRP; however, it was used to help the Technical Working Group identify where the future pinch points may be and when they could materialize. This information can also be useful for communities conducting Community Energy Plans, for the Technical Working Group in determining areas to monitor in future planning cycles, and for communities and stakeholders as they think about various projects in the region. Moreover, during this IRRP, the Technical Working Group also considered the flexibility of evaluated options to accommodate greater long-term growth. This is later described in Section 7.

5.8 Hourly Forecast Profiles

In addition to the annual peak forecast, hourly load profiles (8,760 hours per year over the 20-year forecast horizon) for certain stations with identified needs were developed to characterize their needs with finer granularity. The profiles were based on historical load data, adjusted for variables that impact demand such as calendar day (i.e., holidays and weekends) and weather. The profiles were then scaled to match the IRRP peak planning forecast for each year. As described later in Section 7, these profiles were used to quantify the magnitude, frequency, and duration of needs to better evaluate the suitability of generation and distributed energy resource options.

Additional load profile details including hourly heat maps for each need can be found in Appendix D. Note that this data is used to roughly inform the overall energy requirements needed to develop and evaluate alternatives; it cannot be used to deterministically specify the precise hourly energy requirements. Real-time loading is subject to various factors like actual weather, customer operation strategies, and future customer segmentation. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification are more widely adopted. Hence, these hourly forecasts are only used to select suitable technology types and roughly

[4] See footnote 2.

estimate costs for the needs and options studied in the IRRP. The Technical Working Group will continue to monitor forecast changes as part of implementation of the plan.

6. Needs

6.1 Needs Assessment Methodology

Based on the planning demand forecast, system capability, the transmitter's identified asset replacement plans, and the application of ORTAC, NERC TPL-001-4, and Northeast Power Coordinating Council ("NPCC") Directory #1 standards, the Technical Working Group identified electricity needs in the near-, medium- and long-term timeframes. These needs can be categorized according to the following:

- **Station Capacity Needs** describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations during peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day Limited Time Rating ("LTR") of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be more limited by downstream or upstream equipment, i.e., breakers, disconnect switches, low-voltage bus or high voltage circuits.
- **Supply Capacity Needs** describe the electricity system's inability to provide continuous supply to a local area during peak demand. This is limited by the LMC of the transmission supply. The LMC is determined by evaluating the maximum demand that can be supplied to an area after accounting for limitations of the transmission elements (i.e., a transmission line, group of lines, or autotransformer), when subjected to contingencies and criteria prescribed by ORTAC, TPL-001-4, and NPCC Directory #1. LMC studies are conducted using power system simulation analyses.
- **Asset Replacement Needs** are identified by the transmitter by an asset condition assessment, which is based on a range of considerations such as equipment deterioration due to aging infrastructure or other factors; technical obsolescence due to outdated design; lack of spare parts availability or manufacturer support; and/or potential health and safety hazards, etc. Replacement needs identified in the near- and early mid-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium- to long-term needs should reflect the potential for the need date to change as condition information is routinely updated.
- **Load Security and Restoration Needs** describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC.

Technical study results for the Niagara IRRP can be found in Appendix G. The needs identified are discussed in Sections 6.2 – 6.5 below.

6.2 Station Capacity Needs

In the near/mid-term, there are summer station capacity needs at Beamsville TS, Murray TS, Crowland TS, and Niagara West MTS. In the longer term, there are station capacity needs at Carlton TS, Vineland DS, and Kalar MTS. Table 2 below summarizes transformer capacity limitations for the Niagara Region.

Table 2 | Summary of Station Capacity Needs in the Niagara Region

Need	10-day LTR Rating (MW)[5]	Need Date[6]	Size of Need by 2041
Beamsville TS	57	2022	44
Murray TS (T11/T12)	72	2022	14
Crowland TS	96	2022	25
Niagara West MTS	60	2026	22
Carlton TS	94	2028	11
Kalar MTS	68	2030	7
Vineland DS	25	2030	3

6.2.1 Beamsville TS, Niagara West MTS, and Vineland DS

The three stations supplying the Lincoln, West Lincoln, and Grimsby areas (Beamsville TS, Niagara West MTS, and Vineland DS) are forecast to reach their individual station limits, as well as their collective limit (sum of their LTRs). Beamsville TS and Vineland DS each comprise two 115 kV/27.6 kV transformers, with summer LTRs of 57 MW and 25 MW, respectively. The Beamsville TS capacity need exists today (Figure 10), whereas the Vineland DS need is forecast to start in 2030 (Figure 12). Niagara West MTS consists of two 230 kV/27.6 kV transformers, with a summer LTR of 60 MW and a need beginning in 2026 (Figure 11). Cumulatively, the capacity need at these three stations grows to 57 MW by 2041 (Figure 13).

[5] Assuming a 0.9 power factor.
[6] Based on non-coincident station forecasts, as explained in Section 5.6.

Figure 10 | Beamsville TS Capacity Need

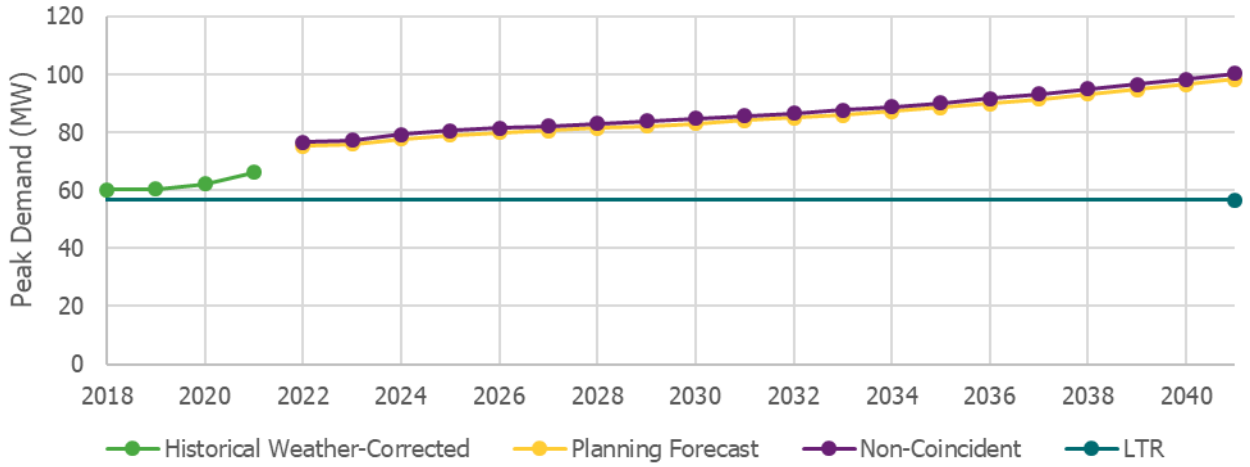


Figure 11 | Niagara West MTS Capacity Need

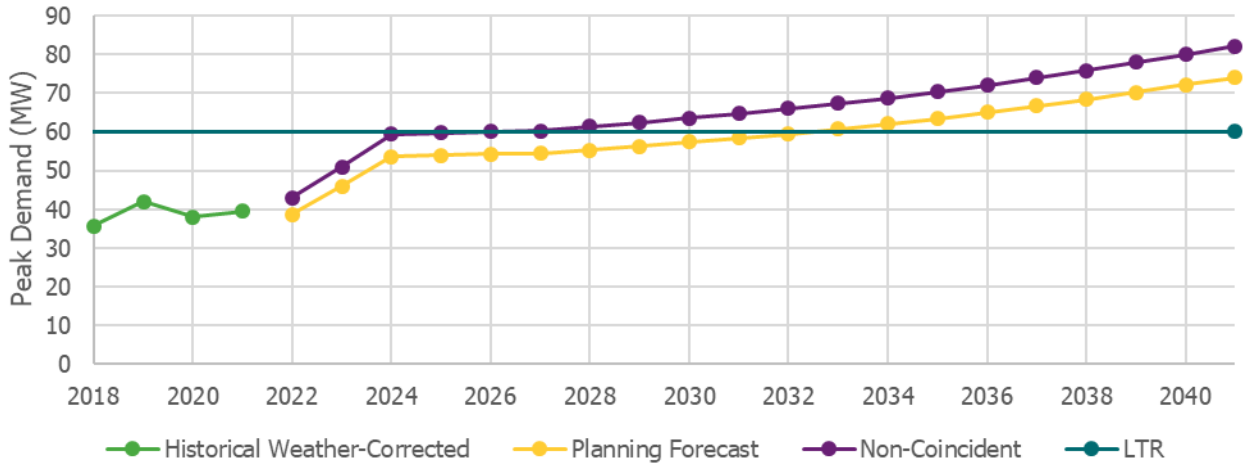

Figure 12 | Vineland DS Capacity Need

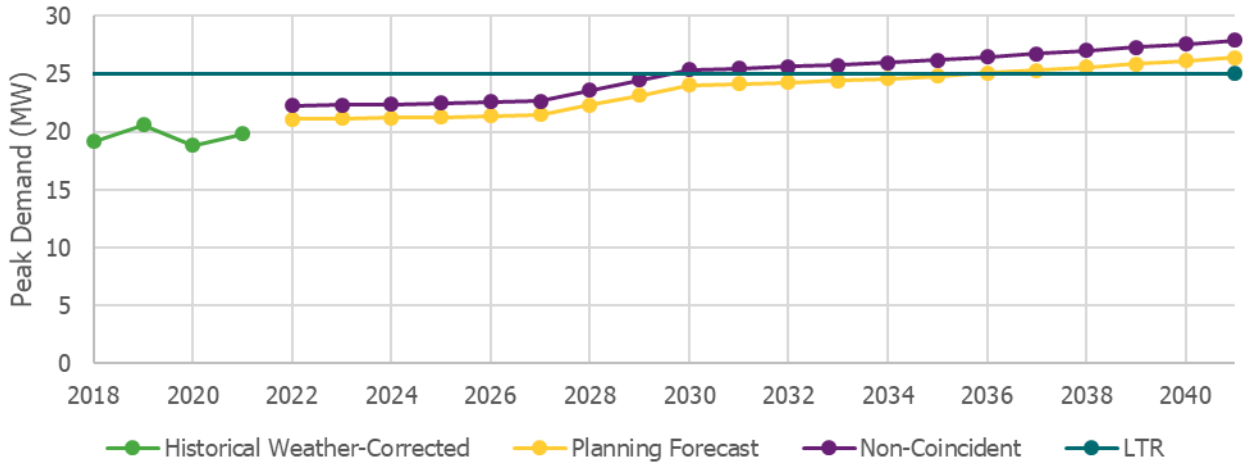

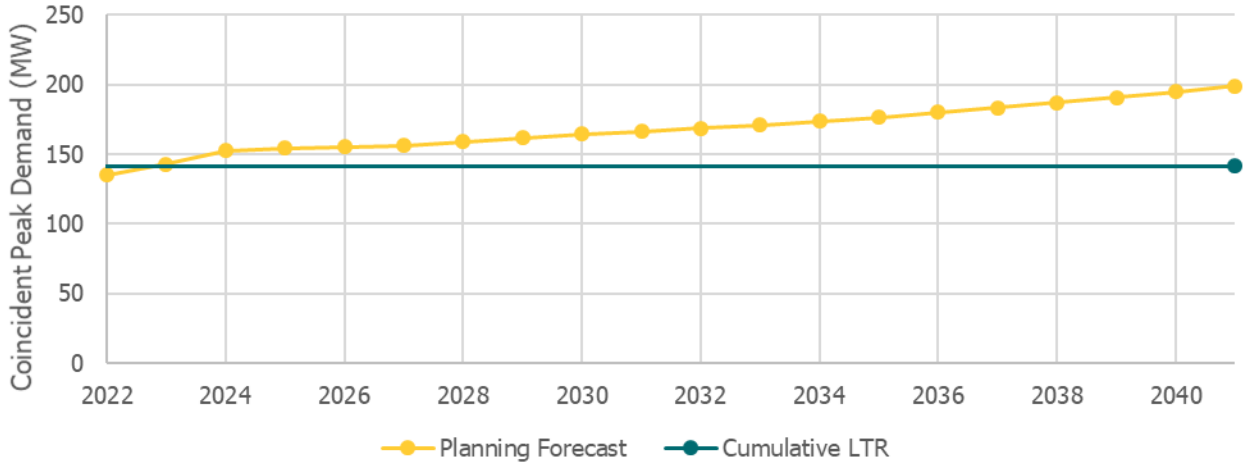

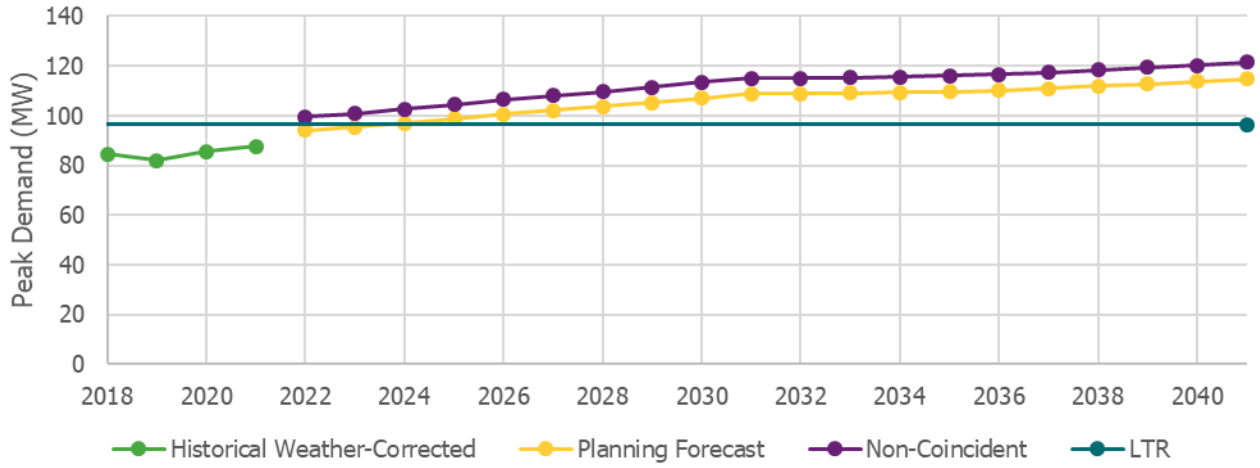

Figure 13 | Beamsville TS, Vineland DS, and Niagara West MTS Cumulative Coincident Capacity Need

6.2.2 Crowland TS

Supplying Welland, Crowland TS is forecast to reach its summer station capacity limit in 2022 and grow to a 25 MW need by 2041. This station comprises two 115 kV/27.6 kV transformers with an LTR of 96 MW.

Figure 14 | Crowland TS Capacity Need

6.2.3 Carlton TS, Kalar MTS, and Murray TS (T11/T12)

Carlton TS and Kalar MTS each comprise two 115 kV/13.8 kV transformers, with summer LTRs of 94 MW and 68 MW, respectively. Carlton TS is forecast to reach capacity starting in 2028 (Figure 15) while the Kalar MTS need arises in 2030 (Figure 16). Each need will increase to 11 MW and 7 MW, respectively, by 2041. Murray TS consists of four 230 kV/13.8 kV transformers; T11 and T12 have a summer LTR of 72 MW, whereas T13 and T14 are rated to 77 MW. The T11/T12 capacity need exists today, growing to 14 MW by 2041 (Figure 17).

Figure 15 | Carlton TS Capacity Need

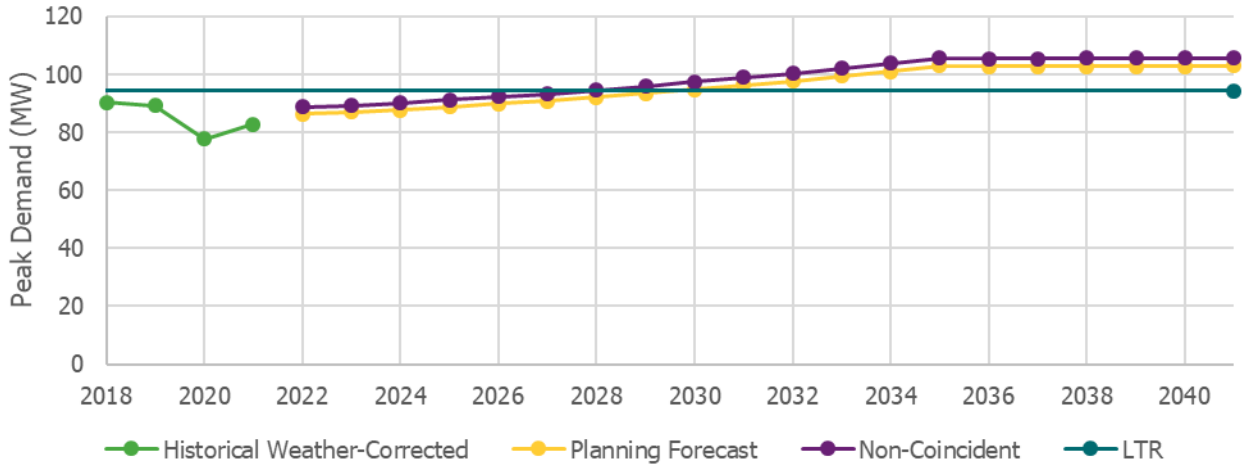

Figure 16 | Kalar MTS Capacity Need

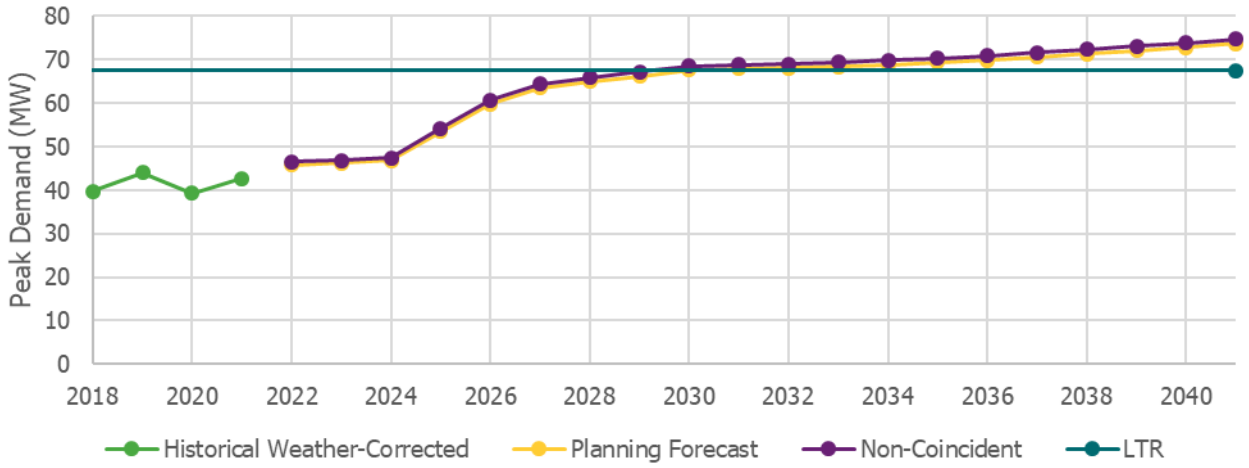

Figure 17 | Murray TS (T11/T12) Capacity Need

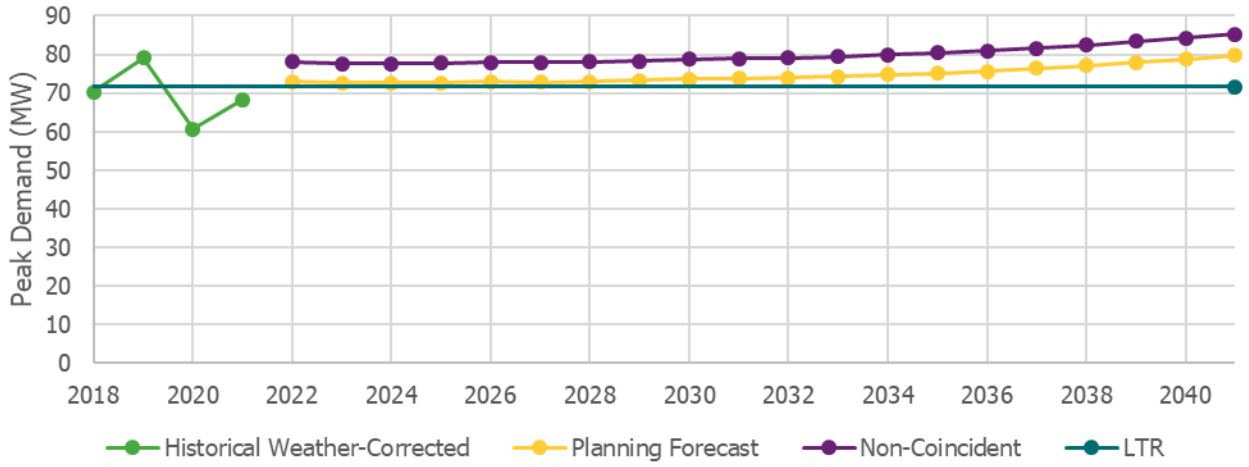

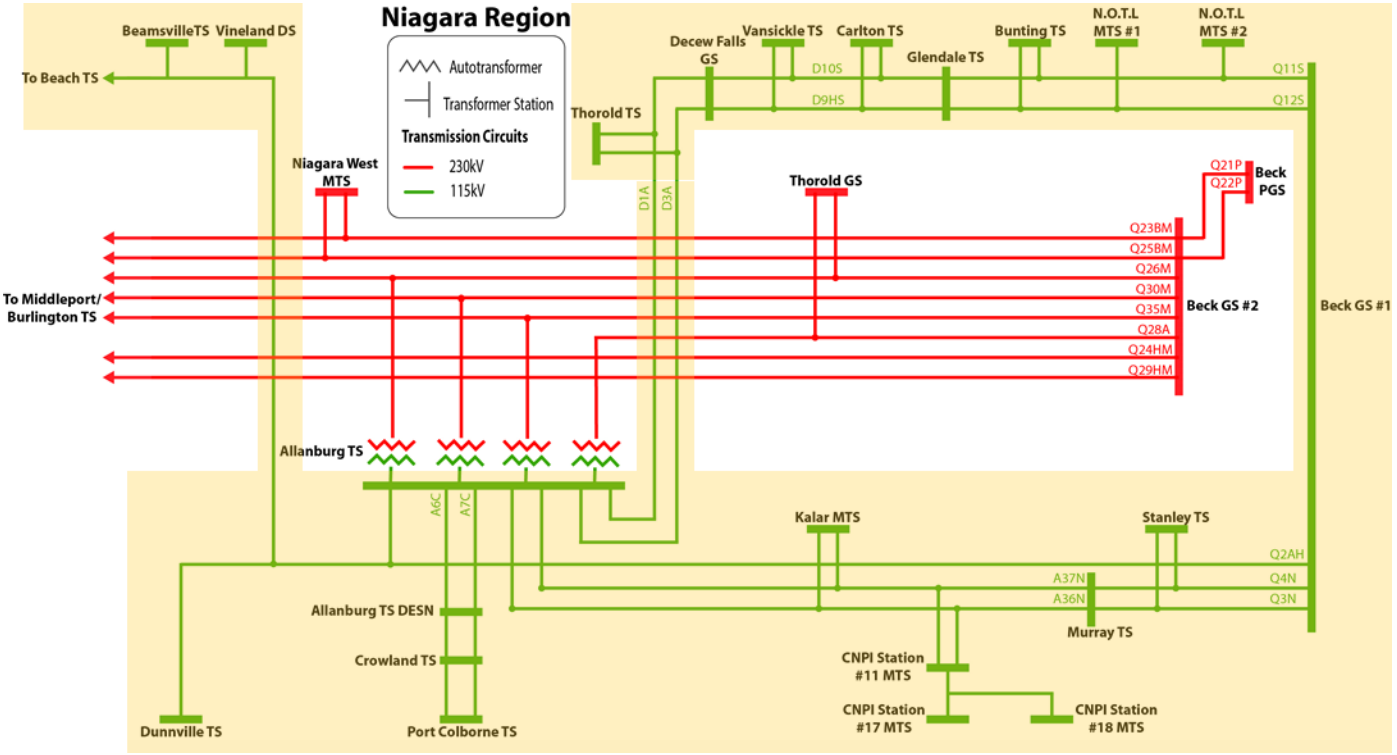

Figure 15 to Figure 17 demonstrate the non-coincident peak demand forecasts at these stations compared to their individual LTRs. Note that these station capacity needs have been presented

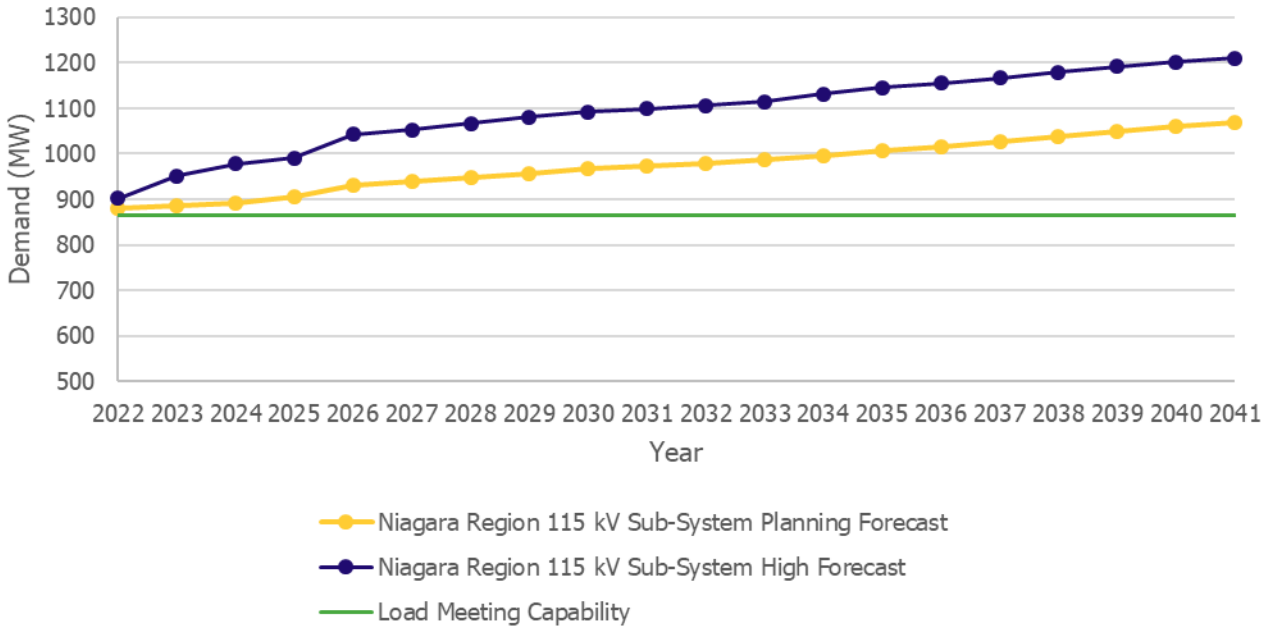
together in this sub-section, since this IRRP is not yet recommending infrastructure reinforcements to address them. Section 7.2.1.3 describes this in more detail.

6.3 Supply Capacity Needs

The majority of load in the Niagara Region is supplied through its 115 kV transmission sub-system, which in turn is supplied from the 230/115 kV autotransformers at Allanburg TS, Sir Adam Beck GS #1, and Decew Falls GS. The LMC of the 115 kV sub-system is therefore limited by the capability at Allanburg TS under the various planning scenarios and applicable contingencies. The sub-system is demonstrated in Figure 18.

Figure 18 | Niagara Region's 115 kV Sub-System (Highlighted Yellow)



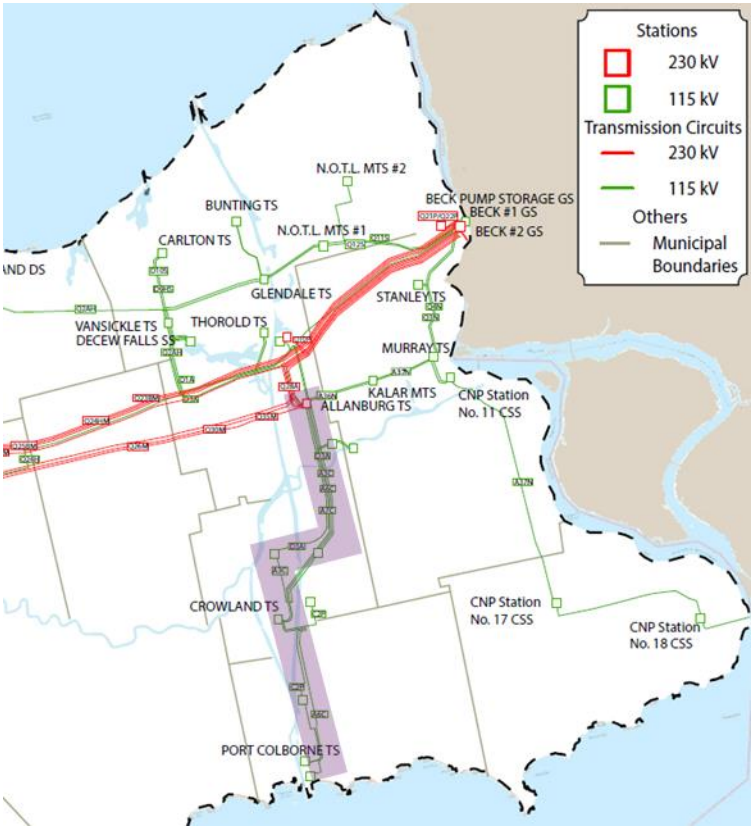
The LMC of the Niagara 115 kV sub-system, presented in Figure 19 against the forecast load, reflects limitations of the existing transmission system. Under certain outage and contingency conditions (such as contingencies impacting two circuits between Beck GS #2 and Middleport/Burlington, or Beck GS #1), the lowest-rated Allanburg autotransformer is overloaded and is the first limiting phenomenon that restricts total reliable supply into the 115 kV sub-system. However, the LMC for this area can also be restricted by other phenomena, including the thermal capability of a section of Q28A during other contingency events and specific generation outage conditions. There are further, more local restrictions within this sub-system too – such as thermal constraints limiting the supply to loads between Allanburg TS and Beck GS #1 through the 115 kV circuits.[7] All of these transmission limits are described in Appendix G.

[7] This particular need, which occurs under outage conditions, could be addressed through permissible operational control actions and would be impacted by a customer's System Impact Assessment that is ongoing at the time of regional planning.

Between 2018 – 2021, the 115 kV sub-system has had a peak coincident weather-corrected load of up to approximately 830 MW. With the reference planning forecast, the 115 kV sub-system load increases such that the supply capacity need grows to approximately 200 MW by 2041; under the high scenario, it is about 340 MW.

Figure 19 | Niagara Region 115 kV Supply Capacity Need

6.4 Asset Replacement Needs



At the time of the Niagara Region Needs Assessment, Hydro One identified a number of assets requiring replacement in the next 10 years. This included Crowland TS, whose transformers were originally scheduled to be replaced with like-for-like 115/27.6 kV 83 megavolt ampere ("MVA") units before 2026. As described in the Niagara Region Scoping Assessment, the Technical Working Group agreed that sustainment plans identified by Hydro One would be assumed to proceed as described in the Needs Assessment – unless an opportunity arose for "right-sizing".

Through the development of the IRRP, during which a more comprehensive demand forecast was created and extended to a 20-year planning horizon, and additional needs were identified or refined, the Crowland TS like-for-like replacement plan was reconsidered. This need and its relevance to the other regional needs are described further in Section 7.4.

6.5 Load Security Needs

The circuits designated as A6C/A7C form a 115 kV double-circuit line from Allanburg TS to Crowland TS, before supplying Port Colborne TS as A6C and C2P. These circuits also serve a number of transmission-connected industrial customers that are south of Allanburg TS, primarily east of the Welland Canal. Figure 20 provides an overview of this portion of the transmission system in the Niagara Region.

Figure 20 | Niagara Region Transmission System: A6C/A7C (Highlighted Purple)

The aforementioned stations and transmission-connected customers on the A6C/A7C circuits are included in the Allanburg Load Rejection Scheme; operational actions are taken to disconnect these loads in the event of certain contingencies to prevent voltage decline upon the coincidental loss of Allanburg T1 and T2. At the 2022 expected load levels on the A6C/A7C circuits, a double contingency on the Q26M and Q28A circuits will trigger over 180 MW of load being disconnected from the system. This is a violation of Section 7.1 of the ORTAC, which specifies that only up to 150 MW of planned load curtailment is permissible under these conditions. The load supplied by A6C/A7C is also expected to grow throughout the study period (i.e., up to 2041). By 2041, it is expected that the load security need will grow to approximately 75 MW in excess of the permissible amount. More details regarding this load security need are provided in Appendix G.

6.6 Summary of Identified Needs

Below is an overview of all needs identified in this Niagara IRRP.

Table 3 | Summary of Needs in the Niagara Region

Need	Need Date
Beamsville TS Station Capacity	2022
Murray TS (T11/T12) Station Capacity	2022
A6C/A7C Load Security Need	2022

Need	Need Date
Niagara 115 kV Sub-System Supply Capacity	2022
Crowland TS Station Capacity	2022
Crowland TS Asset Replacement	2026
Niagara West MTS Station Capacity	2026
Carlton TS Station Capacity	2028
Kalar MTS Station Capacity	2030
Vineland DS Station Capacity	2030

7. Plan Options and Recommendations

This section describes the options considered and recommendations to address the needs in the Niagara Region. In developing the plan, the Technical Working Group considered a range of integrated options. Considerations in assessing alternatives included maximizing use of existing infrastructure, provincial electricity policy, feasibility, cost, and consistency with longer-term needs in the area.

Generally speaking, there are two approaches for addressing regional needs that arise as electricity demand increases:

- Build new infrastructure to increase the LMC of the area. These are commonly referred to as "wires" options and can include things like new transmission lines, autotransformers, step-down transformer stations, voltage control devices, or upgrades to existing infrastructure. Wires options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate certain reliability concerns.
- Install or implement measures to reduce the net peak demand to maintain loading within the system's existing LMC. These are commonly referred to as "non-wires" options and can include things like local utility-scale generation, distributed energy resources (including distribution-connected generation and demand response), or CDM.

Section 7.1 begins with a more in-depth overview of all option types considered in IRRPs. Section 7.2 describes the screening approach used to assess which needs would be best suited for a more detailed assessment for non-wires options. Subsequently, Section 7.3 to Section 7.5 present the options that were ultimately developed and evaluated (including a cost comparison) before the Technical Working Group made a recommendation.

7.1 Options Considered in IRRPs

Wires options are always considered in regional planning, and are developed by designing transmission reinforcements or control actions that are appropriate for the specific limiting phenomenon (voltage, thermal, stability, etc) of each need. These are identified through discussions with the Technical Working Group.

While traditional wires infrastructure is always a viable option for regional needs, some non-wires options are more suitable for specific need types and characteristics. Hence, to select and size suitable generation and other non-wires options, additional work is required – including creation of an hourly load profile, as described in Section 5.8. The most suitable technology type and capacity is chosen by examining the "unserved energy" profile, which is the hourly demand above the existing LMC. The profile indicates the duration, frequency, magnitude, and total energy associated with each need. Some of these characteristics are shown visually in Appendix D for the Niagara Region needs.

High-level cost estimates for wires options are usually provided by the transmitter. In contrast, cost estimates for generation and other non-wires options are based on benchmark capital and operating cost characteristics for each resource type and size. Generally speaking, the most cost-effective

transmission-connected options for meeting local needs in the Niagara Region are resources with a performance and costs on par with simple cycle gas turbines. New natural gas-fired generation was considered in the economic analysis for illustrative purposes, as it was representative of the lowest cost generation option. Energy storage, such as lithium nickel manganese cobalt oxide batteries, are also becoming cost-competitive due to declining technology costs and the expectation of carbon prices increasing in line with federal policy. Other energy resources (which are typically distribution-connected) are also considered.

CDM measures can also help decrease the net electricity demand. Centrally delivered energy efficiency measures under the 2021-2024 CDM Framework and Save on Energy brand are already included in the load forecast, as discussed in the Section 5.4. As part of this current Framework, the IESO was directed to deliver a new program to address regional and/or local system needs. The Local Initiative Program is now one tool that is available to target the delivery of additional CDM savings at specific areas of the province with identified system needs. LDCs can also use the Ontario Energy Board's CDM Guidelines to leverage distribution rates to help address distribution and transmission system needs using non-wires alternatives.[8] Generally, incremental CDM measures are suitable for needs where growth is slow and the magnitude of the overload relative to the total demand is very small (i.e., on the order of few percent per year). These considerations are discussed further in Section 7.2, as part of the screening of options that was conducted.

For both wires and non-wires options, the upfront capital and operating are compiled to generate levelized annual capacity costs ($/kW-year). A cash flow of the levelized costs for the options are compared over the lifespan of the wires option (typically 70 years for transmission infrastructure). The non-wires options also include any system capacity benefit that they could contribute to provincial resource adequacy needs, ensuring that they are both sized to address the local need and are comparable to the wires options. The net present value (in 2021 CAD dollars) of these levelized costs are the primary basis through which feasible options are compared.

It is important to recognize that there is a significant error margin around costs estimates at the planning stage, as they are only intended to enable comparison between options during the IRRP. The RIP (which is conducted after the IRRP) performs additional detailed analysis and allows the opportunity to refine wires cost estimates before implementation work begins. The IESO continues to participate in the Technical Working Group during the RIP and revisits these recommendations if costs estimates differ significantly. Furthermore, in cases where other barriers downstream of the regional planning process (i.e., regulatory frameworks for cost-sharing and recovery, or operationalization to meet local reliability constraints) impede the adoption of some of these cost-effective options, pilot or demonstration projects can be explored.[9]

The list of assumptions made in the economic analysis can be found in Appendix F.

7.2 Screening Options

As explained in Section 7.1, an array of options can be developed to meet local needs during an IRRP, but options are ultimately evaluated to recommend the most cost-effective and technically

[8] More information about the CDM Guidelines is available on the Ontario Energy Board's website.
[9] Barriers to non-wires alternatives and recommendations to address them were a part of the Regional Planning Process Review.

feasible solution. This process is complemented by considerations for stakeholder preferences and feedback.

Screening occurs early in the IRRP study after local reliability needs are known but before options analysis. It helps direct time-intensive aspects of detailed non-wires analysis (hourly need characterization, options development, financial analysis, and engagement) towards the most promising options. The three-step, high-level approach is shown in Figure 21, and the results of its application to the Niagara IRRP needs are summarized in Table 4 and then further described in the sections below. More details on the steps and inputs used in the screening mechanism can be found in Appendix C.

Figure 21 | IRRP Screening Mechanism

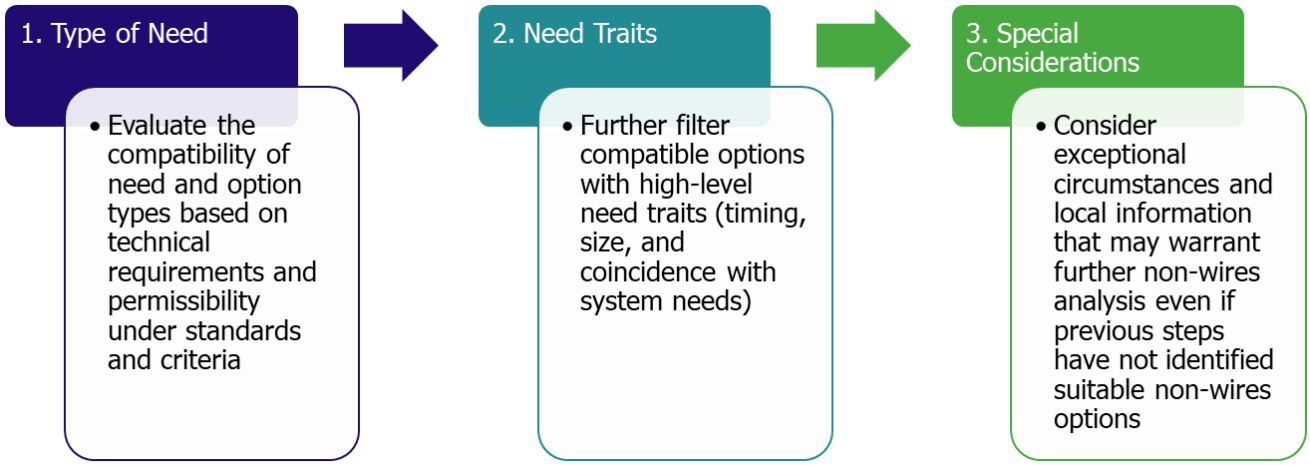


Table 4 | Results of Niagara IRRP Screening

Need Type	Impacted Element	Options Screened In	Options Screened Out
Station capacity	Beamsville TS	Wires, demand response ("DR"), DG, CDM	Transmission-connected generation
Station capacity	Vineland DS	Wires, CDM	Transmission-connected generation, DR, DG
Station capacity	Crowland TS	Wires, DR, DG, CDM	Transmission-connected generation
Station capacity	Kalar MTS	Wires, CDM	Transmission-connected generation, DR, DG
Station capacity	Carlton TS	Wires	All non-wires

Need Type	Impacted Element	Options Screened In	Options Screened Out
Station capacity	Murray TS (T11/T12)	Wires	All non-wires
Supply capacity	Niagara 115 kV sub-system	Wires, transmission-connected generation, CDM	DR, DG
Asset replacement	Crowland TS	Coordinated with the Crowland TS station capacity need	Coordinated with the Crowland TS station capacity need
Load security	Load supplied by A6C/A7C circuits	Wires	All non-wires

7.2.1 Non-Wires Options for the Capacity Needs

Based on the nature of the need, Step 1 of the screening mechanism identifies that in general, non-wires options can resolve supply and station capacity needs by reducing net load in the affected area. For station capacity needs specifically, these options must be resources that are connected downstream of the limiting step-down transformer. The following sections outline when Steps 2 and 3 of the screening resulted in further analysis of non-wires options.

7.2.1.1 Beamsville TS, Niagara West MTS, and Vineland DS

As described previously in Section 6.2.1, there are forecast station capacity needs at Beamsville TS, Niagara West MTS, and Vineland DS, as well as a collective capacity shortfall in the area supplied by the three stations. Though eventually considered together given their geographic proximity, Beamsville TS and Vineland DS were screened independently. For Beamsville TS, with its large near-term capacity need, all applicable non-wires options were considered. Conversely, for the small long-term need at Vineland DS, the focus (in terms of a non-wires option) was on incremental CDM.

At the time of screening, the Technical Working Group did not identify a station capacity need at Niagara West MTS; this occurred later in the IRRP development when the forecast was updated by Grimsby Power. Hence, formal screening was not conducted for Niagara West MTS – but this IRRP does ultimately include recommendations that address its need (see Section 7.3).

7.2.1.2 Crowland TS

For Crowland TS, all applicable non-wires options were developed in further detail. Initially, at the time of the screening, the Crowland TS and Kalar MTS station needs were approached together given their perceived geographic proximity. However, recommendations were eventually made for these stations separately after considering factors that made an integrated approach impractical. These factors include distribution voltage level differences, distance to supply forecast growth areas, and misaligned capacity need timing between the two stations.

7.2.1.3 Carlton TS, Kalar MTS, and Murray TS (T11/T12)

For some needs, further analysis of non-wires is not warranted if there is the high potential for an inexpensive and simple wires alternative that maximizes the use of existing infrastructure. This can include load transfers or control actions that are sufficient to meet the need.

This was the case for the station capacity needs at Carlton TS and Murray TS (T11/T12). At the time of screening, Alectra Utilities indicated plans to reallocate some forecast demand at Carlton TS to a nearby station with additional capacity (Bunting TS). At Murray TS, NPEI is supplied by both T11/T12 and T13/T14. While forecast demand for T11/T12 exceeds its LTR, there is sufficient remaining capacity at T13/T14.[10] Managing the load distribution between the four transformers at Murray TS is expected to address the need at T11/T12.

For the small long-term need at Kalar MTS, incremental CDM was screened in for additional analysis.

7.2.1.4 Niagara 115 kV Sub-System Supply

Due to the nature of supply capacity needs, most non-wires options can be potential solutions – either alone or as a part of an integrated package of recommendations. However, for the Niagara 115 kV sub-system, the magnitude of the capacity need was large enough that the option development focused on transmission-connected generation or storage, with some consideration for additional locally targeted CDM.

Other non-wires options such as DR and DG were screened out from further analysis for a number of reasons. For instance, the connection of DG (regardless of fuel type) is subject to equipment limitations such as minimum loading, feeder capacity, station thermal capacity, and short circuit requirements. With an approximately 200 MW supply capacity need, the amount of incremental DG required would not be able to connect to a single transformer station in the Niagara Region, and would be unlikely to be accommodated, coordinated, and operated across multiple stations to meet the local supply constraint.[11] Recall that existing contracted DG output at peak was already accounted for during the development of the net demand forecast.

Similarly, DR was screened out due to the magnitude of the Niagara 115 kV supply capacity need. Though DR can be considered as a potential option to the extent that loads in the area can be curtailed during peak hours, the amount of DR that has historically been acquired for system capacity needs can help indicate this option's feasibility. For the 2021 summer obligation period in the capacity auction, approximately 20 MW of total capacity cleared for the Niagara zone. These past auction results provide context as to the scale of demand response that would be required to address the Niagara supply capacity need; this is unlikely to be achievable in the near-term. It is also worth noting that the Capacity Auction acquires resources designed to meet provincial adequacy rather than specific local or regional needs.

[10] Approximately 50 MW of remaining capacity is available at Murray TS (T13/T14) according to the IRRP reference planning forecast.
[11] For existing station DG connection availability, consider Hydro One's capacity evaluation tool for generation applicants.

7.2.2 Non-Wires Options for the Asset Replacement Needs

Outcomes of screening non-wires options for the Crowland TS asset replacement need were aligned with the screening outcomes for the Crowland TS incremental station capacity need (i.e., the capacity need that persists even if the station is replaced like-for-like).

7.2.3 Non-Wires Options for the Load Security Needs

Due to the nature of planning criteria outlined in ORTAC 7.2, non-wires options such as CDM and DG cannot be applied to load security needs because they usually do not enable uninterruptable power supply to customers in the event of transmission contingencies. While voluntary load loss such as DR could help address the intent of load security planning criteria, it is an option type currently procured through the provincial capacity auction. This implementation mechanism is not the optimal approach, as its current design does not include the monitoring of local adequacy nor permit immediate responses after specific local contingencies. For these reasons, non-wires options are typically screened out for load security needs unless there are exceptional circumstances identified during the IRRP development.

7.3 Options and Recommendations for Meeting the Beamsville TS, Niagara West MTS, and Vineland DS Needs

7.3.1 Transmission Options

Due to the geographic proximity of Beamsville TS, Niagara West MTS, and Vineland DS, integrated transmission options were developed to address the station capacity needs in a coordinated manner. Three options for additional station capacity for the area were considered:

1. The replacement of existing Niagara West MTS with new 2 x 75/125 MVA transformers;
2. The expansion of Niagara West MTS with two new 67 MVA transformer units; or
3. A new, separate 230 kV station supplied from Q23BM and Q25BM.

Option 1 was ruled out, given that there was no indication of asset replacement needs at the existing Niagara West MTS (resulting in stranded asset costs), plus the risk of reduced reliability expected when implementing the replacement. Option 2 was estimated to cost as little as $17M and require three years from the commitment date, whereas Option 3 was estimated to cost up to $40M (depending on the size of the transformers and implementer) and would take three to four years.[12]

Given the immediate need at Beamsville TS, the Technical Working Group also considered load transfer capabilities in the near-term. Beamsville TS and Niagara West MTS both supply Grimsby Power, NPEI, and Hydro One Distribution, while Vineland DS supplies only NPEI. At the time of this IRRP, Grimsby Power estimated the ability to transfer approximately 7 MW of NPEI's forecast load at Beamsville TS to Niagara West MTS. Beyond this amount, the Niagara West MTS station capacity need would arise sooner than already forecast. There is also some remaining capacity (approximately 4 MW) expected at Vineland DS.

[12] All cost estimates, unless otherwise specified, are net present values based on a levelized cash flow analysis rather than capital costs – see Appendix F. In this case, a capital cost estimate of $19M (+/-15%) was provided for Option 2 and $25M - $40M for Option 3.

7.3.2 Non-Wires Options

As explained in Section 7.2.1.1, non-wires options were screened in for additional evaluation for the Beamsville TS and Vineland DS needs.

For Beamsville TS, a number of measures were assessed – such as combinations of incremental targeted CDM with battery storage or gas generation.[13] The most cost-effective non-wires solution portfolio included incremental CDM (approximately 6 MW of additional savings by 2041), plus battery storage assumed to be installed in two phases (2025 and 2038) to match the need profile.[14] For Vineland DS, the incremental CDM potential was also calculated: approximately 2 MW of additional demand savings by 2041.

The net present value ("NPV") of the portfolio of non-wires options for both Beamsville TS and Vineland TS was calculated to be $30M - $57M. The lower cost assumed that the incremental CDM is already system cost-effective based on provincial resource adequacy, whereas the higher cost assumed that the demand savings targeted to these stations would be incremental to the provincial CDM framework. More details on the CDM potential methodology and results are provided in Appendix E.

7.3.3 Recommendation

During the development of the IRRP, the forecasts at Beamsville TS and Niagara West MTS were updated by the impacted LDCs as growth trended higher and new potential customers were identified. By the conclusion of the IRRP, this reinforced the preference for the integrated wires options due to their cost-effectiveness and ability to address the capacity needs at all three stations.

The original scope of the non-wires options that were developed only addressed the Beamsville TS and Vineland DS needs, but were collectively $13M – $40M more expensive than the least expensive wires option. The increased forecast for Niagara West MTS did not impact the wires option of a new 230 kV station in the area – it only increased its cost-effectiveness. Another portfolio of non-wires options sized for Niagara West MTS' final reference forecast capacity need would have increased the non-wires costs further. Reallocating the load forecast on the 115 kV stations to 230 kV supply also helps alleviate the broader Niagara 115 kV sub-system capacity need.

Therefore, due to the cost-effectiveness and ability to meet the multiple needs, the Technical Working Group recommends near-term load transfers to offload Beamsville TS, plus a new 230 kV station supplied from Q23BM and Q25BM. This could be accomplished by expanding the existing Niagara West MTS. The station should be in-service as soon as possible and accommodate at least 57 MW of pre-contingency load in the area by 2041.

It is recommended that after the IRRP, the impacted LDCs coordinate the magnitude and timing of load transfers between the three stations to manage and monitor the Beamsville TS capacity need until the new station is in-service. Moreover, the LDCs and Hydro One should coordinate during the RIP to establish the lead implementer of the new station. Timing, siting, and size of the new

[13] Based on the unserved energy profile forecast at Beamsville TS, the gas generator option was assumed to be a simple cycle gas turbine facility.

[14] This included an 18 MW, 144 MWh battery storage facility. The Beamsville TS forecast was updated and increased near the end of the IRRP forecast; cost range estimate would only increase with larger battery storage.

transformers should be factored into the decision – in addition to a comprehensive economic comparison that accounts for both the cost of the transformer station and the distribution-level costs that could incur if the station is sited farther west and away from the service territories that are expected to grow.

7.4 Options and Recommendations for Meeting the Crowland TS, Load Security, and Niagara 115 kV Sub-System Needs

The Crowland station capacity and asset replacement needs, as well as the A6C/A7C load security and Niagara 115 kV sub-system capacity needs, share common transmission elements and impact each other. As such, both wires and non-wires options were developed to address these four needs in an integrated fashion.

7.4.1 Transmission Options

Two sets of transmission options were identified – one that largely involves the continued buildout of the 115 kV system in the Niagara Region, and another that expands the 230 kV supply.

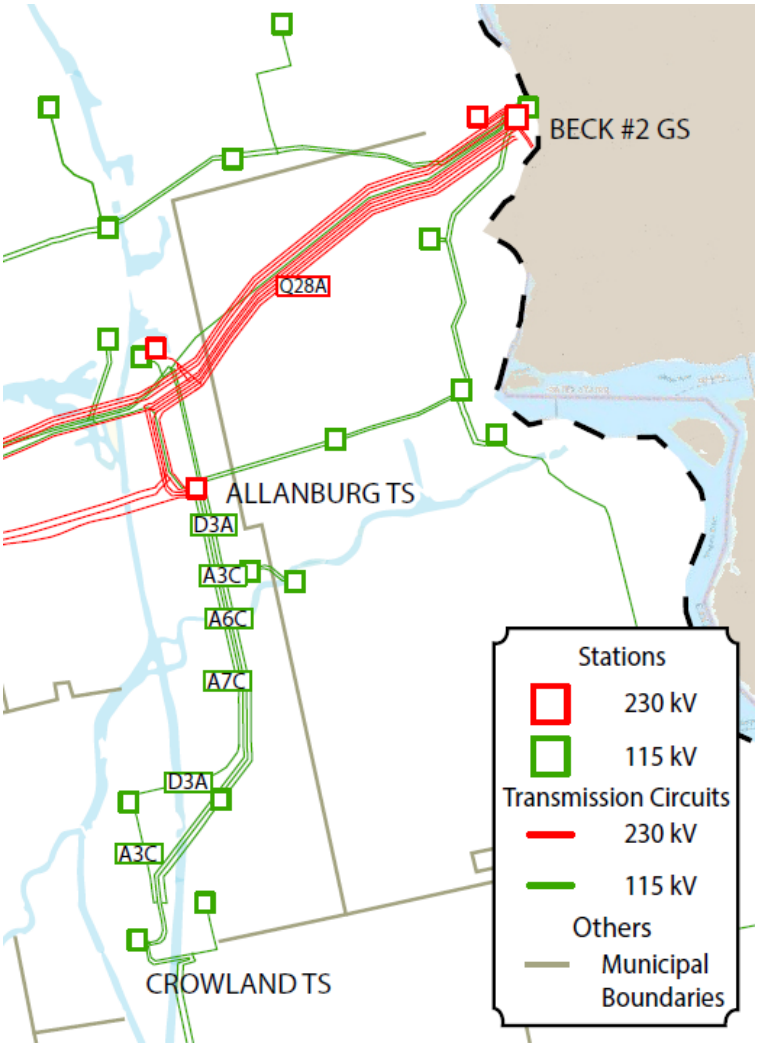
Option Set 1 includes:

- New 115 kV station in Welland, supplied by the existing A6C/A7C circuits (to address the Crowland TS capacity need);
- New 230 kV Allanburg bus (to improve supply to the 115 kV sub-system and mitigate the A6C/A7C load security need); and
- Re-building of 115 kV Crowland TS like-for-like (to address the asset replacement need).

Option Set 2 includes:

- Replacement of sections of 115 kV D3A/A3C circuits with approximately 18 km of new 230 kV double-circuit supply lines tapping off Q24HM and Q29HM; and
- The replacement of Crowland TS with a 230 kV station (to address its asset replacement and capacity needs, offload the Niagara 115 kV sub-system, and mitigate the A6C/A7C load security need).

In terms of preliminary capital costs, Option Set 1 was estimated to be approximately $253M - $353M[15] in total, whereas Option Set 2 may cost $128M.[16] Option Set 1 will require a minimum of three years; Option Set 2 will need six years.



[15] The high end of the cost estimate range for Option Set 1 includes the potential for new 115 kV circuits and other reinforcements if the existing A6C/A7C circuits cannot accommodate the new 115 kV station in Welland.

[16] Capital cost estimates provided by Hydro One during the IRRP were prepared based on preliminary information and intended to provide a ballpark figure to be used strictly for initial options comparison. No engineering or field work was completed as part of the development of these cost allowances and as such, these cost allowances provide no cost guarantee or accuracy range. Costs allocations were derived from previous historical costs/unit costs and were to be used strictly for options comparison; Hydro One may refine and update cost estimates as part of the RIP.

To accommodate the planning forecast, the uprating of an existing 230 kV circuit, Q28A, is also required in addition to either Option Set. The cost and feasibility of this reinforcement is currently being assessed by Hydro One and is estimated to require until at least 2024 to be in-service.

The components of these Option Sets are identified conceptually on the map of Niagara Region's existing transmission system in Figure 22.

Figure 22 | Impacted Areas by the Transmission Options

Under some of the contingencies and conditions expected to limit the 115 kV sub-system LMC, operational measures such as load rejection are permissible according to ORTAC. Therefore, the benefit of a new load rejection scheme was also factored in when assessing the supply capability with each of the wires options described above. It was assumed that this scheme, developed and implemented by Hydro One for the Niagara 115 kV sub-system, could be installed in 2024 or later.[17]

[17] The ultimate in-service date will depend on the complexity of the scheme's design and NPCC approval timelines.

7.4.2 Non-Wires Options

As explained in Section 7.2.1.2 and 7.2.1.4, non-wires options were screened in for additional evaluation for the Crowland TS and 115 kV sub-system supply needs.

For the Crowland TS capacity need alone, incremental targeted CDM, battery storage, and gas generation were all considered either as standalone or integrated options.[18] The most cost-effective non-wires solution portfolio for the Crowland capacity need included incremental CDM (approximately 10 MW of additional savings by 2041), plus a 10 MW/40 MWh battery storage facility installed in two phases (2025 and 2038) to match the need profile. The NPV of this portfolio was calculated to be in the range of $17M - $53M. Similar to what was described for the Beamsville TS non-wires options, this cost range is attributed to the provincial CDM assumptions.[19]

As the Niagara IRRP progressed and the interplay between the Crowland TS needs and the broader Niagara 115 kV supply capability became clearer, a non-wires option was also considered at a high level. An all-generation, 240 MW alternative was sized to compare to the lowest cost transmission option set; 240 MW is the expected increase in the 115 kV sub-system supply capability enabled by Option Set 2 described previously. However, this non-wires option is not a feasible solution due to various factors. While an all-generation option was identified to compare to the wires option on a MW basis, there are significant challenges to implementing and operating a resource to address the multiple, layered, and local needs. For instance, for 240 MW of generation to address both the Crowland TS capacity and replacement needs, as well as the broader 115 kV supply needs, a portion of the generation must be sited on the distribution system to supply customers currently served by Crowland TS and the remaining must be targeted to the region's 115 kV system. There may also be thermal or short circuit limitations to connecting this amount of generation on the distribution system. Moreover, as described in Section 7.2.3, generation is typically not considered a feasible option to solve load security needs.

7.4.3 Recommendation

When comparing the two wires option sets, Option Set 2 is preferred for a number of reasons. It is the more cost-effective option, evaluated at more than $100M less expensive than Option Set 1 (based on capital cost estimates), even though both offer similar 115 kV sub-system supply capability and are sufficient according to the reference planning forecast. Qualitatively, by expanding the 230 kV transmission system, Option Set 2 also offers long-term flexibility to accommodate more load growth in the southern portion of the Niagara Region – particularly along the industrial and commercial hub around the Welland Canal. Option Set 1 provides limited growth options in the area in comparison to Option Set 2, without extensive station expansion at Allanburg TS. Meanwhile, converting the existing 115 kV Crowland TS to 230 kV in Option Set 2 allows the other 115 kV stations in the Niagara Region to accommodate new growth and maximizes the use of existing infrastructure with the available capacity normally utilized by the 115 kV Crowland TS. Triggering the

[18] Based on the unserved energy profile forecast at Crowland TS, the gas generator option was assumed to be a simple cycle gas turbine facility.

