Connecting power and possibility™

EB-2026-0164

SECTION 1.0 – SPF – INTRODUCTION TO THE SYSTEM PLANS FRAMEWORK

1.0.1 THE SYSTEM PLANS

The sections contained in this Exhibit form Hydro One's five-year Transmission and Distribution system plans for the 2028 to 2032 planning period, and Hydro One Sault Ste. Marie LP's (HOSSM) six-year system plan for the 2027 to 2032 planning period.[1] The Transmission System Plan (TSP), Distribution System Plan (DSP), and General System Plan (GSP) collectively comprise the System Plans.

The System Plans have been prepared in accordance with the OEB's Chapter 2 Filing Requirements for Electricity Distribution Cost of Service Rate Applications (December 16, 2025), Transmission Chapter 2 Filing Requirements for Revenue Requirement Applications (October 30, 2025) and Chapter 5 Filing Requirements for Distribution System Plans for Electricity Distribution Cost of Service Rate Applications (December 16, 2025), as applicable. To assist parties in their review, Hydro One has provided applicable references to the Filing Requirements in the Tables of Concordance which are provided in the Overview sections of each of the System Plans. Furthermore, the System Plans continue to be responsive to the OEB's March 16, 2018, direction to apply for rates for the Transmission and Distribution business segments in a single application.

Although Hydro One Transmission, HOSSM and Hydro One Distribution are distinct and their approved revenue requirements are established separately, many planning and operational elements are common, and are described here in the System Plans Framework (SPF) section. Aspects reflecting the unique transmission and distribution businesses are detailed in the individual plans through the TSP and DSP. Unique aspects of General Plant planning are described in the GSP with costs allocated to Hydro One Transmission and Distribution.

[1] EB-2026-0170, Decision and Order, 14 July 2026: The OEB approved HOSSM's 2027 revenue requirement on an interim basis; 2027 to 2032 is being rebased as part of this Application.

The System Plans are organized into four chapters, as follows, with the chapter content shown in Table 1 and Table 2 below:

[Chapter 1] - The SPF summarizes the overall planning process and drivers for Hydro One and HOSSM, reflecting common context, practices, inputs and considerations reflected in each of the TSP, DSP, and GSP. The contents of Chapter 1 are as follows:

Table 1 - SPF Chapter Sections, Content

Exhibit B1
System Plans Framework
1.0, Introduction to the System Plans Framework
1.1, System Plans Framework Overview
1.2, Coordination Through Regional Planning
1.3, Third-Party Reports
1.4, Productivity Framework
1.5, Performance Measurement and Outcomes
1.6, Customer and Indigenous Communities Engagement
1.7, Investment Planning Process
1.8, Managing Market Cost Pressure

[Chapters 2 - 4] - These chapters provide the TSP, DSP, and GSP, respectively. Each chapter provides an overview of Hydro One's or HOSSM's respective network systems and the various system-specific factors and outcomes that were considered by Hydro One in developing its capital expenditure plans.

Each of Chapters 2 - 4 contain parallel subsections that detail specific asset information and life-cycle optimization strategies, which determine the portfolio of investments required to achieve the specific outcomes in each of the System Plans. These chapters detail Hydro One's and HOSSM's capital expenditure plans, including factors such as asset information, benchmarking, productivity, performance management, and other capital planning drivers and considerations, including customer needs and preferences.

The table below provides a roadmap of related sections across Chapters 2 - 4.

Table 2 - TSP, DSP and GSP Chapters - Sections, Content

Exhibit B2	Exhibit B3	Exhibit B4
Transmission System Plan	**Distribution System Plan**	**General Plant System Plan**
2.0, Transmission System Plan	3.0, Distribution System Plan	4.0, General Plant System Plan
2.1, Overview	3.1, Overview	4.1, Overview
2.2, Asset Information and Lifecycle Strategies	3.2, Asset Information and Lifecycle Strategies	4.2, Asset Information and Lifecycle Strategies
2.3, Benchmarking and Other Studies	3.3, Benchmarking and Other Studies	4.3, Benchmarking and Other Studies
2.4, Transmission System Reliability	3.4, Connecting DER Resources	4.4, [blank]
2.5, Performance Measurement and Outcomes	3.5, Performance Measurement and Outcomes	4.5, [blank]
2.6, Other Capital Planning Factors and Considerations	3.6, Other Capital Planning Factors and Considerations	4.6, Other Capital Planning Factors and Considerations
2.7, Investment Planning Process	3.7, Investment Planning Process	4.7, Investment Planning Process
2.8, Capital Expenditures and Trends	3.8, Capital Expenditures – and Trends	4.8, Capital Expenditures and Trends
2.9, Capital Expenditure Variances	3.9, Capital Expenditure Variances	4.9, Capital Expenditure Variances
2.10, HOSSM Capital System Plan	3.10, Capital Work Execution Strategy	4.10, Capital Work Execution Strategy
2.11, Capital Work Execution Strategy	3.11, Material Investment Summary Documents	4.11, Material Investment Summary Documents
2.12, Material Investment Summary Documents		

The culmination of these factors and inputs are the capital expenditure plans, which are the product of the asset life-cycle optimization strategies identified in TSP Section 2.2, DSP Section 3.2 and GSP Section 4.2, and the investment planning process as described in SPF Section 1.7 (and further described in TSP Section 2.7, DSP Section 3.7 and GSP Section 4.7). Chapters 2 – 4 provide Investment Summary Documents (ISDs) detailing specific planned capital expenditures. The ISDs are informed and guided by the

overarching drivers of the System Plans, including comprehensive customer engagement, benchmark performance and other inputs described in Chapter 1. They are also the product of factors that are specific to the transmission and distribution systems and common assets, as set out in the respective chapters of the System Plans.

The ISDs provide details regarding investments with forecast spending over $4M for Hydro One Transmission and $0.29M for HOSSM in the TSP, and over $1M for Hydro One Distribution in the DSP. The GSP includes ISDs where the Transmission-allocated portion exceeds $4M or Distribution-allocated portion exceeds $1M during any year within the planning period.[2]

[2] Determined pursuant to Section 2.1.5 of the OEB's Transmission Chapter 2 Filing Requirements for Revenue Requirement Applications (October 30, 2025), and Section 2.0.8 of the Chapter 2 Filing Requirements for Electricity Distribution Cost of Service Rate Applications (December 16, 2025).

SECTION 1.1 – SPF – SYSTEM PLANS FRAMEWORK OVERVIEW

1.1.1 INTRODUCTION

The sections contained in this Exhibit form Hydro One's five-year Transmission and Distribution system plans for the 2028 to 2032 planning period, and Hydro One Sault Ste. Marie LP's (HOSSM) six-year system plan for the 2027 to 2032 planning period.[1] The Transmission System Plan (TSP), Distribution System Plan (DSP), and General Plant System Plan (GSP) collectively comprise the System Plans.

The System Plans provide comprehensive and detailed explanations of Hydro One's capital investment plans for its transmission and distribution systems and how these plans are aligned with the principles and expectations articulated by the Ontario Energy Board (OEB) in the Renewed Regulatory Framework (RRF)[2].

To prepare the System Plans, Hydro One engaged its direct transmission and distribution customers. Hydro One has carefully considered and set out its proposed investment plans over the course of the planning period, with a view to ensuring they are appropriate in their focus, scope and pacing, having regard to the needs and preferences of customers, the stewardship of the power system, and the objectives of the Company.

Although Hydro One Transmission, HOSSM and Hydro One Distribution are distinct, many planning and operational elements are common, and are described here in the System Plans Framework (SPF) section (Exhibit B-01-01).

1.1.1.1 FORMAT OF THE SYSTEM PLANS

As outlined in SPF Section 1.0, the System Plans comprise four chapters:

- **Chapter 1** sets out the common SPF, including the overall planning process, customer engagement and regional planning, and other inputs or common

[1] EB-2026-0170, Decision and Order, 14 July 2026: The OEB approved HOSSM's 2027 revenue requirement on an interim basis; 2027 to 2032 is being rebased as part of this Application.
[2] OEB, Report of the Board - Renewed Regulatory Framework for Electricity Distributors: A Performance-Based Approach, October 18, 2012.

processes, the contents of which are set out in Table 1 and summarized in Section 1.1.3 below; and

- **Chapters 2 to 4** present the TSP, DSP and GSP, respectively, addressing system-specific factors, including asset management and life-cycle optimization strategies, capital expenditure plans, and Investment Summary Documents. These plans and investments reflect the processes and inputs described in Chapter 1.

Table 1 - SPF Chapter Sections, Content

1.8, Managing Market Cost Pressure	1.1.3.7

Unless otherwise specified, the asset information contained in the System Plans is as of December 31, 2025.

1.1.1.2 RESPONSIVENESS TO OEB DECISIONS

Exhibit A-02-04 summarizes relevant directions and settlement commitments from past OEB proceedings and explains the steps Hydro One has taken to address them as part of this Application. Each of these aspects is elaborated upon throughout the System Plans.

This Exhibit is organized as follows:

- Section 1.1.2 provides an overview of Hydro One's system
- Section 1.1.3 provides an overview of each of the SPF sections and their common influence on the TSP, DSP and GSP.

1.1.2 HYDRO ONE AND HOSSM'S SYSTEM

Hydro One and HOSSM's transmission systems and Hydro One's distribution system play a vital role in Ontario's electricity system and the customers they serve.

1.1.2.1 THE TRANSMISSION SYSTEM

Hydro One's and HOSSM's transmission system transmits electricity throughout the Province of Ontario between supply points (i.e., generation) and delivery points (i.e., load customers, distribution systems) and is generally comprised of three types of infrastructure: transmission lines, transmission stations and system operations facilities.

Hydro One's transmission system interconnects with transmission systems in five neighboring jurisdictions in Canada and the United States (Manitoba, Quebec, Minnesota, Michigan and New York) and enables electricity transactions with those jurisdictions through interconnections. Therefore, the transmission system is subject to the Independent Electricity System Operator's (IESO) Market Rules, the OEB's Transmission System Code (TSC), and other mandatory industry standards such as those established by the North American Electric Reliability Corporation and Northeast Power Coordinating Council.

Hydro One's and HOSSM's transmission system is deemed to be critical infrastructure for the Province of Ontario because of its scale and service territory.[3] The transmission system has been referred to as the "backbone" of Ontario's electricity system.[4] Given the potential downstream impacts that can result from a transmission system failure, the reliability of Hydro One's and HOSSM's transmission system is essential to the province's economy and service quality of Ontario electricity customers.

Additional discussion regarding the transmission system and service area, planning considerations and proposed investments are provided in the TSP (Exhibit B-02-01).

[3] See Ontario Critical Infrastructure Assurance Program Strategy | ontario.ca
[4] Energy for Generations: Ontario's Integrated Plan to Power the Strongest Economy in the G7, p.83.

1.1.2.2 THE DISTRIBUTION SYSTEM

Hydro One's distribution system plays a critical role in Ontario's electricity system and in the daily lives of the customers and communities it serves. The distribution system delivers electricity from transmission delivery points to end-use customers across urban, suburban, rural, and remote areas of Ontario. The system is comprised of distribution lines, distribution stations, substations, protection and control equipment, and supporting system operations and information technology infrastructure.

Hydro One operates one of the largest and most geographically diverse distribution systems in North America. The size, scope, and configuration of the distribution system are characterized by long feeder lengths, significant rural and radial supply, and exposure to severe weather, which together create unique operational, reliability, and asset management challenges. While the predominantly radial design of the distribution system enables cost-effective service to low-density areas, it also limits redundancy and increases the likelihood that asset failures translate directly into customer interruptions.

The distribution system is subject to a comprehensive regulatory and standards framework, including the OEB's Distribution System Code (DSC), conditions of Hydro One's distribution license and applicable provincial and federal requirements. Distribution planning must also respond to evolving public policy objectives, including electrification, economic growth, integration of distributed energy resources, and resilience. The distribution system is recognized as critical infrastructure for the Province of Ontario, and its safe and reliable operation is essential to customer service quality and public safety.

Additional discussion regarding the distribution system and service area, planning considerations and proposed investments are provided in the DSP (Exhibit B-03-01).

1.1.2.3 THE GENERAL PLANT

Hydro One's General Plant assets provide the shared operational resources and enabling capabilities required to execute its Transmission and Distribution work programs and deliver safe and reliable electricity service across Ontario.

Fleet assets enable field crews to reach work locations, transport personnel, tools and materials, perform construction and maintenance activities, and respond to outages and major storms. Facilities & Real Estate assets provide the work centres, garages, warehouses, administrative spaces, transmission facilities, training campuses, fleet repair shops, helicopter hangars, and control centres required to deploy crews, protect equipment, manage materials, and maintain business continuity. Digital & Technology Solutions provide the information technology, operational technology, data analytics, artificial intelligence, and security capabilities required to operate the grid, manage work programs, support customers, and conduct corporate operations.

General Plant assets are essential to the safe and reliable operation of Hydro One's electricity system because Transmission and Distribution work cannot be delivered without suitable vehicles, equipment, facilities, digital systems, security capabilities, and control-centre infrastructure. System Operations relies on the Integrated System Operations Centre and the Back-up Ontario Grid Control Centre to monitor, control, coordinate, and restore the electricity system on a continuous basis. Operational technology provides real-time visibility and control of the grid, while physical and cybersecurity systems protect critical facilities, operational environments, corporate systems, and information from intrusion, cyber threats, unauthorized access, and other security risks.

Additional discussion regarding General Plant assets, planning considerations and proposed investments are provided in the GSP (Exhibit B-04-01).

1.1.3 OVERVIEW OF THE SPF SECTIONS

This section provides an overview of each of the SPF sections and their common influence on the TSP, DSP and GSP.

1.1.3.1 COORDINATION THROUGH REGIONAL PLANNING (SPF SECTION 1.2)

Regional planning is a foundational input into Hydro One's and HOSSM's investment planning processes and is an OEB-established process developed through amendments to the TSC and DSC and subsequently enhanced through the OEB's regional planning

review process. Hydro One participates as the lead transmitter in many planning regions and works collaboratively with the IESO, local distribution companies, customers, and other transmission asset owners through Technical Working Groups. Hydro One Transmission is the lead transmitter in 20 of Ontario's 21 regional planning regions, while HOSSM serves as the lead transmitter for the East Lake Superior Region.

The regional planning process provides a structured and transparent mechanism for identifying electricity system needs, developing alternatives, evaluating solutions and recommending investments. The process includes Needs Assessments, Scoping Assessments, Integrated Regional Resource Plans, and Regional Infrastructure Plans. Regional planning evaluates both wires and non-wires alternatives, considers load forecasts, asset condition, customer growth, reliability requirements, regional development needs, and broader bulk system planning considerations.

This process aligns with OEB expectations that infrastructure planning be coordinated on a regional basis and integrated with broader electricity system planning. It also aligns with Ontario's Integrated Energy Plan, which emphasizes coordinated long-term planning among electricity sector participants and across energy systems.

Regional planning outputs directly inform Hydro One's investment plans by identifying system access, system service and asset renewal needs that are subsequently incorporated into the capital plans proposed in the TSP and DSP. Further details regarding the regional planning framework, planning cycles, stakeholder roles, regional planning reports and associated investment recommendations are provided in SPF Section 1.2 Additional discussion regarding how regional planning informs the proposed capital plans is provided in TSP Section 2.6, TSP Section 2.12 investment summary documents, TSP Section 2.10 (HOSSM), DSP Section 3.6, DSP Section 3.11 investment summary documents, and the associated regional planning reports attached to SPF Section 1.2.

1.1.3.2 THIRD-PARTY REPORTS (SPF SECTION 1.3)

Hydro One relies on independent third-party studies, benchmarking, and independent expert reviews to inform and validate elements of its investment planning and business

practices. These reports provide external perspectives on customer engagement, asset management practices, project delivery, productivity, supply chain management, vegetation management, compensation benchmarking and procurement practices.

The use of independent experts supports transparency and evidence-based decision-making by providing external review of key planning assumptions, methodologies and business practices. Notable examples include customer engagement studies conducted by Innovative Research Group (IRG), transmission project execution reviews by E Source, benchmarking studies by Guidehouse and First Quartile, vegetation management reviews by CN Utility Consulting, and supply chain practice reviews by Wood Mackenzie.

These independent assessments help demonstrate that Hydro One's planning processes and business practices are consistent with industry best practices and support the reasonableness of the proposed investment plans. The associated reports are provided in TSP Section 2.3, DSP Section 3.3, GSP Section 4.3, and throughout other evidence sections of the Application.

1.1.3.3 PRODUCTIVITY FRAMEWORK (SPF SECTION 1.4)

The Productivity Framework is Hydro One's enterprise-wide process for identifying, implementing, measuring and governing productivity initiatives that reduce costs while maintaining or improving service quality and work outputs. The framework applies across Transmission, Distribution and shared functions and therefore serves as a common input into all System Plans.

The framework includes internal governance, initiative identification, implementation, ongoing tracking, reporting and auditing activities. Productivity savings are incorporated into business planning and help offset cost pressures while maintaining required service levels and performance outcomes. The framework has generated substantial productivity savings and remains a core component of Hydro One's planning and execution processes.

The Productivity Framework was previously reviewed by Concentric Energy Advisors (Concentric), an external independent consultant retained in Hydro One's previous

application. Concentric concluded that Hydro One's productivity approach was effective and robust relative to utility peers. Hydro One will continue to use the same framework to deliver productivity savings as the System Plans are carried out.

1.1.3.4 PERFORMANCE MEASUREMENT AND OUTCOMES (SPF SECTION 1.5)

Hydro One's planning process is directly linked to performance outcomes and OEB regulatory expectations. The Company has aligned its planning, execution and reporting functions with the OEB's RRF outcomes of Customer Focus, Operational Effectiveness, Public Policy Responsiveness and Financial Performance.

Performance outcomes are monitored through a structured governance framework that includes transmission, distribution and HOSSM regulatory scorecards, as well as internal corporate scorecards. Performance measures are monitored to ensure the System Plans produce outcomes valued by customers and the OEB.

The investment plans described in the TSP, DSP and GSP are intended to achieve these performance outcomes while balancing customer preferences, system needs, regulatory obligations and affordability considerations.

Further details on specific performance measures, performance history and targets are provided in TSP Section 2.5, HOSSM scorecards in TSP Section 2.10 Attachment 3, and DSP Section 3.5. For more information on Performance Reporting Governance, see SPF Section 1.5.

1.1.3.5 CUSTOMER, STAKEHOLDER AND INDIGENOUS COMMUNITIES ENGAGEMENT (SPF SECTION 1.6)

Customer engagement is a core input into the development of Hydro One’s and HOSSM’s investment plans and forms an integral component of the SPF. Customer engagement was integrated directly into investment planning and plan refinement. Hydro One retained an independent expert consultant, IRG, to design and execute a two-phase application-specific customer engagement process that first identified customer needs, priorities and outcome preferences and subsequently obtained feedback on draft investment plans and

associated investment trade-offs. More than 100,000 customers participated through focus groups, in-depth interviews and surveys. The engagement activities also included interviews with Indigenous leadership, municipalities and stakeholders.

The engagement process aligns with OEB expectations for customer-informed planning by using an independent expert consultant, broad and representative participation, multiple engagement methodologies and direct integration of customer feedback into investment decision-making. Phase I was undertaken before development of the draft plans and focused on identifying customer priorities, while Phase II was undertaken after preparation of draft investment plans and provided customers with an opportunity to provide feedback on the proposed investment levels, associated investment trade-offs and bill impacts. The results of both phases were provided directly to planners and informed development and finalization of the proposed plans.

Across all customer types, most customers support Hydro One spending at or above the level of investment included in the draft plans. Customers generally demonstrated support for replacing aging assets, improving resilience to severe weather, enabling economic growth and enhancing system visibility and performance. This feedback provided validation that the proposed plans appropriately balance reliability, affordability, customer service and growth objectives.

The engagement survey included dedicated engagement with Indigenous customers, First Nation leadership and the Métis Nation of Ontario. Hydro One also maintains ongoing engagement and partnerships with Indigenous communities through both project-specific consultations and broader Indigenous relations initiatives. These relationships provide an additional source of planning input and help ensure that investments reflect the evolving needs of Indigenous communities across the province.

Hydro One maintains ongoing customer engagement through customer contact centre interactions, customer satisfaction research, large customer account management functions, stakeholder oversight committees, Indigenous engagement programs, government and municipal relations activities and the Hydro One Ombudsman. These

ongoing engagement channels provide Hydro One with insight into customer needs, emerging issues and future investment requirements.

Further information regarding the customer engagement process, ongoing customer engagement, and how customer feedback informed investment planning is provided in SPF Section 1.6, SPF Section 1.7 and in TSP Section 2.7, TSP Section 2.10 (HOSSM), DSP Section 3.7 and GSP Section 4.7.

1.1.3.6 INVESTMENT PLANNING PROCESS (SPF SECTION 1.7)

The Investment Planning Process is the central integrating element of the SPF and the section explains how Hydro One and HOSSM translate customer needs, asset condition information, performance objectives, regional planning requirements, productivity expectations and risk assessments into coordinated investment plans. It describes the common planning methodology used across transmission, distribution and general plant planning. This structured, repeatable and evidence-based planning process is used to develop the proposed investment plans.

The investment planning process is outcome-focused and risk-based. Inputs from customer engagement, system performance analysis, regional planning activities, asset condition assessments, reliability requirements, regulatory obligations and operational experience are evaluated together to identify investment needs and develop candidate investment solutions. The planning process is designed to ensure that investments are aligned with customer priorities while maintaining safe, reliable and cost-effective service.

Common planning assumptions, customer engagement findings, performance objectives and risk management frameworks are applied across the organization. This provides a consistent decision-making framework for both Hydro One and HOSSM and ensures that investments are evaluated using comparable criteria regardless of the business area from which they originate.

The investment planning process is also aligned with OEB expectations for outcome-based and customer-focused planning. The planning framework links investment

decisions to measurable customer and system outcomes, incorporates feedback obtained through the customer engagement process and uses risk-informed prioritization techniques to assess competing investment needs. Further, proposed investments are subject to challenge and refinement throughout the planning process before final plans are established.

SPF Section 1.7 provides the framework and roadmap, while the detailed application of the planning process is presented in TSP Section 2.7, DSP Section 3.7 and GSP Section 4.7.

1.1.3.7 MANAGING MARKET COST PRESSURES (SPF SECTION 1.8)

Market cost pressures have been a significant common input into the Hydro One and HOSSM investment plans. Since 2021, the utility sector has experienced persistent and materially higher inflation that exceeded previous planning assumptions. These trends are supported by Handy-Whitman utility indices and Hydro One's procurement experience for critical utility equipment and materials.

Higher costs for major transmission and distribution equipment and materials have been driven by supply-chain disruptions, constrained manufacturing capacity, commodity price increases, tariffs and growing demand associated with electrification, economic growth, system renewal and grid modernization.

Hydro One actively manages these pressures through procurement and sourcing strategies designed to improve supply resilience and mitigate cost volatility, and pursues productivity and efficiency initiatives to partially offset external cost pressures.

Inflationary pressures, together with increasing volumes of mandatory and customer-driven work, required Hydro One to prioritize available funding during the 2023-2027 period, deferring work where timing flexibility existed. While these deferrals were necessary, the underlying deferred work remains prudent and required. Accordingly, this work has been incorporated into the investment plan.

Project cost estimates included in the System Plans have been updated to reflect current market prices for critical equipment, materials and services which have been impacted by the materially higher inflation that has occurred since 2021.

SECTION 1.2 – SPF – COORDINATION THROUGH REGIONAL PLANNING

1.2.1 INTRODUCTION

Regional infrastructure planning with key stakeholders supports transparency and the cost-effective development of electricity infrastructure in Ontario. This is consistent with one of the guiding principles in the OEB's Renewed Regulatory Framework (RRF), which states that infrastructure planning on a regional basis, between licensed transmitters, the Independent Electricity System Operator (IESO) and local distribution companies (LDCs), is to be undertaken to ensure that regional issues and requirements are integrated into a utility's planning processes.

To enable transparent, coordinated, and cost-effective planning of regional electricity infrastructure, the OEB convened a stakeholder working group (the Planning Process Working Group, or PPWG) in 2013 to prepare a Report to the OEB (the PPWG Report) that set out the details of an appropriate regional planning process. Upon release of the PPWG Report, the OEB endorsed the recommended process and established the regional planning process through amendments to the Transmission System Code (TSC) and Distribution System Code (DSC). In late 2020, the OEB initiated another consultation process to review and update the regional planning process to improve its efficiency and effectiveness (EB-2020-0176). This consultation resulted in a set of recommendations that build upon the foundational 2013 PPWG report and were formally approved by the OEB in April 2022.

As the largest transmitter and distributor in the province, Hydro One plays a key role in the regional planning process. Hydro One Transmission is the lead transmitter in 20 of the 21 regional planning regions and is responsible for leading the development of the Needs Assessments and Regional Infrastructure Plans (RIP) in those regions. Hydro One Distribution, as a LDC is one of the key stakeholders in 20 of the 21 regions that provides input, data and guidance regarding the regional and local distribution needs. One of the 20 regions, East Lake Superior, is led by Hydro One Sault Saint Marie (HOSSM), an affiliate of Hydro One Networks and a co-applicant in the 2028-2032 rate period.

This exhibit provides further details about the regional planning process. In accordance with the TSC and DSC, Hydro One Transmission, HOSSM and Hydro One Distribution, each have distinct roles in the process. As such, this exhibit discusses their respective roles and responsibilities and summarizes Hydro One Transmission's and Hydro One Distribution's capital investment needs that have been identified through the regional planning process in separate sections.

Attachment 1 provides additional context regarding the Ministry of Energy and Mines' Integrated Energy Plan and how provincial energy policy considerations inform Hydro One's regional planning activities.

1.2.2 REGIONAL PLANNING FRAMEWORK

Overview

As described in the *PPWG Report*, planning for the electricity system in Ontario is generally conducted at three levels:

1. Bulk system planning;
2. Regional system planning; and
3. Distribution system planning.

The IESO leads the bulk system planning process in close coordination with transmitters and individual LDCs undertake distribution system planning for their respective systems. While bulk and distribution system planning are being undertaken separately from the regional planning process, there can be an overlap between these processes that may trigger bulk or distribution planning investments to be considered as part of regional planning activities, as further described below.

Regional planning addresses supply and reliability issues at a regional and/or localized level, such as the supply facilities that connect and deliver power to a group of load stations in an area or region. Regional planning generally considers the 115kV and 230kV portions of the power system, that supply various parts of the province but can overlap with bulk system planning and/or distribution system planning at the interface points or

where there may be regional resource options or distribution solutions to address the broader local area for the specific region.

The regional planning process is typically initiated by the transmitter resulting from a planning trigger. Potential triggers may include but are not limited to the transmitter's regularly scheduled Needs Assessment, a Government directive, a significant change to the TSC, or an emergent need brought forward by the transmitter, distributors, customers, or IESO that must be addressed before the next scheduled review. Regional planning is intended to be undertaken for each of the planning regions identified in the PPWG Report on a five-year cycle beginning in 2013; though the process may occur more frequently depending upon the emergence of new needs.

Once the regional planning process is initiated by a planning trigger, the process unfolds through the following phases:

i. Needs Assessment;
ii. Scoping Assessment;
iii. Integrated Regional Resource Plan (IRRP); and
iv. Regional Infrastructure Plan (RIP).

Needs Assessment

The Needs Assessment for a given region, is led by the lead transmitter in that region with participation from nominated subject matter experts (SMEs) from the transmitter, local LDC(s) and the IESO (collectively referred to as the "Technical Working Group (TWG)"[1]). As part of the Needs Assessment, the TWG collects a ten-year outlook of major high voltage equipment replacement candidates based on condition, analyzes and identifies emerging needs in the region by utilizing load forecast (reference, high, and low demand scenarios), CDM and DER penetration forecasts, and assesses alternatives to address the identified needs. The objective of the Needs Assessment is to ensure that the needs over the near to midterm are met in the most economical and efficient manner.

[1] The *Working Group* as described in the PPWG report is equivalent to *Study Team* as referred to by Hydro One and is the current terminology utilized in the RIP reports.

At the end of the Needs Assessment, a decision is made by the TWG as to whether further regional coordination is necessary to address some or all of the regional needs. If no further regional coordination is required, recommendation to implement the preferred option and any resulting investments are planned directly by local LDC(s) (or customers) and the lead transmitter. The TWG can also recommend that a lead transmitter and local LDCs undertake a local planning process for further assessment when needs (a) are local in nature (b) require limited investments in "wires" (i.e. transmission or distribution) solutions, and (c) do not require upstream transmission investments.

Scoping Assessment

If during the Needs Assessment, the TWG identifies that further planning at the regional or sub-regional level is required, the IESO then takes the lead and initiates the Scoping Assessment phase. In this phase, the IESO, in collaboration with the lead transmitter and impacted LDCs, reviews the information collected during the Needs Assessment phase, along with the additional information on potential "non-wires" alternatives or resources and determines the most appropriate regional planning approach. If there is the potential to integrate a mix of different options, such as conservation, generation, distribution or new technologies, the IRRP is recommended. If needs can be met through focusing only on wires, meaning additions or improvements to transmission lines or infrastructure, a RIP led by the transmitter is recommended. A third option includes the local LDC and the transmitter working together to plan necessary local infrastructure investments.

Integrated Regional Resource Plan

If the Scoping Assessment concludes that an IRRP is required, a TWG, comprised of the IESO, lead transmitter, and local LDCs works together to develop a plan that integrates resource options to address the electricity needs of the region. The IRRP process involves identifying, evaluating and integrating potential wires and non-wires solutions at the regional or sub-regional level. The IRRP phase generally assesses "non-wires" resource (i.e., generation and/or conservation and demand management) versus "wires" infrastructure options at a higher level with sufficient details to allow for adequate comparison of options. If during this phase it is determined that "non-wires" resource

options are best suited to meet a need, then those options are further planned by the IESO. However, if the “wires” options are the more appropriate alternative, then those options are further assessed and/or planned by a lead transmitter as part of the RIP process.

Regional Infrastructure Plan

The RIP process is the final phase of the regional planning process and involves review and confirmation of previously identified needs, identification of any new needs that may have emerged since the start of the planning cycle (including transmission asset needs that may influence a solution to address broader regional needs), and development of a “wires” plan to address the identified needs. This phase is led and coordinated by a lead transmitter, and the deliverable from this phase is a comprehensive report setting out a “wires” plan from a regional planning perspective, known as a RIP Report. This report may include transmission and/or distribution investments needed to address the identified regional needs. A transmitter responsible for each region will implement the recommended transmission investments and local LDCs will undertake the recommended distribution investments in their respective service territories. Transmitters and LDCs include the recommended regional plan investments as part of their respective rate filings with the OEB.

Figure 1 below provides an overview of the various phases of the regional planning process described above. The flowchart also illustrates the relationship between the IESO-led IRRP process and Hydro One-led RIP process.

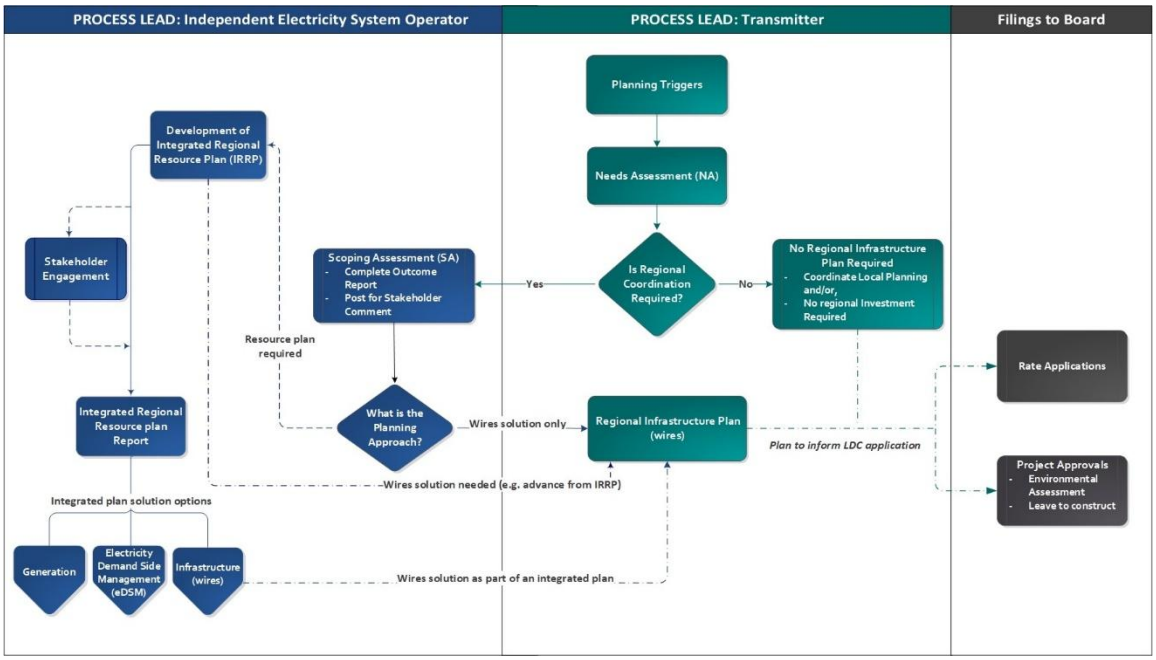

Figure 1: Regional Planning Process

1.2.3 REGIONAL PLANNING REGIONS

For the purpose of regional planning, Ontario has been divided into 21 electrical regions presented in Table 1 and illustrated in Figure 2 below. Hydro One Transmission (including HOSSM) is the lead transmitter in all regions, except North of Moosonee.[2] Hydro One Distribution is an LDC participating in 20 regions of the 21 regions.

[2] Five Nations Energy Inc. is the lead transmitter for this region.

Table 1 - Regional Planning Regions

Burlington to Nanticoke	Greater Bruce/Huron	Sudbury/Algoma
Windsor-Essex	East Lake Superior (Hydro One SSM)	Renfrew
GTA North	GTA East	North/East of Sudbury
Greater Ottawa	Peterborough to Kingston	St. Lawrence
Toronto	South Georgina Bay/Muskoka	Niagara
Kitchener-Waterloo-Cambridge-Guelph	Northwest Ontario	Chatham/Lambton/Sarnia
GTA West	London Area	North of Moosonee[3]

1.2.3.1 STATUS OF REGIONAL PLANNING ACTIVITIES

Regional planning is an inherently iterative process. Pursuant to the TSC, the Needs Assessment is undertaken at least once every five years or more frequently if required by reason of forecasted load or demand growth within a local LDC's licensed service area, requests for connection received by the transmitter or other events that the TWG believes may trigger the need for investment in transmission facilities, distribution facilities or both in a region. With energy transition accelerating, in the current third regional planning cycle to date, regional planning was accelerated for four regions: Greater Ottawa, London Area, Peterborough to Kingston and St Lawrence. Each region underwent a thorough study, resulting in timely recommendations to address the emerging new needs. We anticipate that additional regions in the fourth regional planning cycle will require advancing. The first cycle of regional planning activities was completed between 2013 and 2017, and the second cycle was completed in 2023 for all 21 regions, including the 20 regions for which Hydro One is designated the lead transmitter. Currently, the third cycle of regional planning activities is underway. Table 2 below summarizes the status of second and third cycles for each region, indicating the planning phases that are in progress/in future or have been completed. A letter from the IESO on the overall regional planning status is included in Attachment 3.

Table 2 - Regional Planning Status Summary

Region	Sub-region	2nd Cycle (2017-2023)				3rd Cycle (2022→)			
		NA (1)	**SA** (1)	**IRRP** (1)	**RIP** (1)	**NA** (1)(3)	**SA** (1)(3)	**IRRP** (1)(3)	**RIP** (1)(3)

North of Moosonee									

Notes: (1): NA: Needs Assessment; SA: Scoping Assessment; IRRP: Integrated Regional Resource Plan; RIP: Regional Infrastructure Plan
(2): Note that St. Lawrence 2nd cycle NA was initiated two (2) months over the five (5) year period because of an error in oversight.
(3): All future completion dates are tentative based on Regional Planning Process timeline requirements.
(4):The IESO's recommended delaying the needs assessment for North/East of Sudbury until after the conclusion of the bulk plan. OEB agreed and granted extension to start NA in September 2026.

1.2.3.2 OEB REVIEWS AND PROCESS DEVELOPMENTS

In December 2020, the OEB initiated a consultation process to review the regional planning process that applies to Ontario's electricity sector. The primary purpose of this review was to improve the efficiency and effectiveness of the regional planning process at the time. The review was completed in December 2021 with recommendations to improve the process that were formally approved by the OEB in April 2022. The recommendations resulted in amendments to licenses and codes, which continue to inform regional planning today.

In December 2025, the OEB launched a review of the regional and bulk planning processes (EB-2025-0248) in response to the Ministry of Energy and Mines' Integrated Energy Plan (IEP) Directive. The OEB established a new Regional and Bulk Planning Process Advisory Group (RBPPAG) to assist the OEB in identifying opportunities for enhancing the regional and bulk planning processes. This review was completed in February 2026. The OEB provided an overview of proposed actions resulting from this review in their report back to Ministry on March 31, 2026.

1.2.4 HYDRO ONE TRANSMISSION

1.2.4.1 ROLES AND RESPONSIBILITIES OF HYDRO ONE TRANSMISSION

As the largest transmitter in Ontario, Hydro One Transmission plays a key role and is actively involved in the regional planning process. As the lead transmitter in 20 of the 21 regions, Hydro One Transmission takes the lead in triggering the regional planning cycle with the Needs Assessment and finally developing a wires plan for the region during the RIP phase of the process taking into consideration recommendations made during IRRP. In this role, Hydro One Transmission identifies the information or data required to carry out the necessary assessments; ensures that the appropriate LDCs have been informed of their requirement to participate in the process; ensures that all participants are treated in fair manner; conducts studies and shares findings with the TWG; and completes and publishes Needs Assessment and RIP reports. Where issues overlap with other regions, Hydro One Transmission may provide for inter-regional coordination and advise what LDCs are required to participate in each planning study.

Throughout the Needs Assessment and RIP phases, Hydro One Transmission undertakes extensive engagements and discussions with all stakeholders to identify needs and develop appropriate solutions to address the identified needs. Hydro One Transmission undertakes the following activities:

1. Data gathering: Hydro One Transmission collects information, such as, but not limited to historical load data, municipal communication and their input on electricity demand and emission reduction goals, future load forecast, DER and CDM forecasts, and a list of major equipment warranting replacement based on asset condition assessments. A clear and consistent approach is employed to ensure accurate information is collected. A methodical load forecast data gathering and development approach is used in accordance with OEB's Load Forecast Guideline and in coordination with the IESO and local LDCs taking into consideration CDM, DERs, municipal planning input, demand scenarios, and emerging technologies like electrical vehicles, battery energy storage, etc. A ten-year outlook of asset replacement needs based on asset condition assessment is identified for all major high voltage transmission assets.

   a) Every investment whose condition warrants replacement is considered for "right-sizing" opportunity. Where forecasted demand growth or decline is identified during the regional planning process and where a transmitter is making investments, considerations are made to right-size the transmission equipment, either by removing equipment in the case of demand decline or upgrading equipment in the case of demand growth.

2. Pre-meeting Conference Calls/Webinars: In advance of each phase of the regional planning process, local LDCs and the IESO are notified of upcoming regional planning activities and provided with an overview of the process. Hydro One Transmission also proactively notifies municipalities via annual emails (since 2023) of upcoming regional planning activities so they can begin preparing their input to share/discuss with their respective LDC(s). To facilitate this, Hydro One

provides municipalities with a template they can use to enter their electricity demand and emission reduction plans based on OEB's Municipal Information Guideline. Hydro One Transmission also reaches out to its large transmission-connected customers to obtain and update their electricity load forecasts.

3. Kick-off Meetings/Conference Calls/Webinars: Kick-off meetings with the TWG are organized to initiate each of the phases of the regional planning process and provide information on regional updates, schedules, and high-level deliverables for each phase. Follow-up meetings occur on a regular basis to discuss various planning matters such as assessment methodology, right sizing opportunities for deteriorated assets that require replacement, customer needs, and regional needs and timing before recommending a preferred plan.

4. Feedback from TWG: Hydro One Transmission regularly communicates with LDCs and IESO to seek feedback on prioritization and scheduling of regional planning for the regions, as well as seeking suggestions for enhancements in the upcoming cycles of regional planning.

Throughout the Scope Assessment and IRRP phases, the IESO also engages with local and regional communities to gather input that informs planning activities and supports the development of the IRRP. Hydro One Transmission, along with the other TWG members, also seeks further input as needed from stakeholders such as, local municipalities, Indigenous communities, business groups, citizen groups, consumers and environmental and conservation groups.

Outside of regional planning activities, Hydro One Transmission has the following requirements that pertain to the process:

- Submit an annual report to the OEB describing the status of the regional planning activities for all regions where it is a lead transmitter. The last report, 2025 Status Report, was filed on October 31, 2025.[4]
- Pursuant to section 2.4.3 of the OEB's Chapter 2 Filing Requirements for Electricity Transmission Applications, where regional planning is underway, but a RIP has not yet been completed for the applicable region, Hydro One Transmission is required to submit a letter from the IESO, identifying the status of the regional planning process, and the potential impacts on the Hydro One Transmission's investment plans. The letter is found at Attachment 3.
- To provide Planning Status Letters to all participating LDCs confirming the status of regional planning for a region, suitable for the purpose of supporting a rate application. In its 2025 Status Report, Hydro One Transmission identifies the LDCs to whom it has provided Planning Status Letters since November 2024. In addition to those LDCs, Hydro One Transmission has recently provided a Planning Status Letter to Milton Hydro, Enova Power Corporation, London Hydro, Canadian Niagara Power Inc. and Hydro One Distribution.

1.2.4.2 HYDRO ONE PROCESS IMPROVEMENTS

Over the three regional planning cycles to date, Hydro One has identified several lessons and opportunities for improvement related to the regional planning process and its deliverables. These improvements include recommendations from the OEB's Regional Planning Process Advisory Group (RPPAG), internal process and regional planning report updates, and feedback from regional TWG members. Hydro One has proactively implemented these improvements over the last three regional planning cycles which have led to a more effective and efficient process along with its deliverables.

Following the completion of the first cycle of regional planning activities, Hydro One Transmission undertook the initiative to enhance the regional planning process and to

[4] 2025 Regional Planning Process Annual Status Report to the Ontario Energy Board, October 31, 2025, https://www.oeb.ca/sites/default/files/HONI_OEB_RP_STATUS_REPORT_20251031.pdf.

identify areas for improvement. Hydro One Transmission sought feedback from various stakeholders and shared its own lessons learned with the IESO and OEB. Some of the key lessons learned during the first cycle included improving overall stakeholder engagement and data input with respect to asset conditions. Those improvements are further described below.

1.2.4.3 MUNICIPAL ENGAGEMENT FOR REGIONAL PLANNING

Hydro One created a new template that can be used by municipal planners to provide input to LDCs to inform the LDC's demand forecast. This template is aligned with OEB RPPAG's Municipal Information Guideline, "Improving the Electricity Planning Process in Ontario: Enhanced Coordination between Municipalities and Entities in the Electricity Sector." This template is intended to streamline the information exchange between LDCs and municipalities as it provides the format and specificity of the information required by municipalities. Following the distribution of this template to municipalities, and direct engagement with the Association of Municipalities Ontario, we observed a more positive engagement and a greater number of municipalities are now engaged and have begun completing and forwarding it to their respective LDCs. This marks another proactive measure by Hydro One to strengthen coordination with municipalities, offer support and improve load forecasting to help ensure their electricity and/or emission reduction plans are considered.

In addition, Hydro One has met with various municipalities and LDCs to support engagement and discuss any needs brought forward, including through attendance at the Association of Municipalities Ontario (AMO) 2025 Annual Conference, one-on-one meetings, and email outreach.

1.2.4.4 NATURAL GAS COORDINATION

Hydro One continues discussions with Enbridge Gas Inc. on how the two entities can further enhance coordination between Natural Gas and Electricity Regional Planning. Hydro One has developed a draft template to coordinate input from municipalities on gas and electricity needs. This is being further discussed as part of the ongoing OEB consultation on Gas-Electric Co-ordination and Information Sharing (EB-2025-0227).

1.2.4.5 EXPEDITING REGIONAL PLANNING PROCESS

Hydro One has consistently focused on improving efficiency in the regional planning process and enhancing responsiveness to benefit local priorities and broader system

requirements as the grid transformation accelerates. For example, although the Needs Assessment must be initiated every five years, emerging demands – such as sudden large connection requests – have necessitated earlier assessments in some regions. In the current third regional planning cycle to date, regional planning was accelerated for four regions: Greater Ottawa, London Area, Peterborough to Kingston and St Lawrence. Each region underwent a thorough study, resulting in timely recommendations to address the emerging new needs. We anticipate that additional regions in the fourth regional planning cycle will require advancing. In addition, Hydro One has initiated consultation and has been working proactively with the IESO and in parallel with the Regional Planning process, to evaluate system architecture, address and mitigate increased short circuit levels in some areas such as GTA East, Peterborough to Kingston, GTA West, Burlington to Nanticoke, Toronto, etc. to enable generation procurement.

1.2.4.6 STAKEHOLDER ENGAGEMENT

Hydro One Transmission has implemented an engagement phase prior to initiating the Needs Assessment and RIP processes by incorporating one-on-one pre-Regional Planning meetings with key stakeholders such as local LDCs to better understand their emerging needs and collect relevant information. These meetings have resulted in improved collaboration and efficiency during regional planning meetings with the Study Team members by having a head start in identifying emerging needs, discussing LDC-specific issues and concerns that may have an impact on regional planning.

1.2.4.7 TEN-YEAR OUTLOOK ON ASSET REPLACEMENT NEEDS

Managing aging infrastructure based on asset condition to determine its replacement or refurbishment is the primary accountability of asset owners for safe, secure and reliable operation. Each of the major assets, such as transformers, breakers and conductors require special technical expertise about the equipment and to develop a strategy for their replacement where warranted. Since the end of the first regional planning cycle, Hydro One Transmission enhanced its processes for data collection, analysis and supplying relevant information as part of regional planning studies. Given that sometimes the replacement of major equipment may also provide a broader planning opportunity, Hydro

One Transmission developed an internal process to collect and provide best available information for major high voltage transmission equipment for assessment and consideration during the regional planning process to ensure various planning alternatives are considered. For each of the regions, Hydro One Transmission provides a list of major equipment that is planned for replacement/refurbishment based on asset condition. Once it is determined that replacing the deteriorated equipment is the most appropriate approach, the TWG assesses, discusses planning alternatives and recommends the preferred approach, which may include:

- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement);
- Replacing equipment with similar equipment of higher / lower ratings i.e. right sizing opportunity and built to current standards;
- Replacing equipment with lower ratings and built to current standards by transferring some load to other existing facilities;
- Eliminating equipment by transferring all of the load to other existing facilities.

In 2022, the RPPAG formalized the process and recommended that going forward all transmission asset owners (TAO) provide a ten-year outlook related to their major transmission assets requiring replacement during the Needs Assessment phase. Hydro One successfully implemented this process and is documented in both the Needs Assessment and RIP reports for each region, thereby enhancing the quality of the planning deliverables.

1.2.4.8 SUMMARY OF HYDRO ONE TRANSMISSION NEEDS AND ASSOCIATED INVESTMENTS

This section provides further details regarding capital investment recommendations scheduled for each region and sub-region over the 2028 to 2032 period addressed in this Exhibit. While emerging system or customer needs may accelerate additions to the current regional plans, this Application includes transmission investments arising from regional planning recommendations. Additional long-term capital planning information filed in response to Hydro One's settlement commitment is provided in Attachment 2. The

investments arising from the recommendations of the TWG are summarized below by region, with further details provided in TSP Section 2.12 and in the corresponding Needs Assessment, IRRP and RIP reports included as attachments to this section at Attachments 4-46.

Burlington to Nanticoke

The Burlington to Nanticoke region is comprised of four sub-regions: Brant, Bronte, Greater Hamilton, and Caledonia-Norfolk. This region encompasses the municipalities of Burlington, Hamilton, Oakville, Brantford, and the Counties of Brant, Haldimand, and Norfolk. The participants in the region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Alectra Utilities Corporation
- Burlington Hydro Inc.
- Grand Bridge Energy Inc.
- Hydro One Networks Inc. (Distribution)
- Oakville Hydro Electricity Distribution Inc.

The third regional planning cycle for this region was concluded with the publication of the RIP Report in June 2025. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found in Attachment 4 and 5. However, the IESO will issue an IRRP addendum for the Hamilton sub-region and the Bronte TS supply area. The RIP, incorporating the final recommendations based on the TWG's assessment of the additional alternatives, will be re-released accordingly. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Beach TS: Auto-Transformer (T1/T7/T8) Replacement and DESN Switchgear (T-SR-01);
- Burlington TS: T12 Autotransformer and LV Switchgear (T-SR-01);
- Birmingham TS: MV Metalclad Switchgear Refurbishment (T-SR-03);
- Lake TS– T2, T3 and T4 transformers replacement. (T-SR-03)
- Nebo TS– T3 and T4 transformer replacement. (T-SR-03)
- Beach TS – T5 and T6 transformers replacement. (T-SR-03)
- Caledonia TS – T2 transformer replacement (T-SR-03)
- Gage TS – T8 and T9 transformer replacement. (T-SR-03)
- Jarvis TS – T3 and T4 transformers replacement. (T-SR-03)
- Dundas Area Capacity – Two new transformation facilities near Dundas TS. (T-SA-11)
- Brant Area Capacity – Two new transformation facilities near Brant TS. (T-SA-11)

Greater Ottawa

The Greater Ottawa Region is comprised of two sub-regions: Ottawa Area and Outer Ottawa. This region encompasses the municipalities bordering the Ottawa River from Stewartville in the West to Hawkesbury in the East and North of Highway 43. The participants in the region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Hydro Hawkesbury Inc.
- Hydro One Networks Inc. (Distribution)
- Hydro Ottawa Limited
- Ottawa River Power Corporation
- Hydro 2000 Inc.
- Renfrew Hydro Inc.

The third regional planning cycle for this region was concluded with the publication of the RIP Report in February 2026. The RIP is a comprehensive, region-wide detailed wires

plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found at Attachment 6 and 7. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Albion TS – T1 and T2 transformer replacement. (T-SR-03)
- Merivale TS – T22 and T23 transformer replacement and six 230 kV and four 115 kV breaker replacement. (T-SR-01)
- Nepean TS – T3 and T4 transformer replacement. (T-SR-03)
- 115 kV S7M – 6.5 km line refurbishment. (T-SR-13)
- South March TS – T1 and T2 transformer replacement. (T-SR-03)
- Lisgar TS – T2 transformer replacement (T-SR-03)
- Riverdale TS – Breaker replacement (T-SR-03)
- Build new 230 kV circuit Merivale TS X Greenbank MTS (T-SA-11)
- Merivale TS Supply Reliability – Split breaker position M1R and L2M (T-SS-12)
- Orleans TS – Provide second 230kV supply (T-SS-12)
- Kanata Area Transmission Reinforcement (T-SS-12)

GTA East

The GTA East Region is comprised of two sub-regions: Pickering-Ajax-Whitby and Oshawa-Clarington. This region encompasses the municipalities of Pickering, Ajax, Whitby, Oshawa, and parts of Clarington and other parts of Durham Region. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Hydro One Networks Inc. (Distribution)
- Oshawa PUC Networks Inc.
- Elexicon Energy Inc.

The second cycle RIP for this region was completed in February 2020 and is found at Attachment 8. The second cycle Needs Assessment suggested that no further regional coordination was required and so the TWG proceeded directly to the RIP phase. The third cycle Needs Assessment was completed in December 2024 (Attachment 9) and has identified needs that require further regional coordination. The third cycle IRRP is currently underway with a tentative completion date of November 2026. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Cherrywood TS – ABCB Breaker Replacement (T-SR-02).
- Wilson TS – T3 and T4 Transformer replacement. (T-SR-03)
- Whitby TS Station Capacity - Connect new Whitby MTS (T-SA-11)

GTA North

The GTA North Region is comprised of two sub-regions: York and Western. This region encompasses the Regional Municipality of York, and includes parts of the Cities of Toronto, Brampton, and Mississauga. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Alectra Utilities Corporation
- Hydro One Networks Inc. (Distribution)
- Newmarket-Tay Power Distribution Ltd.
- Toronto Hydro-Electric System Limited (THESL)

The third regional planning cycle for this region was concluded with the publication of the RIP Report in May 2026. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found at Attachment 10 and 11. The following material transmission investments have capital expenditures during the 2028–2032 rate

period; however, the in-service dates for these projects may extend beyond the rate period:

- Woodbridge TS – T5 transformer Replacement. (T-SR-03)
- Build new Markham TS #5 (T-SA-18)
- Build new Northern York TS 1 and 2 (T-SA-09)
- New DESN in Northern York Region (T-SA-09)
- New DESN #2 in Northern York Region (T-SA-11)
- Connect Vaughan MTS#5 (T-SA-11)
- Buttonville T3/T4 and component replacement (T-SR-03)
- Connect new Markham MTS#5 (T-SA-11)
- Buttonville Tap-Reconduct Parkway to Markham MTS#4 (T-SS-12)

GTA West

The GTA West Region is comprised of two sub-regions: Northwestern and Southern. This region encompasses the Regional Municipalities of Halton and Peel, and comprises the municipalities of Brampton, South Caledon, Halton Hills, Mississauga, Milton, Oakville, and parts of Burlington. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Alectra Utilities Corporation
- Burlington Hydro Inc.
- Halton Hills Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- Milton Hydro Distribution Inc.
- Oakville Hydro Electricity Distribution Inc.

The second regional planning cycle for this region was concluded with the publication of the RIP Report in February 2022. The RIP is a comprehensive, region wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The

IRRP and RIP reports for this region are found at Attachment 12 and 13. The third cycle Needs Assessment was completed in August 2024 (Attachment 14) and has identified needs that require further regional coordination. The third cycle IRRP is currently underway with a tentative completion date of November 2026. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Bramalea TS – T3/T4 Transformer and Component Replacement (T-SR-03);
- Reconductor 230kV H29/H30 Transmission Line. (T-SA-08)
- Halton TS New DESN - Build new DESN (T-SA-03)
- Palermo TS - T3/T4 transformer replacement (T-SR-03)
- Pleasant TS – T5 and T6 transformer replacement (T-SR-03)
- Construct new 230kV double circuit from Hurontairo SS to Meadowvale TS (T-SS-12)
- Hurontario SS Reconfiguration (T-SS-12)

Kitchener-Waterloo-Cambridge-Guelph (KWCG)

The KWCG Region includes the municipalities of Kitchener, Waterloo, Cambridge and Guelph, as well as portions of Perth and Wellington counties and associated townships in the area. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Centre Wellington Hydro Ltd.
- Alectra Utilities Corporation
- Halton Hills Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- Milton Hydro Distribution Inc.
- Wellington North Power Inc.
- Enova Power Corporation
- Grandbridge Energy

The second regional planning cycle for this region concluded with the publication of the RIP Report in December 2021. The RIP is a comprehensive, region wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The RIP report for this region is found at Attachment 15. The third cycle Needs Assessment was completed in April 2024 (Attachment 16) and has identified needs that require further regional coordination. The third cycle IRRP was also completed in July 2026 (Attachment 17), and the RIP is currently underway with a tentative completion date of February 2027. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Campbell TS: PCT and Component Replacement; (T-SR-03)
- Cedar TS: Transformer (T7/T8) Replacement; (T-SR-03)
- D6V/D7V - Upgrade circuits out of Detweiler TS (T-SS-12)
- Wellington TS: Build new 500kV/230kV Station (T-SS-12)
- 115kV Upgrades (B5/6C, D7/9F, F11/12C) (T-SS-12)

Toronto

The Toronto Region is comprised of two sub-regions: Central Downtown and Northern. This region comprises the area within the municipal boundary of the City of Toronto. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- IESO
- Alectra Utilities Corporation
- Hydro One Networks Inc. (Distribution)
- Toronto Hydro-Electric System Limited (THESL)
- Elexicon Energy Inc.

The third regional planning cycle for this region was concluded with the publication of the RIP Report in May 2026. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also

incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found at Attachment 18 and 19. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Bermondsey TS – Transformer (T3/T4) Replacement (T-SR-03)
- Leslie TS – Transformer (T1) Replacement; (T-SR-03)
- 115kV H1L/H3L/H6LC/H8LC Transmission Lines – Refurbish line sections from Leaside Junction to Bloor St. Junction; (T-SR-13)
- HV UG Cable - Replace H1L/H3L & H2JK (T-SR-16)
- 115kV L9C/L12C Transmission Lines – Refurbish line sections from Leaside TS to Balfour Junction (T-SR-13)
- Strachan TS – T13, T14 and T15 transformer replacement. (T-SR-03)
- Duplex TS – T1, T2, T3 and T4 transformer replacement. (T-SR-03)
- Basin TS – T3 and T5 transformer replacement. (T-SR-03)
- Fairchild TS – T1, T3 and T4 transformer replacement. (T-SR-03)
- Bermondsey TS – T3 and t4 transformer replacement. (T-SR-03)
- Manby TS – T7, T9 & T12 transformer (T-SR-01) and T13 & T14 auto-transformer replacement (T-SR-03).
- Richview TS to Manby TS 230 kV Corridor Reinforcement: Replace existing idle 115 kV double circuit line with new 230 kV double circuit line between Richview TS and Manby TS. (T-SS-06)
- Manby X Riverside supply capacity - Increase transmission capacity by upgrading circuits from Manby TS to Riverside TS (T-SS-12)

Northwest Ontario

The Northwest Ontario Region is comprised of several sub-regions: North of Dryden, Greenstone-Marathon, City of Thunder Bay, and West of Thunder Bay. This region encompasses a large geographic area, stretching from the town of Marathon to the western and northern borders of the province and consists of the districts of Kenora, Rainy River, and Thunder Bay, which is roughly the area north of Lake Superior stretching from

the Wawa area in the east and the Manitoba border in the west. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Atikokan Hydro Inc.
- Fort Frances Power Corporation
- Hydro One Networks Inc. (Distribution)
- Synergy North
- Sioux Lookout Hydro Inc.
- Wataynikaneyap Power LP
- NextBridge Infrastructure LP

The third regional planning cycle for this region was concluded with the publication of the RIP Report in August 2023. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found at Attachment 20 and 21. An addendum to the IRRP was also published in August 2025 for North of Dryden Sub-Region (Attachment 22). The third cycle Needs Assessment was completed in September 2025 (Attachment 23) and has identified needs that require further regional coordination. The third cycle IRRP is currently underway with a tentative completion date of April 2027. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Wawa TS – T1 and T2 autotransformers replacement. (T-SR-01)
- Marathon TS – 230 kV,115 kV breakers and associated equipment replacement. (T-SR-01)
- Lakehead TS – 230 kV,115 kV breakers and associated equipment replacement. (T-SR-01)
- Lakehead TS – Condenser C8 will be replaced with a STATCOM. (T-SR-01)

- Fort Frances TS – 230 kV breakers and associated equipment's replacement. (T-SR-01)
- Kenora TS –T1 transformer replacement. (T-SR-01)
- North of Dryden Transmission Reinforcement or "Red Lake Transmission Project" – stations portion (T-SS-12)

Windsor-Essex

The Windsor-Essex Region is in the southernmost part of Ontario, extending from Chatham southwest to Windsor. This region encompasses the City of Windsor, the Municipality of Leamington, the Town of Amherstberg, the Town of Essex, the Town of Kingsville, the Town of Lakeshore, the Town of LaSalle, the Town of Tecumseh, and the Township of Pelee, as well as the western portion of the Municipality of Chatham-Kent. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- E.L.K. Energy Inc.
- Entegrus Powerlines Inc. (Chatham-Kent)
- EnWin Utilities Ltd.
- Essex Powerlines Corporation
- Hydro One Networks Inc. (Distribution)

The third regional planning cycle for this region was concluded with the publication of the RIP Report in October 2025. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found at Attachment 24 and 25. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Lauzon TS – T7 and T8 transformer and Component Replacement (T-SR-03)
- Keith TS – Phase Angle Regulator PSR5 replacement. (T-SR-01)
- West Essex and Windsor sub-system supply capacity: Construction of new 22 km double circuit 230 kV from Lakeshore TS to supply the new Leamington DESN 5 and 6. (T-SA-10)
- Coatsworth Area supply capacity: Construction of new 230 kV double-circuit transmission line that taps the Chatham-by-Lakeshore circuits. (T-SA-11)
- Coatsworth Area Greenhouse Supply Station: Construction of new Coatsworth Area 75/125 MVA 230/27.6 -27.6 kV DESN1. (T-SA-11)
- Windsor Lakeshore Transmission Line Project – Station portion (T-SS-12)

London Area

The London Area Region is comprised of five sub-regions: Greater London, Aylmer-Tillsonburg, Strathroy, Woodstock, and St. Thomas. This region encompasses the Cities of Woodstock, London and St. Thomas as well as the Counties of Middlesex, Elgin, and Oxford. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Entegrus Powerlines Inc.
- ERTH Power Inc.
- Hydro One Networks Inc. (Distribution)
- London Hydro Inc.
- Tillsonburg Hydro Inc.

The second cycle RIP for this region was issued in August 2022 and is found at Attachment 26. The Needs Assessment suggested that no further regional coordination was required and the TWG proceeded directly to the RIP phase. The third cycle Needs Assessment was completed in November 2024 (Attachment 27) and has identified needs that require further regional coordination. The third cycle IRRP is currently underway with a tentative completion date of November 2026. The following material transmission

investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Buchanan TS – T2, T3 transformer and Component Replacement (T-SR-01);
- Clarke TS: T3 and T4 transformer replacement (T-SR-03);
- Talbot TS – T3 and T4 transformer replacement (T-SR-03)

Peterborough to Kingston

The Peterborough to Kingston Region includes the area roughly bordered geographically by the municipality of Clarington on the West, North Frontenac County on the North, Frontenac County on the East, and Lake Ontario on the South. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Hydro One Networks Inc. (Distribution)
- Kingston Hydro Corporation
- Peterborough Distribution Inc. (Recently acquired by Hydro One Distribution)
- Elexicon Energy Inc.
- Lakefront Utilities Inc.
- Eastern Ontario Power Inc.

The second regional planning cycle for this region was concluded with the publication of the RIP Report in August 2022. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP report for this region is found at Attachment 28 and 29. The third cycle Needs Assessment was completed in December 2024 (Attachment 30) and has identified needs that require further regional coordination. The third cycle IRRP is currently underway with a tentative completion date of November 2026. Additionally, IESO published Gatineau Corridor EOL study in December 2022, which recommended building a new 230kV double circuit line from Clarington TS to Dobbin TS (attachment 31). The following material transmission investments have capital expenditures during the 2028–

2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Port Hope TS – T3 and T4Transformer Replacement (T-SR-03);
- Dobbin TS – T1/T2 autotransformer replacement and T5 decommissioning(T-SR-03)
- Cataraqui TS – T1 and T2 autotransformer replacement(T-SR-01)

South Georgian Bay/Muskoka

The South Georgian Bay/Muskoka Region is comprised of two sub-regions: Barrie/Innisfil and Parry Sound/Muskoka. This region is the area roughly bordered by West Nippising on the North-West, the Algonquin Provincial Park on the Northeast, Scugog on the South, Erin on the South-West, and Grey Highlands on the West. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Alectra Utilities Corporation
- Hydro One Networks Inc. (Distribution)
- InnPower Corporation
- Orangeville Hydro Ltd.
- Elexicon Energy Inc.
- Lakeland Power
- EPCOR Electricity Distribution Ontario Inc.
- Newmarket-Tay Power Distribution Ltd.
- Wasaga Distribution Inc.

The second regional planning cycle for this region was concluded with the publication of the RIP Report in December 2022. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found at Attachment 32 and 33. The third cycle Needs Assessment was completed in August 2025 (Attachment 34) and has identified

needs that require further regional coordination. The third cycle IRRP is currently underway with a tentative completion date of June 2027. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Wallace TS – T3/T4 transformers replacement (T-SR-03)
- Midhurst TS – T4 transformer replacement (T-SR-03)
- Waubaushene TS – T5 and T6 transformer replacement (T-SR-03)
- Sections of E8V/E9V circuits line refurbishment (T-SR-13)
- Barrie TS station capacity – Extend E28B/E29B circuits to connect new 230/27.6kV DESN Innpower MTS. (T-SA-11)

Sudbury/Algoma

The Sudbury/Algoma Region includes the Greater Sudbury Area, Manitoulin Island, and Townships of Verner, Warren, Elliot Lake, Blind River, and Walden. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Greater Sudbury Hydro Inc.
- North Bay Hydro
- Hydro One Networks Inc. (Distribution)

The second cycle RIP for this region was issued in December 2020 and is found at Attachment 35. The Needs Assessment suggested that no further regional coordination was required and so the TWG proceeded directly to the RIP phase. The third cycle Needs Assessment was completed in October 2025 (Attachment 36) and has identified needs that require further regional coordination. The third cycle IRRP is currently underway with a tentative completion date of August 2027. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Martindale TS: T25 & T26 Transformer Replacement (T-SR-03);
- Clarabelle TS: T1 & T2 Transformer Replacement (T-SR-03);

Chatham/Lambton/Sarnia

The Chatham-Lambton-Sarnia Region includes the municipalities of Lambton Shores and Chatham-Kent, as well as associated townships in the area. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Bluewater Power Distribution Corporation
- Entegrus Powerlines Inc. (Chatham-Kent)
- Hydro One Networks Inc. (Distribution)

The second cycle RIP for this region was issued in August 2022 and is found at Attachment 37. The Needs Assessment and Scoping Assessment suggested that no further regional coordination was required and so the TWG proceeded directly to the RIP phase. The third cycle of Needs Assessment will be completed in November 2026. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Kent TS – T2 Transformer and switchyard replacement (T-SR-03)
- 115kV S2N – Line refurbishment between Scott TS and Adelaide Jct. (T-SR-13)

Greater Bruce / Huron

The Greater Bruce/Huron region includes the municipalities of Arran–Elderslie, Brockton, Kincardine, Northern Bruce Peninsula, and South Bruce. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Entegrus Powerlines Inc.
- ERTH Power corporation
- Festival Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- Wellington North Power Inc.

- Westario Power Inc.

The third cycle RIP report for this region was published in April 2025 and is found at Attachment 38. The Needs Assessment suggested that no further regional coordination was required and so the TWG proceeded directly to the RIP phase. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Owen Sound TS – T5 autotransformer replacement (T-SR-01)

Niagara

The Niagara Region comprises the municipalities of City of Port Colborne, City of Welland, City of Thorold, City of Niagara Falls, Town of Niagara-On-The-Lake, City of St. Catharines, Town of Fort Erie, Town of Lincoln, Township of West Lincoln, Town of Grimsby, Township of Wainfleet, and Town of Pelham. Haldimand County. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Alectra Utilities Corporation
- Canadian Niagara Power Inc.
- Grimsby Power Inc.
- Hydro One Networks Inc. (Distribution)
- Niagara-on-the-Lake Hydro Inc.
- Welland Hydro Electric System Corp.
- Niagara Peninsula Energy Inc.

The second regional planning cycle for this region was concluded with the publication of the RIP Report in July 2023. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found at Attachment 39 and 40. The third cycle Needs Assessment was completed in July 2026 (Attachment 41) and has identified needs

that require further regional coordination. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Glendale TS – T1 transformers replacement. (T-SR-03)
- Murray TS – T11/12 and T13/T14 transformers replacement. (T-SR-03)
- Allanburg TS – T3 autotransformer replacement (T-SR-03)
- 115 kV Q2AH – Conductor replacement Rosedene JCT X St. Anns JCT (T-SR-13)
- Crowland TS station capacity – Build new 230kV line into Welland and construct new Crowland TS. (T-SA-11)

North/East of Sudbury

The North/East of Sudbury Region is the area roughly bordered by Moosonee to the North, Hearst to the North-West, Ferris to the South, and Kirkland Lake to the East. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Hearst Power Distribution Company Ltd.
- Hydro One Networks Inc. (Distribution)
- North Bay Hydro Distribution Ltd.
- Northern Ontario Wires Inc.
- Greater Sudbury Hydro Inc.

The second regional planning cycle for this region was concluded with the publication of the RIP Report in November 2023. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found at Attachment 42 and 43. The IESO recommended delaying the third cycle Needs Assessment for North/East of Sudbury until after the conclusion of the bulk plan. OEB agreed and granted extension to start the Needs Assessment in September 2026. The following material transmission investments have

capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Otto Holden TS – T3/T4 autotransformers replacement. (T-SR-01)
- Timmins TS – T2 transformer replacement. (T-SR-03)
- Crystal Falls TS – T5/T6 transformer replacement. (T-SR-03)
- Trout Lake TS – T3/T4 transformers replacement. (T-SR-03)
- A4H/A5H – Overhead Conductor replacement and circuit refurbishment between Tunis Jct. x Fournier Jct. (T-SR-13)
- D2H/D3H – Overhead Conductor replacement and circuit refurbishment between Hunta SS x Abitibi Canyon SS. (T-SR-13)

Renfrew

The Renfrew Region includes all of Renfrew County that is made up of 17 municipalities and City of Pembroke. The rough boundaries of this Region are Ottawa River on the North-East, Algonquin Provincial Park on the West, and Route 508 on the South. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independant Electricity System Operator (IESO)
- Hydro One Networks Inc. (Distribution)
- Ottawa River Power Corporation

The second regional planning cycle for this region was concluded with the publication of the RIP Report in July 2023. The RIP is a comprehensive, region-wide detailed wires plan that consolidates recommendations from all phases, including local plans and also incorporates any new needs and developments that have arisen since the IRRP. The IRRP and RIP reports for this region are found at Attachment 44 and 45. The third cycle Needs Assessment was completed in July 2026 (Attachment 46) and has identified needs that require further regional coordination. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- D6, Des Joachims TS X Petawawa DS, Tx Line Refurbishment (T-SR-13)

St. Lawrence

The St. Lawrence Region covers the southeastern part of Ontario bordering the St. Lawrence River. The region starts at Gananoque on the eastern end of Lake Ontario and extends to the inter-provincial boundary with Quebec. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Hydro One Networks Inc. (Distribution)
- Cooperative Hydro Embrun Inc.
- Rideau St. Lawrence Distribution Inc.

The second cycle RIP for this region was issued in March 2022 and is found at Attachment 47. The second cycle Needs Assessment suggested that no further regional coordination was required and so the TWG proceeded directly to the RIP phase. The third cycle Needs Assessment was completed in March 2026 (Attachment 48) and has identified needs that require further regional coordination. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Brockville TS: Installation of new LV Capacitor bank to mitigate the voltage issues. (T-SS-12)

East Lake Superior

The East Lake Superior Region includes all of Hydro One Sault Ste. Marie's 560km high-voltage transmission lines as well as ties to the rest of the provincial grid at Wawa TS in the northwest and Mississagi TS in the northeast. The participants in this region's TWG include representatives from the following organizations:

- Hydro One Networks Inc. (Lead Transmitter)
- Independent Electricity System Operator (IESO)
- Hydro One Networks Inc. (Distribution)
- Algoma Power Inc.
- Chapleau Public Utilities Corporation (now Hydro One Networks Inc. Distribution)
- PUC Distribution Inc.

The first cycle of the Regional Planning process for the East Lake Superior region was initiated by the former Great Lakes Power Transmission ("GLPT"). The second cycle of regional planning was carried out by Hydro One Transmission on behalf of Hydro One Sault Ste. Marie . The RIP for this region was issued in October 2021 and is found at Attachment 49. The third cycle Needs Assessment was completed in October 2024 (Attachment 50) and has identified needs that require further regional coordination. The third cycle IRRP was also completed in July 2026 (Attachment 51), and RIP is currently underway with a tentative completion date of February 2027. The following material transmission investments have capital expenditures during the 2028–2032 rate period; however, the in-service dates for these projects may extend beyond the rate period:

- Patrick St. TS – 115 kV breakers replacement. (T-SR-03)
- Northern Ave TS – T1 transformers replacement. (T-SR-03)
- Clergue TS – Metal clad switchgear replacement. (T-SR-03)
- D.A Watson TS – Metal clad switchgear replacement. (T-SR-03)
- Goulais Component Replacement (T-SR-03)
- Hollingsworth TS Protection Upgrade (T-SR-03)

North of Moosonee

Five Nations Energy Inc. (FNEI) is the lead transmitter for this region and is therefore responsible for the RIP. The TSP does not contemplate any regional planning transmission infrastructure investments in this region.

1.2.5 HYDRO ONE DISTRIBUTION

1.2.5.1 ROLES AND RESPONSIBILITIES OF HYDRO ONE DISTRIBUTION

As a province-wide distributor, Hydro One Distribution actively participates in regional planning activities. Hydro One Distribution's assets are located in 20 of the 21 regions that have been identified for the purpose of regional planning. These regions correspond to the same 20 regions where Hydro One Transmission is the lead transmitter.

By participating as a TWG member in the regional planning process, Hydro One Distribution is actively engaged in various phases of the process. Hydro One Distribution's

role is to provide the lead transmitter with the information and data required to complete the RIP process, including information based on its embedded distributors' data. Hydro One Distribution assesses the impact of regional supply plans to its distribution systems and where appropriate, develops and reviews potential distribution options to address the identified regional needs. Hydro One Distribution is also expected to support regional planning by identifying to the lead transmitter, any activity/elements on a sub-regional level that may impact a review cycle in a region to the transmitter.

More particularly, throughout the Needs Assessment, Scoping Assessment, Stakeholder Engagement, IRRP and RIPs, Hydro One Distribution may be requested to provide the following input:

- Provide short-term and long-term load forecasts to the lead transmitter and the IESO. Hydro One Distribution provides "gross" and "net" peak demand forecasts for the short-term (five years) and medium-term (ten years), as well as the unbundled information used to show how they arrived at the "net" peak demand forecast.
- Provide background on the distribution system including information on past system performance;
- Identify local supply needs or constraints from the local LDC perspective;
- Participate in community engagement sessions such as LACs or with local municipalities and other stakeholders;
- Participate in local planning led by the lead transmitter to address local supply needs as determined through the Needs Assessment stage;
- Identify and evaluate potential distribution based wires solutions to meet regional or local infrastructure needs;
- Attend regularly scheduled IRRP and RIP Working Group meetings at the regional and sub-regional level as required;
- Provide input and comments to proposed wires and non-wires solutions to address identified system needs; and
- Review and provide comments on draft planning reports/documents prepared by the IESO and the lead transmitter.

- Provide ten-year outlook related to the end-of-life of major transmission voltage assets. For this, major transmission voltage assets include transformers; circuit breakers (where replacement includes the lesser of six breakers or more than 50% of station breakers); overhead lines (where replacement exceeds two kilometers and is over 50 kV); and underground cables (where replacement exceeds two kilometers and is over 50 kV)
- Provide prompt notice of any developments in that part of the region in which its licensed service area is located that may trigger the need for investments in transmission facilities, distribution facilities or both, as applicable, or that may otherwise reasonably be expected to affect the lead transmitter's conduct of a needs assessment for the region.

As further described in section above, to meet the requirements of its distribution rate application, Hydro One Distribution requested Hydro One Transmission to provide a letter confirming the status of regional planning for its regions. This letter also ensures the alignment between Hydro One Distribution, as a local LDC and Hydro One Transmission, as a lead transmitter in regards of the identified needs in each region. A copy of the Regional Planning Status Letter is provided at Attachment 52.

Attachment 50 – 3rd cycle NA Report: East Lake Superior
Attachment 51 – 3rd cycle IRRP Report East Lake Superior
Attachment 52 – Hydro One Transmission Regional Planning Status Letter to Hydro One Distribution

SECTION 1.2 – ATTACHMENT 1 – INTEGRATED ENERGY PLAN (IEP)

1.0 INTRODUCTION

Ontario's Energy for Generations: Ontario's Integrated Energy Plan (IEP) establishes a coordinated, whole-system planning framework to 2050 integrating electricity, natural gas, hydrogen, storage, and other energy sources to guide smarter, more coordinated investments in infrastructure, supply, and innovation. The IEP positions integrated planning as essential to delivering affordable, secure, reliable and clean energy for Ontarians. This Exhibit reinforces and builds upon the principles and outcomes described in SPF Section 1.2. Accordingly, this exhibit explains how the planning processes and considerations reflected in the IEP are incorporated into Hydro One's planning approach, including recent and ongoing planning process enhancements, the key transmission system expansion drivers arising from growth, and the alignment between transmission projects identified in the IEP and those proposed in Hydro One's 2028–2032 capital plan.

1.1 PRIORITIES FOR ONTARIO'S INTEGRATED ENERGY PLANNING

The government has established the following priorities to guide future energy planning:

- Develop a Single, Integrated Plan for All Energy Needs:
  Future planning must consider all fuels and technologies together - electricity, natural gas, hydrogen, biofuels, other fuels, and energy storage - to ensure Ontario has the affordable energy it needs to power a clean and growing economy.
- Plan on a Regular Cycle with Robust Indigenous and Stakeholder Engagement:
  Each five-year planning cycle will incorporate input from the public, Indigenous communities, energy stakeholders, and sector experts to ensure the plan reflects real-world needs and opportunities across Ontario.
- Coordinate Forecasting Across Energy Agencies and Utilities:
  The IESO, natural gas distributors, electricity utilities, and other market participants will be expected to work together toward using shared, evidence-based forecasts to ensure system-wide alignment across all types of energy use.

- Plan for High Growth:
  To ensure planning processes are better able to match the pace of growth, the IESO will be expected to coordinate frequent load growth forecasting with utilities and other stakeholders, and to identify transmission projects that would be needed to address capacity constraints that would arise under high growth forecasts.
- Ensure Regulatory Alignment and Implementation:
  The OEB will continue to play a central role in implementing the plan's direction through efficient regulation of and guidance to the sector.
- Incorporate Independent, Expert Advice:
  Integrated planning will be supported by independent, external advice on how best to align energy decisions with broader government priorities such as housing, economic development, and competitiveness.

The above priorities of the Province are expected to reduce system-wide costs, avoid overbuilding or underbuilding infrastructure, enable fuel-switching, focus on total customer energy bills, reduce shortages and economic risk, support energy export capacity, and improve stakeholder participation.

Implementing the government's priorities will shift Hydro One from being a primarily grid asset manager to a central system enabler of Ontario's economic and energy transition, with corresponding impacts such as the following:

- Expanded role in integrated, multi-fuel planning
- Expanded role in coordination and engagement
- More complex data analytics and integration
- Accelerated transmission development under high-growth scenarios

1.2 ALIGNMENT WITH HYDRO ONE'S PLANNING GOALS

Hydro One's current and planned practices align with the IEP's priorities in the following ways:

- Proactive growth planning, including advancing regional and bulk system plans in areas experiencing or expected to experience significant load growth
- Improved forecasting inputs, through enhanced coordination with municipalities, local distribution companies (LDCs), the IESO, and other stakeholders to inform load and timing assumptions
- Engagement, by maintaining ongoing, structured participation with municipalities, Indigenous groups, and expanding engagement to include Enbridge to support coordinated planning
- Active participation in OEB regulatory consultations aimed at improving planning processes, efficiency, transparency and alignment (e.g. Regional and Bulk Planning Process Advisory Group and Gas-Electric Coordination and Information Sharing Forum).

1.2.1 PROACTIVE GROWTH PLANNING

- Successful completion of two regional planning cycles, with a third currently underway, including advancing regional planning timelines ahead of their scheduled timeline, in high-growth regions in response to feedback from LDCs and municipalities (e.g., St. Lawrence, London Area, Peterborough to Kingston, and Greater Ottawa).

1.2.2 IMPROVED FORECASTING INPUTS

- Development of scenario-based regional demand forecasts informed by municipal input on electricity needs and emissions reduction goals, existing and new customer demand, CDM and DER assumptions, and electrification scenarios.
- Development of standardized input templates for municipalities, LDCs, and other transmission-connected customers to support consistent forecasting and effective, data sharing.

1.2.3 ENGAGEMENT

- Outreach to the Association of Municipalities Ontario and over 250 municipalities since 2023, including meetings with municipal representatives to enable better understanding of the electricity demand expectations and support coordinated planning toward affordable, secure, reliable, and clean energy outcomes.
- Coordination, both within the existing regional planning process, and directly between electric and gas utilities for high growth areas where new gas infrastructure investments are being explored.

1.2.4 REGULATORY AND PROCESS MODERNIZATION PARTICIPATION

- Active participation on the OEB's Regional and Bulk Planning Process Advisory Group (RBPP AG), supporting improvements to planning efficiency, alignment with growth timelines, and consistency in demand forecasting.
- Active participation in the OEB's Gas-Electric Coordination and Information Sharing consultation, building on prior coordination discussions with Enbridge regarding load forecasts and planning assumptions.

2.0 PLANNING FOR GROWTH: UPDATES TO REGIONAL AND BULK PLANNING PROCESSES

To respond to rapid growth:

- The OEB will continue to play a central role in implementing the plan's direction through efficient regulation of and guidance to the sector.
- The IESO will hold annual regional Technical Working Group meetings, including participation from Hydro One.
- Major Project Identification Committees (MPICs) will be established to detect new housing, industrial, mining, or transit projects early.
- The IESO, transmitters, and LDCs will identify bottlenecks proactively.
- Hydro One and the IESO working jointly to continue to support integration of new generation (nuclear, hydro, others) into regional and provincial systems.

Collectively, these changes improve planning responsiveness by enabling earlier identification of major projects, strengthening coordination across electricity and natural gas planning, enabling new generation resources and supporting more timely alignment of transmission development with emerging load growth and system constraints.

2.1 REVIEW OF PLANNING PROCESSES

The OEB launched a formal Regional and Bulk Planning Process Review in October 2025, which examined how to better align planning with actual load growth, improve flexibility and responsiveness, and reduce planning timelines.

The RBPPAG was composed of 21 members representing electricity and natural gas distributors, transmitters, large and small resource suppliers, municipalities, Indigenous communities, consumer groups, and non-government organizations. Its mandate was to provide expert input, advise on gaps and inefficiencies in the current framework, and support the OEB in developing recommendations that improve integration, transparency, and overall process performance. The group played a central role in helping the OEB ensure that planning processes are more adaptable to rapid load growth and better coordinated across sectors.

Hydro One Transmission, as a lead transmitter in 20 regions, worked closely with the OEB, IESO, local distribution companies (LDCs), natural gas distributors, municipalities, and other stakeholders to support OEB in developing recommendations to the Minister of Energy and Mines. Hydro One actively participated in these discussions and provided relevant information to the OEB. The recommendations from RBPPAG focused on improving forecasting methodologies, ensuring planning reflects emerging high-growth demand drivers, and pursuing procedural improvements that enable faster, more coordinated, and more cost-effective system planning across both regional and bulk levels. The RBPPAG provided its findings and proposed improvements in “Review of Ontario’s Regional and Bulk Planning Processes Report” to the Minister of Energy and Mines on March 31, 2026, and is waiting for feedback from the Ministry.

2.2 ELECTRICITY – NATURAL GAS COORDINATION IN REGIONAL PLANNING

A formal process will be established to engage gas distributors in regional planning and avoid misalignments such as heat pump electrification outpacing electricity system capacity or infrastructure investments being made without evaluating cross-fuel alternatives.

Coordination between fuels will move from ad hoc to formalized through:

- An ongoing OEB-led Information Sharing Forum (launched in Dec. 2025).
- Coordinated scenario modelling across electricity and gas utilities.
- Stronger utility participation in regional and bulk planning.
- Municipal and Indigenous engagement to improve alignment with local priorities.

3.0 IMPACT OF THE IEP ON HYDRO ONE'S TRANSMISSION CAPITAL PLAN

3.1 TRANSMISSION EXPANSION IN THE IEP: KEY DRIVERS

The IEP supports and indicates that Ontario will accelerate transmission development and add thousands of kilometers of new lines in the future. Key drivers for transmission expansion include:

- Increased electricity demand from population growth and electrification;
- New industrial development (e.g., EV and battery manufacturing, mining, greenhouse operations);
- Connection of new clean generation, including hydroelectric and nuclear facilities;
- Improved regional reliability and system flexibility; and
- Long-term planning to prevent future land-use conflicts and development delays.

3.2 IEP PRIORITY TRANSMISSION PROJECTS REFLECTED IN HYDRO ONE'S 2028–2032 CAPITAL PLAN

This section identifies the transmission projects included in Hydro One's proposed 2028–2032 capital plan that are also reflected in the Integrated Energy Plan (IEP), including those identified in the IEP as priority transmission projects or otherwise explicitly referenced for advancement. Where applicable, this section also identifies projects undertaken in compliance with the conditions of Hydro One's transmitter license arising from Ministerial directives to the OEB, as well as projects declared priority by the

Lieutenant Governor in Council. The projects listed below provide a clear linkage between the priorities and projects identified in the IEP and the corresponding investments included in this application.

In the 2028–2032 period, IEP aligned transmission investments are estimated at approximately $10 billion on a gross basis, reflecting the scale of transmission development required to support growth. A significant portion of this total (approximately $8.2 billion) is associated with Affiliate Transmission Partnerships and does not enter Hydro One Networks' regulated rate base. The investments focus on:

- Strengthening north–south transfer capability to move power from northern generation to southern demand centers
- Targeted regional investments in the GTA, Southwest, Eastern, and Northern Ontario to support growth and avoid bottlenecks
- Early planning and corridor protection to ensure future transmission can be delivered quickly, cost-effectively, and with minimized land impacts; and
- Early, ongoing Indigenous engagement and partnership, including equity participation and economic opportunities.

The major transmission investments recommended in the IEP that fall within the 2028-2032 application period are summarized below. These projects reflect provincial priorities to support economic growth, electrification, and system reliability, and are advanced to support timely delivery of critical energy infrastructure. Where applicable, these projects have been formally designated as priority transmission projects through an Order in Council (OIC). For the purposes of this section, priority transmission projects refers to such designations by the Lieutenant Governor in Council.

3.2.1 BUILDING A STRONGER NORTH-SOUTH ELECTRICITY BACKBONE

- **Barrie to Sudbury Transmission Line** (Essa TS to Hanmer TS, new single-circuit 500 kV line – target in service 2032) – T-SS-11
- **Orangeville to Barrie Reconductoring** (230 kV –target in service 2030) – T-SS-11

3.2.2 POWERING GROWTH IN THE GREATER TORONTO AREA (GTA)

- **Manby to Riverside Junction Reconductoring** (115 kV –target in service 2028)– T-SS-12
- **Bowmanville to GTA Transmission Line** (New double-circuit 500 kV is required to connect OPG's SMR units 2, 3 and 4 at Darlington to the grid and send additional electricity to the GTA and downtown core – target in service 2032) – T-SS-11
- **Downtown Toronto Third Major Transmission Line** (New Underwater cables; target in service mid-2030s) – T-SS-11

3.2.3 SUPPORTING ECONOMIC GROWTH IN SOUTHWEST ONTARIO

- **Longwood to Lakeshore Phase 1** (Single circuit 500 kV transmission line from Lakeshore TS to Longwood TS – target in service 2030) – T-SS-09
- **Windsor to Lakeshore Line** (230 kV transmission line from Lauzon Transformer Station to Lakeshore Transformer Station – target in service 2032) – T-SS-12

3.2.4 PLANNING FOR GROWTH IN EASTERN ONTARIO

- Durham-Kawartha Power Line (Dobbin TS to Clarington TS – target in service 2029) – T-SS-11

3.2.5 UNLOCKING NORTHERN OPPORTUNITIES

- **Wawa to Porcupine Transmission Line** (230 kV line between Wawa Transformer Station (south of Wawa) and Porcupine Transformer Station (Timmins) built to 500 kV standards – target in service 2030) – T-SS-11
- **North Shore Link Project** (Mississagi TS to Third Line TS – target in service 2029) – T-SS-11
- **Northeast Power Line** (Mississagi TS to Hanmer TS, 500 kV – target in service 2029) – T-SS-11

3.2.6 THE GREENSTONE AREA

- **Greenstone Transmission Line** (Longlac TS to Nipigon GS, connecting to East-West Tie – target in service 2032) – T-SS-10

3.2.7 ADVANCING TRANSMISSION IN THE RED LAKE AREA

- **North of Dryden Area Reinforcement**, as identified in the 2025 Northwest IRRP Addendum (230 kV transmission line from Dryden TS to Ear Falls TS, and another from Ear Falls TS to Red Lake SS, with autotransformers at Ear Falls TS and Red Lake SS) – T-SS-12

3.3 COMPLETED IEP PRIORITY TRANSMISSION PROJECTS

This section identifies the transmission projects identified as priority transmission projects in the Integrated Energy Plan (IEP) that Hydro One has completed or anticipates immaterial expenditures over the 2028 - 2032 period.

3.3.1 SUPPORTING ECONOMIC GROWTH IN SOUTHWEST ONTARIO

- **Chatham to Lakeshore Line** (230kV transmission line from Chatham Switching Station to Lakeshore Transformer Station) – completed January 2025
- **St. Clair Line** (230 kV transmission line from Lambton Transformer Station to Chatham Switching Station) – target completion in 2027

This page has been left blank intentionally.

SECTION 1.2 – ATTACHMENT 2 – LONG-TERM CAPITAL PLAN INFORMATION

1.0 INTRODUCTION

In EB-2021-0110, the Parties agreed that Hydro One would provide, with its next cost-based rate application, a summary of available long-term (10–20-year) forecast information for Transmission and Distribution from Regional Planning Reports and IESO Bulk planning, consistent with the framework being developed by the Regional Planning Process Advisory Group (RPPAG).

The information presented in the sections below provides directional, long-term capital planning context only. It does not represent a new Hydro One load forecast, does not reconcile to the load forecasts used elsewhere in this Application, and should not be interpreted as establishing the need, timing or scope of any individual investment.

1.1 HYDRO ONE'S RESPONSE TO THE SETTLEMENT COMMITMENT

Hydro One has prepared this summary in response to the EB-2021-0110 Settlement Agreement commitment related to long-term capital plan information. This section describes how Hydro One has addressed the commitment by consolidating available 10–20-year forecast information from regional planning materials and IESO planning inputs in a manner consistent with the intent of the Settlement Agreement.

The summary consolidates forecast data for the 20 regions where Hydro One is the lead transmitter, using the latest available second/third cycle Regional Infrastructure Plan (RIP) reports and third cycle Needs Assessment where 20-year RIP forecast was not available. Consolidating this information provided the basis for a 12-year forecast covering the 2026-2038 period.

The regional planning forecasts were prepared through separate regional planning processes completed at different points in time in accordance with the OEB's load forecast guidance document. As a result, the forecasts reflect assumptions and information from

different points in time that may have changed as regional circumstances evolved. Furthermore, the forecasts were not developed to establish Hydro One's revenue requirement or to support the need, timing, scope or cost of the individual investments proposed in this Application. This includes investments that may have emerged or evolved after the applicable regional planning forecast was prepared.

Accordingly, consolidating the regional planning forecasts into a common 12-year forecast provides directional, long-term capital planning context only. The forecasts reflect the sum of non-coincident peaks at the station level and therefore do not add up to Ontario's total peak demand. They also reflect load at the planning stage rather than the outcome of regional planning. For example, where station-level capacity issues are addressed through load transfers, the coincident peak across the affected stations, and therefore Ontario's peak demand, does not change, although the non-coincident peak at the stressed station is reduced. Similarly, where non-wires solutions are implemented to address capacity needs, actual load may be lower than the load forecast at the planning stage.

In contrast, the load forecast prepared for setting transmission rates in this Application forecasts future system load rather than load at the planning stage. These differences mean that the consolidated forecast is not directly comparable to the load forecast prepared for setting transmission rates in this Application. It therefore does not represent a new Hydro One load forecast, reconcile to the load forecasts used elsewhere in this Application, or provide a project-level investment forecast. For details regarding Hydro One's proposed transmission capital expenditures in this Application, refer to TSP Section 2.8.

Table 1 presents the consolidated 12-year regional load forecast for the 20 regions where Hydro One is the lead transmitter.

1 **Table 1 - Regional Load Forecast Summary for Hydro One Lead-Transmitter Regions (MW), 2026–2038**

Region	Regional Load Forecast (MW)													Average Annual Load Growth (%)	Total load Growth (2026-2038) (%)

Witness: Mark Brodie

As shown in Table 1, the 2026–2038 regional load forecast provides a consolidated view of available long-term forecast information within the 10–20-year horizon contemplated by the EB-2021-0110 Settlement Agreement commitment. The RIP forecasts adopt the IESO's Integrated Regional Resource Plan (IRRP) load forecasts, subject to updates where material changes are identified through the technical working group process. The IRRP forecasts are prepared by the IESO using information and analytical foundations that also inform other long-term adequacy assessments, including bulk system planning. Accordingly, the RIP-based approach provides a practical mechanism for incorporating IESO planning context into Hydro One's regional forecast summary.

The forecast shows that growth is not uniform across the province. Regions in and around the Greater Toronto Area exhibit higher growth than outer and more rural areas of Ontario. The highest average annual growth is observed in GTA North at 5.28%, while the lowest is observed in North/East of Sudbury at 0.66%. Across all 20 regions, the compiled forecast reflects total load growth of approximately 24% over the 2026–2038 period, or approximately 2% average annual growth.

Taken together, this information responds to the EB-2021-0110 Settlement Agreement commitment by providing a consolidated summary of available long-term regional forecast information using the latest regional planning and IESO planning inputs.

Ajay Garg
Director, Long-term Strategic Transmission System Planning
Hydro One Networks Inc.
483 Bay Street,
Toronto, ON, M5G 2P5

Dear Mr. Garg:

Re: Regional Planning Progress Update

The Independent Electricity System Operator (IESO) has been notified of Hydro One Networks Inc.'s (Hydro One Transmission) and Hydro One Sault Ste. Marie's (HOSSM) upcoming transmission revenue requirement applications with the Ontario Energy Board (OEB) and has been requested to provide a status update for regions where regional planning is currently underway, but a Regional Infrastructure Plan (RIP) has not yet been completed. This includes regions undergoing a Needs Assessment (NA), Scoping Assessment (SA), or Integrated Regional Resource Plan (IRRP).

This request is based on the requirements of Section 2.4.3 of the OEB's *Chapter 2 Filing Requirements for Electricity Transmission Applications*[1], which state:

> *2) Where regional planning is underway, but a Regional Infrastructure Plan has not yet been completed for the applicable region, the applicant shall submit a letter from the IESO, identifying the status of the regional planning process, and the potential impacts on the applicant's investment plans.*

Pursuant to the above-noted filing requirements, the IESO hereby provides the status of regional planning as follows:

Regional Planning Status Summary

Table 1 summarizes the status of regional planning activities undertaken by the IESO across all 20 regions where Hydro One Transmission is designated as the lead transmitter.

The table identifies completed, ongoing, and future planning phases for the third cycle of regional planning, including NAs, SAs, IRRPs, and RIPs, as applicable.

[1] OEB's *Chapter 2 Filing Requirements for Electricity Transmission Applications, October 30, 2025, p. 19.*

Needs Assessments are undertaken by the lead transmitter in a region, while subsequent SA and IRRP regional planning phases are coordinated by the IESO. For regions or sub-regions where certain planning phases were deemed not to be required, this determination reflects the conclusions of the applicable planning studies.

Region	Regional Planning Stage / Completion Date [2]			
	NA [1]	SA [1]	IRRP [1]	RIP [1]
Kitchener-Waterloo-Cambridge-Guelph	Apr. 2024	Jul. 2024	Jul. 2026	TBD
GTA West	Aug. 2024	Nov. 2024	Nov. 2026	TBD
East Lake Superior [3]	Oct. 2024	Jan. 2025	Jul. 2026	TBD

Burlington to Nanticoke [4]	Sep. 2022	Dec. 2022	Nov. 2024	Jun. 2025
Niagara	Jul. 2026	Oct. 2026	TBD	TBD

Region	Regional Planning Stage / Completion Date [2]			
	NA [1]	SA [1]	IRRP [1]	RIP [1]
North/East of Sudbury [5]	TBD	TBD	TBD	TBD
Renfrew	Jul. 2026	TBD	TBD	TBD
St. Lawrence	Mar. 2026	Apr. 2026	Oct. 2027	TBD

Notes:

(1): NA: Needs Assessment; SA: Scoping Assessment; IRRP: Integrated Regional Resource Plan; RIP: Regional Infrastructure Plan

(2): Dates shown represent completion dates. Future dates are tentative and based on Regional Planning Process timeline requirements.

(3): HOSSM is the lead transmitter in the East Lake Superior region.

(4): An IRRP was issued for the Hamilton, Brant, and Caledonia-Norfolk sub-regions. An Addendum for the Hamilton sub-region is underway to address supply needs for the 230 kV subsystem and station capacity needs in the Hamilton sub-region.

(5): Hydro One is initiating the third cycle of Regional Planning for the Region approximately four months later than OEB mandated date, given the significant overlap with the North of Sudbury Bulk Plan currently being developed by the IESO which is set for publication in Q3 2026. Aligning the Regional and Bulk Planning processes supports efficient planning and minimizes duplication of effort.

Ongoing IRRPs, as well as any ongoing addendum studies, may result in changes to the recommendations made by Regional Planning Study teams. The IESO is currently completing an Addendum to the 2024 Burlington to Nanticoke IRRP focusing on the Hamilton sub-region.

In addition, while bulk system planning is distinct from the regional planning process summary described above, the IESO also notes that bulk system planning work remains ongoing at the time of Hydro One's filing. Through its bulk-planning engagements, the IESO continues to assess bulk system needs across the province. As this work is finalized and additional bulk plans are issued, relevant recommendations may have implications for Hydro One's transmission investment plans.

Should you have any questions regarding the regional planning status or require further clarification on specific regions or planning phases, please do not hesitate to contact us.

Sincerely,

Kennan Ip

Executive Summary

The Burlington to Nanticoke Integrated Regional Resource Plan (IRRP) addresses the electricity needs of the Burlington to Nanticoke Region over a 20-year period, from 2023 to 2042. The Burlington to Nanticoke Region is located in southwestern Ontario and includes all or part of the following Counties and Districts: City of Hamilton, County of Brant, the City of Brantford, Haldimand County, Norfolk County, the City of Burlington and the town of Oakville.

For the purposes of the IRRP, the region has been divided into four subregions: Brant, Bronte, Caledonia-Norfolk, and Hamilton. The Scoping Assessment Outcome Report completed in December 2022, identified no needs for coordinated regional planning in the Bronte subregion, and most needs in the Hamilton subregion will be addressed in an upcoming addendum to be started in early 2025 (see Section 2.5.1). As a result, this IRRP largely focuses on the needs and recommendations for the Brant and Caledonia-Norfolk subregions.

Need assessments for the 115 kV subsystem in the Brant subregion (the "Brant 115 kV Subsystem") could not be conducted in isolation from the 115 kV subsystem in the Hamilton subregion and the 115 kV subsystem in the City of Woodstock (outside of the Burlington to Nanticoke Region). This is because of interconnections within the 115 kV subsystem. Therefore, the combined 115 kV subsystem spanning from Karn TS in Woodstock through the Brant subregion and into the Hamilton subregion was studied as whole. This combined subsystem is referred to as the "Brant 115 kV Extended Area", and consists of the: "Hamilton 115 kV Subsystem", the Brant 115 kV Subsystem, and the "Woodstock 115 kV Subsystem".

Studies on the Brant 115 kV Extended Area were used to identify needs, assess options, and produce recommendations for supply and station capacity needs in the Brant subregion, and for supply needs for the Hamilton 115 kV Subsystem. Supply needs for the 230 kV subsystem and station capacity needs in the Hamilton subregion will be addressed in the Hamilton addendum. The Woodstock 115 kV Subsystem falls outside of the Burlington to Nanticoke Region and is instead part of the London Area Region. As a result, needs of the Woodstock 115 kV Subsystem will be assessed and addressed in the ongoing cycle of regional planning for the London Area, with the Needs Assessment expected to be published by Hydro One by the end of 2024.

The electricity demand forecast shows substantial growth for the Burlington to Nanticoke Region, with demand forecasted to grow by 50%, 180%, and 80% for the Brant, Caledonia-Norfolk, and Hamilton subregions, respectively, by 2042, relative to 2023 demand. Growth is driven by industrial expansion, housing growth, and decarbonization initiatives. To meet long-term needs, the Load Meeting Capability (LMC) for each of the 115 kV subsystems in the Region must approximately double from its existing value. These 115 kV subsystems are: the combined Brant and Hamilton 115 kV Subsystems, the Brant 115 kV Subsystem, and the Norfolk-Bloomsburg Area. In addition, each of these 115 kV subsystems, and several substations supplied by these subsystems, have immediate capacity needs.

To address needs, wires and non-wires options were considered, and ultimately a combination is recommended by the Technical Working Group. Wires solutions are recommended to address long-

term needs, as the most cost-effective and technically feasible solutions. Non-wires options are recommended to meet near-to-medium term needs, due to: their shorter lead times, the lower magnitude of needs in the near-to-medium term, and their system benefits.[1]

To address near-to-medium term needs, the Technical Working Group recommends the pre-contingency opening of bus-tie breakers, and load transfers between nearby stations at the distribution level, where viable and cost-effective. The opening of bus-tie breakers is needed to address near-to-medium term supply capacity needs for the combined Brant and Hamilton 115 kV subsystems, the Brant 115 kV Subsystem, and the Norfolk-Bloomsburg Area, and to address several station capacity needs where load transfers cannot resolve needs.

In the medium-term, the Technical Working Group recommends the procurement of a battery energy storage system, and the construction of a new substation[2] near Dundas TS. These recommendations will address supply capacity needs in the Norfolk-Bloomsburg Area, and on the Hamilton 115 kV Subsystem and at Dundas TS, respectively. The new substation will also address station capacity needs at Dundas TS.

In the long-term, the Technical Working Group recommends constructing two sets of new 230 kV transmission lines and associated substations, separating the Woodstock 115 kV Subsystem from the Brant 115 kV Subsystem:

- New 230 kV transmission lines from Nanticoke TS into the Simcoe community, and a new station[2] to entirely offload Norfolk and Bloomsburg 115 kV stations.
- A new double-circuit transmission line constructed as an extension from the existing Middleport-Detweiler corridor (in the Kitchener/Waterloo/Cambridge/Guelph region) into County of Brant, and two new stations[2] to entirely offload Brant and Powerline 115 kV stations.

Cost-effective CDM at Brantford TS and Caledonia TS is also recommended to defer station capacity needs. Once the Brant 115 kV Subsystem has been offloaded by the above recommendation, the Technical Working Group recommends separating the Woodstock 115 kV Subsystem from the Brant 115 kV Subsystem when the total net load in the Woodstock 115 kV Subsystem exceeds the limit.

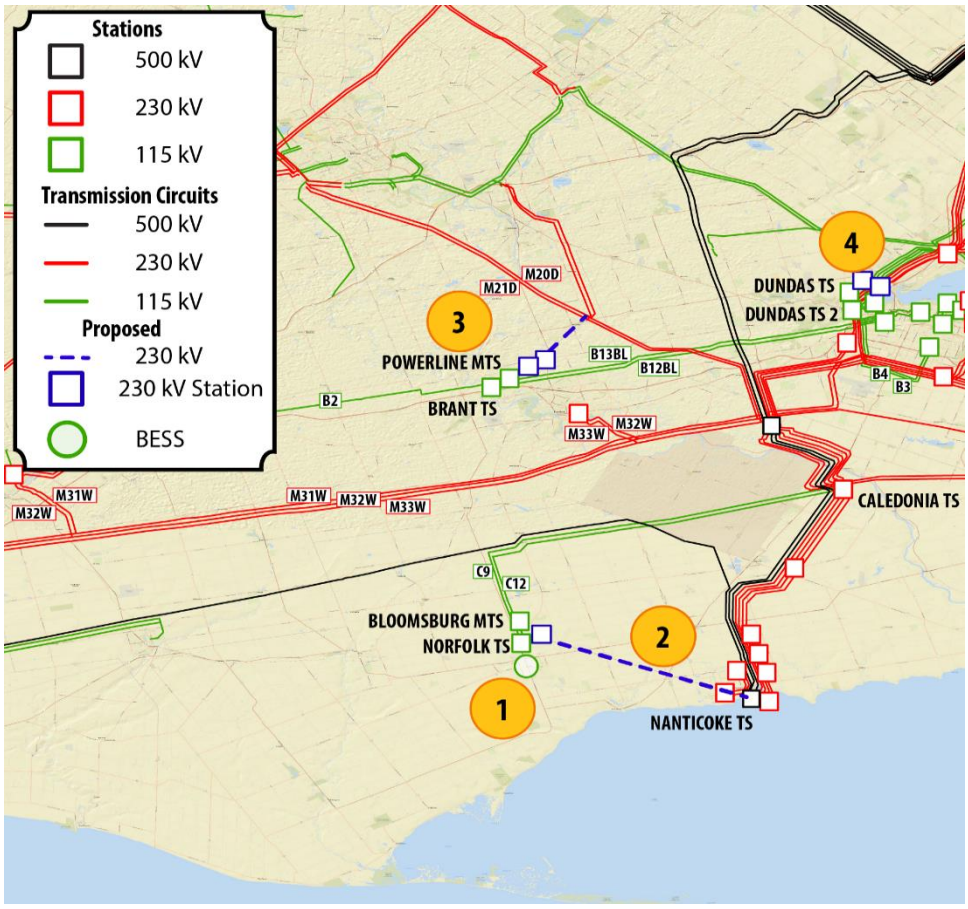
Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and perspectives of the public, market participants, municipalities, stakeholders, communities, Indigenous communities, and customers to be considered in the development of the plan. Furthermore, engagement helps lay the foundation for successful implementation.

The Technical Working Group will continue to monitor growth at Brantford TS and Caledonia TS, as well as across the region. This includes any future community energy planning, electrification trends, datacentres, or industrial load. The Technical Working Group will meet at regular intervals to complete the recommended Hamilton addendum, monitor developments and track progress toward plan deliverables. If underlying assumptions change significantly, local plans may be revisited through

[1] Non-wires options, such as conservation and demand management (CDM), storage procurement, or generation procurement, help meet the CDM and procurement needs of the provincial grid, thereby providing benefits to the system while addressing local needs.

[2] Converting the existing 115 kV DESNs to 230 kV is equivalent to constructing new stations when addressing supply capacity needs. The subsequent Transmitter-led Regional Infrastructure Plan (RIP) will identify the most cost-effective solution and develop a detailed plan for implementation.

an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the Ontario Energy Board.



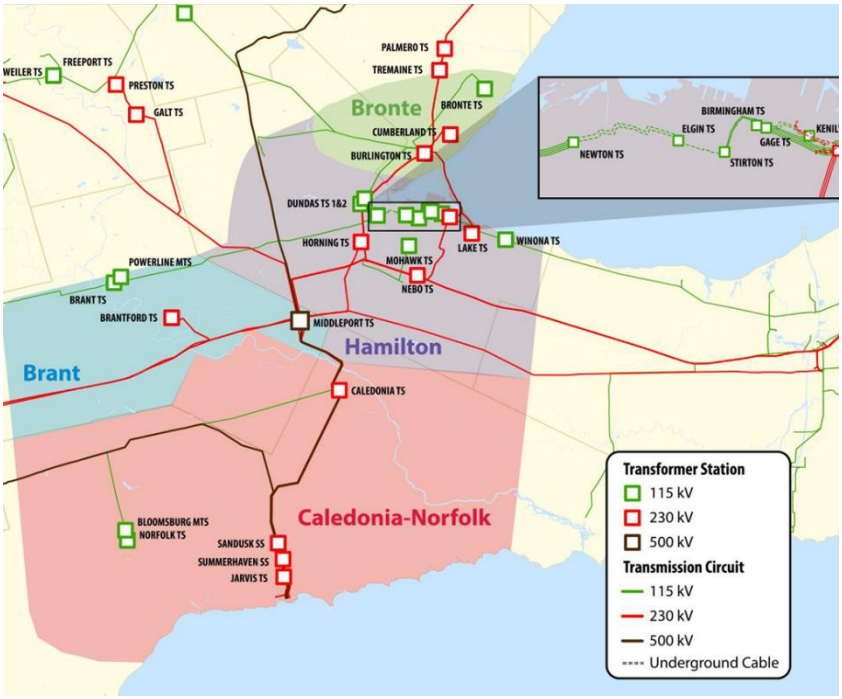
Summary of Recommendations

The medium and long-term recommendations for the Burlington to Nanticoke region are shown in the figure below and include:

1. Build a transmission-connected battery energy storage system (BESS) facility capable of continuously providing voltage support near Norfolk TS.
2. Build new transmission lines from Nanticoke TS into the Simcoe community, and a new station[2] to entirely offload Norfolk and Bloomsburg 115 kV stations.
3. Build a new double-circuit transmission line as an extension from the existing Middleport-Detweiler corridor (in the Kitchener/Waterloo/Cambridge/Guelph region) into County of Brant, and two new stations[2] to entirely offload Brant and Powerline 115 kV stations.
4. Build new 230kV stations[2] at Dundas TS connecting to the adjacent Middleport-Burlington circuits to entirely offload the Dundas load from the 115 kV stations to 230 kV.

In the interim, operational measures such as opening station bus-tie breakers combined with feasible and cost-effective load transfer between stations on a permanent or temporary basis are recommended to resolve supply and station capacity needs.

Medium/Long-Term Recommendations in the Burlington Nanticoke Region



1 Introduction

This Integrated Regional Resource Plan (IRRP) addresses the electricity needs of the Burlington to Nanticoke Region (the "Region") over a 20-year period, from 2023 to 2042. The Burlington to Nanticoke Region is located in southwestern Ontario and includes all or part of the following Counties and Districts: City of Hamilton, County of Brant, the City of Brantford, Haldimand County, Norfolk County, the City of Burlington and the town of Oakville. For electricity planning purposes, the planning region is defined by electricity infrastructure boundaries, not municipal boundaries.

Several Indigenous communities are located in or near the Region including: Mississaugas of the Credit First Nation, Six Nations of the Grand River, and a number of Métis Nation of Ontario (MNO) councils including MNO Clear Waters Métis Council and MNO Grand River Métis Council.

For the purposes of regional planning, the Burlington to Nanticoke region has historically been sub-divided into four subregions: Brant, Bronte, Caledonia-Norfolk, and Hamilton. The electricity infrastructure supplying the Burlington to Nanticoke region and the subregions are shown in Figure 1. The Burlington Nanticoke Region is summer-peaking, and over 2019 to 2023, normal weather peak electrical demand has remained steady at approximately 1,825 MW.

Figure 1 | Overview of the Burlington Nanticoke Region[3]

The Bronte subregion includes Burlington TS and the 230 kV and 115 kV supply northeast of the station which services Cumberland TS and Bronte TS, respectively. The 115 kV supply southwest from Burlington TS and the 230 kV supply from Beach TS service the 115 kV network in the Hamilton subregion, while 230 kV circuits between Burlington TS and Beach TS, Beach TS and Middleport TS,

[3] IRRP regions are defined by electricity infrastructure; geographical boundaries are approximate.

and Middleport TS and Burlington TS supply the Hamilton subregion's 230 kV connected load supply stations. The 230 kV supply south from Middleport TS supplies the 230 kV connected stations in the Caledonia-Norfolk subregion, including Caledonia TS. The 115 kV supply from Caledonia TS then supplies Bloomsburg DS and Norfolk TS. The Brant subregion is supplied from the 230 kV supply west from Middleport TS and a 115 kV supply from Burlington TS. Because of tight connection between i) the Brant 115 kV supply, ii) part of the Hamilton 115 kV supply and iii) the 115 kV supply to the City of Woodstock, the regional plan considered the capability of the broader Brant 115 kV Extended Area which includes theses three subsystems comprising the entire 115 kV network between Burlington TS and Karn TS.

The region's electricity is delivered by five local distribution companies (LDCs): Alectra Utilities Corporation, Burlington Hydro Inc. (BHI), GrandBridge Energy Inc., Hydro One Networks Inc. (Distribution), and Oakville Hydro Inc. Hydro One Networks Inc. (Transmission) is the primary transmission asset owner. This IRRP report was prepared by the Independent Electricity System Operator (IESO) on behalf of a Technical Working Group, composed of the LDCs, Hydro One, and the IESO.

Development of the Burlington Nanticoke IRRP was initiated in December 2022, following the publication of the Needs Assessment report in September 2022 by Hydro One and the Scoping Assessment Outcome Report in December 2022 by the IESO. The Scoping Assessment identified the area's needs should be further assessed through an IRRP. The Technical Working Group was then formed to gather data, identify near- to long-term needs in the region, and develop the recommended actions included in this IRRP.

This report is organized as follows:

- A summary of the recommended plan for the region is provided in Section 2;
- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the region and the study scope are discussed in Section 4;
- Demand forecast scenarios, and conservation and demand management and distributed generation assumptions, are described in Section 5;
- Electricity needs in the region are presented in Section 6;
- Alternatives and recommendations for meeting needs are addressed in Section 7;
- A summary of engagement activities is provided in Section 8; and
- The conclusion is provided in Section 9.

2 The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of the Burlington to Nanticoke Region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system, as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by the North American Electric Reliability Corporation (NERC). The IRRP's recommendations are informed by an evaluation of different options to meet the needs and consider reliability, cost, technical feasibility, maximizing the use of the existing electricity system (where economic), and feedback from stakeholders.

The Burlington to Nanticoke electricity demand forecast, provided by the LDCs, anticipates sustained growth driven by industrial expansion, housing growth, and decarbonization initiatives. These drivers are present across all municipalities in the Region.

In the Brant subregion, residential housing is a primary driving factor in the forecast along with industrial customers which have shown interest and purchased property both within City of Brantford and County of Brant. One customer has already scheduled an expansion project with a significant quantity of new load. With the annexation of 2,720 hectares of land from County of Brant to the City of Brantford, there is an expectation of intense development in the north of Brantford. Beyond 2030, 4 per cent growth is expected for electrification.

In the Caledonia-Norfolk subregion, the forecast is mainly driven by economic factors, e.g. housing and GDP, and community/municipal energy and decarbonization plans. Industrial and residential development in Courtland has a large effect in the Norfolk forecast. New residential and employment growth is forecasted to be 1% per annum into the future.

In the Hamilton subregion, the forecast is driven primarily by economic factors, and supplemented by electric vehicle growth. Economic factors include: population and employment growth, housing activities, and commercial and industrial development.

Following a review on the status of the plans recommended in the last cycles of IRRP, the recommendations in this cycle of IRRP are organized under interim and permanent plans. This distinction reflects the different levels of lead time for development and planning commitment required. This approach ensures that the IRRP provides clear direction on investments needed in the near and medium term, while initiating projects with long lead times that are ultimately needed.

2.1 Status of Plans from Previous IRRP Cycles

Following the previous cycle of region planning, and concluding with the 2nd Cycle RIP report, several projects were recommended which have now been completed or are presently underway. The projects consisted largely of replacements, in addition to two capacitor bank installations, and two sets of distribution-level load transfers. The status of these projects is summarized in Table 1 below.

Table 1 | Summary of Ongoing and Recently Completed Plans

Station/Line Section	Need	Expected In-Service
Cumberland TS	Power factor correction: capacitor bank installed at customer level	2019 (Completed)
115 kV B3/B4	Line section Horning Mountain Jct. X Glanford Jct. replacement	2020 (Completed)
Elgin TS	Transformer and switchgear replacement	2022 (Completed)
Gage TS	Transformer and switchgear replacement	2024 (Completed)
Newton TS	Transformer replacement	2020 (Completed)
Norfolk-Bloomsburg Area Supply Capacity	Load transfers to Jarvis TS: 3 MW	2026
Kenilworth TS	Transformer and switchgear replacement	2023 (Completed)
Kenilworth TS	Power factor correction: capacitor bank installation	2025 (Completed)
115 kV B7/B8	Line section Burlington TS X Nelson Jct. replacement	2024
Dundas TS	Load transfers to Dundas 2 TS: 20 MW	2025
Newton TS	115 kV breaker refurbishment	2022 (Completed)

2.2 Interim Plans

For the interim, until permanent solutions are placed in service, the Technical Working Group recommends operational measures to address near-/medium-term supply and station capacity needs. This includes the pre-contingency opening of bus-tie breakers, as needed, to secure the system and resolve the needs.

The recommended operational measures also include load transfers between nearby stations at the distribution level. The Technical Working Group recommends that LDCs assess the feasibility and cost-effectiveness of transferring loads on a temporary or permanent basis with consideration to the recommended long-term solutions which resolve supply or station capacity needs. Moreover, coordination between load transfer and opening station bus-tie breakers is necessary since opening

bus-tie breakers may still be required either to make the system secure or because the amount of load transferred is not sufficient to resolve the needs. Where viable and cost-effective, the Technical Working Group prefers transferring loads since opening station bus-tie breakers may interrupt electricity service to a higher number of customers following a network outage.

Note that the Technical Working Group makes these interim recommendations strictly on a provisional basis, until solutions with longer lead times are in place.

Table 2 | Interim Plans for Station and Supply Capacity Needs

Need	Recommendation	Lead Responsibility
Various station and supply capacity	As required, open bus-tie breakers at Bloomsburg DS, Norfolk TS, Brant TS, Powerline MTS, Dundas 1 and 2 TS, Newton TS, Mohawk TS, Nebo, Woodstock TS and Commerce Way TS	Hydro One, GrandBridge Energy, Alectra
Various station and supply capacity	If feasible and cost-effective, permanently/temporarily transfer load from Bloomsburg DS, Norfolk TS, Brant TS, Powerline MTS, Dundas 1 and 2 TS, Newton TS, Mohawk TS, and Nebo to nearby stations	Hydro One, GrandBridge Energy, Alectra

2.3 Medium-Term Plans

The Technical Working Group recommends the medium-term plans summarized in Table 3 to bridge the gap between the interim and long-term solutions. Multiple needs are grouped together when they will be resolved by the same solution. The following sections discuss these medium-term plans.

2.3.1 Battery Energy Storage System in the Norfolk-Bloomsburg Area

To address the Norfolk-Bloomsburg Area supply capacity in the medium term ahead of a long-term wires solution, the Technical Working Group recommends a battery energy storage system (BESS). The BESS should be connected to both 115 kV supply circuits (C9 and C12) between the Bloomsburg junctions and Norfolk TS, preferably at Norfolk TS.

To be a viable solution, the BESS must always remain connected to the transmission system and provide reactive power (Mvar) support for extended periods of time, irrespective of its active power output. The continuous reactive power capability would determine the minimum requirements of rated capacity and storage (MW/MWh) for a viable BESS solution. Because of the timing, specific location and combination of active and reactive power requirements, the IESO will investigate the most appropriate implementation mechanism to procure the BESS.

The operational measures described in the previous section may be necessary to secure the system under outages on the BESS solution.

2.3.2 Two New 230 kV DESNs at Dundas Station

As part of the long-term solution, discussed in the next section, and to address the supply capacity needs for the Hamilton 115 kV Subsystem within the Brant 115 kV Extended Area, the Technical

Working Group recommends transferring the loads of both Dundas TS DESNs from the 115 kV subsystem to the 230 kV subsystem. This may be achieved by either: constructing two new 230 kV Dual Element Spot Network (DESN) at the Dundas switchyard, or converting the existing DESNs from 115 kV to 230 kV supply. In either case, the 230 kV supply will be the existing 230 kV Middleport to Burlington circuits, M27B and M28B, which pass next to the station.

If the new DESNs are pursued, each should have an approximate LTR of 200 MVA, and the LDCs (Hydro One Distribution and Alectra Utilities Corporation) should entirely transfer the loads from the existing Dundas TS DESNs onto the new 230 kV DESNs.

The choice between constructing new DESNs or converting existing DESNs will be determined in the upcoming Regional Infrastructure Planning (RIP) led by the transmitter. However, constructing new DESNs will also resolve the Dundas station capacity needs, whereas converting the existing DESNs will not resolve these needs.

Table 3 | Medium-Term Plans for Supply and Station Capacity Needs

Need	Recommendation	Lead Responsibility	Expected In-Service
Norfolk-Bloomsburg Area Supply Capacity	Procure BESSs[*] capable of always providing reactive power support[**] connecting to C9 and C12 between the Bloomsburg junctions and Norfolk TS	IESO	2029 or earlier[***]
Hamilton 115 kV Subsystem Supply Capacity and Dundas 1 and 2 Station Capacity	Construct two new 230 kV DESNs[****] each with an LTR of ~200 MVA at the Dundas switchyard connecting to the nearby Middleport to Burlington circuits (M27B and M28B)	Hydro One	2032 or earlier[***]
	Entirely transfer the Dundas loads from the existing 115 kV DESNs to the new 230 kV DESNs	Hydro One and Alectra	

[*] Under BESS outage conditions, operational measures discussed in Section 2.2 for the Norfolk-Bloomsburg Area may be required to secure the system.

[**] Depending on the amount of reactive power (Mvar) support the BESSs can constantly provide, minimum requirements on the rated capacity and storage (MW/MWh) of the BESSs are specified and the BESSs may potentially be combined with other NWAs, e.g., renewables, CDM or load transfer, to make this option viable and cost-effective.

[***] Provided years are estimated maximum timelines to bring solution in-service; however, implementation should be expedited to bring in-service as soon as possible.

[****] Rather than building a new DESN, the existing DESNs may be converted from a 115 kV supply to a 230 kV supply by replacing all 115 kV station equipment. The subsequent Transmitter-led Regional Infrastructure Plan (RIP) will identify the most cost-effective approach that addresses the needs and develop a detailed plan for implementation.

2.4 Long-Term Plans

The long-term plans comprise several recommendations to resolve needs and to support long-term load growth. These recommendations are summarized in Table 3 and further discussed below. The recommended wires solutions will need to be initiated as soon as possible, starting with the upcoming Regional Infrastructure Planning (RIP) led by the transmitter.

The operational procedures which were recommended as the interim solutions will no longer be required after the needs are addressed with the long-term plans.

Table 4 | Long-Term Plans for Supply and Station Capacity Needs

Need	Recommendation	Lead Responsibility	Expected In-Service
Norfolk-Bloomsburg Area Supply and Station Capacity	Construct one new 230 kV DESN* with an LTR of ~200 MVA within or in the vicinity of Simcoe connecting to the Nanticoke TS with a new 230 kV double-circuit line*	Hydro One	2035
	Entirely transfer the Norfolk and Bloomsburg loads to the new 230 kV DESN	Hydro One	
Brant 115 kV Subsystem Supply Capacity and Brant and Powerline Station Capacity	Construct two new 230 kV DESNs* each with an LTR of ~200 MVA within or in the vicinity of County of Brant connecting to the Middleport to Detweiler corridor with new 230 kV extensions**	Hydro One	2035
	Entirely transfer the Brant and Powerline loads to the new 230 kV DESNs	GrandBridge Energy	
Woodstock 115 kV Subsystem	If the Woodstock Subsystem total net load exceeds 113 MW, separate it from Brant Subsystem by pre-contingency opening the Brant DB2 breaker	IESO and Hydro One	***
Caledonia Station Capacity	Implement targeted and cost-effective CDM to defer the need from 2034 and monitor the demand growth for advancing the need	IESO	****
Brantford Station Capacity	Implement targeted and cost-effective CDM to defer the need from 2035 and monitor the demand growth for advancing the need	IESO	****

* Rather than building a new DESN, the existing DESNs may be converted from a 115 kV supply to a 230 kV supply by replacing all 115 kV station equipment. The subsequent Transmitter-led Regional Infrastructure Plan (RIP) will identify the most cost-effective solution and develop a detailed plan for implementation.

** Since new DESNs are connected to the lines in the Kitchener/Waterloo/Cambridge/Guelph (KWCG) region, the ongoing KWCG IRRP will finalize the connection arrangement and details of this option.

*** The timing of this option is after the load transfers of Dundas 1 and 2, Brant and Powerline Stations from the existing 115 kV to new 230 kV DESNs are complete.

**** CDM program design and implementation start after the IRRP is finished and continue over the planning horizon.

2.4.1 One New 230 kV DESN and Transmission Line into Simcoe

To address the supply capacity need to the Norfolk-Bloomsburg Area and to address station capacity needs at Bloomsburg DS and Norfolk TS, the Technical Working Group recommends constructing a new 230 kV double-circuit transmission line from Nanticoke TS into the vicinity of Simcoe, and either:

constructing one new 230 kV DESN, or converting Bloomsburg DS and Norfolk TS from 115 kV to 230 kV supply.

If the new DESN is pursued, it should have an approximate LTR of 200 MVA, and Hydro One Distribution should entirely transfer the loads from Bloomsburg DS and Norfolk TS onto the new 230 kV DESN.

The line routing and choice between constructing a new DESN or converting existing DESNs will be determined in the upcoming Regional Infrastructure Planning (RIP) led by the transmitter. However, constructing new DESNs will also resolve the Bloomsburg DS and Norfolk TS station capacity needs, whereas converting the existing DESNs will not resolve these needs.

2.4.2 Two New 230 kV DESNs and Transmission Line into County of Brant

To address supply capacity needs to the Brant 115 kV Subsystem and to address station capacity needs at Brant TS and Powerline MTS, the Technical Working Group recommends constructing a new 230 kV double circuit extension of the Middleport to Detweiler corridor into the vicinity of County of Brant, and either: constructing two new 230 kV DESNs, or converting Brant TS and Powerline MTS from 115 kV to 230 kV supply. However, constructing new DESNs will also resolve the Brant TS and Powerline MTS station capacity needs, whereas converting the existing DESNs will not resolve these needs.

If the new DESNs are pursued, each should have an approximate LTR of 200 MVA, and GrandBridge Energy Inc. should entirely transfer the loads from Brant TS and Powerline MTS onto the new 230 kV DESNs.

Since the DESNs (new or converted) are connected to the lines in the KWCG region, the ongoing KWCG IRRP will finalize the connection arrangement and details of this option.

Please note that this plan in combination with the new Dundas 230 kV DESNs (see Section 2.3.2) will address the supply capacity need in the Hamilton 115 kV Subsystem up to the sum of the capacities of the remaining stations, namely, Elgin, Mohawk and Newton TS and CTS3.

2.4.3 Separate Woodstock 115 kV Subsystem from Brant 115 kV Subsystem

To address the supply capacity need to the Woodstock 115 kV Subsystem after transferring the loads to new 230 kV DESNs as explained in Section 2.3.2 and 2.4.2, the Technical Working Group recommends that the Brant DB2 115 kV circuit breaker be opened pre-contingency for a total net load in the Woodstock Subsystem above 113 MW. This will separate the Woodstock from Brant 115 kV Subsystem and increase the LMC of the Woodstock 115 kV Subsystem to 210 MW.

2.5 Ongoing Initiatives

In addition to the plans above, four ongoing actions were identified to manage long-term needs for the Burlington to Nanticoke Region in general and for the Hamilton subregion, in particular.

2.5.1 Undertake a Comprehensive Study of the Hamilton Subregion

Following Public Webinar #1 for the Burlington to Nanticoke IRRP in September 2023, electrification and decarbonization plans were identified which will have a significant impact on the Hamilton area.

In response, a new forecast for Hamilton was produced in June 2024, which resulted in a 230 MW or 11 per cent increase relative to the previous forecast.

Based on the new Hamilton demand forecast, several station capacity needs were identified. To the extent possible, some of these needs were assessed as part of this IRRP. Specifically, assessment of the Hamilton 115 kV Subsystem within the Brant 115 kV Extended Area and subsequent long-term recommendation will help address some of these supply and station capacity needs, namely at Dundas TS. The remaining needs warrant a more fulsome assessment of needs, which were too significant to fully assess and address within the IRRP timelines. Given the rapid growth in the Area, collecting more information on supply options and conducting integrated planning for the revised needs is critical to ensuring the continued reliability of this subregion. Thus, the Technical Working Group recommends that a Hamilton Addendum be undertaken, to fully assess and address the needs of the Hamilton subregion. Please see Appendix J for an initial scope of the Addendum.

The Addendum will kick-off in 2025 and finish within 12 months of formal kick-off. In early 2025, the terms of reference will be published by the TWG and will build upon the scope outlined in Appendix J, by confirming the objectives and establishing timelines. An engagement plan will also be created, which will outline expectations for webinars and targeted outreach with key stakeholders over the 12-month addendum process.

2.5.2 Monitor Load Growth and Continue to Explore Opportunities for Targeted CDM

The Technical Working Group recommends that the LDCs and IESO continue to monitor long-term growth at Brantford TS and Caledonia TS between regional planning cycles to determine when decisions on the long-term plan are required and inform the next cycle of regional planning for the region, as required.

In addition, the Technical Working Group recommends continuing to consider opportunities for targeted CDM, identifying the benefits and potential of incremental, cost-effective CDM particularly if targeted to help manage near-term needs until transmission reinforcements are in-service or to defer long-term needs. The Technical Working Group should continue to support and monitor CDM uptake and bring these insights into the next cycle of regional planning for the Burlington to Nanticoke Region.

2.5.3 Data Centre and Industrial Load Growth

The IESO has been made aware of a growing number of large data centre connection requests (100-1000 MW each) throughout the province, as well as an increase in requests for industrial load growth (see Section 6.2.4). At the time of this IRRP publication, the Technical Working Group is aware of significant interest from multiple potential customers throughout the region at various commitment levels, with interest from 700-1,700 MW of data centre connections within the Caledonia-Norfolk Subregion alone, which have not been captured in this IRRP forecast. Given the magnitude of such load growth, wires solutions are commonly the only technically feasible solution but require a lead time of 7-10 years.

To help mitigate the risks posed by these large but uncertain connection requests, the IESO will continue to monitor data centre and industrial growth patterns within the Burlington to Nanticoke Region and the province at large. The IESO is also undertaking a South and Central Bulk Plan to review the capability of the bulk system to support future generation connections and demand

growth in key areas throughout southern and central Ontario to enable a decarbonized power system in the future. This study will continue the assessment of the bulk transmission system between the Hamilton and Windsor areas to understand future transmission needs that could result from further economic development. In addition, when developing solutions to address needs, the IESO will evaluate different scenarios, to support more complex considerations, to ensure that recommendations are optimal under a range of future scenarios.

3 Development of the Plan

3.1 The Regional Planning Process

In Ontario, preparing to meet the electricity needs of customers at a regional level is achieved through regional planning. Regional planning assesses the interrelated needs of a region – defined by common electricity supply infrastructure – over the near, medium, and long-term, and results in a plan to ensure cost-effective and reliable electricity supply. A regional plan considers the existing electricity infrastructure in an area, forecasts growth and customer reliability, evaluates options for addressing needs, and recommends actions.

The current regional planning process was formalized by the Ontario Energy Board in 2013 and is performed on a five-year cycle for each of the 21 planning regions in the province. The process is carried out by the IESO, in collaboration with the transmitters and LDCs in each region. The process consists of four main components:

1. A Needs Assessment, led by the transmitter, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;
2. A Scoping Assessment, led by the IESO, which identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities;
3. An IRRP, led by the IESO, which proposes recommendations to meet the identified needs requiring coordinated planning; and/or
4. A RIP, led by the transmitter, which provides further details on recommended wires solutions.

Regional planning is not the only type of electricity planning in Ontario. Other types include bulk system planning and distribution system planning. There are inherent overlaps in all three levels of electricity infrastructure planning. Further details on the regional planning process and the IESO's approach to it can be found in Appendix A.

The IESO has recently completed a review of the regional planning process, following the completion of the first cycle of regional planning for all 21 regions. Additional information on the Regional Planning Process Review, along with the final report is posted on the IESO's website.

3.2 Burlington to Nanticoke IRRP Development

The process to develop the Burlington to Nanticoke IRRP was initiated in December 2022, following the publications of the Needs Assessment Report in September 2022 by Hydro One and the Scoping Assessment Outcome Report in December 2022 by the IESO. The Scoping Assessment recommended that the needs identified for the Burlington to Nanticoke Region be considered through an IRRP in a coordinated regional approach, supported with public engagement. The Technical Working Group was then formed to develop the terms of reference for this IRRP, gather data, identify needs, develop options, and recommend solutions for the region.

4 Background and Study Scope

This is the third cycle of regional planning for the Burlington to Nanticoke Region. This Region is located in southwestern Ontario and includes all or part of the following Counties and Districts:

City of Hamilton	City of Brantford	Norfolk County	Town of Oakville
County of Brant	Haldimand County	City of Burlington	

For electricity planning purposes, the planning region is defined by electricity infrastructure boundaries, not municipal boundaries.

This Region also includes several Indigenous communities, located within or near the Region:

Mississaugas of the Credit First Nation	Métis Nation of Ontario:
Six Nations of the Grand River	Clear Waters Métis Council
Haudenosaunee Confederacy Chiefs Council	Grand River Métis Council

Following a Needs Assessment and Scoping Assessment in 2017, an IRRP and subsequent RIP were initiated and published in 2019, concluding the second planning cycle for the Region.

This IRRP develops and recommends options to meet the electricity needs of the Burlington to Nanticoke Region in the near, medium, and long term. The plan was prepared by the IESO on behalf of the Technical Working Group, and includes consideration of forecast electricity demand growth, CDM, distributed generation (DG), transmission and distribution system capability, relevant community plans, condition of transmission assets, and developments on the bulk transmission system.

The following transmission facilities were included in the scope of this study:

Transformer stations:

Beach TS	Bronte TS	Dundas 2 TS	Kenilworth TS	Norfolk TS
Birmingham TS	Burlington TS	Elgin TS	Lake TS	Powerline MTS
Bloomsburg DS	Caledonia TS	Gage TS	Mohawk TS	Stirton TS
Brant TS	Cumberland TS	Horning TS	Nebo TS	Winona TS
Brantford TS	Dundas TS	Jarvis TS	Newton TS	CTS1 to CTS6

115 kV transmission circuits:

B3	B6G	B10	B13BL	HL3	H6K	K2G
B4	B7	B11	C9	HL4	H9W	Q2AH
B5G	B8	B12BL	C12	H5K	K1G	

230 kV transmission circuits:

B18H	M34H	M20D	M31W	N6M	N20K	Q30M
B20H	H35D	M21D	M32W	N21J	Q24HM	Q29HM
B40C	H36D	M27B	M33W	N22J	Q23BM	S39M
B41C	K40M	M28B	N5M	N37S	Q25BM	

The Burlington to Nanticoke Region covers a large portion of the transmission system in southwest Ontario, and for this reason it has been broken up into four subregions:

- Brant Subregion
- Bronte Subregion
- Caledonia-Norfolk Subregion
- Hamilton Subregion

Based on the Needs Assessment led by Hydro One in the beginning of the planning process, regional planning was required for the Burlington to Nanticoke Region except for the Bronte Subregion. Figure 2 to Figure 4 show single line diagrams of the subregions and subsystems for which the regional plan was conducted.

The Brant subregion consists of the following stations:

Brant TS	Brantford TS	Powerline MTS.

The Caledonia-Norfolk subregion consists of the following stations:

Bloomsburg DS	Jarvis TS	Caledonia TS
Norfolk TS	CTS1	CTS2

The Hamilton subregion consists of the following stations:

Beach TS	Dundas 2 TS	Horning TS	Mohawk TS	Stirton TS
Birmingham TS	Elgin TS	Kenilworth TS	Nebo TS	Winona TS
Dundas TS	Gage TS	Lake TS	Newton TS	CTS3 to CTS5

Note need assessments for the Brant 115 kV Subsystem, that includes Brant TS and Powerline MTS, could not be conducted in isolation and the area of study was extended to the entire 115 kV system enclosed between the Burlington and Karn 115 kV stations. Therefore, in addition to the Woodstock 115 kV Subsystem in the London Area, CTS3, Dundas, Dundas 2, Mohawk, Newton and Elgin stations in the Hamilton 115 kV Subsystem were also included in the studies. This is referred to as the Brant 115 kV Extended Area and is shown in Figure 2.

The Woodstock 115 kV Subsystem is not part of the Burlington to Nanticoke Region and was considered in the analysis of this IRRP because of its impact on the 115 kV Subsystems in the Brant and Hamilton subregions (please see "Brant 115kV Extended Area" in Section 6.3). The Woodstock subregion is part of the London Area Region, and consists of Commerce Way TS, Woodstock TS and CTS6.

Note that the bulk system transfer capabilities on the Buchanan Longwood Input (BLIP) and Queenston Flow West (QFW) interfaces through the region is not within the scope of the IRRP and would be separately studied in a bulk transmission plan, as required. The schedule of bulk planning activities is identified through the IESO's Annual Planning Outlook.

Figure 2 | Single Line Diagram of Brant 115 kV Extended Area, the Brant 115 kV Subsystem, the Hamilton 115 kV Subsystem, and the Woodstock 115 kV Subsystem

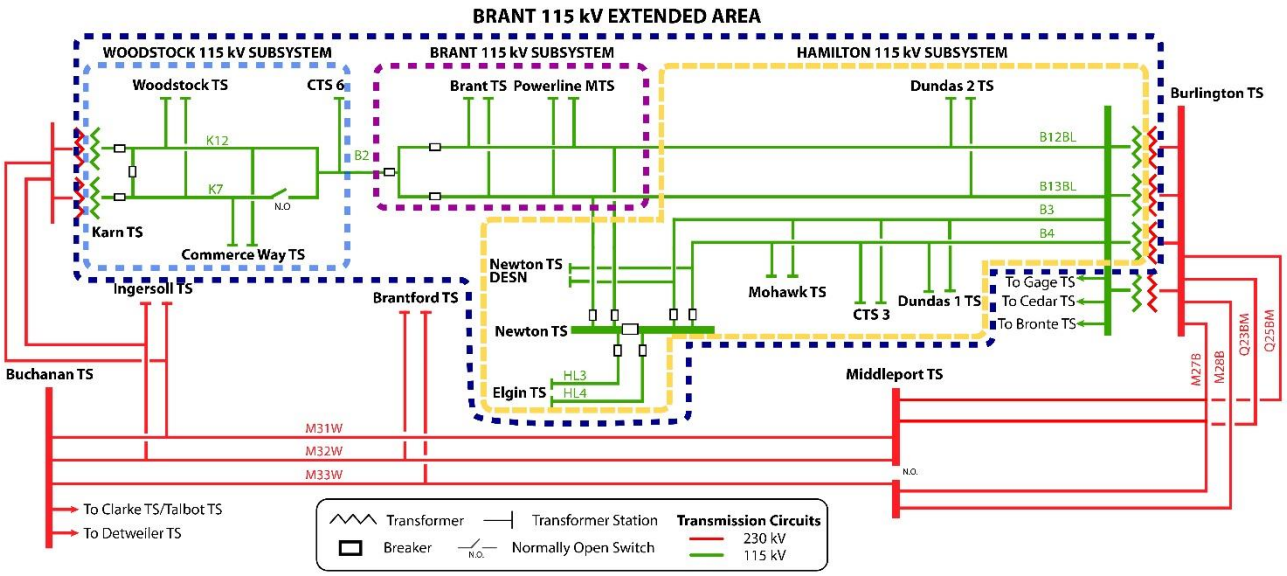


Figure 3 | Single Line Diagram of the Caledonia-Norfolk Subregion and Norfolk-Bloomsburg Area

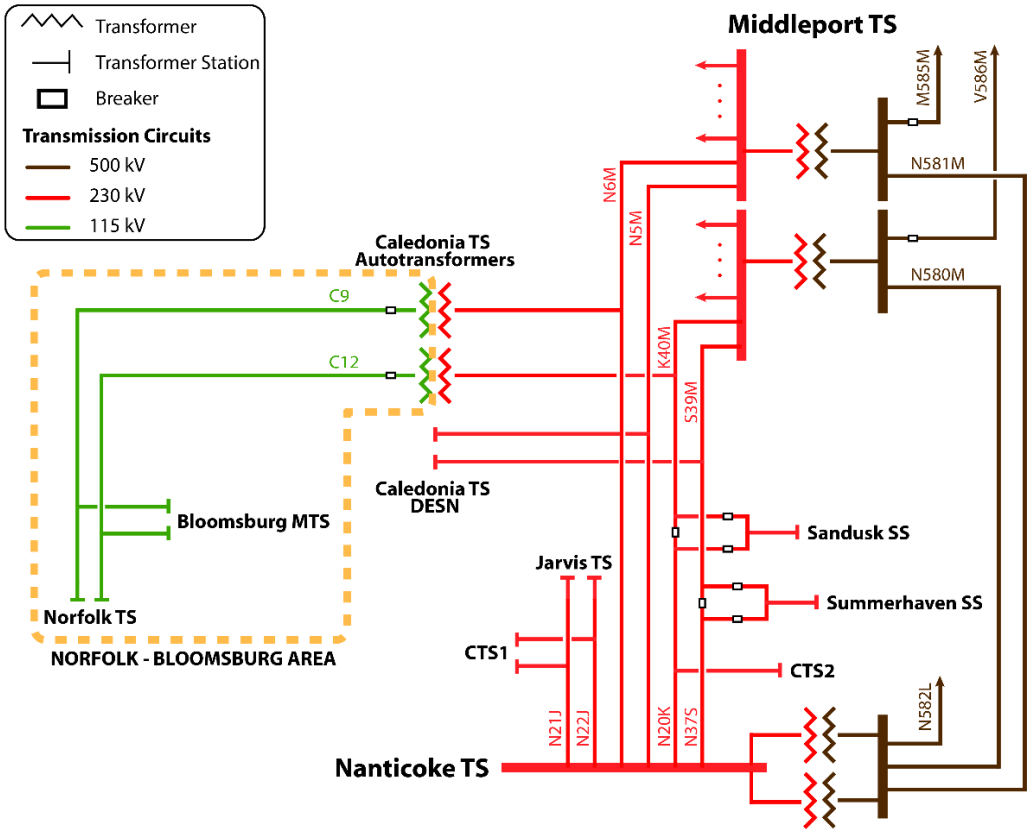

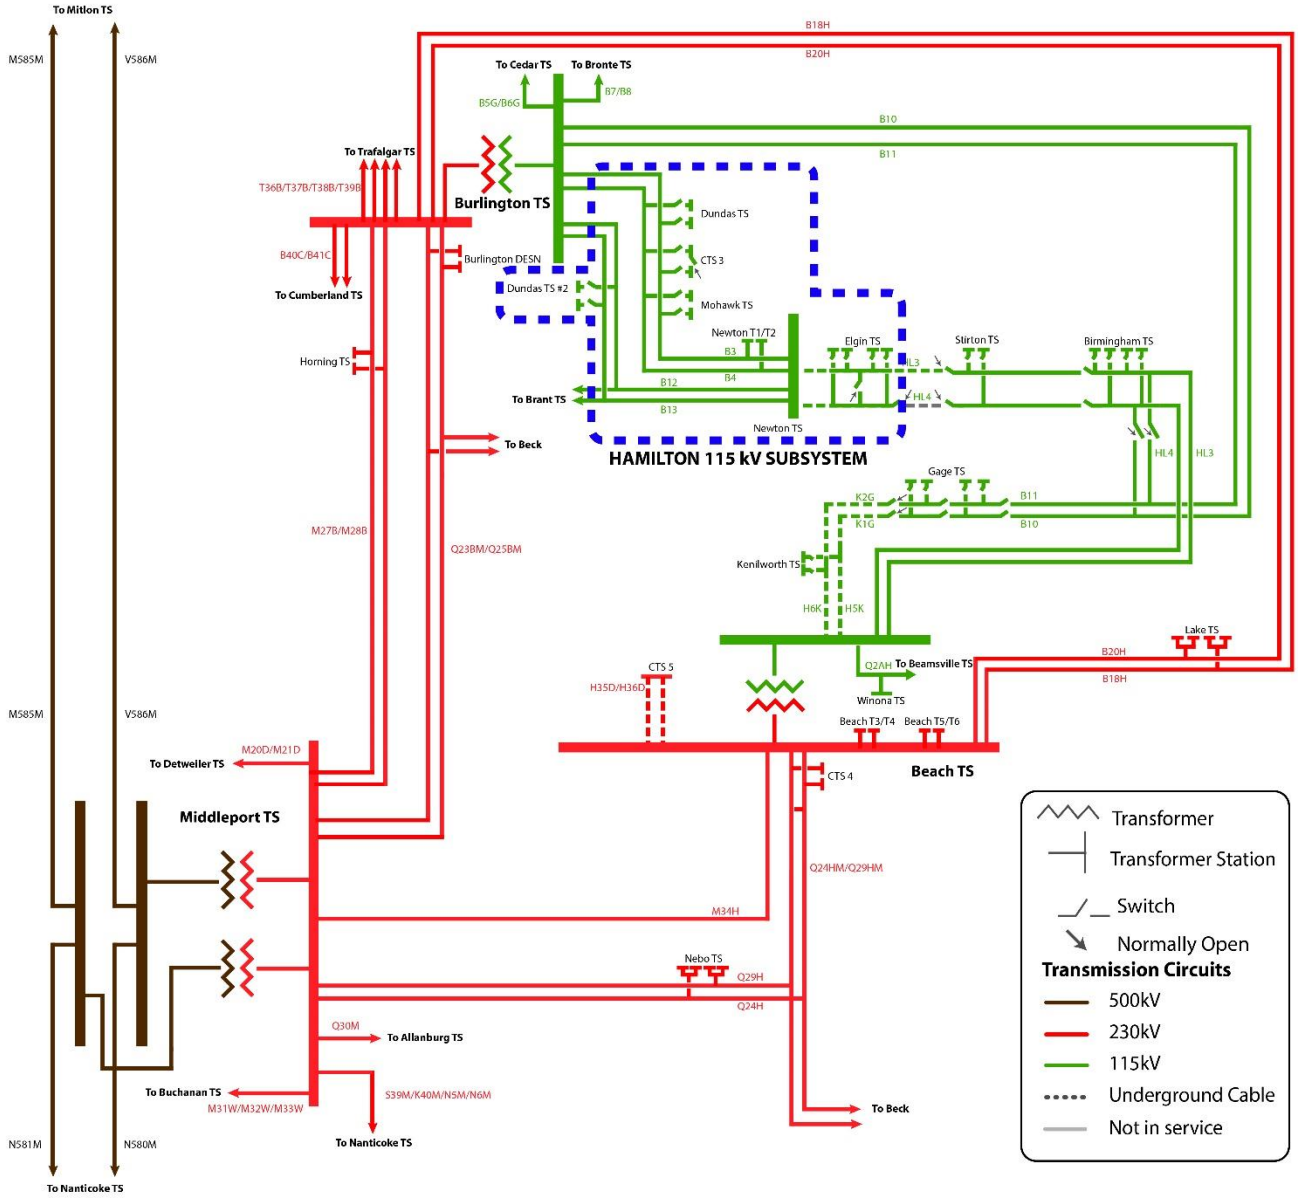

Figure 4 | Single Line Diagram of the Hamilton Subregion and Hamilton 115 kV Subsystem

The Burlington to Nanticoke IRRP was developed by completing the following steps:

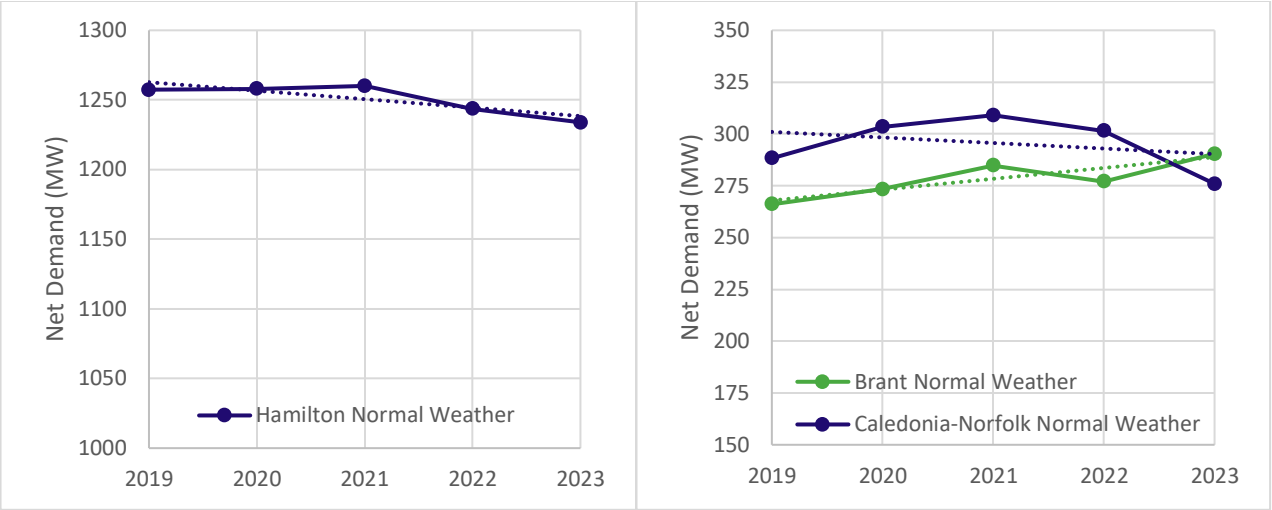
- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe (as described in the following steps);
- Examining the load meeting capability (LMC) and reliability of the existing transmission system, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC and NERC criteria.
- Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO-controlled grid.
- Confirming identified asset replacement needs and timing with the transmitter and LDCs.

- Establishing alternatives to address system needs including, where feasible and applicable, generation, transmission and/or distribution, and other approaches such as non-wire alternatives including CDM.
- Engaging with the community on needs and possible alternatives.
- Evaluating alternatives to address near- to long-term needs; and
- Communicating findings, conclusions, and recommendations within a detailed plan.

5 Electricity Demand Forecast

Regional planning in Ontario is driven by having to meet peak electricity demand requirements in the region. This section describes the development of the demand forecast for the Burlington to Nanticoke Region. It highlights the assumptions made for peak demand forecasts, including weather correction, and the contribution of CDM and DG. Both a reference and high growth scenario were provided by Hydro Onde Distribution for their service territory, while the other LDCs only provided a reference scenario. Compared with their reference scenario, Hydro One Distribution's high growth scenario additionally considered potential upcoming load connections with a lower degree of commitment (e.g., capacity inquiries, long-term assumptions from municipal plans, etc.). The high growth scenario from Hydro One Distribution was used for the "planning" forecast, since the difference with the reference scenario they provided was only marginal.

To evaluate the reliability of the electricity system, the regional planning process is typically concerned with the coincident peak demand for a given area. This is the demand observed at each station for the hour of the year in which overall demand in the study area is at its maximum. In the case of this IRRP, three study areas were developed corresponding to the three subregions: Brant, Caledonia-Norfolk, and Hamilton.



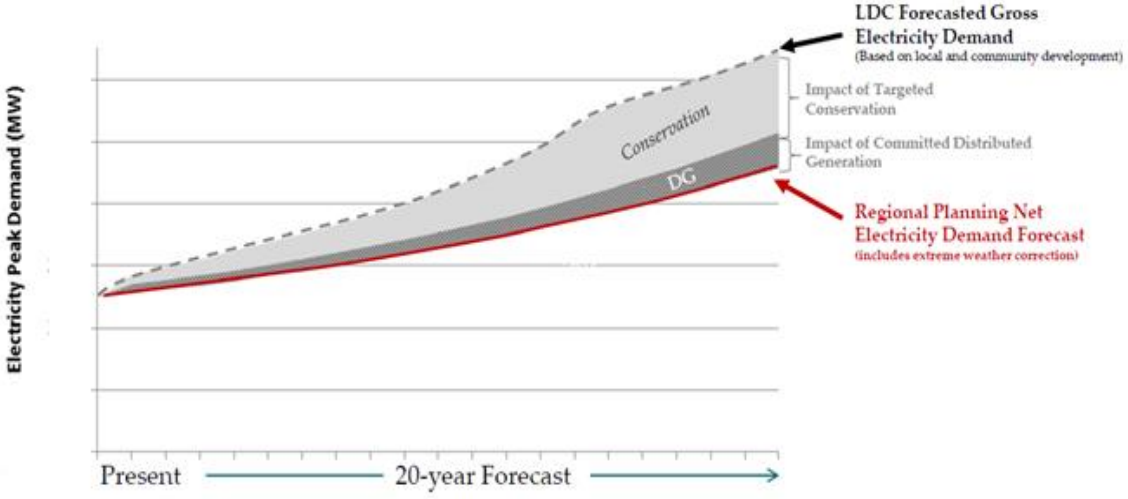
The coincident peak differs from a non-coincident peak, which refers to each station's individual peak, regardless of whether these peaks occur at different times. Each subregion of the Burlington to Nanticoke Region is summer peaking.

5.1 Historical Demand

Peak electricity demand within the Burlington to Nanticoke Region has been on average steady over 2019 to 2023. Figure 5 below shows the coincident net normal weather-corrected (adjusted to reflect normal weather conditions) historical demand for each subregion, which have unique trends. Weather-corrected historical demands have been shown to remove the effect of weather on annual changes in demand. Weather-corrected demand is more appropriate for evaluating growth trends. The peak demand hour for each year occurred consistently in the summer between approximately 2 PM to 7 PM.

The net weather-corrected demand for the Brant, Caledonia-Norfolk, and Hamilton subregions has averaged 278 MW, 296 MW, and 1251 MW, respectively, over the last five years with negligible upward or downward trends. Demand has slightly been increasing for the Brant subregion while slightly declining for the Caledonia-Norfolk and Hamilton subregions.

Figure 5 | Historical Subregion Normal-Weather Demands



5.2 Demand Forecast Methodology

The methodology used to develop a 20-year IRRP peak demand forecast starting from LDC forecasts is illustrated in Figure 6. Gross demand forecasts, which assume the weather conditions of a normal year based on historical weather conditions (referred to as "normal weather"), were developed by the LDCs. These forecasts were then modified to reflect the peak demand impacts of provincial conservation targets and DG contracted through previous provincial programs, such as Feed-In Tariff (FIT) and microFIT, and adjusted to reflect extreme weather conditions in order to produce a reference forecast for planning assessments. This net forecast was then used to assess the electricity needs in the region.

Additional details related to the development of the demand forecast are provided in Appendix B. The Ontario Energy Board also since published a Load Forecast Guideline for regional planning, through the Regional Planning Process Advisory Group.

Figure 6 | Illustrative Development of Demand Forecast

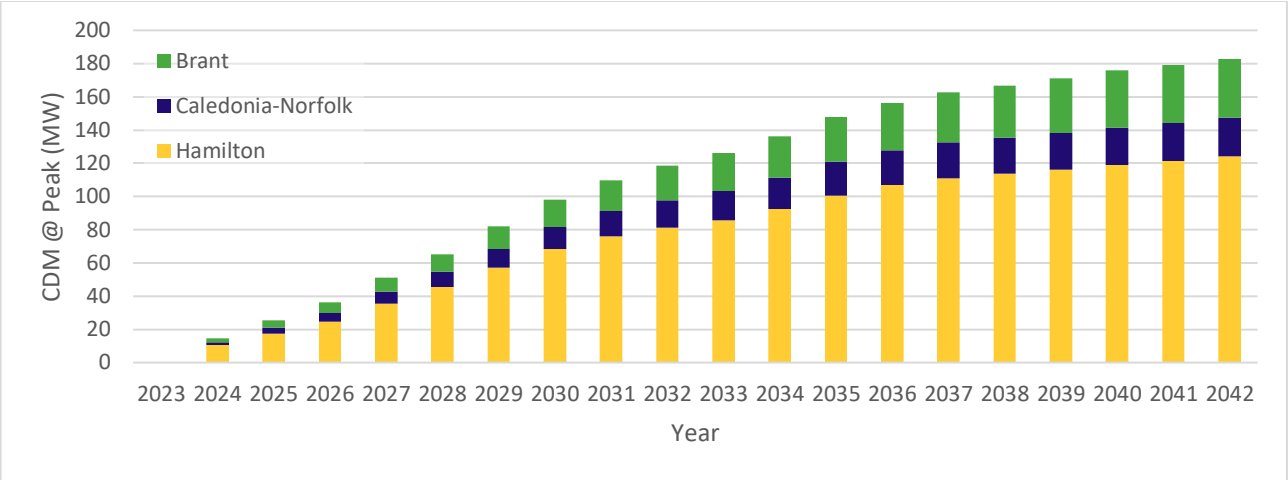
5.3 Gross LDC Forecast

Each participating LDC in the Burlington to Nanticoke Region prepared gross demand forecasts at the station level, or at the station bus level for multi-bus stations. These gross demand forecasts account for increases in demand from new or intensified development, plus known connection applications. In addition, when producing these gross demand forecasts, the impact of existing DG was removed, as DG impacts are accounted for later (see Section 5.5). Therefore, gross demand forecasts show the demand expected without any DG contributions, new or existing. Please see Section B.1 of Appendix B for more detail.

The LDCs cited alignment with municipal and regional plans and credited them as a source for input data. LDCs were also expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices (natural conservation), but not for the impact of future DG or new conservation measures (such as codes and standards and CDM programs), which are accounted for by the IESO (discussed in Section 5.4). The gross LDC forecast assumes normal weather conditions (e.g. median weather, expected 1 in 2 years), and peak station loading which may be non-coincident to the regional peak.

LDCs have a better understanding of future local demand growth and drivers than the IESO, since they have the most direct involvement with their customers, connection applicants, municipalities and communities which they serve. The IESO typically carries out demand forecasting at the provincial level. More details on the LDCs' load forecast assumptions can be found in Appendix B.

5.4 Contribution of Conservation to the Forecast



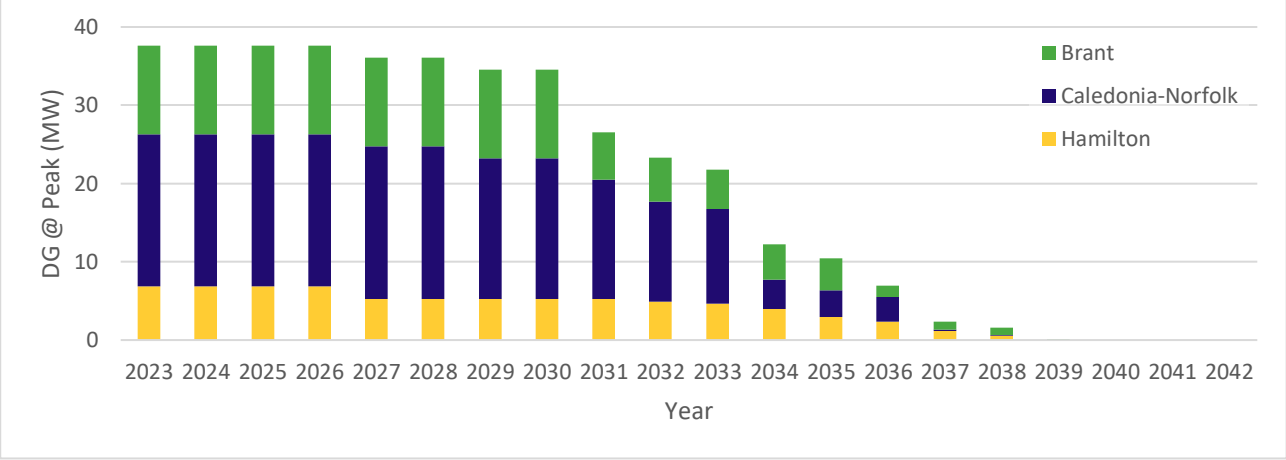
Conservation and demand management is a non-emitting and cost-effective resource that helps meet Ontario's electricity needs by reducing electricity consumption and peak-demand, and has been an integral component of provincial and regional planning. Conservation is achieved through a mix of codes and standards amendments, as well as CDM program-related activities. These approaches complement each other to maximize conservation results.

The estimated demand reduction from codes and standards is based on expected improvement in the codes for new and renovated buildings, and through regulation of minimum efficiency standards for equipment used by specified categories of consumers (i.e., residential, commercial and industrial consumers).

The estimated demand reduction from program-related activities is based on the 2021-2024 CDM Framework, federal programs that result in electricity savings in Ontario, and forecasted long-term energy efficiency programs assumed to be consistent with current framework savings levels. Through the ongoing 2021-2024 CDM Framework the IESO centrally delivers programs on a province-wide basis to serve business and low-income customers, as well as Indigenous communities. At the time of forecast development and IRRP publication, actual energy and peak demand savings targets for the new 2025-2036 framework are not confirmed. Should the new savings targets be higher, it may push out the timing or reduced the magnitude of identified needs.

Figure 7 shows the estimated total yearly reduction to the demand forecast due to conservation (from codes, standards, and CDM programs) for each subregion. Additional details are provided in Appendix B.

Figure 7 | Peak Demand Reduction Due to Conservation and Demand Management



5.5 Contribution of Distributed Generation to the Forecast

In addition to conservation resources, DG is also forecasted to offset peak-demand requirements. The introduction of Ontario's FIT and microFIT Programs increased the significance of distributed renewable generation which, while intermittent, contributes to meeting the province's electricity demands. The installed DG capacity by fuel type and the associated contribution factor assumptions can be found in Appendix B. Most of the total contracted installed DG capacity in the Burlington to Nanticoke Region is solar generation, but there is a comparable quantity of non-renewable generation. In the Brant and Hamilton subregions, the split is approximately equal, but in the Caledonia-Norfolk region there is only renewable generation, which is almost entirely solar.

Figure 8 shows the estimated impact of DG on the Burlington to Nanticoke Region demand forecast. Note that any facilities without a contract with the IESO are not currently included in the DG peak demand reduction forecast.

In the long term, the contribution of DG is expected to diminish as their contracts expire. A total of 38 MW of peak contribution is identified for the Burlington to Nanticoke Region in 2023, reducing to zero by 2039 throughout the 2030s. This reduction is reflected in the Planning forecast as discussed in the next section.

Figure 8 | Peak Demand Reduction Due to Distributed Generation

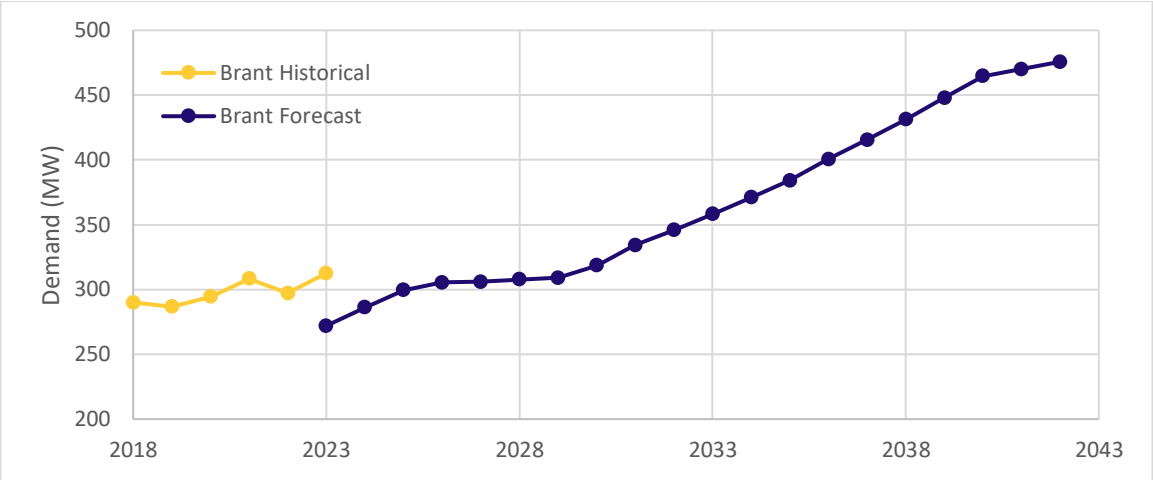
5.6 Net Extreme Weather (Planning) Forecast

The net extreme weather forecast, also known as the "planning" forecast, is traditionally a region-wide coincident forecast, meaning that each station forecast reflects its expected contribution to the regional peak demand. This supports the identification of need dates for regional needs that are driven by more than one station.

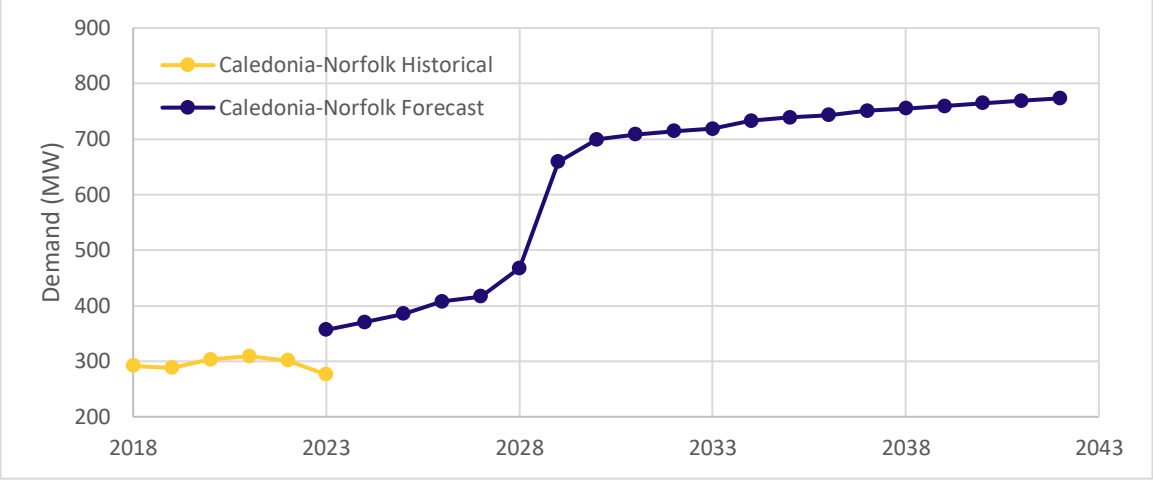
Due to the specific needs of the three subregions within the Burlington to Nanticoke Region (the Brant, Caledonia-Norfolk, and Hamilton subregions), and due to the small or lack of excess capacity remaining on these subregions, the "planning" forecast was produced as a subregion coincident forecast. This means that each station forecast reflects its expected contribution to its subregion 's peak demand rather than the regional peak demand. This puts a greater focus on identifying subregion needs, which was required due to the high level of loading in these subregions.

The planning forecast is produced from three main steps: converting to a coincident forecast, adjusting for extreme weather, and converting to a net forecast.

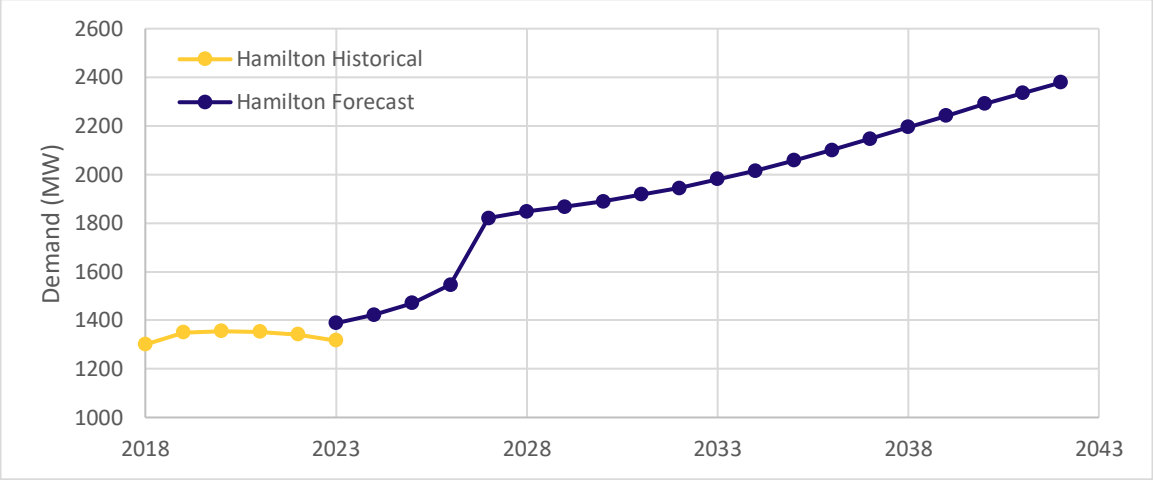
As discussed in Section 5.3, LDCs provide gross forecasts assuming normal weather conditions, and peak station loading that is non-coincident to the region or subregion. Therefore, the first step is to convert this non-coincident forecast to a coincident forecast, by applying a coincidence factor to each station. The factor is based on the station's historical contribution to the subregion peak demand compared to the station's non-coincident peaks over the past five years (2018-2022 in this case). This results in a subregion coincident gross forecast which assumes normal weather.



The second step is to adjust the resulting coincident gross normal weather forecast for extreme weather conditions. The weather correction methodology is described in Appendix B. This results in a coincident gross forecast which assumes extreme weather.



The last step is to adjust the resulting coincident gross extreme weather forecast for DG and conservation impacts. This is done by subtracting the forecasted DG and conservation impacts (as described in the above Sections) from the coincident gross extreme weather forecast. Finally, this results in a (subregional) coincident net extreme weather forecast, which is the "planning" forecast used to identify needs.



For station-specific needs, a non-coincident net extreme weather forecast used instead. The process for producing this forecast is similar as described above, except the first step is skipped.

The subregion coincident net extreme weather forecast ("planning" forecast) for each subregion in the Burlington to Nanticoke Region is shown in Figure 9 below. Historical net extreme weather demands have also been added for reference. The large increases in demand between 2026 to 2030 in the Caledonia-Norfolk and Hamilton subregions are caused by demand increases from a small number of existing industrial customers supplied by the 230 kV subsystems. These demand increases are unrelated to the needs and recommendations discussed in the following sections, which concern the 115 kV subsystems.

Figure 9 | Historical Demand and Planning Forecast for the Subregions

5.7 Hourly Forecast Profiles

In addition to the annual peak demand forecast, hourly demand profiles (8,760 hours per year over the 20-year forecast horizon) for the Bloomsburg DS and Norfolk TS stations were developed to better assess non-wire alternatives to address needs at these stations. In particular, these profiles were used to quantify the magnitude, frequency, and duration of needs, as described later in Section

7. The profiles were based on historical demand data, adjusted for variables that impact demand such as calendar day (i.e., holidays and weekends) and weather. The profiles were then scaled to match the IRRP peak planning forecast for each year.

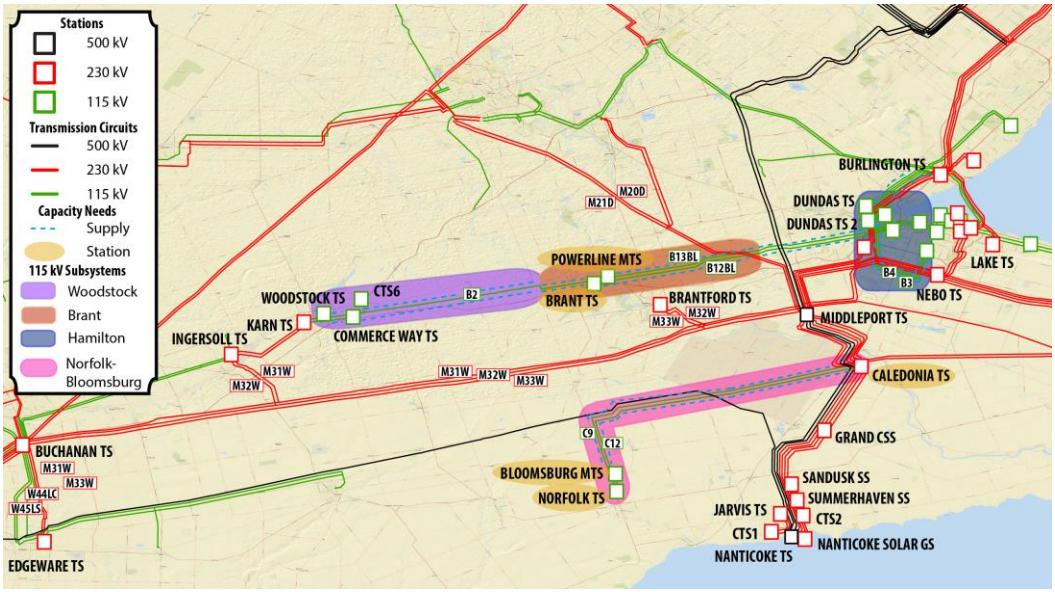
Additional load profile details including hourly heat maps for each need can be found in Appendix D. Note that this data is used to roughly inform the overall energy requirements needed to develop and evaluate alternatives; it cannot be used to deterministically specify the precise hourly energy requirements. Real-time loading is subject to various factors like actual weather, customer operation strategies, and future customer segmentation. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification are more widely adopted. Hence, these hourly forecasts are only used to select suitable technology types and roughly estimate costs for the needs and options studied in the IRRP. The Technical Working Group will continue to monitor forecast changes as part of implementation of the plan.

6 Needs

6.1 Needs Assessment Methodology

Based on the planning demand forecast, system capability, the transmitter's identified asset replacement plans, and the application of ORTAC, NERC TPL-001-4, and Northeast Power Coordinating Council (NPCC) Directory #1 standards, the Technical Working Group identified electricity needs in the near-, medium- and long-term timeframes. These needs can be categorized according to the following:

Station Capacity Needs describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations during peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day Limited Time Rating (LTR) of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be more limited by the thermal ratings of downstream or upstream equipment, i.e., breakers, disconnect switches, medium-voltage bus or high voltage circuits; or, by voltage drop limitations, which are independent of thermal ratings.



Supply Capacity Needs describe the electricity system's inability to provide continuous supply to a local area during peak demand. This is limited by the LMC of the transmission supply. The LMC is determined by evaluating the maximum demand that can be supplied to an area after accounting for limitations of the transmission elements (i.e., a transmission line, group of lines, or autotransformer), when subjected to contingencies and criteria prescribed by ORTAC, TPL-001-4, and NPCC Directory #1. LMC studies are conducted using power system simulation analyses.

Asset Replacement Needs are identified by the transmitter by an asset condition assessment, which is based on a range of considerations such as equipment deterioration due to aging infrastructure or other factors; technical obsolescence due to outdated design; lack of spare parts availability or manufacturer support; and/or potential health and safety hazards, etc. Replacement needs identified in the near- and early mid-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium- to long-term needs should reflect the potential for the need date to change as condition information is routinely updated.

Load Security and Restoration Needs describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC.

Technical study results for the Burlington to Nanticoke IRRP can be found in Appendices G and H. The needs identified are discussed in the following sections, and are shown in Figure 10 below.

Figure 10 | Needs Identified in the Burlington to Nanticoke Region

6.2 Station Capacity Needs

Many station capacity needs emerge in the Burlington to Nanticoke region as shown in Table 5 with the majority in the near-/medium-term. Please see Appendix I, Figures of Station and Supply Capacity Needs, for graphical representation of these needs.

Table 5 | Station Capacity Needs

Time Horizon	Station	Subregion	Emerging Year	2042 Need (MW)
Near-term	Bloomsburg DS	Caledonia-Norfolk	2023	16
	Dundas 2 TS	Hamilton	2023	40
	Nebo TS (T1/T2)*	Hamilton	2023	142
	Nebo TS (T3/T4) *	Hamilton	2023	50
	Dundas TS	Hamilton	2025	59
	Powerline MTS	Brant	2026	68
	Mohawk TS	Hamilton	2026	46
	Brant TS	Brant	2027	41
Medium-term	Norfolk TS	Caledonia-Norfolk	2031	16
	Newton TS	Hamilton	2031	31

Time Horizon	Station	Subregion	Emerging Year	2042 Need (MW)
Long-term	Caledonia TS	Caledonia-Norfolk	2034	20
	Brantford TS	Brant	2035	54
	Lake TS (T1/T2) *	Hamilton	2035	19
	Elgin TS	Hamilton	2037	23
	Horning TS*	Hamilton	2038	14
	Beach TS (T5/T6) *	Hamilton	2042	2

*The station capacity needs were identified using the station load meeting capabilities (LMC) calculated by the IESO from load flow studies, or, if the LMC calculations were deferred to the addendum, using the station limited time ratings (LTR) provided in the transmitter-led Needs Assessment report.

6.2.1 Brant Subregion Station Capacity Needs

The three stations supplying the Brant subregion, Powerline MTS, Brant TS and Brantford TS, are forecasted to exceed their station capacity within the next decade. For a time, overloading at Brant TS and Powerline MTS can be addressed through distribution-level load transfers to Brantford TS until Brantford TS exceeds its capacity. However, by 2031 Brantford TS would no longer have capacity to provide relief, and new capacity is needed in the subregion. Additionally, the technical requirements and cost of upgrading the distribution system may limit the feasibility or viability of load transfer to Brantford TS.

6.2.2 Caledonia-Norfolk Subregion Station Capacity Needs

Half of the stations supplying the Caledonia-Norfolk subregion, Bloomsburg DS, Norfolk TS and Caledonia TS, are forecasted to exceed their station capacity within the next decade. For a time, overloading at these stations can be lessened through distribution-level load transfers to Jarvis TS. However, by 2035 Jarvis TS would no longer have capacity to provide relief, and new station capacity is needed in the subregion. Additionally, feasibility and economic reasons may restrict the amount of the load transfers.

6.2.3 Hamilton Subregion Station Capacity Needs

In the Hamilton subregion, ten out of 19 DESNs are forecasted to exceed their station capacity within the planning horizon. Notably six of these DESNs, i.e., Dundas TS, Dundas 2 TS, Mohawk TS, Nebo TS (T1/T2) and (T3/T4) and Newton TS, are identified with station capacity needs with a near- or medium-term timeframe.

The majority of needs for the Hamilton subregion will be addressed in the Hamilton Addendum as discussed in Section 2.5.1. However, the needs of the Dundas stations will be addressed by the Technical Working Group recommendations as part of the Brant 115 kV Extended Area as described in Section 6.3.

6.2.4 Customer-Owned Transformer Stations

Two customer-owned transformer stations (CTS) within the Burlington to Nanticoke Region are forecasted to exceed their station capacity. Since these stations are privately owned, the private owners will need to coordinate their solution with the IESO and transmitter (Hydro One) via the Connection Assessment and Approval (CAA) process.

6.3 Supply Capacity Needs

Supply capacity needs for the majority of the Hamilton subregion will be assessed and addressed in the addendum as discussed in Section 2.5.1. However, a portion of the Hamilton 115 kV system was included in the need assessments for the Brant subregion because of their impact on one another. This larger area is referred to as the Brant 115 kV Extended Area which, similarly, was further extended on the opposite side to include the Woodstock 115 kV Subsystem. In summary, the Brant 115 kV Extended Area consists of:

- **Brant 115 kV Subsystem:** the Powerline and Brant stations in the Brant subregion supplied via B12BL, B13BL, and B2
- **Hamilton 115 kV Subsystem:** the Dundas, Dundas 2, Mohawk, Newton, Elgin and CTS3 stations in the Hamilton subregion supplied via B12BL, B13BL, B3, and B4
- **Woodstock 115 kV Subsystem:** the Woodstock, Commerce Way and CTS6 stations in the Woodstock subregion of the London Area supplied via K7, K12 and B2

Table 6 shows the supply capacity needs identified for the Norfolk-Bloomsburg Area in the Caledonia-Norfolk subregion and various Subsystems in the Brant 115 kV Extended Area. Please see Appendix I, Figures of Station and Supply Capacity Needs, for graphical representation of these needs.

The LMC of the Norfolk-Bloomsburg Area, which is radially supplied via circuits C9 and C12, is limited by voltage constraints to 80 MW, well below the thermal limitation of the circuits at 150 MW. This Area has an immediate need of 33 MW in 2023 which increases to 78 MW in 2042.

Supply capacity needs for the Brant 115 kV Extended Area were identified based on its Subsystems: the Brant, Hamilton and Woodstock 115 kV Subsystems.

- The Brant 115 kV Subsystem has an immediate need of 3 MW in 2023 and a long-term need of 129 MW in 2042. The LMC of the Brant 115 kV Subsystem is presently limited by thermal limitations on circuits B12BL and B13BL to 134 MW, but following that, voltage constraints limit the LMC to nearly the same limit of 137 MW.
- The combined Brant and Hamilton 115 kV Subsystems has an immediate need of 66 MW in 2023 which increases to 483 MW in 2042. The LMC of the combined Subsystems is presently limited by thermal limitations on circuits B12BL and B13BL to 500 MW, but following that, voltage constraints limit the LMC to nearly the same limit of 535 MW.
- The Woodstock 115 kV Subsystem has an immediate need of 20 MW in 2023 which increases to 47 MW in 2042. The LMC of the Woodstock 115 kV Subsystem is presently limited by voltage constraints to 85 MW.

The magnitudes of the needs shown in Table 6 can reach approximately 100 per cent of the LMC. This indicates that significant reinforcements that are required for the 115 kV Subsystems listed in this table.

Table 6 | Supply Capacity Needs

			Need Magnitude (MW)	
Subregion	**Subsystem**	**LMC (MW)**	**2023**	**2042**
Caledonia-Norfolk Subregion	Norfolk-Bloomsburg Area	80	33	78
Brant 115 kV Extended Area	Brant 115 kV Subsystem	134	3	129
	Combined Brant and Hamilton 115 kV Subsystems	500	66	483
	Woodstock 115 kV Subsystem	85	20	47

6.4 Asset Replacement Needs

At the time of the Burlington to Nanticoke Region Needs Assessment, Hydro One identified a number of assets requiring replacement in the next 10 years. These needs and recommendations from the Technical Working Group have been included in Table 7.

Table 7 | Asset Replacement Needs

Timeframe	Station	Asset	Recommendation
Medium-term	Beach TS	230/115 kV autotransformers DESN transformers	Proceed with like-for-like replacement
	Birmingham TS	DESN transformers and switchgear	Proceed with like-for-like replacement
	Caledonia TS	DESN transformer (T1)	Station capacity need identified; replace with maximum-rated unit
	Gage TS (T8/T9)	DESN transformers and switchgear	Proceed with replacement with nearest standard units
	Jarvis TS	DESN transformers	Proceed with like-for-like replacement; assess if current-limiting reactors can be removed*
	Lake TS	DESN transformers and switchgear	Station capacity need identified; replace with maximum-rated unit

Timeframe	Station	Asset	Recommendation
	Nebo TS (T3/T4)	DESN transformers	Station capacity need identified; replace with maximum-rated unit
	Norfolk TS	DESN switchgear	Defer replacement if possible, New 230 kV DESNs recommended (Section 7.3.2.3)
Long-term	Dundas TS	DESN switchgear	Defer replacement if possible, New 230 kV DESNs recommended (Section 7.3.2.3)

* The current-limiting reactors reduce the station LMC by 25 MW from ~125 MW to ~100 MW.

6.5 Load Security and Load Restoration Needs

The recommended interim solutions to open station bus-tie breakers can be violations to the load security criteria. However, the LDCs and transmitter can apply for exemptions until the medium-/long-term plans to address the needs are placed in service after which opening bus-tie breakers would not be needed.

The Technical Working Group did not identify any restoration needs.

7 Plan Options and Recommendations

This section describes the options considered and recommendations to address the needs in the Burlington to Nanticoke Region. In developing the plan, the Technical Working Group considered a range of integrated options. Considerations in assessing alternatives included feasibility, cost, lead time, system benefits, and consistency with longer-term needs in the area.

Generally speaking, there are two approaches for addressing regional needs that arise as electricity demand increases:

- Build new transmission or distribution infrastructure. These are commonly referred to as "wire" options and can include things like new transmission lines, autotransformers, step-down transformer stations, voltage control devices, upgrades to existing infrastructure, or distribution-level load transfers. Wire options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate certain reliability concerns.
- Install or implement measures to reduce the net peak demand to maintain loading within the system's existing LMC. These are commonly referred to as "non-wire" options and can include things like local utility-scale generation or storage, distributed energy resources (including distribution-connected generation and demand response), or CDM.

Section 7.1 begins with a more in-depth overview of all option types considered in IRRPs. Section 7.2 describes the screening approach used to assess which needs would be best suited for a more detailed assessment for non-wire option. Subsequently, Section 7.3 to Section 7.4 present the options that were ultimately developed and evaluated (including a cost comparison) before the Technical Working Group made a recommendation.

7.1 Options Considered in IRRPs

Wire options are always considered in regional planning and while they are always viable options for regional needs, non-wire option may be more suitable for specific need types and characteristics. Hence, to select and appropriately size non-wire option such as generation or battery storage, additional work is required – including creation of an hourly load profile, as described in Section 5.7. The most suitable technology type and capacity is chosen by examining the "unserved energy" profile, which is the hourly demand above the existing LMC. The profile indicates the duration, frequency, magnitude, and total energy associated with each need. Some of these characteristics are shown visually in Appendix D for the Burlington to Nanticoke Region needs.

High-level cost estimates for wire options are based on input provided by the transmitter and transmission benchmark costs. In contrast, cost estimates for non-wire options are based on benchmark capital and operating cost characteristics for each resource type and size. Due to policy considerations and decarbonization efforts, new natural gas-fired generation was not considered as a generation option for local needs identified by the regional plan. Battery energy storage, solar generation, and wind generation were considered for generation options.

New CDM measures can also help decrease the net electricity demand. Centrally delivered energy efficiency measures under the 2021-2024 CDM Framework and Save on Energy brand are already included in the load forecast, as discussed in the Section 5.4. As part of this current Framework, the IESO was directed to deliver a new program to address regional and/or local system needs. The Local Initiative Program is now one tool that is available to target the delivery of additional CDM savings at specific areas of the province with identified system needs. LDCs can also use the Ontario Energy Board's Non-Wires Solutions Guidelines for Electricity Distributors (previously "CDM Guidelines) to leverage distribution rates to help address distribution and transmission system needs using non-wire alternatives. Generally, incremental CDM measures are suitable for needs where growth is slow and the magnitude of the overload relative to the total demand is very small (i.e., on the order of few percent per year). These considerations are discussed further in Section 7.2, as part of the screening of options that was conducted.

For both wire and non-wire options, the upfront capital and operating are compiled to generate levelized annual capacity costs ($/kW-year). A cash flow of the levelized costs for the options are compared over the lifespan of the wire option (typically 70 years for transmission infrastructure). The net present value (in 2024 CAD for this report) of these levelized costs is the primary basis through which feasible options are compared.

It is important to recognize that there is a significant error margin around cost estimates at the planning stage, as they are only intended to enable comparison between options during the IRRP. The transmitter-led RIP (which is conducted after the IRRP) performs additional detailed analysis and allows the opportunity to refine cost estimates of wire options before implementation work begins. The IESO continues to participate in the Technical Working Group during the RIP and revisits these recommendations if costs estimates differ significantly. Furthermore, pilot or demonstration projects can be explored in cases where other barriers (e.g., regulatory frameworks for cost-sharing and recovery, or operationalization to meet local reliability constraints) impede the adoption of some of these cost-effective options following the completion of the IRRP.

The list of assumptions made in the economic analysis can be found in Appendix F.

7.2 Screening Options

As explained in the previous section, an array of options is developed to meet local needs during an IRRP and then each option is evaluated to recommend the option which is the most cost effective or the option which best balances cost and risk mitigation when substantial additional risks not captured by the Planning forecast are present. This process is complemented by considerations for stakeholder preferences and feedback.

Screening occurs early in the IRRP study after local reliability needs are known but before options analysis. It helps direct time-intensive aspects of detailed non-wires analysis (hourly need characterization, options development, financial analysis, and engagement) towards the most promising options. The three-step, high-level approach is shown in Figure 11 and further discussed in the next sections for the needs identified in the Burlington to Nanticoke region.

Station capacity needs identified for the Hamilton subregion in Section 6.2.3 are not included here, as the needs for the Hamilton subregion will be addressed in the addendum (see Section 2.5.1). More details on the steps and inputs used in the screening mechanism can be found in Appendix C, and a

summary of the options screening results for Burlington to Nanticoke Region is provided in Table 8 for station capacity needs, and in Table 9 for supply capacity needs.

Figure 11 | IRRP NWAs Screening Mechanism

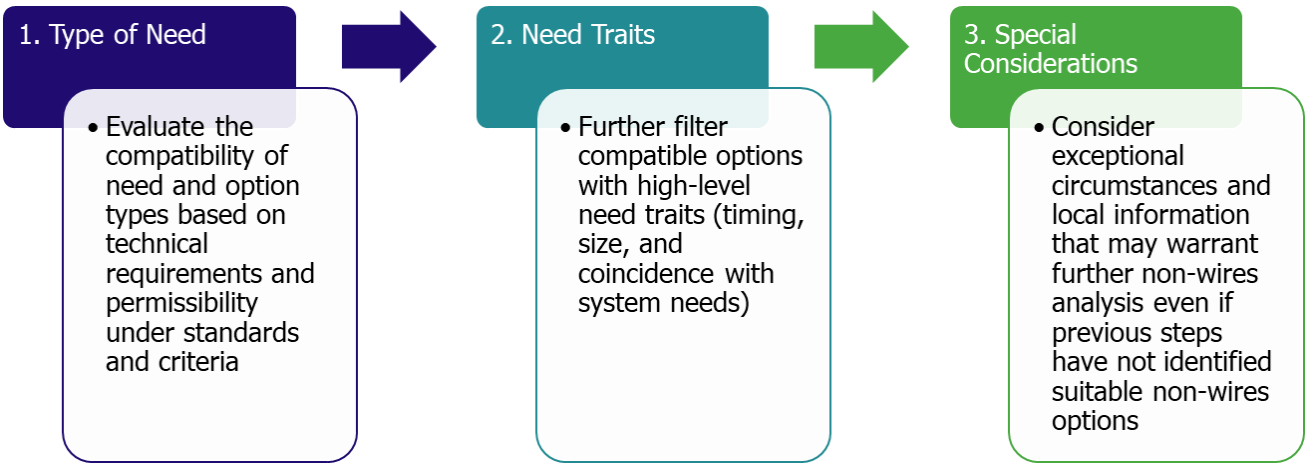


Table 8 | Options Screening Results for Station Capacity Needs

Need	Screened In	Screened Out
Station Capacity: Bloomsburg DS, Norfolk TS, Caledonia TS, Brant TS, Powerline MTS	• Operational measures • CDM • Distributed generation[4] • Wires options	• Demand response – due to magnitude and timing of need

Table 9 | Options Screening Results for Supply Capacity Needs

Need	Screened In	Screened Out
Supply Capacity: Line C9 and C12, Brant 115 kV Subsystem, Hamilton 115 kV Subsystem, Woodstock 115 kV Subsystem	• Operational measures • CDM • Distributed generation[4] • Transmission-connected generation • Wires options	• Demand response – due to magnitude and timing of need

7.2.1 Non-Wires Options for the Station Capacity Needs

[4] Later found to be technically infeasible due to short circuit limitations

Non-wires options cannot typically resolve the station capacity needs for the Burlington to Nanticoke region. The magnitude of the needs is too great to be addressed via CDM and DR and significantly exceeds the amount of DG that is technically feasible to connect at the distribution level due to short circuit and thermal constraints. Transmission-connected generation was also excluded because resources must be connected downstream of the limiting step-down transformer to have an impact on the station capacity needs.

Nevertheless, CDM has been considered for deferring long-term station capacity needs.

7.2.2 Non-Wires Options for the Supply Capacity Needs

Non-wires options, except transmission-connected resources, cannot resolve the supply capacity needs for the Burlington to Nanticoke Region since these needs are large in magnitude. Nevertheless, non-wire options can be explored in combination with wire options.

Only non-emitting resources such as battery storage and renewables were included in the option assessments.

7.3 Options and Recommendations for the Brant Subregion

7.3.1 Station Capacity Needs

The three stations supplying the Brant subregion, Powerline MTS, Brant TS and Brantford TS, are forecasted to exceed their station capacity, in the same order, within the next decade.

The needs at Powerline MTS and Brant TS are too large to be addressed by CDM or DR and DG is not viable because of short-circuit and thermal limitations at the stations. For a time, overloading at Powerline MTS and Brant TS can be addressed through distribution-level load transfers to Brantford TS until Brantford TS exceeds its capacity. The technical requirements and cost of upgrading the distribution system may limit the feasibility or viability of this load transfer.

Normally, the wire option, that is to upgrade the Powerline and Brant transformers, is recommended at this point. However, since there is also a supply capacity need for these stations, it would be more efficient and cost-effective to recommend a solution that resolves all supply and station capacity needs in the area, as discussed in the next section.

Therefore, as an interim solution, it is recommended to open bus-tie breakers at Powerline MTS and Brant TS, as required, to resolve their station capacity needs.

Load transfer to Brantford TS on a permanent or temporary basis may be used to reduce or resolve the station capacity needs but should be coordinated with the recommended interim option for resolving the supply capacity needs for the area explained in Section 7.3.2.1.

Since the Brantford station capacity need is in the long term, no immediate action is required. The Technical Working Group will monitor the load growth at the station for any change that can advance the need to take an appropriate action.

7.3.2 Supply Capacity Needs

No supply capacity need was identified for Brantford TS which is supplied from M32W and M33W, the 230 kV double-circuit line between Middleport and Buchanan.

Needs for the Brant 115 kV Subsystem, 115 kV circuits B12BL, B13BL and B2 supplying Powerline MTS and Brant TS, could not be identified and addressed in isolation due to its tight connectivity with the neighboring subregions. As such, the area of study was extended to the entire 115 kV system enclosed between the Burlington and Karn 115 kV stations. This study area is referred to as the Brant 115 kV Extended Area which, in addition to the Brant 115 kV Subsystem, consists of the Hamilton 115 kV Subsystem plus Woodstock 115 kV Subsystem, which are the Dundas, Dundas 2, Mohawk, Newton, Elgin and CTS3 stations in the Hamilton subregion supplied via B12BL, B13BL, B3 and B4 plus the Woodstock, Commerce Way and CTS6 stations in the Woodstock subregion of the London Area supplied via K7, K12 and B2.

7.3.2.1 Interim Solution – Operational Measures

As presented in Section 6.3, there are immediate supply capacity needs in the Brant 115 kV Extended Area.

Therefore, as an interim solution, it is recommended to take some operational measures to maintain system security by opening station bus-tie breakers within each Subsystem to maintain the post-contingency total load within the applicable load meeting capability. Effort should be taken to minimize the overall number of bus-tie breakers that must be open based on system conditions.

7.3.2.2 Non-Wire Options

Due to the large magnitude of the supply capacity needs in the Brant 115 kV Extended Area, CDM, DR and DG were not found to be adequate to resolve the needs. Transmission-connected resources, such as battery storage, are the only non-wire options with the potential to address these needs.

Due to the large area spanned when evaluating the resource option, a minimum of two facilities were needed, one at Brant TS and one at Newton TS with a total capacity of 450-600 MW. To be viable, the battery storage at both places should be paired with wind and solar generation because there are extended periods of time when the batteries cannot be charged from the grid due to extremely limited supply capacities. This implies having 600-1,500 MW wind and solar farms within the densely populated urban areas of Hamilton, which is not practical. As a result, transmission-connected resources were not considered feasible to meet this need and are not recommended.

7.3.2.3 Wire Options

Wire options listed in Table 10 were considered for resolving supply capacity needs in the Brant 115 kV Extended Area with additional information provided in the following sections.

Option 1: Reinforcing 115 kV and Dynamic Voltage Support

Based on load flow studies, almost all the 115 kV lines – 30 km of a single-circuit lines and 80 km of double/quadruple-circuit lines – must be reinforced with higher capacity wires by a factor ranging

from 1.35 to 3 in various sections. Additionally, dynamic voltage support devices, e.g. STATCOM, SVC or synchronous condenser, with a total post-contingency capacity of 500 Mvar at the Karn, Brant and Powerline stations are required to stabilize the voltage. It can take up to $790 M and 10 years to implement this option and still the long-term needs are not resolved let alone enabling future load growth.

Option 2: Upgrading 115 kV to 230 kV

This option entails replacing towers and wires on 85 km of double/quadruple-circuit lines and 2x8 stepdown transformers serving loads at eight stations. In addition to being prohibitively costly and lengthy, implementing this option is not practical since the lines pass through dense urban areas or along busy roads with a tight right of way.

Option 3: Adding New Supply Point Via 230/115 kV Autotransformers

None of the three alternatives considered for this option showed better load meeting capabilities than Option 1 although similar 115 kV reinforcements and dynamic voltage support were necessary and reinforcing 230 kV system might also be required. This implies this option has a higher cost and longer implementation time than Option 1 with no additional benefits.

Option 4a: Offloading 115 kV System to MxD and MxB 230 kV Circuits

Option 4a is the recommended solution since it can resolve both supply and station capacity needs for the Brant and Powerline and Dundas and Dundas 2 stations within an acceptable cost and timeframe without any negative impact on major bulk interfaces. Furthermore, the 115 kV system can supply the remaining Hamilton stations, CTS3, Mohawk, Newton and Elgin TS, up to their capacities without any additional reinforcement. Supply and station capacity needs, which would still limit the expected load growth for these remaining Hamilton stations, will be further assessed and addressed in the addendum discussed in Section 2.5.1.

To address supply capacity needs, rather than constructing new DESNs, it is possible to convert the existing DESNs at Brant TS and Powerline MTS from 115 kV to 230 kV supply. However, this will not resolve station capacity needs, and additional measures will be needed.

The choice between constructing new DESNs or converting existing DESNs, and the siting of potential new DESNs will be determined in the upcoming Regional Infrastructure Planning (RIP) led by the transmitter. The point of connections to Middleport-Detweiler corridor will be finalized via the ongoing KWCG IRRP since these circuits are in the KWCG region.

Option 4b: Offloading 115 kV System to MxW and QxBM 230 kV Circuits

Option 4b is an alternative to Option 4a with similar benefits. However, the circuits to which load is transferred are part of major interfaces. Addition of load to these circuits negatively affect power transfer across the province and should be avoided. Otherwise, reinforcements are required to compensate for the negative impact.

Table 10 | Wire Options for Brant 115 kV Extended Area*

#	Description	Cost ($M)	Note
1	Reinforce 115 kV lines and add dynamic voltage support at Karn, Brant and Powerline	750-800	Does not resolve the long-term needs or enable future growth
2	Upgrade 115 kV lines and stations to 230 kV	1,000-1,500	Impractical and prohibitively costly and lengthy
3	Add new supply point via 230/115 kV autotransformers using either of the following alternative connections: - from Brantford TS to Brant TS on B12BL and B13BL - from Brantford TS to Alford Junctions on B12BL and B13BL - from Horning Mountain Junctions on M27B and M28B to Newton TS	850-1,000	Worse than Option 1; does not resolve the long-term needs or enable future growth; requires similar 115 kV reinforcements and dynamic voltage support as Option 1; may require 230 kV reinforcements
4a	Offloading 115 kV system to 230 kV: - Transfer Brant and Powerline loads to new 230 kV DESNs supplied from new taps on The Middleport-Detweiler corridor** - Transfer Dundas and Dundas 2 loads to new 230 kV DESNs at Dundas switchyard supplied from M27B and M28B***	200-300	**Recommended option.** Resolve supply and station capacity needs for Brant and Powerline and Dundas and Dundas 2; 115 kV system can supply the remaining Hamilton stations up to their capacities with no additional reinforcement****
4b	Offloading 115 kV system to 230 kV: - Transfer Brant and Powerline loads to new 230 kV DESNs supplied from Brantford TS or new taps on M32W and M33W - Transfer Dundas 1 and 2 loads to new 230 kV DESNs at Dundas switchyard supplied from Q23BM and Q25BM	300-400	Same benefits as Option 4a but not recommended due to negative impact on power transfer across the province as the circuits are part of major interfaces

* Line notations:
B12BL and B13BL: 115 kV circuits between Burlington, Brant and Newton, supplying Brant and Powerline loads
M27B and M28B: 230 kV circuits between Middleport and Burlington
M20D and M21D: 230 kV circuits between Middleport and Detweiler
M32W and M33W: 230 kV circuits between Middleport and Buchanan, part of a major interface transferring power across Ontario
Q23BM and Q25BM: 230 kV circuits between Beck 2, Burlington and Middleport, part of a major interface transferring power across Ontario

** DESN placements and point of connection to the Middleport-Detweiler corridor will be finalized via ongoing KWCG IRRP.

*** Transmitter-led Regional Infrastructure Plan (RIP) assesses and develops a detailed plan for implementation.

**** Woodstock 115 kV System LMC increases to 113 MW after which operational measures should be used to secure the system. Opening Brant DB2 115 kV breaker is recommended.

7.4 Options and Recommendations for the Caledonia-Norfolk Subregion

7.4.1 Station Capacity Needs

Three out of six stations supplying the Caledonia-Norfolk subregion, Bloomsburg DS, Norfolk TS and Caledonia TS, are forecasted to exceed their station capacity, in the same order, within the next decade.

The needs at Bloomsburg DS and Norfolk TS are too large to be addressed by CDM or DR and DG is not viable because of short-circuit and thermal limitations at the stations. For a time, overloading at Bloomsburg DS can be addressed through distribution-level load transfers to Norfolk TS until Norfolk TS exceeds its capacity after which Bloomsburg and Norfolk loads may be transferred to Jarvis TS. However, Hydro One Distribution has indicated limited ability to cost-effectively transfer load to Jarvis TS, and estimates that more than 20 km of new distribution line is needed meet long term needs.

Normally, the wire option, that is to upgrade the Bloomsburg and Norfolk transformers, is recommended at this point. However, since there is also a supply capacity need for these stations, it would be more efficient and cost-effective to recommend a solution that resolves all supply and station capacity needs in the area, as discussed in the next section.

Therefore, as an interim solution, it is recommended to open bus-tie breakers at Bloomsburg DS and Norfolk TS, as required, to resolve their station capacity needs.

Load transfer from Bloomsburg DS to Norfolk TS and additional load transfer from any of these stations to Jarvis TS on a permanent or temporary basis may be used to reduce or resolve the station capacity needs but should be coordinated with the recommended interim solution for resolving the supply capacity needs for the area explained in Section 7.4.2.1.

Since the Caledonia station capacity need is in the long term, no immediate action is required. The Technical Working Group will monitor the load growth at the station for any change that can advance the need, and consider the use of CDM closer towards the needs date to defer needs.

7.4.2 Supply Capacity Needs

As presented in Section 6.3, there is a supply capacity need in the Norfolk-Bloomsburg Area. No supply capacity need was identified for Caledonia TS or Jarvis TS.

7.4.2.1 Interim Solution – Operational Measures

To address the immediate supply capacity need in the Norfolk-Bloomsburg Area, an immediate interim solution is needed until permanent solutions can be put in place.

Therefore, as an interim solution, it is recommended to take some operational measures and open station bus-tie breakers at Bloomsburg DS or Norfolk TS, as required, to ensure the

security of the system by maintaining the post-contingency total load within the applicable load meeting capability.

Permanent or temporary load transfer to Jarvis TS may be used to reduce reliance on opening bus-tie breakers.

7.4.2.2 Non-Wire Options

Due to the large magnitude of the supply capacity needs in the Norfolk-Bloomsburg Area, CDM, DR and DG were not found to be adequate to resolve the needs. Transmission-connected resources, such as battery storage, are the only non-wire options with the potential to address these needs. However, due to the sizeable capacity required to meet needs, this non-wire option is only economically viable when considering the system benefit that resources provide to the provincial system.

Load flow analyses showed battery energy storage systems (BESS) are viable if they:

- constantly control the voltage of the points of interconnection (POI) to the grid by providing enough reactive power (Mvar) support to the system.
- connect on both 115 kV lines, C9 and C12, between Bloomsburg Junctions and Norfolk TS, preferably at Norfolk TS.
- have enough redundancy in components and connections not to lose active/reactive power support and voltage control under any outage conditions; otherwise, the operational measures recommended as the interim solution in the previous section must be taken.

Minimum requirements for the rated capacity (MW) and energy (MWh) of a viable BESS are dependent on the minimum reactive power (Mvar) support that the BESS can constantly provide. Higher constant reactive power support results in lower rated capacity and energy requirements which may imply the BESS reactive power support exceeds the reactive power requirement from Market Rules Appended 4.2 – Category 5.

If the BESS option is found unviable because of low reactive power support, it may be possible to make it viable by pairing with renewables. Further analyses are needed to determine the capacity of wind and solar generation needed for this, and the associated feasibility of building sufficient wind and solar farms in the area.

As discussed in the next section, the recommended long-term solution for the Norfolk-Bloomsburg Area is a 230 kV wire option. However, since the needs are immediate and the implementation of the wire option can take up to 10 years, to bridge the gap until the Norfolk-Bloomsburg long-term wire solution is placed in service, a medium-term solution is also recommended.

Therefore, as a medium-term solution, a BESS capable of continually providing reactive support to control the voltage at the points of interconnection is recommended. The BESS may potentially be combined with other NWAs such as renewables.

7.4.2.3 Wire Options

The transmission-connected resources recommended in the previous section would not enable future long-term growth in the Area. In addition, a heavily loaded Norfolk-Bloomsburg 115 kV system would significantly restrict the load meeting capabilities of the upstream 230 kV system. Connecting new large loads, such as industrial projects or AI/data centres, with a magnitude of 1,000-2,000 MW to the Nanticoke-Middleport corridor or Nanticoke 230 kV TS may not be feasible unless the Norfolk-Bloomsburg Area is offloaded. As such, wire options listed in Table 10 were explored. Additional information is provided in the following sections.

Option 1: Dynamic Voltage Support and CDM

Based on load flow studies, dynamic voltage support devices, e.g. STATCOM, SVC or synchronous condenser, with a total post-contingency capacity of 100 Mvar are required to stabilize the voltage and increase the load meeting capability of the Norfolk-Bloomsburg Area to its thermal limit of 150 MW. Combined with new CDM programs, this option can meet the supply capacity need for the 20-year forecast without enabling any further growth. However, it does not resolve the station capacity needs at Bloomsburg DS and Norfolk TS. In addition, a limitation on the upstream 230 kV system is also present.

Option 2: Upgrading 115 kV System to 230 kV

This option entails replacing 115 kV wires along 45 km of double-circuit lines and adding two sets of stepdown transformers serving loads at the two stations. Implementing this upgrade would require frequent outages to the system including the 500 kV circuit that shares towers with the 115 kV circuits. The cost and lead time of this option are the largest among the wire options without providing any additional benefits comparing to Options 3a and 3b.

Option 3a and 3b: Transferring Load to a New 230 kV DESN Supplied Via New Lines Connecting to the Nanticoke-Middleport 230 kV Corridor or Nanticoke TS

Option 3 has two alternatives, a and b, with similar cost, timeline, and benefits.

Option 3b, constructing a new DESN and connecting to Nanticoke TS, is recommended because it addresses the long-term supply and station capacity needs and enables future growth for the Norfolk-Bloomsburg Area. Option 3b is preferred over 3a, since it can address the needs for multiple areas, including possible growth due to industrial projects or AI/data centers in the vicinity of Nanticoke TS.

To address supply capacity needs, rather than constructing a new DESN, it is possible to convert the existing DESNs at Bloomsburg DS and Norfolk TS from 115 kV to 230 kV supply. However, this will not resolve station capacity needs, and additional measures will be needed.

The choice between constructing a new DESN or converting existing DESNs, the siting of new transmission lines, and the siting of potential new DESNs will be determined in the upcoming Regional Infrastructure Planning (RIP) led by the transmitter.

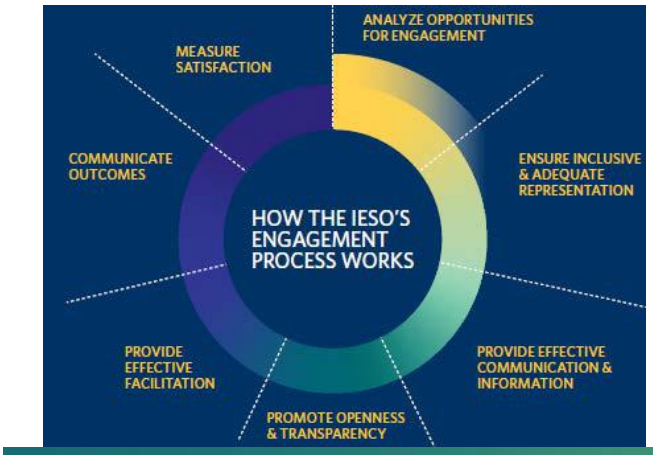
Depending on the implementation of the medium-term recommendation for a BESS in the Norfolk area, and the pace of load growth and distributed generation connections in the area over the near and medium term, there may be an opportunity to further defer the need for the long-term solution. However, given the interest from large loads in the Nanticoke area and the long lead time of the solution, it is recommended that as the work proceeds on the long-term solution, the TWG continues to monitor interest from load connections in the area. In the next planning cycle, the TWG will review the proposed in-service date and determine if any changes are needed.

Table 11 | Wire Options for Norfolk-Bloomsburg Area

#	Description	Cost ($M)	Note
1	Add dynamic voltage support + new CDM at Norfolk and Bloomsburg	100-200	Barely meets the 20-year supply capacity need; does not resolve station capacity needs; does not enable future growth; limits upstream 230 kV system
2	Upgrade 115 kV lines and stations to 230 kV	250-350	Resolves supply and station capacity needs and enable future growth at highest cost
3a	Transfer Norfolk and Bloomsburg loads to a new 230 kV DESN supplied via new lines connecting to the Nanticoke-Middleport 230 kV corridor	150-200	Resolves supply and station capacity needs; enable future growth
3b	Transfer Norfolk and Bloomsburg loads to a new 230 kV DESN supplied via new lines connecting to Nanticoke TS*	150-200	**Recommended long-term option.** Same benefits as Option 3; additionally, can address needs in multiple areas

* Transmitter-led Regional Infrastructure Plan (RIP) assesses and develops a detailed plan for implementation.

For a summary of recommendations with timing and lead responsibility, please refer Table 2, Table 3, and Table 4 in Sections 2.2 to 2.4.



8 Community and Stakeholder Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and perspectives of the public, which for these purposes, refers to market participants, municipalities, stakeholders, communities, Indigenous communities, customers and the general public, to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles and activities undertaken to date for the Burlington to Nanticoke IRRP.

8.1 Engagement Principles

The IESO's External Relations Engagement Framework is built on a series of key principles that respond to the needs of the electricity sector, communities and the broader economy. These principles ensure that diverse and unique perspectives are valued in the IESO's processes and decision-making. We are committed to engaging with purpose with external audiences to foster trust and build understanding as the energy transition continues.

Figure 12 | The IESO's Engagement Principles

The IESO applies these principles to every engagement, ensuring that we honour our commitment to partners:

Purposeful
Initiate meaningful conversations that move the sector forward

Accessible
Ensure we meet people where they are on their energy journey

Inclusive
Invite many voices and diverse perspectives to the table

Traceable
Allow everyone to follow the path that is being taken

Timely
Seek input and insight when it can have the most impact

Transparent
Show how engagement has shaped final outcomes

8.2 Engagement Approach

To ensure that the Plan reflects the needs of market participants, municipalities, stakeholders, communities, Indigenous communities, customers and the general public, engagement involved:

- Leveraging the Burlington to Nanticoke engagement webpage to post updated information, engagement opportunities, meeting materials, input received and IESO responses to feedback.
- Timely and targeted discussions with transmission-connected loads and municipalities to help inform the engagement approach for this planning cycle;
- Hosted a series of public webinars at major junctions in the plan development to share plan details, understand feedback and answer questions, and
- Communications and other engagement tactics to enable a broad participation through email and IESO's weekly Bulletin updates.

As a result, the engagement plan for this IRRP included:

- A dedicated webpage on the IESO website to post all meeting materials, feedback received and IESO responses to the feedback throughout the engagement process;
- Regular communication with interested communities and stakeholders by email or through the IESO weekly Bulletin;
- Public webinars; and
- Targeted one-on-one outreach with specific communities and stakeholders to ensure that their identified needs are addressed (see Section 8.4).

8.3 Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for the third round of planning, and to establish new relationships and dialogue in this region where there has been no active engagement previously. This started with the Scoping Assessment Outcome Report for the Burlington to Nanticoke Region. An invitation was sent to targeted municipalities, Indigenous communities, and those with an identified interest in regional issues, to announce the commencement of a new planning cycle and invite interested parties to provide input on the Burlington to Nanticoke Region Scoping Assessment Report finalization. A public webinar was held in November 2022 to provide an overview of the regional electricity planning process and seek input on the high-level needs identified and proposed approach. The final Scoping Assessment was posted later in December 2022, identifying the need for a coordinated regional planning approach and an IRRP.

Following finalizing the Scoping Assessment, several targeted outreach meetings then began to involve large customers and municipalities in the region to ensure growth and development plans have been accurately captured in the Technical Working Group's draft demand forecast and solicit early feedback on the IESO's approach to engagement. The launch of a broader engagement initiative followed, with an invitation to IESO subscribers of the Burlington to Nanticoke Region to ensure that all interested parties were made aware of this opportunity for input. Three public webinars were held at major stages during the IRRP development to give interested parties an

opportunity to hear about its progress and provide comments on key components of the plan. These webinars were attended by a cross-representation of community representatives, businesses, and other stakeholders, and written feedback was collected following a comment period after each webinar.

The three stages of engagement at which input was invited:

1. The draft engagement plan, electricity demand forecast, and early identified needs – to set the foundation of this planning work.
2. The defined electricity needs for the region and high-level screening of potential options to meet the identified needs.
3. The analysis of options and draft IRRP recommendations.

Comments received during this engagement primarily focused on:

- Organic growth and economic development projects across the region;
- Interest in leveraging existing and local generation; and
- Interest in ensuring electricity infrastructure can accommodate economic development.

Feedback received during the written comment periods for these webinars helped to guide further discussions throughout the development of this IRRP, as well as add due consideration to the final recommendations.

All interested parties were kept informed throughout this engagement initiative via email to Burlington to Nanticoke's Region subscribers, municipalities, and Indigenous communities.

Based on the discussions through this engagement initiative, a key priority was to ensure the IRRP and recommended actions aligned with strong forecast growth and development both within specific municipalities and the region more broadly (e.g. future urban expansion as shared by Norfolk County, residential growth as shared by Haldimand County, and capacity concerns as shared by Hamilton). These insights have been valuable to the IESO – as they supported an understanding of local growth and an accurate electricity demand forecast, the determination of needs, and the recommendation of solutions to ensure adequate and reliable long-term supply.

Additionally, participants would like to be engaged when there is additional information to share regarding Hamilton's needs, options and draft recommendations as well as progress in-between planning cycles. To that end, ongoing discussions will continue through the Hamilton Addendum to keep interested parties engaged in a two-way dialogue. Additionally, municipalities are encouraged to ensure their local distribution company is aware of any changes and updates to their growth and development plans.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's Burlington to Nanticoke IRRP engagement webpage.

8.4 Involving Municipalities in the Plan

The IESO held meetings with municipalities to seek input on their planning and to ensure that key local information about growth and development and energy-related initiatives were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings were held with the upper- and lower-tier municipalities in the region to discuss key issues of concern, including forecast regional electricity needs, options for meeting the region's future needs, and broader community engagement. These meetings helped to inform the municipal/community electricity needs and priorities, establish new relationships, and provided opportunities for ongoing dialogue beyond this IRRP process.

Through these discussions valuable feedback was received around strong anticipated growth in major growth centres in the region and community preferences around solutions:

- Over the next 20 years, significant residential growth in Caledonia with 4,000 to 5,000 residential dwellings, Hagersville with 3,000 to 3,500 residential dwellings and Jarvis and Dunnville with 500.
- There is a potential urban boundary expansion in Norfolk County and a new employment area in Delhi.
- Significant growth is anticipated for St. George (when wastewater treatment plant expansion is completed), Burford (servicing master plan is underway) and Oakland/Scotland areas in the County of Brant.
- Electrification initiatives within City of Brantford are underway such as the construction of a transit hub.
- Capacity concerns for Dundas and Dundas 2 were raised by the City of Hamilton prompting those station capacity needs to be explored in this study rather than the Hamilton Addendum.
- Several municipalities are exploring local energy projects to support their energy needs and would like to have these, or other non-wire alternatives, considered as solutions for the IRRP.

8.5 Engaging with Indigenous Communities

To raise awareness about the regional planning activities underway and invite participation in the engagement process, regular outreach was made to Indigenous communities within the Region throughout the development of the plan. This includes the Mississaugas of the Credit First Nation, Six Nations of the Grand River, and a number of MNO councils located within or near the Region including MNO Clear Waters Métis Council and MNO Grand River Métis Council.

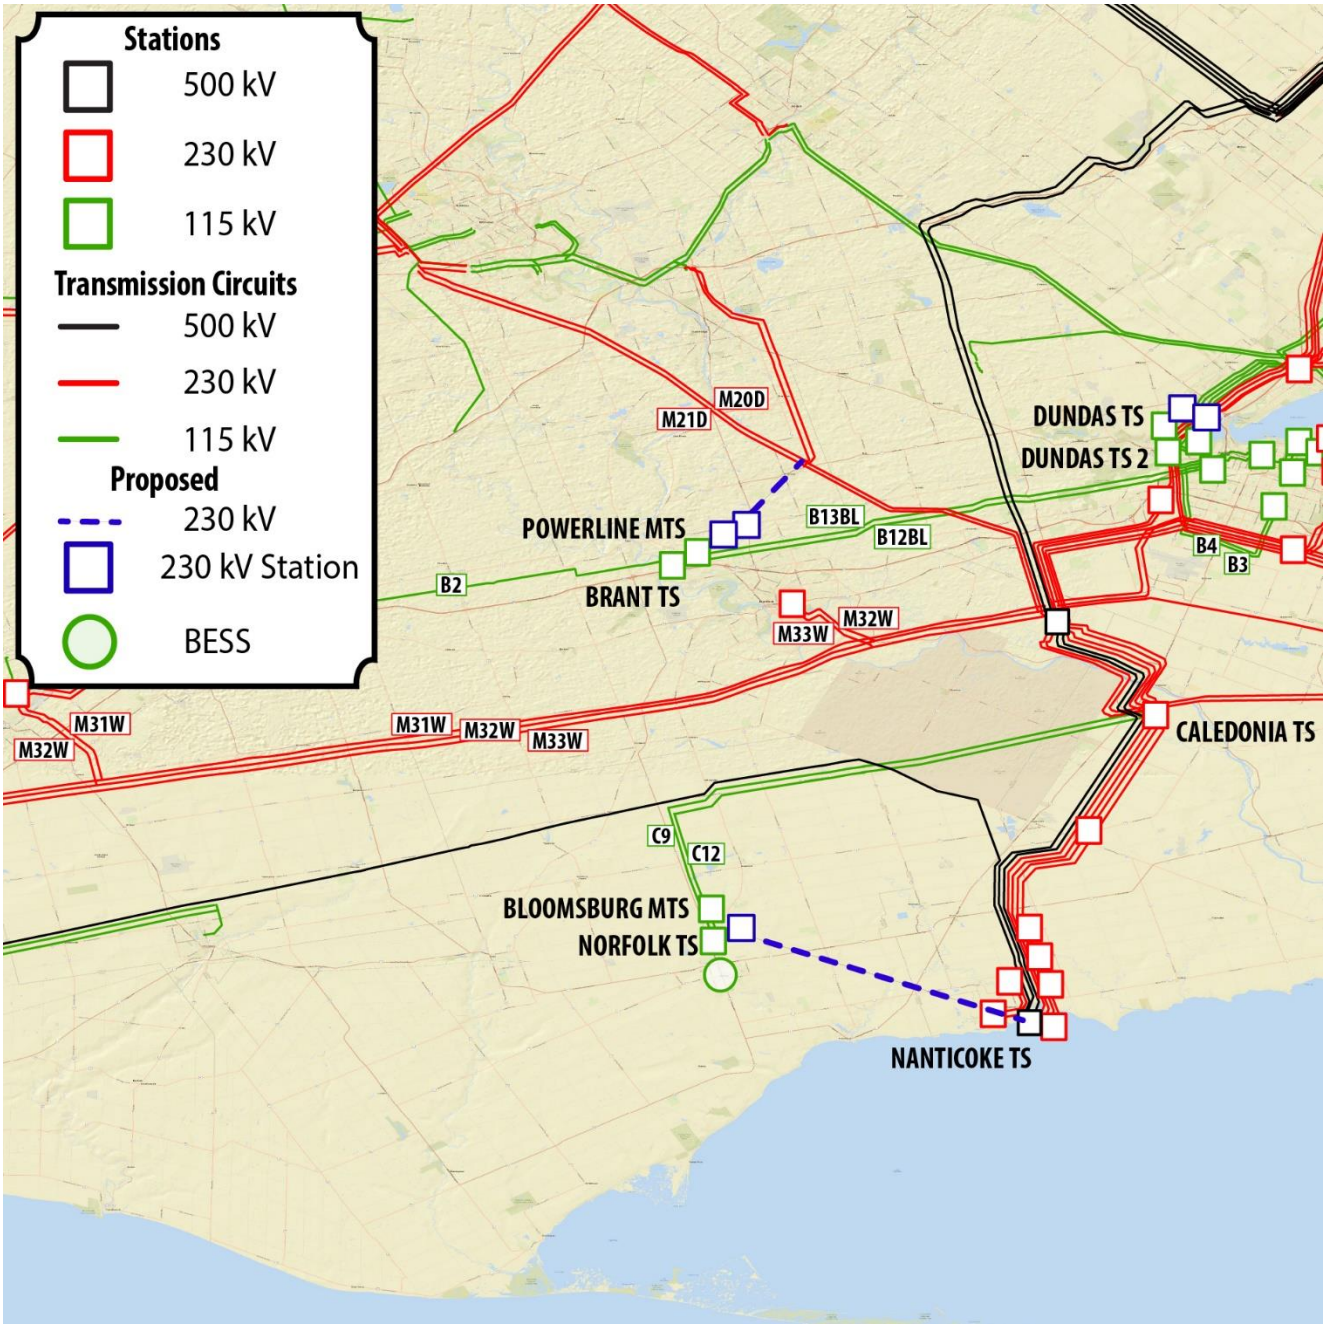
The IESO remains committed to an ongoing, effective dialogue with communities to help shape long-term planning in regions all across Ontario.

9 Conclusions

The Burlington to Nanticoke IRRP identifies electricity needs in the region over the 20-year period from 2023 to 2042, and recommends a plan to address needs from the immediate to long-term. The IESO will continue to participate in the Technical Working Group during the next phase of regional planning, the RIP, to provide input and ensure a coordinated approach.

In the near-to-medium term, the Technical Working Group recommends the pre-contingency opening of bus-tie breakers, and load transfers between nearby stations at the distribution level, where viable and cost-effective. These recommendations are needed at several stations supplied by the 115 kV transmission system and one by the 230 kV transmission system.

In the medium-term, the Technical Working Group recommends the procurement of a BESS in the Norfolk-Bloomsburg Area, and the construction of a new substation[5] near Dundas TS. These recommendations will respectively address needs in the Norfolk-Bloomsburg Area, and on the Hamilton 115 kV Subsystem and at the Dundas and Dundas 2 stations.



Finally, in the long term, the Technical Working Group recommends constructing two new double-circuit transmission lines and associated substations[5], separating the Woodstock 115 kV Subsystem from the Brant 115 kV Subsystem, and considering cost-effective CDM at Brantford TS and Caledonia TS closer to needs dates to defer capacity needs at these stations. A map outlining the medium- and long-term recommendations is provided in Figure 13.

The first transmission line is recommended from Nanticoke TS into the Norfolk-Bloomsburg Area, and a new station with an LTR of approximately 200 MVA is recommended at the end of the line. The Technical Working Group then recommends that Norfolk TS and Bloomsburg TS be entirely offloaded onto the new substation[5]. The second transmission line is recommended as an extension from the existing Middleport-Detweiler corridor in the Kitchener/Waterloo/Cambridge/Guelph region into County of Brant, and a new station with an LTR of approximately 400 MVA is recommended at the end of this line. The Technical Working Group then recommends that Brant TS and Powerline MTS be entirely offloaded onto the new substation[5]. Last, the Woodstock 115 kV Subsystem is recommended to be separated from the Brant 115 kV Subsystem by opening the Brant DB2 breaker.

The Technical Working Group will continue to monitor growth at Brantford TS and Caledonia TS and across the region. This includes any future community energy planning, electrification trends, datacentres, or industrial load. Additionally, there are benefits to investigating opportunities to target incremental CDM to the region. The Technical Working Group will meet at regular intervals to complete the Hamilton addendum, monitor developments and track progress toward plan deliverables. In the event that underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the Ontario Energy Board.

[5] Rather than building a new station, the existing DESNs may be converted from a 115 kV supply to a 230 kV supply by replacing all 115 kV station equipment. The subsequent Transmitter-led Regional Infrastructure Plan (RIP) will identify the most cost-effective solution and develop a detailed plan for implementation.

REGIONAL INFRASTRUCTURE PLAN REPORT

Burlington to Nanticoke

Regional Infrastructure Plan Report

Burlington to Nanticoke

June 16, 2025

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

Burlington to Nanticoke Technical working group

Page intentionally left blank.

Disclaimer

This Regional Infrastructure Plan (RIP) Report for Burlington to Nanticoke region was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group (TWG).

The preferred solution(s) that have been recommended in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP TWG at the time.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	**Burlington to Nanticoke** (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")
START DATE: December 18, 2024	**END DATE:** June 16, 2025

1. INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process for the Burlington to Nanticoke region, preceded by, the publication of Needs Assessment (NA) report in September 2022 by Hydro One, followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) which were published in December 2022 and in November 2024 respectively, by the Independent Electricity System Operator (IESO). The assessment for Hamilton sub-region was not completed in the November 2024 IRRP and re-assessment of the Bronte TS supply area due to upcoming load forecast revision will be completed as an addendum to the IRRP.

Hydro One as the lead transmitter undertakes the development of a RIP with input from the TWG for the region and publishes an RIP report. The RIP report includes a common discussion of all the options and recommended plans, and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs. The RIP load forecast was refreshed for the next 10 years following the completion of IRRP based on input from WG members and developed an additional alternative for one of the 115kV supply capacity needs in Brant Area as well as an alternative location for one of the Dundas DESNs recommended in the IRRP south of Hamilton near Hydro One's existing Middleport TS. In addition, Hydro One will issue an addendum to this RIP with a final recommendation based on the findings of the Technical Working Group for the additional alternatives within 90 days of the IESO Hamilton area addendum IRRP kickoff.

Objectives:

- Provide a comprehensive summary of needs and wires plans to address the needs for the Burlington to Nanticoke region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

Scope:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs 2025 - 2035 identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, or Integrated Regional Resource Plan).

- Identification of any new needs over the 2025-2035 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified by the TWG.

2. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

This section provides a detailed overview of the various steps followed during different phases of Regional Planning Process and their outcomes starting with the Needs Assessment, Scoping Assessment, Integrated Regional Resource Plan and finally details the Regional Infrastructure plan Methodology.

3. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

This section provides a general overview of the Geographical boundaries, Circuit connections and Stations located in the Burlington to Nanticoke region though a regional planning area map and a Single Line diagram.

The Burlington to Nanticoke region covers the City of Brantford, Municipality of Hamilton, counties of Brant, Haldimand and Norfolk. The portions of Cities of Burlington and Oakville south of Dundas Street are included in the Burlington to Nanticoke region up to Third Line Road in the east.

4. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR UNDERWAY

This section provides a summary and brief description of all the projects completed in the past ten years or are currently underway.

i. The following major projects were completed during the last ten years:

i. Burlington TS (2016) – Installed an additional 230 kV circuit breaker to reduce probability of the simultaneous loss of two autotransformers to improve supply reliability of the stations supplied from 115 kV bus.

ii. Transformer replacement at stations: Dundas TS (T1&T2 -2015), Brant TS (T1&T2 -2016), Beach TS (T3 &T4 -2018), Mohawk TS (T1&T2 -2018) and Newton TS (T1&T2 - 2020).

iii. B7/B8 115 kV Transmission line capacity (2018) – addressed supply capacity constraint to Bronte TS through distribution load transfers.

iv. Horning TS (2018) – replaced 230/ 13.8 kV transformers (T1 &T2) & LV switchgear.

v. Bronte TS (2019) – replaced 115/ 27.6 kV transformers (T5 &T6) & associated LV switchgear.

vi. Brant Switching Station (2019) – installed three (3) 115 kV breakers at Brant TS integrating 115 kV B12BL/B13BL circuits with 115 kV B2 circuit from Karn TS, to provide additional supply capacity for Brant TS and Powerline MTS.

vii. Cumberland TS (2019): Power factor correction – Capacitors installed at customer level.

viii. 115 kV B3/B4 (2020): Refurbished line section from Horning Mountain Jct. to Glanford Jct. based on asset condition assessment.

ix. Elgin TS (2022): Transformers & switchgear replacement based on asset condition assessment and reconfiguring from two (2) DESNs to a single DESN.

x. Kenilworth TS (2023): Transformer & switchgear replacement based on asset condition assessment and reconfiguration from two (2) DESNs to single DESN.

xi. Gage TS (2024): Transformers & switchgear replacement based on asset condition assessment, reconfiguring station from a three (3) DESNs station to a two (2) DESNs station replacing equipment.

ii. The following major projects are underway:

i. Kenilworth TS: Power factor correction (2025)

ii. Dundas TS: Load Balancing between DESNs (2025)

iii. Norfolk area supply capacity – Load transfer and additional reactive support (2026)

iv. 115 kV B7/B8: Refurbish of line section from Burlington TS to Nelson Jct. (2025)

v. Beach TS: Autotransformer (T1/ T7/T8) Replacement (2028)

vi. Lake TS: Transformer (T2) Replacement (2028)

Note: The planned in-service year for the above projects are tentative and are subject to change.

5. LOAD FORECAST AND STUDY ASSUMPTIONS

During the study period, the load in the Burlington to Nanticoke region is expected to grow at an average annual rate of approximately 3.1% in summer from 2025 to 2035. The Region is summer peaking, so this assessment is based on summer peak loads.

The following actions and assumptions are made in this report.

- The study period for the RIP assessments is 2025-2035.
- LDCs are requested to confirmed load forecasts up to 2035 in the area.
- The CDM values were updated based on the 2025 APO to incorporate the expanded eDSM programs.
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- The Region is summer peaking, so this assessment is based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or based on historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR) based on 35°C ambient temperature.
- Bulk transmission line capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations uses non-coincident peak loads.
- Adequacy assessment is conducted as per required regulations.

6. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying Burlington to Nanticoke region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway are completed.

Needs identified in the region:

a. Asset Renewal for Major HV Transmission Equipment

i. Nebo TS: Transformer (T3/ T4) refurbishment
ii. Lake TS: DESN (T3/T4) refurbishment
iii. Beach TS: DESN (T5/T6) refurbishment
iv. Caledonia TS: Transformer (T2) refurbishment
v. Birmingham TS: Transformer (T1) and MV Metalclad Switchgear refurbishment
vi. Gage TS: DESN (T8/T9) refurbishment
vii. Jarvis TS: Transformer (T3/T4) refurbishment

The refurbishment needs that currently fall beyond the study period of this report are not included in this report and will be reassessed, as needed, during the next planning cycle. The Hamilton 115 kV cable refurbishment needs will be studied as part of the upcoming Hamilton IRRP report, led by the IESO.

b. Area Supply Needs

i. Brant Area
ii. Norfolk Area
iii. Dundas Area
iv. Bonte Area

c. Station Capacity

i. Nebo TS (T3/T4) 13.8 kV DESN
ii. Mohawk TS
iii. Newton TS
iv. Nebo TS (T1/T2) 27.6 kV DESN

The station capacity needs beyond the study period of this report are not included in this report and will be reassessed, as needed, during the next planning cycle.

d. Transmission Line Supply Capacity

The TWG identified overloading of 115 kV B2 intertie line between Brant and Woodstock area which is studied as part of the Brant area supply needs and supply capacity of C9/C12 will be studied as part of Norfolk area supply need.

e. System Reliability, Operation and Load restoration

The Technical Working Group did not identify any other reliability, operation and load restoration needs for this region during this regional planning cycle.

7. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the Burlington to Nanticoke Region. The needs include those previously identified in the NA and IRRP for the Burlington to Nanticoke Region as well as any new needs identified during the RIP phase.

8. CONCLUSION AND RECOMMENDATIONS

The major infrastructure investments recommended by the TWG in the Burlington to Nanticoke region are given below:

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Section No.
Asset Renewal Needs				
Nebo TS	Transformer (T3/ T4) refurbishment	Hydro One	2030-2035	8.1.1
Lake TS	DESN (T3/T4) Refurbishment	Hydro One	2030-2035	8.1.2
Beach TS	DESN (T5/T6) Refurbishment	Hydro One	2030-2035	8.1.3
Caledonia TS	Transformer (T2) refurbishment	Hydro One	2030-2035	8.1.4
Birmingham TS	Transformer (T1) and MV Metalclad Switchgear Refurbishment	Hydro One	2030-2035	8.1.5
Gage TS	DESN (T8/T9) Refurbishment	Hydro One	2030-2035	8.1.6
Jarvis TS	Transformer (T3/T4) refurbishment	Hydro One	2030-2035	8.1.7
Area Supply Needs				
Brant Area*	Two (2) new 230kV/ 27.6 kV 200 MVA transformation facilities near the existing Brant TS.	Hydro One	2029	8.2.1
Norfolk Area	Load transfers, additional reactive support and large Battery Storage.	Hydro One	2025	8.2.2

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Section No.
Dundas Area*	Two (2) new 230kV/ 27.6 kV 200 MVA transformation facilities near existing Dundas TS.	Hydro One	2035	8.2.3
Bronte Area	To be assessed as part of the upcoming Hamilton IRRP	Hydro One	TBD	8.2.4
Station Capacity Needs				
Nebo TS (T3/T4) 13.8 kV DESN	Transformers are to be replaced based on their asset condition assessment with Hydro One standard units	Hydro One	2025	8.3.1
Mohawk TS	Load monitoring, load transfers to neighboring stations and operational measures as required. This need to be reassessed during the next regional planning cycle	Hydro One	2035	8.3.2
Newton TS	Load monitoring, load transfers to neighboring stations and operational measures. This need to be reassessed during the next regional planning cycle	Hydro One	2035	8.3.4
Nebo TS (T1/T2) 27.6 kV DESN	Load monitoring, load transfers to neighboring stations and operational measures. Additional transformation required in the forecasted timeframe south of Hamilton.	Hydro One/ Alectra	2031	8.3.5
Transmission Line Capacity Needs				
The overloading of 115 kV B2 intertie line between Brant area and Woodstock area is included as part of the Brant area and supply capacity of C9/C12 115 kV circuits as part of the Norfolk area supply needs.				
System Reliability, Operation and Load restoration Needs				
No other system reliability, operation and load restoration needs have been identified for this region				

**- New options identified during RIP phase for these needs and will be assessed as an addendum to this report.*

Note: The planned in-service dates are tentative and subject to change.

1. INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of the Regional Planning Process. Hydro One as the lead transmitter undertakes the development of a RIP with input from the Technical Working Group (TWG) for the region and publishes a RIP report. The third cycle of the Regional Planning process for the Burlington to Nanticoke region initiated with the publication of Needs Assessment (NA) and the report published in September 2022 by Hydro One. This followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) which were published in December 2022 and November 2024 respectively, by the Independent Electricity System Operator (IESO). Typically, an IRRP takes 18 months to complete. However, due to the complex nature of the needs in the region, the IESO requested a six-month extension from the OEB to finalize the plan. The 3rd cycle IRRP did not include the assessment for Hamilton sub-region which is planned for completion in 2026 and will be an addendum to this IRRP. The LDCs supplied by Bronte TS are currently updating their load forecast. The assessment of Bronte area supply will be completed in the Hamilton IRRP addendum.

The RIP report includes a common discussion of all the options and recommended plans, and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs.

This report was prepared by Burlington to Nanticoke TWG, led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by Hydro One, the Local Distribution Companies ("LDC"), the Municipalities and the IESO. Participants of the TWG are listed below in Table 1.

Table 1: Burlington to Nanticoke Region TWG Participants

Sr. no.	Name of TWG Participants
1	Alectra Utilities Corporation
2	Burlington Hydro Inc.
3	Grand Bridge Energy Inc.
4	Hydro One Networks Inc. (Distribution)
5	Independent Electricity System Operator (IESO)
6	Oakville Hydro
7	Hydro One Networks Inc. (Lead Transmitter)

2. OBJECTIVES AND SCOPE OF REGIONAL INFRASTRUCTURE PLAN

This RIP report examines the needs in the Burlington to Nanticoke region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs for the Burlington to Nanticoke region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major high voltage transmission equipment, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near- and medium- term needs (2025-2035) identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the 2025-2035 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in Burlington to Nanticoke IRRP, Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

3.1 Overview

Bulk System Planning, Regional Planning and Distribution Planning are the three levels of planning for the electricity system in Ontario. Bulk system planning typically looks at issues that impact the system on a provincial level and require longer lead time and larger investments. Comparatively, planning at the regional and distribution levels looks at issues on a more regional or localized level. Typically, the most

essential and effective regional planning horizon is the near- to medium-term (1- 10 years), whereas long-term (10-20 years) regional planning mostly provides an outlook with little details about investments because the needs and other factors may vary over time. On the other hand, bulk system plans are developed for the long term because of the larger magnitude of investments.

The regional planning process begins with a Needs Assessment which is led by the transmitter to identify, assess, and document which of the needs that,

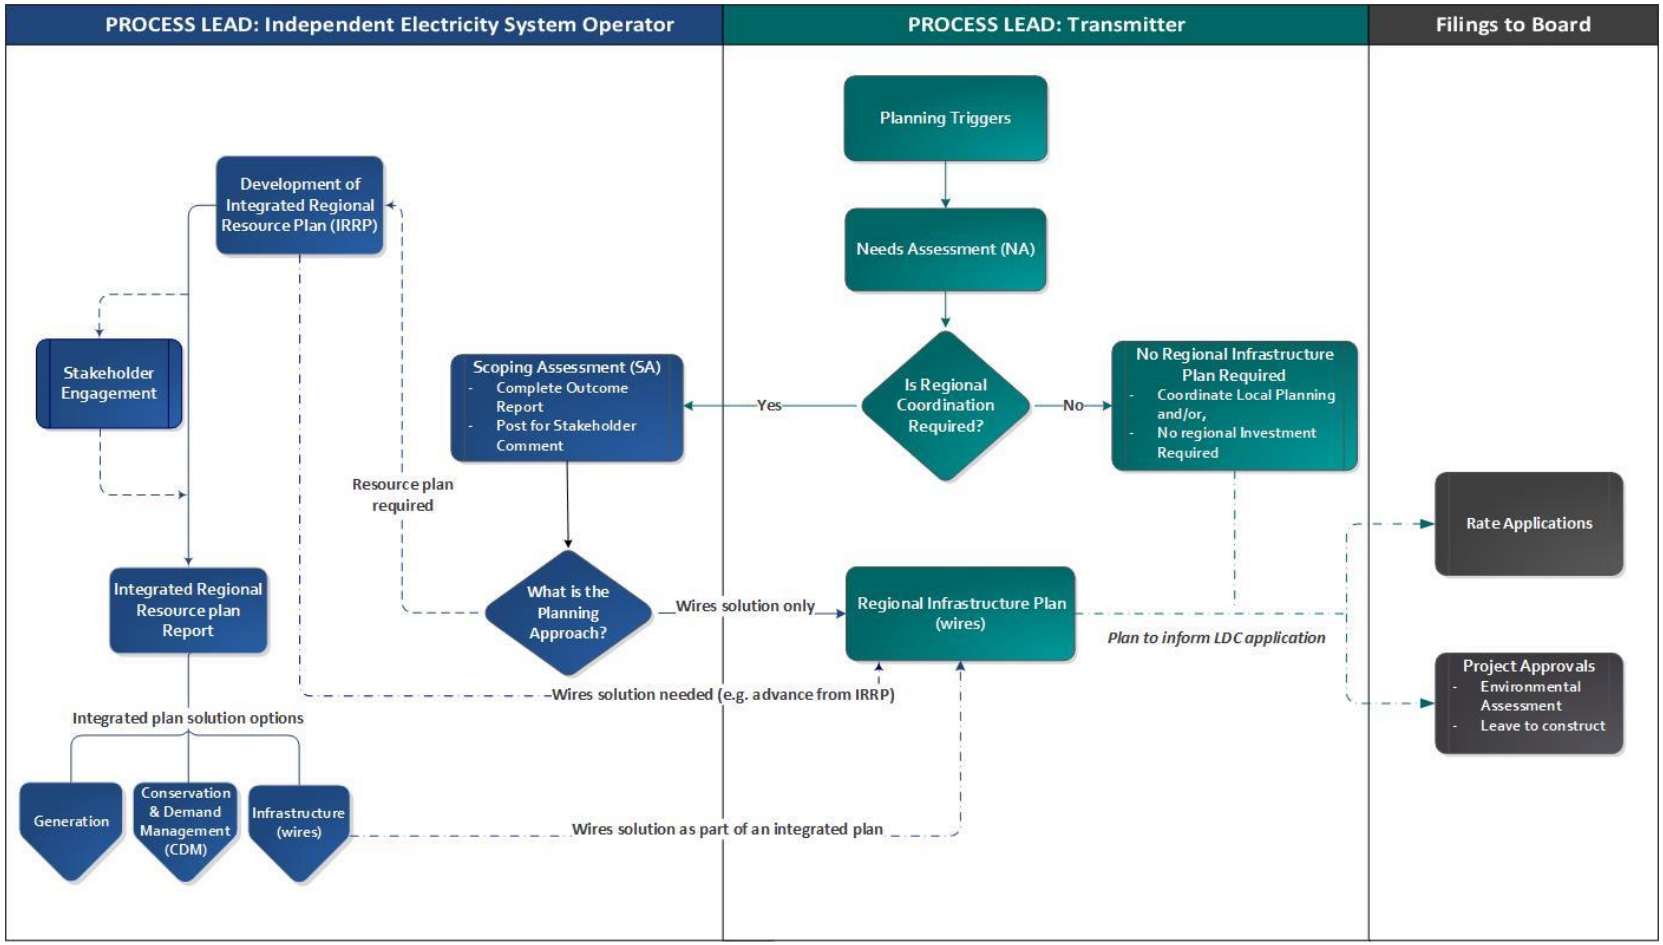
a) can be addressed directly between the customer and transmitter along with a recommended plan, and;
b) require further regional coordination and identification of Local Distribution Companies (LDCs) to be involved in further regional planning activities for the region.

At the end of the NA, a decision is made by the TWG as to whether further regional coordination is necessary to address some or all regional needs. If no further regional coordination is required, recommendation to implement the recommended option and any necessary investments are planned directly by the LDCs (or customers) and the transmitter. The region's TWG can also recommend to the transmitter and LDCs to undertake a local planning process for further assessment when needs are:

a) local in nature;
b) require limited investments in wires (transmission or distribution) solutions, and;
c) do not require upstream transmission investments.

If coordination at the regional or sub-regional levels is required for identified regional needs, then the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires or resource alternatives, e.g., Conservation and Demand Management (CDM), Distributed Generation (DG), etc., in order to make a decision on the most appropriate regional planning approach including Local Plan (LP), IRRP and/or RIP.

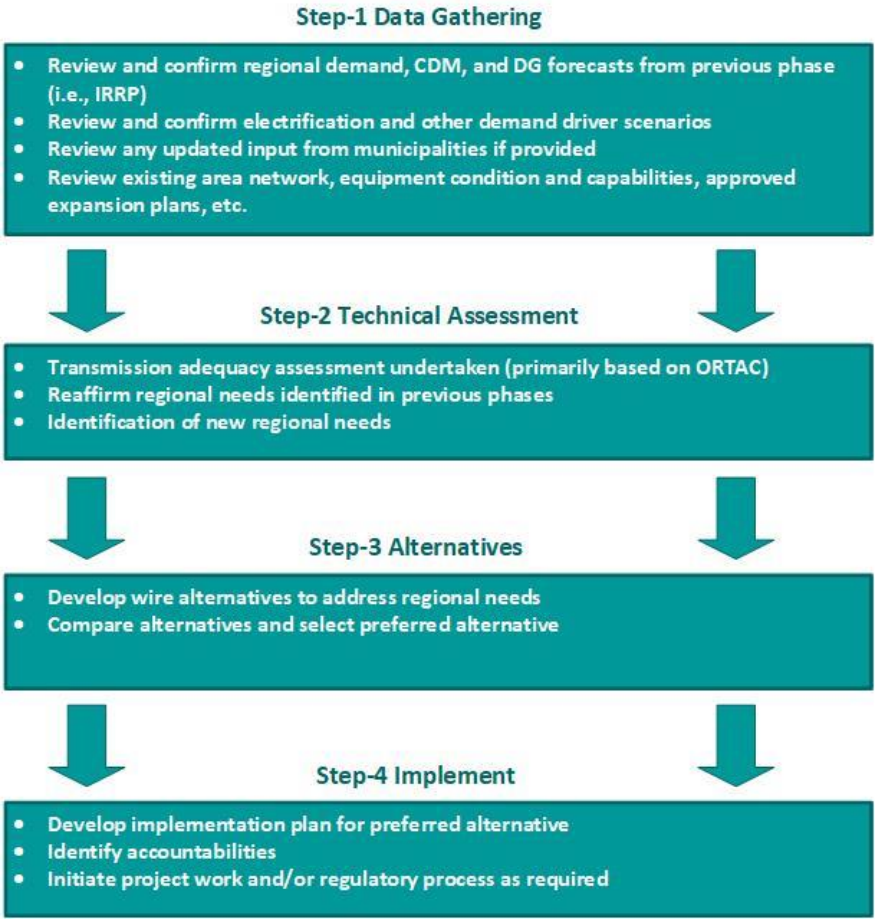
The primary purpose of the IRRP is to identify and assess both resource and wires options at a higher or macro level, but sufficient to permit a comparison of resource options vs. wire infrastructure to address the needs. Worth noting, the LDCs' CDM targets as well as contracted DG plans provided by IESO and LDCs are reviewed and considered at each step in the regional planning process.



If and when an IRRP identifies that resource and/or wires options may be most appropriate to meet a need, resource/wires planning can be initiated in parallel with the IRRP or in the RIP phase to undertake a more detailed assessment, develop specific resource/wires alternatives, and recommend a preferred wires solution.

The RIP phase is the final phase of the regional planning process and involves discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address these needs. This phase is led and coordinated by the transmitter, and the deliverable is a comprehensive and consolidated report of a wires plan for the

region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.



The various phases of Regional Planning Process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome are shown below in figure-1.

Figure-1 Regional Planning Process Flowchart

3.2 Regional Infrastructure Plan Methodology

Figure-2 Regional Infrastructure Plan Methodology

Regional Infrastructure Plan phase is a four-step process which are described below:

3.2.1. Data Gathering:

The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with TWG to reconfirm or update the information as required. The data collected includes:

- Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs. The municipalities were contacted as part of IRRP stakeholder engagement process to get their insight on the future load growth and was translated into the load forecast through inputs provided by their respective

LDCs. As agreed by TWG members, the load forecast from the IRRP to be used for this RIP unless material changes in the load forecast are envisaged.

- Review and confirm electrification and other growth scenarios which affect the projects recommended in previous stages.
- Existing area network and capabilities including any bulk system power flow assumptions.
- Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

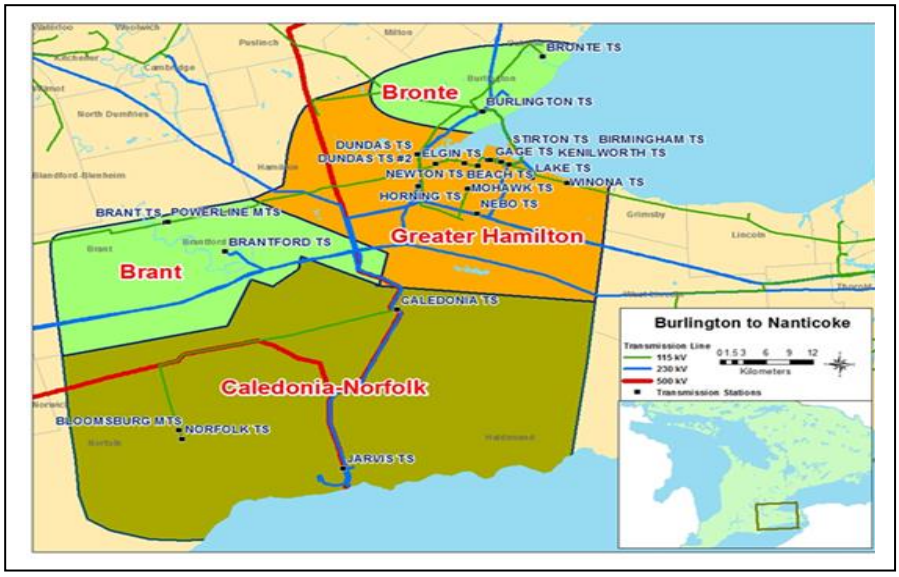
3.2.2. Technical Assessment:

The second step is a technical assessment to review the adequacy of the regional system, including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3.2.3. Alternative Development:

The third step is the development of wires options to address needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

3.2.4. Implementation Plan:



The fourth and last step is the development of the implementation plan for the preferred alternative, identifying accountabilities and initiating project work or obtaining permission from the Regulatory Commission, if any.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The Burlington to Nanticoke region covers the city of Brantford, municipality of Hamilton, and counties of Brant, Haldimand and Norfolk. Portions of Burlington and Oakville south of Dundas Street are included in the Burlington to Nanticoke region up to Third Line Road in the east.

The geographical boundaries of the Burlington to Nanticoke Region are shown in Figure 3 below.

Figure 3: Map of Burlington to Nanticoke Regional Planning Area

Bulk electrical supply to the Burlington to Nanticoke Region is provided through the 500/230 kV autotransformers at Nanticoke TS and Middleport TS and 230 kV circuits from Middleport TS, Nanticoke TS and Beck TS. The 115 kV network is supplied by 230/115 kV autotransformers at Burlington TS, Beach TS and Caledonia TS. The area loads are supplied by a network of 230 kV and 115 kV transmission lines and step-down transformation facilities. The area has been divided into four sub-regions as shown in Figure 3 and described below:

The **Brant sub-region** encompasses the County of Brant, City of Brantford, and surrounding areas. Electricity supply to the sub-region is provided by:

- Brant TS and Powerline MTS are supplied by 115 kV double circuit B12BL/B13BL line and B2 single circuit line.
- Brantford TS supplied by the 230 kV double circuit transmission line M32W/M33W.

The Brant Sub-region transmission facilities are shown in Figure 3-1.

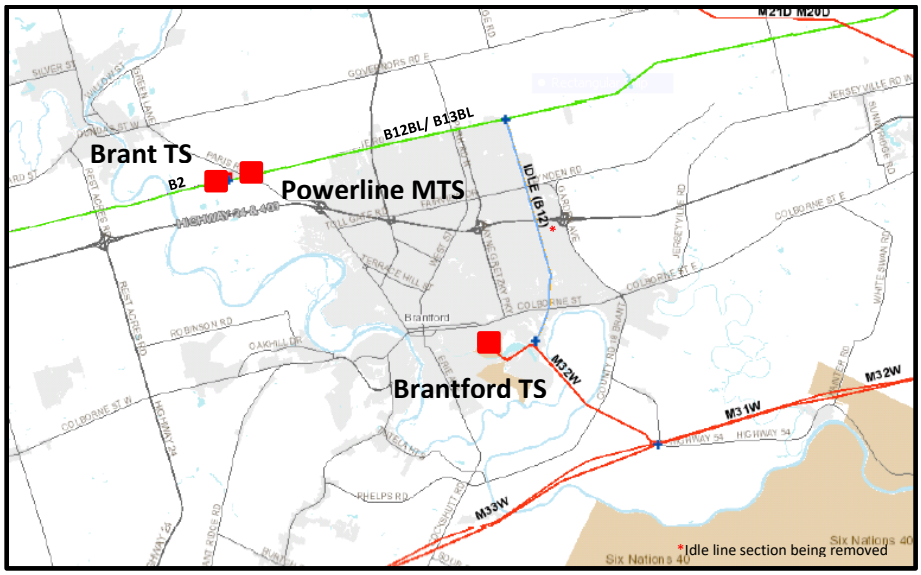


Figure 3-1 Brant sub-region

The total 2024 non-coincident peak demand for the three stations was 278 MW. GrandBridge Energy Inc. is the main LDCs that serves the electricity demand for the City of Brantford. Hydro One Distribution supplies load in the outlying areas of the sub-region. The electricity demand is comprised of residential, commercial, and industrial customers.

