1.0 DISTRIBUTION SYSTEM PLAN

On October 18, 2012, the Ontario Energy Board ("Board" or "OEB") released its *Renewed Regulatory Framework for Electricity Distributors: A Performance-Based Approach* ("RRF"), and on March 28, 2013 the Board issued its filing requirements for Consolidated Distribution System Plans pursuant to the RRF. The Board's RRF framework calls for distributors to focus on customer needs and preferences and to demonstrate that their investment plans support cost- effective planning and operation of the distribution network.

The Board expects each distributor to prepare its application to fit its particular circumstances and to measure its performance to ensure the company is delivering on its plan. The RRF emphasizes the achievement of outcomes that ensure that Ontario's electricity system provides value for money for customers. The Board believes that emphasizing results rather than activities will better respond to customer needs and preferences, and enhance distributor productivity and promote innovation.

MAP TO OEB REQUIREMENTS

Hydro One's Distribution System Plan has been prepared in accordance with Chapter 5 of *Filing Requirements for Electricity Transmission and Distribution Applications* (March 28, 2013) ("DS Plan Filing Requirements"). Table 1 below maps each Chapter 5 requirement to a section in this DSP.

Table 1 Mapping of OEB Requirements to DSP

THIRD PARTY REVIEW OF DSP

To ensure that the Hydro One DSP was complete and constructed in accordance with industry practice, Hydro One sought counsel from an independent third party. AESI Inc. ("AESI") is an international firm that has consulted with several local distributors in Ontario and has significant experience in preparing system plans at many utilities across the province. AESI was asked to review the Hydro One DSP and provide advice with respect to suitability and compliance. Hydro One relied upon that advice in preparing the DSP.

Exhibit B1, Schedule 1, Tab 2 includes the attestation of AESI that this DSP satisfies the *OEB's Chapter 5 Consolidated Distribution System Plan Filing Requirements*. Included, as well, is a final report outlining the findings and recommendations from their review.

INFORMATION FOR ACQUIRED UTILITIES

Hydro One, since its last rebasing of rates for 2015-2017, has acquired three local distribution companies – Haldimand County Hydro Inc. ("HCHI"), Norfolk Power Distribution Inc. ("NPDI"), and Woodstock Hydro Services Inc. ("WHSI") (collectively the "Acquired Utilities"). Operationally, all three of the Acquired Utilities have been integrated into normal Hydro One operations. The investment planning for these areas follows the process described in Section 2.1 of the DSP. The Asset registry information and the Asset Strategies employed to monitor and maintain the Acquired Utilities' assets are included in Sections 2.2 and 2.3 of the DSP.

For rate making purposes the Acquired Utilities have been kept separate from Hydro One. The financial information presented in the DSP excludes the financial information for the Acquired Utilities until January 1, 2021. Details regarding the financial integration of the Acquired Utilities are included in Exhibit A, Tab 7, Schedule 1.

Separate DSPs were not prepared for each of the Acquired Utilities. Details regarding the characteristics of the assets of the Utilities are included as Appendix A attached to the Hydro One DSP at Exhibit B1, Tab 1, Schedule 1.

1.1 (5.2.1) DISTRIBUTION SYSTEM PLAN OVERVIEW

Hydro One's Distribution System Plan (DSP) is the product of an investment planning process in which Hydro One engaged directly with customers to learn their needs and preferences. Customers want their rates to be kept as low as possible. To specifically address these rate sensitivities, Hydro One has right-sized its 2018 capital plan by increasing its efficiency and reducing its OM&A costs before asking customers to pay higher rates. The DSP reflects Hydro One's plan to appropriately prioritize and pace its capital investments over the 2018 to 2022 period which will align: (a) customer needs to keep rates as low as possible and a preference to maintain current service levels; (b) asset needs driven by condition and compliance requirements; and (c) rate impacts.

The process to prepare a Distribution System Plan is long, complex and iterative. The process involves accumulating and assessing a significant amount of information that supports decisions related to a system with assets worth $7.7 billion (2018 distribution rate base) that serves approximately 1.3 million residential customers and a network of unique commercial and industrial customers with varying needs and preferences.

For this Application, Hydro One is very aware that customers are experiencing increasing and, in some cases, unmanageable electricity bills. These increases have been driven by many factors, including investments by generators, the need to invest in the end-of-life wires infrastructure and material changes in generation mix, from lower-cost coal to a higher reliance on cleaner and more efficient natural gas, nuclear and renewable generation. In addition, conservation and demand management initiatives have increased costs, on a per kWh basis, as the predominantly fixed system investment is now being recovered over lower total Ontario demand.

Hydro One's approach has been shaped by: (i) a thorough investigation of opportunities to reduce its costs and increase efficiencies; (ii) ensuring investments support specific customer feedback on needs and preferences; and (iii) reducing or deferring investment levels to align customer rate impacts and potential impacts on reliability.

Hydro One cares about all of its customers. It is very concerned about the effect of electricity costs on its most vulnerable customers. In some cases, bills for a low-density customer, even after the upcoming provincial rebates and existing support programs, can represent 18% of household net income. Studies presented to the OEB in the past have drawn the affordability line at 4-6% of household net income. About 71,000 Hydro One customers exceed the Statistics Canada Low-Income Cut-offs, with 3,500 of those experiencing electricity costs greater than 10% of net income. Hydro One's customer service representatives manage these customer impacts with as much empathy as possible and encourage these customers to fully avail themselves of existing support programs. Hydro One is also participating in OEB initiatives and studies, such as the First Nations rate recommendations, and is sharing and communicating specific support programs and ways to reduce consumption within First Nations communities.

Initially, Hydro One prepared an asset investment plan, known as Plan A, which focused on maintaining or improving reliability for customers, and responded to specific feedback received from a wide variety of customers. It included significant efficiency improvements and focused on reducing backlog of deteriorated assets over the five-year period. Plan A resulted in a 7.1%[1] Hydro One rate increase in 2018 (average of 3.8% over the five years), and forecasted improvement of approximately 6% in SAIDI and 4%

---

[1] The rate impacts and reliability projections included in Section 1.1 are equal to the numbers used during the business plan review period ending November 2016 described in this section. Current rate impacts using revised data have subsequently been calculated and a complete list of the rate impacts are included in Exhibit H, Tab 4, Schedule 1.

in SAIFI[2] related to the company's most significant areas of reliability risk over the five-year period. Plan A was supported by detailed analysis, iteration and assessment of investment candidates and asset sustainment plans, and reductions of certain candidate investments.

Hydro One then prepared a detailed plan using lower levels of investment than in the Plan A recommendation. Based on these inputs and feedback from executive management, an alternative investment "Plan B" was produced that reduces the rate impact in 2018 by 1%, to 6.2% (average of 3.5% over the five years), and also delivers a reliability improvement (approximately 3% SAIDI, 2% SAIFI).

The Plan A and Plan B alternatives were further discussed with the Executive Leadership Team and, subsequently, the Board of Directors. These discussions explored further options to mitigate rate effects and, in particular, options to reduce the effect on customer rates in 2018 while maintaining responsible system investments, acceptable reliability and other outcomes.

Hydro One also considered what would be required to achieve the lowest 2018 rate increase without material disruption to its operations. Presented as the "Plan C" scenario, Hydro One's conclusion was that this option as a whole was not viable due to the estimated degradation of approximately 2% in both SAIDI and SAIFI that would result from such a reduced level of sustainment capital investment and reductions in work programs and the associated increased backlog of assets in poor condition.

---

[2] Detailed, updated SAIDI and SAIFI projections by component are included in Section 2.4.

However, Hydro One also considered an option known as "Plan B – Modified." This option reduces the immediate impact on rates in 2018 to 5.4% while holding reliability performance constant over the planning period. The remainder of the DSP details the process followed to arrive at Hydro One's final investment plan, Plan B – Modified.

Section 1 of the DSP provides information on critical inputs into the formation of Hydro One's investment plan, specifically, customer engagement results, regional plans, internal productivity analyses and external benchmarking analyses.

Section 2 discusses the Investment and Asset strategies followed by Hydro One with respect to its asset base. The planning and optimization processes undertaken to determine the appropriate portfolio of investments and a detailed description of the system and its components are included here.

Section 3 describes the specifics about the selected investments including a set of Investment Summary Documents ("ISD") describing all investments over $1 million.

1.1.1 (5.2.1 A) KEY ELEMENTS OF THE DSP

Alignment of Business Objectives

The Business Objectives for Hydro One's Distribution System Plan reflect its assessment of customer needs and preferences. Other drivers of investment planning include public and worker safety, productivity and efficiency improvements, compliance with regulations, codes and rules and environmental sustainability.

Hydro One has appropriately prioritized and paced the elements of its proposed plan to align customers' needs regarding service levels with rate impacts and system reliability. Complete details on Hydro One's customer engagement activities are in Section 1.3.

Hydro One's DSP is the result of applying its planning process to produce an investment plan that meets Hydro One's Business Objectives. These Objectives align with the OEB's Renewed Regulatory Framework Performance Outcomes. The Business Objectives and processes are explained in detail in Section 2.1. The alignment of Hydro One Business Objectives and RRF Outcomes is listed in the table below for convenience.

Table 1: OEB Performance Outcomes and Hydro One Business Objectives

OEB RRF Performance Outcomes	**Hydro One Business Objectives**
Customer Focus Services are provided in a manner that responds to identified customer preferences	**Customer** • Improve current levels of customer satisfaction • Engage with our customers consistently and proactively • Ensure our investment plan reflects our customers' needs and desired outcomes
Operational Effectiveness Continuous improvement in productivity and cost performance is achieved; and distributors deliver on system reliability and quality objectives	**Safety** • Drive towards achieving an injury-free workplace for employees and the public
	Reliability • Provide reliability consistent with customer expectations
	Productivity • Actively control and lower costs through OM&A and capital efficiencies
	Employees • Achieve and maintain employee engagement
Public Policy Responsiveness Distributors deliver on obligations mandated by government (e.g., in legislation and in regulatory requirements imposed further to Ministerial directives to the Board).	**Shareholder Value** • Ensure compliance with all codes, standards, and regulations • Partner in the economic success of Ontario
	Environment • Sustainably manage our environmental footprint

OEB RRF Performance Outcomes	Hydro One Business Objectives
Financial Performance Financial viability is maintained; and savings from operational effectiveness are sustainable.	**Financial Benefit** • Achieve the ROE allowed by the OEB • Manage planning and spending to mitigate customer impacts

Hydro One's planning process produced a sustainable and prudent five-year plan that will allow the company to deliver on the Business Objectives listed above from 2018 to 2022. This plan seeks to achieve the desired Business Objectives over the long term by managing foreseeable changes and requirements on its distribution system.

Regional Planning

Based on the results of regional planning activities described in Section 1.2, a number of investments are included in the DSP which are related to regional infrastructure needs. This is aligned with customer preferences to ensure adequate capacity is available and to connect new customers to the system. These consist of capital contributions to the transmitter, for new or upgraded connection facilities and construction of new feeders to utilize such transmission connection capacity.

Customer Engagement

The DSP is designed to show how Hydro One understands customers' needs and preferences and that this understanding is reflected in its investment plan. Some of the specific measures being taken to address the customer engagement information are listed below.

Through customer engagement activities, customers indicated that keeping rates low was their top priority and many customers, especially residential customers, ranked reliability performance second to rate impacts. In alignment with customer needs and preferences, Hydro One has deliberately deferred some early year capital spending in order to pace investments in such a way as to minimize rate impacts and offset the effects of a reduced load forecast. This includes managing rate of replacement and, where appropriate, accepting short-term, small scale reliability impacts to reduce or defer capital spending requirements and minimize rate impacts.

A top priority for Large Customers is to improve power quality. To address this, Hydro One has created an OM&A program to assist Large Distribution Account customers with investigations to determine the source of the power quality issue they are experiencing. Furthermore, a capital power quality program has been incorporated into the plan. Hydro One has also increased the funding for reliability enhancement projects to specifically target Large Distribution Account ("LDA") and mid-size industrial customers.

Residential and Small Business customers requested that Hydro One maintain its existing level of reliability. In an effort that shows an understanding of its customers, Hydro One has assessed the condition of its key assets and has developed an investment plan that properly paces renewal investments to sustain reliability performance across the province. By responding to customer preferences, Hydro One has created a distribution outcome that is valued by its customers. Supporting this are System Renewal projects and programs such as the Pole Replacement Program, Distribution Station Refurbishment Projects, and Line Renewal Projects.

The pole replacement program will be replacing 77,400 poles over the planning period to manage the volume of poles in poor condition. Similarly, the number of distribution stations that are refurbished has been established to sustain the condition of the fleet. Reliability performance of specific feeders that have outlier performance will be addressed by correcting the root cause of reliability on a case by case basis. Some feeder performance improvements will be accomplished through remote monitoring and control of switches and breakers as well as fault locating technology and additional protective devices.

Further details regarding customer engagement are included in Section 1.3.

Outcome Measures

Productivity and outcome measures are used to drive continuous improvement in asset management planning, work execution, and in customer-oriented performance. The measures are driven by the alignment of Hydro One's performance measures with its Business Objectives and the corresponding RRF Outcomes described in Table 1 above. Furthermore, Section 1.4 details the outcome measures that will demonstrate performance in:

- Customer Focus;
- OM&A and Capital Efficiencies;
- Managing Public Safety Risk;
- Providing Reliability Consistent with Customer Expectations; and
- Public Policy Responsiveness.

Productivity

To support the accomplishment of its Business Objectives, Hydro One has reaffirmed its commitment to continuous improvement and providing outcomes which are valued by customers, including cost efficiency. This renewed focus on productivity has become central to the planning and execution of work programs across the Company.

Hydro One has undertaken a number of initiatives to reduce costs while maintaining service quality and work outputs. These initiatives are the result of an internal evaluation of the Company to determine where productivity improvements could be made. Recommendations were made and evaluated to determine feasibility and to ensure that sustainable improvement would be the result. These quantifiable cost improvements were then embedded in the business plan with respective managers accountable for delivering the expected savings.

The following items summarize the planned productivity initiatives.

- More effective procurement programs, including investments in new processes and tools;
- Reductions in administrative expenditures through improved processes and optimization of internal staff skills;
- Rationalization of IT spending;
- Improved field efficiency through improved work planning; and
- Development of analytical measures, including more linkages for projects and programs to reliability performance to enable tracking of outcomes and better leverage of existing spending.

More details on these items and the specific initiatives planned are included in Section 1.5.

Benchmarking

Benchmarking is increasingly being referenced as a means of monitoring company performance. With the vision of excellence in execution, Hydro One has conducted the following studies:

- Total Factor Productivity;
- Pole Replacement and Station Refurbishment;
- Vegetation Management;
- IT Budget Assessment;

- Total Compensation; and
- Total Cost.

In summary, Hydro One is addressing the following key recommendations:

- Institute productivity initiatives to lower cost (see Section 1.5 for details on those initiatives);
- More comprehensive but less frequent pole inspections;
- Investigate the feasibility of pole refurbishment;
- Increase pole replacement rate;
- Implementing a formal data governance process for equipment data;
- Enhance cost and work completion reporting;
- Develop a more comprehensive set of key performance indicators on reliability, cost and asset health;
- Continue expansion of Hydro One's station-centric approach to refurbishment; and
- Maintain the current condition profile and reliability for stations.

The findings and recommendations from the studies are described in detail in Section 1.6.

Asset Management Process

Infrastructure Asset Management is the combination of management, financial, economic, engineering, and other practices applied to physical assets, with the objective of providing a level of service that is consistent with customer needs and preferences, consistent with asset needs and responsive to rate impacts. Hydro One's asset management goal is to monitor system assets and determine the optimal timing of asset maintenance and capital investments throughout the asset life cycle. This is done to manage risks and to support the achievement of Hydro One's Business Objectives, while managing total cost and customer rate impacts.

For the planning of capital investments, Hydro One utilizes a comprehensive investment planning process for identification, prioritization and optimization of asset and capital investments. An overview of the investment planning process is included in Section 2.1.

On the asset maintenance side, strategies are developed based on the condition and requirements of the various assets themselves. A high level summary of Hydro One's distribution system and associated key distribution assets outlining the specific maintenance and replacement strategies for each of these various assets is contained in Section 2.2.

As described in Section 2.3, a large number of Hydro One's assets require significant investment to maintain supply reliability and to mitigate the associated risks to Hydro One's Business Objectives.

Hydro One has a number of proactive investment programs that aim to pre-emptively address critical assets where a failure would impact a large number of customers. Hydro One has maintenance programs to address less pervasive assets and to quickly respond to events such as asset failures on a reactive basis. Finally, Hydro One has comprehensive demand-driven programs that react to unforeseen incidents that affect the entire system, such as storms or other external factors.

Capital Expenditure Plan

The investments reflected in the DSP are grouped into four categories: System Access, System Renewal, System Service, and General Plant. Nearly half of Hydro One's distribution capital plan is focused on System Renewal investments where an asset's condition warrants replacement. A summary of Hydro One's capital expenditure plan by these four categories is provided in Tables 2 and 3 below.

Table 2: 2018 – 2022 Capital Spending Forecast ($ Million)

Category	**2018**	**2019**	**2020**	**2021**	**2022**
System Access	154.6	157.6	160.9	165.9	170.0
System Renewal	248.6	318.7	336.7	362.5	451.1
System Service	81.8	93.4	85.6	78.8	69.5
General Plant	149.0	187.1	135.8	133.4	136.6
Total	**633.9**	**756.8**	**719.0**	**740.7**	**827.2**

Table 3: 2018 – 2022 Capital Spending Forecast (% by Category)

Category	**2018**	**2019**	**2020**	**2021**	**2022**
System Access	24%	21%	22%	22%	21%
System Renewal	39%	42%	47%	49%	55%
System Service	13%	12%	12%	11%	8%
General Plant	23%	25%	19%	18%	17%
Total	**100%**	**100%**	**100%**	**100%**	**100%**

Investment Summary Documents ("ISD") detailing the specifics for each material investment with spending greater than $1 million in any one year are listed in Section 3.7 and included in Section 3.8. An overview of the main factors driving the investments in each of these categories is included below.

System Access

New connections, line relocations, and service upgrades make up the bulk of activities in this category. Most of this spending is non-discretionary in nature and is dominated by the New Load Connections program (ISD SA-04) as it relates to providing customers with access to the system. Average spending is expected to increase less than 0.2% over the forecast period.

System Renewal

System Renewal investment costs are projected to increase by an average of 12.3% annually during the forecast period. Storm damage restoration and trouble calls, pole replacements, and distribution station refurbishments (ISD SR-07, ISD SR-09, and ISD SR-06, respectively) make up the bulk of activities in this category. Storm damage restoration and trouble call costs have been forecast based on multi-year historical experience and are expected to remain stable and consistent over the period of the DSP with normal year over year volatility due to weather patterns.

The pole replacement program (ISD SR-09) is planned to be lower in 2018, to address customer rate sensitivities. The program will then increase until 2020 and level off in 2021 and 2022. There is a low reliability impact associated with this plan. Hydro One's goal is to sustain or modestly improve the condition of the pole fleet through the investment planning period.

In order to align customer rate sensitivities with rate impacts, the station refurbishment program (ISD SR-06) is expected to decrease in 2018 and then continue to increase until 2020. This also will have limited reliability impacts over the short term and the increase towards the end of the plan reflects the growing number of assets forecast to be in deteriorated condition and requiring refurbishment to avoid negative reliability performance impacts.

A significant increase in projected spending for 2022 reflects the required replacement of smart meters that begin reaching the end of their useful life (ISD SR-14).

System Service

After 2018, System Service investment costs are projected to trend downward over the forecast period. Hydro One expects variability from year to year based on specific investment needs but spending over the 5 year period is expected to increase by an average of 0.8% annually. The bulk of these investments address the system constraints caused primarily by increases in load and ensure that customers continue to receive consistent service. To alleviate constraints, a multitude of investments throughout the province are planned to upgrade the capacity of Hydro One's distribution assets. Material investments designed to upgrade capacity include System Upgrades Driven by Load Growth (ISD SS-02). Hydro One has selected and is targeting the feeder performance outliers on the system for improvement (ISD SS-06). Hydro One will expand this program throughout the forecast period. This investment will improve system reliability for feeder performance outliers.

General Plant

The largest single portion of General Plant spending supports transport and work equipment investments (ISD GP-01). The next largest portion funds general facility improvements (ISD GP-02). General Plant investment costs are generally expected to decline modestly until the end of the forecast period in 2022 except for the spending associated with the planned new Integrated System Operations Centre (ISD GP-18). This will replace the existing backup power system control and telecommunications management centres and accommodate a new security operations centre to meet business and regulatory requirements.

Overall, General Plant investments are expected to decline over the period by an average of 1.4% per year.

Further Details on the Capital Expenditure Plan are included in Section 3.0.

1.1.2 (5.2.1 B) COST SAVINGS

To support the accomplishment of its Business Objectives, Hydro One has reaffirmed its commitment to continuous improvement and providing outcomes which are valued by customers, including cost efficiency. This renewed focus on productivity has become central to the planning and execution of work programs across the company.

Hydro One has undertaken a number of initiatives to reduce costs while maintaining service quality and work outputs. These initiatives are the result of an internal evaluation of the company to determine where productivity improvements could be made. Recommendations were made and evaluated to determine feasibility and to ensure that sustainable improvement would result, leading to reduced customer rates. These quantifiable improvements were then embedded in the business plan with respective managers accountable for delivering the expected savings. The planned savings are summarized in the table below. Details of the major productivity initiatives and forecast savings are included in Section 1.5.

Table 4 - Productivity Savings Forecast Summary

$ Millions	**2018**	**2019**	**2020**	**2021**	**2022**
Capital	25.5	26.8	32.2	33.7	34.6
OM&A	34.5	40.5	43.2	45.5	49.8
Corporate Common	3.2	3.3	3.3	3.3	3.3
Total Savings	**63.2**	**70.5**	**78.7**	**82.5**	**87.6**

Witness: Darlene Bradley

1.1.3 (5.2.1 C) PERIOD COVERED BY THE DSP

The DSP covers the historical period from 2013 to 2016, the Bridge period of 2017, where the financial information is based on the first quarter forecast for the year end totals, and the test years from 2018 to 2022.

1.1.4 (5.2.1 D) VINTAGE OF THE INFORMATION

Information contained in this DSP is considered current as of the end of 2016. The asset assessment information utilized in the report (e.g., condition data and performance data) is based on data as of August 2016 to allow time to process and analyze the information to facilitate preparation of the DSP for this rate filing. The asset registry information is current as of October 2016 to allow adequate time for incorporation into the DSP.

1.1.5 (5.2.1 E) CHANGES TO ASSET MANAGEMENT PROCESS

Since Hydro One's last distribution application, it has implemented several improvements to its asset management process, such as restructuring the training process and content, improving data quality assurance and enhancing the enterprise engagement experience.

Investment Planning Training

Investment planning training was restructured into major components of the overall process to assist planners and management in the development of investment plans.

The first training segment outlines key influences on the investment planning process, such as regulatory requirements and details various aspects, requirements and deliverables during the process cycle. This segment is to help ensure planners and managers understand the expectations and conditions in which to develop plans.

The second segment was developed to assist planners in developing appropriate risk assessments for candidate investments. Illustrative examples are used to help planners understand the alignment of investments to the overall corporate business objectives and foster consideration of alternative approaches to articulate investment risk.

The third segment details the elements of the Asset Investment Planning ("AIP") tool to ensure planner awareness of optimization criteria that would affect investment candidates during the optimization process.

In the interest of operating as one company, Hydro One structured training sessions for each of the key asset management business units involved in the planning process to create a focused environment and ensure consistency across the planning groups. Further review of the investment planning process resulted in an initiative for management training on optimization. This detailed overview provides management insight into the optimization process and its effect on their candidate investments within Hydro One's overall investment portfolio.

Data Quality Assurance

The quality assurance process within the investment planning process was further developed to ensure the investment plan is successful in meeting customer expectations and corporate business objectives. Enhancements to the quality assurance process include weekly reporting to planners and management of investment data quality issues, a checklist for management review and a dedicated risk calibration session prior to optimization to promote risk assessment consistency across planning groups. Mitigation of potential issues in advance of optimization sets the appropriate criteria for investment candidates during optimization and warrants a more effective investment plan as a result.

A risk to corporate project prioritization is related to consistency of the risk assessments across planning groups. Hydro One continues to employ quality assurance to harmonize these assessments and build a more standardized planning process across the various planning groups.

Enterprise Engagement

Enterprise engagement is used to describe the collaboration of stakeholders, planning and operations, during the investment planning process. Previously, this was a specific dedicated segment held during post-optimization. However, the concept has now been further developed in order to foster communication between stakeholders throughout the investment planning process. Stakeholder sessions were implemented prior to the start of the investment planning process to set expectations, gather feedback of any future concerns and ensure fundamentals, such as unit cost updates, are in place as a foundation to success. Collaboration during the development of an investment candidate promotes consideration of appropriate unit costs, execution strategies and historical results leading to a more robust investment definition and strategy. The dedicated post-optimization enterprise engagement segment, which is described in Section 2.1.5.2, was lengthened to support a thorough review of resource capabilities, execution risks and assurance of outcome measures.

1.1.6 (5.2.1 F) WORK CONTINGENT ON HISTORIC/FUTURE ACTIVITIES

Some investments in the General Plant and System Service categories are contingent on the outcome of ongoing activities. The level of System Access investment related to connecting new customers, distributed generation connections or third party infrastructure projects is dependent on externally-driven requests.

Hydro One Distribution is commonly required to make a capital contribution to support required capital investments on the transmission system. These transmission assets are needed in order to accommodate Hydro One Distribution load increases. These investments are categorized as General Plant investments. General Plant investments related to Hydro One Distribution's capital contribution for investments on the transmission system are contingent on the approval and schedule of the associated transmission projects. A list of the investments to which Hydro One Distribution is forecast to make capital contributions during the period of the DSP are:

- Leamington TS, (ISD GP-25);
- Hanmer TS, (ISD GP-26); and
- Enfield TS, (ISD GP-27).

System Service investments to fund the new Leamington TS and Enfield TS feeder development projects are contingent on the approval and schedule for Hydro One's Leamington TS and Enfield TS transmission investments.

Several General Plant investments are common to both Hydro One's transmission and distribution businesses. These common investments are contingent on the approval of Hydro One's transmission portion of the investment.

1.2 (5.2.2) COORDINATED PLANNING WITH THIRD PARTIES - REGIONAL PLANNING

Planning transmission and distribution infrastructure on a regional basis helps promote the cost effective development of the electricity infrastructure in Ontario. This is one of the key guiding principles in the Board's Renewed Regulatory Framework[1] requirements which states that infrastructure planning on a regional basis, between licensed transmitters and distributors, is to be undertaken to ensure that regional issues and requirements are integrated into the utility's planning processes.

Hydro One Distribution is actively involved in the regional planning process. This is consistent with Hydro One's business objectives of addressing customer needs and responding to public policy initiatives as well as contributing to the continued economic success of the province.

The following sections outline: (a) the regional planning process as outlined in the "The Process for Regional Infrastructure Planning in Ontario" report[2] endorsed by the Board; (b) Hydro One Distribution's participation in the consultation process; and (c) the status of regional planning activities and how these are reflected in the distribution system plan.

[1] http://www.ontarioenergyboard.ca/oeb/_Documents/Documents/Report_Renewed_Regulatory_Framework_RRFE_20121018.pdf - Page 39
[2] http://www.ontarioenergyboard.ca/oeb/_Documents/EB-2011-0043/PPWG_Regional_Planning_Report_to_the_Board_App.pdf

1.2.1 (5.2.2 A) OVERVIEW OF THE REGIONAL PLANNING PROCESS

Regional planning addresses supply and reliability issues at a localized level. The regional planning process focuses on coordinating the planning of transmission-level investments that provide supply to more than one distributor. Distribution-level investments are considered when such investments address a regional need more effectively than other transmission options.

Figure 1 illustrates the various phases of the regional planning process and the trigger, process lead, and outcome for each respective phase, as documented in the "The Process for Regional Infrastructure Planning in Ontario" report endorsed by the Board. It is intended that this process be repeated for each of the 21 regions in the province every five years. The process may be more frequent, depending upon the emergence of new needs.

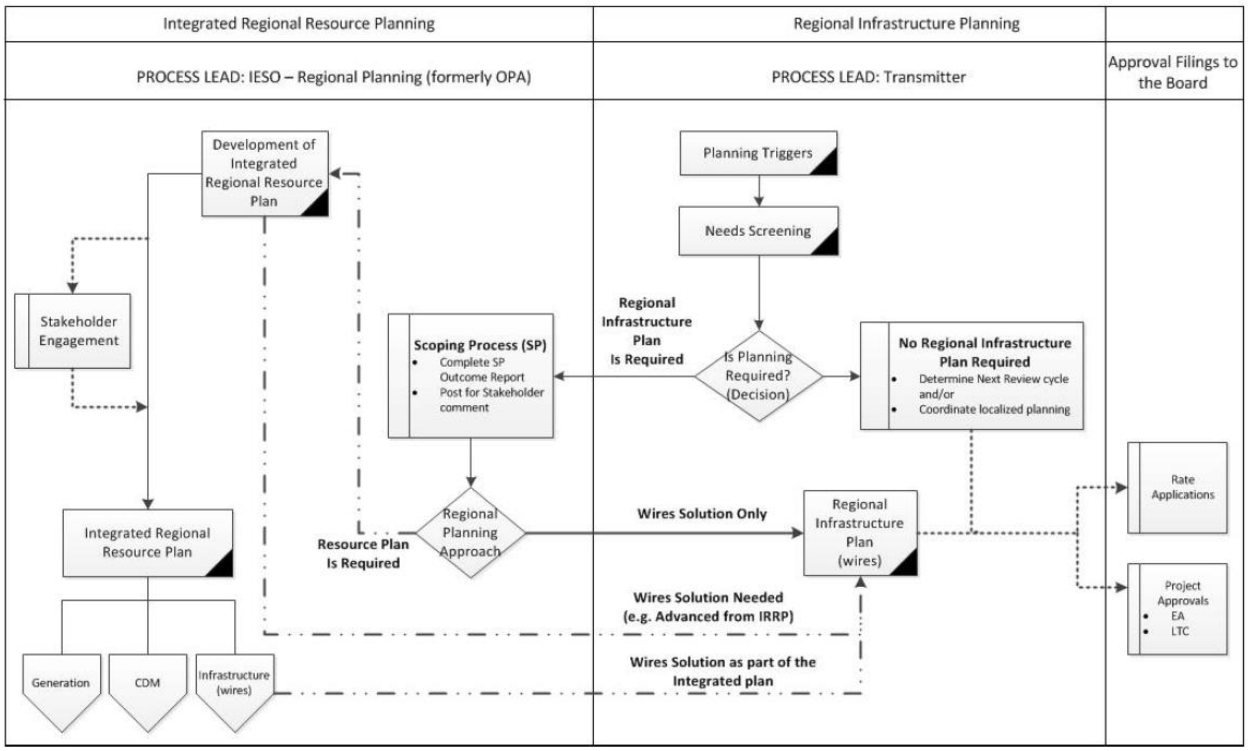

Figure 1 - Regional Planning Process

In general, the process consists of the following phases:

- Needs Screening (or Needs Assessment ("NA"));
- Scoping Process (or Scoping Assessment ("SA"));
- Integrated Regional Resource Plan ("IRRP"); and
- Regional Infrastructure Plan ("RIP").

The regional planning process begins with planning triggers. Planning triggers include:

- a regularly scheduled Needs Assessment by the transmitter (every five years);
- a scheduled review specified in an existing RIP;
- a Government directive;
- a significant change to codes and standards; or

Witness: Darlene Bradley / Lyla Garzouzi

- an emergent need brought forward by the transmitter, distributors, customers, or the Independent Electricity System Operator ("IESO") that cannot wait until the next scheduled review.

The initial phase of the regional planning process is the Needs Assessment phase which is led by the transmitter. In this phase, needs are identified in consultation with distributors and the IESO, and a high level assessment is undertaken to determine potential alternatives or solutions to address the needs.

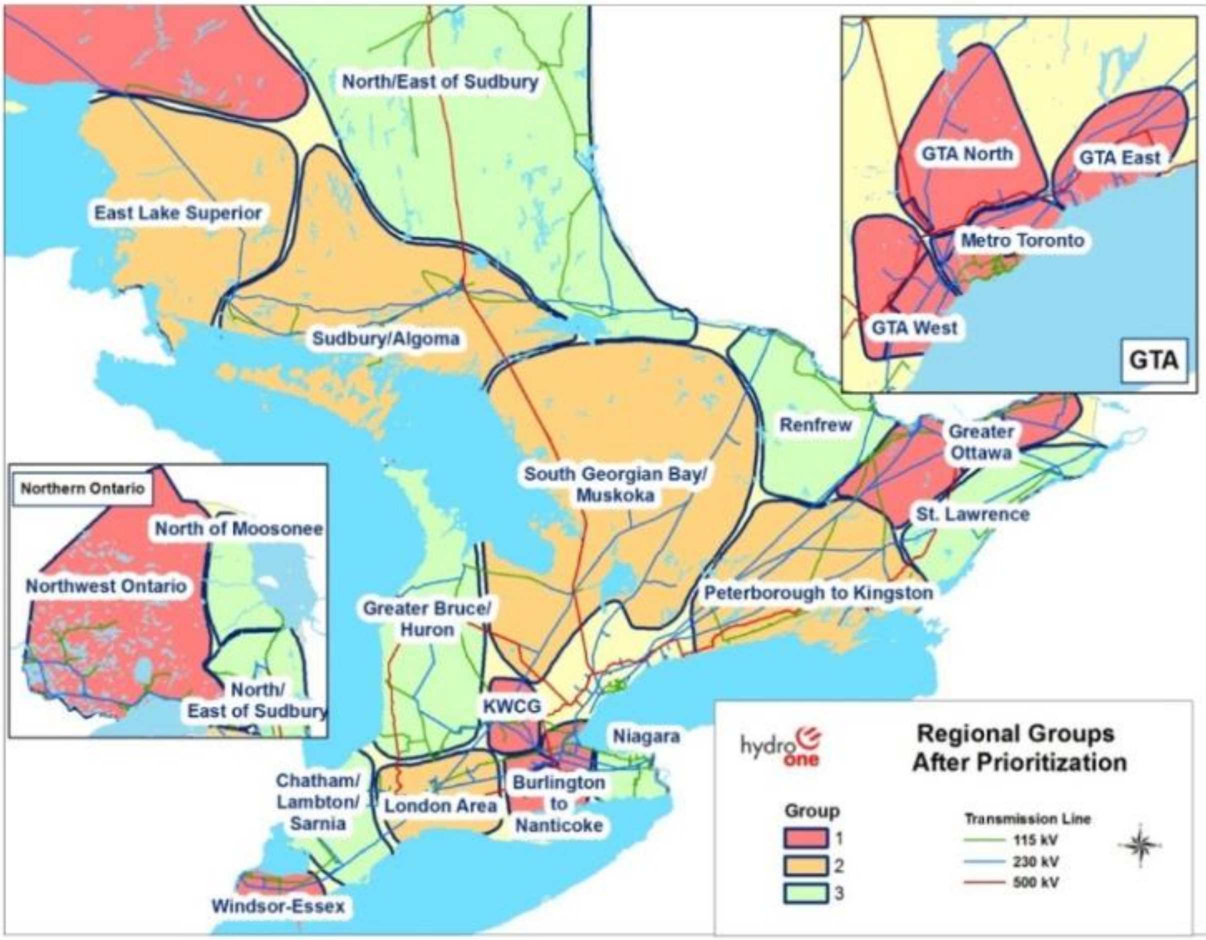
In cases where: (a) the needs are local or limited in nature; (b) further regional coordination is not required; and (c) the needs can be addressed directly by the transmitter and distributor(s) or other transmission connected customer(s) through transmission and/or distribution facilities ("wires") solution(s), then a local plan is developed. The local plan(s) ultimately becomes part of the RIP for the region.

In other cases where further planning studies and coordination are necessary, the IESO initiates the Scoping Assessment phase. The IESO, in collaboration with the transmitter and impacted distributors, reviews the information collected during the Needs Assessment phase. The IESO also considers information relating to potential non-wires alternatives (e.g. conservation, generation). Based on these analyses, the IESO determines the most appropriate regional planning approach, (i.e. whether an IRRP or an RIP or both are required), to address the needs in the region or sub-region.

The IRRP process involves the identification, evaluation and integration of potential wires and non-wires solutions at the regional or sub-regional level. The IRRP phase generally assesses resource versus wires infrastructure options at a higher level, but with sufficient detail to allow for a comparison of options. If the IRRP determines that resource options are best suited to meet a need, then those options are further planned by the IESO. However, if wires options are the more appropriate alternative, then those options are further assessed as part of the RIP process.

The RIP process is the final phase of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs. This phase is led and coordinated by the transmitter, and the deliverable of this phase is a comprehensive report of a wires plan for the region.

To undertake the regional planning process, the province was divided into 21 electrical regions for the purposes of conducting assessments and developing regional plans. Each of these 21 regions have been assigned to one of the three regional planning groups in order to prioritize and manage the regional planning process, as noted in Figure 2 below. Hydro One Distribution is a participant in all regions, except East Lake Superior and North of Moosonee.



Group 1	Group 2	Group 3
1. Burlington to Nanticoke	1. East Lake Superior (2)	1. Chatham/Lambton/Sarnia
2. Greater Ottawa	2. London Area	2. Greater Bruce/Huron
3. GTA East	3. Peterborough to Kingston	3. Niagara
4. GTA North	4. South Georgian Bay/Muskoka	4. North of Moosonee (2)
5. GTA West	5. Sudbury/Algoma	5. North/East of Sudbury
6. KWCG (1)		6. Renfrew
7. Metro Toronto		7. St. Lawrence
8. Northwest Ontario		
9. Windsor-Essex		

Figure 2 - Regional Planning Groups

Note: (1) "KWCG" stands for Kitchener-Waterloo-Cambridge-Guelph
(2) Hydro One Distribution is not a participant in this region

1.2.2 (5.2.2 A) REGIONAL PLANNING CONSULTATION DESCRIPTION

As part of the regional planning process, the lead transmitter undertakes consultation with stakeholders to identify needs and develop plans as envisioned by the Board in its Renewed Regulatory Framework. Hydro One, one of the LDC stakeholders, delivers its planning needs through this process and collaborates with the other LDC stakeholders as necessary. The customers of Hydro One benefit from this process in two key ways. First, the capacity needs of the system are addressed to ensure that expansion requirements to address load growth and new connections are undertaken in advance of customer in-service requirements. Second, any cost effective opportunities to collaboratively address capacity requirements with another LDC(s) are discussed and executed where feasible.

Over the last three years, working groups comprising representatives from the IESO, LDCs, Hydro One Distribution and Hydro One Transmission were established in all of the 19 regions across the province in which Hydro One Distribution manages assets. Hydro One Distribution's participation in the regional planning consultation for each of the regions includes:

1. **Pre-meeting Conference Calls / Webinars:** At the beginning of each phase, Hydro One Distribution, regional LDCs and the IESO are notified in advance of upcoming regional planning activities and are provided an overview of the process by the lead transmitter.
2. **Kick-Off Meeting: A** kick-off meeting with the working group takes place to initiate each of the phases of the regional planning process and provide templates for the collection of information/data.
3. **Additional Face to Face Meetings / Conference Calls / Webinars:** The working group meets on a regular basis to discuss planning matters such as assessment methodology, customer needs, and regional needs and timing before recommending a preferred solution.

Hydro One Distribution has been and continues to be an active participant in the regional planning process providing input into the Needs Assessment, Community Engagement, Scoping Assessment, Local Planning Reports, IRRP and RIP Reports. Specific input that has been provided by Hydro One Distribution includes:

- Providing short-term and long-term load forecasts to the transmitter and the IESO - both Gross and Net (with Conservation Demand Management & Distributed Generation) load forecasts are provided;
- Providing background on the distribution system including information on past system performance;
- Identifying local supply needs or constraints from the LDC perspective;
- Participating in community engagement sessions with local municipalities and other stakeholders;
- Participating in meetings of Local Advisory Councils;
- Participating in local planning led by the transmitter to address local supply needs as determined through the Needs Assessment stage;
- Identifying and evaluating of potential distribution based wires solutions to meet regional or local infrastructure needs;
- Attending regularly scheduled IRRP and RIP Working Group meetings at the regional and sub-regional level as required;
- Providing input and comments to proposed wires and non-wires solutions to address identified system needs; and
- Reviewing and providing comments on draft planning reports/documents prepared by the IESO and the transmitter.

For specific details at the regional level on all the participants involved, please refer to the reports filed as Attachments to this exhibit or to Hydro One's Regional Planning website:

http://www.hydroone.com/RegionalPlanning/Pages/home.aspx

These consultations ensure transparency of regional activities that may influence stakeholders' future planning strategies. The nature and prospective timing of the final deliverables that resulted from the consultations and their effect on distributor's Distribution System Plan are provided in the following sections.

1.2.3 STATUS OF REGIONAL PLANNING ACTIVITIES

As a province wide distributor, Hydro One Distribution's assets are located in 19 of the 21 regions that have been identified for the purpose of regional planning. These regions correspond to the same 19 regions where Hydro One Transmission is the lead transmitter. A copy of the latest Regional Planning Status Letter provided by Hydro One Transmission, as required under Section 3C.2.2 of the Transmission System Code, is provided in Attachment 2.

The initial cycle of regional planning has been completed, or deemed completed, for 12 out of the 19 regions that Hydro One belongs to, and the regional planning activities are in progress on the remaining 7 regions. A summary of the status of these regional planning activities for each region involving Hydro One Distribution, showing sub-regions where applicable, is provided in Table 5 below. The subsequent sections provide details on the regional planning activities that were completed or are underway for each region. For regions or sub-regions where planning has been completed, a description of the recommendations is provided as well as an indication of whether Hydro One Distribution is impacted by the recommendations.

Table 5: Regional Planning Status Summary

STATUS:		Completed		Not Required		In Progress		Not Started Yet

Region	Sub-Region	NA	SA	IRRP	RIP
Burlington to Nanticoke	Brant				
	Bronte				
	Greater Hamilton				
	Caledonia-Norfolk				
Greater Ottawa	Ottawa				
	Outer Ottawa				
GTA East	Oshawa-Clarington				
	Pickering-Ajax-Whitby				
GTA North	York				
	Western				
GTA West	Northwestern				
	Southern				
Kitchener-Waterloo Cambridge-Guelph (KWCG)					
Metro Toronto	Central Downtown				
	Northern				
Northwest Ontario	North of Dryden				
	Greenstone-Marathon				
	City of Thunder Bay				
	West of Thunder Bay

Niagara					
North/East of Sudbury					
Renfrew					
St. Lawrence					

Note: The asterisk (*) represents that a Local Planning Report is In Progress

NA=Needs Assessment; SA=Scoping Assessment; IRRP=Integrated Regional Resource Plan; RIP=Regional Infrastructure Plan

Burlington to Nanticoke Region

The Burlington to Nanticoke Region comprises four sub-regions: (i) **Brant,** (ii) **Bronte,** (iii) **Greater Hamilton**, and (iv) **Caledonia-Norfolk**. An IRRP for the Brant and Bronte sub-regions was completed and these reports are presented in Attachments 3 and 4 to this Exhibit.

The IRRP for the Brant and Bronte sub-regions did not identify any actions for Hydro One Distribution, as the recommended plans involve actions by the transmitter and other LDCs of the region. For the other two sub-regions, it was determined that the needs were local in nature. A Local Planning Report developed by Hydro One Distribution and impacted LDCs is presented in Attachment 5 of this Exhibit.

Consistent with the Local Planning Report, there are two local needs in the Burlington to Nanticoke Region which will require action by Hydro One Distribution, the Dundas TS Station Capacity (Project LG-28) and Reactive Support in Norfolk Area.

The RIP for the region is currently underway and is scheduled for completion in Q1 2017.

Greater Ottawa Region

The Greater Ottawa Region comprises of two sub-regions: (i) **Ottawa Area**; and (ii) **Outer Ottawa**. An RIP for this region was completed and is presented in Attachment 6 to this Exhibit.

The RIP for the Greater Ottawa Region did not identify any actions for Hydro One Distribution. All recommended plans will be implemented by Hydro One Transmission and/or another LDC from this region.

GTA East Region

The GTA East Region comprises two sub-regions: (i) **Pickering-Ajax-Whitby**; and (ii) **Oshawa-Clarington**. An IRRP for the Pickering-Ajax-Whitby sub-region was completed and is presented in Attachment 7 to this Exhibit. The recommended plan for this sub-region does not require any action by Hydro One Distribution.

For the Oshawa-Clarington sub-region, it was determined that the needs were local in nature. A Local Planning Report for Wilson TS and Thornton TS was developed by Hydro One and the impacted LDCs and is presented in Attachment 8 to this Exhibit. Consistent with the Local Planning Report, a new load station, "Enfield TS," to relieve Wilson TS and Thornton TS, is to be constructed. Hydro One Distribution is required to make a capital contribution to Enfield TS as per Section 6.3.1 of the TSC, (ISD GP-27). In addition, a coordinated review of feeder load transfer capabilities by Hydro One Distribution and Oshawa PUC was conducted in order to optimize the utilization of existing capacity at Wilson TS and Thornton TS.

The RIP for the region was completed in January 2017 and is presented in Attachment 28.

GTA North

The GTA North Region comprises two sub-regions: (i) **York**; and (ii) **Western**, with the York sub-region further defined into the Southern York Area and Northern York Area for planning purposes. An RIP for this region was completed and is presented in Attachment 9 to this Exhibit.

The RIP for the GTA North Region identified a number of non-wires alternatives that may address or defer the need for further transformation capacity in the Northern York Area. Despite the non-wires solutions proposed in the RIP, there continues to be a need to address both the transformation capacity and transmission capacity limits in the Northern York Area as early as 2023. The working group expects to finalize a plan to address these needs in an IRRP update currently scheduled for completion in 2017. Hydro One Distribution is affected by the Northern York Area and as such will continue to be an active member of the working group as plans to address the medium and long-term needs in this area are developed.

GTA West

The GTA West Region comprises two sub-regions: (i) **Northwestern**; and (ii) **Southern**. An RIP for this region was completed and is presented in Attachment 10 to this Exhibit.

The RIP for the GTA West Region identified several needs and recommended actions to address the short and medium term needs in the region. The majority of these actions will be implemented by Hydro One Transmission and/or other LDCs within this region.

Kitchener-Waterloo-Cambridge-Guelph (KWCG)

An RIP for the KWCG Region was completed and is presented in Attachment 11 to this Exhibit. The RIP for the KWCG Region did not identify any actions for Hydro One Distribution. All recommended plans will be implemented by Hydro One Transmission and/or other LDCs from this region.

Metro Toronto

The Metro Toronto Region comprises of two sub-regions: (i) **Central Downtown**; and (ii) **Northern**. An RIP for this region was completed and is presented in Attachment 12 to this exhibit.

Hydro One Distribution has no customers in the Metro Toronto Region, however it is a member of the region since it owns distribution assets that are used to transfer power from stations located within Toronto Hydro service territory to other LDC's outside the region. The RIP for the Metro Toronto Region identified plans to address needs in the Central Downtown sub-region which do not impact Hydro One Distribution. The RIP also concluded that there were no needs in the Northern sub-region.

Northwest Ontario

Northwest Ontario Region comprises of five sub-regions: (i) **North of Dryden**; (ii) **Greenstone-Marathon**; (iii) **City of Thunder Bay**; (iv) **West of Thunder Bay**; and (v) **Remote Communities**. The IRRP's for the North of Dryden, Greenstone-Marathon and West of Thunder Bay sub-regions were completed and are presented in Attachments 13, 14 and 15 to this Exhibit. The IRRP for the City of Thunder Bay sub-region was completed in December 2016.

Several needs and recommended actions were identified for the four sub-regions with completed IRRP's. Consistent with the IRRP, one of the recommendations involves transmission upgrades that impact load connection assets to which Hydro One Distribution is required to make a capital contribution as per Section 6.3.1 of the TSC.

The region's RIP will be initiated in Q1 2017. Other plans identified for the Northwest Ontario Region are not expected to impact Hydro One Distribution.

Windsor-Essex Region

The RIP for the Windsor-Essex Region was completed and is presented in Attachment 16 to this Exhibit. The RIP for the Windsor-Essex Region identified several needs and recommended actions. Consistent with the RIP, the Supply to Essex County Transmission Reinforcement ("SECTR") project is being undertaken to address the need for new transmission facilities to which Hydro One Distribution is required to make a capital contribution as per Section 6.3.1 of the TSC, (ISD GP-25).

London Area

The London Area Region comprises of five sub-regions: (i) **Greater London**; (ii) **Aylmer-Tillsonburg**; (iii) **Strathroy**; (iv) **Woodstock**; and (v) **St. Thomas**.

The IRRP for the Greater London sub-region is currently underway and is scheduled for completion in Q1 2017. The Needs Assessment for the London Area Region determined that, for the other four sub-regions, the needs were local in nature. The Needs Assessment report is presented in Attachment 17 to this Exhibit.

The RIP for the region will be initiated after the IRRP and sub-region RIP are completed.

Peterborough to Kingston

The RIP for the Peterborough to Kingston Region was completed and the report is presented in Attachment 18 to this Exhibit. The assessment determined that the needs in this region were local in nature. Consistent with the RIP, transformation capacity relief is required for Gardiner TS.

South Georgian Bay/Muskoka

The South Georgian Bay/Muskoka Region comprises two sub-regions: (i) **Parry Sound/Muskoka**; and (ii) **Barrie/Innisfil.** A Needs Assessment Report was completed for this Region and is presented in Attachment 19 to this Exhibit. The NA identified a requirement to complete IRRPs for both sub-regions which were completed in December 2016. These are presented in Attachments 29 and 30. The NA for this region also identified a local need concerning end-of-life assets at Orangeville TS. A Local Need Report for this is presented as Attachment 20.

For the Parry Sound/Muskoka IRRP, a near-term need to provide load relief to Parry Sound TS and Waubaushene TS was identified. The report recommended that Hydro One Distribution undertake distribution load transfers to mitigate overloading of these stations. The cost for Hydro One Distribution to construct these new distribution facilities is expected to be approximately $5M – $6M (LG-24 ISD SS-02).

The IRRP for Barrie/Innisfil identified an urgent need to upgrade Barrie TS and the existing E3/4B 115 kV transmission line with new 230 kV infrastructure as soon as possible. Hydro One Distribution has no distribution customers fed from Barrie TS but is a transmission connected customer at the station providing embedded LDC supply to InnPower via an idle 115 kV transmission line operating at 44 kV. The report recommends that Hydro One Distribution and InnPower develop a plan to build a new two-circuit 44 kV distribution line outside of the transmission corridor to meet future load needs in the area (LG-26).

The RIP for the region is scheduled for completion in 2017.

Sudbury/Algoma

The RIP for the Sudbury/Algoma Region was completed and the report is presented in Attachment 21 to this Exhibit. The assessment determined that the needs in this region were local in nature. A Local Planning Report was developed by Hydro One Distribution and impacted LDCs to address low incoming 115 kV supply voltage at Manitoulin TS.

The Needs Assessment report also references the construction of a new 230/44kV transformer station at Hanmer TS to replace the existing 115/22kV Coniston TS to which Hydro One Distribution is required to make a capital contribution, as per Section 6.3.1 of the TSC (ISD GP 26).

Chatham/Lambton/Sarnia

A Needs Assessment for the Chatham/Lambton/Sarnia Region was completed and the report is presented in Attachment 22 to this Exhibit. The assessment determined that the needs in this region were local in nature. A Local Planning Report is currently underway involving Hydro One Transmission and the affected LDC's, including Hydro One Distribution, to address these needs. The Local Planning Report is scheduled for completion by Q1 2017. The RIP will be finalized once the Local Planning report is completed.

Greater Bruce/Huron

A Needs Assessment for the Greater Bruce/Huron Region was completed and the report is presented in Attachment 23 to this Exhibit. The assessment determined that the needs in this region were local in nature. A Local Planning Report is currently underway involving Hydro One Transmission and the affected LDCs, including Hydro One Distribution, as well as the affected transmission connected customers, to address these needs. The Local Planning Report is scheduled for completion by Q2 2017. The RIP will be finalized once the Local Planning report is completed.

Niagara

A Needs Assessment for the Niagara Region was completed and the report is presented in Attachment 24 to this Exhibit. The assessment concluded that no regional infrastructure needs exist and no further planning is required at this point.

North/East of Sudbury

The Needs Assessment for the North/East of Sudbury Region was completed and the report is presented in Attachment 25 to this Exhibit. The assessment determined that the needs in this region were local in nature and that there are existing operating procedures in place to deal with potential low voltage conditions in the Timmins and Kirkland Lake areas. Hydro One Distribution will continue to monitor loading and voltage conditions in these areas and implement further planning as required.

Renfrew

The RIP for the Renfrew Region was completed and the report is presented in Attachment 26 to this Exhibit. The assessment concluded that no regional infrastructure needs and no further planning is required at this point.

St. Lawrence

The RIP for the St. Lawrence Region was completed and the report is presented in Attachment 27 to this Exhibit. The assessment concluded that no regional infrastructure needs exist and no further planning is required at this point.

1.2.4 (5.4.1 E) HOW THE PLAN REFLECTS REGIONAL PLANNING

Based on the results of regional planning activities described in the previous section, a number of investments are included in the DSP which are related to regional infrastructure needs. These consist of capital contributions to the transmitter for new connection facilities and construction of new feeders to incorporate new or existing transmission connection capacity. The table below summarizes the investments that are informed by the regional planning activities described in the previous section. The table contains the regional planning group, project description reference, timeline and expected costs where available.

Table 6 - Regional Planning Project Summary

Project ID	Project Name	In-Service Date	Project Plan	Project Cost	Region
ISD SS-02 Project LG-28	Dundas TS #2 Feeders	10/2020	Construct 2 x 44 kV feeder positions & 10 km of new line	$6.7M	Burlington to Nanticoke
ISD GP-27	Enfield TS - capital contribution	05/2019	C Build a new 230/44 kV 170 MVA TS shared between Hydro One and Oshawa PUC	$5.0M	GTA East
ISD SS-02 Project LG-11	Enfield TS Feeder Development	05/2019	Construct 20km of new 44 kV feeder lines	$8.0M	GTA East
ISD GP-25	Leamington TS Capital Contribution	04/2018	Build a new 230 kV – 27.6 kV DESN TS	$6.7M	Windsor-Essex
ISD SS-02 Project LG-14	Leamington TS Feeder Development	06/2019	Construct 20 km of new 27.6 kV lines	$10.5M	Windsor-Essex

Project ID	Project Name	In-Service Date	Project Plan	Project Cost	Region
	Kingston Gardiner TS M26 Feeder Development	10/2018	Develop 1 new 44 kV Feeder	$0.9M	Peterborough to Kingston
ISD GP-26	Hanmer TS Capital Contribution	02/2019	Add two new 50/83 MVA step-down transformers and associated switchgear at Hanmer TS	$16M	Sudbury/Algoma
ISD SR-11 Project LC-10	Hanmer TS Feeder Development	02/2019	Build 2.4 km new 44 kV line	$1.4M	Sudbury/Algoma
ISD SS-02 Project LG-24	Muskoka TS M5 x M1 Feeder Tie	12/2019	Build 14 km new 44 kV line	$5.3M	Southern Georgian Bay/Muskoka
ISD SS-02 Project LG-26	Barrie TS – Construct new Feeders	12/2020	Build 8km new 2-circuit 44 kV line	$2.6M	Southern Georgian Bay/Muskoka

Note: In all cases, the Project Costs included above refer to the amount that Hydro One Distribution will pay towards completion of the overall project. This may represent the net amount contributed toward a project to be completed by Hydro One Transmission or the amount net of contributions from other parties such as LDCs and Large Customers.

IESO Letter of Comment

Hydro One Networks Inc.

Distribution System Plan

March 9, 2017

Connecting Today.
Powering Tomorrow.

Introduction

On March 28, 2013, the Ontario Energy Board ("the OEB" or "Board") issued its Filing Requirements for Electricity Transmission and Distribution Applications; Chapter 5 – Consolidated Distribution System Plan Filing Requirements (EB-2010-0377). Chapter 5 implements the Board's policy direction on 'an integrated approach to distribution network planning', outlined in the Board's October 18, 2012 Report of the Board - A Renewed Regulatory Framework for Electricity Distributors: A Performance Based Approach.

As outlined in the Chapter 5 filing requirements, the Board expects that the Ontario Power Authority[1] ("OPA") comment letter will include:

- the applications it has received from renewable generators through the FIT program for connection in the distributor's service area;
- whether the distributor has consulted with the OPA, or participated in planning meetings with the OPA;
- the potential need for co-ordination with other distributors and/or transmitters or others on implementing elements of the REG investments; and
- whether the REG investments proposed in the DS Plan are consistent with any Regional Infrastructure Plan.

Hydro One Networks Inc. – Distribution System Plan

On February 27, 2017, Hydro One Networks Inc. ("Hydro One") provided its Renewable Energy Generation Investments Information ("Plan") to the Independent Electricity System Operator ("IESO") covering a 5-year forecast planning period. The IESO has reviewed Hydro One's Plan and provides the following comments.

OPA FIT/microFIT Applications Received

On Table 1 of its Plan, Hydro One indicates that they have connected and/or committed to connect the following renewable generation projects:

- 247 Capacity Allocation Required (CAR) projects with a total capacity of 1746.7 MW
- 729 Capacity Allocation Exempt (CAE) projects with a total capacity of 136.2 MW
- 13,885 MicroFIT projects with a total capacity of 125.9 MW.

[1] On January 1, 2015, the Ontario Power Authority ("OPA") merged with the Independent Electricity System Operator ("IESO") to create a new organization that will combine the OPA and IESO mandates. The new organization is called the Independent Electricity System Operator.

Independent Electricity System Operator
1600 – 120 Adelaide Street West, Toronto, ON M5H 1T1
t 416 967-7474 f 416 967-1947 toll free 1-800-797-9604 customer.relations@ieso.ca www.ieso.ca

The IESO records as of January 31, 2017 indicate that the following REG projects have connected or approached Hydro One for connection based on IESO (and former OPA) contracts:

- 253 Capacity Allocation Required (CAR) projects with a total capacity of 1849 MW
- 816 Capacity Allocation Exempt (CAE) projects with a total capacity of 161 MW
- 13,114 MicroFIT projects with a total capacity of 122 MW.

The information provided by Hydro One is therefore reasonably consistent with that of the IESO.

The IESO also has 379 REG contracts under FIT 4 procurement program that will be connecting to Hydro One's distribution system. Hydro One's Plan refers to these 379 REG projects showing consistency with the IESO's records, however, the contract holders have not yet approached Hydro One for connection.

The renewable generation procurement program under FIT 5 is underway and the final outcome of this process will not be available until early summer. Hydro One's Plan estimates 200 CAE projects under the FIT 5 program to be connecting to its distribution system. The IESO believes this estimate is reasonable based on the information available to date.

In accordance with the September 27, 2016 direction from the Ministry of Energy, the IESO has ceased the Large Renewable Procurement program. Also, the Minister's December 16, 2016 direction amended the FIT 5 procurement target and directed the IESO to cease accepting applications under the FIT program by December 31, 2016. Therefore, future renewable generation projects will not be based on IESO contracts until further direction is given to the IESO. Hydro One has provided a forecast of distribution connection generation connection for the 2017-2022 period. However because of government direction to cease procurements under the noted REG programs, the IESO provides no comment on Hydro One's forecast.