[19] Another sensitivity was conducted for the battery storage sizing, resulting in a higher cost range of $25M - $61M. See Appendix D.3 for more details.

reconfiguration is also a time-sensitive opportunity, since Crowland TS is expected to require asset replacement in the near term.[20]

Long-term flexibility can also be considered by comparing the options and their ability to accommodate the high IRRP forecast scenario. According to the reference forecast, approximately 200 MW of extra 115 kV supply capability is required by 2041. As shown in Section 6.3, the high scenario increased this requirement to 340 MW. Both Option Sets 1 and 2 enable the increased capability required for the reference forecast, and neither Option Set precludes a further wires or non-wires option in the long-term. These future actions can include new generation resources or additional 230/115 kV auto-transformation. In contrast, a non-wires option sized precisely to meet the reference need would have less flexibility to accommodate growth that exceeds today's expectations.

Regardless, none of the non-wires options described in Section 7.4.2 can sufficiently address the multiple needs at once. Wires Option Set 2 would cost-effectively resolve the Crowland capacity and replacement needs, the A6C/A7C security issue, and enable other load growth on the 115 kV sub-system. For these reasons, the Technical Working Group recommends the replacement of Crowland TS with a new 230 kV station, supplied by new 230 kV double-circuit lines from Q24HM/Q29HM, as well as the uprating of Q28A. A new load rejection scheme should also be developed to manage the Niagara 115 kV sub-system need. The load forecast should be monitored between regional planning cycles, and there are benefits to targeting incremental CDM to the 115 kV sub-system in order to manage load growth beyond the reference scenario. The technical feasibility and costs of the wires recommendations should be further analyzed in the RIP; the IESO will continue to participate in the RIP Working Group to provide advice and input on this matter.

7.5 Summary of Recommended Actions and Next Steps

The Technical Working Group recommends the actions summarized in Table 5 to meet identified needs in the Niagara IRRP.

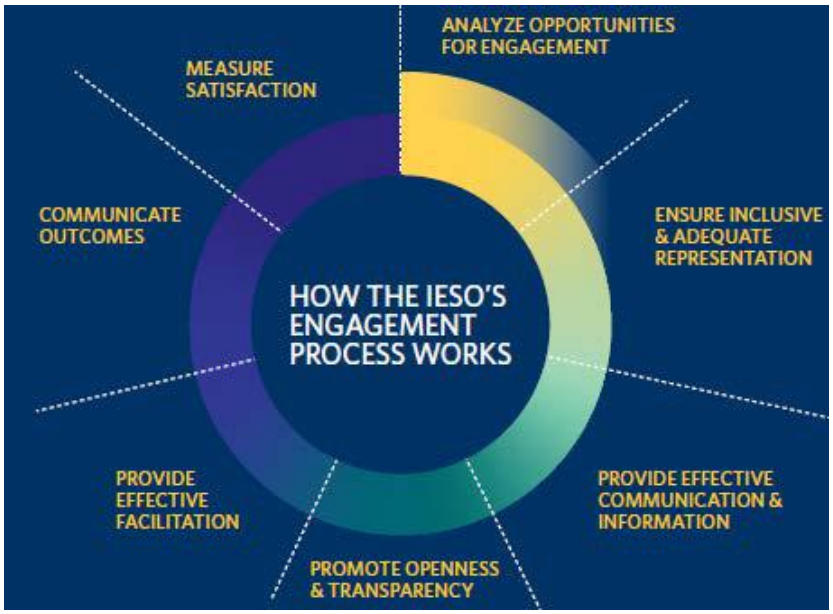
Table 5 | Summary of Needs and Recommended Actions

Need(s)	Lead Responsibility	Technical Working Group Recommendation	Expected In-Service Date
• Beamsville TS station capacity	• Grimsby Power • NPEI • Hydro One Distribution	• Coordinate load transfers to offload Beamsville TS to Niagara West MTS in the near-term	• 2023

[20] All final cost estimates have accounted for the asset replacement value for Crowland TS.

Need(s)	Lead Responsibility	Technical Working Group Recommendation	Expected In-Service Date
• Beamsville TS, Niagara West MTS, and Vineland DS station capacity • Niagara 115 kV sub-system supply capacity	• Grimsby Power • NPEI • Hydro One Distribution • Hydro One Transmission	• Initiate development for a new 230 kV station supplied from Q23BM and Q25BM, or an expansion of Niagara West MTS	• 2026-2027
• Beamsville TS, Niagara West MTS, and Vineland DS station capacity	• Grimsby Power • NPEI • Hydro One Distribution	• Monitor load growth between regional planning cycles	• Ongoing
• Beamsville TS and Vineland DS station capacity	• Technical Working Group	• Investigate opportunities to target incremental CDM to Beamsville TS and Vineland DS	• Ongoing
• Crowland TS station capacity and asset replacement • A6C/A7C load security • Niagara 115 kV sub-system supply capacity	• Hydro One Transmission	• Initiate development for the replacement of Crowland TS with a new 230 kV station, supplied by new 230 kV double-circuit lines from Q24HM and Q29HM	• 2028
• Niagara 115 kV sub-system supply capacity	• Hydro One Transmission	• Develop and implement a new 115 kV sub-system load rejection scheme	• 2024
• Niagara 115 kV sub-system supply capacity	• Hydro One Transmission	• Uprate Q28A	• 2024
• Niagara 115 kV sub-system supply capacity	• Technical Working Group	• Monitor load growth between regional planning cycles	• Ongoing

Need(s)	Lead Responsibility	Technical Working Group Recommendation	Expected In-Service Date
• Niagara 115 kV sub-system supply capacity	• Technical Working Group	• Investigate opportunities to target incremental CDM to the 115 kV sub-system	• Ongoing
• Murray TS (T11/T12) station capacity	• NPEI • Hydro One Transmission	• Transfer load in excess of the station limit to Murray TS T13/T14	• 2023
• Carlton TS station capacity	• Alectra	• Monitor load growth between regional planning cycles • Transfer load in excess of the station limit to Bunting TS	• 2028
• Kalar MTS station capacity	• NPEI	• Monitor load growth between regional planning cycles and consider future opportunities for incremental CDM	• 2030



8. Community and Stakeholder Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and preferences of communities to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the activities undertaken to date for the Niagara IRRP.

8.1 Engagement Principles

The IESO's engagement principles help ensure that all interested parties are aware of and can contribute to the development of this IRRP. The IESO uses these principles to ensure inclusiveness, sincerity, respect, and fairness in its engagements, striving to build trusting relationships as a result.

Figure 23 | The IESO's Engagement Principles

8.2 Creating an Engagement Approach for Niagara Region

The first step in ensuring that any IRRP reflects the needs of community members and interested stakeholders is to create an engagement plan to ensure that all interested parties understand the scope of the IRRP and are adequately informed about the background and issues in order to provide meaningful input on the development of the IRRP for the region.

Creating the engagement plan for this IRRP involved:

- Targeted discussions to help inform the engagement approach for this planning cycle;
- Communications and other engagement tactics to enable a broad participation, using multiple channels to reach audiences; and

- Identifying specific stakeholders and communities who may have a direct impact in this initiative and that should be targeted for further one-on-one consultation, based on identified and specific needs in the region.

As a result, the engagement plan for this IRRP included:

- A dedicated webpage on the IESO website to post all meeting materials, feedback received and IESO responses to the feedback throughout the engagement process;
- Regular communication with interested communities and stakeholders by email or through the IESO weekly Bulletin;
- Public webinars; and
- Targeted one-on-one outreach with specific communities and stakeholders to ensure that their identified needs are addressed (see Section 8.4).

8.3 Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for this second round of planning, and to establish new relationships and dialogue in this region where there has been no active engagement previously. This started with the Scoping Assessment Outcome Report for the Niagara Region. An invitation was sent to targeted municipalities, Indigenous communities, and those with an identified interest in regional issues, to announce the commencement of a new planning cycle and invite interested parties to provide input on the Niagara Region Scoping Assessment Report finalization. A public webinar was held in August 2021 to provide an overview of the regional electricity planning process and seek input on the high-level needs identified and proposed approach. The final Scoping Assessment was posted later in August 2021, identifying the need for a coordinated regional planning approach and an IRRP.

Following finalizing the Scoping Assessment, targeted outreach then began with municipalities in the region to inform early discussions for development of the IRRP, including the IESO's approach to engagement. The launch of a broader engagement initiative followed, with an invitation to IESO subscribers of the Niagara Region to ensure that all interested parties were made aware of this opportunity for input. Three public webinars were held at major stages during the IRRP development to give interested parties an opportunity to hear about its progress and provide comments on key components of the plan. These webinars were attended by a cross-representation of community representatives, businesses, and other stakeholders, and written feedback was collected over a 21-day comment period after each webinar.

The three stages of engagement at which input was invited:

1. The draft engagement plan, electricity demand forecast, and early identified needs – to set the foundation of this planning work.
2. The defined electricity needs for the region and high-level screening of potential options to meet the identified needs.
3. The analysis of options and draft IRRP recommendations.

Comments received during this engagement were primarily focused on:

- Ensuring key areas of growth in specific pockets in the Niagara Region (including the City of Niagara Falls and Town of Fort Erie), have been considered and accounted for in the IRRP work;
- Ensuring there are procedures to alter the implementation of plan recommendations should changes occur in the region; and
- Keeping lines of communication following the plan completion to share information and updates.

Feedback received during the written comment periods for these webinars helped to guide further discussions throughout the development of this IRRP, as well as add due consideration to the final recommendations.

All interested parties were kept informed throughout this engagement initiative via email to Niagara Region subscribers, municipalities, and Indigenous and Métis communities.

Based on the discussions through this engagement initiative, a key priority was to ensure the IRRP and recommended actions aligned with strong forecast growth and development both within specific municipalities and the region more broadly (e.g. future urban expansion and employment areas as outlined in the updated Niagara Region Official Plan). This insight has been valuable to the IESO – it supported an understanding of local growth and an accurate electricity demand forecast, the determination of needs, and the recommendation of solutions to ensure adequate and reliable long-term supply. To that end, ongoing discussions will continue through the IESO's Southwest Regional Electricity Network to keep interested parties engaged in a two-way dialogue on local developments, priorities, and initiatives to prepare for the next planning cycle.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's Niagara IRRP engagement webpage.

8.4 Bringing Municipalities to the Table

The IESO held meetings with municipalities to seek input on their planning and to ensure that key local information about growth and development and energy-related initiatives were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings were held with the upper- and lower-tier municipalities in the region to discuss key issues of concern, including forecast regional electricity needs, options for meeting the region's future needs, and broader community engagement. These meetings helped to inform the municipal/community electricity needs and priorities, establish new relationships, and provided opportunities for ongoing dialogue beyond this IRRP process.

Through these discussions valuable feedback was received around strong anticipated growth in major growth centres in the region:

- Strong population growth across the Niagara Region based on 2051 growth projections and in some areas above and beyond the regional forecast (i.e. even higher growth expected in the City of Welland);
- Notable growth in the Town of Lincoln (greenhouses, Secondary Plan areas, potential GO Transit development), along the QEW corridor in Grimsby, and in Thorold;

- Strong economic development around the Welland Canal (e.g. Thorold Multimodal Hub "Niagara Ports");
- Key areas of growth in the City of Niagara Falls within intensification nodes and corridors, projects around the GO Transit Station and the new Niagara South Hospital, wastewater treatment plant, and residential new construction;
- Industrial, commercial, institutional, and residential development in the Town of Fort Erie and Secondary Plan areas; and
- Potential urban boundary expansion in the region totaling 130 hectares of residential and 150 hectares of employment lands.

8.5 Engaging with Indigenous Communities

To raise awareness about the regional planning activities underway and invite participation in the engagement process, regular outreach was made to Indigenous communities within the Niagara Region throughout the development of the plan. This includes the communities of the Mississaugas of the New Credit, Oneida Nation of the Thames and Six Nations of the Grand River (Six Nations Elected Council and Haudenosaunee Confederacy Chiefs Council) and Métis Nation of Ontario Niagara Region Métis Council.

The IESO remains committed to an ongoing, effective dialogue with communities to help shape long-term planning in regions all across Ontario.

9. Conclusion

The Niagara IRRP identifies electricity needs in the region over the 20-year period from 2022 to 2041, recommends a plan to address immediate and near-term needs, and lays out actions to monitor long-term needs. The IESO will continue to participate in the Technical Working Group during the next phase of regional planning, the RIP, to provide input and ensure a coordinated approach.

In the near term, the IRRP recommends load transfers off Beamsville TS and a new or expanded 230 kV station supplied by Q23BM and Q25BM. The IRRP also recommends the implementation of control actions on the Niagara 115 kV sub-system to manage overloads during outage conditions, plus the replacement of Crowland TS with a new 230 kV station supplied by new 230 kV lines from Q24HM and Q29HM. Q28A should be uprated, and a portion of the load at Murray TS (T11/T12) should be transferred to Murray TS (T13/T14). Responsibility for these actions has been assigned to the appropriate members of the Technical Working Group.

In the long term, the IRRP recommends that the Technical Working Group monitor growth in the Niagara 115 kV sub-system, Carlton TS, and Kalar MTS to determine if or when further reinforcements will be needed. This includes monitoring any future community energy planning or electrification trends. Additionally, there are benefits to investigating opportunities to target incremental CDM to the region – particularly to the Beamsville TS/Vineland DS/Niagara West MTS areas and 115 kV sub-system in the near-term, and Kalar MTS in the long-term.

The Technical Working Group will meet at regular intervals to monitor developments and track progress toward plan deliverables. In the event that underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the Ontario Energy Board.

NIAGARA
REGIONAL INFRASTRUCTURE PLAN

July 12, 2023

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

Niagara Technical Working Group

DISCLAIMER

This Regional Infrastructure Plan (RIP) Report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group (TWG).

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Technical Working Group.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE TECHNICAL WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE NIAGARA REGION.

The participants of the Niagara Region Regional Infrastructure Plan ("RIP") Technical Working Group ("TWG") included members from the following organizations:

- Alectra Utilities Corporation ("Alectra")
- Canadian Niagara Power Inc. ("CNP")
- Grimsby Power Inc. ("Grimsby Power")
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Independent Electricity System Operator ("IESO")
- Niagara-on-the-Lake Hydro Inc. ("NOTL")
- Niagara Peninsula Energy Inc. ("NPEI")
- Welland Hydro Electric System Corp. ("Welland Hydro")

This RIP is the final phase of the second cycle of the Niagara Region regional planning (RP) process and it follows the completion of the Niagara Region Integrated Regional Resource Plan ("IRRP") [1] in December 2022; and the Niagara Region Needs Assessment ("NA") [2] and Scoping Assessment ("SA") in May 2021 and August 2021, respectively. This RIP provides a consolidated summary of needs and recommended plans for the Niagara Region over a 10-year planning horizon (2023-2032) based on available information. The load forecast for the 2033-2042 period is provided to show the longer-term needs and trend. All needs for this long-term horizon will be covered and confirmed in future regional planning cycles.

The first cycle of Regional Planning process was completed in March 2017 with the publication of the Niagara Region RIP [3], which provided a description of needs and recommendations of preferred wires plans to address near-term needs. Since the previous planning cycle, the following projects have been completed:

- Decew Falls SS (2017) – Five (5) 115kV breakers were replaced with sulfur hexafluoride (SF_6) equivalent breakers to improve supply reliability.

- Q4N Line Section Upgrade (2019) – Line section of 115kV Q4N circuit between Beck SS #1 x Portal Junction section (egress out from the generation station) was upgraded to meet load supply needs.

- A6C Line Section Refurbishment (2020) –115kV A6C circuit line conductor between Crowland TS and Port Colborne TS was replaced. The conductor needed replacement due to its asset condition.

- Stanley TS (2022) – The existing 40/53/67 MVA, 115/13.8 kV transformer T2 was replaced with a 45/60/75 MVA unit. This transformer needed replacement due to asset condition. Some 13.8kV switchyard components and protection and control equipment were also replaced due to asset condition.

- Port Colborne TS (2022) – The 28/37/47 MVA, 115/27.6 kV transformers T61 and T62 were replaced with 50/66.7/83.3 MVA units. These transformers needed replacement due to asset condition. The 27.6kV switchyard components and protection and control equipment were also replaced due to asset condition to improve the reliability of supply.

The recommended major infrastructure investments including assets replacements in the Niagara Region over the near and medium-term (2023-2032) period are given in Table 1 on the next page, along with their planned in-service date and budgetary estimate for planning purposes.

The Niagara Region TWG recommends that:

- Hydro One and LDCs continue with the implementation of infrastructure investments listed in Table 1 while keeping the TWG apprised of project status;
- All the other identified needs/options are to be further reviewed by the TWG in the next regional planning cycle.

The next regional planning cycle for the Niagara Region must be triggered within five years, beginning with the Needs Assessment ("NA") phase. It is expected that the next NA will be initiated in 2026. However, the next regional planning cycle can be started earlier if required to address any new emerging needs.

Table 0-1 Niagara Region - Recommended Plans over the 2023-2032 Study Period

No.	Investments	I/S Date	Cost[1]
A	**Increase Capacity**		
1	230 kV circuit Q28A – Uprate circuit between Beck 2 SS and Abitibi Jct.	TBD	$3M
2	Lincoln Area: Build new 230/27.6 kV, 50/83 MVA transformer station	2026	$45M
4	Crowland TS: Convert station to 230 kV with new 230/27.6 kV, 75/125 MVA transformer station and build a new 18 km of double circuit line from Abitibi Jct to Crowland TS	2027	$128M
5	Murray TS: Uprate T11/T12 75 MVA transformers with new 100MVA units	2027	$41M
6	Carlton TS: Transfer excess load to Bunting TS	2029	$5M
B	**Asset Replacement**		
1	Thorold TS: Replace Transformer T1	2024	$43M
2	Glendale TS: Replace Transformers T1 and T2	2027	$55M
3	Carlton TS: Replace LV Switchgear	2027	$55M
4	Bunting TS: Replace existing Transformers T1 and T2	2029	$45M
5	Murray TS: Replace Transformers T13 and T14	2031	$27M
6	Vansickle TS: Replace LV Switchgear	2032	$14M
7	Allanburg TS: Replace Transformer T3	2032	$20M
8	115kV Line D1A/D3A: Refurbish line section between Gibson Jct and Thorold TS	2024	$4M
9	115kV Line Q2AH: Refurbish line section between Rosedene Jct. and St. Anns Jct.	2025	$10M

[1] These costs are budgetary estimates for planning purposes only.

1 INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE NIAGARA REGION.

The report was prepared by Hydro One Networks Inc. (Transmission) ("Hydro One") on behalf of the Niagara Region Technical Working Group ("TWG") in accordance with the regional planning process established by the Ontario Energy Board ("OEB") in 2013. The TWG included members from the following organizations:

- Alectra Utilities Corporation ("Alectra")
- Canadian Niagara Power Inc. ("CNP")
- Grimsby Power Inc. ("Grimsby Power")
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Independent Electricity System Operator ("IESO")
- Niagara-on-the-Lake Hydro Inc. ("NOTL")
- Niagara Peninsula Energy Inc. ("NPEI")
- Welland Hydro Electric System Corp. ("Welland Hydro")

The Niagara Region includes the Regional Municipality of Niagara as shown in Figure 1-1. It includes the Cities of Niagara Falls, Port Colborne, St. Catharines, Thorold and Welland, the Towns of Fort Erie, Grimsby, Lincoln, Niagara-on-the-Lake and Pelham and the Townships of Wainfleet and West Lincoln.

Electrical supply to the Niagara region is provided through a network of 230kV and 115kV transmission circuits supplied mainly by the local generation from Sir Adam Beck Generating Station (GS) #1, Sir Adam Beck GS #2, Decew Falls GS, Thorold GS and the 230kV/115kV autotransformers at Allanburg TS. Bulk supply is provided through the 230kV circuits (Q23BM, Q24HM, Q25BM, Q26M, Q28A, Q29HM, Q30M, and Q35M) connecting the Sir Adam Beck #2 Switching Station (SS) to stations in the Hamilton/Burlington area. The summer 2022 non-coincident peak load of the Region was about 977 MW.

Figure 1-1: Niagara Region Map

1.1 Scope and Objectives

This RIP report examines the needs in the Niagara Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop wires plans to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near- and medium-term needs (2023-2032) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan);
- Identification of any new needs over the 2023-2032 period and wires plans to address these needs based on new and/or updated information;
- Consideration of long-term needs identified by the TWG.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process;
- Section 3 describes the region;
- Section 4 describes the transmission work completed over the last ten years;
- Section 5 describes the load forecast and study assumptions used in this assessment;
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs;
- Section 7 discusses the needs and provides the alternatives and preferred solutions; and,
- Section 8 provides the conclusion and next steps.

2 REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs, and the Technical Working Group (TWG) determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and a Local Plan ("LP") is developed to address them. These needs are local in nature and can be best addressed by a straightforward wires solution.

In situations where identified needs require further coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the TWG, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and decides on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

[1] also referred to as Needs Screening

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive and consolidated report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, plan level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the regional planning process taking effect;
- The NA, SA, IRRP and LP phases of regional planning;
- Conducting wires planning as part of the RIP for the region or sub-region;
- Planning for connection capacity requirements with the LDCs and transmission connected customers.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

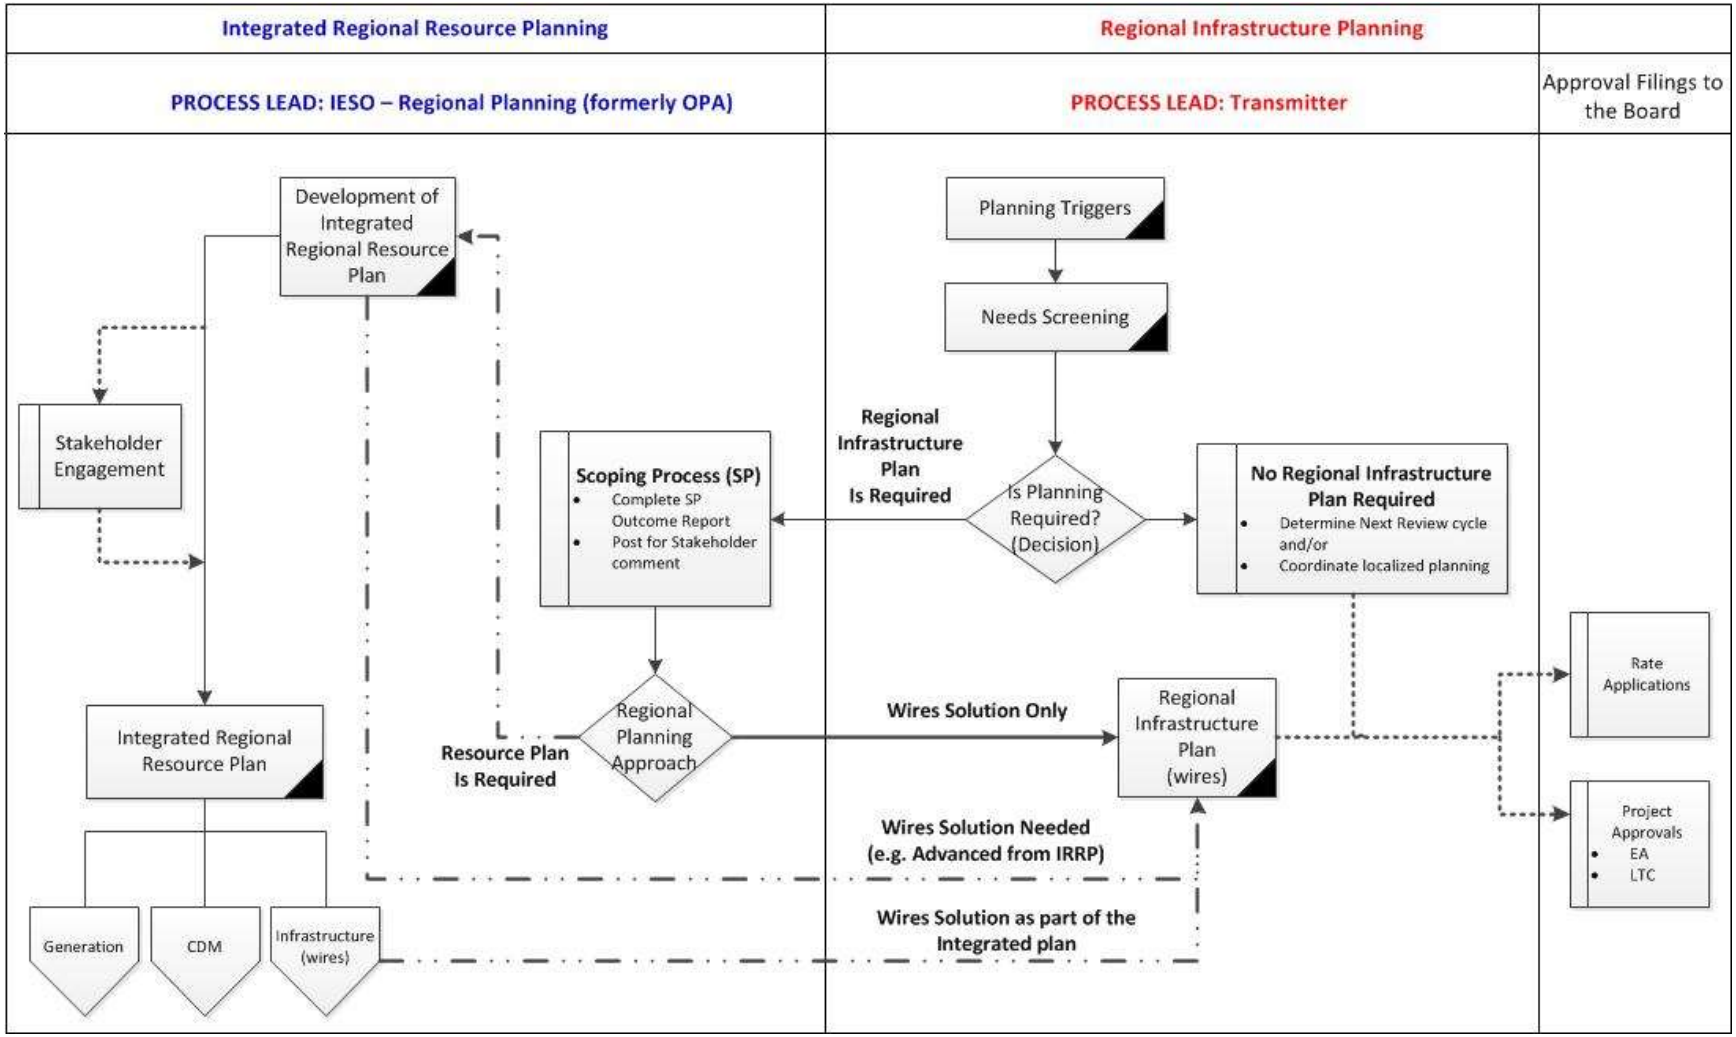

Figure 2-1: Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see

Figure 2-2) as follows:

1. Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
    - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
    - Existing area network and capabilities including any bulk system power flow assumptions.
    - Other data and assumptions as applicable such as asset conditions, load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

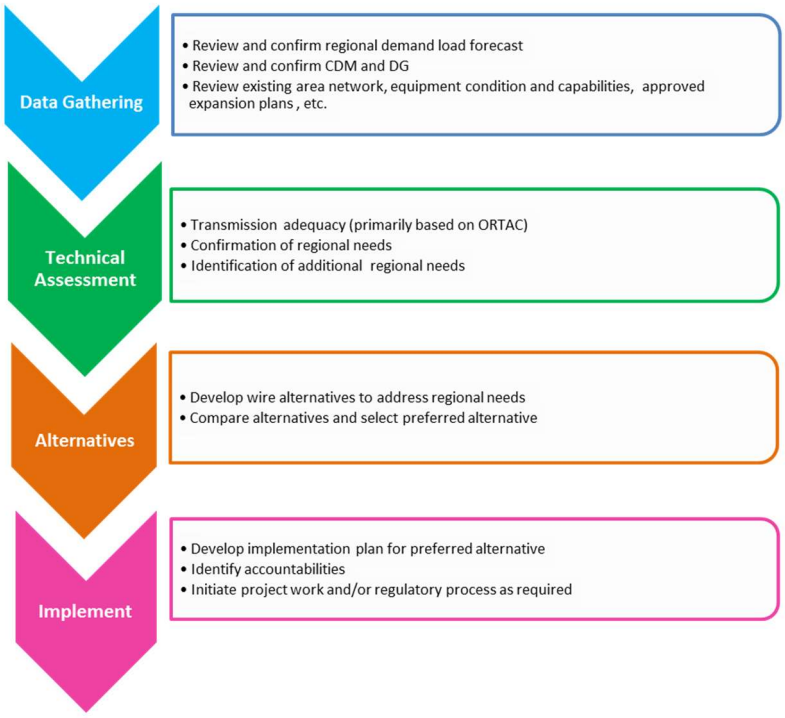

Figure 2-2: RIP Methodology

3 REGIONAL CHARACTERISTICS

THE NIAGARA REGION COVERS THE REGIONAL MUNICIPALITY OF NIAGARA AND INCLUDES THE CITIES OF NIAGARA FALLS, PORT COLBORNE, ST. CATHARINES, THOROLD AND WELLAND, THE TOWNS OF FORT ERIE, GRIMSBY, LINCOLN, NIAGARA-ON-THE-LAKE AND PELHAM AND THE TOWNSHIPS OF WAINFLEET AND WEST LINCOLN.

The Local Distribution Companies in the Niagara Region are Alectra Utilities Corporation, Canadian Niagara Power Inc., Grimsby Power Inc., Hydro One Networks Inc. (Distribution), Niagara-on-the-Lake (NOTL) Hydro Inc., Niagara Peninsula Energy Inc., and Welland Hydro Electric System Corp. A listing of the LDCs along with the associated supply stations is given in Appendix C. The high-voltage system in this Region also provides supply to number of direct transmission-connected customers transformer stations.

Electrical supply to the Niagara region is provided through a network of 230kV and 115kV transmission circuits supplied mainly by the local generation from Sir Adam Beck GS #1, Sir Adam Beck GS #2, Decew Falls GS, Thorold GS and the 230kV/115kV autotransformers at Allanburg TS. The 230kV circuits (Q23BM, Q24HM, Q25BM, Q26M, Q28A, Q29HM, Q30M, and Q35M) from Sir Adam Beck #2 SS connect this region to Hamilton/Burlington. The power is distributed through thirteen (13) HONI and six (6) LDC owned step-down transformer stations (please see Appendix B for a complete list. The distribution system in this Region is at two voltage levels, 27.6 kV and 13.8 kV. An electrical single line diagram for the Niagara Region transmission facilities is shown in Figure 3-1. The circuits and stations are provided in Table 3-1.

Table 3-1: Station and Circuits in the Niagara Region

115kV circuits	230kV circuits	Hydro One Transformer Stations	Generation Stations
Q3N, Q4N, Q11S, Q12S, A36N, A37N, A6C, A7C, D9HS, D10S, D1A, D3A, Q2AH	Q23BM, Q24HM, Q25BM, Q26M, Q28A, Q29HM, Q30M, Q35M, Q10P	Allanburg TS*, Beamsville TS, Bunting TS, Carlton TS, Crowland TS, Dunnville TS, Glendale TS, Kalar MTS, Niagara Murray TS, Niagara West MTS, NOTL York MTS, NOTL #2 MTS, Port Colborne TS, Stanley TS, Thorold TS, Vansickle TS, Vineland DS, CNPI Station #17 MTS, CNPI Station #18 MTS	Sir Adam Beck GS #1, Sir Adam Beck GS #2, Sir Adam Beck PGS, Thorold CGS, Decew Falls GS

*Station with Autotransformers installed

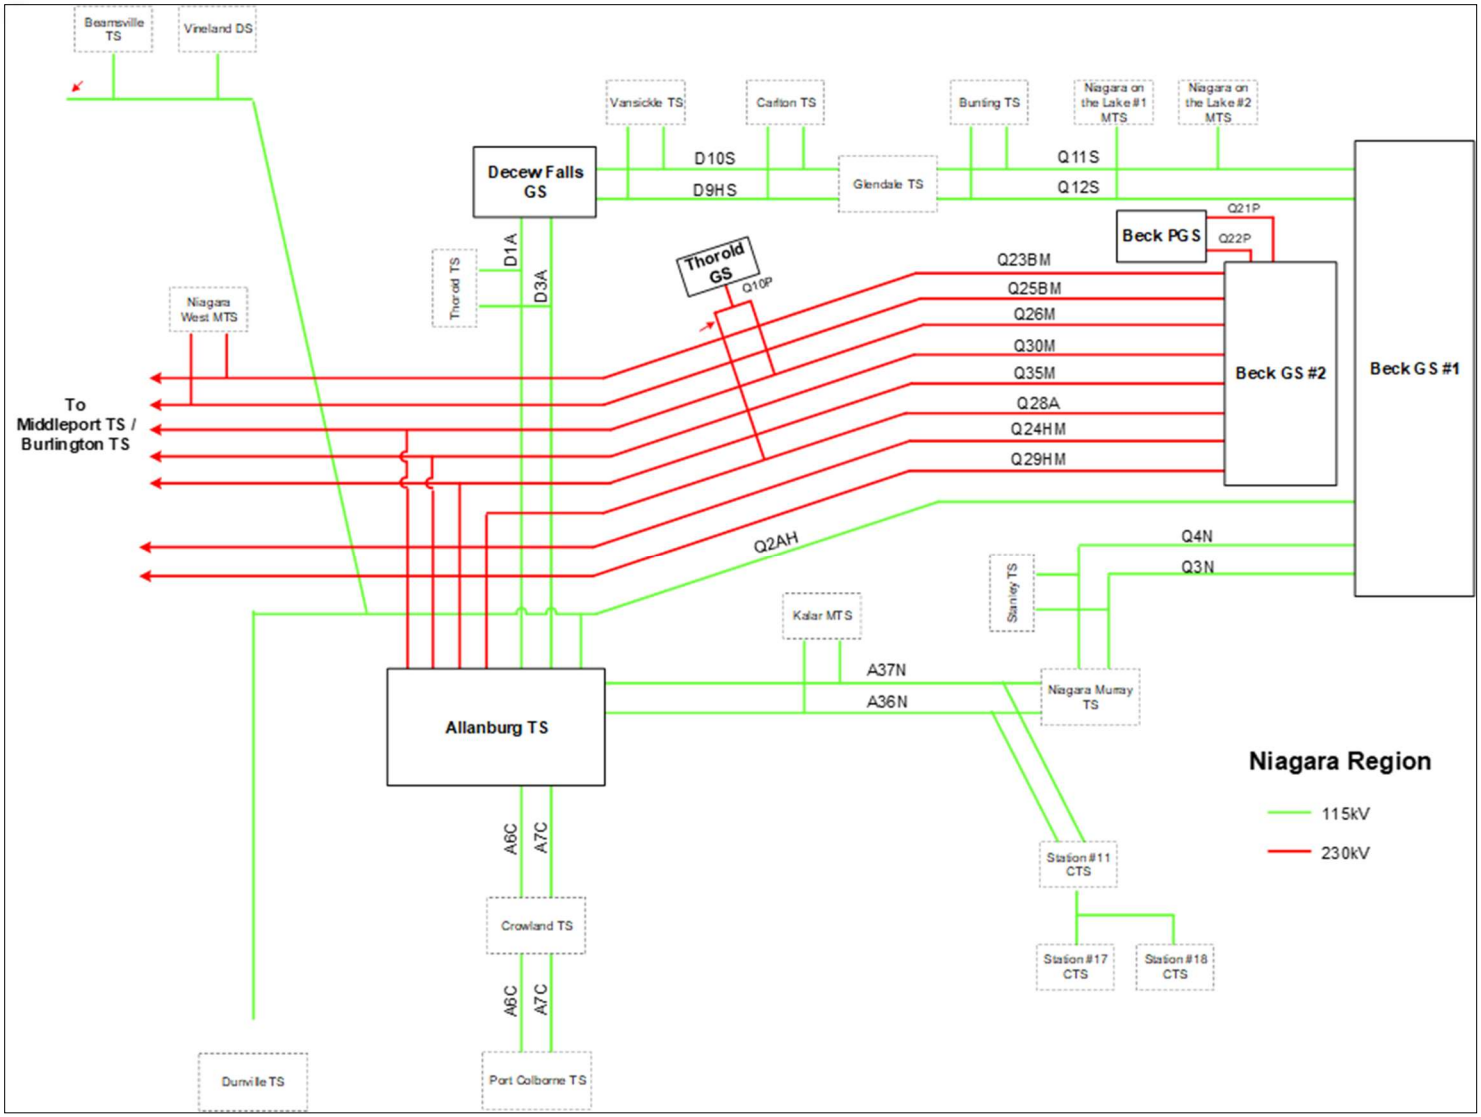

Figure 3-1: Niagara Region Single Line Diagram

4 TRANSMISSION FACILITIES COMPLETED AND/OR UNDERWAY IN THE LAST TEN YEARS

IN THE LAST TEN YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND UNDERTAKEN BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY CAPABILITY AND RELIABILITY IN THE NIAGARA REGION.

A summary and brief description of the major projects completed and/or currently underway over the last ten years is provided below:

Projects Completed

- Decew Falls SS (2017) – Existing five (5) 115kV breakers were replaced with sulfur hexafluoride (SF6) equivalent breakers to improve supply reliability.

- Q4N Line Section Upgrade (2019) – Line section of 115kV Q4N circuit between Beck SS #1 x Portal Junction section (egress out from the generation station) was upgraded to meet load supply needs.

- A6C Line Section Refurbishment (2020) –115kV A6C circuit line conductor between Crowland TS and Port Colborne TS was replaced. The conductor needed replacement due to its asset condition.

- Stanley TS (2022) – Existing 40/53/67 MVA T2 transformer was replaced with a 45/60/75 MVA unit. This transformer needed replacement due to asset condition. Work at 13.8kV switchyard components and protection and control equipment were also replaced due to asset condition.

- Port Colborne TS (2022) – Existing T61 and T62 28/37/47 MVA transformers was replaced with 50/66.7/83.3 MVA units. These transformers needed replacement due to asset condition. The 27.6kV switchyard components and protection and control equipment were also replaced due to asset condition to improve the reliability of supply.

5 LOAD FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

A detailed load forecast for the Niagara region was developed as part of the area IRRP study. The TWG participants, including representatives from LDC's, IESO and Hydro One provided information and input for the IRRP Load forecast.

The IRRP forecast used in this RIP study includes minor increases at a few stations as per the LDCs[2]. Also included is a LDC connected industrial customer with curtailable load under specific outage conditions.

The load in the Niagara Region is expected to grow at an average rate of approximately 2.3% annually from 2023 to 2032. However, a major portion of this load increase is due to industrial customers. The growth rate for the LDCs, not accounting for the industrial customers, is about 1.3%. Longer term growth rate between 2033 to 2042 for all customers is forecast to be about 0.9%.

Figure 5-1 shows the Niagara region extreme summer weather net forecast from 2023-2042. The forecast shown is the regional non-coincident forecast and shows the load for all Niagara customers as well as the load for all the LDCs. The regional non-coincident peak load is forecast to increase from approximately 1092MW in 2023 to about 1505MW in 2042.

[2] Loading at Crowland TS adjusted as per new forecast from Welland Hydro. Loading at NOTL #2 MTS and NOTL York MTS adjusted as per new forecast from NOTL Hydro.

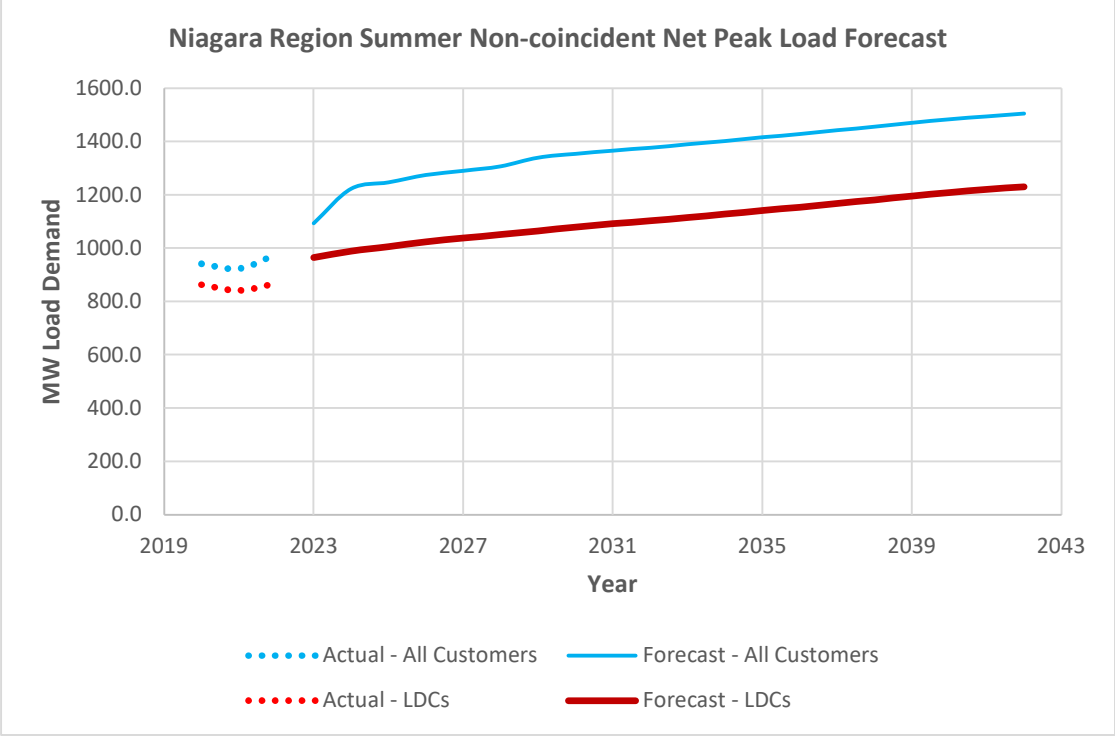

Figure 5-1: Niagara Region Summer Non-Coincident Weather Corrected Forecast

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2023-2032. However, a longer term forecast up to 2042 is provided to identify long-term needs and align with the Niagara region IRRP.
- LDCs reconfirmed load forecasts up to 2041. The additional year of forecast to 2042 was extrapolated to complete the 20 year period.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings for this region. The assessment is therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, where the power factor used for the load stations are from the IRRP Appendix G.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR).
- Bulk transmission line capacity adequacy is assessed by using coincident peak loads in the area. Radial line adequacy is assessed using non-coincident peak loads.
- Adequacy assessment is conducted as per ORTAC.

6 SYSTEM ADEQUACY AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND TRANSFORMER STATION FACILITIES SUPPLYING THE NIAGARA REGION AND LISTS FACILITIES REQUIRING REINFORCEMENT OVER THE 2023-2032 PERIOD.

In the current regional planning cycle, the three regional assessments were completed for the Niagara Region and their findings were used as inputs to this RIP report. These assessments are:

- Niagara Region Needs Assessment (NA) Report, May 2021.
- Niagara Region Scoping Assessment (SA) Report, August 2021
- Niagara Region Integrated Regional Resource Plan (IRRP), December 2022 and Appendices, February 2023

The NA and IRRP reports identified several needs because of the forecasted load demand and condition of major high voltage transmission assets. This section reviews the adequacy of the transmission lines and stations in the Niagara Region based on the updated regional load forecast provided in Appendix C. Sections 6.1 to 6.3 present the results of this review. Asset replacement needs identified in the previous NA report are discussed in Section 6.4 of this report. Load security and load restoration needs are discussed in Section 6.5.

6.1 230 kV and 115kV Transmission Circuits

All 230 kV transmission circuits in the Niagara Region are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the Ontario's transmission system, carry power from the Niagara River Generation to the rest of Ontario and are part of the interconnection path that connects Ontario to neighboring New York State at the Beck 2 SS. The 230 kV circuits Q26M, Q28A, Q30M and Q35M circuits also supply the 230/115 kV autotransformer station at Allanburg TS to serve local area stations within the region. The power flow on these circuits depend on the bulk system transfers as well as the local area loads.

Over the study period 2023-2032 the RIP reviewed the capacity of all the 230kV and 115kV Transmission lines within the Niagara Region. The NA and IRRP studies had previously indicated that the following Transmission lines require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast and following contingencies, the Transmission lines which require capacity relief during the study period are shown in Table 6-1 below. The need date defines the time when the peak load forecast exceeds the most limiting summer Limited Time Ratings. Mitigation measures are discussed in Section 7.1.

Table 6-1: Niagara Region - Lines Sections Exceeding Ratings

No.	Voltage	Line	Section	Contingency	Line Rating MW	Need Date
1	230kV	Q28A	Beck 2 x Abitibi Jct.	N-2[1]	386	2024[2]
2	115kV	A6C/A7C	Allanburg TS x Crowland TS	N-1	214	2029

1. Loss of double circuit line Q26M/Q35M
2. Need date dependent on customer forecast load increase

6.2 230/115kV Transformation Facilities

Almost ninety percent of the Niagara Region load is supplied from the 115 kV transmission system. This power is supplied to the 115kV system through the four 230/115 kV autotransformers at Allanburg TS together with 115kV generation at Sir Adam Beck #1 GS and Decew Falls GS.

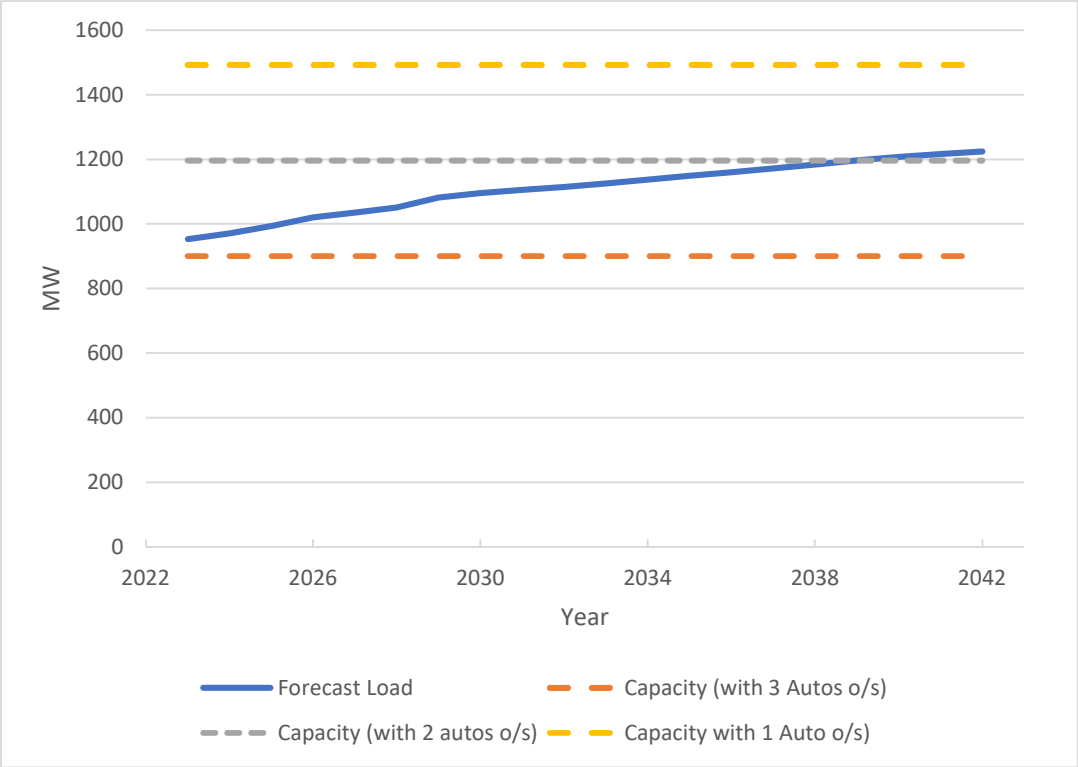

Figure 6-1: Niagara Region – 115kV Area Load and Supply Capacity

The forecast loading on the 115kV system is shown in Figure 6-1, together with the supply capacity with one, two and three autotransformers out of service at Allanburg TS and the local 115kV generation at 605MW[3]. There is adequate supply capacity in the region for the loss of up to 2 of the 4 autotransformers beyond the 2023-2032 RIP study period. However, since the autotransformers are connected to the 230kV circuits directly – loss of up to three autos can occur under an outage condition followed by a double circuit line outage – resulting in load exceeding supply capacity (N-1-2 contingency). Mitigation measures to address this issue are described in Section 7.2.

6.3 Step Down Transformation Facilities

There are a total of twenty-six (26) step-down transformer stations supplying power to customers in the Niagara Region as listed in Table 6-2. These include thirteen stations owned by Hydro One, six by area LDCs and seven (7) by direct industrial customers. The stations' summer peak load forecast is given in Appendix D Table D-1.

Table 6-2: Niagara Region - Step-Down Transformer Stations

Allanburg TS	CNPI Station #18 MTS	Murray TS	Stanley TS
Beamsville TS	Crowland TS	Niagara West MTS	Thorold TS
Bunting TS	Dunnville TS	NOTL #2 MTS	Vansickle TS
Carlton TS	Glendale TS	NOTL York MTS	Vineland DS
CNPI Station #17 MTS	Kalar MTS	Port Colborne TS	CTS #1
CTS #2	CTS #3	CTS #4	CTS #5
CTS #6	CTS #7		

Over the study period 2023-2032 the RIP reviewed the capacity of all the 230kV and 115kV transformer stations within the Niagara Region. The NA and IRRP studies had previously indicated that the following stations require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast, the stations which require capacity relief during the study period are shown in Table 6-3.

[3] Beck GS #1 is assumed at 490MW and Decew Falls GS at 115 MW.

The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer) Limited Time Ratings. Mitigation measures to address this issue are described in Section 7.3.

Table 6-3: Niagara Region Station Capacity Needs in the Study Period

No.	Station Name	Capacity (MVA)	2023 Loading (MW)	Station 10- day LTR (MW)	Need Date
1	Beamsville TS	25/42	64.2	59.0	2023
2	Murray TS T11/T12	45/75	77.7	73.2	2023
3	Niagara West MTS	40/67	54.6	66.0	2024
4	Crowland TS	50/83	100.9	101.7	2024
5	Carlton TS	45/75	89.2	95.4	2029

6.4 Asset Replacement Needs for Major High Voltage (HV) Transmission Equipment

Several Hydro One facilities in the Niagara Region will require asset renewal work over the 2023-2032 study period. These needs are determined by asset condition based on a range of considerations such as equipment deterioration, technical obsolescence due to outdated design, lack of spare parts availability or manufacturer support, and/or potential health and safety hazards.

Asset replacement work is planned over the study period at area transformer stations and lines listed in Table 6-4. The options and preferred solutions to address these needs are discussed further in Section 7.4 of the report.

Table 6-4: Niagara Region - Planned Replacement Work

No.	Station	Planned I/S Date
A - Station Work		
1	Thorold TS	2024
2	Glendale TS	2027
3	Murray TS T11/T12	2027
4	Carlton TS	2027
5	Crowland TS	2027
6	Bunting TS	2029
7	Murray TS T13/T14	2031
8	Vansickle TS	2032
9	Allanburg TS	2032
B – Lines Work		
1	115kV D1A/D3A	2024
2	115kV Q2AH	2025

6.5 Load Security and Load Restoration Needs

Load security and load restoration needs were reviewed as part of the current study and one load security need has been identified for the region. The ORTAC requires that not more than 150MW of load may be interrupted by planned load curtailment or load rejection and the Allanburg Load Rejection scheme does not meet the criteria.

6.5.1 A6C/A7C Load Security

The loss of the 230kV double circuit line Q26M/Q28A, will result in the coincidental loss of autotransformers T1 and T2 at Allanburg TS and the separation of the 115kV A6C/A7C and D1A and A36N circuits from the Allanburg TS 115kV bus. Under this scenario the Allanburg Load Rejection scheme trips the A6C and A7C circuits to prevent loads connected to the A6C/A7C circuits from excessive voltage declines. The load on the A6C/A7C is currently about 200MW and forecast to increase to 278MW by the end of the plan period. The amount of load rejected is thus more than the permitted amount of 150 MW allowed under ORTAC. Mitigation measures to address this need are discussed in Section 7.5.

7 REGIONAL PLANS

THIS SECTION DISCUSSES NEEDS, PRESENTS WIRES ALTERNATIVES AND THE PREFERRED WIRES SOLUTIONS FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS FOR THE NIAGARA REGION.

The electrical infrastructure needs for the Niagara Region are summarized in Table 7-1. These needs include those previously identified in the Niagara Region NA and IRRP as well as those resulting from the adequacy assessment carried out as part of this RIP report. The details of the project/plan to address these needs are provided in Sections 7.1 through 7.5.

Table 7-1: Niagara Region – Identified Near and Medium-Term Needs

Section	Facilities	Need	Timing
Transmission Line Capacity Needs			
7.1.1	Q28A -Beck 2 TS to Abitibi Jct.	Line Capacity Exceeded	2024
7.1.2	115 kV Circuits A6C and A7C – Allanburg TS to Crowland TS	Line Capacity Exceeded	2029

7.4	115kV Line Q2AH	Rosedene Jct. x St. Anns Jct.	2025
Load Security			
7.5	115kV A6C/A7C Load Security	Forecast exceeds ORTAC load rejection Criteria	2023

7.1 Transmission Line Capacity

This section describes work required to address the transmission line capacity needs associated with the 230kV circuit Q28A and 115kV circuits A6C and A7C as described in Section 6.1.

7.1.1 230kV circuit Q28A – Beck #2 TS x Abitibi Junction

7.1.1.1 Introduction

The 230kV circuit Q28A is part of the eight transmission circuits egressing from Beck #2 GS and connects to Allanburg TS. The planning forecast based on new customer load indicates that the loading will exceed the circuit 980A rating by summer 2024 for a loss of the double circuit line Q26M/Q35M.

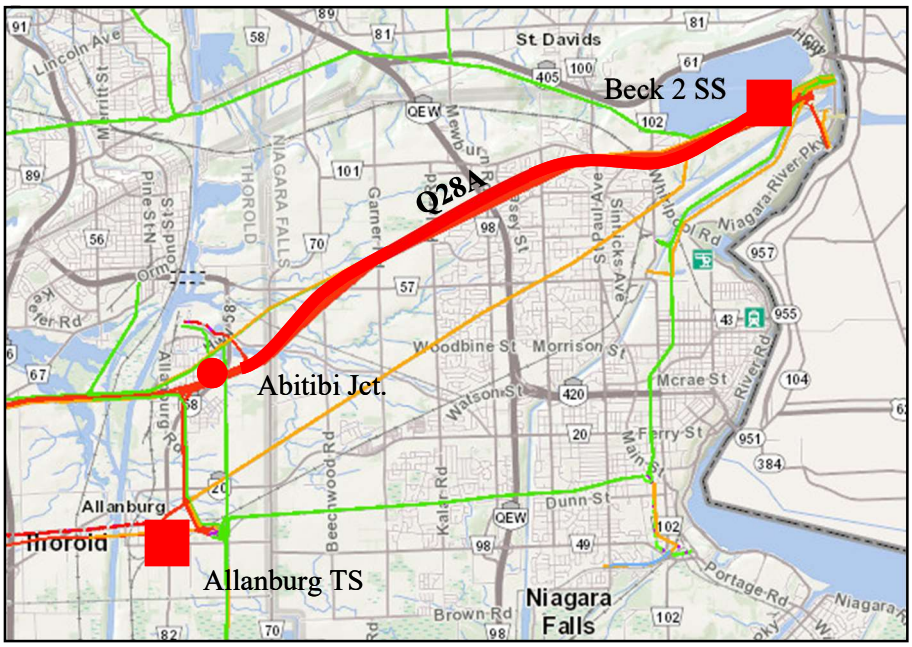

Figure 7-1: Uprate Q28A Circuit

7.1.1.2 Alternatives and Recommendation

The following alternatives were considered to address the 230kV circuit Q28A capacity need:

- **Alternative 1 – Maintain Status Quo:** This alternative is not viable as it does not address meeting the area customers' load requirements. It is therefore not considered further.
- **Alternative 2 – Uprate 230kV Q28A Circuit:** This alternative considers uprating the conductor by tensioning the conductors to reduce the line sag and allow the line conductor to operate at a higher temperature. This will increase the circuit rating from 980A to 1310A. The estimated cost of the work is about $3M.

The TWG recommends Alternative 2 as the preferred and cost-effective alternative for increasing the capacity of the line. Hydro One has advised the customer of the proposed work and will initiate the work once confirmed by the customer.

7.1.2 115 kV Circuits A6C and A7C – Allanburg TS to Crowland TS

7.1.2.1 Introduction

The 115 kV double circuit line A6C/A7C supplies Crowland TS and Port Colborne TS along with several directly connected transmission customers as shown in Figure 7-2. The load connected on this line is forecast to exceed the line capacity by summer 2029 as shown in Table 7-2.

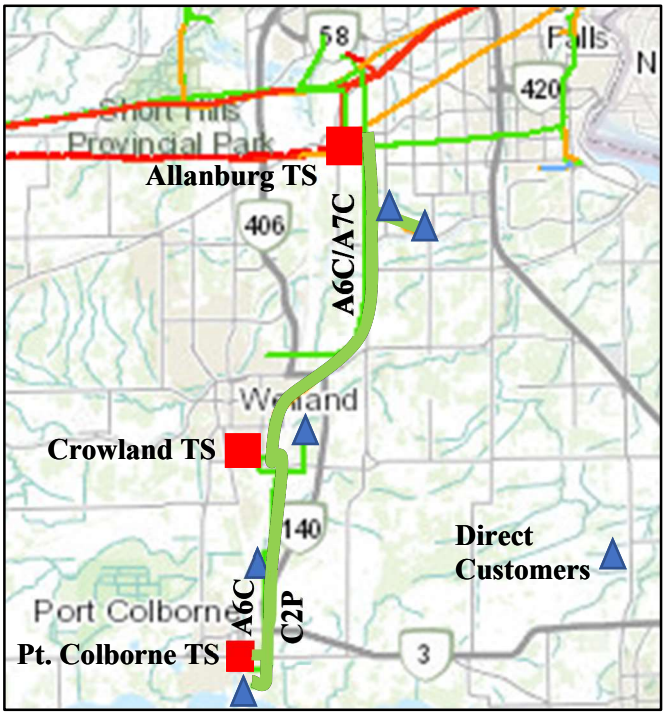

Figure 7-2: Map of 115kV A6C/A7C Circuits

Table 7-2: 115kV circuit A6C/A7C -Connected Loads

Load	Circuit Limit	Act.[1]	Load Forecast											Need Date
		2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2042	
A6C/A7C[2]	213.9[3]	169.5	174.0	182.4	191.6	202.2	206.8	211.6	232.7	234.9	236.8	236.9	246.1	2029
Crowland TS		93.6	100.9	108.8	110.6	112.6	114.1	115.9	117.6	119.6	121.3	121.2	128.5	---

1. Actual summer load adjusted for extreme weather
2. Loading excludes Allanburg TS DESN
3. Rating of A6C/A7C circuit between Allanburg TS DESN and Crowland TS

4. After Crowland TS conversion to 230KV as per Section 7.3.2 in 2027

7.1.2.2 Alternatives and Recommendation

The following alternatives were considered to address the overloading issue on the 115kV line A6C/A7C line:

- **Alternative 1 – Maintain Status Quo:** This alternative is not viable as it does not address meeting the area customers' load requirements. It is therefore not considered further.
- **Alternative 2 – Uprate the A6C and A7C Circuits:** This alternative considers reconductoring the A6C/A7C line between Allanburg TS and Crowland TS (~ 14.5 km) using a higher rated conductor. This will increase the circuit rating from 214 MW to about 280 MW. The estimated cost of the work is $23M.
- **Alternative 3 – Reduce Loading on A6C/A7C:** This alternative reduces loading on circuits A6C and A7C by rebuilding Crowland TS[4] as a 230/27.6 kV station supplied from and supplying it from a new 230kV circuit line.