The **Bronte sub-region** covers the City of Burlington and the western part of the City of Oakville up to Third Line Road. Electricity supply to the sub-region is provided by:

- Bronte TS is supplied by 115 kV double circuit line B7/B8.
- Burlington TS is supplied by 230 kV double circuit line Q23BM/ Q25BM.
- Cumberland TS supplied by 230 kV double circuit transmission line B40C/ B41C.

The Bronte sub-region transmission facilities are shown in Figure 3-2.

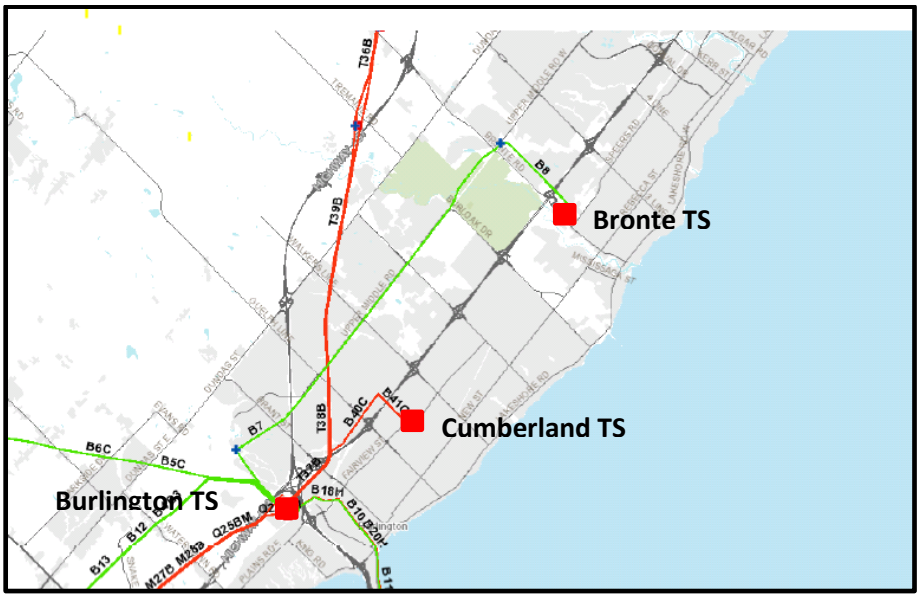

Figure 3-2 Bronte sub-region

This area is served by Burlington Hydro and Oakville Hydro. The electricity demand is comprised of residential, commercial, and industrial customers. The total 2024 non-coincident peak station demand for the three stations was 361 MW.

The **Greater Hamilton sub-region** encompasses the City of Hamilton that includes the Townships of Flamborough and Glanbrook and towns of Dundas and Stoney Creek. The electricity supply to the sub-region is as follows:

- Beach TS 115 kV area which includes four 115 kV step down stations Birmingham TS, Kenilworth TS, Stirton TS and Winona TS supplied from the 230/115 kV autotransformers at Beach TS.
- Burlington TS 115kV area which includes Dundas TS, Dundas #2, Elgin TS, Gage TS, Mohawk TS, Newton TS and one customer owned transformer station (CTS) supplied from the 230/115 kV autotransformers at Burlington TS.
- 230 kV area which includes Beach TS (T3/T4 & T5/T6 DESNs), Horning TS, Nebo TS, Lake TS and two customer owned stations supplied from 230 kV circuits connecting into Beach TS and Burlington TS.

The Greater Hamilton sub-region transmission facilities are shown in Figure 3-3.

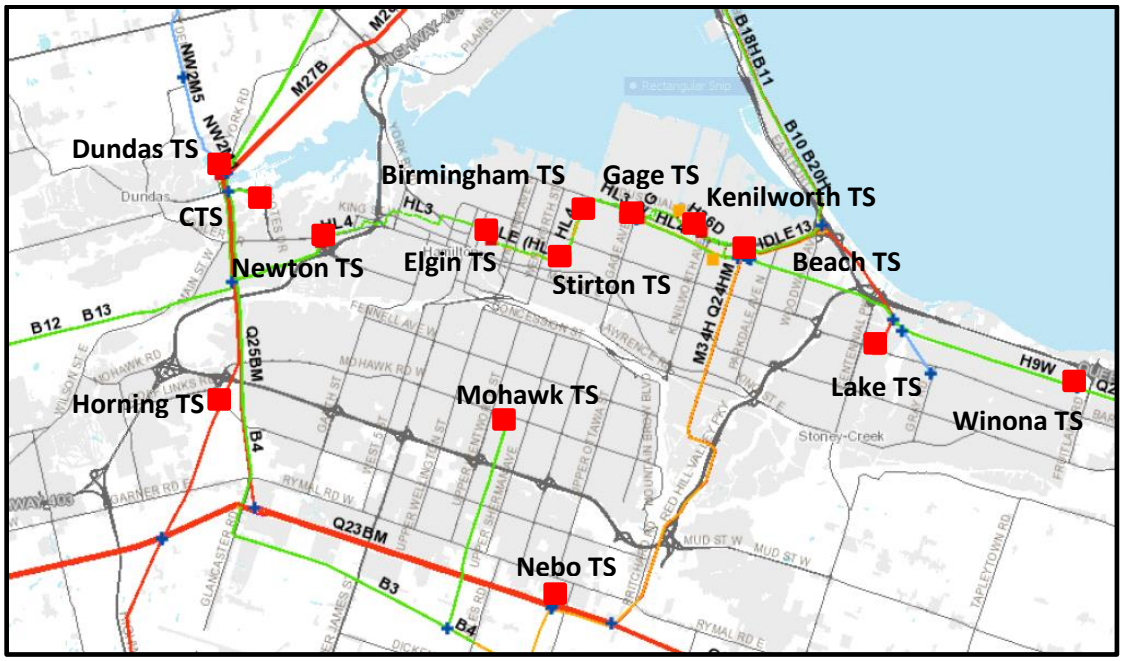

Figure 3-3 Greater Hamilton sub-region

The total 2024 non-coincident peak demand for the Greater Hamilton sub-region was 1330 MW. The area is served by Alectra Utilities, Hydro One Distribution, and CTSs comprise a significant number of large industrial customers along with commercial and residential customers.

The **Caledonia Norfolk sub-region** covers the eastern part of Norfolk County and the western part of Haldimand County. Electricity supply to the Sub-region is provided by:

- Caledonia TS supplied by 230 kV double circuit line N5M/S39M.
- Jarvis TS, a large Battery Energy Storage System (BESS) and two CTSs supplied from the 230 kV double circuit line N21J/N22J.
- One CTS is supplied from the 230 kV single circuit N20K.
- Bloomsburg DS and Norfolk TS are supplied from 115 kV double circuit transmission line C9/C12.

The Caledonia Norfolk sub-region transmission facilities are shown in Figure 3-4.

The area is served by Hydro One Distribution. The electricity demand mix is comprised of residential, commercial and industrial uses. The 2024 non-coincident peak demand for this sub-region was 429 MW.

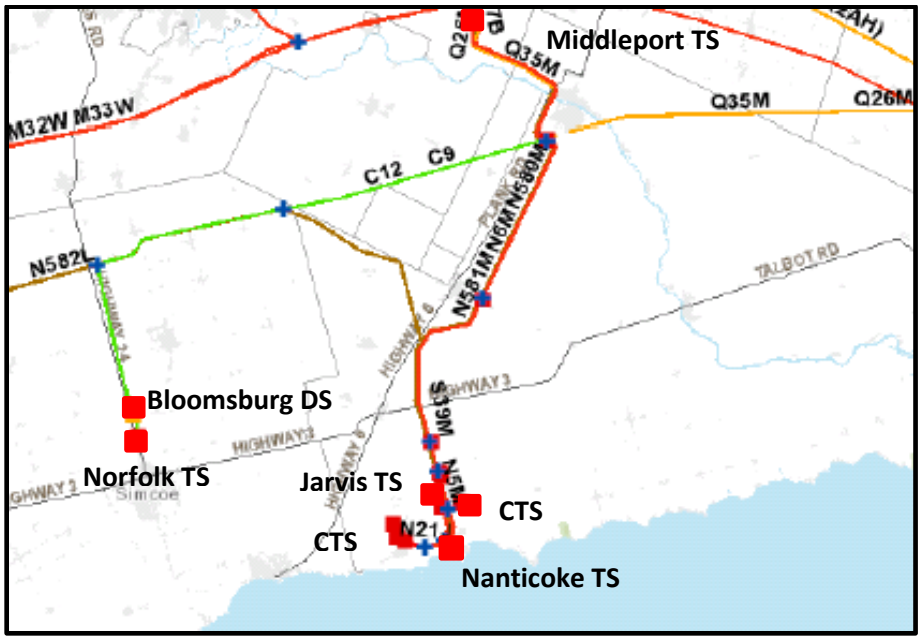

Figure 3-4 Caledonia Norfolk sub-region

The circuits and stations of the area are summarized in Table 2 below:

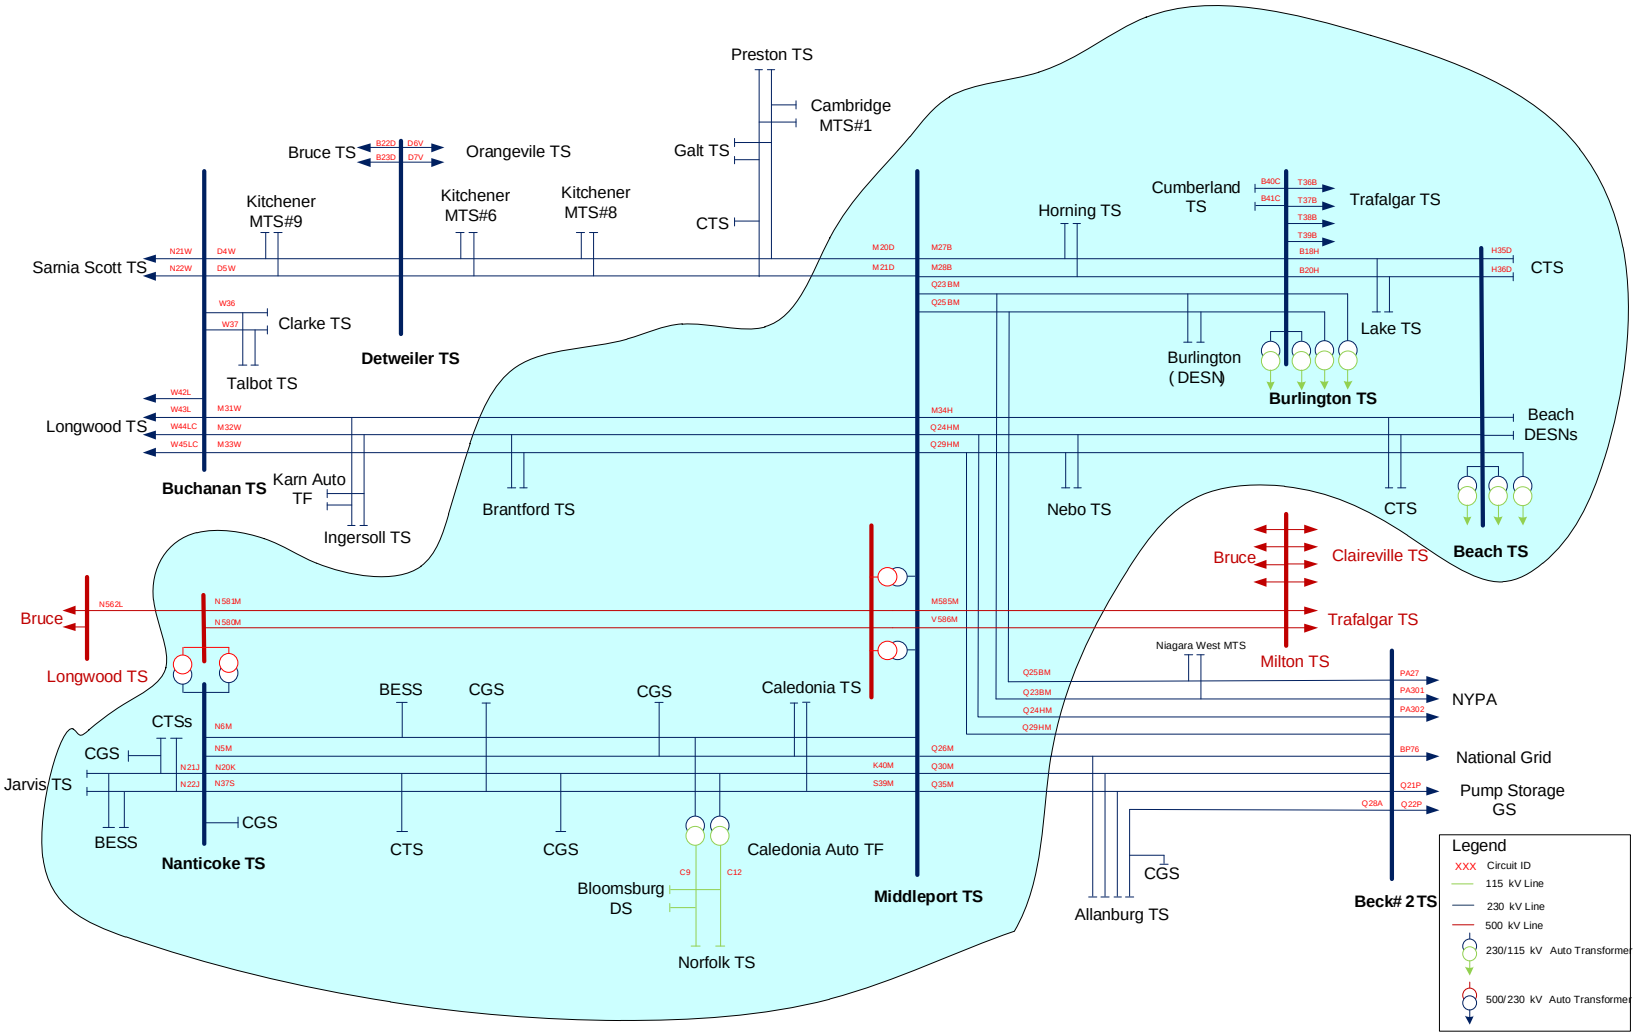
Table 2: Transmission Station and Circuits in the Burlington to Nanticoke region

115kV circuits	230kV circuits	Hydro One Transformer Stations	Generation Stations
B10, B11, H5K, H6K, HL3, HL4, Q2AH, H9W, B12BL, B13BL, B7, B8, B5G, B6G, B3, B4, C9, C12, K1G, K2G	H35D, H36D, B18H, B20H, M34H, Q24HM, Q29HM, B40C, B41C, M27B, M28B, Q23BM, Q25BM, Q30M, M31W, M32W, M33W, M20D, M21D, N5M, N6M, S39M, K40M, N21J, N22J, N37S, N20K	Beach TS*, Birmingham TS, Bloomsburg DS, Brant TS, Brantford TS, Bronte TS, Burlington TS*, Caledonia TS*, Cumberland TS, Dundas TS, Dundas TS #2, Elgin TS, Gage TS, Horning TS, Jarvis TS, Kenilworth TS, Lake TS, Mohawk TS, Nebo TS, Newton TS, Norfolk TS, Powerline MTS, Stirton TS, Winona TS, CTS#1, CTS#2, CTS#3, CTS#4, CTS#5, CTS#6	CGS#1, CGS#2, CGS#3, CGS#4, CGS#5, BESS#1, BESS#2

*Stations with 230kV/ 115kV Autotransformers installed

The single line diagram of the Transmission Network of Burlington to Nanticoke region is shown in Figure 4 below.

Figure 4: Burlington to Nanticoke Region Transmission Single Line Diagram



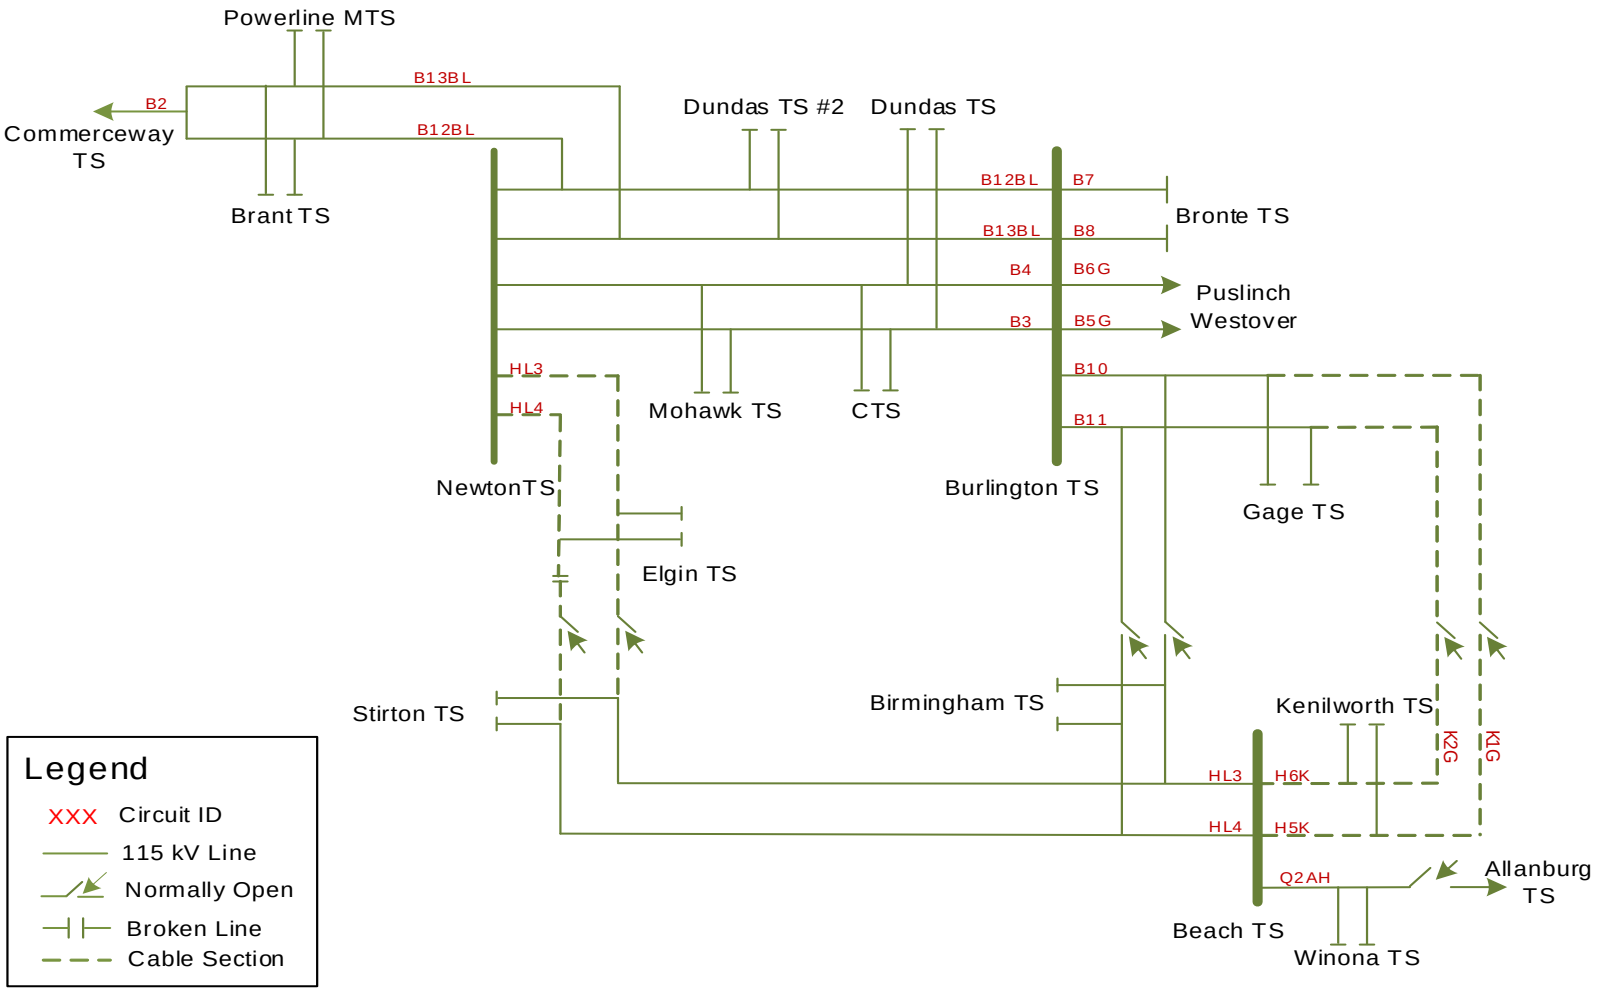


Figure 5: Burlington to Nanticoke Region Transmission Hamilton- Brant Area Single Line Diagram

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR ARE UNDERWAY

In this section a complete list of all the projects that have been completed in the past ten years or are currently underway is provided and are briefly discussed in the sub-sections. As a part of this or previous Regional Planning Cycle(s), several "Major HV Transmission Projects" were recommended in the Burlington to Nanticoke region to improve the supply capability and reliability.

Hydro One, being the only Transmission Asset Owner (TAO) in the region, has undertaken the execution of the projects recommended in the past ten years. A summary and brief description of all the projects completed or are currently underway is given below:

I. The following major projects were completed during the last ten years:

i. Burlington TS (2016) – installed an additional 230 kV circuit breaker to reduce probability of the simultaneous loss of two autotransformers to improve supply reliability of the stations supplied from 115 kV bus.

ii. Transformer replacement at stations: Dundas TS T1&T2 (2015), Brant TS T1&T2 (2016), Beach TS T3&T4 (2018), Mohawk TS T1&T2 (2018) and Newton TS T1&T2 (2020).

iii. B7/B8 115 kV Transmission line capacity (2018) – addressed supply capacity constraint to Bronte TS through distribution load transfers (Ongoing)

iv. Horning TS (2018) – replaced 230/ 13.8 kV transformers (T1/T2) & LV switchgears.

v. Bronte TS (2019) – replaced 115/ 27.6 kV transformers (T5/T6) & associated LV switchgear.

vi. Brant Switching Station (2019) – installed three (3) 115 kV breakers at Brant TS integrating 115 kV B12BL/B13BL circuits with 115 kV B2 circuit from Karn TS, to provide additional supply capacity for Brant TS and Powerline MTS.

vii. Cumberland TS (2019): Power factor correction – Capacitors installed at customer level.

viii. 115 kV B3/B4 (2020): Based on asset condition assessment refurbish line section from Horning Mountain Jct. to Glanford Jct.

ix. Elgin TS (2022): Transformers & switchgear replacement based on asset condition assessment and reconfiguring from two (2) DESNs to a single DESN.

x. Kenilworth TS (2023): Transformer & switchgear replacement based on asset condition assessment and reconfiguration from two (2) DESNs to single DESN.

xi. Gage TS (2024): Transformers & switchgear replacement based on asset condition assessment, reconfiguring station from a three (3) DESNs station to a two (2) DESNs station replacing equipment based on their asset condition assessment.

II. Following Major projects are underway:

i. Kenilworth TS: Power factor correction (2025)
ii. Dundas TS: Load Balancing between DESNs (2025)
iii. Norfolk area supply capacity – Load transfer and reactive support (2026)
iv. 115 kV B7/B8: Refurbish line section from Burlington TS to Nelson Jct. (2025)
v. Beach TS: Autotransformer (T1/ T7/T8) replacement (2028)
vi. Lake TS: Transformer (T2) Replacement (2028)

Note: The planned in-service year for the above projects is tentative and is subject to change.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

6.1. Load Forecast

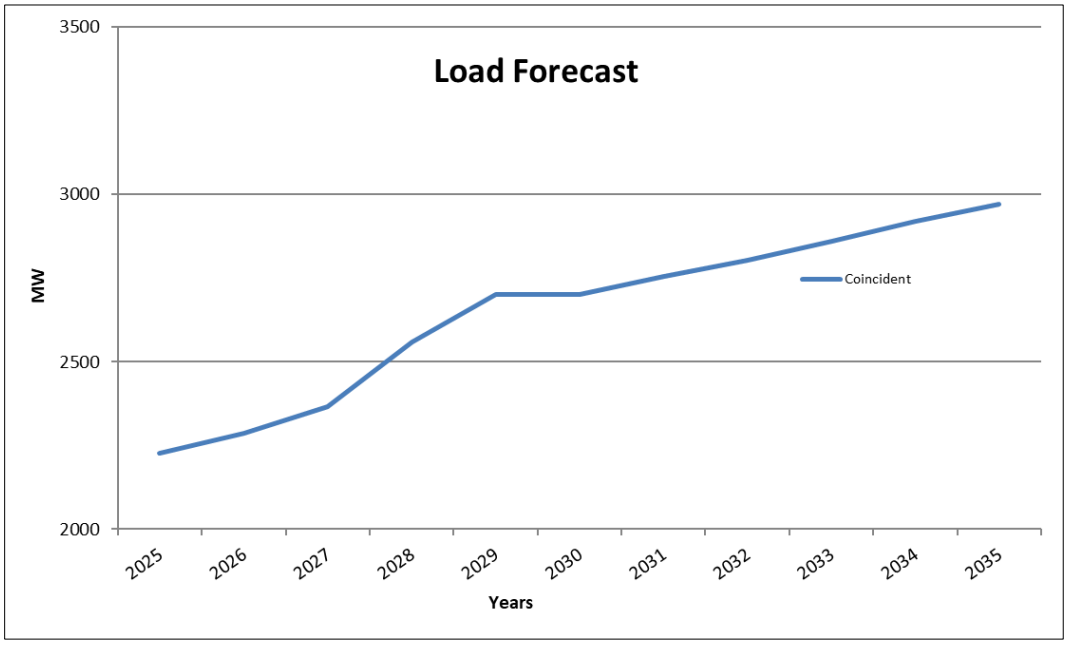
The loading pattern for the years prior to 2024 (2019 – 2023) were impacted by COVID 19 and may not provide a good base load for future load forecasting. A new load forecast has been developed with participation of the TWG using 2024 station loads as base year, updated CDM from the IESO and revised load forecast from GrandBridge Energy. This results in a 3.2% lower load forecast than IRRP. The municipalities were contacted as part of IRRP stakeholder engagement process to get their insight into the future load growth and was translated into the load forecast through inputs provided by their respective LDCs. TWG participants, including representatives from LDC's, IESO and Hydro One provided information and input for this new Load forecast that will be used in this report.

During the study period, the load in the Burlington to Nanticoke region is expected to grow at an average annual rate of approximately 3.1% in summer from 2025 to 2035. The Region is summer peaking, so this assessment is based on summer peak loads.

Figure 5 & 6 shows the Burlington to Nanticoke region extreme summer weather net coincident and non-coincident load forecast from 2025 to 2035. The load forecasts from the Burlington to Nanticoke region were adopted as agreed by the TWG. The load forecast shown is the regional non-coincident forecast, representing the sum of the load in the area for the step-down transformer stations.

Non-coincident and coincident forecast for the individual stations in the region is available in Appendix A and is used to determine any need for station capacity relief in the region.

Figure 6: Burlington to Nanticoke region summer coincident Net Peak Load Forecast



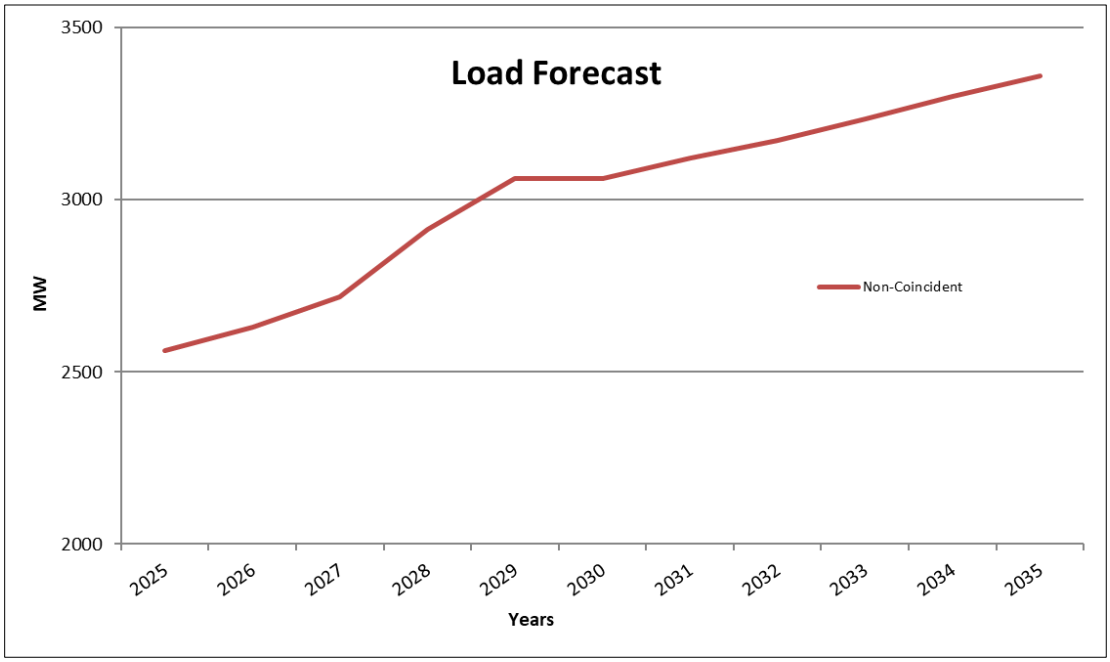


Figure 7: Burlington to Nanticoke region summer Non-coincident Net Peak Load Forecast

6.2. Other Study Assumptions

The following other actions and assumptions are made in this report.

- The study period for the RIP assessments is 2025-2035.
- Most LDCs reconfirmed and GrandBridge Energy updated the load forecast up to 2035 in the area.
- All planned facilities for which work has been initiated and are listed in section 5 are assumed to be in-service.
- The Region is peaking in summer, so this assessment is based on 2024 summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks or based on historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR) based on 35°C ambient temperature.
- Bulk transmission line capacity adequacy is assessed by using coincident peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations uses non-coincident peak loads.
- All Battery storage projects are assumed to only charge during off-peak hours. Any future charging of these battery storage projects may impact LMC (Load Meeting Capability) of some circuits.
- Adequacy assessment is conducted as per required regulations.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying Burlington to Nanticoke region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway, listed in **"Section 5"**, are completed.

In the current regional planning cycle, the following regional assessments were completed, and their findings were used as inputs to this RIP report:

- Burlington to Nanticoke region Third cycle Needs Assessment Report, Completed in September 2022 by Hydro One
- Burlington to Nanticoke region Third cycle Scoping Assessment Report, Completed in December 2022 by the IESO

- Burlington to Nanticoke region Third cycle Integrated Regional Resource Plan Report, Completed in November 2024 by the IESO

The Technical Working Group identified several regional needs based on the forecasted demand over the near-to-mid-term period in the reports mentioned above. The results of the Adequacy Assessment to define the needs are discussed in sub-sections "7.1 to 7.4" and a detailed description and status of plans to meet these needs are given in **"Section 8"** of this report.

7.1. Asset Renewal Needs for Major HV Transmission Equipment

In addition to the asset renewal needs identified in previous regional planning cycle, Hydro One and TWG have also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the Burlington to Nanticoke region. The complete list of major HV transmission equipment requiring replacement in the Burlington to Nanticoke region is provided in table 3 in this sub-section. Hydro One is the only Transmission Asset Owner (TAO) in the Region.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers.
- 230 and 115kV breakers where:
    - replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

Table 3: Major HV Transmission Asset assessed for Replacement in the Region

Station/Circuit	Need Description	Planned ISD
Nebo TS	Transformer (T3/ T4) refurbishment	2030 - 2035
Lake TS	T3/T4 DESN refurbishment	2030 – 2035
Beach TS	T5/T6 DESN refurbishment	2030 – 2035
Caledonia TS	Transformer (T2) refurbishment	2030 – 2035
Birmingham TS	Transformer (T1) and MV Metalclad Switchgear refurbishment	2030 – 2035
Gage TS	T8/T9 DESN refurbishment	2030 – 2035
Jarvis TS	Transformer (T3/T4) refurbishment	2030 - 2035

The above refurbishment needs are currently planned but may be adjusted or reconsidered based on a variety of evolving factors. The refurbishment needs T12 autotransformer at Burlington TS and MV switchgear refurbishment needs at Burlington TS, Dundas TS and Norfolk TS included in the earlier phases of Regional Planning cycle fall outside the study period of this report and will be reassessed during the next planning cycle. Any refurbishment needs for 115 kV cables in the Hamilton area will be assessed as part of the upcoming Hamilton IRRP report.

Note: The planned in-service timeframe for the above projects is tentative and is subject to change.

7.2. Area Supply Needs

Over the study period 2025-2035, RIP reviewed the area supply capacity needs that include combination of both the line and station supply capacity adequacy for isolated areas with limited available transfer capacities. During the earlier phases of this regional planning cycle two such areas, i.e. Norfolk and Brant areas, were identified requiring reinforcement/s. The future station supply capacity need at Dundas TS and Dundas TS#2 are combined as a single 27.6 kV Dundas area need. After the completion of the IRRP in late 2024, Burlington Hydro and Oakville Hydro approached TWG to revise the load forecast to accommodate additional supply capacity need in the area supplied by Bronte TS.

Sr. No.	Name of Area	Need	Maximum capacity	Current loading	Need Year
1	Brant Area	Supply Capacity	134 MW	148 MW	Current and 2029[1]
2	Norfolk Area	Line supply Capacity	80 MW	101 MW	Current
3	Dundas Area	Station Capacity	188MW	151 MW	2035[2]
4	Bonte Area	TBD*	135 MW	122 MW	TBD[3]

1- LDC will transfer loads to Brantford TS to adhere to 134 MW limit. Brantford TS will reach its supply capacity by 2029, assuming no transfer constraints. Need may be sooner as load balancing between the stations may be limited due to physical constraints.

2- Need may be sooner due to load transfer constraints between the stations

3- Burlington Hydro and Oakville Hydro, the local LDCs are in the process of developing a revised load forecast

7.3. Station Capacity Needs

Over the study period 2025-2035, RIP reviewed the capacity of all the 230kV and 115kV Transforming stations within the Burlington to Nanticoke region. The NA and IRRP studies had previously indicated that the following stations require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast, the stations which require capacity relief during the study period are shown in Table 4 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer) Limited Time ratings.

Table 4: Burlington to Nanticoke region Station Capacity Needs in the study period

Sr. No.	Station Name	Station LTR(MW) (Summer)	2024 Loading (MW) (Summer)	Need Date
1	Nebo TS (T3/T4) 13.8 kV DESN	51	52	Current*
2	Mohawk TS	90	72	2035
3	Newton TS	75	48	2035
4	Nebo TS (T3/T4) 27.6 kV DESN	178	145	2031

*- The LDC has historically maintained the load power factor closed to unity that provides a little more supply capacity, and the loading has remained around its supply capacity.

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.4. Transmission Line Supply Capacity Needs

Over the study period 2025-2035 RIP reviewed the capacity of all the 230kV and 115kV Transmission lines within the Burlington to Nanticoke region. The NA and IRRP studies had previously indicated that the following Transmission lines require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast and following contingencies, the Transmission lines which require capacity relief during the study period are shown in Table 5 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer) Limited Time ratings.

Table 5: Burlington to Nanticoke region Transmission Line Capacity Needs in the study period

Sr.no.	Name of Circuit	Name of Section	Maximum capacity	Current loading	Need Date
The overloading of 115 kV B2 intertie line between Brant area and Woodstock area is included in Brant area supply need and the supply capacity of 115 kV C9/C12 line is included in the Norfolk area need.					

7.5. System Reliability, Operation and Load Restoration Needs

Load security and load restoration needs were reviewed as part of the current study. The ORTAC Section 7 requires that no more than 600 MW of load be lost as a result of a double circuit contingency.

Further, loads are to be restored in the restoration times[1] specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

The RIP further confirms that there are no violations identified in the region with regards to System Reliability, Operation and Load restoration requirements.

[1] These approximate restoration times are intended for locations that are near staffed centers. In more remote locations, restoration times should be commensurate with travel times and accessibility

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the Burlington to Nanticoke Region. These needs include those previously identified in the NA and IRRP for the Burlington to Nanticoke Region as well as any new needs identified during the RIP phase. All estimated costs included in the alternative analysis are considered as planning budgetary estimates and are used for comparative purposes only and may vary. The Needs in the region are summarized below in Table 6 below:

Table 6: Near/ Mid-term Needs Identified in the Region

Area/ Station/Circuit	Description of Need	Need Date	RIP Report Section
Asset Renewal Needs*			
Nebo TS	Replace T3/ T4 transformers	2030 - 2035	8.1.1
Lake TS	Replace T3/T4 transformers and switchgear	2030 - 2035	8.1.2
Beach TS	Replace T5/T6 transformers and switchgear	2030 - 2035	8.1.3
Caledonia TS	Replace T2 transformer	2030 - 2035	8.1.4
Birmingham TS	Replace T1 Transformer and MV Switchgears	2030 - 2035	8.1.5
Gage TS	Replace T8/T9 transformers and switchgear	2030 - 2035	8.1.6
Jarvis TS	Replace T3/ T4 transformers	2030 - 2035	8.1.7
Area Supply Needs			
Brant Area	Supply capacity	Current and 2029**	8.2.1
Norfolk Area	Transmission line supply capacity	Current	8.2.2
Dundas Area	Station supply capacity constraint	2035	8.2.3
Bonte Area	LDC developing load forecast to identify additional needs above current supply capacity	TBD	8.2.4
Station Capacity Needs			
Nebo TS (T3/T4) DESN	Nebo T3/T4 is a 230kV / 13.8kV DESN operating around its supply capacity for a long time	Current	8.3.1
Mohawk TS	Mohawk TS will be approaching its supply capacity by the end of study period.	2035	8.3.2
Newton TS	Newton TS is a 115kV/ 13.8 kV single DESN station supply loads in western part of city of Hamilton	2035	8.3.3

Nebo TS (T1/T2) DESN	Nebo T1/T2 is a 230kV / 27.6 kV DESN requiring additional transformation capacity in the need timeframe.	2031	8.3.4
Transmission Line Capacity Needs			
The overloading of 115 kV B2 intertie line between Brant area and Woodstock area is included in Brant area supply need and the supply capacity of C9/C12 line is included in the Norfolk area need.			
System Reliability, Operation and Load restoration Needs			
The Technical Working Group did not identify any other reliability, operation and load restoration needs for this region.			

*- The above refurbishment needs are currently planned but may be adjusted or reconsidered based on a variety of evolving factors.

**- LDC will transfer loads to Brantford TS to adhere to 134 MW limit. Need may be sooner due to physical load transfer constraints.

8.1 Asset Renewal Needs for Major HV Transmission Equipment

The Asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities;
- Eliminating equipment by transferring all the load to other existing facilities;
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement); and
- Replacing equipment with higher ratings and built to current standards.

From Hydro One's perspective as a facility owner and operator of its transmission equipment, doing nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance costs and longer duration of customer outages.

8.1.1 Nebo TS - Replace T3/ T4 Transformers

Nebo TS is located south of the city of Hamilton, having two DESNs units T1/T2 and T3/T4 supplying loads in the city of Hamilton and surrounding areas. The loads at T3/T4 13.8 kV DESN at Nebo TS has been historically around its supply capacity and is currently marginally overloaded, supplying loads of 52 MW against its supply capacity of 51 MW. The loads at this DESN are currently forecasted to grow above and beyond its supply capacity.

At this time both T3/T4 230 kV / 13.8 kV 75 MVA transformers are planned for replacement based on their asset condition assessment in the next 10 years.

Alternatives and Recommended Plan

The following alternatives are considered to address Nebo TS asset replacement needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset conditions and would result in increased maintenance costs.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring T3/T4 DESN at Nebo TS. This alternative was considered but is not feasible.
- Replacement of the assets: Replace existing nonstandard 75 MVA T3/ T4 transformers with 100 MVA Hydro One standard units.

The TWG recommended that Hydro One and Alectra monitor the loading at Nebo TS T3/T4 DESN and take remedial measures, if required, until replacement of these transformers is completed. The TWG recommends that Hydro One replace T3/T4 transformers at Nebo TS with Hydro One standard 100 MVA units.

8.1.2 Lake TS - T3/ T4 DESN Refurbishment

Lake TS is located south-east of the city of Hamilton, having two DESNs units T1/T2 and T3/T4 supplying loads in the city of Hamilton and surrounding areas. T1/T2 is a 27.6 kV DESN with a current load of 49 MW having a sufficient supply capacity of 94 MW over the study period. The T3/T4 13.8 kV DESN is currently supplying 45 MW of loads having a sufficient supply capacity of 113 MW over the study period.

At this time both 230kV/13.8kV 75 MVA T3/ T4 transformers at Lake TS are planned for future replacement based on their asset condition assessment.

Alternatives and Recommended Plan

The following alternatives are considered to address Lake TS asset replacement needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset conditions and would result in increased maintenance costs.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring T3/T4 DESN at Lake TS. This alternative was considered but is not feasible.
- Replacement of the assets: Replace existing nonstandard 75 MVA T3/ T4 transformers with 100 MVA Hydro One standard units.

The TWG recommends that Hydro One replace T3/T4 transformers at Lake TS with Hydro One standard 100 MVA units.

8.1.3 Beach TS - T5/T6 DESN Refurbishment

Beach TS is located inside the city of Hamilton, having two DESNs units T3/T4 and T5/T6 having supply capacities of 135 MW and 96 MW and supplying loads of 16 MW and 64 MW respectively. The supply capacities of both T3/ T4 and T5/ T6 DESNs are sufficient over the study period.

At this time both 230 kV/ 13.8 kV T5/ T6 DESN transformers have been identified by Hydro One for future replacement based on their asset condition assessment.

Alternatives and Recommended Plan

The following alternatives are considered to address Beach TS asset replacement needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset conditions and would result in increased maintenance costs.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring T5/T6 DESN at Beach TS. This alternative was considered but is not feasible due to customer requirements.
- Replacement of the assets: Replace T5/T6 DESN replacing existing nonstandard 75 MVA T5/ T6 transformers with 100 MVA Hydro One standard units.

The TWG recommends that Hydro One replace T5/T6 transformers at Beach TS with Hydro One standard 100 MVA units.

8.1.4 Caledonia TS-Replace T2 Transformer

Caledonia TS is located in the Haldimand area supplying area loads. Caledonia TS is a single T1/T2 DESN station having 83 MVA transformers supplying loads of 53 MW and having a sufficient supply capacity of 99 MW over the study period.

At this time the T2 83 MVA 230 kV/ 27.6 kV transformer has been identified by Hydro One for replacement based on asset condition assessment.

Alternatives and Recommended Plan

The following alternatives are considered to address Caledonia TS asset replacement needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance cost.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring T1/T2 DESN at Caledonia TS. This alternative was considered but is not feasible as there are no nearby stations to transfer existing DESN loads.
- Replacement of the assets: Replace T2 transformer replacing existing 83 MVA transformer with a similar Hydro One standard unit.

The TWG recommends that Hydro One replace the T2 transformer at Caledonia TS with a similar sized Hydro One standard unit.

8.1.5 Birmingham TS - Replace T1 Transformer and MV Switchgears

Birmingham TS is located in the city of Hamilton, having two DESN units T1/T2 and T3/T4 of 75MVA each with supply capacities of 76 MW and 91 MW respectively which is sufficient over the study period. Birmingham TS mainly supplies a large industrial customer with unique connection requirements.

At this time, one 115 kV/ 13.8 kV transformer and three 13.8 kV MV Metalclad switchgears have been identified by Hydro One for future replacement based on asset condition assessment of these assets.

Alternatives and Recommended Plan

The following alternatives are considered to address Birmingham TS asset replacement needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset conditions and would result in increased maintenance costs.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring Birmingham TS. This alternative was considered but is not feasible due to the customer's unique needs.
- Replacement of the assets: Replace the T1 transformer with a similar unit and replace three (3) Metalclad switchgears.

The TWG recommends replacing the T1 transformer and three 13.8 kV LV Metalclad switchgears at Birmingham TS to meet the unique connection needs of the customer at this station with similar equipment.

8.1.6 Gage TS - T8/T9 DESN Refurbishment

Gage TS is located inside the city of Hamilton, having two DESNs units T8/ T9 and T11/ T12 having supply capacities of 123 MW and 132 MW and supplying loads of 18 MW and 34 MW respectively. The supply capacities of both T8/ T9 and T11/ T12 DESNs are sufficient over the study period.

At this time both 115 kV/ 13.8 kV T8/T9 DESN having 120 MVA transformers have been identified by Hydro One for refurbishment.

Alternatives and Recommended Plan

The following alternatives are considered to address Gage TS asset replacement needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset conditions and would result in increased maintenance costs.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring T8/T9 DESN at Gage TS. This alternative was considered but is not feasible due to customer requirements.
- Replacement of the assets: Replace T8/T9 DESN, nonstandard 120 MVA T8/ T9 transformers with 100 MVA Hydro One standard units.

TWG recommends that Hydro One replace T8/T9 DESN at Gage TS. Replacing the existing 120 MVA nonstandard transformers with Hydro One standard 100 MVA units.

8.1.7 Jarvis TS - Replace T3/ T4 Transformers

Jarvis TS is in Haldimand County, having a single T3/T4 DESN of 83 MVA 230 kV / 27.6 kV transformers supplying local area loads. Jarvis TS has a sufficient supply capacity of 99 MW over the study period.

Both 230kV/ 27.6kV 83 MVA T3/T4 transformers have been identified by Hydro One for future replacement based on asset condition assessment.

Alternatives and Recommended Plan

The following alternatives are considered to address Jarvis TS asset replacement needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset conditions and would result in increased maintenance costs.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring T3/T4 DESN at Jarvis TS. This alternative was considered but it is not feasible.
- Replacement of the assets: Replace existing 83 MVA T3/ T4 transformers with similar Hydro One standard units.

TWG recommends that Hydro One continue with the replacement of the T3/T4 transformers replacing existing 83 MVA transformers with similar standard Hydro One units.

8.2 Area Supply Needs

An area supply capacity assessment was performed over the study period 2025-2035 for the 115kV Brant and Norfolk areas. This included both transmission line supply capacity as well as station supply capacity needs using the summer peak load forecast developed based on the information from TWG. The local distribution companies supplying the Bronte area are working on the revised long-term load forecasts and this area will be reassessed as part of the upcoming IRRP for Hamilton sub-region.

8.2.1 Brant Area Supply

The 115 kV Brant area is supplied by two stations, Brant TS and Powerline MTS. They currently supply 69 MW and 79 MW loads and have supply capacities of 101 MW and 114 MW respectively. The area supply is limited by the capacity of its transmission system.

In the IRRP completed by the IESO, it was indicated that with the current system conditions the Brant area's supply capacity is limited to 134 MW, which is a reduction from 165 MW that was previously identified. The current total coincident peak load in the Brant area already exceeds this supply capacity of 134 MW. The supply capacity in the Brant area depends on overall system flows, loading in the Woodstock

and Hamilton areas and higher loading in Brant area may be possible depending on system conditions and loading in the Woodstock and Hamilton areas. The only nearby station where the Brant area loads can be transferred to is Brantford TS.

The combined supply capacity and loading in the Brant area and Brantford TS is as follows:

Supply Capacity	2025	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
322*	283	296	313	320	331	338	350	358	366	374	383

*- Brant TS and Powerline MTS together limited to 134 MW

The loads in the Brant area and Brantford TS are forecasted to exceed the supply capacity by 2029 if managed through load transfers. The need may arise sooner due to physical constraints in load transfers.

Alternatives, Recommended Plan and Current Status

- Maintain status quo: This alternative was considered and rejected as it does not address the Brant area's load supply needs.
- Transfer excess Brant area loads to Brantford TS: Moving loads in excess to the Brant area supply capacity to Brantford TS as much available through load transfers, keeping the Brant area loads below supply capacity. This option will require reconfiguring distribution assets by the LDCs.
- Operational Measures: Increasing Brant area's supply capacity through operational measures including but not limited to opening DB2 115 kV breaker at Brant TS on 115 kV B2 circuit and opening the LV bus-tie breakers at Brant TS and Powerline MTS
- New 230kV area supply: A new 230 kV double circuit supply is being considered North of Brant area tapping 230 kV M20D/ M21D circuits and supplying loads through two (2) new 230 kV stations in the area offloading 115 kV system.
- These following new interim options have emerged after the completion of the IRRP.
    - New 115 kV Area Supply: The Commerce Way TS to Brant TS 115 kV is a single circuit built on a double circuit tower line. An additional circuit can easily be added to the existing towers:
        i. A new approximately 30km 115kV circuit from Commerce Way TS to Brant TS connected to existing B2 115 kV circuit increasing the capacity of the B2 circuit, a super circuit option.
        ii. A new approximately 30km 115kV circuit from Commerce Way TS to Brant TS parallel to existing B2 115 kV circuit along with an additional 115 kV breaker at Brant TS creating two (2) separate circuits. This will effectively extend 115kV circuit K7 parallel to the existing B2 / K12 circuit to Brant TS. This will increase transmission supply capacity to Brant area.

      These two different options for configuring additional circuit parallel to B2, may provide sufficient capacity for the Brant area over the study period.

TWG recommends transfer of load in excess of the supply capacity from Brant area to Brantford TS along operational measures as required within the near term. TWG recommends Hydro One and GrandBridge Energy to work together for the implementation of the above recommendations. Since the capacity need is in 2029 timeframe and a 230 kV solution takes at least 5-7 years to implement. A 230kV solution alone may not be a viable alternative to meet need timelines of 2029. Since a new interim alternative has emerged the TWG further recommends assessing the new 115 kV options that may provide sufficient time for the implementation of the 230 kV solution recommended in the IRRP. The assessment of this interim solution will be published in addendum to this RIP. The TWG recommends continuing with the IRRP solution of a new 230 kV double circuit supply tapping 230 kV M20D/ M21D circuits and supplying loads through two (2) new 230 kV stations in the area offloading 115 kV system.

8.2.2 Norfolk Area Supply

The Norfolk area loads are supplied through Norfolk TS and Bloomsburg DS supplied through two 115 kV circuits from Caledonia autotransformers. The current supply capacity of the Norfolk area is limited by the two (2) 115kV circuits supplying this area, which is approximately 80 MW. Norfolk TS and Bloomsburg DS are currently supplying loads of 61MW and 41MW and have supply capacities of 97MW and 49MW respectively. The total supply capacity of Norfolk TS and Bloomsburg DS are sufficient over the study period, however load balancing between the two stations through distribution load transfers will be required. These loads already exceed the Norfolk area supply capacity of 80 MW. An earlier IESO assessment has recommended load transfers out of the Norfolk area and additional reactive support at Norfolk TS to provide local area voltage support.

Alternatives, Recommended Plan and Current Status

- Maintain status quo: This alternative was considered and rejected as it does not address the Norfolk area's load supply needs.
- Opening LV bus-tie breakers at Norfolk TS and Bloomsburg DS
- Additional Reactive Support and Load Transfers: Installing additional reactive support (capacitor bank) at Norfolk TS and moving Norfolk area loads to Jarvis TS as much is available through load transfers. This work is already in progress.
- Battery Storage in Norfolk Area: Install a new battery energy storage system close to Norfolk TS capable of providing dynamic reactive power support connecting to both 115 kV C9 and C12 circuits and offsetting area loads. Reactive support should be able to provide sufficient support to maintain adequate voltages in the Norfolk area for the loss of one of the C9/ C12 circuits under peak load conditions over the study period and beyond. Load balancing between Norfolk TS and Bloomsburg DS will be required. A sufficient sized Battery Storage System (BES) close to Norfolk TS meeting MW and MVAR requirements to allow the area load meeting capability to increase to about 150 MW. This is expected to defer the need for area transmission reinforcement well beyond the study period.
- New 230kV area supply: A new 230 kV double circuit supply extending 230 kV N21J/N22J circuits to Norfolk area supplying a new 230 kV supply station in Norfolk area.

TWG recommends continuing with the load transfers out of the Norfolk area and providing new additional reactive support at Norfolk TS, and opening the LV bus-tie breakers at Norfolk TS and Bloomsburg DS as required until a new battery energy storage system is procured capable of providing the required dynamic reactive support and providing peak load reducing function. This recommendation is in line with the IRRP completed for the Burlington to Nanticoke region led by IESO. The arrangement to install BESS to provide the above-mentioned functions will be sufficient to meet the load supply needs over the study period and beyond. The ultimate supply solution will be a new 230 kV/ station in the Norfolk area, but the need is currently beyond the foreseeable future.

8.2.3 Dundas Area Supply

The Area west of Hamilton are supplied through a 27.6 kV distribution system. Dundas TS (T1/T2) and Dundas TS #2 (T5/T6) are supplying a total peak load of 151 MW at the west end of the city of Hamilton. The total supply capacity of both stations is 188 MW with loads forecasted to reach this supply capacity by the end of the study period.

Alternatives and Recommended Plan

The following alternatives are considered to address supply for supply capacity need at these three stations:

- Maintain status quo: This alternative was considered and rejected as it does not address the customer's supply capacity needs.
- Load Transfers or Station/load consolidation: Moving excess loads to the neighboring station/s or moving all loads to neighboring station/s and retiring assets at Dundas TS or Dundas TS #2 and opening the LV bus-tie breakers at these stations.
- Two (2) New 200 MVA 230/ 27.6 kV DESNs near Dundas: The recently completed IRRP proposed two (2) new 200 MVA 230/27.6 kV stations near Dundas TS transferring all existing Dundas TS and Dundas TS#2 load to the 230 kV system to address 115 kV system future needs.
- Build New Middleport DESN south of Hamilton: This new option emerged after the completion of the IRRP. Due to forecasted load growth in the south of Dundas area a new supply station of 200 MVA in the area close to Hydro One's existing 500 kV Middleport TS may be preferrable.

TWG recommended Hydro One and Alectra to continue with load balancing between the two Dundas transformer stations and monitor the loading levels at these stations. If required, to proceed with load transfers and opening LV bus-tie breakers. TWG recommends continuing with the IRRP recommendation of building two (2) new 200 MVA transformations near Dundas TS. The alternate 200 MVA transformation location close to Middleport TS assessment will be published as an addendum to this RIP.

8.2.4 Bronte TS Area Supply

An IRRP was completed in 2016 to address the supply capacity issues for the loads supplied by Bronte TS. Bronte TS has a supply capacity of 208 MVA and is radially supplied from the double-circuit 115 kV transmission line B7/B8 originating from Burlington TS. The supply capacity from Bronte TS is limited to 135 MW as recommended by the IRRP mainly due to thermal limitations of 115kV B7/B8 supply circuits.

Recently Oakville Hydro and Burlington Hydro, the local distribution companies serving area loads, informed TWG of future additional supply capacity needs from Bronte TS.

Alternatives, Recommended Plan and Current Status

- Maintain status quo: This alternative was considered and rejected as it does not address the Bronte TS supply area's needs.
- Transfer customer load to Neighboring Stations: Moving loads in excess to the Bronte TS area supply capacity to neighboring stations.
- Upgrade 115 kV B7/B8 circuits: Upgrade the 115 kV B7/B8 3 km long line section with larger conductor.
- Additional Reactive Support: Additional reactive support at Bronte TS to maintain pre and post contingency voltages at this station.
- New 230kV area supply: A new 230 kV double circuit supply from Burlington TS, replacing the existing 115 kV circuits and transformers or a new additional 230 kV supply and station to supply additional loads.

Oakville Hydro and Burlington Hydro, the LDCs supplied by this station are working to develop a long-term load forecast for Bronte TS area to determine timeframe and amount of additional supply capacity needs. A decision can't be made until Oakville Hydro and Burlington Hydro finalize their load forecast.

TWG recommends that the additional supply capacity need of more than 135 MW at Bronte TS be assessed as part of the upcoming IRRP for Hamilton sub-region to be completed by the IESO.

8.3 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2025-2035 for the 230kV and 115kV Transforming stations in the Burlington to Nanticoke region using the summer peak load forecasts that were provided by the study team. Based on the results, the following Station capacity needs have been identified during the study period:

8.3.1 Nebo TS (T3/T4) DESN

Nebo TS is located south of the city of Hamilton, having two DESNs units T1/T2 and T3/T4 supplying loads in the city of Hamilton and surrounding areas. The current loads at T3/T4 13.8 kV DESN is 52 MW and have been historically around the same level against its supply capacity of 51MW. The loads at this DESN are currently forecasted to grow well above its supply capacity.

At this time both T3/T4 230 kV / 13.8 kV 75 MVA Hydro One nonstandard transformers have been identified by Hydro One for future replacement based on their asset condition assessment.

Alternatives and Recommended Plan

The following alternatives are considered to address Nebo TS supply capacity needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance cost.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring T3/T4 DESN at Nebo TS. This alternative was considered but is not feasible.
- Opening LV bus-tie breakers at Nebo T3/T4 DESN and transferring excess loads to neighboring stations
- Replacement of the assets: Replace existing nonstandard 75 MVA T3/ T4 transformers with 100 MVA Hydro One standard units.

The TWG recommends that Hydro One and Alectra monitor the loading at Nebo TS T3/T4 DESN and take remedial measures like transferring excess loads and opening the LV bus-tie breaker, if required, until replacement of these transformers is completed. Hydro One would replace the existing 75 MVA nonstandard transformers with Hydro One standard 100 MVA units providing sufficient supply capacity over the foreseeable future.

8.3.2 Mohawk TS

Mohawk TS is a single DESN 115kV / 13.8 kV station located in the city of Hamilton. This station has a supply capacity of 90 MW and currently supplying about 72MW of loads. The station is forecasted to approach its supply capacity by the end of the study period.

Alternatives and Recommended Plan

The following alternatives are considered to address Mohawk TS supply capacity needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the customer's supply capacity needs at this station.
- Load Transfers or Station/load consolidation: Moving excess loads to the neighboring station/s or moving all loads to neighboring station/s and retiring Mohawk TS. This alternative was considered but is not feasible as there are no nearby station/s having sufficient surplus capacity to accommodate these loads.
- Opening LV bus-tie breakers at Mohawk TS
- Additional Station Supply: Replace existing 75 MVA transformers with 100 MVA Hydro One standard units.

TWG recommends that Hydro One and Alectra monitor the loading at Mohawk TS as the supply capacity need is close to the end of the study period and open the LV bus-tie breaker at this station, if required. This need will be again reassessed during the next regional planning cycle.

8.3.3 Newton TS

Newton TS is a single DESN 115kV / 13.8 kV station located in the city of Hamilton. This station has a supply capacity of 75 MW and currently supplying about 48MW of loads. The station is forecasted to be approaching its supply capacity by the end of the study period.

Alternatives and Recommended Plan

The following alternatives are considered to address Newton TS supply capacity needs:

- Maintain status quo: This alternative was considered and rejected as it does not address the customer's supply capacity needs at this station.
- Load Transfers or Station/load consolidation: Moving excess loads to the neighboring station/s or moving all loads to neighboring station/s and retiring Newton TS. This alternative was considered but is not feasible as there are no nearby station/s having sufficient surplus capacity to accommodate these loads.
- Opening LV bus-tie breakers at Newton TS
- Additional Station Supply: Replace existing 75 MVA transformers with 100 MVA Hydro One standard units.

TWG recommends that Hydro One and Alectra monitor the loading at Newton TS as the need is close to the end of the study period and open the LV bus-tie breaker, if required. This need will be again reassessed during the next regional planning cycle.

8.3.4 Nebo TS (T1/T2) DESN

Nebo TS is located south of the city of Hamilton, having two DESNs units T1/T2 and T3/T4 supplying loads in the city of Hamilton and surrounding areas. The current loading at T1/T2 27.6 kV DESN is 145 MW having a supply capacity of 178MW. The loads at this 27.6 kV DESN are forecasted to reach its supply capacity by 2031.

Alternatives and Recommended Plan

The following alternatives are considered to address Nebo TS supply capacity needs:

- Maintain status quo: This alternative was considered and rejected as it does not meet customer needs.
- Station/load consolidation: Moving loads to neighboring station(s) and retiring T1/T2 DESN at Nebo TS. This alternative was considered but is not feasible.
- Transferring loads to neighboring stations and opening LV bus-tie breakers at Nebo T1/T2 DESN

The TWG recommends that Hydro One and Alectra monitor the loading at Nebo TS T1/T2 DESN and take remedial measures like transferring loads to neighboring stations and opening the LV bus-tie breaker, if required.

8.4 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period 2025-2035 for the 115kV Transmission line circuits in the Burlington to Nanticoke region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater for this need. The TWG identified overloading of 115 kV B2 intertie line between Brant and Woodstock area which is studied as part of the Brant area supply needs and the supply capacity need of 115 kV C9/C12 circuits as part of the Norfolk area study.

8.5 System Reliability, Operation and Restoration Needs

The Technical Working Group did not identify any restoration needs during this regional planning cycle.

9. CONCLUSION AND RECOMMENDATION

This section concludes the Regional Infrastructure plan Report for Burlington to Nanticoke region. The Major Infrastructure investments recommended by the TWG in the near and mid-term planning horizon [2025-2035] are provided in Table 7 below, along with their planned in-service dates (ISD) and budgetary estimates for planning purposes.

Table 7: Recommended Plans over the next 10 Years

Station/Circuit Name	Recommended Plan	Lead	Planned ISD
Asset Renewal Needs			
Nebo TS	Replace T3/ T4 transformers	Hydro One	2030-2035
Lake TS	Replace T3/T4 transformers and switchgear	Hydro One	2030-2035
Beach TS	Replace T5/T6 transformers and switchgear	Hydro One	2030-2035
Caledonia TS	Replace T2 transformer	Hydro One	2030-2035
Birmingham TS	Replace T1 Transformer and MV Switchgears	Hydro One	2030-2035
Gage TS	Replace T8/T9 transformers and switchgear	Hydro One	2030-2035
Jarvis TS	Replace T3/ T4 transformers	Hydro One	2030-2035
Area Supply Needs			
Brant Area	Two (2) new 230kV/ 27.6 kV 200 MVA transformation facilities near the existing Brant TS.	Hydro One/ GBE	2029
Norfolk Area	Battery Storage along with load transfers, additional reactive support and operational measures.	Hydro One	2025
Dundas Area	Two (2) new 230kV/ 27.6 kV 200 MVA transformation facilities near existing Dundas TS.	Hydro One/ Alectra	2035
Bonte Area	LDC developing load forecast to identify additional need above current supply capacity	Hydro One/ Oakville Hydro/ Burlington Hydro	TBD
Station Capacity Needs			
Nebo TS (T3/T4) DESN	Nebo T3/T4 is a 230kV / 13.8kV DESN transformers to be replaced with Hydro One standard 100 MVA units. In the meantime, operational measures, if required	Hydro One/ Alectra	Current
Mohawk TS	The loading at this station to be monitored and as required excess load transferred to neighboring station/s along with operational measures, if required	Hydro One/ Alectra	2035
Newton TS	The loading at this station to be monitored and as required excess load transferred to neighboring station/s along with operational measures, if required	Hydro One/ Alectra	2035
Nebo TS (T1/T2) DESN	Nebo T1/T2 is a 230kV / 27.6kV DESN. The loading at this station to be monitored and as required excess	Hydro One	2031

Station/Circuit Name	Recommended Plan	Lead	Planned ISD
	load transferred to neighboring station/s along with operational measures, if required		
Transmission Line Capacity Needs			
The Technical Working Group did not identify any other line capacity needs. The overloading of 115 kV B2 intertie line between Brant area and Woodstock area is included in Brant area supply need.			
System Reliability, Operation and Load restoration Needs			
The Technical Working Group did not identify any reliability, operation and load restoration needs for this region.			

Note: The planned in-service dates are tentative and subject to change.

Executive Summary

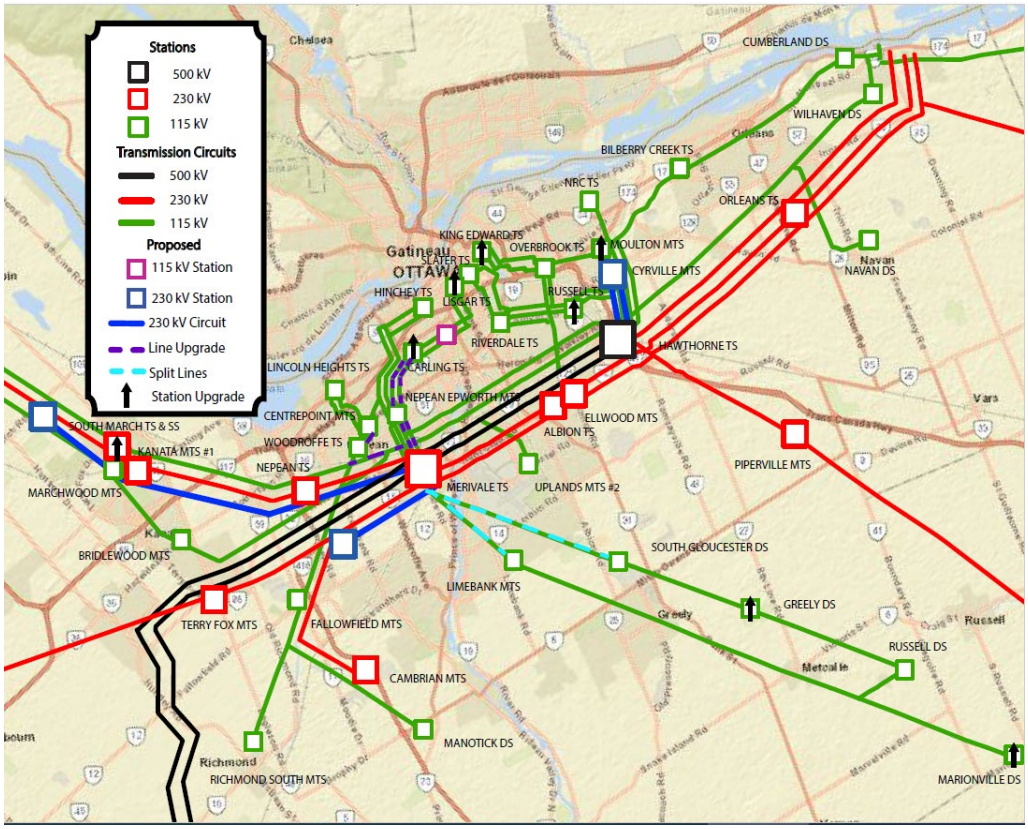
This Integrated Regional Resource Plan (IRRP) addresses the electricity needs of the Ottawa Area Sub-Region over a 20-year horizon. Developed by the Independent Electricity System Operator (IESO) in collaboration with Hydro Ottawa Limited (Hydro Ottawa), Hydro One Networks Inc. (Distribution), and Hydro One Networks Inc. (Transmission), the plan outlines recommendations to ensure a reliable and cost-effective electricity supply that can support continued economic development and the City of Ottawa's decarbonization objectives.

The Ottawa Area Sub-Region includes the City of Ottawa and the Village of Casselman, and falls within the traditional territory of the Algonquins of Ontario, Kitigan Zibi Anishinabeg, Pikwakanagan First Nation, and Métis Nation of Ontario Region 5. This plan is part of Ontario's broader regional planning framework, now in its third cycle, and reflects the coordinated input of local distribution companies, transmission asset owners, and regional stakeholders.

The need for this IRRP was confirmed through the Scoping Assessment, which identified the Ottawa Area Sub-Region as requiring regional coordination and consideration of non-wires alternatives. The plan is shaped by the City's electrification and decarbonization targets, customer connection requests, and ongoing engagement with groups such as Invest Ottawa. These drivers signal a broader shift toward city-wide energy transformation, with particularly strong momentum in areas like Kanata-Stittsville.

This IRRP marks a notable evolution in planning by integrating electrification as a core assumption from the outset. Load forecasting was developed in collaboration with Hydro Ottawa and Hydro One Distribution, incorporating multiple scenarios with varying degrees of electrification. The selected reference forecast balances feasibility and risk, and reflects a likely trajectory of sustained load growth, winter-peaking demand, and increased system complexity.

In response, the plan provides a flexible sequence of near-, medium-, and long-term actions designed to manage uncertainty while ensuring the system remains prepared to accommodate growth. It reflects established planning best practices, including ongoing adaptation to evolving conditions. Key near-term investments include new transformer stations, line upgrades, and system reinforcements to address station and system capacity needs, asset replacement, and load security and restoration concerns.



Non-wires solutions play an increasingly important role in the plan. Several large-scale Battery Energy Storage System (BESS) projects identified through the IESO's Long-Term Procurement I (LT1) will enhance reliability, voltage performance, and system resilience. In parallel, the Local Achievable Potential Study (LAPS) will inform targeted demand-side measures that may defer or reduce the need for major infrastructure upgrades, especially in the downtown core.

The recommendations outlined in this IRRP represent a balanced, cost-effective path forward that supports Ottawa's growth while maintaining reliability and customer value. Annual monitoring of load growth and system conditions will inform future updates and help determine when to initiate the next regional planning cycle. A summary of the recommendations can be seen in **Figure 1.**

In summary, the plan proposes to:

- Build new or upgrade Transformation Stations to increase station capacity:
    - Three new 230 kV stations: Kanata North area, Core West area and Cyrville MTS (converted from 115 kV)
    - One new 115 kV station: Core East area (a new MTS by converting from existing distribution station)
    - Station upgrades: Carling TS, Lisgar TS, King Edward TS, Moulton MTS, Russell TS, Greely DS, South March TS and Marionville DS
- Build new or upgrade transmission lines to connect new stations and increase System Capacity:
    - Two new 230 kV transmission lines to connect new stations (Kanata North and Core West areas) from Merivale TS
    - A new 230 kV switching station in Kanata North area
    - 115 kV transmission line uprating: portions of M4G and M5G
- Modify connection configuration to improve load security:
    - Install new circuit breaker at Merivale TS and separate L2M and M1R
    - Provide second supply to Nepean TS via new transmission circuit from Merivale TS.
- Transfer load between stations through the distribution system to balance and optimize the utilization of station capacity
- Integrate the eDSM program opportunities identified as part of LAPS
- Formalize adaptive pathways for each subsystem

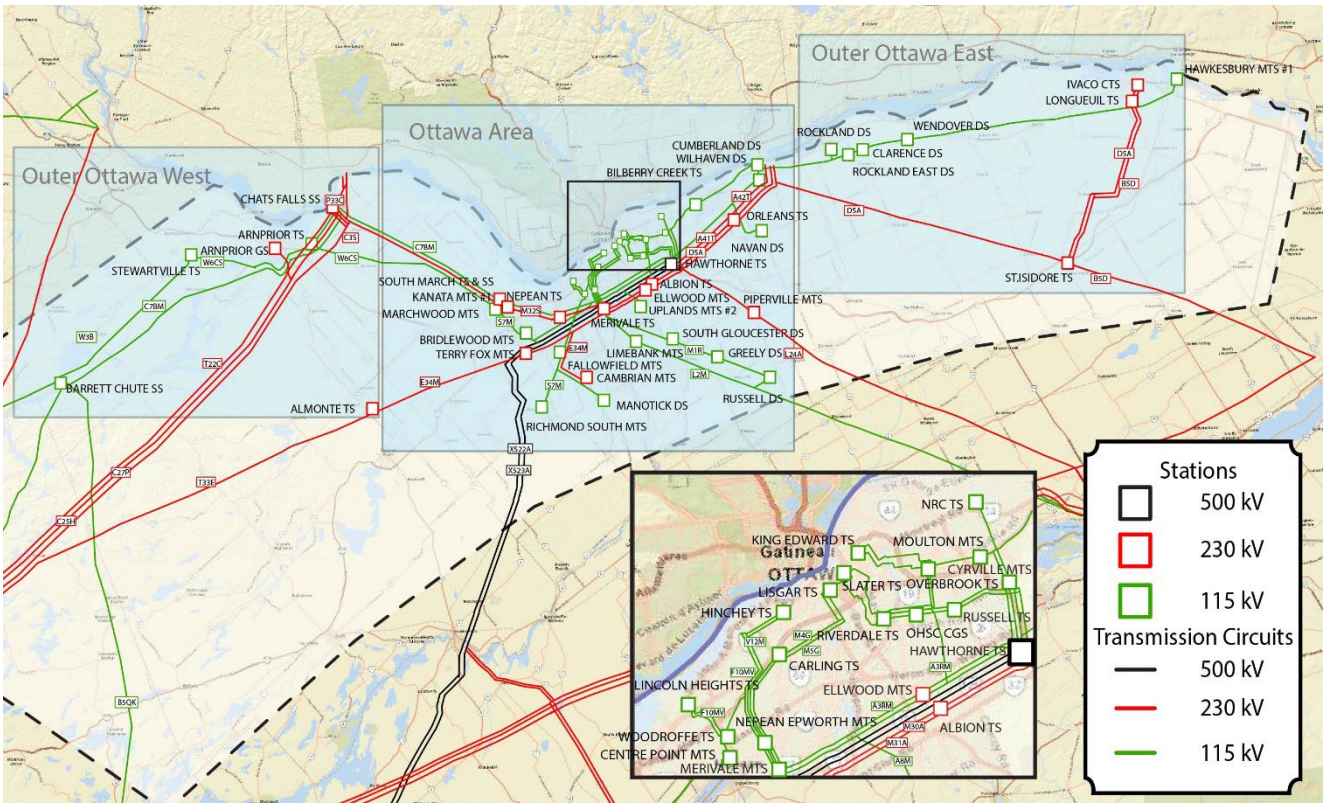
Figure 1 | Map of Recommendations for Ottawa Area Sub-Region

1. Introduction

This IRRP documents the recommendations required to address the electricity needs for the Ottawa Area Sub-Region over the next 20 years. It was prepared by the IESO on behalf of a technical working group (Working Group) composed of the IESO, Hydro Ottawa, Hydro One Distribution, and Hydro One Transmission. Hydro Ottawa, a municipally owned utility that operates in the City of Ottawa (City) and in the Village of Casselman, and Hydro One Distribution are local distribution companies (LDCs) that serve customers in the sub-region. Hydro One is the transmission asset owner in the sub-region.

This sub-region also includes the following First Nations and Métis Nation of Ontario councils:

- Algonquins of Ontario
- Kitigan Zibi Anishinabeg
- Pikwakanagan First Nation
- Métis Nation of Ontario Region 5



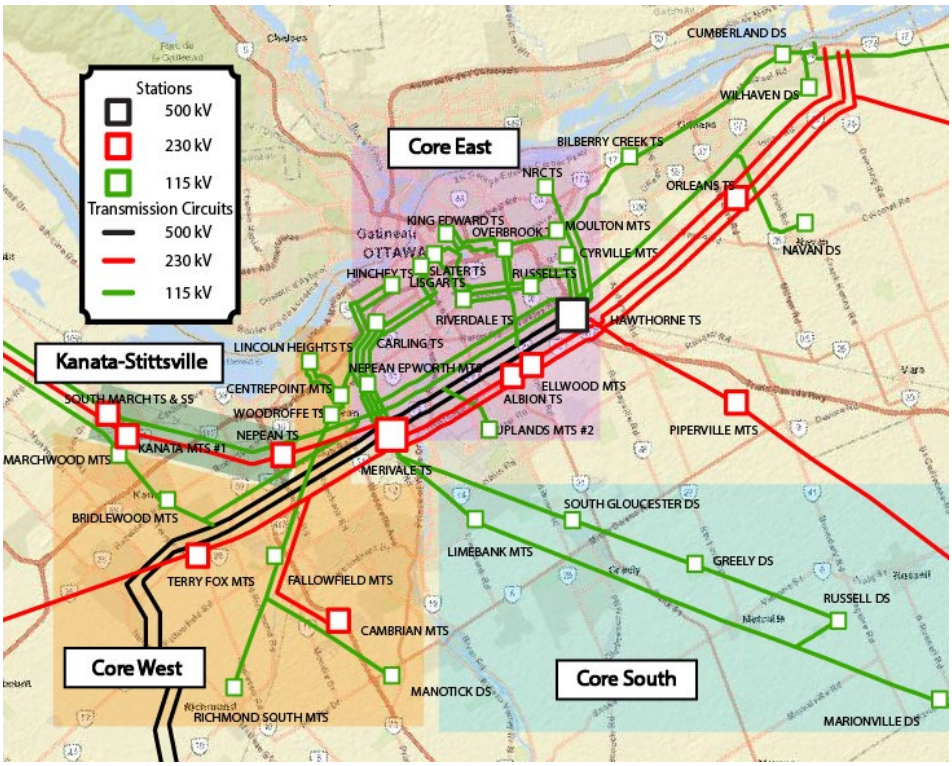
In Ontario, planning to meet the electrical supply and reliability needs of a large area or region is carried out through regional electricity planning, a process that was formalized by the Ontario Energy Board (OEB) in 2013. In accordance with this process, transmitters, distributers, and the IESO are required to carry out regional planning activities for 21 electricity planning regions across Ontario, at least once every five years. This is the third cycle of regional electricity planning, which resulted in the third IRRP for the Ottawa region.

For the purposes of regional planning, the Ottawa region has historically been subdivided into three major sub-regions, as shown in **Figure 2**. One of the main purposes of an IRRP is to foster collaboration where coordination between multiple stakeholders in a region is required. Hydro Ottawa is the main LDC that serves the electricity demand for the City of Ottawa. Hydro One Distribution supplies load in the surrounding areas of the sub-region. Both Hydro Ottawa and Hydro One Distribution receive power at the step-down transformer stations (TS) and distribute it to end users, including industrial, commercial, and residential customers.

The Scoping Assessment confirmed the need for regional coordination and the importance of evaluating non-wires alternatives to address emerging electricity needs. As a result, the Working Group determined that this IRRP will focus on the Ottawa Area Sub-Region, while the remaining sub-regions will be addressed through the Regional Infrastructure Plan (RIP) led by Hydro One Transmission as those sub-regions are predominantly served by Hydro One Distribution.

The Ottawa Area Sub-Region encompasses the City, including the Kanata, Nepean, and Orléans communities. To further simplify the organization and analysis, the Working Group further divided the sub-region into four subsystems based on their geographic and electrical characteristics. The four subsystems can be seen in **Figure 3** and this report will address each subsystem separately throughout. A more thorough description of each of the subsystems can be found in Section 4 (background) and Section 6 (needs).

Figure 2 |Overview of the Greater Ottawa Sub-Regions



Every plan faces its own unique challenges, and this third cycle of regional planning for the Ottawa area is no exception. The City of Ottawa and the federal government have set ambitious decarbonization and electrification goals, which serve as a foundational input to this IRRP. These goals, supported by customer connection requests, projected growth trends, and consultations with economic sector participants such as Invest Ottawa, reflect a broader shift toward city-wide economic transformation — with particular momentum in areas like Kanata-Stittsville. While previous regional plans included electrification among several scenarios, this IRRP distinguishes itself by embedding electrification as a core planning assumption from the outset, recognizing both the uncertainty it introduces and the opportunity to plan proactively to meet emerging system demands.

The Working Group convened a series of discussions with the City and various energy stakeholders during the development of the plan, aiming to collaboratively shape the demand forecast and align on anticipated decarbonization trends. These conversations helped inform the demand forecasts developed by Hydro Ottawa and Hydro One Distribution. Several scenarios were developed with varying degrees of electrification. By balancing risk and feasibility, one of these scenarios was selected as the reference demand forecast that drove the needs, options, and recommendations found in this report. A high-growth scenario was also identified for sensitivity analysis.

The forecasted economic development, decarbonization, and electrification would result in a substantial increase in peak electricity demand over the next 20 years. Furthermore, the forecast indicates that the region will soon become winter-peaking, due in large part to the effects of transitioning heating from natural gas to electric or hybrid. This ultimately led to the identification of numerous needs in the sub-region that span the near-, medium-, and long -terms which refer to outlooks in the 5-, 10-, and 20-year horizons respectively.

Figure 3 | Overview of the Four Ottawa Area Subsystems

Anticipated electricity demand growth in Ottawa presents a planning challenge: ensuring the system is positioned to support organic growth and economic development, while avoiding the premature construction of assets that may not be needed in the near term. Missed opportunities to enable new connections or achieve the City's decarbonization targets could have lasting impacts. At the same time, overbuilding infrastructure too far in advance could result in unnecessary costs to electricity customers.

To manage these risks, this plan takes a flexible and phased approach — one that reflects good planning practice and builds on how the electricity sector in Ontario has adapted to uncertainty over time. This IRRP outlines a sequence of actions that can evolve as conditions change, providing a framework to respond to growth while managing uncertainty responsibly.

Multiple BESS projects in the sub-region have been recommended through the IESO's LT1 initiative. Once developed, these large-scale batteries will help improve voltage performance, enhance reliability, and provide added flexibility and resilience to the grid.

In addition, a LAPS is expected to inform targeted conservation and demand management opportunities. These measures may help defer large, costly upgrades — particularly in the downtown core — by reducing strain on existing infrastructure.

The firm recommendations in this IRRP are designed to address near-term system and station capacity needs, asset replacement requirements, and load security and restoration needs, while laying the groundwork for longer-term improvements. Annual monitoring of potential issues will provide additional input on when the next regional planning cycle should be initiated.

This report is organized as follows:

- A summary of the recommended plan for the region is provided in Section 2;
- The process and methodology used to develop the plan are presented in Section 3;
- The context for electricity planning in the region and the study scope are described in Section 4;
- Demand forecast scenarios, and electricity Demand Side Management (eDSM) and distributed generation assumptions, are described in Section 5;
- Electricity needs in the region are presented in Section 6;
- Alternatives and recommendations for meeting needs are addressed in Section 7;
- A summary of engagement activities is provided in Section 8; and
- The conclusion is provided in Section 9.

2. The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of the Ottawa Area Sub-Region over the next 20 years. The identified needs are based on the demand growth anticipated in the region and the capability of the existing transmission system, as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by the North American Electric Reliability Corporation (NERC). The IRRP's recommendations are informed by an evaluation of different options to meet the needs and consider reliability, cost, technical feasibility, and maximizing the use of the existing electricity system (where economically feasible). The plan also reflects feedback from stakeholders and seeks to balance the need to ensure the system is poised to enable growth — including economic development — with the risk of building investments too early.

The Ottawa Area Sub-Region electricity demand forecast, provided by the LDCs, projects sustained growth driven by municipal growth, commercial development, and the effects of electrification and decarbonization. The planned phase-out of gas heating in the region is also a major driver of the demand forecast and electricity supply needs in the sub-region, especially in later years of the demand forecast.

The IRRP recommendations are organized into a near-term plan and a set of ongoing or medium- to long-term initiatives. This structure reflects the varying degrees of forecast certainty, development lead times, and planning commitments required over different timeframes. By doing so, the IRRP offers clear guidance on immediate investment needs while maintaining flexibility to adapt over the medium and long term as electrification, energy efficiency, and development plans continue to evolve.

2.1 Near-Term Plan

The near-term plan consists of several recommendations to accommodate load growth, maintain reliability, and optimize asset replacement. Many of these needs are driven by the strong growth in the winter demand forecast. The major recommendations are summarized in **Table 1**.

Table 1 | Summary of Recommendations

Need Type	Affected Element(s)	Recommendation	High Level Planning Cost Estimate[1]
System Capacity (Transformation, Voltage Stability)	Kanata-Stittsville	Build new 230kV Transformer Station north of existing stations. Connect to C3S and new transmission line from Merivale TS. Interim station name: Kanata North Municipal Transformer Station (MTS).	$45M
		Build new 230kV transmission line from Merivale TS by rebuilding C7BM corridor, connecting Nepean TS and new Kanata North MTS	$185M
		Build a switching station that connects existing and new 230kV stations to improve resiliency and flexibility	$65M
System Capacity (Transformation)	Core East	Build new 115kV Transformer Station by converting existing distribution station. Connect to M4G and M5G. Interim station name: Bronson MTS.	$65M
System Capacity (Thermal Overload)	Core East	Upgrade portions of existing 115kV circuits M5G and M4G.	$35M
System Capacity (Transformation)	Core East	Convert Cyrville MTS (115kV) to 230kV thereby preserving capacity on autotransformers for growth on the 115kV downtown system	$75M
		Pursue eDSM program opportunities identified as part of LAPS to reduce demand and delay large scale infrastructure upgrades.	N/A

[1] All cost estimates are capital cost values

Need Type	Affected Element(s)	Recommendation	High Level Planning Cost Estimate[1]
System Capacity (Transformation)	Core West	Build new Transformer Station to meet demand growth and need for 28kV supply west of Merivale TS. Interim station name: Greenbank MTS.	$40M
		Build new 230kV transmission line from Merivale TS to supply new Greenbank MTS.	$50M
Load Security	Core South	Install new circuit breaker at Merivale TS and separate L2M and M1R	$30M
Planning	N/A	Working Group to produce Adaptive Pathways documents for each subsystem following the publishing of the IRRP. Utilize Annual Working Group meeting to refine and communicate the pathways to relevant stakeholders.	

A complete list of recommendations can be found in Section 7.8.

A high-level planning estimate based on 2025 capital costs for the proposed suite of solutions is approximately $900 million, with a recommended In-Service Date (ISD) ranging between 2029-2032, based on the growth forecast. The identified needs have been grouped to align with integrated solution sets, as outlined in Section 6 of this report. The recommendations from this report will be further prioritized during the RIP. The near-term recommendations represent critical first steps in expanding the electricity grid's capabilities to support the region's goals in a timely manner.

2.2 Medium-, to Long-Term Plan

While most of the recommended actions from the Ottawa Area Sub-Region IRRP are planned for the near-term (within the next five years), the sections below outline potential medium- to long-term recommendations beyond that horizon. The actions described below illustrate the adaptive pathways identified through this regional planning process. These pathways are subject to change and will be continuously re-evaluated as planning progresses, based on new information and actual load growth. Awareness of these plans is important to enable timely decision-making. Further details on the adaptive pathways, including the subway-style maps, are provided in Section 7. It is recommended that the Working Group finalize the long-term adaptive pathway plan for each subsystem following the completion of this cycle of regional planning.

Kanata-Stittsville Subsystem

To address the significant capacity needs at Kanata MTS, South March TS and, eventually, Nepean TS a new switching station is planned to interconnect these key sites. This switching station will provide critical resiliency, operational flexibility, and expandability for future load growth. Additionally, the station will serve as a hub for a new transmission line extending north to Chats Falls TS, pending upgrades at Chats Falls to support the connection. This project will not only diversify supply paths and increase the Load Meeting Capability (LMC) for the area, but also improve Ottawa's overall system strength.

The East Bulk Study, currently underway, is exploring potential reinforcements to strengthen the supply path into Ottawa. As part of this, the proposed switching station is being evaluated for its potential to support the expansion of the 230 kV network. In addition to enhancing regional integration, this connection would diversify supply sources and improve the overall resilience of the electricity system in the Ottawa area.

Core East Subsystem

Core East faces the most acute and widespread capacity challenges, particularly in the 115 kV downtown network. Due to physical constraints on system expansion, eDSM program opportunities identified in the LAPS could play a crucial role in regulating and managing downtown load growth. Long-term planning includes expanding Hawthorne TS, extending a mix of 115 kV and 230 kV circuits into the downtown core, and constructing additional supply stations to relieve pressure on aging infrastructure. A fourth autotransformer at Merivale TS is also under consideration, which would enhance transfer capability and reduce strain on nearby stations. To further alleviate pressure on the 115 kV system, a planned conversion of S7M will allow additional load to be shifted off the constrained network.

Core West Subsystem

With station overloads emerging across Marchwood, Fallowfield, Manordale, and others, the long-term strategy for Core West centres on the conversion of circuit S7M to 230 kV. This will relieve the 115 kV system, preserving capacity for downtown load growth while supporting suburban development. The new circuit can be extended to provide a second supply path to Terry Fox MTS and Cambrian MTS, enhancing reliability and operational flexibility. This conversion will also unlock the full potential of a large-scale BESS identified in the LT1 framework. Additional transmission work, including uprating portions of C7BM and F10MV, is planned to mitigate thermal overloads and enhance backbone performance.

Core South Subsystem

Future planning in Core South hinges on the findings of the East Bulk Study, with a possible 230 kV transmission line from the St. Lawrence area offering the potential to fully convert the pocket to 230 kV operation. Limebank MTS, forecast to exceed capacity in the medium term, will require a second supply path as load grows; monitoring and proactive circuit upgrades will be key. A new autotransformer station in western Ottawa is also under consideration, and its implementation will influence future planning and routing decisions for Core South.

3. Development of the Plan

3.1 The Regional Planning Process

In Ontario, preparing to meet the electricity needs of customers at a regional level is achieved through regional planning. Regional planning assesses the inter-related needs of a region—defined by common electricity supply infrastructure—over the near-, medium-, and long -term, and results in a plan to ensure cost-effective and reliable electricity supply. A regional plan considers the existing electricity infrastructure in an area, forecasts growth and customer reliability, evaluates options for addressing needs, and recommends actions.

The current regional planning process was formalized by the Ontario Energy Board in 2013 and is performed on a five-year cycle for each of the 21 planning regions in the province. The process is carried out by the IESO, in collaboration with the transmitters and LDCs in each region. The process consists of four main components:

1. A **Needs Assessment**, led by the transmitter, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;
2. A **Scoping Assessment**, led by the IESO, which identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities;
3. An **IRRP**, led by the IESO, which proposes recommendations to meet the identified needs requiring coordinated planning; and/or
4. An **RIP**, led by the transmitter, which provides further details on recommended wires solutions.

Regional planning is not the only type of electricity planning in Ontario. Other types include bulk system planning and distribution system planning. There are inherent overlaps in all three levels of electricity infrastructure planning. Further details on the regional planning process and the IESO's approach to it can be found in Appendix A.

3.2 Ottawa Area Sub-Region IRRP Development

The process to develop the Ottawa Area Sub-Region IRRP started in March 2023, following the publication of the **Needs Assessment Report** in December 2022 by Hydro One and the **Scoping Assessment Outcome Report** in February 2023 by the IESO. The Scoping Assessment recommended that the needs identified for the Ottawa Area Sub-Region be considered through an IRRP in a coordinated regional approach, supported with public engagement. The Working Group was then formed to develop the terms of reference for this IRRP, gather data, identify needs, develop options, and recommend solutions for the region.

Given the significant uncertainty surrounding the impacts of electrification and decarbonization, the Working Group has taken several important steps to manage this risk. Recognizing Ottawa's unique combination of rapid urban growth, economic development opportunities, and decarbonization initiatives, it was clear that a flexible and forward-looking approach was necessary. As a first step, the LDC engaged a third-party consultant to develop a series of load forecast scenarios that

incorporated full decarbonization by 2050. This process ensured that the forecasts accounted for electrification in a meaningful way and were developed with a high degree of objectivity and technical rigour. The resulting scenarios highlighted the challenge of managing substantial load growth over a relatively short period of time, which further reinforced the need for a more flexible planning approach.

The Working Group remains committed to ongoing monitoring of actual load growth, technological developments, and policy changes, ensuring the plan continues to reflect real-world conditions. This approach reflects a foundational aspect of electricity planning in Ontario — the recognition that flexibility and regular updates are essential in the face of evolving system needs. The adaptive approach outlined in this IRRP provides a structured yet flexible roadmap that enables the electricity system to grow in step with Ottawa's evolving demand, while maintaining reliability, cost-effectiveness, and resilience. It also aligns with the City of Ottawa's direction on electrification and supports local aspirations related to the energy transition.

4. Background and Study Scope

4.1 Previous Regional Planning Cycle

This is the third cycle of regional planning for the Ottawa Area Sub-Region. The previous cycle of regional planning for the Ottawa Area Sub-Region was carried out from 2018 to 2020 and resulted in the publishing of an IRRP and an RIP. Furthermore, between-cycle planning occurred in 2022 to revisit a previous recommendation for the Orléans area. The Working Group reconvened and decided not to refurbish Billberry Creek as previously recommended and will instead decommission the station and focus on new infrastructure in the Orleans area. The recommendations are described within the report.

The previous Ottawa Area Sub-Region IRRP was published in March 2020. The IRRP used a 20-year demand forecast and made recommendations to monitor long-term needs in the region, while providing clear direction on actions required in the near-term. This included several distribution load transfers and asset replacements as described below. Furthermore, the plan recognized the need for a long-term solution for the Kanata-Stittsville area but decided that interim measures in the forms of enhanced IESO led energy efficiency programs were more prudent at that stage. This plan picks up where the previous plan left off and provides the next steps for expanding the electricity system to meet growing demand.

The plan also identified two supply deficiencies in the southwest and southeast areas of the Ottawa Area Sub-Region. In the southwest, referred to as the Core West subsystem in this report, the Cambrian MTS station was brought into service in 2022. Originally identified in 2008 and approved by the IESO in 2016, this new station addresses growing demand in the area. In the southeast, a new station, Piperville MTS, is currently under construction. This station will relieve neighbouring stations and provide additional capacity to support emerging load growth in the region.

Additionally, to accommodate both load growth and the end-of-life considerations in the Orléans area, it is recommended that the Billberry Creek station be decommissioned. In its place, a new station—tentatively named Mer-Bleue MTS—will be required to serve the existing load, with an expected in-service date of 2027. Finally, the introduction of a new electrified municipal bus fleet will necessitate the construction of a bus charging station near Hawthorne TS, referred to as Hydro Road MTS in the current plan

2020 Ottawa Integrated Regional Resource Plan Recommendations

- Hydro Ottawa is to implement the North Kanata Retrofit Top-Up Program and the North Kanata Smart Thermostat Program, which are targeted commercial and residential energy efficiency programs. Hydro Ottawa is also planning distribution system transfers to reduce demand at heavily loaded stations.
- Hydro One is to replace Merivale TS Transformer T22 with one that is equivalent to T21.
- Hydro One is to proceed with the like-for-like refurbishment of Bilberry Creek TS, which is approaching its end-of-life, and expand the station to accommodate two additional breaker positions to supply Hydro Ottawa customers.

- Hydro One is to replace Slater TS T2 and T3, which are approaching their end-of-life, with larger transformers, approximately 100 megavolt amperes (MVA), as was done for the recent replacement of T1.
- Hydro One is to replace the two 75 MVA transformers at Albion TS, which are approaching their end-of-life, with similar size transformers.
- Hydro One is to replace the two 75 MVA transformers at Lincoln Heights TS, which are approaching their end-of-life, with similar size transformers.
- Hydro Ottawa is to plan and seek approval for a new 230 kV connected supply station in southeast Ottawa.

2020 Ottawa Regional Infrastructure Plan Recommendations

- Replace end-of-life transformers T1/T2 at Lincoln Heights TS: complete in 2024, 2023 respectively (45/60/75 MVA).
- Replace end-of-life transformers T3/T4 at Longueuil TS: in-service date of 2025.
- Replace end-of-life 115 kV breakers at Riverdale TS: In-service date of 2028.
- Increase transformation capacity in southeast Ottawa, with Hydro Ottawa building a transformer station: station named Piperville TS, expected in-service date 2026.
- Replace end-of-life transformers T1/T2 and circuit breakers at Albion TS.
- Replace end-of-life transformers at Russel TS.
- Determine limitation of low voltage-cables, upgrade cables at Overbrook TS: station Limited Time Rating (LTR) increased between cycles, which reflects this change.
- Upgrade Hawkesbury MTS station capacity.
- Refurbish Bilberry Creek TS end-of-life: the Working Group recommends decommissioning Billberry Creek in favour of new DESN, as described within the report.
- Replace T22 at Merivale TS: this project is ongoing and is part of the Merivale project, which is in service in 2029
- Voltage performance of 79M1 evaluated as part of next IRRP: moving to 2025 RIP

4.2 Bulk Planning and Other Developments

Beyond historical regional planning efforts, the Ottawa Area Sub-Region has also been the focus of bulk planning initiatives and other key developments.

2022 Gatineau Corridor Study

- Refurbish all 800 km of 230 kV circuits on the Gatineau Corridor identified as nearing end-of-life.
- Build a new double-circuit 230 kV transmission line into Dobbin TS (in Peterborough) from Clarington TS (in Oshawa), with a planned in-service date of 2029.

- Pursue up to 230 megawatts (MW) of additional system cost-effective energy efficiency in the Ottawa area over the 20-year planning horizon, while monitoring demand growth and resource acquisition activities in the Ottawa zone.
- Update and expand the use of remedial action schemes (RASs) in the Peterborough and Ottawa areas to meet planning standards and further improve the load meeting capabilities of both areas.
- Implementation of recommendations is ongoing.

2023 Orléans Area Study

To manage forecast risks from high electrification growth, maintain reliability, and defer major upgrades to Ottawa's 115 kV system beyond the third autotransformer at Merivale TS, an integrated solution package is recommended. This includes decommissioning Bilberry Creek TS, building a new 230 kV circuit from Hawthorne TS to Orléans TS, and upgrading Orléans TS to a 230 kV DESN.

IESO Long-Term 1 Procurement

During the IRRP process, the IESO launched its Long-Term 1 Procurement, which has led to competitive pricing for new resources, municipal support, and significant Indigenous participation and equity ownership in projects. The IESO entered into contracts with 13 selected proponents, securing approximately 2,200 MW of new capacity, set to come online between 2026 and 2028. Among these procurements are two large-scale BESS located in the Kanata-Stittsville and Core West subsystems to the west of Ottawa.

Although the IRRP evaluated batteries as part of the non-wires solutions process and found that they could not fully address the identified needs on their own, they offer valuable benefits, including improvements in voltage stability, peak demand management, and enhanced system reliability. This plan supports the technical advantages of these projects and acknowledges that a diversified system will be crucial for realizing the long-term vision of the electricity landscape.

Eastern Ontario Bulk Plan

- The IESO is carrying out an Eastern Ontario Bulk Study to assess the sufficiency of the bulk transmission system to reliably supply the demand growth expected in Greater Ottawa areas. The bulk plan will be coordinating with this IRRP regarding demand forecast and regional assumptions to ensure alignment and efficiency.
- The targeted completion of this bulk plan is Q1 2026.

4.3 Current Cycle of Regional Planning

The current cycle of regional planning began in 2023 with the publication of the Needs Assessment Report, where several needs requiring further regional coordination were identified. The 2023 Ottawa Scoping Assessment recommended an IRRP for the Ottawa Area Sub-Region to address needs in a coordinated manner. This report presents an integrated regional electricity plan for the next 20-year period starting from 2024.

This IRRP develops and recommends options to meet the electricity needs of the Ottawa Area Sub-Region in the near-, medium-, and long-term. The plan was prepared by the IESO on behalf of the

Working Group, and considers forecast electricity demand growth, eDSM, distributed generation (DG), transmission and distribution system capability, relevant community plans, condition of transmission assets, and developments on the bulk transmission system.

The transmission facilities included in the scope of this study are shown in **Table 2**, **Table 3**, and **Table 4**:

Table 2 | Transformer Stations

Albion TS	Bridlewood MTS	Cambrian MTS	Carling TS
Centrepoint MTS	Cumberland DS	Cyrville MTS	Ellwood MTS
Fallowfield MTS	Greely DS	Hawthorne TS	Hinchey TS
Kanata MTS	King Edward TS	Limebank MTS	Lincoln Heights TS
Lisgar TS	Manordale MTS	Manotick DS	Marchwood MTS
Marionville DS	Merivale MTS	Moulton MTS	National Aeronautical CTS
National Research Council CTS	Navan DS	Nepean Epworth MTS	Nepean TS
Piperville MTS	Orléans TS	Overbrook TS	Richmond South MTS
Riverdale TS	Russell DS	Russell TS	Slater TS
South Gloucester DS	South March TS	Terry Fox MTS	Uplands MTS
Wilhaven DS	Woodroffe TS	Hydro Road MTS

Figure 4 | Single Line Diagram of the Ottawa Area Sub-Region

The single line diagram of the Ottawa Area Sub-Region is shown in **Figure 4**. Note that the bulk system transfer capabilities on the Flow-into-Ottawa (FIO) interface into the region is not within the scope of this IRRP and was separately studied in the East bulk transmission plan. The schedule of bulk planning activities is identified through the IESO's **Annual Planning Outlook**.

Ottawa is a major load centre in eastern Ontario, which is primarily supplied by:

- two 500 kV circuits from Lennox TS in Lennox and Addington County
- two 230 kV circuits from St. Lawrence TS in Cornwall
- one 230 kV circuit from Chats Falls SS
- one 115 kV circuit from Barrett Chute GS
- one 115 kV circuit from Stewartville GS
- an inter-connection with Quebec's transmission system at Hawthorne TS, located in the east side of Ottawa

The transmission system serving Ottawa has several interfaces that can limit the ability to meet demand within the city and efficiently transfer power from generation and imports in eastern Ontario across the provincial grid. Ottawa's electricity needs are primarily met by a series of 230 kV and 115 kV transmission circuits that emanate from the Merivale TS and Hawthorne TS stations, which serve as the central hubs for the city's power supply.

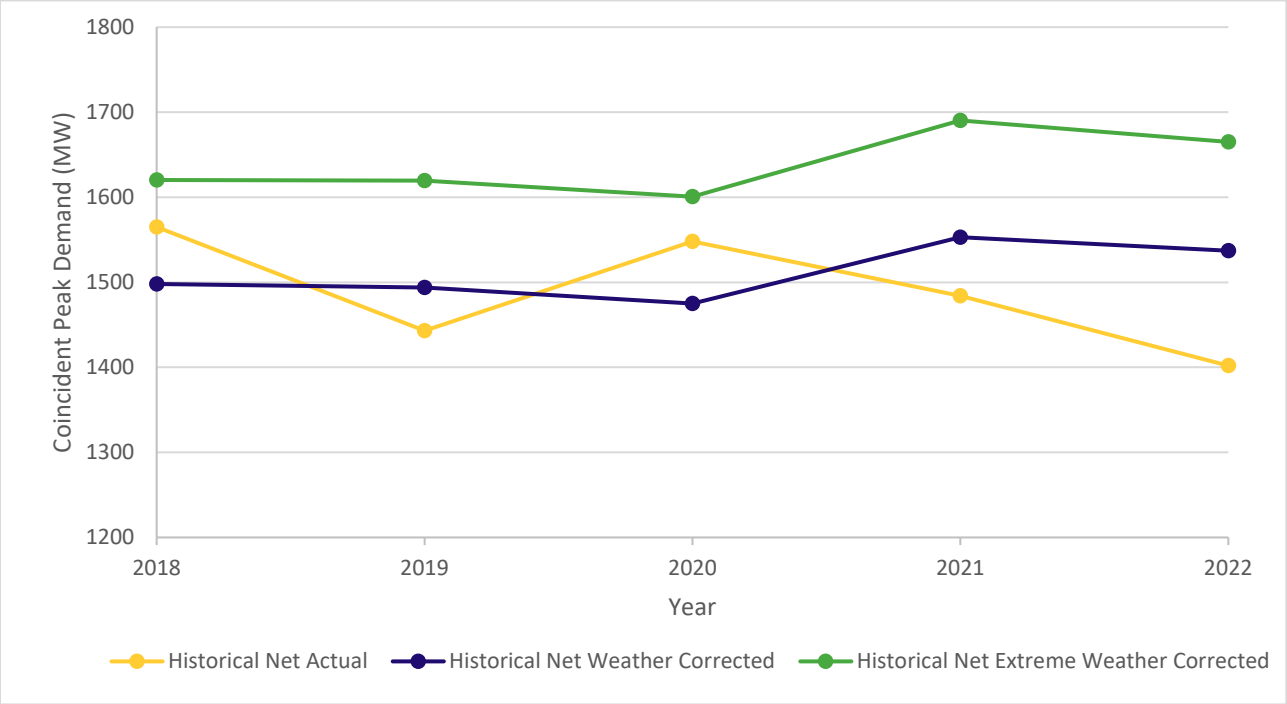
Historically, Ottawa experiences peak demand during the summer, with loads reaching approximately 1,600–1,700 MW. However, over the next 20 years, demand is expected to grow significantly, and the region is forecast to transition into a winter-peaking area as early as 2030. There is minimal internal generation capacity in Ottawa, with only one transmission-connected generator—a 70 MW combined-cycle gas plant. In addition, there are several distribution-connected generators within the city, with the most notable being the Chaudière Falls hydroelectric plants, which collectively contribute around 90 MW of capacity

The Ottawa IRRP was developed by completing the following steps:

1. Preparing a 20-year electricity demand forecast and establishing needs over this timeframe.
    a. Examining the LMC and reliability of the existing transmission system, considering facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC and NERC criteria.
    b. Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO-controlled grid.
    c. Confirming identified asset replacement needs and timing with the transmitter and LDCs.
2. Establishing alternatives to address system needs including, where feasible and applicable, generation, transmission and/or distribution, and other approaches, such as non-wires alternatives including eDSM.
3. Engaging with the community on needs and possible alternatives.
    a. Evaluating alternatives to address near- and long-term needs.
    b. Considering the impact of the high forecast as a sensitivity of the flexibility and optionality of the potential alternatives.
4. Communicating findings, conclusions, and recommendations within a detailed plan.

5. Electricity Demand Forecast

Regional planning in Ontario is driven by the need to meet peak electricity demand requirements in a region. This section describes the development of the demand forecast for the Ottawa Area Sub-Region. It highlights the assumptions made for peak demand forecasts, including weather correction, the contribution of eDSM and DG, and the development of a high-growth scenario. The reference net extreme weather demand forecast is used in assessing the electricity needs of the area over the planning horizon; the high forecast scenario, used as the basis for a sensitivity analysis, is described further in Section 5.6.2.



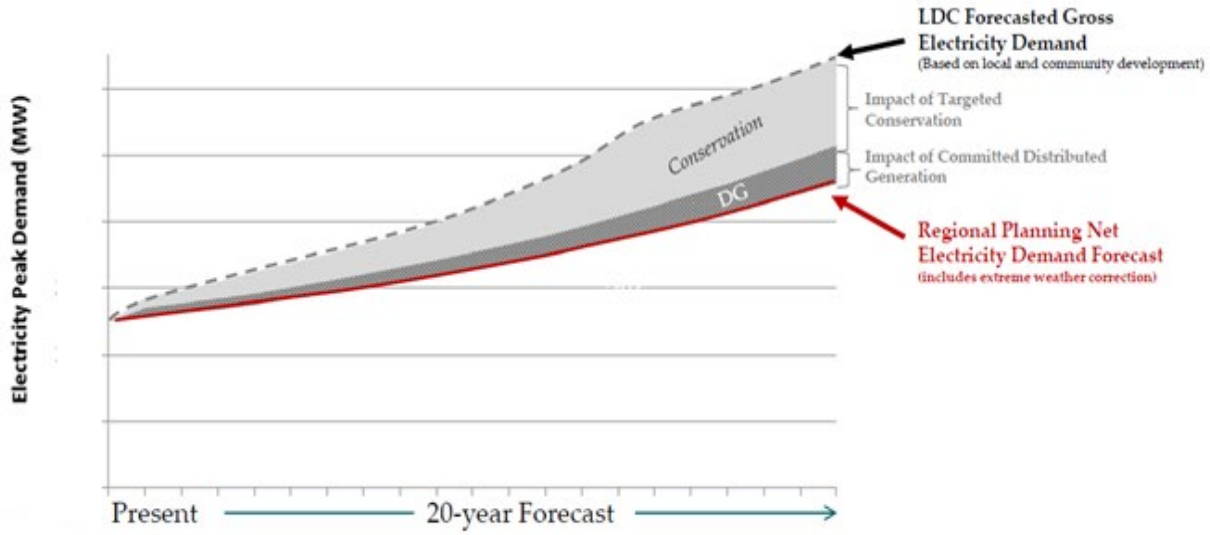
To evaluate the reliability of the electricity system, the regional planning process is typically concerned with the coincident peak demand for a given area. This is the demand observed at each station for the hour of the year in which overall demand in the study area is at its maximum. This differs from a non-coincident peak, which refers to each station's individual peak, regardless of whether these peaks occur at different times. Within the Ottawa Area Sub-Region, the peak loading hour for each year has historically occurred in the summer. However, with the recent and projected growth of electric heating, the region is projected to become winter-peaking.

5.1 Historical Demand

Summer peak electricity demand within the Ottawa Area Sub-Region has remained stable in the five years prior to this planning cycle. **Figure 5** shows the coincident net actual (as observed at the metering point), net median weather-corrected (adjusted to reflect median weather conditions), and net extreme weather-corrected (adjusted to reflect extreme weather conditions) historical demand. The summer net median weather-corrected demand has averaged 1,500 MW over the past five years, with the peak demand hour for each year occurring between approximately 3 PM to 5 PM.

Since the forecast was developed in 2023, only the 2022 values were available to create gross starting points. The starting points used the median weather corrected 2022 values, adding the effect of DG to make it a gross weather-corrected starting point.

Figure 5 | Historical Peak Demand in the Ottawa Area Sub-Region



5.2 Demand Forecast Methodology

The steps taken to develop a 20-year IRRP peak demand forecast are depicted in **Figure 6**. Gross demand forecasts, which assume the weather conditions of an average year based on historical weather conditions (referred to as "normal weather"), were developed by the LDCs. These forecasts were then modified to reflect the peak demand impacts of provincial eDSM targets and DG contracted through previous provincial programs such as Feed-In Tariff (FIT) and microFIT and adjusted to reflect extreme weather conditions to produce a reference forecast for planning assessments. This net forecast was then used to assess the electricity needs in the region.

Additional details related to the development of the demand forecast are provided in Appendix B. The Ontario Energy Board has also published a **Load Forecast Guideline** for regional planning, through the **Regional Planning Process Advisory Group**.

Figure 6 | Illustrative Development of Demand Forecast

5.3 Gross LDC Forecasts

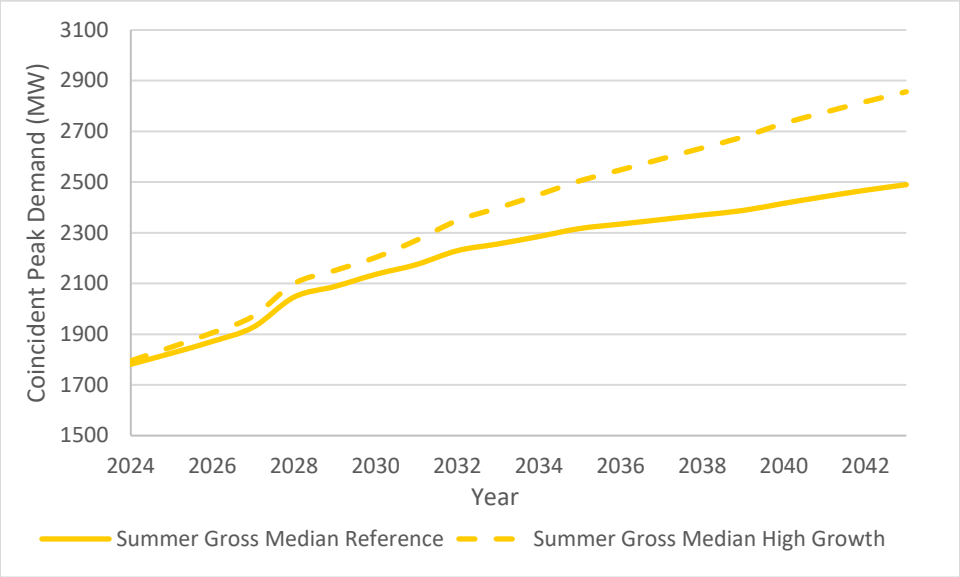
Each participating LDC in the Ottawa Area Sub-Region prepared gross demand forecasts at the station level. These gross demand forecasts account for increases in demand from new or intensified development, plus known connection applications. The LDCs cited alignment with municipal and regional official plans and credited them as a source for input data. LDCs were also expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices ("natural conservation"), but not for the impact of future DG or new conservation measures (such as codes and standards and eDSM programs), which are accounted for by the IESO (discussed in Section 5.45).

The gross LDC forecasts assume median on-peak weather conditions and loading that is coincident to each station. A coincident demand forecast was used instead of a non-coincident forecast because it better reflects the system-level peak, which is critical for planning shared infrastructure. While some individual stations may experience higher non-coincident peaks, these are typically captured in the winter forecast, which drives most station capacity needs. However, this approach can introduce some uncertainty, particularly for the winter period, and may understate summer needs in some areas—potentially shifting the summer need date slightly later.

LDCs have a better understanding of future local demand growth and drivers than the IESO, since they have the most direct involvement with the customers, connection applicants, and municipalities and communities that they serve. The IESO typically carries out demand forecasting at the provincial level. More details on LDC load forecast assumptions can be found in Appendix B.2 to B.6. **Figure 7** and **Figure 8** show the total reference and high-growth gross coincident demand forecasts provided by the LDCs for the Ottawa Area Sub-Region.

Hydro Ottawa worked closely with Enbridge Inc. to develop electrification scenarios dealing with the transition from natural gas to heat-pump based electrical heating. A full breakdown of each LDC's methodology can be found in the Appendix B and on the IESO's Ottawa engagement webpage.

Figure 7 | Total Summer Gross Coincident Demand Forecasts Provided by LDCs (Median Weather)



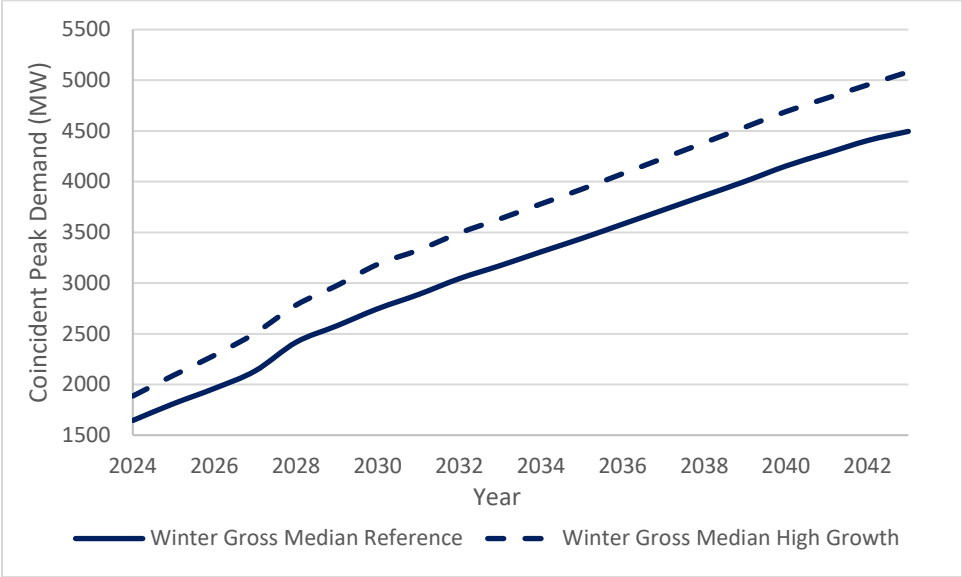


Figure 8 | Total Winter Gross Coincident Demand Forecasts Provided by LDCs (Median Weather)

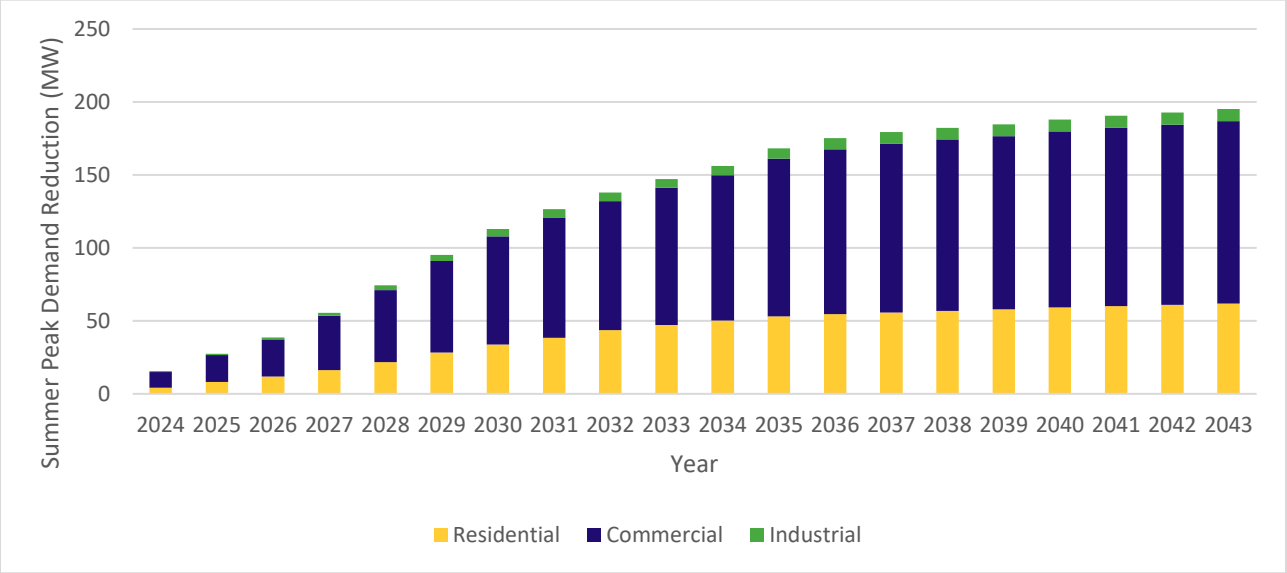
5.4 Contribution of eDSM to the Forecast

Electricity Demand Side Management is a clean and cost-effective resource that helps meet Ontario's electricity needs and has been an integral component of provincial and regional planning. eDSM is achieved through both codes and standards amendments, as well as eDSM incentive program-related activities. These approaches complement each other to maximize results.

In alignment with the language of the November 7, 2024, directive to the IESO regarding a new energy efficiency framework for 2025–2036, this IRRP uses the term "electricity demand-side



management" replacing "conservation and demand management (CDM)" used in previous IRRPs and other IESO planning reports.

The estimate of demand reduction due to codes and standards are based on expected improvement in the codes for new and renovated buildings, and through regulation of minimum efficiency standards for equipment used by specified categories of consumers (i.e., residential, commercial and industrial consumers).

The estimates of demand reduction due to program-related activities account for the IESO's 2021-2024 eDSM Framework, federal programs that result in electricity savings in Ontario, and forecasted long-term energy efficiency programs. At time of forecast development, the 2021 – 2024 eDSM framework was the main piece, in which the IESO centrally delivered programs to serve business and residential customers, including Indigenous communities, across the province.[2]

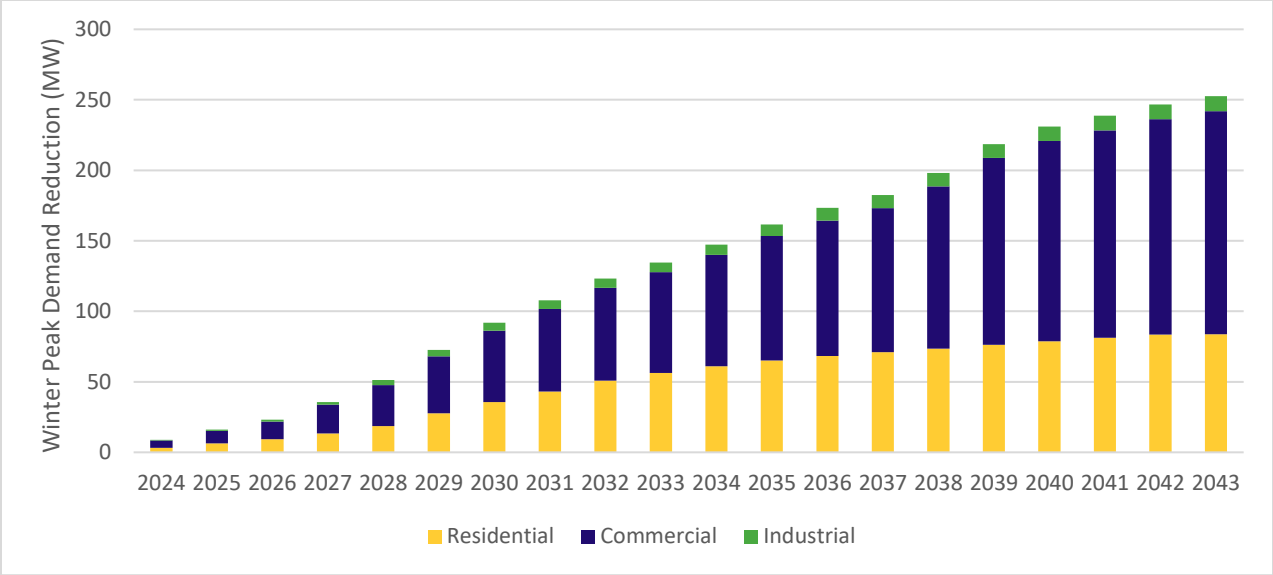


Figure 9 and **Figure 10** show the estimated total yearly reduction to the demand forecast due to conservation (from codes, standards, and eDSM programs) for each of the residential, commercial, and industrial consumers. Additional details are provided in Appendix B.4.

Figure 9 | Total Summer Forecast Peak Demand Reduction (Codes, Standards, and eDSM Programs)

[2] The IESO has received a directive to continue delivering eDSM programs for 2025-2036.

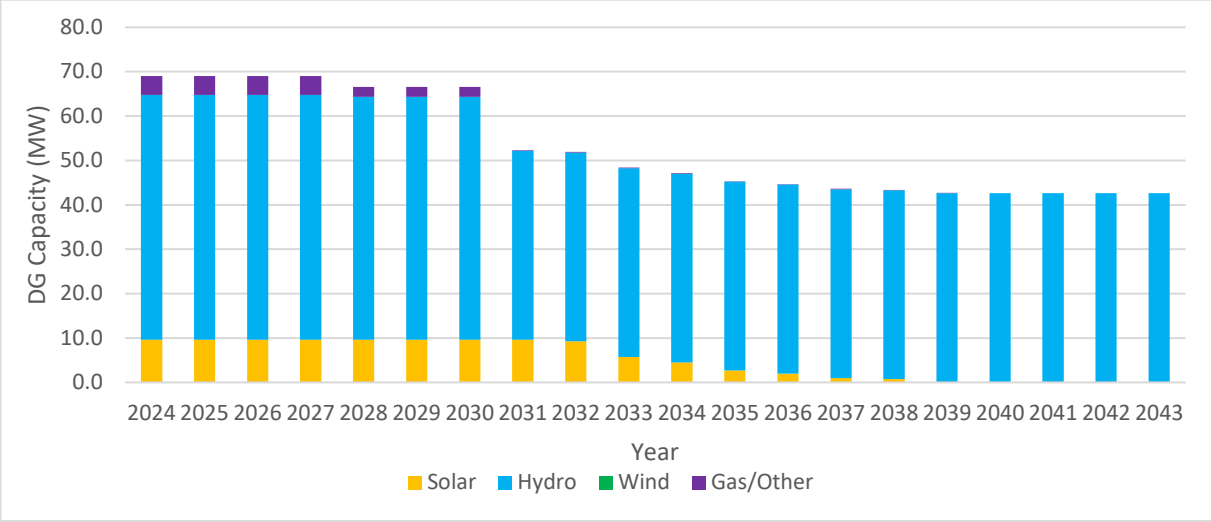
Figure 10 | Total Winter Forecast Peak Demand Reduction (Codes, Standards, and eDSM Programs)

5.5 Contribution of Distributed Generation to the Forecast

In addition to eDSM, DG in the Ottawa Area Sub-Region is also forecast to offset peak demand requirements. The introduction of Ontario's FIT Program increased the significance of distributed renewable generation that, while intermittent, contributes to meeting the province's electricity demands. The installed DG capacity by fuel type and contribution factor assumptions can be found in Appendix B. Most of the total contracted installed DG capacity in the Ottawa Area Sub-Region is solar and hydro, with the remainder being gas or wind facilities.

After reducing the demand forecast due to eDSM, as described in Section 5.4, the forecast is further reduced by the expected contribution from contracted DG, except for DG facility information provided directly by the LDCs. **Figure 11** and **Figure 12** show the impact of DG on reducing the Ottawa Area Sub-Region demand forecasts. Note that facilities without a contract with the IESO were not included in the DG peak demand reduction forecast, except for DG facility information provided directly by the LDCs.

Figure 11 | Summer Peak Demand Reduction Due to DG



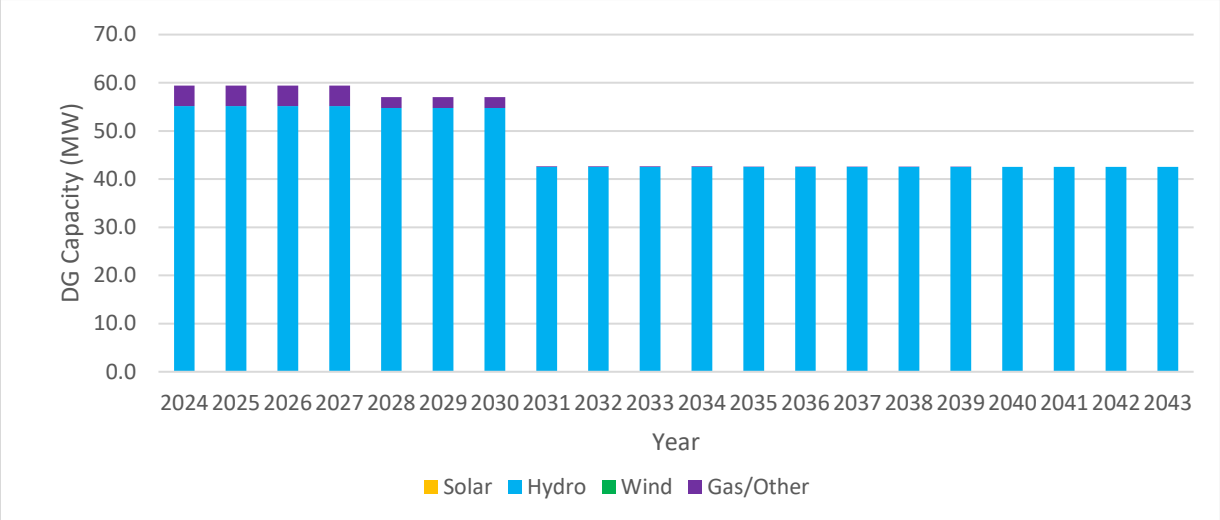


Figure 12 | Winter Peak Demand Reduction Due to DG

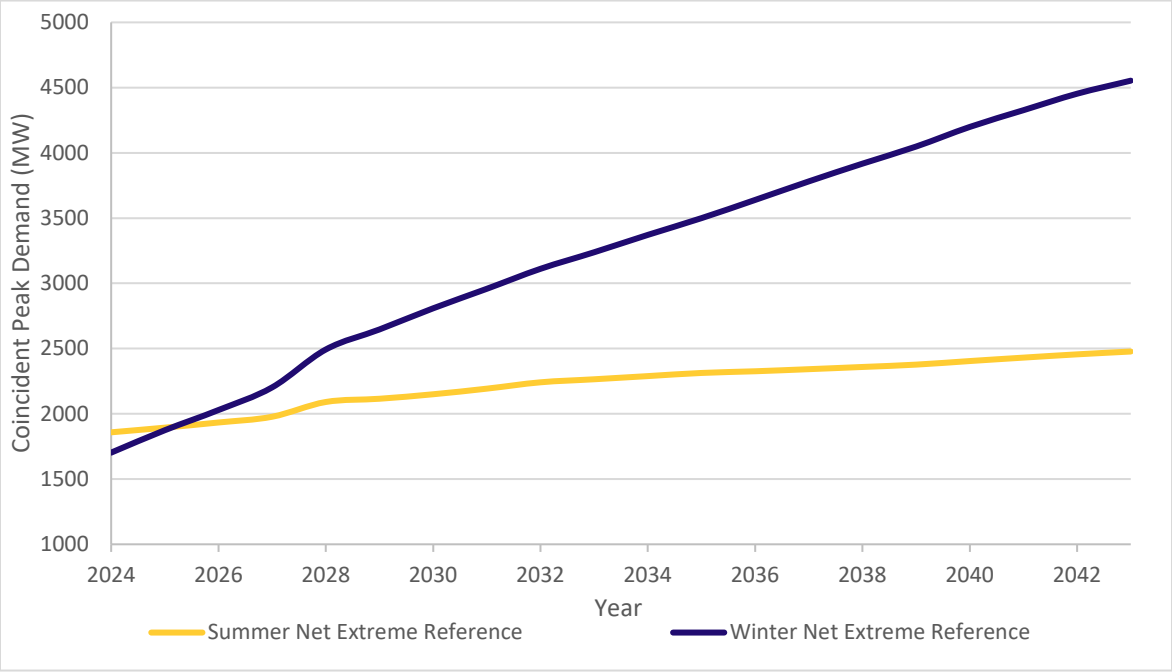
A decision was made within the Working Group to consider the expected lifespan of each distributed generation facility based on resource type, rather than assuming that facilities will not be re-contracted past their current contract end date. In alignment with the IESO 2024 Annual Planning Outlook, the assumption for resource expected lifespans was 25 years for solar, and 30 years for wind, natural gas and biogas.

A total of 115 MW of DG summer peak contribution and is identified for the Ottawa Area Sub-Region in 2024, reducing throughout the 2030s to 43 MW by 2043. In the winter, the DG peak contribution decreases from 70 MW in 2024 to 43 MW by 2043.

5.6 Planning Forecasts

After taking into consideration the combined impacts of eDSM and DG, a 20-year planning Reference and High forecast was produced for the Ottawa Area Sub-Region.



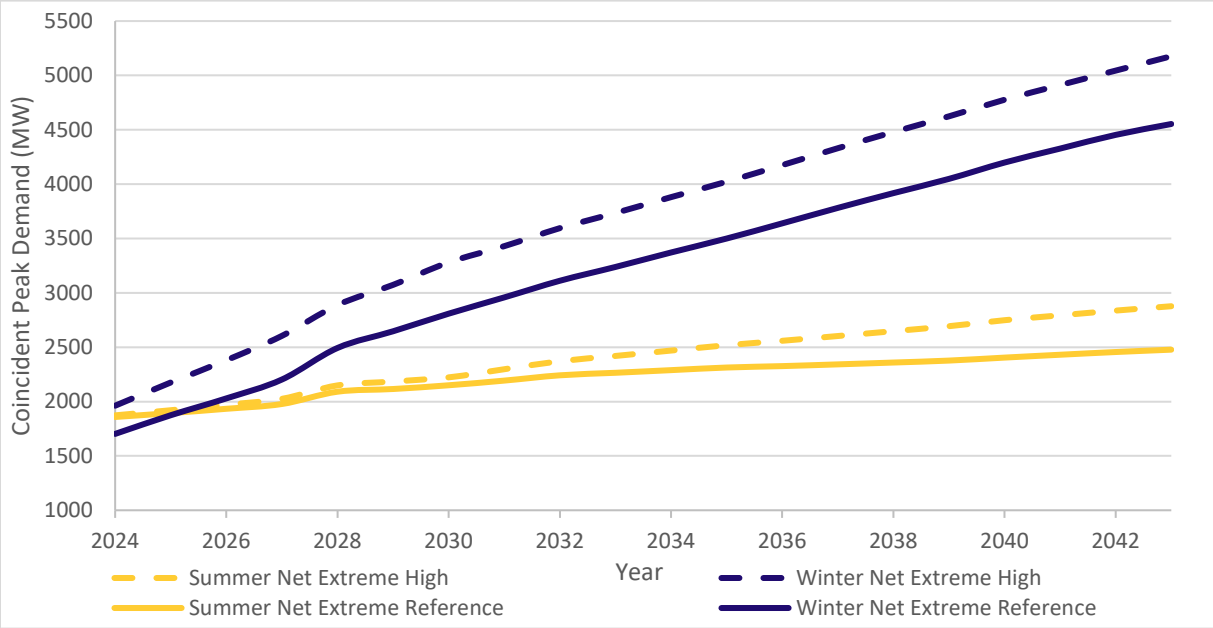
5.6.1 Net Extreme Weather (Planning) Forecast

The net extreme weather forecast, also known as the "planning" forecast, is created by adjusting the net median weather forecast (the gross demand forecast, plus the forecast DG and eDSM impacts as described above) for extreme weather conditions. The weather correction methodology is described in Appendix B.1.

Note that this planning forecast is coincident, meaning that each station forecast reflects its expected contribution to the regional peak demand level. This supports the identification of need dates for regional needs that are driven by more than one station.

The coincident net extreme weather forecast for the Ottawa Area Sub-Region is shown in **Figure 13**.

Figure 13 | Net Extreme Weather (Planning) Forecast for the Ottawa Area Sub-Region



5.6.2 High Forecast Scenario

The Working Group chose to develop a high-growth sensitivity scenario for the Ottawa Area Sub-Region. This scenario modifies assumptions around the adoption of electrification technologies and assumes a faster pace of decarbonization. While both the reference and high-growth scenarios aim for a net-zero future by 2050, they differ in the speed at which that transition occurs. The higher demand scenario was not used to drive firm recommendations in this IRRP; however, it served as a tool for the Working Group to identify potential future pinch points and the timelines in which they might emerge. This information is also valuable for communities working on Community Energy Plans for the Working Group as it determines areas to monitor in future planning cycles and for local

stakeholders considering various regional projects. Additionally, during the course of this IRRP, the Working Group assessed the flexibility of the evaluated options to accommodate long-term growth.

Figure 14 | High Forecast Scenario for the Ottawa Area Sub-Region

The higher demand scenario, as seen in **Figure 14**, was not used to drive any firm recommendations for this IRRP; however, it was used to help the Working Group identify where the future pinch points may be and when they could materialize. This information can also be useful for communities conducting Community Energy Plans, for the Working Group in determining areas to monitor in future planning cycles, and for communities and stakeholders as they think about various projects in the region. Moreover, during this IRRP, the Working Group also considered the flexibility of evaluated options to accommodate greater long-term growth.

5.7 Hourly Forecast Profiles

In addition to the annual peak forecast, hourly load profiles (8,760 hours per year over the 20-year forecast horizon) for station(s) included in identified needs were developed to characterize the needs with finer granularity. The profiles were based on historical load data, adjusted for variables that impact demand, such as calendar day (i.e., holidays and weekends) and weather as well as future electrification. They were also based off of hourly load forecasts provided by the LDCs. The profiles were then scaled to match the IRRP peak planning forecast for each year. As described in Section 7, these profiles were used to quantify the magnitude, frequency, and duration of needs to better evaluate the suitability of generation and distributed energy resource options.

Additional load profile details, including hourly heat maps for each need, can be found in Appendix D. Note that this data is used to roughly inform the overall energy requirements needed to develop and evaluate alternatives; it cannot be used to deterministically specify the precise hourly energy requirements. Real-time loading is subject to various factors, like actual weather, customer operation

strategies, and future customer segmentation. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification are more widely adopted. Hence, these hourly forecasts are only used to select suitable technology types and roughly estimate costs for the needs and options studied in the IRRP. The Working Group will continue to monitor forecast changes as part of the implementation of the plan.

6. Needs

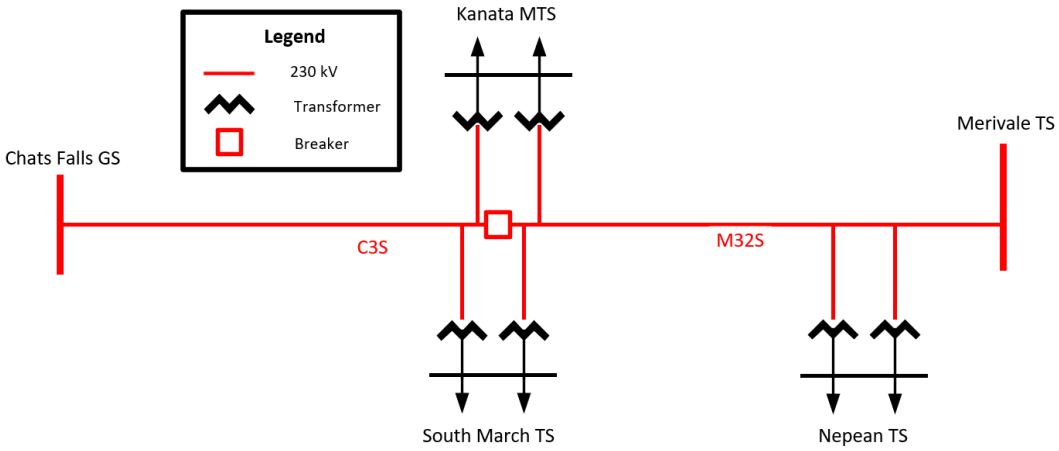
This section summarizes the needs identified through the IRRP process. The projected impacts of economic growth, decarbonization, and electrification—particularly the transition from natural gas to electric or hybrid heating—are expected to place increasing pressure on the electricity system, especially during winter months. In response, a range of electricity needs have been identified across near-, medium-, and long-term horizons.

6.1 Needs Assessment Methodology

Based on the planning demand forecast, system capability, the transmitter's identified asset replacement plans, and the application of ORTAC, NERC TPL-001-4, and Northeast Power Coordinating Council (NPCC) Directory #1 standards, the Working Group identified electricity needs that generally fall into the following categories:

- **Station Capacity Needs** describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations during peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day LTR of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be more limited by downstream or upstream equipment (i.e., breakers, disconnect switches, low-voltage bus or high-voltage circuits).
- **System Capacity Needs** describe the electricity system's inability to provide continuous supply to a local area during peak demand. This is limited by the LMC of the transmission supply. The LMC is determined by evaluating the maximum demand that can be supplied to an area after accounting for limitations of the transmission elements (i.e., a transmission line, group of lines, or autotransformer), when subjected to contingencies and criteria prescribed by ORTAC, TPL-001-4, and NPCC Directory #1. LMC studies are conducted using power system simulation analyses.
- **Asset Replacement Needs** are identified by the transmitter using an asset condition assessment, which is based on a range of considerations, such as equipment deterioration due to aging infrastructure or other factors; technical obsolescence due to outdated design; lack of spare parts availability or manufacturer support; and/or potential health and safety hazards, etc. Replacement needs identified in the near- and early medium-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium- to long-term needs should reflect the potential for the need date to change as condition information is routinely updated.
- **Load Security and Restoration Needs** describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of

both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC.



Technical study results for the Ottawa IRRP can be found in Appendix G. The needs identified are discussed in Sections 6.2 to 6.5, below, for each of the four subsystems.

6.2 Ottawa Subsystems

To support detailed technical analysis, the Ottawa Area Sub-Region has been further subdivided into four major subsystems: Kanata-Stittsville, Core East, Core West, and Core South. These subdivisions reflect the electrical connectivity of the transmission network and group together stations, supply circuits, and infrastructure that operate as electrically cohesive units. This approach allows for more accurate modelling of system performance, localized planning for station and System Capacity needs, and alignment with regional infrastructure development. Within each subsystem, further division into pockets is used where necessary to better reflect local electrical boundaries and simplify LMC assessments, as illustrated in **Figures 15–18**.

Located west of Merivale TS, the Kanata-Stittsville subsystem is supplied by two 230 kV circuits—one from Merivale TS and another from Chats Falls TS, which is approximately 25 km to the north and includes a hydroelectric generation component. These lines supply Kanata MTS and South March TS, both of which are projected to reach capacity in the near term and are identified as key station needs. As shown in **Figure 15** this subsystem's layout enables focused planning to address rising demand and operational risk. While Marchwood MTS and Bridlewood MTS are located geographically within this area, they are supplied via the 115 kV system and are therefore included in the Core West subsystem.

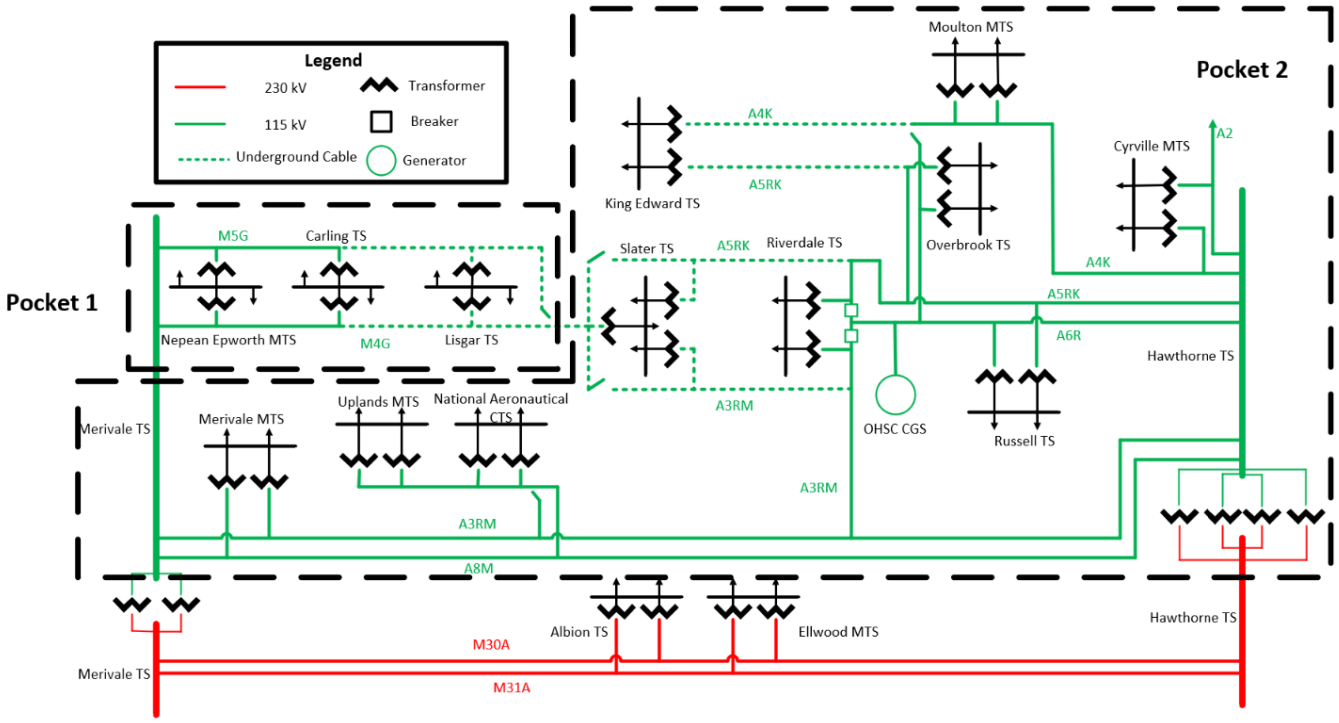


Figure 15 | Overview of the Ottawa Kanata-Stittsville area

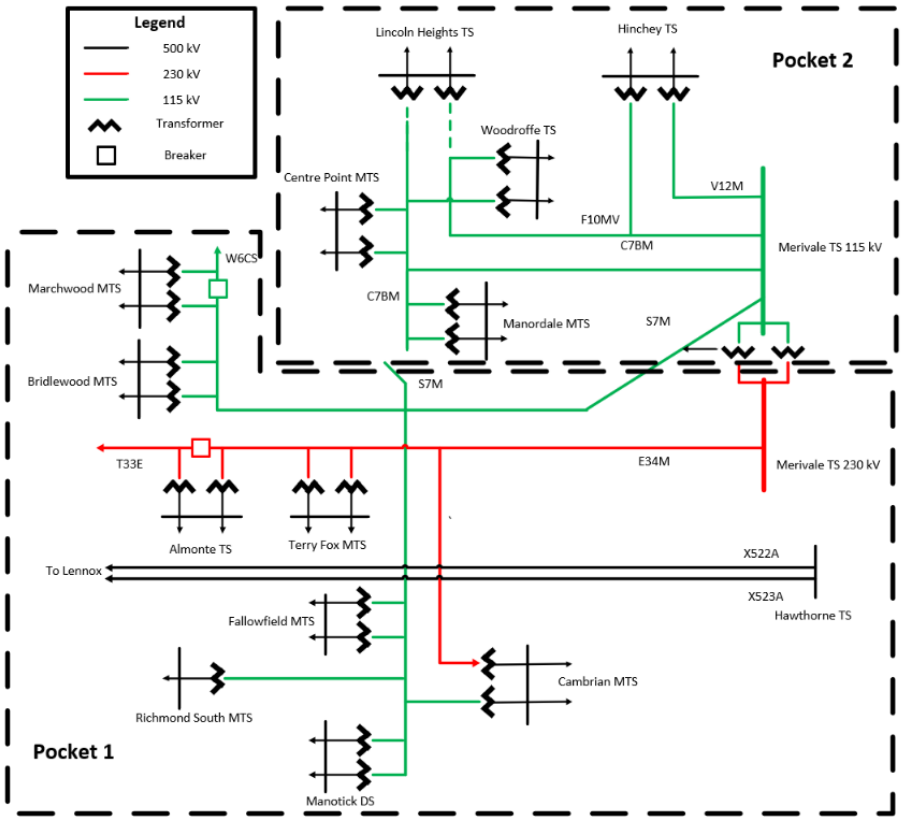
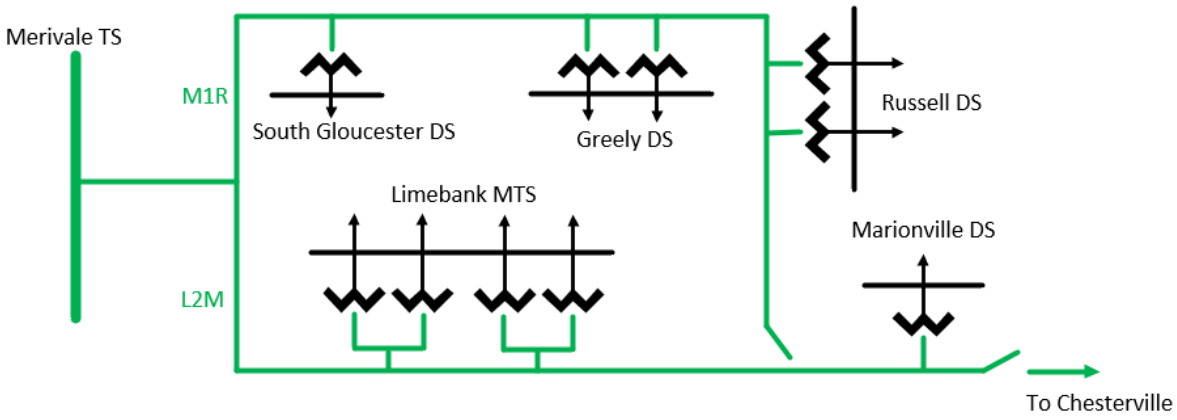
The Core East subsystem represents Ottawa's urban downtown core and is characterized by a large, interconnected 115 kV system. For the purposes of the technical studies and to support more



manageable modelling, Core East is divided into two pockets. Pocket 1 consists of circuits M4G and M5G, which supply Nepean Epworth MTS, Carling TS, and Lisgar TS. Notably, M4G also provides one of three supplies to Slater TS. The remaining 115 kV circuits form Pocket 2, supplying the remaining downtown stations predominantly east of the Rideau River. **Figure 16** illustrates this breakdown, allowing for better assessment of local supply adequacy and reinforcement needs.

Figure 16 | Overview of the Ottawa Core East Area



Core West has also been divided into two pockets to reflect the operational and electrical characteristics of the area. Pocket 1 includes stations supplied by 115 kV circuits S7M and W6CS, as well as 230 kV circuit E34M. All three connect at Cambrian TS, where a Fast Transfer Scheme (a RAS) is used to quickly restore load in the event of a circuit loss, avoiding the need for more expensive dual 230 kV supply infrastructure. This pocket includes several stations experiencing or approaching capacity limits. **Figure 17** depicts the full subsystem and pocket breakdown, supporting the identification of local needs and future conversion opportunities.

Figure 17 | Overview of the Ottawa Core West Area

The Core South subsystem comprises the area south of Ottawa's urban core and includes five supply stations served radially by two 115 kV circuits. The stations are relatively remote and less interconnected compared to those in other subsystems. **Figure 18** shows the simplified layout of this subsystem. The 2020 Ottawa IRRP identified the need for a new 230 kV station—Piperville MTS—to support rapid growth in the southeastern portion of the city. Connected to circuit L24A, Piperville MTS is expected to be energized in 2026 and will play a key role in alleviating station capacity constraints in the area and supporting long-term system reliability.

Figure 18 | Overview of the Ottawa Core South Area

6.3 Station Capacity Needs

Many station capacity needs emerge in the Ottawa Area Sub-Region, as shown in **Table 5** with the majority in the near/medium term.

Table 5 | Summary of Station Capacity Needs in the Ottawa Area Sub-Region

Time Horizon	Station	Subsystem	Emerging Year Summer	Emerging Year Winter	2043 Need Summer (MW)	2043 Need Winter (MW)
Near Term	Carling TS	Core East – Pocket 1	2028	2029	40	130
	Lisgar TS	Core East – Pocket 1	2025	2027	30	120
	Nepean Epworth MTS	Core East – Pocket 1	2031	2028	1	10
	Cyrville MTS	Core East – Pocket 2	-	2029	0	40
	King Edward TS	Core East – Pocket 2	2037	2026	10	160
	Moulton MTS	Core East – Pocket 2	2028	2028	3	30
	Riverdale TS	Core East – Pocket 2	2038	2028	8	110
	Ellwood MTS	Core East – Pocket 2	2024	2027	60	5
	Bridlewood MTS	Core West – Pocket 1	2032	2029	1	20

Time Horizon	Station	Subsystem	Emerging Year Summer	Emerging Year Winter	2043 Need Summer (MW)	2043 Need Winter (MW)
	Fallowfield MTS	Core West – Pocket 1	2024	2030	7	40
	Marchwood MTS	Core West – Pocket 1	2025	2025	8	40
	Centrepoint MTS	Core West – Pocket 2	2024	2026	2	20
	Manordale MTS	Core West – Pocket 2	2024	2025	3	20
	Greely DS	Core South	2024	2024	10	10
	Limebank MTS	Core South	-	2030	0	50
	Marionville DS	Core South	2026	2026	10	10
	Kanata MTS	Kanata-Stittsville	2024	2026	20	40
	South March TS	Kanata-Stittsville	2027	2027	20	100
Medium Term	Overbrook TS	Core East – Pocket 2	-	2032	0	90
	Hawthorne TS	Core East – Pocket 2	-	2031	0	60
	Hinchey TS	Core West – Pocket 2	-	2033	0	60
	Nepean TS	Kanata-Stittsville	-	2031	0	100
Long Term	Merivale MTS	Core East – Pocket 2	-	2039	0	7
	Uplands MTS	Core East – Pocket 2	-	2041	0	5
	Albion TS	Core East – Pocket 2	-	2035	0	40
	Cambrian MTS	Core West – Pocket 1	-	2038	0	20
	Richmond South MTS	Core West – Pocket 1	-	2037	0	10
	Terry Fox MTS	Core West – Pocket 1	-	2037	0	30
	Lincoln Heights TS	Core West – Pocket 2	-	2040	0	10
	Woodroffe TS	Core West – Pocket 2	-	2040	0	10

6.3.1 Station Capacity Needs Kanata-Stittsville Subsystem

Kanata MTS has an LTR of 54 MW and is forecast to exceed capacity by 2024 in summer and 2026 in winter. By 2030, the projected winter overload is 15 MW, indicating continued and significant growth in demand. This early emerging need reflects increasing development across the Kanata area, necessitating reinforcements or capacity upgrades within the near term.

South March TS, with a winter LTR of 120 MW and summer LTR of 105 MW, is forecast to reach capacity by 2027 in both seasons. By 2030 the winter overload is projected to reach 23 MW. The station's two 230/44 kV transformers, in service since 1971, are due for replacement between 2030–2032, and the Working Group is evaluating whether to replace them with larger 75/100/125 MVA units.

Nepean TS has a winter LTR of 170 MW and is expected to exceed this rating by 2031. Although there is no summer need forecasted, the station is facing a load security issue: winter peak demand is projected to exceed 150 MW by 2029, and with M32S as the sole supply, an outage would violate ORTAC criteria by resulting in a full load loss. Addressing this concern will require both capacity and contingency planning for secure operation in the Kanata-Stittsville area.

6.3.2 Station Capacity Needs Core East Subsystem

Carling TS has a summer LTR of 100 MW and a winter LTR of 132 MW. It is projected to exceed capacity in 2028 (summer) and 2029 (winter). By 2030, the winter overload is expected to reach 17 MW, driven by ongoing electrification in Ottawa's downtown core. It is important to note that both Carling TS and Lisgar TS have hydroelectric generation supplying each station which has been accounted for in the forecast but contributes to the variability of the station capacity need.

Lisgar TS has an LTR of 77 MW (summer) and 86 MW (winter), with capacity needs emerging as early as 2025 (summer) and 2027 (winter). By 2030, the projected winter overload reaches 40 MW, one of the highest in the region driven by winter heating load as well as large customer connections.

Nepean Epworth MTS has an LTR of 13 MW for both summer and winter. It is forecast to reach capacity in 2031 (summer) and 2028 (winter), with a 2 MW winter overload expected by 2030. This modest but significant overload reflects continued urban infill in the surrounding residential area, requiring minor station upgrades or targeted load transfers.

Cyrville MTS, rated at 45 MW, is forecast to exceed capacity in 2029 (winter). The projected winter overload by 2030 is 3 MW. While no summer need is currently identified, load growth in the adjacent industrial and commercial areas is expected to continue contributing to the station's winter peak constraint.

King Edward TS has LTRs of 92 MW (summer) and 96 MW (winter). The winter capacity need is projected to emerge by 2026, with the overload reaching 40 MW by 2030. Though the summer need emerges much later (2037), the station will require substantial reinforcement to manage escalating winter demand, especially from institutional and high-density residential growth downtown.

Moulton MTS is rated at 33 MW in both seasons. It is expected to exceed capacity by 2028 (both summer and winter), with an 8 MW winter overload forecasted for 2030. Located in a growing mixed-use area, the station will require capacity upgrades or operational measures to accommodate new developments.

Riverdale TS has a summer LTR of 118 MW and a winter LTR of 124 MW. While its summer need arises in 2038, winter constraints begin much sooner, with a need emerging in 2028 and a 20 MW overload projected by 2030. The area includes a mix of mature neighbourhoods and new high-rise developments, putting increasing strain on winter capacity.

6.3.3 Station Capacity Needs Core West Subsystem

Bridlewood MTS has an LTR of 23 MW in both summer and winter. Winter need is expected by 2029, with a 2 MW overload projected by 2030. The summer need follows in 2032. This modest overload is driven by steady residential development and densification in the surrounding suburbs.

Centrepoint MTS has an LTR of 13 MW for both seasons and is expected to exceed capacity by 2024 (summer) and 2026 (winter). By 2030, the winter overload is forecast at 5 MW, indicating a strong and persistent local demand requiring targeted capacity relief in the near term.

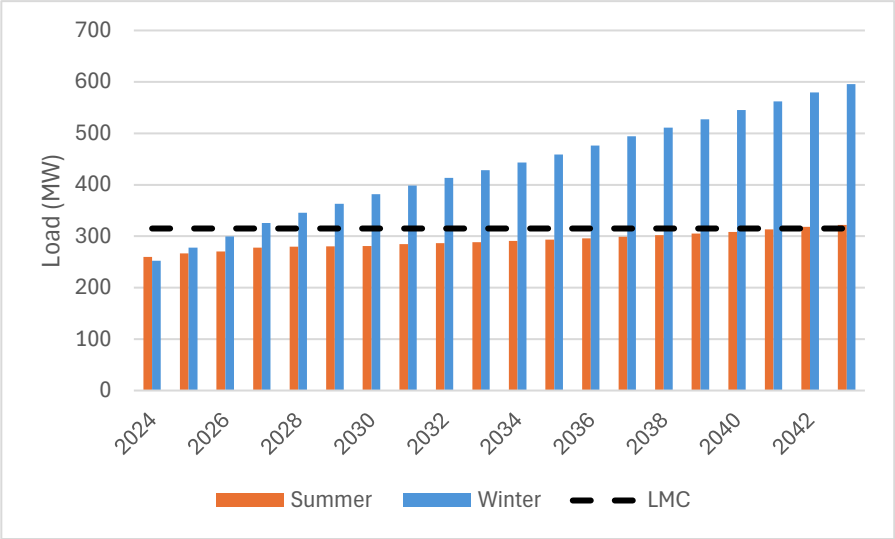
Fallowfield MTS is rated at 25 MW and is projected to reach its summer capacity by 2024, followed by winter needs emerging in 2030. An 11 MW summer overload is forecast for 2030. Situated near key growth corridors, this station will need reinforcement to manage short- and medium-term demand increases.

Manordale MTS has an LTR of 9 MW and is expected to exceed capacity by 2024 (summer) and 2025 (winter). The projected winter overload reaches 5 MW by 2030. The small size of the station and its location in a maturing neighborhood mean that even moderate demand growth results in capacity pressure.

Marchwood MTS is rated at 30 MW and is expected to exceed capacity in both 2024 (summer) and 2025 (winter). By 2030, the winter overload is projected to reach 17 MW, making it one of the most constrained stations in the Core West subsystem. Rapid suburban expansion and limited load transfer capability intensify the need for reinforcement.

6.3.4 Station Capacity Needs Core South Subsystem

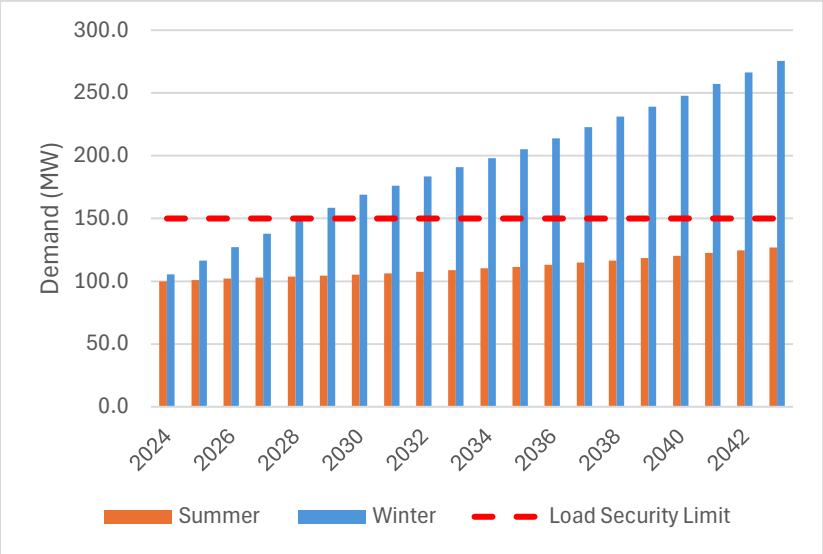
Limebank MTS has an LTR of 89 MW and is forecast to reach capacity in 2030 (winter), the LTR is limited by a load security constraint, once this is remedied the LTR of the station increases significantly. By 2030, the projected winter overload is modest at 1 MW, but demand is expected to intensify as development continues along the expanding Limebank corridor. Early planning for reinforcement may help pre-empt longer-term constraints. Greely DS is expected to reach its LTR in 2024 and Marionville DS in 2026.



6.4 System Capacity Needs

6.4.1 System Capacity Needs Kanata-Stittsville Subsystem

This subsystem is supplied by two transmission circuits, one from Chats Falls (C3S) and one from Merivale TS (M32S). The loss of both of these circuits would mean all stations in the area (Kanata MTS, South March TS, and Nepean TS) would be out of power. This would be a load security consideration, the maximum allowable load lost by configuration for two elements is 600 MW and as their combined LTR is 312 MW in the summer and 345 MW in the winter. The subsystem only reaches 600 MW in the winter in 2043 which assumes a fully electrified heating load.



Losing either of the circuits supplying the area leads to voltage instability at varying load levels and it was found that the most limiting configuration is having M32S on outage followed by a contingency on C27P. This occurs at roughly 310 MW which is near the summer LTR for the subsystem as seen in **Figure 19**. There are no System Capacity needs for the summer forecast.

Figure 19 | Reference Forecast vs LMC for Kanata-Stittsville

There is also an additional load security issue in this subsystem as well. For an M32S contingency, beyond losing one of the two supply circuits for this subsystem, the entire load at Nepean TS is lost by configuration as well. Load security requires that no more than 150 MW can be lost for a single element contingency. **Figure 20** shows the Nepean TS forecast compared to this limit. This limit is not reached in the summer forecast, but is reached in 2029 in the winter forecast.

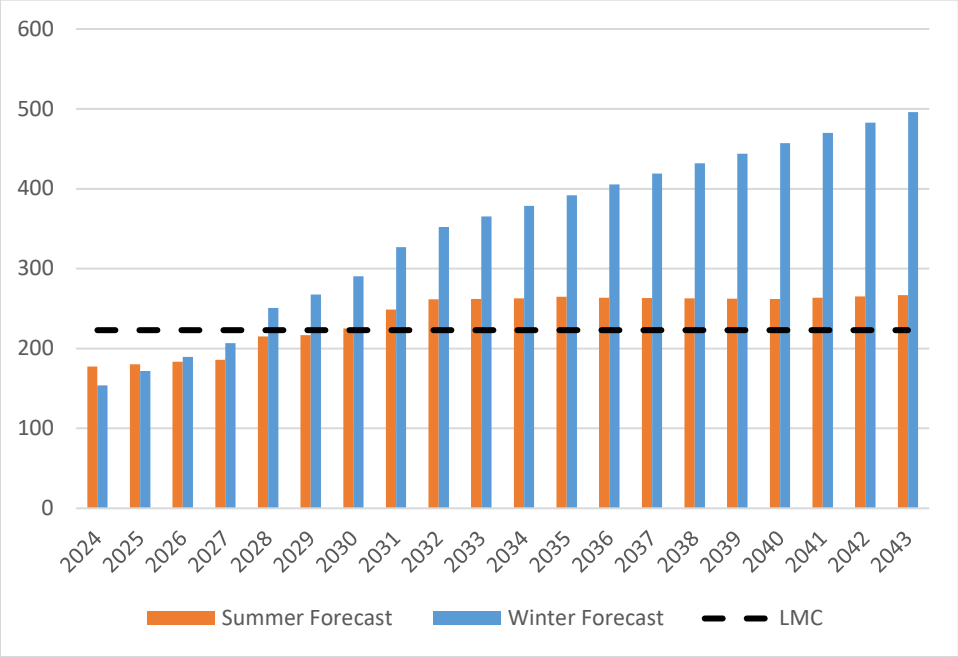
Figure 20 | Nepean Load Forecast vs Load Security Limit

6.4.2 System Capacity Needs Core East

Core East Pocket 1 is supplied by circuits M5G and M4G. The limiting phenomenon is a thermal overload on each circuit when the companion circuit is lost, as both Lisgar TS and Carling TS would be fully supplied by the remaining circuit. It was found that a contingency to M5G was more limiting, leading to an LMC of 223 MW, as seen in **Figure 21**.

Core East Pocket 2 consists of many more circuits and stations. The combined LTR of all the stations is about 600 MW, or just above 750 MW, including Slater TS. This is important because the summer forecast does not reach this figure, while the winter forecast exceeds it by over 600 MW as seen in **Figure 22**. The studies evaluating the system today find that voltage instability issues occur at a loading above the combined station LTR.

Figure 21 | Reference Forecast vs LMC for Pocket 1



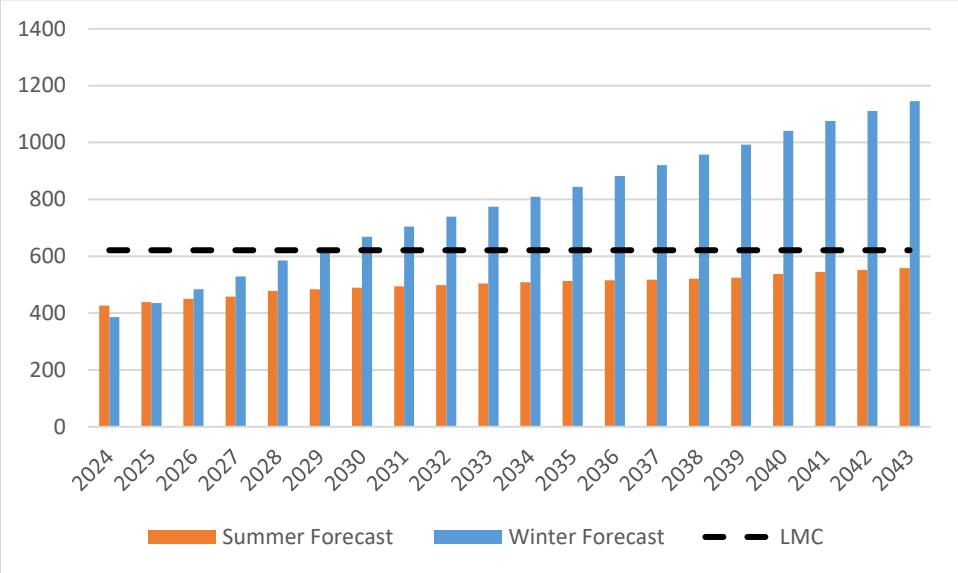


Figure 22 | Reference Forecast vs LMC for Pocket 2

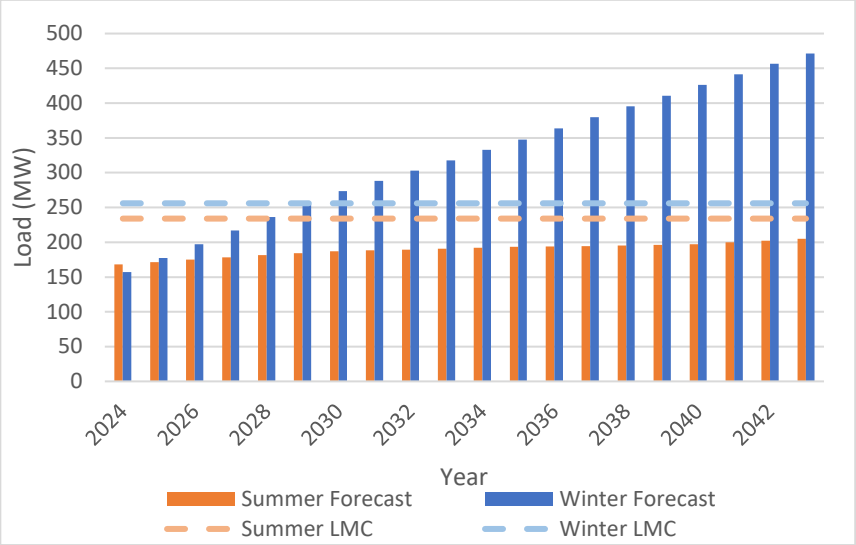
6.4.3 System Capacity Needs Core West Subsystem

The Core West subsystem was found to have healthy voltages, and no voltage violations were found as part of the technical studies. The LMC of the two pockets was found to be limited by thermal overloads. For Pocket 1, which is made up of loads supplied by S7M, as seen in **Figure 17**, the most limiting contingency is a loss of E34M, which transfers Cambrian MTS onto S7M, leading to a thermal

overload on the branch of circuit emanating from Merivale TS to the junction right before the circuit continues south, which is approximately 5km long. **Figure 23** shows that the forecast will not exceed the identified limit of approximately 250 MW in the summer but will do so in the winter in the medium-term.

As for pocket 2, the thermal overload identified as the most limiting occurs during a contingency to F10MV which places both Woodroffe TS and Lincoln Heights TS solely on C7BM, where thermal overloads begin to occur at around 230 MW of combined station load. The loss of C7BM also causes an overload on certain sections of F10MV, but is not more limiting. **Figure 23** and **Figure 24** illustrate the limits versus the expected forecast. In both cases, these needs occur only in the winter.

Figure 23 | Reference Forecast vs LMC for Core West Pocket 1



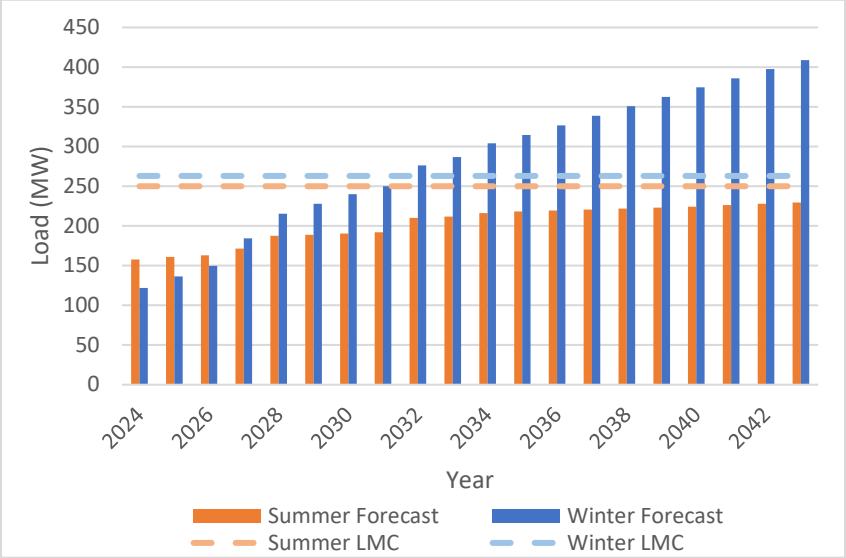


Figure 24 | Reference Forecast vs LMC for Core West Pocket 2

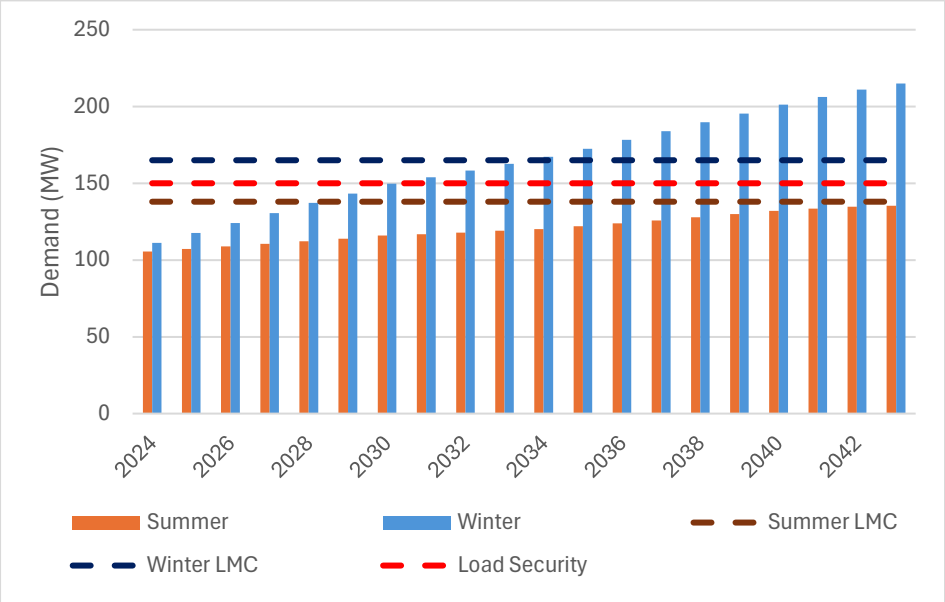

6.4.4 System Capacity Needs Core South Subsystem

There are no relevant contingencies to study in this area, since the loss of either circuit results in both circuits being tripped. This is due to L2M and M1R sharing a breaker position at Merivale TS. The limiting phenomenon in Core South is a thermal overload on the portion of L2M between Merivale TS and Limebank MTS, which occurs around the end of the medium term (2034). By scaling the stations how they are expected to grow in the next 20 years, this thermal overload happens at a load of 140 MW in the summer and 165 MW in the winter among the five stations in the subsystem. This overload is almost entirely caused by the loading on Limebank MTS. The second most limiting phenomenon in this subsystem would be voltage instability, but this limit is not approached in the 20-year forecast. The combined LTR of the stations in Core South is 160 MW in both summer and winter, meaning the limit of this subsystem is reached around the same time the station capacities would be reached.

Core South also has a limit on its total load growth of 150 MW, due to load security as seen in **Figure 25**. By design, the system must limit load loss to no more than 150 MW if a single element fails. In Core South, however, the two lines share a breaker position, so a contingency (fault) on one line causes both to be out of service. This effectively makes the two circuits a single element. As a result, this configuration becomes the most limiting factor in the winter.

Figure 25 | Reference Forecast vs LMC for Core South

6.5 End-of-Life/Asset Replacement Needs

6.5.1 Asset Replacement Needs Core East Subsystem

Lisgar TS has an LTR that is expected to be exceeded in 2026, based on the coincident forecast. Transformer T1 was in-serviced in 1974 and needs replacement. This replacement to a 45/60/75MVA transformer was planned to be in-serviced 2031–2033.

The Working Group determined that the transformer should be upgraded to a 60/80/100 MVA unit, instead of a 45/60/75MVA unit.

6.5.2 Asset Replacement Needs Core West Subsystem

Sections of circuit S7M have asset renewal needs. Decisions on the preferred option to address the asset renewal need should consider prefer supply configuration for the area. Two sections that need to be refurbished are Manotick JCT x Richmond MTS (5.2km) and STR 673N JCT x Manordale MTS (1.4km). The Working Group recommends the need be further reviewed to determine the preferred supply option for the area.

6.5.3 Asset Replacement Needs Core South Subsystem

No asset replacement needs were identified for Core South.

6.5.4 Asset Replacement Needs Kanata-Stittsville Subsystem

South March TS has an LTR that is expected to be exceeded in 2027 based on the coincident forecast.

South March has two 230kV/44kV, 50/67/83 MVA transformers in-serviced in 1971 which need replacement. The Working Group recommends to upgrade the transformers to 75/125 MVA units. This project is planned to have an in-service date of 2030–2032.

7. Plan Options and Recommendations

This section outlines the options considered and presents recommendations to address the electricity needs in the Ottawa Area Sub-Region. In developing the plan, the Working Group considered a range of integrated solutions, taking into account factors such as feasibility, cost, implementation timelines, system benefits, and consistency with the region's long-term electricity needs.

To meet the growing regional electricity demand, there are generally two types of approaches:

- Transmission/Distribution Infrastructure Expansion ("Wires" Options): These involve building new facilities or upgrading existing assets to increase the area's LMC. Examples include new transmission lines, autotransformers, step-down transformer stations, voltage control devices, or enhancements to existing infrastructure. Wires solutions may also encompass operational measures such as control actions or protection schemes that optimize system performance and mitigate reliability concerns.
- Demand Reduction, Management, or Local Generation ("Non-Wires" Solutions): These aim to reduce peak electricity demand so that it remains within the system's existing LMC. Examples include local utility-scale generation or energy storage, distributed energy resources (such as distribution-connected generation and demand response), demand-side management programs, and distribution-level load transfers.

Section 7.1 provides a detailed overview of the various types of options typically considered in Integrated Regional Resource Plans. Section 7.2 outlines the screening methodology used to identify which needs were most appropriate for further assessment of non-wires solutions. Sections 7.3 through Section 7.6 present the specific options that were developed and evaluated, leading to the Working Group's final recommendation.

7.1 Options Considered in IRRPs

Wires solutions are a core part of regional planning and are developed by identifying transmission upgrades or control measures tailored to address the specific technical limitations—such as voltage, thermal, or stability concerns—associated with each need. These solutions are shaped through collaboration with the Working Group.

While traditional wires infrastructure remains a reliable solution for addressing regional electricity needs, certain non-wires options may be better suited to specific types of needs and system characteristics. Selecting and sizing these alternatives—such as local generation or storage—requires additional analysis, including the development of an hourly load profile, as outlined in Section 5.7. The most appropriate technology and capacity are determined by examining the "unserved energy" profile, which highlights the portion of demand that exceeds the area's existing LMC. This profile provides key insights into the duration, frequency, magnitude, and total energy shortfall for each identified need. Visual representations of these characteristics for the Ottawa Area Sub-Region are provided in Appendix D.

High-level cost estimates for wires options are provided by the transmitter. For non-wires alternatives—such as generation or storage—cost estimates are based on industry benchmarks for capital and operating cost characteristics for each resource type and size. The costs for wires options presented are in terms of capital costs and represent a high level planning estimate while non-wires costs are net present value. In line with current policy direction and decarbonization goals, new natural gas-fired generation was not considered. Instead, battery energy storage, solar, and wind generation were evaluated as potential non-wires solutions.

Additional eDSM programming can also help decrease the net electricity demand. Expected peak demand savings from the 2021-2024 eDSM framework and subsequent frameworks (under the **Save on Energy brand**) are already included in the load forecast, as discussed in the Section 5.4. As part of this framework and the new 2025-2036 framework, the IESO was enabled to deliver a new program to address regional and/or local system needs. The **Local Initiative Program** is now one tool that is available to target the delivery of additional eDSM savings at specific areas of the province with identified system needs. LDCs can also use the Ontario Energy Board's Non-Wires Solutions Guidelines for Electricity Distributors to leverage distribution rates to help address distribution and transmission system needs using non-wires alternatives.[3] Generally, incremental eDSM measures are suitable for needs where growth is slow and the magnitude of the overload relative to the total demand is very small (i.e., on the order of few percent per year). These considerations are discussed further in Section 7.2, as part of the screening of options that was conducted.

For both wires and non-wires options, the upfront capital and operating costs are compiled to generate levelized annual capacity costs ($/kW-year). A cash flow of the levelized costs for the options are compared over the lifespan of the wires option (typically 70 years for transmission infrastructure). The net present value (in 2024 CAD dollars) of these levelized costs are the primary basis through which feasible options are compared.

It's important to note that planning-level cost estimates carry a significant margin of uncertainty, as they are developed without detailed engineering design or field assessments. These estimates are intended to support high-level comparisons between options during the IRRP process, rather than provide precise project costs. The RIP, which follows the IRRP and/or supports specific projects, includes more detailed analysis and provides an opportunity to refine cost estimates for wires solutions. The IESO remains actively involved in the Working Group during the RIP and engages with the transmitter if significant differences in cost estimates arise. In cases where downstream barriers—such as regulatory challenges around cost-sharing or the need to address local reliability constraints—limit the implementation of otherwise cost-effective solutions, pilot or demonstration projects may be pursued to explore their feasibility.[4]

The list of assumptions made in the economic analysis can be found in Appendix F.

[3] More information about the eDSM Guidelines is available on the Ontario Energy Board's **website**

[4] Barriers to non-wires alternatives and recommendations to address them were a part of the **Regional Planning Process Review**

7.2 Screening Options

As explained in Section 7, an array of options can be developed to meet local needs during an IRRP, but options are ultimately evaluated to recommend the option that is most cost effective, or the option that best balances cost and risk mitigation when substantial additional risks not captured by the Planning forecast are present. This process is complemented by considerations for stakeholder preferences and feedback.

Screening occurs early in the IRRP study after local reliability needs are known but before options analysis. It helps direct time-intensive aspects of detailed non-wires analysis (hourly need characterization, options development, financial analysis, and engagement) toward the most promising options. The three-step, high-level approach is shown in **Figure 26**, and the results of its application to the Ottawa Area Sub-Region IRRP needs are summarized in **Table 6** and then further described in **Table 7** and in the sections below.

More details on the steps and inputs used in the screening mechanism can be found in Appendix C.

Figure 26 | IRRP Screening Mechanism

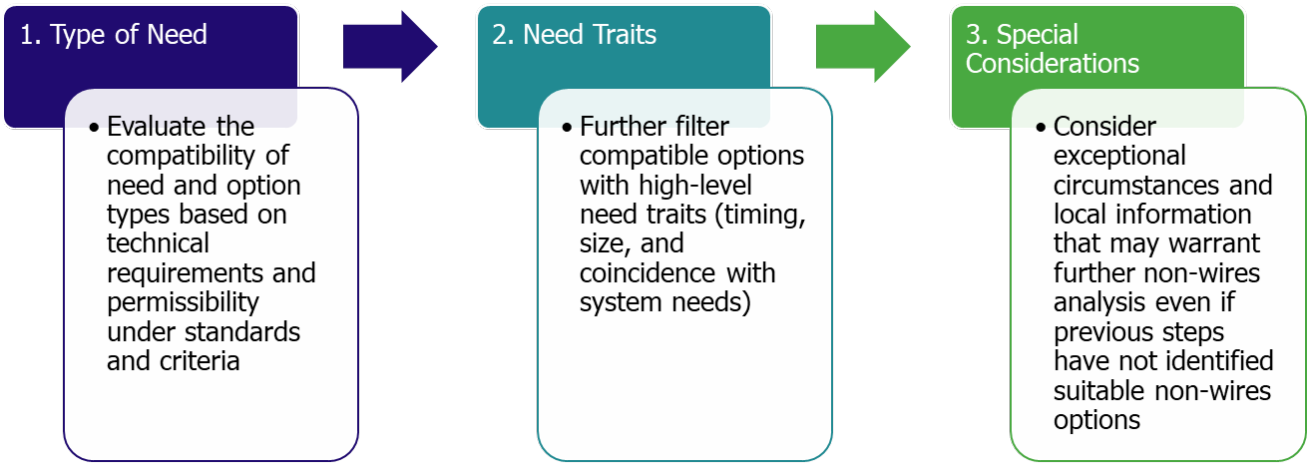

Table 6 | Options Screening Results for Station Capacity Needs

Need	Screened In	Screened Out
Station Capacity	• eDSM • Distributed generation • Wires options	• Demand response – due to magnitude and timing of needs, and limited DR capacity historically offered in this area • Operational measures

Table 7 | Options Screening Results for System Capacity Needs

Need	Screened In	Screened Out
System Capacity: Thermal, Voltage, Load Security	• eDSM • Distributed generation • Transmission-connected generation • Wires options	• Demand response – due to magnitude and timing of needs, and limited DR capacity historically offered in this area • Operational measures due to complexity of Ottawa system

7.2.1 Non-Wires Options for the Station Capacity Needs

A range of non-wires solutions—including transmission-connected generation, BESS, demand response, and hybrid approaches—were considered as part of the planning process. Given the significant forecasted load growth and the resulting number of station capacity needs, a practical screening approach was necessary to focus on the most feasible and impactful options. While eDSM programs alone are unlikely to significantly defer most of the identified needs, they remain important for slowing the pace of demand growth—supporting the timely development of long-term infrastructure solutions.

Due to the time and resources required for in-depth evaluation, it was not practical to assess non-wires options at every individual station. Instead, needs were grouped and prioritized based on where non-wires solutions—such as wind, solar, and battery storage—were most likely to be viable. This focused analysis was conducted for station groups within the Kanata-Stittsville, Core East Pocket 1, and Core East Pocket 2 subsystems.

7.2.2 Non-Wires Options for the System Capacity Needs

Among the System Capacity needs identified, four circuits were found to be limited by thermal constraints. Based on the current range of non-wires solutions, none were considered feasible for addressing these specific limitations. In contrast, the voltage stability concern identified in the Kanata-Stittsville subsystem was well suited for non-wires options and was therefore examined in greater detail. Additionally, two major battery storage projects—each exceeding 100 MW—have been proposed in the Ottawa area. Their potential impact on the regional electricity system has been assessed, with findings and observations outlined below.

7.3 Options and Recommendations for the Kanata-Stittsville Subsystem

The Kanata-Stittsville subsystem, while relatively straightforward in design, is facing rapid load growth and is expected to reach its LMC in the near term. Technical studies show that the loss of either of the two existing supply circuits—particularly from Merivale TS—would cause voltage stability issues under peak conditions, and a contingency at Nepean TS is projected to become a load security concern by 2029 in the winter if the electrification load materializes are projected.

To meet increasing demand and improve reliability, a new transformer station and an additional 230 kV transmission circuit are required. A preferred option has been identified to connect a new "Kanata North" station to C3S from Chats Falls TS and a new 230 kV circuit from Merivale TS, potentially achieved by rebuilding M32S or C7BM. This not only adds transformation capacity but also helps relieve pressure at Kanata MTS and South March TS while supporting future growth at nearby stations like Marchwood and Bridlewood.

A key component of the recommended solution is the development of a switching station in the area. The switching station will serve as a central hub, enabling better contingency response, operational flexibility, and future expansion potential, including the ability to connect additional infrastructure or circuits as system needs evolve. Consistently highlighted during public engagement, the switching station responds directly to local priorities around improving resiliency and reliability. Strategically, it also positions the system to accommodate future upgrades, including a potential second connection to Chats Falls or integration with a broader 230 kV network, depending on outcomes from the East Bulk Study.

While large-scale non-wires alternatives such as wind, solar, and nuclear were considered, they were found to be potentially economically practical but technically infeasible for the identified needs. A combination of a renewable resource and a BESS requires a substantial amount of land. However, this approach does not address station capacity needs. While it may provide energy to support load growth, the electricity is still constrained by the capacity of the station's transformers. As a result, new transformation stations are still required. However, with consideration of system benefits (i.e. avoided provincial capacity and energy), it is *possible* that these provide ratepayer value, though a larger bulk system study is needed to inform where to optimally place utility-scale resources to address provincial needs.

A proposed BESS project from the LT1 procurement—originally intended for another municipality—has been relocated to the Kanata-Stittsville area, where it can deliver greater grid benefit by discharging during peak periods and improving load-serving capability. This means that the Kanata-Stittsville area will be reinforced with both wires and non-wires solutions.

In summary, the recommended plan for Kanata-Stittsville includes:

A new transformer station north of the existing Kanata MTS,

A new 230 kV transmission line from Merivale TS, 18km

Connection to the existing C3S line,

A strategically located switching station,

Station upgrades at South March TS, and

A second supply to Nepean TS

Together, these elements form a resilient and scalable infrastructure solution that addresses near-term needs while establishing a strong foundation for long-term system performance.

Figure 27 | Kanata-Stittsville Recommendations

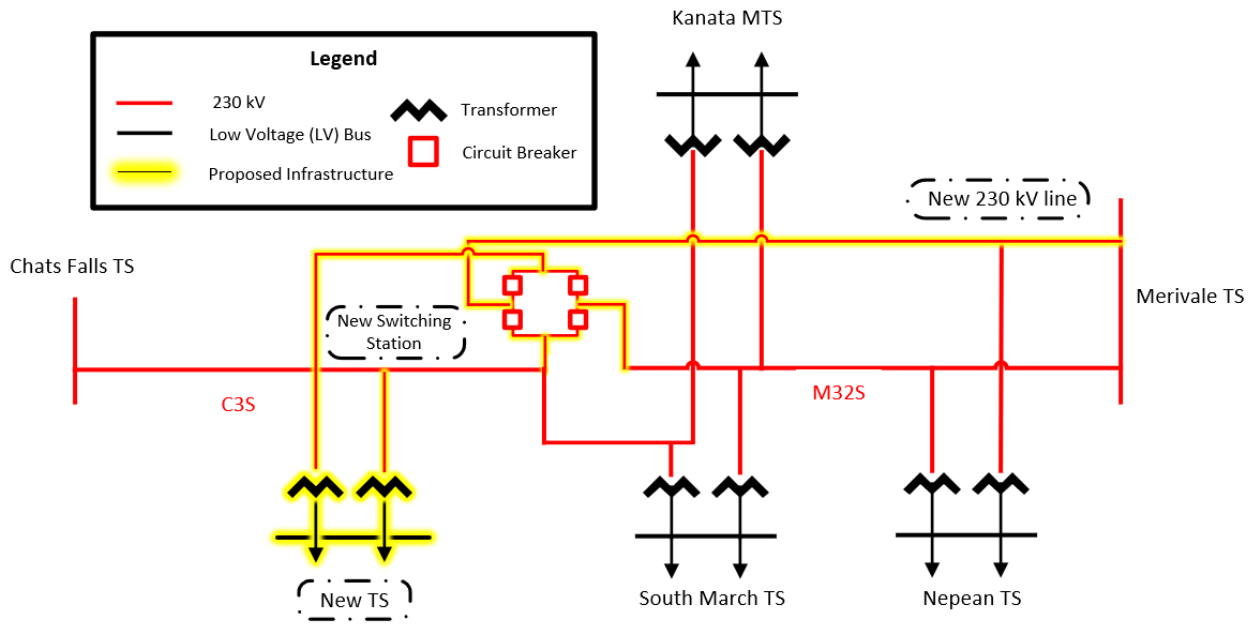

Table 8 | Wires Options for Kanata-Stittsville Subsystem

#	Description	High Level Planning Cost Estimate[5]
1	New 230 kV circuit to connect to the new station and Nepean TS from Merivale TS. The new station will tap to C3S	$185M+$45M
2	New 230 kV circuit from Merivale TS to switching station at South March TS. Nepean TS becomes double supply, all other stations connect to the switching station including a new station	$250M+$45M
3	Station transfer Kanata MTS to new station	$5-10M
4	Station transfer South March TS to new station	$0-5M
5	Station upgrade at South March TS	$40M

[5] All cost estimates are capital cost values

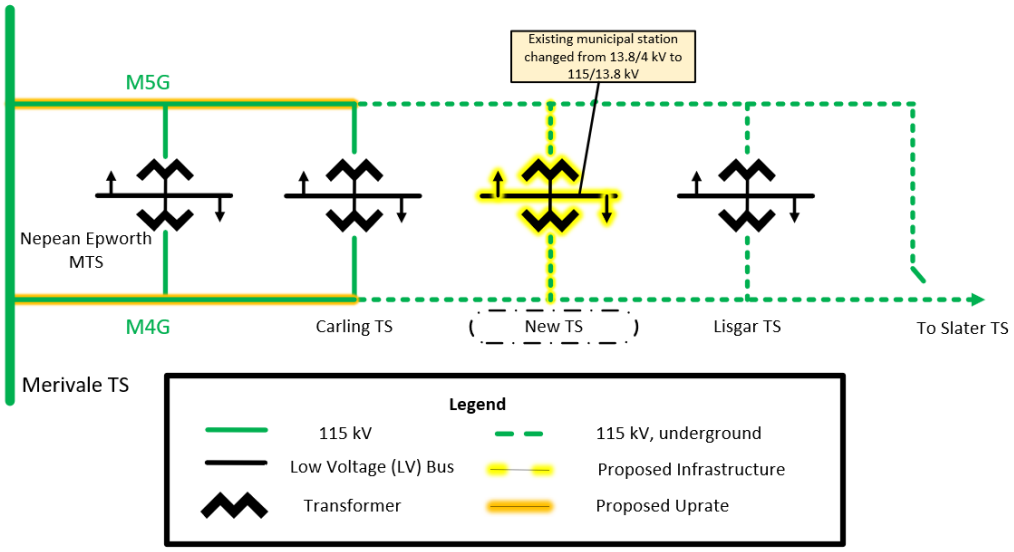
7.4 Options and Recommendations for the Core East Subsystem

7.4.1 Core East Subsystem – Pocket 1

Capacity needs in Pocket 1—especially at Lisgar TS, Carling TS, and Nepean Epworth MTS—are projected to emerge within five years and intensify during winter. Demand at Lisgar and Carling is expected to exceed LTRs by 30–40 MW, requiring a stepwise approach across the short, medium, and long term.

Near-term relief could come from transferring load to Nepean Epworth MTS, which is connected to Merivale TS, where about 15 MW of spare capacity is available. While Slater TS also has capacity, only Lisgar TS is a feasible candidate for transfers due to the lack of distribution ties.

Station upgrades offer another path:



- At Carling TS, an upgrade could mitigate low-voltage limitations.
- At Lisgar TS, replacing transformer T2 and associated equipment could add ~45 MW.

Other options, such as relocating Carling TS to V12M and F10MV, were found to offer limited benefit due to space constraints and their inability to add new capacity.

Building a new transformer station and transmission lines in this dense area is technically viable but faces steep costs and logistical challenges. However, a promising alternative is to convert Bronson Station from a municipal distribution station to a 115 kV DESN station. Located between Carling TS and Lisgar TS along the M4G/M5G corridor, Bronson MTS could relieve adjacent stations via load transfers and by servicing future load. It is situated in a convenient location close to the 115 kV transmission lines but will require new transformers and significant cable connections. The approximate cost for this conversion is $65 million. This option would require uprating M4G and M5G to address thermal constraints.

Given the densely populated area, wind and/or solar options were screened out as feasible NWA's given the size of the need, and the land-use requirement of the facility that would be required to serve this need. However, A BESS-only NWA was assessed as a possible option, though it would only provide transmission deferral value through deferring investment by 2 years, but at a significant cost of $3.8 to 4.2B. Accordingly, the most practical solution for Pocket 1 is a combination of station expansions, targeted load transfers, and development of Bronson MTS.

Figure 28 | Core East Pocket 1 Recommendations

7.4.2 Core East Subsystem – Pocket 2

Pocket 2 encompasses much of Ottawa's downtown and is supplied by a tightly integrated 115 kV network. Nearly all stations are forecast to reach capacity within 20 years, particularly in winter, posing a major long-term planning challenge.

Given the urban density, expanding the network—especially with 230 kV infrastructure—is technically complex and expensive. Required upgrades at Hawthorne TS, the use of underground cables, and land constraints for new stations further limit this pathway.

Instead, the focus is on maximizing existing infrastructure and pursuing targeted improvements while managing the pace of demand growth. Near-term investments include:

- King Edward TS: ~35 MW through breaker and cable upgrades
- Albion TS: potential expansion through transformer upgrades

The upcoming LAPS will help identify eDSM opportunities, including energy efficiency, demand response, and behind-the-meter solar and storage measures. Demand reduction remains the most effective way to delay or avoid large-scale upgrades—every deferred megawatt reduces long-term cost and complexity.

A medium-term solution is to convert Cyrville TS to 230 kV using circuits D5A and a new A25, which would alleviate 115 kV constraints and allow for relocation of Cyrville MT's transformers to Moulton TS, upgrading both stations in the process.

An ongoing project at Merivale will add a third autotransformer by 2029 which will help support growth in the medium/longer term. It is possible to install a fourth autotransformer in the future, but

beyond that, capital investments exceeding $1 billion could be unavoidable if demand continues rising.

Build a new 115kV Transformer Station east of Carling TS by converting existing Bronson distribution station

Connect the new Transformer Station to existing 115 kV transmission circuits M4G and M5G

Uprate sections of M4G and M5G, 12km

Proceed with station upgrades at Albion TS, Carling TS, Lisgar TS, Russel TS, King Edward TS

Proceed with distribution load transfers at Riverdale TS, Nepean Epworth MTS, Ellwood MTS

Convert Cyrville MTS from 115kV to 230kV station

Repurpose Cyrville MTS transformers at Moulton TS for station rating increase

Leverage insights from the LAPS to help slow demand growth in the downtown core, while continuing to monitor load trends between planning cycles

Figure 29 | Core East Recommendations

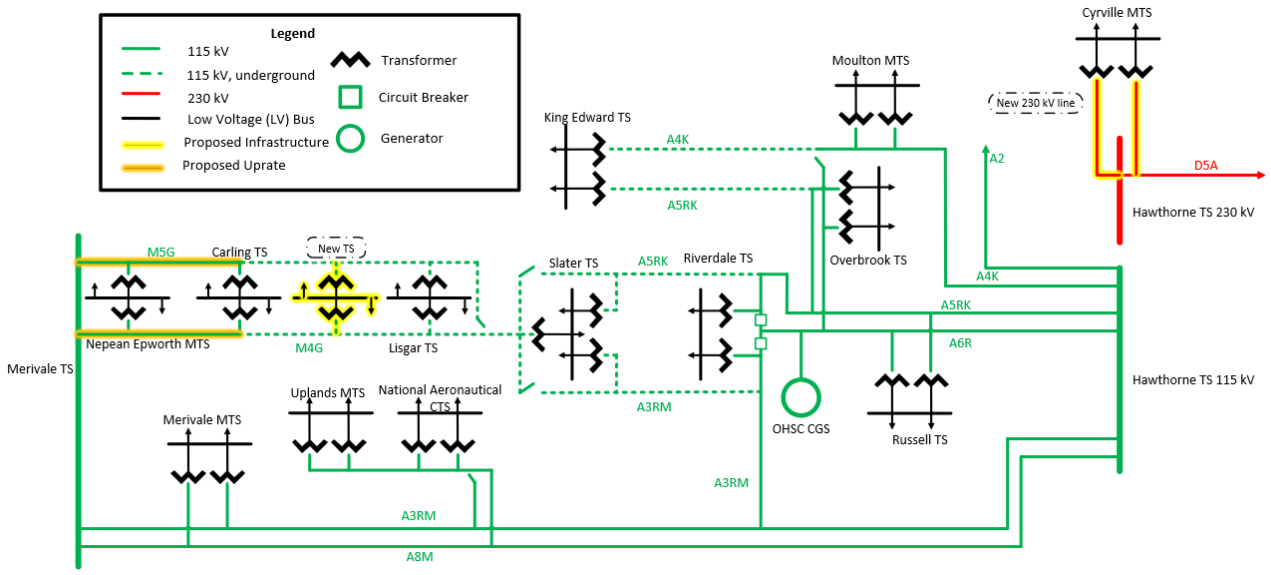


Table 9 | Wires Options for Core East Subsystem

#	Description	High Level Planning Cost Estimate[6]
1	New 115kV Transformer Station Connected to M5G and M4G, Convert Existing Bronson Station	$35M + $65M
2	Connect Carling TS to V12M and F10MV	$30M
3	Convert Cyrville TS to 230kV	$40M
4	Distribution Load Transfers – Hydro Ottawa/Hydro One Distribution	$0-5M per station

7.5 Options and Recommendations for the Core West Subsystem

7.5.1 Core West Subsystem – Pocket 1

For the area supplied by circuits S7M, W6CS, and E34M, three near-term station capacity needs have been identified—Bridlewood MTS, Marchwood MTS, and Fallowfield MTS—with three more expected in the long term.

Bridlewood MTS and Marchwood MTS are located in or near the Kanata-Stittsville area. Addressing their needs should align with broader upgrades planned for Kanata-Stittsville. As described in Section 7.3, the recommended approach for Kanata-Stittsville involves building a new 230 kV transformer station, supplied by a new 230 kV circuit from Merivale TS, which would also provide a secondary supply to Nepean TS. Since South March TS and Kanata TS will also benefit from additional capacity in the area, to address Bridlewood and Marchwood's capacity needs in the short term, the Working Group recommends implementing distribution load transfers—an efficient and cost-effective solution compared to building or upgrading stations.

Fallowfield MTS requires additional consideration. Several factors shape the recommendation:

- Circuit breakers were upgraded in 2018.
- Part of the S7M line has already been refurbished for future 230 kV operation.
- Load growth is expected in the area immediately north of the station, particularly for 28 kV distribution supply.

Based on these factors, multiple options were considered: upgrading the station, transferring load to Cambrian MTS, or transferring to a future new station. The Working Group recommends a phased approach:

- Short term: Transfer load to Cambrian MTS.

[6] All cost estimates are capital cost values

- Medium term: Shift load to a new station north of Fallowfield MTS.
- Long term: Upgrade Fallowfield MTS to 230 kV (requires conversion of S7M to 230 kV operation).

A separate thermal overload concern was identified in Pocket 1 during a contingency involving the loss of E34M and the transfer of Cambrian MTS load onto S7M. To address this long-term need, the Working Group assessed both wires and non-wires options and views the voltage conversion of S7M and the stations in the area to 230 kV would offer several benefits:

- Converting stations to 230 kV would result in increased station capacity to support future load growth.
- Shifting load from the 115 kV system to the 230 kV system would preserve load growth capacity for other stations, particularly those in densely built areas like the downtown core, where expansion is difficult.
- A new circuit could provide a second supply to Terry Fox MTS, which, like Nepean TS, currently relies on a single supply circuit with measures in place to allow for faster restoration.

To manage costs and avoid asset stranding, the S7M conversion should be implemented in phases. The Working Group recommends converting only the southern section of S7M, maintaining the northern portion that supplies Bridlewood MTS and Marchwood MTS and retaining its open-point connection to C7BM to preserve to ensure the 115kV generation connections northwest of the city are maintained.

The first step in the transition involves constructing a new 230 kV circuit from Merivale TS westward to the new station, which could later be extended to supply Terry Fox MTS. Station upgrades would follow at Manotick DS, Richmond South MTS, and Cambrian MTS, with the circuit initially connecting at the S7M junction. Once complete, these upgrades will provide a second 230 kV source to key stations, significantly improving system resilience.

In the medium-term, thermal overload risks remain on the Merivale TS end of S7M during an E34M outage. Until the full conversion is completed, interim relief could be provided through non-wires alternatives and distribution load transfers from Cambrian MTS to the new station if demand rises quickly.

Finally, the Working Group reviewed the proposed Trail Road BESS battery project, announced under the LT1 procurement. While it will support overall grid resilience, it connects to E34M and would not relieve loading on S7M unless a direct connection is also established.

7.5.2 Core West Subsystem – Pocket 2

Two smaller stations in this pocket—Manordale MTS and Centrepoint MTS—are facing capacity constraints. Due to growing demand and specific large customer requests, there is a need for 28 kV distribution in the area. However, both stations currently operate at only 8 kV, making them unable to meet this requirement. As a result, a new transformer station is needed.

One option considered was redeveloping Manordale MTS as a DESN station, but this was deemed unfeasible due to space limitations at the site. The alternative is to construct a new station at a

different location. While a final site has not yet been selected, Hydro Ottawa is actively evaluating several options and is responsible for determining the final location.

The northern portion of the system was found to have thermal overloads. The main stations contributing to this are Lincoln Heights TS and Woodroffe TS and are not forecast to reach their capacity until the winter in the long-term. Therefore, the most economical solution is to simply uprate the segments of cables identified.

Build a new 230kV Transformer Station west of Merivale TS

Build a new 230kV transmission line westwards from Merivale TS along existing corridor, 5 km

Connect the new Transformer Station to E34M and new transmission circuit

Uprate sections of M4G and M5G, 10km

Uprate sections of C7BM and F10MV, 8km

Incorporate BESS resulting from LT1 procurement to improve area's voltage and reliability

Figure 30 | Core West Recommendations

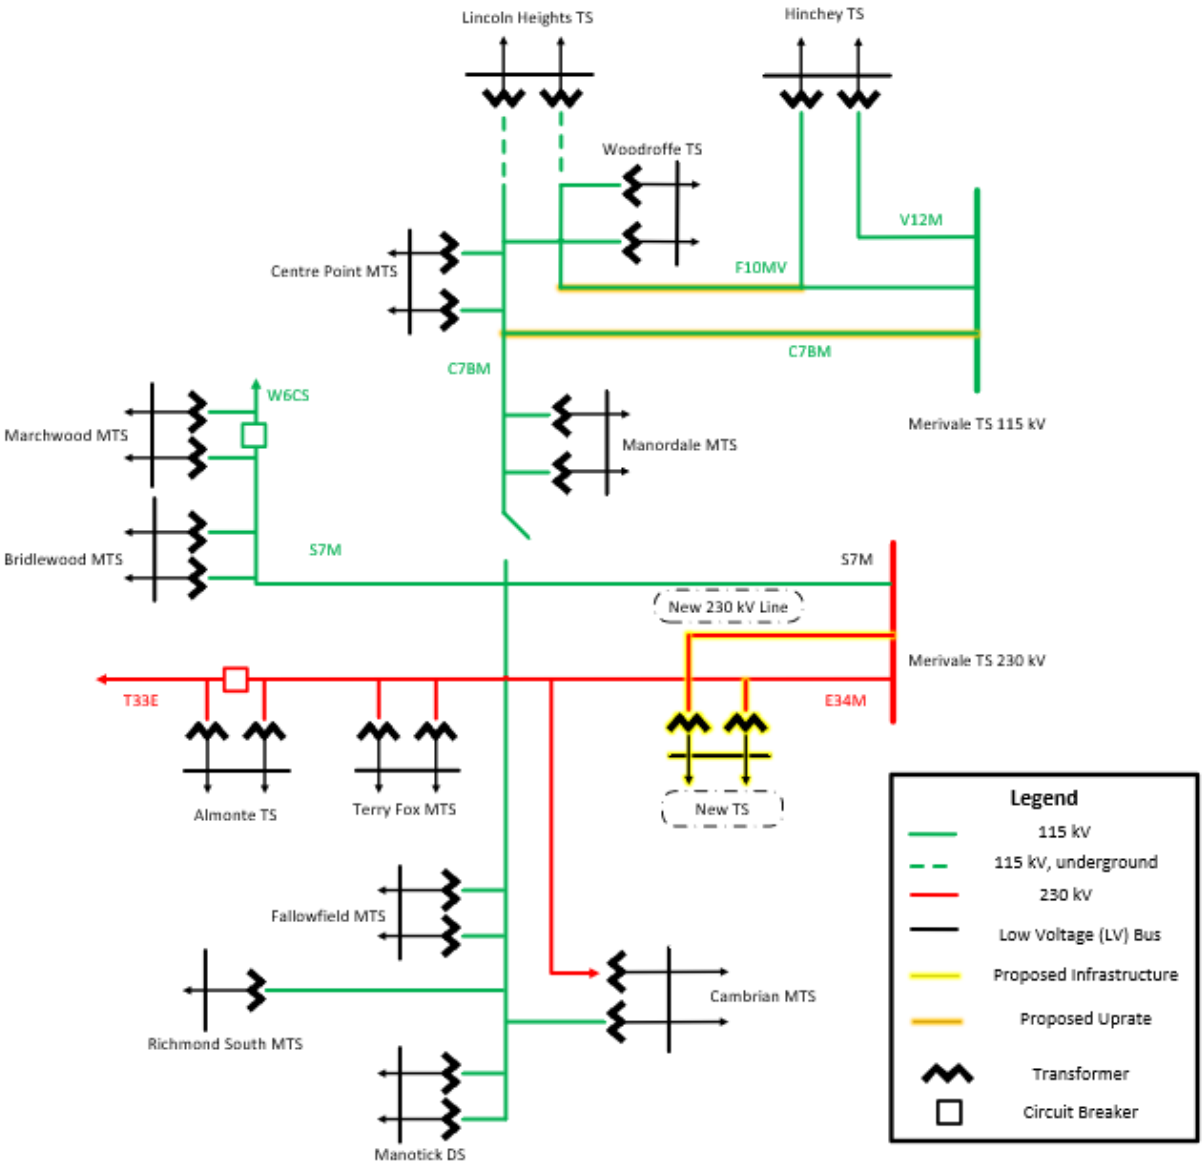

Table 10 | Wires Options for Core West Subsystem

#	Description	High Level Planning Cost Estimate[7]
1a	Fully Convert S7M to 230 kV	-
2a	New 230kV Circuit to S7M STR Junction, Convert Southern Portion of S7M to 230kV, Keep Existing 115kV S7M Connecting to W6CS	$100M
2b	New 230kV Circuit to Connect Terry Fox MTS and new Greenbank MTS	$90M
2c	New 230 kV Circuit to Terry Fox, Convert Southern Portion of S7M to 230 kV, Keep Existing 115 kV S7M Connecting to W6CS	$140M
3a	Fully uprate C7BM and F10MV	$50M
4a	Reconductor S7M, keep 115kV	$15M
5	Distribution Load Transfers – Hydro Ottawa/Hydro One Distribution	$0-5M per station

7.6 Options and Recommendations for the Core South Subsystem

Three stations in Core South—Limebank MTS, Greely DS, and Marionville DS—are forecast to exceed their long-term ratings (LTRs) within the next five years, requiring immediate action to address upcoming capacity shortfalls.

Given the scale and timing of these needs, station transfers and upgrades were the only solutions considered, as building a new station was deemed cost-prohibitive relative to projected demand outlook. In the near term, minor overloads at Limebank MTS can be addressed through distribution-level load transfers to Piperville MTS, which is scheduled for energization in 2026 and will be connected to the 230 kV L24A circuit. This transfer also reduces loading on the 115 kV system, contributing to better overall system balance.

For Marionville DS, the recommended action is to install a second transformer to increase capacity. At Greely DS, the proposed solution involves enabling supervisory control and data acquisition (SCADA) monitoring, allowing for an increase in respected transformer limits and improving station performance.

To meet load security requirements in Core South, the most effective strategy is the installation of a breaker between circuits L2M and M1R at Merivale TS. This change would ensure that a loss of both

[7] All cost estimates are capital cost values

circuits would only occur under a double contingency, which is significantly less likely and subject to a higher load rejection threshold of 600 MW.

For medium-term System Capacity needs, three main options were assessed:

1. Uprating segments of circuit L2M between Merivale TS and Limebank MTS to avoid thermal overloads.
2. Converting Limebank MTS to a 115 kV DESN, supplied by M1R and L2M. While Limebank's projected peak load remains below 150 MW (permissible under single contingency criteria), the station has four transformers, and adding a second supply would significantly improve system reliability.
3. A long-term option involves converting Limebank MTS to a 230 kV DESN, supplied by two new circuits from the St. Lawrence region. However, this would require comprehensive bulk system studies to determine the feasibility of extending 230 kV infrastructure from the St. Lawrence area to Merivale TS. As such, this remains a long-term vision rather than a near- or medium-term solution.

Build a new breaker position at Merivale TS and separate circuits M1R and L2M

Proceed with station upgrades at Greely DS and Marionville DS

Distribution load transfer from Limebank TS to Piperville TS

Figure 31 | Core South Recommendations

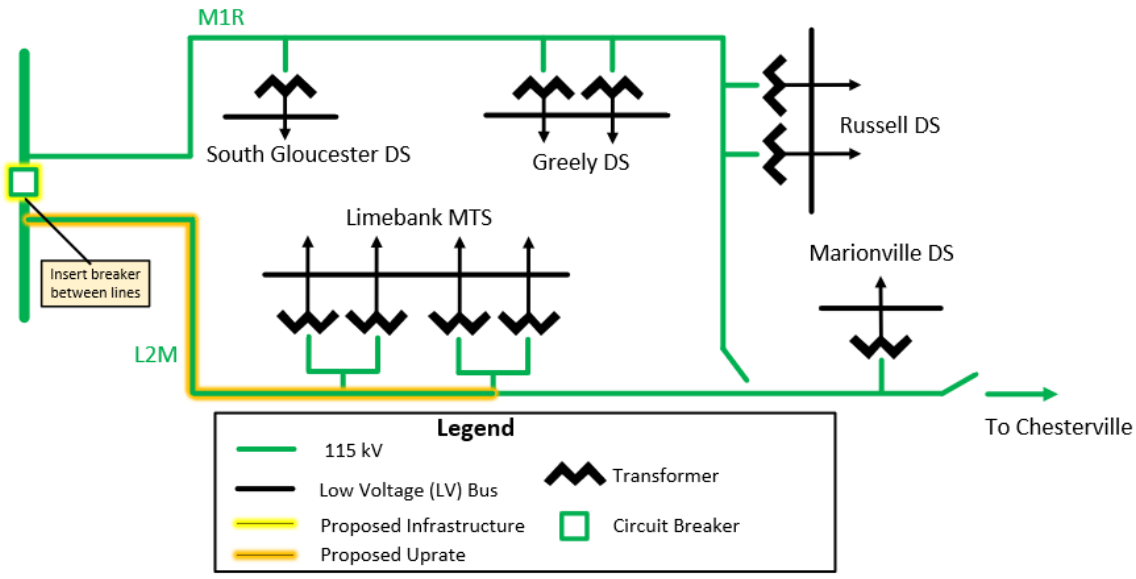

Table 11 | Wires Options for Core South Subsystem

#	Description	High Level Planning Cost Estimate[8]
1	New breaker position at Merivale TS to separate L2M and M1R	$30M
2	Uprate segments of L2M from Merivale TS to Limebank MTS	$25M
3	Convert Limebank MTS to 115 kV DESN	N/A
4	Convert Limebank MTS to 230 kV DESN	N/A
5	Station transfers	$5M
6	Station upgrades	$12M+$3M

[8] All cost estimates are capital cost values

7.7 Long-Term Considerations

7.7.1 Kanata-Stitsville Subsystem

This subsystem, defined by the 230 kV transmission circuits and transformer stations that supply the Kanata-Stittsville area, is experiencing a period of rapid economic development, which will require accessible and reliable electricity. A number of investments—including a new transformer station, transmission circuit, switching station, and potential BESS site—have been recommended in this report to help meet these goals. These investments are designed to increase both station and System Capacity, improve resiliency via the switching station, and enhance power quality and flexibility through the proposed BESS project.

Once these investments are implemented, the Kanata-Stittsville Subsystem will consist of one transmission circuit from the Chats Falls area (C3S), two circuits from Merivale TS (including M32S and the proposed new circuit), four transformer stations to supply power, and a strategically located BESS which can help meet peak demand and support voltage stability in the area.

The long-term vision for this subsystem continues to reinforce each component. The new circuit and switching station significantly improve supply from the Merivale side but do not yet enhance the supply path from Chats Falls. As such, a future consideration is to extend the new transmission circuit to Chats Falls TS, which would increase the LMC of the subsystem and provide a second path for hydroelectric generation to reach Ottawa loads. In general, the growth projected by demand forecasts will require reinforcement of Ottawa's western supply, which is being explored under the East Bulk Plan. One promising option includes the development of a new autotransformer station—similar to Merivale TS and Hawthorne TS—in western Ottawa. The proposed switching station has been recommended with this potential in mind and is being designed to accommodate a connection to this new substation, further strengthening the capability and flexibility of the Kanata-Stittsville system.

If demand grows at a faster pace than forecast—particularly due to unforeseen industrial or large commercial developments—a second transformer station beyond what is currently planned (e.g., in addition to Kanata North MTS) may be required. A more detailed assessment of the Kanata study area will help clarify the actual capacity available within this new configuration and determine the timing and scope of future infrastructure.

7.7.2 Core East Subsystem

This subsystem is defined by the 115 kV network that supplies most of Ottawa's downtown core. Given the complexity and limited physical space for new infrastructure in the downtown area, the focus of this plan is to maximize existing assets and strategically pursue upgrades to avoid large-scale overhauls. This plan recommends increasing station capacity by upgrading Carling TS, Lisgar TS, and Riverdale TS, while also gaining additional capacity through the conversion of Bronson TS from a distribution station to a transmission supply point, and converting Cyrville MTS from 115 kV to 230 kV.

The Working Group recommends implementation of the additional cost-effective eDSM potential that will be identified in the LAPS, which promote non-wires alternatives to mitigate load growth, including energy efficiency programs, distributed energy resources (DERs), and demand response initiatives. Additional optimization is possible by leveraging Slater TS, which is centrally located and supplied by

three independent circuits. Slater's robust configuration makes it a strong candidate for load transfers, and future development should be encouraged near this area to capitalize on its reliability and existing capacity.

Monitoring the evolution of winter peak demand will be critical. If these trends materialize as expected, a major decision will be required, as the 115 kV network alone cannot accommodate long-term growth in its current configuration. One response may involve installing a fourth autotransformer at Merivale TS to support increasing inter-pocket transfers. More broadly, planners will need to decide between:

1. Introducing a new 230 kV supply path into the downtown core;
2. Converting select segments of the 115 kV system to 230 kV; or
3. Build new transmissions lines into the downtown core.

All options would ultimately require significant expansion work at Hawthorne TS, which serves as a key transmission node for the eastern subsystem.

The long-term vision for the broader region anticipates that most expansion will occur west of Ottawa, reducing the need for major downtown build-outs. With the implementation of the upgrades and strategies outlined in this plan, the Core East subsystem will largely be able to rely on enhanced operational efficiency and, at most, require one to two new transformation stations to support long-term growth.

7.7.3 Core West Subsystem

Following the uprate of C7BM and F10MV the rest of the stations in Pocket 2 of the Core West subsystem will be able to grow to their LTR which is sufficient for the 20-year demand forecast. The area will also have a new 230kV transformer station that will help offload the smaller stations in the area. The long-term vision for this subsystem is to expand the 230kV transmission circuit west. By doing so, it allows for multiple successive investments. These include providing a second supply to Terry Fox MTS, converting S7M to 230kV, and providing a second supply to Cambrian MTS as well. Further, depending on the outcomes of the Bulk Study, a potential 230kV autotransformer station will allow for expansion in this area to meet growing demand.

7.7.4 Core South Subsystem

The future of this subsystem will depend on the outcome of the East Bulk study. A potential 230kV transmission line from St. Lawrence presents to opportunity to convert the entire pocket.

The load at Limebank MTS is to be monitored and will eventually require a second supply. The circuits will also need to be uprated as the load grows.

A new auto-transformer station in the west of Ottawa would also impact how this system is planned and depend again on the East Bulk Study.

7.8 Summary of Recommended Actions and Next Steps

The Working Group recommends the actions summarized in **Table 12** to meet identified needs in the Ottawa Area Sub-Region IRRP.

Table 12 | Summary of the Near-Term Plan for the Ottawa Area Sub-Region IRRP

Need Type	Affected Element(s)	Recommendation	High Level Planning Cost Estimate[9]
System Capacity (Transformation)	Core East Pocket 1	Build new Transformer Station by converting existing Distribution Station. Connect to M4G and M5G. Interim station name: Bronson MTS.	$65M
System Capacity (Thermal Overload)	M4G, M5G	Uprate portions of M5G and M4G.	$35M
System Capacity (Transformation)	Core East Pocket 2 A5RK, A6R, A4RK, A3RM, A8M, A2	Convert Cyrville MTS (115kV) to 230kV thereby preserving capacity on autotransformers for growth on the 115kV downtown system. Pursue eDSM program opportunities as part of LAPS to reduce demand and delay large-scale infrastructure upgrades.	$75M TBD
Station Capacity	Carling TS	Upgrade secondary cables to increase station rating. Distribution load transfer to new Bronson MTS.	$40M $0-5M
Station Capacity	Lisgar TS	Increase station rating by upgrading limiting LV element	$20M
Station Capacity	Riverdale TS	Distribution load transfer to new Bronson MTS.	$0-5M
Station Capacity	Nepean Epworth MTS	Distribution load transfer to Merivale MTS.	$100K
Station Capacity	King Edward TS	Upgrade cables to increase station rating.	$40M

[9] All cost estimates are capital cost values

Need Type	Affected Element(s)	Recommendation	High Level Planning Cost Estimate[9]
Station Capacity	Cyrville MTS	Station voltage conversion from 115kV to 230kV to increase station rating.	$75M
Station Capacity	Moulton MTS	Repurpose 115kV transformers from Cyrville MTS voltage conversion to increase station rating. Estimate does not consider any circuit upgrade that may be required.	$5M
Station Capacity	Ellwood MTS	Distribution load transfer to Albion TS.	$0-5M
System Capacity (Transformation, Voltage Stability)	Kanata-Stittsville	Build a new Transformer Station north of existing stations. Connect to C3S and new transmission line from Merivale TS. Interim station name: Kanata North MTS. Build a new 230kV transmission line from Merivale TS by rebuilding C7BM corridor, connecting Nepean TS and the new Kanata North MTS. Build a switching station that connects existing and new 230kV stations to improve resiliency and flexibility.	$45M $185M $65M
Load Security	Nepean TS	Provide second supply to Nepean TS via new transmission circuit from Merivale TS. Same circuit that is being built to supply new Kanata North MTS.	$5M
Station Capacity	Kanata MTS Marchwood MTS	Distribution load transfer to new Kanata North MTS.	$6-8M
End-of-Life Station Capacity	South March TS	Upgrade transformers at South March TS to increase station rating.	$40M
System Capacity (Thermal Overload)	Core West Pocket 1 F10MV, C7BM	Uprate portions of C7BM and F10MV.	$50M

Need Type	Affected Element(s)	Recommendation	High Level Planning Cost Estimate[9]
System Capacity (Transformation)	Core West Pocket 2	Build a new Transformer Station to meet demand growth and need for 28kV supply west of Merivale TS. Interim station name: Greenbank MTS.	$40M
		Build new 230kV transmission line from Merivale TS to supply new Greenbank MTS.	$40M
Station Capacity	Centrepoint MTS Fallowfield MTS Manordale MTS	Distribution load transfer to new Greenbank MTS.	$0-5M
Station Capacity	Bridlewood MTS	Distribution load transfer to Terry Fox MTS.	$0-2M
Load Security	Core South L2M, M1R	Install a new breaker at Merivale TS and separate L2M and M1R.	$30M
Station Capacity	Marionville DS	Install a second transformer to increase station rating.	$12M
Station Capacity	Greely DS	Install SCADA transformer monitoring to increase station rating.	$3M
Station Capacity	Limebank MTS	Distribution load transfer to Piperville MTS.	$5M
Planning	N/A	Working Group to produce Adaptive Pathways documents for each subsystem following the publishing of the IRRP.	

8. Community and Sector Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and perspectives of the public, which for these purposes, refers to market participants, municipalities, stakeholders, communities, Indigenous communities, customers and the general public, to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles and activities undertaken to date for the Ottawa Area Sub-Region IRRP.

8.1 Engagement Principles

The IESO's **External Relations Engagement Framework** is built on a series of key principles that respond to the needs of the electricity sector, communities and the broader economy. These principles ensure that diverse and unique perspectives are valued in the IESO's processes and decision-making. We are committed to engaging with purpose to foster trust and build understanding as the energy transition continues.

Figure 32 | The IESO's Engagement Principles

8.2 Engagement Tactics

To ensure that the IRRP reflects the needs of market participants, municipalities, stakeholders, communities, Indigenous communities, customers and the general public, engagement tactics involved:

- Leveraging the **Ottawa Area Sub-Region engagement webpage** to share information including engagement opportunities, meeting materials, input received and the IESO's response to feedback;

- Leading targeted discussions with key municipal staff to help inform the engagement approach for this planning cycle;
- Hosting public webinars at major junctions in the plan development to share plan details, understand feedback and answer questions, and;
- Providing written updates through email and IESO's weekly Bulletin updates to all subscribers.

8.3 Engagement Approach

Four public engagement webinars were held at major stages during the Scoping and IRRP development to give interested parties an opportunity to hear about its progress and provide comments on key components of the plan. Unique to the IRRP was a Local Achievable Potential Study (LAPS) for the Ottawa Area taking place in parallel. Feedback on the Local Achievable Potential Study was solicited during the webinar on "Needs and Potential Wire Options."

Public engagement webinars were attended by several representatives from the City of Ottawa, community representatives, businesses, Indigenous communities, and other stakeholders with an identified interest, and written feedback was collected following a comment period after each webinar. The four stages of engagement at which input was invited were:

1. The draft scoping outcome assessment report to share the planning approach before delving into the full IRRP study.
2. The draft engagement plan, electricity demand forecast, and early identified needs – to set the foundation of this planning work.
3. The defined electricity needs for the region and potential wire options to meet the identified needs, as well as
4. The analysis of all feasible wire and non-wire options and draft IRRP recommendations.

Comments received during the development of the IRRP primarily focused on:

- Accounting for growth and economic development projects across the region;
- Ensuring climate impacts are accounted for throughout the development of the IRRP, and;
- Exploring alternative solutions, such as non-wire options, to meeting the area's electricity needs.

Feedback received during the written comment periods for these webinars helped to guide further discussions throughout the development of this IRRP, as well as add due consideration to the final recommendations, and are outlined in the stages below.

8.3.1 Scoping Assessment

As part of the 2020 Ottawa Sub-Region IRRP, the Technical Working Group recommended to monitor the City of Ottawa's Energy Evolution mandate in future planning cycles. During the monitoring, the Technical Working Group recommended to advance the planning cycle. When regional planning kicked off, the draft 2023 Scoping Assessment Outcome Report recommended focused discussions to

take place with the City of Ottawa, the local distribution companies and the IESO on the impacts of Energy Evolution and GHG emission targets on the demand forecast.

Once the draft report was completed, an email communication was sent to all subscribers of the Greater Ottawa Region, including municipalities, Indigenous communities, and those with an identified interest in regional issues, to announce the commencement of a new planning cycle and encourage participation on the Greater Ottawa Scoping Assessment Report finalization. A public webinar was held in February 2023 to provide an overview of the regional electricity planning process, the draft report and proposed approach.

Feedback received during this milestone encouraged the IESO to obtain data from large customers electrification plans and to review opportunities for distributed energy resources to reduce electricity demand. The Technical Working Group confirmed a process to collect input from municipalities, businesses, Indigenous communities and other interested parties will take place in the next milestone. The Technical Working Group also committed to explore opportunities for distributed energy resources and will enhance engagement to increase opportunities for input. The final Scoping Assessment was posted in March 2023, identifying the need for a coordinated regional planning approach for the Ottawa Area.

8.3.2 Demand Forecast

Following finalizing the Scoping Assessment, the Technical Working Group began the development of Ottawa's electricity demand forecast. IRRP recommendations are typically driven by the Reference Demand Forecast, which includes firm loads (current and planned), organic growth, residential, electrification and energy plans, and industrial growth. The Technical Working Group sought input from the City of Ottawa and large electricity customers (including school boards). The reference forecast assumes most likely electrification adoption rates based on current policies and includes eDSM forecasts based on provincial and federal policies, as well as the impact of existing and expected DERs in Ottawa.

In parallel, the Technical Working Group determined the need to develop a High Growth Demand Forecast to capture growth and trends that are less certain such as full decarbonization of the city or large-scale customer connections. To achieve this, the City of Ottawa, the local distribution companies and the IESO participated in several focused discussions to capture the effects of economic development, electrification and decarbonization in the city. Hydro One Transmission and Enbridge Gas Inc. participated in these "Decarbonization Focus Group" meetings as observers. In 2023 the IESO piloted an approach in both the Toronto and Ottawa IRRPs, to engage Enbridge Gas Inc. throughout the demand forecasting process as an observer. The observer's role was limited to subject matter experts providing feedback on the discussions where applicable. The purpose of the "Decarbonization Focus Group" was to determine a high growth demand forecast for the Ottawa Area that reflects the full decarbonization of the city.

During this time, six meetings from March to December 2023 took place within the Decarbonization Focus Group to obtain insights including shared experience with decarbonization. Key discussion items raised included the importance of visibility into planned major energy efficiency projects and understanding how to share updates on when this load is materializing. After gathering all insights, Hydro Ottawa engaged a third-party consultant to capture the effects of electrification and decarbonization into five forecasts. The reference and high growth forecast scenarios were chosen

and all forecasts were shared through the launch of a broader public engagement initiative. Communications to IESO subscribers of the Greater Ottawa Region ensured all interested parties were made aware of the opportunity for input.

During this milestone, key information shared was that the electricity demand is growing significantly in the Ottawa area with demand estimated to grow by 33% in the winter and 166% in the summer by 2043. The primary drivers of growth are economic growth and decarbonization initiatives which promote the intensification of electricity use, resulting in a substantial demand increase, particularly in the winter. The reference forecast will be used to drive recommended solutions, however the Technical Working Group will identify options for long-term electricity needs and high-growth scenarios, refining these options in future planning cycles and activating them as growth occurs.

Based on the feedback through this engagement initiative, a key priority was to ensure the IRRP considered climate impacts into the demand forecast and incorporated resiliency into recommended actions. The Technical Working Group ensures the forecast reflects extreme weather conditions in various scenarios, which includes the system's ability to respond to disturbances, and committed to ongoing discussions about resiliency throughout plan development. Additionally, feedback was centred around ensuring alternative solutions, such as non-wire options, are explored. The Technical Working Group committed to evaluating wire and non-wire options and sharing the analysis as planning work advances. Additionally, the IESO informed the public that details about the Local Achievable Potential Study underway for the Ottawa Area will be shared in future engagements.

8.3.3 Electricity Needs and Potential Wire Options

During this milestone, the Technical Working Group identified significant station capacity, System Capacity, end-of-life, load restoration and load security needs throughout the Ottawa area, with several of these needs emerging in the near-term. Therefore, the Technical Working Group determined it was necessary to prioritize options that met near- and medium-term needs. Given the magnitude and timing of the near- and medium-term needs, potential wire options were developed and shared with the community at this milestone with a commitment to presenting a comprehensive analysis for all feasible wire and non-wire options later.

Feedback at this stage of the engagement sought to further clarify the options analysis stage of the IRRP, particularly if wire and non-wire options would be considered as alternatives to each other. Additionally, feedback received urged for resiliency to be considered when finding options to meet needs. The Technical Working Group confirmed wire and non-wire options, or any combination of both, will be evaluated to meet the area's needs. Additionally, the Technical Working Group acknowledges the importance of resiliency and will consider this in the detailed options analysis.

Feedback was also solicited for the Local Achievable Potential Study and the community recommended to broaden the scope of the study. The project team for the local APS confirmed several considerations raised, including leveraging Dunsky's 2022 provincial DER potential study, inclusion of thermal storage, consideration of decreasing costs of technologies overtime and more were incorporated into the report. The IESO also clarified that front-of-meter DER was being considered outside of the Local Achievable Potential Study in the IRRP and explained why vehicle-to-grid technology was excluded. Engagement with the City of Ottawa and the Decarbonization Focus Group were undertaken as part of this milestone.

8.3.4 Options Analysis and Draft Recommendations

During this milestone, the Technical Working Group shared the options analysis for all feasible wire and non-wire options and shared the draft recommendations. The draft recommendations included two new transmission lines within existing corridors, two new stations and two significant upgrades to existing stations. Informed by feedback about resiliency, the draft recommendations also include a switching station to improve transmission reliability by rerouting power during outages or maintenance, minimizing disruptions and enhancing grid flexibility.

The outreach strategy for this milestone included briefing various City of Ottawa staff as well as councillors whose riding is located where the draft recommendations are. A public engagement webinar was hosted to share the detailed analysis and draft recommendations, as well as an update on the Local Achievable Potential Study and a suite of Save on Energy programs available to Ottawa small businesses and residents. A touchpoint with the Decarbonization Focus Group was hosted to solicit feedback into the final IRRP.

8.4 Involving Municipalities in the Plan

Throughout the IRRP engagement, valuable feedback was received and incorporated into the final IRRP including:

- Enhancing webinar materials to share technical updates in a digestible manner.
- Undergoing a Local Achievable Potential Study which would study the potential of behind-the-meter options, including distributed energy resources, with the commitment to hosting a webinar later in Q3 to share the findings and next steps of the study.
- Including the City of Ottawa's Energy Evolution plans in the reference and high forecast scenarios.
- Incorporating information about economic development in Ottawa, particularly around the Kanata North area.
- Incorporating feedback around resiliency into the recommendation of a switching station to enhance transmission reliability.

8.5 Engaging with Indigenous Communities

To raise awareness about the regional planning activities underway and invite participation in the engagement process, regular outreach was made to Indigenous communities within the Ottawa Area Sub-Region throughout the development of the plan. This includes the communities of the Algonquins of Ontario, Pikwakanagan First Nation, and Métis Nation of Ontario Region 5.

The IESO remains committed to an ongoing, effective dialogue with communities to help shape long-term planning in regions all across Ontario.

9. Conclusion

This report documents an IRRP that has been carried out for the Ottawa Sub-Region of the OEB's Greater Ottawa planning region. The IRRP identifies electricity needs in the sub-region over the 20-year period from 2024-2043 and recommends preferred solutions to address near-term needs. The Working Group recommends Hydro One initiate a RIP. The Working Group will continue to provide support throughout the RIP process, and assist with any regulatory matters that may arise during plan implementation.

The IRRP also identifies actions to monitor, defer, and address remaining needs and to inform the next regional planning cycle. The Ottawa Sub-Region Working Group will continue to meet at regular intervals to monitor developments in the sub-region and track progress toward the plan deliverables. In the event that underlying assumptions change a new regional planning cycle may be initiated sooner than the OEB mandated five-year schedule.

REGIONAL INFRASTRUCTURE PLAN REPORT

GREATER OTTAWA

Regional Infrastructure Plan Report

Greater Ottawa

February 09, 2026

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

Greater Ottawa Technical Working Group

Page intentionally left blank

Disclaimer

This Regional Infrastructure Plan (RIP) Report for the Greater Ottawa region was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group (TWG).

The preferred solution(s) that have been recommended in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP TWG at the time.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	**Greater Ottawa** (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")

START DATE: August 18, 2025 **END DATE:** February 09, 2026

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process for the Greater Ottawa region, preceded by, the publication of Needs Assessment (NA) report in December 2022 by Hydro One which was triggered early due to high growth in the region followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) which were published in March 2023 and in July 2025 respectively, by the Independent Electricity System Operator (IESO).

Hydro One as the lead transmitter undertakes the development of a RIP with input from the Technical Working Group (TWG) for the region (includes representatives from Hydro One Transmission, IESO and LDCs and publishes a RIP report. The RIP report includes a discussion of all options and plans identified in earlier phases and recommends a preferred wires plan to address the near, medium, and long - term needs over a twenty-year study period.

The objectives and scope of the RIP are:

- A consolidated report of the needs and relevant wires plans to address near, and medium-term needs (2025-2034) identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identify any new need(s) over the 2025-2034 that may have emerged since previous planning phases. Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.
- Consideration of long-term needs identified in the Ottawa area sub-region IRRP, Bulk system studies or as identified by the TWG.

Since the IRRP study addressed needs only for the Ottawa Area Sub-region, the RIP as per TWG discussions developed a new load forecast for stations outside the IRRP scope and revised forecasts for certain stations. For the remaining stations, the IRRP load forecast was adopted for the RIP study, as no material changes were identified. During the IRRP stakeholder engagement process, IESO received municipal input on future load growth for consideration in the IRRP load forecast.

The list of major infrastructure investments recommended by the TWG in the region is given below. The needs include those previously identified in the NA and IRRP, as well as any new needs identified during the RIP phase, if any.

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Budgetary Cost ($M)
Asset Renewal Needs				
South March TS	Replacement of T1/T2 transformers with upgraded units based on asset conditions and capacity needs.	Hydro One	2029	$40M
Albion TS	Replacement of T1/T2 transformers with upgraded units based on asset condition and capacity needs.	Hydro One	2031	$60M
Nepean TS	Replacement of T3/T4 transformers based on asset condition	Hydro One	2034	$30M
S7M	Refurbishment of line section between Manotick JCT x Richmond South MTS and S7M 673N x Manordale JCT	Hydro One	2030	$5M
Station Capacity Needs				
South March TS	Replacement of T1/T2 transformers with upgraded units based on asset conditions and capacity needs.	Hydro One	2029	$40M
Carling TS	Replacement of limiting LV cables.	Hydro One	2030	$10M
Lisgar TS	Replacement of T2 transformer and LV cables/breakers - Greenfield	Hydro One	2034	$50M
	Replacement of T2 transformer and LV cables/breakers – In Situ	Hydro One	2031	$30M
King Edward TS	Replacement of LV cables and breakers.	Hydro One	2033	$20M

Cyrville MTS	Station voltage conversion from 115kV to 230kV to increase station rating and upgrade station transformation capacity.	Hydro One/ Hydro Ottawa	2029	$85M*
Moulton MTS	Relocate 50 MVA ,115kV transformers from Cyrville MTS after voltage conversion to increase station rating at Moulton TS.	Hydro Ottawa	2029	$5M
Bronson MTS	Build a new 115kV Transformer Station east of Carling TS by converting existing Bronson distribution station	Hydro One/ Hydro Ottawa	2031	$110M*
Greenbank MTS	Build new Transformer Station to meet demand growth and need for 28kV supply west of Merivale TS.	Hydro One/ Hydro Ottawa	2028	$100M*
Kanata North MTS	Build a new Transformer Station by connecting 230 kV C3S and new transmission line from South March TS	Hydro One/ Hydro Ottawa	2028	$100M*
Marionville DS	Install a second transformer to increase station rating.	Hydro One Dx	2029	$12M*
Greely DS	Install Scada Fan monitoring to increase transformer rating.	Hydro One Dx	2026	$2M*
Rockland DS	Install Scada Fan monitoring to increase transformer rating.	Hydro One Dx	2026	$2M*
Rockland East DS	Install Scada Fan monitoring to increase transformer rating.	Hydro One Dx	2027	$3M*

Transmission Line Capacity Needs				
M4G/M5G	Uprate Line section between Merivale TS x Carling TS	Hydro One	2030	$30M
L2M	Uprate line section between Merivale TS x Limebank JCT	Hydro One	2032	$30M
System Reliability, Operation and Load restoration Needs				
Kanata Area	Kanata Area Transmission Reinforcement	Hydro One	2033	$250M
Nepean TS – Load Security Criteria	Second 230 kV Supply to station	Hydro One	2032	$70M
M1R+L2M	Split Breaker position for M1R and L2M at Merivale TS	Hydro One	2032	$45M
East Ottawa Area	Supply to East Ottawa	Hydro One	2029-2030	$165M*

* These investment costs include associated distribution system costs.

Note:

a) The planned in-service dates are tentative and subject to change.
b) Costs are high-level planning estimates and actual costs may vary.

1. INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of the Regional Planning Process. Hydro One as the lead transmitter undertakes the development of a RIP with input from the Technical Working Group (TWG) for the region (includes representatives from Hydro One Transmission, IESO and LDCs) and publishes a RIP report. The third cycle of the Regional Planning process for the Greater Ottawa region was initiated early due to high growth in the region with the publication of Needs Assessment (NA) and the report was published in December 2022 by Hydro One. This was followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) only for the Ottawa Sub-Region Area which were published in March 2023 and July 2025 respectively, by the Independent Electricity System Operator (IESO).

This RIP report is for the "Greater Ottawa Region" and includes the municipalities bordering the Ottawa River from Arnprior in the West to Hawkesbury in the East and North of County Road 43 (Highway 43) and includes a common discussion of all the options and recommended plans and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs.

This report was prepared by the Greater Ottawa TWG, led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by Hydro One, the Local Distribution Companies (LDC), the Municipalities and the IESO. Participants of the TWG are listed below in Table 1-1.

Table 1-1: Greater Ottawa region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Networks Inc. (Transmission)
2	Independent Electricity System Operator (IESO)
3	Hydro One Networks Inc. (Distribution)
4	Hydro Ottawa Limited
5	Hydro Hawkesbury
6	Renfrew Hydro Inc.
7	Hydro 2000 Inc.
8	Ottawa River Power Corp.

2. OBJECTIVES AND SCOPE OF REGIONAL INFRASTRUCTURE PLAN

This RIP report examines the needs in the Greater Ottawa region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs of the Greater Ottawa region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major high voltage transmission equipment, transmission and distribution system capability along with any updates with respect to local plans, Electricity Demand Side Management ("eDSM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs 2025-2034 identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the 2025-2034 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the Ottawa area sub-region IRRP, Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

3.1 Overview

Bulk System Planning, Regional Planning and Distribution Planning are the three levels of planning for the electricity system in Ontario. Bulk system planning typically looks at issues that impact the system on a provincial level and require longer lead time and larger investments. Comparatively, planning at the regional and distribution levels looks at issues on a more regional or localized level. Typically, the most essential and effective regional planning horizon is the near- to medium-term (1- 10 years), whereas long-term (10-20 years) regional planning mostly provides a future outlook with little details about investments because the needs and other factors may vary over time. On the other hand, bulk system plans are developed for the long term because of the larger magnitude of investments.

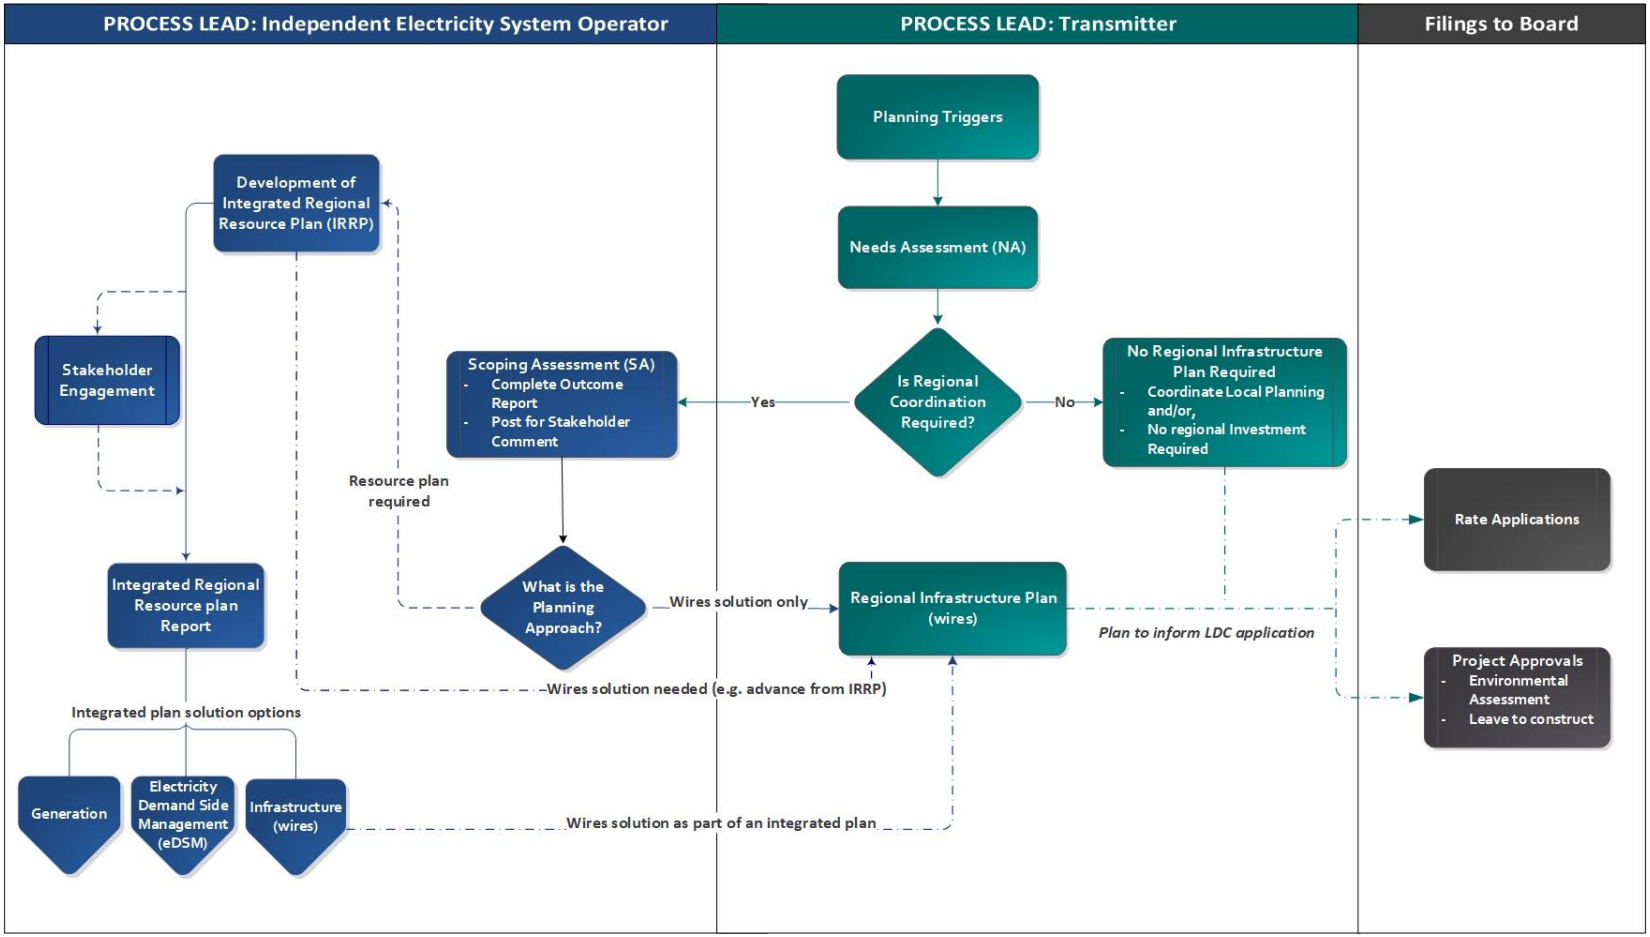
The regional planning process begins with a Needs Assessment which is led by the transmitter to identify, assess, and document which of the needs that,

a) can be addressed directly between the customer and transmitter along with a recommended plan, and.
b) require further regional coordination and identification of Local Distribution Companies (LDCs) to be involved in further regional planning activities for the region.

At the end of the NA, a decision is made by the TWG as to whether further regional coordination is necessary to address some or all the regional needs. If no further regional coordination is required, the recommended options are implemented, and any necessary investments are planned directly by the LDCs (or customers) and the transmitter. The region's TWG can also recommend to the transmitter and LDCs to undertake a local planning process for further assessment when needs

a) are local in nature,
b) require limited investments in wires (transmission or distribution) solutions, and.
c) do not require upstream transmission investments.

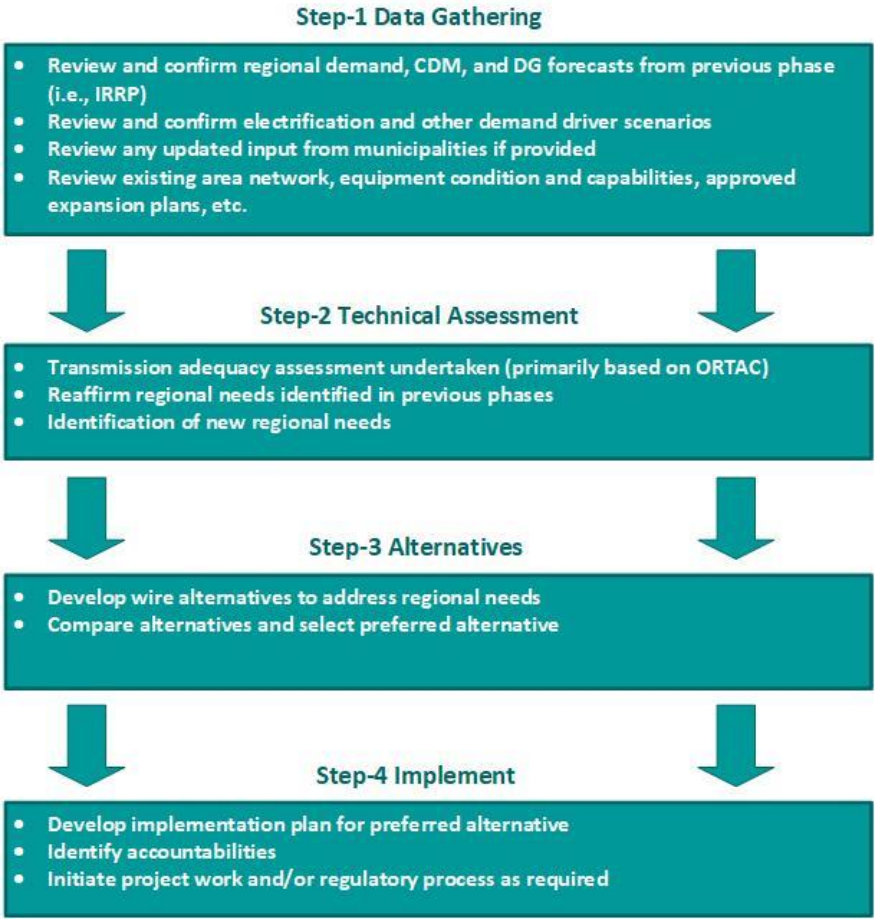
If coordination at the regional or sub-regional levels is required for identified regional needs, then the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires or resource alternatives, e.g., Electricity Demand Side Management ("eDSM"), Distributed Generation (DG), etc., in order to make a decision on the most appropriate regional planning approach including Local Plan (LP), IRRP and/or RIP.



The primary purpose of the IRRP is to identify and assess both resource and wires options at a higher or macro level, but sufficient to permit a comparison of resource options vs. wire infrastructure to address the needs. Worth noting, the LDCs' eDSM targets as well as contracted DG plans provided by IESO and LDCs are reviewed and considered at each step in the regional planning process.

If and when an IRRP identifies that resource and/or wires options may be most appropriate to meet a need, resource/wires planning can be initiated in parallel with the IRRP or in the RIP phase to undertake a more detailed assessment, develop specific resource/wires alternatives, and recommend a preferred wires solution.

The RIP phase is the final phase of the regional planning process and involves discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive and consolidated report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.



The various phases of Regional Planning Process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome are shown below in Figure 3-1.

Figure 3-1 Regional Planning Process Flowchart

3.2 Regional Infrastructure Plan Methodology

Figure 3-2 Regional Infrastructure Plan Methodology

Regional Infrastructure Plan phase is a four-step process which are described below:

3.2.1. Data Gathering:

The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with TWG to reconfirm or update the information as required. The data collected includes:

- Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or eDSM programs. As agreed by TWG members, the load forecast from the Ottawa Area sub-region IRRP was used for this RIP with modifications to some stations and developed a load forecast for the outer Ottawa stations which were not covered in the IRRP.

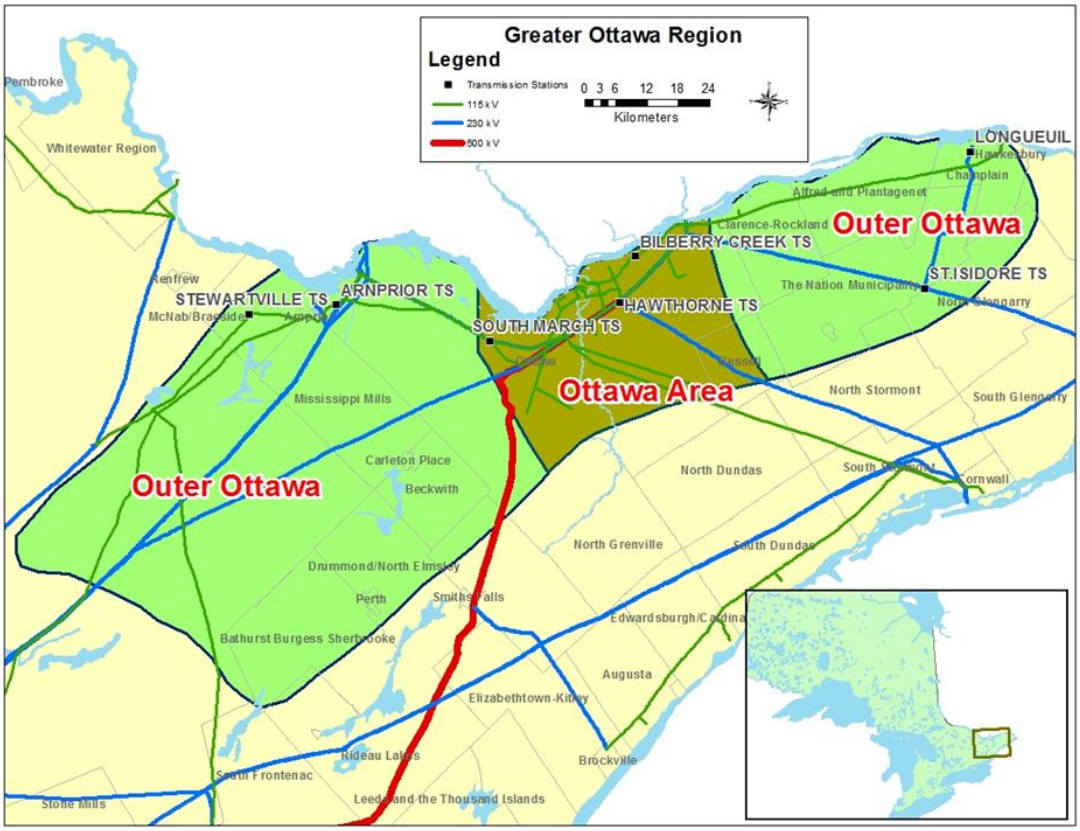
- Review and confirm electrification and other growth scenarios which affect the projects recommended in previous stages.
- Existing area network and capabilities including any bulk system power flow assumptions.
- Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

3.2.2. Technical Assessment:

The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3.2.3. Alternative Development:

The third step is the development of wires options to address the needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.