With respect to REG investments, Hydro One's Plan indicates that for the planning period it has not forecast any investments for the purposes of enabling renewable energy generation connection. This fact eliminates the necessity of the IESO to comment on whether there is a potential need for coordination with others on implementing elements of the REG investments, and whether the REG investments proposed in the Plan are consistent with any Regional Infrastructure Plan.

The responsibilities of both Hydro One and the IESO are outlined in the OEB Transmission System Code, and the IESO's licence with respect to the province's regional planning process, and because of this there is, and will be, ongoing collaboration in developing and implementing regional plans.

The IESO looks forward to its continued work with Hydro One on regional planning and appreciates the opportunity to comment on the REG information provided as part of its distribution system plan.

January 26th, 2017

Mr. Paul Brown
Director, Distribution Asset Management
Hydro One Distribution
483 Bay Street
Toronto, ON M5G 2P5

Dear Mr. Brown,

Subject: Regional Planning Status – Hydro One Distribution

This letter is in response to your request for a Planning Status letter for your cost of service application. The province has been divided into 21 Regions for the purpose of regional planning, which are assigned to one of the 3 Groups to prioritize and manage the regional planning process. A map showing details with respect to the 21 Regions and the list of LDCs in each Region are attached in Appendix A and B respectively. Hydro One Distribution belongs to 19 Regions, as listed below, in which Hydro One Networks Inc. (HONI) is the lead transmitter:

Group 1 Regions	**Group 2 Regions**	**Group 3 Regions**
Burlington to Nanticoke	London Area	Chatham/Lambton/Sarnia
Greater Ottawa	Peterborough to Kingston	Greater Bruce/Huron
GTA East	South Georgian Bay/Muskoka	Niagara
GTA North	Sudbury/Algoma	North/East of Sudbury
GTA West		Renfrew
KWCG		St. Lawrence
Metro Toronto		
Northwest Ontario		
Windsor-Essex		

This letter confirms that Needs Assessment (NA) for all of the 19 Regions have been completed or deemed to be completed for the first cycle of regional planning process. In addition, Regional Infrastructure Plans (RIP) for 12 Regions have been completed and remaining 7 are expected to be completed by August 2017. An overview of Ontario's regional planning process is available on Hydro One's Regional Planning homepage. Each region's current status and corresponding reports are also published online and can be accessed using the links above. The planning status for the 19 Regions is briefly discussed below.

Group 1 Regions

Burlington to Nanticoke

The Scoping Assessment (SA) recommended to undertake Integrated Regional Resource Plan (IRRP) for Brant and Bronte Sub-Regions which were completed in April 2015 and June 2016, respectively. In addition, for other local needs, a Local Planning (LP) report, led by Hydro One, was published in October 2015 to address the transformation capacity need for Dundas TS T1/T2, Nebo TS T3/T4, and Mohawk TS. The report recommended that LDCs undertake distribution load transfers to mitigate overloading of respective stations.

A RIP report for the region is underway and is expected to be completed by Q1 2017. Currently, reconfiguration and installation of breakers at Brant TS is the major investment stemming from regional planning process. In addition, there are several end of life asset refurbishments in the region underway and/or planned over the next few years. It is expected that there will be little or no cost implications for Hydro One Distribution in the region.

Greater Ottawa

The first Regional Planning cycle for Greater Ottawa Region is now complete and the RIP report was published in December 2015. It is expected that there will be no cost implications for Hydro One Distribution in the region as a result of recommendations stemming from regional planning process. The next planning cycle for this region will be initiated in Q4 2017 or Q1 2018.

GTA East

The first Regional Planning cycle for GTA East is now complete and the RIP report was published in January 2017. GTA East has been divided into Pickering-Ajax-Whitby and Oshawa-Clarington Sub-Regions and the NA report for the region was completed in August 2014. The IRRP report for the Pickering-Ajax-Whitby Sub-Region was completed in June 2016 and it identified transformation capacity need at 27.6kV voltage level due to development of new community of Seaton in northern Pickering. A new transformer station, called Seaton MTS, is planned to be built by Veridian Connections Inc. and commissioned in 2019 to address the capacity need.

Also, as recommended in the SA, a wires plan was developed to address the transformation capacity at Wilson TS and Thornton TS as part of the LP report in May 2015. The Working Group recommended a new DESN, Enfield TS, at Clarington TS site. Currently it is expected to be in-service by 2019 with an approximate budgetary cost of $34M. Consistent with the TSC, it is currently estimated that Hydro One Distribution will have to make a capital contribution of approximately $5M.

GTA North

The first Regional Planning cycle for the GTA North Region is now complete and the RIP report was published in February 2016.

The GTA North Region consists of the York and Western Sub-Regions. The following needs were identified for the York Sub-Region during the regional planning process:

- Transformation capacity in Vaughan, Markham and Northern York Area
- Load Security and Load Restoration capability on the lines from Claireville to Parkway (V71P/V75P) and Claireville to Brown Hill (B82V/B83V)
- Transmission Capacity on the Claireville to Brown Hill line (B82V/B83V)

Work on a new transformer station, Vaughan MTS #4, is underway by PowerStream to address the near-term transformation capacity need in Vaughan. The expected in-service date is May 2017. There are no cost implications for Hydro One Distribution.

The construction of inline breakers and switches at Holland TS along with a Special Protection Scheme is underway to address the near term needs for the Claireville to Brown Hill line (B82V/B83V). The expected in-service date is October 2017 and there are no cost implications for Hydro One Distribution.

Work on inline switches on the Claireville to Parkway line (V71P/V75P) is underway to address the load restoration need and the expected in-service date is May 2018. There are no cost implications for Hydro One Distribution.

A load restoration need for the loss of the Claireville to Kleinburg line (V43/V44) was identified in the Western Sub-Region. The study team recommended that this need be addressed as part of the IESO led GTA West Bulk System Planning initiative.

GTA West

GTA West was divided into Northwestern and Southern Sub-Regions for regional planning purpose. The first Regional Planning cycle for GTA West Region is now complete and RIP report was published in January 2016.

The following major needs were identified during the regional planning process:

- Station capacity for Halton TS and Erindale TS T1/T2
- Transmission circuit capacity for R14T/R17T, R19TH/R21TH, H29/H30, T38B/T39B
- Load restoration/security capability for above circuits plus V41H/V42H and B15C/B16C

Two new transformer stations, Halton Hills Hydro MTS and Halton TS #2, have been proposed to relieve Halton TS capacity by 2018 and 2020, respectively. A new DS has also been proposed to relieve Erindale TS T1/T2 capacity. However, there is no cost implications for Hydro One Distribution. A need to upgrade 230kV line H29/H30 conductor is also identified, and will be finalized in the next regional planning cycle.

KWCG

The first Regional Planning cycle for KWCG Region is complete and RIP report was published in December 2015.

The following needs were identified as part of the regional planning process:

- Transmission circuit capacity for B5G/B6G, D7F/D9F, and F11C/F12C
- Load restoration capability for Waterloo-Guelph and Cambridge-Kitchener 230kV subsystems

As part of the Guelph Area Transmission Reinforcement (GATR) project, 115kV transmission systemwas reinforced in 2016 by introducing a new 230/115kV injection point at Cedar TS using two new 230kV/115kV autotransformers. Also, two new 230kV in-line switches were installed in 2016 to address the load restoration need near Guelph North Junction on D6V/D7V to isolate faulted elements in Waterloo-Guelph subsystem. The cost of GATR project is estimated to be about $95 million and will be a transmission pool investment.

To address the load restoration need in Cambridge-Kitchener subsystem, two new 230kV in-line switches on M20D/M21D are recommended near Galt Junction to isolate faulted elements. This project is estimated to cost $6 million and will be a transmission pool investment.

As a result of above investments, there will be no cost implications for Hydro One Distribution.

Metro Toronto

The first Regional Planning cycle for Metro Toronto Region is complete and RIP report was published in January 2016.

The following needs were identified during the regional planning process:

- Transformation station capacity in the West Toronto, Southwest Toronto and Downtown Core areas
- Transmission line capacity for the 115kV Manby x Wiltshire corridor, and the 230kV Richview x Manby corridor

The transformation capacity needs will be addressed by adding 115/27.6kV, 230/27.6kV, or 115/13.8kV DESNs in low capacity areas. The transmission line capacity need in the West Toronto area will be addressed by upgrading the 115kV circuits between Manby TS and Wiltshire TS, with an estimated cost of $30 million approximately to be recovered in accordance with the TSC. The 230kV Richview x Manby transmission corridor will also be reinforced while different alternatives are being evaluated and estimated currently. The investment cost will be in the range of $20-30 million, to be recovered in accordance with the TSC.

It is expected that the next planning cycle for this region will be initiated over the next 2 years.

Northwest Ontario

In March 2014, Working Group members from the LDCs, IESO, and Hydro One collected the LDC load forecast and concluded that the primary objective of the Needs Assessment (NA) to identify needs in the region had been already established in the region. As a result, Working Group decided that a NA report was not required and IESO should initiate the SA process for this region.

Northwest Ontario Region was divided into 4 Sub-Regions: City of Thunder Bay, West of Thunder Bay, North of Dryden, and Greenstone-Marathon. SA report for this region was completed in January 2015. Planning for Remote Communities was already underway and a draft plan referred to as "Remote Communities Plan" has been developed. IRRPs for the four regions were also completed as discussed below -

The North of Dryden IRRP report, published in January 2015, has following recommendations:

- New 230kV transmission line from Dryden/Ignace area to Pickle Lake plus a 230/115kV autotransformer with related infrastructure
- Upgrading 115kV transmission lines; Dryden to Ear Falls (E4D) and Ear Falls to Red Lake (E2R)

It is expected that there will be some cost implications for Hydro One Distribution resulting from upgrade of E4D. However, currently this project is on hold awating customer confirmation.

The Greenstone-Marathon IRRP, published in June 2016, has following recommendations:

- Install a new 230 kV single-circuit line from the East-West Tie near Nipigon or Marathon to Longlac, and a new 230/115 kV auto-transformer and related switching and voltage control facilities at Longlac Transformer Station ("TS") to be in-service coincident with the pumping stations loads.
- Install a new 115 kV single-circuit line from Longlac TS to Manitouwadge TS and related switching and voltage control facilities, to be in-service coincident with the incorporation of the pumping stations as part of the major pipeline conversion project.
- Mine developers in Greenstone have the option of upgrading circuit A4L from Alexander Switching Station ("SS") to Beardmore TS as an economic alternative for supplying the Beardmore mine and additional mining in Greenstone.

It is expected that there will be no cost implications for Hydro One Distribution as a result of the above recommendations.

The West of Thunder Bay and Thunder Bay IRRPs were published in July and December 2016, respectively, where no needs were identified in the Sub-Region.

The planning for Remote Communities Sub-Region is being led by the IESO and a draft Connection Plan has been developed. The plan has not yet been fully reviewed by the stakeholders and awaiting community engagement to be finalized. It is expected that there will be limited, if any, cost implications for Hydro One Distribution.

The IRRPs for all Sub-Regions are now complete by the IESO and Hydro One is expected to initiate the RIP process by end of January 2017. It is expected that the RIP for the region will be completed by August 2017.

Windsor-Essex

Planning activities for the Windsor-Essex Region were already underway before the new regional planning process was introduced. The NA and SA phases were deemed to be completed and the planning status for the region was considered to be in the IRRP phase of the regional planning process. The IRRP and RIP reports for the region were completed in April 2015 and December 2015, respectively. During the regional planning process, the following needs were identified that are being addressed by wires solution in the region:

- Supply Interruptions in the J3E-J4E Subsystem
- Additional Supply Capacity requirement in the Kingsville-Leamington Area

The above needs will be addressed by the new Supply to Essex County Transmission Reinforcement ("SECTR") project as an integrated solution for both needs. The SECTR project consists of:

- A new 230/27.6 kV Leamington TS in the Municipality of Leamington
- Distribution investment for Leamington TS; includes additional feeder positions and protection upgrades for in-service Kingsville DG transferred to Leamington TS.
- Construction of a 13 km double-circuit 230 kV line to connect the existing C21J/C22J circuits to the new transformer station.

Sufficient load is also planned to be transferred to the new TS from Kingsville TS to provide relief to the station. The estimated completion date for the SECTR project, as per the RIP report, is June 2018. As per the latest estimates, the SECTR project is estimated to cost about $78M for building transmission infrastructure. In addition, Hydro One Distribution is expected to invest in building distribution

January 26th, 2017

Mr. Paul Brown
Director, Distribution Asset Management
Hydro One Distribution
483 Bay Street
Toronto, ON M5G 2P5

Dear Mr. Brown,

Subject: Regional Planning Status – Hydro One Distribution

This letter is in response to your request for a Planning Status letter for your cost of service application. The province has been divided into 21 Regions for the purpose of regional planning, which are assigned to one of the 3 Groups to prioritize and manage the regional planning process. A map showing details with respect to the 21 Regions and the list of LDCs in each Region are attached in Appendix A and B respectively. Hydro One Distribution belongs to 19 Regions, as listed below, in which Hydro One Networks Inc. (HONI) is the lead transmitter:

Group 1 Regions	**Group 2 Regions**	**Group 3 Regions**
Burlington to Nanticoke	London Area	Chatham/Lambton/Sarnia
Greater Ottawa	Peterborough to Kingston	Greater Bruce/Huron
GTA East	South Georgian Bay/Muskoka	Niagara
GTA North	Sudbury/Algoma	North/East of Sudbury
GTA West		Renfrew
KWCG		St. Lawrence
Metro Toronto		
Northwest Ontario		
Windsor-Essex		

This letter confirms that Needs Assessment (NA) for all of the 19 Regions have been completed or deemed to be completed for the first cycle of regional planning process. In addition, Regional Infrastructure Plans (RIP) for 12 Regions have been completed and remaining 7 are expected to be completed by August 2017. An overview of Ontario's regional planning process is available on Hydro One's Regional Planning homepage. Each region's current status and corresponding reports are also published online and can be accessed using the links above. The planning status for the 19 Regions is briefly discussed below.

The above needs will be congregated and addressed further in a RIP report for South Georgian Bay/Muskoka Region, expected to be completed by August 2017.

Sudbury/Algoma
The NA and LP Reports for Sudbury/Algoma Region were completed in March and September 2015. Considering that no further regional coordination was required, the NA and LP reports were deemed to form the RIP report for the region, and published in June 2016.

A new 230/44kV DESN at Hanmer TS is proposed to replace the 115/22kV Coniston TS at a total cost of approximately $30M. The project has not yet been released for estimating and current cost estimates are budgetary only. Consistent with the TSC, it is expected that LDC contribution will be approximately $16 million subject to change based on final estimates. All loads will be transferred to the new DESN and supplied at 44kV voltage level by 2019.

The voltage regulation issue at Manitoulin TS was further assessed by the Working Group and it was determined that this can be dealt with Under Load Tap Changers (ULTC) on the power transformers to regulate voltages within the range outlined in the TSC. No further action is required at this time.

Group 3 Regions

Chatham/Lambton/Sarnia
Regional Planning for the Chatham/Lambton/Sarnia Region started with the Information Gathering in December 2015 and the NA report was completed in June 2016.

The study team's recommendation was that no further regional coordination is required. Based on the net load forecast, Kent TS T3/T4 is forecasted to exceed its 10 – Day LTR in 2016. A wires' solution, led by Hydro One and in collaboration with relevant distributors, has been recommended to address this need in a LP report, to be completed in Q1 2017.

The NA and LP reports for the Region will be deemed to form the RIP report because no further regional coordination was required. The RIP report for Chatham/Lambton/Sarnia Region is expected to be completed in Q2 2017.

Greater Bruce/Huron
The NA for the Greater Bruce-Huron Region was completed in May 2016. The following needs were identified:

- Poor power factor at Wingham TS (and resulting voltage deficiency) and Bruce HWP B TS
- Transmission circuit capacity for L7S
- Customer Delivery Point Performance

The Working Group concluded no further regional coordination was required via an Integrated Regional Resource Plan. As a result plans to mitigate the needs are currently being pursued via the Local Planning process and Hydro One's OEB-approved process for addressing poor performance.

LP reports were developed for needs at Wingham TS and L7S circuit capacity and there will be no cost implications for Hydro One Distribution. Another LP is currently being developed for the Bruce HWP B

TS need and as Hydro One Distribution is not a customer at this station, there will not be cost implications for them.

Hydro One Transmission is currently investigating poor customer delivery point performance in the Region and will work with Hydro One Distribution as well as the other LDC's in the Region and transmission customers to develop a plan. Any cost implications for Hydro One Distribution will be incorporated into the Region's RIP report.

The NA report and all LP reports for the Region will be deemed to form the RIP report because no further regional coordination was required. The RIP report for Greater Bruce/Huron Region is expected to be completed in Q2 2017.

Niagara

Regional Planning for the Niagara Region started with the Information Gathering in November 2015 and the NA report was completed in April 2016.

The study team addressed the thermal overloading of 115kV circuit Q4N as part of a LP report completed in November 2016. As part of the Beck #1 Refurbishment project, the section of the 115kV circuit Q4N between Sir Adam Beck SS #1 and Portal JCT is to be uprated from 680A to 910A ampacity. The expected in-service date is December 2019. There will be no cost implications for Hydro One Distribution.

The NA and LP reports for the Region will be deemed to form the RIP report for the Niagara Region because no further regional coordination was required. It is expected that the RIP report will be issued in Q1 2017.

North/East of Sudbury

Based on the findings of the NA, completed in April 2016, the Working Group recommends that no further regional coordination is required.

Voltage regulation needs at Timmins TS and Kirkland Lake TS were identified and addressed in the LP report completed in August 2016. Existing operating measure exists to address these issues, and the working group members agreed these methods continue to be acceptable ways of managing system voltages in the area. Hydro One Networks investments are not required at this time and Hydro One will monitor load growth in the area and take corrective actions as required. There will be no cost implications for Hydro One Distribution.

The NA and LP reports for the Region will be deemed to form the RIP report for the North/East of Sudbury Region because no further regional coordination was required. The RIP report for the Region is expected to be completed by Q1 2017.

Renfrew

The first Regional Planning cycle for Renfrew Region is now complete. The NA report was completed in March 2016 and no needs were identified in the Region. The NA report was deemed to form the RIP report for the Renfrew Region because no regional coordination was required. There will be no cost implications for Hydro One Distribution.

St. Lawrence
The first Regional Planning cycle for St .Lawrence Region is now complete. The NA report was completed in April 2016 and no needs were identified in the Region. The NA report was deemed to form the RIP report for the St. Lawrence Region because no regional coordination was required. There will be no cost implications for Hydro One Distribution.

Acquisition of Local Distribution Companies by Hydro One

Norfolk Power Inc.
In July 2014, the OEB issued a decision and order that approved the acquisition of Norfolk Power Inc. by Hydro One. Norfolk Power Inc. served approximately 18,000 customers in Port Dover, Simcoe, Waterford, and the urban areas of Delhi and Port Rowan in the Norfolk County, mainly supplied by Norfolk TS and Tillsonburg TS, located in southern Ontario. Norfolk Power Inc. was part of Burlington to Nanticoke and London Area Regions. RIP report for Burlington to Nanticoke region is currently underway while RIP report for London Area will be initiated following the completion of the IRRP, expected to be completed by end of January 2017. Based on the previous regional planning assessments no needs were identified in the area that may have any cost implications for the LDC.

Haldimand County Hydro
In March 2015, the OEB approved the acquisition of Haldimand County Hydro by Hydro One. Haldimand County Hydro served approximately 21,200 customers in the Haldimand County spanning across Caledonia, Cayuga, and other southern rural areas along Lake Ontario which is part of the Burlington to Nanticoke and Niagara Regions. Caledonia TS, Nanticoke TS, and Dunnville TS are the main transmission facilities supplying the electrical demand in the area. RIPs for both of these regions are currently underway and expected to be completed in Q1 and Q2 2017, respectively. However, based on the previous regional planning assessments no needs were identifued in the area that may have any cost implications for the LDC.

Woodstock Hydro Services Inc.
In September 2015, the OEB approved the acquisition of Woodstock Hydro Services Inc. by Hydro One. Woodstock Hydro served approximately 15,800 customers in the city of Woodstock, mainly through Woodstock TS and Karn TS, located in London Area Region. RIP for London Area will be initiated following the completion of the IRRP, expected to be completed by end of January 2017.

Further details will be discussed with the Working Group and communicated as they become available. Hydro One looks forward to working with Hydro One Distribution in executing the regional planning process. Please feel free to contact me if you have any questions.

Sincerely,

Ajay Garg, Manager - Regional Planning Coordination
Hydro One Networks Inc.

Appendix A: Map of Ontario's Planning Regions

Northern Ontario

Southern Ontario

Greater Toronto Area (GTA)

Group 1	Group 2	Group 3
Burlington to Nanticoke	East Lake Superior	Chatham/Lambton/Sarnia
Greater Ottawa	London area	Greater Bruce/Huron
GTA East	Peterborough to Kingston	Niagara
GTA North	South Georgian Bay/Muskoka	North of Moosonee
GTA West	Sudbury/Algoma	North/East of Sudbury
Kitchener- Waterloo-Cambridge-Guelph (“KWCG”)		Renfrew
Metro Toronto		St. Lawrence
Northwest Ontario		
Windsor-Essex		

<u>Appendix B: List of LDCs for Each Region</u>

[Hydro One as Upstream Transmitter]

Region	LDCs
1. Burlington to Nanticoke	• Brant County Power Inc. • Brantford Power Inc. • Burlington Hydro Inc. • Haldimand County Hydro Inc.** • Horizon Utilities Corporation • Hydro One Networks Inc. • Norfolk Power Distribution Inc.** • Oakville Hydro Electricity Distribution Inc.
2. Greater Ottawa	• Hydro 2000 Inc. • Hydro Hawkesbury Inc. • Hydro One Networks Inc. • Hydro Ottawa Limited • Ottawa River Power Corporation • Renfrew Hydro Inc.
3. GTA North	• Enersource Hydro Mississauga Inc. • Hydro One Brampton Networks Inc. • Hydro One Networks Inc. • Newmarket-Tay Power Distribution Ltd. • PowerStream Inc. • PowerStream Inc. [Barrie] • Toronto Hydro Electric System Limited • Veridian Connections Inc.
4. GTA West	• Burlington Hydro Inc. • Enersource Hydro Mississauga Inc. • Halton Hills Hydro Inc. • Hydro One Brampton Networks Inc. • Hydro One Networks Inc. • Milton Hydro Distribution Inc. • Oakville Hydro Electricity Distribution Inc.

5. Kitchener- Waterloo-Cambridge-Guelph (“KWCG”)	• Cambridge and North Dumfries Hydro Inc. • Centre Wellington Hydro Ltd. • Guelph Hydro Electric System - Rockwood Division • Guelph Hydro Electric Systems Inc. • Halton Hills Hydro Inc. • Hydro One Networks Inc. • Kitchener-Wilmot Hydro Inc. • Milton Hydro Distribution Inc. • Waterloo North Hydro Inc. • Wellington North Power Inc.
6. Metro Toronto	• Enersource Hydro Mississauga Inc. • Hydro One Networks Inc. • PowerStream Inc. • Toronto Hydro Electric System Limited • Veridian Connections Inc.
7. Northwest Ontario	• Atikokan Hydro Inc. • Chapleau Public Utilities Corporation • Fort Frances Power Corporation • Hydro One Networks Inc. • Kenora Hydro Electric Corporation Ltd. • Sioux Lookout Hydro Inc. • Thunder Bay Hydro Electricity Distribution Inc.
8. Windsor-Essex	• E.L.K. Energy Inc. • Entegrus Power Lines Inc. [Chatham-Kent] • EnWin Utilities Ltd. • Essex Powerlines Corporation • Hydro One Networks Inc.

9. East Lake Superior	N/A → This region is not within Hydro One's territory
10. GTA East	• Hydro One Networks Inc. • Oshawa PUC Networks Inc. • Veridian Connections Inc. • Whitby Hydro Electric Corporation
11. London area	• Entegrus Power Lines Inc. [Middlesex] • Erie Thames Power Lines Corporation • Hydro One Networks Inc. • London Hydro Inc. • Norfolk Power Distribution Inc.** • St. Thomas Energy Inc. • Tillsonburg Hydro Inc. • Woodstock Hydro Services Inc.**
12. Peterborough to Kingston	• Eastern Ontario Power Inc. • Hydro One Networks Inc. • Kingston Hydro Corporation • Lakefront Utilities Inc. • Peterborough Distribution Inc. • Veridian Connections Inc.

13. South Georgian Bay/Muskoka	• Collingwood PowerStream Utility Services Corp. (COLLUS PowerStream Corp.) • Hydro One Networks Inc. • Innisfil Hydro Distribution Systems Limited • Lakeland Power Distribution Ltd. • Midland Power Utility Corporation • Orangeville Hydro Limited • Orillia Power Distribution Corporation • Parry Sound Power Corp. • Powerstream Inc. [Barrie] • Tay Power • Veridian Connections Inc. • Veridian-Gravenhurst Hydro Electric Inc. • Wasaga Distribution Inc.
14. Sudbury/Algoma	• Espanola Regional Hydro Distribution Corp. • Greater Sudbury Hydro Inc. • Hydro One Networks Inc.

BRANT AREA INTEGRATED REGIONAL RESOURCE PLAN

Part of the Burlington-Nanticoke Planning Region | April 28, 2015

ieso
Independent Electricity System Operator

Integrated Regional Resource Plan

Brant Area

This Integrated Regional Resource Plan ("IRRP") was prepared by the IESO pursuant to the terms of its Ontario Energy Board licence, EI-2013-0066.

This IRRP was prepared on behalf of the Brant Area Working Group, which included the following members:

- Independent Electricity System Operator
- Brant County Power Inc.
- Brantford Power Inc.
- Hydro One Networks Inc. (Distribution) and
- Hydro One Networks Inc. (Transmission)

The Brant Area Working Group assessed the adequacy of electricity supply to customers in the Brant Area over a 20-year period; developed a flexible, comprehensive, integrated plan that considers opportunities for coordination in anticipation of potential demand growth scenarios and varying supply conditions in the Brant Area; and developed an implementation plan for the recommended options, while maintaining flexibility in order to accommodate changes in key assumptions over time.

Brant Area Working Group members agree with the IRRP's recommendations and support implementation of the plan through the recommended actions. Brant Area Working Group members do not commit to any capital expenditures and must still obtain all necessary regulatory and other approvals to implement recommended actions.

1. Introduction

This Integrated Regional Resource Plan ("IRRP") addresses the electricity needs of the Brant Area ("Area") over the next 20 years from 2014 to 2033. This report was prepared by the IESO on behalf of a Technical Working Group composed of the IESO, Brant County Power Inc., Brantford Power Inc., Hydro One Distribution, and Hydro One Transmission ("the Working Group").

The Brant Area encompasses the County of Brant, City of Brantford and surrounding areas. It has an estimated population of over 136,000 people. The electricity demand mix is comprised of residential, commercial and industrial uses. The Brant Area is supplied by the Brant TS, Powerline MTS and Brantford TS.

In Ontario, planning to meet the electrical supply and reliability needs of a large area or region is done through regional electricity planning, a process that was formalized by the Ontario Energy Board ("OEB" or "Board") in 2013. In accordance with the OEB regional planning process, transmitters, distributers and the IESO are required to carry out regional planning activities for the twenty-one electricity planning regions at least once every five years.

Under the Province's Growth Plan for the Greater Golden Horseshoe,[1] the Brant Area is expected to experience continued population growth in the coming decades. It continues to attract industrial and commercial customers and create opportunities for future development. This IRRP will help to ensure that the electricity system will support the expected development over the long term.

The Brant Area is a sub-region within the Burlington/Nanticoke region established through the OEB regional planning process. This report therefore contributes to fulfilling the requirements for the Burlington/Nanticoke region as mandated by the OEB. A second sub-region of the Burlington/Nanticoke region consists of the Bronte Area of Oakville and Burlington; this sub-region will be studied as a separate IRRP and is not included in the scope of this IRRP.

This IRRP for Brant identifies and coordinates options to meet electricity needs in the Area over the next 20 years ("study period") and is sub-divided into the near term (0-5 years, or 2014 through 2018), medium term (6-10 years, or 2019 through 2023) and longer term (11-20 years, or 2024 through 2033). Specifically, this IRRP identifies investments for immediate

[1] *Growth Plan for the Greater Golden Horseshoe, 2006 under the Places to Grow Act, 2005*

implementation to meet near- and medium-term needs in the Area, respecting expected lead times for development. This IRRP also identifies a number of options to meet longer-term needs, but given forecast uncertainty, the longer development lead time and the potential for technological change, the plan maintains flexibility for longer-term options and does not recommend specific projects at this time. Instead, the long-term plan identifies near-term actions to develop alternatives and engage with the community, to gather information and lay the groundwork to meet future needs, should they arise. These actions are intended to be completed before the next IRRP cycle, scheduled for 2020, so that the results of these actions can inform a decision should one be needed at that time.

This report is organized as follows:

- A summary of the recommended plan for the Brant Area is provided in Section 2;
- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the Brant Area and the study scope are discussed in Section 4;
- Demand forecast scenarios, and conservation and distributed generation assumptions, are described in Section 5;
- Near- medium- and long-term electricity needs in the Brant Area are presented in Section 6;
- Options for meeting near- and medium-term needs are assessed and recommendations for the near-term plan are provided in Section 7;
- Alternatives for meeting long-term needs are discussed and actions to support development of the long-term plan are provided in Section 8;
- A summary of community, aboriginal and stakeholder engagement to date in developing this IRRP and moving forward is provided in Section 9; and
- A conclusion is provided in Section 10.

2. The Integrated Regional Resource Plan

The Brant IRRP provides recommendations to address the Area's forecast electricity needs over the next 20 years, based on application of the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC"). This IRRP identifies forecast electricity needs in the Area over near term (0-5 years, or 2014 through 2018), medium term (6-10 years, or 2019 through 2023) and longer term (11- 20 years, or 2024 through 2033). These planning horizons are distinguished in the IRRP to reflect the different level of commitment required over these time horizons. The plans to address these timeframes are coordinated to ensure consistency. The IRRP was developed based on consideration of planning criteria, including reliability, cost, feasibility, and maximization of the use of the existing electricity system, where it is economic to do so.

This IRRP identifies specific projects for implementation in the near and medium term. This is necessary to ensure that they are in-service in time to address the Area's more urgent needs, respecting the lead time for development of the recommended infrastructure.

This IRRP identifies a number of alternatives to prepare to meet the Area's longer-term electricity needs. However, as these needs are forecast to arise in the future, it is not necessary (nor would it be prudent given forecast uncertainty and the potential for technological change) to recommend specific projects at this time. Instead, near-term actions are identified to develop alternatives and engage with the community, to gather information and lay the groundwork for future options. These actions are intended to be completed before the next IRRP cycle so that their results can inform a decision at that time.

2.1 Near-Term and Medium-Term Plan (2014 through 2023)

Near-Term Need
• Supply capacity in the Brant-Powerline 115 kV sub-system is inadequate today

The first element of the near-term plan is to account for targeted conservation and contracted distributed generation ("DG"). To address urgent supply capacity needs, two transmission projects are also recommended. The development of one of the transmission projects is currently underway; the former OPA issued a letter[2] to Hydro One Networks Inc.

[2]Letter to Hydro One: http://www.hydroone.com/RegionalPlanning/Burlington/Documents/OPA Letter - Burlington Nanticoke - Brant.pdf

("Hydro One") supporting this near-term project in order to ensure it was initiated and brought into service in time to address an urgent need. The second transmission project is under discussion between Brantford Power Inc., Brant County Power Inc. and Hydro One. These projects are described below and their respective locations are shown in Figure 2-1. The estimated cost of these transmission projects is approximately $13-16 million. Together, these projects can increase the load meeting capability ("LMC") of the 115 kV sub-system from 104 MW to approximately 165 MW. Combined with the other near- and medium-term recommendations, these projects will be sufficient to meet the forecast demand growth until the end of the study period.

Figure 2-1: Brant Area Electricity System

These recommendations meet the near- and medium-term electricity needs of the Brant Area in a timely and cost-effective manner, and were developed with a view to maximizing the use of the existing system.

Recommended Actions

1. Implement conservation and distributed generation and monitor results

The implementation of provincial conservation and DG targets established in the 2013 Long Term Energy Plan ("LTEP") are key components of the near- and medium-term plan for the

Brant Area. In developing the demand forecast, peak-demand impacts associated with the provincial targets were assumed before identifying any residual needs, consistent with the provincial Conservation First policy.[3] Conservation resources account for approximately 40% of the forecast demand growth during the first 10 years of the study.

As the provincial conservation targets are energy[4] based, the IESO with the Area local distribution companies ("LDCs") will monitor the magnitude of the peak demand savings resulting from these targets in the Brant Area. This will be an important element of the near-term plan, and will also lay the foundation for the long-term plan by gauging actual performance of specific conservation measures, and assessing potential in the Area for further conservation efforts.

Provincial programs that encourage the development of distributed generation, such as the Feed-in-Tariff ("FIT"), microFIT, and Combined Heat and Power Standard Offer ("CHPSOP") programs, can also contribute to reducing peak demand in the Region, dependent , in part, on local interest and opportunities for development. Existing and committed distributed generation impacts were also assumed before identifying needs for the Area. It is expected that distributed generation resources will reduce the gross forecast for the Area by approximately 5 % for the study period. The LDCs and the IESO will continue their activities to support DG initiatives where appropriate and monitor their impacts.

2. Install capacitor banks at Powerline MTS

To meet the urgent need to provide capacity relief to the Area's 115 kV supply pocket the Working Group recommended the installation of 30 MVAR of capacitor banks at Powerline MTS. The estimated cost from Brantford Power and Brant County Power for this project is approximately $1-million. These capacitor banks are expected to be in-service for the summer of 2015, and will provide additional capacity of 21 MW to the Brant-Powerline sub-system. Implementation began in 2014 with the former OPA issuing a letter supporting this project so that it could be brought into service in time to address urgent needs.

---

[3] Conservation First policy:
http://www.energy.gov.on.ca/en/conservation-first/http:/www.energy.gov.on.ca/en/conservation-first/
[4] The provincial targets are for energy and have to be converted to capacity to calculate impact on peak demand by conservation.

3. Connect existing 115 kV Circuits B12/13 to B8W

To meet the remaining supply capacity need in the near term, the Working Group recommended the installation of three (3) 115 kV breakers to connect the existing circuits B12/13 from Hamilton to B8W from Woodstock. The budgetary estimate for this project is $12-15 million with an in-service date of 2017. These switching facilities are expected to provide additional capacity of 40 MW to the Brant-Powerline sub-system after the addition of the capacitor banks at Powerline MTS.

4. Demand response Pilot Program for Brant

A pilot demand response ("DR") program will be considered by the IESO in order to identify costs and determine feasibility and potential of DR to meet supply capacity needs in the Area. If DR proves to be feasible and economic, it could play an important role in long-term planning for the Area.

2.2 Near- and Medium-Term Actions in Support of Long-Term Plan (2024 through 2033)

The recommended near- and medium-term solutions are expected to satisfy the forecast demand growth for the expected-growth scenario until the end of the study period. In the long term, the Brant Area electricity system's ability to supply load will be constrained if additional industrial loads arise in the Area or higher demand growth occurs. Thus, the Working Group believes it is prudent to plan to meet a higher-demand scenario for the longer term. This will provide a capacity margin to supply emerging needs, and allow flexibility and time to plan for the next round of growth should a supply gap materialize.

A number of alternatives are possible to meet the Area's longer-term needs under in the high-demand growth scenario, including combinations of conservation, local generation, "wires" (transmission and distribution) and other emerging technologies. While specific solutions do not need to be committed today, it is prudent to begin work now in order to gather information, monitor developments, engage the community, and develop alternatives to meet the needs and to support decision-making in the next iteration of the IRRP. The longer-term plan sets out the near-term actions required to ensure that options remain available to address future needs if and when they arise. Long-term options will be reviewed in subsequent Burlington-Nanticoke regional planning studies.

Recommended Actions

1. Monitor load growth and conservation achievement and distributed generation performance

On an annual basis, the IESO will coordinate a review of conservation achievement, the uptake of provincial DG projects, and actual demand growth in the Brant Area. This information will be used to track the expected timing of longer-term needs to determine when a decision on the long-term plan is required. Information on conservation and DG performance will also provide useful feedback into the ongoing development of these options as potential long-term solutions. Additionally, the IESO will also monitor results and the incorporation of lessons learned from the DR pilot if it is implemented.

2. Undertake community engagement

Broad community and public engagement is essential to development of a long-term plan. As no long-term needs have been identified for the Brant Area, there is no requirement at this time for engagement on long-term options.

A Local Advisory Committee ("LAC") may be established for the broader Burlington to Nanticoke region once the IRRP process for the one remaining area in the Burlington to Nanticoke region has been completed. A LAC's purpose is to provide input and advice on regional plans and the engagement of those plans for an area or region. It is expected that a LAC will consist of community representatives and stakeholders. Advice from the LAC will be incorporated in developing engagement plans for the Area.

3. Continue ongoing work to develop transmission/generation options

The Working Group will continue to work together to evaluate the transmission and generation alternatives to meet the potential long-term needs.

3. Development of the IRRP

3.1 The Regional Planning Process

In Ontario, planning to meet the electricity needs of customers at a regional level is done through regional planning. Regional planning assesses the interrelated needs of a region - defined by common electricity supply infrastructure over the near, medium and long term, and develops a plan to ensure cost-effective, reliable, electricity supply. Regional plans consider the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluate options for addressing needs, and recommend actions.

Regional planning has been conducted on an as needed basis in Ontario for many years. Most recently, the former Ontario Power Authority ("OPA") carried out regional planning activities to address regional electricity supply needs. The OPA conducted joint regional planning studies with distributors, transmitters, the IESO and other stakeholders in regions where a need for coordinated regional planning had been identified.

In 2012, the Ontario Energy Board convened the Planning Process Working Group ("PPWG") to develop a more structured, transparent, and systematic regional planning process. This group was composed of industry stakeholders including electricity agencies, utilities, and stakeholders. In May 2013, the PPWG released the Working Group Report to the Board, setting out the new regional planning process. Twenty-one electricity planning regions in the province were identified in the Working Group Report and a phased schedule for completion was outlined. The Board endorsed the Working Group Report and formalized the process timelines through changes to the Transmission System Code and Distribution System Code in August 2013, as well as through changes to the OPA's licence in October 2013. The OPA license changes required it to lead a number of aspects of regional planning, including the completion of comprehensive IRRPs. Following the merger of the IESO and the OPA on January 1, 2015, the regional planning responsibilities identified in the OPA's licence were transferred to the IESO.

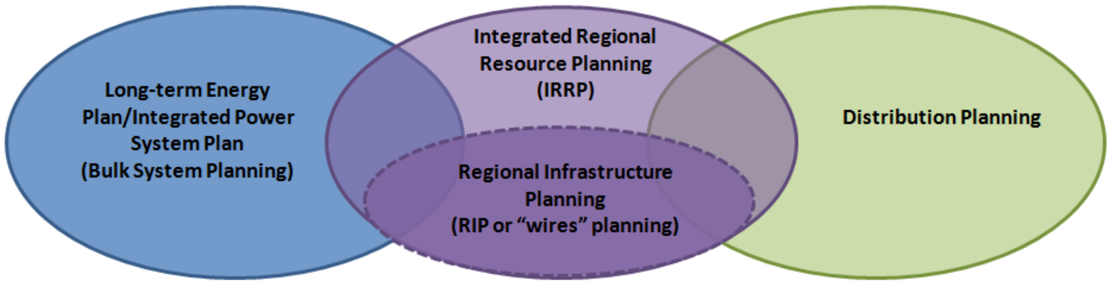
The regional planning process begins with a Needs Screening process performed by the transmitter, which determines whether there are needs requiring regional coordination. If regional planning is required, the IESO then conducts a scoping assessment to determine whether a comprehensive IRRP is required, which considers conservation, generation, transmission, and distribution solutions, or whether a straightforward "wires" solution is the only option. If the latter applies, then a transmission and distribution focused Regional Infrastructure Plan ("RIP") is required. The Scoping Assessment process also identifies any sub-regions that require assessment. There may also be regions where infrastructure investments do not require regional coordination and can be planned directly by the distributor and transmitter, outside of the regional planning process. At the conclusion of the Scoping Assessment, the IESO produces a report that includes the results of the Needs Screening process – identifying whether an IRRP, RIP or no regional coordination is required - and a preliminary Terms of Reference. If an IRRP is the identified outcome, then the IESO is required to complete the IRRP within 18 months. If a RIP is required, the transmitter takes the lead and has six months to complete it. Both RIPs and IRRPs are to be updated at least every five years.

The final IRRPs and RIPs are to be posted on the IESO and relevant transmitter websites, and can be used as supporting evidence in a rate hearing or leave to construct application for specific infrastructure investments. These documents may also be used by municipalities for planning purposes and by other parties to better understand local electricity growth and infrastructure requirements.

Regional planning, as shown in Figure 3-1, is just one form of electricity planning that is undertaken in Ontario. There are three types of electricity planning in Ontario:

- Bulk system planning
- Regional system planning
- Distribution system planning

Figure 3-1: Levels of Electricity System Planning



Bulk System Planning

- 500 kV & 230 kV transmission
- Interconnections
- Inter-area network transfer capability
- System reliability (security and adequacy) to meet NERC, NPCC, ORTAC
- Congestion and system efficiency
- System supply and demand forecasts
- Incorporation of large generation
- Typically medium- and long-term focused

Regional Planning

- 230 kV & 115 kV transmission
- 115/230 kV autotransformers and associated switchyard facilities
- Customer connections
- Load supply stations
- Regional reliability (security and adequacy) to meet NERC, NPCC & ORTAC
- ORTAC local area reliability criteria
- Regional/local area generation & CDM resources
- Typically near- & medium-term focused

Distribution Network Planning

- Transformer stations to connect to the transmission system
- Distribution network planning (e.g. new & modified Dx facilities)
- Distribution system reliability (capacity & security)
- Distribution connected generation & CDM resources
- LDC demand forecasts
- Near- & medium-term focused

Planning at the bulk system level typically considers the 230 kV and 500 kV network. It is typically carried out by the IESO and considers the major transmission facilities and assesses the resources needed to adequately supply the province. Distribution planning, which is carried out by local distribution companies, looks at specific investments on the low voltage, distribution system.

Regional planning can overlap with bulk system planning. For example, overlap can occur at interface points where regional resource options may also address a bulk system issue. Similarly, regional planning can overlap with the distribution planning of LDCs. An example of this is when a distribution solution addresses the needs of the broader local area or region. Therefore, to ensure efficiency and cost effectiveness, it is important for regional planning to be coordinated with both bulk and distribution system planning.

By recognizing the linkages with bulk and distribution system planning, and coordinating multiple needs identified within a given region over the long term, the regional planning process provides an integrated assessment of needs. Regional planning aligns near- and long-term solutions and allows specific investments recommended in the plan to be understood as part of a larger context. Furthermore, regional planning optimizes ratepayer interests by avoiding piecemeal planning and asset duplication, and allows Ontario ratepayers' interests to be represented along with the interests of LDC ratepayers. Where IRRPs are undertaken, they allow an evaluation of the multiple options available to meet needs, including conservation, generation, and "wires" solutions. Regional plans also provide greater transparency through engagement in the planning process, and by making plans available to the public.

3.2 The IESO's Approach to Regional Planning

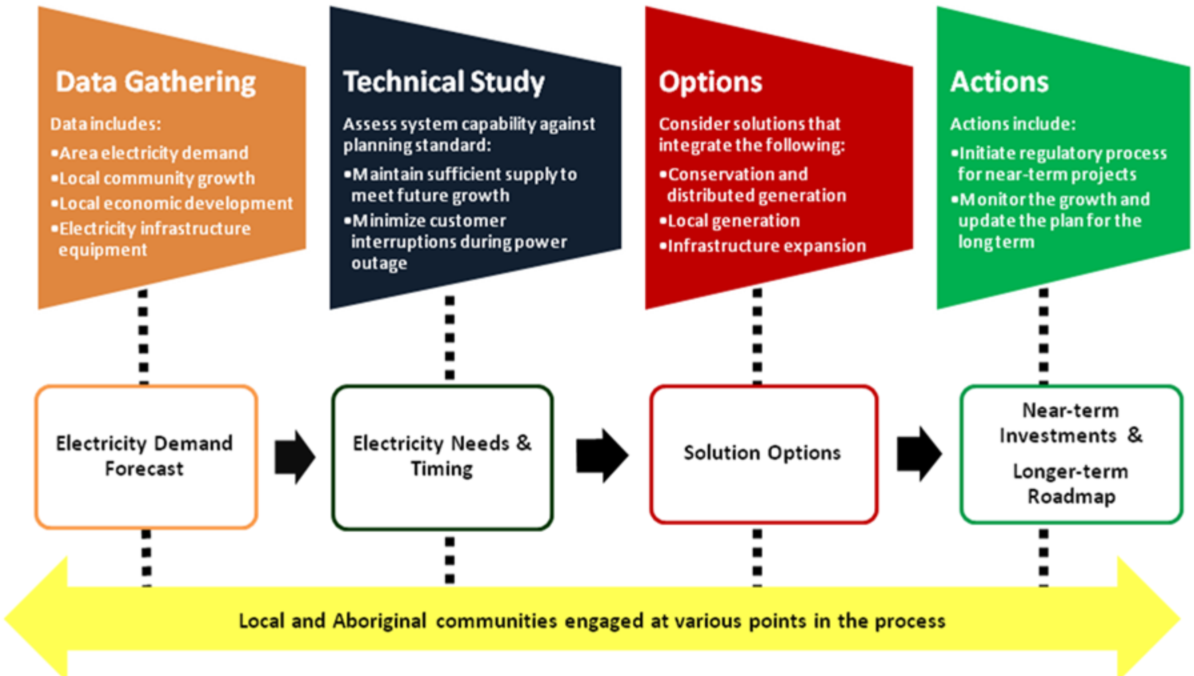
IRRPs assess electricity system needs for a region over a 20-year period. The 20-year outlook anticipates long-term trends so that near-term actions are developed within the context of a longer-term view. This enables coordination and consistency with the long-term plan, rather than simply reacting to immediate needs.

In developing an IRRP, a different approach is taken to developing the plan for the first 10 years of the plan—the near- and medium-term—than for the longer-term period of 10-20 years. The plan for the first 10 years is developed based on best available information on demand, conservation, and other local developments. Given the long lead time to develop electricity infrastructure, near-term electricity needs require prompt action to enable the specified solutions in a timely manner. By contrast, the long-term plan is characterized by greater forecast uncertainty and longer development lead time; as such solutions do not need to be committed to immediately. Given the potential for changing conditions and technological development, the IRRP for the long term is more directional, focusing on developing and maintaining the viability of options for the future, and continuing to monitor demand forecast scenarios.

In developing an IRRP, the IESO and regional working group (see below) carry out a number of steps. These steps include electricity demand forecasts; technical studies to determine electricity needs and the timing of these needs; the development of potential options; and, a recommended plan including actions for the near and long term. Throughout this process, engagement is carried out with stakeholders and First Nations and Métis communities and stakeholders. The steps of an IRRP are illustrated in Figure 3-2 below.

The IRRP report documents the inputs, findings and recommendations developed through the process described above, and provides recommended actions for the various entities responsible for plan implementation. Where "wires" solutions are included in the plan recommendations, the completion of the IRRP report is the trigger for the transmitter to initiate an RIP process to develop those options. Other actions may involve: development of conservation, local generation, or other solutions; community engagement; or information gathering to support future iterations of the regional planning process in the region.

Figure 3-2: Steps in the IRRP Process



3.3 Brant Area Working Group and IRRP Development

The Brant IRRP is a "transitional" IRRP in that it began prior to formalization of OEB's regional planning process and some of the study was conducted before the new process and its requirements were known. While much of the work completed in the early days of the study is consistent with the new process, certain aspects of the development of the IRRP have been refined, and the underlying data and assumptions, such as demand forecasts, have been updated to reflect changes since the study began.

In 2013, the Working Group was formed to assess the supply capacity for Brant Area. The Working Group developed a Terms of Reference for the study,[5] gathered data, identified near- to long-term needs in the Area, and recommended the near- and medium-term actions included in this IRRP.

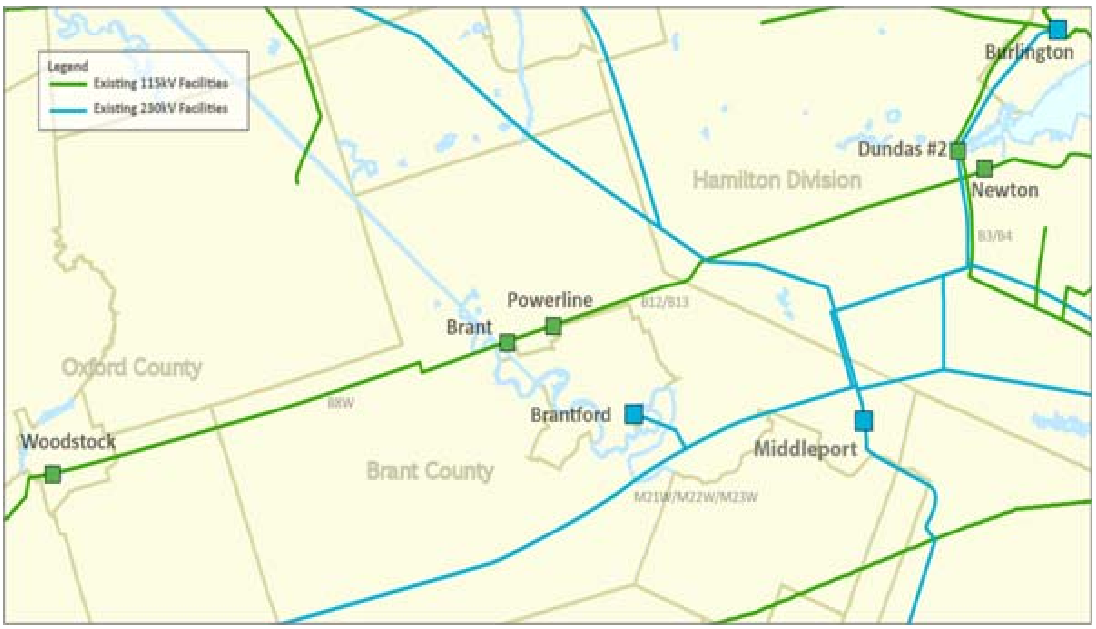
[5] Brant IRRP Terms of Reference: http://powerauthority.on.ca/sites/default/files/planning/Brant-Terms-of-Reference.pdf

4. Background and Study Scope

This report presents an IRRP for the Brant Area over a 20-year period from 2014 to 2033. The Brant Area is a sub-region within the Burlington/Nanticoke region.

The geographic scope of the Brant IRRP includes the County of Brant and the City of Brantford. The electricity supply to the study Area is provided by three step-down stations: Brant TS, Powerline MTS and Brantford TS, as shown in Figure 4-1.

Figure 4-1: Brant Area and Vicinity



Brant TS and Powerline MTS are connected to the double-circuit 115 kV transmission line, B12/13[6] originating from Burlington TS. These stations are also backed up in emergencies by the 115 kV line B8W from Woodstock. Under normal operation, the B8W circuit is not connected to the Brant-Powerline sub-system circuits B12/13. The Brantford TS is supplied at 230 kV from the double-circuit transmission line M32/33W between Middleport TS (Hamilton) and Buchanan TS (London). The coincident peak demand of the three stations in summer 2014

[6] Circuits B12/13 also supply two other DESN stations, Dundas #2 TS and Newton TS in the Hamilton area serving customers of Horizon Utilities Corporation and Hydro One Distribution. As Dundas #2 TS and Newton TS are not directly impacted by the supply issues associated with the Brant Area in this study, a detailed assessment of these two stations is covered in the broader region needs screening of Burlington-Nanticoke.

was approximately 250 MW. Distribution service to customers in the Area is provided by Brant County Power Inc., Brantford Power Inc. and Hydro One Distribution.

For the purposes of this IRRP, the term "Brant Area" is used to more precisely define the Area supplied by the following transformer stations: Brant TS, Powerline MTS and Brantford TS.

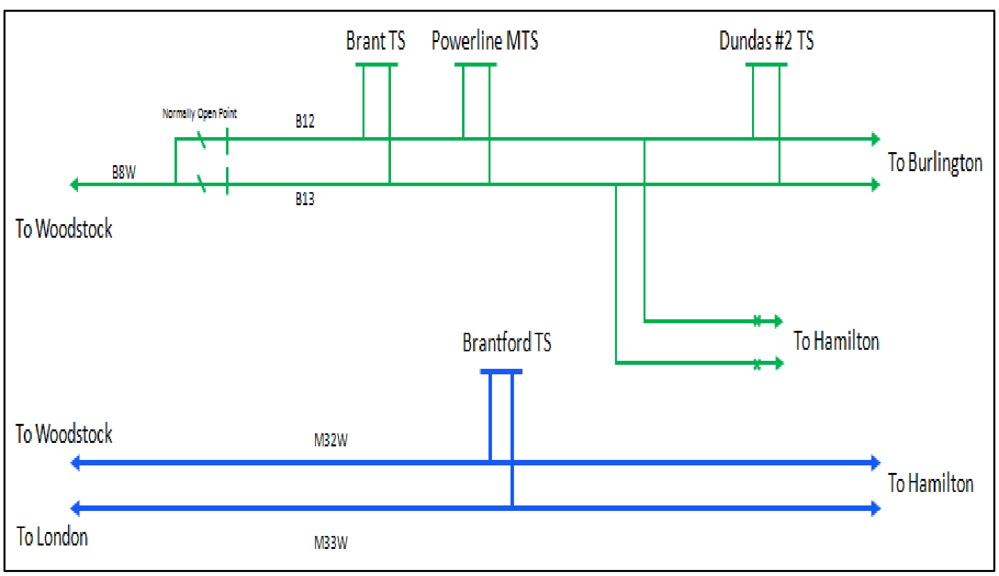
For the purposes of this IRRP, the transmission system in the Brant Area is further divided into two sub-systems:

1. The Brant Powerline sub-system: customers supplied from Brant TS and Powerline MTS via the B12/B13 115 kV transmission line; and
2. The Brantford TS sub-system: customers supplied from Brantford TS via the 230 kV transmission line M32W/M33W.

While there is some emergency transfer capability between the two Brant Area sub-systems, they are normally operated independently.

These two sub-systems are shown in Figure 4-2 below.

Figure 4-2: Brant Area Sub-systems

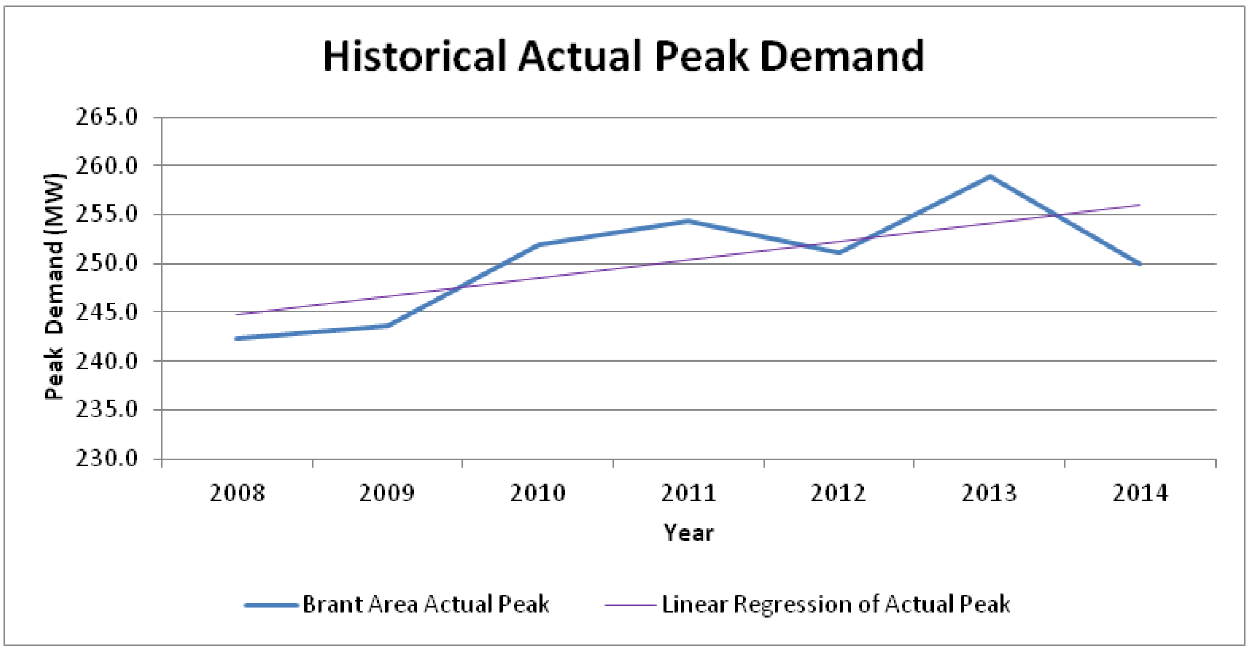


5. Demand Forecast

5.1 Historical Demand

Actual peak electricity demand in the Brant Area has increased moderately from 242 MW in 2008 to 259 MW in 2013, with a modest drop to 250 MW in 2014. This represents a nominal growth rate of 1.9 %, as shown in Figure 5-1. The historical peak demand reflects the weather experienced at the time of the system's coincident peak, and includes the impacts of conservation and DG.

Figure 5-1: Brant Area Historical Electricity Demand



5.2 Demand Forecast Methodology

Regional electricity needs are driven by the limits of the infrastructure supplying an area, which is sized to meet peak demand requirements of that area. Therefore, regional planning typically focuses on growth in regional-coincident peak demand. Energy adequacy is usually not a concern of regional planning, as the region can generally draw upon energy available from the provincial electricity grid, with energy adequacy for the province being planned through a separate process.

The near- and medium-term aspects of a forecast are closely linked to the historical growth experienced in an area and is usually based on loads expected to be in-service within a few years of growth being planned. Unmet needs forecast to arise during this time frame typically require solutions to be developed and implemented during the current planning cycle. The long-term forecast is typically used to identify emerging issues and to set longer-term priorities, with the goal of ensuring near- and medium-term actions will not be stranded or somehow limited in value by the most likely long-term outcomes.