The TWG recommends Alternative 3 as the preferred and cost-effective alternative addressing the overloading issue on the A6C/A7C line. Transferring of Crowland TS to a 230 kV supply also addresses multiple other issues; reduces load on the Allanburg TS autotransformers (See Section 7.2.2), allows increase capacity at Crowland TS (see Section 7.3.2), and reduces the severity of the load security issue (Section 7.5).

7.2 115kV Supply Area Capacity

7.2.1 Introduction

As shown in Section 6.2, the loads on the Niagara Region 115kV system exceeds the 115 kV system supply capability under certain contingency conditions which result in three out of the four autotransformers being out of service at Allanburg TS. Specifically, this occurs under a 230kV outage condition followed by a double 230kV circuit line outage (N-1-2 contingency).

7.2.2 Alternatives and Recommendation

The following alternatives were considered to address the 115 kV supply capacity:

- **Alternative 1 – Maintain Status Quo:** This alternative is not viable as it does not address meeting the area customers' load requirements. It is therefore not considered further.

[4] Crowland TS needs to be refurbished and will be rebuilt. Please refer to Section 7.3.2 and 7.4 for more details.

- **Alternative 2 – Modify Existing Load Rejection Scheme for 115kV Subsystem:** This alternative modifies the Allanburg load rejection scheme to include rejection of up to 150MW of load whenever three autotransformers are out. The estimated cost of this alternative is about $8M.
- **Alternative 3 – New 230kV Switchyard at Allanburg TS:** The work required in this alternative is to build a new 230kV switchyard to eliminate the N-1-2 contingency at Allanburg TS (loss of three autotransformers contingency) to supply more power to the 115kV network. The work required would consist of four new 230kV bus diameters, each accommodate an autotransformer to eliminate any coincidental loss of the autotransformers. This work has an estimated cost of $253M.
- **Alternative 4** – **Reduce load on 115kV system by introducing 230kV Supply to the Welland Area** - This alternative would transfer Crowland TS to 230kV supply by building a 18km double circuit 230kV transmission line from Q24HM/Q29HM to connect to a new 230/27.6kV transformer station at the Crowland TS site. The new TS will replace the existing station that requires replacement. This work has an estimated cost of $128M.

The TWG recommends Alternative 4 as the most cost effective and preferred alternative. Besides addressing the 115kV supply capacity needs, this alternative also addresses; the A6C/A7C overloading issue (Section 7.1.2); the Crowland TS capacity needs (Section 7.3.2); the Crowland TS asset renewal needs (Section 7.4); and reduces the severity of the A6C/A7C load security issue (Section 7.5). The work is planned to be in service by summer 2027.

7.3 Station Capacity Needs

This section describes the work required to address the station capacity needs identified in Section 6.3.

7.3.1 Beamsville TS, Vineland DS, Niagara West MTS – 115kV Lincoln Area

7.3.1.1 Introduction

Beamsville TS and Vineland DS are 115/27.6kV stations and Niagara West MTS is a 230/27.6kV station which supplies the towns of Grimsby, West Lincoln, and Lincoln. The area is experiencing load growth where the summer weather extreme demand forecast will exceed the area normal supply capacity.

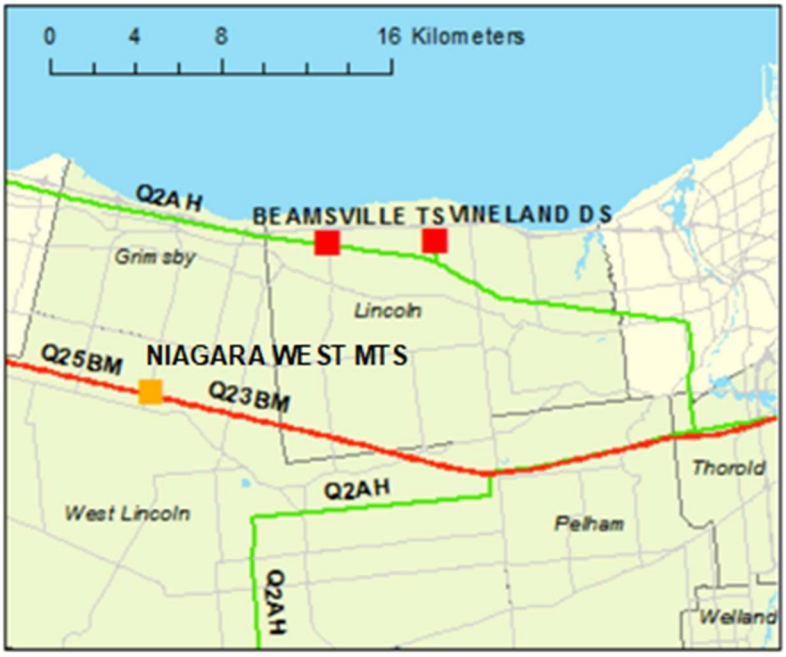

Figure 7-3: Map of 115kV Lincoln Area

Beamsville TS presently has 115kV/27.6kV 42MVA transformers (T3/T4) with a summer LTR of 59.0MW. This station has operated at or slightly over the LTR over the past few years.

Table 7-3 shows the forecast for the three area stations. The forecast shows that the combined capacity of the three stations would be exceeded by summer 2024. The TWG agrees that a solution is required to address the upcoming supply capacity needs.

Table 7-3: 115kV Lincoln Area Stations Load Forecast

Station	LTR MW	Act.[1]	Load Forecast											Need Date
		2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2042	
Beamsville	59.0	63.1	77.2	79.2	80.5	81.4	82.1	82.9	83.7	84.6	85.6	86.5	101.9	---
Niagara West MTS[2]	63.4	41.6	49.0	56.8	57.6	58.2	58.9	60.3	61.7	63.2	64.7	66.2	84.3	---
Vineland DS	26.4	20.5	20.7	20.9	21.1	21.3	21.6	22.5	23.5	24.5	24.7	25.0	27.6	---
Total	148.8	125.3	147.0	156.9	159.2	161.0	162.5	165.7	168.9	172.3	175.0	177.7	213.8	2024

1. Actual summer load adjusted for extreme weather

7.3.1.2 Alternatives and Recommendation

The following alternatives were considered to address the area capacity need:

- **Alternative 1 – Maintain Status Quo:** This solution is not recommended as it does not address the supply capacity needed in the area. This solution will also prevent load growth in this area.

- **Alternative 2 – Load Transfer to Neighbouring Stations:** This solution is not viable as there is no nearby station where the load can be transferred.
- **Alternative 3 – Replace Beamsville and Niagara West transformers:** Replace existing Beamsville TS T3/T4 transformers and Niagara West MTS T1/T2 with larger 50/83MVA units, providing total additional capacity of 100 MW at both stations to address the existing and future load demand. Additional feeder positions will be required at both stations to utilize the additional capacity. The cost of this work is estimated to be about $48M.
- **Alternative 4 – Build new 230/27.6kV DESN station in Local Area:** This alternative would build a new 230/27.6kV DESN station to supply the increased load demand forecast required in the local area. The new station would be supplied by the double circuit 230kV transmission line Q23BM/Q25BM with new 50/83MVA transformers. The new station will provide about 102 MW of new capacity. The estimated cost of this alternative is about $45M.

The TWG recommends proceeding with Alternative 4. This alternative provides a robust transmission solution to meeting the area LDCs demand forecast and will also allow for future load growth beyond the study period on the 230kV system. This solution will also provide better reliability for future loads as the new station will have dual incoming transmission supplies into station instead of being on a single supply like Beamsville TS. Loads will be managed by the respective LDCs between 2024 and 2027 when the new facility is expected to go into service.

Hydro One will work with all the respective parties to find a suitable location to meet the load. Possible locations could be an expansion at Niagara West MTS or a location central to Vineland DS and Beamsville TS to supply local growth (e.g., the southwest corner in the Town of Lincoln).

7.3.2 Crowland TS

7.3.2.1 Introduction

Crowland TS is a 115/27.6kV 50/83MVA transformer station located in Welland. The station load is at or near its 10-day LTR of 101.7 MW and load is forecasted[5] to increase up to 121MW by the end of 2032 as shown in Table 7-4 below. A permanent supply solution is required for the increased load growth as the current loading will surpass the station capacity in 2024.

The transformers, T5 and T6, at Crowland TS are about 55 years old and based on asset condition assessment Crowland TS has been identified for asset renewal by summer 2027.

[5] Forecast updated from IRRP as per Welland Hydro

Figure 7-4: Map of Crowland TS

Table 7-4: Crowland TS Load Forecast

Station	LTR MW	Act.[1]	Load Forecast											Need Date
		2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2042	
Crowland TS	101.7	93.6	100.9	108.8	110.6	112.6	114.1	115.9	117.6	119.6	121.3	121.2	128.5	2024

1. Actual summer load adjusted for extreme weather

7.3.2.2 Alternatives and Recommendation

The following alternatives were considered to address Crowland TS capacity need:

- **Alternative 1 – Maintain Status Quo:** This alternative was considered and rejected as it does not provide supply capacity to area customers during the study period. Under this scenario load cannot be increased at this station.
- **Alternative 2 – Rebuild existing DESN at Crowland TS and add a second DESN at Crowland TS:** Under this alternative the existing Crowland TS transformers will be replaced, and the station refurbished. A new second DESN would be built to handle the increased load. This alternative would maintain the existing 115kV loading on the Allanburg autotransformers and work will be required to address the issue. Work also would be required to address the capacity need on the A6C/A7C circuits and address the load security concern at Allanburg TS. This alternative is estimated to cost $78M for the refurbishment work and new DESN at Crowland TS. An additional $253M will be required to provide additional switching at Allanburg TS to reinforce the 115kV supply.

- **Alternative 3 – Provide a new 230kV Supply to Welland Area and convert Crowland TS to 230kV:** Under this alternative the existing Crowland TS would be replaced with a new 230/27.6 kV DESN station with 75/125 MVA transformers to supply the increased load demand. A new 18km double circuit 230kV transmission line will be constructed to supply this new transformer station from the double circuit 230 kV line Q24HM/Q29HM. This new station would allow the station LTR to increase to approximately 170 MW (summer) with 75/125MVA transformers. The estimated cost of this alternative is about $128M.

The TWG recommends Alternative 3 as it is the lowest cost alternative. It provides new area transmission and load growth opportunities. The conversion of Crowland TS to 230kV will reduce the loading on the 115kV autotransformer at Allanburg TS, alleviating the constrained supply to the 115 kV sub-system described previously. It will also remove the existing Crowland TS loads from the 115kV A6C/A7C circuits, alleviating the severity of the load security constraint at Allanburg TS. This alternative will also provide a parallel opportunity for load growth on the 115kV A6C/A7C circuits as the Crowland TS load is removed from the 115kV system.

7.3.3 Murray TS and Kalar MTS – Niagara Falls

7.3.3.1 Introduction

Murray TS and Kalar TS are two transformer stations located in Niagara Falls. Murray TS has two 115/13.8 DESNs, T11/T12 and T13/T14, with a summer LTR of 73.2MW and 79.8MW respectively. Kalar MTS has one 115/13.8 kV DESN with a summer LTR of 72.0 MW. The stations forecast loads are given in Table 7-5. Considerable new loads are expected to connect in the area. Loading on the Murray TS T11/T12 DESN is forecast to exceed its LTR by summer 2023. Loading on Kalar MTS is forecast to exceed LTR by summer 2028.

The Murray TS transformers, T11, T12, T13 and T14 are between 46 and 52 years old and have been identified for replacement due to asset condition. It is planned to replace T11 and T12 by summer 2027. This will be followed by the replacement of the T13 and T14 transformers by summer 2031.

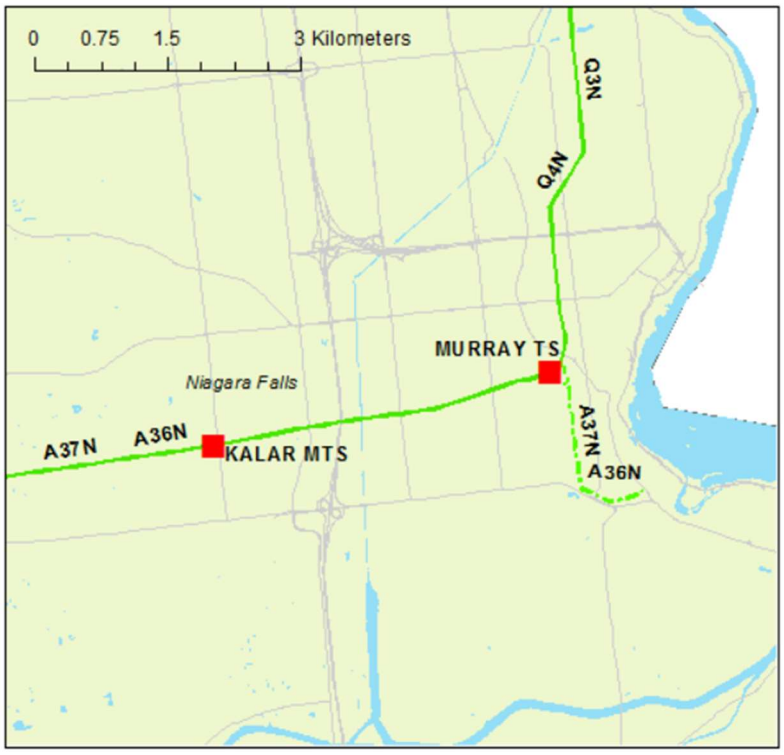

Figure 7-5: Map of Murray TS and Kalar MTS

Table 7-5: Murray TS, and Kalar MTS Load Forecast

Station	LTR MW	Act[1]	Load Forecast											Need Date
		2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2042	
Murray TS T11/T12	73.2	66.3	77.7	77.7	77.8	78.0	77.9	78.1	78.3	78.7	78.9	79.1	86.2	2023[2]
Murray TS T13/T14	79.8	41.7	42.0	42.2	42.4	42.6	42.9	43.1	43.3	43.5	43.8	44.0	46.6	Note[3]
Kalar MTS	72.0	46.5	46.9	47.4	54.2	60.7	64.4	65.8	67.1	68.6	68.8	69.0	75.1	2039
Total	225.0	166.3	166.6	167.3	174.4	181.3	185.2	187.0	188.7	190.8	191.5	192.1	207.9	

1. Actual summer load adjusted for extreme weather
2. Earliest replacement to happen by 2027
3. The transformers T13 and T14 will be replaced in 2031as per asset condition.

7.3.3.2 Alternatives and Recommendation

The following alternatives were considered to address the current and future capacity need:

- **Alternative 1 – Maintain Status Quo:** This alternative was considered and rejected as it does not address the need as the near and mid-term load forecast exceeds the LTR at Murray TS T11/T12. Asset renewal needs are also not addressed.
- **Alternative 2 – Replace T11/T12 at Murray TS with 60/100MVA transformers:** This alternative would replace the T11/T12 transformers with larger 60/100MVA transformers, with an approximate

LTR of 130MW instead of the 45/60/75MVA units specified for the asset renewal project at Murray TS. This will increase supply capacity of approximately 43MW at Murray TS at an estimated incremental cost of $2M to the asset renewal upgrade cost of $39M. The earliest this work can be done is summer 2027.

- **Alternative 3 – Transfer T11/T12 load to T13/T14 at Murray TS:** This alternative would transfer load from T11/T12 to T13/T14 at a cost of $5M. The T13/T14 bus supplies a large industrial load customer with fluctuating load and customers connected to the bus would experience power quality issues.
- **Alternative 4 – Build new 115kV/13.8kV Station near Kalar MTS:** This alternative would build a new 115/13.8kV DESN station with 25/41.7MVA transformers to supply the increased load demand forecast required at Kalar MTS and Murray TS T11/T12. This new station would provide the station an LTR of 51MW (summer). The estimated cost for this alternative is expected to be $40M.

The TWG recommends Alternative 2 as the preferred alternative for addressing the capacity need as it is the most economical alternative with the ability to increase supply capacity. Alternative 3 is not recommended since is more expensive, will introduce power quality issues to the transferred load and is not acceptable to the LDC. Loading will be monitored and managed at Murray TS by the LDC and Hydro One in the interim before the additional capacity is provided in 2027. The Kalar MTS load growth will be monitored to verify if the actual summer peak loads are close to the mid-term forecast. When the actual load is approaching the forecast, the respective LDC will re-evaluate and can transfer the extra load from Kalar MTS to Murray TS.

7.3.4 Carlton TS and Bunting TS – St. Catharines

Carlton TS and Bunting TS are two transformer stations located in St. Catharines. Carlton TS has one 115/13.8 kV T1/T2 DESN with a summer LTR of 95.4 MW. Bunting TS has one 115/13.6 kV T1/T2 DESN with a summer LTR of 78.2 MW. The stations forecast loads are given in Table 7-6. Loading on Carlton TS is forecast to exceed its LTR by summer 2029. Bunting TS is adequate over the study period.

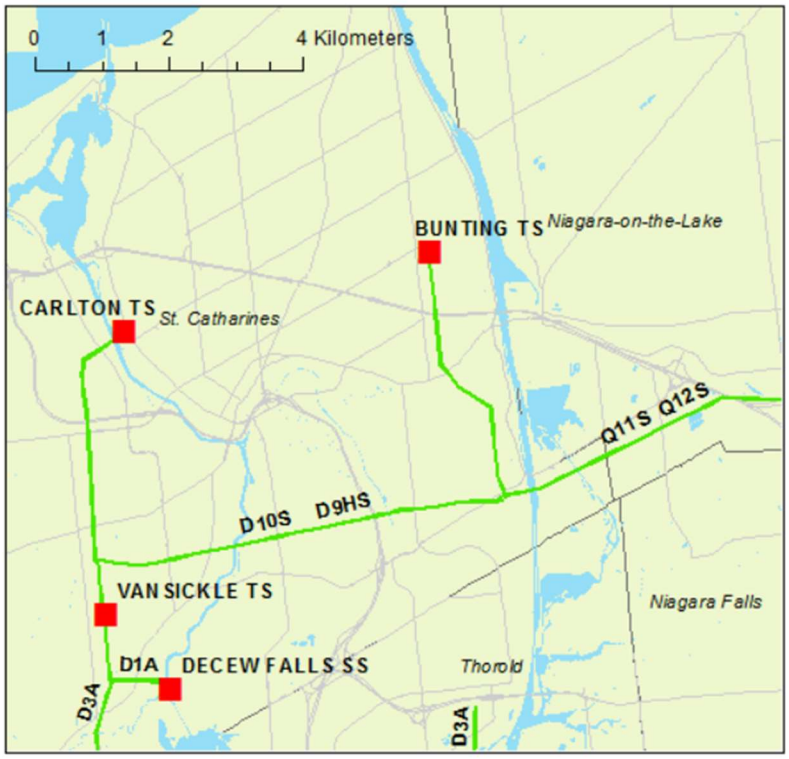

Figure 7-6: Map of Carlton TS and Bunting TS

Table 7-6: Carlton TS and Bunting TS Load Forecast

Station	LTR MW	Act. [1]	Load Forecast											Need Date
		2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2042	
Carlton TS	95.4	82.6	89.2	90.1	91.1	92.2	93.3	94.6	95.9	97.3	98.9	100.3	105.7	2029
Bunting TS	78.2	54.4	57.8	58.3	58.8	59.6	60.4	61.4	62.4	63.6	64.7	65.9	77.1	---
Total	173.6	137.0	147.1	148.4	149.9	151.8	153.7	156.0	158.3	160.9	163.6	166.2	182.8	----

1. Actual summer load adjusted for extreme weather

Both Carlton TS and Bunting TS also have renewal work planned. The LV switchyard at Carlton TS is over 50 years old and refurbishment is required. The Transformer T3 at Bunting TS is also over 50 years and identified for replacement.

7.3.4.1 Alternatives and Recommendation

The following alternatives were considered to address the current and future capacity need:

- **Alternative 1 – Maintain Status Quo:** This alternative was considered and rejected as it does not address the stations sustainment need. Carlton TS load also exceeds its LTR and action is required to address the issue.

- **Alternative 2 –Carry out Asset Renewal at Carlton TS and Bunting TS**: Monitor Carlton TS loading and transfer excess load to Bunting TS: The station refurbishment work will be carried out at both stations. Carlton TS load growth will be monitored to see if the actual summer peak loads are close to the mid-term forecast. When the actual load is approaching the forecast, the respective LDC will re-evaluate and transfer the excess load over the LTR from Carlton TS to Bunting TS. The cost to transfer the load between stations is estimated to be $5M.

The TWG recommendation is that it is prudent to monitor the area load and complete load transfer at nearby stations with available station capacity when required. The TWG recommends Alternative 2 as the preferred and cost-effective alternative for addressing the need.

7.4 Asset Replacement for Major HV Transmission Equipment

As discussed in Section 6.3, Hydro One has identified the need for replacement of major HV transmission assets over the next ten years at several Niagara Region Hydro One stations as well as two small line sections. Details of the work along with its planned in-service year is given in Table 7-7.

Table 7-7: Niagara Region – Asset Replacement Plans

No.	Station /Line	Planned Work	Planned I/S Date[1]
1	Thorold TS	Replace the existing 45/60/75 MVA T1 transformer with a new 45/60/75 MVA unit.	2024
2	Glendale TS	Replace the existing T1/T2 45/60/75 MVA transformers, with new 45/60/75 MVA units.	2027
3	Crowland TS	The existing 115/27.6 kV T5/T6 DESN will be replaced by a new 230/27.6 kV DESN rated for 170 MW.	2027
4	Murray TS	Replace the existing 45/60/75 MVA transformers T11 and T12 with new 60/80/100 MVA units. Replace the existing 45/60/75 MVA transformers T13 and T14 with new 60/80/100MVA units.	2027 2031
5	Bunting TS	Replace the existing 40/53/67 MVA transformers, with new 45/60/75 MVA units	2029
6	Vansickle TS	Replace LV Switchgear	2032
7	Allanburg TS	Replace Autotransformer T3	2032
8	115kV Line D1A/D3A	115kV kV line refurbishment of a 5 km line section between Gibson Jct and Thorold TS with conductor to be replaced due to asset condition	2024
9	115kV Line Q2AH	115kV line refurbishment of 11.2km between Rosedene Jct. and St. Anns Jct. with conductor to be replaced due to asset condition	2025

1. The planned in-service date is tentative and is subject to change

The TWG recommends that Hydro One proceed with the above work to ensure that the system meets reliability criteria and supply to customers is not affected.

7.5 Load Security – 115kV circuits A6C/A7C

As discussed in Section 6.4.1 the *Allanburg Load Rejection scheme* trips 115kV circuits A6C/A7C under certain contingencies to prevent stations supplied from these circuits being subjected to excessive voltage declines.

The *Allanburg Load Rejection Scheme* is designed to address post contingency voltage decline issues following the coincident loss of Allanburg 230/115 kV Autotransformers T1 and T2. The coincidental loss of Allanburg T1 and T2 transformers will result in circuits A6C and A7C being disconnected from the Allanburg TS 115kV and buses radially connected to circuits D1A and A36N, respectively. As such, this causes excessive voltage to decline at stations supplied from circuits 115kV A6C and A7C. The scheme rejects the load connected to circuits A6C and A7C and will prevent the radial feeds (from Decew Fall GS on D1A and the Niagara Corridor on A36N) from trying to support the load of A6C and A7C.

The load security need arises from Section 7.1 of the ORTAC. As defined under this section, Not more than 150MW of load may be interrupted by configuration and by planned load curtailment or load rejection, excluding voluntary demand management. The A6C/A7C load forecast is provided in Table 7-8.

Table 7-8: 115kV Circuit A6C/A7C -Connected loads

Load	ORTAC L/R Limit	Act.[1]	Load Forecast										
		2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2042
A6C/A7C	150	209.6	219.3	227.8	237.1	247.9	252.6	257.5	278.7	281.1	283.1	283.4	297.0
Crowland TS		93.6	100.9	108.8	110.6	112.6	114.1	115.9	117.6	119.6	121.3	121.2	128.5
A6C/A7C post Crowland[2]		-	-	-	-	-	138.5	141.7	161.2	161.5	161.9	162.2	168.5

1. Actual summer load adjusted for extreme weather
2. After Crowland TS conversion to 230KV as per Section 7.3.2

This forecast exceeds the permissible limit set by ORTAC. It also exceeds the A6C/A7C line limit for loss of one of the two circuits.

7.5.1.1 Alternatives and Recommendation

The following alternatives were considered to address the current and future capacity need:

- **Alternative 1 – Maintain Status Quo:** This alternative was considered and rejected as it does not address the ORTAC load security need.
- **Alternative 2 – Reduce Loading on A6C/A7C:** This alternative reduce loading on 115kV circuits A6C and A7C by removing Crowland TS from the A6C/A7C supply. Crowland TS is rebuilt as a 230/27.6 kV station supplied from a new 230kV double circuit line.

The TWG recommends Alternative 2 as the preferred alternative to addressing the load security issue in the ORTAC. This alternative will be partially addressed by converting Crowland TS to a 230kV supply as described in Section 7.3.2. Since the Crowland TS work will not be completed till 2027, the issue will be

managed by operational measures. Load can be restored within 15 minutes by opening both T1 and T2 disconnect switches and supplying all the Allanburg 115kV load from the remaining T3 and T4 autotransformers during a coincident T1 and T2 outage. This work reduces the severity of the load security issue. The loading on the A6C/A7C will continue to be monitored and reviewed in the next planning cycle with the option to transfer Allanburg TS DESN to 230kV.

8 CONCLUSION AND RECOMMENDATION

This Regional Infrastructure Plan report concludes the Regional Planning process for the Niagara Region.

The major Infrastructure investments recommended by the TWG in the near and mid-term planning horizon 2023-2032 are provided in Table 8-1 below, along with their planned in-service dates (ISD) and budgetary estimates for planning purposes.

Table 8-1: Recommended Plans over the next 10 Years

No.	Need	Recommended Action Plan	Lead	Timing[1]	Budgetary Estimates[2]
1	230 kV circuit Q28A – Additional capacity required	Uprate circuits between Beck 2 SS and Abitibi Jct. to meet expected load demand	Hydro One	TBD[3]	$3M
2	Loading in the Lincoln area exceeding supply capability	Build new 2 x 50/83MVA, 230kV/27.6 station	Hydro One	2028	$45M
3	Crowland TS: Station loading exceeds LTR	Build new 2 x 75/125MVA, 230kV/27.6 station and a new 18 km line from Abitibi Jct to Crowland TS	Hydro One	2027	$128M
4	Murray TS T11/T12 DESN: DESN loading exceeds LTR. Transformers T11/T12 need to be replaced	Replace existing 45/75MVA transformers with larger 60/100MVA units	Hydro One	2027	$41M
5	Carlton TS: T1/T2 DESN loading exceeds LTR	Transfer excess load to Bunting TS	Alectra	2029	$5M
6	**Asset Replacement:** Thorold TS Glendale TS Carlton TS Bunting TS Murray TS T13/T14 Vansickle TS Allanburg TS 115kV Line D1A/D3A 115kV Line Q2AH	Refurbish/replace major high voltage transmission equipment	Hydro One	 2024 2027 2027 2029 2031 2032 2032 2024 2025	 $43M $55M $55M $45M $27M $14M $20M $4M $10M

1. The planned in-service dates are tentative and subject to change
2. Costs are based on budgetary planning estimates and excludes the cost for distribution infrastructure (if required)
3. Contingent on customer

APPENDIX D: LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CEP	Community Energy Plan
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CSS	Customer Switching Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DS	Distribution Station
GS	Generating Station
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MEP	Municipal Energy Plan
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
STG	Steam Turbine Generator
TS	Transformer Station

NEEDS ASSESSMENT REPORT

Niagara Region

Needs Assessment Report
Niagara Region
July 20th 2026

Lead Transmitter:
Hydro One Networks Inc.

Prepared by: Niagara Region Technical Working Group

Page intentionally left blank.

Disclaimer

This Needs Assessment (NA) Report was prepared for the purpose of identifying potential needs in the Niagara Region and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the NA phase and b) require further assessment and regional coordination. The results reported in this NA are based on the input and information provided by the Technical Working Group (TWG) for this region at the time. Updates may be made based on the best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION Niagara Region (the "Region")

LEAD Hydro One Networks Inc. ("HONI")

START DATE: March 24th 2026 **END DATE:** July 20th 2026

The 2nd cycle Regional Planning cycle for the Niagara Region was completed in July 2023 with the publication of the Regional Infrastructure Plan ("RIP") report.

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. Considering these timelines, the 3rd Regional Planning cycle was triggered in March 2026 for this Region. The planning horizon for this Needs Assessment ("NA") is ten years. A 20-year planning assessment is undertaken in the next phases of regional planning, i.e., IRRP and RIP phases.

The purpose and scope of the NA is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group (TWG) comprises of representatives from Local Distribution Companies ("LDC"), the Independent Electricity System Operator ("IESO"), and Hydro One Transmission. They provide input and relevant information for the region and undertake a technical assessment to identify the electrical infrastructure needs in the region. They collaborate to develop both summer and winter gross and net peak electricity demand forecasts (including input from municipalities), which form the basis for the technical assessment. The following are key considerations of the technical assessment:

a) Current and future station capacity and transmission adequacy.
b) System reliability needs and operational concerns.
c) Major HV transmission equipment requiring replacement with consideration to "right-sizing"; and,
d) Sensitivity analysis to capture uncertainty in the load forecast as well as variability of demand drivers such as electrification.

In this Needs Assessment, TWG has identified the following regional needs and recommendations:

Needs that require further regional coordination.

#	Need Location	Need Description
1	Allanburg DESN TS	Load demand at Allanburg TS exceeds its capacity in 2028.
2	Carlton TS	Load demand at Carlton TS exceeds its capacity in 2028.
3	D9HS/D10S – Vansickle TS x Louth Jct	The section of the D9HS/D10S between Vansickle TS x Louth Junction is approaching its limit by 2035.

Needs that do not require further regional coordination.

#	Need Location	Need Description
1	Glendale TS T1/T2	Replace the existing T1/T2 45/60/75 MVA transformers with like-for-like units.
2	Murray TS T11/T12	Replace the existing 45/60/75 MVA transformers T11 and T12 with new 60/80/100 MVA units.
3	Murray T13/T14	Replace the existing 45/60/75 MVA transformers T13 and T14 with like-for-like units.
4	Allanburg TS T3	Replace the existing 150/250 MVA autotransformer with a like-for-like unit.
5	Vansickle TS LV Switchyard	Replace the BY MV switchgear with like-for-like unit.
6	Bunting TS T3	Replace the existing 45/60/75 MVA T3 transformer like-for-like unit.
7	115kV Q2AH – Rosedene Jct. x St. Anns Jct	Line refurbishment to address asset renewal need.

List of LDC(s) to be involved in further regional planning phases:

- Alectra Utilities
- Canadian Niagara Power
- Grimsby Power
- Hydro One Distribution
- Niagara-on-the-Lake Hydro
- Niagara Peninsula Energy
- Welland Hydro Electric System

1. INTRODUCTION

The second cycle of the Regional Planning process for the Niagara Region was completed in July 2023 with the publication of the Regional Infrastructure Plan ("RIP") report. The RIP report included a common discussion of all the options and recommended plans for preferred wire infrastructure investments to address the near- and medium-term needs.

This Needs Assessment initiates the third regional planning cycle for the Niagara Region. The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years. A flow chart of the Regional Planning Process is shown in Figure 1 below.

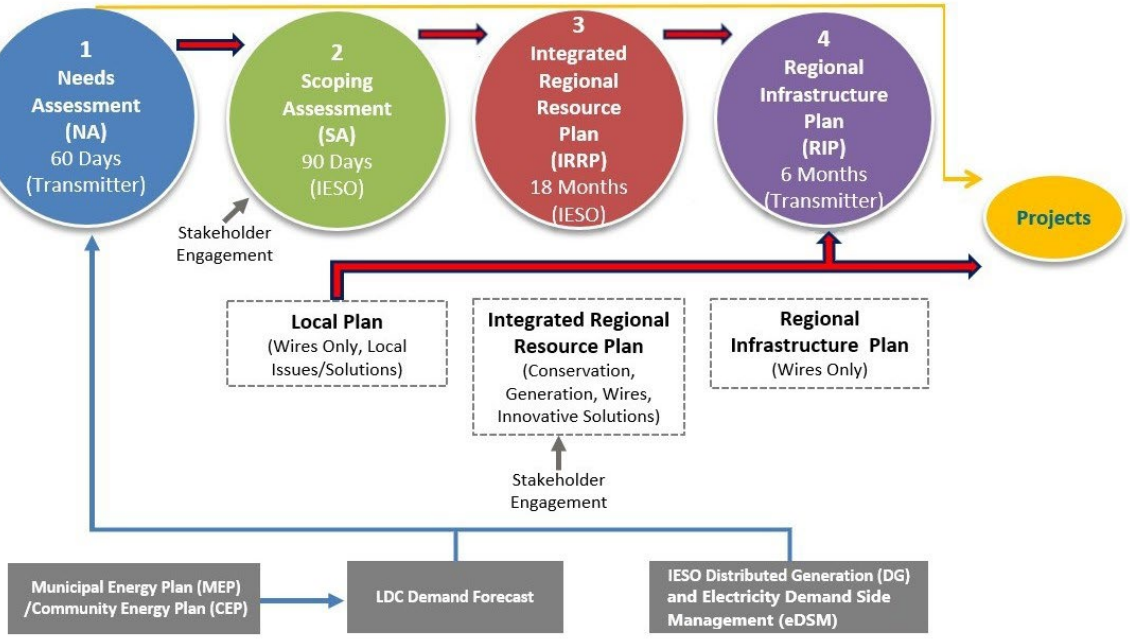

Figure 1: Regional Planning Process

This report was prepared by the Niagara Region Technical Working Group("TWG"), led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC") and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: Niagara Region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Networks Inc. (Lead Transmitter)
2	Alectra Utilities
3	Canadian Niagara Power Inc.
4	Grimsby Power Inc.
5	Hydro One Networks Inc. (Distribution)
6	Independent Electricity System Operator
7	Niagara-on-the-Lake Hydro Inc.
8	Niagara Peninsula Energy Inc.
9	Welland Hydro Electric System Corp.

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. As such, the 3rd Regional Planning cycle was triggered for the Niagara Region.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this NA covers the Niagara Region and includes:

- Review and reaffirm needs/plans identified in the previous cycle RIP (as applicable),
- Identify any new needs resulting from this assessment,
- Recommend which need(s) require further assessment and regional coordination in the next phases of the regional planning cycle to develop a preferred plan; and,
- Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no

regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), Local plan (LP) and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is 10 years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

For regional planning purposes, the Niagara region includes the City of Port Colborne, City of Welland, City of Thorold, City of Niagara Falls, Town of Niagara-on-the-Lake, City of St. Catharines, Town of Fort Erie, Town of Lincoln, Township of West Lincoln, Town of Grimsby, Township of Wainfleet, and Town of Pelham. Haldimand County has also been included in the regional infrastructure planning needs assessment for Niagara region.

The Local Distribution Companies in the Niagara Region are Alectra Utilities Corporation, Canadian Niagara Power Inc., Grimsby Power Inc., Hydro One Networks Inc. (Distribution), Niagara-on-the-Lake (NOTL) Hydro Inc., Niagara Peninsula Energy Inc., and Welland Hydro Electric System Corp. The high-voltage system in this Region also provides supply to several direct transmission-connected industrial customers transformer stations.

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits supplied mainly by the local generation from Sir Adam Beck #1, Sir Adam Beck #2, Decew Falls GS, Thorold GS and the 230kV/115kV autotransformers at Allanburg TS.

The 230kV circuits (Q23BM, Q24HM, Q25BM, Q26M, Q28A, Q29HM, Q30M, and Q35M) from Sir Adam Beck #2 SS connect this region to Hamilton/Burlington. The power is distributed through thirteen (13) HONI and six (6) LDC owned step-down transformer stations. The distribution system in this Region is at two voltage levels, 27.6 kV and 13.8 kV.

The geographical boundaries of the Niagara Region are shown in Figure 2.

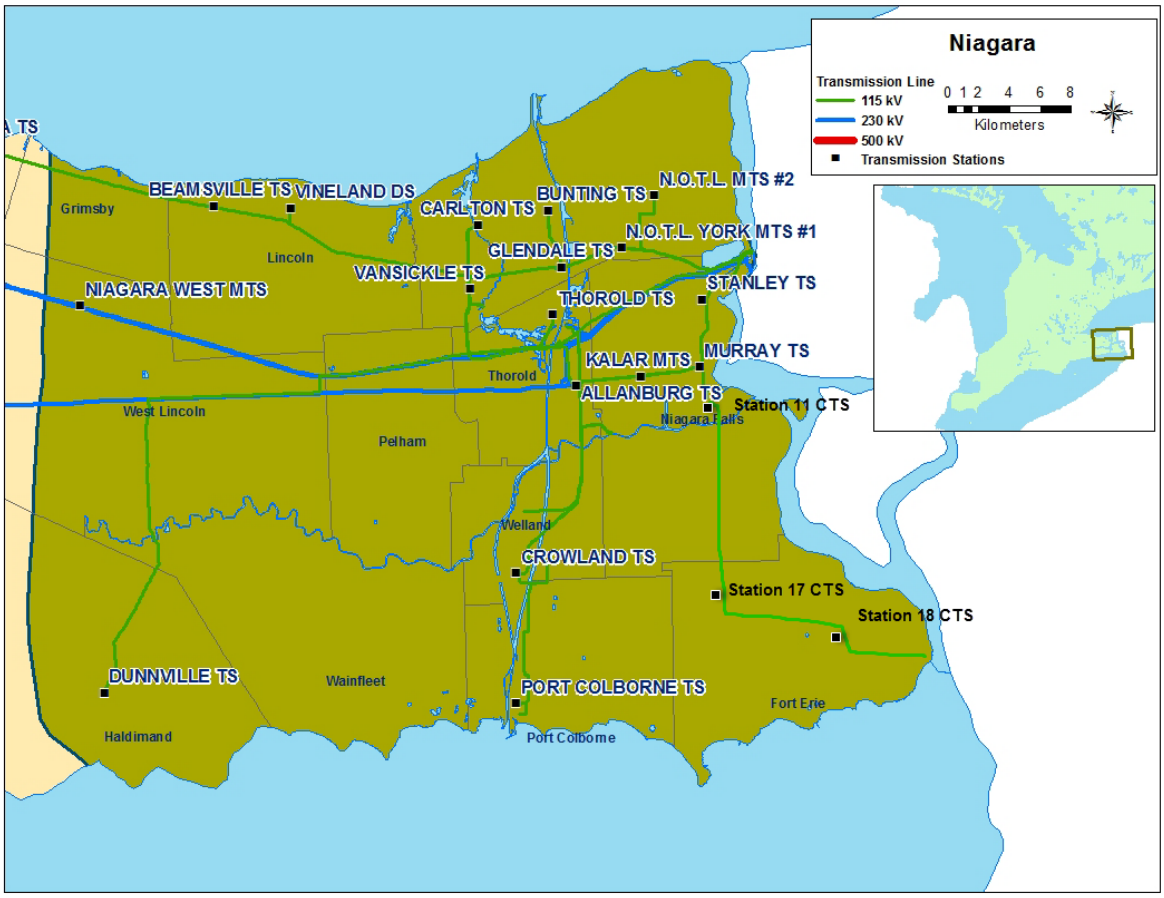

Figure 2: Map of Niagara Region Planning Area

The circuits and stations of the area are summarized in Table 2 below:

Table 2: Transmission Station and Circuits in the Niagara Region

115kV circuits	230kV circuits	Transformer Stations	Generation Stations

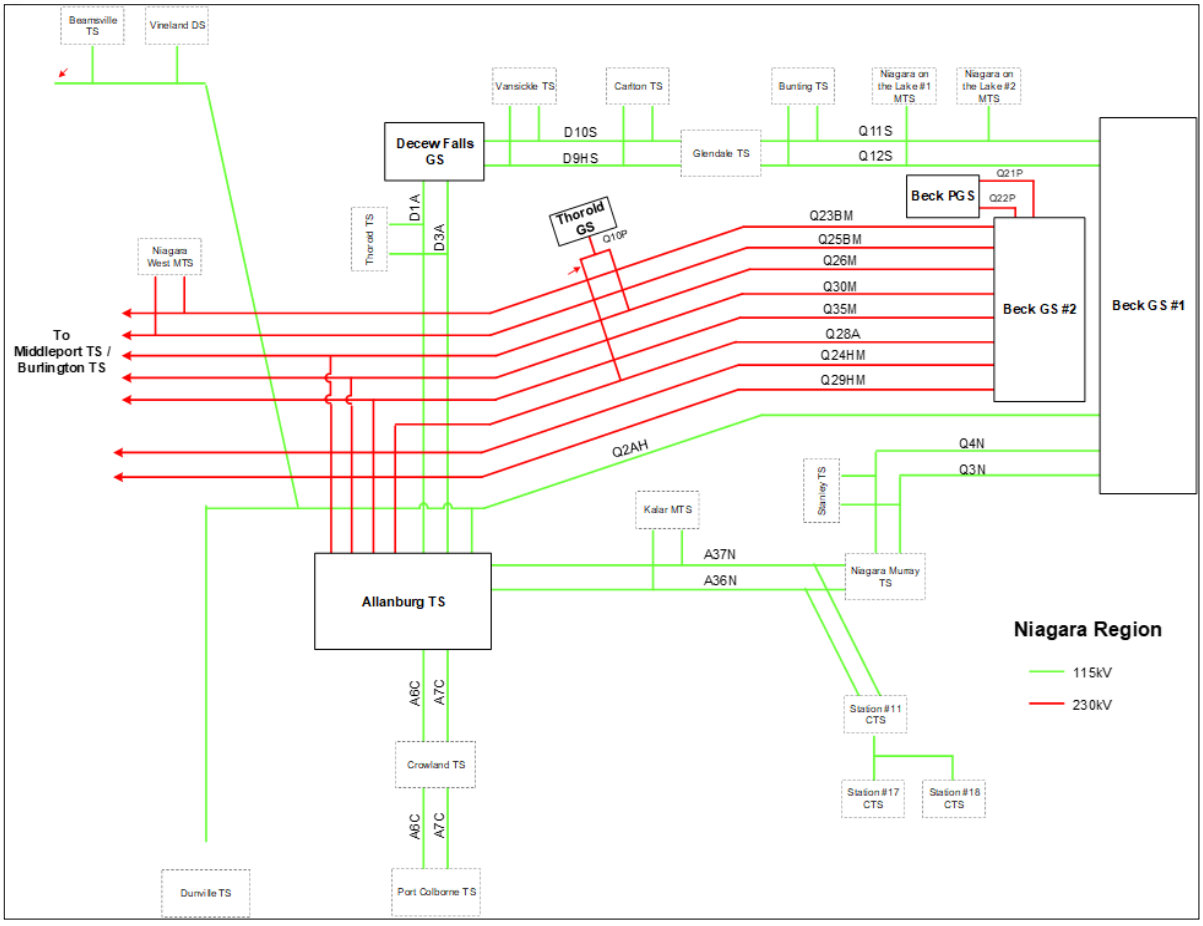

Figure 3: Niagara Region Transmission Single Line Diagram

5. INPUTS AND DATA

TWG participants, including representatives from LDCs, IESO, and Hydro One provided information and input for the Niagara Region Needs Assessment. With respect to the load forecast information, the OEB Regional Planning Process Advisory Group (RPPAG) recently published a document called “Load Forecast Guideline for Ontario” in Oct. 2022. The objective of this document is to provide guidance to the TWG in the development of the load forecasts used in the various phases of the regional planning process with a focus on the NA and the IRRP. One of the inputs into the LDC’s load forecast that is called for in this

guideline is information from Municipal Energy Plans (MEP) and/or Community Energy Plans (CEP). The list of all the Municipalities falling under the geographical boundaries of the region are given in Appendix-E.
The information provided includes the following:

- Niagara Region 10-year summer and winter Load Forecasts for all supply stations inclusive of the inputs provided by the municipalities (e.g. through their MEPs & CEPs). Sensitivity analysis is undertaken which captures uncertainties via different growth scenarios.
- Known capacity and reliability needs, operating issues, and/or major assets requiring replacement/ refurbishment; and
- Planned/foreseen transmission and distribution investments that are relevant to Regional Planning for the Niagara Region.
- Captured uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

6. ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in development of this Needs Assessment:

6.1 Technical Assessments and Study Assumptions

The technical assessment of needs was undertaken based on:

- Current and future station capacity and transmission adequacy.
- System reliability and operational considerations.
- Asset renewal for major high voltage transmission equipment requiring replacement with consideration to “right-sizing”; and,
- Load forecast data was requested from industrial customers in the region, and
- This assessment is based on summer peak loads. Three forecasts were developed i.e. Normal Growth scenario, High and Low Growth scenarios. The High and Low Growth scenarios were developed to conduct a sensitivity analysis to cover unforeseen developments such as fuel switching, Government policies, higher than expected EV charging trend during peak load conditions, etc.

The following other assumptions are made in this report.

- The study period for this Needs Assessment is 2026-2035.
- The Region is summer peaking, so this assessment is based on summer peak loads.
- Line capacity adequacy is assessed by using coincidence peak loads in the area.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station’s normal planning supply capacity, assuming a 90% lagging power factor for stations

having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.

- Normal planning supply capacity for transformer stations is determined by the Hydro One summer 10-Day Limited Time Rating (LTR) of a single transformer at that station.
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).

6.2 Information Gathering Process

6.2.1. Load forecast:

The LDCs provided their load forecasts for summer and winter for all the stations supplying their loads in the Niagara Region for the 10-year study period including the inputs from the Municipalities such as MEPs and CEPs. The IESO provided an Electricity Demand Side Management ("eDSM"), and Distributed Generation ("DG") forecast for the Niagara Region. The region's extreme summer non-coincident peak gross load forecasts for each station were prepared by applying the LDC load forecast growth rates to the actual 2025 summer peak extreme weather corrected loads. The extreme summer weather correction factors were provided by Hydro One. The net extreme summer weather forecasts were produced by reducing the gross load forecasts for each station by the percentage eDSM and then by the amount of effective DG capacity provided by the IESO for that station. It is to be noted that as contracts for existing DG resources in the region begin to expire, at which point the load forecast has a decreasing contribution from local DG resources, and an increase in net demand. This extreme summer weather corrected net load forecast for the individual stations in the Niagara Region is given in Appendix A.

6.2.2. Sensitivity Analysis:

A sensitivity analysis was undertaken by the TWG to capture uncertainty in the load forecast as well as variability of drivers such as electrification. Hence, the NA recommendations are not necessarily linked to sensitivity scenarios; but rather are used to identify any emerging needs for consideration in developing recommendations. The impact of sensitivity analysis for the high and low growth scenarios is provided in section 8 of this report.

6.2.3. Asset Renewal Needs for Major HV Equipment:

List of major HV transmission equipment planned and/or identified to be refurbished and/or replaced based on asset condition assessment, relevant for Regional Planning purposes. This includes HV transformers, autotransformers, HV Breakers, HV underground cables and overhead lines. The scope of equipment considered is given in section 7.1.

6.2.4. System Reliability and Operational Issues:

Relevant information regarding system reliability and operational issues in the region as feedback provided by the IESO during the NA phase.

7. NEEDS

This section describes emerging new needs identified in the Niagara Region and/or updates on previously identified needs since the completion of Previous Regional Planning cycle.

Needs that were identified in the previous regional planning cycle with associated projects that were recently completed and reaffirmed needs that are underway are briefly described below with relevant updates and will not be discussed further in this report.

1. Circuit D1A/D3A (Gibson Jct x Thorold TS) Replacement – Line refurbishment to address asset renewal need. Completed in Q4 2023.
2. Thorold TS T1 Transformer Replacement – Replace existing 45/60/75 MVA T1 transformer with a new 45/60/75 MVA unit. Completed in Q4 2023.
3. Station No. 11 CSS 2nd Breaker Replacement - Completed in Q4 2025.
4. Circuit Q28A Additional Supply Capacity Need - Re-tensioning to higher capacity is in progress and planned to be placed in service in Q2 2027.
5. Lincoln Area Supply Capacity Need – Project to build a new 2 x 50/83MVA, 230kV/27.6 station is in progress and planned to be placed in service in Q4 2027.
6. Carlton TS LV Switchyard Refurbishment – Project is in progress and planned to be placed in service in Q1 2028.
7. Crowland TS Station Capacity Need – Replace 115/27.6 kV T5/T6 DESN with a new 230/27.6 kV DESN and supply with a new 230kV transmission circuit. Project is in progress and planned to be placed in service in Q3 2029.
8. Carlton TS Station Capacity: Project to transfer excess load from Carlton T1/T2 DESN to Bunting TS is in progress and planned to be completed in Q4 2029.

The planned in-service year for the above underway projects is tentative and is subject to change.
All near and mid-term needs that are discussed as a part of this report are summarized in Table 3 below.

Table 3: Near/Mid-term Needs Identified in this NA and/or Updated from Previous RIP

Need Location	Need Description/Update	NA Report Section
Asset Renewal Needs		
Glendale TS T1/T2	Replace the existing T1/T2 45/60/75 MVA transformers with like-for-like units. Expected in service date is updated as Q4 2031.	7.1.1
Murray TS T11/T12	Replace the existing 45/60/75 MVA transformers T11 and T12 with new 60/80/100 MVA units. Expected in service date is updated as Q4 2032.	7.1.2
Murray T13/T14	Replace the existing 45/60/75 MVA transformers T13 and T14 with like-for-like units. Expected in service date is updated as Q4 2032.	7.1.2
Allanburg TS T3	Replace the existing 150/250 MVA autotransformer with a like-for-like unit. Expected in service date is updated as Q4 2032.	7.1.3
Vansickle TS LV Switchyard	Replace the BY MV switchgear with like-for-like unit. Expected in service date is updated as Q4 2034.	7.1.4
Bunting TS T3	Replace the existing 45/60/75 MVA T3 transformer like-for-like unit. Expected in service date is updated as beyond 2035.	7.1.5
Q2AH - Rosedene Jct. x St. Anns Jct	Line refurbishment to address asset renewal need. Expected in service date is updated as Q4 2031.	7.1.6
Station Capacity Needs		
Allanburg DESN TS	Load demand at Allanburg TS exceeds its capacity in 2028.	7.2.1
Carlton TS	Load demand at Carlton TS exceeds its capacity in 2028.	7.2.2
Murray TS	Load demand at Murray TS exceeds its capacity in 2031.	7.2.3
Transmission Line Capacity Needs		
115kV D9HS/D10S – Vansickle TS x Louth Junction	The section of the D9HS/D10S between Vansickle TS x Louth Junction is approaching its limit by 2034.	7.3.1

7.1 Asset Renewal Needs for Major HV Transmission Equipment

In addition to the previously identified asset renewal needs from the second regional planning cycle, Hydro One and the TWG identified new asset renewal needs for major HV transmission equipment over the next 10 years in the Niagara Region. They are listed in Table 4 below. Hydro One and Canadian Niagara Power are the only Transmission Asset Owners (TAO) in the Region.

Asset renewal needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
  replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

The asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement)
- Replacing equipment with higher ratings and built to current standards

From Hydro One's perspective as a facility owner and operator of its transmission equipment, doing nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance costs and longer duration of customer outages.

There are no major HV transmission assets requiring replacement in the Niagara Region in the next 10 years.

7.1.1 Glendale TS – T1/T2 Replacement

Glendale TS is comprised of two DESN units, T1/T2 and T3/T4. The T1 transformer has been identified for asset renewal. The scope of the project is to replace the existing 45/60/75 MVA T1 transformer with a like-for-like new 45/60/75 MVA unit. The in-service date for this asset renewal has been updated to Q4 2031.

7.1.2 Murray TS – T11/T12, T13/T14 Replacement

Murray TS is currently comprised of two DESN units, T11/T12 and T13/T14. All four existing transformers units have a rating of 45/75MVA. The current asset renewal plan is to replace the existing 45/60/75 MVA transformers T11 and T12 with new 60/80/100 MVA units, while the T13/T14 units will be like-for-like new 45/75MVA units. The in-service date for this asset renewal has been updated to Q4 2032.

7.1.3 Allanburg TS – T3 Replacement

Allanburg TS is comprised of four autotransformer units, T1, T2, T3, and T4. The T3 transformer has been identified for asset renewal. The scope of the project is to replace the existing 150/250 MVA T3 transformer with a like-for-like new 150/250 MVA unit. The in-service date for this asset renewal has been updated to Q4 2032. The need for this asset renewal is subject to change based on the findings of the IESO's Niagara Bulk Plan study, currently scheduled for completion in Q3 2027.

7.1.4 Vansickle TS – LV Switchyard Replacement

Vansickle TS is comprised of two DESNs, BY and JQ, supplied by T5 and T6. The BY MV switchgear has been identified for asset renewal. The scope of the project is to replace the existing switchgear. The in-service date for this asset renewal has been updated to Q4 2034.

7.1.5 Bunting TS – T3 Replacement

Bunting TS is comprised of a single DESN supplied by transformers T3/T4. The T3 transformer has been identified for asset renewal. The scope of the project is to replace the existing 45/60/75 MVA T3 transformer with a like-for-like new 45/60/75 MVA unit. The in-service date for this asset renewal has been updated to beyond 2035.

7.1.6 Q2AH - Rosedene Jct. x St. Anns Jct – Line Refurbishment

The portion of the single 115kV circuit Q2AH supplying Dunnville TS, between Rosedene Jct and St.Anns Jct, has been identified for asset renewal. The length of this portion of circuit is approximately 11km. The scope of the project is to replace the asset with a like-for-like equivalent conductor size. The in-service date for this asset renewal has been updated to Q4 2031.

7.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2026-2035 for the 230kV and 115kV Transforming stations in the Niagara Region using either the summer or winter peak load forecasts that were provided by the Technical Working Group. Based on the results, the following Station capacity needs have been identified during the study period:

7.2.1 115kV Allanburg TS – Station Capacity

The load at Allanburg TS is expected to exceed its 10-Day LTR within the 2027-2035 time period.

Allanburg TS is comprised of one DESN with transformers T7/T8 with a rating of 25/42MVA, having a summer 10-Day LTR of 58.0 MW. The station's actual non-coincident summer peak load in 2025 was about 48MW and is forecasted to almost 79MW (net adjusted for extreme weather) by 2035. However, there is an immediate need by 2028 to increase the station capacity. This unexpected increase in forecasted load was identified during the Needs Assessment process.

The TWG recommends reviewing the load forecast and if necessary, initiating discussions for transformer replacement at Allanburg TS with larger units.

7.2.2 115kV Carlton TS – Station Capacity

The load at Carlton TS is expected to exceed its 10-Day LTR within the 2029-2035 time period.

Carlton TS is currently a single DESN facility, with transformers T1 and T2. The existing transformers T1/T2 have a rating of 45/75MVA, with a summer 10-Day LTR of 99.6MW. The station's actual non-coincident summer peak load in 2025 was about 84.4MW and is forecasted to be approximately 122.4MW (net adjusted for extreme weather) by 2035.

However, there is a need by 2028 to increase the station capacity. This unexpected increase in forecasted load was identified during this Needs Assessment process. At this time, the LDC planned load transfers to Bunting TS by 2029 and additional capacity through expansion from Vansickle TS is expected to aid capacity needs over the current planning horizon. Station capacity needs at Carlton TS will continue to be monitored. Should additional capacity be required, transformer upgrades to 60/100 MVA could be considered to address future capacity needs.

7.2.3 115kV Murray TS – Station Capacity

The load at Murray TS (T11/T12) is expected to exceed its 10-Day LTR by 2031 with its current transformers.

Murray TS is currently comprised of two DESN units, T11/T12 and T13/T14. Both DESNs are currently considered for asset renewal by 2032. The existing transformers T11/T12 have a rating of 45/75MVA, with a summer 10-Day LTR of 71.6MW. The station's 2025 actual non-coincident summer peak load was about 66.8MW and is forecasted to be approximately 72MW (net adjusted for extreme weather) by 2031. The current asset renewal plan is to replace the existing 45/60/75 MVA transformers T11 and T12 with new 60/80/100 MVA units, which will provide approximately a 10-Day LTR of 122MW. Expected in service date is updated as Q4 2032.

At this time, the asset renewal project and forecast will be both closely monitored and adjusted to ensure the station capacity meets the future load requirement.

7.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period 2026-2035 for the 230kV and 115kV Transmission line circuits in the Niagara Region by assessing thermal limits of the circuit and the voltage range as per ORTAC Local Area Contingency-Based Assessment to cater to this need.

Based on the results, the following line capacity needs have been identified during the study period.

7.3.1 115kV D9HS/D10S – Vansickle TS x Louth Junction

The double 115kV circuits D9HS/D10S between Decew Falls GS and Glendale TS are an alternate supply path for loads in the St.Catharines area, via Carlton TS and Glendale TS.

With the increasing demand forecasted on this corridor, a section of the D9HS/D10S is potentially overloaded in the long term, specifically the 1km of overhead D9HS/D10S section between Vansickle TS x Louth Junction following the loss of all generation from 115kV Sir Adam Beck GS via the Beck E-bus contingency.

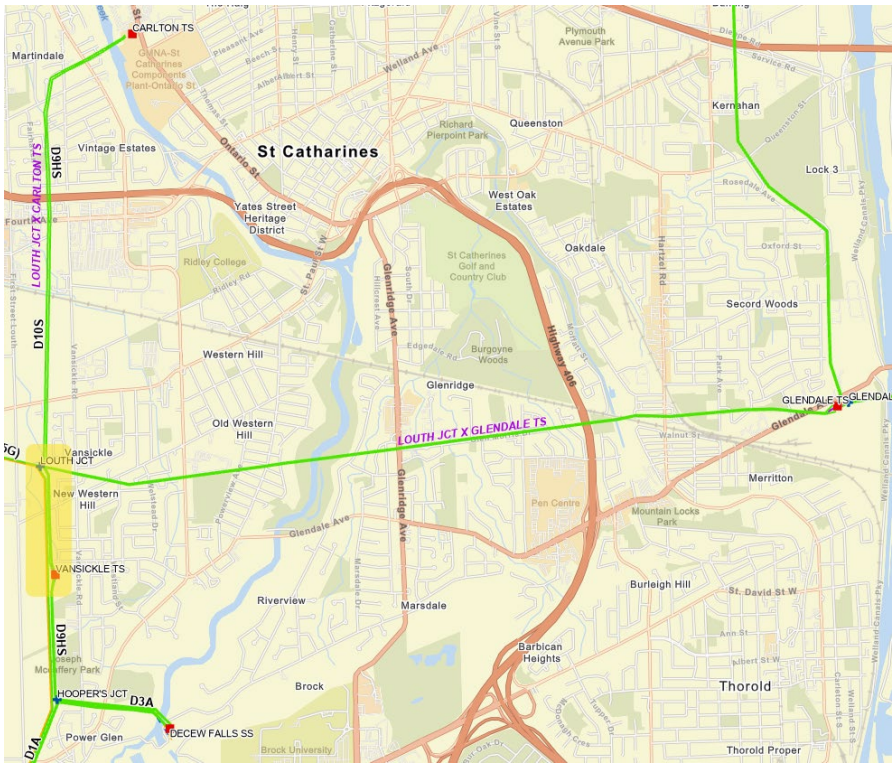

Figure 4: 115kV D9HS/D10S – Vansickle TS x Louth Junction (highlighted)

This section is shown in Figure 4. The calculated need for this line capacity upgrade is by 2035 if the current load forecast in this area holds true.