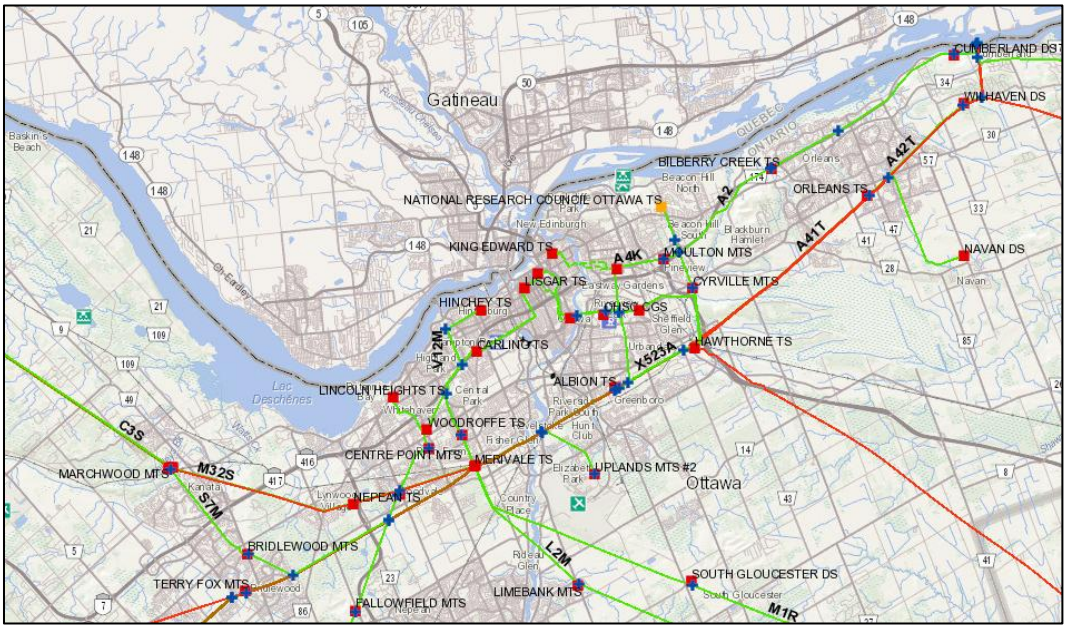
3.2.4. Implementation Plan:

The fourth and last step is the development of the implementation plan for the preferred alternative, identify accountabilities and initiate project work or obtain permissions from the Regulatory Commission if any.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

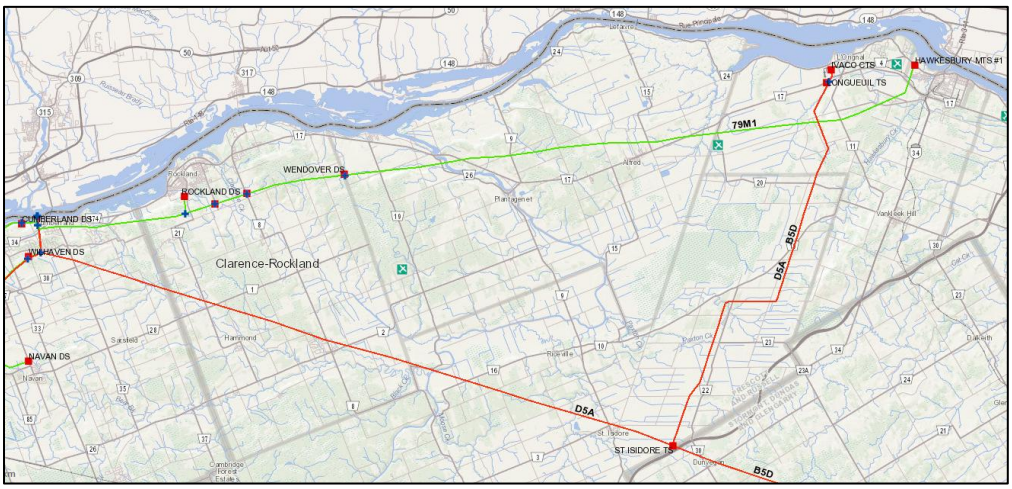
The Greater Ottawa Region covers the municipalities bordering the Ottawa River from Arnprior in the West to Hawkesbury in the East and North of County Road 43 (Highway 43). At the center of this region is the City of Ottawa. Electrical supply to the Region is provided from fifty-two (52) 230 kV and 115 kV step-down transformer stations. The boundaries of the Region are shown in Figure 4-1 below. The outer regions are referred to as the East and West Outer Ottawa sub-regions. The central region comprising of City of Ottawa is referred to as the Ottawa sub-region

Figure 4-1: Map of Greater Ottawa Regional Planning Area



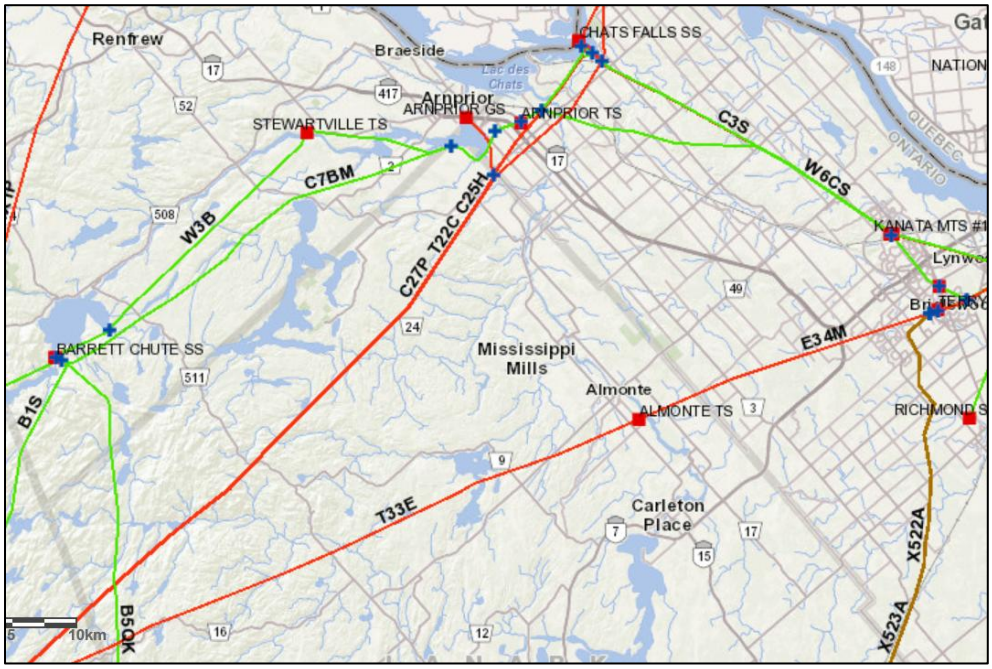
Bulk electrical supply to the Greater Ottawa Region is provided through the 500/230 kV Hawthorne TS autotransformers and a network of 230 kV and 115 kV transmission lines and step-down transformation facilities. The area has been divided into two sub-regions as shown in Figure 4-1 and described below:

The Ottawa Area Sub-region comprises primarily the City of Ottawa. It is supplied by two (2) 230/115 kV autotransformer stations (Hawthorne TS and Merivale TS), eight (8) 230 kV and thirty-three (33) 115 kV transformer stations stepping down to lower voltages. Local generation in the area consists of the 74 MW



Non-Utility Generator ("NUG") CGS-2 located near the downtown area and connected to the 115 kV network. The Ottawa Area Sub-region is shown in Figure 4-2 below. Hydro Ottawa is the main LDC that serves the electricity demand for the City of Ottawa. Hydro One Distribution supplies load in the outlying areas of the sub-region. Both Hydro Ottawa and Hydro One Distribution receive power at the step-down transformer stations and distribute it to end users, including industrial, commercial and residential customers.

Figure 4-2: City of Ottawa Sub-Region Map



The Outer Ottawa Sub-Region covers the remaining area of the Greater Ottawa Region. The eastern area as shown in Figure 4-3 below is served by three (3) 230 and five (5) 115 kV step-down transformer stations. Hydro One Distribution and Hydro Hawkesbury are the LDCs in the area that distribute power from the stations to their end use customers. Hydro 2000 is an embedded LDC that supplies its customers from Longueuil TS via Hydro One Distribution's 44kV feeders. It also includes a large industrial customer, in L'Orignal, Ontario.

Figure 4-3: Outer Ottawa Sub-Region Map (Eastern Part)

The western area of the Outer Ottawa Sub-Region, shown in Figure 4-4 is served by one (1) 230 kV and two (2) 115 kV step-down transformer stations. Hydro One Distribution is the LDC that supplies its end use customers from these stations. Ottawa River Power Corp. is an embedded LDC that supplies its customers from Almonte TS via Hydro One Distribution's 44kV feeders. Renfrew Hydro is an embedded LDC that supplies its customers from Stewartville TS via Hydro One Distribution's 44kV feeders. The area includes the following generating stations: Barrett Chute GS, Chats Falls GS and Stewartville GS with a peak generation capacity of about 450 MW.

Figure 4-4: Outer Ottawa Sub-Region Map (Western Part)

Electricity demand in the region is projected to grow steadily over the forecast horizon, primarily driven by municipal expansion, increased commercial development, and the accelerating impacts of electrification and decarbonization initiatives. A key factor influencing long-term demand and supply requirements is the planned phase-out of natural gas heating, which is expected to significantly increase electricity consumption in the sub-region, particularly in the latter years of the forecast period. The circuits and stations of the area are summarized in Table 4-1 below:

Table 4-1: Transmission Station and Circuits in the Greater Ottawa region

115kV circuits	230kV circuits	Hydro One Transformer Stations		Generation Stations
A2	B5D	Albion TS	Marchwood MTS	CGS-1
A3RM	C3S	Almonte TS	Marionville DS	CGS-2

*****Stations with Autotransformers installed

** Planned to decommission

The single line diagram of the existing Transmission Network of Greater Ottawa region is shown in Figure 4-5 below.

Figure 4-5: Greater Ottawa Transmission Single Line Diagram

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR ARE UNDERWAY

In this section a complete list of all the projects that were completed in the past ten years or are currently underway is provided and is briefly discussed in the sub-sections. As a part of this or previous Regional Planning Cycle(s), several "Major HV Transmission Projects" were recommended in the **Greater Ottawa region** to improve the supply capability and reliability.

Hydro One Transmission, Hydo Ottawa Ltd and Hydro Hawkesbury are the Transmission Asset Owner (TAO) in the region and have undertaken the execution of the projects recommended in the past ten years. A summary and brief description of all the projects completed or are currently underway is given below:

I. Following Major projects were completed during the last ten years:

1. Build New Orleans TS (2015) – built a new step-down transformer station in East Ottawa supplied from 230 kV circuit D5A and 115 kV circuit H9A. This station provides additional load meeting capability to meet Hydro One Distribution and Hydro Ottawa requirements. It provides improved reliability for Hydro One Distribution customers in the Orleans-Cumberland area.
2. Hinchey TS (2015) – Connected idle winding of transformers T1/T2 to new Hydro Ottawa metalclad switchgear to provide additional load meeting capability at the station.
3. Add 230 kV inline breaker on 230 kV circuit M29C at Almonte TS (2015) – added breaker to improve reliability of supply for Almonte TS and Terry Fox MTS and split line M29C into E34M and E29C (now T33E)
4. Overbrook TS (2017): Replaced 45/60/75 MVA, 115/13.8 kV step down transformers with new 60/80/100 MVA, 115/13.8 kV based on asset condition assessment replaced transformers with higher capacity units to provide additional load meeting capability at the station due to anticipated load growth.
5. Hawthorne TS (2019): Replaced 50/67/83 MVA, 230/44 kV step down transformers with new 75/100/125 MVA, 230/44 kV units based on asset condition assessment replaced transformers with higher capacity units to provide additional load meeting capability at the station due to anticipated load growth.
6. Change supply to Overbrook TS (2019) – Reduced the loading on A4K by modifying the supply to Overbrook TS by connecting transformer T1 to A6R instead of A4K. This was accomplished by rebuilding the line section of A5RK from Riverdale JCT to Overbrook TS as a double circuit 115 kV line and tapping A6R at Riverdale JCT.
7. Connection of CGS 1 wind farm (2020) – connection of 100 MW wind farm to 230 kV circuit L24A.

8. Hawthorne TS T5 and T6 autotransformer replacement (2021): Replace 225 MVA, 230/115 kV autotransformers T5 and T6 with new 250 MVA, 230/115 kV autotransformers to provide additional 230/115 kV transformation capacity.
9. King Edward TS transformer T3 replacement (2021): Replacement of 45/60/75 MVA, 115/13.8 kV step down transformer T3 with upgraded 60/80/100 MVA, 115/13.8 kV to match the existing rating of T4 and to provide additional load meeting capability at the station.
10. Connection of Cambrian MTS (2022): connect a new Hydro Ottawa owned transformer station in the South Nepean area. The station is supplied from 230kV circuit E34M with alternate supply from 115kV circuit S7M. S7M was rebuilt as a double circuit line from the main line (S7M STR673JCT to Cambrian JCT (~10.9km) with a 1.3km extension to Cambrian MTS.
11. Overbrook TS LV cable review (2022): the transformer cable capacity limitation review was analyzed. The transformer LTR was increased based on the result of the study.
12. Arnprior TS T1/T2 replacement (2023): The two 25/33/42 MVA 115.5kV/44kV transformers were replaced like-for-like with new standard 25/33/42 MVA 110kV/44kV transformers.
13. M30A/M31A upgrade (2023): Increase the power interface limit between Hawthorne TS and Merivale TS by replacing the existing conductor 1843.2kcmil with new twin bundled 1443.7 kcmil conductor (2 conductors per phase).
14. Slater TS T2/T3 replacement (2024): Replaced 38/63 MVA, 110/12 kV step down transformers T2 and T3 with new 60/80/100 MVA, 110/14.2 kV units based on asset condition assessment replaced transformers with higher capacity units to provide additional load meeting capability at the station.
15. Lincoln Heights TS T1/T2 (2024): Like-for-like replacement of the two 45/60/75 MVA 110kV/14.2kV transformers.
16. Longueuil TS T1/T2 replacement (2025): Replacement of 50/75/93 MVA 235kV/44kV transformers T1/T2 with standard 50/67/83 MVA 215.5kV/44kV units.
17. Lisgar TS T1 replacement (2025): Replacement of 45/60/75 MVA 110/14.2-14.2 kV transformer T1 with standard 60/80/100 MVA 110/14.2-14.2kV unit.

II. Following Major projects are underway:

1. Piperville MTS – Connection of Hydro Ottawa's new transformer station to 230 kV L24A circuit with in-service date in Q2 2026.
2. Russell TS – T1/T2 transformers (45/60/75 MVA) will be replaced with 60/80/100 MVA transformers. The planned in-service date is 2027.
3. Connection of Hydro Rd. MTS – Connection of new Hydro Ottawa station to 230kV circuits M30A/M31A near Hawthorne TS. Building ~500m line tap to the new station. The planned in-service date for connection of this new station is October 2027.
4. Connection of Mer Bleue MTS - Connection of new Hydro Ottawa station to 230kV circuits D5A about 10km east of Hawthorne TS. The planned in-service date for connection of this

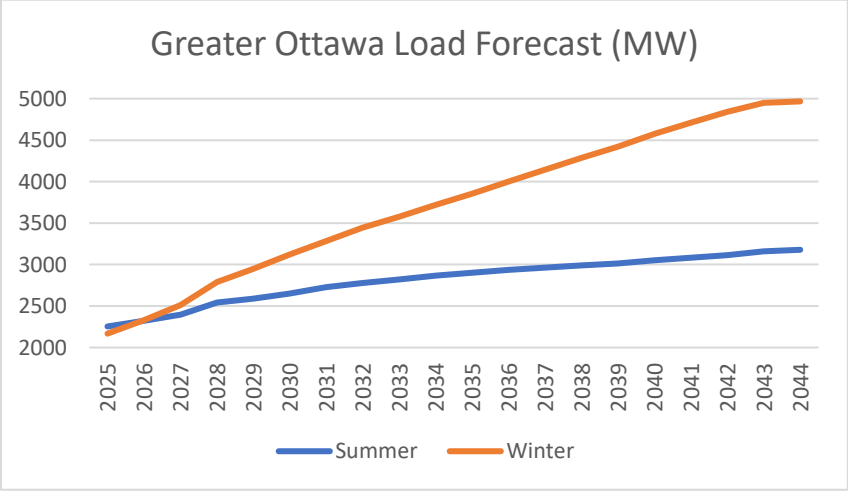
new station is July 2027. This project is also planned to connect to circuit A25 with expected in-service in June 2029. Please refer to section 8.4.5 for further information.

5. Connection of South March BESS – Connection of new 250MW Battery Energy Storage System to 230kV circuit C3S about 11.5km from South March TS. The planned in-service date for connection is Q2 2027.
6. Connection of Trail Road BESS - Connection of new 159MW Battery Energy Storage System to 230kV circuit E34M about 275m from Cambrian JCT. The planned in-service date for connection is 2027.
7. Hawkesbury MTS: Project for transformer upgrade with a new 15MVA transformer unit is underway and is being led by Hydro Hawkesbury. The planned in-service date is 2027-2028.
8. Merivale TS T22/T23 – The planned in-service date for replacement of autotransformer T22 and addition of new autotransformer T23 and for replacement of six (6) 230 kV circuit breakers and four (4) 115 kV circuit breakers is 2029.
9. Bilberry Creek TS – The station is expected to be retired around 2030. Its load will be transferred to Mer Bleue MTS and Orleans TS. Please refer to section 8.4.5 for further information.
10. Orleans TS – The station will be upgraded from dual supply of 230/27.6 kV 115/27.6 kV to 230/27.6 kV DESN. The planned in-service date is June 2029. Please refer to section 8.4.5 for further information.

Note: The planned in-service year for the above projects is tentative and is subject to change.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

6.1. Load Forecast



The TWG developed a load forecast for stations in the Outer Ottawa area as these were outside the IRRP scope. The LDCs also reviewed the IRRP forecast and provided revisions for some of the stations. For the remaining stations, the IRRP load forecast was adopted for the RIP study, as no changes were required by the LDCs. TWG participants, including representatives from LDCs, IESO and Hydro One provided information and input for the IRRP and RIP Load forecasts. During the IRRP stakeholder engagement process, IESO received municipal input on future load growth for consideration in the IRRP load forecast.

During the study period, the load in the Greater Ottawa region is expected to grow at an average annual rate of approximately 2% in summer and 4% in winter from 2025 to 2044. The region is currently summer-peaking, however based on the forecast it is expected that the region will transition to winter-peaking in the near future. This shift is largely driven by electrification such as the ongoing transition of heating systems from natural gas to electric or hybrid solutions, which will significantly increase electricity demand during winter months.

Figure 6-1 shows the Greater Ottawa region extreme summer/winter weather net load MW forecast from 2025 to 2044. The load forecasts from the Ottawa sub-region were updated from the IRRP forecast as agreed by the TWG.

The forecast for the individual stations in the region is available in Appendix A and is used to determine any need in the region.

Figure 6-1: Greater Ottawa region summer/winter Net Peak Load Forecast

6.2. Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2025-2044.
- LDCs have reviewed the forecast and provided updates where necessary and reconfirmed load forecasts up to 2044 in the area.
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- The Region is currently summer peaking but expected to become winter peaking within the study period, so this assessment considers both summer and winter peak loads.
- Station capacity adequacy is assessed by comparing the station peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR) based on 35°C ambient temperature.
- Adequacy assessment is conducted as per ORTAC.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying the Greater Ottawa region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway, listed in **"Section 5"** are completed as per their respective in-service dates.

In the current regional planning cycle, the following regional assessments were completed, and their findings were used as inputs to this RIP report:

- Greater Ottawa region Third cycle Needs Assessment Report, Completed in December 2022 by Hydro One
- Greater Ottawa region Third cycle Scoping Assessment Report, Completed in March 2023 by the IESO
- Greater Ottawa region Third cycle Integrated Regional Resource Plan Report, Completed in July 2025 by the IESO

The Technical Working Group identified several regional needs based on the forecasted load demand over the near to mid-term period in the reports mentioned above. The results of the Adequacy Assessment to define the needs are discussed in sub-sections "7.1 to 7.4" and a detailed description and status of plans to meet these needs are given in **"Section 8"** of this report.

7.1. Asset Renewal Needs for Major HV Transmission Equipment

In addition to the asset renewal needs identified in the previous regional planning cycle, Hydro One and TWG have also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the Greater Ottawa region. The complete list of major HV transmission equipment requiring replacement in the Greater Ottawa region is provided in Table 7-1 in this sub-section. Hydro One along with Hydro Ottawa Ltd and Hydro Hawkesbury are the only Transmission Asset Owner (TAO) in the Region

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
    - replacement of six breakers or more than 50% of station breakers, the lesser of the two

- 230 and 115kV transmission lines requiring refurbishment where:
  - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
  - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

Table 7-1: Major HV Transmission Asset assessed for Replacement in the region planned in next 10 years

Station/Circuit	Need Description	Planned ISD
South March TS	T1/T2 Transformers replacement	2031
Albion TS	T1/T2 Transformers replacement	2031
Nepean TS	T3/T4 Transformers replacement	2034
S7M	Refurbishment of line section between Manotick JCT x Richmond South MTS and S7M 673N x Manordale JCT	2030

Note: The planned in-service year for the above projects is tentative and is subject to change.

7.2. Station Capacity Needs

Over the study period **2025 -2044** RIP reviewed the capacity of all the 230kV and 115kV Transforming stations within the **Greater Ottawa region**. The NA and IRRP studies had previously indicated that the following stations require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast, the stations which require capacity relief during the study period are shown in Table 7-2 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer and winter) Limited Time ratings.

Table 7-2: Greater Ottawa region Station Capacity Needs in the study period

Sr.no.	Station Name	Station LTR (MW) (Summer/Winter)	2024 Loading (MW) (Summer/Winter)	Need Date (Summer/Winter)	High Forecast Need Date (Summer/Winter)
1	Albion TS	86.5/101.7	57.4/47.0	-/2034	2043/2030
2	Arnprior TS	54.9/59.4	36.9/37.5	2044/-	2043/-
3	Bridlewood MTS	23.5/23.5	29.6/19.7	2035/2030	2029/2027
4	Cambrian MTS	114/123.5	58.7/33.6	-/2041	-/2033
5	Carling TS	95/124.3	67.7/64.9	2028/2028	2028/2028
6	Centrepoint MTS	13.3/13.3	14.6/11.9	2032/2027	2027/2025

7	Cumberland DS	6.8/8.6	5.5/5.0	2037/-	2036/-
8	Cyrville MTS	47.5/47.5	33.6/24.4	2028/2030	2028/2028

10	Fallowfield MTS	27.2/27.2	35.6/14.4	2026/2030	2026/2028
11	Greely DS	20.7/25.2	19.5/16.3	2025/2025	2025/2025
12	Hawkesbury MTS	18/18	13.3/14.9	-/2037	-/2036
13	Hawthorne TS	144.8/	106.1/97.1	2038/2031	2038/2028
14	Hinchey TS	85.6/95.0	45.4/40.8	-/2031	-/2029
15	Kanata MTS	51.5/51.5	53.2/55.8	2025/2025	2025/2025
16	King Edward TS	86.9/90.3	80.0/77.7	2033/2026	2030/2025
17	Limebank MTS	75.0/75.0	48.1/38.2	2031/2028	2031/2026
18	Lincoln Heights TS	99.4/113.1	40.3/40.9	-/2039	-/2035
19	Lisgar TS	83.4/105.1	42.7/58.9	2028/2028	2028/2027
20	Manordale MTS	9.6/9.6	11.0/8.4	2026/2026	2025/2025
21	Manotick DS	7.7/10.4	9.5/8.1	2025/2025	2025/2025
22	Marchwood MTS	32.3/32.3	46.3/42.5	2025/2025	2025/2025
23	Marionville DS	13.5/13.5	14.4/12.1	2025/2025	2025/2025
24	Moulton MTS	32/32.0	21.6/16.6	2028/2028	2028/2028
25	Nepean Epworth MTS	12.9/12.9	11.4/11.4	2035/2028	2029/2026
26	Nepean TS	144.1/160.7	113.2/108.6	-/2030	-/2027
28	Richmond South MTS	49.0/49.0	19.4/6.9	2034/2028	2034/2028
29	Riverdale TS	110.8/117.0	92.4/71.5	2030/2028	2029/2026
30	Rockland DS	7.8/10.5	7.8/4.1	2025/2031	2025/2030
31	Rockland East DS	15.5/20.9	14.3/12.4	2026/2040	2026/2040
32	South March TS	99.2/113.7	95.9/72.2	2026/2028	2026/2027
33	Terry Fox MTS	91.7/105.8	53.9/41.7	-/2038	-/2032
34	Woodroffe TS	97.4/102.4	33.4/28.9	-/2039	-/2034

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.3. Transmission Line Capacity Needs

Over the study period **2025-2044** RIP reviewed the capacity of all the 230kV and 115kV Transmission lines within the **Greater Ottawa region**. The NA and IRRP studies had previously indicated that the following Transmission lines require capacity relief within the study period. This RIP has further confirmed those needs and based on the load forecast and following contingencies, the Transmission lines which require capacity relief during the study period are shown in Table 7-3 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer or winter) Limited Time ratings.

Table 7-3: Greater Ottawa region Transmission Line Capacity Needs in the study period

Sr.no.	Name of Circuit	Name of Section	Maximum capacity	Current loading	Need Date
1	M4G/M5G	Merivale TS x Carling TS	1279 A	503 A	2030
2	L2M	Merivale TS X Limebank JCT	467 A	339 A	2028
3	S7M	Merivale TS x STR654JCT (Fallowfield tap)	1381 A	488 A	2032
4	C7BM	Merivale TS x NQL1 JCT	777 A	455 A	2034 (winter)
5	F10MV	City View JCT x Woodroffe TS	777 A	402 A	2034 (winter)
6	A4K	Hawthorne TS x Cyrville JCT x Overbrook TS	1214 A	550 A	2032/33 (winter)
7	A4K	Overbrook TS x King Edward TS	800 A	204 A	2032/33 (winter)
8	A3RM	Ellwood JCT x Riverdale JCT	1016 A	235 A	2034
9	A5RK	Hawthorne TS x Russel TS	1595 A	538 A	2034
10	A6R	Hawthorne TS x Russel TS	1703 A	489 A	2034

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.4. System Reliability, Operation and Load Restoration Needs

Load security and load restoration needs were reviewed as part of the current study. The ORTAC Section 7 requires that no more than 600 MW of load be lost as a result of a double circuit contingency.

Further, loads are to be restored in the restoration times[1] specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

The following load security needs were reviewed as a part of RIP:

M32S

Nepean TS is supplied solely by the 230 kV M32S circuit, and a contingency on M32S would result in the complete loss of load at Nepean TS due to its configuration. Under current load security criteria, no more than 150 MW should be lost for a single element contingency. While this limit is not exceeded in the summer forecast, it is projected to be reached in the winter forecast by 2029. A working group recommendation is discussed in section 8.4.

M1R+L2M

Circuits M1R and L2M share a breaker position at Merivale TS, so the loss of either circuit results in both being tripped. This configuration affects stations including Limebank MTS, Marionville DS, South Gloucester DS, Greely DS, and Russell DS. For this group, the 150 MW load security threshold is expected to be reached in the summer forecast by 2040 and in the winter forecast by 2031. A working group recommendation is discussed in section 8.4.

Load Restoration for C3S/M32S

M32S is a 230kV circuit connecting Merivale TS to South March TS, and 230kV circuit C3S connecting Chats Falls SS to South March TS. The two circuits are connected through an in-line breaker A1A2 at South March TS. Stations South March TS and Kanata MTS are supplied by both C3S and M32S. Nepean TS is only fed from circuit M32S. Load restoration was assessed for A1A2 breaker fail. The breaker fail condition can lead to no supply to all three stations. The loss of the two circuits results in approximately 330MW of load loss during summer. As per ORTAC, 80MW have to be restored in 30 minutes, 150MW restored in 4 hours and the entire load in 8 hours. Nepean TS can be restored by opening circuit switcher M32S-1 within 30 minutes. The breaker A1A2 disconnect switches at South March TS can be opened within 30 minutes to restore load stations from either C3S or M32S. All load can be restored within 4 hours. In addition, as discussed in section 8.4 a new switching station is planned at South March TS, which will eliminate this problem.

[1] These approximate restoration times are intended for locations that are near staffed centers. In more remote locations, restoration times should be commensurate with travel times and accessibility

Load Restoration for S7M

Circuit S7M and W6CS are tie via an in-line breaker L6L7 at South March SS. A L6L7 breaker failure results in no supply to Fallowfield MTS, Richmond MTS, Manotick DS, Bridlewood MTS, and Marchwood MTS. The amount of load loss is about 199 MW by the end of the study period in summer. As per ORTAC, all load above 150MW must be restored in 4 hours and all load restored in 8 hours. All load can be restored by opening breaker L6L7 disconnect switches at South March SS within 4 hours. The Study Team recommends that no further action is required at this time.

During winter time under contingency of S7M 150 MW can be interrupted by configuration by 2036. TWG recommends monitoring the winter load and addressing the need in the next regional planning cycle.

Load Restoration for D5A/B5D

Circuits D5A and B5D supply Longueuil TS, St Isidore TS, and Ivaco CTS. The worst contingency for the area can result in approximately 212MW of load loss. Hydro One prepared a Local Planning report which considered the loss of up to 174MW of load for the same contingency. Hydro One has reviewed the report and determined that the conclusions of the report are still applicable to the new load forecast. The report shows that all load can be restored in at least 4 hours, meeting ORTAC restoration criteria. The Study Team recommends that no further action is required at this time.

Load Restoration for M4G/M5G

Load restoration was assessed for the 115 kV double-circuit M4G/M5G supply serving Nepean–Epworth MTS, Carling TS, and Lisgar TS in downtown Ottawa. Although Slater TS is also supplied from M4G, it was excluded from this assessment because it has alternate supply from two other circuits and therefore does not drive the same restoration need. Based on the load forecast, the combined demand on M4G/M5G is expected to exceed 250 MW in the mid-term; under ORTAC, loads greater than 250 MW must be restored within 30 minutes following a contingency. To ensure compliance with this requirement as loading increases, Hydro Ottawa and Hydro One will review restoration options, which may include LV load transfers and/or additional switching and operational restoration actions. The TWG recommends that this review be reviewed as part of the M4G/M5G upgrade and/or the Bronson connection project scopes, where practical restoration enhancements can be implemented and validated against the 30-minute restoration criterion.

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the Greater Ottawa region. These needs include those previously identified in the NA and IRRP for the Greater Ottawa region as well as any new needs identified during the RIP phase. All estimated costs included in the alternative analysis are considered as planning budgetary estimates and are used for comparative purposes only and may vary. The Needs in the region are summarized below in Table 8-1 below:

Table 8-1: Near/Mid-term Needs Identified in the region

Station/Circuit Name	Description of Need	Need Date	RIP Report Section
Asset Renewal Needs			
South March TS	Replacement of T1/T2 transformers with upgraded units based on asset conditions and capacity needs.	2031	8.1.1
Albion TS	Replacement of T1/T2 transformers with upgraded units based on asset condition and capacity needs.	2031	8.1.2
Nepean TS	Replacement of T3/T4 transformers based on asset condition	2034	8.1.3
S7M	Refurbishment of line section between Manotick JCT x Richmond South MTS and S7M 673N x Manordale JCT	2030	8.1.4
Station Capacity Needs			
Kanata North MTS	Build a new Transformer Station by connecting 230 kV C3S and a new transmission line from Merivale TS.	2028	8.2.1
Bronson MTS	Build a new 115kV Transformer Station east of Carling TS by converting existing Bronson distribution station	2031	8.2.2
Greenbank MTS	Build new Transformer Station to meet demand growth and need for 28kV supply west of Merivale TS.	2028	8.2.3

South March TS	Replacement of T1/T2 transformers and associated equipment's with upgraded units based on capacity needs.	2026	8.2.4
Albion TS	Replacement of T1/T2 transformers and associated equipment's with upgraded units based on capacity needs.	2031	8.2.5
Carling TS	Station capacity will be exceeded due to limiting components at LV side. Replacing limiting LV cables will add capacity to station.	2028	8.2.6
Lisgar TS	Station capacity will be exceeded due to limiting LV cables and 75 MVA transformer unit (T2).	2028	8.2.7
King Edward TS	Station capacity will be exceeded due to limiting components at LV side. Replacing LV components will add capacity to station.	2026	8.2.8
Nepean TS	Station capacity will be exceeded during winter season.	2030	8.2.9
Riverdale TS	Station capacity will be exceeded due to limiting LV components and 75 MVA transformer units.	2028	8.2.10
Cyrville MTS	Station voltage conversion from 115kV to 230kV to increase station rating.	2028	8.2.11
Moulton MTS	Relocate 50 MVA ,115kV transformers from Cyrville MTS after voltage conversion to increase station rating at Moulton TS.	2028	8.2.12
Marionville DS	Install a second transformer to increase station rating.	2025	8.2.13
Greely DS	Install SCADA transformer fan monitoring	2025	8.2.14
Manotick DS	Load transfer from T1 to T2 at Manotick DS	2025	8.2.15
Hinchey TS	Load to be monitored and necessary actions to be taken as load picks up.	2031	8.2.16
Rockland DS	Install SCADA transformer fan monitoring	2025	8.2.17
Rockland East DS	Install SCADA transformer fan monitoring	2026	8.2.18
Manordale MTS	Load transfers to existing stations	2026	8.2.19

Nepean Epworth MTS	Load transfers to existing stations	2028	8.2.19
Kanata MTS	Load transfers to existing stations	2025	8.2.19
Ellwood MTS	Load transfers to existing stations	2027	8.2.19
Limebank MTS	Load transfers to existing stations	2028	8.2.19
Bridlewood MTS	Load transfers to existing stations	2030	8.2.19
Marchwood MTS	Load transfers to existing stations	2025	8.2.19
Centrepoint MTS	Load transfers to existing stations	2027	8.2.19
Fallowfield MTS	Load transfers to existing stations	2026	8.2.19
Transmission Line Capacity Needs			
M4G/M5G	Uprate Line section between Merivale TS x Carling TS	2030	8.3.1
L2M	Uprate line section between Merivale TS x Limebank JCT	2028	8.3.2
A4K	Continue to monitor the winter load.	2032/33	8.3.3
System Reliability, Operation and Load restoration Needs			
Load Security issue due to contingency of M32S	Provide a second supply to Nepean TS via a new transmission circuit from Merivale TS.	2029	8.4.1
Kanata Area	New Switching Station to improve reliability and flexibility in Kanata Area		8.4.2
Load Security issue due to contingency of M1R+L2M	Install a new breaker at Merivale TS and separate L2M and M1R breaker positions.	2031	8.4.3
Loading and voltage issues on S7M	Continue monitoring load growth and system performance	2032	8.4.4
East Ottawa Area	Supply in East Ottawa Area	2029-2030	8.4.5

8.1 Asset Renewal Needs for Major HV Transmission Equipment

The Asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo.
- Replacing equipment with similar equipment with *lower* ratings and built to current standards.
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement)
- Replacing equipment with higher ratings and built to current standards.

From Hydro One's perspective as a facility owner and operator of its transmission equipment, doing nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

8.1.1 South March TS T1/T2

The existing transformers 50/83 MVA 230/44 kV T1 and T2 at South March TS were originally commissioned in 1971 and based on asset condition assessment, they are identified for replacement in 2031.

A like-for-like replacement of these units would not be adequate in meeting the load during the study period. However, as discussed in Section 8.2, there are station capacity needs in the near term which require upsizing the transformers.

As outlined in the Ottawa area sub-region IRRP and endorsed by the TWG, the recommended solution is to replace the existing transformers with new 75/125 MVA units. This upgrade will ensure adequate capacity and reliability for the growing load in the South March area. Hydro One is working to accelerate the replacement schedule to 2029–2030 to address reliability risks and align with regional planning objectives.

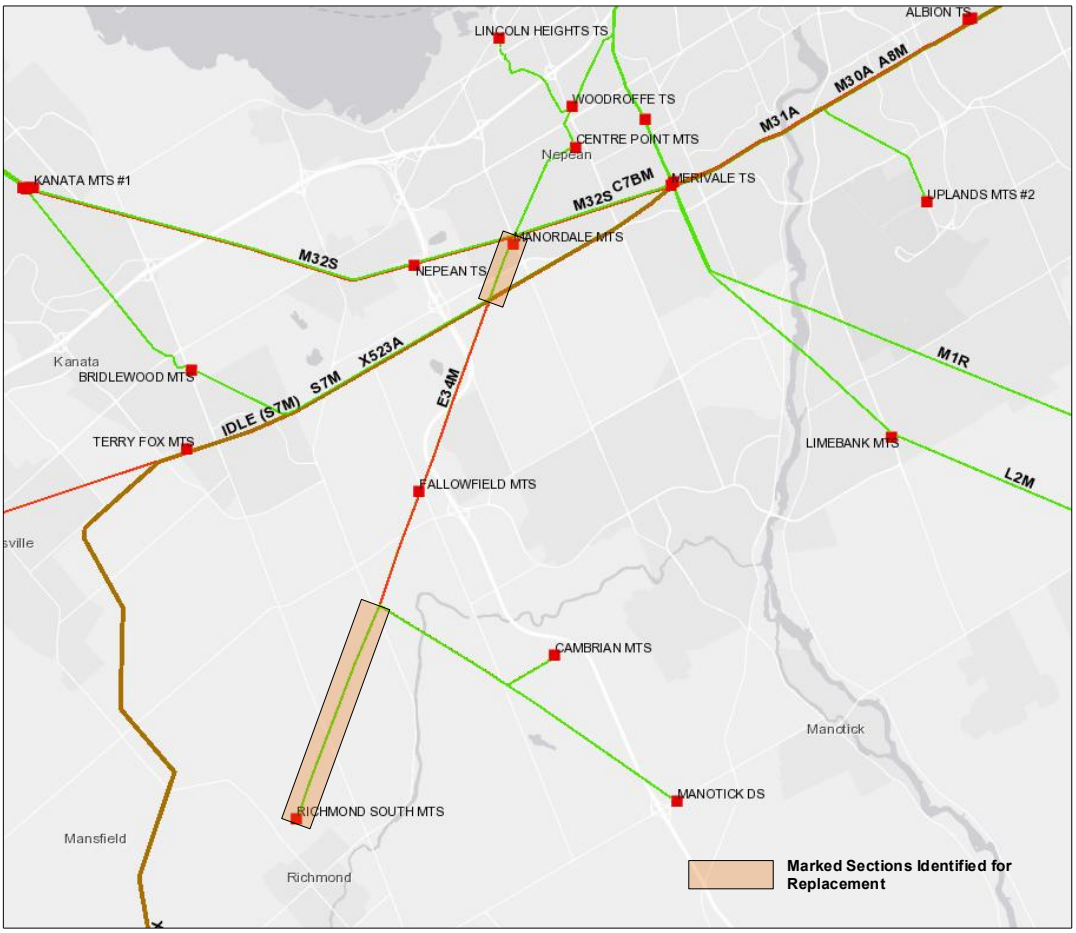
8.1.2 Albion TS T1/T2

Albion TS has two power transformers rated at 45/60/75 MVA, 230 kV / 14 kV / 14 kV, built in 1970. Based on asset condition assessment, these transformers are identified for replacement in 2031.

The 13.8 kV metalclad switchgear installed since 1971 contains six air circuit breakers and two SF6 capacitor bank breakers. The station also has four 13.8 kV conventional SF6 breakers. All circuit breakers require replacement in the near to medium term planning horizon.

The existing transformers at Albion TS will be replaced with new standard 60/80/100 MVA units. These are closest standard size units to the existing transformers. All existing Hydro One owned circuit breakers will be replaced with breakers of similar rating. This alternative would address the asset renewal needs and would maintain reliable supply to customers.

However, as discussed in Section 8.2, additional station capacity will be required in the mid-term, necessitating upgrades at Albion TS.



8.1.3 Nepean TS T3/T4

Nepean TS has two power transformers rated at 75/125 MVA, 230 kV / 14 kV / 14 kV, built in 1970's. Based on asset condition assessment, these transformers are identified for replacement in with like-for-like units as this is the highest rating available, with a planned in-service date of 2034.

8.1.4 S7M Line Refurbishment

Two sections of circuit S7M between Manotick JCT × Richmond MTS (5 km) and S7M STR 673N JCT × Manordale JCT (1.4 km) are identified for replacement as shown in Figure 8-1. These sections are 115 kV predominantly wood pole transmission line that was originally placed in service in 1928. Asset renewal is required on these line sections.

Figure 8- 1: S7M section requiring sustainment highlighted

Two possible options are considered for this line section rebuild:

Alternative 1 - Rebuild H frame wood structures: This alternative would be a like for like rebuild of the existing 5km of 115kV transmission line. This would be adequate to supply the forecasted load at Richmond South MTS. The planned in-service date for this refurbishment is 2030.

Alternative 2 - Upgrade to 230 kV ready operation by rebuilding the 115kV single circuit line as a double circuit 230kV line. This would be similar to upgrade done to S7M for the Cambrian MTS Connection as described in Section 5. This alternative considers possible area conversion to 230kV by making the rebuild ready for the upgrade. This would be in accordance with the long-term plan for the area as described in IRRP.

Recommendation:

The recommended near-term plan is to refurbish these line sections to maintain reliability. However, this line section may also be considered for a configuration change refer to Section 8.4.3. Further discussion will occur as part of bulk system planning.

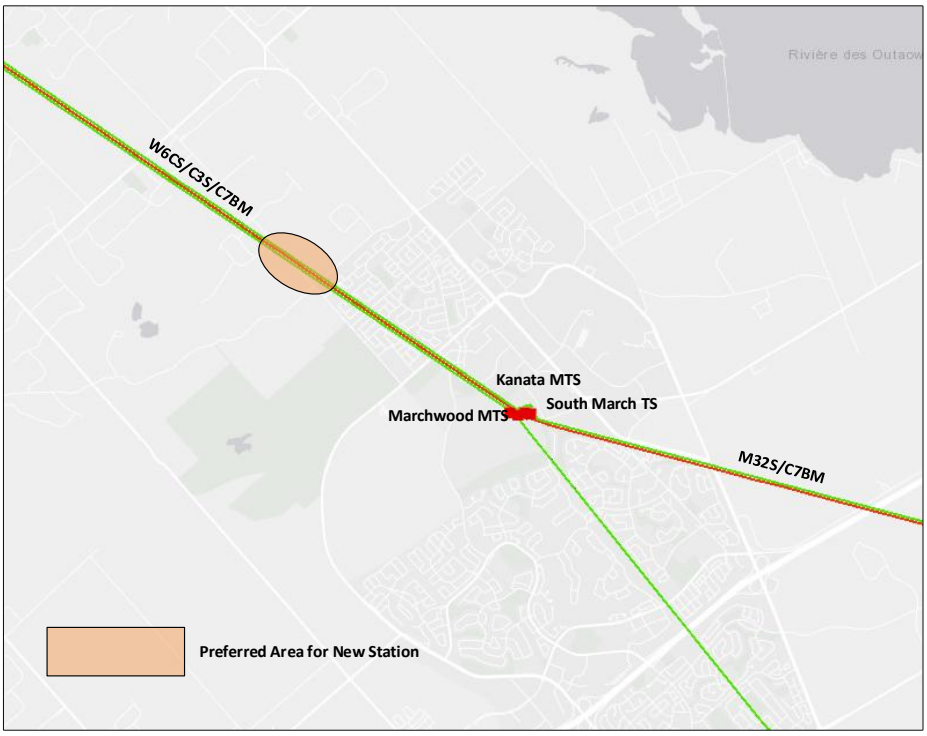
8.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period **2025-2044** for the 230kV and 115kV Transformer stations in the **Greater Ottawa region** using both the summer and winter peak load forecasts that were provided by the study team. This section describes the following capacity needs that have been identified during the study period

To address the station capacity needs, the recommendation of this planning cycle is a combination of new transformer stations and upgrades at existing stations. The new stations are described first, followed by the upgrades considered at the existing stations. The RIP focuses on wire alternatives, however where possible non-wire alternatives are also considered as per the IRRP.

As can be seen in Section 6 Figure 6-1, the area winter load is expected to increase significantly over the study period. The greater Ottawa region has historically been a summer peaking region; however, the region is forecasted to become winter peaking in the near term due to the impact of measures such as electrification and decarbonization. The winter load forecast shows many stations reaching their capacity in the near midterm. Plans have been identified to address these needs and are discussed in this section.

The working group will monitor closely the winter load to track its growth and determine if the forecasted trends materialize in the short term. Many stations are forecasted to go over their transformation capacity and in the long term are expected to far exceed the station LTR. Significant investments will be required at the bulk and regional level to meet this load. Thus, the TWG will monitor the demand in the coming winters and may decide to trigger the next regional planning cycle earlier to address these emerging needs.



Also, please note there are several downtown stations that are recommended for upgrades in similar timeframes. The ISD highlighted in this section is based on preliminary information. Hydro Ottawa and

Hydro One will work together to review the work required and timing for each upgrade to better coordinate the plans. The dates are subject to change based on the review and determination of the preferred path to achieve all the upgrades listed.

8.2.1 Kanata North – Stittsville Area

Significant growth and capacity needs have been identified in Kanata North and Stittsville area. The area is supplied mainly through three transformer stations: Marchwood MTS, Kanata MTS, and South March TS. Based on the load forecast, all 3 stations will reach their LTR in the short term. Hydro One is proceeding with capacity upgrade at South March TS as described in section 8.2.4. However, additional transformation capacity is required and TWG, as part of the IRRP, has recommended building a new station to address this need. Hydro Ottawa has identified preferred location for the station as shown in Figure 8-2 below.

Figure 8-2: Preferred Location of New Station in Kanata North – Stittsville Area

The following alternatives were considered to meet the growth of the area.

Alternative 1: New station supplied from existing single circuit 230kV line.

Build a new station and connect to 230kV circuit C3S as shown in Figure 8-3. The station would have sufficient capacity to address the growth of the area over the study period. However, a single circuit supply would not provide the same level of reliability as the stations in the area currently have. Also, depending on the dispatch of resources and system configuration of the area, the existing system capacity to meet the demand is limited.

Alternative 2: New station supplied from two 230kV circuits.

Build the station as described in Alternative 1 and bring an additional 230kV supply. Please refer to Figure 8-4 below. The new circuit would be extended from M32S at South March TS and would help meet load growth over a wider range of system conditions. The new circuit would make use of the existing right of way by rebuilding one of the 3 circuits as a double circuit line.

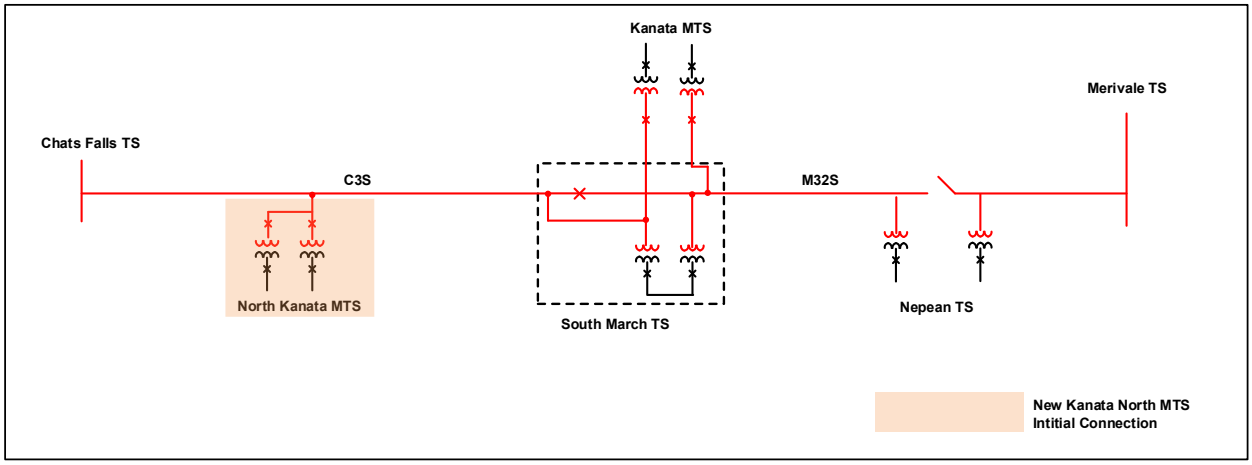
Preliminary review of possible transfers to the new station has been considered and a revised forecast for the stations in the area is shown in Table 8-2.

Table 8-2. Updated summer forecast (MW) with transfers to Kanata North Considered.

	LTR (MW)	2027	2028	2029	2030	2031	2032	2033	2034	2035
Marchwood MTS	32.2	52.9	33.1	34.3	35.3	36.4	37.4	38.7	39.4	39.2
Kanata MTS	51.5	53.8	36.8	36.4	36.2	36.0	35.7	35.6	35.6	35.4
Kanata North MTS	108[1]	0	38	38.4	38.7	39.1	39.4	39.8	40	40.4

[1]Capacity for the new station will be confirmed as the project progresses.

Figure 8-3: Connection of New Kanata North MTS to C3S (initial connection)



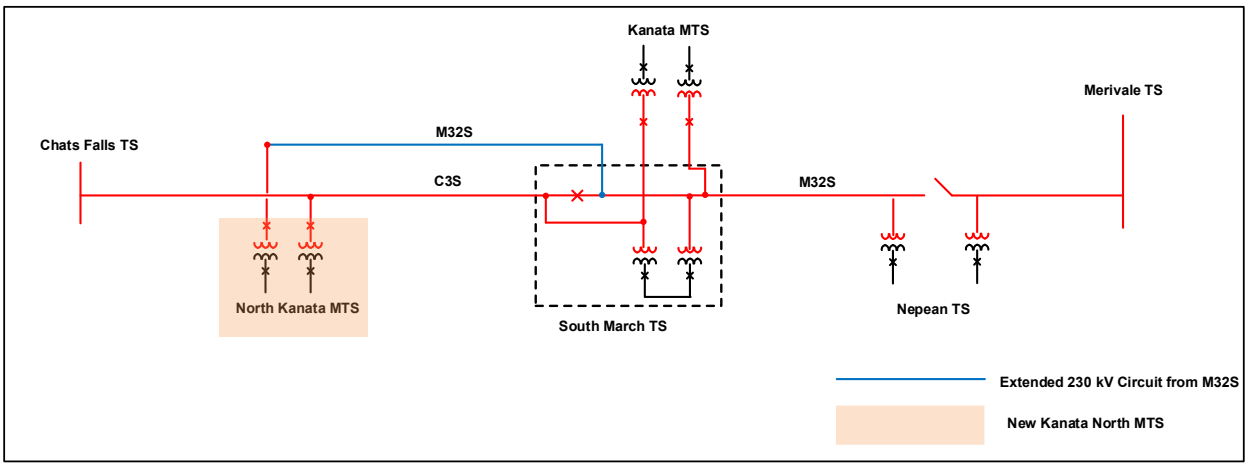


Figure 8-4: Connection of New Kanata North MTS to C3S and New Circuit (recommended alternative)

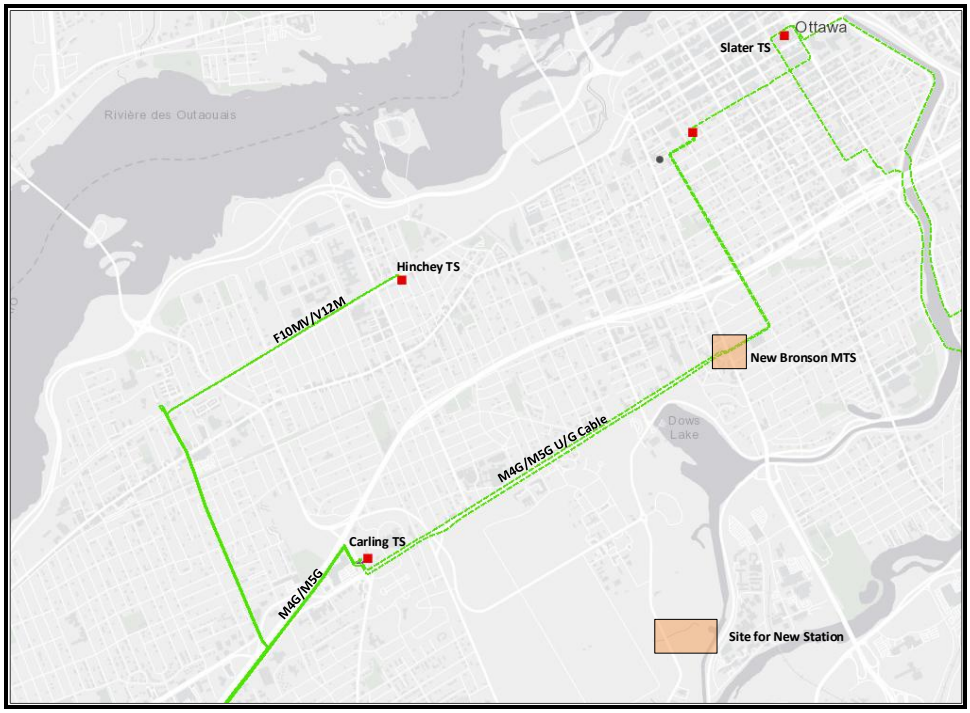


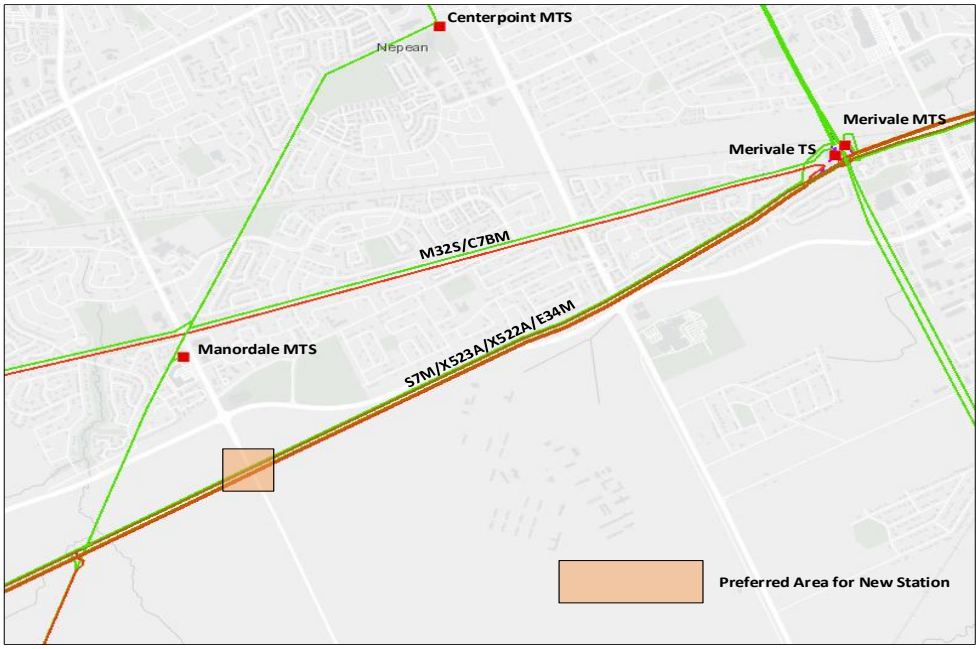
The TWG recommends Hydro Ottawa and Hydro One proceed with Alternative 2. This option will provide the necessary transformation capacity for the area and will provide higher level of reliability by having two circuits supplying the station. Based on the immediate need for transformation capacity, Hydro Ottawa is planning to build the station by 2028. In order to meet this in-service date, the station will be connected initially to existing 230kV circuit C3S only as described in Alternative 1. The second circuit is expected to be completed by 2031.

8.2.2 Bronson MTS

Several stations supplied from the 115kV network in the downtown core have been identified as reaching their capacity in the short term. Upgrading some of these stations is feasible to increase their transformation capacity. However, given the magnitude of the growth expected, additional transformation capacity in the form of a new station is required. Hydro Ottawa has identified a site for a new station: the alternative considered is to convert an existing Hydro Ottawa owned distribution station into a 115 kV DESN. The site of this station is adjacent to an underground cable section of M4G/M5G between Carling TS and Lisgar TS as shown in Figure 8-5.

Figure 8-5: Ottawa Downtown Area Map with new Bronson MTS

This conversion to a 115 kV DESN would increase the transformation capacity of the station. It would also enable load transfers from nearby stations and allow for new developments in Ottawa's Core East area, which is experiencing significant growth driven by urban densification, electrification of heating and transportation, and federal decarbonization initiatives. To note, this option would necessitate uprating circuits M4G and M5G to address thermal limitations, as discussed in Section 8.3 of this report.



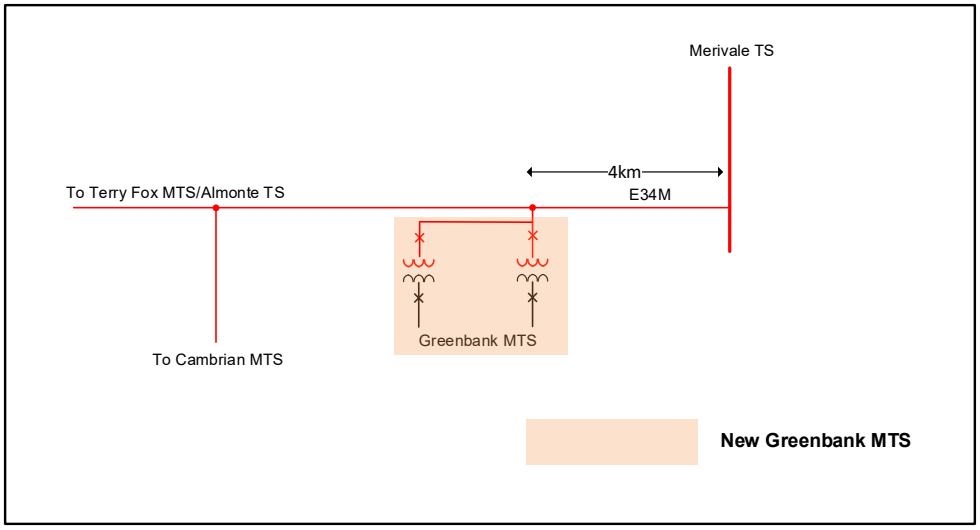
This plan was initially proposed as part of the IRRP. TWG has reviewed the need and proposed solution and reaffirmed the plan as the preferred alternative.

Hydro Ottawa and Hydro One are proceeding into studies to determine how the station will be connected to the existing 115kV underground cables. The proposed in-service date for the station is 2031.

8.2.3 Greenbank MTS

Another area expected to experience high growth is in the west of the city. The existing stations have limited capacity and TWG is recommending a new station to be built to address this need. Hydro Ottawa has identified preferred location for the station as shown in Figure 8-6 below.

Figure 8-6: Preferred Location of New Station in West Ottawa

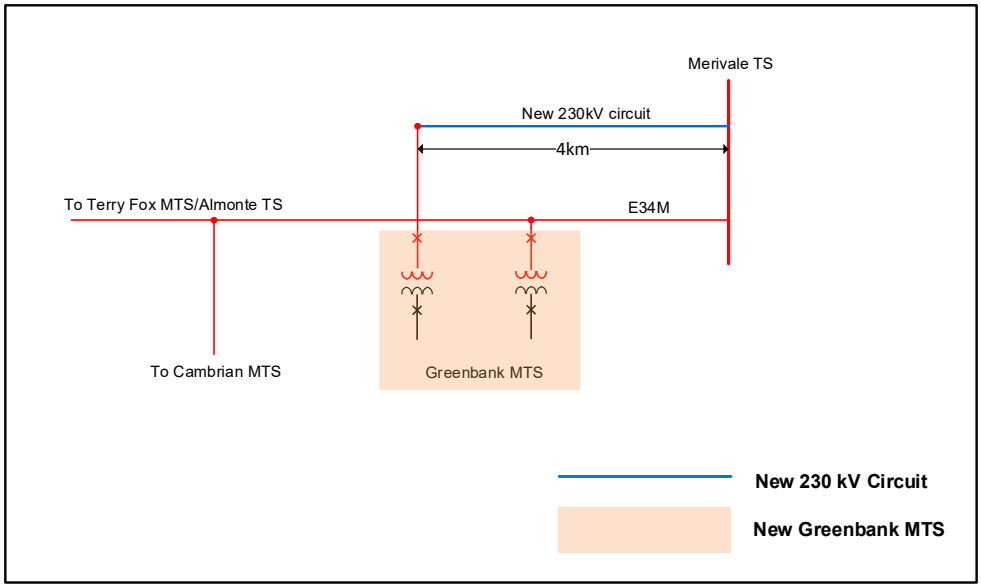


The following alternatives were considered to meet the growth of the area.

Alternative 1: New station supplied from existing single circuit 230kV line.

Build a new station and connect to 230kV circuit E34M as shown in Figure 8-7. The station would have sufficient capacity to address the growth of the area over the study period. However, connection to E34M alone would limit the growth that can be supplied from the station. In addition, the circuit needs to be connected at Merivale TS for the voltage to be acceptable.

Figure 8-7: Connection of New Greenbank MTS to E34M



Alternative 2: New station supplied from two 230kV circuits.

Build the station as described in Alternative 1 and bring an additional 230kV supply. Please refer to Figure 8-8 below. The new circuit would be extended from Merivale along the E34M corridor. The new circuit would alleviate the concerns identified for Alternative 1 and would help meet load growth over a wider range of system conditions.

Alternative 2 was initially proposed as part of the IRRP. TWG has reviewed the need and proposed solution and reaffirms the plan as the preferred alternative.

Hydro Ottawa and Hydro One are proceeding with a project to connect the new station to the 230kV system. Hydro Ottawa's new station is planned for in-service in 2028. The new circuit must be coordinated with the Merivale TS upgrade described in Section 6 and is currently expected for in-service in 2031. Both transformers at the new station will be supplied by circuit E34M as per Alternative 1 until the new circuit is available. Operating measures may be required to help supply the load should there be issues with E34M until the second circuit is available.

Figure 8-8: Connection of New Greenbank MTS to E34M and new circuit

8.2.4 South March TS – T1/T2

South March TS, located in the Kanata–Stittsville area currently served by 230 kV circuits M32S and C3S. The station is equipped with two aging 50/83MVA 230kV/44kV transformers (T1/T2) which, based on their condition, were identified for replacement in 2030–2032 as outlined in Section 8.1.1.

Based on the updated load forecast, South March TS is projected to exceed its summer LTR by approximately 3 MW in 2026 and its winter LTR by about 6 MW in 2028, with the high-growth scenario the need date is 2026 for summer and 2027 for winter. TWG has recommended upgrading the existing

transformers to new 75/125 MVA units. The tentative planned ISD for this upgrade project is scheduled in 2031- 2032. Hydro One is working to expedite the replacement work to 2029-2030 to meet the rising load growth.

In the interim, coordination with LDCs will be required to explore load transfer opportunities to adjacent stations or other operating measures to manage short-term capacity constraints until the transformer replacement is completed should there be any issues at the station.

8.2.5 Albion TS T1/T2

Albion TS is a 230 kV / 14-14 kV DESN station supplied from circuits M30A and M31A. The station's two 75 MVA, 230 kV / 14-14 kV transformers were identified for replacement based on condition assessments. Planned in-service date for this work is 2031(refer to Section 8.1.2).

Based on the load forecast, Albion TS is projected to exceed its winter LTR by approximately 3 MW in 2034, while the summer LTR remains within limits over the study period. Under the high-growth scenario, the need date is 2030 for winter and 2043 for summer.

To address the loading issue, TWG has recommended upgrading the two transformers to standard 100 MVA units, along with the metalclad switchgear upgrade. The tentative in-service date for this upgrade is 2031. A feasibility study will be conducted to determine the preferred option to upgrade the metalclad as the existing installation has space limitations which may restrict the possible upgrade.

8.2.6 Carling TS – T1/T2

Carling TS is a transformer station that steps down voltage from 115 kV to 13.2 kV that is supplied from circuits M4G and M5G. Each transformer is rated at 115/14.2/14.2 kV, 60/80/100 MVA.

Based on the forecasts, Carling TS will exceed its summer LTR by approximately 11 MW and its winter LTR by about 1 MW by 2028. The current capacity limitation is primarily due to the existing series-connected low-voltage (LV) cables which limit the station capacity.

To address this constraint, TWG recommends upgrading the LV cables associated with both transformers as the preferred solution, as it will increase station capacity and eliminate low-voltage limitations. This upgrade project is tentatively planned for an in-service date in summer 2030.

8.2.7 Lisgar TS T1/T2

Lisgar TS is an indoor facility that steps down voltage from 115 kV to 13.2 kV that is supplied from circuits M4G and M5G. Replacement of 75 MVA transformer T1 with a 100 MVA unit was recently completed in December 2025. Following this replacement, the forecasts indicate that the station will exceed its summer LTR by approximately 13 MW and its winter LTR by about 8 MW by 2028. Under the high-growth scenario, the winter need date is advanced to 2027.

The current capacity limitation is primarily due to the existing LV cables and metalclad breakers, which limit the station capacity. To address this constraint and meet future demand, TWG recommends replacing 75MVA transformer T2 with a 100 MVA unit that will match T1 and upgrading the LV cables and metalclad breakers. Based on preliminary review by Hydro One, two options are identified for the station upgrade.

Alternative 1: In-Situ replacement of transformer T2

Under this option, transformer T2 will be replaced at its existing location within Lisgar TS. During the replacement process, the entire station load will temporarily be supplied by transformer T1, which will require careful operational planning to avoid overloading. To facilitate this, Hydro Ottawa will need to implement targeted load transfers to adjacent stations to reduce stress on T1 during the outage. This approach minimizes the need for major civil works and leverages existing infrastructure. The target in-service date for this In-Situ replacement is 2031.

Alternative 2: Greenfield Replacement of transformer T2

If operational constraints or stranded load conditions make it impractical to transfer Lisgar TS load to other stations during the replacement, a greenfield approach will be considered. This involves installing the new transformer at a new location within the station property, which will require extension of the existing building and additional civil works. The target in-service date for this approach is 2034.

A conceptual layout for this greenfield approach is shown in Figure 8-9.

Figure 8-9: Lisgar TS extension under alternative 2

Recommendation:

A feasibility study will be conducted to evaluate both alternatives in detail, considering technical, and operational implications. Hydro Ottawa and Hydro One will review the options following the feasibility

study and decide on the preferred alternative. In the interim, coordination with LDCs will be required to explore load transfer opportunities to adjacent stations to manage short-term capacity constraints until the transformer and component replacements are completed should there be any issues at the station.

8.2.8 King Edward TS

King Edward TS, located in the downtown core of Ottawa, supplies Hydro Ottawa customers. The station is fed by two underground 115 kV cables from A4K and A5RK. The station capacity is limited due to the existing metalclad breakers and LV cables. The forecasts indicate that King Edward TS will exceed its winter LTR by approximately 9 MW as early as 2026 and its summer LTR by about 1 MW in 2033. Under the high-growth scenario, the need dates advance significantly to 2025 for winter and 2030 for summer.

The proposed solution involves upgrading the metalclad breakers and LV cables to increase station capacity and support future downtown demand. This upgrade project is tentatively planned for an in-service date of 2033. In the interim, coordination with LDCs will be required to explore load transfer options to manage short-term capacity limitations until the upgrades are completed should there be any issues at the station.

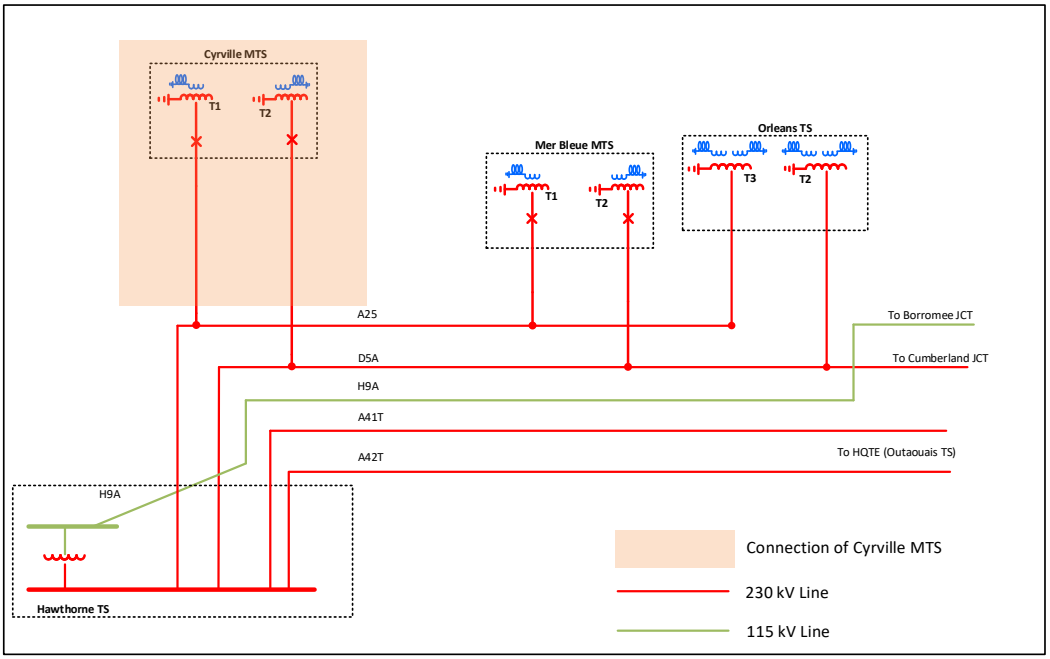
8.2.9 Nepean TS T3/T4

Nepean TS is supplied from 230 kV circuit M32S and steps down voltage to 44 kV for local Hydro Ottawa customers. Regional load forecasts indicate that Nepean TS is expected to exceed its winter LTR by approximately 9 MW in 2030, while summer LTR is projected to remain within limits throughout the study period. Since this need is primarily in the winter timeframe, the TWG recommends monitoring winter load growth and revisiting this capacity need in the next regional planning cycle which can be triggered in advance if load growth is significant.

8.2.10 Riverdale TS T2/T3

Riverdale TS T2/T3 is a 45/75 MVA 115 kV/13.2 kV facility located in downtown Ottawa, supplied by three 115 kV circuits: A5K, A3RM, and A6R. The forecasts indicate that Riverdale TS will exceed its summer LTR by approximately 2 MW in 2030 and its winter LTR by about 9 MW in 2028. Under the high-growth scenario, the summer need date advances to 2029 and the winter need date to 2026.

The station’s transformation capacity is limited due to LV cables. Replacing the LV cables will provide additional capacity, enabling Riverdale TS to support projected load growth and relieve constraints in the Core East area. However, Hydro Ottawa has confirmed that some load transfers to nearby stations are available, which can help manage growth in the foreseeable future. Therefore, TWG recommends monitoring load growth at Riverdale TS and proceed with distribution load transfers as necessary until further upgrades are deemed required.



8.2.11 Cyrville MTS

Cyrville MTS is currently supplied by 115 kV circuits A4K and A2. The forecasts indicate that Cyrville MTS will exceed its summer LTR by approximately 1 MW in 2028 and its winter LTR by about 1 MW in 2030. Under the high-growth scenario, the winter need date advances to 2028.

The current plan as recommended in IRRP is to convert Cyrville MTS from a 115 kV station to a 230 kV station with two 100 MVA transformers by connecting to existing circuit D5A and a new 230 kV circuit A25

from Hawthorne TS, with a tentative in-service date of 2029. The planned conversion of Cyrville MTS will not only address near-term capacity needs but also position the station to accommodate future electrification and resilience requirements for Ottawa's east end. Please refer to Figure 8-10 for the planned connection. Hydro One is working on feasibility study to determine the preferred corridor for the connection of the station to the 230kV in collaboration with Hydro Ottawa.

Figure 8-10: New Cyrville MTS connected to D5A and new A25 circuit

8.2.12 Moulton MTS

Moulton MTS has a LTR of 32 MW in both summer and winter seasons. The forecasts indicate that the station will exceed its summer LTR by approximately 5 MW and its winter LTR by about 6 MW by 2028. To address this need, TWG has recommended to repurpose two 50 MVA, 115 kV transformers from Cyrville MTS following its planned conversion to 230 kV. Relocating these transformers to Moulton MTS will provide additional transformation capacity to meet projected demand growth. This approach leverages existing assets efficiently while supporting reliability in the growing east-end area.

8.2.13 Marionville DS

Marionville DS is forecasted to exceed its summer and winter Planned Loading Limit (PLL) as early as 2025.To address this need, the recommended action is to install a second transformer rated at 20 MVA and construct approximately 4.2 km of new distribution feeder to integrate the additional capacity. The tentative in-service date for this upgrade is December 2029. In the interim, Hydro One Distribution will manage load growth through transfers to nearby stations to maintain reliability until the new transformer and feeder build are completed.

8.2.14 Greely DS

Greely DS is projected to reach its summer and winter PLL in 2025. To address this the recommended action is to install SCADA fan monitoring for transformers T1 and T2 (115 kV to 28 kV). This upgrade will enable fan monitoring and allow higher ratings for both transformers, increasing their capacity from 23 MVA to 38 MVA in summer time and 28 MVA to 43 MVA in winter. The planned in-service date for SCADA fan monitoring is scheduled for 2026.

8.2.15 Manotick DS

Manotick DS has a summer PLL of 8.6 MVA and a winter PLL of 11.6 MVA. This PLL considers the loss of one transformer. Load forecasts indicate that the station will exceed these limits in both summer and winter starting in 2025.

Hydro One Distribution has operating measures to deal with station load in the near and medium term should one of the transformers fail such as use of Mobile Unit Substation (MUS)

Other measures such as Scada fan monitoring can be considered and will be reviewed as a part of next regional planning cycle.

8.2.16 Hinchey TS

Load forecasts indicate that Hinchey TS is expected to exceed its winter LTR by approximately 2 MW in 2031, while summer LTR is projected to remain within limits throughout the study period. Since this need is primarily in the winter timeframe. TWG is recommending monitoring winter load growth and revisiting this capacity need in the next regional planning cycle which can be triggered in advance if load growth is significant.

8.2.17 Rockland DS

Rockland DS is forecasted to reach its summer PLL in 2025, TWG recommends the implementation of SCADA monitoring of transformer fan. This will increase the summer PLL to 14.4 MVA and alleviate the overload at station. The planned in-service date for the fan monitoring installation is 2026.

In the interim, LDCs will implement operational measures, to manage loading and maintain system reliability until the permanent solution is in place.

8.2.18 Rockland East DS

Rockland East DS is forecasted to reach its summer PLL in 2026. TWG recommends the implementation of SCADA monitoring for transformer fans. The planned ISD for the fan monitoring installation is 2027.

In the interim, LDCs will implement operational measures to manage loading and maintain system reliability until the permanent solution is in place.

8.2.19 Additional Transformation Capacity needs

Several stations in the Greater Ottawa area are forecasted to exceed their LTR within the study period. The following summarizes the anticipated capacity needs:

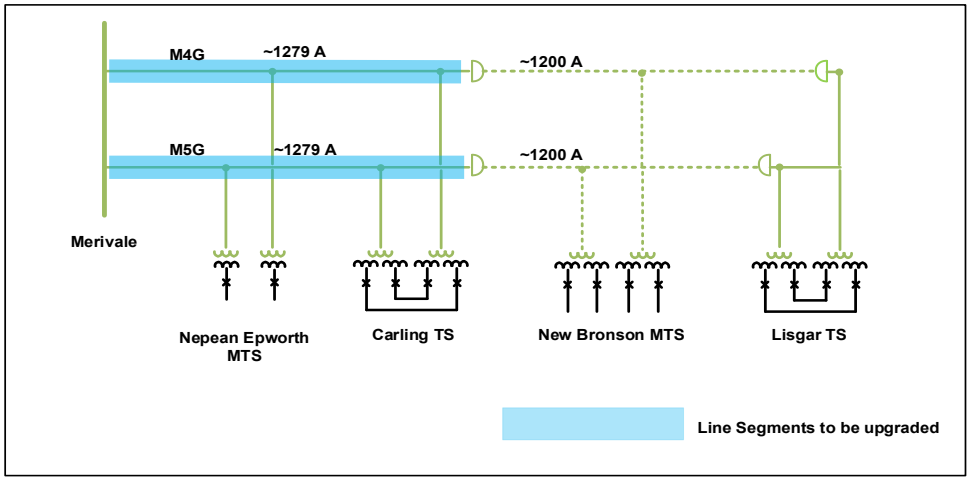
- Nepean Epworth MTS – Expected to exceed its LTR in 2028 (winter) and 2035 (summer).
- Kanata MTS – Projected to exceed its summer and winter LTR in 2025.

- Ellwood MTS – Forecasted to exceed its summer and winter LTR in 2027.
- Limebank MTS – Expected to exceed its LTR in 2028 (winter) and 2031 (summer).
- Bridlewood MTS – Projected to exceed its LTR in 2030 (winter) and 2035 (summer).
- Marchwood MTS – Anticipated to exceed its summer and winter LTR in 2025.
- Centrepoint MTS – Expected to exceed its LTR in 2027 (winter) and 2032 (summer).
- Manordale MTS – Forecasted to exceed its LTR in 2026 (winter and summer).
- Fallowfield MTS – Projected to exceed its LTR in 2030 (winter) and 2026 (summer).

Hydro Ottawa has confirmed that loading at these stations can be managed through operational load transfers to nearby stations in the near term. Additionally, the commissioning of new stations—Kanata North MTS, Mer Bleue MTS, Greenbank MTS, Bronson MTS and Piperville MTS—will allow permanent load shifts, providing long-term relief to these stations and addressing regional capacity needs.

8.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period **2025-2044** for the 230kV and 115kV Transmission line circuits in the **Greater Ottawa region** by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater to this need. Based on the results, the following line capacity needs have been identified during the study period:



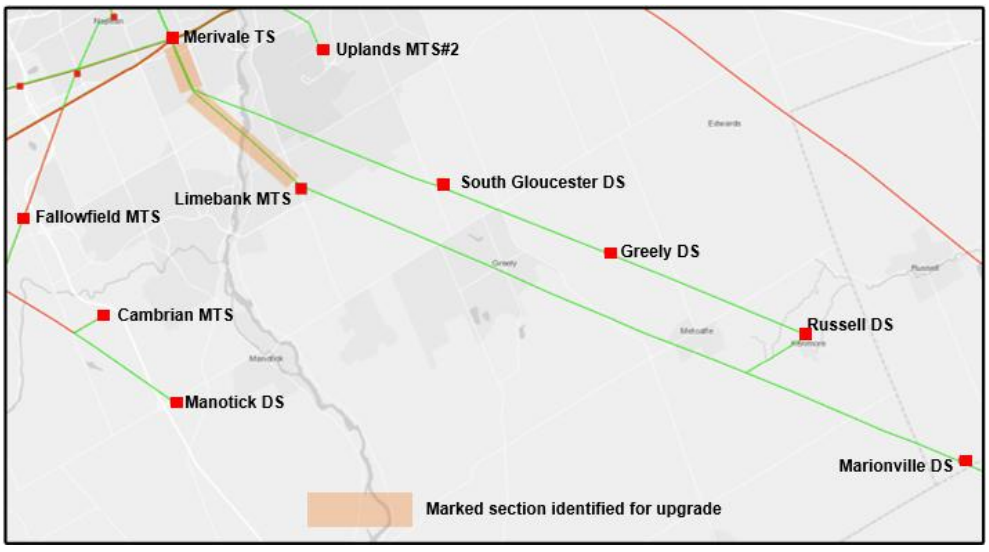
8.3.1 M4G/M5G – 115 kV – Section Uprate

The M4G and M5G circuits, which supply Nepean Epworth MTS, Carling TS and Lisgar TS, are forecasted to experience thermal constraints under contingency conditions as downtown Ottawa load continues to grow. When one circuit is out of service, the remaining circuit would be required to fully supply all stations, resulting in thermal overload conditions. Based on the regional load forecast, this limit is expected to be reached in the summer of 2030 and in the winter of 2032.

To address this issue, the recommended action is to upgrade sections of M4G and M5G between Merivale TS and Carling TS to remove thermal constraints and support higher downtown load.

Based on studies, this load pocket can supply about 360 MW before voltage issues arise. Hydro One will consider different conductor options to meet this load. The feasibility of using ACSS (Aluminum Conductor Steel Supported) conductor options will be explored to provide sufficient capacity while maintaining reliability.

Figure 8-11: Uprate Section from Merivale TS to Carling TS



Regional planning emphasizes that downtown Ottawa is a critical load pocket with limited space for new infrastructure, making reinforcement of existing transmission corridors essential. Since Bronson MTS is also planned as a new station to relieve downtown capacity constraints, uprating the M4G/M5G corridor is a key enabler for this project and for supporting long-term growth in the Core East area.

8.3.2 L2M – 115 kV – Uprating Merivale TS x Limebank MTS

Thermal constraints have been identified on the L2M transmission line section between Merivale TS and Limebank MTS, which supplies Limebank MTS and Marionville DS as shown in Figure 8-12. These constraints are primarily driven by the increasing load forecast at Limebank MTS, as identified in the regional planning load forecast. The section of L2M has a summer rating of 93 MVA (477 A) and based on the study results, the 7.8km line section between Merivale TS and Limebank MTS is expected to reach its thermal capacity limit in the near term by 2028.

Figure 8-12: Uprate Section from Merivale TS to Limebank MTS

Alternative 1 - Remove sag limitation

The rating of circuit L2M between Merivale TS and Limebank MTS is currently limited due to clearance concerns. This option looks to increase the thermal capacity of L2M by addressing the conductor's sag issue. Hydro One has previously reviewed the work necessary to remove the limitation and has determined that approximately 3.2km of the line section would have to be rebuilt in addition to modification to some existing towers and insulators where no rebuilding is required. This work would remove the clearance limitation and would allow the circuit capacity to be increased to approximately 106MW in summer and 131 MW in winter. This allows us to meet the demand up to the mid-term.

Alternative 2: Rebuild the circuit

This alternative would look at rebuilding the 7.8km circuit L2M between Merivale TS and Limebank MTS to increase the circuit's thermal rating. Two options were considered.

> **Alt 2a:** This option would rebuild the existing 7.8km as a single circuit 115kV line. It would address the thermal rating constraint currently on the circuit and would be adequate to supply the forecasted load of Marionville DS and Limebank MTS. However, with this option, Limebank MTS and Marionville DS would remain on a single circuit supply.
>
> **Alt 2b:** This option would rebuild the existing 7.8km as a double circuit 115kV line. Similar to Alternative 2a, this option would address the thermal rating issue. This option would also help improve the reliability of supply to Limebank MTS by providing a second supply to the station.

Recommendation

TWG recommends uprating L2M to support the south-end growth and align with recommendations for proactive reinforcement of critical transmission corridors. A feasibility study will be done after which Hydro One and LDCs will review the different options. The selected alternative will follow the recommendation to uprate the section of L2M from Merivale TS to Limebank MTS, with a tentative in-service date of 2032.

8.3.3 A4K – 115 kV

Hawthorne TS x Overbrook TS section

Under the winter peak forecast for 2032, thermal overload has been identified on a critical section of the A4K corridor, specifically between Hawthorne TS x Overbrook TS, under the contingency of either circuit A5RK or A6R. When either of the circuits are out of service, the resulting increased loading on A4K is beyond its thermal capability.

Overbrook TS x King Edward TS section

This section is an underground cable section, and it exceeds its capacity due to King Edward TS being overloaded beyond the capacity described in section 8.2. If the station load is to increase as per the winter forecast, the upgrades to the station (beyond what is described in section 8.2) would have to be done in coordination with upgrades to cables.

TWG has reviewed the overload scenarios, and the recommended approach is to monitor load growth of the stations on A4K over the coming years. As demand continues to increase, TWG will reassess the situation and develop an appropriate action plan, which may include options such as reconductoring, circuit upgrades, or alternative reinforcement strategies to ensure compliance with thermal limits and maintain system reliability.

8.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, and to provide a median-economic forecast for an extended period with any one transmission element out of service. A study has been performed, considering the net load forecast and the loss of one element over the study period 2025-2044 to cater for this need**.** Based on the results, the following system reliability, operating and restoring issues have been identified for this Region.

8.4.1 Load Security issue due to contingency of M32S

Nepean TS currently relies on a single 230 kV transmission supply circuit (M32S) from Merivale TS to South March TS. Under an M32S contingency, the entire load at Nepean TS would be lost due to configuration. According to ORTAC criteria, load security requires that no more than 150 MW of load can be lost for a single element contingency. While this limit is not exceeded in the summer forecast, it is projected to be reached in the winter forecast by 2029, when Nepean TS's peak demand is expected to surpass 150 MW. This creates a load security concern, as an outage of M32S would result in a full load loss, violating ORTAC requirements.

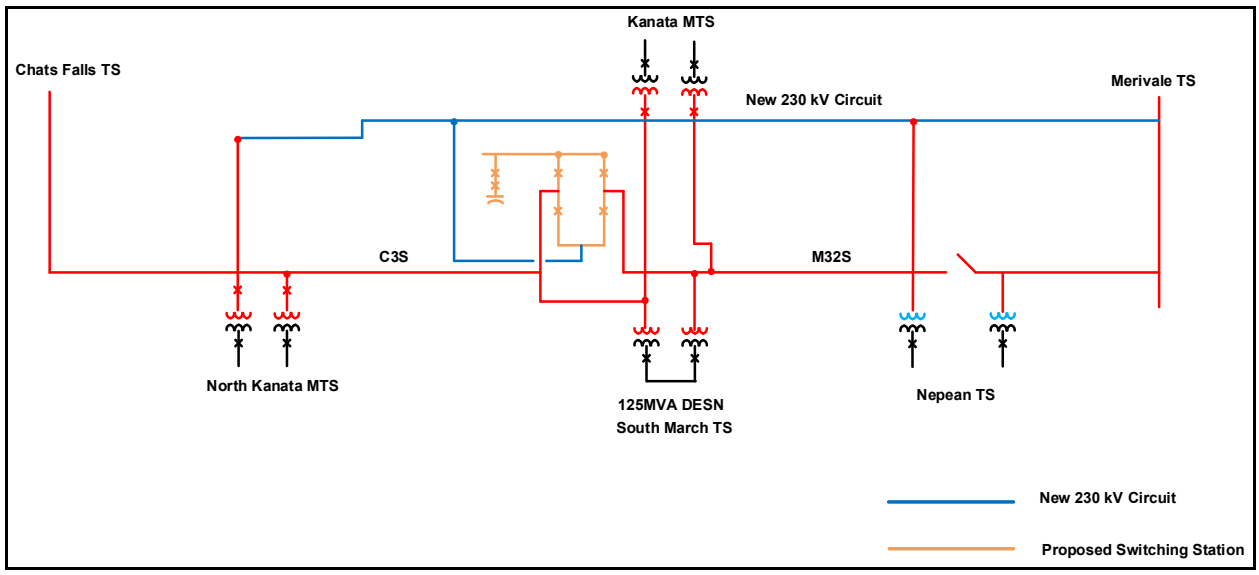
To address this issue, the recommended plan includes providing Nepean TS with a second transmission supply circuit originating from Merivale TS. This will ensure compliance with ORTAC and enhance the station reliability. The timing of this plan will be determined based on ongoing load monitoring and coordination with the Merivale TS upgrade project.

8.4.2 New Switching Station to improve reliability and flexibility in Kanata Area

As discussed in Section 8.2, one of the recommended plans includes the development of a new 230 kV Kanata North MTS, which will initially connect to the existing 230 kV circuit C3S. To enhance reliability, a second supply will be brought from M32S. This second supply will be enabled by rebuilding one of the existing transmission lines in the C7BM/C3S/W6CS corridor to double circuit 230kV line, thus connecting M32S to the new Kanata North MTS.

With the addition of Kanata North MTS and potential load transfers from Marchwood MTS and Kanata MTS, the summer and winter load forecasts were preliminary revised for the stations in the Kanata area as shown in Tables 8-3 below.

Table 8-3: Updated summer and winter load forecast (in MW) with preliminary transfers to Kanata North Considered



SUMMER											
Station	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038
KANATA MTS	37	36	36	36	36	36	36	35	36	36	36
NEPEAN TS	127	128	128	128	128	128	128	129	129	130	131
SOUTH MARCH TS	112	112	114	122	121	122	126	127	128	129	130
Kanata North MTS	38	38	39	39	39	40	40	40	41	41	41
Load in 230 kV area	314	314	317	325	324	325	330	331	333	336	338
WINTER											
	2028	2029	2030	2031	2032	2033	2034	2035	2036	2037	2038
KANATA MTS Revised	49	50	52	54	57	59	61	63	65	67	69
NEPEAN TS	148	159	169	176	184	191	198	205	214	223	231
SOUTH MARCH TS	119	124	132	143	147	151	158	162	168	173	179
Kanata North MTS	38	38	39	39	39	40	40	40	41	41	41
Load in 230 kV area	354	371	392	412	427	440	457	471	488	504	520

Analysis of contingencies on the 230 kV system indicates that stations supplied by these circuits can reliably support up to 340 MW of load while maintaining system performance. This threshold is expected to be reached under the summer forecast by 2038 and under the winter forecast as early as 2028.

To address this emerging constraint, the current strategy is to monitor winter load growth closely while advancing plans for a new switching station in the Kanata area. This switching station will facilitate flexible interconnections among Chats Falls TS, Merivale TS, South March TS, Nepean TS, and the new Kanata North MTS, thereby providing support for additional capacity, operational flexibility, and improved resiliency for the regional network. The conceptual layout of this switching station and its integration into the transmission system is illustrated in Figure 8-13.

The line that is planned from Merivale to Nepean as described in section 8.4.1 can be extended to the new switching station.

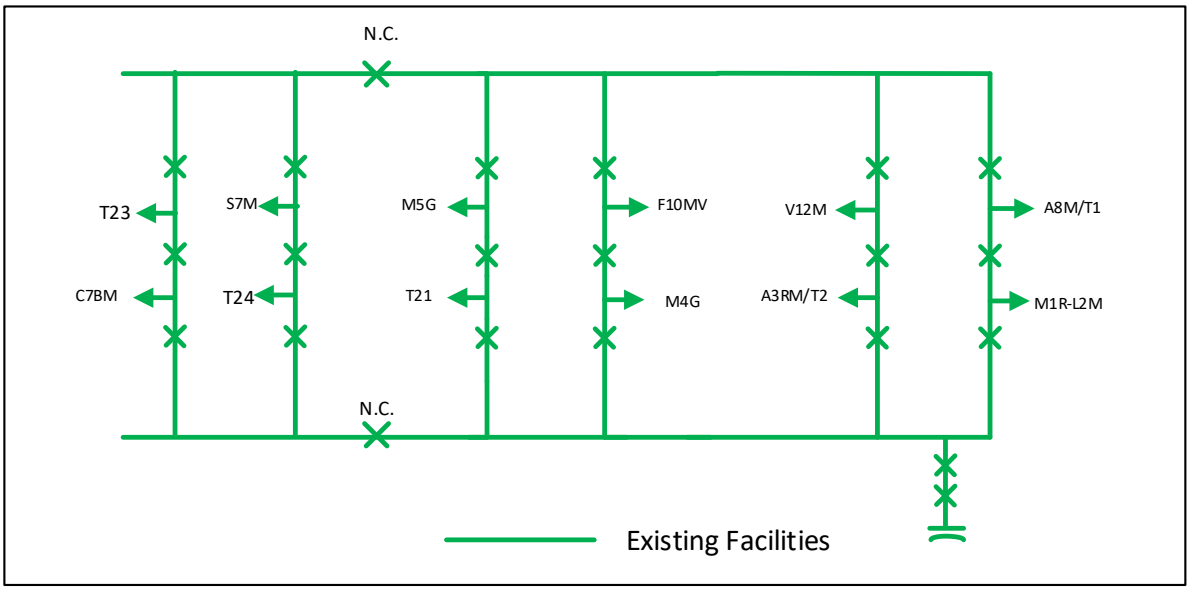
Figure 8-13: Proposed new 230 kV Line along with Switching Station

8.4.3 Load Security issue due to contingency of M1R+L2M

Merivale TS currently supplies two 115 kV circuits, M1R and L2M, which share a common breaker position. This configuration creates a common-mode outage risk: the loss of either circuit results in both circuits being tripped. Under ORTAC criteria, load security requires that no more than 150 MW of load can be lost for a single element contingency. While this limit is not exceeded in the summer forecast until 2040, it is projected to be reached in the winter forecast by 2031. This creates a load security concern, as an outage of either circuit would result in a full loss of supply to connected stations, violating ORTAC requirements.

To address these issues and improve reliability, the plan includes installing a new breaker at Merivale TS to separate circuits M1R and L2M into two independent 115 kV paths. This will eliminate the common-mode outage risk and ensure compliance with ORTAC load security criteria. The timing of this plan is driven by the emerging winter load security need, with a targeted in-service date of 2032. This solution also supports long-term thermal performance and operational flexibility. Figure 8-14 shows the 115 kV yard at Merivale TS following completion of Merivale TS upgrade project and Figure 8-15 shows the split M1R/L2M configuration that will be providing a separate breaker position for each line.

Figure 8-14: 115 kV Merivale TS after Merivale TS upgrade project



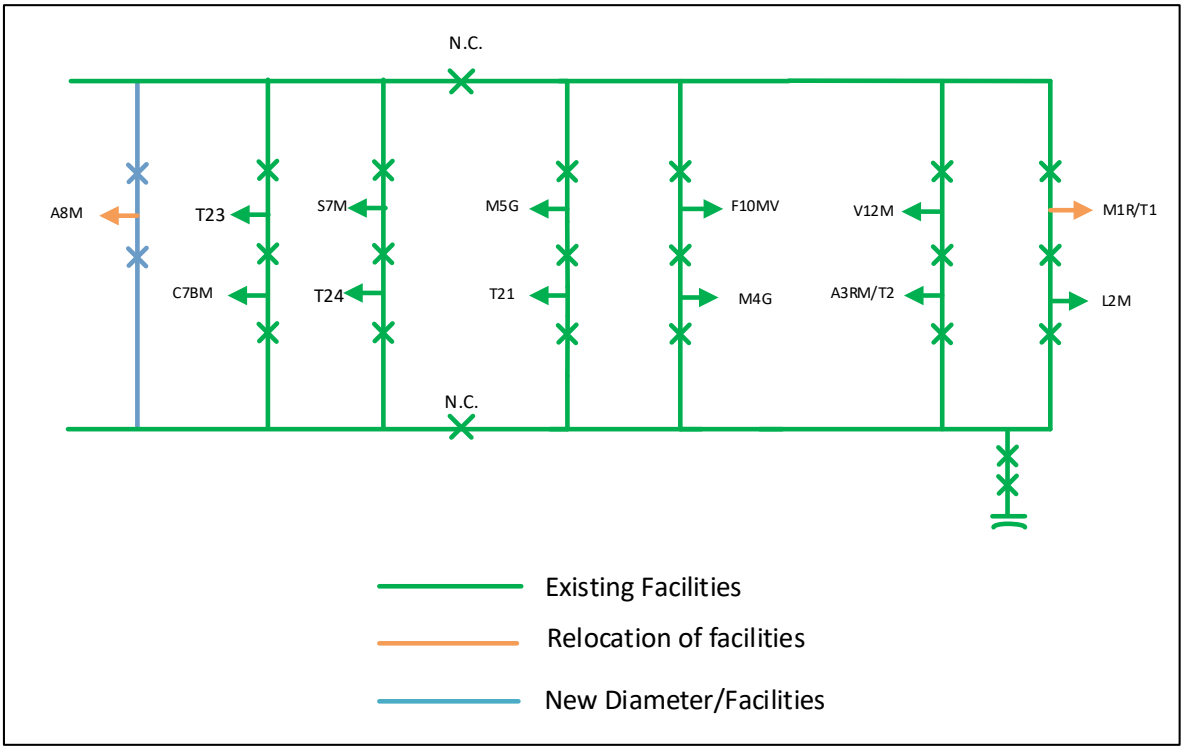


Figure 8-15 Different breaker positions of M1R and L2M

8.4.4 Loading and Voltage issues on S7M

Under the medium-term planning horizon, there is a limitation on the amount of load that can be transferred from Cambrian MTS to S7M under the contingency of E34M. This constraint arises due to both loading and voltage performance issues observed on S7M when additional load from Cambrian MTS is transferred to it during contingency conditions.

To address these challenges, several options are being considered. One potential solution is the planned conversion of S7M to 230 kV, which would significantly improve its capacity and voltage performance under contingency scenarios. Another option is to explore reactive power (VAR) support as load continues to grow, which could help maintain acceptable voltage levels and system stability. At this stage, the recommendation is to continue monitoring load growth and system performance, and to review the needs as part of the next cycle of regional planning. Ongoing bulk study may make recommendations that could impact the area, such as 230kV conversion.

8.4.5 Supply to East Ottawa

In the previous regional planning cycle, the recommended plan for the East Ottawa area included refurbishment of Bilberry Creek TS and the addition of two new feeder breakers. While the Greater Ottawa regional planning process was inactive, new information related to load growth and system conditions prompted a re-evaluation of the supply plan. In 2023, the TWG reviewed updated growth expectations for the area, the sustainment need at Bilberry Creek TS, and the capability of the 115 kV system to support future growth. Based on this review, TWG agreed to revise the recommendations for the area.

TWG's revised plan and new recommendation includes three components.

Retirement of Bilberry Creek TS

The TWG recommends retiring Bilberry Creek TS due to aging infrastructure and associated sustainment requirements. The revised approach shifts supply for the area away from continued reinvestment at Bilberry Creek TS resulting in removing load from 115 kV system and instead transitioning the connected load to the 230 kV system to support longer-term capacity and system reliability.

Upgrade at Orleans TS

As part of this approach, Orleans TS will be upgraded from dual supply 230/27.6 kV and 115/27.6 kV to 230/27.6 kV DESN. This upgrade includes a new 230 kV circuit A25 between Hawthorne TS and Orleans TS (~11km). The planned in-service date for the Orleans TS upgrade and the A25 circuit is June 2029.

Connection of new Mer Bleue MTS

The revised plan also includes the connection of a new Hydro Ottawa station, Mer Bleue MTS, to the 230 kV system. Mer Bleue MTS will be connected to 230 kV circuits D5A approximately 10 km east of Hawthorne TS, with a planned in-service date of July 2027. The project is also planned to connect to circuit A25 with an expected in-service date of June 2029.

This new recommendation provides the following benefits:

i. Addresses the Limited growth available on the 115kV system. The Ottawa 115kV system is mainly supplied via 250MVA autotransformers at Hawthorne TS and Merivale TS. East Ottawa 115kV system is connected to Hawthorne TS and most of its supply is from the station's autotransformers. These autotransformers are heavily loaded and limit the growth that can supplied from 115kV. Installing additional autotransformers at the station will be very challenging due to space constraints and short circuit level considerations. As such removing load from the 115kV system and transferring it to the 230kV wherever possible, helps preserve the current capacity on the 115kV to address the growth at existing stations that cannot be converted to 230kV at reasonable cost. This Project helps by reducing the 115kV loading and transferring the load to 230kV.

ii. The Project avoids significant refurbishment work at the station as the load can be transferred onto the 230kV system and Bilberry Creek TS can be retired instead of refurbished. In addition, there is also limited growth available at Bilberry Creek even if the station is refurbished.

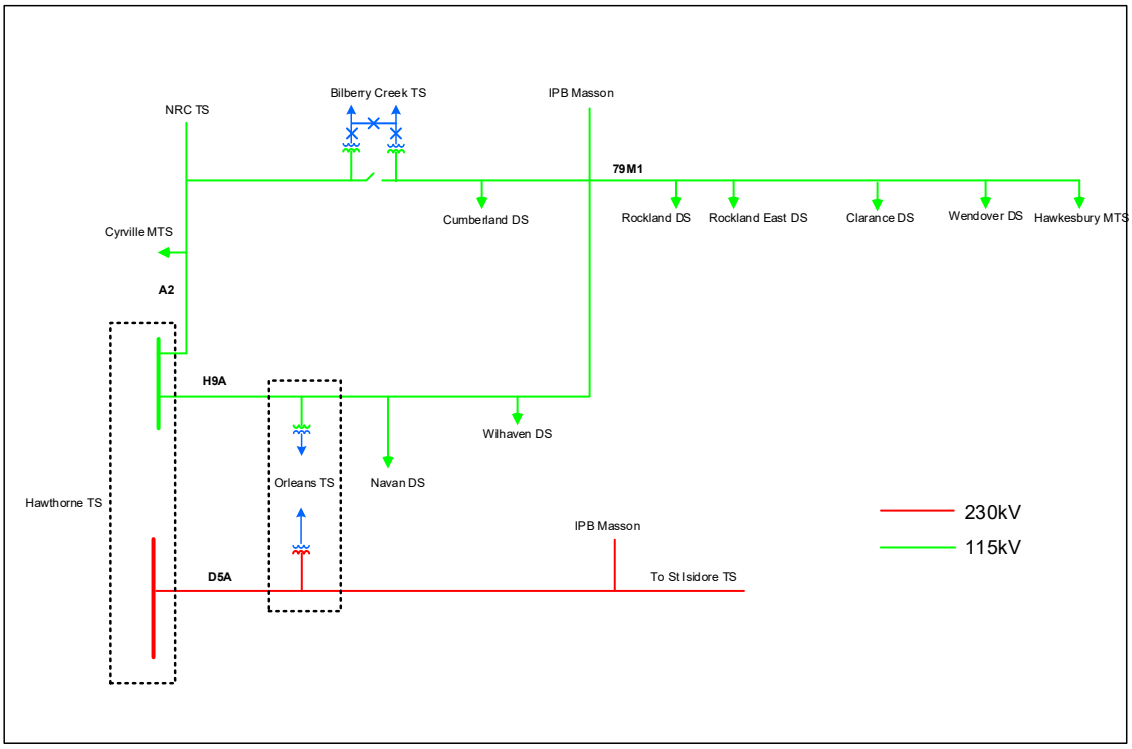
iii. Orlean TS will no longer be subject to momentary interruptions due to its configuration.

iv. The new 230kV circuit will allow more growth and improve supply reliability in the Orleans area. Currently connection on the 230 kV in the Orleans area will have to be limited to 100 MW. With the new circuit the area can support over 300 MW.

The RIP concludes that retiring Bilberry Creek TS, upgrading Orleans TS, and completing the associated 230 kV circuit and station connections is the most cost-effective option to address the long-term needs in East Ottawa. This combined set of projects is being pursued as an alternative to the sustainment and upgrade work at Bilberry Creek TS that was recommended in the previous regional planning cycle.

From a reliability perspective, the revised plan reduces dependence on aging station equipment, increases supply robustness by serving the area from the higher-capacity 230 kV network, and improves operational flexibility during planned outages or contingencies by enabling better load restoration options across the East Ottawa supply area.

Figure 8-16 Existing Orleans Area



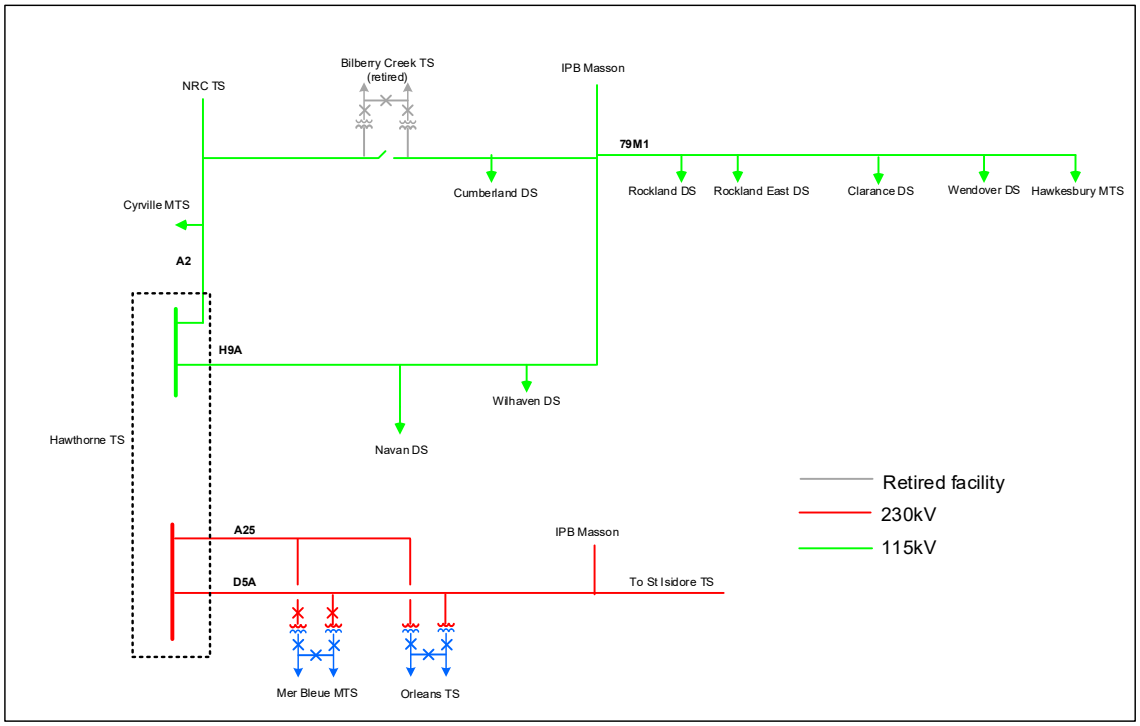


Figure 8-17 Orleans Area after Upgrade

9. CONCLUSION AND RECOMMENDATION

This section concludes the Regional Infrastructure plan Report for the Greater Ottawa region. The Major Infrastructure investments recommended by the TWG in the near and mid-term planning horizon 2025-2044 are provided in Table 7 below, along with their planned in-service dates (ISD) and budgetary estimates for planning purposes.

Table 9: Recommended Plans over the next 10 Years

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Budgetary Cost ($M)
Asset Renewal Needs				
South March TS	Replacement of T1/T2 transformers with upgraded units based on asset conditions and capacity needs.	Hydro One	2029	$40M
Albion TS	Replacement of T1/T2 transformers with upgraded units based on asset condition and capacity needs.	Hydro One	2031	$60M
Nepean TS	Replacement of T3/T4 transformers based on asset condition	Hydro One	2034	$30M
S7M	Refurbishment of line section between Manotick JCT x Richmond South MTS and S7M 673N x Manordale JCT	Hydro One	2030	$5M
Station Capacity Needs				
South March TS	Replacement of T1/T2 transformers with upgraded units based on asset conditions and capacity needs.	Hydro One	2029	$40M
Carling TS	Replacement of limiting LV cables.	Hydro One	2030	$10M

Lisgar TS	Replacement of T2 transformer and LV cables/breakers - Greenfield	Hydro One	2034	$50M
	Replacement of T2 transformer and LV cables/breakers – In Situ	Hydro One	2031	$30M
King Edward TS	Replacement of LV cables and breakers.	Hydro One	2033	$20M
Cyrville MTS	Station voltage conversion from 115kV to 230kV to increase station rating and upgrade station transformation capacity.	Hydro One/ Hydro Ottawa	2029	$85M*
Moulton MTS	Relocate 50 MVA ,115kV transformers from Cyrville MTS after voltage conversion to increase station rating at Moulton TS.	Hydro Ottawa	2029	$5M
Bronson MTS	Build a new 115kV Transformer Station east of Carling TS by converting existing Bronson distribution station	Hydro One/ Hydro Ottawa	2031	$110M*
Greenbank MTS	Build new Transformer Station to meet demand growth and need for 28kV supply west of Merivale TS.	Hydro One/ Hydro Ottawa	2028	$100M*
Kanata North MTS	Build a new Transformer Station by connecting 230 kV C3S and new transmission line from South March TS	Hydro One/ Hydro Ottawa	2028	$100M*
Marionville DS	Install a second transformer to increase station rating.	Hydro One Dx	2029	$12M*
Greely DS	Install Scada Fan monitoring to increase transformer rating.	Hydro One Dx	2026	$2M*

Rockland DS	Install Scada Fan monitoring to increase transformer rating.	Hydro One Dx	2026	$2M*
Rockland East DS	Install Scada Fan monitoring to increase transformer rating.	Hydro One Dx	2027	$3M*
Transmission Line Capacity Needs				
M4G/M5G	Uprate Line section between Merivale TS x Carling TS	Hydro One	2030	$30M
L2M	Uprate line section between Merivale TS x Limebank JCT	Hydro One	2032	$30M
System Reliability, Operation and Load restoration Needs				
Kanata Area	Kanata Area Transmission Reinforcement	Hydro One	2033	$250M
Nepean TS – Load Security Criteria	Second 230 kV Supply to station	Hydro One	2032	$70M
M1R+L2M	Split Breaker position for M1R and L2M at Merivale TS	Hydro One	2032	$45M
East Ottawa Area	Supply to East Ottawa	Hydro One	2029-2030	$165M*

* These investment costs include associated distribution system costs.

Note:

a) The planned in-service dates are tentative and subject to change.
b) Costs are high-level planning estimates and actual costs may vary.

Disclaimer

This Regional Infrastructure Plan ("RIP") report is an electricity infrastructure plan to identify and address near and long-term based on information provided and/or collected by the Study Team.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Study Team.

Study Team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH PARTICIPATION AND INPUT FROM THE RIP STUDY TEAM IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE PLANNED, DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE GTA EAST REGION.

The participants of the Regional Infrastructure Planning ("RIP") Study Team included members from the following organizations:

- Elexicon Energy Inc.
- Oshawa PUC Networks Inc.
- Independent Electricity System Operator (IESO)
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Lead Transmitter)

The last regional planning cycle for the GTA East Region was completed in January 2017 with the publication of the RIP report.

This RIP is the final phase of the 2nd regional planning cycle and follows the 2nd Cycle GTA East Region's Needs Assessment ("NA") in August 2019. Based on the findings of the NA, the Study Team recommended no further regional coordination is required at this time. Hence, RIP is based on the recommendations of NA report.

This RIP provides a consolidated summary of the outcome of the needs and recommended plans for the GTA East region as identified by the regional planning study team. The RIP also discusses needs identified in the previous regional planning cycle and the Needs Assessment report for this cycle; and the projects developed to address these needs. Implementation plans to address some of these needs are already completed or are underway. Since the previous regional planning cycle, following projects have been completed:

- Enfield TS: 75/100/125 MVA transformation capacity in Oshawa-Clarington sub-region (Completed in 2019)

The major infrastructure investments recommended by the Study Team over the near- and mid-term are provided in below Table 1, along with their planned in-service date and budgetary estimates for planning purpose.

Table 1: Recommended Plans in GTA East Region over the Next 10 Years

No.	Needs	Plans	Planned I/S Date	Budgetary Estimate ($M)
1	Increase Transformation Capacity in Pickering-Ajax-Whitby Sub-region	Build Seaton MTS	2021	43
2	Cherrywood TS – 230kV & 500kV Breaker Replacements (multi-phase projects)	Replace 230 kV and 500 kV Air Blast Circuit Breakers (ABCB) at Cherrywood TS	2027	184
3	Cherrywood TS – LV DESN Switchyard Refurbishment	Existing 44kV DESN switchyard replacement at Cherrywood TS	2025	12
4	Wilson TS – T1, T2 and Switchyard Refurbishment	Existing T1, T2 and 44 kV BY bus switchyard replacement	2022	36

The Study Team recommends:

- Continue with the investments listed in Table 1 while keeping the Study Team apprised of project status.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE GTA EAST REGION BETWEEN 2019 AND 2029.

The report was prepared by Hydro One Networks Inc. ("Hydro One") with input from Study Team members during the NA phase and documents the results of the Needs Assessments and recommended plan. RIP Study Team members included representative from Elexicon Energy Inc. ("Elexicon"), Oshawa PUC Networks Inc. ("OPUCN"), Hydro One Distribution, and the Independent Electricity System Operator ("IESO") in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The GTA East Region comprises the municipalities of Pickering, Ajax, Whitby, Oshawa, Clarington, and Durham area. Electrical supply to the GTA East Region is provided through 500/230kV autotransformers at Cherrywood Transformer Station (TS) and Clarington TS and five 230 kV transmission lines connecting Cherrywood TS to Eastern Ontario. There are five Hydro One step-down transformer stations and three other direct transmission connected load customers. The distribution system is at two voltage levels, 44kV and 27.6kV. The boundaries of the GTA East Region are shown below in Figure 1-1.

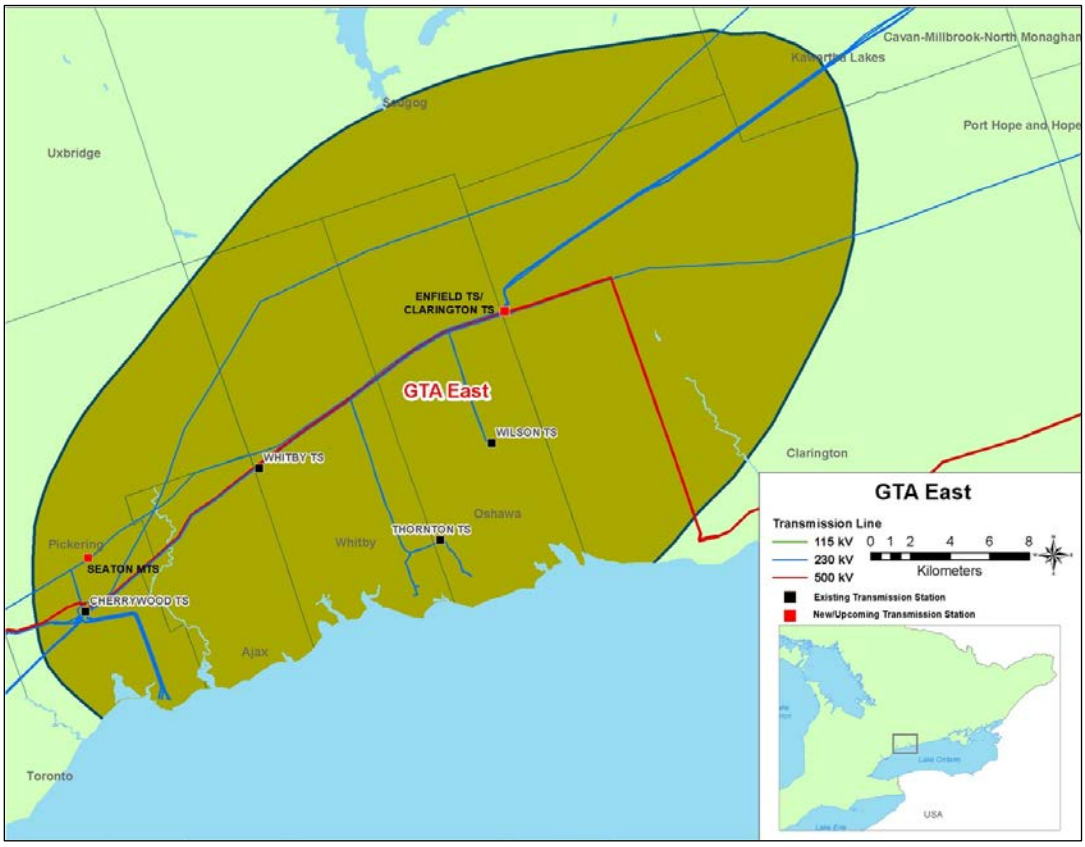

Figure 1-1: GTA East Region

1.1 Objective and Scope

The RIP report examines the needs in the GTA East Region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs;
- Identify any new needs that may have emerged since previous planning phases e.g., Needs Assessment ("NA") and/or Integrated Regional Resource Plan("IRRP");
- Assess and develop a wires plan to address these new needs; and
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, major high voltage sustainment issues emerging over the near, mid and long-term, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- Discussion of any other major transmission infrastructure investment plans over the near, mid and long-term (0-20 years)
- Identification of any new needs and a wires plan to address these needs based on new and/or updated information, if any.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the regional characteristics.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies needs.
- Section 7 discusses the needs and provides the alternatives and preferred solutions.
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Study Team determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region.

[1] Also referred to as Needs Screening

The RIP phase is the fourth and final phase of the regional planning process and involves: discussion and reconfirmation of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and/or LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect.
- The NA, SA, and LP phases of regional planning.
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.
- Working and planning for connection capacity requirements with the LDCs and transmission connected customers.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

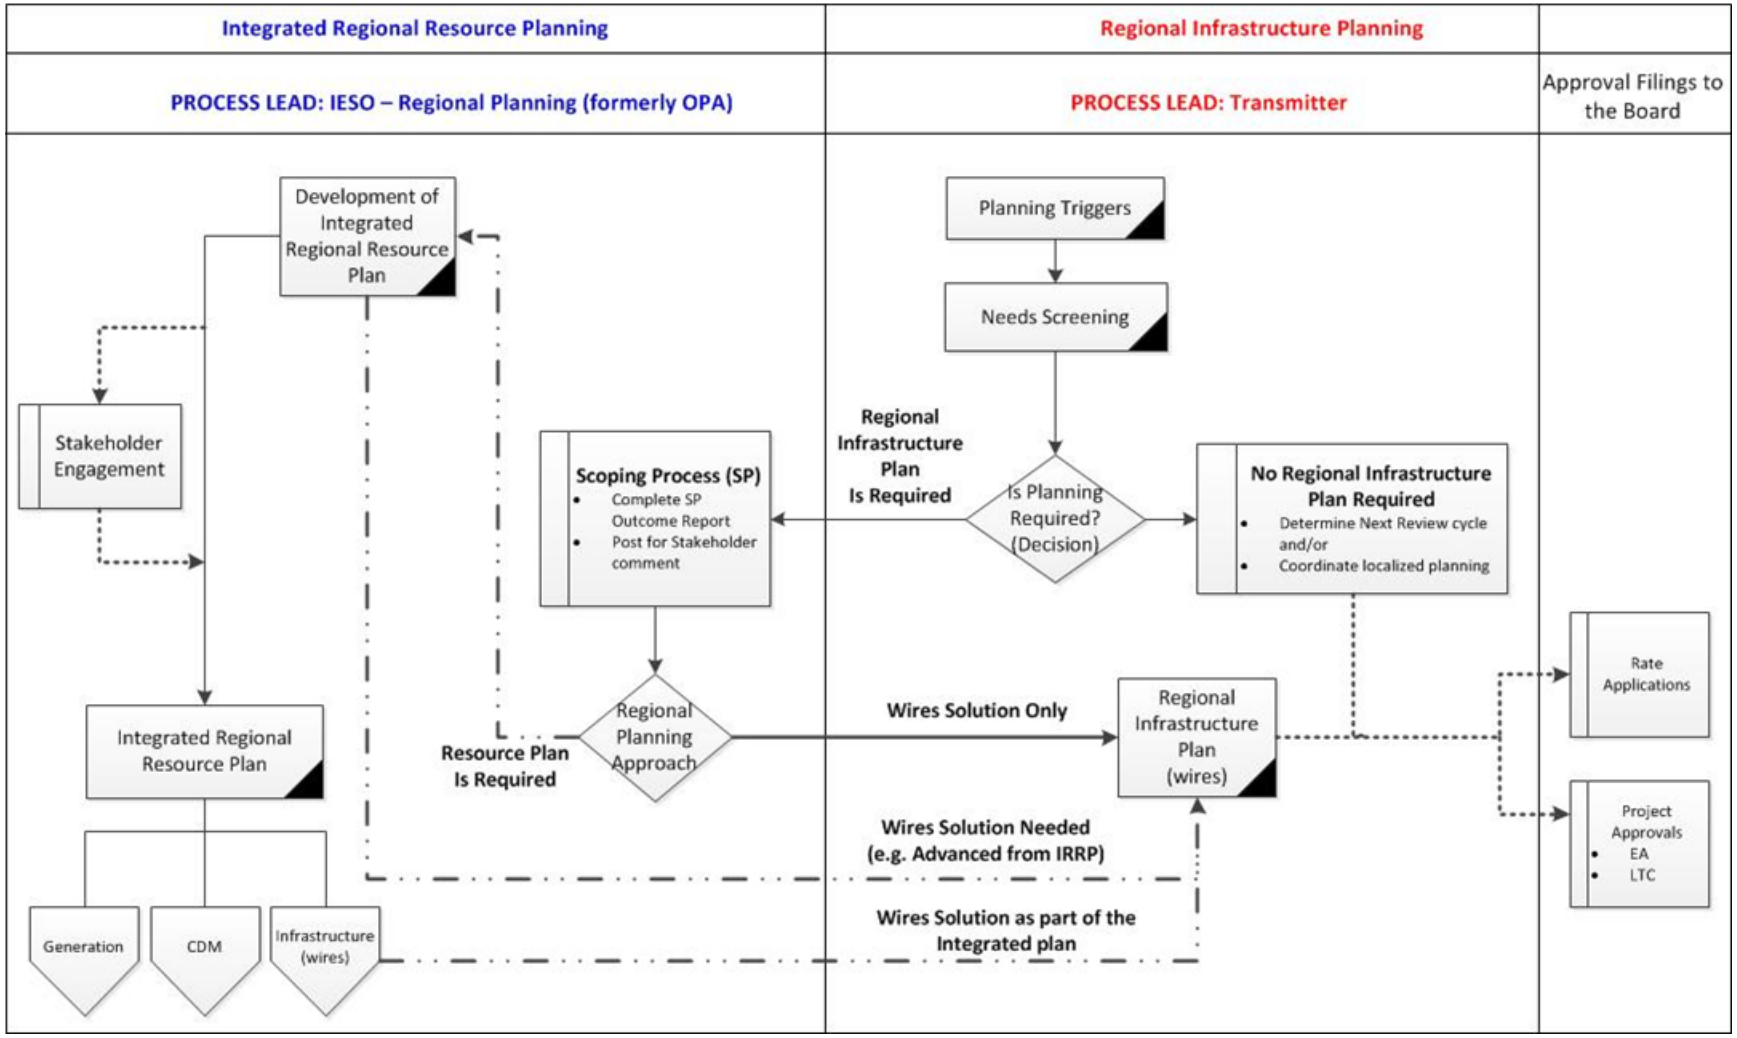

Figure 2-1: Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous phase of the regional planning process. Hydro One collects this information and reviews it with the Study Team to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Depending upon the changes to load forecast or other relevant information, regional technical assessment may or may not be required or be limited to specific issue only. Additional near and mid-term needs may be identified in this phase.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

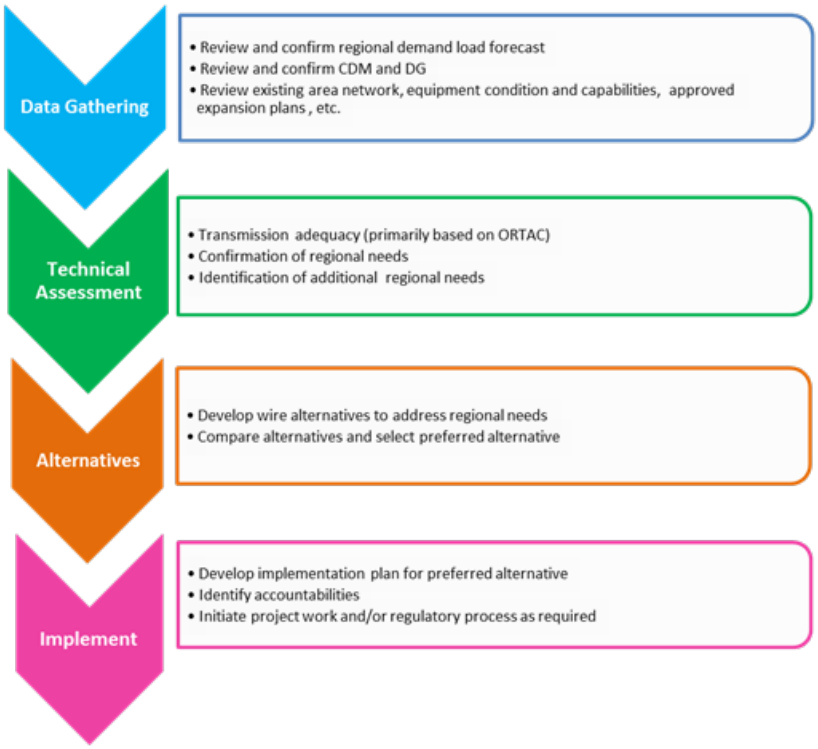

Figure 2-2: RIP Methodology

3. REGIONAL CHARACTERISTICS

THE GTA EAST REGION IS COMPRISED OF THE PICKERING-AJAX-WHITBY SUB-REGION AND THE OSHAWA-CLARINGTON SUB-REGION. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM FIVE 230KV STEP-DOWN TRANSFORMER STATIONS.

Bulk electrical supply to the GTA East Region is currently provided through Cherrywood TS and Clarington TS, two major 500/230kV autotransformer station in the region, and five 230kV circuits emanating east from Cherrywood TS. Five local area step-down transformer stations and three other direct transmission connected load customers are connected to the 230 kV system in the region. Major generation in the area includes the Pickering Nuclear Generating Station ("NGS") which consists of six generating units with a combined output of approximately 3000 MW and is connected to the 230kV system at Cherrywood TS.

The August 2019 GTA East Region NA report, prepared by Hydro One, considered the entire GTA East Region. For simplicity, this report divides GTA East Region into two sub-regions, Pickering-Ajax-Whitby Sub-region and Oshawa-Clarington Sub-region, as described below.

3.1 Pickering-Ajax-Whitby Sub-region

The Pickering-Ajax-Whitby Sub-region comprises primarily the City of Pickering, Town of Ajax, part of the Town of Whitby, and part of the Townships of Uxbridge and Scugog. It is supplied by Cherrywood TS, a 500/230kV autotransformer station, two 230kV transformer stations, namely Cherrywood TS DESN and Whitby TS (2 DESNs), that step down the voltage to 44kV and 27.6kV. The LDCs supplied in the Sub-region are Hydro One Distribution, and Elexicon.

The Pickering-Ajax-Whitby Sub-region transmission facilities are shown in Figure 3-1.

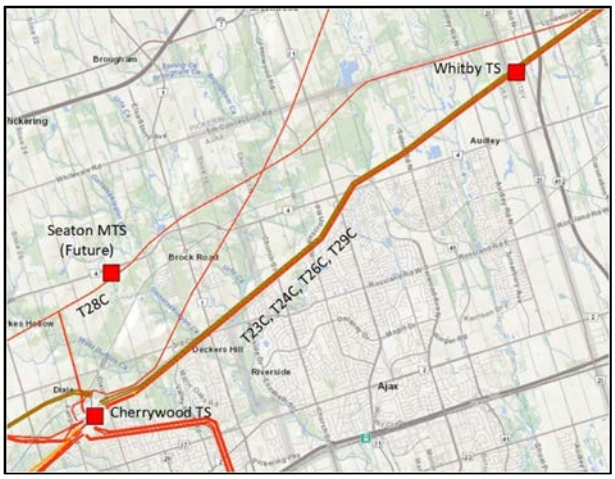

Figure 3-1: Pickering-Ajax-Whitby Sub-region

3.2 Oshawa-Clarington Sub-region

The Oshawa-Clarington sub-region comprises primarily the City of Oshawa, part of the Municipality of Clarington, part of Whitby, and part of the Township of Scugog. It is supplied by Cherrywood TS, a 500/230kV autotransformer station to the west, two 230kV transformer stations, namely Wilson TS (2 DESNs) and Thornton TS, that step down the voltage to 44kV at distribution level. The sub-region also includes three direct transmission connected load customers. Local generation in the area consists of the 60 MW Whitby Customer Generating Station ("CGS"), a gas-fired cogeneration facility that connects to 230kV circuit T26C. Thornton TS also supplies some load within the Pickering-Ajax-Whitby sub-region. The LDCs supplied in the sub-region are Elexicon, Hydro One Distribution, and OPUCN.

A new 500/230kV autotransformer station in the GTA East Region within the township of Clarington, Clarington TS, went into service in 2018. The new Clarington TS provided additional load meeting capability in the region and will eliminate the overloading of Cherrywood autotransformers that may result after the retirement of the Pickering NGS in the near future.

The new autotransformer station consists of two 750MVA, 500/230kV autotransformers and a 230kV switchyard. The autotransformers will be supplied from two 500kV circuits that pass next to the proposed site. The 230kV circuits supplying the east GTA will be terminated at Clarington TS. Clarington TS will become a major supply source for the GTA East Region load.

A new 230/44kV transformer station, Enfield TS, was in-serviced in March 2019. The transformer station provided relief to overloading at Wilson TS and supplies Hydro One Distribution and Oshawa PUC. The station is located inside the Clarington TS yard and is directly connected to the Clarington TS 230 kV bus.

The Oshawa-Clarington Sub-region transmission facilities are shown in Figure 3-2.

Figure 3-2: Oshawa-Clarington Sub-region

A single line diagram of the GTA East Region transmission system is shown in Figure 3-3.

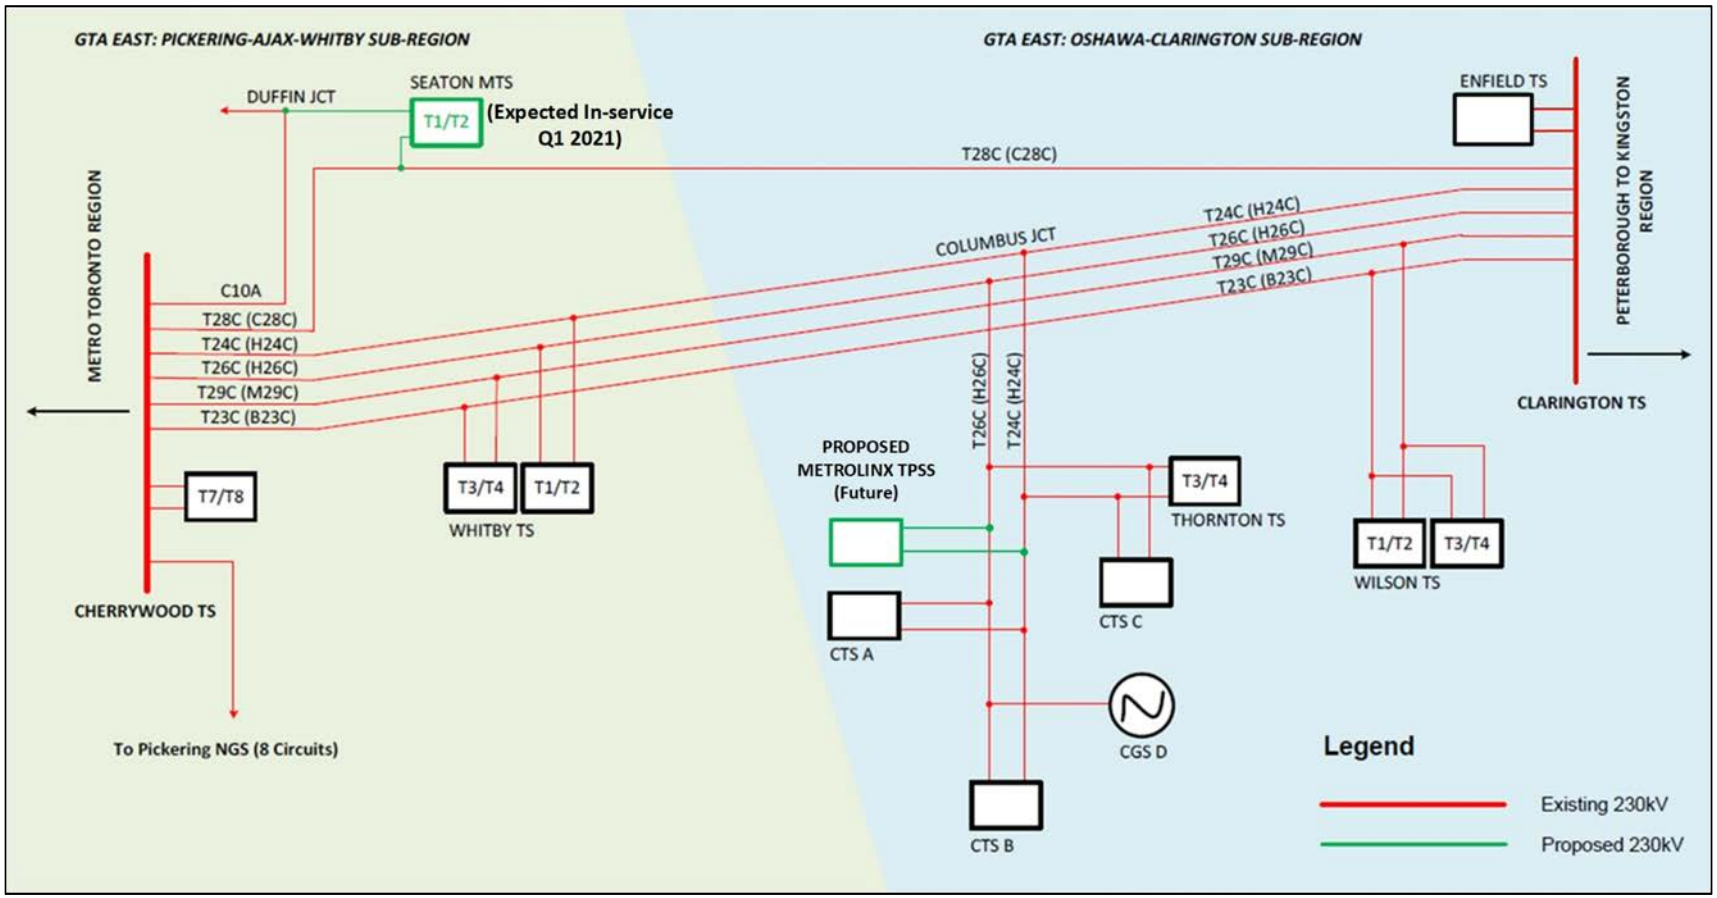

Figure 3-3: Single Line Diagram of GTA East Region

4. TRANSMISSION PROJECTS COMPLETED OVER LAST TEN YEARS

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, IN CONSULTATION WITH THE LDCs AND/OR THE IESO, AIMED TO MAINTAIN OR IMPROVE THE RELIABILITY AND ADEQUACY OF SUPPLY IN THE GTA EAST REGION.

A summary and description of the major projects completed and/or currently underway over the last ten years is provided below.

- Whitby TS T1/T2 (2009) – built a new step-down transformer station supplied from 230kV circuits T24C and T26C in municipality of Whitby to increase transformation capacity for Elexicon requirements.

- Wilson TS T1/T2 DESN1 (2015) – installed LV neutral grounding reactors to reduce line-to ground short circuit fault levels to facilitate DG connections.

- Thornton TS T3/T4 (2016) – replaced end-of-life transformers. Also installed LV neutral grounding reactors to reduce line-to-ground short circuit fault levels to facilitate DG connections.

- Clarington TS (2018) – built a new 500/230kV autotransformer station to increase transmission supply capacity to the GTA East Region, eliminate the overloading of Cherrywood TS autotransformers that may result after the retirement of Pickering NGS, and improve supply reliability to the Region.

- Enfield TS (2019) – built a new 230/44kV transformer station to provide relief for Wilson TS and for future load growth in Oshawa-Clarington sub-region.

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

Figure 5-1 shows the GTA East Region's summer peak coincident and non-coincident load forecast. The non-coincident load forecast was used to determine the need for station capacity and the coincident load forecast was used to assess need for transmission line capacity in the region.

The load forecasts for the region were developed using the summer 2018 actual peak adjusted for extreme weather and applying the station net growth rates provided by the LDCs. The load in the GTA East Region is expected to increase at an annual rate of approximately 2.8% between 2019 and 2029. The gross and net non-coincident and coincident load forecast, adjusted for extreme weather, CDM, and DG, for each station in the region are provided in Appendix D and E.

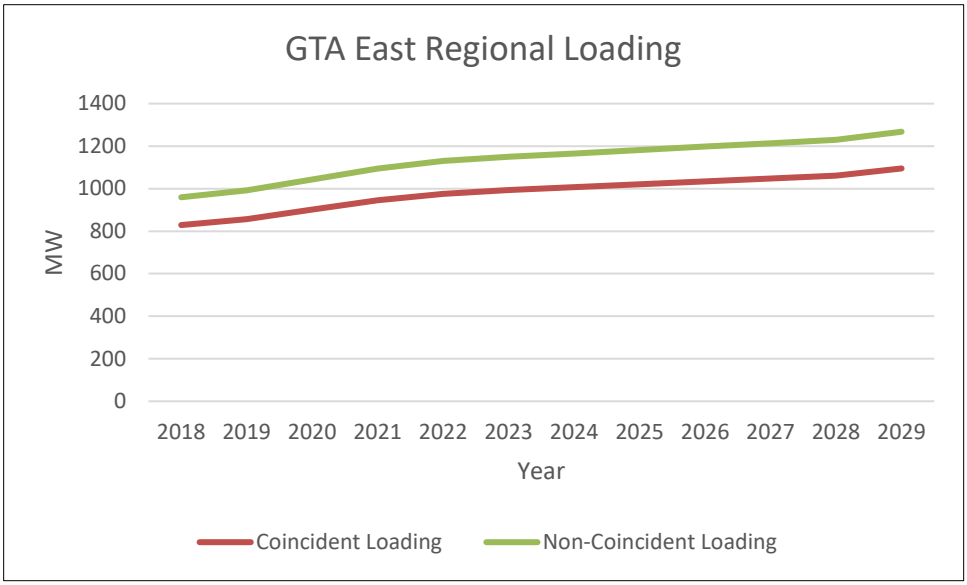

Figure 5-1 GTA East Region Net Load Forecast

5.2 Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2019-2029.
- All facilities listed in Section 4 are in-service.
- Where applicable, industrial loads have been assumed based on historical information.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
- Line capacity adequacy is assessed by using coincident peak loads.
- Normal planning supply capacity for transformer stations in this sub-region is determined by the Hydro One summer 10-Day Limited Time Rating (LTR).
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).
- Metrolinx plans to connect a Traction Power Substation (TPSS) to Hydro One's 230 kV circuits T24C and T26C in East Whitby. The Metrolinx TPSS loads have not been included in the forecast as the timing is uncertain and the loads do not impact the need or timing of new facilities.

6. ADEQUACY OF FACILITIES

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND DELIVERY STATION FACILITIES SUPPLYING THE GTA EAST REGION OVER THE 2019-2029 PERIOD.

Within the current regional planning cycle one regional assessment have been conducted for the GTA East Region. The study is shown below:

1) 2019 GTA East Needs Assessment (NA) Report

The NA report identified a number of needs to meet the forecast load demands and EOL asset issues. A review of the loading on the transmission lines and stations in the GTA East Region was also carried out as part of the RIP report using the latest regional load forecast as given in Appendix D. Sections 6.1 to 6.5 present the results of this review. Further description of assessments, alternatives and preferred plan along with status is provided in Section 7.

All the needs in the previous RIP have been addressed. Enfield TS is in-service and Seaton MTS is under contstruction.

6.1 230 kV Transmission Facilities

The GTA East Region is comprised of five 230kV circuits, T23C/T29C, T24C/T26C, and T28C, supplying both the Pickering-Ajax-Whitby Sub-region and the Oshawa-Clarington Sub-region. Refer to Figure 3-3 for the single line diagram of the transmission facilities in the Region.

1. Cherrywood TS to Clarington TS 230 kV circuits - T23C, T29C, T24C, T26C, and T28C

The Cherrywood TS to Clarington TS circuits, carry bulk transmission flows as well as serve local area station loads within the Region. These circuits are adequate over the study period. Pickering NGS is connected to the Cherrywood TS through 8 dedicated 230 kV circuits. Pickering NGS is expected to be retire in 2025.

6.2 500/230 kV Autotransformer Facilities

The 230 kV autotransformers facilities in the region consist of the following elements:

a. Cherrywood TS 500/230 kV autotransformers: T14, T15, T16, T17
b. Clarington TS 500/230 kV autotransformers: T2, T3

The autotransformers at Cherrywood TS and Clarington TS serve the 230 kV transmission network and local loads in GTA East. The Cherrywood TS autotransformer and Clarington TS autotransformer facilities are adequate over the study period.

6.3 Pickering-Ajax-Whitby Sub-region's Step-Down Transformer Station Facilities

There are two step-down transformer stations connected in the Pickering-Ajax-Whitby sub-region, summarized in Table 6-2. The station coincident and non-coincident forecasts are given in Appendix D.

Table 6-2: Transformation Capacities in the Pickering-Ajax-Whitby Sub-region

Facilities	Station MW Load			Station Limited Time Rating (LTR) MW	Need Date
	2030	2035	2040		
Cherrywood TS T7/T8 (44 kV)	160	160	160	160	2040+
Whitby TS T1/T2 (27.6 kV)	90	90	90	90	2040+
Whitby TS T1/T2 (44 kV)	70	74	83	90	2040+
Whitby TS T3/T4 (44 kV)	162	170	179	187	2040+
Seaton MTS (27.6kV)	75	79	83	153	2040+

Based on the submitted load forecasts, the stations in Pickering-Ajax-Whitby sub-region have adequate transformation capacity to supply the load in long term.

6.4 Oshawa-Clarington Sub-region's Step-Down Transformer Station Facilities

There are three step-down transformer stations in the Oshawa-Clarington Sub-region, summarized in Table 6-3.

Table 6-3: Transformation Capacities in the Oshawa-Clarington Sub-Region

Facilities	Station MW Load			Station Limited Time Rating (LTR) MW	Need Date
	2030	2035	2040		
Wilson TS T1/T2 (44 kV)	161	161	161	161	2040+
Wilson TS T3/T4 (44 kV)	134	134	134	134	2040+
Thornton TS T3/T4 (44 kV)	143	149	154	159	2040+
Enfield TS T1/T2 (44 kV)	144	171	202	157	2030-2035

The previous Regional Planning cycle recommended a new station, named Enfield TS, in the area mainly to relieve the Wilson TS from overloading as well as to meet the new load growth in the area. As per recommendation, Hydro One has installed a new 230kV / 44kV Enfield TS with six (6) 44kV feeder breaker positions with provision for two (2) additional 44kV future feeder breaker positions. The new Enfield TS is located on the the Clarington TS site and will supply OPUC through four (4) feeders and Hydro One Dx

through two (2) feeders. The station went in-service in March 2019 and currently feeder load transfer work is in progress to transfer some existing load from Wilson TS to Enfield TS.
Based on the submitted load forecasts, additional transformation capacity will be required in the long term.

6.5 End-Of-Life (EOL) Equipment Needs

Hydro One and LDCs have provided high voltage asset information under the following categories that have been identified at this time and are likely to be replaced over the next 10 years:

- Autotransformers
- Power transformers
- HV breakers
- Transmission line requiring refurbishment where an uprating is being considered for planning needs and require Leave to Construct (i.e., Section 92) application and approval
- HV underground cables where an uprating is being considered for planning needs and require EA and Leave to Construct (i.e., Section 92) application and approval

The end-of-life assessment for the above high voltage equipment typically included consideration of the following options:

1. Replacing equipment with similar equipment and built to current standards (i.e., “like-for-like” replacement);
2. Replacing equipment with similar equipment of higher / lower ratings i.e. right sizing opportunity and built to current standards;
3. Replacing equipment with lower ratings and built to current standards by transferring some load to other existing facilities;
4. Eliminating equipment by transferring all of the load to other existing facilities;

In addition, from Hydro One’s perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

Accordingly, major high voltage equipment has been identified as approaching its end of life over the next 10 years and assessed for right sizing opportunity in section 7.

6.6 System Reliability and Load Restoration

In case of contingencies on the transmission system, ORTAC provides the load restoration requirements relative to the amount of load affected. Planned system configuration must not exceed 600 MW of load curtailment/rejection. In all other cases, the following restoration times are provided for load to be restored for the outages caused by design contingencies.

a. All loads must be restored within 8 hours.
b. Load interrupted in excess of 150 MW must be restored within 4 hours.
c. Load interrupted in excess of 250 MW must be restored within 30 minutes.

The previous regional planning (RP) comprehensively assessed circuit pairs T29C/T23C and T24C/T26C as they are on the same tower line and the possibility of loss of either pair of circuits during peak load may result in load shortfall/outage exceeding the limits of 150MW and 250MW to be restored within 4 hours and 30 minutes, respectively. However, based on the analysis, historical performance and reliability data for these circuits in the region, the Study Team recommended that no action is required at this time. There is no change on the assumptions used in this report resulting in any significant system reliability or load restoration concerns in the region.

6.7 Longer Term Outlook (2030-2040)

While the RIP was focused on the 2019-2029 period, the Study Team has also looked at longer-term loading between 2030 and 2040.

No long term needs for the Pickering-Ajax-Whitby Sub-Region have been identified. Seaton MTS is expected to supply the Sub-Region's demand adequately over the next two decades.

The demand in Oshawa-Clarington Sub-Region is expected to grow over the long term period. The new Enfield TS will provide load relief to Wilson TS through distribution load transfer capability. As the demand grows in the northern Oshawa area in the long term, additional transformation capacity may have to be planned for in future. Further review and assessment will commence in next Regional Planning cycle to identify and develop alternatives to address new needs, if any.

Municipalities in region may develop their community energy plans with a primary focus to reduce their energy consumption by local initiatives over next 25 to 30 years. With respect to electricity, these communities may plan for an increased reliance on community energy sources such as distributed generation, generation behind the meters like rooftop solar systems and local energy battery storage systems to reduce cost and for improved reliability of electricity supply.

Some of the communities in Ontario are working towards self-sufficiency by improving efficiencies of existing local energy systems i.e. reducing energy consumption and losses by means of utilizing smarter buildings, houses, efficient heating, cooling, appliances, equipment, and processes for all community needs. Ultimately, the objective of these energy plans in the region is to be a net zero carbon community over the next 25 to 30 years.

Community energy plans may have potential to supplement and/or defer future transmission infrastructure development needs. The Study Team therefore recommends LDCs to review their respective regional community energy plans and provide updates to the working group of any potential projects that may affect future load forecasts in the next cycle of regional planning.

7. REGIONAL NEEDS & PLANS

THIS SECTION DISCUSSES ELECTRICAL INFRASTRUCTURE NEEDS IDENTIFIED IN THE PREVIOUS REGIONAL PLANNING CYCLE, THE NEEDS ASSESSMENT REPORT FOR THIS CYCLE; AND SUMMARIZES THE PLANS DEVELOPED TO ADDRESS THESE NEEDS.

This section outlines and discusses infrastructure needs and plans to address these needs for the near-term (up to 5 years) and the mid- term (5 to 10 years) and the expected planned in-service facilities to address these needs.

There are no new needs identified in the GTA East Region. Current development and sustainment plans are further discussed below.

7.1 Seaton MTS - Increase Transformation Capacity in Pickering-Ajax-Whitby Sub-Region

7.1.1 Description

The Pickering-Ajax-Whitby Sub-Region is supplied by Cherrywood TS at 44kV level and Whitby TS at 27.6kV and 44kV levels. Over the next 10 years, the load in this Sub-Region is forecasted to increase at approximately 2.9% annually.

With the proceeding of a new residential and mixed use commercial area in the Seaton are, significant increase in load demand is expected at 27.6kV level resulting in a shortage of transformation capacity at Whitby TS 27.6kV by 2021.

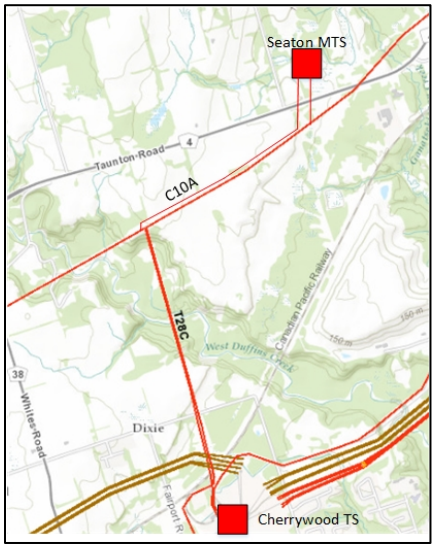

Figure 7-1: Location of Seaton MTS

The following alternatives were considered to address the Transformation Capacity in Pickering-Ajax-Whitby Sub-Region need:

1. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the expected thermal overloading at Whitby TS 27.6 kV due to the load growth in the Sub-Region.
2. **Alternative 2 – Build Seaton MTS:** Elexicon to proceed with the installation of a new Seaton MTS. To feed the new Seaton MTS, Hydro One will be converting an existing single circuit 230 kV transmission line (T28C) to a double circuit line from Duffin Jct to Seaton MTS to serve the station. Hydro One is working with Elexicon and planning for Q1 2020 in-service. This alternative would address the expected thermal overloading at Whitby TS 27.6kV due to the load growth in the Sub-Region.

7.2 Cherrywood TS – 230kV & 500kV Breaker Replacements (multi-phase project) Mid-Term End of Life Transformer Replacements

7.2.1 Description

Cherrywood TS is a major Bulk Electricity System (BES), Northeast Power Coordination Council (NPCC) station, located at east end of Greater Toronto Area (GTA). The station includes 500 kV and 230 kV switchyards, four autotransformers that transfer electricity from Darlington and Pickering Nuclear Generating Station into GTA, and a 44kV DESN tapped off the 230kV bus which delivers power to Elexicon. The existing 500kV and 230kV Air Blast Circuit Breaker (ABCBs), with an average age of 48 years are obsolete and at end of life. These are Bulk System elements and not in the scope of regional planning. Discussion is provided for information only.

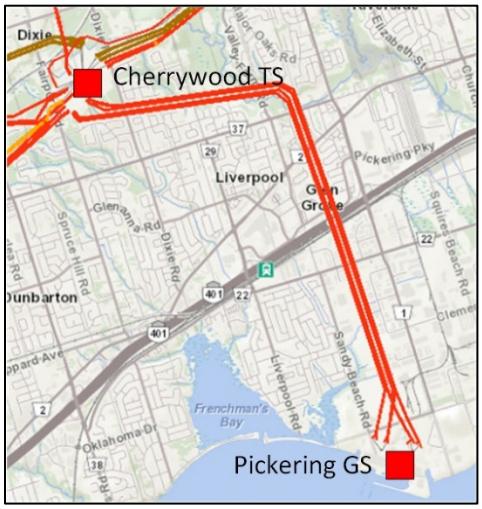

Figure 7-2: Cherrywood TS

The scope of this project is to replace the existing eight (8) 500kV and thirty (30) 230kV air-blast circuit breakers in a multi-phase project release. The targeted in-service for the final phase is in year 2027.

The following alternatives were considered to address Cherrywood TS HV Breakers end-of-life assets need:

3. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.
4. **Alternative 2 - Like-for-like replacement with similar equipment:** Proceed with these end of life asset replacement as per existing refurbishment plan for the HV breakers at Cherrywood TS. This alternative would address the end-of-life assets need and would maintain reliable supply to the customers in the area.

7.3 Cherrywood TS – LV DESN Switchyard Refurbishment Mid-Term End of Life Breaker Replacement

7.3.1 Description

The LV switchyard for the 44 kV DESN T7/T8 at Cherrywood TS is at end of life due to age and condition. The scope of this project is to replace all 44 kV switchyard assets with the current standard equipment. The targeted in-service is in year 2025.

The following alternatives were considered to address Cherrywood TS DESN LV breaker end-of-life assets need:

1. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.
2. **Alternative 2 - Like-for-like replacement with similar equipment:** Proceed with these end of life asset replacement as per the existing refurbishment plan for the LV breakers at Cherrywood TS DESN. This alternative would address the end-of-life assets need and would maintain reliable supply to the customers in the area.

7.4 Wilson TS – T1, T2 and Switchyard Refurbishment

7.4.1 Description

Wilson TS is located in Oshawa and it contains 4 X 75/100/125 MVA, 230/44 kV, transformers that supplies city of Oshawa through OPUCN feeders and surrounding areas of Oshawa through Hydro One Dx owned feeders. The T1 and T2 transformers at Wilson TS and majority of assets within 44 kV BY switchyard have reached end of life. The associated spill containment structure do not meet current standard.

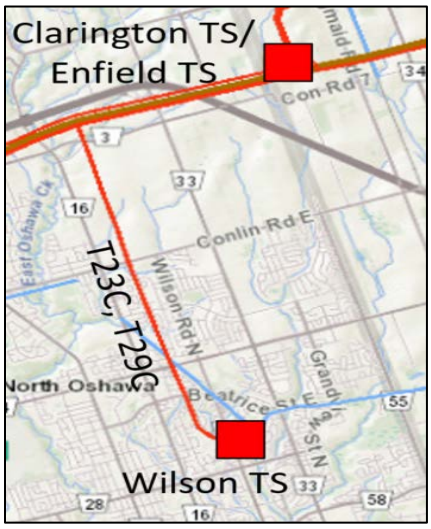

Figure 7-3: Wilson TS

The scope of this project is to replace T1/T2 step-down transformers, associated spill containment structure and majority of assets within 44 kV BY switchyard. The targeted in-service is in year 2022.

The Study Team has assessed downsizing and/or upsizing need for these transformers. The Working Group concluded that reducing the size of these transformers is not an option as the load in the area is increasing. Upsizing is also not an option because this is the highest rating of transformer. Accordingly, replacing these transformers with similar size is the only "right sizing" option.

The following alternatives were considered to address Wilson TS end-of-life assets need:

1. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.
2. **Alternative 2 - Like-for-like replacement with similar equipment:** Proceed with these end of life asset replacement as per the existing refurbishment plan for the transformers at Wilson TS. This alternative would address the end-of-life assets need and would maintain reliable supply to the customers in the area.

8. CONCLUSION AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN (RIP) REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GTA EAST REGION.

The major infrastructure investments recommended by the Study Team in the near and mid-term planning horizon are provided in Table 8-1 below, along with their planned in-service date and budgetary estimates for planning purpose.

Table 8-1: Recommended Plans in GTA East Region over the Next 10 Years

No.	Needs	Plans	Planned I/S Date	Budgetary Estimate ($M)
1	Increase Transformation Capacity in Pickering-Ajax-Whitby Sub-region	Build Seaton MTS	2021	43
2	Cherrywood TS – 230kV & 500kV Breaker Replacements (multi-phase projects)	Replace 230 kV and 500 kV Air Blast Circuit Breakers (ABCB) at Cherrywood TS	2027	184
3	Cherrywood TS – LV DESN Switchyard Refurbishment	Existing 44kV DESN switchyard replacement at Cherrywood TS	2025	12
4	Wilson TS – T1, T2 and Switchyard Refurbishment	Existing T1, T2 and 44 kV BY bus switchyard replacement	2022	36

The Study Team recommends that:

- Hydro One and Elexicon continue with the infrastructure projects as listed above in Table 8-1 while keeping the Study Team apprised of project status.
- No additional transformation capacity is required in the Pickering-Ajax-Whitby sub-region in the long term.
- Additional transformation capacity may be required in the Oshawa-Clarington sub-region in the long term.

APPENDIX F: LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CSS	Customer Switching Station
CTS	Customer Transformer Station
DCF	Discounted Cash Flow
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GATR	Guelph Area Transmission Reinforcement
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

NEEDS ASSESSMENT REPORT

Greater Toronto Area East

Needs Assessment Report

Greater Toronto Area (GTA) East Region

December 11, 2024

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

GTA East Technical Working Group

Page intentionally left blank

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Greater Toronto Area East and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the Needs Assessment phase and b) require further assessment and regional coordination. The results reported in this Need Assessment are based on the input and information provided by the Technical Working Group (the "TWG") for this region at the time. Updates may be made based on best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	Greater Toronto Area East (GTA East) Region (the "Region")
LEAD	Hydro One Networks Inc. ("Hydro One")
START DATE: August 13, 2024	**END DATE:** December 11, 2024

1. INTRODUCTION

The second Regional Planning cycle for the GTA East Region was completed in February 2020 with the publication of the Regional Infrastructure Plan ("RIP") report (RIP Report). This is the third cycle of Regional Planning for the region.

The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,

b) Recommend which needs:
i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted Local Distribution Company ("LDC") to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years.

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. Considering these timelines, the 3rd Regional Planning cycle was triggered for the GTA East Region on August 13th , 2024.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the GTA East Region NA includes:

a) Review and reaffirm needs/plans identified in the previous regional planning cycle RIP (as applicable),

b) Identify any new needs resulting from this assessment,

c) Recommend which needs require further assessment and regional coordination in the next phases of the regional planning cycle to develop a preferred plan; and,
d) Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDCs to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment (SA), Integrated Regional Resource Plan (IRRP), and RIP, based on updated information available at that time.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The GTA East Region comprises the municipalities of Pickering, Ajax, Whitby, Oshawa and parts of Clarington, and other parts of the Durham area.

5. INPUTS/DATA

The TWG comprises of representatives from LDCs, the Independent Electricity System Operator ("IESO"), and Hydro One and provides input and relevant information for the Region regarding capacity needs, reliability needs, operational issues, and major high-voltage ("HV") transmission assets requiring replacement over the planning horizon. The LDCs also capture input from municipalities in the development of their 10-year summer and winter load forecast.

In accordance with the regional planning process, stakeholder engagement takes place during the IRRP phase.

6. ASSESSMENT METHODOLOGY

The need assessment's primary objective is to identify the electrical infrastructure needs in the Region over the 10-year planning horizon. A 20-year planning assessment is undertaken in the next phases of regional planning, i.e., IRRP and RIP phases. The assessment methodology includes a review of planning information such as load forecast (which factors various demand drivers and consideration of MEPs and/or CEPs where available), conservation and demand management ("CDM") forecast, distributed generation ("DG") forecast, system reliability and operation, and major HV transmission assets requiring replacement.

A technical assessment of needs is undertaken based on:

a) Current and future station capacity and transmission adequacy
b) System reliability needs and operational concerns
c) Major HV transmission equipment requiring replacement with consideration to "right-sizing"

d) Sensitivity analysis to capture uncertainty in the load forecast as well as variability of demand drivers such as electrification.

7. NEEDS

I. Updates on needs identified during the previous regional planning cycle

The following needs discussed in the GTA East Region second cycle RIP have been completed:

- Increase Transformation Capacity in Pickering-Ajax-Whitby Sub-region: Seaton MTS has been built and placed in-service in 2023.
- Wilson TS – T1, T2 and Switchyard Refurbishment: Wilson TS T1/T2 have been replaced and new T7/T8 were placed in service in early 2024, maintaining station reliability and ensuring continued supply reliability to Oshawa PUC Inc. (OPUC) and Hydro One Distribution (H1DX) customers.

The following needs and projects discussed in the GTA East second cycle RIP are currently underway:

- Cherrywood TS 230kV Breaker Replacement (multi-phase projects): Two phases are underway with currently planned in-service dates of 2033 and 2037 respetively.

II. Newly identified needs in the region

The following are new needs that were identified as part of this assessment:

a) Asset Renewal for Major HV Transmission Equipment

- Wilson TS - T3/T4 Replacement

b) Station Capacity

- Whitby TS T1/T2 DESN (44kV)
- Thornton TS T3/T4 DESN
- Wilson TS T7/T8 DESN
- Wilson TS T3/T4 DESN

c) Transmission Line Capacity

- No new transmission Line Capacity need identified

d) System Reliability, Operation and Load Restoration

- T23C/T29C corridor may exceed load security limit of 600MW in 2032 if all forecasted loads at the current stations are supplied from original connection points

e) Transmission System Reinforcement

- Major transmission expansion in Oshawa-Clarington sub-region area will be needed to accommodate increasing new large load connection requests. Existing 230kV transmission facilities do not have sufficient capacity to supply the new demand.

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

The impact of the sensitivity analysis for the high and low growth scenarios identified the following updates to need dates and new station capacity needs. These needs will be assessed again during the next phases of this Regional Planning cycle.

No.	Need Identified	Need Date		
		Normal Growth Scenario	High Growth Scenario	Low Growth Scenario
Needs update under high and low load growth scenarios				
1	Whitby TS T1/T2 (44kV) LTR	2032	2030	Beyond 2033
2	Thornton TS T3/T4 LTR	2031	2027	Beyond 2033
3	Wilson TS T7/T8 LTR	2032	2029	Beyond 2033
4	Wilson TS T3/T4 LTR	2024 (2025*)	2024 (2025*)	2024 (Beyond 2033*)
Additional capacity needs under high growth scenario				
5	Cherrywood T7/T8 LTR	Beyond 2033	2031	Beyond 2033
6	Seaton MTS LTR**	Beyond 2033	2032	Beyond 2033
7	Whitby TS T3/T4 LTR	Beyond 2033	2031	Beyond 2033

* If the transformers are replaced with higher LTR rating units as planned.

** Based on the LDC provided LTRs of 153MW (Summer) and 180MW (Winter) for Seaton MTS

9. RECOMMENDATIONS

The TWG recommendations are as follows:

I. Needs that require further assessment and regional coordination

These needs may have broader regional impacts and require further assessment and coordination during the next phases[1] of the regional planning cycle. A list of these needs are as follows:

a) Integrated Transmission reinforcement at Oshawa-Clarington Sub-region area to accommodate large load connection requests and address T23C/T29C corridor load security issue
b) Station capacity need at Thornton TS in Oshawa area due to load growth
c) Station capacity need at Wilson TS T7/T8 in Oshawa area due to load growth
d) Station capacity need at Wilson TS T3/T4 in Oshawa area due to load growth

II. Needs that do not require further regional coordination

These needs can be addressed by a straightforward transmission and/or distribution wires solution, or they are local in nature and do not have a regional impact. They either do not require investment in any upstream transmission facility or require Leave to Construct (i.e., Section 92) approvals. These needs generally impact a limited number of LDCs and can be addressed directly between Hydro One and the LDC(s) to develop a preferred local plan. A list of these needs are as follows:

a) Cherrywood TS 230kV Breaker Replacement
b) Wilson TS - T3/T4 Transformer Replacement
c) Station capacity need at Whitby TS T1/T2 (44kV) in North Whitby area due to load growth

List of LDC(s) to be involved in further regional planning phases:

- Elexicon Energy Inc.
- Oshawa PUC Networks Inc.
- Hydro One Networks Inc. (Distribution)

[1] Non-wires options are further considered (i.e. incremental to CDM and DG that is considered in this NA) as potential options in addressing these needs during the IRRP phase.

1. Introduction

The second cycle of the Regional Planning process for the GTA East Region was completed in February 2020 with the publication of the Regional Infrastructure Plan ("RIP") Report [1] - (RIP link). The RIP report included a common discussion of all the options and recommended plans for preferred wire infrastructure investments to address the near- and medium-term needs.

This Needs Assessment initiates the third regional planning cycle for the GTA East Region. The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years. The flow chart of the Regional Planning Process is shown in Figure 1 below.

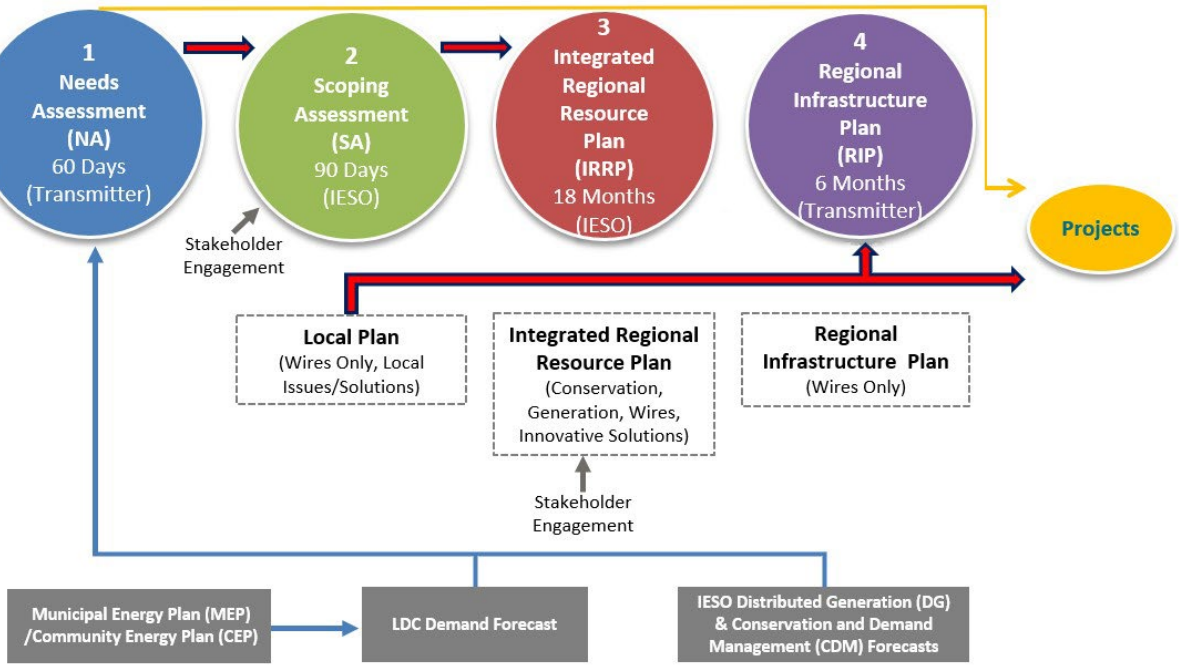

Figure 1: Regional Planning Process

This report was prepared by the GTA East Technical Working Group("TWG"), led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC") and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: GTA East Region TWG Participants

No.	Name of TWG Participants
1	Hydro One Networks Inc. (Transmission) - (Lead Transmitter)
2	Independent Electricity System Operator
3	Elexicon Energy Inc.
4	Oshawa PUC Networks Inc.
5	Hydro One Networks Inc. (Distribution)

2. Regional Issue/Trigger

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. As such, the third Regional Planning cycle was triggered for the GTA East Region.

3. Scope of Needs Assessment

The scope of this NA covers the GTA East region and includes:

- Review and update needs and plans identified in the previous cycle RIP,
- Identify any new needs resulting from this assessment,
- Recommend which needs require further assessment and regional coordination in the next phases of the regional planning cycle to develop a preferred plan, and
- Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDCs to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), Local plan (LP) and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is 10 years.

4. Regional Description and Connection Configuration

The GTA East Region comprises the municipalities of Pickering, Ajax, Whitby, Oshawa and parts of Clarington, and other parts of the Durham area.

The geographical boundaries of the Region are shown in Figure 2.

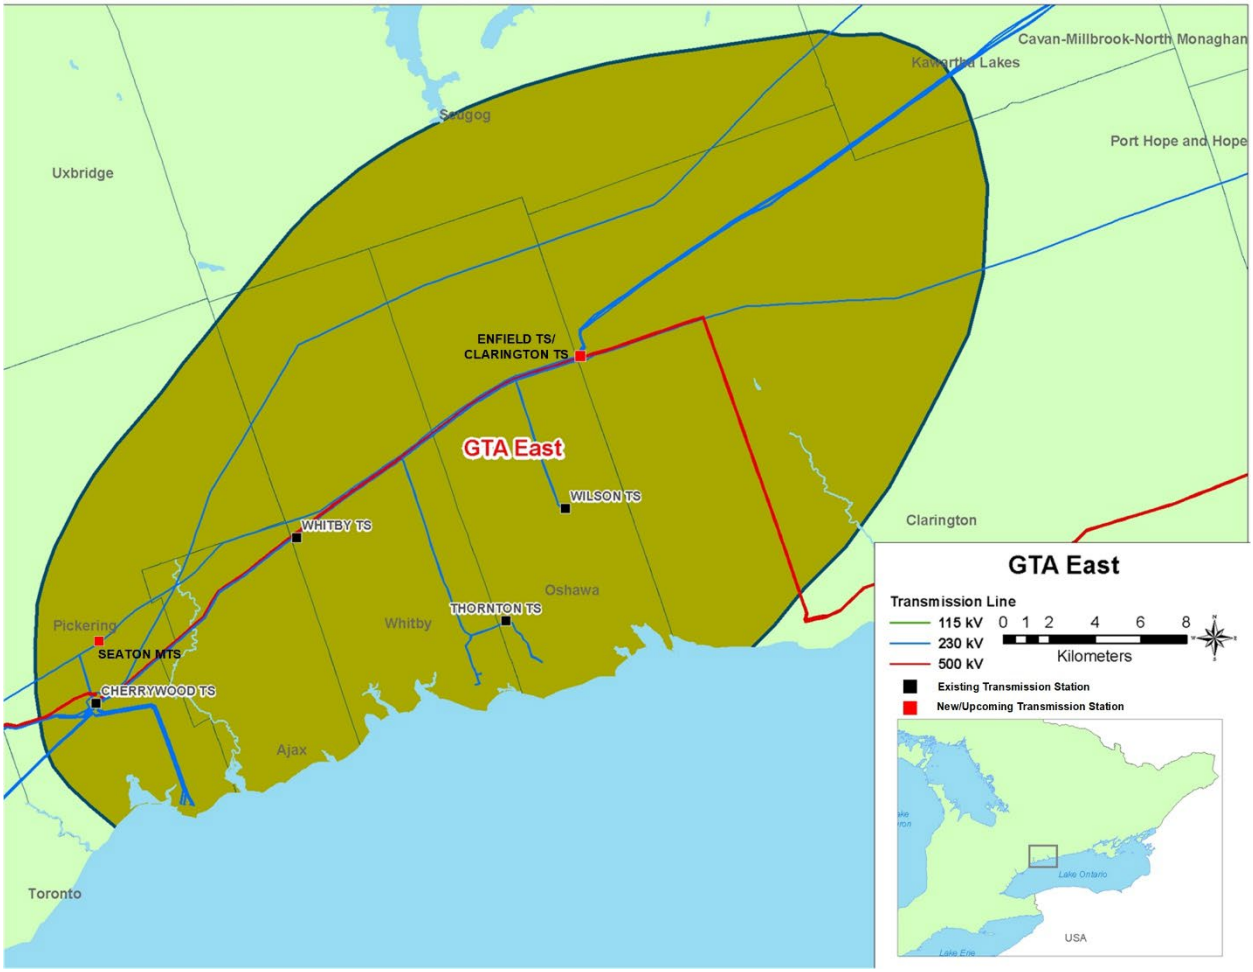

Figure 2: Map of GTA East Regional Planning Area

Electrical supply to the GTA East Region is provided through 500/230kV autotransformers at Cherrywood Transformer Station (TS) and Clarington Transformer Station (TS) and six 230 kV transmission lines connecting Cherrywood to Eastern Ontario. There are six step-down transformer stations (five Hydro One owned and one LDC owned), and three direct transmission connected load customers. Metrolinx Traction Power Substation (TPSS) is proposed to be in service in 2029. The distribution system is at two voltage levels, 44kV and 27.6kV.

The Local Distribution Customers (LDC) in the Region include Elexicon Energy Inc., Oshawa PUC Networks Inc. and Hydro One Networks Inc. (Distribution). An electrical single line diagram for the GTA East Region facilities is shown in Figure 3.

The circuits and stations of the area are summarized in Table 2 below:

Table 2: Transmission Station and Circuits in the GTA East Region

230kV circuits	Transformer Stations	Generation Stations
T23C T24C T26C T28C T29C C10A	Cherrywood TS[1] Seaton MTS Thornton TS Whitby TS Wilson TS Enfield TS CTS A CTS B CTS C Metrolinx TPSS (in-service 2029)	CGS D, 60MW gas-fired cogeneration Pickering Nuclear Generating Station (NGS), approximately 3000 MW

1: 500kV Stations with Autotransformers installed

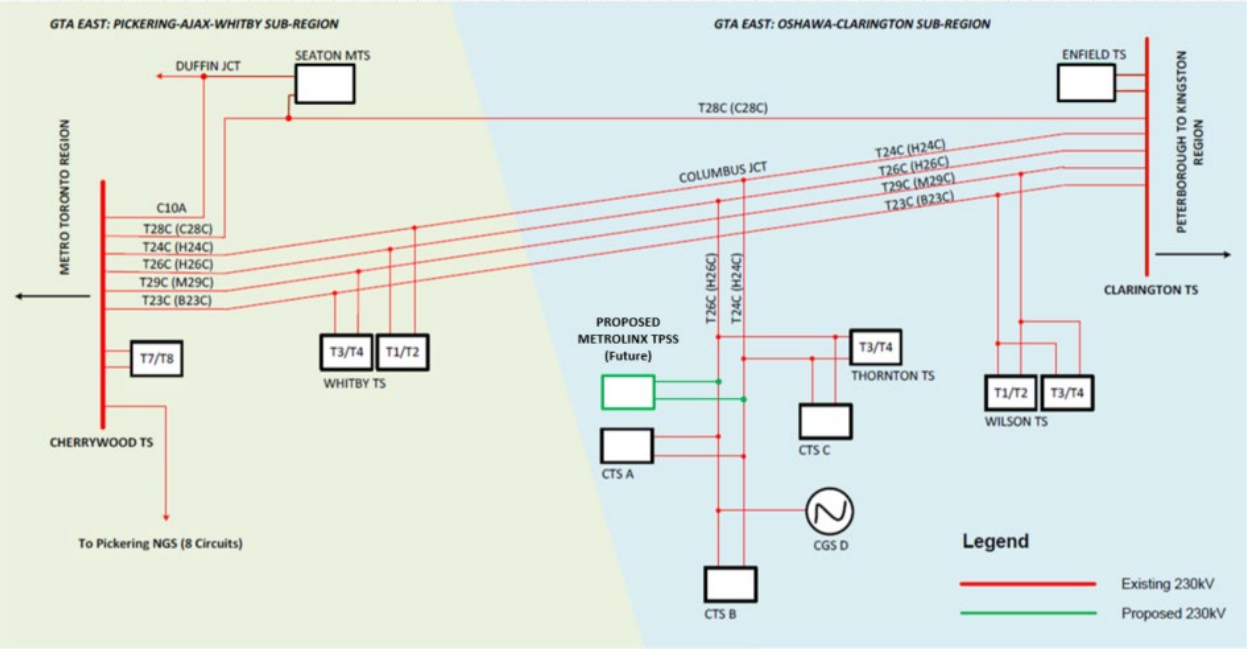

Figure 3: GTA East Transmission Single Line Diagram

5. Inputs and Data

TWG participants, including representatives from LDCs, IESO, and Hydro One provided input for the GTA East NA. With respect to the load forecast information, the OEB Regional Planning Process Advisory Group (RPPAG) recently published a document called "Load Forecast Guideline for Ontario" in Oct. 2022 [2]. The objective of this document is to provide guidance to the TWG in the development of the load forecasts used in the various phases of the regional planning process with a focus on the NA and the IRRP. One of the inputs into the LDC's load forecast that is called for in this guideline is information from Municipal Energy Plans (MEP) and/or Community Energy Plans (CEP). The list of all the Municipalities falling under the geographical boundaries of the region are given in Appendix-E.

The information provided includes the followings:

- GTA East 10-year summer and winter load forecast for all supply stations inclusive of the inputs provided by the municipalities listed in Appendix E
- Known capacity and reliability needs, operating issues, and/or major assets requiring replacement or refurbishment
- Planned transmission and distribution investments that are relevant to Regional Planning for the GTA East
- Captured uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

6. Assessment Methodology

The following methodology and assumptions are made in development of this Needs Assessment:

6.1 Technical Assessments and Study Assumptions

The technical assessment of needs was undertaken based on:

- Current and future station capacity and transmission adequacy
- System reliability and operational considerations
- Asset renewal for major high voltage transmission equipment requiring replacement with consideration to "right-sizing"
- Load forecast data requested from industrial customers in the region
- Summer and Winter peak load conditions. Three load forecasts were developed for Summer and Winter respectively, i.e. normal growth scenario, high and low growth scenario. The high and low growth load forecasts are developed to conduct a sensitivity analysis to cover unforeseen developments such as fuel switching, government policies, higher than expected EV charging trend during peak load conditions, etc.

The following assumptions are made in this report:

- The study period for this Needs Assessment is 2024-2033.
- The Region is summer peaking, but will be transitioning to winter peaking for most of transformer stations in this study period, so this assessment is based on both summer and winter peak loads.
- Line capacity adequacy is assessed by using coincident peak loads in the area.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations without low-voltage capacitor banks and 95% lagging power factor for stations with low-voltage capacitor banks.
- Normal planning supply capacity for transformer stations is determined by the Hydro One Summer/Winter 10-Day Limited Time Rating (LTR) at 35 and 10 degree celcius respectively for Summer/Winter of a single transformer at that station.
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC)[3] .

6.2 Information Gathering Process

6.2.1 Load forecast

The LDCs provided their summer and winter load forecast for all the stations supplying their loads in the GTA East region for the 10-year study period including the inputs from the Municipalities such as MEPs and CEPs. The IESO provided a Conservation and Demand Management ("CDM") and Distributed Generation ("DG") forecast for the Region. The net extreme summer weather load

forecasts were produced by reducing the gross load forecasts for each station by the percentage CDM and then by the amount of effective DG capacity provided by the IESO for that station. It is to be noted that as contracts for existing DG resources in the region begin to expire, at which point the load forecast has a decreasing contribution from local DG resources, and an increase in net demand. This extreme summer weather corrected net load forecast for the individual stations in the Region is given in Appendix A.

6.2.2 Sensitivity analysis

A sensitivity analysis was undertaken by the TWG to capture uncertainty in the load forecast as well as variability of drivers such as electrification. Hence, the NA recommendations are not necessarily linked to sensitivity scenarios; but rather are used to identify any emerging needs for consideration in developing recommendations. The impact of sensitivity analysis for the high and low growth scenarios are provided in section 8 of this report.

6.2.3 Asset renewal needs for major HV equipment

A list is generated for major HV transmission equipment planned or identified to be replaced based on asset condition assessment, relevant for Regional Planning purposes. This includes HV transformers, HV Breakers, HV underground cables and overhead lines. The scope of equipment considered is given in section 7.1.

6.2.4 System reliability and operational issues

Relevant information regarding system reliability and operational issues in the region as feedback is provided by the IESO during the NA phase.

7. Needs

This section describes new needs identified in the Region and updates on previously identified needs since the completion of previous regional planning cycle.

Needs that were identified and discussed in the previous regional planning cycle with associated projects that were recently completed and reaffirmed needs that are underway, are briefly described below with relevant updates:

- Increase Transformation Capacity in Pickering-Ajax-Whitby Sub-region: Seaton MTS has been built and placed in-service in 2023.
- Wilson TS – T1, T2 and Switchyard Refurbishment: Wilson TS T1/T2 have been replaced and new T7/T8 were placed inservice in early 2024, maintaining station reliability and ensuring continued supply reliability to Oshawa PUC Inc. (OPUC) and Hydro One Distribution (H1DX) customers.
- Cherrywood TS – 230kV Breaker Replacements (multi-phase projects): Two phases are underway with currently planned in-service dates of 2033 and 2037 respectively.

All near and midterm needs that are discussed as a part of this report are summarized in Table 3. Note the planned in-service year for the projects is tentative and is subject to change.

Table 3: Near/Mid-term Needs Identified in Previous RIP and/or this NA

Need Description	Recommended Plan/Update	Previous RIP Report Section	NA Report Section
Asset Renewal Needs			
Cherrywood TS 230kV Breaker Replacements (multi-phase projects)	Two phases are underway with currently planned in-service dates of 2033 and 2037 respectively.	Sec. 7.2	Sec. 7.1
Wilson TS T3/T4 Transformer Replacement	Replacement of T3/T4 transformers with planned in-service date of 2031.	N/A	Sec. 7.1
Station Capacity Needs			
Whitby TS T1/T2 (44kV) Station Capacity need	Plan a new Transformer Station at North Whitby area, tapping on 230kV circuits of P15C and T28C. TWG agreed to proceed with local planning, no further regional coordination is required.	N/A	Sec. 7.2.1
Thornton TS T3/T4 Station Capacity need	Further regional coordination to address this need along with the identified new needs at Wilson TS T3/T4 and Wilson TS T7/T8 in Oshawa area (see Section 7.2.3 and 7.2.4).	N/A	Sec. 7.2.2

Wilson TS T7/T8 Station Capacity need	Further regional coordination required to address this need along with the identified new needs at Wilson TS T3/T4 (Section 7.2.4), and a new Transformer Station will be required.	N/A	Sec. 7.2.3
Wilson TS T3/T4 Station Capacity need	A new Transformer Station will be required as early as 2028/2029 and further regional coordination to address this need along with the needs at Wilson TS T7/T8 and Thornton TS T3/T4 (Section 7.2.2 and 7.2.3). As a near term solution, the LDCs are encouraged to continue transferring loads to Enfield TS.	N/A	Sec. 7.2.4
System Reliability, Operation and Load restoration Needs			
T23C/T29C corridor exceeds load security limit of 600MW	Further regional coordination required, especially when determining where to connect new Transformer Station to accommodate new needs identified in Section 7.2.2, 7.2.3 and 7.2.4.	N/A	Sec. 7.4
Transmission System Reinforcement Needs			
Oshawa-Clarington Sub-region area transmission reinforcement for load supply	Further regional coordination to address the capacity needs. Coordinated efforts from IESO bulk system planning, Hydro One, LDCs and major customers should continue in developing solutions.	N/A	Sec. 7.5

7.1 Asset Renewal Needs for Major HV Transmission Equipment

In addition to the previously identified asset renewal needs from the second regional planning cycle, Hydro One and TWG has also identified new asset renewal need for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the Region. The complete list of planned major HV transmission equipment requiring replacement is provided in Table 4. Note the in service year is subject to change as the asset renewal planning is a dynamic process.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors
- Technical obsolescence due to outdated design
- Lack of spare parts availability or manufacturer support and/or
- Potential health and safety hazards.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230 load serving step down transformers
- 230kV breakers where:

replacement of six breakers or more than 50% of station breakers, the lesser of the two

- 230kV transmission lines requiring refurbishment where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230kV underground cable requiring replacement where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

The Asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement)
- Replacing equipment with higher ratings and built to current standards.

From Hydro One's perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

7.1.1 Wilson TS T3/T4

Based on asset condition assessment, Wilson TS T3/T4 transformers are newly identified assets for replacement with currently planned in-service date of 2031. The existing T3 and T4 (75/100/125 MVA) transformers at Wilson TS and associated LV equipment require replacement. It is expected that Wilson TS T3/T4 capacity will increase to approximate 160 MW for Summer and 180 MW for Winter, once being replaced with the new standard 75/100/125 MVA transformers (Section 7.2.4).

No other HV station equipment or transmission lines in the GTA East region have been identified for replacement at this time over the next ten year. If and when new and/or additional information is available, it will be provided during the next regional planning phases.

The needs below in Table 4 do not need further regional coordination.

Table 4: Major HV Transmission Asset Assessed for Replacement in the Region in Next 10 Years

Station/Circuit	Need Description	Planned ISD
Cherrywood TS	230kV Breaker Replacements (multi-phase projects), two phases are underway	2033/2037
Wilson TS T3/T4	Asset condition based replacement with "like for like" standard units	2031

7.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2024-2033 for the 230kV Transforming stations in the Region using the summer and winter peak load forecasts. Based on the results, the identified station capacity needs are flagged in Table 5. Comparing with the recommendations in RIP 2022 [1], all Transformer Stations below are newly identified needs in this NA period.

Table 5: Stations with Capacity Need

TS	Season	LTR (MW)	Net Load Forecast (MW)									
			2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
Whitby TS T1/T2 (44kV)	Winter	113.2	36.6	47.5	56.9	66.6	76.7	87.1	98.1	107.4	118.2	130.1
Thornton TS T3/T4	Summer	154.9	138.0	138.8	139.5	140.0	141.1	142.4	144.7	147.7	151.5	156.2
	Winter	175.5	154.5	157.8	160.3	162.6	165.6	168.9	173.3	178.0	183.7	190.4
Wilson TS T7/T8	Summer	169.1	139.7	147.5	149.1	150.8	155.7	159.5	163.4	168.2	174.1	181.3
Wilson TS T3/T4	Summer	130.2	144.6	161.2	176.0	187.7	198.8	213.6	232.2	254.6	290.5	311.6
	Winter	152.0	136.1	154.7	171.5	185.1	198.2	214.6	234.6	257.2	293.0	312.8

7.2.1 Whitby TS T1/T2 (44kV)

Whitby TS T1/T2 (44kV) supplies loads from one LDC - Elexicon at 44kV level. Elexicon forecasts rapid annual gross load growth of approximate 6.3% at its 44kV service area in North Whitby in next ten years. With forecasted DG and CDM in place, the forecasted net load at Whitby TS T1/T2 (44kV) is expected to exceed its Winter LTR in 2032/2033 by 5MW or 17 MW respectively. In addition, the LDC has indicated that its 44kV distribution capacity at Whitby area will be exceeded by Summer 2032, and majority of the load growth in North Whitby area, which is currently supplied through Whitby TS T3/T4 and Whitby T1/T2 (27.6kV and 44kV), is highly expected post 2033. Also, in Northeast Pickering, there is projected load in the region that cannot be supplied by Whitby TS due to the long distance of the load center from the station.

In order to accommodate these needs, the LDC is currently consulting with Hydro One Tx to build a new Transformer Station, with preliminary option of tapping on two 230kV transmission circuits in the region, namely T28C and P15C. This new Transformer Station will address future projected load growth from North Whiby and North Pickering area. The TWG recommends LDC and Hydro One to proceed to local planning as no expected network reinforcement is required. No further regional coordination is required.

7.2.2 Thornton TS T3/T4

Thornton TS T3/T4 supplies loads from two LDCs, namely Hydro One Distribution (H1DX, with Elexicon's load embedded in) and Oshawa PUC Networks Inc. (OPUC), at 44kV level. OPUC forecasts rapid annual load growth of approximate 4.6% at Thornton TS T3/T4 in next ten years, while Elexicon load forecast remains flat in the study period. With forecasted DG and CDM in place, the net forecasted load at

Thornton TS T3/T4 is expected to exceed its LTRs as early as 2031 for Winter, or 2033 for Summer. The TWG recommends further regional coordination to address this need along with the identified new needs at Wilson TS T7/T8 and Wilson TS T3/T4 in Oshawa area (see Section 7.2.3 and 7.2.4 below).

7.2.3 Wilson TS T7/T8

Wilson TS T7/T8 serves loads from two LDCs, including OPUC and Hydro One Distribution (H1DX) at 44kV level. The two transformers have recently been replaced in early 2024 with largest size as per Hydro One standard transformer specification. Both LDCs forecast similar moderate annual gross load growth of approximate 3.2-3.7% at Wilson TS T7/T8 in next ten years. The net forecasted load at Wilson TS T7/T8 is expected to exceed its LTR as early as 2032 for Summer. The TWG recommends further regional coordination to address this need along with the identified new needs at Wilson TS T3/T4 (Section 7.2.4), and acknowledges that a new Transformer Station will be required for these needs.

7.2.4 Wilson TS T3/T4

Wilson TS T3/T4 serves loads from LDCs OPUC and Hydro One Distribution (H1DX) at 44kV level, with Elexicon's load embedded in H1DX. H1DX (including Elexicon) forecasts approximate 12% annual load growth at Wilson TS T3/T4 in next ten years, while OPUC forecasts moderate growth of approximate 3.6% annually in next ten years. The net forecasted load at Wilson TS T3/T4 is expected to exceed its LTR as early as 2024 for Summer, and 2025 for Winter.

As mentioned in Section 7.1.1, based on asset condition assessment, the T3 and T4 transformers at Wilson TS and associated LV equipment have been identified for replacement. Hydro One has identified the replacement of Wilson TS T3/T4 with planned in-service date of 2031. As the existing transformers have substandard LTRs, it is expected that Wilson TS T3/T4 will be replaced with standard 75/100/125 MVA transformers, and the capacity will increase from the current 130 MW for Summer and 152 MW for Winter to approximately 160 MW for Summer and 180 MW for Winter.

However, even with higher ratings of the new transformers, Wilson TS T3/T4 LTRs will still be exceeded based on load forecast. As a near term solution, the LDCs are encouraged to continue transferring loads to Enfield TS which can accommodate the additional loads that exceed Wilson TS T3/T4 station capacity. By doing so, the station capacity need could potentially be deferred for a few years. The TWG acknowledges that a new station will be required as early as 2028/2029 even with load transfers, and recommends further regional coordination to address this need along with the need in Section 7.2.2 and 7.2.3.

7.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A

Transmission Lines Capacity Assessment was performed over the study period 2024-2033 for the 230kV Transmission line circuits in the Region by assessing thermal limits of the circuit and the voltage range as per ORTAC[3].

Based on the results, there is no new transmission line capacity need identified.

7.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. The system should also meet load security and load restoration criteria as defined in ORTAC[3]. Based on input from the IESO and LDCs, the following system reliability, operational and restoration issues were identified:

- The new load forecast suggests T23C/T29C corridor will exceed load security limit of 600MW[3] in 2032. Table 6 shows load growth of all double-circuit corridors in the Region (assuming all forecasted loads were supplied from original connection points). The TWG recommends further regional coordination to address the T23C/T29C corridor load security issue, especially when determining where to connect the new Transformer Station to accommodate new needs identified in Section 7.2.3 and 7.2.4. The other T24C/T28C corridor will not have more than 600MW net loads in the assessment window.

Table 6: Double-circuit Corridor Non-coincident Load

Circuits		Non-coincident Load served by the double circuits (MW)									
		2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
T23C/T29C	Summer	442.6	468.3	486.1	500.7	518.2	538.2	562.8	592.4	638.0	671.0
	Winter	362.1	395.3	420.3	442.1	466.3	493.1	524.0	557.0	605.3	639.5
T24C/T26C	Summer	412.9	418.5	424.1	429.5	435.7	472.5	480.9	489.8	501.5	515.4
	Winter	399.0	414.9	428.3	441.7	456.4	501.6	518.7	534.2	552.6	573.3

- All double-circuit corridor loads will exceed 250MW in this assessment timeframe. The ORTAC[3] requires the amount of load interruption in excess of 250MW must be restored within 30 minutes (and within 4 hours for load loss more than 150MW). The TWG surveyed transmission load interruption performance data from 2014 to 2024 for the Region. The results show that delivery points supplied by the circuits in Table 6 did not log load loss of more than 250MW for longer than 30 minutes, or loss of more than 150MW for longer than 4 hours in the past 10 years. Based on past performance data, the TWG would not recommends capital investment for load restoration at this point. Hydro One shall proactively monitor load restoration data and identify opportunities to reduce risk of prolonged load restoration.

7.5 Transmission System Reinforcement Needs

Oshawa-Clarington Sub-region area transmission reinforcement:

In addition to the rapid organic load growth forecasted in T23C/T29C/T24C/T26C corridors, multiple proponents have requested to connect large-scale loads in Oshawa-Clarington Sub-region area. Majority of the requests are large data centers. It is not feasible for the existing 230kV transmission infrastructure in Oshawa-Clarington Sub-region area to accommodate such sizeable loads. Due to the scale and complexity of such connections, the TWG recommends further regional coordination to address these potential capacity needs. Coordinated efforts from IESO bulk system planning, Hydro One, LDCs and major customers should continue in developing solutions.

8. Sensitivity Analysis

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments. The TWG determined that the key electric demand driver in the GTA East region to be considered in this sensitivity analysis is electric vehicle (EV) penetration and unforeseen electrification which would cause the load to increase at a faster rate than shown in the forecast; or the potential delay in some projects which could result in less demand than anticipated.

The TWG reviewed EV scenarios and any unforeseen electrification needs to develop high demand growth forecasts by applying 50% additional growth to the growth rate on the extreme summer/winter corrected Normal Growth net load forecasts. The low growth scenario was obtained by reducing the growth rate by 50%.

The impact of sensitivity analysis for the high and low growth scenario is shown in Table 7. The additional capacity needs identified towards the end of the study period will be assessed again during the next phases of the Regional Planning cycle where another sensitivity anaylyis will be undertaken based on updated information.

Table 7: Impact of Sensitivity Analysis on Capacity Needs in the Region

No.	Need Identified	Need Date		
		Normal Growth Scenario	High Growth Scenario	Low Growth Scenario
Needs update under high and low load growth scenarios				
1	Whitby TS T1/T2 (44kV) LTR	2032	2030	Beyond 2033
2	Thornton TS T3/T4 LTR	2031	2027	Beyond 2033
3	Wilson TS T7/T8 LTR	2032	2029	Beyond 2033
4	Wilson TS T3/T4 LTR	2024 (2025*)	2024 (2025*)	2024 (Beyond 2033*)
Additional capacity needs under high growth scenario				
5	Cherrywood T7/T8 LTR	Beyond 2033	2031	Beyond 2033
6	Seaton MTS LTR**	Beyond 2033	2032	Beyond 2033
7	Whitby TS T3/T4 LTR	Beyond 2033	2031	Beyond 2033

* If the transformers are replaced with higher LTR rating units as planned.

** Based on the LDC provided LTRs of 153MW (Summer) and 180MW (Winter) for Seaton MTS

9. Conclusion and Recommendation

The Technical Working Group's recommendations to address the needs identified are as follows:

Table 8: Needs that Do Not Require Further Regional Coordination

No.	Need	Recommendation
1	Cherrywood TS 230kV Breaker Replacement	Replace 230kV Breaker in multi phases. Two phases are underway with currently planned in-service dates of 2033 and 2037 respectively.
2	Wilson TS T3/T4 Transformer Replacement	Replace Wilson TS T3/T4 transformers with "like for like" standard units with currently planned in service date of 2031.
3	Station capacity need at Whitby TS T1/T2 (44kV) due to load growth	Plan a new Transformer Station at North Whitby area, tapping on 230kV circuits of P15C and T28C. TWG agreed to proceed with local planning and no further regional coordination is required.

Table 9: Needs Requiring Further Regional Coordination

No.	Need
1	Transmission reinforcement at Oshawa-Clarington Sub-region area to accommodate large load connection requests and address potential load security issue
2	Station capacity need at Thornton TS T3/T4 due to load growth
3	Station capacity need at Wilson TS T7/T8 due to load growth
4	Station capacity need at Wilson TS T3/T4 due to load growth

List of LDC(s) to be involved in further regional planning activities:

- Elexicon Energy Inc.
- Oshawa PUC Networks Inc.
- Hydro One Networks Inc. (Distribution)

Executive Summary

The GTA North (York Region) Integrated Regional Resource Plan (IRRP) addresses the electricity needs of the GTA North Region over a 20-year period, from 2024 to 2043. The GTA North Region is located in southern Ontario and is defined by electrical infrastructure boundaries, not municipal, yet roughly includes the municipalities of Aurora, East Gwillimbury, Georgina, King, Markham, Newmarket, Richmond Hill, Vaughan, Whitchurch-Stouffville, and parts of Simcoe County, including Bradford-West Gwillimbury. Because these municipalities primarily fall within York Region, the terms "GTA North Region" and "York Region" are used interchangeably in this study.

For the purposes of this IRRP, the region is often divided into four electrical subsystems: Northern York, Kleinburg, Southern Vaughan-Richmond Hill, and Markham and Area. These subsystems reflect the configuration of the transmission system and the location of major step-down transformer stations and other points of system supply. The IRRP focuses on identifying and addressing electricity needs in each of these subsystems, while also coordinating with broader bulk system planning and other coordinated planning efforts, including regional planning in GTA West and South Georgian Bay-Muskoka, and corridor identification and preservation initiatives.

The Region of York is growing rapidly, with a population of 1.26 million in 2024, and is expected to grow to over 2 million by 2051. Existing infrastructure supplying York Region is insufficient to meet anticipated growth in electricity demand. Some sections of northern York in particular are already experiencing challenges in connecting new customer loads. Investing in new transmission infrastructure would have a positive impact on the region, especially increasing the ability for new loads to connect, and maintaining the reliability of existing customers throughout York Region.

The electricity demand forecast for York Region shows significant growth over the planning horizon, driven by residential intensification, commercial development (including large energy-intensive customers), and electrification trends (such as electric vehicles and heat pumps). Summer peak demand is expected to nearly double by 2043, while winter peaks could potentially triple depending on the pace of electrification. While the region has historically been summer-peaking, winter peaks could become more limiting by the early-2030s. Given the uncertainty associated with long-term growth forecasts, particularly with respect to winter peaks that rely on new customer behaviour and technological availability, this study has placed a greater emphasis on managing uncertainty and risk in demand forecasts. In practice, only summer peak forecasts have been used to make recommendations which require immediate action. For longer term needs, dates associated with summer peaks have been the primary driver for planning during this cycle. The impacts of higher potential winter peaks have been considered and will continue to be monitored through the Annual Working Group to determine the need to trigger long term system reinforcements.

To identify near-, medium-, and long-term needs, the Technical Working Group assessed station capacity, supply capacity, reliability, and load security needs across the region. A combination of wires and non-wires solutions were evaluated, with a number of recommendations made to address near-term needs. Options for addressing longer-term needs are also proposed, but do not yet require action, except to preserve long-term viability of the solution options. Non-wires alternatives (NWAs) such as targeted electricity demand-side management (eDSM) and distributed energy resources

(DERs) have been recommended to help manage near-term reliability risks and potentially defer longer-term infrastructure requirements.

Additional consideration has also been given to long term impacts of reduced reliance on York Energy Centre, following its contract expiry in 2035. This includes evaluation of the impact of the loss of supply on the local system, and potential solutions which may need to be pursued if this facility is no longer available.

The study has also considered points of coordination with an ongoing bulk planning initiative, the South and Central Bulk Plan, which is studying bulk system needs and potential upgrades with a notional 2035 focus. A second, longer-term bulk planning study, expected to be initiated in 2026 with a focus on bulk system needs into the 2040s, will similarly consider potential impact of bulk enhancements on regional supply. Both studies have the potential to affect longer-term needs and feasibility of solutions available to in the area, particularly for needs emerging post 2035 or 2040.

Engagement was a key component of this IRRP. The IESO engaged with municipalities, Indigenous communities, stakeholders, and the public throughout the planning process. Feedback received helped shape the demand forecast, identify local priorities, and inform the recommended solutions.

The Technical Working Group will continue to monitor growth, electrification trends, and large customer connections across the region. The group will meet regularly to track progress, assess changing conditions, and update the plan as needed. If underlying assumptions change significantly, the IRRP may be amended, or a new planning cycle initiated ahead of the standard five-year schedule mandated by the Ontario Energy Board.

Summary of Recommendations

Near-term recommendations emerging from this plan will provide increased station and system capacity across the region and allow for anticipated load growth to be reliably met into the 2030s. Immediate action is recommended to implement the following:

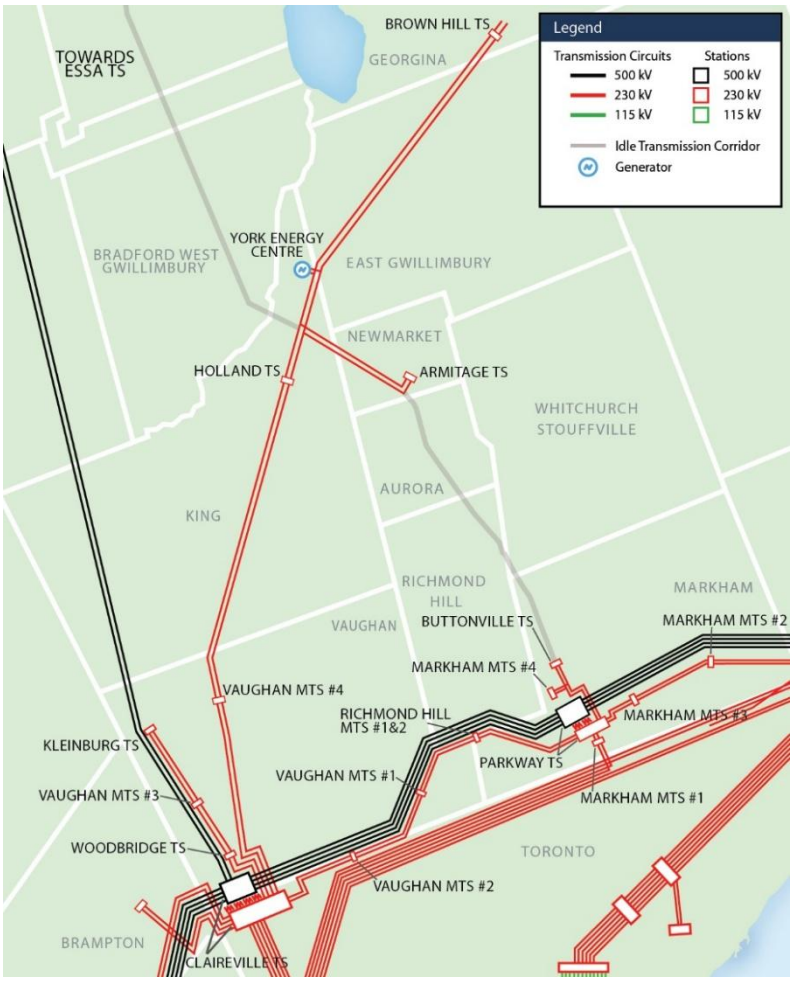
Table 1| Summary of Near-Term Recommendations

Project	Need	Need Timing	Expected In-Service
Additional targeted incremental eDSM to manage demand and ease pressure on the system	Station and Supply Capacity in Northern York, Markham, Richmond Hill, and Whitchurch-Stouffville	Ongoing	Ongoing
Reconfigure York Energy Centre Station Service Supply	Supply Capacity in Northern York	Immediate	2026
Develop Northern York TS #1	Station Capacity in Northern York	Immediate	2030
Develop Markham MTS #5	Station Capacity in Markham	2029	2028/2029

Project	Need	Need Timing	Expected In-Service
Develop Richmond Hill MTS #3	Station Capacity in Richmond Hill	2030	2030
Install new breakers along Parkway to Claireville corridor	Load Security in Vaughan and Richmond Hill	Immediate	2028/2029
Reconductor Circuit P45/46 from Parkway to Buttonville TS to support Markham TS #5 (in phases)	Supply Capacity in Markham	2029	2029
Build a new 230kV transmission line along the future Highway 413 corridor (Kleinburg – Kirby Transmission Line)	Supply Capacity in Northern York	2030	2031/2032
Develop/preserve viability of long-term capacity options through corridor identification and preservation initiatives	Station and Supply Capacity	Ongoing	Ongoing

The Technical Working Group will continue to monitor and may recommend action based on revised forecasts and demand growth for these medium- to long-term needs and recommendations:

Table 2| Summary of Medium- to Long Term Recommendations



Project	Need	Need Timing	Expected In-Service
Develop Vaughan MTS #5	Station Capacity in Vaughan	2033	2033
Extend transmission from Buttonville TS and develop Northern York TS #2 and Markham TS #6	Station Capacity in Markham, Richmond Hill, and Whitchurch-Stouffville	2034	2034
Monitor future electricity needs and begin early planning for new infrastructure including Northern York TS #3 and the Holland switching station	Station and Supply Capacity in Northern York	2035	2035

1 Introduction

This Integrated Regional Resource Plan (IRRP) addresses electricity needs for the GTA North Regional Planning area ("GTA North" or "York Region") between 2025 and 2043. This report was prepared by the Independent Electricity System Operator (IESO) on behalf of the York Region Technical Working Group comprising the IESO, Alectra Utilities Corporation (Alectra), Newmarket-Tay Power Distribution Ltd. (NT Power), Hydro One Networks Inc. (Hydro One Distribution), and Hydro One Networks Inc. (Hydro One Transmission).

In Ontario, planning to meet the electrical supply and reliability needs of a local area or region is carried out through regional electricity planning, a process that was formalized by the Ontario Energy Board (OEB) in 2013. In accordance with this process, transmitters, distributors and the IESO are required to carry out regional planning activities for 21 electricity planning regions across Ontario, at least once every five years. The GTA North Region, shown in Figure 1, roughly corresponds with the municipal boundaries of York Region. For the purposes of this plan, GTA North and York Region can be used interchangeably.

Figure 1| Overview of the GTA North (York) Region

Development of the GTA North (York Region) IRRP was initiated in October 2023, following the publication of the Needs Assessment report in July 2023 by Hydro One and the Scoping Assessment Outcome Report in October 2023 by the IESO. The Scoping Assessment identified the area's needs should be further assessed through an IRRP. The Technical Working Group was then formed to gather data, identify near-, medium-, and long-term needs in the region, and develop the recommended actions included in this IRRP.

This report is organized as follows:

- A summary of the recommended plan for the region is provided in Section 2
- The process and methodology used to develop the plan are discussed in Section 3
- The background for electricity planning in the region and the study scope is discussed in Section 4
- The development of the demand forecast, including electricity Demand Side Management (eDSM) and distributed generation assumptions, are described in Section 5
- Electricity needs in the region are presented in Section 6
- Alternatives and recommendations for meeting needs are addressed in Section 7
- Linkages to the South and Central Bulk Study is outlined Section 8
- A summary of engagement activities is provided in Section 9, and
- The conclusion is provided in Section 10.

2 The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of York Region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system, as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by the North American Electric Reliability Corporation (NERC) and Northeast Power Coordinating Council (NPCC). The IRRP's recommendations are informed by an evaluation of different options to address the region's needs in consideration of reliability, cost, technical feasibility, maximizing the use of the existing electricity system (where economic), and feedback from communities and stakeholders.

2.1 Status of Projects from Previous IRRP Cycles

Following the previous cycle of regional planning, which concluded with the 2nd Cycle RIP report, several projects were recommended that have now been completed or are presently underway. The status of these projects is summarized in Table 3.

Table 3| Needs Identified in the Previous Cycle with Revised In-Service Date

Project	Need	Expected In-Service
Collect Information on future NWAs and opportunities in York Region to inform the next IRRP	Station and Supply Capacity	Ongoing
Reconfigure York Energy Centre Station Service Supply	Supply Capacity	2026
Develop Markham MTS #5	Station Capacity	Expected in Service Date in 2028/2029
Reconductor Circuit P45/46 from Parkway to Markham MTS #4	Supply Capacity	Expected in Service Date in 2029
Develop Northern York TS #1	Station Capacity	Expected in Service Date in 2030
Develop/Preserve Viability of Long-term Capacity Options	Station and Supply Capacity	Ongoing

2.2 Plan for Near-Term Needs (2026-2030)

The near-term plan consists of several recommendations to enable load growth and maintain reliability. Many of these needs are immediate, and based on today's peak demand, while others are based on strong anticipated load growth over the next five years. Implementation should be initiated immediately to ensure required in service dates can be met.

Additional targeted incremental eDSM to manage demand and ease pressure on the system. As an interim measure, eDSM may be considered to manage shortfalls where the infrastructure solution is not expected to be in service in time to meet existing or anticipated needs. eDSM also has the potential to defer the need for additional infrastructure investments anticipated to be required in the medium- to long-term.

Reconfigure York Energy Centre (YEC) Station Service Supply. Upgrading the station supply arrangement for YEC would allow for this facility to remain operational for a wider range of transmission outage conditions. This would have an immediate reliability benefit for local customers and improve the ability to supply load in the area. Cost and in-service timelines will be evaluated following more detailed site-specific analysis.

Develop Northern York TS #1. The need for additional station capacity in Northern York is immediate. Based on existing loads and near-term demand forecast, it is recommended that Hydro One proceed with the acquisition of land, the design, and the construction of a new step-down station by 2029 to serve Northern York Region, in the vicinity the Holland TS area. Typical development costs for these types of stations, including real estate, are generally $60 million.

Develop Markham TS #5. The need for additional station capacity for Markham area was identified in the previous IRRP and reaffirmed with the latest demand forecast to be required by 2029. Alectra has identified a suitable location for the next Markham MTS #5 near the existing Buttonville TS on the P45/46 circuits, and this project is currently under development. Typical development costs for these types of stations, including real estate, are generally $60 million.

Develop Richmond Hill MTS #3. The need for additional station capacity in Richmond Hill is expected by 2030, triggered by new development applications in proximity to the planned Yonge subway extension. Alectra has identified a suitable location for the next Richmond Hill MTS #3, and this project is currently under development. The proposed connection point will be along the V71/75V circuits, near the existing Richmond Hill MTS #1 and #2. Typical development costs for these types of stations, including real estate, are generally $60 million.

Install new breakers along Parkway to Claireville corridor. The existing V71/75P transmission corridor between Claireville TS and Parkway TS are currently loaded at over 600 MW during summer peak, with demand having exceeded 730 MW in 2025. This violates applicable security criteria, and loading is expected to worsen following the connection and loading of Richmond Hill MTS #3 in 2030 and Vaughan MTS #5 in 2033. Estimated costs are $30-35 million.

Reconductor Circuit P45/46 from Parkway to Buttonville TS to support Markham TS #5. Connection and loading of the new Markham MTS #5 is expected to trigger thermal needs on P45/46. Reconductoring of the existing lines will enable full loading of this station, which comes into service in 2028/2029. The cost of reconductoring the entire facility is estimated at $14, though there are opportunities to carry out this work on a phased basis.

Build a new 230kV transmission line along the future Highway 413 corridor (Kleinburg – Kirby Transmission Line). A new, six-km double circuit 230kV transmission line is proposed adjacent to the planned Highway 413 in Vaughan. This new transmission line, referred to as the Kleinburg – Kirby Transmission Link, would create a connection between the existing Kleinburg radial tap, and connect to a point north of the exiting Vaughan MTS #4 along the H82/83V circuits. It would enable the connection and full loading of the next Northern York TS #1 step down station. The cost of this transmission is estimated at $40 million, with an estimated in-service date of 2031-2032. Operation of this facility will require coordination with bulk system upgrades at Kleinburg TS, as under development in the ongoing Bulk System Plan for South & Central Ontario (see Section 8).

2.3 Plan for Medium to Long-Term Needs (2031-2040)

While most recommended actions from this plan are concerned with addressing near term needs (within the next five years), the sections below outline potential medium- to long-term recommendations beyond that horizon. These recommendations, including their targeted in-service dates, are subject to change and will be continuously re-evaluated as planning progresses, based on new information and actual load growth. Early identification of these plans is important to ensure ongoing engagement with potentially affected communities, coordination with broader regional and bulk system planning, and to enable timely implementation when required. It is recommended that the Working Group finalize a long-term adaptive pathway[1] for each subsystem following the completion of this cycle of regional planning.

Develop Vaughan MTS #5. The need for additional station capacity in downtown Vaughan is expected in 2033, triggered by intensified development in the Vaughan Metropolitan Centre (VMC). Alectra is in the process of evaluating potential locations for the next Vaughan MTS #5. The ultimate connection point will likely be along the V71/75V circuits, between the existing Vaughan MTS #1 and the Richmond Hill MTSs. Typical development costs for these types of stations, including real estate, are generally $60 million.

Extend transmission from Buttonville TS and develop Northern York TS #2 and Markham TS #6. The need for additional station capacity in the areas of northern Markham, northern Richmond Hill, and Whitchurch-Stouffville is expected to trigger the need for the development of two new step-down stations, Markham MTS #6 and Northern York TS #2, in the mid 2030s. In order to supply these stations, an approximate 7-km extension of the existing P45/46 circuits is recommended into northern Markham, along an existing, idle transmission right of way. Costs of this transmission could range from $45 million to $175 million, depending on the technology selected during the project scoping and environmental assessment process (e.g., overhead versus underground). This solution would also require development of a new transmission tap to remove Markham MTS #4 from P45/46 supply. The preferred location to supply this station would be the C35/36P circuits, with a likely additional cost of $9 million.

[1] Adaptation pathways are sequences of actions, which can be implemented progressively, depending on future dynamics and uncertain variables.

Monitor future electricity needs in northern York and begin early planning for new infrastructure including Northern York TS #3 and the Holland switching station. Longer-term station capacity needs will likely trigger additional transmission upgrades in Northern York including, at a minimum, a new switching station in the vicinity of Holland Marsh junction to coincide with the development of Northern York TS #3 in the mid 2030s. Switching stations typically cost $200-250 million, though it would also have bulk system benefits. The potential retirement of York Energy Centre post-2035 has also been identified as a key driver of future supply needs and would likely trigger the development of additional infrastructure in the area. The exact nature of options and recommendations will continue to be evaluated and will be informed by ongoing bulk system studies.

3 Development of the Plan

3.1 The Regional Planning Process

In Ontario, preparing to meet the electricity needs of customers at a regional level is achieved through regional planning. Regional planning assesses the interrelated needs of a local area – defined by common electricity supply infrastructure – over the near, medium, and long term periods. The result is a plan aimed at ensuring cost-effective and reliable electricity supply. A regional plan considers the existing electricity infrastructure in an area, forecasts growth and customer reliability, evaluates options for addressing needs, and recommends actions.

The current regional planning process was formalized by the Ontario Energy Board in 2013 and is performed on a five-year cycle for each of the 21 planning regions in the province. The process is carried out by the IESO, in collaboration with the transmitters and LDCs in each region. The process consists of four main components:

1. A Needs Assessment, led by the transmitter, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;
2. A Scoping Assessment, led by the IESO, which identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities;
3. An IRRP, led by the IESO, which proposes recommendations to meet the identified needs requiring coordinated planning; and/or
4. A RIP, led by the transmitter, which provides further details on recommended wires solutions.

Regional planning is not the only type of electricity planning in Ontario. The IESO also carries out bulk system planning and Local Distribution Companies are responsible for distribution system planning. There are inherent linkages in all three levels of electricity infrastructure planning. Further details on the regional planning process and the IESO's approach to it can be found in Appendix A.

3.2 GTA North IRRP Development

The process to develop the GTA North (York) Region IRRP was initiated in October 2023, following the publications of the Needs Assessment Report in July 2023 by Hydro One and the Scoping Assessment Outcome Report in October 2023 by the IESO. The Scoping Assessment recommended that the needs identified for GTA North Region be considered through an IRRP in a coordinated regional approach, supported with public engagement. The Technical Working Group was then formed to develop the terms of reference for this IRRP, gather data, identify needs, develop options, and recommend solutions for the region.

4 Background and Study Scope

This is the third cycle of regional planning for the GTA North (York) Region. This Region is located in southern Ontario and includes all or part of the following cities, towns and townships:

Aurora	Bradford West Gwillimbury	East Gwillimbury	Georgina
King	Markham	Newmarket	Richmond Hill
Simcoe County	Vaughan	Whitchurch-Stouffville	

For electricity planning purposes, the planning region is defined by electricity infrastructure boundaries, not municipal boundaries. This Region also includes several Indigenous communities that may be potentially impacted or may have an interest based on treaty territory, traditional territory or traditional land use:

Alderville First Nation, Beausoleil First Nation, Chippewas of Georgina Island First Nation, Chippewas of Rama First Nation, Curve Lake First Nation, Hiawatha First Nation, Mississaugas of Scugog Island First Nation, Mississaugas of the Credit First Nation, Six Nations of the Grand River as represented by Six Nations Elected Council as well as the Haudenosaunee Confederacy Chiefs Council, Métis Nation of Ontario.

Following a Needs Assessment in March 2018 and a Scoping Assessment in August 2018, an IRRP and subsequent RIP were initiated and published in February 2020 and October 2020, concluding the second planning cycle for the Region.

This IRRP develops and recommends options to meet the electricity needs of the GTA North (York) Region in the near, medium, and long term. The plan was prepared by the IESO on behalf of the Technical Working Group, and includes consideration of forecast electricity demand growth, eDSM, distributed energy resources (DERs) transmission and distribution system capability, relevant community plans, condition of transmission assets, and developments on the bulk transmission system.

The GTA North (York) Region covers a large portion of the transmission system in both the Toronto and Essa IESO electrical zones. As all the transmission facilities in the region are included in the scope of this study, it has often been broken up into four subsystems:

- **Northern York Subsystem (B88H/B89H, H82V/H83V) Subsystem**

  This subsystem consists of five step-down transformer stations that supply northern Vaughan and communities in Northern York Region (Aurora, Newmarket, King, East Gwillimbury, Whitchurch-Stouffville and Georgina and the Chippewas of Georgina Island). York Energy Centre is connected to these 230 kV circuits. This subsystem also serves as a pathway for power to flow between northern and southern Ontario.

- **Kleinburg (V44/V43) Subsystem**

  This subsystem consists of three step-down transformer stations that primarily supply rural and urban communities in Vaughan and Caledon, as well as some areas of Brampton, Mississauga, and Toronto. Power is delivered into this subsystem from Claireville TS.

- **Southern Vaughan-Richmond Hill Subsystem (V75P/V71P, P21R/P22R)**

  This subsystem consists of four step-down transformer stations that supply the southern parts of urban communities in the Markham, Richmond Hill and Vaughan areas.

- **Markham and Area Subsystem (P45/P46, C35P/C36P)**

  This subsystem consists of 6 step-down transformer stations that are located in urban communities primarily in the Markham. This subsystem also serves as a pathway for power to flow across the GTA along the Parkway Belt/Highway 407 transmission corridor.

The Northern York subsystem consists of the following stations:

Brown Hill TS	Armitage TS	Holland TS	Vaughan MTS #4

The Kleinburg subsystem consists of the following stations:

Kleinburg TS	Vaughan MTS #3	Woodbridge TS

The Southern Vaughan-Richmond Hill subsystem consists of the following stations:

Vaughan MTS #1	Vaughan MTS #2	Richmond Hill MTS #1	Richmond Hill MTS #2

The Markham and Area subsystem consists of the following stations:

Buttonville TS	Markham MTS #1	Markham MTS #2	Markham MTS #3	Markham MTS #4

The GTA North (York) IRRP was developed by completing the following steps:

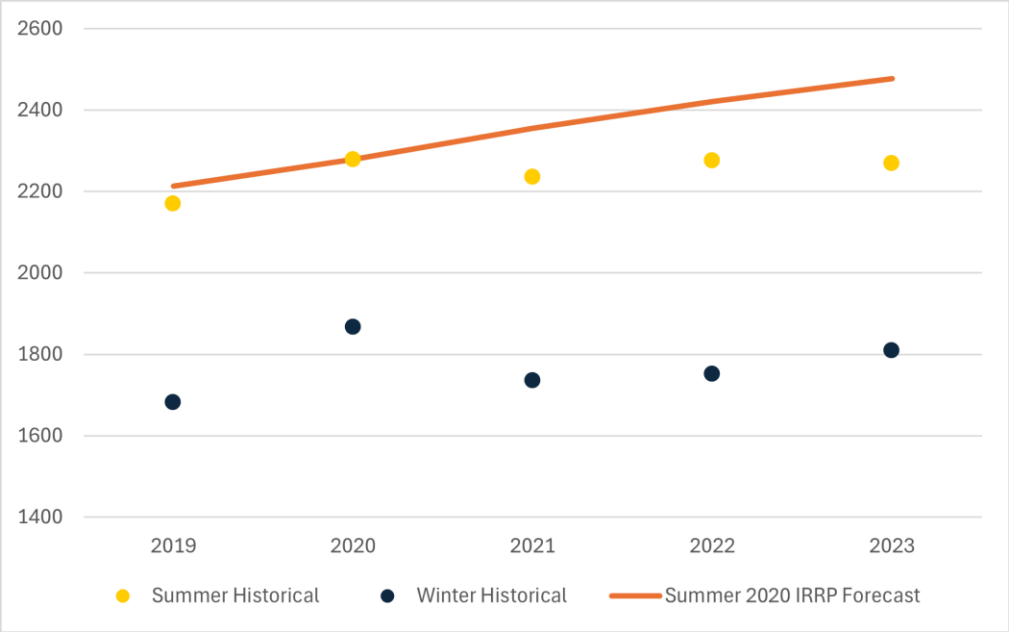
- Preparing a 20-year electricity demand forecast and establishing needs over the 2024-2043 timeframe (as described in Section 5);
- Examining the load meeting capability (LMC) and reliability of the existing transmission system, taking into account facility ratings and the performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying the criteria and standards from ORTAC, NPCC, and NERC.
- Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO-controlled grid.
- Confirming identified asset replacement needs and timing with the transmitter and LDCs.

- Establishing alternatives to address system needs including, where feasible and applicable, generation, transmission and/or distribution, and other approaches such as non-wire alternatives including eDSM.
- Engaging with the community on needs and possible alternatives.
- Evaluating alternatives to address near-, medium-, and long-term needs; and communicating findings, conclusions, and recommendations within a detailed plan.

5 Electricity Demand Forecast

Regional planning in Ontario is driven by having to meet peak electricity demand requirements in the region. This section describes the development of the demand forecast for the GTA North (York) Region. It highlights the assumptions made for peak demand forecasts, including weather correction, and the contribution of eDSM and DG. The LDCs in the region provided both a winter and summer 20-year forecast that incorporates organic growth and growth associated with drivers like electrification (e.g., heating load and electric vehicles).

To evaluate the reliability of the electricity system, the regional planning process is typically concerned with the coincident peak demand for a given area. This is the demand observed at each station for the hour of the year in which overall demand in the study area is at its maximum.



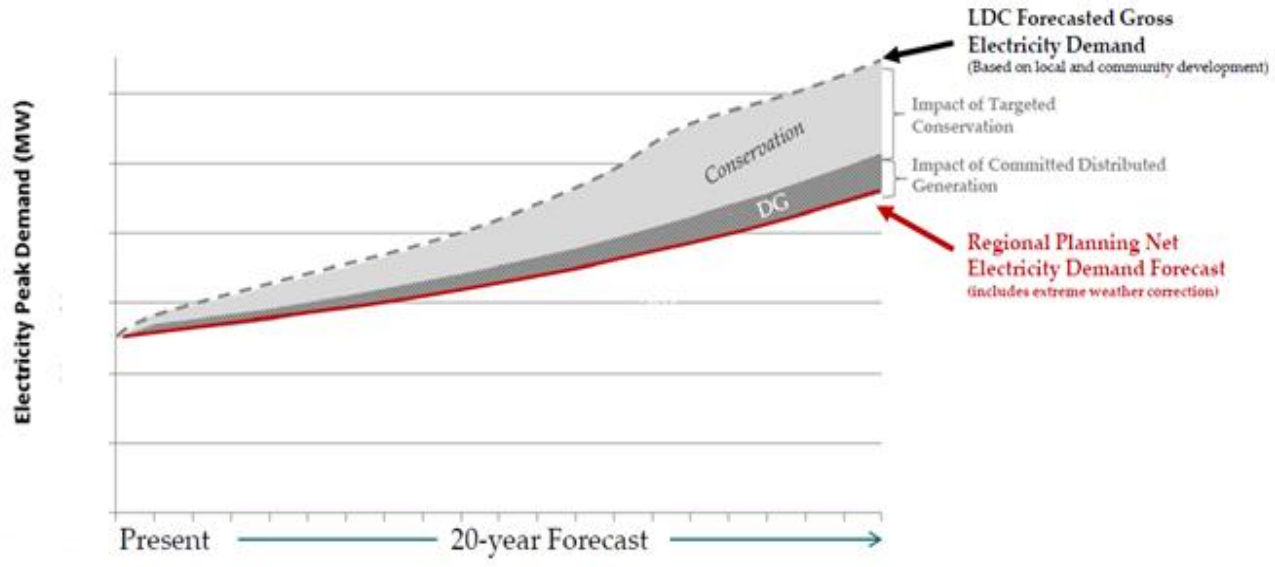
The regional planning process also considered non-coincident peaks which refers to each station's individual peak, regardless of whether these peaks occur at different times. Non-coincident peaks are used to understand the potential needs of the stations.

5.1 Historical Demand

Peak electricity demand within GTA North has historically occurred in the summer season. Figure 2, below, shows both the winter and summer coincident gross normal weather-corrected (adjusted to reflect normal weather conditions) historical demand for the GTA North region. Weather-corrected historical demands have been shown to remove the effect of weather on annual changes in demand, as they are more appropriate for evaluating growth trends. For context, Figure 2 also includes the summer peak demand forecast for the same years from the 2020 IRRP.

The gross weather-corrected demand for the GTA North region has averaged 2,245 MW in the summer and 1769 MW in the winter over the last five years preceding the IRRP start date (2019-2023).

Figure 2| Summer and Winter Historical Weather-Corrected Coincident Peak



5.2 Demand Forecast Methodology

The methodology used to develop a 20-year IRRP peak demand forecast is illustrated in Figure 3. A gross demand forecast, which assumes the weather conditions of a normal year based on historical weather conditions (referred to as "normal weather"), was developed by the LDCs. This forecast was then adjusted to reflect the expected impact of extreme weather conditions to produce a reference forecast for planning assessments. Extreme weather conditions, as defined by the IESO, assume the worst observed weather over the previous 30 years. The forecast was then modified to reflect the expected peak demand impacts of provincial demand side management programs and DG contracted through previous provincial programs, such as renewable Feed-In Tariff (FIT) and microFIT standard offer programs. This net demand forecast was used to assess the electricity needs in the region.

Additional details related to the development of the demand forecast are provided in Appendix B. The load forecast methodology is also informed by the Load Forecast Guideline for regional planning, which was formalized by the OEB's Regional Planning Process Advisory Group.

Figure 3| Illustrative Development of Demand Forecast

5.3 Gross LDC Forecast

LDCs are responsible for preparing the gross demand forecast as they have the most direct understanding of future local demand growth and drivers, informed by involvement with their customers, connection applicants, municipalities and the communities which they serve. Gross demand forecasts were prepared by the participating LDCs at the station level, or at the station bus level for multi-bus stations. The gross demand forecast generally accounts for increases in demand from new or intensified development, plus known connection applications. In addition, when producing the gross demand forecast, the impact of existing DG was removed, as DG impacts are accounted for later (see Section 5.5). More details are provided in Appendix B.

The LDCs' forecasts considered the appropriate municipal plans for their service territories. The LDCs were also expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices (natural conservation), but not for the impact of future DG or new demand side management activities (such as codes and standards and eDSM programs), which are accounted for by the IESO (discussed in Section 5.4). The gross LDC forecast assumes normal weather conditions (e.g. median weather, expected 1 in 2 years), and provided station level loading at the time of the regional peak.

The IESO typically carries out demand forecasting at the provincial level, which is more applicable for bulk system analysis than regional. More details on the LDC load forecast assumptions can be found in Appendix B.

5.4 Contribution of Electricity demand Side Management

Electricity demand side management (eDSM, formerly Conservation and Demand Management or CDM) is a non-emitting and cost-effective resource that helps meet Ontario's electricity needs by reducing electricity consumption and peak demand and has become an integral component of provincial and regional planning. Electricity savings from demand side management is achieved

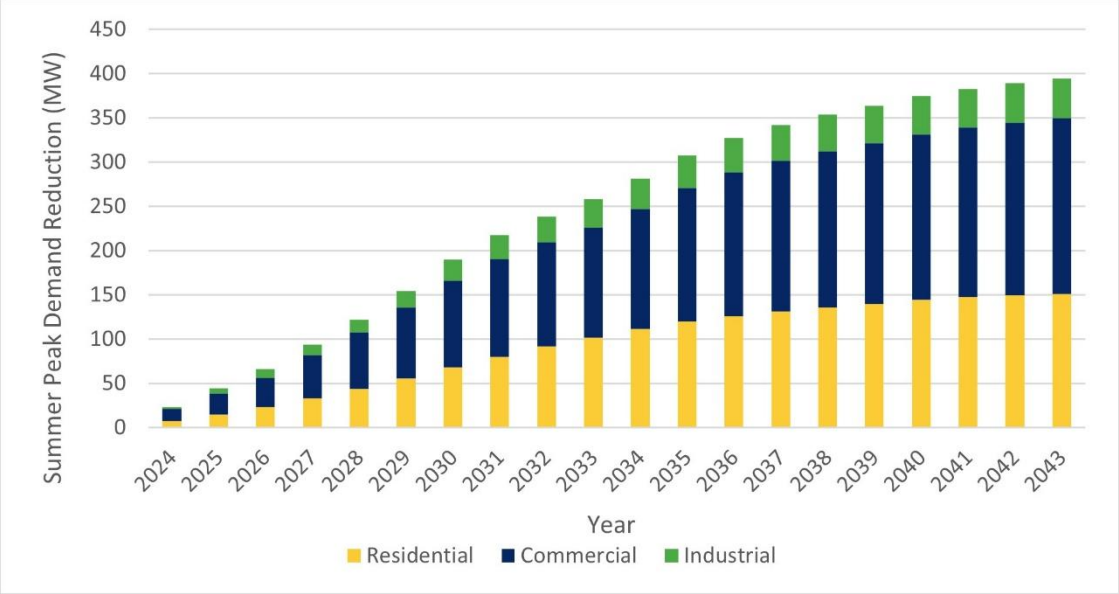
through a mix of efficiency codes and standards, as well as eDSM program-related activities. These approaches complement each other to maximize results.

The estimated demand reduction from codes and standards is based on expected improvement in the codes for new and renovated buildings, and through regulation of minimum efficiency standards for equipment used by specified categories of consumers (e.g., residential, commercial and industrial consumers).

The estimated demand reduction from program-related activities was based on the IESO's 2024 Annual Planning Outlook eDSM savings forecast informed by the then current 2021-2024 Conservation and Demand Management (CDM) Framework, federal programs that result in electricity savings in Ontario, and forecasted long-term energy efficiency programs assumed to be consistent with 2021-2024 framework savings levels. Through the 2021-2024 CDM Framework the IESO centrally delivered programs under the Save on Energy brand s to serve business and residential customers, as well as Indigenous communities. Following finalization of the IRRP's demand forecast, the Ontario government provided the IESO with the directive for the 2025-2036 Electricity Demand Side Management Framework, which expands the scale and scope of the Save on Energy programs, including launch of the Home Renovations Saving program for residential customers and new incentives for rooftop solar for both residential and business customers. Higher savings targets under the new framework may impact the timing or reduce the magnitude of identified needs.

Figure 4 and Figure 5 show the estimated total yearly reduction to the demand forecast due to demand side management (from codes, standards, and eDSM programs). Additional details are provided in Appendix B.

Figure 4| Summer Peak Demand Reduction Due to Demand Side Management



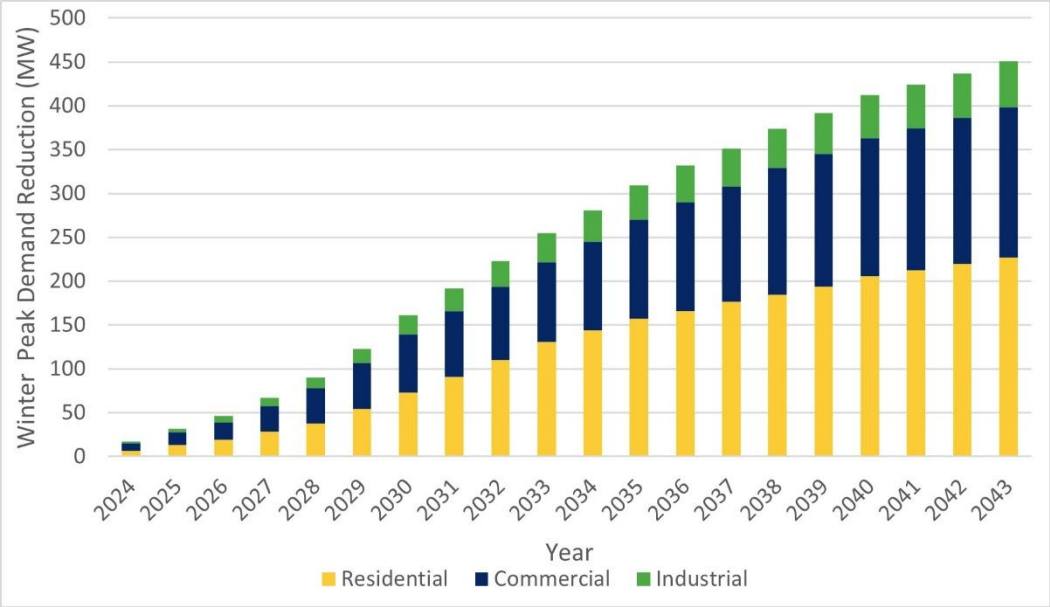


Figure 5| Winter Peak Demand Reduction Due to Demand Side Management

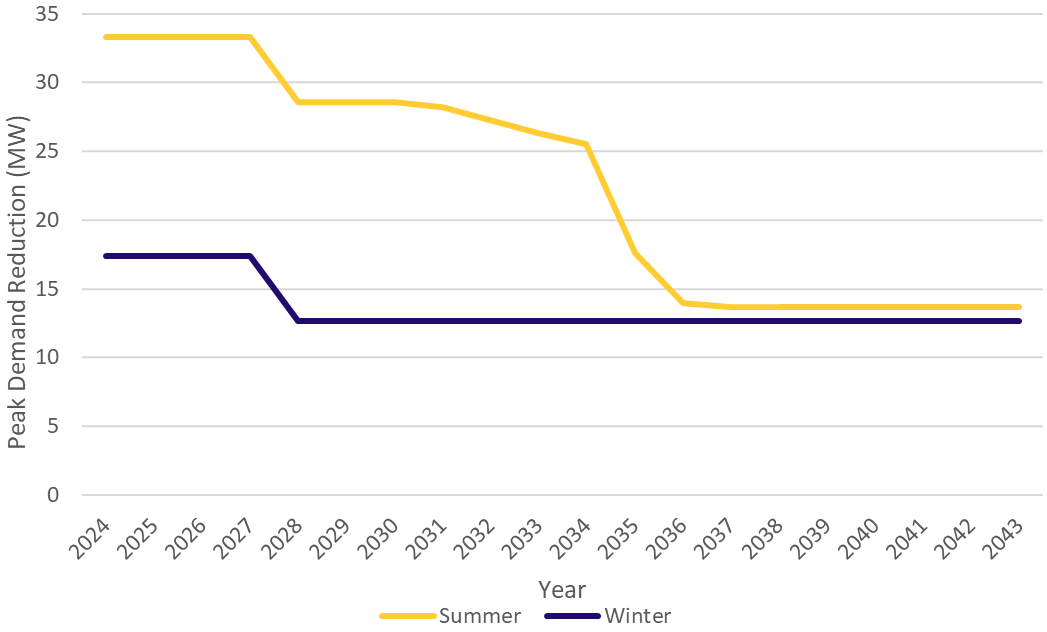


5.5 Contribution of Distributed Energy Resources to the Forecast

In addition to demand side management programs (which can include behind the meter DG), DG is forecasted to offset peak-demand requirements. The introduction of Ontario's FIT and microFIT Programs increased the significance of distributed renewable generation which, while intermittent, contributes to meeting the province's electricity demands. The installed DG capacity by fuel type and the associated contribution factor assumptions can be found in Appendix B. The total contracted installed DG capacity in the GTA North Region is composed of a mix of renewable and non-renewable sources.

Figure 6 shows the estimated impact of DG on the GTA North Region demand forecast. The forecasted impact declines as existing FIT and microFIT contracted facilities reach the end of their contract terms throughout the late 2020s and into the mid-2030s.

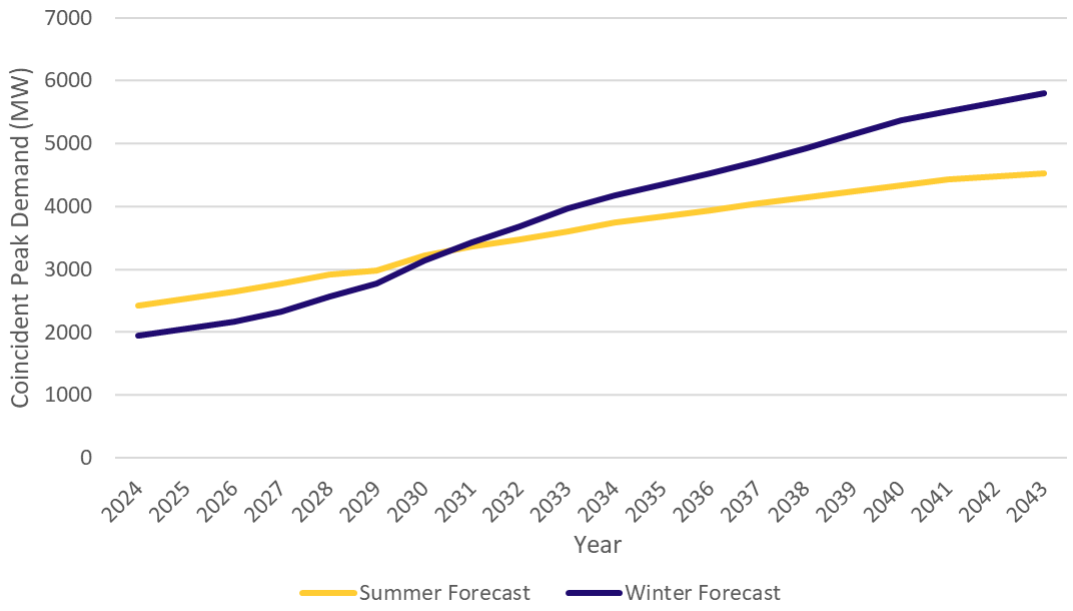
Figure 6| Peak Demand Reduction Due to Distributed Energy Resources

5.6 Net Extreme Weather (Planning) Forecast

The net extreme weather forecast, also known as the "planning" forecast, is traditionally a region-wide coincident forecast, meaning that each station forecast reflects its expected contribution to the regional peak demand. This supports the identification of need dates for regional needs driven by more than one station.

The planning forecast is produced from two main steps: adjusting for extreme weather and converting to a net forecast.

The first step is to adjust the coincident gross normal weather forecast for extreme weather conditions. The weather correction methodology is described in Appendix B. This results in a coincident gross forecast which assumes extreme weather. Two separate weather scenarios were prepared; one for extreme summer conditions, and one for extreme winter conditions.



Historically, York Region has experienced its highest loading conditions during summer months, driven by air conditioning loads. This is consistent with overall provincial peak conditions, which often occur on the same day and on similar, late afternoon hours as York Region. However, the expected adoption of electrified heating, namely heat-pumps, is forecast to significantly increase winter demand over the coming decades. While there is uncertainty around the rate of uptake, technology types, and operational decisions, a winter demand forecast was also developed to study the impact of higher winter peak growth rates. Both summer and winter peak forecasts were considered in this IRRP.

The last step is to adjust the resulting coincident gross extreme weather forecast for the impact of DG and demand side management. This is done by subtracting the forecasted DG and electricity demand side management (as described in the above Sections) from the coincident gross extreme weather forecast. This results in a coincident net extreme weather forecast, which is the "planning" forecast used to identify needs. Separate impacts were calculated based on typical summer and

winter contributions of the load modifying resources during the peak hours, based on technology type.

The coincident net extreme weather forecasts ("planning" forecasts) for GTA North Region are shown in Figure 7.

Figure 7| GTA North Region Net Extreme Weather Coincident Forecast

5.7 Hourly Forecast Profiles

In addition to the annual peak demand forecast, hourly demand profiles (8,760 hours per year over the 20-year forecast horizon) for various collections of stations were developed to better assess the potential for non-wire alternatives to address needs. These profiles were used to quantify the magnitude, frequency, and duration of needs, as described later in Section 7. The profiles were based on historical demand data, adjusted for variables that impact demand such as calendar day (i.e., holidays and weekends) and weather. The profiles were then scaled to match the IRRP peak planning forecast for each year.

Additional details on how load profiles were created can be found in Appendix C. Note that this data is used to roughly inform the overall energy requirements needed to develop and evaluate alternatives; it cannot be used to deterministically specify the precise hourly energy requirements. Real-time loading is subject to various factors like actual weather, customer operation strategies, and future customer segmentation. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification are more widely adopted. Hence, these hourly forecasts are used to select suitable technology types and roughly estimate costs for the needs and options studied in the IRRP. The Technical Working Group will continue to monitor forecast changes through an Annual Working Group Meeting and as part of implementation of the plan.

5.8 Uncertainty in the Demand Forecast

The forecast for GTA North considers various growth drivers that each have an associated degree of uncertainty. The uncertainty in the regional planning process is managed through a flexible and adaptive approach that emphasizes monitoring, scenario analysis, and preserving future options. Development is only triggered when specific conditions are met within the designated development window, ensuring that investments are made based on clear and timely signals.

Based on the current forecast, the possibility of significantly higher winter growth rates may drive winter conditions to become more "limiting", or determine station capacity need dates, within the 2030s. This is in spite of winter ratings for transmission lines and stations being higher in winter than in the summer.

However, these winter forecasts also carry higher uncertainty due to factors like technology adoption and operational decisions, making them less reliable for immediate investment planning. Unlike summer peaks, which are largely informed by existing customer behaviour and technologies (notably widely used air conditioning), winter peaks assume continuous shifting of behaviour through adoption of electric heating and phase-out of existing gas heating. The adoption of electric heating is currently mainly driven through various level of government policies, economic incentives, and customer preferences. Due to the challenges with assuming how policy and technology will evolve over 20 years, the longer-term winter forecasts (2031-2043), have a greater level of uncertainty associated with them. They are considered in this IRRP for determining measures to preserve future options, but emphasis was placed on summer needs when determining timing of the required reinforcements.

Summer peak demand was used as a more certain foundation for guiding investment decisions, while actual winter demand trends will continue to be closely monitored to inform future adjustments. This strategy lays the groundwork for the plan to evolve cycle-to-cycle as clearer patterns emerge.

6 Needs

6.1 Needs Assessment Methodology

Based on the planning demand forecast, system capability, the transmitter's identified asset replacement plans, and the application of established power system reliability standards and criteria (IESO ORTAC, NERC TPL-001-4, and Northeast Power Coordinating Council (NPCC) Directory #1 standards), the Technical Working Group identified electricity needs in the near-term, medium-, and long-term timeframes. Near-term needs are expected to emerge within 5 years, and/or where immediate action is required. Medium- and Long-term needs are expected to emerge more than 5 years out, and immediate actions are not generally required, unless to preserve future options.

These needs are categorized according to the following:

Station Capacity Needs describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations during periods of peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day Limited Time Rating (LTR) of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be more limited by the thermal ratings of downstream or upstream equipment, e.g., breakers, disconnect switches, medium-voltage bus or high voltage circuits; or, by voltage drop limitations, which are independent of thermal ratings.

Supply Capacity Needs describe the electricity system's inability to provide continuous supply to a local area during peak demand. This is limited by the load meeting capability (LMC) of the transmission supply. The LMC is determined by evaluating the maximum demand that can be supplied to an area after accounting for limitations of the transmission elements (i.e., a transmission line, group of lines, or autotransformer), when subjected to contingencies and criteria prescribed by ORTAC, TPL-001-4, and NPCC Directory #1. LMC studies are conducted using industry standard power system simulations.

Asset Replacement Needs are identified by the transmitter, informed by asset condition assessments, based on a range of considerations such as equipment deterioration due to age, weathering, heat stress or other factors; technical obsolescence due to outdated design; lack of spare parts availability or manufacturer support; and/or potential health and safety hazards, etc. Asset replacement needs identified in the near-term timeframe would typically reflect condition-based information, while replacement needs identified in the longer term are often based on the equipment's expected service life. As such, any recommendations for medium- or long-term needs should reflect the potential for the need date to change as condition information is routinely updated.

Load Security and Load Restoration Needs describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power

to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements for Ontario are described in Section 7 of the ORTAC.

Technical study results for the GTA North IRRP can be found in Appendix E. The needs identified are discussed in the following sections and are shown in the proceeding sections.

6.2 Near-Term Needs (2026-2030)

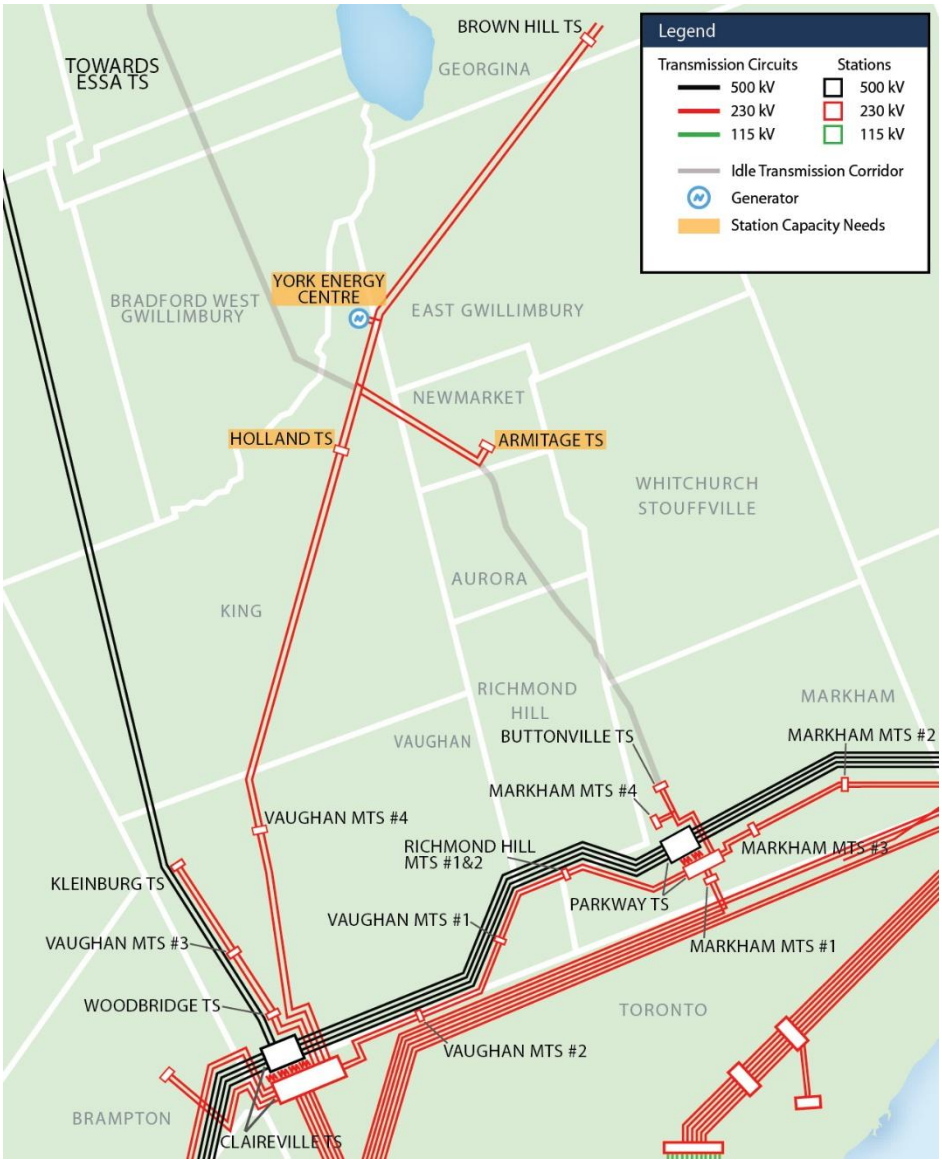
6.2.1 Station Capacity Needs

Step-down station capacity needs are determined by comparing the station peak demand forecast to the facility's LTR. In many cases, need dates can be deferred by transferring load at a station expected to reach or exceed its LTR to another nearby station that has available capacity. Feasible load transfers are already assumed in the station-level demand forecast based on input from LDC members of the Technical Working Group about the transfer capabilities and typical loading practices.

Stations will typically have a lower LTR for summer months than for winter months, as colder ambient temperatures allow more power to flow through equipment without overheating transformers and other station equipment. When a station reaches its annual peak during summer months, this becomes the only forecast scenario which requires study, as it is the most limiting condition. When stations reach their peak during winter months, however, both summer and winter forecasts should be considered as the higher winter loading may be offset with higher ratings, and either season could ultimately be the more "limiting" scenario.

When a step-down station's capacity is reached (summer or winter), and after feasible load transfers are accounted for, options for addressing the need include reducing peak demand in the supply area (i.e.., through EE or DERs) or building new step-down transformer capacity to serve incremental growth.

Typically, where there is sustained new urban growth and development in an area, measures to reduce the peak demand cannot defer or avoid the need for new station capacity indefinitely. Planning recommendations are informed by comparing the cost of these measures to the value of deferring construction of a new or expanded station.



Before a new step-down station can be built, a suitable location must be identified. Stations must be connected to a part of the broader transmission system with enough incremental capacity available to reliably supply the station load. The station must also be located close enough to the anticipated customer demand to ensure that the distribution network is capable of supplying customers reliably.

Additional information on specific station capacity needs anticipated in GTA North in the near term are provided in the sections that follow.

6.2.1.1 Northern York

Northern York Region[2] electrical service territory is currently supplied by four step-down stations. Armitage TS and Holland TS are located in proximity to Newmarket and Holland Marsh, respectively, while Brown Hill TS is located further north, near Georgina, and Kleinburg TS further south, at the border between Caledon and Vaughan. Recent load growth within northern York has been served through Armitage TS and Holland TS, and forecast growth continues to be concentrated in the areas supplied by these two stations.

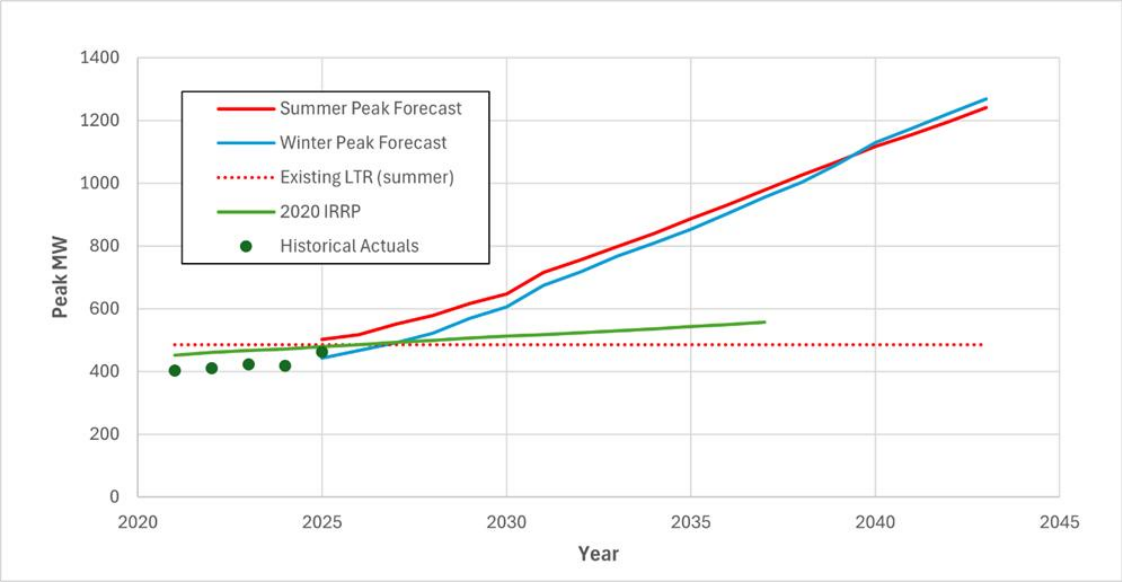
Figure 8| Northern York Station Needs

Although electrical service territories do not correspond directly to municipal boundaries, Armitage TS and Holland TS generally supply Newmarket, Aurora, East Gwillimbury, and parts of Bradford-West Gwillimbury, King Township, and Whitchurch-Stouffville.

[2] Term is used to refer to areas served by electrical infrastructure in the northern half of the North GTA planning area. While this roughly aligns with northern York Region, it is also inclusive of parts of neighbouring municipalities such as Bradford West Gwillimbury (county of Simcoe)

Brown Hill TS, being further north and east, supplies mainly rural areas with lower anticipated growth rates, though there is potential for longer term growth within its service territory, primarily Georgina and East Gwillimbury.

Kleinburg TS primarily serves loads in and around Bolton, as well as some rural loads throughout King township and Caledon. Supply options to meet growth in the Kleinburg TS service area, primarily concentrated in Bolton and Caledon, are currently being studied in the GTA West IRRP, though outcomes have been factored into system models used in this study.



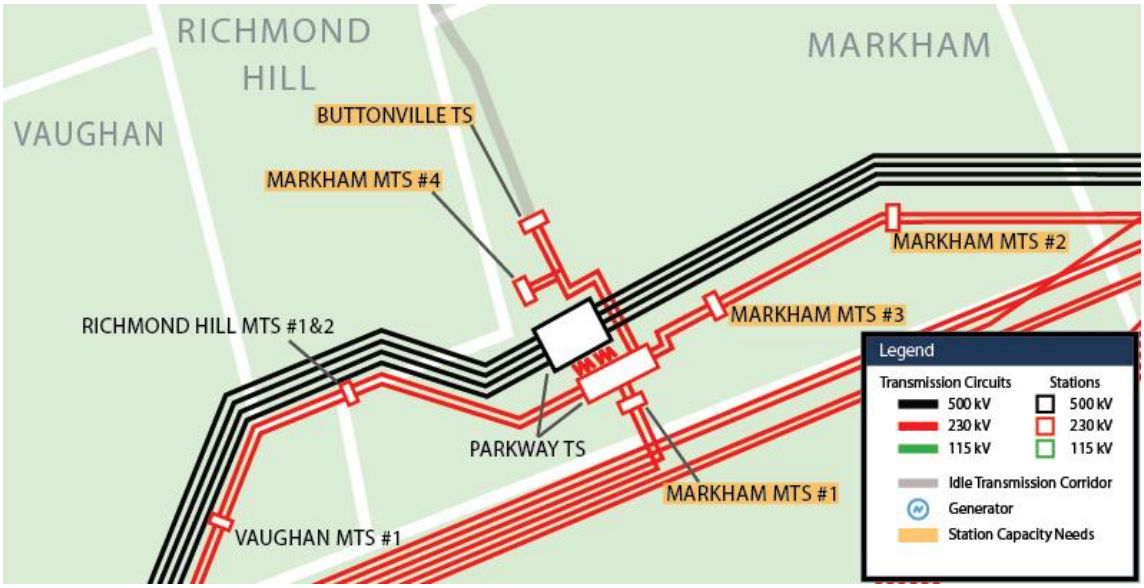
Of the four existing step-down stations, all but Brown Hill TS are currently loaded close to the maximum capability. Due to the distance between Brown Hill TS and the Armitage TS and Holland TS service territory, Brown Hill TS is not a suitable facility for transferring excess load without incurring significant distribution costs. The combined station capacity need in Northern York is summarized in Table 4. There is an immediate need to supply an additional 16 MW of demand and thus need increases to 750 MW by the end of the study forecast period.