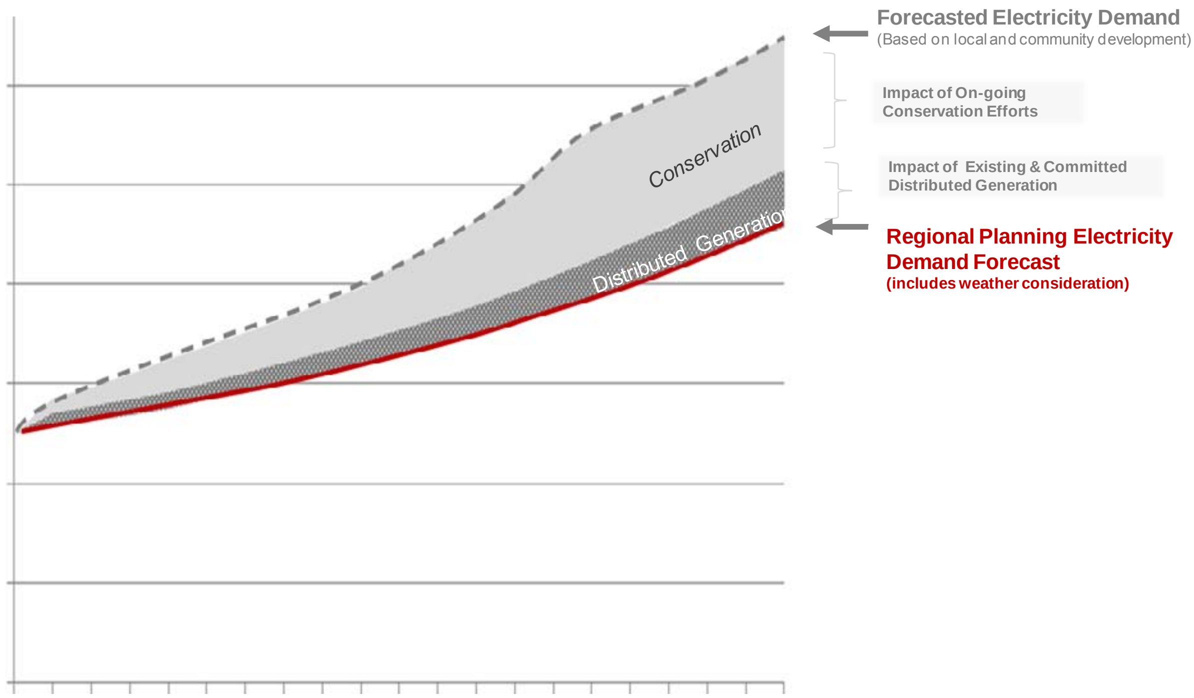
After taking into consideration the combined impacts of conservation and DG, a 20-year planning forecast was produced based on the LDCs' gross demand forecasts and reflecting the 2013 LTEP growth assumptions - this is the expected-growth forecast. Additionally, a second net demand forecast was prepared for the longer term to account for added planning uncertainty, based on the provincial Places to Grow Act - this is referred to as the higher-growth forecast.

5.2.1 Near- and Medium-Term (2014 through 2023)

For the near and medium term, a regional peak demand forecast was developed as shown in Figure 5-2. Gross demand forecasts, assuming normal-year weather conditions, were provided by the LDCs. The LDCs' forecasts are based on growth projections included in regional and municipal plans, which in turn reflect the province's Places to Grow policy. These forecasts were then modified to reflect the peak demand impacts of provincial conservation targets and DG contracted through provincial programs such as FIT and microFIT, and adjusted to reflect extreme weather conditions, to produce a planning forecast. The planning forecast was then used to assess any growth-related electricity needs in the region.

Using a planning forecast that is net of provincial conservation targets provides consistency with the province's Conservation First policy by reducing demand requirements before assessing any growth-related needs. The planning forecast assumes that these conservation targets will be met and that the targets, which are energy-based, will produce the expected local peak demand impacts. Therefore, an important aspect of plan implementation will be monitoring the actual peak demand impacts of conservation programs delivered by the local LDCs.

Figure 5-2: Development of Demand Forecasts



5.2.2 Longer Demand Forecast (2024 through 2033)

For the longer-term outlook, two demand forecast scenarios were developed to reflect the inherent uncertainty associated with forecasting this far in the future.

1. **"Expected Growth":** This scenario was developed consistent with the growth assumptions embodied in the government's provincial energy plan. As with the near and medium-term (0-10 years) forecast, the provincial conservation targets up to 2032 are deducted from the gross demand projections to produce a planning forecast net of conservation.
2. **"Higher Growth":** This scenario was developed to reflect continued development in Brant Area consistent with the projections associated with the province's *Places to Grow Act, 2005*. This higher-growth forecast scenario is consistent with the growth assumptions associated with the long-term municipal plan projections. As with the near- and medium-term forecasts, the provincial conservation targets up to 2032 are deducted from the gross demand projections to produce a planning forecast net of conservation.

Additional details related to the development of the demand forecasts are provided in Appendix A.

5.3 Gross Demand Forecast

The gross demand forecast for the Brant Area was developed by the Area LDCs based on historical growth rates. The forecast population is based on the Ministry of Finance's Spring 2013[7] population projection for the Brant Census Division, which includes the City of Brantford and Brant County. The Brant Census Division forecasts an average annual population growth rate of 0.9% from 2012-2031.

Area LDC forecasts are based on historical growth rates, supported by Municipal and Regional Official Plans as a primary source for input data. Other common considerations included known connection applications, and typical electrical demand intensity for similar customer types.

Additional background on the methodology used by each LDC to prepare their gross demand forecasts are available in Appendix A.

5.4 Conservation Assumed in the Forecast

Conservation plays a key role in maximizing the useful life of existing infrastructure, and maintaining reliable supply. Conservation is achieved through a mix of program-related activities, including behavioral changes by customers and mandated efficiencies from building codes and equipment standards ("C&S"). These approaches complement each other to maximize conservation results. The conservation savings forecast for Brant Area are applied to the gross peak demand forecast.

In December 2013 the Ministry of Energy released a revised Long-Term Energy Plan ("LTEP"), which outlined a provincial conservation target of 30 TWh of energy savings by 2032. In order to represent the effect of these targets within regional planning, the IESO developed an annual forecast for peak demand savings resulting from the provincial energy savings target, which was then expressed as a percentage of demand in each year. These percentages were applied to the LDCs' demand forecasts to develop an estimate of the peak demand impacts from the provincial targets in the Brant Area.

---

[7] Ministry of Finance Spring 2013 population projection
http://www.fin.gov.on.ca/en/economy/demographics/projections/table6.html

It is assumed existing DR already in the base year will continue. Savings from potential future DR resources are not included in the forecast and are instead considered as possible solutions to identified needs.

5.5 Distributed Generation Assumed in the Forecast

In addition to conservation resources, DG in the Brant Area is also applied to offset peak demand requirements. Distributed generation resource development in Ontario has been encouraged by the *Green Energy Act, 2009* and associated procurements such as the Feed-in Tariff ("FIT") program. These procurements have increased the significance of DG in Ontario. This generation, while intermittent in nature, contributes to meeting the electricity demands of the province. These procurements take into consideration the system need for generation as well as cost.

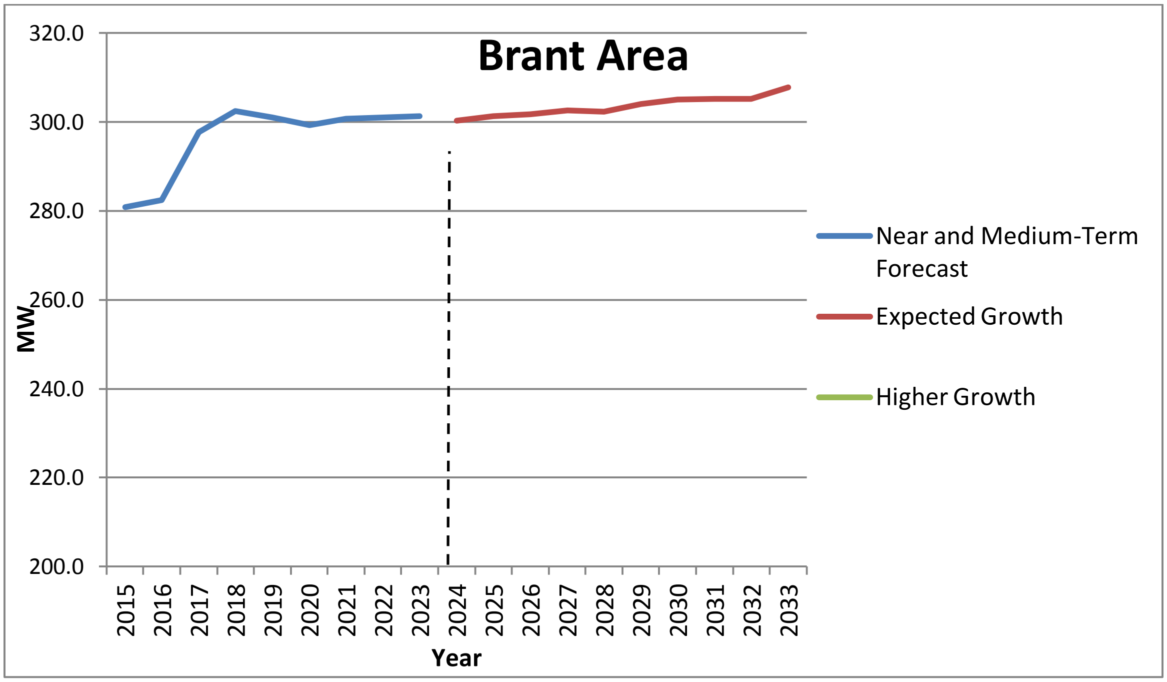
One aspect related to DG that should be noted is that DG resources, such as intermittent renewable generation resources like wind and solar, are not always available at the time of system peak. Therefore, the assumed effective capacity of these facilities (approximately 20 MW), not the full installed capacity, is applied to the Brant Area peak demand.[8] The location, contract capacity, and effective contribution of these resources in the Brant Area can be found in Appendix A.

[8] Effective capacity is the portion of installed capacity that contributes at the time of system peak.

5.6 Planning Forecasts

5.6.1 Total Demand Forecast in Brant Area

Figure 5-3: Brant Area Total Demand Forecast



5.6.1.1 Near- and Medium-Term (2014 through 2023)

The near- and medium-term aspects of a forecast are closely linked to the historical growth experienced in an area and are usually based on loads expected to be in-service within a few years or growth being planned.

The summer peak demand planning forecast of the Brant Area is shown in Figure 5-3 . There is a noticeable step increase in peak demand from the year 2015 to 2018. This is based on customers requesting connection over the next three years. Approximately 37 MW of industrial demand was added to the demand forecast in 2014, which is roughly 15% of the total Area demand. These types of loads often arise on short notice and in large blocks as is evidenced from the in-service dates of 2015 through 2018 and the step changes noticeable in the graph. For example, a forging expansion project will need additional 16 MW supply capacity by 2016.

Table 5-1 below shows the size of the large industrial loads which have been considered in the demand forecast based on LDCs information.

Table 5-1: Near-Term Industrial Load

Proposed Connection Station	LDCs	Estimated Size (MW)
Brantford TS	Brantford Power Inc.	16
Brant TS	Brantford Power Inc.	6
Powerline MTS	Brant County Power Inc.	8
Brantford TS	Brant County Power Inc.	4
Brant TS	Brant County Power Inc.	3
Total Load Added		**37**

The type of block industrial load that has been considered in the near- to medium-term forecast is difficult to forecast for the long term. As seen in Table 5-1, the loads are not concentrated at one station or within one LDC and these types of block loads can also appear with short notice. Consequently, industrial growth incremental to the loads indicated in Table 5-1 were not forecast as part of the medium-term forecast.

5.6.2 Long-Term (2024 through 2033)

For the longer-term outlook, two demand forecast scenarios were developed to reflect the inherent uncertainty associated with forecasting this far in the future.

The "expected-growth scenario" was developed consistent with the growth assumptions embodied in the government's 2013 LTEP. This scenario was a continuation of the forecast used for the near- and medium-term. The expected-growth scenario represents a future with lower electricity demand growth, due to higher electricity prices, increased electricity conservation, and lower energy intensity of the economy. The long-term Area forecast under the expected-growth scenario grows 27 MW from 281 MW to 308 MW. This includes the reduction in demand of approximately 49 MW from conservation, and approximately 18 MW from DG.

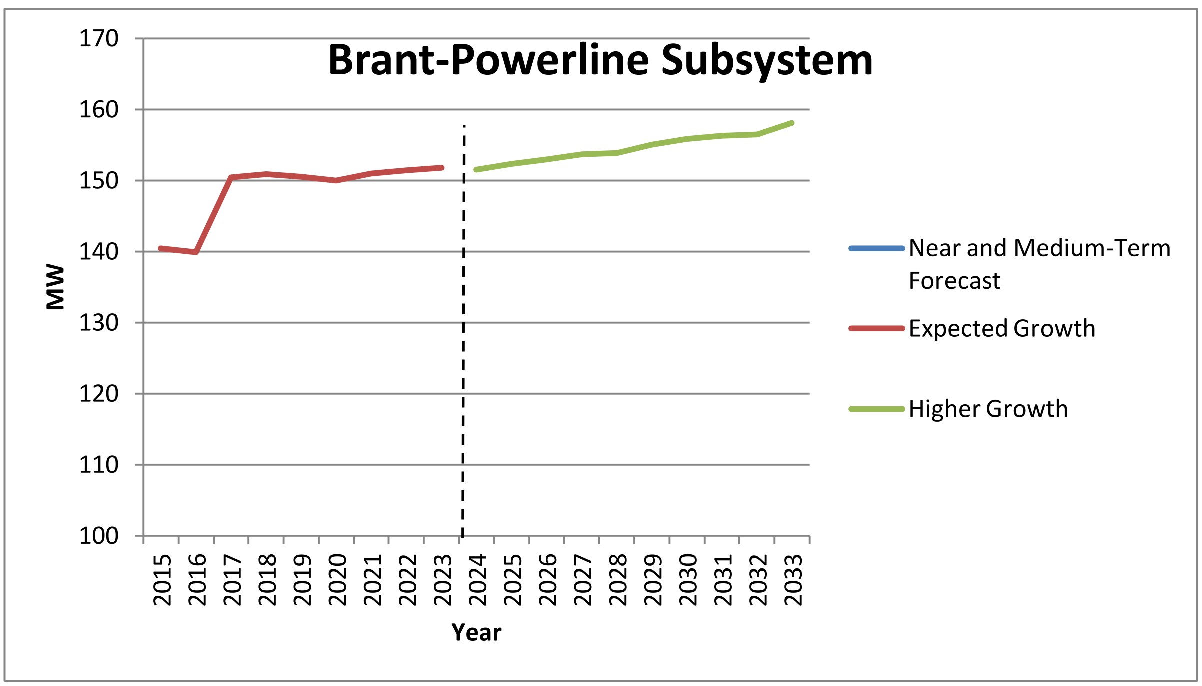
Taking into account the type of load growth the Brant Area has experienced (i.e., fast developing, large block loads), the Working Group examined an additional scenario to consider the possible impact of higher growth on the Area's needs. A higher-growth scenario was developed to reflect continued development in the Brant Area consistent with the projections associated with the province's Places to Grow policy. This forecast scenario is also consistent with growth assumptions associated with the long-term municipal plan projections for the Brant Area.

The higher-growth forecast assumes a total of 57 MW of new savings from conservation targets across the Brant Area over the next 20 years.

5.6.3 Sub-system Forecasts

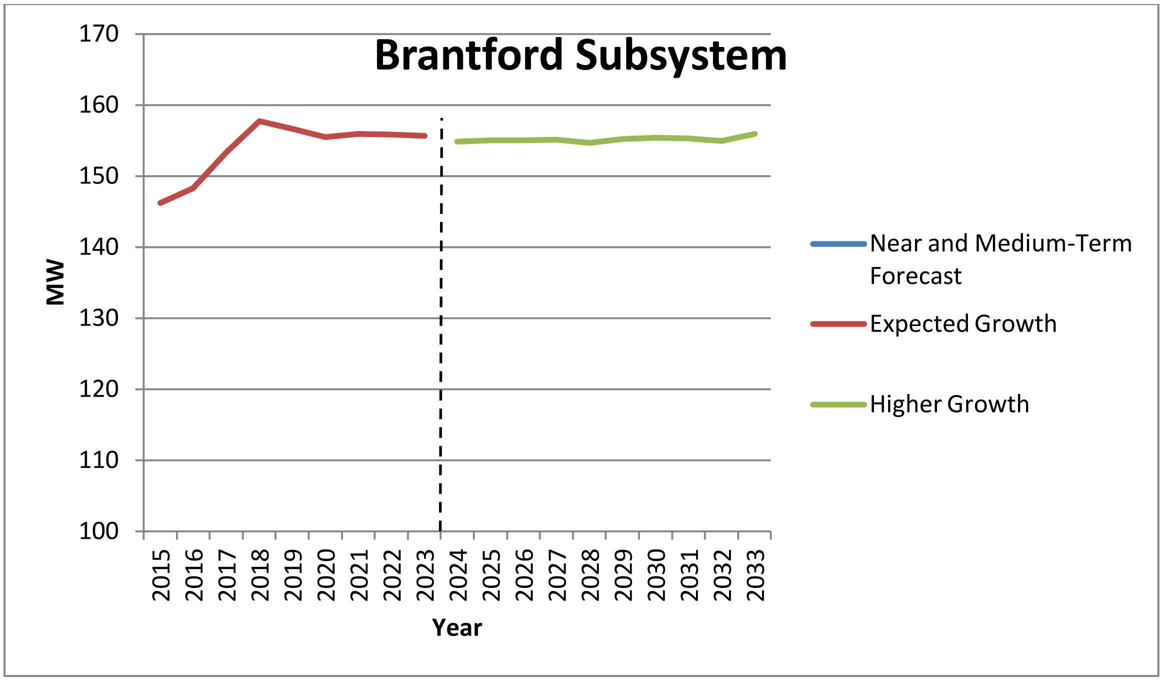
For the Brant-Powerline sub-system, the forecast demand under the expected-growth scenario grows from 140 MW to 158 MW from 2015 to 2033. This includes the reduction of approximately 25 MW from conservation, and approximately 9 MW from DG, with approximately 13 MW of demand reduction through conservation expected in the 2024-2033 timeframe. For the higher-growth scenario, the forecast grows from 157 MW in 2024 to 177 MW in 2033.

Figure 5-4: Brant TS and Powerline MTS Forecast



For the Brantford TS pocket, the forecast demand under the expected-growth scenario grows from 146 MW to 156 MW from 2015 to 2033. This includes the reduction of approximately 25 MW from conservation, and approximately 10 MW from DG. For the higher-growth scenario, the forecast grows from 165 MW in 2024 to 182 MW in 2033.

Figure 5-5: Brantford TS Planning Forecast



6. Electricity System Needs

Based on the demand forecasts, system capability, and the Ontario Resource and Transmission Assessment Criteria ("ORTAC")[9] criteria, the Working Group identified electricity needs in the near-to-medium term (0-10 years), and in the long term (11-20 years). This section describes the identified needs for the Brant Area.

6.1 Needs Assessment Methodology

Provincial assessment criteria and standards (ORTAC) were applied to assess the capability of the existing electricity system to supply forecast electricity demand growth in the Brant Area over the next 20 years (refer to Section 5). These criteria were applied to assess three broad categories of needs.

- Supply capacity requirements were assessed using PSS/E, a power flow simulation tool, to analyze the capability of the existing system, including transmission and local generation infrastructure, to supply load growth. Technical study is provided in Appendix B.
- ORTAC standards were applied to identify areas with needs to address the impacts of potential major supply interruptions. The amount of customer load supplied from specific circuits before and after potential contingencies, and the capability to restore interrupted loads following a contingency, either through transmission system switching or transfers on the distribution system, were assessed in accordance with these criteria.
- Step-down station capacity needs were identified by comparing forecast demand growth to the 10-day Limited Time Rating ("LTR"), or thermal capacity, of the existing stations in the Area, to determine the net incremental requirement for transformation capacity in the Area.

6.2 Ontario Resource and Transmission Assessment Criteria

The ORTAC the provincial standard for assessing the reliability of the transmission system, were applied to assess supply capacity and reliability needs.

The ORTAC includes criteria related to assessment of the bulk transmission system, as well as the assessment of local or regional reliability requirements. The latter criteria are relevant to this study and guided the technical studies performed in assessing the electricity system needs

[9] http://www.ieso.ca/imoweb/pubs/marketadmin/imo_req_0041_transmissionassessmentcriteria.pdf

in Brant Area. The needs can be broadly categorized as addressing two distinct aspects of reliability: (1) providing supply capacity, and (2) limiting the impact of supply interruptions. Further details on the application of these criteria are provided in Appendix B.

6.3 Near- and Medium-Term Needs

Near- to medium-term needs often require action immediately to ensure that a solution is in place to address the need by the time it arises.

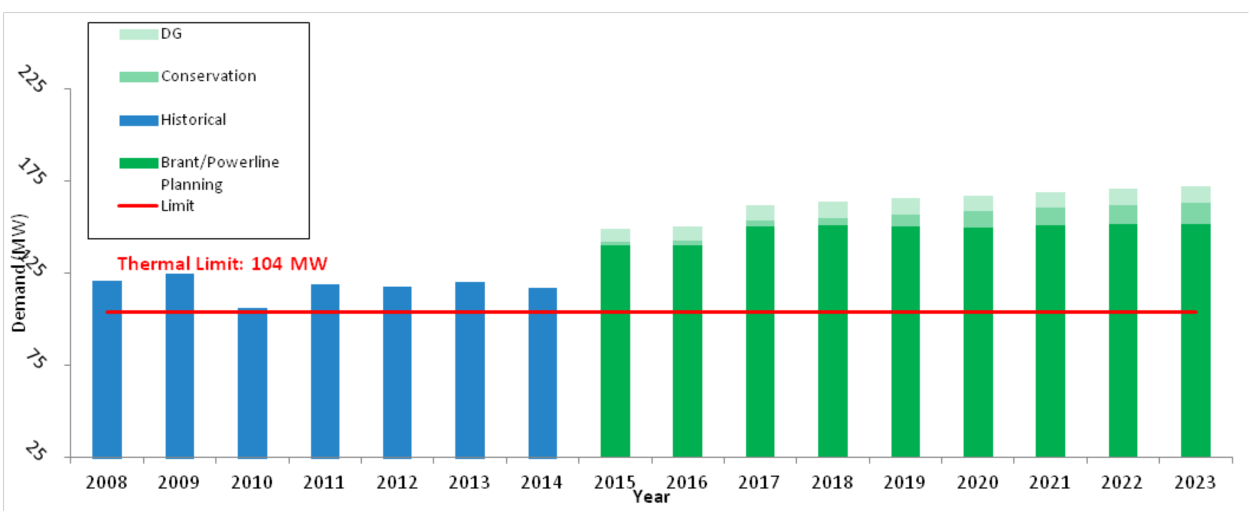
6.3.1 Need for Additional Supply Capacity

Brant-Powerline Sub-system

Today, the B12/B13 115 kV transmission line serving the Brant-Powerline sub-system has a LMC of approximately 104 MW. This limit is based on the violation of the voltage criteria following the loss of one of the B12/13 circuits.

As shown in Figure 6-1 below, peak demand for this sub-system has already exceeded the LMC, and is forecast to continue to exceed this limit throughout the study period.

Figure 6-1: Historical and Forecast Electricity Demand and Supply Capability in the Brant-Powerline Sub-system



Based on the forecast, additional capacity is required to meet current and future electricity demand in the Brant-Powerline sub-system. Until additional capacity is provided, operating measures such as temporary load transfers or interruption of load following a single contingency will be required. The existing system does not meet the ORTAC criteria for supply capacity in the near and medium term.

Brantford TS Sub-system

The Brantford TS sub-system meets the ORTAC criteria for supply capacity for the reference forecast throughout the study period.

6.3.2 Load Restoration Needs

Brant -Powerline Sub-system

Brant TS and Powerline MTS sub-system meets the ORTAC restoration criteria until the end of the study period.

Brantford TS Sub-system

The Brantford TS sub-system meets the ORTAC restoration criteria until the end of the study period.

6.3.3 Conclusion Near- and Medium-Term Electricity Needs

The Brant-Powerline sub-system has already exceeded the LMC of the supply circuits and there is further significant step load growth identified by the LDCs forecast over the next five years. Therefore, an urgent need has been identified to provide additional capacity to the Brant-Powerline 115 kV sub-system.

6.4 Long-Term Needs

To assess needs in the long term, two demand forecast scenarios were considered: expected-growth and high-growth (see Section 5.2). As described in Section 7, the near- and medium-term plan is expected to meet the needs of the Area until the end of the study period.

However, if Area demand is consistent with the higher-growth scenario, additional electricity capacity needs may arise before the end of the study period. Thus, the analysis in this section is to address a scenario where there is a potential need for additional long-term Area supply.

Higher Growth Scenario

The Brant Area peak demand is forecast to grow to 352 MW by 2033 under the higher-growth scenario. At the sub-system level, the Brant-Powerline sub-system is forecast to grow to 177 MW and the Brantford TS sub-system to 182 MW under this scenario by 2033.

Table 6-1: Capacity Gap in 2033 under Higher-Growth Scenario

	Limit after Near- and Medium-Term Solutions (MW)	Higher Growth Forecast demand in 2033 (MW)	Higher Growth Capacity Gap in 2033 (MW)
Brant-Powerline sub-system	165	177	12
Brantford TS sub-system	178	182	4
Brant Area	343	352	9

In the long term, the Brant Area electricity system's ability to supply load will be constrained if additional industrial block loads arise in the Area, or higher demand growth is experienced consistent with the higher-growth scenario (Section 5.6.2). Supply constraints will leave the LDCs unable to connect new customers without additional supply in the Area. Consequently, the Working Group agreed to develop a strategic plan to consider higher demand growth based on the Places to Grow assumptions or additional industrial block loads.

7. Near- and Medium-Term Plan

The plan to address the near- and medium-term electricity needs of the Brant Area consists of specific actions and projects for immediate implementation, reflecting the urgency of the needs and the load time for developing solutions (refer to Section 6.3).

This section describes the alternatives considered in developing the near-term plan for the Brant Area and provides details and rationale for the recommended plan.

7.1 Alternatives for Meeting Near- and Medium-Term Needs

In developing the near- and medium-term plan, the Working Group considered a range of integrated options. Considerations in assessing alternatives included maximizing use of existing infrastructure, provincial electricity policy, feasibility, cost, and consistency with longer-term needs in the Brant Area.

7.1.1 Conservation

Conservation was considered as the first alternative to meet the electricity needs through the development of a planning forecast that includes the peak-demand effects of the provincial conservation targets,[10] along with contracted DG (see Sections 5.4 and 5.5). These conservation resources account for approximately 30 MW, or approximately 40% of the forecast demand growth during the first 10 years of the study period (through 2024).

Additional conservation beyond the targeted amounts included in the demand forecast may assist in meeting growth-related needs, such as the need to provide additional LMC in the Brant-Powerline sub-system. To meet these needs with conservation, an additional 50 MW of peak-demand reductions (i.e., 45% of sub-system load), incremental to the forecast of 12 MW from the LTEP conservation target would be required by 2023. This 50 MW plus the 12 MW targeted conservation amounts to approximately 45% of sub-system load. Given the immediate need and magnitude of the needs relative to the LTEP conservation target, the Working Group agreed that additional conservation beyond the targeted amounts is not a feasible option to meet the needs of the Area. However, efforts in the near- and medium-term should be focused on ensuring that the provincial conservation targets are met and monitoring the associated

[10] The provincial targets are for energy and have to be converted to capacity to calculate impact on peak demand by conservation

peak-demand savings that were assumed for the Brant Area. Therefore, conservation efforts to meet this goal are included as a recommendation in the near-term plan.

A provincial DR pilot is expected to roll out in the 2015-2016 time period. The Working Group believes it is prudent to consider this pilot program for the Brant Area to investigate opportunities, costs and feasibility in order to better understand its potential to address the Area's long-term supply capacity needs. A pilot can provide insights into the existence of willing DR participants in the Area. Knowledge and experience gained by way of a pilot will be useful when DR capacity markets are implemented by the IESO in the future and will help to address system as well as regional needs in the Brant Area and other areas of the province. At this time large scale use of DR has not been used as a solution to address local area's needs. Thus, a DR pilot program for the Brant Area could demonstrate its potential to be a technically feasible and cost-effective solution to provide a capacity buffer for the Area and defer larger and more costly infrastructure alternatives.

7.1.2 Local Generation

While in general local generation has the potential to meet both supply capacity and load restoration needs, this alternative was ruled out by the Working Group for meeting the near- to medium-term needs.

For the Brant Area, a natural gas plant for peak supply could meet the capacity needs at a cost of approximately $700-1000/kW with a 2-3 year in-service lead time.

It is the Working Group's view that local generation is not a cost effective option when compared to the recommended transmission options discussed below. Local generation is also not able to maximize the use of the existing Brant-Powerline sub-system infrastructure.

7.1.3 Transmission

Since the LMC of circuits B12/13 is primarily voltage limited, a number of voltage support options were considered to meet the near- and medium-term capacity needs of the Brant Area.

Capacitor Banks at Powerline MTS

Capacitor banks provide reactive support, boosting the voltage in an area. In doing so, they increase the voltage limit which is the first limiting factor in the 115 kV Brant-Powerline sub-system. The IESO and Hydro One studies have shown that 30 MVAR of reactive support at

Powerline TS can raise the LMC of the Brant-Powerline sub-system to 125 MW from 104 MW, thus increasing the useable capacity in the 115 kV Brant-Powerline sub-system. Capacitor banks also have relatively short 1-2 year in-service lead times. This option would cost approximately $1.0 million or $48/kW based on preliminary cost estimates by the LDC's and Hydro One.

Switching Facilities at Brant TS

This option connects the B8W and B12/13 circuits by installing three 115 kV breakers to close the existing normally open points. This option by itself can provide approximately 40 MW of additional supply to the limiting B12/13 circuits. Combined with the capacitor banks option as described above, the LMC of the Brant-Powerline sub-system can be further increased to approximately 165 MW.

It is estimated that the breakers can be in-service by 2017 and the budgetary estimate is $12-15 million based on Hydro One's preliminary cost estimates or $300-$375/kW. Hydro One and LDCs can together develop an implementation plan.

7.1.4 Distribution Options

Load transfers move load from one station to another and are currently used in the Brant Area on a temporary basis to maintain the loading on the 115 kV radial pocket within its LMC during peak demand conditions.

Depending on system conditions, Brantford Power has indicated that it has the ability to transfer up to 10 MW on a temporary, short-term basis from Powerline MTS and/or Brant TS to the Brantford TS. However, due to existing demand and future load growth, Brantford Power does not have the capacity at Brantford TS for permanent load transfers from the 115 kV sub-system. The incremental load at Brant Powerline sub-system in 2015 that is over the current 104 MW limit is expected to be 36 MW; this amount of load would be enough to exceed the limit at the Brantford TS. Therefore, load transfers are not a solution for the Area's capacity needs, as the surplus capacity that exists in the Area will be used up immediately.

7.2 Recommended Near- and Medium-Term Plan

The Brant Area Working Group assessed these alternatives in Section 7.1 as the basis for the following recommendations. Successful implementation of this plan will address the Area's electricity needs until the end of the study period.

To ensure the reliability of the Brant-Powerline sub-system before any permanent solutions are put in place, temporary load transfers will continue to be used in the near and medium term as required by the LDCs to address operational requirements.

Conservation

Meeting the conservation targets is assumed before identifying residual needs for the Area. The Working Group recommends that LDCs' conservation efforts be focused on measures that balance the needs for energy savings to meet the Conservation First targets while maximizing peak-demand reductions. Monitoring of conservation success, including measurement of peak demand savings, will be an important element of the near- and medium-term plan, and will also lay the foundation for the long-term plan by reviewing the performance of specific conservation measures in the Brant Area, and assessing potential in the Area for further conservation efforts.

Capacitor Banks at Powerline MTS

The Working Group recommended the installation of capacitor banks at Powerline MTS to raise the LMC of the circuits to 125 MW. The implementation of the capacitor bank solution was assigned to Hydro One by way of a letter[11] from the former OPA in February 2014. The capacitor banks are expected to be in-service for summer 2015 and the implementation is being undertaken by Brantford Power Inc. and Brant County Power Inc.

Switching Facilities at Brant TS

The Working Group recommends utilizing the existing B8W circuit by adding three breakers on circuits B12/13 and B8W. Combined with the capacitor banks, the LMC of the Brant-Powerline sub-system can be further increased to approximately 165 MW. As shown in Figure 7-1, the supply capacity needs under the expected-growth forecast will be addressed by implementing these two stages of transmission reinforcement.

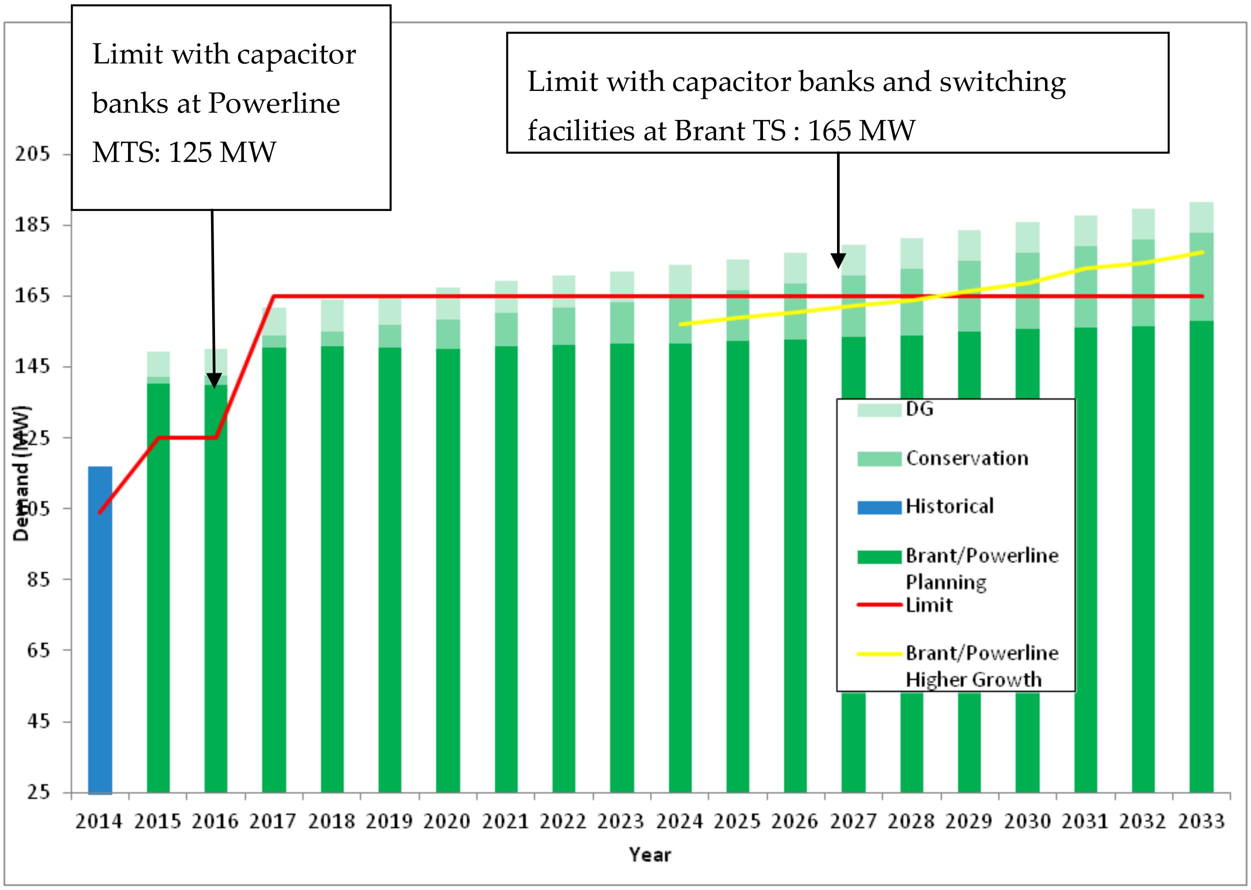
Demand Response

The Working Group has also considered investigating DR opportunities in the Brant Area by way of a DR pilot. The pilot program would be undertaken by the IESO in conjunction with

[11] http://www.hydroone.com/RegionalPlanning/Burlington/Documents/OPA Letter - Burlington Nanticoke - Brant.pdf

Area LDCs to investigate opportunities, costs and quantity of DR available in the Brant Area. Knowledge and experience gained by way of a pilot will be useful to provide options for addressing potential future capacity needs under a high-growth scenario.

Figure 7-1: Brant-Powerline Sub-system Planning Forecast and LMC



As shown in Figure 7-1, the recommended near- and medium-term solutions meet the needs of the Area until the end of the study period for the expected-growth scenario. These solutions are foundational for any longer-term considerations should electricity demand growth correspond with the higher-growth scenario or the Area experiences greater industrial load growth than is forecast.

7.3 Implementation of Near- and Medium-Term Plan

To ensure that the near-term electricity needs of Brant Area are addressed, it is important that the near- and medium-term plan recommendations be implemented in a timely manner. The specific actions and deliverables associated with the near- and medium-term plan are outlined in Table 7-1 below, along with their recommended timing, and the parties with lead responsibility for implementation.

Table 7-1: Implementation of Near- and Medium-Term Plan for the Brant Area

Recommendation	Action(s)/Deliverable(s)	Lead Responsibility	Timeframe
1. Implement conservation and DG	Develop CDM plans	LDCs	May 2015
	Implement LDC CDM programs	LDCs	2015-2020
	Conduct Evaluation, Measurement and Verification (EM&V) of programs, including peak-demand impacts, and provide results to Working Group	IESO	annually
	Continue to support provincial DG programs	LDCs/IESO	ongoing
2. Add capacitor banks at Powerline MTS	Design, develop and construct capacitor banks at Powerline MTS	Brantford Power Inc. and Brant County Power Inc.	ongoing and expected to be in-service summer 2015
3. Add switching facilities at Brant TS	Design, develop and construct new switching facilities at Brant TS	Hydro One, Brantford Power Inc. and Brant County Power Inc.	in-service summer 2017
4. Consider DR pilot for the Area	Continue to investigate opportunities for a DR pilot in the Brant Area	IESO	ongoing

8. Long-Term Plan (2024 through 2033)

The approach to developing long-term electricity plans is somewhat different than for near- or medium-term plans. There is inherently greater certainty in assessment of near- and medium-term electricity needs. For these needs, specific projects may need to be committed to ensure they are available to meet the forecast need. For longer-term electricity needs, there is an opportunity to develop and explore a broader set of options, as specific projects typically do not need to be committed urgently. Instead, the focus is on identifying potential need and on exploring alternatives to meet these needs. There is flexibility to assess alternatives that are not in widespread use but which show promise for the future. There is also opportunity to engage with stakeholders and communities to identify alternatives, to set out preliminary actions, and to monitor actual load growth and the underlying drivers. This approach is designed to: maintain flexibility; avoid committing ratepayers to investments before they are needed; provide adequate time to gauge the success and future potential of conservation measures; test out emerging technologies; engage with communities and stakeholders; coordinate with municipal or community energy planning ("MEP/CEP") activities; to lay the foundation for well-informed decisions in the future; and support decision-making in the next iteration of the IRRP.

An important consideration in developing a long-term plan is recognizing the timeframe within which decisions will need to be committed. This involves integrating the projected timing of needs with the expected in-service lead times when identifying and considering alternatives. The longest lead time among all the possible alternatives is usually associated with new major transmission infrastructure, which typically requires 5-7 years to bring into service (including conducting development work, gaining regulatory and other approvals, construction and commissioning).

Based on the expected timing of the long-term needs in the Brant Area and the 5-7-year lead time for major infrastructure alternatives, the Working Group expects that a decision on the long-term plan will likely be required around 2028. Therefore, it is recommended that demand growth be monitored regularly as part of the implementation of this IRRP and, if necessary, that the IRRP be revisited ahead of the 5-year schedule mandated by the OEB's regional planning process.

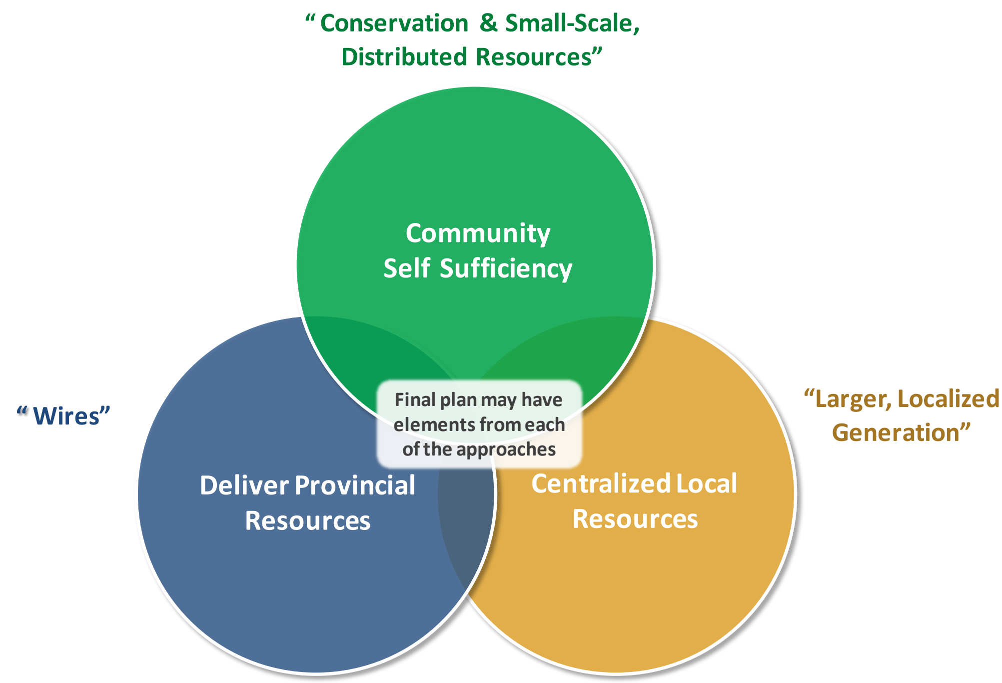
The following sections describe various approaches for meeting the long-term electricity needs of the Brant Area, and lay out recommended actions to develop the longer-term plan, and their implementation.

8.1 Approaches to Meeting Long-Term Needs

In recent years, a number of trends, including technology advances, policy changes supporting DG, greater emphasis on conservation as part of electricity system planning, and increasing community interest and desire for involvement in electricity planning and infrastructure siting, are changing the landscape for regional electricity planning. Traditional, "wires" based approaches to electricity planning, while still technically feasible, may not be the best fit for all communities. New approaches that acknowledge and take advantage of these trends should also be considered.

To facilitate discussions about how a community might plan its future electricity supply, three conceptual approaches for meeting a region's long-term electricity needs provide a useful framework (see Figure 8-1). Based on regional planning experience across the province over the last 10 years, it is clear that different approaches are preferred in different regions, depending on local electricity needs and opportunities, and the desired level of involvement by the community in planning and developing its electricity infrastructure.

Figure 8-1: Approaches to Meeting Long-Term Needs



The three approaches are as follows:

- **Delivering provincial resources**, or "wires" planning, is the traditional regional electricity planning approach associated with the development of centralized electric power systems over many decades. This approach involves using transmission and distribution infrastructure to supply a region's electricity needs, taking power from the provincial electricity system. This model takes advantage of generation that is planned at the provincial level, with generation sources typically located remotely from the region. In this approach, utilities (transmitters and distributors) play a lead role in development.
- The **Centralized local resources** approach involves developing one or a few large, local generation resources to supply a community. While this approach shares the goal of providing supply locally with the community self-sufficiency approach below, the emphasis is on large central-plant facilities rather than smaller, distributed resources.
- The **Community self-sufficiency** approach entails an emphasis on meeting community needs largely with local, distributed resources, which can include: aggressive conservation beyond provincial targets; demand response; distributed generation and storage; smart grid technologies for managing distributed resources; integrated heat/power/process systems; and electric vehicles. While many of these applications are not currently in widespread use to address regional capacity needs, for regions with

long-term needs (i.e., 10-20 years in the future) there is an opportunity to develop and test out these options to provide firm capacity resources at the local level before long-term plan commitment decisions are required. The success of this approach depends on early action to explore potential and develop options, and on the local community taking a lead role. This could be through a MEP/CEP process, or an LDC or other local entity taking initiative to pursue and develop options.

The intent of this framework is to identify which approach is to be emphasized in a particular region. In practice, certain elements of electricity plans will be common to all three approaches, and there will necessarily be some overlap between them. For example, provincially mandated conservation targets will be an element in all regional electricity plans, regardless of which planning approach is adopted for a region. In fact, it is likely that all plans will contain some combination of conservation, local generation, transmission, and distribution elements. Once the decision on the basic approach is made, the plan is developed around that approach, which affects the relative balance of conservation, generation, and "wires" in the plan.

8.1.1 Delivering Provincial Resources

Under a "wires" based approach, the long-term needs of Brant Area would be met primarily through transmission and distribution system enhancements. If the substantial needs forecast under the higher-growth scenario or additional industrial load arise, this could involve major new transmission development to deliver power from the major sources supplying the Area to where the power is needed.

Transmission options typically provide large capacity additions and can take 3-5 years to come into service from time of initiation. Such options could also require approval of leave to construct to the OEB as well as environmental assessments.

8.1.2 Large, Localized Generation

Addressing the Brant Area's long-term needs primarily with large local generation would require that the size, location and characteristics of local generation facilities be consistent with the needs of the Area. As the requirements are for additional capacity during times of peak demand, a large generation solution would need to be capable of being dispatched when needed and to operate at an appropriate capacity factor. This would mean that peaking facilities, such as a simple-cycle gas turbine ("SCGT") technology, would be more cost-effective than technologies designed to operate over a wider range of hours, or that are optimized to a host facility's requirements.

Based on the long-term demand forecast, a local generation source could be helpful if it is located at Brant TS or Powerline MTS to further relieve the 115 kV sub-system. The cost of this option would depend on the size and technology of the units chosen, as well as the degree to which they can contribute to a provincial capacity or energy need.

8.1.3 Community Self-Sufficiency

Addressing the long-term needs of Brant Area through a Community Self-Sufficiency approach requires leadership from the community itself to identify opportunities and deploy solutions. As this approach relies to a great degree on emerging technologies, there will be a need to develop and test out solutions to establish their potential and cost-effectiveness, so that they can be appropriately assessed in future regional plans.

In the Brant Area, this approach will be led by municipalities, the LDCs and First Nations communities if desired in identifying and developing opportunities.

8.2 Recommended Actions in Support of Long-Term Plan

At this time, while the Working Group does not recommend any specific commitment of investment and facilities to addresses potential longer-term needs (beyond 2025). To prepare for potential longer-term electricity load growth in this Area, the Working Group will investigate opportunities and potential for further cost-effective conservation and generation, as well as any relevant transmission investments.

Monitoring of growth in electricity demand and the achievement of conservation and DG targets in the Brant Area, will also be key components of ongoing electricity planning in the region and the needs and the options in the longer term will be reviewed in subsequent Burlington-Nanticoke regional planning studies.

1. Monitor Load Growth and Conservation Achievement and DG Performance

On an annual basis, the IESO will coordinate a review of conservation achievement, the uptake of provincial DG projects, and actual demand growth in the Brant Area. This information will be used to track the expected timing of long-term needs to determine when a decision on the long-term plan is required. Information on conservation and DG performance will also provide useful feedback into the ongoing development of these options as potential long-term solutions.

Additionally, the IESO will monitor results and incorporate lessons learned from the DR pilot, if it is implemented.

As the long-term needs for the Brant Area becomes more certain, additional measures to meet these needs, including but not limited to, large infrastructure investments, can be triggered in the next planning cycle with appropriate lead times to ensure that the needs will be met.

2. Undertake community engagement

Broad community and public engagement is essential to development of a long-term plan. As no long-term needs have been identified for the Brant Area, there is no requirement at this time for engagement on long-term options.

However, a LAC may be established for the broader Burlington to Nanticoke region when the regional planning process is complete for the whole region.

A LAC's purpose is to provide input and advice on engagement plans for an area or region. It is expected that a LAC will consist of community, First Nations and Métis representatives and stakeholders. Advice from the LAC will be incorporated in developing engagement plans for an area/region.

3. Continue ongoing work to develop transmission/generation options

The IESO and Hydro One will continue working with the working group to evaluate the transmission or generation options to meet the potential long-term needs.

8.3 Recommended Actions and Implementation

A number of alternatives are possible to meet the region's long-term needs if they arise. While specific solutions do not need to be committed today, it is appropriate to begin work now to gather information, monitor developments, engage the community, and develop alternatives, to support decision-making in the next iteration of the IRRP. The long-term plan sets out the near-term actions required to ensure that options remain available to address future needs if and when they arise.

The recommended actions and deliverables for the long-term plan are outlined in Table 8-1, along with their recommended timing, and the parties with lead responsibility for implementation are assigned.

Table 8-1: Implementation of Near-Term Actions in Support of the Long-Term Plan for the Brant Area

Recommendation	Action(s)/Deliverable(s)	Lead Responsibility	Timeframe
1. Undertake engagement	Undertake public/community engagement as required	LDCs	2015-2017
	Engage with First Nations communities and the Métis Nation of Ontario	IESO	2015-2017
2. Monitor load growth, CDM achievement, and DG uptake	Prepare annual update to the Working Group on demand, conservation and DG trends in the Area, based on information provided by Working Group	IESO	Annually
	Identify long-term CDM potential	IESO	2016
3. Continue ongoing work to develop transmission / generation options	The IESO and Hydro One will continue working with the working group to evaluate the transmission or generation options to meet the potential long-term needs.	IESO/Hydro One	As required based on monitoring of growth
4. Initiate the next regional planning cycle early, if needed	Based on results of monitoring (see recommendation 4), commence the next regional planning cycle in advance of the OEB-mandated schedule, if needed, to enable sufficient time to develop options	IESO	As required

9. Community, Aboriginal and Stakeholder Engagement

Community engagement is an important aspect of the regional planning process. Providing opportunities for input in the regional planning process enables the views and preferences of the community to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles. It also addresses activities undertaken to date for the Brant Area IRRP and those that will take place to discuss the long-term needs identified in the plan and obtain input in the development of options.

A phased community engagement approach has been developed for the Brant IRRP based on the core principles of creating transparency, engaging early and often, and bringing communities to the table (see Figure 9-1). These principles were articulated as a result of the IESO's outreach with Ontarians to determine how to improve the regional planning process and they are now guiding the IRRP outreach with communities.

Figure 9-1: Summary of Brant IRRP Community Engagement Process

Creating Transparency: ***Creation of Brant IRRP Information Resources***	• Dedicated Brant IRRP web page created on IESO (former OPA) website providing background information, the IRRP Terms of Reference and listing of the Working Group members • Dedicated web page added to Hydro One website, and information posted on LDC websites • Self-subscription service established for Brant IRRP for subscribers to receive regional specific updates • Status: complete
Engaging Early and Often: ***Municipal, First Nation & Métis Outreach***	• Presentation and discussion at four group meetings with municipal planners from across the planning region • Information provided to First Nation communities with known interest in the planning area with an invitation to meet • Presentation and discussion with First Nation communities as requested • Information provided to Métis Nation of Ontario • Status: initial outreach complete; dialogue to continue
Bringing Communities to the Table: ***Broader Community Outreach***	• Presentations for Municipal Councils, First Nation communities and the Métis Nation of Ontario as requested • Webinar to discuss electricity needs and near-term solutions • Outreach with the broader community and formation of a Local Advisory Committee to be determined following the launch of the Burlington sub-region IRRP also within the Burlington - Nanticoke planning region • Status: beginning in May 2015; no time limit

Creating Transparency

To start the dialogue on the Brant IRRP and build transparency in the planning process, a number of information resources were created for the plan. A dedicated web page was created on the IESO (former OPA) website to provide a map of the regional planning Area, information on why the plan was being developed, the Terms of Reference for the IRRP and a listing of the organizations involved was posted on the websites of the Working Group members. A dedicated email subscription service was also established for the Brant IRRP where communities and stakeholders could subscribe to receive email updates about the IRRP.

Engaging Early and Often

The first step in the engagement of the Brant IRRP was meeting with representatives from the municipalities and First Nations communities in the region. For the municipal meetings, presentations were made to the Brant Area municipal planners at two group meetings held in Brant and Brantford in 2013, and again in 2015 after Area load forecasts were updated due to expected increases in near-term demand. The IESO held a separate meeting with representatives of the Six Nations Elected Council.

During these meetings, key topics of discussion involved confirmation of increased growth projections for the Area, which included addressing the near- and medium-terms needs through the installation of capacitor banks at the Powerline MTS and switching facilities at Brant TS, and continued CDM efforts, with the possibility of a DR pilot program in the Area, and potential actions to prepare for the long-term need if it materializes. Invitations to meet to discuss the Brant IRRP were also extended to the Mississaugas of the New Credit First Nation and to the Haudenosaunee Confederacy Chiefs Council. The IESO remains committed to responding to any questions or concerns from other communities who may have an interest in the planning Area.

Information on these project-level engagements, if required, will be provided on Hydro One's website and will also be listed on the IESO's Brant IRRP main webpage.

Bringing Communities to the Table

This engagement will begin with a webinar hosted by the working group to discuss the plan and potential approaches of possible long-term options. Presentations on the Brant IRRP will also be made to Municipal Councils, First Nations communities and the Métis Nation of Ontario on request.

Decision on broader community outreach activities, including whether to form a LAC will be made after the launch of the Bronte sub-region IRRP that is also within the Burlington – Nanticoke planning region. As LACs are generally formed at the regional planning level, not the sub-region level, additional work is required on the Bronte sub-region IRRP prior to initiating the formation of the LAC. In general, LACs are established as a forum for members to be informed of the regional planning processes. Their input and recommendations, information on local priorities, and ideas on the design of community engagement strategies will be considered throughout the engagement, and planning processes. Local Advisory Committee meetings are open to the public and meeting information is posted on the IESO website.

Strengthening processes for early and sustained engagement with communities and the public were introduced following an engagement held in 2013 with 1,250 Ontarians on how to enhance regional electricity planning. This feedback resulted in the development of a series of recommendations that were presented to, and subsequently adopted by the Minister of Energy. Further information can be found in the report entitled "Engaging Local Communities in Ontario's Electricity Planning Continuum"[12] available on the IESO website.

Information on outreach activities for the Brant IRRP can be found on the IESO website and updates will be sent to all subscribers who have requested updates on the Burlington to Nanticoke IRRP.

10. Conclusion

This report documents an IRRP that has been carried out for the Brant Area, a sub-region of the Burlington to Nanticoke planning region.[13] The IRRP identifies electricity needs in the Area over the 20-year study period from 2014 to 2033, recommends a plan to address near- and medium-term needs, and identifies actions to develop broad options for the long term.

Implementation of the near-term plan is already underway, with the LDCs developing conservation plans consistent with the Conservation First policy and infrastructure projects being developed by the LDCs and Hydro One.

To support development of the long-term plan, a number of actions have been identified to monitor growth, engage with the community, and develop alternatives in the Area, and responsibility has been assigned to appropriate members of the Working Group for these actions. Information gathered and lessons learned as a result of these activities will inform development of the next iteration of the Brant Area IRRP. A RIP is not required because transmission infrastructure planning to address the needs identified are already at the project level.

The planning process does not end with the publishing of this IRRP. Communities will be engaged in the development of the options for the long term. In addition, the Working Group will continue to meet regularly throughout the implementation of the plan to monitor progress and developments in the Area and will produce annual update reports that will be posted on the IESO website. Of particular importance, the Working Group will track closely the expected timing of the needs that are forecast to arise in the long term under the higher-growth scenario or arrival of additional industrial load. If demand growth follows the expected-growth scenario or conservation achievement is higher than forecast, the plan may be revisited according to the OEB-mandated 5-year schedule. This outcome would allow more time to develop alternatives and to take advantage of advances in technology in the next planning cycle.

[13] The Brant and Bronte area of Oakville and Burlington form part of the larger Burlington to Nanticoke region.

BRONTE SUB-REGION INTEGRATED REGIONAL RESOURCE PLAN

Part of the Burlington-Nanticoke Planning Region | June 30, 2016

ieso
Connecting Today. Powering Tomorrow.

Integrated Regional Resource Plan

Bronte Sub-region

This Integrated Regional Resource Plan ("IRRP") was prepared by the Independent Electricity System Operator ("IESO") pursuant to the terms of its Ontario Energy Board licence, EI-2013-0066.

The IESO prepared the IRRP on behalf of the Bronte Sub-Region Working Group (the "Working Group"), which included the following members:

- Independent Electricity System Operator
- Oakville Hydro Electricity Distribution Inc.
- Burlington Hydro Inc.
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)

The Working Group assessed the adequacy of electricity supply to customers in the Bronte Sub-region over a 20-year period; developed a flexible, comprehensive, integrated plan that considers opportunities for coordination in anticipation of potential demand growth scenarios and varying supply conditions in the Bronte Sub-region and developed an implementation plan for the recommended options, while maintaining flexibility in order to accommodate changes in key conditions over time.

The Working Group members agree with the IRRP's recommendations and support implementation of the plan through the recommended actions, subject to obtaining all necessary regulatory and other approvals.

1. Introduction

This Integrated Regional Resource Plan ("IRRP") addresses the electricity needs for the Bronte Sub-region over the next 20 years. This report was prepared by the Independent Electricity System Operator ("IESO") on behalf of the Technical Working Group composed of the IESO, Oakville Hydro Electricity Distribution Inc. ("Oakville Hydro"), Burlington Hydro Inc. ("Burlington Hydro"), Hydro One Distribution and Hydro One Transmission [1] (the "Working Group").

The Bronte Sub-region is within the Burlington-Nanticoke planning region. In municipal terms, it roughly encompasses the cities of Burlington and Oakville. The study is focused on the area served by Bronte Transformer Station ("TS"), but the scope will also include consideration of the broader Burlington Hydro and Oakville Hydro service territories, which include portions of the Greater Toronto Area ("GTA") West planning region. Bronte TS is radially supplied from the double-circuit 115 kV transmission line B7/B8 originating from Burlington TS. The study area, including all area transformer stations, is shown in Figure 1-1.

Figure 1-1: Map of Bronte Sub-region

[1] For the purpose of this report, "Hydro One Transmission" and "Hydro One Distribution" are used to differentiate the transmission and distribution accountabilities of Hydro One Networks Inc., respectively.

In Ontario, planning to meet the electrical supply and reliability needs of a large area or region is done through regional electricity planning, a process that was formalized by the Ontario Energy Board ("OEB" or "Board") in 2013. In accordance with the OEB regional planning process, transmitters, distributers and the IESO are required to carry out regional planning activities for 21 electricity planning regions at least once every five years.

This IRRP identifies power system capacity and reliability requirements, and coordinates the options to meet customer needs in the sub-region over the next 20 years. Specifically, this IRRP identifies investments for immediate implementation necessary to meet near- and medium-term needs in the sub-region, respecting the lead time for development.

This IRRP also identifies options to meet long-term needs, but given forecast uncertainty, the longer development lead time and the potential for technological change, the plan maintains flexibility for long-term options and does not recommend specific projects at this time. Instead, the long-term plan identifies near-term actions to consider and develop alternatives, engage with the community and gather information and lay the groundwork for future options. These actions are intended to be completed before the next IRRP cycle, scheduled for 2020 or sooner, depending on demand growth, so that the results can inform decisions should any decisions need to be made at that time.

This report is organized as follows:

- A summary of the recommended plan for the Bronte Sub-region is provided in Section 2;
- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the Bronte Sub-region and the study scope are discussed in Section 4;
- Demand forecast scenarios, and conservation and distributed generation ("DG") assumptions, are described in Section 5;
- Electricity needs in the Bronte Sub-region are presented in Section 6;
- Alternatives and recommendations for meeting needs are addressed in Sections 7 and 8;
- A summary of engagement to date and moving forward is provided in Section 9; and
- A conclusion is provided in Section 10.