7.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, and to provide a median-economic forecast for an extended period with any one transmission element out of service. A study has been carried out, considering the net coincident load forecast and the loss of one element over the study period 2026-2035 to cater for this need**.** Based on the results, no significant new system reliability, operating and restoring issues have been identified for this Region.

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments. The TWG determined that the key electric demand driver in the Niagara Region to be considered in this sensitivity analysis is electric vehicle (EV) penetration and unforeseen electrification which would cause the load to increase at a faster rate than shown in the forecast; or the potential delay in some projects which could result in less demand than anticipated.
The TWG reviewed EV scenarios, and any unforeseen electrification needs to develop high demand growth forecasts by applying 50% additional growth to the growth rate on the extreme summer/winter corrected Normal Growth net load forecasts. The low growth scenario was obtained by reducing the growth rate by 50%. The normal and high growth forecasts are shown in Tables A.1, A.2, A.3 and A.4.

The impact of sensitivity analysis for the high and low growth scenario identified the following updates or new Station/Line capacity needs:

Table 4: Impact of Sensitivity Analysis on Station/Line capacity Needs in the Region

Sr.no.	Need Identified	Normal Growth Scenario	High Growth Scenario	Low Growth Scenario
1	Allanburg DESN TS	2028	2028	2028
2	Carlton TS	2028	2028	2030
3	Murray T11/T12 TS	2031	2029	2034
4	115kV D9HS/D10S Vansickle TS x Louth Junction	2035	2034	-
5	Bunting TS	-	2032	-

The sensitivity analysis identified the additional capacity needs for Bunting TS towards the end of the study period. These needs will be assessed again during the next phases of this Regional Planning cycle.

9. CONCLUSION AND RECOMMENDATION

The Technical Working Group's recommendations to address the needs identified are as follows:

Table 5: Needs that Do Not Require Further Regional Coordination

#	Need Location	Need Description
1	Glendale TS T1/T2	Replace the existing T1/T2 45/60/75 MVA transformers with like-for-like units.
2	Murray TS T11/T12	Replace the existing 45/60/75 MVA transformers T11 and T12 with new 60/80/100 MVA units.
3	Murray T13/T14	Replace the existing 45/60/75 MVA transformers T13 and T14 with like-for-like units.
4	Allanburg TS T3	Replace the existing 150/250 MVA autotransformer with a like-for-like unit.
5	Vansickle TS LV Switchyard	Replace the BY MV switchgear with like-for-like unit.
6	Bunting TS T3	Replace the existing 45/60/75 MVA T3 transformer like-for-like unit.
7	115kV Q2AH – Rosedene Jct. x St. Anns Jct	Line refurbishment to address asset renewal need.

Table 6: Needs that Require Further Regional Coordination

#	Need Location	Need Description
1	Allanburg DESN TS	Load demand at Allanburg TS exceeds its capacity in 2028.
2	Carlton TS	Load demand at Carlton TS exceeds its capacity in 2028.
3	D9HS/D10S – Vansickle TS x Louth Jct	The section of the D9HS/D10S between Vansickle TS x Louth Junction is approaching its limit by 2035.

List of LDC(s) to be involved in further regional planning phases:

- Alectra Utilities
- Canadian Niagara Power
- Grimsby Power
- Hydro One Distribution
- Niagara-on-the-Lake Hydro
- Niagara Peninsula Energy
- Welland Hydro Electric System

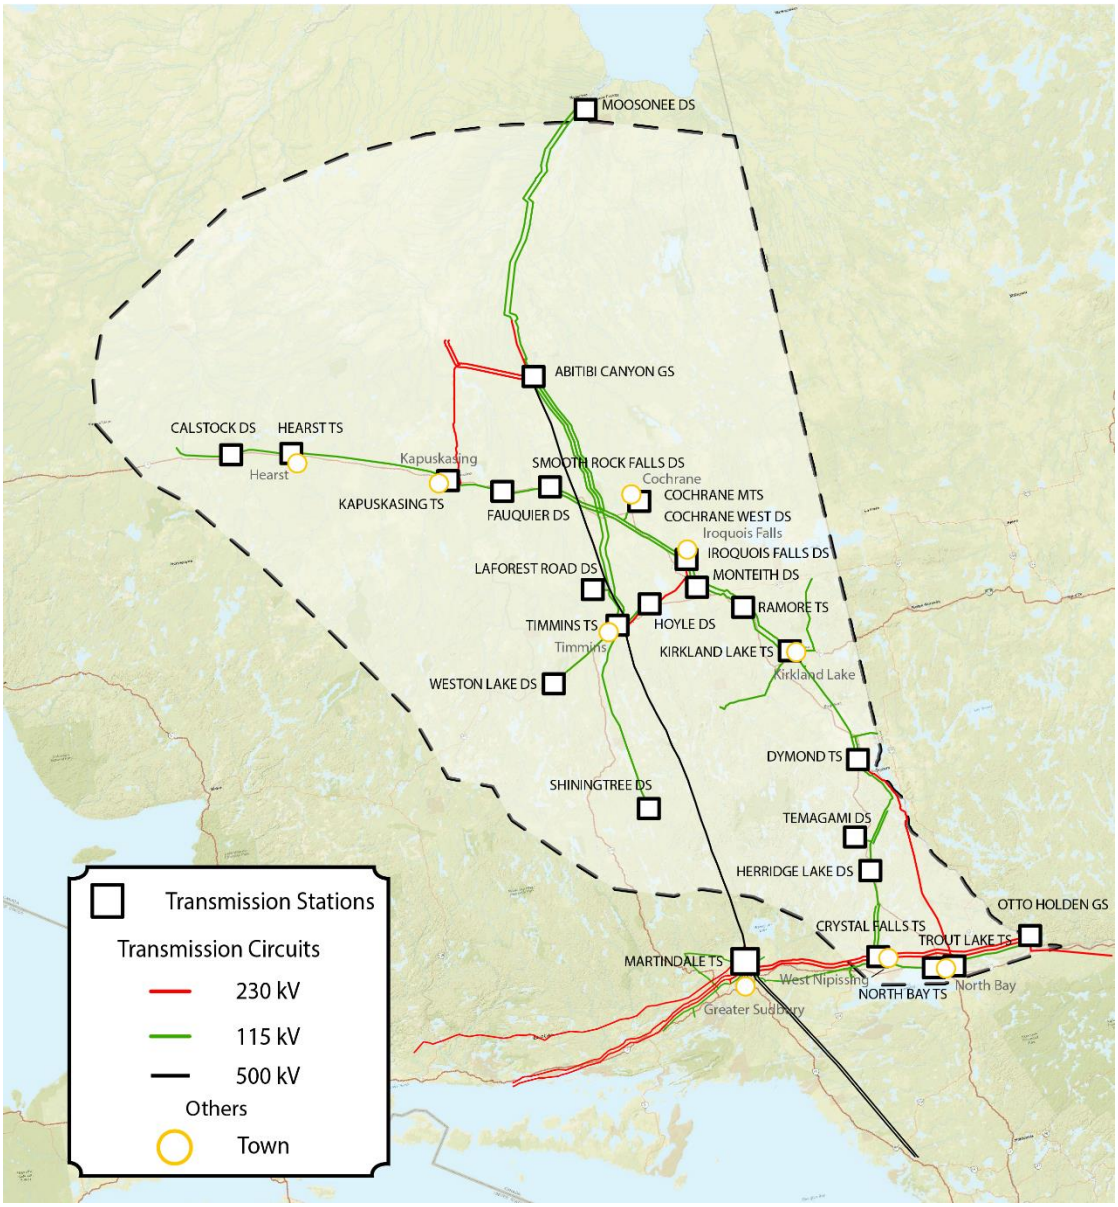
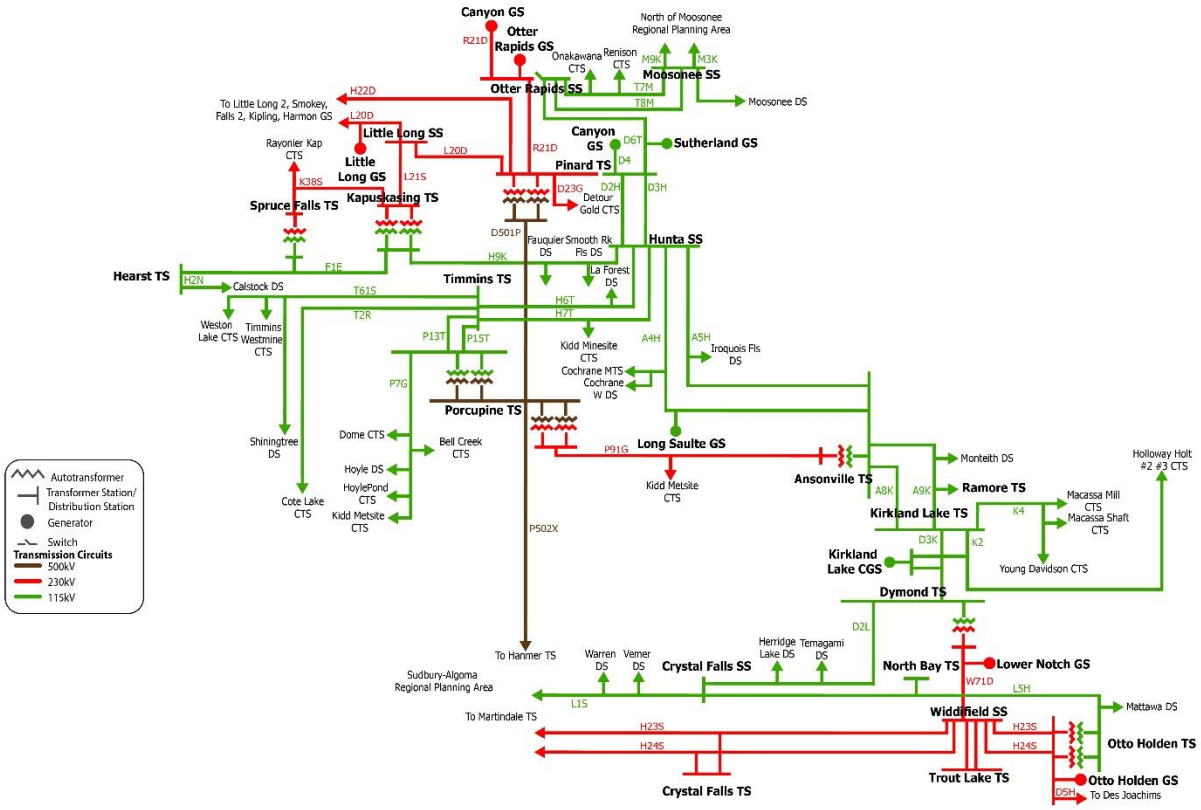
1. Introduction



1.1 Overview of Region and Background

The North & East of Sudbury region is a large area supplied by the electricity infrastructure that extends north and east from, but not including, the City of Sudbury. Extending from south of the town of Moosonee in the north to the City of North Bay and town of East Ferris in the south, it includes the towns of Hearst, Kapuskasing, Smooth Rock Falls, Cochrane, Foleyet, Iroquois Falls, Kirkland Lake and Englehart. It also includes the townships of Black River Matheson and East Ferris, the cities of North Bay, Temiskaming Shores and Timmins and the municipality of West Nipissing. The North & East of Sudbury region is also home to First Nation communities listed in Table 1. A map of the area indicating the location of transmission assets is found in Figure 1.

Table 1 | List of First Nation Communities in the North & East of Sudbury Region



Constance Lake First Nation
Flying Post First Nation
Matachewan First Nation

Missanabie Cree First Nation
Moose Cree First Nation
Nipissing First Nation
Taykwa Tagamou First Nation
Temagami First Nation
Wahgoshig First Nation
Wahnapitae First Nation

Figure 1 | Map of the North & East of Sudbury Area

Note that, for regional electricity planning purposes, the region is defined by electrical infrastructure rather than geography. The region is supplied through 500/230 kV autotransformers at Porcupine TS and Pinard TS and encompasses the 230 kV circuits east of Martindale TS in the west to Otto Holden TS in the east as well as the 500 kV circuits from Hammer TS to Pinard TS and the 115 kV sub-systems in between. For clarity, the North & East of Sudbury region does not include the area north of Moosonee. There are non-synchronous interconnections with Quebec at Dymond TS and Otto Holden TS. At Dymond TS, intertie circuit D4Z at Dymond TS can deliver imports from generation located in Quebec, and industrial load in Quebec (i.e., a paper plant in Témiscaming, Quebec) can be supplied radially via the 115 kV intertie circuit H4Z. This Quebec load is not part of this study as it can also be supplied from Quebec. A single line diagram of the electricity infrastructure in the region is shown in Figure 2.

Figure 2 | Electricity Infrastructure in the North & East of Sudbury Region

Demand in this region is winter peaking and a large share of this demand is high electricity intensity industries, primarily mining and forestry operations. Demand growth in this area is primarily forecast to be in the mining sector, where project development is highly dependent on factors such as commodity prices and access to financing.

The region has over 2,600 MW of generation, including numerous hydroelectric facilities, solar, gas and bio-fuel facilities. The lead transmitter for the region is Hydro One Networks Inc. and the local distribution companies (LDCs) are North Bay Hydro, Northern Ontario Wires Inc., Hearst Power Distribution Co., Greater Sudbury Hydro, and Hydro One Networks Inc. (Distribution).

2. The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of the North & East of Sudbury region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by North American Electric Reliability Corporation (NERC). The IRRP's recommendations are informed by an evaluation of options that considers reliability, cost, technical feasibility, maximizing the use of the existing electricity system (where economic), and feedback from stakeholders.

Table 2 summarizes the needs identified in this study and the IRRP's recommendations to address them.

Table 2 | Summary of Needs and Recommendations for North & East of Sudbury IRRP

No.	Need Description	Recommendation	Need Date
1	Station Capacity at Ramore TS	Load growth at Ramore TS will be monitored and revisited in the next cycle of regional planning	2033
2	Voltage control issues with existing capacitors at Dymond TS	Hydro One to investigate options to improve operability of existing capacitors in the upcoming RIP	2030
3	Voltage control issues in the Kirkland Lake area	Hydro One to investigate options of adding reactive devices in the Kirkland Lake area in the upcoming RIP	2030
4	Voltage control issues at Ansonville, Hunta, Kapuskasing Area	Various recommendations, including a new RAS, replacing failed equipment and additional voltage support	Near to Mid-term
5	Thermal overload of circuit D3K upon loss of A8K or A9K when its companion is out of service	The new Kirkland Lake RAS installed in 2022 addresses this issue. Additional load in the area beyond the current forecast will require further study	2030
6	A4H/A5H End-of-Life Need	Hydro One to proceed with plans to replace the affected circuit sections with a like-for-like replacement	2027

No.	Need Description	Recommendation	Need Date
7	D2H/D3H End-of-Life Need	Hydro One to proceed with plans to replace the affected circuit sections with a like-for-like replacement	2026
8	ORTAC load security criteria not met for 500 kV circuit outages	Partially addressed by the recent Northeast Bulk Plan. An update to this plan is recommended should significant new resources and/or load connect to the North & East of Sudbury region.	Existing Need
9	Difficulty supplying loads during planned outages to circuit D501P	Study this need as part of the next bulk system plan for Northeast Ontario in combination with other drivers of system expansion as they develop	Existing Need

3. Development of the IRRP

3.1 The Regional Planning Process

In 2013, the OEB created a formal process for regional planning which is carried out by the IESO, in collaboration with the transmitters and LDCs in each planning region. The regional planning formal process sets out 21 electricity planning regions for the province. Regional planning assesses the interrelated needs of a region over the near, medium, and long term and develops a plan to ensure cost-effective, reliable electricity supply. Regional plans consider the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluate options for addressing needs, and recommend actions to be undertaken.

The process consists of four main components:

1. A Needs Assessment, led by the lead transmitter in the region, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;
2. A Scoping Assessment, led by the IESO, which identifies the most appropriate planning approach to address identified needs;
3. An IRRP, also led by the IESO, which proposes recommendations to meet the identified needs requiring coordinated planning; and/or
4. A Regional Infrastructure Plan (RIP), led by the lead transmitter, which provides further details on recommended wires solutions.

Further details on the components of the regional planning process in Ontario and the IESO's approach to regional planning can be found in Appendix A.

In addition to regional planning, there are also bulk system planning and distribution network system planning processes. Bulk system planning typically considers the 230 kV and 500 kV network and examines province-wide system issues, and distribution network planning considers the adequacy and reliability of the distribution system(s) supplying customers within a particular community. Regional planning sits between bulk planning and distribution planning and focuses on ensuring that an area can be reliably supplied given forecast demand growth and other developments in a region.

A review of the regional planning process was finalized in 2021 following the completion of the first cycle of regional planning for all 21 regions. The Regional Planning Process Review Final Report is published on the IESO's website.

3.2 North & East of Sudbury and IRRP Development

The process to develop the North & East of Sudbury IRRP was initiated following the publication of Hydro One's North & East of Sudbury Needs Assessment report in May 2021 and the IESO's Scoping Assessment Outcome report in August 2021. The Scoping Assessment report recommended that the needs identified for the North & East of Sudbury region be considered through an IRRP using a coordinated regional approach. The Scoping Assessment Working Group, consisting of the IESO, the transmitter and the LDCs in the region, was then formed to develop the terms of reference for this IRRP, gather data, identify needs, develop options and recommend solutions for the North & East of Sudbury region.

4. Background and Study Scope

This is the second cycle of regional planning for the North & East of Sudbury region. During the first cycle of regional planning, a Needs Assessment was conducted in April 2016 that was led by the transmitter, Hydro One Networks Inc. Transmission. After reviewing the needs identified in the report, the Technical Working Group recommended that further regional coordination was not required and a Regional Infrastructure Plan, also led by the transmitter, was published in April 2017.

This cycle of regional planning started with a Needs Assessment published by Hydro One in May 2021 which identified a number of needs requiring further regional coordination. This was followed by a Scoping Assessment process which was finalized in August 2021. The Scoping Assessment Outcome report recommended that an IRRP be initiated. This report is the outcome of the IRRP process and presents an integrated regional electricity plan for the next 20-year period from 2021 to 2040.

4.1 Study Scope

This IRRP was prepared by the IESO on behalf of the Technical Working Group and recommends options to meet the electricity needs of the North & East of Sudbury region of the study period with a focus on providing an adequate, reliable supply to support community growth. The plan includes consideration of forecast electricity demand growth, conservation and demand management (CDM), distributed generation (DG), transmission and distribution system capability, relevant community plans, condition of transmission assets and developments on the bulk transmission system. The full scope of the study can be found in Appendix D.

4.1.1 Planned Projects Considered in the IRRP

The following projects were already planned or underway when the IRRP was initiated, and were assumed to be in service in developing the IRRP assumptions.

1. Ansonville to Kirkland Lake Line Upgrade: Upgrading of end-of-life circuits A8K and A9K from 230 A to 550 A capacity.
2. Kapuskasing Area Reinforcement: Upgrading two sections of circuit H9K (from Spruce Falls JCT to Carmichael Falls JCT and Gemini Smooth Rock Falls JCT to H9K Structure 127A JCT) to higher 550 A capacity.

The North & East of Sudbury IRRP was developed by completing the following steps:

- Preparing a 20-year electricity demand forecast;
- Examining the capacity and reliability of the existing transmission system, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC and NERC planning criteria, and considered the findings and recommendations made through other planning processes being carried out in parallel, namely the Northeast Bulk Plan;
- Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO controlled grid as described in section 7 of ORTAC;
- Confirming identified end-of-life asset replacement needs and timing with Hydro One;
- Establishing alternatives to address system needs, including, where feasible and applicable, possible wires alternatives (e.g., transmission and/or distribution) and non-wires alternatives (e.g., energy efficiency, local generation, storage and other distributed energy resources);
- Engaging with the community on needs, findings and possible alternatives;
- Evaluating alternatives to address near and long-term needs; and
- Communicating findings, conclusions and recommendation within a detailed plan.

4.2 Coordination with Bulk Planning Initiatives

In addition to the Regional Planning activities being undertaking for the North & East of Sudbury region, a number of Bulk Planning initiatives have recently been undertaken or are currently underway with the potential to affect assumptions and outcomes in the area. Two initiatives in particular, the Northeast Bulk Plan, and the Northern Voltage Study, have implications for the current Regional Planning process, with further details described below.

4.2.1 Northeast Bulk Planning Study

A bulk planning study was initiated for northeastern Ontario in 2021 that was completed in October 2022. This study examined a number of needs in the area, and paid particular focus to improving supply security for growing demand in and around the cities of Sault Ste. Marie and Timmins. Compared to a regional planning focus, the goal of the bulk study was to ensure sufficient power could be delivered to load centres, but did not include final customer delivery, including step down or local voltage needs.

Recommendations made during this study were treated as input assumptions for the current North & East of Sudbury IRRP, and were assumed to come into service at their target date. The Northeast Bulk Plan recommended the following system reinforcements.

1. A new ~260 km single circuit 230 kV transmission line (built to 500 kV standards) between Wawa Transformer Station (TS) and Porcupine TS to be in-service in 2030;
2. A new ~205 km single circuit 500 kV transmission line between Mississagi TS and Hanmer TS and addition of two new autotransformers at Mississagi TS to be in-service in 2029; and
3. A new ~75 km double circuit 230 kV transmission line between Mississagi TS and Third Line TS to be in-service in 2029.

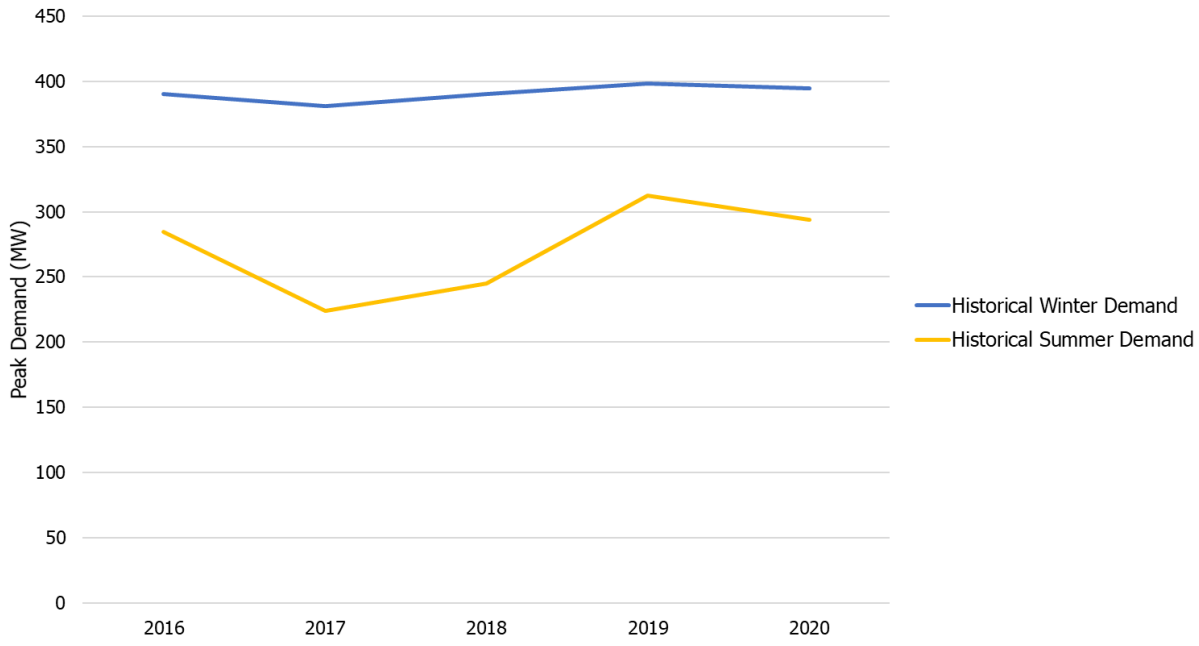
Additional information on this study is available on the IESO website, here.

4.2.2 Northern Voltage Study

The Northern Voltage Study was initiated recognizing that the voltage profile across northern Ontario was set to change with system expansions planned in northeast Ontario (i.e., the Northeast Bulk Plan recommendations) as well as in northwestern Ontario (i.e., the East West Tie expansion, the Waasigan line and the Wataynikaneyap line). The study examines reactive requirements associated with these new lines and the resulting changes to the voltage profile. In addition, it addresses existing challenges managing system voltages in northern Ontario as reported by the IESO's control room operators and identifies requirements to improve operability.

Although the scope of the Northern Voltage study is much wider than the North & East of Sudbury IRRP, and tends to focus on contingencies and operational concerns outside the typical scope of Regional Planning, the potential for needs and recommended solutions from one study to affect system assumptions for the other required that these two studies be carried out in a coordinated manner. Since bulk system reactive requirements were being studied through the Northern Voltage Study, the North & East of Sudbury IRRP did not address these issues and instead focused on identifying and addressing localized voltage concerns in the region.

5. Electricity Demand Forecast



Regional planning is driven in large part by the need to meet peak electricity demand requirements in the region under study. This section describes the specific details of the development of the demand forecast for the North & East of Sudbury region, which is comprised of an LDC demand forecast as well as a forecast of transmission-connected loads (i.e., large industrial customers). It highlights the assumptions made for peak demand forecasts including the contribution of CDM and distributed generation to reducing peak demand. The resulting net demand forecast, termed the planning forecast, is used in assessing the electricity needs of the area over the planning horizon.

To evaluate the reliability of the electricity system, the regional planning process is typically concerned with the coincident peak demand for a given area. This is the demand observed at each station for the hour of the year in which overall demand in the study area is at a maximum. This differs from a non-coincident peak, which refers to each station's individual peak, regardless of whether these peaks occur at different times. Within the North & East of Sudbury region, the peak loading hour for each year occurs in the winter season.

5.1 Historical LDC Electricity Demand

Historical LDC electricity demand in the North & East of Sudbury region is primarily driven by residential and commercial customers (with the exception of Ramore TS and North Bay TS which are largely industrial driven) and demand typically peaks during the winter months. Winter demand is also typically much higher than summer demand as seen in Figure 3 below.

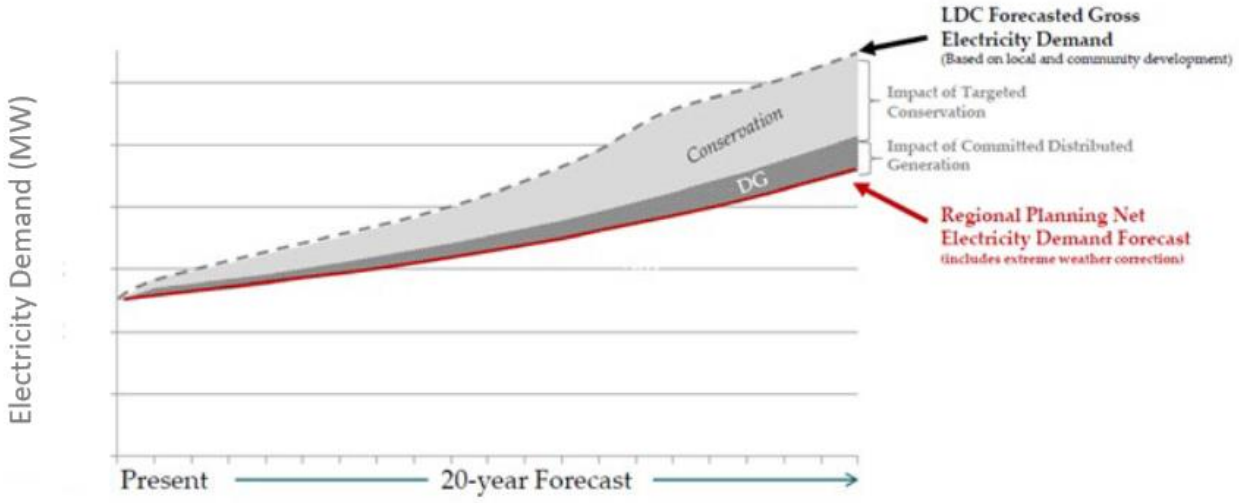


Figure 3 | Historical LDC Winter and Summer Peak Demand for the North & East of Sudbury Region

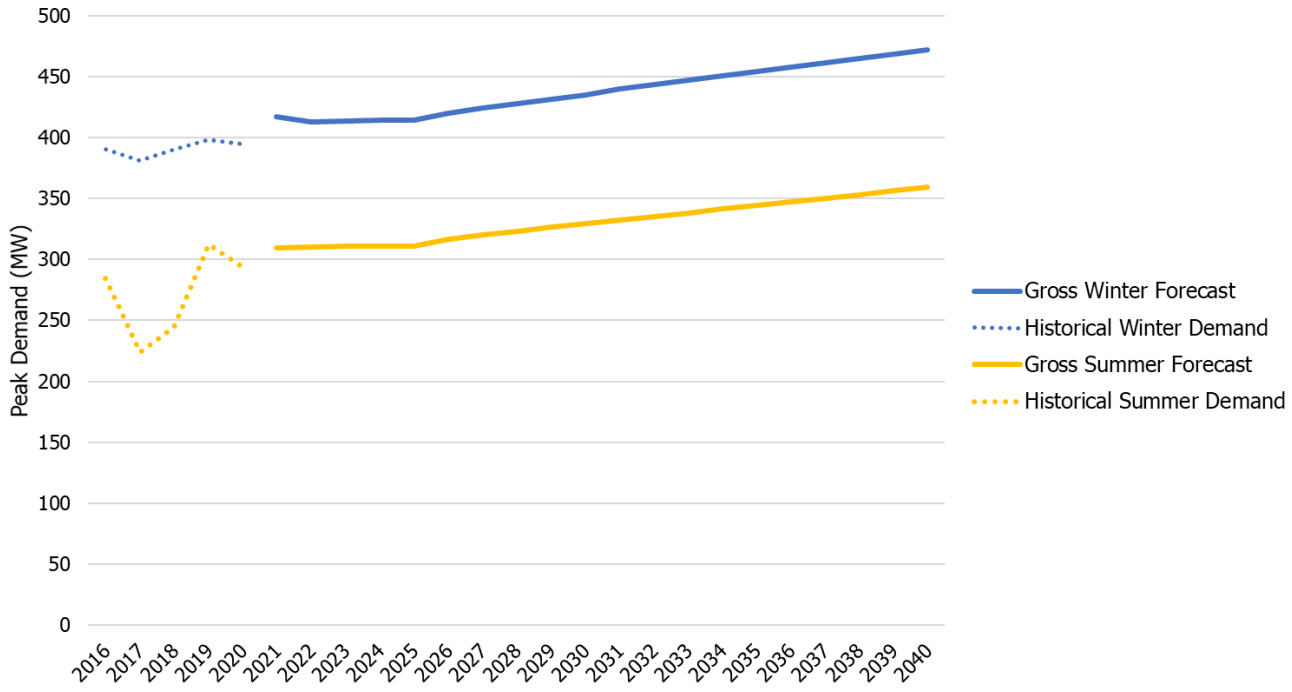
5.2 LDC Demand Forecast Methodology

A 20-year regional peak demand forecast was developed to assess reliability needs for the North & East of Sudbury sub-region; Figure 4 shows the steps taken to develop this. Gross demand forecasts, which assume the weather conditions of an average year based on historical weather conditions i.e., normal weather, were provided by the LDCs. These forecasts were then modified to reflect the peak demand impacts of provincial conservation savings and DG contracted through previous provincial programs such as FIT and microFIT. The forecasts were then adjusted to reflect extreme weather conditions in order to produce a reference forecast for planning assessments to assess the electricity needs in the region. An illustrative example is provided in Figure 4. Additional details related to the development of the demand forecast are provided in Appendix B.

Figure 4 | Illustrative Development of the Demand Forecast



5.3 LDC Gross Demand Forecast

Gross demand forecasts were submitted by each participating LDC in the North & East of Sudbury region. LDCs have knowledgeable insights into future local demand growth and drivers due to their direct involvement with their customers. These insights include future connection applications and knowledge of typical electrical demand trends for different types of customer groups.

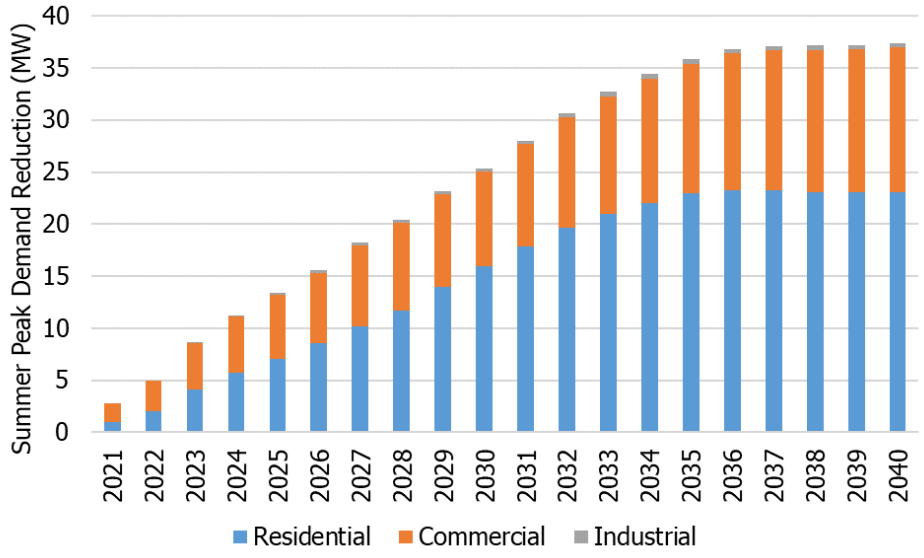
The LDC gross demand forecasts account for increases in demand due to factors such as new or intensified development, economic growth, population growth, changes in consumer behaviour. Most LDC's cited alignment with municipalities and credited them as a primary source for input data. LDCs are also expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices, i.e., "natural conservation", but not for the impact of future DG or new conservation measures, such as codes and standards and CDM programs, which are accounted for by the IESO as discussed in Section 5.4 below. The gross LDC forecast assumes median on-peak weather conditions.

More details on the individual LDCs' load forecast methodology can be found in Appendix B. Figure 5 below shows the total gross coincident LDC forecast for both summer and winter demand.

Figure 5 | Gross Winter and Summer LDC Forecast for the North & East of Sudbury Region

5.3.1 Contribution of Conservation to the LDC Demand Forecast

Conservation and demand management is a clean and cost-effective resource that helps meet Ontario's electricity needs and has been an integral component of provincial and regional planning. Conservation is achieved through a mix of codes and standards amendments as well as CDM program-related activities. These approaches complement each other to maximize conservation results.



The estimate of demand reduction due to codes and standards is based on expected improvement in the codes for new and renovated buildings and through regulation of minimum efficiency standards for equipment used by specified categories of consumers (i.e. residential, commercial and industrial consumers).

The estimates of demand reduction due to program-related activities account for the provincial 2021-2024 CDM Framework, federal programs that result in electricity savings in Ontario, and assumptions regarding continuing provincial CDM programming after 2024.

CDM savings have been applied to the North & East of Sudbury region's LDC gross peak demand forecast for median weather, along with DG (as described in Section 5.3.2) to determine the net peak demand for the region. This takes into account both conservation through the provincial CDM Framework, as well as expected peak demand impacts due to building codes and equipment standards for the duration of the forecast.

Figure 6 shows the estimated total yearly reduction to the LDC demand forecast due to conservation from codes, standards and CDM programs for each of the residential, commercial and industrial consumers. Additional details are provided in Appendix B.3.1.

Figure 6 | Estimated total yearly reduction to the LDC demand forecast due to conservation

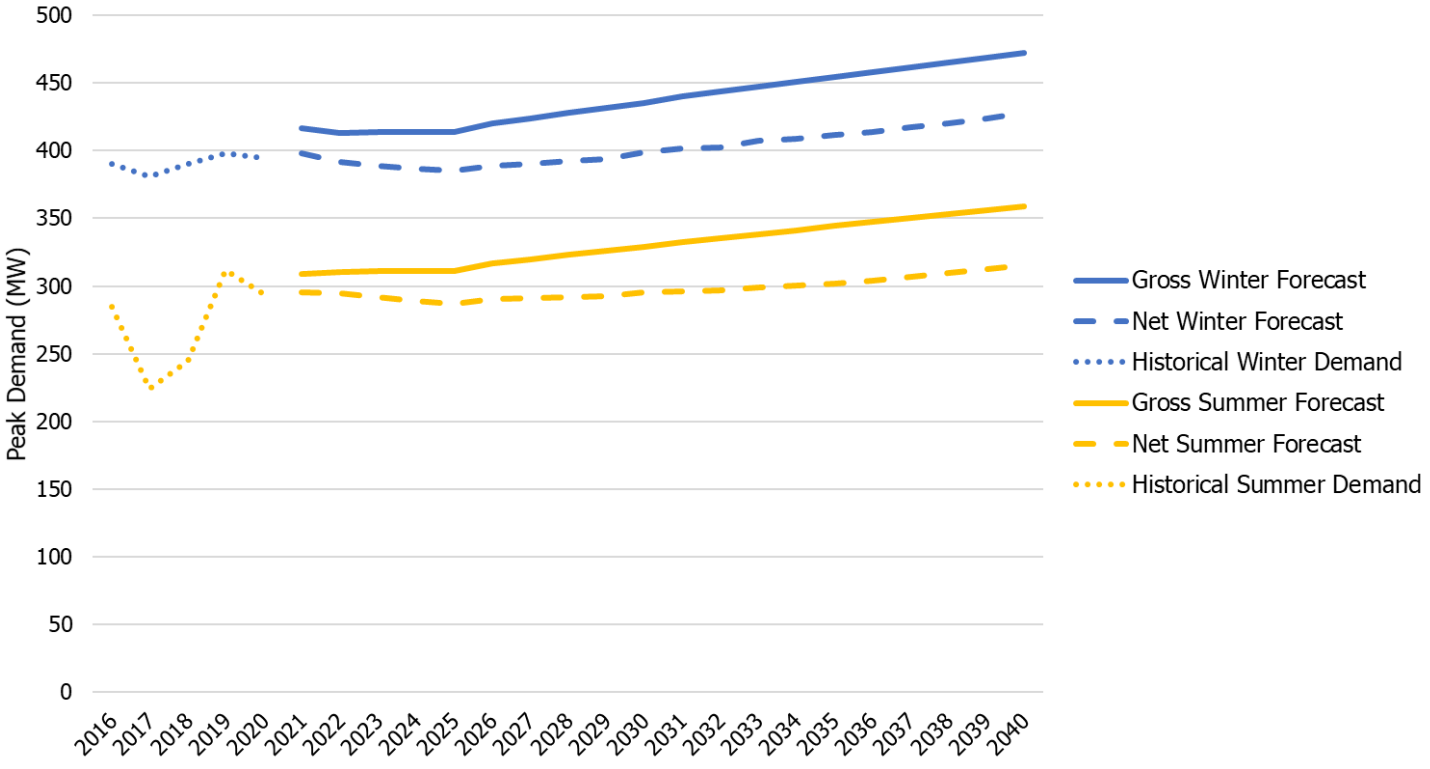
5.3.2 Contribution of Distributed Generation to LDC Demand Forecast

The effect of Distributed Generation (DG) in offsetting demand is also factored in to the North & East of Sudbury region gross peak demand forecast for median weather. No assumptions were made regarding DG growth as in the long term, as the contribution of DG is expected to diminish as contracts expire. The resources that were included in the DG forecast were comprised of solar and hydroelectric projects. Specific capacity contribution factors were attributed to each resource type in order to estimate the effective capacity that would be available to shave load during the regional peak hours. Upon applying the associated capacity contribution factors to each resource in the DG list, the data was then aggregated on a station level in order to put together a forecast specifying the estimated peak load reduction due to DG output.

The following load supply stations included in this IRRP have embedded DG resources:

- Crystal Falls TS
- Kapuskasing TS
- Ramore TS
- Timmins TS
- Dymond TS
- Trout Lake TS

The effective winter capacity of DG across the region totaled 16 MW in 2022. The expected annual peak demand contribution of contracted DG in the North & East of Sudbury region and capacity contribution factors can be found in Appendix B.



5.3.3 LDC Net Extreme Weather Planning Forecast

The net extreme weather planning forecast, also known as the "planning" forecast, is the coincident peak demand forecast for the region and is used to carry out system studies for identifying potential needs in the North & East of Sudbury region. This forecast is created in three steps:

1. The gross median weather forecast, provided by the LDCs, is adjusted to extreme weather conditions, according to the methodology described in Appendix B. The result is a gross extreme weather forecast.
2. The impacts of forecast CDM savings and DG output are subtracted from the gross extreme weather forecast to produce a net extreme weather forecast, or planning forecast.
3. A coincidence factor is applied to the forecast at each station to create a non-coincident forecast. The coincidence factor is based on the contribution of each station to the region's coincident peak over the past five years. Non-coincident station forecasts are utilized for assessing the capacity adequacy of each transformer station in the region.

The gross and net extreme weather coincident forecasts for the North & East of Sudbury region are shown in Figure 7 below for summer and winter.

Figure 7 | Extreme Weather Gross and Net Winter and Summer LDC Forecasts for the North & East of Sudbury Region

5.4 Transmission-Connected Forecast

Forecast demand growth among transmission-connected customers in the North & East of Sudbury area primarily consists of new or expanded mining projects and associated industrial processes (e.g. refining). The transmission-connected forecast represents the most up to date information on the timing, size and likelihood of these mining customers either increasing their existing demand or connecting to the system as a new customer.

The mining forecast is project-based and built from the bottom up based on known mining exploration or projects collected from proponents, industry publications, utility companies, and government. Each project is assigned one of four "likelihood" factors ranging from "most likely" to "least likely" that represents the probability of its electricity demand materializing to enable the creation of scenarios that represent different potential future outcomes.

A project's likelihood is informed by factors such as the reliability of available data sources, development stage of the project, project timing, and permitting information. The IESO also incorporates input from the Ministry of Mines on the forecast and likelihood factors. The mining forecast scenarios are summarized in Table 3 below.

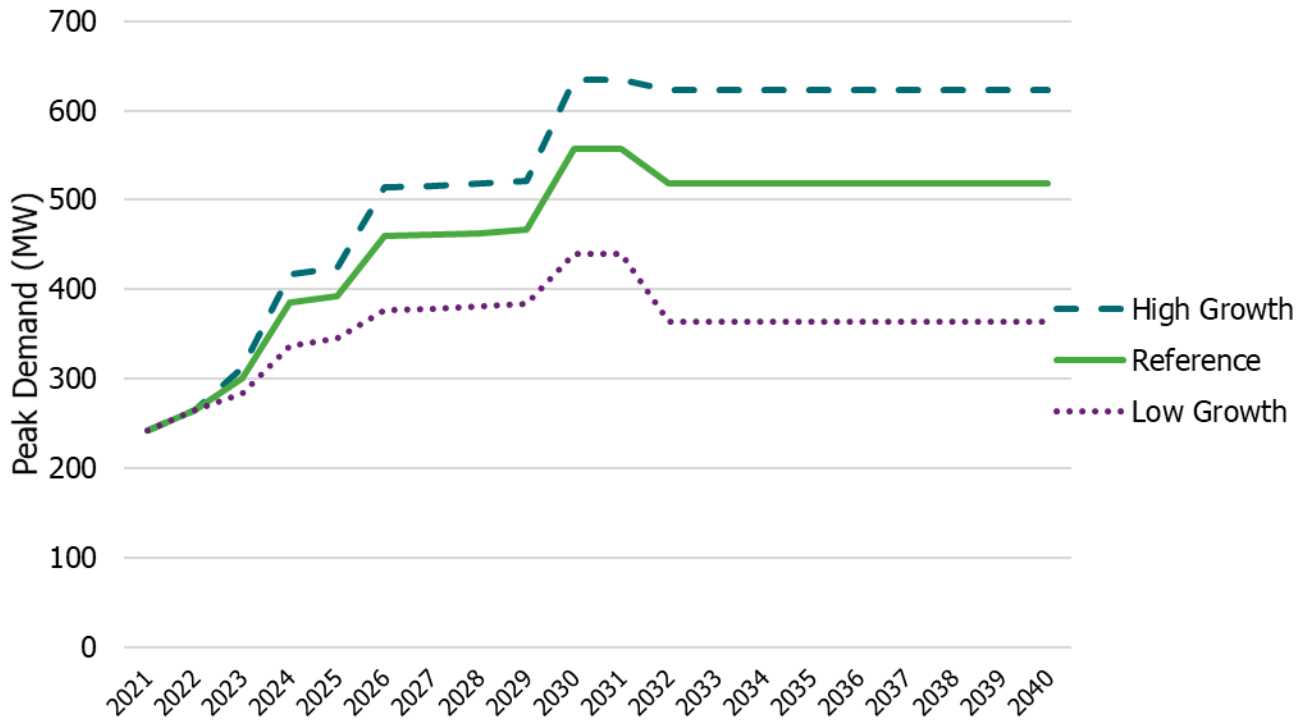


Table 3 | Mining Forecast Scenario Descriptions

Scenario	Description
Low	- Conservative scenario including only existing mining projects and their extension/expansion/retirement plans - The full demand forecast for all existing mining projects is included
Reference	- Includes all demand in the low scenario plus demand forecast from projects classified as "most likely" and "likely" discounted according to their likelihood classification: o "Most likely" project forecasts are not discounted o "Likely" project forecasts discounted to 80% of their full project demand - Aligned with 2021 Annual Planning Outlook[1] reference scenario
High	- Includes all known mining projects with each project's demand forecast discounted according to their likelihood classification: o "Most likely" project forecasts are not discounted o "Likely" project forecasts discounted to 80% of their full project demand o "Less likely" project forecasts discounted to 50% of their full project demand o "Least likely" project forecasts discounted to 20% of their full project demand - Aligned with 2021 Annual Planning Outlook high scenario

The transmission-connected forecast for the North & East of Sudbury area is comparable in size to the LDC forecast. However, transmission-connected customers tend to have a more noticeable impact on the transmission system as they tend to have a flat demand profile (i.e., 24/7 operation) and are large loads. Large step increases in demand from new or expanded transmission-connected customers can stress the system more quickly than growth in LDC load which tends to have a more predictable and slower growth rate as seen in Figure 7 above. Therefore, these transmission-connected customers are more likely to drive system enhancements to support their growth/new connections. The transmission-connected forecast is shown in Figure 8 below.

[1] The Annual Planning Outlook forecasts electricity demand, assesses the reliability of the electricity system, identifies capacity and energy needs, and explores the province's ability to meet them. The latest Annual Planning Outlook is available on the IESO's Planning and Forecasting webpage.

Figure 8 | Transmission-Connected Forecast

5.5 Load Profiling

In addition to the annual peak demand forecast, hourly load profiles (8,760 hours per year over a 20 year forecast horizon) for a station with an identified capacity need were developed to characterize these needs with finer granularity. The profiles are based on historical data adjusted for variables that impact demand such as calendar day (e.g. holidays and weekends) and weather impacts (e.g. extreme weather events like ice storms or heat waves). The profiles are then scaled to match the annual peak demand forecast for each year. These profiles are used to quantify the magnitude, frequency and duration of needs to better evaluate the suitability of non-wires alternatives options.

Additional load profile details including summary tables and hourly heat maps for each need (where appropriate) can be found in Section 6.2.1.1 and Appendix B.

6. Electricity System Needs

6.1 Needs Assessment Methodology

Based on the net extreme weather planning demand forecast, the transmission-connected forecast, the transmitter's identified end-of-life asset replacement plans, and the application of ORTAC planning criteria and North American Electric Reliability Corporation (NERC) TPL-001-4 Standard, the Working Group identified electricity needs for the following categories:

- **Station Capacity Needs** describe the electricity system's inability to deliver power to the local distribution network through regional step-down transformer stations during peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day LTR of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be limited when downstream or upstream equipment, e.g., breakers, disconnect switches, low-voltage bus or high voltage circuits, is undersized relative to the transformer rating.
- **Supply Capacity Needs** describe the electricity system's inability to provide continuous supply to a local area at peak demand. This is limited by the load meeting capability (LMC) of the transmission supply to an area. The LMC is determined by evaluating the maximum demand that can be supplied to an area accounting for limitations of the transmission elements, e.g., a transmission line, group of lines, or autotransformer, when subjected to contingencies and criteria prescribed by ORTAC and TPL-001-4. LMC studies are conducted using power system simulation analysis. An area's LMC can be limited by the thermal ratings of the equipment, or the voltage levels/changes following a contingency in the area.
- **End-of-life Asset Refurbishment Needs** describe the needs identified by the transmitter with consideration to a variety of factors such as asset age, the asset's expected service life, risk associated with the failure of the asset and its condition. Replacement needs identified in the near-and early mid-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium-to long-term needs should reflect the potential for the need date to change as condition information is routinely updated.
- **Load Security and Restoration Needs** describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC.

In addition, for the North & East of Sudbury IRRP, several existing operational needs were identified through discussion with the IESO's control room operators and outage planning staff. These needs include localized voltage control issues and difficulty planning 500 kV outages while still maintaining supply to customers in the area.

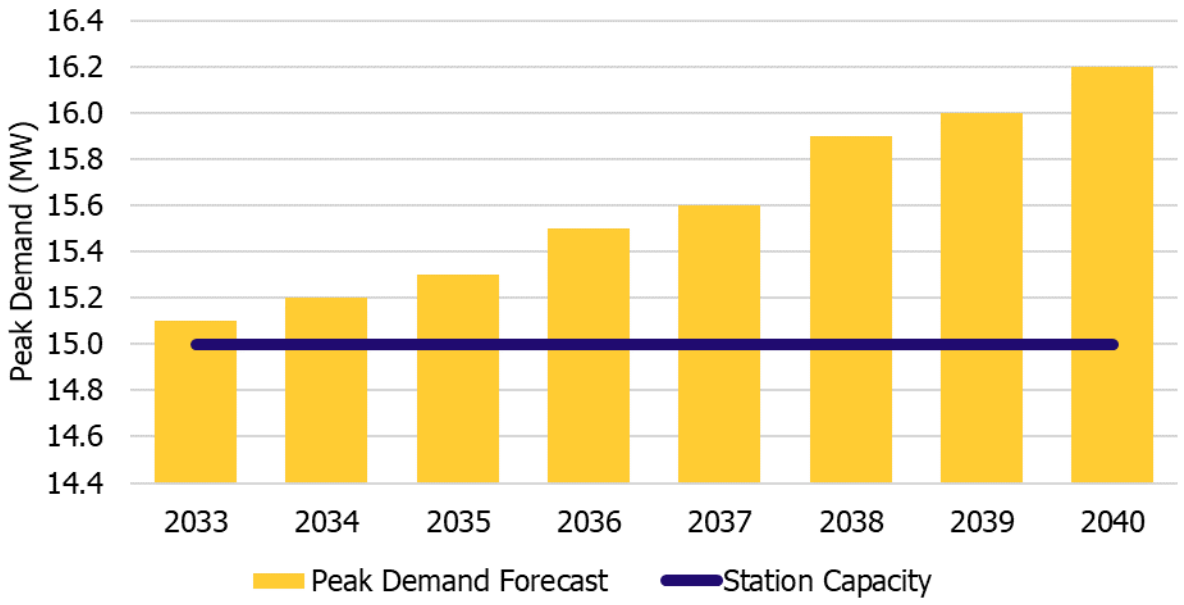
Technical study results can be found in Appendix D. The needs identified in this IRRP are discussed in the section below.

6.2 Needs Identified

Table 4 below summarizes the needs identified by the North & East of Sudbury IRRP. Some needs previously identified (e.g. Kirkland Lake TS capacity need in 2040, higher than standard operating voltages in the Porcupine to Hunta area) were deferred to the next round of regional planning. For Kirkland Lake TS, the uncertainty regarding certain mining loads and the long term nature of the need means that the need could be deferred. The high operating voltages from Porcupine to Hunta requires more coordination and discussion with existing customers whose equipment are designed to operate at these high voltages. Furthermore, the North of Moosonee region will need to be studied to see if lower operating voltages can be accommodated. Such an activity is outside the scope of this regional plan and is suggested to be addressed in the North of Moosonee regional planning process.

Table 4 | Summary of Needs for North & East of Sudbury IRRP

No.	Need Description	Need Date
1	Station Capacity at Ramore TS	2033
2	Voltage control issues with existing capacitors at Dymond TS	2030
3	Voltage control issues in the Kirkland Lake area	2030
4	Voltage control issues at Ansonville, Hunta, Kapuskasing Area	Near to Mid-term
5	Thermal overload of circuit D3K upon loss of A8K or A9K when its companion is out of service	2030
6	A4H/A5H End-of-Life Need	2027
7	D2H/D3H End-of-Life Need	2026
8	ORTAC load security criteria not met for 500 kV circuit outages	Existing Need
9	Difficulty supplying loads during planned outages to circuit D501P	Existing Need



6.2.1 Station Capacity Needs

6.2.1.1 Ramore TS

Winter peak demand growth at Ramore TS is expected to exceed the station's capacity in 2033. The non-coincident winter peak forecast for Ramore TS is found in Figure 9 below.

Note that load growth in the Ramore TS service area is expected to be primarily driven by new or expanding industrial customers. These types of loads are inherently more difficult to forecast beyond the near term as growth tends to occur in large blocks if/when economic conditions support investment. As a result, the timelines associated with this need are understood to be beyond the near term (when actual applications for connection would already be known), but may be triggered with relatively short lead time thereafter. Potential options to address this need should be evaluated to ensure any necessary upgrades can be triggered with minimal planning lead time when required, as opposed to working towards a firm anticipated in-service date of 2033.

Figure 9 | Ramore TS Winter Peak Forecast

6.2.2 Supply Capacity Needs

6.2.2.1 Dymond TS Voltage Control

IESO control room operators report existing operational issues associated with the two existing capacitors at Dymond TS. They observe that the two capacitors at Dymond TS cannot be placed into service without exceeded the maximum voltage allowed by IESO Market Rules, an indication that they are too large for the area under current system conditions.[2] They also note that the existing Dymond capacitor switching scheme is a manual scheme with no telemetered status to either the IESO's or Hydro One's control rooms. This means that staff must be called out to the station to confirm or update the status of the scheme, and this can cause delays in responding to outages.

System studies show that a failure of the AL3 breaker at Dymond TS to open when called upon to clear a fault can cause voltage decline at Dymond TS, beginning in 2030. Voltage decline usually occurs when there is a large amount of load and/or lack of available reactive power resources (e.g. shunt capacitors) to provide voltage support. There are currently capacitors at Dymond TS that may address this issue. However, operators have found the current capacitors are too large to use to prevent this voltage depression.

6.2.2.2 Kirkland Lake Area Voltage Control

IESO system operators report difficulties maintaining minimum operating voltages in the Kirkland Lake area under outage conditions with recent demand growth and changes to the operation of local gas generation. System studies confirm that concurrent outages to the Kirkland Lake SVC and all units at the Northland Power Kirkland Lake Generating Station cause voltage decline issues in the Kirkland Lake area. Specifically, minimum voltages cannot be maintained at the end of the radial K2 circuit.

[2] It is likely that when these capacitors were designed, they were sized appropriately for the area but changing system conditions over time have led to them being oversized.

6.2.2.3 Ansonville, Hunta, Kapuskasing Area Voltage Control

There are post contingency voltage control issues at Ansonville TS, Kapuskasing TS and Hunta TS for the loss of Ansonville T2 and Canyon Units.

6.2.2.4 D3K Thermal Overload

D3K is a 115 kV circuit that supplies Kirkland Lake TS from the south. Kirkland Lake TS is also supplied from the north by two 115 kV circuits, A8K and A9K. Upon the loss of either A8K or A9K when its companion is on outage, Kirkland Lake is supplied radially from the south via D3K. With forecast demand growth in the area, this outage condition will cause D3K to be thermally overloaded (102% of LTE) beginning in 2030.

6.2.3 End-of-Life Refurbishment Needs

6.2.3.1 A4H/A5H End-of-Life

Conductors on sections of A4H and A5H, namely the 25 km sections from Tunis JCT to Fournier JCT, are reaching end-of-life and are planned for replacement in 2027. This IRRP investigated whether there are other needs in the region for which there is an opportunity to right-size the ampacity of the conductors.

6.2.3.2 D2H/D3H End-of-Life

Conductors on sections of D2H and D3H, namely the 90 km sections of these circuits from Pinard TS to Hunta SS, are reaching end-of-life and are planned for replacement in 2026. This IRRP investigated whether are other needs in the region for which there is an opportunity to right-size the ampacity of the conductors.

6.2.4 Load Security and Restoration Needs

6.2.4.1 500 kV Load Security

The North & East of Sudbury region is supplied by two 500 kV circuits, P502X from Hanmer TS to Porcupine TS and D501P from Porcupine TS to Pinard TS, that are operated in parallel with a relatively weak 115 kV system. The system was developed not only to supply loads in the region, but also to integrate a substantial amount of hydroelectric generation on the Moose River which, when generating at full output result in substantial southbound flows on the 500 kV system. The need to respect the loss of either of these 500 kV circuits significantly limits the capability of this system because the 115 kV path cannot handle the post-contingency flows that would result when the 500 kV system is loaded to capacity. To address this, the system was designed around a Remedial Action Scheme (RAS), the Northeast Load and Generation Rejection Scheme (the "Northeast LGR") that enables full use of the system pre-contingency, while protecting it post-contingency by arming generation, loads, or the cross-tripping of circuits (which may also reject generation or loads by configuration) for the loss of the 500 kV path. This is a legacy system that does not meet today's planning criteria. For example, ORTAC planning criteria do not permit the use of load rejection following the loss of a single transmission element. However, bringing it up to current standards would involve substantial capital investment that is difficult to justify without the introduction of new needs (e.g., additional demand growth or resource development that would outstrip the system's current capability).

Nonetheless, the IESO recognizes customer reliability concerns and the need to work toward bringing this system up to current standards over time through its bulk and regional planning processes. The recent Northeast Bulk Plan recommendation to add a new single-circuit 500 kV line (operated at 230 kV) between Porcupine TS and Wawa TS, is a first step toward reducing reliance on load rejection in the North & East of Sudbury area. This new line is expected to reduce the frequency and amount of load rejection arming needed to respect the loss of P502X as it provides another supply point into Porcupine TS. This will, however, not address reliability concerns following the loss of D501P, which supplies the most northeastern portions of the system.