Table 4| Northern York Station Capacity Needs

Stations	Timing	2025	2035	2043
Holland TS Armitage TS	Immediate	16 MW	400 MW	755 MW

The combined summer peak demand forecast of the approximate Armitage TS and Holland TS service territory is shown in Figure 9 along with their combined maximum rated station capacity. Also shown for comparison is the demand forecast from the 2020 York IRRP.

Figure 9| Northern York Demand Forecast

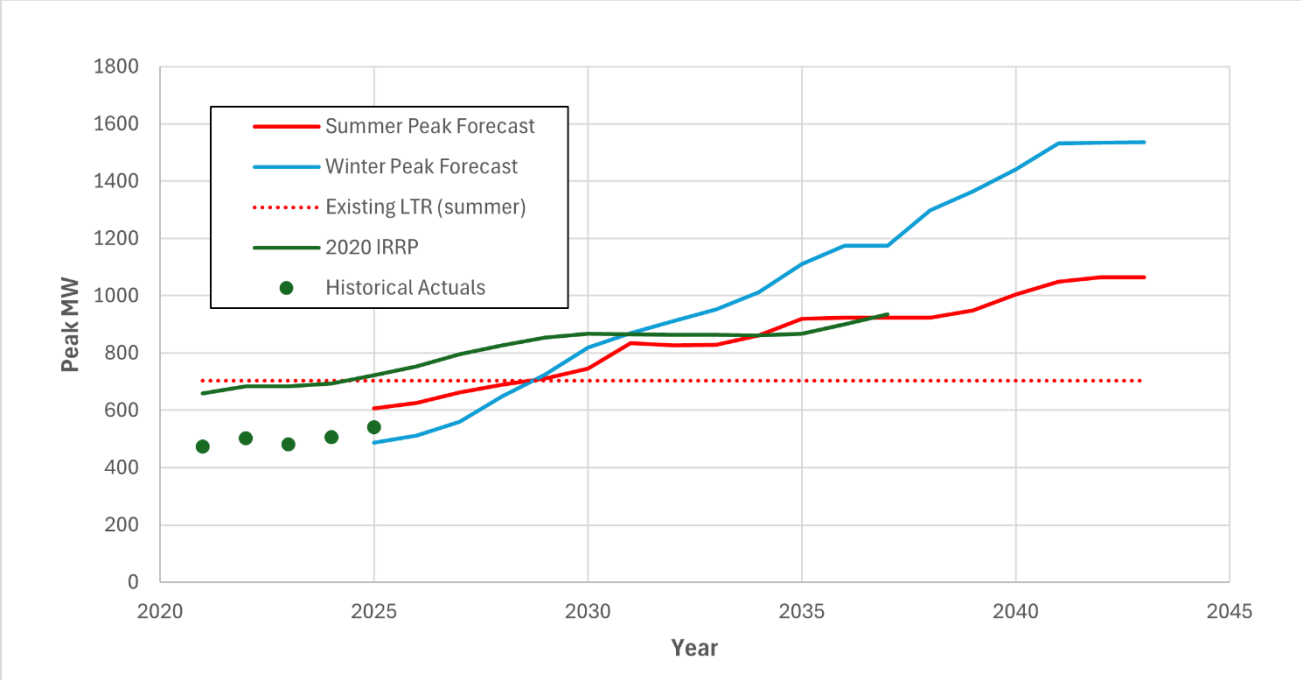


The previous IRRP had identified Northern York as having station capacity needs emerging in 2027. The development of Northern York TS #1 was recommended to address this need with a targeted in-service date of 2027, and a connection point in the vicinity of the existing Holland TS. However, based on revised demand forecasts, the need has been advanced and is now considered immediate.

6.2.1.2 Markham

Due to the ability to transfer loads between their southern stations, Alectra has typically alternated construction and loading of new stations between Markham and Vaughan to serve loads within their southern York service territory (roughly aligned with Vaughan, Richmond Hill, and Markham).

Figure 10| Markham and Area Station Needs



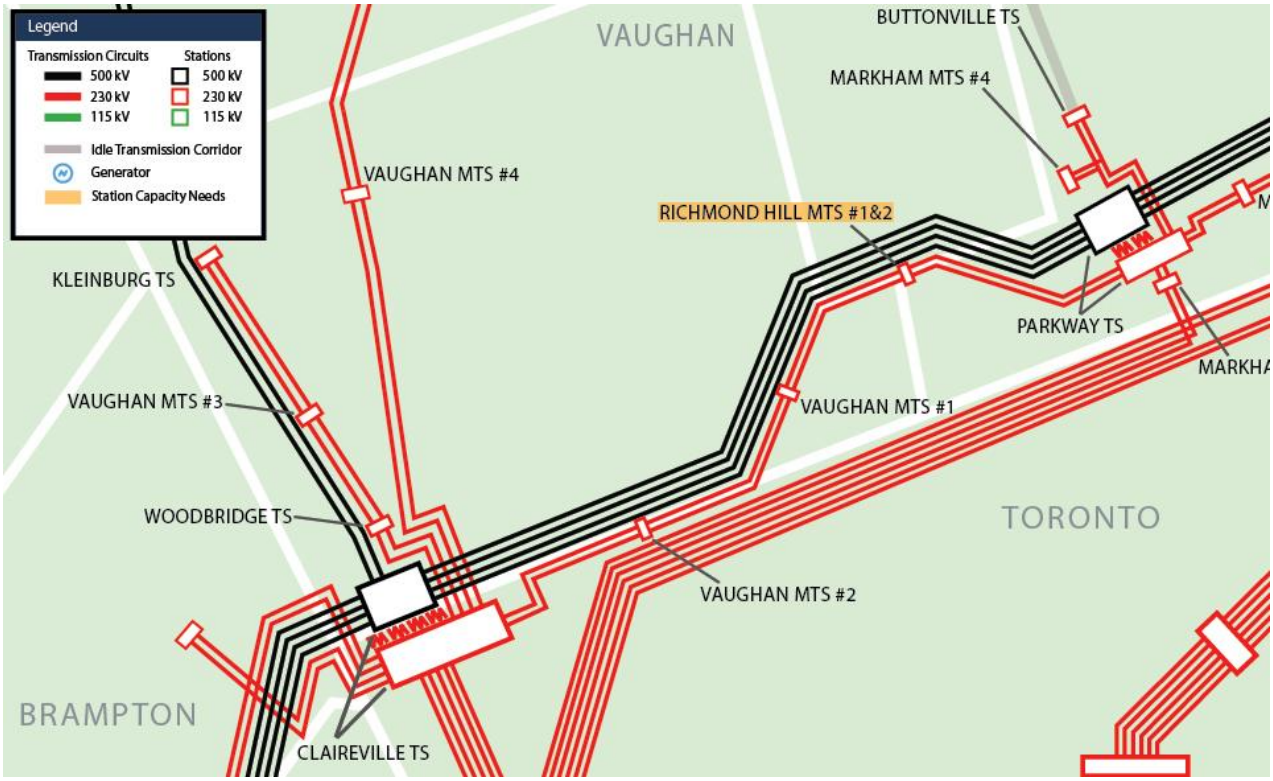
The last stations placed in service for southern York Alectra customers was Vaughan MTS #4 in 2018, preceded by Markham MTS #4 in 2011. Both of these stations had been located along the two possible transmission sections which span north from the main transmission supply path along the southern border of York region (adjacent to Highway 407). This had been done to meet the challenge of connecting increasingly northern development despite a transmission system that remains concentrated to the south.

Table 5| Markham and Area Station Capacity Needs

Stations	Timing	2025	2035	2043
Markham MTSs	Near-term	0 MW	241 MW	426 MW

The combined summer peak demand forecasts of Markham area stations (including Markham MTS #1, #2, #3, #4, and Buttonville TS) are shown in Figure 11, below, along with their combined maximum rated station capacity. Also shown for comparison is the equivalent demand forecast from the 2020 York IRRP.

Figure 11| Markham and Area Demand Forecast



Periods of the forecast which show a relatively flat profile indicate the years in which incremental growth is expected to be met through allocation to a future Vaughan area station, resulting in no incremental growth being applied to Markham area stations. The next Vaughan area station is not expected to be required until the early 2030s (See section 7.4.1.1).

In addition to meeting total supply capacity needs of customers, addressing stations needs will also require consideration of the suitable location to site future stations, to ensure proximity to end use customers. Locating step down stations too far from customers can result in lower customer reliability and power quality, and additional distribution costs to run feeders to connect customers. Finding suitable locations to site stations to serve southern York customer loads has been increasingly challenging in recent years, as limited transmission paths exist north of the southern border.

6.2.1.3 Richmond Hill

Richmond Hill is currently the site of two step-down stations, Richmond Hill MTS #1, and Richmond Hill MTS #2. Both stations have been loaded to capacity for most of the past few summers, with new load growth in Richmond Hill supplied via load transfers to stations in Vaughan or Markham.

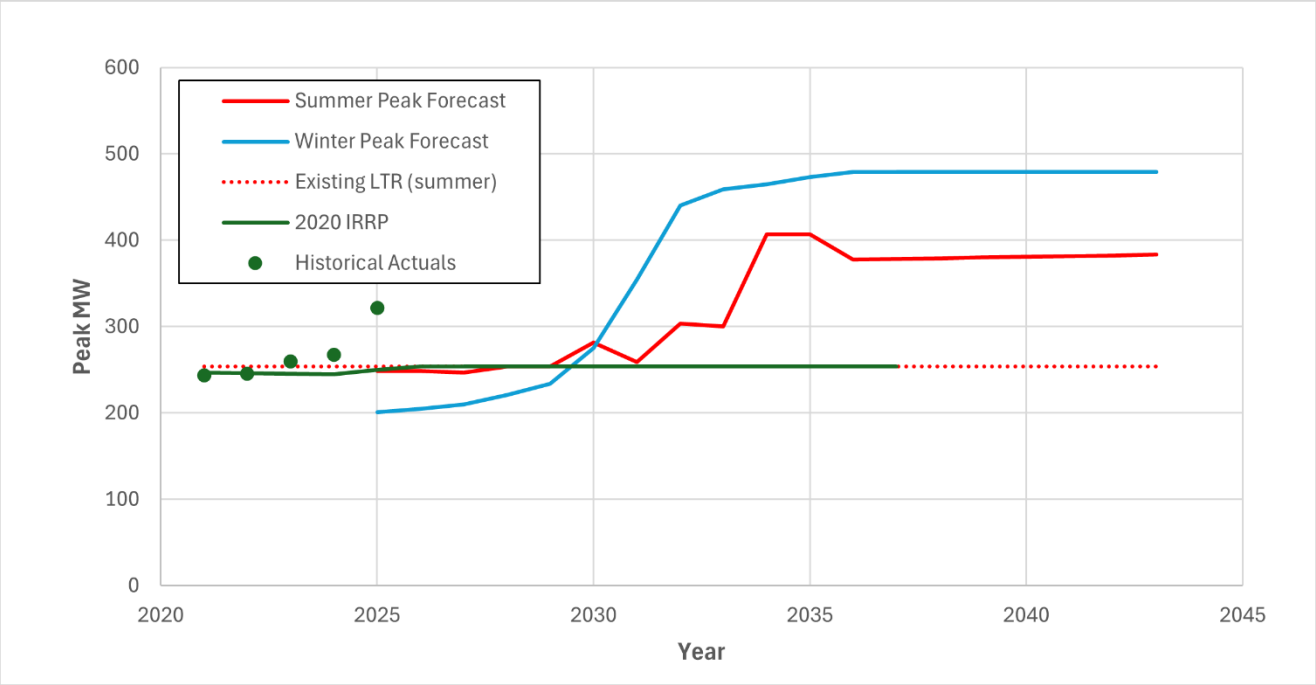


Figure 12| Richmond Hill Station Capacity Needs

Although Richmond Hill has been managing similar complexities of providing supply to increasingly northern development, a new area of intensification is emerging in the southern part of this municipality. The area, roughly corresponding to the Richmond Hill Centre (RHC) Urban Growth Centre, is the result of the planned extension of the Yonge subway into Richmond Hill and Markham. Significant, intensified development, with associated electrical demand, is anticipated in the vicinity of these new development zones.

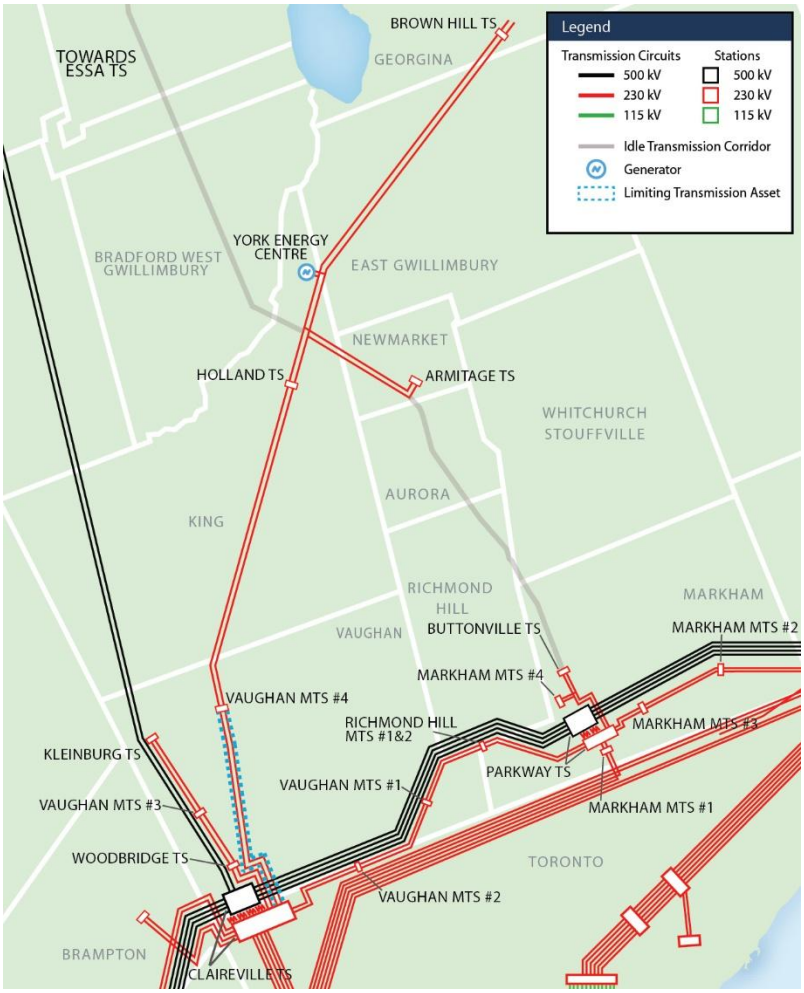
Figure 13 shows the relatively steady loading at the existing Richmond Hill stations in recent years, and the expected impact of new growth over the coming years in the surrounding area. Growth anticipated around the new subway extension has been included in this grouped area, while growth further north (better served through northern stations in Markham and Vaughan) has not been included. Note a large jump in actual peak demand for the summer of 2025 is the result of load transfers supplied by Richmond Hill TSs during emergency conditions. The irregular loading of the summer forecast is the result of anticipated load shifting as new stations come online.

Figure 13| Richmond Hill Demand Forecast

The need for a new step-down station in Richmond Hill was not identified in the previous IRRP published in 2020. Instead, this new need is in direct response to new, intensified development in proximity to the planned Yonge subway extension. The anticipated need date for additional station capacity is 2030.

6.2.2 Supply Capacity Needs

Supply capacity needs are often described in terms of a system's Load Meeting Capability (LMC), which is the maximum amount of demand that can be supplied by a transmission circuit or group of circuits, before specific system criteria are violated. Where the demand forecast is expected to exceed the LMC, mitigation measures will be required. These can vary from lowering load to at or below the system LMC (through NWA or similar measures), upgrading the system to a higher LMC, or, depending on the type of criteria, arming load rejection (to automatically disconnect loads during a contingency to keep total demand below the LMC).



Supply capacity needs are determined based on the system performance following the simulation of standard criteria or "contingency events" during peak demand conditions. The loss of a single transmission element is referred to as an N-1 event, while simultaneous loss of 2 elements is N-2. Following N-2 events, the criteria allow for customer load loss up to a certain amount in order to keep loading on the remaining transmission facilities within acceptable limits. These "load rejection", or LR events, represent lower reliability for customers, but only in the event of a major transmission outage occurring during peak loading conditions. Although a certain amount of LR is permitted in these cases, it is not a preferred outcome, particularly when designing solutions to fully address

system needs. As a result, this study distinguishes between needs and solutions required to meet N-2 conditions both with and without LR. No load loss is permitted following N-1 contingencies.

6.2.2.1 Northern York

The Northern York electrical region is primarily supplied by one double-circuit 230 kV transmission line, which transfers power stepped down from the bulk 500 kV network at Claireville TS, and transports it northward to supply the step-down stations of Northern York. The line also directly supplies large customer connections and will supply a planned Go Transit power traction station. A second supply source connected to these 230 kV circuits is the York Energy Centre (YEC) peaker plant. This 400 MW gas-powered facility generates power when local demand exceeds the ability of the existing transmission line to reliably supply local needs and can also be dispatched to ensure provincial resource adequacy in high-demand periods. Due to its ability to rapidly respond to sudden changes in demand, YEC is useful for balancing output from intermittent energy sources, or to respond quickly following system contingencies and outages.

Figure 14| Northern York Supply Capacity Needs

There are two main double-element contingencies that result in the thermal overload on H82/83V based on the current demand forecast.

- The loss of T1B breaker at Holland TS causes the simultaneous loss of H83V and the York Energy Centre from service as YEC's stations service is supplied from Holland TS. Due to the loss of YEC's station service, approximately 400 MW of capacity is also lost. Due to these conditions, the companion circuit, H82V becomes overloaded in 2025.[3] Note that the recently commissioned Battery Energy Storage System (BESS) at YEC remains in service during this outage and improves the LMC of the system by approximately 50 MW.
- A breaker failure at L82L88 at Holland TS simultaneously removes circuits H82V and B88H from service. While this does not remove YEC from service, under normal operating conditions it will remove the G1 unit, and up to ~200 MW of generation. The BESS unit, which is connected through the G1 yard, would also be removed from service during this contingency. At peak demand, due to these conditions, the companion circuit, H82V would become overloaded in 2027.[4]

Additional Needs in Northern York – Under and Over Voltage

Undervoltage

In the event of the simultaneous loss of H82V + H83V, this sub-system becomes radially supplied from the north, via Minden TS through B88/89H. Due to the length of B88/89H, especially in high load conditions, the subsystem's voltage drops to unacceptable levels. With the loss of H82/83V, York Energy Centre is unable to provide voltage support due the station supply coming from Holland TS (which is lost by configuration following this contingency).

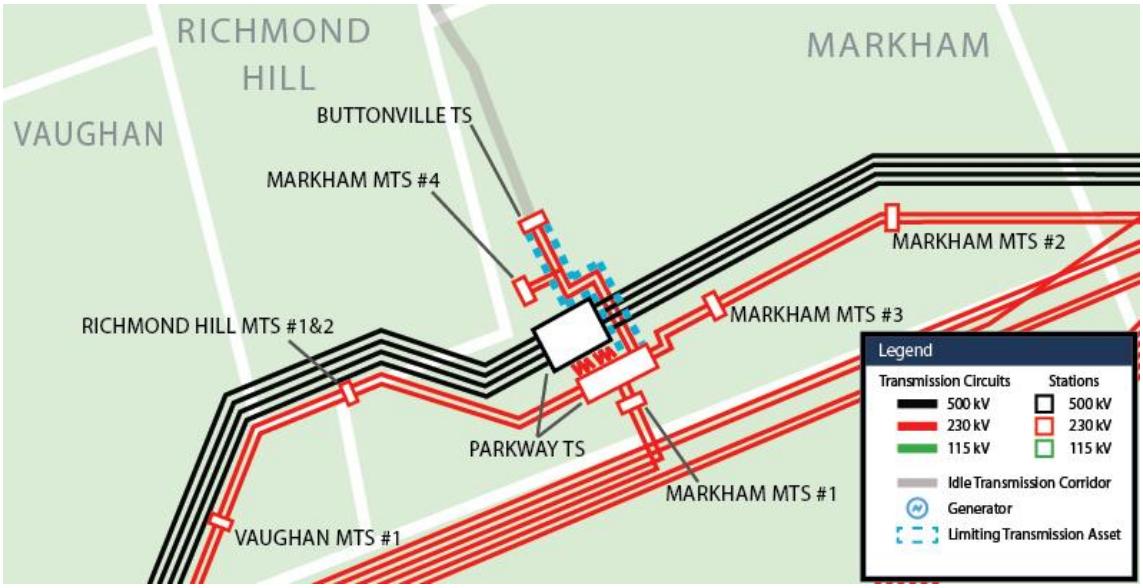
In addition to unacceptably low voltage levels within York region, under high load conditions this contingency would cause overloads on sections of the M6E circuits running between Essa TS and Minden TS, as this becomes one of the few remaining routes for power to flow into northern York.

The YEC BESS is not removed from service by this contingency, and while it does help provide support, it is not sufficient to address voltage needs in Northern York or overloads on M6E. Based on the current forecast, this need materializes in 2025.[5]

Overvoltage

The simultaneous loss of B88H and B89H removes Armitage TS, Brown Hill TS, and YEC from service, and leaves a lightly loaded radial circuit from Minden TS supplying the relatively smaller load centres at Beaverton TS and Lindsay TS. Due to the length of the circuits from Minden TS towards Northern York, especially in lighter load conditions, the subsystem is like to experience an unacceptable increase in voltage. This is further exacerbated by the presence of the use of capacitor banks at Beaverton TS and Lindsay TS, which help support low voltage conditions when the full system is in service and voltages are at risk of running low. This need had been identified within the last IRRP. Although actions have not yet been taken to fully address it, unacceptably high voltages haves not been observed within the area

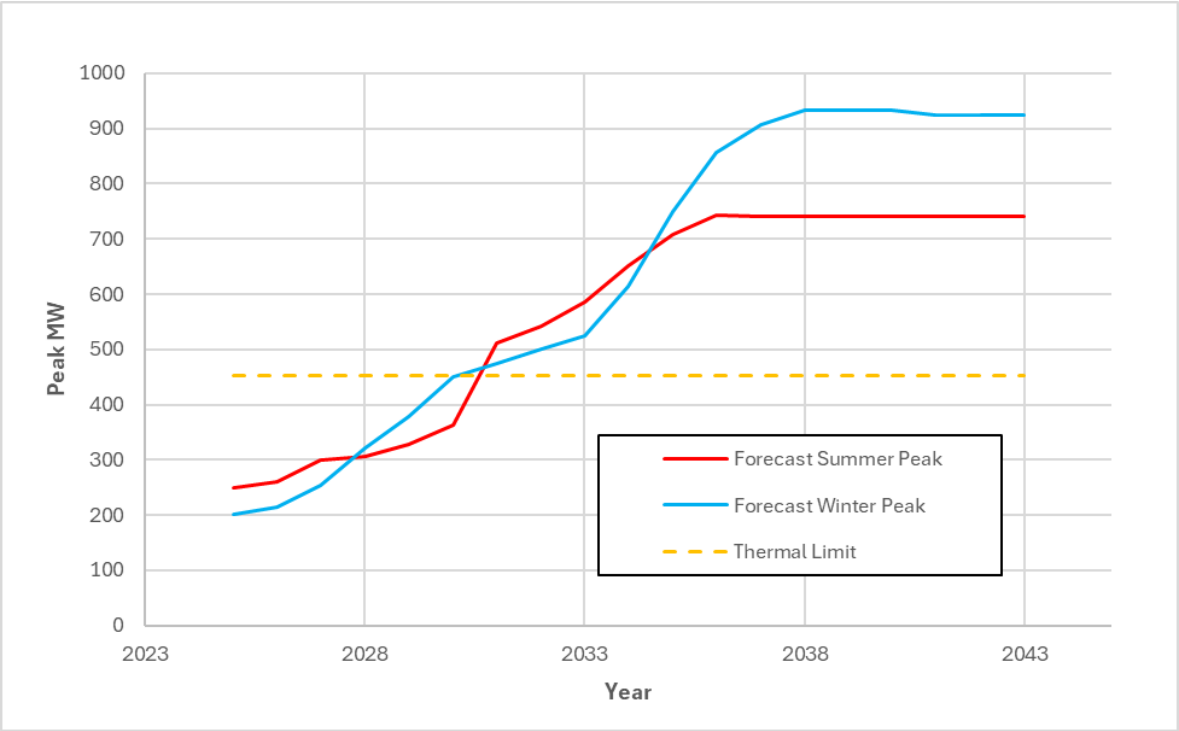
[3] Including load rejection of 150MW. Note that the system is currently relying on arming Load Rejection (LR) during peak periods in order to manage the risks associated with the T1B breaker failure.



[4] Including load rejection of 150MW. Note that the system is currently relying on arming Load Rejection (LR) during peak periods in order to manage the risks associated with the T1B breaker failure.

[5] Including load rejection of 150MW. Note that the system is currently relying on arming Load Rejection (LR) during peak periods in order to manage the risks associated with the T1B breaker failure.

6.2.2.2 Markham and Area (Parkway-Buttonville)



The Parkway – Buttonville radial circuit is a two circuit (P45/46), 230 kV transmission tap which currently stretches approximately 6 km north of Parkway TS into Markham region. Power stepped down from the bulk 500 kV system at Parkway TS and flows north to supply two step-down stations, Markham MTS #4 and Buttonville TS.

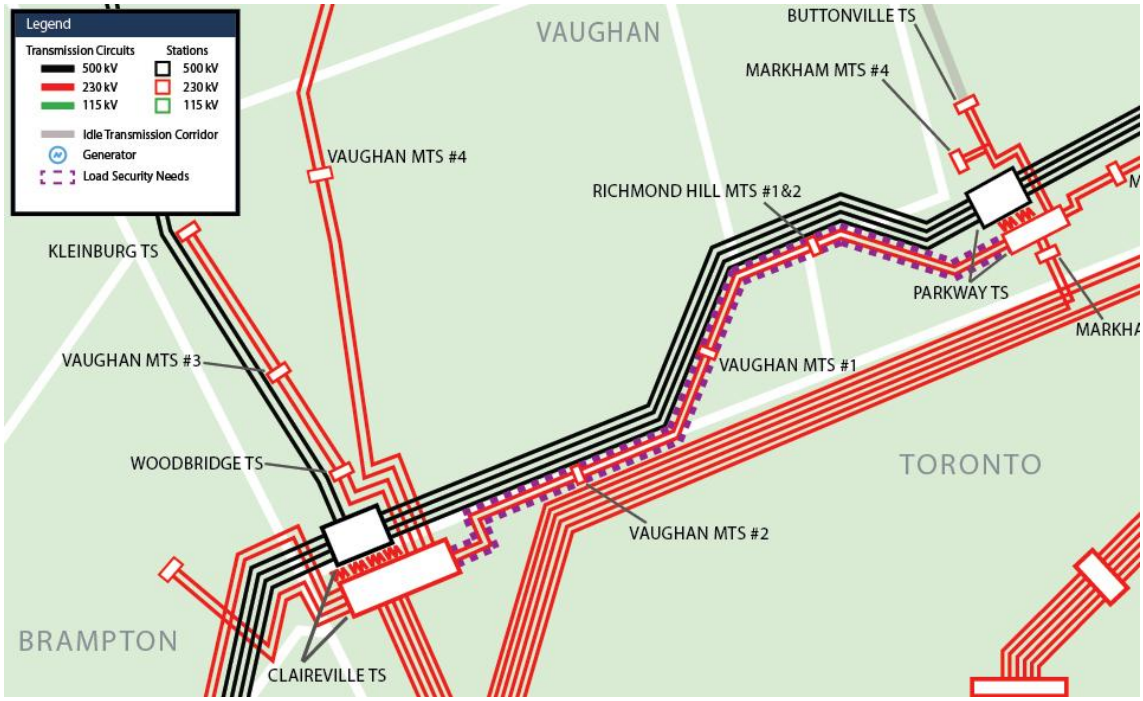
Figure 15| Parkway-Buttonville Supply Capacity Needs

As the only existing northern link into Markham region, this circuit is expected to be loaded with a new step-down station, Markham MTS #5, recommended in the previous IRRP. The maximum loading on this circuit is approximately 450 MW and is based on the thermal limit of the companion circuit when one of either P45 or P46 is out of service. The forecast load to be served by this circuit is shown in the graph below, along with the existing transmission thermal limit:

Figure 16| P45/46 loading forecast for southern section, and Thermal Limit

The existing transmission circuits are roughly sufficient for serving both existing stations to their summer LTR, plus an additional 133 MW from a new step-down station. Based on the planned in-service date of Markham MTS #5, and loading rate, this need is expected to be reached in 2031.

6.2.3 Load Security and Load Restoration Needs



Load Security and Load Restoration needs refer to the level of reliability customers can expect when major contingencies occur. Security refers to the maximum amount of load which can be simultaneously lost following any of the defined planning contingency types as specified in ORTAC. In general, no more than 600 MW is permitted to be lost after an N-2 contingency through a combination of loss by configuration (from loss of supply to a station), or Load Rejection (automatically tripped load to keep remaining facilities within their applicable loading limits). Load Restoration refers to how quickly load can be reconnected after a major transmission outage. It can be determined by factors such as the distribution network's ability to transfer loads to other nearby stations, remoteness, and the nature of the interruption/equipment affected (e.g., overhead versus underground facilities) York Region typically performs well for restoration, given Alectra's meshed distribution network, the proximity of Hydro One crews and equipment to the GTA, and the mainly overhead transmission system. Due to good historical performance, no restoration needs have been identified in this area which require actions to be taken at this time. Security needs are outlined below.

6.2.3.1 Southern Vaughan/Richmond Hill (Parkway-Claireville) Security Needs

The Parkway to Claireville circuits are a double 230 kV transmission line which spans between Claireville TS and Parkway TS, roughly adjacent to Highway 407, along the southern border of Vaughan, Richmond Hill, and western Markham. Supply is provided from the bulk network at both ends of this corridor, as Claireville TS and Parkway TS both have autotransformer connections to supply the 230 kV system from the 500 kV system.

Five municipal step-down stations are connected to the corridor today (Vaughan MTS #1, Vaughan MTS #1E, Vaughan MTS #2, Richmond Hill MTS #1, and Richmond Hill MTS #2). When all stations are fully loaded to their LTRs, up to 713 MW can be supplied at once, with the 600 MW security limit frequently being exceeded. These load levels were exceeded during the recent 2025 summer peak, when total loads reached 734 MW due to load transfers from neighbouring stations to address a separate distribution outage.

Figure 17| Parkway to Claireville circuits (V71/75P)

This corridor has previously been flagged as being at risk of violating security limits. In previous regional plans, it was recommended that remote operated switching facilities be installed along this corridor. These have since come into service and allow approximately half the load along this corridor to be restored in a short amount of time in the event of an N-2 contingency removing the entire corridor from service. Although this does not eliminate the risk of losing over 600 MW, it was determined that this solution would substantially address customer reliability needs, at a relatively low cost, while improving operational flexibility.

However, the present-day security need is expected to worsen when the planned Richmond Hill MTS #3 comes into service, tentatively scheduled for 2030. When all stations are fully loaded up to their LTRs, up to 866 MW could potentially be at risk of interruption in the event of a N-2 contingency occurring during summer peak.

Table 6| Parkway to Claireville Load Security Needs

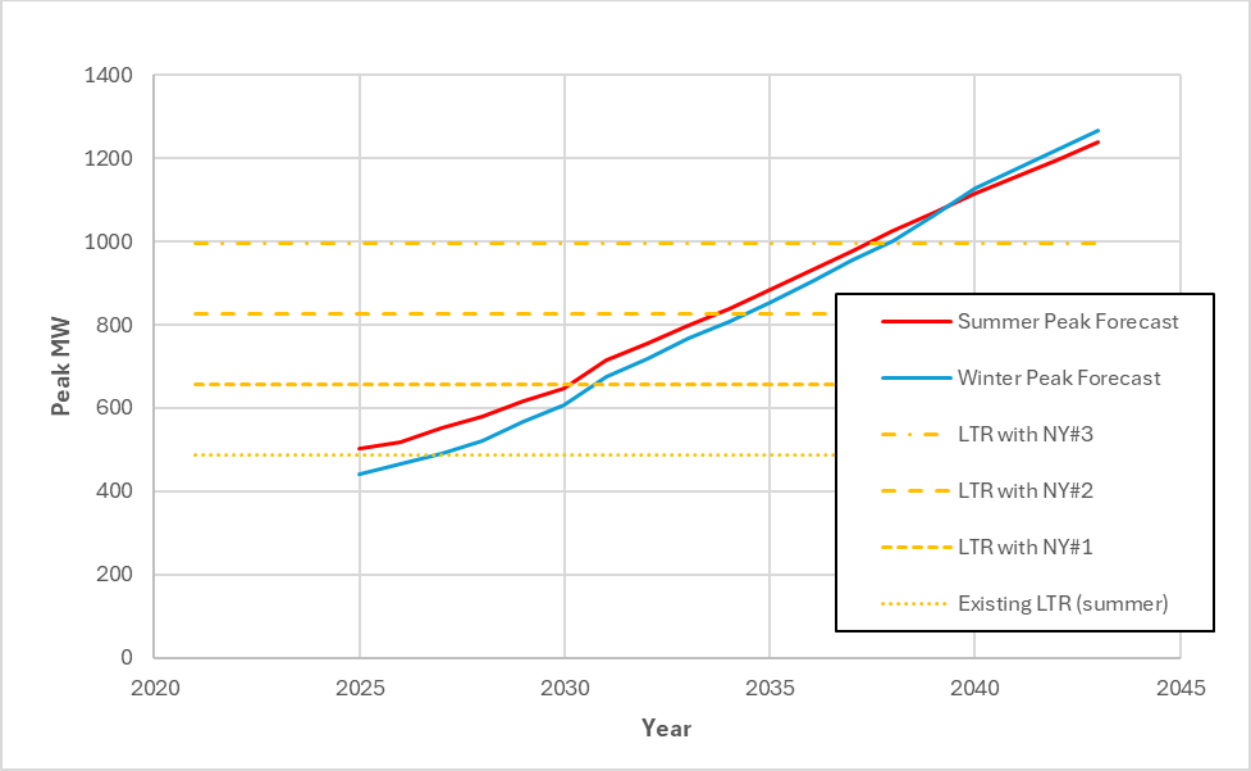
Infrastructure	Timing	2025	2035	2043
Parkway to Claireville 230 kV	Immediate	94 MW	293 MW	359 MW

This represents a significant increase in the potential violation of security criteria for the area. The application of security criteria has also recently been amended through a revision to ORTAC, placing greater urgency on the need to address outstanding security needs, and only consider exemptions (as had been in place) as a temporary measure. Both the increases in demand forecasts and changes to security criteria, now require this security need to be treated as urgent.

6.3 Medium- and Long-Term Needs (2031-2040)

This section outlines longer term needs (expected to arise in 5+ years timeline), where development actions are not yet required to be undertaken. However, actions may still be required to preserve options, for instance, in the identification and preservation of land to accommodate future facilities. This is particularly the case for needs anticipated within the 5 to 10 year timeframe (medium- term needs).

GTA North is expected to be a winter-peaking region by early 2030s. As discussed in Section 5.8, demand forecasts associated with winter peaks carry a level of uncertainty as they are associated with customer behaviours and the rate of adoption of electric heating. Understanding where future needs are expected to emerge will influence planning on the transmission system to ensure upgrades can be made in time to allow for reliable connection.



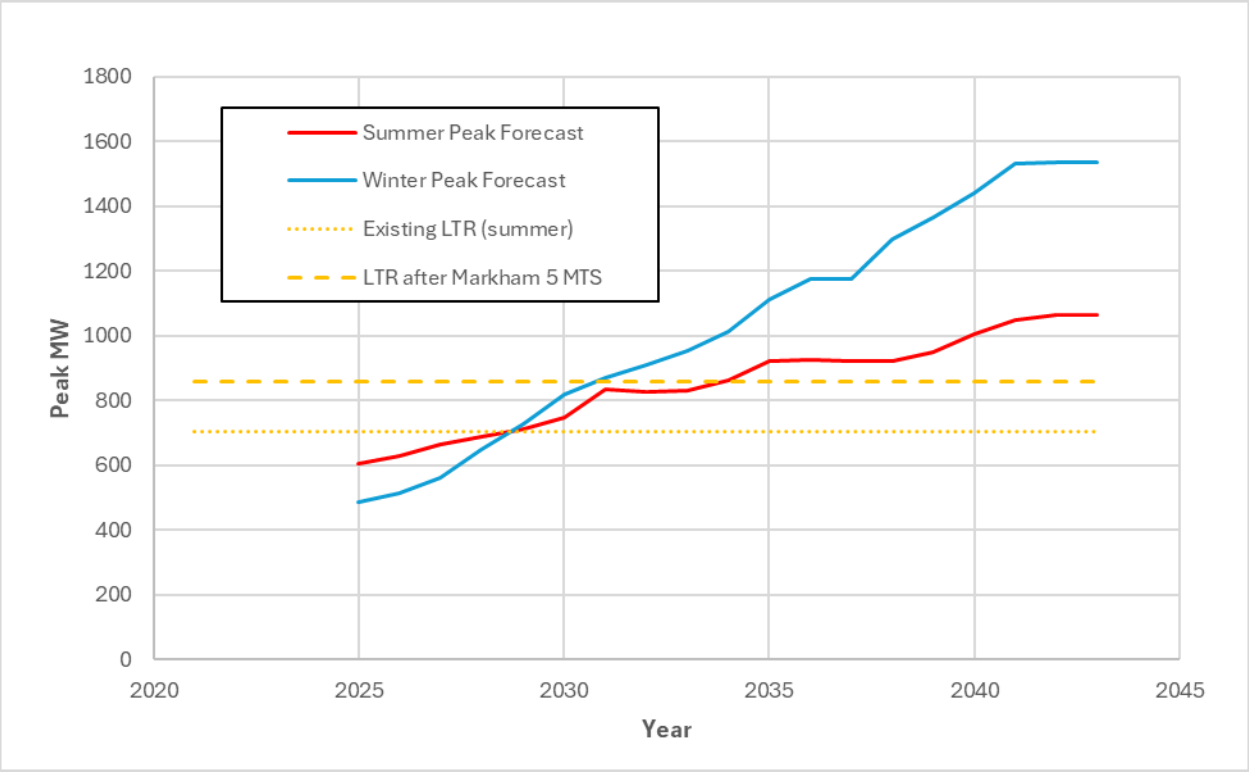
6.3.1 Station Capacity Needs

The need for step-down stations beyond the next five years is predominantly based on longer-term municipal growth forecasts and is subject to change as actual connection requests and development occurs. In particular, sudden large connection requests for major commercial customers (such as data centres) could significantly advance need dates. Longer-term step-down station needs may also need to account for winter loading conditions.

6.3.1.1 Northern York

Northern York Region is expected to continue to see significant increases in electrical demand over the next 5-15 years, driven by new development, large customer loads, and electrification of transportation and home heating. After the planned development of the future Northern York TS #1, whose need was described section 6.2.1.1, growth is expected to continue throughout the area. The graph below shows the incremental long-term challenges of meeting station capacity needs when both summer and winter needs are considered:

Figure 18| Northern York station capacity limits



Need-dates for the second new station will depend on actual growth rates. Given the size of northern York regional, there may also be challenges associated with serving growth in the Whitchurch-Stouffville area from the future Northern York TS #1 (expected to be located over 20 km away, in King). As a result, a second new station to serve Northern York (notionally Northern York TS #2) is recommended to be located in closer proximity to eastern York load centres. In the longer term, current growth rates suggest new Northern York step-down stations may be triggered roughly every four or five years for summer-peaking conditions, or more frequently if winter-peak demand growth conditions emerge as per the forecast.

6.3.1.2 Markham

Long-term growth throughout the Alectra service territory of southern York is expected to continue at an aggressive pace in the longer term. Based on the existing summer peak forecast, and assuming the near-term need for capacity is met through Markham MTS #5, additional step-down capacity would be required in 2034.

Figure 19| Markham supplying stations, and station capacity limits

Factors such as DER uptake, pace of electrification, and residential and commercial development rates can all affect the actual need date.

As described in section 6.2.1.2, finding locations suitable for new step-down stations to meet forecast load growth in Markham has been challenging in recent years, as the existing bulk transmission system runs roughly along Highway 407 in the area, with only a 3 km extension northward. Solutions to meet near term stations capacity needs generally only consider connections to the existing transmission system as new transmission cannot be developed in less than five years. However, for longer term station needs, consideration can be given to connection points along new transmission if no feasible connection points exist from either a capacity perspective or geographic proximity. Based on concerns expressed by LDCs with serving anticipated growth centres throughout northern Markham (and northern Richmond Hill) from the existing network, siting Markham MTS #6 cannot be accomplished without new transmission in order to site the step-down capacity closer to the anticipated growth.

6.3.1.3 Vaughan

Similar to the near-term needs identified in southern Richmond Hill (described in section 6.2.1.3), there is a longer term need to provide step-down station capacity in southern Vaughan. This is directly the result of new major commercial and residential development and intensification from the Vaughan Metropolitan Centre (VMC) Urban Growth Centre. As a result, the need is not linked to remaining capacity at other nearby stations, but to the intensified demand associated with growth in this pocket. The current anticipated need date is 2033, and while this is just outside the 5-year horizon defined as near term, work is ongoing by Alectra to find suitable land and begin development to meet the targeted in-service date. The notional Vaughan MTS #5 is likely to seek connection to the existing V71/75P circuits, as these transmission facilities are near the anticipated VMC growth area. This would exacerbate existing security needs along V71/75P corridor. This would exacerbate existing security needs along V71/75P corridor.

6.3.2 Supply Capacity Needs

Supply capacity needs emerging in the longer term are generally a result of either higher loading requirements due to new step-down stations or impacts on local supply capacity resulting from potential phase out of local generators as contracts expire. System conditions can also be impacted by planned changes to the bulk system, with implications for both system needs and available solutions.

6.3.2.1 Northern York

Capacity needs for supplying incremental load growth in the near term were described in section 6.2.2.16.2.1.1, and roughly correspond to the amount of supply required to enable the connection and full loading of one additional step down station, notionally Northern York TS #1, in addition to incremental loading to bring existing stations up to their full summer LTR, and additional loads associated with electrification of Go Transit. Assuming recommendations to address these needs are put into service, additional needs will begin to emerge in the long term based on two main drivers: Continued incremental load growth associated with an additional new step-down station in Northern York and the potential retirement of York Energy Centre.

Accommodating further step-down stations in Northern York

As described in section 6.3.1.1, ongoing load growth in Northern York Region is expected to trigger the need for new step-down stations roughly every four years (summer peaking) or potentially as often as every three years (assuming high electrified heating and winter growth scenario) in the longer term.

Measures to address near term needs will be sufficient to meet the need for Northern York TS #1, while the assumed location for future Northern York TS #2 is eastward, outside of the electrical system defined as Northern York. Assuming the next station is once again sited in this area, needs should be evaluated on the assumption that additional station loading emerges in roughly the mid 2030s.

Given uncertainty with long-term growth rates, and the risk of sudden, large surges in customer demand from new development or electrification, the local system should be designed to be capable of supplying the full load of this future station, before permitting its connection. The exact nature of needs emerging from this station would depend on its connection location, as well as system changes which may be required to address the potential phase out of YEC.

At a minimum, adding this future station would trigger security needs regardless of whether it is connected on the H82/83V circuits (same protection zone as Vaughan MTS #4, Holland TS, and future Northern York TS #1), or B88/89H circuits (Armitage TS and Brown Hill TS). Seeking exemptions to security needs is not desirable in this area, given the existing operational challenges for managing this system, including maintaining adequate voltage and finding suitable windows for regular outages for maintenance.

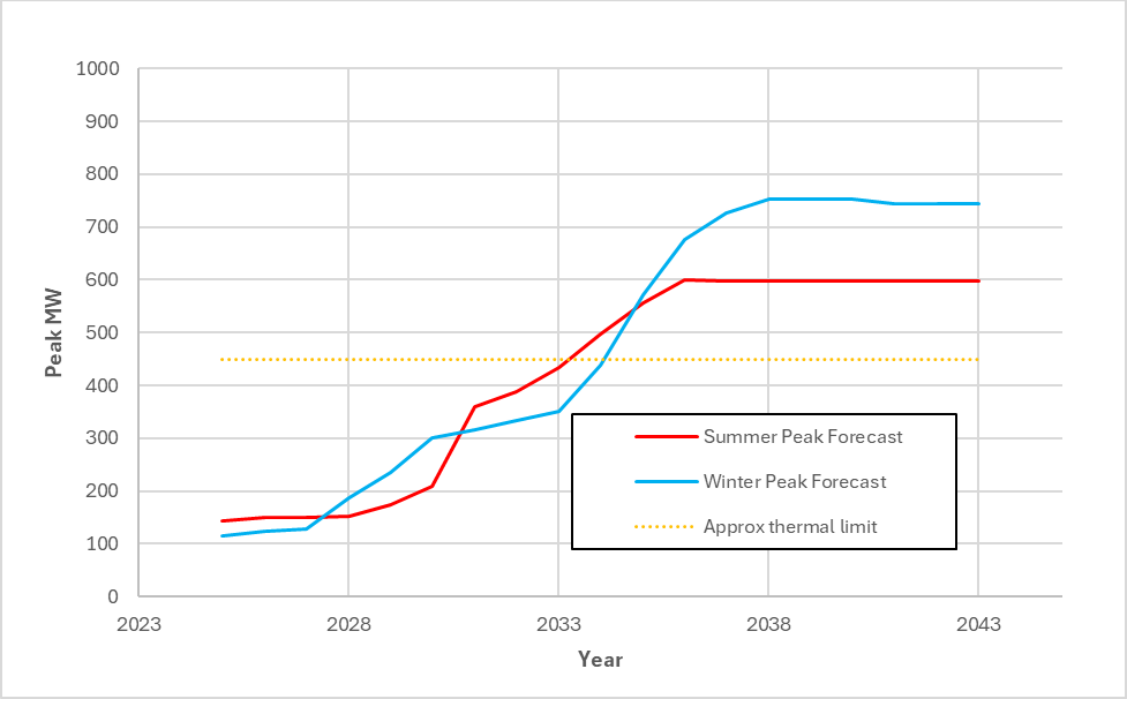
Both scenarios, where YEC (or similar-sized generation) would remain in service, or new transmission is added to provide supply from elsewhere in the system, contribute unique challenges to the operation of this system. With the addition of potential security violations, new sectionalization should be considered a mandatory starting point to accommodate a future station. The manner of this sectionalization will ultimately influence the maximum system capability (LMC).

These options are described in more detail in section 7.4.3.4.

Considering a Potential Future without YEC

The York Energy Centre (YEC) currently serves roughly 400 MW of peak summer demand for Northern York, reducing the amount which needs to be supplied into the area from elsewhere. This facility was originally sited in Northern York specifically to offset the need for new transmission and has successfully managed the ability for the area to grow without new transmission since 2012. The contract for YEC is currently set to expire in 2035, and if it is removed from service, would represent an immediate 400 MW shortfall to local capacity to meet the area's peak demand. This 400 MW shortfall would be in addition to incremental needs from regular customer growth.

Even after the incremental upgrades recommended in section 7.3.2.2 are implemented, there would be a significant mismatch between local demand and the ability of the system to provide reliable supply. Where options to address near term needs considered measures such as reconductoring, bypassing limiting sections, and NWAs, options to meet needs of 400 MW or more are generally



limited to new transmission lines (typically ~600 MW or more of new capacity), or local generation of a similar size and operational characteristics as what had been phased out. These options are explored in greater detail in section 7.4.3.3. If YEC were phased out without a major new supply source, it would severely affect reliability for existing customers and likely limit the ability to connect any incremental load within northern York.

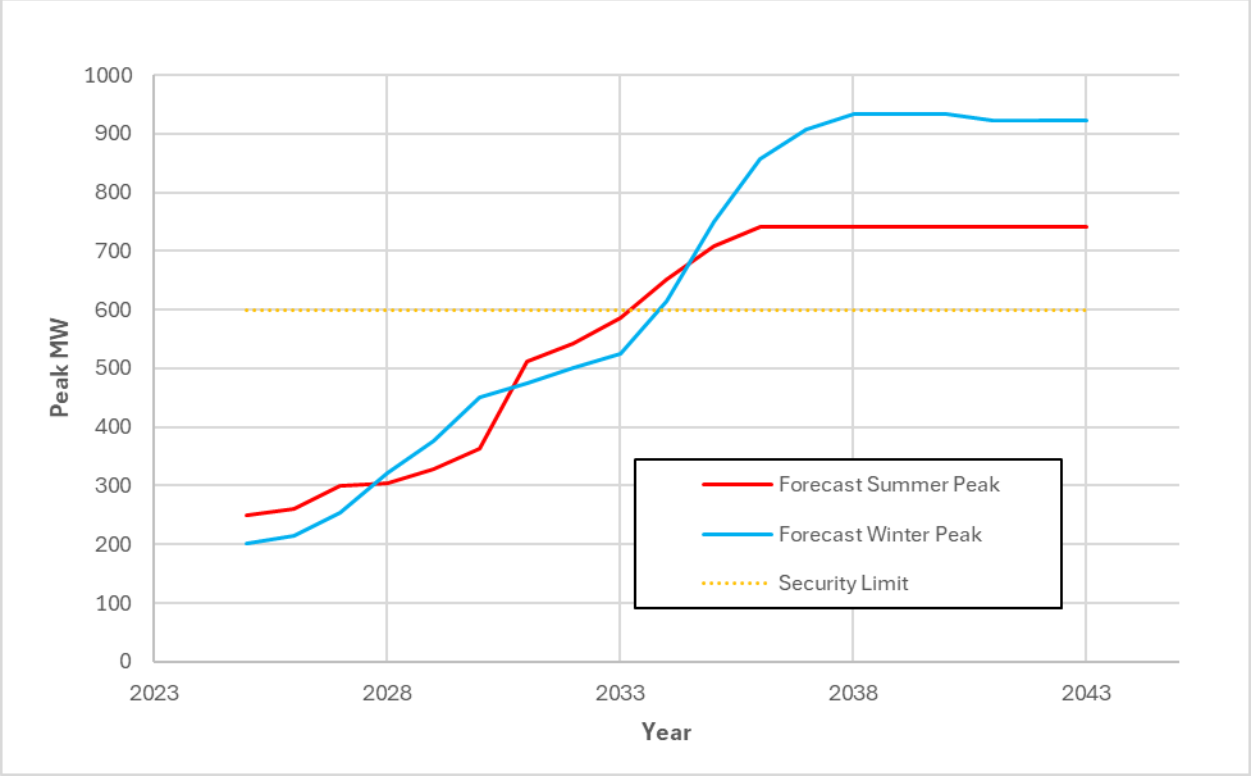
6.3.2.2 Parkway-Buttonville

Capacity needs associated with the Parkway-Buttonville pocket arising in the near term were described in section 6.2.2.2, and emerge along the southern end of the P45/46 circuits, between Parkway TS and Markham MTS #4. In the longer term, demand for additional step-down stations to supply growing loads in Northern Markham, Northern Richmond Hill, and the eastern section of Northern York (including Whitchurch-Stouffville), is expected to further load this corridor. This will trigger similar thermal needs on the remaining northern section of P45/46, between Markham MTS #4 and present-day Buttonville TS. These needs are expected to be triggered when the total load of Buttonville TS, Markham MTS #5, (future) Markham MTS #6, and (future) Northern York TS #2 reach approximately 450 MW, although actual LMC could vary depending on future station, circuit and customer load characteristics. This is in addition to security needs described in section 6.3.3.1, below.

The graph below shows the impact this will have on anticipated need dates for further upgrades, under anticipated summer peak conditions, and a potential higher growth winter peak scenario.

Figure 20|Circuit loading on northern section of P45/46 circuits (Markham MTS #4 to Buttonville), and thermal limit

Note that total summer load is expected to plateau in the mid to late 2030s, as stations reach their individual LTR, and incremental growth is instead supplied by stations in neighbouring systems. This profile could change if future stations are instead located within this supply pocket.



6.3.3 Load Security and Load Restoration Needs

New load security needs have the potential to emerge in the longer term as load growth increases the areas supplying over 600 MW during peak conditions. This becomes more severe when higher growth winter peak scenarios are considered. In many cases, load growth can trigger both capacity needs as well as security needs, with common solution often able to address both. The conditions under which security needs are triggered, and whether they are expected to be addressed through other initiatives, is described below.

6.3.3.1 Markham and Area (Parkway-Buttonville)

The demand forecast for this load pocket load is expected to exceed 600 MW in 2034 (both summer and winter peak forecast) which would violate applicable load security criteria. The graph in Figure 21 below shows the applicable loading, which accounts for all P45/46 connected stations (this is different from Figure 20, above, which only considered load north of Markham MTS #4):

Figure 21 | Full circuit loading on P45/46 circuits, and security limit

This assumes that the need for future step-down stations (either Markham MTS #6 or Northern York TS #2) is triggered, and transmission is available to enable their connection via a Parkway-Buttonville transmission extension. These options are described in sections 7.4.2.1, 7.4.2.2 and 7.4.2.3 and, are preconditions for triggering this security need. Note that this security need is in addition to thermal needs which are triggered in the same approximate time and are described in section 6.3.2.2. Separate solutions are required for each.

6.3.3.2 Kleinburg Radial Tap

The Kleinburg Radial tap refers to the pair of 230 kV circuits, V43 and V44, which span northwest from Claireville TS. These circuits currently supply Woodbridge TS, Vaughan MTS #3, and Kleinburg TS, with plans underway to develop a new step-down station, Vaughan MTS #6, to supply commercial loads in the area. Under normal operating conditions, part of the southern end of this corridor also partially supplies the neighbouring Goreway TS, in Brampton.

Peak demand for the Kleinburg radial pocket is expected to exceed 600 MW in summer 2029, and potentially in winter as soon as 2030. Recommendations to address supply capacity needs for Northern York are expected to address these security needs as well. Details on these proposed solutions are provided in section 7.3.2.2.

6.3.3.3 Parkway-Claireville

Based on the near-term need for an additional station to serve southern Richmond Hill (notionally Richmond Hill MTS #3), and a longer-term need for an additional step-down station to serve southern Vaughan (notionally Vaughan MTS #5), the Parkway to Claireville corridor could potentially be exposed to interruption of approximately 960 MW of peak demand. This would assume all stations are loaded to their LTR, and an N-2 contingency occurring during summer peak. In the event of winter peaks emerging in the longer term, this security risk could approach 1200 MW.

Although the security limit is exceeded today, it is unlikely that a similar exemption would be approved as additional stations seek connection. Load losses of these magnitudes, especially without comparable generation tripped from loss of the same circuits, can introduce significant challenges for balance of supply and demand at the broader bulk level. Updates to applicable security criteria in ORTAC have also introduced a requirement to pursue a permanent solution for load security needs and to only consider exemptions as a temporary measure to avoid delaying the connection of new customer loads.

Near-term recommendation outlined in section 7.3.3.1 are expected to also address this longer-term need.

6.4 Post-2040 System Considerations

Near the end of the planning horizon considered in this IRRP (2040 and beyond), identifying specific needs and developing options to address them becomes more challenging. There is, however, time to study options in subsequent planning cycles.

Understanding needs requires detailed assumptions about anticipated customer demand, seasonal peaks, and hourly profiles on a geographic basis. Given the potential for very high growth rates resulting from electrification, major new large commercial/industrial load centres, in addition to more typical growth rates associated with organic population and employment growth, predicting actual demand this far out cannot be accomplished with sufficient confidence.

The demand forecasts for summer peak, which relies more closely on existing customer behaviour and more modest electrified technology uptake, currently forecasts up to 2,100 MW of demand growth throughout York region over the next 20 years, of which roughly 1,500 MW is accounted for in this IRRP through new step-down stations and associated system upgrades to supply them. If a higher growth winter forecast is used, with more aggressive assumptions related to electrified heating in particular, up to 3,400 MW of demand growth is possible in the same time frame, with approximately 2,200 MW accounted for in this IRRP.

Supplying growth at the higher end of these projections would require greater consideration of the impact on the broader bulk electrical network. Typically, regional planning assumes the bulk system is a static source of power with sufficient ability to supply any required level of local demand. This assumption becomes challenged when considering levels of demand with the potential to affect provincial interface flows, and approach loading limits on what is typically much higher rated bulk equipment. Additionally, a future scenario where extreme demand growth is observed throughout York region would likely mean similar levels of extreme growth are emerging throughout the province, which would trigger the need for significant upgrades on the bulk system as a whole.

The combination of local demand driving bulk system needs, and assumption that bulk upgrades are required throughout the province, means that planning under this long-term high growth scenarios require close coordination between regional and bulk system plans.

Long-term bulk planning is currently underway through the development of the South and Central Bulk Plan, which considers transmission needs out to 2035, in addition to accommodating several planned changes to the provincial supply portfolio. The York IRRP has been carried out in close coordination with this plan, with implications for system assumptions and options available. These points of coordination are highlighted in the following section when options are described in greater detail.

7 Plan Options and Recommendations

This section describes the options considered and recommendations to address the needs in York Region. In developing the plan, the Technical Working Group considered a range of integrated options. Considerations in assessing alternatives included feasibility, cost, lead time, system benefits, and consistency potential options for addressing longer-term needs in the area.

There are two approaches for addressing regional needs that arise as electricity demand increases:

- Build new or reinforce transmission or distribution systems. These are commonly referred to as "wire" options and can include things like new transmission lines, autotransformers, step-down transformer stations, voltage control devices, upgrades to existing infrastructure, or distribution-level load transfers. Wire options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate certain reliability concerns.
- Install or implement measures to manage the peak demand to maintain loading within the system's existing LMC. These are commonly referred to as "non-wire" options and can include alternatives such as local utility-scale generation or storage, distributed energy resources (including distribution-connected generation and demand response), or eDSM.

Section 7.1 begins with a more in-depth overview of all option types considered in IRRPs. Section 7.2 describes the screening approach used to assess which needs would be best suited for a more detailed assessment for non-wire options. Subsequently, Section 0 to Section 7.4 present the options that were ultimately developed and evaluated to the address near- and longer-term needs, respectively. Opportunities for NWAs are highlighted in their relevant options sections, with additional details provided in section 7.5.

7.1 Options Considered in IRRPs

Both wire and non-wire options are considered in regional planning, although some options may be more suitable for specific need types and characteristics. When evaluating non-wire options such as generation, local distributed energy resources, or energy storage, additional work is required to understand these specific need characteristics, including creation of hourly load profiles, as described in Section 5.7. The suitable technology types and capacities are determined by examining "unserved energy" profiles, representing the hourly demand above the existing LMC. The load profile indicates duration, frequency, magnitude, and total energy associated with each need.

High-level cost estimates for wire options are based on input provided by the transmitter and transmission benchmark costs. In contrast, cost estimates for non-wire options are based on benchmark capital and operating cost characteristics for each resource type and size. Due to policy considerations and decarbonization efforts, new natural gas-fired generation was not considered as a generation option for local needs identified by the regional plan. Energy storage, solar generation, and wind generation were considered for generation options.

New eDSM measures can also help decrease the net electricity demand. Centrally delivered energy efficiency measures under the 2021-2024 CDM Framework and Save on Energy brand are already

included in the load forecast, as discussed in the Section 5.4. As part of this framework and the new 2025-2036 framework, the IESO has flexibility to deliver new programs or offer regional incentive adders for existing province-wide programs to help address regional and/or local system needs. LDCs can also use the Ontario Energy Board's Non-Wires Solutions Guidelines for Electricity Distributors (previously "CDM Guidelines") to leverage distribution rates to help address distribution and transmission system needs using non-wire alternatives. NWA considerations are discussed further in Section 7.2, as part of the screening of options that was conducted. (previously "CDM Guidelines") to leverage distribution rates to help address distribution and transmission system needs using non-wire alternatives. At time of IRRP publication, the Ontario Energy Board is currently considering a proposal from the IESO and the Local Distribution Company community to enhance this existing mechanism to better enable IESO-LDC collaboration and co-funding of eDSM initiatives that provide both local and provincial system benefits. NWA considerations are discussed further in Section 7.2, as part of the screening of options that was conducted.

For both wire and non-wire options, the upfront capital and operating costs are compiled to generate levelized annual capacity costs ($/kW-year). A cash flow of the levelized costs for the options are compared over the lifespan of the wire option (typically 70 years for transmission line infrastructure). The net present value (in 2025 CAD for this report) of these levelized costs is the primary basis through which feasible options are compared.

It is important to recognize that there is a significant error margin around cost estimates at the planning stage, as they are only intended to enable comparison between options during the IRRP. The transmitter-led RIP (which is conducted after the IRRP) performs additional detailed analysis and allows the opportunity to refine cost estimates of wire options before implementation work begins. Costs are typically further refined over the course of project development work. The IESO continues to participate in the Technical Working Group during the RIP and will revisit a recommendation if estimates change significantly. Furthermore, smaller scale demonstration projects can be explored in cases where other barriers (e.g., regulatory frameworks for cost-sharing and recovery, or operationalization to meet local reliability constraints) impede the adoption of some of these cost-effective options following the completion of the IRRP.

The list of assumptions made in the economic analysis is found in Appendix F.

7.2 Screening Options

As described in the previous section, an array of options is developed to meet identified needs during an IRRP, and each option is then evaluated to determine which are feasible and successfully address all needs. Final recommendations are typically made for those which are the most cost effective, although increasingly a wider range of factors are considered, including community preferences, flexibility, or providing some degree of reliability and demand forecast uncertainty risk mitigation. This process is complemented by stakeholder engagement and feedback.

Screening occurs early in the IRRP study after local reliability needs are known but before options analysis. It helps direct time-intensive aspects of detailed non-wires analysis (hourly need characterization, options development, financial analysis, and engagement) towards the most promising options. The three-step, high-level approach is shown in Figure 22 and further discussed in the next sections for the identified needs.

More details on the steps and inputs used in the screening mechanism can be found in Appendix C, and a summary of the options screening results for York Region is provided in Table 7**Error! Reference source not found.** for station capacity needs, and in Table 8| for supply capacity needs.

Figure 22|IRRP NWAs Screening Mechanism

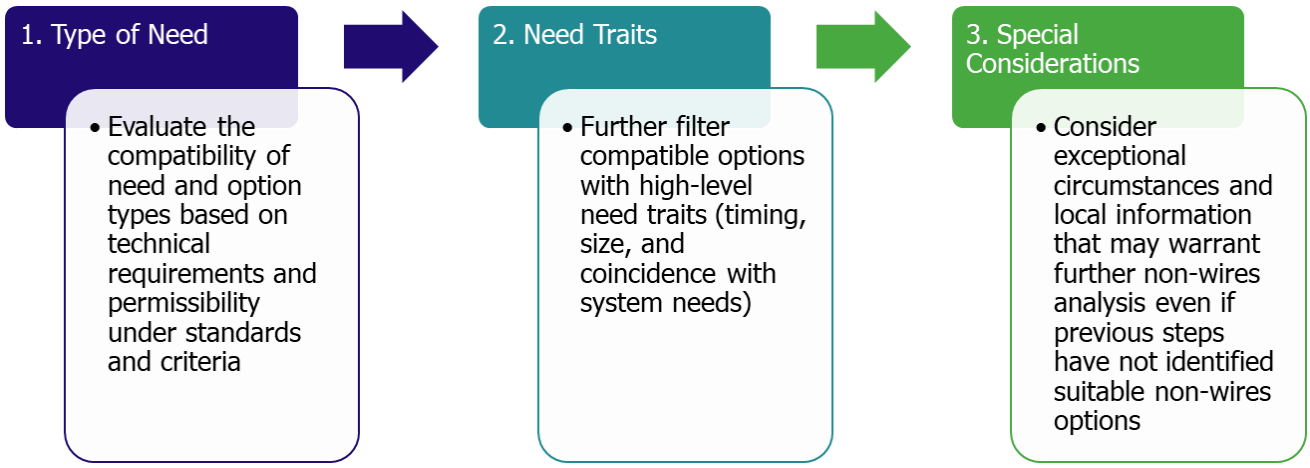


Table 7| Options Screening Results for Station Capacity Needs

Need	Screened In	Screened Out
Station Capacity: All Subregions	• Operational measures • eDSM • Distributed generation • Wires options	• Demand response – due to magnitude and timing of need

Table 8| Options Screening Results for Supply Capacity Needs

Need	Screened In	Screened Out
Supply Capacity: Parkway TS to Buttonville TS Claireville TS to Brown Hill TS	• Operational measures • eDSM • Distributed generation • Transmission-connected generation • Wires options	• Demand response – due to magnitude and timing of need

7.3 Options and Recommendations for Addressing Near-Term Needs

The following sections describe recommendations for addressing near-term needs. Unless stated otherwise, implementation is recommended to proceed immediately to ensure upgrades can be in place to address expected need dates. Where options are not expected to be in place in time, alternative measures have been highlighted to help address short term needs.

7.3.1 Options for Addressing Station Capacity Needs

The need for three step-down stations has been identified in the near term. Work should continue to identify and secure appropriate land and proceed with station development.

7.3.1.1 Northern York TS #1

The need for a new step-down station to serve growing customer demand in Northern York Region is immediate. However, the timeline for design, approval, and construction of this type of infrastructure typically spans around 4-5 years. As a result, this station is not expected to come into service any earlier than 2029.

Several approaches are recommended in the interim to manage growing customer demands before the infrastructure solution can come into service:

1. Additional electricity demand side management should be targeted in northern York region, to assist in ensuring some capacity remains available for growth of existing customer loads. Additionally, lowering peak demand through incremental eDSM would reduce the risk of Load Rejection in the event of an outage during peak load conditions, thereby improving customer reliability. Programming targeting the areas of Newmarket, Aurora, East Gwillimbury, and West Gwillimbury would be the most effective at deferring these step-down station needs.
2. Hydro One Distribution is investigating options to transfer additional loads at the boundary between the Holland TS/Armitage TS service territory and neighbouring Brown Hill TS service territory. Although large scale transfers are unlikely to be feasible given the distances between these stations, small service territory adjustments at the boundary may be effective to manage growth in the near term and still provide longer term reliability benefit due to enhanced restoration capability. Enhancing restoration capability ensures this interim measure remains cost effective by providing enduring customer benefit, even once the future station comes into service.
3. New, load connections have to seek connection through other Northern York stations with remaining capacity. It should be noted, however, that this may incur larger distribution related costs as new feeder lines may be required to cover long distances. The nearest step-down station with significant remaining or unallocated capacity is Brown Hill TS, which is located approximately 15 km northeast from the preferred location of Northern York TS #1. Until connection costs are brought down with a nearer connection point, this may delay Northern York's ability to connect new large load customers.

Based on existing loads and near-term demand forecast, it is recommended that Hydro One proceed with the acquisition of land, the design, and the construction of a new step-down station by 2029 to serve Northern York Region, in the vicinity the Holland TS area. Typical development costs for these types of stations, including real estate, are generally $60 Million[6].

For the purposes of this study, the new step-down station was modelled as connecting to the H82/83V circuits, which exacerbates the existing supply needs for this corridor, as described in section 6.2.2.1. Measures to address these needs are described and recommendations made in section 7.3.2.2. Timelines to address these needs should not interfere with the immediate development of the step-down station, as incremental needs can be met on an interim basis through the arming of load rejection through the existing Remedial Action Scheme (RAS) for Northern York Region.

7.3.1.2 Markham MTS #5

Based on existing peak demand and forecast near-term growth, the need for the next Markham area station is anticipated by 2029. Alectra has identified a suitable location for the next Markham MTS #5, and this project is currently under development. Based on recommendation from the previous IRRP, Markham MTS #5 is planned for connection near the existing Buttonville TS, supplied from the P45/46 circuits. The expected in-service date of this station is 2028-2029. Typical development costs for these types of stations, including real estate, are generally $60 Million. Supplying the full rated capacity of this station and the existing Buttonville TS and Markham MTS #4 will require supply capacity increases to the southern section of P45/46 circuits, further described in section 7.3.2.3.

7.3.1.3 Richmond Hill MTS #3

As described in section 6.2.1.3, significant development pressure in the vicinity of the Richmond Hill Centre Urban Growth Centre will require additional step-down station capacity by 2030 to reliably supply new and intensified customer demand. The area of intensification to be supplied by this new station is roughly bounded by Yonge St to the west, Steeles Ave to the south, 16th Ave to the north and Leslie St to the east. Alectra has identified a suitable location for the next step-down station to supply this forecasted growth, Richmond Hill MTS #3, which is currently under development. The proposed connection point will be along the V71/75V circuits, near the existing Richmond Hill MTS #1 and #2. The expected in-service date of this station is 2030. Typical development costs for these types of stations, including real estate, are generally $60 Million.

Once connected, loading up this new station will exacerbate existing security needs along the corridor. Although an exemption to security criteria is in place today, continued load growth on this corridor, as anticipated through the connection of Richmond Hill MTS #3 in the near term and Vaughan MTS #5 in the longer term, will require a wires solution to be put in place to address security needs. This is further described in section 7.3.3.1.

[6] Actual costs can vary depending on factors such as land costs and equipment ratings

7.3.2 Options for Addressing Supply Capacity Needs

In some cases, measures to address capacity needs will also have the benefit of addressing security needs. Where a proposed solution addresses both sets of needs, it is discussed in the sections below.

7.3.2.1 York Energy Centre Station Service

When operating, the York Energy Centre (YEC) injects power through its transmission connection point along the B88/89H circuits. However, the station service (power used to run station equipment), is normally supplied through a distribution connection from Holland TS, which is connected to the H82/83V circuits to the south of YEC. These two sets of circuits, B88/89H and H82/83V, are connected through a set of breakers that were installed in 2017, several years after YEC came into service. This created a condition where the loss of H82/83V will remove Holland TS, and subsequently YEC, from service without interrupting supply to B88/89H. This creates potential capacity and voltage related needs for the local system (described in section 6.2.2.1), which would not be as severe if YEC remained in service.

Changing the station supply arrangement for YEC would allow for YEC to remain operational under the loss of H82/83V, and the loss of the T1B breaker at Holland TS (current worst-case N-2 contingency). The impact of resolving the YEC station service issue would result in an increase of approximately 90MW in the LMC from the worst-case contingency.

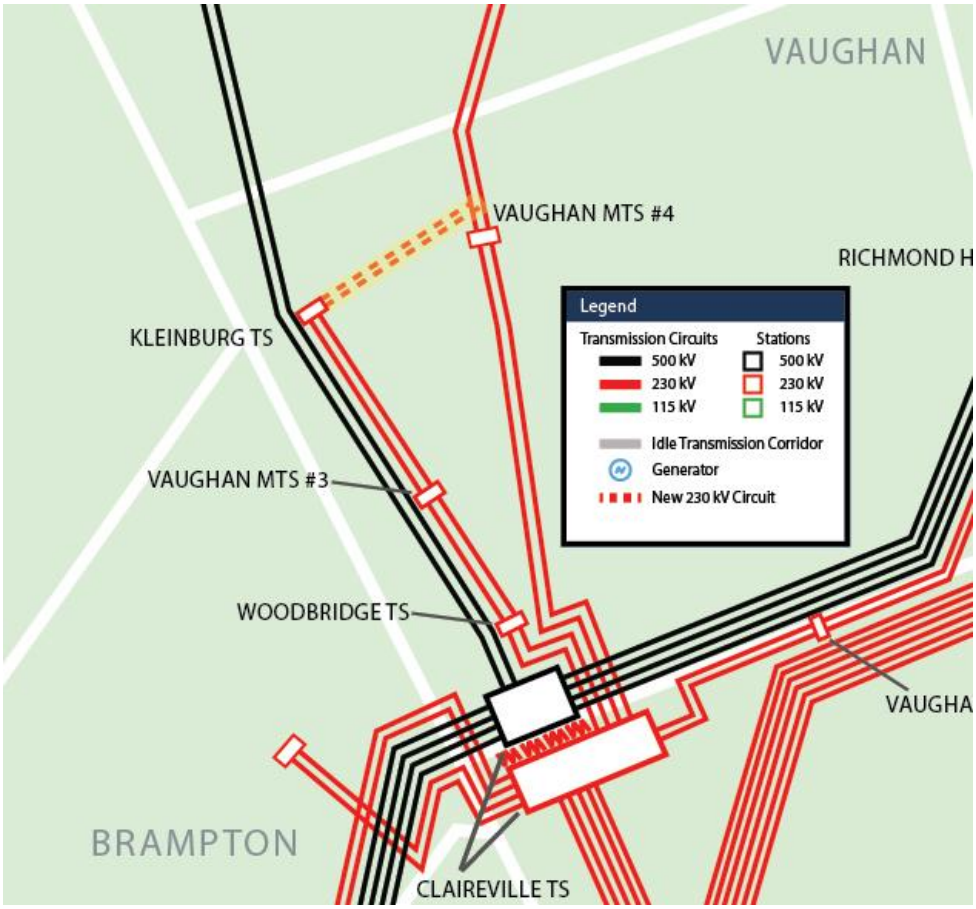
There are different potential ways in which YEC station service could be addressed including:

- Installing second step-down transformer via the B89H tap point, allowing for station service to be drawn under regular operating conditions from B89H as well as the existing supply available from B88H, or;
- Installing a potential automatic station service transfer arrangement to allow for automatic transfer between the Holland TS distribution service and B88H supply points during a contingency.

The ultimate preferred service arrangement should be determined based on deeper engineering study of the cost and technical feasibility of different possible arrangements. It is recommended that the station owner work with the connecting transmitter, Hydro One, to identify and implement this system upgrade. The final configuration should allow for uninterrupted operation of YEC under all applicable N-1 and N-2 transmission planning contingencies affecting H82/83V, as well as all N-1 contingencies affecting either B88H or B89H.

Although cost estimates for this upgrade are not yet available, alternatives to provide to similar level of reliability would be orders of magnitude more costly and disruptive than the proposed station service work, and either require new transmission to create redundant supply paths into the area, or the construction of a similar sized generation facility (~400 MW) to provide redundant supply. By contrast, all anticipated upgrade options could be accommodated entirely within the existing station boundary.

In addition to improving reliability for the local area, this will allow YEC to remain operational under a wider range of system conditions, which in turn improves power and ancillary service availability for the province as a whole.



Consideration of new regulatory or contractual mechanisms may be required to finance this type of system upgrade. There is no existing mechanism for costs incurred by the station owner to be reimbursed, and it also does not fit within the existing competitive procurement streams.

Addressing this station service issue will have an immediate benefit to local customer reliability by lowering exposure to Load Rejection (LR) events, and allowing the local system to accommodate some of the additional load growth associated with the connection and loading of Northern York TS #1. Additional technical details of this analysis are included in Appendix E.

7.3.2.2 Kleinburg-Kirby Transmission Link

After addressing the York Energy Centre (YEC) station service issue (see section, 7.3.2.1), the next most limiting contingency affecting Northern York is triggered by thermal violations of the southernmost section of circuits H82/83V, which span from Claireville TS to Vaughan MTS #4. Due to a narrow transmission corridor, and close proximity to development along this route, this section is not a good candidate for reconductoring to increase capacity of the line. Instead, a new transmission route is proposed to bypass this limiting section and improve supply capacity into Northern York. This new transmission line, referred to as the Kleinburg – Kirby Transmission Link, would create a connection between the existing Kleinburg radial tap, and connect to a point north of the exiting Vaughan MTS #4. The notional location of the facilities is shown in Figure 23.

Figure 23| Potential Kleinburg – Kirby location

Creating this bypass would reduce the amount of power that would have to flow north from Claireville TS to Vaughan MTS #4 to reach stations further to the north. The impact on LMC depends on where new stations are ultimately located in Northern York, and the balance of demand between them, however this upgrade is expected to allow for the connection and full loading of Northern York TS #1.

The long-term need for this corridor to supply Northern York, as well as northern Peel and Halton regions, had previously been identified through the regional planning process. Additionally, the Ministry of Transportation (MTO), dealing with similar growth and intensification needs from a transportation perspective, has been working to develop the proposed Highway 413 in the same general area. More information on MTO's process is available on the project website, linked here. In accordance with the Provincial Policy Statement, which recognizes the value of co-locating linear infrastructure from a land use perspective, the IESO and Ministry of Energy and Mines have been working for over a decade to identify and preserve land in the same general vicinity as the proposed highway. This new transmission corridor would roughly parallel Highway 413, with minor deviations where required to connect with specific transmission supply points or avoid areas unsuitable for transmission. The final route, when fully built, would provide a transmission route connecting a future Milton TS to Kleinburg TS. This line would connect with the extension further east to the H82/83V

circuits in Vaughan, at a point north of Vaughan MTS #4, close to the intersection of Kipling and Kirby Rd. This proposed transmission line is referred to as the Kleinburg to Kirby link.

As an initial configuration, a double-circuit 230 kV is envisioned along this route. In the longer term, a second double-circuit line could potentially be required to further reinforce and create a separate redundant supply path to serve the southern sections of H82/83V, if additional step-down stations are required in the vicinity of the existing Vaughan MTS #4. The initial 6 km double-circuit 230 kV Kleinburg to Kirby link is estimated to cost $40 million and would likely take 6-7 years from project initiation until in service date (timelines aligned with Bulk Kleinburg TS build out, described in section 8.1). This assumes a steel lattice tower design and does not account for any additional land costs.

7.3.2.3 Reconductoring P45/46

As described in section 6.3.2.2, thermal limits of the existing P45/46 circuits are expected to be exceeded following the loss of the companion circuit when total loading on the stations supplied by these circuits (Markham MTS #4, Buttonville TS, and the future Markham MTS #5) exceeds approximately 450 MW.

Based on a review by Hydro One, it is technically feasible to upgrade the limiting conductors along this transmission corridor. Reconductoring the section between Parkway TS and Markham MTS #4 would allow the P45/46 corridor to support the full LTR at Markham MTS #4, Buttonville TS, and the future Markham MTS #5. The estimated cost would be $4.3 million.

Based on current forecasts, the need date for this upgrade is approximately 2031. However, there is value in advancing this work to coincide with the planned in-service date of Markham MTS #5 (2028-2029) for two reasons. First, once connected, there may be value in utilizing new step-down station assets at a quicker rate, such as when transferring loads during an outage on a neighbouring station, or to make more efficient use of distribution assets closer to actual customer loads. For that reason, it may not be efficient to curtail load at this station once it is connected. The second reason deals with operational and logistic challenges of managing reconductoring work. Typically, one of the conductors being upgraded would need to be taken out of service for long periods of time, limiting supply capacity of the system for weeks, or even months at a time. This timing of work will need to be carefully planned to coincide with periods of time when demand is expected to be lower. However, the longer the work is delayed, the more challenging it can be to carry out, as available windows for taking these types of long outages become shorter.

Hydro One, with the IESO, should determine a preferred window for carrying out this work as part of the RIP process.

7.3.3 Options for Addressing Load Security Needs

The sections below describe preferred solutions to address load security needs. In the past, LDCs and transmitters have had the option of jointly applying for exemptions to security criteria, where the cost of upgrades is expected to exceed customer benefit. Although the IESO has typically granted these exemptions, revisions to applicable criteria now only permit exemptions as a temporary, or stop gap measure, where longer term solutions may take additional time to implement.

7.3.3.1 V71/75P Circuit Breakers

As described in sections 6.2.1.3 and 6.3.1.3, security limits are exceeded along the V71/75P circuits today, and this is expected to worsen once Richmond Hill MTS #3 connects, and in the longer term Vaughan MTS #5. Although an exemption to security criteria is in place today, it is not anticipated that it will continue to apply as revisions to security criteria now require longer term plans to address needs to be in place. Additionally, the scale of the security need has surpassed 730 MW during the most recent 2025 summer peak, and rapid anticipated load growth from new stations on the corridor is (linked to existing urban development plans). As a result, there is an immediate need to address load security for stations supplied by these circuits.

Existing switching facilities along this corridor allow for the partial restoration of load following the loss of two transmission elements, but they do not prevent the full load along the corridor from being lost immediately following a double contingency affecting both circuits. By adding inline breakers near the midpoint of the V71/75P circuits, a contingency affecting both circuits would only cause the loss of roughly half of the connected stations, significantly reducing the amount of load interrupted. The exact amount of load lost would depend both on the placement of the breakers, and the future connection points of Richmond Hill MTS #3 and Vaughan MTS #5. A suitable location for these breakers would be one where the simultaneous loss of the V71/75P circuits at a single point along the corridor (i.e., a credible common tower contingency) would not interrupt more than 600 MW of load.

Given the proposed connection point for Richmond Hill MTS #3, one notional option would be to locate these breakers along the 6 km stretch between present day Vaughan MTS #1, and Richmond Hill MTS #1. When Richmond Hill MTS #3 is connected, and all six stations on the corridor are fully loaded to their summer LTRs, this would expose a maximum of 459 MW to interruption for a common tower double-circuit contingency. Assuming the future Vaughan MTS #5 is connected east of these breakers, along the same section as the Richmond Hill MTSs #1, #2, and #3, the longer-term maximum interruptible load would be 560 MW, still within acceptable security limits. An ideal location for these breakers would therefore be between present day Vaughan MTS #1 and the future Vaughan MTS #5.

Identifying the exact location for the future breakers will require detailed review of the existing transmission corridor, both to find an area where they can be accommodated without requiring additional land acquisition and ensure development work can be undertaken without disrupting operation of any existing facilities. The Working Group recommends that Hydro One identify a preferred location for connecting in line breakers along V71/75P within the scope of the upcoming York RIP and then proceed to implement this project. Typical costs for this type of infrastructure range from $30 million to 35 million and take approximately three to four years to develop. As the V71/75P circuits are owned and operated by Hydro One, it is not a suitable candidate for competitive procurement.

7.4 Options for Longer-Term Needs

Longer term options to address needs throughout York Region will be informed by actual demand growth, location of future step-down stations, and longer-term local generation supply availability. The following sections describe potential outcomes based on best available estimates of how these factors will evolve. Unless stated specifically, actions are generally not required at this time, unless it is to preserve longer term options.

7.4.1 Options to Address Southern Vaughan, Richmond Hill, and Markham Needs

The area served by stations connected to the V71/75P circuits roughly aligns with Southern Vaughan, Richmond Hill, and Markham. Security needs exist today, though are managed through exemptions to applicable criteria. Longer-term needs and options are linked to ongoing customer growth, intensification, and managing security needs as they worsen when new step-down stations connect.

7.4.1.1 Vaughan MTS #5

The longer-term need for a new step-down station to supply southern Vaughan is described in section 6.3.1.3. The preferred location for future connection would be in the vicinity of Vaughan Metropolitan Centre (VMC), which is easily accessible from connection points along the V71/75P circuits. Although security limits are already exceeded along this corridor today, the ideal location of these circuits make any other connection point for a station intended to supply VMC impractical. Instead, Vaughan MTS #5 is recommended for connection along V71/75P, and measures to address outstanding and worsening security needs will be explored separately. Near-term recommendations for addressing security needs have considered the anticipated longer-term impact of connecting this step-down station. Details on recommendations to address security needs are provided in section 7.3.3.1.

The need date for Vaughan MTS #5 is linked to growth within the VMC pocket, and not to overall capacity at remaining southern York stations. Alectra has indicated that they are working towards a 2033 in service date, based on connection applications and approved municipal plans. Actual need date may vary depending on develop timelines for new customers in the area. Although the need date is outside of the five-year near-term window, work should continue towards this targeted completion date. Typical development costs for these types of stations, including real estate, are generally $60 million.

7.4.2 Options to Address Northern Markham, Richmond Hill, and Whitchurch-Stouffville Needs

The areas of northern Markham and Richmond Hill, in addition to eastern sections of Northern York, currently have limiting step down station capacity due to their long distances from the existing transmission network. As urban boundaries continue to expand northward, and rural loads intensify, this will trigger the need for new transmission stations, and transmission infrastructure to supply them. Individual options and their timing are described below.

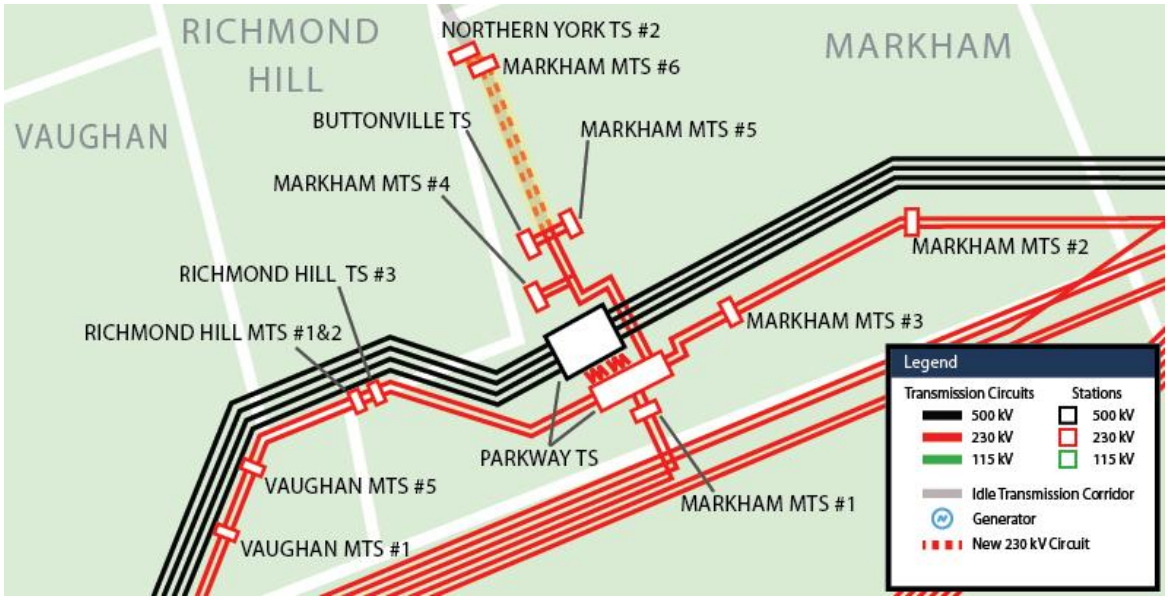
7.4.2.1 Northern York TS #2

As described in section 6.3.1.1, the preferred location for the future Northern York TS #2 would be in closer proximity to growing load centres in the eastern half of Northern York. Whitchurch-Stouffville has been identified as a particularly challenging area for meeting long term distribution connection requests as it is expected to see significant load growth over the coming 20 years, and is also far removed from existing transmission infrastructure. Supplying customer loads, especially denser demand from high electricity use customers or more urban/suburban development, becomes more challenging for distribution networks the further they are from the transmission supply point. This can result in more expensive connections, and poor customer reliability.

Additionally, the most recent step-down stations built to supply Northern York (Holland TS and Northern York TS #1) have been or will be built in the same general area in western Northern York, with connection to the same supplying circuits. Diversifying the location of step-down stations provides benefit to customer reliability by allowing alternate supply paths through the distribution network to manage planned or emergency outage conditions.

An ideal location for Northern York TS #2 would therefore be close to the eastern sections of Northern York. No transmission infrastructure currently exists in this area, which means triggering development of this step-down station will also require development of new transmission to supply the station. Typical development costs for these types of stations, including real estate, are generally $60 million.

7.4.2.2 Markham MTS #6



As described in section 6.3.1.2 continued urban expansion throughout northern Markham and Richmond Hill is expected to trigger the need for a new step-down station in around 2034. Actual need date could vary depending on actual demand growth in the area, which is influenced both by new as well as intensified customer demand, but also by the successful uptake of NWA where it can offset peak demand growth. Because the driver for this station is growth in the northern section of these municipalities, and because transmission does not currently extend beyond ~3km from the south of Markham, this station could not be built in a way that allows for efficient or reliable service to customers today. As a result, pursuing the development of this future step-down station will also require a parallel development of new transmission to allow connection closer to anticipated load centres. An existing, idle transmission corridor already exists in a suitable area and could be leveraged to enable this connection. This is explored in section 7.4.2.3, below. Typical development costs for these types of stations, including real estate, are generally $60 million.

7.4.2.3 P45/46 Transmission Extension

As described above, connecting and supplying the future Northern York TS #2 and Markham MTS #6 in the longer term will require extending the existing transmission system a further 7 km (approximately) into northern Markham. An idle transmission corridor already exists and can be repurposed for new infrastructure without requiring new land acquisitions. The existing towers and

conductors, rated for 115 kV, would need to be rebuilt to a 230 kV standard. The location of the idle transmission corridor and the general location of future step-down stations are shown in Figure 24.

Figure 24| P45/46 transmission circuit extension into northern Markham

Alternative connection points for the future Northern York TS #2 and Markham MTS #6 stations would require either developing new transmission rights-of-way to supply the emerging load in northern Markham or locating the new station capacity along the existing transmission, which would be far from the anticipated growth. Neither of these alternatives are preferred to repurposing the idle transmission corridor. New transmission corridors through heavily built-up areas would be significantly more costly and disruptive to the community. Alternatively, locating new step-down stations farther away from the load would require long distance distribution lines and would introduce reliability risks and potential voltage support challenges due to the load density and distance from the transmission supply.

Based on comments received through engagement, there is a strong local preference for deferring the need for new transmission infrastructure in Markham for as long as possible, and for considering less visually intrusive technology types when the transmission is ultimately required.

The need for new transmission is directly linked to the need for new step-down transmission stations to serve Markham, northern Richmond Hill, and the eastern half of Northern York region. Measures that target peak demand reductions in these areas could have deferral benefits pushing the need for these stations and consequential transmission expansion. As a result, it is recommended that NWAs be targeted in this area, with particular focus on Markham, parts of northern Richmond Hill (i.e., in areas not associated with intensification along Highway 407 and Yonge subway extension), Aurora, and Whitchurch-Stouffville. These initiatives could produce net positive economic benefits by deferring infrastructure needs. The combined station development costs, including real estate, are estimated at approximately $120 million, while the minimum transmission cost is estimated at $45.5 million, and costs could be higher depending on the transmission technology type (e.g., monopole towers or undergrounding).

Should the transmission expansion be required to supply growth in northern Markham, there are technology types that can be considered at the time of designing the facilities to reduce the potential visual impact. For example, steel monopole tower designs, although more expensive than lattice tower structures, can be used in urban areas to minimize foundations and leaves more space for secondary uses. These alternative tower types may also be preferred by neighbouring communities due to their less industrial aesthetic. Underground transmission may also be preferred by communities, but undergrounding is generally reserved for cases where overhead facilities are not technically feasible due to their very high costs. Underground transmission cables can be several times more expensive than overhead lines, with the incremental cost related to undergrounding likely borne by the benefitting community. Other trade-offs associated with underground cables are a lower asset life expectancy, and longer and costlier repair and maintenance. Cables are less likely to experience outages due to factors such as weather, animal contact, and vehicular accidents, but may be more prone to impact from overland flooding or drought conditions. Given that this transmission corridor would be supplying radial loads (i.e., no redundant supply from both ends), interruption to customer loads could be significant if a contingency impacted an underground cable. A comparison of overhead and underground technologies for this transmission is provided in Table 9.

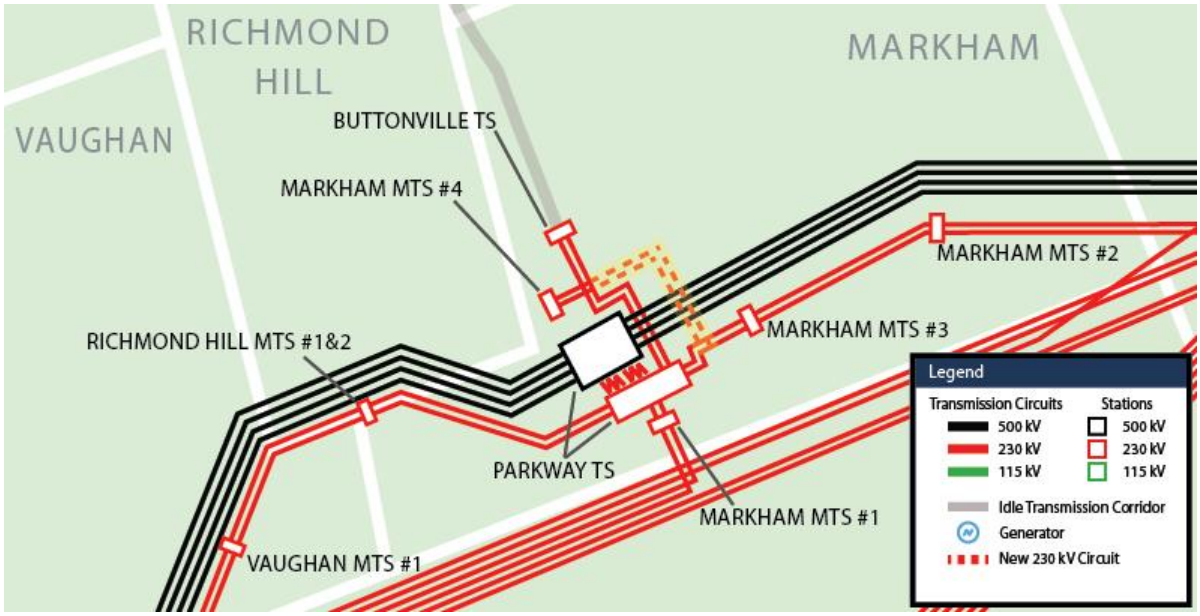
Table 9| Estimated cost of ~7km transmission extension along existing Right of Way in Markham

	Life of Asset (Years)	Cost ($M)
Lattice Tower	90-100	45.5
Cable	40-50	175

Decisions for the final technology type of new transmission lines are not typically made until the Environmental Assessment (EA) stage of line design.

7.4.2.4 P45/46 reconductoring to Buttonville

The near-term recommendation to reconductor the limiting section of P45/46 circuits (described in section 7.3.2.3) only considered the need to reconductor the section between Parkway TS and Markham MTS #4. This upgrade would allow for the full loading up to station LTR of Markham MTS #4, Buttonville TS, and future Markham MTS #5. In the longer-term, step-down station needs are expected to trigger the extension of circuits P45/46 and connection of two additional step-down stations: Northern York TS #2 and Markham MTS #6. The collective load of these five step-down stations would exceed both security limits and supply meeting (thermal) capacity of the remaining P45/46 circuits section between present day Markham MTS #4 and Buttonville TS. Options to address security needs are described in section 7.4.2.5, below.



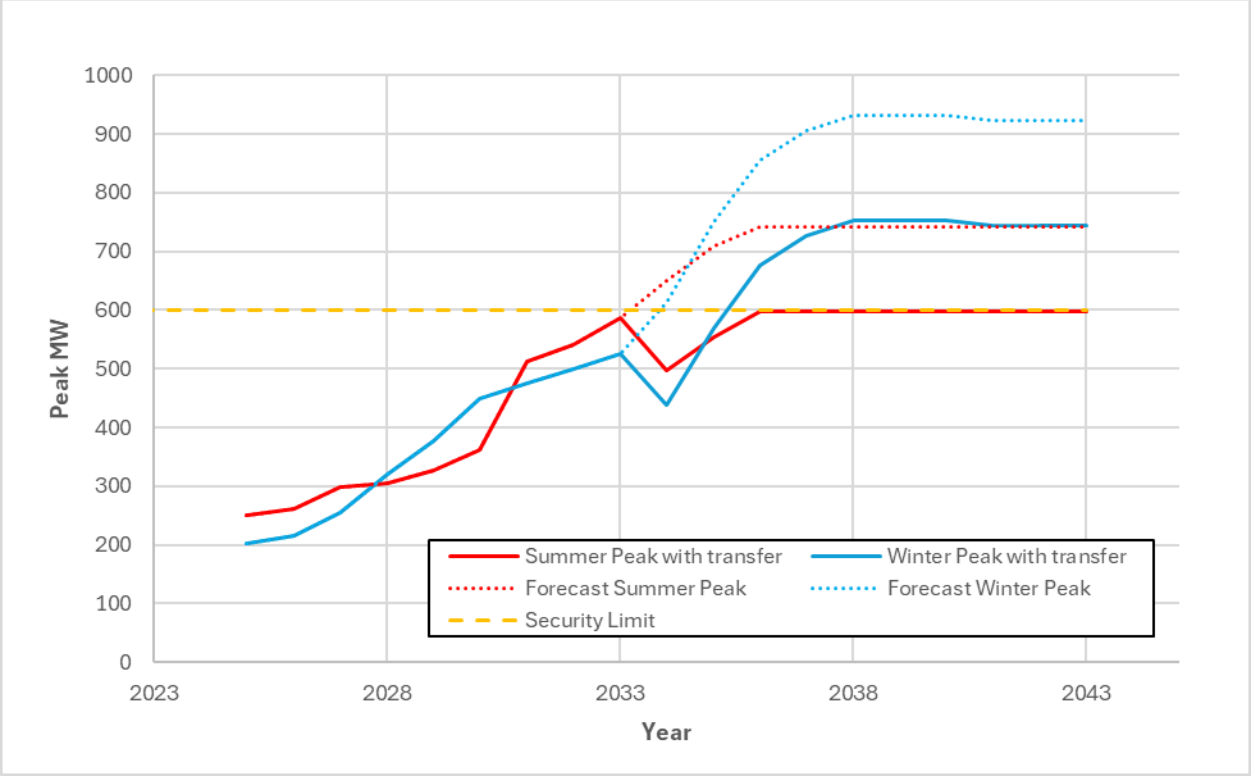
Thermal needs would be triggered when combined load at Buttonville TS, Markham MTS #5, Markham MTS #6, and Northern York TS #2 exceeds approximately 450 MW. These needs can be addressed by reconductoring the remaining ~2.7 km section of P45/46 circuits between Markham MTS #4 and Buttonville TS, with an approximate cost of $9.5 million.

The need date for this reconductoring work is when the collective load of Buttonville TS, Markham MTS #5, Markham MTS #6, and Northern York TS #2 exceeds 450 MW. To ensure that newly connected stations can make full use of their assets, this work should occur no later than the connection of either Markham MTS #6 or Northern York #2 TS, whichever comes first. However, it can often be challenging for facility owners and operators to manage outages required during reconductoring work. As a result, this work may be advanced at Hydro One's discretion, particularly if project efficiencies are identified from pairing this work with the reconductoring of the adjacent Parkway TS to Markham MTS #4 section of P45/46.

7.4.2.5 Markham MTS #4 radial tap

After addressing thermal needs with the reconductoring described above, the connection and loading of longer-term stations to the P45/46 circuits would still cause security needs to emerge when total load exceeds 600 MW. To address security needs, a new radial transmission circuit could be extended from the existing transmission corridor in the south (adjacent to Highway 407), to connect Markham MTS #4, and remove it from the remaining P45/46 circuits. This would increase the LMC of the area by roughly one station worth of load. This is shown conceptually in Figure 25.

Figure 25| Possible Radial Tap of Markham MTS #4



Markham MTS #4 is the preferred station for tapping off with a new transmission connection, as it is located close to alternate transmission points, with potentially as little as 1.5 km of new transmission required. Several potential connection points for this extension exist, including direct connection to Parkway TS, and tapping of the existing C35/36P circuits. The latter option is currently preferred as it would be significantly less costly than a connection within Parkway TS, which would incur additional upgrade costs to existing bulk system infrastructure at the station due to space constraints. The estimated present-day cost of the Markham MTS #4 tap from C35/36P circuits is $9 million. Making a

direct connection within Parkway TS, while offering improved reliability by reducing the number of stations served by a single transmission asset, would likely incur a minimum additional cost of $70 million to upgrade existing Air Insulated Switchgear (AIS) to Gas Insulated Switchgear (GIS). Both candidate transmission connection points can be accommodated within existing transmission corridor right of ways.

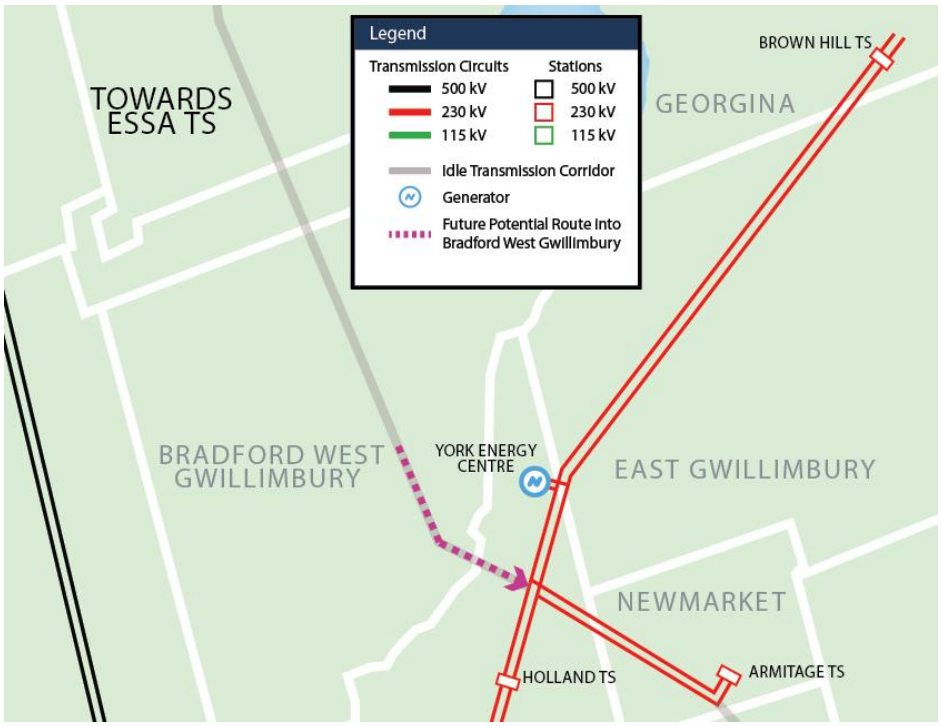
It is recommended that this work be undertaken to coincide with the connection of either Markham MTS #6 or Northern York TS #2, whichever is ultimately required first. This will allow LDCs to make full use of connection facilities once they become available. Identification of a preferred connection point for the Markham MTS #4 radial tap should be reevaluated during the next planning cycle, as development work is not expected to be required within the next 5 years. Cost assumptions related to different connection points may change in the interim based on bulk planning outcomes and/or upgrades required for new customer connections. This also provides time to monitor demand growth, and to implement measures aimed at managing the demand growth in order to defer the need for new infrastructure as long as possible.

Figure 26 shows the impact of removing Markham MTS #4 from the P45/46 circuits (notionally shown in year 2034) enables the remaining stations to be loaded up to the forecast summer peak.

Figure 26| P45/46 Circuit Loading

In the event that higher winter peaks begin to emerge in the long term, violations of security criteria are possible, with peaks potentially reaching 740 MW. If forecast winter peaks begin to emerge, NWA may provide a good solution to address periods of time where there is a risk of exceeding security limits, particularly as resources would only be required for short periods of time over the year.

7.4.3 Options to Address Northern York Needs



Preferred options to address longer term needs in Northern York will ultimately depend on the location of future Northern York step down stations, and whether YEC is assumed to continue commercial operation after 2035. Potential options are described below, although actions will not need to be taken to advance solutions at this time.

7.4.3.1 Northern York TS #3

As outlined in section 6.3.1.1, by the mid 2030s, growth rates in Northern York are expected to require a new step-down station to serve growing customer demands approximately every 4 years. This could further increase if large loads associated with major customer connections begin to emerge. The general preferred location for Northern York TS #1 and #2 has already been identified based on existing capacity limitations and anticipated high growth areas (the general vicinity of Holland TS and future Markham MTS #6, respectively). The preferred location for Northern York TS #3 is not yet known but would likely be in the general vicinity of Holland Marsh junction, where it would be located to accommodate growth throughout the communities of King, Newmarket, East Gwillimbury, and Bradford West Gwillimbury. This is because these communities are the furthest from the planned location of Northern York TS #2, so, as with Southern York region today, it is reasonable to assume alternating new stations between the east and west sides of the Northern York area.

An existing, idle transmission corridor currently stretches from the Holland Marsh junction, northwest through Bradford-West Gwillimbury, and ultimately through Simcoe County to connect with the existing Barrie TS and planned Innisfil TS (stations are within the South Georgian Bay/Muskoka regional planning area).

Figure 27| Conceptual route along idle corridor between Essa TS and Holland Marsh JCT

Making use of this corridor should be evaluated closer to the Northern York TS #3 need date to determine if the incremental benefit of providing step down capacity closer to load growth centres would offset the increased transmission cost. These benefits could include lower distribution infrastructure costs, lower connection costs for large customers, and higher reliability and power quality depending on the future areas of highest demand growth. Having this station on a separate transmission radial link could also potentially improve future capacity constraints on the remaining network circuits in Northern York (H82/93V and B88/89H), but this would need to be evaluated when actual longer-term supply and demand conditions are better known.

7.4.3.2 York Energy Centre Continued Operation

As described in section 6.3.2.1, the phase out of YEC following its contract expiry in 2035 would introduce a sudden 400 MW shortfall of local capacity in Northern York region. The supply gap would be in addition to organic load growth already defined in the load forecast. Meeting a sudden supply requirement of this magnitude would either require similar sized generation to take its place, or new transmission to bring capacity into he same general area where generation is lost.

In order to replace the existing, single cycle gas supply, a generation option would need to have similar operational characteristics as YEC today. This means the ability to rapidly ramp up operation, adjust generation levels to match local demand levels, and operate continuously throughout periods of peak demand, which can last for several hours in a day, and last several days in a row. Intermittent generation sources, such as solar and wind, would not be suitable alternatives due to significant land requirements to account for lower capacity factors for these generation types. Pairing

with batteries would also pose challenges, as the size of batteries required would need to account for worst expected duration of needs over several years, which would not be economic since these conditions are by definition rare events.

It is important to note the that the local requirements to operate YEC (or a similar sized and technology type resource) are only triggered for short periods of the year. This would include hours where local demand is at its highest, or during planned or emergency system outages. While fully offsetting the need for the full 400 MW of available capacity would be very challenging without significant transmission infrastructure to replace this shortfall, adding additional energy sources, such as a Battery Energy Storage System (BESS), would lower the number of hours of the year in which YEC would be expected to operate.

Local communities have consistently indicated a strong preference for lowering greenhouse gases (GHG) emissions released in the area, where achievable with minimal disruption to the surrounding agricultural land use. Capital Power, the owner of YEC, has recently installed a 132 MW BESS to one of the two yards that YEC operates out of. The existing BESS, while able to lower expected GHG from normal operation, does not have a significant impact on local capacity or reliability needs.

If a second, similarly sized BESS were connected to the B89H circuit (either at YEC, or elsewhere on the circuit section), the combined impact of the two BESS units would improve system reliability performance, as at least one could be assumed in service under all contingencies in which either B88H or B89H remain operable. The reliability benefit for adding a second, identically sized BESS within the B89H corridor would be equivalent to approximately 60 MW of reliable local capacity, after accounting for typical operational profiles of BESS technology.

However, the supply capacity increase from this second BESS would not be sufficient to offset near term needs, nor would it have an impact on longer-term step-down station capacity needs. For that reason, it is not included as a recommendation in this study. A combination of short circuit and congestion issues also currently prevent new local resources, including BESSs, from connecting in this area. However, if these issues are resolved in the longer term, this project, or other similar sized generation projects, could help defer longer term needs in the area while reducing the amount of time YEC could be expected to run in the near term, thereby lowering GHG emissions within the area. This makes it a potentially higher value location for siting BESS technologies within York Region, when considering reliability and environmental factors. These benefits would be unique to generation sources which are dispatchable, non emitting, and able to be connected to the B88/89H (preferably B89H) circuits.

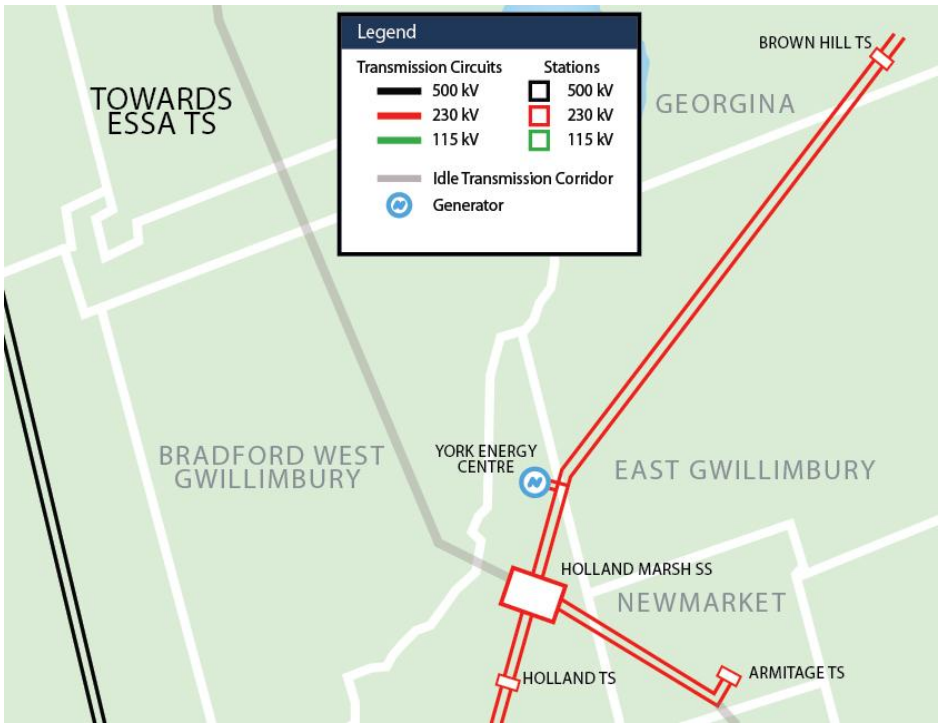
7.4.3.3 New Northern York transmission supply

In the event that YEC is phased out following its contract expiry in 2035, and equivalent generation is not located in the same general area, it would trigger the need for a new transmission circuit to deliver capacity into Northern York. A typical double-circuit 230 kV line can transfer at least 600 MW of power, though design factors can influence total capacity. Planning this type of infrastructure would require consideration of the initial supply point, the termination, and route between these two points. For a supply point, the anticipated and nearby Kleinburg TS would provide an excellent source of bulk power and given it is expected to come into service in the early 2030s, would likely have

more than sufficient capacity for this project. As a termination point, a connection in the same general vicinity as YEC, or at a minimum on the B88/89H circuits would be preferred. This would ensure that new capacity can push against the typically limiting flow away from Kleinburg TS along H82/83V. An ideal connection point would be a new Switching Station (SS), described in the section below, which would link the existing H82/83V circuits with B88/89H, while creating new terminations for the Armitage radial pocket. Having a supply path into this SS would ensure each of the supply points emanating from this station could have a redundant source of supply under multiple configurations and contingencies.

Based on an initial review of the existing corridor between Kleinburg TS and the Holland Marsh area, a new transmission right of way would need to be identified and land acquired to enable this connection. The first section of a proposed corridor could make use of the planned Kleinburg – Kirby transmission link, adjacent to the future Highway 413. Sufficient land is being set aside to enable two double-circuit transmission lines along this route. The first, described in section 7.3.2.2, is expected to be developed in the near term, while the space allocated for the second could be leveraged here. This would allow for a partial new corridor between Kleinburg TS and the approximate intersection of Kirby and Kipling. The remaining ~23km to the Holland Marsh area has an existing transmission line, but there is insufficient land along this corridor to enable a second transmission line. Additionally, there are several points along this corridor where buildings and other geographic features unsuitable for transmission use are immediately adjacent, meaning acquiring new land adjacent to the existing line is either not preferable, or infeasible. As a result, a new route would need to be identified, largely through King township. Given the complexities of siting transmission, namely requiring a linear corridor, with fixed start and end points, and compatible adjacent land uses for the entire route, this could be a costly and disruptive undertaking for the community.

No actions or recommendations are required at this time. However, if YEC is assumed to come out of service in 2035, work should begin no later than 2028 to identify land suitable for a new transmission corridor and initiate development work. Although no site-specific analysis has been undertaken to produce formal cost estimates, typical new corridors of this size, including transmission infrastructure and real estate costs, could be $200-300M.



7.4.3.4 Holland Marsh Switching Station

As described in section 7.5.3.1, the connection of a third Northern York TS along the Claireville to Minden corridor will trigger a security need regardless of whether it is connected to the H82/83V or B88/89V circuits. In addition to the security needs triggered, this section of the grid has been cited by operators as posing significant challenges due to the presence of two sets of inline breakers, and a major system resource facility (YEC). Sectionalizing the existing circuits through a Switching Station (SS) would greatly streamline the operational characteristics, while enabling the connection of Northern York TS #3, and eliminate the most limiting breaker failure contingencies currently affecting the area.

A long-term switching station configuration would be positioned at the existing Holland Marsh junction, to allow for separate circuit termination for the existing H82/83V, modified B88/89H circuits (only the section north of the Armitage junction), and a new, separate radial pocket for Armitage TS. Circuit positions should also be made available for the connection of any future radial circuits

required for supply to the Bradford-West Gwillimbury area, and for connection of any new supply transmission line which may be required in the long term, as outlined in Section 7.4.3.3.

Figure 28| Potential future location of Holland Marsh SS

The ultimate configuration of the SS is outside the scope of this study but should be investigated to eliminate the possibility of a common breaker failure triggering simultaneous loss of one H82/83V circuit and one B88/89V circuit. This would eliminate the most limiting breaker failure contingency. If a longer-term connection line into West Gwillimbury is ultimately developed to connect the future Northern York TS #3, an initial preferred switching station arrangement could assume that line terminations are alternated between network lines (B88/89H and H82/83V) and radial lines (Armitage tap, West Gwillimbury Tap).

At this time, the development of a Holland Marsh Switching Station is not required. The current demand forecast suggests that Northern York TS #3, and as a result Holland Marsh SS, would be required in the mid 2030s. However, these assumptions should be revisited during future studies based on actual growth rates, preferred location for future stations, and ultimate connection arrangements. Hydro One has indicated that existing land rights are expected to be sufficient to accommodate this facility when required, with no additional acquisitions required. Switching Stations of this size, including all associated switchgear and breakers, typically cost $200-250 million.

7.4.3.5 Reconductoring H82/83V

As described in section 7.3.2.2, reconductoring of the limiting section of H82/83V between Claireville TS and Vaughan MTS #4 is not a viable option, as the existing corridor is too narrow, and development too close, to allow the work to be completed. However, development north of the proposed Kleinburg-Kirby connection point along H82/83V is significantly less dense. Based on a

review undertaken by Hydro One, reconductoring the remaining section between the Kleinburg-Kirby link and Holland Marsh junction is likely feasible.

Following completion of the YEC station service project and the Kleinburg-Kirby link, additional load meeting capability in Northern York is not expected to be required until an additional step-down station is required (notionally Northern York TS #3), and/or following the potential retirement of YEC.

The benefit provided by this reconductoring would depend on the longer-term configuration of the system, including location of demand, supply, and any new infrastructure such as switching facilities. Where thermal limits along the H82/83V circuits are found to be limiting, reconductoring this section could potentially increase LMC by providing improved capacity into a future Holland Marsh SS.

7.5 Opportunities for Non-Wires Alternatives

7.5.1 Large-scale Non-Wires Alternatives

Transmission-connected resources such as large-scale solar, wind, BESS or a combination of these resources were found not adequate to resolve the supply capacity needs covered in Section 6. This is mainly due to 1) connection restrictions in the area due to short circuit limitations at Claireville TS and congestions on the circuits covered in the needs 2) the large magnitude of land required to meet the supply capacity needs of each region sufficiently to defer wires reinforcements.

Installing large transmission-connected resources also do not resolve the station capacity needs in the region, especially in Northern York and the Markham area where downstream feeders cannot viably connect to the system unless new step-down stations are implemented. It is expected that the near-term recommendations described in Section 7.3.2.2, along with the required bulk upgrades described in Section 8.1, will help enable the connection of some resources by resolving the short circuit limitations of Northern York, but congestion constraints will remain in the area, and short circuit issues remain in Southern York.

7.5.2 Demand Side Management

Incremental eDSM can help manage the demand until the next major grid reinforcement or step-down station would be required to cater to the large supply capacity needs. The table below provides a year over year cumulative breakdown of the incremental eDSM potential available per subregion above and beyond that already captured in the IRRP demand forecast.

Table 10| Estimated Incremental eDSM Potential (Cumulative MW) by Subregion

	Northern York	Kleinburg subsystem	Southern Vaughan-Richmond Hill	Markham and Area
2025	18.4	7.7	10.3	9.9
2026	26.3	10.7	13.3	13.4
2027	44.0	17.6	20.3	23.8
2028	35.1	14.1	16.9	18.0
2029	52.5	20.7	23.3	29.1
2030	60.2	23.5	26.8	34.4
2031	70.3	28.1	35.7	45.3
2032	82.5	33.9	47.8	55.9
2033	92.8	38.9	58.9	66.8
2034	103.1	42.5	68.0	78.2
2035	123.9	46.9	76.8	95.5
2036	112.8	44.5	71.7	86.9
2037	141.4	49.6	80.5	100.5
2038	161.0	52.4	84.9	105.7
2039	177.0	55.2	89.1	113.0
2040	190.9	57.6	92.8	123.0
2041	200.0	59.4	96.1	131.5
2042	**211.6**	**61.5**	**99.3**	**137.4**

8 South and Central Bulk Study

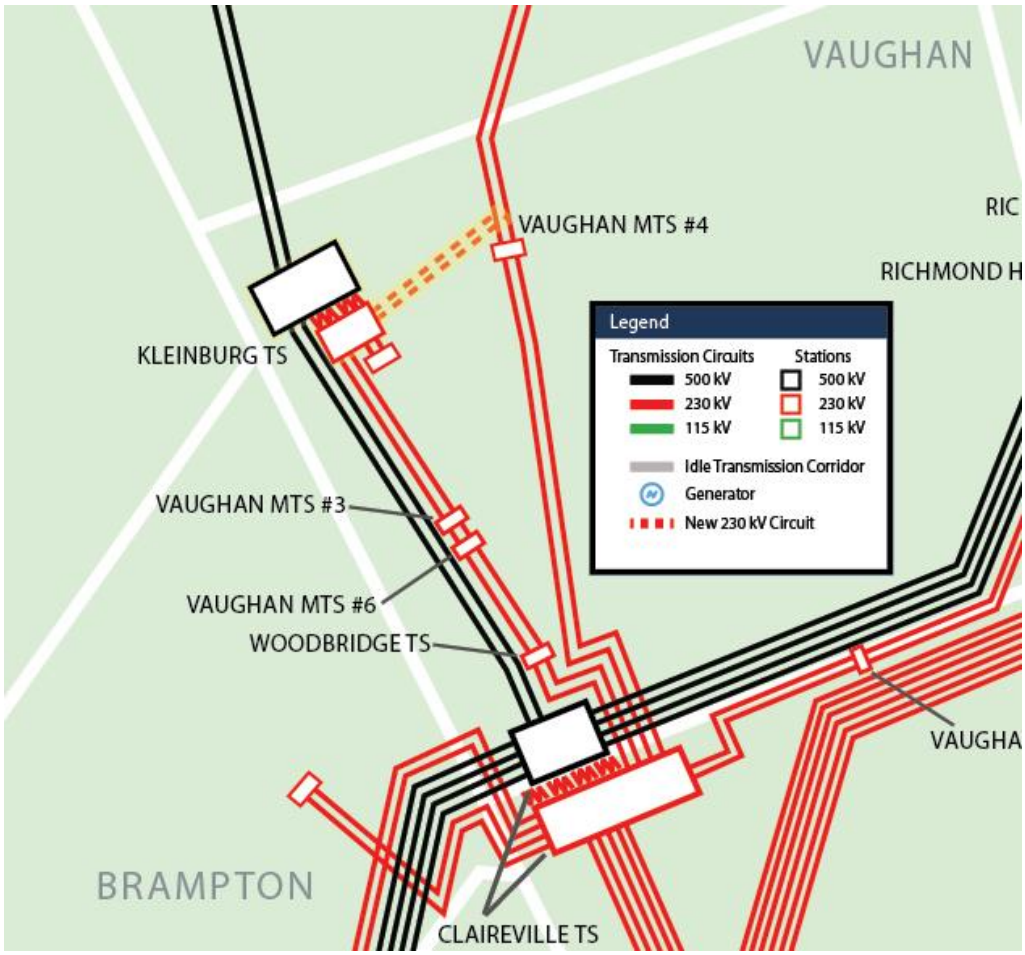
IESO is currently also undertaking a bulk study focused on the Southwestern and Central regions of Ontario, particularly along the Windsor to Hamilton corridor as well as the urban centers in the GTA.

This bulk study is closely linked to the GTA North IRRP and will be key in enabling some of the near-term recommendations discussed above.

Some of the key linkages from the bulk study to this IRRP are as follows:

- Upgrading station (Kleinburg TS) from 230kV to 500kV to support provincial and local needs
- Building an additional circuit from Essa (Barrie) to Kleinburg TS to strengthen electricity flows north/south
- Improving bulk system supply from east GTA towards Parkway TS to help support growth in GTA North
- Determining transmission required to enable decreased bulk system reliance on YEC
- Protecting strategic corridors for future infrastructure to support economic development and community growth

8.1 Bulk Considerations for Enabling the Kleinburg-Kirby Transmission Link



Placing the Kleinburg – Kirby link in service discussed in section 7.3.2.2 will require additional capacity to be available at Kleinburg TS to supply northern York. In the absence of a new supply source, the existing Kleinburg radial tap would become thermally overloaded north of Claireville TS, as the V43/44 circuits would have to carry all existing supply for the local pocket, as well as incremental demand for customers in northern York.

The existing Kleinburg TS, located at the northernmost point of the V43/44 circuits, is currently operated as a step-down station primarily providing distribution supply to customers in Vaughan, Brampton, and Caledon. However, when this site was originally developed, its access to both the regional 230 kV and bulk 500 kV transmission network made it a suitable candidate as a future bulk supply point. Enough land was acquired when developing this station to accommodate additional switching and autotransformer facilities to create a 500kV to 230 kV bulk supply point once required. Based on the current needs for supplying local growth, and broader bulk system benefits identified through a separate bulk planning process, it is recommended that the development of Kleinburg TS as a bulk supply point proceed.

In order to manage higher order contingency scenarios required for the bulk system, three 500 kV to 230 kV autotransformers will initially be required at this site. Space should be set aside to enable the long-term connection of a fourth autotransformer, as a final build out option. Supply to the new autotransformers is to be accomplished through bisecting and re-terminating the existing two 500 kV circuits between Claireville TS and Essa TS. This will require a single 500 kV bus at Kleinburg TS with an initial four 500 kV connection points – two connecting Kleinburg TS to Claireville TS, and two connecting Kleinburg TS to Essa TS.

On the 230 kV yard, space should initially be set aside for six circuit terminations. These would consist of the original two V43/44 circuits, the new double-circuit Kleinburg-Kirby link, and a double-circuit tap to directly supply the existing Kleinburg TS step down station (referred to as Kleinburg DESN hereafter for clarity). Providing a separate connection for the existing Kleinburg DESN would address potential security needs on the Kleinburg radial tap by reducing the amount of capacity supplied by the V43/44 circuits (see section 6.3.3.2). Selecting Kleinburg DESN for direct connection to the 230 kV bus work would minimize connection costs as the station is already located within the facility. In addition to these initial six 230 kV termination points, space should also be set aside for a minimum of four additional positions, to accommodate a potential longer-term need for a new double-circuit 230 kV line into northern York, and a double-circuit 230 kV line spanning westward to supply local demand in northern Brampton and southern Caledon. This latter route would also make use of the planned transmission corridor adjacent to Highway 413. The notional layout of these new facilities is provided below:

Figure 29| Future Kleinburg TS and Kleinburg – Kirby transmission link

This configuration should be considered preliminary at this point and is provided to aid in system evaluation and preliminary site design. Review and further recommendations for the configuration and layout of the Kleinburg TS 500 kV and 230 kV station yards should be carried out by Hydro One as part of the Regional Infrastructure Planning (RIP) process, and final design through the applicable approvals process.

Given that Kleinburg TS is owned and operated by Hydro One today, the development of the Kleinburg TS bulk supply station is not suitable for competitive procurement.

Providing capacity at Kleinburg TS through new local generation, as opposed to creating a new bulk supply point, is not preferred for several reasons.

1. Short circuit levels at Claireville TS are elevated today and will require operational changes at the 230 kV level in order to accommodate additional supply (transmission or generation) at Kleinburg TS.
2. Using a generation source of supply, as opposed to transformers, would require continuous operation and significant load following capability to match local demand. These types of operational requirements are not practical or cost effective for a local system.
3. Transformers are preferred as they provide the benefit to the overall bulk transmission system. Introducing this new supply point in the GTA will provide needed offloading for Claireville TS, enabling growth and the connection of some local resources in the surrounding regions including City of Toronto and Regions of Peel and Halton. while improving long term ability to disperse flows into Essa towards the higher demand centres to the south.

The estimated cost for the development of Kleinburg TS, including all associated switching gear, autotransformers, and reconfiguration of the existing 500 kV system, is approximately $400 M. This station is needed in the near term to accommodate regional growth as well as primarily to serve a bulk system function by managing supply between the existing Claireville TS bulk supply point to the south, and the new supply point to the north, which is better located for accommodating growth throughout northern Halton, Peel, and York regions. The Kleinburg to Kirby link is likewise performing a bulk system function by allowing supply from the new Kleinburg TS to be accessible for regional customers.

Timelines for the implementation of the Kleinburg-Kirby link, and bulk system build out of Kleinburg TS, would ideally align with the proposed in-service date of Northern York TS #1, to ensure infrastructure can be loaded to its full capacity once available. Given typical rates at which new stations are loaded, however, the connection of Northern York TS #1 could be advanced, so long as total loading on the Claireville TS – Brown Hill TS corridor remains under 848 MW, assuming the YEC station service issue has been resolved. This loading level is roughly equivalent to Vaughan MTS #4, Holland TS, and Armitage TS at their full respective LTRs[7], Brown Hill TS loaded at its current summer peak, and the new Northern York TS #1 loaded to 38 MW. Loads of these levels are typical for the first one to two years of a newly in service station. Above this load level, more frequent arming of the existing RAS would be required until the transmission solution has come into service.

8.2 Bringing Bulk Supply from East GTA towards Parkway TS

New generation resources located near Darlington Nuclear Generation stations will become available in early to mid 2030s. The IESO has previously identified a need for a double-circuit going west towards the GTA as an early action to supply the urban centres in the GTA, including the Region of

[7] Inclusive of new Metrolinx loads in Newmarket

York. Parkway TS has been preliminarily selected to be connected to the new double-circuit to reinforce supply into the region while catering for growing demand in the surrounding regions. This option also makes the best of use of available corridor and station real estate in the GTA. It also allows for reconfiguration of existing loads between the key GTA transformer stations, taking short circuit limitations and supply capability into account.

The study will also consider any system reinforcements required to accommodate the new supply downstream of the station in the GTA 230 kV system.

8.3 Additional Essa (Barrie) to Kleinburg TS

In the longer term, larger bulk flows into Essa will also require a third 500 kV line to be built between Essa TS and the proposed Kleinburg TS. This could be triggered from either higher procurement of generation in northern Ontario (such as through expanded hydro development), or the completion of Bruce to Essa transmission upgrades to incorporate expansion at Bruce nuclear GS or large-scale pumped storage between Bruce and Essa zones. This need is based purely on bulk system considerations, and as such timing for the third line will be outside the scope of the GTA North IRRP.

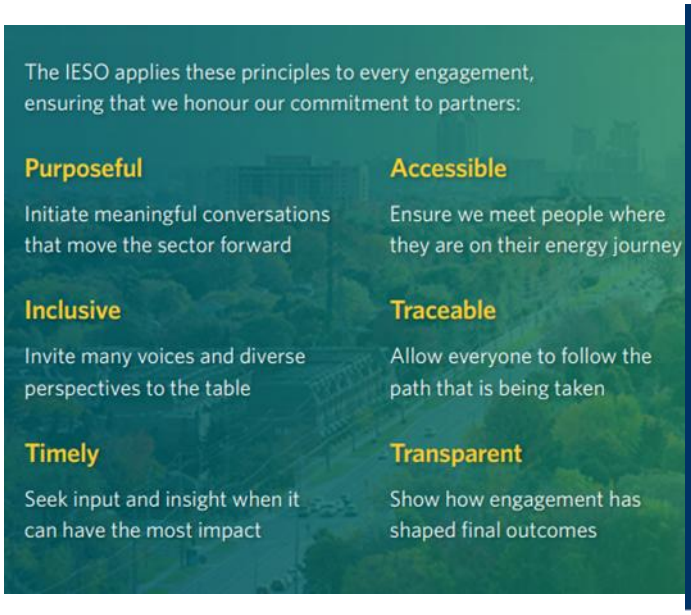
8.4 Decreasing Bulk System Reliance on YEC in the Long Term

As discussed in Section 6.3.2.1, should YEC be phased out following its contract expiry in 2035 or at its eventual retirement at the end of its life cycle, and equivalent generation is not located in the same general area, new transmission infrastructure may be required to cover the capacity shortfall. The bulk study is aimed at studying the impact of the absence of YEC at a wider system level and any potential reinforcements required to adequately supply the region.

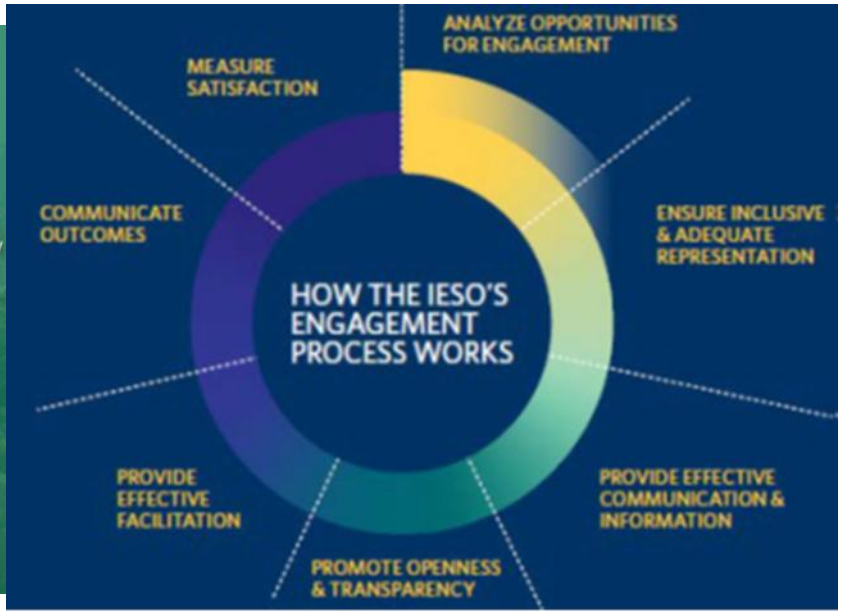
8.5 Protecting Strategic Corridors

The IESO is taking early action to identify and protect strategic corridors to enable the long-term infrastructure discussed in the sections above and beyond to enable and support electrification, residential and economic intensification. Three key studies are identified in high-growth areas, including York Region, where land is limited and electricity systems are nearing capacity:

- **Parkway Belt West Corridor**: Exploring future high-voltage transmission lines and transformer stations to support GTA growth and to enable new generation resources.
- **Barrie to Markham Corridor**: Preserving land for a future transmission line to further link Northern and Southern Ontario, to enable growth in Northern Ontario and to supply Southern Ontario with diversified resources.
- **Northwest GTA Corridor**: Refining plans near Highway 413 to support future infrastructure in York, Peel, and Halton.



9 Community and Stakeholder Engagement



Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and perspectives of the public, which for these purposes, refers to Indigenous communities, market participants, municipalities, stakeholders, communities, customers and the general public, to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles and activities undertaken to date for the GTA North IRRP.

9.1 Engagement Principles

The IESO's External Relations Engagement Framework is built on a series of key principles that respond to the needs of the electricity sector, communities and the broader economy. These principles ensure that diverse and unique perspectives are valued in the IESO's processes and decision-making. We are committed to engaging with purpose with external audiences to foster trust and build understanding as the energy transition continues.

Figure 30| The IESO's Engagement Principles

9.2 Engagement Approach

To ensure that the Plan reflects the needs of market participants, municipalities, stakeholders, communities, Indigenous communities, customers and the general public, engagement involved:

- Leveraging the GTA North engagement webpage to post updated information, engagement opportunities, meeting materials, input received and IESO responses to feedback;

- Encouraging participants to visit the Powering the GTA website, dedicated to exploring electricity needs and solutions across the GTA;
- Timely and targeted discussions with municipalities and letters prepared for Mayors and Councillors to help inform the engagement approach for this planning cycle;
- Hosted a series of public webinars at major junctions in the plan development to share plan details, understand feedback and answer questions; and
- Communications and other engagement tactics to enable a broad participation through email and IESO's weekly Bulletin updates.

As a result, the engagement plan for this IRRP included:

- A dedicated webpage on the IESO website to post all meeting materials, feedback received and IESO responses to the feedback throughout the engagement process;
- Regular communication with interested communities and stakeholders by email or through the IESO weekly Bulletin;
- Public webinars; and
- Targeted one-on-one outreach with specific communities and stakeholders to ensure that their identified needs are addressed (see Section 9.4).

9.3 Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for the third round of planning, and to establish new relationships and dialogue in this region where there has been no active engagement previously. This started with the Scoping Assessment Outcome Report for the GTA North Region. An invitation was sent to targeted municipalities, Indigenous communities, and those with an identified interest in regional issues, to announce the commencement of a new planning cycle and invite interested parties to provide input on the GTA North Scoping Assessment Report finalization. A public webinar was held in September 2023 to provide an overview of the regional electricity planning process and seek input on the high-level needs identified and proposed approach. The final Scoping Assessment was posted later in October 2023, identifying the need for a coordinated regional planning approach and an IRRP.

Following finalizing the Scoping Assessment, several targeted outreach meetings then began to involve municipalities in the region to ensure growth and development plans have been accurately captured in the Technical Working Group's draft demand forecast and solicit early feedback on the IESO's approach to engagement. The launch of a broader engagement initiative followed, with an invitation to IESO subscribers of the GTA North Region to ensure that all interested parties were made aware of this opportunity for input. Three public webinars were held at major stages during the IRRP development to give interested parties an opportunity to hear about its progress and provide comments on key components of the plan. These webinars were attended by a cross-representation of community representatives, businesses, and other stakeholders, and written feedback was collected following a comment period after each webinar. The three stages of engagement at which input was invited:

1. The draft engagement plan, electricity demand forecast, and early identified needs – to set the foundation of this planning work.
2. The defined electricity needs for the region and high-level screening of potential options to meet the identified needs.
3. The analysis of options and draft IRRP recommendations.

Comments received during public engagements primarily focused on:

- Significant population growth and economic development projects across the region;
- Aligning infrastructure with community infrastructure development;
- Interest in leveraging existing and local generation;
- Alignment of electricity planning with local priorities, such as community and energy plans; and
- Exploring alternative solutions, such as non-wire options, to meet the area's electricity needs.

Feedback received during the written comment periods for these webinars helped to guide further discussions throughout the development of this IRRP, as well as add due consideration to the final recommendations.

All interested parties were kept informed throughout this engagement initiative via email to GTA North Region subscribers, municipalities, and Indigenous communities.

Based on the discussions through this engagement initiative, a key priority was to ensure the IRRP and recommended actions aligned with the significant forecasted growth and development both within specific municipalities and the region more broadly (e.g. significant population and employment growth shared by the City of Richmond Hill, constrained land use shared by the Cities of Richmond Hill and Markham, and capacity constraints shared by Bradford West Gwillimbury). Another key priority was to understand community perspectives on keeping York Energy Centre (YEC) in service past the 2035 contact expiration, which received general support from municipalities and stakeholders highlighting concerns for the remaining supply gap without the facility. These insights have been valuable to the IESO – as they supported an understanding of local growth and an accurate electricity demand forecast, the determination of needs, and the recommendation of solutions to ensure adequate and reliable long-term supply.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's GTA North engagement webpage.

9.4 Involving Municipalities in the Plan

The IESO held meetings with municipalities to seek input on its planning and to ensure that key local information about growth and development and energy-related initiatives were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings were held with the lower-tier municipalities in York Region to share key developments and to provide an opportunity for municipal feedback on the forecasted regional electricity needs, options for meeting the region's future needs, and broader community engagement. These meetings helped to inform the municipal and community electricity needs and priorities, establish new relationships, and provide opportunities for ongoing dialogue beyond this IRRP process. Additionally, the IESO led

council outreach that included letters prepared for mayors and councillors, and one-on-one councillor meetings to provide elected officials with updates on electricity planning developments, and to provide an opportunity for discussion.

Through these discussions, valuable feedback was received and incorporated in the final IRRP recommendations, including:

- The Town of Stouffville recommended sharing the methodology on how the demand forecast is calculated, including the different variables that are considered.
- The Township of King, the City of Markham and the City of Richmond Hill expressed the need for early and detailed coordination with municipalities to ensure electricity planning aligns with land use policies and congested municipal right-of-ways (ROWs).
- The City of Markham emphasized their preference for utilizing existing station and transmission infrastructure corridors to avoid expanded or new corridors, reducing impact on development and adjacent communities.
- The City of Richmond Hill, and the Town of Whitchurch-Stouffville requested sharing a layout of the power distribution network and detailed mapping of locations for future infrastructure requirements to understand compatibility.
- The Cities of Richmond Hill, Markham and Vaughan detailed significant population and development growth projections in their cities to ensure it is captured in the demand forecast.
- Station capacity concerns were raised in Bradford West Gwillimbury at their Holland TS, and in the City of Vaughan along the Yonge/Steeles corridor.
- Several municipalities highlighted their energy, and sustainability plans and encouraged consideration for non-wire alternatives as solutions in the IRRP in order to align with their net-zero and decarbonization targets.
- King Township and the City of Markham support keeping YEC in service considering the facility already exists and reduces the need for widespread transmission infrastructure and suggest exploring deep retrofits that align the facility with climate goals.

9.5 Engaging with Indigenous Communities

The IESO remains committed to ongoing, effective dialogue with Indigenous communities to help shape long-term planning across Ontario. To raise awareness about the regional planning cycle in the GTA North (York Region) and provide opportunities for input, the IESO invited Indigenous communities that may be potentially impacted or may have an interest based on treaty territory, traditional territory or traditional land use to participate in engagement efforts that included webinars and meeting discussions (virtual or in-person).

The IESO remains committed to an ongoing, effective dialogue with communities to help shape long-term planning in regions across Ontario.

10 Summary and Conclusion

The York Region Integrated Regional Resource Plan (IRRP) identifies electricity needs across the region over the 20-year planning horizon from 2024 to 2043 and recommends a coordinated set of actions to address these needs in the near term to enable growth in the region and identifies potential options which may be required in the longer term. The IESO will continue to participate in the Technical Working Group during the next phase of planning, the Regional Infrastructure Plan (RIP), to support implementation and ensure alignment with broader system planning.

In the near term, the Technical Working Group recommends immediate action to address station and supply capacity needs in Northern York, Markham, and Richmond Hill. This includes the development of new step-down transformer stations (Northern York TS #1, Markham MTS #5, and Richmond Hill MTS #3), a new 6-7 km transmission line along the future Highway 413 corridor in Vaughan, reconductoring of existing transmission circuits in Markham, and sectionalization devices to address security needs. To improve reliability, operational measures including reconfiguration of York Energy Centre's power supply, and targeted incremental eDSM are also recommended to manage reliability risks and defer longer-term infrastructure needs.

In the medium- to long- term, the Technical Working Group recommends planning for additional step-down transformer stations (Northern York TS #2 and #3, Markham MTS #6, Vaughan MTS #5), and transmission enhancements to ensure these stations can be reliably supplied. This includes extending the existing Markham transmission line approximately 7 km into northern Markham, to enable the connection and supply of new step-down stations to serve customers in the vicinity of northern Markham, northern Richmond Hill, and Whitchurch-Stouffville. Longer-term needs associated with Northern York TS #3 will likely require additional transmission upgrades in Northern York, including, at a minimum, a new switching station in the vicinity of Holland Marsh junction. The potential retirement of York Energy Centre post-2035 has also been identified as a key driver of future supply needs and would likely trigger the development of a comparably size generator, or a new transmission corridor into Northern York, if this supply source is phased out.

The Technical Working Group will continue to monitor regional developments, including electrification trends, large customer connections, and community energy planning. Opportunities to target incremental eDSM and non-wires alternatives will be evaluated to defer infrastructure needs where feasible. The Working Group will meet regularly to track progress, assess changing conditions, and update the plan as needed. Should significant changes in assumptions arise, the IRRP may be amended or a new planning cycle initiated ahead of the standard five-year schedule.

REGIONAL INFRASTRUCTURE PLAN REPORT

GTA North

Regional Infrastructure Plan Report

GTA North

May 6, 2026

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

GTA North Technical Working Group

Page intentionally left blank.

Disclaimer

This Regional Infrastructure Plan (RIP) Report for GTA North region was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group (TWG).

The preferred solution(s) that have been recommended in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP TWG at the time.

The cost figures presented are high-level allocations in 2025 dollars and have not been informed by detailed engineering design or development work. Accordingly, these estimates are preliminary in nature, subject to material change, and are intended for options analysis purposes only.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

Region	**GTA North** (the "Region")
Lead	Hydro One Networks Inc. ("HONI")
Start Date: November 7, 2025	**End Date:** May 6, 2026

The Regional Infrastructure Plan (RIP) represents the final phase of the Regional Planning Process for the GTA North region. It builds on earlier planning activities, including the Needs Assessment (NA) report published by Hydro One on July 14, 2023, followed by the Scoping Assessment and Integrated Regional Resource Planning (IRRP) reports which were released by the Electricity System Operator (IESO) on October 12, 2023 and on October 10, 2025 respectively.

As the lead transmitter, Hydro One developed the RIP in collaboration with the GTA North Technical Working Group (TWG) for the region and is responsible for publishing the final report. The RIP report consolidates the analysis of options, recommended plans, and preferred wire infrastructure investments identified in earlier planning phases to address the near- and medium-term electricity needs. The load forecast used in this RIP has been adopted from the IRRP report, as no material changes were identified relative to the load forecast submitted during the IRRP Phase. The forecast period covers the 10 years following the completion of IRRP.

The objectives and scope of the RIP are:

- Compile and present a consolidated summary of regional needs and corresponding wires plans to address near and medium-term requirements (2026-2035) identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identify any new need(s) that may have emerged over 2026-2035 period.
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.
- Consideration of long-term needs identified in the Toronto IRRP, Bulk system studies or as identified by the TWG.

The major infrastructure investments recommended by the TWG in the GTA North region for the next ten years are given below. A single line diagram with the new investments marked is given Appendix G.

Recommendations

Station/Circuit Name	Recommended Plan	Lead	Planned ISD[1]	Section No.
Asset Renewal Needs				
Woodbridge TS	Transformer (T5) refurbishment	Hydro One	2032	8.1.1
Station Capacity Needs				
Kleinburg TS	Adding Kleinburg TS (T3/T4) 230/44kV DESN	Hydro One	2028	8.2.1.1
Vaughan MTS #6	Build Vaughan MTS #6 230/27.6 kV DESN	Alectra	2027	8.2.1.2
Northern York TS #1	Build Northern York TS #1 230/44kV DESN	Hydro One	2031	8.2.2.1
Northern York TS #3	Build Northern York TS #3 230/44kV DESN	Hydro One	2035	8.2.2.2
Richmond Hill MTS #3	Build Richmond Hill MTS #3 230/27.6kV DESN	Alectra	2030	8.2.3.1
Vaughan MTS #5	Build Vaughan MTS #5 230/27.6kV DESN	Alectra	2033	8.2.3.2
Buttonville TS #2 (Previously referred to as Markham MTS #5)	Build Buttonville TS #2 230/27.6kV DESN	Hydro One	2030	8.2.4.1
Markham MTS #6	Build Markham MTS #6 230/27.6kV DESN	Alectra	2034[2]	8.2.4.2
Northern York TS #2	Build Northern York TS #2 230/44kV DESN	Hydro One	2034[2]	8.2.4.3
Transmission Line Capacity Needs				
P45/P46	Upgrade P45/P46 from Parkway TS to Markham MTS #4	Hydro One	2031	8.3.1.1
P45/P46	Upgrade P45/P46 from Markham MTS #4 to Buttonville TS	Hydro One	2034	8.3.1.2

C35P/C36P	Reconnect Markham MTS #4 to C35P/C36P	Hydro One	To be discussed in the next Regional Planning cycle	8.3.1.4

Station/Circuit Name	Recommended Plan	Lead	Planned ISD[1]	Section No.
System Reliability				
Kleinburg TS	Build Kleinburg to Kirby Transmission Link	Hydro One	2031-2032	8.4.1
Kleinburg TS	Bulk Supply - 500/230 kV Transformer Station[3]	Hydro One	2031-2032	8.4.2
York Energy Centre	York Energy Centre – Station Service Upgrade	IESO/Capital Power	2026 (Current)	8.4.3
Holland Marsh SS	Holland Marsh Switching Station	IESO / Hydro One	TBD[4]	8.4.4
New Northern York Transmission Supply	Reinforce transmission supply to Northern York	IESO / Hydro One	TBD[4]	8.4.5
V71P/V75P	In-line breakers New 230kV inline breakers on V71P/V75P circuits	Hydro One	2030	8.4.6
H82V/H83V & B82H/B83H	Claireville to Minden - Over voltages and Under voltage needs.	IESO / Hydro One	TBD[5]	8.4.7
Section of H82V/H83V from Kirby towards Holland	Add new Circuits/Upgrading H82V/H83V circuits from Kirby Jct. to Holland Marsh.	IESO / Hydro One	TBD[5]	8.4.8
Load Security and Restoration				
V43/V44	Load Security on Kleinburg Radial Tap	Hydro One	2031-2032[6]	8.5.1
V71P/V75P	Load Security and Restoration on V71P/V75P	Hydro One	2030[7]	8.5.3
P45/P46	Load Security and Restoration on Buttonville Corridor (P45/P46)	Hydro One	2034[8]	8.5.4

[1] The in-service dates are tentative and subject to change.

[2] The in-service date for Northern York TS #2 and Markham MTS #6 will be coordinated with the P45/P46 Line Extension Project.

[3] This project has been recommended by the IESO's South and Central bulk system study and is part of bulk system reinforcement.

[4] The need, scope and timing of this work will be further discussed in the next planning cycle.

[5] TWG will continue to monitor status.

[6] This issue will be addressed by the Kleinburg TS 500/230kV Station project.

[7] This issue will be addressed by the V71P/V75P in-line breakers project.

[8] This issue will be addressed by reconnecting Markham MTS #4 to circuits C35P/C36P project.

1 INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of the Regional Planning Process. Hydro One as the lead transmitter undertakes the development of a RIP with input from the Technical Working Group (TWG) for the region and publishes a RIP report. The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process for the GTA North region, preceded by, the publication of Needs Assessment (NA) report in July 14, 2023 by Hydro One, followed by the Scoping Assessment (SA) & Regional Resource Planning (IRRP) which were published in October 12, 2023 and in October 10, 2025 respectively, by the Independent Electricity System Operator (IESO). Typically, an IRRP takes 18 months to complete. However, due to the complex nature of the needs in the region, the IESO requested a six-month extension from the OEB to finalize the plan.

The RIP report includes a common discussion of all the options and recommended plans, and preferred wire infrastructure investments identified in earlier phases to address the near- and medium-term needs.

This report was prepared by GTA North TWG, led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by Hydro One, the Local Distribution Companies ("LDC"), the Municipalities and the IESO. Participants of the TWG are listed below in Table 1.

Table 1: GTA North Region TWG Participants

No.	Name of TWG Participants
1	Hydro One Networks Inc. (Transmission)
2	Hydro One Networks Inc. (Distribution)
3	Alectra Utilities Inc.
4	Newmarket-Tay Power Distribution LTD (NT Power)
5	Toronto Hydro
6	Independent Electricity System Operator (IESO)
7	Elexicon Energy

2 OBJECTIVES AND SCOPE OF THE REGIONAL INFRASTRUCTURE PLAN

This RIP report examines the needs in the GTA North region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs for the GTA North region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP adopted the IRRP provided load forecast, asset renewal for major high voltage transmission equipment, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near- and medium- term needs (2026-2035) identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the 2026-2035 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in GTA North IRRP, Bulk system studies or as identified by the TWG, are excluded but briefly touched upon.

2.1 Structure

The rest of the report is organized as follows:

- Section 3 provides an overview of the regional planning process.
- Section 4 describes the regional characteristics.
- Section 5 describes the transmission work completed over the last ten years.
- Section 6 describes the load forecast and study assumptions used in this assessment.
- Section 7 describes the adequacy of the transmission facilities in the region over the study period.
- Section 8 discusses the needs and provides the alternatives and preferred solutions.

3 REGIONAL PLANNING PROCESS & RIP METHODOLOGY

3.1 Overview

Bulk System Planning, Regional Planning and Distribution Planning are the three levels of planning for the electricity system in Ontario. Bulk system planning typically looks at issues that impact the system on a provincial level and require longer lead time and larger investments. Comparatively, planning at the regional and distribution levels looks at issues on a more regional or localized level. Typically, the most essential and effective regional planning horizon is the near- to medium-term (1- 10 years), whereas long-term (10-20 years) regional planning mostly provides an outlook with little details about investments because the needs and other factors may vary over time. On the other hand, bulk system plans are developed for the long term because of the larger magnitude of investments.

The regional planning process begins with a Needs Assessment which is led by the transmitter to identify, assess, and document which of the needs that,

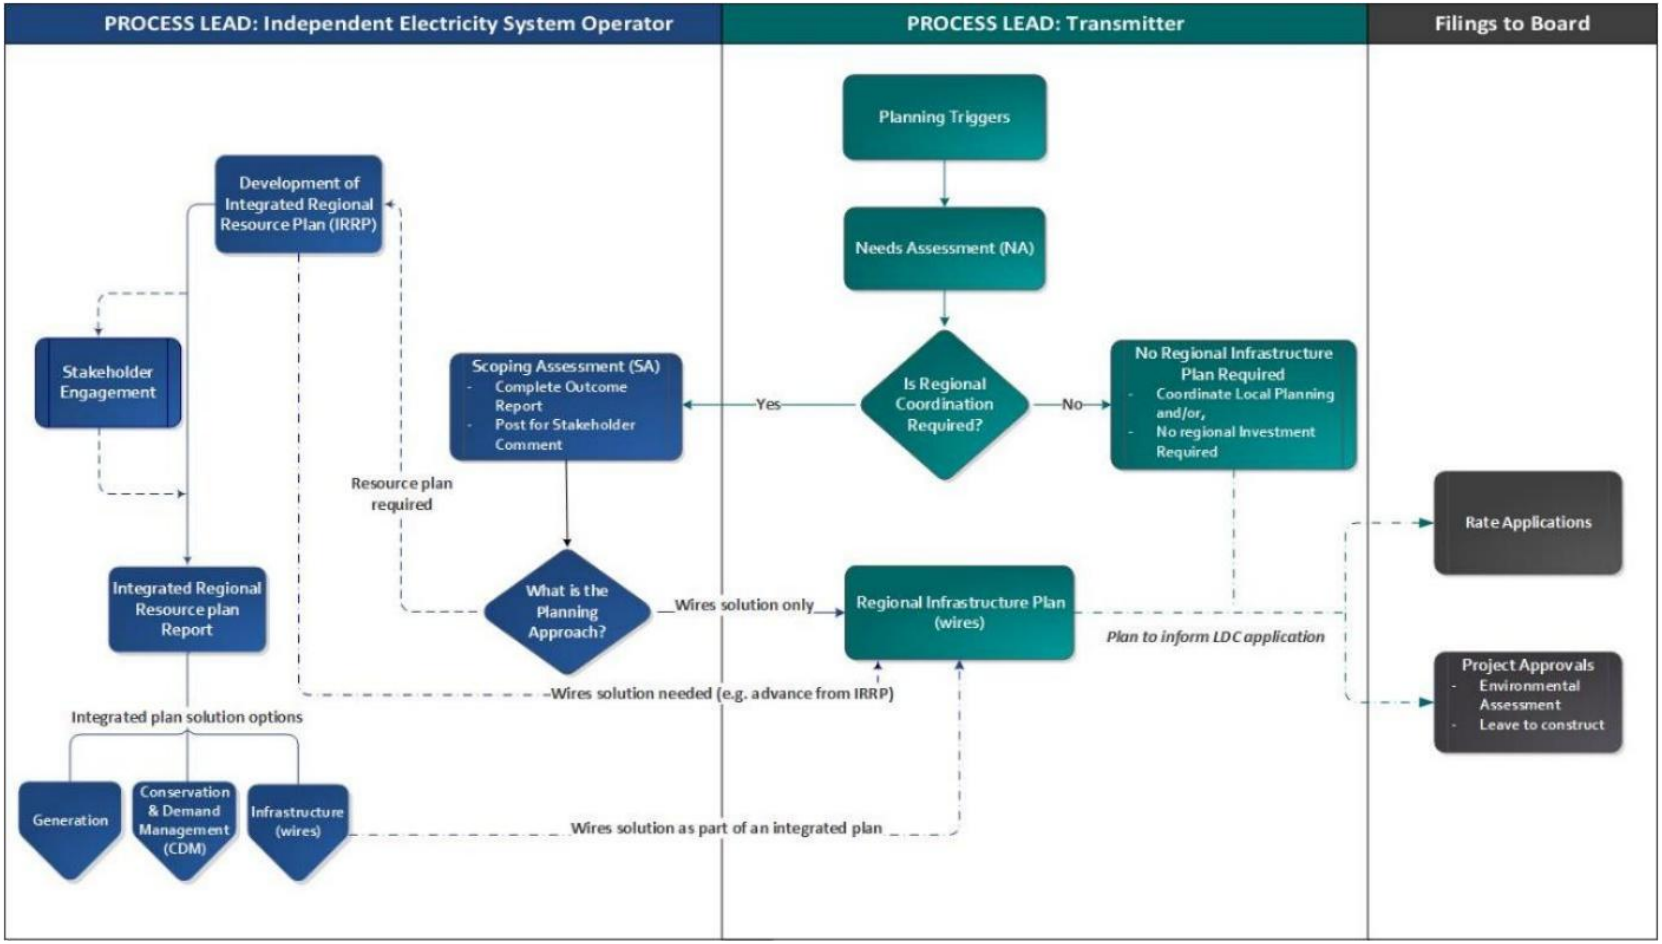
a) can be addressed directly between the customer and transmitter along with a recommended plan, and;
b) require further regional coordination and identification of Local Distribution Companies (LDCs) to be involved in further regional planning activities for the region.

At the end of the NA, a decision is made by the TWG as to whether further regional coordination is necessary to address some or all regional needs. If no further regional coordination is required, recommendation to implement the recommended option and any necessary investments are planned directly by the LDCs (or customers) and the transmitter. The region's TWG can also recommend to the transmitter and LDCs to undertake a local planning process for further assessment when needs are:

a) local in nature;
b) require limited investments in wires (transmission or distribution) solutions, and;
c) do not require upstream transmission investments.

If coordination at the regional or sub-regional levels is required for identified regional needs, then the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires or resource alternatives, e.g., Conservation and Demand Management (CDM), Distributed Generation (DG), etc., in order to make a decision on the most appropriate regional planning approach including Local Plan (LP), IRRP and/or RIP.

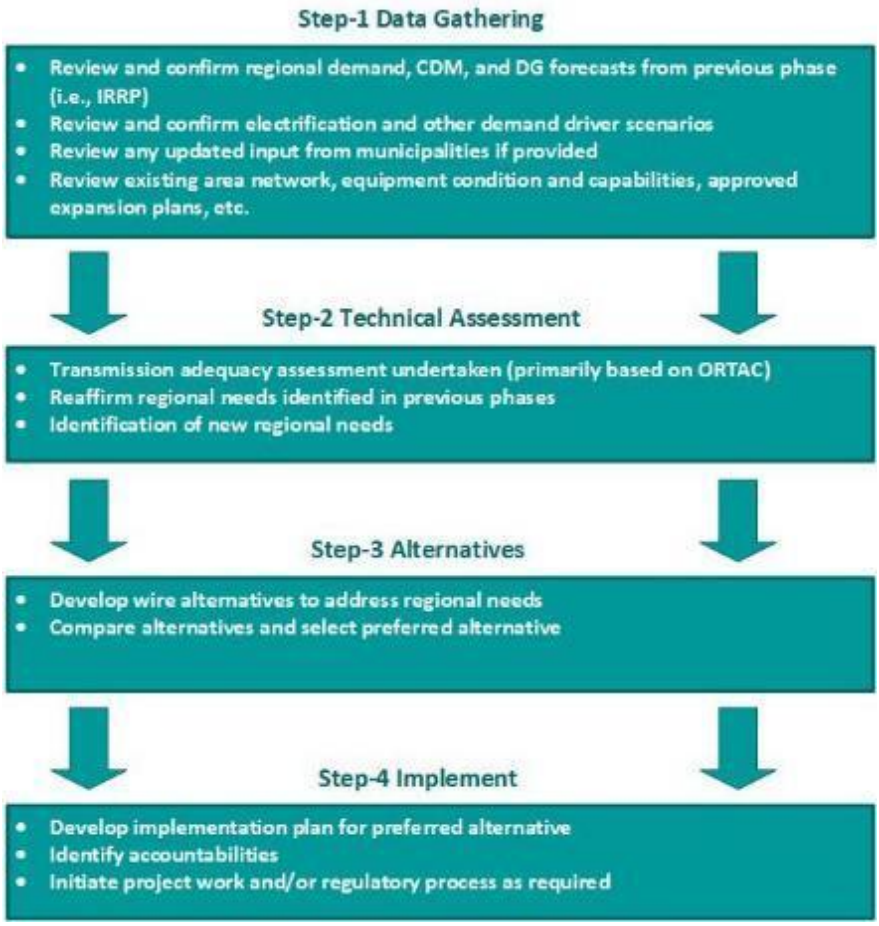
The primary purpose of the IRRP is to identify and assess both resource and wires options at a higher or macro level, but sufficient to permit a comparison of resource options vs. wire infrastructure to address



the needs. Worth noting, the LDCs' CDM targets as well as contracted DG plans provided by IESO and LDCs are reviewed and considered at each step in the regional planning process.

If and when an IRRP identifies that resource and/or wires options may be most appropriate to meet a need, resource/wires planning can be initiated in parallel with the IRRP or in the RIP phase to undertake a more detailed assessment, develop specific resource/wires alternatives, and recommend a preferred wires solution.

The RIP phase is the final phase of the regional planning process and involves discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address these needs. This phase is led and coordinated by the transmitter, and the deliverable is a comprehensive and consolidated report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.



The various phases of Regional Planning Process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome are shown below in Figure 1.

Figure 1: Regional Planning Process Flowchart

3.2 Regional Infrastructure Plan Methodology

Figure 2: Regional Infrastructure Plan Methodology

Regional Infrastructure Plan phase is a four-step process which are described below:

3.2.1 Data Gathering:

The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with TWG to reconfirm or update the information as required. The data collected includes:

- Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs. The municipalities were contacted as part of IRRP stakeholder engagement process to get their insight on the future load growth and was translated into the load forecast through inputs

provided by their respective LDCs. As agreed by TWG members, the load forecast from the IRRP is to be used for this RIP unless material changes in the load forecast are envisaged.

- Review and confirm electrification and other growth scenarios which affect the projects recommended in previous stages.
- Existing area network and capabilities including any bulk system power flow assumptions.
- Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

3.2.2 Technical Assessment:

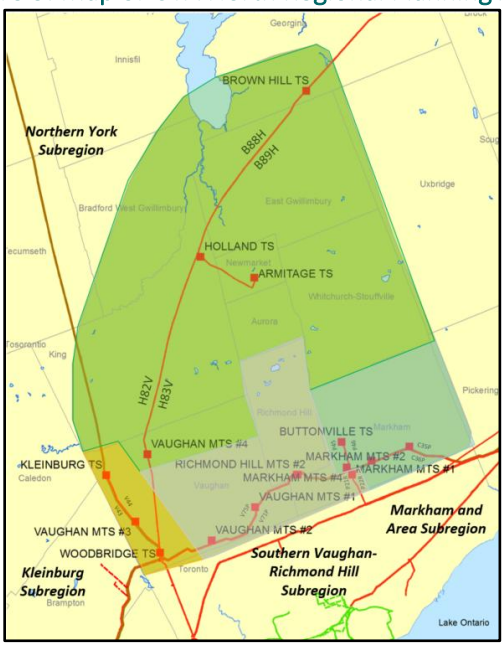
The second step is a technical assessment to review the adequacy of the regional system, including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3.2.3 Alternative Development:

The third step is the development of wires options to address needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

3.2.4 Implementation Plan:

The fourth and last step is the development of the implementation plan for the preferred alternative, identifying accountabilities and initiating project work or obtaining permission from the Regulatory Commission, if any.



4 REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

THE GTA NORTH REGION IS COMPRISED OF THE WESTERN AREA, NORTHERN YORK AREA, SOUTHERN VAUGHAN-RICHMOND HILL AREA AND THE MARKHAM AREA. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM SIXTEEN 230 KV STEP-DOWN TRANSFORMER STATIONS. THE 2025 SUMMER PEAK AREA LOAD OF THE REGION WAS APPROXIMATELY 2337 MW.

Electrical supply to the GTA North Region is primarily provided from three major 500/230 kV autotransformer stations, namely Claireville TS, Parkway TS, and Cherrywood TS, and a 230 kV transmission network supplying the various step-down transformation stations in the region. Local generation in the Region consists of the 393 MW York Energy Centre connected to the 230 kV circuits B88H/B89H in King Township. Refer to Appendix A: Net Summer Peak Load Forecast, Appendix B: Lists of Step-Down Transformer Stations, and Appendix C: List of LDC's for further details

The area has been divided into four sub-regions as shown in Figure 3 and described below:

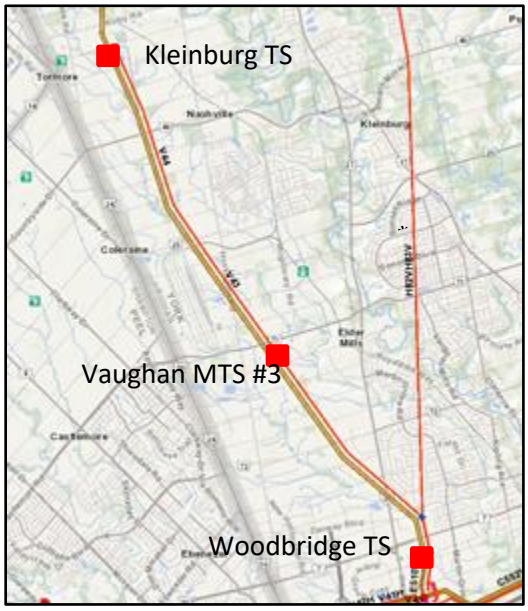


Figure 3: Map of GTA North Regional Planning Area

The **Western Area Subregion** comprises the western portion of the municipality of Vaughan. Electrical supply to the area is provided through Claireville TS, a 500/230 kV autotransformer station, and a 230 kV double circuit line (V43/V44) that supplies three 230 kV transformer stations

(Woodbridge TS, Vaughan MTS#3, Kleinburg TS) stepping down the voltage to 44 kV and 27.6 kV. The Western Sub-region transmission facilities are shown in Figure 4.

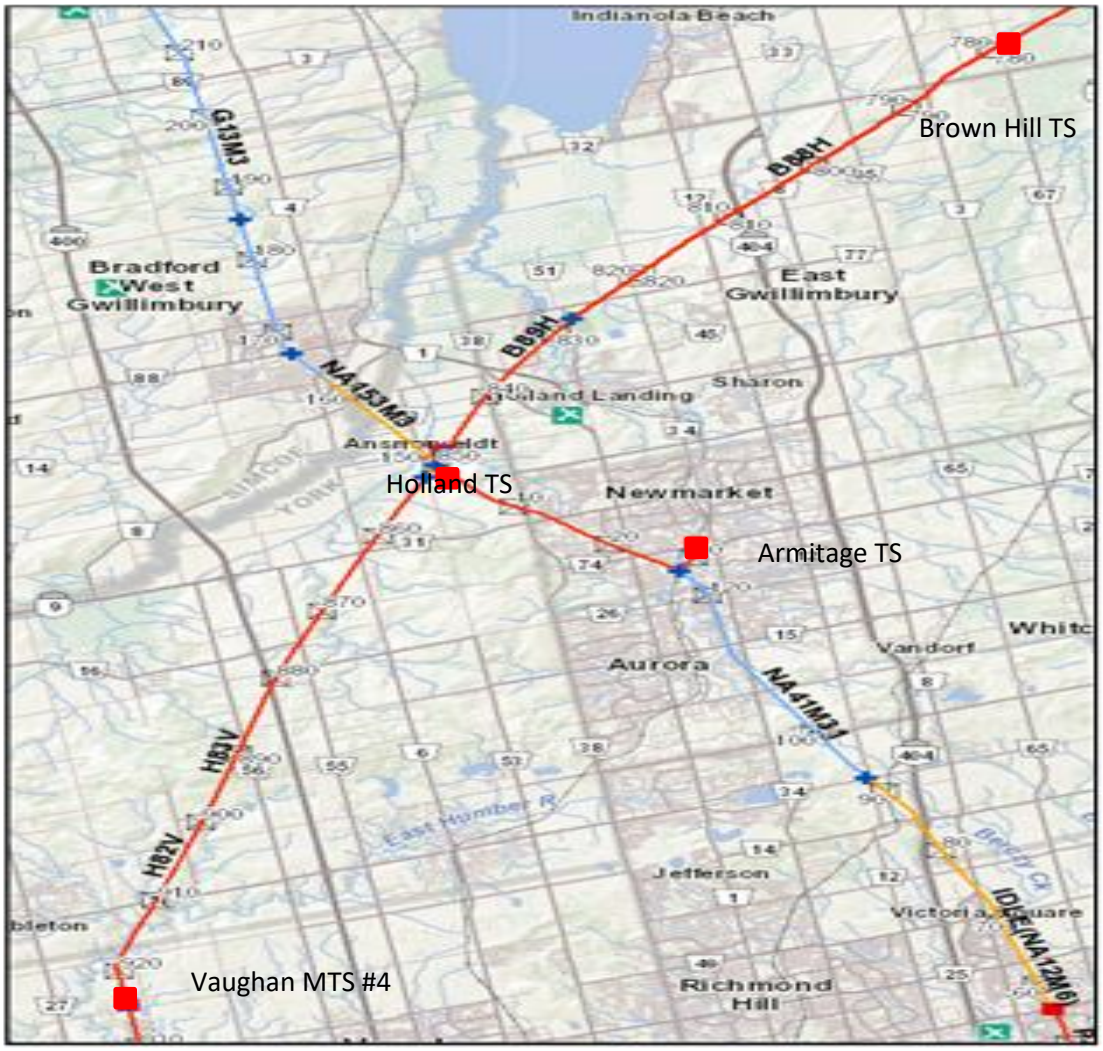

Figure 4: Western Area Subregion

The total 2025 net summer peak demand for three stations was 482 MW. Alectra Utilities is the main LDC that serves the electricity demand for the City of Vaughan. Hydro One Distribution and Toronto Hydro supplies load in the outlying areas of the sub-region. The electricity demand is comprised of residential, commercial, and industrial customers.

The **Northern York Area subregion** covers northern area of the City of Vaughan as well as the Townships of Aurora, Newmarket, King, East Gwillimbury, Whitchurch-Stouffville, Georgina, and includes the Chippewas of Georgina Island. Electricity supply to the sub-region is provided from Claireville TS via a double circuit 230kV transmission corridor extending north to Brownhill TS. The H82V/H83V circuits supply Vaughan MTS #4 and Holland TS along the section between Claireville TS and the Holland Marsh Junction, while the B88H/B89H circuits supply Armitage TS and Brown Hill TS along the section between the Holland Marsh Junction and Brown Hill TS. The York Energy Centre provides a local supply source. The Northern York Area sub-region transmission facilities are shown in Figure 5.

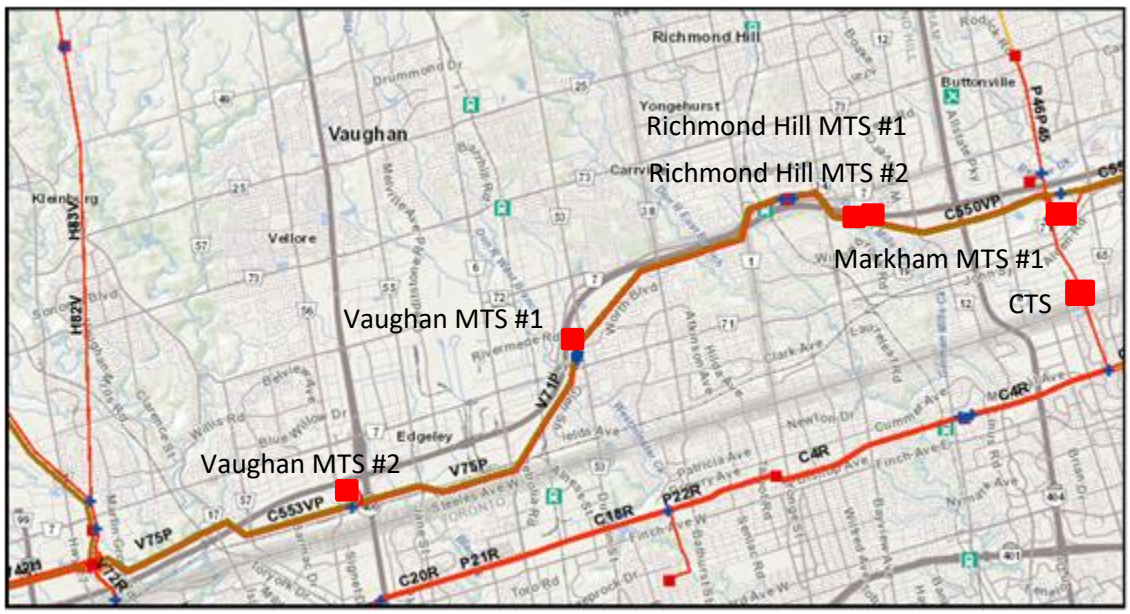

Figure 5: Northern Area Subregion

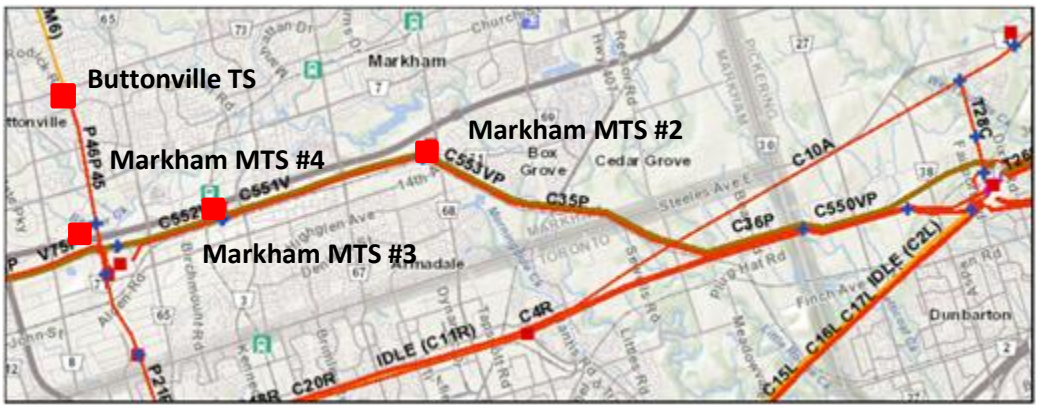
This area is served by Alectra Utilities, Newmarket-Tay Power Distribution, and Hydro One Distribution. The electricity demand is comprised of residential, commercial, and industrial customers. The total 2025 net summer peak demand for the two stations connected to H82V/H83V circuits was 248 MW and for the two stations connected to B88H/B89H circuits was 360 MW.

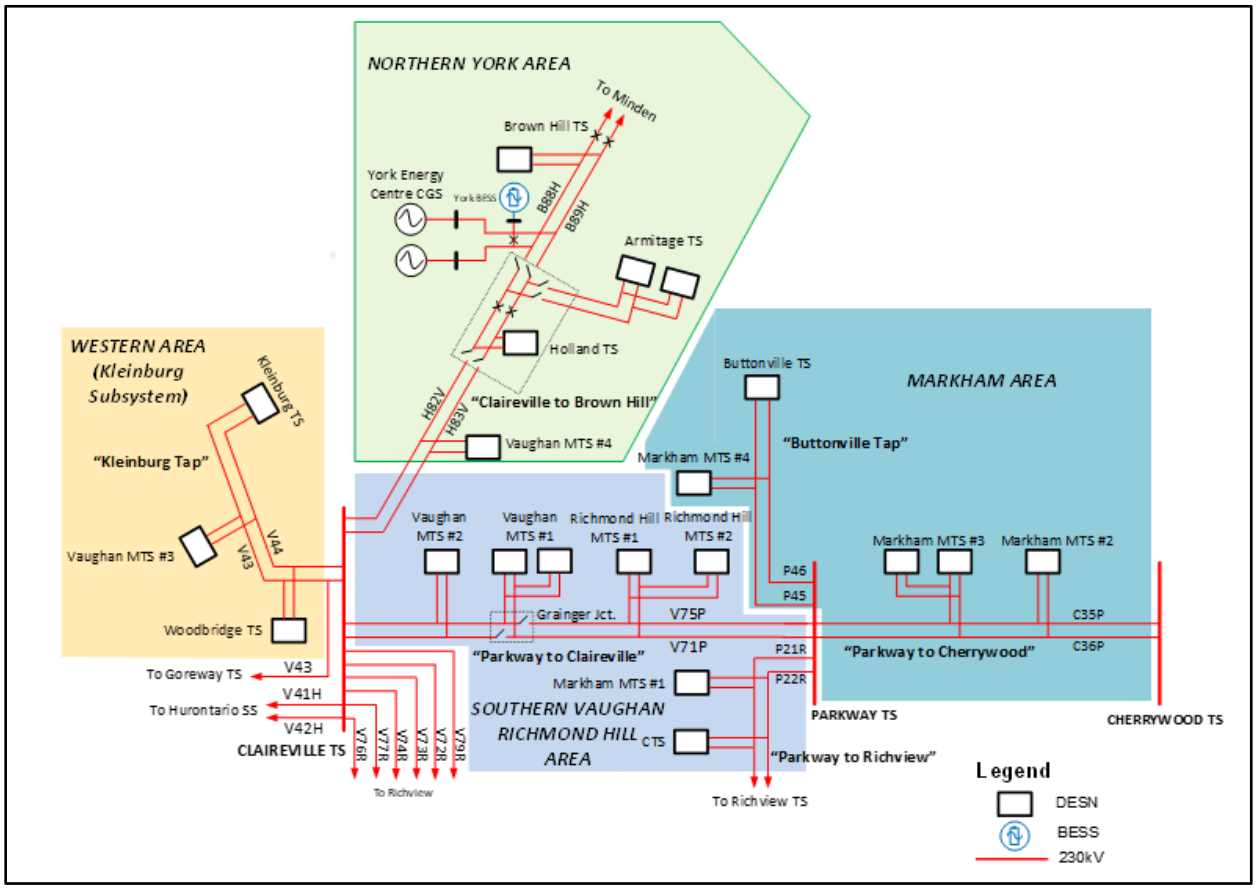
The **Southern Vaughan-Richmond Hill Area subregion** encompasses southern parts of the City of Markham, City of Richmond Hill, and the City of Vaughan. The electricity supply to the sub-region is provided through two 230 kV double-circuit transmission corridors: the V71P/V75P circuits supplying Vaughan MTS #1, Vaughan MTS #2, Richmond Hill MTS #1, and Richmond Hill MTS #2, and the P21R/P22R circuits supplying Markham MTS #1 and one direct transmission connected load customer. The Southern Vaughan-Richmond Hill Area sub-region transmission facilities are shown in Figure 6.

Figure 6: Southern Vaughan - Richmond Hill Area Subregion



The area is served by Alectra Utilities, and the electricity demand is comprised of residential, commercial, and industrial customers. The total 2025 net summer peak demand for the stations supplied by V71P/V75P and P21R/P22R circuits was 735 MW and 65 MW respectively.

The **Markham Area subregion** encompasses most of the City of Markham. Electricity supply to the Sub-region is provided from Parkway TS by two 230 kV double-circuit transmission corridors, with the P45/P46 circuits supplying Buttonville TS and Markham MTS #4, and the C35P/C36P circuits supplying Markham MTS #2 and Markham MTS #3. The Markham Area sub-region transmission facilities are shown in Figure 7.



The area is served by Alectra Utilities, and the electricity demand mix is comprised of residential, commercial and industrial uses. The 2025 net summer peak demand for the stations on the P45/P46 circuit was 207 MW and was 267 MW for stations on the C35P/C36P circuit.

Figure 7: Markham Area Subregion

The single line diagram of the Transmission Network of GTA North region is shown in Figure 8 below.

Figure 8: GTA North Region Transmission Area Single Line Diagram

5 TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR ARE UNDERWAY

OVER THE LAST TEN YEARS, A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND UNDERTAKEN TO MAINTAIN THE RELIABILITY AND ADEQUACY OF ELECTRICITY SUPPLY TO THE GTA NORTH REGION.

A summary and brief description of all the projects completed or are currently underway is given below:

5.1 Completed Projects

- Vaughan #4 MTS (2017) – To increase transformation capacity in the City of Vaughan
- Holland breakers, disconnect switches and special protection scheme (2017) – to increase the transmission supply capacity and load restoration capability of the Northern York area.
- Inline switches on the Parkway belt (V71P/V75P) at Grainger Jct. (2018) – to improve reliability for stations in Southern Richmond Hill and Vaughan area.

5.2 Projects initiated and underway.

- Kleinburg TS T3/T4, add two new transformers, and feeder breaker positions (NTD Inservice date) – Increase 44kV transformation capacity at Kleinburg TS
- Vaughan MTS #6: New transformer station – Increase transformation capacity in the City of Vaughan
- Northern York TS #1 (NY-TS#1): New 230/44kV DESN – Increase transformation capacity in Northern York subregion.
- Markham MTS#5/Buttonville TS #2: New 230/27.6kV DESN – Increase transformation capacity in the City of Markham.
- Richmond Hill MTS#3 – New 230/27.6kV DESN - Increase transformation capacity in the City of Richmond Hill

6 LOAD FORECAST AND STUDY ASSUMPTIONS

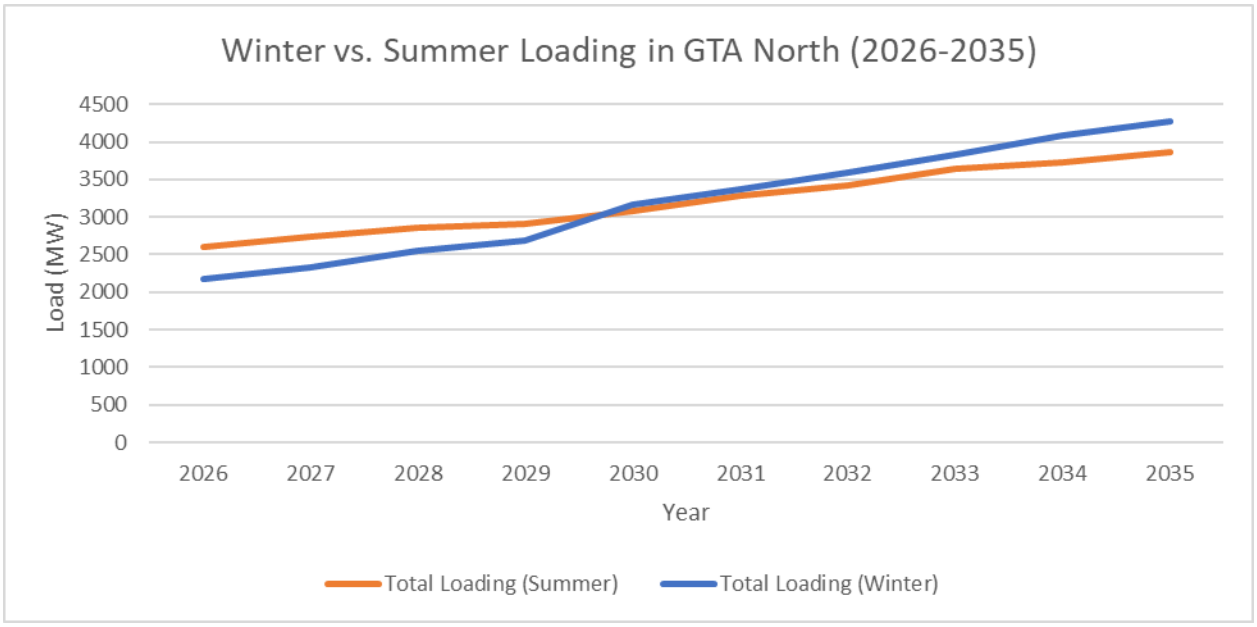
THIS SECTION PRESENTS THE LOAD FORECAST AND THE STUDY ASSUMPTIONS USED FOR CARRYING OUT THE GTA NORTH REGIONAL PLANNING STUDY.

6.1 Load Forecast

The RIP phase has adopted the load forecast developed during the IRRP which incorporates the impact of the conservation and demand management (CDM), distributed generation (DG) and weather correction factors. The municipalities were contacted as part of IRRP stakeholder engagement process to get their input on future load growth and this has been incorporated into the forecast provided by their respective LDCs. The TWG participants, including representatives from LDC's, the IESO and Hydro One, have reviewed and confirmed the continued use of the IRRP load forecast for this report.

Figure 9 and Figure 10 present the GTA North regional summer and winter net peak load forecasts for the periods 2026 - 2035 and 2036-2043, respectively. Summer peak demand is forecast to grow at an average annual rate of approximately 4.0% between 2026 and 2035, moderating to about 2.0% between 2036 and 2043. Winter peak demand is expected to grow more rapidly due to electrification and is expected to grow at an average growth rate of about 7% between 2026 and 2035 and about 3.85% between 2036 and 2043. The GTA Region is expected to become winter peaking beyond 2030.

Figure 9: GTA North Summer and Winter Net Peak Load Forecast



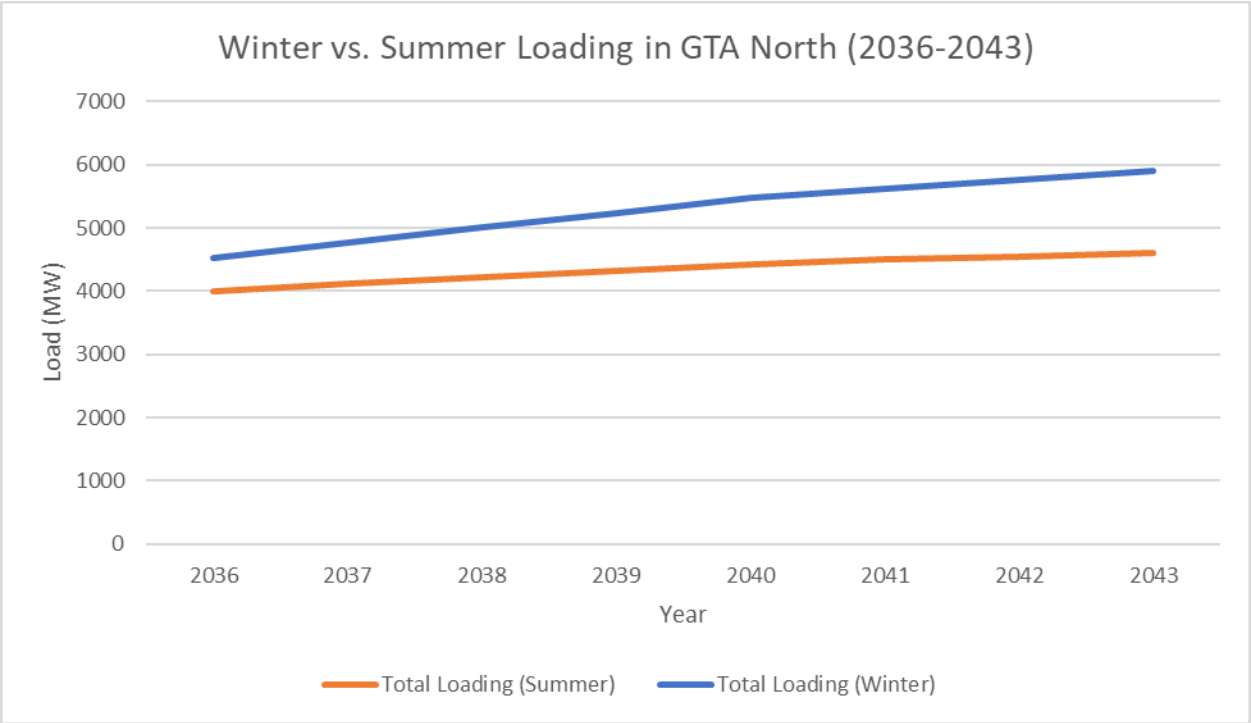


Figure 10: GTA North Summer and Winter Net Peak Load Forecast (2036-2043)

6.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2026-2035.
- While the Region is changing from summer to winter peaking by 2030, summer remains the critical period with respect to line and transformer loadings over the study period of 2026-2035. The assessment is therefore based on summer peak loads.
- Since GTA North stations peak at roughly the same time, the TWG has assumed no difference between the coincident and non-coincident demands, and a single set of load forecast for the RIP purposes has been considered – termed as 'Net Peak Load Forecast'.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks or based on historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR) based on 35°C ambient temperature.
- Bulk transmission line capacity adequacy is assessed by using net summer peak loads in the area. Capacity assessment for radial lines and stepdown transformer stations uses non-coincident peak loads.

- All Battery storage projects are assumed to only charge during off-peak hours. Any future charging of these battery storage projects may impact LMC (Load Meeting Capability) of some circuits.
- Adequacy assessment is conducted as per Ontario Resource and Transmission Assessment Criteria (ORTAC).

7 SYSTEM ADEQUACY AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND TRANSFORMER STATION FACILITIES SUPPLYING GTA NORTH REGION OVER THE RIP STUDY PERIOD 2026-2035.

In the current regional planning cycle, the following regional assessments were completed, and their findings were used as inputs to this RIP report:

- GTA North region Third cycle Needs Assessment Report, Completed in September 2022 by Hydro One
- GTA North region Third cycle Scoping Assessment Report, Completed in October 2023 by the IESO
- GTA North region Third cycle Integrated Regional Resource Plan Report, Completed in October 2026 by the IESO

The Technical Working Group identified several regional needs based on the forecasted demand over the near-to-mid-term period in the reports mentioned above. The results of the Adequacy Assessment to define the needs are discussed in sub-sections “7.1 to 7.4” and a detailed description and status of plans to meet these needs are given in “Section 8” of this report.

7.1 Asset Renewal Needs for Major HV Transmission Equipment

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The list of major HV transmission equipment requiring replacement in the GTA North region is provided in Table 2 below

Table 2: Major HV Transmission Asset assessed for Replacement in the Region

Station/Circuit	Need Description	Planned ISD
Woodbridge TS	Transformer T5 refurbishment	2032

7.2 Station Capacity Needs

Over the 2026-2035 study period, the RIP assessed the capacity of all the 230kV transformer stations in the GTA North region. Previous NA and IRRP studies identified several stations requiring capacity relief within this timeframe. This RIP confirms those findings and, based on the load forecast, identifies the stations requiring capacity relief as summarized in Table 3. The need date represents the point at which forecast peak demand exceeds the most limiting seasonal (summer) Limited Time ratings.

Table 3: GTA North region Station Capacity Needs in the study period

Sr. No.	Station Name	Station LTR(MW) (Summer)	2026 Loading (MW) (Summer)	Need Date
1	Kleinburg TS	180	214	Current[1]
2	Holland TS	168	169	Current[2]
3	Armitage TS	317	317	Current[2]
4	Brown Hill TS	184	177	2027
5	Richmond Hill MTS #1&#2	254	249	2030[2]
6	Buttonville TS	166	151	2030[2]
7	Vaughan MTS #1	306	301	2033

[1] Work is underway to add a new T3/T4 DESN at Kleinburg TS
[2] Work to provide relief has been initiated

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.3 Lines Capacity Needs

The RIP assessed the capacity of all 230kV transmission lines within the GTA North region and confirmed previously identified needs using the transmission lines and confirmed those needs based on the load forecast. Transmission lines requiring capacity relief during the study period are summarized in Table 4 below. The need timeframe represents the point at which the forecast peak demand exceeds the most limiting seasonal (summer) Limited Time Emergency ratings.

Table 4: GTA North region Transmission Line Capacity Needs in the study period

No.	Name of Circuit	Name of Section	Maximum capacity Long Term Emergency (LTE)	Current loading	2035 Loading	Need Date
1	H82V/H83V	Woodbridge Jct. to Vaughan #4 Jct.	1090A	<LTE	> 170%	2030
2	P45/P46	Parkway TS to Markham #4 Jct.	1103A	< LTE	> 120% of LTE	2031
3	P45/P46	Markham #4 Jct. to Buttonville TS	1103A	< LTE	> 150% of LTE	2034

7.4 System Reliability

The RIP reviewed the reliability of the system as per IRRP recommendations provided for the GTA North region. System upgrades required to ensure reliability in the area, and which have been recommended through the GTA North IRRP and South & Central bulk study, are shown in Table 5 below. The need timeframe defines the time when the projects require support from the IESO as part of Bulk system input and need.

Table 5: GTA North region System Reliability Needs in the study period

Station/Circuit	Need Description	Need Date
Kleinburg Kirby Transmission Line K43H/K44H [1]	Provide relief for loading on circuits H82V/H83V	2031-2032
Kleinburg TS – 500/230kV station expansion[2]	Provide additional supply to local area	2031-2032
YEC -Station Service Upgrade	Station Service Upgrade- mitigate load restoration concerns	Immediate
Holland Marsh Switching Station (SS)	Switching station enhances restoration and mitigate load security concerns	TBD[3]
New Transmission Supply corridor	Linking Kleinburg TS or Essa/Barrie to Holland Marsh SS	TBD[3]

[1] Assumed nomenclature for new line.
[2] Bulk system upgrade recommended by South and Central bulk system study.
[3] Option to be reviewed in next planning cycle.

7.5 Load Security and Restoration Needs

Load security and load restoration needs were reviewed as part of the current study. The ORTAC Section 7 requires that no more than 600 MW of load be lost as a result of a double circuit contingency.

Further, loads are to be restored in the restoration times[1] specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

Load Security needs for loss of double circuits lines are listed in Table 6. The needs and the TWG recommendations to address the needs are discussed in more detail in Section 8.5.

Table 6: GTA North region System Reliability Needs in the study period

Circuit	Need Description	Need Date
V43/V44	Loads in excess of 250 MW cannot be restored in less than 30 minutes as per the ORTAC restoration criteria.	Current[1]
H82V/H83V	Loads in excess of 250 MW cannot be restored in less than 30 minutes as per the ORTAC restoration criteria.	Current[1]
B88H/B89H	Loads in excess of 250 MW cannot be restored in less than 30 minutes as per the ORTAC restoration criteria.	Current[1]
V71P/V75P	Loading on this line exceeds the 600 MW limit as per ORTAC security criteria.	Current[1]
P45/P46	Loads in excess of 250 MW cannot be restored in less than 30 minutes as per the ORTAC restoration criteria.	2030

[1] Current issue

[1] These approximate restoration times are intended for locations that are near staffed centers. In more remote locations, restoration times should be commensurate with travel times and accessibility

8 REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the GTA North Region. These needs include those previously identified in the NA and IRRP for the GTA North Region as well as any new needs identified during the RIP phase. All estimated costs included in the alternative analysis are considered as planning budgetary estimates and are used for comparative purposes only and may vary. The Needs in the region are summarized below in Table 7 below:

Table 7: Near/ Mid-term Needs Identified in the Region

Sub-Region	Area/ Station/Circuit	Description of Need	Need Date	RIP Report Section
Asset Renewal Needs				
Western Area	Woodbridge TS	Transformer T5 replacement	2032	8.1.1
Station Capacity Needs				
Western area	Kleinburg TS (T3/T4)	New T3/T4 230/44kV DESN as T1/T2 DESN approaching its supply capacity.	2028	8.2.1.1
	Vaughan MTS #6	New Station 230/27.6kV DESN accommodate Customer	2027	8.2.1.2
Northern York Area	Build Northern York TS #1 230/44kV DESN	To meet forecast load	2031	8.2.2.1
	Build Northern York TS #3 230/44kV DESN	To meet forecast load	2035	8.2.2.2
Southern Vaughan - Richmond Hill Area	Build Richmond Hill MTS #3 230/27.6kV DESN	To meet forecast load	2030	8.2.3.1
	Build Vaughan MTS #5 230/27.6kV DESN	To meet forecast load	2033	8.2.3.2
Markham Area	Build Buttonville TS#2 230/27.6kV DESN	To meet forecast load	2030	8.2.4.1
	Build Markham MTS #6	To meet customer load.	2034	8.2.4.2

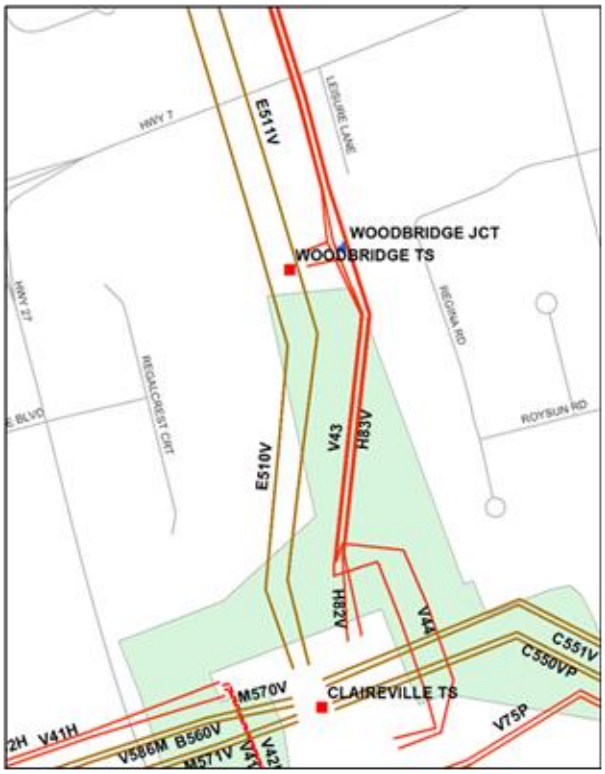
Sub-Region	Area/ Station/Circuit	Description of Need	Need Date	RIP Report Section
	230/27.6kV DESN			
	Build Northern York TS #2 230/44kV DESN	To meet customer load.	2034	8.2.4.3
Transmission Line Capacity Needs				
Markham Area- Parkway TS to Buttonville TS	Upgrade P45/P46	Upgrade P45/P46 230kV conductors from Parkway to Markham MTS#4 Junction to accommodate Buttonville TS #2	2031	8.3.1.1
	Upgrade P45/P46	Upgrade P45/P46 230kV conductor from Markham MTS#4 Jct. to Buttonville TS, before connecting either Northern York TS#2 or Markham MTS#6, whichever comes first.	2034	8.3.1.2
	Extend P45/P46	Extend the P45/P46 circuits 7 km north of Buttonville TS along the idle 115kV corridor[2].	2034	8.3.1.3
Markham Area- Parkway TS to Cherrywood TS	Re-terminate Markham MTS#4 from P45/P46 to C35P/C36P	Re-terminate Markham MTS#4 from P45/P46 to C35P/C36P to offset the future loading concerns.	To be discussed in the next Regional Planning cycle	8.3.1.4
System Reliability				
Bulk System- Western and Northern Area sub-systems	Build Kleinburg to Kirby Transmission Link	Supply capability of H82V/H83V- Claireville to Holland Marsh Jct. exceeded.	2031-2032	8.4.1
Bulk System	Kleinburg TS: Build new 500/230 kV station	Provide additional supply to local area[3]	2031-2032	8.4.2

[2] The distance varies depending upon the location of the future Markham MTS#6 and Northern York TS#2 Stations.
[3] Bulk system upgrade recommended by IESO's South and Central bulk system study.

Sub-Region	Area/ Station/Circuit	Description of Need	Need Date	RIP Report Section
Northern Area	York Energy Centre – Station Service Upgrade	Mitigate load security issue for loss of Station service.	2026 (Current)	8.4.3
Bulk System	Build Holland Marsh Switching Station	Reinforce supply to Newmarket and Armitage area	To be discussed in the next planning cycle	8.4.4
Bulk System	New Transmission Supply to Holland Jct	Supply capability of H82V/H83V- Claireville to Holland Marsh Jct. exceeded.	To be discussed in next planning cycle	8.4.5
Southern Vaughan - Richmond Hill Area	Add new 230kV inline breakers on V71P/V75P circuits	Mitigate load security issue	2030	8.4.6
Northern Area	H82V/H83V – B88H/B89H-M6E/M7E	Mitigate Claireville to Minden-Over voltages and Under voltage needs. Thermal Overloads-M6E/M7E	Continue to be monitored -No action except for M6E/M7E thermal overloads	8.4.7
Bulk System	Add/Upgrade Kirby Jct to Holland Marsh Jct (23 km)	Upgrade the limiting section	To be discussed in the next planning cycle	8.4.8
Load Security and Restoration Needs				
Western Area	V43/V44	Mitigate Load Security on Kleinburg Radial Tap	2031-2032	8.5.1
Northern Area	H82V/H83V	Load Restoration from Claireville TS to Holland TS Circuits (H82V/H83V)	No Needs identified	8.5.2.1
Northern Area	B88H/B89H	Monitor Load Security Issue	2035	8.5.2.2
Southern Vaughan - Richmond Hill Area	V71P/V75P	Mitigate Load Security concerns on V71P/V75P	2030	8.5.3
Markham Area	P45/P46	Monitor Load Security concerns on Buttonville Corridor (P45/P46)	2034	8.5.4

8.1 Asset Renewal Needs for Major HV Transmission Equipment

The Asset renewal assessment considers the following options for "right sizing" the equipment:



- Maintaining the status quo;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities;
- Eliminating equipment by transferring all the load to other existing facilities;
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement); and
- Replacing equipment with higher ratings and built to current standards.

From Hydro One's perspective as a facility owner and operator of its transmission equipment, doing nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance costs and longer duration of customer outages.

8.1.1 Woodbridge TS: T5 End-of-Life Transformer

Woodbridge TS comprises one DESN unit, T3/T5 (75/125 MVA), with two secondary winding voltages at 44 kV and 27.6 kV, each with a summer 10-Day LTR of 80 MW, supplying both Alectra and THESL, having geographic location as shown in Figure 11. The station's 2025 actual peak load was 128 MW. Transformer T5 is currently about 54 years old and is planned for replacement.

Figure 11: Woodbridge TS Project Location

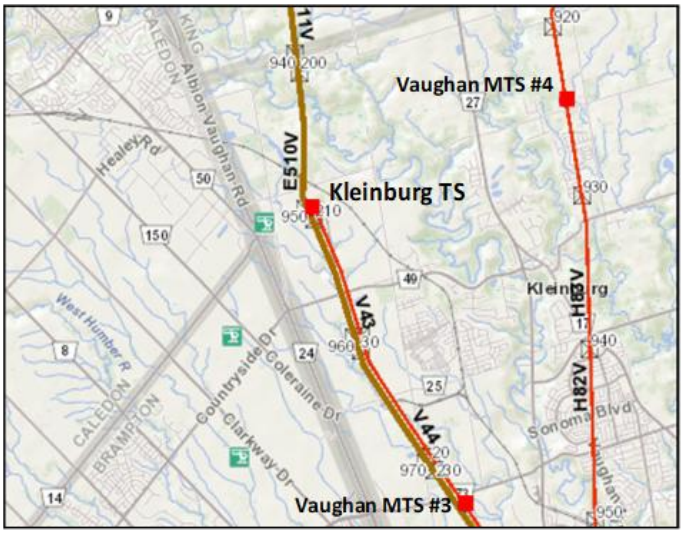
Alternatives and Recommended Plan

The following alternatives were considered to address the Woodbridge T5 end-of-life need:

1. **Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One's obligation to provide reliable supply to the customers.
2. **Replace with similar type and size equipment as per current standard:** Under this alternative the existing transformer T5 at Woodbridge TS is replaced with a new 75/125 MVA 230/44-27.6 kV transformer. This alternative would address the need and would maintain reliable supply to the customers in the area.
3. **Re-configure Woodbridge TS as two separate 44 kV and 27.6 kV DESNs:** Hydro One has not considered this option further since there is currently no need for the additional transformation capacity, and there are limitations on the high voltage supply circuits. The cost of rebuilding the station would also be high.

The Working Group has recommended that Hydro One proceed with Alternative 2 and coordinate the replacement plan with affected LDCs. The estimated project cost is to be determined and is work is planned to be completed in 2032.

8.2 Station Capacity Needs



A Station Capacity assessment was performed over the study period 2026-2035 for the 230kV transformer stations in the GTA North region using the net summer peak load forecasts that were provided by the study team. Based on the results, the following Station capacity needs have been identified during the study period:

8.2.1 Western Sub Region

8.2.1.1 Kleinburg TS T3/T4 Addition

Kleinburg TS in King Township (see Figure 12) consists of two existing dual winding 230/44/27.6 kV transformers T1 and T2. The 44kV winding supplies a 44kV LV yard that serves Hydro One Distribution load. The 27.6kV winding supplies a 27.6kV LV yard that serves both Hydro One Distribution and Alectra load. The station 2025 actual 44kV peak load of 105 MW exceeds the 44kV kV winding rating of 99 MW. Hydro One Distribution has asked for additional 44kV supply capacity to support increased demand in the Caledon area.

Figure 12: Kleinburg TS Project Location

Alternatives and Recommended Plan

The following alternatives were considered to address the increased load demand:

1. **Maintain Status Quo**: Existing transformer T1 and T2 assets and 27.6 kV and 44 kV switchyard configurations at the Kleinberg TS are nearing capacity limits. Not addressing these assets needs will result in Hydro One Distribution not being able to meet its customer connection obligations. Therefore, this option is rejected.
2. **Add two new 75/125 MVA, 230kV/44kV transformers and reconnect the 44kV yard supply from the T1/T2 transformers to the new T3/T4**. Under this option the existing 44kV yard together with the new T3/T4 transformers become a separate 230/44kV DESN increasing the 44kV supply capability to 200 MVA.

The Working Group has recommended that Hydro One proceeds with Alternative 2 and coordinates the replacement plan with affected LDCs. The project estimated cost is around $40M and work is currently underway with a planned completion date of 2028.

8.2.1.2 Vaughan MTS #6 TS (T3/T4) 27.6 kV DESN

Vaughan MTS #6 was identified in the NA as triggered by a dedicated Customer need. Alectra has started building a new station to provide supply to a large customer, having geographic location as shown in Figure 13. The new station will have 2 x 75/125 MVA, 230/27.6kV transformers, and a 27.6kV switchgear building. Alectra has requested that Hydro One build a short underground line tap to supply the new station from the 230kV Claireville TS x Kleinburg TS double circuit line V43/V44.

Figure 13: Vaughan MTS #6 Location

Table 8: Vaughan MTS #6 MW Summer Demand and Forecast Loading on the 230kV Claireville TS x Kleinburg TS line V43/V44

Transformer Station/ Corridor	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Vaughan MTS #6 (28kV)	0	0	30	29	49	48	56	76	92	90
Total Load on V43/V44	522	535	596	607	644	645	656	675	690	687

Table 8 shows the forecast load for Vaughan MTS #6 and the total load connected to the line. There is adequate capacity on the line to supply the loads over the study period.

Feasibility study for the line connection and SIA and CIA for the dedicated customer load have been completed. Hydro One has initiated consultations with Alectra for the design and execution of the Project and planned in-service date for the station is 2027. The project estimated cost is in the range of $55M-$65M.

8.2.2 Northern York Area Sub-Region

8.2.2.1 Northern York TS #1

Additional step-down transformation capacity is needed for the areas supplied by Armitage TS and Holland TS. A new station Northern York TS #1, located south of Holland Marsh Jct., and supplied by the Claireville TS x Holland Marsh Jct. 230 kV circuits H82V/H83V (see Figure 14) is proposed to meet this need. Please refer to Table 9 below for the load forecast and in-service timeline for the Station. While the IRRP had identified the need for the station as immediate, the earliest possible in-service date for the project is 2031.

Figure 14: Northern York TSs #1 and 3

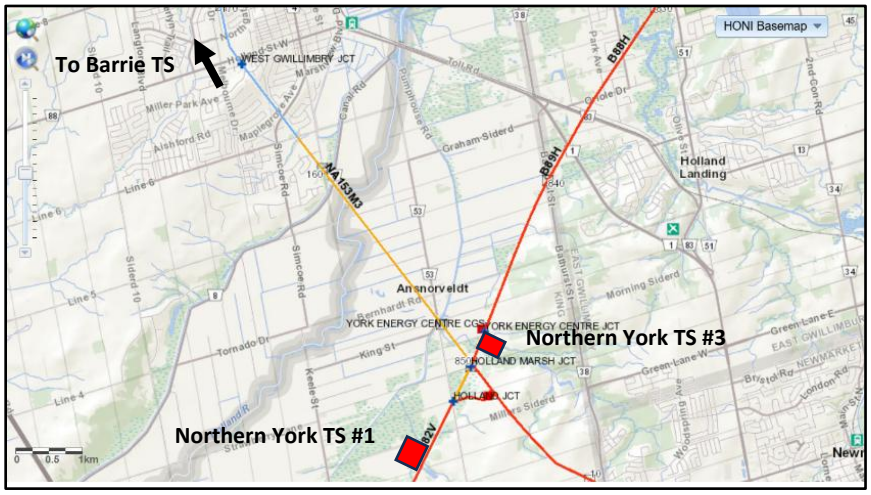


Table 9: Northern York Area MW Summer Demand Forecast

Station	LTR (MW)	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Need for Northern York Region TS #1 and #3											
Holland TS	168	169	169	169	169	169	169	169	169	169	169
Armitage TS	317	317	317	317	317	317	317	317	317	317	317
Northern York TS #1	170	0	0	0	0	0	32	65	92	130	170
Northern York TS #3	170	0	0	0	0	0	0	0	0	0	4

Alternatives and Recommended Plan

Status Quo is not an option as not proceeding with this investment will result in Hydro One not meeting the Customer's in-service date. This alternative presents regulatory and customer risks. With this alternative, Hydro One's obligation to connect load customers upon request would not be met.

The Northern York TS #1 station project is currently in the project development phase. Funding has been released for selecting a suitable site for the new station, and preliminary engineering and initial environmental assessment activities have been initiated, including early engagement to inform and seek input from the affected communities and Indigenous groups. The project estimated cost is in the range of $55M-$65M. The planned in-service date is 2031.

8.2.2.2 Northern York TS#3

By the mid-2030s, electricity demand in Northern York is expected to grow to the point that another new transformer station will be required in northern York region by 2035 (please see Table 9 above). The new station Northern York TS #3 will support the forecasted growth at Northen York TS #1 and future growth at Holland TS and Armitage TS area. The location for the Northern York TS #3 has not yet been confirmed. However, based on projected development patterns, the most suitable area would likely be near the Holland Marsh Junction, where it would be well positioned to supply the communities of King, Newmarket, East Gwillimbury, and Bradford West Gwillimbury.

It is anticipated that the station will connect to Holland Marsh Jct. x Brown Hill TS 230kV circuits B88H/B89H. However, additional transmission reinforcements are expected to be required to support this connection.

One option is to reinforce the existing H82V/H3V circuits that connect into Holland Marsh Jct. A second option, see Figure 14 above, is to build a new 230kV double circuit line from Barrie TS to Holland Marsh Jct. utilizing the existing idle transmission corridor that extends from Holland Marsh Jct., northwest through Bradford West Gwillimbury and into Simcoe County, to Barrie TS. Potential advantages of this option include improved voltage performance and system reliability, and and relief of future loading pressure on the core Northern York transmission path (H82/83V). This option is further discussed in Section 8.4.5.

A switching station at Holland Marsh Jct. may also be required at Holland Marsh Jct. to incorporate the new line from Barrie TS (please see Section 8.4.4 for further discussion on Holland Marsh switching station). The TWG will review and finalize the reinforcement options in the next planning cycle

Alternatives and Recommended Plan

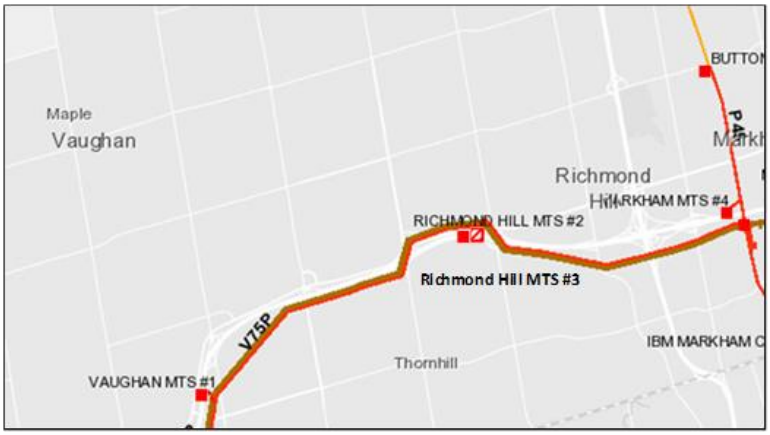
As noted above, it is planned to connect the new station to circuits B88H/B89H. Further coordination between Hydro One and the affected LDCs will be required to confirm the preferred station location and connection point through future planning activities. The TWG will monitor the area growth rate, and the timing of the station in-service date of 2035 will be refined based on need.

The capital cost of the new station is currently estimated to be in the range of $55M-$65M. Any required transmission reinforcements and their associated costs will be determined in the next planning cycle, once the scope and configuration of the work have been further defined.

8.2.3 Southern Vaughan -Richmond Hill Area

8.2.3.1 Richmond Hill MTS #3

The Richmond Hill South area is seeing significant growth. The existing stations Richmod TS MTS #1 and MTS #2 are operating at capacity limit and additional transformation capacity is required. Alectra plans to



develop a new transformer station Richmond Hill MTS #3 adjacent to the existing Richmond Hill MTS #2 to meet forecast growth. Please see Table 10 below for the area forecast.

Table 10: Richmond Hill Area MW Summer Demand Forecast

Station	LTR (MW)	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Richmond Hill MTS #1	153	150	148	153	153	153	153	153	153	153	153
Richmond Hill MTS #2	101	99	98	101	101	101	101	101	101	101	101
Richmond Hill MTS #3	153	0	0	0	0	26	48	61	86	115	129

The proposed station will consist of 2 x 75/125 MVA, 230/27.6kV transformers and a 27.6kV switchyard. Alectra has requested that Hydro One connect the new station to the 230kV Claireville TS x Parkway TS double circuit line V71P/V75P as shown in Figure 15.

Figure 15: Richmond Hill MTS #3 Location

The IRRP has identified load security concerns with the V71P/V75P lines as connected loads exceed the 600 MW limit as per the ORTAC security criteria. The connection of this new station will further increase loading on the line. To connect the station and address the load security need, TWG has recommended the addition of in-line breakers to sectionalize the circuits. The issue is further discussed in the Section 8.4.6 on in-line breakers and Section 8.5.3 on load security assessment

Alternatives and Recommended Plan

The status quo option was eliminated as increasing residential and commercial load growth is driving the need for additional transformation capacity in the area. Accordingly, the TWG recommends proceeding with the development of the new station, with an estimated capital cost of $55M-$65M and a target in-service date of 2030.

8.2.3.2 Vaughan MTS #5

Significant growth is also happening in the Vaughan MTS #1 and Vaughan MTS #2 supply area driven by major commercial and industrial development associated with the Vaughan Metropolitan Center. Both stations operate at capacity limits and additional transformation capacity is required. Please see Table 11 below for the area load forecast.

Table 11: Southern Vaughan Area MW Demand Forecast

Net Summer Peak Demand Forecast- by Station (MW)											
Station	LTR (MW)	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Vaughan MTS #1	306	301	300	306	306	306	306	306	306	306	291
Vaughan MTS #2	153	150	149	153	153	153	153	153	153	153	144
Vaughan MTS #5	153	0	0	0	0	0	0	35	99	33	52

Alectra is proposing to build a new station Vaughan MTS #5 consisting of 2x75/125 MVA, 230/27.6kV transformers and a 27.6kV switchyard and connect it to the V71P/V75P circuits west of Yonge Street. While this would further exacerbate the already existing load security issue; the issue will be mitigated through the installation of in-line breakers as discussed in Section 8.4.6 and the associated load Security assessment in Section 8.5.3.

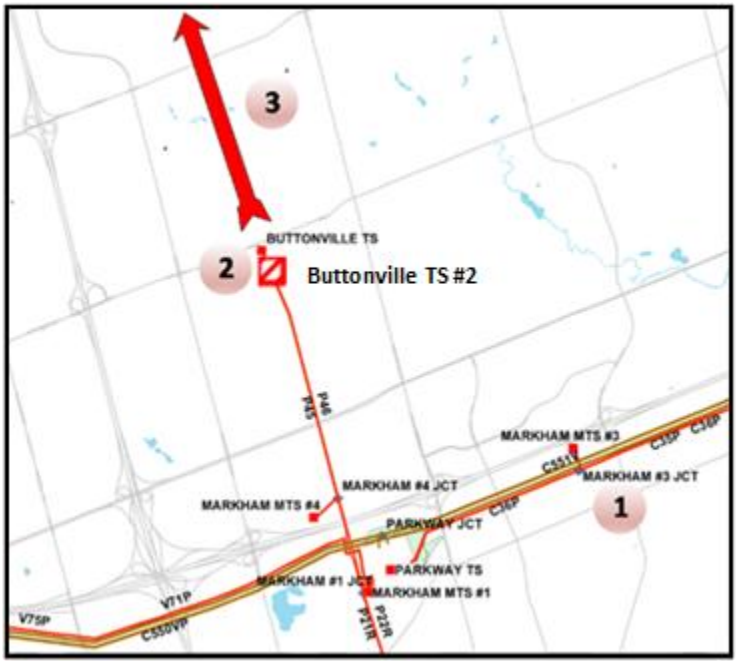
Figure 16: Vaughan MTS #5 Location

Alternatives and Recommended Plan

There are no alternatives to building a new station to meet the area load growth as all area stations are at their limits. The station location as shown in Figure 16 is an assumption and the exact location of the Station is yet to be determined by the LDC.

The Working group has recommended proceeding with the project with the estimated cost in the range of $55M-$65M. The planned in-service date is 2033.

8.2.4 Markham Area



8.2.4.1 Markham MTS #5/Buttonville TS #2

Significant load growth is forecast for the area currently supplied from Buttonville TS and Markham MTS #4 as a result of urban development in the City of Markham. Forecast load is presented below in Table 12 below which shows a need for additional transformation in the area. Alectra proposed building a new Markham MTS #5 station consisting of 2x75/125 MVA, 230/27.6kV transformers and a 27.6kV switchyard supplied from the 230kV circuits P45/P46.

Table 12: Markham Area MW Summer Demand Forecast

Net Summer Peak Demand Forecast- by Station (MW)											
Station	LTR (MW)	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Buttonville TS	166	150	150	149	147	146	146	145	145	145	144
Markham MTS #4	153	111	150	153	153	153	153	153	153	153	153
Markham MTS #5	153	0	0	4	27	63	110	144	146	143	143
Markham MTS #6	153	0	0	0	0	0	0	0	0	40	98

Figure 17: Proposed Locations of Markham MTS #5/Buttonville TS #2

Alternatives and Recommended Plan

As shown in Figure 17, three alternative locations for the new Markham MTS #5 were considered:

Alternative 1 - Building the new station along the Parkway belt and connecting to the C35P/ C36P circuits: The C35P/C36P transmission circuits are capable of supplying the full capacity of the station, but the alternative has been ruled out because the physical location of the station would be far from the area of anticipated growth resulting in high distribution costs. There is also a risk that the capacity of this station will become stranded if it becomes technically infeasible to supply load concentrated along Markham's northern border

Alternative 2 - Building the station at the existing Buttonville TS and connecting to the P45/P46 circuits: This alternative is closer to the area of anticipated load growth than alternative 1, and lesser distribution infrastructure is required as compared to Alternative 1. A 1.1 km section of the 230kV double circuit line P45/P46 between Parkway TS and the Markham MTS #4 Jct. would need to be uprated.

Alternative 3 - Building the station in north Markham and extending circuits P45/P46 from Buttonville TS to connect the new station: This location is nearest to the area of anticipated load growth. However, it requires rebuilding approximately 6 km of a single circuit 115 kV transmission line as a 230 kV double circuit transmission line. A new station property would also need to be acquired.

Alternative 1 was not considered further due to the high distribution costs. Of the remaining two alternatives, the study team recommends Alternative 2 - building the new station at Buttonville TS. While

the distribution costs are higher under this option compared to Alternative 3, the high costs of extending the transmission line north from Buttonville for Alternative 3 made these two alternatives comparable. Alternative 2 was selected as the preferred option as it also allows the new station to be in service at an earlier date to meet the forecast load requirement.

The TWG has recommended proceeding with the project, with the station capital costs estimated in the range of $55 million to $65 million, and associated line costs estimated at approximately $5 million, as outlined in Section 8.3.1.1. While the identified need date is 2029, the project is expected to be placed in service in 2030. Alectra will be managing the area load till the Station is placed in-service.

8.2.4.2 Markham MTS #6

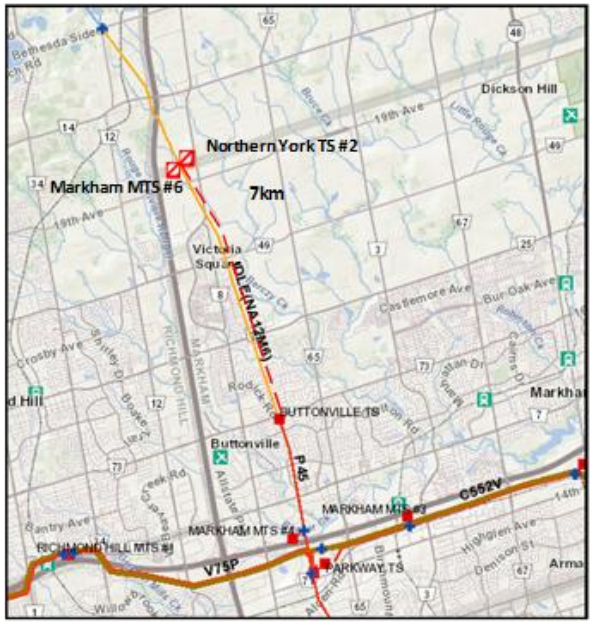
A second station will be required in the Markham area towards the end of the study period (see Table 12). Alectra's preferred location for this station is about 7 km north of Buttonville TS and would require extending circuits P45/P46 from Buttonville TS to the new station as shown in Figure 18. This option requires replacing approximately 7 km of an idle single circuit 115 kV transmission line with a 230 kV double circuit transmission line.

Figure 18: Proposed Location of Markham MTS #6

Alternatives and Recommended Plan

The status quo option was eliminated. as rising demand driven primarily by increased residential and commercial development necessitates additional transformation capacity. Accordingly, the development of a new station is required. The estimated capital cost of the station is in the range of $55M-$65M,

excluding the cost of associated transmission line work which is discussed separately in Section 8.3.1.3. The planned in-service date for the station is 2034.



8.2.4.3 Northern York TS #2

Significant load growth is forecast in the eastern portion of Northern York subregion, particularly in Whitchurch-Stouffville. This area currently lacks transmission infrastructure and is primarily served by long distribution feeders, resulting in higher connection costs, and reduced reliability. Hydro One Distribution has identified the need for a new step-down transformer station to meet forecast demand and improve service reliability in this area. The area load forecast is given in Table 13 below.

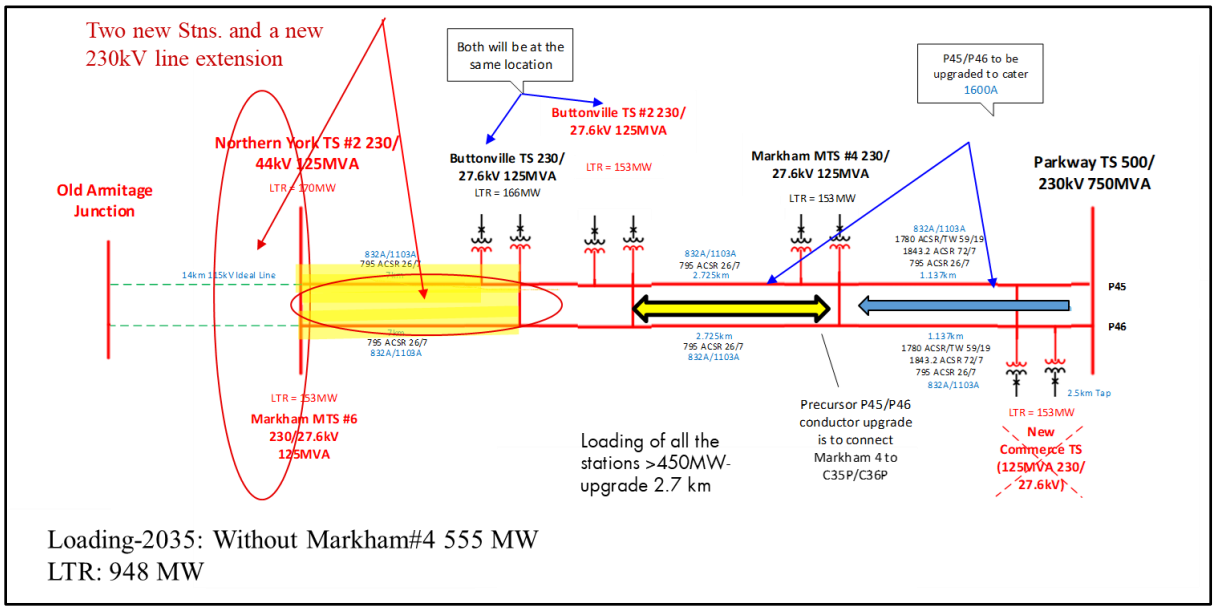
Table 13: Northern York TS #2 MW Summer Demand Forecast

Station	LTR (MW)	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Northern York TS #2	170	0	0	0	0	0	60	99	142	170	170

Figure 19: Proposed Location for Northern York TS #2

Hydro One Distribution preferred location for the station is shown in Figure 19. The station will be slightly north of Markham MTS #6, and it will be supplied from the 230kV line P45/P46 extension from Buttonville TS.

Alternatives and Recommended Plan



There are no viable alternatives to constructing the new station to address meet the forecast Hydro One Distribution's capacity requirements. The TWG will continue to monitor the load growth and has asked that Hydro One coordinate the station and associate transmission line with the facilities required to connect Markham MTS #6. The estimated project cost for the Station is in the range of $55M-$65M, excluding transmission line costs. Transmission line costs are discussed in Section 8.3.1.3. Given that the earliest possible in-service date for the line is 2034, the station's in-service date will need to be aligned accordingly. In the interim, Hydro One Distribution will manage the area load.

8.3 Line Capacity Needs

8.3.1 Markham Area - Parkway to Buttonville including extension on idle corridor North

Markham area line upgrades, for the recommended projects combined, are shown in the SLD - Figure 20 below displaying each segment length, existing ratings, stations connected including future planned ones and also the preferred circuit upgrade rating[4] for each section.

Figure 20: Future P45/P46 Single Line Diagram

Below are the detailed needs assessments for each of the line segments in Markham area:

[4] Preferred circuit ratings are subject to change as further studies are done.

8.3.1.1 Upgrade from Parkway TS to Markham MTS #4

The connection of the new Buttonville TS #2 to the Parkway TS x Buttonville TS 230kV double circuit line P45/P46 circuits (see Figure 21 below) will increase the loading on this line. Forecast loading, along with applicable long term emergency line rating is given in Table 14.

Figure 21: Parkway TS x Buttonville TS P45/P46 Limiting Section

The transmission capacity is thermally limited by an approximately 1.1 km long section between Parkway TS and Markham #4 Jct. Loading is expected to exceed the rating by 2031. This section will need to be uprated to at least 1600A loading before 2031 to fully supply Buttonville TS #2.

Table 14: MW Loading on the P45/P46 Circuits

P45/P46	Yearly Loading (MW)										
Station	Line Rating	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Markham MTS #4		111	150	153	153	153	153	153	153	153	153
Buttonville TS		150	150	150	149	147	146	146	145	145	145
Buttonville TS #2		0	0	4	27	63	110	144	146	143	143
Northern York TS #2		0	0	0	0	0	60	99	142	170	170
Markham MTS #6		0	0	0	0	0	0	0	0	40	98

Loading – Parkway TS x Markham MTS #4 Jct.	450	261	299	306	327	363	512	542	587	651	708
Loading – Markham MTS #4 to Buttonville TS	450	150	150	153	174	210	316	389	434	498	555

Alternatives and Recommended Plan

Two alternatives were considered to provide adequate capacity on the P45/P46 circuits:

1. **Increase thermal capability of existing line.** It is expected that the thermally limiting section of this line can be increased by changing the conductor to be capable of supplying the forecasted load with these circuits.
2. **Reduce loading on the P45/P46 circuits by transferring Markham MTS #4 to the Cherrywood TS x Parkway TS C35P/C36P circuits:** This alternative frees up capacity on the P45/P46 circuits to supply Northern York TS #2 or Markham MTS #6. It requires building a new 1.5 km long 230kV double circuit line from Markham MTS #4 Jct. to the C35P/C36P that is discussed in separate section. This alternative was ruled out until Northern York TS #2 or Markham MTS #6 is needed to be supplied.

The Working Group recommends uprating the line from Parkway TS to Markham MTS #4 Jct. to at least minimum 1600A loading before 2031 to fully supply Buttonville TS #2. A high-level estimate for this work is estimated to be around $5M.

8.3.1.2 Upgrade from Markham MTS #4 to Buttonville TS

The connection of the new Markham MTS #6 or Northern York TS-2, whichever comes earlier, to the Parkway TS x Buttonville TS circuit P45/P46 circuits (see Figure 22 below) will further increase the loading on the Markham MTS #4 Jct. x Buttonville section of the line. The forecast loading along with the long term emergency line rating for this section is also provided in Table 14 and Figure 20 above.

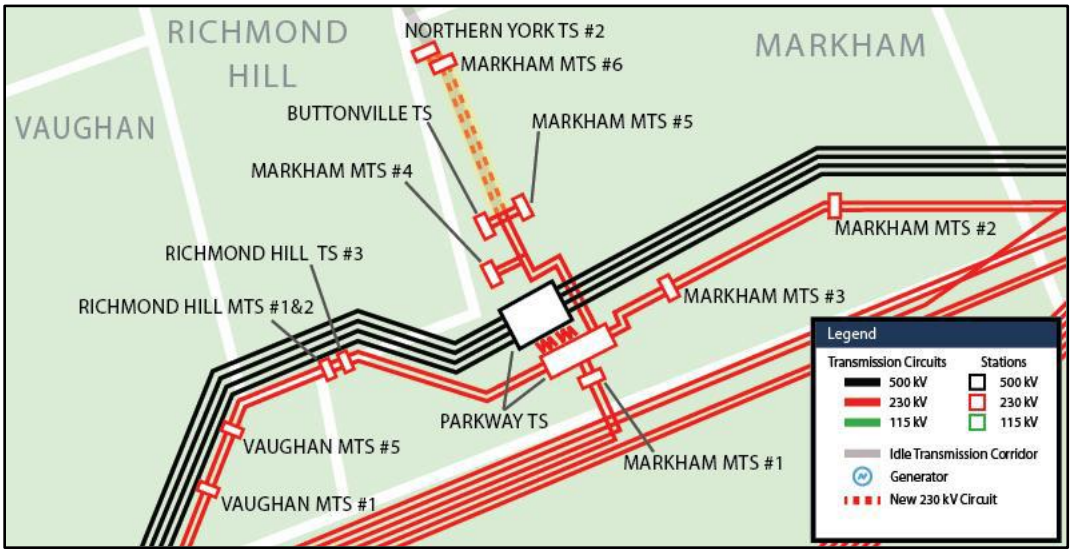
Figure 22: P45/P46 Corridor Line Reinforcement Section

The transmission capacity is thermally limited by an approximately 2.7 km long section between Markham #4 Jut to Buttonville TS. Loading is expected to exceed the rating with the addition of Northern York TS #2 and Markham MTS #6. This section will need to be uprated to at least 1600A prior to connecting these two stations.

Alternatives and Recommended Plan

Maintaining the status quo is not a viable option, as loading levels following the in-service of either Buttonville TS #2 or Northern York TS #2 would exceed the existing long-term emergency (LTE) circuit rating.

The need date[5] for this upgrade is triggered when the combined loading of Buttonville TS, Buttonville TS #2, Markham MTS #6, and Northern York TS #2 exceeds the existing rating of the line which is 1103 A/ 450 MW. Upgrading will be done in conjunction with the new stations' construction schedule with in-service date of 2034. The cost of the project is approximately estimated at $10M.



[5] Simultaneously Implementing the two upgrades from Parkway TS to Markham MTS# 4 Jct. and to Buttonville TS concurrently enhance the supply capability of P45/P46. The transmitter may consider uprating these circuits simultaneously to minimize the load at risk during construction-related outages.

8.3.1.3 Extending P45/P46 Circuits - 7 km north from Buttonville TS

The need for extending P45/P46 circuits 7km north of Buttonville TS, on the existing idle corridor, is to be able to supply future Northern York TS #2 and Markham MTS #6 as shown in Figure 23 below.

This work will require rebuilding the existing towers and conductors – which were built to 115kV standards- and ratings, to 230 kV standard. The approximate cost of this work ranges from $50M to $175M depending upon the type of tower structure and overhead conductor or underground cable selection. The cable option is contingent upon the customers' acceptance of the cost, longer outages' duration and expensive repair during contingency with the benefit of aesthetic considerations. The final option for choosing the technology type for the new transmission extension will be dependent upon the outcome of the Environmental Assessment (EA) of the line design.

Figure 23: P45/P46 Circuit extension (Courtesy: IESO)

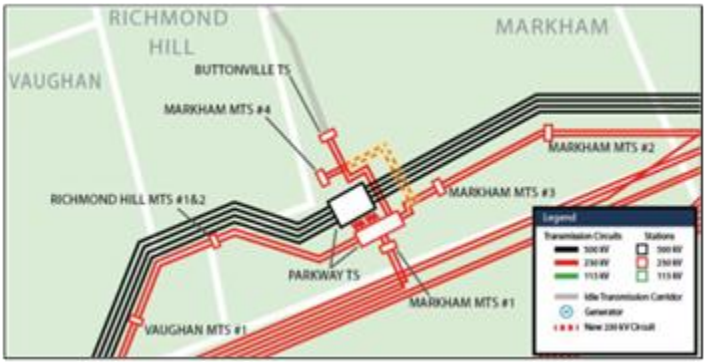
Alternatives and Recommended Plan

There are essentially no viable alternatives to extending the existing P45/P46 line along the idle corridor. The TWG therefore agreed to extend the line to supply the new stations. The rating of the line extension will be finalized during the next regional planning cycle. The need date is dependent upon the date of either of the two stations' connections. The estimated cost of $50-175M will be refined and revisited during the next planning cycle.

8.3.1.4 Reconnect Markham MTS #4 to C35P/C36P

The need to reconnect Markham MTS #4 from C35P/C46P reduces the loading on the P45/P46 circuits by transferring Markham MTS #4 to the Cherrywood TS x Parkway TS C35P/C36P circuits, hence alleviates

the load security concerns at P45/P46 corridor. It requires building a new 1.5 km long 230kV double circuit line from Markham MTS #4 Jct. to the C35P/C36P.



Alternatives and Recommended Plan

1. The status quo of keeping the Markham MTS #4 remain supplied from P45/P4 was not feasible as it will exceed the thermal capacity and ultimately would exacerbate further the already existing load security issues in the long run.

2. Reconnect Markham MTS #4: This alternative frees up capacity on the P45/P46 circuits to accommodate Northern York TS #2 or Markham MTS #6. Several potential connection points are available for this extension, including a direct tie-in at Parkway TS or a tap of the existing C35/36P circuits. The latter is currently the preferred option, as it offers a significantly lower-cost solution. In contrast, establishing a connection within Parkway TS would require extensive upgrades to existing bulk system infrastructure due to space limitations, resulting in substantially higher costs.

The reconnection diagram is shown in Figure 24 below.

Figure 24: Proposed Radial Tap for Markham MTS #4 (Courtesy: IESO)

While working group agreed option 2 was the preferred option, a final decision of the connection will be taken in the next planning cycle. This work will be aligned with the connection of either Markham MTS #6 or Northern York TS #2, whichever is required first, to enable LDCs to fully utilize available connection facilities.

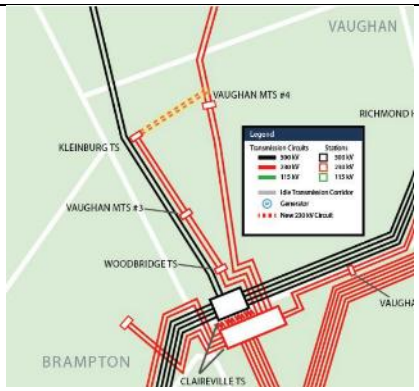
The approximate cost is estimated around $10M.

8.4 System Reliability

8.4.1 Build Kleinburg to Kirby Transmission Link

The Kleinburg–Kirby transmission link is a proposed 230 kV transmission reinforcement designed to increase supply capacity and improve reliability in York Region as electricity demand continues to grow. The project consists of constructing approximately 6 km of new 230 kV transmission line to connect an expanded Kleinburg TS with the H82/83V circuits near Kirby Road, north of Vaughan MTS #4.

The link is intended to relieve loading on the Claireville–Holland Marsh Jct. section of circuit H82V/H83V, which currently carries most of the supply to Northern York Region and is expected to face increasing constraints due to population growth, development activity, and electrification. Establishing this new transmission path would provide an alternative supply route and support the connection and full utilization of future step-down transformer stations required to meet long-term demand.



IESO South and Central bulk planning studies have identified the need for adding bulk supply capacity at Kleinburg TS to enable load growth in the area. Because the station is connected to both the regional 230 kV network and is near the provincial 500 kV bulk system, it is well positioned to function as a major supply hub. To accommodate higher power transfers associated with the Kleinburg–Kirby link, additional bulk facilities—such as switching equipment and new autotransformers—are required at Kleinburg TS. These enhancements would add the ability to step down bulk supply and deliver it effectively into the regional system; enable the Kleinburg – Kirby Link and other future supply projects in York and Peel Region. (see Section 8.4.2 for details on the Kleinburg 500/230kV transformer station).

During the regional planning process, several alternatives were evaluated, including reconductoring existing transmission lines to increase thermal capacity, and redeveloping the Buttonville–Armitage corridor to provide additional supply capability into Northern York Region.

While these measures can defer some needs in the near term, studies conclude that additional transmission capacity will still be required to support long-term growth in York Region. As such, the Kleinburg–Kirby link remains a key option.

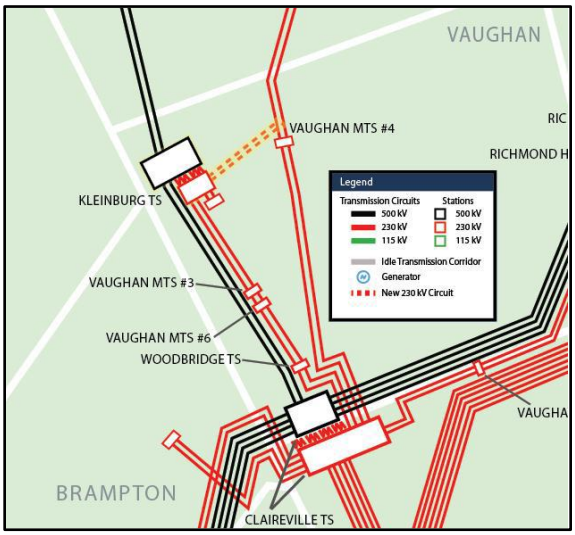
Together with future upgrades at Kleinburg TS, the Kleinburg–Kirby transmission link is intended to ensure that York Region's electricity system can reliably accommodate future growth, electrification, and new customer connections

Figure 25: The Kleinburg-Kirby Transmission Link (Map & Conceptual SLD)

Proposed Highway 413 - Kleinburg-Kirby Transmission Link	Proposed SLD – Kleinburg-Kirby Transmission Link
	

The IESO has asked Hydro One to proceed with the development work on the project. IESO's March 20, 2026, correspondence to Hydro One regarding the Kleinburg–Kirby 230 kV Transmission Link Project is appended as Appendix F: IESO Letter for Kleinburg-Kirby Transmission Link. The IESO letter confirms the system need, implementation urgency, and the expected project configuration, including the connection between the expanded Kleinburg TS and the H82/83V circuits near Kirby Road. Figure 25 illustrates an approximate transmission line routing along the proposed Highway 413 corridor along with a conceptual single-line diagram of the Kleinburg -Kirby Transmission Link.

The TWG recommends that the proposed Kleinburg–Kirby transmission link be designed to support a minimum LTE rating of 2000A provided that achieving this capacity does not introduce significantly higher additional cost. This higher rating is advisable given the strong likelihood that this section of the network will be utilized in the longer term as part of an independent supply path.



The expected completion date for the Kleinburg -Kirby Transmission corridor is around 2031-2032 with the expected cost range from $40M to $60M.

8.4.2 Bulk Supply – Kleinburg 500/230kV Transformer Station

The in-service of the Kleinburg–Kirby 230kV transmission link will necessitate additional bulk supply capacity at Kleinburg TS to reliably support forecast load growth in Northern York Region. Without a new bulk source, the existing V43/44 radial circuits north of Claireville TS would become thermally constrained as new stations are added and electrification-driven demand materializes. Kleinburg TS was initially envisioned as a 500/230kV station and has access to both the 230kV and 500kV networks. It includes sufficient reserved land and is a suitable and efficient location to advance bulk system capability. The need for the Kleinburg autos has been further described in the South & Central Bulk system study.

Development of Kleinburg TS as a 500/230 transformer station, as shown in Figure 26 below, has been identified as a preferred option to establish a bulk supply node. This would involve integrating the station into the transmission network by building 500kV and 230kV switchyards and installing three 500/230kV autotransformers, with provision for a fourth to accommodate longer-term demand.

Figure 26: Future Kleinburg TS and Kleinburg -Kirby transmission link (Courtesy: IESO)

This expansion would relieve pressure on Claireville TS, improve bulk power flow distribution, and enable effective utilization of the Kleinburg–Kirby link. On the 230kV side, targeted yard expansion would accommodate existing circuits, the new transmission link, and future regional reinforcements, while improving security by reducing reliance on the V43/44 corridor. Detailed configuration and sequencing would be finalized by Hydro One in coordination with IESO once the South and Central Bulk system planning studies are finalized.

Alternative solutions, such as local generation, were assessed but found to be less effective due to short-circuit constraints, operational inefficiencies, and limited bulk system benefits. The estimated capital cost of advancing Kleinburg TS as a bulk supply point is approximately $400 million, representing a cost-effective investment relative to other options. To maximize system benefits, the timing of the bulk expansion should align with the Kleinburg–Kirby link and the in-service date of Northern York TS #1. While early loading of Northern York TS #1 may be possible under constrained conditions, delays in completing the bulk enhancements would increase reliance on remedial action schemes. The working group agreed to initiate the project following the IESO's recommendation on the need, alternatives, and configuration of the Kleinburg autotransformer as part of Central Bulk System Planning with a potential in-service time frame of 2031-2032.

8.4.3 York Energy Centre- Station Service Upgrade

The York Energy Centre (YEC) currently depends on Holland TS for its station service supply. When the H82/83V circuits fail, both Holland TS and YEC lose power, even though YEC's generation path through B88/89H remains unaffected. This forced outage limits the ability to restore load quickly and creates unnecessary capacity and voltage challenges in the local system. Addressing this vulnerability requires a new station service arrangement that allows YEC to stay operational during these contingencies. IRRP suggested possible solutions include adding a second transformer fed from B89H or installing an automatic transfer system that switches between Holland TS and B88H. Fixing this issue would improve local reliability, reduce exposure to load rejection events, and increase system capability by roughly 90 MW without requiring major new transmission infrastructure. Looking ahead, YEC plays a critical role in meeting Northern York's peak demand—about 400 MW.

The working group has considered different alternatives to enhance YEC station service upgrade including adding a second supply via the B89H tap or by implementing an automatic transfer between the Holland TS distribution supply and the existing B88H source during contingencies.

The preferred station service configuration should be determined through a detailed engineering evaluation of technical feasibility and cost.

If YEC retires when its contract expires in 2035, the region would face a large capacity shortfall that cannot be addressed through incremental upgrades alone. Without a comparable replacement (new transmission or new local generation), reliability would significantly decline, and connecting new loads in the area would become severely constrained.

The Working Group concurs that the IESO should formally engage with Capital Power to examine and evaluate potential alternative solutions in the event of a YEC phase-out by 2035, including consideration of a station service upgrade.

8.4.4 Holland Marsh Switching Station

The IRRP has identified the requirement for a Switching Station at the Holland Marsh junction arising from the planned addition of a third Northern York Transformer Station (TS) along the Claireville–Minden transmission corridor. The introduction of this new transformation facility will impose additional system security requirements, irrespective of whether it interconnects with circuits H82/83V or B88/89V. This portion of the transmission network is already operationally complex due to the presence of multiple inline breakers and its interface with the York Energy Centre (YEC).

The establishment of a new Switching Station (SS) at the Holland Marsh junction and sectionalizing the existing circuits at this Holland Marsh location would simplify system operations, facilitate the future integration of Northern York TS #3, and mitigate the most critical breaker failure contingencies that currently constrain system reliability. The proposed configuration would provide dedicated terminations for circuits H82/83V and the modified B88/89H circuits, a new radial supply connection for Armitage TS,

and allowance for future radial circuits serving the Bradford–West Gwillimbury area or other long term transmission developments.

Sufficient existing land rights are available to host the proposed facility, and the estimated capital cost for a switching station of this scale is in the range of $200–250 million. Final design and configuration details for the Switching Station will be addressed in the subsequent regional planning cycle.

The TWG will monitor the area loading and need and timing for Holland Marsh switching station will be reviewed in the next planning cycle.

8.4.5 New Northern York transmission supply option connecting Northern York area

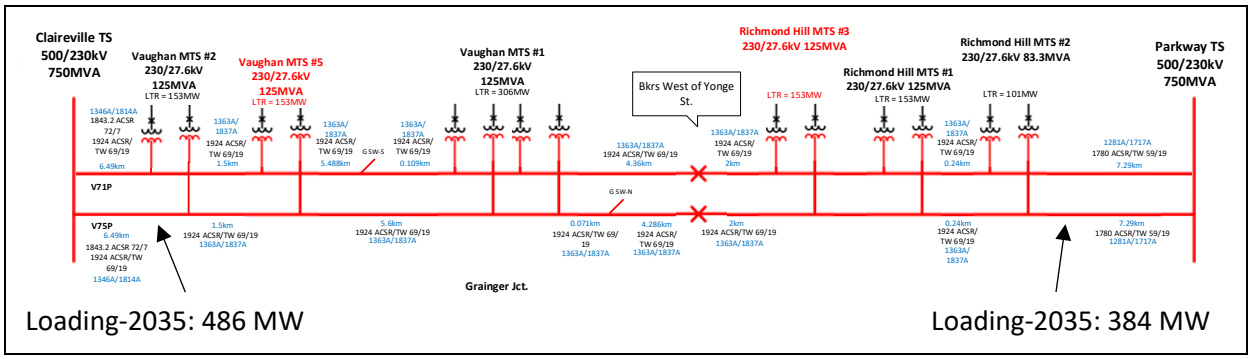
In addition to the Holland Marsh switching station described above, incorporating Northern York TS #3 or any other load request around this area beyond the planned Northern York TS #1 will also require additional supply resources. Options could include new transmission or potentially new generation facilities. One transmission option could be via an existing idle transmission corridor that runs from the Holland Marsh junction northwest through Bradford West Gwillimbury and onward into Simcoe County, connecting to Barrie TS and the planned Innisfil TS.

Utilization of this corridor will be assessed as the need date for Northern York TS #3 approaches to determine whether the benefits of positioning transformation capacity closer to emerging load centers outweigh the incremental transmission costs. Such benefits may include lower distribution system build-out costs, reduced connection costs for large customers, and improved reliability and power quality depending on where demand growth ultimately materializes.

Connecting any future station on a separate radial transmission path from Essa TS, as shown in Figure 27 below may help alleviate future capacity limitations on the Northern York circuits (H82/93V and B88/89H).

Figure 27: Conceptual Corridor route between Essa TS and Holland Marsh JCT (Courtesy: IESO)

An alternative option would be to upgrade the H82V/H83V circuit between Kirby Jct. and Holland Marsh Jct. The TWG will be further evaluating these options in the next planning cycle as longer-term supply and demand conditions become clearer such as YEC continued operation continuity and its Stations Service upgrade.



8.4.6 V71P/V75P 230kV in-line Breakers

The GTA north IRRP Study concluded that two in-line breakers are needed across that corridor to facilitate the restoration of load and mitigating the load security concerns to comply with Ontario Resource and Transmission Assessment Criteria (ORTAC). Although, the exact location of the in-line breakers will be determined considering the space availability and load distribution on both sides of breakers as per the table below, the working group has so far determined the location of the inline breakers on west of Yonge Street, between the Vaughan MTS #1 and Richmond Hills MTS #1/Richmond Hill MTS #2 as shown in the map (Figure 28) and single line diagram (Figure 29) below. Existing Grainger Jct. location may be utilized for the in-line breakers.

Figure 28: Approximate Location of V71P/V75P In-line Breakers

Figure 29: V71P/V75P 230kV In-line breakers SLD

The timing of this project's in-service is planned as year 2030 and shall be coordinated simultaneously with the addition of new Richmond Hill MTS #3 connection project. The approximate estimate for the cost is around $30M – $35M and will take around 3-4 years to complete the work. With the installation of in-line breakers, there will be a quick restoration of the load and load security concerns exceeding 600 MW load interruption will be mitigated.

8.4.7 Claireville to Minden - Over voltages and Under voltage needs.

8.4.7.1 Overvoltages

It is appropriate to mention the previously identified overvoltage concerns for YEC Station Service upgrade as the simultaneous loss of B88H and B89H removes Armitage TS, Brown Hill TS, and YEC from service, resulting in a lightly loaded radial supply from Minden TS to Beaverton TS and Lindsay TS. Due to the long circuit lengths and low load conditions, this configuration can lead to unacceptably high voltages. The risk is further exacerbated by capacitor banks at Beaverton and Lindsay TS, which are designed to support voltage under higher load conditions. Although this issue was identified in the previous IRRP too and mitigation measures have not yet been fully implemented. Unacceptable high voltages have not been observed to date. The working group agrees to continue monitoring the overvoltage issue and left open for discussion for the next planning cycle.

8.4.7.2 Undervoltages and M6E/M7E Thermal Overloads

Following the simultaneous loss of H82V and H83V, the subsystem becomes radially supplied from the north via Minden TS on B88/89H. Due to the long circuit lengths - particularly under high load conditions—voltage drops to unacceptable levels. In this configuration, York Energy Centre is unable to provide voltage support, as its station supply from Holland TS is lost. This contingency also results in overloads on sections of the M6E/M7E[6] circuits between Cooper Falls X Orillia along Essa TS and Minden TS corridor, which

[6] This was flagged as an issue for H82/83V outages which also take YEC out of service. Once the YEC station service issue is resolved this should not be a problem for York region at least.

become a primary remaining supply path into Northern York. While the YEC BESS remains in service and provides limited support, it is insufficient to resolve either the voltage issues or the M6E/M7E overloads. This need will be studied under the South Georgian Bay Muskoka IRRP.

8.4.8 Upgrading H82V/H83V circuits from Kirby Jct. to Holland Marsh Jct.

As discussed below, reconductoring the most constrained portion of circuits H82/83V between Claireville TS and Vaughan MTS #4 is not considered feasible due to the limited width of the existing transmission corridor and the close proximity of surrounding development. These physical constraints significantly limit constructability within this section.

North of the proposed Kleinburg–Kirby connection point development along the H82/83V corridor is substantially less dense. Based on a review conducted by Hydro One, reconductoring the portion of H82/83V as shown in Figure 30 between Kirby Jct. and the Holland Marsh junction is expected to be technically feasible.

Figure 30: Section of H82V/H83V from Kirby Jct. to Holland Marsh (23 km)

Following the completion of the York Energy Centre (YEC) station service project as discussed in Section 8.4.3, and the Kleinburg–Kirby Transmission Link, additional load meeting capability in Northern York is not anticipated to be required until a further step-down station is needed (notionally Northern York TS #3) and/or in the event of a potential retirement of YEC.

The degree of benefit provided by reconductoring this northern section of H82/83V would be dependent on the long-term configuration of the transmission system, including the spatial distribution of future demand and supply, as well as the development of any new infrastructure such as switching facilities. Where thermal limitations on the H82/83V circuits become binding, reconductoring this section could

help alleviate those constraints and increase load meeting capability by providing additional capacity into a future Holland Marsh Switching Station as discussed in Section 8.4.4.

Reconductoring the northern portion of H82/83V presents a potential cost-effective means of increasing capacity where corridor constraints are less pronounced and constructability risks are reduced. This option leverages existing infrastructure and rights-of-way, potentially avoiding the need for new corridors. However, its benefits are highly dependent on future system topology, including the timing and location of new step-down stations, changes in load growth patterns, and the availability of complementary infrastructure such as switching stations. As a result, reconductoring should be considered a conditional or enabling measure rather than a standalone solution and will be further discussed further in the next regional planning cycle.