2. The Integrated Regional Resource Plan

The Bronte Sub-region IRRP provides recommendations to address the sub-region's forecast electricity needs over the next 20 years, based on the application of the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC"). This IRRP identifies forecast electricity needs in the sub-region over the near term (0-5 years, or 2015 through 2019), medium term (6-10 years, or 2020 through 2024) and longer term (11- 20 years, or 2025 through 2034). These planning horizons are distinguished in the IRRP to reflect the different levels of forecast certainty, lead time for development and planning commitment required over these time horizons. The IRRP was developed based on consideration of planning criteria, including reliability, cost, feasibility, and maximization of the use of the existing electricity system, where it is economic to do so.

This IRRP identifies and recommends specific projects for implementation in the near term. This is necessary to ensure that they are in-service in time to address the area's more urgent needs, respecting the shorter lead time for development of the recommended projects or actions. This IRRP also identifies possible longer-term electricity needs. However, as these needs are forecast to arise in the future, it is not necessary, nor would it be prudent given forecast uncertainty and the potential for technological change to recommend specific projects at this time. Instead, near-term actions are identified to gather information and lay the groundwork for future options. These actions are intended to be completed before the next IRRP cycle so that their results can inform further discussion at that time.

2.1 Near-Term and Medium-Term Plan (2015 through 2024)

Near/Medium-Term Needs and Plan

- Thermal loading of B7/B8 exceeds capacity following loss of companion circuit – 2018
- Post contingency voltage drop exceeds 10% at Bronte TS – 2021
- Address both needs by transferring one feeder (approximately 15 MW) of load from Bronte TS to Tremaine TS - 2018
- Details of implementation to be developed as part of RIP process.

By 2018, peak summer electrical demand on Bronte TS is expected to exceed 135 MW, triggering overloads on the supplying B7/B8 circuits following the loss of the companion circuit. By 2021, forecast station loading is expected to exceed the maximum 10% post contingency voltage drop criteria; although it may be possible to delay this occurrence by as much as 10 years by better distributing load between buses. Since both of these needs are the direct result of loading on Bronte TS, the near-term plan considered options to immediately lower peak electrical demand and the longer-term plan considered ways to maintain total load below 135 MW.

Two near-term options were identified, each capable of meeting near- and medium-term needs:

1. Upgrade transmission line supplying Bronte TS, and redistribute loads between buses
2. Transfer one feeder of load from Bronte TS to Tremaine TS

Recommended Actions

1. Transfer one feeder of load from Bronte TS to Tremaine TS

The shortest lead-time option for reducing load at Bronte TS is to transfer load to an adjacent station. This can be accomplished by constructing additional distribution infrastructure to enable either temporary or permanent connections between the service areas of Bronte TS and a nearby station (Tremaine TS). If a transfer can be accomplished for $9.7 million or less (the alternate cost of a transmission solution), then it is the most economic course of action.

Burlington Hydro has indicated that it would be possible to construct additional transfer capability between Bronte TS and Tremaine TS by 2019 for an approximate cost of $4.5 million. This is significantly less expensive than the alternative of upgrading the limiting section of B7/B8 supply circuits, at an estimated cost of $9.7 million. Oakville Hydro has indicated that it is not technically feasible to transfer loads from the Bronte TS service territory to other stations serving its franchise territory.

Transferring one feeder worth of load will reduce peak electrical demand at Bronte TS by approximately 15 MW, reducing total station load to approximately 120 MW in the near term, and permitting up to 15 MW of continued growth at the station in the mid and long term. Based on the planning forecast, this new capacity would primarily support Oakville Hydro customers, particularly those located in the Bronte village and midtown regions.

Burlington Hydro has indicated that it is concerned about longer-term growth in the Bronte service area impacting future costs. As a result, Burlington Hydro is concerned with relinquishing capacity at Bronte TS on a permanent basis. As part of the implementation Burlington Hydro has proposed a long-term (i.e., 10 years) lease arrangement. Details related to implementation will be developed as part of the Regional Infrastructure Plan ("RIP").

The IESO has committed to working with affected parties to ensure that costs borne by LDCs for the construction and operation of distribution infrastructure are appropriately allocated between the benefiting parties. The specific cost allocation challenges for this option are further discussed in Section 7.3.1.

2.2 Longer-Term Plan (2025-2034)

In the event that long-term load growth within the Burlington service territory requires a return of the 15 MW of capacity to Bronte TS, an alternative infrastructure solution will be required to serve the anticipated 15 MW of incremental Oakville Hydro growth. Oakville Hydro has indicated that distribution transfers from Bronte TS are not feasible at this time, but this assumption should be revisited in the future as changes to system configurations may occur. Assuming distribution transfers are not feasible, the alternative would be to upgrade the transmission line supplying Bronte TS.

If higher than anticipated load growth materializes in the long term, other measures, such as incremental DG or demand response ("DR") programs may become effective options to defer future infrastructure investment. These options will be considered during future regional planning studies when the nature of the long-term needs, alternatives, and associated costs become clearer. In the meantime, Working Group members will continue to engage with local planning bodies to coordinate community planning initiatives and identify cost effective opportunities for supplying local energy needs.

3. Development of the IRRP

3.1 The Regional Planning Process

In Ontario, planning to meet the electricity needs of customers at a regional level is done through regional planning. Regional planning assesses the interrelated needs of a region—defined by common electricity supply infrastructure—over the near, medium, and long term and develops a plan to ensure cost-effective, reliable electricity supply. Regional plans consider the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluate options for addressing needs, and recommend actions.

Regional planning has been conducted on an as needed basis in Ontario for many years. Most recently, the former Ontario Power Authority ("OPA") carried out planning activities to address regional electricity supply needs. The OPA conducted joint regional planning studies with distributors, transmitters, the IESO and other stakeholders in regions where a need for coordinated regional planning had been identified.

In the fall of 2012, the Board convened a Planning Process Working Group ("PPWG") to develop a more structured, transparent, and systematic regional planning process. This group was composed of industry stakeholders including electricity agencies, utilities, and stakeholders, and in May 2013, the PPWG released its report to the Board[2] ("PPWG Report"), setting out the new regional planning process. Twenty-one electricity planning regions were identified in the PPWG Report, and a phased schedule for completion was outlined. The Board endorsed the PPWG Report and formalized the process timelines through changes to the Transmission System Code and Distribution System Code in August 2013, as well as through changes to the OPA's licence in October 2013. The OPA's licence changes required it to lead a number of aspects of regional planning. After the merger of the IESO and the OPA on January 1, 2015, the regional planning responsibilities identified in the OPA's licence were transferred to the IESO.

The regional planning process begins with a Needs Screening process performed by the transmitter, which determines whether there are needs requiring regional coordination. If regional planning is required, the IESO then conducts a Scoping Assessment to determine whether a comprehensive IRRP is required, which considers conservation, generation,

---

[2] http://www.ontarioenergyboard.ca/OEB/_Documents/EB-2011-0043/PPWG_Regional_Planning_Report_to_the_Board_App.pdf

transmission, and distribution solutions, or whether a more limited "wires" solution is the preferable option such that a transmission and distribution focused Regional Infrastructure Plan ("RIP") can be undertaken instead. The Scoping Assessment determines what type of planning is required for each region. There may also be regions where infrastructure investments do not require regional coordination and so can be planned directly by the distributor and transmitter outside of the regional planning process. At the conclusion of the Scoping Assessment, the IESO produces a report that includes the results of the Needs Screening process and a preliminary Terms of Reference. If an IRRP is the identified outcome, the IESO is required to complete the IRRP within 18 months. If an RIP is the identified outcome, the transmitter takes the lead and has six months to complete it. Both RIPs and IRRPs are to be updated at least every five years. The draft Scoping Assessment Outcome Report is posted to the IESO's website for a 2-week comment period prior to finalization.

The final IRRPs and RIPs are posted on the IESO's and relevant transmitter's websites, and may be referenced and submitted to the Board as supporting evidence in rate or "Leave to Construct" applications for specific infrastructure investments. These documents are also useful for municipalities, First Nation communities and Métis community councils for planning, conservation and energy management purposes, as information for individual large customers that may be involved in the region, and for other parties seeking an understanding of local electricity growth, CDM and infrastructure requirements. Regional planning is not the only type of electricity planning that is undertaken in Ontario. As shown in Figure 3-1, there are three levels of planning that are carried out for the electricity system in Ontario:

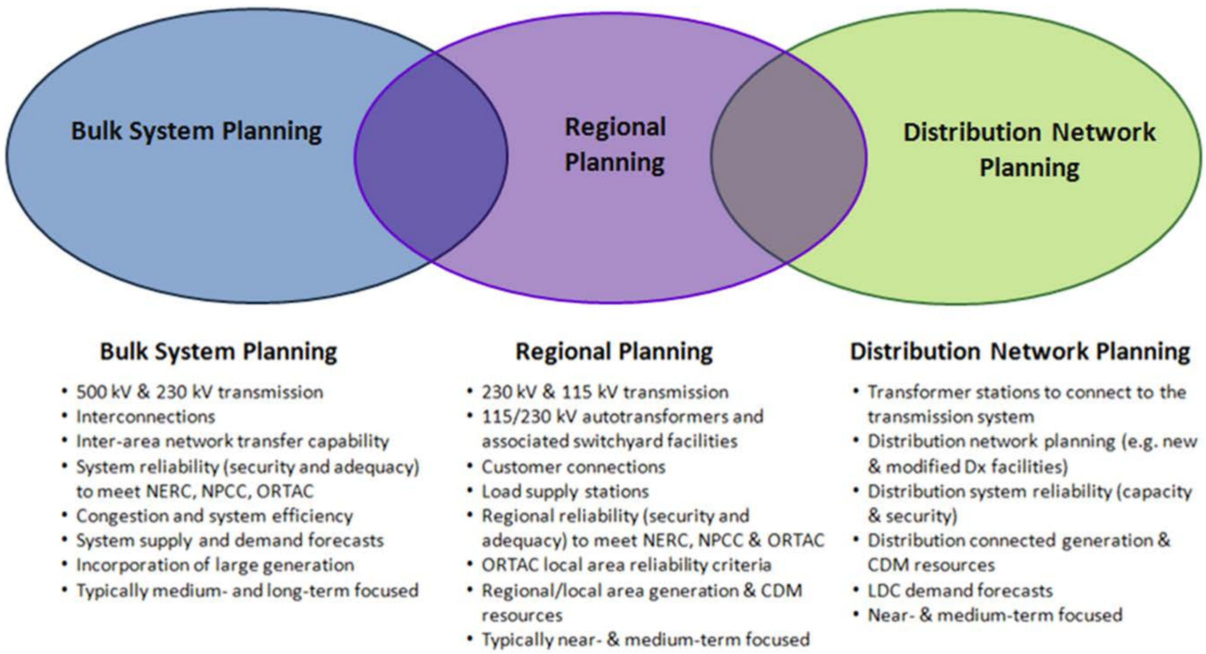
- Bulk system planning
- Regional system planning
- Distribution system planning

Planning at the bulk system level typically considers the 230 kV and 500 kV network and examines province-wide system issues. Bulk system planning considers not only the major transmission facilities or "wires", but it also assesses the resources needed to adequately supply the province. This type of planning is typically carried out by the IESO pursuant to government policy. Distribution planning, which is carried out by Local Distribution Companies ("LDCs"), considers specific investments in an LDC's territory at distribution level voltages.

Regional planning can overlap with bulk system planning. For example, overlaps can occur at interface points where there may be regional resource options to address a bulk system issue.

Similarly, regional planning can overlap with the distribution planning of LDCs. For example, overlaps can occur when a distribution solution addresses the needs of the broader local area or region. Therefore, it is important for regional planning to be coordinated with both bulk and distribution system planning as it is the link between all levels of planning.

Figure 3-1: Levels of Electricity System Planning



By recognizing the linkages with bulk and distribution system planning, and coordinating multiple needs identified within a region over the long term, the regional planning process provides a comprehensive assessment of a region's electricity needs. Regional planning aligns near- and long-term solutions and puts specific investments and recommendations coming out of the plan in perspective. Furthermore, regional planning optimizes ratepayer interests by avoiding piecemeal planning and asset duplication, and allows Ontario ratepayer interests to be represented along with the interests of LDC ratepayers, and individual large customers. IRRPs evaluate the multiple options that are available to meet the needs, including conservation, generation, and "wires" solutions. Regional plans also provide greater transparency through engagement in the planning process, and by making plans available to the public.

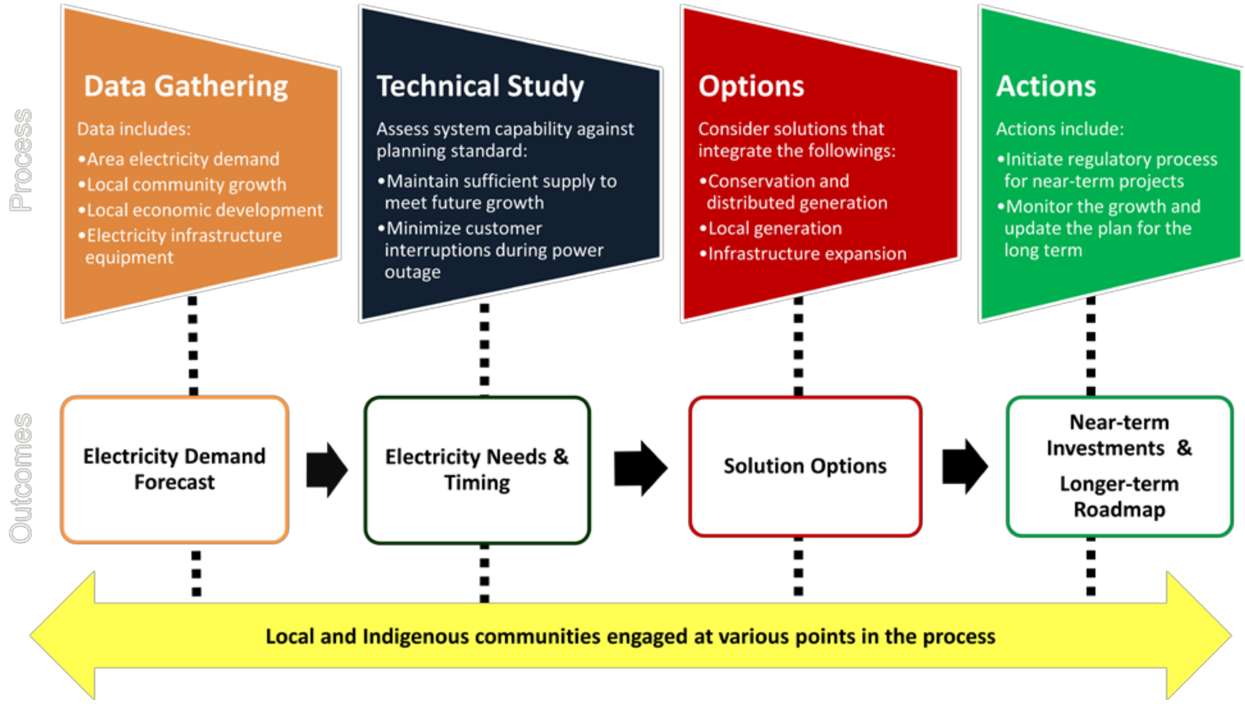
3.2 The IESO's Approach to Regional Planning

IRRPs assess electricity system needs for a region over a 20-year period. The 20-year outlook anticipates long-term trends so that near-term actions are developed within the context of a longer-term view. This enables coordination and consistency with the long-term plan, rather than simply reacting to immediate needs.

In developing an IRRP, a different approach is taken to developing the plan for the first 10 years of the plan—the near and medium term—than for the longer-term period of 10-20 years. The plan for the first 10 years is developed based on best available information on demand, conservation, and other local developments. Given the long lead time to develop electricity infrastructure, near-term electricity needs require prompt action to enable the specified solutions in a timely manner. By contrast, the long-term plan is characterized by greater forecast uncertainty and longer development lead time; as such solutions do not need to be committed to immediately. Given the potential for changing conditions and technological development, the IRRP for the long term is more directional, focusing on developing and maintaining the viability of options for the future, and continuing to monitor demand forecast scenarios.

In developing an IRRP, the IESO and the Working Group (see Figure 3-2 below) carry out a number of steps. These steps include electricity demand forecasts; technical studies to determine electricity needs and the timing of these needs; the development of potential options; and, a recommended plan including actions for the near and long term. Throughout this process, engagement is carried out with stakeholders and First Nation and Métis communities who may have an interest in the area. The steps of an IRRP are illustrated in Figure 3-2, below.

Figure 3-2: Steps in the IRRP Process



The IRRP report documents the inputs, findings and recommendations developed through the process described above, and provides recommended actions for the various entities responsible for plan implementation. Where "wires" solutions are included in the plan recommendations, the completion of the IRRP report is the trigger for the transmitter to initiate an RIP process to develop those options. Other recommendations in the IRRP may include: development of conservation, local generation, or other solutions; community engagement; or information gathering to support future iterations of the regional planning process in the region or sub-region.

3.3 Bronte Sub-region Working Group and IRRP Development

The process to develop the Bronte IRRP was initiated in 2014 with the release of the Needs Screening report for the Burlington-Nanticoke Region. This product was produced by Hydro One Transmission with participation from the OPA and IESO, Brant County Power Inc.[3],

[3] Brant County Power Inc. and Cambridge and North Dumfries Hydro Inc. became one company on January 1, 2016 when the two LDCs legally joined together as Energy+ Inc.

Brantford Power Inc., Burlington Hydro Inc., Haldimand County Hydro Inc.[4], Horizon Utilities Corporation, Hydro One Distribution, Norfolk Power Distribution Inc.[5], and Oakville Hydro Electricity Distribution Inc. The Needs Screening process was carried out to identify needs which may require coordinated regional planning in those sub-regions of Burlington-Nanticoke which had not already undergone a regional planning process. The subsequent Scoping Assessment Report recommended that the needs identified for the Bronte Sub-region should be further pursued through an IRRP owing to the potential for coordinated solutions.

In 2015 the Working Group was formed to develop a Terms of Reference for this IRRP, gather data, identify near- to long-term needs in the sub-region, and recommend the near and medium term actions.

---

[4] On March 12, 2015, the OEB approved Hydro One Network Inc.'s ("Hydro One") acquisition (EB-2014-0244) of all of the issued and outstanding shares of Haldimand County Power Inc. ("Haldimand Power"). The OEB also approved the transfer of distribution assets from Haldimand Power to Hydro One.

[5] On July 3, 2014, the OEB approved Hydro One's acquisition (EB-2013-0187) of all of the issued and outstanding shares of Norfolk Power Distribution Inc. ("Norfolk Power"). The OEB also approved the transfer of distribution assets from Norfolk Power to Hydro One.

4. Background and Study Scope

This report presents an integrated regional resource plan for the Bronte Sub-region for the 20-year period from 2015 to 2034.

To set the context for this IRRP, the scope of the planning study and the sub-region's existing electricity system are described in Section 4.1. A brief outline of the ongoing bulk system study being undertaken in the same general area, including considerations for coordination, is included in Section 4.2.

4.1 Study Scope

This IRRP develops and recommends options to meet supply needs of the Bronte Sub-region in the near-, medium and long term. The plan was prepared by the IESO on behalf of the Working Group. The plan includes consideration of forecast electricity demand growth, conservation and demand management ("CDM" or "conservation") in the area, transmission and distribution system capability, relevant community plans, developments on the bulk transmission system, Feed-in Tariff ("FIT") and other generation uptake through province-wide programs.

This IRRP addresses regional needs in the Bronte Sub-region, including adequacy, security and relevant asset end-of-life consideration.

The following existing transmission facilities and assumptions were included in the scope of this study:

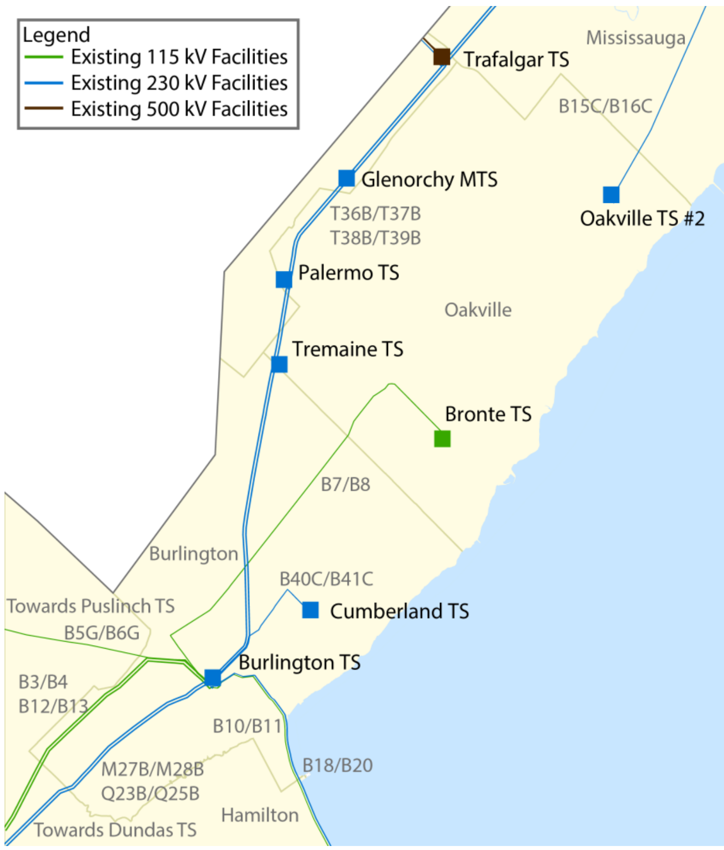
- Stations—Bronte TS, Cumberland TS, Palermo TS, Tremaine TS, Glenorchy MTS, Oakville TS #2 and Burlington DESN
- Transmission circuits—B7/B8, B40/41C, T36/37B, B15/16C

The Bronte IRRP was developed by completing the following steps:

- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe.
- Examining the Load Meeting Capability ("LMC") and reliability of the existing transmission system supplying the Bronte Sub-region, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC.

- Establishing feasible integrated alternatives to address needs, including a mix of CDM, generation, transmission and distribution facilities, and other electricity system initiatives.
- Evaluating options using decision-making criteria which included: technical feasibility, cost, reliability performance, flexibility, environmental and social factors.
- Developing and communicating findings, conclusions and recommendations.

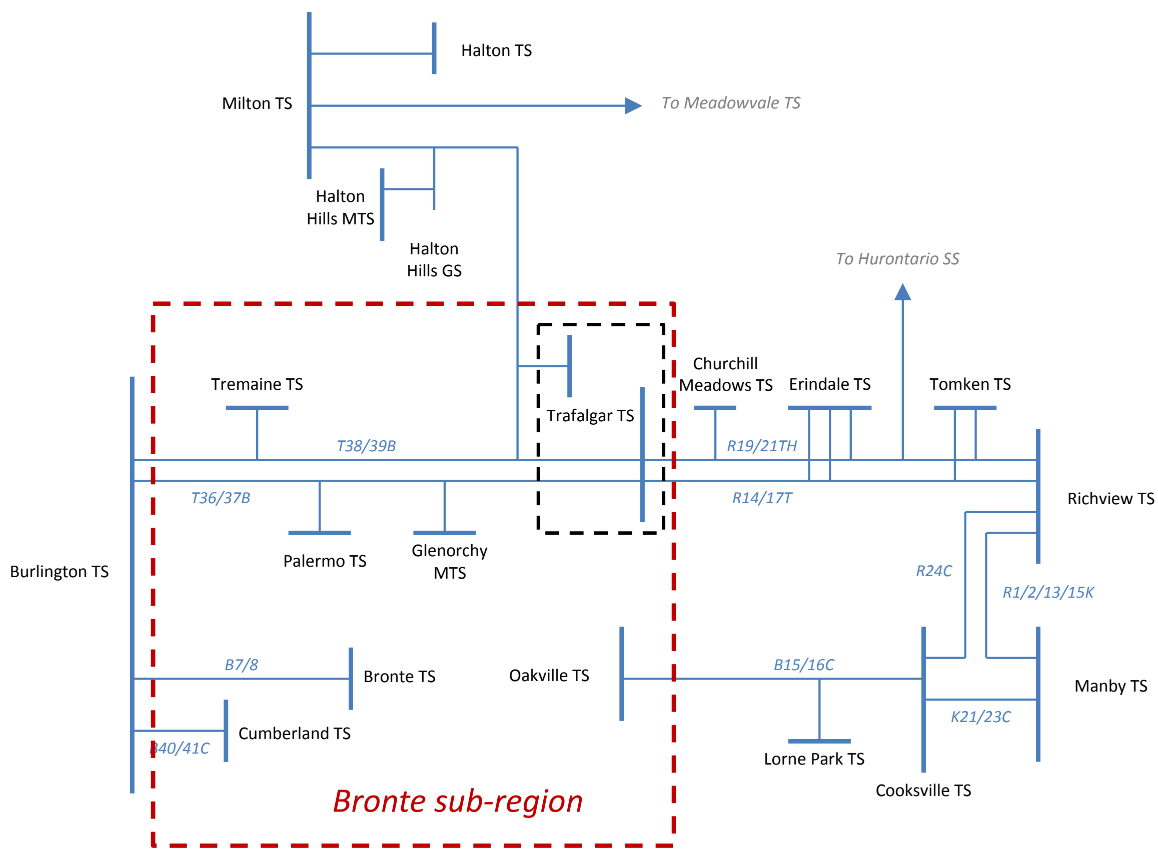
Figure 4-1: Regional Transmission Facilities



Of the step-down stations included in the Bronte Sub-region, only Bronte TS, Cumberland TS, and Burlington DESN were originally part of the Burlington-Nanticoke Region. The defined area of Bronte Sub-region, however, has been expanded outside this area to include step-down stations that serve Burlington Hydro and Oakville Hydro in the GTA West Region (Tremaine TS, Palermo TS, Glenorchy MTS, Trafalgar DESN, and Oakville TS #2). Expanding the scope of the study area to include these stations ensured that a full range of transmission and distribution alternatives was considered within the study.

Figure 4-2 shows the electrical configuration of the main stations, supply sources, and transmission assets for the Bronte Sub-region, and southern GTA West Region. Note that this diagram shows anticipated outcomes from the ongoing "GTA West Bulk System Study", detailed in Section 4.2. This includes retermination of circuits at Milton TS, and a new supply arrangement for Halton TS and Meadowvale TS. Also included is the proposed Halton Hills Hydro Inc. ("HHH") MTS, recommended as part of the North West GTA IRRP, and currently seeking approval through the HHH rate application.

Figure 4-2: Bronte Sub-region Electrical Sub-systems



4.2 Bulk Transmission System Study

Due to the potential for overlap between bulk and regional planning, as described in Section 3.1, it is important for regional planning to be coordinated with bulk system planning. This is particularly important when there is ongoing bulk planning within the study area. That is because a bulk system study can integrate bulk and regional needs that may be more efficiently solved through bulk system evaluations. Regional planning therefore needs to account for planned bulk system upgrades.

A bulk system study was initiated by the IESO for GTA West in 2014 to identify and recommend solutions to address emerging bulk transmission system needs. These needs differ from those driving the regional plan, as they are impacted by changes in the broader Ontario electricity system, rather than the local system. These needs include planned refurbishment and retirement of nuclear generation facilities, incorporating renewable generation in southwest Ontario and changes in electricity consumption patterns across the GTA.

Preliminary results indicated that upgrades to the bulk transmission system in the GTA West area are linked to the retirement of Pickering Nuclear Generation Station ("Pickering NGS"). Recommended upgrades include the installation of new autotransformers at Milton Switching Station ("SS"), incorporation of a 230 kV switchyard, and reconfiguration of the 230 kV transmission system serving the area.

In early 2016 the Ontario government and IESO announced plans for the extended operation of Pickering NGS to 2024. This updated generation assumption requires that the original bulk system study be revised. This work is currently underway.

Following the completion of the updated bulk system study and the release of the 2017 LTEP, a review will be conducted to ensure that any outcomes of the Bronte Sub-region IRRP remain valid in light of any changing assumptions.

5. Demand Forecast

This section outlines the forecast of electricity demand within the Bronte Sub-region. It highlights the assumptions made for peak-demand load forecasts, and the contribution of conservation and DG to reducing peak demand. The resulting net demand forecast is used in assessing the electricity needs of the area over the planning horizon.

To evaluate the adequacy of the electric system, the regional planning process involves measuring the demand observed at each station for the hour of the year when overall demand in the study area is at a maximum. This is called "coincident peak demand" and represents the moment when assets are most stressed and resources most constrained. This differs from a non-coincident peak, which is measured by summing each station's individual peak, regardless of whether the stations' peaks occur at different times of the area's overall peak.

Within the Bronte Sub-region, the peak loading hour for each year typically occurs in mid-afternoon of the hottest weekday during summer, driven by the air conditioning loads of residential and commercial customers. This typically occurs on the same day as the overall provincial peak, but may occur at a different hour in the day.

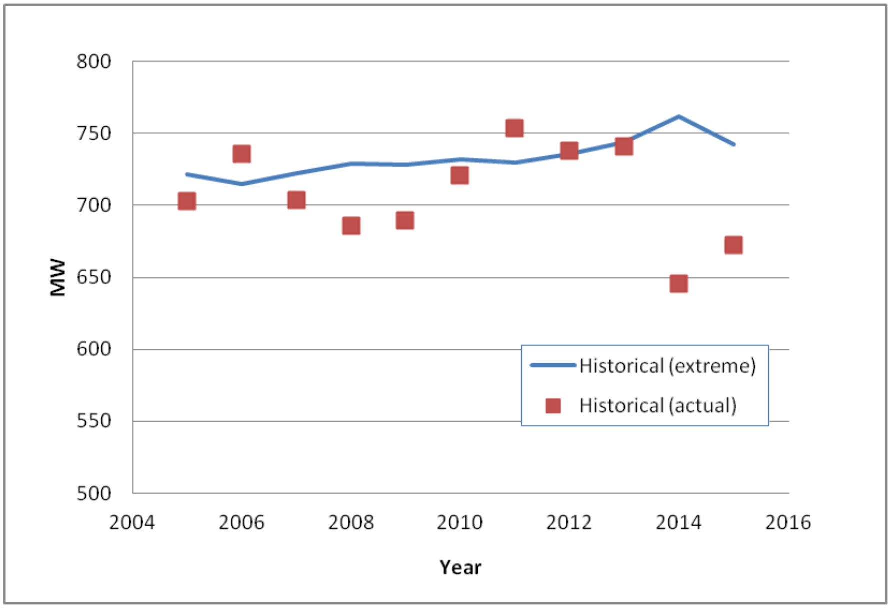
Section 5.1 begins by describing the historic electricity demand trends in the sub-region from 2005 to 2014. Section 5.2 describes the demand forecast used in this study and the methodology used to develop it.

5.1 Historical Demand

The Burlington and Oakville Hydro coincident peak electrical demand for the Bronte Sub-region is shown in Figure 5-1. The historical actual data (in red) shows the coincident peak demand for the year.

The historical extreme weather line (in blue) shows the demand at the same hour, but it has been adjusted to reflect the expected behaviour under extreme weather conditions. Correction factors between actual and extreme conditions are produced on a zonal basis by Hydro One, the transmitter in this area.

Figure 5-1: Historical Peak Demand in the Bronte Sub-region

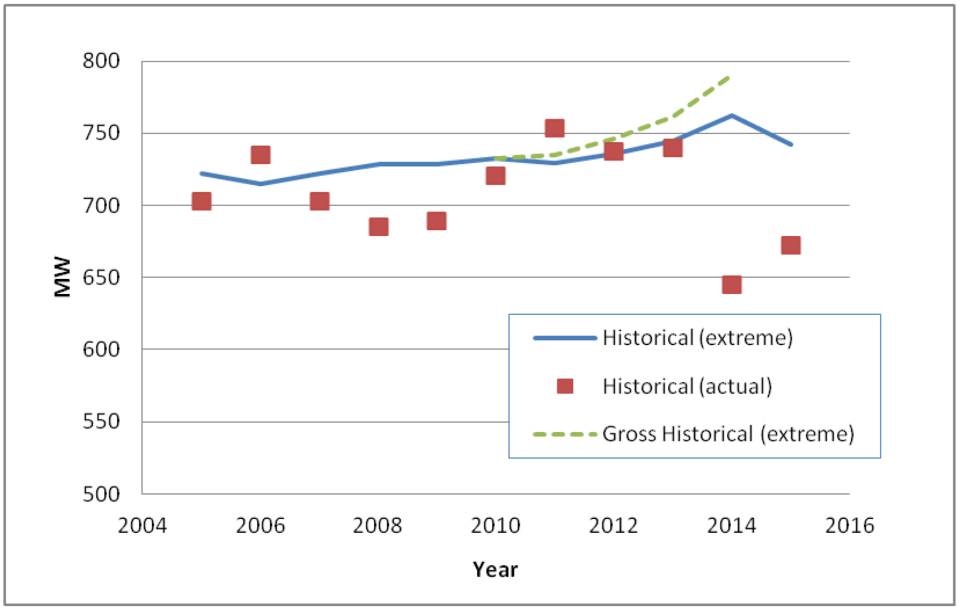


The weather corrected peak shows that demand has been generally increasing over the past decade, with a slight dip in the most recent year. However, the data for summer of 2014 and 2015 should be regarded as less reliable due to abnormally cool summer conditions. Although an extreme weather correction has been applied in all cases, these methodologies are generally not designed to make such extreme adjustments.

Historical demand, as measured at the station level, already accounts for the impact of conservation measures and other demand reducing programs in service at the time of peak. For example, verified peak demand savings from conservation programs show that 24.3 MW of peak demand was offset in 2014 across the combined Burlington Hydro and Oakville Hydro loads. In the absence of these conservation programs, growth in peak demand would have been more pronounced. The graph below shows the extreme weather corrected peak for 2010-2014[6], and the equivalent peak without the reduction from verified CDM programs from 2011-2014:

[6] Verified conservation impacts for summer of 2015 will be available September 2016

Figure 5-2: Historical Peak Demand in the Bronte Sub-region, Gross and Net



5.2 Demand Forecast Methodology

For the purpose of the IRRP, a 20-year planning forecast was developed to assess electricity supply and reliability needs at the regional level.

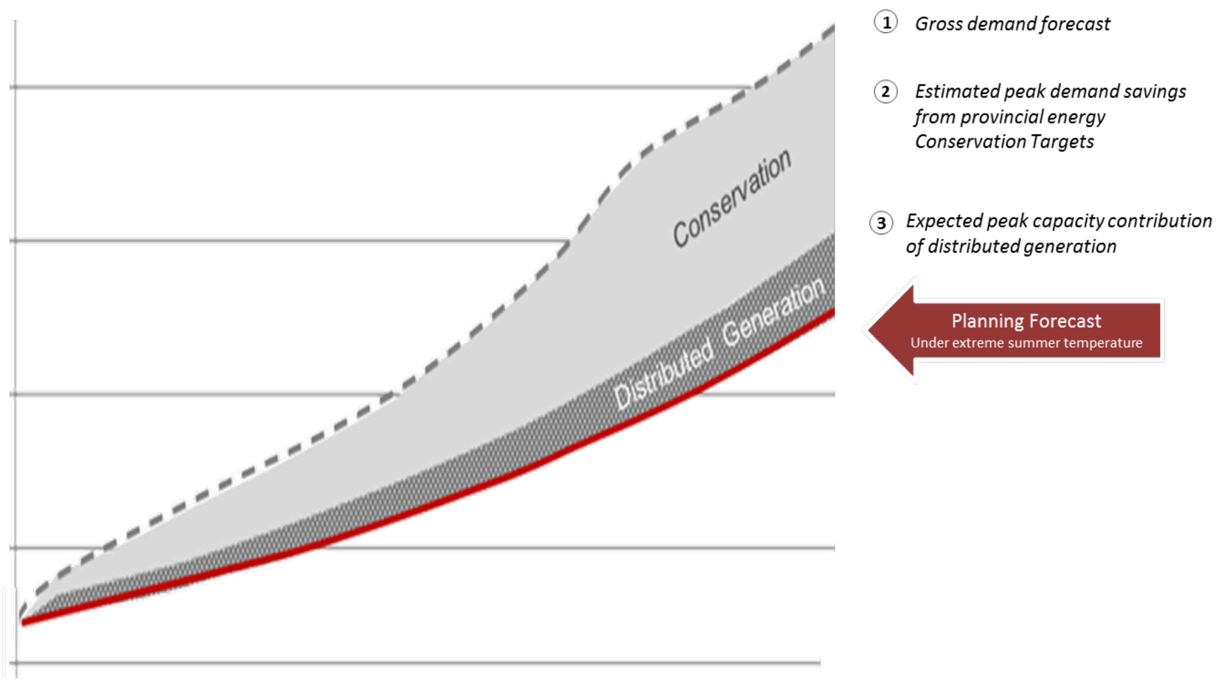
Regional electricity needs are driven by the limits of the transmission infrastructure supplying an area, which is sized to meet peak-demand requirements. Regional planning therefore typically focuses on growth in regional-coincident peak demand.

The 20-year planning forecast is divided notionally into three timeframes. The near term (0-5 years) has the highest degree of certainty; any near-term needs must typically be addressed through regional transmission or distribution solutions as there is not sufficient time to address longer-term conservation or DG solutions. The medium term (5-10 years) provides more lead time to develop and incorporate conservation and DG options. The long-term forecast covers the 10-20 year period and has the lowest degree of certainty. It is used for identifying potential longer-term needs and, as necessary, considering and developing integrated solutions (including conservation, DG, major transmission upgrades). Early identification of these needs and potential solutions makes it possible to begin engagement with the local community and all levels of government long before the need is triggered. This provides the greatest opportunity to gain input on decision making, and to ensure local planning can account for new infrastructure.

The regional peak demand forecast was developed as shown in

Figure 5-3. Gross demand forecasts, assuming normal-year weather conditions, were provided by the LDCs and the transmission-connected customers in the LDC's service territory. The LDC forecasts are based on growth projections included in regional and municipal plans, which in turn reflect the province's Places to Grow policy. These forecasts were then modified to produce a planning forecast — i.e., they were adjusted to reflect the peak demand impacts of provincial conservation targets and DG contracted through provincial programs such as FIT and microFIT and to reflect extreme weather conditions. The planning forecast was then used to assess any growth-related electricity needs in the region.

Figure 5-3: Development of Demand Forecast



Using a planning forecast that is net of provincial conservation targets is consistent with the province's Conservation First policy. However, it also assumes that the targets will be met and that the targets, which are energy-based, will produce corresponding local peak demand reductions. An important aspect of plan implementation will be monitoring the actual peak demand impacts of conservation programs delivered by the local LDCs and, as necessary, adapting the plan. Additional details related to the development of the demand forecast are provided in Appendix A.

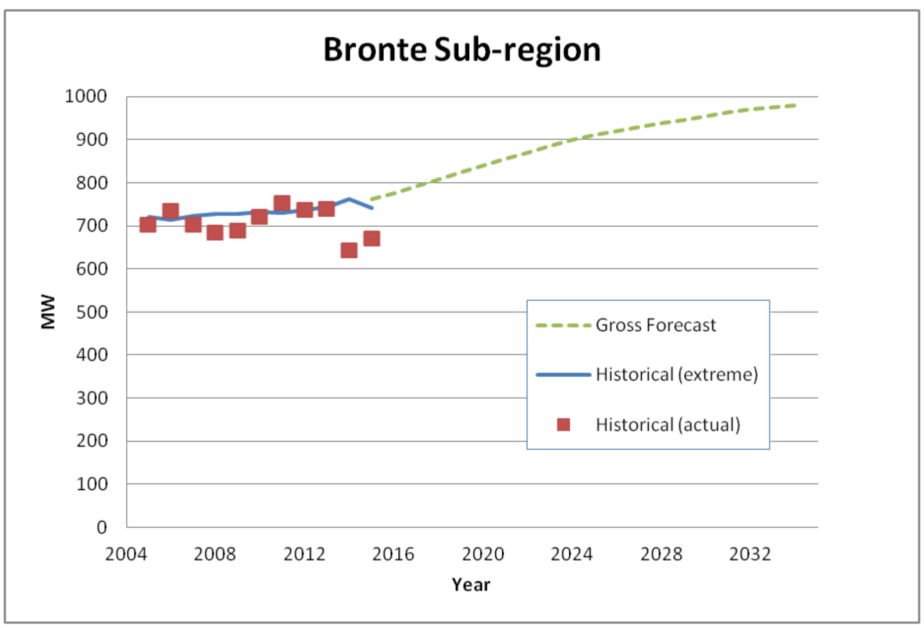
5.3 Gross Demand Forecast

Each participating LDC in the Bronte Sub-region prepared gross demand forecasts at the transformer station level or bus level for multi-bus stations. Gross demand forecasts account for increases in demand from new or intensified development, but do not account for the impact of new conservation measures such as codes & standards or DR programs. However, LDCs are expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices, which is termed "natural conservation".

Since LDCs have the most direct experience with customers and applicable local growth expectations, their information is considered the most accurate for regional planning purposes. Most LDCs cited alignment with municipal and regional official plans as a primary source for input data. Other common considerations included known connection applications and typical electrical demand intensity for similar customer types.

The graph below shows the gross demand forecast information provided by LDCs for the Bronte Sub-region, with historical data points provided for comparison.

Figure 5-4: Bronte Sub-region Gross Forecast



Total annual growth averages 1.3% for the study area over the 20-year planning horizon. Growth is highest in the first 10 years at an average of 1.9% per year, before reducing to an average of 0.8% per year for the second 10 years. Although the forecast is shown for the entire study area, individual stations are forecast to experience different growth rates.

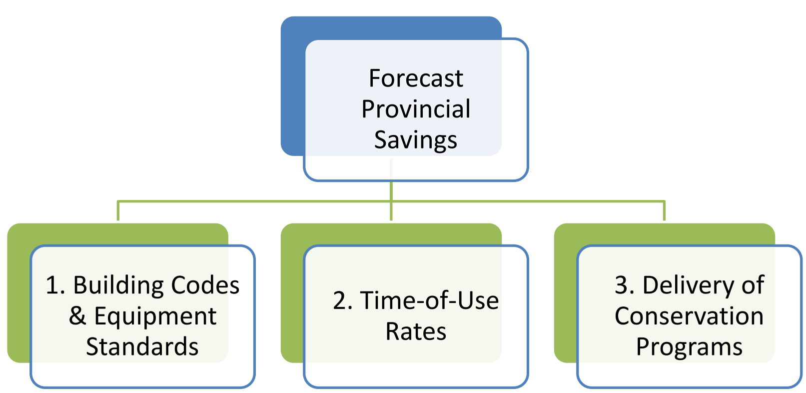
Forecasts were provided based on best available information and, as appropriate, will be updated going forward. The gross demand forecasts by station are provided in Appendix A.

5.4 Conservation Assumed in the Forecast

Conservation is the first resource to be considered in planning, approval and procurement processes. It plays a key role in maximizing the utilization of existing infrastructure and maintaining reliable supply by keeping demand within equipment capability. Conservation is achieved through a mix of program-related activities, rate structures, and mandated efficiencies from building codes and equipment standards. The conservation savings forecast for the Bronte Sub-region have been applied to the gross peak-demand forecast, along with DG resources (described in Section 5.5), to determine the net peak demand for the sub-region.

In December 2013 the Ministry of Energy released a revised LTEP that outlined a provincial conservation target of 30 terawatt-hours ("TWh") of energy savings by 2032. The expected peak demand savings from meeting this target was estimated for the Bronte Sub-region. To estimate the impact of the conservation savings in the sub-region, the forecast provincial savings were divided into three main categories:

Figure 5-5: Categories of Conservation Savings



1. *Savings due to Building Codes & Equipment Standards*
2. *Savings due to Time-of-Use Rate structures*
3. *Savings due to the delivery of Conservation Programs*

The impact of estimated savings for each category was further broken down for the Bronte Sub-region by the residential, commercial and industrial customer sectors. The IESO worked together with the LDCs to establish a methodology to estimate the electrical demand impacts of the energy targets by the three customer sectors. This provides a better resolution of forecast conservation, as conservation potential estimates vary by sector due to different energy consumption characteristics and applicable measures.

For the Bronte Sub-region, LDCs were requested to provide a breakdown of their gross demand forecast, and a breakdown of electrical demand by sector for the forecast, at each TS. For TSs that an LDC could not provide gross load segmentation, the IESO and the LDC worked together using best available information and assumptions to derive sectoral gross demand. For example, LDC information found in the OEB's Yearbook of Electricity Distributors[7] was used to help estimate the breakdown of demand. Once sectoral gross demand at each TS was estimated, the next step was to estimate peak demand savings for each conservation category: codes and standards, time-of-use rates, and conservation programs. The estimates for each of the three savings groups were done separately due to their unique characteristics and available data.

The table below shows the final estimated conservation reductions applied to the gross demand to create the planning forecast. Note that only the impacts from Burlington Hydro and Oakville Hydro customers are included (as opposed to total conservation within the sub-region, including from other LDCs).

Table 5-1: Peak Demand MW Savings from 2013 LTEP Conservation Targets, Select Years

Year	2016	2018	2020	2022	2024	2026	2028	2030	2032
Savings (MW)	9.1	19.8	36.2	45.7	57.3	70.9	83.1	94.5	100.4

Additional conservation forecast details are provided in Appendix A.

[7] OEB Yearbook of Electricity Distributors:
http://www.ontarioenergyboard.ca/OEB/Industry/Rules+and+Requirements/Reporting+and+Record+Keeping+Requirements/Yearbook+of+Distributors

5.5 Distributed Generation Assumed in the Forecast

In addition to conservation resources, DG in the Bronte Sub-region is also forecast to offset peak demand requirements. The introduction of the *Green Energy and Green Economy Act, 2009*, and the associated development of Ontario's FIT program, has increased the significance of distributed renewable generation in Ontario. This renewable generation, while intermittent in nature, contributes to meeting the electricity demands of the province.

After applying the conservation savings to the demand forecast as described above, the forecast is further reduced by the expected peak contribution from contracted, but not yet in-service, DG in the sub-region. The effects of projects that were already in-service prior to the base year of the forecast were not included as they are already embedded in the actual demand which is the starting point for the forecast. Potential future (but uncontracted) DG uptake was not included and is instead considered as an option for meeting identified needs.

Based on the IESO contract list as of September 2015, new DG projects are expected to offset an incremental 2.68 MW of peak demand within the Bronte Sub-region by 2018. All contracts are for small scale solar projects (<500 kW). A capacity contribution of 34% has been assumed to account for expected output during peak summer conditions.

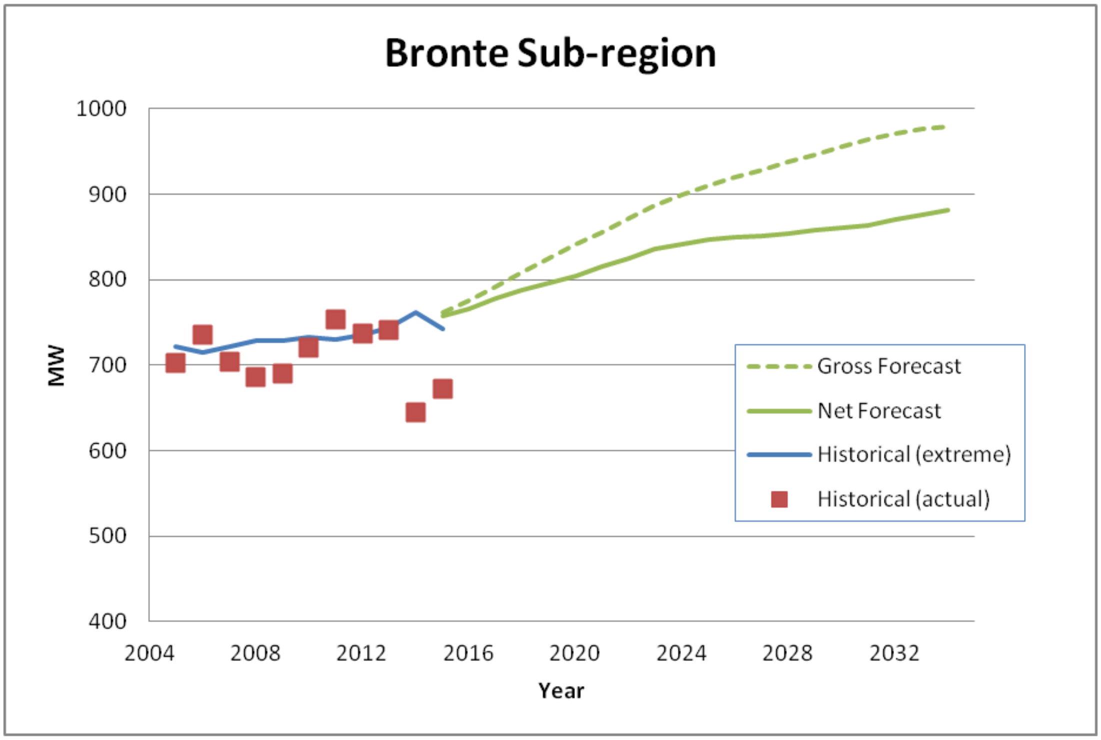
Additional details of the regional demand reductions from province-wide DG programs are provided in Appendix A.

5.6 Planning Forecasts

After taking into consideration the combined impacts of conservation and DG, a 20-year planning forecast was produced.

Figure 5-6 below illustrates the planning forecast, along with historic demand in the area. Note that the net forecast is for extreme weather conditions. Further details of the planning forecast scenarios are provided in Appendix A.

Figure 5-6: Bronte Sub-region Planning Forecast



6. Needs

Based on the planning forecasts, system capability, and application of provincial planning criteria, the Bronte Sub-region Working Group identified electricity needs in the near, medium, and long term. This section describes the identified needs for these three time horizons in the Bronte Sub-region.

6.1 Needs Assessment Methodology

ORTAC[8], the provincial standard for assessing the reliability of the transmission system, was applied to assess supply capacity and reliability needs. ORTAC includes criteria related to the assessment of the bulk transmission system, as well as the assessment of local or regional reliability requirements (see Appendix B for more details).

Through the application of these criteria, four broad categories of needs have been identified for the Bronte Sub-region IRRP:

- **Transformer Station Capacity** is the electricity system's ability to deliver power to the local distribution network through the regional transformer stations. This is limited by the 10-day Limited Time Rating ("LTR") of the step-down transformer stations in the local area. Transformer station capacity need is identified when the peak demand at step-down transformer stations in the local area exceeds the combined LTR ratings.
- **Supply Capacity** is the electricity system's ability to provide continuous supply to a local area. This is limited by the load meeting capability ("LMC") of the transmission lines supplying the area. The LMC is the maximum demand that can be supplied on a transmission line or group of lines as prescribed by ORTAC. LMC studies are conducted using power system simulations analysis (see Appendix B for more details). Supply capacity needs are identified when peak demand on the transmission lines exceeds the LMC.
- **Load Security and Restoration** is the electricity system's ability to keep the magnitude of electrical demand interrupted after a major prolonged transmission outage within the levels specified in ORTAC, including the time required to restore service. A major transmission outage would include a contingency on a double-circuit tower line resulting in the prolonged loss of both circuits. Load security concerns the magnitude of peak customer electrical demand which is susceptible to supply interruption in the event of a major transmission outage. Load restoration concerns the time periods within

[8] http://www.ieso.ca/imoweb/pubs/marketadmin/imo_req_0041_transmissionassessmentcriteria.pdf

which the interrupted customer demand should be restored following a major prolonged transmission outage. The specific load security and restoration requirements prescribed by ORTAC are described in Appendix B.

- **Service quality** concerns factors which can impact the effective, efficient, or economic operation of the local power system, both under normal operating conditions and following contingency events. This includes maintaining voltage within specified limits, and overall reliability performance.

The needs assessment may also identify requirements related to equipment end-of-life and planned sustainment activities. Equipment reaching end-of-life and planned sustainment activities may have an impact on the needs assessment and option development.

6.2 Needs

Two separate needs were identified which impact the ability of Bronte TS to serve local loads:

1. **Overloads of 115 kV B7/B8 circuits.** The two 115 kV circuits supplying Bronte TS are limited by a 3 km line section which is rated at 750 A and is susceptible to overloading. This is lower than the 850 A for the remaining 14 km, which is not overloaded. As a result, load at Bronte TS must be kept below approximately 135 MW in order to respect the long-term emergency rating of the line.
2. **Post contingency voltage drop below acceptable criteria**. Bronte TS is made up of two separate buses, BY and Q. When load on BY exceeds approximately 80 MW, and total station load exceeds approximately 149 MW, the bus voltage drops more than 10% following the loss of circuit B7. Voltage drops of this magnitude are not acceptable under ORTAC. The exact loading limit for Bronte TS depends on the load balance between the two buses.

In addition to the two issues impacting Bronte TS, the following needs were also identified within the broader sub-region:

1. **Power Factor at Cumberland TS**. The IESO Market Rules require a station to be operated with a power factor of 0.9 or higher. Lower ratings indicate less efficient operation and can trigger thermal and voltage issues.
2. **Capacitor bank operation at Oakville TS #2**. Due to concerns over voltage imbalance, a station capacitor bank cannot currently be used. This limits the amount of load which can be served.
3. **Restoration needs**. Two areas within the Bronte study area have been identified as being at risk for not meeting restoration levels as defined in ORTAC.

These needs are described in greater detail in the following sections.

6.2.1 Overload of B7/B8

Bronte TS is served by two 115 kV circuits (B7 and B8) which emanate from Burlington TS and end at Bronte TS. Under ORTAC, each circuit must be capable of supplying total peak load for Bronte TS, without the need to curtail (reject) load, following the sudden loss of the companion circuit.

For the B7/B8 circuits, the most limiting contingency is the loss of B7, as the Long Term Emergency ("LTE") rating of B8 is the lower of the two, at 750 A (compared to 770 A). Further, the limiting section of B8 is 3 km in length, while the remaining 14 km has a slightly higher rating, at 850 A. Since the lowest rating must be respected, the effective LTE rating of the entire line is therefore 750 A.

The load in MW that can be accommodated by a rating of 750 A can vary depending on system conditions (including customer power factor and system voltage). In this case, it was determined to be approximately 135 MW based on prevailing conditions.

Total Bronte TS load is forecast to exceed 135 MW beginning in 2018 however this limit has already been exceeded during the 2012 and 2013 summer peaks. In each of these instances, B7 and B8 circuits were both in service, and as a result operated within their thermal limits. Had one of the lines experienced a sudden fault during these peaks, system operators would have required the immediate transfer of load away from the station, or load shedding, to keep the remaining circuit below its LTE. Actual LTE at the time of any fault would have been influenced by actual weather conditions, including temperature, sunlight, and wind.

Although the sudden loss of circuit is a relatively rare event, ORTAC requires that the system be capable of supplying all peak load in the event of this type of contingency.

6.2.2 Bronte TS – Post Contingency Voltage Drop

Immediately following the loss of any one system element, ORTAC requires that voltage on the distribution side of a step-down station drop no more than 10%.

The risk of a large sudden voltage drop is greater with radially supplied loads, and increases as more load is being supplied, particularly as the thermal limit of the station transformers is approached. These conditions apply at Bronte TS, making it particularly vulnerable.

Due to the configuration of Bronte TS, the loss of the B7 circuit triggers a larger voltage drop than the loss of B8, so it is again the more limiting of the two contingencies.

Voltage drop is also impacted by the distribution of load between the two Bronte TS buses. Based on the loading profiles provided by LDCs when developing the load forecast, the 10% post contingency voltage drop constraint is expected to become limiting when total station load reaches 143 MW, which is forecast to occur in 2021. This assumes BY bus loading of 83 MW, and Q bus loading of 60 MW.

However, if load is optimally distributed between the two buses, up to 149 MW of load could be served before reaching the 10% post contingency voltage drop, which is forecast to occur in 2033. This assumes BY bus loading of 79 MW, and Q bus loading of 70 MW.

Additional information on this need is provided in Appendix B.

6.2.3 Cumberland TS – Power Factor

An investigation was undertaken over the course of the IRRP to examine reported power factor issues at the Cumberland TS.

Based on historical records of hourly power factor data, it was determined that Cumberland TS has been frequently operating below a 0.9 power factor over the past several years. Lower power factors represent a less efficient operation of the system (by lowering the amount of active power which can be provided to customers), and can have a negative impact on local service quality. In addition, the high voltage side of a transformer must maintain a power factor of 0.9 or higher (leading or lagging) as per ORTAC.

This particular issue can be addressed by "wires" infrastructure. Hydro One and Burlington Hydro will further assess this issue and develop a mitigation plan as part of the RIP.

6.2.4 Oakville TS #2 – Capacitor Bank Operation

Oakville TS #2 station capacity is dependent on the operation of the capacitor bank located at one of the two buses. If not in operation, station loading is limited to around 138 MW, in order to respect 10% post contingency voltage drop. If the capacitor bank is in operation, up to 152 MW can be accommodated at the station. Although use of the capacitor bank improves load meeting capability as well as providing additional local benefits (power factor control), it has not been used over the past few years. Hydro One indicated that the reason it has not been operated is that energizing the bank could create a voltage imbalance of over 7% between the two buses, which may lead to false operation of protections at the station. Protections quickly disconnect faults which could endanger safety or cause damage to equipment if it remains energized. False operation of protections cause unnecessary interruption to customers and should be avoided.

Adding a second capacitor bank (such that both buses have equal voltage support) would eliminate this constraint and effectively increase Oakville TS #2 loading capacity from 138 MW to 169 MW. This would cost approximate $3 million.

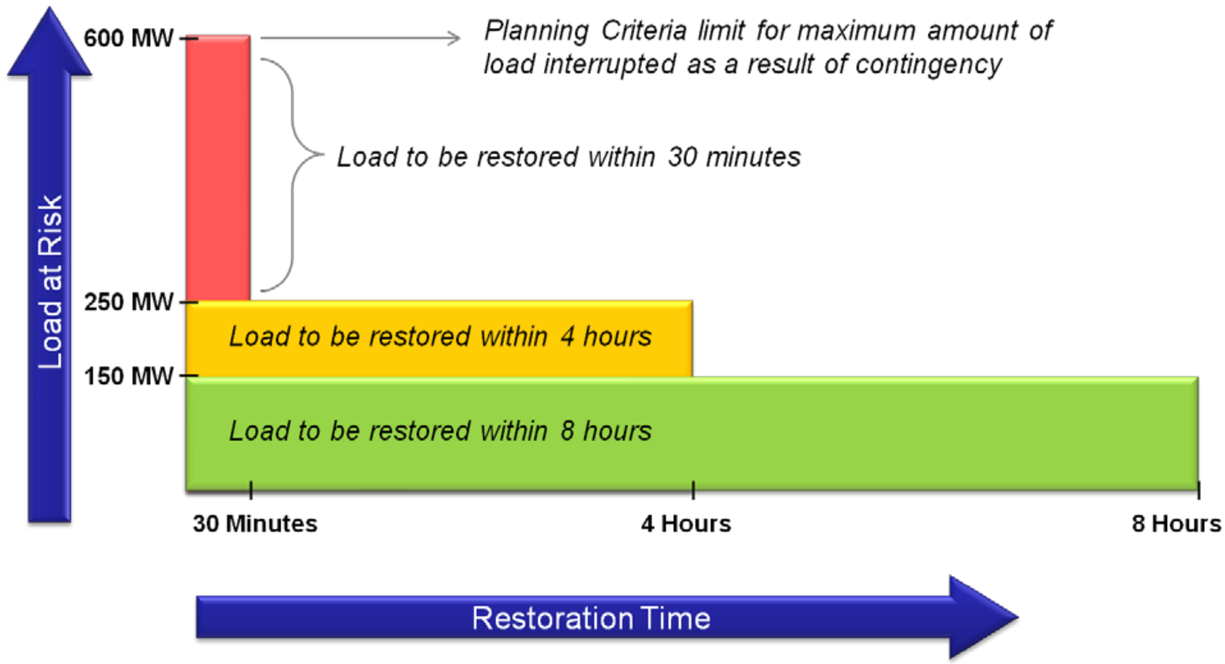
It should be noted, however, that, even with this increased station capacity, Oakville TS #2 is not a suitable location for providing supply to Bronte TS (see Section 7.1.3.2), and as a result it is not anticipated that additional capacity will be required over the study period at this station. In the event that electrical demand at Oakville TS #2 exceeds 138 MW (which may occur if a large customer connects), it is recommended that this constraint be reviewed. This need will not be considered further in the scope of this IRRP.