6.2.4.2 Difficulty supplying loads during planned outages to circuit D501P

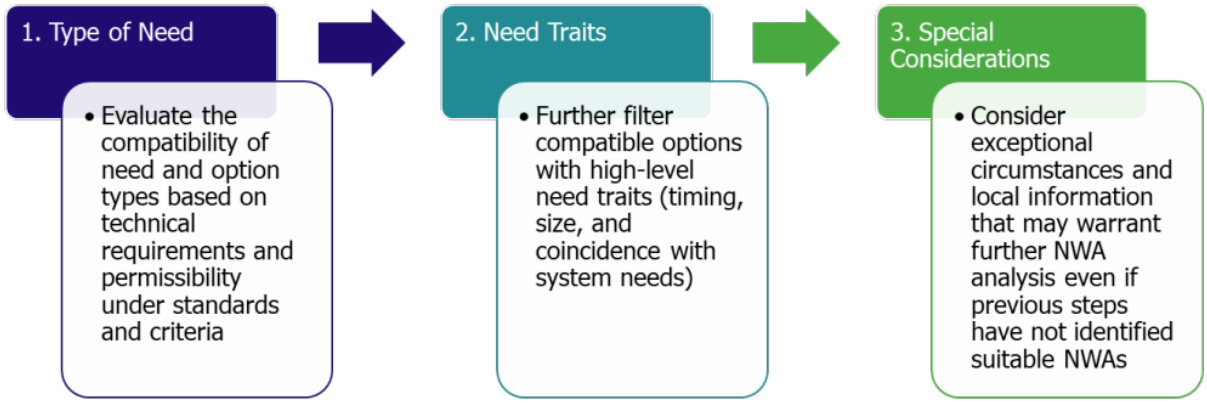
IESO's outage planning staff have also identified that during recent outages to D501P, it has not been possible to supply all customer load in the area due to limitations on the 115 kV system, and certain industrial customers have been forced to reduce their production. These concerns have also been raised by these customers themselves. During D501P outages, generation must also be significantly curtailed, which can remove substantial capacity from the Ontario system.

6.2.4.3 Load Restoration Needs

No load restoration needs were identified in this IRRP.

7. Plan Options and Recommendations

In developing the plan, the Technical Working Group considered a range of integrated options. Considerations in assessing alternatives included maximizing use of existing infrastructure, provincial electricity policy, feasibility, cost, and consistency with longer-term needs in the area.



Generally speaking, there are two approaches for addressing regional needs that arise as electricity demand increases:

1. Build new infrastructure to increase the load meeting capability of the area. These are commonly referred to as "wires" options and can include recommendations such as new transmission lines, autotransformers, step-down transformer stations, voltage control devices or upgrades to existing infrastructure. Wires options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate certain reliability concerns.
2. Install or implement measures to reduce the net peak demand to maintain loading within the system's existing load meeting capability. These are commonly referred to as "non-wires" alternatives and can include recommendations such as local generation, distributed energy resources, or conservation and demand management.

The IESO utilized a screening approach for assessing which needs would be best suited to undergoing a detailed assessment for non-wires alternatives, including CDM. The initial screening exercise examined the duration, frequency, timing, and magnitude of the need, as well as cost of traditional wires solutions, for each identified need. Screening occurs early in the IRRP study after local reliability needs are known but before options analysis. It helps direct time-intensive aspects of detailed NWA analysis (hourly need characterization, options development, financial analysis, and engagement) towards the most promising options. The three-step, high-level approach is shown in Figure 10.

The screening process resulted in NWA being considered for the station capacity need at Ramore TS. NWAs were found to not be suitable for end-of-life and voltage control needs. A like-for-standard sustainment plan is appropriate for the end-of-life needs given that the system studies did not identify any regional needs related to these assets. Needs characterization was completed for the Ramore TS station capacity need.

Figure 10 | IRRP Options Screening Mechanism

7.1 Options and Recommendations for Meeting Near- and Medium-Term Needs

7.1.1 Ramore TS Station Capacity Need

Options to address station capacity needs can be broadly sorted into two categories:

1. Keep peak loading below existing capacity, using measures such as conservation or distributed energy resources ("Non-wires alternatives), or;
2. Upgrade the station to enable additional capacity (conventional, or "Wires" solution)

Often the two categories can be considered together, with measures to offset peak demand relied upon until no longer feasible or cost effective, at which point an infrastructure upgrade becomes preferred. This type of approach can be preferable if peak capacity is expected to only marginally exceed ratings for the first few years (common in areas with relatively slower load growth), if there is insufficient lead time to accommodate a station upgrade before the need is triggered, or if uncertainty exists in the demand forecast, meaning a capacity upgrade could be "stranded" if the need never materializes. In the case of Ramore TS, there is significant uncertainty in the actual need date due to the high proportion of industrial load at the station, plus under the existing forecast assumptions, load will be only marginally above existing capacity within the study horizon. For both of these reasons, Ramore TS is considered to be a good candidate to consider non-wires measures to keep loading below existing capacity, and consider a station upgrade if and when required. Two non-wires options in particular may be beneficial for this need.

7.1.1.1 Conservation/Energy Efficiency

Conservation (or energy efficiency) involves the use of incentive programs to reduce electricity demand by upgrading/replacing existing equipment with more energy efficient alternatives. In Ontario, the IESO is currently delivering a suite of province-wide programs under the 2021-2024 Conservation and Demand Management Framework. The framework is designed to produce energy savings and offset system peak demand (which occurs in the summer). A component of this framework is the Local Initiatives Programs, which enables the IESO to pursue additional conservation in specific areas to address local electricity system needs while also contributing to meeting provincial system needs.

Given the size and timing of the need, the inherent difficulties of predicting blocky industrial load, and the misalignment with current (summer) system peak, it is recommended to defer a review and decision on targeting conservation as a solution to the Ramore TS need until the next IRRP cycle.

7.1.1.2 Distributed Energy Resources

In order to assess the appropriate DER option, a load duration forecast was created for Ramore TS. This duration forecast consists of a series of year-long hourly profiles ("8760 profile", based on the number of hours in a year), which have been scaled to the appropriate annual peak demand. These profiles are studied to determine the feasibility of using DERs to address the region's needs and determine which type of DERs may be best suited to meet the needs.

Based on the profiles generated for Ramore TS, it was determined that a battery storage solution would be the best fit for the need. The battery storage solution would have a capacity of 1.2 MW and would be able to provide energy for up to six hours. The estimated cost of this battery storage solution is $3 to $3.7 million.

Given that the anticipated need for Ramore TS capacity upgrade is still several years out, it is not recommended that a non-wires alternative be developed at this time. Instead these options should be considered as potential deferral strategies and would be best pursued when actual demand and/or connection requests suggest a capacity need within the next 2-3 years. If these options prove to be insufficient to meet demand, or costlier than a wires alternative, then development work should be initiated to upgrade the station.

7.1.1.3 Station Upgrade

Ramore TS is current made up of a single 10/17 transformer, with a winter LTR of 15 MW. Hydro One has indicated that the station could be upgraded by adding a second, equally sized transformer. This type of upgrade would be expected to cost around $10-$15 million, and can be implemented with about three years' lead time.

Table 5 below shows a comparison of these alternatives, their potential capacity impact, and estimated cost. Note that due to the lead time expected before this work would be triggered, all cost and timing estimates should be considered preliminary, as they will need to be updated closer to when the work is undertaken.

Table 5 | Comparison of Ramore TS options

Option	Capacity Impact	Estimated Cost	Lead Time
Distributed Energy Resources	Increase by 1.2 MW	$3 to $3.7 million	Three years
Station Upgrade	Increase by 15 MW	$10-15 million	Three years

NWA can be viable alternatives should demand grow as projected in Section 6.2.1.1. Otherwise, new solutions may have to be drawn up should a large industrial customer wish to connect to the station. Based on the options above, the Working Group recommends that the station loading at Ramore TS be monitored in between cycles in preparation for the next regional planning cycle.

7.1.2 A4H/A5H End-of-Life Needs

No other regional needs were identified that could be addressed by right-sizing the end-of-life replacement of the A4H/A5H circuits, based on the IRRP demand forecast. Therefore, the Working Group recommends that Hydro One proceed with a like-for-standard replacement for these end-of-life needs. Nonetheless, future system developments (e.g., additional demand growth or resource development in the area) could drive a need for reinforcement in this area in the future. Therefore, the Working Group recommends continued monitoring of developments in the area between regional planning cycles, and that Hydro One touch base with the Working Group before the like-for-standard replacement project is committed, to determine if this recommendation should be revisited.

7.1.3 D2H/D3H End-of-Life Needs

No other regional needs were identified in the IRRP that could be addressed by right-sizing the end-of-life replacement of the D2H/D3H circuits. The Working Group recommends that Hydro One proceed with a like-for-standard replacement for these end-of-life needs.

7.1.4 D3K Thermal Overload

This need was identified in the Needs Assessment stage of regional planning. Since that time, a new RAS has come into service in the Kirkland Lake area to maintain system reliability following various contingencies in the Kirkland Lake area. This RAS will be able to address the identified post-contingency overloading of D3K by arming load rejection for the appropriate A8K or A9K contingency. Therefore, at this time, the Working Group does not recommend any further actions to address this need.

However, the RAS may need to be expanded and/or the system may need to be reinforced should additional demand beyond what was included in the IRRP forecast connect to the system in the Kirkland Lake area. The Working Group recommends that this area be monitored in between regional planning cycles.

7.1.5 Ansonville, Hunta, Kapuskasing Area Voltage Control

The IRRP reviewed the post contingency voltages at Ansonville TS and Hunta SS following the loss of Ansonville T2 and Canyon GS units. The IRRP found that post contingency voltage levels meet ORTAC criteria (Hunta SS is permitted to operate up to 138 kV). Hydro One is currently studying a possible expansion to the Kirkland Lake RAS. This will allow operators to take control actions following the loss of Ansonville T2, among other contingencies. This will give more flexibility to operators should post contingency voltage issues be seen in the future. The Working Group recommends that Hydro One continue to study the possible expansion of the Kirkland Lake RAS. New reactive devices (a 10 MVAr reactor and a 10 MVAr capacitor), controlled by a new remedial action scheme will soon come into service in the Kapuskasing area. These improvements were designed to ensure voltage criteria is met following certain contingencies at Kapuskasing TS, Spruce Falls TS, and Pinard TS. No additional recommendations are required in this IRRP to address voltage control issues in the Kapuskasing area.

Additional reactive devices will be recommended in the Northern Voltage Study to support the broader bulk system across northern Ontario (see Section 4.2.2). The recommendations of this study will provide further reactive support to help alleviate voltage control issues in the North & East of Sudbury area.

7.2 Options and Recommendations for Meeting Longer-Term Needs

7.2.1 Dymond Area Voltage Control Needs

The Working Group recommends that Hydro One investigate right-sizing the capacitors at Dymond TS so that they may be used more effectively to manage voltage in the area. This can be accomplished by reducing the size of the existing capacitors to improve their flexibility. The Working Group recommends that the exact sizing be explored in the RIP in coordination with gathering information on feasible resizing options. The Working Group also recommends Hydro One investigate the feasibility of introducing remote monitoring of the status of the Dymond TS capacitor switching scheme to improve operational visibility.

7.2.2 Kirkland Lake Area Voltage Control Needs

Based on system studies performed in the IRRP, it was found that under the conditions noted in section 6.2.2.2, a 20 MVAr reactive device located at Kirkland Lake TS or a 10 MVAr reactive device at the remote end of circuit K2 would address this need. The Working Group recommends that Hydro One, in the upcoming RIP, further develop options for adding reactive support in the Kirkland Lake area.

7.3 Load Security

7.3.1 Considerations on existing reliance on Remedial Action Schemes in the Northeast and Load Security Needs

Several investments were made over the years to strengthen the area (e.g. Kapuskasing Area Reinforcement). Despite these investments, the reliability issues following the loss of D501P still remains. While proven reliable to protect the rest of the system, the continued long-term reliance on the Northeast LGR may hamper growing interest to connect additional loads (e.g. new mines, mining expansions) and generators in the area.

As the circuit D501P is part of the Bulk Power System, the Working Group recommends that the next bulk system plan in Northeast Ontario address the load security concerns following an outage on D501P. This bulk plan should be triggered if substantial load increases/new resources are expected in the Kapuskasing and northern Cochrane areas.

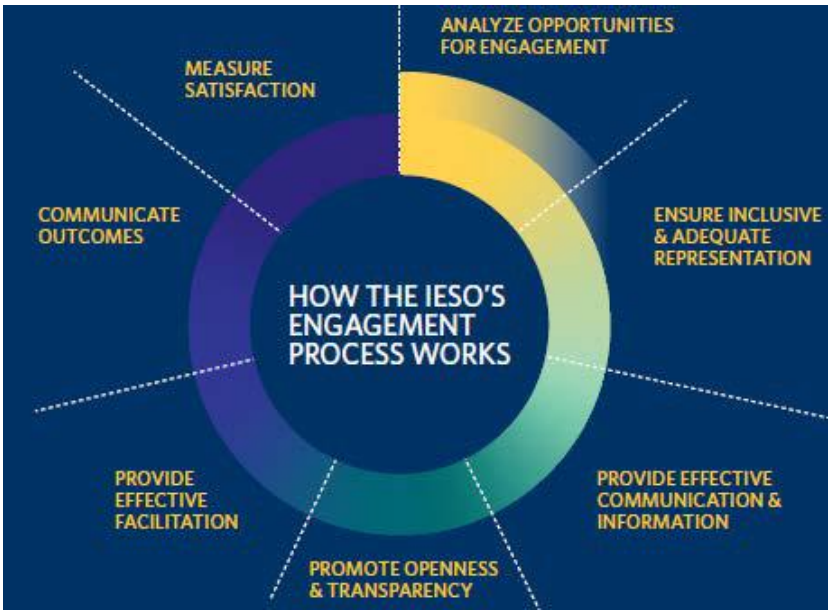
7.4 Summary of Recommended Actions and Next Steps

Table 6 below shows a summary of all recommended actions as outlined in Section 7.

Table 6 | Summary of Recommended Actions and Next Steps

No.	Need Description	Recommendation	Need Date
1	Station Capacity at Ramore TS	Load growth at Ramore TS will be monitored and revisited in the next cycle of regional planning	2033
2	Voltage control issues with existing capacitors at Dymond TS	Hydro One to investigate options to improve operability of existing capacitors in the upcoming RIP	2030
3	Voltage control issues in the Kirkland Lake area	Hydro One to investigate options of adding reactive devices in the Kirkland Lake area in the upcoming RIP	2030
4	Voltage control issues at Ansonville, Hunta, Kapuskasing Area	Various recommendations, including a new RAS and additional voltage support	Near to Mid-term
5	Thermal overload of circuit D3K upon loss of A8K or A9K when its companion is out of service	The new Kirkland Lake RAS installed in 2022 addresses this issue. Additional load in the area beyond the current forecast will require further study	2030
6	A4H/A5H End-of-Life Need	Hydro One to proceed with plans to replace the affected circuit sections with a like-for-like replacement	2027
7	D2H/D3H End-of-Life Need	Hydro One to proceed with plans to replace the affected circuit sections with a like-for-like replacement	2026
8	ORTAC load security criteria not met for 500 kV circuit outages	Partially addressed by the recent Northeast Bulk Plan. An update to this plan is recommended should significant new resources and/or load connect to the North & East of Sudbury region.	Existing Need

No.	Need Description	Recommendation	Need Date
9	Difficulty supplying loads during planned outages to circuit D501P	Study this need as part of the next bulk system plan for Northeast Ontario in combination with other drivers of system expansion as they develop	Existing Need



8. Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and preferences of communities to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the activities undertaken for the IRRP.

8.1 Engagement Principles

The IESO's engagement principles help ensure that all interested parties are aware of and can contribute to the development of this IRRP. The IESO uses these principles to ensure inclusiveness, sincerity, respect and fairness in its engagements, striving to build trusting relationships as a result.

Figure 11 | The IESO's Engagement Principles

8.2 Creating an Engagement Approach for North & East of Sudbury

The first step in ensuring that any IRRP reflects the needs of community members and interested stakeholders is to create an engagement plan to ensure that all interested parties understand the scope of the IRRP and are adequately informed about the background and issues in order to provide meaningful input on the development of the IRRP for the region.

- Creating the engagement plan for this IRRP involved:
- Discussions to help inform the engagement approach for the planning cycle;
- Developing and implementing engagement tactics to allow for the widest communication of the IESO's planning messages, using multiple channels to reach audiences; and
- Identifying specific stakeholders and communities that should be targeted for one-on-one consultation, based on identified and specific needs.

As a result, the engagement plan for this IRRP included:

- A dedicated webpage on the IESO website to post all meeting materials, feedback received and IESO responses to the feedback throughout the engagement process;
- Regular communication with interested communities and stakeholders by email or through the IESO weekly Bulletin;
- Public webinars;
- Targeted individual and small group meetings; and
- One-on-one outreach with specific stakeholders to ensure that their identified needs are addressed (see Section 8.3).

8.3 Engage Early and Often

Preliminary discussions were held to help inform the engagement approach and lay the foundation for dialogue in this region where the IESO has not actively engaged with communities and stakeholders. This started with an invitation to targeted municipalities, Indigenous communities, and those with an identified interest in regional issues, to announce the commencement of a new planning cycle and opportunity to provide input on the North & East of Sudbury Region Scoping Assessment Outcome Report. A public webinar was held in June 2021 to provide an overview of the regional electricity planning process and seek input on the high-level needs identified and proposed approach to address them moving forward. Interested parties were invited to submit written feedback on a draft report that was posted for review over a three-week comment period. The final Scoping Assessment was posted later in August 2021, identifying the need for a coordinated regional planning approach and an IRRP.

Following the publication of the final Scoping Assessment, targeted outreach began with municipalities in the region to inform early discussions in the development of the IRRP, including the IESO's approach to engagement. The launch of a broader engagement initiative followed to ensure all interested parties were made aware of this opportunity for input. Three public webinars were held at major stages during IRRP development to give interested parties an opportunity to hear about its progress and provide comments on key components of the plan. These webinars were attended by a

cross-representation of community representatives, businesses, and other stakeholders, and written feedback was collected over a 21-day comment period after each webinar.

The three stages of engagement at which input was invited:

1. The draft engagement plan, electricity demand forecast, and early identified needs – to set the foundation of this planning work.
2. The defined electricity needs for the region and high-level screening of potential options to meet the identified needs.
3. The analysis of options and draft IRRP recommendations.

Comments received were primarily focused on:

- Pockets of development in certain areas (I.e. City of Temiskaming Shores, Town of Iroquois Falls and Town of Moosonee)
- Interest in exploring DERs and other non wires alternatives to address regional needs and defer the need for new transmission or large scale generation
- Reliability is a key issue and priority
- Engagement with local First Nations communities, customers and stakeholders is important to understand planned growth and opportunities to participate in developing solutions to meet emerging needs.

Feedback received during the written comment periods for these webinars helped to guide further discussions throughout the development of this IRRP, as well as add due consideration to the final recommendations.

All interested parties were kept informed throughout this engagement initiative via email to North & East of Sudbury subscribers, municipalities, and Indigenous and Métis communities. All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's North & East of Sudbury engagement webpage.

Ongoing discussions will be encouraged through the IESO's Northeast Regional Electricity Network to keep interested parties engaged in a two-way dialogue on local developments, priorities, and initiatives to prepare for the next planning cycle. Join the Northeast Network on the IESO website.

8.4 Bringing Municipalities to the Table

The IESO held meetings with municipalities to seek input on their planning and to ensure that key local information about growth and development and energy-related initiatives were taken into consideration in the development of this IRRP.

This targeted outreach was undertaken in tandem with the Northeast Bulk Plan work and engagement given the interrelations of some of the needs at the provincial and regional level, as well as to streamline discussions with local communities. Discussions were held with the Federation of Northern Ontario Municipalities (FONOM) Board of Directors, City of Timmins, Town of Iroquois Falls and Town of Cochrane. These discussions helped to build an understanding about the municipal/community electricity needs and priorities and provided opportunities to strengthen this relationship for ongoing dialogue beyond this IRRP process.

8.5 Engaging with Indigenous Communities

To raise awareness about the regional planning activities underway and invite participation in the engagement process, regular communications were sent to Indigenous communities within the North & East of Sudbury electricity planning region or that may have interests in the region throughout the development of the plan. This includes the First Nation communities of Constance Lake First Nation, Flying Post First Nation, Matachewan First Nation, Mattagami First Nation, Missanabie Cree, Moose Cree First Nation, MoCreebec Council of the Cree Nation, Nipissing First Nation, Taykwa Tagamou First Nation, Temagami First Nation, Wahgoshig First Nation, Wahnapitae First Nation, Northern Lights Métis Council, Timmins Métis Council, Temiskaming Métis Council and Chapleau Métis Council. This electricity planning initiative was also discussed during broader outreach meetings with Indigenous communities in the region.

9. Conclusion

The North & East of Sudbury IRRP identifies electricity needs in the region and opportunities to improve system reliability and operability for the next 20 years. This report recommends a plan to address near- to medium-term issues, and lays out actions to monitor, defer, and/or address long-term needs. The IESO will continue to participate in the Working Group during the next phase of regional planning, the Regional Infrastructure Plan, to provide input and ensure a coordinated approach with bulk system planning where such linkages are identified in the IRRP.

To support the development of the plan, this IRRP includes recommendations with respect to developing alternatives, and monitoring load growth. Responsibility for these actions has been assigned to the appropriate members of the Technical Working Group.

The Technical Working Group will meet at regular intervals to monitor developments and track progress toward plan deliverables. In the event that underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the OEB.

REGIONAL INFRASTRUCTURE PLAN REPORT

[North and East of Sudbury]

Regional Infrastructure Plan Report

North and East of Sudbury

[Date: November 03, 2023]

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

North & East of Sudbury Technical working group

Page intentionally left blank

Disclaimer

This Regional Infrastructure Plan (RIP) Report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group (TWG).

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Technical Working Group.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	**North and East of Sudbury** Region (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")
START DATE: May 10,2023	**END DATE:** November 03, 2023

1. INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process for the North & East of Sudbury Region, preceded by, the publication of Needs Assessment (NA) report in May 2021 by Hydro One, followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) in August 2021 and in April 2023 published by the IESO respectively.

Hydro One as the lead transmitter undertake the development of a RIP with input from the TWG for the region and publishes a RIP report. The RIP report includes a common discussion of all the options and recommended plans and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs. This is second cycle of RIP.

2. OBJECTIVES AND SCOPE

Objectives:

- Provide a comprehensive summary of needs and wires plans to address the needs for the North & East of Sudbury Region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

Scope:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs [2023-2033] identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the 2023-2043 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the North & East of Sudbury IRRP, Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

This section provides a detailed overview of the various steps followed during different phases of Regional Planning Process and their outcomes starting with the Needs Assessment, Scoping Assessment, Local Plan, Integrated Regional Resource Plan and finally details the Regional Infrastructure Plan Methodology.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

This section provides a general overview of the Geographical boundaries, Circuit connections and Stations located in the North & East of Sudbury Region though a regional planning area map and a Single Line diagram.

The North & East of Sudbury Region are bounded by regions of North Bay, Timmins, Hearst, Moosonee, Kirkland Lake and Dymond. Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits. This area is further reinforced through the 500kV circuits P502X and D501P connecting Hanmer TS to Pinard TS.

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR UNDERWAY

This section provides a summary and brief description of all the projects completed or are currently underway in past ten years.

I. Following Major projects were completed during the last ten years:

- Kapuskasing Area Reinforcement – H9K Circuit Upgrade (2020)
- Kirkland Lake TS (T12/T13) transformers (2017)
- Dymond TS (T3/T4) transformers (2016)
- Timmins TS (T63/T64) with single 83MVA (2016)
- Hanmer TS Northern Station Replacement Project (2022)

II. Following Major projects are underway:

- Kapuskasing Area Reinforcement – Install 115kV Reactive Devices (2023)
- Kirkland Lake TS – Replace low voltage breakers, Instrument Transformers, P&C equipment (2025)
- Hearst TS - Replace low voltage breakers, P&C Equipment, switches (2028)
- Hunta SS - Replace P&C Equipment (2025)
- Porcupine TS – Replace 1 - 500kV/230kV autotransformer (T7), 2- 500kV/115kV autotransformers (T3/T4), switches, station service and P&C equipment (2025)

- Otto Holden TS - Replace 2 – 230 kV/115 kV autotransformers (T3/T4), high voltage breakers, switches, station service equipment, and protections (2027)
- K4 circuit - Refurbish Kirkland Lake TS X Matachewan JCT (10km) (2024)
- A8K/A9K circuits – Refurbish A8K/A9K (90km) (2023)

Note: The planned in-service year for the above projects is tentative and is subject to change.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

During the study period, the load in the North & East of Sudbury Region is expected to grow at an average annual rate of approximately 0.50% in winter and 0.25% in summer from 2023 to 2043.

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2023-2043.
- LDCs reconfirmed load forecasts up to 2040. The additional 3 years of forecasts were extrapolated based on the growth rate as a reasonable position to complete the 20-year period.
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- The Region is winter peaking, so this assessment is based on winter peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR).
- Regional transmission line and auto transformer capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Resources assumptions align with the IRRP.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying the North & East of Sudbury Region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway are completed.

I. Needs identified in the region

a. Asset Renewal for Major HV Transmission Equipment

- Kirkland Lake TS
- Hunta SS
- Porcupine TS
- Otto Holden TS
- Hearst TS
- Timmins TS
- Kapuskasing TS
- Dymond TS
- Ansonville TS
- Crystal Falls TS
- Trout Lake TS
- A8K/A9K circuits
- K4 circuit
- T61S circuit
- K1/K2 circuits
- D2H/D3H circuits
- A4H/A5H circuits

b. Station Capacity

- Ramore TS

c. Transmission Line Capacity

- D3K

d. System Reliability, Operation and Load restoration

- Dymond TS - Voltage violation
- Kirkland Lake TS - Voltage control
- Ansonville, Hunta, Kapuskasing TS - Voltage control
- ORTAC load security criteria not met for 500 kV circuit outages
- Difficulty supplying loads during planned outages to circuit D501P

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the North & East of Sudbury Region. The needs include those previously identified in the NA and IRRP for the North & East of Sudbury Region as well as any new needs identified during the RIP phase.

9. CONCLUSION AND RECOMMENDATIONS

The major infrastructure investments recommended by the TWG in the North & East of Sudbury Region is given below:

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Asset Renewal Needs				
Kirkland Lake TS	Replacement of Instrument Transformers, P&C equipment, station service equipment and low voltage circuit breakers.	Hydro One Transmission	2025	36
Hunta SS	Replacement of P&C and telecom equipment.	Hydro One Transmission	2025	12
Porcupine TS	Replacement of 1-500/230kV 360MVA autotransformer (T8), 2- 500/115kV 225MVA autotransformers (T3/T4), switches, station service equipment and P&C equipment.	Hydro One Transmission	2026	91
Otto Holden TS	Replacement of 2-230/115 kV 60MVA autotransformers (T3/T4), high voltage circuit breakers, switches, station service equipment, and P&C equipment.	Hydro One Transmission	2027	74
Hearst TS	Replacement of low voltage circuit breakers, switches, P&C Equipment.	Hydro One Transmission	2028	19
Timmins TS	Replacement of 1-115/27.6kV 83MVA (T2) transformer and associated protections.	Hydro One Transmission	2028	14

Kapuskasing TS	Replace low voltage circuit breakers, switches, station service equipment and protections.	Hydro One Transmission	2030	24
Dymond TS	Replacement of low voltage breakers, and associated P&C equipment.	Hydro One Transmission	2031	42
Ansonville TS	Replace P&C equipment, Instrument transformers, station service equipment.	Hydro One Transmission	2031	11
Crystal Falls TS	Replacement of 2-230/44kV 42MVA (T5/T6) transformers, station service equipment, switches and P&C equipment.	Hydro One Transmission	2031	32
Trout Lake TS	Replacement of 2–230/44 kV 125MVA (T3/T4) transformers, low voltage circuit breakers and surge arresters.	Hydro One Transmission	2033	17
K4	Replace conductor and refurbish circuit Kirkland Lake TS X Matachewan JCT (10km)	Hydro One Transmission	2024	4
T61S	Replace conductor and refurbish circuit Timmins TS x Shiningtree JCT (115km)	Hydro One Transmission	2024	
K1/K2	Replace conductor and refurbish circuit Kirkland Lake TS x American Barrick JCT (14km)	Hydro One Transmission	2024	4
D2H/D3H*	Replace conductor and refurbish circuit Hunta SS x Abitibi Canyon SS (183km)	Hydro One Transmission	2029	96
A4H/A5H**	Replace conductor and refurbish circuit Tunis JCT x Fournier JCT (47km)	Hydro One Transmission	2027	22
Station Capacity Needs				
Ramore TS	To be monitored and reviewed in next planning cycle	Hydro One Distribution	NA	NA
Transmission Line Capacity Needs				
D3K	Monitoring & further exploration in future RIP cycle	Hydro One Transmission	NA	NA

System Reliability, Operation and Load restoration Needs				
Dymond TS	Continue to investigate sizing of the existing 115kV SC11 & SC12 capacitor banks	Hydro One Transmission	NA	NA

Note:

a) The planned in-service dates are tentative and subject to change
b) Costs are based on budgetary planning estimates and excludes the cost for distribution infrastructure (if required)

* IESO to inform by end of Q2 2025 if an upgrade is required

** IESO to inform by end of 2024 if an upgrade is required

1. INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process where, Hydro One as the lead transmitter undertakes the development of a RIP with input from the TWG for the region and publishes a RIP report. The second cycle of the Regional Planning process for the North & East of Sudbury Region was initiated with the publication of Needs Assessment (NA) report in May 2021 by Hydro One, followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) in August 2021 and in April 2023 published by the IESO respectively.

The RIP report includes a common discussion of all the options and recommended plans and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs.

This report was prepared by the North & East of Sudbury Technical Working Group("TWG"), led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC"), the Municipalities and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: North & East of Sudbury Region TWG Participants

Hydro One Networks Inc. (Lead Transmitter)	Lead Transmitter
Independent Electricity System Operator ("IESO")	System Operator
Hydro One Networks Inc. (Distribution)	LDC
North Bay Hydro	LDC
Northern Ontario Wires Inc.	LDC
Hearst Power Distribution Co.	LDC
Greater Sudbury Hydro Inc.	LDC

2. OBJECTIVES AND SCOPE OF REGIONAL INFRASTRUCTURE PLAN

This RIP report examines the needs in the North & East of Sudbury Region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs for the North & East of Sudbury region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major high voltage transmission equipment, transmission, and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs (2023-2033) identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the 2023-2033 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the North & East of Sudbury IRRP, Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

3.1 Overview

Bulk System Planning, Regional Planning and Distribution Planning are the three levels of planning for the electricity system in Ontario. Bulk system planning typically looks at issues that impact the system on a provincial level and requires longer lead time and larger investments. Comparatively, planning at the regional and distribution levels look at issues on a more regional or localized level. Typically, the most

essential and effective regional planning horizon is the near- to medium-term (1- 10 years), whereas long-term (10-20 years) regional planning mostly provides a future outlook with little details about investments because the needs and other factors may vary over time. On the other hand, bulk system plans are developed for the long term because of the larger magnitude of the investments.

The regional planning process begins with a Needs Assessment (NA) which is led by the transmitter to identify, assess, and document which of the needs

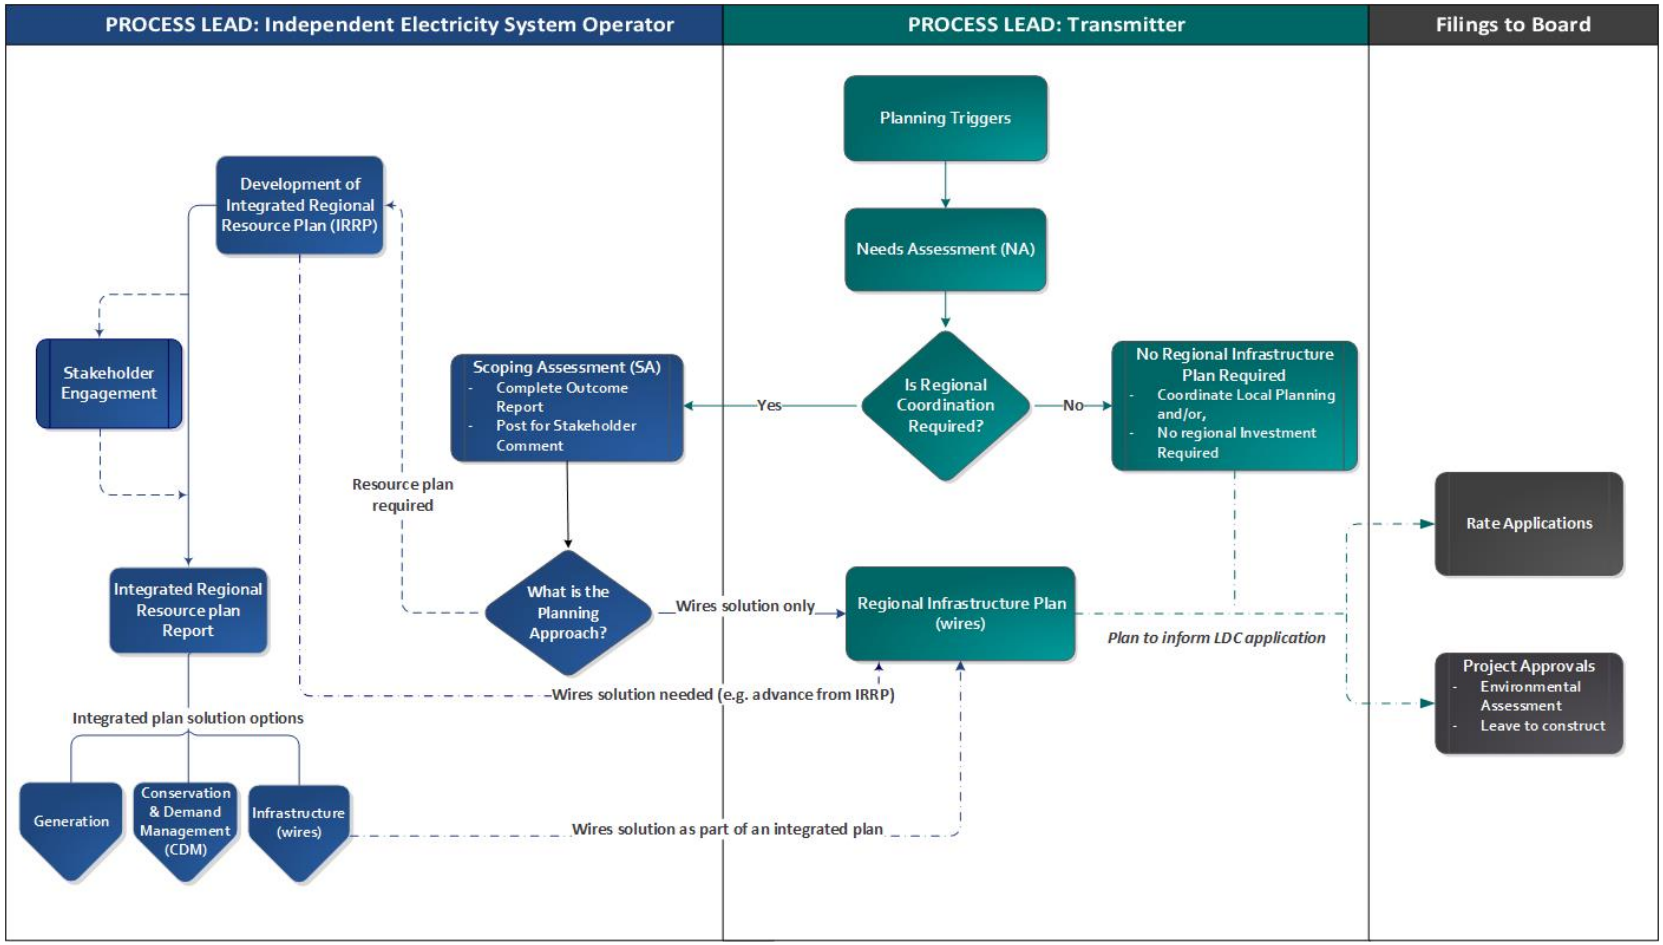
a) can be addressed directly between the customer and transmitter along with a recommended plan, and;
b) that require further regional coordination and identification of Local Distribution Companies (LDCs) to be involved in further regional planning activities for the region.

At the end of the NA, a decision is made by the Technical Working Group (TWG) as to whether further regional coordination is necessary to address some or all the regional needs. If no, further regional coordination is required, recommendation to implement the recommended option and any necessary investments are planned directly by the LDCs (or customers) and the transmitter. The Region's TWG can also recommend to the transmitter and LDCs to undertake a local planning process for further assessment when needs

a) are local in nature,
b) require limited investments in wires (transmission or distribution) solutions, and;
c) do not require upstream transmission investments.

If coordination at the regional or sub-regional levels is required for identified regional needs, then the Independent Electricity System Operator (IESO) initiates the Scoping Assessment (SA) phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires or resource alternatives, e.g., Conservation and Demand Management (CDM), Distributed Generation (DG), etc., in order to make a decision on the most appropriate regional planning approach including Local Plan (LP), Integrated Regional Resource Plan (IRRP) and/or Regional Infrastructure Plan (RIP).

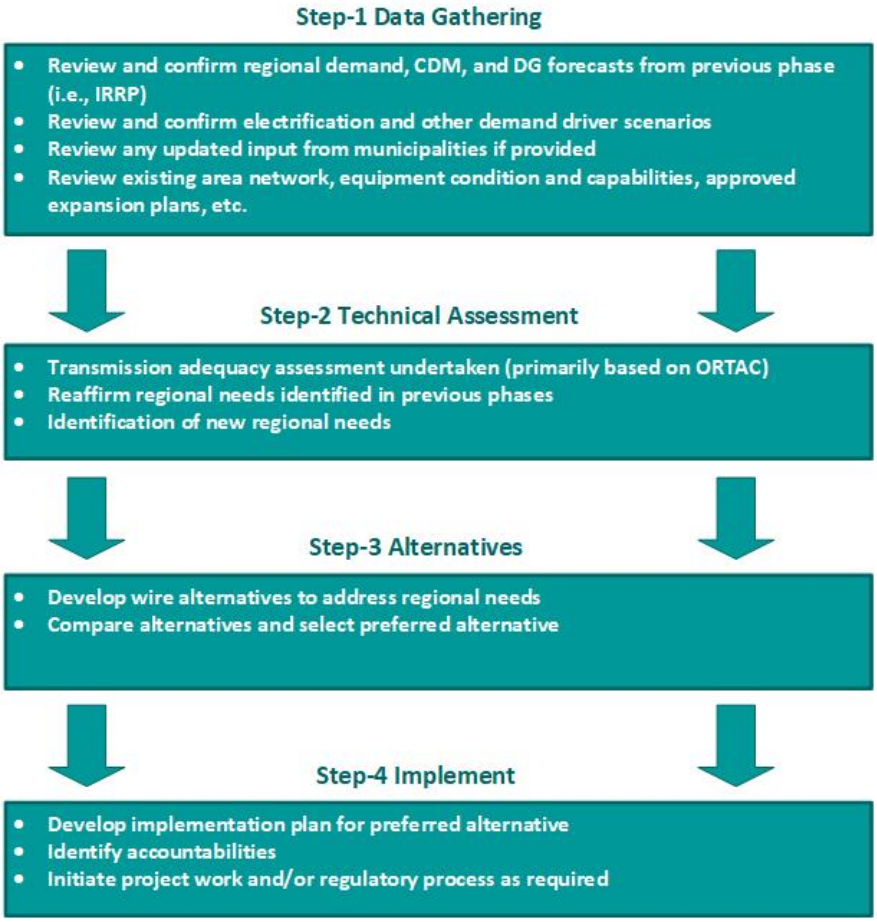
The primary purpose of the IRRP is to identify and assess both resource and wires options at a higher or macro level, but sufficient to permit a comparison of resource options vs. wire infrastructure to address the needs. Worth noting, the LDCs' CDM targets as well as contracted DG plans provided by IESO and LDCs are reviewed and considered at each step in the regional planning process.



If and when an IRRP identifies that resource and/or wires options may be most appropriate to meet a need, resource/wires planning can be initiated in parallel with the IRRP or in the RIP phase to undertake a more detailed assessment, develop specific resource/wires alternatives, and recommend a preferred wires solution.

The RIP phase is the final phase of the regional planning process and involves: discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and, development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive and consolidated report of a wires plan for the

region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the Ontario Energy Board (OEB) timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.



The various phases of Regional Planning Process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome are shown below in Figure-1.

Figure-1 Regional Planning Process Flowchart

3.2 Regional Infrastructure Plan Methodology

Figure-2 Regional Infrastructure Plan Methodology

Regional Infrastructure Plan phase is a four-step process which are described below:

3.2.1. Data Gathering:

The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the technical working group (TWG) to reconfirm or update the information as required. The data collected includes:

- Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs. As agreed by TWG members, the load forecast from the IRRP was used for this RIP.

- Review and confirm electrification and other growth scenarios which effects the projects recommended in in previous stages and also update the inputs provided by the Municipalities.
- Existing area network and capabilities including any bulk system power flow assumptions.
- Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

3.2.2. Technical Assessment:

The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3.2.3. Alternative Development:

The third step is the development of wires options to address the needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

3.2.4. Implementation Plan:

The fourth and last step is the development of the implementation plan for the preferred alternative, identifying accountabilities and initiate project work or obtain permissions from Regulatory Commission if any.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The North & East of Sudbury Region are bounded by regions of North Bay, Timmins, Hearst, Moosonee, Kirkland Lake and Dymond. The geographical boundaries of the North & East of Sudbury region is shown in Figure 3 below.

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits. This area is further reinforced through the 500kV circuits P502X and D501P connecting Hanmer TS to Pinard TS.

This region has the following four local distribution companies (LDC):

- Hydro One Networks (distribution)
- Northern Ontario Wires Inc
- Hearst Power Ltd
- North Bay Hydro Distribution Ltd.
- Greater Sudbury Hydro Inc.

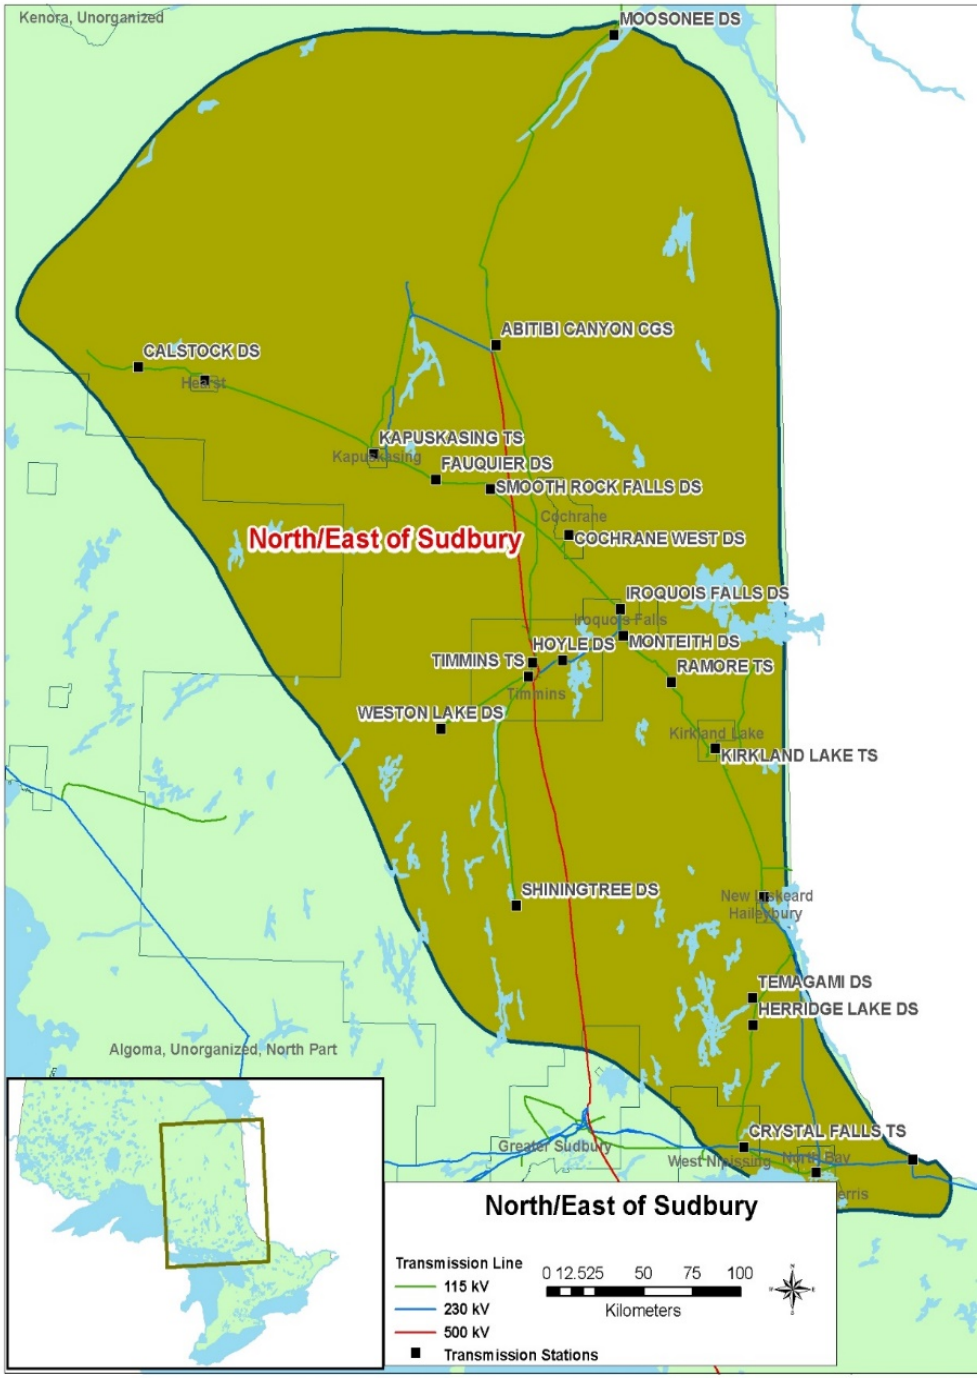


Figure 3: Map of North & East of Sudbury Regional Planning Area

The circuits and stations of the area are summarized in the Table 2 below:

Table 2: Transmission Station and Circuits in the North & East of Sudbury Region

115kV circuits	230kV circuits	Hydro One Transformer Stations	Generation Stations
A4H/A5H	D23G	Ansonville TS*	Otter Rapids GS
A8K/A9K	H22D	Crystal Falls TS	Abitibi Canyon GS
D2H/D3H	H23S/H24S	Dymond TS*	Empire CGS (10 MW)
H6T/H7T	K38S	Hearst TS	Martin's Meadows CGS (10 MW)
P13T/P15T	L20D	Hunta SS	Abitibi CGS (10 MW)
T7M/T8M	L21S	Kapuskasing TS	Long Lake CGS (10 MW)
D2L	P91G	Kirkland Lake TS	Kipling GS (164 MW)
H9K	R21D	Little Long SS	Kipling 2 GS (79 MW)
K2	W71D	Moosonee SS	Harmon GS (140 MW)
K4		North Bay TS	Harmon 2 GS (78 MW)
L1S		Otter Rapids SS	Smoky Falls 2 GS (264 MW)
L5H		Otto Holden TS*	Little Long GS (MW)
D3K		Pinard TS*	Little Long 2 GS (70 MW)
P7G		Porcupine TS*	A.P. Kapuskasing CGS (57 MW)
T61S		Ramore TS	Nagagami CGS (18 MW)
F1E		Spruce Falls TS	A.P. Calstock CGS (39 MW)
T2R		Timmins TS	Carmichael Falls CGS (18 MW)
		Trout Lake TS	Smooth Rock Fall CGS (8 MW)
		Widdifield SS	Yellow Falls CGS (16 MW)
			Iroq Falls Power CGS (126 MW)
			New Liskeard CGS (30 MW)
			Northland Power Kirkland Lake CGS (172 MW)

*Stations with Autotransformers installed

The single line diagram of the Transmission Network of North & East of Sudbury region is shown in Figure 4 below.

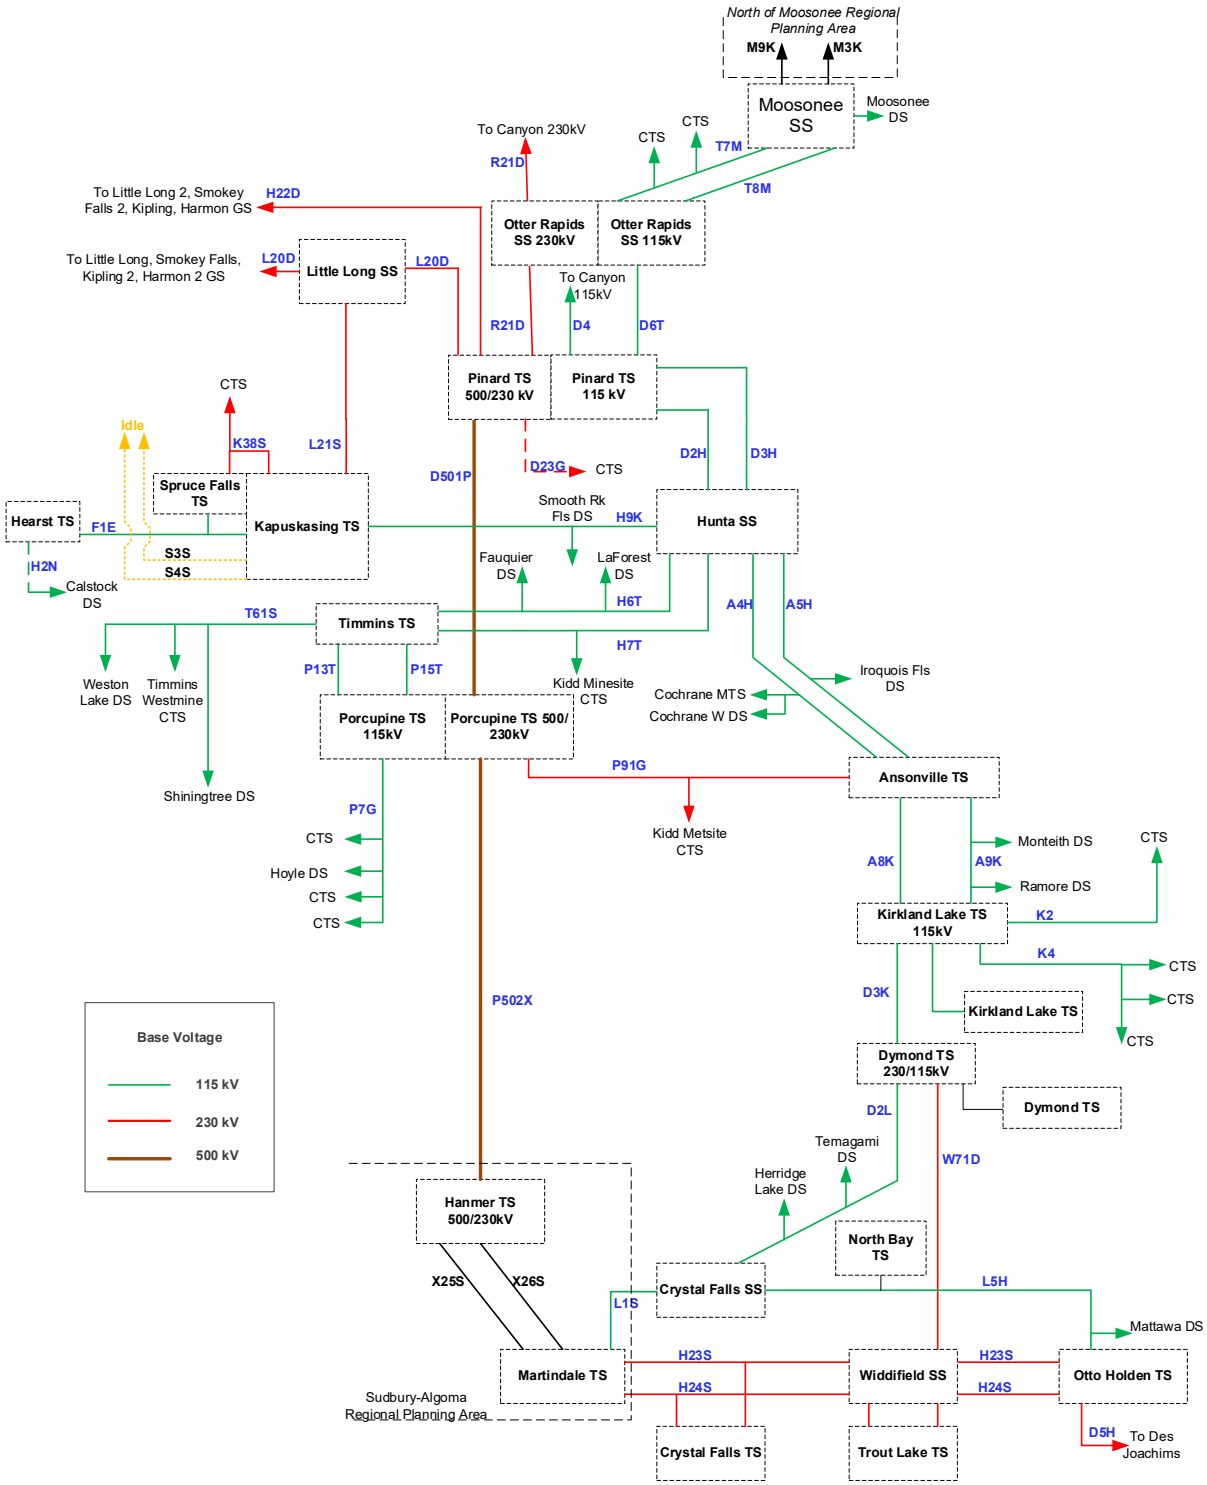

Figure 4: North & East of Sudbury Transmission Single Line Diagram

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR ARE UNDERWAY

In this section a complete list of all the projects that are completed in past ten years or are currently underway is provided and are briefly discussed in the sub sections. As a part of this or previous Regional Planning Cycle(s), several "Major HV Transmission Projects" were recommended in the **North & East of Sudbury** Region to improve the supply capability and reliability.

Hydro One, being the only Transmission Asset Owner (TAO) in the region have undertaken execution of the projects recommended in the past ten years. A summary and brief description of all the projects completed or are currently underway is given below:

I. Following Major projects were completed during the last ten years:

- Kapuskasing Area Reinforcement – H9K Circuit Upgrade (ISD 2020)
- Kirkland Lake TS (T12/T13) transformer replacement (ISD 2017)
- Dymond TS (T3/T4) transformer replacement (ISD 2016)
- Timmins TS (T63/T64) replace with a single 83MVA (ISD 2016)

II. Following Major projects are underway:

- Kapuskasing Area Reinforcement – Install 115kV Reactive Devices (ISD 2023)
- Kirkland Lake TS – Replace low voltage breakers, Instrument Transformers, P&C equipment (ISD 2025)
- Hearst TS - Replace low voltage breakers, P&C Equipment, switches (ISD 2028)
- Hunta SS - Replace P&C Equipment (ISD 2025)
- Porcupine TS – Replace 1 - 500kV/230kV autotransformer (T7), 2- 500kV/115kV autotransformers (T3/T4), switches, station service and P&C equipment (ISD 2025)
- Otto Holden TS - Replace 2 – 230 kV/115 kV autotransformers (T3/T4), high voltage breakers, switches, station service equipment, and protections (ISD 2027)
- K4 circuit - Refurbish Kirkland Lake TS X Matachewan JCT (10km) (ISD 2024)
- A8K/A9K circuits – Refurbish A8K/A9K (90km) (ISD 2023)

Note: The planned in-service year for the above projects is tentative and is subject to change.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

6.1. Load Forecast

The TWG participants reviewed and verified that there is no material change in load forecast from those used in the North & East of Sudbury Region IRRP Load Forecasts (April 2023). Thus, the IRRP forecasts were used in development of this Report. TWG participants, including representatives from LDC's, IESO and Hydro One, provided information and input for the IRRP Load forecast, which also includes the inputs from the Municipal Energy Plans (MEP) and/or Community Energy Plans (CEP). New industrial/mining load connections requests have been received after publication of IRRP report. These new potential load connections have not been explicitly listed in the load forecast tables, however these loads have been studied in the RIP to assess their impact to the area.

During the study period, the load in the North & East of Sudbury Region is expected to grow at an average annual rate of approximately 0.50% in winter and 0.25% in summer from 2023 to 2043. The Region is winter peaking, so this assessment is based on winter peak loads. This growth does not include significant increases in the industrial sector.

Figures 5 & 6 shows the North & East of Sudbury Region extreme summer/winter weather net coincident and non-coincident load forecast from 2023 to 2043. The load forecasts from the North & East of Sudbury Region were adopted as agreed to by the TWG. The load forecast shown is the regional non-coincident forecast, representing the sum of the load in the area for the step-down transformer stations.

Non-coincident and coincident forecast for the individual stations in the region is available in Appendix A and is used to determine any need for station capacity relief in the region.