Figure 31: a & b Alternate Route - Section upgrade north of Kirby to Holland Marsh (Courtesy: IESO)

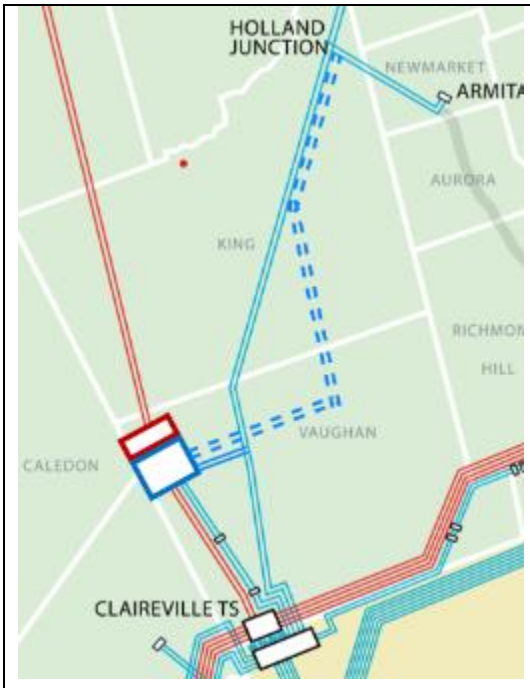


Figure 31-a

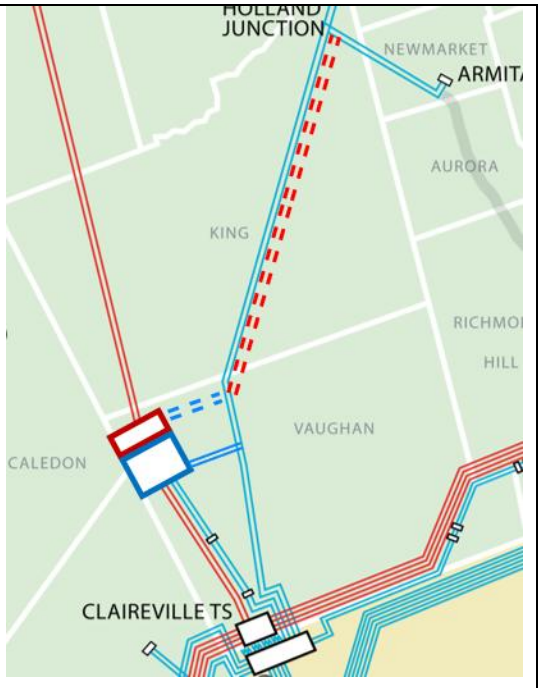

Figure 31-b

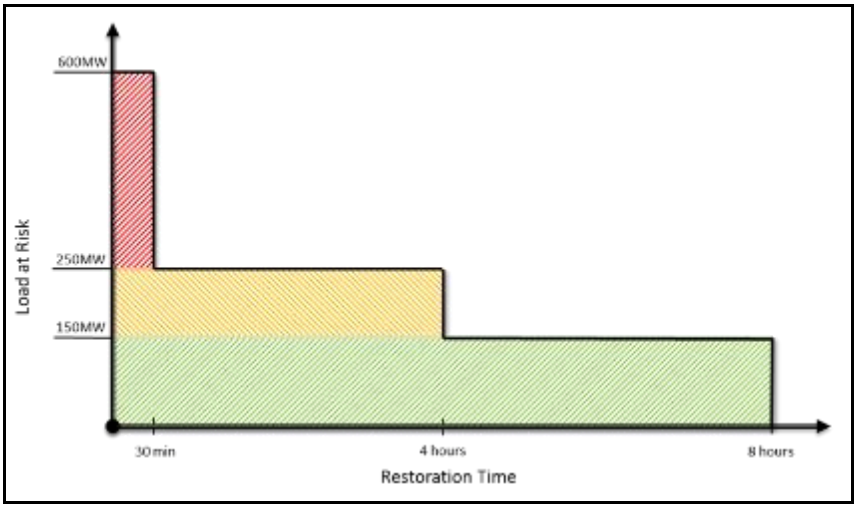
Alternatives and Recommended Plan



The working group has also considered the alternate route – new 230 kV circuits as shown in Figure 31-a, but not preferred due to the cost, timelines and challenges associated with acquiring new right of way and Environmental Screening. The working group has also explored to run the new line parallel to the existing one as it is easier to widen the existing right of way versus building brand new one as shown in Figure 31-b.

The TWG agreed to examine alternatives in the next regional planning cycle, including reconductoring the H82V/H83V segment north of Kirby Junction or developing a new line parallel to the existing infrastructure and any other options best suited to the needs of the region.

8.5 Load Security and Restoration Needs

Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to a customer affected by a transmission outage within specified time frames. Both transmission and distribution (transfer) measures are considered when evaluating restoration capability. The load restoration criteria is defined in ORTAC and summarized in Figure 32.

Figure 32: ORTAC Criteria

8.5.1 Western Area: Load Security and Restoration on Kleinburg Radial Tap (V43/44)

The Kleinburg Radial tap consists of the two 230kV transmission circuits, V43 and V44, which extend northwest from Claireville TS. These circuits currently supply Woodbridge TS, Vaughan MTS #3, and Kleinburg TS, with ongoing development plans for a new step-down facility, Vaughan MTS #6, intended to serve growing commercial demand in the area. Under normal system conditions, the southern portion of this corridor also provides partial supply support to the adjacent Goreway TS in Brampton.

Peak demand within the Kleinburg radial load pocket is projected to exceed 600 MW by summer 2029 as shown in the Table 15 below.

Table 15: Load Security and Restoration on Kleinburg Radial Tap

V43/V44	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Kleinburg tap Load (MW)	522	534	597	607	644	645	656	676	691	687

Load Security

As described in Section 8.4.2, the proposed Kleinburg 500/230 kV Auto Station will address supply capacity and load security requirements in the Western region. By connecting the Kleinburg DESNs directly to the new 230 kV bus, loading on V43/V44 will be reduced to less than 600 MW, improving overall system performance.Load Restoration

Load restoration was assessed for 230kV radial double circuit line V43/V44 supplying the stations. In case of a double circuit outage of the V43/V44 line, not all loads in excess of 250 MW can be restored within 30 minutes, as per the ORTAC restoration criteria. The V43/V44 line is approximately 12 km long with good accessibility by maintenance crews and Hydro One expects all load to be restored within 4 hours with at least one circuit back into service.

Alternatives and Recommendations

The Working Group agreed that no further action is required at this time. However, the need will be reviewed in the next iteration of the regional planning cycle. The historical reliability of these circuits has been good with no coincidence outages of the two circuits; there have only been two direct outages[7] to circuit V43 since 2008 and no direct outages to circuit V44 since 2009. While there are no short-term plans to address this need, the Kleinburg to Kirby option to address supply capacity needs in the long term would also improve the load restoration capability for these circuits.

8.5.2 Northern Area - Load Security and Restoration[8]

8.5.2.1 Northern Area - Load Restoration from Claireville TS to Holland TS circuits (H82V/H83V)

Load restoration was assessed for 230kV circuits H82V/H83V supplying Vaughan #4 MTS and Holland TS. In case of a double circuit outage of H82V/H83V, not all loads exceeding 250 MW can be restored within 30 minutes per the ORTAC criteria. However, Hydro One expects all loads to be restored within 4 hours with one circuit back in service.

[7] A direct outage is reported whenever a major component is in the outage state due to a condition or equipment failure directly associated with it.

[8] H1-Dx is assessing limited service territory adjustments at the Holland–Armitage and Brown Hill TS boundary to enhance restoration capability. While large-scale load transfers are constrained, targeted boundary changes could provide near-term flexibility and deliver lasting restoration benefits, maintaining value even after a future station enters service.

Alternatives and Recommendations

Following the loss of H82V/H83V, the normal station service supply to YEC generation will also be lost. Holland TS cannot be restored from B88H/B89H until YEC generation is restored. Transferring YEC to an alternate source of station service supply cannot be completed within 30 minutes. Therefore, the Working Group recommends that the IESO identify and consider the possibility of a new station service supply arrangement at YEC to enable faster restoration of load on H82V/H83V, consistent with the load restoration criteria.

8.5.2.2 Northern Area- Load Restoration from Holland TS to Brown Hill TS circuits (B88H/B89H)

Load security issues would arise by the year 2035 where load more than 600 MW could be interrupted as shown in Table 16 below, that will be further discussed in the next planning cycle.

Table 16 Load Security Issue on B88H/B89H

Net Summer Load Forecast										
B88H/B89H	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Holland TS- Brown Hill TS (MW)	494	501	501	501	576	576	576	576	589	636

Load restoration was assessed for 230kV circuits B88H/B89H supplying Armitage TS, Northern York TS-1 and Brownhill TS and the customer Load. In case of a double circuit outage of B88H/B89H, not all loads exceeding 250 MW can be restored within 30 minutes per the ORTAC criteria. However, Hydro One expects all loads to be restored within 4 hours with one circuit back in service.

8.5.3 Southern Vaughan -Richmond Hill Area- Load Security and Restoration on V71P/V75P

The Parkway to Claireville line (V71P/V75P) is located on the Parkway Belt and supplies five load stations with a combined load of approximately 700 MW under current summer peak loading conditions. The load security criteria in ORTAC limits the amount of load that can be interrupted due to the loss of two elements (e.g.: a double circuit line outage) to 600 MW under peak load. On the Parkway to Claireville line, that limit is exceeded.

The load on the corridor already exceeded 600 MW ORTAC Criteria and in the past the transmitter installed in-line switches at Grainger Jct. just outside the Vaughan MTS #1 to mitigate the restoration concerns. But there are existing load security issues that will further exacerbate the load security concerns with the addition of two new transformer stations by 2035. Table 17 below is the summary of the loading on the corridor till 2035.

Table 17: Load Security > 600 MW (V71P/V75P)

Clareville X Parkway	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
V71P/V75P Loading (MW)	700	695	713	713	739	761	809	898	862	870

To address the existing load security issue, working group has recommended the installation of inline breakers as discussed in Section 8.4.6

Load restoration was assessed for 230kV circuits V71P/V75P supplying Vaughan MTS #2, Vaughan MTS #5, Vaughan MTS #1, Richmond Hill MTS #1, Richmond Hill MTS #2, and Richmond Hill MTS #3. In case of a double circuit outage of V71P/V75P, not all loads exceeding 250 MW can be restored within 30 minutes per the ORTAC criteria. However, Hydro One expects all loads to be restored within 4 hours with one circuit back in service.

8.5.4 Markham Area- Load Security and Restoration on Buttonville Corridor (P45/P46)

Load security issues would arise by the year 2034 where load in excess of 600 MW could be interrupted as shown in Table 18 below. Woking group will continue to monitor the load growth in the area and will discuss the potential solutions in the next planning cycle.

Table 18: Load Security on Buttonville Tap (P45/P46)

P45/P46 Corridor	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Total Load (MW)	261	299	306	327	363	512	542	587	651	708

Following reconductoring of P45/P46 to address thermal constraints; the addition of longer-term stations on the P45/46 circuits would still trigger load security needs once total load exceeds 600 MW. To mitigate this, and as discussed in Section 8.3.1.4, a new radial circuit could be extended from the southern transmission corridor near Highway 407 to supply Markham MTS #4, removing it from P45/46. This would increase area load meeting capability by approximately one station's worth of load and simultaneously mitigating the load security issue on P45/46 corridor as shown in Table 19 below, as no ORTAC > 600 MW load security violation observed till year 2035.

Table 19: Load Security on Buttonville Tap (P45/P46)- after Markham MTS #4 off loading

P45/P46- Corridor	2026	2027	2028	2029	2030	2031	2032	2033	2034	2035
Total Load (MW)	150	150	153	174	210	316	389	434	498	555

Load restoration was assessed for 230kV radial double circuit line P45/P46 supplying Markham MTS #4, and Buttonville TS, and in future Buttonville TS #2, Northern York TS #2 and Markham MTS #6 supplying primarily urban communities in Markham Area.

In case of a double circuit outage of the P45/P46 line, not all loads more than 250 MW can be restored within 30 minutes, as per the ORTAC restoration criteria. The P45/P46 line is approximately 4 km long with good accessibility by maintenance crews of Alectra expect all load to be restored within 4 hours with at least one circuit back into service.

9 CONCLUSION AND RECOMMENDATION

This section concludes the Regional Infrastructure plan Report for GTA North region. The Major Infrastructure investments recommended by the TWG in the near and mid-term planning horizon [2026-2035] are provided in Table 20 below, along with their planned in-service dates (ISD) and budgetary estimates for planning purposes.

Table 20: Recommended Plans over the next 10 Years

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Budgetary Cost ($M) *
Asset Renewal Needs				
Woodbridge TS	Transformer (T5) refurbishment	Hydro One	2032	TBD
Station Capacity Needs[11]				
Kleinburg TS	Adding Kleinburg TS (T3/T4) — (230/44kV)	Hydro One	2028	$40M
Vaughan MTS #6	Build Vaughan MTS #6 (T3/T4) 27.6 kV DESN	Alectra	2027	$55M-$65M
Northern York TS #1	Build Northern York TS #1 230/44kV DESN	Hydro One	2031	$55M-$65M[12]
Northern York TS #3	Build Northern York TS #3 230/44kV DESN	Hydro One	2035	$55M-$65M
Richmond Hill MTS #3	Build Richmond Hill MTS #3 230/27.6kV DESN	Alectra	2030	$55M-$65M
Vaughan MTS #5	Build Vaughan MTS #5 230/27.6kV DESN	Alectra	2033	$55M-$65M
Buttonville TS #2	Build Buttonville TS #2 230/27.6kV DESN	Hydro One	2030	$55M-$65M

[11] Costs for the new Stations can vary based on location, configuration, layout, environmental issues etc.

[12] Additional cost could incur depending upon the location of the Tx Station and the circuit tap length– overhead / underground required.

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Budgetary Cost ($M) *
Markham MTS #6	Build Markham MTS #6 230/27.6kV DESN	Alectra	2034	$55M-$65M[13]
Northern York TS #2	Build Northern York TS #2 230/44kV DESN	Hydro One	2034	$55M-$65M[14]
Transmission Line Capacity Needs				
P45/P46	Upgrade P45/P46 from Parkway TS to Markham MTS #4	Hydro One	2031	$5M
P45/P46	Upgrade P45/P46 from Markham MTS #4 to Buttonville TS	Hydro One	2034	$10M
P45/P46	Extend and build P45/P46 Buttonville TS 7km North	Hydro One	2034	$50M
C35P/C36P	Reconnect Markham MTS #4 to C35P/C36P	Hydro One	To be discussed in the next Regional Planning cycle[15]	$9M
System Reliability				
Kleinburg TS	Build Kleinburg to Kirby Transmission Link	Hydro One	2031-2032	$40M - $60M[16]
Kleinburg TS	Bulk Supply - 500/230 kV Transformer Station	Hydro One	2031-2032	$400M
York Energy Centre	York Energy Centre – Station Service Upgrade	Capital Power	2026 (Current)	IESO to coordinate with Capital Power
Holland Marsh SS	Holland Marsh Switching Station	IESO	To be discussed in the next	TBD-Next Planning Cycle

[13] The cost does not include building 230kV line to supply the new TS
[14] The cost does not include building 230kV line to supply the new TS
[15] IRRP recommended that this coincides with connection of Markham#6 or NY-TS2 (whichever is required first)
[16] Refer to Appendix-F for additional reference to the need, recommendation and the cost.

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Budgetary Cost ($M) *
			Regional Planning cycle	
Essa/Barrie to Holland Marsh	New Northern York Transmission Supply	IESO	To be discussed in the next Regional Planning cycle	TBD-Next Planning Cycle
V71P/V75P	In-line Breakers	Hydro One	2030	$30M-$35M
H82V/H83V-B88H/B89H and M6E/M7E[17]	Claireville to Minden: Over voltages (H82V/H83V); Under voltages (B88H/B89H), and Thermal Needs (M6E)	IESO/Hydro One	TBD/Continued to be monitored	TBD/Continued to be monitored
H82V/H83V	Upgrading the portion of H82V/H83V from Kirby Jct. to Holland Marsh (23km)	IESO /Hydro One	To be discussed next Regional Planning cycle	(To be discussed next Planning Cycle)
Load Security and Restoration				
V43/V44	Load Security on Kleinburg Radial Tap	Hydro One	2031-2032	N/A
H82V/H83V and B88H/B89H	Load Security and Restoration in Northern Area	Hydro One	2031-2032[18]	N/A
H82V/H83V	Load Restoration from Claireville TS to Holland TS Circuits (H82V/H83V)	Hydro One	2031-2032	N/A
B88H/B89H	Load Restoration from Holland TS to Brown Hill TS	Hydro One	2031-2032	N/A

[17] M6E/M7E circuit boundaries are outside of GTA North Region Scope and thermal issues will be dealt by IESO at Bulk level.

[18] YEC Station Service upgrade and Marsh Switching Station would mitigate load restoration and security issue.

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Budgetary Cost ($M) *
	Circuits (B88H/B89H)			
V71P/V75P	Load Security and Restoration on V71P/V75P	Hydro One	2030	$35M[19]
P45/P46	Load Security and Restoration on Buttonville Corridor (P45/P46)	Hydro One	2034[20]	$9M[21]

* The cost figures presented are high-level allocations in 2025 dollars and have not been informed by detailed engineering design or development work. Accordingly, these estimates are preliminary in nature, subject to material change, and are intended for options analysis purposes only

[19] The $-figure reflects the cost associated with inline breakers at V71P/V75P to mitigate load security issues.
[20] Load Security issue is triggered in year 2034 when LF > 600 MW.
[21] The $-figure reflects the cost associated with Markham MTS#4 re-termination to C35P/C36P

March 20, 2026

Robert Reinmuller

Vice President, Transmission System Planning and Large Customer Accounts Hydro One Networks, Inc.

483 Bay Street, TCT 14

Toronto, ON

M5G 2P5

Dear Robert:

Implementation Update for the Kleinburg-Kirby 230 kV Transmission Link

The IESO is providing this letter to Hydro One Networks Inc. (“Hydro One”) in response to

Hydro One’s ongoing development of the GTA North (York Region) Regional Infrastructure Plan (“RIP”). The RIP is expected to include a near-term recommendation to proceed with a new double-circuit 230 kV transmission line, the Kleinburg–Kirby Link (the “Project”), consistent with the recommendations in the 2025 IESO’s GTA North (York Region) Integrated Regional Resource Plan (“IRRP”). The IESO requests that

Hydro One append this letter to the RIP to identify the IESO's recommendations on the Project's scope, timing, and implementation.

The 2025 GTA North (York Region) IRRP was published on October 10th, 2025. Among its recommendations was the development of the Project, to be co-located with the future Highway 413 corridor, to support growing electricity demand in northern York region. The Project will establish a new connection between the existing 230 kV radial transmission system in Kleinburg (at the proposed expanded Kleinburg TS) and the 230 kV transmission system north of Claireville TS, terminating on the existing H82/83V circuits north of Vaughan MTS #4, close to the intersection with Kirby Rd. This new connection is critical for enabling the full loading of the recommended Northern York TS #1 and was recommended in the 2025 GTA North (York Region) IRRP to come in service in 2032.

Following the publication of the 2025 GTA North (York Region) IRRP, the IESO assessed whether the Project was suitable for development under the Transmitter Selection Framework ("TSF"). The IESO has determined that the Project is not a candidate for the TSF for the following reasons:

1. Project scope and cost: The expected cost of the Project is well below the $100 million proposed eligibility criterion for the TSF. Transmission line construction costs for the Project are projected to be approximately $40 million (2025 dollars). While the IESO recognizes that additional project costs due to factors such as land topography, finalized routing and design, land acquisition, community engagement and system integration are possible, the total cost of the Project, inclusive of these factors, is still expected to remain well below $100 million.
2. Development timeline: Meeting the targeted 2032 in-service date is essential to enabling forecast customer growth and connections throughout northern York region, as identified in the 2025 GTA North (York Region) IRRP. The TSF is not anticipated to launch prior to 2027, so using a TSF procurement process could create a material risk of missing the Project's 2032 targeted in-service date.

For these reasons, the IESO recommends that Hydro One proceed with the necessary development work for this Project. This development work should align with the outcomes of the RIP and remain consistent with the IRRP's recommendations and support achieving the targeted 2032 in-service date.

The IESO looks forward to continued collaboration as Hydro One advances this important infrastructure project.

Yours truly,

Gabriel Adam, P.Eng.

Director, Transmission Integration

List of Acronyms

Acronym	Definition
CCAP	Climate Change Action Plan
CCGT	Combined Cycle Gas Turbine
CDM	Conservation and Demand Management
CEP	Community Energy Plan
DER	Distributed Energy Resource
DG	Distributed Generation
ERP	Enabling Resource Program
FETT	Flow East Towards Toronto
GS	Generating Station
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
LDC	Local Distribution Company
LTE	Long-term Emergency (Equipment Rating)
MTO	Ministry of Transportation
NCM	Lithium Nickel Manganese Cobalt Oxide
NERC	North American Electric Reliability Corporation
OEB	Ontario Energy Board
ORTAC	Ontario Resource and Transmission Assessment Criteria
RIP	Regional Infrastructure Plan
SCGT	Simple Cycle Gas Turbine
STE	Short-term Emergency (Equipment Rating)
TS	Transformer Station

This Integrated Regional Resource Plan (IRRP) was prepared by the Independent Electricity System Operator (IESO) pursuant to the terms of its Ontario Energy Board licence, EI-2013-0066.

This IRRP was prepared on behalf of the Technical Working Group (Working Group) of the Greater Toronto Area West (GTA West) region which included the following members:

Independent Electricity System Operator

Hydro One Networks Inc. (Distribution)

Hydro One Networks Inc. (Transmission)

Alectra Utilities

Burlington Hydro Inc.

Milton Hydro Distribution Inc.

Oakville Hydro Electricity Distribution Inc.

Halton Hills Hydro

The Working Group assessed the reliability of electricity supply to customers in the GTA West Region over a 20-year period beginning in 2019; developed a plan that considers opportunities for regional coordination in anticipation of potential demand growth and varying supply conditions in the region; and developed an implementation plan for the recommended options, while maintaining flexibility in order to accommodate changes in key conditions over time.

The GTA West Working Group members agree with the Integrated Regional Resource Plan (IRRP)'s recommendations and support implementation of the plan, subject to obtaining necessary regulatory approvals and appropriate community consultations. The GTA West Working Group members do not commit to any capital expenditures and must still obtain all necessary regulatory and other approvals to implement recommended actions.

1. Introduction

This Integrated Regional Resource Plan (IRRP) addresses the electricity needs of the Greater Toronto Area West region (GTA West) over the next 20 years from 2019 to 2038. The GTA West region is located in central Ontario and includes the Regional Municipalities of Halton and Peel. The region includes the area roughly bordered geographically by Highway 27 to the north east, Highway 427 to the south east, Regional Road 25 to the west, King Street to the north and Lake Ontario to the south. The GTA West region comprises the municipalities of Brampton, Caledon, Halton Hills, Mississauga, Milton, Oakville and portions of Burlington.

During discussions with communities, the IESO received feedback that the name "GTA West Regional Planning" was challenging to differentiate from other initiatives underway in the area with a similar naming convention, thus, the region was changed to "Peel/Halton (GTA West) Region" for engagement purposes. Official planning documents continue to adhere to the regulatory name of "GTA West Region".

The GTA West region is summer peaking and, over the last five years, electrical demand has grown on average by 1.3% per year. Electrical supply to the GTA West region is provided through 500/230 kV autotransformers at Trafalgar TS and at Claireville TS and 230 kV transmission lines and step-down transformation facilities as shown in Figure 1.1. The GTA West Region is defined electrically by the 230 kV transmission circuits bounded by Claireville TS, Richview TS and Manby TS to the east and Burlington TS to the west. Local generation in the area includes two gas fired plants: the 1250 MW Goreway Generating Station (GS) in Brampton and the 600 MW Halton Hills GS in Halton Hills.

The region's electricity is delivered by six local distribution companies (LDCs): Hydro One Networks, Alectra Utilities, Burlington Hydro, Milton Hydro Distribution, Oakville Hydro Electricity Distribution, and Halton Hills Hydro. Hydro One Networks is also the primary transmission asset owner. This IRRP report was prepared by the Independent Electricity System Operator (IESO) on behalf of a Working Group composed of the aforementioned LDCs and transmitter.

Development of the GTA West IRRP was initiated in August 2019 following the publication of the Needs Assessment report in May 2019 by Hydro One and the Scoping Assessment Outcome Report in August 2019 by the IESO. The Scoping Assessment identified needs that should be further assessed through an IRRP. The Working Group was then formed to gather data, identify near- to long-term needs in the region and develop the recommended actions included in this IRRP.

This report is organized as follows:

- A summary of the recommended plan for the region is provided in Section 2;
- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the region and the study scope are discussed in Section 4;

- Demand forecast scenarios, and conservation and demand management and distributed generation assumptions, are described in Section 5;
- Electricity needs in the region are presented in Section 6
- Alternatives and recommendations for meeting needs are addressed in Section 7
- A summary of engagement to date and moving forward is provided in Section 8; and
- The conclusion is provided in Section 9

Figure 1.1 | Geographical area of the GTA West region with electrical layout

2. The Integrated Regional Resource Plan

This Integrated Regional Resource Plan (IRRP) provides recommendations to address the electricity needs of the GTA West region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by the North American Electric Reliability Corporation (NERC). The IRRP's recommendations are informed by an evaluation of options, representing alternative ways to meet the needs, that consider: reliability, cost, technical feasibility, maximizing the use of the existing electricity system (where economic), and feedback from stakeholders.

The GTA West electricity demand forecast projects sustained growth driven by urbanisation and development particularly in the northern areas of the region. Municipalities have also published community energy plans and/or climate change action plans that call for greater electrification which could drive additional upward pressure on the demand forecast.

The IRRP recommendations below are organized under a near-/medium-term plan and a long-term plan. This distinction reflects the different levels of forecast certainty, lead time for development, and planning commitment required over these time horizons. This approach ensures that the IRRP provides clear direction on investments needed in the near future while remaining flexible to new information as electrification, energy efficiency, and development plans evolve.

2.1 Near-/Medium-Term Plan

The near- and medium-term plan is comprised of several recommendations to accommodate load growth, maintain reliability, and optimize end-of-life asset replacement. The recommendations are summarized in Table 2.1 and further discussed below.

Table 2.1 | Summary of Near-/Medium-term Plan for the GTA West Region

Need Description	Recommendation	Lead Responsibility	Required By
After a loss of either H29 or H30, the remaining circuit will exceed its LTE rating	H29/H30 reconductoring	Hydro One	2025
After a loss of V42H and H29, R19TH will exceed its LTE rating. After a loss of V41H and H30, R21TH will exceed its LTE rating	Control actions and/or load rejection scheme	Hydro One	Today

Need Description	Recommendation	Lead Responsibility	Required By
Transformers T3 and T4 at Palermo TS will reach end-of-life	Upsize transformers at end-of-life to the larger 75/125 MVA transformers	Hydro One	2025
Simultaneous loss of both T38B and T39B would result in over 600MW of load being lost by configuration	Further analysis of wires options including circuit sectionalisation and/or reterminating supply stations	Hydro One	2025
30-minute load restoration following V41H/V42H, R19TH/R21TH, and R14T/R17T6 contingencies	Investigate opportunities to enhance distribution load transfer capabilities	LDCs with loads on impacted circuits	Ongoing

2.1.1 H29/H30 Reconductoring

When load at Pleasant TS exceeds approximately 417 MW and one of the H29/30 circuits that supplies Pleasant TS is out of service, there is a potential for overloads on the companion circuit. This need was originally identified in the 2015 Northwest GTA IRRP and upgrading the H29/H30 circuits with conductors of a higher rating was recommended. At the time, the demand forecast was only expected to reach 417 MW in 2033 but the IRRP recognized that this timing could change significantly if higher growth or lower conservation adoption materialized and consequently recommended that the load at Pleasant TS should be monitored and the reconductoring work should be pursued when demand reaches approximately 400 MW.

As discussed in the 2019 GTA West Scoping Assessment report, the role of the current IRRP is to update the implementation timing of this upgrade, not further investigate alternatives to it, given the relatively straightforward scope. The current forecast for Pleasant TS projects demand to reach 417 MW by 2027. However, the observed 2020 summer peak demand was much higher than anticipated and reached 410 MW during a July heat wave. At this time, it is still unclear whether this is an isolated event related to the ongoing COVID-19 pandemic and associated electricity consumption patterns or if this will be an enduring trend. Given that the lead time required to implement the reconductoring work will be at least three years, the IRRP recommends that Hydro One should begin implementation as soon as possible for a targeted in-service date around 2025.

2.1.2 Pleasant TS Control Actions

Post-contingency thermal violations during outage conditions are expected to occur on the R19TH/R21TH circuits leading into Hurontario SS by 2021. This type of contingency is expected to be very infrequent since it only occurs under the confluence of peak load conditions, hot weather, pre--existing forced outage on one element and a subsequent contingency on another. As a result, this need is most economically managed by control actions or load rejection schemes. Alternative options considered are further discussed in Section 7.2.

In the near- to medium-term, the overloads on R19TH/R21TH are expected to exceed their long-term emergency (LTE) but not their short-term emergency (STE) rating. During this period, manual post--contingency control actions such as unloading one of the two transformers at Jim Yarrow TS can provide relief by reducing circuit loading below the LTE rating provided that such actions can be completed within 15 minutes. As load continues to grow, the overloads are expected to exceed STE by 2038 at which point an automatic load rejection scheme at Pleasant TS will be required. The IRRP recommends that the Regional Infrastructure Plan (RIP) led by Hydro One should develop and implement control actions as soon as possible.

2.1.3 Upsizing Palermo TS at End-of-Life

The existing T3 and T4 transformers at Palermo TS will reach end-of-life in 2025. Palermo TS is fully utilized today and there is no remaining capacity for growth. Tremaine TS, a nearby station, is also expected to exceed capacity in 2033.

Refurbishing Palermo TS with larger 75/125 MVA transformers would require significant station reconfiguration. However, Hydro One indicated that the yard itself is in relatively poor condition, had recently been downgraded, and will likely need to be replaced in less than 10 years regardless of the transformer size chosen. Based on planning-level cost estimates, the cost of upsizing Palermo TS when its transformers reach end-of-life in 2025 is substantially more cost-effective than the alternative of refurbishing Palermo TS like-for-like in 2025 followed by subsequent upsizing or building a new station when capacity needs arise in 2033. This financial analysis is further discussed in Section 7.3. The IRRP recommends that the RIP should perform additional analysis to reaffirm the cost estimate and develop an implementation plan for upsizing Palermo TS in 2025.

2.1.4 Further Wires Analysis for T38B/T39B Load Security

The load security need on T38B/T39B was initially documented in the 2015 Northwest GTA IRRP and was expected to materialized between 2024 and 2026. No firm recommendation was made at the time because the need was still approximately 10 years off and future bulk system reinforcements along the Flow East Towards Toronto (FETT) interface may also address the load security need.

The current IRRP forecast reaffirms that the load security need is expected to materialize in 2025. Furthermore, in December 2020, the IESO determined that the most suitable and cost-effective bulk system FETT interface reinforcement are conductor upgrades to the Richview TS x Trafalgar TS 230 kV transmission lines which does not resolve the load security need on T38B/T39B. The FETT interface bulk study is further discussed in Section 4.2.

The IRRP considered the merits of generation, non-wires options and an integrated transmission option, the Hurontario SS x Meadowvale TS transmission reinforcement, that could simultaneously improve bulk system transfer capabilities and help alleviate the load security need on T38B/T39B. Ultimately, wires options such as reterminating Tremaine TS on the companion T36B/T37B circuits or installing breakers at Lantz Junction to sectionalize T38B/T39B are the most suitable and -cost-effective solution at this time. The options analysis is further discussed in Section 7.4.

The IRRP recommends that the RIP should perform detailed analysis to further refine the technical feasibility and costs of these wires options. As part of this work, the RIP should update the near-term load forecast for the stations served on T38B/T39B. The IRRP also recognizes that there may be merit in applying to the IESO for an ORTAC exemption to accept a lower performance level for a few years until future FETT transfer capability needs in the late 2020's are known given the potential integrated nature of the solutions that could address these needs. The IESO will continue to participate in the RIP technical working group to provide advice and input on this matter.

2.1.5 Explore Opportunities to Enhance Distribution Transfer Capabilities

All stations in the GTA West region have dual supply meaning that no load would be lost by configuration for any single contingency. However, there are multiple areas in the GTA West region where major transmission contingencies (such as the simultaneous loss of two elements) would interrupt supply to many customers and where full restoration would be delayed until the transmission contingency has been cleared. The GTA West region is a densely populated and well serviced area so it is assumed that all contingencies can be restored within eight hours consistent with ORTAC load restoration criteria. Most major contingencies have historically been of short duration due to close proximity to staffed maintenance centres. Of the remaining restoration criteria, the 30-minute restoration of all load lost above 250 MW is the most limiting since it relies on remote control actions such as emergency distribution load transfers.

As discussed in the Scoping Assessment, major infrastructure solutions such as new transmission facilities are not generally appropriate since the cost of the solution would exceed the expected benefit to customers. However, restoration needs were kept in scope for this IRRP to evaluate if planned infrastructure solutions for other needs can be modified in ways that maximize restoration capability.

Of the double circuit contingencies where the 30-minute restoration criteria cannot be met, infrastructure solutions for H29/H30 was deemed uneconomic in the previous IRRP due to the high cost and low probability of the contingency occurring while T38B/T39B restoration needs can be significantly improved through the wires options discussed in the previous section for addressing load security.

There remain three double contingencies that are at risk of not meeting 30-minute restoration criteria: V41H/V42H, R19TH/R21TH, and R14T/R17T. At this time, there are no planned infrastructure reinforcements for other needs that can also help improve load restoration on these circuits. However, the IRRP recommends that local distributors, in conjunction with Hydro One where appropriate, investigate opportunities to improve distribution load transfer capability from the stations supplied on these circuits to other nearby stations to maximize restoration capability.

In the long term, future transmission reinforcement projects such as the NW GTA Transmission Corridor can help improve load restoration by providing additional supply points from which northern loads can be restored.

2.2 Long-Term Plan

In addition to the near- and medium-term plan above, there are four items to monitor and develop in the long term.

2.2.1 Monitor Halton Pocket Growth and T38B/T39B Reconductoring

During an outage to Halton Hills GS, post-contingency thermal violations on T38B/T39B are expected to occur by 2031. The thermal violation is on a short 400-meter section of T38B/T39B immediately north of Lantz Junction. This radial portion of T38B/T39B serves the Halton Pocket including Trafalgar DESN, Halton TS, Halton TS #2, Halton MTS, and Meadowvale TS.

Reconductoring the limiting section is the most cost-effective option. The options analysis is further discussed in Section 7.5. Given the timing of the need, no firm recommendation is required at this time. The Working Group will continue to monitor load growth in the Halton Pocket and revisit this need, and its potential alternatives, in the next cycle of regional planning.

2.2.2 Monitor Growth at Cardiff TS and Jim Yarrow TS

Cardiff TS and Jim Yarrow TS are expected to reach capacity in 2029 and 2032, respectively. Given the timing of the need, no firm recommendation is required at this time. The Working Group will continue to monitor load growth and revisit this need in the next cycle of regional planning.

2.2.3 Supporting Community Energy Plans and Monitoring Energy Efficiency and Electrification Trends

Most lower- and upper-tier municipalities in the GTA West region have published community energy plans (CEP) or climate change action plans (CCAP) including the:

- Region of Peel's Climate Change Master Plan,
- Town of Oakville's Community Energy Strategy,
- Town of Caledon Community Climate Change Action Plan,
- Town of Halton Hills' Community Energy Plan,
- City of Brampton Community Energy and Emissions Reduction Plan,
- City of Burlington's Climate Action Plan, and
- City of Mississauga Climate Change Action Plan to name a few.

The scope varies by municipality and plan but the general aim is to promote energy efficiency, improve resiliency, lower greenhouse gas emissions, and invest in the local economy.

While the IRRP seeks to align with these plans where possible, not all of the objectives fall within the scope of the regional planning nor the IESO's mandate. For example, absent of provincial government policy, the IESO is technology agnostic and will generally choose the most economic option that adequately resolves the need and meets applicable reliability standards. Greenhouse gas emissions are considered in the IRRP's options analysis by accounting for the carbon price associated with emitting resources, but the IESO does not have emission reduction targets unless directed by government policy. Furthermore, while regional planning is responsible for ensuring electricity ratepayer value and minimizing electricity costs, the IESO relies on government policy for broader socioeconomic considerations.

There are three CEP and CCAP objectives that the IESO and regional planning can play a role in supporting. First, the IESO recognizes that distributed energy resources (DER) are becoming increasingly prevalent and features prominently in many CEPs and CCAPs. DERs can provide benefits to both customers as well as the distribution and transmission systems. By enabling DERs to provide wholesale services, system costs can be reduced and opportunities for customers and investors can be increased. The IESO's Enabling Resources Program (ERP) will produce a 5-10 year plan to enable resources to provide services they cannot or cannot fully currently provide. The ERP has identified storage, hybrids, and DERs as high-priority opportunities. The IESO is developing a DER roadmap which is expected to be shared with stakeholders in the fall of 2021 to provide clarity on IESO objectives, initiatives, and timing for DER integration. More information can be found on the Distributed Energy Resource Roadmap engagement page.

Second, the Working Group will continue to support and monitor energy efficiency uptake. Conservation expected to be achieved through codes, standards, and program delivery has already been included in the planning forecast as described in Section 5.4. On September 30, 2020 the IESO received a Ministerial directive to implement a new 2021-2024 Conservation and Demand Management (CDM) Framework. The new CDM Framework will contribute to lowering the net demand as seen on the transmission system and ensures energy efficiency can continue to play a role in meeting the region's needs. The Working Group will monitor uptake of the CDM framework as well as energy efficiency initiatives in CEPs and assess the impact of these additional savings on the timing of local reliability needs.

Finally, the Working Group will monitor electrification trends and their impact on the demand forecast. The Working Group recognizes that many CEPs and CCAPs are calling for ambitious electrification targets as a means to achieve carbon emission reductions. It is not yet clear how impactful electrification will be to the load forecast in the near-term but it could drive significantly higher demand in the long term that will necessitate new electricity supply into the area. While it is still difficult to establish when firm investments or infrastructure reinforcements will be needed, it is prudent to prepare for a future where electricity demand could potentially be significantly higher than forecast.

The IESO and local distribution companies will continue to participate in local community energy planning initiatives such as the Heritage Heights Community Energy Plan Working Group at the request of municipal staff.

2.2.4 NW GTA Transmission Corridor

While the IRRP has not identified a firm need date for new transmission infrastructure in the northern areas of the region, Halton Hills, Brampton and Caledon are experiencing rapid growth in areas that are increasingly further away from existing transmission infrastructure. As discussed in the previous section, high electrification uptake could also significantly impact electricity demand.

The Ministry of Transportation (MTO) is currently planning for a new 400-series highway in the same approximate area as the anticipated long-term need for new transmission in the region. Provincial policy encourages colocation of linear infrastructure to reduce land use impacts and the IESO and Ministry of Energy are conducting a joint study to ultimately identify a suitable corridor of land that can be preserved for future transmission infrastructure should the need arise. The expectation is that the preferred route for this future transmission corridor will largely align with MTO's highway study area. Although co-location of linear infrastructure provides benefits from a land use perspective, it is important to note that the need associated with future transmission is linked to the size and location of anticipated growth, and not any specific transportation or other infrastructure plan. Protecting land for a future transmission corridor maintains flexibility to accommodate future demand growth in the northern areas beyond what is already captured in the IRRP forecast and mitigates the challenges of needing to build transmission infrastructure through developed land.

3. Development of the Plan

3.1 Regional Planning Process

In Ontario, preparing to meet the electricity needs of customers at a regional level is achieved through regional planning. Regional planning assesses the interrelated needs of a region—defined by common electricity supply infrastructure—over the near, medium, and long term and results in a plan to ensure cost-effective and reliable electricity supply. A regional plan considers the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluates options for addressing needs, and recommends actions.

The current regional planning process was formalized by the OEB in 2013 and is performed on a five-year planning cycle for each of the 21 planning regions in the province. The process is carried out by the IESO, in collaboration with the transmitters and LDCs in each planning region. The process consists of four main components:

1. A Needs Assessment, led by the transmitter, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;

2. A Scoping Assessment, led by the IESO, which identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities;

3. An IRRP, led by the IESO, which proposes recommendations to meet the identified needs requiring coordinated planning; and/or

4. A RIP, led by the transmitter, which provides further details on recommended wires solutions.

Further details on the regional planning process and the IESO's approach to regional planning can be found in Appendix A.

Regional planning is not the only type of electricity planning in Ontario. Other types include bulk system planning and distribution system planning. There are inherent overlaps in all three levels of electricity infrastructure planning.

The IESO has recently completed a review of the regional planning process following the completion of the first cycle of regional planning for all 21 regions. Additional information on the Regional Planning Process Review along with the final report is posted on the IESO's website.

3.2 GTA West and IRRP Development

The process to develop the GTA West IRRP was initiated in August 2019 following the publication of the Needs Assessment report in May 2019 by Hydro One and Scoping Assessment Outcome Report in August 2019 by the IESO.

In October 2020, the IESO wrote to the Ontario Energy Board (OEB) to provide notice of expected delays in completing three ongoing IRRPs including the GTA West IRRP. The additional time to complete the GTA West IRRP provided the IESO the opportunity to align the timing with that of the bulk system plan for the Flow East Toward Toronto (FETT) and further investigate higher than expected actual demand observed at some of the transformers stations within the region in 2020. The IESO estimated that 3-6 months of additional time was required beyond the original completion date of February 8th, 2021.

4. Background and Study Scope

This is the second cycle of regional planning for the GTA West region. In the first cycle of regional planning, the region was divided into two sub-regions: Northwest GTA and Southwest GTA. The Northwest GTA sub-region roughly encompassed the municipalities of Milton, Halton Hills, Caledon and Brampton while the Southwest GTA sub-region encompassed Mississauga, Oakville, and parts of Burlington. Following a Needs Assessment and Scoping Assessment in 2014, an IRRP was initiated for the Northwest GTA sub-region and subsequently published in 2015. The first cycle concluded in 2016 with the publication of a Regional Infrastructure Plan.

The current cycle of regional planning began in 2019 with the publication of the GTA West Needs Assessment Report where a number of needs requiring further regional coordination was identified. The 2019 GTA West Scoping Assessment recommended an IRRP for the entire region to address needs in a coordinated manner. This report presents an integrated regional electricity plan for the next 20-year period starting from 2019.

4.1 Study Scope

This IRRP develops and recommends options to meet the electricity needs of the GTA West Region in the near, medium, and long term. The plan was prepared by the IESO on behalf of the Working Group. The plan includes consideration of forecast electricity demand growth, conservation and demand management (CDM), distributed generation (DG), transmission and distribution system capability, relevant community plans, condition of transmission assets and developments on the bulk transmission system.

The following transmission facilities were included in the scope of this study:

- Step-down transformer stations: Halton TS, Halton Hills MTS, Meadowvale TS, Jim Yarrow MTS, Pleasant TS, Cardiff TS, Bramalea TS, Goreway TS, Tremaine TS, Trafalgar TS, Palermo TS, Glenorchy MTS #1, Churchill Meadows TS, Erindale TS, Tomken TS, Oakville TS #2, Lorne Park TS, Cooksville TS
- Transmission lines: H29/H30, R14T/R17T, R19TH/R21TH, T36B/T37B, T38B/ T39B, V41H/V42H, V43/V44, B15C/B16C, K21C/K23C, R24C

The single line diagram of the GTA West region is shown in Figure 4.1 below. Note that the 500 kV circuits and bulk system transfer capabilities through the region is not within the scope of the IRRP and separately studied in the FETT interface bulk transmission study which is discussed further below in Section 4.2.

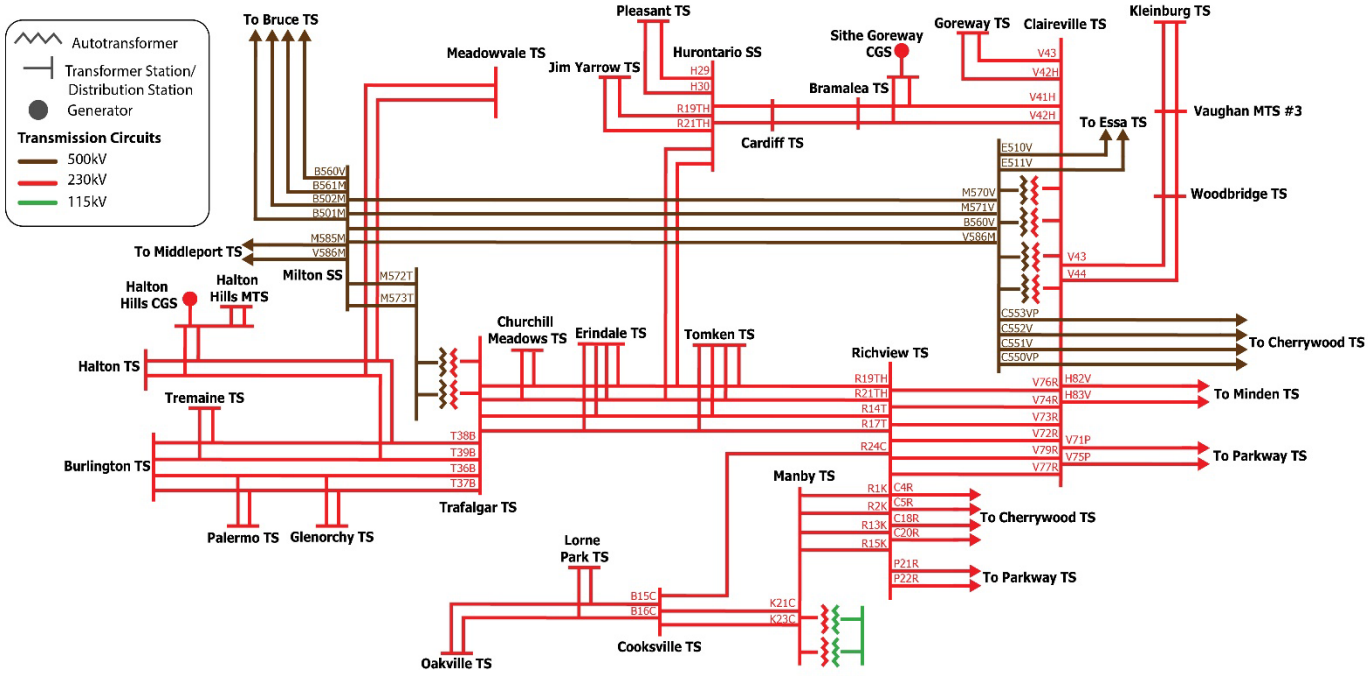

Figure 4.1 | Single Line Diagram of the GTA West Region

The GTA West IRRP was developed by completing the following steps:

- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe (as described in the following steps);
- Examining the load meeting capability (LMC) and reliability of the existing transmission system, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC and NERC criteria;
- Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO-controlled grid;
- Confirming identified end-of-life asset replacement needs and timing with LDCs;
- Establishing alternatives to address system needs including, where feasible and applicable, generation, transmission and/or distribution, and other approaches such as non-wires alternatives including conservation and demand management;
- Engaging with the community on needs and possible alternatives;

- Evaluating alternatives to address near- and long-term needs; and
- Communicating findings, conclusions, and recommendations within a detailed plan.

4.2 FETT Interface Bulk Transmission Study

Flow East Towards Toronto (FETT) is a transmission interface that delivers electricity from western to eastern Ontario and consists of three paths: (a) four 500 kV circuits into Claireville TS from the west, (b) four 230 kV circuits between Trafalgar TS and Richview TS, and (c) two 230 kV circuits between Orangeville TS and Essa TS.

Supply capacity in eastern Ontario is expected to decline over the next decade, which contributes to a provincial need for capacity and, because of limits on the transfer capability of the FETT interface, ~2000 MW of that capacity will have to be sited east of the FETT interface by 2026. To reduce the amount of capacity that must be sited in eastern Ontario, the IESO issued a letter in December 2020 recommending that Hydro One proceed with conductor upgrades to the R14T/R17T and R19TH/R21TH circuits between Trafalgar TS and Richview TS as a first stage to increase the FETT transfer capability.

Future FETT interface needs beyond these conductor upgrades are not known at this time and will depend on the future resources acquisition framework and availability of potential resources east of FETT. The IESO will continue participate in the Working Group during the RIP to help ensure recommendations are aligned with the latest bulk system information.

5. Electricity Demand Forecast

Regional planning in Ontario is driven by the need to meet peak electricity demand requirements in the region. This section describes the development of the demand forecast for the GTA West Region. It highlights the assumptions made for peak demand forecasts including weather correction and the contribution of CDM and DG. The resulting net extreme weather demand forecast is used in assessing the electricity needs of the area over the planning horizon.

5.1 Historical Demand

Growth within the GTA West region has been steady over the last five years, largely driven by expanding urban boundaries and intensifying urban areas. Figure 5.1 below shows the net actual (as observed at metering point), net median weather corrected (adjusted to reflect median on peak weather conditions), and gross median weather corrected (impact of DG removed) historical demand. The gross median weather corrected electrical demand has grown at an average rate of 1.3% over the past five years, representing an increase of approximately 150 MW for the study area. The peak demand hour for each year occurs in the summer from approximately 3 PM to 7 PM.

Generally speaking, the 2018 gross median weather corrected peak at each station was used as the starting point for the forecast unless adjustments were necessary to remove outliers.

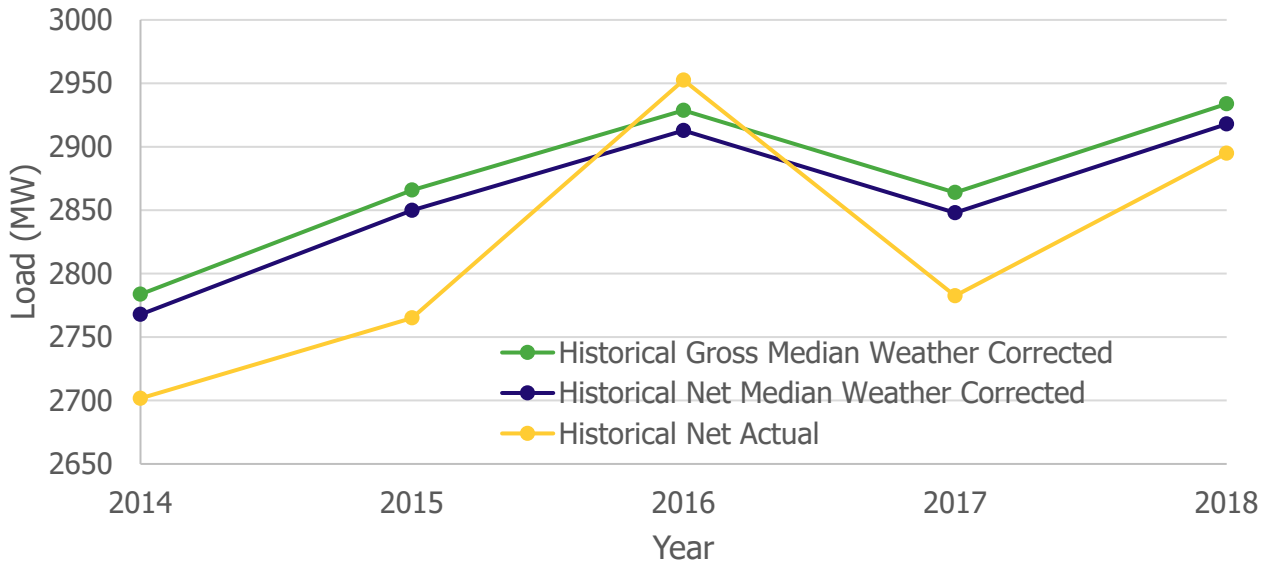

Figure 5.1 | Historical Demand in the GTA West Region

5.2 Demand Forecast Methodology

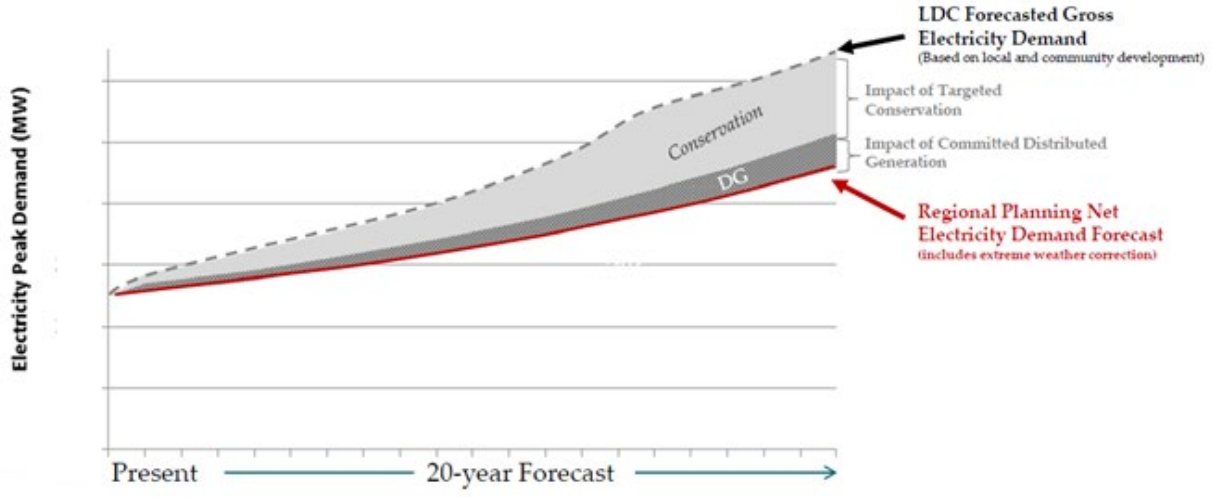

Figure 5.2 | Illustrative Development of Demand Forecast

For the purpose of this IRRP, a 20-year regional peak demand forecast was developed to assess reliability needs for GTA West. The steps taken to perform this are depicted in Figure 5.2. Gross demand forecasts, which assume the weather conditions of an average year based on historical weather conditions and referred to as normal weather, were developed by the LDCs. These forecasts were then modified to reflect the peak demand impacts of provincial conservation targets and DG contracted through previous provincial programs such as FIT and microFIT, and adjusted to reflect extreme weather conditions in order to produce a reference forecast for planning assessments. This net forecast was then used to assess the electricity needs in the region. Additional details related to the development of the demand forecast are provided in Appendix B.

5.3 Gross LDC Forecast

Each participating LDC in the GTA West Region prepared gross demand forecasts at the station level, or at the station bus level for multi-bus stations. These gross demand forecasts account for increases in demand from new or intensified development and known connection applications. Most LDCs cited alignment with municipal and regional official plans and credited them as a primary source for input data. LDCs are also expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices, i.e., "natural conservation", but not for the impact of future DG or new conservation measures, such as codes and standards and CDM programs, which are accounted for by the IESO as discussed in Section 5.4 below. The gross LDC forecast assumes median on-peak weather conditions.

LDCs have a better understanding of future local demand growth and drivers than the IESO, since they have the most direct involvement with their customers, connection applicants and municipalities and communities which they serve. The IESO typically carries out demand forecasting at the provincial level. More details on the LDCs' load forecast assumptions can be found in Appendix B.2 to B.7. Figure 5.3 below shows the total gross LDC forecast for the GTA West region.

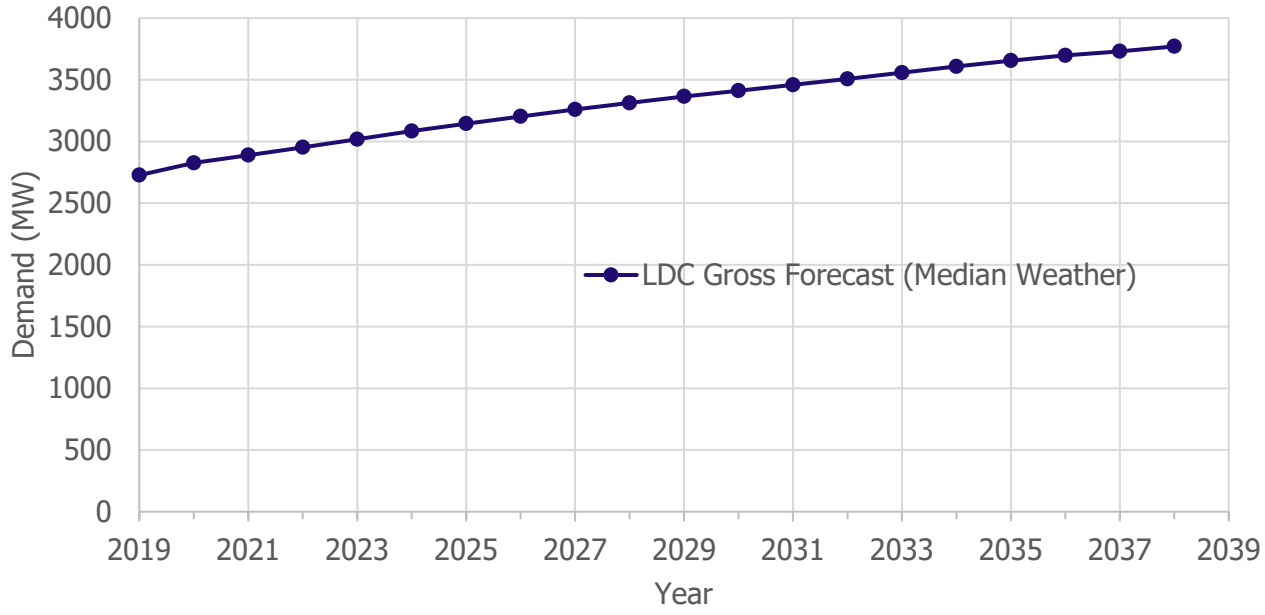

Figure 5.3 | Total Gross LDC Forecast (Median Weather)

5.4 Contribution of Conservation to the Forecast

Conservation and demand management, is a clean and cost-effective resource that helps meet Ontario's electricity needs and has been an integral component of provincial and regional planning. Conservation is achieved through a mix of codes and standards amendments as well as CDM program-related activities These approaches complement each other to maximize conservation results.

The estimate of demand reduction due to codes and standards are based on expected improvement in the codes for new and renovated buildings and through regulation of minimum efficiency standards for equipment used by specified categories of consumers, i.e. residential, commercial and industrial consumers.

The estimates of demand reduction due to program-related activities account for Save on Energy[1] programs, as well as those that will be implemented as part of the 2021-2024 CDM Framework, which started in January 2021. The IESO centrally delivers programs on a province-wide basis to serve business and low-income customers, as well as Indigenous communities.

[1] https://www.saveonenergy.ca/

Figure 5.4 shows the estimated total yearly reduction to the demand forecast due to conservation (from codes, standards and CDM programs) for each of the residential, commercial and industrial consumers. Additional details are provided in Appendix B.8.

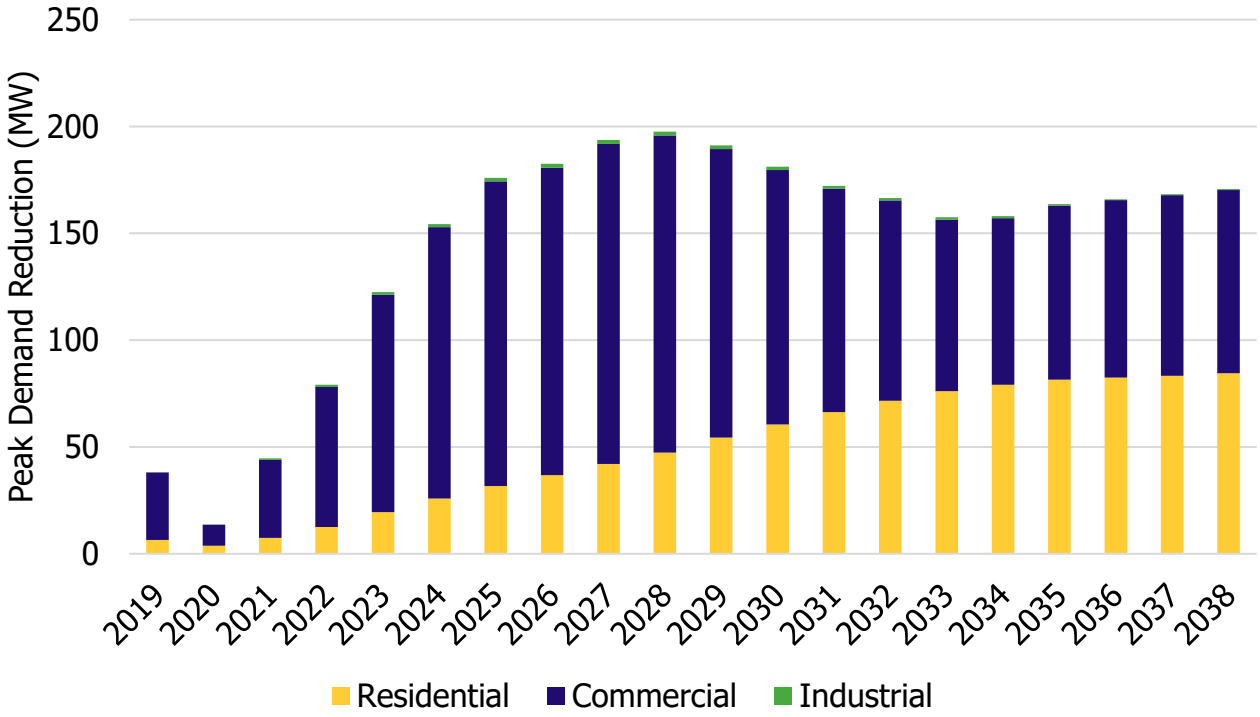

Figure 5.4 | Total Forecast Peak Demand Reduction (Codes, Standards, and CDM Programs)

5.5 Contribution of Distributed Generation to the Forecast

In addition to conservation resources, DG in the GTA West Region is also forecast to offset peak-demand requirements. The introduction of the Green Energy and Green Economy Act, 2009, and the associated development of Ontario's FIT Program, has increased the significance of distributed renewable generation which, while intermittent, contributes to meeting the province's electricity demands. The installed DG capacity by fuel type and contribution factor assumptions can be found in Appendix B.9.

After reducing the demand forecast due to conservation as described above, the forecast is further reduced by the expected contribution from contracted DG in the region. Figure 5.5 shows the impact of DG on reducing the demand forecast. In the long term, the contribution of DG is expected to diminish as these contracts expire. Additionally, any facilities without a contract with the IESO are not currently included in the DG peak demand reduction forecast.

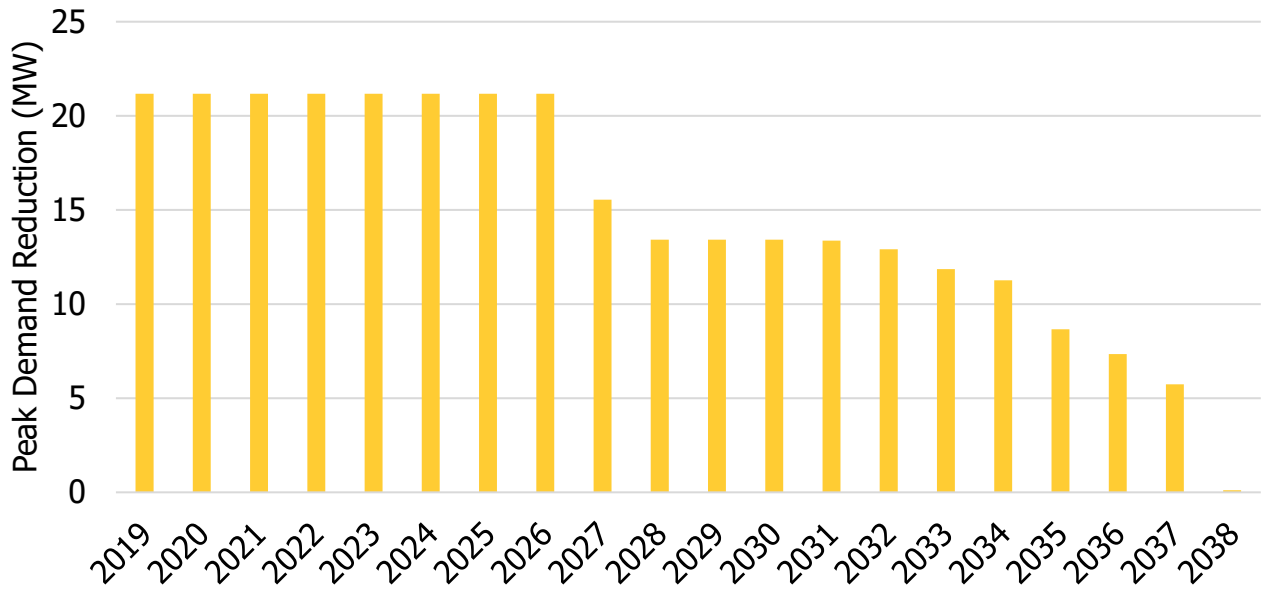

Figure 5.5 | Peak Demand Reduction to Demand Forecast due to DG

5.6 Net Extreme Weather ("Planning") Forecast

The net extreme weather forecast, as known as the "planning" forecast, is created in two steps. First the gross LDC median weather forecast is adjusted for extreme weather conditions according to the methodology described in Appendix B.1. This results in the gross extreme weather forecast. The net extreme weather forecast is then obtained by adding in the forecast DG and conservation impacts described in Section 5.4 and 5.5 above. Note that this planning forecast is non-coincident meaning that each station in the region is forecast separately at their own peak demand.

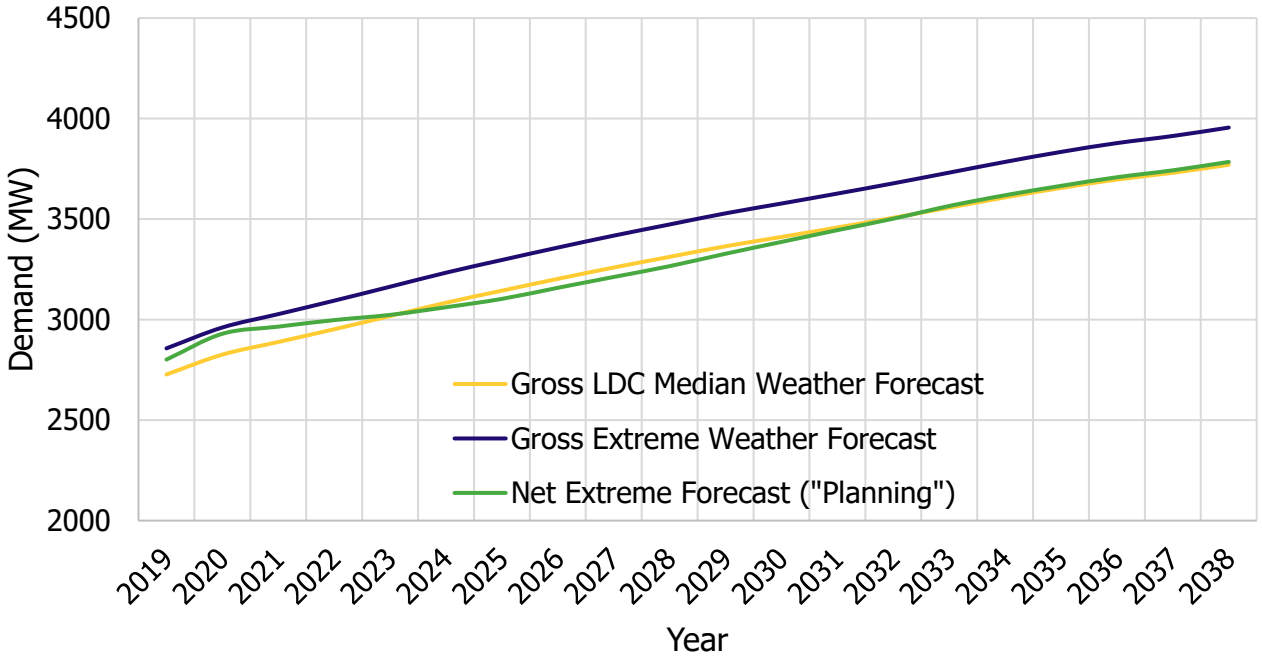

Figure 5.6 | Net Extreme Weather ("Planning") Forecast for the GTA West Region

To determine the need date for needs that are driven by more than one station, the coincident planning forecast for the relevant group of stations are found by applying a coincidence factor. The coincidence factor is based on the contribution of each station to the group's coincident peak over the past five years. The net extreme weather forecast for the GTA West region is shown in Figure 5.6 below.

5.7 Load Profiling

In addition to the annual peak forecast, hourly load profiles (8,760 hours per year over the 20 year forecast horizon) for certain stations or group of stations with identified needs were developed to characterize their needs with finer granularity. The profiles are based on historical data adjusted for variables that impact demand such as calendar day (e.g. holidays and weekends) and weather (e.g. extreme weather events like ice storms or heat waves) impacts. The profiles are then scaled to match the annual peak forecast for each year. As described in Section 7.1, these profiles are used to quantify the magnitude, frequency, and duration of needs to better evaluate the suitability of generation and distributed energy resource options.

Additional load profile details including summary tables and hourly heat maps for each need can be found in Appendix D. Note that this data is used to roughly inform the overall energy requirements that a non-wire alternative would need to meet for the purposes of evaluating alternatives; it cannot be used to deterministically specify the precise hourly energy requirements. Further, this data is only used to select suitable technology types and roughly estimate operating costs. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification achieve greater adoption. The Working Group will continue to monitor these changes as part of implementation of the plan.

6. Needs

6.1 Needs Assessment Methodology

Based on the planning demand forecast (extreme weather, net demand), system capability, the transmitter's identified end-of-life asset replacement plans, and the application of ORTAC and North American Electric Reliability Corporation (NERC) TPL-001-4 Standard, the Working Group identified electricity needs in the near-, medium- and long-term timeframe for the following categories:

- **Station Capacity Needs** describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations at peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day Limited Time Rating (LTR) of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be limited when downstream or upstream equipment, e.g., breakers, disconnect switches, low-voltage bus or high voltage circuits, is undersized relative to the transformer rating.

- **Supply Capacity Needs** describe the electricity system's inability to provide continuous supply to a local area at peak demand. This is limited by the LMC of the transmission supply to an area. The LMC is determined by evaluating the maximum demand that can be supplied to an area accounting for limitations of the transmission elements, e.g., a transmission line, group of lines, or autotransformer, when subjected to contingencies and criteria prescribed by ORTAC and TPL-001-4. LMC studies are conducted using power system simulations analysis.

- **End-of-life Asset Refurbishment Needs** are identified by the transmitter with consideration to a variety of factors such as asset age, the asset's expected service life, risk associated with the failure of the asset, and its condition. Replacement needs identified in the near- and early mid-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium- to long-term needs should reflect the potential for the need date to change as condition information is routinely updated.

- **Load Security and Restoration Needs** describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC.

Technical study results can be found in Appendix C. The needs identified are discussed in Sections 6.2 and 6.3 below.

6.2 Near-/Medium-Term Needs Identified

Table 6.1 below summarizes the near- and medium-term needs identified by this IRRP.

Table 6.1 | Summary of Near and Medium-Term Needs

Need	Need Description	Need Date
H29/H30 Supply Capacity	After a loss of either H29 or H30, the remaining circuit (i.e. H30 or H29) will exceed its LTE rating.	2027[2]
R19TH/R21TH Supply Capacity	After a loss of V42H and H29, R19TH will exceed its LTE rating. After a loss of V41H and H30, R21TH will exceed its LTE rating.	Today
Palermo TS End-of-Life Refurbishment	Transformers T3 and T4 at Palermo TS will reach end-of-life.	2025
T38B/T39B Load Security	Simultaneous loss of both T38B and T39B would result in over 600 MW of load being lost by configuration.	2025
Load Restoration Needs	30-minute restoration of all load lost above 250 MW not achievable with current load transfer capabilities after select N-2 contingencies	Ongoing

[2] Note that the "Required By" date for this need in Section 2.1 is 2025. This reflects the recommendation to advance the H29/H30 work to help mitigate the risk of high than anticipated growth.

6.2.1 Station Capacity Needs

There are no station capacity needs in the near term.

6.2.2 Supply Capacity Needs

6.2.2.1 H29/H30 Supply Capacity Need

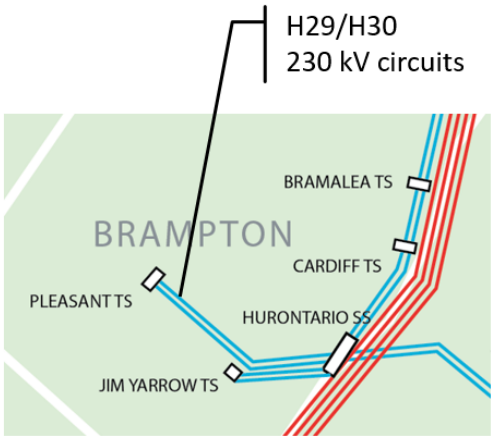

Figure 6.1 | H29/H30 230 kV Circuits

The circuits identified as H29 and H30 form an 8.5 km, 230 kV double-circuit supplying Pleasant TS, as shown in Figure 6.1 above.

According to the demand forecast, this need is expected to exceed the identified LMC of 417 MW by 2027. It is important to note that the 2020 actual peak demand at Pleasant TS reached 410 MW during the July 2020 summer peak. This is shown in Figure 6.2 below. However, it may be too early to conclude if this was an isolated event related to the COVID-19 pandemic or an enduring trend. This need was also identified in the 2015 GTA West IRRP.

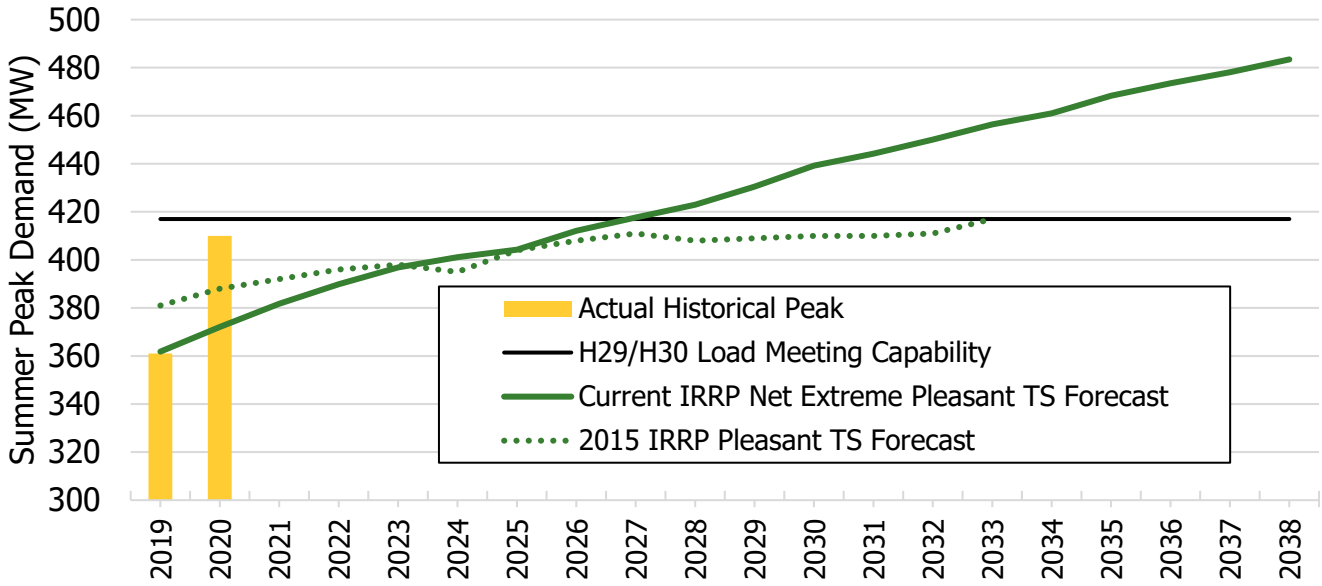

Figure 6.2 | Pleasant TS Historical and Forecast Demand

6.2.2.2 R19TH/R21TH[3] Supply Capacity Need

The circuits R19TH and R21TH form a 230 kV double-circuit from Richview TS to Trafalgar TS. These circuits also extend from Hanlan JCT northward towards Hurontario SS. These circuits provide a supply path to Jim Yarrow MTS, Pleasant TS, Cardiff TS, and Bramalea TS. Figure 6.3 below shows an overview of the area.

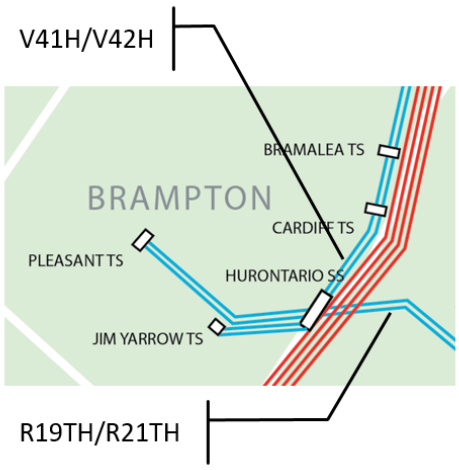

Figure 6.3 | R19TH and R21TH 230 kV Circuits

[3] The limiting sections of R19TH/R21TH referred to here are different from the ones that will be upgraded as the result of the FETT Interface Bulk Transmission Study (Section 4.2).

This need occurs only for specific contingencies during a pre-existing outages (N-1-1 contingency). When V42H is experiencing an outage followed by an H29 contingency, the circuit section of R19TH from Hanlan JCT to Hurontario SS will start to exceed its LTE rating by 2021 and will exceed its STE rating by 2038. The need is primarily driven by growth at Pleasant TS. This is also true for the circuit section of R21TH from Hanlan JCT to Hurontario SS when V41H is experiencing an outage followed by an H30 contingency. The need is illustrated in Figure 6.4 below.

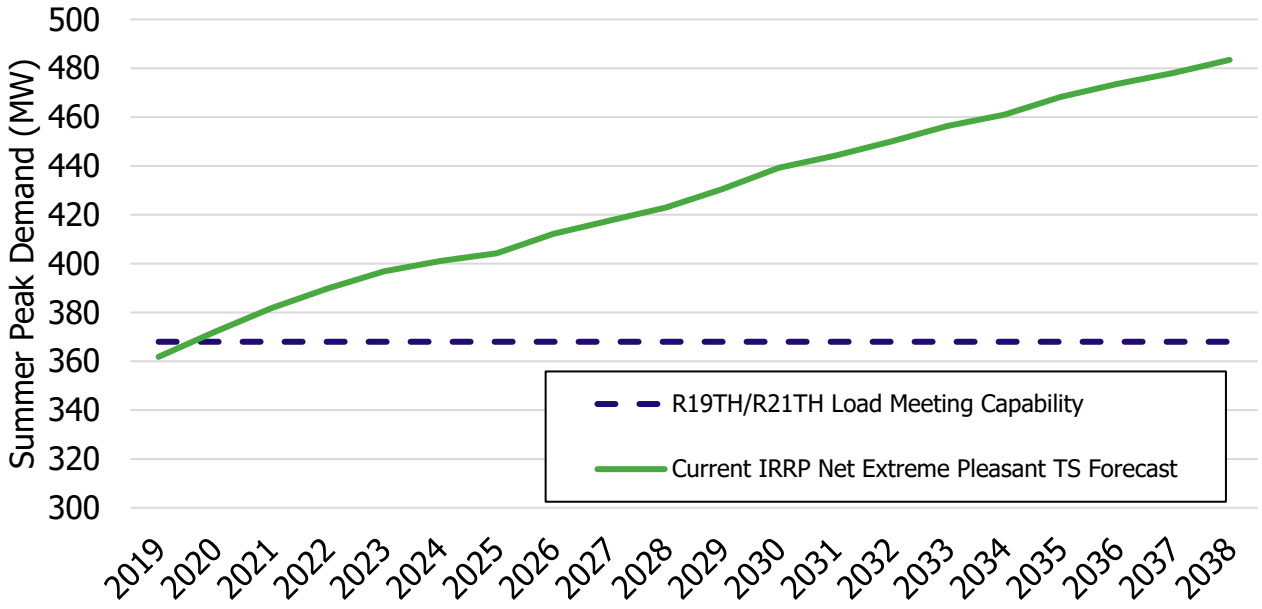

Figure 6.4 | R19TH/R21TH Supply Capacity Need

6.2.3 End-of-Life Refurbishment Needs

6.2.3.1 Palermo TS

Palermo TS is a transformer station that serves load of Burlington Hydro Inc., Milton Hydro Inc. and Oakville Hydro in the municipalities of Burlington, Milton, and Oakville. The transformers at Palermo TS (T3 and T4) are sized up to 83 MVA and will reach end-of-life in 2025.

It is important to note that the nearby Tremaine TS is expected to exceed its station supply capacity limits by 2033 (details of which are found in Section 6.3.2 below). Therefore, it is prudent to consider the needs of Tremaine TS when addressing the end-of-life issues at Palermo TS. Figure 6.5 below shows a geographical overview of Palermo TS and Tremaine TS within the GTA West system.

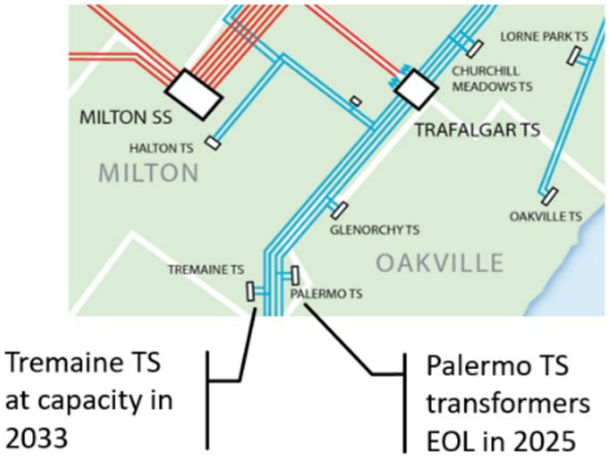

Figure 6.5 | Overview of Palermo TS and Tremaine TS

6.2.4 Load Security

6.2.4.1 T38B/T39B Load Security Need

The circuits designated as T38B/T39B form a 230 kV double-circuit from Burlington TS to Trafalgar TS. These circuits serve numerous transformer stations including Tremaine TS, Trafalgar DESN, Meadowvale TS, Halton TS, Halton #2 TS (future), and Halton Hills MTS. The local 683 MW gas-powered Halton Hills Generating Station also provides power to the province via these two circuits. The area served by this double-circuit is often referred to as the "Halton Pocket". Figure 6.6 provides an overview of the Halton Pocket.

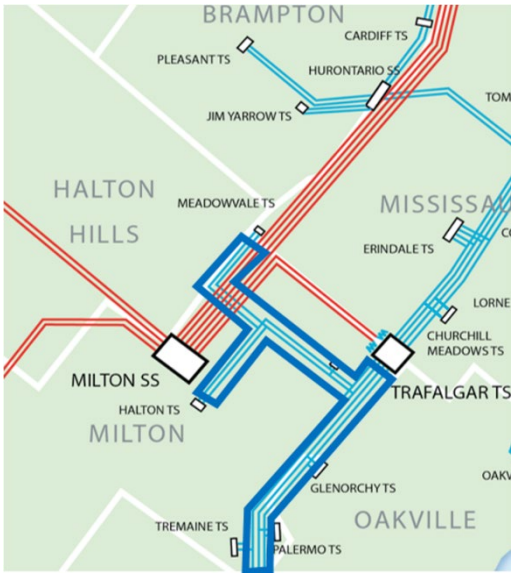

Figure 6.6 | Overview of the Halton Pocket

Starting in 2025, the loss of both T38B and T39B circuits will result in over 600 MW of load being disconnected from the system, and is a violation of Section 7.1 of the ORTAC. This is due to all the aforementioned stations being served solely by these two circuits. The load of at the Halton pocket is expected to grow throughout the study period (i.e. 2020 to 2038). By 2038, it is expected that up to 775 MW of coincident load will be lost following the loss of both these circuits. This is shown in Figure 6.7.

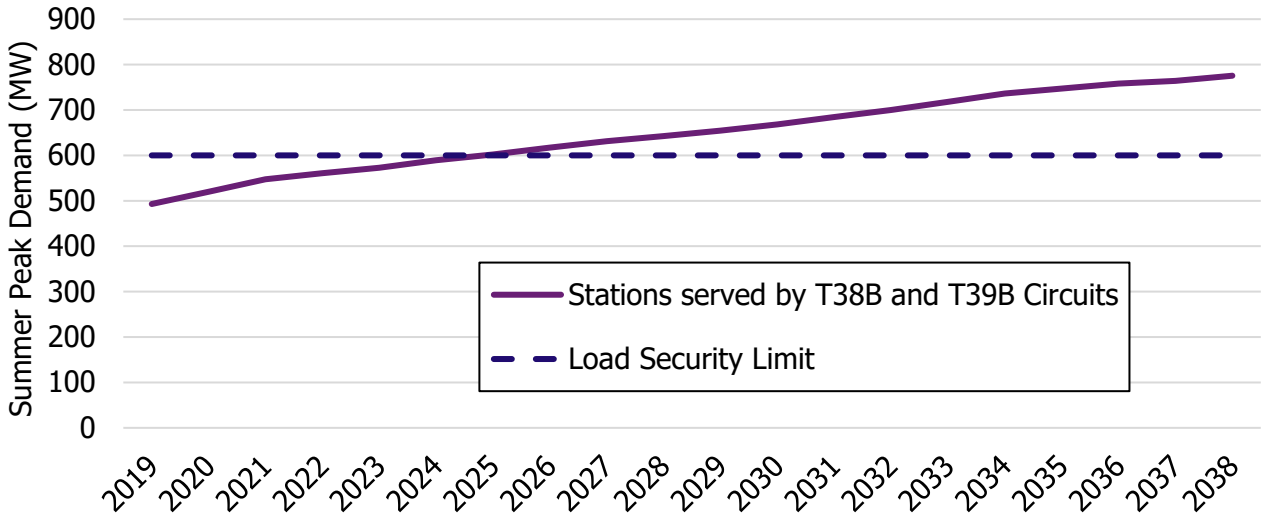

Figure 6.7 | T38B and T39B Load Security Need

6.2.5 Load Restoration

The Needs Assessment and Scoping Assessment reports both identified several load restoration needs in the GTA West Region, as outlined below:

1. Kleinburg Radial Pocket (V43/V44)
2. Halton Radial Pocket (T38B/T39B)
3. Pleasant Radial Pocket (H29/H30)
4. Cardiff/Bramalea Supply (V41H/V42H)
5. West of Cooksville (B15C/B16C)
6. Richview X Trafalgar (R19TH/R21TH)
7. Richview X Trafalgar (R14T/R17T)

For the load restoration needs #1 and #5, it is found that the 4-hour and 8-hour load restoration can be substantially met throughout the forecast. The load serving West of Cooksville and Kleinburg Radial Pocket circuits do not exceed 250 MW throughout the forecast and so the 30-minute requirement does not apply. In addition, need #2 will also be investigated in the RIP in conjunction with the load security need identified above.

In the 2015 GTA West IRRP, addressing the load restoration need #3 (Pleasant Radial Pocket) was ruled out as a cost justification assessment revealed that mitigating solutions were estimated to be significantly costlier to customers in the area than the status quo. This is primarily due to the low probability of the event (loss of H29/H30) occurring and the high cost of building a third supply circuit to Pleasant TS. The 2020 GTA West IRRP takes the same position; it is still not economically prudent to pursue a transmission- or distribution-based solution at this time.

Therefore, for the purposes of this IRRP, the outstanding restoration needs in this IRRP are the Cardiff/Bramalea Supply, and the two Richview x Trafalgar supplies (needs #4, #6, and #7). The 30-minute restoration of all load lost above 250 MW is the most limiting restoration criteria since it relies on remote control actions such as emergency distribution load transfers. 30-minute restoration needs in these pockets existing today and will persist throughout the forecast horizon as demand grows.

6.3 Long-Term Needs Identified

Table 6.2 below summarizes the long-term needs identified by this IRRP:

Table 6.2 | Summary of Long-Term Needs

Need	Need Description	Need Date
Halton Pocket Supply Capacity	Under outage conditions of the local generator, loss of T38B or T39B will lead to the remaining T39B or T38B to exceed its LTE rating	2031
Station Capacity Needs	Cardiff TS, Jim Yarrow MTS, and Tremaine TS are expected to exceed their station capacity limits	2029, 2032, and 2033, respectively
NW GTA Transmission Corridor	There is an anticipated need for future transmission in the GTA West area. This is linked to expected population and employment growth projections.	N/A

6.3.1 Halton Pocket Supply Capacity Need

The load growth at the Halton Pocket is expected to introduce supply capacity needs in the area. Under an outage condition at the Halton Hills Generating Station, the loss of T38B or T39B is expected to cause its remaining companion circuit (i.e. either T39B or T38B, respectively) to exceed its LTE rating. Specifically, this limiting portion of T38B and T39B is a 400-meter section from Lantz JCT to the Trafalgar DESN JCT. This is expected to occur starting in 2031. Figure 6.8 below shows an overview of the limiting section on T38B and T39B. Figure 6.9 shows the limit vs. the forecasted demand in the area.

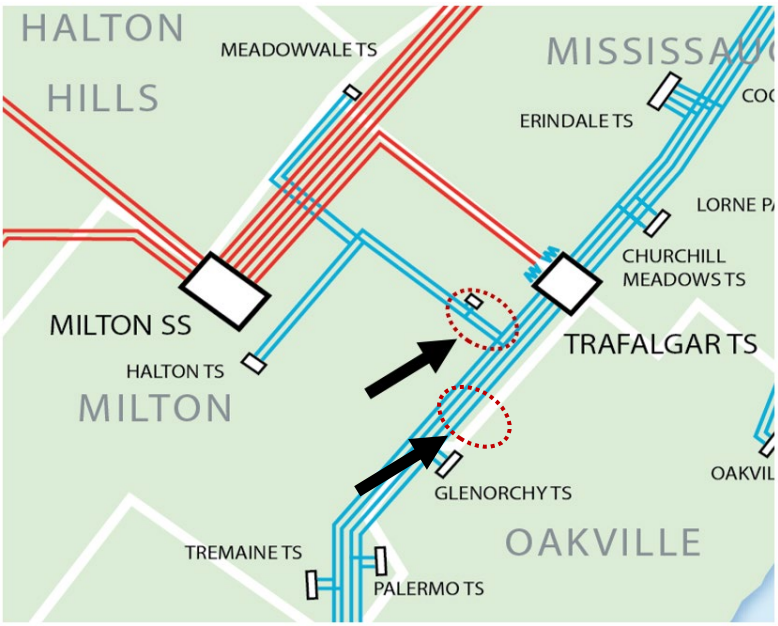

Figure 6.8 | Overview of limiting section on T38B and T39B

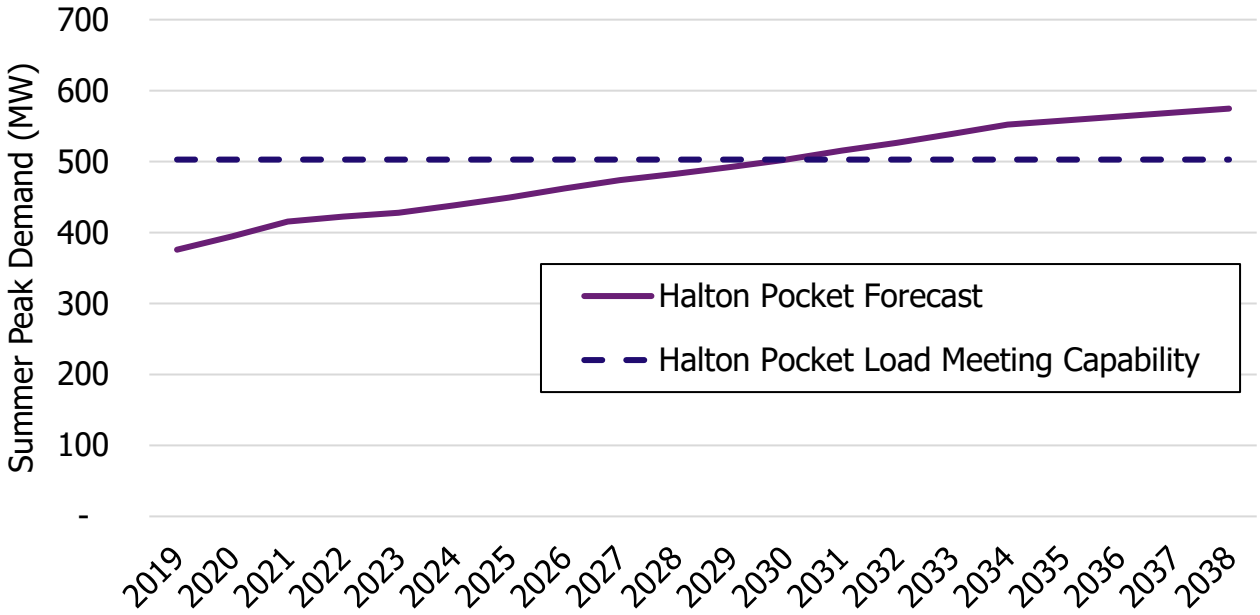

Figure 6.9 | Halton Pocket Supply Capacity Need

6.3.2 Station Capacity Needs

The growth at Cardiff TS is driven mainly by the expansion of a large customer. This expansion was initially slated for mid-2020s but has been put on hold until 2029 due to the effects of the COVID-19 pandemic. Similarly, the growth at Jim Yarrow MTS is primarily driven by load transfers from other stations in Mississauga to Jim Yarrow MTS. However, these load transfers have been delayed to 2032 due to the effects of the COVID-19 pandemic.

The growth at Tremaine TS is expected to exceed station capacity by 2033. A nearby station, Palermo TS, is expected to reach end-of-life by 2025. It is prudent planning practice to consider the needs of both stations when addressing the station capacity needs at Tremaine TS.

7. Plan Options and Recommendations

This section describes the options considered to address system needs in the GTA West region. Section 7.1 to 7.5 documents alternatives to the recommendations described in Section 2 and the rationale for choosing these recommendations. Note that H29/H30 reconductoring is not further discussed here because this recommendation was made in the previous regional planning cycle and this IRRP is only updating the need date. Section 7.6 discusses the Hurontario x Meadowvale transmission option which had the potential to address multiple needs and provide bulk system benefits but was ultimately not selected.

7.1 Options Development and Cost Estimates

Generally speaking, there are two approaches for addressing regional needs that arise as electricity demand increases:

- Build new infrastructure to increase the LMC of the area. These are commonly referred to as "wires" options and can include things like new transmission lines, autotransformers, step-down transformer stations, voltage control devices or upgrades to existing infrastructure. Wires options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate certain reliability concerns.

- Install or implement measures to reduce the net peak demand to maintain loading within the system's existing LMC. These are commonly referred to as "non-wires" options and can include things like local utility scale generation, distributed energy resources, or conservation and demand management.

Wires options are developed by designing transmission reinforcements or control actions that are appropriate for the specific limiting phenomenon (voltage, thermal, stability, etc.) of each need. These options are developed through discussions with the Working Group.

To select and size suitable generation and other non-wires options, an hourly load profile is first created as described in Section 5.6. The most suitable technology type and capacity is chosen by examining the "unserved energy" profile which is the hourly demand above the existing LMC. The profile indicates the duration, frequency, magnitude, and total energy associated with each need. These characteristics are shown visually in Appendix D.

The high-level cost estimates for wires options are provided by the transmitter, Hydro One. There is a significant error margin around these estimates as they are only intended to enable comparison between options during the IRRP. As a standard practice, the IRRP performs sensitivity analysis (-25% to +50% costs) to ensure that the recommendations are robust. The Regional Infrastructure Plan (RIP) following the IRRP will perform additional detailed analysis and refine these cost estimates before implementation work begins. The IESO will continue to participate in the Working Group during the RIP and revisit these recommendations if costs estimates differ significantly.

Cost estimates for generation and other non-wires alternatives are based on benchmark capital and operating cost characteristics for each resource type and size. Generally speaking, the most cost-effective transmission-connected options for meeting local needs in GTA West are resources with performance and costs on par with simple cycle gas turbines (SCGT) or combined cycle gas turbines (CCGT) generators depending on the relative size of the capacity versus energy requirements. New natural gas-fired generation was considered in the economic analysis for illustrative purposes to represent the cost of new generation. In some cases, energy storage such as lithium nickel manganese cobalt oxide (NMC) batteries are also becoming competitive due to declining technology costs and the expectation of carbon prices increasing in line with federal policy. Other distributed energy resources which are typically distribution-connected are also considered. The most cost-effective distributed options are typically a combination of smaller-scale storage and demand response. For each of the above options, the system capacity value is "credited" back to arrive at the net cost to meet local reliability needs. This is done to ensure a level playing field comparison between resources that provide capacity and wires options that address the local need but do not provide system capacity benefits.

CDM measures can also help decrease the net electricity demand. Centrally delivered energy efficiency measures under the 2021-2024 Conservation and Demand Management framework are already included in the load forecast as discussed in the Section 5.4. Incremental CDM measures are suitable for needs where growth is slow and the magnitude of the overload relative to the total demand is very small (e.g. on the order of few percent per year). Given the timing, high rate of growth, and MW magnitude of the needs observed, incremental CDM measures are not suitable for the needs identified in this IRRP.

Both the upfront and operating cost of the wires options, generation, and distributed energy resources are compiled to generate levelized annual capacity costs ($/kW-yr) over the lifespan of the asset in question (typically 70 years for transmission infrastructure) for each option. The net present value of these levelized costs are the primarily basis through which options are compared below. Unless stated otherwise, the net present values discussed in the following sections are in 2020 CAD dollars. The list of assumptions made in the economic analysis can be found in Appendix E.

7.2 Alternatives to Pleasant TS Control Actions

Post-contingency thermal violations during outage conditions are expected to occur on the R19TH/R21TH circuits leading into Hurontario SS by 2021. The magnitude of the need is expected to reach 115 MW by 2038. Since this is a post-contingency limitation during pre-existing outage conditions (referred to as an N-1-1 contingency), a load rejection scheme or manual control actions are permitted by ORTAC load security criteria. While a number of stations contribute to this overload, a load rejection scheme at Pleasant TS is most effective to manage this need and is expected to be relatively simple since it is limited to monitoring the immediate circuits (H29/H30) supplying Pleasant TS. As noted in Section 2.1.2, manual control actions are also feasible in the near- to medium-term when overloads exceed long-term emergency (LTE) but not short-term emergency (STE) ratings. For the purpose of comparing the costs of alternative options, this section will assume that a load rejection scheme is installed today at the cost of $5MM.

In most cases where control actions are sufficient to meet the need, other options will typically be orders of magnitude more expensive. Other transmission, generation, and distributed energy resource options do exist and they are included here for completeness. Table 7.1 summarizes the options considered and the net present value of the their levelized costs. A load rejection scheme is the most cost-effective option and the IRRP recommends that the Regional Infrastructure Plan (RIP) led by Hydro One should develop and implement control actions by 2023.

Table 7.1 | Alternatives to Pleasant TS Control Actions and Costs

Option	Cost NPV
Pleasant TS load rejection scheme	$5MM
Install bus at Hurontario SS to maintain dual supply to Pleasant TS during V42 outage/H29 contingency and V41H outage/H30 contingency N-1-1 combinations	$52MM
Local generation portfolio made up of SCGT generation and demand response installed in three phases between today and 2030 as demand increases[4]	$200MM
Distributed energy resource portfolio made up of NMC batteries installed in three phases between today and 2030 as demand increases	$368MM

[4] As discussed in Section 7.1, the cost of new natural gas-fired generation was considered in the economic analysis for illustrative purposes to represent the cost of new generation.

7.3 Alternative to Upsizing Palermo TS at End-of-Life

The 83 MVA transformers at Palermo TS (T3 and T4) will reach end-of-life in 2025 and will need to either be replaced either like-for-like or upsized to 75/125 MVA transformers. Today, Palermo TS is able to supply a maximum of 110 MW and is fully loaded with no room for additional growth. Upsizing the transformers and reconfiguring the station will allow Palermo TS to serve approximately 40-50 MW of additional load. Note that the station yard is in relatively poor condition, had recently been de-rated in 2019, and will likely need to be replaced in less than 10 years regardless of the transformer size chosen. The approximately cost of a like-for-like replacement is $30MM. Upsizing will cost approximately $5MM more for a total cost of $35MM. These costs can vary significantly depending on the extent to yard work needed so the IRRP uses $25MM and $35MM for the like-for-like and upsized costs, respectively. This is a more conservative assumption with a higher incremental cost of upsizing.

Tremaine TS, a nearby station 3 km from Palermo TS, can serve a maximum of 190 MW and is forecast to reach capacity in 2033. This is a good opportunity to look at the Palermo TS end-of-life need and Tremaine TS capacity need together and select an optimal refurbishment option to serve regional needs at the lowest cost to ratepayers.

The first option is to refurbish Palermo TS like-for-like in 2025 followed by a subsequent upsizing or new station in 2033 when the capacity need arises. The second option is to upsize Palermo TS at a higher cost when it reaches end-of-life in 2025 and simultaneously resolve the capacity need albeit earlier than necessary. Table 7.2 below summarizes these two options and the associate net present value of the costs. Option 2 is significantly more cost-effective than Option 1 and the IRRP recommends that the RIP should perform additional analysis to reaffirm the cost estimates and develop an implementation plan for upsizing Palermo TS in 2025.

Table 7.2 | Alternatives to Upsizing Palermo TS at End-of-Life and Costs

Option	2025 Action	2033 Action	NPV
Option 1	Refurbish Palermo TS like-for-like - $25MM	Upsize Palermo TS - $35MM	$47MM
Option 2	Upsize Palermo TS - $35MM	None	$32MM

7.4 Alternatives to Local Wires Solutions for T38B/T39B Load Security

Starting in 2025, the loss of both T38B and T39B circuits will result in over 600 MW of load being disconnected from the system, and is a violation of Section 7.1 of the ORTAC. By 2038, it is expected that up to 775 MW of coincident load will be lost following the loss of both these circuits.

The purpose of ORTAC load security criteria is to specify the maximum permitted amount of load lost following recognized contingencies which limits the magnitude of customer interruptions. Installing incremental generation and distributed energy resources are not considered suitable options for addressing the load security need because, while they can reduce the net demand (loading observed on the transmission system), they do not reduce the gross demand (actual electricity consumption) that is interrupted post-contingency. For example, the existing Halton Hills GS has a capacity of 640 MW which is more than the combined coincident peak load of all the stations served on T38B/T39B today. However, in the event of a common tower contingency, all load stations and Halton Hills GS would be interrupted by configuration regardless of the generator's output. The same logic applies to distributed energy resources connected on the distribution system. While it is possible to configure some distributed resources like batteries to provide backup power when grid supply is lost, that is a matter of load restoration rather than load security.

The IRRP considered options to either resupply the Trafalgar DESN at Trafalgar TS or to reconfigure the radial portion of T38B/T39B so that it is supplied directly from Trafalgar TS rather than branching northward at Lantz Junction. This would sectionalize T38B/T39B and reduce the total load lost during double circuit contingencies. These options were ruled out because Trafalgar TS is a gas insulated station with large SF_6 insulated ducts which makes additional connections to the bus impractical. Supplying the Trafalgar DESN or additional circuits would require adding new diameters which would cost on the order of $40MM to $50MM based on previous study estimates.

The IRRP also considered opportunities to align with the FETT bulk study and select a common solution to meeting both regional and bulk system needs simultaneously. This is further discussed in Section 7.6 but ultimately, the most capable and cost-effective solution for addressing bulk system needs at this time, the R14T/R17T/R19TH/R21TH conductor upgrades, will not resolve the T38B/T39B load security need.

The remaining options are local transmission solutions like reterminating supply stations on lighter loaded circuits or installing breakers to sectionalize T38B/T39B. The cost of installing breakers to sectionalize T38B/T39B at Tremaine TS or Lantz Junction is approximately $5MM. For the same cost, Tremaine TS can also be reterminated from T38B/T39B to the companion T36B/T37B circuits since the station sits immediately under the transmission corridor. More detailed wires analysis is needed to refine these cost estimates and further study the technical feasibility of installing breakers or reterminating stations at various points along the circuits. The IRRP recommends that the RIP should carry out detailed wires analysis including updating the near-term demand forecast for the stations served on T38B/T39B. As additional bulk system needs on the FETT interface in the late 2020's become more clear, the IESO will continue to provide input on the Working Group to help ensure that the RIP recommendations are aligned with the latest bulk system information.

7.5 Alternatives to T38B/T39B Reconductoring for Halton Pocket Supply

During an outage to Halton Hills GS, post-contingency thermal violations on T38B/T39B are expected to occur by 2031. The thermal violation is on a short 400-meter section of T38B/T39B immediately north of Lantz Junction. This radial portion of T38B/T39B serves the Halton Pocket including Trafalgar DESN, Halton TS, Halton TS #2, Halton MTS, and Meadowvale TS. By 2038, the coincident demand at these stations will exceed the LMC by approximately 70 MW.

The transmission, utility generation, and distributed energy resource options considered are shown in Table 7.3. Upgrading the conductors on the limiting section of T38B/T39B is the most cost-effective option to meet the supply capacity need in the Halton Pocket. Although load rejection is permitted to account for local generation outages, upgrading T38B/T39B is still cheaper due to the short length of the limiting section. A load rejection scheme would also be more complex to operate and reduce reliability for local customers. Note that if Halton Hills GS were to not continue operation after its contract expiry, load rejection would also no longer be an option. Given the timing of the need, no firm recommendation is required at this time. The Working Group will continue to monitor load growth in the Halton Pocket and revisit this need in the next cycle of regional planning.

Table 7.3 | Alternatives to T38B/T39B Reconductoring and Costs

Option	NPV of Levelized Cost Net of System Capacity Value (if applicable)
Upgrade limiting section of T38B/T39B	<$1MM
Local generation portfolio made up of SCGT generation and demand response installed in two phases between 2030 and 2036 as demand increases[5]	$97MM
Distributed energy resource portfolio made up of NMC batteries installed in two phases between 2030 and 2034 as demand increases	$50MM

7.6 Hurontario SS x Meadowvale TS Transmission Option

The Meadowvale SS x Hurontario TS (MxH) transmission option is a new double 230 kV circuit line from Meadowvale TS to Hurontario SS along the existing transmission corridor. This is an integrated option that has potential benefits for both bulk and regional needs. The MxH option is estimated to cost $47MM. This includes the cost of the 8 km line between Meadowvale TS and Hurontario SS as well as an additional 5 km of transmission between Meadowvale TS and Halton TS to allow for a connection to Milton SS if 500-230 kV autotransformers are installed in the future.

From a regional perspective, the MxH option can address the R19TH/R21TH supply capacity, T38B/T39B load security, and T38B/T39B supply capacity needs. The cost of addressing these needs separately through the recommendations above is $5MM in 2023 (Pleasant TS load rejection scheme), $5MM in 2025 (retermination/sectionalisation for T38B/T39B load security), and $1MM in 2033 (T38B/T39B reconductoring) for a total net present value of $10MM. On regional needs alone, it is more cost-effective to address each need separately rather than together through the MxH option.

[5] As discussed in Section 7.1, the cost of new natural gas-fired generation was considered in the economic analysis for illustrative purposes to represent the cost of new generation.

From a bulk perspective, the MxH option introduces a new path along the FETT interface which would improve transfer capability. However, the MxH option alone would not provide sufficient additional transfer capability. The FETT interface is currently thermally limited by the Richview TS x Trafalgar TS circuits. Upgrading the conductors on these circuits (R14T/R17T/R19TH/R21TH) yields an approximately three-fold higher incremental transfer capability increase than the MxH option would provide.

Furthermore, even after discounting the cost of the MxH option by the avoided regional reliability costs, the per MW capability cost of the MxH option is still roughly double that of the Richview TS x Trafalgar TS conductor upgrades. The IESO issued a letter in December 2020 recommending that Hydro One should proceed with conductor upgrades to the R14T/R17T/R19TH/R21TH circuits between Trafalgar TS and Richview TS as a first stage to increase the FETT transfer capability.

Future FETT interface needs beyond these conductor upgrades are not known at this time and will depend on the future resources acquisition framework and availability of potential resources east of FETT. The IESO will continue to participate in the Working Group during the RIP to help ensure recommendations are aligned with the latest bulk system information.

8. Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and preferences of communities to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the activities undertaken to date for the GTA West IRRP.

8.1 Engagement Principles

The IESO's engagement principles[6] help ensure that all interested parties are aware of and can contribute to the development of this IRRP. The IESO uses these principles to ensure inclusiveness, sincerity, respect and fairness in its engagements, striving to build trusting relationships as a result.

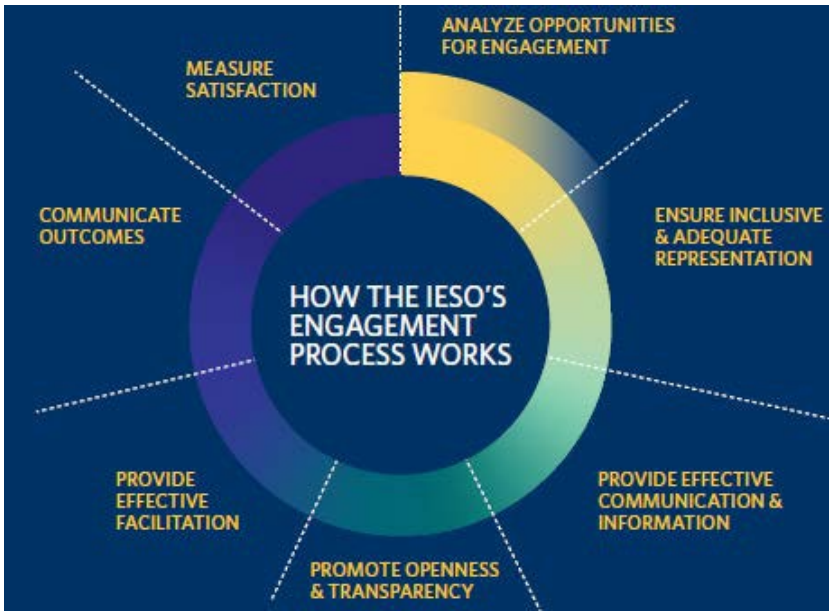

Figure 8.8.1 | The IESO's Engagement Principles

8.2 Creating an Engagement Approach for GTA West (Peel/Halton)

The first step in ensuring that any IRRP reflects the needs of community members and interested stakeholders is to create an engagement plan to ensure that all interested parties understand the scope of the IRRP and are adequately informed about the background and issues in order to provide meaningful input on the development of the IRRP for the region.

[6] https://www.ieso.ca/en/sector-participants/engagement-initiatives/overview/engagement-principles

Creating the engagement plan for this IRRP involved:

- Targeted discussions to help inform the engagement approach for this planning cycle;
- Communications and other engagement tactics to enable a broad participation, using multiple channels to reach audiences; and
- Identifying specific stakeholders and communities who may have a direct impact in this initiative and that should be targeted for further one-on-one consultation, based on identified and specific needs in the region.

As a result, the engagement plan for this IRRP included:

- A dedicated webpage[7] on the IESO website to post all meeting materials, feedback received and IESO responses to the feedback throughout the engagement process;
- Regular communication with interested communities and stakeholders by email or through the IESO weekly Bulletin;
- Public webinars;
- Face-to-face meetings; and
- One-on-one outreach with specific stakeholders to ensure that their identified needs are addressed (see Section 8.4 Bringing Communities to the Table).

8.3 Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for this second round of planning, leveraging existing relationships built through the previous planning cycle. This started with the Scoping Assessment Outcome Report for the GTA West region. An invitation to targeted municipalities, Indigenous communities and those with an identified interest in regional issues to announce the commencement of a new regional planning cycle and invite interested parties to provide input on the GTA West Scoping Assessment Report before it was finalized.

Feedback was received and focused on the need to align community energy plans and other planning initiatives in the development of the IRRP, and for the final plan to consider designated land use in the region including a recreational aircraft flying space in the event of any potential infrastructure siting recommendations. Along with a response to the feedback received, the final Scoping Assessment was posted in August 2019 which identified the need for a coordinated regional planning approach done through an IRRP for the GTA West Region.

[7] Regional Electricity Planning - Peel/Halton (GTA West) Region (ieso.ca)

Following the finalization of the Scoping Assessment, outreach then began with targeted municipalities to inform early discussions for the development of the IRRP including the IESO's approach to engagement. The launch of a broader engagement initiative followed with an invitation to IESO subscribers of the GTA West planning region to ensure that all interested parties were made aware of this opportunity for input. Three public webinars were held at major stages during the IRRP development to give interested parties an opportunity to hear about progress and provide comments on key components of the plan. These webinars received strong participation with a cross-representation of stakeholders and community representatives. Written feedback was received as a result during a 21-day comment period following each webinar.

The three stages of engagement invited input on:

1. The draft engagement plan, the electricity demand forecast and the early identified needs to set the foundation of this planning work.
2. The defined electricity needs for the region and potential options to meet the identified needs.
3. The analysis of options and draft IRRP recommendations.

Comments received during this engagement focused on the following major themes:

- Consideration should be given to local developments and growth plans
- Alignment and coordination is needed with other community planning and projects in the region. Future infrastructure and/or electricity supply should consider the priorities of energy and climate action plans and, in particular, alternative energy systems, renewable generation and electrification
- Incorporate shifting economies into planning assumptions and cost benefit analysis
- Integrated options that provide both local and broader provincial system benefit should be considered
- Consideration should be given to non-wires alternatives as part of the recommended solutions in the IRRP

Feedback received during the written comment periods for these webinars helped to guide further discussion throughout the development of this IRRP as well as add due consideration to the final recommendations.

All interested parties were kept informed throughout this engagement initiative via email to GTA West region subscribers, municipalities and communities as well as the members of the GTA/Central Regional Electricity Network.

Based on the discussions both through the GTA West IRRP engagement initiative and broader network dialogue, there is a clear interest to further discuss the potential for alternative energy solutions as a way to meet local needs particularly as communities shift towards electrification. This insight has been valuable to the IESO and will help to inform future discussions to examine and consider these types of initiatives and the opportunities that they may present in future planning efforts. To that end, ongoing discussions will continue through the IESO's GTA/Central Regional Electricity Network to keep interested parties engaged in a two-way dialogue on local developments, priorities and planning initiatives to prepare for the next planning cycle.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's Peel/Halton (GTA West) IRRP engagement webpage.

8.4 Bringing Municipalities to the Table

The IESO held meetings with municipalities to seek input on their planning and to ensure that these plans were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings were held with the upper- and lower-tier municipalities in the region to discuss: key issues of concern, including forecast regional electricity needs; options for meeting the region's future needs; and, broader community engagement. Meetings were also held to discuss the joint NW GTA Corridor Study underway by the IESO, Ministry of Energy, Northern Development and Mines; coinciding with the Ministry of Transportation's Transportation Corridor Study that is also underway. These meetings helped to inform the municipal/community electricity needs and priorities and provided opportunities to strengthen this relationship for ongoing dialogue beyond this IRRP process.

During discussions with communities, the IESO received feedback that the name "GTA West Regional Planning" was challenging to differentiate from other initiatives underway in the area with a similar naming convention, thus, the region was changed to "Peel/Halton (GTA West) Region" for engagement purposes. Official planning documents continue to adhere to the regulatory name of "GTA West Region".

8.5 Engaging with Indigenous Communities

To raise awareness about the regional planning activities underway and invite participation in the engagement process, regular outreach was made to Indigenous communities within the GTA West electricity planning region throughout the development of the plan. This includes the communities of Alderville First Nation, Curve Lake First Nation, Haudenosaunee Confederacy Chiefs Council, Hiawatha First Nation, Huron-Wendat, Kawartha Nishnawbe First Nation, Mississaugas of Scugog Island First Nation, Mississauagas of the Credit First Nation, and Six Nations of the Grand River.

The IESO remains committed to an ongoing, effective dialogue with communities to help shape long-term planning in regions all across Ontario.

9. Conclusion

The GTA West IRRP identifies electricity needs in the region over the 20-year period from 2019 to 2038, recommends a plan to address immediate and near-term needs, and lays out actions to monitor long-term needs. The IESO will continue to participate in the Working Group during the next phase of regional planning, the Regional Infrastructure Plan, to provide input and ensure a coordinated approach with bulk system planning where such linkages are identified in the IRRP.

In the near term, the IRRP recommends the implementation of control actions at Pleasant TS to manage overloads during outage conditions, upsizing Palermo TS at end-of-life, and further wires analysis for T38B/T39B load security needs during the Regional Infrastructure Plan. Responsibility for these actions has been assigned to the appropriate members of the Technical Working Group.

In the long term, the IRRP recommends that the Working Group monitor growth in the Halton Pocket and at Cardiff TS and Jim Yarrow TS to determine when further reinforcements will be needed. The IESO and the Working Group will also continue to monitor community energy planning and monitor electrification trends. The IESO and the Ministry of Energy will continue the NW GTA Transmission Corridor study to identify a suitable corridor of land that can be preserved for future transmission infrastructure should the need arise.

The Technical Working Group will meet at regular intervals to monitor developments and track progress toward plan deliverables. In the event that underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the OEB.

GTA West

REGIONAL INFRASTRUCTURE PLAN

February 23, 2022

[This page is intentionally left blank]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Alectra Utilities Corporation (Alectra)
Burlington Hydro Electric Inc.
Halton Hills Hydro Inc.
Hydro One Networks Inc. (Distribution)
Independent Electricity System Operator
Milton Hydro Distribution Inc.
Oakville Hydro Electricity Distribution Inc.

Disclaimer

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE TECHNICAL WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE GTA WEST REGION.

The participants of the GTA West Regional Infrastructure Plan ("RIP") Technical Working Group ("TWG") included members from the following organizations:

- Alectra Utilities Corporation ("Alectra")
- Burlington Hydro Electric Inc.
- Halton Hills Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Independent Electricity System Operator ("IESO")
- Milton Hydro Distribution Inc.
- Oakville Hydro Electricity Distribution Inc.

This RIP is the final phase of the second cycle of the GTA West regional planning (RP) process and it follows the completion of the GTA West Integrated Regional Resource Plan ("IRRP") [1] in August 2021; and the GTA West Needs Assessment ("NA") [2] and Scoping Assessment ("SA") in May 2019 and August 2019, respectively. This RIP provides a consolidated summary of needs and recommended plans for the GTA West Region over a 10-year planning horizon (2021-2031) based on available information. The load forecast for the 2032-2041 period is provided to show the longer term needs and trend. All needs for this long term horizon will be reviewed and confirmed in future regional planning cycles.

The first cycle of Regional Planning process was completed in January 2016 with the publication of the GTA West RIP [3], which provided a description of needs and recommendations of preferred wires plans to address near-term needs. Since the previous planning cycle the following projects have been completed:

- Halton Hills Hydro MTS (completed in 2018)
- Tremaine TS: Add 4 x 27.6 kV feeders (completed in 2020)

The recommended major infrastructure investments including assets replacements in the GTA West Region over the near and medium-term (2021-2031) period are given in Table 1 below, along with their planned in-service date and budgetary estimate for planning purposes.

Table 1. GTA West Region - Recommended Plans over the 2021-2031 Study Period

No.	Investments	I/S Date	Cost[1] ($M)
A	**Increase Capacity**		
1	Palermo TS: Refurbish and Upgrade Transformers T3 and T4 and add new 27.6 kV yard	2026	30
2	Hurontario TS x Pleasant TS: Reconductor circuits H29/H30 with higher ampacity conductor	2027	8
B	**Asset Replacement**		
1	Bramalea TS: Replace Transformers T3 and T4	2028	20
2	Tomken TS: Replace Transformers T1 and T2	2029	49
3	Lorne Park TS: Replace Transformer T2	2030	14

[1] These costs are budgetary estimates for planning purposes unless otherwise specified

A number of potential capacity needs were also identified with the following facilities expected to exceed capacity limits over the medium to long term as listed below. The stations loading will continue to be monitored with medium term needs being managed at the distribution level utilizing capacity at adjacent area stations. All needs will be reviewed in the next regional planning cycle.

Medium Term Capacity Needs 2027 - 2031

- Pleasant TS: T1/T2 DESN – 2027
- Erindale TS: T1/T2 DESN – 2028
- Cardiff TS: T1/T2 DESN – 2029
- Erindale TS: T5/T6 DESN – 2031

Longer Term Capacity Needs 2032 – 2041

- Kleinburg TS: T1/T2 DESN – 2032
- Jim Yarrow MTS: T3/T4 DESN - 2032
- T38B/T39B: Lantz Jct x Trafalgar DESN – 2033
- Goreway TS: T5/T6 DESN - 2034
- Bramalea TS:T3/T4 DESN - 2036
- Tremaine TS: T1T2 DESN - 2039

The GTA West TWG recommends that:

- Hydro One and LDCs continue with the implementation of infrastructure investments listed in Table 1 while keeping the TWG apprised of project status;
- All the other identified needs/options are to be further reviewed by the TWG in the next regional planning cycle.

The next regional planning cycle for the GTA West Region must be triggered within five years, beginning with the Needs Assessment ("NA") phase. It is expected that the next NA will start in Q1 2024. However, the next regional planning cycle can be started earlier if required to address any new emerging needs.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE GTA WEST REGION.

The report was prepared by Hydro One Networks Inc. (Transmission) ("Hydro One") on behalf of the Technical Working Group ("TWG") in accordance with the regional planning process established by the Ontario Energy Board ("OEB") in 2013. The Working Group included members from the following organizations:

- Alectra Utilities Corporation ("Alectra")
- Burlington Hydro Electric Inc.
- Milton Hydro Distribution Inc.
- Halton Hills Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Independent Electricity System Operator ("IESO")
- Oakville Hydro Electricity Distribution Inc.

The GTA West Region encompasses the municipalities of Brampton, southern Caledon, Halton Hills, Mississauga, Milton, and Oakville[1]. The region includes the area roughly bordered geographically by Highway 27 to the northeast, Highway 427 to the southeast, Regional Road 25 to the west, King Street to the north and Lake Ontario to the south, as shown in Figure 1-1.

Bulk electricity in the region is supplied by Burlington TS from the west, Claireville TS from the north, Richview TS and Manby TS from the east, and from the 500/230 kV autotransformers at Trafalgar TS, and distributed by a network of 230 kV transmission lines and twenty (20) step-down transformer stations. The summer 2021 non-coincident peak load of the region was approximately 3184 MW.

[1] Some parts of the City of Burlington are also supplied from Palermo and Tremaine transformer stations, located in the GTA West region.

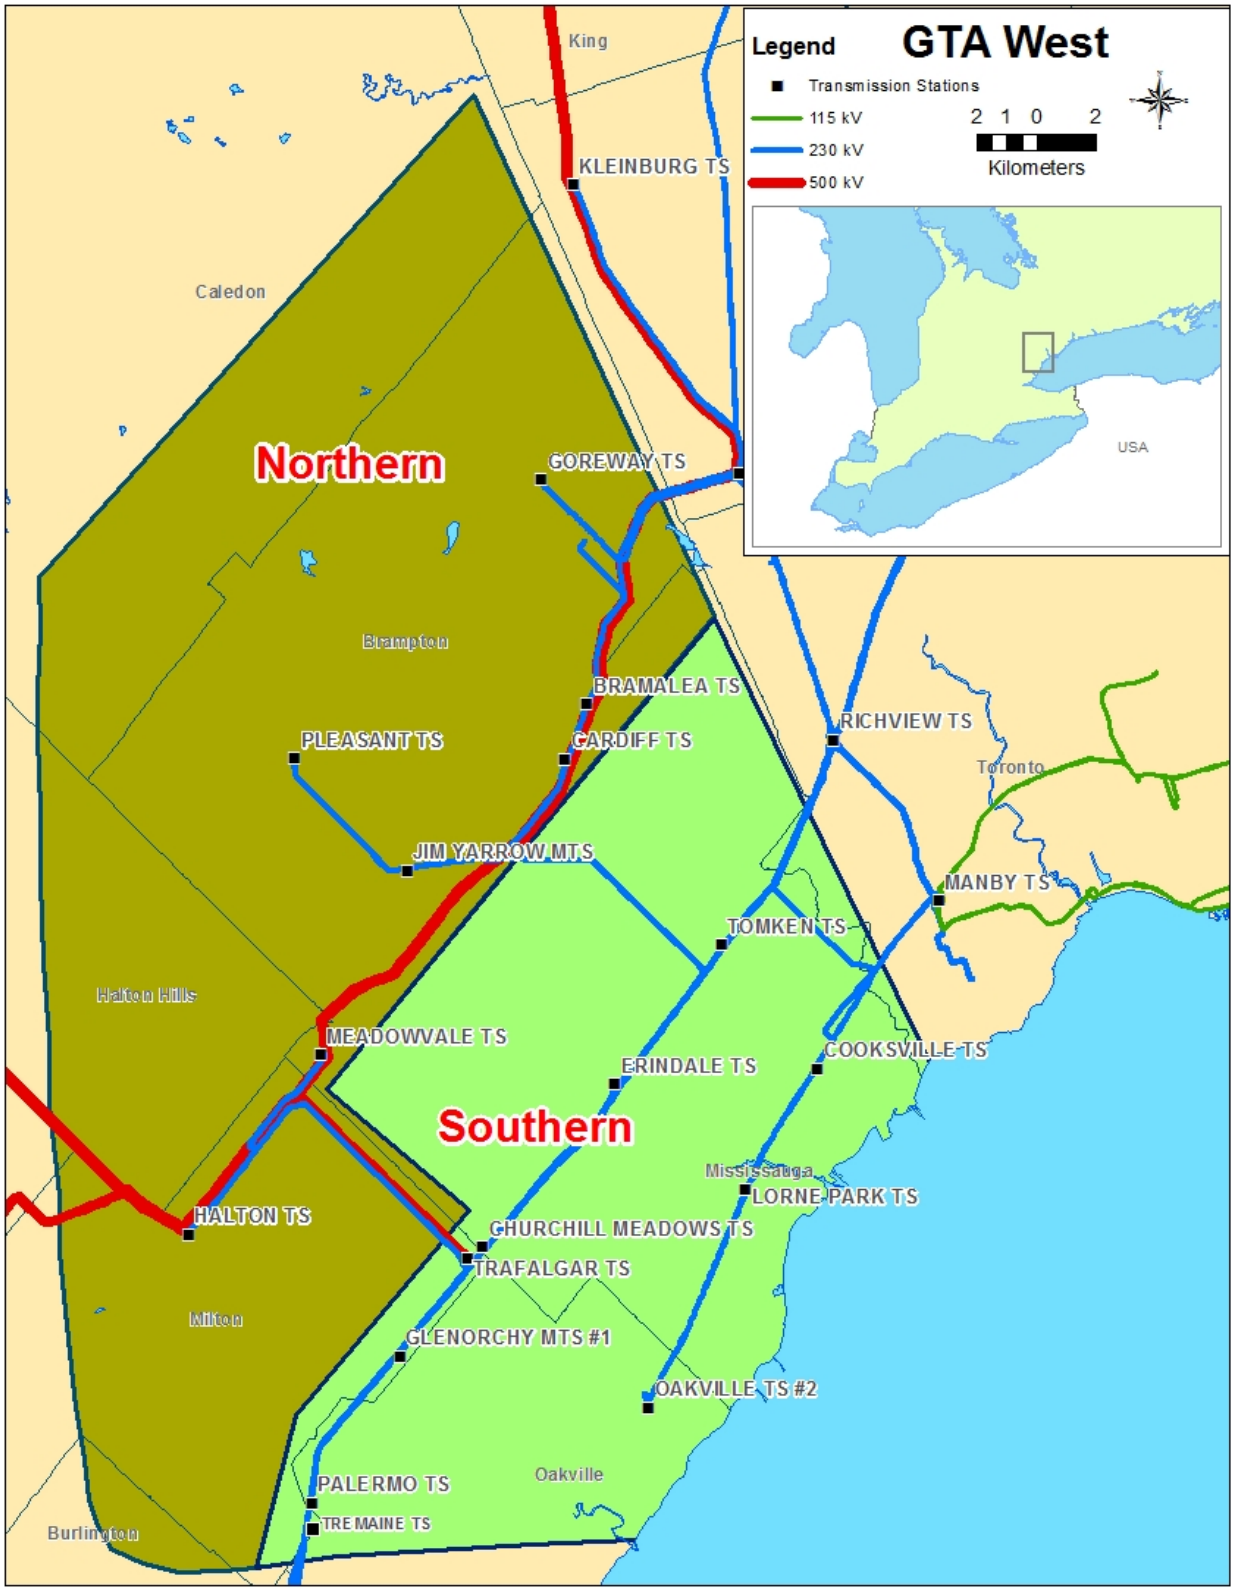

Figure 1-1 GTA West Region Map

1.1 Scope and Objectives

This RIP report examines the needs in the GTA West Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop wires plans to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs (2021-2031) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan);
- Identification of any new needs over the 2021-2031 period and wires plans to address these needs based on new and/or updated information;
- Consideration of long-term needs identified by the TWG.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process;
- Section 3 describes the region;
- Section 4 describes the transmission work completed over the last ten years;
- Section 5 describes the load forecast and study assumptions used in this assessment;
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs;
- Section 7 discusses the needs and provides the alternatives and preferred solutions; and,
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [2] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Technical Working Group (TWG) determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and a Local Plan ("LP") is developed to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require further coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the TWG, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led

[2] also referred to as Needs Screening

stakeholder engagement with municipalities and establishes a Local Advisory Committee (LAC) in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive and consolidated report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, plan level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the regional planning process taking effect;
- The NA, SA, IRRP and LP phases of regional planning;
- Conducting wires planning as part of the RIP for the region or sub-region;
- Planning for connection capacity requirements with the LDCs and transmission connected customers.

Figure 2 -1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

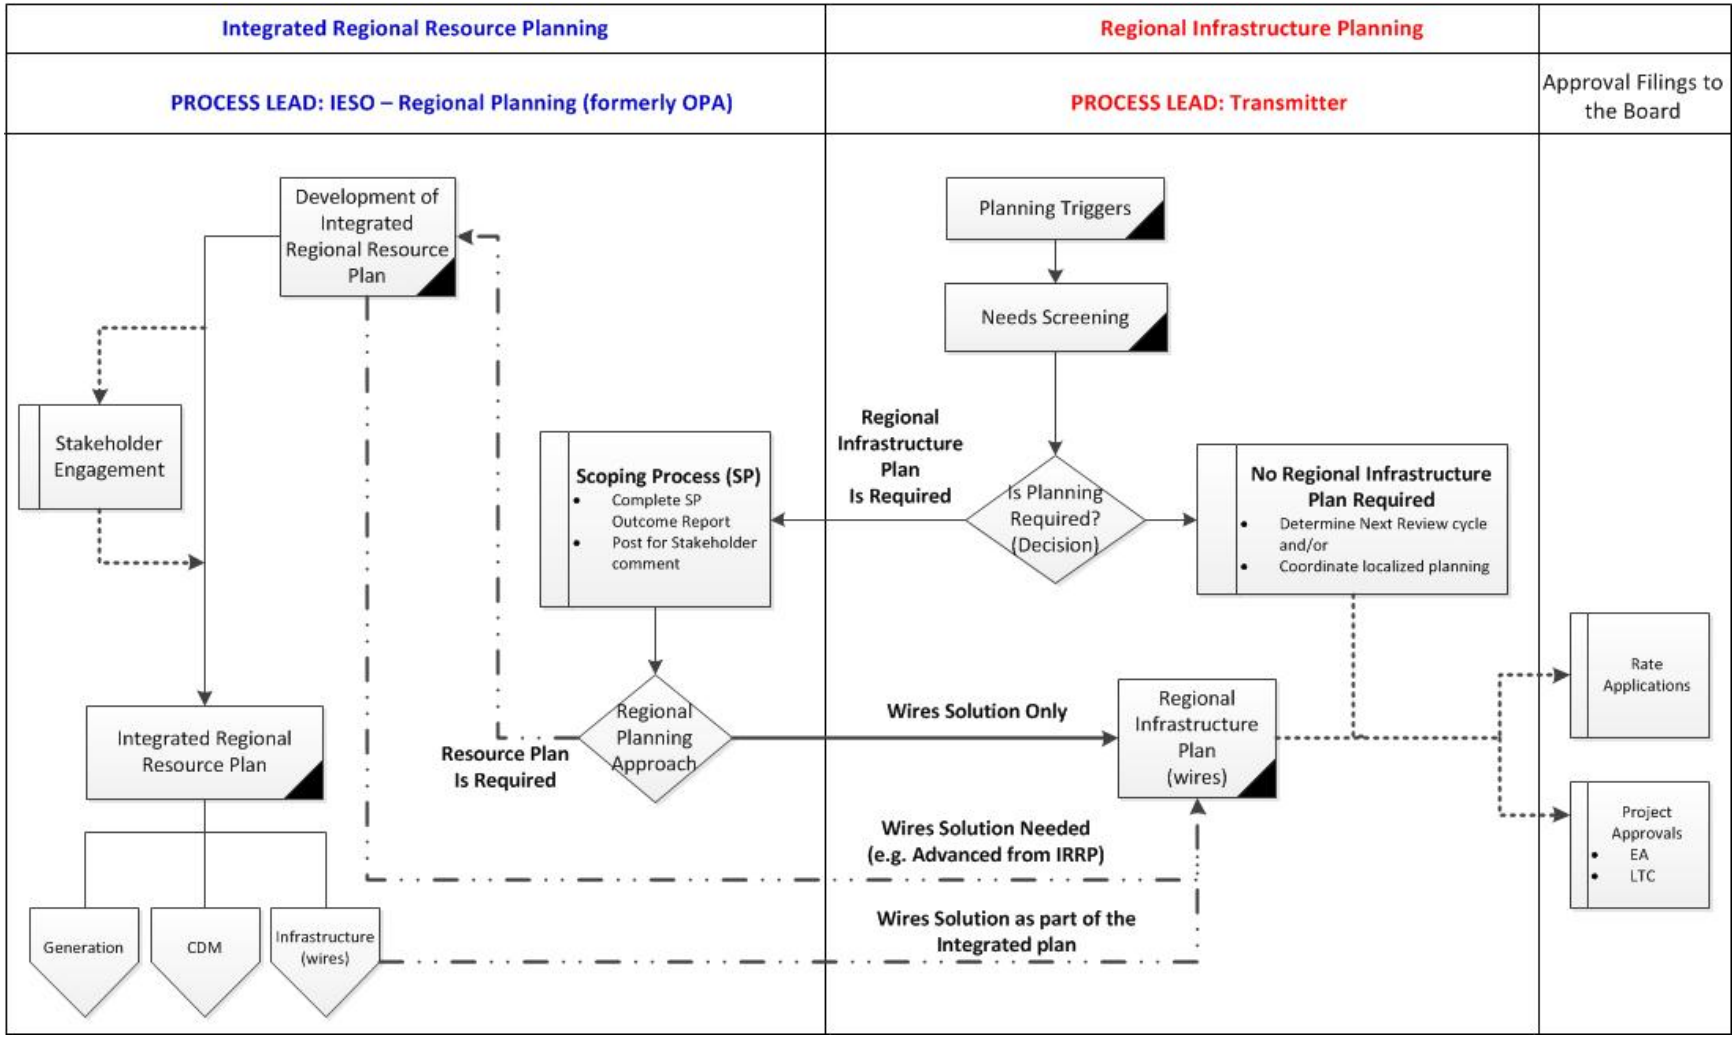

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1. Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions, load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

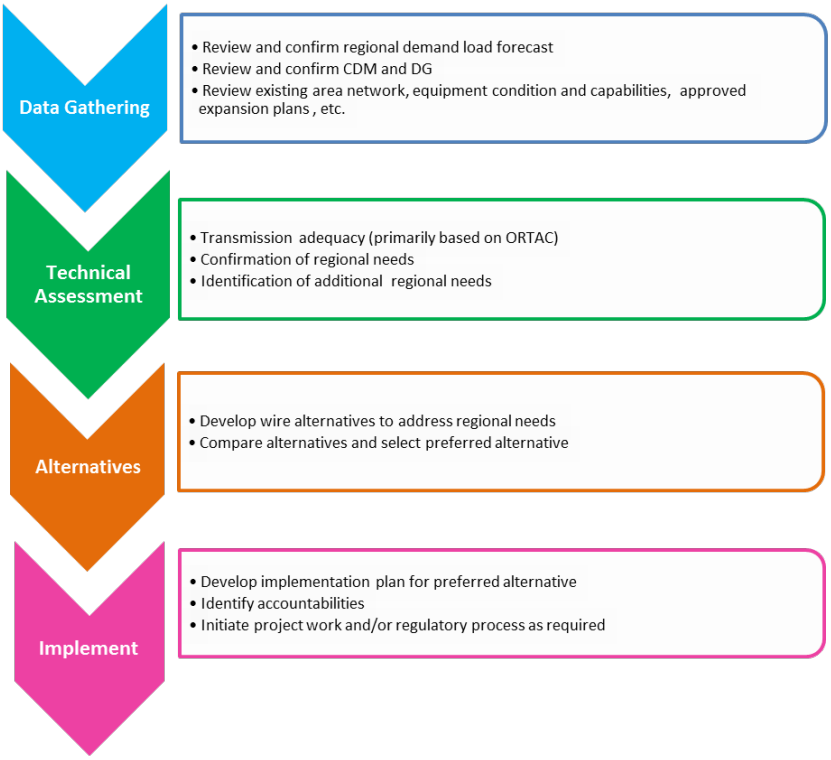

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE GTA WEST REGION COVERS THE REGIONAL MUNICIPALITIES OF HALTON AND PEEL AND INCLUDES THE MUNICIPALITIES OF BRAMPTON, SOUTHERN CALEDON, HALTON HILLS, MISSISSAUGA, MILTON, AND OAKVILLE. THE REGION INCLUDES THE AREA ROUGHLY BORDERED GEOGRAPHICALLY BY HIGHWAY 27 TO THE NORTH-EAST, HIGHWAY 427 TO THE SOUTH-EAST, REGIONAL ROAD 25 TO THE WEST, KING STREET TO THE NORTH AND LAKE ONTARIO TO THE SOUTH.

Bulk electricity in the region is supplied by Burlington TS from the west, Claireville TS from the north, Richview TS and Manby TS from the east, and from the 500/230 kV autotransformers at Trafalgar TS, and distributed by a network of 230 kV transmission lines and twenty (20) step-down transformer stations (see Appendix A and B for a complete list). The distribution system in this Region is at two voltage levels, 44 kV and 27.6 kV. Local generation in the area include the two gas fired plants, the 1250 MW Sithe Goreway GS in Brampton and the 683 MW Halton Hills GS in Halton Hills.

The Local Distribution Customers (LDC) in the GTA West Region are Alectra Utilities Co., Burlington Hydro Inc., Halton Hills Hydro Inc., Hydro One Networks Inc., Milton Hydro Distribution Inc. and Oakville Hydro Electricity Distribution Inc. A listing of the LDCs along with the associated supply stations is given in Appendix C. The high-voltage system in this Region also provides supply to one direct transmission connected custormer's transformer station. An electrical single line diagram for the GTA West Region facilities is shown in Figure 3-1.

Kleinburg TS is located near Bolton, Ontario and has been part of the GTA North regional planning process. However, majority of the Kleinburg TS transformational capacity is being used to supply communities located into GTA West region. Due to this reason, the Kleinburg TS has been included as part of the GTA West Regional Planning process as well.

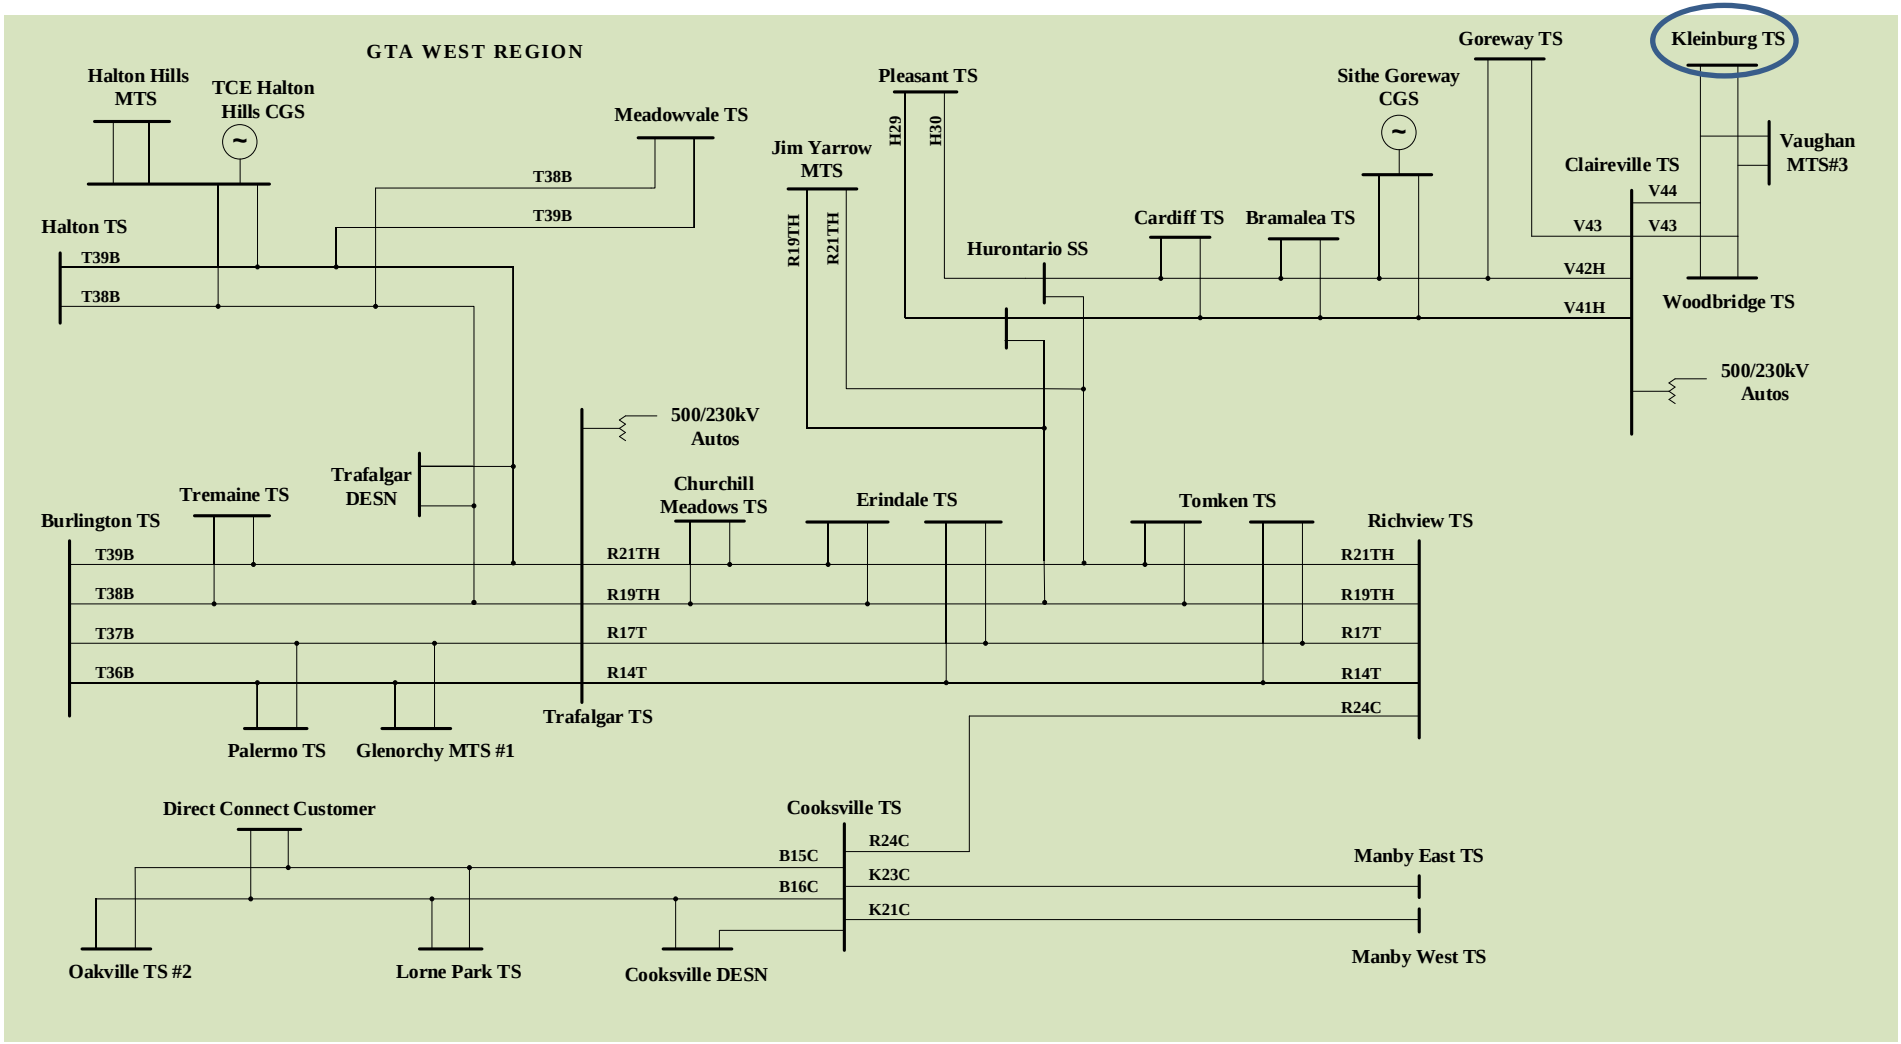

Figure 3-1 GTA West Region Single Line Diagram

4. TRANSMISSION FACILITIES COMPLETED AND/OR UNDERWAY IN THE LAST TEN YEARS

IN THE LAST TEN YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND UNDERTAKEN BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY CAPABILITY AND RELIABILITY IN THE GTA WEST REGION.

A summary and brief description of the major projects completed and/or currently underway over the last ten years is provided below:

- Churchill Meadows TS (2010) – built a new step down transformer station consisting of two 75/125 MVA transformers in Mississauga supplied from 230 kV circuits R19TH and R21TH. This station provided additional load meeting capability to meet Alectra Inc. requirements.
- Hurontario SS and underground cable work (2010) - built a new switching station Hurontario SS, 4.2 km of double circuit 230 kV Line from Hurontario SS to Cardiff TS and 3.3 km of underground cable from Hurontario SS to Jim Yarrow MTS. The new switching station and associated line work connects the R19T/R21T circuits and the V42/V43H circuits to provide relief and improved reliability to Pleasant TS and Jim Yarrow MTS.
- Halton Hills GS (2010) – connected a new 683 MW gas-fired combined cycle generation station in Halton Hills connected to 230 kV circuits T38B and T39B. This generation station provided necessary local power to supply the GTA West Region.
- Glenorchy MTS#1 (2011) – connected new Oakville Hydro-owned Glenorchy MTS to 230 kV circuits T36B and T37B. This station provided additional load meeting capability to meet Oakville Hydro requirements
- Tremaine TS (2012) – built a new step down transformer station consisting of two 75/125 MVA transformers in Burlington supplied from 230 kV circuits T38B and T39B. This station provided additional load meeting capability to meet Burlington Hydro and Milton Hydro requirements.
- Richview TS x Trafalgar TS 230 kV Line Upgrade (Currently Underway) – The two 230 kV double circuits lines R14T/R17T and R19TH/T21TH between Richview TS and Trafalgar TS are being upgraded to provide additional bulk power transfer capability. The planned in-service date is Q2 2026.
- In addition to Hydro One, Halton Hills Hydro has also built the new Halton Hills Hydro MTS in 2019. This is a 230/28kV station with two 50/83MVA transformers and is connected to the 230 kV bus of the Halton Hills GS. This station has provided load meeting capability to supply Halton Hills Hydro loads.

5. FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the GTA West Region is expected to grow at an average rate of approximately 1.6% annually from 2021 to 2031, and 1.2% annually from 2031 to 2041. The growth rate varies across the region ranging from 1.4% in the Central Mississauga area to 2.4% in the West Oakville /Milton/Halton Hills area.

Figure 5-1 shows the GTA West Region extreme summer weather net load forecast from 2021 to 2041. The forecast shown is the regional non-coincident forecast, representing the sum of the load in the area for the 20 step-down transformer stations. The regional non-coincident peak load is forecast to increase from approximately 3184 MW in 2021 to 4212 MW in 2041. Non-coincident forecast for the individual stations in the region is available in Appendix D, and is used to determine any need for station capacity relief.

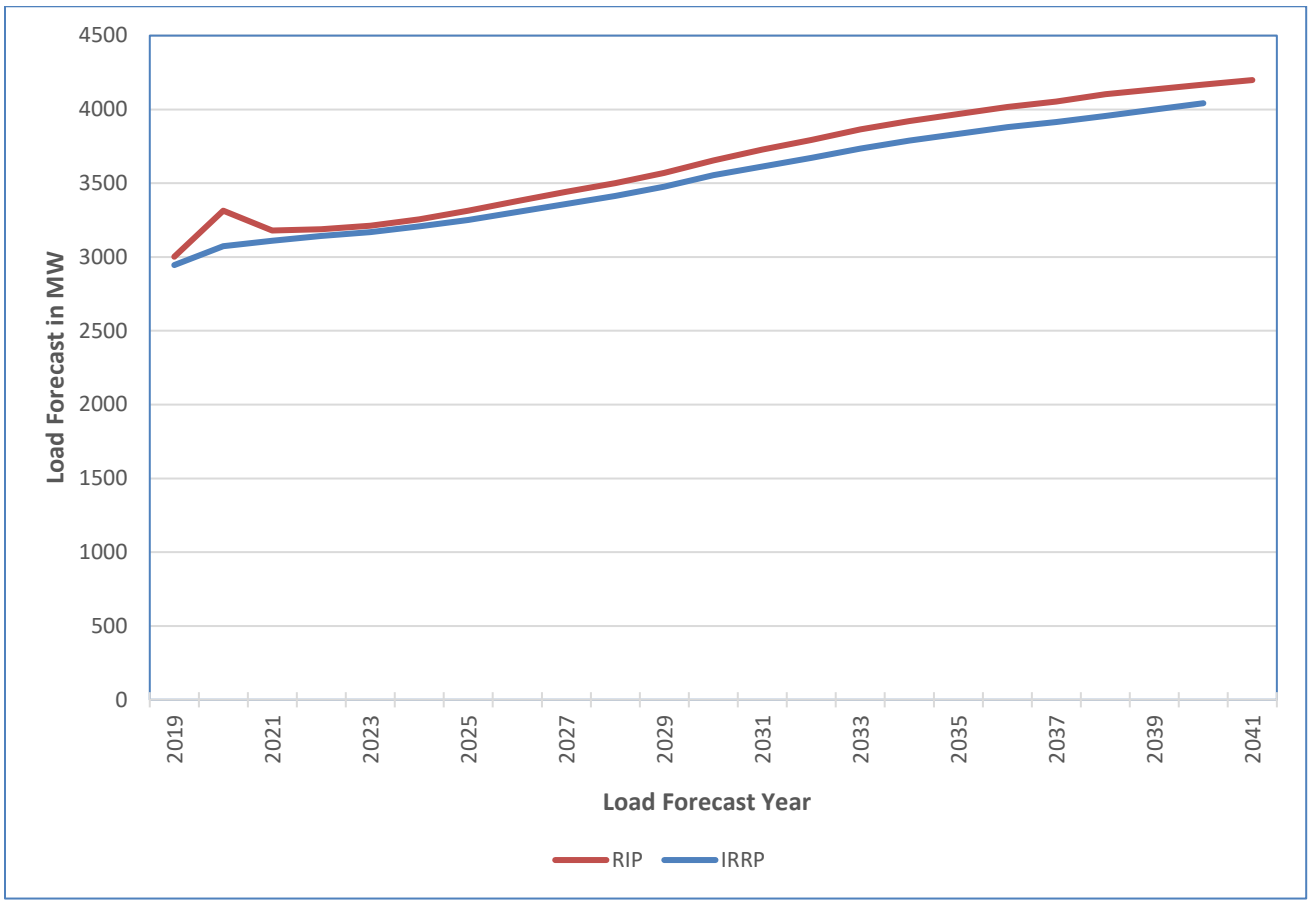

Figure 5-1 GTA West Region Non–Coincident Net Summer Peak Load Forecast

The regional non-coincident load forecast was developed by projecting the 2021 summer peak loads corrected for extreme weather, using the area stations growth rates as per the July 2021 IESO GTA West IRRP with

subsequent additional load forecast information provided by Alectra and Milton Hydro[3]. The IRRP forecast is shown for comparison. The growth rate accounts for CDM measures and connected DG. Details on CDM and connected DG information used to update the stations forecast in this report are provided in the GTA West IRRP [3] and are not repeated in this report.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2021-2031. However, a longer term forecast up to 2041 is provided to identify long-term needs and align with the IESO GTA West IRRP.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is based therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR).
- Line capacity adequacy is assessed by using peak loads in the area.

[3] As a result of the need to refurbish Palermo TS and the decision to upgrade the station transformers (see Section 7.1), Milton Hydro plan to increase the loading on Palermo TS and have reduced their forecast for Halton TS.

6. ADEQUACY OF EXISTING FACILITIES AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND TRANSFORMER STATION FACILITIES SUPPLYING THE GTA WEST REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE 2021-2031 PERIOD.

Within the current regional planning cycle, three regional assessments have been conducted for the GTA West Region. The findings of these assessments are inputs to this RIP. These assessments are:

1) GTA West Region Needs Assessment (NA) Report, May 9, 2019
2) GTA West Region Scoping Assessment (SA) Report, August 8, 2019
3) GTA West (Peel Halton) Integrated Regional Resource Plan (IRRP) and Appendices, July 2021

The NA and IRRP reports identified a number of needs as a result of the forecasted load demand and condition of major high voltage transmission assets. This section reviews the adequacy of the transmission lines and stations in the GTA West Region based on the updated regional load forecast provided in Appendix D. Sections 6.1 to 6.2 present the results of this review. Asset replacement needs identified in the previous NA report are discussed in Section 6.3 of this report. Load security and load restoration needs are discussed in Section 6.4.

6.1 500 kV and 230 kV Transmission Facilities

All 500 kV and 230 kV transmission circuits in the GTA West Region with the exception of the Hurontario SS to Pleasant TS 230 kV circuits H29 and H30 are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the rest of Ontario's transmission system. The 230 kV circuits also serve local area stations within the region and the power flow on them depends on the bulk system transfers as well as the local area loads.

6.1.1 500/230 kV Transformation Facilities

Bulk power supply to the GTA West Region is provided by 500/230 kV autotransformers at Trafalgar TS and Claireville TS, as well as 230 kV supply from Burlington TS, Richview TS and Manby TS. Additional support is provided from the 230 kV generation facilities at Halton Hills GS and Sithe Goreway GS. Both Claireville TS and Trafalgar TS are expected to require relief in the 2030s.

6.1.2 230 kV Transmission Circuits

The 230kV circuits in the region are as follows (please refer to Figure 3-1):

1. Claireville TS to Hurontario SS (230 kV Circuits V41H, V42H, V43) – Supply Bramalea TS, Cardiff TS, and Goreway TS
2. Hurontario SS to Pleasant TS (230 kV Circuits H29, H30) – Supply Pleasant TS

3. Trafalgar TS to Burlington TS (230 kV Circuits T36B, T37B, T38B, T39B) – Supply Glenorchy MTS #1, Palermo TS, and Tremaine TS
4. Trafalgar TS to Halton TS (Radial Tap from 230 kV Circuits T38B, T39B) – Supply Trafalgar DESN, Meadowvale TS and Halton TS
5. Richview TS to Trafalgar TS (230 kV Circuits R14T, R17T) – Supply Erindale TS and Tomken TS
6. Richview TS to Trafalgar TS, with tap to Hurontario SS (230 kV Circuits R19TH, R21TH) – Supply Churchill Meadows TS, Erindale TS, Jim Yarrow MTS, and Tomken TS
7. Richview TS and Manby TS to Cooksville TS (230 kV Circuits R24C, K21C, K23C, B15C, B16C) – Supply Cooksville DESN, Ford Oakville CTS, Lorne Park TS, and Oakville TS #2.

The Richview TS x Trafalgar TS 230 kV circuits, R14T/R17T and R19TH/R21TH, are part of the "Flow East toward Toronto" interface ("FETT") and the flow on these circuits is expected to increase as a result of the change in generation resource following the retirement of the Pickering Nuclear Generating Station in 2025. As the result, these circuits need to be upgraded. OEB Leave to Construct ("Section 92") approvals have been obtained for the project and work is underway on reconductoring these circuits with new conductors that have a 2000A summer continuous rating. The planned in-service date for the project is Q2 2026.

Other line sections expected to exceed their ratings during the study period are listed in Table 6-1 below.

Table 6-1 GTA West Region - Lines Sections Exceeding ratings

No.	Line	Section	Contingency	Line Rating MW	Year Line Rating exceeded
1	H29/H30	Hurontario SS x Pleasant TS	N-1[1]	419	2027
2	T38B/T39B	Lantz Jct x Trafalgar DESN	N-1[1]	535	2033
3	R19TH/R21TH	Hanlan Jct x Hurontario TS	N-1-1[2,3]	416	2021

[1] Loss of one circuit of the double circuit line
[2] R19TH is overloaded when H29 and V42H are out of service
[3] R21TH is overloaded when H30 and V41H are out of service

The planned solutions to address these needs are discussed further in Section 7 of the report.

6.2 Step-Down Transformation Facilities

There are a total of twenty (20) step-down transformer stations in the GTA West Region as listed in Table 6-2. Nineteen (19) supply electricity to LDCs and one is a transmission connected industrial customer station. Of the nineteen stations, three (3) are owned and operated by the LDCs.

The stations summer peak load forecast is given in Appendix D Table D-1.

Table 6-2 GTA West Region - Step-Down Transformer Stations

Bramalea TS	Glenorchy MTS#1	Kleinburg TS	Pleasant TS
Cardiff TS	Goreway TS	Lorne Park TS	Tomken TS
Churchill Meadows TS	Halton Hills MTS	Meadowvale TS	Trafalgar TS
Cooksville TS	Halton TS	Oakville TS #2	Tremaine TS
Erindale TS	Jim Yarrow MTS	Palermo TS	Customer #1 CTS

This RIP reviewed the step-down transformation capacity for the stations within the GTA West Region. The NA and IRRP studies had previously indicated that a second Halton TS DESN would be required by summer 2022. Subsequent to those studies, and as part of the discussions for this RIP, Milton Hydro provided a revised load forecast with new load being supplied from Glenorchy MTS #1, Halton Hills MTS, and Palermo TS. As a result of this update,the need for the second Halton TS DESN has been deferred to 2033. Based on the load forecast, the following stations would require capacity relief during the 2021-2031 study period as shown in Table 6-3 below. The need timeframe defines the time when the peak load forecast exceeds the DESN's Summer 10-day LTR.

Table 6-3 GTA West Region - Step-Down Transformer Stations Requiring Relief

Station	Capacity (MW)	2021 Loading (MW)	Need Date
Palermo TS: T1/T2 DESN refurbishment	110	124	2027
Pleasant TS: T1/T2 DESN	148	138	2027
Erindale TS: T1/T2 DESN	181	142	2028
Cardiff TS: T1/T2 DESN	113	103	2029
Erindale: T5/T6 DESN	185	142	2031

Further, based on the load forecast, the stations requiring relief beyond 2031 are listed below:

- Jim Yarrow MTS: T3/T4 DESN – 2032
- Kleinburg TS: T1/T2 DESN – 2032
- Goreway TS: T5/T6 DESN – 2034
- Bramalea TS: T3/T4 DESN – 2036
- Tremaine TS: T1/T2 DESN – 2039

6.3 Asset Replacement Needs for Major High Voltage (HV) Transmission Equipment

A number of Hydro One facilities in the GTA West Region will require replacement over the 2021-2031 study period. These needs are determined by asset condition based on a range of considerations such as equipment deterioration, technical obsolescence due to outdated design, lack of spare parts availability or manufacturer support, and/or potential health and safety hazards.

Asset replacement work is planned over the study period at area transformer stations listed in Table 6-4. Palermo TS work is discussed in Section 7.1. Details for the remaining stations are provided in Section 7.5.

Table 6-4 GTA West Region - Planned Replacement Work

No.	Station	Planned I/S Date
1	Palermo TS	2026
2	Bramalea TS	2028
3	Tomken TS	2029
4	Lorne Park TS	2030

6.4 Load Security and Load Restoration

Load security and load restoration needs were reviewed as part of the current study. For load security ORTAC requires that no more than 600 MW of load be lost as a result of a double circuit contingency.

Further, loads are to be restored in the restoration times specified as follows:

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interruped in excess of 250 MW must be restored within 30 minutes.

6.4.1 T38B/T39B Load Security

The 2021 IRRP had identified that the loading on the double circuit 230kV line T38B/T39B corridor was forecast to exceed the 600 MW limit by 2025. However, as mentioned in Sections 5 and 6.2, Milton Hydro plan to increase loading on Palermo TS and have updated the forecast for Halton TS. As a result, the loading on T38B/T39B circuits has been reduced. The current revised forecast (See Table 6-5) indicates that the non-coincident connected load on the T38B/T39B circuits will exceed the 600 MW limit by 2030.

Table 6-5 GTA West Region – Load connected to 230kV double circuit line T38B/T39B

Circuit	Limit MW	Act.	Forecast - Connected Load (MW)										
		2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2041
T38B/T39B	600	523	516	529	555	566	580	578	584	598	**613**	631	843

This load security need is further discussed in section 7.6

6.4.2 Load Restoration

Load restoration needs in the Region were previously identified in the NA, SA and IRRP. These were again reviewed by the Working Group in the RIP. The lines, stations served and the loads at the end of the study period on the lines in the Region are given in Table 6-6 below:

Table 6-6 GTA West Region – Load Connected to Various Transmission Lines

No.	Lines/ Circuits	Connected Stations	Line Length (km)	Year 2031 Connected Load (MW)	Load subject to 30 minute criteria (MW)
1	B15/B16	Lorne Park TS, Oakville #2 TS	12.5	278	28
2	H29/H30	Pleasant TS	8.5	459	209
3	R14T/R17T	Erindale TS (T1/T2) & (T3/T4), Tomken T1/T2	21.7	479	229
4	R19TH/ R21TH	Churchill Meadows TS, Erindale TS (T5/T6), Tomken TS (T3/T4), Jim Yarrow TS	33.3	583	333
5	T36B/T37B	Palermo TS, Glenorchy MTS#1	24.5	272	22
6	T38B/T39B[1]	Tremaine TS, Trafalgar DESN, Halton TS, Meadowvale TS and Halton Hills MTS	42.7	631	381
7	V41H/V42H	Bramalea TS, Cardiff TS	17/26.3[2]	435	185
8	V42H/V43	Goreway TS	17/21.4[2]	269	19
9	V43/V44	Woodbridge TS, Vaughan MTS#3, Kleinburg TS[3]	21.4/12[2]	498	248

[1] Trafalgar DESN, Halton TS, Meadowvale TS and Halton Hills TS are on a radial tap connected to the T38B/T39B line.

[2] Tap length for the two circuits are different

[3]Vaughan MTS#3 and Woodbridge TS are also supplied from the V43/V44 line and loads are taken from the 2020 GTA North RIP report.

The Table shows that all lines in the Region have connected load greater than 250MW. For lines 1, 5, 8 the load in excess of 250MW is small and transfers can be managed at the distribution levels. For all other lines, the load in excess of 250MW cannot be restored within 30 minutes. However, all lines are short; reliability of the lines is good and the incidents of overlapping outages very rare. The lines are located in the GTA, with good accessibility for maintenance crews and Hydro One expects all loads to be restored within 4 hours with at least one circuit back into service.

Any mitigation measure to meet the 30 minute restoration requires building new lines and/or installing additional switching facilities. The work will be extremely expensive and have substantial environmental and public impact. Given the past reliability performance and expectation to restore the load within 4 hours, the TWG does not recommend any further action.

7. REGIONAL PLANS

THIS SECTION DISCUSSES NEEDS, PRESENTS WIRES ALTERNATIVES AND THE PREFERRED WIRES OPTIONS FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS FOR THE GTA WEST REGION..

The electrical infrastructure needs for the GTA West Region are summarized in Table 7-1. These needs include those previously identified in the GTA West NA and IRRP as well as those resulting from the adequacy assessment carried out as part of this RIP report. The details of the project/plan to address these needs are provided in Sections 7.1 through 7.7.

Table 7-1 GTA West Region – Identified Near, Medium-Term and Long Term Needs

Section	Facilities	Need	Timing
7.1	Palermo TS	Transformers T3 and T4 replacement. Milton Hydro capacity requirements	2026
7.2	H29/H30: Hurontario TS x Pleasant TS	Line upgrade required to supply Pleasant TS	2027
7.3	R19TH/R21H	Overload under certain outage conditions	Existing
7.4	Pleasant TS: T1/T2 DESN	Load exceeding DESN capacity	2027
7.4	Erindale TS: T1/T2 DESN	Load exceeding DESN capacity	2028
7.4	Cardiff TS: T1/T2 DESN	Load exceeding DESN capacity	2029
7.4	Kleinburg TS: T1/T2 DESN	Load exceeding DESN capacity	2030
7.4	Erindale: T5/T6 DESN	Load exceeding DESN capacity	2031
7.5	Bramalea TS	Transformer T3 and T4 replacement	2028
7.5	Tomken TS	Transformers T1 and T2 replacement	2029
7.5	Lorne Park TS	Transformer T2 replacement	2030
7.6	Load Security	T38B/T39 Loading	2030
7.7	Load Restoration	ORTAC 30 minutes restoration criteria not met.	---[1]
7.8	Longer Term Needs	Capacity Exceeded Lines - T38B/T39B: Lantz Jct x Trafalgar DESN Stations - Jim Yarrow MTS: T3/T4 DESN Kleinburg TS: T1/T2 (27.6kV) DESN Goreway TS: T5/T6 DESN Bramalea TS:T3/T4 DESN Tremaine TS: T1T2 DESN	 2033 2032 2032 2034 2036 2039

[1]No action is planned. Please see sections 6.4.2 and 7.7.

7.1 Palermo TS: T3/T4 Replacement and Milton Hydro Capacity Requirements

7.1.1 Description

Palermo TS is a 230/27.6 kV transformer station that facilitates load delivery to Burlington Hydro Inc., Milton Hydro Inc. and Oakville Hydro customers in the cities of Burlington, Milton and Oakville, respectively (see Figure 7-1). Peak station demand was about 124 MW in summer 2021 as compared to the station 10 day LTR of 110 MW.

The transformers, T3 and T4, at Palermo TS are over 50 years old and based on asset condition assessment require replacement in the near-term. The current plan is to replace these transformers by Q4 2026.

Palermo TS is currently a “restricted station” due to short circuit constraints and new DER resources cannot connect to feeders from the station.

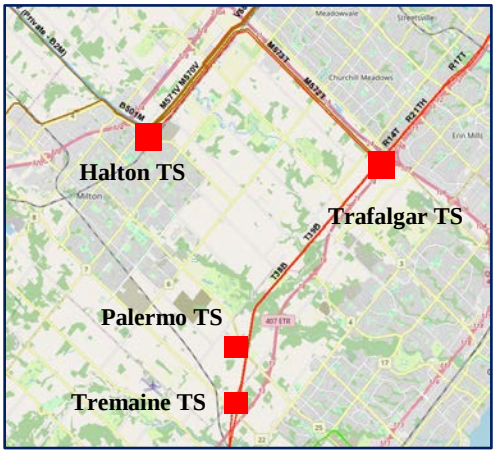

Figure 7-1 Palermo TS

The earlier NA and IRRP reports had identified the need for adding a second DESN at Halton TS by 2022 and that the loading on Tremaine TS would be exceeded by 2033. The IRRP had also identified upsizing the Palermo TS transformers as a more cost effective alternative to replacing the transformer like for like. As part of this RIP, Milton Hydro reviewed their load forecast and now plan to utilize the increased capacity at Palermo TS, thereby deferring the need for a second DESN at Halton TS to 2033. The Palermo TS upgrade also defers the need for providing relief for Tremaine TS to 2039. The Palermo TS forecast is given below in Table 7-2 and reflects the revised loading provided by Milton Hydro and assumes that Burlington Hydro and Oakville Hydro existing load on Palermo TS remains constant.

Table 7-2 Palermo TS Load Forecast

Station	LTR (MW)	Act.	Load Forecast										
		2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2041
Palermo TS	110/180[1]	124	115	113	113	112	112	129	133	134	135	137	155

[1]The station existing LTR is 110 MW. With new 75/125MVA transformers the LTR will increase to 180 MW.

7.1.2 Alternatives and Recommendation

The following alternatives were considered to address Palermo TS T3/T4 replacement need as well as meet future demand requirements:

- **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not address the risk of failure due to asset condition and would result in increased maintenance expenses and will not meet Hydro One’s obligation to provide reliable supply to the customers.

- **Alternative 2 – Replace T3/T4 with similar type and size equipment as per current standard:** Under this alternative the existing T3/T4 transformers at Palermo TS will be replaced with new 50/83 MVA, 230/27.6 kV transformers. This alternative would address the need and maintain reliable supply to the customers in the area. It would not however, provide additional capacity to meet the future load growth as per the load forecast. It would also not allow additional DER resources to connect to the station since the short circuit constraints will remain due to the lower impedances of the 50/83MVA transformers.
- **Alternative 3 – Replace T3/T4 with larger size 230/27.6 kV, 75/125MVA transformers:** This alternative would require replacing the existing T3/T4 transformers with larger size transformers. Since the new transformers will be dual-winding transformers, the existing low voltage switchyard will need to be modified and additional feeders added to utilize the increased capacity. The modified station will have dual 27.6 kV buses with reduced fault current level and station capacity will increase from current 110 MW to 180 MW. This alternative will thus provide additional capacity to meet future load growth and the reduced fault current will permit DER resources to connect to the station.

The TWG recommends Alternative 3 as the preferred and cost effective alternative for addressing the need and taking "right-sizing" into consideration. It provides capacity to meet future load growth, removes the restriction on DER to connect to the station, maintains reliable supply to the customers in the area while increasing system resiliency and flexibility. While the incremental cost difference between the 50/83MVA and the 75/125MVA transformers is small (<$1M), planning estimates for the LV yard expansion and additional feeder positions are between $7-10M.

7.2 230 kV Circuits H29/H30 Conductor Upgrade

7.2.1 Description

Pleasant TS is located in Brampton and has two 230/27.6 kV DESNs and one 230/44kV DESN. The station is supplied by the 230 kV double circuit line H29/H30 from Hurontario SS (see Figure 7-2). The station serves Alectra – Brampton loads. The summer 2021 peak station load was about 383 MW.

The existing conductor used for 230 kV circuits H29/H30 going to Pleasant TS is 795.0 kcmil ACSR 26/7 with summer long term emergency rating of 1090 A (at 127°C). This rating limits the maximum load-carrying capacity to approximately 419 MW of load at Pleasant TS. As mentioned in Table 6.1 the line flows are forecast to exceed line rating by summer 2027.

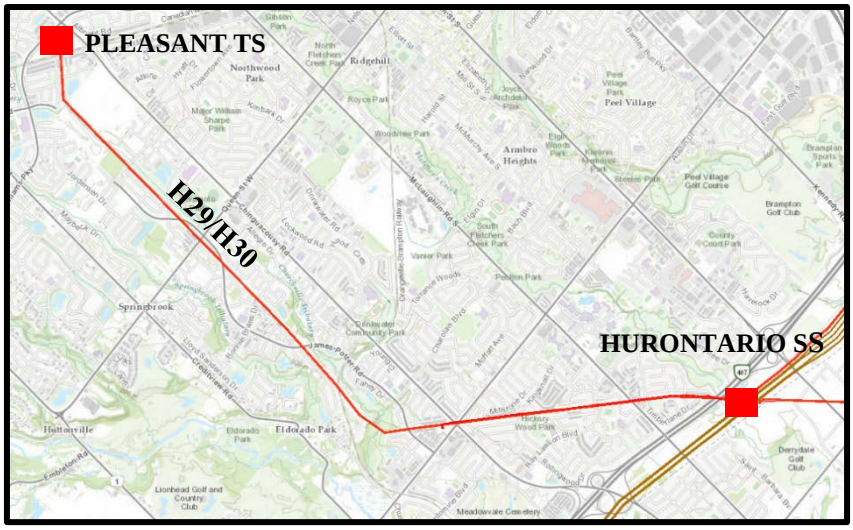

Figure 7-2 Radial Circuits of H29/H30 Supplying Pleasant TS

7.2.2 Alternatives and Recommendation

The following alternatives were considered to address upgrading of the H29/H30 line:

1. **Alternative 1 - Maintain Status Quo**: This alternative was considered and rejected as it does not provide adequate transmission capacity to supply the load demand at Pleasant TS.
2. **Alternative 2 – Upgrade Line conductor:** This alternative covers upgrading the line by replacing the existing conductor with a conductor with a higher current rating.

Other alternatives such as building a second 230 kV line to Pleasant TS or transferring load away from Pleasant TS were considered and ruled out as impractical and not cost effective.

The TWG recommends Alternative 2 as the technically preferred and cost effective alternative for reinforcing the supply to Pleasant TS. Hydro One will consider transmission losses while selecting the conductor. OEB approval under Section 92 of the Electricity Act will be required. The estimated cost of the project is about $8M.

7.3 230 kV Circuits R19TH/R21TH - Overload under certain outage conditions

7.3.1 Description

The loads at Jim Yarrow MTS and Pleasant TS are supported by the 230 kV line V41H/V42H from Claireville and the R19TH/R21TH line as shown in Figure 7-3, Under certain outage conditions all loads at Pleasant TS and half the load on Jim Yarrow MTS can end up on one of the R19TH or the R21TH section between Hanlan Jct and Hurontario SS.

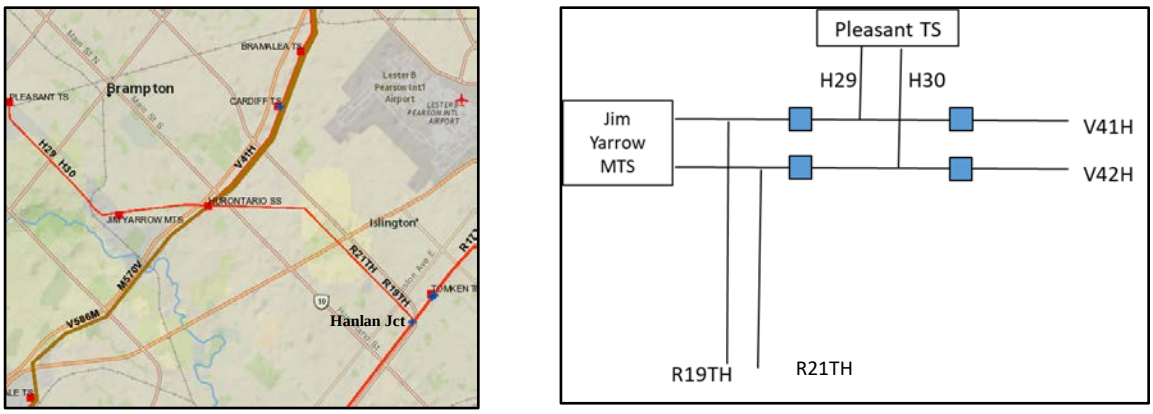

Figure 7-3 Supply to Jim Yarrow MTS and Pleasant TS

The two outage scenarios are:

- R19TH overloaded for overlapping outages of V41H and H30 (V41H out of service and H30 lost or H30 out of service and V41H lost).
- R21TH overloaded for overlapping outages of V42H and H29) (V42H out of service and H29 lost or H29 out of service and V42H lost).

7.3.2 Alternatives and Recommendation

The IRRP had considered a number of alternatives to address this issue ranging from a local load rejection scheme at Pleasant TS to reinforcing the supply to Hurontario SS.

Following discussions with IESO and Hydro One Operating groups, given the fact that the possibility of the overlapping outages is rare, manual operator action can be taken to relieve the line overloads and will be adequate over the near to medium-term (till 2030). Hydro One has implemented an operating procedure under which Jim Yarrow MTS load is transferred to R21TH if V41H or H30 are out of service pre-contingency and to R19TH if V42H or H29 are out of service pre-contingency.

The TWG recommends that the loading on the R19TH/R21TH and the performance of the manual scheme be monitored. The timing (currently forecast to be around 2030) and the preferred option alternative for the LR scheme will be reviewed in the next planning cycle.

7.4 Station Capacity - DESN Stations Exceeding LTR

As discussed in Section 6.2 the loading on five DESN stations – Palermo TS T3/T4, Erindale TS T1/T2, Pleasant TS T1/T2, Cardiff TS T1/T2, Erindale T5/T6 - is expected to exceed station LTR during the 2021-2031 study period. Palermo TS has been discussed in Section 7.1. The remaining stations are discussed here.

All these remaining DESNs supply Alectra utilities load. Erindale TS and Cardiff TS supply load in Mississauga and Pleasant TS supplies load in Brampton (Figure 7-4). The stations forecast loads and need dates are given in Table 7-3 below.

Table 7-3 Forecast Loads on DESNs Overloaded during Plan Period

Station	LTR MW	Act.	Load Forecast											Need Date
		2021	2022	2023	2024	2025	2026	2027	2028	2029	2030	2031	2041

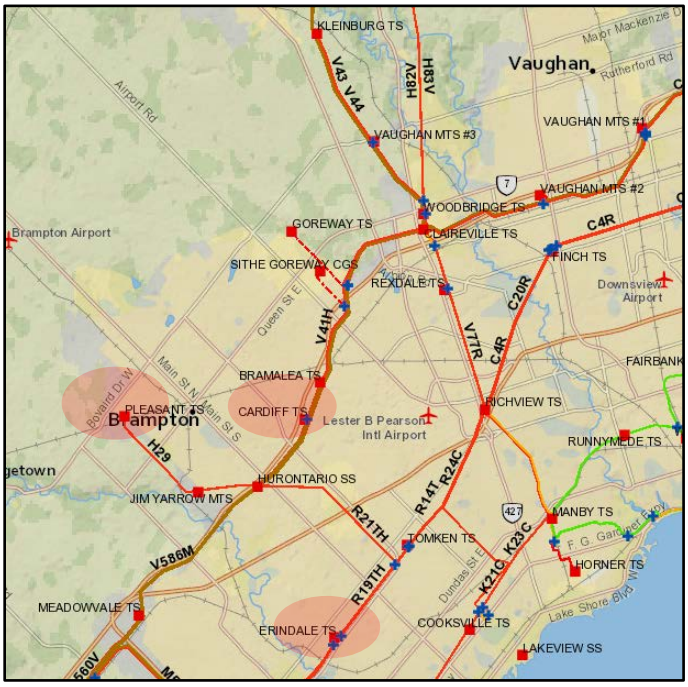

Figure 7-4 GTA West Region - Pleasant TS, Cardiff TS and Erindale TS

Options for providing the required relief for Erindale TS T1/T2 DESN were previously investigated in 2015 Local Planning Report for Erindale TS [4]. As discussed in the 2019 GTA West Region NA Report [2], this need is being managed by Alectra and no transmission upgrades are required.

The loading issues at the Pleasant TS T1/T2 DESN, Cardiff TS T1/T2 DESN, and the Erindale TS T5/T6 DESN are similar to those of Erindale T1/T2 DESN. The TWG recommends that these loading issues be managed at the Distribution level in the near term and it will be reviewing the station loadings in the next regional planning cycle.

7.5 Asset Replacement for Major HV Transmission Equipment

As discussed in Section 6.3, Hydro One has identified the need for replacement of major HV transmission assets over the next ten years at a number of GTA West Region Hydro One stations – Palermo TS, Bramalea TS, Tomken TS and Lorne Park TS –. Palermo TS T3/T4 replacement is discussed in section 7.1.

Details of thework at the remaining stations along with their planned in-service year are given in Table 7-4 below:

Table 7-4 GTA West Region – Asset Replacement Plans

No.	Station	Planned work	In-service year(1)
1	Bramalea TS	The work includes replacement of the 230/44kV, 50/83MVA transformers, T3 and T4 with larger size 230/44kV, 75/125MVA units.	2028
2	Tomken TS	The work includes like-for-like replacement of 230/44 kV, 75/125 MVA transformers T1 and T2.	2029
3	Lorne Park TS	The work includes like-for-like replacement of 230/27.6 kV, 50/83MVA transformer T2.	2030

(1) The planned in-service year is tentative and is subject to change

The above asset replacement plans have taken “right sizing” into consideration. Based on the load forecast, Bramalea TS T3/T4 transformers will be replaced with larger size 75/125MVA units as the load forecast indicates that increased capacity would be required by 2036. The Lorne Park TS T2 transformer is planned to be replaced with “like-for-like” 50/83MVA units and Tomken TS T1/T2 transformers will be replaced with “like-for-like” 75/125MVA units (which is the largest standard size for these transformers).

The TWG recommends that Hydro One proceed with the above work to ensure that the system meet reliability criteria and supply to customers is not affected.

7.6 Load Security – 230 kV circuits T38B/T39B

7.6.1 Load Security

As discussed in Section 6.4.1 loads connected to the 230 kV circuits T38B/T39B will exceed the 600 MW by summer 2030. The circuit T38B/T39B will not be able to meet the ORTAC supply security criteria, which states that no more than 600 MW can be interrupted by configuration.

7.6.2 Alternatives and Recommendations

There were a number of alternatives suggested in the IRRP to ensure compliance with the ORTAC load security criteria. These included sectionalizing the T38B/ T39B circuits using breakers or re-terminating the stations to reduce loads connected to the T38B/T39B circuits. However, as per the current forecast, load is not expected to exceed 600 MW till summer 2030 due to the lower than expected load at Halton TS and Milton Hydro supplying some of the projected area load from the upsized Palermo TS.

The TWG recommends that Hydro One continue to monitor the load and that it wll review the the need the next regional planning cycle.

7.7 Load Restoration

Load restoration following outages was discussed in Section 6.4.2 As mentioned, there are a number of lines that do not meet the IESO criteria of the restoration of all load above 250 MW in 30 minutes.

However, given the high cost for mitigation measures, the low probability of the event happening and the ability to restore load within 4 hours, the TWG agrees that no further action is required.

7.8 Long Term Considerations

7.8.1 Capacity needs for 2032-2041

A number of capacity needs were identified in Section 6 over the longer term. These are summarized here.

1. Line capacity – Loading on a small 300m section of the T38B/T39B line, between Lantz Jct and Trafalgar DESN, will exceed the line rating by 2033.
2. Station Capacity – The following stations are expected to require relief:

    - Jim Yarrow MTS: T3/T4 DESN - 2032
    - Kleinburg TS: T1/T2 (27.6 kV) - 2032
    - Goreway TS: T5/T6 DESN - 2034
    - Bramalea TS: T3/T4 DESN – 2036[4]
    - Tremaine TS: T1/T2 DESN - 2039

The TWG will be reviewing these needs in the next regional planning cycle.

7.8.2 Long-Term Growth & NWGTA Electricity Corridor Need

The 2015 GTA West RIP had indicated the need for a new transmission corridor connecting Milton TS in the west to Kleinburg TS in the east. The corridor was proposed to provide the necessary transmission infrastructure required to support the load growth expected in the in northern part of the GTA West region as a result of the Provincial Government growth plans.

The Ministry of Energy and the Independent Electricity System Operator (IESO) have been working on the proposal to identify and protect a corridor of land for the future transmission corridor [5]

The TWG supports the initiative for the development of the new corridor as it will be essential to meet the future area growth. The progress of corridor development will be reviewed in the next regional planning cycle.

[4] This need will be addressed by the planned replacement of Bramalea TS T3 and T4 230/44kV, 50/83MVA transformers in 2028 with larger size 75/125MVA units.

8. CONCLUSIONS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GTA WEST REGION.

The major infrastructure investments recommended by the Technical Working Group (TWG) in the near and medium-term planning horizon (2021-2031) are provided in Table 8-1 below, along with their planned in-service dates and budgetary estimates for planning purposes.

Table 8-1 Recommended Plans in Toronto Region over the Next 10 Years

No.	Need	Recommended Action Plan	Lead	Timing	Budgetary Estimates[1]
1	Palermo TS: Transformers T3 and T4 replacement. Also increased capacity required for Milton Hydro	Replace existing transformers with larger 75/125MVA units and modify/upgrade existing LV switchyard	Hydro One	2026	$30M
2	Relief required for H29/H30 line supplying Pleasant TS	Reconductor line to meet expected load demand	Hydro One	2027	$8M
3	Section of R19TH/R21H overloaded under certain outage conditions	Review Mitigation[2]	Hydro One	2030	TBD[3]
4	Station loading exceeds LTR • Pleasant TS: T1/T2 DESN • Erindale TS: T1/T2 DESN • Cardiff TS: T1/T2 DESN • Erindale: T5/T6 DESN	Balance load between DESNs	Alectra/ Hydro One	 2027 2028 2029 2031	TBD[3]
5	Asset Replacement: • Bramalea TS • Tomken TS • Lorne Park TS	Refurbish/replace major high voltage transmission equipment	Hydro One	 2028 2030 2030	 $20M $49M $14M
6	T38B/T39 Loading exceed load security criteria	Review Mitigation[2]	Hydro One	2030	TBD[3]

[1] Excludes cost for distribution infrastructure.

[2] The IRRP had proposed alternatives for mitigation. The alternatives and project timing will be reviewed and finalized in the next regional planning cycle.

[3] TBD – To be determined. The costs will depend on the alternative selected and therefore are not available at this time.

The GTA West TWG recommends that:

- Hydro One and LDCs to continue with the implementation of infrastructure investments listed in Table 8-1.
- All the other identified needs/options will be further reviewed by the TWG in the next regional planning cycle.

The next regional planning cycle for the GTA West Region must be triggered within five years, beginning with the Needs Assessment ("NA") phase. It is expected that the next NA will start in Q1 2024. If a need(s) emerges before this time, the next regional planning cycle can be started earlier to address the need(s).

Notes:

- Load forecast is based on the IESO July 2021 IRRP forecast and adjusted for input provided by Alectra, Milton Hydro and Hydro One Distribution..
- Halton TS# 2 is assumed to be in service in 2033

APPENDIX E. LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
GS	Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DER	Ditributed Energy Resource
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

NEEDS ASSESSMENT REPORT

Greater Toronto Area West

Needs Assessment Report

Greater Toronto Area (GTA) West Region

August 30, 2024

Lead Transmitter:

Hydro One Networks Inc.

Prepared by: GTA West Technical Working Group

Page intentionally left blank

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Greater Toronto Area West and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the Needs Assessment phase and b) require further assessment and regional coordination. The results reported in this Need Assessment are based on the input and information provided by the Technical Working Group (the "TWG") for this region at the time. Updates may be made based on best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	Greater Toronto Area West (GTA West) Region (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE:	May 3, 2024	**END DATE:**	August 30, 2024

1. INTRODUCTION

The second Regional Planning cycle for the GTA West Region was completed in February 2022 with the publication of the Regional Infrastructure Plan ("RIP") report (RIP Report). This is the third cycle of Regional Planning for the region.

The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted Local Distribution Company ("LDC") to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years.

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least every five years. Considering these timelines, the 3rd Regional Planning cycle was triggered for the GTA West Region on May 3rd, 2024.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the GTW West Region NA includes:

a) Review and reaffirm needs/plans identified in the previous regional planning cycle RIP (as applicable),
b) Identify any new needs resulting from this assessment,
c) Recommend which needs require further assessment and regional coordination in the next phases of the regional planning cycle to develop a preferred plan; and,
d) Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDCs to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment (SA), Integrated Regional Resource Plan (IRRP), and RIP, based on updated information available at that time.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The GTA West Region includes the area roughly bordered by Highway 27 to the northeast, Highway 427 to the southeast, Regional Road 25 to the west, King Street to the north and Lake Ontario to the south. The Region area comprises the municipalities of Brampton, South Caledon, Halton Hills, Mississauga, Milton, Oakville and portions of Burlington.

5. INPUTS/DATA

The TWG comprises of representatives from LDCs, the Independent Electricity System Operator ("IESO"), and Hydro One and provides input and relevant information for the Region regarding capacity needs, reliability needs, operational issues, and major high-voltage ("HV") transmission assets requiring replacement over the planning horizon. The LDCs also capture input from municipalities in the development of their 10-year summer and winter load forecast.

In accordance with the regional planning process, stakeholder engagement takes place during the IRRP phase.

6. ASSESSMENT METHODOLOGY

The assessment's primary objective is to identify the electrical infrastructure needs in the Region over the 10-year planning horizon. The assessment methodology includes a review of planning information such as load forecast (which factors various demand drivers and consideration of MEPs and/or CEPs where available), conservation and demand management ("CDM") forecast, distributed generation ("DG") forecast, system reliability and operation, and major HV transmission assets requiring replacement.

A technical assessment of needs is undertaken based on:

a) Current and future station capacity and transmission adequacy

b) System reliability needs and operational concerns

c) Major HV transmission equipment requiring replacement with consideration to "right-sizing"

d) Sensitivity analysis to capture uncertainty in the load forecast as well as variability of demand drivers such as electrification.

7. NEEDS

I. Updates on needs identified during the previous regional planning cycle

The following needs discussed in the GTW West second cycle RIP have been addressed or updated:

- R19TH/R21TH overload under specific N-1-1 contingencies at peak load condition: A Key Operation Point ("KOP") procedure has been implemented in Hydro One control room to manage the N-1-1 post contingency thermal overload.
- Erindale T1/T2 DESN load will exceed station LTR by 2028: New forecast suggests the need will trigger in 2030. The TWG recommends this need is addressed with further regional planning coordination in conjunction with other capacity needs in Mississauga.
- Cardiff TS load will exceed station LTR by 2029: New forecast suggests the need will trigger in 2030. The TWG recommends this need is addressed with further regional planning coordination in conjunction with other capacity needs in Mississauga.
- Pleasant T1/T2 DESN capacity will be exceeded in 2027: Transformer replacement with standard LTR will provide sufficient capacity for forecasted loads.
- Erindale T5/T6 DESN load will exceed station LTR by 2031: New load forecast in this NA suggests the need will trigger beyond 2033.
- Lorne Park T2 replacement: Planned in service beyond 2033
- Bramalea T3/T4 replacement: Planned in service beyond 2033
- Tomken T1/T2 replacement: Planned in service beyond 2033
- T38B/T39B loads will exceed 600MW load security criteria in 2030: New load forecast suggests the threshold will be reached in 2029.

The following needs and projects discussed in the GTA West second cycle RIP are currently underway:

- Circuits H29/H30 reconductoring: planned in service in Q2, 2028.
- Palermo TS transformer replacement with larger capacity units: planned in service in Q4, 2027.

II. Newly identified needs in the region

The following are new needs that were identified as part of this assessment:

a) Asset Renewal for Major HV Transmission Equipment

- Halton T3/T4 (27.6kV)
- Pleasant T5/T6 (27.6kV)

b) Station Capacity

- Halton TS (27.6kV)
- Bramalea T1/T2 DESN (27.6kV)
- Cooksville T1/T2 DESN and T3/T4 DESN (all 27.6kV)
- Pleasant T5/T6 DESN (27.6kV)

- Jim Yarrow T1/T2 (27.6kV)
- Goreway T5/T6 DESN (27.6kV).
- Bramalea T3/T4 DESN (44kV)
- Lorne Park T1/T2 DESN (27.6kV)

c) Transmission Line Capacity

- No new transmission Line Capacity need identified

d) System Reliability, Operation and Load Restoration

- Trafalgar 230kV bus over-voltage issue under light load condition as reported by IESO.

e) Transmission System Reinforcement

- Major transmission expansion in Milton area will be needed to accommodate increasing new load connection requests including large transmission-connected data centers. Existing 230kV facilities, especially the radial section of T38B/T39B from Trafalgar TS, do not have sufficient capacity to supply the new demand and may not be simply addressed by reconductoring. In addition, T38B/T39B corridor will exceed the load security limit of 600MW in this NA timeframe

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

The impact of the sensitivity analysis for the high and low growth scenarios identified the following updates to need dates and new station capacity needs. These needs will be assessed again during the next phases of this Regional Planning cycle

No.	Need Identified	Normal Growth Scenario	High Growth Scenario	Low Growth Scenario
Needs update under high and low load growth scenarios				
1	Halton TS LTR	2026	2026	2029
2	Cardiff TS LTR	2030	2028	2032
3	Erindale T1/T2 LTR	2030	2027	2032
4	Bramalea T1/T2 LTR	2031	2030	Beyond 2033
5	Bramalea T3/T4 LTR*	2024	2024	2024
6	Lorne Park LTR*	2031	2030	Beyond 2033
7	Cooksville T1/T2 LTR	2030	2030	Beyond 2033

8	Cooksville T3/T4 LTR	2030	2029	Beyond 2033
9	Pleasant T1/T2 LTR*	2027	2026	Beyond 2033
10	Pleasant T5/T6 LTR	2026	2025	2027
11	Jim Yarrow T1/T2 LTR	2030	2028	Beyond 2033
12	Goreway T5/T6 LTR	2026	2025	2026
Additional capacity needs under high growth scenario				
13	Meadowvale TS LTR	Beyond 2033	2029	
14	Palermo TS LTR	Beyond 2033	2029	
15	Tremaine TS LTR	Beyond 2033	2029	
16	Tomken T1/T2 LTR	Beyond 2033	2031	
* The need can be addressed by transformer renewal with higher LTR specification				

9. RECOMMENDATIONS

The TWG recommendations are as follows:

I. Needs that require further assessment and regional coordination

These needs may have broader regional impacts and require further assessment and coordination during the next phases[1] of the regional planning cycle. A list of these needs are as follows:

a) Integrated transmission reinforcement plan in Milton area to accommodate new transmission and distribution connected loads including large data centers. A reinforcement plan should also help to manage T38B/T39B load security. The TWG recommends further regional coordination to address the capacity constraints. Coordinated efforts from IESO bulk system planning, Hydro One, LDCs and major customers should continue in developing such plan.

b) Accommodation of loads growth beyond LTR at Halton TS with a new 230/27.6kV Halton #2 station

c) Accommodation of load growth beyond LTRs at Bramalea T1/T2, Erindale T1/T2 and Cardiff TS in Mississauga area

d) Accommodation of load growth beyond LTRs at Cooksville T1/T2 and Cooksville T3/T4 in Mississauga area

e) Accommodation of load growth beyond LTRs at Pleasant T5/T6 and Jim Yarrow T1/T2 in Brampton area

f) Accommodation of load growth beyond LTRs at Goreway T5/T6 and Bramalea T1/T2 in Brampton area.

II. Needs that do not require further regional coordination

[1] Non-wires options are further considered (i.e. incremental to CDM and DG that is considered in this NA) as potential options in addressing these needs during the IRRP phase.

These needs are local in nature and do not have a regional impact. They can be addressed by a straightforward transmission and/or distribution wires solution. They do not require investment in any upstream transmission facility or require Leave to Construct (i.e., Section 92) approvals. These needs generally impact a limited number of LDCs and can be addressed directly between Hydro One and the LDC(s) to develop a preferred local plan. A list of these needs are as follows:

a) Accommodation of load growth at Pleasant T1/T2 through transformer renewals with standard LTR specification
b) Accommodation of load growth at Bramalea T3/T4 through transformer renewals with upsized rating
c) Accommodation of load growth at Lorne Park T1/T2 through T2 renewal with standard LTR specification (T1 has sufficient LTR).

List of LDC(s) to be involved in further regional planning phases:

- Alectra Utilities Co.
- Milton Hydro Distribution Inc.
- Halton Hills Hydro Inc.
- Oakville Hydro Electricity Distribution Inc.
- Burlington Hydro Inc.
- Hydro One Networks Inc. (Distribution)

1. Introduction

The second cycle of the Regional Planning process for the GTA West Region was completed in February 2022 with the publication of the Regional Infrastructure Plan ("RIP") Report [1] - (RIP link). The RIP report included a common discussion of all the options and recommended plans for preferred wire infrastructure investments to address the near- and medium-term needs.

This Needs Assessment initiates the third regional planning cycle for the GTA West Region. The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   i) require further assessment and regional coordination to develop a preferred plan (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years. The flow chart of the Regional Planning Process is shown in Figure 1 below.

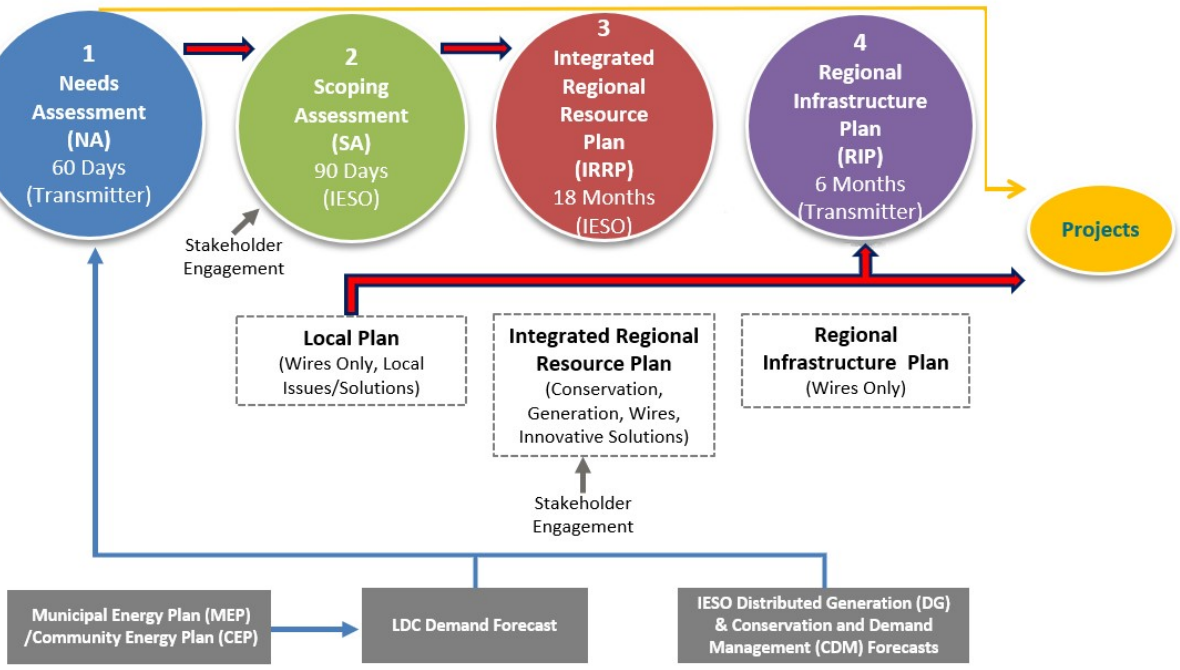

Figure 1: Regional Planning Process

This report was prepared by the GTA West Technical Working Group("TWG"), led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One, the Local Distribution Companies ("LDC") and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: GTA West Region TWG Participants

No.	Name of TWG Participants
1	Hydro One Networks Inc. (Transmission) - (Lead Transmitter)
2	Hydro One Networks Inc. (Distribution)
3	Independent Electricity System Operator
4	Alectra Utilities Co.
5	Burlington Hydro Inc.
6	Milton Hydro Distribution Inc.
7	Halton Hills Hydro Inc.
8	Oakville Hydro Electricity Distribution Inc.

2. Regional Issue/Trigger

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. As such, the third Regional Planning cycle was triggered for the GTA West Region.

3. Scope of Needs Assessment

The scope of this NA covers the GTA West region and includes:

- Review and update needs and plans identified in the previous cycle RIP,
- Identify any new needs resulting from this assessment,
- Recommend which needs require further assessment and regional coordination in the next phases of the regional planning cycle to develop a preferred plan, and
- Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDCs to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), Local plan (LP) and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is 10 years.

4. Regional Description and Connection Configuration

The GTA West Region includes the area roughly bordered geographically by Highway 27 to the northeast, Highway 427 to the southeast, Regional Road 25 to the west, King Street to the north and Lake Ontario to the south. The GTA West Region area comprises the municipalities of Brampton, South Caledon, Halton Hills, Mississauga, Milton, Oakville and portions of Burlington.

The geographical boundaries of the Region are shown in Figure 2.

Figure 2: Map of GTA West Regional Planning Area

Electrically the GTA West Region is bounded by Richview TS to Manby TS 230 kV circuits on the east, Richview TS to Trafalgar TS to Burlington TS 230 kV circuits on the north and Manby TS to Cooksville TS to Oakville TS 230 kV circuits on the south. The distribution system in this Region is at two voltage levels, 44 kV and 27.6 kV. Local generation in the area include the two gas fired plants, the 1196MVA Goreway CGS in Brampton and the 755MVA TCE CGS in Halton Hills.

The Local Distribution Customers (LDC) in the Region include Burlington Hydro Inc., Alectra Utilities Co., Halton Hills Hydro Inc., Hydro One Networks Inc. (Distribution), Milton Hydro Distribution Inc. and Oakville Hydro Electricity Distribution Inc. The high-voltage system in this Region also provides supply to one customer owned transformer station. An electrical single line diagram for the GTA West Region facilities is shown in Figure 3.

The circuits and stations of the area are summarized in Table 2 below:

Table 2: Transmission Station and Circuits in the GTA West Region

230kV circuits	Transformer Stations	Generation Stations
H29/H30 R14T/R17T R19TH/R21TH T36B/T37B T38B/ T39B V41H/V42H V43 B15C/B16C K21C/K23C, R24C	Bramalea TS Cardiff TS Churchill Meadows TS Claireville TS[1] Cooksville TS Erindale TS CTS-1 Glenorchy MTS Goreway TS Halton TS Halton Hills MTS Jim Yarrow MTS Lorne Park TS Meadowvale TS Oakville TS Palermo TS Pleasant TS Richview TS Tomken TS Trafalgar TS[1] Tremaine TS (Hurontario SS)	Sithe Goreway CGS, 787MW[2]/1196MVA TCE Halton Hills CGS, 526MW[3]/755MVA

1: 500kV Stations with Autotransformers installed

2: At 35°C ambient temperature. Generation capacity will increase by 40MW under IESO's Expedited Long-term RFP

3: At 35°C ambient temperature. Generation capacity will increase by 29MW under IESO's Expedited Long-term RFP

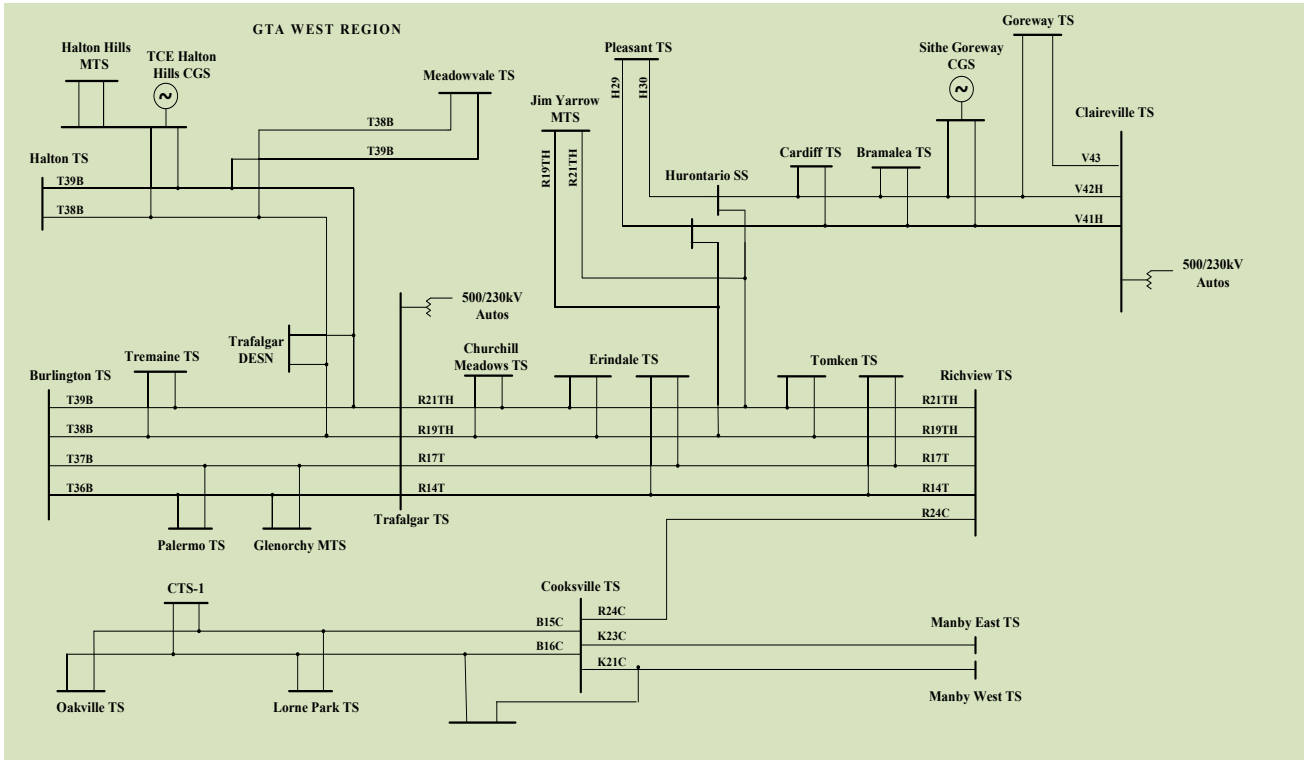

Figure 3: GTA West Transmission Single Line Diagram

5. Inputs and Data

TWG participants, including representatives from LDCs, IESO, and Hydro One provided input for the GTA West NA. With respect to the load forecast information, the OEB Regional Planning Process Advisory Group (RPPAG) recently published a document called "Load Forecast Guideline for Ontario" in Oct. 2022 [2]. The objective of this document is to provide guidance to the TWG in the development of the load forecasts used in the various phases of the regional planning process with a focus on the NA and the IRRP. One of the inputs into the LDC's load forecast that is called for in this guideline is information from Municipal Energy Plans (MEP) and/or Community Energy Plans (CEP). The list of all the Municipalities falling under the geographical boundaries of the region are given in Appendix-E.

The information provided includes the followings:

- GTA West 10-year summer and winter load forecast for all supply stations inclusive of the inputs provided by the municipalities listed in Appendix E
- Known capacity and reliability needs, operating issues, and/or major assets requiring replacement or refurbishment
- Planned transmission and distribution investments that are relevant to Regional Planning for the GTA West
- Captured uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

6. Assessment Methodology

The following methodology and assumptions are made in development of this Needs Assessment:

6.1 Technical Assessments and Study Assumptions

The technical assessment of needs was undertaken based on:

- Current and future station capacity and transmission adequacy
- System reliability and operational considerations
- Asset renewal for major high voltage transmission equipment requiring replacement with consideration to "right-sizing"
- Load forecast data requested from industrial customers in the region
- Summer peak load condition. Three load forecasts were developed, i.e. normal growth scenario, high and low growth scenario. The high and low growth load forecasts are developed to conduct a sensitivity analysis to cover unforeseen developments such as fuel switching, government policies, higher than expected EV charging trend during peak load conditions, etc.

The following assumptions are made in this report:

- The study period for this Needs Assessment is 2024-2033.
- The Region is summer peaking, so this assessment is based on summer peak loads.
- Line capacity adequacy is assessed by using coincident peak loads in the area.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations without low-voltage capacitor banks and 95% lagging power factor for stations with low-voltage capacitor banks.
- Normal planning supply capacity for transformer stations is determined by the Hydro One summer 10-Day Limited Time Rating (LTR) of a single transformer at that station.
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC) [3].

6.2 Information Gathering Process

6.2.1 Load forecast

The LDCs provided their summer and winter load forecast for all the stations supplying their loads in the GTA West region for the 10-year study period including the inputs from the Municipalities such as MEPs and CEPs. The IESO provided a Conservation and Demand Management ("CDM") and Distributed Generation ("DG") forecast for the Region. The net extreme summer weather load forecasts were produced by reducing the gross load forecasts for each station by the percentage CDM and then by the amount of effective DG capacity provided by the IESO for that station. It is to be noted that as contracts for existing DG resources in the region begin to expire, at which point

the load forecast has a decreasing contribution from local DG resources, and an increase in net demand. This extreme summer weather corrected net load forecast for the individual stations in the Region is given in Appendix A.

6.2.2 Sensitivity analysis

A sensitivity analysis was undertaken by the TWG to capture uncertainty in the load forecast as well as variability of drivers such as electrification. Hence, the NA recommendations are not necessarily linked to sensitivity scenarios; but rather are used to identify any emerging needs for consideration in developing recommendations. The impact of sensitivity analysis for the high and low growth scenarios are provided in section 8 of this report.

6.2.3 Asset renewal needs for major HV equipment

A list is generated for major HV transmission equipment planned or identified to be replaced based on asset condition assessment, relevant for Regional Planning purposes. This includes HV transformers, HV Breakers, HV underground cables and overhead lines. The scope of equipment considered is given in section 7.1.

6.2.4 System reliability and operational issues

Relevant information regarding system reliability and operational issues in the region as feedback is provided by the IESO during the NA phase.

7. Needs

This section describes new needs identified in the Region and updates on previously identified needs since the completion of previous regional planning cycle.

Needs that were identified and discussed in the previous regional planning cycle with associated projects that were recently completed and reaffirmed needs that are underway and are briefly described below with relevant updates:

- Palermo T3/T4 replacement with larger capacity units: project is in progress with planned in service in Q4, 2027.
- Tomken T1/T2 replacement: expected in service date is updated as Q4, 2035.
- Lorne Park T2 replacement: expected in service date is updated as Q4, 2034.
- Bramalea T3/T4 replacement with larger capacity units: expected in service date is updated as Q2, 2040.
- Pleasant T1/T2 capacity need: will plan to replace T1/T2 with standard LTR rating, in service date is to be determined.
- Erindale T5/T6 capacity need: updated load forecast suggests the need is beyond 2033.
- Circuit H29/H30 capacity need: reconductoring to higher capacity is in progress, expected in service date is Q2, 2028.
- R19TH/R21TH post-contingency overload under specific N-1-1 scenarios: operational KOP has been implemented in Hydro One control room.
- T38B/T39B Lantz Junction to Trafalgar DESN (~200m) post-contingency overload: being re-evaluated since more new load connection requests are received, this could be included an integrated transmission reinforcement plan in the area.

All new near and midterm needs that are discussed as a part of this report are summarized in Table 3. Note the planned in-service year for the projects is tentative and is subject to change.

Table 3: Near/Mid-term Needs Identified in Previous RIP and/or this NA

Need Description	Recommended Plan/Update	Previous RIP Report Section	NA Report Section
Asset Renewal Needs			
Halton T3/T4 end-of-life replacement	Planned in service Q4, 2035	N/A	Sec. 7.1
Pleasant T5/T6 End-of-life replacement	Planned in service Q3, 2037	N/A	Se. 7.1

Station Capacity Needs			
Halton TS Forecasted demand will exceeds LTR in 2026.	Plan Halton TS #2 to accommodate new load.	Sec. 6.2	Sec. 7.2.1
Bramalea T1/T2 Forecasted demand will exceed LTR in 2031	Plan Mississauga and Brampton areas to accommodate new load	N/A	Sec.7.2.2
Erindale T1/T2 Forecasted demand will exceed LTR in 2030.	Plan area to accommodate new load	Sec. 6.2, 7.4	Sec. 7.2.4
Cardiff T1/T2 Forecasted demand will exceed LTR in 2030.	Plan area to accommodate new load	Sec. 6.2, 7.4	Sec. 7.2.5
Lorne Park T1/T2 Forecasted demand will exceed LTR in 2031	Replace Lorne Park T2 with standard LTR	N/A	Sec. 7.2.6
Cooksville T1/T2, T3/T4 Forecasted demand will exceed LTR in 2030	Plan area to accommodate new load	N/A	Sec. 7.2.7
Pleasant T5/T6 Forecasted demand will exceed LTR in 2026	Plan area to accommodate new load	N/A	Sec. 7.2.9
Jim Yarrow T1/T2 Forecasted demand will exceed LTR in 2030.	Plan area to accommodate new load	Sec. 7.8.1	Sec. 7.2.10
Goreway T5/T6 Forecasted demand will exceed LTR in 2026.	Plan area to accommodate new load	Sec. 6.2	Sec. 7.2.11
System Reliability, Operation and Load restoration Needs			
T38B/T39B load security and restoration	Consolidate with Milton area transmission reinforcement need and assess further in next phase of regional planning	Sec. 7.6	Sec. 7.4
Trafalgar 230kV high voltage control under light load condition	IESO and Hydro One operations coordinate to assess solutions	N/A	Sec. 7.4
Transmission System Reinforcement Needs			
Milton area reinforcement for load supply and security	Develop an integrated transmission system reinforcement plan in further regional planning phases to address substantial new load connection requests in Milton area	N/A	Sec. 7.5

7.1 Asset Renewal Needs for Major HV Transmission Equipment

In addition to the previously identified asset renewal needs from the second regional planning cycle, Hydro One and TWG has also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the Region. The complete list of planned major HV transmission equipment requiring replacement is provided in Table 4. Only Palermo T3/T4 will be put in service in next 10 years according to Hydro One's recent investment planning. Note the in service year is subject to change as the asset renewal planning is a dynamic process.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors
- Technical obsolescence due to outdated design
- Lack of spare parts availability or manufacturer support and/or
- Potential health and safety hazards.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230 load serving step down transformers
- 230kV breakers where:
  replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230kV transmission lines requiring refurbishment where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230kV underground cable requiring replacement where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

The Asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement)
- Replacing equipment with higher ratings and built to current standards.

From Hydro One's perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

In the list of Table 4, Halton T3/T4 and Pleasant T5/T6 transformers are newly identified asset for replacement but the in-service dates will be outside of this NA window based on recent Hydro One investment planning outcome. It is expected that Lorne Park TS capacity will increase once T2 is replaced

with standard LTR specification (sec. 7.2.6). Bramalea T3/T4 may also be replaced with larger capacity to address the capacity issue (sec. 7.2.3).

Table 4: Major HV Transmission Asset Assessed for Replacement in the Region in Next 10 Years

Station/Circuit	Need Description	Planned ISD
Palermo T3/T4	Built in 1969, applied in 1970, replacement with upsized units	2027
Assets planned for replacement post 2033		
Halton T3/T4	Built in 1989, applied in 1990	Beyond 2033
Pleasant T5/T6	Built in 1988, applied in 1991	Beyond 2033
Lorne Park T2	Built in 1974, applied in 1975	Beyond 2033
Tomken T1/T2	Built and applied in 1970	Beyond 2033
Bramalea T3/T4	Built in 1970, applied in 1983	Beyond 2033

7.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2024-2033 for the 230kV Transforming stations in the Region using the summer peak load forecasts. Based on the results, the identified station capacity needs are flagged in Table 5. Comparing with the recommendations in RIP 2022 [1], Bramalea T1/T2, Cooksville T1/T2, T3/T4 and Pleasant T5/T6 are newly identified needs in this NA period. Previously identified capacity need of Erindale T5/T6 in [1] has been updated to post 2033.

Table 5: Stations with Capacity Need

TS	LTR (MW)	Load Forecast (MW)									
		2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
Halton T3/T4	195	154.0	179.1	**215.9**	234.4	231.3	250.2	264.2	266.5	268.8	273.5

Goreway T1/T2	180	74.4	77.3	80.7	84.3	88.4	92.1	96.3	100.8	105.9	111.4

7.2.1 Halton TS

Halton TS (27.6kV) supplies loads from Milton Hydro and Halton Hills Hydro. Milton Hydro forecasts rapid load growth at Halton TS in next three years, while Halton Hills Hydro load forecast remain flat in next 10 years. By end of this assessment cycle, Milton Hydro forecasts nearly 80MW loads beyond Halton TS LTR need to be served from other supplies. As the LTR at Halton TS cannot be increased through standard transformer replacement, a new station Halton TS #2 as previously suggested in [1,6] could be appropriate to address the need. In near term, Milton Hydro plans to use Oakville Hydro's Glenorchy MTS and upsized Palermo TS to meet the increasing demand before Halton TS #2 is available. The TWG recommends that the capacity need at Halton TS be investigated further through the regional planning process in conjunction with Milton area load supply planning (sec. 7.5).

7.2.2 Bramalea T1/T2

Bramalea TS has three DESNs as shown in Table 5, supplying Alectra's loads in Mississauga and Brampton. T1/T2 is the only 27.6kV DESN in Bramalea. The forecasted load at T1/T2 is expected to exceed its LTR in 2031. As Erindale T1/T2 (27.6kV) and Cardiff TS (27.6kV) in Mississauga will have similar capacity need (7.2.4 and 7.2.5 below) in medium term, the TWG acknowledges that a new station might be one option and recommends further regional coordination to address this need.

7.2.3 Bramalea TS T3/T4

Bramalea T3/T4 (44kV) are 83.3MVA CGE units built in 1970. Operating data shows the actual peak load at T3/T4 has slightly exceeded summer LTR and the load will grow at moderate rate near 2%. The issue can be addressed by replacing the transformers with higher rating such as standard 125MVA units. At interim, Alectra may balance the 44kV load with Bramalea T5/T6 DESN that can accommodate extra load. The TWG acknowledges load rebalance and transformer replacement could address the issue.

7.2.4 Erindale TS T1/T2

Erindale TS has three DESNs as shown in Table 5, all supplying Alectra's loads. T1/T2 is the only 27.6kV DESN in Erindale. The forecasted load will exceed T1/T2 LTR in 2030. The TWG acknowledges that a new station might be one option and recommends that further regional coordination takes place to address this need.

7.2.5 Cardiff TS

Cardiff T1/T2 (27.6kV) serves Alectra's loads with two 83.3MVA transformers built in 2004. The LTRs of the transformers are further limited by its MVGIS breakers. Load forecast suggests the station will be overloaded by 2030. Since it is impractical to upsize the transformers and MVGIS still in good condition, the TWG acknowledges that a new station might be one option and recommends that further regional coordination takes place to address this need.

7.2.6 Lorne Park TS

Lorne Park T1/T2 (27.6kV) serves Alectra loads only. The LTR of the station is determined by T2 (built in 1974) that has lower overloading capability than T1 (built in 2008). The forecast shows that Lorne Park TS load will exceed T2 LTR in 2031 and further growth is moderate. The TWG acknowledges that T2 replacement with standard LTR should be one option to address the issue.

7.2.7 Cooksville TS

Cooksville TS (27.6kV) has two DESNs, T1/T2 and T3/T4, supplying Alectra's loads only. All the transformers are 83.3MVA units built in 2013. Alectra forecasts significant load growth at Cooksville after 2028 as shown in Table 5. Lakeview Village, Rangeview, Dixie Mall conversion, Trillium Hospital new building, Water and Wastewater Treatment Plants expansion are examples of the new need to be served. The load growth rates will peak at 60% for T1/T2 DESN and 50% for T3/T4 DESN in 2030. As a result, the LTRs at both DESNs will be exceeded in 2030. Considering the existing transformers are still young and the T1/T2 27.6kV yard was just rebuilt in 2014, the TWG acknowledges that a new station might be one option and recommends that further regional coordination takes place to address this need.

7.2.8 Pleasant TS T1/T2

Pleasant TS has three DESNs. T1/T2 DESN (44kV) supplies loads from Alectra, Hydro One Distribution and Halton Hills Hydro. Combined load forecasts from the three LDCs suggest moderate LTR violation after 2027 as shown in Table 5. T1/T2 are Westinghouse 125MVA units built in 1975 and their LTRs are lower than today's standard (above 180MVA). The TWG recommends this issue is addressed by regular transformer end-of-life renewal with standard LTR specifications.

7.2.9 Pleasant T5/T6

Pleasant T5/T6 (27.6kV) supplies Alectra load only. The DESN is heavily loaded at present. Alectra's load forecast suggests steady annual growth rate near 5% throughout the assessment period and the DESN LTR will be exceeded as early as 2026. As another 27.6kV station adjacent to Pleasant, Jim Yarrow MTS (sec. 7.2.10) also forecasts its LTR will be exceeded during this NA timeframe, the TWG acknowledges that a new station might be one option and recommends that further regional coordination take place to address this need.

7.2.10 Jim Yarrow T1/T2

Jim Yarrow MTS is an Alectra-owned station built in 2004. The load at the MTS is forecasted to grow at approximately 4.4% annually and its LTR will be exceeded in 2030. Since adjacent Pleasant TS is also expected to reach full capacity in this assessment period, the TWG acknowledges that a new station might be one option and recommends that further regional coordination takes place to address this need.

7.2.11 Goreway T5/T6

Goreway TS has two 27.6kV DESNs T1/T2, T5/T6 and one 44kV supply from T4, all supplying Alectra load. The forecasted demand at T5/T6 DESN will exceed LTR in 2026 and keep growing at approximately 4% per year. As Alectra forecasts additional new Brampton loads beyond Bramalea T1/T2 capacity, the TWG acknowledges that a new station in the area may be appropriate and recommends that further regional coordination takes place to address this need. In near term, available capacity from Goreway T1/T2 could be utilized to meet the load growth need in the area.

7.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such

as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period 2024-2033 for the 230kV Transmission line circuits in the Region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater this need. Based on the results, there is no new transmission line capacity need other than identified in the second cycle RIP [1].

7.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. The system should also meet load security and load restoration criteria as defined in ORTAC [3]. Based on input from the IESO and LDCs, the following operational issues are identified:

- The new load forecast suggests T38B/T39B corridor will exceed load security limit of 600MW [3] in 2029. Table 6 shows load growth of all double-circuit corridors in the Region (assuming the new Halton TS #2 will still tap to T38B/T39B in 2030). The TWG recommends further regional coordination to address the T38B/T39B load security issue. All other double circuits corridors will not have more than 600MW net loads in the assessment window.

- All double-circuit corridor loads will exceed 250MW in this assessment timeframe. The ORTAC [3] requires the amount of load interruption in excess of 250MW must be restored within 30 minutes (and within 4 hours for load loss more than 150MW). The TWG surveyed transmission load interruption performance data from 2014 to 2024 for the Region. The results show that delivery points supplied by the circuits in Table 6 did not log load loss of more than 250MW for longer than 30 minutes, or loss of more than 150MW for longer than 4 hours in the 10 years. Based on past performance data, the TWG would not recommends capital investment for load restoration at this point. Hydro One shall proactively monitor load restoration data and identify opportunities to reduce risk of prolonged load restoration.

Table 6 Double-circuit Corridor Load

Circuits	Loads served by the double circuits (MW)									
	2024	2025	2026	2027	2028	2029	2030	2031	2032	2033
T38B/T39B	444.8	492.1	558.6	570.3	588.3	**606.9**	676.2	688.6	703.7	721.2
T36B/T37B	231.6	236.1	241.2	247.5	299.1	283.0	294.5	304.8	314.7	327.6
R14T/R17T	449.9	459.0	466.2	474.7	483.9	483.7	484.2	486.4	491.8	502.7
R19TH/R21TH	456.5	463.2	470.1	476.3	487.4	505.6	510.1	515.4	520.1	526.0
H29/H30	395.0	411.0	431.6	444.1	450.2	454.6	459.2	464.8	471.7	479.3
B15C/B16C	220.1	224.0	230.1	235.8	242.7	249.6	257.9	268.6	277.7	282.1
V41H/V42H	371.7	378.2	383.7	393.8	405.7	421.8	436.9	459.0	482.8	496.6

- IESO reports high voltage at Trafalgar 230kV bus under light load conditions. Hydro One and IESO operation departments are coordinating to assess alternatives including Trafalgar TS Autotransformer tap changer position adjustment.

7.5 Transmission System Reinforcement Needs

Milton area transmission reinforcement:

In addition to the rapid organic load growth forecasted in T38B/T39B corridor, multiple proponents have requested to connect large-scale loads in Milton area, especially in proximity to Milton SS. Majority of the requests are large data centers with combined capacity exceeding 1000MW. It is not feasible for the existing 230kV transmission infrastructure in Milton area to accommodate such sizeable loads. Due to the scale and complexity of such connections, the TWG recommends further regional coordination to address the capacity needs. Coordinated efforts from IESO bulk system planning, Hydro One, LDCs and major customers should continue in developing solutions.

8. Sensitivity Analysis

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments. The TWG determined that the key electric demand driver in the GTA West region to be considered in this sensitivity analysis is electric vehicle (EV) penetration and unforeseen electrification which would cause the load to increase at a faster rate than shown in the forecast; or the potential delay in some projects which could result in less demand than anticipated.

The TWG reviewed EV scenarios and any unforeseen electrification needs to develop high demand growth forecasts by applying 50% additional growth to the growth rate on the extreme summer corrected Normal Growth net load forecasts. The low growth scenario was obtained by reducing the growth rate by 50%.

The impact of sensitivity analysis for the high and low growth scenario is shown in Table 7. The additional capacity needs identified towards the end of the study period will be assessed again during the next phases of the Regional Planning cycle.

Table 7: Impact of Sensitivity Analysis on Capacity Needs in the Region

No.	Need Identified	Normal Growth Scenario	High Growth Scenario	Low Growth Scenario
Needs update under high and low load growth scenarios				
1	Halton TS LTR	2026	2026	2029
2	Cardiff TS LTR	2030	2028	2032
3	Erinddale T1/T2 LTR	2030	2027	2032
4	Bramalea T1/T2 LTR	2031	2030	Beyond 2033
5	Bramalea T3/T4 LTR*	2024	2024	2024
6	Lorne Park LTR*	2031	2030	Beyond 2033
7	Cooksville T1/T2 LTR	2030	2030	Beyond 2033
8	Cooksville T3/T4 LTR	2030	2029	Beyond 2033
9	Pleasant T1/T2 LTR*	2027	2026	Beyond 2033
10	Pleasant T5/T6 LTR	2026	2025	2027
11	Jim Yarrow T1/T2 LTR	2030	2028	Beyond 2033
12	Goreway T5/T6 LTR	2026	2025	2027
Additional capacity needs under high growth scenario				
13	Meadowvale TS LTR	Beyond 2033	2029	
14	Palermo TS LTR	Beyond 2033	2029	
15	Tremaine TS LTR	Beyond 2033	2029	
16	Tomken T1/T2 LTR	Beyond 2033	2031	
* The need can be addressed by transformer renewal with standard rating specification				

9. Conclusion and Recommendation

The Technical Working Group's recommendations to address the needs identified are as follows:

Table 8: Needs not Requiring Further Regional Coordination

No.	Need	Recommendation
1	Bramalea T3/T4 DESN LTR violation	Replace T3/T4 with higher rating during transformer renewal. Balance T3/T4 load with Bramalea T5/T6 as interim solution.
2	Pleasant T1/T2 DESN moderate LTR violation	Replace T1/T2 with standard LTR.
3	Lorne Park T1/T2 DESN moderate LTR violation	Replace T2 with standard LTR.

Table 9: Needs Requiring Further Regional Coordination

No.	Need
1	Transmission reinforcement at Milton area to accommodate large load connection requests including data centers and manage load security
2	Accommodate Halton TS load growth beyond LTRs
3	Accommodate Mississauga 27.6 kV load growth beyond LTRs at Cardiff T1/T2, Bramalea T1/T2 and Erindale T1/T2
4	Accommodate Mississauga 27.6kV load growth beyond LTRs at Cooksville T1/T2 and T3/T4
5	Accommodate Brampton 27.6 kV load growth beyond LTRs at Pleasant T5/T6 and Jim Yarrow T1/T2
6	Accommodate Brampton 27.6kV load growth beyond LTRs at Goreway T5/T6 and Bramalea T1/T2

List of LDC(s) to be involved in further regional planning activities:

- Alectra Utilities Co.
- Milton Hydro Distribution Inc.
- Halton Hills Hydro Inc.
- Oakville Hydro Electricity Distribution Inc.
- Burlington Hydro Inc.
- Hydro One Networks Inc. (Distribution)

Note	1. Capacity can be increased by transformer renewal with higher LTR 2. Assumption based on typical station, final LTR will be determined after the station is built 3. Assumption for upsized transformers, final LTR will be determined after transformers are delivered 4. Presently limited to 419 MW by upstream transmission lines H29/H30

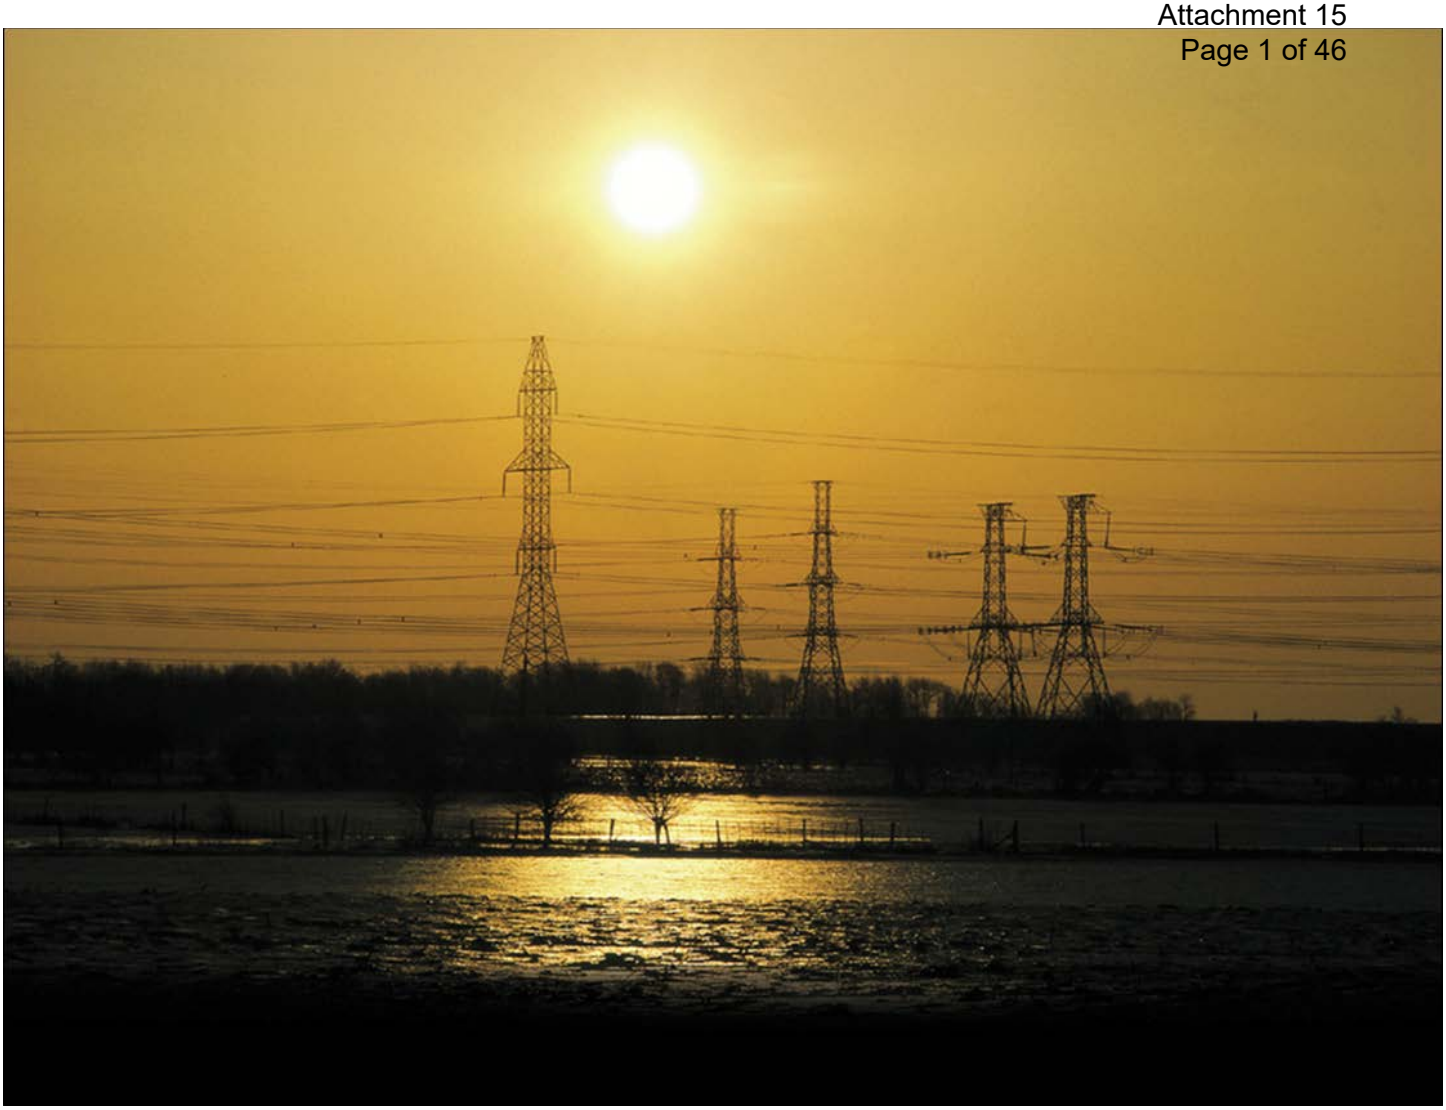
7	**Cooksville TS*,** Lorne Park TS, CTS-1, Oakville TS	B15C/B16C	230
8	**Manby TS*, Cooksville TS***	K21C/K23C	230
9	**Claireville TS*,** Goreway TS	V43	230
10	**Richview TS*, Cooksville TS***	R24C	230
*: terminal stations, others are stations tapped to the circuits			

Appendix D: List of LDC's



No.	Name of LDC
1	Alectra Utilities Co.
2	Burlington Hydro Inc.
3	Halton Hills Hydro Inc.
4	Milton Hydro Distribution Inc.
5	Oakville Hydro Electricity Distribution Inc.
6	Hydro One Networks Inc. (Distribution)

Appendix E: List of Municipalities in the region

No.	Name of Municipality
1	Brampton
2	Burlington
3	Caledon
4	Halton Hills
5	Milton
6	Mississauga
7	Oakville

Appendix F: Acronyms

Acronym	Description
CDM	Conservation and Demand Management
CEP	Community Energy Plan
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DS	Distribution Station
GS	Generating Station
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
KOP	Key Operating Point
kV	Kilovolt
LDC	Local Distribution Company
LTE	Long Term Emergency
LP	Local Plan
LTR	Limited Time Rating
LV	Low Voltage
MEP	Municipal Energy Plan
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
MVGIS	Medium Voltage Gas Insulated Switchgear
NA	Needs Assessment
OEB	Ontario Energy Board
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
SA	Scoping Assessment
SS	Switching Station
TS	Transformer Station

Kitchener-Waterloo-Cambridge-Guelph Regional Infrastructure Plan

December 10, 2021

[This page is intentionally left blank]

Prepared and supported by:

Company
Hydro One Networks Inc. (Transmission)
Independent Electricity System Operator (IESO)
Alectra Utilities Corporation
Centre Wellington Hydro Ltd.
Energy+ Inc.
Halton Hills Hydro Inc.
Hydro One Networks Inc. (Distribution)
Kitchener-Wilmot Hydro Inc.
Milton Hydro Distribution Inc.
Waterloo North Hydro Inc.
Wellington North Power Inc.

Disclaimer

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and any additional needs identified based on new and/or updated information provided by the RIP Study Team.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Study Team.

Study Team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

Executive Summary

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE RIP STUDY TEAM IN ACCORDANCE TO THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE KITCHENER WATERLOO CAMBRIDGE GUELPH REGION.

The participants of the Regional Infrastructure Plan ("RIP") Study Team included members from the following organizations:

- Alectra Utilities Corporation ("Alectra")
- Centre Wellington Hydro Ltd. ("CWH")
- Energy + Inc. ("Energy+")
- Halton Hills Hydro Inc. ("HHH")
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Independent Electricity System Operator ("IESO")
- Kitchener Wilmot Hydro Inc.("KWH")
- Milton Hydro Distribution Inc. ("MHD")
- Waterloo North Hydro Inc. ("WNH")
- Wellington North Power Inc. ("WNP")

In the first cycle of the Regional Planning (RP) process for the KWCG Region, an Integrated Regional Resource Plan ("IRRP") was published in April 2015. The first cycle of RP process was completed in December 2015 [1] with the publication of the Regional Infrastructure Plan ("RIP") which provided a description of needs and recommendations of preferred wires plans to address near-term needs.

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least every five years. In light of the timing of the needs identified in the previous IRRP and RIP reports as well as new replacement/ refurbishment needs identified in the KWCG Region, the 2nd Regional Planning cycle was triggered for the KWCG region in Q4 2018.

This RIP is the final phase of the second cycle of Kitchener Waterloo Cambridge Guelph (KWCG) regional planning process, which follows the completion of the KWCG Integrated Regional Resource Plan ("IRRP") in April 2021 [2][3] and the KWCG Region Needs Assessment ("NA") in December 2018 [4]. This RIP provides a consolidated summary of the needs and recommended plans for KWCG Region over the planning horizon (1 – 20 years) based on available information.

It discusses needs identified in the previous regional planning cycle, the Needs Assessment and IRRP reports for this cycle, and wires solutions recommended to address these needs. Implementation plans to address some of these needs are already completed or are underway.

The following needs identified in the first regional planning cycle have been addressed:

Needs	Needs Details
115kV System Supply Capacity	GATR Project Two new 230/115kV autotransformers at Cedar TS to reinforce supply to both 115kV sub-systems in the region.
230kV Load Restoration Needs	GATR Project Two new 230 kV in-line switches on D6V/D7V circuits to improve restoration capability of Waterloo-Guelph 230 kV sub-system.
	Galt Junction Two new 230kV in-line switches on M20D/M21D circuits to improve restoration capability of the Cambridge-Kitchener 230 kV sub-system.
Station Short Circuit Capacity	Arlen MTS Install 13.8 kV series reactors to mitigate LV bus short circuit levels.

Other projects completed in the region since the completion of first regional planning cycle are listed below:

Stations Refurbishment Project	
Campbell TS	Transformers T1 and T2 Replacement
Detweiler TS	AC Station Service and Component Replacement
Detweiler TS	230 /115 kV Auto Transformers T2 and T4 Replacement
D7F / D9F	115 kV Tower Refurbishment – Tower 157 near Freeport SS
D6V / D7V	230 kV Lines Refurbishment between Fergus TS and Campbell TS

The major infrastructure investments recommended for the KWCG Region over the near and mid-term planning horizon are provided in the Table 1 below, are all end of life needs along with their planned in-service date and budgetary estimates for planning purpose.

Table 1. Recommended Plans in KWCG Region over the Next 10 Years

Stations / Lines Project	Details	Timeframe	High Level Cost ($M)[1]
Hanlon TS	Transformers T1 and T2 Replacement	2022-2023	17.8
Kitchener MTS #5	Transformers T9 and T10 Replacement	2023-2024	7.5
Scheifele MTS	Transformers T1 and T2 Replacement	2025-2026	-
B5C/B6C	115KV Lines Refurbishment, refurbishing section from Burlington TS to a CTS	2025-2026	16.8
Preston TS	Transformers T3 and T4 Replacement	2026-2027	22.9
Cedar TS	Transformers T7 and T8 Replacement	2026-2027	23.7
Fergus TS	Transformers T3 and T4 Replacement	2028-2029	30.0
Galt TS	Breakers and Component Replacement	2028-2029	12.0
Campbell TS	Breakers and Component Replacement	2028-2029	18.1

The Study Team recommends that:

- Hydro One and LDCs to continue with the implementation of infrastructure investments listed in Table 1 above while keeping the Study Team apprised of project status;
- All the other identified needs/options in the long-term will be further reviewed by the Study Team in the next regional planning cycle.

1. Introduction

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE KITCHENER WATERLOO CAMBRIDGE GUELPH (KWCG) REGION BETWEEN 2021 AND 2041.

The report was prepared by Hydro One Networks Inc. (Transmission) ("Hydro One") on behalf of the Study Team that consists of Hydro One, Alectra Utilities ("Alectra"), Centre Wellington Hydro Ltd., Energy+ Inc., Halton Hills Hydro Inc., Hydro One Networks Inc. (Distribution), the Independent Electricity System Operator ("IESO"), Kitchener-Wilmot Hydro Inc., Milton Hydro Distribution Inc., Waterloo North Hydro Inc. and Wellington North Power Inc., in accordance with the new Regional Planning process established by the Ontario Energy Board in 2013 [5].

The Kitchener, Waterloo, Cambridge and Guelph (KWCG) region is located to the west of the Greater Toronto area in southwestern Ontario. The KWCG Region includes the cities of Kitchener, Waterloo, Cambridge and Guelph, portions of Oxford and Wellington counties and the townships of North Dumfries, Puslinch, Woolwich, Wellesley and Wilmot. Electrical supply to the Region is provided from eleven 230 kV and thirteen 115 kV step-down transformer stations. The approximate boundaries of the KWCG Region are shown below in Figure 1-1.

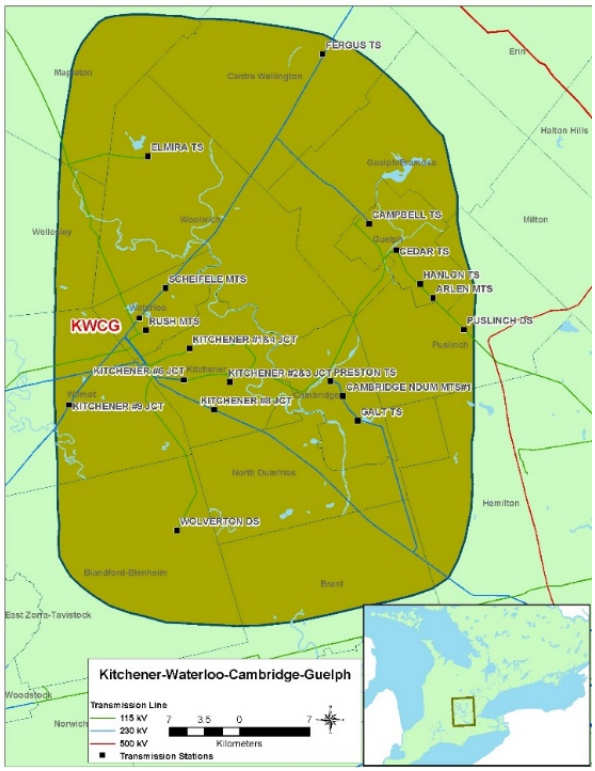

FIGURE 1-1: KWCG REGION MAP

1.1. Objectives and Scope

The RIP report examines the needs in the KWCG Region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs;
- Identify any new needs that may have emerged since previous planning phases e.g., Needs Assessment ("NA"), Scoping Assessment ("SA"), and/or Integrated Regional Resource Plan ("IRRP");
- Assess and develop a wires plan to address these needs; and
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, major high voltage sustainment issues emerging over the near, mid- and long-term horizon, transmission and distribution system capability along with any updates to local plans, conservation and demand management ("CDM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the relevant wires plans to address near and medium-term needs identified in previous planning phases (Needs Assessment, Scoping Assessment, and/or Integrated Regional Resource Plan);
- Discussion of any other major transmission infrastructure investment plans over the planning horizon;
- Identification of any new needs and a wires plan to address these needs based on new and/or updated information;
- Develop a plan to address any longer term needs identified by the Study Team.

1.2. Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the regional characteristics.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the adequacy of the transmission facilities in the region over the study period.
- Section 7 discusses the needs and provides the alternatives and preferred solutions.
- Section 8 provides the conclusion and next steps.

2. Regional Planning Process

2.1. Overview

Planning for the electricity system in Ontario is done at three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2. Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[2] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Study Team determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (non-wires alternatives) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO.

[2] Also referred to as Needs Screening

The IRRP phase also includes IESO led stakeholder engagement with municipalities, Indigenous communities, business sectors and other interested stakeholders in the region.

The RIP phase is the fourth and final phase of the regional planning process and involves discussion of previously identified needs and plans, identification of any new needs that may have emerged since the start of the planning cycle, and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive report of a wires plan for the region. Once completed, this report is also referenced in transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and/or LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region;
- Working and planning for connection capacity requirements with the LDCs and transmission connected customers.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

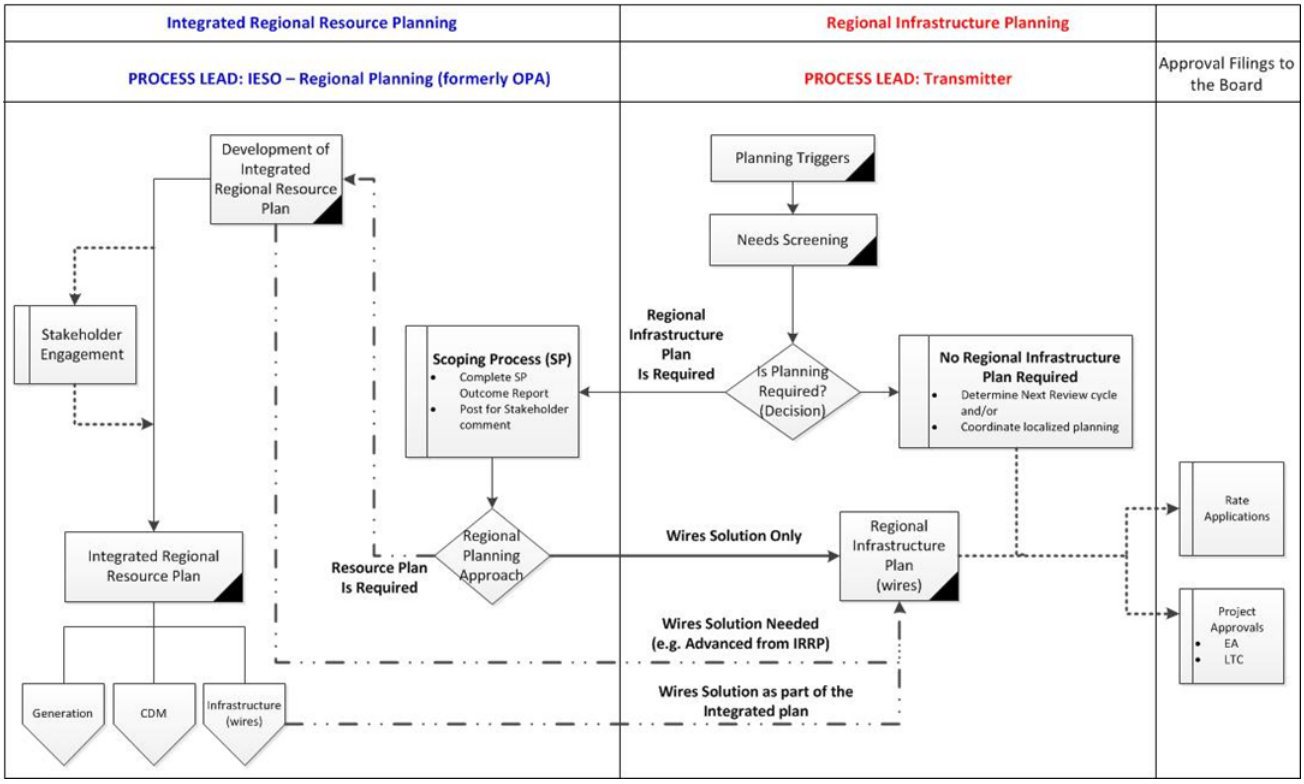

FIGURE 2-2: REGIONAL PLANNING PROCESS FLOWCHART

2.3. RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1) Data Gathering: The first step of the process is the review of planning assessment data collected in the previous phase of the regional planning process. Hydro One collects this information and reviews it with the Study Team to reconfirm or update the information as required. The data collected includes:

   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.

2) Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Depending upon the changes to load forecast or other relevant information, regional technical assessment may or may not be required or be limited to specific issue only. Additional near and mid-term needs may be identified in this phase.

3) Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4) Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

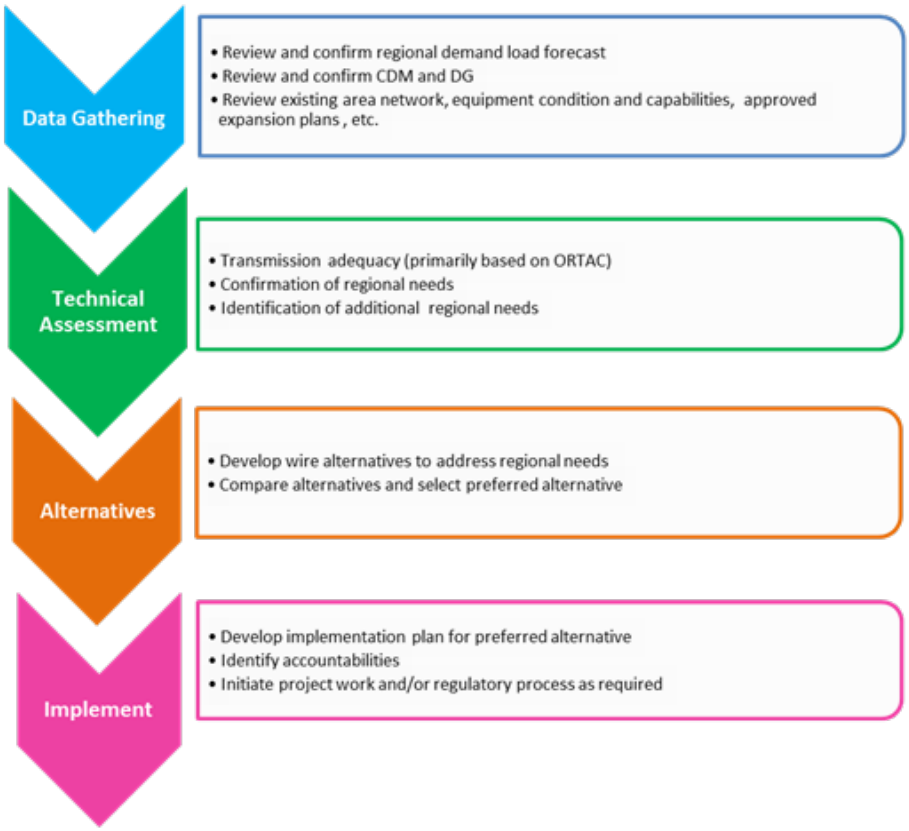

FIGURE 2-3: RIP METHODOLOGY

3. Regional Characteristics

THE KWCG REGION COMPRISES OF THE CITIES OF KITCHENER, WATERLOO, CAMBRIDGE AND GUELPH, PORTIONS OF OXFORD AND WELLINGTON COUNTIES AND THE TOWNSHIPS OF NORTH DUMFRIES, PUSLINCH, WOOLWICH, WELLESLEY AND WILMOT AS SHOWN IN FIGURE 3-1.

The main sources of electricity into the KWCG Region are from four Hydro One transformer stations: Middleport TS, Detweiler TS, Orangeville TS and Burlington TS. Electricity is transformed from 500 kV and 230 kV to 230 kV and 115 kV, respectively, at these stations. Electricity is then delivered to the end users of LDCs and directly-connected industrial customers by twenty-four (24) step-down transformer stations.

A single line diagram showing the electrical facilities of the KWCG Region is provided in Figure 3-1, which illustrates these stations as well as the four major regional sub-systems: Waterloo-Guelph 230 kV sub-system, Cambridge-Kitchener 230 kV sub-system, Kitchener-Guelph 115 kV sub-system and South-Central Guelph 115 kV sub-system.