6.2.5 Restoration Needs

Restoration needs refer to the ability of the system to restore sufficient amount of load within required periods of time following the prolonged loss of a major supply source from the transmission system.

Several areas within the Bronte Sub-region have been identified as being at risk for not meeting restoration levels as defined in ORTAC. ORTAC indicates that, for the loss of two elements, any load in excess of 250 MW should be restored within 30-minutes and any load in excess of 150 MW should be restored within 4 hours. The assessment also considers restoration of all loads within eight hours. These restoration levels are summarized in Figure 6-1, below.

Figure 6-1: ORTAC Load Restoration Criteria



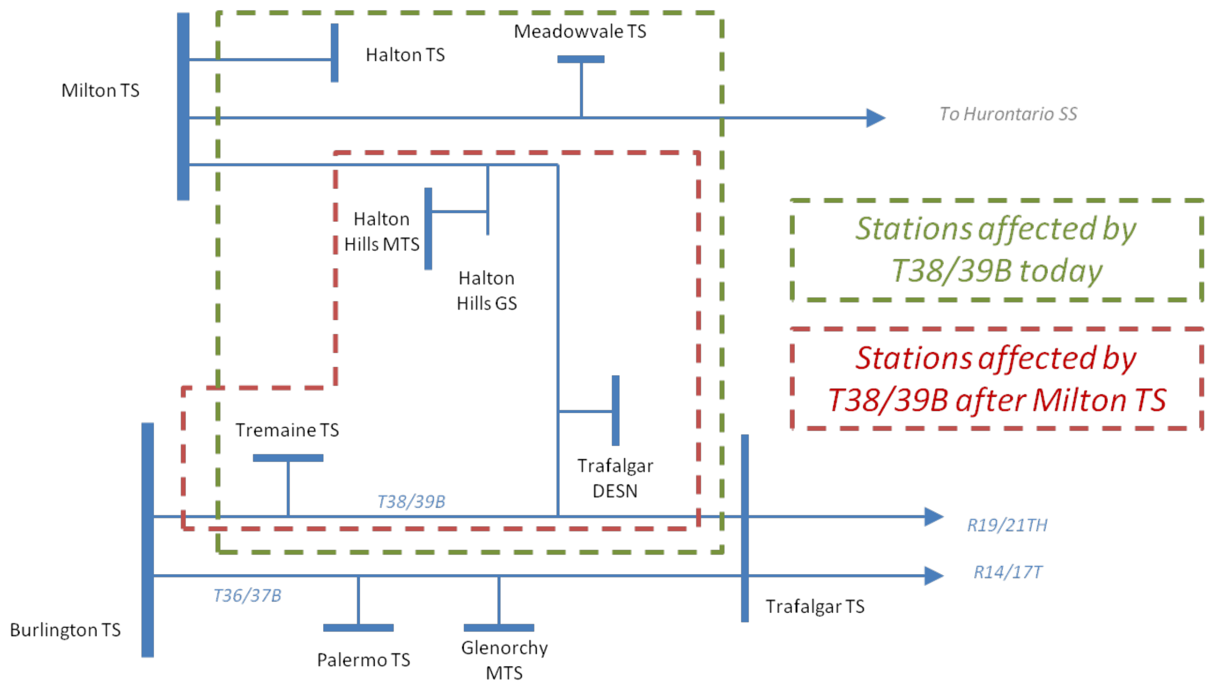
Given that the sudden loss of two transmission elements is a relatively rare event, ORTAC allows for some discretion in applying this criteria: Where a restoration need is identified, "transmission customers and transmitters can consider each case separately taking into account the probability of the contingency, frequency of occurrence, length of repair time, the extent of hardship caused and cost".[9]

Some previously identified restoration needs affecting stations in this sub-region are being investigated through the West GTA Bulk System Study (more details provided in Section 4.2), particularly those related to the T38/39B circuits. It is expected that the gap in meeting restoration criteria associated with T38/39B will no longer occur following the bulk system changes planned as part of the West GTA Bulk System Study. This bulk plan includes implementing 230 kV to 500 kV transformers and a 230 kV switchyard at the existing Milton SS, and reconfiguration/retermination of transmission circuits in the area. This will remove Halton TS (including any future station expansion) and Meadowvale TS from T38/39B, lowering

[9] ORTAC Section 7.4 Application of Restoration Criteria - http://www.ieso.ca/documents/marketAdmin/IMO_REQ_0041_TransmissionAssessmentCriteria.pdf

the amount of load at risk of interruption. Stations which will continue to be served by T38/39B are Tremaine TS, Trafalgar DESN, and the future HHH MTS. These measures will reduce the amount of load at risk of interruption by 2034 from 646 MW to 241 MW (already meeting acceptable 30 minute restoration criteria). Combined with the present day 4 hour restoration capability of 99 MW for these stations, this means that these restoration needs will be met following the expected bulk system upgrade in GTA West.

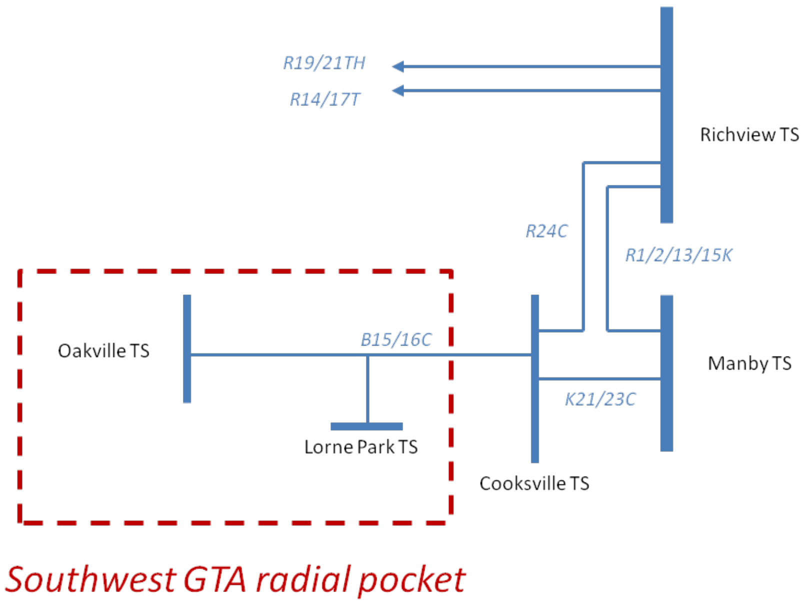
Figure 6-2: Restoration Pocket for T38/39B



Also being considered from a restoration perspective are Palermo TS and Glenorchy MTS. As shown in Figure 6-2, above, both are at risk of supply interruption following the loss of the T36/37B circuits. However, the current forecast shows the coincident load of these stations only reaching 192 MW over the next 20 years, with 61 MW capable of being restored within of 30 minute and 116 MW capable of being restored within 4 hours through distribution transfers. This means that these stations are currently meeting restoration guidelines and do not require further analysis.

The remaining area of the Bronte Sub-region which is at risk of failing to meet restoration guidelines is the southwest GTA radial pocket. Following the simultaneous loss of both B15C and B16C circuits, supply is interrupted to Oakville TS #2 and Lorne Park TS, in addition to local direct connect industrial loads (not shown in Figure 6-3, below).

Figure 6-3: Restoration Pocket for Southwest GTA, West of Cooksville



The net forecast prepared for this IRRP shows that demand is expected to be relatively flat over the next 20 years, as new demand is largely offset by new conservation initiatives. In order to fully meet criteria guidelines, all load in excess of 250 MW must be restored within 30 minutes, and all load in excess of 150 MW within 4 hours, following the sudden loss of the B15/16C circuits. Given the proximity of emergency crew and equipment, all loads should be able to be restored within 8 hours through conventional transmission supply.

Table 6-1 below shows the total peak load at risk of interruption for select years, and the 30 minute and 4 hour restoration capability which would be required to meet this criteria:

Table 6-1: Peak Load and Restoration Requirements for West of Cooksville Pocket

	2016	2018	2020	2022	2024	2026	2028	2030	2032	2034
Forecast Peak Demand	257.6	261.9	262.3	266.5	270.3	273.9	276.5	280.0	284.3	292.8
Targeted 30 Minute Restoration	7.6	11.9	12.3	16.5	20.3	23.9	26.5	30.0	34.3	42.8
30 Minute Shortfall	0	0	0	0	0	0	0	0	0	0
Targeted 4 Hour Restoration	107.6	111.9	112.3	116.5	120.3	123.9	126.5	130.0	134.3	142.8
4 Hour Shortfall	0	2.2	2.6	6.8	10.6	14.2	16.8	20.3	24.6	33.1

Based on discussions with area LDCs, up to 46 MW can be restored through distribution transfers within 30 minutes under the current supply arrangement and 110 MW within 4 hours.[10] The West of Cooksville pocket is expected to be able to meet the 30 minute restoration criteria over the entire study period. This leaves a 4 hour restoration shortfall beginning in year 2018, and extending throughout the rest of the study period, up to a maximum of 33 MW by 2034.

Although the magnitude of the 4 hour restoration need is small, the vulnerability to loss of supply for customers in the West of Cooksville area was highlighted during the July 8, 2013 summer rain storm. This section of line was interrupted for several hours due to outages at Richview TS and Manby TS. The likelihood of a similar outage occurring in the future is low, as preventative measures have been implemented, based on root cause analysis. However, Enersource Hydro Mississauga Inc. ("Enersource") and Oakville Hydro have indicated that there are ongoing concerns about this reliability risk. It should be noted the bulk plan for the area is considering options which may address this situation.

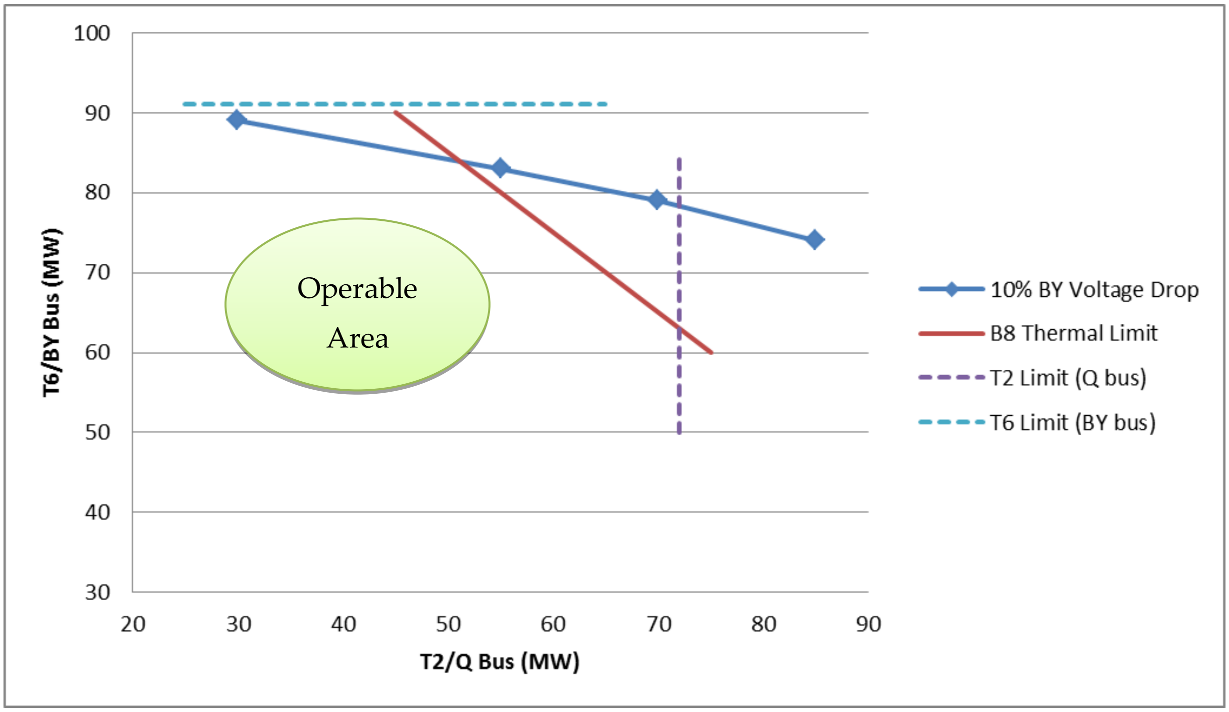
6.3 Needs Summary

The majority of needs in the Bronte Sub-region concern various loading limits on Bronte TS.

Figure 6-4, below, shows the operable area for Bronte TS, with consideration for the B7/B8 thermal limits, 10% voltage drop criteria, and LTR of the transformers following the loss of B7 (most constraining scenario).

[10] Burlington to Nanticoke Scoping Assessment Report, http://www.ieso.ca/Documents/Regional-Planning/Burlington_to_Nanticoke/Scoping%20Assessment%20Outcome%20Report.pdf

Figure 6-4: Loading Limits on Bronte TS, Multiple Constraints, for Loss of B7



The maximum load that can be carried by Bronte TS is 135 MW in order to respect thermal limits of the B8 circuit (as shown by the legend line in red). Since this limit is not sensitive to the distribution of load between buses, any point along the limit corresponds to the same 135 MW total.

If this limit were neglected, the next highest possible load which could be carried by Bronte TS is 149 MW, which coincides with the intersection between the 10% voltage drop limit and the T2 loading limit (line in blue and broken line in purple, respectively). Note that this limit is sensitive to loading between buses, which means the maximum occurs when load on the Q bus is approximately 70 MW, and load on the BY bus is 79 MW.

In addition to Bronte TS, Cumberland TS is also currently experiencing service quality needs related to the low power factor at the high voltage bus. This need will be addressed directly between the transmitter and distributor, and will not be studied further as a part of this IRRP.

An operational issue has also been identified at Oakville TS #2, which is preventing the use of the capacitor bank, and hence limiting the loading capability of the station. However, since Oakville TS #2 is currently not forecast to exceed the reduced loading limit, this need will not be studied further as part of this IRRP.

Finally, two restoration needs currently exist in the Bronte Sub-region: T38/39B, and the West of Cooksville radial pocket. The former need is expected to be addressed through the implementation following the GTA West Bulk System Study, and as a result will not be studied further as a part of this IRRP.

The table below provides a brief summary of needs which will be considered during the development of options for the plan.

Table 6-2: Summary of Needs in Bronte Sub-region

Area	Need	Description	Need Date
Bronte TS	Thermal limit of B7/B8	Flows on B8 circuit exceeds Long Term Emergency Rating following loss of B7 when load is in excess of 135 MW	2018
Bronte TS	Post contingency 10% voltage drop	Voltage at Bronte TS may drop by more than 10% following loss of B7 when load is in excess of 143 MW (or 149 MW of loads can be redistributed between buses)	2021
West of Cooksville	Restoration	Restoration shortfall for the 4 hour timeline defined by ORTAC	2018

7. Near- and Medium-Term Plan

This section describes the alternatives considered in developing the near- and medium-term plan for the Bronte Sub-region, provides details of and rationale for the recommended plan, and outlines an implementation plan.

7.1 Alternatives for Meeting Near- and Medium-Term Needs

In developing the near- and medium-term plan, the Working Group considered a range of integrated options. The Working Group further considered technical feasibility, cost and consistency with long-term needs and options in the Bronte Sub-region when evaluating alternatives. Solutions that maximize the use of existing infrastructure were given priority, where they were otherwise determined to be cost effective.

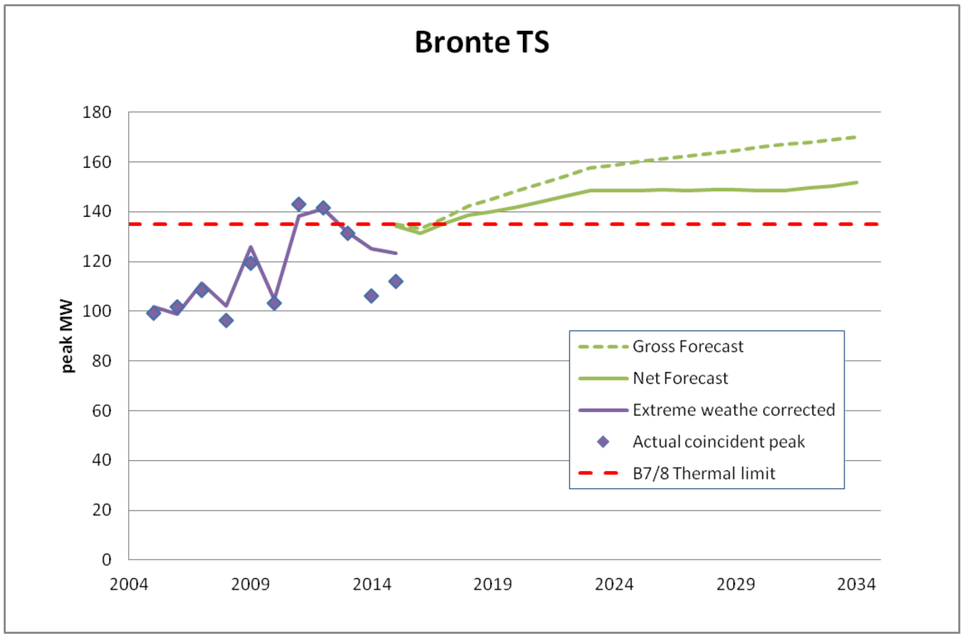
The following sections detail the alternatives considered and address their performance in the context of the criteria described above. The alternatives are grouped according to three major solution categories: (1) conservation, (2) local generation and (3) transmission and distribution.

7.1.1 Conservation

Conservation was considered as part of the planning forecast, which includes the local peak-demand effects of the provincial conservation targets (see Section 5.4). Across the planning area, the LTEP energy reduction targets account for approximately 57 MW, or 41% of the forecast demand growth during the first 10 years of the study. Achieving the estimated peak demand reductions of the provincial conservation targets significantly reduces the extent of the Bronte TS thermal and voltage drop needs. This results in only a 15 MW capacity gap, which makes a distribution solution viable. It also effectively offsets new demand growth at this station from 2023-2030. As a result, a solution developed to address near-term needs would be sufficient for the area until roughly 2030.

In Figure 7-1, below, Bronte TS load is shown under both the gross and net forecasts (accounting for expected conservation and contracted DG). The thermal limit of B7/B8 is also shown, as it is the more constraining of the two needs identified at Bronte TS.

Figure 7-1: Effect of Conservation Targets on Bronte TS Peak Load



Note that the majority of conservation targets are provided in terms of energy offsets (measured over an entire year), while transmission needs are triggered based on peak demand (single highest observation in a year). As a result, in order to reduce, defer, or otherwise address needs, conservation programs must have an impact during the hour of peak demand. In the case of the Bronte Sub-region, this typically means late afternoon on the hottest weekdays of summer.

The net forecast is an estimate of how meeting the mostly energy based targets translates into peak demand reductions. There is, however, uncertainty in meeting energy conservation targets and determining how meeting those targets will translate into peak demand savings. As such, there is a wide range of potential demand impacts which could be experienced (both higher and lower than forecast), even while still achieving full conservation targets. Therefore, LDCs are encouraged to focus their Conservation First Framework ("CFF") funding (Oakville Hydro - $24,575,982 and Burlington Hydro - $25,825,521) towards measures and programs that can also reduce peak and overall demand–particularly in areas where needs have been identified through regional planning–when they are working towards achieving their CFF energy savings targets.

As part of the implementation of this plan, the Working Group will review actual peak demand, including the impact of conservation, on an annual basis. The IESO is willing to consider requests from LDCs for support with the development of a localized achievable potential study to determine the specific conservation savings potential associated with Bronte TS. The study could be used to help design conservation/DSM programs that deliver optimal customer and system benefits. If net demand trends lower at Bronte TS than expected, need dates may be deferred. On the other hand, if growth trends higher, and cannot be offset through conservation or other peak reducing activities (such as DG), additional measures may be required to address needs.

The other major need identified in the Bronte Sub-region is the restoration need following a loss of transmission supply in the West of Cooksville radial pocket. Restoration is required following a loss of supply. Power must be restored through an alternate electrical supply path, or when the original fault is cleared. Conservation does not have a bearing on these factors, and as a result is not a suitable option for addressing these types of needs.

7.1.2 Local Generation

Large, transmission-connected generation and small-scale distribution-connected DG options were ruled out as viable alternatives for meeting near-term needs in the Bronte Sub-region. The sections below explain why.

7.1.2.1 Generation-based Solution to Address Bronte TS Needs

Two sets of needs are associated with Bronte TS: overloads on the B7/B8 supply circuits, and post contingency voltage drop at the station itself.

Based on the planning forecast, a transmission connected generator of approximately 20 MW would be suitable for addressing the circuit overload needs expected to emerge in 2018, but would not impact the voltage drop needs expected to begin in 2021. Although this could address some of the near-term Bronte TS needs, it was still not considered an appropriate solution for several reasons. First, it is not technically feasible to approve and construct this type of facility within the short lead time required to meet near-term needs. Second, it would be difficult and possibly infeasible to find a suitable location to host this type of facility in close proximity to Bronte TS, which is located within a highly developed area of southwest Oakville. Third, local generation would add to the overall generation capacity for the province and therefore the generation capacity situation at the provincial level must be considered. Currently, the province has a surplus of generation capacity, and no new capacity is forecast to be needed until the mid-2020s at the earliest.

Instead of a single large transmission connected generation facility, 20 MW worth of DG projects could address both the B7/B8 overload and Bronte TS voltage drop needs into the long term. However, DG projects were also determined to be technically, logistically and economically infeasible for addressing these needs because the DG facilities would need to be optimally dispersed across a number of distribution feeders. Generation would, in effect, have to fully offset any incremental demand, and be matched precisely where local demand requires. Developing and implementing such a complex solution within the time period of the need in this densely developed area was determined to be impractical.

While DG projects are not suitable for addressing near-term needs, they offer good potential for managing ongoing load growth, and thereby deferring longer-term needs. New development in the Town of Oakville offers potential to identify opportunities for large steam host customers to integrate combined heat and power ("CHP") projects at the earliest stage of community design to meet demand and heat needs. Typically large commercial or institutional customers have suitable profiles to accommodate this type of facility. The Town of Oakville has identified goal 2.1.1 in their Environmental Strategic Plan to "Work with Oakville Hydro and other community partners to expand, access and promote alternative green energy resources (geothermal, solar, combined heat and power, etc.)".[1] Additionally, the City of Burlington has proposed a target of 12.5 MW of peak electrical demand to be met through local sustainable generation by 2031.[11] Locating distributed energy resources in the Bronte TS service territory could provide value in deferring the need for additional investments.

Based on the planning forecast, long-term growth within the Bronte TS area is expected to average less than 1 MW per year. Assuming the recommended option (described in greater detail in Section 7.2) is adopted, new needs may begin to emerge after 2030. Acquiring approximately 10 MW of DG capacity, with the ability to dispatch during local peak demand, would thereby defer potential long-term needs for over a decade.

Potential for incremental DG to address long-term needs will be reviewed as part of future regional planning cycles, while actual uptake will be monitored on a yearly basis.

11 Burlington Community Energy Plan, https://www.burlington.ca/en/live-and-play/resources/Environment/Burlington_Community_Energy_Plan.pdf

7.1.2.2 Generation-based Solution to Address Restoration Needs

Generation was ruled out as a possible option to address restoration needs in the West of Cooksville radial pocket. Large generation is not a suitable option for addressing restoration needs, as it would require the facility to have blackstart and islanded operation capabilities, a costly generation and system design feature. Additionally, finding a suitable location for major generation infrastructure could be challenging given that the West of Cooksville area is largely built up with significant residential zoning.

Smaller scale DG was determined to be impractical from a technical and economic perspective, given the scale and number of facilities that would be required within the sub-region. In order to provide restoration, each of these facilities would also have to be able to supply their local loads in islanded mode. Some high value loads (such as pumping and water purification facilities) are typically developed with on-site gas or diesel generation to ensure they can continue to operate during a power supply outage. While there is benefit to building this type of supply redundancy to ensure restoration capability for some loads, it is impractical on a large scale to address local restoration needs.

7.1.3 Transmission and Distribution

A number of transmission and distribution, or "wires," solutions were considered by the Working Group to meet the near-term needs. "Wires" infrastructure solutions can refer to new or upgraded transmission or distribution system assets, including lines, stations, or related equipment. These solutions are often characterized by high upfront capital costs, but have high reliability over the lifetime of the asset.

If net growth at Bronte TS cannot be fully offset through conservation, DR, or local generation initiatives, constraints on the transmission system will have to be addressed through an electricity infrastructure based solution. Even under the full achievement of conservation targets, peak demand is forecast to exceed the existing transmission system capacity by 15 MW over the next 15 years. There are potential transmission and distribution solutions to address the Bronte TS need; these are described in greater detail in Sections 7.1.3.1 and 7.1.3.2.

Likewise, an electricity infrastructure based solution could address the restoration need for the West of Cooksville radial pocket. However, given the high costs associated with electricity infrastructure solutions, low exposure to risk represented by this event, and low likelihood of occurrence, any measure would have to be assessed to ensure it is economic before it is recommended. This is further discussed and investigated in Section 7.1.3.3.

7.1.3.1 Transmission-based Solution to Address Bronte TS Need

The two 115 kV circuits supplying Bronte TS are limited by a 3 km section which is rated at 750 A for circuit B8, and 770 A for circuit B7. These are lower ratings than the remaining 14 km of the lines (850 A for B8, and 880 A for B7). As a result, load at Bronte TS must be kept below approximately 135 MW in order to respect the 750 A minimum LTE rating of the line. If the limiting 3 km line section was uprated, the new thermal limit of the remaining section would be approximately 150 MW (corresponding to 850 A). Assuming full achievement of CDM targets, this measure would successfully defer the thermal need until 2033 (assuming load distributed optimally between buses according to: maximum 79 MW on BY bus, 70 MW on Q bus). At this loading level, needs associated with post contingency voltage drop would also become limiting, and no incremental load could be served at Bronte TS. This transmission upgrade would therefore enable the full usage of the step-down transformer facilities.

B7/B8 Palermo Junction to Bronte TS (3 km) is the limiting line section. Uprating will require complete rebuild of this line section using new steel poles and 585 kcmil 26/7 Aluminum Conductor, Steel Reinforced (“ACSR”) conductor. Hydro One has indicated that budgetary estimate for rebuilding this 3 km line section is approximately $9.7 million.

The estimated time required for uprating Palermo Junction to Bronte TS line section is about three years which includes the OEB leave to construct application (Section 92), and environmental approvals.

7.1.3.2 Distribution-based Solution to Address Bronte TS Need

As an alternative to uprating the limiting section of B7/B8, needs associated with Bronte TS could be addressed by keeping the total station load below 135 MW. Assuming full achievement of conservation targets, this would require approximately 15 MW of additional capacity relief to defer the need past 2030. This relief could be achieved by transferring 15 MW of load (approximately 1 feeder worth) from Bronte TS to a neighboring station. This would require investment in the distribution system to expand the service territory of another station into an area which is currently served by Bronte TS.

There are four stations within the general vicinity of Bronte TS which are forecast to have remaining station capacity over the 20-year planning horizon, and which currently serve load from either Burlington Hydro or Oakville Hydro. These stations were reviewed to determine suitability for load transfer:

1. **Glenorchy MTS** is located approximately 14 km north and east of Bronte TS, and primarily serves Oakville Hydro load, with some embedded demand. Under the current planning forecast, over 40 MW of capacity will be available at this station over the next 20 years. Oakville Hydro has indicated that it would not be technically or economically feasible to build transfer capability between Bronte TS and Glenorchy MTS, mainly due to the presence of the Queen Elizabeth Way ("QEW") highway, which would have to be spanned or tunneled under for a connection between the two systems to be made.
2. **Trafalgar TS** is approximately 17 km north and east of Bronte TS, and serves Oakville Hydro load exclusively. Load at this station is forecast to remain steady over the next 20 years, and could accommodate up to 40 additional MW of demand. However, 17 km is too far for 27.6 kV distribution feeders to span and supply dense urban loads without a negative impact on voltage.
3. **Oakville TS #2** is located approximately 10 km east of Bronte TS, and serves load from Oakville Hydro and Enersource (City of Mississauga). This station is forecast to have at least 40 MW of available capacity over the next 20 years. Although Oakville Hydro has existing emergency transfer capability between Bronte TS and Oakville TS #2, it has indicated that it would not be technically feasible to build enhanced ties, or operate emergency transfers for prolonged periods of time.
4. **Tremaine TS** is located 8 km north and east of Bronte TS, and serves load from Burlington Hydro and Milton Hydro. Under the planning forecast, Tremaine TS is expected to have at least 80 MW of available capacity over the next 20 years. Burlington Hydro has indicated that it would be technically feasible to expand the Tremaine TS service territory southward to create an alternate supply path for the western Bronte service territory, at a cost of approximately $4.5 million.

Given that the alternative to the distribution transfer is to upgrade the transmission supply circuits at approximately two times the cost, the Tremaine TS distribution transfer is recommended as the preferred option for the near-term Bronte TS need. Burlington Hydro expects that the transfer could be made within two years.

7.1.3.3 Infrastructure-based Solution to Address Cooksville West Restoration Need

Infrastructure, such as a transmission or distribution facility, is typically the only suitable solution to address restoration needs. It provides a means of isolating a faulted section and restoring electrical demand from an alternate source. However, building redundant supply paths can be a high cost solution, depending on the configuration of the local system. Accordingly, ORTAC allows for some discretion when applying this criteria: where a restoration need is identified, "transmission customers and transmitters can consider each case separately taking into account the probability of the contingency, frequency of occurrence, length of repair time, the extent of hardship caused and cost".[12] Additionally, these parties may also agree on higher or lower levels of reliability for technical, economic, safety and environmental reasons.

Additionally, as described in Section 4.2, a bulk system study is currently underway in West GTA to address overload issues on the 500 kV and some 230 kV transmission assets in the area. The bulk transmission study will investigate major changes to the transmission system. Some local restoration needs (such as the Halton radial pocket (T38/39B), described in Section 6.2.5), are already expected to be addressed through planned system upgrades.

Work on the GTA West Bulk System Study is still underway, and final configuration and timing have not yet been determined. As a result, standalone infrastructure solutions to address restoration needs for the West of Cooksville radial pocket will not be further investigated in this IRRP.

If these restoration needs are not adequately addressed through the bulk transmission study, they will be revisited as part of the regional planning process. The criteria outlined in ORTAC (probability of the contingency, frequency of occurrence, length of repair time, the extent of hardship caused and cost) will be considered before a solution is recommended to address this need.

---

[12] ORTAC Section 7.4 Application of Restoration Criteria - http://www.ieso.ca/documents/marketAdmin/IMO_REQ_0041_TransmissionAssessmentCriteria.pdf

7.2 Recommended Near- and Medium-Term Plan

The Working Group recommends the actions described below to meet the near-term electricity needs of the Bronte Sub-region. Successful implementation of these actions, in addition to achievement of targeted conservation measures, is expected to address the sub-region's electricity needs until the early 2030s.

1. Transfer one feeder (approximately 15 MW) of distribution load from Bronte TS to Tremaine TS. This action should be initiated as soon as possible to address the near-term risk of thermal overloads on B7/B8 and post contingency voltage drop at Bronte TS. The implementation details for this "wires" solution will be carried out through a RIP process.
2. Pursue economic options to offset new load growth in the Bronte TS service area with CDM (including DR), and investigate opportunities for local generation, including CHP projects, where cost effective. In order to defer further long-term "wires" investments, total peak demand at Bronte TS must be kept below 135 MW.

If load at Bronte TS cannot be kept below 135 MW, additional "wires" infrastructure will be required. The preferred option would likely be a second feeder transfer from Bronte TS to a neighbouring supply station, but given the long-term nature of this need, the preferred options should be re investigated with consideration of the system in place at that time.

7.3 Implementation of Near- and Medium-Term Plan

To ensure that the near-term electricity needs of Bronte Sub-region are addressed, it is important that the plan recommendations be implemented as soon as possible. The specific actions and deliverables are outlined in Table 7-1, along with the recommended timing.

Table 7-1: Summary of Needs and Recommended Actions in Bronte Sub-region

Need	Recommended Action	Need Date
Overloads on B7/B8 circuits (2018), post contingency voltage drop at Bronte TS (2021)	Burlington Hydro to transfer one feeder from Bronte TS to Tremaine TS. Detailed design and study will be carried out through a RIP process.	2018
Ongoing load growth on	Pursue economic peak	ongoing

Need	Recommended Action	Need Date
Bronte TS potentially triggering same needs in the medium to long term	demand reducing measures, including CDM and DG, to keep Bronte TS demand below 135 MW	

In order to implement the recommended near-term actions in a timely manner, an RIP should be initiated for the Bronte Sub-region upon IRRP completion. This process will allow for detailed design and study of distribution infrastructure expansion required to complete this transfer. Both LDCs have indicated that revisions to their load forecasts may be required within the next few months, which will help inform the local "wires" plan.

The outcome of the RIP will be a more detailed development plan, including a refined estimate of expected costs and benefits to customers.

7.3.1 Implementation Challenges

Under the net forecast used in this IRRP, near-term load growth at Bronte TS is expected to be driven by Oakville Hydro, the result of intensification within Oakville's Bronte village and the midtown core. Burlington Hydro is not forecasting to increase electrical demand at this TS. This means that under the recommended solution, Burlington Hydro would implement infrastructure that serves growth in Oakville.

However, there may be additional benefits to Burlington Hydro as a result of transferring load from Bronte TS to Tremaine TS. Tremaine TS is a relatively new Hydro One Transmission owned station, currently only loaded at 45% of rated capacity. Transferring this load should contribute to Burlington Hydro's outstanding "true-up" charges. Determining the amount of relief which Burlington Hydro could expect from this transfer would require a detailed evaluation of the Connection Cost Recovery Agreement ("CCRA") in place between the two parties, in particular, as related to the Tremaine and Bronte stations. This evaluation should consider the nature and circumstances of the transfer, namely, would the transfer be on a permanent basis, or only occur during high load periods (seasonal transfer) or following the loss of a circuit when load is high (emergency transfer). It is the IESO's view that seasonal or emergency transfers would provide value to local customers by addressing the Bronte TS capacity needs in a least cost manner, and should therefore be given consideration when revising true up agreements.

In discussing implementation considerations, Burlington Hydro has indicated that it is concerned about longer-term growth in the Bronte TS service area impacting future costs. As a result, Burlington Hydro is concerned with relinquishing capacity at Bronte TS on a permanent basis. As part of the implementation Burlington Hydro has proposed a long-term (ie, 10 year) lease arrangement. Details related to implementation will be developed as part of the RIP.

The IESO has committed to working with the affected parties to assist with any regulatory matters which may arise, including providing rationale for the attribution of costs among the benefiting entities.

8. Long-Term Plan

Based on the electrical demand forecasts provided by Burlington Hydro and Oakville Hydro, implementation of the recommended near-term plan is expected to address long-term needs in the Bronte Sub-region until the early 2030s.Due to the inherent uncertainty associated with producing long-term load forecasts, there is potential that additional load could materialize within the Bronte TS service territory, potentially exceeding the load meeting capability. The solutions available to address this potential risk are dependent on the magnitude and pace of the longer-term electrical demand which may materialize.

If the magnitude and pace of growth in electrical demand is moderate in nature (up to 1.5% per year gross), it is likely that the needs over the next 20 years will be small and manageable. The anticipated needs (small in scale, spread out over many customers, and driven more by intensification than by significant new greenfield developments) are well suited to community driven solutions. This may include implementation of local distributed energy resource projects (such as small scale CHP, solar and/or storage technologies) or targeted conservation initiatives that contribute to peak demand reduction (such as DR programs). Identifying potential candidate projects or initiatives should be part of the ongoing planning and engagement process between the Working Group, local communities/ municipalities, and other stakeholders in the area. The development of local Community Energy Plans provide a valuable resource for aligning the local electricity needs with municipal goals and objectives, where appropriate.

In the event that the magnitude and pace of growth in electrical demand is higher (over 2% per year gross), an infrastructure solution may be required. Such increased demand could be the result of a single new customer (such as a data centre), changing demand profiles of existing customers (for example, as a result of widespread adoption of electrification technologies), or a combination of these factors. Higher long-term electrical demand within the Bronte Sub-region could also result from the return of the 15 MW transfer to Bronte TS, due to changed operational circumstances. This would trigger an alternative long-term infrastructure solution to serve the anticipated 15 MW of incremental Oakville Hydro growth (Burlington Hydro load would be returned to its present level). Oakville Hydro has indicated that distribution transfers from Bronte TS are not feasible at this time, but this assumption may need to be revisited in the future as changes to system configurations may occur in the interim. Assuming distribution transfers are not feasible, a likely alternative solution would be to upgrade the transmission line supplying Bronte TS.

The Working Group will work with the local communities to monitor leading indicators for growth in the Bronte Sub-region. This includes monitoring changes to growth targets, the composition and location of specific customer segments (residential, commercial, industrial) and effects on electricity related to the implementation of community energy plans. If these or other factors impact service reliability or capacity of the local electricity delivery systems a new IRRP process may be initiated ahead of the 5 year planning cycle. The potential for other measures, such as incremental DG or DR programs, will continue to be discussed through engagement with local municipalities, and in particular as the nature of the long-term needs, alternatives, and associated costs become clearer.

9. Engagement Activities

Keeping communities up-to-date on regional electricity planning is important. For the Bronte IRRP, this included meetings with the City of Burlington and the Town of Oakville to share the needs identified in the regional plan and the actions being undertaken by the IESO, Transmission Company and LDCs to ensure a reliable and economic level of service is maintained. The meetings also provided an opportunity to begin discussions with the municipalities on planning for the longer term. While no longer-term needs have been identified for the Bronte Sub-region in this planning cycle, discussions that take place now on community energy planning and municipal sustainability initiatives will help to inform future electricity plans and bring all of these processes closer together.

While this dialogue for the longer-term continues with municipalities and communities, and as future planning initiatives unfold, the Working Group will engage in accordance with the established community engagement principles.[13] Any updates will be posted on the dedicated Bronte planning webpage[14] on the IESO website. Since the Bronte planning area includes part of the broader Burlington to Nanticoke, and the GTA West planning regions, updates will be sent to all subscribers who have requested updates on these regions.

---

[14] http://www.ieso.ca/Pages/Ontario%27s-Power-System/Regional-Planning/Burlington-to-Nanticoke/Bronte.aspx

10. Conclusion

This report documents an IRRP that has been carried out for the Bronte area, a sub-region of the OEB's Burlington-Nanticoke planning region. The IRRP identifies electricity needs in the Bronte Sub-region over the 20-year period from 2015-2034, identifies a preferred "wires" solution to address near-term needs, and lays out actions to monitor, defer, and address needs that may arise in the long term.

In order to further refine and implement the preferred near-term "wires" solution, it is recommended that an RIP be initiated. The RIP is to be led by Hydro One Transmission and include Burlington Hydro and Oakville Hydro as working group members.

The IESO will continue to provide support throughout the RIP process, and assist with any regulatory matters which may arise as challenges to plan implementation.

The Bronte Sub-region Working Group will continue to meet at regular intervals to monitor developments in the sub-region and to track progress toward the plan deliverables. In particular, the actions and deliverables associated with peak demand reducing initiatives will require annual review of system demand and program achievement to determine whether new initiatives are required. In the event that underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the OEB-mandated 5-year schedule.

LOCAL PLANNING REPORT

BURLINGTON TO NANTICOKE REGION

Revision: Final

Date: October 28, 2015

Prepared by: Burlington to Nanticoke Region Local Planning Study Team

Burlington to Nanticoke Region Local Planning Study Team
Hydro One Networks Inc. (Lead Transmitter)
Burlington Hydro Inc.
Horizon Utilities Corporation
Hydro One Networks Inc. (Distribution)

Disclaimer

This Local Planning Report was prepared for the purpose of developing a plan to address the local needs for which straight forward wires-only options are the only alternatives and recommending a preferred solution(s) that were identified in the Needs Assessment (NA) report for the Burlington to Nanticoke Region. These local needs do not require further coordinated regional planning. The preferred solution(s) that have been identified through this Local Planning Report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Local Planning Report are based on the information and assumptions provided by study team participants as part of the NA process.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Local Planning Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Local Planning Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Local Planning Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Local Planning Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

Executive Summary

REGION	Burlington to Nanticoke Region (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	September 15, 2014	**END DATE**	October 28, 2015

1. INTRODUCTION

The purpose of this Local Planning (LP) report is to develop wires-only options and recommend a preferred solution that will address the local needs identified in the Needs Assessment (NA) report for the Burlington to Nanticoke Region. The development of the LP report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

For needs that required further regional planning and coordination, were further assessed as part of the Scoping Assessment (SA) process to determine whether an Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both were required. There are two IRRPs in the region for the two sub-regions. A) Brant sub-region IRRP was completed in April 2015 B) Bronte sub-region IRRP is currently in progress.

2. LOCAL NEEDS ADDRESSED IN THIS REPORT

The Local needs addressed in this report include the following:

- Dundas TS T3/T4/T5/T6 Station Capacity
- Mohawk TS Supply Capacity
- Nebo TS T3/T4 Station Capacity
- Power factor at Cumberland TS
- Power factor at Kenilworth TS
- Power factor at Beach TS
- Reactive support for the Norfolk area
- System Reliability, Operation and Load Restoration

3. CONCLUSIONS AND RECOMMENDATIONS

1. **Dundas TS T3/T4/T5/T6 Station Capacity**
   There are 115/27.6 kV two (T3/T4 and T5/T6) DESNs at Dundas TS. The load at T3/T4 DESN has exceeded the supply capacity however the combined capacity of both DESNs is sufficient over the study period. By the end of the study period the combined load of both DESNs at Dundas is forecasted to be approaching the total capacity of the T3/T4 and T5/T6 DESNs.

   As a result, the study team recommended that the LDCs (Hydro One distribution and Horizon Utilities) will plan and undertake distribution load transfers from T3/T4 DESN to T5/T6 DESN to mitigate overloading of T3/T4 DESN at Dundas TS.

2. **Mohawk TS Supply Capacity**
   The load at Mohawk TS marginally exceeds station supply capacity and by the end of study period will marginally exceed the capacity of circuits supplying Mohawk TS. However, load growth in the area is small

   T1/T2 transformers at Mohawk TS are approaching end of life and are already scheduled for replacement in 2018 with the larger transformers which will address the issue of station supply capacity. In the interim, the study team recommended that Horizon Utilities manage the overloads (under contingency) by distribution loads transfers to other stations in the area.

3. **Nebo TS T3/T4 Station Capacity**
   The load at existing Nebo TS (T3/T4) DESN also exceeds marginally over station supply capacity. However, load growth in the area is small.

   The Nebo TS (T3/T4) transformers are approaching their end of life and are already scheduled for replacement with larger capacity transformers in 2022. The capacity of the new replacement transformers will be sufficient over the study period.

   In the interim, the study team recommended that Horizon Utilities manage the overload (under contingency) by distribution loads transfers to other stations in the area and also undertake any targeted and effective CDM to keep the loading within supply capacity of existing facilities.

4. **Power factor at Cumberland TS**
   The power factor at Cumberland TS under peak load conditions is lagging slightly below the ORTAC requirement of 0.9.

   The study team recommended that Burlington Hydro work with their load customers supplied by Cumberland TS and install capacitor banks on distribution system as required to meet the power factor requirement of 0.9. Burlington Hydro will provide an update of the plan by Q2 2016.

5. **Power factor at Kenilworth TS**
   The power factor at Kenilworth TS is lagging below the ORTAC requirement of 0.9.

   The study team recommended that Horizon Utilities install capacitor bank on distribution system and/ or work with load customers supplied by Kenilworth TS to meet ORTAC power factor requirement of 0.9. Horizon Utilities will provide an update of the plan by Q2 2016.

6. **Power factor at Beach TS (115 kV T3/T4 DESN)**
   The power factor at Beach TS is leading beyond the ORTAC requirement of 0.9.

   The study team reviewed this requirement and recommended that no action is required at this time.

7. **Reactive support in Norfolk Area**
   The coincident load at Norfolk TS and Bloomsburg TS can be managed by load transfer and kept below the area supply limit of 87MW. The study team recommended that Hydro One distribution can manage the overload in Norfolk area by distribution loads transfers to neighboring stations.

8. **System Reliability, Operation and Load Restoration**
   In some cases, double circuit lines in the Region carry loads in excess of 150 MW and 250 MW thresholds.

   The study team based on the historical reliability data for the circuits in the region recommended that no action is required at this time.

1 Introduction

The Needs Assessment (NA) for the Burlington to Nanticoke Region ("Region") was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. Prior to the new regional planning process coming into effect, planning activities were already underway in the Region to address some specific area supply needs. The NA for the Burlington to Nanticoke Region was prepared jointly by the study team, including LDCs (Local Distribution Company), Independent Electric System Operator (IESO), Ontario Power Authority (merged with IESO as of January 2015 and herein referred to as IESO), and Hydro One Networks Inc.. The NA report can be found on Hydro One's Regional Planning website. The study team identified needs that are emerging in the Burlington to Nanticoke Region over the next ten years (2014 to 2023) and recommended whether they should be addressed by the transmitter-led Local Planning (LP) process or to be further assessed by the IESO-led Scoping Assessment (SA) process.

This report was prepared by the Burlington to Nanticoke Region LP study team (Table 1) and led by the transmitter, Hydro One Networks Inc. (HONI). The report captures the results of the assessment based on information provided by IESO, LDCs and HONI.

Burlington to Nanticoke Region: Description and Connection Configuration

The Burlington to Nanticoke Region is located in Southern Ontario and comprises the municipalities of Burlington, Hamilton, Oakville, Brantford, Brant County, Haldimand County, and Norfolk County. The approximate boundaries of the Burlington to Nanticoke region and its four sub-regions (areas) are shown below in Figure 1.

The Burlington to Nanticoke 230 kV and 500 kV systems are part of East-West bulk power system transfers mainly from the generation located in Western Ontario towards the GTA. This region has two 500 kV stations, Nanticoke TS and Middleport TS, interconnected through two 500 kV circuits and connected to 500 kV Longwood TS and Milton TS. Both these 500 kV stations have transformation capacities to 230 kV systems. The Burlington to Nanticoke region's 230 kV system has three autotransformer stations at Burlington TS, Beach TS, and Caledonia

TS supplying the 115 kV transformer stations. The Dunnville TS has been included in the Niagara Region (Group 3, Region 17) instead of the Burlington to Nanticoke Region (Group 1, Region 1)- a change to the May 17, 2013 OEB Planning Process Working Group Report.

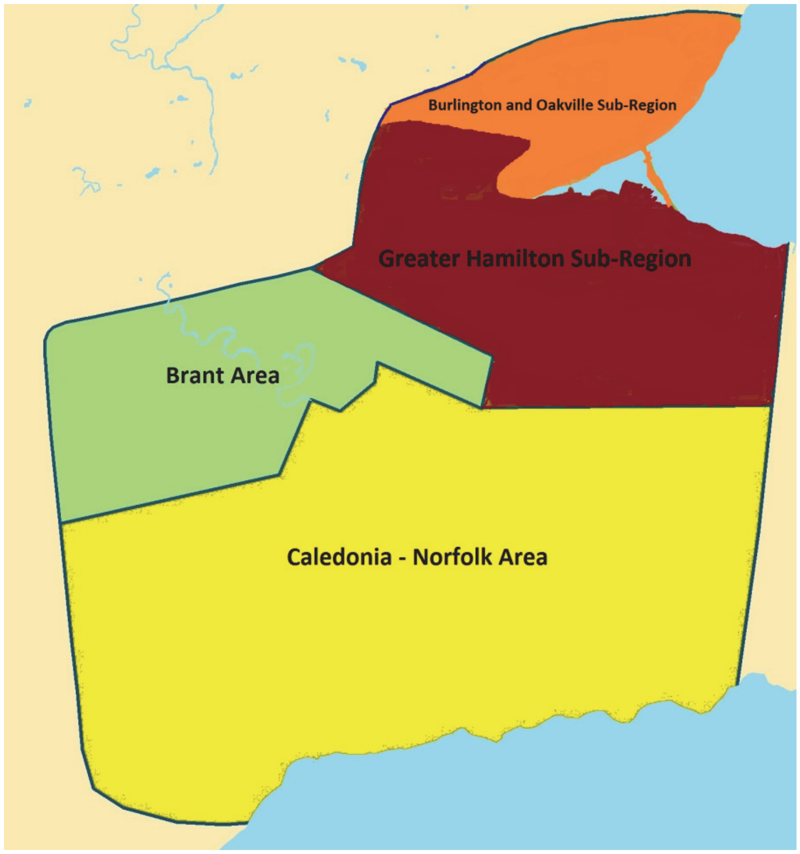

Figure 1: *Region and Sub-Region Approximate Boundaries*

The 230 kV interconnections of Burlington to Nanticoke Region to the rest of system consist of two circuits to Detweiler TS, three circuits to Buchanan TS and seven circuits to Beck TS. The 115 kV circuits are supplied from Burlington TS, Beach TS and Caledonia TS. A single line diagram of the 500kV, 230kV and 115 kV systems in the Burlington to Nanticoke Region is shown below in Figures 2 and 3.

The needs identified in the Needs Assessment are further reviewed in the next sections to determine the scope and type of regional planning study if appropriate for each of the relevant sub-regions.

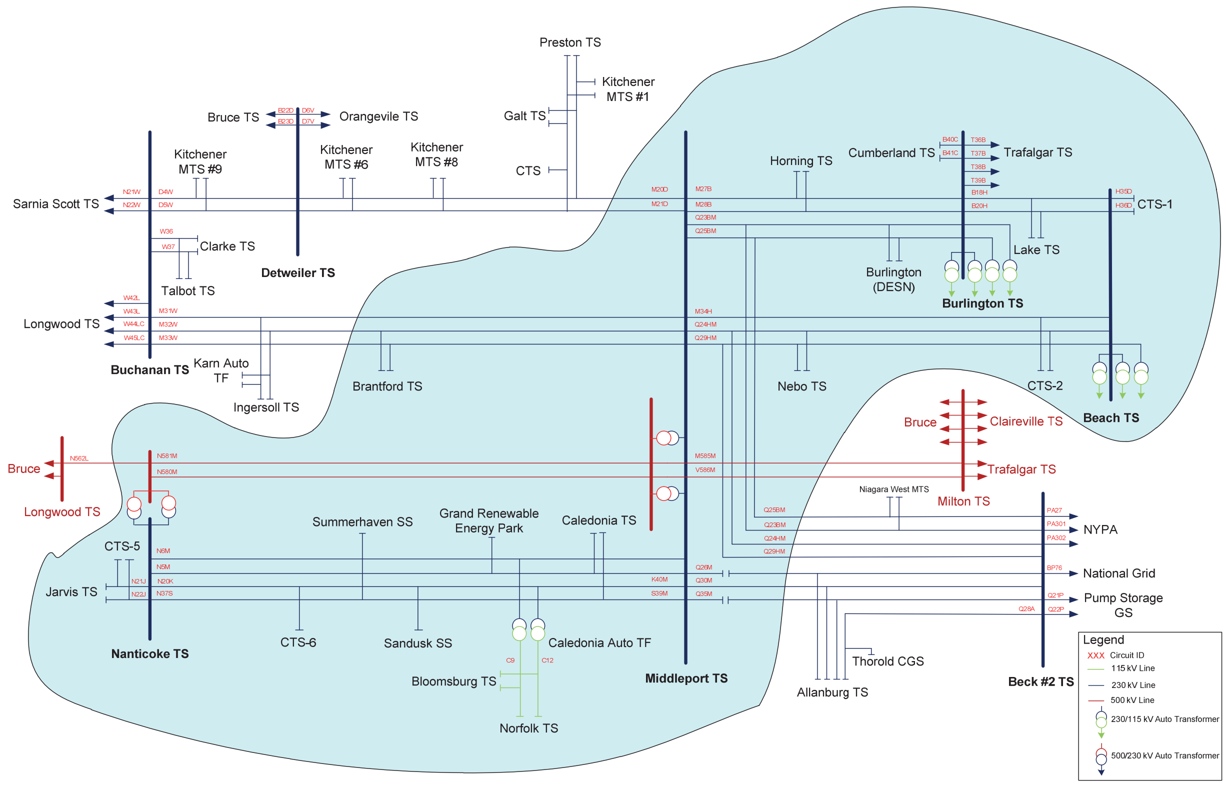

Figure 2: *Burlington to Nanticoke Region – 230 and 500 kV Single Line Diagram*

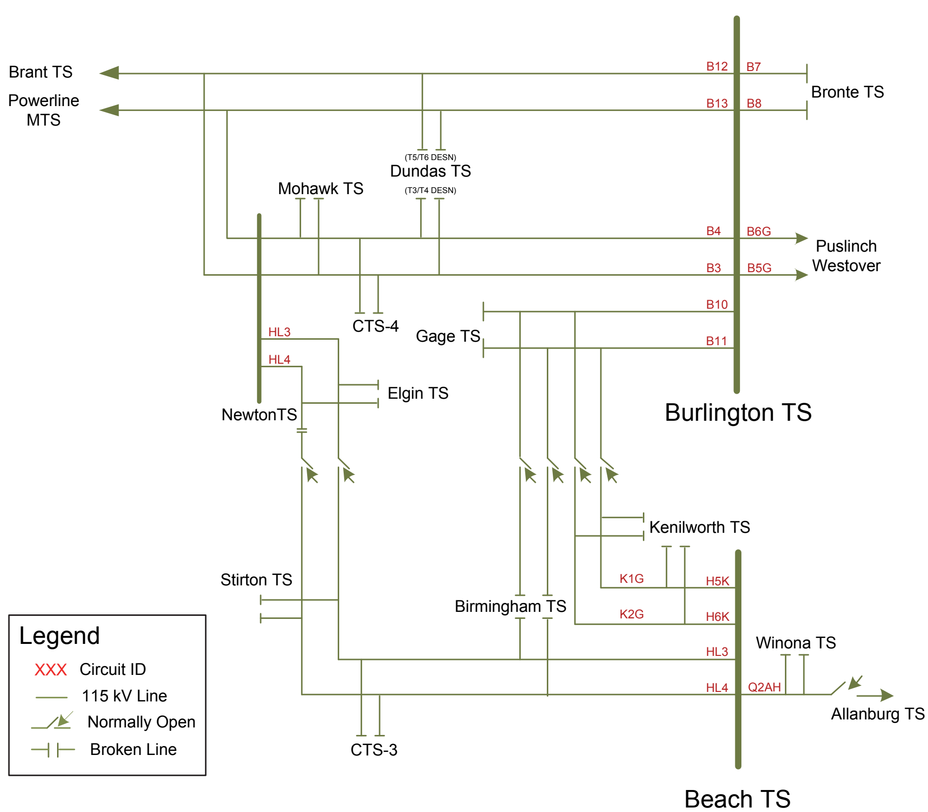

Figure 3: *Burlington and Beach 115 kV Single Line Diagram*

2 Burlington to Nanticoke Region Needs

The Brant Area (sub-region) assessment was in progress even prior to start of the Regional Planning process. An IRRP for this sub-region was completed on April 28, 2015.

Under Regional Planning process, the study team identified several needs after the Needs Assessment in the Burlington to Nanticoke Region that require further assessment and planning. The study team recommended that some of the near-term needs required “localized” wires only planning, while others required coordinated regional planning. The Needs Assessment is based upon the forecast prepared for the Burlington to Nanticoke Needs Assessment report given in Appendix –A. Where local planning was recommended to address the needs, Hydro One, as transmitter, with the impacted LDCs, further undertook planning assessments to develop options and recommend a wires only solution(s). For needs that required further regional planning and coordination, Scoping Assessment was done to determine if Integrated Regional Resource Planning (IRRP) or RIP process should be undertaken to address the needs. As a result, there are two IRRPs in the region for the two sub-regions. A) Brant sub-region IRRP was completed in April 2015 B) Bronte sub-region IRRP is currently under progress.

Brant IRRP identified that wires solution are required to provide additional capacity to serve the load as forecasted by the LDCs. The capacity needs at Bronte TS is part of the IRRP study that is still in progress while the issues with the loss of autotransformers at Burlington TS is being assessed as part of the Bulk System study led by the IESO.

The local needs identified and assessed in this region are as follow:

- Dundas TS T3/T4/T5/T6 Station Capacity
- Mohawk TS Supply Capacity
- Nebo TS T3/T4 Station Capacity
- Power factor at Cumberland TS
- Power factor at Kenilworth TS
- Power factor at Beach TS (115 kV T3/T4 DESN)
- Reactive support in Norfolk area
- System Reliability, Operation and Load Restoration

The load forecast provided in Appendix-A includes the forecast for Dundas TS, Mohawk TS and Nebo TS where capacity needs were identified in the Needs Assessment report. This forecast was prepared for the Burlington to Nanticoke Needs Assessment report and 2013 actual loads were used as a reference point. It is worth noting that the summer 2014 actual loads were lower than 2013 due to colder than normal summer and not used for planning purpose. The above listed needs are addressed in detail in the following sections and where applicable, the capital cost comparison for options for each need is provided in Appendix-B.

3 Dundas TS (T3/T4/T5/T6) Station Capacity

There are two 115/27.6 kV DESNs (T3/T4 and T5/T6) at Dundas TS with a total station capacity of 175.6 MW. The load at T3/T4 DESN exceeds its supply capacity.
The combined loading of the T3/T4 and T5/T6 DESNs at Dundas TS is forecasted to be 175.6 MW in 2023. The total capacity of the two DESNs at Dundas TS is thus sufficient over the study period i.e. until 2023.

3.1 Alternatives Considered

i. Transferring excess load from the overloaded T3/T4 DESN to the T5/T6 DESN

This was an obvious choice and no other option was considered to mitigate overloading of the Dundas TS T3/T4 DESN.

3.2 Next Steps

The study team recommends that Horizon Utilities and Hydro One Distribution develop a plan by the end of Q1 2016 and implement load balancing between the two DESNs by the end of 2016 as part of distribution planning. LDCs will provide a load balancing plan confirmation to Hydro One transmission by the end of Q1 2016.

4 Mohawk TS Supply Capacity

Mohawk TS and its supply circuits have load supplying capacity of 75.4 MW and 84.6 MW respectively. The load growth at Mohawk TS is slow with load forecast to increase from 83 MW in 2013 to 88.3 MW in 2023 exceeding station capacity by 12.9 MW.