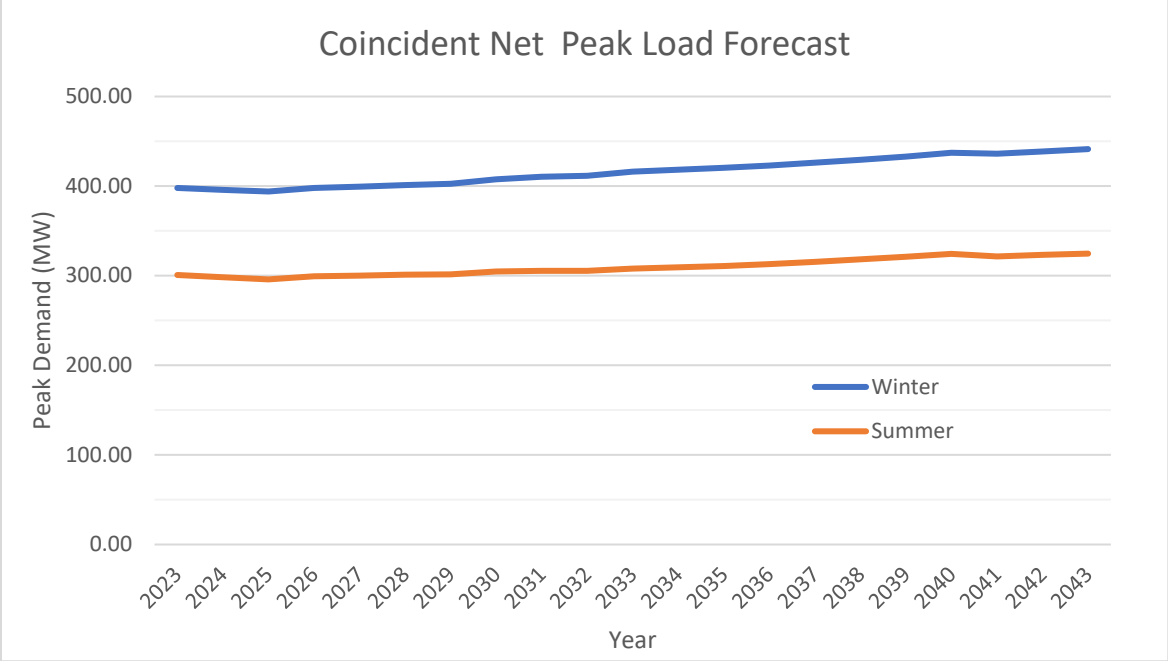

Figure 5: North & East of Sudbury Region summer/winter coincident Net Peak Load Forecast

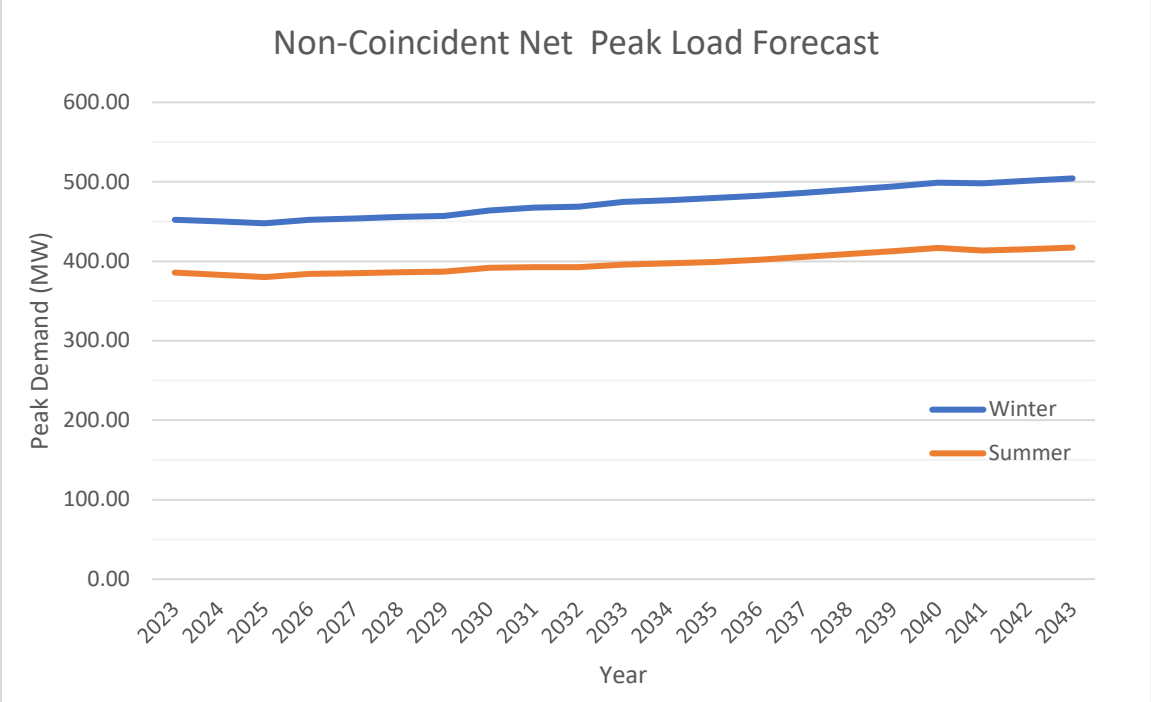

Figure 6: North & East of Sudbury Region summer/winter Non-coincident Net Peak Load Forecast

6.2. Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2023-2043.
- LDCs reconfirmed load forecasts up to 2040. The additional 3 years of forecasts were extrapolated based on the growth rate as a reasonable position to complete the 20-year period.
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- The Region is winter peaking, so this assessment is based on winter peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the winter 10-day Limited Time Rating (LTR).
- Regional transmission line and auto transformer capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Resources assumptions align with the ORTAC.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying the North & East of Sudbury Region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway, listed in **"Section 5"** are completed.

In current regional planning cycle, the following regional assessments were completed, and their findings were used as inputs to this RIP report:

- North & East of Sudbury Region Second cycle Needs Assessment Report, Completed in May 2021 by Hydro One
- North & East of Sudbury Region Second cycle Scoping Assessment Report, Completed in August 2021 by the IESO
- North & East of Sudbury Region Second cycle Integrated Regional Resource Plan Report, Completed in April 2023 by the IESO

The Technical Working Group identified several regional needs based on the forecasted load demand over the near to mid-term period in the reports mentioned above. The results of the Adequacy Assessment to define the needs are discussed in sub-sections "7.1 to 7.4" and a detailed description and status of plans to meet these needs are given in **"Section 8"** of this report.

7.1. Asset Renewal Needs for Major HV Transmission Equipment

In addition to the asset renewal needs identified in previous regional planning cycle, Hydro One and TWG has also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the **North & East of Sudbury** Region. The complete list of major HV transmission equipment requiring replacement in the **North & East of Sudbury** Region is provided in table 3 in this sub-section. Hydro One is the only Transmission Asset Owner (TAO) in the Region

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
  replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:

Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

Table 3: Major HV Transmission Asset assessed for Replacement in the region

Station/Circuit	Need Description	Planned ISD
Kirkland Lake TS	Replacement of Instrument Transformers, P&C equipment, station service equipment and low voltage circuit breakers.	2025
Hunta SS	Replacement of P&C and telecom equipment.	2027

Porcupine TS	Replacement of 1-500/230kV 360MVA autotransformer (T8), 2- 500/115kV 225MVA autotransformers (T3/T4), switches, station service equipment and P&C equipment.	2026
Otto Holden TS	Replacement of 2-230/115 kV 60MVA autotransformers (T3/T4), high voltage circuit breakers, switches, station service equipment, and P&C equipment.	2027
Hearst TS	Replacement of low voltage circuit breakers, switches, P&C Equipment.	2030
Timmins TS	Replacement of 1-115/27.6kV 83MVA (T2) transformer and associated protections.	2028
Kapuskasing TS	Replace low voltage circuit breakers, switches, station service equipment and protections.	2030
Dymond TS	Replacement of low voltage breakers, and associated P&C equipment.	2031
Ansonville TS	Replace P&C equipment, Instrument transformers, station service equipment.	2032
Crystal Falls TS	Replacement of 2-230/44kV 42MVA (T5/T6) transformers, station service equipment, switches and P&C equipment.	2031
Trout Lake TS	Replacement of 2–230/44 kV 125MVA (T3/T4) transformers, low voltage circuit breakers and surge arresters.	2033
K4	Replace conductor and refurbish circuit Kirkland Lake TS X Matachewan JCT (10km)	2024
T61S	Replace conductor and refurbish circuit Timmins TS x Shiningtree JCT (115km)	2024
K2	Replace conductor and refurbish circuit Kirkland Lake TS x American Barrick JCT (14km)	2024
D2H/D3H*	Replace conductor and refurbish circuit Hunta SS x Abitibi Canyon SS (183km)	2029
A4H/A5H**	Replace conductor and refurbish circuit Tunis JCT x Fournier JCT (47km)	2027

Note: The planned in-service year for the above projects is tentative and is subject to change.

* IESO to inform by end of Q2 2025 if an upgrade is required

** IESO to inform by end of 2024 if an upgrade is required

7.2. Station Capacity Needs

Over the study period [2023-2043] RIP reviewed the capacity of all the 230kV and 115kV Transforming stations within the North & East of Sudbury Region. The NA and IRRP studies had previously indicated that the following stations require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast, the stations which require capacity relief during the study period are shown in Table 4 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer or winter) Limited Time ratings.

Table 4: North & East of Sudbury Region Station Capacity Needs in the study period

Station Name	Capacity (MW)	2023 Loading (MW)	Station 10 day LTR (MW)	Need Date
Ramore TS	15	12	15	2033

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.3. Transmission Line Capacity Needs

Over the study period [2023-2033] RIP reviewed the capacity of all the 230kV and 115kV Transmission lines within the North & East of Sudbury Region. The NA and IRRP studies had previously indicated that the following Transmission lines require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast and following contingencies, the Transmission lines which require capacity relief during the study period are shown in Table 5 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer or winter) Limited Time ratings.

Table 5: North & East of Sudbury Region Transmission Line Capacity Needs in the study period

Sr.no.	Name of Circuit	Name of Section	Contingency	Need Date
1	D3K	Dymond x Kirkland Lake	N-1-1 (AxK O/S + loss of companion circuit)	2030

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.4. System Reliability, Operation and Load Restoration Needs

Load security and load restoration needs were reviewed as part of the current study. The ORTAC Section 7 requires that no more than 600 MW of load be lost as a result of a double circuit contingency.

Further, loads are to be restored in the restoration times[1] specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

The post contingency voltage control issues have also been listed in Table 6 below.

Table 6: North & East of Sudbury Region System Operational Needs and Voltage Control in the study period

Sr.no.	Reliability / Operational Need	Description	Need Date
1	Dymond TS	Voltage control violations when switching existing 115kV Dymond TS capacitor banks	2030
2	Kirkland Lake TS	Voltage control challenges in Kirkland Lake area during concurrent outages to Kirkland Lake TS SVC and Northland Power Kirkland Lake GS.	2030
3	Ansonville, Hunta, Kapuskasing	Post contingency voltage control challenges for the loss of Ansonville T2 and Canyon Units.	Existing

[1] These approximate restoration times are intended for locations that are near staffed centers. In more remote locations, restoration times should be commensurate with travel times and accessibility

4	ORTAC load security criteria not met for 500 kV circuit outages	Loss of load and resources during outages to any of the two major 500kV transmission lines in the Northeast	Existing
5	Difficulty supplying loads during planned outages to circuit D501P	Area loads cannot be adequately supplied during planned circuit outages	Existing

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the North & East of Sudbury Region. These needs include those previously identified in the NA and IRRP for the North & East of Sudbury Region as well as any new needs identified during the RIP phase. All estimated costs included in the alternative analysis are considered as planning budgetary estimates and are used for comparative purposes only and may vary. The Needs in the region are summarized below in Table 6 below:

8.1 Asset Renewal Needs for Major HV Transmission Equipment

The Asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement)
- Replacing equipment with higher ratings and built to current standards

From Hydro One's perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

8.1.1. Asset Name – Location

Table 7: Needs identified in the region

Station/Circuit	Need Description	Planned ISD
Kirkland Lake TS	Replacement of Instrument Transformers, P&C equipment, station service equipment and low voltage circuit breakers. This investment will replace equipment that is in poor condition and deemed end of life.	2025
Hunta SS	Replacement of P&C and telecom equipment. This investment will replace equipment that is in poor condition and deemed end of life.	2025
Porcupine TS	Replacement of 1-500/230kV 360MVA autotransformer (T8), 2- 500/115kV 225MVA autotransformers (T3/T4), switches, station service equipment and P&C equipment. This investment will replace end of life transformers to reduce the risk of interruptions caused by transformer asset failure.	2026
Otto Holden TS	Replacement of 2-230/115 kV 60MVA autotransformers (T3/T4), high voltage circuit breakers, switches, station service equipment, and P&C equipment. This investment will replace equipment that is in poor condition and deemed end of life. It will also replace end of life transformers to reduce the risk of interruptions caused by transformer asset failure. The new transformers will be installed in a greenfield location and connected to the existing 230kV bus at Holden CGS via a 230 conductor/bus. The replacement transformers and associated equipment will be constructed within the limits of a new station called Antonie TS	2027
Hearst TS	Replacement of low voltage circuit breakers, switches, P&C Equipment. This investment will replace equipment that is in poor condition and deemed end of life.	2028

Timmins TS	Replacement of 1-115/27.6kV 83MVA (T2) transformer and associated protections. This investment will replace equipment that is in poor condition and deemed end of life. It will also help maintain reliability of supply to area customers and reduce the risk of interruptions caused by transformer asset failure.	2028
Kapuskasing TS	Replace low voltage circuit breakers, switches, station service equipment and protections. This investment will replace equipment that is in poor condition and deemed end of life.	2030
Dymond TS	Replacement of low voltage breakers, and associated P&C equipment. This investment will replace equipment that is in poor condition and deemed end of life.	2031
Ansonville TS	Replace P&C equipment, Instrument transformers, station service equipment. This investment will replace equipment that is in poor condition and deemed end of life.	2031
Crystal Falls TS	Replacement of 2-230/44kV 42MVA (T5/T6) transformers, station service equipment, switches and P&C equipment. This investment will replace equipment that is in poor condition and deemed end of life. It will also help maintain reliability of supply to area customers and reduce the risk of interruptions caused by transformer asset failure.	2031
Trout Lake TS	Replacement of 2–230/44 kV 125MVA (T3/T4) transformers, low voltage circuit breakers and surge arresters. This investment will replace equipment that is in poor condition and deemed end of life. It will also help maintain reliability of supply to area customers and reduce the risk of interruptions caused by transformer asset failure.	2033
A8K/A9K	Replace conductor and refurbish circuit Ansonvillle x Kirkland Lake (180km) This investment will replace the conductor and also increase the thermal capacity to meet system needs.	2023

K4	Replace conductor and refurbish circuit Kirkland Lake TS X Matachewan JCT (10km) This investment will replace the conductor with a like for standard conductor. Right sizing has been taken into consideration to meet supply capacity of loads on the line.	2024
T61S	Replace conductor and refurbish circuit Timmins TS x Shining tree JCT (115km) This investment will replace the conductor with a like for standard conductor. Right sizing has been taken into consideration to meet supply capacity of loads on the line.	2024
K2	Replace conductor and refurbish circuit Kirkland Lake TS x American Barrick JCT (14km) This investment will replace the conductor with a like for standard conductor. Right sizing has been taken into consideration to meet supply capacity of loads on the line.	2024
D2H/D3H	Replace conductor and refurbish circuit Hunta SS x Abitibi Canyon SS (183km) This investment will replace the conductor with a like for standard conductor.	2029
A4H/A5H	Replace conductor and refurbish circuit Tunis JCT x Fournier JCT (47km) This investment will replace the conductor with a like for standard conductor.	2027

8.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period [2023-2043] for the 230kV and 115kV Transforming stations in the North & East of Sudbury Region using either the summer or winter peak load forecasts that were provided by the study team. Based on the results, the following Station capacity needs have been identified in the during the study period:

8.2.1 Ramore TS

Ramore TS is a single transformer 115/27.6kV 17MVA station. The summer and winter 10-Day LTR is 15MW, and load at this station is expected to exceed the LTR in 2033.

Table 8: Ramore TS Load Forecast

Station	LTR (MW)	Load Forecast										
		2023	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
Ramore TS	15	13.7	13.8	13.9	14	14.2	14.3	14.4	14.8	14.9	15	15.1

The following alternatives were considered to address Ramore TS capacity need:

Alternative 1 - Maintain Status Quo: Ramore TS will continue to operate with the existing installed capacity, and Hydro One will monitor load growth to ensure supply needs are met.

Alternative 2 – Replace T1 with a new 115/27.6 42MVA unit: Replacing T1 with the next largest standard size unit will increase the station LTR to 38MW. The station LTR will remain limited to the size of the transformer as there will still only be a single unit installed at the station. This was considered and rejected as this would result in additional cost of approximately $10M and prematurely retire T1 transformer. This transformer remains in acceptable condition and is not scheduled to be replaced by Hydro One within the study period due to end-of-life needs.

The TWG recommends Alternative 1 as the preferred and cost effective alternative for addressing the need. The capacity need will arise in 2033 and will allow both Hydro One and area LDCs to monitor load growth and take corrective action when needed. This need will also be refreshed in the next cycle or regional planning.

8.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period [2023-2043] for the 230kV and 115kV Transmission line circuits in the North & East of Sudbury Region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater this need. Based on the results, the following line capacity needs have been identified in the during the study period:

No new line capacity needs have been identified in this planning cycle.

8.3.1 D3K (Thermal Violation)

D3K is a single circuit 115kV transmission line which provides a critical network path between Dymond TS and Kirkland Lake TS. This circuit is approximately 80km in length and serves to provide connection to generating stations and provide a path for network flows. Sections of this line will start to experience supply capacity violations at the end of the study period and will require mitigating solutions to allow for increased flows. The circuit section is described below;

1. Dymond TS x Kirkland Lake TS (80km) – For the loss of A8K and A9K, the companion circuit will exceed its Long-Term Emergency (LTE) rating. As studied in the IRRP and verified in the RIP this is expected to occur as early as 2030 based on demand forecast.

Solutions to address these needs will be further explored in future planning cycles given the long-term nature of this need. Flows on this line and its violations are heavily influenced by area resource assumptions, and demand forecast for customers in the Kirkland Lake area. In addition, a new Kirkland Lake RAS (Remedial Action Scheme) has been installed to initiate control actions such as load rejection for system contingencies. Currently, this RAS will trip loads and avoid the D3K thermal violation. This scheme will continue to be utilized by control room operators and it is expected that reliance on this scheme will gradually be reduced as system upgrades and replacements are complete in the future. The TWG will continue to monitor this need in future planning cycles and initiate an investment should this violation be advanced due to changing system conditions.

8.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. A study has been performed, considering the net coincident load forecast and the loss of one element over the study period [2023-2043] to cater this need**.**

8.4.1 Dymond TS – Voltage Control

IESO operations team has reported voltage violations at Dymond TS during capacitor bank switching. Dymond TS has two 115kV shunt capacitor banks (SC11/SC12) each rated at 24MVar. IESO has observed that switching the banks under certain system conditions voltages can exceed the maximum voltage and step change permitted by IESO Market Rules. These violations are largely dependent on system configuration (W71D O/S + Loss of D3K) and less sensitive to area loading patterns. Voltage violations are not observed during system conditions where all elements are In-service, or one element is O/S as there is sufficient reactive support from adjacent stations to support Dymond pre-contingency.

Alternative 1 - Maintain Status Quo: IESO and Hydro One operations will continue to control the system with other reactive devices in the northeast. The existing capacitor banks can continue to be utilized to help meet single contingency planning scenarios.

Alternative 2 – De-rate the Existing capacitor banks (SC11/SC12) Hydro One can de-rate the capacitor bank between 14-16MVar to ensure voltage limits upon cap bank switching remain within acceptable limits. This option helps with operations primarily for a W71D+D3K contingency. This option reduces the total var support at Dymond by 50% and due to the de-rating in size. It has been discussed with the TWG that operations may have to rely on other reactive devices in the northeast to provide steady state voltage support for other system configurations.

The TWG recommends to continue to investigating the need to a de-rate the existing capacitor banks and provide enhanced automation and visibilty.

8.4.2 Kirkland TS – Voltage Control

IESO has reported difficulties in maintaining adequate system voltages in the Kirkland Lake area during outage conditions. Concurrent outages to the Kirkland Lake SVC and Northland Power Kirkland Lake Generating facility result in declining voltages at the end of the radial K2 transmission line.

Kirkland Lake TS presently has a 115kV connection SVC, and shunt capacitor bank to help maintain voltages during steady state, and contingencies.

K2 circuit is a radial line with multiple industrial customers tapped of this circuit. Voltage performance on this circuit is directly attributed to the load pattern of these customers. It is expected that future loads connecting to this circuit will be required to maintain their voltage within reasonable limits as a condition to connect. A new Kirkland Lake RAS is also available to address thermal and voltage violations in the area as a control action and can be expanded to include additional inputs and outputs. Planning level cost for a new 115kV capacitor bank will cost between $10M-$15M, and will be largely influenced by the available space at the station and the control building.

The TWG recommends to monitor the voltage performance at Kirkland Lake TS bus and ensure that voltages on the K2 delivery points remain within reasonable limits. Hydro One and IESO will engage in further discussion on system operating limits, and resource options to mitigate this finding.

8.4.3 Ansonville, Hunta, Kapuskasing Voltage Control

Voltage violations at Ansonville TS, Hunta TS, and Kapuskasing TS can occur for the loss of Ansonville T2 and Abitibi Canyon generating units. This is coupled with the general challenge of maintaining system voltages within acceptable limits in the northeast as a whole. A new Kirkland Lake RAS (remedial action scheme) has been installed to help operators take control actions for system contingencies. This RAS can also be expanded to accommodate changing system needs which will help to provide operating flexibility

in the future. Kapuskasing RAS will also be installed to provide voltage support in the Kapuskasing area for system contingencies. This RAS can also be expanded when needed to meet future system needs.

Porcupine SVC will also be refurbished in the planning cycle and will provide much needed reactive support for the northeast.

The TWG will continue to address voltage control issues as needed to accommodate system needs. IESO and Hydro One continues to work towards finding robust solutions that provide voltage support without over reliance on load rejection and other adverse control actions. No additional investments are required from this regional infrastructure plan to address this need.

8.4.4 ORTAC load security criteria not met for 500 kV circuit outages

The North & East of Sudbury region is supplied by two 500 kV circuits, P502X from Hanmer TS to Porcupine TS and D501P from Porcupine TS to Pinard TS.

The system connects substantial amount of hydroelectric generation on the Moose River and loads in the region. The planning requirement to respect the loss of either of the 500kV circuits results in the need to rely on a Remedial Action Scheme (RAS), the Northeast Load and Generation Rejection Scheme (the "Northeast LGR"), that enables full use of the scheme following the loss of a single transmission element.

This is a legacy system that does not meet today's planning criteria for the use of load rejection following the loss of a single transmission element. However, bringing it up to current standards would involve substantial capital investment that is difficult to justify without the introduction of new needs. Future bulk projects such as the new 230kV line between Porcupine TS and Wawa TS will help to reduce reliance on area RASs following a P502X outage, however, does not address the loss of D501P and will still result in load rejection for area customers. The Working Group (TWG) recommends that the next bulk system plan in Northeast Ontario address the load security concerns following an outage on D501P and develop a plan to proactively reduced reliance on RAS.

8.4.5 Difficulty supplying loads during planned outages to circuit D501P

IESO's outage planning staff have also identified that during recent outages to D501P, it has not been possible to supply all customer load in the area due to limitations on the 115 kV system, and certain industrial customers have been forced to reduce their production. These concerns have also been raised by these customers themselves. During D501P outages, generation must also be significantly curtailed, which can remove substantial capacity from the Ontario system.

Hydro One recently implemented a protection scheme to allow D501P outages and working to address the shortfalls experienced during the implementation. TWG recommends to continue discussions with Hydro One and IESO operation to ensure future projects can be completed effectively during 500kV

outages and the project team will work to develop effective solutions for the specific projects in question. These solutions may include modifications/additions to area RASs schemes or new transmission facilities.

8.5 Long Term Considerations

Like many other regions in Ontario, load growth in North & East of Sudbury region will be directly impacted by new energy policies specifically those which help drive electrification. In addition, it is anticipated large market participants will also have incentive programs to modify operations/technologies to reduce greenhouse emissions. Details of how future programs will impact demand is unknown at this time thus the TWG will continue to monitor these trends throughout planning cycles to identify areas in need of investment. Future connection requests in the region will be assessed as needed to determine system requirements.

9. CONCLUSION AND RECOMMENDATION

This section concludes the Regional Infrastructure Plan Report for North & East of Sudbury Region. The Major Infrastructure investments recommended by the TWG in the near and mid-term planning horizon [2023-2033] are provided in Table 7 below, along with their planned in-service dates (ISD) and budgetary estimates for planning purposes.

Table 9: Recommended Plans over the next 10 Years

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Asset Renewal Needs				
Kirkland Lake TS	Replacement of Instrument Transformers, P&C equipment, station service equipment and low voltage circuit breakers.	Hydro One Transmission	2025	36
Hunta SS	Replacement of P&C and telecom equipment.	Hydro One Transmission	2025	12
Porcupine TS	Replacement of 1-500/230kV 360MVA autotransformer (T8), 2- 500/115kV 225MVA autotransformers (T3/T4), switches, station service equipment and P&C equipment.	Hydro One Transmission	2026	91
Otto Holden TS	Replacement of 2-230/115 kV 60MVA autotransformers (T3/T4), high voltage circuit breakers, switches, station service equipment, and P&C equipment.	Hydro One Transmission	2027	74
Hearst TS	Replacement of low voltage circuit breakers, switches, P&C Equipment.	Hydro One Transmission	2028	19
Timmins TS	Replacement of 1-115/27.6kV 83MVA (T2) transformer and associated protections.	Hydro One Transmission	2028	14
Kapuskasing TS	Replace low voltage circuit breakers, switches, station service equipment and protections.	Hydro One Transmission	2030	24
Dymond TS	Replacement of low voltage breakers, and associated P&C equipment.	Hydro One Transmission	2031	42

Ansonville TS	Replace P&C equipment, Instrument transformers, station service equipment.	Hydro One Transmission	2031	11
Crystal Falls TS	Replacement of 2-230/44kV 42MVA (T5/T6) transformers, station service equipment, switches and P&C equipment.	Hydro One Transmission	2031	32
Trout Lake TS	Replacement of 2–230/44 kV 125MVA (T3/T4) transformers, low voltage circuit breakers and surge arresters.	Hydro One Transmission	2033	17
K4	Replace conductor and refurbish circuit Kirkland Lake TS X Matachewan JCT (10km)	Hydro One Transmission	2024	4
T61S	Replace conductor and refurbish circuit Timmins TS x Shiningtree JCT (115km)	Hydro One Transmission	2024	
K1/K2	Replace conductor and refurbish circuit Kirkland Lake TS x American Barrick JCT (14km)	Hydro One Transmission	2024	4
D2H/D3H*	Replace conductor and refurbish circuit Hunta SS x Abitibi Canyon SS (183km)	Hydro One Transmission	2029	96
A4H/A5H**	Replace conductor and refurbish circuit Tunis JCT x Fournier JCT (47km)	Hydro One Transmission	2027	22
Station Capacity Needs				
Ramore TS	To be monitored and reviewed in next planning cycle	Hydro One Distribution	NA	NA
Transmission Line Capacity Needs				
D3K	Monitoring & further exploration in future RIP cycle	Hydro One Transmission	NA	NA
System Reliability, Operation and Load restoration Needs				
Dymond TS	Continue investigating to correctly size the existing 115kV SC11 & SC12 capacitor banks	Hydro One Transmission	NA	NA

Note:

a) The planned in-service dates are tentative and subject to change

b) Cost are based on budgetary planning estimates and excludes the cost for distribution infrastructure (if required)

* IESO to inform by end of Q2 2025 if an upgrade is required

** IESO to inform by end of 2024 if an upgrade is required

Appendix C: Voltage Performance Analysis at Dymond TS

To address the on-going voltage issue due to operation of SC11& SC12 Capacitor banks at Dymond TS under N-1-1 contingency, Hydro One can de-rate the capacitor bank between 14-16MX. The capacitor banks can only be physically de-rated in the steps of 3MX.

Following table shows a PSSE simulation result with both capacitors de-rated to 15MX. (*Hydro One 2022 Winter Base case used for simulation purpose).*

Bus	Contingency														
	N-0					D3K O/S					D3K O/S +W71D				
		24+24 MX Caps		15+15 MX Caps			24+24 MX Caps		15+15 MX Caps			24+24 MX Caps		15+15 MX Caps	
	No Cap	ON	% Change	ON	% Change	No Cap	ON	% Change	ON	% Change	No Cap	ON	% Change	ON	% Change
Dymond TS 220	243.89	246.62	1.12	245.59	0.69	244.44	248.25	1.56	246.80	0.96					
Dymond TS 115	123.49	125.67	1.77	124.84	1.10	124.05	127.08	2.44	125.92	1.50	117.51	131.96	12.30	125.76	7.03
Dymond TS 44	46.35	47.11	1.63	46.82	1.02	46.55	47.59	2.25	47.19	1.39	44.28	49.37	11.50	47.15	6.47
Temagami 115	123.41	124.93	1.22	124.35	0.76	123.98	126.06	1.68	125.27	1.04	119.78	129.21	7.88	125.19	4.52

Capacitor bank switching under the studied scenario is infrequent due to the N-1-1 condition and voltage change limits shall take this into consideration. Sizing the capacitor banks between 14-16MX is shown to reduce the voltage change to reasonable limits based on the in frequent nature of the occurrence. This reduction allows for reactive support at Dymond TS to remain at a level that can still help with normal operations during non-contingency scenarios or system changes such as load growth. Simulation results will continue to be studied to correctly size the capacitor banks.

1. Introduction

This Integrated Regional Resource Plan (IRRP) for the Renfrew region addresses the regional electricity needs over the study period, i.e., from 2021 to 2042. The Renfrew region is located in Eastern Ontario with the majority of the population residing along the Ottawa river. It is bounded by two hydro generating stations, Des Joachims in the west and Chenaux in the east. The Renfrew region, shown in Figure 1, includes five Indigenous and Metis communities and 18 municipalities with a total population of approximately 100,000 people.

Figure 1 | Renfrew Region Map

The purpose of this IRRP is to document the findings and actions required to address the transmission system issues in the region. The IRRP is one part of the overall planning process and this report is the final product of this stage. The regional electricity planning process was formalized by the Ontario Energy Board (OEB) in 2013, and it requires transmitters, distributers, and the Independent Electricity System Operator (IESO) to carry out regional planning activities for the 21 electricity planning regions across Ontario at least once every five years. This is the first time that issues have been identified in Renfrew that require further regional coordination and, as a result, this is the first IRRP for the Renfrew region.

The region has historically had low growth, however, the electricity demand is slowly reaching the capacity of the transmission system. Specifically, there have been station capacity issues identified in the Pembroke, Petawawa, and Laurentian Valley areas. The scope of this IRRP is centered around addressing these issues and the Technical Working Group has taken this opportunity to engage on a broader scale with municipalities, large electricity customers, and other relevant stakeholders in order to understand some of the electricity trends that are affecting the region.

Through public webinars, stakeholder feedback, and individual engagements a number of trends impacting the region's future electricity demand have been identified. Several communities are seeing larger migrations from urban centers and are preparing for residential developments. The majority of existing residential areas do not have air conditioners and also utilize gas heating both of which when installed and converted will contribute to peak energy consumption in the summer and winter, respectively. Lastly, the impact of electrification, which is being felt across the province, could further constrain the transmission system that has historically seen flat growth.

This IRRP report summarizes upcoming power system capacity, reliability, and end-of-life asset replacement issues and recommends specific investments to address the most imminent issues. This IRRP also recommends near-term activities to manage longer-term requirements. The next planning cycle is scheduled to be initiated in 2026. Annual monitoring of potential issues will provide additional input on when the next regional planning cycle should be initiated.

The report is organized as follows:

- A summary of the recommended plan for the Renfrew region is provided in Section 2;
- The process and methodology used to develop the plan is discussed in Section 3;
- A background of the Renfrew region is presented in Section 4;
- The development and methodology of creating the 20-year long-term forecast is presented in Section 5;
- The electricity issues for the Renfrew region are presented in Section 6;
- Options, alternatives, and recommendations to address the issues are presented in Section 7;
- A summary of engagement activities to date, and moving forward, is provided in Section 8;
- The conclusion is provided in Section 9.

2. The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of the Renfrew region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by the North American Electric Reliability Corporation (NERC).

This IRRP identifies three planning horizons: near-term (year 1 to 5), medium-term (year 6 to 10), and long-term (year 11 to 20) from the base year (2020). These planning horizons reflect the inverse relationship between the length of time and demand certainty (in that the longer the outlook, the less certain it is), lead time for electricity resource development, and planning commitment required. This IRRP identifies and recommends specific projects for implementation in the near-term. This is necessary to ensure that they are in-service in time to address the area's more urgent needs, respecting the lead-time for development of the recommended projects or actions.

This IRRP also identifies possible long-term electricity needs, some of which may advance to the near- or medium-term for a high growth scenario. However, as these needs are forecast to arise in the future, it is not necessary, nor would it be prudent given forecast uncertainty and the potential for technological change, to commit specific projects at this time. Instead, near-term actions are identified to gather information and lay the groundwork for future options. These actions are intended to be completed before the next IRRP cycle so that their results can inform further discussion at that time or so the Technical Working Group can respond in a timely manner, if a high growth scenario were to materialize.

2.1 Near- to Medium- Term Plan

Recommended Actions

1. **Build new station at Pembroke, finalize scope during Regional Infrastructure Plan (RIP) period**

The existing Pembroke Transformer Station (TS) supplies the City of Pembroke. Two Local Distribution Companies (LDC) supply customers from Pembroke TS, Hydro One Distribution and Ottawa River Power Corporation (ORPC), as an embedded customer to Hydro One Distribution. The station has an existing 1 MW station capacity issue that is forecast to increase to 14 MW, in the summer, over the study period. A new station, targeting an in-service date of 2027 has been identified as the preferred option to address the need. Both a High Voltage Distribution Station (HVDS) and a standard dual-element spot network (DESN) transformer station were considered as options.

Both would meet the long-term forecast and each have their benefits and risks. A standard DESN station is preferred from a reliability perspective and would better prepare the area to accommodate long-term needs, but comes at an increased cost. The Technical Working Group recommends that further analysis be conducted during the RIP stage of regional planning to refine costs and benefits and confirm the additional cost of a DESN station is warranted.

2. **Perform a 2 MW load transfer from Forest Lea Distribution Station (DS) to Craig DS**

Forest Lea DS is located in Laurentian Valley and currently has a 1 MW station capacity issue. There is an existing tie-point on the distribution system between Forest Lea DS and Craig DS that can be used for load transfer. The Technical Working Group recommends this tie-point be utilized to transfer 2 MW of load from Forest Lea DS to Craig DS. This action is estimated to take 1-2 years to complete, targeting an in-service date of 2025. Further, if additional capacity is needed in the future the Technical Working Group recommends installing transformer fan cooling and Supervisory Control and Data Acquisition (SCADA) monitoring at Forest Lea DS to increase the station limit by an additional 4 MW.

3. **Build a new HVDS at Petawawa DS**

Petawawa DS supplies both the town of Petawawa and a large institutional customer, with the large customer representing the majority of the load supplied from the station. Due to upcoming development on the customer's site and forecast growth for the town of Petawawa, the station capacity is forecasted to be exceeded in 2029. Further, through the engagement process a growth scenario was developed to reflect significant load increase due to fuel switching in the long-term. The Technical Working Group recommends to build a new HVDS near Petawawa to meet the forecast demand growth. The expected in service year for the new station is 2027.

2.2 Long- Term Plan

Recommended Actions

1. **Monitor the load on the Des Joachims sub-system**

Through discussions with the stakeholders in the region, the Technical Working Group developed two growth scenarios, primarily driven by two separate large scale projects. If both projects materialize the Des Joachims sub-system will require upgrades. If only one project materializes, a capacitor installed at the end of the line will improve the limit of the system sufficiently to meet the forecast demand. Due to the uncertainty and long-term nature of the projects, the Technical Working Group recommends continuing to monitor the load growth on the sub-system and install a capacitor in the Petawawa region to increase the load meeting capability of the sub-system when deemed necessary.

3. Development of the Plan

In Ontario, planning to meet an area's electricity needs at a regional level is completed through the regional planning process, which assesses regional needs over the near-, medium-, and long-term, and develops a plan to ensure cost-effective, reliable electricity supply. A regional plan considers the existing transmission electricity infrastructure, local supply resources, forecast growth and area reliability; evaluates options for addressing needs; and recommends actions to be undertaken.

The process consists of four main components:

1. A Needs Assessment, led by the transmitter, which completes an initial screening of a region's electricity needs;
2. A Scoping Assessment, led by the IESO, which identifies the appropriate planning approach for the identified issues and the scope of any recommended planning activities;
3. An IRRP, led by the IESO, which identifies recommendations to meet issues requiring coordinated planning; and
4. A Regional Infrastructure Plan, led by the transmitter, which provides further details on recommended wires solutions

More information on the regional planning process and he IESO's approach to regional planning can be found in Appendix B – Development of the Plan.

In addition to regional planning process, there are bulk planning and distribution planning processes. Distribution system planning is for system at 44 kV and lower, while bulk and regional planning are for higher voltages. Furthermore, regional planning focuses more on a particular, local part of the grid, while bulk planning reviews electricity transfers across the province. There are inherent overlaps in all three levels of electricity infrastructure planning.

The IESO has recently completed a review of the regional planning process following the completion of the first cycle of regional planning for all 21 regions. Additional information on the Regional Planning Process Review along with the final report is posted on the IESO's website.

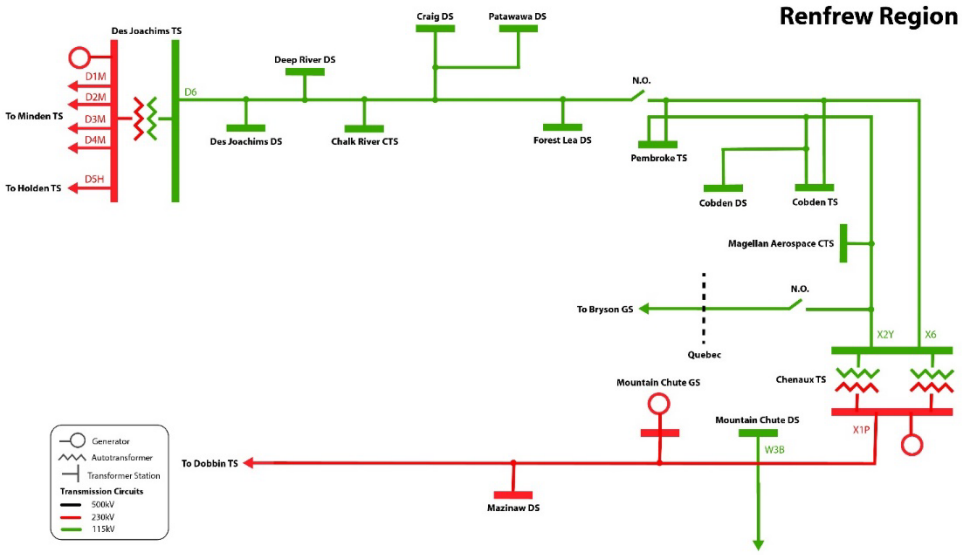
3.1 Renfrew IRRP Development

Development of the Renfrew IRRP was initiated in 2021 with the release of the Needs Assessment report. This product was prepared by Hydro One (Transmission) with participation from the IESO, Hydro One (Distribution), and ORPC. Screening for issues was carried out to identify issues that may require coordinated regional planning. The subsequent Scoping Assessment Outcome Report, which was prepared by the IESO, recommended that an IRRP should be developed to address previously identified and new needs in this region due to the potential for coordinated solutions. In 2021, the Technical Working Group was formed to develop a finalized Terms of Reference for this IRRP, gather data, identify near- to long-term needs in the region, and recommend actions to address them.

4. Background and Region Overview

4.1 Region Overview

The Renfrew region is home to Indigenous communities including: Algonquins of Pikwakanagan, Algonquins of Ontario (AOO Consultation Office), Huron Wendat, MNO Ottawa Region Métis Council, and MNO High Land Waters Métis Council. A full list of Indigenous communities that were invited to participate in the regional planning engagements can be found in Section 8.5. The region is also comprised of the following communities: Township of Admaston/Bromley, Township of Bonnechere Valley, Township of Brudenell, Lyndoch, and Raglan, Township of Greater Madawaska, Township of Head, Clara, and Maria, Township of Horton, Township of Killaloe, Hagarty, and Richards, Township of Laurentian Valley, Township of Madawaska Valley, Township of McNab/Braeside, Township of North Algona Wilberforce, Township of Whitewater Region, Town of Arnprior, Town of Deep River, Town of Laurentian Hills, Town of Petawawa, Town of Renfrew, and the City of Pembroke.



Hydro One Distribution is the main LDC for the region with Ottawa River Power Corp. embedded at Pembroke TS. ORPC is responsible for managing the distribution system for the central Pembroke area. The Hydro One portion of the station is predominantly industrial based. The ORPC portion of the load is largely residential loads. Pembroke is also unique in the fact that it has a tie to the Brookfield generator in Quebec and has been importing energy from the generator since 1893. The generator was established in Pembroke at the same time as the lumber mill and allowed for the first street lighting in Canada. The ownership and management of the generator has changed hands many times but it remains a core characteristic of the city's electrical supply.

Petawawa is the next largest municipality in the region and is served by Craig TS, Craig DS, and Petawawa DS. An industrial customer makes up a significant portion of the Petawawa DS load. The region is also home to two transmission connected customers in Chalk River Nuclear Laboratories and Magellan Aerospace. The majority of the remaining Renfrew region is made up of townships with predominantly residential loading.

4.2 Electrical System

Two hydro electric generation stations supply either end of the transmission system. Power is stepped down from 230 kV to 115 kV at Des Jaochims TS and Chenaux TS. The Des Joachims sub-system consists of 115 kV transmission circuit D6 while the Chenaux sub-system is supplied by the X2Y and X6 transmission circuits. A normally open point is found between Pembroke TS and Forest Lea DS which separates the two sytems under normal operations but can be closed in order to supply the 115 kV system during planned and unplanned outages from either Des Joachims TS or Chenaux TS. The region has two transmission connected customers: Chalk River Nuclear Laboratories and Magellan Aerospace. Figure 2 shows the electric system for Renfrew.

Figure 2 | Single Line Diagram of Renfrew Electric System

4.3 Previous Planning Activities

The most recent cycle of regional planning for the Renfrew region began with a Needs Assessment, carried out by Hydro One, that was published in May of 2021. The Needs Assessment developed a 10 year forecast and identified several needs in the region. Two end-of-life asset issues were addressed: refurbishment of Chenaux T3/T4 Auto transformers and 115 kV switchyard, and the refurbishment of the D6 line from Des Joachims TS to Petawawa DS. Finally, the Needs Assessment identified the station capacity need at Pembroke TS and recommended that the next stage of regional planning, the Scoping Assessment, should determine whether further regional planning coordination is required.

The Scoping Assessment began immediately following the Needs Assessment and was published in August of 2021. This step in the process is lead by the IESO and includes one public webinar to present the Technical Working Group's recommendation on the next steps. Through deliberation it was decided that further coordination and assessing the possibility of non-wires alternatives (NWA) to address the capacity issue at Pembroke TS was necessary which moved the Renfrew region to the IRRP stage.

4.4 Scope of Work

There are several key steps to an IRRP that are taken in order for the Technical Working Group to be able to come to a consensus on what the ultimate recommendations will be for each issue. First is the development of a planning forecast. The Technical Working Group is tasked with analyzing historical demand and then projecting anticipated demand over a 20-year period while taking into account the effect of generation, conservation and demand management, and extreme weather. The IRRP for the Renfrew region produced non-coincident planning forecasts which serve as an aid in identifying transmission system issues.

The Needs Assessment identified a station capacity issues at Pembroke TS but following the completion of the planning forecast several other issues were found. The scope of this IRRP includes station capacity issues at Pembroke TS, Forest Lea DS, Petawawa DS, and examines the Load Meeting Capability (LMC) of both the Des Joachims and Chenaux sides of the transmission system. Details regarding each of these issue is outlined in the Section 6 – Transmission System Issues.

The next steps are then to identify suitable solutions for each of the issues which are covered in the options analysis in Section 7. The IRRP considers wires, non-wires alternatives, including energy efficiency solutions, and accesses each based on cost, feasibility, and timing. Stakeholders are consulted throughout the planning process in the form of individual engagements as well as three public webinars. Finally, recommendations are provided which outline the best course of action as agreed upon by all members of the Technical Working Group.

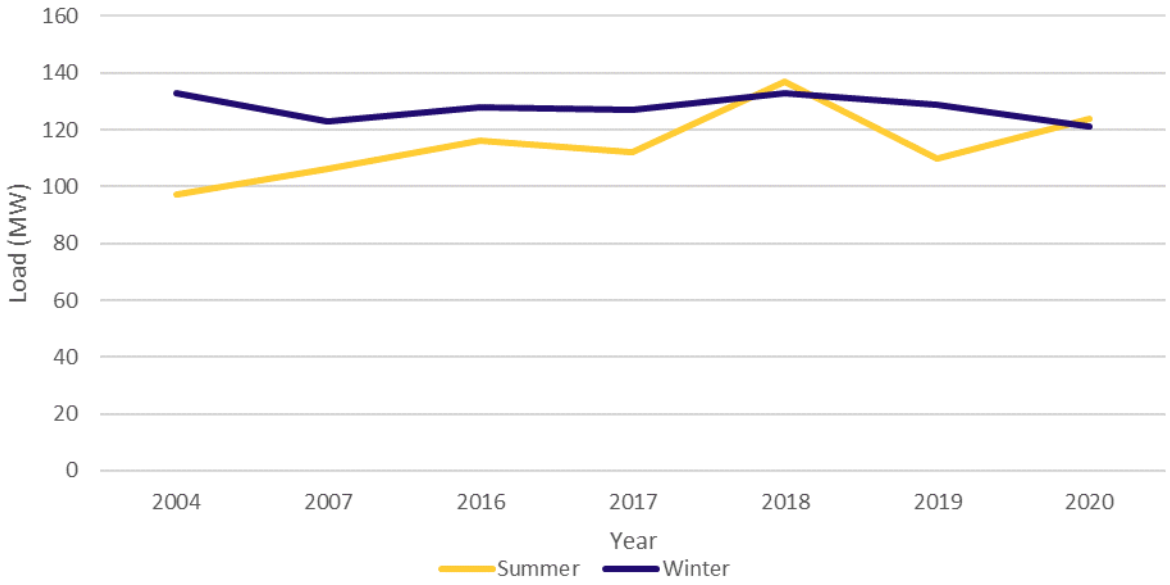
5. Electricity Demand Forecast

Regional planning in Ontario is driven by the need to meet peak electricity demand requirements in a region. In order for the Technical Working Group to plan for the future transmission system issues of a region, a 20- year planning demand forecast is developed. This section outlines the demand forecast methodology, discusses historical electricity demand trends, development of the planning demand forecasts as well as the expected contributions of conservation and demand management (CDM) and distributed generation (DG) towards reducing the peak demand in the region. By taking all of these factors into consideration the planning demand forecast is developed and is used to plan the transmission grid such that the grid can operate reliably and economically in the long-term. In addition to this, the final sections will examine higher growth scenarios and their impact on the region's transmission system.

5.1 Demand Forecast Methodology

The goal of creating a 20-year forecast is to understand how electricity demand will change in the region, on a station by station basis, in order to understand which parts of the electricity system will require further planning decisions. The planning forecast serves as a reference with the understanding that true, actualized demand may be higher or lower. In order to develop the planning forecast it is important to consider how to treat past electricity demand. Naturally demand fluctuates hour by hour, day by day, and seasonally so the basis of the forecast is annual peak demand. The reference forecast is based on the annual peak as this is the highest demand that the electricity system is expected to experience in the year and must be able to handle in accordance with planning criteria.

The planning forecast is divided into three time horizons: near-, medium-, and long-term. The near-term (one to five years) has the highest degree of certainty and any issues are typically met using regional transmission or distribution solutions. The medium- (five to ten years) and long-term (ten to twenty years) issues will also examine non-wires alternatives such as generation and CDM solutions. In addition to this, a summer and a winter forecast can be developed to account for regions that experience peaking in both seasons. For the Renfrew region both a summer and winter non-coincident forecast were produced.



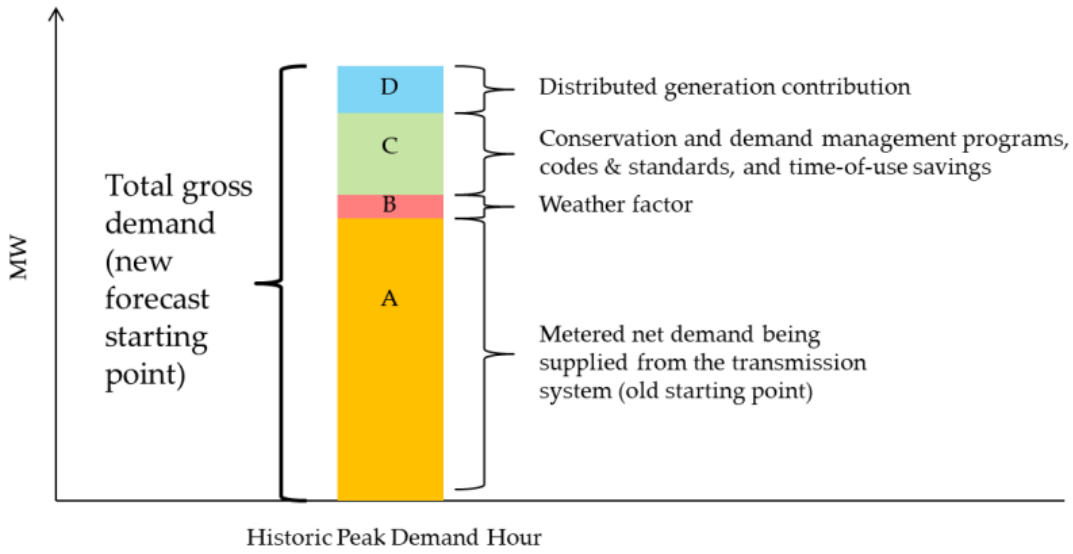
The process of developing the planning forecast starts with the development of the starting points. These consider several factors including historical load, weather, and generation at each of the stations. Using these starting points, distributors develop a 20-year gross demand forecast by accounting for known customer connections, predicted growth in population, and other electricity considerations that planners are privy to. Then, the forecast accounts for the effects of CDM and DG by subtracting them from the demand to produce a Reference Forecast. This is then adjusted for extreme weather which is represented by the hottest year in thirty years, as this will likely be seen over the course of the planning horizon.

Additional details on the demand outlook assumptions can be found in Appendix A.1 - Methodology and Assumptions for Demand Forecast as well as Appendix A.5 for the forecasts themselves. The demand outlook was used to assess any growth-related transmission system issues in the region.

5.2 Historical Electricity Demand

The Renfrew region has historically been a winter peaking region but has seen two of the past five years reach a higher demand in the summer. Going further back to the mid-2000s Figure 3 shows that as a whole the region has seen little growth in peak coincident demand in general. In fact, it appears as though winter demand has slightly decreased while summer demand has been consistently increasing. The region is predominantly made up of residential loads while the larger municipalities such as Pembroke and Petawawa have larger industrial customers.

Figure 3 | Renfrew Historical Coincident Demand



Based on the historical trend it is might be thought that the next twenty years will continue to see little to no growth. However, it is precisely the summer forecast's gradual increase that is telling of trends that could have a significant effect. The ratings of the power system electrical equipment are lower in the summer than in the winter because the natural ambient air cooling is not present and higher temperatures tend to further constrain the equipment's electrical capabilities. The Technical Working Group learned that a vast majority of the residential customer do not have air conditioners. AC units are one of the most impactful contributors to peak loads as they are typically used on the hottest days while the system is seeing its largest demand. Further, residential customers are also mainly using gas heating which means fuel-switching could also increase the winter demand over the next twenty years.

5.3 Gross Demand Forecast Starting Point

The purpose of the starting point is to allow LDCs to forecast their growth from a common place. Gross is used as it is a better approximation of true demand. The starting points are developed by first examining the past five years of historical hourly peak data for each station. For the Renfrew region the base year chosen was 2020 as the IRRP was started in 2021. The hourly demand data for each of the five years is adjusted for normal and extreme weather which is done by taking a weighted average of the 30 years of daily max temperature for the region. The daily peaks for temperature are found for all five years and graphed against daily peak consumption. Certain portions of the data are filtered out to ensure proper correlation is established between temperature and load including outliers, holidays, and weekends. A linear regression is performed to establish a line of best fit and the 90th percentile represents extreme temperature while to 50th percentile is normal temperature.

Typically, the effects of DG and CDM are taken into account as well in order to produce the gross starting point. In the case of Renfrew this was done by identifying the DG in the area and applying a contribution factor which varies by technology type, season of use, and region. The effects of CDM are typically analysed by reviewing the historical demand management programs, codes & standards, and time-of-use savings data available. Figure 4 shows the makeup of the starting point. As mentioned, LDCs then forecast the gross demand for each station based on their own methodologies.

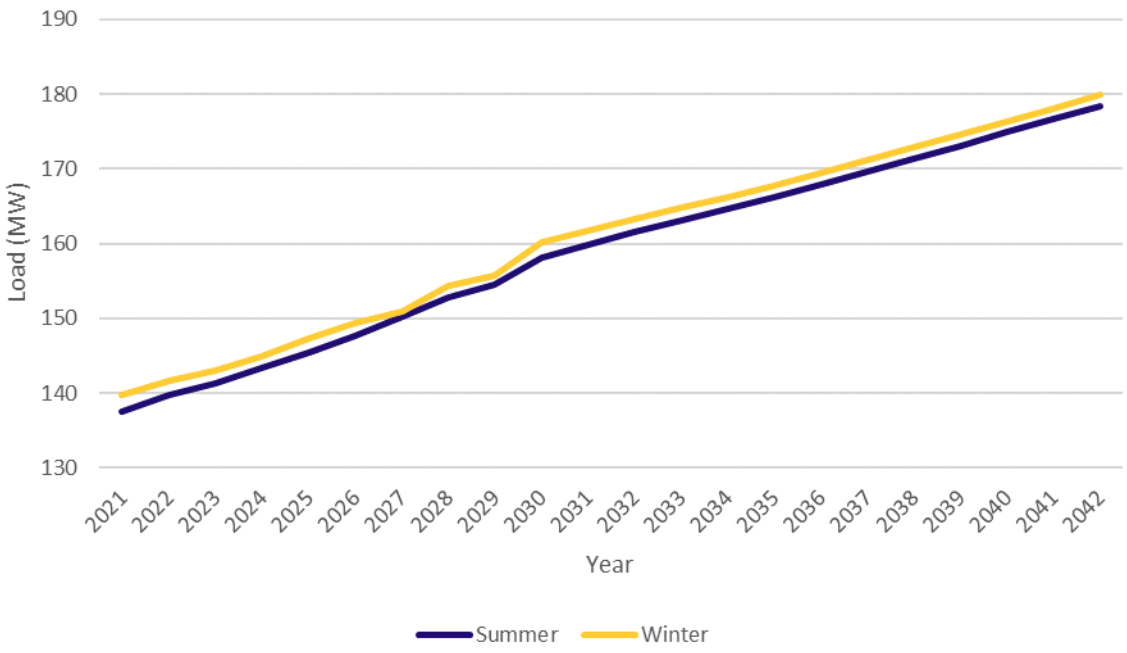


Figure 4 | Load Unbundling to Establish a Gross Demand Starting Point for Forecasting

5.4 Gross Demand Forecast

The gross demand forecast for the 20 year planning period is developed by each LDC. In the case of Renfrew, Hydro One Distribution developed the forecast for all stations with the exception of Pembroke TS which was jointly developed with the embedded LDC ORPC. The LDCs have better insights into the load growth supplied by the distribution stations through their customer connections, management of the station assets, and engagements with electricity customers. The purpose of the gross demand forecast is to serve as a reference which means only load growth that is committed or has a strong chance of materializing is to be considered. Figure 5 shows the summer and winter gross demand forecasts.

Figure 5 | Renfrew Region Non-Coincident Gross Median Demand

5.5 Contribution of Conservation on Forecast

CDM helps in meeting Ontario's electricity needs by reducing demand. This is achieved through a mix of codes and equipment standards amendments as well as CDM program-related activities.

Demand reduction due to codes and standards are based on expected improvement in the codes for new and renovated buildings and through regulation of minimum efficiency standards for equipment used by specified categories of consumers. Program-related activities include the Save on Energy programs being implemented as part of the 2021-2024 CDM framework.

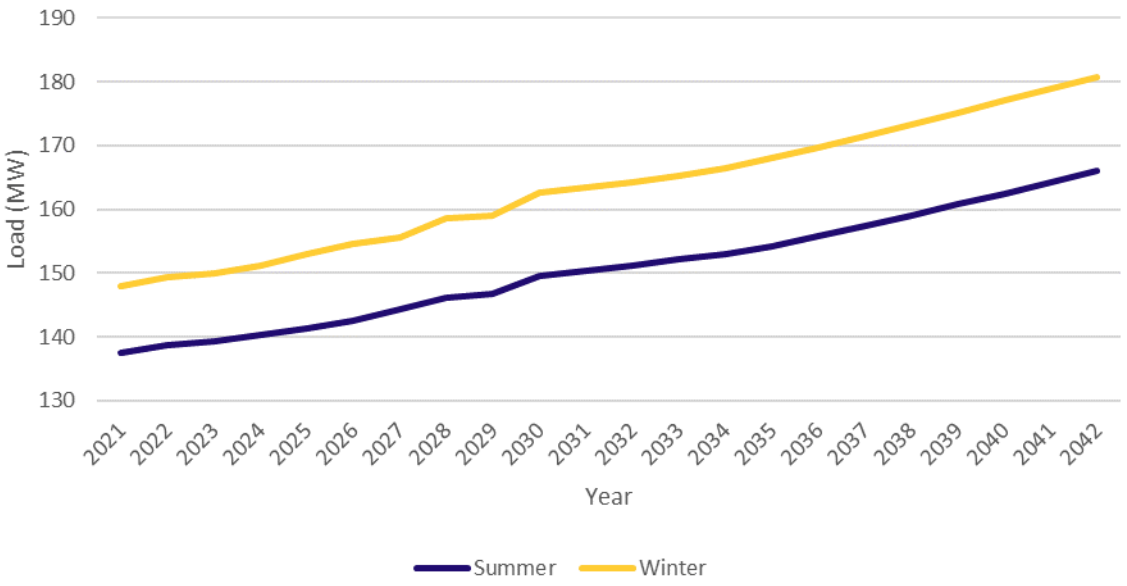
For the Renfrew region, the total forecast conservation savings at the time of summer peak are shown in Table 1 for a selection of the forecast years. These savings are subtracted from the gross median demand forecast as described in Section 5.4. Additional information is provided on Appendix B.

Table 1 | MW Savings from Conservation and Demand Management

Year	2022	2024	2026	2028	2030	2032	2034	2036	2038	2040	2042
Summer Savings (MW)	2	4	6	8	10	12	13	14	14	14	14

5.6 Contribution of Distributed Generation on Forecast

In addition to conservation resources, DG in the Renfrew region is also forecasted to offset peak demand requirements. The resources that were included in the DG forecast reflect resources that have contracts with the IESO as a result of previous procurement programs, such as the FIT and microFIT programs. In the Renfrew region, the contracted DG resources are all solar projects.



The effective capacity, i.e., the MW output at the time of regional peak, was determined at a resource level, and the data was aggregated at a station level in order to put together a forecast specifying the estimated peak demand reduction due to DG output. From 2021 to 2042, the expected annual peak demand contribution of contracted DG in the Renfrew region is 1.7 MW. The DGs included in the Renfrew IRRP are connected from the following stations:

- Deep River
- Des Joachims
- Cobden
- Pembroke

5.7 Planning Demand Forecast

In order to determine whether transmissions system issues exist it is important to consider the net demand for each station. The net demand represents the peak load level that the transmission system actually experiences and needs to serve. The final net demand forecast, adjusted for extreme weather, for the Renfrew region can be seen in Figure 6. The growth seen here is consistent with the electricity trends that have been noted throughout the report. The planning forecast for each of the stations in the region can be found in Appendix A.5. The planning forecast is used to determine where the issues in a region are and the Technical Working Group ensured the accuracy of the forecast by meeting with stakeholders in those areas to inquire about specific electricity plans.

Figure 6 | Renfrew Region Non-Coincident Extreme Weather Planning Demand Forecast

5.8 Sensitivity Scenario: Higher Growth Forecast

The concept of sensitivity is an important consideration for the planning process. It refers to the idea of stressing a system or examining alternative scenarios. The previous sections have dealt with a reference scenario which is akin to a middle-of-the-road path. It has a higher degree of certainty and by nature discounts extreme growth or extreme decline. Growth scenarios are examined when there is a trend or large project not considered in the reference forecast. Two such scenarios were identified during the planning process. Through discussions with stakeholders it was discovered that two prominent electricity customers in the Renfrew region have tentative plans to increase their load consumption on the order of 20 MW each. The customers are on the Des Joachims sub-system so this IRRP examined one growth scenario where a single increase takes place as well as a scenario where both increases take place. These scenarios occur in the long-term and due to their uncertainty will not have formal recommendations, however, the IRRP will provide insight into how the transmission system can be modified to accommodate this potential growth.