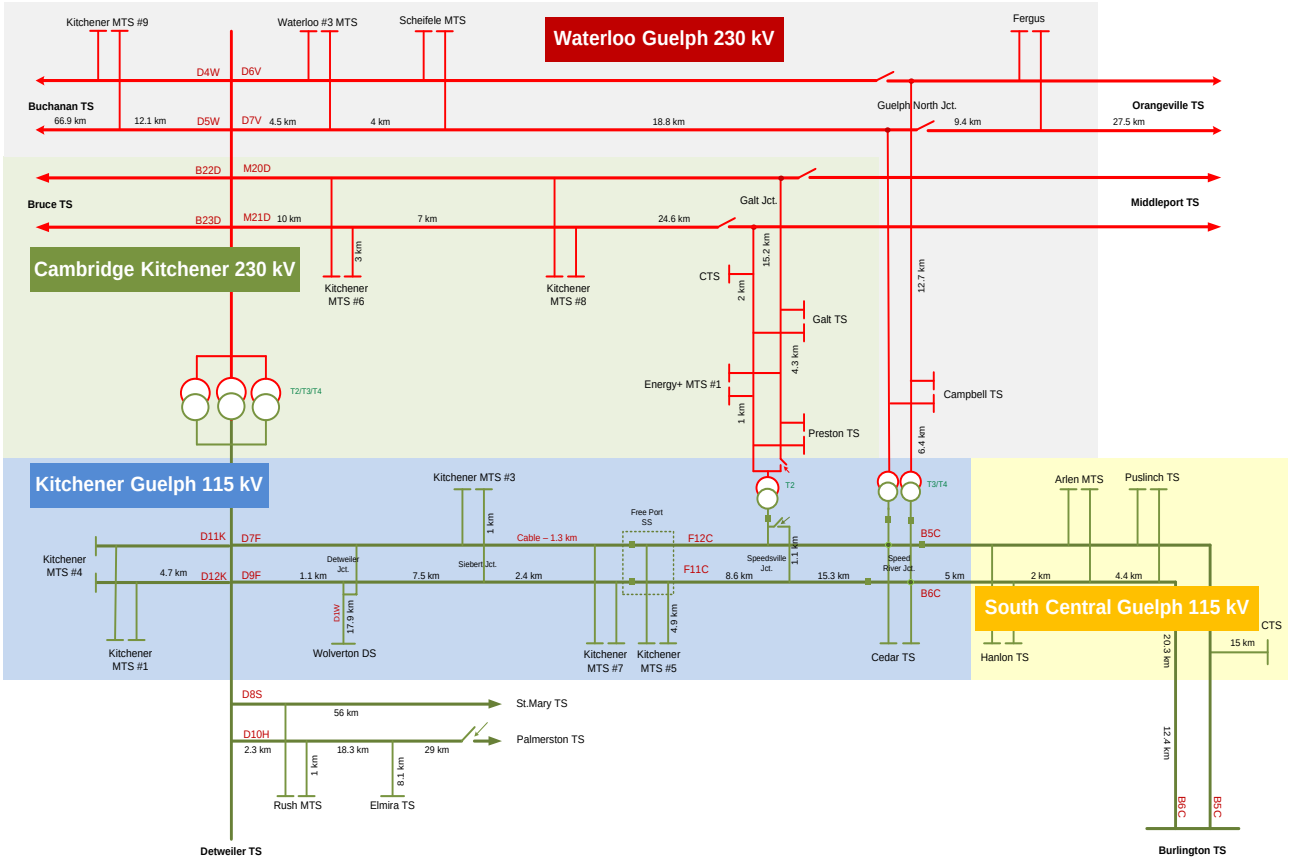

FIGURE 3-4: SINGLE LINE DIAGRAM OF THE KWCG REGION'S TRANSMISSION NETWORK

The twenty-four (24) KWCG's transformer stations can be grouped into six electrical (four major) zones based on their HV supply network:

1. **Waterloo-Guelph 230 kV Area:** The transformer stations in this area are supplied by Detweiler TS 230kV. This area includes transformer stations connected to the 230 kV circuits between Detweiler TS and Orangeville TS D6V/D7V, serving customers in the KWCG area. Below are the transformer stations in Waterloo-Guelph 230 kV area.
    - Campbell TS
    - Fergus TS
    - Scheifele MTS
    - Waterloo North MTS# 3

2. **Cambridge-Kitchener 230 kV Area:** The transformer stations in this area are supplied by Detweiler TS 230kV. This area includes transformer stations connected to the 230 kV circuits between Detweiler TS and Middleport TS M20D/M21D, serving customers in the KWCG area. Below are the transformer stations in Cambridge-Kitchener 230 kV area.
    - Energy + MTS# 1
    - Galt TS
    - Preston TS
    - Kitchener MTS# 6
    - Kitchener MTS# 8
    - CTS# 1

3. **Kitchener-Buchanan 230 kV Area:** The transformer stations in this area are supplied by Detweiler TS 230kV. This area includes transformer stations connected to the 230 kV circuits between Detweiler TS and Buchanan TS. This area has only one transformer station.
    - Kitchener MTS# 9.

4. **Kitchener-Elmira 115 kV Area:** This area covers the north-western part of the KWCG area which is supplied by the Detweiler TS 230/115 kV autotransformers. The transformer stations in this area are:
    - Elmira TS
    - Rush MTS

5. **Kitchener-Guelph 115 kV Area:** This area covers the Kitchener area and northern Guelph area, which is supplied by the Detweiler TS 230/115 kV autotransformers. The transformer stations in this area are:
    - Cedar TS
    - Kitchener MTS# 1
    - Kitchener MTS# 3
    - Wolverton DS
    - Kitchener MTS# 4
    - Kitchener MTS# 5

- Kitchener MTS# 7

6. **South-Central Guelph 115 kV Area:** This area covers the southern part of Guelph, which is supplied by the Burlington TS 230/115 kV autotransformers. The transformer stations in this area are:
    - Arlen MTS
    - Puslinch DS
    - Hanlon TS
    - CTS# 2

4. Transmission Facilities/ Projects Completed and/or Underway Over the Last Ten Years

OVER THE LAST TEN YEARS, A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND UNDERTAKEN BY HYDRO ONE AIMED TO MAINTAIN THE RELIABILITY AND ADEQUACY OF ELECTRICITY SUPPLY TO THE KWCG REGION.

A summary and description of the major projects completed and/or currently underway over the last ten years is provided below. These projects were identified as a result of joint planning studies undertaken by Hydro One, IESO and the LDCs; or initiated to meet the needs of the LDCs; and/or to meet Provincial Government policies. A brief listing of the completed projects is given below.

For distribution voltage level transformation capacity needs:

- Arlen MTS connected in 2011

For reactive and voltage support needs:

- 230 kV SVC (+350 MVAr @ 250 kV) installed at Detweiler TS in 2011[3]
- 115 kV shunt capacitor bank installed at Detweiler TS in 2012

For 230 kV transmission circuit capacity needs:

- 230 kV M20D/M21D circuit sections capacity increased by sag limit mitigation in 2014

For 115 kV transmission circuit capacity and 230 kV load restoration needs:

- Guelph Area Transmission Reinforcement (GATR) project in 2016 that includes:
  - extension the 230kV circuits D6V/D7V to Cedar TS;
  - two new 250 MVA, 230/115kV autotransformers at Cedar TS;
  - And two 230 kV in-line switches at Guelph North Junction on circuits D6V/D7V.

  This project reinforces the Kitchener-Guelph and South-Central Guelph 115kV sub-systems as well as improves restoration capability to the Waterloo-Guelph 230 kV sub-system.

- Two new additional 230kV in-line switches on M20D/M21D circuits installed at Galt Junction in 2017 to improve restoration capability of the Cambridge-Kitchener 230 kV sub-system

For station short circuit capacity needs:

[3] Two SVCs were installed for the contingency support in the South-western Ontario

- 13.8 kV series reactors were installed to mitigate short circuit levels at Arlen MTS. This project was identified in the last RIP phase.

For end of life needs addressed:

- Galt TS T7 and T8 Transformers Replacement
- Campbell TS T1 and T2 Transformers Replacement
- Detweiler TS AC Station Service and Component Replacement
- D7F / D9F 115 kV Tower Refurbishment, Tower 157 near Freeport SS
- D6V / D7V 230 kV Lines Refurbishment between Fergus TS and Campbell TS
- Detweiler TS 250 MVA 230/115 kV T2 and T4 autotransformers replaced

5. Load Forecast and Study Assumptions

5.1. Load Forecast

The electricity demand in the KWCG Region is anticipated to grow by about 10% over the next ten years. Figure 5-1 shows the KWCG Region's planning load forecast (summer net, coincident extreme weather corrected peak) developed during this RIP phase.

This RIP load forecast was used to determine the loading that would be seen by transmission lines and autotransformer stations and to identify the need for additional line and auto-transformation capacity.

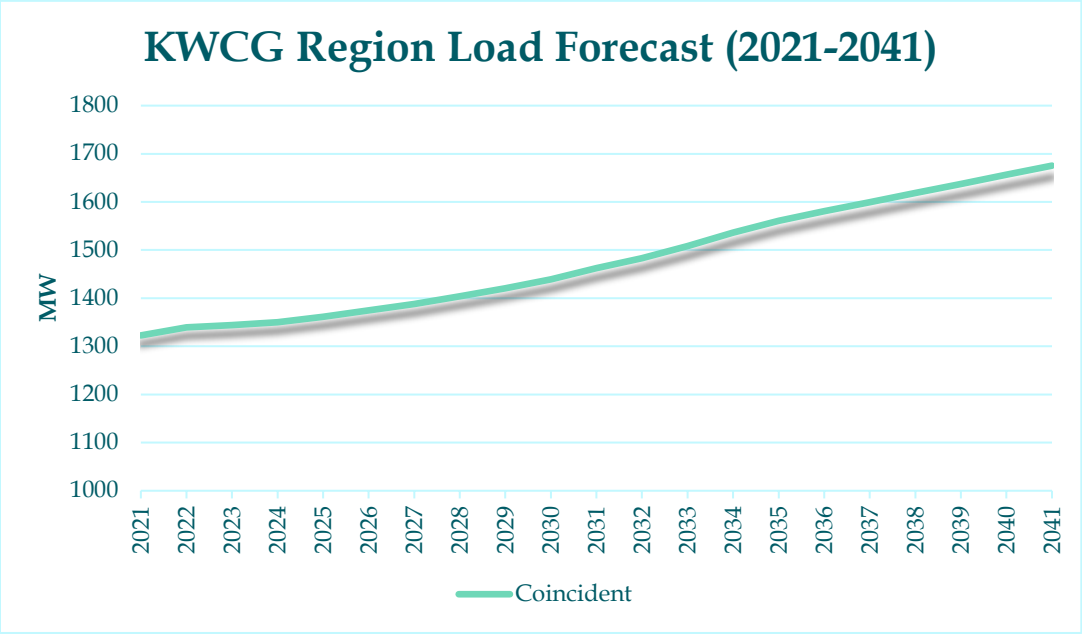

FIGURE 5-5: KWCG REGION LOAD FORECAST

The regional-coincident load forecast represents the total peak load of the 24 step-down transformer stations in the KWCG Region. The Region's peak summer load is forecasted to increase from 1323 MW in 2021 to 1462 MW by 2031.

The load forecast for KWCG RIP is provided in Appendix D. This load forecast is based upon the 2020 actual loads and the load forecast prepared by the IESO for the recently completed IRRP. The NA and the IRRP used the 2018 actual loads as the base. More than two years have passed since then and though 2020 seems to be unusual year in light of the COVID-19 pandemic; with all the applicable adjustments and the comparisons with 2018, 2019 and 2021 actual loads, it made sense to base the load forecast on 2020 actual station loads.

This approach was reviewed and accepted by the Study Team during the RIP phase. During the data gathering, some LDCs provided a revised load forecast while the other confirmed no changes to their load forecasts provided earlier to the IESO for the IRRP during the current

Regional Planning cycle. The IESO also updated the CDM and DG targets for the preparation of this RIP load forecast. The load forecast for this RIP was prepared by adjusting the actual 2020 summer peak loads applying an extreme weather correction factor and then applying growth rates derived from the LDCs' forecast. This forecast was further adjusted taking into account the impact of CDM and DGs provided by the IESO. Further details regarding the CDM and connected DG are provided in reference [2] [3]. The load forecast prepared for this RIP is slightly lower than the one prepared by the IESO for the purpose of IRRP but is in the same order of magnitude. The change in the load forecast due to the factors listed above has resulted in the shifting or elimination of previously identified needs, along with the emergence of new needs close to the end of the study period.

5.2. Study Assumptions

The following assumptions are made in this report.

- The study period for the RIP assessments is 2021-2041.
- All facilities that are identified in Section 4 and that are planned to be placed in-service within the study period are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low voltage capacitor banks. Normal planning supply capacity for transformer stations is determined by the summer 10-day Limited Time Rating (LTR).
- Line capacity adequacy is assessed by using coincident peak loads in the area.
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC) [6].

6. Adequacy of Existing Facilities

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND TRANSFORMER STATION FACILITIES SUPPLYING THE KWCG REGION OVER THE PLANNING PERIOD (2021-2041).

During this regional planning cycle three (3) separate assessments have been completed for the KWCG Region. The findings of these studies are the inputs to this Regional Infrastructure Plan (RIP). These assessments are:

- 2018 KWCG Region Needs Assessment ("NA") Report
- 2019 KWCG Region Scoping Assessment ("SA") Report
- 2021 KWCG Integrated Regional Resource Plan ("IRRP") Report

The NA and IRRP reports identified a number of needs to meet the forecasted load demands and assets approaching end of life (EOL). This section provides a review of the adequacy of the transmission lines and stations in the KWCG Region. The adequacy is assessed using the latest regional load forecast provided in Appendix D from a loading perspective. Sections 6.1 to 6.6 present the results of this review. Sustainment aspects were identified in the NA report and are addressed in Section 7 of this report.

6.1. 230 kV Transmission Facilities

All 230 kV transmission circuits in the KWCG Region are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the rest of the Ontario's transmission system and are also part of the transmission path from generation in Southwestern Ontario to the load centers in the Hamilton, Niagara and GTA areas. These circuits also serve local area stations within the Region and the power flow on them depends on the bulk system transfer as well as local area loads. These circuits are as follows (please refer to Figure 3-1):

a) Detweiler TS to Orangeville TS 230 kV circuits D6V and D7V
   - supplies Fergus TS, Campbell TS, Waterloo North MTS# 3 and Scheifele MTS

b) Detweiler TS to Middleport TS 230 kV circuits M20D and M21D
   - supplies Kitchener MTS# 6, Kitchener MTS# 8, Energy + MTS# 1, Galt TS, Preston TS and Customer # 1 CTS

c) Detweiler TS to Buchanan TS 230 kV circuits D4W and D5W
   - supplies Kitchener MTS# 9

The RIP review of the current load forecast shows that based on the forecasted station loadings, all the above three (3) 230 kV transmission lines are expected to be adequate over the study period.

6.2. 230/115 kV Autotransformer Facilities

Bulk power supply to the KWCG Region is provided by Hydro One's 500 kV to 230 kV and 230 kV to 115 kV autotransformers. The number and location of these autotransformers are as follows:

a) Two 500/230 kV autotransformers at Middleport TS
b) Four 230/115 kV autotransformers at Burlington TS
c) Three 230/115 kV autotransformers at Detweiler TS
d) Two 230/115 kV autotransformers at Cedar TS
e) One 230/115 kV autotransformer at Preston TS

Middleport autotransformers are part of the south-western Ontario bulk supply system and will be studied separately under Middleport bulk planning studies for a more comprehensive understanding of the bulk system needs. However for the purpose of KWCG regional planning needs, these auto-transformer facilities are adequate over the study period.

Burlington TS autotransformers supply the South-Central Guelph 115 area that in turn supply Arlen MTS, Hanlon TS, Customer# 2 CTS and Puslinch DS. The Burlington TS autotransformer facilities are adequate over the study period.

Detweiler TS, Preston TS and Cedar TS autotransformers supply the Kitchener-Guelph 115 kV area that in turn supply Cedar TS, Kitchener MTS #1, Kitchener MTS #3, Kitchener MTS #4, Kitchener MTS #5, Kitchener MTS #7, Elmira TS, Rush MTS and Wolverton DS. The transformation facilities are adequate over the study period.

Note that the Preston TS autotransformer and the 115 kV Kitchener Guelph supply system may not have adequate supply capacity due to its inherent limitation of 115 kV supply system to address the load restoration concerns beyond the study period in case of the simultaneous loss of both the 230 kV circuits, M20D and M21D.

6.3. 115 kV Transmission Facilities

The KWCG Region contains five pairs of double circuit 115 kV lines. This 115 kV network serves local area load. The 115 kV transmission facilities can be divided into five main corridors summarized below.

a) Detweiler TS to Freeport SS 115 kV transmission circuits D7F/D9F
    - supplies Wolverton DS, Kitchener MTS #3, Kitchener MTS#7
b) Freeport SS to Cedar TS 115 kV transmission circuits F11C/F12C
    - supplies Kitchener MTS #5 and Cedar T1/T2 transformers
c) Burlington TS to Cedar TS 115 kV transmission circuits B5C/B6C
    - supplies Puslinch DS, Arlen MTS, Hanlon TS, Customer #2 CTS and Cedar T7/T8 transformers
d) Detweiler TS 115 kV radial transmission circuit D11K/ D12K

- supplies Kitchener MTS #1 and Kitchener MTS #4

e) Detweiler TS to Seaforth TS / Hanover TS 115 kV transmission circuit D8S/D10H with Normally Open (N/O) points

- supplies Rush MTS and Elmira TS (D10H only)

In the near and mid-term, all the 115 kV circuits are adequate and no supply capacity needs are identified under loss of one element. A marginal overloading was identified during the IRRP phase on B5C under the outage scenario of B6C and a subsequent loss of F12C. This marginal overloading can be managed by coordinated outage planning.

In the long term, near the end of the study period, the section of 115 kV D10H circuit between Detweiler TS and tap to Rush MTS may slightly be overloaded following the loss of companion D8S circuit under a peak load scenario. This is a need in the long term and will be revisited in the next planning cycle.

6.4. Step-Down Transformer Station Facilities

There are 24 step-down transformer stations within the KWCG Region. Twenty-two supply electricity to LDCs and two are transmission-connected customer transformer stations. These stations are listed within the load forecast in Appendix D. Of those 24 stations, 15 of them are owned and operated by the LDCs.

The stations summer peak non-coincident load forecast is given in Table D-1 of Appendix D.

TABLE 6-1: KWCG STEP-DOWN EXISTING TRANSFORMER STATIONS

230 kV		115 kV	
Campbell TS	Preston TS	Arlen MTS	Kitchener MTS #5
Energy + MTS # 1	Scheifele MTS	Cedar TS	Kitchener MTS #7
Fergus TS	Waterloo North MTS# 3	Elmira TS	Puslinch DS
Galt TS	CTS# 1	Hanlon TS	Rush MTS
Kitchener MTS # 6		Kitchener MTS# 1	Wolverton DS
Kitchener MTS # 8		Kitchener MTS# 3	CTS # 2
Kitchener MTS # 9		Kitchener MTS # 4	

As a part of RIP assessment, the step-down transformation station capacity was reviewed considering the non-coincident load forecast. Accordingly, the following step down transformation capacity needs are identified. The need timeframe defines the time when the peak load forecast first approaches the station's summer 10 day LTR:

TABLE 6-2: KWCG STEP-DOWN TRANSFORMER STATIONS SUPPLY CAPACITY NEEDS

Stations	Need Timeframe
Kitchener MTS # 5	2028
Cedar TS (T7/T8)	2030
Kitchener MTS # 8 T15/T16	2033
Energy + MTS # 1	2036

Waterloo North MTS # 3	2041

6.5. System Reliability and Load Restoration

In case of contingencies on the transmission system, ORTAC provides the load restoration requirements relative to the amount of load affected. Planned system configuration must not exceed 600 MW of load curtailment/rejection. In all other cases, the following restoration times are provided for load to be restored for the outages caused by design contingencies.

- All loads must be restored within 8 hours.
- Load interrupted in excess of 150 MW must be restored within 4 hours.
- Load interrupted in excess of 250 MW must be restored within 30 minutes.

After the in-service of the Guelph Area Transmission Reinforcement project that included the installation of two new 230/115kV autotransformers at Cedar TS, two new 230 kV in-line switches on D6V/D7V circuits to improve restoration capability of Waterloo-Guelph 230 kV sub-system and two new 230kV in-line switches on M20D/M21D circuits to improve restoration capability of the Cambridge-Kitchener 230 kV sub-system; it is expected that all loads can be restored within 8 hours in the KWCG Region over the study period.

A simultaneous loss of M20D and M21D will result in the loss of up to 375 MW of load, by 2041, in the Cambridge area. Up to 150 MW of this load must be restored within 30 minutes as required by ORTAC. This is within the capability of the system and, so, no load restoration concern has been identified in this RIP. However, the Study Team agrees to monitor the load in the region for any new developments to ascertain that load restoration concern are identified ahead of time. Note that the Preston TS autotransformer and the 115 kV Kitchener Guelph supply system may not be adequate due to its inherent limitations to address the load restoration concerns beyond the study period in case of the simultaneous loss of both 230 kV circuits, M20D/M21D.

6.6. Station Short Circuit Capacities [2][3]

The regional planning process identified a need to examine short circuit levels at all the stations in the region as they pertain to LDC equipment ratings as well as to generation or storage resources connection challenges. The particular concerns raised at the time of initiation of this second cycle of the regional planning for the region have since been satisfactorily resolved. However, the Study Team recognizes the importance of a holistic system planning approach, which includes analysis related to short circuit levels.

Distribution system short circuit levels, as measured at the low-voltage (LV) bus of transmission connected transformer stations, are subject to change due to two main driving factors: changes in upstream impedance and changes in amount and type of DERs connected to the station. Changes in upstream impedance typically result from transmission system changes, such as network expansion or reconfiguration or changes in transformer impedance at the time of transformer replacement.

The upstream impedance generally has minimal impact on the station LV actual short circuit level because of the dominant effect of the station transformers impedance. However, changes in the amount and type of DERs connected to a LV bus of a station, unlike changes in upstream impedance, have a significant and direct impact on the station's LV short circuit level.

While equipment which limits the available short circuit capacity on the LV side of a transformer station may have options to be upgraded with higher rated equipment, the Study Team is cognizant that there is an effective practical limit to this rating established by in Appendix 2 of the Transmission System Code. Distribution systems components, including equipment owned by end-use customers, in Ontario, is designed, manufactured, and applied to this standard, which effectively is:

- 500 MVA @ 13.8 kV
- 800 MVA @ 27.6 kV
- 1500 MVA @ 44 kV

The amount of DER that can be connected to a station LV bus is thus limited by the above-mentioned short circuit level requirements. Some stations may have a smaller value due to pre-existing legacy equipment which was adequate and is deemed to be grandfathered. Hence, in examining the rated short circuit capacity of LV station components, the Study Team used lowest equipment rating, or TSC rating, whichever is lower in identifying stations that are at or approaching short circuit capacity limits.

Appendix E lists all stations in the KWCG region where new DER connection is restricted due to the LV short circuit level being extremely high, that is approximately equal to or greater than 90% of the equipment ratings or the TSC ratings capacity. The information presented in this table is obtained with consideration of known generation connections as of March 2021 and is subject to change primarily due to new DER connections.

The appropriate LDC should be consulted for up-to-date short circuit information and feasibility of connecting new DER.

6.7. Longer Term Outlook

While the RIP was focused on the 2021-2041 period, the Study Team has also looked at longer-term electricity sector scenarios and uncertain load growth possibilities within the study period under certain pockets within the KWCG region. Following two subsections describes two such items that requires longer-term insight for the regional needs.

6.7.1. Other Planning Considerations in the KWCG Region

Municipalities in KWCG region have developed their community energy plans with a primary focus to reduce their energy consumption by local initiatives over next 25 to 30 years. With respect to electricity, these communities are planning for an increased reliance on community energy sources such as distributed generation, generation behind the meters like rooftop solar systems and local battery storage systems to reduce cost and for improved reliability of electricity supply. The implementation timelines, as suggested in these plans, starts in longer term just near the end of the study period and requires greater attention in the next regional planning cycle.

Note that community energy plans may have potential to supplement and/or defer future transmission infrastructure development needs. The Study Team therefore recommends reviewing the community energy plans in the next regional planning cycle.

There are situations where behind the meter battery storage cannot be connected due to technical constraints. The LDCs in this region and Hydro One, outside the regional planning forum, can undertake the task of exploring the issue to assess technical constraints and /or other solutions that can facilitate connection of additional battery storage.

In parallel and within the Conservation and Demand Management initiatives, communities are also working towards self-sufficiency by improving efficiencies of existing local energy systems i.e. reducing energy consumption and losses by means of utilizing smarter buildings, houses, efficient heating, cooling, appliances, equipment, and processes for all community needs. Ultimately, the objective of these energy plans in the region is to be a net zero carbon community.

6.7.2. Uncertain Load Growths

There are some load growth possibilities in pockets of the region where, due to lack of confirmed status of development projects or uncertainty with connection point, were not included in the load forecast. These load growth triggers will be closely monitored and reviewed for further analysis in the next regional planning cycle:

- Metrolinx electrification project: Metrolinx is electrifying its rail lines and planning a traction power substation (TPSS). The amount of traction load is insignificant but has a very sensitive and peculiar characteristics that makes it troublesome for other customers in a weaker system. The connection point of TPSS is not yet finalized and therefore has a higher uncertainty.
- East Side Lands: Energy + is expecting load growth in its east side lands and are planning Energy + MTS # 2 to meet the increased load demand which has not materialized yet. Similarly, Waterloo North Hydro is also anticipating load growth in

the east side lands near Scheifele TS and are planning WNH MTS # 4 to cater the new load growth and some existing loads currently supplied from Scheifele TS. In addition, Hydro One is carrying out end of life like for like replacement of transformers at Preston TS in the 2026-2027 timeframe that will impart additional supply capacity to the station due to the alleviation of an inherent equipment limitation. This incremental capacity to be available in 2026 at Preston TS would be examined to determine if it is technically and economically feasible, meeting power quality requirements, to service both Energy+ and Waterloo North Hydro's East Side Lands development and surrounding areas under normal and/or contingency situations. These needs along with increased station capacity, therefore, will be revisited in the next regional planning cycle for optimal solution, hoping to have more clarity on the development projects in the pocket by then.

- Development of other projects such as Data Centers and Light Rail Transit from Kitchener to Cambridge will be monitored and assessed in the next regional planning cycle.

7. Regional Needs and Plans

THIS SECTION DISCUSSES ELECTRICAL INFRASTRUCTURE NEEDS IN THE KWCG REGION IDENTIFIED IN THE PREVIOUS REGIONAL PLANNING CYCLE, THE NEEDS ASSESSMENT REPORT FOR THIS CYCLE, SCOPING ASSESSMENT AND THE IRRP; AND SUMMARIZES THE PLANS DEVELOPED TO ADDRESS THESE NEEDS.

This section outlines and discusses infrastructure needs and plans to address these needs for the near-term (up to 5 years) and the mid-to long-term (beyond 5 years) planning horizon. This includes long-term needs associated with sustainment plans and the supply capacity needs. The long term needs will be assessed in the next regional planning cycle.

The near-term and mid to long-term electrical infrastructure needs in the Region are summarized below in Table 7.1 and Table 7.2, respectively. The details of the project / plan are discussed further in sections 7.1 and 7.2.

TABLE 7-3: IDENTIFIED NEAR AND MID-TERM NEEDS IN KWCG REGION

No.	Needs	Project / Need Timeframe	Section
1	Hanlon TS: EOL T1/T2 Supply Transformers Replacement	2022-2023	7.2
2	Kitchener MTS #5: EOL T9/T10 Supply Transformers Replacement	2023-2024	7.2
3	Scheifele MTS: EOL T1/T2 Supply Transformers Replacement	2025-2026	7.3
4	115 kV B5C/ B6C**:** EOL Burlington TS to Westover CTS Line Sections Refurbishment	2025-2026	7.2
5	Preston TS: EOL T3/T4 Supply Transformers Replacement	2026-2027	7.3
6	Cedar TS: EOL T7/T8 Supply Transformers Replacement	2026-2027	7.3

TABLE 7-4: IDENTIFIED LONG-TERM NEEDS IN KWCG REGION

No.	Needs	Timing	Section
1	Fergus TS: EOL T3/T4 Supply Transformers Replacement	2028-2029	7.3
2	Galt TS: EOL Breakers and other component Replacement	2028-2029	7.3
3	Campbell TS: EOL three (3) Breakers and other component Replacement	2028-2029	7.3
4	Kitchener MTS # 8 (T15/T16): Station Supply Capacity	2033	7.4
5	Energy + MTS # 1: Station Supply Capacity	2036	7.4
6	Campbell TS (T1/T2): Station Supply Capacity	2038	7.4

7	Arlen MTS: Station Supply Capacity	2040	7.4
8	Elmira TS: Station Supply Capacity	2041	7.4
9	Waterloo North MTS # 3: Station Supply Capacity	2041	7.4

7.1. Deteriorating Infrastructure, Optimization Opportunities and Replacement Plan of Major Equipment

7.1.1. Deteriorating Infrastructure

Hydro One and LDCs have provided high voltage asset information under the following categories that have been identified at this time and are likely to be replaced over the next 10 years:

- Autotransformers
- Power transformers
- HV breakers
- Transmission lines requiring refurbishment where an uprating is being considered for planning needs and require Leave to Construct (i.e., Section 92) application and approval
- HV underground cables where an uprating is being considered for planning needs and require EA and Leave to Construct (i.e., Section 92) application and approval

The end-of-life (EOL) assessment, which includes right sizing, for the above high voltage equipment typically includes consideration of the following options:

1. Maintaining the status quo;
2. Replacing equipment with similar equipment of lower ratings and built to current standards;
3. Replacing equipment with lower ratings and built to current standards by transferring some load to other existing facilities;
4. Eliminating equipment by transferring all of the load to other existing facilities;
5. Replacing equipment with similar equipment and built to current standards (i.e, “like-for-like” replacement);
6. Replacing equipment with higher ratings and built to current standards; and
7. Station reconfiguration

Accordingly, following major high voltage equipment has been identified as approaching its end of life, based on current condition information, over the next 10 years.

TABLE 7-5: DETERIORATING INFRASTRUCTURE, EOL NEEDS IN KWCG REGION

Stations / Lines Project	Details	Timeframe	High Level Cost[4] ($M)
Hanlon TS	T1/ T2 Transformer Replacement	2022-2023	17.8
Kitchener MTS #5	T9/ T10 Transformer Replacement	2023-2024	7.5
Scheifele MTS	T1/ T2 Transformer Replacement	2025-2026	-
B5C/B6C	Refurbishing 115kV line section from Burlington TS to Enbridge Westover CTS	2025-2026	16.8
Preston TS	T3/ T4 Transformer Replacement	2026-2027	22.9
Cedar TS	T7/ T8 Transformer Replacement	2026-2027	23.7
Fergus TS	T3/ T4 Transformer Replacement	2028-2029	30.0
Galt TS	Breakers and Other Component Replacement	2028-2029	12.0
Campbell TS	Breakers and Other Component Replacement	2028-2029	18.1

Maintaining status quo is not an option for any of the end of life autotransformers, station transformers or line sections due to risk of equipment failure, and would result in increased maintenance cost and prolonged customer outages and interruptions. Replacing “like-for-like” with nonstandard transformers would result in complexity with failures, difficulty with spares management strategies and with unique installation requirements. Nonstandard equipment also poses serious safety risk for employees under normal and emergency situations.

No other lines or HV station equipment in the KWCG region than listed above, have been identified for major replacement/refurbishment at this time.

7.1.2. Optimization Opportunities and Replacement Plans

For stations in the Cambridge-Guelph sub region, an analysis of the current distribution situation that includes under-utilized dedicated feeder capacities, determined that there are not enough spare feeder positions and capacity at HONI and Alectra stations to reallocate DESN loads in the sub-system without significant distribution system and neighboring station upgrades.

Similar is the situation with Kitchener-Waterloo sub region and therefore there are little or no significant optimization opportunities present at this time.

[4] Budgetary estimates

Hence, the Study Team recommends that the LDCs undertakes replacement of their end-of-life high voltage equipment as planned with standard size units, being technically and economical most suitable solution.

7.2. Needs in Near-Term (Projects in Execution)

The following end-of-life refurbishment needs are under execution. These needs were identified in the earlier phases of this 2nd cycle of regional planning.

7.2.1.115 kV B5C/ B6C Line Sections

The 115 kV B5C/B6C circuits consist of about 45 km of double circuit line and 15 km of single circuit line supplying South-Central Guelph 115 kV loads. About 12 km of double circuit line section from Burlington TS to Harper's Jct. and about 15 km B5C 115 kV line tap from Harper's Jct. to a Westover Jct. requires refurbishment.

Not refurbishing these line sections would increase risk of failure due to asset condition, maintenance expenses and reduce supply reliability to the customers.

The refurbishment of the 27 km 115 kV B5C/B6C line sections from Burlington TS to a CTS is currently under execution and the work is planned to be completed by the end of year 2025. The delay in the in-service is attributed to a hold on project due to outage concerns with a customer.

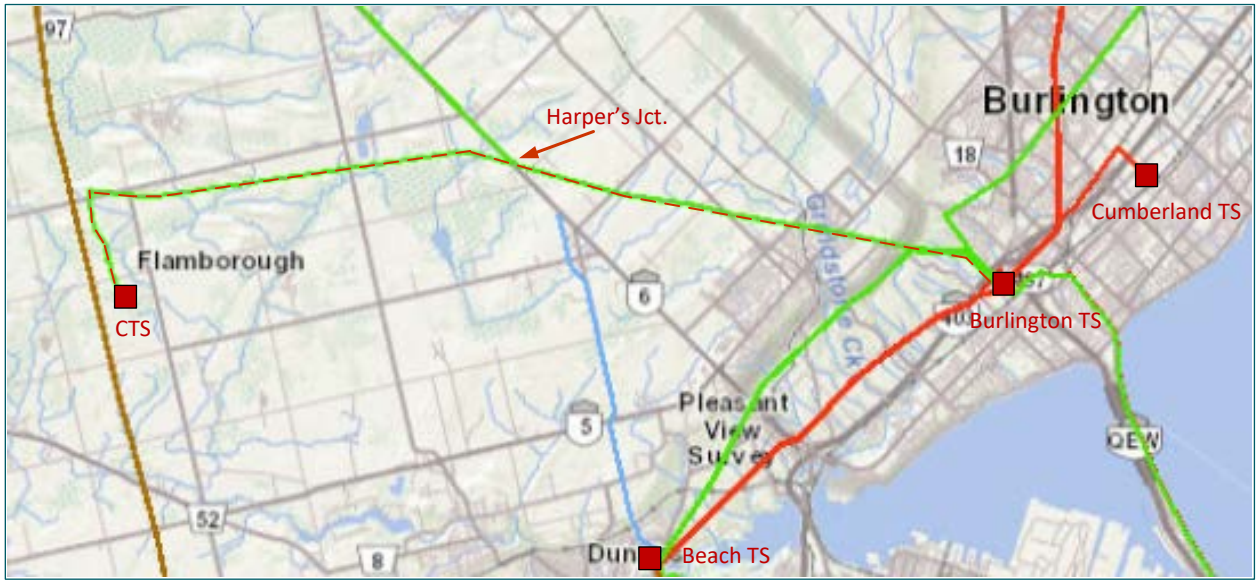

FIGURE 7-6: BURLINGTON TS TO HARPER'S JCT. TO CTS

7.2.2. Hanlon TS T1/T2 Transformer

Hanlon TS is located south of the city of Guelph supplying Alectra loads. Hanlon TS is a single T1/T2 DESN station of 33 MVA nonstandard transformers having a LTR of 48 MVA (43 MW @ 0.9 PF). This station is currently supplying about 27.5 MW of peak load. The loads at Hanlon TS are currently forecasted to remain flat over the entire study period. The supply capacity of this station is therefore expected to be sufficient over and beyond the study period.

The T1/T2 transformers were built in 1955-56 and have been identified as EOL due to poor condition requiring replacement. At this time none of other HV/LV equipment at this station has been identified as approaching EOL over the next 5-10 years.

There are no nearby supply stations to Hanlon TS with surplus capacity where this station's loads can be transferred therefore Hydro One plans to replace these EOL transformers with standard size units of 42 MVA in 2022-2023.

7.2.3. Kitchener MTS #5 T9/T10 Transformers

Kitchener MTS #5 is located in the city of Kitchener supplying Kitchener-Wilmot Hydro Inc. loads. Kitchener MTS #5 is a 115/ 13.8 kV single T9/T10 DESN station of 83 MVA nonstandard transformers having a LTR of 89 MVA (80 MW @ 0.9 PF), currently supplying 67 MW of peak load. The loads at Kitchener MTS #5 are currently forecasted to grow at about 15% over the entire study period and approaches the supply capacity of this station by 2028.

Both the T9/T10 transformers at this station have been identified as approaching end of life requiring replacement. At this time none of other HV/LV equipment at this station has been identified as approaching EOL over the next 5-10 years.

The station cannot be downsized or eliminated because there is no nearby supply station/s to Kitchener MTS #5 having surplus capacity where this station's loads can be transferred. The Study Team recommends replacing the T9/T10 nonstandard transformers with standard units of similar or greater size, that can provide higher LTR for station capacity to be sufficient beyond study period, is the preferred option. Kitchener-Wilmot Hydro Inc. and Hydro One will coordinate the replacement plan of these transformers. The replacement of the EOL equipment is expected to be completed by 2023-2024.

7.3. Needs in Near, Mid and Long Term

The following end-of-life refurbishment needs have been identified in this regional planning cycle:

7.3.1. Scheifele MTS – T1/ T2 Transformers

Scheifele MTS is located in the city of Waterloo supplying Waterloo North Hydro Inc. loads. Scheifele MTS has four 230/13.8 kV transformers T1 and T2 of 69 MVA (LTR), and T3 and T4 of 110 MVA (LTR) currently supplying 145 MW of peak loads. The load at this station is forecasted to remain almost flat over the entire study period. The total supply capacity of Scheifele MTS is 161 MW expected to be sufficient over the study period, except marginal overloading in 2041.

The T1/T2 transformers based on their age have been identified by Waterloo North Hydro Inc. as approaching end of life potentially requiring replacement in the 2025- 2026 timeframe. Waterloo North Hydro will be monitoring the condition of these transformers to assess their replacement need. At this time none of other HV/LV equipment at this station has been identified as approaching EOL over the next 5-10 years.

The station cannot be downsized or eliminated because there is no nearby supply station/s to Scheifele MTS having surplus capacity where this station's loads can be transferred. The Study Team recommends that Waterloo North Hydro continue monitoring the condition of these T1/T2 transformers at Scheifele MTS and if required, proceed with replacement plan otherwise this need may be reassessed in the next regional planning cycle.

7.3.2. Cedar TS – T7/ T8 Transformers

Cedar TS is located in the city of Guelph supplying Alectra loads. Cedar TS has two 115/13.8 kV DESN units T1/T2 and T7/T8 of 75 MVA with a LTR of 115 MVA (103 MW @ 0.9 PF) and 37 MVA with a LTR of 44 MVA (40 MW @ 0.9 PF), currently supplying 67 MW and 36 MW of peak loads respectively. The loads at both Cedar TS DESNs are currently forecasted to grow at an average of about four percent (4%) over the entire study period. The supply capacity of T7/T8 may approach its LTR by year 2030 while that of T1/T2 is expected to be sufficient over the study period.

The T7/T8 DESN 38 MVA nonstandard transformers were built in 1958 and have been identified for replacement due to poor condition. The T1/T2 transformers are relatively newer and were built in early 1990s. At this time none of other HV/LV equipment at this station has been identified as approaching EOL over the next 5-10 years.

The station cannot be downsized or eliminated because there is no nearby supply station/s to Cedar TS having surplus capacity where this station's loads can be transferred therefore the Study Team recommends replacing the nonstandard transformers with standard units of 42 MVA in 2026-2027 timeframe, which will impart sufficient capacity (higher LTR) to the station over the study period.

7.3.3. Preston TS T3/T4 Transformers

Preston TS (DESN) is located in the city of Cambridge supplying Energy+ loads. Preston TS is a single T3/T4 DESN station of 125 MVA transformers with no additional LTR capability available i.e. 125 MVA (113 MW @ 0.9 PF). This station is currently supplying about 92 MW of peak load. The loads at Preston TS are currently forecasted to peak at about 120 MW during the study period.

The T3/T4 transformers are almost 50 years old, having been built in 1968. Condition assessment has identified that both T3/T4 transformers at EOL, requiring replacement. At this time none of other HV/LV equipment at this station has been identified as EOL over the next 5-10 years.

The station cannot be downsized or eliminated because there is no nearby supply station/s to Preston TS having spare supply capacity where this station's loads can be transferred. The Study Team recommends replacing the existing 125 MVA 230/ 27.6 kV T3/T4 transformers at Preston

TS with 125 MVA standard units. This will also result in an increased supplying capacity at Preston TS due to the alleviation of an inherent equipment limitation, required to meet the future Energy+ needs in the Cambridge distribution area. This incremental capacity may be available for Waterloo North Hydro's East-Side-Lands development as deemed technically and economically feasible, meeting power quality requirements. The replacement plan for the equipment will be developed by Hydro One and coordinated with the affected LDC and/or customers and it is expected to be completed by 2026-2027.

7.3.4. Fergus TS T3/T4 Transformers

Fergus TS is located in the township of Fergus supplying various loads LDCs in the KWCG region. Fergus TS has two 230/ 44 kV transformers T3 and T4 of 75/100/125 MVA, currently supplying 90 MW of peak loads. The load at this station is forecasted to grow at about 20 percent over the entire study period. The total supply capacity of Fergus TS is 154 MW expected to be more than adequate over the study period.

The T3/T4 transformers are almost 50 years old, having been built in 1972. Condition assessment has identified that both T3/T4 transformers and the feeder breakers are at their EOL requiring replacement.

The station cannot be downsized or eliminated because there is no nearby supply station/s to Fergus TS having surplus capacity where this station's loads can be transferred. The Study Team recommends that Hydro One continue monitoring the condition of these T3/T4 transformers and other components at Fergus TS and if required proceed with the replacement plan by 2028-2029 or otherwise this need may be reassessed in the next regional planning cycle.

7.3.5. Galt TS Breakers and Components

Galt TS is located in the city of Cambridge supplying Energy + loads in the KWCG region. Galt TS has two 230/ 28-28 kV transformers T7 and T8 of 75/100/125 MVA, currently supplying 112 MW of peak loads. The load at this station is forecasted to grow at about 20 percent over the entire study period. The total supply capacity of Galt TS is 169 MW, expected to be more than adequate over the study period.

The T7/T8 transformers were replaced in 2010 and 2012 respectively to technical issue with the transformers. The breakers and other component at the station are almost 50 years old. Condition assessment has identified that these components are at EOL, requiring replacement.

The station cannot be downsized or eliminated because there is no nearby supply station/s to Galt TS having surplus capacity where this station's loads can be transferred. The Study Team recommends that Hydro One continue monitoring the condition of these EOL components at Galt TS and if required proceed with the replacement plan by 2028-2029 or otherwise this need may be reassessed in the next regional planning cycle.

7.3.6. Campbell TS (T1/T2) Breakers

Campbell TS is located in the city of Guelph supplying Alectra loads. Campbell TS has two 230/ 13.8 kV DESNs T1/T2 and T3/T4, both 100 MVA transformers. The loads on these two DESNs are currently supplying about 89 MW and 47 MW respectively and their loads are forecasted to grow at about 9 percent by the end of study period.

Two feeder breakers and a tie breaker for T1/T2 DESN are deemed to be end of life and requires replacement. Replacing these three breakers will impart additional 5 to 7 MW of capacity to the DESN, help mitigating the marginal station supply capacity concern at the end of the study period. The Study Team recommends implementing replacement plan by 2028-2029.

7.4. Mid and Long Term Supply Capacity Needs

When the station capacities were reviewed considering the net peak load forecast, below listed ten (10) stations were identified to approach their 10 day LTR. The last four stations were found to approach their 10 day LTR just at the end of the study period of this second regional planning cycle.

TABLE 7-4: KWCG STEP-DOWN TRANSFORMER STATIONS SUPPLY CAPACITY NEEDS

Stations	Need Timeframe
Kitchener MTS #5	2028
Cedar TS (T7/T8)	2030
Kitchener MTS #8 T15/T16	2033
Energy + MTS # 1	2036
Campbell TS (T1/T2)	2038
Preston TS	2038
Arlen MTS	2040
Scheifele MTS	2041
Elmira TS	2041
Waterloo North MTS # 3	2041

The deteriorating infrastructure replacement plans at Kitchener MTS # 5 (T9/T10), Scheifele MTS, Preston TS and Cedar TS (T7/T8) will help mitigate the station supply capacity needs of these stations over and beyond the study period. The Study Team recommends to review other long term station supply capacity needs in the next regional planning cycle.

8. Conclusions and Next Steps

THIS REGIONAL INFRASTRUCTURE PLAN CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE KWCG REGION.

The major infrastructure investments recommended by the Study Team in the near and mid-term planning horizon are provided in Table 8-1 below are all end of life needs, along with their planned in-service date and budgetary estimates for planning purpose.

TABLE 8-6: RECOMMENDED PLANS IN KWCG REGION OVER THE NEXT 10 YEARS

Stations / Lines Project	Details	Timeframe	High Level Cost[5] ($M)
Hanlon TS	Transformers T1 and T2 Replacement	2022-2023	17.8
Kitchener MTS #5	Transformers T9 and T10 Replacement	2023-2024	7.5
Scheifele MTS	Transformers T1 and T2 Replacement	2025-2026	-
B5C/B6C	115KV Lines Refurbishment, refurbishing section from Burlington TS to Enbridge Westover CTS	2025-2026	16.8
Preston TS	Transformers T3 and T4 Replacement	2026-2027	22.9
Cedar TS	Transformers T7 and T8 Replacement	2026-2027	23.7
Fergus TS	Transformers T3 and T4 Replacement	2028-2029	30.0
Galt TS	End of life Breakers and Other Component Replacement	2028-2029	12.0
Campbell TS	End of life Breakers and Other Component Replacement	2028-2029	18.1

The Study Team recommends that:

- Hydro One and LDCs to continue with the implementation of infrastructure investments listed in Table 8-1 above while keeping the Study Team apprised of project status;
- All the other identified needs/options in the long-term will be further reviewed by the Study Team in the next regional planning cycle.

NEEDS ASSESSMENT REPORT

KWCG

[Date: April 09, 2024]

Needs Assessment Report

Final

KWCG

[Date: April 09, 2024]

Lead Transmitter:

Hydro One Networks Inc.

Prepared by: KWCG Technical Working Group

Page intentionally left blank

Disclaimer

This Needs Assessment (NA) Report was prepared for the purpose of identifying potential needs in the KWCG region and to recommend which needs a) do not require further regional coordination and can be directly addressed by developing a preferred plan as part of the NA phase and b) require further assessment and regional coordination. The results reported in this NA are based on the input and information provided by the Technical Working Group (TWG) for this region. Updates may be made based on best available information throughout the planning process.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION	**KWCG** Region (the "Region")
LEAD	Hydro One Networks Inc. ("HONI")
START DATE: December 11, 2024	**END DATE:** April 09, 2024

1. INTRODUCTION

The 2nd Regional Planning cycle for the KWCG Region was completed in December, 2021 with the publication of the Regional Infrastructure Plan ("RIP") report. This is the 3rd cycle of Regional Planning for the region.

The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
i) require further assessment and regional coordination (and hence, proceed to the next phases of regional planning); and,
ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years.

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. Considering these timelines, the 3rd Regional Planning cycle was triggered in December 2023 for the KWCG Region.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the KWCG Region NA and includes:

a) Review and reaffirm needs/plans identified in the previous regional planning cycle RIP (as applicable),
b) Identify any new needs resulting from this assessment,
c) Recommend which need(s) require further assessment and regional coordination in the next phases of the regional planning cycle; and,
d) Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is ten (10) years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The KWCG Region covers the cities of Kitchener, Waterloo, Cambridge and Guelph, portions of Oxford and Wellington counties and the townships of North Dumfries, Puslinch, Woolwich, Wellesley and Wilmot. Electrical supply to the Region is provided from eleven 230 kV and thirteen 115 kV step-down transformer stations. The summer 2022 non-coincident regional loads were about 1436 MW.

5. INPUTS/DATA

The TWG comprises of representatives from Local Distribution Companies ("LDC"), the Independent Electricity System Operator ("IESO"), and Hydro One and provides input and relevant information for the KWCG Region regarding capacity needs, reliability needs, operational issues, and major high-voltage (HV) transmission assets requiring replacement over the planning horizon. The LDCs also capture input from municipalities in the development of their 10-year load forecast.

In accordance with the regional planning process, stakeholder engagement takes place during the IRRP phase.

6. ASSESSMENT METHODOLOGY

The assessment's primary objective is to identify the electrical infrastructure needs in the Region over the 10-year planning horizon. The assessment methodology includes a review of planning information such as load forecast (which factors various demand drivers and consideration of municipal energy plan(MEPs) and/or Community Energy plans (CEPs) where available), conservation and demand management ("CDM") forecast, distributed generation ("DG") forecast, system reliability and operation, and major HV transmission assets requiring replacement.

A technical assessment of needs is undertaken based on:

a) Current and future station capacity and transmission adequacy;

b) System reliability needs and operational concerns;

c) Major HV transmission equipment requiring replacement with consideration to "right-sizing"; and,

d) Sensitivity analysis to capture uncertainty in the load forecast as well as variability of demand drivers such as electrification.

7. NEEDS

I. Updates on needs identified during the previous regional planning cycle

The following needs and projects discussed in the 2nd cycle RIP report for KWCG region have been completed:

- Hanlon TS Transformers T1/ T2 Replacement (2022).

The following needs and projects discussed in the 2nd cycle RIP report for KWCG region are currently underway:

- **Burlington TS to CTS 1 Line Section:** The refurbishment of 115 kV B6C/ B6C line section from Burlington TS to Harper's Junction was completed in 2019. The refurbishment of line tap section from Harper's Junction to CTS1

is progressing slowly due to outage availability from the customer. This refurbishment work is currently forecasted to be completed in Q3/ Q4 2025 timeframe.

- **Kitchener MTS #5 – T9/T10 Transformers Replacement**: The existing 83 MVA T9/ T10 transformers are planned to be replaced with new 100 MVA units. This work is currently forecasted to be completed by Q1 2025.
- **Preston TS - T3/T4 Transformer Replacement:** Condition assessment of T3/ T4 transformers have identified these units for replacement. These units are currently planned to be replaced by the end of 2027 with similar Hydro One standard units. This replacement will also remove the existing supply capacity constraint due to a technical limitation in the existing units. The new LTR will be 180 MW

The remaining needs and projects discussed in the 2nd cycle RIP report for KWCG region are as follows:

- **Scheifele MTS - T1/T2 and T3/T4 Transformer Replacement**: These four (T1/T2/T3/T4) transformers are expected to approach end of life over the next 10 year horizon and are planned for replacement by Enova Power Corp. Enova Power Corp will continue monitoring the condition of these transformers with its maintenance program. The expected year of replacement is between 2029-2033.
- **Cedar TS - T7/ T8 Transformer Replacement**: Replacing the existing non-standard T7/T8 transformers with Hydro One standard units of higher capacity. Based on latest condition assessment of these units. These units are to be replaced beyond the study period (10 years) of this report. However, this transformer replacement may need to be advanced due to capacity needs.
- **Campbell TS - Breakers and Component replacement:** Replace breakers deemed to be approaching expected service life. This work is planned to be completed by 2032.
- **Fergus TS – T3/T4 Transformer Replacement:** Hydro One will continue monitoring the condition of these T3/T4 transformers and other components at Fergus TS. Hydro One will proceed with the replacement plan, if required. Otherwise, this need will be reassessed in the next regional planning cycle.
- **Galt TS – Breakers and Component Replacement:** Hydro One will continue monitoring the condition of these components at Galt TS and proceed with the replacement plan as required.

II. Newly identified needs in the region

Based on the new and updated information, a summary of the results of this Needs Assessment is provided below:

a. Asset Renewal for Major HV Transmission Equipment

- No new Asset Renewal Needs

b. Transformation Capacity

- The supply capacity needs at Preston TS, Energy + MTS, Cedar T7/T8 and Campbell TS (T3/T4) have been identified in the near term while the needs at Cedar TS T1/T2 DESN, Cedar T7/T8 DESN, Kitchner MTS #7, Waterloo MTS, and Rush MTS have been identified in the middle term.

c. Transmission System Capacity

- During the study period. Post contingency overload violations were observed on 230 kV M20D/M21D and 115 kV D11K/ D12K circuits for the loss of companion circuits.

d. System Reliability, Operation and Load restoration

- During the study period, post contingency voltage violations were observed on 230 kV M20D/M21D for the loss of companion circuits.
- Load restoration violations on 230 kV D6V/D7V circuits in the long term and system security and load restoration violation on the M21D/M20D circuit in the mid term and near term respectively, for a single tower contingency.

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

The impact of the sensitivity analysis for the high and low growth scenarios identified the following updates to need dates and/or new station/line capacity needs: These needs will be assessed again during the next phases of this Regional Planning cycle.

Sr. no	Need Identified	Normal Growth Scenario	High Growth Scenario	Low Growth Scenario
1	Preston TS - Capacity need	2026	2026	2029
2	Galt TS- Capacity need	Reaches capacity in 2032	2030	Long term

9. RECOMMENDATIONS

The TWG recommendations are as follows:

I. Needs that require further assessment and regional coordination

These needs may have broader regional impacts and require further assessment and coordination during the next phases[1] of the regional planning cycle. These needs are as follows:

a. Transmission System Capacity

- M20D/M21D post contingency violation (Galt Jct x Cambridge #1 Jct)- Near term
- D11K/D12K post contingency violation (Detweiler x Kitchener #1 & 4 Jct) – Mid Term

b. System Reliability, Operation and Load restoration

- System security violation on the M21D/M20D circuit in the Mid term
- Load restoration for M20D/M21D – Near term
- Voltage violations on M20D or M21D due to outage on companion circuit -Near term

c. Transformation Capacity Needs

- Preston TS (T3/T4) – Near term
- Energy Inc MTS (T1/T2) – Near term

Transmission system capacity and restoration needs are likely to trigger system reinforcement needs in the KWCG region.

II. Needs that do not require further regional coordination

These needs are local in nature and do not have a regional impact. They can be addressed by a straightforward transmission and/or distribution wires solution. They do not require investment in any upstream transmission facility or Leave to Construct (i.e., Section 92) approvals. These needs generally impact a limited number of LDCs and can be addressed directly between Hydro One and the LDC(s) to develop a preferred local plan. A list of these needs are as follows:

[1] Non-wires options are further considered (i.e. incremental to CDM and DG that is considered in this NA) as potential options in addressing these needs during the IRRP phase.

a. Transformation Capacity Needs

- Campbell TS (T3/T4) – Mid term
- Cedar TS (T1/T2) – Mid term
- Kitchener MTS #7 (T14/T13) – Mid term
- Cedar (T7/T8) – Near term
- Rush MTS – Mid term
- Waterloo North MTS #3 - Mid term

List of LDC(s) to be involved in further regional planning activities:

- Grandbridge Energy
- Enova Power Corp

List of LDC(s) which are not required to be involved in further regional planning phases:

- Hydro One Networks Inc. (Distribution)
- Alectra Inc.
- Center Wellington Hydro
- Halton Hills Hydro Inc.
- Wellington North Power

1. INTRODUCTION

The second cycle of the Regional Planning process for the KWCG Region was completed in [December 10, 2021] with the publication of the Regional Infrastructure Plan ("RIP") Report The RIP report included a common discussion of all the options and recommended plans and preferred plans for wire infrastructure investments to address the near- and medium-term needs.

This Needs Assessment initiates the third regional planning cycle for the KWCG Region. The purpose of this Needs Assessment ("NA") is to:

a) Identify any new needs and reaffirm needs identified in the previous regional planning cycle; and,
b) Recommend which needs:
   ii) require further assessment and regional coordination (and hence, proceed to the next phases of regional planning); and,
   ii) do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The planning horizon for this NA assessment is ten years. The flow chart of the Regional Planning Process is given below in Figure 1 below.

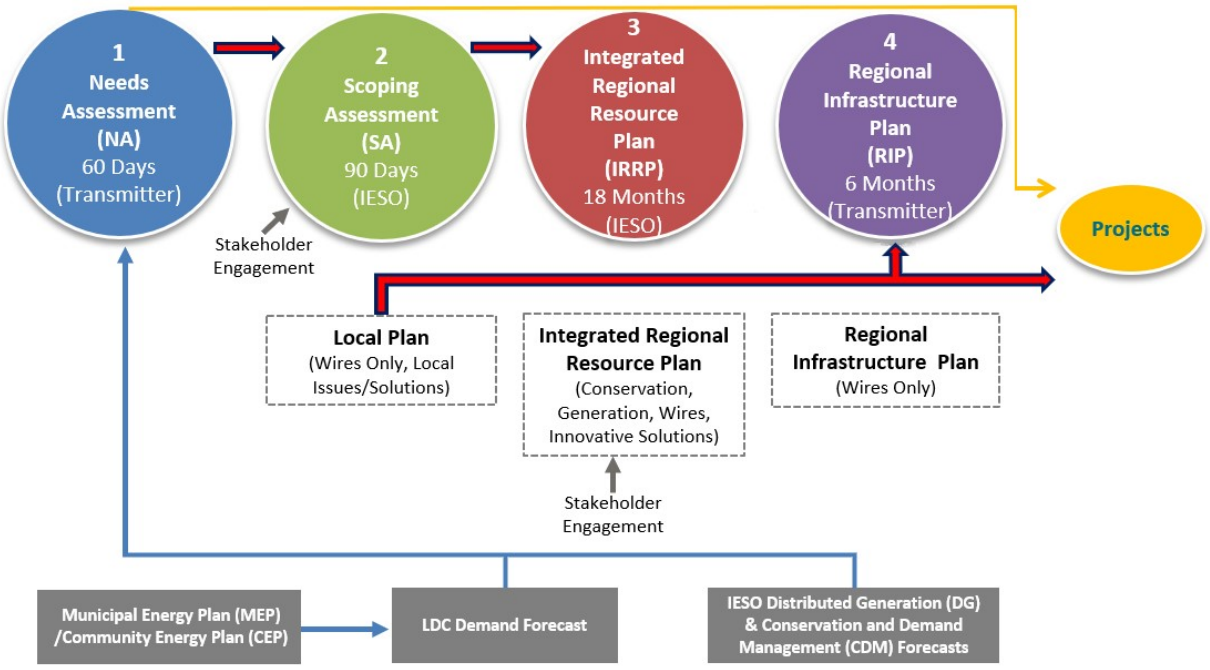

Figure 1: Regional Planning Process

This report was prepared by the KWCG Technical Working Group("TWG"), led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by the Hydro One,

the Local Distribution Companies ("LDC") and the Independent Electricity System Operator ("IESO"). Participants of the TWG are listed below in Table 1.

Table 1: KWCG Region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Networks Inc. (Lead Transmitter)
2	Independent Electricity System Operator ("IESO")
3	Enova Power Corp.
4	Alectra Inc.
5	Grandbridge energy
6	Centre Wellington
7	Wellington North
8	Halton Hills Hydro Inc.
9	Hydro One Networks Inc. (Distribution)

2. REGIONAL ISSUE/TRIGGER

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least once every five years. As such, the 3rd Regional Planning cycle was triggered for the KWCG region.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this NA covers the KWCG region and includes:

- Review and reaffirm needs/plans identified in the previous cycle RIP (as applicable),
- Identify any new needs resulting from this assessment,
- Recommend which need(s) require further assessment and regional coordination in the next phases of the regional planning cycle; and,

- Recommend which needs do not require further regional coordination (i.e., can be addressed directly between Hydro One and the impacted LDC(s) to develop a preferred plan and/or no regional investment is required at this time and the need may be reviewed during the next regional planning cycle).

The Technical Working Group TWG may also identify additional needs during the next phases of the planning process, namely Scoping Assessment ("SA"), Integrated Regional Resource Plan ("IRRP"), Local plan (LP) and RIP, based on updated information available at that time.

The planning horizon for this NA assessment is 10 years.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The KWCG Region covers the cities of Kitchener, Waterloo, Cambridge and Guelph, portions of Oxford and Wellington counties and the townships of North Dumfries, Puslinch, Woolwich, Wellesley and Wilmot. Electrical supply to the Region is provided from eleven 230 kV and thirteen 115 kV step-down transformer stations. The accumulative summer 2022 non-coincident loads were about 1477 MW. The approximate boundaries of the KWCG Region are shown below in Figure 1.

The main sources of electricity into the KWCG Region are from five Hydro One stations: Middleport TS, Buchanan TS, Detweiler TS, Orangeville TS and Burlington TS. At these stations electricity is transformed from 500 kV and 230 kV to 230 kV and 115 kV levels, respectively. Electricity is then delivered to the end users of LDCs and transmission connected industrial customers through 26 (supply transformer stations) step-down transformer stations. Figure 2 illustrates these stations as well as the four major regional sub-systems: Waterloo-Guelph 230 kV sub-system, Cambridge-Kitchener 230 kV sub-system, Kitchener Guelph 115 kV sub-system and South-Central Guelph 115 kV sub-system. The single line diagram of the KWCG region is shown in Figure 3 below.

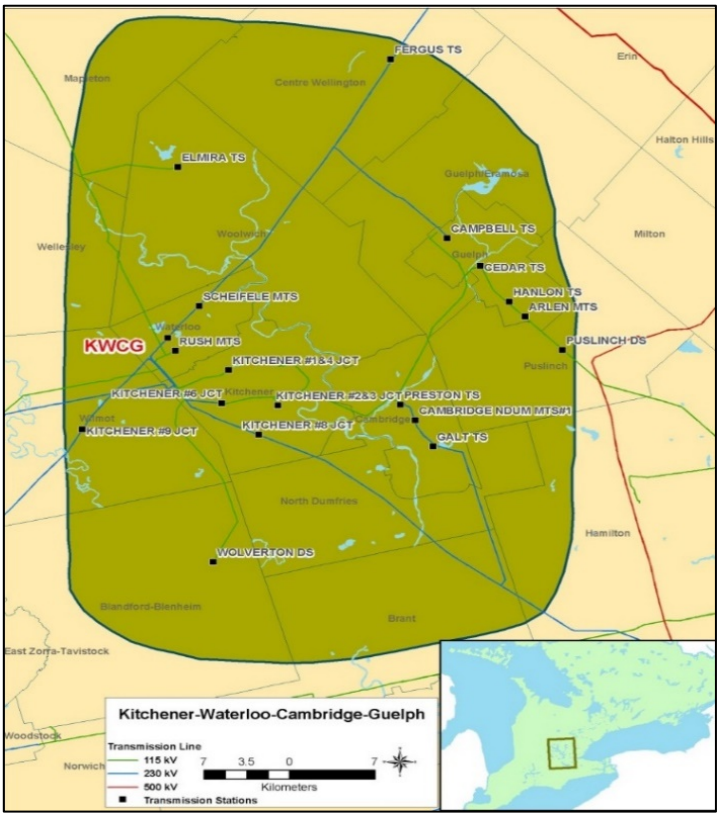

Figure 2: Map of KWCG Regional Planning Area

The circuits and stations of the area are summarized in the Table 2 below:

5. INPUTS AND DATA

TWG participants, including representatives from LDCs, IESO, and Hydro One provided information and input for the KWCG NA. With respect to the load forecast information, the OEB Regional Planning Process Advisory Group (RPPAG) recently published a document called “Load Forecast Guideline for Ontario” in Oct. 2022. The objective of this document is to provide guidance to the TWG in the development of the load forecasts used in the various phases of the regional planning process with a focus on the NA and the IRRP. One of the inputs into the LDC’s load forecast that is called for in this guideline is information from Municipal Energy Plans (MEP) and/or Community Energy Plans (CEP). The list of all the Municipalities falling under the geographical boundaries of the region are given in Appendix-E.

The information provided includes the following:

- KWCG 10-year Load Forecast for all supply stations inclusive of the inputs provided by the municipalities (e.g. through their MEPs & CEPs),
- Known capacity and reliability needs, operating issues, and/or major assets requiring replacement/ refurbishment; and
- Planned/foreseen transmission and distribution investments that are relevant to Regional Planning for the KWCG.
- Captured uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments.

6. ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in development of this Needs Assessment:

6.1 Technical Assessments and Study Assumptions

The technical assessment of needs was undertaken based on:

- Current and future station capacity and transmission adequacy;
- System reliability and operational considerations;
- Asset renewal for major high voltage transmission equipment requiring replacement with consideration to “right-sizing”; and,
- Load forecast data was requested from industrial customers in the region, and
- This assessment is based on Summer peak loads. Three load forecasts were developed i.e. Normal Growth scenario, High & low Growth scenario. The High and low Growth scenario load forecast was developed to conduct a sensitivity analysis to cover unforeseen developments such as, fuel switching, Government policies, higher-than-expected EV charging trend during peak load conditions, etc.

The following other assumptions are made in this report.

- The study period for this Needs Assessment is 2023-2032.
- The Region is summer peaking, so this assessment is based on summer peak loads.
- Line capacity adequacy is assessed by using coincident peak loads in the area.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station’s normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.

- Normal planning supply capacity for transformer stations is determined by the Hydro One summer 10-Day Limited Time Rating (LTR) of a single transformer at that station.
- Adequacy assessment is conducted as per Ontario Resource Transmission Assessment Criteria (ORTAC).

6.2 Information Gathering process

6.2.1. Load forecast:

The LDCs provided their load forecast for all the stations supplying their loads in the KWCG region for the 10-year study period including the inputs from the Municipalities such as MEPs and CEPs. The IESO provided a Conservation and Demand Management ("CDM") and Distributed Generation ("DG") forecast for the KWCG region. The region's extreme summer non-coincident peak gross load forecasts for each station were prepared by applying the LDC load forecast growth rates to the actual 2022 summer peak extreme weather corrected loads. The extreme summer weather correction factors were provided by Hydro One. The net extreme summer weather load forecasts were produced by reducing the gross load forecasts for each station by the percentage CDM and then by the amount of effective DG capacity for the contracted projects only provided by the IESO for that station. It is to be noted that as contracts for existing DG resources in the region begin to expire, at which point the load forecast has a decreasing contribution from local DG resources, and an increase in net demand. This extreme summer weather corrected net load forecast for the individual stations in the KWCG region is given in Appendix A.

A very few of the stations have winter peaks marginally higher than summer peaks. The higher winter transformer and line ratings are adequate to accommodate the marginally higher loads. Therefore, only the Summer Assessment was carried out.

Alectra recently advised the TWG that a revised forecast, to better account for their community's decarbonization activities, will soon be available. This updated forecast will be included in later stages of the regional planning process and may impact the area's overall needs and/or may require the creation of a regional winter forecast.

6.2.2. Sensitivity Analysis:

A sensitivity analysis was undertaken by the TWG to capture uncertainty in the load forecast as well as variability of drivers such as electrification. Hence, the NA recommendations are not necessarily linked to sensitivity scenarios; but rather are used to identify any emerging needs for consideration in developing recommendations. The impact of sensitivity analysis for the high and low growth scenarios are provided in section 8 of this report.

Relevant information regarding system reliability and operational issues in the region; and

6.2.3. Asset renewal Needs for Major HV Equipment:

List of major HV transmission equipment planned and/or identified to be refurbished and/or replaced based on asset condition assessment, relevant for Regional Planning purposes. This includes HV transformers, autotransformers, HV Breakers, HV underground cables and overhead lines. The scope of equipment considered is given in section 7.1; and

6.2.4. System Reliability and Operational Issues:

- Palmerston-to-Detweiler transfer during Hanover bank outages:
  With current load forecast, this issue does not exist.

TWG members identified the following bulk system issues in the KWCG region to be discussed outside of the RP process:

- Detweiler TS configuration and operating instruction asking for multiple equipment to be out of service during contingency
- Detweiler TS Station Service Auto-Transfer Issues
- Palmerston-to-Detweiler transfer during Hanover bank outages.

7. NEEDS

This section describes emerging new needs identified in the KWCG Region and/or updates on the previously identified needs since the completion of Previous Regional Planning cycle.

Needs that were identified and discussed in the previous regional planning cycle with associated projects that were recently completed and reaffirmed needs that are underway are briefly described below with relevant updates and will not be discussed further in the report. These projects include:

- Hanlon T1/T2 transformer replacement was completed in 2022.
- Kitchener MTS #5 project is currently underway, existing 83MVA transformers to be replaced by 100MVA units. The planned in-service date is Q3 2024 for T10 and Q1 2025 for T9.
- Preston TS: Project for like-for-like replacement of transformers T3/T4 is underway. The planned in-service date is 2027.
- B5C/B6C 115kV line section refurbishment: The Burlington TS to Harper junction line refurbishment was completed in 2019. The refurbishment of line tap from Harper junction to CTS-1 is progressing slowly due to outage availability from customer. Expected completion date is Q3/Q4 2025.
- Galt TS: The asset condition assessment identified breakers and other components needs to be replaced in long-term. Hydro One will continue to monitor the condition of these components and if required, proceed with the replacement plan.
- Campbell TS: Two feeder breakers and a bus tie breaker for T1/T2 DESN were identified for replacement. The planned in-service date is 2032.

- Scheifele MTS T1/T2/T3/T4 Transformer replacement: These four (T1/T2/T3/T4) transformers are expected to approach end of life over the next 10-year horizon and are planned for replacement by Enova Power Corp. The expected year of replacement is between 2029-2033.

Note: The planned in-service year for the above projects is tentative and is subject to change.

All near, and mid-term needs that were discussed as a part of this report are summarized in table 3 below.

Table 3: Near/Mid-term Needs Identified in Previous RIP and/or this NA

Need Description	Recommended Plan/Update	Previous RIP Report Section	NA Report Section
Asset Renewal Needs			
Cedar TS	T7/T8 Transformers Replacement	7.3.2	7.1.1
Fergus TS	T3/T4 Transformers Replacement	7.3.4	7.1.2
Galt TS	Breakers and Component Replacement	7.3.5	7.1.4
Campbell TS	Breakers and Component Replacement	7.3.6	7.1.3
Station Capacity Needs			
Preston TS	Preston T3/T4 is forecasted to exceed its supply capacity during the study period (beyond the anticipated LTR of the new transformers)	N/A	7.2.1
Energy Inc MTS	The load at Energy Inc MTS is forecasted to exceed its supply capacity in the near term.	N/A	7.2.2
Campbell TS (T3/T4)	The load at Campbell TS (T3/T4) is forecasted to exceed its supply capacity in the near term.	N/A	7.2.3
Cedar TS	Load demand at both Cedar TS T1/T2 and T7/T8 DESNs is forecasted to exceed supply capacities in the mid and near term respectively.	N/A	7.2.4
Kitchener MTS#7	The load at Kitchener MTS#7 is forecasted to exceed its supply capacity in the mid-term.	N/A	7.2.5

Waterloo North MTS #3	The load at Waterloo North MTS#3 is forecasted to exceed its supply capacity in the mid-term.	N/A	7.2.6
Rush MTS	The load at Rush MTS is forecasted to exceed its supply capacity in the mid-term.	N/A	7.2.7
Transmission Line Capacity Needs			
M20D/M21D	The 230 kV M20D/M21D circuits supply transformer stations connected between Detweiler TS and Middleport TS. Loading violations were observed on M20D/ M21D circuits starting 2026 on the sections between Galt Jct. and Cambridge Jct. .	N/A	7.3.1
D11K/D12K	D11K/D12K supplies Enova Power Corp stations, Kitchener MTS#1 and Kitchener MTS#4. Loading violations were observed on these circuits for the loss of companion circuit in the mid-term.	N/A	7.3.2
D10H	The 115 kV D10H circuit between Detweiler TS and Hanover TS supplies loads at Rush MTS, Elmira TS and Palmerston TS with a normally open motorized switch just south of Palmerston TS. During the outage of 115 kV D8S circuit, loading violations were observed on a section of 115 kV D10H circuit in the long term.	N/A	7.3.3
System Reliability, Operation and Load restoration Needs			
M20D/ M21D	For the loss of two elements M20D/M21D on the 230 kV system, the load interrupted by configuration will exceed 600MW based on the peak coincident load, resulting in violation of ORTAC security criteria in the mid-term.	N/A	7.4.1
M20D/M21D	Load restoration violations observed on the M20D/M21D 230 kV circuits	N/A	7.4.1
D6V/ D7V	Marginal load restoration violations were observed for D6V/D7V 230 kV circuits	N/A	7.4.2
Voltage Performance			

M20D/M21D	Several voltage violations were observed in the near term.	N/A	7.4.3

7.1 Asset Renewal Needs for Major HV Transmission Equipment

Hydro One and TWG has identified asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the **KWCG** Region. The complete list of major HV transmission equipment requiring replacement in the **KWCG** Region is provided in table 4 in this section. Hydro One and Enova Power Corp are the Transmission Asset Owners (TAO) in the Region.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:
  replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
  Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

The Asset renewal assessment considers the following options for “right sizing” the equipment:

- Maintaining the status quo
- Replacing equipment with similar equipment with *lower* ratings and built to current standards
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities
- Eliminating equipment by transferring all the load to other existing facilities
- Replacing equipment with similar equipment and built to current standards (i.e., “like-for-like” replacement)
- Replacing equipment with higher ratings and built to current standards

From Hydro One’s perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

Table 4: Major HV Transmission Asset assessed for Replacement in the region over the next 10 years

Station/Circuit	Need Description	Planned ISD
Kitchener MTS #5	The existing T10 & T9 83 MVA transformers to be replaced by 100 MVA units	T10-2024 T9-2025
Preston TS	Replacement of existing T3 & T4 transformers with similar size units.	2027
B5C/B6C	Refurbishment of B5C/B6C line between Burlington TS to CTS1.	2025
Scheifele MTS	The existing four transformers are expected to approach end of service life over the next 10 years Horizon	2029-2033

7.1.1 Cedar TS (T7/T8)

Cedar TS is located in the city of Guelph supplying Alectra loads. Cedar T7/T8 is a 115/13.8 kV DESN station with an LTR of 44 MVA (40 MW @ 0.9 PF), and 40 MW of peak load in 2022. Hydro One will continue to monitor the condition of these transformers. Based on asset condition assessment, T7/T8 are expected to reach end of life beyond the 10-year planning horizon. The station capacity need at this station is discussed in Section 7.2.4 of this report.

7.1.2 Fergus TS (T3/T4)

Fergus TS is a 230 kV/ 44 kV single DESN station having two 125 MVA transformers located in the township of Fergus having a supply capacity of 154 MW and supplying 94 MW of loads. The supply capacity of this station is forecasted to be sufficient over the study period and beyond. Based on asset condition assessment, T7/T8 are expected to reach end of life beyond the 10-year planning horizon.

The TWG recommended Hydro One to keep monitoring the condition of these transformers. No further regional planning coordination is required at this time.

7.1.3 Campbell TS (T1/T2) Breakers and Components

Campbell TS is located in the city of Guelph supplying Alectra loads. Campbell TS has two 230/13.8 kV DESNs T1/T2 and T3/T4, having supply capacities of 94 MW and 56 MW respectively. The loads on these two DESNs are currently supplying about 86 MW and 47 MW of loads respectively.

In the previous regional planning RIP report, two feeder breakers and a bus tie breaker for T1/T2 DESN were identified for replacement. Based on asset condition assessment, the equipment at this station are

expected to reach end of life within 10 year planning horizon. No further regional coordination is required at this time.

7.1.4 Galt TS Breakers and Components

Galt TS is located in the city of Cambridge supplying Energy + loads in the KWCG region. Galt TS has two 230/ 28-28 kV transformers T7 and T8 of 75/100/125 MVA, currently supplying 115 MW of peak loads. The total supply capacity of Galt TS is 169 MW, expected to be more than adequate over the study period.

The T7/T8 transformers were replaced in 2010 and 2012 respectively due to technical issues with the transformers. The breakers and other component at the station are almost 50 years old. Condition assessment has identified that these older components to be replaced in the long term.

The station cannot be downsized or eliminated because there is no nearby supply station/s having surplus supply capacity for transferring loads. Hydro One will continue monitoring the condition of these components at Galt TS and if required proceed with the replacement plan as required.

7.2 Station Capacity Needs

A 'Station Capacity' assessment was performed over the study period 2023-2032 for the 230kV and 115kV Transforming stations in the KWCG Region using the non-coincident summer peak load forecasts provided by the Technical Working Group. Based on the results, the following Station capacity needs have been identified during the study period:

7.2.1 Preston TS Supply Transformers

Preston TS (DESN) is located in the city of Cambridge supplying Grandbridge energy loads. Preston TS is a single T3/T4 DESN station of 125 MVA transformers with no additional LTR capability available. This station is currently supplying loads to its supply capacity. The non-coincident loads at Preston TS are currently forecasted to reach 242 MW[2] by the end of study period. The replacement of these station supply transformers is underway and forecasted to be completed by Q2 of 2027. Upon completion, the new station LTR is expected to be in the range of 180 MW. The Preston TS loads are currently forecasted to reach this new supply capacity in the in-service timeframe of these new transformers. A near-term solution is required to address this need. The TWG recommends to further review this need in next regional planning phases.

[2] Note: Due to the load limit on M20D/M21D imposed by ORTAC's load security criteria, the coincident peak loading on M20D/M21D is limited to 600 MW forecasted to exceed in 2032.

7.2.2 Energy MTS#1

Energy + MTS#1 is located in the city of Cambridge supplying Grandbridge Energy loads in the KWCG region. This station has an LTR of 102 MW and forecasted to exceed its supply capacity near the end of the study period. The loading at this station will be monitored by Grandbridge Energy and this need will be further assessed in the next regional planning phase. Grandbridge Energy is working on measures to transfer load within the distribution system to Galt TS to address near term loading concerns. Hydro One and Grandbridge will continue to monitor load levels.

7.2.3 Campbell TS Transformer

Campbell TS is located in the city of Guelph supplying Alectra loads. Campbell TS has two 230/13.8 kV DESNs units supplying through T1/T2 and T3/T4 transformers, having supply capacities of 94 MW and 56 MW respectively. These two Campbell TS DESNs are currently supplying about 81 MW and 45 MW of loads respectively and their combined loads at Campbell TS are forecasted to exceed the total station supply capacity close to the end of the study period.

Alectra to propose measures to address capacity needs at this station, if required. Hydro One and Alectra will continue to monitor load levels. The TWG recommends that no further regional coordination is required at this time.

7.2.4 Cedar T1/T2 and T7/T8

Cedar TS is located in the city of Guelph supplying Alectra loads. Cedar TS has two 115/13.8 kV DESN stations T1/T2 and T7/T8 of 75 MVA with a LTR of 115 MVA (103 MW @ 0.9 PF) and 37 MVA with a LTR of 44 MVA (40 MW @ 0.9 PF), currently supplying 82 MW and 40 MW of peak loads respectively. The total load of both DESNs is forecasted to exceed its supply capacity in the near term.

Alectra to propose measures to address this capacity needs, if required. Hydro One and Alectra to continue monitoring load levels. The TWG recommends that no further regional coordination is required at this time.

7.2.5 Kitchener MTS #7

Kitchener MTS #7 is located in the city of Kitchener supplying Enova Power Corp loads. Kitchener MTS #7 is a 115/ 13.8 kV single T13/T14 DESN station having 50 MVA transformers and a LTR of 60 MVA (54 MW @ 0.9 PF). This station is currently supplying 37 MW of peak load. The loads at Kitchener MTS #7 are currently forecasted to grow approaching its supply capacity near the end of the study period.

Enova Power Corp to monitor the loading on this station and manage any overloading through load transfers, if required. The TWG recommends that no further regional coordination is required at this time.

7.2.6 Waterloo North MTS #3

Waterloo North MTS#3 is located in the city of Waterloo supplying Enova Power Corp. Waterloo North MTS#3 is a 230/27.6 kV single T1/T2 DESN station having an LTR of 85MVA. This station is currently supplying 48 MW of peak load. The loads at Waterloo North MTS#3 is currently forecasted to grow approaching its supply capacity near the end of the study period. Enova Power Corp to monitor the loading on this station and manage any overloading in the mid term through load transfers and a new supply station in the long term. The TWG recommends that no further regional coordination is required at this time.

7.2.7 Rush MTS

Rush MTS is located in the city of Waterloo supplying Enova Power Corp loads. Rush MTS is a 115/ 13.8 kV single T1/T2 DESN station having an LTR of 68 MW. This station is currently supplying 50 MW of peak load. The loads at Rush MTS is currently forecasted to grow approaching its supply capacity near the end of the study period. Enova Power Corp to monitor the loading on this station and manage any overloading in the mid term through load transfers and a new supply station in the long term. The TWG recommends that no further regional coordination is required at this time and will be reviewed in next regional planning cycle.

7.3 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period 2023-2032 for the 230kV and 115kV Transmission line circuits in the KWCG Region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater this need. Based on the results, the following line capacity needs have been identified in the during the study period:

7.3.1 M20D/M21D – 230 kV – Transmission Circuit Supply

The M20D/M21D is a 230kV double circuit line about 58 km long, supplying the following stations:

- Kitchener MTS #6
- Kitchener MTS #8
- Galt TS
- Preston TS
- Energy + Inc.
- A Customer CTS

For the loss of one of the M20D or M21D 230 kV circuits, the loading on the Galt JCT to Cambridge JCT section exceeds its rating starting in 2026 (Summer load forecast). The TWG recommends to further review this need in next regional planning phases.

7.3.2 D11K/D12K

D11K/D12K is a 115 kV line supplying Enova Power Corp stations of Kitchener MTS#1 and Kitchener MTS#4. With the current load forecast on the above stations, these D11K and D12K 115 kV circuits will be experiencing overloading for the loss of companion circuits by the end of the study period (2032). The TWG recommends to further review this need in next regional planning phases.

7.3.3 D10H

The 115 kV D10H circuit between Detweiler TS and Hanover TS supplies loads to Rush MTS and Elmira TS. The D10H circuit has a normally open point just south of Palmerston TS through a motorized disconnect switch for emergency supply to Palmerston TS. The northern section of D10H is supplied from Hanover TS radially supplying Palmerston TS loads. The southern section of D10H is supplied through Detweiler TS radially supplying Enova Power Corp's 34 MW of Elmira TS peak loads. D10H also supplies Rush MTS which has a dual supply through 115 kV D8S circuit from Detweiler TS. For any outage of 115 kV D8S circuit. The D10H line section between Detweiler and Leong Jct is approaching its supply capacity close to the end of the study period.

7.4 System Reliability, Operation and Restoration Needs

The transmission system must be planned to satisfy demand levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. A study has been performed, considering the net coincident load forecast and the loss of one element over the study period 2023-2032 to cater this need**.** Based on the results, some system reliability, operating and restoring issues have been identified for this Region.

7.4.1 M20D/M21D Load Security and Restoration Needs

As per the load security criteria (ORTAC Section 7.1), with one element out of service, planned load curtailment or load rejection is permissible only to account for local generation outages; and not more than 150MW of load may be interrupted by configuration, planned load curtailment or rejection. With two elements out of service, not more than 600 MW of load may be interrupted by configuration, planned load curtailment or rejection.

As per the load restoration criteria (ORTAC Section 7.2), interrupted load must be restored within the following timelines:

- Load above 250 MW, within 30 minutes;
- Load above 150 MW, within 4 hours; and
- All load, within 8 hours.

For the loss of double 230kV circuits (M20D/M21D), a total peak coincident load of 638 MW will be interrupted in 2032 by configuration which violates ORTAC load security criteria since not more than 600 MW of load may be interrupted by configuration.

With respect to load restoration, a total of 638 MW (2032 forecast) will be interrupted by configuration, of which, 388 MW needs to be restored within 30 mins as per ORTAC criteria. For a double line fault on Galt Jct. to Preston TS section, only 210 MW (out of the 388MW required to be restored) of that load is restorable. Kitchener MTS#6 and MTS#8 load can be restored via Galt Jct in-line switches and approximately 100 MW of load can be restored at Preston TS. This can be accomplished by opening the M20/211D line disconnect switches at Preston TS and back-feed Preston TS T2 230-115 kV autotransformer to supply load at Preston TS only.

Therefore, the existing restoration capability to loads connected to M20/21D does not meet criteria for the duration of the study period. The TWG recommends to further review this need in next regional planning phases.

7.4.2 D6V/D7V Restorations Needs.

By year 2032, the total peak coincident forecasted load connected to D6V/D7V is 517 MW. Loss of this double circuit line (Tower Contingency) would result in the loss of all 517 MW which is below the ORTAC load security limit. To restore load to these stations, the 230 kV in-line switches will be utilized to isolate the problem and return to service the remaining healthy circuit sections. These switches allow for more flexibility to restore load to the affected stations in a timely fashion. Non-restorable load within 30

minutes is estimated to be about 256 MW. Hence, the load restoration criterion is substantially met. Therefore, no additional transmission restoration capability is warranted at this time, and the loading levels will be monitored.

7.4.3 Voltage Performance

M20D or M21D post contingency voltage change exceeds the 10% pre-tap and 5% post-tap limits on the low voltage side at Preston TS and Energy + Inc MTS within the near-term coincident forecast. The post contingency voltages also drop beyond the allowable voltage range. The situation is further worsened in the subsequent years.

In the midterm, the voltage change limits on the high side of Preston TS, Galt TS and Energy + Inc MTS are violated for the post-contingency loss of M20D or M21D circuits. Voltage also drops below the allowable voltage range. The TWG recommends to further review this need in next regional planning phases.

8. SENSITIVITY ANALYSIS

The objective of a sensitivity analysis is to capture uncertainty in the load forecast as well as variability of electric demand drivers to identify any emerging needs and/or advancement or deferment of recommended investments. The TWG determined that the key electric demand driver in the KWCG region to be considered in this sensitivity analysis is electric vehicle (EV) penetration and unforeseen electrification which would cause the load to increase at a faster rate than shown in the forecast; or the potential delay in some projects which could result in less demand than anticipated.

The TWG reviewed EV scenarios and any unforeseen electrification needs to develop high demand growth forecasts by applying 50% additional growth to the growth rate on the extreme summer corrected Normal Growth net load forecasts. The low growth scenario was obtained by reducing the growth rate by applying -50% growth to the annual growth rate on the extreme summer corrected Normal Growth net load forecasts.

The normal and high growth forecasts are shown in Tables A.1, A.2, A.3 and A.4.

The impact of sensitivity analysis for the high and low growth scenario identified the following updates or new Station/Line capacity needs:

Table 5: Impact of Sensitivity Analysis on Station/Line capacity needs in the region

Sr.no	Need Identified	Normal Growth Scenario	High Growth Scenario	Low Growth Scenario
1	Preston TS- Capacity need	2026	2026	2029
2	Galt TS- Capacity need	Reaches capacity in 2032	2030	Long term
3	Energy Inc MTS - Capacity need	2023	2023	2023
4	Rush MTS - Capacity need	2030	2029	Long term
5	Waterloo North MTS #3 - Capacity need	2030	2030	Long term
6	Campbell TS (T3/T4)- Capacity need	2026	2025	2030
7	Cedar TS (T7/T8)- Capacity need	2024	2024	2024
8	Cedar TS (T1/T2)- 115kV- Capacity need	2031	2029	Long term
9	Kitchener MTS#7	2031	2030	Long term
10	M20D/M21D Transmission Circuit Supply	2026	2024	2026
11	D11K/D12K- Transmission Circuit Supply	2032	2030	Long term
12	D10H - Transmission Circuit Supply	Long term	2030	Long term
13	M20D/M21D Load Security	2032	2028	Long term
14	M20D/M21D Restoration Needs	2025	2023	2025
15	D6V/D7V Restoration Needs	Long term	2030	Long term
16	Voltage change violation on M20D/M21D	2026	2025	2026

The sensitivity analysis identified the additional capacity needs towards the end of the study period and advanced the triggering date of all the needs. These needs will be assessed again during the next phases of this Regional Planning cycle.

The 2022 forecast from last year's RIP aligns with the actual 2022 loading. Therefore, the high growth scenario can be discounted for now, and monitoring the load growth is recommended.

9. CONCLUSION AND RECOMMENDATION

The Technical Working Group's recommendations to address the needs identified are as follows:

Table 7: Needs which do not require regional coordination

Sr.no.	Need	Recommendation
1	Campbell TS (T3/T4) Station Capacity	LDC to propose measures to address capacity needs, if required, Hydro One and Alectra to continue to monitor load levels.
2	Cedar TS (T1/T2) Station Capacity	LDC to propose measures to address capacity needs, if required, Hydro One and Alectra to continue to monitor load levels.
3	Kitchener MTS #7 Station Capacity	LDC to monitor load levels and manage any overloading through load transfers.
4	Cedar TS (T7/T8) Station Capacity	LDC to propose measures to address capacity needs, if required. Hydro One and Alectra to continue to monitor load levels. Advancing and upsizing Cedar transformers is also being considered as an option
5	Waterloo North MTS #3 Station Capacity	LDC to monitor the loading on this station and manage any overloading in the mid term through load transfers and a new supply station in the long term.
6	Rush MTS Station Capacity	LDC to monitor the loading on this station and manage any overloading in the mid term through load transfers and a new supply station in the long term.

Table 8: Needs which require further regional coordination

Sr.no.	Need	Recommendation
1	Preston TS Station Capacity	To be further assessed in the next RP phases. Hydro One and Grandbridge Energy to keep monitoring load levels
2	Energy Inc MTS Station Capacity	To be further assessed in the next RP phases. Grandbridge Energy to monitor load levels

3	Overload - M20D/M21D post contingency capacity violation (Galt Jct x Cambridge #1 Jct)-	To be further assessed in the next RP phases.
4	System security violation - M21D/M20D 230 kV circuits	To be further assessed in the next RP phases.
5	Voltage violations – On 230 kV M20D or M21D circuit for loss of companion circuit.	To be further assessed in the next RP phases.
6	Load restorations -M20D or M21D due to single tower outage	To be further assessed in the next RP phases.
7	Overload - D11K/D12K 115 kV circuits experience post contingency violation (Detweiler TS x Kitchener MTS#1 & #4 Jct.)	To be further assessed in the next phases. Enova Power Corp to explore load transfers between their stations. H1 and Enova Power Corp to monitor load levels.

List of LDC(s) to be involved in further regional planning activities:

- Grandbridge Energy
- Enova Power Corp.

List of LDC(s) which are not required to be involved in further regional planning phases: (if any)

- Hydro One Networks Inc. (Distribution)
- Alectra Inc.
- Center Wellington Hydro
- Halton Hills Hydro Inc.
- Wellington North Power

26.	CTS - 2	115	B5C/B6C

Appendix C: Lists of Transmission Circuits

Sr. No.	Connecting Stations	Circuit ID	Voltage (kV)
1.	D6V/ D7V	Detweiler TS	Orangeville TS
2.	M20D/ M21D	Detweiler TS	Middleport TS
3.	D4W/ D5W	Detweiler TS	Buchanan TS
4.	B22D/ B23D	Detweiler TS	Bruce TS
5.	D7F/ D9F	Detweiler TS	Free Port SS
6.	F11C/ F12C	Free Port SS	Cedar TS
7.	B5C/ B6C	Cedar TS	Burlington TS
8.	D11K/ D12K	Detweiler TS	Kitchener MTS #4
9.	D8S	Detweiler TS	St. Mary TS
10.	D10H	Detweiler TS	Hanover TS

Appendix D: List of LDC's

Sr. no.	Name of LDC
1	Energy + Inc
2	Alectra
3	H1 Distribution
4	Enova Power Corp
5	Centre Wellington Hydro
6	Halton Hills Hydro
7	Milton Hydro
8	Wellington North Power Inc

Appendix E: List of Municipalities in the region

Sr. no.	Name of Municipality
1	Township of Blandford-Blenheim
2	City of Cambridge
3	City of Kitchener
4	City of Waterloo
5	Regional Municipality of Waterloo
6	Township of North Dumfries
7	Township of Wellesley
8	Township of Wilmot
9	Township of Woolwich
10	Region of Waterloo
11	City of Guelph
12	County of Wellington
13	Township of Centre Wellington
14	Township of Puslinch
15	County of Perth
16	Town of St. Marys

Appendix F: Acronyms

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CEP	Community Energy Plan
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CSS	Customer Switching Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DS	Distribution Station
GS	Generating Station
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MEP	Municipal Energy Plan
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board

ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
STG	Steam Turbine Generator
TS	Transformer Station

Kitchener-Waterloo-Cambridge-Guelph Integrated Regional Resource Plan

TS	Transformer Station

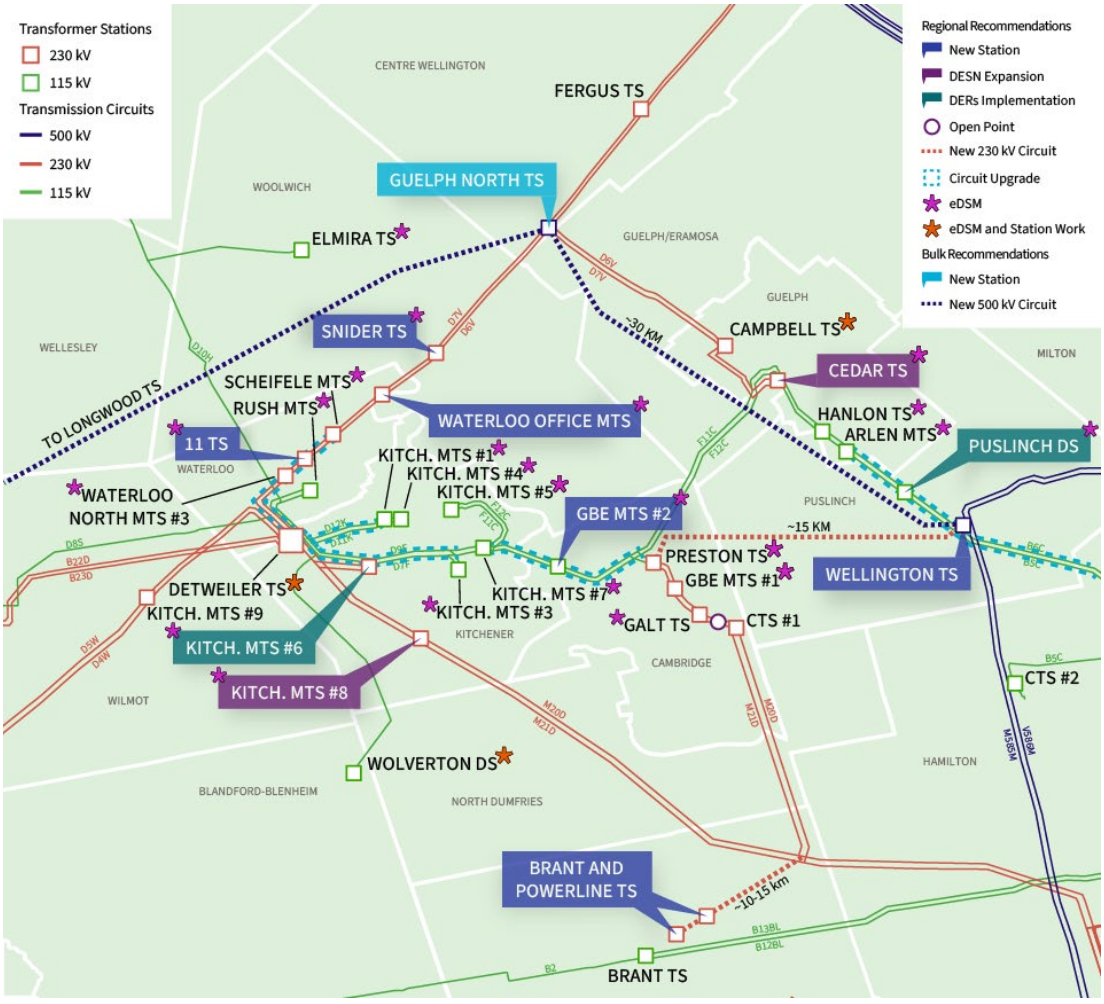
Executive Summary

The Kitchener-Waterloo-Cambridge-Guelph Integrated Regional Resource Plan (KWCG IRRP) addresses electricity needs in the region over the twenty-year period from 2026-2045. The KWCG region is in southwestern Ontario, and encompasses the Region of Waterloo, the cities of Kitchener, Waterloo, Cambridge, and Guelph, and the townships of Wellesley, Woolwich, Wilmot, North Dumfries, portions of Perth, and Oxford. Wellington county and the municipalities of Blandford-Blenheim, Centre Wellington, Guelph/Eramosa, and Puslinch are also included.

Regional electricity planning for the KWCG region has occurred regularly, with this being the third IRRP published since 2015. This IRRP builds upon those previous regional and bulk plans to continue to ensure reliable electricity supply across the region. In this iteration, electricity demand in KWCG is expected to grow rapidly, driven by strong residential, commercial, and industrial development, increasing electrification, and new large loads such as data centres. Significant population and employment growth —alongside major developments like new housing, healthcare facilities, and commercial expansion — will further accelerate electricity needs. In addition, climate change and local climate action plans are expected to increase demand through greater adoption of electric heating, cooling, and electric vehicles, contributing to higher winter peaks.

Engagement was a key input to the development of this IRRP. The IESO engaged with municipalities, stakeholders, and the public throughout the planning process. Activities included targeted one-on-one discussions and four public webinars to share information and solicit written feedback. The overarching themes of feedback received primarily focused on demand forecast inputs and assumptions; leveraging existing and local generation; and regulations for reserving capacity for critical public infrastructure. The feedback received helped shape the demand forecast, identify local priorities, and inform the recommended solutions.

In response to significant growth, the Technical Working Group recommends both immediate actions and longer-term investments:



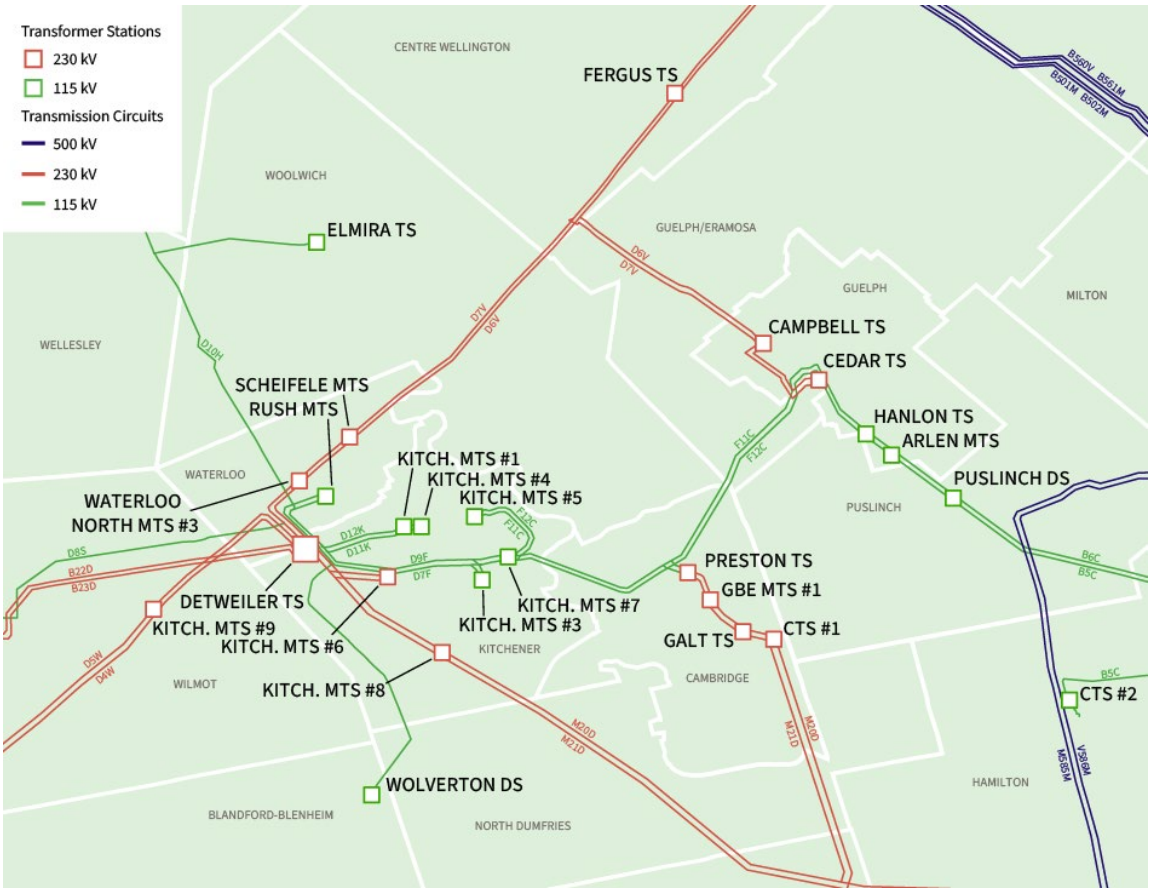
- Considering additional peak demand savings available from electricity demand-side management programming;
- Constructing a 500/230 kV autotransformer station in Puslinch, with a double-circuit 230 kV transmission line connecting it with Preston Transformer Station (TS);
- Conducting station work at Detweiler TS to mitigate the adverse impact of the existing operating instructions to manually trip the static VAR compensator or capacitor under certain breaker-open conditions, and exploring reactive support on the 115 kV sub-system;
- Converting Cedar T7/T8 to 230 kV upon its end of life to address the local station capacity need;
- Uprating various existing 115 kV circuits, as well as sections of the 230 kV circuits between Detweiler and Orangeville;
- Transferring loads on the distribution system to maximize the use of existing transformer stations and supply capability;

- Constructing new 115 kV and 230 kV transformer stations in Cambridge, Kitchener, Guelph, and the Waterloo area;
- Implementing station work at Campbell TS and Wolverton Distribution Station (DS) to increase their capacity; and
- Implementing distributed energy resources at Puslinch DS and Kitchener Municipal Transformer Station #6 to solve station capacity needs.

The Technical Working Group will continue to monitor growth across the region to determine if or when further reinforcements will be needed — including long-term options identified in this plan for a switching station at Galt and further 230 kV transmission lines to Waterloo or Kitchener. The Technical Working Group will meet to develop the Regional Infrastructure Plan, as well as annually between regional planning cycles to monitor any future community energy plans, electrification trends, customer connection queues, and changes to local generation. If underlying assumptions change significantly, plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the Ontario Energy Board.

The figure below visually depicts the near- to medium-term IRRP recommendations across the KWCG region (note that distribution-level load transfers are omitted for simplicity).

Figure 1 | Overview of Recommended Solutions for the KWCG IRRP



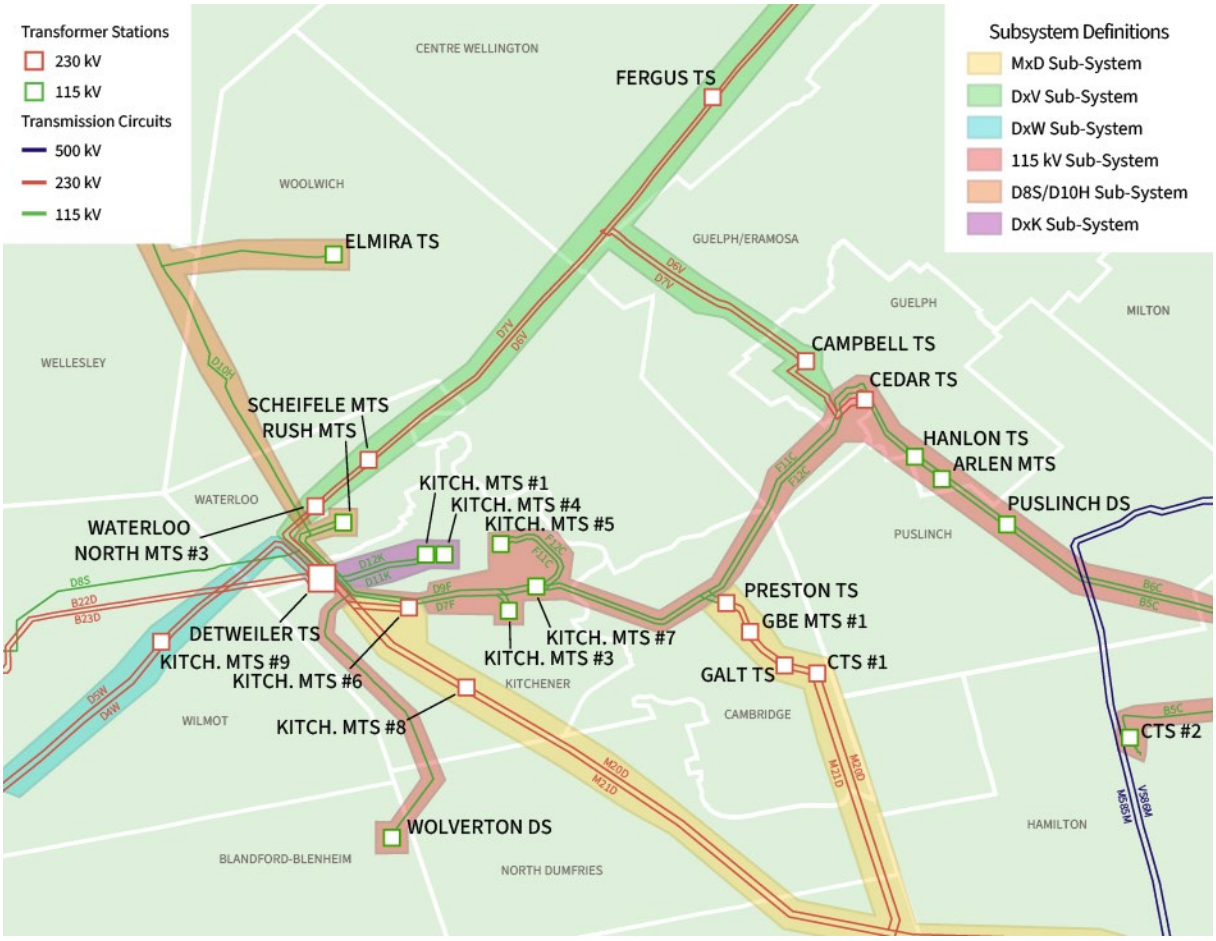
1. Introduction

This Integrated Regional Resource Plan (IRRP) addresses the electricity needs of the Kitchener-Waterloo-Cambridge-Guelph (KWCG) region over the 20-year period from 2026 to 2045. The KWCG region is in southwestern Ontario, and encompasses the Region of Waterloo, the cities of Kitchener, Waterloo, Cambridge, and Guelph, and the townships of Wellesley, Woolwich, Wilmot, North Dumfries, portions of Perth, and Oxford. Wellington county and the municipalities of Blandford-Blenheim, Centre Wellington, Guelph/Eramosa, and Puslinch are also included in the region.

The IESO also acknowledges that KWCG is the traditional territory of many nations, and is committed to ongoing, meaningful dialogue with Indigenous communities to inform long-term planning in the region and across Ontario. To raise awareness about the regional planning cycle in KWCG, and invite participation in the engagement process, the IESO's engagement efforts included outreach to Indigenous communities throughout the development of the plan, including to the Mississaugas of the Credit First Nation, Six Nations of the Grand River as represented by Six Nations Elected Council as well as the Haudenosaunee Confederacy Chiefs Council, and Métis Nation of Ontario.
The region's electricity is delivered by eight Local Distribution Companies (LDCs): Enova Power, Alectra Utilities, GrandBridge Energy, Centre Wellington Hydro, Wellington North Power, Halton Hills Hydro Inc., Hydro One Networks Inc. ("Hydro One Distribution"), and Milton Hydro. Hydro One Networks Inc. ("Hydro One Transmission") is the primary transmission asset owner. This IRRP report was prepared by the Independent Electricity System Operator (IESO) on behalf of a Technical Working Group, composed of the LDCs, Hydro One Transmission, and the IESO.

Figure 2 depicts the electrical transmission infrastructure for the KWCG region. Power is transmitted into the region via 230 kilovolt (kV) and 115 kV circuits originating from Detweiler Transformer Station (TS) and Burlington TS. There are also load stations supplied by double-circuit 230 kV lines connecting Detweiler TS from Orangeville TS (D6V & D7V), Middleport TS (M20D & M21D), and Buchanan TS (D2W & D5W).

Figure 2 | Map of the KWCG Region and Transmission System



For the purposes of regional planning, the KWCG region has been divided into multiple electrical sub-systems, as shown below in Figure 3.

Detweiler is currently the key bulk supply point for the KWCG region, so many of the sub-systems are defined with this station. For instance, the **Middleport to Detweiler (MxD) sub-system** in the south of the region is electrically defined by the 230 kV supply that connects Detweiler TS in Kitchener to Preston TS in Cambridge, as well as beyond the KWCG region and into Brant. Multiple transformer stations across Kitchener and Cambridge are served by these MxD circuits.

KWCG is characterized by two other 230 kV sub-systems: the double-circuit lines that connect **Detweiler to Orangeville (DxV)**, and **Detweiler to Buchanan (DxW)**. These sub-systems connect the KWCG region to neighbouring regions, but they also supply stations across Waterloo, Wilmot, Guelph, and Centre Wellington.

Much of the KWCG region is otherwise supplied by three lower voltage sub-systems: the **115 kV sub-system** that serves most of Kitchener and to the northeast in Guelph and Puslinch, as well as radial 115 kV lines between **Detweiler and Elmira TS (D10H), Detweiler and Rush Municipal Transformer Station (MTS) (D8S/D10H)**, and **Detweiler and Kitchener MTS #1 and #4 (DxK)**.

Figure 3 | Map of the KWCG Region Sub-Systems

There are two transmission-connected customers in the region served by Customer Transformer Stations (CTS). The distribution-connected resources (DERs), or distributed generation (DG), in the region include solar and wind resources; there are currently no local generation resources connected at the transmission level.

This report is the culmination of the KWCG IRRP, which was initiated in July 2024 following the publication of the Needs Assessment Report in April 2024 by Hydro One, and the Scoping Assessment Outcome Report in July 2024 by the IESO. The Scoping Assessment identified needs requiring further assessment through an IRRP. The Technical Working Group was then formed to gather data, identify near- to long-term needs in the region, and recommend appropriate investments or other electricity system initiatives.

2. The Integrated Regional Resource Plan

The electricity demand forecast, provided by the LDCs for this IRRP, anticipates significant growth over the twenty-year period from 2026 to 2045, driven by population and employment growth, electrification, urban intensification, and commercial sector expansion in KWCG. This IRRP provides recommendations to address electricity needs that arise from this growth. Needs are identified based on the capability of the existing transmission system, as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC), as well as reliability standards governed by the North American Electric Reliability Corporation. The IRRP's recommendations are informed by an evaluation of different options to meet the needs, considering reliability, cost, technical feasibility, maximizing use of the existing electricity system (where economical), and feedback from stakeholders.

The IRRP recommendations below are organized by near-term, medium-term, and other ongoing or long-term initiatives to address needs within the KWCG network. This distinction reflects the different levels of forecast certainty, lead time for development, and planning commitment required over different time horizons. This approach ensures that the IRRP provides clear direction on investments needed in the near and medium term, while retaining flexibility over the long term as electrification, energy efficiency, and development plans evolve.

2.1 Status of Ongoing Work

Following the last cycle of region planning, several projects previously recommended have now been completed or are presently underway. The status of these projects is summarized in Table 1.

Table 1 | Summary of Ongoing and Recently Completed Projects

Circuit/Station	Need	Recommended Action	Status
B5C 115 kV transmission line	End of life (EOL)	Line section replacement; line tap section from Harper's JCT to CTS 1	Completed Q3 2025
Hanlon TS (T1 & T2)	EOL	Transformer replacement	Completed Q3 2022
Kitchener MTS #5 (T9 & T10)	EOL	Transformer replacement	Completed Q2 2025
Preston TS (T3 & T4)	EOL	Transformer replacement	Completed Q2 2026
Campbell TS (T1 & T2)	EOL	Breaker replacement	Expected completion in 2032

Circuit/Station	Need	Recommended Action	Status
Scheifele MTS (T1, T2, T3 & T4)	EOL	Transformer replacement	T3/T4 expected completion in 2029-2030; T1/T2 expected completion in 2033-2034
Galt TS	EOL	Breaker and component replacement	Hydro One will continue to monitor and take appropriate action
Fergus TS (T3 & T4)	EOL	Transformer replacement	Hydro One will continue to monitor and take appropriate action
GrandBridge Energy MTS #1 (T1 & T2)	Station Capacity	Load transfer to Galt TS and Preston TS	Underway
Preston TS	Station Capacity	Load transfer to Galt TS and GrandBridge Energy MTS #1	Underway
Scheifele MTS (T1+T3)/(T2+T4)	Station Capacity	Load transfer to Waterloo North MTS #3, Rush MTS, and Elmira TS	Evaluated by Enova Power and completed as needed
Campbell TS (T3 & T4)	Station Capacity	Load transfer to Cedar TS and Cedar TS T1/T2	Need re-evaluated and addressed in this IRRP

2.2 Near- to Medium-Term Plan

The Technical Working Group recommends the near- to medium-term plan outlined below, including several recommendations to accommodate load growth, maintain reliability, and optimize asset replacement. These investments include new stations in Cambridge, Puslinch, Waterloo, and Guelph, upgrades to existing transmission lines, station expansions and load transfers in Kitchener, new lines between Cambridge and Puslinch, additional electricity demand-side management (eDSM), and distributed resources.

Table 2 summarizes the near- to medium-term recommendations for KWCG, organized by need and timing.

Table 2 | Summary of the Near- to Medium-Term Plan

Need(s)	Technical Working Group Recommendation	Lead Responsibility	Expected In-Service Date
Wolverton DS station capacity need	Install fan monitoring project.	Hydro One Distribution	2027

Need(s)	Technical Working Group Recommendation	Lead Responsibility	Expected In-Service Date
DxV sub-system supply capacity need	Transfer load from DxV sub-system to DxW sub-system.	Enova Power	2028
115 kV sub-system supply capacity need	Uprate B5C/B6C, D7F/D9F, and F11C/F12C.	Hydro One Transmission	2028
Preston TS, GrandBridge Energy (GBE) MTS #1, and Galt TS station capacity needs	Construct a new 115 kV transformer station (GBE MTS #2) to supply up to 75 MW of load.	GrandBridge Energy	2028
Puslinch DS station capacity need	Implement distributed energy resources.	Hydro One Distribution, with IESO support to explore value-stacking opportunities	2030-2042
Rush MTS, Scheifele MTS, and Waterloo North MTS #3 station capacity needs	Construct 230 kV stations, including 11 TS, Office MTS, and Snider TS	Enova Power	2030+
Kitchener MTS #8 station capacity need	Expand with a new 230 kV Dual-Element Spot Network (DESN).	Enova Power	2030+
MxD sub-system supply, restoration, and security needs	Construct a new 500/230 kV autotransformer station (Wellington TS) in Puslinch, with new double-circuit 230 kV lines to Preston TS and a normally open point at Ameristeel junction. Per the 2024 Burlington to Nanticoke IRRP: Construct two new 230 kV DESNs within or in the vicinity of County of Brant, connecting to the MxD lines.	Hydro One Transmission	2031 or earlier

Need(s)	Technical Working Group Recommendation	Lead Responsibility	Expected In-Service Date
Campbell TS station capacity needs	Install additional metal-clad switchgear to fully utilize T3/T4 capacity and transfer load from T1/T2.	Alectra and Hydro One Transmission	2031
DxV sub-system supply capacity need	Uprate DxV and implement station work at Detweiler TS to mitigate existing operating instructions. Evaluate reactive support (such as low-voltage capacitor at Elmira TS) in the Regional Infrastructure Plan to meet interim needs.	Hydro One Transmission	2031
Cedar T1/T2 and T7/T8 station capacity needs, T7/T8 end-of-life need	Replace T7/T8 with a 230 kV DESN and transfer load from T1/T2 to T7/T8.	Alectra and Hydro One Transmission	2032
Rush MTS station capacity need	Transfer load to new 230 kV stations on DxV sub-system.	Enova Power	2032
Kitchener MTS #1, 4, 5, 6, 7 station capacity needs	Optimize existing station capacity and transfer load on the distribution system between stations.	Enova Power	2033
DxK supply capacity need	Uprate D11K/D12K.	Hydro One Transmission	2033
Kitchener MTS #6 station capacity need	Implement distributed energy resources.	Enova Power, with IESO support to explore value-stacking opportunities	2034-2042

2.3 Long-Term Plan and Other Initiatives

In the long term, the KWCG region's electricity demand is projected to continue to grow. This IRRP recommends long-term actions to ensure that options are preserved to address future needs in the most efficient and cost-effective way, if and when they ultimately arise. Table 3 summarizes the long-term recommendations for KWCG, organized by need.

Table 3 | Summary of the Long-Term Plan for the KWCG IRRP

Need(s)	Technical Working Group Recommendation	Lead Responsibility	Timing
Arlen TS and Hanlon TS station capacity needs	Monitor long-term load growth (including eDSM savings); provide update at the next Annual Technical Working Group meeting between regional planning cycles.	Alectra	2028 (next Annual Technical Working Group meeting)
MxD supply capacity and restoration needs	Monitor long-term load growth between Detweiler TS and Middleport TS and re-evaluate need for Galt Switching Station (SS).	Technical Working Group	2028 (next Annual Technical Working Group meeting)
Kitchener MTS #1, 4, 5, 6, 7 station capacity needs	Monitor distribution load transfers and long-term load growth. In the next regional planning cycle, re-assess needs and 230 kV supply options for a new 230 kV DESN in the Kitchener Freeport area.	Enova Power	2029 (next cycle of regional planning in KWCG begins)
DxV sub-system supply capacity need	Monitor long-term load growth and re-evaluate the need for double-circuit 230 kV lines from Guelph North TS to the Waterloo area in future planning cycles.	Hydro One Transmission, Enova Power	2029 (next cycle of regional planning in KWCG begins)
Preston TS, GBE MTS #1, and Galt TS station capacity needs	Construct a new 230 kV transformer station in Cambridge (GBE MTS #3).	GrandBridge Energy	2035 or earlier (in-service)

3. Development of the Plan

3.1 Regional Planning Process

In Ontario, preparing to meet the electricity needs of customers at a regional level is achieved through regional planning. Regional planning assesses the interrelated needs of a region — defined by common electricity supply infrastructure — over the near, medium, and long term, and results in a plan to ensure cost-effective and reliable electricity supply. A regional plan considers the existing electricity infrastructure in an area, forecasts growth and customer reliability, evaluates options for addressing needs, and recommends actions.

The current regional planning process was formalized by the Ontario Energy Board in 2013 and is performed on a five-year cycle for each of the 21 planning regions in the province. The process is led by the IESO, in collaboration with the transmitters and LDCs in each region. It consists of four main components:

1. A Needs Assessment, led by the transmitter, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;
2. A Scoping Assessment, led by the IESO, which identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities;
3. An IRRP, led by the IESO, which identifies the appropriate mix of investments in conservation and demand management, generation, transmission facilities or distribution facilities, or other electricity system initiatives to address the identified needs of a region requiring coordinated planning; and/or
4. A Regional Infrastructure Plan (RIP), led by the transmitter, which provides further details on recommended wires solutions.

Regional planning is not the only type of electricity planning in Ontario. Other types include bulk system planning and distribution system planning. There are inherent overlaps in all three levels of electricity infrastructure planning. Further details on the regional planning process and the IESO's approach to it can be found in the appendix.

The IESO has recently completed a review of the regional planning process, following the completion of the first cycle of regional planning for all 21 regions. Additional information on the Regional Planning Process Review, along with the final report, is posted on the IESO's website.

3.2 Kitchener-Waterloo-Cambridge-Guelph and IRRP Development

The development of the KWCG IRRP was initiated in July 2024, following the publication of the Needs Assessment report in April 2024 by Hydro One and the Scoping Assessment Outcome Report in July 2024 by the IESO. The Scoping Assessment recommended that the needs identified for the KWCG region be considered through an IRRP in a coordinated regional approach, supported with public engagement. The Technical Working Group was then formed to develop the terms of reference for this IRRP, gather data, identify needs, develop options, and recommend solutions for the region.

4. Background and Study Scope

Electricity planning in Ontario typically occurs on a cyclical basis; this is the third cycle of regional planning for the KWCG region, with earlier IRRPs published in 2015 and 2021. The previous regional recommendations are summarized in the sections below, alongside information on current regional and bulk planning that impacts the KWCG region.

4.1 Previous Regional Planning Cycle

The previous cycle of regional planning for the KWCG region in 2021 implemented a multi-pronged approach to address electricity needs across the region. This includes:

- EOL transformer replacements at Hanlon TS (T1/T2), Kitchener MTS #5 (T9/T10), Preston TS (T3/T4), Scheifele MTS (T1/T2, T3/T4), and Fergus TS (T3/T4);
- EOL breaker replacements at Campbell TS (T1/T2) and Galt TS;
- EOL transmission line replacements on a section of the 115 kV B5/6C line; and
- Various load transfers off stations forecast to be at capacity (GBE MTS #1, Preston TS, Scheifele MTS, Campbell TS (T3/T4), Kitchener MTS #7 (T13/T14), and Kitchener MTS #8 (T15/T16).

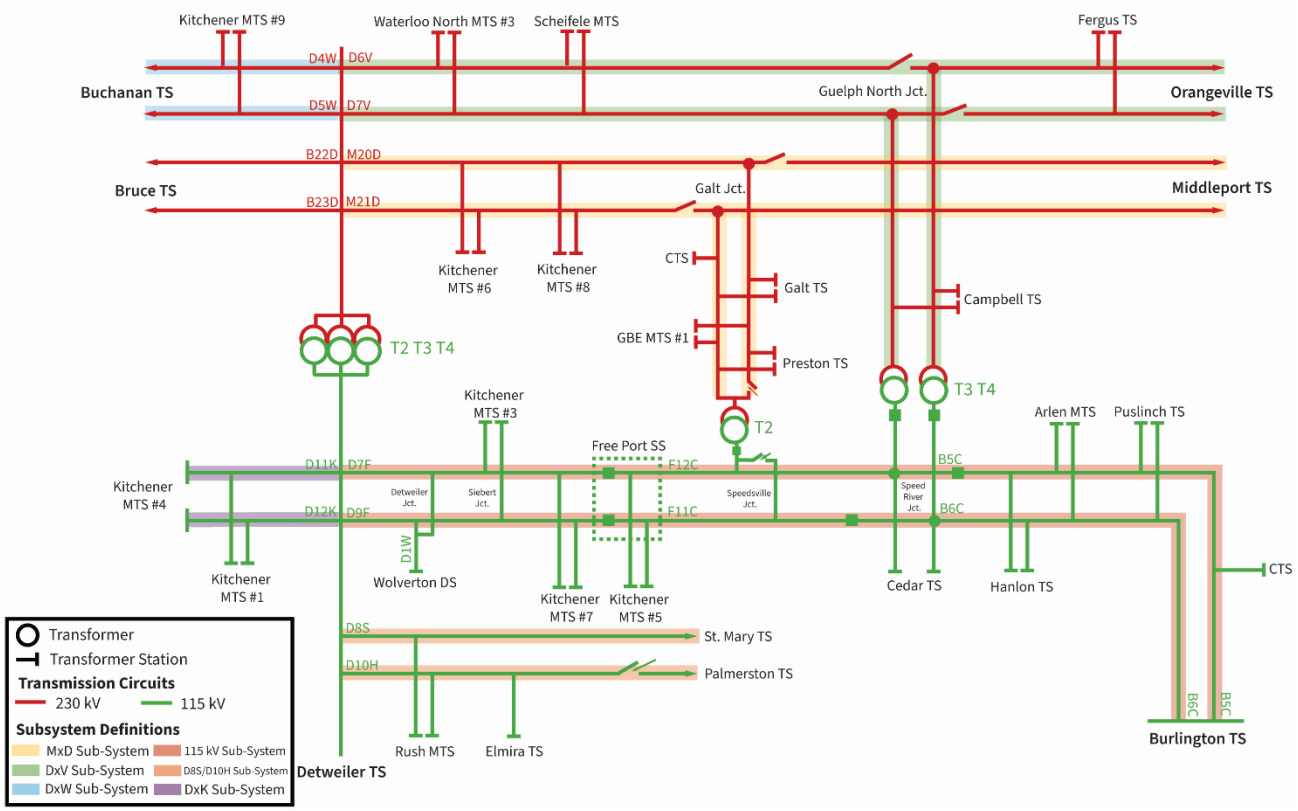
The 2021 KWCG IRRP also identified multiple longer-term needs to monitor and assess: supply capacity needs along the B5C and D10H circuits, station capacity needs at Arlen MTS, Hanlon TS, Rush MTS, Elmira TS, Kitchener MTS #1, and Waterloo North MTS #3, and a load restoration need on the M20D/M21D 230 kV lines.

4.2 Bulk Planning and Other Developments

The KWCG region is included in the South and Central Bulk Plan, which the IESO developed to address transmission limitations in a wide-spanning geographic area from Bruce to the Greater Toronto Area, and along the Windsor to Hamilton corridor. The objectives of the study are to enable new generation, enable the phase-out of emitting resources, and support future growth and economic development across various load centres in Ontario.

4.3 Current Cycle of Regional Planning

The current cycle of regional planning began in 2024, with the publication of the Needs Assessment. The 2023 Scoping Assessment recommended an IRRP for the entire region to address needs in a coordinated manner. This report presents an integrated regional electricity plan that covers the time period from 2026 to 2045; recommendations are made to meet KWCG regional electricity needs in the near, medium, and long term.



The plan was prepared by the IESO on behalf of the Technical Working Group, and considers forecast electricity demand growth, eDSM, DG, transmission and distribution system capability, relevant community plans, condition of transmission assets, and developments on the bulk transmission system.

The following transmission facilities were included in the scope of this study:

- Transformer stations: Arlen MTS, Campbell TS (T1/T2), Campbell TS (T3/T4), Cedar TS (T1/T2), Cedar TS (T7/T8), Elmira TS, GrandBridge Energy MTS #1, Fergus TS, Galt TS, Hanlon TS, Kitchener MTS # 1, Kitchener MTS # 3, Kitchener MTS # 4, Kitchener MTS #5, Kitchener MTS #6, Kitchener MTS #7, Kitchener MTS #8, Kitchener MTS #9, Preston TS, Puslinch DS, Rush MTS, Scheifele MTS, Waterloo North MTS #3, Wolverton DS, and two CTS.
- 115 kV transmission circuits: D7F/D9F, F11C/F12C, B5C/B6C, D11K/D12K, D8S, and D10H.
- 230 kV transmission circuits: D6V/D7V, M20D/M21D, D4W/D5W, and B22D/B23D.

The single line diagram of the KWCG region is shown in Figure 4. Note that the bulk system transfer capabilities into the region are not within the scope of the IRRP, and are encompassed in the South and Central Bulk Plan. The schedule of bulk planning activities is identified through the IESO's Annual Planning Outlook.

Figure 4 | Single Line Diagram of the KWCG Region

The KWCG IRRP was developed by:

- Establishing alternatives to address system needs, including (where feasible and applicable): generation, transmission and/or distribution, and other approaches such as non-wires alternatives, including additional eDSM.
- Engaging with the community on needs and possible alternatives.
- Evaluating alternatives to address near- and long-term needs.

- Considering the impact of the low and high forecast as a sensitivity of the flexibility and optionality of potential alternatives.
- Communicating findings, conclusions, and recommendations within a detailed plan.

5. Electricity Demand Forecast

Regional planning in Ontario is driven by having to meet peak electricity demand requirements in the region. This section describes the development of the demand forecast for the KWCG region. It highlights assumptions made for peak demand forecasts, including weather correction, the contribution of eDSM and DG, and the development of low and high growth forecast scenarios. The reference case "Planning Scenario" was derived based on firm loads (current and planned), organic growth, residential development, electrification, community energy plans, and industrial growth as described in more detail in the appendix. The "Planning Forecast" is net of existing DG and eDSM and corrected for extreme weather. It is used to assess the electricity needs of the area over the planning horizon.

The "High Scenario" incorporates potential demand growth that is less certain, in terms of timelines, magnitude, and location, into the Planning Scenario. The "High Forecast" is also the result of the High Scenario adjusted to be net of existing DG and eDSM, and corrected for extreme weather. The High Forecast is used as the basis for sensitivity analysis as described further in Section 5.7.2.

The "Low Scenario" accounts for uncertainty of growth and reconsiders committed growth that may not materialize due to delayed timelines and technological, economical, and political circumstances. The "Low Forecast" is also the result of the Low Scenario adjusted to be net of existing DG and eDSM, and corrected for extreme weather. The Low Forecast is used as the basis for sensitivity analysis as described further in Section 5.7.3.

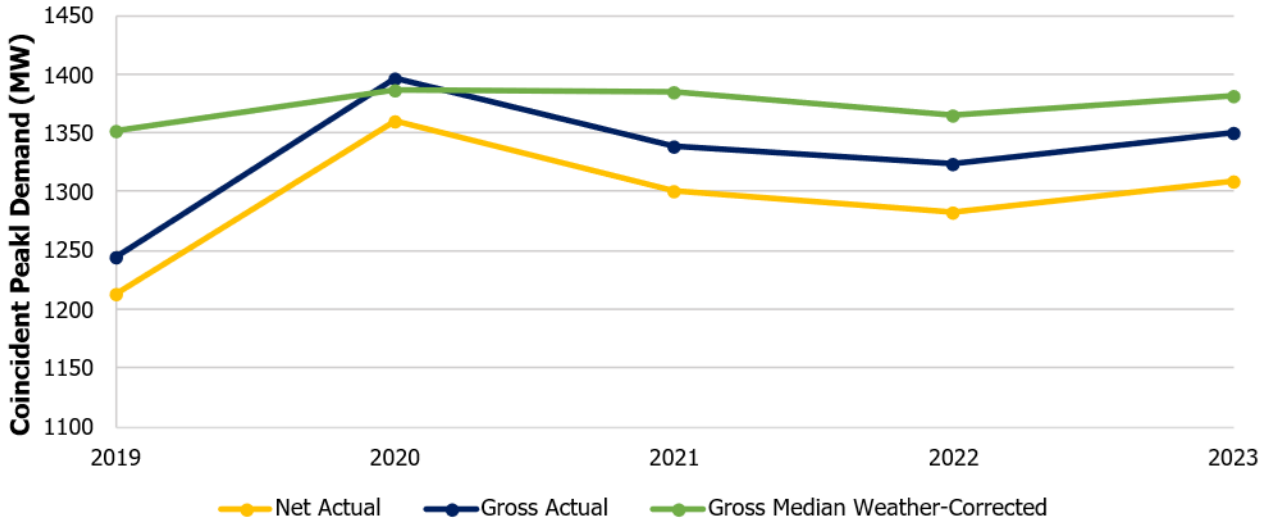
To evaluate the reliability of the electricity system, the regional planning process is typically concerned with the coincident peak demand for a given area. This is the demand observed at each station for the hour of the year in which overall demand in the study area is at its maximum. This differs from a non-coincident peak, which refers to each station's individual peak, regardless of whether these peaks occur at different times. In the past, the KWCG region peak loading has historically occurred in the summer. However, with recent developments in electrification and decarbonization, the region is shifting towards winter-peaking.

5.1 Historical Demand

Summer peak electricity demand within the KWCG region has remained stable in the five years prior to this IRRP, which began in 2024. Figure 5 shows the summer coincident net actual, gross actual, and gross median weather-corrected historical demand. The summer gross median weather-corrected demand has averaged just under 1,400 MW over the past five years, with the peak demand hour for each year occurring between approximately 11 a.m. to 5 p.m. in the summer and 2 p.m. to 7 p.m. in the winter.

Since the forecast was developed in 2024, the 2023 summer and winter gross median weather-corrected peaks at each station in the KWCG region were used as the starting points for the forecast.

Figure 5 | Historical Summer Peak Demand in the KWCG Region



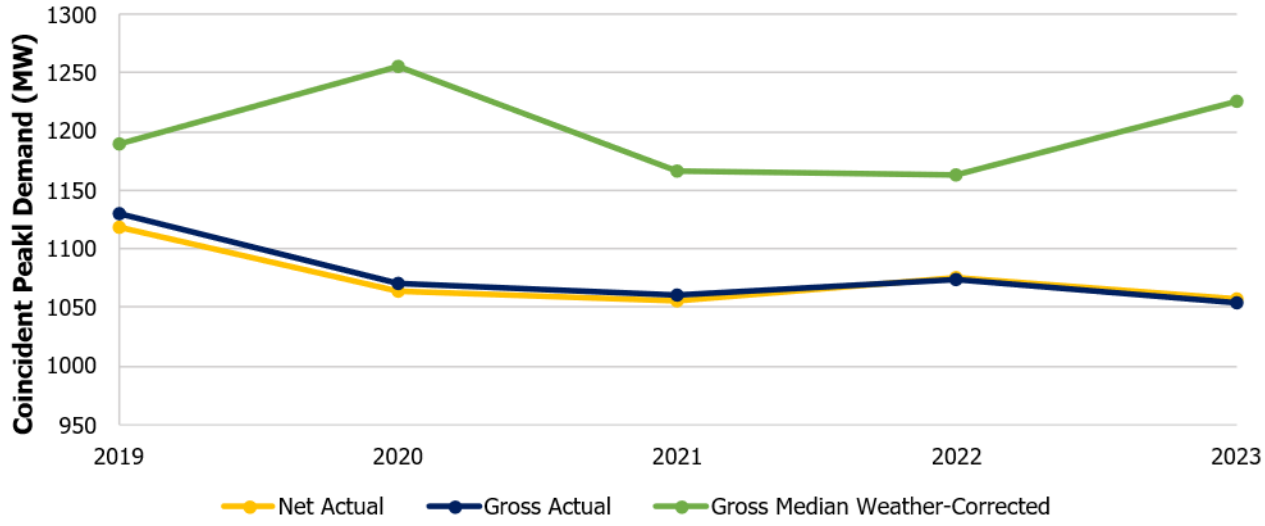


Figure 6 | Historical Winter Peak Demand in the KWCG Region

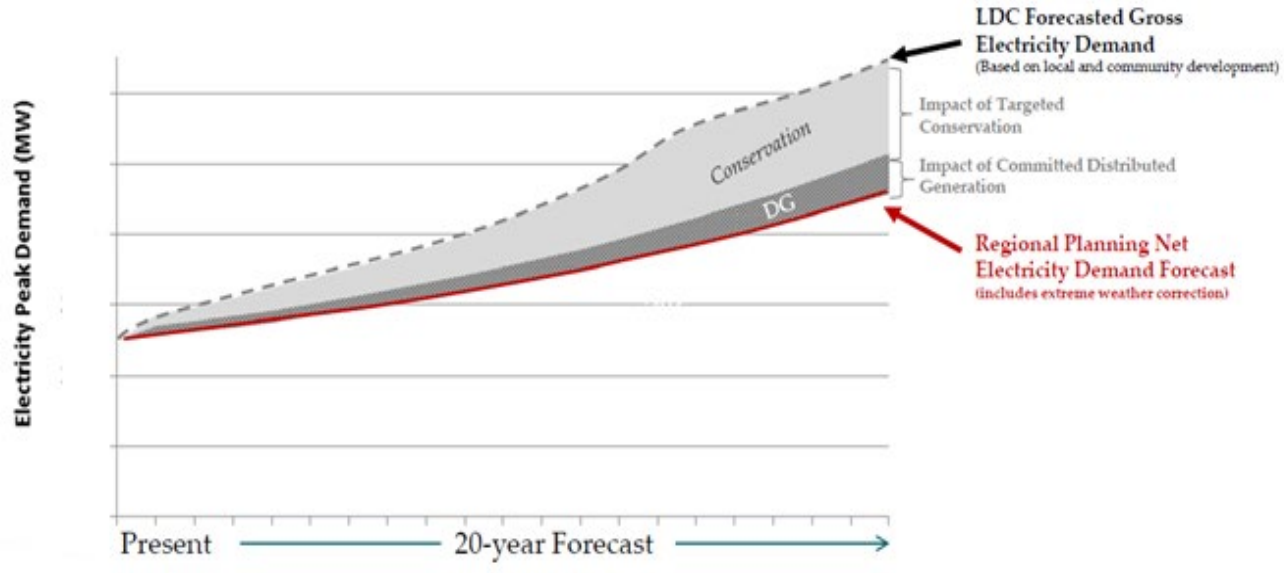
5.2 Current Drivers of Load Growth

Electricity demand in the KWCG region is projected to grow at a rapid pace due to residential, commercial, and industrial growth, electrification, and several new large developments. This includes several requests to connect from potential data centre customers. Broader economic development across the region and local climate action plans are also expected to be key factors for future electricity needs. These drivers of growth are used by the LDCs to inform the forecasts developed for the region and are discussed in more detail below.

Load growth based on organic growth in the residential, commercial, and industrial sectors is driven by population growth, employment growth, housing activities, and industrial and commercial building activities. The population in the KWCG region is expected to see a large increase over the next 25 years according to the Region of Waterloo Official Plan (923,000 increase by 2051) and City of Guelph Official

Plan (208,000 increase by 2051). This population growth will encourage residential development, and the region expects steady increases in housing as detailed in the Region of Waterloo, County of Wellington, and City of Guelph municipal plans. Employment in the KWCG region is also expected to see an increase over the next 25 years. This is accompanied by new commercial and industrial development, informed by the region's stakeholders which include cities, townships, and large customers. Some examples include new large-scale subdivision expansion, a new Waterloo hospital, planned expansion to existing customer facilities, and new large data centres.



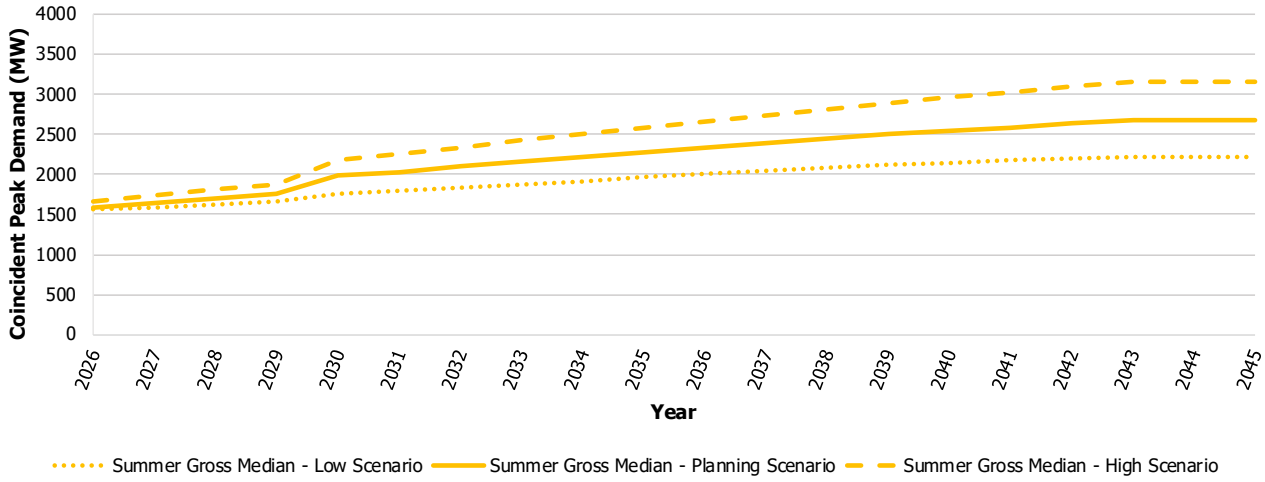
The region anticipates climate change and resulting extreme weather will have an impact on electricity demand due to electrification. As highlighted by Region of Waterloo and City of Guelph climate action plans, the KWCG region will see an increase in temperatures and number of warm days, driving up the need for electric cooling. The electrification of heating is also a key driver and contributes to higher winter demand peaks. In addition to electric heating, electric vehicle uptake is expected to increase in the area due to municipal fleets and more broadly by community members.

5.3 Demand Forecast Methodology

The steps taken to develop a 20-year IRRP peak demand forecast are depicted in Figure 7. Gross demand forecasts, which assume the weather conditions of an average year based on historical weather conditions (referred to as "normal weather"), were developed by the LDCs. These forecasts were then modified to reflect the peak demand impacts of provincial conservation targets and DG contracted through previous provincial programs, such as Feed-In Tariff (FIT) and microFIT, and adjusted to reflect extreme weather conditions to produce a Planning Forecast for planning assessments. This net forecast was then used to assess the electricity needs in the region.

Additional details related to the development of the demand forecast are provided in the appendix. The Ontario Energy Board has also published a Load Forecast Guideline for regional planning, through the Regional Planning Process Advisory Group.

Figure 7 | Illustrative Development of Demand Forecast



5.4 Gross LDC Forecasts

Each participating LDC in the KWCG region prepared gross demand forecasts at the station level, or at the station bus level for multi-bus stations. These gross demand forecasts account for increases in demand from new or intensified development, plus known connection applications. The LDCs cited alignment with municipal and regional official plans and credited them as a source for input data. LDCs were also expected to account for changes in consumer demand resulting from typical efficiency improvements and in response to increasing electricity prices ("natural conservation"), but not for the impact of future DG or new conservation measures (such as codes and standards and eDSM programs), which are accounted for by the IESO (discussed in Section 5.5). The gross LDC forecasts assume median on-peak weather conditions and loading that is coincident to each station.

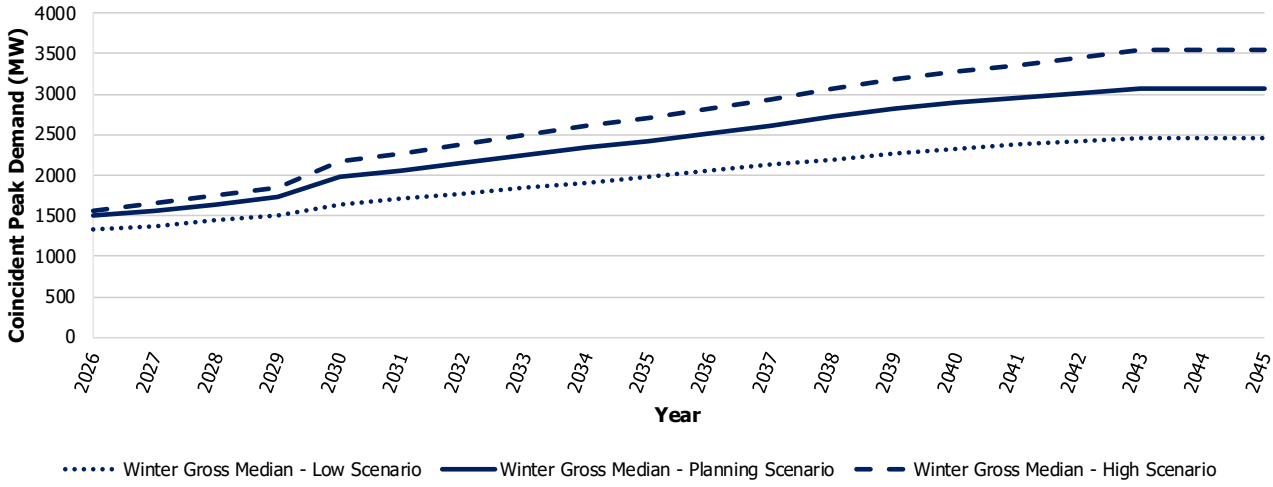


Figure 8 and Figure 9 show the gross coincident demand forecasts provided by the LDCs for the KWCG region under the Low Scenario, Planning Scenario, and High Scenario for summer and winter peak demand.

Figure 8 | Total Summer Gross Coincident Demand Forecasts Provided by LDCs (Median Weather)[1]

[1] Excludes existing transmission-connected industrial customers in the KWCG region (historically contributing an average of 9 MW to the summer coincident peak demand).

Figure 9 | Total Winter Gross Coincident Demand Forecasts Provided by LDCs (Median Weather)[2]

LDCs have a better understanding of future local demand growth and drivers than the IESO, since they have the most direct involvement with their customers, connection applicants, and the municipalities and communities that they serve. The IESO typically carries out demand forecasting at the provincial level. More details on LDC load forecast assumptions can be found in the appendix.

5.5 Contribution of Energy Efficiency to the Forecast

Energy efficiency is a clean and cost-effective resource that helps meet Ontario's electricity needs and is an integral component of provincial and regional planning. Energy efficiency is achieved through a mix of codes and standards amendments, as well as eDSM program-related activities. These approaches complement each other to maximize conservation results.

The estimate of demand reduction due to codes and standards are based on expected improvement in the codes for new and renovated buildings, and regulation of minimum efficiency standards for equipment used by specified categories of consumers (i.e., residential, commercial and industrial consumers).

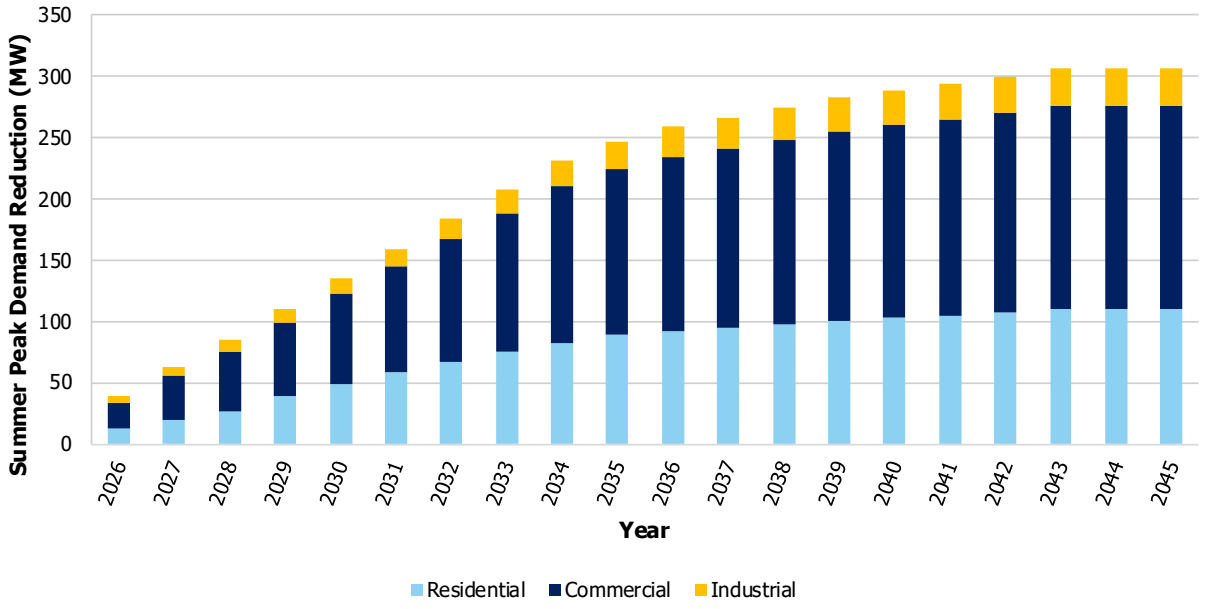
The estimates of demand reduction due to eDSM program-related activities account for the 2021–2024 Conservation and Demand Framework, federal programs that result in electricity savings in Ontario, and forecasted long-term energy efficiency programs. Under the 2021–2024 Conservation and Demand Management Framework, the IESO centrally delivered programs on a province-wide basis to serve business and residential customers, as well as Indigenous communities.

The KWCG demand forecast was finalized before approval of the new 2025–2036 eDSM Framework and its savings targets, and assumes that programs continue at 2021–2024 Conservation and Demand Framework levels, with adjustments for gross demand growth. The increased targets under the new framework may impact the exact scale and timing of needs.

[2] Excludes existing transmission-connected industrial customers in the KWCG region (historically contributing an average of 7 MW to the winter coincident peak demand).

Figure 9 shows the estimated total yearly reduction to the demand forecast due to energy efficiency (from codes, standards, and eDSM programs) for each of the residential, commercial, and industrial consumers. Additional details are provided in the appendix.

Figure 10 | Total Summer Forecast Peak Demand Reduction (Codes, Standards, and eDSM Programs)



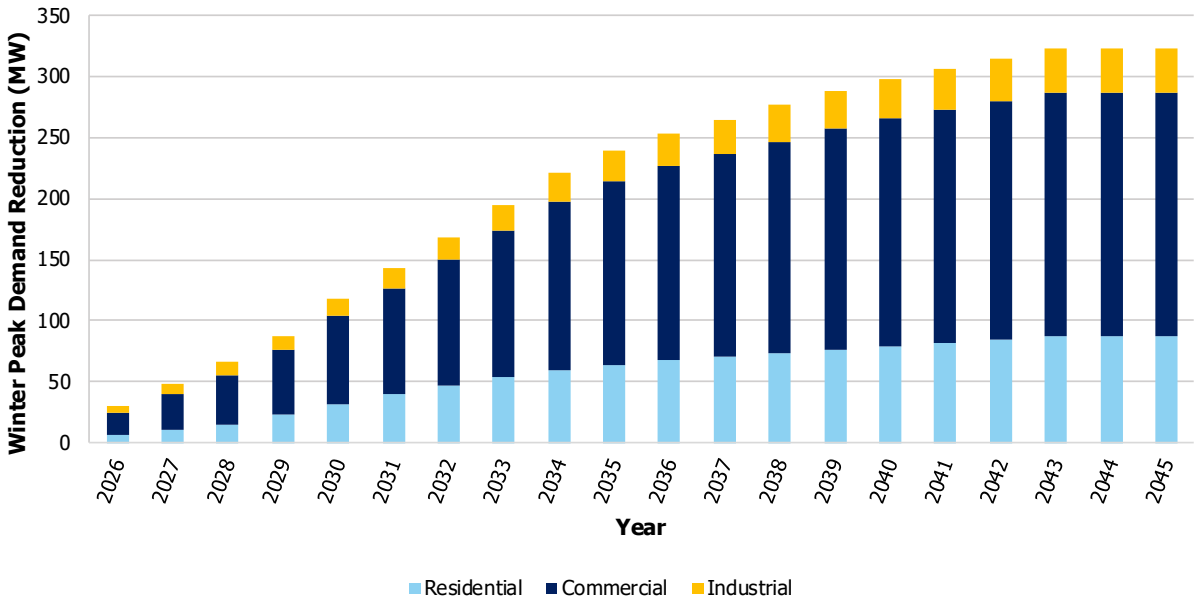


Figure 11 | Total Winter Forecast Peak Demand Reduction (Codes, Standards, and eDSM Programs)

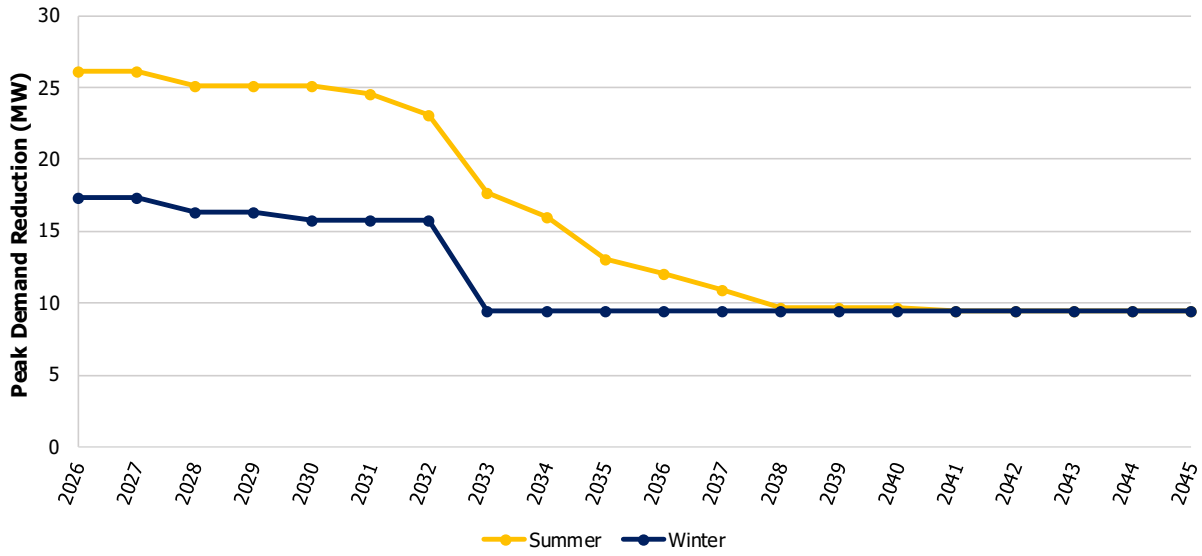


5.6 Contribution of Distributed Generation to the Forecast

In addition to energy efficiency, DG in the KWCG region is also forecast to offset peak demand requirements. The introduction of Ontario's FIT Program increased the significance of distributed renewable generation which, while intermittent, contributes to meeting the province's electricity demands. The installed DG capacity by fuel type and contribution factor assumptions can be found in of the accompanying IRRP Data Tables (provided as a separate Excel file). All the installed DG capacity in the KWCG region is wind and solar.

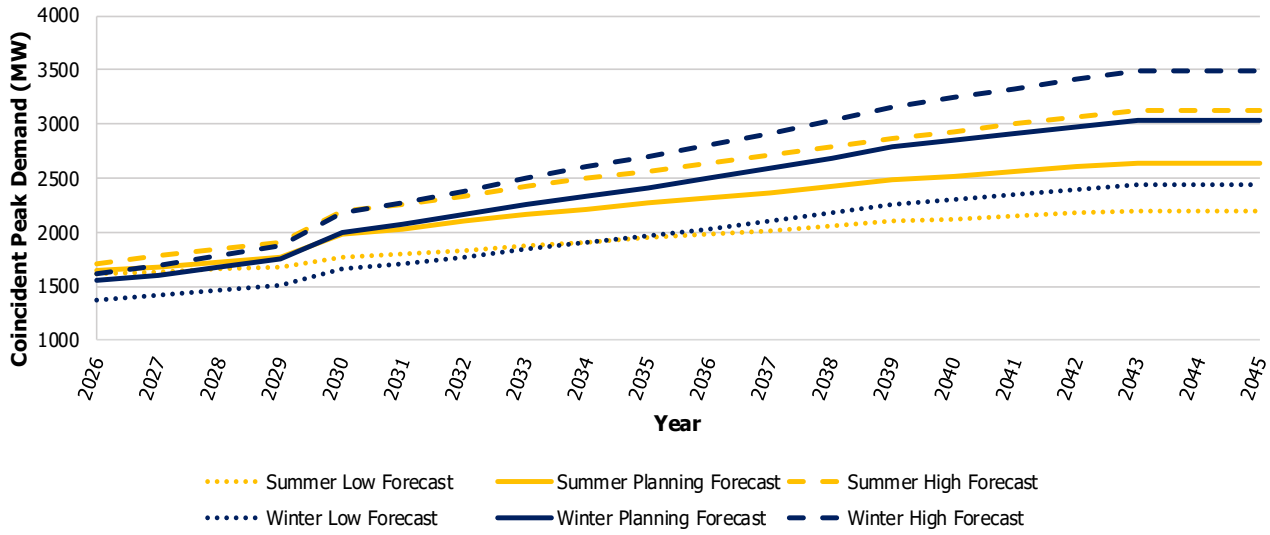
After reducing the demand forecast due to energy efficiency (as described in Section 5.5), the forecast is further reduced by the expected contribution from contracted DG. Figure 12 shows the impact of DG on reducing the KWCG region demand forecasts. Note that facilities without a contract with the IESO were not included in the DG peak demand reduction forecast.

Figure 12 | Peak Demand Reduction Due to DG

5.7 Planning Forecasts

After taking into consideration the combined impacts of energy efficiency and DG, a 20-year net demand forecast was produced for the KWCG region considering the Low Scenario, Planning Scenario, and High Scenario. The following subsections describe the implementation of weather correction to create the Low Forecast, Planning Forecast, and High Forecast, and the total demand outlook for the region.

5.7.1 Net Extreme Weather Planning Forecast



The net extreme weather forecast is created by adjusting the net median weather forecast (the gross demand forecast including the forecast DG and eDSM impacts) for extreme weather conditions. The weather correction methodology is described in the appendix. The Planning Forecast results from the net extreme-weather forecast applied to the Planning Scenario.

Note that this Planning Forecast is coincident, meaning that each station forecast reflects its expected contribution to the regional peak demand level. This allows need dates to be identified for regional

needs that are driven by more than one station. For station-specific needs, the non-coincident forecast is calculated by applying a non-coincidence factor. The factor is based on the historical non-coincident peaks of each station compared to the station's contribution to the region's coincident peaks over the past five years.

The coincident net extreme weather forecast for the KWCG region is shown in Figure 13 for the Low Forecast, Planning Forecast, and High Forecast representing peak summer and winter demand.

Figure 13 | Net Extreme Weather Planning Forecast, Low Forecast, and High Forecast for the KWCG Region

5.7.2 High Forecast Scenario

The Technical Working Group developed a High Forecast sensitivity scenario for the KWCG region, which is also shown in Figure 13. The High Forecast is meant to quantify prospective development in the KWCG region that is not yet committed. This higher demand scenario is driven by increased electrification rates and increased commitment from prospective large-scale customers looking to connect.

The High Forecast can be used as a proxy for a variety of factors that could drive demand higher over the next 20 years, including, but not limited to:

- electric vehicle charging;
- electrified space and water heating;
- a faster pace of residential development;
- unanticipated new industrial customers of growth among existing industrial customers; and
- data centres.

The higher demand scenario was not used to drive any firm recommendations for this IRRP; however, it was used to help the Technical Working Group identify where the future electricity concerns may be and when they could materialize. This information can also be useful for communities conducting community energy plans, for the Technical Working Group in determining areas to monitor in future planning cycles, and for communities and stakeholders to consider when planning various projects in

the region. Moreover, while developing this IRRP, the Technical Working Group also considered the flexibility of evaluated options to accommodate greater long-term growth. This is later described in Section 7.

5.7.3 Low Forecast Scenario

The Technical Working Group also developed a Low Forecast sensitivity scenario, which is also shown in Figure 13. The Low Forecast is meant to consider slowed organic growth and prospective development in the KWCG region that is committed, but sensitive to economical, technological, political, and social factors. This lower demand scenario is primarily driven by lower electrification rates and lower demand from large-scale customers.

The lower demand scenario was not used to drive any firm recommendations for this IRRP; however, it was used to help the Technical Working Group identify where growth could slow down and where future electrical infrastructure improvements could be delayed. Similarly to the High Forecast scenario, this information can be useful for communities conducting community energy plans, for the Technical Working Group in determining areas to monitor in future planning cycles, and for communities and stakeholders to consider when planning various projects in the region. Moreover, while developing this IRRP, the Technical Working Group also considered the flexibility of evaluated options to accommodate lower long-term growth.

5.8 Hourly Forecast Profiles

In addition to the annual peak forecast, hourly load profiles (8,760 hours per year over the 20-year forecast horizon) were developed to characterize some needs with finer granularity. The profiles were based on historical load data and adjusted for variables that impact demand, such as calendar day (i.e., holidays and weekends) and weather. The profiles were then scaled to match the IRRP peak Planning Forecast for each year. As described later in Section 7, these profiles were used to quantify the magnitude, frequency, and duration of needs to better evaluate the suitability of resource options.

Additional load profile details can be found in the appendix. Note that this data is used to roughly inform the overall energy requirements needed to develop and evaluate alternatives; it cannot be used to deterministically specify precise hourly energy requirements. Real-time loading is subject to various factors, like actual weather, customer operation strategies, and future customer segmentation. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification are more widely adopted. Hence, these hourly forecasts are only used to select suitable technology types and roughly estimate costs for the needs and options studied in the IRRP. The Technical Working Group will continue to monitor forecast changes as part of the implementation of the plan.

6. Needs

6.1 Needs Assessment Methodology

Based on the planning demand forecast, system capability, the transmitter's identified asset replacement plans, and the application of ORTAC, North American Electric Reliability Corporation TPL-001-5.1, and Northeast Power Coordinating Council Directory #1 standards, the Technical Working Group identified electricity needs in the near-, medium- and long-term timeframes. These needs can be categorized according to the following:

- **Station Capacity Needs** describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations during peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day Limited Time Rating (LTR) of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be more limited by downstream or upstream equipment (i.e., breakers, disconnect switches, low-voltage bus, or high voltage circuits) or by voltage drop limitations, which are independent of thermal ratings.
- **Supply Capacity Needs** describe the electricity system's inability to provide continuous supply to a local area during peak demand. This is referred to as the load-meeting capability (LMC) of the transmission supply. The LMC is determined by evaluating the maximum demand that can be supplied to an area after accounting for limitations of the transmission elements (i.e., a transmission line, group of lines, or autotransformer), when subjected to contingencies and criteria prescribed by ORTAC, TPL-001-5.1, and Northeast Power Coordinating Council Directory #1. LMC studies are conducted using power system simulation analyses.
- **Asset Replacement Needs** are identified by the transmitter or LDC by an asset condition assessment, which is based on a range of considerations, such as equipment deterioration due to aging infrastructure or other factors; technical obsolescence due to outdated design; lack of spare parts availability or manufacturer support; and/or potential health and safety hazards, etc. Replacement needs identified in the near- and early medium-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium- to long-term needs should reflect the potential for the need date to change as condition information is routinely updated.
- **Load Security and Restoration Needs** describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC.

Technical study results for the KWCG IRRP can be found in the appendix. The needs identified are discussed in Sections 6.3 to 6.7 for each season of each sub-system.

6.2 115 kV Sub-System

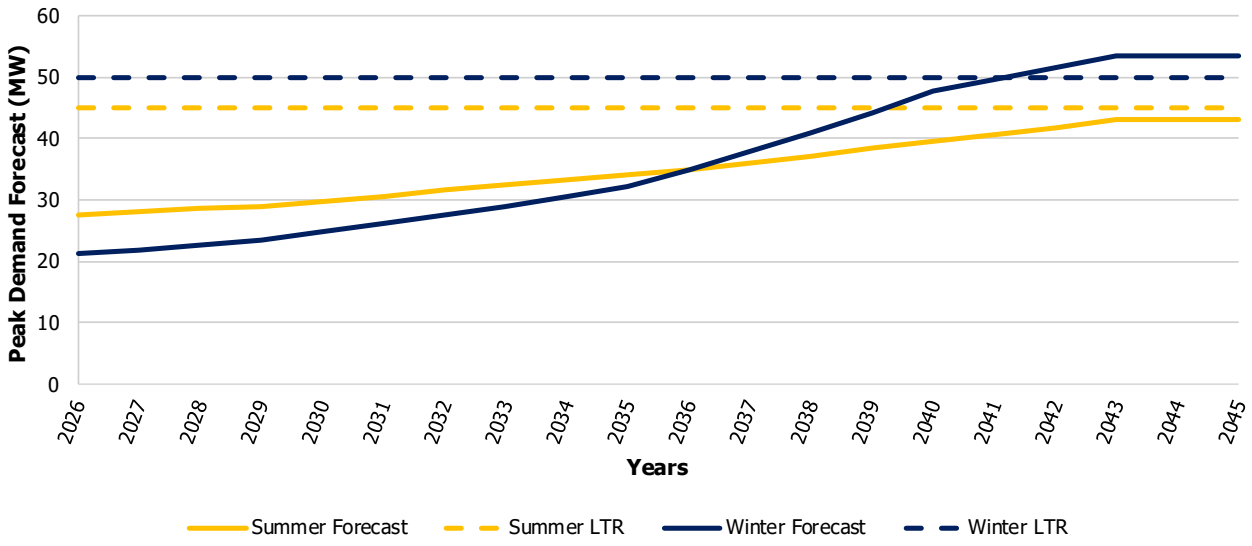
The 115 kV sub-system refers to the stations in Kitchener, Guelph, and Puslinch that are served by the Detweiler-Freeport (DxF), Freeport-Cedar (FxC), and Burlington-Cedar (BxC) double-circuit 115 kV circuits. There is an asset replacement need at Cedar TS T7/T8 and station capacity needs at Arlen TS, Cedar TS T1/T2, Cedar TS T7/T8, Hanlon TS, Kitchener MTS #5, Kitchener MTS #7, Puslinch DS, and Wolverton DS. There are also supply capacity needs on the 115 kV sub-system transmission circuits. The table below summarizes the needs for the 115 kV sub-system under the Planning Forecast.

Table 4 | Summary of 115 kV Sub-System Planning Needs

Need	Summer Need Date	Summer Need by 2045 (MW)	Winter Need Date	Winter Need by 2045 (MW)
Cedar TS T7/T8 end-of-life	2032	N/A	2032	N/A
Arlen TS station capacity	N/A	N/A	2042	4
Cedar TS T1/T2 station capacity	2034	25	2037	37
Cedar TS T7/T8 station capacity	2033	13	2037	19
Hanlon TS station capacity	2042	1	2038	15
Kitchener MTS #5 station capacity	2037	10	2043	<1
Kitchener MTS #7 station capacity	2036	12	2032	39
Puslinch DS station capacity	2029	13	2036	4
Wolverton DS station capacity	Immediately	17	Immediately	11
115 kV supply capacity	2037	22	2036	50

6.2.1 Asset Replacement Needs

6.2.1.1 Cedar TS T7/T8



Cedar TS T7/T8 transformers were identified as requiring replacement based on asset condition by 2032. The IRRP 20-year demand forecast also identified station capacity needs at Cedar TS T7/T8, necessitating the need to consider increasing capacity over a like-for-like replacement.

6.2.2 Station Capacity Needs

6.2.2.1 Arlen TS

Arlen TS consists of two 115 kV/13.8 kV transformers with a summer LTR of 45 MW and a winter LTR of 50 MW. Arlen TS has a station capacity need of 2 MW in winter 2042, which increases to 4 MW by winter 2045. Figure 14 shows the Arlen TS demand forecast in relation to the summer and winter LTR values.

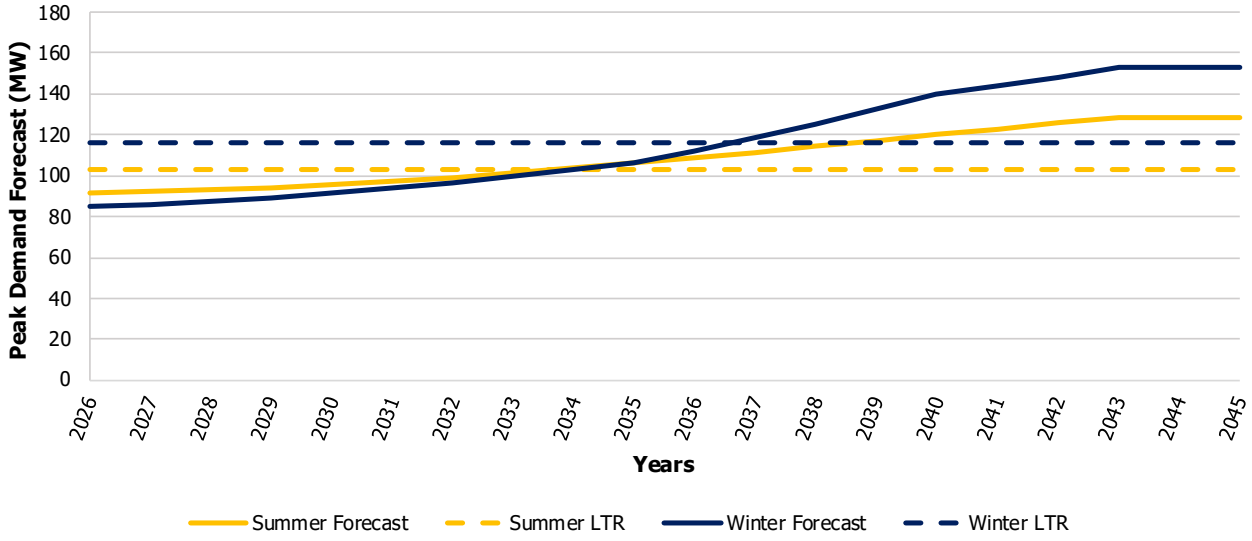


Figure 14 | Arlen TS Station Capacity Need

6.2.2.2 Cedar TS T1/T2

Cedar TS T1/T2 consists of two 115 kV/13.8 kV transformers with a summer LTR of 103 MW and a winter LTR of 116 MW. Cedar TS T1/T2 has a station capacity need of less than a megawatt in summer 2034, which increases to 37 MW by winter 2045. Figure 15 shows the Cedar TS T1/T2 demand forecast in relation to the summer and winter LTR values.

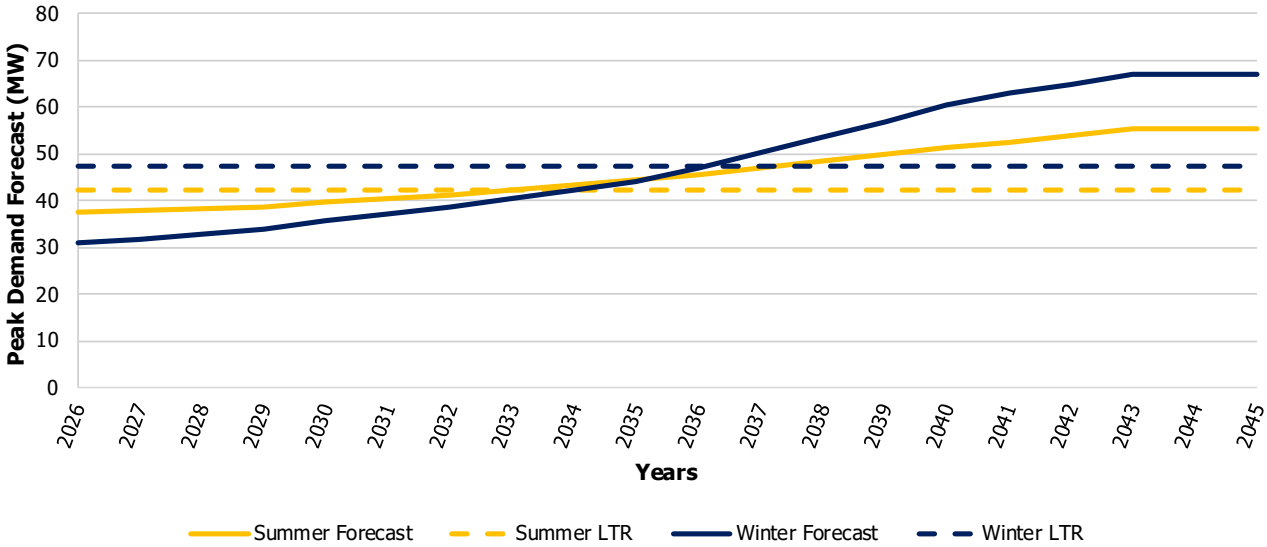

Figure 15 | Cedar TS T1/T2 Station Capacity Need

6.2.2.3 Cedar TS T7/T8

Cedar TS T7/T8 consists of two 115 kV/13.8 kV transformers with a summer LTR of 42 MW and a winter LTR of 47 MW. Cedar TS T7/T8 has a station capacity need of under one megawatt in summer 2033, which increases to 19 MW by winter 2045. Figure 16 shows the Cedar TS T7/T8 demand forecast in relation to the summer and winter LTR values.

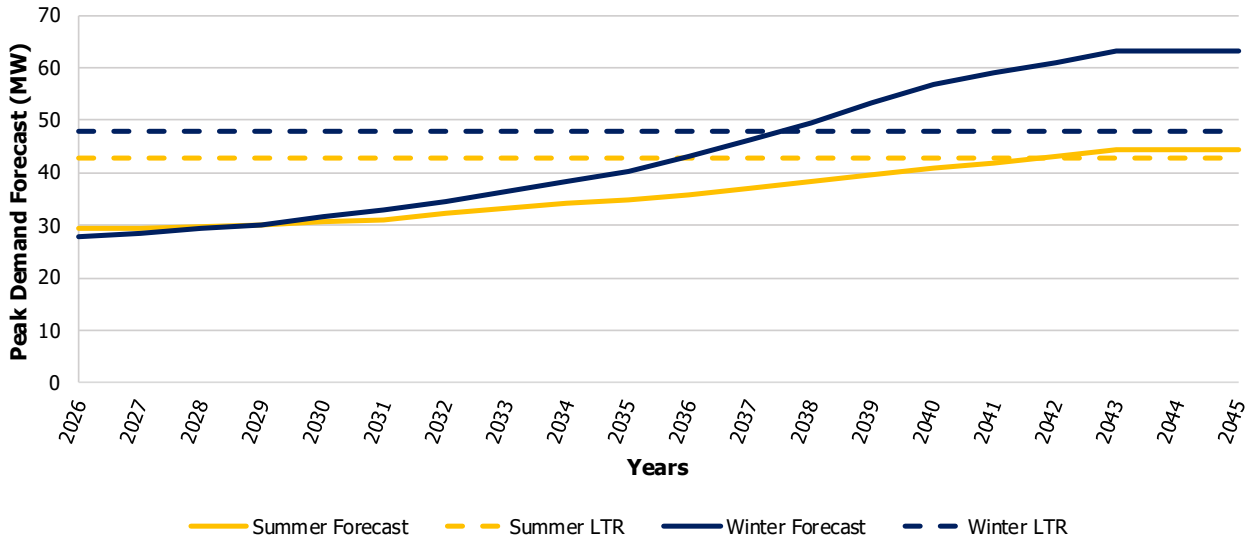

Figure 16 | Cedar TS T7/T8 Station Capacity Need

6.2.2.4 Hanlon TS

Hanlon TS consists of two 115 kV/13.8 kV transformers with a summer LTR of 43 MW and a winter LTR of 48 MW. Hanlon TS has a station capacity need of 2 MW in winter 2038, which increases to 15 MW by winter 2045. Figure 17 shows the Hanlon TS demand forecast in relation to the summer and winter LTR values.

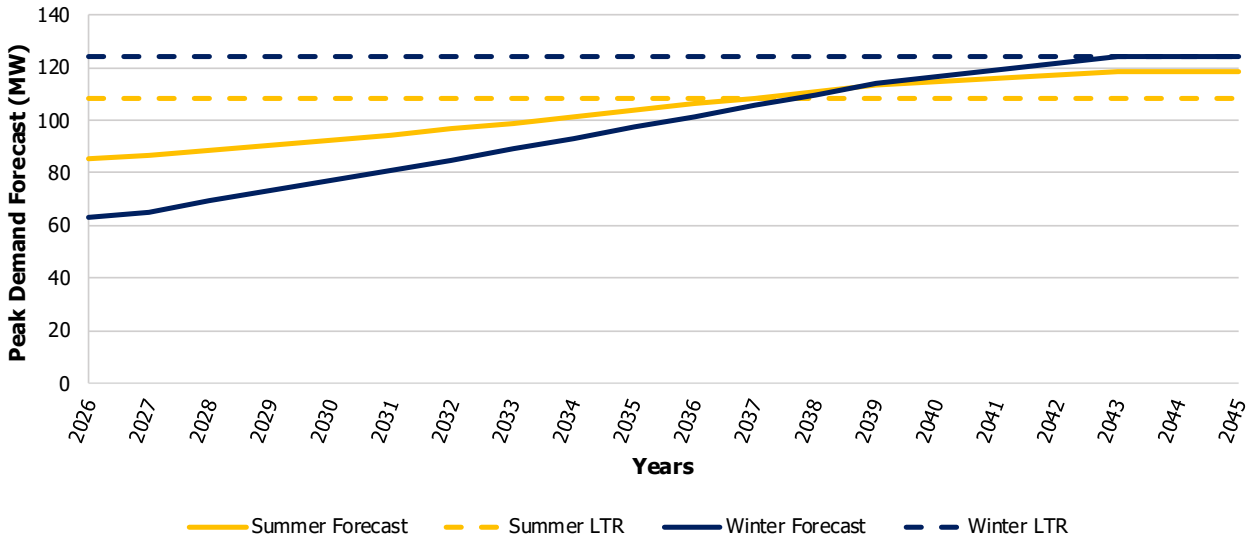

Figure 17 | Hanlon TS Station Capacity Need

6.2.2.5 Kitchener MTS #5

Kitchener MTS #5 consists of two 115 kV/13.8 kV transformers with a summer LTR of 108 MW and a winter LTR of 124 MW. Kitchener MTS #5 has a station capacity need of 1 MW in summer 2037, which increases to 10 MW by summer 2045. Figure 18 shows the Kitchener MTS #5 demand forecast in relation to the summer and winter LTR values.

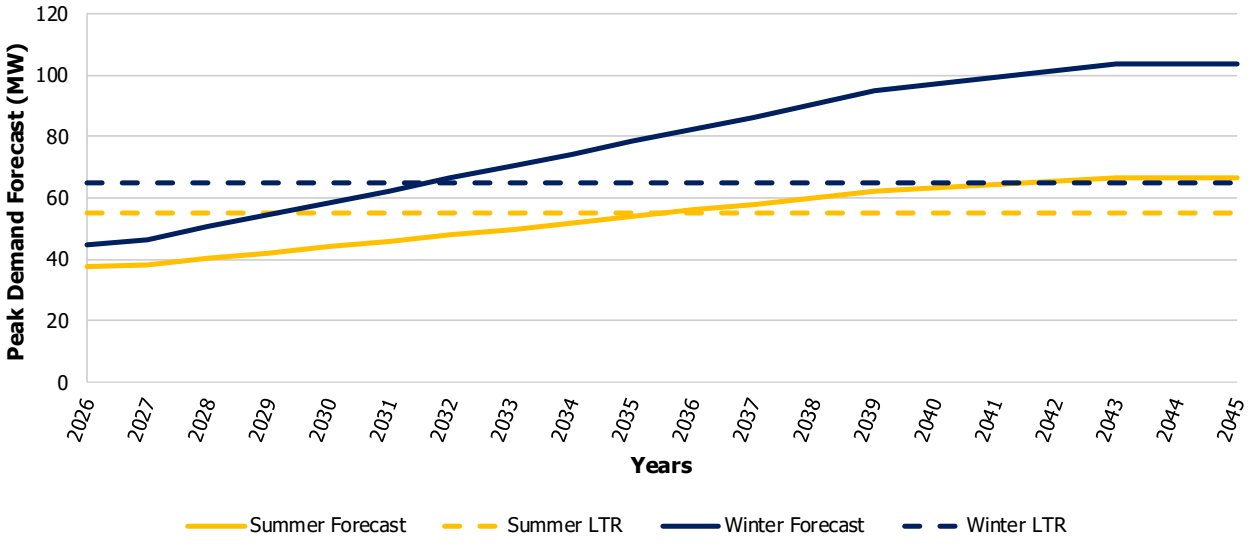

Figure 18 | Kitchener MTS #5 Station Capacity Need

6.2.2.6 Kitchener MTS #7

Kitchener MTS #7 consists of two 115 kV/13.8 kV transformers with a summer LTR of 55 MW and a winter LTR of 65 MW. Kitchener MTS #7 has a station capacity need of 2 MW in winter 2032, which increases to 39 MW by winter 2045. Figure 19 shows the Kitchener MTS #7 demand forecast in relation to the summer and winter LTR values.

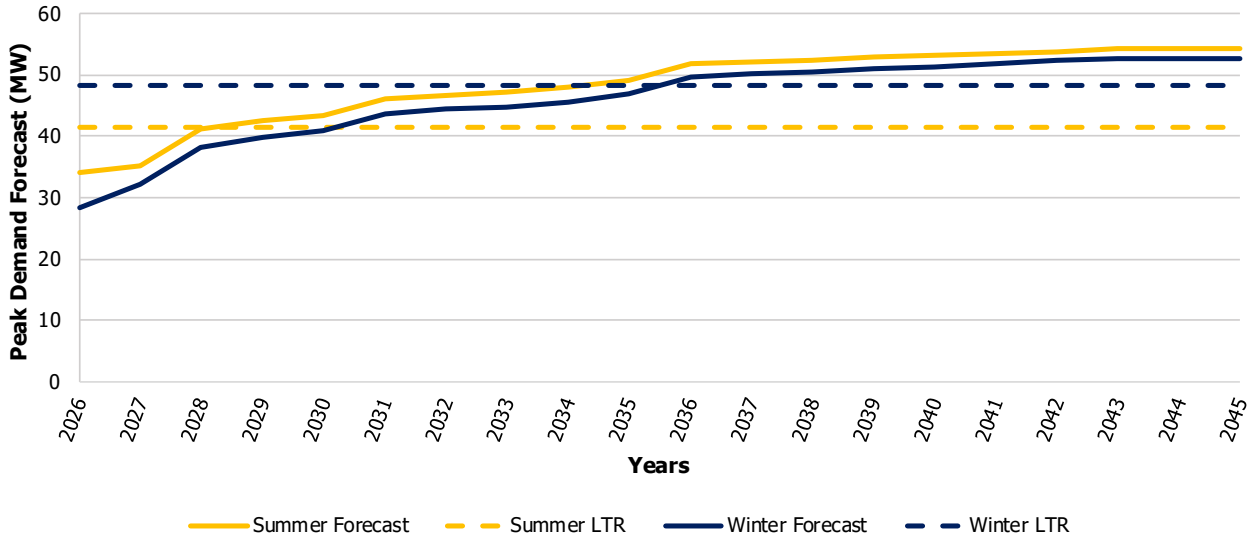

Figure 19 | Kitchener MTS #7 Station Capacity Need

6.2.2.7 Puslinch DS

Puslinch DS consists of two 115 kV/27.6 kV transformers with a summer LTR of 42 MW and a winter LTR of 48 MW. Puslinch DS has a station capacity need of 1 MW in summer 2029, which increases to 13 MW by summer 2045. Figure 20 shows the Puslinch DS demand forecast in relation to the summer and winter LTR values.

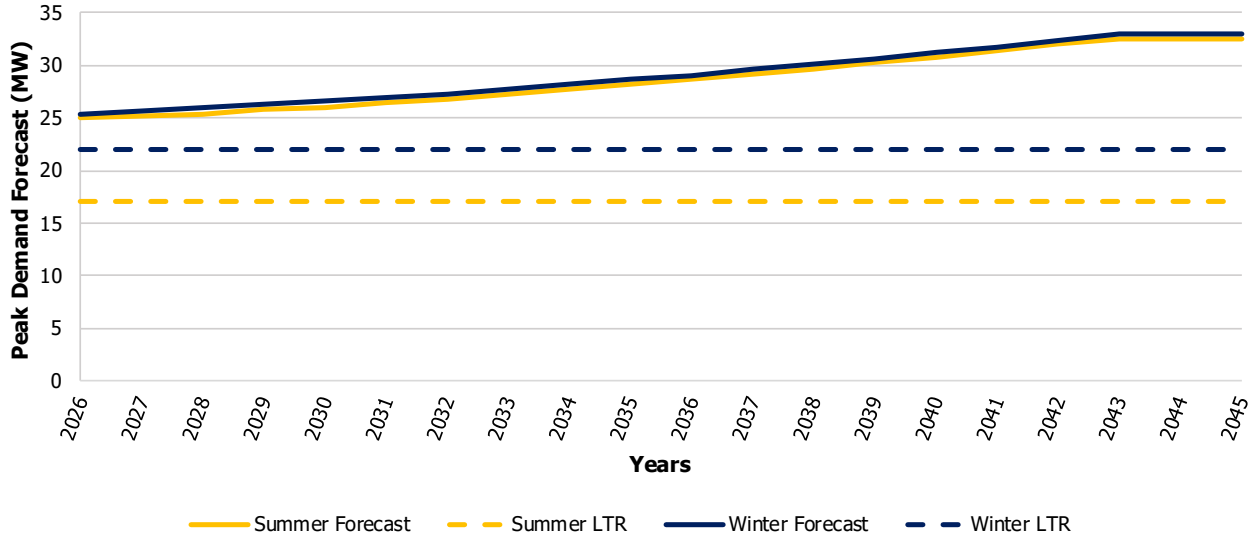

Figure 20 | Puslinch DS Station Capacity Need

6.2.2.8 Wolverton DS

Wolverton DS consists of two 115 kV/27.6 kV transformers with a summer LTR of 17 MW and a winter LTR of 22 MW. Wolverton DS has an immediate summer station capacity need of 8 MW, which increases to 16 MW by summer 2045. Figure 21 shows the Wolverton DS demand forecast in relation to the summer and winter LTR values.

Figure 21 | Wolverton DS Station Capacity Need

6.2.3 Supply Capacity Need

The load in the 115 kV sub-system is supplied through 115 kV transmission lines between Detweiler TS, Freeport SS, Cedar TS, and Burlington TS. The 230/115 kV autotransformers at Detweiler TS, Cedar TS, and Preston TS supply the 115 kV circuits and there is no local transmission-connected generation. There are two distinct load groups in the 11 5kV sub-system. One group consists of Kitchener MTS #3, Kitchener MTS #5, and Kitchener MTS #7 which are served by the 115 kV circuits between Detweiler TS and the Preston TS autotransformer. The second group consists of Hanlon TS, Arlen TS, and Puslinch DS which are served by the 115 kV circuits between Burlington TS and the Cedar TS autotransformers.

Supply on the 115 kV Sub-System Between Detweiler TS and Preston TS Autotransformer

The LMC of 115 kV supply between Detweiler TS and Preston TS autotransformer is limited to 230 MW in the summer and 260 MW in the winter based on the thermal capability of circuit sections from Detweiler TS going towards Freeport SS, under the various planning scenarios and applicable contingencies to the DxF circuits. Considering the forecast growth in the area, this part of the sub-system has a supply capacity need of 3 MW in summer 2037 which increases to 22 MW by summer 2045 and 50 MW by winter 2045.

Supply on the 115 kV Sub-System Between Burlington TS and Cedar TS Autotransformers

The LMC of 115 kV supply between Burlington TS and Cedar TS autotransformers are impacted by the loading between Detweiler TS and Preston TS autotransformer and the MxD sub-system. Considering the expected Detweiler TS-Preston TS autotransformer loading, the LMC of this part of the sub-system is limited to 155 MW in the summer and 187 MW in the winter based on the thermal capability of circuit

sections from Burlington TS going towards Cedar TS, under the various planning scenarios and applicable contingencies to the MxD and BxC circuits.

There is no need on the BxC transmission lines if only accounting for load connected to BxC. However, increasing load on the MxD and 115 kV sub-systems between Detweiler TS and Preston autotransformer can introduce limitations on the BxC transmission lines. Therefore, BxC circuits become constraining for future load growth in these other load pockets.

6.2.4 Low and High Forecast Needs

Depending on the low or high forecast, the 115 kV supply capacity need ranges from 32 MW to 77 MW, and timing ranges from 2034 to 2038.

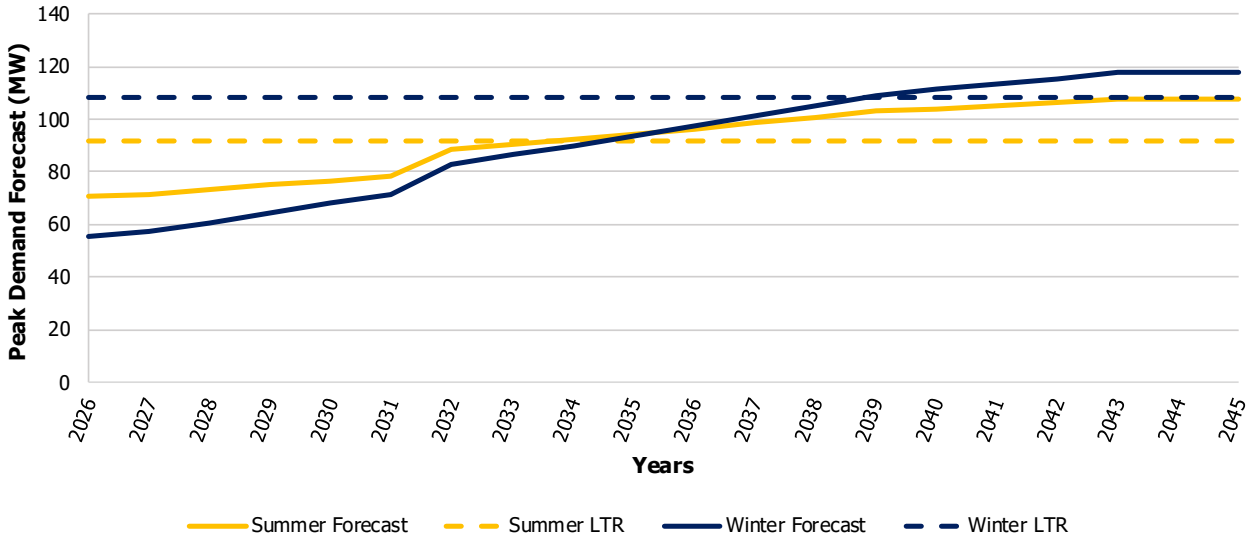
The station capacity needs of the stations in the 115 kV sub-system vary in need sizes and timing across the different planning scenarios and could be delayed as much as up to five years, or advanced by three years depending on the scenario.

6.3 MxD Sub-System

The MxD sub-system refers to the stations (primarily in Kitchener and Cambridge) that are served by the 230 kV Middleport to Detweiler circuits. In this sub-system, there are station capacity needs at Kitchener MTS #6, Kitchener MTS #8, Preston TS, GBE MTS #1, and Galt TS. There are also supply capacity, load security, and load restoration needs on the M21D/M22D circuits. The table below summarizes the needs for the MxD sub-system under the Planning Forecast.

Table 5 | Summary of MxD Sub-System Planning Needs

Need	Summer Need Date	Summer Need by 2045 (MW)	Winter Need Date	Winter Need by 2045 (MW)
Kitchener MTS #6 station capacity	2034	16	2039	10
Kitchener MTS #8 station capacity	2029	40	2030	81
Preston TS station capacity	See note below			
GBE MTS #1 station capacity	See note below			
Galt TS station capacity	See note below			
MxD supply capacity	Immediate	230	2032	202
MxD load security	2033	159	2033	210
MxD load restoration	Immediate	472	Immediate	471



Preston TS, GBE MTS #1, and Galt TS have been loaded up to their LTRs in all planning scenarios. The cumulative need of these stations is 7 MW in 2029, and it increases to 147 MW in the summer 2045 and 130 in winter 2045. As there is no capacity at Preston TS, GBE MTS #1, and Galt TS, this additional load will have to be sited at a different station – this is explained further in Section 7.2.2.

6.3.1 Station Capacity Needs

6.3.1.1 Kitchener MTS #6

Kitchener MTS #6 consists of two 230 kV/13.8 kV transformers with a summer LTR of 92 MW and a winter LTR of 108 MW. Kitchener MTS #6 has a station capacity need of 1 MW in summer 2034, which increases to 16 MW by summer 2045. Figure 22 shows the Kitchener MTS #6 demand forecast in relation to the summer and winter LTR values.

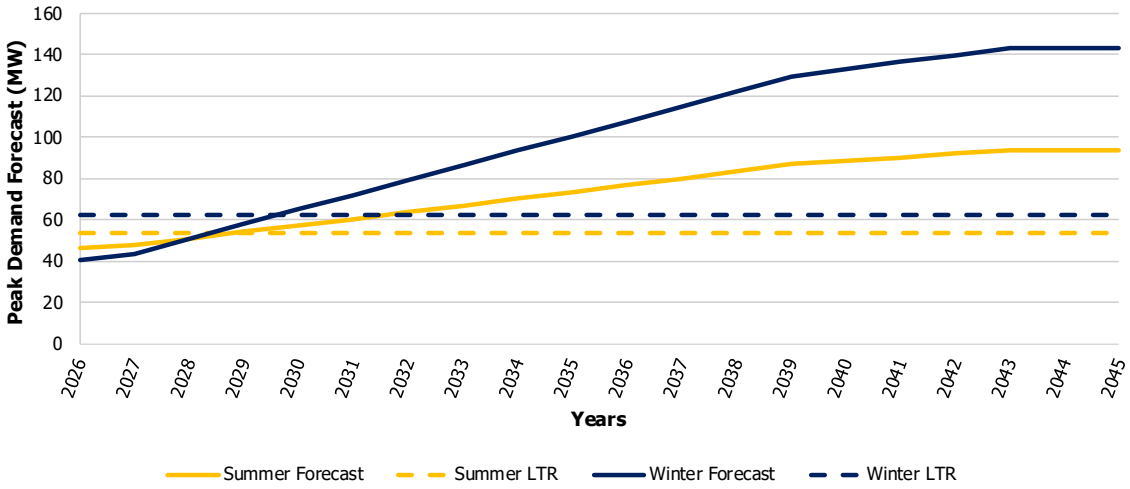


Figure 22 | Kitchener MTS #6 Station Capacity Need

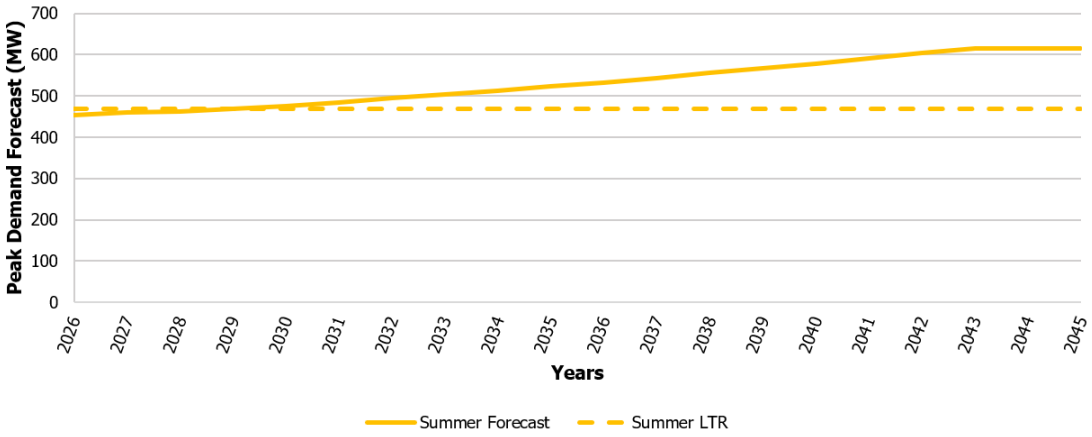
6.3.1.2 Kitchener MTS #8

Kitchener MTS #8 consists of two 230 kV/13.8 kV transformers with a summer LTR of 54 MW and a winter LTR of 62 MW. Kitchener MTS #8 has a station capacity need of under a megawatt in summer 2029, which increases to 81 MW by winter 2045. The figure below shows the Kitchener MTS #8 demand forecast in relation to the summer and winter LTR values.

Figure 23 | Kitchener MTS #8 Station Capacity Need

6.3.1.3 Preston TS, Galt TS, and GBE MTS #1



As noted with Table 5, Preston TS, GBE MTS #1, and Galt TS have been loaded up to their LTRs in all planning scenarios. Demand growth is expected to continue beyond the combined station capacity and will need to be sited at a future station (GBE MTS #2). Before a new station can be built, load will be managed between the existing MxD stations, which is described below.

- Preston TS consists of two 230 kV/27.6 kV transformers with a summer LTR of 190 MW and a winter LTR of 210 MW[3].
- Galt TS consists of two 230 kV/27.6 kV transformers with a summer LTR of 178 MW and a winter LTR of 201 MW.
- GBE MTS #1 consists of two 220 kV/27.6 kV transformers with a summer LTR of 102 MW and a winter LTR of 120 MW.

The figure below shows the cumulative Preston TS, Galt TS, and GBE MTS #1 station forecasts relative to their combined summer and winter LTR values. This highlights the outstanding station capacity need in this part of the sub-system.

[3] Upon completion of the ongoing Preston T3/T4 transformer replacement, new station LTR is expected to be in the range of 190 MW.

Figure 24 | Cumulative Preston TS, Galt TS, and GBE MTS #1 Station Capacity Needs[4]

6.3.2 Supply Capacity Need

The load in the MxD sub-system is supplied through 230 kV transmission lines between Galt junction and Detweiler TS, Preston TS, and Middleport TS. There is bulk supply at the 500/230 kV autotransformers at Middleport TS. Moreover, the MxD sub-system also connects to the KWCG region's 115 kV sub-system.

There are two distinct load groups in the MxD sub-system. One group consists of Preston TS, GBE MTS #1, Galt TS, and a CTS which are supplied by the MxD circuits between Galt junction and Preston TS. The second group consists of Kitchener MTS #6 and Kitchener MTS #8 which are supplied by the MxD circuits between Detweiler TS and Galt junction.

Load Supply Between Galt Junction and Preston TS

The load supply capacity between Galt junction and Preston TS is impacted by the loading between Detweiler TS and Galt junction. Accounting for expected Detweiler TS-Galt junction loading, the LMC between Galt TS and Preston TS is limited to 391 MW in the summer and 442 MW in the winter based on the thermal capability of the circuits between Preston TS and Galt junction under the various planning scenarios and applicable contingencies. Considering the forecast, this part of the sub-system has an immediate 17 MW summer supply capacity need which increases to 181 MW by summer 2045 and 129 MW by winter 2045.

Load Supply Between Galt Junction and Detweiler TS

The load supply capacity between Detweiler TS and Galt junction is impacted by loading between Galt TS and Preston TS. Accounting for expected Galt TS-Preston TS loading, the LMC of the sub-system between Detweiler TS and Galt junction is limited to 138 MW in the summer and 166 MW in the winter. This is due to the thermal capability of the BxC circuits in the 115 kV sub-system under the loss of D7V and M21D circuits; under these contingencies, flow through the BxC circuits from Burlington TS must increase to compensate for loss of supply from Detweiler TS. Considering the forecast, this part of the

[4] Winter forecast and LTR have been omitted as updates are required. Will be updated for the Regional Infrastructure Plan.

sub-system has a supply capacity need starting in summer 2032 with 3 MW, which increases to 49 MW by summer 2045 and 73 MW by winter 2045.

6.3.3 Load Security and Restoration Needs

As per ORTAC Section 2.4.10.1[5], no more than 150 MW is allowed to be interrupted by configuration following a single-element contingency, and no more than 600 MW by configuration following a two-element contingency. Over the forecast period, there is a load security need of 6 MW in 2033 which increases to 159 MW in summer 2045 and 210 MW by winter 2045 when there is a loss of both M20D and M21D circuits.

By the end of the study period, all forecast load (over 750 MW) on the MxD circuits would be interrupted following an outage to both circuits, M20D and M21D, by configuration. Of this load, Hydro One Transmission has indicated that approximately 100 MW Preston load, and the Kitchener MTS #6 and Kitchener MTS #8 load could be restored in a timely fashion through existing 230 kV in-line switches at Galt junction and Preston TS. Thus, the restoration targets of load in excess of 250 MW cannot be restored within 30 minutes, nor can the load in excess of 150 MW be restored within four hours. This is in violation of load restoration planning requirements (ORTAC Section 2.4.10.2) and is summarized below.

Table 6 | Load Restoration Planning Requirements on the MxD Supply Lines

Time Post-Contingency	ORTAC Requirement: Restoration Target	2045 Peak Load to be Restored	Achievable Based on the Current and Planned Transmission System?
Within 30 minutes	Load in excess of 250 MW	509 MW	No
Within four hours	Load in excess of 150 MW	609 MW	No, only 287 MW is achievable
Within eight hours	All load	759 MW	Exceeds 600 MW load security limits

6.3.4 Low and High Forecast Needs

Depending on the low or high forecast, the MxD supply capacity need ranges from 97 MW to 461 MW, but the timing is immediate regardless. This illustrates the urgency and magnitude of the supply need in this sub-system regardless of the forecast scenario. The timing and magnitude of load security and restoration needs would be adjusted similarly to the supply needs.

The station capacity needs at Kitchener MTS #6 and Kitchener MTS #8 could be delayed by up to 4 years, or advanced by 2 years depending on the forecast scenario.

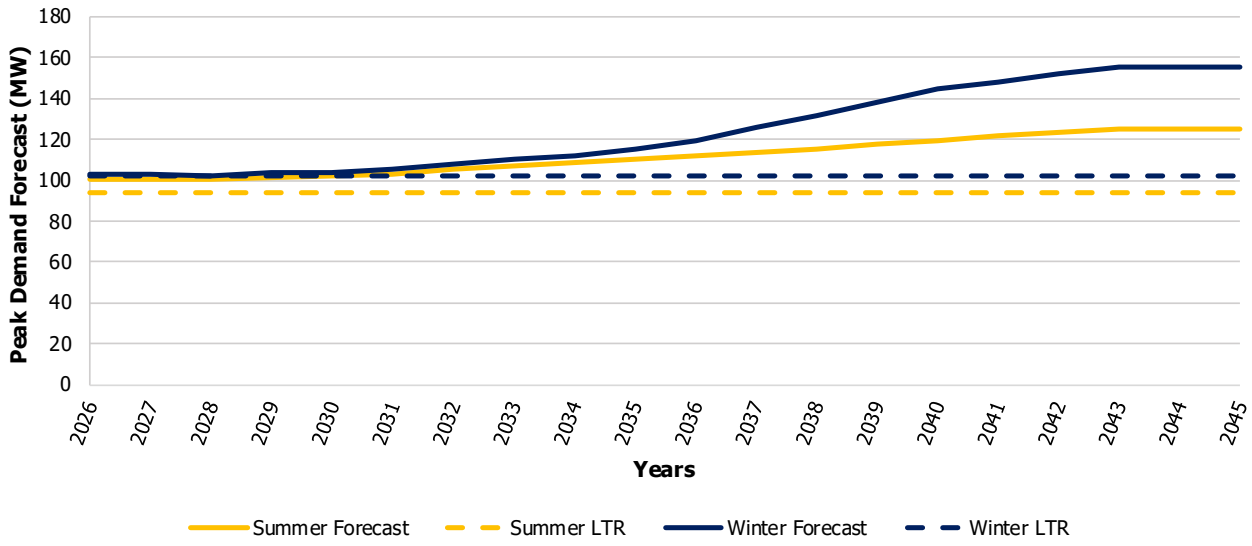
The cumulative need at Preston TS, GBE MTS #1, and Galt TS could be delayed by up to eight years, or advanced by two years depending on the forecast scenario.

[5] The assumption is that there is no load curtailment and rejection.

6.4 DxV Sub-System

The DxV sub-system refers to the stations in Waterloo, Centre Wellington, and Guelph that are served by the double-circuit 230 kV DxV lines. There are multiple forecast station capacity needs. There are also supply capacity, load restoration, and load security needs affecting the overall DxV sub-system; the LMC is limited to 350 MW based on the thermal capability of the circuits between Detweiler TS and Waterloo North MTS #3. DxV supply can also be limited depending on other scenarios and applicable contingencies; its LMC is interdependent with the load on the DxW sub-system. Table 7 summarizes the needs for the DxV sub-system under the Planning Forecast.

Table 7 | Summary of DxV Sub-System Planning Summer Needs



Need	Summer Need Date	Summer Need by 2045 (MW)	Winter Need Date	Winter Need by 2045 (MW)
Campbell TS T1/T2 station capacity	Immediate	31	Immediate	54
Campbell TS T3/T4 station capacity	Immediate	17	2035	22
Scheifele MTS station capacity	2028	144	2029	185
Waterloo MTS #3 station capacity	Immediate	254	2028	243
DxV supply capacity	Immediate	574	Immediate	640
DxV load security	2030	324	2030	435
DxV load restoration	Immediate	663	Immediate	774

6.4.1 Station Capacity Needs

6.4.1.1 Campbell TS T1/T2

Campbell TS T1/T2 consists of two 230 kV/13.8 kV transformers with a summer LTR of 93 MW and a winter LTR of 101 MW. It has an immediate summer station capacity need, growing to a 54 MW need in the winter of 2045. The figure below shows the Campbell TS T1/T2 demand forecast in relation to the summer and winter LTR values.

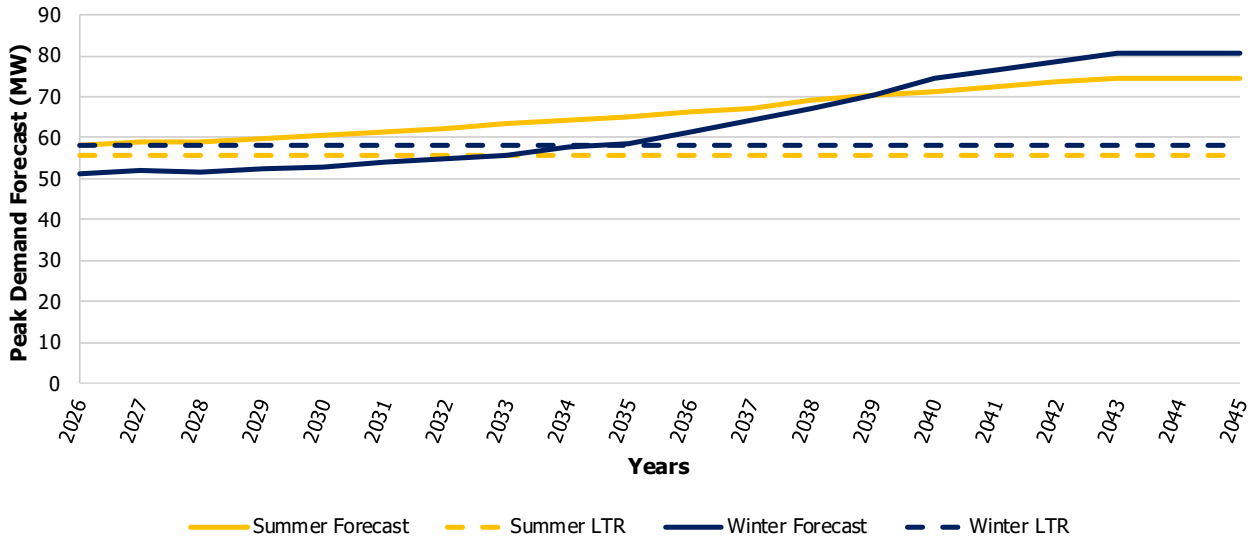


Figure 25 | Campbell TS T1/T2 Station Capacity Need

6.4.1.2 Campbell TS T3/T4

Campbell TS T3/T4 consists of two 230 kV/13.8 kV transformers with a summer LTR of 56 MW and a winter LTR of 58 MW. It has an immediate summer station capacity need, growing to a 22 MW need in the winter of 2045. Figure 26 shows the Campbell TS T3/T4 demand forecast in relation to the summer and winter LTR values.

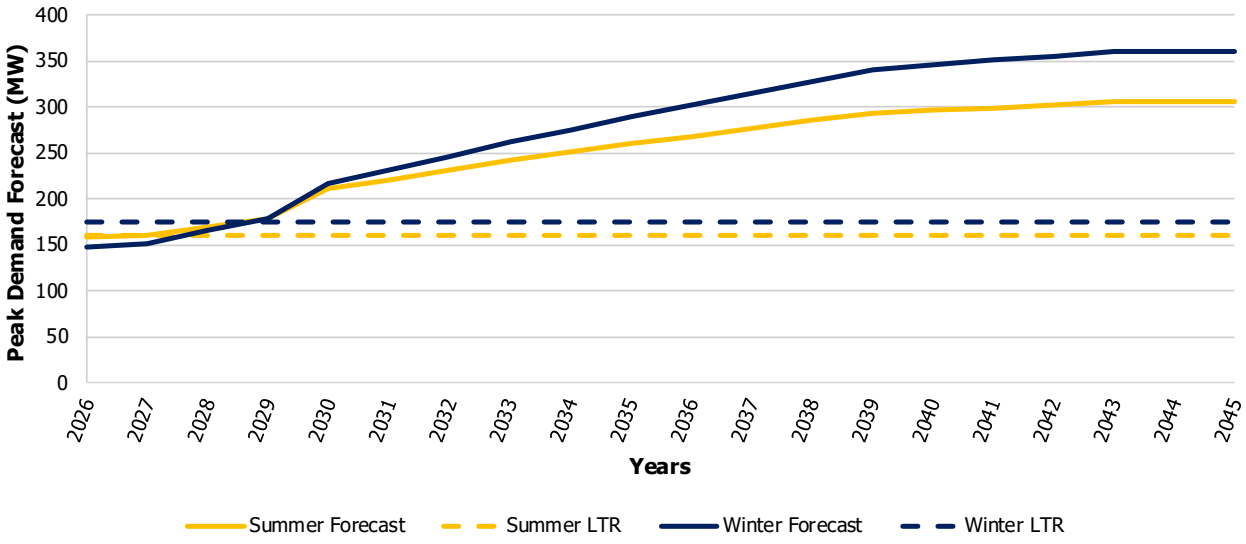

Figure 26 | Campbell TS T3/T4 Station Capacity Need

6.4.1.3 Scheifele MTS

Scheifele MTS consists of four 230kV/13.8kV transformers with a summer LTR of 161 MW and a winter LTR of 175. It is forecast to have a summer station capacity need starting in 2028, growing to a 185 MW need in the winter of 2045.

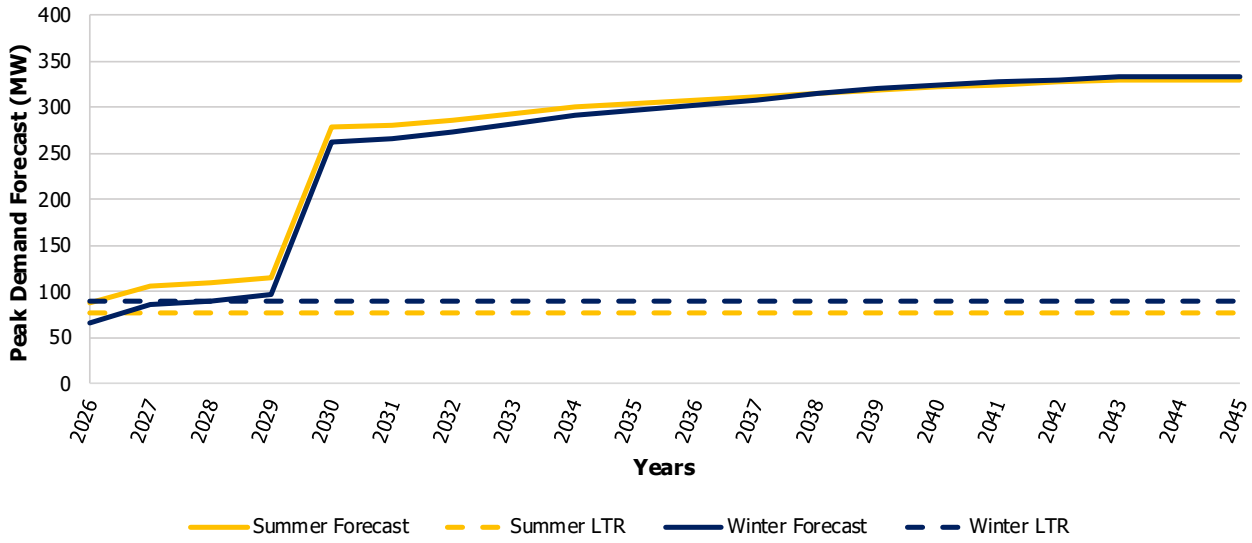

Figure 27 | Scheifele MTS Station Capacity Need

6.4.1.4 Waterloo North MTS #3

Waterloo North MTS #3 consists of two 230 kV/27.6 kV transformers with a summer LTR of 76 MW and a winter LTR of 90 MW. It is forecast to have a summer station capacity need starting in 2026, growing to a 254 MW need in the summer of 2045.

Figure 28 | Waterloo North MTS #3 Station Capacity Need

6.4.2 Supply Capacity Need

The 230 kV DxV transmission lines connect from Detweiler TS in Kitchener to Fergus TS in Centre Wellington, to Cedar TS in Guelph. The sub-system does not have any local transmission-connected generation. The LMC is limited to 350 MW in the summer and 395 MW in the winter, and it is based

on the thermal capability of the circuits between Detweiler TS and Waterloo North MTS #3.[6] Considering the forecast growth in the sub-system, there is an immediate supply capacity need in both summer and winter that increases to 574 MW by summer of 2045 and 640 MW in the winter.

6.4.3 Load Security and Restoration Needs

As per ORTAC Section 2.4.10.1, no more than 150 MW is allowed to be interrupted by configuration following a single-element contingency, and no more than 600 MW by configuration following a two-element contingency. Over the forecast period, there is a load security need of 129 MW in 2030 which increases to 324 MW in summer 2045 and 435 MW by winter 2045 when there is a loss of both D6V and D7V circuits.

By the end of the study period, all forecast load (more than 900 MW) on the DxV circuits would be interrupted following an outage to both circuits, D6V and D7V, by configuration. Of this load, Hydro One Transmission has indicated that only approximately 260 MW of the load could be restored in a timely fashion through existing 230 kV in-line switches. Thus, the restoration targets of load in excess of 250 MW cannot be restored within 30 minutes, nor can the load in excess of 150 MW be restored within four hours. This is in violation of load restoration planning requirements (ORTAC Section 2.4.10.2) and is summarized in Table 8.

Table 8 | Load Restoration Planning Requirements on the DxV Lines

Time Post-Contingency	ORTAC Requirement: Restoration Target	2045 Peak Load to be Restored	Achievable Based on the Current and Planned Transmission System?
Within 30 minutes	Load in excess of 250 MW	676 MW	No
Within four hours	Load in excess of 150 MW	776 MW	No, only 260 MW is achievable
Within eight hours	All load	926 MW	Exceeds 600 MW load security limits

6.4.4 Low and High Forecast Needs

Depending on the low or high forecast, the DxV supply capacity need ranges from 403 MW to 801 MW, and the timing is immediate regardless. This illustrates the urgency and magnitude of the supply need in this sub-system regardless of the forecast scenario. The timing and magnitude of load security and restoration needs would be adjusted similarly to the supply needs.

The station capacity needs at Campbell TS, Scheifele MTS, and Waterloo North MTS #3 could be delayed by up to one year, or advanced by two years depending on the forecast scenario.

[6] This is based on the simultaneous forecast loading on the DxW sub-system, since the LMCs for the DxW and DxV sub-systems are interdependent.

6.5 DxW Sub-System

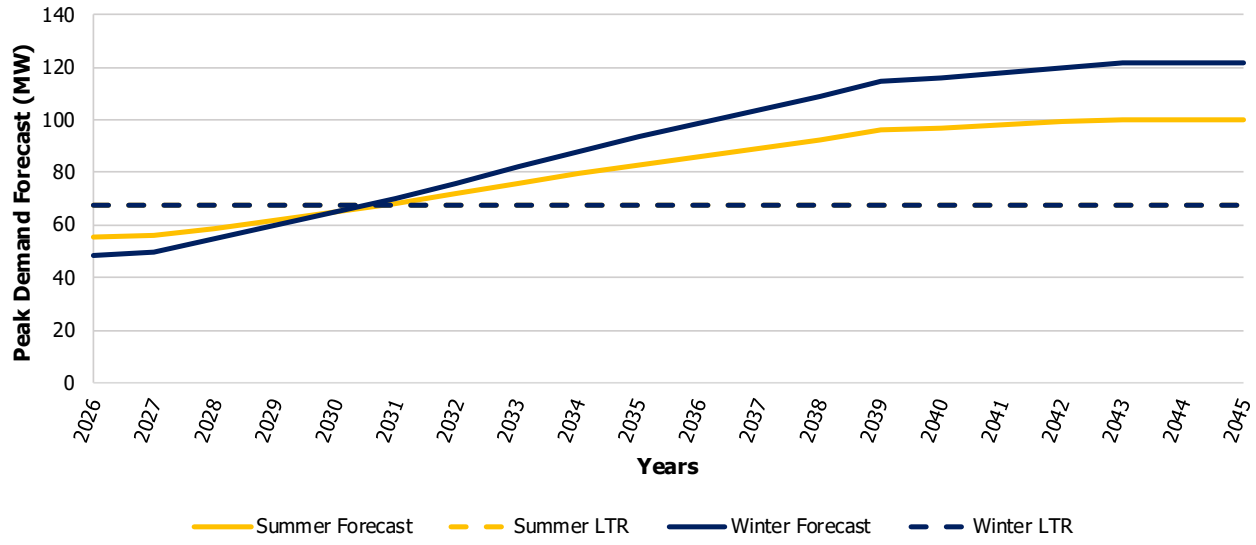
The 230 kV DxW transmission lines supply Detweiler TS from Buchanan TS in London and includes no local transmission-connected generation. The LMC of the DxW sub-system is interdependent with the LMC of the DxV subsystem; it also is impacted by assumed loading at Preston TS. With a total of approximately 400 MW at Preston, GBE MTS#1 and Galt TS, and with the load on the DxV circuits at the maximum limit (350 MW, as described in Section 6.4.2), DxW supply is limited to 100 MW. This is due to voltage violations at Preston TS or GBE MTS#1 TS after contingencies resulting in the loss of an MxD circuit and the static VAR compensator or a shunt capacitor at Detweiler TS. Increased loading between Preston TS and Galt TS degrades the DxV and DxW LMCs further on the existing system – in fact, additional load on the MxD and 115 kV sub-systems generally can reduce DxV and DxW supply.

There is no direct need on the DxW transmission lines if only accounting for the Kitchener MTS #9 forecast. However, as described above, the DxW LMC depends on the DxV sub-system loading. This is described further in Section 7.2.3.

6.6 D8S/D10H Sub-System

The D8S-D10H sub-system refers to the stations within the KWCG region that are served by the Detweiler-Seaforth (D8S) and Detweiler-Hanover (D10H) circuits. There is a station capacity need at Rush MTS and a supply capacity need on the D8S-D10H circuits transmission circuits, which are 115 kV circuits from Detweiler TS towards Seaforth TS and Hanover TS. Table 9 summarizes the needs for the D8S/D10H sub-system under the Planning Forecast.

Table 9 | Summary of D8S/D10H Sub-System Planning Needs



Need	Summer Need Date	Summer Need by 2045 (MW)	Winter Need Date	Winter Need by 2045 (MW)
Rush MTS station capacity	2031	33	2031	54
D8S-D10H supply capacity	2033	26	2037	19

6.6.1 Station Capacity Needs

6.6.1.1 Rush MTS

Rush MTS consists of two 115 kV/13.8 kV transformers with an LTR of 68 MW. Rush MTS has a station capacity need of 3 MW in winter 2031, which increases to 54 MW by winter 2045. Figure 29 shows the Rush MTS demand forecast in relation to the summer and winter LTR values.

Figure 29 | Rush MTS Station Capacity Need

6.6.2 Supply Capacity Need

The load in the D8S-D10H sub-system is supplied through 115 kV transmission lines between Detweiler TS, Seaforth TS, and Hanover TS. The 230/115 kV autotransformers at Detweiler TS supply the D8S-D10H sub-system. The LMC of the sub-system is limited to 120 MW in the summer and 144 MW in the winter based on the thermal capability of the circuits between Detweiler TS, Leong junction, and Waterloo junction. Considering the forecast growth in the area, this sub-system has a 2 MW supply capacity need starting in 2033 that increases to 26 MW by 2045.

6.6.3 Low and High Forecast Needs

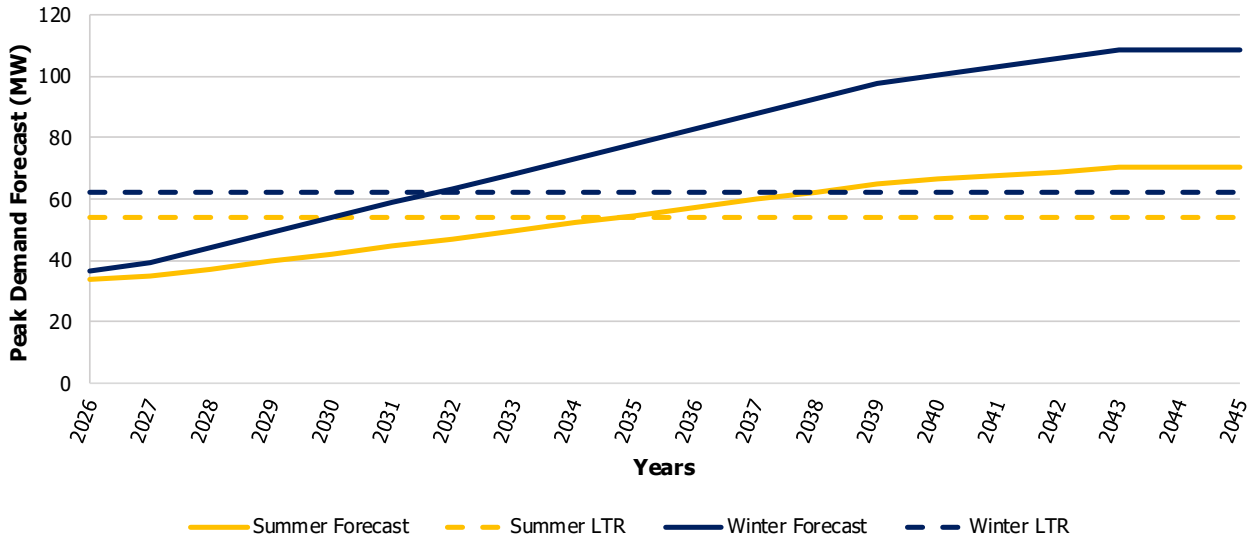
Depending on the low or high forecast, the D8S-D10H supply capacity need ranges from 2 MW to 47 MW, and timing ranges from 2030 to 2041. This suggests that the need is sensitive to different forecast scenarios and growth should be closely monitored.

The station capacity need at Rush MTS could be delayed by five years, or advanced by one year depending on the forecast scenario.

6.7 DxK Sub-System

The DxK sub-system refers to Kitchener MTS #1 and Kitchener MTS #4 and their radial double-circuit 115 kV supply from the Detweiler-Kitchener transmission circuits. There are station capacity needs at Kitchener MTS #1 and #4, and a supply capacity need on the DxK circuits. Table 10 summarizes the needs for the DxK sub-system under the Planning Forecast.

Table 10 | Summary of DxK Sub-System Planning Summer Needs



Need	Summer Need Date	Summer Need by 2045 (MW)	Winter Need Date	Winter Need by 2045 (MW)
Kitchener MTS #1	2035	16	2032	46
Kitchener MTS #4	2035	19	2032	50
DxK supply capacity	2033	42	2031	96

6.7.1 Station Capacity Needs

6.7.1.1 Kitchener MTS #1

Kitchener MTS #1 consists of two 115 kV/13.8 kV transformers with a summer LTR of 54 MW and a winter LTR of 62 MW. Kitchener MTS #1 has a station capacity need of 1 MW in winter 2032, which increases to 46 MW by winter 2045. Figure 30 shows the Kitchener MTS #1 demand forecast in relation to the summer and winter LTR values.

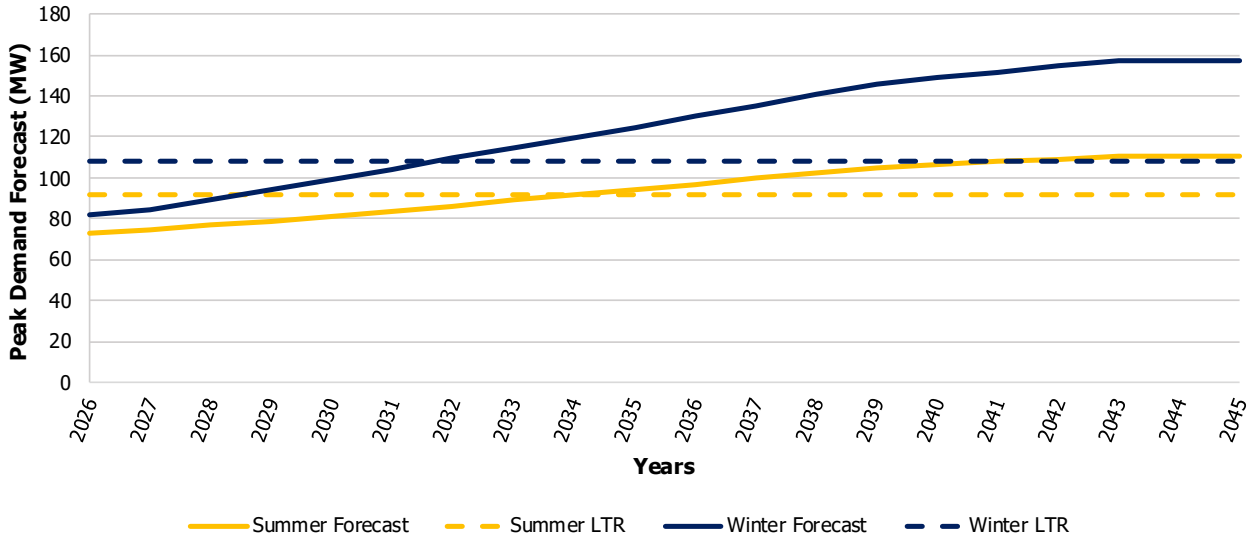


Figure 30 | Kitchener MTS #1 Station Capacity Need

6.7.1.2 Kitchener MTS #4

Kitchener MTS #1 consists of two 115 kV/13.8 kV transformers with a summer LTR of 92 MW and a winter LTR of 108 MW. Kitchener MTS #4 has a station capacity need of 1 MW in winter 2032, which increases to 50 MW by winter 2045. Figure 31 shows the Kitchener MTS #4 demand forecast in relation to the summer and winter LTR values.

Figure 31 | Kitchener MTS #4 Station Capacity Need

6.7.2 Supply Capacity Need

The load in the DxK sub-system is supplied through radial 115 kV transmission lines from the Detweiler TS 115 kV bus. The LMC of the sub-system is limited to 127 MW in the summer and 148 MW in the winter based on the thermal capability of the circuits between Detweiler TS, Kitchener MTS #1, and Kitchener MTS #4. Considering the forecast growth in the area, this sub-system has a 1 MW supply capacity need starting in 2031 which increases to 96 MW in 2045.

6.7.3 Low and High Forecast Needs

Depending on the low or high forecast, the DxK supply capacity need ranges from 79 MW to 117 MW, and timing ranges from 2031 to 2032. This illustrates the magnitude and firmness of the supply need in this sub-system regardless of the forecast scenario.

The station capacity needs at Kitchener MTS #1 and Kitchener MTS #4 could be either delayed or advanced by one year depending on the forecast scenario.

6.8 Operability and Operational Issues

Operational issues are not defined as planning needs. However, if they affect the reliability of the region, the Technical Working Group may consider opportunities to address operational issues while addressing planning needs.

Operational issues that impact reliability were identified for the KWCG region; they are driven by the switchyard/breaker configuration at Detweiler TS. Detweiler TS is a major supply point for the region and these operational issues have significant impact on potential LMCs.

With the existing Detweiler switchyard configuration, the Detweiler static VAR compensator or capacitors may cause damaging ferroresonance oscillations or high voltages under certain forced or planned outage conditions – for example, a bus fault if followed by specific secondary forced outages. To protect equipment from damage, Hydro One has operating procedures to manually remove the

Detweiler static VAR compensator or capacitors from service under these outage conditions before the secondary forced outages occur.

If these operating restrictions are executed, there are post-outage instances in which up to six elements at Detweiler TS, including both capacitors and the static VAR compensator, would be lost. This can significantly reduce the supply capability for the region.

As the Technical Working Group explores solutions to eliminate the need for these operating procedures (such as protection schemes and/or reconfiguring the Detweiler TS switchyard), their impact on the reported LMCs was ignored. This is described further in Section 7.2.3.

6.9 Bulk Supply into KWCG

The focus of regional planning is to ensure reliable supply within a region. Supply into the region is out of scope, but it is studied in the South and Central Bulk Plan, which was developed in parallel with the KWCG IRRP. This bulk plan includes:

- Identifying/confirming the transmission required to enable the connection of future bulk generation resources.
- Exploring the transmission required to enable decreased reliance on emitting resources.
- Determining transmission required to enable reliable supply under high economic growth/ electrification scenarios, including the connection of new large loads and data centres in the Greater Toronto Area and the Hamilton to Windsor corridor.
- Identifying opportunities to assess and preserve potential new or expanded corridors for future electricity infrastructure.

7. Plan Options and Recommendations

This section describes the options considered and recommendations to address the needs in the KWCG region. When developing the plan, the Technical Working Group considered a range of integrated options. Considerations in assessing alternatives included maximizing use of existing infrastructure, provincial electricity policy, federal regulations, technical feasibility, cost effectiveness, lead time, local preferences, and consistency with longer-term needs in the area.

There are generally two approaches to address regional needs:

- Build new transmission or distribution infrastructure. These are commonly referred to as wire options and can include things like new transmission lines, autotransformers, step-down transformer stations, voltage control devices, upgrades to existing infrastructure, or distribution-level load transfers. Wire options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate certain reliability concerns.
- Install or implement measures to reduce the net peak demand to maintain loading within the system's existing capability. These are commonly referred to as non-wire alternatives (NWAs) and can include things like local utility-scale generation or storage, distributed energy resources (including distribution-connected generation and demand response), or additional eDSM.

Section 7.1 provides a more in-depth overview of the NWA considerations in this IRRP. Subsequently, Section 7.2 presents the options that were ultimately developed and evaluated (including a cost comparison) before the Technical Working Group made a recommendation.

7.1 Non-Wires Analysis Process in IRRPs

Wires options are always considered in regional planning, and while they are always viable options for regional needs, NWAs may be more suitable for specific need types and characteristics. To select and appropriately size NWAs like generation or battery storage, additional work is required — including the creation of an hourly load profile, as described in Section 5.8. The most suitable technology type and capacity is chosen by examining the unserved energy profile, which is the hourly demand above the existing station or system capability The profile indicates the duration, frequency, magnitude, and total energy associated with each need. More details on the NWA process and analysis are provided in appendix.

7.1.1 Approach to Needs Screening

NWAs are suitable for specific types of needs, as described in the Integrated Regional Resource Plans: Guide to Assessing Non-Wires Alternatives. An initial screening step is performed to identify which NWAs may be suitable for the type of need addressed.

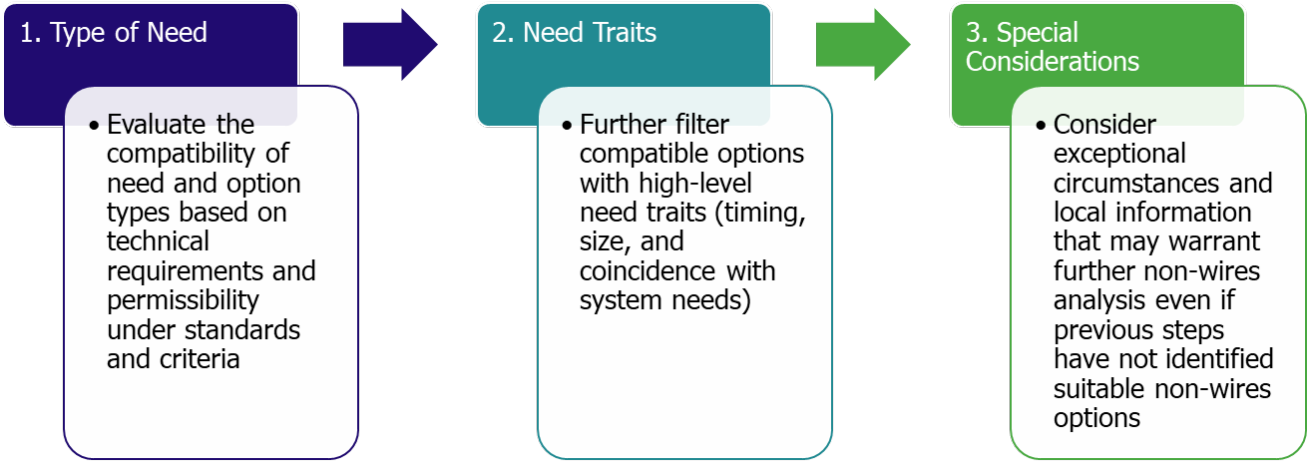
High-level cost estimates for wire options are based on input provided by the transmitter and transmission benchmark costs. Similarly, cost estimates for non-wire options are based on benchmark capital and operating cost characteristics for each resource type and size. The complete list of assumptions used in the needs screening and options analysis is provided in the appendix.

The IESO is mandated to centrally deliver province-wide eDSM programs for Ontario that target businesses, residential customers, and First Nations. The IESO offers incentives and rebates to electricity customers through a suite of Save On Energy programs, which provide a valuable and cost-effective system resource that helps customers better manage their energy costs. Demand savings from centrally-delivered energy efficiency programs under the 2021–2024 Conservation and Demand Management Framework and Save on Energy brand are already included in the load forecast, as discussed in Section 5.5. This forecast assumed the programming continues through the forecast period at levels consistent with the 2021-2024 CDM Framework.

Additional eDSM above and beyond that included in the demand forecast can also play a key role in maximizing the useful life of existing infrastructure and maintaining reliable supply. Results from the IESO's latest (2022) provincial energy efficiency Achievable Potential Study inform estimates of the additional peak demand savings potential available from eDSM programming, and the cost to acquire those peak demand savings.

The new 2025-2036 eDSM Framework provides the IESO with a twelve-year mandate and $10.9B budget ceiling to expand and enhance eDSM programming. Higher provincial savings targets under the new framework relative to the 2021-2024 CDM Framework may contribute to delivering additional eDSM recommended to address specific regional needs. The new framework also establishes new mechanisms for IESO and Local Distribution Company eDSM collaboration, including specific funding for LDC-delivered programming that provides both local and regional or provincial benefits.

Generally, additional eDSM programming is suitable for needs where growth is slow and the magnitude of the overload relative to the total demand is very small (i.e., on the order of few per cent per year). These considerations are discussed further in Section 7.1.2. LDCs can also use the Ontario Energy Board's Non-Wires Solutions Guidelines for Electricity Distributors to leverage distribution rates to help address distribution and transmission system needs using NWAs. In some cases, NWAs can help manage needs in the interim before wires reinforcements are in-service.



Where NWAs are screened in and determined to be feasible, the upfront capital and operating costs for both wire options and NWAs are compiled to generate levelized annual capacity costs (measured in dollars per kW per year). In this scenario, the cash flow of the levelized costs for the options are compared over the lifespan of the wire option and the net present value of these levelized costs is the primary basis through which feasible options are compared. Where NWAs are screened out or determined to be infeasible for meeting the need, overnight capital costs for wire options are used instead.

NWAs are subject to uncertainties in the procurement in terms of both the resource costs bid my proponents and the overall success of the procurement. Moreover, it is important to recognize that there is a significant uncertainty around cost estimates at the planning stage (from minus 50 per cent on the low side to plus 100 per cent on the high side), as they are only intended to enable comparison between options during the IRRP. The transmitter-led Regional Infrastructure Plan (which is conducted after the IRRP) performs additional detailed analysis and allows the opportunity to refine cost estimates of wire options before implementation work begins. The IESO continues to participate in the Technical Working Group during the Regional Infrastructure Plan and revisits these recommendations if cost estimates differ significantly.

7.1.2 Non-Wires Screening Results

Screening occurs early in the IRRP development – after local reliability needs are known but before options analysis. It helps direct time-intensive aspects of detailed NWA analysis (hourly need characterization, options development, financial analysis, and engagement) toward the most promising options. The three-step, high-level approach is shown in Figure 32.

Figure 32 | IRRP Screening Mechanism

The results of applying the screening mechanism to the KWCG IRRP needs are summarized and described in the sections below. More details on the steps and inputs used in the screening mechanism can be found in the appendix. The list of assumptions made in the needs screening and option analysis can also be found in the appendix.

Table 11 | Results of the KWCG IRRP Screening

Sub-System	Need	Options Screened In	Options Screened Out[7]
Middleport to Detweiler, MxD	Station capacity, supply capacity, load restoration and security	Additional eDSM DG Demand response Transmission-connected generation Wires	
115 kV	Station capacity and supply capacity	Additional eDSM Demand response DG Wires	Transmission-connected generation

[7] Since the IESO is mandated to centrally deliver provincial eDSM programs, the incremental eDSM potential is estimated for each need regardless of its ability to meet the need.

Sub-System	Need	Options Screened In	Options Screened Out[7]
Detweiler to Orangeville, DxV	Station capacity, supply capacity, load restoration and security	Additional eDSM Wires	DG Demand response Transmission-connected generation
Detweiler towards Elmira, D8S/D10H	Station capacity and supply capacity	Additional eDSM Wires	Transmission-connected generation
Detweiler to Kitchener MTS #1 and #4, DxK	Station capacity and supply capacity	Additional eDSM DG Demand response Transmission-connected generation Wires	

7.2 Options Evaluation and Recommendations

7.2.1 115 kV Sub-System

Options for Station Capacity Needs

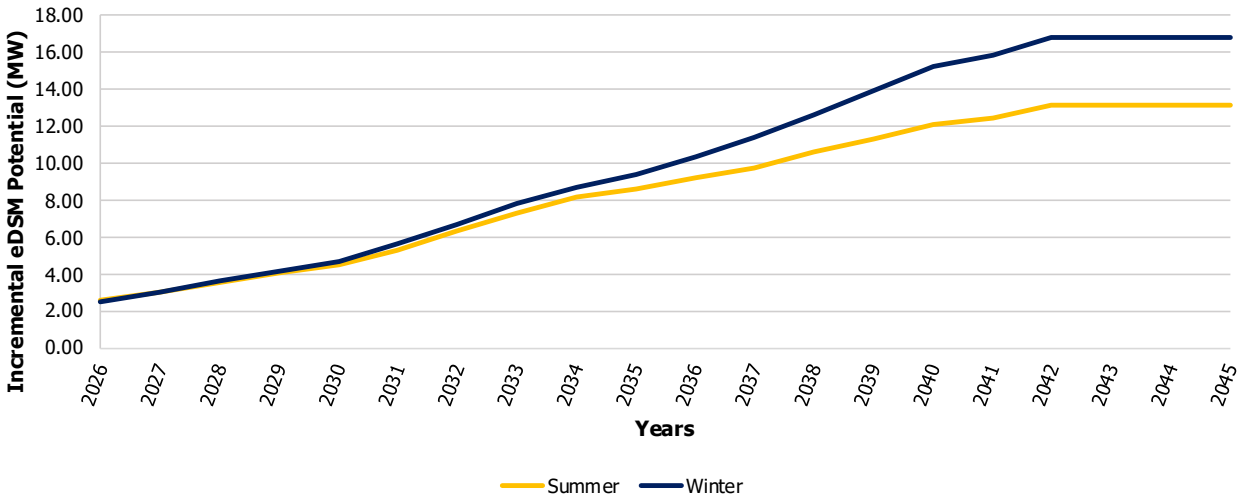
Arlen TS and Hanlon TS

With station capacity needs arising in the long term (more than 10 years out), options for Arlen TS and Hanlon TS are not required currently. This is applicable even under the high forecast scenario. However, the Technical Working Group can continue to monitor load growth the Guelph area and re-assess these station capacity needs in the next cycle of regional planning.

Cedar TS

Additional eDSM programs could meet 19 MW of the 38 MW summer station capacity need in 2045, as illustrated below. The estimated cost of achieving these eDSM savings is $58 million, which is considered cost effective for provincial adequacy needs.

Figure 33 | Estimated Incremental eDSM Potential for Cedar T1/T2



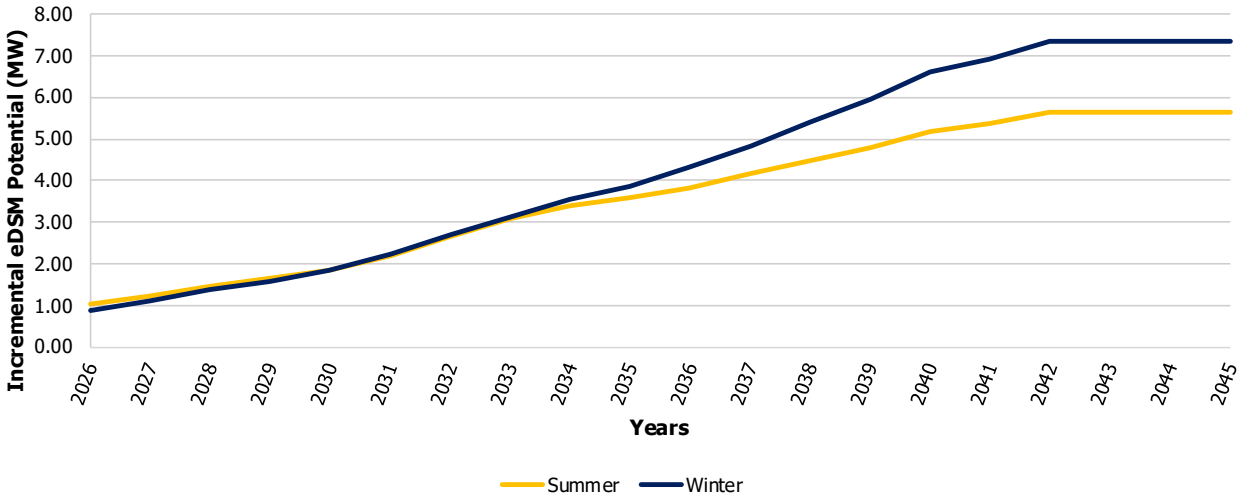


Figure 34 | Estimated Incremental eDSM Potential for Cedar T7/T8

For the end-of-life need at Cedar T7/T8 in 2032, only wires options were considered:

1. Like-for-like 115 kV transformer replacement ($20 million, three-years lead time);
2. Upsized 115 kV transformer replacement ($55 million, four-years lead time)[8]; or
3. Voltage conversion of existing 115 kV DESN to a new 230 kV DESN ($60M, four-years lead time).

Option 1 addresses the end-of-life need and increases the LTR to 58 MVA (52 MW), which does not meet the T7/T8 station capacity need in the long term. Options 2 and 3 provide more station capacity, with both offering an LTR of 140 MVA (126 MW). This not only accommodates the capacity need at T7/T8 but can address the capacity need at T1/T2 if load is transferred on the distribution system.

Option 3 offers an additional benefit to offload the constrained 115 kV sub-system. 230 kV supply to a new 230 kV Cedar T7/T8 is enabled by the DxV sub-system recommendations (see Section 7.2.3); in

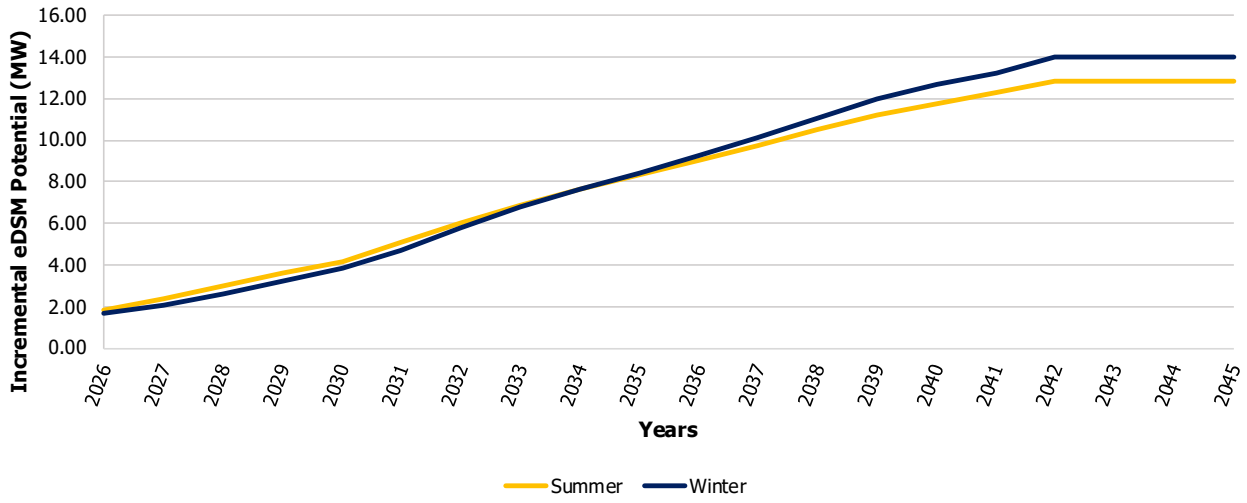
[8] Assumes new transformers and second metal-clad switchgear.

contrast, option 2 is not feasible without further 115 kV sub-system reinforcements — beyond those described later in this in section.

Kitchener MTS #5 and #7

Additional eDSM programs could meet 13 MW of the Kitchener MTS #5's summer station capacity need of 10 MW in 2035 and 7 MW of MTS #7's summer station capacity need of 12 MW in 2035, as illustrated in Figure 38. The estimated cost of achieving these eDSM savings is $72.7 million, which is considered cost effective for provincial adequacy needs.

Figure 35 | Estimated Incremental eDSM Potential for Kitchener MTS #5



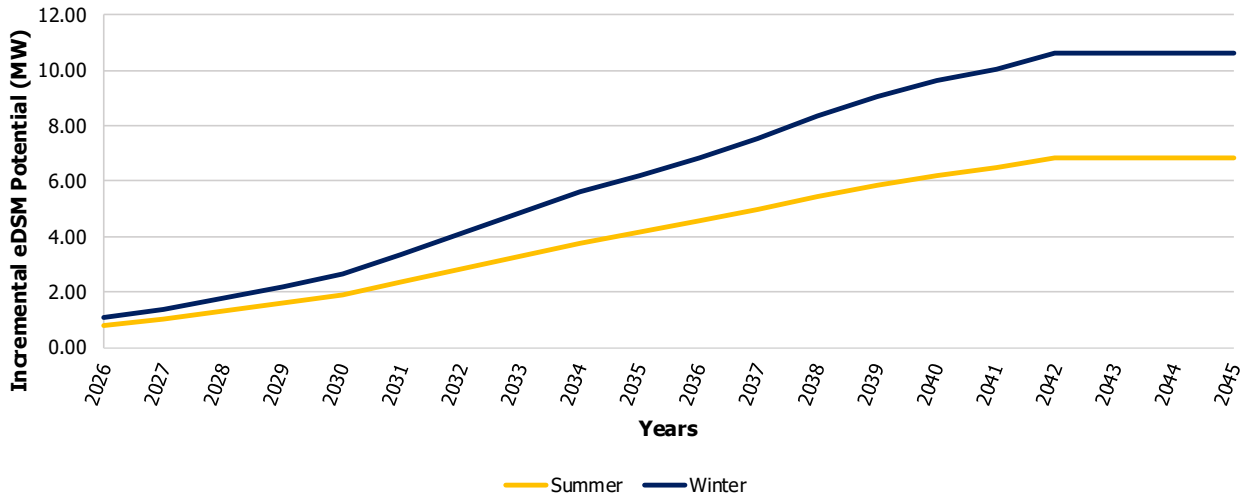


Figure 36 | Estimated Incremental eDSM Potential for Kitchener MTS #7

Given the nearer term need at Kitchener MTS #7, other non-wires options were evaluated:

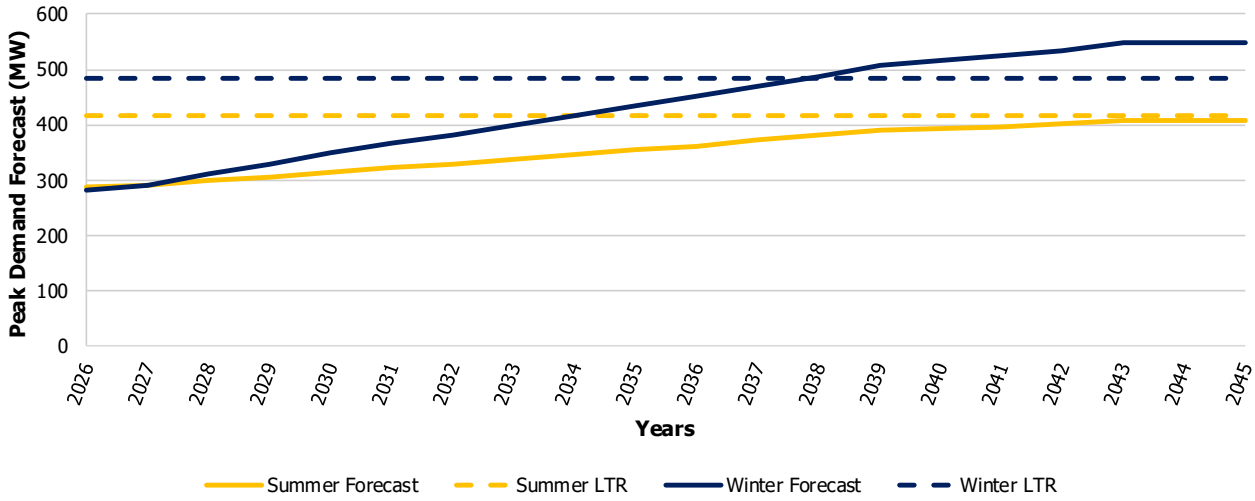
1. DG; and
2. demand response.

By 2045, the need profile for Kitchener MTS #7 net of additional eDSM peaks at 32 MW, lasts up to 90 consecutive hours, and sums to approximately 40,000 MWh of energy. The need also occurs primarily in the winter. Based on these need characteristics, the following options were screened in:

- wind;
- BESS;
- combined wind and BESS;
- combined wind and solar;
- combined solar and BESS;
- combined solar, wind, and BESS; and
- demand response.

Solar as a standalone option was screened out due to the winter need, and small modular reactors were screened out since the need size does not warrant this type of technology. Natural gas was screened out to focus the analysis on options that reduce reliance on emitting resources. This complements the municipal preferences of the city of Kitchener.

Among the screened-in generation options, none were feasible either because of the need profile and size, and/or the available DG connection capacity at the station. For the latter, consideration was given to Enova Power undertaking feeder breaker and switchgear replacement work to increase the short circuit rating by 20 per cent. Even if ignoring DG connection capacity, feasible options would have a land requirement (like wind and BESS, at an estimated total of 15 km^2) that can be difficult to accommodate near Kitchener MTS #7.



For the station capacity needs at Kitchener MTS #5 and #7, the following wires options were evaluated:

1. load transfers on the distribution system starting in 2032[9]; and
2. new station in Kitchener.

Option 1 is to leverage capacity on the existing transmission system to transfer and optimize load between the 115 kV Kitchener stations (both in the 115 kV sub-system and in the DxK sub-system). Currently, Kitchener MTS #5 has ties with MTS #1, #4, and #7; MTS #7 has ties with MTS #3 and #5. There is sufficient station capacity for the 115 kV Kitchener stations until 2039 (including those served by the DxK sub-system), assuming distribution-level load transfers to enable the optimal load reallocation are possible. Each new distribution tie is estimated to cost $500,000.

[9] Could be delayed depending on the amount of additional eDSM savings are achieved.

Figure 37 | Cumulative Station Capacity Needs at 115 kV Kitchener Stations[10]

Option 2 can be considered alongside option 1 for an integrated solution. Option 2 involves a new station sited in Kitchener in the Freeport area to provide enough station capacity (at least 70 MW) for the cumulative station needs at Kitchener MTS #1, 4, and 7. It would be required starting in 2039 if distribution load transfer capability allows all existing station capacity to be utilized, but could also be later depending on additional eDSM savings. If the new station is connected to the 230 kV system, options include:

- A 6.5 km, 230 kV double-circuit line extension from Kitchener MTS #6 to Kitchener MTS #7, where:
  - MTS #7 is converted to 230 kV ($2-5 million); or
  - a new 230 kV station is built on its existing property ($30-45 million).

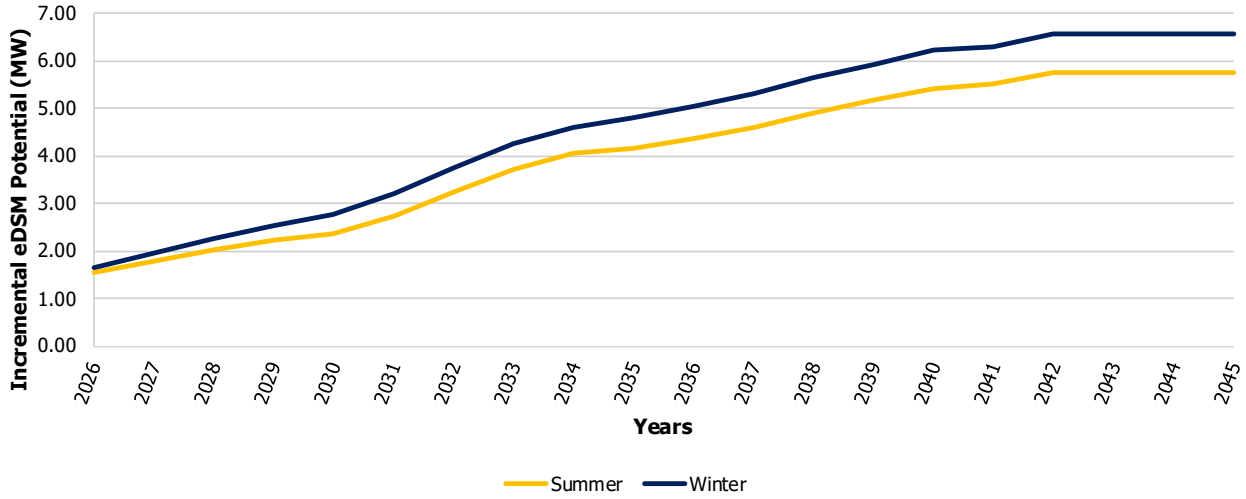
About 1.3 km of the 230 kV line extension may utilize the existing underground duct bank and cost $30 million; the remaining overhead line is expected to cost $44 million. It is also possible for the new 230 kV double-circuit line extension to come from Preston TS to the Kitchener Freeport area.