At present the load at Mohawk TS exceeds station supply capacity and by the end of study period will marginally exceed the capacity of circuits supplying Mohawk TS.

4.1 Alternatives Considered

The mitigation options considered to address the overloading at Mohawk TS were:

i. Transfer excess load from Mohawk TS to adjacent area stations (Horning TS and Nebo TS) to reduce the loading levels under contingency conditions. There is adequate transfer capability between the stations for this purpose.

ii. Mohawk TS (T1/T2) transformers are approaching end of life and are already scheduled for replacement in 2018. The replaced T1/T2 transformers will be of higher capacity (about 90 MW) and sufficient beyond the study period.

4.2 Preferred Alternative

The preferred alternative is to replace the existing transformer with higher load supply capacity which is already scheduled to be complete in 2018. The capacity of new transformers will be sufficient over the study period and beyond.

Horizon Utilities will manage the loading at Mohawk TS within station and its supply circuit capacities during the study period by implementing operating measures such as load transfers.

4.3 Next Steps

Hydro One transmission will continue with the end of life replacement of transformers. In the interim, Horizon Utilities will develop a distribution load transfer plan to manage the load at Mohawk TS.

5 Nebo TS (T3/T4 DESN) Station Capacity

The 2013 summer peak load of Nebo TS 230 kV/13.8 kV T3/T4 DESN was 52.8 MW and exceeds the station supply capacity of 50.7 MW. The station load growth is slow with load forecasted to increase from 52.8 MW in 2013 to 54.2 MW in 2023 thus exceeding the station capacity by 3.5 MW.

5.1 Alternatives Considered

The mitigation options considered to address the overloading at Nebo TS were:

i. Transfer excess load to adjacent area station (Mohawk TS) to reduce loading under contingency conditions.

ii. Install additional new switchgear to utilize the capacity of the idle winding on the existing T3/T4 transformers. This will provide sufficient additional capacity to meet the currently projected load growth over and beyond the study period.

iii. Nebo TS (T3/T4) transformers are approaching end of life and are already scheduled for replacement in 2022. The replaced T3/T4 transformers will be of higher capacity (about 65 MW), which is sufficient over and beyond the study period.

5.2 Preferred Alternative

The preferred alternative is to transfer loads to neighboring stations until the transformers at Nebo TS are replaced in 2022. This is the most economical solution as it does not require any capital investments.

5.3 Next Steps

Hydro One will continue with the replacement of transformers reaching end of life. In the interim, Horizon Utilities will manage any overloading under contingency through distribution load transfer. Horizon Utilities will share details of load transfer plans with the study team by the end of Q2 2016 to manage overloading under emergency situations.

6 Power Factor at Cumberland TS

Cumberland TS is a 230/ 27.6 kV station having a load supplying capacity of 174.4 MW and 2013 peak load of about 135.2 MW. Under peak load conditions the power factor of Cumberland TS is 0.88 marginally below the ORTAC requirement of 0.9 lagging. An additional 8 MVARs of capacitor banks are required to meet power factor requirement.

6.1 Alternatives Considered

The options considered to improve the power factor at Cumberland TS were:

i. Installation of 20 MVAr capacitor bank (Hydro One standard size) at Cumberland TS.

ii. Installation of 8 MVAr of capacitor banks on the distribution system.

iii. Burlington Hydro to work with their existing load customers supplied by Cumberland TS to improve power factor.

6.2 Preferred Alternative

The preferred alternative is for Burlington Hydro to plan and work with their load customers supplied from Cumberland TS, and, if required, install capacitor banks on distribution system to meet the power factor requirement of 0.9. This is the most economical solution to improve the power factor at Cumberland TS.

6.3 Next Steps

The study team recommended Burlington Hydro to work with the load customers supplied by Cumberland TS to improve power factor and if needed develop a plan to install capacitor banks on distribution system. Burlington Hydro will develop and provide a distribution plan to Hydro One transmission by the end of Q2 2016.

7 Power Factor at Kenilworth TS

At present power factor at Kenilworth TS is lagging below ORTAC requirement of 0.9 lagging. Majority of the Kenilworth TS load is supplied to a large industrial customer.

7.1 Alternatives Considered

i. Installation of 20 MVAr capacitor bank (Hydro One standard size) at Kenilworth TS.

ii. Horizon Utilities to work with its load customer/s supplied at Kenilworth TS to improve power factor and/or install a 12MVar of capacitor banks on distribution system.

7.2 Preferred Alternative

The preferred alternative is for Horizon Utilities to work with the load customers supplied by Kenilworth TS and if needed install capacitor banks on distribution system to improve the power factor. This is the most economical solution for improving the power factor.

7.3 Next Steps

Horizon Utilities is requested to work with its load customer/s supplied at Kenilworth TS to improve power factor and if needed develop a plan to install capacitor bank on distribution system. Horizon Utilities will provide an update of their distribution plan to the study team by the end of Q2 2016 to improve power factor at Kenilworth TS.

8 Power Factor at Beach TS (115 kV T3/T4 DESN)

The power factor at Beach TS is leading beyond 0.9 while it is required to remain between 0.9 lagging and 0.9 leading.

8.1 Alternatives Considered

The study team reviewed this requirement and recommended that operating measures are in place and no further action is required.

8.2 Next Steps

The study team recommended that no action is required at this time.

9 Reactive support for the Norfolk area

Reactive support is required post single line contingency (for the loss of one of C9 or C12 circuits) in Norfolk area (Norfolk TS and Bloomsburg TS) when the total combined coincident load of Norfolk TS and Bloomsburg TS exceeds 87 MW. The 2013 coincident peak load of Norfolk TS and Bloomsburg TS was 85.8 MW and is forecasted to approach 87 MW by the year 2021 and 92.3 MW in 2023, exceeding Norfolk area supply limit by 5.3 MW as provided in Appendix-C.

9.1 Alternatives Considered

The following options were considered to address low voltage issue at Norfolk TS and Bloomsburg TS:

i. Installation of 20 MVAr capacitor bank at Bloomsburg TS.

ii. Installation of capacitor banks on distribution system in Norfolk area.

iii. Norfolk TS and Bloomsburg TS loads of about 6MW can be seasonally or permanently transferred to Jarvis TS.

9.2 Preferred Alternative

The preferred alternative is to transfer 6.0 MW of load from Norfolk TS and Bloomsburg TS to Jarvis TS which is sufficient to offset the 5.3 MW of load in excess of 87 MW in 2023. For the study period beyond 2021 (till 2023) the coincident load at Norfolk TS and Bloomsburg TS can be kept below the area supply limit of 87 MW through load transfers, if required. This solution requires the least investment and therefore was chosen as being the most economical.

9.3 Next Steps

Hydro One distribution will further investigate the load transfer capability from Norfolk and Bloomsburg TS to Jarvis TS and develop a distribution load transfer/s plan. Hydro One distribution will provide an update to Hydro One transmission by the end of Q2 2016.

10 System Reliability, Operation and Load Restoration

Load loss of 150 MW or more should be restored within 4 hours and 250 MW or more within 30 minutes or as agreed between the transmitter and the LDC.

By the year 2023, at peak load times only, the following circuits in the region are expected to supply loads of over 250 MW:

- Q24HM+Q29HM
- B3+B4

And over 150 MW:

- N21J+N22J
- M32W+ M33W
- Q23BM+Q25BM
- H35D+H36D
- HL3+HL4 (Load connected to Beach TS)
- B7+B8

10.1 Further Review and Assessment

The table below contains historic reliability data of last 25 years for the circuits in the region.

Table 2: Common Mode Reliability Statistics for Circuits Carrying more than 150 MW

No.	Circuits	No. of Momentary Outages	No. of Sustained Outages	Longest Outage Duration (Min)	Average Outage Duration (Min)
1	Q24 HM/ Q29HM	1	0	0	0
2	M32W/ M33W	1	1	3	3
3	N21J/ N22J	0	1	9	9
4	Q23BM/ Q25BM	0	1	7	7
5	H35D/ H36D	0	0	0	0
6	B7/ B8	0	0	0	0
7	B3/ B4	6	3	8	5.3
8	HL3/ HL4	0	1	3	3

During the past 25 years, the eight (8) pair of circuits in the above had only eight (8) momentary and seven (7) non-momentary outages. The longest non-momentary outage was nine (9) minutes which is well within the most stringent ORTAC restoration criteria of 30 minutes.

Based on the above information, Hydro One transmission and the relevant LDC/s agree that reliability and load restoration in the above area has a :

a) Historically good supply reliability and load restoration, and
b) Restoration time gains will be insignificant by line sectionalizing, and
c) Any infrastructure investments will have little or no benefit but result in cost for rate payers

As a result, no further action is required, unless there is a significant change in system conditions or configuration.

10.2 Next Steps

Based on the historical reliability data for the circuits in the region, the study team recommends that no action is required at this time.

Hydro One Networks Inc. (Lead Transmitter)
Hydro Ottawa Limited
Independent Electricity System Operator
Hydro One Networks Inc. (Distribution)
Hydro Hawkesbury Inc.
Ottawa River Power Corporation

[This page is intentionally left blank]

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE GREATER OTTAWA REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro Ottawa Limited
- Hydro Hawkesbury Inc.
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator
- Hydro One Networks Inc. (Transmission)
- Ottawa River Power Corporation

This RIP provides a consolidated summary of needs and recommended plans for both the Ottawa Area Sub-Region and Outer Ottawa Area Sub-Region that make up the Greater Ottawa Region for the near term (up to 5 years) and the mid-term (5 to 10 years). No long term needs and associated plans (10 to 20 years) have been identified.

This RIP is the final phase of the regional planning process and it follows the completion of the Ottawa Sub-Region's Integrated Regional Resource Plan ("IRRP") by the IESO in April 2015 and the Outer Ottawa Area Sub-Region's Needs Assessment ("NA") Study by Hydro One in July 2014.

The major infrastructure investments planned for the Greater Ottawa Region over the near and mid-term, identified in the various phases of the regional planning process, are given in the Table below.

No.	Project	I/S date	Cost
1	Almonte TS: addition of breaker to sectionalize line M29C	November 2015	\$4.7M
2	Russell TS and Riverdale TS: construction of feeder ties to allow extra load transfers	2017-2020	\$2.0M
3	Lisgar TS: replacement of transformers T1 and T2	December 2017	\$13.9M
4	Hawthorne TS: replacement of autotransformers T5 and T6	May 2018	\$15.7M
5	Overbrook TS: replacement of transformers T3 and T4	June 2018	\$1.1M(1)
6	115kV Circuit A6R: additional tap to off load Circuit A4K	June 2019	\$9-11M
7	Hawthorne TS: replacement of transformers T7 and T8 and add one 44kV feeder position	October 2019	\$1.1M(2)
8	King Edward TS: Replace Transformer T4	June 2021	\$12M

(1) The transformers are at end of life and are being replaced as part of Hydro One sustainment program. The cost shown here represents the incremental cost of installing the next larger size units.
(2) Incremental cost for larger transformer only.

The IRRP study had also identified the need for additional 230/115 kV autotransformation capacity at Merivale TS and provision for a supply for a new station in the southwest area. The options to address these needs are still being studied by the Working Group and as part of the IESO community engagement activities. The Working Group expects to finalize recommendation to address these needs by summer 2016.

Investments to address the other mid-term needs, for cases where a decision is not required until 2020, will be reviewed and finalized in the next regional planning cycle.

No long term needs were identified at this time. As per the OEB mandate, the Regional Plan should be reviewed and/or updated at least every five years. The region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN (“RIP”) TO ADDRESS THE ELECTRICITY NEEDS OF THE GREATER OTTAWA REGION.

The report was prepared by Hydro One Networks Inc. (“Hydro One”) and documents the results of the joint study carried out by Hydro One, Hydro Ottawa Limited (“Hydro Ottawa”), Hydro Hawkesbury Inc. (“Hydro Hawkesbury”), Ottawa River Power Corporation (“ORPC”) and the Independent Electricity System Operator (“IESO”) in accordance with the Regional Planning process established by the Ontario Energy Board (“OEB”) in 2013.

The Greater Ottawa Region covers the municipalities bordering the Ottawa River from Arnprior in the West to Hawkesbury in the East and North of Highway 43. At the center of this region is the City of Ottawa. Electrical supply to the Region is provided from fifty-two 230 kV and 115 kV step-down transformer stations. The summer 2015 area load of the Region was about 1800 MW. The boundaries of the Region are shown in Figure 1-1 below.

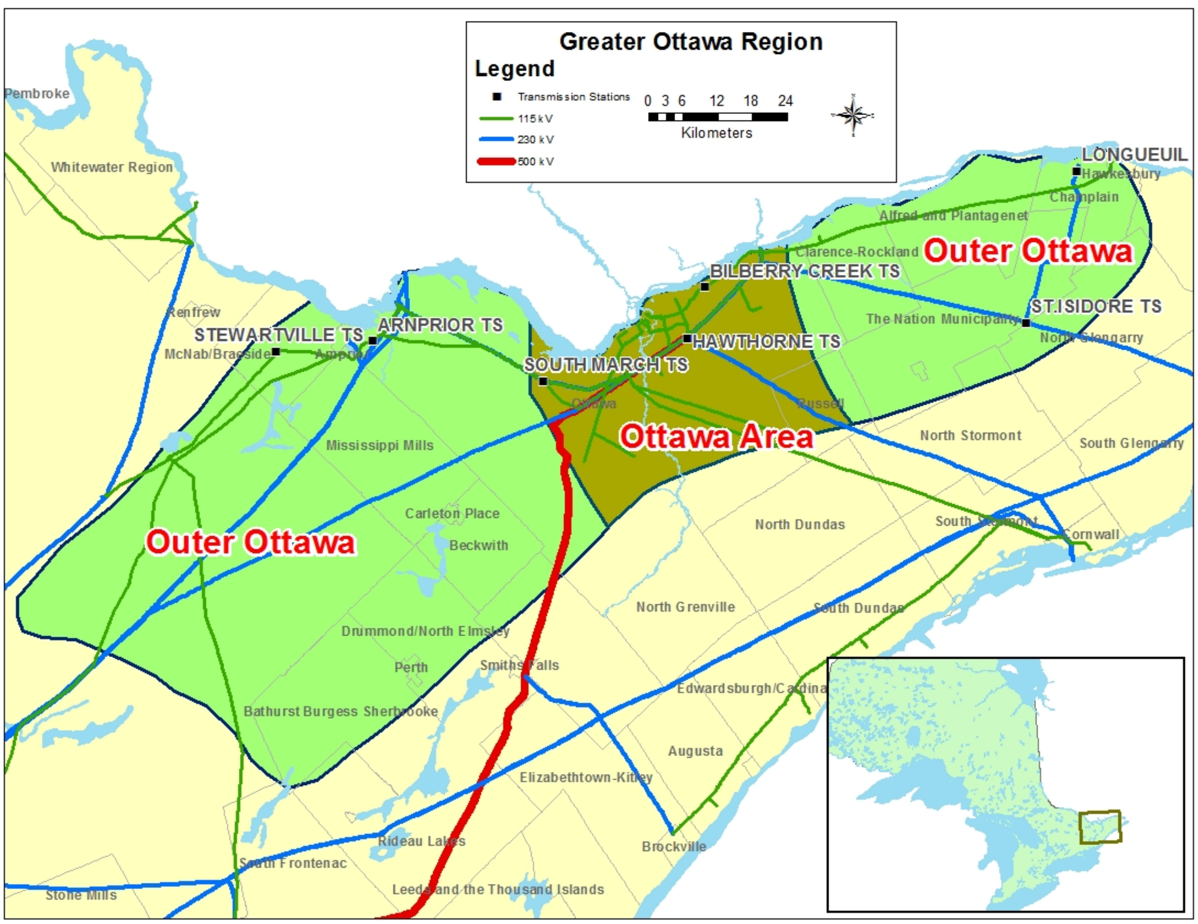

Figure 1-1 Greater Ottawa Region

1.1 Scope and Objectives

This RIP report examines the needs in the Greater Ottawa Region. Its objectives are to: identify new supply needs that may have emerged since previous planning phases (e.g. Needs Assessment, Local Plan, and/or Integrated Regional Resource Plan); assess and develop a wires plans to address these needs; provide the status of wires planning currently underway or completed for specific needs; and identify investments in transmission and distribution facilities or both that should be developed and implemented to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant plans to address near and mid-term needs (2015-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan or Integrated Regional Resource Plan).
- Identification of any new needs over the 2015-2025 period and a wires plan to address these needs based on new and/or updated information.
- Develop a plan to address any longer term needs identified by the Working Group

The IRRP or RIP Working Group did not identify any long term needs at this time. If required, further assessment will be undertaken in the next planning cycle because adequate time is available to plan for required facilities.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the region.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs.
- Section 7 discusses the needs and provides the alternatives and preferred solutions.
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend

---

[1] Also referred to as Needs Screening.

a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region. Since the Ottawa Sub-Region was in transition to the new regional planning process, the IESO led IRRP engagement for this sub-region was initiated after the completion of the IRRP.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

The regional planning process specifies a 20 year planning assessment period for the IRRP. No specific period has been specified for the RIP. The RIP focuses on the wires options and, given the forecast uncertainty and the fact that adequate time is available to identify and plan new wire facilities in subsequent planning cycles, a study period of 10 years is considered adequate for the RIP. The only exception would be the case where major regional transmission is required for an area with limited or no transmission facilities. In these cases the RIP would review and assess longer term needs if identified in the IRRP.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect.
- The NA, SA, and LP phases of regional planning.
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

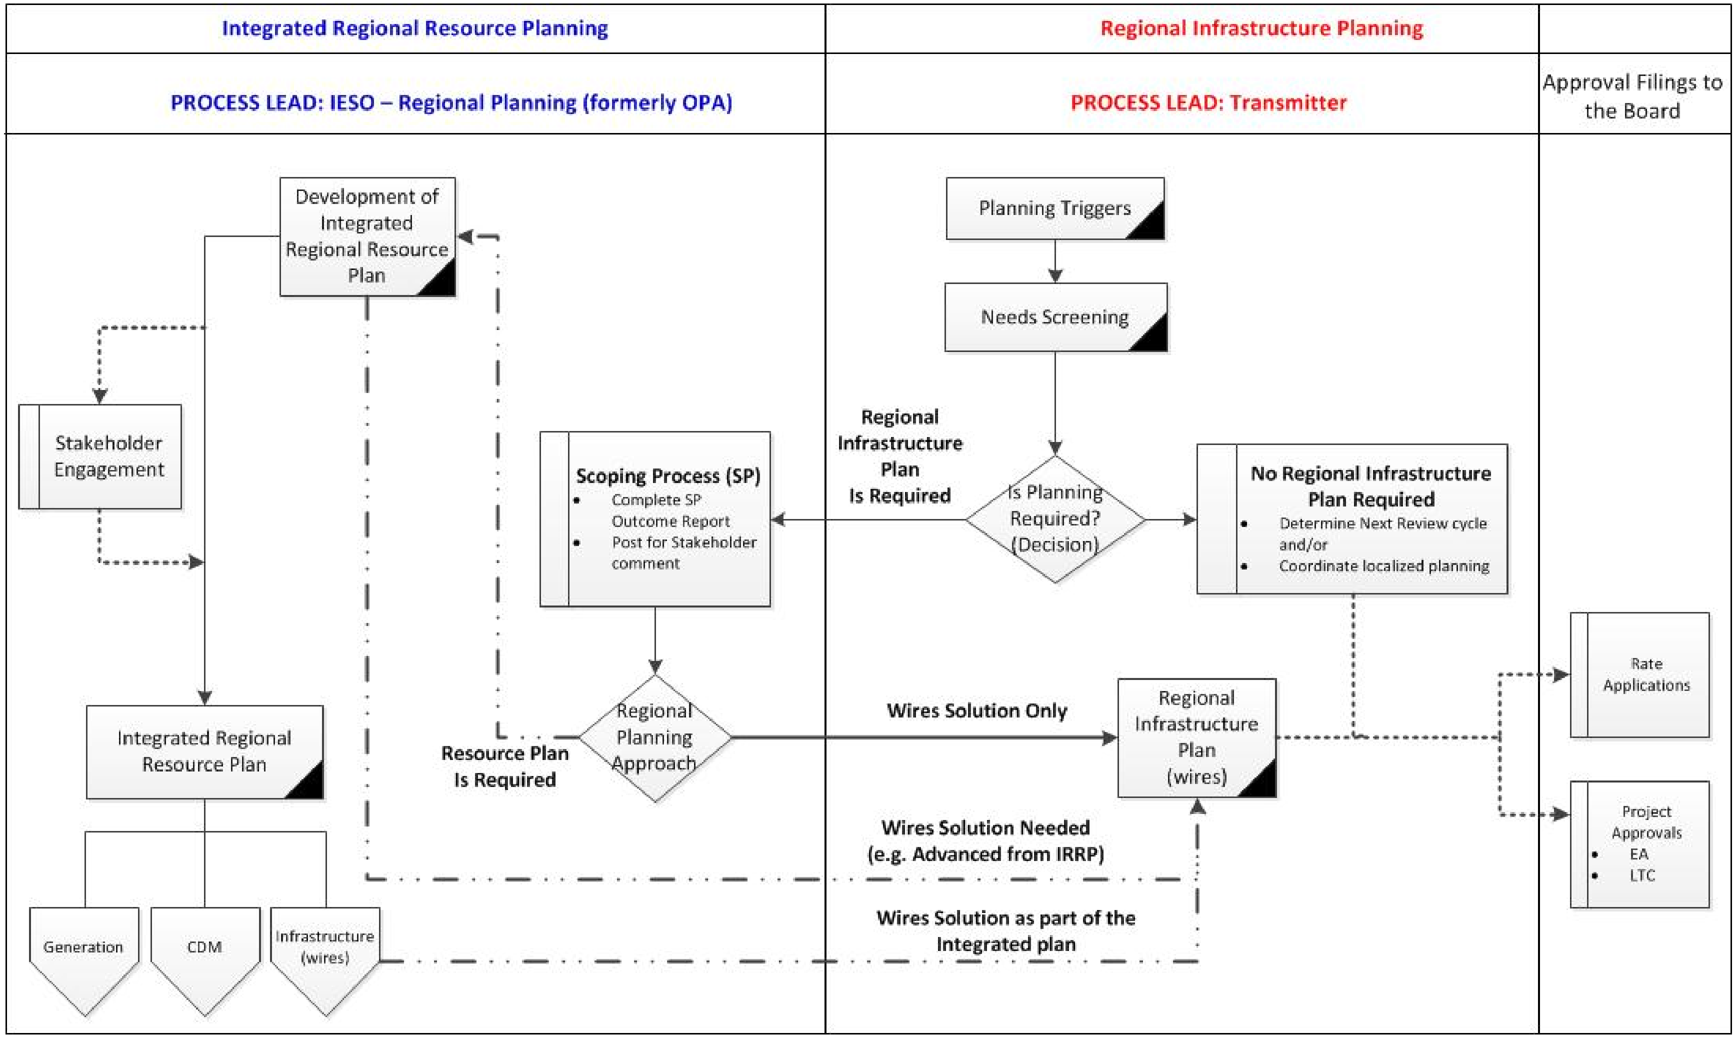

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

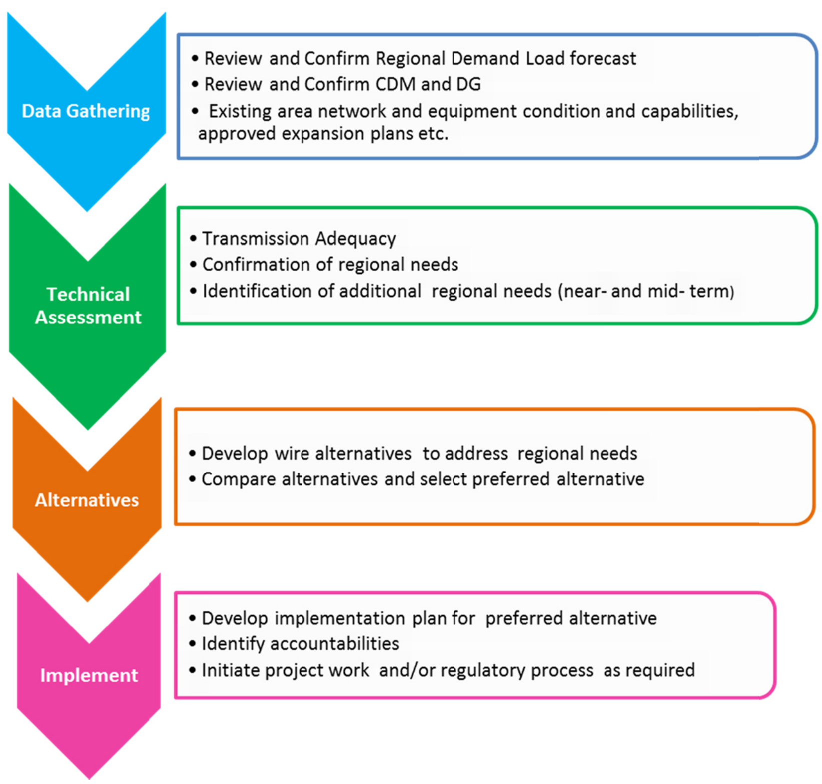

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE GREATER OTTAWA REGION COVERS THE MUNICIPALITIES BORDERING THE OTTAWA RIVER FROM ARNPRIOR IN THE WEST TO HAWKESBURY IN THE EAST AND NORTH OF HIGHWAY 43. AT THE CENTER OF THIS REGION IS THE CITY OF OTTAWA (SEE FIGURE 3-1). ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM FIFTY-TWO 230 KV AND 115 KV STEP-DOWN TRANSFORMER STATIONS. THE 2015 SUMMER PEAK AREA LOAD OF THE REGION WAS APPROXIMATELY 1840 MW.

Bulk electrical supply to the Greater Ottawa Region is provided through the 500/230 kV Hawthorne TS and a network of 230 kV and 115 kV transmission lines and step-down transformation facilities. The area has been divided into two sub-regions as shown in Figure 1-1 and described below:

- The Ottawa Sub-Region comprises primarily the City of Ottawa. It is supplied by two 230/115 kV autotransformer stations (Hawthorne TS and Merivale TS, eight 230 kV and thirty-three 115 kV transformer stations stepping down to a lower voltage. Local generation in the area consists of the 74 MW Ottawa Health Science Non-Utility Generator ("NUG") located near the downtown area and connected to the 115 kV network. The Ottawa Sub-Region is shown in Figure 3-1 below.

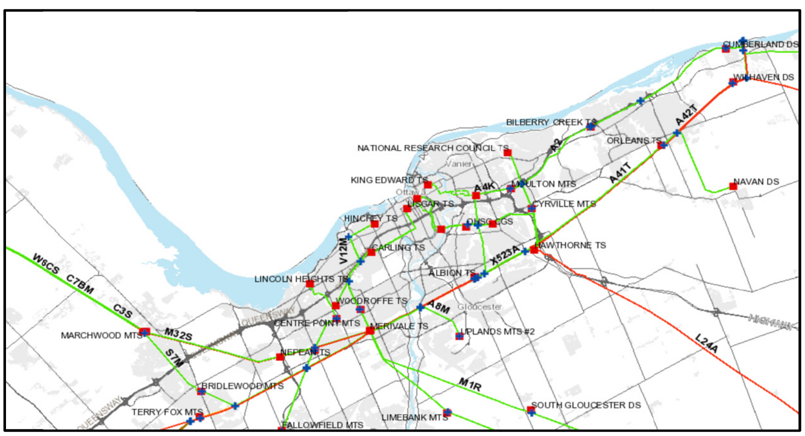

Figure 3-1 Ottawa Sub-Region

Hydro Ottawa is the main LDC that serves the electricity demand for the City of Ottawa. Hydro One Distribution supplies load in the outlying areas of the sub-region. Both Hydro Ottawa and Hydro One Distribution receive power at the step-down transformer stations and distribute it to the end users, i.e. industrial, commercial and residential customers.

- The Outer Ottawa Sub-Region covers the remaining area of the Greater Ottawa Region. The eastern area (shown in Figure 3-2) is served by three 230 and five 115 kV step-down transformer stations. Hydro One Distribution and Hydro Hawkesbury are the LDCs in the area that distribute power from the stations to the end use customers. It also includes a large industrial customer, Ivaco Rolling Mills, in L'Orignal, Ontario.

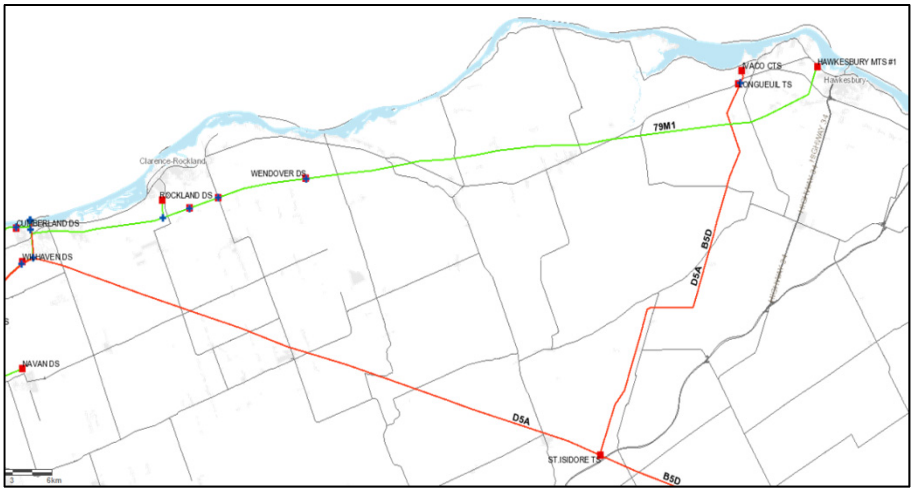

Figure 3-2 Outer Ottawa Sub-Region, Eastern Area

The western area of the Outer Ottawa Sub-Region is served by one 230 kV and two 115 kV step-down transformer stations. Hydro One Distribution is the LDC that supplies end use customers for these stations. The area includes the following generating stations: Barrett Chute GS, Chats Falls GS and Stewartville GS with a peak generation capacity of about 450 MW.

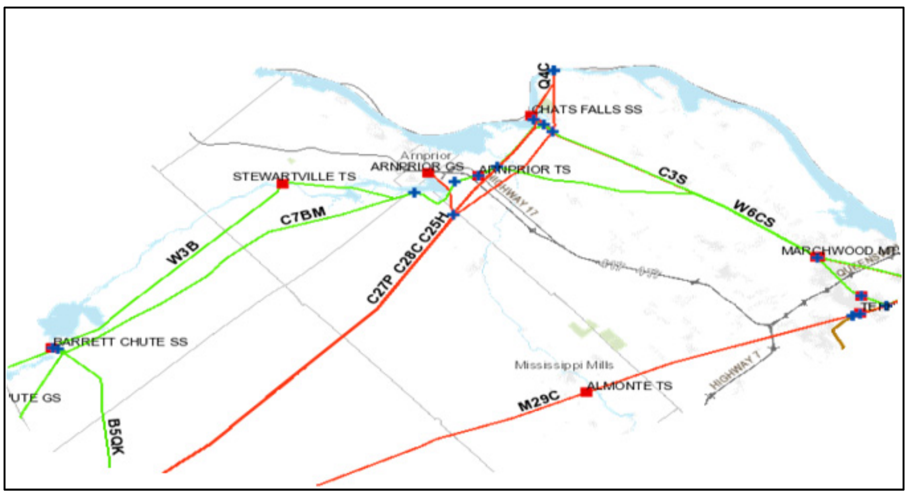

Figure 3-3 Outer Ottawa, Western Area

An electrical single line diagram for the Greater Ottawa Region facilities is shown in Figure 3-4.

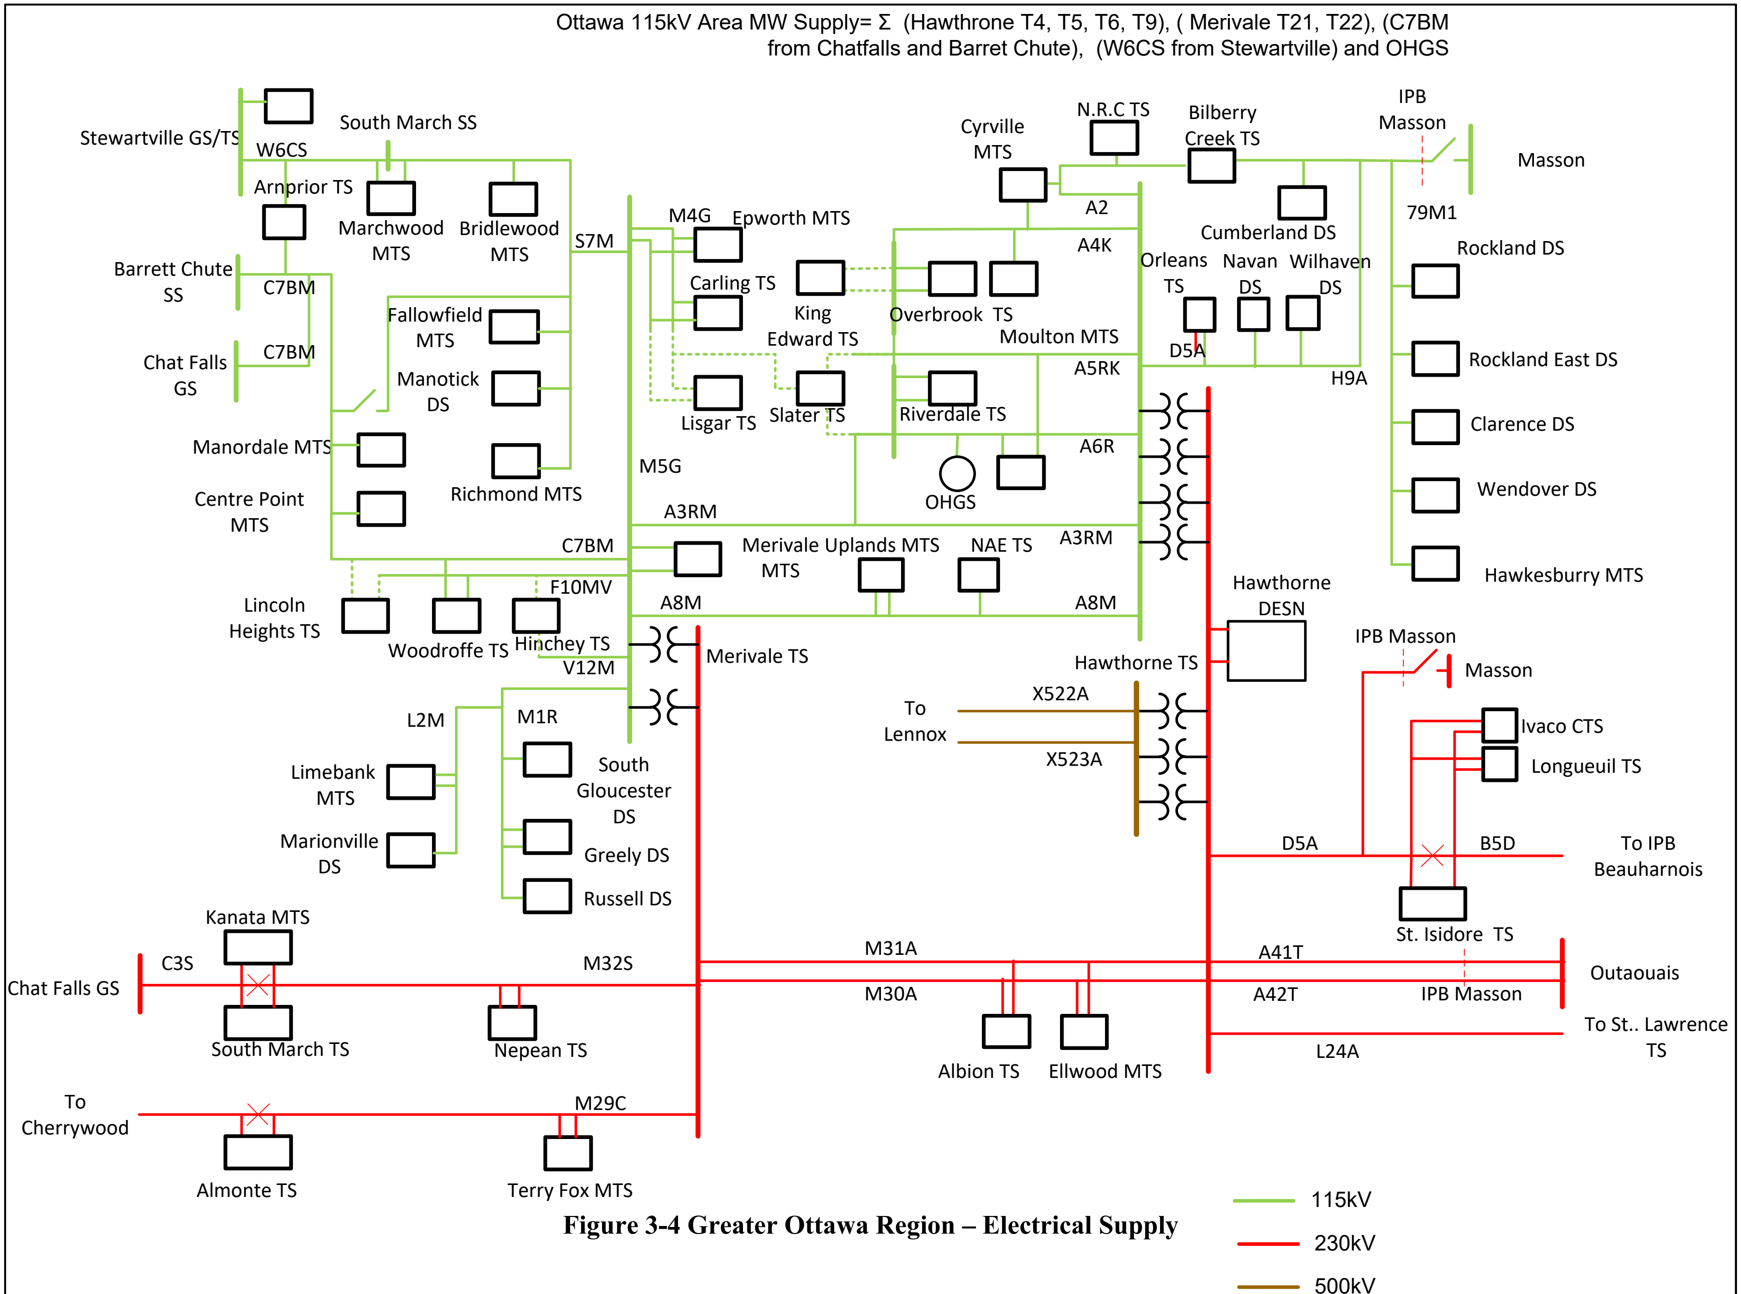

Figure 3-4 Greater Ottawa Region – Electrical Supply

21

4. TRANSMISSION FACILITIES COMPLETED OVER LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE GREATER OTTAWA REGION IN GENERAL AND THE CITY OF OTTAWA IN PARTICULAR.

These projects were identified as a result of either: joint Hydro One, IESO and Hydro Ottawa planning studies to meet the needs of Hydro Ottawa or Hydro One Distribution; and/or, to meet provincial government policies. A brief listing of the completed projects over the last 10 years is given below:

- Hawthorne TS x Gamble Junction double circuit 230 kV Overhead line (2008) – the single 115 kV circuit H9A was rebuilt as a two circuit 230 kV tower line with increased capacity. Connect Cyrville MTS (2008) – connected new Hydro Ottawa owned Cyrville TS to 115 kV circuits A4K and A2.
- Hawthorne TS x Outaouais TS double circuit 230 kV line (2009) – built to provide up to 1250MW of transfer capability with Hydro Quebec as part of the new HVDC interconnection.
- Connect Ellwood MTS (2012) – connected new Hydro Ottawa owned Ellwood TS to 230 kV circuits M30A and M31A.
- Connect Terry Fox MTS (2013) – connected new Hydro Ottawa owned Terry Fox MTS to 230 kV circuit M29C.
- Hawthorne TS 115 kV switchyard Upgrade (2014) – replaced 115 kV breakers with inadequate short circuit capability with new breakers of higher short circuit capability. This work improved system reliability by allowing 115kV switchyards to be operated with bus tie closed. This work also facilitated incorporation of DG in the Ottawa area.
- Build new Orleans TS (2015) – built a new step-down transformer station in East Ottawa supplied from 230 kV circuit D5A and 115 kV circuits H9A. This station will provide additional load meeting capability to meet Hydro One Distribution and Hydro Ottawa requirements. It will also provide improved reliability for Hydro One Distribution customers in the Orleans-Cumberland area.
- Hinchey TS (2015) – Connect idle winding of transformer T1/T2 to new Hydro Ottawa metalclad switchgear.

The following projects are currently underway:

- Add 230 kV inline breaker on 230 kV circuit M29C at Almonte TS (2015) – to improve reliability of supply for Almonte TS and Terry Fox MTS.
- Replace 45/75 MVA, 115/13.2 kV step down transformers with new 60/100 MVA, 115/13.2 kV at Overbrook TS (2017) – the existing transformers are at end-of-life and the new replacement transformers have a higher rated capacity and will provide additional load meeting capability.

- Replace 225 MVA, 230/115 kV autotransformers T5 and T6 at Hawthorne TS with new 250 MVA, 230/115 kV autotransformers (2018) – the existing transformers have inadequate capacity and were identified and recommended for replacement during the IRRP phase for the Ottawa Sub-Region [1].
- Replace 50/83 MVA, 230/44 kV step down transformers with new 75/125 MVA, 230/44 kV units at Hawthorne TS (2019) – the existing transformers are at end-of-life and the new replacement transformers have a higher rated capacity and will provide additional load meeting capability.

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the Greater Ottawa Area is forecast to increase at an average rate of approximately 2.25% annually up to 2020, at 0.96% between 2020 and 2025 and at 0.45% beyond 2025. The growth rate varies across the Region with most of the growth concentrated in the Ottawa Sub-region.

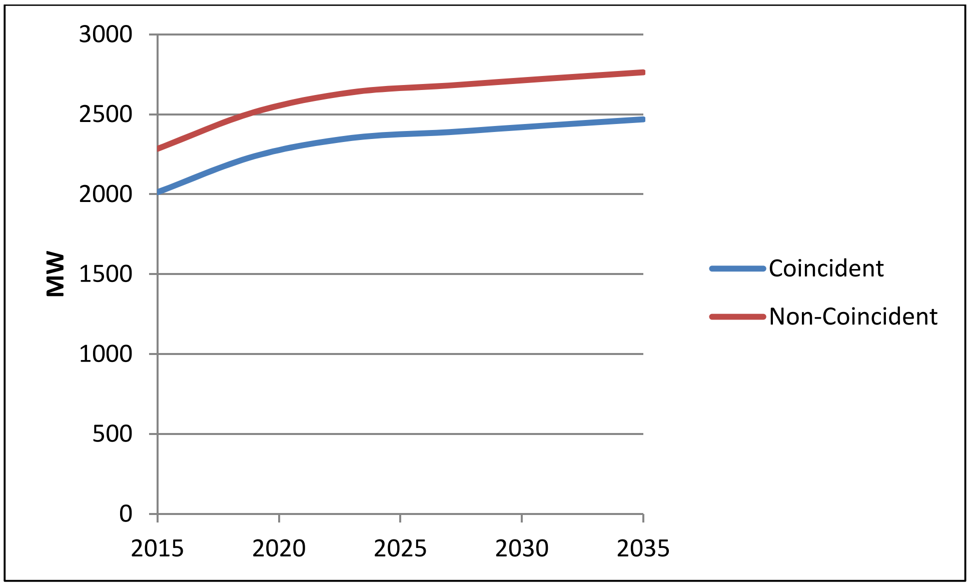

Figure 5-1 Greater Ottawa Region Summer Extreme Weather Peak Forecast

Figure 5-1 shows the Greater Ottawa Region extreme weather peak summer coincident and non-coincident load forecast. The coincident forecast represents the sum of the peak load at the time of the region's peak load and represents loads that would be seen by the autotransformer stations and is used to determine the need for additional auto-transformation capacity. The non-coincident forecast represents the sum of the individual stations peak load and is used to determine the need for stations and line capacity. Coincident and Non-coincident load forecasts for the individual stations in the Greater Ottawa Region are given in Appendix A.

The RIP load forecast was developed as follows:

- RIP Working Group participants confirmed that the load forecast, CDM, and DG information used in the IESO's 2015 IRRP for the Ottawa Sub-Region[1] and Hydro One's 2014 NA [2] was still valid and there were no changes.
- The station coincident loads used in the RIP are as given in the IRRP for Ottawa Sub-Region and NA for the Outer Ottawa Sub-Region. The coincident loading is used for evaluating the adequacy of bulk transmission circuits and the 230/115kV autotransformers.

- Stations non-coincident load forecast was developed using the summer 2015 actual peak load adjusted for extreme weather and applying the station net growth rates as identified in the IRRP and NA. The non-coincident forecast is used to determine adequacy of station capacity. The net growth rate accounts for CDM measures and connected DG. Details on the CDM and connected DG are provided in the IRRP [1] and NA for Ottawa Sub-Region [2] and are not repeated here.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP Assessments is 2015-2025.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is based therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks. Normal planning supply capacity for transformer stations in this Sub-Region is determined by the summer 10-Day Limited Time Rating (LTR).
- Adequacy assessment is conducted as per ORTAC.

6. ADEQUACY OF FACILITIES AND REGIONAL NEEDS OVER THE 2015-2025 PERIOD

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND DELIVERY STATION FACILITIES SUPPLYING THE GREATER OTTAWA REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM. NO LONG TERM NEEDS HAVE BEEN IDENTIFIED.

Within the current regional planning cycle two regional assessments have been conducted for the Greater Ottawa Region. The April 2015 Ottawa Sub-Region IRRP report [1] was prepared by the IESO in conjunction with Hydro One and Hydro Ottawa. The July 2014 Outer Ottawa Sub-Region NA report [2] was prepared by Hydro One and considered the remainder of the Greater Ottawa region.

The IRRP [1] and NA [2] planning assessments identified a number of regional needs to meet the area forecast load demand over the near to mid-term between 2015 and 2025. These regional needs are summarized in Table 6.1 and include needs for which work is already underway and/or being addressed by an LP study. A detailed description and status of work initiated or planned to meet these needs is given in Section 7.

A review of the loading on the transmission lines and stations in the Greater Ottawa Region was also carried out as part of the RIP report. Sections 6.1 to 6.3 present the results of this review. Additional needs identified as a result of the review are also listed in Table 6-1.

Table 6-1 Near and Mid-Term Regional Needs

Type	Section	Needs	Timing(4)
Needs identified in IRRP [1] and NA [2]			
230/115kV Transformation Capacity	7.1	Hawthorne TS T5 and T6 – LTR(1) exceeded	2018(2)
	7.2.1	Merivale TS T22 - LTR(1) exceeded	2019
Transmission Circuit Capacity	7.2.2	S7M Circuit – Capacity	2019 and 2026
	7.3	A4K Circuit - Capacity	2019(2)
Station Capacity	7.4	Center 115kV Area - Capacity	2017-2021(3)
	7.5	Hawthorne TS T7 and T8 – LTR(1) exceeded	2019
	7.2.2	South West Area - Capacity	2020
	7.6	Bilberry Creek TS - Refurbishment	2023
Supply Security, Reliability and Restoration	7.7	Almonte TS/Terry Fox MTS - Reliability	2015
	7.8	Orleans TS - Reliability	No plan recommended(5)
	7.9	B5D+D5A Circuits – Restoration	No plan recommended(5)
	7.10	Load Loss for S7M Contingency	No plan recommended(5)
Voltage Regulation	7.11	79M1 Circuit – Voltage Regulation	2023
	7.12	Stewartville TS – Voltage Regulation	No plan recommended(5)
	7.13	Almonte TS/Terry Fox MTS –Voltage Regulation	No plan recommended(5)
	7.14	Almonte TS – Low Power Factor	No plan recommended(5)
Additional Needs identified in RIP			
	7.2.1	Merivale TS T22 and Hawthorne TS T9 – Continuous ratings exceeded	2024/25
	7.4.2.4	King Edward TS – Capacity	2021

(1) LTR – Limited time ratings to accommodate emergency loading for a short time under contingency conditions
(2) Projects have been initiated.
(3) Miscellaneous stations. Some are already in execution.
(4) Timing shows the proposed in service date for project underway, and the need date for the projects not yet started.
(5) Review did not recommend plan for mitigation. Please see the need details in Section 7.

6.1 500 and 230 kV Transmission Facilities

All 500 kV and 230 kV transmission circuits in the Greater Ottawa Region are classified as part of the Bulk Electricity System (“BES”). They connect the Region to the rest of Ontario’s transmission system and to the Hydro Quebec transmission system. A number of these circuits also serve local area stations within the region and the power flow on them depends on the bulk system transfers as well as local area loads. These circuits are as follows (refer to Figure 3-4):

1. Hawthorne TS to Merivale TS 230 kV transmission circuits M30A/M31A – supply Albion TS and Ellwood TS.
2. Hawthorne TS to Cornwall 230 kV transmission circuits D5A/B5D/B31L – supply Orleans TS, St. Isidore TS and Longueuil TS. Also connects to Hydro Quebec at Beauharnois Station and to Lievre Power at Masson GS.
3. Merivale TS to Chats Falls 230 kV transmission circuits M32S/C3S – supply Nepean TS, South March TS and Kanata MTS
4. Merivale TS x Cherrywood TS 230 kV transmission circuits E29C/E34M (M29C) – supply Terry Fox MTS and Almonte TS.

Based on current forecast station loadings and bulk transfers, the M30A/M31A circuits will require reinforcement by 2020. The M30A/M31A upgrade will be addressed by Hydro One based on the recommendation stemming from an IESO Bulk System Planning study [6]. All other 230 kV circuits are expected to be adequate over the study period.

6.2 230/115 kV Transformation Facilities

Almost sixty percent of the Region load is supplied from the 115 kV transmission system. The primary source of 115 kV supply is from 230/115 kV autotransformers at Hawthorne TS and Merivale TS. Additional support is provided from 115 kV generation at Barrett Chute GS, Stewartville GS, part of Chats Falls GS, and the Ottawa Health Science NUG and the Ottawa River generation at Chaudière. Support from DG and CDM was considered as part of the load forecast.

Table 6-2 summarizes the results of the adequacy studies and gives the need dates for reinforcement of the 230/115 kV autotransformer facilities at Hawthorne TS and Merivale TS. Assuming no change in the system configuration, the forecasted loading will result in the Limited Time Rating (“LTR”) of the Merivale autotransformer being exceeded by 2019 and the continuous rating of the Merivale and Hawthorne autotransformers by 2024/25.

The need dates are sensitive to the availability of hydraulic generation from Barrett Chute GS, Stewartville GS and Chats Falls GS and are based on 98% dependable generation availability as per ORTAC criteria. This corresponds to about 18 MW of available generation. A higher level of generator output from these stations would defer the need dates.

The need dates assume that the Hawthorne TS 225 MVA, 230/115 kV autotransformers T5 and T6 have been replaced with new 250 MVA units. The T5 and T6 replacement work is underway and is therefore not identified in the table below.

Table 6-2 Adequacy of 230/115 kV Autotransformer Facilities

Overloaded Facilities	2015 MVA Loading	MVA Load Meeting Capability	Limiting Contingency	Need Date
Merivale TS 230/115kV autotransformer T22	261	312[1]	T21	2019
Merivale TS 230/115kV autotransformer T21	182	250	[2]	2024
Hawthorne TS 230/115kV autotransformer T9	189	250	[2]	2025

(1) Limited time rating exceeded.

(2) Continuous rating exceeded with all elements in service based on existing system configuration

6.3 115 kV Transmission Facilities

The Greater Ottawa Region 115 kV transmission facilities can be divided in five main sections: Please see Figure 3-4 for the single line diagram.

1. Hawthorne 115 kV Center – has four circuits A3RM, A4K, A5RK and A6R. Reinforcement is required for the A4K circuit as a loss of the A5RK circuit would result in the loading exceeding the rating on the A4K circuit between Hawthorne TS and Moulton MTS (for details see Section 7.3).
2. Hawthorne 115 kV East – has two circuits A2 and H9A/79M1. These are expected to be adequate over the study period.
3. Merivale 115 kV Center – has two circuits M4G and M5G. These are expected to be adequate over the study period.
4. Merivale 115 kV West – has five circuits C7BM, F10MV, S7M, V12M and W6CS. Upgrading is required of the S7M tap to Fallowfield TS since forecasted loading will exceed circuit continuous rating (for details see section 7.4)
5. Merivale 115 kV South – has two circuits L2M and M1R. These circuits are adequate for the study period.

The loading on the limiting sections is summarized in Table 6-3.

Table 6-3 Adequacy of 115 kV Circuits

Corridor	Section	Overloaded Circuit	Rating (A)	Contingency	2015 Loading (A)	Need Date
1. Hawthorne TS x Blackburn Jct. x Overbrook TS	Hawthorne TS x Moulton TS	A4K	1070	A5RK	1006	2017
4. S7M tap to Fallowfield MTS	STR R14-R15 x Fallowfield Jct.[(2)]	S7M	590	All facilities in-service[(1)]	278	2024

[(1)] Continuous rating exceeded.
[(2)] Please see Figure 7-4.

6.4 Step-Down Transformation Facilities

There are a total of fifty-two step-down transmission connected transformer stations in the Greater Ottawa Region. The stations have been grouped based on the geographical area and supply configuration. The non-coincident station loading in each area and the associated station capacity and need date for relief is provided in Table 6-4 below. As shown areas requiring additional transformation capacity are the Center 115kV area, the South West 115kV area and the South 115kV area. Table 6-5 shows the non-coincident station loads for all areas which are adequate over the 2015-2025 study period. Details of the areas and associated stations are given in Appendix B.

Table 6-4 Adequacy of Step-Down Transformer Stations - Areas Requiring Relief

Area/Supply	Capacity (MW)	2015 Loading (MW)	Need Date
Center 115	569[(1)]	516	2018
South West 115	70	60	2019
South 115	182	151	2024

[(1)] With Overbrook TS 45/75 MVA transformers replaced with larger 60/100 MVA units.

Table 6-5 Adequacy of Step-Down Transformer Stations – Areas Adequate

Area/Supply	Capacity (MW)	2015 Loading (MW)	2025 Loading (MW)
East 115	340	231	229
West 115	504	351	425
Center 230/13.2kV	147	121	126
Center 230/44kV	153 (1)	103	136
West 230	397	382	389
Outer East 115	80	56	62
Outer West 115	106	83	96
Outer East 230	149 (2)	92	90
Outer West 230	100	48	45

(1) With Hawthorne TS 50/83 MVA transformers replaced with larger 75/125 MVA size units.
(2) Includes Longueuil TS and St Isidore TS load.

7. REGIONAL PLANS

This section discusses needs, presents wires alternatives and the current preferred wires solution for addressing the electrical supply needs for the Greater Ottawa Region. These needs are listed in table 6-1 and include needs previously identified in the IRRP for the Ottawa Sub-Region [1] and the NA for the Outer Ottawa Sub-Region [2] as well as the adequacy assessment carried out as part of the current RIP report.

7.1 Hawthorne Autotransformer T5 and T6

7.1.1 Description

Hawthorne TS is a major supply point for the city of Ottawa (Figure 7 -1). The station has four 230kV/115 kV autotransformers. Two of these autotransformers, T5 and T6, have lower ratings, with 225 MVA continuous and 256 MVA LTR, respectively. Under contingency conditions, i.e. one of the autotransformers out of service, the ratings of these two autotransformers are exceeded and this limits the supply to the 115 kV network from the 230 kV system. As the load continues to grow on the 115 kV network, this limitation needs to be addressed. This had been identified as a near term need in the Ottawa Sub-Region IRRP [1] and was included in the Ontario Power Authority's ("OPA", now part of IESO) June 2014 letter to Hydro One [5].

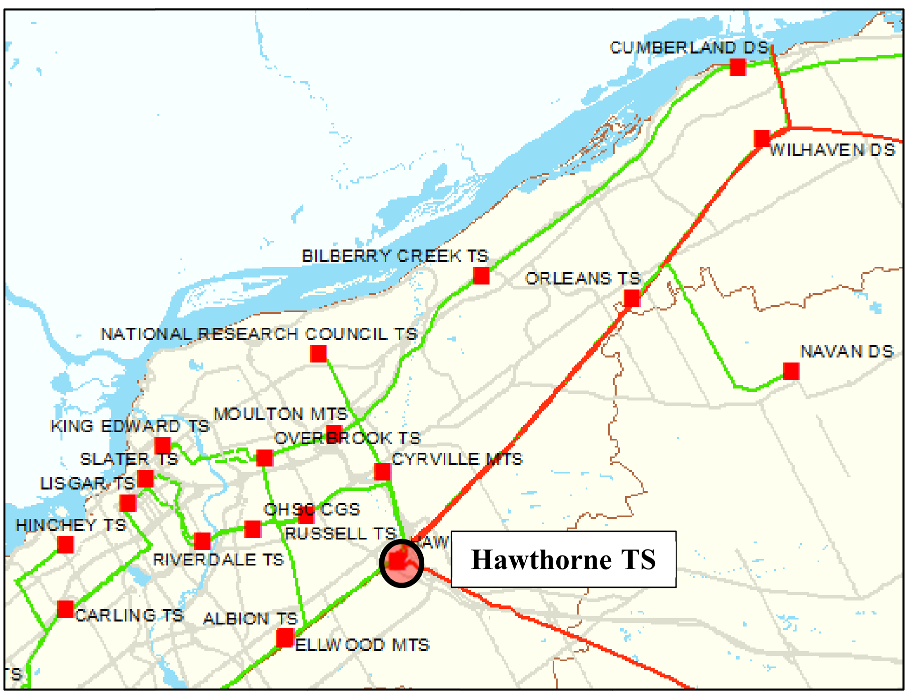

Figure 7-1 Hawthorne TS

7.1.2 Recommended Plan and Current Status

Hydro One has established a project to replace autotransformers T5 and T6 with new higher rated autotransformers. These autotransformers will have an LTR of at least 350 MVA. This investment will provide additional capacity and meet the needs of the area. It is expected that the project will be completed in 2018.

The cost of this project is expected to be $15.7 million. The project will be a transmission pool investment as the autotransformers provide supply to all customers in the Greater Ottawa Region.

7.2 Autotransformation Capacity and South West Area Station Capacity

7.2.1 Merivale TS Autotransformers T21 and T22/Hawthorne Autotransformer T9

Merivale TS has two 230 kV/115 kV autotransformers with an LTR station capacity of 312 MVA. The station is supplied from Hawthorne TS and from generators located west of Ottawa, along the Ottawa River and the Madawaska River. Merivale TS is shown in Figure 7-2.