5.9 Hourly Forecast Profiles

In addition to the annual peak forecast, hourly load profiles (8,760 hours per year over the 20-year forecast horizon) for certain station with identified needs were developed to characterize their needs with finer granularity. The profiles were based on historical load data, adjusted for variables that impact demand such as calendar day (i.e., holidays and weekends) and weather. These profiles were used to quantify the magnitude, frequency, and duration of needs to better evaluate the suitability of generation and distributed energy resource options.

Additional load profile details including hourly heat maps for each need can be found in Appendix D. Note that this data is used to roughly inform the overall energy requirements needed to develop and evaluate alternatives; it cannot be used to deterministically specify the precise hourly energy requirements. Real-time loading is subject to various factors like actual weather, customer operation strategies, and future customer segmentation. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification are more widely adopted. Hence, these hourly forecasts are only used to select suitable technology types and roughly estimate costs for the needs and options studied in the IRRP. The Technical Working Group will continue to monitor forecast changes as part of implementation of the plan.

6. Transmission System Issues

Based on the demand outlook, system capability, application of provincial planning criteria, and the transmitter's identified end-of-life asset replacement issues, the Renfrew IRRP Technical Working Group determined transmission system issues in the near-, medium-, and long-term. This section describes the capacity issues in the Renfrew region. No end-of-life or reliability issues were identified as part of this IRRP cycle but the methodology is still described below.

6.1 Transmission System Issues Methodology

Based on the application of ORTAC and NERC TPL 001-4 Standard, the Technical Working Group identified transmission system issues related to local or regional reliability requirements for the following categories:

- **Station Capacity Issues** describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations at peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day Limited Time Rating (LTR) of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be limited when downstream or upstream equipment, e.g., breakers, disconnect switches, low-voltage bus or high voltage circuits, is undersized relative to the transformer rating.
- **Supply Capacity Issues** describe the electricity system's inability to provide continuous supply to a local area at peak demand. This is limited by the LMC of the transmission supply to an area. The LMC is determined by evaluating the maximum demand that can be supplied to an area accounting for limitations of the transmission elements, e.g., a transmission line, group of lines, or autotransformer, when subjected to contingencies and criteria prescribed by ORTAC and TPL 001-4. LMC studies are conducted using power system simulations analysis.
- **End-of-life Asset Replacement Issues** are identified by the transmitter with consideration to a variety of factors such as asset age, the asset's expected service life, risk associated with the failure of the asset, and its condition. Replacement issues identified in the near- and early mid-term timeframe would typically reflect more condition-based information, while replacement issues identified in the medium- to long-term are often based on the equipment's expected service life. As such, any recommendations for medium- to long-term issues should reflect the potential for the need date to change as condition information is routinely updated.

- **Load Security and Restoration Issues** describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC. No load security and restoration issues were identified as part of this IRRP.

6.2 Near- to Medium-Term Needs

6.2.1 Station Capacity Issues

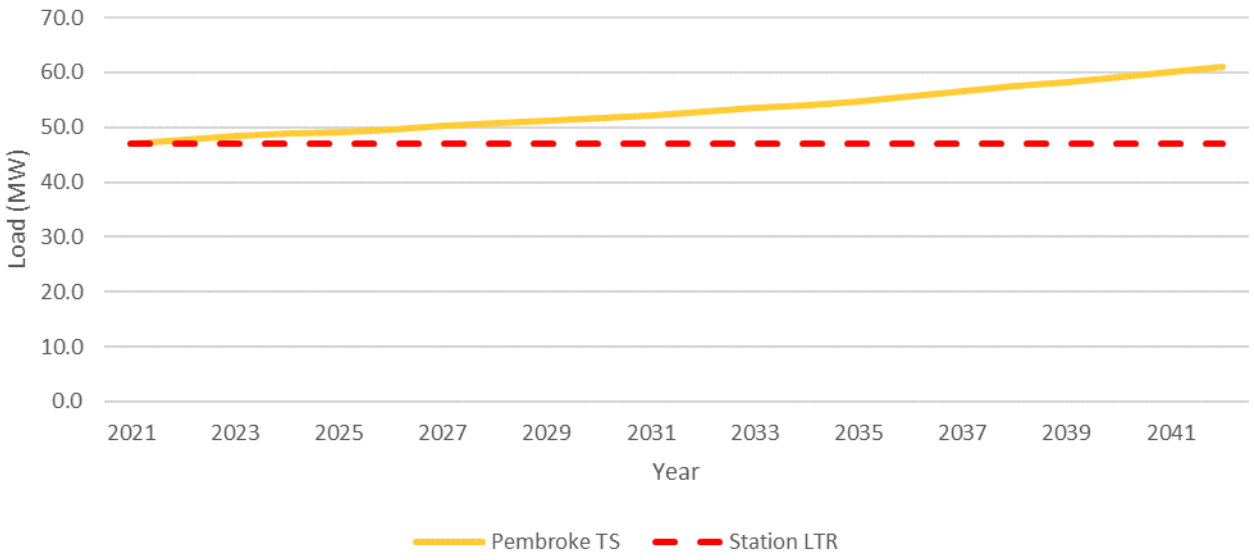
Station Capacity Issues have been identified for Pembroke TS, Forest Lea DS, and Petawawa DS.

6.2.1.1 Pembroke TS Capacity Issue

Pembroke TS is owned by Hydro One Transmission and managed by Hydro One Distribution while Ottawa Power River Corp is an embedded customer and LDC. Pembroke TS has three distribution feeders that supply both LDC loads. Hydro One supplies Pembroke DS and Greenwood DS as well as other larger commercial and industrial customers while ORPC utilizes two of the distribution feeders to supply seven of their own distribution stations throughout the core of the city. The distribution feeders that supply the core part of the city are also tied with the Brookfield generator from Pontiac Hydro, the details of the relationship with the generator can be found in section 4.1.

The planning forecast confirms and refines the capacity issue at Pembroke TS. Based on the load growth from the demand forecast the issue will grow to approximately 14 MW in the summer and 12 MW in the winter. The summer loading is more constraining as the equipment ratings in the summer are lower. The Technical Working Group met with key industrial customers to inquire about future plans and confirmed the accuracy of the planning demand forecast.

Figure 7 | Summer Non-Coincident Demand Forecast for Pembroke TS



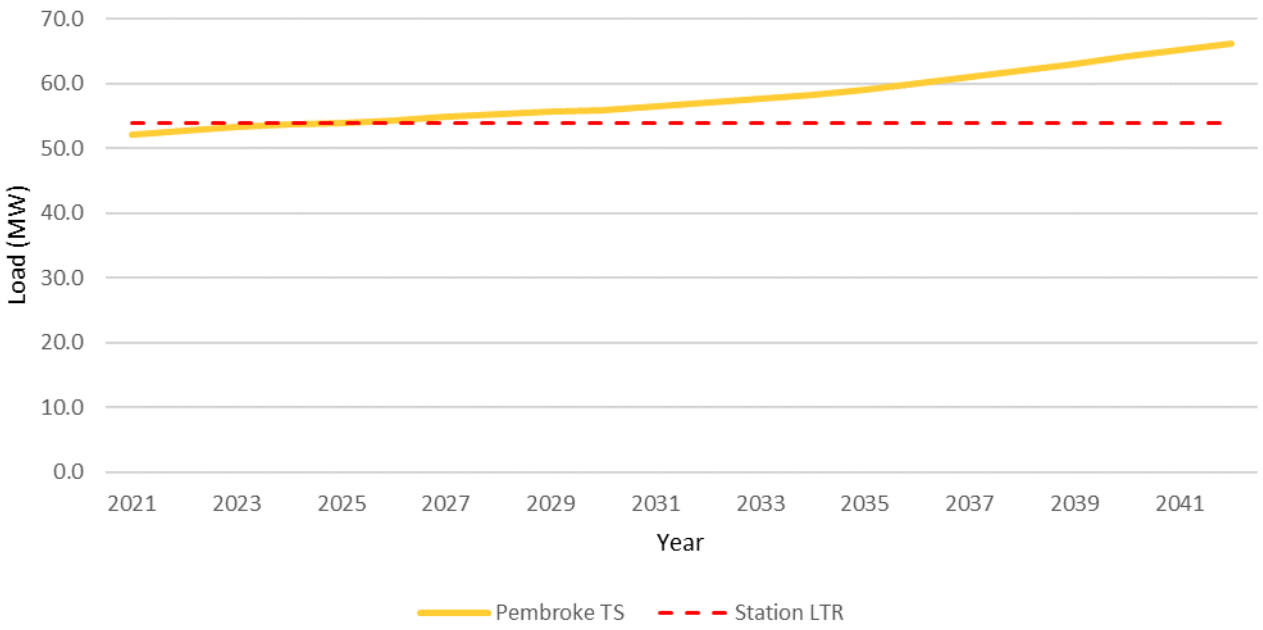


Figure 8 | Winter Non-Coincident Demand Forecast for Pembroke TS

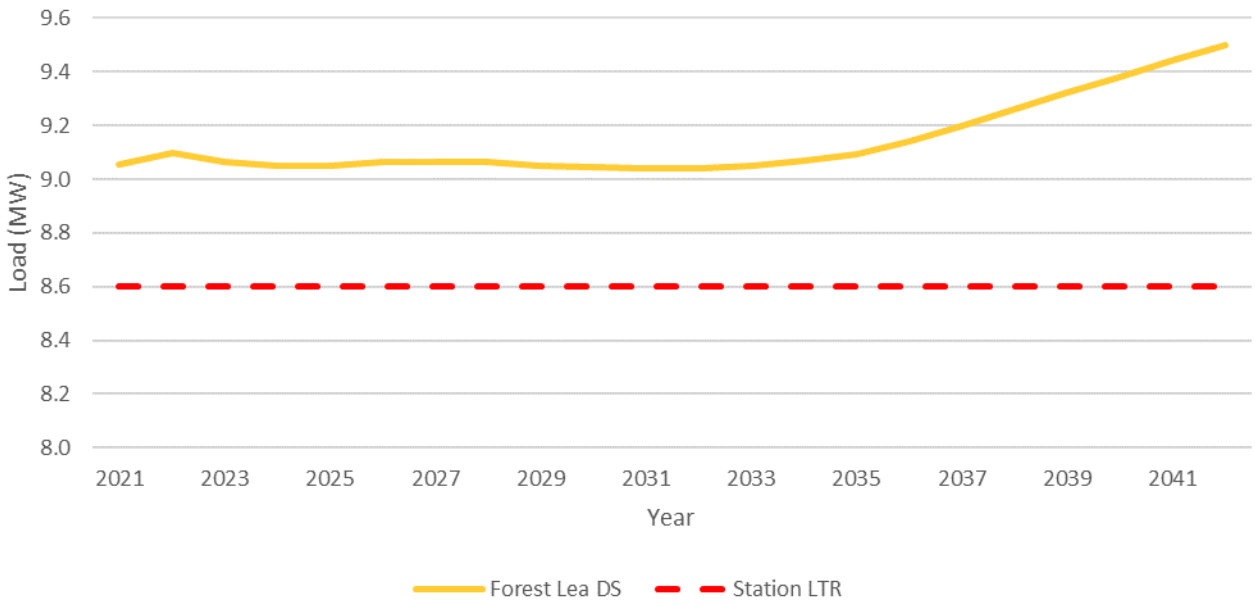
6.2.1.2 Forest Lea DS Capacity Issue

Forest Lea DS is located in Laurentian Valley Hills, just outside the city of Pembroke. It is near the end of the circuit D6, close to Petawawa DS and Craig DS. The station is owned by Hydro One Distribution and has two 7.5 MVA, 115 kV to 13.4 kV, stepdown transformers that were installed in 1974. They are in good working condition and have not been targeted for replacement or refurbishment in a capital program as of the publishing of this report. The station's peak demand currently exceeds its LTR in the summer by approximately half a megawatt and will increase to nearly a full megawatt by 2042 as seen in Figure 10. In the winter, the station is expected to reach its LTR by 2025 and exceed that rating by just over half a megawatt by 2042 as seen in Figure 9.

Figure 9 | Summer Non-Coincident Demand Forecast for Forest Lea DS



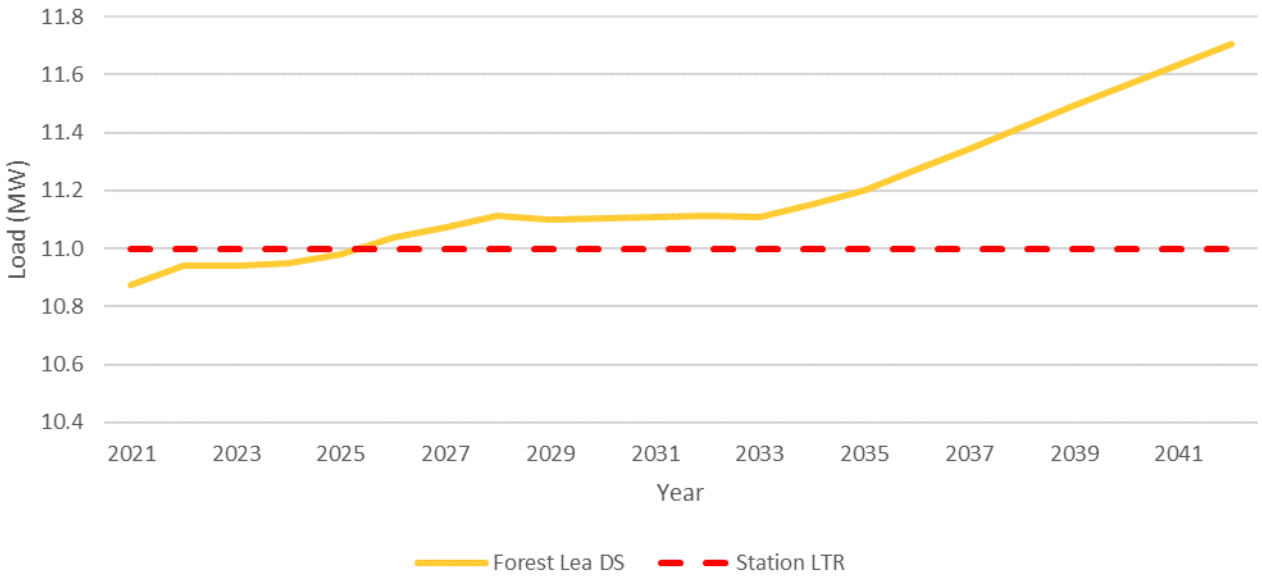


Figure 10 | Winter Non-Coincident Demand Forecast for Forest Lea DS

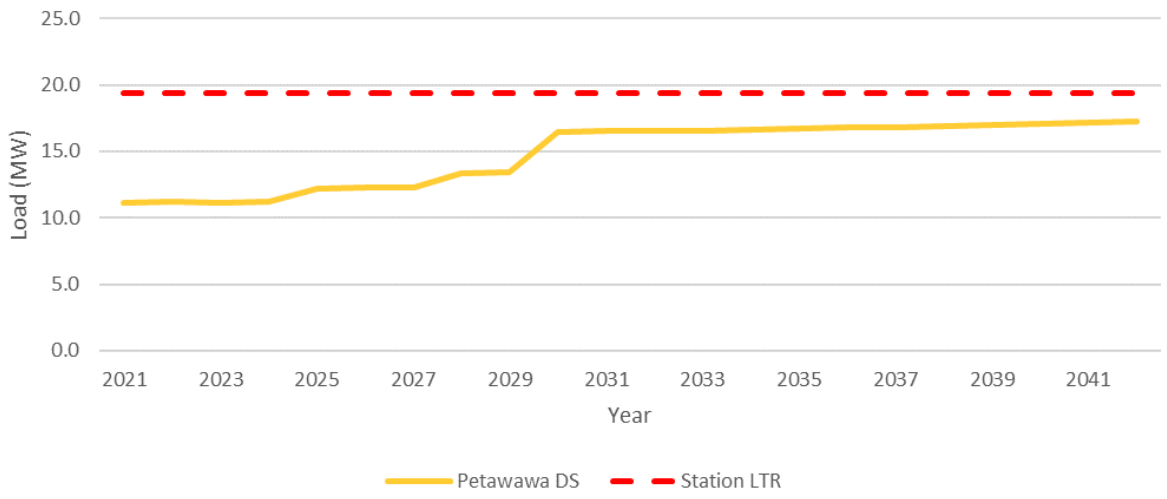
6.2.1.3 Petawawa DS Capacity Issue

Petawawa DS is supplied by circuit D6 and is located at the end of the circuit alongside Craig DS. The station is owned by Hydro One Distribution and has two 7.5 MVA, 115 kV to 13.4 kV, stepdown transformers that were installed in 1976. They are in good working condition and have not been targeted for replacement or refurbishment in a capital program as of the publishing of this report. The station's load is predominantly made up of one large industrial customer with the rest being the town of Petawawa. Two outreach meetings were held with the customer to finalize the planning forecast and the outcomes of the discussions made it clear that there is both medium- and long-term plans for further electricity consumption. The final forecast can be seen in Figure 11 which includes the medium-term expansion project. The station is anticipated to reach its limit by 2030 in the summer and based on the latest forecast will be within its winter rating. Further, the engagement also revealed a very sizeable heating load at the industrial customer which will need to be converted as part of the Canadian Net-Zero Emissions Accountability Act. This development is one of the basis for the growth scenarios developed as part of this regional plan and further details can be found in Section 6.3. It is considered a growth scenario as opposed to part of the planning forecast due to the uncertainty of the size and exact timing of the project.

Figure 11 | Summer Non-Coincident Demand Forecast for Petawawa DS



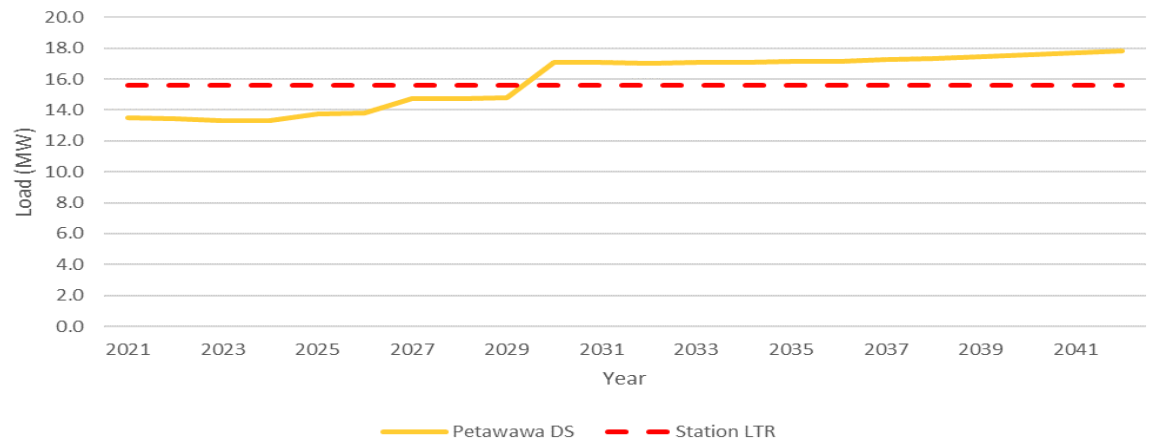


Figure 12 | Winter Non-Coincident Demand Forecast for Petawawa DS

6.3 Long-Term Needs

6.3.1 Supply Capacity Issues

6.3.1.1 Des Joachims Sub-System Capacity Issue

The Renfrew electricity system is comprised of two sub-systems, the Des Joachims and Chenaux sub-systems. The Des Joachims sub-system refers to the transmission line D6 and the generating station in the Western part of the Renfrew Region called Des Joachims TS while the Chenaux sub-system refers to the transmission lines X2Y and X6 and associated stations. As part of the planning process the LMCs are determined for the relevant parts of the transmission system. It was found that there are no long-term issues under the planning forecast for the Chenaux sub-system. Growth scenarios were developed for the Des Joachims sub-system and long-term issues were identified. With one element out and a contingency to a generator at Des Joachims TS, under peak coincident demand and low generation conditions, there is a voltage change violation at end-of-line stations such as Petawawa DS, Forest Lea DS, and Craig DS on the Des Joachims sub-system. That LMC is approximately 80 MW as seen in Figure 13.

Figure 13 | Des Joachims Side Summer Coincident Load Forecast

7. Options and Recommendations

This section describes the options considered and recommendations to address the issues in the Renfrew Region. In developing the plan, the Technical Working Group considered a range of integrated options. Considerations in assessing alternatives included maximizing use of existing infrastructure, provincial electricity policy, feasibility, cost, and consistency with longer-term needs in the area.

Generally speaking, there are two approaches for addressing regional needs that arise as electricity demand increases:

- Build new infrastructure to increase the LMC of the area. These are commonly referred to as "wires" options and can include things like new transmission lines, autotransformers, step-down transformer stations, voltage control devices, or upgrades to existing infrastructure. Wires options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate certain reliability concerns.
- Install or implement measures to reduce the net peak demand to maintain loading within the system's existing LMC. These are commonly referred to as "non-wires" options and can include things like local utility scale generation, distributed energy resources, demand response, or energy efficiency.

Section 7.1 begins with a more in-depth overview of all option types considered in IRRPs. The IESO utilized a screening approach to assess which needs would be best suited to a detailed assessment for non-wires options, this is first described in Section 7.2. Section 7.3 covers the options and recommendations for meeting the near- to medium-term issues, and is followed by Section 7.4 which discusses the options and recommendations for the long-term. The summary and next-steps is found in in Section 7.5.

7.1 Options Considered in IRRPs

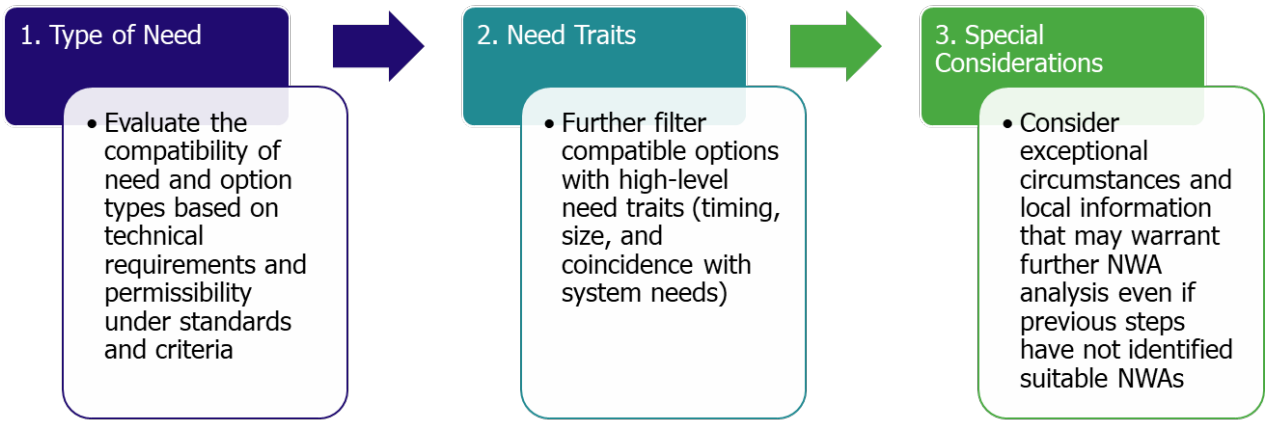
Wires options are developed by designing transmission reinforcements or control actions that are appropriate for the specific limiting phenomenon (voltage, thermal, stability, etc.) of each need. These options are developed through discussions with the Technical Working Group. These wire options consider the capital cost of the line and stations plus the energy cost associated with the unserved energy profile.

The high-level cost estimates for wires options are provided by the transmitter, Hydro One. The RIP, following the IRRP, will perform additional detailed analysis and refine these cost estimates before implementation work begins. The IESO will continue to participate in the Technical Working Group during the RIP and revisit these recommendations if costs estimates differ significantly.

To select a non-wire options an hourly load profile is first created as described in Section 5.9. The most suitable technology type and capacity is chosen by examining the "unserved energy" profile which is the hourly demand above the existing LMC. The profile indicates the duration, frequency, magnitude, and total energy associated with each need.

Cost estimates for generation and other non-wires alternatives are based on benchmark capital and operating cost characteristics for each resource type and size. The use of new natural gas-fired generation is considered in the economic analysis for illustrative purposes to represent the lowest cost of generation. The use of energy storage such as a lithium nickel manganese cobalt oxide (NMC) batteries is also considered as it becomes competitive due to declining technology costs and the expectation of increasing carbon prices in line with federal policy. Conservation demand management (CDM) are also non-wires alternatives that can be considered based on regional availability.

For all of the above options, the system capacity value if applicable is "credited" back to arrive at the net cost to meet local reliability needs. This is done to ensure a level playing field comparison between resources that provide capacity and wires options that address the local need but do not provide system capacity benefits.



Both the upfront capital and operating cost of the wires options, generation, and distributed energy resources are compiled to generate levelized annual capacity costs ($/kW-yr) over the lifespan of the asset in question (for Renfrew a 45-year lifespan is assumed for the station infrastructure) for each option. The net present value (NPV) of these levelized costs are the primarily basis through which options are compared below. Unless stated otherwise, the costs are net present values and in 2021 CAD dollars. The list of assumptions made in the economic analysis can be found in Appendix C.

7.2 Screening Options

As explained in Section 7.1, different options can be developed to meet local needs during an IRRP based on the needs requirement. Options are then evaluated to recommend the most cost-effective and technically feasible solution. This process is complemented by considerations for stakeholder preferences and feedback.

Screening occurs early in the IRRP study after local reliability needs are known but before options analysis. It helps direct time-intensive aspects of detailed NWA analysis (hourly need characterization, options development, financial analysis, and engagement) towards the most promising options. The three-step, high-level approach is shown in Figure 14.

Figure 14 | IRRP Screening Mechanism

Note that the screening mechanism only acts as a guideline; many other considerations for its application in the Renfrew IRRP are described in the following sections.

7.2.1 Non-Wires Options for the Capacity Needs

In general, non-wires options can resolve supply and station capacity needs by reducing net load in the affected area. For station capacity needs specifically, these options must be connected downstream of the limiting step-down transformer.

7.2.1.1 Pembroke TS

As described previously in Section 6.2.1.1, there are forecast station capacity needs at Pembroke TS. Since the capacity need at Pembroke TS is existing today, and grows to 14 MW and 12 MW in the summer and winter, respectively, a DR solution was screened out as prior years' auction indicates there isn't sufficient DR potential in the east zone for 16 MW for both summer and winter seasons.

7.2.1.2 Petawawa DS

As described in Section 6.2.1.2, there is a forecast station capacity need at Petawawa DS. Due to consideration of the growth scenario, a DR solution was screened out. Further, in 2042 there will be a station capacity need at Petawawa DS 47% of the time in July, which is not a good candidate for DR. Lastly, CDM was screened out as the station supplies one large industrial customer which greatly reduces the available programs and initiatives.

7.2.1.3 Forest Lea DS

For Forest Lea DS, all options except transmission-connected generation were developed in further detail.

7.2.1.4 Des Joachims Sub-System Supply

Due to the nature of supply capacity needs, most non-wires options can be potential solutions – either alone or as a part of an integrated package of recommendations. However, for the Des Joachims sub-system, the need was only forecast to emerge under the growth scenario. To focus non-wires alternative analysis on the needs emerging under the reference forecast, only wires options were evaluated.

7.2.1.5 Summary of Screening Outcomes

Table 2 | Results of Renfrew IRRP Screening

Need Type	Impacted Element	Options Screened In	Options Screened Out
Station capacity	Pembroke TS	Wires, DG, CDM	Transmission-connected generation, DR
Station capacity	Petawawa DS	Wires, DG	Transmission-connected generation, DR, CDM
Station capacity	Forest Lea DS	Wires, DR, DG, CDM	Transmission-connected generation
Supply capacity	Des Joachims Sub-system	Wires	Transmission-connected generation, DR, DG, CDM

7.3 Options for Meeting Near- to Medium-Term Issues

7.3.1 Options for Meeting Pembroke TS Station Capacity Need

Pembroke TS supplies both Hydro One Distribution and ORPC load. The embedded ORPC load is supplied from two of the existing feeders. These feeders provide both a normal and back up supply to seven ORPC owned distribution stations throughout the core of the city. The feeders mentioned distribute power at a voltage of 44 kV which is stepped down at the DS. The station LTR is currently exceeded by 1 MW and this is forecast to increase to 14 MW, in the summer, over the course of the 20 year forecast.

7.3.1.1 Transmission Options

Two feasible wires options were considered:

- Building a new HVDS, or
- Building a new DESN station, or "TS".

These options differ both in the capacity they are capable of offering and the secondary, or distribution voltage, available.

The HVDS would be built by converting the existing Pembroke DS to an HVDS. It would be connected to only one of the two transmission circuits that currently supply Pembroke TS, X2Y or X6. An HVDS would provide 18 MW of capacity at a cost $13M (NPV), which includes $11M (NPV) for building the station and at a least an additional $2M (NPV) for distribution costs. Due to configuration of the existing system, the HVDS would be used to supply existing load, freeing up space for new load on Pembroke TS. The new HVDS would supply existing ORPC load which would split the ORPC distribution system into two distinct sub-systems: the existing system and a new radial system. The existing system utilizes the two feeders from Pembroke TS with ties between them to improve reliability and flexibility during planned outages and contingencies. Further, ORPC and Hydro One Distribution utilize different voltages which will require further analysis and cost in order to implement the HVDS solution.

Maintaining two separate systems with different levels of reliability could prove to be an operational challenge and any growth beyond the forecast would likely necessitate the expansion of this new less reliable radial 12 kV system in the future, once the capacity is exceeded. As the HVDS would only have one upstream transmission supply, this also represents a decrease in reliability over the LDC's existing supply arrangement at Pembroke TS. From a capacity standpoint, this option leaves 2 MW of remaining capacity at the new HVDS and 2 MW of remaining capacity at Pembroke TS at the end of the 20 year forecast period, which would not be sufficient to accommodate a high growth scenario.

The other option is to build a new DESN station, or TS, near the existing Pembroke TS, connected to both the X2Y and X6 circuits. It would cost approximately $28M (NPV) to build the station. Transferring existing load to the new station is estimated to have negligible cost, as no new feeders would need to be constructed. While the new supply station would be rated for 47 MW, the station will only be able to supply up to 36 MW of load due to upstream transmission constraints on 115 kV circuits. By transferring 6 MW of Greenwood DS load and 12 MW of Hydro One Distribution load to the new TS, ORPC will be able to supply their 20 year forecasted growth using their existing distribution system. This leaves 18 MW of capacity at the new TS and 4 MW of capacity at the existing TS. Compared to the HVDS option, the TS option provides higher levels of reliability, consistent with what the LDCs currently experience and provide today, as it is a dual supply station, maintains ORPC's current distribution configuration which provides back-up supply, and provides 22 MW of spare capacity for the future versus 4 MW. These additional benefits would come at an incremental cost of $15M (NPV) compared to the HVDS option.

7.3.1.2 Non-wires Options

The non-wires alternative options considered for Pembroke TS were distributed generation and additional energy efficiency. For the distributed generation option gas generation and storage were evaluated. Solar and wind were not considered due to a lack of alignment between their typical production profiles and the hourly need requirement. The gas generation option was based on costs for a 16 MW reciprocating engine located in eastern Ontario. A 93% effective capacity for system benefit was assumed in the analysis.

This option was estimated to cost of $47M (NPV). The storage option required 16 MW of capacity and 10.3 hours of storage. This option was estimated to cost $96M (NPV). The development of cost for the storage option assumed a 10 MW capacity battery with 10 hr reservoir would be installed in 2026, with an additional 6 MW installed in 2035.

Lastly, analysis of the potential for additional energy efficiency, on top of the already committed CDM programs, reveals there is the potential for approximately 6 MW of additional savings over the 20 year forecast at a cost of $31M (NPV) by 2038. This option would be insufficient to meet the need requirement of 10 MW by 2038.

7.3.1.3 Recommendations

Building a new TS in the Pembroke area will maintain current levels of reliability, will allow ORPC to continue growing their system under the current methodologies and level of distribution reliability, and allows for a substantial amount of new capacity for flexibility in meeting long-term demand compared to the HVDS option. However, this comes at an increased upfront cost for the capacity. While the technical challenges and reliability limitations associated with the HVDS are considerable, the Technical Working Group has decided the difference in cost warrants a more detailed study of the costs of the proposed HVDS connection and distribution impacts in the RIP to confirm the additional cost associated with the TS solution is warranted. The targeted in-service date for a new station in Pembroke is 2027.

7.3.2 Options for Meeting Petawawa DS Station Capacity Need

Petawawa DS supplies the town of Petawawa and a large institutional customer. The majority of the load, an upwards of 80%, is consumed by the customer. Engagements with the customer have revealed that there are developments planned for expanding several buildings on their campus which led the Technical Working Group the revise the draft forecast. The forecast now estimates the station will be overloaded in the near-term by approximately 2-3 MW.

7.3.2.1 Transmission Options

There were several wires options identified to provide the additional capacity. First, the transformers at the station could be upgraded to a larger size which would add only 3 MW of incremental capacity to the station rating. This comes at a cost of approximately $5M (NPV). Alternatively, a new HVDS could be built at a cost of approximately $10M (NPV) and would add an additional 18 MW of incremental capacity. The working group also examined the feasibility of conducting a load transfer to Craig TS but, as that station does not have a significant amount of spare capacity, it was deemed that load transfer is not suitable in this case.

The upgrade of the transformers would meet the forecast demand but offer no spare capacity. A new HVDS, however, is $5M more expensive but provides significantly more capacity and allows for flexibility to meet the challenge presented in the growth scenarios.

7.3.2.1 Non-wires Options

From a non-wires alternative perspective, a number of options were considered but only a generation option was developed as it fit the nature of the need profile. The generation option evaluated was a simple cycle gas turbine (SCGT) facility for the 2 MW need. This comes at a cost of $11M in net-present value. Wind and solar resource options were not evaluated as the load requirement does not match their production profiles. Based on comparison of the costed gas generation option to the lower cost wires options, a storage solution was not evaluated as it would be higher cost than the gas option.

7.3.2.3 Recommendations

Building a new HVDS for the Petawawa DS station capacity need is recommended. The targeted in-service date for the new HVDS is 2027. This solution will provide ample capacity to meet the immediate planned growth in demand from the institutional customer as well as provide flexibility in the future as the customer converts their gas heating load. This is the most cost effective solution that ensures capacity for the long-term growth of Petawawa.

While comparable on a cost basis, the options of incremental energy efficiency and replacement of existing station transformers would provide insufficient margin of available capacity in the area to manage the high growth scenarios at Petawawa DS, resulting in the electricity system potentially limiting the ability of customers to electrify in a manner consistent with their plans or policies.

7.3.3 Options for Meeting Forest Lea DS Station Capacity Need

Forest Lea DS has a station limit of 8.6 MW in the summer and is currently over that limit but will only exceed it by 1 MW in the 20 year forecast.

7.3.3.1 Transmission Options

A number of wires solutions were considered, including distribution load transfers to nearby stations, improving the ratings of the existing station transformers and building a new HVDS. First, the possibility of transferring load to a nearby station was explored for both existing ties with Pembroke DS and Craig DS. A 1 MW load transfer to Craig DS can be done with minimal work resulting in a capital cost of only $50k (which is equal to $55k (NPV)). A transfer to Pembroke DS, although technically feasible, would currently result in a further overload of the upstream Pembroke TS. Depending on the solution executed for the Pembroke station capacity issue it could be possible to offload Forest Lea DS but for these reasons transferring load to Craig DS is favourable.

There are two options for upgrading the capacity of Forest Lea station: upgrading the transformers or installing fan cooling and a SCADA monitoring system to the existing transformers. The former option adds 10 MW of capacity for a capital cost of $4.5M ($4.4M NPV) while the latter provides 4 MW at a capital cost of $0.6M ($0.6M NPV).

Building a new HVDS for the Forest Lea area is also possible and would add 18 MW of load at a capital cost of $12M ($11.7 M NPV). However, this option provide capacity that far exceeds what would be required, even under consideration of a high growth scenario.

7.3.3.2 Non-wires Options

For the need at Forest Lea DS, demand response, distributed generation (storage), and incremental energy efficiency were evaluated. The demand response option is based on prior capacity auction potential of an additional 1 MW in the area to meet the need and the 2018-2021 costs from capacity auctions. The effective capacity for demand response is 69% and is based on the summer effective capacity in the 2022 APO. This option comes at a cost of $1M (NPV). The storage option examined is a 1 MW battery with a 4-hour battery life and a cost based on National Renewable Energy Laboratory (NREL) Annual Technology Baseline (ATB). This resource option is estimated to cost $1.6M (NPV). Lastly, analysis of the potential for additional system cost effective energy efficiency, on top of the already committed CDM programs, reveals there is approximately 1 MW of achievable potential over the 20 year forecast at a cost of $6.1M (NPV) by 2038. However, due to the small amount of load supplied by Forest Lea DS there is a higher degree of uncertainty associated with realizing these additional savings given the top-down estimate approach and there is no margin of potential additional savings when compared to the identified need.

7.3.3.2 Recommendations

Since the need at Forest Lea DS is existing and is only expected to grow to just over 1 MW in the long-term it is recommended that the 2 MW load transfer to Craig TS be executed. The targeted date for this load transfer is 2026.

In the event of further load growth beyond the reference forecast, it is recommended that the upgrade to fan cooling at the station and the installation of SCADA monitoring be implemented to allow for an additional 4 MW limit increase.

7.4 Options for Meeting Long-Term Issues

7.4.1 Options for Meeting the Des Joachims Sub-System Capacity Issue

During the course of the engagement stage of the IRRP two growth scenarios were identified for the Des Joachims Sub-system. Each scenario signifies approximately 20 MW of additional growth in the form of a large scale energy project. If one of these events were to take place it would bring the sub-system to its LMC. At this level of loading, and other assumptions, there would be voltage issues at the end of the line at stations like Forest Lea DS and Petawawa DS. The LMC can be improved to 90 MW by installing shunt capacitors at the end of the transmission line (D6). By examining the two growth scenarios outlines, growth scenario 1 being an additional 20 MW and growth scenario 2 being an additional 40 MW, the current LMC will be violated by both scenarios while the improved LMC can handle growth scenario 1 but not growth scenario 2.

7.4.1.1 Transmission Options

Installing capacitor banks at one of these stations would improve the LMC by approximately 10 MW. This means that for the more aggressive load growth scenario the Des Joachims sub-system would be 10 MW over what the system can adequately supply. In this scenario a future cycle of regional planning would need to examine options including a new transmission line.

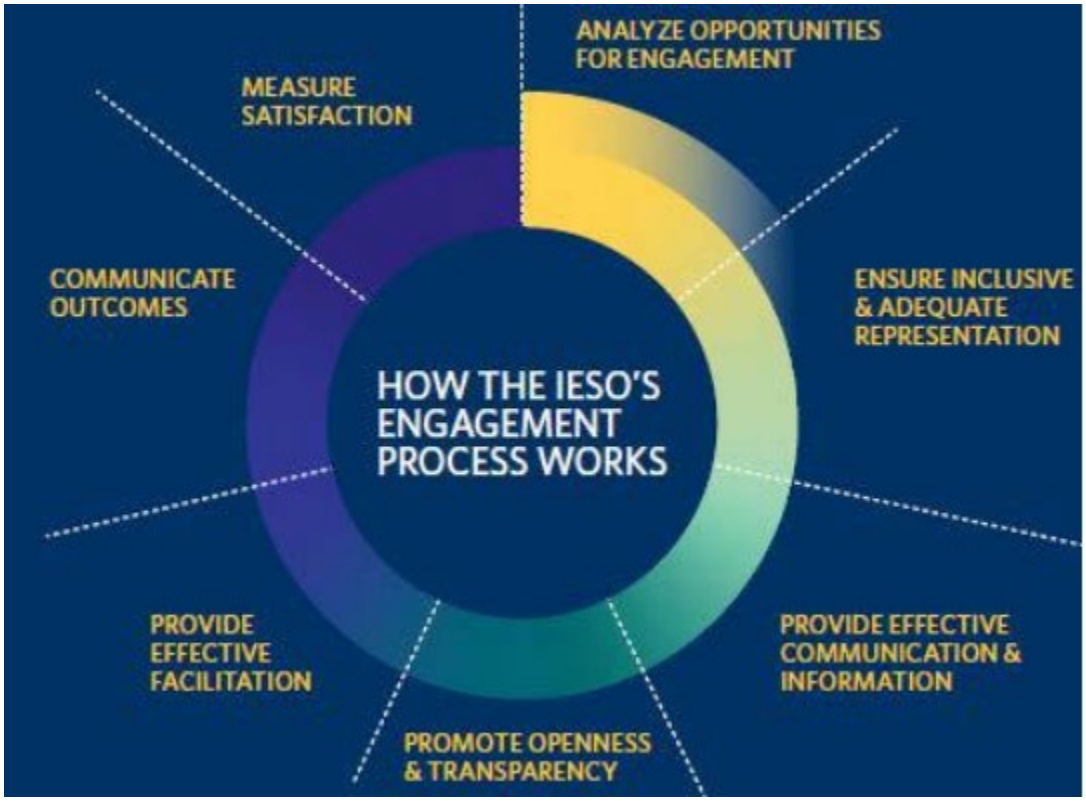
7.4.1.2 Recommendations

As both growth scenarios are in the mid- to long-term and have a fair amount of uncertainty it is recommended that the Planning Technical Working Group continues to monitor the state of the projects and triggers the capacitor upgrade if a need were to arise ahead of the next planning cycle.

7.5 Summary of Actions and Next Steps

Table 3 | Summary of Actions and Next Steps

Need(s)	Lead Responsibility	Technical Working Group Recommendation	Expected In-Service Date
Pembroke Station Capacity	Hydro One Transmission	Build a new station; conduct further analysis during the RIP period to finalize decision between new TS or HVDS	2027
Forest Lea Station Capacity	Hydro One Distribution	Transfer 2 MW of load from Forest Lea DS to Craig DS using existing tie	2025-2026
Petawawa Station Capacity	Hydro One Distribution	Build a new HVDS transformer station at Petawawa	2027
Des-Joachims Sub-System System Supply	IESO	Monitor load growth in the area and wait to trigger investment	N/A



8. Engagement

The engagement process is critical to the development of the IRRP. Identifying, interacting, and collaborating with stakeholders in the region allows for the collection of knowledge and input which directly shapes how the plan is developed. Engagement is conducted in various forms and the details of the process as well as the feedback heard for the Renfrew region is described in this section.

8.1 Engagement Principles

The IESO's engagement principles help ensure that all interested parties are aware of and can contribute to the development of this IRRP[1]. The IESO uses these principles to ensure inclusiveness, sincerity, respect and fairness in its engagements, striving to build trusting relationships as a result.

Figure 15 | IESO's Engagement Principles

[1] https://www.ieso.ca/en/sector-participants/engagement-initiatives/overview/engagement-principles

8.2 Developing an Engagement Plan for Renfrew

The first step in ensuring that any IRRP reflects the needs of community members and interested stakeholders is to create an engagement plan to ensure that all interested parties understand the scope of the IRRP and are adequately informed about the background and issues in order to provide meaningful input on the development of the IRRP for the region. As part of the engagement process, it is important to seek out information and input on the region's electricity needs and growth plans. This helps to ensure that the IRRP captures the most accurate and up-to-date information.

Creating the engagement plan for this IRRP involved:

- Discussions to help inform the engagement approach for the planning cycle;
- Communications and other engagement tactics to enable a broad participation, using multiple channels to reach audiences; and
- Identifying specific stakeholders and communities who may have a direct impact on this initiative and that should be targeted for further one-on-one consultation, based on identified and specific needs in the region.

As a result, the engagement plan for this IRRP included:

- A dedicated webpage on the IESO website to post all meeting materials, feedback received and IESO responses to feedback throughout the engagement process;
- Regular communication with interested communities, rights-holders and stakeholders by e-mail or through the IESO weekly Bulletin;
- Public Webinars;
- Targeted one-on-one outreach with specific stakeholders and communities to ensure that their identified needs are addressed.

8.3 Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for this new round of planning and establish new relationships with communities and stakeholders in the region where there has been no active engagement previously. This started with the Scoping Assessment Outcome Report for the Renfrew Region. An invitation was sent to targeted municipalities, Indigenous communities and those with an identified interest in regional issues to announce the commencement of a new regional planning cycle and invite interested parties to provide input on the draft Renfrew Scoping Assessment Outcome before it was finalized. A public webinar was held in July 2021 to provide an overview of the regional electricity planning process and seek input on the high level needs identified and proposed approach. The final Scoping Assessment was posted later in August 2021 which identified the need for a coordinated regional planning approach to develop the first IRRP for the Renfrew Region.

Following the finalization of the Scoping Assessment, the launch of a broader engagement initiative followed with an invitation to subscribers of the Renfrew Region to ensure that all interested parities were made aware of this opportunity for input.

Three public webinars were held at major stages during the IRRP development to give interested parties an opportunity to hear about progress and provide comments on key components of the plan. These webinars were attended by a cross-representation of community representatives, businesses and other stakeholders and written feedback was collected over a 21-day comment period following each webinar.

The three stages of engagement invited input on:

1. The draft engagement plan, electricity demand forecast and early identified needs to set the foundation of this planning work.
2. The defined electricity needs for the region and high level screening of potential options to meet the identified needs.
3. The analysis of options and draft IRRP recommendations.

The first Webinar centered around presenting the draft demand forecast as well as preliminary issues identified in the region. Input was requested on major electricity demand projects that may not have been captured in the forecast as well as any ideas about the development of the engagement plan. The second Webinar presented a completed forecast, list of issues, as well as a slate of wires and non-wires alternatives options for each issue. At this point the public was asked to provide input on the options to help shape the recommendations. The final Webinar presented the recommendations found in Section 7 and feedback on the final outcome was requested.

One-on-one outreach to communities, and stakeholders, including the largest electricity customers, located where stations that were over or close to their Long-Term Rating was influential in informing updates to the long-term forecast and ultimately to the report recommendations. Discussions addressed long-term energy plans as electricity customers' expansion and/or decommissioning plans.

Comments received during this engagement were primarily focused on ensuring that the growth plans of communities and large electricity users have been considered and accounted for in the IRRP work as well as the type of solutions addressing those needs. Feedback received during the written comment periods for these webinars helped to guide further discussion throughout the development of this IRRP as well as add due consideration to the final recommendations.

All interested parties were kept informed throughout this engagement initiative via email to Renfrew Region subscribers, municipalities and communities as well as to the members of the East Ontario Regional Electricity Network.

Based on the discussions through the Renfrew IRRP engagement initiative, a key priority is to ensure that the IRRP and recommended actions align with the accelerated demand for housing in the region as well as can prepare to accommodate potential large scale increase in electricity needs by two large customers in the area. These insights have been valuable to the IESO in understanding how the region is growing to ensure an accurate electricity demand forecast, determination of needs and recommendation of solutions to ensure the adequacy and reliability of supply over the long-term.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's Renfrew Region IRRP engagement webpage.

8.4 Bringing Municipalities to the Table

The IESO held meetings with municipalities to seek input on local planning and development activities related to electricity to ensure that these plans were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings with the upper- and lower-tier municipalities in the region were held to discuss: key issues of concern, including forecast regional electricity needs; options for meeting the region's future needs; and, other opportunities for broader community engagement. These meetings helped to inform the municipal/community electricity needs and provided opportunities to strengthen this relationship for ongoing dialogue beyond this IRRP process.

Through these discussions valuable feedback was received around anticipated growth in specific municipalities in the region. New insights on notable residential growth, in particular in exurban areas, was identified through discussions with the Town of Petawawa, City of Pembroke, Town of Laurentian Valley, and the Town of Deep River, which is reflected in the demand forecast and associated IRRP recommendations.

8.5 Engaging with Indigenous Communities

The IESO remains committed to an ongoing, effective dialogue with communities to help shape long-term planning across Ontario. To raise awareness about the regional planning cycle in Renfrew, the IESO invited Indigenous communities located in or near the Renfrew region to participate in webinars that were held on July 21, 2021, February 9, 2022 and November 1, 2022. These communities included: Alderville, Algonquins of Ontario (AOO Consultation Office), Algonquins of Pikwakanagan, Curve Lake, Hiawatha, Mississaugas of Scugog Island, the Metis Nation of Ontario Ottawa Region Metis Council, and the Metis Nation of Ontario High Land Waters Metis Council. The Huron-Wendat Nation, now located in Wendake, Quebec, was also invited due to their historical presence in southern Ontario and their interest in archaeological resources. The IESO also invited the Haudenosaunee Chiefs Confederacy Council to the July and November 2022 webinars upon being informed of their interest in Renfrew.

Indigenous Participation and Engagement in Transmission Development

By conducting regional planning, the IESO determines the most reliable and cost-effective option after it has engaged with stakeholders and Indigenous communities, and publishes those recommendations in the applicable regional or bulk planning report. Where the IESO determines that the lead time required to implement those solutions require immediate action, the IESO may provide those recommendations ahead of the publication of a planning report, such as through a hand-off letter to the lead local transmitter in the region, for example.

As part of the overall transmission development process, a proponent applies for applicable regulatory approvals, including an Environmental Assessment that is overseen by the Ministry of Environment, Conservation and Parks (MECP). This process includes, where applicable, consultation regarding Aboriginal and treaty rights, with any approval including steps to avoid or mitigate impacts

to said rights. MECP oversees the consultation process generally but may delegate the procedural aspects of consultation to the proponent. Following development work, the proponent will then need to apply to the OEB for approval through a Leave to Construct hearing, and only if approval is granted, can it proceed with the project. In consultation with MECP, project proponents are encouraged to engage with Indigenous communities on ways to enable participation in these projects.

9. Conclusion

The Renfrew IRRP identifies electricity needs in the region over the 20-year period from 2022 to 2042, recommends a plan to address immediate and near-term needs, and lays out actions to monitor long-term needs. The IESO will continue to participate in the Technical Working Group during the next phase of regional planning, the RIP, to provide input and ensure a coordinated approach.

In the near term, the IRRP recommends a load transfer from Forest Lea DS to Craig DS on the order of 2 MW. Further, it is recommended to build a new HVDS near Petawawa DS to help meet both the near term expected expansion work as well support future anticipated larger scale fuel-switching initiatives. Lastly, it is recommended that further analysis is conducted during the RIP period to choose between building a new HVDS or new TS in the city of Pembroke in order to select the most prudent investment. Responsibility for these actions has been assigned to the appropriate members of the Technical Working Group.

In the long term, the IRRP recommends that the Technical Working Group continues to monitor the development of the two large scale energy projects that have been identified in the region. The size and timing of the projects will determine when and where further action will need to be taken. Installing a capacitor will likely be sufficient to accommodate one of the two scenarios but both will require a more robust solution which will be developed by the Technical Working Group.

The Technical Working Group will meet at regular intervals to monitor developments and track progress toward plan deliverables. In the event that underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the Ontario Energy Board.

REGIONAL INFRASTRUCTURE PLAN

July 13, 2023

[This page is intentionally left blank]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Independent Electricity System Operator (IESO)
Hydro One Networks Inc. (Distribution)
Ottawa River Power Corporation (ORPC)

Disclaimer

This Regional Infrastructure Plan (RIP) Report for Renfrew region was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group (TWG).

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Technical Working Group.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE TECHNICAL WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE RENFREW REGION.

The participants of the Renfrew Regional Infrastructure Plan ("RIP") Technical Working Group ("TWG") included members from the following organizations:

- Independent Electricity System Operator ("IESO")
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Ottawa River Power Corporation (ORPC)

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process. Hydro One, as the lead transmitter undertakes the development of a RIP with input from the Technical Working Group (TWG) for the region and publishes a RIP report. The second cycle of the Regional Planning process for the Renfrew region was initiated with Needs Assessment (NA) and the report was published in May 2021 by Hydro One. This was followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) which were published in August 2021 and December 2022, respectively, by the Independent Electricity System Operator (IESO).

The Renfrew RIP provides a consolidated summary of needs and recommended plans for the region over a study period of 2022-2042 based on available information. In this regional planning cycle, plans are recommended for the near to medium-term needs. The needs for the longer term were assessed but due to uncertainties in the load growth, long-term needs will be monitored and further reviewed in next regional planning cycle.

I. Following Major projects were completed during the last ten years:

- Chenaux TS: 230/115 kV, T3 & T4 Autotransformers replaced with new 75/100/125 MVA units along with regulators TR3 and TR4, 115kV oil circuit breakers 4X6 and 4X2Y, completed in 2021.

II. Following Major projects are underway:

- 115kV D6 Circuit: Complete line refurbishment of 76.8 km Line section between Des Joachims TS and Petawawa/Craig DS, planned in-service date in 2025.

III. New needs identified during the second cycle regional planning:

a. Asset Renewal for Major HV Transmission Equipment

- No new major HV Transmission Asset renewal identified.

b. Station Capacity

- Pembroke TS: Currently exceeding summer station LTR.
- Forest Lea DS: Currently exceeding summer station LTR.
- Petawawa DS: Update on need as identified in IRRP.

c. Transmission Line Capacity

- No new Transmission Line capacity identified.

d. System Reliability, Operation and Load restoration

- No System Reliability, Operation and Load restoration issues identified.

e. Long term needs

- Des Joachims sub-system supply capacity: Monitor load growth in the area.

The major infrastructure investments in this second cycle recommended by the TWG in the Renfrew Region over the near, medium and long-term period are given in Table 1 below, along with their planned in-service date and estimate for planning purposes.

Table 1. Renfrew Region - Recommended Plans over the 2022-2042 Study Period

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Station capacity needs				
Pembroke TS	Hydro One Dx and ORPC to continue to explore both the new TS and HVDS options and determine most feasible solution	Hydro One Tx	2028	14-30
Forest Lea DS	Transfer 2 MW load to Craig TS	Hydro One Dx	2026	0.05
Petawawa DS	No longer needed as Load Forecast is revised.	Hydro One Dx	-	-
Long-term Supply capacity needs				
Des Joachims sub-system	Monitor load growth in the area and wait for confirmation of investments.	IESO	-	-

Note:
a) The planned in-service dates are tentative and subject to change.
b) Costs are based on planning estimates may exclude the cost for distribution infrastructure (if required)

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE RENFREW REGION.

The report was prepared by Hydro One Networks Inc. (Transmission) ("Hydro One") on behalf of the Technical Working Group ("TWG") in accordance with the regional planning process established by the Ontario Energy Board ("OEB") in 2013. The TWG included members from the following organizations:

- Independent Electricity System Operator ("IESO")
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Ottawa River Power Corporation (ORPC)

The Renfrew region is located in Eastern Ontario with the majority of load along the Ottawa river. For electrical planning purposes this region includes eighteen municipalities including the towns of Arnprior, Deep River, Laurentian Hills, Petawawa and Renfrew. As well as the townships of Admaston/Bromley, Bonnechere Valley, Brudenell, Lyndoch and Raglan, Greater Madawaska, Head, Clara and Maria, Horton, Killaloe, Hagarty and Richards, Laurentian Valley, Madawaska Valley, McNab/Braeside, North Algona Wilberforce and Whitewater Region; as well as the City of Pembroke. Figure 1-1 represents the Renfrew Region Map.

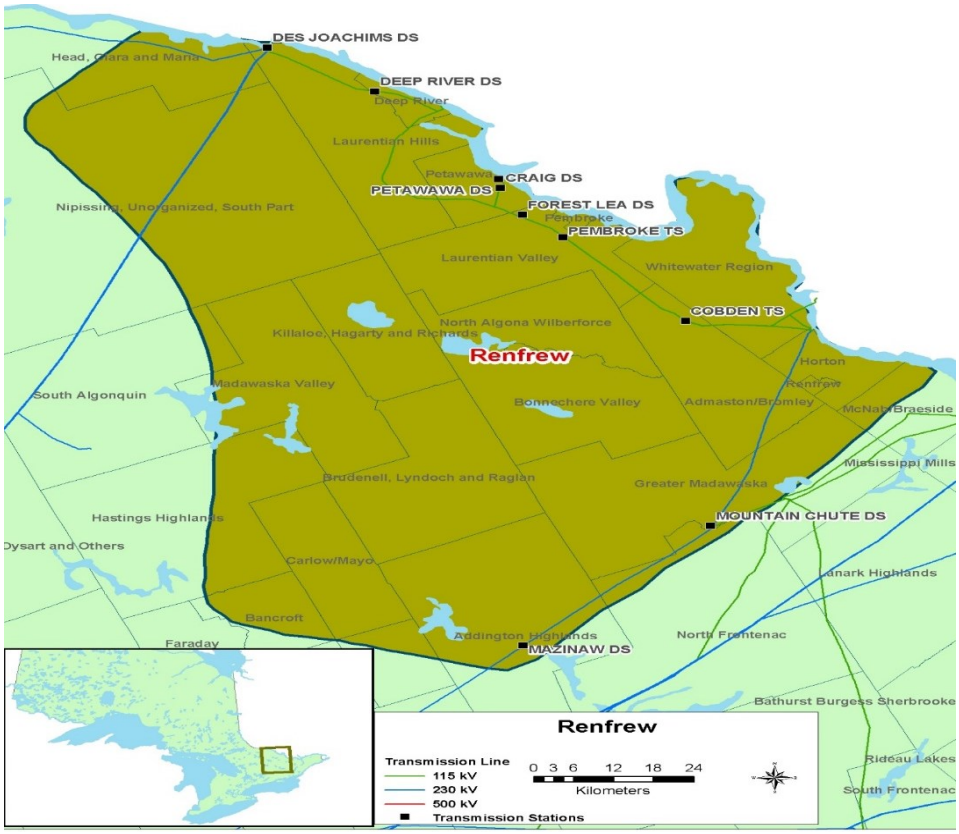

Figure 1-1 Renfrew Region Map

1.1 Objectives and Scope

This RIP report examines the needs in the Renfrew Region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs for the region;
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major high voltage transmission equipment, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near, and medium-term needs identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the study period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the Renfrew IRRP or identified by the TWG.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the regional characteristics.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the results of the adequacy assessment of the transmission facilities in the region over the study period and identifies the needs.
- Section 7 discusses the needs, provides alternatives to address each need, and recommends a preferred solutions; and,
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: The Needs Assessment ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Technical Working Group (TWG) assess, and document which of the needs that,

a. can be addressed directly between the customer and transmitter along with a recommended plan, and;
b. require further regional coordination and identification of LDCs to be involved in further regional planning activities for the region.

At the end of the NA, a decision is made by the TWG as to whether further regional coordination is necessary to address some or all the regional needs. If no, further regional coordination is required, recommendation to implement the recommended option and any necessary investments are planned directly by the LDCs (or customers) and the transmitter. The Region's TWG can also recommend to the transmitter and LDCs to undertake a local planning process for further assessment when needs,

a. are local in nature,
b. require limited investments in wires (transmission or distribution) solutions, and;
c. do not require upstream transmission investments.

In situations where identified needs require further coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the TWG, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and decides on the most appropriate regional planning approach. The approach is either a RIP,

which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region were identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities, Indigenous communities, business sectors and other interested stakeholders and establishes a Local Advisory Committee (LAC) in the region or sub-region.
The RIP phase is the final phase of the regional planning process and involves: discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive and consolidated report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the regional planning process taking effect.
- The NA, SA, IRRP and LP phases of regional planning.
- Conducting wires planning as part of the RIP for the region or sub-region.
- Planning for connection capacity requirements with the LDCs and transmission connected customers.