Alternatively, new station capacity in Kitchener could be added at the 115 kV level. Given the 115 kV sub-system limitations described in Section 6.2, this can occur in two ways:

- reinforcements to the 115 kV sub-system beyond the circuit upgrades recommended in later this this section; or
- long-term offloading of the 115 kV sub-system through a 230 kV line extension from Preston TS to a converted GrandBridge Energy MTS #2 (also described in Section 7.2.2).

Puslinch DS

The following non-wires options were evaluated for the station capacity need at Puslinch DS:



1. Additional eDSM;
2. DG; and

[10] Graph includes Kitchener MTS #1, 3, 4, 5, and 7.

3. demand response.

Additional eDSM programs could meet 6 MW of the 13 MW summer station capacity need in 2035. The estimated cost of achieving these eDSM savings is $15.6M, which is cost-effective for provincial adequacy needs.

Figure 38 | Estimated Incremental eDSM Potential for Puslinch DS

By 2045, the need profile for Puslinch DS peaks at 13 MW, lasts up to 17 consecutive hours, and sums to approximately 2,500 MWh of energy. Based on these need characteristics, the following non-wires options were screened in:

- solar;
- BESS;
- combined solar and BESS;
- combined solar, wind, and BESS;
- demand response; and
- natural gas.

Wind as a standalone option and wind with BESS were screened out due to the need primarily occurring during summer daylight hours, and small modular reactors were screened out since the need size does not warrant this type of technology.

Among the screened-in DG options, only two could meet the need profile into the long term:

- 12 MW of solar and 8 MW/47 MWh of BESS[11] deployed between 2030 and 2042; or
- 13 MW of natural gas.[12]

[11] Could meet the reference need until 2042.

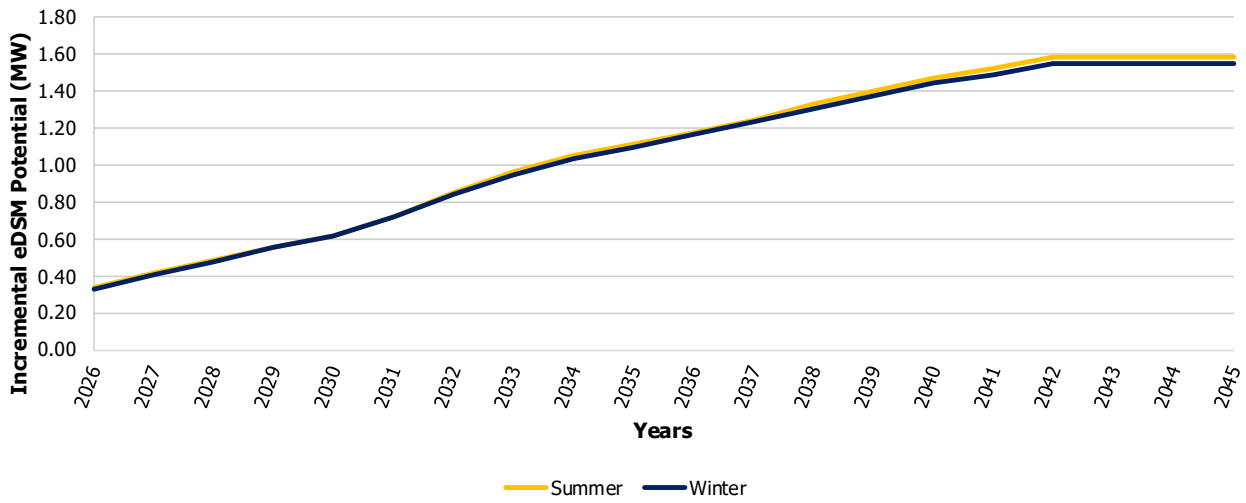
[12] While this IRRP has primarily focused on options that reduce the reliance on emitting resources, gas generation was explored to help provide context on the cost and feasibility of alternatives to the solar and BESS option.

Between the feasible options, solar and BESS are estimated to cost $41-50 million compared to $101 million for natural gas. Of these total costs, up to $41 million and $34 million could be attributed to system benefits (i.e., contribute to provincial resource adequacy needs), respectively. Therefore, the net cost of the most cost-effective non-wires option of solar and BESS is $0 to $9 million, with the latter being more applicable since it represents distribution-connected rather than utility-scale resources. Distribution-connected resources are required for station capacity needs.

A wires option was also considered for the Puslinch DS need: reconfiguring the station to a new 230 kV DESN for $65 million with a five-year lead time. This option is more expensive, however, does offer additional station capacity for growth beyond the high forecast. The station should be at the 230 kV level given the constrained 115 kV sub-system in the KWCG region.

The economic assessment for the options at Puslinch DS is summarized in the table below. Note that these are planning-level cost estimates subject to change during implementation.

Table 12 | Summary of Economic Assessment of Options for Puslinch DS[13]



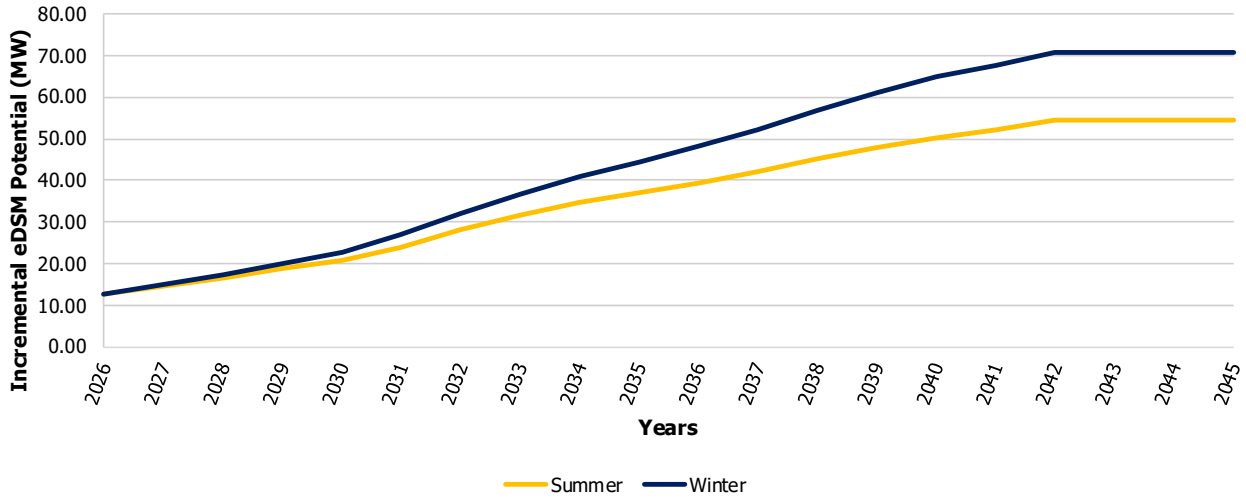
Option	Total Cost	System Benefits (Utility Scale)[14]	Net Benefit (Cost to Ratepayer)
New 230 kV station with overnight capital cost of $65M	$65M	$0M	-$65M
BESS and solar	$41M to $50M	$41M	$0M to -$9M
Natural gas	$101M	$34M	-$67M

Wolverton DS

Additional eDSM targeted to Wolverton DS could meet 2 MW of the 16 MW summer station capacity need in 2035. The estimated cost of achieving these eDSM savings is $5.2 million, which is cost-effective for provincial adequacy needs.

[13] Costs are net present values for 2026 to 2073 in 2025 real dollars.
[14] Estimates based on changing system needs as identified by the Annual Planning Outlook.

Figure 39 | Estimated Incremental eDSM Potential for Wolverton DS



The wires option considered for the Wolverton need is the fan monitoring project already underway by Hydro One Distribution. Once implemented by early 2027, the LTR increases to 31 MVA and 40 MVA for summer and winter respectively. Combined with additional eDSM, this project defers the Wolverton DS station capacity need to 2041.

Options for 115 kV Supply

Given the nature of the 115 kV sub-system supply constraints described in Section 6.2, the only non-wires option considered was additional eDSM (see Figure 40). Additional eDSM programs could meet 54 MW of the 90 MW summer station capacity need in 2045, as illustrated below. The estimated cost of achieving these eDSM savings is $172.2 million, which is considered cost-effective for provincial adequacy needs.

Figure 40 | Estimated Incremental eDSM Potential for 115 kV Sub-System

Other non-wires options, such as transmission-connected resources, were screened out from further analysis due to increased operational complexity and the specific requirements of any resource option:

- Multiple generation units would have to be sited at both Freeport junction and Puslinch TS and connected to both 115 kV circuits.
- A three-breaker ring bus configuration ($60M, two-to-three-year lead time) or tap ($3 million, one-to-two-year lead time) would be required for each generation connection.
- Deliverability of resources connected to the BxC and FxC circuits was limited per the LT2 RFP connection guidance.

Alternatively, three sets of circuit uprates were evaluated for wires options:

1. B5C between Burlington and Harper ($3.5M) and D9F between Detweiler and Siebert ($12 million);
2. B6C between Harper and Puslinch ($2.2M) and F12C between Speedville and Freeport ($18 million); and
3. further uprates to B5C between Harper and Puslinch, and B6C between Burlington and Harper ($3 million total).

With uprates sets #1 and #2, the 115 kV sub-system supply capacity need is addressed, with additional room for up to 75 MW. Set #3 of uprates increases this by another 20 MW, depending on where on the 115 kV network load is added. Beyond these uprates, the 115 kV sub-system becomes voltage-limited.

Upgrading the companion sections on the D7F circuit at an estimated cost of $6 million, as well as the F11C circuit at an estimated $9 million, enables more flexibility for future connections to be supplied by both circuits in the double-circuit line.

Recommendations

Additional eDSM that is cost-effective to the system should be targeted to all station capacity needs in the KWCG 115 kV sub-system.

For the station capacity need at Wolverton DS, Hydro One Distribution should proceed with the fan monitoring project to increase the station LTR by early 2027.

To address the 115 kV sub-system supply capacity need, it is recommended for Hydro One to implement upgrades to increase the thermal ratings of B5C/B6C, D7F/D9F, and F11C/F12C by 2028, per sets 1 and 2 upgrades described above.

To address the station capacity needs at Cedar T1/T2 and T7/T8 DESN, as well as the end-of-life need at the latter, it is recommended that T7 & T8 are replaced by 2032 with a new 230 kV DESN supplied by the existing DxV transmission lines.

Starting in 2033, load between Kitchener MTS #5 and #7 should be transferred off as required to respect their station LTRs. This is recommended to be implemented through the distribution system between Kitchener MTS #1, 3, 4, and 6. In the long-term, a new station is required in the Kitchener Freeport area. In future planning, the Technical Working Group should consider cost-effective opportunities for 230 kV reinforcements to address long-term needs, given the constraints and less flexibility of the 115 kV sub-system.

In the long term, load growth (including the impact of eDSM savings) should be monitored at Arlen TS and Hanlon TS to manage potential station capacity needs.

To address the Puslinch DS station capacity need, it is recommended to implement distribution-connected resources between 2030 and 2042.

Two key considerations accompany this non-wires recommendation:

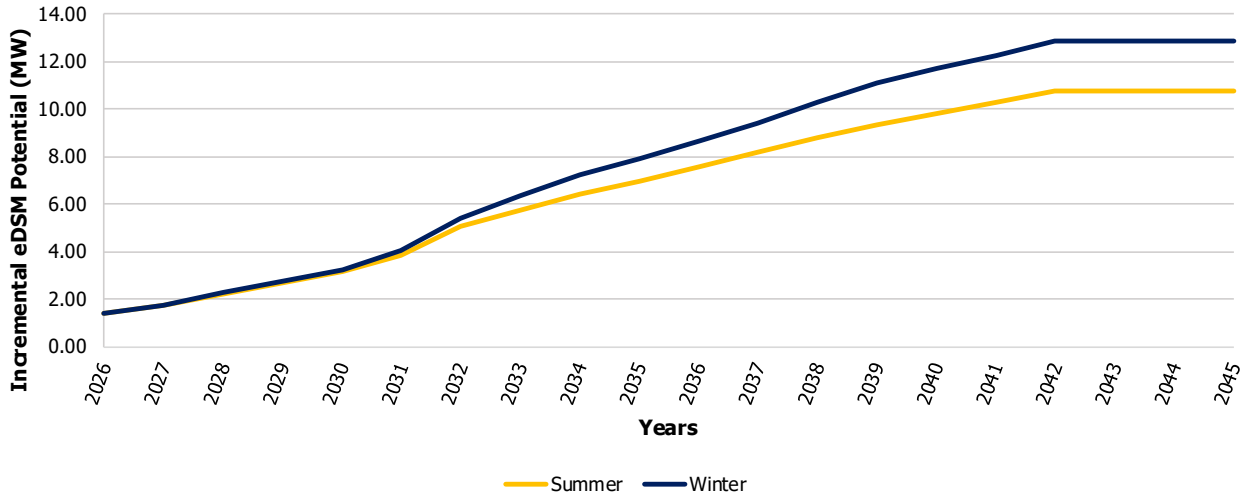
- potential for Hydro One Distribution's low or high forecast at Puslinch DS to materialize; and
- implementation mechanisms for DERs for regional planning needs.

While the most cost-effective, feasible option for Puslinch DS' reference case need is the combination of solar and BESS, Hydro One Distribution should consider the potential for its low or high forecast to occur. Load trending closer to the low forecast scenario would re-affirm the value of proceeding with non-wires options that can be sized in smaller increments and staged over multiple years to avoid overbuilding — as opposed to the wires alternative of a 230 kV DESN that offers excess capacity. In contrast, if load trends beyond the high forecast scenario, the integrated non-wires recommendation should be re-evaluated and a new station may be required or may be more cost-effective.

The analysis in this IRRP also specifically identified that an integrated package of 12 MW of solar and 8 MW/47 MWh of BESS, staged over the period of 2030 to 2042, is the most cost-effective solution given the wires alternative for Hydro One Distribution's station capacity need. The non-wires solution also has system value – it can contribute as part of the new resources that otherwise would have to be acquired for provincial resource adequacy needs, as signaled through the Annual Planning Outlook. Any resources participating in IESO procurements would need to ensure they are able to comply with the requirements of those procurements and associated contractual obligations. Other combinations and timing of distributed resources may be sufficient for Puslinch DS, if they can adequately address the need profile (see KWCG IRRP Data Tables), meet technical requirements, and are more cost-effective than the wires alternative explored in this IRRP.

At least three years is the typical lead time for new solar and BESS, but timelines may vary depending on the implementation approach. The IESO signals system needs through connection guidance and future procurement processes, including the LT2 RFP. These procurements are technology-agnostic and are open to distribution-connected projects. Distributed resources can also participate in the Capacity Auction to help meet system needs. In parallel, various initiatives are underway by the Ontario Energy Board that can impact the implementation of non-wires options, including initiatives on distribution system operator capabilities. Related, the Benefit-Cost Analysis Framework sets out guidance for LDCs when assessing the economic feasibility of non-wires solutions for distribution need — including an Energy System Test that accounts for impacts to the broader energy system.

The implementation mechanism for the non-wires recommendations for Puslinch DS will be identified after the IRRP. As a next step, the Technical Working Group will monitor Puslinch DS' forecast such that the wires alternative of a new 230 kV DESN is triggered if still required and the non-wires recommendation cannot be implemented in time. The IESO will work with the LDC to support the exploration of value-stacking opportunities.



7.2.2 MxD Sub-System

Options for Station Capacity Needs

Kitchener MTS #6

Additional eDSM programs could meet 11 MW of the 16 MW summer station capacity need in 2045, as illustrated below. The estimated cost of achieving these eDSM savings is $40.5 million, which is considered cost effective for provincial adequacy needs.

Figure 41 | Estimated Incremental eDSM Potential for Kitchener MTS #6

Other non-wires options were evaluated:

1. DG; and
2. Demand response.

By 2045, the need profile for Kitchener MTS #6 net of additional eDSM peaks at 12 MW, lasts up to eight consecutive hours, and sums to approximately 290 MWh of energy. The need also occurs primarily in the summer evening.

Based on these need characteristics, BESS was screened in for further evaluation. Solar and wind as standalone options were screened out due to the primarily summer need occurring in the evenings. Small modular reactors were screened out since the need size does not warrant this type of technology. Demand response is possible only until 2036 as the energy shortfall and number of consecutive hours of need grows over the planning horizon. Lastly, natural gas was screened out to focus the analysis on options that reduce reliance on emitting resources. This complements the City of Kitchener's participation in ClimateActionWR, a collaborative effort with local municipalities and organizations to reduce community-wide GHG emissions. The City has set GHG reduction targets, including an 80 per cent reduction by 2050 from 2010 levels, with interim goals such as a 30 per cent reduction by 2030.

12 MW/58 MWh of BESS, deployed between 2034 and 2042, was assessed to be feasible to meet the need profile and estimated to cost $25-30 million. Of these total costs, $25 million could be attributed to system benefits (i.e., contribute to provincial resource adequacy needs). Therefore, the net cost of the cost-effective non-wires option of BESS is $0 to $4 million, with the latter being more applicable

since it represents distribution-connected rather than utility-scale resources. For the Kitchener MTS #6 station capacity need, the BESS should be distribution-connected at or downstream of the MTS. Land requirements for the BESS are estimated to be 0.002 km^2.

A wires option was also considered for MTS #6: expanding the station with a new 230 kV DESN for $30-45M. This option is more expensive but offers additional station capacity for growth beyond the high forecast. Kitchener MTS #6 also has distribution ties for load transfers with MTS #4 and #8, but those stations are also reaching their LTRs.

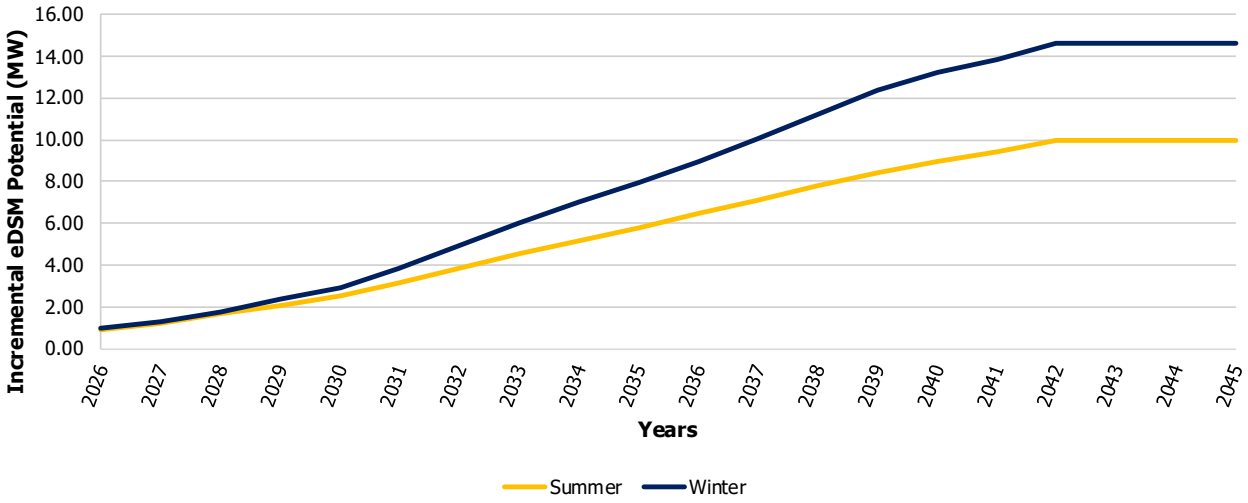


Table 13 | Summary of Economic Assessment of Options for Kitchener MTS #6[15]

Option	Total Cost	System Benefits (Utility Scale)[16]	Net Benefit (Cost to Ratepayer)
New 230 kV station with overnight capital cost of $30M to $45M	$26M to $39M	$0M	-$26M to -$39M
BESS-only	$25M to $30M	$25M	$0M to -$4M

Kitchener MTS #8

Additional eDSM was screened in for further consideration at Kitchener MTS #8. This non-wires option could meet 10 MW of the 40 MW summer station capacity need in 2045, as illustrated in Figure 33. The estimated cost of achieving these eDSM savings is $38.6 million, which is considered cost effective for provincial adequacy needs.

Figure 42 | Estimated Incremental eDSM Potential for Kitchener MTS #8

[15] Costs are net present values for 2026 to 2073 in 2025 real dollars. Note that these are planning-level cost estimates subject to change during implementation.

[16] Estimates based on changing system needs as identified by the Annual Planning Outlook.

While eDSM can help reduce the station capacity need, it is not sufficient alone and does not defer it. A wires alternative is to expand Kitchener MTS #8 with a new 230 kV DESN at a cost estimate of $30-45 million, in-service by 2030 when the need arises. There are also distribution ties for load transfers to Kitchener MTS #3 and #6, but capacity at the former is already required to offload some of the 115 kV Kitchener stations. At the latter, there is already a station capacity need.

Preston TS, GBE MTS #1, and Galt TS

Due to the urgent and large station capacity needs between Preston TS, GBE MTS #1, and Galt TS, eDSM was considered to help manage needs until wires options could be implemented. Additional eDSM could address 49 MW of the station capacity needs between Preston TS, GBE MTS #1, and Galt TS by 2045. The estimated cost of achieving these eDSM savings is $144.3 million, which is considered cost effective for provincial adequacy needs.

Otherwise, the Technical Working Group focused on the following wires options:

1. 115 kV station ($40 million) supplied by the existing F11C/F12C circuits; or
2. 230 kV station ($45 million) supplied by a new 230 kV double-circuit line from Preston TS ($75M).

These options' ability to meet the collective KWCG station capacity needs in GrandBridge Energy's service territory are closely intertwined with the 115 kV sub-system and MxD sub-system supply needs.

Option 1 provides station capacity in the Cambridge area as early as 2028 since its preferred location enables connection to existing 115 kV circuits. However, there is limited 115 kV supply capacity, even after accounting for the circuit upgrades recommended in Section 7.2.1. In contrast, Option 2 requires longer to implement for two reasons: new 230 kV double-circuit lines are needed to connect the station (depending on where the station can be sited), and reinforcements for MxD supply also need to be in-service first (see next section).

An integrated solution is also possible. With the 115 kV circuit upgrades recommended in Section 7.2.1, option 1 can provide 75 MW of station capacity to the Cambridge area in the near term, meeting the cumulative need until 2035 (or earlier, if load materializes at a faster rate than in the reference forecast). After, when the MxD supply reinforcements are in-service, a new larger 230 kV DESN can meet the remaining capacity needs in the longer term.[17] Its siting in the eastern part of Cambridge (near the Speedsville and Maple Grove area) is subject to where GrandBridge Energy load growth materializes in the 2030s, as well as routing of new 230 kV transmission lines connecting Puslinch with Cambridge.

Wires Options for MxD Supply, Load Restoration, and Load Security

The following wires options were considered to address MxD supply capacity needs:

1. Reconductor 19 km of the MxD line, from Cambridge junction to Galt junction ($40 million);
2. Rebuild 19 km of the MxD line, from Cambridge junction to Galt junction ($115 million);

[17] Planning-level cost estimate is subject to the size of the new DESN, depending on how load materializes.

3. Sectionalize the MxD lines at Galt junction with a new 230 kV SS (including two 195 MVAR capacitor banks) ($170 million), reconductor between Galt and Preston, and build:
    a. 32 km double-circuit 230 kV lines to Detweiler ($380 million); or
    b. 25 km double-circuit 230 kV lines to Middleport ($310 million).
4. Build new 500/230 kV autotransformer station ("Wellington TS") near Puslinch (including two 100 MVAR capacitor banks[18]) and 15 km double-circuit 230 kV line to Preston TS ($280 million total), with:
    a. Normally open point at Ameristeel junction; or
    b. 230 kV switching station at Galt junction ($160 million).
5. Build new 46 km double-circuit 230 kV line from Middleport to Galt to Preston ($480 million); and
6. Build new 53 km double-circuit 230 kV line from Detweiler to Galt to Preston ($550 million).

Option 1 increases the supply capability between Galt TS and Preston TS by approximately 50 MW; Option 2's performance is similar, though offers higher thermal ratings on the transmission lines.

Options 3a and 3b increase supply capability between Galt SS and Preston TS by approximately 110 MW and 130 MW, respectively. In contrast, options 4a and 4b increase supply capability between Preston TS and Wellington TS by about approximately 100-170 MW[19] and 400 MW[20], respectively. Since these options address the MxD supply capacity needs, the more expensive options 5 and 6 were not studied further.

Consideration for Brant and Powerline Load

In the 2024 Burlington to Nanticoke IRRP, two 230 kV DESNs were recommended to address capacity needs at Brant TS and Powerline MTS in the County of Brant. These new stations are to be connected to the MxD circuits, pending outcomes of the KWCG IRRP.

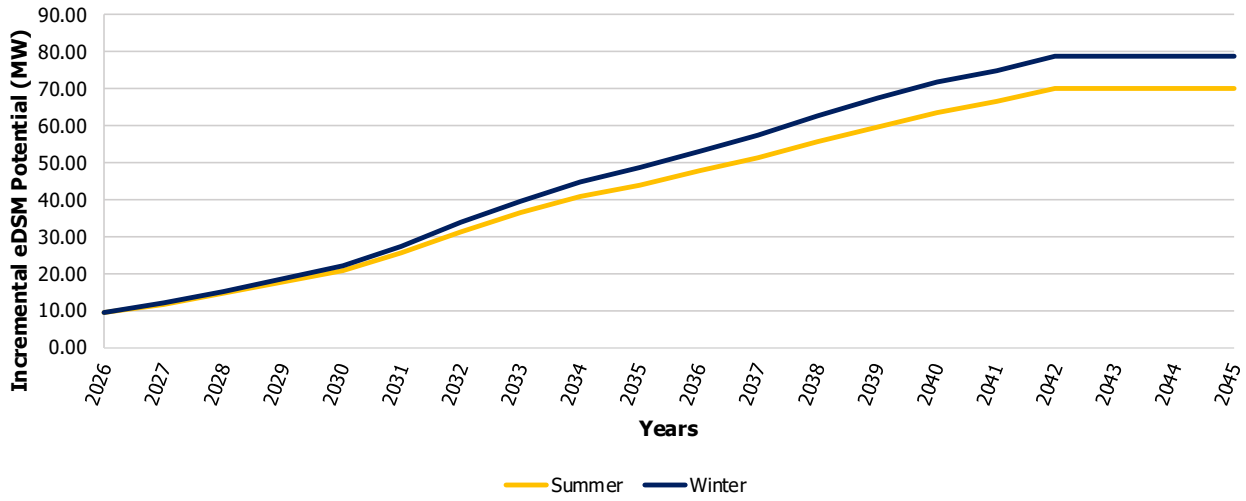
Therefore, the KWCG Technical Working Group considered each MxD wires option and their LMC for load supply to the Brant/Powerline area:

- Options 3a and 3b enable the new DESNs to be connected with new radial 230 kV lines from Galt SS. However, neither provide sufficient capacity for the forecast (300 to 350 MW) required for Brant/Powerline.
- Options 4a and 4b allow the new DESNs to tap the MxD lines between Detweiler TS and Middleport TS, or Galt SS, respectively, and enables up to the 600 MW load security limit on the Kitchener MTS #6/#8 and Brant/Powerline side.

[18] Additional capacitor banks may be required in the longer term as load grows.
[19] Supply capability ultimately depends on where additional load (such as GBE MTS #3) is sited; if close to Preston TS, the LMC increases by 170 MW. If load is sited closer to Galt TS, the LMC will be lower.
[20] The 600 MW total load security criterion will be limiting first.

Consideration for Load Security and Restoration Needs

As described in Section 6.3.3, supply capacity needs on the MxD sub-system are also accompanied by load security and load restoration needs. Therefore, the Technical Working Group considered the security and restoration benefits offered by options 4a and 4b (the only wires options capable of solving the supply capacity needs, as described above).



With either the open point or SS, security needs are resolved because the loads on the current MxD lines would be sectionalized such that no more than 600 MW of load could be interrupted by a contingency event based on configuration of the system alone. There are also load restoration benefits: with option 4a, motorized switches on both the Detweiler side and Middleport side of Galt junction allow the restoration of Kitchener MTS #6 and #8, as well as Brant/Powerline load, depending on where the contingency occurs. Restoration of loads between Galt TS and Preston TS would be possible from Wellington TS. The Galt SS in option 4b offers even greater restoration capability through re-termination of the existing MxD circuits at Galt junction.

Non-Wires Options for MxD Supply

For the MxD supply capacity need, two types of non-wires options were evaluated: additional eDSM and transmission-connected resources.

Additional eDSM programming targeting load supplied by the MxD sub-system could meet 79 MW of the 202 MW winter 2045 need. This is illustrated below. The estimated cost of achieving these eDSM savings is $246.5 million, which is considered cost effective to the system.

Figure 43 | Estimated Incremental eDSM Potential for MxD Sub-System

Given the magnitude of needs affecting the MxD sub-system, the Technical Working Group considered the feasibility of an integrated solution where a new transmission-connected resource is implemented alongside a Galt SS to defer additional 230 kV transmission lines. To achieve this and meet the need, the resource would have to be sited on the 230 kV side of Preston TS. It would also necessitate a three-breaker ring bus at Preston TS ($60 million, two to three-year lead time).

By 2045, the need profile for this resource (after additional eDSM is accounted for) peaks at 337 MW, lasts up to 334 consecutive hours, and sums to approximately 865,000 MWh of energy. Based on these characteristics, the following resource types were screened in:

- combined wind and BESS;
- combined solar and BESS; and
- combined solar, wind, and BESS.

Solar, wind, and BESS as standalone options were screened out due to the need characteristics, and small modular reactors were screened out since the need size does not warrant this type of technology. Natural gas was screened out given municipal preferences to phase out natural gas, and federal policy direction per the Clean Electricity Regulations at the time of IRRP development.

All screened-in generation options have a large land requirement, and of them, only the combination of wind, solar, and BESS could meet the need profile. This option is estimated to require almost 400 km^2 (1,115 MW of wind, 432 MW of solar, and 1,089 MW/10,000 MWh of BESS). This is not feasible given the specific siting requirements for the generation, and the dense urban area and limited space around Preston TS.

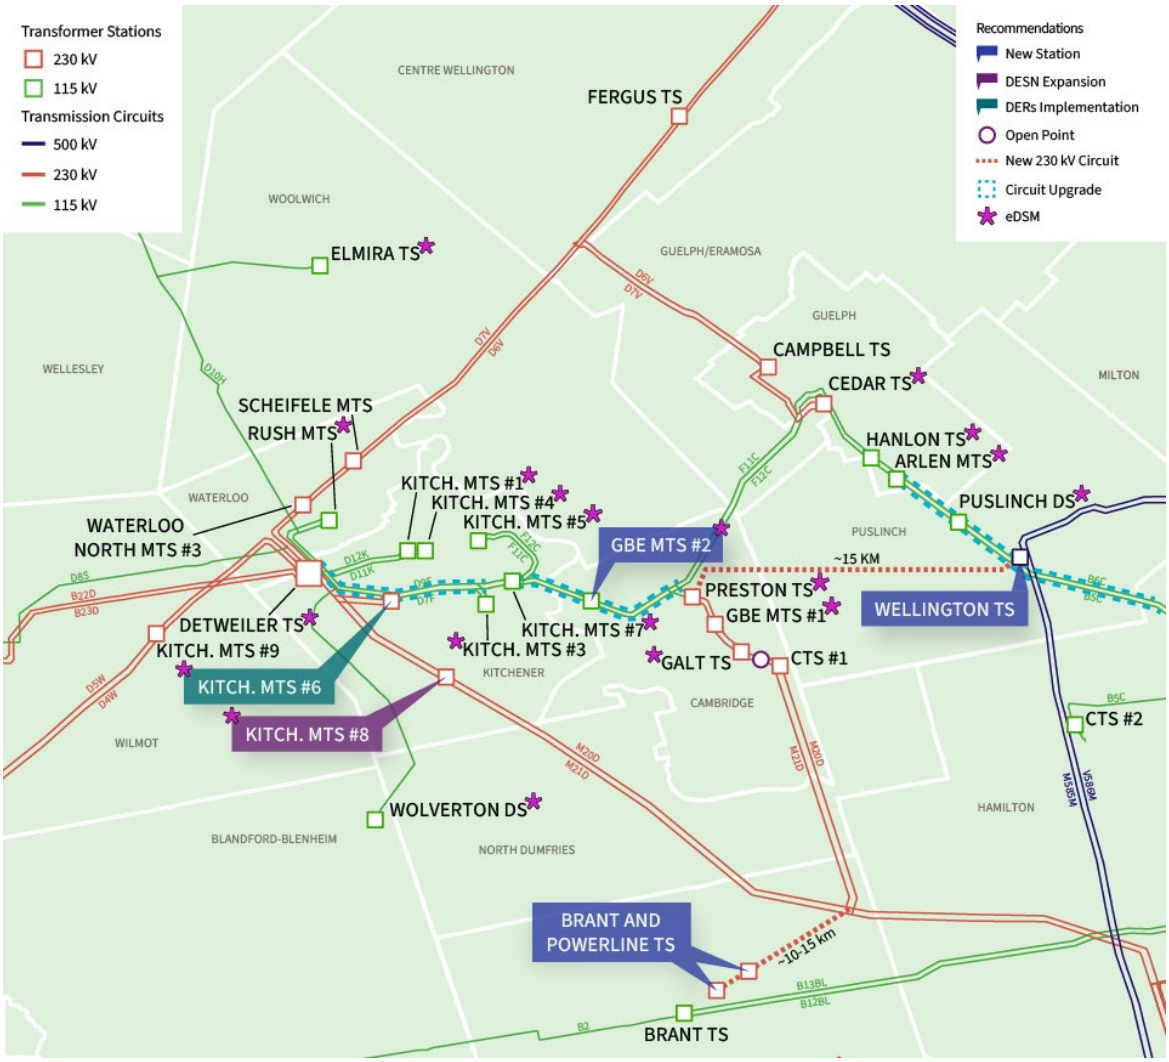
Recommendations

Additional eDSM that is cost-effective to the system should be targeted to all station capacity needs in the KWCG MxD sub-system.

To address the station capacity needs in the near term, a new 230 kV DESN expansion at Kitchener MTS #8 is recommended by 2030. In Cambridge, a new 115 kV station (GBE MTS #2) supplied by F11C/F12C should be implemented by 2028, accommodating up to 75 MW.

GrandBridge Energy may choose to explore a dual-voltage TS for its MTS #2, with a primary operating voltage of 115 kV and 230 kV and a secondary distribution voltage of 27.6 kV, at an additional cost of $2 million. This 230 kV capability may offer flexibility for future load connection requirements, which could be considered in subsequent planning cycles as circumstances evolve.

For the broader MxD supply, security, and restoration needs, a 500/230 kV autotransformer station (Wellington TS) in the Puslinch area is required by 2031 (or as early as 2029), as well as a new 230 kV double-circuit line from this station to Preston TS and a normally open point at Ameristeel junction.



A subsequent 230 kV DESN (GBE MTS #3) is recommended by 2035 (or earlier, depending on how load materializes) for longer term station capacity needs in Cambridge after MTS #2 is fully subscribed.

The siting of GBE MTS #3 and its 230 kV supply is subject to where long-term load growth materializes in GrandBridge Energy's service territory and the routing of the new 230 kV Wellington TS to Preston

TS line. MTS #3 may be required earlier depending on the pace of forecast growth – under the high scenario, it should be in-service by 2031. At the time of this IRRP publication in 2026, GrandBridge Energy's forecast information indicates that load is trending towards the high scenario, with MTS #3 potentially required as early as 2032.

Note that the recommendations above also enable connection of two new 230 kV transformer stations to Galt junction. This enables the offloading of the 115 kV Brant TS and Powerline TS, as recommended by the 2024 Burlington to Nanticoke IRRP to address immediate capacity needs in the Brant 115 kV Extended Area.

Figure 44 | Map of MxD Sub-System Near- to Medium-Term Recommendations[21]

In the long-term, the Technical Working Group should monitor the amount of load supplied by the MxD transmission lines; when forecast demand between Detweiler TS and Middleport TS exceeds the load security threshold of 600 MW, a switching station at Galt junction is required. The need for this switching station is not expected in this IRRP's planning horizon under the reference scenario.

[21] Distribution-level load transfers are not shown, for simplicity.

For the station capacity need at Kitchener MTS #6, it is recommended to implement additional eDSM immediately, as well as distribution-connected resources starting in 2034.

The analysis in this IRRP identified that 12 MW/58 MWh of BESS, staged over the period of 2034 to 2042, is the most cost-effective solution given the wires alternative for Enova Power's station capacity need. The BESS option also has system value — these distributed energy resources can contribute as part of the new resources that otherwise would have to be acquired anyway for provincial resource adequacy needs, as signaled through the Annual Planning Outlook. Any resources participating in IESO procurements would need to ensure they are able to comply with the requirements of those procurements and associated contractual obligations. Other combinations and timing of distributed resources may be sufficient for Kitchener MTS #6, if they can adequately address the need profile (see KWCG IRRP Data Tables), meet technical requirements, and are more cost-effective than the wires alternative explored in this IRRP and summarized in Table 13.

At least three years is the typical lead time for new BESS, but timelines may vary depending on the implementation approach. The IESO signals system needs through connection guidance and future procurement processes, including the LT2 RFP. These procurements are technology-agnostic and open to distribution-connected projects. Distributed resources can also participate in the Capacity Auction to help meet system needs. In parallel, various initiatives are underway by the Ontario Energy Board that can impact the implementation of non-wires options, including initiatives on distribution system operator capabilities. Related, the Benefit-Cost Analysis Framework sets out guidance for LDCs when assessing the economic feasibility of non-wires solutions for distribution need — including an Energy System Test that accounts for impacts to the broader energy system.

The implementation mechanism for the non-wires recommendations for Kitchener MTS #6 will be identified following the IRRP. The IESO will work with the LDC to support the exploration of value-stacking opportunities. The Technical Working Group will monitor Kitchener MTS #6's forecast such that the wires alternative of a new 230 kV DESN is triggered if still required and the non-wires recommendation cannot be implemented in time.

7.2.3 DxV Sub-System

As presented in Section 6.4, station and supply capacity needs were identified for the DxV sub-system. Options to address these needs are described below.

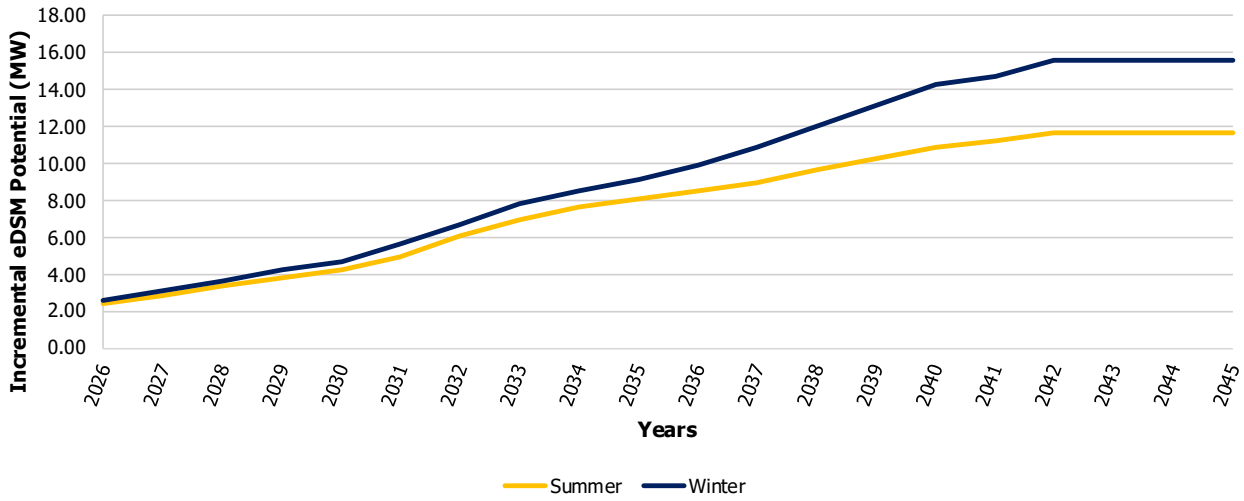
Wires Options for Campbell TS

A wires option to address station capacity needs at Campbell TS is to install additional metal-clad switchgear on T3/T4's spare winding to utilize the full LTR potential of 100 MVA (90 MW). This is estimated to cost $25 million and can be implemented as early as 2031. The additional station capacity at T3/T4 can also be used to accommodate forecast growth at Campbell T1/T2 through load transfers on the distribution system.

Non-Wires Options for Campbell TS

New eDSM programs in the area could meet 19 MW of the 50 MW summer station capacity need in 2035, as illustrated below. The estimated cost of achieving these eDSM savings is $52.6 million, which is considered cost effective for provincial adequacy needs.

Figure 45 | Estimated Incremental eDSM Potential for Campbell T1/T2



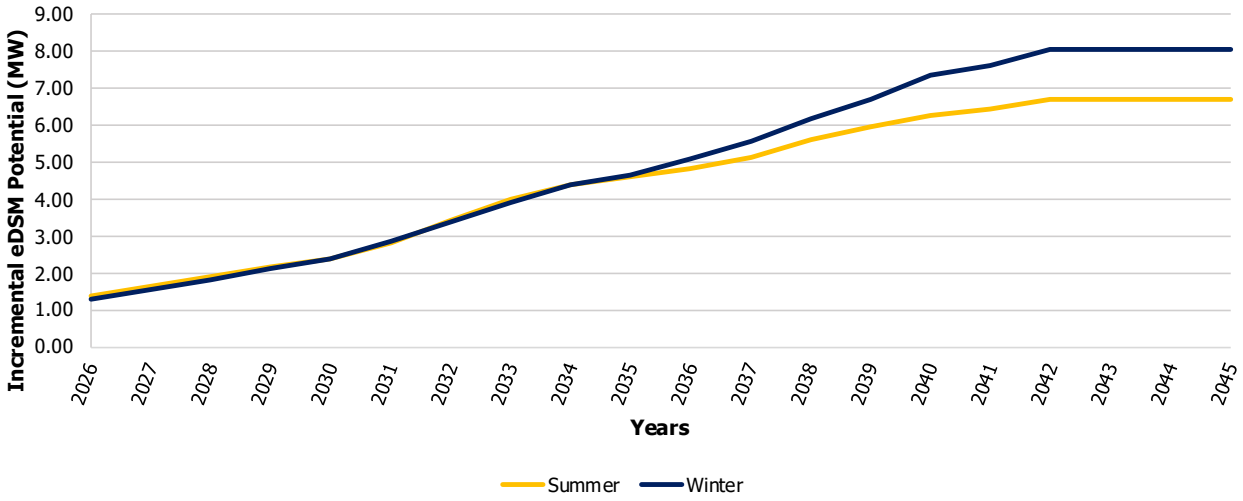


Figure 46 | Estimated Incremental eDSM Potential for Campbell T3/T4

Wires Options for Other DxV Sub-System Needs

Based on the location of forecast growth and new large load customers, Enova Power identified three potential new 230 kV stations (11 TS, Office MTS, and Snider TS) in Waterloo that, together, would provide sufficient station capacity for needs at Rush MTS, Scheifele MTS, and Waterloo North MTS #3.

To address the supply capacity needs of the DxV sub-system and to enable new 230 kV stations, transmission expansion options were evaluated. Given the scale and urgency of the needs, options to address thermal and voltage limitations in the near- to medium-term were assessed alongside longer term supply options for when DxV loads exceeded the 600 MW load security threshold. Moreover, due

to the phased approach taken during the development of the IRRP where recommendations for the MxD sub-system were made first, the second option below accounts for reinforcements described in Section 7.2.2 and includes Wellington TS. LMCs specified below also assume the DxW sub-system forecast of about 50 MW by 2045.

DxV Sub-System: Near-Term Options

The following wires options were evaluated to increase DxV supply capability in the near term:

1. Voltage support at the Preston 230 kV junctions ($95 million) and at Speedville 115 kV junctions ($95M), plus uprates to the DxV circuits between Detweiler TS and the new Waterloo stations ($15 million);
2. A double-circuit 230 kV line ($150 million) from Wellington TS to Cedar TS, a 230 kV switchyard at Cedar TS ($65 million), DxV uprates between Detweiler TS and the new Waterloo stations ($15 million), and additional capacitor bank at Elmira TS ($5 million); or
3. Reconfiguration work at Detweiler TS, and DxV uprates between Detweiler TS and the new Waterloo stations ($15 million).

With each option, the DxV LMC is still limited by the ORTAC load security criteria at 600 MW. Option 1 requires four years of development and comes at a cost estimate of $205M. Option 2 is the most expensive near/medium-term option at a cost of $235 million and can take up to five years, though it can be considered in future planning cycles for supply to the Guelph area.

Option 3 has the potential to be the most cost-effective option and fastest to implement among the three options above. Specifically, option 3 aims to mitigate the most limiting contingency at Detweiler TS that defines the DxV sub-system LMC; this includes the existing operating instructions that would result in the removal of Detweiler static VAR compensator and/or 230kV capacitor bank(s) upon 230 kV bus fault or specific breaker failures contingencies.

Option 3 also has the benefit of increasing the DxV supply capability in near to medium term, as well as in the long term. In the near to medium term, option 3 can increase DxV supply capability to the 600 MW load security limit. It is also required to achieve the LMC described in the next section for option C of the DxV long-term options.

In addition to the three options listed above, up to 150 MW of load transfers to the DxW sub-system is possible based on supply capability with Wellington TS in-service. As described in Section 6.5, the LMCs between the DxV and DxW sub-systems are related. Depending on the location of the load growth, distribution buildout, and existing distribution ties, Enova Power could leverage the DxW supply capability for some forecast load currently allocated to stations served by the DxV sub-system.

DxV Sub-System: Medium- to Long-Term Options

In the medium to long term, further reinforcements and points of supply to the DxV area are still required given the magnitude of the needs.

Hydro One Transmission input during early options development indicated limited feasibility to expand Detweiler 230 kV yard or construct a new 500 kV yard at the existing Detweiler site. As such, the following wires options were considered to address DxV supply capacity needs in the long term and to supply Enova Power's proposed transformer stations in the Waterloo area ($30–45 million each):

A. Build a double-circuit 230 kV line ($360 million) from Wellington TS to new transformer stations in Waterloo;

B. Leverage the preliminary bulk option identified in the South and Central Bulk Plan: build a single-circuit 500 kV line from Longwood TS to a 500/230 kV station near Detweiler TS on the DxW circuits ("Detweiler #2 TS"), and a single-circuit 500 kV line from Detweiler #2 TS to Milton TS; or

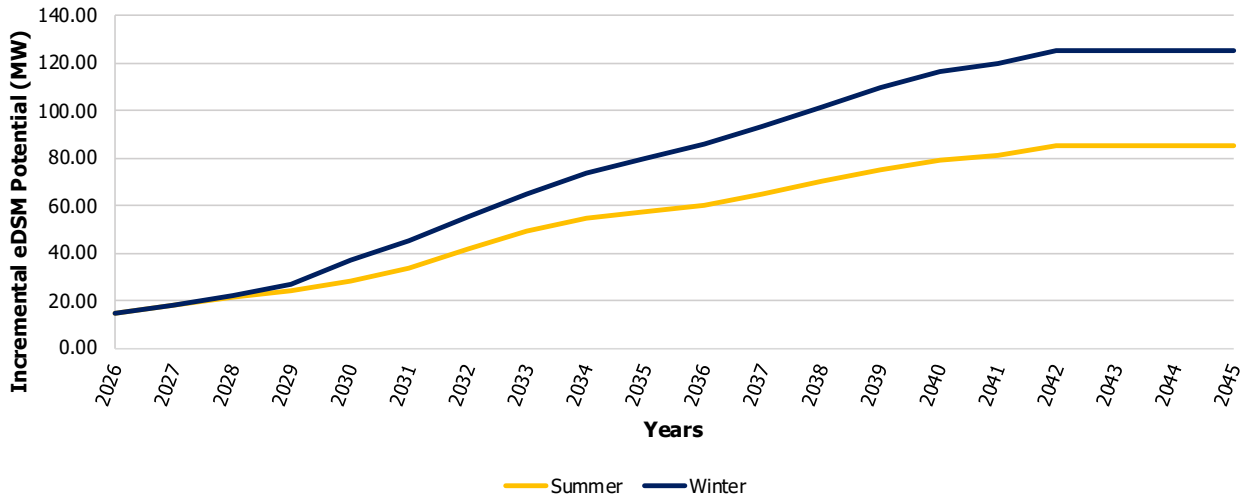
C. Leverage the final bulk option identified in the South and Central Bulk Plan: build a single-circuit 500 kV line from Longwood TS to a 500/230 kV station at Guelph North junction ("Guelph North TS") ($270 million), and a single-circuit 500 kV line from Guelph North TS to Wellington TS.

Option A can increase supply to Waterloo by 400 MW, but the overall LMC depends on the amount of load served by the 230 kV circuits from Wellington TS to Preston TS (recommended in Section 7.2.2). Option B was determined infeasible for regional needs because it necessitates extensive circuit and tower upgrades for the DxV and DxW paths, and separate reinforcements for 115 kV system voltage violations. Conversely, Option C increases supply between Detweiler TS and Guelph North TS on the existing DxV lines to approximately 900 MW. However, the load security limit of 600 MW applies. With new, approximately 15 km, radial, double-circuit, 230 kV lines to Waterloo from Guelph North TS ($180 million), another 600 MW can be supplied to the area.

While both options A and C meet the reference forecast supply and load security needs, option C has a few key advantages for regional needs:

- It offers more total supply capability than option A — enough for the high forecast scenario.
- The introduction of Guelph North TS sectionalizes the existing DxV circuits, which allows new stations in Waterloo to be sited and supplied directly from the DxV circuits rather than from new longer (30 km) radial lines (as is the case for option A).
- Option C can be staged in a flexible way such that radial lines/or other options are not triggered until needed, unlike with option A.
- It increases capacity for the DxV sub-system without using up the supply capability from Wellington TS for MxD sub-system needs.
- It introduces a new supply point through Guelph North TS, which sectionalizes and re-terminates the existing DxV lines – therefore offering more restoration capability to the DxV sub-system and diversifying paths of supply to the region.

Option C is enabled by the South and Central Bulk Plan recommendations. The 500 kV reinforcements from Longwood TS to the KWCG region, enabled by new 500 kV supply points at Guelph North TS and Wellington TS, are required for addressing bulk system transfer needs. These options were studied as part of the bulk plan's Portfolio B, which are the preferred set of recommendations to meet the South and Central Bulk Plan objectives. The bulk needs and options are described in detail in the final report issued in Q3 2026.



Recognizing that long-term solutions could have a longer lead time relative to the pace of load growth, the Technical Working Group investigated interim solutions of implementing reactive support within KWCG's 115 kV sub-system, such as at Elmira TS, at 10-20 MVAR each. Analysis shows that, while the addition of capacitor(s) cannot fully satisfy the sub-system's load forecast, it increases the DxV sub-

system LMC in the interim until bulk reinforcements for 500 kV supply into the region is in-service. Once 500 kV bulk supply into Guelph North TS is in-service, supply capacity needs are met even without this additional reactive support.

Non-Wires Options for Other DxV Sub-System Needs

As presented in Section 7.1.2, eDSM was screened in further consideration for the DxV needs. Under the existing eDSM framework and programs, up to 85 MW of additional total summer peak savings could be achieved at an expected cost of $247.8 million. eDSM is important for managing demand in Ontario and plays a key role in maximizing the useful life of existing infrastructure and maintaining reliable supply.

Figure 47 | Estimated Incremental eDSM Potential for the Overall DxV Sub-System

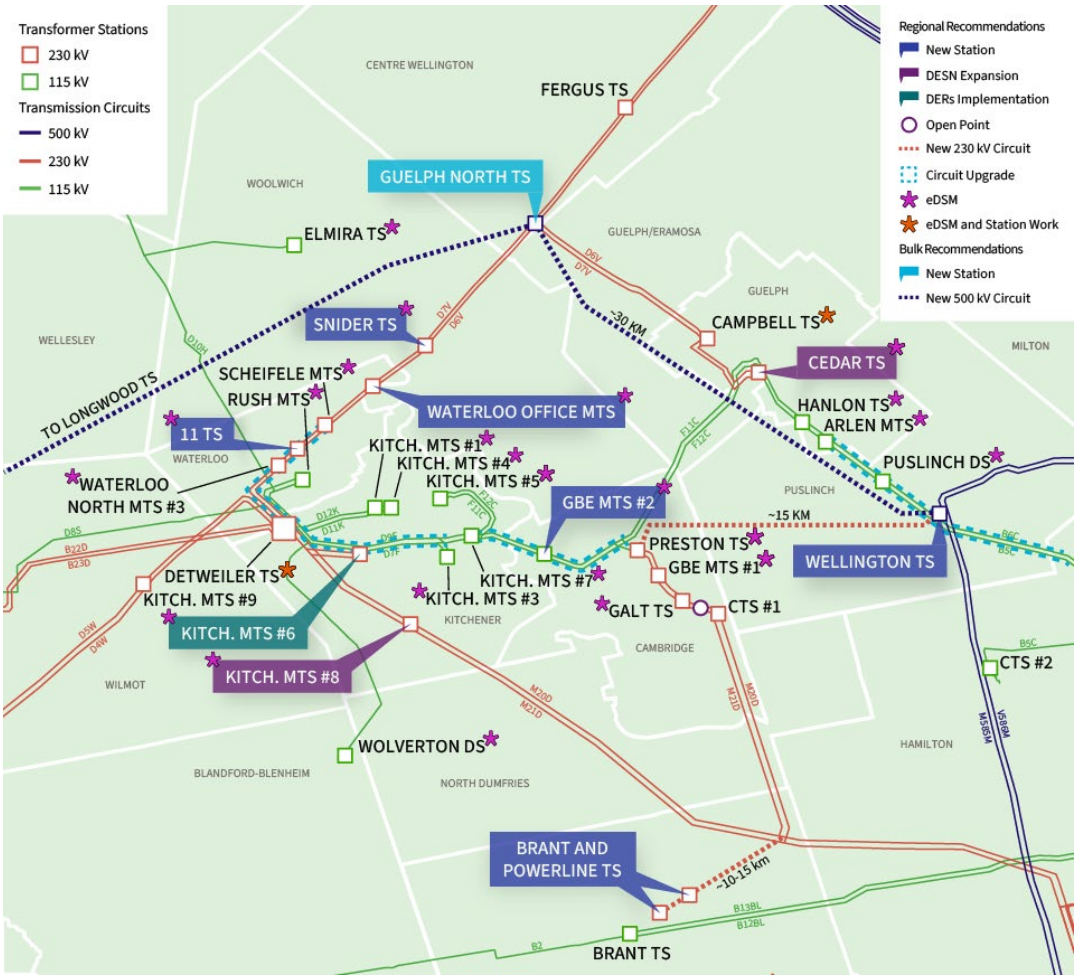
Recommendations

It is recommended to target additional eDSM programs in the DxV sub-system to increase capacity and provide broader system benefits.

Considering the uncertainty among the forecast drivers in the region and the increased eDSM targets under the new 2025–2036 eDSM Framework, the Technical Working Group will continue to monitor growth in the region to determine whether sector trends and connection requests indicate a need for development beyond the reference planning forecast.

In the near term, the recommendation to address the Campbell TS station capacity need is to implement additional system cost-effective eDSM and install metal-clad switchgear at T3/T4 to increase its LTR. After this is implemented by 2031, 19 MW of load should be transferred through the distribution system from T1/T2 to T3/T4. Needs in the interim, before additional station capacity is available, will be monitored and evaluated by Alectra.

To address the remaining DxV station capacity, supply capacity, load security, and load restoration needs, the Technical Working Group recommends the integrated wires option that



includes, in the near term: DxV uprates and station work at Detweiler TS mitigate the impact of existing operating instructions. By the mid-2030s, bulk reinforcements recommended from the South and Central Plan are required: a new 500/230 kV Guelph North TS, and a single-circuit 500 kV line from Longwood TS to Guelph North TS to Wellington TS. Specifically, the Guelph North TS and 500 kV line to from Guelph North TS to Wellington TS should be advanced to 2031 for regional needs.

The Technical Working Group should closely monitor the pace of load growth on the DxV sub-system. If the longer-term recommendations are delayed, additional load growth in the near term should be enabled by installing a new 10-20 MVAR capacitor at Elmira TS.

Lastly, new 230 kV transformer stations in Waterloo are recommended to be supplied by the existing DxV lines. In the long term, the Technical Working Group should monitor load growth and re-evaluate the need for new radial 15 km double-circuit 230 kV lines from Guelph North TS to the Waterloo area.

This set of recommendations is shown in Figure 48.

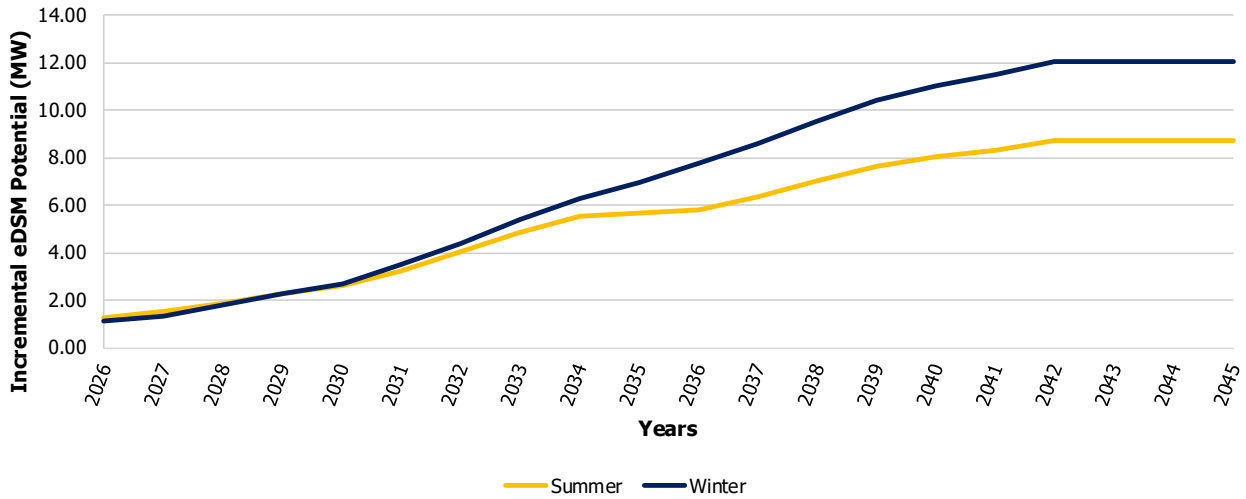
Figure 48 | Map of DxV and MxD Sub-System Near- to Medium-Term Recommendations[22]

[22] Distribution-level load transfers are not shown, for simplicity.

The KWCG Regional Infrastructure Plan, led by Hydro One after the IRRP, should further assess and refine the scope of work at Detweiler TS required to mitigate the loss of a static VAR compensator and/or capacitor after outages. Additionally, the cost and feasibility for low voltage capacitors at Elmira TS or on the 115 kV sub-system should be evaluated to bridge the supply capacity gap until the long-term solution for 500 kV bulk reinforcements to the region are implemented. Other alternatives, such as operational measures like undervoltage load shedding schemes, for resolving post-contingency voltage decline violations, can also be considered.

7.2.4 D8S/D10H Sub-System

Options for Rush MTS



Wires options for the station capacity need at Rush MTS were considered in conjunction with Enova Power's station needs at Scheifele MTS and Waterloo North MTS #3. As described in Section 7.2.3, the three new 230 kV stations proposed (11 TS, Office MTS, and Snider TS) should be sized to meet the cumulative station capacity needs between Rush MTS, Scheifele MTS, and Waterloo North MTS #3.

For Rush MTS, the following non-wires options were also assessed:

1. Additional eDSM; and
2. DG.

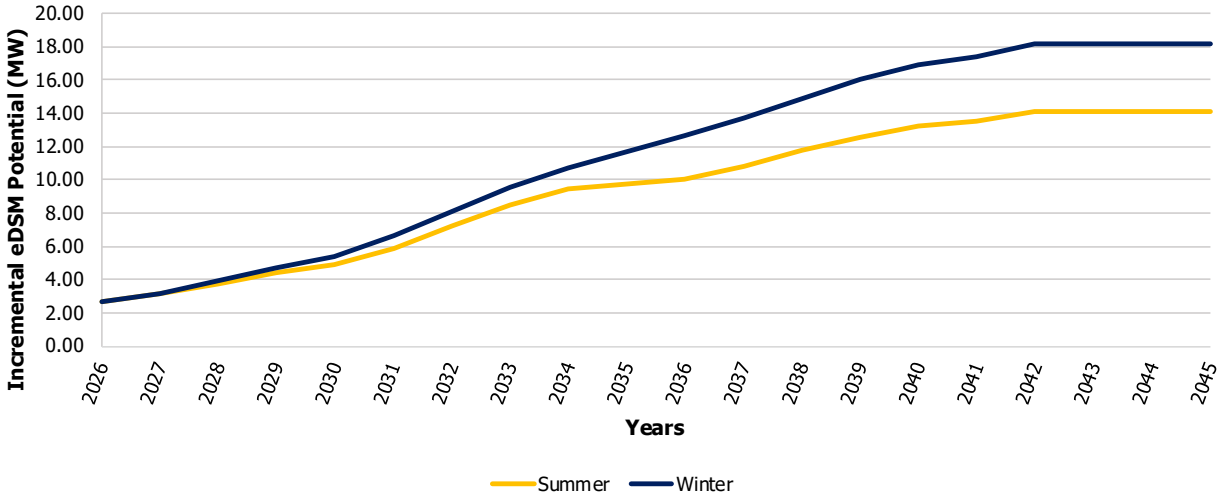
Additional eDSM programs could meet 9 MW of the 33 MW summer station capacity need in 2035, as illustrated in Figure 49. The estimated cost of achieving these eDSM savings is $26 million, which is considered cost effective to the system.

Figure 49 | Estimated Incremental eDSM Potential for Rush MTS

By 2045, the need profile for Rush MTS peaks at 51 MW, lasts up to 94 consecutive hours, and sums to approximately 42,000 MWh of energy. Based on these need characteristics, the following non-wires options were screened in:

- wind;
- BESS;

- combined wind and BESS;
- combined wind and solar;
- combined solar and BESS; and
- combined solar, wind, and BESS.



Solar as a standalone option was screened out due to the need occurring in both summer and winter and often at night. Small modular reactors were screened out since the need size does not warrant this type of technology. Natural gas was screened out to focus the analysis on options that reduce reliance on emitting resources. Note that the City of Waterloo has set greenhouse gas reduction targets similar to the City of Kitchener, reducing community-wide emissions by 30 per cent by 2030 and 80 per cent by 2050, through the TransformWR strategy from ClimateActionWR.

Among the screened-in generation options, none were feasible given the need profile and/or the DG connection capacity at Rush MTS, even if assuming Enova Power undertakes feeder breaker and switchgear replacement work to increase the short circuit rating by 20 per cent. Moreover, if these solutions were feasible, they would have to be sited relatively close to Rush MTS on primarily residential land.

Options for D8S/D10H Supply

Additional eDSM programs (savings shown in Figure 50) could meet 14 MW of the 26 MW D8S/D10H supply capacity need and defer the need until 2032. The estimated cost of achieving these eDSM savings is $40.7 million, which is considered cost effective to the system.

Figure 50 | Estimated Incremental eDSM Potential for D8S/D10H Sub-System

A few wires options were also considered:

1. reconductoring the D8S and D10H circuits to 719 A and 920 A, respectively ($3.5M to $5M, one to two years lead time); or
2. offloading some load from Rush MTS to the DxV sub-system through the new 230 kV stations recommended in Section 7.2.3.

Recommendations

In the near term, the recommendation to address the Rush MTS station and D8S/D10H supply capacity needs is to implement additional system cost-effective eDSM.

By 2032, load in excess of the Rush MTS LTR should be transferred on the distribution system to instead be served by the DxV sub-system.

These recommendations are sufficient to meet the reference need for this IRRP's planning horizon. In the long term, or if higher growth materializes, the reconductoring of D8S and D12H may be required – this results in supply capacity for approximately another 28 MW beyond Rush MTS' current LTR, as well as another 25 MW beyond Elmira TS' current LTR.

7.2.5 DxK Sub-System

Wires Options for Kitchener MTS #1 and #4

For the station capacity needs at Kitchener MTS #1 and #4, the same wires options were evaluated as for Kitchener MTS #5 and #7:

1. Load transfers on the distribution system starting in 2032.
2. New station in Kitchener.

Considering option 1, Kitchener MTS #1 has distribution-level ties with MTS #3 and #4; MTS #4 has ties with MTS #1 and 6. Option 2 was described in more detail in Section 7.2.1.

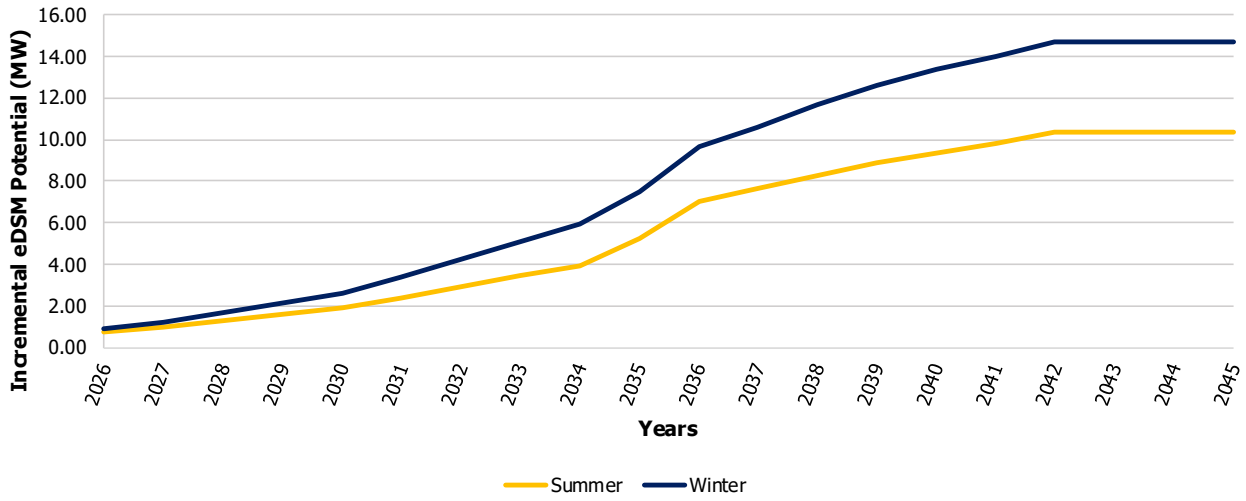
Non-Wires Options for Kitchener MTS #1 and #4

For Kitchener MTS #1 and #4, the following non-wires options were assessed:

1. Additional eDSM;
2. DG; and
3. demand response.

eDSM programs targeting load supplied by Kitchener MTS #1 and #4 could meet 10 MW of the 16 MW summer 2035 station capacity need and 11 MW of the 19 MW summer 2035 station capacity need, respectively. The estimated cost of achieving these eDSM savings is $40 million and $42 million respectively, which is considered cost effective to the system.

Figure 51 | Estimated Incremental eDSM Potential for Kitchener MTS #1



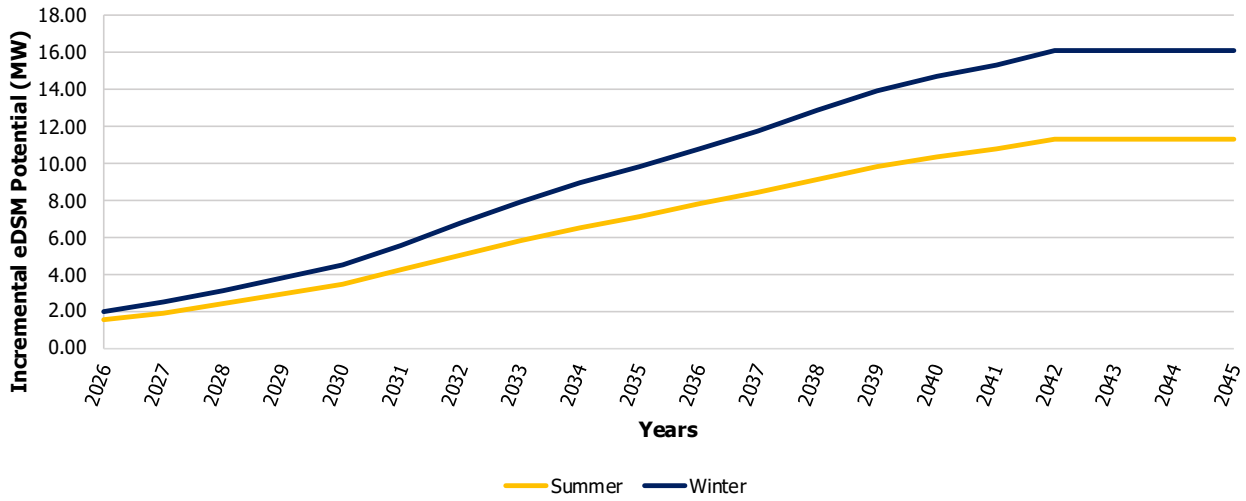


Figure 52 | Estimated Incremental eDSM Potential for Kitchener MTS #4

By 2045, the need profile for Kitchener MTS #1 peaks at 43 MW, lasts up to 21 consecutive hours, and sums to approximately 30,000 MWh of energy. Based on these need characteristics, the following non-wires options were screened in:

- wind;
- BESS;
- combined wind and BESS;
- combined wind and solar;
- combined solar and BESS;
- combined solar, wind, and BESS; and
- demand response.

Solar as a standalone option was screened out due to the need occurring in the winter, and small modular reactors were screened out since the need size does not warrant this type of technology. Natural gas was screened out to focus the analysis on options that reduce reliance on emitting resources. There are also municipal preferences that support the reduction of greenhouse gas emissions.

Among the screened-in generation options, none were feasible given either the need profile and/or the DG connection capacity at Kitchener MTS #1, even if assuming Enova Power undertakes feeder breaker and switchgear replacement work to increase the short circuit rating by 20 per cent. Even if these solutions were feasible, they would have to be sited relatively close to Kitchener MTS #1 on heavily developed residential and commercial urban land.

For Kitchener MTS #4, the non-wires analysis yielded similar results. By 2045, the need profile for Kitchener MTS #4 peaks at 47 MW, lasts up to 46 consecutive hours, and sums to approximately 44,000 MWh of energy. Based on these need characteristics, the same resource types were screened in for further analysis as for Kitchener MTS #1. Outcomes of the evaluation were also similar: the NWAs were infeasible given the need profile and/or the DG connection capacity at Kitchener MTS #4, even if assuming upgrades to increase short circuit capability. Depending on the option, up to 9 km^2 of land would be required near the station in urban Kitchener.

Wires Options for DxK Supply

A wires option to address DxK supply is the reconductoring of D11K and D12K to increase its summer Long-Term Emergency thermal rating to 1035 A (and 1180 A for winter). This is expected to cost $6.3 million and take 1-2 years, and with additional DSM, will meet the summer supply need and delay the winter need until 2041.

Non-Wires Options for DxK Supply

For the DxK supply capacity need, the same non-wires options were assessed as for Kitchener MTS #1 and #4: wind, BESS, solar, demand response, and additional eDSM (as illustrated in the figures earlier). However, given the nature of supply capacity needs, potential resource options can also be transmission-connected (not just distribution-connected).

By 2045, the need profile for the DxK supply need grows to 90 MW and more than 100,000 MWh. The need occurs in the winter and lasts up to 141 consecutive hours – requiring infeasibly large resource options in a dense urban area.

Meanwhile, the cumulative additional eDSM at Kitchener MTS #1 and #4 can delay the DxK supply need until 2033.

Recommendations

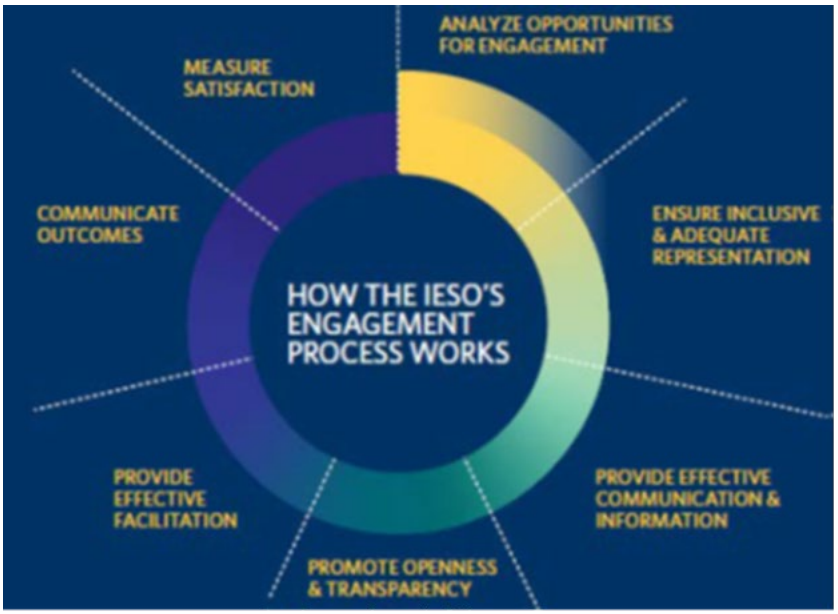
In the near term, the recommendation to address the Kitchener MTS #1 and #4 station capacity needs is to implement additional system cost-effective eDSM, and optimize and transfer load through the distribution system starting in 2033 between Kitchener MTS #1, 3, 4, and 6. In the

long-term, a new station is required in the Kitchener Freeport area, should the reference load forecast materialize.

Considering long-term forecast uncertainty in the region and potential for increased eDSM, the Technical Working Group will continue to monitor where, when, and how much electricity demand grows. These factors, alongside any new resources and other system changes, can influence the need and options for long-term Kitchener station capacity needs.

In the medium-term, the recommendation to address the DxK supply capacity need is to reconductor both D11K and D12K to increase its summer Long Term Emergency thermal rating to 1035 A (and 1180 A for winter).

Given the Planning Forecast, this uprate should be implemented by 2033. Under the low and high reference scenarios, timing of the uprate can shift up to two years.



8. Community and Stakeholder Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and perspectives of the public, which for these purposes, refers to Indigenous communities, market participants, municipalities, stakeholders, communities, customers and the general public, to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles and activities undertaken to date for the KWCG IRRP.

8.1 Engagement Principles

The IESO's External Relations Engagement Framework is built on a series of key principles that respond to the needs of the electricity sector, communities and the broader economy. These principles ensure that diverse and unique perspectives are valued in the IESO's processes and decision-making. We are committed to engaging with purpose with external audiences to foster trust and build understanding as the energy transition continues.

Figure 53 | The IESO's Engagement Principles

8.2 Engagement Approach

To ensure that the IRRP reflects the unique needs and perspectives of market participants, municipalities, stakeholders, communities, Indigenous communities, customers and the general public, engagement involved:

- Leveraging the KWCG engagement webpage to post updated information, engagement opportunities, meeting materials, input received and IESO responses to feedback.
- Timely and targeted discussions with municipalities to help inform the engagement approach for this planning cycle.

- Sharing letters with relevant Mayors and Councillors to provide informative updates on the plan to foster purposeful engagement.
- Hosting a series of public webinars at major junctions in the plan development to share plan details, understand feedback and answer questions.
- Encouraging all interested parties to stay informed on the planning underway through communications and other engagement tactics to enable a broad participation through email and IESO's weekly Bulletin updates.
- Hosting targeted discussions with specific communities and stakeholders to clearly communicate updates as planning progressed and ensure that their identified needs are addressed.

8.3 Engage Early and Often

The IESO held preliminary discussions to help inform the engagement approach for the third round of planning for the KWCG region, and to establish new relationships and dialogue where there has been no active engagement previously. This started with the Scoping Assessment Outcome Report that involved sending an invitation to targeted municipalities, Indigenous communities, and those with an identified interest in regional issues, to announce the commencement of a new planning cycle and invite interested parties to provide input on the KWCG Scoping Assessment Outcome Report. A public webinar was held in June 2024 to provide an overview of the regional electricity planning process and seek input on the high-level needs identified and proposed planning approach moving forward. The final report was posted later in July 2024, identifying the need for a coordinated regional planning approach and development of an IRRP.

Later in December 2024, a targeted outreach meeting involving all municipalities in the region was hosted to ensure growth and development plans were accurately captured in the Technical Working Group's draft demand forecast, and to solicit early feedback on the IESO's approach to engagement. The launch of a broader engagement initiative followed, with an invitation to subscribers of IESO updates for the KWCG region to ensure that all interested parties were made aware of this opportunity for input.

Four public webinars were held at major stages during the IRRP development to give interested parties an opportunity to hear about its progress and provide comments on key components of the plan. These webinars were attended by a cross-representation of community representatives, businesses, and other stakeholders, and written feedback was collected following a comment period after each webinar. The four stages of engagement at which input was invited were:

1. The draft engagement plan, electricity demand forecast, and early identified needs — to set the foundation of this planning work.
2. The identified priority electricity needs for the region and high-level screening of potential options to meet the identified priority needs.
3. The analysis of options and draft IRRP recommendations to address priority needs, and the high-level screening of potential options to meet the identified remaining needs.
4. The analysis of options and draft IRRP recommendations to address remaining needs.

Comments received during public engagements primarily focused on:

- Questions regarding inputs and assumptions considered by the IESO when developing the demand forecast scenarios, and how municipalities can influence routing and property impacts.
- Significant population growth, transit and economic development projects across the region.
- Alignment of electricity planning with local priorities, such as local Climate Action Plans.
- Regulations regarding reserving capacity for critical public infrastructure.
- The importance of addressing immediate capacity needs to ensure the region remains resilient.
- Interest in leveraging existing and local generation.
- Exploring and understanding alternative solutions, such as non-wire options, to meet the area's electricity needs.

Feedback received during the written comment periods for these webinars helped to guide further discussions throughout the development of this IRRP, as well as add due consideration to the final recommendations.

In recognition of the interdependencies between a parallel South and Central Bulk Plan looking at the provincial electricity system's broad capability to support future generation connections, and demand growth in key areas throughout southern and central Ontario, KWCG engagement focused on establishing linkages between the bulk and regional electricity plans. The IESO has undertaken efforts to ensure engagement activities and recommendations for the KWCG IRRP are aligned and integrated with those of the South and Central Bulk Plan.

All interested parties were kept informed throughout this engagement initiative via email to KWCG subscribers, municipalities, and Indigenous communities. Based on the discussions through this engagement initiative, a key priority was to ensure the IRRP and recommended actions aligned with the significant forecasted growth and development both within specific municipalities and the region more broadly (e.g., new large-scale customers and electrification, planned development and growth). Through the development of the IRRP it was determined that the existing electricity system did not meet reliability standards. With that, another key focus area was developing an approach to quickly identify, engage on, and develop solutions to address priority electricity needs while also balancing addressing remaining electricity needs. These insights have been valuable to the IESO — as they supported an understanding of local growth and an accurate electricity demand forecast, the determination of needs, and the recommendation of solutions to ensure adequate and reliable long-term supply.

All background information, including engagement presentations, recorded webinars, detailed feedback submissions, and responses to comments received, are available on the IESO's KWCG engagement webpage.

8.4 Involving Municipalities in the Plan

The IESO held meetings with municipalities to seek input on its planning and to ensure that key local information about growth and development and energy-related initiatives were taken into consideration in the development of this IRRP. At major milestones in the IRRP process, meetings were held with all municipalities in the KWCG electrical region to share key developments and to provide an opportunity for municipal feedback on the forecasted regional electricity needs, options for meeting the region's

future needs, and broader community engagement. Through engagement it was learned that the tiered approach of addressing needs in the region added an extra layer of complexity in understanding the development of the IRRP.

To address this feedback, additional engagement was conducted to foster education and understanding of the recommendations to address priority needs. This included the IESO engaging elected officials and all municipalities impacted by the recommendations to address priority needs by sharing letters prepared for mayors and councillors and hosting an information session with elected officials and municipal staff to review the electricity planning developments, and to provide an opportunity for discussion. These meetings helped to inform the municipal and community electricity needs and priorities, establish new relationships, and provide opportunities for ongoing dialogue beyond this IRRP process.

Through these discussions, valuable feedback was received and considered in the final IRRP recommendations, including:

- The City of Kitchener encouraged the inclusion of multiple forecast scenarios in the IRRP process and collaboration between municipalities and local distribution companies to understand the development of the electricity demand forecast scenarios. Additionally, the City emphasized their commitment to supporting the energy transition by leveraging its role as a gas distributor and focusing on the electrification of transportation and space and water heating. The City also encouraged the IESO to consider efficient, low-carbon heating solutions, including the use of waste heat from large electricity users.
- The City of Guelph recommended sharing the assumptions used when calculating the electricity demand forecast scenarios, addressing short circuit limitations at Campbell TS as it is hindering solar PV projects, and also raised the need for additional support to promote eDSM initiatives.
- Several municipalities emphasized that population growth, transit expansion, climate action, and energy plans should be reflected in electricity demand forecasts, and they encouraged the use of non-wire alternatives to support their net-zero and decarbonization goals.
- Municipalities also suggested improving future engagement materials by clearly outlining municipal boundaries on study-area maps, reducing industry-specific terminology to more easily understand the process to develop the IRRP, and providing increased clarity on the interaction of eDSM and electrification efforts on a region's electricity capacity and needs.
- Enbridge Gas Inc. recommended co-ordinated energy system (gas and electric) planning be completed and due consideration be given to a diversified energy system approach in the forecasts for the KWCG electrical region.

8.5 Engaging with Indigenous Communities

The IESO remains committed to an ongoing, meaningful dialogue with Indigenous communities to help shape long-term planning in regions across Ontario. This engagement was part of a broader commitment to fostering respectful relationships, ensuring transparency, and supporting informed participation in regional energy planning. Throughout the development of this plan, the IESO's engagement with Indigenous communities included inviting Indigenous communities to participate in

online information sessions (held on December 12, 2024, May 27, 2025, September 23, 2025 and June 10, 2026), as well as extending the opportunity to meet one-on-one to ask questions and provide input.

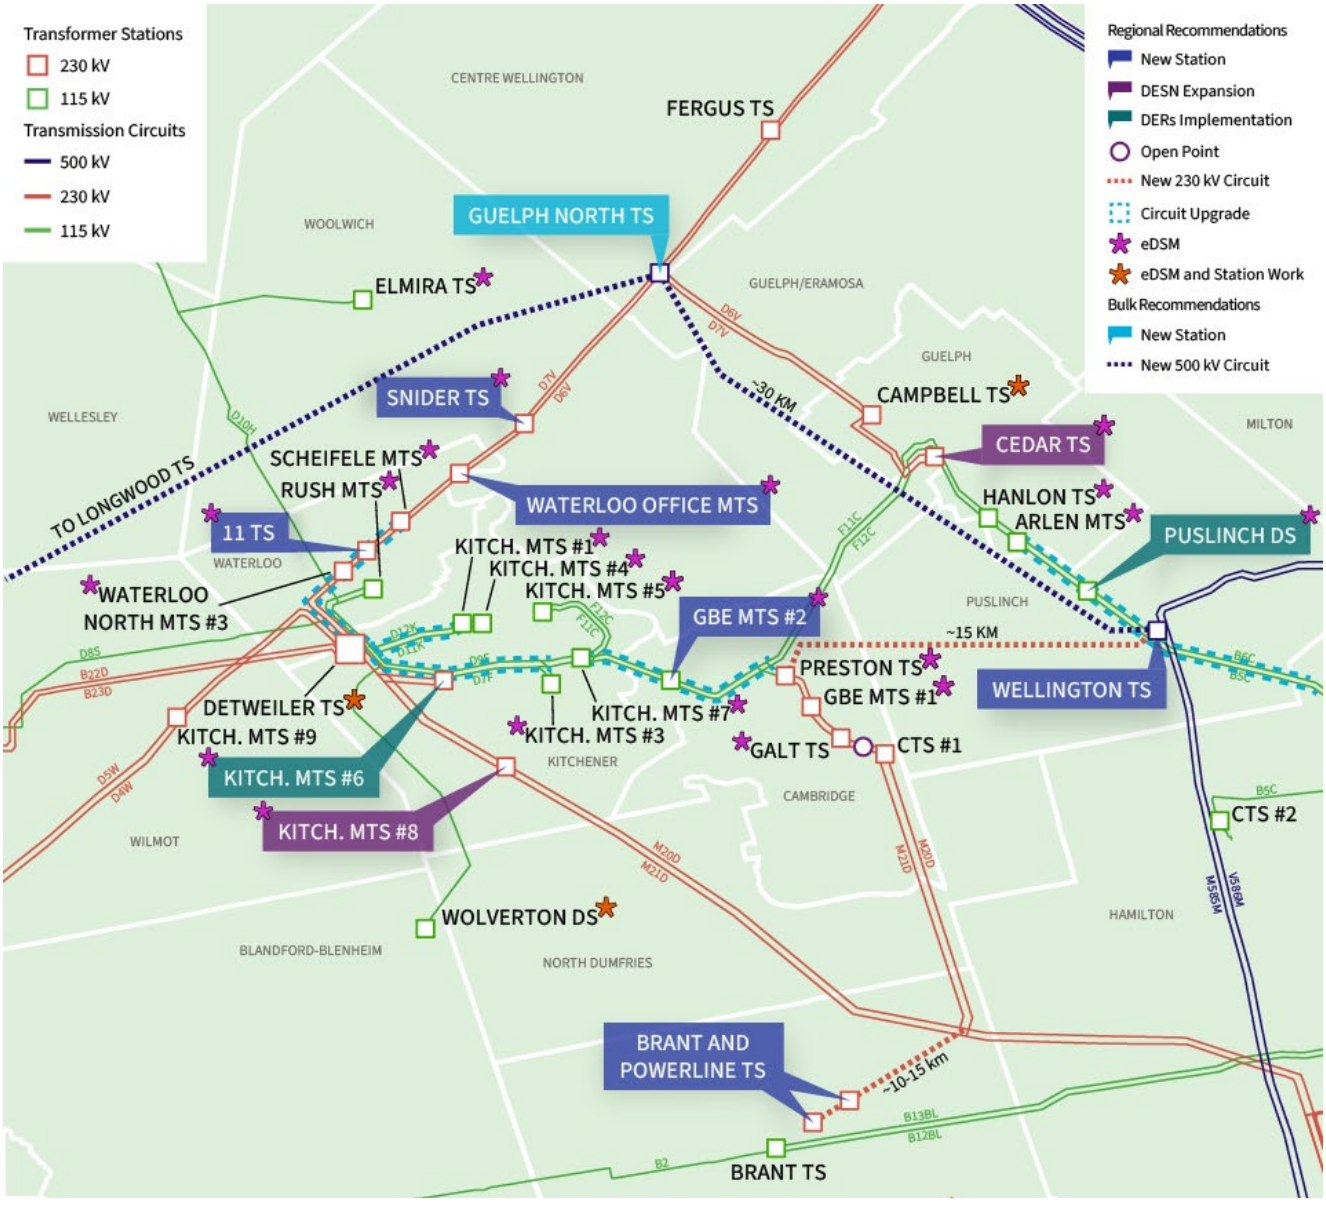
To share information about the regional planning activities and invite participation in the engagement process, outreach was made to the following Indigenous communities:

- Mississauga of the Credit Frist Nation;
- Six Nations of the Grand River, represented by the Six Nations Elected Council and Haudenosaunee Confederacy Chiefs Council; and
- Métis Nation of Ontario.

Detailed non-confidential feedback submitted to the IESO and the IESO's responses can be viewed on the KWCG engagement webpage. However, the IESO did not receive feedback from the identified First Nation communities. Although invitations were extended to participate in the webinar and to engage in one-on-one meetings, no responses or feedback were provided.

Indigenous Participation and Engagement in Transmission Development

Indigenous engagement during the regional planning process assists the IESO in its assessment of various options to address future transmission system needs. By conducting regional planning, the IESO determines the most reliable and cost-effective option after it has engaged with stakeholders and Indigenous communities and publishes those recommendations in the applicable IRRP. Where the IESO determines that the lead time required to implement those solutions requires immediate action, the IESO may provide those recommendations ahead of the publication of a planning report, such as through a hand-off letter to the lead local transmitter in the region.



If a recommendation is made in an IRRP to proceed with a transmission solution, the transmission project proponent (not the IESO) will be responsible for obtaining applicable regulatory approvals from the provincial and/or federal governments, including an Environmental Assessment (EA). Where an EA is required, Indigenous consultation will be undertaken as part of the EA process. Other regulatory processes may also trigger the duty to consult. The relevant Crown entity is responsible for consultation but will delegate certain aspects of consultation to the proponent to carry out. In addition to fulfilling these delegated consultation obligations, project proponents are encouraged to engage early with Indigenous communities on ways to enable participation in particular projects.

In addition to the EA process, a project proponent will need to submit a Leave to Construct application to the Ontario Energy Board prior to starting construction. The *Ontario Energy Board Act, 1998* limits the scope of the Ontario Energy Board's determination on whether the project is in the public interest to consideration of price, reliability, and quality of electricity service. Accordingly, it is not within the Ontario Energy Board's purview to assess whether the Crown's duty to consult has been satisfied in respect of the transmission project.

9. Conclusion

The KWCG IRRP identifies electricity needs in the region over the 20-year period from 2026 to 2045, recommends a plan to address immediate and near-term needs, and lays out actions to monitor long-term needs. Figure 54 visually depicts these recommendations across the region.

Figure 54 | Overview of Recommended Near- to Medium-Term Solutions for KWCG IRRP[23]

Overall, the Technical Working Group recommends targeting eDSM programs across the KWCG region to support both near-term and long-term growth.

[23] Distribution-level load transfers are not shown, for simplicity.

In the near and medium term, the Technical Working Group recommends multiple integrated solutions: 115 kV line upgrades, new 115 kV and 230 kV stations in Waterloo, Cambridge, and Kitchener, a 500/230 kV autotransformer stations, a new double-circuit 230 kV line, and a normally open point at Ameristeel junction. Projects should also proceed to increase station capacity: at Wolverton DS and Campbell TS, through station work; at Cedar TS, through the conversion to 230 kV when T7/T8 reach end of life. Moreover, the Technical Working Group recommends the optimization of existing station capacity where possible by leveraging distribution load transfers. Finally, at Puslinch DS and at Kitchener MTS #6, distribution-connected resources are required.

Some of these near-term recommendations were issued before this IRRP was finalized, through an urge letter focused on the immediate supply needs on the Middleport to Detweiler transmission lines. This was coordinated with the 2024 Burlington to Nanticoke IRRP recommendations for the Brant 115 kV Extended Area.

In the long term, the Technical Working Group should continue monitoring and re-assessing regional needs through future planning cycles and annual Technical Working Group meetings. In particular, demand growth, eDSM savings, and distribution load transfers should be monitored at Arlen TS, Hanlon TS, the MxD sub-system, and across multiple Kitchener MTS — especially those at the 115 kV voltage level. The need for a switching station at Galt junction should also continue to be considered, as well as a new 230 kV station and 230 kV connection lines in the Kitchener Freeport area.

The IESO will continue to participate in the Technical Working Group during the next phase of regional planning, the Regional Infrastructure Plan, to provide input and ensure a co-ordinated approach. The Technical Working Group will continue to monitor growth across the region to determine if or when further reinforcements will be needed. This includes any future community energy plans, electrification trends, customer connection queues, changes to local generation, and changes to eDSM programs. The Technical Working Group will meet at regular intervals to monitor developments and track progress toward plan deliverables. If underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the five-year schedule mandated by the Ontario Energy Board.

Executive Summary

This Integrated Regional Resource Plan (IRRP) addresses electricity needs in the Toronto Region over a 20-year period, to 2044. The Toronto Region is defined by electrical infrastructure boundaries and the municipal boundaries of the City of Toronto.

For the purposes of this IRRP, the Toronto Region has been divided into three electrical subsystems: Northern, Western, and Eastern Toronto. These subsystems reflect the configuration of the transmission system and the location of major step-down transformer stations and other points of system supply. The IRRP focuses on identifying and addressing electricity needs in each of these subsystems, while also coordinating with broader bulk system planning.

The IRRP considers the reliability impacts of the significant demand growth forecast for the Toronto Region. Peak demand is expected to nearly double by 2043 and while the region has historically been summer-peaking, the region could become winter peaking by the early-2030s. The plan considered reference and high electrification forecast scenarios to determine the needs of the region, identify potential investments to address those needs, and offer corresponding recommendations to ensure the system remains reliable and resilient to demand growth uncertainties in the long term.

To identify near, medium, and long-term needs, the Technical Working Group[1] assessed station capacity, supply capacity, reliability, and load security needs across the region. A combination of wires and non-wires solutions were evaluated, with a number of recommendations made to address needs as they arise.

Recommendations include immediate actions to develop infrastructure such as new and expanded transmission stations to increase the amount of electricity that can flow into Toronto, and two locations for energy storage facilities to inject electricity when needed and improve reliability.

Given the pace of growth in the City of Toronto, the IESO is also recommending a new underwater transmission line connecting downtown Toronto to Bowmanville via Lake Ontario. While the IESO assessed alternative options including over and underground transmission options, the underwater Third Line is the preferred option. This line can accommodate significantly more growth in Toronto and the GTA, enabling 900 MW of supply to flow from the east; improving supply diversity and resilience by introducing a true third supply path into the downtown core; as well as supporting load restoration following major power disruptions, among other benefits.

Non-wires alternatives (NWAs) such as targeted electricity demand-side management (eDSM) and distributed energy resources (DERs) including solar and storage, are also recommended to help potentially defer long-term infrastructure requirements. The plan recommends an incremental 320 MW of summer and 121 MW of winter savings by 2045, on top of the planned delivery of 847 MW of summer and 756 MW of winter savings through Save on Energy programs. For context, the current peak demand of Toronto is close to 5,000 MW. These local programs will be developed and made available to Toronto residents and businesses as part of the new eDSM Framework. The

[1] The Technical Working Group includes the IESO, the Local Distribution Company, Toronto Hydro Electric-System Limited and the lead transmitter, Hydro One Networks Inc.

Technical Working Group encourages all Toronto residents and businesses to take full advantage of Save on Energy programs to maximize incremental eDSM achieved in the City.

Options for monitoring long-term needs, towards the end of the study period, are also proposed. While they do not yet require action, it is important to preserve the long-term viability of certain solutions.

PEC is currently critical to the reliability of both Toronto's and the broader province's electricity supply. The Third Line is foundational to a future without PEC; however, the line is needed regardless of the future of PEC. Once the line comes into service, local reliance on PEC will be reduced, but it may still be needed to meet the provincial grid's peak needs. The Toronto IRRP is focused on local supply and does not address matters of provincial supply.

The study has also considered points of coordination with ongoing bulk planning initiatives, including the South and Central Bulk Plan, which is studying bulk system needs and potential upgrades with a notional 2035 focus. A second, longer term bulk planning study, expected to be initiated later in 2026 will focus on bulk system needs into the 2040s, including the potential impact of bulk enhancements on regional supply. Both studies have the potential to affect longer term needs and the feasibility of solutions available to/in the area. Specifically, in terms of PEC's contribution to provincial resource adequacy, the Bulk Plan will be looking at the need and timing of bulk transmission upgrades needed for a future where PEC (and other emitting resources in the GTA) may be out-of-service. The current study is expected to be complete in early 2026.

Engagement was a key input to the development of this IRRP. The IESO engaged with municipalities, Indigenous communities, stakeholders, and the public throughout the planning process. Activities included targeted one-on-one discussions with the City of Toronto and Indigenous communities, technical briefings with communities and six public webinars to share information and solicit written feedback. The overarching themes of feedback received during the development of the IRRP primarily focused on the future of PEC; preference for non-wire options; enhanced transparency for data/information and decision rationale; alignment with City of Toronto decarbonization initiatives; recognition of the need for a third supply line; coupled with requests for more information on the evaluation of options, impacts of routing options, and concern it would bring nuclear energy into the City. The feedback received helped shape the demand forecast, identify local priorities, and inform the recommended solutions.

The Technical Working Group will continue to monitor growth, electrification trends, and large customer connections across the region. The group will meet regularly to track progress, assess changing conditions, and update the plan as needed. If underlying assumptions change significantly, the IRRP may be amended, or a new planning cycle initiated ahead of the standard five-year schedule mandated by the Ontario Energy Board.

Summary of Recommendations

Needs identified and resulting recommendations[2] emerging from this plan to enable growth driven by urban and economic development and electrification, consist of:

[2] All technical energy storage assumptions in this report assume the use of lithium-ion battery technology.

Table 1 | Northern Toronto Recommendations

Need	Project	Expected In-Service (based on Reference Forecast)
Overall Station Capacity and Supply Capacity	Build Downsview MTS	2033

Table 2 | Western Toronto Recommendations

Need	Project	Expected In-Service (based on Reference Forecast)
Manby TS (West) Autotransformers	Reliance on the Manby Remedial Action Scheme[3]	Ongoing
	Permanent transfer of Copeland MTS T2/T4 to Leaside Supply	2026
	Incremental eDSM	Ongoing
	Develop Energy Storage Systems at or downstream of the Manby West autotransformers	2029/2030
Manby TS (East) Autotransformers	Reliance on the Manby Remedial Action Scheme	Ongoing
	Permanent Load Transfer from Fairbank TS to Downsview MTS	2037
	Incremental eDSM	Ongoing
Manby to Riverside Circuits	Increase transmission capacity by upgrading circuits from Manby TS to Riverside TS[4]	2028
St Clair to Fairbank Circuits	Permanent Load Transfer from Fairbank TS to Downsview MTS	2037
Fairbank TS	Permanent Load Transfer from Fairbank TS to Downsview MTS	2037
Strachan TS	Incremental eDSM	Ongoing
Manby DESN	Monitor station capacity need as need arises towards the end of forecast	Ongoing

[3] A scheme designed to detect predetermined system conditions and automatically take corrective actions that may include, but are not limited to, adjusting or tripping generation (MW and MVar), tripping load, or reconfiguring the system.

Table 3 | Eastern Toronto Recommendations

Need	Project	Expected In-Service (based on Reference Forecast)
Leaside to Bridgman to Dufferin Circuits	Increase transmission capacity to Dufferin TS by upgrading underground circuits between Dufferin TS and the Bartlett/Dufferin Junctions	2036
	Transfer Dufferin TS load to upgraded Wiltshire TS	2036
	Develop Energy Storage Systems at or downstream of Dufferin TS	2036
Leaside to Bloor to Hearn Circuits	Increase transmission capacity by upgrading circuits from Leaside TS to Bloor JCT and from Hearn SS to Basin TS	2036
	Incremental eDSM	Ongoing
Scarboro TS, Warden TS, and Sheppard TS	Develop an additional DESN at Scarboro TS to increase capacity	2035
Glengrove TS	Investigate the feasibility of load transfers from Glengrove TS to Duplex TS	2042
Dufferin TS	Develop Energy Storage Systems at or downstream of Dufferin TS	2040
Basin TS	Develop an expansion of Basin TS or add a new station in the area.	2036
Overall Supply Capacity	Develop underwater HVDC transmission supply towards Hearn SS	2034

1 Introduction

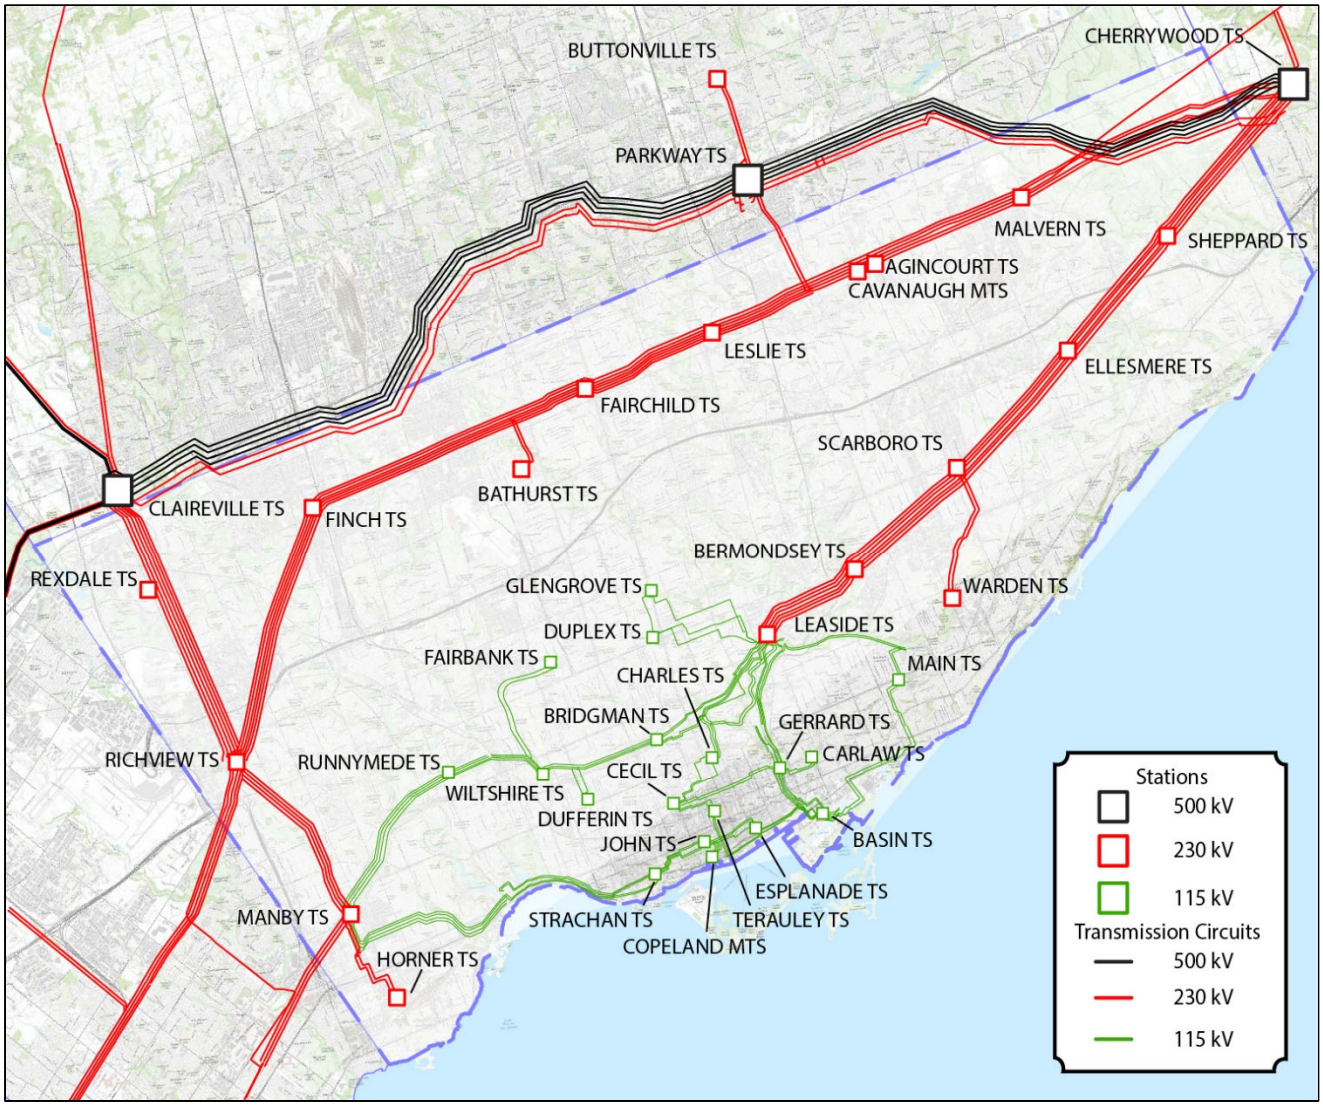
This Integrated Regional Resource Plan (IRRP) addresses the electricity needs of the Toronto Region (the "Region") over a 20-year period, from 2025 to 2044. The Toronto electricity planning region includes the area within the municipal boundary of the City of Toronto. The electricity supply to the Toronto Region is shown in Figure 1. The region is supplied by a network of 230 kV lines that run along the northern and western edges of the city, and into the core from the east, providing supply points for step-down stations that supply these areas. The central core of the City of Toronto is supplied by a 115 kV network that connects to the 230 kV system through two 230/115 kV autotransformer stations – Leaside Transformer Station (TS) and Manby TS. A small number of distribution feeders from Toronto also supply customers in the neighbouring cities of Mississauga and Pickering.

In addition to the transmission infrastructure, the Portlands Energy Centre (PEC) is a 600-megawatt (MW) capacity natural gas-fired combined cycle power plant that provides a major source of supply to Toronto. This station is located near the Eastern waterfront and is connected to the Hearn Switching Station (SS), south of Basin TS, as shown in Figure 1.

The region is summer peaking and the 2022 weather-corrected peak summertime electricity demand in the Toronto region was approximately 4,600 MW.[5]

The region's electricity is delivered by the local distribution company (LDC) Toronto Hydro-Electric System Limited (Toronto Hydro). Hydro One Networks Inc. (Hydro One) is the primary transmission asset owner. This IRRP report was prepared by the Independent Electricity System Operator (IESO) on behalf of a Technical Working Group, composed of Toronto Hydro, Hydro One, and the IESO.

The IESO also acknowledges that Toronto is the traditional territory of many nations, and is committed to ongoing, meaningful dialogue with Indigenous communities to inform long-term planning in Toronto and across Ontario. To raise awareness about the regional planning cycle in Toronto, and invite participation in the engagement process, the IESO's engagement efforts included outreach to Indigenous communities throughout the development of the plan, including to the Mississaugas of the Credit First Nation, Six Nations of the Grand River as represented by Six Nations Elected Council as well as the Haudenosaunee Confederacy Chiefs Council, Alderville First Nation, Beausoleil First Nation, Chippewas of Georgina Island First Nation, Chippewas of Rama First Nation, Curve Lake First Nation, Hiawatha First Nation, Mississaugas of Scugog Island First Nation, and Métis Nation of Ontario.



This report is organized as follows:

- A summary of the recommended plan for the region is provided in Section 2;
- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the region and the study scope are discussed in Section 4;

[5] The peak electricity demand in summer 2006 was 5,305 MW; in summer 2022, demand was 4,356 MW.

- Demand forecast scenarios, and electricity Demand Side Management (eDSM) and distributed generation assumptions, are described in Section 5;
- Electricity needs in the region are presented in Section 6;
- Alternatives and recommendations for meeting needs are addressed in Section 7;
- An overview with the linkages to the South and Central Bulk Study in Section 8; and
- A summary of engagement activities is provided in Section 9;

Figure 1 | Overview of the Toronto Region[6]

[6] IRRP regions are defined by electricity infrastructure; geographical boundaries are approximate.

2 The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of the Toronto Region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system, as evaluated through application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by the North American Electric Reliability Corporation (NERC). The IRRP's recommendations are informed by an evaluation of different options to meet the needs and consider reliability, cost, technical feasibility, maximizing the use of the existing electricity system (where economic), and feedback from stakeholders.

2.1 Status of Plans from Previous IRRP Cycles

Following the previous cycle of region planning, which concluded with the 2nd Cycle RIP report, several projects were recommended which have now been completed or are presently underway. The status of these projects is summarized in Table 4.

Table 4 | Needs Identified in the Previous Cycle with Implementation Plan Update

Infrastructure	Need	Expected In-Service
Bridgman TS	Transformer replacement (T11, T12, T13, T14)	2024
Fairbank TS	Transformer replacement (T1, T2, T3, T4)	2024
Main TS	Transformer replacement (T3, T4)	2024
John TS	Transformer replacement (T5, T6)	2025
Between Esplanade TS and Terauley TS	C5E/C7E underground cable replacement	2026
Richview TS to Manby TS	Corridor Upgrade: 115 kV double-circuit line is rebuilt to operate at 230 kV	2026
Copeland TS Phase 2	Capacity need: additional DESN added	2026
Horner TS	Installation of second DESN	2022 (Complete)
Runnymede TS	Transformer replacement (T3, T4)	2021-2022 (Complete)
Sheppard TS	Transformer replacement (T3, T4)	2021-2022 (Complete)
Strachan TS	Transformer replacement (T12)	2021-2022 (Complete)
John TS	Transformer replacement (T1, T2, T4)	2019-2021 (Complete)

2.2 IRRP Recommendations for Northern Toronto

Table 5 provides a summary of recommendations to address the needs and accommodate load growth and maintain reliability in Northern Toronto.

Table 5 | Northern Toronto Recommendations

Infrastructure	Project	Expected In-Service (based on Reference Forecast)
Station Capacity and Supply Capacity	Build Downsview MTS	2033

2.3 IRRP recommendations for Western Toronto

Table 6 provides a summary of recommendations to address the needs and accommodate load growth and maintain reliability in Western Toronto.

Table 6 | Western Toronto Recommendations

Infrastructure	Project	Expected In-Service (based on Reference Forecast)
Manby TS (West) Autotransformers	Reliance on the Manby Remedial Action Scheme	Ongoing
	Permanent transfer of Copeland MTS T2/T4 to Leaside Supply	2026
	Incremental eDSM	Ongoing
	Develop Energy Storage Systems at or downstream of the Manby West autotransformers	2029/2030
Manby TS (East) Autotransformers	Reliance on Manby RAS	Ongoing
	Permanent Load Transfer from Fairbank TS to Downsview MTS	2036
	Incremental eDSM	Ongoing
Manby to Riverside Circuits	Increase transmission capacity by upgrading circuits from Manby TS to Riverside TS[7]	2028
St Clair to Fairbank Circuits	Permanent Load Transfer from Fairbank TS to Downsview MTS	2037
Fairbank TS	Permanent Load Transfer from Fairbank TS to Downsview MTS	2037
Strachan TS	Incremental eDSM	Ongoing
Manby DESN	Monitor station capacity need as need arises towards the end of forecast	Ongoing

[7] Note that this was also recommended by the 2022 Needs Assessment Report, https://www.hydroone.com/abouthydroone/CorporateInformation/regionalplans/toronto/Documents/Toronto_Region_Needs_Assessment_Report_Third_Cycle_Regional_Planning.pdf

2.4 IRRP Recommendations for Eastern Toronto

Table 7 provides a summary of recommendations to address the needs and accommodate load growth and maintain reliability in Eastern Toronto.

Table 7 | Eastern Toronto Recommendations

Infrastructure	Project	Expected In-Service (based on Reference Forecast)
Leaside to Bridgman to Dufferin Circuits	Increase transmission capacity to Dufferin TS by upgrading underground circuits between Dufferin TS and the Bartlett/Dufferin Junctions	2036
	Transfer Dufferin TS load to upgraded Wiltshire TS	2036
	Develop Energy Storage Systems at or downstream of Dufferin TS	2036
Leaside to Bloor to Hearn Circuits	Increase transmission capacity by upgrading circuits from Leaside TS to Bloor JCT and from Hearn SS to Basin TS	2036
	Incremental eDSM	Ongoing
Scarboro TS, Warden TS, and Sheppard TS	Develop an additional DESN at Scarboro TS to increase capacity	2035
Glengrove TS	Investigate the feasibility of load transfers from Glengrove TS to Duplex TS	2042
Dufferin TS	Develop Energy Storage Systems at or downstream of Dufferin TS	2040
Basin TS	Develop an expansion of Basin TS or add a new station in the area.	2036
Overall Supply Capacity	Develop underwater HVDC transmission supply towards Hearn SS	2034

3 Development of the Plan

3.1 The Regional Planning Process

In Ontario, preparing to meet the electricity needs of customers at a regional level is achieved through regional planning. Regional planning assesses the interrelated needs of a region – defined by common electricity supply infrastructure – over the near, medium, and long-term, and results in a plan to ensure cost-effective and reliable electricity supply. A regional plan considers the existing electricity infrastructure in an area, forecasts growth and customer reliability, evaluates options for addressing needs, and identifies appropriate investments to meet the needs of a region over the next 20 years.

The current regional planning process was formalized by the Ontario Energy Board in 2013 and is performed on a five-year cycle for each of the 21 planning regions in the province. The process is carried out by the IESO, in collaboration with the transmitters and LDCs in each region. The process consists of four main components:

1. A Needs Assessment, led by the transmitter, which completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination
2. A Scoping Assessment, led by the IESO, which identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities
3. An IRRP, led by the IESO, which identifies the appropriate mix of investments in conservation and demand management, generation, transmission facilities or distribution facilities, or other electricity system initiatives in order to address the identified needs of a region and/or
4. A RIP, led by the transmitter, which provides further details on recommended wires solutions.

Regional planning is not the only type of electricity planning in Ontario. The IESO also carries out bulk system planning and Local Distribution Companies are responsible for distribution system planning. There are inherent linkages in all three levels of electricity infrastructure planning.

3.2 Toronto IRRP Development

The process to develop the Toronto IRRP was initiated in May 2023, following the publications of the Needs Assessment Report in December 2022 by Hydro One and the Scoping Assessment Outcome Report in March 2023 by the IESO. The Scoping Assessment recommended that the needs identified for the Toronto Region be considered through an IRRP in a coordinated regional approach, supported with public engagement. The Technical Working Group was then formed to develop the terms of reference for this IRRP, gather data, identify needs, develop options, and recommend solutions for the region. On April 5, 2024, the IESO requested an extension for the Toronto IRRP to March 20, 2025 due to the complexity of developing forecast scenarios, and additional scope included into the plan to enable the consideration of the impacts of retiring PEC, which requires the IESO to introduce additional engagement to ensure governments, businesses, developers, Indigenous communities, the City of Toronto and residents are informed and can provide input to efforts taken to decarbonize the electricity system in Toronto. On January 20, 2025, the IESO requested for an additional extension

to October 31, 2025, to accommodate the results of a Local Achievable Potential Study in the IRRP in recognition of the keen interest from communities and stakeholders on renewable generation, energy storage, and energy efficiency. The IESO received approval for the extension on March 31, 2025.

4 Background and Study Scope

This is the third cycle of regional planning for the Toronto Region. The previous planning cycle for the Region concluded in 2020. For electricity planning purposes, planning regions are generally defined by the electricity infrastructure boundaries; however, the Toronto Region roughly conforms to an area within the City of Toronto municipal boundary.

The IESO acknowledges that Toronto is the traditional territory of many nations, and is committed to ongoing, meaningful dialogue with Indigenous communities to help inform long-term planning. To raise awareness about the regional planning cycle in Toronto, and invite participation in the engagement process, the IESO's engagement efforts included outreach to Indigenous communities throughout the development of the plan, including to the Mississaugas of the Credit First Nation, Six Nations of the Grand River as represented by Six Nations Elected Council as well as the Haudenosaunee Confederacy Chiefs Council, Alderville First Nation, Beausoleil First Nation, Chippewas of Georgina Island First Nation, Chippewas of Rama First Nation, Curve Lake First Nation, Hiawatha First Nation, Mississaugas of Scugog Island First Nation, and Métis Nation of Ontario.

This IRRP develops and recommends options to meet the electricity needs of the Toronto Region in the near, medium, and long term. The plan was prepared by the IESO on behalf of the Technical Working Group, and includes consideration of forecast electricity demand growth, eDSM, distributed generation (DG), transmission and distribution system capability, relevant community plans, age and condition of transmission infrastructure assets, and bulk transmission system needs and opportunities.

The following transmission facilities were included in the scope of this study:

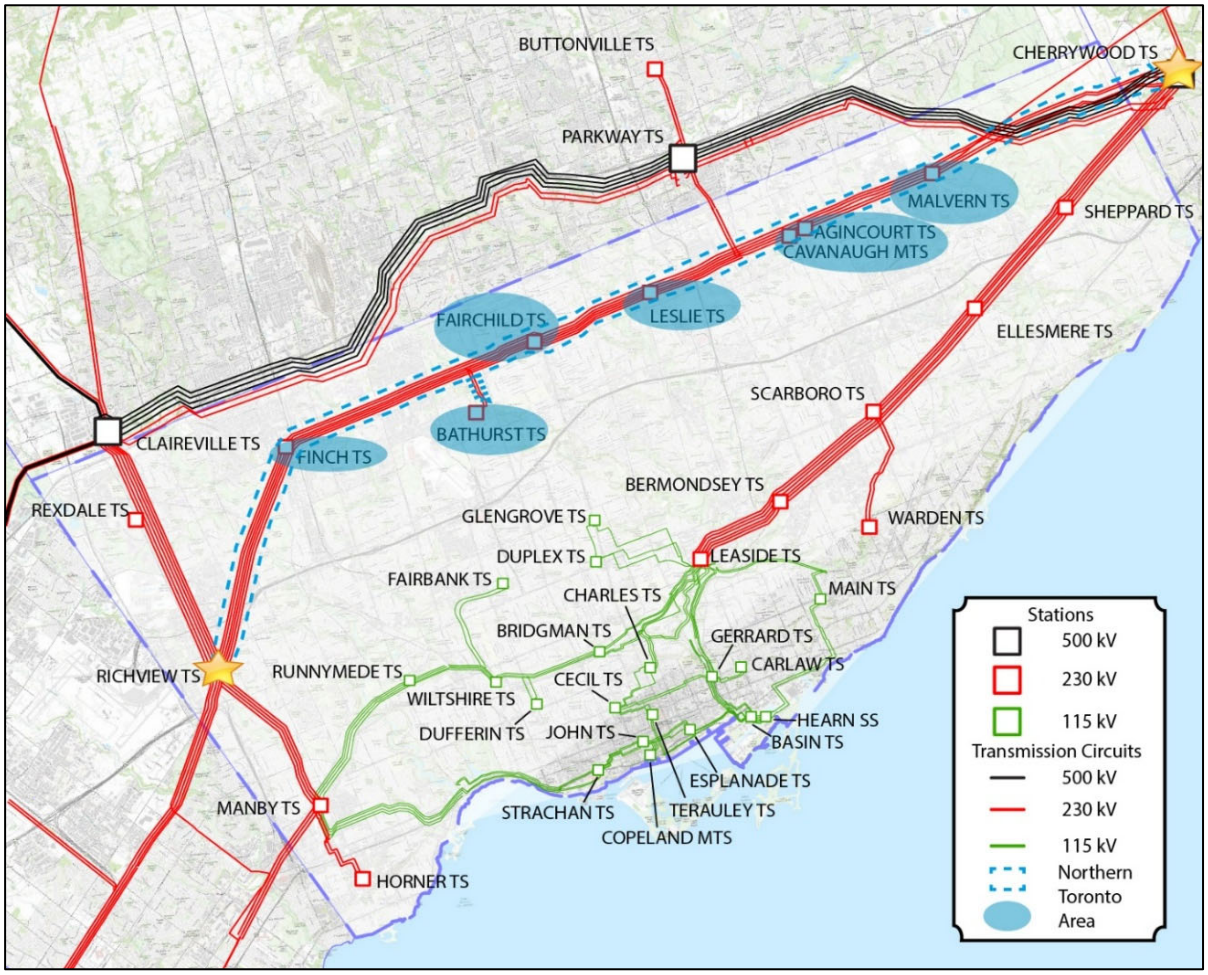
Transformer stations:

Agincourt TS	Cecil TS	Fairbank TS	Leaside TS	Runnymede TS
Basin TS	Charles TS	Fairchild TS	Leslie TS	Scarboro TS
Bathurst TS	Copeland MTS	Finch TS	Main TS	Sheppard TS
Bermondsey TS	Dufferin TS	Gerrard TS	Malvern TS	Strachan TS
Bridgman TS	Duplex TS	Glengrove TS	Manby TS	Terauley TS
Carlaw TS	Ellesmere TS	Horner TS	Rexdale TS	Warden TS
Cavanagh MTS	Esplanade TS	John TS	Richview TS	Wiltshire TS

230 kV transmission circuits:

C10A	C15L	C5R	K23C	R13K	V72R	V77R
C2L	C16L	C18R	R24C	R15K	V73R	V79R
C3L	C17L	C20R	R1K	P21R	V74R	
C14L	C4R	K21C	R2K	P22R	V76R	

115 kV transmission circuits:



C5E	H9DE	H7L	K13J	K12W	L16D	L2Y
C7E	H10DE	H11L	K14J	L4C	L13W	
D11J	H2JK	H6LC	K1W	L9C	L14W	
D12J	H1L	H8LC	K3W	L12C	L15	
D6Y	H3L	K6J	K11W	L5D	L18W	

The Toronto Region can be further categorized into three sub-areas, which align with the main direction of incoming transmission supply in each area:

- **Northern Toronto**

Northern Toronto consists of the 230 kV circuits and stations supplied from the 230 kV transmission corridor between Richview TS to Cherrywood TS, also known as the Finch Corridor. This area primarily serves the northern areas of the City of Toronto, including North York and the northern areas of Etobicoke and Scarborough. A map of Northern Toronto is shown in Figure 2.

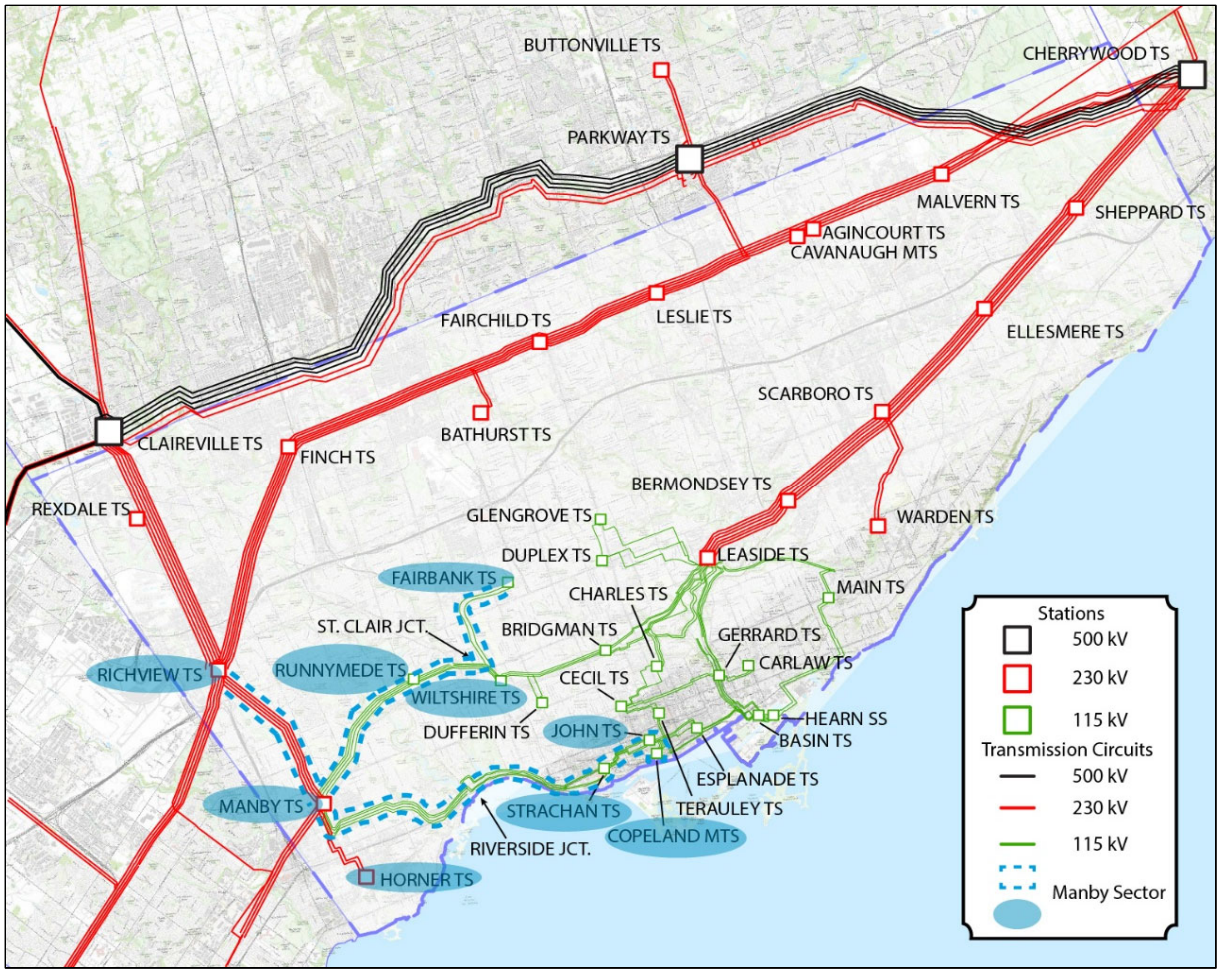


Figure 2 | Map of Northern Toronto Area

- **Western Toronto**

Western Toronto consists of the stations and circuits downstream of the Richview to Manby transmission corridor in Etobicoke. The area is serviced by a combination of 230 kV and 115 kV lines and nine stations, which provide power to southern Etobicoke and portions southwest Toronto and the downtown core. The electricity supplied by the six 115 kV stations in central Toronto and the 230 kV Horner TS in Etobicoke flows through the transmission infrastructure at Manby TS. A map of the Western Toronto area is shown in Figure 3.

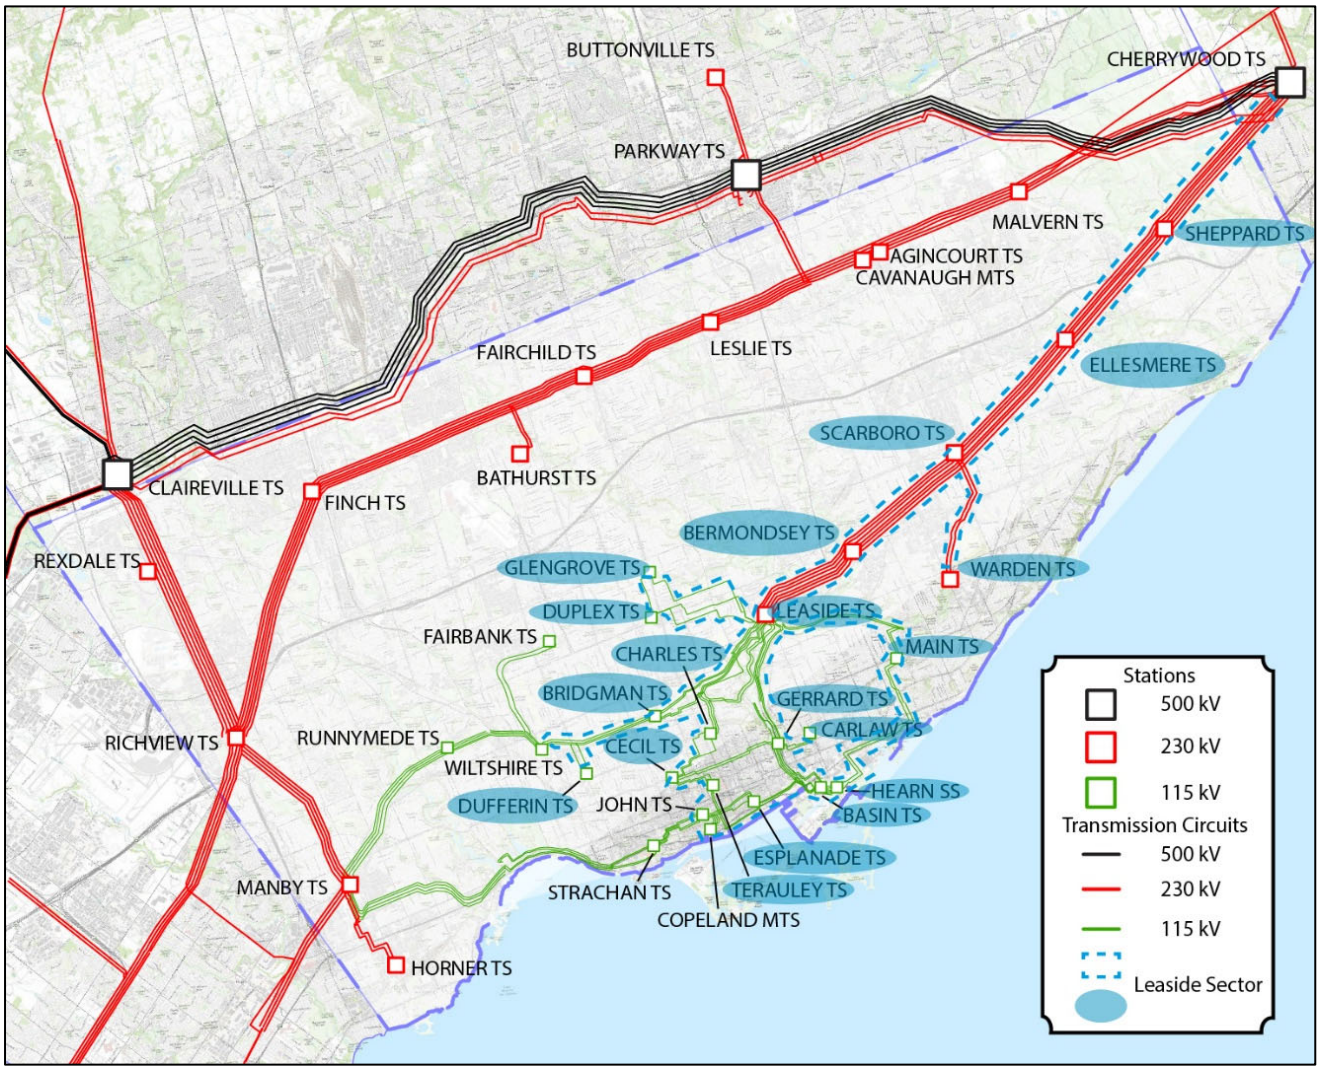

Figure 3 | Map of Western Toronto Area

- **Eastern Toronto**

Eastern Toronto includes the stations and circuits that are supplied by the Cherrywood TS to Leaside TS corridor (also known as the Gatineau Energy Corridor, and the Meadoway). These transmission lines and stations serve most of Scarborough, portions of the downtown core, East York and York. PEC is located in this area and provides local capacity that is crucial to maintaining local reliability during periods of peak demand or during transmission outages. A map of the area is shown in Figure 4.

Figure 4 | Map of Eastern Toronto Area

The Toronto IRRP was developed by completing the following steps:

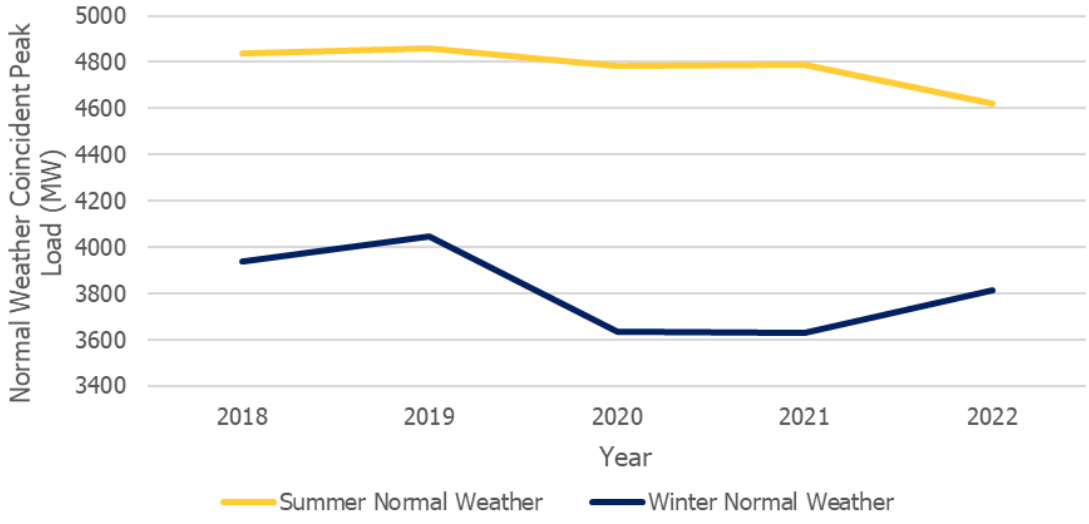
- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe (as described in the following steps).
- Examining the load meeting capability (LMC) and reliability of the existing transmission system, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC, NPCC and NERC standards and criteria.
- Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO-controlled grid.
- Confirming identified asset replacement needs and timing with the transmitter and the LDC.
- Establishing alternatives to address system needs including, where feasible and applicable, generation, transmission and/or distribution, and other approaches such as non-wire alternatives including additional eDSM.
- Engaging with communities on needs and possible alternatives.
- Evaluating alternatives to address near-term to long-term needs.
- Communicating findings, conclusions, and recommendations within a detailed plan.

5 Electricity Demand Forecast

Regional planning in Ontario is driven by having to meet peak electricity demand requirements in the region. This section describes the development of the demand forecast for the Toronto region. It highlights the assumptions made for peak demand forecasts, including weather correction, and the contribution of eDSM and distributed generation (DG). Toronto Hydro, the only LDC in this region, provided forecasts for a reference case, and a high growth scenario. Toronto Hydro's scenarios considered different levels of growth for three drivers: electric vehicles, electrified heating, and data centres.

To evaluate the reliability of the electricity system, the regional planning process is typically concerned with the coincident peak demand for a given area. This is the demand observed at each station for the hour of the year in which overall demand in the study area is at its maximum.

The regional planning process also considered non-coincident peaks which refers to each station's individual peak, regardless of whether these peaks occur at different times. Non-coincident peaks are used to understand the potential needs of the stations.



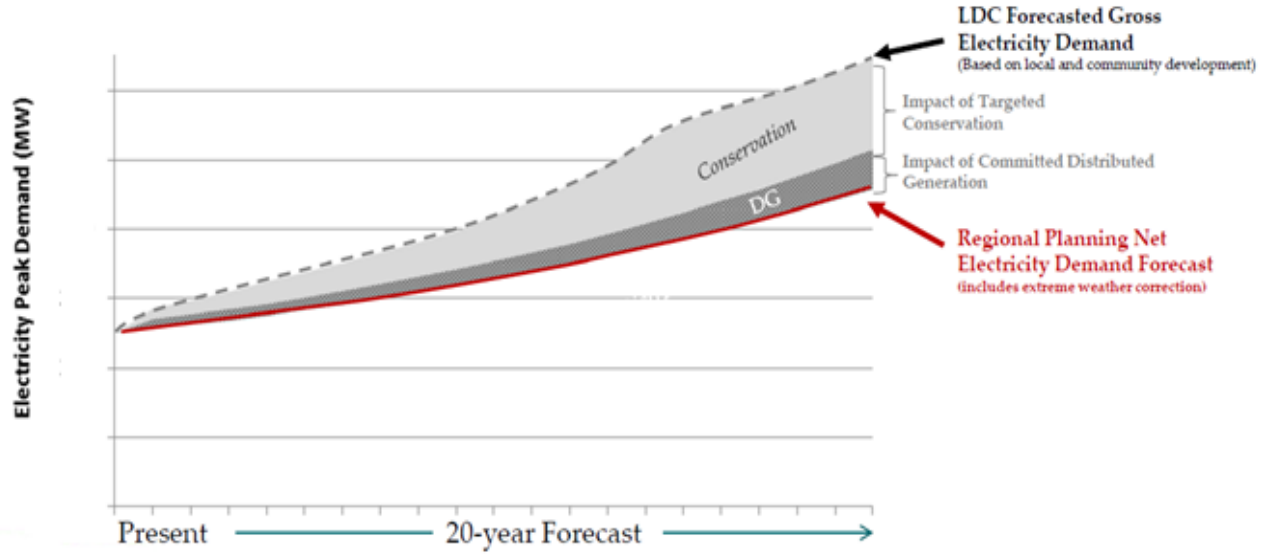
5.1 Historical Demand

The peak electricity demand within Toronto has been flat or slightly downward trending over the years preceding the forecast for this IRRP, from 2018 to 2022.

Figure 5 shows both the winter and summer coincident normal weather-corrected (adjusted to reflect normal weather conditions) historical demand for the Toronto region. Weather-corrected historical demands have been shown to remove the effect of weather on annual changes in demand. Weather-corrected demand is more appropriate for evaluating growth trends.

The weather-corrected demand for the Toronto region has averaged 4,780 MW in the summer and 3,813 MW in the winter over the last five years.

Figure 5 | Toronto Region Historical Normal Weather Coincident Forecast



5.2 Demand Forecast Methodology

The methodology used to develop a 20-year IRRP peak demand forecast starting from LDC forecasts is illustrated in Figure 6. A gross demand forecast, which assume the weather conditions of a normal year based on historical weather conditions (referred to as "normal weather"), was developed by Toronto Hydro. The forecast was then modified to reflect the forecasted peak demand impacts of eDSM and DG as contracted through previous provincial programs, such as Feed-In Tariff (FIT) and microFIT. Finally, the forecast was adjusted to reflect extreme weather conditions to produce a reference forecast for planning assessments. This net, extreme-weather forecast was then used to assess the electricity needs in the region.

LDCs have a better understanding of future local demand growth and drivers than the IESO since they have the most direct involvement with their customers, connection applicants, municipalities and communities which they serve. The IESO typically carries out demand forecasting at the provincial level. More details on the components of the demand forecast are provided in the following sections. Assumptions specific to Toronto Hydro's forecast are provided in Section 5.8. The Ontario Energy Board has also published a Load Forecast Guideline for regional planning, through the Regional Planning Process Advisory Group.

Figure 6 | Illustrative Development of Demand Forecast

5.3 Gross LDC Forecast

Toronto Hydro prepared a gross demand forecast at the station level, or at the station bus level for multi-bus stations. The gross demand forecast accounts for increases in demand from new or intensified development, plus known customer connection applications. In addition, when producing the gross demand forecast, the impact of existing DG was removed, as DG impacts are accounted for later (see Section 5.5). Therefore, gross demand forecasts show the demand expected without any DG contributions, new or existing.

Toronto Hydro cited alignment with municipal plans and credited the City of Toronto as a source for input data. Toronto Hydro was also expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices (natural

conservation), but not for the impact of future eDSM measures (such as codes and standards and eDSM programs), which are accounted for by the IESO (discussed in Section 5.4). The gross LDC forecast assumes normal weather conditions, e.g., median weather, or 1-in-2 year expected weather, representing the station level loading at the time of the regional peak.

5.4 Contribution of eDSM to the Forecast

Electricity Demand Side Management[8] (eDSM) is a non-emitting and cost-effective resource that helps meet Ontario's electricity needs by reducing electricity consumption and peak-demand and has been an integral component of provincial and regional planning. EDSM is achieved through a mix of codes and standards amendments, as well as eDSM program-related activities. These approaches complement each other to maximize conservation results.

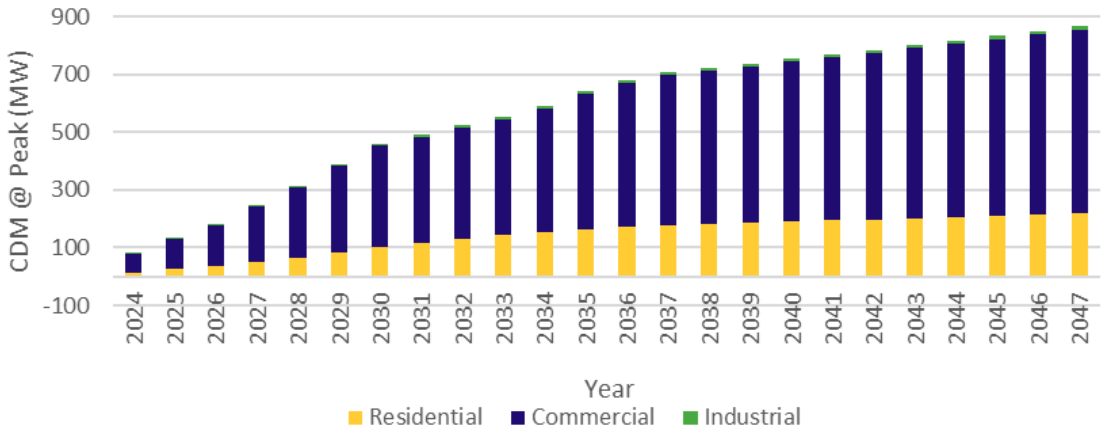
The estimated demand reduction from codes and standards is based on expected improvement in the codes for new and renovated buildings, and through regulation of minimum efficiency standards for equipment used by specified categories of consumers (i.e., residential, commercial and industrial consumers).

The estimated demand reduction from program-related activities is based on the IESO's Annual Planning Outlook eDSM savings forecasts which were informed by the 2021-2024 Conservation and Demand Management (CDM) Framework programs, federal programs expected to result in electricity savings in Ontario and forecasted long-term energy efficiency program savings aligned with the 2021-2024 framework. Through the 2021-2024 CDM Framework the IESO centrally delivered programs on a province-wide basis to residential, commercial and institutional customers, as well as Indigenous communities. Following finalization of the IRRP's demand forecast, the Ontario government directed the IESO to create the 2024-2036 eDSM Framework, which expands the scale and scope of the Save-on Energy programs, including launch of the Home Renovation Savings program for residential customers and new incentives for rooftop solar for both residential and business customers. Higher savings targets under the new framework may impact the timing or magnitude of identified needs.

[8] In alignment with the language of the November 7, 2024 directive to the IESO regarding a new program framework for 2025-2036, this IRRP uses the term "electricity demand side management" replacing "conservation and demand management" used in previous IRRPs and other IESO planning documents.

Figure 7 and Figure 8 show the estimated total yearly reduction to the peak electrical demand due to eDSM, from codes and standards and eDSM programs, for the winter and summer peaks.

Figure 7 | Peak Winter Demand Reduction Due to eDSM



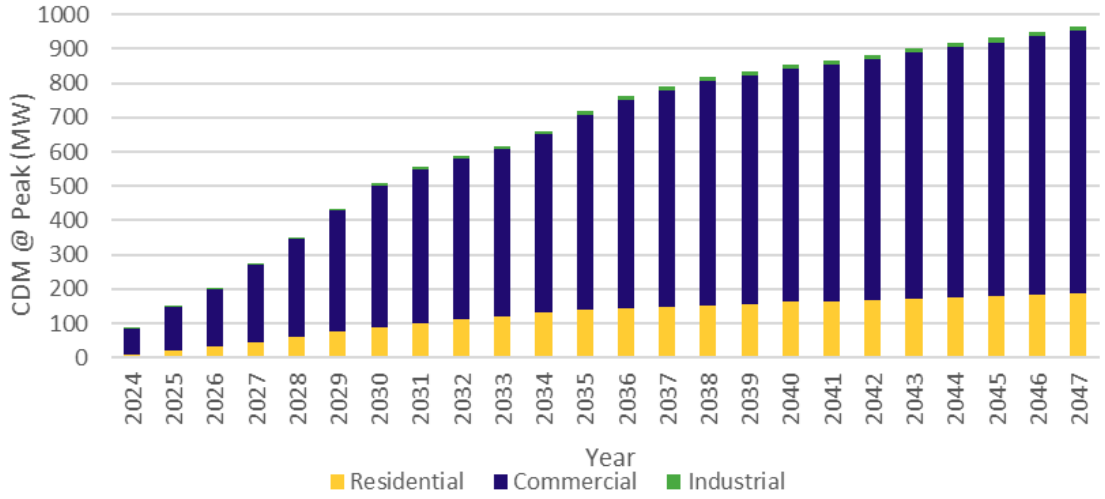


Figure 8 | Peak Summer Demand Reduction Due to eDSM

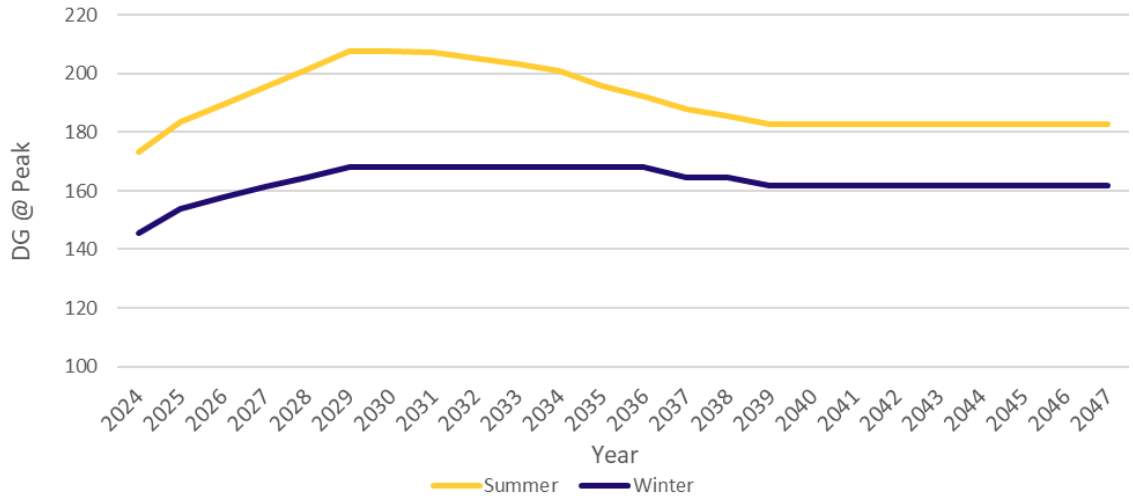


5.5 Contribution of Distributed Generation to the Forecast

In addition to eDSM resources, DG is also forecasted to offset peak-demand requirements. This includes resources contracted under Ontario's FIT and microFIT programs which increased the significance of distributed renewable generation which, while intermittent, contributes to meeting the province's electricity demands. The installed DG capacity by fuel type and the associated contribution factor assumptions can be found in data tables posted on the IESO website.[9] Most of the total contracted installed DG capacity in the Toronto region is non-renewable.

[9] Regional Electricity Planning – Toronto, https://ieso.ca/torontoplanning

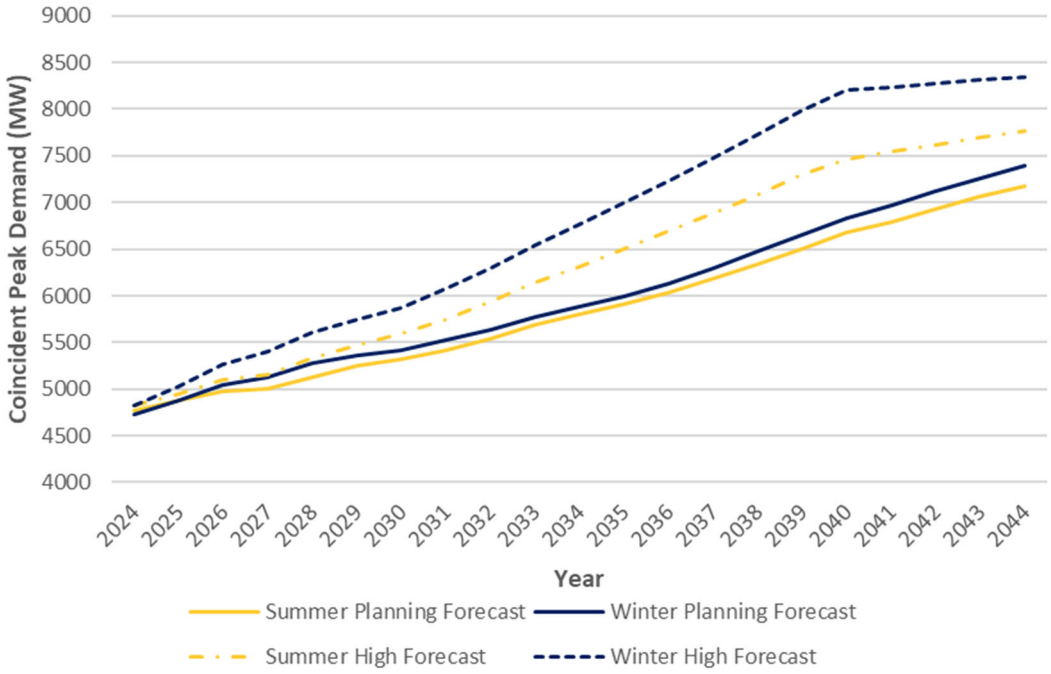
Figure 9 shows the estimated impact of DG on the Toronto Region demand forecast. Note that any facilities without a contract with the IESO are not currently included in the DG peak demand reduction forecast, and therefore the total contribution of DG in Toronto is higher than shown (e.g., net metered and other behind-the-meter and non-contracted facilities).

Figure 9 | Peak Demand Reduction Due to Distributed Generation

5.6 Net Extreme Weather (Planning) Forecast

The net extreme weather forecast, also known as the "planning" forecast, is traditionally a region-wide coincident forecast, meaning that each station forecast reflects its expected contribution to the regional peak demand. This supports the identification of need dates for regional needs that are driven by more than one station and allows for temporary load transfer capabilities between stations to be accounted for when assessing supply capacity.

The planning forecast is produced from two main steps: adjusting for extreme weather and converting to a net forecast.



The first step is to adjust the coincident gross normal weather forecast for extreme weather conditions. This results in a coincident gross forecast which assumes extreme weather.

The last step is to adjust the resulting coincident gross extreme weather forecast for DG and conservation impacts. This is done by subtracting the forecasted DG and eDSM impacts (as described in the above Sections) from the coincident gross extreme weather forecast. This results in a coincident net extreme weather forecast, which is the "planning" forecast used to identify system needs.

For station-specific needs, a non-coincident net extreme weather forecast is used instead. The process for producing this forecast is similar to above and includes an additional step. The coincident forecast is first converted to a non-coincident forecast by applying a coincidence factor to each station. The factor is based on the station's non-coincident peaks compared to the station's historical contribution to the regional peak demand over the past five years (2018-2022 in this case).

The coincident net extreme weather reference and high electrification summer and winter forecasts (together forming the "planning" forecasts) for the Toronto Region is shown in Figure 10.

Figure 10 | Toronto Region Net Extreme Weather Coincident Forecast

5.7 Hourly Forecast Profiles

In addition to the annual peak demand forecast, hourly demand profiles (8,760 hours per year over the 20-year forecast horizon) for various collections of stations were developed to better assess non-wire alternatives to address needs. These profiles were used to quantify the magnitude, frequency, and duration of needs, as described later in Section 7. The profiles were based on historical demand data, adjusted for variables that impact demand such as calendar day (i.e., holidays and weekends) and weather. The profiles were then scaled to match the IRRP peak planning forecast for each year.

Hourly profiles of the identified needs have been posted to the IESO Toronto IRRP webpage. Note that this data is used to roughly inform the overall energy requirements needed to develop and evaluate alternatives; it cannot be used to deterministically specify the precise hourly energy requirements. Real-time loading is subject to various factors like actual weather, customer operation strategies, and future customer segmentation. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification are more widely adopted. Hence, these hourly forecasts are used to select suitable technology types and roughly estimate costs for the needs and options studied in the IRRP. The Technical Working Group will continue to monitor forecast changes as part of implementation of the plan through Annual Working Group meetings until the next cycle of regional planning.

5.8 Toronto IRRP Forecast Methodology and Assumptions

Toronto Hydro, with input from the Technical Working Group, developed the forecast methodology and assumptions for the IRRP. The primary drivers of the forecast include economic growth, electrification trends, customer connection activity, and municipal development plans. These drivers are modeled to reflect their impact on electricity demand across the City of Toronto over the planning horizon. Below is a summary of the main drivers found in the forecast methodology document.[10]

5.8.1 Economic Growth

Economic activity is a foundational input to the demand forecast. Historical non-coincident system peak loads are regressed against economic indicators to establish relationships between load and macroeconomic conditions. Then, these relationships are used to project future system peaks under normal temperature conditions. Due to the lack of long-term GDP forecasts, GDP growth is held constant beyond the five-year outlook.

5.8.2 Electrification Trends

Electrification is a critical driver of future load growth, particularly in the context of market trends and the City of Toronto's Net Zero "TransformTO" strategy. The methodology incorporates three key electrification components:

5.8.2.1 Electric Vehicles

Electric vehicle (EV) adoption is forecasted across light-, medium-, and heavy-duty vehicle segments. Adoption rates vary by scenario, with the high scenario aligned with TransformTO targets (30% EVs by 2030, 100% by 2040). EV load is allocated geographically based on the distribution of existing vehicles, assuming electrification of current fleets. Hourly charging profiles are applied to estimate contributions to system peak.

5.8.2.2 Electrified Heating

Electrified heating adoption is modeled as the percentage of buildings using electric heating systems. Residential and commercial/industrial adoption rates are forecasted separately. Allocation to the bus level is based on customer counts, with higher adoption assumed in areas with greater density. Electrified heating is a significant contributor to winter peak demand.

5.8.2.3 Transit Electrification

Transit electrification is modeled based on TTC's commitment to electrify its bus fleet by 2040. The forecast assumes 190 buses are electrified annually. Space heating for transit stations is also included, modeled at 0.05 kW/m² and converted to electrical demand using a Coefficient of Performance of 2.5.

[10] Toronto Forecast Methodology, https://ieso.ca/-/media/Files/IESO/Document-Library/regional-planning/Toronto/toronto-irrp-20240416-forecasting-methodology.pdf

5.8.3 Data Centres

Data centre development is expected to drive substantial near-term load growth. Forecasts incorporate known firm connection requests and anticipated developments. Load is allocated using a combination of proximity to existing stations, historical data centre locations, and random distribution with a bias toward downtown Toronto. Saturation is assumed by 2038 due to land constraints.

5.8.4 Customer Connection Activity

Firm customer connection requests are integrated into both the high electrification and reference forecasts. These requests provide specific timing, and demand estimates for new developments. Additionally, planned permanent load transfers are included to reflect operational changes in the distribution system.

5.8.5 Municipal Development Plans

Municipal planning documents are referenced to align the forecast with expected urban growth and electrification goals. These include:

- City of Toronto Official Plan
- Secondary Plan Areas (including the Port Lands, Update Downsview and the Golden Mile)
- TransformTO Net Zero Strategy
- TTC Green Bus Program

Load projections from City development plans are included based on high certainty of execution. These projections are derived from consultations with the City of Toronto staff and third-party consultants.

5.8.6 Scenario-Based Modeling

To address uncertainty, the reference forecast was developed using a probabilistic approach. Key drivers—temperature, economic growth, EVs, heating, and data centres—were treated as random variables. Monte Carlo simulations were used to generate a distribution of outcomes, with the median forming the final reference forecast. Before performing the Monte Carlo simulation to arrive at the reference forecast, four scenarios (High, Medium, Low, Business as Usual) were defined to reflect varying levels of policy implementation and market adoption.

6 Needs

6.1 Needs Assessment Methodology

Based on the planning demand forecast, system capability, the transmitter's identified asset replacement plans, and the application of the IESO's ORTAC, Northeast Power Coordinating Council (NPCC) Directory #1 Criteria, and NERC TPL-001-4 Standards. The Technical Working Group identified electricity needs in the near-, medium- and long-term timeframes. These needs can be categorized according to the following categories.

Station Capacity Needs describe the electricity system's inability to deliver power to the local distribution network through the regional step-down transformer stations during peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day Limited Time Rating (LTR) of a station's smallest transformer under the assumption that the largest transformer is out of service. A transformer station can also be more limited by the thermal ratings of downstream or upstream equipment, i.e., breakers, disconnect switches, medium-voltage bus or high voltage circuits; or, by voltage drop limitations, which are independent of thermal ratings.

Supply Capacity Needs describe the electricity system's inability to provide continuous supply to a local area during peak demand. This is limited by the LMC of the transmission supply. The LMC is determined by evaluating the maximum demand that can be supplied to an area after accounting for limitations of the transmission elements (i.e., a transmission line, group of lines, or autotransformer), when subjected to contingencies and criteria prescribed by ORTAC, TPL-001-5, and NPCC Directory #1. LMC studies are conducted by performing power system simulation analyses using industry-standard software. A summary of the criteria used is below:

- N-1, N-1-1 and N-2,[11] events were evaluated for the forecasted extreme weather demand.
- Per section 2.6 of the ORTAC, "(w)here reliability depends on local generation, sensitivity studies should be done to assess the impact of outages of local generation." For example, such N-G-1 and N-G-2 events were evaluated assuming G3 at PEC is O/S for normal weather demand. Only subareas which are impacted by the status of PEC unit status were evaluated.
- N-1-2 scenarios were only evaluated on areas designated NPCC Bulk Power System (BPS) for normal weather demand.

[11] The ORTAC does not require double element contingency events to be evaluated for local area (non-bulk) transmission systems, unless the contingency propagates to a higher voltage level or causes a net load loss greater than 1,000 MW. However, for the City of Toronto double element contingencies were evaluated due to the social and economic importance of continuous electricity supply to the area. It is important to note that the post-contingency topology of N-1-1 and N-2 events are similar in many cases as such the needs reflected from N-2 events would also be present for N-1-1 events in lieu of the available system control actions between contingencies.

Asset Replacement Needs are identified by the transmitter by an asset condition assessment, which is based on a range of considerations such as equipment deterioration due to aging infrastructure or other factors; technical obsolescence due to outdated design; lack of spare parts availability or manufacturer support; and/or potential health and safety hazards, etc. Replacement needs identified in the near- and early mid-term timeframe would typically reflect more condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. As such, any recommendations for medium- to long-term asset replacement needs should reflect the potential for the date to change based on updated information concerning the asset condition.

Load Security and Restoration Needs describe the electricity system's inability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 2.4.10 of ORTAC.

6.2 Needs Identified in Northern Toronto

6.2.1 Station Capacity Needs

Two stations supplying Northern Toronto are expected to exceed their station capacity, namely Bathurst TS and Finch TS. Table 8 shows the year each station is expected to reach its capacity need and the MW exceedances at the end of the study period, for both the reference and high electrification forecast. These needs are primarily due to expected new community developments per the City of Toronto's Update Downsview Secondary Plan.

Table 8 | Northern Toronto Station Capacity Needs

	Reference Forecast		High Electrification Forecast	
Station	**Need Year**	**2044 Need (MW)**	**Need Year**	**2044 Need (MW)**
Bathurst TS	2034	201	2034	211
Finch TS	2038	41	2034	71

6.2.2 Supply Capacity Needs

Like the station capacity needs, the supply capacity needs in Northern Toronto are primarily due to expected new developments as a result of the City of Toronto's Update Downsview Secondary Plan. The Bathurst TS tap lines are expected to reach their LMC by 2038 in the reference forecast and 2037 in the high electrification forecast, respectively.

6.3 Needs Identified in Western Toronto

6.3.1 Supply Capacity Needs

6.3.1.1 Manby West Autotransformers

The Manby West autotransformers are expected to reach their LMC of 490 MW by 2028 in both reference and high electrification forecasts. The LMC is reached when T1/T12 exceeds its LTR following the loss of two autotransformers (as an outage + contingency scenario), with the Manby RAS fully utilized. This need arises primarily due to planned load increases at the Copeland MTS downtown, and due to growth at John TS and Strachan TS. High electrification does not accelerate the need, but it results in higher levels of unserved load.

Hydro One has indicated that Manby West T12 is expected to be replaced in 2029-2030 as per the Needs Assessment. At the time of this assessment, no new parameters were available, and the existing parameters were used. The existing T12 autotransformer has the lowest rating of the existing Manby West autotransfomers.

6.3.1.2 Manby East Autotransformers

The Manby East autotransformers are expected to reach their LMC of 500 MW by 2044 and 2035 for the reference and high electrification scenarios, respectively. The LMC is reached when T7 exceeds its LTE following the loss of two autotransformers, with the Manby RAS fully utilized. It should be noted that Hydro One has indicated that Manby East T7 and T9 are expected to be replaced in 2029-2030 as per the Needs Assessment. The existing T7 autotransformer has the lowest rating of the existing Manby East autotransformers.

6.3.1.3 Manby to Riverside Junction Circuits

The loss of K6J or H2JK plus K13J or K14J leads to K14J or K13J to exceed its short-term emergency (STE) ratings starting in 2026. This need is coincident with planned load increases at Copeland MTS. High electrification does not accelerate the need but does result in additional amounts of unserved load.

6.3.1.4 St. Clair to Fairbank Circuits

The loss of K1W or K3W will result in the companion circuit exceeding LTE rating by 2036 and 2031 for the reference and high electrification forecasts, respectively. It is recognized that Hydro One plans to replace approximately 3.2 km of the 4.5 km section of K1W and K3W with higher ampacity conductors by 2029 leaving a 1.3 km section unmodified.

6.3.1.5 Richview to Manby Circuits

The Richview to Manby circuits are currently undergoing an upgrade, referred to as the Etobicoke Greenway Project.[12] This project involves decommissioning an existing, idle 115 kV double circuit transmission like and replacing it with a new 230 kV double circuit line. This project is expected to be in-service by 2026. In addition, two of the existing 230 kV circuits from Richview to Manby are

[12] Etobicoke Greenway Project (Hydro One), https://www.hydroone.com/about/corporate-information/major-projects/etobicoke-greenway

expected to be unbundled and tie Claireville TS and Richview TS, further increasing the LMC to 1,840 MW. This unbundling project is expected to be completed no later than 2031 and was recommended in the 2019 Toronto IRRP.

Due to the expected load growth in the Manby sector, the circuits are expected to reach their new LMC by 2032 and 2030 under the reference and high electrification forecasts, respectively. This limitation is caused by breaker fail contingency at Richview, which would remove two circuits from service, resulting in a remaining circuit exceeding its long-term emergency (LTE) rating.

6.3.2 Station Capacity Needs

Three load supply stations in West Toronto are expected to exceed their station capacity, namely Fairbank TS, Strachan TS, and the Manby DESN. Table 9 shows the year each station is expected to reach its capacity need and the capacity exceedances (in MW) at the end of the study period, for both the reference and high electrification forecasts.

Table 9 | Western Toronto Station Capacity Needs

	Reference Forecast		High Electrification Forecast	
Station	**Need Year**	**2044 Need (MW)**	**Need Year**	**2044 Need (MW)**
Fairbank TS	2042	12	2036	38
Strachan TS	2039	22	2033	47
Manby DESN	2043	5	2037	21

6.4 Needs Identified in Eastern Toronto

6.4.1 Supply Capacity Needs

The following circuits and stations were identified to have supply capacity needs in Eastern Toronto.

Table 10 shows the year each need emerges and the MW exceedances at the end of the study period at the circuits and stations for the reference and high electrification forecast, respectively. Two City of Toronto Secondary Plans, namely the Port Lands redevelopment and Golden Mile, are major drivers of growth in the Eastern Toronto area.

Table 10 | Eastern Toronto Supply Capacity Needs

	Reference Forecast	High Electrification Forecast
Circuit/Station	**Need Year**	**Need Year**
L13W and L18W Bridgman x Barlet / Dufferin JCT.	2036	2029
L18W Leaside TS to Bridgman TS	2041	2033

	Reference Forecast	High Electrification Forecast
Circuit/Station	**Need Year**	**Need Year**
L15 Leaside TS x Bridgman TS	2036	2026
L14W Birch JCT x Bridgman TS	-	2037
H1L/H3L Leaside TS x Bloor St.	2036	2036
H1L/H3L Hearn SS x Basin TS	2041	2037
C2L + C3L Double Contingency	<2025	<2025
Leaside Area Voltage Support	2038	2034

6.4.1.1 Leaside to Bridgman to Dufferin Circuits

The circuits that supply Bridgman TS and Dufferin TS from Leaside TS (namely L13W, L15, L14W, and L18W) are expected to reach their LMC by the 2036 winter reference forecast (potentially as soon as 2026 for the high electrification forecast). The most limiting element is L15, which will overload following the loss of L13W and L18W. Overloading on other circuits (e.g., L14W and L18W) occurs later but is caused by the same growth drivers at Dufferin TS and Bridgman TS.

6.4.1.2 Leaside to Bloor Circuits

The sections between Leaside TS and Bloor Junction (JCT) on H1L and H3L are expected to be overloaded by 2036, for both the reference and high electrification case, during an outage at PEC (G3 unit) followed by a breaker failure at Hearn. In their Needs Assessment, Hydro One indicated the overhead sections of H1L and H3L between Leaside TS and Bloor JCT are to be replaced with the largest size possible conductor while retaining existing tower structures.

6.4.1.3 Hearn to Basin Circuits

The 0.5 km sections between Hearn SS and Basin TS on H1L and H3L are expected to be overloaded by 2041 and 2036 for the reference and high electrification case, respectively. These circuits will exceed their LTE ratings following the loss of the companion circuit. This need is driven by the additional load attributed to the Port Lands Secondary Plan development.

6.4.1.4 Cherrywood to Leaside Circuits

The loss of two of the Cherrywood TS to Leaside TS circuits, namely C2L and C3L, results in voltage instability in the Leaside sector when loading is sufficiently high. This need exists in the current system and is managed by control actions.

As load continues to grow, the contingencies that can lead to voltage instability expands beyond what can be managed with existing control actions. Instability is forecast to occur between 2035 and 2039 for the loss of C16L or C17L followed by the loss of two elements that remove two Cherrywood

to Leaside (CxL) circuits and two capacitors at Leaside TS (i.e., specific Leaside breaker failures). In subsequent years this need continues to expand to include other combinations of transmission equipment outages.

Given ORTAC's requirement of keeping within a 10% margin on voltage stability, LMC of the Cherrywood to Leaside circuits is about 2,610 MW, resulting in a need date corresponding to 2038 and 2034 for the reference and high electrification forecasts, respectively. The size of the need (due to the demand forecast) and considering a scenario with reduced reliance on PEC necessitates that a new supply be built to Toronto. More details can be found in Section 6.5 below.

6.4.2 Station Capacity Needs

Six load supply stations in Eastern Toronto are expected to exceed their station capacity, namely Scarboro TS, Sheppard TS, Warden TS, Glengrove TS, Dufferin TS, and Basin TS. Table 11 shows the year each of these needs emerges, and the MW exceedances at these stations at the end of the study period for the reference and high electrification forecast, respectively.

Table 11 | Eastern Toronto Station Capacity Needs

	Reference Forecast		High Electrification Forecast	
Station	**Need Year**	**2044 Need (MW)**	**Need Year**	**2044 Need (MW)**
Scarboro TS	2035	166	2034	181
Sheppard TS	2038	27	2033	48
Warden TS	2036	28	2032	42
Glengrove TS	2042	10	2035	31
Dufferin TS	2040	27	2033	66
Basin TS	2036	79	2036	81

6.5 Need for New Supply in Eastern Toronto

Electricity system needs in the East Toronto area in the medium term (up to 2035) are driven primarily by local growth and development plans, including secondary plans for the Port Lands district and the Golden Mile in Scarborough. Together with other policy and economic drivers such as urban intensification, electrification and decarbonization, the electricity demand in East Toronto is expected to exceed the capacity of the transmission system within the next 10 to 15 years. The largest of the needs involves the 230 kV transmission supply from Cherrywood TS. More specifically, load growth will cause exceedances of the line capacity of the 230 kV transmission circuits between Cherrywood TS and Leaside TS, and the autotransformers at Leaside TS. With PEC in-service, planning studies show that credible planning contingencies such as the loss of two 230 kV supply circuits will result in voltage instability by 2038.

6.5.1 Portlands Energy Centre Scenario

The IRRP investigated a scenario with PEC out-of-service (i.e., not operating/contributing to meeting demand in Toronto). This scenario was driven by a need to consider options for maintaining cost-effective and reliable electricity supply given the facility's contract expiration date of April 2034. Both the *Pathways to Decarbonization* and *Powering Ontario's Growth* reports indicated a need to study the transmission reinforcements required to eventually phase out local gas-fired generation in consideration of the development lead time to implement transmission alternatives. The retirement scenario is also responsive to local community opposition to the continued operation of the gas plant in the urban centre, and a 2024 Toronto City Council resolution requesting the IESO to study phasing out PEC by 2035.[13] Given the facility's contribution to local reliability, the IRRP technical studies confirmed that a transmission reinforcement would be needed to accommodate a future without PEC, and must be in place before the facility can retire With or without the capacity contribution of PEC, the transmission is still needed to supply the forecasted load growth. The IESO will continue to investigate possible measures that can reduce local reliance on PEC in the interim period while a transmission solution is being implemented.[14]

In addition, while local reliance on PEC will be reduced once the Third Line is in place, it may still be needed to meet the provincial grid's peak needs into the 2030s. The Toronto IRRP is focused on local supply and does not address matters of provincial supply.

6.6 Addressing Resilience of Toronto's Electricity System

Through the engagement of the Toronto IRRP, the Technical Working Group heard that system resilience should be an important consideration to the plan. Based on this feedback, the Technical Working Group considered resilience in the development of IRRP options, and to inform future planning.

6.6.1 Flooding of Manby Transformer Station

In July 2024, Toronto experienced a severe summer storm that caused flash floods across the city. One of the most significant impacts was the flooding at Manby TS, which is one of two major transmission supply paths into downtown Toronto. The storm caused widespread outages, affecting the electricity supply to about 190,000 customers.[15] The flooding of Manby TS and subsequent load loss underscores the importance of system resilience especially from extreme weather events, and considering climate change.

[13] Toronto City Council Meeting, Item – 2024.MM19.9, https://secure.toronto.ca/council/agenda-item.do?item=2024.MM19.9

[14] Some non-wires alternatives may also serve to mitigate against possible timeline risks of the transmission solution.

[15] Severe Toronto storm causes flooding, major power outages | CBC News

7 Plan Options and Recommendations

This section describes the options considered and offers recommendations to address the needs in the Toronto Region. In developing the plan, the Technical Working Group considered a range of integrated options, which included combinations of options. These options were screened and further evaluated based on key considerations including technical feasibility, cost, lead time, other benefits, and consistency with longer-term needs in the area.

Generally, there are two approaches for addressing regional needs that arise as electricity demand increases:

- Build new transmission or distribution infrastructure. These are commonly referred to as "wire" options and can include utility investments such as new transmission lines, autotransformers, step-down transformer stations, voltage control devices, upgrades to existing lines and stations, or distribution-level load transfers. Wire options may also include control actions or protection schemes that influence how the system is operated to avoid or mitigate reliability concerns.
- Install or implement measures to reduce the net peak demand to maintain loading within the system's existing LMC. These are commonly referred to as "non-wire" options and can include measures such as locally sited generation or storage resources connected to the transmission system, distributed energy resources including generation and demand response that are distribution-connected, or additional eDSM.

Section 7.1 begins with an in-depth overview of options considered in IRRPs. Section 7.2 provides a summary of the Local Achievable Potential Study, and Section 7.3 speaks to thermal energy networks and the opportunity to coordinate with long-term electricity system planning. Section 7.4 describes the screening approach used to assess which needs would be best suited for wires and/or non-wires options. Subsequently, Sections 7.6 to 7.9 present the options ultimately developed and evaluated according to cost and other factors to inform the IRRP recommendations.

7.1 Options Considered in the IRRP

Both wire and non-wire options were considered in the development of this IRRP. Wire options are well suited for addressing a range of power system reliability issues and generally provide a substantial increase in the LMC for both summer and winter peak seasons. Non-wire options such as eDSM, locally sited renewable resources or storage generally help to maintain or reduce energy demand requirements, with significant variances among these various resources in terms of their ability to target the winter and/or summer peak demand. To evaluate non-wire options such as local generation or energy storage, the additional step of creating hourly load profiles is required, as described in Section 5.7. Suitable technology types are chosen by examining the "unserved energy" profile, which represents the hourly duration and magnitude of the demand that exceeds the system LMC. The load profile indicates the duration, magnitude as well as the frequency and total energy requirement associated with each need. Hourly profile data for the Toronto IRRP have been published on the IESO's webpage.

Planning level cost estimates for wire options were based on input provided by Hydro One and Toronto Hydro, as well as informed by transmission costs from other IESO planning studies and industry benchmarks. Cost estimates for non-wire options were based on benchmark capital and operating cost characteristics for each resource type and size. Due to policy considerations and community preferences, new natural gas-fired generation was not considered an option for addressing local needs in the City of Toronto. Energy storage, solar PV, and wind generation were considered.

The assumed energy efficiency savings from programs under the 2021-2024 CDM Framework and Save on Energy brand were included in the demand forecast, as discussed in the Section 5.4. The IESO was also directed to deliver a new program to address regional and/or local system needs. The Local Initiative Program is one tool that is available to target the delivery of additional savings at specific areas of the province with identified system needs. LDCs can also use the Ontario Energy Board's Non-Wires Solutions Guidelines for Electricity Distributors (previously "CDM Guidelines") to leverage distribution rates to help address distribution and transmission system needs using non-wire alternatives. Additional demand savings from the eDSM framework beyond those already embedded in the forecast were evaluated as potential options to address identified regional needs. Generally, eDSM is suitable for needs where growth is gradual to and the magnitude of the overload relative to the total demand is small (i.e., on the order of few percent per year). These considerations are discussed further in Section 7.4, as part of the options screening.

For both wire and non-wire options, the upfront capital and operating costs are compiled to generate levelized annual capacity costs ($/kW-year). A cash flow of the levelized costs for the options are compared over the lifespan of the wire option (typically 70 years for transmission line infrastructure). The net present value (in 2024 $CAD for this report) of these levelized costs is the primary basis through which feasible options are compared.

It is important to recognize the error margin around cost estimates at the planning stage. These costs serve to enable comparison of the different options during the IRRP. The transmitter-led RIP (following the IRRP) is an opportunity to carry out further analysis allowing for cost estimates to be refined prior to implementation. The Technical Working Group can revisit specific recommendations if cost estimates or other parameters change significantly. Further, certain options including non-wires could be tested through pilot or demonstration projects in cases where other barriers or implementation challenges need to be worked through (e.g., regulatory frameworks for cost-sharing and recovery, or operationalization to meet local reliability constraints).

7.2 Local Achievable Potential Study

To further enhance and supplement the regional planning work underway for Toronto, the IESO retained energy consultancy ICF International to conduct a local achievable potential study (LAPS) to identify the potential for additional eDSM programming, above and beyond the already planned eDSM included in the IRRP demand forecasts, to cost-effectively meet regional needs. The purpose of the study was to identify and quantify both electricity energy and demand savings potential attainable through a range of behind-the-meter DERs, with associated costs. Energy efficiency, demand response, and other resources including solar PV and energy storage were considered over the 20-year period. Although a long-term view was included in scope for the LAPS, there remains much uncertainty about the timing of technology advancements in the DER space. The study results

will inform decisions in the near-term (first five years of the plan), while still allowing for innovation to happen in eDSM and DER programs/procurements and/or pilots and demonstration projects. The LAPS results are not intended to represent a maximum of the amount of savings that may be achieved through province-wide and/or local program performance; and it is not intended to preclude new measures from being introduced as program offerings in the future.

The LAPS was carried out for two local forecasts aligned with the IRRP reference and high demand forecast scenarios. For each scenario, the study used a bottom-up approach to determine the energy savings potential from technical, economic and achievable perspectives.

- Technical Potential is the estimated savings resulting from the implementation of all technically feasible measures, ignoring cost-effectiveness, customer awareness, equipment turnover rates, or other "real world" barriers.
- Economic Potential is the savings resulting from the implementation of all technically feasible measures that pass a cost-effectiveness test (Program Administrator Cost or "PAC" test).
- Achievable Potential is the final savings remaining after adoption rates over the period of the study are applied and is intended to represent a realistic estimate of the savings that could be acquired through programs.

These savings are simulated at the building level using a "digital twin" model for the residential and commercial sectors and aggregated to the station level for each scenario. Measures in scope include:

- Behind-the-Meter DER including energy storage systems, solar PV and thermal storage.
- Energy Efficiency measures including heat pumps, HVAC, lighting, appliances, weatherization, and hot water.
- Demand Response including EV charging, HVAC equipment, and water heaters.

Under the reference demand scenario, the LAPS estimates a total of 1,167 MW of summer peak demand savings potential and 878 MW of winter peak demand savings potential over 20 years. After deducting savings from planned eDSM already captured in the demand forecast this represents an incremental opportunity of 320 MW of summer and 121 MW of winter peak demand savings.

The LAPS Final Report will be published and made available on the IESO website. These documents provide detailed descriptions of the methods, data sources, input assumptions, and results of the study.

In reviewing the LAPS results, it is important to acknowledge that planners must consider several factors in assessing whether estimated eDSM potential can help address an identified need. These include:

- How much of the estimated achievable potential is incremental to the savings already captured in the eDSM savings forecast?
- Can the incremental eDSM potential satisfy both summer and winter needs if applicable?
- How much incremental achievable potential is available in the specific need area (e.g. additional potential in Etobicoke cannot help a station capacity need in Scarborough)?

- How does the timing of incremental eDSM potential becoming available align with the timing of need?

These key considerations will help inform the implementation of IRRP recommendations to acquire incremental eDSM savings throughout Toronto.

7.3 Thermal Energy Networks

The City of Toronto presented to Toronto Hydro and the IESO results of their *Toronto Port Lands Demand Justification & DER Potential Assessment*. Their study reviewed the potential for thermal energy networks (TENs) and stringent Building Performance Standards to reduce the summer and winter peak demand impact of planned mixed-use urban development in the Port Lands. The scope of this study was specifically the loads served, or to be supplied by Basin TS.

The Technical Working Group recognizes the potential for district energy to continue to be a valuable resource that will contribute meaningfully to the City of Toronto's future energy needs, particularly in the context of reducing emissions and meeting the city's climate goals. District energy systems distribute thermal energy to multiple buildings and offer scalable, efficient, lower carbon solutions that align with the City of Toronto's TransformTO climate action plan and net-zero targets. The successful development and integration of district energy projects will require continued leadership from the City of Toronto and active participation from district energy service providers, developers and customers.

Municipal coordination, policy support, and investment are essential to unlocking the full potential of district energy as part of a diversified and resilient energy strategy for the City. The Technical Working Group recommends the City of Toronto keep Toronto Hydro informed of plans to implement district energy systems to ensure their impact on the electricity system can be properly assessed in local and regional plans. As it will take new developments like the Port Lands, as well as Downsview and the Golden Mile several decades to be fully realized, there is time for coordinated planning and action to understand the potential co-benefits of new thermal energy networks for deferring or avoiding additional investment in electricity transmission and distribution infrastructure.

7.4 Options Screening Results

As explained in the previous section, an array of options to meet local needs is developed during an IRRP. Each of these options is screened based on whether it meets the technical requirements for a solution, and the technically feasible options are then evaluated to arrive at a set of recommended options. Options are preferred based on their cost-effectiveness, as well as other decision-making factors including risk mitigation as it relates to future costs, implementation considerations, and community and stakeholder preferences and feedback, amongst other considerations.

Screening occurs early in the IRRP study after local reliability needs are known but before detailed analysis. It helps direct time-intensive aspects of detailed non-wires analysis (hourly need characterization, options development, financial analysis, and engagement) towards the most promising options. The three-step, high-level approach is shown in Figure 11 and further discussed in the next sections. A summary of the options screening results for the Toronto IRRP is provided in Table 12.

Figure 11 | IRRP NWAs Screening Mechanism

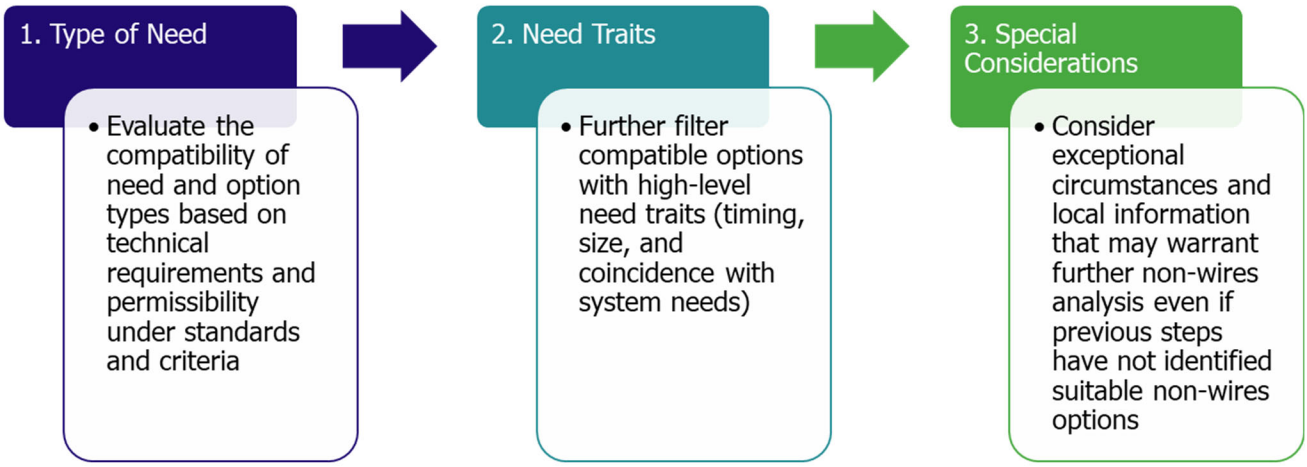


Table 12 | Options Screening Results for Toronto Needs

Area	Need	Screened In	Screened Out
Northern Toronto	**Supply Capacity**	• Wires (new transmission lines) • Wires plus integrated approaches including additional eDSM, DERs	• Transmission connected generation such as wind generation, and wind and/or solar + energy storage • Gas generation
	Station Capacity	• Wires (new station) • Wires plus integrated approaches including additional eDSM, DERs	• Transmission connected generation such as wind generation, and wind and/or solar + energy storage • Gas generation
Western Toronto	**Supply Capacity**	• Wires (upgrades to existing lines) • Energy Storage[16] • Wires plus integrated approaches including energy storage, additional eDSM, DERs	• Transmission connected generation such as wind generation, and wind and/or solar + energy storage • Gas generation

[16] All technical energy storage assumptions in this report assume the use of lithium-ion battery technology.

Area	Need	Screened In	Screened Out
	Station Capacity	• Wires (new or expanded stations) • Wires plus integrated approaches including additional eDSM, DERs	• Transmission connected generation such as wind generation, and wind and/or solar + energy storage • Gas generation
Eastern Toronto	**Supply Capacity**	• Wires (new and upgraded transmission lines) • Wires plus integrated approaches including energy storage, additional eDSM, DERs	• Transmission connected generation such as wind generation, and wind and/or solar + energy storage • Gas generation
	Station Capacity	• Wires (new or expanded stations) • Wires plus integrated approaches including additional eDSM, DERs	• Transmission connected generation such as wind generation, and wind and/or solar + energy storage • Gas generation

7.5 Options and Recommendations for Northern Toronto

In Northern Toronto, the supply and station capacity needs have common drivers. Load growth at both Bathurst TS and Finch TS (and the circuits supplying the two stations) will exceed their capacity limits due to electricity demand growth driven by the Update Downsview Secondary Plan. As this Secondary Plan involves brand new communities, new transmission and distribution infrastructure will be needed to supply them. A new Downsview MTS would also provide an opportunity to offload Bathurst TS, Finch TS, Fairchild TS and Fairbank TS, thereby ensuring these stations remain within their capacity limits.

As a result, Toronto Hydro, as part of their 2025 Distribution System Plan, proposed a new transformer station named Downsview MTS to be connected to the Finch Corridor circuits. This new station was approved by the OEB as part of Toronto Hydro's recent rates application. The Technical Working Group supports this decision and continues to recommend Downsview MTS be built to meet needs of the area.

As part of the IRRP, two potential connection arrangements were studied for Downsview MTS. The first arrangement would involve building a Downsview Switching Station (SS) which would connect all six circuits on the Finch Corridor to Downsview SS which would then feed Downsview MTS. The

second arrangement would involve connecting Downsview MTS directly to two of six Finch Corridor circuits.

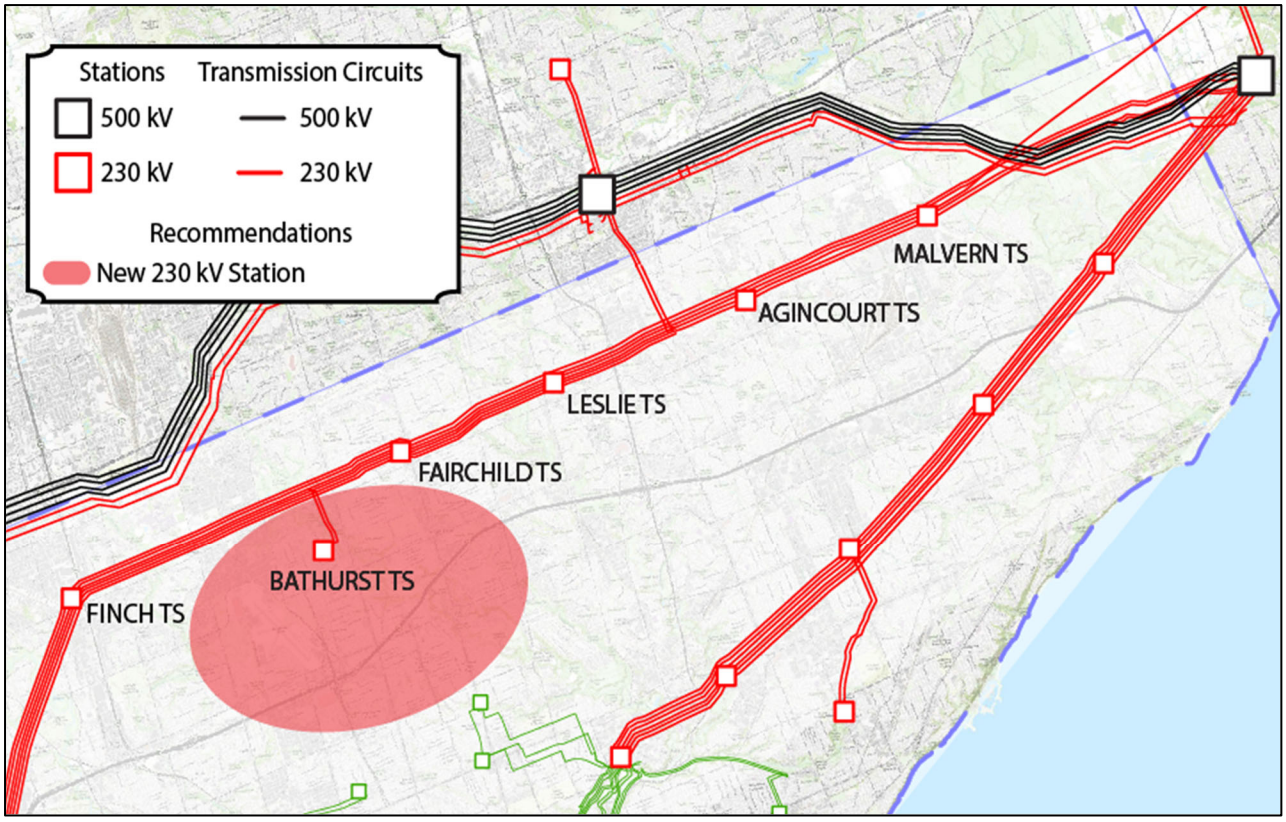
7.5.1 Wires Options – Build Downsview SS and Downsview MTS

The proposed Downsview SS would consist of two 230 kV buses each tapping three of the six 230 kV circuits in the Finch Corridor. The two supplies for Downsview MTS would then come from the two 230 kV buses at Downsview SS. The construction of Downsview MTS/SS, along with the load transfers to Downsview from the surrounding load stations, defers the expected timing when sections of P21R reaches its LTE ratings for select N-1-1 events to 2042 (for both the reference and the high electrification forecast). This exceedance can be mitigated if manual load rejection (up to 150 MW) post contingency at Downsview MTS is possible within 15 minutes, as the STE rating is not forecast to be exceeded. Alternatively, small amounts of incremental eDSM and/or DER starting in 2040 would defer the need past the forecast period (i.e., beyond 2044).

7.5.2 Wires Options – Connect Downsview MTS directly to two of Finch Corridor Circuits

An alternate arrangement was assessed to determine if Downsview MTS could be connected directly to two of the six circuits between Richview TS and Cherrywood TS/Parkway TS thereby eliminating the need for Downsview SS. The pairs of circuits assessed in this alternative are listed below:

1. C4R and C18R
2. C4R and C20R
3. C4R and P22R
4. C5R and C18R
5. C5R and C20R
6. C5R and P22R
7. P21R and C18R
8. P21R and C20R
9. P21R and P22R



Study results show that any option involving P21R or P22R (i.e., pairs 3, and pairs 6 – 9) are the most limiting arrangements. Any option involving these circuits leads to supply limitations starting in 2038 (via the loss of non-Parkway to Richview circuit overloading the remaining Parkway to Richview circuit). For all the other options, the six circuits between Richview TS and Cherrywood TS/Parkway TS remain under LTE ratings within the forecast period, for all the single and multiple-element contingencies considered.

7.5.2.1 Recommendation for Northern Toronto

The studies demonstrate both connection arrangement options allow for the reliable connection of the new Downsview MTS and its associated forecast demand. It is important to note that while the Downsview SS and Downsview MTS combined option was approved by the OEB, while the further analysis carried out in this IRRP shows that connecting Downsview MTS directly to two of the Finch Corridor circuits leads to lower overall costs for Toronto Hydro.

This recommended action is expected to cost approximately $170 Million in Canadian dollars and is expected to have a lead time of five to seven years.

Figure 12 | Recommended Option for Northern Toronto

Therefore, the Technical Working Group recommends that Toronto Hydro proceed with Downsview MTS, and that Toronto Hydro and Hydro One finalize their preferred connection arrangements in the upcoming RIP, keeping in mind that a solution should be in place by 2034.

7.6 Options and Recommendations for Western Toronto

In the following sections, the options that passed the initial screening to address system needs in Western Toronto are discussed. The Western Toronto supply capacity needs, as discussed in Section 6.3.1, include overloads at the Manby TS autotransformers (Manby West and Manby East), the Manby TS to Riverside Junction 115 kV transmission circuits, the Richview TS to Manby TS 230 kV circuits, and the St. Clair to Fairbank TS circuits. Stations in Western Toronto that are expected to reach their capacity in the study period include Fairbank TS, Strachan TS, and the Manby DESN.

The recommended actions for Western Toronto are a mix of integrated solutions including investments in wires and non-wires.

7.6.1 Options for Addressing Manby West Autotransformers

7.6.1.1 Wires Options – Manby Crossover Option

One option that could alleviate autotransformer loading at Manby West involves swapping K13J (or K14J) terminals at the Manby West 115 kV yard with the any one of the Manby to Wiltshire circuits in the Manby East 115 kV yard ("Manby Crossover Option"). This would result in more even distribution of power flow between the Manby East and Manby West autotransformers. It also provides additional system redundancy in the event of a loss of an autotransformer in either yard as it will allow for Manby East to support Manby West and vice-versa. Further, implementing this option would reduce the need to rely on the existing Manby RAS until the 2042 high electrification forecast materializes.

Hydro One estimates this option would cost between $15 million and $20 million to implement. However, short circuit studies performed by Hydro One demonstrate that the Manby Crossover Option will greatly increase fault levels at Manby, imposing a severe constraint on future system development including the addition of any new DERs in the area. Additional costs are expected to remediate the resulting short circuit limitations at impacted stations. Future studies would be needed to determine the feasibility of addressing these limitations and the additional costs.

7.6.1.2 Wires Options – Reliance on Manby RAS

The Manby Remedial Action Scheme (Manby RAS) is an existing scheme that allows operators to arm certain loads for rejection upon the loss of one or more autotransformers at Manby TS. For example, upon the loss of any Manby West autotransformer, transferring the entire Copeland MTS facility to Leaside supply in case of the loss of a second autotransformer defers the needs past the end of the study period for the high electrification forecast, provided up to 150 MW of load rejection between John TS and Strachan TS is used following the loss of the second autotransformer. This level of load rejection is allowable per the IESO's ORTAC.

The HVDC Third Supply increases available capacity to the Leaside sector and allows for this option to be implemented. It should be noted that this option would limit the emergency load transfer of Esplanade TS, which is normally supplied by Leaside, to Manby supply in an emergency event. Further studies, including extreme contingency events and their likelihood can inform whether future actions to enhance emergency load transfer capabilities should be explored.

7.6.1.3 Wires Options – Permanent transfer of Copeland MTS T2/T4 to Leaside Supply

This option involves permanently transferring supply of Copeland MTS T2/T4 from Manby to Leaside supply starting in 2026. This will alleviate overloading issues at the Manby West autotransformers.

7.6.1.4 Non-wires Options – Incremental eDSM

Informed by the local achievable potential study, incremental eDSM potential was estimated at the stations downstream of Manby West, namely Strachan TS and John TS. This incremental eDSM is in addition to that to the planned eDSM that is already assumed in the demand forecast. Table 13 shows the incremental eDSM potential at five-year intervals over the planning horizon. It is important to note that the planned and incremental eDSM savings also provide a net provincial system benefit by avoiding generation at peak.

Table 13 | Incremental eDSM at Strachan TS and John TS

Station	Incremental eDSM (MW, cumulative)			
	2025	2030	2035	2040
Strachan TS	3	9	13	16
John TS	1	7	14	17

7.6.1.5 Non-wires Options – Energy Storage Systems

The hourly profile of this need aligns well with the capabilities of an energy storage solution.[17] Table 14 shows the minimum capacity and energy build-out requirements, assuming either a single ESS or multiple ESS that are aggregated, to meet the need on an annual basis. Locating ESS in Manby West will not only serve both the identified regional need but will also contribute to provincial resource adequacy. Note that for the ESS to address the Manby West autotransformer need, they would need connect to the transmission system via any combination of K13J, K14J, H2JK, or K6J circuits or the Manby 115 kV bus. The ESS can also be connected to the distribution system if they eventually connect downstream of:

- Strachan TS
- John TS
- Copeland MTS (T1/T3 only[18])

Table 14 | Requirements for ESS to meet Manby West Autotransformer Need

Year	ESS Incremental Capacity Requirements (MW)	ESS Incremental Energy Storage Requirements (MWh)
2029	5	20
2030	6	35
2031	6	44
2032	9	75
2033	16	162
2034	-	-
2035	-	-
2036	-	-
2037	7	70
2038	9	95
2039	8	70
2040	6	60
Total	**72**	**631**

[17] All technical energy storage assumptions in this report assume the use of lithium-ion battery technology.
[18] Assuming Copeland MTS T2/T4 is permanently transferred to Leaside supply.

This local ESS is expected to have a net system cost of $0 to $30 million, which accounts for the broader system benefit it enables through a reduction in overall provincial capacity needs. The combination of addressing local and provincial needs, along with using less land and having a shorter lead-time than other NWAs, make this option an attractive one for the Manby West Autotransformer need.

7.6.1.6 Recommendation to Address Manby West Autotransformer Needs

The Technical Working Group recommends the following integrated set of options to address the Manby autotransformer need:

- Continued reliance on Manby RAS
- Permanent transfer of Copeland MTS T2/T4 to Leaside Supply
- Incremental eDSM
- Energy Storage Systems

The above options are recommended as they take advantage of the existing transmission system's transfer and operational capabilities (e.g., reliance on existing Manby RAS and permanent transfer of Copeland MTS T2/T4). The permanent transfer of Copeland MTS T2/T4 will need to be in place by 2026 to address the supply capacity needs in the Manby to Riverside Junction circuits prior to its upgrade as discussed in Section 7.6.3 below, according to both the reference and high electrification forecasts. Incremental eDSM can be targeted as part of the current eDSM framework.

An ESS (or multiple ESS) capable of meeting the incremental capacity and energy requirements is also recommended to mitigate the risk of load rejection being used. Local ESS connected to the aforementioned stations and circuits can provide local capacity should an autotransformer suffer an outage during a period of high demand.

The IESO and Toronto Hydro will need to collaborate to scope the technical requirements, achievable implementation timelines, and decide on the most suitable procurement approaches. The IESO and Toronto Hydro will ensure the Technical Working Group is kept updated on progress and any challenges through annual Technical Working Group meetings.

Although the Manby Crossover option greatly increases capacity, the short circuit limitations at Manby do not allow it to be recommended at this time. In order to preserve this option for the future, it is recommended that Hydro One determine the scope a detailed short circuit study for the Toronto Region. This study scope should include timelines for completing the studies, with the objective of identifying options that can alleviate transmission short circuit constraints in Toronto, should any exist. Insights from this study will allow this option to be more fulsomely considered in future regional plans.

A summary of the expected costs and lead times for the recommended wires options is provided in Table 15.

Table 15 | Recommended Wires Options to address Manby West Autotransformer Needs

Recommendation	Capital Costs ($M CAD)	Lead Time
Reliance on Manby RAS	N/A	Ongoing
Permanent transfer of Copeland MTS T2/T4 to Leaside Supply	N/A	1 year

7.6.2 Options for Addressing Manby East Autotransformers

7.6.2.1 Wires Options – Reliance on Manby RAS

This option involves continuing to rely on the existing Manby RAS. Upon the loss of any Manby East autotransformer, transferring the Wiltshire T2/T7 DESN to Leaside supply defers the needs past the end of the study period for the high electrification forecast, provided up to 150 MW of load rejection between Runnymede TS, Fairbank TS, and Wiltshire T1/T6 is utilized.

The HVDC Third Supply increases available capacity on the Leaside sector and allows for this solution to be implemented. It should be noted that this option would limit the emergency load transfer of Dufferin TS to Manby supply in an emergency event on the Leaside sector. Further studies, including extreme contingency events and their likelihood can inform whether future actions to enhance emergency load transfer capabilities should be explored.

7.6.2.2 Wires Options – Permanent Load Transfer from Fairbank to Downsview

This option involves transferring from 10 MW to 77 MW of load from Fairbank TS to the new Downsview MTS by 2044 (i.e., the same solution proposed in Section 7.6.4). This action would remove this load from the Manby to Wiltshire circuits as Downsview MTS will connect to circuits in northern Toronto. More details on the new Downsview MTS can be found in Section 7.5.

The Technical Working Group acknowledges that transferring load from a transmitter-owned station to an LDC-owned station when station load is below a station's LTR may incur by-pass compensation as per the Transmission System Code. By-pass compensation, in addition to project costs should be examined when comparing wires options in further detail in the Regional Infrastructure Plan.

7.6.2.3 Non-wires Options – Incremental eDSM

The LAPS identified up to 32 MW of incremental eDSM (and behind-the-meter) potential that can be achieved by 2044 in the Manby East area, specifically at Runnymede TS, Fairbank TS, and Wiltshire TS. These incremental eDSM measures pass system cost effectiveness tests, meaning they provide system benefits outweighing their costs.

7.6.2.4 Non-wires Options – Energy Storage Systems

The hourly profile of this need aligns well with the capabilities of a ESS solution. However, the need only emerges towards the later end of the forecast. The Technical Working Group will continue monitoring this need and update the feasibility of ESS in future regional plans.

7.6.2.5 Recommendation to address Manby East Autotransformer needs

The Technical Working Group recommends the following integrated set of options to address the Manby East autotransformer need:

- Continued reliance on Manby RAS
- Permanent Load Transfer from Fairbank TS to the new Downsview MTS
- Incremental eDSM

The above options are recommended as they take advantage of the existing transmission system's operational capabilities and new recommended transmission infrastructure in Northern Toronto through the reliance on existing Manby RAS and permanent transfer of load to Downsview MTS. Incremental eDSM can be targeted as part of the current eDSM framework. A ESS is not recommended at this time, given that it is only needed towards the end of the forecast. A ESS solution can be considered in future regional plans should the load increase more than currently expected.

A summary of the expected costs and lead times for the recommended wires options is provided in Table 16.

Table 16 | Recommended Wires Options to address Manby East Autotransformer Need

Recommendation	Capital Costs ($M CAD)	Lead Time
Reliance on Manby RAS	N/A	Ongoing
Permanent Load Transfer from Fairbank TS to Downsview MTS	To be developed further in upcoming RIP	Less than 3 years (Requires Downsview MTS to be in-service)

7.6.3 Options for Addressing Manby to Riverside Circuits

7.6.3.1 Wires Option – Reconductoring of K13J and K14J from Manby to Riverside

Hydro One first identified the need to upgrade the Manby to Riverside circuits (specifically K13J and K14J) in the 2022 Toronto Needs Assessment Report.[19] Hydro One is currently developing a transmission solution to increase capacity on K13J and K14J to be at least equal to that found on K6J and H2JK circuits. Furthermore, in Energy for Generations,[20] the Ministry of Energy and Mines confirmed support for Hydro One developing this transmission solution.

[19] Hydro One, Needs Assessment Report: Toronto Region, December 2022, https://www.hydroone.com/abouthydroone/CorporateInformation/regionalplans/toronto/Documents/Toronto_Region_Needs_Assessment_Report_Third_Cycle_Regional_Planning.pdf

[20] Ministry of Energy and Mines, Energy for Generations, July 2025, https://www.ontario.ca/page/energy-generations#section-7

7.6.3.2 Recommendation to address Manby to Riverside Circuits

The Technical Working Group recommends Hydro One continue developing the transmission solution for the Manby to Riverside circuit upgrades in the upcoming RIP. Hydro One estimates that this upgrade will cost $25 million and is expected to be in-service by 2028.

7.6.4 Options for Addressing St Clair to Fairbank Circuits

7.6.4.1 Wires Options – Permanent Load Transfer from Fairbank to Downsview

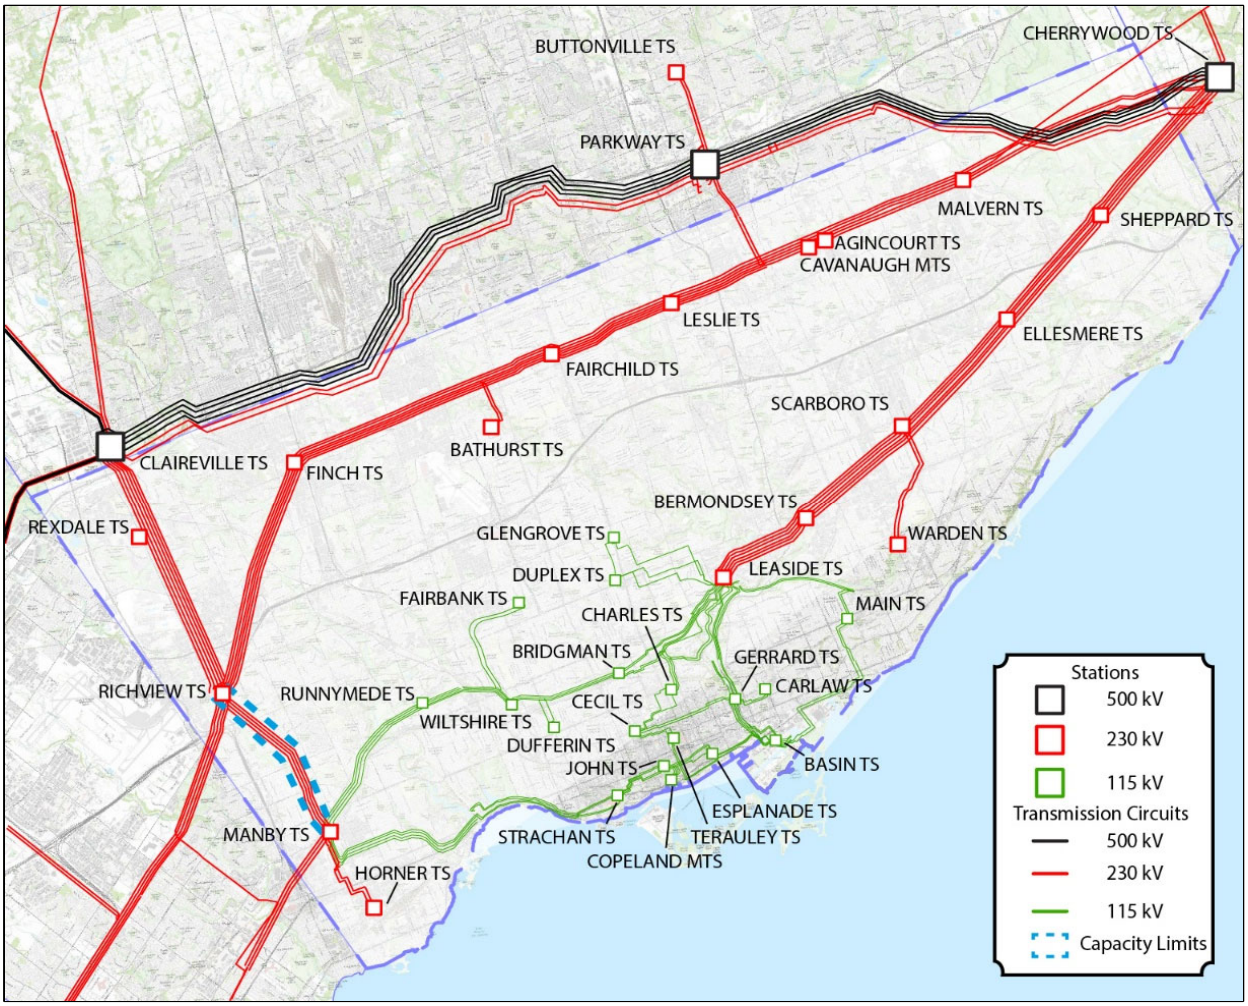
This option involves transferring between 10 MW and 77 MW of load (reference and high electrification forecasts, respectively) from Fairbank TS to the new Downsview MTS by 2044. This also reduces the loading on the Manby East autotransformers as Downsview MTS will connect to circuits in northern Toronto. More details on the new Downsview MTS can be found in Section 7.5. Transfers should begin by 2036 (i.e., when Fairbank TS demand reaches 179 MW) to respect the current limits of the K1W and K3W circuits.

The Technical Working Group acknowledges that transferring load from a transmitter-owned station to an LDC-owned station when station load is below a station's LTR may incur by-pass compensation as per the Transmission System Code. By-pass compensation, in addition to project costs should be examined when comparing wires options in further detail in the Regional Infrastructure Plan.

7.6.4.2 Recommendation to address St Clair to Fairbank Circuits

The Technical Working Group recommends implementing the load transfer from Fairbank TS to Downsview MTS to alleviate constraints on the St Clair to Fairbank TS circuits. Transfers should be completed by 2036 to respect limits of the K1W and K3W circuits (transfers would need to begin by 2031 to respect the high electrification forecasts).

This cost of this recommended action is included in the Downsview MTS development cost detailed in Section 7.5.2.1. The action is expected to have a lead time of less than three years and requires Downsview MTS to be in-service.



7.6.5 Options for Addressing Richview to Manby Circuits

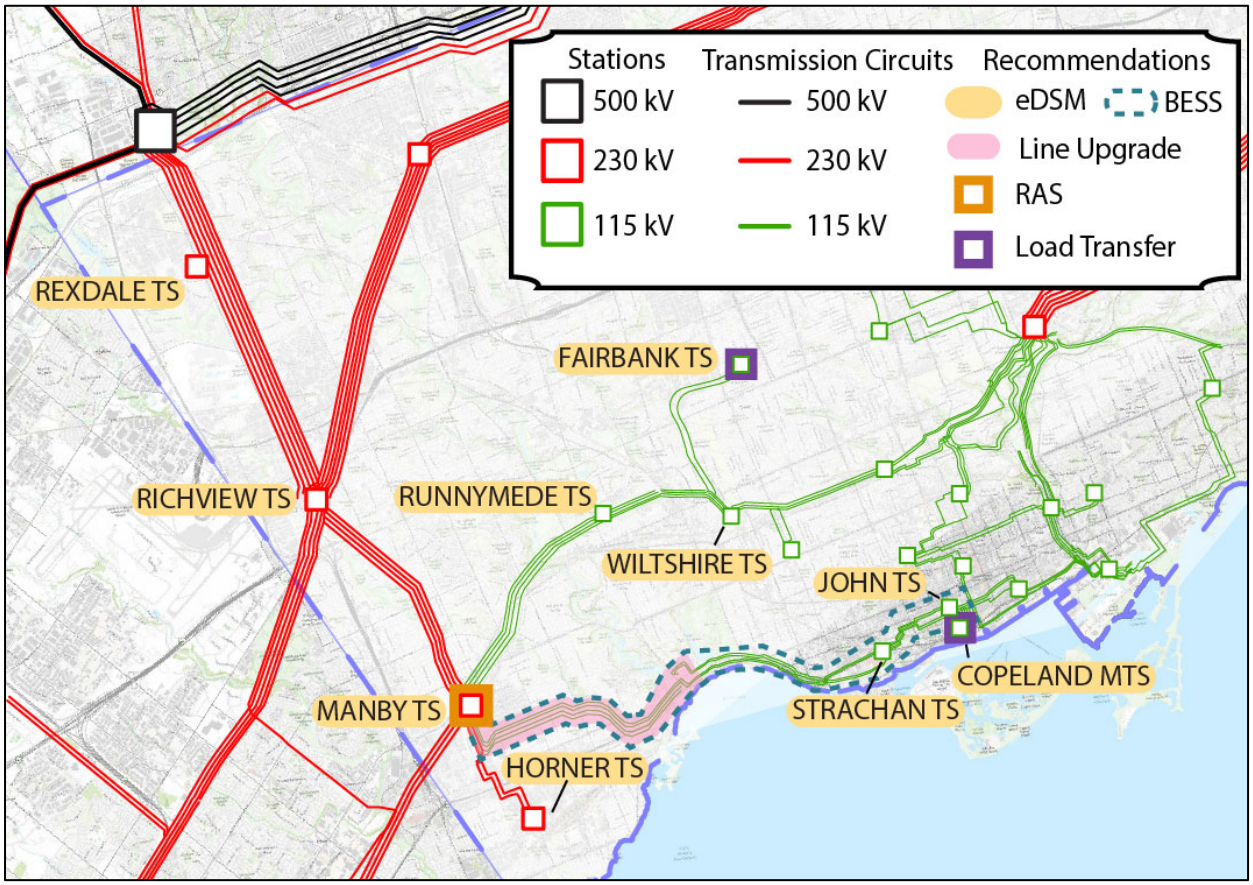
The Richview to Manby 230 kV circuits supply the western portion of downtown Toronto, Etobicoke, and southern Mississauga (which is part of the GTA West region), as shown in Figure 13. The forecast for the GTA West region, released in May 2025, shows significant load growth especially in southern Mississauga, which will further strain the Richview to Manby circuits. The South and Central Bulk Study is considering wires solutions to meet the needs of both GTA West and Toronto regions. One such solution undergoing evaluation in the South and Central Bulk Study is a 230 kV double circuit line from Trafalgar TS to Oakville TS. This solution will be further explored in the GTA West IRRP where the forecast growth in both GTA West and Toronto regions will be considered. From 2032 in the reference forecast more than 150 MW of load will be required to be shed post contingency to return the loading to below the LTE rating which is a violation of the ORTAC.

Therefore, the Technical Working Group recommends further evaluation of the Trafalgar TS to Oakville TS option continue as part of the South and Central Bulk Study and the GTA West IRRP. The

South and Central Bulk Study and GTA West IRRP expect to publish their findings by Q1 2026 and mid-to-late 2026, respectively.

Figure 13 | Richview to Manby Circuits

7.6.6 Options for Addressing Station Capacity Needs in Western Toronto



Three stations supplying West Toronto are expected to exceed their station capacity, namely Fairbank TS, Strachan TS, and the Manby DESN. The options identified in the preceding sections will also alleviate the needs at Fairbank TS and Strachan TS. For Fairbank TS, transferring up to 77 MW of load to Downsview MTS to address supply capacity needs will also eliminate the capacity need at the station. Similarly, estimated incremental eDSM at Strachan TS of up to 19 MW by 2040 can defer station capacity needs to the latter part of the forecast. Therefore, the Strachan station capacity need can be further reviewed in the next regional planning cycle.

The needs at Manby DESN occur towards the end of the forecast period, following the asset renewal replacement of the transformers. Since the need isn't expected to occur until 2042 or 2037 under the reference and high electrification forecasts respectively, the Technical Working Group recommends this need be monitored in future regional planning cycles.

This cost of this recommended action is to be developed further in the upcoming Regional Infrastructure Plan. The action is expected to have a lead time of less than three years and requires Downsview MTS to be in-service.

Figure 14 shows the location/connection points of the recommended solutions in Western Toronto

Figure 14 | Recommended Options for Western Toronto

7.7 Options and Recommendations for Eastern Toronto Needs

7.7.1 Options for Addressing Leaside to Bridgman to Dufferin Circuits

7.7.1.1 Wires Option – Increase transmission capacity to Dufferin TS

This option involves upgrading 1.3 km of underground circuits between Dufferin TS and the Bartlett/Dufferin Junctions to a higher capacity (similar ratings to the new C5E and C7E circuits between Terauley TS and Esplanade TS). This option allows for Dufferin TS to be loaded to its station limit (180 MW in summer and 203 MW in winter), as it is currently limited to 135 MW by the transmission supply into Dufferin TS.

7.7.1.2 Wires Option – Permanently transfer Dufferin TS load to expanded Wiltshire TS

This option involves upsizing the T1/T6 transformers at Wiltshire TS to add an additional 62 MW of capacity. This will then allow up to 62 MW of load to be transferred from Dufferin TS to Wiltshire TS. Note that this requires the load transfers from Manby East to Northern Toronto as detailed in Section 7.6.4 to be feasible.

While an upgrade at Wiltshire TS provides the station capacity needed to enable significant load transfers, there are physical limitations based on available underground space in the road allowance and other geographical constraints between the two stations. These limitations make it challenging and expensive to transfer large amounts of load between the stations and will limit how much load can ultimately be transferred.

7.7.1.3 Wires Option – Resolve transmission limits on all lines supplying Dufferin TS

This option involves increasing transmission capacity to Dufferin TS (as seen in Section 7.7.1.1) and from Leaside TS to Bartlett JCT. This will require rebuilding overhead lines including 1.7 km from Leaside TS to Bayview JCT, 2.2 km from Bayview JCT to Birch JCT, and 1.4 km from Birch JCT to Bridgman TS. In addition, a 2.2 km underground section between Bayview JCT to Birch JCT will need to be upgraded.

7.7.1.4 Non-wires Options – Incremental eDSM

The LAPS identified up to 36 MW of incremental eDSM (and behind-the-meter) potential that can be achieved by 2044 in the Leaside to Bridgman to Dufferin area, specifically at Dufferin TS and Bridgman TS. These incremental eDSM activities pass system cost effectiveness tests, meaning they provide system benefits outweighing their cost.

7.7.1.5 Non-wires Options – Energy Storage Systems

The hourly profile of this need aligns well with the capabilities of an energy storage solution[21]. Table 17 shows the minimum capacity and energy build-out requirements, assuming either a single ESS or multiple ESS that are aggregated, to meet the need on an annual basis. Although the ESS will be

[21] All technical energy storage assumptions in this report assume the use of lithium-ion battery technology.

locally connected, it would serve both the identified regional need and also contribute to provincial resource adequacy. The ESS can be connected to the distribution system or to the transmission system at one of the following locations:

- Dufferin TS (preferred location)
- L13W and L18W (from Dufferin TS to Barlett JCT, must connect to both circuits)

The buildout up to (and including) 2041 meets the need until 2043.

Table 17 | Requirements for ESS to meet Leaside to Bridgman to Dufferin Need

Year	ESS Incremental Capacity Requirements (MW)	ESS Incremental Energy Storage Requirements (MWh)
2037	2	12
2038	4	40
2039	4	37
2040	7	69
2041	24	243
Total	**41**	**401**

This local ESS is expected to have a net system cost of up to $18 million, which accounts for the broader system benefit it enables through a reduction in overall provincial capacity needs. The combination of addressing local and provincial needs, along with using less land, make this option an attractive one for the Leaside to Bridgman to Dufferin need.

7.7.1.6 Recommendation for Leaside to Bridgman to Dufferin Circuits

The Technical Working Group recommends the following options to address the Leaside to Bridgman to Dufferin need:

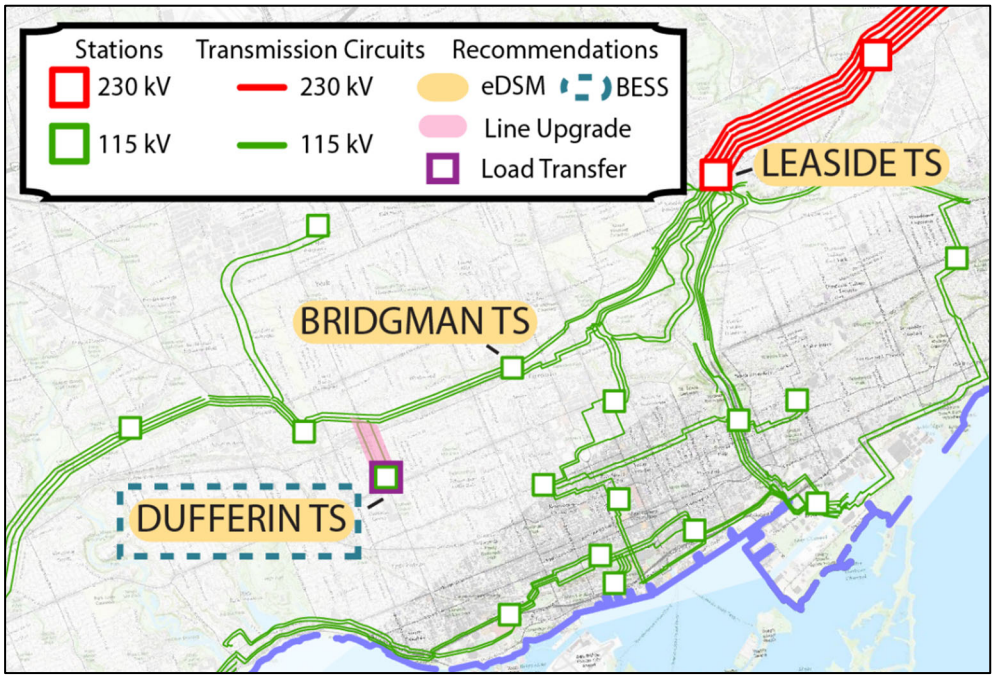
- Increase transmission capacity to Dufferin TS
- Transfer of Dufferin TS load to upgraded Wiltshire TS
- Energy Storage Systems[22]

To address the upstream supply needs for Dufferin TS the IRRP recommends the cables supplying Dufferin TS be upgraded to fully utilize the capacity available at Dufferin TS. The ratings on the new cables should have similar ratings to the new C5E and C7E cables between Terauley TS and Esplanade TS. Demand in excess of the Dufferin TS station limit can then be transferred to an upgraded Wiltshire TS. These recommendations will be further studied in the upcoming RIP.

A ESS solution capable of meeting the incremental capacity and energy requirements is also recommended to alleviate upstream supply issues (from Leaside TS to Bridgman TS). Given the lead time available for the ESS to be in place, several procurement mechanisms (including future iterations of the IESO's Long-Term procurement) can be used to address both local and provincial

[22] All technical energy storage assumptions in this report assume the use of lithium-ion battery technology.

supply constraints. The preferred location for ESS, either a large system or multiple smaller systems that are aggregated, is at or downstream (i.e., distribution-connected) from Dufferin TS.



The IESO and Toronto Hydro will need to collaborate to scope the technical requirements, achievable implementation timelines, and decide on the most suitable procurement approaches. The IESO and Toronto Hydro will ensure the Technical Working Group is kept updated on progress and any challenges through annual Technical Working Group meetings.

A summary of the expected costs and lead times for the recommended wires options is provided in Table 18 below.

Table 18 | Recommended Wires Options to address Leaside to Bridgman to Dufferin Circuits

Recommendation	Capital Costs ($M CAD)	Lead Time
Increase transmission capacity to Dufferin TS	33	7 years
Transfer Dufferin TS load to upgraded Wiltshire TS	60	5 years

Figure 15 | Recommended Options for Leaside to Bridgman to Dufferin Area

7.7.2 Options for Addressing Leaside to Bloor to Hearn Circuits

7.7.2.1 Wires Option – Address End-of-Life on circuits from Leaside TS to Bloor JCT

Hydro One identified that the Leaside TS to Bloor JCT sections of the H1L and H3L 115 kV circuits will require asset renewal in the near-term. The IRRP analysis also identified capacity needs on the same sections of the line by 2036. This option is to renew this section of this line, bringing it up to a modern standard and providing an opportunity to increase the capacity limit of the lines.

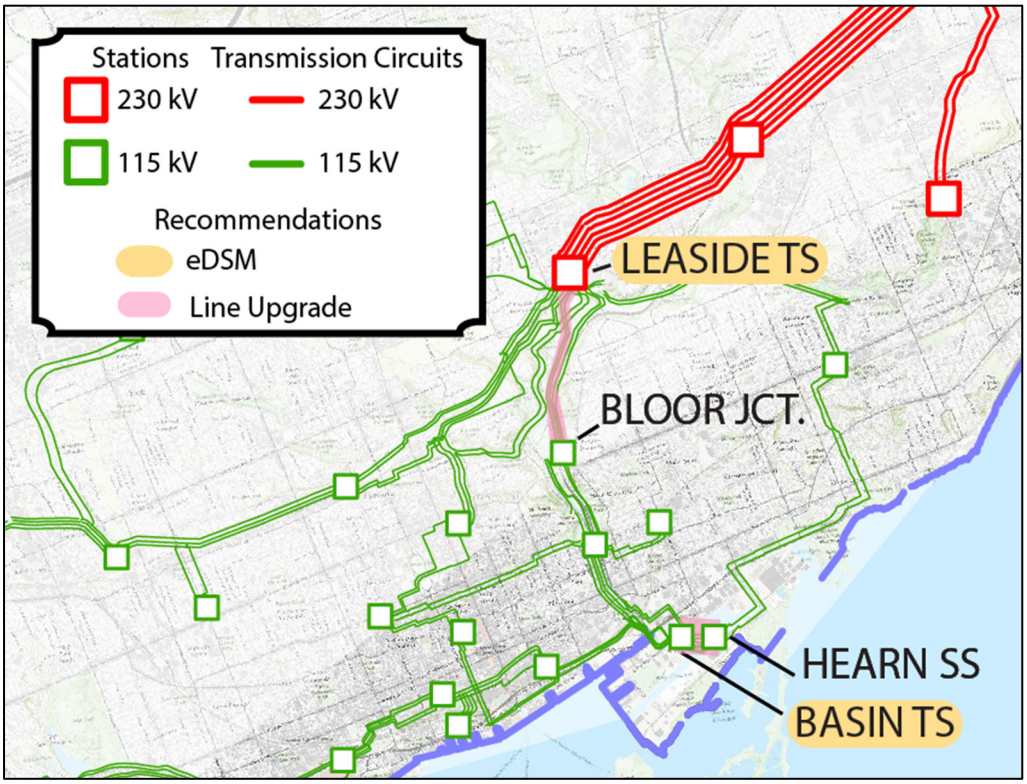
7.7.2.2 Wires Option – Increase transmission capacity on circuits from Hearn SS to Basin TS

The need on the H1L and H3L circuits from Hearn SS to Basin TS is expected to coincide with the load growth at Basin TS from the expected Port Lands development (2041 and 2037 for reference and high electrification forecasts, respectively). This option involves reconductoring a short span of this 115 kV line (0.5 km) with higher capacity conductors with ratings equal or higher than the new Manby TS to Riverside JCT portion of K13J and K14J.

7.7.2.3 Non-wires Options – Incremental eDSM

The LAPS identified up to 16 MW of incremental eDSM potential that can be achieved by 2044 in the Leaside to Basin to Hearn area, specifically at Carlaw TS, Gerrard TS, and Basin TS. These incremental eDSM measures pass system cost effectiveness tests, meaning they provide both local and provincial system benefits.

7.7.2.4 Recommendation for Leaside to Bloor to Hearn Circuits



The Technical Working Group recommends that the following options be implemented to address the Leaside to Bloor to Hearn need:

- Increase transmission capacity on H1L and H3L circuits from Leaside TS to Bloor JCT and from Hearn SS to Basin TS.
- Incremental eDSM.

Due to the short span of the Hearn to Basin section (0.5 km) and the end-of-life needs on the Leaside to Bloor circuits, it is recommended that Hydro One investigate reconductoring the aforementioned sections with conductors having ampacity ratings equal to or higher than the new Manby TS to Riverside JCT portion of K13J and K14J. This upgrade will also enable more transfer of power from the Hearn SS and the recommended HVDC Third Supply. Incremental eDSM can help reduce the loading on the circuits, should any delays occur in the replacement of the circuit sections. The locations of transmission facilities from Leaside TS to Bloor, and Hearn SS to Basin TS, are shown in Figure 16.

This recommended wires-option is expected to cost approximately $25 Million and is expected to have a lead time of seven years.

Figure 16 | Recommended Options for Leaside to Bloor to Hearn Area

7.7.3 Options for Addressing Station Capacity Needs in Eastern Toronto

7.7.3.1 Scarboro TS, Warden TS, and Sheppard TS

The needs at Scarboro TS, Warden TS, and Sheppard TS are driven by local growth, specifically the Golden Mile Secondary Plan. As this Secondary Plan involves brand new communities, new transmission and distribution infrastructure will be needed to supply them. In their most recent rates application, Toronto Hydro proposed an additional DESN at Scarboro TS to increase capacity to the area to meet the demand growth from the Golden Mile Secondary Plan. This proposal has been accepted by the OEB.

The new DESN at Scarboro TS would also offload Warden and Sheppard TS, thereby ensuring these stations do not exceed their capacity limits. Over the long-term, a station capacity need at Sheppard TS may still arise. Toronto Hydro has proposed utilizing an unused winding at Sheppard TS to address long-term needs which will continue to be monitored. This recommended action is expected to cost $60 Million and is expected to have a lead time of seven years.

7.7.3.2 Glengrove TS

The need at Glengrove TS occurs in 2042 for the reference forecast and can come up as soon as 2035 in the high electrification scenario. Toronto Hydro identified that there may be opportunity to transfer load from Glengrove TS to Duplex TS. There is also limited opportunity for incremental eDSM (up to 4 MW by 2040) to meaningfully delay any upgrades.

Therefore, the Technical Working Group recommends that Toronto Hydro and Hydro One investigate the feasibility of load transfers from Glengrove TS to Duplex TS in the upcoming RIP. The Technical

Working Group will also continue to monitor load growth at Glengrove TS in upcoming cycles of regional planning.

7.7.3.3 Dufferin TS

The need at Dufferin TS occurs in 2040 for the reference forecast and can come up as soon as 2033 in the high electrification scenario. There is an opportunity to concurrently address station and supply capacity needs by placing the recommended ESS at Dufferin TS. This can defer the need at Dufferin TS to the end of the forecast period. There is some incremental eDSM potential at Dufferin TS (up to 7 MW by 2040) which can further alleviate station capacity needs in the area.

Therefore, the Technical Working Group reiterates the recommendation for the ESS to be connected to Dufferin TS. The Technical Working Group will also continue to monitor load growth at Dufferin TS in upcoming cycles of regional planning.

7.7.3.4 Basin TS

The need at Basin TS is heavily tied to the expected new development at the Port Lands, specifically the developments at Ookwemin Minising and McCleary Districts. The Technical Working Group received a study from the City of Toronto that details the load growth and potential for district energy systems to play an important role in meeting the area's energy needs. The study shows that district energy can potentially reduce the summer and winter peak demands. Despite this predicted demand reduction, a new station or expanded Basin TS will still be needed to supply new community growth and development in the area.

Therefore, the Technical Working Group recommends Hydro One investigate the feasibility of either expanding Basin TS or adding a new station in the area. With the input of the Technical Working Group, this station should be right-sized to meet the future needs of Basin TS after accounting for the impacts of the planned district energy system in the Port Lands, as well as updated information about the timing and magnitude of development. The City of Toronto will need to continue working closely with Toronto Hydro and Hydro One to finalize the site for a new or expanded Basin TS.

7.8 New Supply Options for Eastern Toronto

7.8.1 Need for Transmission Reinforcement

This need for transmission reinforcement was confirmed by assessing a suite of non-wires alternatives compared to the transmission option. Capacity needs were assessed on an hourly basis for the 20-year IRRP planning horizon and further modeled using an energy production simulation. This approach was taken to understand the timing, magnitude, and duration of peak demands on the existing system, and the total energy requirements to ensure local area reliability. Relying solely on locally sited renewable resources, both standalone and paired with energy storage, as well as a large standalone energy storage system (assumed to be ESS technology), was found to be not feasible to address the total energy need in East Toronto. A significant amount of land area would be required to site these resources at the scale needed to match the size of the need in eastern Toronto.

Other technically feasible local resource options such as utility-scale gas generation and small modular reactors (in combination with ESS) were ruled out due to community preferences and siting

challenges. Gas generation would be especially misaligned with the policy position from Toronto City Council. Similarly, incremental eDSM and DERs also cannot fully address the required need. However, both eDSM and DERs can help manage peak demand and, over time, reduce the size of the system need that must be met by other solutions. While these incremental measures could provide some local benefit while a transmission solution is being implemented, findings from the LAPS indicate the achievable potential of these local resources.[23]

While the PEC out-of-service scenario would drive an earlier need date, transmission reinforcement is still required by 2037 to address the capacity need forecasted to emerge in 2038.

Both during the IRRP development and in past transmission plans and studies, the IESO found that due to the built-up nature of the City of Toronto, options for siting new transmission facilities (both lines and stations) are extremely limited. The three possible transmission options studied for the IRRP reflects these limitations. These three options were developed with the objectives of being able to address the local capacity need, while reducing future reliance on PEC for local reliability.

All three options originate from east of the city. They either utilize existing transmission rights-of-way or utilize new paths that minimally impact existing land-uses.

7.8.2 Current Supply Constraints and Future Demand

Downtown Toronto is currently supplied by two transmission corridors: one from the west via Manby TS and one from the east via Leaside TS. A third transmission supply would support future growth and maintain system reliability in the downtown core. This provides an opportunity to address both resilience and capacity needs with a singular solution and was used as one of the considerations when choosing the recommended option for the third transmission line.

7.8.3 Overland Option: Expand 230 kV Leaside TS and New Supply from Cherrywood TS

This option involves expanding the Leaside TS by adding three new 230/115 kV autotransformers at Leaside TS, to complement the existing six, adding six new inline 230 kV circuit breakers between Cherrywood TS and Leaside TS and rebuilding a presently idled overhead transmission line between Cherrywood TS and Leaside TS. There is an idle transmission line along most of the 26 km distance between these two stations. A portion of this line is currently being used by Toronto Hydro for distribution.

This option requires Hydro One to expand the existing Leaside TS by redeveloping adjacent lands available to them starting in 2030,[24] and to rebuild and/or reconductor the existing transmission line structures between Cherrywood TS and Leaside TS. Most of this right-of-way is adjacent to homes, and it transects the Rouge National Urban Park. Some work to re-terminate the existing 230 kV circuits may be required to make this option feasible, as well as upgrades to portions of the 115 kV

[23] Small-scale behind-the-meter resources are not the only tools available for the IESO and Toronto Hydro to manage local demand and maintain local reliability. Larger, front-of-the-meter (FTM) generation resources can participate in ongoing and future IESO procurements; and the IESO is developing a Local Generation Program targeting smaller-scale FTM resources. There are also mitigation measures available in the operational timeframe, such as new and expanded Remedial Action Schemes, to manage a range of reliability risks. These types of measures are often deployed as interim measures while grid reinforcements are being planned or implemented.

[24] Pers. Comm. From Hydro One to the Technical Working Group.

transmission system between Leaside TS and Hearn SS. These 115 kV lines are aging, and upgrade work could be timed to coincide with the work needed to refurbish these facilities at their end-of-life.

7.8.4 Overland and Underground Option: Build a New 230 kV Transformer Station Downtown Supplied from Cherrywood TS

This option involves adding two 230/115 kV autotransformers at Hearn SS and building a double circuit 230 kV line between Cherrywood TS and Hearn SS by rebuilding about two-thirds of the existing idle line between Cherrywood TS and Scarboro TS. This option also requires reinforcing or expanding the existing overhead 230 kV transmission line from Scarboro TS to Warden TS, extending a new 230 kV line from Warden TS a further 3 km to Lumsden Junction, and finally constructing new underground 230 kV cables approximately 9 km to Hearn SS in the Port Lands. This option will require additional inline breakers on the Cherrywood TS to Leaside TS circuits, between Scarboro TS and Leaside TS, and additional 230 kV reconfiguration work between Scarboro TS and Warden TS to re-terminate existing circuits. This option would also allow the retirement of approximately 7 km of 115 kV cable sections of H7L and H11L between Hearn SS and Main TS.

7.8.5 Underwater Option: New HVDC Transmission Supplying Downtown from the East

The third option considered is a new high-voltage direct current (HVDC) link into the Port Lands in downtown Toronto from the bulk transmission network east of Toronto. Two potential points of origin were considered for this option where there is existing transmission infrastructure with available capacity east of Toronto near the Lake Ontario shoreline (Bowmanville SS and Pickering). Both high voltage alternating current (AC) and HVDC technologies were considered in the analysis.

Bowmanville SS was selected as the preferred point of origin because injecting bulk supply into Toronto from this location delivers additional benefits for the bulk network by bypassing Cherrywood TS altogether and freeing up additional capacity at the station to supply growth elsewhere in the Greater Toronto Area (GTA). HVDC technology was chosen over AC because it offers additional benefits and ancillary services, and becomes more cost-effective than AC for submarine cable lengths greater than approximately 50 km. The IESO has carried out a preliminary land review and assessed there is undeveloped land available to accommodate HVDC converter stations near the Bowmanville SS and the Hearn SS.

This HVDC Option involves installing approximately 65 km of submarine HVDC cables underneath Lake Ontario. Horizontal directional drilling is a common approach to make the transition from land to water while minimizing surface and sediment disruption. Voltage-source converter (VSC) stations, a key component to HVDC transmission, are a mature technology that continues to improve in key areas such as losses and compactness of the station footprint. A VSC station would need to be sited and constructed at each terminal end. Some additional work on the 115 kV system in the Port Lands in Toronto will be required to accommodate a higher power injection as compared to the injection through PEC, and inline breakers will need to be added to the Cherrywood TS to Leaside TS 230 kV transmission circuits to add further resiliency to the current supply to East Toronto.

7.9 Third Supply Options Analysis

To arrive at a recommendation, the IESO received information from the IRRP Technical Working Group, including exploratory cost estimates and preliminary project scope information for the overland and overland and underground transmission options. The IESO consulted with the transmission development community to obtain additional information for submarine HVDC technologies. These discussions focused on underwater HVDC facilities built in the last ten to 15 years and covered technical aspects of project planning, construction, operation and maintenance, environmental challenges and project economics. This research, extensive engagement, and the IESO's system studies have informed the detailed evaluation of the three transmission options summarized in this section.

The planning considerations factored into the assessment of the transmission options are introduced below, and each is summarized in the sub-sections that follow.

- **Reliability performance –** Ability to supply Toronto's future demand in accordance with the established reliability criteria for electric power systems, without reliance on PEC.
- **System resilience** – Impact on the power system's ability to withstand or recover from major events such as a loss of Manby TS or Leaside TS, and the flexibility to support a range of possible futures.
- **Bulk power system impact –** Benefits for the upstream bulk transmission network.
- **Implementation complexity –** Impacts on land-use and ability to manage potential risks throughout development and implementation of the option.
- **Cost-effectiveness for ratepayers –** cost effectiveness of the option in providing power reliably and safely to consumers.

7.9.1 Reliability Performance

7.9.1.1 Load Meeting Capability

The performance of each transmission option was studied in terms of its ability to supply Toronto's forecasted electrical demand. Each option provides a substantial increase in load meeting capability in Toronto and can meet the identified supply capacity needs.

The HVDC Option was shown to provide the largest increase to the system's load meeting capability. With the inclusion of incremental eDSM and/or local DERs, an integrated solution comprising the HVDC line and additional local measures can also meet needs driven by the high electrification forecast. In addition to offloading the transformers at Leaside TS, a capacity injection at Hearn SS would also offload the transmission system further upstream including the transformers at Cherrywood TS.

By comparison, the Leaside TS expansion option provides enough incremental new capacity to defer these system needs to 2042; and the combined overhead and underground option to the Port Lands can defer these system needs to 2044 under the reference case forecast. These options would require additional eDSM and/or DERs to meet these needs further into the future and additional transmission reinforcement would be required sooner to equal the additional load meeting capability of the HVDC Option.

7.9.1.2 Ancillary Services – Voltage Control

The VSC station technology that accompanies the implementation of an HVDC transmission line can provide specific reliability benefits through dynamic reactive power, providing voltage control and maintaining energy flows independent of power system conditions. Voltage control is critical in reducing risk of voltage collapse that could result in blackouts on a local or system-wide level. Specifically, in this case, the location of a VSC station near the Hearn SS is expected to provide reactive power support where it is needed within the load centre, and near Bowmanville SS, close to the Darlington Nuclear complex. This benefit is expected be quantified in further studies of the option as part of the detailed design process. Even if the underwater cable portion is out of service, the VSC stations can operate in STATCOM mode to continue to regulate voltage and support grid stability.

Reducing reliance on PEC also means losing the voltage support capabilities currently provided by the facility. HVDC with VSC technology can provide this voltage support. Neither of the AC options can provide this service.

7.9.2 System Resilience Benefits

7.9.2.1 Supply Diversity

The theme of resilience has consistently been raised by stakeholders as an objective of electricity planning. This reflects local concerns about climate change, aging infrastructure, and the impact of major events like the loss of Manby TS supply due to flooding that occurred in July 2024 and previously in July 2013. The three transmission options were reviewed in terms of their ability to deliver improved system resilience. While system resilience itself is not easily measured, incremental improvement to resilience is partly a function of the diversity of supply to an area, and the degree to which the different sources of supply can support each other during system outages.

The root of this issue is the reliance of Toronto's dense urban centre on two radial 230 kV transmission paths, Manby TS and Leaside TS, each with limited ability to back up the other. Leaside TS is reliant on a single radial 230 kV supply path from Cherrywood TS. A loss of Leaside TS can interrupt supply to half of the central 115 kV system, and a loss of Cherrywood TS can interrupt supply to this area plus a large part of the remaining eastern half of the city including East York and a significant portion of Scarborough.

The HVDC Option would bring a new, geographically and electrically separated source of supply directly into the urban centre. It has the capacity to replace PEC as a local source of supply, while adding redundancy in the event of transmission outages. Major events such as the 2024 flooding event at Manby TS that disconnected about 900 MW of load, and the similar 2013 event that disconnected about 3,800 MW of load impacted hundreds of thousands of customers. Toronto has experienced at least three 1-in-100-year rainfall events since 2005, and, due to the aging network and increasing frequency of extreme weather, both planned maintenance and the likelihood of unplanned outages are expected to increase into the future. If an event of a similar magnitude to the two Manby TS outages interrupted supply from Leaside TS for an eight-hour period, the economic consequences could be in the order of $400 million.[25]

[25] Based on an assumed load interruption of 900 MW for an eight-hour period, using a Value of Lost Load calculator recommended in the Ontario Energy Board's Vulnerability Assessment & System Hardening Report.

A new diversified supply source can provide better continuity of supply and better load restoration capability in East Toronto during and/or after major events, should one impact supply from Leaside TS or Cherrywood TS. Additionally, with minimal upgrades to the 115 kV system connecting the Manby TS (western) and Leaside TS (eastern) sectors, the supply to a large portion of the financial district in Downtown Toronto could be transferred to the new third supply source. This would extend the reliability benefits from East Toronto into the western Toronto Manby TS sector. These benefits include reducing the loading on Manby TS, and potentially deferring other future system upgrades needed to ensure reliability.

Lastly, as the HVDC cables would be submerged, they will be more immune to the effects of extreme weather compared to overhead transmission.

The Leaside TS expansion option does not provide the same level of system resilience benefit that a true third point of supply to the downtown can provide. Like the HVDC Option, with additional 115 kV system reinforcements, an expanded Leaside TS could facilitate increased load transfers from Leaside TS to Manby TS and provide some co-benefits for the Manby TS sector. The combined overhead and underground option to the Port Lands also provides some of the same benefits for reliability and system resilience. However, this option results in the East Toronto supply remaining reliant on supply from Cherrywood TS, and potentially vulnerable to major events impacting Cherrywood TS and multi-element contingencies impacting the Cherrywood TS to Leaside TS transmission corridor.

7.9.2.2 Operational Flexibility

The power flows across HVDC transmission systems are highly controllable, as the technology allows grid operators to dial the flow up or down, in either direction, across the line independent from the interconnected AC grid. This operational flexibility is beneficial under normal operation as demand in Toronto fluctuates through the day, as well as during periods of maintenance and/or outages on other parts of the local 115 kV transmission system.

Neither of the AC transmission options allows for comparable level of controllability, and therefore neither option provides system operators an equivalent level of real-time operational flexibility. In addition, because of this bi-directional control, the HVDC Option provides flexibility over a longer timeframe, making it compatible with a range of possible futures. For example, functioning as a transmission infeed to the city, the line benefits a future Toronto in which the city remains at a supply deficit and maintains a strong reliance on the interconnected grid for local electricity supply. Conversely, if a long-term future scenario unfolds with high penetration of local DERs (including storage), the flows across the HVDC line could be reversed to export power to the provincial grid.

HVDC technology contributes very little to fault current levels on the surrounding AC transmission system.[26] High fault current levels have been a limiting factor on the amount of DERs that can be integrated into Toronto's legacy 115 kV system, and while actions have been undertaken over many years to increase equipment ratings, this issue persists today. As HVDC lines and converter stations contribute very little fault current compared to AC transmission and synchronous generators (such as

[26] "Fault current" refers to extremely high magnitude of current that flows through a circuit during a fault, such as a short circuit or a line to ground fault. These fault currents can be significantly higher than the normal operating current of the system, and must be managed within the capabilities of the equipment to avoid causing severe damage to equipment and disrupting power supply.

PEC), the HVDC Option can contribute to alleviating technical barriers to higher DER penetration rates in the City of Toronto. These benefits will be evaluated through subsequent planning and short circuit studies and through preliminary project scoping and development.

7.9.2.3 Ancillary Services – Black-start Capability

Black start refers to the process of re-energizing a power system following a full or partial outage event without requiring additional power from the grid. In the case of a high impact, low probability event (e.g., complete loss of Leaside supply), power can be restored to the city through the HVDC cable. It therefore can play a critical part in improving restoration times in the event of a loss of supply from other sources.

Neither of the AC options can provide this service, and this is not a service that PEC currently provides. For the HVDC Option to provide this service, it would need to be intentionally scoped into the project design and built into the cost.

7.9.3 Bulk Power System Impact

7.9.3.1 Benefit to Cherrywood TS and 500 kV Network

Only the HVDC Option that originates to the east of Toronto can provide benefits to the bulk power system in addition to the Toronto local area. Cherrywood TS is the main bulk point of supply into the Eastern Toronto system, and it also acts as a critical bulk supply hub interconnecting Pickering Nuclear Generation and linking the GTA to Eastern Ontario. It is already one of the most heavily loaded bulk stations in the GTA. As the HVDC Option would bypass Cherrywood TS by providing a new path into the downtown core, it can reduce bulk congestion and defer the forecasted need to increase transformation capacity at the station. It may also defer or avoid the need for new 500 kV transmission from Cherrywood TS to Parkway TS in addition to additional 500 kV transformation capacity. This frees up the existing bulk transmission assets to supply additional load growth not only in Toronto but also in the Regions of Durham and York and surrounding areas. And by alleviating congestion on the bulk system east of Toronto, the new supply path into the load centre can also allow more generation to connect in the east, which is currently limited due to limitations on the current transmission interface governing power flows from east to west in the GTA.

The full scope of these bulk system benefits is being assessed as part of the South and Central Bulk Study and will continue to be assessed in subsequent bulk studies. If a 500 kV station and/or new 500 kV lines can be avoided, the ratepayer savings could be in the order of $100 million to $300 million or more (this preliminary estimate will be refined in subsequent studies). Neither of the AC options can provide similar benefits to the broader provincial bulk transmission network outside of the Toronto local area.

7.9.4 Implementation Complexity

7.9.4.1 Land-use Impacts

As the HVDC Option is expected to be built under Lake Ontario, with HVDC converter stations enclosed in buildings sited on presently vacant land and/or former industrial sites, it has the least land-use impact among the three options. All options will require a similar amount of land area for

stations. The IESO learned through engaging with HVDC transmission system owner-operators that horizontal directional drilling is a common method of making the land-water transition, which would have no surface impact beyond the construction phase. As compared to the AC options, less coordination to navigate through built-up areas would be required during construction and for routine maintenance or repair. Horizontal directional drilling, as an alternative to trenching methods, can avoid disturbing contaminated near-shore sediments in Toronto's inner harbour and is a method that has been successfully used in Lake Ontario.[27]

Both AC options would require construction through heavily built-up urban areas and would disturb existing secondary uses (e.g., community gardens, recreation, active transportation corridors). A significant amount of effort and investment has been made in the Meadoway project on portions of the existing Gatineau transmission corridor from Cherrywood TS. This corridor also crosses the Rouge National Urban Park. Delays may occur to manage the reconfiguration and outages of multiple key circuits supplying East Toronto as would be expected for any construction within the existing Cherrywood TS to Leaside TS corridor.

7.9.4.2 Project Development Challenges

The underwater HVDC transmission line would be the first of its kind in Ontario. There will be challenges associated with the novelty of the technology and its application as an underwater cable. Key project development steps including environmental and regulatory approvals and permitting, including provincial and federal environmental assessments. Environmental assessments may be coordinated so that a single environmental assessment meets the legal requirements of both jurisdictions.[28]

Through engagements, the IESO learned that there is a wealth of worldwide experience building similar projects and interest in developing transmission systems in Ontario. HVDC technology is the most common means of interconnecting offshore wind projects to the electricity grid and for building interties between jurisdictions over various distances up to hundreds of kilometers apart. Several similar projects are in the presently under construction worldwide. The IESO is confident, based on this growing volume of experience planning and executing similar projects, that implementation challenges can be effectively managed.

HVDC technology is currently in high demand, and there are a limited number of original equipment manufacturers (OEMs) that are commercially producing cables and VSC station components. The IESO learned that there are factory production queues for equipment, and due to bespoke nature of HVDC technology solutions, it is advantageous for developers to secure their slots in the production queue as early as possible. Once in a queue, production timelines can be three to four years (current estimate, as of August 2025), during which time the developer can continue to proceed with obtaining the various approvals and permits. For Toronto's third supply, there is time to meet the in-service date as long as implementation, concurrent with further community engagement and project scoping, continues without significant delay following the IRRP publication.

---

[27] For example, the pipe connecting to Hydrostor's compressed air energy storage pilot was installed by directionally drilling approximately 1 km into Lake Ontario at depths up to 45m deep.

[28] Canadian Environmental Assessment Act, 2012. Requests must be made formally and approved by the federal Minister. Separate provincial and federal decisions are still required for the substituted process.

7.9.5 Cost Effectiveness

7.9.5.1 Cost of the Three Options

All three transmission options are major infrastructure investments, and all are estimated to cost in the order of $1 billion to $1.5 billion. The HVDC Option, based on a combination of sources, is estimated to cost approximately $1.5 billion, with a range of uncertainty equivalent to a Class 5 "exploratory" cost estimate.[29] The final cost will depend largely on the specific technical and design attributes of the project. For example, a bipole line will cost more than a symmetrical monopole line,[30] while offering a higher level of redundancy in the event of a cable fault.

Hydro One provided preliminary cost estimates for the AC alternatives which indicate that these options have a lesser upfront capital cost than the HVDC Option. Hydro One also indicated that these estimates are preliminary and lack defined uncertainty ranges.

As the HVDC and the two AC options have very different performance attributes and deliver different benefits both for Toronto customers and provincial ratepayers, it is not appropriate to select the preferred option based on the initial cost alone. At the same time, many of the additional benefits the HVDC Option provides are challenging to express quantitatively, including the provision of voltage support, operational flexibility, compatibility with a range of uncertain futures, potential for black-start capability, and land-use impacts. The bulk system benefit to ratepayers of the HVDC Option could be several hundred million dollars, which alone brings the cost of HVDC much closer to the other two options. And while extreme weather-related major events are still relatively rare, occurring about once per decade, the resilience benefit of the HVDC Option for reducing the impact and improving restoration following these events is significant. On balance, the IESO is confident the underwater HVDC Option provides positive benefits to ratepayers and the community, relative to the understood costs.

7.9.5.2 Realizing the Value of Long-term Transmission Investments

Over the last 20 years, while making investments in Toronto's 115 kV system, Hydro One has taken advantage of opportunities to upgrade 115 kV transmission equipment to a 230 kV design standard. For example, the John TS to Esplanade TS underground cable, the cable replacements between Riverside Junction and Strachan TS, and the Terauley TS to Esplanade TS underground cable (presently under construction) have all been built to a 230 kV standard. These enabling investments were undertaken to work toward a future operating voltage conversion from 115 kV to 230 kV in parts of the downtown core.

The HVDC Option preserves the optionality to convert parts of the downtown transmission system to 230 kV operation. The combined overland and underground option terminating in the Port Lands would also provides this potential benefit, but the overland option that reinforces the supply via Leaside TS does not.

---

[29] Expected accuracy range from a low of -20% to -50% to a high of +30% to +100%. This is an industry standard estimate of the typical low and high ranges based on the maturity level of the project definition. The expected accuracy narrows as the project scope is further defined in the later stages of project development.

[30] HVDC systems can be configured as monopole (one conductor with ground or sea return) or bipole (two conductors, positive and negative). Bipole usually offers better reliability.

7.9.6 Recommended New Supply for Eastern Toronto

The IESO's recommendation for the preferred third transmission option is the underwater HVDC Option. This option addresses the long-term supply capacity need in East Toronto that exists with or without PEC in-service. When interconnected with the bulk transmission network at Bowmanville SS, it also delivers broader bulk system benefits. The HVDC technology provides additional reliability and resilience benefits to Toronto, including:

- Accommodating the highest incremental demand growth among the three options,
- Improved supply diversity and system resilience by introducing a true third supply path into the downtown core,
- Bulk reinforcement, deferral, enables system resources east of Toronto
- Ability to control power flows independent of conditions on the rest of the IESO-controlled grid,
- Additional ancillary services such as voltage control and black-start capability (e.g., ability to restore power following a local blackout), and
- Improved system performance and load restoration following major events beyond the normal planning criteria for the electric power system (e.g., events such as a complete loss of Manby TS[31] or Leaside TS).

The proposed connection points of the HVDC Option are shown for illustrative purposes in Figure 17. The project developer would be responsible for leading the design, undertaking route studies, establishing the route, seeking approvals, and constructing the facilities.

[31] Examples of such events include the July 2013 and July 2024 floods that both led to loss of Manby TS supply.

Figure 17 | Illustrative Map of the Toronto Area Showing the HVDC Option

Table 19 provides a summary of all three options for a new supply to Toronto.

Table 19 | Summary of Three New Supply Options to Toronto

	Option 1: Overhead	Option 2: Overhead + Underground	Option 3: Underwater (Recommended Option)
Estimated Capital Cost	$800 million	$900 million	$1.5 billion
Avoided Bulk System Reinforcements	N/A	N/A	Up to $300 million[32]
Year of Growth Enabled	2042	2044	Beyond 2044 (past the IRRP study timeline)
Load Meeting Capability (MW)	3,350	3,400	>3,400
$/MW Capacity Enabled	$1.5 million[33]	$1.5 million	$1.7 million[34]

[32] Preliminary estimate – the bulk system benefits are being evaluated in the South and Central Bulk Study.
[33] Includes preliminary cost estimate of bulk system reinforcements avoided by the HVDC Option.
[34] Does not consider the value of other local system benefits, including voltage support, black-start capability, or improved system resilience.