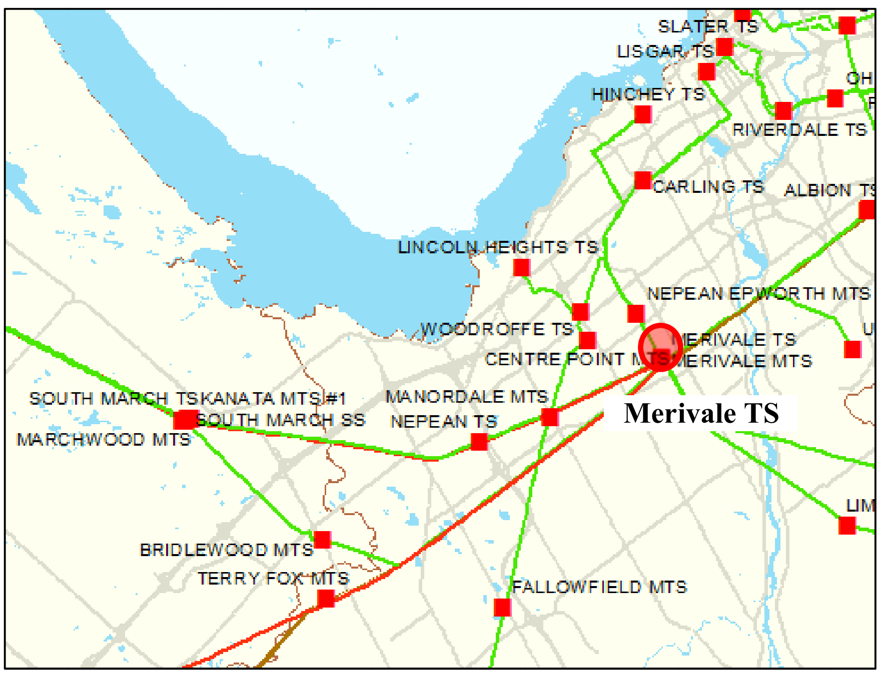

Figure 7-2 Merivale TS

The expected load growth provided by the LDCs and the minimum hydro generation assumption described in Section 6.2 causes the station capacity to be exceeded under contingency conditions by 2019. In addition, it is expected that autotransformers at Merivale TS and Hawthorne TS will reach their continuous loading limits of 250 MVA by 2024 and 2025. The exact timing of the autotransformer needs is dependent on the following factors:

- The South West area load forecast includes a proposed connection of a single large load increase coming into service in 2019.
- The need date is sensitive to generation at Stewartville GS, Barrett Chute GS and Chats Falls GS as its effect is to reduce the flow through the autotransformers.
- A potential solution to the need for additional supply capacity in the South West Area is a new 230 kV supply station which would remove some of the demand growth and existing load from the 115 kV network (see Section 7.2.2 for a complete description of this issue). This work would also help defer the need for additional autotransformer capacity at Merivale TS.

In order to address the Merivale TS autotransformer capacity concerns, additional 230/115 kV transformation capacity or load transfer from the 115 kV to the 230 kV system is required.

The provision of additional transformation capacity requires replacing the Merivale TS T22 autotransformer with a newer higher rated transformer in 2019 and adding a third autotransformer at the station in 2024. Alternatively a third transformer can be added at Merivale TS by 2019. To meet the required 2019 need date a decision on the autotransformer work is required by summer 2016.

Transferring load to the 230kV system requires establishing a new 230/27.6kV transformer station in the South West area to pick up some of the existing load and all of the new load growth. This is described in the following section.

7.2.2 Supply to South West Area – Line and Station Capacity

The South West area is served by Fallowfield MTS, Richmond MTS and Manotick DS connected to the 115kV circuit S7M out of Merivale TS. Load demand in the area is expected to increase by 52 MW in the next 10 years and both the line and station capacity are forecast to be exceeded by 2019.

The line limitation was identified in the OPA's June 2014 letter [5] to Hydro One. A section of the S7M circuit between the main line at STR R14-R15 JCT and Fallowfield Junction (see Figure 7-3 below) had a capacity of 420A. Hydro One review of the line capacity showed that the line rating was limited to respect safety clearances due to an underbuilt distribution feeder at Fallowfield MTS. This issue has been resolved with Hydro Ottawa carrying out the necessary work to lower the distribution feeder and increase the transmission line clearance. The line rating has been increased to 590A and is now adequate to meet forecast load until 2026.

Additional transformation capacity is required in the South West Area and both Fallowfield MTS and Richmond DS require load relief. Hydro Ottawa is planning for a capacity increase at Richmond DS and potentially a new station to relieve Fallowfield MTS in the Barrhaven area.

The IESO has initiated a public engagement process to gather community input for a preferred supply plan for the area including consideration of the potential for incremental CDM and DG resources and/or transmission expansion in the form of a new TS. The IRRP [1] recommended that given the required timeline, it would be beneficial for early transmission planning options to be started in parallel to the engagement process, prior to completing the integrated plan.

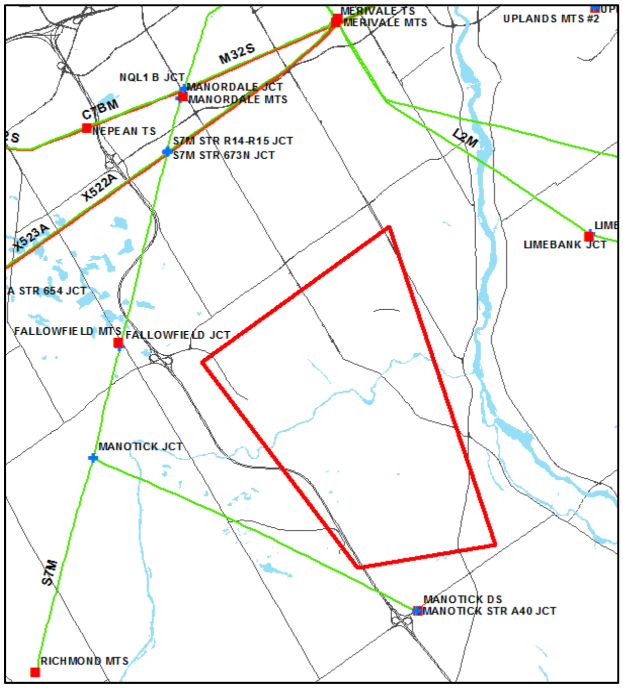

Figure 7-3 South West Area

At a high level, there are two main wire options to supply the South West area:

a) 115kV Option: Build a new 115/27.6kV transformer station and reinforce the existing 115 kV supply
b) 230kV option: Build a new 230/27.6kV transformer station and provide a new 230 kV transmission supply to the area.

The main advantage of the 115 kV option is that it defers the need for new transmission line until 2026. It however has a number of disadvantages: (a) loading will continue to increase on the 115kV system necessitating additional transformation capacity a Merivale TS by 2019 and Hawthorne TS by 2025, (b) all area stations remain on a single line supply until new transmission is built, and (c) the new 115 kV supply will provide less incremental capacity for the future.

The 230 kV option has the advantage of providing relief for the 230/115 kV autotransformers at Merivale TS and Hawthorne TS as well as provide more capacity to serve the area load. It also improves the area reliability by providing a second source of supply. The disadvantage is that transmission reinforcement will be required by 2019 and decision needs to be made as soon as possible.

The RIP has considered two options as examples for providing 230 kV supply to the area. Both examples consider building new double circuit 230 kV lines on existing Right of Way ("ROW") in accordance with the provincial government policy to maximize ROW use. The two options are described below (also refer to Figure 7-3).

- *S7M Based Option - Rebuild S7M as a double circuit 230 kV line.*

  This option would require rebuilding the existing single circuit115 kV circuit S7M tap to Fallowfield MTS as a new double circuit 230 kV line. The line would extend from the S7M STR R14-R15 JCT (on the main line) to Manotick Jct. Depending on the station location, a part of S7M from Manotick JCT to Manotick DS would also have to be rebuilt for a total line rebuild of up to 15.5 km. One circuit would be operated at 115 kV and continue to supply Fallowfield MTS, Richmond DS and Manotick DS. The other circuit would be tapped off the 230 kV circuit M29C which is adjacent to S7M at STR R14-R15 JCT and will be used to supply the new Hydro Ottawa station. This option may require sections of the existing ROW to be widened to accommodate the 230 kV circuits. Additional real estate rights will have to be obtained. EA and OEB Leave to Construct (Section 92) approvals will also be required.

- *L2M Based Option - Rebuild L2M as a double circuit 230 kV Line*

  This option would require rebuilding the existing 115 kV circuit L2M from Merivale TS to past Limebank MTS as a new double circuit 230 kV line. This section of the line would be constructed using the existing L2M ROW for a distance of 8.5 km. A new 6-8 km long ROW would need to be acquired going west from the L2M ROW to bring the transmission line to the load area, crossing the Rideau River. One circuit on the new line would remain L2M and be operated at 115 kV. The other circuit would connect to circuit M32S at Merivale TS and be operated at 230 kV. The new station will be supplied from the 230 kV circuit.

7.2.3 Recommended Plan and Current Status

The needs for autotransformation capacity and a new station in south west are interrelated. Further analysis is required to determine the impact of the 230 kV supply options for the new south west station on the Merivale TS and Hawthorne TS autotransformers. The planning assessment will consider whether a 115kV supply to the new station in combination with the addition of an autotransformer at Merivale is more cost effective than a 230kV supply.

The IESO is currently carrying out community engagement activities in the Ottawa region. The Working Group will be discussing the supply options for the South West area in conjunction with the autotransformer upgrade work at Merivale TS and expect to recommend a preferred plan for the area by summer 2016.

7.3 115 kV Transmission Circuit A4K Supply Capacity

7.3.1 Description

Circuit A4K is a 115 kV circuit supplying four downtown stations: Overbrook TS, King Edward TS, Cyrville MTS and Moulton MTS. Loading on the A4K this circuit can exceed its rating under peak load conditions for loss of 115 kV circuit A5RK. This need was identified as a near term need in the Ottawa Sub-Region IRRP [1] and included in the OPA's June 2014 letter to Hydro One [5]. In this letter, the preferred plan to relieve circuit A4K is outlined. This plan consists of rebuilding an approximately 2 km long section of single circuit 115 kV circuit A5RK between Overbrook TS to Riverdale Jct. as a double circuit line (see Figure 7-4). One of the circuits would remain A5RK and the other would be tapped to circuit A6R. Overbrook TS will be reconfigured to be supplied from circuits A5RK/A6R instead A4K/A5RK. This reconfiguration would remove Overbrook TS load from 115 kV circuit A4K and eliminate the overloading on A4K for the loss of A5RK.

7.3.2 Current Status

Hydro One has initiated the development work for this line rebuild. The project is currently in the engineering and estimating phase. The project is not expected to require Leave to Construct (Section 92) approval, but will require Environmental Assessment ("EA") approvals.

The project is expected to be in service by spring 2019 and preliminary estimates suggest the cost to be approximately $9 million to $11 million. This work will be part of the Line Connection pool and costs will be recovered from the rate revenue and/or customer capital contribution in accordance with the TSC. As a result, the LDC may be required to make a capital contribution.

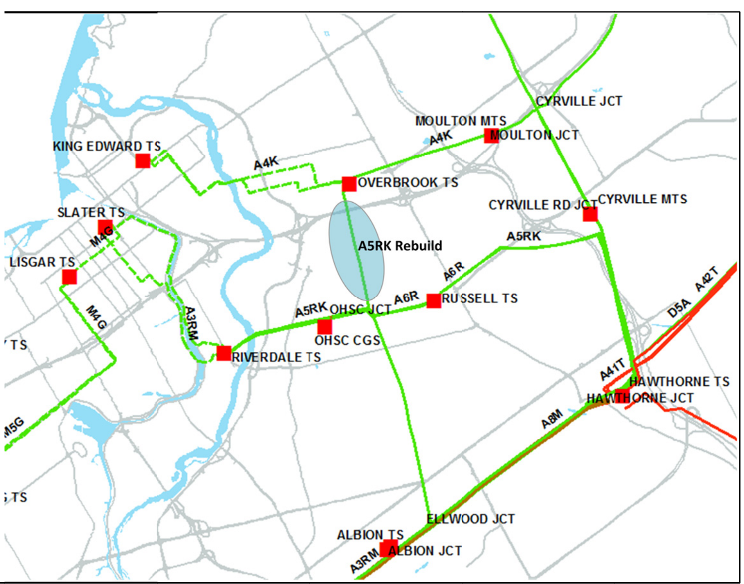

Figure 7-4 Option to Rebuild A5RK as Double-Circuit 115 kV Line

In the interim, Hydro One and Hydro Ottawa have operational mitigating measures to manage the overload on 115 kV circuit A4K if it becomes of concern before Hydro One has completed the line rebuild work. These measures include the transfer of Cyrville MTS to single supply from circuit A2 only by opening the A4K breaker at Cyrville MTS, and the transfer of some load from Moulton MTS to other stations in the area.

7.4 Station Capacity – Ottawa Centre 115 kV Area

7.4.1 Description

The Ottawa Center 115 kV area covers the City of Ottawa downtown district and extends from the Ottawa River in the north to Smyth Road in the south as shown in Figure 7-5 below. It is served by six 115/13.2 kV step-down transformer stations – King Edward TS, Lisgar TS, Overbrook TS, Riverdale TS, Russell TS and Slater TS. Most of the area stations are at or near capacity. Even with the Overbrook upgrade work now underway additional load meeting capability is forecast to be required by 2018 as shown in Table 6.3.

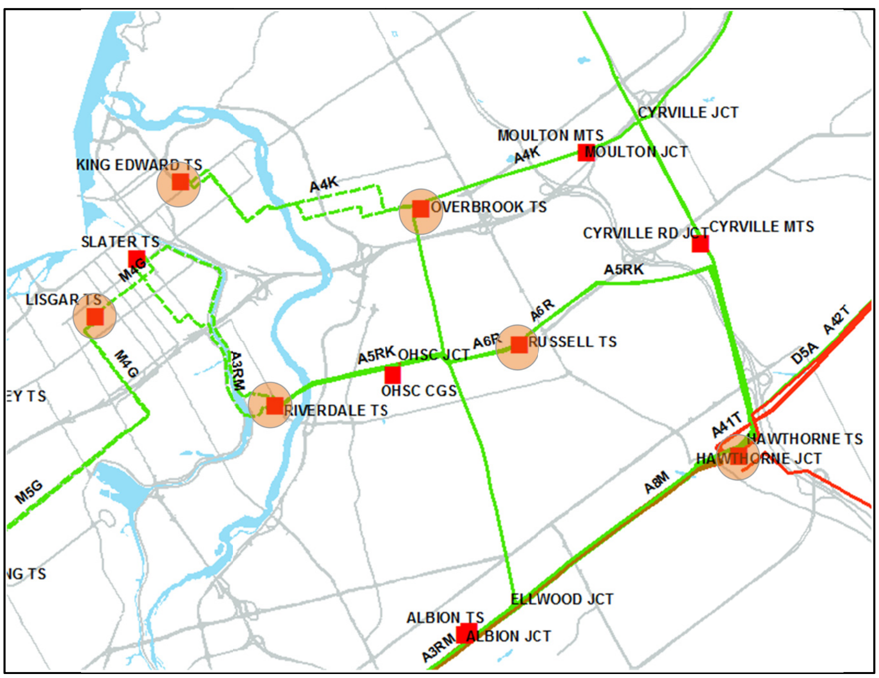

Figure 7-5 Downtown Ottawa Stations

7.4.2 Recommended Plan and Current Status

The existing step-down stations in the area are equipped with older 45/75 MVA transformers which have a LTR of between 70-80 MW. The preferred alternative to provide additional transformation capacity in the area is to replace these units with larger sized 100 MVA units where possible with an LTR of up to 130 MW.

During this regional planning cycle, the Working Group participants agreed to take advantage of transformer replacements necessitated by end-of-life considerations as this was the lowest cost and most practical option to provide additional capacity. The alternative of building a new station to provide capacity was ruled out because of the high cost and the difficulty in acquiring an appropriate site.

Upgrade of the end of life transformers at Overbrook TS is currently underway. In the future, the Working Group will continue to look for opportunities to upgrade based on end-of-life considerations of transformers. Hydro One will keep the Working Group informed of these opportunities. In addition, load transfers are also recommended to utilize available capacity at adjacent stations.

7.4.2.1 Russell TS and Riverdale TS

The loading on these stations will be kept within limits by Hydro Ottawa building feeder ties to transfer excess loads to other area stations. This will keep the loading on the transformers at these stations within their rating. A high level cost estimate of Hydro Ottawa's distribution work is $2 million.

7.4.2.2 Overbrook TS

Hydro One had identified that the step-down transformers at Overbrook TS were approaching end-of-life and consideration was therefore given to upgrading the transformers at the station. Accordingly Overbrook TS transformers are being replaced with larger sized units which will increase the station capacity from 72 MW to 130 MW. The work is underway and planned to be completed in Q2 2018. The incremental cost of upgrading to larger transformers is estimated to be $1.1 million. The cost of upgrading is expected to be recovered from incremental rate revenue in accordance with the TSC. Based on current forecast Hydro Ottawa is not expected to pay any capital contribution for this project.

7.4.2.3 Lisgar TS

Lisgar TS has two 75 MVA transformers. To meet the forecast load requirement additional transformation capacity is required in the Central 115kV area. Hydro Ottawa has therefore asked that the Lisgar TS transformers be replaced with larger 100 MVA units. The cost of the work is estimated to be about $14 million and will be recovered from rate revenue and customer capital contribution in accordance with the TSC. The target in-service date is Q4 2017.

7.4.2.4 King Edward TS

The capacity at King Edward TS is 71 MW. By replacing the limiting transformer T4 and additional low voltage ("LV") components such as circuit breakers and cable, a higher capacity of up to 130 MW can be achieved at King Edward TS.

Considering the Overbrook TS and Lisgar TS upgrades, adequate capacity will be available in the Center area until 2021. After discussion with Hydro Ottawa, the King Edward TS transformer upgrade work is tentatively scheduled for an in-service date of 2021. The project cost is estimated to be about $12M and will be recovered from rate revenue and customer capital contribution in accordance with the TSC.

7.5 Station Capacity - Hawthorne TS 44kV

Hawthorne TS has two 50/83 MVA, 230/44kV transformers with an LTR of 89 MW. Additional 44kV capacity is required at the station. Hydro One identified that the step- down transformers at Hawthorne TS were approaching end-of-life and needed to be replaced. The lowest cost alternative to provide this additional capacity was to take advantage of the transformer replacement work and install larger 75/125 MVA transformers with an LTR of 153 MW. This work is currently underway and planned to be completed by summer 2019.

Additional 44kV feeder positions will be required to utilize this increased capacity. These feeders will be added as required.

The incremental cost of upgrading to larger transformers is estimated to be approximately $1.1 million. Feeder position costs have not been estimated at this time. Incremental transformer costs and the feeder costs will be recovered in accordance with the TSC. Based on the current forecast Hydro Ottawa is not expected to pay any capital contribution for this project.

7.6 Bilberry Creek TS End of Life

7.6.1 Description

Bilberry Creek TS is a 115/27.6 kV step-down transformer in East Ottawa, supplying up to 85 MW of load customers to both Hydro Ottawa and Hydro One Distribution. The station was built in 1964 and a number of its key components have been identified for replacement by Hydro One. This station's refurbishment work is to be complete by 2023. A decision will be required by 2020 on whether to refurbish the station and keep the load on the 115 kV system or to retire the station and move the load over to the 230 kV system by supplying it from the newly built Orleans TS.

A Local Plan [3] carried out by Hydro One shows that the two options are similar in costs. The retirement option however, may be more attractive particularly if 115 kV load growth rate is high in the Ottawa Center area. The retirement option will reduce the loading of the 230 kV/115 kV autotransformers at Hawthorne TS and Merivale TS and make it available for the Ottawa Center 115 kV load. Figure 7-6 shows the area under consideration.

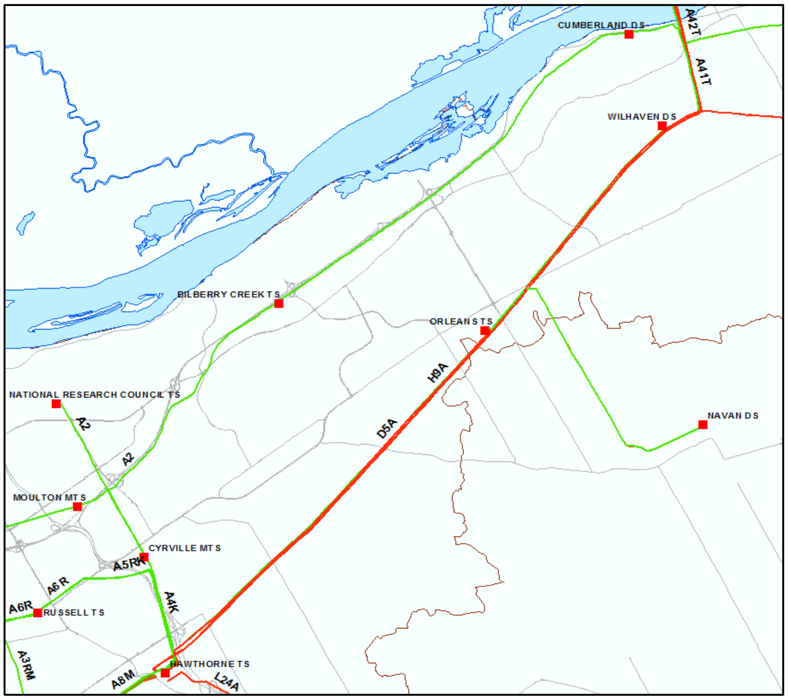

Figure 7-6 Bilberry Creek TS and the East Ottawa Area

7.6.2 Recommended Plan and Current Status

The two alternatives are very similar in cost and each has its own pros and cons. The refurbishment option minimizes work on the distribution system, but leaves the load on the 115kV system and with lower overall capacity to meet long term growth. The retirement option moves Bilberry Creek load to the 230kV system with higher long term load meeting capability but involves relocating distribution feeders from Bilberry Creek TS to Orleans TS.

The Working Group has recommended that a decision on Bilberry Creek refurbishment be deferred to the next regional planning cycle as there is still sufficient time to make an investment decision.

7.7 Almonte TS and Terry Fox TS Reliability

7.7.1 Description

Almonte TS and Terry Fox MTS are supplied from the 319 km long 230kV circuit M29C, see Figure 7-7. Due to the long length of the line the exposure to outages is high. The line has averaged approximately 6-7 interruptions per year over the last 10 years. With Terry Fox MTS coming into service in 2013, concerns were expressed about the number of outages that would be seen by the station. This issue was identified in the Ottawa Sub-Region IRRP [1] and the OPA's June 2014 letter [5].

7.7.2 Recommended Plan and Current Status

Hydro One had initiated a project in 2012 to install a 230 kV circuit breaker at Almonte TS. This breaker would sectionalize the M29C line into two sections: E29C – 281 km Cherrywood TS to Almonte TS; and E34M – 38 km Almonte TS to Merivale TS. This breaker will help with the number of interruptions at Almonte TS and Terry Fox MTS by eliminating outages due to the Almonte TS x Cherrywood section of the circuit.

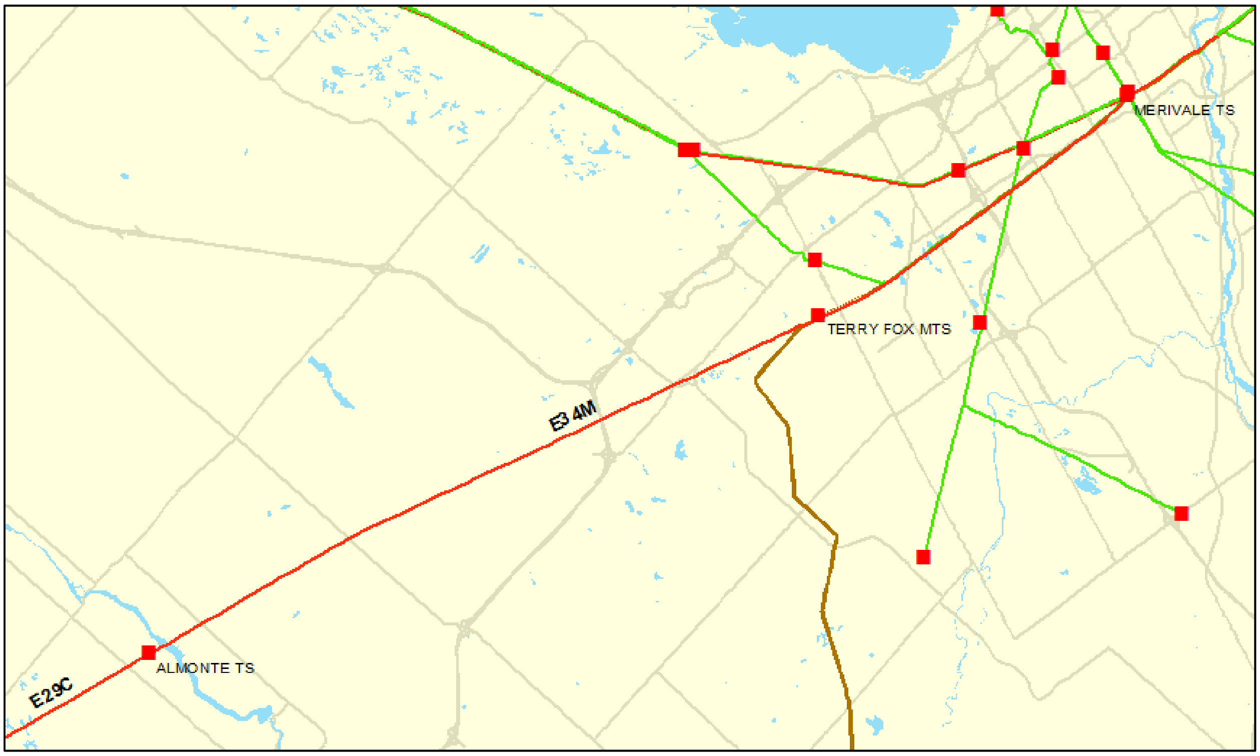

Figure 7-7 Lines E29C and E34M (M29C). In-Line Breaker at Almonte TS.

The total cost of this project is estimated to be $4.7 million and the project is scheduled to be completed by December 2015.

A second supply from Merivale TS to Terry Fox MTS was previously considered as an option to improve reliability. However it was decided to install the in-line breaker at Almonte TS since it was the cost effective and provided reliability improvement to both Almonte TS and Terry Fox MTS.

It should be noted that the Terry Fox TS is operated with the LV bus tie open. This arrangement has the disadvantage that in case of a transformer outage, the load connected to that transformer will be lost momentarily before the bus tie is closed to allow all loads to be supplied from the other side. A second supply to Terry Fox MTS can still be considered to address this issue as the load increases as part of a longer term supply plan. This will continue to be reviewed.

7.8 Orleans TS Reliability

7.8.1 Description

Orleans TS is a new station Hydro One built in East Ottawa to provide additional transformation capability and improve supply reliability for Hydro One Distribution customers connected to the 115 kV circuit H9A.

The Orleans TS is built adjacent to the double circuit H9A/D5A line about 10 km from Hawthorne TS and has one step-down transformer station supplied from 230 kV circuit D5A and the second step-down transformer supplied from the 115 kV circuit H9A. The station is operated with the LV bus tie open so as to avoid any power flow between the 230 kV and 115 kV systems through the station transformers. This arrangement has the disadvantage that in case of a circuit or transformer outage, the load connected to that circuit or transformer will be lost momentarily before the bus tie is closed to allow all loads to be supplied from the other side.

7.8.2 Recommended Plan and Current Status

Orleans TS has greatly improved the reliability of customers previous supplied from Wilhaven DS and Navan DS connected to 115kV circuit H9A. The customers experienced sustained interruptions every time circuit H9A had an outage. With the Orleans TS LV bus tie arrangement customer are exposed to a momentary interruption only as the load is picked up by closing the bus tie. This arrangement was accepted as a cost effective alternative to building 10 km of transmission line between Hawthorne TS and Orleans TS to provide a dual supply to Orleans TS.

Depending on the decision taken for Bilberry Creek TS described in section 7.6, Orleans TS could be converted to a 230 kV station and the LV bus tie closed. This option would be preferred if Bilberry Creek TS is recommended to be retired. If Bilberry Creek TS is refurbished then the plan will see Orleans TS continued operation with two different voltage supplies.

The Working Group recommendation is to monitor the performance of Orleans TS to see if mitigation measures are warranted. The Working Group will further review this issue in the next regional planning cycle as part of the Bilberry TS retirement study. No further action is required at this time.

7.9 Load Restoration for the Loss of B5D/D5A

7.9.1 Description and Current Status

The NA report for the Outer Ottawa Sub-Region [2] identified that the combined loss of circuits D5A and B5D would result in a load loss of up to 174 MW. The stations considered in this analysis are St Isidore TS, Longueil TS, and Ivaco CTS. Orleans TS is also supplied by D5A however; its second supply is H9A and is not considered for the combined loss of D5A/B5D. As indicated in ORTAC, any load lost above 150 MW must be restored within 4 hours and all load be restored within 8 hours.

A LP report [4] carried out by Hydro One shows that historically, the coincidental occurrence of forced sustained outages of B5D and D5A are rare and in all cases one of the circuits was restored in less than 4 hours as per ORTAC. The report concludes that no further action is required at this time.

7.10 Load Loss for S7M Contingency

7.10.1 Description and Current Status

Circuit S7M is the single supply for the following stations: Bridlewood MTS, Fallowfield MTS, Manotick DS, and Richmond DS. The combined load at these four stations is expected to exceed 150 MW by 2022. The ORTAC requires that not more than 150MW of load may be interrupted by configuration. However, given that the 150 MW limit is anticipated in the long term, no action is required at this time.

7.11 Voltage Regulation on 115kV Circuit 79M1

7.11.1 Description and Current Status

The 115 kV circuit 79M1 supplies Rockland DS, Rockland East DS, Clarence DS, Wendover DS, and Hawkesbury MTS. The NA for Outer Ottawa Sub-Region [2] identified that the voltage at Hawkesbury TS will approach operating limits under peak load and contingency conditions by 2023.

As mentioned in the Outer Ottawa Sub-Region NA report [2], Hydro One monitors the status of the network. Given the timing for this need, this will be reassessed during the next regional planning cycle.

7.12 Voltage at Stewartville TS

7.12.1 Description and Current Status

The load on the Stewartville TS is expected to increase significantly as a result of the connection of a large utility load forecasted for 2018. This load may require reactive support to help maintain the voltages within limits during peak load conditions and no generation at Stewartville GS.

A connection impact assessment will be undertaken by Hydro One as part of connecting the utility load. Any requirements to connect the load, including reactive power support, will be outlined in the document.

7.13 Voltage Drop at Terry Fox MTS for E34M open at the Merivale End

7.13.1 Description

Circuit E34M/E29C (new name for circuit M29C following the installation of a breaker at Almonte TS) is a 319 km line between Cherrywood TS in Pickering, and Merivale TS in Ottawa. If the circuit E34M (Almonte-Merivale) is open at the Merivale end, Terry Fox MTS and Almonte TS will be supplied radially by Cherrywood TS. Given the distance between the Greater Ottawa stations and Cherrywood TS, voltages are lower than acceptable limits during normal and peak load periods and only load of up to 25 MW can be supplied with acceptable voltage. The 2012 IESO System Impact Assessment ("SIA") recommended the installation of 20 MVARs of capacitor banks at Terry Fox MTS to meet a peak load of up to 48 MW.

7.13.2 Recommended Plan and Current Status

It is recommended that Hydro Ottawa install 20 MVARs of capacitor banks at Terry Fox MTS. This should be adequate for the near term.

Terry Fox MTS is part of the Ottawa Area under voltage load rejection scheme ("UVLS"). This scheme is designed to shed the station load if the 230 kV supply voltage to the station drops below 204 kV when it is activated. Currently the scheme is only armed when the entire Ottawa Area UVLS is armed. It is proposed to modify the scheme so that it can be selectively armed when loading levels are higher than 48MW and under conditions that may result in a circuit M29C line end open at Merivale TS.

Historically the probability of this line end open occurring is low and it would typically occur while terminal maintenance is done at Merivale. By scheduling maintenance during off peak periods, the impact can be significantly reduced. No mitigation measures are therefore recommended at this time. Hydro One and Hydro Ottawa will be monitoring the system performance and the matter will be reconsidered in the next planning cycle based on operating experience.

7.14 Low Power Factor at Almonte TS

7.14.1 Description and Current Status

The IESO's SIA for Almonte T3 replacement noted a low power factor at Almonte TS. This potential issue was also reported in the Outer Ottawa Sub-Region NA report [2].

Hydro One has reviewed the power factor at Almonte TS. The station power factor varies from 0.89 to 0.95 at the LV bus which translates into approximately 0.86 to 0.92 on the HV bus. Part of the reason for the lower power factor is that the station has 29 MW of DG which generally operates at unity power factor. The generation reduces the net power in MW seen at the metering point. This reduction in power results in a lower power factor as seen from the HV bus since the generation does not offset the reactive power demand of the station. No action is required as the load power factor without DG is within the acceptable limits.

8. CONCLUSION AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GREATER OTTAWA REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses near term and mid-term regional needs identified in the earlier phases of the Regional Planning process and during the RIP phase. Next Steps, Lead Responsibility, and Timeframes for implementing the wires solutions for the near term needs are summarized in the Table 8-1 below.

Investments to address the mid-term needs, for cases where there is time to make a decision, will be reviewed and finalized in the next regional planning cycle. These needs are summarized in Table 8-2.

No long term needs were identified at this time. As per the OEB mandate, the Regional Plan should be reviewed and/or updated at least every five years.. The region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

Table 8-1 Regional Plans – Next Steps, Lead Responsibility and Plan In-Service Dates

No.	Project	Next Steps	Lead Responsibility	I/S Date	Cost
1	Almonte TS: addition of breaker to sectionalize line M29C	Construction in the final stages	Hydro One	Dec. 2015	$4.7M
2	Russell TS and Riverdale TS: construction of feeder ties to allow extra load transfers	LDC will lead this work	Hydro Ottawa	2017-2020	$2.0M
3	Lisgar TS: replacement of transformers T1 and T2	Transmitter to carry out this work	Hydro One	Dec. 2017	$13.9M
4	Hawthorne TS: replacement of autotransformers T5 and T6	Transmitter to carry out this work	Hydro One	May 2018	$15.7M
5	Overbrook TS: replacement of transformers T3 and T4	Transmitter to carry out this work	Hydro One	June 2018	$1.1M(1)
6	A6R: additional tap to offload A4K	Transmitter to carry out this work	Hydro One	June 2019	$9-11M
7	Hawthorne TS: replacement of transformers T7 and T8 and add one 44kV feeder position	Transmitter to carry out this work	Hydro One	Oct. 2019	$1.1M(2)
8	New South West Station And Merivale 230/115kV Transformation Capacity	IESO and Hydro Ottawa leading consultation	IESO/Hydro Ottawa	2020	--- (3)
9	King Edward TS: Replace Transformer T4	Transmitter to carry out this work	Hydro One	June 2021	$12M

(1) Incremental cost for larger transformer only.
(2) Incremental cost for larger transformer only. Feeder costs have not been estimated at this time.
(3) The Working Group expects to make a final recommendation on this plan by early 2016.

Table 8-2 List of Mid-Term Needs to be Reviewed in Next Regional Planning Cycle

No.	Need	Timing
1	Bilberry Creek TS - Refurbishment	2023
2	Orleans TS - Reliability	2023[(1)]
3	79M1 Circuit – Voltage regulation	2023

(1) Performance will be monitored to see if mitigation measures are warranted. Need will be reviewed along with Bilberry Creek TS refurbishment.

PICKERING-AJAX-WHITBY SUB-REGION INTEGRATED REGIONAL RESOURCE PLAN

Part of the GTA East Planning Region | June 30, 2016

ieso
Connecting Today. Powering Tomorrow.

Integrated Regional Resource Plan

Pickering-Ajax-Whitby Sub-region

This Integrated Regional Resource Plan ("IRRP") was prepared by the Independent Electricity System Operator ("IESO") pursuant to the terms of its Ontario Energy Board licence, EI-2013-0066.

This IRRP was prepared on behalf of the Pickering-Ajax-Whitby Sub-region Working Group ('the Working Group"), which included the following members:

- Independent Electricity System Operator
- Veridian Connections Inc.
- Whitby Hydro Electric Corporation
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)

The Working Group assessed the adequacy of electricity supply to customers in the Pickering-Ajax-Whitby Sub-region over a 20-year period beginning in 2015; developed a flexible, comprehensive, integrated plan that considers opportunities for coordination in anticipation of potential demand growth and varying supply conditions in the Pickering-Ajax-Whitby Sub-region; and developed an implementation plan for the recommended options, while maintaining flexibility in order to accommodate changes in key conditions over time.

Working Group members agree with the IRRP's recommendations and support implementation of the plan through the recommended actions. The Pickering-Ajax-Whitby Sub-region Working Group members do not commit to any capital expenditures and must still obtain all necessary regulatory and other approvals to implement recommended actions.

Whitby Hydro	Whitby Hydro Electric Corporation
Working Group	Technical Working Group for Pickering-Ajax-Whitby IRRP

1. Introduction

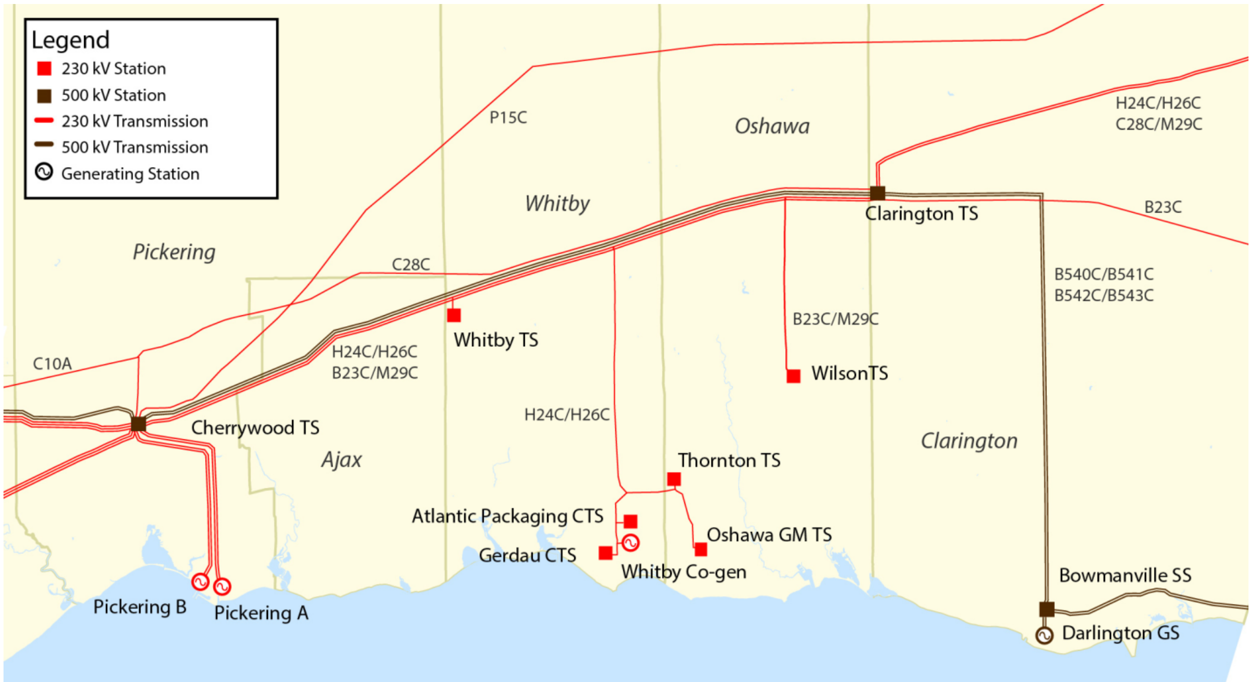
This Integrated Regional Resource Plan ("IRRP") addresses the electricity needs for the Pickering-Ajax-Whitby Sub-region (the "sub-region") over the next 20 years, from 2015-2034. This report was prepared by the Independent Electricity System Operator ("IESO") on behalf of the Technical Working Group composed of the IESO, Veridian Connections Inc. ("Veridian"), Whitby Hydro Electric Corporation ("Whitby Hydro"), Hydro One Distribution and Hydro One Transmission [1] (the "Working Group").

The sub-region is part of the GTA East planning region ("GTA East Region"). The GTA East Region is within the Region of Durham and extends from Lake Ontario northward to the southern parts of Scugog and Uxbridge, and includes the municipalities of Pickering, Ajax, Whitby, Oshawa and the eastern part of Clarington. The area is supplied by several transformer stations ("TS") fed by the 230 kV transmission system in the area. The local distribution companies ("LDCs") providing services to the GTA East Region include: Hydro One Distribution, Oshawa PUC Networks ("Oshawa PUC"), Veridian and Whitby Hydro.

The sub-region includes the City of Pickering, Town of Ajax, the Town of Whitby and the southern parts of the Townships of Uxbridge and Scugog. The sub-region is currently served by Cherrywood TS 230/44 kV step-down transformers, Whitby TS and a portion of Thornton TS. The scope of this sub-region IRRP also includes consideration of the entire GTA East regional supply for the purposes of restoration analysis. A map of the GTA East Region is provided in Figure 1-1 below.

[1] For the purpose of this report, "Hydro One Transmission" and "Hydro One Distribution" are used to differentiate the transmission and distribution accountabilities of Hydro One Networks Inc., respectively.

Figure 1-1: Map of Region



Source: Data provided by Hydro One Networks Inc.

In Ontario, planning to meet the electrical supply and reliability needs of a large area or region is done through regional electricity planning, a process that was formalized by the Ontario Energy Board ("OEB" or "Board") in 2013. In accordance with the OEB's regional planning process, transmitters, distributers and the IESO are required to carry out regional planning activities for the province's 21 electricity planning regions at least once every five years. The GTA East Region is one of these planning regions.

This IRRP identifies power system capacity and reliability requirements, and coordinates the options to meet customer needs in the sub-region over the next 20 years. Specifically, this IRRP identifies investments for immediate implementation necessary to meet near-term needs in the sub-region, respecting the lead time for development.

This IRRP also identifies planning considerations over the longer term. It does not identify or recommend any specific projects for the longer term at this time but maintains flexibility to meet longer-term needs as they arise by monitoring growth and impacts of conservation and distributed generation ("DG") uptake at area transformer stations.

This report is organized as follows:

- A summary of the recommended plan for the Pickering-Ajax-Whitby Sub-region is provided in Section 2;
- The process and methodology used to develop the plan is discussed in Section 3;
- The context for electricity planning in the Pickering-Ajax-Whitby Sub-region and the study scope are discussed in Section 4;
- Demand forecast scenarios, and conservation and DG assumptions, are described in Section 5;
- Electricity needs in the Pickering-Ajax-Whitby Sub-region are presented in Section 6;
- Alternatives and recommendations for meeting needs are addressed in Section 7;
- Considerations for meeting regional growth needs in the longer term are discussed as in Section 8;
- A summary of engagement carried out to date in developing this IRRP and moving forward is provided in Section 9; and
- A conclusion is provided in Section 10.

2. The Integrated Regional Resource Plan

This IRRP addresses the sub-region's electricity needs over the next two decades, based on application of the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC").[2] The IRRP identifies the needs that are forecast to arise in the near term (0-5 years or 2015 through 2020) and medium to long term (6-20 years or 2021 through 2034). The medium to longer term is referred to as the longer-term plan throughout this report as no distinct needs have been identified for the area past the near-term horizon. These two planning horizons are distinguished in the IRRP to reflect the level of commitment required to address needs over these time periods. The plans for both timeframes are coordinated to ensure consistency. The IRRP was developed based on consideration of planning criteria and input received during engagement with local communities and other stakeholders. The planning criterion includes technical feasibility, cost, reliability, and, in the near-term, the IESO sought to maximize the economic use of existing electricity infrastructure.

This IRRP identifies specific projects for implementation in the near- term. This is necessary to ensure that they are in-service in time to address the sub-region's more urgent needs while respecting the lead time for development of the recommended and required infrastructure.

The IRRP also identifies possible longer-term electricity needs and considerations to keep in mind for the next round of planning. In preparation for the longer term, actions are identified to gather information and lay the groundwork for future planning processes. These actions are intended to be completed before the next IRRP cycle so that their results can inform further consideration at that time.

The needs and recommended actions comprising the near-term plan, as well as the long-term plan, are summarized below.

[2] ORTAC Section 7.4 Application of Restoration Criteria - http://www.ieso.ca/Documents/marketAdmin/IMO_REQ_0041_TransmissionAssessmentCriteria.pdf

2.1 Near-Term Plan (Up to 2020)

> **Near-Term Needs**
>
> - Need for additional 27.6 kV transformation capacity to supply growth
> - Need to conduct analysis to assess the economic justification for addressing the restoration shortfall for the 30 minute and 4 hour timelines

By 2019, peak summer 27.6 kV electrical demand at Whitby TS is expected to exceed the Limited Time Rating[3] ("LTR") of the transformer that supplies electricity at the 27.6 kV level by 12 MW, increasing to 132 MW by end of the study period in 2034. This increased loading is chiefly influenced by the forecast growth in demand in the greenfield community of Seaton in North Pickering. As the transformation capacity need is triggered by a new growth pocket with no current access to transmission supply, the near-term plan considers options to provide additional 27.6 kV supply to meet the entire capacity need of the new Seaton community.

Currently, a portion of customers supplied from the circuits H24/26C and M29/B23C in the GTA East Region would not be able to be restored within ORTAC timelines for rare failure events at peak times. A restoration shortfall exists for the 30 minute and 4 hour timelines. The 2015 30 minute and 4 hour shortfalls are 49 MW and 64 MW for the H24/26C circuits and 81 MW and 29 MW for the M29/B23C circuits respectively. The near-term plan considers the relative benefit of wires options versus the status quo for the 30 minute and 4 hour restoration timelines for rare double element failure events.

Recommended Actions

1. Build a new 230/27.6 kV station and upgrade an existing 230 kV line

Action is required to provide additional 27.6 kV supply capacity for the sub-region, specifically in proximity to the greenfield community of Seaton. Feeders are currently being built from Whitby TS to the new load centre to provide some additional supply to Seaton, however, the 27.6 kV transformation capacity at Whitby TS is forecast to be exceeded by 2019 and additional 27.6 kV capacity will be required to meet the forecast demand. Based on the analysis, included as Appendix B and summarized in Section 7.1.3, it has been determined that the most economic

[3] LTR determines the capacity of a station to serve load

course of action is to construct a new 230/27.6 kV station and upgrade an existing 230 kV line in the proximity of Seaton by 2018 in order to meet the need for additional capacity in 2019 (hereinafter, this solution is referred to as “Seaton MTS”). An Environmental Assessment (“EA”), which is currently underway, will recommend the preferred site for Seaton MTS. Based on the anticipated needs and lead time required for approvals and construction, it is recommended that Hydro One and Veridian undertake further planning and project development along with approval for implementation of Seaton MTS.

2. Undertake further restoration analysis and recommend next steps as part of the RIP for the GTA East Region

Preliminary technical and economic analysis indicates that the cost of addressing the restoration shortfall may be less than the potential cost of prolonged supply interruptions to local electricity customers. This preliminary analysis accounted for the low likelihood of the rare failure event (the simultaneous and prolonged loss of two supply lines serving the area) and assumed the higher end of customer interruption costs.

Based on this preliminary analysis it is recommended that the transmission and distribution companies conduct detailed studies to determine if specific restoration facilities can be justified. These detailed studies should be conducted as part of the Regional Infrastructure Plan (“RIP”) for the GTA East Region and should consider outage statistics, associated wires solutions/costs and incremental reliability benefits.

2.2 Longer-Term Plan (2021-2034)

Over the long term, factors such as intensification of established areas, progress on community energy plans, conservation, DG uptake at the transformation station level and the electrification of the transportation sector could affect electrical service for the sub-region. These factors could impact the capacity of the existing electricity supply infrastructure. Near-term actions in order to prepare for the long term will focus on monitoring these factors.

3. Development of the IRRP

3.1 The Regional Planning Process

In Ontario, planning to meet the electricity needs of customers at a regional level is done through regional planning. Regional planning assesses the interrelated needs of a region - defined by common electricity supply infrastructure — over the near, medium and long term and develops a plan to ensure cost-effective and reliable electricity supply. Regional plans consider the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluate options for addressing needs and recommend actions.

Regional planning has been conducted on an as needed basis in Ontario for many years. Most recently, the Ontario Power Authority ("OPA") carried out regional planning activities to address regional electricity supply needs. The OPA conducted joint regional planning studies with distributors, transmitters, the IESO and other stakeholders in regions where a need for coordinated regional planning had been identified.

In the fall of 2012, the Ontario Energy Board ("OEB") convened the Planning Process Working Group ("PPWG") to develop a more structured, transparent and systematic regional planning process. This group was composed of industry stakeholders including electricity agencies, utilities and stakeholders. In May 2013, the PPWG released the Working Group Report to the Board ("PPWG Report"), setting out the new regional planning process. Twenty-one electricity planning regions in the province were identified in the Working Group Report and a phased schedule for completion was outlined. The Board endorsed the Working Group Report and in August 2013 formalized the process timelines through changes to the Transmission System Code and Distribution System Code, as well as through changes to the OPA's licence in October 2013. The OPA licence changes required it to lead a number of aspects of regional planning, including the completion of comprehensive IRRPs. Following the merger of the IESO and the OPA on January 1, 2015, the regional planning responsibilities identified in the OPA's licence were transferred to the IESO.

The regional planning process begins with a Needs Screening process performed by the transmitter, which determines whether there are needs requiring regional coordination. If regional planning is required, the IESO then conducts a Scoping Assessment to determine whether a comprehensive IRRP is required, which considers conservation, generation, transmission and distribution solutions, or whether a "wires" solution is the best option. If the

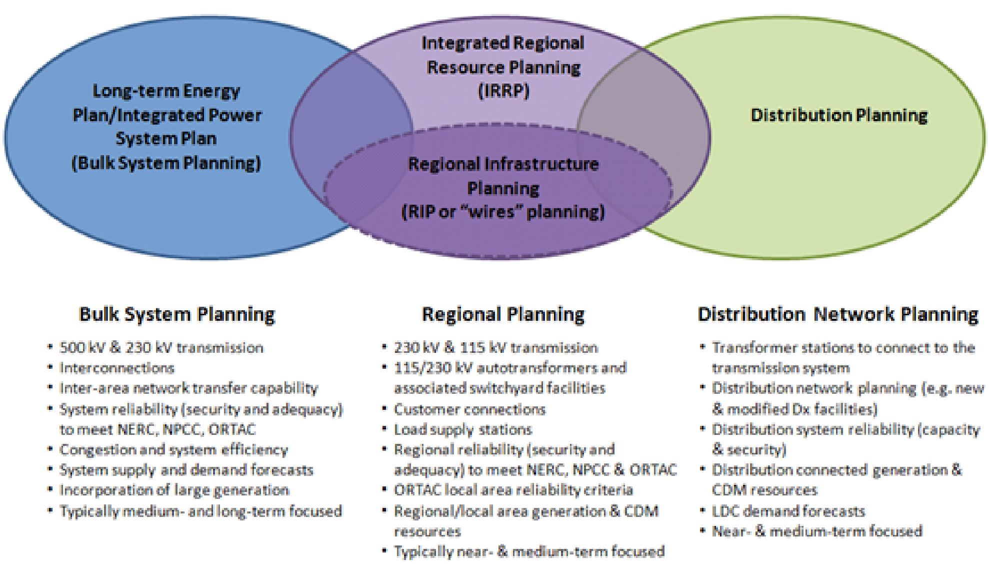
IESO recommends a wires solution, then a transmission- and distribution-focused RIP is developed. The Scoping Assessment process also identifies any sub-regions that require assessment. There may also be regions where infrastructure investments do not require regional coordination and can be planned directly by the distributor and transmitter, outside of the regional planning process. At the conclusion of the Scoping Assessment process, the IESO produces a report that includes the results of the Needs Screening process – identifying whether an IRRP, RIP or no regional coordination is required – and a preliminary Terms of Reference. If an IRRP is recommended, then the IESO is required to complete the IRRP within 18 months. If a RIP is required, the transmitter takes the lead and has six months to complete it following the completion of the IRRP. Both RIPs and IRRPs must be updated at least every five years.

The final IRRPs and RIPs must be posted on the IESO and relevant transmitter websites and can be used as supporting evidence in a rate application or leave to construct. They may also be used by municipalities for planning purposes and by other parties to facilitate a better understanding of local electricity growth and infrastructure requirements.

Regional planning, as shown in Figure 3-1, is just one forms of electricity planning that is undertaken in Ontario. There are three types of electricity planning in Ontario:

- Bulk system planning
- Regional system planning
- Distribution system planning

Figure 3-1: Levels of Electricity System Planning



Planning at the bulk system level typically considers the 230 kV and 500 kV network. Bulk system planning considers the major transmission facilities and assesses the resources needed to adequately supply the province. Bulk system planning is typically carried out by the IESO in accordance with government policy. Distribution planning, which is carried out by local distribution companies, looks at specific investments on the low voltage, distribution system.

Regional planning can overlap with bulk system planning. For example, overlap can occur at interface points where regional resource options may also address a bulk system issue. Similarly, regional planning can overlap with the distribution planning of LDCs. An example of this is when a distribution solution addresses the needs of the broader local area or region. Therefore, to ensure efficiency and cost effectiveness, it is important for regional planning to be coordinated with both bulk and distribution system planning.

By recognizing the linkages with bulk and distribution system planning and coordinating multiple needs identified within a given region over the long term, the regional planning process provides an integrated assessment of needs. Regional planning aligns near and long-term solutions and allows specific investments recommended in the plan to be understood as part of a larger context. Furthermore, regional planning optimizes ratepayer interests by avoiding piecemeal planning and asset duplication and allows Ontario ratepayers' interests to be represented along with the interests of LDC ratepayers. Where IRRPs are undertaken, they allow an evaluation of the multiple options available to meet needs, including conservation, generation and "wires" solutions. Regional plans also provide greater transparency through engagement in the planning process and by making plans available to the public.

3.2 The IESO's Approach to Regional Planning

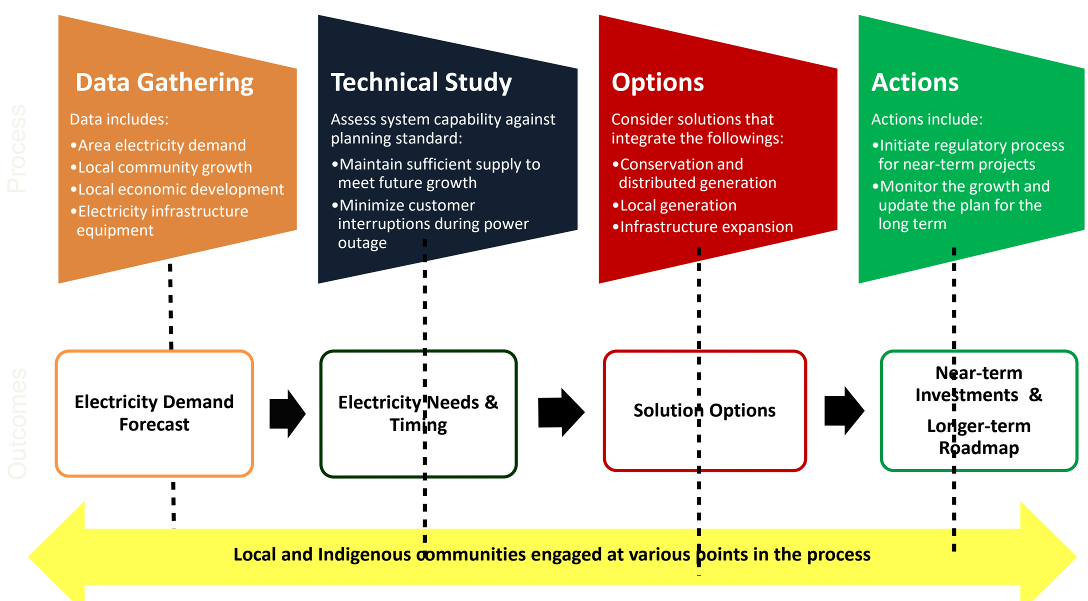
IRRPs assess electricity system needs for a region over a 20-year period. The 20-year outlook anticipates long-term trends so that near-term actions are developed within the context of a longer-term view. This enables coordination and consistency with the long-term plan, rather than simply reacting to immediate needs.

In developing an IRRP, a different approach is taken to developing the plan for the first 10 years of the plan than for the longer-term period of 10-20 years. The plan for the first 10 years is developed based on best available information on demand, conservation and other local developments. Given the long lead time to develop electricity infrastructure, near-term electricity needs require prompt action to enable the specified solutions in a timely manner. By contrast, the long-term plan is characterized by greater forecast uncertainty and longer development lead time, as such solutions do not need to be committed to immediately. Given the potential for changing conditions and technological development, the IRRP for the long term is more directional, focusing on developing and maintaining the viability of options for the future and continuing to monitor demand forecast scenarios.

In developing an IRRP, the IESO and technical working group (see Figure 3-2 below) carry out a number of steps. These steps include electricity demand forecasts; technical studies to determine electricity needs and the timing of these needs; the development of potential options; and a recommended plan including actions for the near and long term. Throughout this process, engagement is carried out with stakeholders and First Nation and Métis communities who may have an interest in the region. The steps of an IRRP are illustrated in Figure 3-2.

The IRRP report documents the inputs, findings and recommendations developed through the process described above and provides recommended actions for the entities responsible for plan implementation. Where "wires" solutions are included in the plan recommendations, the completion of the IRRP report is the trigger for the transmitter to initiate an RIP process. Other recommendations in the IRRP may include: development of conservation, local generation, or other solutions; community engagement; or information gathering to support future iterations of the regional planning process in the region.

Figure 3-2: Steps in the IRRP Process



3.3 Pickering-Ajax-Whitby Sub-region Working Group and IRRP Development

The initial impetus for the sub-region IRRP was a 2014 Needs Screening report for GTA East. This report was produced by Hydro One Transmission with input from the OPA and IESO, Veridian, Whitby Hydro, Oshawa PUC and Hydro One Distribution. The Needs Screening was carried out to identify any needs which required coordinated regional planning. The Needs Screening Report found that there were needs which potentially required regional coordination, therefore the former OPA conducted a Scoping Assessment process and issued a Scoping Assessment Report in December 2014, in which it identified needs in the Pickering-Ajax-Whitby Sub-region that should be further assessed through an IRRP.

In late 2014 the Working Group was formed to develop a Terms of Reference for the IRRP, gather data, identify near to long-term needs in the sub-region, and develop the near-term recommend actions included in this IRRP.

4. Background and Study Scope

This report presents an IRRP for the Pickering-Ajax-Whitby Sub-region for the 20-year period from 2015 to 2034.

The IRRP planning approach for this sub-region was determined during the GTA East Region Scoping Assessment process. The combination of greenfield growth in North Pickering and supply capacity limitations in the area triggered the need for a coordinated approach by way of an IRRP for the sub-region.

A greenfield community -Seaton is planned to be developed in north Pickering, just north of the Cherrywood TS, within Veridian's service territory. This development is being planned for residential capacity for up to 70, 000 people and 35,000 jobs. Veridian plans to supply this new community load at 27.6 kV. Hydro One and Veridian assessed the station capacity requirements and plans for a proposed new 230/27.6 kV station called "Seaton MTS" prior to the regional planning process for the sub-region. Further assessment of the 27.6 kV supply situation was undertaken as part of this IRRP.