Figure 2 -1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

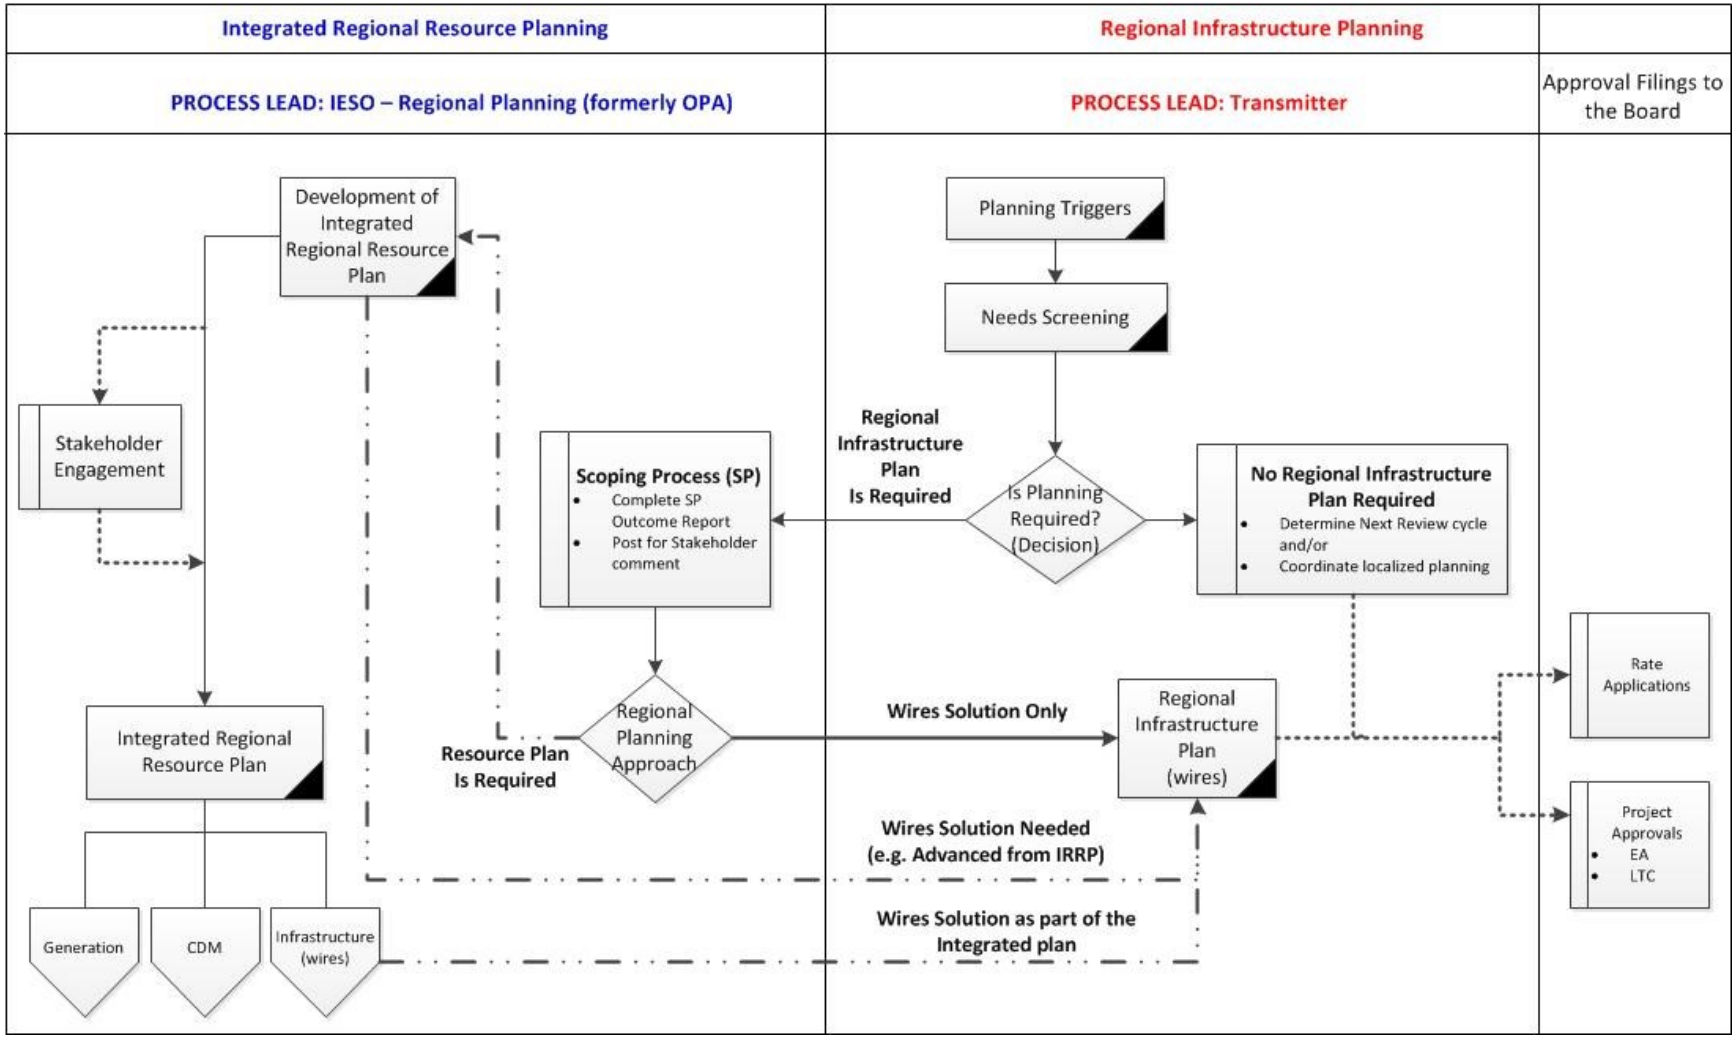

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four-step process (see **Error! Reference source not found.**) as follows:

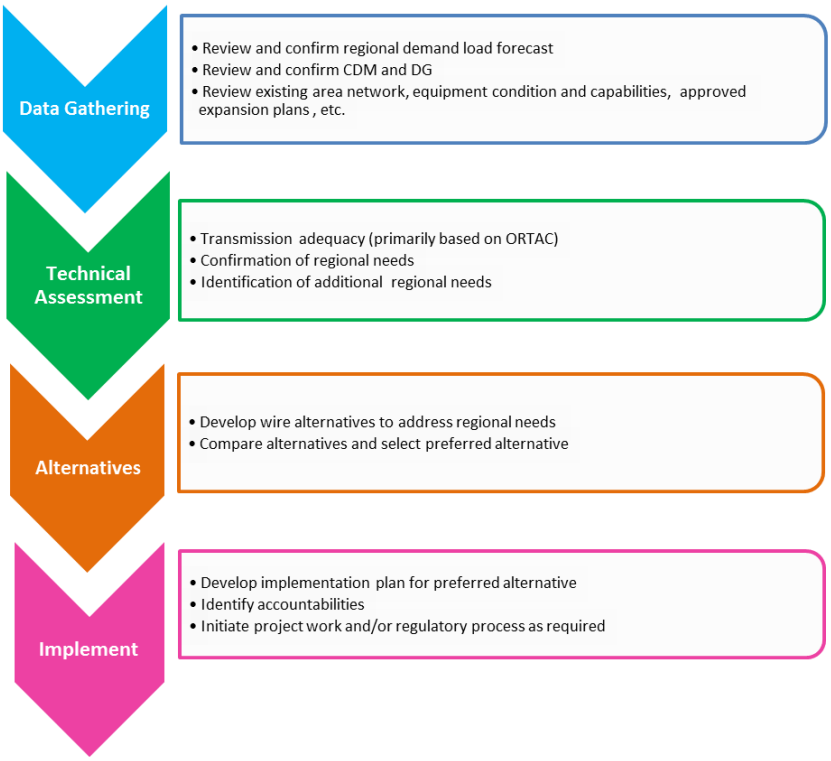

Figure 2-2 RIP Methodology

1. Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the technical working group (TWG) to reconfirm or update the information as required. The data collected includes:

    - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs. As agreed by TWG members, the load forecast from the IRRP was adopted for this RIP, with the exception of Petawawa DS.
    - Review and confirm electrification, other growth scenarios, etc. which effects the projects recommended in in previous stages.
    - Existing area network and capabilities including any bulk system power flow assumptions.
    - Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3. Alternative Development: The third step is the development of wires options to address the needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative, identifying accountabilities and initiate project work or obtain permissions from Regulatory Commission if any.

3. REGIONAL CHARACTERISTICS

THE RENFREW REGION IS LOCATED IN EASTERN ONTARIO WITH THE MAJORITY OF LOAD ALONG THE OTTAWA RIVER. THE ELECTRICITY SUPPLY TO THE REGION IS PROVIDED THROUGH ONE 230KV CIRCUIT X1P AND THREE 115 KV RADIAL CIRCUITS: D6, X6 AND X2Y. THE 115KV CIRCUITS ARE SUPPLIED BY 230/115 KV AUTOTRANSFORMERS AT CHENAUX TRANSFORMER STATION (TS) FROM THE EAST AND DES JOACHIMS TS FROM THE WEST. A NORMALLY OPENED 115KV SWITCH AT PEMBROKE TS ISOLATES THE EAST AND THE WEST SIDES OF THE REGION.

The Renfrew region is bounded by the Des Joachims TS on the West and Chenaux TS on the East, and 230kV circuit X1P to the South. The distribution system in this region consists of voltage levels 44 kV and 12.5 kV. The main generation facilities in the Renfrew region are Chenaux Generation Station (GS) of 143.7 MW, Mountain Chute GS of 170.2 MW and Des Joachims GS of 432.5 MW

Hydro One Networks Inc. (Distribution) is the main LDC in the area. Other LDCs supplied from electrical facilities in the Renfrew region include Ottawa River Power Corporation and Renfrew Hydro Inc., both are embedded into Hydro One's distribution system. Renfrew Hydro Inc. customers are being fed from Stewartville TS which is part of the Greater Ottawa Regional Planning. As such, Renfrew Hydro Inc. has not been included as part of this NA.

The existing facilities in the Region are summarized below and depicted in the single line diagram shown in Figure 3-1.

- Chenaux TS is a major 230kV station in the region. The station has 143.7MW of hydraulic generation connected to the 230kV bus. The station connects to the bulk system via a single 230kV circuit X1P. Two autotransformers step down the voltage to 115kV to supply two radial circuits X6 and X2Y
- The 115kV circuits X6 and X2Y from Chenaux TS supply four stations: Pembroke TS, Cobden TS, Cobden DS and Customer Transformer Station (CTS-1).
- Des Joachim TS is the other major 230kV transformer station in the Region. There are 432.5MW of hydraulic generation connecting to the 230kV bus. The station interconnects to the Bulk Electric System (BES) via five 230kV circuits which are not in the scope of this regional assessment. Two autotransformers (one operates as standby) step down the voltage to 115kV to supply one radial circuit D6.
- The 115kV circuit D6 from Des Joachim TS 115kV bus supplies six stations: Des Joachims Distribution Station (DS), Deep River DS, Craig DS, Forest Lea DS, Petawawa DS, and Customer Transformer Station (CTS-2)
- Bryson GS from Hydro Quebec can be radially connected to Renfrew region via X2Y, when required.
- The 230kV single circuit X1P from Dobbin TS to Chenaux TS connects two stations in Renfrew region: Mountain Chute GS (with hydraulic generation of 170.2MW) and Mazinaw DS.

- Mountain Chute DS, a 115kV station adjacent to Mountain Chute GS, is supplied by a circuit W3B from outside of the studied region.

The circuits and stations of the area are summarized in the Table 2-1 below:

Table 1-1: Transformer Station and Circuits in the Renfrew region

115kV circuits	230kV circuits	Transformer Stations	Generation Stations
D6, X6 and X2Y	X1P	Des Joachims TS*, Des Joachims DS, CTS-1, Deep River DS, Chalk Craig DS, Petawawa DS, Forest Lea DS, Pembroke TS, Cobden TS, Cobden DS, CTS-2, Chenaux TS*, Mountain Chute DS and Mazinaw DS.	Mountain Chute GS (170.2MW) Des Joachims GS (432.5MW) Chenaux GS (143.7MW)

*Stations with Autotransformers installed

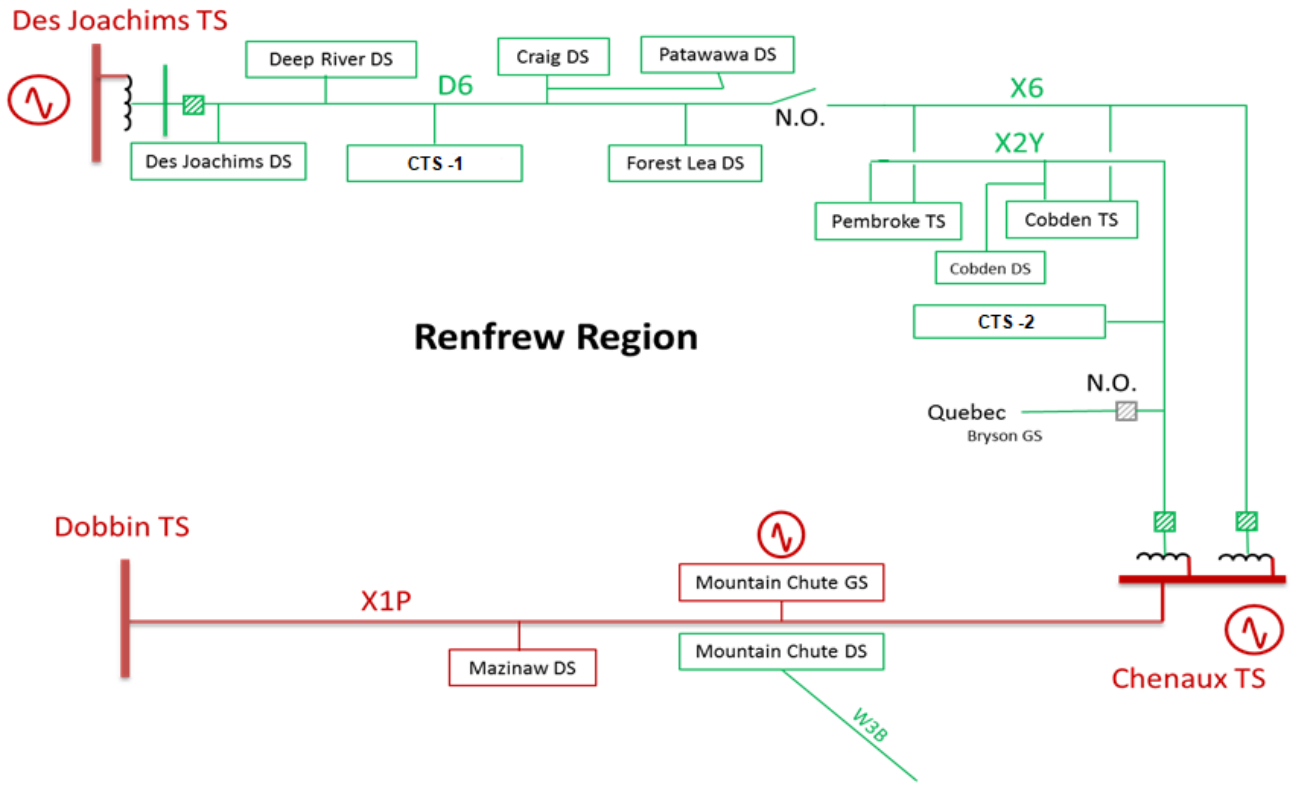

Figure 3-1 Renfrew Region Single Line Diagram

4. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR UNDERWAY

OVER THE LAST TEN YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED BY HYDRO ONE, OR ARE CURRENTLY UNDERWAY, AIMED AT IMPROVING THE SUPPLY CAPABILITY AND RELIABILITY IN THE RENFREW REGION.

A list of all the projects that are completed in past ten years or are currently underway is provided and are briefly discussed in the sub-sections. As a part of this or previous Regional Planning Cycle(s), several "Major HV Transmission Projects" were recommended in the Renfrew region to improve the supply capability and reliability.

Hydro One, being the only Transmission Asset Owner(TAO) in the region, has undertaken the execution of the projects recommended in the past ten years. A summary and brief description of all the projects completed or are currently underway is given below:

I. Following Major projects were completed during the last ten years:

1. Chenaux TS Autotransformer Replacement (2021): The 230/115 kV T3/T4 Autotransformers were replaced by new 75/100/125 MVA units along with associated facilities.

II. Following Major projects are underway:

1. 115kV D6 Line refurbishment (2025): This project is currently underway and includes complete refurbishment of 76.8km line between Des Joachims TS and Petawawa/Craig DS due to its condition assessment.

Note: The planned in-service year for the above projects is tentative and is subject to change.

5. FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

The TWG adopted the IRRP load forecasts for this RIP as no material change was identified, with the exception of Petawawa DS. At Petawawa DS, the load increased abnormally in June 2020 due to generator refurbishment work at a customer facility connected to Petawawa DS which resulted in adding about 3.1 MW to station peak. The load returned to its normal value after the work was completed in July 2020. The updated load forecast for Petawawa DS considers the updated actual peak load recorded in 2021.

The TWG participants, including representatives from LDC's, IESO and Hydro One provided information and input for the IRRP Load forecast. The municipalities were contacted as part of IRRP stakeholder engagement process to get their insight on the future load growth and was considered during IRRP load forecast development. During the study period, the load in the Renfrew region is expected to grow at an average annual rate of approximately 1.5% in summer from 2022 to 2042. The assessment is based on both summer and winter peak loads.

Figure-5-1 & 5-2 shows the Renfrew region extreme summer & winter weather non-coincident load forecast from 2022 to 2042. The load forecast from the Renfrew region IRRP was adopted as agreed to by the TWG, except for Petawawa DS. The load forecast shown is the regional non-coincident forecast, representing the sum of the load in the area for the step-down transformer stations.

Non-coincident forecast for the individual stations in the region is available in Appendix E and is used to determine any need for station capacity relief in the region.

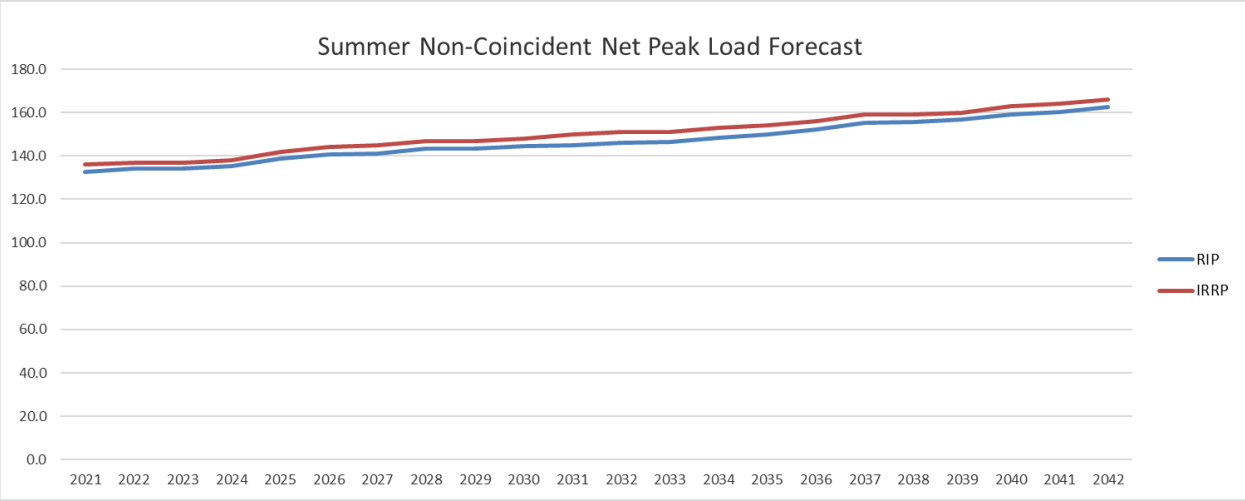

Figure 5-1 Renfrew Region Non–Coincident Net Summer Peak Load Forecast

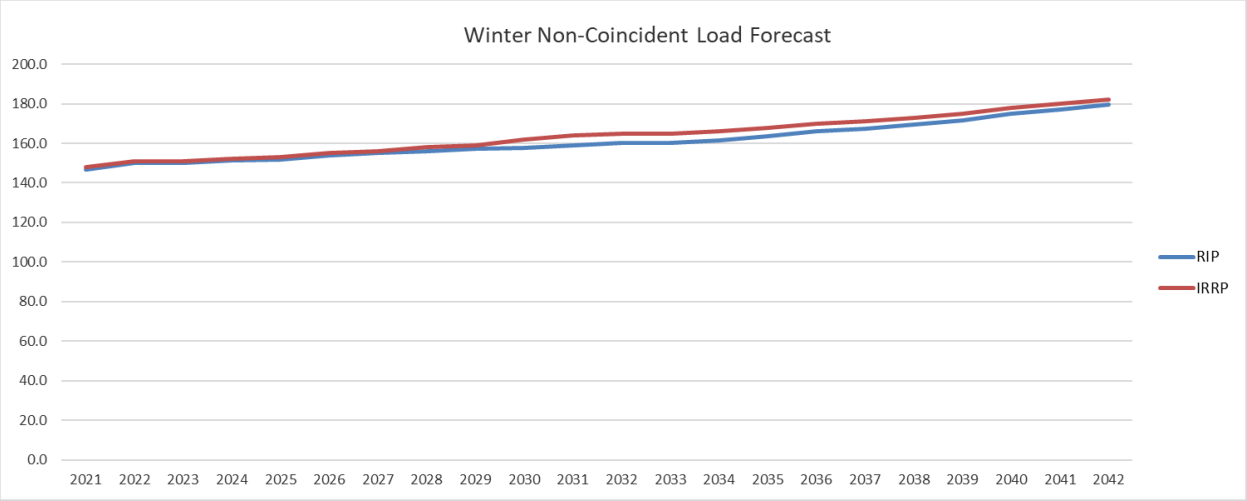

Figure 5-2 Renfrew Region Non–Coincident Net Winter Peak Load Forecast

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2022-2042.
- LDCs reconfirmed load forecasts up to 2042 in the area are the same as the IRRP(except for Petawawa DS).
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- The Region is summer peaking, so this assessment is based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR) based on 35°C ambient temperature.
- Bulk transmission line capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations use non-coincident peak loads.
- Adequacy assessment is conducted as per ORTAC.

6. ADEQUACY OF EXISTING FACILITIES AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND TRANSFORMER STATION FACILITIES SUPPLYING THE RENFREW REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM PERIOD.

In current regional planning cycle, the following regional assessments were completed, and their findings were used as inputs to this RIP report:

- Renfrew region Second cycle Needs Assessment Report, Completed in May 2021 by Hydro One
- Renfrew region Second cycle Scoping Assessment Report, Completed in August 2021 by the IESO
- Renfrew region Second cycle Integrated Regional Resource Plan Report, Completed in December 2022 by the IESO

The NA and IRRP reports identified several regional needs based on the forecasted load demand over the near, mid and long-term period. A detailed description and status of plans to meet these needs is given in Section 7.

This section provides a review of the adequacy of the transmission lines and stations in the Renfrew Region. The adequacy is assessed using the load forecasts provided in Appendices D. The assessment assumes all projects currently underway (described in section 4) are in-service.

Sections 6.1- 6.5 present the results of the adequacy assessment and Table 6-1 lists the region's near, mid, and long-term needs identified in both the IRRP and RIP phases.

6.1 Station Capacity Needs

Over the study period 2022-2042 RIP reviewed the capacity of all the 230kV and 115kV Transformer Stations within the Renfrew region. The NA and IRRP studies had previously indicated that the following stations require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast, the stations which require capacity relief during the study period are shown in Table 6-1 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer or winter) Limited Time ratings.

Table 6-1 Renfrew Region – Station capacity needs

Sr.no.	Station Name	Station LTR (MW) (Summer/Winter)	2022 Loading (MW) (Summer/Winter)	Need Date
1	Pembroke TS	47/57 MW	48/53 MW	Current
2	Forest Lea DS	8.6/11.6 MW	9/11 MW	Current
3	Petawawa DS	16.3/20.2 MW	10/10 MW	*

* Identified during IRRP phase but was eliminated in RIP following the load forecast update for Petawawa DS.

The options and preferred solutions to address these needs are discussed further in Section 7 of the report.

6.2 Transmission Line Capacity Needs

Over the study period 2022-2042 RIP reviewed the capacity of all the 230kV and 115kV Transmission lines within the Renfrew region. It was determined that all Transmission Lines are within the thermal limits of the circuits and within the voltage range as per ORTAC over the study period adequate over the study period for the loss of a single 230/115 kV circuit in the Region.

6.3 Asset Renewal for Major HV Transmission Equipment

Hydro One is the only Transmission Asset Owner (TAO) in the Renfrew region. Hydro One facilities in the region that will require replacement over the near-medium -term period as listed in Table 6-2 below.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers.
- 230 and 115kV breakers where:
  - replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
  - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
  - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

Table 6-2 Renfrew Region - Planned Replacement Work

Station/Circuit	Need Description	Planned ISD
D6	Complete 76.8kM line refurbishment between Des Joachims TS and Petawawa/Craig DS	2025

*The planned in-service dates are tentative and subject to change.

6.4 Load Security and Load Restoration

Load security and load restoration needs were reviewed as part of the current study. The ORTAC Section 7 requires that no more than 600 MW of load be lost as a result of a double circuit contingency.

Further, loads are to be restored in the restoration times[1] specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

This RIP further confirms there are no identified load security and restoration violations within the study period. The technical working group does not recommend any further action.

6.5 Long Term Needs

During IRRP phase, a long-term supply capacity issue has been identified under high growth scenarios in the Des Joachims sub-system. The Des Joachims sub-system refers to transmission line D6 connected to the Des Joachims TS in the west of Renfrew region.
The options and preferred solution to address this need is discussed further in Section 7 of the report.

[1] These approximate restoration times are intended for locations that are near staffed centers. In more remote locations, restoration times should be commensurate with travel times and accessibility.

7. REGIONAL PLANS

THIS SECTION DISCUSSES NEEDS, PRESENTS WIRES ALTERNATIVES AND THE PREFERRED WIRES SOLUTIONS FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS FOR THE RENFREW REGION.

The electrical infrastructure needs for the Renfrew Region are summarized in Table 7-1. These needs include those previously identified in the NA and IRRP for the Renfrew region. All estimated costs included in the alternative analysis are considered as planning estimates and are used for comparative purposes only.

Table 7-1 Renfrew Region – Near, Medium- and Long-Term Needs

Station/Circuit Name	Description of Need	Need Date	RIP Report Section
Station Capacity Needs			
Pembroke TS	Station has exceeded its summer LTR	Current	7.1.1
Forest Lea DS	Station has exceeded its summer LTR	Current	7.1.2
Petawawa DS	Station was expected to exceed its summer LTR	*	7.1.3
Long Term Needs			
Des Joachims sub-system	Supply capacity issue in long-term under high growth scenario	2034	7.5.1

* Identified during IRRP phase but was eliminated in RIP following the load forecast update.

7.1 Station Capacity Needs

A station capacity assessment was performed over the study period 2022-2042 for the 230kV and 115kV transforming stations in the Renfrew region using either the summer or winter peak load forecasts that were provided by the study team. Based on the results, the following station capacity needs have been identified in the during the study period:

7.1.1 Pembroke TS – 115kV

Pembroke TS supplies Hydro One Dx while ORPC is an embedded LDC. It is a 115/44 kV Transmission Station (TS) with two 25/33/42 MVA (T1/T2) transformers supplied by circuits X2Y & X6 with a summer and winter LTR of 47 MW and 57 MW, respectively.

Pembroke TS has three distribution feeders which supplies Hydro One Distribution, with ORPC as an embedded LDC on two feeders. This station has exceeded its normal supply capacity in 2019 and TWG has agreed that a wires solution is required to address this need.

The following alternatives were considered to address the need:

Alternative 1 - Maintain Status Quo:
This solution is not recommended as it does not address the supply capacity need at the station and will prevent future load growth at this station.

Alternative 2 – Build a new HVDS:
A new HVDS would be built near Pembroke TS. An HVDS would provide 18 MW of capacity at an approximate cost of $14M, which includes $11M for building the station and at a least an additional $3M for distribution costs. The new HVDS would be connected to 115kV circuit X6 as during contingency it is less limiting than X2Y as the overall circuit have a higher thermal rating compared to X2Y. The Pembroke DS load, which is expected to be 6 MW, will be transferred to the new HVDS, therefore freeing up capacity for new load on Pembroke TS. The remaining capacity of new HVDS would also be able to supply an additional 12MW of new load at 12kV in the area. Although connecting a HVDS to one circuit is less reliable than a TS connected to both circuits as it does not provide full redundant supply, there is an existing transmission 115kV switch at Cobden TS that can be used to tie X2Y and X6 to restore the load on the new HVDS for in case of a fault East of Cobden TS. All of ORPC load is currently supplied by the existing two 44kV feeders from Pembroke TS. Due to the current distribution configuration of the ORPC system, future ORPC load from the new HVDS will require further modifications at ORPC's operating system within its service territory.

From a capacity standpoint, this option would be able to supply all the forecasted load in area for the long term.

Alternative 3 – Build a new Transmission Station (TS):
Build a new TS consisting of two 115/44 kV 25/33/42 MVA step-down transformers near the existing Pembroke TS, connected to both the X2Y and X6 circuits. This would cost approximately $30M. The new supply station will be able to supply 47 MW, which is more than sufficient for the 20-year load forecast, including Pembroke TS long term growth. Similar to the HVDS option, 115kV circuit X2Y is more limiting and during a contingency situation, the thermally limiting sections on X2Y will prevent the new TS from supplying the full 47 MW station capacity.

Recommendation:
Both alternatives 2 and 3 addresses the need for additional capacity at Pembroke TS during normal operations. However, building a new TS is significantly more expensive than building a new HVDS and will also require an additional cost for transmission line upgrades to utilize the full station capacity. Building a new HVDS which is a less costly alternative, has its own operational limitations and complications for ORPC. As the assessment of both alternatives are very complex, further discussion between Hydro One Tx and the impacted LDCs is required. Both Hydro One Dx and ORPC will continue to explore these two options to determine the most feasible solution to address the capacity need at Pembroke TS.

7.1.2 Forest Lea DS – 115kV

Forest Lea DS is located in Laurentian Valley Hills, outside the city of Pembroke. It is connected at the tail end of the circuit D6, after Petawawa DS and Craig DS. This station is owned and operated by Hydro One Dx. Forest Lea DS is a 115/13.4 kV Step down station and is radially supplied by circuit D6 it has two 7.5/11 MVA (T1/T2) transformers with a summer LTR of 8.6 MW and winter LTR of 11.1 MW.

This station has already exceeded its normal supply capacity but will only increase by slightly over the station LTR at the end of the study period. The TWG has agreed that a solution is required to address this need.
The following alternatives were considered to address the need:

Alternative 1 - Maintain Status Quo:
This solution is not recommended as it does not address the supply capacity need at the station and will prevent future load growth at this station.

Alternative 2 – Load Transfer:
Through existing Dx interties, there is a possibility of transferring load to the Pembroke DS and Craig DS. TWG confirmed that a 1 MW load transfer to Craig DS can be done with minimal work with a capital cost of only $50k. A transfer to Pembroke DS, is also technically feasible, but would result in a further overload of the upstream Pembroke TS and the outcome of the preferred solution for Pembroke TS station capacity issue could affect the load transfer. In light of all these reasons, load transfer at Craig DS is preferred.

Alternative 3 – Upgrading the supply capacity:
The capacity of Forest Lea station can be upgraded using two methods which are:
i) Upgrading the transformers to add 10 MW of capacity for a capital cost of $4.5M or,
ii) Installing fan cooling and SCADA monitoring system to the existing transformers to add 4 MW at a capital cost of $0.6M.

Alternative 4 – Building new HVDS:
It is also possible to build a new HVDS for the Forest Lea area which will add 18 MW of load at a capital cost of $12M. This option will provide a higher capacity, which is not required at this moment, even under consideration of a high growth scenario.

Recommendation:
The need of station capacity at Forest Lea DS is current, but the expected load growth is very low. The load at this station is only expected to grow to slightly over 1 MW in the long-term. Hence, load transfer to Craig TS is considered as the most appropriate as well as cost effective alternative. TWG recommends and agrees to transfer 2 MW load to Craig DS. The expected completion date for this load transfer is 2026.

7.1.3 Petawawa DS – 115kV

Petawawa DS supplies the town of Petawawa and a large customer. The majority of the load i.e., 80% of the total load, is consumed by this large customer. The station is radially supplied by D6 and is located at the end of the circuit, right after Craig DS. It has two 115/13.4 kV Step down 7.5/10/13 MVA (T1/T2) transformers with a summer LTR of about 16 MW and winter LTR of 20 MW.

As per the IRRP Load Forecast the station reaches its summer LTR in 2030 and hence recommended to build a new HVDS transformer station at Petawawa with in-service date of 2027. During the RIP phase it was observed that the load increased abnormally in June 2020 due to generator refurbishment work at the customer's facility in Petawawa DS and resulted in the net load increase by 3 MW at the station. This work was completed in July 2020. As the load displacement generation is permanently operating, the net load at the station returned to its normal value resulting in a net load of approximately 9.8 MW during the year 2021. Hence, the Load Forecast for

Petawawa DS was updated in the RIP, and the 2022 load was determined by considering the actual load in 2021. The updated load forecast yields a lower Net Load at the end of study period.

Recommendation:
Since the elevated load forecast was updated for actual value, the load at Petawawa DS remains below the summer/winter (16.3/20.2 MW) LTRs for the long-term forecast. However, during the IRRP phase the customers in this area have indicated some possible future expansion and heating load conversion under Canadian Net-Zero Emissions Accountability Act that was considered in a high load growth scenario. Hence, for now it is recommended to defer this need as no additional capacity is required at this station for the short to medium term, but the TWG will continue to monitor the future high load growth scenario and trigger regional planning earlier if and when demand arises at the station.

7.2 Transmission Line Capacity Needs

All line and equipment load shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period 2022-2042 for the 230kV and 115kV Transmission line circuits in the Renfrew region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater this need. Based on the results, no new Transmission line capacity needs were identified in the region during the study period.

7.3 Asset Renewal Needs for Major HV Transmission Equipment

The Asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities;
- Eliminating equipment by transferring all the load to other existing facilities;
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement);
- Replacing equipment with higher ratings and built to current standards.

From Hydro One's perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.
No new major HV Asset Renewal Needs were identified in the region during the study period.

7.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. A study has been performed, considering the net coincident load forecast and the loss of one element over the study period 2022-2042 to cater

this need**.** Based on the results, no new significant system reliability, operating and restoring issues have been identified for this Region.

7.5 Long Term Considerations

7.5.1 Des Joachims sub-system – Supply capacity issue

The Des Joachims sub-system refers to transmission line D6 connected to the Des Joachims TS in the west of Renfrew region and ends at Petawawa DS and Forest Lea DS in the east. During IRRP, two high growth scenarios (i.e., increase in load by 20MW & 40MW) were identified as a part of the engagement process for the Des Joachims sub-system. The LMC of Des Joachims sub-system is approximately 80MW and under high growth scenarios, with one element out and a contingency to a generator at Des Joachims TS, under peak coincident demand and low generation conditions, voltage change violations are identified at the stations connected to the end of D6 circuit.

Alternative 1 - Maintain Status Quo:
The need is identified in the medium to long-term, and both high load growth scenarios have fair amount of uncertainties. Monitor the current load growth in the area and maintain status quo until next regional planning cycle.

Alternative 2 – Capacitor banks:
Installing capacitor banks at either Craig DS, Petawawa DS or Forest Lea DS will improve the LMC by approximately 10 MW and can support the first high growth scenario i.e., a load growth of over 20 MW.

Alternative 2 – Transmission options:
For the more aggressive load growth scenario, i.e., load growth of over 40MW, the support provided by capacitor banks will not be enough and there will be a need to construct new transmission line in the area.

Recommendation:
The need is identified in the mid to long-term, and in light of uncertainties of the load growth in the sub-system. Hence, for now it is recommended that TWG will continue to monitor the future high load growth scenario and if required can proceed with the capacitor upgrade if and when need arises.

8. CONCLUSION AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE RENFREW REGION.

The major infrastructure investments recommended by the Technical Working Group (TWG) in the near, medium and long-term are provided in Table 8-1 below, along with their planned in-service dates and estimates for planning purposes.

Table 8-1 Recommended Plans in Region over the 2022-2042 Study Period

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Cost ($M)
Station capacity needs				
Pembroke TS	Hydro One Dx and ORPC to continue to explore both the new TS and HVDS options and determine most feasible solution	Hydro One Tx	2028	14-30
Forest Lea DS	Transfer 2 MW load to Craig TS	Hydro One Dx	2026	0.05
Petawawa DS	No longer needed as Load Forecast is revised.	Hydro One Dx	-	-
Long-term Supply capacity needs				
Des Joachims sub-system	Monitor load growth in the area and wait for confirmation of investments.	IESO	-	-

Note:
a) The planned in-service dates are tentative and subject to change.
b) Costs are based on planning estimates may exclude the cost for distribution infrastructure (if required)

2	Ottawa River Power Corporation (ORPC)

APPENDIX D. RENFREW REGION - MUNICIPALITIES

Sr. no.	Name of Municipality
1	Town of Arnprior
2	Town of Deep River
3	Town of Laurentian Hills
4	Town of Petawawa and Renfrew
5	Township of Admaston/Bromley
6	Township of Bonnechere Valley
7	Township of Brudenell
8	Township of Lyndoch and Raglan
9	Township of Greater Madawaska
10	Township of Head
11	Township of Clara and Maria Horton
12	Township of Killaloe
13	Township of Hagarty and Richards
14	Township of Laurentian Valley
15	Township of Madawaska Valley
16	Township of McNab/Braeside
17	Township of North Algona Wilberforce and Whitewater Region
18	City of Pembroke

APPENDIX F. LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
GS	Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DER	Distributed Energy Resource
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme
TWG	Technical Working Group

NEEDS ASSESSMENT REPORT

Renfrew

Date: July 13, 2026

Needs Assessment Report

Renfrew

Date: July 13, 2026

Lead Transmitter:

Hydro One Networks Inc.

Prepared by: Renfrew Technical Working Group

Page intentionally left blank.

Disclaimer

This Needs Assessment (NA) Report was prepared for the purpose of identifying potential needs in the Renfrew Region and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the NA phase and b) require further assessment and regional coordination. The results reported in this NA are based on the input and information provided by the Technical Working Group (TWG) for this region at the time. Updates may be made based on the best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION Renfrew Region (the "Region")

LEAD Hydro One Networks Inc. ("HONI")

START DATE: May 15, 2026 **END DATE:** July 13, 2026

The second Regional Planning cycle for the Renfrew Region was completed in July 2023 with the publication of the Regional Infrastructure Plan ("RIP") report (RIP Report).

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. Considering these timelines, the 3rd Regional Planning cycle was triggered in January 2026 for this Region. The planning horizon for this Needs Assessment ("NA") is ten years. A 20-year planning assessment is undertaken in the next phases of regional planning, i.e., IRRP and RIP phases.

The purpose and scope of the NA is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group (TWG) comprises of representatives from Local Distribution Companies ("LDC"), the Independent Electricity System Operator ("IESO"), and Hydro One Transmission. They provide input and relevant information for the region and undertake a technical assessment to identify the electrical infrastructure needs in the region. They collaborate to develop both summer and winter gross and net peak electricity demand forecasts (including input from municipalities), which form the basis for the technical assessment. The following are key considerations of the technical assessment:

a) Current and future station capacity and transmission adequacy.
b) System reliability needs and operational concerns.
c) Major HV transmission equipment requiring replacement with consideration to "right-sizing"; and,
d) Sensitivity analysis to capture uncertainty in the load forecast as well as variability of demand drivers such as electrification.

In this Needs Assessment, TWG has identified the following regional needs and recommendations:

Table 1: Needs that Do Not Require Further Regional Coordination

#	Need Location	Need Description
Station Capacity Needs		
1	Cobden DS	Projected to reach capacity in 2029 under normal growth summer forecast and in 2028 under summer High growth scenario.

Table 2: Needs that Require Further Regional Coordination

#	Need Location	Need Description
Station Capacity Needs		
1	Cobden TS T1/T2	Projected to reach capacity in 2033 under summer High growth scenario.
Transmission Capacity Needs		
2	115 kV D6	Projected to reach capacity in 2031 under summer high growth scenario.
3	115 kV X2Y	Projected to reach capacity limits at the end of study period (2035) during X6 contingency and summer high growth scenario.
System Reliability, Operation and Load restoration Needs		
4	115 kV D6 – Voltage Performance	Voltage issues identified in 2035 for normal summer forecast and in 2031 for High growth summer forecast
5	X2Y Load Restoration	Projected to exceed thermal ratings of X2Y when complete load of Cobden TS needs to be restored under X6 contingency in 2029 under normal growth scenario and 2028 under high growth scenario.

List of LDC(s) to be involved in further regional planning phases:

- Hydro One Distribution
- Ottawa River Power Corporation (ORPC)

List of LDC(s) which are not required to be involved in further regional planning phases:

- None

1. INTRODUCTION

The second cycle of the Regional Planning process for the Renfrew Region was completed in July 2023 with the publication of the Regional Infrastructure Plan ("RIP") Report (RIP Report). The RIP report included a common discussion of all the options and recommended plans for preferred wire infrastructure investments to address the near- and medium-term needs.

This Needs Assessment initiates the third regional planning cycle for the Renfrew Region. The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years. A flow chart of the Regional Planning Process is shown in Figure 1 below.

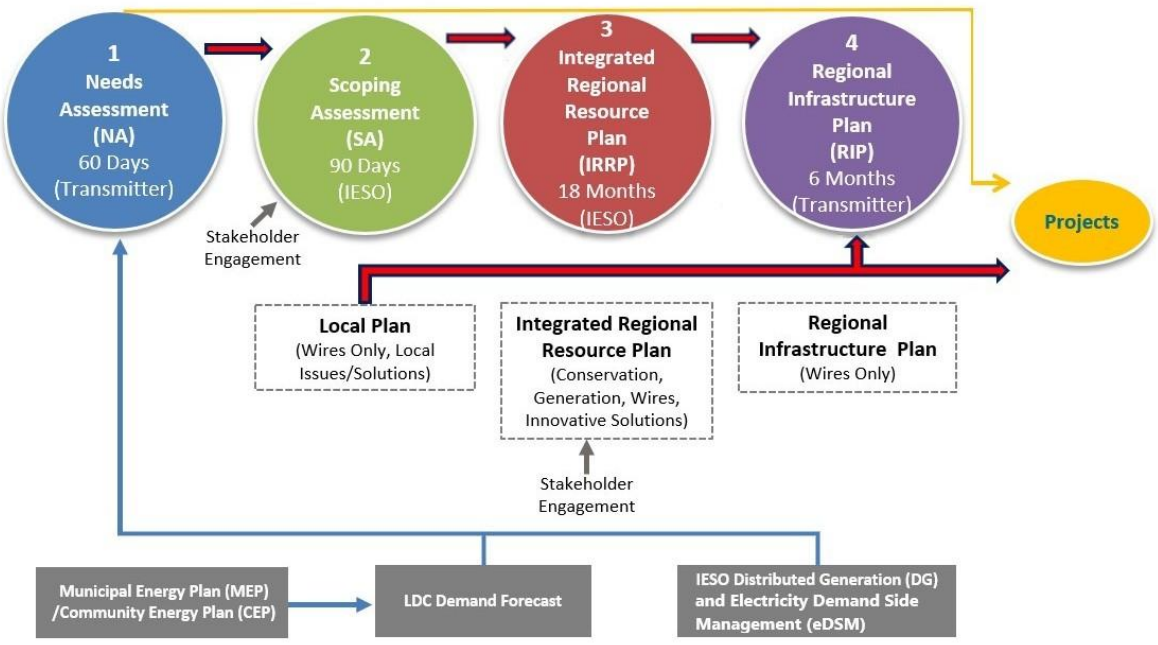

Figure 1: Regional Planning Process

This report was prepared by Renfrew TWG, led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC") and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 3.

Table 3: Renfrew Region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Networks Inc. (Lead Transmitter)
2	Independent Electricity System Operator (IESO)
3	Hydro One Networks Inc. (Hydro One Dx)
4	Ottawa River Power Corporation (ORPC) (embedded to Hydro One Dx)

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. As such, the 3rd Regional Planning cycle was triggered for the Renfrew region.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this NA covers the Renfrew region and includes:

- Review and reaffirm needs/plans identified in the previous cycle RIP (as applicable),
- Identify any new needs resulting from this assessment,
- Recommend which need(s) require further assessment and regional coordination in the next phases of the regional planning cycle to develop a preferred plan; and,
- Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), Local plan (LP) and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is 10 years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The Renfrew region is located in Eastern Ontario with the majority of the load along the Ottawa river. For electrical planning purposes this region includes eighteen municipalities including the towns of Arnprior, Deep River, Laurentian Hills, Petawawa and Renfrew. As well as the townships of Admaston/Bromley, Bonnechere Valley, Brudenell, Lyndoch and Raglan, Greater Madawaska, Head, Clara and Maria, Horton, Killaloe, Hagarty and Richards, Laurentian Valley, Madawaska Valley, McNab/Braeside, North Algona Wilberforce and Whitewater Region; as well as the City of Pembroke. The geographical boundaries of the Renfrew region are shown in Figure 2 below.

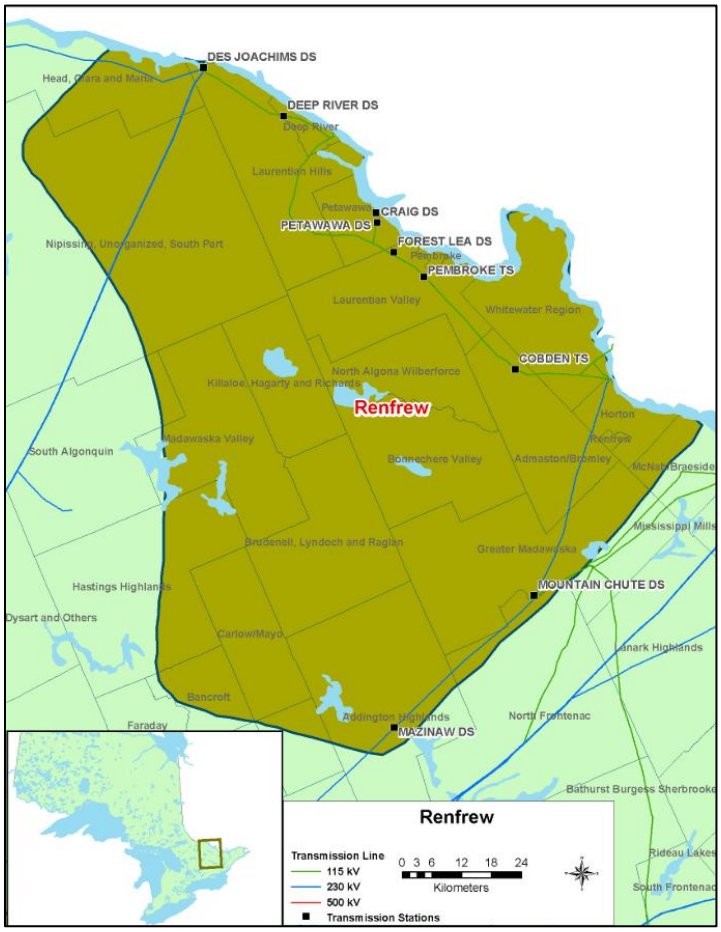

Figure 2: Map of Renfrew Regional Planning Area

The Renfrew region is located in Eastern Ontario, with most of its load concentrated along the Ottawa River. It is bounded by Des Joachims TS to the west, Chenaux TS to the east, and the 230 kV circuit X1P to the south. Electricity supply is provided through one 230 kV circuit (X1P) and three 115 kV radial circuits (D6, X6, and X2Y), with the 115 kV system fed by 230/115 kV autotransformers at Chenaux TS from the east and Des Joachims TS from the west. A normally open 115 kV switch at Pembroke TS separates the eastern and western portions of the region.

The distribution system in the Renfrew region operates at 44 kV and 12.5 kV. The main generation facilities in the area include Chenaux Generation Station (143.7 MW), Mountain Chute Generation Station (170.2 MW), and Des Joachims Generation Station (432.5 MW).

Hydro One Networks Inc. (Distribution) is the main LDC in the area. Other LDCs supplied by electrical facilities in the Renfrew region include Ottawa River Power Corporation and Renfrew Hydro Inc., both are embedded into Hydro One's distribution system. Renfrew Hydro Inc. customers are being fed from Stewartville TS, which is part of the Greater Ottawa Regional Planning. As such, Renfrew Hydro Inc. has not been included as part of this NA.

The existing facilities in the Region are summarized below and depicted in the single line diagram shown in Figure 3.

• Chenaux TS is a major 230 kV station in the region. The station has 143.7MW of hydraulic generation connected to the 230 kV bus. The station connects to the bulk system via a single 230 kV circuit X1P. Two autotransformers step down the voltage to 115 kV to supply two radial circuits X6 and X2Y.

• The 115kV circuits X6 and X2Y from Chenaux TS supply four stations: Pembroke TS, Cobden TS, Cobden DS and Customer Transformer Station (CTS-2).

• Des Joachims TS is the other major 230 kV transformer station in the Region. There are 432.5 MW of hydraulic generation connecting to the 230 kV bus. The station interconnects to the Bulk Electric System (BES) via five 230 kV circuits which are not in the scope of this regional assessment. Two autotransformers (one operates as standby) step down the voltage to 115 kV to supply one radial circuit D6.

• The 115 kV circuit D6 from Des Joachims TS 115 kV bus supplies six stations: Des Joachims Distribution Station (DS), Deep River DS, Craig DS, Forest Lea DS, Petawawa DS, and CTS-1

• Bryson GS from Hydro Quebec can be radially connected to Renfrew region via X2Y, when required.

• The 230 kV single circuit X1P from Dobbin TS to Chenaux TS connects two stations in Renfrew region: Mountain Chute GS (with hydraulic generation of 170.2 MW) and Mazinaw DS.

• Mountain Chute DS, a 115 kV station adjacent to Mountain Chute GS, is supplied by a circuit W3B from outside of the studied region.

The circuits and stations of the area are summarized in Table 4 below:

Table 4: Transmission Station and Circuits in the Renfrew Region

115kV circuits	230kV circuits	Hydro One Transformer Stations	Generation Stations
D6, X6, and X2Y	X1P	Des Joachims TS*, Des Joachims DS, Deep River DS, Chalk Craig DS, Petawawa DS, Forest Lea DS, Pembroke TS, Cobden TS, Cobden DS, Chenaux TS*, Mountain Chute DS, Mazinaw DS, CTS-1, CTS-2	Mountain Chute GS (170.2MW) Des Joachims GS (432.5MW) Chenaux GS (143.7MW)

*Stations with Autotransformers installed

The single line diagram of the Transmission Network of the Renfrew region is shown in Figure 3 below.

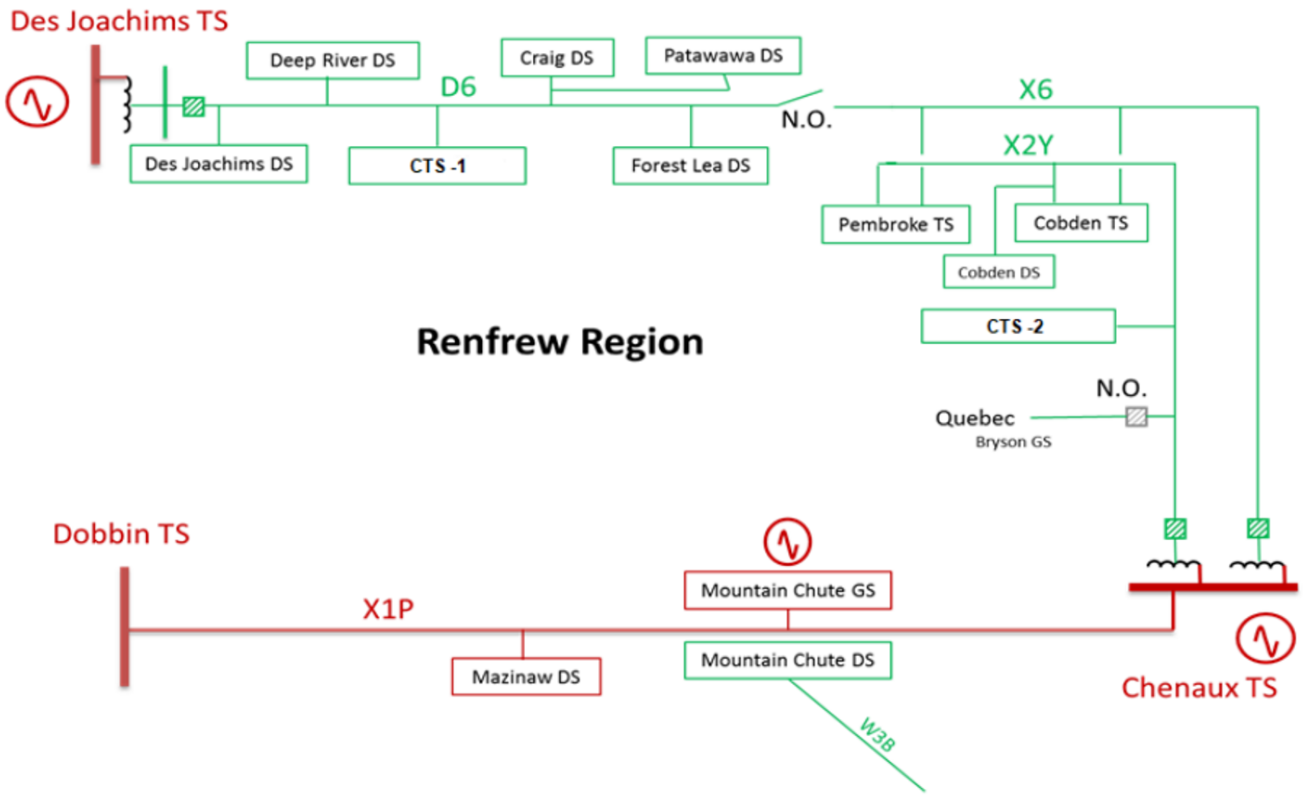

Figure 3: Renfrew Transmission Single Line Diagram

5. INPUTS AND DATA

TWG participants, including representatives from LDCs, IESO, and Hydro One provided information and input for Renfrew region NA. With respect to the load forecast information, the OEB Regional Planning Process Advisory Group (RPPAG) recently published a document called "Load Forecast Guideline for Ontario" in Oct. 2022. The objective of this document is to provide guidance to the TWG in the development of the load forecasts used in the various phases of the regional planning process with a focus on the NA and the IRRP. One of the inputs into the LDC's load forecast that is called for in this guideline is information from Municipal Energy Plans (MEP) and/or Community Energy Plans (CEP). The list of all the Municipalities falling under the geographical boundaries of the region are given in Appendix-E.

The information provided includes the following:

- Renfrew 10-year summer and winter Load Forecasts for all supply stations inclusive of inputs provided by the municipalities.

  However, sensitivity analysis is undertaken which captures uncertainties via different growth scenarios.

- Known capacity and reliability needs, operating issues, and/or major assets requiring replacement/ refurbishment; and

- Planned/foreseen transmission and distribution investments that are relevant to Regional Planning for the Renfrew.

- Captured uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

6. ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in development of this Needs Assessment:

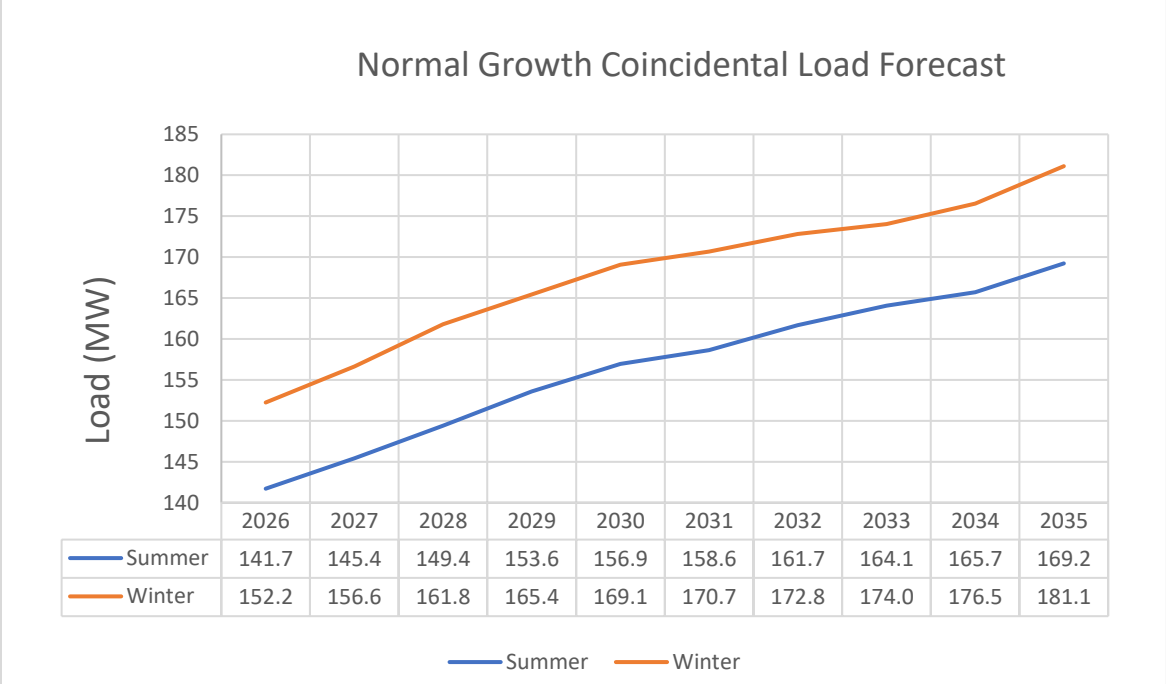
6.1 Technical Assessments and Study Assumptions

The technical assessment of needs was undertaken based on:

- Current and future station capacity and transmission adequacy.
- System reliability and operational considerations.
- Asset renewal for major high voltage transmission equipment requiring replacement with consideration to "right-sizing"; and,
- Load forecast data was requested from industrial customers in the region, and

- This assessment is based on summer and winter peak loads. Three forecasts were developed, i.e. Normal Growth scenario, High and Low Growth scenarios. The High and Low Growth scenarios were developed to conduct a sensitivity analysis to cover unforeseen developments such as fuel switching, Government policies, higher than expected EV charging trend during peak load conditions, etc.

The following other assumptions are made in this report.



- The study period for this Needs Assessment is 2026-2035.
- The Region is winter peaking; however, system performance was assessed under both summer and winter peak load conditions, including studies for summer peak loads.
- System studies and reported results are based on N-1 (single contingency) conditions, meaning the system is assessed to remain within applicable thermal, voltage, and stability limits following the loss of any one credible transmission element, with the system otherwise in the base configuration.
- No import from Quebec from Bryson CGS.