	Option 1: Overhead	Option 2: Overhead + Underground	Option 3: Underwater (Recommended Option)
System Resilience	Similar to today: two supply points	Moderate improvement: new supply to downtown, still reliant on Cherrywood TS	Significant improvement: new supply from a separate bulk connection
Other System Benefits	None	None	Local voltage support Relieves Cherrywood TS Enables more generation to connect in eastern Ontario
Other Development Considerations	Proximity to housing Potential conflict with Meadoway secondary land-use on corridor and Rouge National Urban Park	Underground facilities through built-up areas technically challenging; feasibility not certain	Bespoke equipment with production queues Lack of Ontario transmitter experience building HVDC and long underwater systems

7.9.7 Compatibility with Large ESS in the Port Lands

The IESO's technical studies found that injecting more than 900 MW at the Hearn site can contribute to thermal exceedances on parts of the 115 kV system under certain conditions. This presents challenges with co-locating additional transmission-connected resources (such as a large ESS[35]) in the same location as the HVDC Option. This creates a potential congestion issue when the transmission system is injecting into this location at the same time the ESS is discharging into the system. Therefore, with the HVDC Option, siting a large ESS connected to the Hearn SS may not be technically and economically feasible in the long-term. A smaller size energy storage system may be feasible. The Toronto IRRP has identified other suitable location for ESS, as noted in Sections 7.6.1.5 and 7.7.1.5.

7.9.8 Addressing Resilience of Toronto's Electricity System

7.9.8.1 Increasing Resilience through the HVDC Option

The recommended HVDC option will increase the diversity of supply to downtown Toronto in addition to enabling demand growth over the next 20 years. One of the most significant contributions of the HVDC option to system resilience is the introduction of a third, geographically and electrically distinct supply path into Toronto's urban core. Currently, the city relies heavily on two radial 230 kV transmission paths, Manby TS and Leaside TS, both of which have limited ability to provide emergency supply should one suffer a complete loss of supply. This configuration has proven vulnerable during extreme weather events, such as the 2013 and 2024 floods that disrupted supply from Manby TS, affecting hundreds of thousands of customers. During these events, the limited

[35] All technical energy storage assumptions in this report assume the use of lithium-ion battery technology.

ability to resupply Manby TS from Leaside TS, even with PEC in-service, impacted the duration and severity of the outage.

The HVDC line bypasses Cherrywood TS and injects power directly into the downtown core via Hearn SS. This reduces dependency on the Cherrywood to Leaside corridor, mitigating the risk of cascading failures, and ensures continuity of supply during outages or emergencies for customers in eastern Toronto. It also improves the ability for the City's eastern supply to accommodate loads supplied by Manby TS should a loss of supply event occur in the western Toronto area. In effect, this third point of supply will enable faster restoration of service in the event of major outages.

Increasing frequency of extreme weather events pose serious risks to the electricity system. The HVDC cables, being submerged under Lake Ontario, are inherently more resilient to surface-level disruptions such as wind, ice storms, and flooding. This physical separation from urban infrastructure and environmental hazards significantly lowers the risk of damage, making the system more robust in the face of climate change.

HVDC technology also offers additional operational flexibility. Unlike AC systems, HVDC allows grid operators to control power flows independently of the rest of the grid. This controllability is crucial for managing fluctuating demand, scheduling maintenance, and responding to both planned and unplanned outages. Additionally, the HVDC system can be designed to include black-start capability, allowing it to re-energize the grid after a complete outage without relying on external power sources. This feature is not available in the existing AC options or through PEC, making HVDC a critical asset for emergency restoration and system recovery.

7.9.8.2 Climate Vulnerability Study

To account for climate risk in future system planning studies of Toronto's electricity system, the IESO will undertake a desktop study of climate vulnerabilities as part of ongoing planning. This study will assess climate change-related risks at key points of the electricity system across Toronto. The study is intended to equip planners with insights to determine the scope of extreme contingencies to be assessed in future studies.

The study will involve a comprehensive GIS-based analysis of historical and projected climate data including temperature, precipitation, and flooding trends. It will incorporate data from sources such as Environment and Climate Change Canada, the Climate Atlas of Canada, and regional conservation authorities. By modeling future scenarios under different emissions pathway scenarios, the study will also help planners anticipate how climate risks may evolve over time and affect system performance.

This information is particularly valuable for the IRRP process, which seeks to balance reliability, cost-effectiveness, and resilience. For example, insights from this study can inform decisions about where to prioritize upgrades, reinforce vulnerable assets, or deploy non-wires alternatives like DERs and energy storage. It can also support transmission planning, such as the proposed HVDC line to downtown Toronto, by identifying climate-resilient routing options and station siting considerations.

Moreover, the study's emphasis on visual mapping and trend analysis enhances transparency and engagement. It enables planners, municipalities, and Indigenous communities to better understand the risks and participate meaningfully in shaping resilient energy solutions.

In summary, this climate vulnerability study will provide the IESO with a data-driven foundation for carrying out subsequent planning studies to strengthen Toronto's electricity system against future

climate impacts. It ensures that regional plans are informed by localized risk assessments, enabling proactive, resilient, and adaptive infrastructure planning for a rapidly changing environment.

7.9.8.3 Extreme Contingencies Assessment

Extreme contingencies are high-impact, low-frequency events that could severely disrupt Toronto's electricity supply. Studies of this nature involve identifying system vulnerabilities and mitigating measures to address the risk of extreme contingencies. The recommendations in this IRRP, as described in this report, will help mitigate the risk of some extreme contingencies, but the outlook for demand growth and threat of extreme weather events will likely cause new system vulnerabilities to emerge. Therefore, the IESO will work with Toronto Hydro and Hydro One to assess the scope and timing of an updated extreme contingencies assessment. The results of this work will inform future regional planning cycles. The results of an extreme contingencies assessment are not typically made public because they can contain detailed information about system vulnerabilities that could pose security risks if disclosed.

8 South and Central Bulk Study

IESO is currently undertaking a bulk system study focused on the Southwestern and Central regions of Ontario, particularly along the Windsor to Hamilton corridor as well as the urban centers in the GTA.

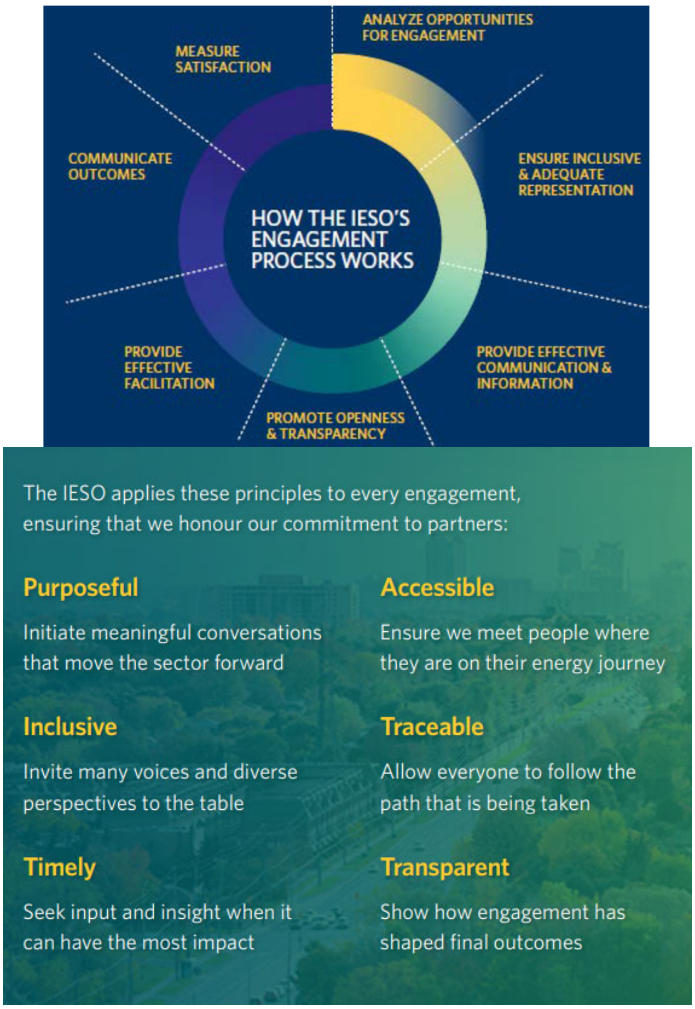
The driver of the South and Central Bulk Study is to support economic growth in Southwestern Ontario and the GTA and enable new supply resources by:

- Confirming the transmission reinforcements required to enable connection of the small modular reactor (SMR) project at Darlington Nuclear Generating Station and expanded nuclear supply at Bruce.
- Determining the transmission upgrades needed to allow decreased reliance on emitting resources at York Energy Center in the York region, PEC in Toronto, Halton Hills generating station in GTA west and Sithe Goreway generating station in Brampton.
- Determining the transmission needed to enable reliable supply in high growth and economic development areas including the GTA and the Windsor to Hamilton corridor.
- Identifying new corridors required for future transmission reinforcements.

The Bulk Study has been carried out in coordination with the Toronto IRRP to integrate options to enable growth in the city and deliver new supply. Some of the key linkages from the bulk study to this IRRP are as follows:

- The buildout of a new double circuit 500 kV line from Bowmanville SS west towards the GTA will enable the connection of the SMR project and increase supply from Eastern Ontario towards the GTA and Southwestern Ontario. This reinforcement from the east will help redistribute load between heavily utilized GTA bulk stations at Cherrywood, Parkway and Claireville which currently supply Toronto along with York and Durham Regions and the western GTA.
- The HVDC third supply to Toronto is also expected to have bulk impacts as it will be another major supply from the east towards the city, providing an alternate independent route to meet the city's growing demand. The feasibility of this option was considered at both the regional and bulk system level. The Bulk Study also examined how the third supply to Toronto would impact how and where the required 500 kV reinforcement from Bowmanville gets terminated in the GTA.

The South and Central Bulk Study will be published in early 2026.



9 Community and Stakeholder Engagement

Engagement is critical in the development of an IRRP. Providing opportunities for input in the regional planning process enables the views and perspectives of the public, which for these purposes, refers to Indigenous communities, market participants, municipalities, stakeholders, customers and the general public, to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles and activities undertaken to date for the Toronto IRRP.

9.1 Engagement Principles

The IESO's External Relations Engagement Framework and Indigenous Engagement Framework is built on a series of key principles that respond to the needs of the electricity sector, communities and the broader economy. These principles ensure diverse and unique perspectives are valued in the IESO's processes and decision-making. We are committed to engaging with purpose with external audiences to foster trust and build understanding as the energy transition continues.

Figure 18 | The IESO's Engagement Principles

9.2 Engagement Tactics

To ensure that the Plan reflects the needs of Indigenous communities, municipalities, stakeholders, communities, market participants, customers and the general public, engagement involved:

- Leveraging the Toronto engagement webpage to post updated information, engagement opportunities, webinar materials, feedback received and the IESO response to feedback, as well as supplementary data and information.
- Targeted one-on-one discussions with Indigenous communities and the City of Toronto to help inform the engagement approach and to ensure that the communities' identified needs are considered.
- Hosted a series of public webinars at major milestones in the development of the plan to share details, understand feedback and answer questions.
- Communications and other engagement tactics to enable a broad participation through email and IESO's weekly Bulletin updates.
- A new PoweringGTA.ca website sharing details of active electricity plans within the GTA, including Toronto.
- Social media content on the IESO's LinkedIn and Instagram accounts to increase awareness of the planning efforts underway.

9.3 Engagement Approach

The engagement for the Toronto IRRP provided valuable insights into the local drivers and pockets of growth, priorities for the City of Toronto, community preferences, and the community vision for the future of Toronto. These insights shaped the development of the Plan and informed an integrated regional resource plan for the City of Toronto that is best suited to meet Toronto's unique and growing needs.

The IESO led an engagement strategy that included targeted one-on-one discussions with the City of Toronto and Indigenous communities, hosted technical briefings with communities as well as 6 public webinars to share information and solicit written feedback from interested rights holders and stakeholders. The purpose of each engagement opportunity was to build awareness and education of the regional planning process, provide updates and information pursuant to the Plan's development, and enable informed and meaningful community and stakeholder feedback. Outcomes of targeted community discussions and stakeholder feedback helped to inform and guide the development of the Plan at each key milestone.

To support the analysis of non-wire options, the IESO retained a consultant to develop a Local Achievable Potential Study (LAPS) to identify opportunities for incremental energy savings through energy efficiency, behind-the-meter distributed energy resources, and demand response. Engagement for the LAPS was included as part of the Toronto IRRP engagement approach.

Public webinars received high registration and were attended by a diverse group of interested stakeholders including the City of Toronto, Indigenous communities, government, industry, environmental associations, and community organizations. Written feedback was invited following each webinar. The six milestones of engagement, and which point feedback was invited, included:

1. Draft scoping outcome assessment report to share the planning approach before commencing the full IRRP study
2. Draft IRRP engagement plan, and draft electricity demand forecast for the region
3. Identified electricity needs for the region and introduction of the Local Achievable Potential Study
4. Results of the options screening for wire and non-wire options to meet the identified needs
5. Draft results for the Local Achievable Potential Study
6. Analysis of options and draft IRRP recommendations

Overarching themes of feedback heard during the development of the IRRP primarily focused on:

- Phase-out of PEC, and avoid new gas generation
- Community preference for non-wire options to meet electricity needs
- Enhanced transparency for data/information and decision-making rationale
- Alignment with City of Toronto decarbonization initiatives such as TransformTO
- Recognition of the need for a third supply line; coupled with requests for more information on the evaluation of options, impacts of routing options, and concern it would bring nuclear energy into the city

Feedback received during the written comment periods for these webinars helped to guide further discussions throughout the development of this IRRP, as well as add due consideration to the final recommendations. A summary of the engagement milestones is described below.

9.3.1 Scoping Assessment

The IESO held preliminary discussions with the City of Toronto to help inform the engagement approach for the third round of planning, and to strengthen relationships and dialogue in this region that would inform the development of the Plan at each milestone. Engagement started with the draft Scoping Assessment Outcome Report for the Toronto Region. An invitation was sent to the City of Toronto, Indigenous communities, other stakeholders, and to the Toronto subscription list to announce the commencement of a new planning cycle and invite interested parties to provide input on the draft Toronto Region Scoping Assessment Outcome Report. A public webinar was held on February 16, 2023, to provide an overview of the regional electricity planning process and the scoping assessment, and to seek input. The final Scoping Assessment Outcome Report was posted on March 21, 2023, identifying the need for a coordinated regional planning approach through the development of an IRRP.

The key themes of feedback received during the scoping assessment milestone included study considerations for modelling extreme weather events, coordination with third party electricity demand studies (i.e., Port Lands DER study), opportunities to facilitate DERs, inclusion of a diversified electric and low-carbon gas scenario, and coordination with institutional customers to factor in their electrification plans into the regional forecast. The IESO considered this feedback in the development of the plan and posted its response to the Toronto engagement website.

9.3.2 Demand Forecast

Following the finalization of the Scoping Assessment, the Technical Working Group began the development of Toronto's electricity demand forecast. IRRP recommendations are typically driven by

the reference demand forecast, which includes firm loads (current and planned), organic growth, residential, electrification and energy plans, and development plans. The Technical Working Group also developed a high electrification scenario to test potential demand growth that is less certain, assuming higher electrification adoption rates. The IESO sought input from the City of Toronto to identify drivers and pockets of growth, decarbonization and electrification initiatives.

To enable meaningful feedback and promote transparency, the IESO publicly posted a detailed forecasting methodology document and load forecast data tables to the engagement website early in the engagement process for stakeholder consideration. On April 16, 2024, the IESO hosted a public webinar to share the draft reference and high electrification scenarios, drivers of growth, draft engagement plan, and to seek stakeholder feedback. Feedback was received from 20 stakeholders, ranging from requests for information on methodology, requests for specific data and assumptions, inquiries on alignment with City of Toronto net zero plans, and requests that non-wires be considered in the Plan's development. Feedback on the draft engagement plan included enhanced collaboration with Indigenous communities and stakeholders throughout the planning process to produce better outcomes. The IESO considered this feedback in the development of the plan and posted its response to the Toronto engagement website.

9.3.3 Electricity Needs

During this milestone, the IESO identified that the growing demand for electricity is causing significant electricity infrastructure needs across the western, northern, and eastern parts of the city. The IESO hosted a public webinar on December 5, 2024, to share the specific station and supply capacity needs in each area, detailing that a mix of large-scale wire and non-wire solutions would be required to meet the growing demand. The IESO further shared that reducing reliance on PEC amid growing demand for electricity would introduce large capacity needs.

During the webinar, the Local Achievable Potential Study (LAPS) was introduced to stakeholders as a tool to inform the non-wire analysis milestone in the Plan. The IESO shared the scope, methodology, and data inputs of the LAPS, and requested feedback from stakeholders.

The IESO received feedback from 21 stakeholders on the electricity needs and the LAPS methodology and scope. Feedback at this stage included additional requests for improved transparency of the demand forecast, support for the scenario without PEC, recommendations to close the facility, consideration of non-wires options to meet needs (including reconsidering offshore wind as an option), and feedback for the LAPS scope and methodology. The IESO considered this feedback in the development of the plan and posted its response to the Toronto engagement website.

9.3.4 Options Screening

During this milestone, the IESO completed the options screening for the wire and non-wire solutions to meet needs across the city. The IESO hosted a public webinar on July 10, 2025, to share the screening criteria, and outcomes of the screening process for each need. Generally, wire options were screened-in as a solution to meet the needs, and non-wire options were screened-in in combination with wire options. The IESO also shared the three potential options for the third supply line in the webinar. The IESO collected written feedback and received 30 feedback submissions.

Feedback on the options screening included continued advocacy that non-wire solutions should play a key role in the Plan, and requests for more information on the analysis of the non-wire solutions

including land-use requirements and capacity. The IESO also heard that alignment of the Plan with decarbonization initiatives such as TransformTO and phase out of PEC with a committed timeline was important to many stakeholders.

Feedback specific to the third supply line demonstrated general support for the need for the third transmission supply line. City of Toronto staff shared general support for the transmission expansion and emphasized accelerating DER deployment for a future without PEC, the need for transparent route selection and stakeholder engagement, and minimizing land disruption and aligning with redevelopment priorities. Additional themes of feedback for the third supply line centered on concerns for prioritizing nuclear resources over the potential for renewable generation and impacts to lands and habitats. Feedback from Indigenous communities include concerns about potential impacts to environmental and archaeological sites, including along the shorelines. Technical briefings were provided to Indigenous communities to help address environmental concerns.

The IESO considered this feedback in the development of the plan and posted its response to the Toronto engagement website.

9.3.5 Draft Results Local Achievable Potential Study

To further enhance and supplement the regional planning work underway for Toronto, the IESO conducted a local eDSM achievable potential (LAPS) study with consultant ICF International. The purpose of the study was to identify and quantify electricity energy savings potential, electricity demand savings potential and associated costs attainable through energy efficiency, demand response, and behind-the-meter DERs over a 20-year period of 2025 to 2045. To inform the development of the study, the IESO held a dedicated public webinar to share the draft results of the study and seek feedback.

The IESO received 11 feedback submissions from interested stakeholders. Key themes of feedback included:

- Opinion that customer program participation assumptions were too conservative
- Interest in district energy systems and front-of-the-meter wind, solar and energy storage (note that these front-of-meter resources have been considered in the Toronto IRRP but outside the LAPS reflecting the LAPS focus on customer-sited behind-the-meter resources).
- Inclusion of local health, economic and climate benefits of additional eDSM investments in the LAPS' cost-effectiveness analysis
- Comparison of draft results previous IESO-procured achievable potential studies and potential estimates of other parties
- Exclusion of vehicle-to-grid/building measures in the study

The IESO considered this feedback as part of the finalization of the Study, including in updates to customer program participation assumptions. The IESO addressed the exclusion of vehicle-to-grid/building measures in a separate memo posted with the draft results to the Toronto engagement website.

9.3.6 Options Analysis and Draft Recommendations

The final stage of engagement included the details of the options analysis and the draft recommendations for the Plan. The IESO hosted a public webinar on September 25, 2025 that provided an update on the Local Achievable Potential Study, shared details of the options analysis (including technical feasibility, ability to meet the need, cost, lead time, and other considerations), and the draft recommendations for each need in the west, north, and eastern parts of the City. The IESO also provided the details of the comparative analysis for each option for the third supply line, and the rationale for the preferred option in this final webinar.

The IESO made great efforts to release all publicly available information and data at key milestones for both the regional plan and the Local Achievable Potential Study to support the engagement process. To assist stakeholders in referencing all the available information, the IESO posted a Toronto Regional Plan Information Package in advance of this webinar, which can be viewed here.

The IESO received 15 feedback submissions on the options analysis and draft recommendations for the IRRP, including the preferred option for the third supply line. General feedback themes included the perspective that the IRRP showed a priority and overreliance on transmission infrastructure over non-wire options, desire for an electricity plan that sought to align with City of Toronto climate initiatives (including the phase out of PEC), support for draft recommendations to use load rebalancing opportunities, ESS, and eDSM where possible, and finally recommendations for implementation pathways for DERs and TENs. The City of Toronto commended the IESO for its transparent planning process and its commitment to modernizing regional energy planning by incorporating municipal input and evaluating innovative solutions like non-wires alternatives, demand-side management, and energy storage in the IRRP. Many stakeholders thanked the IESO for its efforts and due diligence in creating a comprehensive electricity plan.

Feedback on the third supply line included support for the need for the line and the value it will bring to the city. Stakeholders were interested to understand how the third supply line could support decarbonization efforts, such as helping to phase out PEC sooner and connecting to renewable generation outside the city. Some stakeholders shared concerns that the third supply line was prioritizing nuclear energy and untested SMR technology, and the source of nuclear was not in the interest of Canadians at this time.

9.4 Involving Municipalities in the Plan

The IESO engaged early and often with the City of Toronto to ensure that key local information about growth and development, energy-related plans, and environmental initiatives were taken into consideration in the development of this IRRP. These meetings helped to inform the municipal/community electricity needs and priorities, establish new relationships and build trust, and provided opportunities for ongoing dialogue beyond this IRRP process. Additionally, the IESO led council outreach that included letters prepared for mayors and councillors, and one-on-one councillor meetings to provide elected officials with updates on electricity planning developments, and to provide an opportunity for discussion.

Through these discussions valuable feedback was received around growth and community preferences around solutions informing the IRRP, including:

- City of Toronto shared the drivers of load growth and pockets of high growth (i.e., TransformTO, Electric Vehicle Strategy, Secondary Plans, Green Bus Program, City of Toronto Official Plan) to be factored into the demand forecast scenarios and help to identify local needs and opportunities.
- The Technical Working Group leveraged ongoing City of Toronto studies into the IRRP (i.e., Downsview Airport site, Port Lands, Golden Mile Plan, electricity demand studies, and distributed energy resource analysis).
- City initiatives to decarbonize were contemplated at many levels, including for example, TransformTO and other electrification initiatives factored in the demand forecast. In response to the City Council request to align IRRP with City's 2040 target of net zero emissions the IESO included a scenario to understand timing and options for a future without PEC, and the IESO studied the ability of non-wire options to meet electricity needs.
- City perspectives on routing and siting of infrastructure for the third supply line that align with City plans, such as Port Lands redevelopment plans and potential for complementary energy storage.

9.5 Engaging with Indigenous Communities

To raise awareness and share information about the regional planning activities underway and invite participation in the engagement process, regular outreach was made to the following Indigenous communities:

- **Mississaugas of the Credit First Nation**
  Toronto is situated within the lands covered by Treaty 13, signed with the Mississaugas of the Credit First Nation.
- **Alderville First Nation**
- **Beausoleil First Nation**
- **Chippewas of Georgina Island First Nation**
- **Chippewas of Rama First Nation**
- **Curve Lake First Nation**
- **Hiawatha First Nation**
- **Mississaugas of Scugog Island First Nation**
  The preceding seven communities are signatories to the Williams Treaties, which cover parts of the Toronto region. The Mississaugas of Scugog Island First Nation is a Williams Treaties First Nations member inclusive of the "Gunshot Treaty", which covers the north shore of Lake Ontario, beginning at the eastern boundary of the Toronto Purchase, within the City of Toronto.
- **Six Nations of the Grand River**
  The community is represented by the Six Nations Elected Council and Haudenosaunee Confederacy Chiefs Council.
- **Métis Nation of Ontario**

The IESO remains committed to an ongoing, meaningful dialogue with communities to help shape long-term planning in regions across Ontario. This engagement was part of a broader commitment to fostering respectful relationships, ensuring transparency, and supporting informed participation in regional energy planning. Throughout the development of this plan, the IESO's engagement with

Indigenous communities included extending the opportunity to meet one-on-one to address any inquiries or concerns about the IRRP, and the third supply option discussed in Section 7.8 specifically.

9.5.1 Indigenous Engagement Feedback

The following summarizes feedback received in writing and verbal communications with Indigenous communities. Feedback submitted to the IESO can be viewed on the Regional Electricity Planning - Toronto engagement webpage.

Mississaugas of the Credit First Nation (MCFN)

The IESO met with the Mississaugas of the Credit First Nation (MCFN) to provide an overview of the Toronto IRRP, including the region's electricity needs and the three supply line options under consideration. In addition to being treaty rights holders of land within the Toronto region under Treaty 13, the MCFN communicated that they submitted an aboriginal title claim to the water and waterbeds of Lake Ontario. The community has requested that Ontario pause review of that claim. This information may be relevant to the underwater transmission option (Option 3) as discussed in Section 7.8 (New Supply Options for Eastern Ontario), if pursued. The MCFN expressed interest in better understanding the potential environmental and archeological impacts of the underwater transmission option as well as the emergency repair and remediation options available. The MCFN have requested additional information and/or studies to support their review and feedback.

Mississaugas of Scugog Island First Nation (MSIFN)

The Mississaugas of Scugog Island First Nation (MSIFN) expressed a commitment to collaborative solutions that support reliable energy, honour their rights, and foster prosperity for the community. The MSIFN provided feedback on the proposed investments and recommendations contained in the IRRP, with a focus on the underwater transmission option (Option 3) as discussed in Section 7.8 (New Supply Options for Eastern Ontario). In particular, the MSIFN identified land and environmental concerns about the underwater transmission option, if pursued. The MSIFN also expressed an interest in ongoing participation and engagement in the regional planning process.

Hiawatha First Nation

The Hiawatha First Nation communicated concerns with environmental and archaeological sites, including along the shorelines, in a one-on-one meeting discussion. This information may be relevant to the underwater transmission option (Option 3) as discussed in Section 7.8 (New Supply Options for Eastern Ontario), if pursued.

Six Nations of the Grand River (SNGR)

The IESO met with Six Nations of the Grand River (SNGR) to present the Toronto IRRP, outlining the region's electricity needs and the three supply line options under review. SNGR expressed interest in remaining engaged in the IRRP process but did not provide feedback at this time.

REGIONAL INFRASTRUCTURE PLAN REPORT

TORONTO

Regional Infrastructure Plan Report

Toronto

May 27, 2026

Lead Transmitter:

Hydro One Networks Inc.

Prepared by:

Toronto Technical Working Group

Page intentionally left blank

Disclaimer

This Regional Infrastructure Plan (RIP) Report for Toronto region was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Technical Working Group (TWG).

The preferred solution(s) that have been recommended in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP TWG at the time.

The TWG participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") shall not, under any circumstances whatsoever, be liable to each other, to any third party for whom the Regional Infrastructure Plan Report was prepared ("the Intended Third Parties") or to any other third party reading or receiving the Regional Infrastructure Plan Report ("the Other Third Parties"). The Authors, Intended Third Parties and Other Third Parties acknowledge and agree that: (a) the Authors make no representations or warranties (express, implied, statutory or otherwise) as to this document or its contents, including, without limitation, the accuracy or completeness of the information therein; (b) the Authors, Intended Third Parties and Other Third Parties and their respective employees, directors and agents (the "Representatives") shall be responsible for their respective use of the document and any conclusions derived from its contents; (c) and the Authors will not be liable for any damages resulting from or in any way related to the reliance on, acceptance or use of the document or its contents by the Authors, Intended Third Parties or Other Third Parties or their respective Representatives.

Executive Summary

REGION **Toronto** (the "Region")

LEAD Hydro One Networks Inc. ("HONI")

START DATE: November 28, 2025 **END DATE:** May 27, 2026

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process for the Toronto region, preceded by, the publication of Needs Assessment (NA) report in December 2022 by Hydro One followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) which were published in March 2023 and in October 2025 respectively, by the Independent Electricity System Operator (IESO).

Hydro One as the lead transmitter undertakes the development of a RIP with input from the Technical Working Group (TWG) for the region (includes representatives from Hydro One Transmission, IESO and LDCs) and publishes a RIP report. The RIP report includes a discussion of all options and plans identified in earlier phases and recommends a preferred wires plan to address the near, medium, and long - term needs over a twenty-year study period.

The objectives and scope of the RIP are:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs (2026-2035) identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identify any new need(s) over the 2026-2035 period that may have emerged since previous planning phases. Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.
- Consideration of long-term needs identified in the Toronto IRRP, Bulk system studies or as identified by the TWG.

The TWG agreed to adopt the IRRP load forecast for the RIP study because no material changes were identified. For shared stations that also serve Alectra or Elexicon, additional load has been incorporated into the forecasts based on inputs provided by the LDCs. Municipal plans were considered in developing the LDC forecasts, and additional municipal input on future load growth was obtained through the IRRP stakeholder engagement process.

The list of major infrastructure investments recommended by the TWG in the region for the next 10 years is given below. The needs include those previously identified in the NA and IRRP, as well as any new needs identified during the RIP phase, if any.

Station/Circuit Name	Recommended Plan	Lead	Planned ISD
Asset Renewal Needs			
Basin TS	Transformers T3/T5 replacement*	Hydro One	2030
Manby TS	Autotransformers (T7, T9, T12) replacement, Step-down transformer (T13/T14) replacement*(NEW)	Hydro One	2030 2033
Leslie TS	Transformer T1, T4 replacement (T4 NEW)	Hydro One	2032
Dufferin TS	Transformer T2 replacement* (NEW)	Hydro One	2032
Cecil TS	115kV Switchgear replacement (NEW)	Hydro One	2032
Bermondsey TS	Transformers T3/T4 replacement	Hydro One	2033
Strachan TS	Transformers T13/T15 replacement*	Hydro One	2033
Agincourt TS	Transformers T5/T6 replacement (NEW)	Hydro One	2033
Terauley TS	Transformers T1/T2/T3/T4 replacement (NEW)	Hydro One	2033
Carlaw TS	Transformers T1/T2 replacement* (NEW)	Hydro One	2033
Rexdale TS	Transformer T2 replacement (NEW)	Hydro One	2033
John TS	Transformer T3 replacement* (NEW)	Hydro One	2033
Duplex TS	Transformers T1/T2 & T3/T4 replacement*	Hydro One	2034
Fairchild TS	Transformers T1 & T3/T4 replacement	Hydro One	2034
Warden TS	Transformer T4 replacement (NEW)	Hydro One	2035
Finch TS	Transformer T1 replacement (NEW)	Hydro One	2035
H1L/H3L/H6LC/H8LC	Leaside Jct. X Bloor St. Jct. – Overhead line section renewal	Hydro One	2031
L9C/L12C	Leaside TS X Balfour Jct. – Overhead line section renewal	Hydro One	2031
H1L/H3L & H2JK	Underground cable replacement (NEW)	Hydro One	2035

*Transformers to be replaced with higher rated standard units.

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Budgetary Cost ($M) [c]
Station Capacity Needs				
Bathurst TS & Finch TS	Connect Downsview MTS (Load Transfers to new Downsview MTS) - First DESN (Phase 1) - Second DESN (Phase 2)	THESL / Hydro One	 2033 2039	$135-155M[d]
Scarboro TS	Build third Scarboro TS DESN (Load Transfers to new Scarboro DESN)	Hydro One / THESL	2035	$55-65M
Basin TS	Develop an expansion of Basin TS or add a new station in the area.	Hydro One / THESL	2035	$55-65M
Sheppard TS	Expand T1/T2 DESN using the idle windings	Hydro One / THESL	2029	$16M
Transformation Capacity Need				
Manby TS (West) Autotransformers	Load Transfer (Copeland T2/T4 to Leaside Supply) + Reliance on existing Manby Remedial Action Scheme	-	2026	-
Transmission Line Capacity Need				
Manby TS X Riverside Jct.: 115 kV Circuits	Upgrade capacity of 115 kV circuits	Hydro One	2029	$25M
Richview TS X Manby TS: 230 kV Circuits	230 kV Corridor Reinforcement	Hydro One	2032	N/A[b]

Notes:

a) The Planned In-Service dates are tentative and subject to change.
b) The recommended plan to address the Richview TS x Manby TS corridor need is expected by Q4 2026 as part of the GTA West IRRP.
c) Costs are tentative high-level budgetary planning estimates based on 2026 dollars and subject to change.
d) Property procurement costs not included.

Table of Contents

1. INTRODUCTION 12
2. OBJECTIVES AND SCOPE OF REGIONAL INFRASTRUCTURE PLAN 13
3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY 14
   3.1 Overview 14

1. INTRODUCTION

The Regional Infrastructure Plan (RIP) is the final step of Regional Planning Process. Hydro One as the lead transmitter undertakes the development of a RIP with input from the Technical Working Group (TWG) for the region (includes representatives from Hydro One Transmission, IESO and LDCs) and publishes a RIP report. The third cycle of the Regional Planning process for the Toronto region was initiated with the publication of Needs Assessment (NA) and the report was published in December 2022 by Hydro One. This was followed by the Scoping Assessment (SA) & Integrated Regional Resource Plan (IRRP) which were published in March 2023 and in October 2025 respectively, by the Independent Electricity System Operator (IESO).

The RIP report includes a common discussion of all the options and recommended plans and preferred wire infrastructure investments identified in earlier phases to address the near- and medium -term needs.

This report was prepared by the Toronto TWG, led by Hydro One Networks Inc. The report presents the results of the assessment based on information provided by Hydro One, the Local Distribution Companies (LDC), the Municipalities and the IESO. Participants of the TWG are listed below in Table 1-1.

Table 1-1: Toronto region TWG Participants

Sr. no.	Name of TWG Participants
1	Hydro One Networks Inc. (Transmission)
2	Independent Electricity System Operator (IESO)
3	Toronto Hydro-Electric System Limited (“THESL”)
4	Hydro One Networks Inc. (Distribution)
5	Alectra Utilities Corporation (“Alectra”)
6	Elexicon Energy Inc. (“Elexicon”)

2. OBJECTIVES AND SCOPE OF REGIONAL INFRASTRUCTURE PLAN

This RIP report examines the needs in the Toronto region. Its objectives are to:

- Provide a comprehensive summary of needs and wires plans to address the needs for the Toronto region.
- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan).
- Assess and develop wires plans to address these new needs.
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviewed factors such as the load forecast, asset renewal for major high voltage transmission equipment, transmission and distribution system capability along with any updates with respect to local plans, Electricity Demand Side Management ("eDSM") forecasts, renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs 2026-2035 identified in previous planning phases (i.e., Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan).
- Identification of any new needs over the 2026-2035 period and wires plans to address these needs based on new and/or updated information.
- Consideration of long-term needs identified in the Toronto IRRP, Bulk system studies or as identified by the TWG.

3. REGIONAL PLANNING PROCESS & RIP METHODOLOGY

3.1 Overview

Bulk System Planning, Regional Planning and Distribution Planning are the three levels of planning for the electricity system in Ontario. Bulk system planning typically looks at issues that impact the system on a provincial level and requires longer lead time and larger investments. Comparatively, planning at the regional and distribution levels looks at issues on a more regional or localized level. Typically, the most essential and effective regional planning horizon is the near- to medium-term (1- 10 years), whereas long-term (10-20 years) regional planning mostly provides a future outlook with little details about investments because the needs and other factors may vary over time. On the other hand, bulk system plans are developed for the long term because of the larger magnitude of investments.

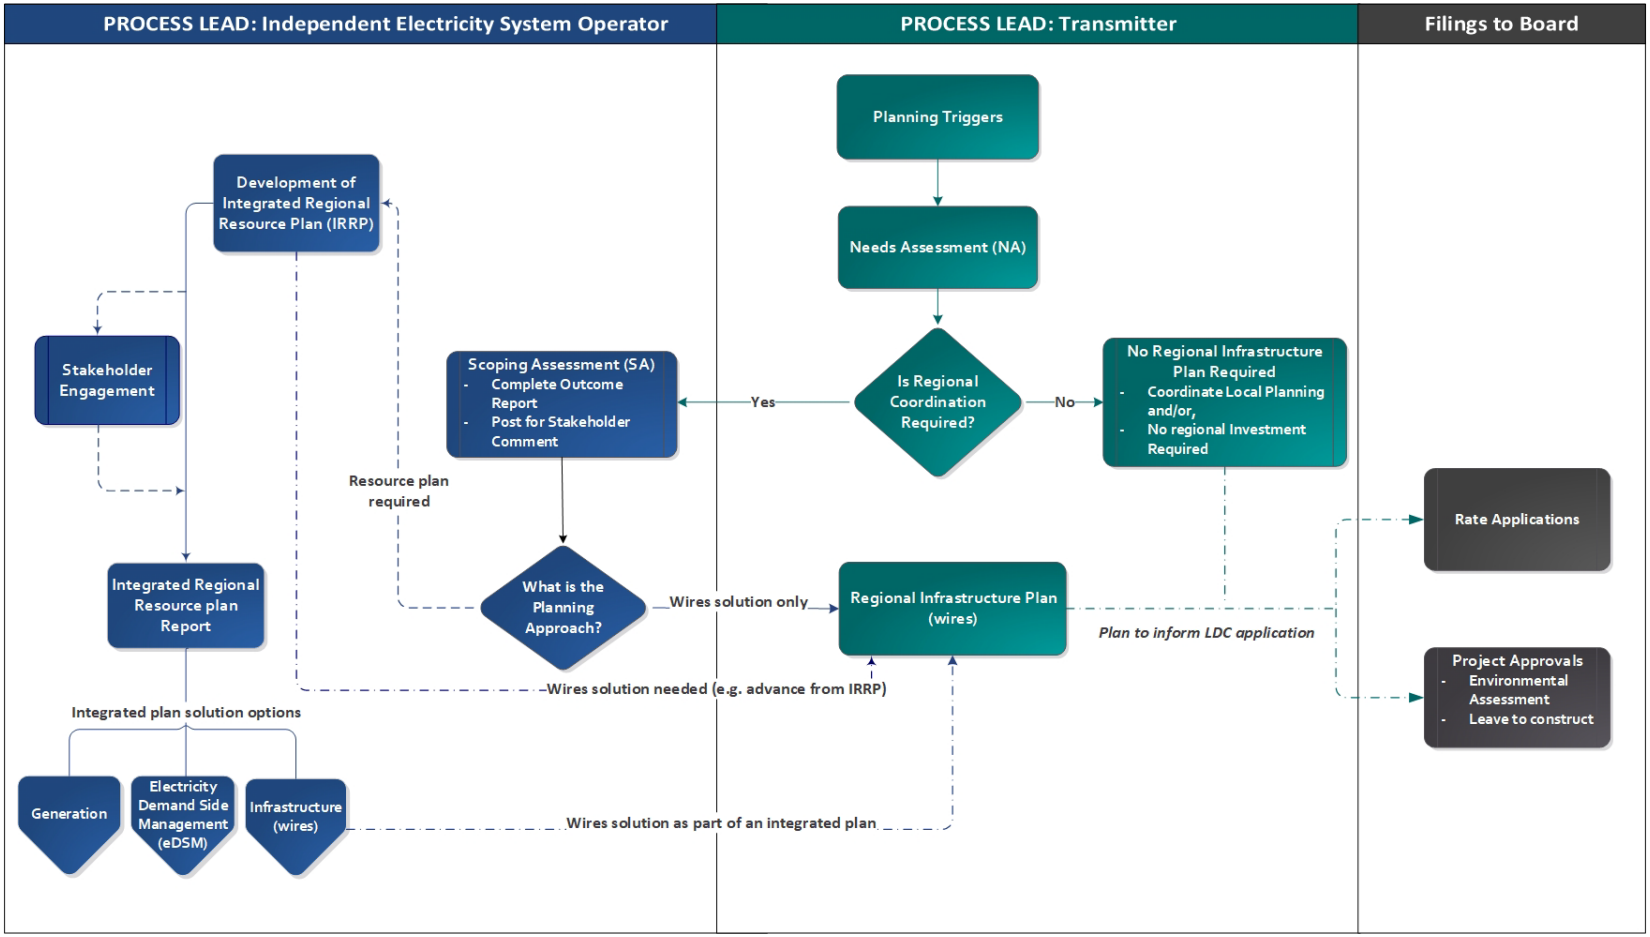
The regional planning process begins with a Needs Assessment which is led by the transmitter to identify, assess, and document which of the needs that,

a) can be addressed directly between the customer and transmitter along with a recommended plan, and;
b) require further regional coordination and identification of Local Distribution Companies (LDCs) to be involved in further regional planning activities for the region.

At the end of the NA, a decision is made by the TWG as to whether further regional coordination is necessary to address some or all the regional needs. If no further regional coordination is required, recommendation to implement the recommended option and any necessary investments are planned directly by the LDCs (or customers) and the transmitter. The region's TWG can also recommend to the transmitter and LDCs to undertake a local planning process for further assessment when needs

a) are local in nature,
b) require limited investments in wires (transmission or distribution) solutions, and;
c) do not require upstream transmission investments.

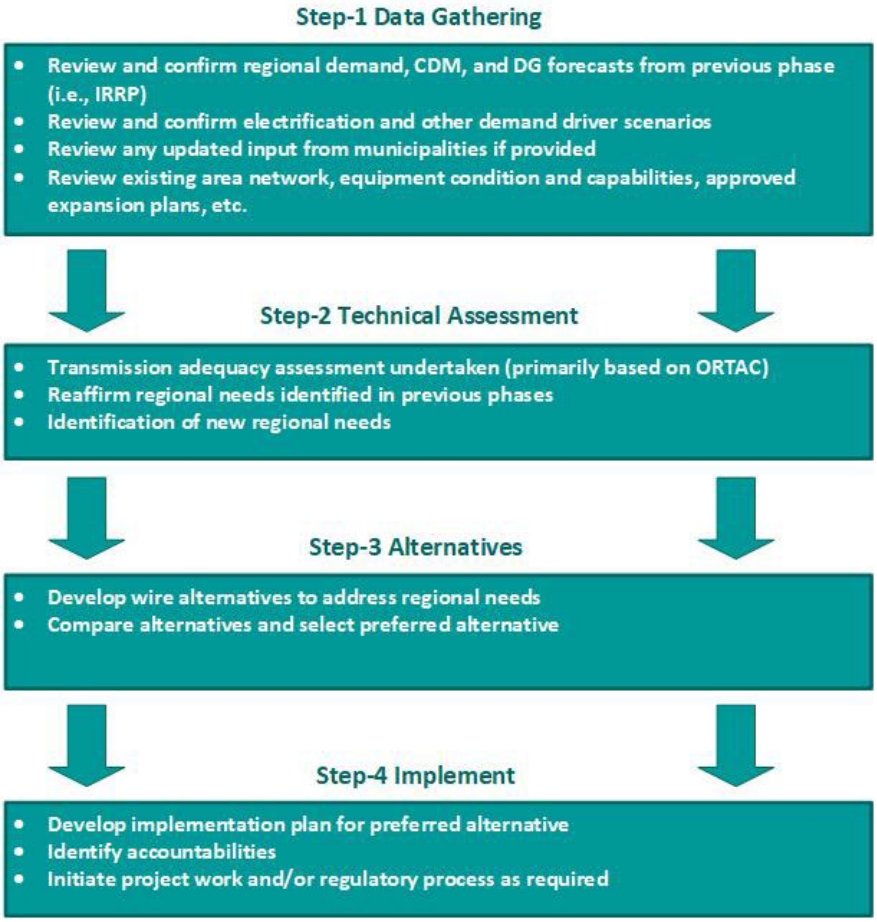
If coordination at the regional or sub-regional levels is required for identified regional needs, then the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires or resource alternatives, e.g., Electricity Demand Side Management ("eDSM"), Distributed Generation (DG), etc., in order to make a decision on the most appropriate regional planning approach including Local Plan (LP), IRRP and/or RIP.



The primary purpose of the IRRP is to identify and assess both resource and wires options at a higher or macro level, but sufficient to permit a comparison of resource options vs. wire infrastructure to address the needs. Worth noting, the LDCs' eDSM targets as well as contracted DG plans provided by IESO and LDCs are reviewed and considered at each step in the regional planning process.

If and when an IRRP identifies that resource and/or wires options may be most appropriate to meet a need, resource/wires planning can be initiated in parallel with the IRRP or in the RIP phase to undertake a more detailed assessment, develop specific resource/wires alternatives, and recommend a preferred wires solution.

The RIP phase is the final phase of the regional planning process and involves discussion of previously identified needs and plans; identification of any new needs that may have emerged since the start of the planning cycle; and, development of a wires plan to address these needs. This phase is led and coordinated by the transmitter and the deliverable is a comprehensive and consolidated report of a wires plan for the region. Once completed, this report is also referenced in the transmitter's rate filing submissions and as part of LDC rate applications with a planning status letter provided by the transmitter to the LDC(s). Respecting the OEB timeline provision of the RIP, planning level stakeholder engagement is not undertaken during this phase. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.



The various phases of Regional Planning Process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome are shown below in Figure 3-1.

Figure 3-1: Regional Planning Process Flowchart

3.2 Regional Infrastructure Plan Methodology

Figure 3-2: Regional Infrastructure Plan Methodology

Regional Infrastructure Plan phase is a four-step process which are described below:

3.2.1. Data Gathering

The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with TWG to reconfirm or update the information as required. The data collected includes:

- Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or eDSM programs. As agreed by TWG members, the load forecast from the Toronto IRRP was used for this RIP with the addition of the Alectra's and Elexicon's load which were not considered in the IRRP.

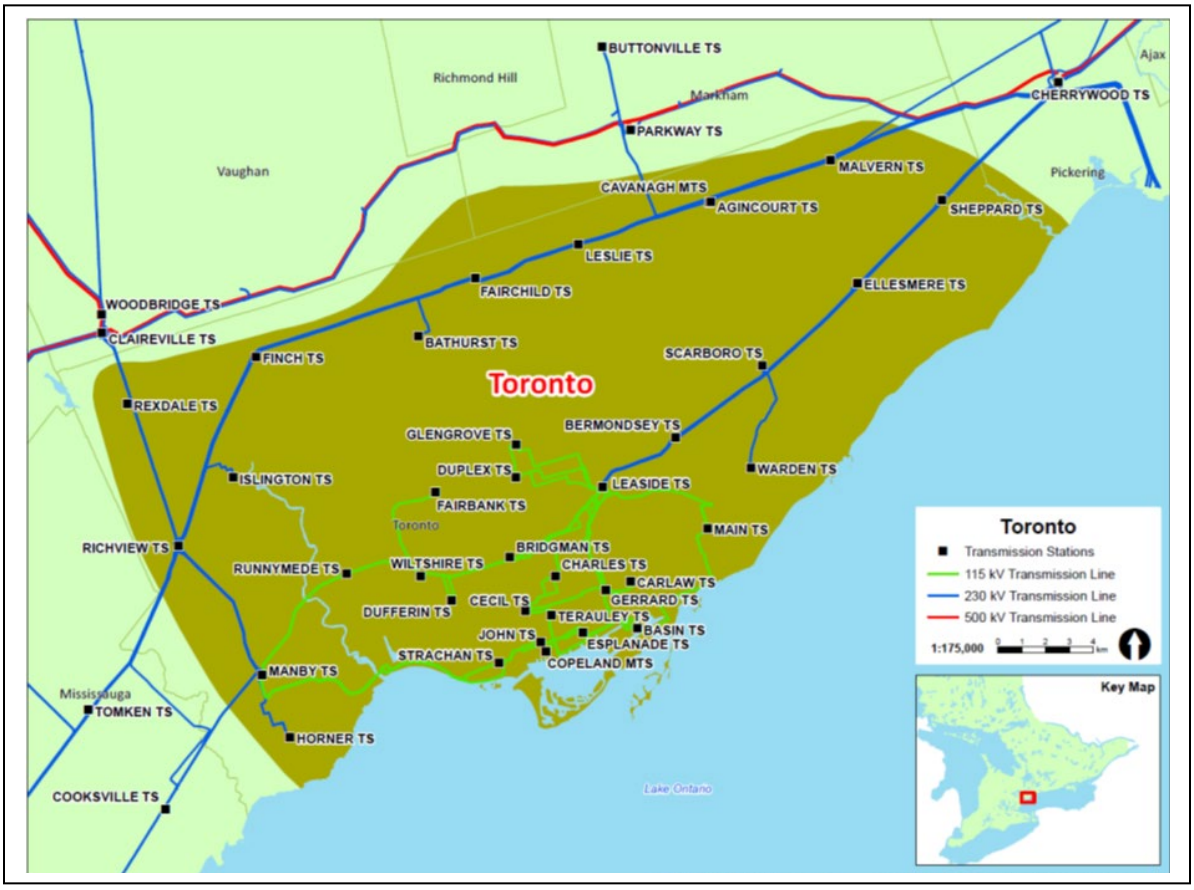
- Review and confirm electrification and other growth scenarios which affect the projects recommended in previous stages.
- Existing area network and capabilities including any bulk system power flow assumptions.
- Other data and assumptions as applicable such as asset condition, load transfer capabilities, and previously committed transmission and distribution system plans.

3.2.2. Technical Assessment

The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and medium-term needs may be identified at this stage.

3.2.3. Alternative Development

The third step is the development of wires options to address the needs and determine a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.



3.2.4. Implementation Plan

The fourth and last step is the development of the implementation plan for the preferred alternative, identify accountabilities and initiate project work or obtain permissions from the Regulatory Commission if any.

4. REGIONAL DESCRIPTION AND CONNECTION CONFIGURATION

The Toronto Region covers the area roughly bordered geographically by Lake Ontario on the south, Steeles Avenue on the north, Highway 427 on the west and Regional Road 30 on the east. It includes the City of Toronto, which is the largest City in Canada and the fourth largest in North America. Electrical supply to the region is provided from thirty-six (36) 230kV and 115kV step-down transformer stations. The boundaries of the Toronto region are shown in Figure 4-1 below.

Figure 4-1: Map of Toronto Regional Planning Area

As shown in Figure 4-2, the eastern, northern, and western parts of the Region are supplied by eighteen (18) 230/27.6kV step-down transformer stations. As shown in Figure 4-3, the central area is supplied by two (2) 230/115kV autotransformer stations (Leaside TS and Manby TS) and sixteen (16) 115/13.8kV and two (2) 115/27.6kV step-down transformer stations. The region is also supplied locally by Portlands Energy Centre ("PEC"), a 600 MW combined-cycle power generating station located in the Port Lands area of the

Toronto Waterfront via Hearn Switching Station ("SS"). The sum of 2024 non-coincident and coincident summer peak load of the Region were about 4,870 MW and 4,430 MW, respectively.

Figure 4-2: Geographical Area of East, North, and West 230 kV Area

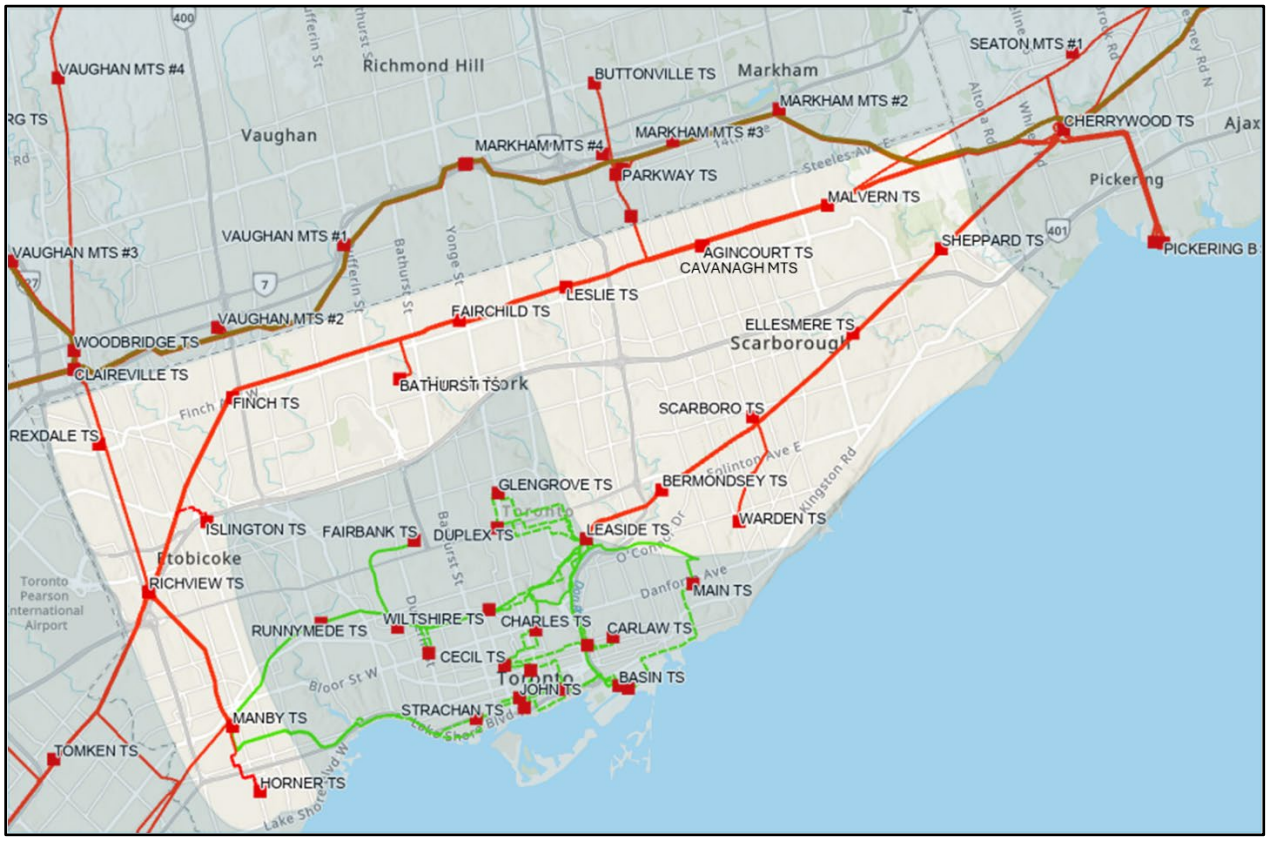


Figure 4-3: Geographical Area of Central 115 kV Area (Manby and Leaside)

Electricity demand in the region is projected to increase steadily over the forecast period, driven primarily by economic growth, electrification initiatives, customer connection activity, and municipal development plans. While the region has historically been summer-peaking, the forecast indicates a potential transition to winter-peaking by the early 2030s. The circuits and stations within the Toronto region are listed in Table 4-1 below:

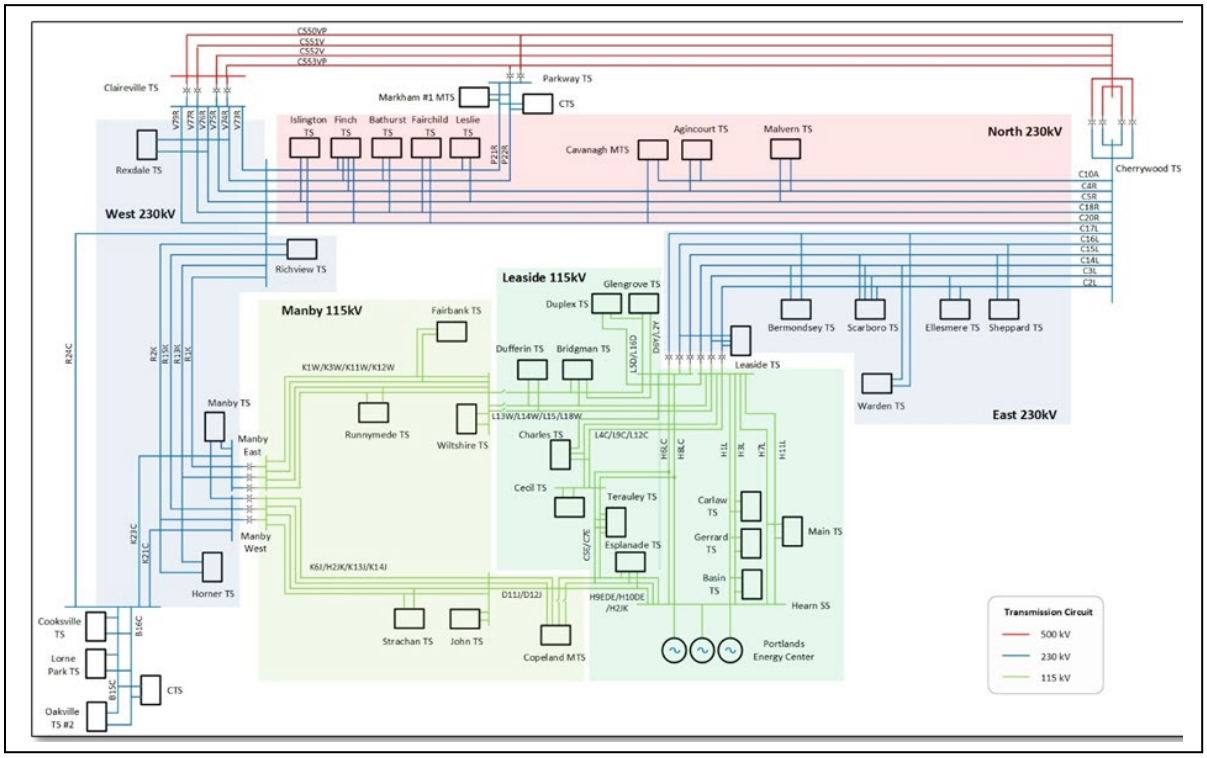

Table 4-1: Transmission Station and Circuits in the Toronto region

115kV Circuits	230kV Circuits	Transformer Stations	Generation Stations
K1W,K3W,K11W, K12W, K6J, K13J, K14J, H2JK, D11J, D12J, H9DE, H10DE, C5E, C7E, H6LC, H8LC, H1L, H3L, H7L, H11L, L13W, L14W, L15, L18W, L4C, L9C, L12C, L5D, L16D, L2Y, D6Y	R1K, R2K, R13K, R15K, R24C, K21C, K23C, C2L, C3L, C14L, C15L, C16L, C17L, C4R, C5R, C18R, C20R, C10A, P21R, P22R, V72R, V73R, V74R, V76R, V77R, V79R	Agincourt TS, Basin TS, Bathurst TS, Bermondsey TS, Bridgman TS, Carlaw TS, Cavanagh MTS, Cecil TS, Charles TS, Copeland MTS, Dufferin TS, Duplex TS, Ellesmere TS, Esplanade TS, Fairbank TS, Fairchild TS, Finch TS, Gerrard TS, Glengrove TS, Horner TS, Islington TS, John TS, Leaside TS*, Leslie TS, Main TS, Malvern TS, Manby TS*, Rexdale TS, Richview TS, Runnymede TS, Scarboro TS, Sheppard TS, Strachan TS, Terauley TS, Warden TS, Wiltshire TS	Portlands Energy Centre

The single line diagram of the Transmission Network of Toronto region is shown in Figure 4-4 below.

Figure 4-4: Toronto Transmission Single Line Diagram

5. TRANSMISSION FACILITIES COMPLETED IN THE LAST TEN YEARS AND/OR ARE UNDERWAY

In this section a complete list of all the projects that were completed in past ten years or are currently underway is provided and is briefly discussed in the sub-sections. As part of this or previous Regional Planning Cycle(s), several "Major HV Transmission Projects" were recommended in the **Toronto region** to improve the supply capability and reliability.

Hydro One is the Transmission Asset Owners (TAO) in the region and has undertaken the execution of the projects recommended in the past ten years. A summary and brief description of all the projects completed or are currently underway is given below:

I. Following Major projects were completed during the last ten years:

1. Midtown Transmission Reinforcement Project (2016) – Covered replacement of the aging L14W underground cable and addition of a new 115 kV circuit between Leaside TS and Bridgman TS.
2. Runnymede TS DESN#2 and Manby TS to Wiltshire TS Circuits Upgrade Project (2018) – covered building of a second 50/83 MVA, 115/27.6 kV DESN at Runnymede TS and reinforcement of the Manby TS to Wiltshire TS 115 kV circuits to accommodate increasing load demand in the area.
3. Clare R. Copeland 115 kV Switching Station (2019) – Built to connect a new THESL owned 115/13.8 kV step-down transformer station (Copeland MTS) in Downtown Toronto.
4. Manby SPS Load Rejection (L/R) Scheme (2019) – Built to ensure that loading on in-service equipment at Manby TS is not exceeded for loss of two out of three autotransformers in the Manby East and Manby West switchyards.
5. John TS transformer replacements (2019-2021) – 115/13.8 kV 45/75 MVA transformers T1, T2, and T4 were replaced with new 60/100 MVA units based on asset condition assessment.
6. Sheppard TS DESN replacement (2021) – 230/27.6 kV 50/83 MVA transformers T3 and T4 were replaced with new same size units T5 and T6 based on asset condition assessment.
7. Strachan TS transformer replacement (2021) – 115/13.8 kV 40/67 MVA transformer T12 was replaced with new 60/100 MVA unit based on asset condition assessment.
8. Runnymede TS DESN replacement (2022) – 115/27.6 kV 58/93 MVA transformers T3 and T4 were replaced with new 50/83 MVA units T5 and T6 based on asset condition assessment.
9. Horner TS new DESN (2022) – covers construction of a second 75/125MVA, 230/28 kV DESN at the Horner TS site to meet the load growth in the southwest Toronto area.
10. Bridgman TS transformer replacements (2024) – 115/13.8 kV 40/67 MVA transformers T11, T12 and T13 and 45/75MVA transformer T14 were replaced with new 60/100 MVA units based on asset condition assessment.

11. Fairbank TS DESN replacement (2024) – 115/27.6 kV 50/83 MVA transformers T1, T2, T3 and T4 were replaced with new same size units T5, T6, T7 and T8 based on asset condition assessment.
12. Scarboro TS transformer replacement (2024) – 230/27.6 kV 75/125 MVA transformer T23 was replaced with new same size unit based on asset condition assessment.
13. Copeland MTS new DESN with spare transformer (2024) – THESL installed new 115/13.8 kV 60/100 MVA transformers T2, T4, T5 at Copeland MTS to meet increasing demand in Downtown Toronto.
14. John TS transformer replacements (2025) - 115/13.8 kV 75/125 MVA transformers T5 and T6 were replaced with new 60/100 MVA units based on asset condition assessment.

II. Following Major projects are underway:

1. Circuits C5E/C7E underground cable replacement between Esplanade TS and Terauley (2026) – A 2.5 km tunnel between Esplanade TS and Terauley TS is to be built.
2. Richview to Manby Corridor Reinforcement (R X K) Project (2026) – Adding a third 230 kV double-circuit line between Richview TS and Manby TS, aimed to increase the transmission line capacity between the two stations to meet forecast load demand in the southwest GTA.
3. Main TS transformer replacement (2026) – 115/13.8 kV 45/75 MVA transformers T3 and T4 are to be replaced with new 60/100 MVA units based on asset condition assessment.
4. Charles TS transformer replacements (2027) – 115/13.8 kV 45/75 MVA transformers T3 and T4 are to be replaced with new 60/100 MVA units based on asset condition assessment.
5. Strachan TS transformer replacement (2027) – 115/13.8 kV 45/75 MVA transformer T14 is to be replaced with new 60/100 MVA unit based on asset condition assessment.
6. Malvern TS transformer replacement (2027) – 230/27.6 kV 75/125 MVA transformer T3 is to be replaced with new same size unit based on asset condition assessment.

Note: The planned in-service year for the above projects is tentative and is subject to change.

6. LOAD FORECAST AND STUDY ASSUMPTIONS

6.1. Load Forecast

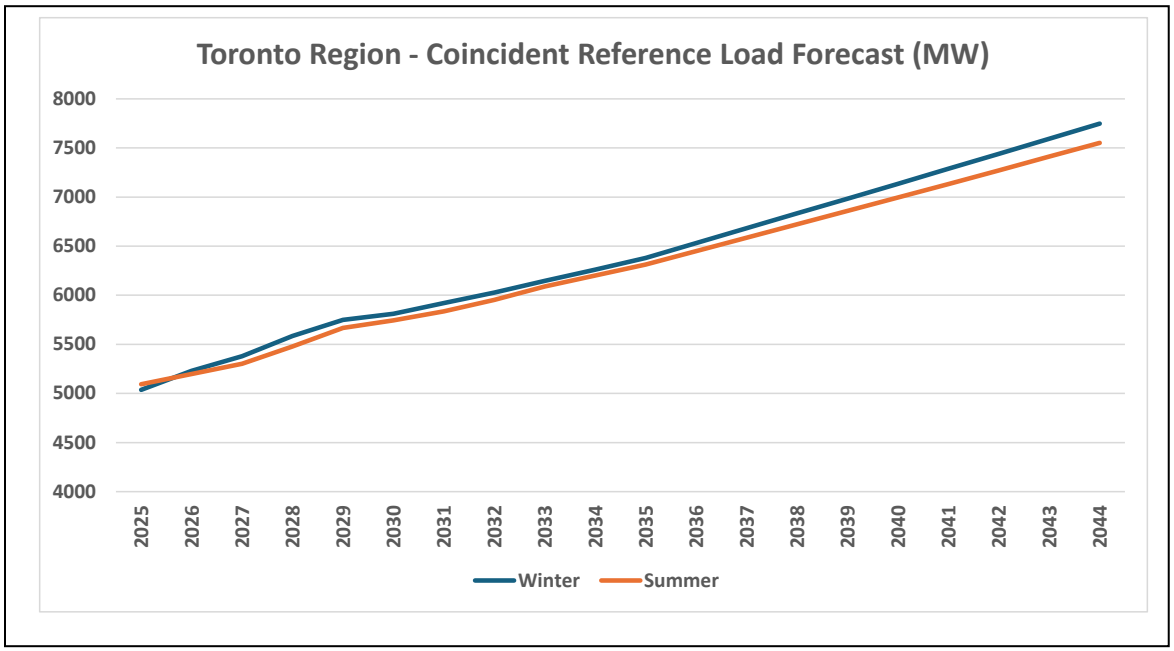
The major LDC in the Toronto region, THESL, has confirmed that there is no material change in the Toronto region IRRP Load Forecasts at this time and thus the IRRP forecasts were used in development of this Report. In addition, the other LDCs have also provided their load forecasts for the stations within the region that currently supply their customers, which were also considered in the development of this Report. TWG participants, including representatives from LDC's, the IESO and Hydro One, provided information and input for the IRRP and RIP load forecasts. Municipal plans were considered in developing the LDC forecasts, and additional municipal input on future load growth was obtained through the IRRP stakeholder engagement process.

During the study period, the load in the Toronto region is expected to grow at an average annual rate of approximately 2.5% in summer and 2.8% in winter from 2025 to 2044. The Region is summer peaking, however based on the forecast it is expected that the region will transition to winter-peaking in the near future. This shift is largely driven by electrified heating, which will significantly increase electricity demand during winter months.

Figure 6-1 & 6-2 show the Toronto region extreme summer/winter weather net coincident and non-coincident load forecast from 2025 to 2044. The load forecasts from the Toronto IRRP, along with the additional information for the shared stations, were used as agreed upon by the TWG.

The non-coincident and coincident reference forecasts for the individual stations in the region are available in Appendix A. These forecasts, along with the high-electrification forecasts in the IRRP, are used to determine any need in the region.

Figure 6-1: Toronto region summer/winter Coincident Net Peak Load Forecast



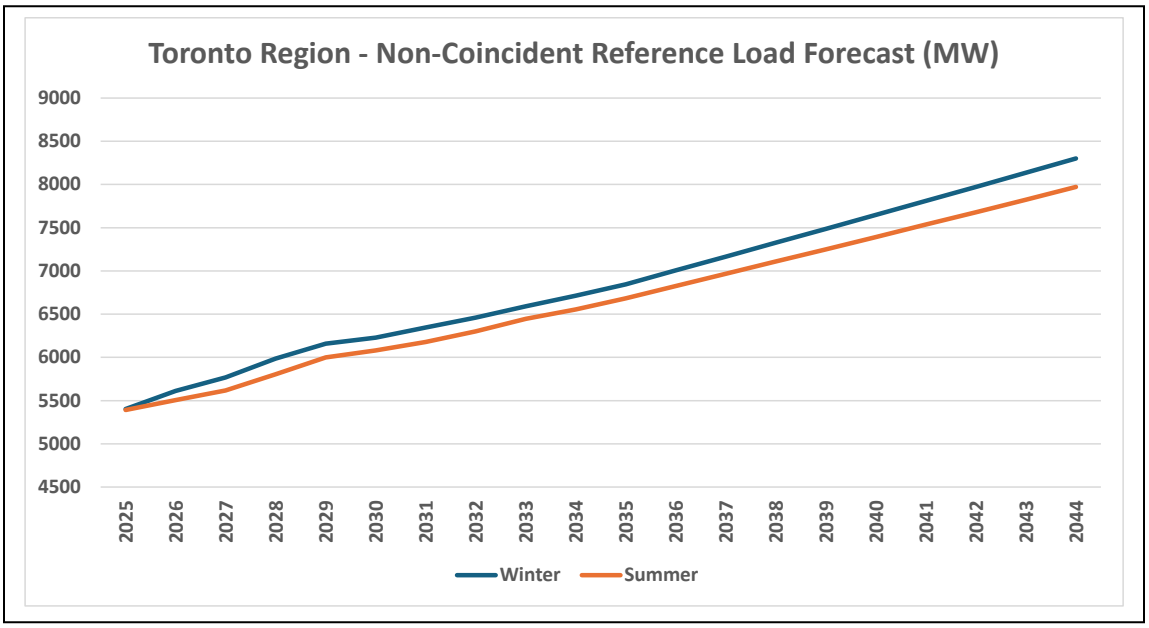


Figure 6-2: Toronto region summer/winter Non-coincident Net Peak Load Forecast

6.2. Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2025-2044.
- THESL has confirmed load forecasts up to 2044 in the area are the same as the IRRP. Alectra and Elexicon have provided load forecasts for the shared stations up to 2044.
- All planned facilities for which work has been initiated and are listed in section 4 are assumed to be in-service.
- The Region is currently summer peaking but is expected to be winter peaking during the study period, so this assessment considers both summer and winter peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR) based on 30°C ambient temperature.
- Adequacy assessment is conducted as per ORTAC. Enhanced criteria used in the IRRP were also considered in this report.[1]

[1] The ORTAC does not require double element contingency events to be evaluated for local area (non-bulk) transmission systems, unless the contingency propagates to a higher voltage level or causes a net load loss greater than 1,000 MW. However, the IRRP also evaluated double element contingencies for the local areas in Toronto region due to the social and economic importance of continuous electricity supply to the area.

7. SYSTEM ADEQUACY AND REGIONAL NEEDS

This section reviews the adequacy of the existing Transmission Systems and Transformer Station facilities supplying the Toronto region and lists the facilities requiring reinforcement over the near and midterm period. The adequacy assessment assumes that all the projects that are currently underway, listed in **"Section 5"** are completed as per their respective in-service dates.

In current regional planning cycle, the following regional assessments were completed, and their findings were used as inputs to this RIP report:

- Toronto region Third cycle Needs Assessment Report, Completed in December 2022 by Hydro One
- Toronto region Third cycle Scoping Assessment Report, Completed in March 2023 by the IESO
- Toronto region Third cycle Integrated Regional Resource Plan Report, Completed in October 2025 by the IESO

The Technical Working Group identified several regional needs based on the forecasted load demand over the near to mid-term period in the reports mentioned above. The results of the Adequacy Assessment to define the needs are discussed in sub-sections "7.1 to 7.4" and a detailed description and status of plans to meet these needs are given in **"Section 8"** of this report.

7.1. Asset Renewal Needs for Major HV Transmission Equipment

In addition to the asset renewal needs identified in previous regional planning cycle, Hydro One and TWG have also identified new asset renewal needs for major high voltage transmission equipment that are expected to be replaced over the next 10 years in the Toronto region. The complete list of major HV transmission equipment requiring replacement in the Toronto region is provided in Table 7-1 in this sub-section. Hydro One and THESL are the only Transmission Asset Owner (TAO) in the Region.

Asset Replacement needs are determined by asset condition assessment. Asset condition assessment is based on a range of considerations such as:

- Equipment deterioration due to aging infrastructure or other factors,
- Technical obsolescence due to outdated design,
- Lack of spare parts availability or manufacturer support, and/or
- Potential health and safety hazards, etc.

The major high voltage equipment information shared and discussed as part of this process is listed below:

- 230/115kV autotransformers
- 230 and 115kV load serving step down transformers
- 230 and 115kV breakers where:

    - replacement of six breakers or more than 50% of station breakers, the lesser of the two
- 230 and 115kV transmission lines requiring refurbishment where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like
- 230 and 115kV underground cable requiring replacement where:
    - Leave to Construct (i.e., section 92) approval is required for any alternative to like-for-like

Table 7-1: Major HV Transmission Asset assessed for Replacement in the region planned in next 10 years

Station/Circuit	Need Description	Planned ISD
Basin TS	Transformers T3/T5 replacement*	2030
Manby TS	Autotransformers (T7, T9, T12) replacement, Step-down transformer (T13/T14) replacement*	2030 2033
Leslie TS	Transformer T1, T4 replacement	2032
Dufferin TS	Transformer T2 replacement*	2032
Cecil TS	115kV Switchgear replacement	2032
Bermondsey TS	Transformers T3/T4 replacement	2033
Strachan TS	Transformers T13/T15 replacement*	2033
Agincourt TS	Transformers T5/T6 replacement	2033
Terauley TS	Transformers T1/T2/T3/T4 replacement	2033
Carlaw TS	Transformers T1/T2 replacement*	2033
Rexdale TS	Transformer T2 replacement	2033
John TS	Transformer T3 replacement*	2033
Duplex TS	Transformers T1/T2 & T3/T4 replacement*	2034
Fairchild TS	Transformers T1 & T3/T4 replacement	2034
Warden TS	Transformer T4 replacement	2035
Finch TS	Transformer T1 replacement	2035
H1L/H3L/H6LC/H8LC	Leaside Jct. X Bloor St. Jct. – Overhead line section renewal	2031
L9C/L12C	Leaside TS X Balfour Jct. – Overhead line section renewal	2031
H1L/H3L & H2JK	Underground cable replacement	2035

*Transformers to be replaced with higher rated standard units.

Note: The planned in-service year for the above projects is tentative and is subject to change.

7.2. Station Capacity Needs

Over the study period 2025-2044 RIP reviewed the capacity of all the 230kV and 115kV Transforming stations within the Toronto region. The IRRP study had previously indicated that Bathurst TS and Scarboro TS require capacity relief within the 2026-2035 period. This RIP has further confirmed those needs. The need date for Sheppard TS and Finch TS capacity relief may also be advanced based on the load forecast considering the addition of Alectra's and Elexicon's load. The stations which require capacity relief during the 2026-2035 period are shown in Table 7-2 below. The need timeframe defines the time when the peak non-coincident reference load forecast exceeds the most limiting seasonal (summer or winter) Limited Time ratings.

Table 7-2: Toronto region Station Capacity Needs in next 10 years

Sr.no.	Station Name	Station LTR (MW) (Summer/Winter)	2025 Loading (MW) (Summer/Winter)	Ref. Forecast Need Date (Summer/Winter)
1	Bathurst TS	361 / 390	278 / 185	2035 / 2042
2	Scarboro TS	364 / 412	214 / 179	2035 / 2039
3	Basin TS	130 after asset renewal (existing LTR 88 / 104)	49 / 54	2035 / 2035
4	Sheppard TS	208 / 231	158 / 115	2029 / 2032
5	Finch TS	366 / 403	280 / 221	2033 / 2042

The options and preferred solutions to address these needs are discussed further in Section 8 of the report.

7.3. Transformation Capacity Needs

Over the study period 2025-2044 RIP reviewed the 230 kV to 115 kV transformation capacity needs within the Toronto region. The IRRP study had previously indicated that the following transformation capacity relief is required within the 2026-2035 period. This RIP has further confirmed this need as shown in Table 7-3 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer) area limit.

Table 7-3: Toronto region Transformation Capacity Needs in next 10 years

Sr.no.	Station Name	Area Limit (MW) (Summer)	2024 Loading (MW) (Summer)	Ref. Forecast Need Date
1	Manby TS (West) Autotransformers	570 (470) (1)	358 (2)	2028 (3)

(1) Area limit of 570 MW is based on the loss of one autotransformer. Area limit of 470 MW is based on the loss of two autotransformers T1 and T2 and 150 MW of load shedding by Manby RAS after the loss of T1 and T2. The limit may increase after the most limiting autotransformer T12 is replaced.

(2) The 2024 summer loading is being used as John T5/T6 2025 loading data is currently missing.

(3) The 2028 need date is based on summer coincident reference forecast and an area limit of 470 MW. If control actions in between the loss of the first and second autotransformers are accounted for, the need date extends beyond 2044.

The need and the preferred solutions to address this need are discussed further in Section 8 of the report.

7.4. Transmission Line Capacity Needs

Over the study period 2025-2044 RIP reviewed the capacity of all the 230kV and 115kV Transmission lines within the Toronto region. The NA and IRRP studies had previously indicated that the following Transmission lines require capacity relief within the 2026-2035 period. This RIP has further confirmed those needs and based on the load forecast and following contingencies, the Transmission lines which require capacity relief during the study period are shown in Table 7-4 below. The need timeframe defines the time when the peak load forecast exceeds the most limiting seasonal (summer or winter) Limited Time ratings.

Table 7-4: Toronto region Transmission Line Capacity Needs in next 10 years

Sr.no.	Name of Circuit	Name of Section	Area Limit (MW) Summer	2025 Summer loading (MW)	Need Date
1	K13J / K14J	Manby TS X Riverside Jct.	510 / 370 (1)	358 (2)	2026 (3)
2	R1K/R2K/R13K/R15K	Richview TS x Manby TS	1840 (4)	1560	2032 (4)

(1) An area limit of 510 MW is based on the loss of one circuit K13J or K14J. An area limit of 370 MW is based on the loss of two circuits simultaneously K13J and K6J / H2JK.

(2) The 2024 summer loading is being used as John T5/T6 2025 loading data is currently missing.

(3) 2026 need date is based on summer coincident reference forecast and area limit of 370 MW.

(4) The area limit and need date based on reference forecast were provided by the IRRP.

The needs and the preferred solutions to address these needs are discussed further in Section 8 of the report.

7.5. Long-Term Capacity Needs

Over the study period 2025-2044 RIP reviewed the capacity of all the 230kV and 115kV Transmission lines within the Toronto region. The IRRP study had previously indicated that the following longer term capacity needs in Table 7-5 below.

Table 7-5: Toronto region Long-Term Capacity Needs in next 10-20 years

Need Type	Long-Term Need	Timing
Station Capacity	Warden TS	2036
	Fairbank TS	2042
	Strachan TS	2039
	Dufferin TS	2040
	Glengrove TS	2042
	Manby DESNs	2043
	Fairchild TS	2040
	Leslie TS	2039
	Duplex TS	2042
	Main TS	2043
	Runnymede TS	2043
Transformation Capacity	Leaside TS Autotransformers	2036
	Manby TS (East) Autotransformers	2041
Line Capacity	K1W/K3W (St.Clair Ave. Jct. X Fairbank TS)	2036
	Leaside TS X Wiltshire TS: 115kV Circuits	2036
	H1L/H3L Capacity – (Leaside TS X Bloor Jct.) and (Hearn SS X Basin TS)	2036 /2041
	Cherrywood TS X Leaside TS: 230kV Circuits	2036

These needs are discussed further in Section 8 of the report, and they will be monitored and evaluated in future planning cycles due to the forecast uncertainty and the longer-term timing of need.

8. REGIONAL PLANS

This section discusses the regional electric supply needs and presents all the wires alternatives considered to address these needs and identifies the best and preferred wires solutions for the Toronto Region. These needs include those previously identified in the NA and IRRP for the Toronto Region as well as any new needs identified during the RIP phase. All estimated costs included in the alternative analysis are considered as planning budgetary estimates and are used for comparative purposes only and may vary. The Needs in the region for the near- and mid-terms are summarized below in Table 8-1 below:

Table 8-1: Near/Mid-term Needs Identified in the region

Station/Circuit Name	Description of Need	Need Date	RIP Report Section
Asset Renewal Needs			
Basin TS	Transformers T3/T5 replacement*	2030	8.1.1
Manby TS	Autotransformers (T7, T9, T12) replacement, Step-down transformer (T13/T14) replacement*	2030 2033	8.1.2
Leslie TS	Transformer T1, T4 replacement	2032	8.1.3
Dufferin TS	Transformer T2 replacement*	2032	8.1.4
Cecil TS	115kV Switchgear replacement	2032	8.1.5
Bermondsey TS	Transformers T3/T4 replacement	2033	8.1.6
Strachan TS	Transformers T13/T15 replacement*	2033	8.1.7
Agincourt TS	Transformers T5/T6 replacement	2033	8.1.8
Terauley TS	Transformers T1/T2/T3/T4 replacement	2033	8.1.9
Carlaw TS	Transformers T1/T2 replacement*	2033	8.1.10
Rexdale TS	Transformer T2 replacement	2033	8.1.11
John TS	Transformer T3 replacement*	2033	8.1.12
Duplex TS	Transformers T1/T2 & T3/T4 replacement*	2034	8.1.13
Fairchild TS	Transformers T1 & T3/T4 replacement	2034	8.1.14
Warden TS	Transformer T4 replacement	2035	8.1.15

Finch TS	Transformer T1 replacement	2035	8.1.16
H1L/H3L/H6LC/H8LC	Leaside Jct. X Bloor St. Jct. – Overhead line section renewal	2031	8.1.17
L9C/L12C	Leaside TS X Balfour Jct. – Overhead line section renewal	2031	8.1.18
H1L/H3L & H2JK	Underground cable replacement	2035	8.1.19
Station Capacity Needs			
Bathurst TS & Finch	Connect Downsview MTS and supply Bathurst load - First DESN (Phase 1) - Second DESN (Phase 2)	 2033 2039	8.2.1
Scarboro TS	Build third Scarboro TS DESN and supply Scarboro load	2035	8.2.2
Basin TS	Develop an expansion of Basin TS or add a new station in the area.	2035	8.2.3
Sheppard TS	Expand T1/T2 DESN using the idle windings	2029	8.2.4
Transformation Capacity Needs			
Manby TS (West) Autotransformers	Area supply is limited by the Limited Time Rating of one autotransformer with 150 MW RAS, if considering the loss of two autotransformers	2028	8.3.1
Transmission Line Capacity Needs			
Manby TS X Riverside Jct.: 115kV Circuits	Upgrade capacity of 115kV circuits.	2026	8.4.1
Richview TS X Manby TS: 230 kV Circuits	230 kV Corridor Reinforcement	2032	8.4.2

*Transformers to be replaced with higher rated standard units.

The potential long-term needs in the 2036 – 2044 timeframe are discussed in Section 8.5.1 to Section 8.5.16 in this report.

8.1 Asset Renewal Needs for Major HV Transmission Equipment

The Asset renewal assessment considers the following options for "right sizing" the equipment:

- Maintaining the status quo;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards;
- Replacing equipment with similar equipment with *lower* ratings and built to current standards by transferring some load to other existing facilities;
- Eliminating equipment by transferring all the load to other existing facilities;
- Replacing equipment with similar equipment and built to current standards (i.e., "like-for-like" replacement);
- Replacing equipment with higher ratings and built to current standards.

From Hydro One's perspective as a facility owner and operator of its transmission equipment, do nothing is generally not an option for major HV equipment due to safety and reliability risk of equipment failure. This also results in increased maintenance cost and longer duration of customer outages.

8.1.1 Basin TS – T3/T5

The existing T3 and T5 transformers at Basin TS are 45/75 MVA units and are currently identified for replacement in 2030 based on asset condition assessment.

These units will be replaced with larger 60/100 MVA units to address asset renewal needs while also helping to address expected future station capacity needs. These replacement upgrades and other ancillary equipment renewals will contribute to increased capacity and maintaining supply reliability in the Basin TS area.

8.1.2 Manby TS – T7/T9/T12 & T13/T14

Several transformers at Manby TS are currently identified for replacement in the early 2030s based on asset condition assessments.

The existing T7, T9, and T12 autotransformers are 150/250 MVA units. These units will be replaced with like-for-like units to address asset renewal needs and contribute to maintaining reliability of supply to the Manby East and Manby West area.

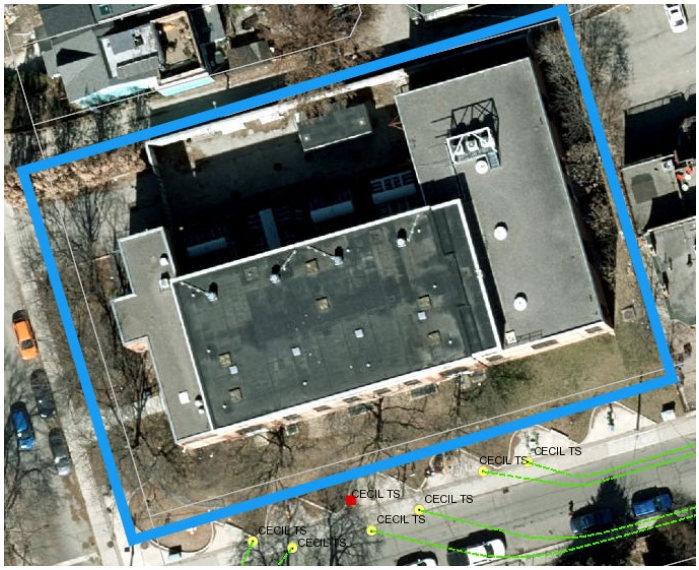
The existing T13 and T14 transformers are 56/93 MVA units. These units will be replaced with the standard 75/125 MVA units to address asset renewal needs to maintain supply reliability in the local area and contribute to addressing expected future station capacity needs.

8.1.3 Leslie TS – T1/T4

The existing T1 and T4 transformers at Leslie TS are 75/125 MVA units and are currently identified for replacement in 2032 based on asset condition assessment.

The existing T1 transformer is a non-standard unit with dual LV voltage levels at 13.8 kV and 27.6 kV. As the 13.8 kV supply will no longer be required from Leslie TS, both T1 and T4 will be replaced with standard 230-27.6-27.6 kV 75/125 MVA units to address asset renewal needs. These replacements and other ancillary equipment renewals will support the ongoing supply reliability in the Leslie TS area. Following the replacement of the existing T2 with a standard unit, the 27.6 kV supply capability at Leslie TS is expected to increase.

8.1.4 Dufferin TS – T2



The existing T2 transformer at Dufferin TS is a 45/75 MVA unit and is currently identified for replacement in 2032 based on asset condition assessment.

This unit will be replaced with a 60/100 MVA unit to meet asset renewal requirements and align with the other units at Dufferin TS. This replacement will contribute to maintaining supply reliability in the Dufferin TS area.

8.1.5 Cecil TS – 115kV Switchgear

The existing Cecil TS 115kV gas-insulated switchgear (GIS) equipment includes eight 115kV breakers and associated ancillary switchgear equipment. This indoor GIS switchgear has been recommended for full replacement to address obsolescence and supportability issues that have started to become a risk from the perspective of maintainability, operability, and reliability.

Figure 8-1: Cecil TS located in Downtown Toronto

Alternative 1 – Standard In-situ Replacement: This alternative would include full replacement of the existing GIS switchgear in the same physical location with new switchgear of similar or better ratings. However, the existing space is very constrained and replacing equipment in-situ while maintaining operations would be a significant risk. As a result, this alternative is not considered feasible and is rejected.

Alternative 2 – Greenfield Replacements: This alternative would include full replacement of the existing GIS switchgear in a new physical location with new switchgear of similar or better ratings. This alternative would allow the switchgear to be replaced in a new greenfield location and minimize project execution risk and system operation risk. This alternative would address asset needs and maintain long-term supply reliability to customers in the region.

The recommended plan is to proceed with Alternative 2 to replace the existing GIS switchgear and maintain long-term supply reliability to customers in the region.

8.1.6 Bermondsey TS – T3/T4

The existing T3 and T4 transformers at Bermondsey TS are 75/125 MVA units and are currently identified for replacement in 2033 based on asset condition assessment.

These units will be replaced with like-for-like units to address asset renewal needs. These replacements and other ancillary equipment renewals will contribute to maintaining supply reliability in the Bermondsey TS area.

8.1.7 Strachan TS – T13/T15

The existing T13 and T15 transformers at Strachan TS are 45/75 MVA units and are currently identified for replacement in 2033 based on asset condition assessment.

These units will be replaced with larger 60/100 MVA units to address asset renewal needs while also helping to address expected future station capacity needs. These replacement upgrades and other ancillary equipment renewals will contribute to increased capacity and maintaining supply reliability in the Strachan TS area.

8.1.8 Agincourt TS – T5/T6

The existing T5 and T6 transformers at Agincourt TS are 75/125 MVA units and are currently identified for replacement in 2033 based on asset condition assessment.

These units will be replaced with like-for-like units to address asset renewal needs. These replacements and other ancillary equipment renewals will contribute to maintaining supply reliability in the Agincourt TS area.

8.1.9 Terauley TS – T1/T2/T3/T4

The existing T1, T2, T3, and T4 transformers at Terauley TS are 75/125 MVA units and are currently identified for replacement in 2033 based on asset condition assessment.

These units will be replaced with standard 60/100 MVA units to address asset renewal needs. These replacements and other ancillary equipment renewals will contribute to maintaining supply reliability in the Terauley TS area.

8.1.10 Carlaw TS – T1/T2

The existing T1 and T2 transformers at Carlaw TS are 45/75 MVA units and are currently identified for replacement in 2033 based on asset condition assessment.

These units will be replaced with larger 60/100 MVA units to address asset renewal needs while also helping to address any future station capacity needs. These replacement upgrades and other ancillary equipment renewals will contribute to increased capacity and maintaining supply reliability in the Carlaw TS area.

8.1.11 Rexdale TS – T2

The existing T2 transformer at Rexdale TS is a 75/125 MVA unit and is currently identified for replacement in 2033 based on asset condition assessment.

This unit will be replaced with a like-for-like unit to address asset renewal needs. This replacement and other ancillary equipment renewals will contribute to maintaining supply reliability in the Rexdale TS area.

8.1.12 John TS – T3

The existing T3 transformer at John TS is a 45/75 MVA unit and is currently identified for replacement in 2033 based on asset condition assessment.

This unit will be replaced with a larger 60/100 MVA unit aligning with other units at John TS to address asset renewal needs while also helping to address any future station capacity needs. This replacement upgrade and other ancillary equipment renewals will contribute to increased capacity and maintaining supply reliability in the John TS area.

8.1.13 Duplex TS – T1/T2/T3/T4

The existing T1, T2, T3, and T4 transformers at Duplex TS are 45/75 MVA units and are currently identified for replacement in 2034 based on asset condition assessment.

These units will be replaced with larger 60/100 MVA units to address asset renewal needs while also helping to address expected future station capacity needs. These replacement upgrades and other ancillary equipment renewals will contribute to increased capacity and maintaining supply reliability in the Duplex TS area.

8.1.14 Fairchild TS – T1/T3/T4

The existing T1, T3, and T4 transformers at Fairchild TS are 75/125 MVA units and are currently identified for replacement in 2034 based on asset condition assessment.

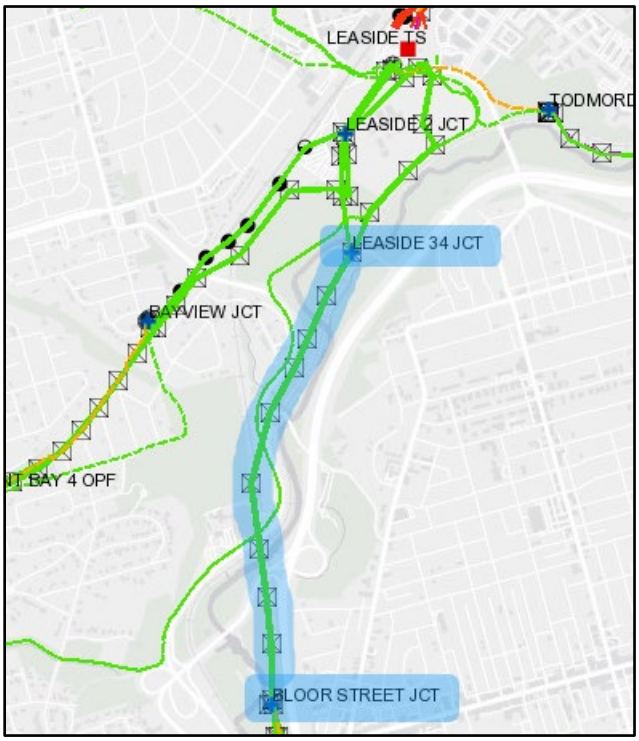
These units will be replaced with like-for-like units to address asset renewal needs. These replacements and other ancillary equipment renewals will contribute to maintaining supply reliability in the Fairchild TS area.

8.1.15 Warden TS – T4

The existing T4 transformer at Warden TS is a 75/125 MVA unit and is currently identified for replacement in 2035 based on asset condition assessment.

This unit will be replaced with a like-for-like unit to address asset renewal needs. This replacement and other ancillary equipment renewals will contribute to maintaining supply reliability in the Warden TS area.

8.1.16 Finch TS – T1



The existing T1 transformer at Finch TS is a 75/125 MVA unit and is currently identified for replacement in 2035 based on asset condition assessment.

This unit will be replaced with a like-for-like unit to address asset renewal needs. This replacement and other ancillary equipment renewals will contribute to maintaining supply reliability in the Finch TS area.

8.1.17 H1L/H3L/H6LC/H8LC – Leaside Jct. X Bloor St. Jct.

The 115 kV circuits H1L/H3L/H6LC/H8LC connect between the Leaside TS, Hearn SS and Cecil TS stations and supply step-down transformers at Basin TS, Gerrard TS, Carlaw TS, and Cecil TS. A 3 km overhead line section of these lines, between Leaside 34 Jct. and Bloor St. Jct., is predominantly steel lattice tower line. This 3 km line section between Leaside 34 Jct. and Bloor St. Jct. has been determined to require renewal. Figure 8-2 shows the Leaside 34 Jct. x Bloor St. Jct. line section of the H1L/H3L/H6LC/H8LC circuits.

Figure 8-2: H1L/H3L/H6LC/H8LC – Leaside 34 Jct. X Bloor St. Jct. Section

The following options were considered for this line section renewal:

Alternative 1 – Standard Renewal of Line Section: This alternative would prescribe a full refurbishment of the overhead line section and reconductor the section with new conductors on the existing towers. The ampacity recommendation in the IRRP will be considered and investigated during the project development stage. This alternative would address asset needs, improve line section capacity and minimize losses, and maintain long-term supply reliability to customers in the region.

Alternative 2 – Rebuild line section to 230 kV standard: This alternative would rebuild the line section to 230 kV standard and thereby allow the lines to potentially be operated at 230 kV in the future if all other sections were also upgraded. However, this alternative would be extremely costly and there are currently no plans to convert the other sections of these lines to higher voltages or to operate the lines at higher voltages. Therefore, this alternative is rejected.

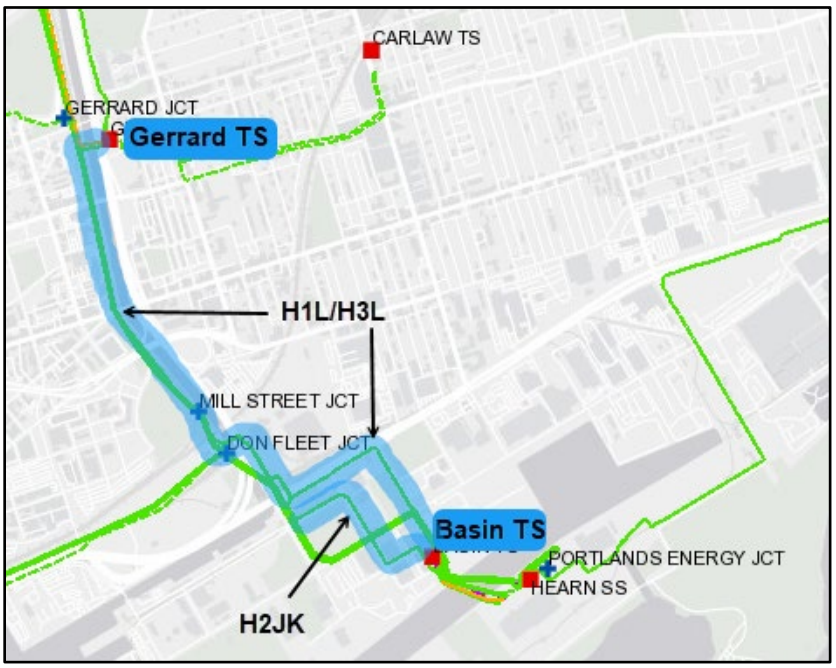
The recommended plan is to proceed with Alternative 1 to most cost effectively renew the line section and maintain long-term supply reliability to customers in the region.

8.1.18 L9C/L12C – Leaside TS X Balfour Jct.

The 115 kV circuits L9C/L12C connect between the Leaside TS and Cecil TS stations and supply step-down transformers at Charles TS and Cecil TS. A 3.5 km overhead line section of these lines, between Leaside TS

and Balfour Jct., is predominantly steel lattice tower line. This 3.5 km line section between Leaside TS and Balfour Jct. has been determined to require renewal. Figure 8-3 shows the Leaside TS x Balfour Jct. line section of the L9C/L12C circuits.

Figure 8-3: L9C/L12C – Leaside TS X Balfour Jct. Section



Preferred plan – Standard Renewal of Line Section: This would prescribe a full refurbishment of the overhead line section and reconductor the section with new conductors on the existing towers. The ampacity capability will be considered and investigated during the project development stage. This alternative would address asset needs, improve line section capacity and minimize losses, and maintain long-term supply reliability to customers in the region.

8.1.19 H1L/H3L & H2JK – Underground Cable Replacement

The 115 kV H1L/H3L circuits connect between the Leaside TS and Hearn SS stations and supply step-down transformers at Basin TS, Gerrard TS, and Carlaw TS. The 115 kV H2JK circuit connects between Hearn SS, John TS, and Manby TS with a normally open point at John TS. East of the John TS normally open point, H2JK primarily supplies Esplanade TS.

A 2.9 km underground cable section of H1L and H3L from Basin TS to Gerrard TS, and a 1.4 km underground cable section of H2JK from Basin TS to Don Fleet Jct. are 115 kV paper-insulated low-pressure oil-filled transmission cables. These cables parallel the Don River, are near Lake Ontario, and located in the Toronto Portlands. These cables are required to be replaced as verified through detailed condition assessments.

Figure 8-4: H1L/H3L – Basin TS X Gerrard TS Section; H2JK – Basin TS X Don Fleet Jct. Section

Preferred Plan – Replacement of Underground Cable Sections: This would prescribe a full replacement of the existing deteriorated oil-filled cables and ancillary equipment with oil-free cross-linked polyethylene (XLPE) cables and/or overhead lines with the largest feasible conductor sizes to minimize losses and improve capacity. This alternative would address asset renewal needs, improve line section capacity and minimize losses, and maintain long-term supply reliability to customers in the region.

8.2 Station Capacity Needs

A Station Capacity assessment was performed over the study period 2025-2044 for the 230kV and 115kV Transforming stations in the Toronto region using both the summer and winter peak load forecasts that were provided by the study team. This section describes the following Station capacity needs have been identified during the 2026-2035 period.

To address the station capacity needs, the recommendation of this planning cycle is a combination of new transformer stations and upgrades at existing stations. The RIP focuses on wire alternatives, however where possible non-wire alternatives are also considered as per the IRRP.

8.2.1 Bathurst TS & Finch TS – 230 kV / 27.6 kV

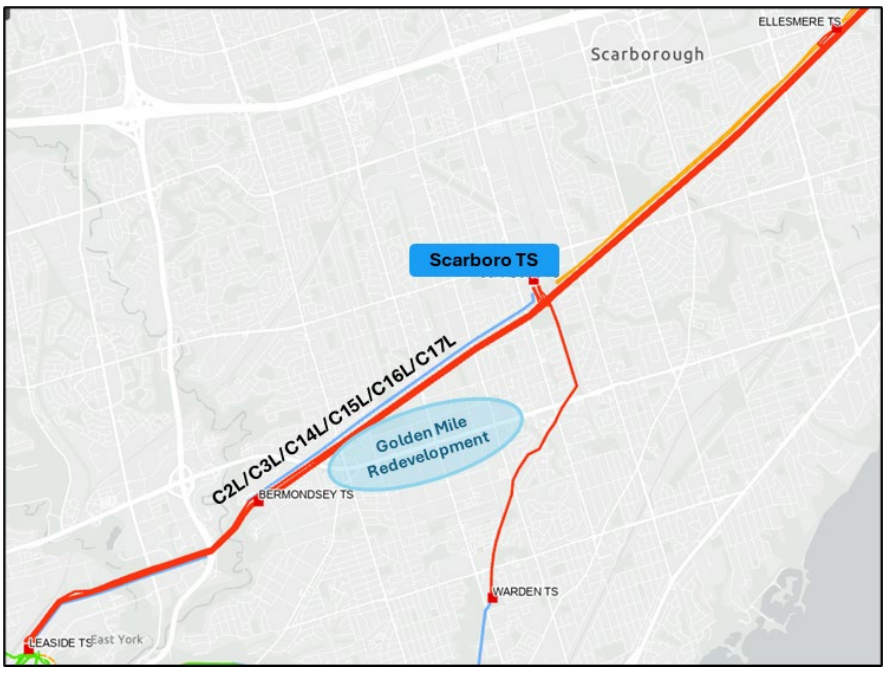
Significant load growth is anticipated in the Northwest Toronto area, particularly around Bathurst TS and Finch TS, primarily driven by the planned redevelopment of the Downsview area near Keele Street and Sheppard Avenue. Figure 8-5 shows the locations of Bathurst TS and Finch TS, along with the approximate area of the Downsview redevelopment plan.

Figure 8-5: Downsview Redevelopment Plan near Bathurst TS & Finch TS

Bathurst TS comprises two DESNs, T1/T2 and T3/T4 (all 75/125 MVA units), having a summer 10-Day LTR of 361 MW. The station's 2025 actual non-coincident summer peak load was about 278 MW and is forecasted to be approximately 370 MW (net adjusted for extreme weather) or 102% of its LTR in 2035, based on summer non-coincident reference forecast.

Finch TS comprises two DESNs, T1/T2 and T3/T4 (all 75/125 MVA units), having a summer 10-Day LTR of 366 MW. The station's 2025 actual non-coincident summer peak load was about 280 MW and is forecasted to be approximately 388 MW (net adjusted for extreme weather) or 106% of its LTR in 2035, based on summer non-coincident reference forecast [2].

To address a station capacity need of approximately 200-300 MW over the next 20 years, a new station or new DESN(s) will be required by 2035. THESL has proposed constructing a new Municipal Transformer



[2] Finch TS T1/T2 supply load for both THESL and Alectra. According to the IESO, Alectra's load was not included in the IRRP forecast. When Alectra's load is added, based on summer non-coincident reference forecast, the need date for station capacity relief at Finch TS advances from 2038 to 2033.

Station (“MTS”) in the vicinity of the Downsview area. Other alternatives, including building new DESN(s) at Bathurst TS and/or Finch TS, were considered. However, insufficient available space at or in proximity to the existing Bathurst TS property renders the addition of new DESN(s) infeasible. Furthermore, the location of Finch TS west of Highway 400 presents technical challenges associated with feeder crossings, making it a less favorable option for supporting the anticipated load growth in the Downsview area. According to the IRRP, the proposed new station with two DESNs can be connected to select Cherrywood TS x Richview TS circuit pairs, that are not on the same tower, along the Finch Corridor without the need for a switching station and without causing thermal overloads within the study period. Hydro One will continue to work closely with THESL in the coming years to support the connection of the new MTS.

8.2.2 Scarboro TS – 230 kV / 27.6 kV

Significant load growth is anticipated in the Scarborough area, particularly around Scarboro TS and Warden TS, primarily driven by the planned redevelopment of the Golden Mile along Eglinton Avenue East between Victoria Park Avenue and Birchmount Road. Figure 8-6 shows the location of Scarboro TS, along with the approximate area of the Golden Mile Secondary Plan.

Figure 8-6: Golden Mile Secondary Plan near Scarboro TS

Scarboro TS comprises two DESNs, T21/T22 (75/125 MVA) and T23/T24 (75/125 MVA), having a summer 10-Day LTR of 364 MW. The station’s 2025 actual non-coincident summer peak load was about 214 MW. Based on summer non-coincident reference forecast, Scarboro TS loading is forecasted to be

approximately 370 MW (net adjusted for extreme weather) by 2035 and over 500 MW by 2044. Its nearby station Warden TS is also forecasted to exceed its station capacity around 2036 and needs relief by transferring load to Scarboro TS. The other closest stations, Bermondsey TS and Ellesmere TS, are also projected to be loaded at about 75% and 100% of their station LTRs by 2044, respectively.

To address a station capacity need of approximately 150 MW over the next 20 years, a new station or DESN will be required by 2035. Spaces are available to accommodate an additional DESN at both the existing Scarboro TS and Warden TS properties. Scarboro TS is located adjacent to the Cherrywood to Leaside corridor, whereas Warden TS is supplied via a 4.5 km double-circuit overhead line tap from the same corridor. From a load reliability and operability perspective, building a new DESN at Scarboro TS represents the preferred alternative. Therefore, the TWG recommends that THESL and Hydro One keep monitoring the station loading and load forecast, and collaborate on the development of a third DESN at Scarboro TS in the next few years.

8.2.3 Basin TS – 115 kV / 13.8 kV

As described in Section 8.1.1, Basin TS currently comprises one DESN, T3/T5 (45/75 MVA), having a summer 10-Day LTR of 88 MW. These transformers will be replaced with 60/100 MVA units, tentatively by end of 2030. The Basin TS station capacity is expected to increase to approximately 130 MW and satisfy the need in the near to medium term. The station's 2025 actual non-coincident summer peak load was about 49 MW. Due to the City's development plan in the Port Lands area, the station loading is projected to reach 130 MW (net adjusted for extreme weather) by 2035, based on summer non-coincident reference forecast. Additional station capacity relief will be required by the end of the medium-term period or within the long-term planning horizon.

Hydro One and THESL have been continuously working with the City of Toronto on their relocation and/or reconfiguration request for the electricity infrastructure in the Port Lands area. While no updates are currently available, Hydro One and THESL will keep the TWG informed of any further developments. The TWG recommends that Hydro One and THESL maintain this collaboration with the City to finalize the site for a new or expanded Basin TS . The TWG will continue to monitor Basin TS loading and review the need in the next RP cycle.

8.2.4 Sheppard TS – 230 kV / 27.6 kV

Sheppard TS comprises two DESNs, T1/T2 (75/125 MVA units with idle winding) and T5/T6 (50/83 MVA units), having a summer 10-Day LTR of 208 MW. The station's 2025 actual non-coincident summer peak load was about 158 MW and is forecasted to be approximately 238 MW (net adjusted for extreme weather) or 114% of its station LTR in 2035, based on summer non-coincident reference forecast[3].

[3] Sheppard TS T5/T6 supply load for both THESL and Elexicon. According to the IESO, Elexicon's load was not included in the IRRP forecast. When Elexicon's load is added, based on summer non-coincident reference forecast, the need date for station capacity relief at Sheppard TS advances from 2038 to 2029.

To address this station capacity need, the TWG recommends utilizing the idle winding on transformers T1/T2. THESL and Hydro One are working together on the development of expanding the 27.6 kV switchyard. This investment is expected to increase the Sheppard TS station capacity by at least 60 MVA and meet the identified need through at least 2040 based on summer non-coincident reference forecast. The TWG further recommends ongoing monitoring and reassessment of Sheppard TS loading to determine any additional long-term needs in the next RP cycle.

8.3 Transformation Capacity Needs

A Transformation Capacity assessment was performed over the study period 2025-2044 for the 230 / 115 kV Manby and Leaside autotransformers in the Toronto region using both the summer and winter peak load forecasts that were provided by the study team. This section describes the following capacity need that has been identified during the 2026-2035 period.

To address the transformation capacity need, the recommendation from the IRRP is a combination of wire and non-wire solutions. The RIP focuses on wire alternatives.

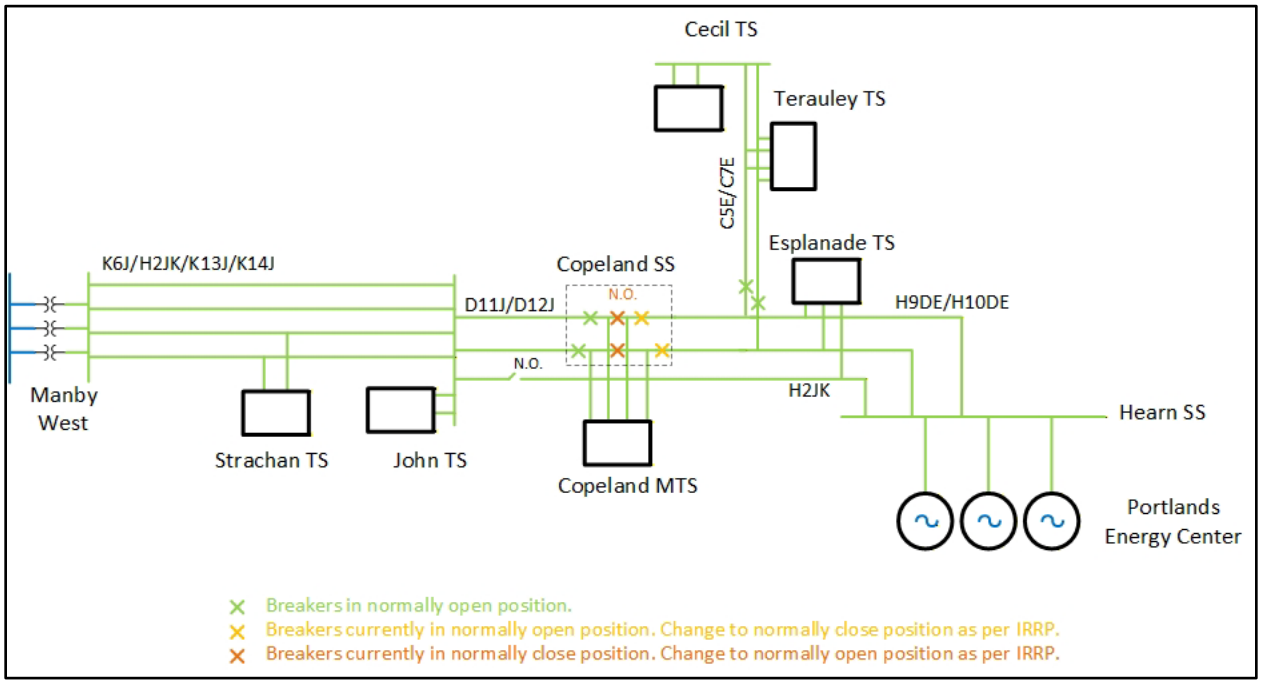
8.3.1 Manby West – 230 / 115 kV Autotransformers

Manby TS is a major bulk electric switching and autotransformer station in the Toronto region. Station facilities include Manby West and Manby East 230 kV and 115 kV switchyards, six 230 / 115 kV autotransformers (T1/T2/T12 for Manby West, and T7/T8/T9 for Manby East), and six 230 / 27.6 kV step-down transformers supplying three DESNs (T3/T4, T13/ T14, and T5/T6).

Manby West and Manby East autotransformers supply two distinct 115kV load pockets. Manby West autotransformers normally supply three downstream 115 / 13.8 kV step-down transformer stations: Strachan TS, John TS, and Copeland MTS. The Manby West autotransformers may also be used in emergency situations to supply Esplanade TS and/or Terauley TS, which are normally served by the Leaside 115 kV transmission network.

The actual 2024 summer coincident loading for the Manby West area was 358 MW. The area limit based on the loss of a single autotransformer at Manby West is 570 MW[4]. According to the summer coincident reference forecast, the projected area load remains within the autotransformer limit; however, under the high-electrification scenario, the area load is expected to exceed the limit by 2043.

Based on the enhanced reliability criteria aligning with the IRRP, the scenario where two autotransformers are lost simultaneously and only one remains in service is also evaluated. Under this condition, the area limit is reduced to 470 MW[5] with the presence of the existing Manby Remedial Action Scheme ("RAS") which allows up to 150 MW of load rejection when two out of the three autotransformers



[4] The existing autotransformer T12 is currently the most limiting unit and is planned for replacement by 2030. Following the T12 replacement, the autotransformer limit is expected to increase.

are out of service at the same time. Based on the summer coincident reference forecast, the projected area load is expected to exceed this limit by 2028.

As outlined in the IRRP, the recommended plan to address this need includes the continued reliance on Manby RAS, permanent transfer of Copeland MTS T2/T4 to the Leaside supply, incremental electricity Demand Side Management ("eDSM"), and the potential connection of Energy Storage Systems ("ESS"). Based on the summer coincident reference forecast, the permanent transfer of Copeland MTS T2/T4 to the Leaside supply keeps the Manby West load under the 465 MW limit within the study period. Under the high-electrification forecast[5], the Many West load is expected to exceed the 465 MW limit by 2036. The potential non-wire solutions would further reduce the net load supplied by Manby West autotransformers and may also decrease the amount of load rejection required when two autotransformers are out simultaneously. The TWG recommends monitoring the demand growth in this area and revisiting this capacity need in the future regional planning cycle if the growth is significant.

Figure 8-7 shows the single line diagram of the Manby West area along with the partial transmission network of the Leaside / Hearn side. As recommended in the IRRP, Copeland T2/T4 is to be transferred to the Leaside / Hearn side by changing the normally open points at Copeland SS.

Figure 8-7: Permanent Transfer of Copeland T2/T4 to the Leaside Supply

[5] For the High Electrification forecast, please refer to https://www.ieso.ca/-/media/Files/IESO/Document-Library/regional-planning/Toronto/toronto-irrp-data-tables.xlsx

8.4 Transmission Lines Capacity Needs

All line and equipment loads shall be within their continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service. Immediately following contingencies, lines may be loaded up to their short-term emergency ratings where control actions such as re-dispatch, switching, etc. are available to reduce the loading to the long-term emergency ratings. A Transmission Lines Capacity Assessment was performed over the study period 2025-2044 for the 230kV and 115kV Transmission line circuits in the Toronto region by assessing thermal limits of the circuit and the voltage range as per ORTAC to cater to this need. The following line capacity needs have been identified during the 2026-2035 period.

8.4.1 K13J / K14J – 115 kV – Manby TS x Riverside Junction Overhead Line Upgrade

As described in Section 8.3.1, the Manby West autotransformers normally supply three downstream 115 / 13.8 kV step-down transformer stations: Strachan TS, John TS, and Copeland MTS. They may also be used in emergency situations to supply Esplanade TS and/or Terauley TS, which are normally served by the Leaside 115 kV transmission network. This supply is supported by a four-circuit corridor (K13J, K14J, K6J, and H2JK) between Manby West and John TS, as well as two underground cable circuits (D11J and D12J) from John TS to Copeland SS. The existing overhead sections of circuits K13J and K14J are the most limiting elements of the Manby West area supply.

The actual 2024 summer coincident loading for the Manby West area was 358 MW. The area limit based on the loss of a single circuit (K13J or K14J) is 510 MW. With Copeland T2/T4 supplied by Manby West, the projected area load is expected to exceed this limit by 2040 under the summer coincident reference forecast, and this need would shift into the near- to medium-term under the high-electrification scenario. If Copeland T2/T4 is permanently transferred to the Leaside supply as described in Section 8.3.1, the Manby West load is expected to remain within the limit under both the reference and high-electrification forecasts[6].

Based on the enhanced reliability criteria aligning with the IRRP, the scenarios involving the simultaneous loss of two circuits are also evaluated. Under this condition, the area limit decreases to 370 MW[7]. Based on the summer coincident reference forecast, the projected area load is expected to exceed this limit by 2026 when Copeland T2/T4 is supplied from Manby West. Even with the permanent transfer of Copeland T2/T4 to the Leaside supply, the need persists and is only deferred to 2027 when double-element contingencies without control actions are considered.

Given the importance of supply reliability for Downtown Toronto and the increasing difficulty in securing outages as load demand grows, the TWG recommends upgrading the 115 kV overhead sections of circuits

[6] For the High Electrification forecast, please refer to https://www.ieso.ca/-/media/Files/IESO/Document-Library/regional-planning/Toronto/toronto-irrp-data-tables.xlsx

[7] The most limiting scenario is the loss of two circuits K13J and K6J / H2JK simultaneously with no control actions considered.

K13J and K14J between Manby TS and Riverside Junction to at least match the ampacity of the other two circuits in the corridor (K6J and H2JK). The current planned in-service date of this line upgrade is Q2-Q3 2029.

8.4.2 R1K / R2K / R13K / R15K – 230 kV – Richview TS x Manby TS

The 230 kV transmission corridor between Richview TS and Manby TS is the main supply path for the Western Sector of Central Toronto. Along this corridor there are four 230 kV circuits R1K, R2K, R13K, and R15K. Together with circuit R24C between Richview TS and Cooksville TS, this corridor also supplies the load in the southern Mississauga and Oakville areas via Manby TS.

As recommended in the previous RP, this corridor requires reinforcement to increase transfer capability in support of continued load growth in these areas. The reinforcement will be implemented in two phases. Phase 1 involves constructing a new 230 kV double-circuit line within the existing corridor and forming two supercircuits, R2K and R15K. Phase 1 is expected to be completed by March 2026. Phase 2 will unbundle these supercircuits, with one new circuit connected to Manby West and the other to Manby East. At Richview TS, the new circuits will be tapped into two existing 230 kV circuits from Claireville TS. Phase 2 is anticipated to be completed around 2030.

As outlined in the IRRP, the post-reinforcement LMC will increase to around 1840 MW, and the area load is expected to reach this limit by 2032 based on the reference forecast, under a breaker failure contingency at Richview TS resulting in the loss of two of the three circuits between Richview TS and Manby West. The TWG recommends further evaluation of this need and options in the GTA West IRRP.

8.5 Long-Term Capacity Needs

Transmission system planning must consider potential long-term needs to help inform current and future planning actions. A number of potential longer term needs have been identified as noted in Table 7-5. These needs will continue to be monitored and evaluated as needed in future regional planning cycles. No planning action or investment is required at this time as long term forecasts are uncertain and subject to potential change and the timing of the needs are longer term. The sections below discuss these potential needs.

8.5.1 Warden TS Capacity

Warden TS is comprised of one DESN unit, T1/T2 (75/125 MVA units), that has a summer 10-Day LTR of approximately 182 MW. The IRRP observes potential future station capacity exceedances in the long-term beginning approximately in 2036. A new DESN station at Scarboro TS has been proposed to address the station capacity needs in the area (see Section 8.2.2) and will also allow load to be offloaded from Warden TS. No investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.2 Fairbank TS Capacity

Fairbank TS consists of two DESN units, T5/T6 (50/83 MVA units) and T7/T8 (50/83 MVA units), that have a combined summer 10-Day LTR of approximately 222 MW. The IRRP observes potential future station capacity exceedances in the long-term beginning approximately in 2042. In addition, the Fairbank TS supply will also be limited to approximately 180 MW by the existing overhead line tap from St. Clair Ave. Jct. (see Section 8.5.14). The IRRP has proposed to address these long-term station and line capacity needs by transferring load from Fairbank TS to the new Downsview MTS (see Section 8.2.1). No investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.3 Strachan TS Capacity

Strachan TS consists of two DESN units, T12/T14 (one 60/100 MVA unit; one 45/75 MVA unit) and T13/T15 (45/75 MVA units), that have a combined summer 10-Day LTR of approximately 171 MW. The IRRP observes potential future station capacity exceedances in the long-term beginning approximately in 2039. The currently anticipated solutions to manage potential future excess load include increased local electricity demand side management and upsizing transformers upon renewal replacement. No other investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.4 Dufferin TS Capacity

Dufferin TS consists of two DESN units, T1/T3 (60/100 MVA units) and T2/T4 (one 45/75 MVA unit; one 60/100 MVA unit), that have a combined summer 10-Day LTR of approximately 180 MW. The IRRP

observes potential future station capacity exceedances in the long-term beginning approximately in 2040. In addition, the Dufferin TS supply is currently limited to approximately 135 MW by the existing underground cable tap from Dufferin Jct. and Barlett Jct. (see Section 8.5.15). A combination of remedies including upgrading the Dufferin TS supply cables, load transfers, increased local energy storage systems, and upsizing transformers upon renewal replacement are currently considered as potential solutions to address possible future excess load. No investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.5 Glengrove TS Capacity

Glengrove TS consists of two DESN units, T1/T3 (25/42 MVA units) and T2/T4 (25/42 MVA units), that have a combined summer 10-Day LTR of approximately 86 MW. The IRRP and RIP observe potential future station capacity exceedances in the long-term beginning approximately in 2042. The currently considered remedy is load transfer to Duplex TS, an adjacent load supply station, to address possible future excess load. No investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.6 Manby TS DESN Switchyards Capacity

Manby TS consists of three DESN units, T13/T14 (56/93 MVA units), T3/T4 (25/42 MVA units), and T5/T6 (25/42 MVA units), that have a combined summer 10-Day LTR of approximately 226 MW. The IRRP and RIP observe potential future station capacity exceedances in the long-term beginning approximately in 2036. The currently anticipated solutions to manage potential future excess load include upsizing transformers via renewal and upgrade replacements (see Section 8.1.2). The LV switchyard supplied by T13 and T14 is also proposed to be reconfigured concurrently with the transformer replacements to enable future LV switchyard replacements at other DESNs and support long-term capacity growth. No other investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.7 Fairchild TS Capacity

Fairchild TS consists of two DESN units, T1/T2 (75/125 MVA units) and T3/T4 (75/125 MVA units), that have a combined summer 10-Day LTR of approximately 346 MW. With the added consideration of Alectra load, the RIP observes potential future station capacity exceedances in the long-term beginning approximately in 2040. It is currently anticipated that any potential future excess load will be able to be managed through load transfers as Fairchild TS is relatively near to the proposed new Downsview MTS area. No investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.8 Leslie TS Capacity

Leslie TS consists of two DESN units, T1/T2 (75/125 MVA units) and T3/T4 (75/125 MVA units), that have a combined summer 10-Day LTR of approximately 323 MW. With the added consideration of Alectra load, the RIP observes potential future station capacity exceedances in the long-term beginning approximately

in 2039. It is currently anticipated that any potential future excess load can be managed primarily through improved capacity via transformer renewal and upgrade replacements (see Section 8.1.3). No other investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.9 Duplex TS Capacity

Duplex TS consists of two DESN units, T1/T2 (45/75 MVA units) and T3/T4 (45/75 MVA units), that have a combined summer 10-Day LTR of approximately 128 MW. The RIP observes potential future station capacity exceedances in the long-term beginning approximately in 2042. It is currently anticipated that any potential future excess load can be managed primarily through upsizing transformers via renewal replacements (see Section 8.1.13). No investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.10 Main TS Capacity

Main TS consists of one DESN unit, T3/T4 (60/100 MVA units), that has a winter 10-Day LTR of approximately 117 MW. The RIP observes potential future station capacity exceedances in the long-term beginning approximately in 2043. It is currently anticipated that any potential future excess load can be managed primarily through renewal replacements of downstream 13.8 kV switchgear that will resolve capacity limitations. No investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.11 Runnymede TS Capacity

Runnymede TS consists of two DESN units, T1/T2 (50/83 MVA units) and T5/T6 (50/83 MVA units), that have a combined winter 10-Day LTR of approximately 238 MW. The RIP observes potential future station capacity exceedances in the long-term beginning approximately in 2043. It is currently anticipated that any potential future excess load can be managed primarily through electricity demand side management measures. No investment or planning actions are required at this time, and the station and area needs will continue to be assessed in future planning cycles.

8.5.12 Cherrywood TS X Leaside TS – 230kV Circuits and Leaside TS Autotransformer Capacity

East Toronto is supplied from the east by six 230kV transmission lines that extend from Cherrywood TS to Leaside TS. The Cherrywood TS X Leaside TS lines directly supply six step-down transformer stations throughout Scarborough and East Toronto and also supply six 230/115 kV autotransformers (150/250 MVA units) at Leaside TS. The six Leaside TS autotransformers supply twelve step-down transformer stations via the Leaside 115 kV system.

The actual 2025 summer coincident peak load on the Cherrywood TS X Leaside TS lines was 2174 MW. Of the 2174 MW total, 1246 MW was supplied to the Leaside 115 kV system via the Leaside TS autotransformers. As outlined in the IRRP, the load meeting capability of the Cherrywood to Leaside lines is limited to approximately 2610 MW as a result of reaching voltage stability limits on the loss of two 230

kV supply circuits. Based on the summer reference load forecast, the Cherrywood to Leaside line loading is projected to reach this load level in approximately 2036.

The actions necessary to address the future long-term exceedances on the 230 kV supply lines and the Leaside autotransformers will be significant. As outlined in the IRRP, the recommended plan to address the Eastern Toronto needs is to introduce new supply. After assessing three distinct supply options, the IESO proposed a new underwater high-voltage direct current (HVDC) link between the Hearn SS area and the Bowmanville SS area as the preferred approach to provide new supply into the Eastern Toronto area. The HVDC link option will include extensive switchyard work at Hearn SS and Bowmanville SS as well as potentially new 230kV in-line breakers at Leaside TS on the Cherrywood TS X Leaside TS lines.

8.5.13 Manby East – 230 / 115 kV Autotransformers

As described in Section 8.3.1, Manby East comprises three 230 / 115 kV autotransformers (T7/T8/T9). They normally supply two 115 / 27.6 kV and one 115 / 13.8 kV step-down downstream transformer stations: Runnymede TS, Fairbank TS, and Wiltshire TS. The Manby East autotransformers may also be used in emergency situations to supply Dufferin TS and Bridgman TS, which are normally served by the Leaside 115 kV autotransformers.

The actual 2025 summer coincident loading for the Manby East area was 319 MW. The area limit based on the loss of a single autotransformer at Manby East is 560 MW[8]. According to the summer coincident reference forecast, the projected area load remains within the autotransformer limit during the study period.

Based on the enhanced criteria aligning with the IRRP, the scenario where two autotransformers are lost simultaneously and only one remains in service is also evaluated. Under this condition, the area limit is reduced to 460 MW with the presence of the existing Manby Remedial Action Scheme ("RAS") which allows up to 150 MW of load rejection when two out of the three autotransformers are out of service at the same time. Based on the summer coincident reference forecast, the projected area load is expected to exceed this limit by 2041.

As outlined in the IRRP, the recommended plan to address this need includes the continued reliance on Manby RAS, permanent load transfer from Fairbank TS to the new Downsview MTS, and incremental eDSM. Given that the planned autotransformer replacements may postpone the need (based on enhanced criteria aligning with the IRRP) to beyond 2044, the TWG recommends monitoring the demand growth in this area and revisiting this capacity need in the future regional planning.

8.5.14 K1W/K3W (St. Clair Ave. Jct. X Fairbank TS) Capacity

K1W and K3W 115 kV lines, extending between Manby TS (East) and Wiltshire TS, supply load to Fairbank TS and Wiltshire TS. Along this line, a 4.5 km tap from St. Clair Ave. Jct. to Fairbank TS supplies the Fairbank

[8] The existing autotransformer T7 is currently the most limiting unit and is planned for replacement by 2030. The other autotransformer T9 is also scheduled to be replaced at the same time. Following these replacements, the autotransformer limits are expected to increase.

TS. A portion of this line tap (~2.5 km) is currently planned to be relocated to accommodate new customer infrastructure.

The actual 2025 summer coincident peak load on the K1W/K3W line taps between St. Clair Ave. Jct. and Fairbank TS was approximately 122 MW. As noted in the IRRP, the load meeting capability of these line taps is approximately 180 MW based on the loss of one of the two circuits. It is currently anticipated and noted in the IRRP that the K1W/K3W line tap is projected to reach this load level in approximately 2036.

The current recommended plan to address this long-term need is to transfer load from Fairbank TS to the proposed Downsview MTS, as needed, to respect the limits of the K1W/K3W circuits. No investment or planning actions are required at this time, and the area supply needs will continue to be assessed in future planning cycles.

8.5.15 Leaside TS X Wiltshire TS – 115kV Circuits Capacity

The Leaside TS X Wiltshire TS corridor facilitates four 115 kV transmission lines (L13W, L14W, L18W, L15) that extend between Leaside TS and Wiltshire TS to supply load at Bridgman TS and Dufferin TS. Each line is comprised of a few distinct sections of either overhead conductors or underground cables. These lines are operated with the Wiltshire TS end normally open so they are, in effect, normally supplied radially from Leaside TS.

The actual 2025 summer coincident peak load on all L13W, L14W, L18W, L15 circuits was approximately 287 MW total. The L18W and L13W lines supply Dufferin TS via 1.3 km cable taps that have a load meeting capability to Dufferin TS of approximately 135 MW. These cable taps are known limitations and load level is managed accordingly to address this. Upgrading the capacity of these Dufferin TS cable taps would allow approximately 18 MW of additional Dufferin TS loading beyond which the main L13W line sections would start to become limiting. In the long term, as load growth at Bridgman TS and Dufferin TS evolves, sections of other lines may also reach limitations for certain contingencies.

As outlined in the IRRP and based on the load forecast that included the higher future Dufferin TS load, the plans to address the needs of this corridor currently include upgrading the capacity of the Dufferin TS supply cable taps, transferring load from the Dufferin TS load pocket to Wiltshire TS (assuming appropriately upgraded), and the installation of local energy storage systems. The TWG recommends monitoring the demand growth in this area and revisiting this capacity need in future regional planning cycles.

8.5.16 H1L/H3L Capacity – (Leaside TS X Bloor Jct.) and (Hearn SS X Basin TS) Sections

H1L and H3L 115 kV lines extend between Leaside TS and Hearn SS to supply load to Gerrard TS, Carlaw TS, and Basin TS. There are five distinct major line sections that make up the main path of each of these lines – two are overhead line sections; three are underground cable sections. The overhead line sections are the sections that may potentially experience capacity needs in the long-term.

The first overhead line section of H1L/H3L, from Leaside TS to Bloor St. Jct., may begin to experience capacity limitations in approximately 2036 when the Portlands Energy Centre G3 is unavailable and an n-2 contingency removes the H1L line, as noted in the IRRP. Similarly, the second overhead line section of

H1L/H3L, from Hearn SS to Basin TS, may begin to experience capacity limitations in approximately 2041 due to n-1 companion circuit outages.

The Leaside 34 Jct. x Bloor St. Jct. section of the H1L/H3L circuits is anticipated to be replaced by approximately 2031 due to asset renewal need. To address the long-term capacity need, the ampacity requirement identified in the IRRP will also be considered during the project development stage. For the Hearn SS X Basin TS section of the H1L/H3L circuits, the current recommended plan to address this long-term need is to reconductor the line section with higher ampacity conductors. No investment or planning actions are required at this time, and the area supply needs will continue to be assessed in future planning cycles.

9. CONCLUSION AND RECOMMENDATION

This section concludes the Regional Infrastructure plan Report for the Toronto region. The Major Infrastructure investments recommended by the TWG in the near and mid-term planning horizon [2026-2035] are provided in Table 9-1 below, along with their planned in-service dates (ISD) and budgetary estimates for planning purposes.

Table 9-1: Recommended Plans over the next 10 Years

Station/Circuit Name	Recommended Plan	Lead	Planned ISD	Budgetary Cost ($M) [c]
Asset Renewal Needs				
Basin TS	Transformers T3/T5 replacement*	Hydro One	2030	-
Manby TS	Autotransformers (T7, T9, T12) replacement, Step-down transformer (T13/T14) replacement*	Hydro One	2030 2033	
Leslie TS	Transformer T1, T4 replacement	Hydro One	2032	
Dufferin TS	Transformer T2 replacement*	Hydro One	2032	
Cecil TS	115kV Switchgear replacement	Hydro One	2032	
Bermondsey TS	Transformers T3/T4 replacement	Hydro One	2033	
Strachan TS	Transformers T13/T15 replacement*	Hydro One	2033	
Agincourt TS	Transformers T5/T6 replacement	Hydro One	2033	
Terauley TS	Transformers T1/T2/T3/T4 replacement	Hydro One	2033	
Carlaw TS	Transformers T1/T2 replacement*	Hydro One	2033	
Rexdale TS	Transformer T2 replacement	Hydro One	2033	
John TS	Transformer T3 replacement*	Hydro One	2033	
Duplex TS	Transformers T1/T2 & T3/T4 replacement*	Hydro One	2034	
Fairchild TS	Transformers T1 & T3/T4 replacement	Hydro One	2034	
Warden TS	Transformer T4 replacement	Hydro One	2035	
Finch TS	Transformer T1 replacement	Hydro One	2035	

H1L/H3L/H6LC/H8LC	Leaside Jct. X Bloor St. Jct. – Overhead line section renewal	Hydro One	2031	
L9C/L12C	Leaside TS X Balfour Jct. – Overhead line section renewal	Hydro One	2031	
H1L/H3L & H2JK	Underground cable replacement	Hydro One	2035	
Station Capacity Needs				
Bathurst TS & Finch TS	Connect Downsview MTS (Load Transfers to new Downsview MTS) - First DESN (Phase 1) - Second DESN (Phase 2)	THESL / Hydro One	 2033 2039	$135-155M[(d)]
Scarboro TS	Build third Scarboro TS DESN (Load Transfers to new Scarboro DESN)	Hydro One / THESL	2035	$55-65M
Basin TS	Develop an expansion of Basin TS or add a new station in the area.	Hydro One / THESL	2035	$55-65M
Sheppard TS	Expand T1/T2 DESN using the idle windings	Hydro One / THESL	2029	$16M
Transformation Capacity Need				
Manby TS (West) Autotransformers	Load Transfer (Copeland T2/T4 to Leaside Supply) + Reliance on existing Manby Remedial Action Scheme	-	2026	-
Transmission Line Capacity Need				
Manby TS X Riverside Jct.: 115 kV Circuits	Upgrade capacity of 115 kV circuits	Hydro One	2029	$25M
Richview TS X Manby TS: 230 kV Circuits	230 kV Corridor Reinforcement	Hydro One	2032	N/A[(b)]

*Transformer units to be replaced with higher rated standard units.

Notes:

a) The Planned In-Service dates are tentative and subject to change.
b) The recommended plan to address the Richview TS x Manby TS corridor need is expected by Q4 2026 as part of the GTA West IRRP.
c) Costs are tentative high-level budgetary planning estimates based on 2026 dollars and subject to change.
d) Property procurement costs not included.

Appendix D: List of LDC's

Sr. no.	Name of LDC
1	Toronto Hydro-Electric System Limited ("THESL")
2	Hydro One Networks Inc. (Distribution)
3	Alectra Utilities Corporation ("Alectra")
4	Elexicon Energy Inc. ("Elexicon")

Appendix E: List of Municipalities in the Region

Sr. no.	Name of Municipality
1	City of Toronto

Appendix F: Acronyms

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CEP	Community Energy Plan
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CSS	Customer Switching Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DS	Distribution Station
eDSM	Electricity Demand Side Management
GS	Generating Station
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	KiloVolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MEP	Municipal Energy Plan
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
ORTAC	Ontario Resource and Transmission Assessment Criteria

PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
SA	Scoping Assessment
SIA	System Impact Assessment
RAS	Remedial Action Scheme
SS	Switching Station
TS	Transformer Station

Integrated Regional Resource Plan

Northwest Region
January 2023

ieso
Connecting Today.
Powering Tomorrow.

In the event there is any conflict or inconsistency between this document and the IESO market rules, any IESO contract, any legislation or regulation, or any request for proposals or other procurement document, the terms in the market rules, or the subject contract, legislation, regulation, or procurement document, as applicable, govern.

Table of Contents

1. Introduction **9**

2. The Integrated Regional Resource Plan **13**

2.1 Near-/Medium-Term Recommendations 14

2.2 Ongoing Monitoring 18

2.3 Coordination with ongoing Bulk Planning and Project Implementation Activities 19

3. Development of the Plan **20**

3.1 Regional Planning Process 20

3.2 The Northwest Region and IRRP Development 21

4. Background and Study Scope **22**

4.1 Study Scope 22

4.2 Parallel Bulk Planning Activities 24

4.3 Supply to the Ring of Fire 25

5. Electricity Demand Forecast **27**

5.1 Historical Demand 28

5.2 Distribution-connected Forecast 29

5.3 Existing Transmission-connected Forecast 33

5.4 Mining Sector Forecast 34

5.5 Total Northwest Demand Forecast Scenarios 36

5.6 Demand Profiling – Kenora MTS 37

6. Needs **39**

6.1 Needs Assessment Methodology 39

6.2 Needs Identified 41

6.3 Potential Needs and High Sensitivities 49

7. Options Considered and Recommendations **58**

7.1 Options and Recommendations for Station Capacity Needs 58

7.2 Options for Improving Customer Reliability at Fort Frances TS 65

8. Supply to the Ring of Fire 68

8.1 Background 68

8.2 Policy Drivers and Demand Forecast 70

8.3 Transmission Supply Options and Cost Estimates 72

8.4 Opportunities for Alignment 74

8.5 Avoided Matawa Communities Diesel System Costs 76

8.6 Avoided Greenhouse Gas (GHG) Emissions 78

8.7 Next Steps 79

9. Engagement 80

9.1 Engagement Principles 80

9.2 Creating an Engagement Approach for the Northwest 81

9.3 Engage Early and Often 82

9.4 Bringing Municipalities to the Table 84

9.5 Engaging with Indigenous Communities 84

10. Conclusion 87

List of Acronyms

Acronym	Definition
APS	Achievable Potential Study
CDM	Conservation and Demand Management
DER	Distributed Energy Resource
DG	Distributed Generation
DS	Distribution Station
GS	Generating Station
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
LDC	Local Distribution Company
LTE	Long-term Emergency
NERC	North American Electric Reliability Corporation
NPCC	Northeast Power Coordinating Council
NWA	Non-wires Alternative
OEB	Ontario Energy Board
ORTAC	Ontario Resource and Transmission Assessment Criteria
RIP	Regional Infrastructure Plan
SCGT	Simple Cycle Gas Turbine
TS	Transformer Station
ULTC	Under-Load Tap Changer

This Integrated Regional Resource Plan (IRRP) was prepared by the Independent Electricity System Operator (IESO) pursuant to the terms of its Ontario Energy Board licence, EI-2013-0066.

This IRRP was prepared on behalf of the Technical Working Group (Working Group) of the Northwest region which included the following members:

Independent Electricity System Operator (IESO)

Hydro One Networks Inc. (Hydro One Transmission)

Hydro One Networks Inc. (Hydro One Distribution)

Atikokan Hydro Inc.

Fort Frances Power Corporation

Sioux Lookout Hydro Inc.

Synergy North

The Working Group assessed the reliability of electricity supply to customers in the Northwest Region over a 20-year period beginning in 2021; developed a plan that considers opportunities for regional coordination in anticipation of potential demand growth and varying supply conditions in the region; and developed an implementation plan for the recommended options while maintaining flexibility to accommodate changes in key conditions over time.

The Northwest Working Group members agree with the Integrated Regional Resource Plan (IRRP)'s recommendations and support the implementation of the plan, subject to obtaining necessary regulatory approvals and appropriate community consultations. The Northwest Working Group members do not commit to any capital expenditures and must still obtain all necessary regulatory and other approvals to implement recommended actions.

1. Introduction

This Integrated Regional Resource Plan (IRRP) addresses the electricity needs of the Northwest region over the next 20 years from 2021 to 2040. The Northwest region includes the area roughly bounded by Lake Superior to the south, the Marathon area to the east, and the Manitoba border to the west. It includes the districts of Kenora, Rainy River and Thunder Bay. A geographic map of the Northwest region is shown in Figure 1-1. Note that, for regional electricity planning purposes, the region is defined by electrical infrastructure rather than geography. The region encompasses the 230 kV circuits from the Manitoba interties in the west to Marathon TS in the east as well as the 115 kV sub-systems in between. A single line diagram of the electrical infrastructure in the region is shown in Figure 1-2.

Northwest regional electricity demand is winter peaking and, over the last five years, has grown on average by 1.1% per year. Electricity supply to the Northwest region is provided through the 230 kV East-West Tie circuits from Wawa TS, as well as from interconnections with Manitoba and Minnesota. Local generation in the region is predominantly hydroelectric and biomass-fueled.

The region's electricity is delivered by five local distribution companies (LDCs): Hydro One Networks Inc., Atikokan Hydro Inc., Fort Frances Power Corporation, Sioux Lookout Hydro Inc., and Synergy North. Hydro One Networks is also the lead transmitter in the region for regional planning purposes. Note that three transmitters own assets in the Northwest region: Hydro One Networks, Nextbridge Infrastructure, and Wataynikaneyap Power. As the lead transmitter, Hydro One Networks coordinates the involvement of other transmitters as necessary. This IRRP report was prepared by the Independent Electricity System Operator (IESO) on behalf of a Working Group composed of the aforementioned LDCs and Hydro One Networks.

Development of the Northwest IRRP was initiated in Jan 2021 following the publication of the Needs Assessment report in July 2020 by Hydro One and the Scoping Assessment Outcome Report in Jan 2021 by the IESO.[1] The Scoping Assessment identified needs that should be further assessed through an IRRP. The Working Group was then formed to gather data, identify near- to long-term needs in the region and develop the recommended actions included in this IRRP.

This report is organized as follows:

- A summary of the recommended plan for the region is provided in Section 2;
- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the region and the study scope are discussed in Section 4;

[1] The Needs Assessment can found on Hydro One's Northwest Ontario regional planning website and the Scoping Assessment Outcome Report can be found on the IESO's Northwest regional planning engagement website.

- Demand forecast scenarios, distributed generation assumptions, and conservation and demand management are described in Section 5;
- Electricity needs in the region are presented in Section 6;
- Alternatives and recommendations for meeting needs are addressed in Section 7;
- An update on the Supply to the Ring of Fire study is provided in Section 8
- A summary of engagement to date and the next steps are provided in Section 9; and
- The conclusion is provided in Section 10

Figure 1-1 | Geographic Map of the Northwest Region

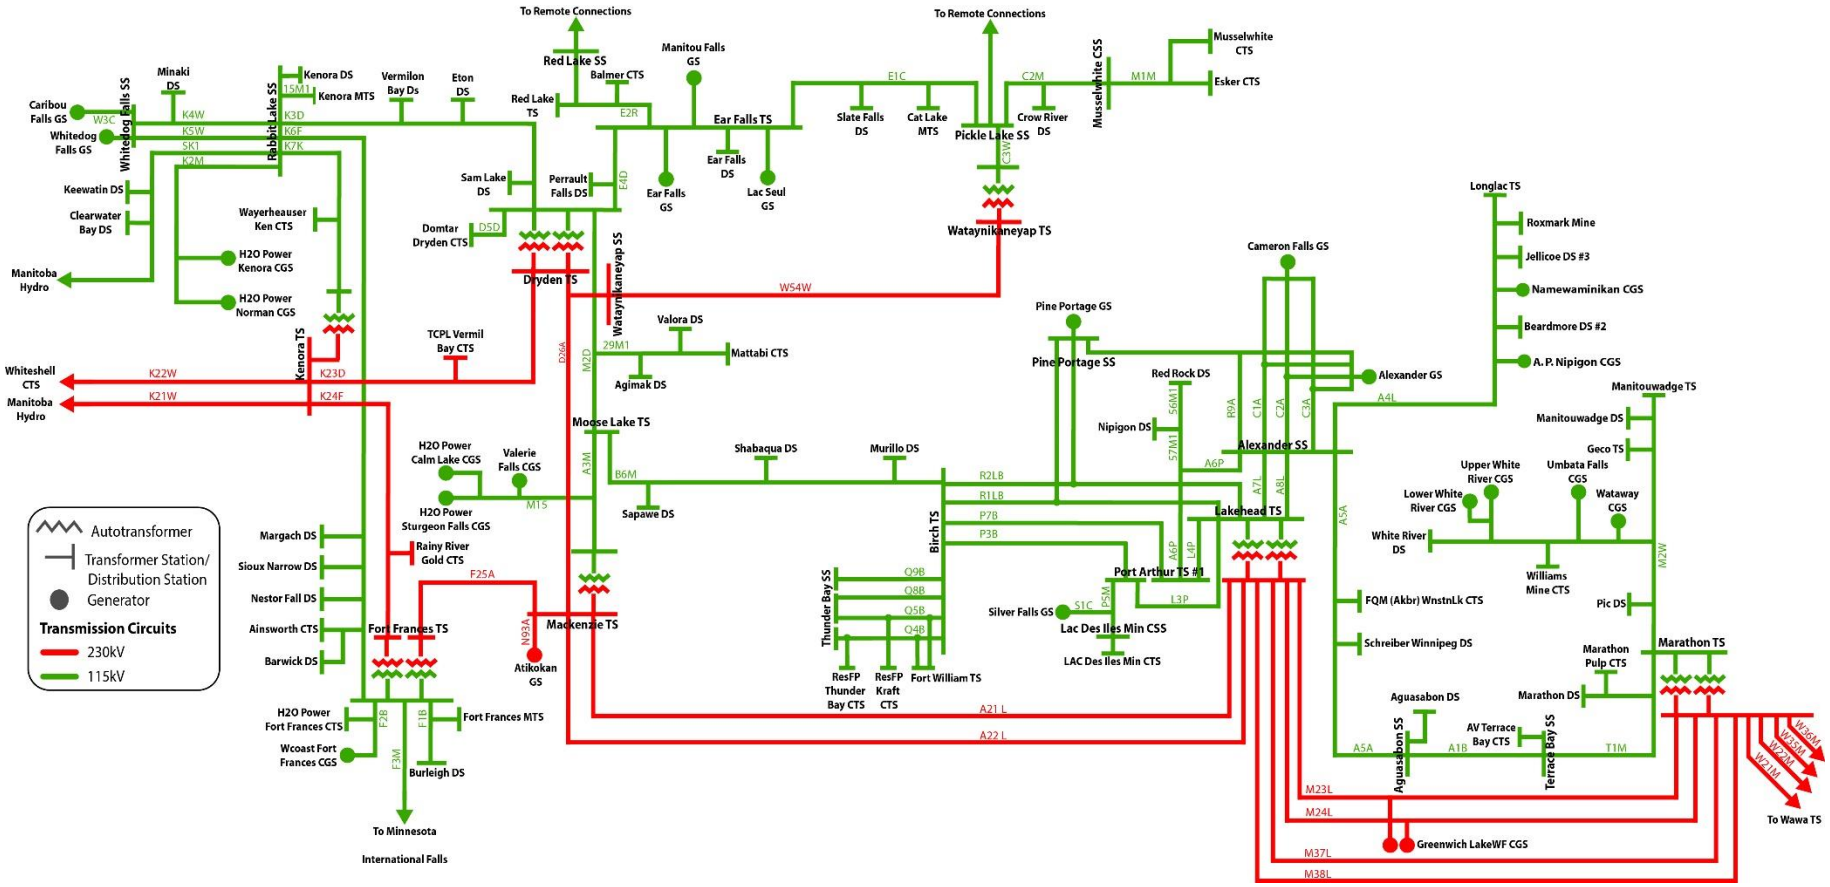

Figure 1-2 | Electricity Infrastructure in the Northwest Ontario Region

2. The Integrated Regional Resource Plan

This IRRP provides recommendations to address the electricity needs of the Northwest region over the next 20 years. The needs identified are based on the demand growth anticipated in the region and the capability of the existing transmission system as evaluated through the application of the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC) and reliability standards governed by the North American Electric Reliability Corporation (NERC) and the Northeast Power Coordinating Council (NPCC). The IRRP's recommendations are informed by an evaluation of options, representing alternative ways to meet the needs, that consider: reliability, cost, technical feasibility, maximizing the use of the existing electricity system (where economic and feasible), and feedback from stakeholders.

There are several recent or ongoing transmission reinforcement projects in the Northwest region including the:

- East-West Tie Reinforcement (new double circuit 230 kV line from Wawa TS to Marathon TS and from Marathon TS to Lakehead TS),
- Waasigan Transmission Line Project (Phase 1 being a new double circuit 230 kV line from Lakehead TS to Mackenzie TS and Phase 2 being a new single circuit 230 kV line from Mackenzie TS to Dryden TS), and
- Wataynikaneyap Transmission Project (new single circuit 230 kV line from Dinorwic Junction near Dryden to Wataynikaneyap TS near Pickle Lake as well as 115 kV remote connection circuits north of Pickle Lake and Red Lake).

Taken together, these projects reinforce many of the 230 kV transmission paths in the region. With these reinforcement projects, the infrastructure in the Northwest will be adequate to support forecast growth except for some station capacity and local operational needs. There are no new transmission projects recommended as a result of this Northwest planning initiative.

Northwest electricity demand growth is driven by the mining sector which tends to add large incremental blocks of load, often with short lead times. Therefore, this IRRP also studied several high growth sensitivities beyond forecast demand levels to test the robustness of the plan.

The plan below is organized into two sections: near-/medium-term recommendations and ongoing monitoring. Near-/medium-term recommendations include actions or further studies to be undertaken by Working Group member(s) by a specified date. These recommendations address needs with a high level of forecast certainty and requires firm commitments in this cycle of regional planning. Ongoing monitoring activities address long-term needs or potential needs flagged in high growth sensitivities that may emerge but are not yet certain based on the latest electricity demand forecast. This approach ensures that the IRRP provides clear guidance on investments needed in the near future while remaining flexible to consider new information such as electrification, energy efficiency, and industrial/mining development plans.

2.1 Near-/Medium-Term Recommendations

The near- and medium-term recommendations are summarized in Table 2-1 and further discussed below.

Table 2-1 | Summary of Near- and Medium-Term Recommendations

Need/Subsystem	Recommendation	Lead Responsibility	Required By
Kenora MTS Station Capacity	Non-wires alternatives (NWAs) can be cost effective depending on distribution system benefits; Kenora MTS will be a potential focus area for the IESO's Local Initiative Program and Synergy North will lead further non-wires analysis in local planning	Synergy North; IESO	2029
Crilly DS Station Capacity	NWAs not suitable; Hydro One Distribution will refine options for refurbishment or a new station in local planning	Hydro One Distribution	2027
Margach DS Station Capacity	NWAs not suitable; Hydro One Dx will install fan monitoring if growth materializes and monitor for additional growth that might necessitate a second transformer	Hydro One Distribution	2023
Fort Frances MTS Customer Reliability	Reconfiguration of Fort Frances TS to reduce supply interruptions to Fort Frances MTS during transmission system outages; Fort Frances Power and Hydro One Transmission will refine configuration in local planning	Fort Frances Power; Hydro One Transmission	As Soon as Practical
E1C Operation and High Voltage	With the new W54W circuit in-service, part of the Wataynikaneyap Transmission Project, E1C will be operated "normally open" and additional reactors will be installed at/near Pickle Lake SS to manage high voltages; Hydro One and IESO will collaborate in the Regional Infrastructure Plan to refine location of open point and reactor sizing	IESO Hydro One Transmission	As Soon as Practical

Note that all costs discussed below are planning-level estimates (-50% to +100%) provided for the purpose of comparing options. Material and labour costs have increased rapidly over the COVID-19 period and there is a high degree of uncertainty in future costs.

2.1.1 Kenora MTS Station Capacity

Kenora MTS is expected to reach capacity in 2029. There are no upstream supply constraints aside from the station capacity itself. The "wires" options range from installing an additional transformer at the existing station ($5M) to a new station across town ($30M) that would also incrementally improve reliability and provide distribution system benefits.[2] The wires options and distribution benefits are further discussed in Section 7.1.4.1. Based on the forecast hourly demand and associated energy-not-served profiles, three non-wires alternatives (NWAs) were identified including a 4 MW gas turbine facility, a 6-hour 4 MW battery, and a hybrid option of energy efficiency and demand response. The cost of these NWAs generally falls between the cost of expanding the existing station and a new station.[2] Therefore, the decision to pursue NWAs versus traditional wires options rests on distribution system benefits that can be realized by each option. NWA options analysis is further discussed in Section 7.1.4.2.

The technologies, regulatory framework, and protocols required to implement dispatchable NWAs to meet local capacity needs are still being tested. The IESO's York Region Non-Wires Alternative Demonstration Project[3] is currently exploring market-based approaches to secure energy and capacity services from distributed energy resources (DERs) for local needs. There is a window of opportunity between today and 2029 when the Kenora MTS capacity need arises to leverage learnings from the York Pilot and further refine NWAs for Kenora MTS.

Therefore, the IRRP recommends that Synergy North lead further NWA analysis and refinement as part of local planning. Synergy North should monitor load growth at Kenora MTS to determine when a firm commitment for additional capacity is required and implement NWAs if they remain feasible and cost-effective. Furthermore, the IESO will consider Kenora MTS as a potential focus area for the Local Initiatives Program[4] under the 2021-2024 Conservation and Demand Management Framework. The IESO will collaborate with Synergy North in 2023 as further details for the next round of the Local Initiatives Program becomes available.

2.1.2 Crilly DS Station Capacity

Crilly DS is expected to reach capacity in 2027. Crilly DS is a small (~2.2 MW) station supplied from a bus shared with Sturgeon Falls CGS, a small hydroelectric plant approximately 50 km west of Atikokan. This is a non-standard supply arrangement that results in annual outages to

[2] The methodology for calculating cost estimates is set out in Section 7.1.1

[3] For more information on the pilot and latest developments, please see the York Region Non Wires Alternatives Demonstration Project engagement webpage.

[4] For more information on the Local Initiatives Program, please see the Save ON Energy Local Initiatives webpage and the 2021-2024 Conservation and Demand Management Framework webpage.

Crilly DS when the generator is undergoing maintenance. Diesel generation is currently used for backup power when Sturgeon Falls is on outage. Furthermore, station equipment is nearing end-of-life and space constraints limit in situ refurbishment options.

Non-wires alternatives are not suitable for Crilly DS due to the existing reliance on backup generation. Distributed energy resources cannot remove the reliance on backup power and provide reliability comparable with other standard supply arrangements. Furthermore, the pool of customers served at Crilly DS is too small to target demand-modifying solutions such as energy efficiency and demand response. The IRRP recommends that Hydro One Distribution conducts local planning, in coordination with the Regional Infrastructure Plan, to refine refurbishment/new station options identified in the IRRP with the goal of balancing reliability improvements and cost. Options considered thus far include:

- Refurbish Crilly DS at its current location (and continue to rely on backup power during outages),
- Rebuild Crilly DS at a different location as a 115/25 kV HVDS,
- Rebuild Crilly DS at a different location as a 230/25 kV HVDS, or
- Replace Crilly DS with a 115:25 kV padmount transformer (transformer enclosed in a grounded cabinet that can be accommodated outside the existing station fence).

Wires options for Crilly DS and the rationale for not pursuing non-wires alternatives are further discussed in Section 7.1.2. Hydro One Distribution should monitor load growth to determine when a firm commitment to refurbish/rebuild Crilly DS is required.

2.1.3 Margach Station Capacity

Margach DS is expected to reach capacity in 2023 due to a large existing industrial customer seeking to be resupplied at Margach DS from a nearby CTS. Margach DS is approximately 10 km east of Kenora. Non-wires alternatives are not capable of addressing this large near-term step increase in demand.

The IRRP recommends that Hydro One distribution install transformer fan monitoring which will increase the station capacity above forecast demand levels. If additional capacity needs arise, a second transformer at the station which currently acts as a spare can be brought into service but no recommendation beyond the fan monitoring is required today. Wires options for Margach DS and the rationale for not pursuing non-wires alternatives are further discussed in Section 7.1.3.

2.1.4 Fort Frances MTS Customer Reliability

Fort Frances MTS, a step-down transformer station that supplies LDC loads in Fort Frances, is supplied from the nearby Fort Frances TS. The two stations are located immediately across the

street from each other. Fort Frances TS is configured in a manner that would result in Fort Frances MTS supply interruptions during certain transmission outages. Fort Frances MTS station equipment is also aging with both transformers and most breakers dating from the 1960s and 1970s. While the station equipment has not yet reached end-of-life, most equipment has reached or exceeded its typical useful life (as defined in the OEB's Asset Depreciation Study[5]) and will need to be replaced gradually over the next 10-15 years. While there is currently no firm station capacity need within the forecast horizon, several potential large customers have approached Fort Frances Power which could quickly use up the remaining station capacity. Furthermore, 115 kV breakers at Fort Frances TS are also approaching end of life around 2027 which presents an opportunity to reconfigure the station to minimize supply interruptions for Fort Frances MTS. Customer reliability, sustainment, and potential capacity needs are further discussed in Sections 6.2.2 and 0.

Fort Frances Power is developing a roadmap for Fort Frances MTS considering the replacement of aging assets, demand growth, and reliability improvements by reconfiguring supply from Fort Frances TS. Considering these needs simultaneously will ensure the most optimal and cost-effective outcome. Hydro One has proposed several Fort Frances TS reconfigurations that would incrementally improve customer reliability for Fort Frances TS and are further discussed in Section 7.2. The IRRP recommends that Fort Frances Power and Hydro One continue to collaborate and refine a configuration in local planning.

2.1.5 E1C Operation and High Voltage

With the new 230 kV Wataynikaneyap circuit W54W in-service, operating circuit E1C closed would result in a loop comprised of the E4D-E1C-W54W circuits. This arrangement would severely limit the transfer capability through E4D and W54W. The IRRP confirms that E1C should be operated normally open. This configuration is consistent with the 2015 North of Dryden IRRP.

With E1C operated normally open, high voltage arises due to line charging. Studies show that opening E1C closer to the Ear Falls TS end minimizes high voltage issues. Additionally, the IRRP recommends an additional reactor (approximately 10 MVar) at or near Pickle Lake SS.

E1C closed loop transfer limitations and E1C normally open high voltage issues are further discussed in Section 6.2.3. The IESO and Hydro One Transmission will collaborate in the Regional Infrastructure Plan to refine the location of the open point on E1C and the sizing of the reactor, considering asset conditions and costs.

[5] The OEB's Asset Depreciation Study can be found on the Ontario Energy Board's website.

2.2 Ongoing Monitoring

In addition to the needs addressed in the near- and medium-term plan above, there are several long-term or potential needs that may emerge over the forecast horizon. These needs will be monitored by the Working Group to determine when future planning studies should be triggered.

2.2.1 Station Capacity Needs Emerging in the Long-term

White Dog DS and Marathon DS are expected to reach capacity in 2032 and 2038 respectively. In both cases, current demand already exceeds 85% of the station capacity but forecast growth is modest over the forecast horizon. As with many stations across the Northwest, growth can materialize quickly if industrial development intensifies. Therefore, White Dog DS and Marathon DS should be monitored, and further planning activities should be triggered at least five years before anticipated capacity needs to enable consideration of non-wires alternatives. White Dog DS and Marathon DS station capacity needs are further discussed in Section 6.2.1.4 and 6.2.1.5.

2.2.2 Potential Growth in the Red Lake Area

The Red Lake area has significant mining activity and electricity demand is forecast to grow from 58 MW today to 70 MW by 2028. The W54W circuit recently completed as part of the Wataynikaneyap Transmission Project will help relieve constraints on the existing 115 kV circuits to Red Lake.

No capacity needs are anticipated based on the current demand forecast which was finalized by the end of 2021. However, the Working Group is aware of additional potential mining projects that are not captured in the current reference scenario demand forecast.[6] The timing and amount of load associated with these mines are not yet certain but, considering the typical size of new mining projects, remaining capacity in the Red Lake area can quickly be exhausted. Section 6.3.1 identifies the load meeting capability for the Red Lake area as well as constraints on the supply to Ear Falls and Dryden. Depending on the demand that materializes, bulk system enhancements beyond the scope of this IRRP (e.g., Waasigan Transmission Line Project Phase 2) may also be required.

The Working Group will monitor growth in the Red Lake area to determine when future planning activities should be triggered. The IESO will also continue to update the mining demand forecast, including mines in the Red Lake area, to inform ongoing bulk planning activities.

[6] As described in Section 5.4, for the purpose of this IRRP, the mining sector demand forecast was finalized by the end of 2021. The Working Group is aware of additional future mining projects that were either brought to the awareness of the Working Group after 2021 or were not yet certain enough for inclusion in the demand forecast. The IESO is updating the mining sector demand forecast by end of Q1 2023 and will provide updates to the Working Group to inform the Regional Infrastructure Plan.

2.2.3 Potential Growth in the Fort Frances Area

Several large industrial customers have expressed interest in connecting in the Fort Frances area; these customers' potential loads are not included in the current demand forecast. While the incremental electricity demand associated with these customers (approximately totalling 100 MW) may be significant, no firm commitments have been made.

No supply capacity needs are anticipated based on the current demand forecast. Section 6.3.2 identifies the load meeting capability of the Fort Frances area. The Working Group will monitor growth in the Fort Frances area to determine when future planning activities should be triggered.

2.3 Coordination with ongoing Bulk Planning and Project Implementation Activities

In April 2022, as part of the IESO's obligation to recommend the specific scope and timing of the Waasigan Transmission Line Project, the IESO recommended a staged approach for construction with Phase 1 (a new line from Thunder Bay to Atikokan) being placed in-service as close to the end of 2025 as possible. The IESO will continue to monitor developments in the region, update the mining sector demand forecast and provide an update on the need for Phase 2 (a new line from Atikokan to Dryden) by Q2 2023.

The IESO is also conducting a Northern Ontario Voltage Study to identify reactive compensation needs across northern Ontario. There are several recently implemented or planned major transmission reinforcement projects in the north including the East-West Tie Reinforcement, Waasigan Transmission Line Project, Wataynikaneyap Transmission Project, and Northeast Bulk Plan recommendations.[7] These projects will impact the voltage characteristics across the northern bulk transmission system, including the Northwest region. The Northern Ontario Voltage Study is expected to be finalized in early 2023.

The Waasigan Transmission Line Project and Northern Ontario Voltage Study are further described in Section 4.2. The IESO will continue to update the Working Group regarding ongoing bulk planning and project implementation developments for consideration in the Regional Infrastructure Plan.

In addition to the plans above, the IESO is carrying out a Supply to the Ring of Fire study in parallel with this IRRP. The preliminary findings are discussed in Section 8. The Supply to the Ring of Fire Study will continue in 2023 and the IESO will update the working group on findings for consideration in future regional planning activities.

[7] The Need for Northeast Bulk System Reinforcements report can found on the Northeast Bulk Planning webpage.

3. Development of the Plan

3.1 Regional Planning Process

In Ontario, preparing to meet the electricity needs of customers at a regional level is achieved through regional planning. Regional planning assesses the interrelated needs of a region—defined by common electricity supply infrastructure—over the near, medium, and long term and results in a plan to ensure cost-effective and reliable electricity supply. A regional plan considers the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluates options for addressing needs and recommends actions.

The current regional planning process was formalized by the OEB in 2013 and is performed on a five-year planning cycle for each of the 21 defined planning regions in the province. The process is carried out by the IESO, in collaboration with the transmitters and LDCs in each planning region. The process consists of four main components:

1. A Needs Assessment, led by the transmitter, completes an initial screening of a region's electricity needs and determines if there are electricity needs requiring regional coordination;

2. A Scoping Assessment, led by the IESO, identifies the appropriate planning approach for the identified needs and the scope of any recommended planning activities;

3. An Integrated Regional Resource Plan (IRRP), led by the IESO, proposes recommendations to meet the identified needs requiring coordinated planning; and/or

4. A Regional Infrastructure Plan (RIP), led by the transmitter, provides further details on recommended wires solutions.

Further details on the regional planning process and the IESO's approach to regional planning can be found in Appendix A.

Regional planning is not the only type of electricity planning in Ontario. Other planning activities include bulk system planning, carried out by the IESO, and distribution system planning, carried out by LDCs. There are inherent overlaps in these three levels of electricity infrastructure planning.

The IESO completed a review of the regional planning process following the completion of the first cycle of regional planning for all 21 regions. The IESO's Regional Planning Process Review report is posted on the IESO's website. Implementation of Regional Planning Process Review recommendations by the IESO, Ontario Energy Board, and its Regional Planning Process Advisory Board are ongoing.

3.2 The Northwest Region and IRRP Development

The process to develop the Northwest IRRP was initiated in January 2021 following the publication of the Needs Assessment report in July 2020 by Hydro One and Scoping Assessment Outcome Report in January 2021 by the IESO. As per the 18-month timeline, triggered by the publication of the Scoping Assessment Outcome Report, the original publication date for the Northwest IRRP was scheduled for July 13, 2022.

In April 2022, the IESO wrote to the Ontario Energy Board (OEB) to provide notice that the IESO required an additional six months to complete the IRRP. The IRRP's original scope was expanded to include additional key developments in the Northwest region. The expanded scope enabled more extensive stakeholder engagement, consideration of additional growth sensitivities, and better alignment with ongoing bulk studies across the Northwest and Northeast regions. Based on the IESO's estimate of the additional time required to incorporate the expanded scope, the new expected posting date for the Northwest IRRP was extended to January 13, 2023.

4. Background and Study Scope

This is the second cycle of regional planning for the Northwest region. In the first cycle of regional planning, the region was divided into four sub-regions, each with its own IRRP:

- Greenstone-Marathon (published June 2016)
- Thunder Bay (published December 2016)
- West of Thunder Bay (published July 2016)
- North of Dryden (published January 2015)

A summary of each of the above IRRPs can be found in the 2021 Scoping Assessment Outcome Report[8]. The Scoping Assessment for this planning cycle recommended a single IRRP covering the entire Northwest region. This report presents an integrated regional electricity plan for the next 20-year period from 2021-2040.

Note that two new transmission system projects, the East-West Tie ("EWT") reinforcement and the Wataynikaneyap Transmission Project ("Watay Project") came into service during the current IRRP study. They were both assumed to be in-service for the purpose of this IRRP's technical assessments. The EWT reinforcement adds four new 230 kV circuits: M37L and M38L from Lakehead TS to Marathon TS and W35M and W36M from Marathon TS to Wawa TS. The new EWT circuits were placed in service in March 2022. The Watay Project includes a new 230 kV circuit, W54W, between Watay 230/115 kV TS and Dinorwic Junction on circuit D26A, which runs between Dryden TS and Mackenzie TS. W54W was placed in service in August 2022. The Watay Project includes the connection of ten remote First Nation communities north of Pickle Lake (electrically supplied by Pickle Lake SS) and an additional seven remote First Nation communities north of Red Lake (electrically supplied by Red Lake SS). As of Q4 2022, work is still underway to connect Pickle Lake and Red Lake remote communities, but they were assumed to be in service for the purpose of this IRRP's technical assessments.

4.1 Study Scope

This IRRP identifies electricity needs in the Northwest Region and develops and recommends options to meet these needs. A list of transmission facilities included in the scope of this study can be found in Appendix C. The plan was prepared by the IESO on behalf of the Working Group. The plan includes consideration of forecast electricity demand growth, conservation, and demand management (CDM), distributed generation (DG), transmission and distribution system

[8] The 2021 Scoping Assessment Outcome Report can be downloaded from the Northwest Regional Planning engagement webpage.

capability, relevant community plans, condition of transmission assets and developments on the bulk transmission system.

The Northwest IRRP was developed by completing the following steps:

- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe (as described in the following steps);
- Examining the load meeting capability (LMC) and reliability of the existing transmission system, considering facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC, NERC, and NPCC criteria;
- Assessing system needs by applying a contingency-based assessment and reliability performance standards for transmission supply in the IESO-controlled grid;
- Confirming identified end-of-life asset replacement needs and timing with LDCs and transmitters;
- Establishing alternatives to address system needs including, where feasible and applicable, generation, transmission and/or distribution, and other approaches such as non-wires alternatives including conservation and demand management;
- Engaging with the community on needs and possible alternatives;
- Evaluating alternatives to address near- and long-term needs; and
- Communicating findings, conclusions, and recommendations within a detailed plan.

For the Northwest IRRP, areas of interest with high growth potential beyond forecast demand levels were identified through stakeholder engagement. Additional high sensitivity studies were performed for these areas to test the robustness of the system to supply higher than forecast demand.

4.1.1 Scope of Regional Planning Regarding New Connections

The purpose of the IRRP is to identify and address reliability needs that require coordination between transmitters, distribution companies, and the IESO. In the Northwest region, growth is driven in large part by industrial customers, predominantly in the mining sector. A subset of these customers are not currently connected to the electricity grid but are pursuing grid connection in the near term. The IRRP used the best available information to accurately simulate the connection arrangement of future customers and projects. However, IRRP technical studies were focused on evaluating the overall adequacy of regional infrastructure to supply forecast demand rather than the capability to supply any specific new project. The IRRP

did not study the local connection requirements of any individual project unless there was an opportunity to align with broader regional needs.[9]

4.2 Parallel Bulk Planning Activities

The Waasigan Transmission Line Project and the Northern Ontario Voltage study are proceeding in parallel with this IRRP and the upcoming Regional Infrastructure Plan. Findings and recommendations from these bulk planning activities will inform ongoing regional planning activities.

4.2.1 Waasigan Transmission Line Project

The Waasigan Transmission Line Project ("Waasigan Project"), formally the Northwest Bulk Line, was identified in the Government's 2013 and 2017 Long Term Energy Plans (the "LTEPs") as a priority project to:

- Increase electricity supply to the region west of Thunder Bay;
- Provide a means for new customers and growing loads to be served with clean and renewable sources that comprise Ontario's supply mix; and,
- Enhance the potential for development and connection of renewable energy facilities.

The LTEPs divided the Waasigan Project into three phases:

- Phase 1 - a line from Thunder Bay to Atikokan;
- Phase 2 - a line from Atikokan to Dryden; and,
- Phase 3 - a line from Dryden to the Manitoba border through Kenora.

Following the 2013 LTEP, the Ontario Government issued an Order in Council, also in 2013, that amended Hydro One's license to develop and seek approval for the Waasigan Project according to the scope and timing specified by the IESO.

In 2018, the IESO recommended that Hydro One commence development work (i.e., complete the Environmental Assessment) for Phase 1 and Phase 2 based on the timing of projected supply capacity needs and the risk of them materializing earlier. The IESO committed to ongoing monitoring to determine when construction of both Phase 1 and Phase 2 should begin and to confirm that they are the best course of action to meet the needs.

[9] Potential customers seeking connection should note that participation in the IRRP does not replace connection processes, namely Customer Impact Assessments (CIA) or System Impact Assessments (SIA). Furthermore, the absence of regional reliability needs identified through the IRRP in a particular area does not guarantee that connection requests in that area will be approved in a CIA or SIA.

In 2022, the IESO updated the demand forecast for the region west of Thunder Bay with information from the IRRP demand forecast and feedback from stakeholders. The mining sector demand forecast drove the majority of the demand growth and is further discussed in Section 5.4. The updated demand forecast showed a need for Phase 1 starting in 2025 and a temporary need for Phase 2 in 2026 and 2027, but not thereafter as some existing mining projects reach end of life. Therefore, the IESO recommended a staged approached for construction where Hydro One would construct the Project to meet near-term system capacity needs, with Phase 1 being placed in service as close to the end of 2025 as possible. The IESO will continue to monitor developments in the Region and provide an update in Q2 2023 on the expected need date for Phase 2. This is a balanced approach to accommodate growth in a timely manner while managing ratepayer risks.

The IESO recognizes that a firm need for Phase 2 could materialize quickly given the potential for additional growth in the region. The IESO is currently in the process of updating the mining demand forecast to reflect additional information received over the past year since the last forecast iteration and to better capture future growth driven by electrification trends and government policy. The forecast update is expected to be completed in Q1 2023.

4.2.2 Northern Ontario Voltage Study

The IESO is conducting a Northern Ontario Voltage Study to identify reactive compensation needs across the bulk system in northern Ontario. The Northern Ontario Voltage Study is expected to be finalized in early 2023.

4.3 Supply to the Ring of Fire

The Ring of Fire is a remote area approximately 500 km north of Thunder Bay rich in critical minerals but without grid power supply. The decision to pursue transmission supply to the Ring of Fire ultimately lies with mining companies and remote communities as they are the direct beneficiaries, or with the provincial and federal governments, to advance broader policy objectives.

Transmission supply to the Ring of Fire was contemplated in the 2015 cycle of regional planning. With renewed interest in developing the Ring of Fire from both government and mining companies, the IESO is updating its Supply to the Ring of Fire study in parallel with this IRRP to help inform government policy and potential customers seeking connection. This study outlines opportunities for alignment, updated high-level transmission supply cost estimates, updated avoided diesel system costs from connecting remote communities, and greenhouse gas reductions as a result of supplying remote communities and potential mines from the electricity grid instead of local generation. The preliminary findings are discussed in Section 8.

The study scope and timing of this ongoing study will evolve with government policy direction. The IESO will share updates with the Working Group to inform upcoming regional planning activities such as the Regional Infrastructure Plan.

5. Electricity Demand Forecast

This section describes the development of the demand forecast for the Northwest Region that underpins this IRRP. The 20-year forecast has three components:

- **Distribution-connected**: The distribution-connected forecast reflects demand served on the distribution systems in the Northwest and is based on information submitted by local distribution companies.
- **Transmission-connected**: The transmission-connected forecast reflects demand served directly from the transmission system. This is typically comprised of large industrial customers that have their own transformation station. The transmission-connected forecast is informed by direct engagement with customers.
- **Mining Sector**: The mining sector forecast captures electricity demand from both existing grid-connected and known future mining projects that are not yet grid-connected. The mining sector forecast is informed by data from government, industry publications, and engagement individual project proponents. Note that electricity demand from existing mining projects is also reflected in the above transmission- and distribution-connected forecast components. When the mining sector component is layered on top of the distribution-connected and transmission-connected components, only the contribution of new mining projects is shown to avoid double counting

Each forecast component is described in detail below. Note that the forecasts in this section refer to the non-coincident peak demand forecast (i.e., the sum of each station's individual peak demand). Coincident forecasts (i.e., contribution of each station to the overall peak demand hour) for the subsystem in question are used for the purpose of identifying need dates and options analysis in Section 6 and 7. Coincident forecasts are found by applying a coincidence factor based on the contribution of each station to the subsystem's coincident peak over the past five years.

Additional details related to the development of the demand forecast are provided in Appendix B. Though the Northwest IRRP forecast was created prior to October 2022, the Ontario Energy Board has also since published a Load Forecast Guideline for regional planning, through the Regional Planning Process Advisory Group.[10]

[10] The Load Forecast Guideline can be found on the Ontario Energy Board's website.

5.1 Historical Demand

Figure 5-1 shows the net and gross historical demand over the last five years in the Northwest region. Distribution-connected customer historically make up approximately 55% of peak demand with the remainder made up of transmission-connected customers. Growth has been steady over the last five years, with an average annual demand growth rate of 1.1% and Northwest demand hovering just over 800 MW from 2018 through 2020. Northwestern Ontario is winter peaking, with the peak demand hour for each year typically occurring on winter evenings between 7 p.m. And 11 p.m.

Existing distributed generation resources historically contributed approximately 10-15 MW during peak demand conditions. This contribution was added back into the net demand forecast to arrive at the gross demand forecast. The 2020 gross demand was used as the starting point for the forecast unless station-level adjustments were necessary to account for anomalous demand conditions on a case-by-case basis.

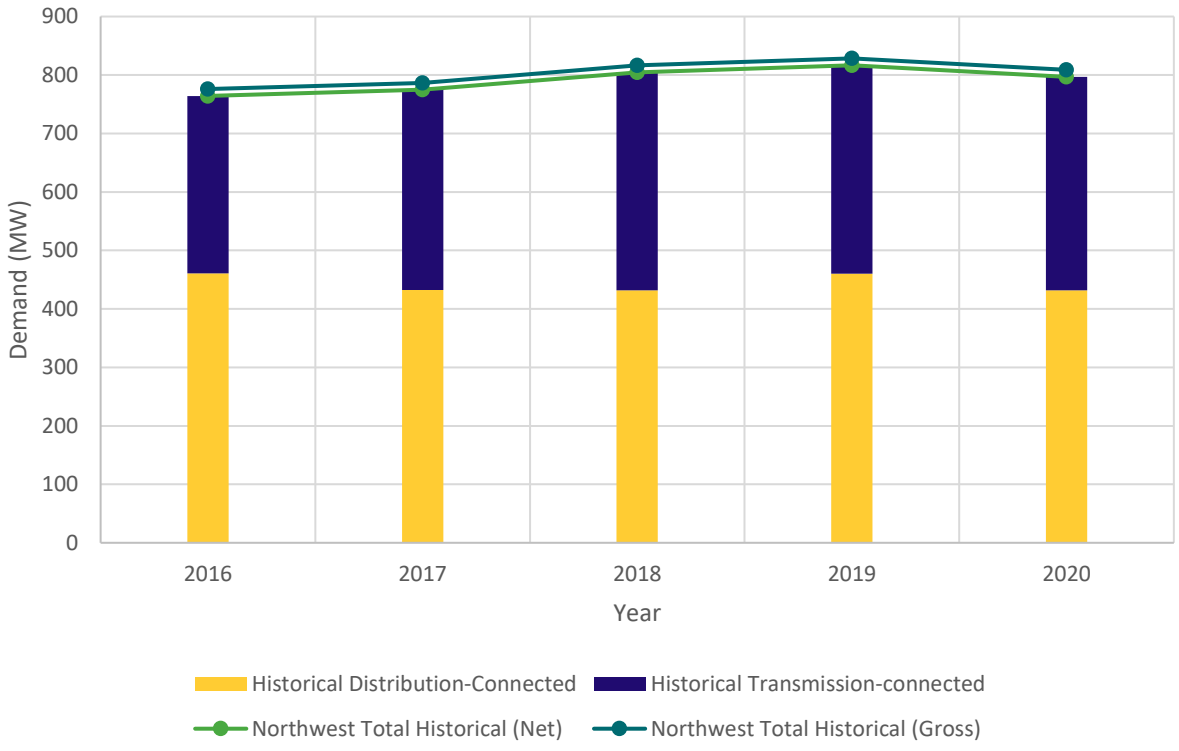

Figure 5-1 | 2016-2020 Historical Demand

5.2 Distribution-connected Forecast

The distribution-connected forecast component starts with a gross station-level demand forecast developed by local distribution companies for their service territory. The gross forecast was then modified to reflect the peak demand impacts of provincial conservation targets and distributed generation contracted through previous provincial programs such as FIT and microFIT[11] and adjusted to reflect extreme weather conditions to produce a reference scenario net forecast for planning assessments. Additional details related to the development of the distribution-connected demand forecast are provided in the sections below and in Appendix B.

5.2.1 Gross Local Distribution Company Forecast

Each participating local distribution company in the Northwest region prepared gross demand forecasts at the station level, or at the station bus level for multi-bus stations. These gross demand forecasts account for increases in demand from new or intensified development and known connection applications within their service territories.

Note that the regional planning process relies on distributors to consider municipal and regional official plans and translate development plans into electrical demand forecasts. Distributors have a better understanding of future local demand growth and drivers than the IESO, since they have the most direct involvement with their customers, connection applicants, and the municipalities they serve. More details on each distributor's demand forecast assumptions can be found in Appendix B.2 to B.6. Distributors are also expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices, i.e., "natural conservation", but not for the impact of future distributed generation or new conservation measures which are accounted for by the IESO, as discussed in Section 5.2.2 and 5.2.3 below.

The distribution-connected demand forecast compiled from distributors is adjusted to account for extreme weather conditions according to the methodology described in Appendix B.1. Figure 5-2 shows the total gross distribution-connected forecast for the Northwest region.

[11] More information about the Feed-in Tariff can be found on the IESO's website.

The distribution-connected demand forecast compiled from distributors is adjusted to account for extreme weather conditions according to the methodology described in Appendix B.1. Figure 5-2 shows the total gross distribution-connected forecast for the Northwest region.

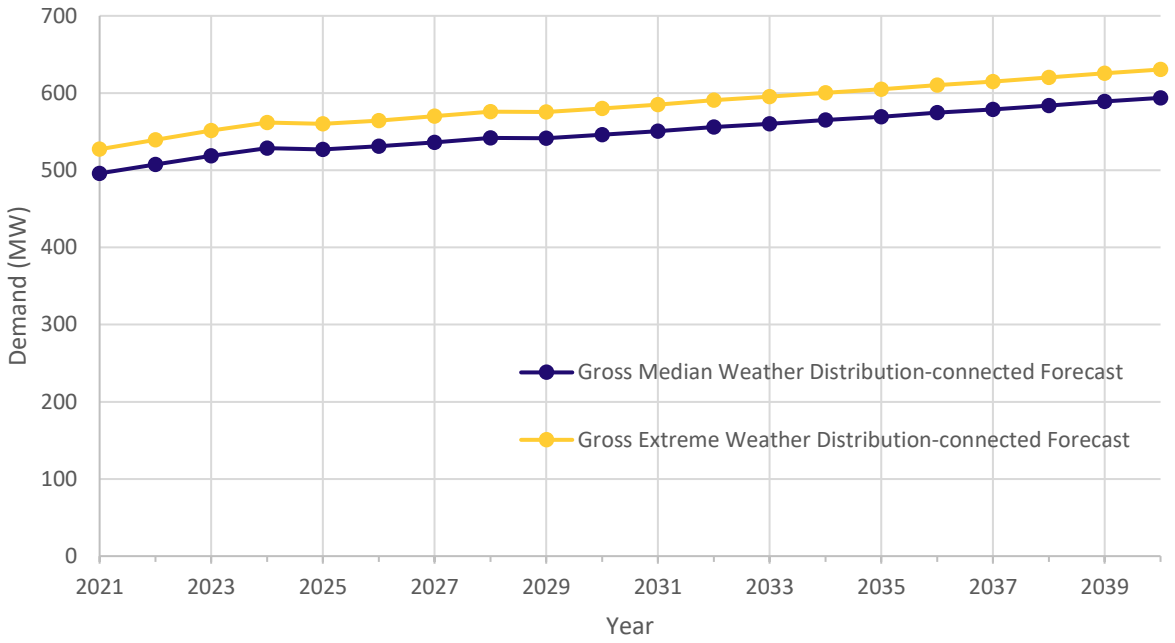

Figure 5-2 | Total Gross Median Weather Distribution-connected Forecast

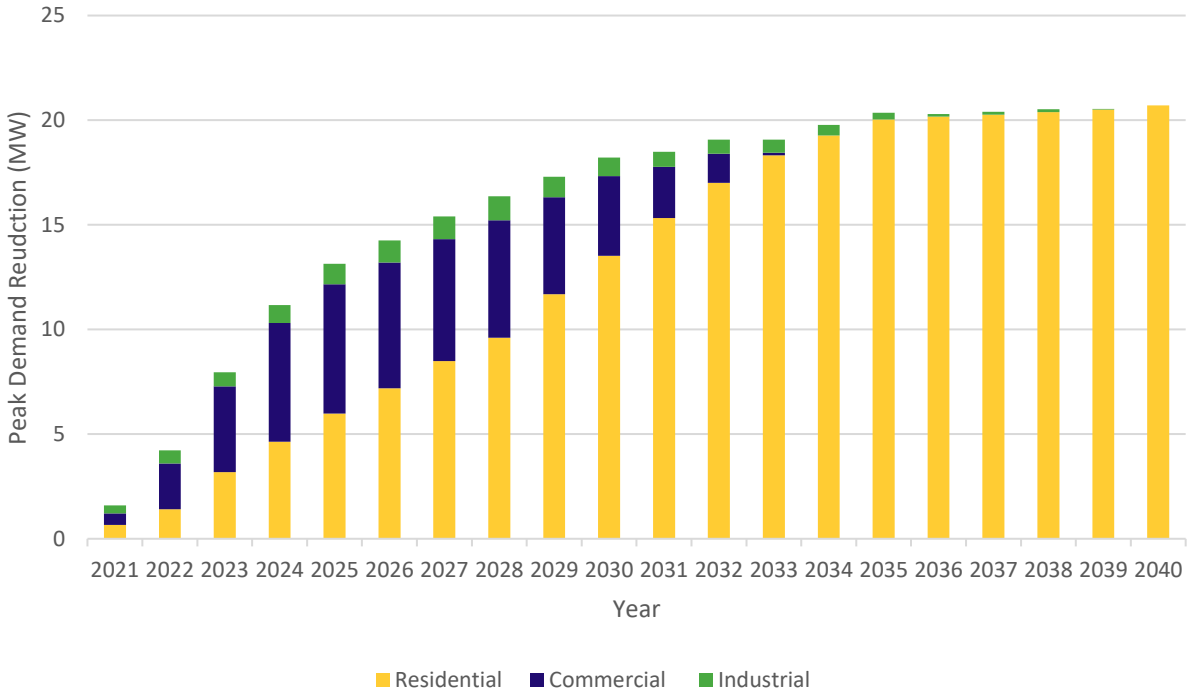

5.2.2 Contribution of Conservation to the Forecast

CDM is a clean and cost-effective resource that helps meet Ontario's electricity needs and is an integral component of provincial and regional planning. Conservation is achieved through a mix of codes and standards amendments as well as program-related activities. These approaches complement each other to maximize conservation results.

The estimate of demand reduction due to codes and standards is based on expected improvement in the codes for new and renovated buildings and through regulation of minimum efficiency standards for equipment used by specified categories of consumers, i.e., residential, commercial, and industrial consumers.

The estimates of demand reduction due to new program-related activities account for Ontario programs, federal programs that result in electricity savings in Ontario, and forecast future energy efficiency programs. The 2021 – 2024 CDM Framework is the central piece in which the IESO delivers programs on a province-wide basis to enable Ontario's electricity consumers to improve the energy efficiency of their homes, businesses, institutions, and industrial facilities.

Figure 5-3 shows the estimated total yearly reduction to the demand forecast due to conservation (from codes, standards and CDM programs) for residential, commercial, and industrial market segments. Additional details on the conservation forecast methodology are provided in Appendix B.9.

5.2.3 Contribution of Distributed Generation to the Forecast

In addition to conservation resources, distributed generation in the Northwest region is also forecast to offset some peak demand requirements. The introduction of the Green Energy and Green Economy Act, 2009, and the associated development of Ontario's FIT Program, has increased the significance of distributed renewable generation which, while intermittent, contributes to meeting the province's electricity demands. The installed distributed generation capacity by fuel type and contribution factor assumptions can be found in Appendix B.10.

After reducing the demand forecast due to conservation as described above, the forecast is further reduced by the expected contribution from contracted distributed generation in the region (similar to the adjustment between net and gross historical demand described in Section 5.1 except with forward looking contracted distributed generation rather than existing distributed generation). Figure 5.5 shows the impact of distributed generation reducing the demand forecast. In the long term, the contribution of distributed generation is expected to diminish as these contracts expire. Note that any facilities without a contract with the IESO are not included in the distributed generation peak demand reduction forecast.

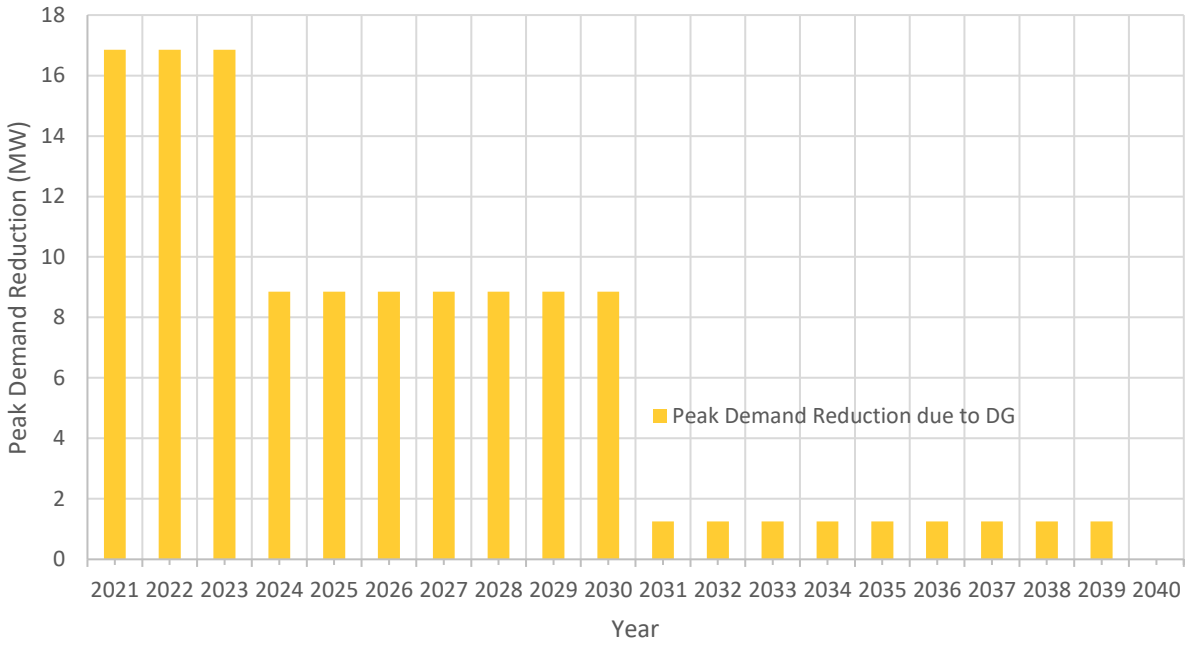

Figure 5-4 | Peak Demand Reduction to Demand Forecast due to Contracted Distributed Generation

5.3 Existing Transmission-connected Forecast

The Northwest region has fifteen customer transformer stations (CTS) that directly serve customers connected to the high-voltage transmission system. The IRRP relies on information from these customers to inform the transmission-connected forecast either directly through their account representative or through comments submitted through the IRRP engagement events. If, for a given station, no information about future demand changes is available, the default assumption is that demand at that station will remain the same as the average historical peak demand over the last five years. Figure 5-5 shows the total non-coincident transmission-connected customer demand forecast. The transmission-connected forecast is generally flat except for a few project expansions/retirements resulting in growth in 2026 and subsequent decline in 2028. Note that, unlike the distribution-connected forecast component, the transmission-connected component is not adjusted for extreme weather because industrial demand does not typically fluctuate with weather. Furthermore, while some customers have behind-the-meter generation facilities, they are not reflected in the forecast unless they are contracted with the IESO.

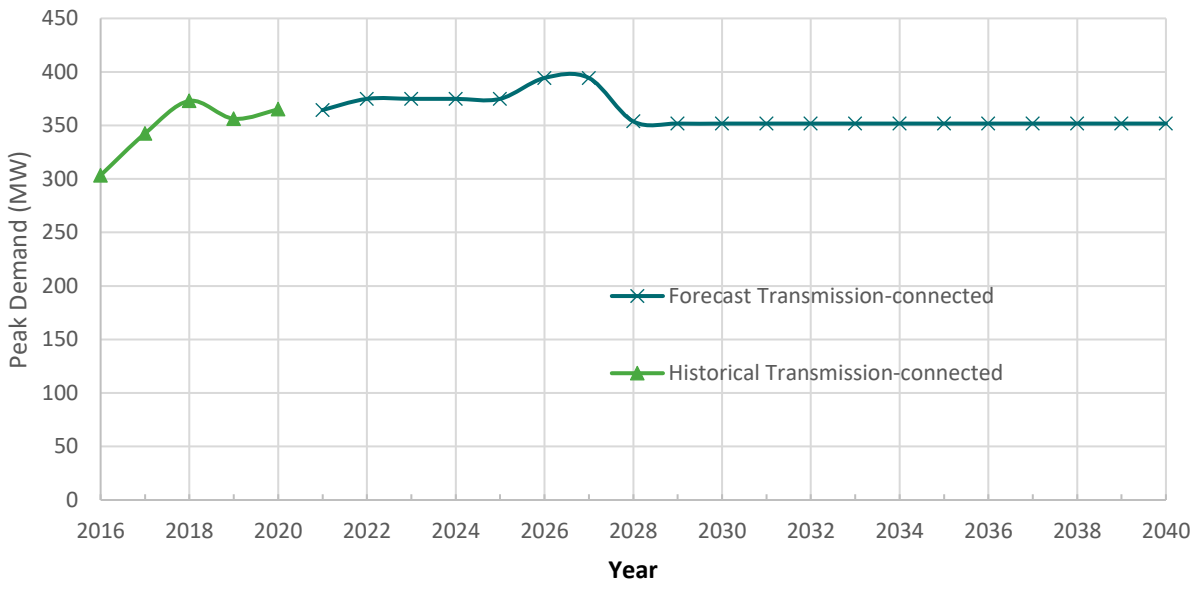

Figure 5-5 | Total Transmission-connected Demand Forecast

5.4 Mining Sector Forecast

In addition to the distribution- and transmission-connected forecasts, expansion of existing mines and new mining projects connecting to the grid are expected to make up the majority of the overall electricity demand growth in the Northwest region. As of Q4 2021, the IESO was aware of more than 20 potential future mining projects in the Northwest region at various stages of planning and development that had known electricity demand forecasts and projected in-service dates. The IESO is also aware of at least ~7-10 projects that are under consideration but have not yet progressed far enough to have an in-service date or electrical demand forecast. Note that information about future mining projects changes frequently. The IESO solicited public feedback on the mining demand forecast and associated list of known mining projects in May 2021. For this IRRP, the mining forecast was considered finalized by the end of 2021 to allow sufficient time for technical assessments that depended on forecast inputs. The mining projects incorporated in the IRRP mining forecast are listed in Appendix B.7.

The mining forecast is project-based and built from the bottom up based on known mining exploration or projects collected from proponents, industry publications, utility companies, and government. Each project is assigned one of four "likelihood" factors ranging from "most likely" to "least likely" that represents the probability of its electricity demand materializing to enable the creation of scenarios that represent different potential future outcomes.

Table 5-1 | Mining Forecast Scenario Descriptions

Scenario	Description
Low	- Conservative scenario including only existing mining projects and their extension/expansion/retirement plans - The full demand forecast for all existing mining projects is included
Reference	- Includes all demand in the low scenario plus the full undiscounted demand forecast from projects classified as "most likely" and "likely" - Aligned with 2021 Annual Planning Outlook[12] reference scenario
High	- Includes all known mining projects with each project's demand forecast discounted according to their likelihood classification: ○ "Most likely" project forecasts are not discounted ○ "Likely" project forecasts discounted to 80% of their full project demand ○ "Less likely" project forecasts discounted to 50% of their full project demand ○ "Least likely" project forecasts discounted to 20% of their full project demand - Aligned with 2021 Annual Planning Outlook high scenario

[12] The Annual Planning Outlook forecasts electricity demand, assesses the reliability of the electricity system, identifies capacity and energy needs, and explores the province's ability to meet them. The latest Annual Planning Outlook is available on the IESO's Planning and Forecasting webpage.

A project's likelihood is informed by factors such as the reliability of available data sources, development stage of the project, project timing, and permitting information. The IESO also incorporates input from the Ministry of Mines on the forecast and likelihood factors. The mining forecast scenarios are summarized in Table 5-1 above.

Figure 5-6 shows the low, reference, and high mining demand forecast scenarios. The total aggregate undiscounted (i.e., without consideration of likelihood factors) forecast demand from all known projects is also shown in a dashed line. Note that the total aggregate undiscounted forecast demand is not a realistic growth scenario since it is highly unlikely for all proposed mining projects to materialized. The undiscounted forecast is provided for transparency to illustrate the scale of potential demand growth considered in the low, reference, and high scenarios.

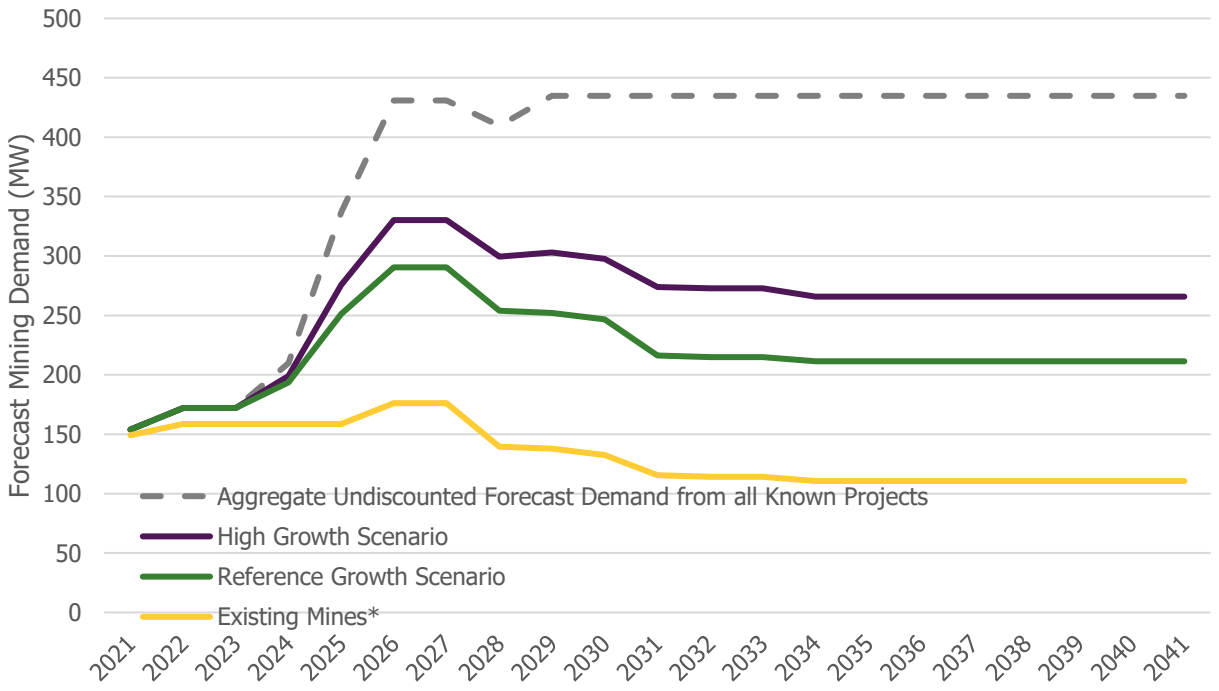

Figure 5-6 | Mining Demand Forecast

The mining sector already accounts for approximately 150 MW of demand today and is projected to grow to 290 MW by 2027 under the reference scenario. The low and high scenarios grow to 175 MW and 330 MW by 2027, respectively. Note that the IRRP does not provide disaggregated project-level forecast to preserve confidentiality.

Generally speaking, the existing mines (low) scenario informs local reliability needs that must be addressed even if no new mines materialize. The reference scenario informs the identification of needs that will likely arise and options to address those needs if/when mines materialize. Finally, the high scenario explores possible additional needs to test the robustness of the IRRP.

Note that in all scenarios, the mining forecast peaks in 2027 before declining for the remainder of the forecast horizon. This is a result of developing a project-based demand forecast as opposed to a top-line forecast for the mining sector as a whole. Information about existing and near-term projects are more readily available than information about long-term projects. Most known near- and mid-term new mining projects plan to come in-service by 2027. After 2027, demand begins to taper off as both existing and new mines reach the end of their planned operating life. The forecast scenarios do account for project extensions beyond their initial operating life but high uncertainty surrounding these extensions has meant that they were assigned low likelihood factors. In sum, the forecast performs well for predicting near- and medium-term mining growth but has less visibility of longer-term trends. Despite this shortcoming, a project-based demand forecast is more useful than a top-line forecast for the purpose of infrastructure planning. The project-based forecast provides relatively detailed information in the near- to mid-term when planning decisions must be made and provides critical geographic granularity necessary for transmission system studies.

5.5 Total Northwest Demand Forecast Scenarios

The total non-coincident Northwest demand forecast is shown in Figure 5-7 below. Note that when the mining forecast component is layered on top of the distribution-connected and transmission-connected components, only the contribution of new mining projects is shown to avoid double counting. The reference scenario Northwest demand grows to 1060 MW by 2027. The low and high scenarios growing to 945 MW and 1100 MW by 2027, respectively. Note that the discontinuity between historical and forecast demand from 2020 to 2021 is partly due to the extreme weather correction applied to the distribution-connected forecast.

The IRRP reference forecast is approximately 20% higher than the Annual Planning Outlook forecast for the Northwest zone. This difference is in part due to the non-coincidence of the IRRP's station-level forecast; the non-coincident forecast is typically 10-15% higher than the coincident forecast in the Northwest. The sum of regional planning forecasts is also generally higher than their bulk planning counterparts since regional forecasts capture potential growth at a greater granularity not all of which may materialize when aggregated at a larger geographic scale.

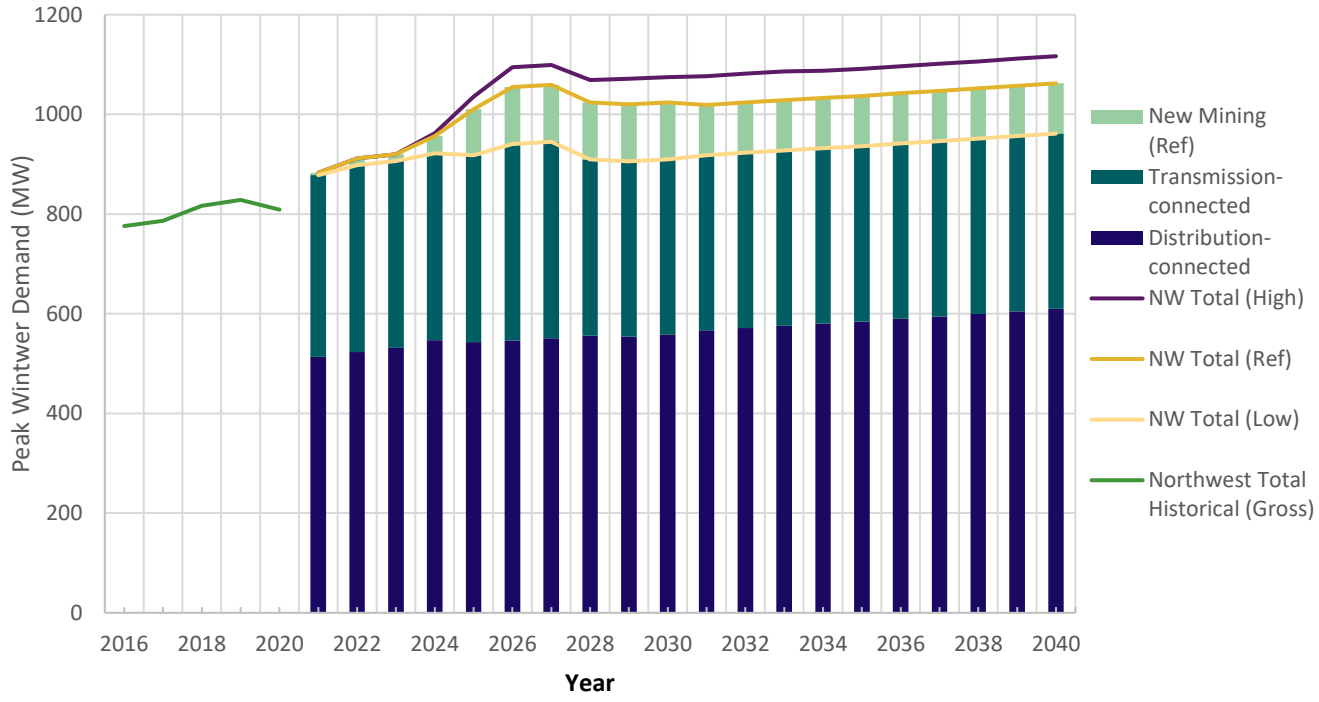

Figure 5-7 | Total Northwest Demand Forecast

5.6 Demand Profiling – Kenora MTS

In addition to the annual peak forecast, hourly load profiles (8,760 hours per year over the 20-year forecast horizon) for stations or groups of stations with identified needs can be developed to characterize their needs with finer granularity. This is typically undertaken to inform an analysis of potential non-wires alternatives.

For this IRRP, hourly demand profiles were developed for Kenora MTS where a firm station capacity need was identified for which non-wires alternatives are promising. The Kenora MTS hourly demand profiles can be found in Appendix D.2. There were no other needs identified in this IRRP which could be addressed by non-wires alternatives.

Hourly demand profiles are created by first training a multiple linear regression model with historical data and then repeatedly applying the model under different weather/calendar variable permutations to forecast a range of possible future hourly profiles. The profiles are then ranked based on their median energy values. The median profile is scaled to match the peak demand forecast in each year and used to size and simulate non-wires alternatives as described in Section 7.1. A more fulsome description of the demand profiling methodology can be found in Appendix D.1.

Note that this data is used to roughly inform the overall energy requirements that a non-wire alternative would need to meet for the purposes of evaluating alternatives; it cannot be used to deterministically specify the precise hourly energy requirements. Further, this data is only used to select suitable technology types and roughly estimate operating costs. Demand patterns can change significantly as consumer behaviour evolves, new industries emerge, and trends like electrification achieve greater adoption. The Working Group will continue to monitor these changes as part of the implementation of the plan.

6. Needs

This section summarizes the needs identified through the IRRP process. Taking into account committed transmission projects identified through bulk planning processes (i.e., the East West Tie expansion and the Waasigan transmission line), the Northwest region is generally adequate to support forecast electricity demand growth. The needs identified in the IRRP deal with localized supply to various pockets of demand in the Northwest as well as high-growth scenarios in areas identified as having strong future development potential.

This section is organized as follows:

- Section 6.1 summarizes the methodology for identifying needs,
- Section 6.2 describes firm station capacity and local operational needs (i.e., needs that would materialize under the reference forecast scenario), and
- Section 6.3 describes potential needs that may arise if higher than forecast growth materializes in select subsystems in the region.

Section 6.2.3 (E1C Operation and High Voltage Need), in addition to specifying the needs identified, will also discuss the recommended solutions since there are no "alternatives" that would normally be discussed in Section 7.

Note that bulk system needs are not in scope for the IRRP, which is focused on local reliability and ensuring that local/regional infrastructure can serve forecast demand. Nonetheless, this IRRP report flags any potential interactions between regional and bulk system needs.

6.1 Needs Assessment Methodology

Based on the reference demand forecast (extreme weather, net demand), system capability, transmitters' identified end-of-life asset replacement plans, and the application of ORTAC and NERC/NPCC standards, the Working Group identified electricity needs which generally fall into the following categories:

- **Station Capacity Needs** arise when the demand forecast exceeds the electricity system's ability to deliver power to the local distribution network through the regional step-down transformer stations at peak demand. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by station equipment. Station ratings are often determined based on the 10-day Limited Time Rating (LTR) of a station's smallest transformer under the assumption that the largest transformer is out of service.[13] A transformer station can also be limited when downstream or upstream equipment (e.g., breakers, disconnect switches, low-voltage bus, or high voltage circuits) is undersized relative to the transformer rating.

- **Supply Capacity Needs** describe the electricity system's ability to provide continuous supply to a local area at peak demand. This is limited by the Load Meeting Capability (LMC) of the transmission supply to an area. The LMC is determined by evaluating the maximum demand that can be supplied to an area accounting for limitations of the transmission elements (e.g., a transmission line, group of lines, or autotransformer) when subjected to contingencies and criteria prescribed by ORTAC and NERC/NPCC standards. LMC studies are conducted using power system simulation analysis. For the high growth sensitivities in Section 6.3, the LMCs for the subsystems in question are higher than the total forecast demand (both reference and high scenarios). Nonetheless, as these areas have been identified to have future development potential, the IRRP explores the existing limitations in these areas to identify the remaining LMC and inform future planning activities should higher growth materialize. Details regarding the power flow simulations, including the system topology and credible contingencies studied, can be found in Appendix C.

- **End-of-life Asset Refurbishment Needs** are identified by the transmitter with consideration to a variety of factors such as asset age, expected service life, risk associated with the failure of the asset, and its condition. Replacement needs identified in the near- and early mid-term timeframe would typically reflect condition-based information, while replacement needs identified in the medium to long term are often based on the equipment's expected service life. Note that IRRPs do not typically study and make recommendations for all end-of-life needs[14] where like-for-like replacements have been established to be appropriate in earlier phases of the regional planning process. Instead, the IRRP focuses on a subset of end-of-life needs where there are interactions with other regional needs and where there may be opportunities to reconfigure or right-size assets. Therefore, in the sections below, end-of-life needs are described in conjunction with other needs where relevant.

[13] Some stations in the Northwest only have a single transformer in which case the transformer's LTR is the limiting element.
[14] A list of transmission assets reaching end-of-life can be found in the Needs Assessment.

- **Load Security and Restoration Needs** describe the electricity system's ability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements are prescribed by Section 7 of ORTAC.

6.2 Needs Identified

Table 6-1 summarizes the firm needs identified in this IRRP and are further discussed in the sections below. Note that the White Dog DS and Marathon DS station capacity needs occur in the long-term and are not further discussed in Section 7 since no firm recommendations are needed at this time.

Table 6-1 | Summary of Needs

Need	Need Description	Need Date
Fort Frances MTS Customer Reliability	Frequent loss of supply due to transmission outages; end-of-life assets at both Fort Frances TS and Fort Frances MTS	Today
E1C Operation	Supply capacity limitations with E1C operated normally closed; high voltage issues with E1C operated normally open	Today
Margach DS	Station step-down transformer capacity	2023
Crilly DS	Station step-down transformer capacity	2027
Kenora MTS	Station step-down transformer capacity	2029
White Dog DS	Station step-down transformer capacity	2032
Marathon DS	Station step-down transformer capacity	2038

6.2.1 Station Capacity Needs

6.2.1.1 Margach DS

Margach DS is approximately 10 km east of Kenora. Margach DS has an LTR of 10.4 MW and historical demand has been stable at just under 10 MW. As shown in Figure 6-1, Margach DS is expected to reach capacity in 2023 due to a large existing industrial customer seeking to be resupplied at Margach DS from a nearby CTS.

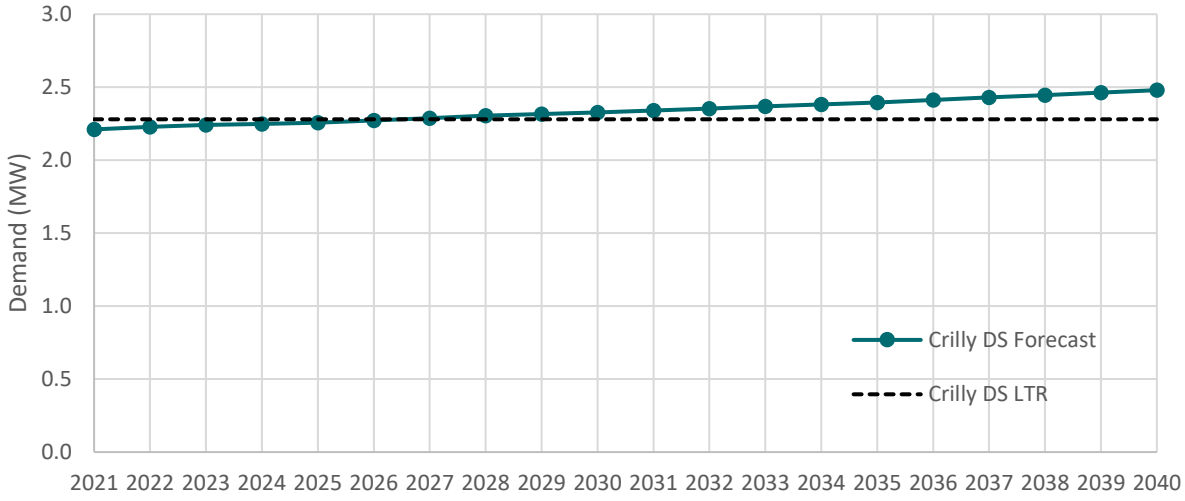

Figure 6-1 | Margach DS Forecast

6.2.1.2 Crilly DS

Crilly DS is a small (~2.2 MW LTR) station supplied from a bus shared with Sturgeon Falls CGS, a small hydroelectric plant approximately 50 km west of Atikokan. This is a non-standard supply arrangement that results in annual outages to Crilly DS when the generator is undergoing maintenance. Diesel generation is currently used for backup power when Sturgeon Falls is on outage. Furthermore, station equipment is nearing end-of-life and space constraints limit in situ refurbishment options.

Crilly DS is expected to reach capacity in 2027 due to incremental growth in the community as shown in Figure 6-2.

6.2.1.3 Kenora MTS

Kenora MTS serves the City of Kenora and has a LTR of 23.4 MW. Synergy North has received inquiries from potential customers seeking new connections, including a new 4 MW project, but no formal agreements have been finalized. While these projects have not been included in the forecast, a relatively high annual growth rate of 1.25% was applied to account for the high degree of development interest.

Figure 6-2 | Crilly DS Forecast

Kenora MTS is expected to reach capacity in 2029 as shown in Figure 6-3.

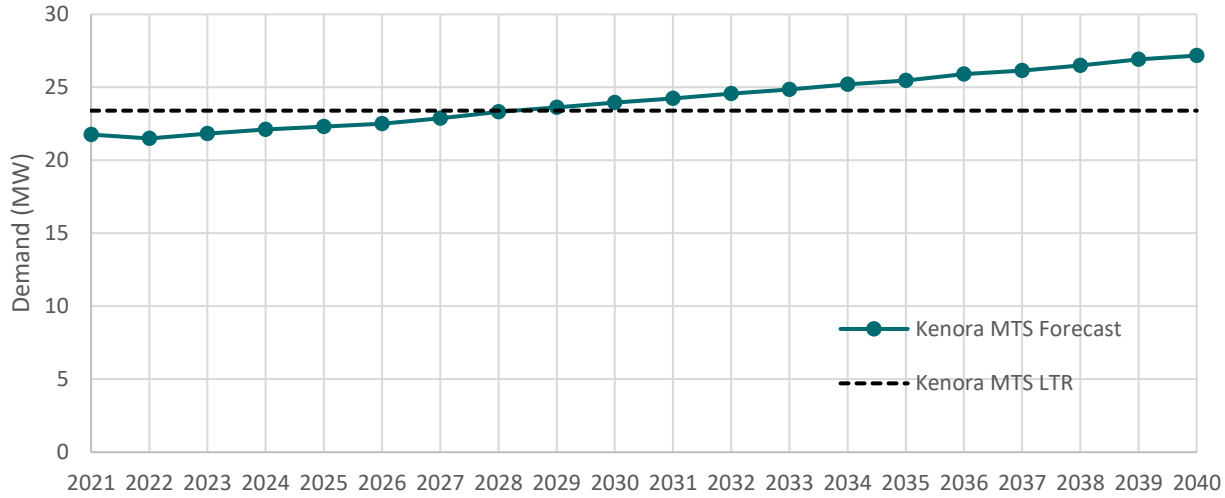

Figure 6-3 | Kenora MTS Forecast

6.2.1.4 White Dog DS

White Dog DS is located approximately 50 km northwest of Kenora and has a LTR of 2.9 MW. White Dog DS demand is expected to grow relatively quickly at an average rate of 1.3% annually due to growth in the community. White Dog DS is expected to reach capacity in 2032 as shown in Figure 6-4.

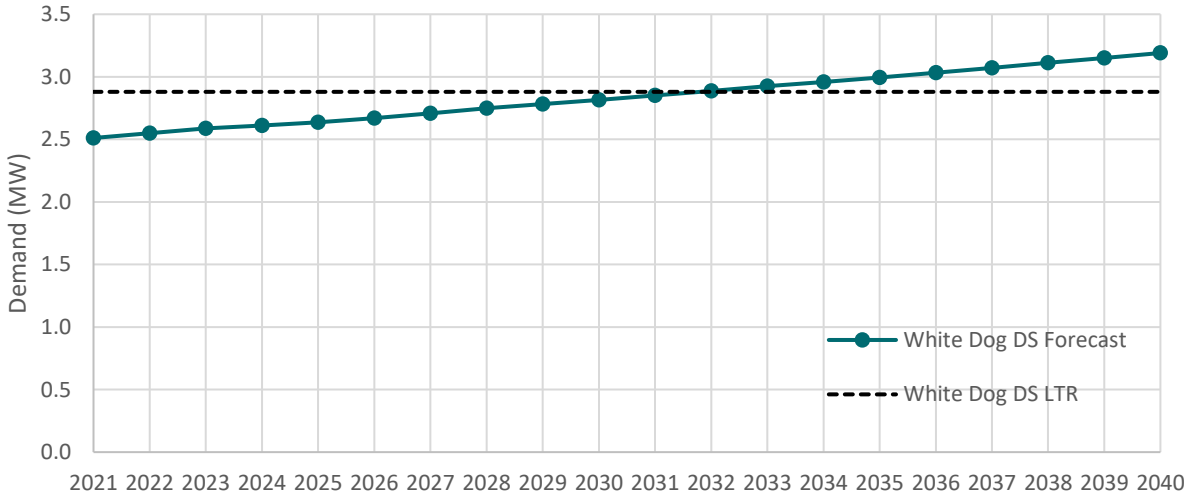

Figure 6-4 | White Dog DS Forecast

6.2.1.5 Marathon DS

Marathon DS serves the Town of Marathon and has a LTR of 10.4 MW. Growth is expected to be moderate and stable at an average annual growth rate of 0.9%. Marathon DS is expected to reach capacity in 2038 as shown in Figure 6-5.

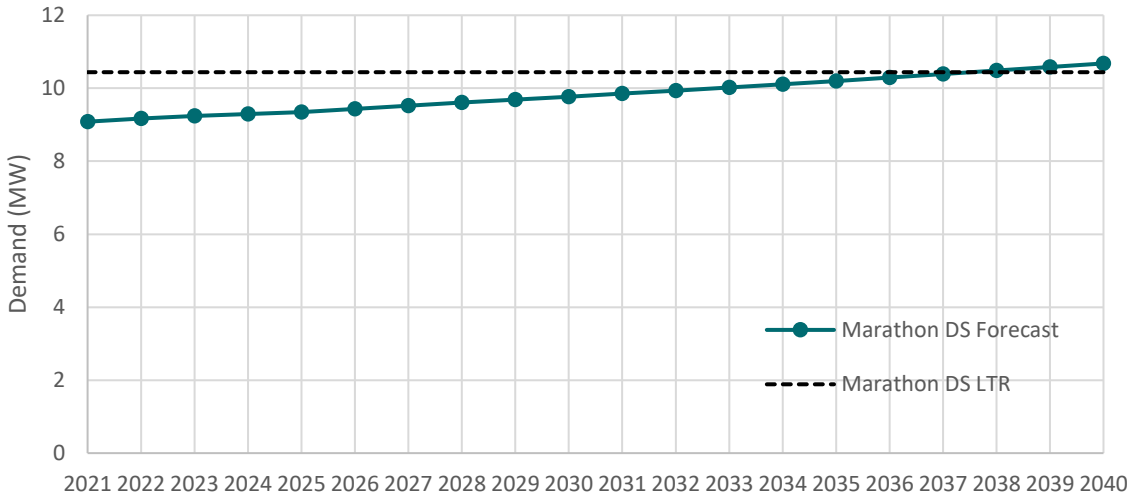

Figure 6-5 | Marathon DS Forecast

6.2.2 Fort Frances Customer Reliability Need

Fort Frances MTS, a step-down transformer station that supplies the Town of Fort Frances, is supplied via a single circuit 115 kV line, F1B, from the nearby Fort Frances TS. The two stations are located across the street from each other as shown in Figure 6-6. Fort Frances MTS experiences outages semi-annually to accommodate planned maintenance outages on F1B. Despite there being two step-down transformers at Fort Frances MTS, the single circuit supply configuration results in community-wide power outages since there is no redundant supply path to the station.

Historically, outage durations ranges from 4 to 8 hours and impact critical loads such as the regional hospital and local health clinics. Customers have raised concerns with interruptions to surgery schedules and vaccine spoilage due to the loss of refrigeration. Power outages also disrupt other commercial and residential customers. Customer surveys conducted by Fort Frances Power suggest that customers can tolerate short outages but are increasing sensitive to prolonged outages. Of the 10 causes of distribution system customer interruptions tracked by the Ontario Energy Board, loss of transmission supply accounts for 90% of Fort Frances Power's customer interruptions over the last 10 years.

Note that this customer reliability issue does not violate ORTAC load security and restoration criteria due to the relatively low total demand served at Fort Frances MTS. Fort Frances MTS serves approximately 16 MW of load today and is expected to grow to 18 MW by the end of the forecast horizon.[15] Load security criteria limits the total amount of demand interrupted with any single element out of service to 150 MW. For loads under 150 MW, load restoration criteria only require that service is restored within 8 hours. Despite compliance with ORTAC criteria, the Fort Frances MTS supply configuration is still highly disruptive for customers and could potentially be improved with relatively low-cost solutions given the proximity to Fort Frances TS.

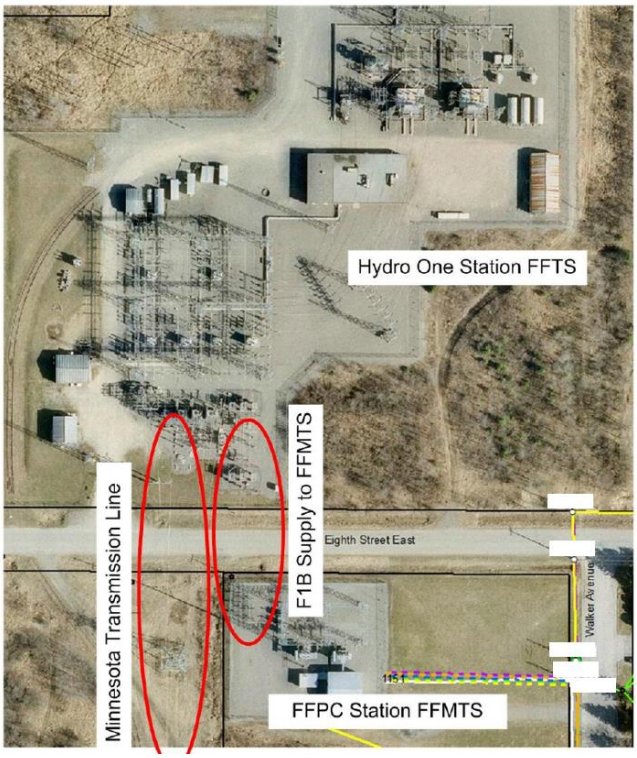

Figure 6-6 | Overhead view of Fort Frances TS (labeled as FFTS) and Fort Frances MTS (labeled as FFMTS)

[15] While there is currently no firm station capacity need within the forecast horizon, several potential large customers have approached Fort Frances Power that could quickly use up the remaining station capacity if they commit. This is further discussed in Section 6.3.2.

Fort Frances MTS station equipment is also aging with both transformers and most breakers dating from the 1960s and 1970s. The OEB's Asset Depreciation Study defines minimum, typical, and maximum useful life for a variety of electricity system assets. Apart from the main station breaker, which was replaced in 2019, all equipment at Fort Frances MTS is between its typical and maximum useful life. Furthermore, Fort Frances TS 115 kV breakers are also approaching end of life around 2027, which presents an opportunity to reconfigure the station to minimize supply interruptions for Fort Frances MTS.

6.2.3 E1C Operations and High Voltage Need

This section discusses the E1C operations with the new 230 kV Wataynikaneyap circuit, W54W, in service. W54W was first energized in Aug 2022. However, C3W, a short 30 m circuit between Wataynikaneyap TS and Pickle Lake SS, is still operated normally open. Therefore, W54W is not yet connected to the existing 115 kV circuits from Ear Falls TS to Pickle Lake SS and Musselwhite CSS (E1C, C2M, and M1M). C3W will be operated closed in the near future so that W54W can help support demand growth on C2M. This is consistent with the IESO's original recommended scope for the Wataynikaneyap Transmission Project in 2016.[16] For the purposes of this IRRP report, W54W being "in-service," refers to the final state with C3W closed. A single-line diagram of the area is shown in Figure 6-7.

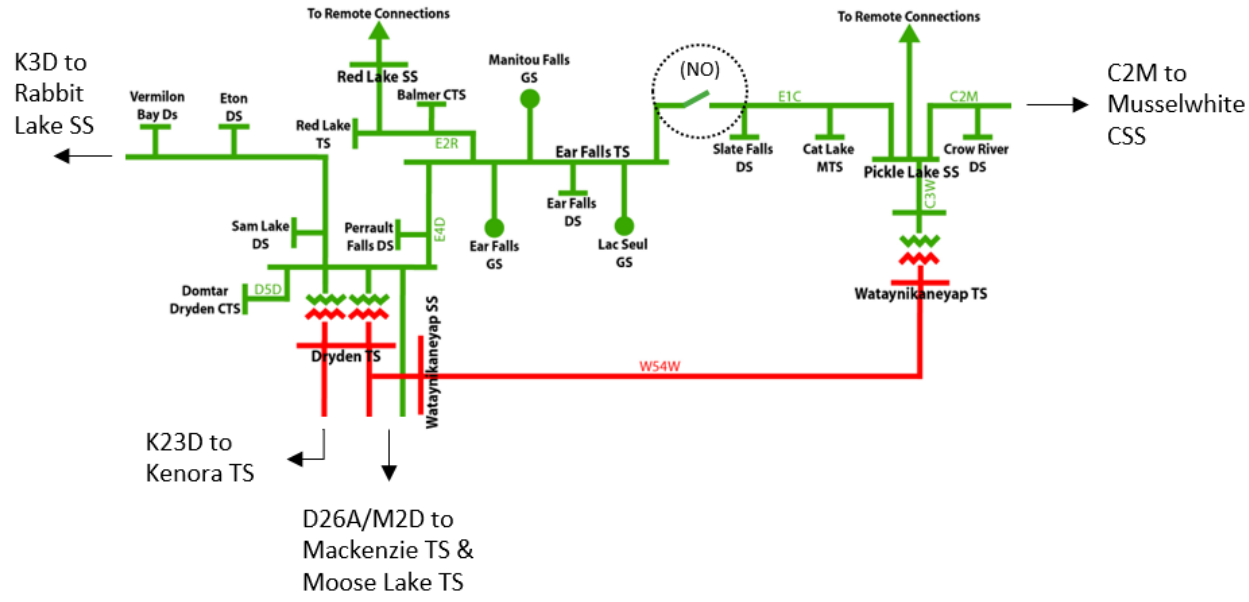

Figure 6-7 | Simplified Single Line Diagram of the Dryden and Pickle Lake Areas with Potential Normally Open Point

[16] The IESO's 2016 Recommended Scope of the new Line to Pickle Lake and Support Scope for the Remotes Connection Project is available on the Ontario Energy Board's priority transmission projects webpage.

With W54W in-service and connected to E1C via C3W, operating circuit E1C normally closed would result in a loop comprised of the E4D-E1C-W54W circuits. This arrangement would severely limit the transfer capability through E4D and W54W as documented in the 2016 W54W System Impact Assessment (SIA) report.[17] When operating with the E4D-E1C-W54W loop closed, loads in the Ear Falls area will remain connected through E1C via the 230 kV path following the loss of E4D. Post-contingency voltage collapse limits the E4D+W54W flow to 57 MW which is insufficient for supplying existing demand in the Ear Falls, Red Lake, and Pickle Lake areas. The SIA notes that E1C must be opened pre-contingency as a mitigating control action when flow exceeds 57 MW and that this could occur multiple times per day at existing demand levels.

Furthermore, the SIA found that with the E4D-E1C-W54W loop closed, the Manitou Falls and Ear Falls hydro generators would remain connected to the grid following the loss of E4D, which causes transient instability when the post-contingency flow on the E1C exceeds 30 MW. To ensure that transient stability of the generators is maintained, pre-contingency generation levels would need to be reduced such that post-contingency flow on E1C does not exceed 30 MW. This reduction of transfer capability on E1C not only violates ORTAC Section 4.1, which limits reduction in transfer capability that results from a new connection, but would bottle hydro-electric generation that is otherwise available to provide capacity to the Northwest system. Therefore, the SIA recommended that the E4D-E1C-W54W loop should be opened pre-contingency to prevent pre-contingency generation reductions.

Due to these documented issues, this IRRP reaffirms that E1C should be operated normally open once W54W is in-service with C3W closed. This configuration resolves the violations described above and the resulting system is adequate to serve forecast demand in the Ear Falls, Red Lake, and Pickle Lake areas. This configuration is consistent with the recommended scope for W54W (which was referred to as the "Line to Pickle Lake") in the 2015 North of Dryden IRRP. Note that operating E1C normally open enables W54W to relieve E4D which allows W54W to serve the dual purposes of improving the load meeting capability of both the Pickle Lake and Ear Falls/Red Lake areas. This was an important consideration that contributed to the recommendation for W54W.

However, with E1C operated normally open, another problem emerges. High voltage violations (voltages exceeding 127 kV) occur post-contingency under light load conditions. High voltages occur on the line end open of E1C and either Pickle Lake SS or Ear Falls TS depending on where the open point on E1C is located. High voltage violations are less severe when opening E1C near Ear Falls TS compared to near Pickle Lake SS. When E1C is open near Ear Falls TS, the most critical contingency is the loss of one of the existing 20 MVar reactors at Wataynikaneyap TS. The high voltage violations can be addressed by installing an additional 10 MVar reactor at or near Pickle Lake SS. The post-contingency voltages at nearby stations with and without this

[17] The 2016 W54W System Impact Assessment report is available on the IESO's Application Status webpage by searching for SIA ID 2016-567.

additional 10 MVar reactor are shown in Table 6-2. The post-contingency voltages exceed 127 kV at the E1C open line end and Pickle Lake SS for the loss of the existing 20 MVar reactor at Wataynikaneyap TS. Post-contingency voltages are maintained below 127 kV with the additional 10 MVar reactor.

Table 6-2 | Post-contingency Voltages with and without Additional 10 MVar Reactor at Pickle Lake SS with E1C Normally Open at Ear Falls TS

Bus/ Station Name	Post-contingency voltage (kV)	Post-contingency voltage (kV) with additional 10 MVar Reactor at Pickle Lake SS
E1C LEO	**130.7**	123.3
Pickle Lake 115	**127.7**	120.6
Watay 115	126	120.1
Watay SS 230	238	235.5
Dinorwic 230	237.8	235.6
Mackenzie 230	244.8	244
Musselwhite 115	120	115.1

The IRRP recommends that the IESO and Hydro One collaborate in the Regional Infrastructure Plan refine the location of the E1C open point and associated reactive compensation devices required. The E1C open point can be fine-tuned to minimize high voltages. The open point on E1C should consider the location and condition of existing switches as well as their accessibility for restoration purposes should E1C be needed to partially restore loads following a W54W or D26A contingency.

Furthermore, the Regional Infrastructure Plan should consider the installation of a voltage-based automatic switching scheme for the reactors at Pickle Lake SS, Wataynikaneyap TS, and Dinorwic Jct similar to existing switching schemes at other stations across the Northwest region. Voltage-based automatic switching would improve the transmission system's operational flexibility, help manage high voltage conditions currently experienced across the Northwest and help reduce post-contingency high voltages to the acceptable continuous maximum voltage within 30 minutes. Potential interactions with the existing Northwest reactor switching scheme should be considered as this scheme is developed.

6.3 Potential Needs and High Sensitivities

No firm regional supply capacity needs were identified in the Northwest in either the reference or high forecast scenarios. However, most of the growth in the Northwest is driven by large mining and industrial development which can add large, incremental blocks of demand with minimal lead time that can quickly use up remaining supply capacity. Through engagement with development proponents and stakeholders, the Working Group identified two areas in the Northwest, the Dryden/Ear Falls/Red Lake area and the Fort Frances area, where there is particularly strong development interest and where the existing transmission system, although adequate for current forecast scenarios, may become constrained if all known proposed projects materialize.

For these two areas, the IRRP studied high growth sensitivities to quantify the load meeting capability and identify the limiting phenomena on the existing system. This was accomplished by adding hypothetical loads at existing stations/busses to simulate new developments and increasing the hypothetical load until a planning standards violation was observed.

As discussed in Section 4.1, the IRRP did not study local connection requirements of any individual project. The purpose of the high growth sensitivity studies is to quantify system limitations so that growth can be more effectively monitored between regional planning cycles and future planning activities can be initiated in a timely manner if growth materializes. Regardless of the availability of regional supply capacity identified in the IRRP, customers seeking connection may be subject to additional requirements and limitations specified in Customer Impact Assessments (CIA) or System Impact Assessments (SIA).

6.3.1 Dryden/Ear Falls/Red Lake Load Meeting Capability

The Dryden/Ear Falls/Red Lake area hosts significant mining activity today. It includes the 115 kV system supplied from the Dryden TS autotransformers, circuit K3D from Rabbit Lake SS, and M2D from Moose Lake TS. The recently completed 230 kV Wataynikaneyap Transmission Project line W54W will help relieve constraints on the 115 kV circuit E4D, once the recommendations in section 6.2.3 are implemented, and no incremental capacity needs are anticipated in this area based on the current demand forecast.[18]

The area's load meeting capability (LMC) is a function of three nested local constraints as shown in Figure 6-8:

(1) Supply to the Red Lake subsystem including: Red Lake TS, Balmer CTS, and Red Lake remote communities

[18] Consistent with the recommendation in Section 2.1.5 (E1C Operation and High Voltage) and the needs discussed in Section 6.2.3, the IRRP technical studies assumes that E1C will be operated normally open at Ear Falls TS.

(2) Supply to the Ear Falls subsystem including: Ear Falls DS, Perrault Falls DS, and the Red Lake subsystem described above

(3) Supply to the Dryden subsystem including: Sam Lake DS, Eton Ds, Vermilion Bay DS, Domtar Dryden CTS, and the Ear Falls subsystem described above

An implication of this "nesting" is that, depending on where new loads connect, they could contribute to one or more subsystem needs. For example, a load connecting close to Dryden would contribute to needs in the Dryden subsystem only, whereas a load connecting at Red Lake would contribute to potential needs in all three subsystems.

The supply capacity in these subsystems may be further constrained by bulk system limitations on the 230 kV supply to the area West of Thunder Bay. Bulk system limitations are outside the scope of regional planning and will be addressed by the Waasigan Transmission Line Project.

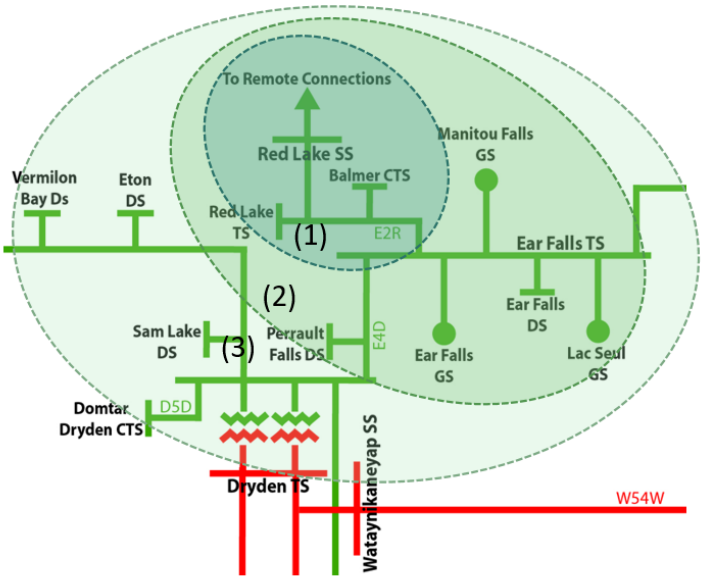

Figure 6-8 | Dryden/Ear Falls/Red Lake Nested Subsystems

Depending on which subsystem was being tested, the load meeting capabilities were derived by adding new hypothetical loads at Red Lake TS, Ear Falls TS, or the 115 kV bus at Dryden TS until a limiting phenomenon was encountered. The load meeting capabilities and the most limiting phenomenon or season for each subsystem is summarized in Table 6-3 and further described below. Note that, since the Northwest region is winter peaking, the IRRP forecast was developed for winter peak demand. However, since the Ear Falls and Red Lake subsystems can be thermally constrained, a summer peak forecast was also developed using the historical ratio between each station's summer and winter peaks.

Table 6-3 | Summary of Dryden/Ear Falls/Red Lake Load Meeting Capabilities

Subsystem	Load Meeting Capability	2032 Reference Peak Demand Forecast	2040 Reference Peak Demand Forecast
1. Red Lake	74 MW (summer thermal limitation)	61 MW summer peak	67 MW summer peak
2. Ear Falls	90 MW (summer thermal limitation)	67 MW summer peak	74 MW summer peak
3. Dryden	160 MW [19](summer/winter voltage decline)	129 MW winter peak	140 MW winter peak

6.3.1.1 Red Lake Subsystem

The Red Lake subsystem load meeting capability is limited in the summer by pre-contingency thermal overload of circuit E2R. The E2R continuous summer rating is 421 A which translates to a load meeting capability of approximately 74 MW.

The winter load meeting capability is higher than the summer capability. The winter load meeting capability is limited to 93 MW due to E2R pre-contingency thermal and voltage limitations. The winter E2R continuous winter rating is 528 A which translates to a load meeting capability of approximately 93 MW. 93 MW of load also causes pre-contingency voltage decline at Red Lake TS (i.e., voltages are under 113 kV). Note that the pre-contingency voltage limitation can be mitigated by installing appropriately sized voltage devices at the connection point of any new load. All load meeting capabilities described for the Red Lake and Dryden subsystems below assume that any new load will be accompanied by voltage devices to maintain adequate voltage performance at the point of connection.

Figure 6-9 below shows the Red Lake subsystem summer and winter peak demand forecast and associated load meeting capabilities.

The summer thermal limitation on E2R could be addressed by upgrading to higher rated conductors. There are several conductor options available with summer continuous ratings ranging from 590 A to 740 A.

[19] This LMC is significant higher than the existing Dryden Area Inflow (DAI) limit in existing System Control Orders documentation. This difference is mainly due to topology changes (i.e. new W54W). The IRRP sensitivity study also assumes that new loads will connect with appropriate voltage control devices installed at the point of connection which alleviates previously documented low voltage issues.

Upgrading to 740 A conductors would result in a summer load meeting capability of approximately 130 MW. Note that upgrading to higher rated conductors would also necessitate replacing existing structures to increase their height so that the conductors can be operated at a higher temperature. Furthermore, Red Lake TS would need an alternative supply while work on E2R is carried out. Upgrading E2R would cost approximately $23M (real $2022 overnight capital cost) based on high-level per km refurbishment costs for typical 115 kV wood pole lines.[20] The cost difference between different conductor choices is relatively insignificant. Note this is a planning-level estimate (-50% to +100%); material and labour costs have increased rapidly over the COVID-19 period and there is a high degree of uncertainty in future costs.

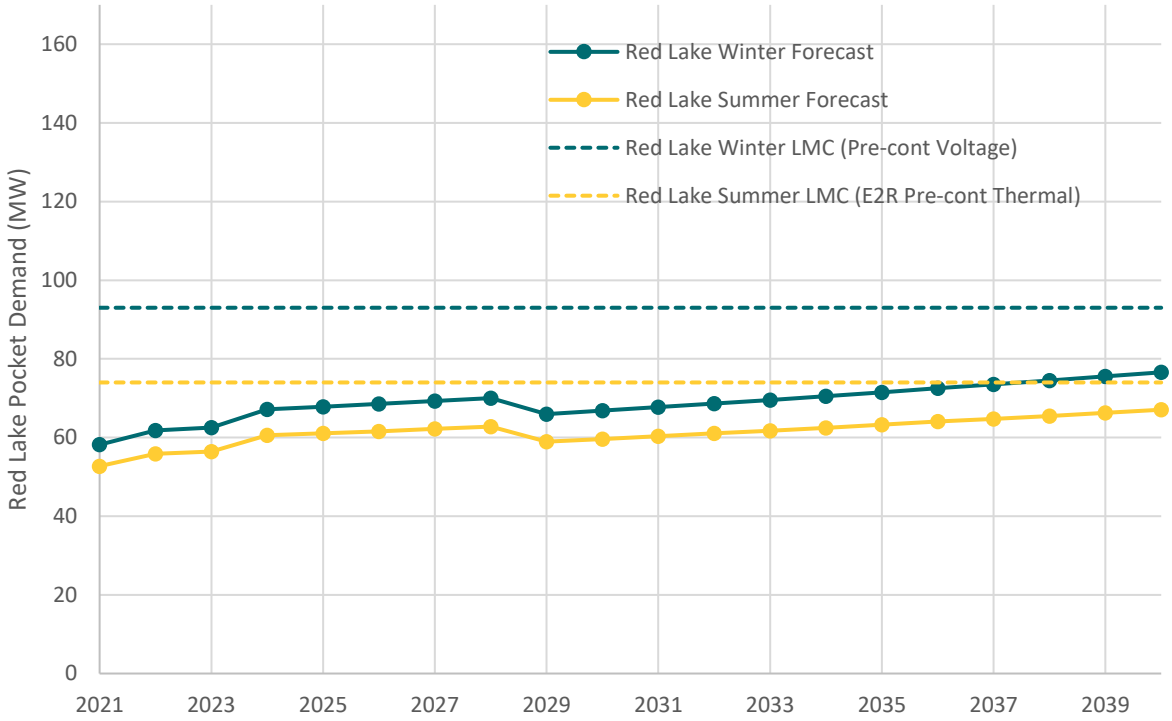

Figure 6-9 | Red Lake Subsystem Load Meeting Capabilities and Demand Forecast

E2R is approximately 75 years old. Hydro One anticipates that the average expected service life for the conductors is 90 years. The wood pole structures have a shorter expected service life at approximately 50 years. The end-of-life date for E2R will be based on actual asset conditions and no date has been determined for E2R as of 2022. If growth materializes, future planning

[20] The provided cost estimates do not include any associated upgrades that may be required to achieve the desired rating (e.g., raising poles, etc.) and should be viewed as high-level minimum costs.

studies should consider the cost of advancing E2R refurbishment as compared to alternatives such as local generation.

6.3.1.2 Ear Falls Subsystem

The Ear Falls subsystem load meeting capability is limited in the summer by E4D pre-contingency thermal overload. The E4D continuous summer rating is 410 A, which translates to approximately 72 MW. There is also a combined 18 MW of summer 98th percentile dependable hydro generation output from Ear Falls GS, Manitou Falls GS, and Lac Seul GS. Together the thermal capability and hydro generation results in a load meeting capability of approximately 90 MW.

Note that the winter load meeting capability is not expected to be limiting since it is significantly higher than the summer capability due to both the higher winter thermal rating of the circuit as well as higher dependable hydro generation output (approximately 64 MW of 98th percentile dependable hydro generation output).

Figure 6-10 below shows the Ear Falls subsystem summer demand forecast and load meeting capability.

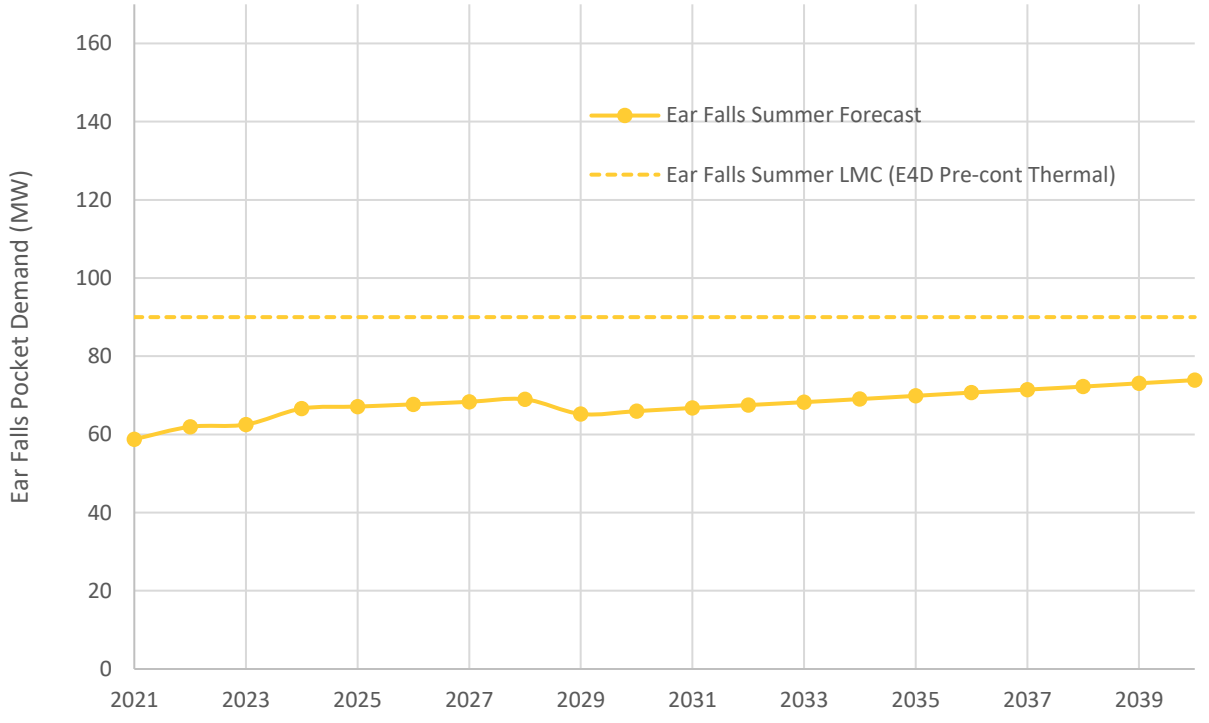

Figure 6-10 | Ear Falls Subsystem Load Meeting Capability and Demand Forecast

The summer load meeting capability for the Ear Falls subsystem can be increased to 130 MW by upgrading E4D with higher rated conductors (740 A summer continuous rating similar to conductors contemplated for E2R in the previous section). Upgrading E4D would cost approximately $35M (real $2022 overnight capital cost) based on high-level per km refurbishment costs for typical 115 kV wood pole lines.[21] Note this is a planning-level estimate (-50% to +100%); material and labour costs have increased rapidly over the COVID-19 period and there is a high degree of uncertainty in future costs. E4D is approximately the same age as E2R; future planning studies should also consider the cost of advancing E4D refurbishment as compared to alternatives such as local generation.

6.3.1.3 Dryden Subsystem

The Dryden subsystem load meeting capability is limited to 160 MW in both the summer and winter due to post-contingency voltage decline following the loss of D26A. When total demand in the Dryden subsystem exceeds 160 MW, the voltage decline at Dryden TS will exceed criteria (10% decline) as shown in Table 6-4. Note that for the purpose of deriving a conservative load meeting capability, a constant MVA load model was used as opposed to a voltage dependent load model.

Table 6-4 | Post-Contingency (D26A N-1) Voltage Change (160 MW Dryden Subsystem Total Demand)

Station	Pre-Cont Voltage	Post-Cont (Pre-ULTC) Voltage	Post-Cont (Post-ULTC) Voltage
Mackenzie TS	247 kV	242 kV	239 kV
Dryden TS	237 kV	216 kV	214 kV (10% decline)
Kenora TS	243 kV	229 kV	230 kV
Fort Frances TS	244 kV	229 kV	231 kV

Dryden TS post-contingency voltage decline will no longer be limiting once Phase 2 of the Waasigan Transmission Line Project is built since it will provide a redundant path from Mackenzie TS to Dryden TS parallel to D26A. Without Phase 2, the post-contingency voltage decline could be addressed by a dynamic voltage device at Dryden TS, but this was not further studied since the device requirements would depend on the connection arrangement and characteristics of future loads.

[21] The provided cost estimates do not include any associated upgrades that may be required to achieve the desired rating (e.g., raising poles, etc.) and should be viewed as high-level minimum costs.

Note that the D26A + K23D N-1-1 contingency results in more severe voltage decline but could be addressed by a load rejection scheme since special protection systems are permitted by ORTAC for outage conditions.

Figure 6-11 shows the Dryden subsystem summer and winter peak demand forecast and associated load meeting capabilities.

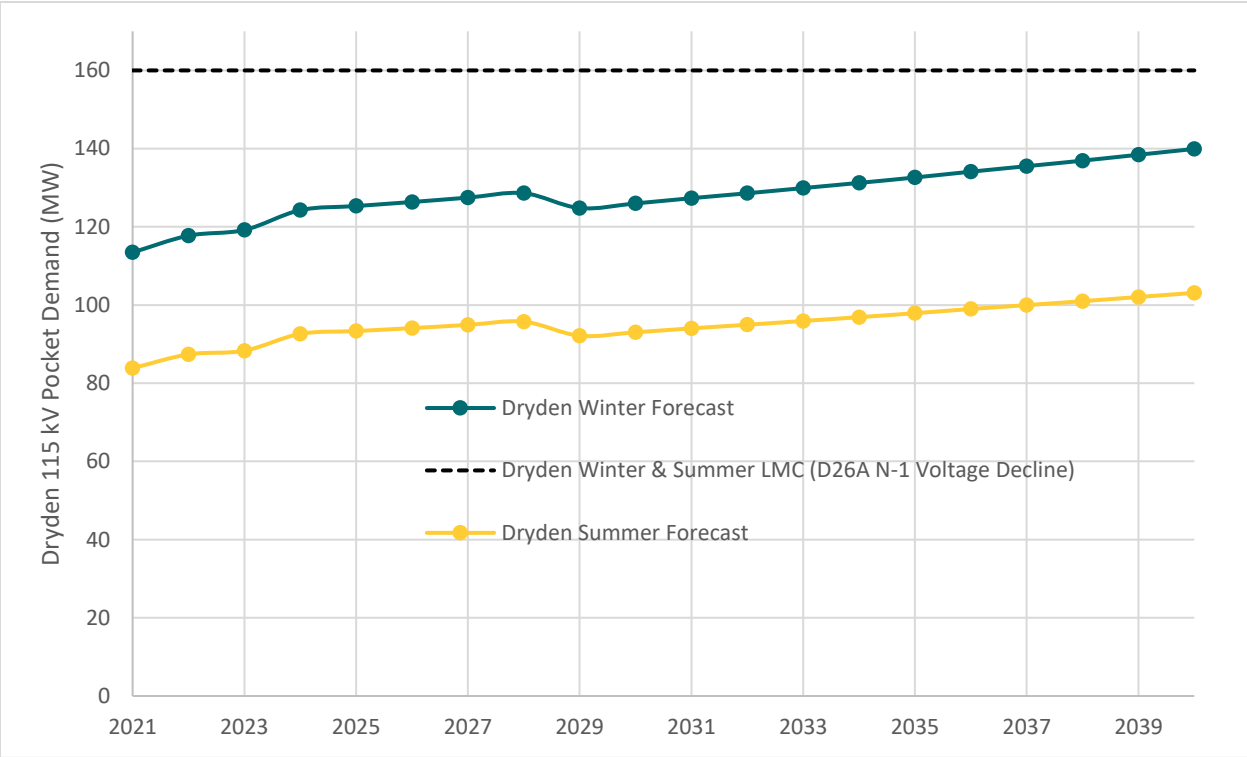

Figure 6-11 | Dryden Subsystem Load Meeting Capabilities and Demand Forecast

6.3.2 Fort Frances Load Meeting Capability

The Fort Frances area includes the 115 kV system supplied from the Fort Frances TS autotransformers and circuit K6F from Rabbit Lake SS as shown in Figure 6-13. For this high-growth sensitivity study, the Fort Frances area includes Fort Frances MTS, Burleigh DS, and a new hypothetical load connected directly to the 115 kV bus at Fort Frances TS. The stations connected to K6F do not materially impact the load meeting capability of the Fort Frances area.

Forecast demand in the Fort Frances area is relatively modest and is expected to grow from 21 MW today to 23 MW in 2040. However, the Working Group is aware of multiple inquiries from potential large new customers seeking connection in the Fort Frances area. Their combined load exceeds 100 MW but there is a high degree of uncertainty in whether their developments will proceed and where they may choose to connect to the grid. Some potential customers are also considering connection points in other parts of the province.