To set the context for this IRRP, the scope of this IRRP and the sub-region's existing electricity system are described in Section 4.1.

4.1 Study Scope

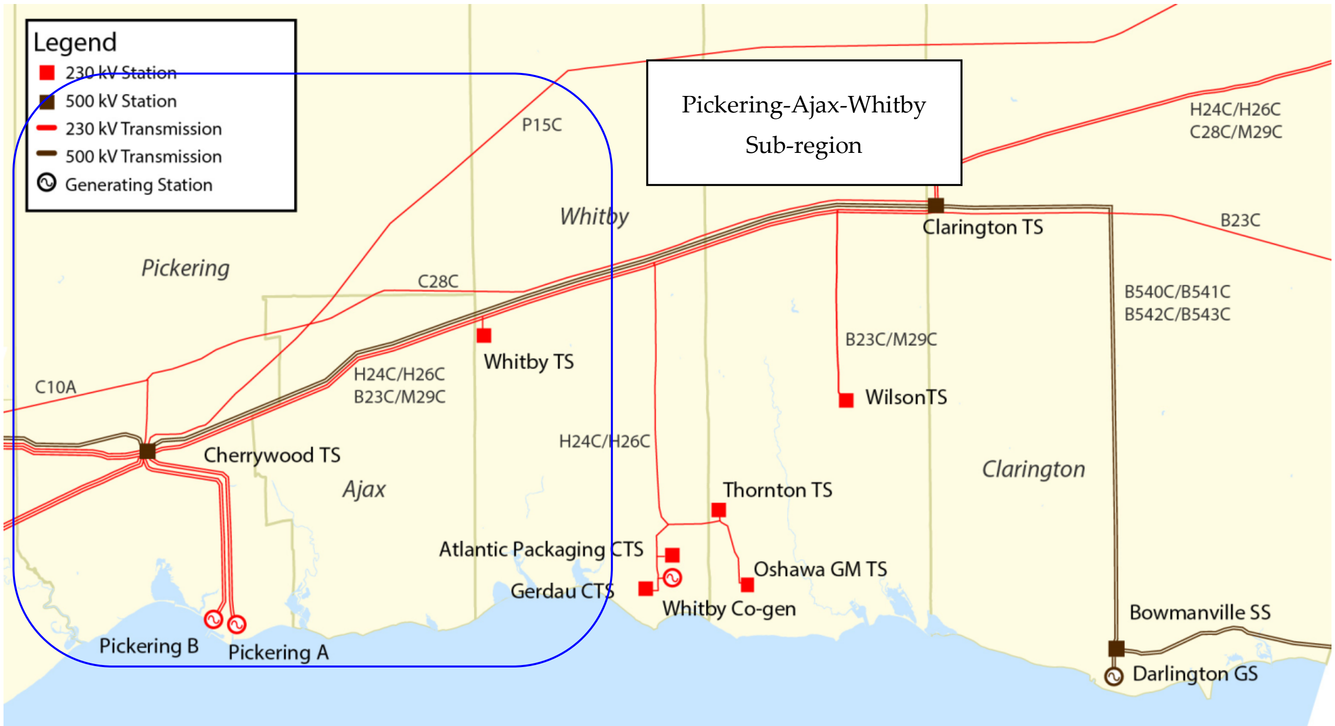
This IRRP recommends options to meet supply needs of the sub-region in the near, and longer term. The plan is a joint initiative involving the Working Group members, the IESO, Veridian, Whitby Hydro, Hydro One Distribution and Hydro One Transmission, and incorporates input from other stakeholders. The plan takes into account forecast electricity demand growth, conservation and demand management ("CDM" or "conservation") in the area, transmission and distribution system capability, relevant community plans, developments on the bulk transmission system, FIT and other generation uptake through province-wide programs.

This IRRP addresses regional needs in the sub-region, including capacity, security, reliability and relevant end-of-life consideration of assets.

The following transmission facilities are included in the plan scope and illustrated in Figure 4-1:

- Stations—Cherrywood TS, Whitby TS
- Transmission circuits—H24/26C and M29/B23C

Figure 4-1: Regional Transmission Facilities



Source: Data provided by Hydro One Networks Inc.

The IRRP was developed by completing the following steps:

- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe.
- Examining the capacity and reliability of the existing transmission system supplying the sub-region, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC.
- Establishing feasible integrated alternatives to address needs, including a mix of conservation, generation, transmission and distribution facilities, and other electricity system initiatives.
- Evaluating options using planning criteria which may include: technical feasibility, cost, reliability performance, environmental and social factors.
- Conducting community engagement to obtain local input on options for meeting the needs.
- Developing and communicating findings, conclusions, and recommendations.

Figure 4-2 below shows the electrical configuration of the main stations, supply sources, and transmission assets for the GTA East Region as a single line diagram. Note that the needs analysis includes Clarington TS which is currently under construction and is expected to be in-service for 2018.

5. Demand Forecast

This section outlines the forecast of electricity demand for the Pickering-Ajax-Whitby Sub-region. It highlights the assumptions made for peak-demand load forecasts and the contributions of conservation and DG to reducing peak demand. The resulting net demand forecast is used in assessing the electricity needs of the area over the planning horizon.

To evaluate the adequacy of the electricity system, the regional planning process involves measuring the demand observed at each station for the hour of the year when overall demand in the study area is at a maximum. This is called "coincident peak demand" and represents the moment when assets are most stressed and resources most constrained. This differs from a non-coincident peak, which is measured by summing each station's individual peak, regardless of whether the stations' peaks occur at different times of the area's overall peak.

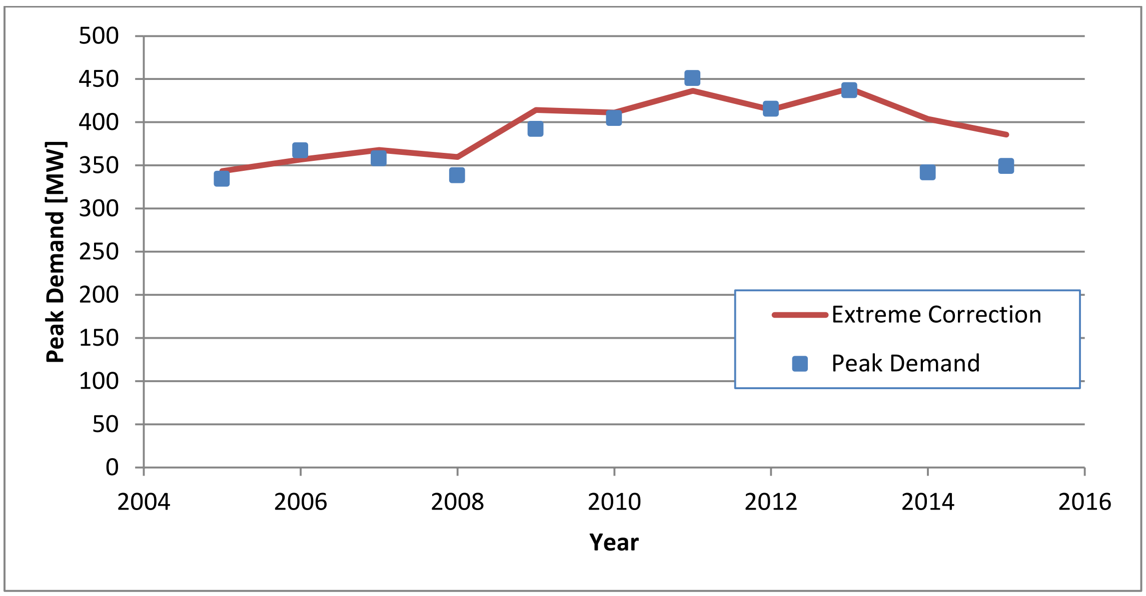
Within the sub-region, the peak loading hour for each year typically occurs in the early-evening of the hottest weekday during the summer. This typically occurs on the same day as the overall provincial peak, but may occur at a different hour in the day. The 2015 regional peak occurred on July 30 at 5:00 pm. Although a large group of industrial customers exists in the GTA East Region, both the regional and sub-regional peak is generally driven by the air conditioning loads of residential and commercial customers. The introduction of the IESO's Industrial Conservation Initiative program in recent years has decreased the overall effect of industrial customer load during peak hours.

Section 5.1 begins by describing the historic electricity demand trends in the sub-region from 2005 to 2015. Section 5.2 describes the demand forecast used in this study and the methodology used to develop it.

5.1 Historical Demand

The sub-region has seen steady demand growth since 2005. The peak demand in this sub-region is heavily driven by weather conditions. Residential and commercial customers combine for approximately 80% of the load in the area and during the summer months, load from air conditioning drives the peak demand. The recent decline in peak demand during 2014 and 2015 can be attributed to the cool summers experienced across the GTA and province-wide. The peak day temperature in 2014 and 2015 averaged 29.4 degrees Celsius, compared to 34.2 degrees Celsius from 2010 to 2013.

Figure 5-1: Historical Peak Demand in Pickering-Ajax-Whitby Sub-region



The red line in Figure 5-1 shows the weather corrected customer demand for the same hour as the actual peak demand. The weather corrected line has been adjusted to reflect the expected behaviour of the load under extreme weather conditions. Correction factors between actual and extreme conditions are produced on a zonal basis by Hydro One, the transmitter in this area.

5.2 Demand Forecast Methodology

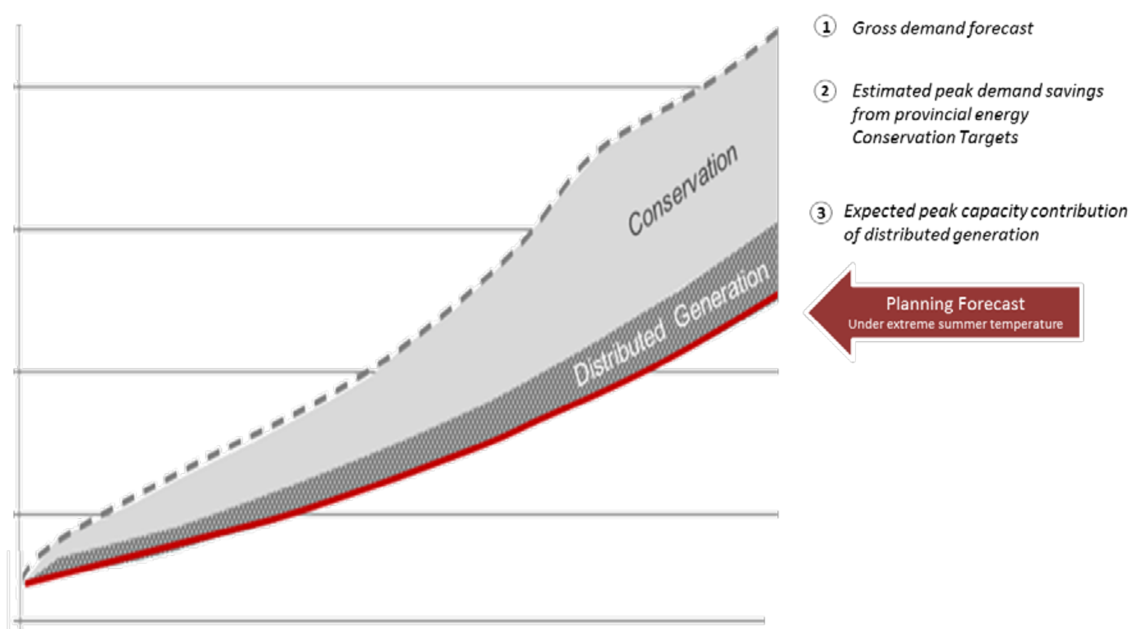
For the purpose of this IRRP, a 20-year planning forecast was developed to assess supply and reliability needs at the regional level.

Regional electricity needs are driven by the limits of the infrastructure supplying an area, which is sized to meet peak-demand requirements. Regional planning typically focuses on growth in regional-coincident peak demand. Energy adequacy is usually not a concern of regional planning, as the region can generally draw upon energy available from the provincial electricity grid, with energy adequacy for the province being planned through a separate process.

The 20-year planning forecast is divided notionally into two timeframes. The near (0-5 years or 2015 through 2020) and medium to long term (6-20 years or 2021 through 2034).

The sub-region's peak demand forecast was developed as shown in Figure 5-2. Gross demand forecasts, assuming normal-year weather conditions, were provided by the LDCs and the transmission-connected customers in the LDCs' service territory. The LDCs' forecasts are based on growth projections included in regional and municipal plans, which in turn reflect the province's Places to Grow policy. These forecasts were then modified to produce a planning forecast - i.e., they were adjusted to reflect the peak demand impacts of provincial conservation targets and DG contracted through provincial programs such as FIT and microFIT, and to reflect extreme weather conditions where necessary. The planning forecast was then used to assess any growth-related electricity needs in the sub-region.

Figure 5-2: Development of Demand Forecast



Using a planning forecast that is net of provincial conservation targets is consistent with the province's Conservation First policy. However, this assumes that the targets will be met and that the targets, which are energy-based, will produce the corresponding local peak demand impacts. An important aspect of plan implementation will be monitoring the actual peak demand impacts of conservation programs delivered by the local LDCs and, as necessary, adapting the plan.

Additional details related to the development of the demand forecasts are provided in Appendix A.

5.3 Gross Demand Forecast

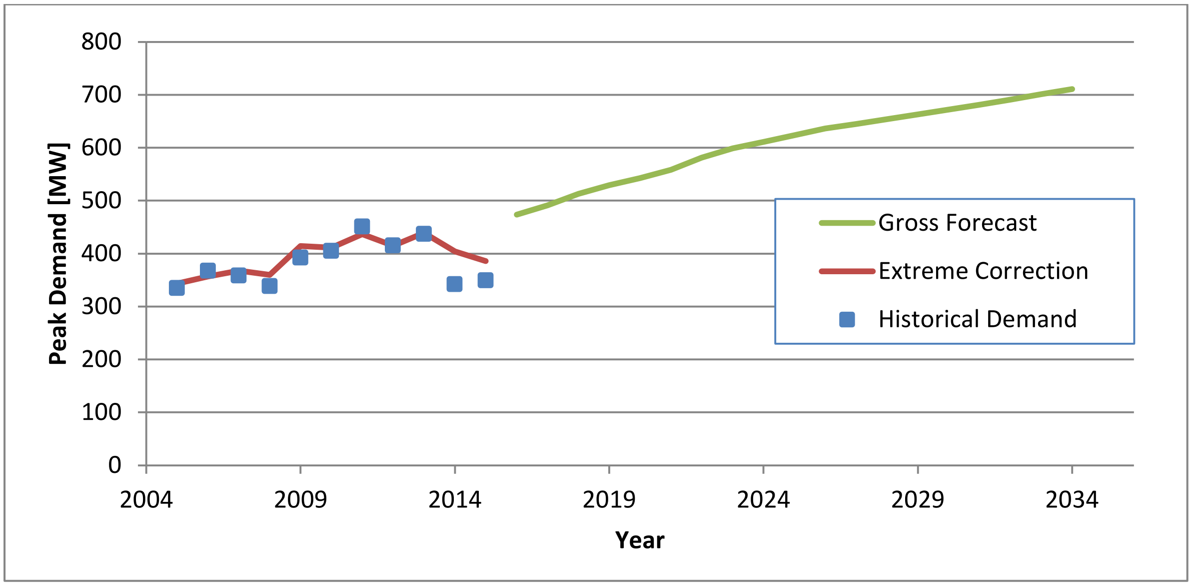
Each participating LDC and transmission-connected customer in the LDCs' service territories prepared gross demand forecasts at the TS level or bus level for multi-bus stations. Gross demand forecasts account for the increases in demand from new or intensified development, but do not account for the impact of new conservation measures such as codes & standards or demand response ("DR") programs. LDCs are only expected to account for changes in consumer demand resulting from efficiency improvements and increasing electricity prices, known as "natural conservation".

Since LDCs have the most direct experience with customers and applicable local growth expectations, their information is considered the most accurate for regional planning purposes. Most LDCs cited alignment with municipal and regional official plans as a primary source for input data. Other common considerations included known connection applications and typical electrical demand intensity for similar customer types.

The graph below shows the gross demand forecast provided by the LDCs[4] for the sub-region, with historical data points for comparison. The demand in the sub-region is serviced by Whitby TS and Cherrywood TS. Whitby TS is split into two DESNs and provides supply at both 27.6 kV and 44.0 kV levels, while Cherrywood TS only provides supply at the 44.0 kV level.

[4] Forecasts are subject to change as population information continues to be updated as part of provincial and local growth plan reviews

Figure 5-3: Sub-region Gross Demand Forecast



Both the weather corrected peak and historical demand shows that demand in the sub-region has been generally increasing over the past decade, with a slight dip in the most recent year. However, the data for summer of 2014 and 2015 should be regarded as less reliable due to abnormally cool summer conditions. Although an extreme weather correction has been applied in all cases, these methodologies are generally not designed to make such extreme adjustments.

The total annual growth for this area averages 2.3% over the 20-year planning horizon. The highest growth is forecast to occur in the near term (year 0-5) at a rate of 3.7%. The demand growth decreases to 2.8% in the medium term (year 5-10) and further declines to 1.5% for the last 10 years of the planning period.

Demand growth in the sub-region is driven by a series of development projects which include the new community of Seaton, and various intensification projects in Pickering, Ajax and Whitby[5]. The new community of Seaton is envisioned as sustainable urban community[6] and is forecast to account for 22% of the total demand in the sub-region by 2034. The resulting demand of this new development will be initially serviced by available 27.6 kV capacity at Whitby TS, but is expected to exceed station capacity in 2019 as shown in Figure 5-4.

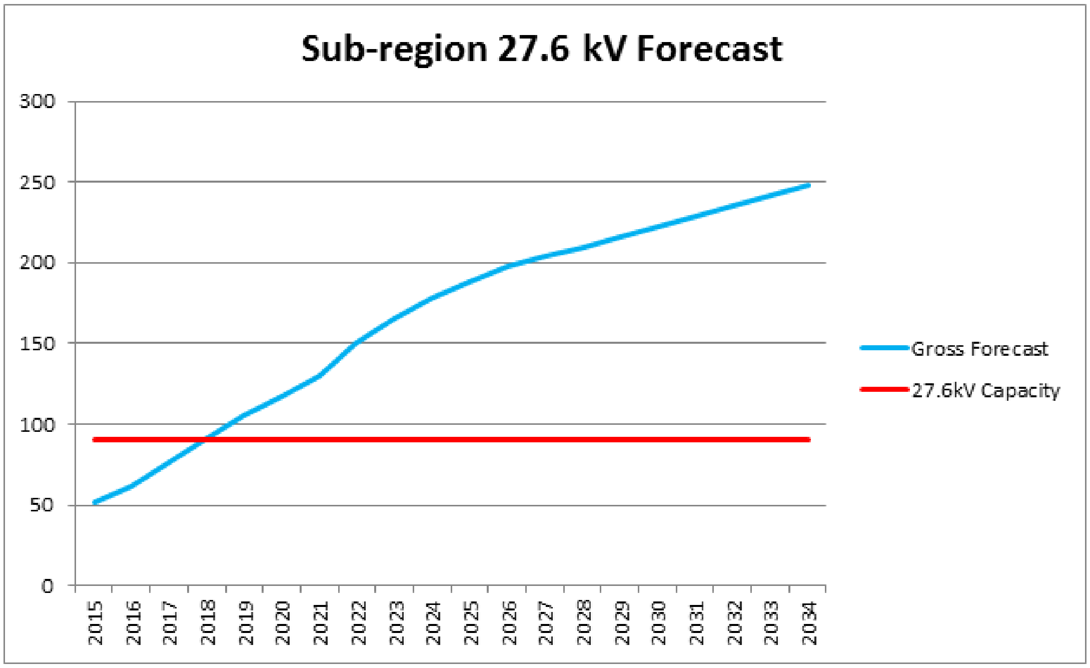
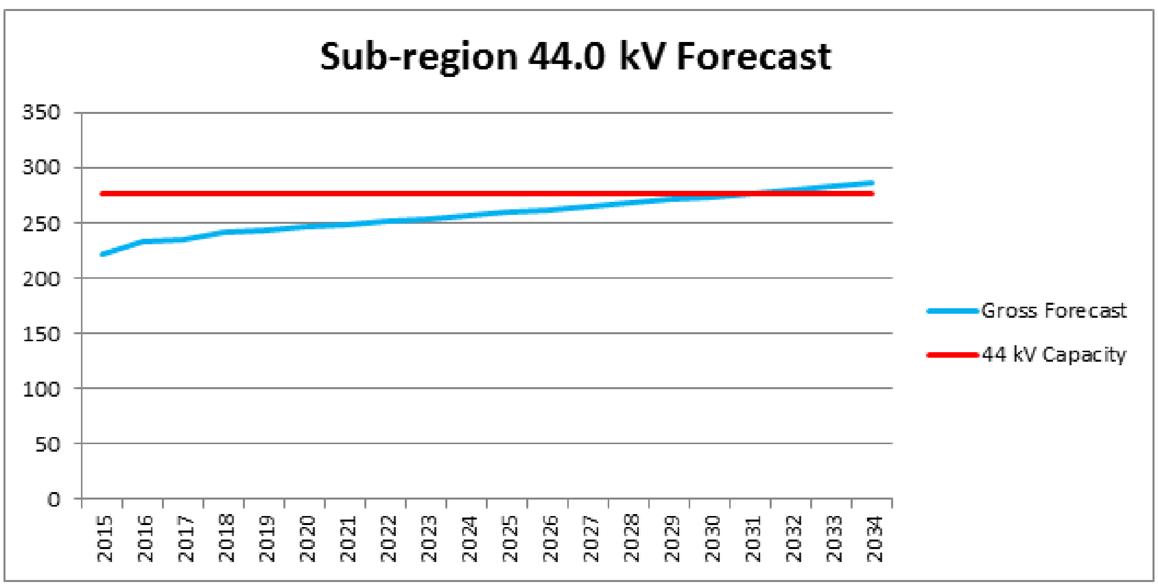
Figure 5-4: Sub-region 27.6 kV Gross Forecast



The 44.0 kV demand in the area is supplied by Whitby TS and Cherrywood TS, and the 44 kV capacity is expected to be sufficient to supply forecast demand into the longer term.

Figure 5-5: Sub-region 44.0 kV Gross Forecast



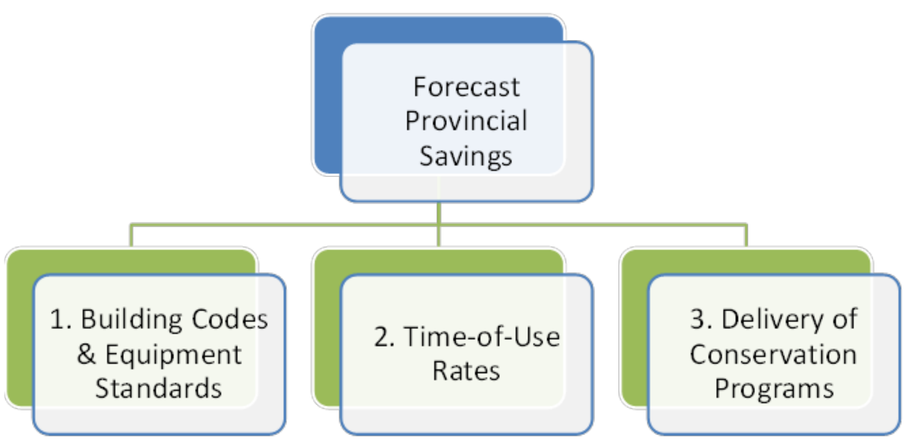
The gross demand forecasts provided by the LDCs, and forecast methodology are provided in Appendix A.

5.4 Conservation Assumed in the Forecast

Conservation is the first resource considered in planning, approval and procurement processes. It plays a key role in maximizing the utilization of existing infrastructure and maintaining reliable supply by keeping demand within equipment capability. Conservation is achieved through a mix of program-related activities, rate structures, and mandated efficiencies from building codes and equipment standards. The conservation savings forecast for the sub-region have been applied to the gross peak demand forecast, along with DG resources (described in Section 5.5), to determine the net peak demand or planning forecast for the sub-region.

In December 2013 the Ministry of Energy released a revised LTEP that outlined a provincial conservation target of 30 terawatt-hours ("TWh") of energy savings by 2032. A portion of this province-wide energy conservation target was allocated to the sub-region, and, as further described below, it was further converted to an estimated peak demand reduction for the sub-region. The expected peak demand savings for the sub-region are shown below in Table 5-1. To estimate the impact of the conservation savings in the area, the forecast provincial savings were divided into three main categories:

Figure 5-6: Categories of Conservation Savings



1. *Savings due to Building Codes & Equipment Standards*
2. *Savings due to Time of Use Rate structures*
3. *Savings due to the delivery of Conservation Programs*

The 2013 LTEP committed to establishing a new 6-year Conservation First Framework ("CFF") beginning in January 2015 to enable the achievement of all cost-effective conservation. In the near-term, Ontario's LDCs have an aggregate energy reduction target of 7 TWh, as well as individual LDC specific targets. These targets are to be achieved between 2015 and the end of 2020 through LDC conservation programs enabled by the CFF. Each LDC was required to prepare a Conservation and Demand Management ("CDM") plan by May 1, 2015 describing how their target will be achieved. LDCs are also required to provide updates to their CDM plans.

As part of the Conservation First policy, the provincial government has adopted a broad definition of conservation that includes various types of customer action and behind-the-meter generation. This means that conservation includes any programs or mechanisms that reduce the amount of energy consumed from the provincial electricity grid. Conservation initiatives, including behind the meter generation projects and on-site generation, are expected to reduce customers' reliance on the provincial electricity grid and contribute to peak demand savings in the sub-region.

To provide a more regional specific forecast, the impact of the savings for each category were broken down by the residential, commercial and industrial customer sectors. The IESO then worked together with area LDCs to establish a methodology to estimate the electrical demand impacts of the energy targets by the three customer sectors. This provides a better resolution of the forecast conservation, as conservation potential varies by sector due to different energy consumption characteristics and conservation opportunities.

For the sub-region, LDCs were requested to provide their gross demand forecast and provide the breakdown of their demand forecast by sector at each TS based on their knowledge of local customers. For TSs that an LDC cannot provide gross load segmentation for, the IESO and the LDC worked together using best available information and assumptions to derive sectoral gross demand. For example, LDC information found in the OEB's Yearbook of Electricity Distributors[7] was used to help estimate the breakdown of demand. Once sector gross demand at each TS was available, the next step was to estimate peak demand savings for each conservation category: codes and standards, time-of-use rate, and conservation programs. The estimates for each of these categories were done separately due to their unique characteristics and data availability. In general, hourly profiles of IESO's gross forecast and conservation

[7] OEB Yearbook of Electricity Distributors: http://www.ontarioenergyboard.ca/OEB/Industry/Rules+and+Requirements/Reporting+and+Record+Keeping+Requirements/Yearbook+of+Distributors

savings were used to determine the impact that each conservation category has on peak demand. Impacts were estimated for residential, commercial and industrial sectors reflecting that various sectors have different conservation opportunities.

The planning forecast assumes that the targets will be met, and will produce the expected local peak demand impacts. Therefore, an important aspect of plan implementation will be monitoring the actual peak demand impacts of conservation programs delivered by the LDCs.

The table below shows the final estimated conservation peak demand savings, which were applied to the gross demand to create the net forecast for the sub-region.

Table 5-1: Peak Demand Savings from 2013 LTEP Conservation Targets, Select Years

Year	2016	2018	2020	2022	2024	2026	2028	2030	2032	2034
Total East GTA Savings (MW)	33	57	74	92	111	134	154	174	184	185
Sub-region Only Savings (MW)	6	14	24	33	44	55	64	72	77	78

Over the 20-year time period, it is expected that conservation savings for the GTA East planning region will amount to the deferral of one TS the size of Cherrywood TS. For the sub-region the conservations savings over the study period are expected to amount to approximately 40% of the capacity provided by a station similar to Cherrywood TS

Additional conservation forecast details are provided in Appendix A.

5.5 Distributed Generation Assumed in the Forecast

In addition to conservation resources, DG in the Pickering-Ajax-Whitby Sub-region is also anticipated to help offset peak demand requirements at select stations. The introduction of the *Green Energy Act, 2009* and the associated development of Ontario's FIT program, have increased the significance of distributed renewable generation in Ontario. This generation, while intermittent in nature, contributes to meeting the electricity demands of the province.

In developing the planning forecast, after applying the conservation savings to the gross demand forecast as described above, the forecast is further reduced by the expected peak contribution from existing and contracted DG in the area. The effects of projects that were already in-service prior to the base year of the gross demand forecast were not included as they are already embedded in the gross demand forecast which is the starting point for the planning forecast. Potential future DG uptake was not included and is instead considered as an option for meeting identified needs.

Based on the IESO contract list as of August 2015, existing and contracted DG projects are expected to offset an incremental 18 MW of peak demand within the sub-region. The largest project in the sub-region is a renewable biomass generator in Ajax with the capability to generate up to 25 MW, and currently contracted for 18 MW. Other projects in the area are small scale solar projects (<500 kW). Table 5-2 shows the DG by technology that is currently under contract in the sub-region.

Table 5-2: Distributed Generation by Technology in the Pickering-Ajax-Whitby Sub-region

Technology	Contract Capacity [MW]	Capacity Contribution [MW]	Capacity Factor
Solar	2	1	32%
Renewable Biomass	18	17	98%

The capacity contribution for each DG project was calculated by applying a capacity factor based on fuel type to the contracted capacity of each project. The capacity factors used in this study are based on historical data gathered during Ontario's overall system peak.

In the sub-region, all of the DG projects are planned to be connected to Whitby TS to help offset some of the load during peak demand hours. Currently, new DG connection is restricted from connecting to Cherrywood TS due to short circuit ("SC") constraints because of an out-of-service 30 MW landfill gas generation facility. Hydro One is in discussions with the land and facility owner and is seeking legal and regulatory advice on the process for the removal of this allocated capacity. If capacity allocation is removed, the SC restriction can be lifted and new DG can apply to connect to this station.

The following table shows the cumulative DG in the sub-region.

Table 5-3: Cumulative DG used for Planning Forecast

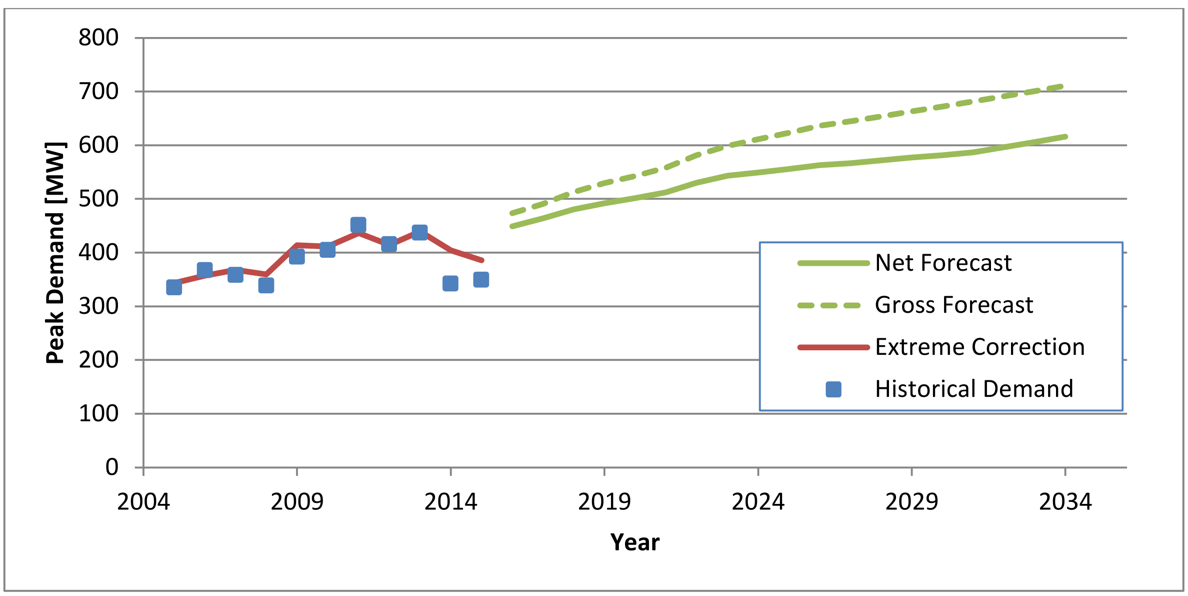
Year	2015	2016	2017	2018	2019	2020	2034
Pickering-Ajax-Whitby [MW]	18	18	18	18	18	18	18

5.6 Planning Forecasts

A 20-year planning forecast was produced based on the LDCs' gross demand forecasts and net of anticipated conservation and DG.

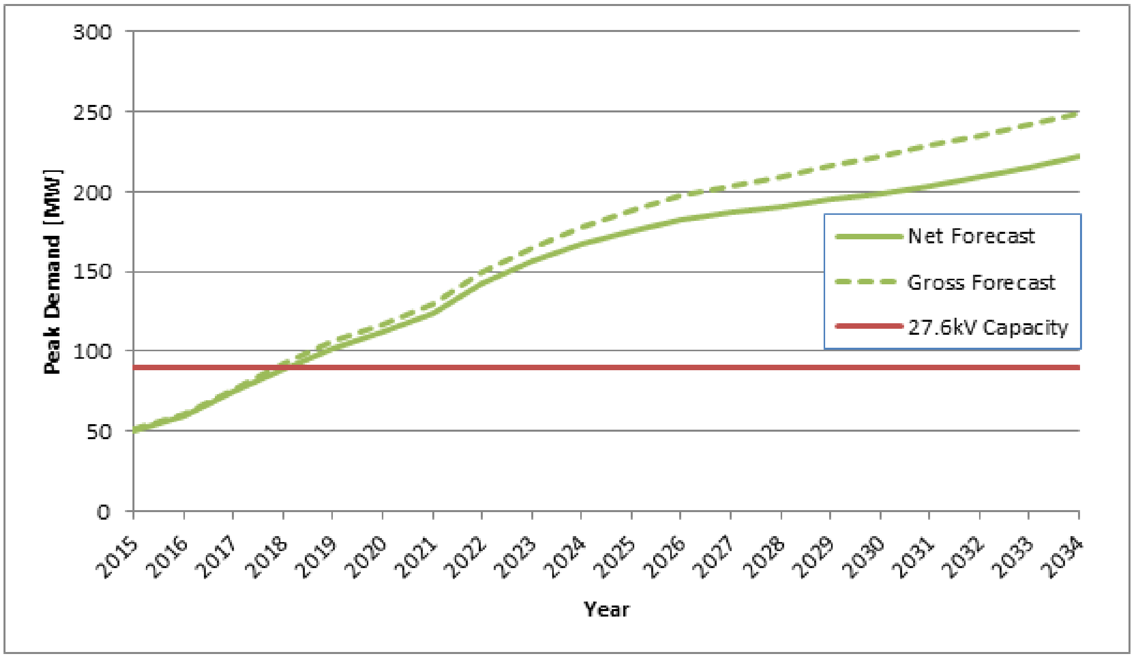
Figure 5-7 illustrates the planning forecast, along with historical demand for the sub-region. The combined effects of DG and conservation are expected to reduce the peak demand in the Pickering-Ajax-Whitby Sub-region by 95 MW by the end of the planning period in 2034. This corresponds to 13% of the overall gross demand in 2034 of 711 MW.

Figure 5-7 Pickering-Ajax-Whitby Sub-region Planning Forecast



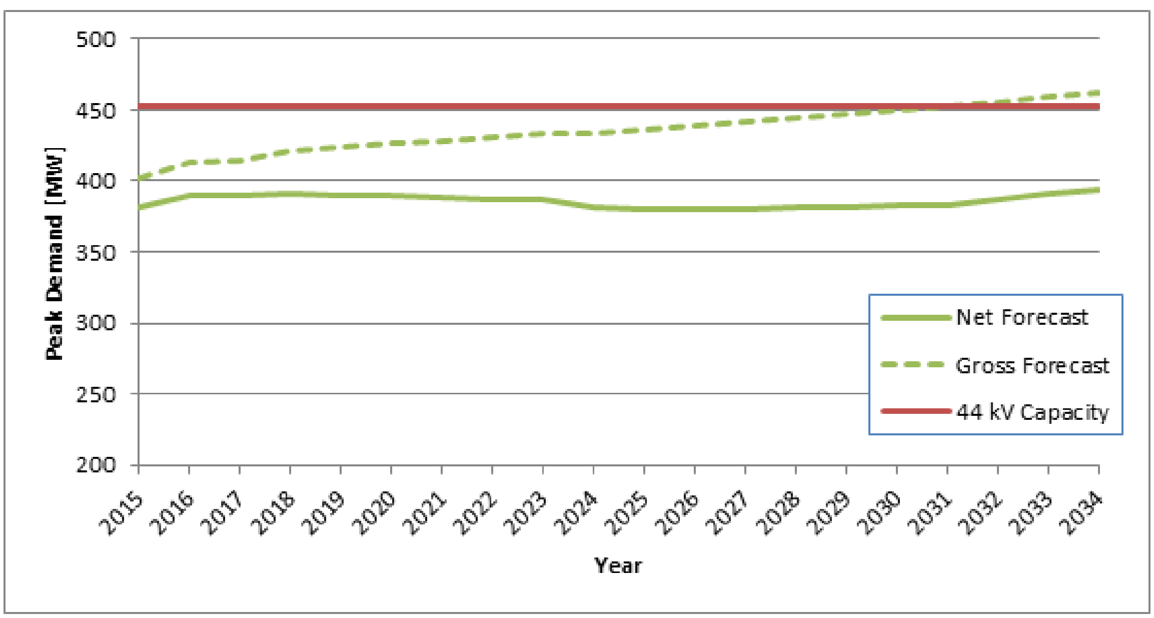
The net 20-year planning forecast for the 27.6 kV load serviced by Whitby TS is shown below in Figure 5-8. By 2034 the combined effects of DG and conservation are expected to decrease the peak demand by 27 MW; this accounts for 11% of the gross demand in 2034.

Figure 5-8 Pickering-Ajax-Whitby Sub-region 27.6 kV Planning Forecast



The net 20-year planning forecast for the 44.0 kV load serviced by Whitby TS and Cherrywood TS is shown in Figure 5-9 below. By 2034 the combined effects of DG and Conservation are expected to decrease the peak demand by 50 MW; these effects account for 15% of the gross demand in 2034.

Figure 5-9 Pickering-Ajax-Whitby Sub-region 44.0 kV Planning Forecast



6. Needs

The Pickering-Ajax-Whitby Sub-region Working Group identified two electricity needs in the near-term, based on the planning forecasts, system capability and application of planning criteria. This section describes the identified needs for the near-term in the sub-region.

6.1 Needs Assessment Methodology

The IESO's ORTAC[8] was applied to assess supply capacity and reliability needs. ORTAC includes criteria related to the assessment of the bulk transmission system, as well as the assessment of local or regional reliability requirements.

The application of these criteria in an area is used to generally identify three broad categories of needs as follows:

- **Transformer Station Capacity** describes the electricity system's ability to deliver power to the local distribution network through the regional transformer stations. This is limited by the 10-day LTR of the step-down transformer stations in the local area. Transformer station capacity need arises when the peak demand at step-down transformer stations in the local area exceeds the combined LTR ratings.
- **Upstream Transmission System Capacity** describes the electricity system's ability to provide continuous supply to a local area. This is limited by the load meeting capability ("LMC") of the transmission line or sub-system and is the maximum demand that can be supplied on a transmission line or sub-system under applicable transmission and generation outage scenarios as prescribed by ORTAC; it is determined through power system simulations analysis (See **Appendix D** for more details). These capacity needs arise when coincident peak demand on a transmission line or sub-system exceeds its LMC.
- **Load Security and Restoration** describes the electricity system's ability to minimize the impacts of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the amount of load susceptible to supply interruptions in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes.

---

[8] http://www.ieso.ca/imoweb/pubs/marketadmin/imo_req_0041_transmissionassessmentcriteria.pdf

6.2 Needs

Two needs were identified in the area which impact the ability to serve local loads:

1. There is a need arising in 2019 for additional 27.6 kV TS capacity to supply new growth.
2. There is a need to conduct detailed analysis to assess the economic justification for addressing a restoration shortfall (MW) that exists in the GTA East Region for rare loss of supply events.

6.2.1 Transformer Station Capacity-27.6 kV

The sub-region is supplied by two stations, Cherrywood TS and Whitby TS. These stations step down the voltage from 230 kV to either the 27.6 kV or 44 kV distribution levels. The Cherrywood TS provides supply at the 44 kV level while Whitby TS provides supply at the 27.6kV and 44 kV levels. Whitby Hydro provides distribution service at the 44 kV level, however Veridian uses both voltage levels to supply its service territory;. Dedicated 27.6 kV feeders from Malvern TS and Sheppard TS also supply the western portion of Veridian's service territory. These two stations are in the eastern part of an adjacent planning region-Metro Toronto.

Figure 6-1 and Figure 6-2 below show the historical and forecast 44 kV peak demand for the study area. Based on the planning forecast, sufficient 44 kV capacity exists to supply current and forecast 44 kV demand in the area until the end of the study period.

Figure 6-1: Planning Forecast for Cherrywood TS 44.0 kV

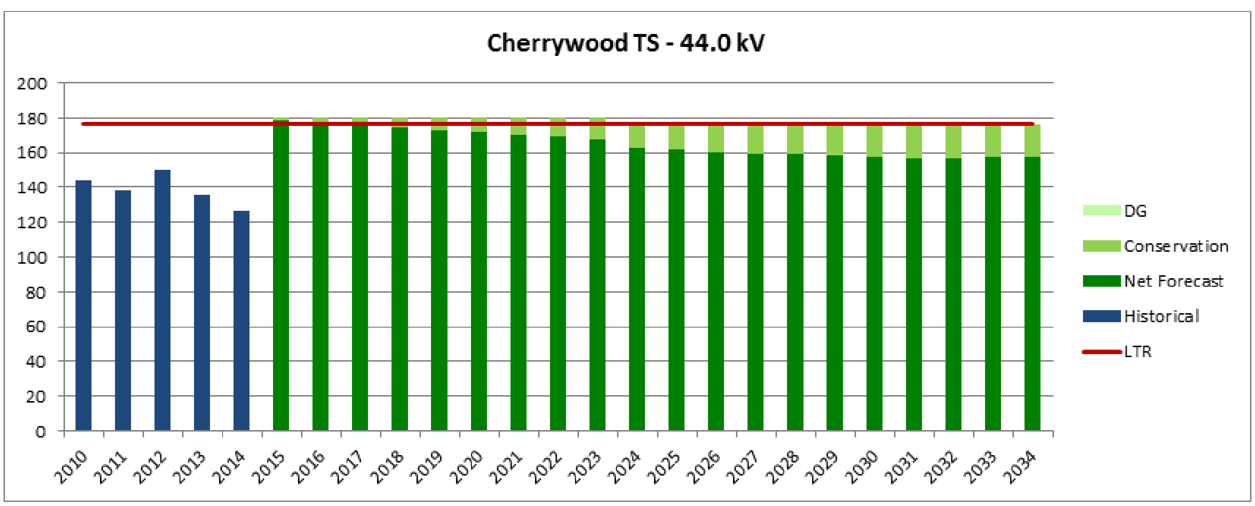


Figure 6-2: Planning Forecast for Whitby TS 44.0 kV

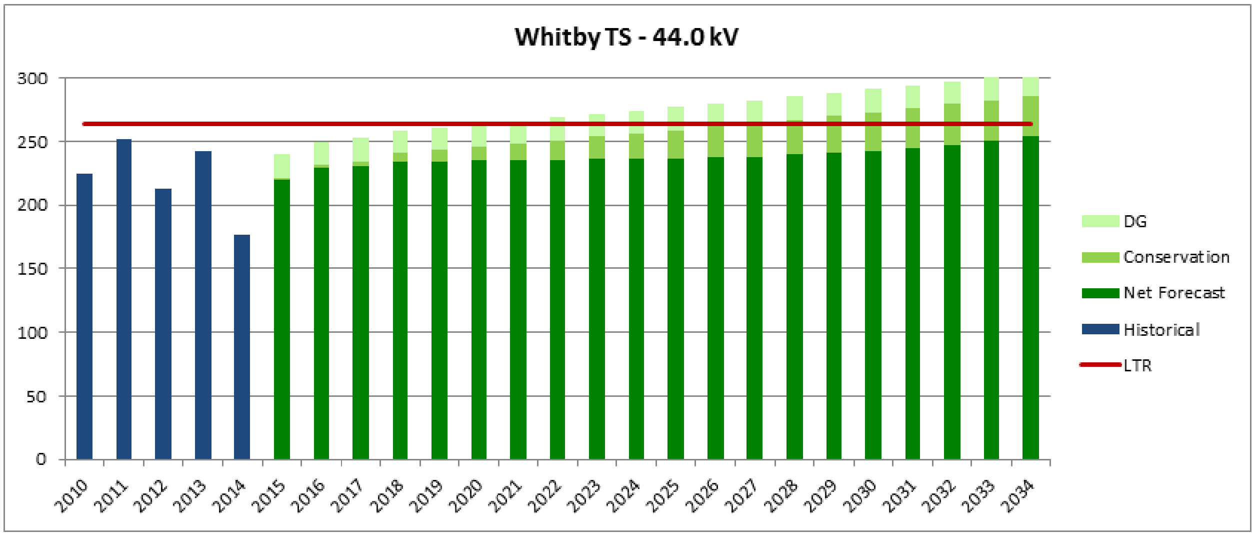

Figure 6-3 below shows the planning forecast for the 27.6 kV demand in the study area. The 27.6 kV demand in the study area is expected to exceed available capacity by 2019.

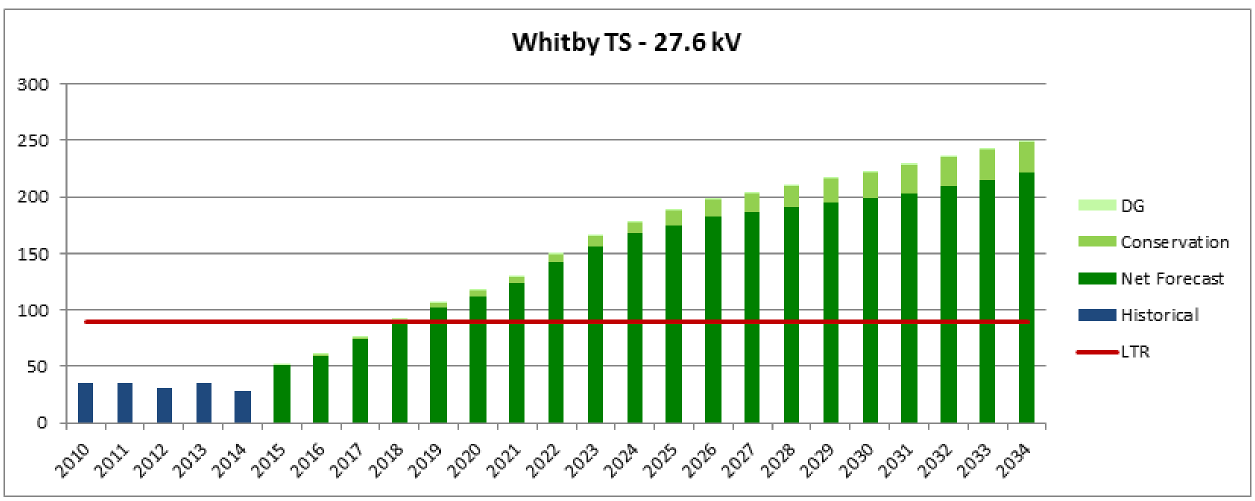
Figure 6-3: Planning Forecast for Whitby TS 27.6 kV



The 10 year forecast for 27.6 kV demand for the sub-region is shown in Table 6-1 below, with figures shown in red indicating demand levels that exceed the 90 MW transformation capacity limit for the 27.6 kV bus.:

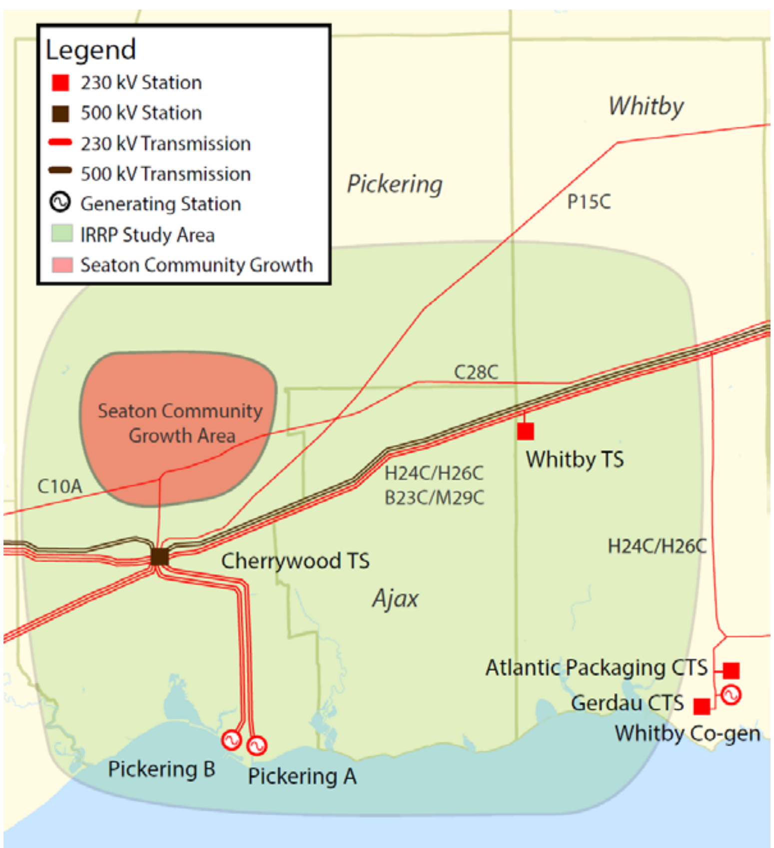
Table 6-1: Sub-region 27.6 kV Planning Forecast from 2015 to 2024

BY bus LTR (MW)	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
90	51	60	74	89	102	112	124	143	156	167

The new community of Seaton in North Pickering accounts for more than 60% of the total 27.6 kV demand by 2034, influencing a transformation capacity shortfall of approximately 12 MW in 2019 and up to 132 MW in 2034.

The location of the greenfield growth due to Seaton relative to the other infrastructure facilities in the area is shown in the figure below (in red). The community of Seaton is just north of Cherrywood TS and west of Whitby TS.

Figure 6-4: Location of Seaton in the Study Area



Source: Data provided by Hydro One Networks Inc. Copyright: Hydro One Networks Inc. [2016].

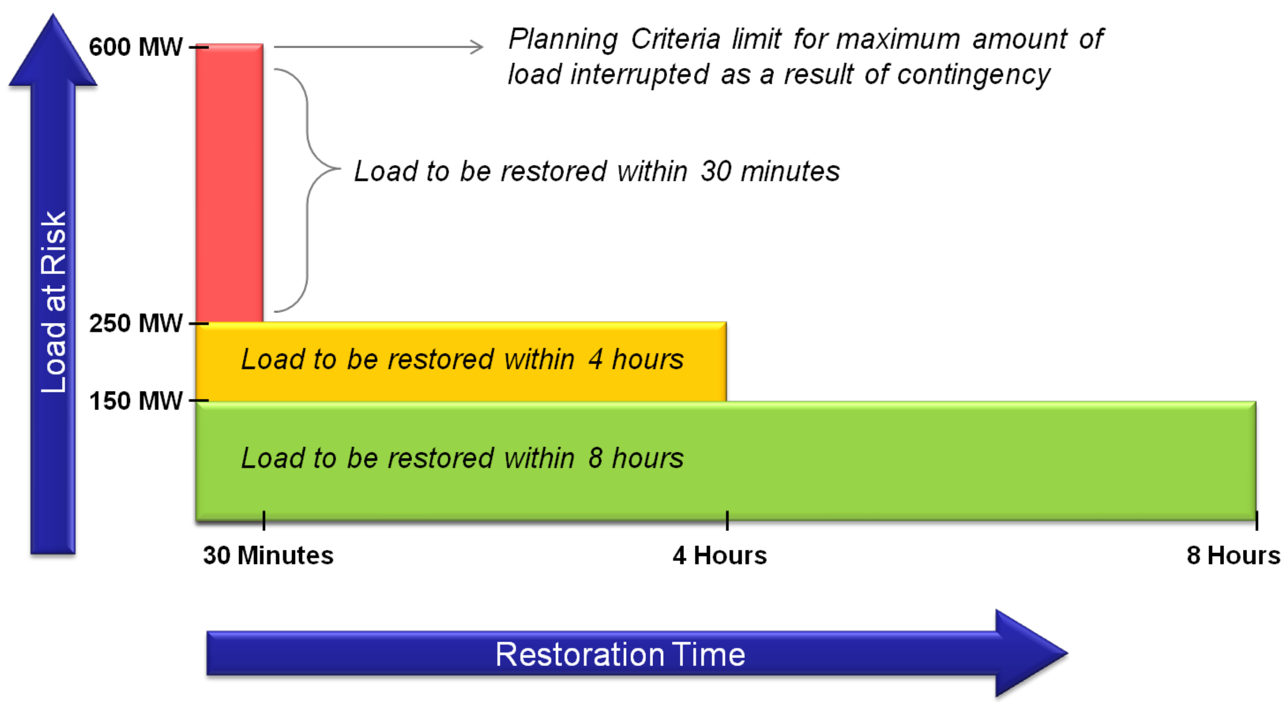
Additional 27.6 kV capacity is required for the sub-region to meet forecast 27.6 kV demand.

6.2.2 Load Restoration

Restoration refers to the ability of the system to restore sufficient amount of load within defined periods of time following the prolonged loss of a major supply source from the transmission system.

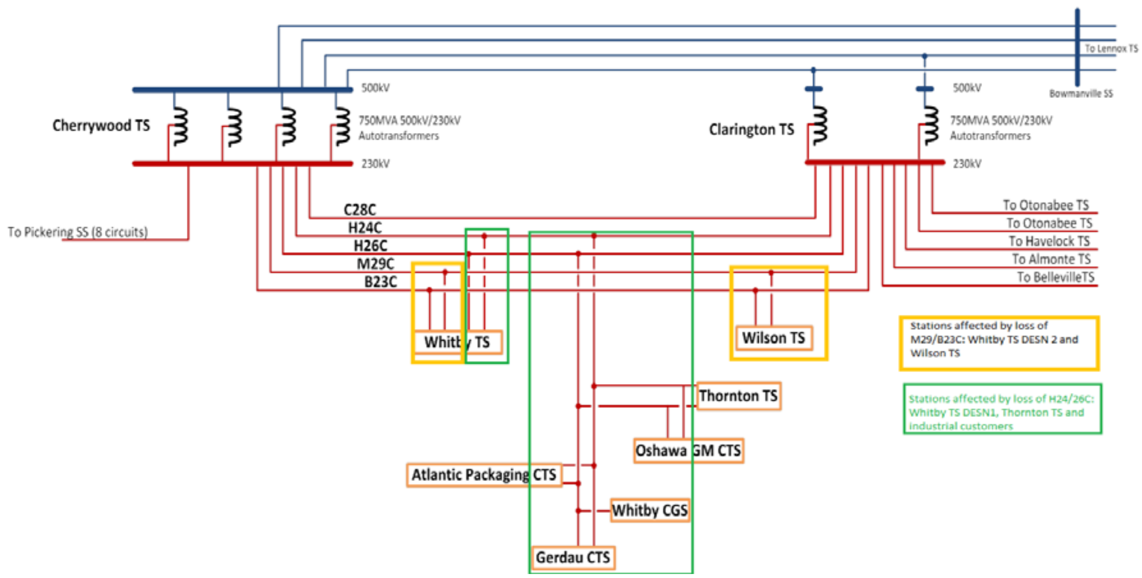
The group of stations and customers supplied from the H24/26C and M29/B23C circuits within the GTA East Region have been identified as being at risk of not meeting restoration levels as defined in ORTAC. ORTAC indicates that, for the loss of two elements, any load in excess of 250 MW should be restored within 30 minutes and any load in excess of 150 MW should be restored within 4 hours. The assessment must also consider restoration of all loads within 8 hours. These restoration levels are summarized in Figure 6-5 below.

Figure 6-5: ORTAC Load Restoration Criteria



The figure below shows the stations and customers served by each of the circuit pairs of H24/26C and M29/B23C.

Figure 6-6: Restoration Pocket for H24/26C and M29/B23C



Source: Hydro One Networks Inc. [2016].

As shown in Figure 6-6 , Whitby TS DESN 1 and the Oshawa radial pocket that includes direct connect customers and Thornton TS are served by the same circuits H24/26C, meaning both are at risk of supply interruption following the simultaneous loss of the pair of circuits. The industrial loads or direct connect customers account for 153 MW of the load supplied by the H24/26C circuits. These industrial loads cannot be restored by the LDCs in the event of an outage as these customers are connected directly to the transmission system.

For the simultaneous loss of the other pair of circuits M29/B23C, the stations Whitby DESN2 and Wilson TS are at risk of supply interruptions.

Table 6-2 below shows the total peak load at risk of interruption for select years, and the 30 minute and 4 hour restoration capability required to meet this criteria for both outages:

Table 6-2: Peak Load at Risk of Interruption for Select Years

Load Pocket	2015 Peak (MW)					2025 Net (MW)				
	Actual Demand	30-Min Restoration	30-Min Restoration Shortfall	4-Hour Restoration	4-Hour Restoration Shortfall	Forecast	30-Min Restoration	30-Min Restoration Shortfal	4-Hour Restoration	4-Hour Restoration Shortfall
M29/B23: Whitby TS DESN2, Wilson TS	436	105	81	257	29	504	105	149	257	97
H24/H26: Including Transmission Connected Customers	356	57	49	142	64	567	57	259	142	275

It is assumed that given the proximity of emergency crews and equipment, all loads would be restored within 8 hours through conventional transmission supply.

Based on discussions with area LDCs, up to 105 MW can be restored through distribution transfers within 30 minutes under the current supply arrangement and 257 MW within 4 hours for customers supplied off the M29/B23C circuits. This leaves a maximum 2015 shortfall of 81 MW after 30 minutes, and 29 MW after 4 hours.

Similarly, for the H24/26C circuits, up to 57 MW can be restored through distribution transfers within 30 minutes under the current supply arrangement and 142 MW within 4 hours for customers supplied off these circuits. This leaves a maximum 2015 shortfall of 49 MW after 30 minutes, and 64 MW after 4 hours.

After taking into account the load transfer capability of LDCs in the area, ORTAC restoration timelines and load levels are currently not met for the 30 minute and 4 hour criteria for both pairs of circuits. According to ORTAC[9], where a restoration need is identified, "transmission customers and transmitters can consider each case separately taking into account the probability of the contingency, frequency of occurrence, length of repair time, the extent of hardship caused and cost. The transmission customer and transmitter may agree on higher or lower levels of reliability for technical, economic, safety and environmental reasons provided the bulk power system adheres to NERC and NPCC standards". For the GTA East Region,

[9] ORTAC Section 7.4 Application of Restoration Criteria - http://www.ieso.ca/documents/marketAdmin/IMO_REQ_0041_TransmissionAssessmentCriteria.pdf

there is a need to assess the economic justification for addressing the restoration shortfall for the 30 minute and 4 hour timelines.

6.3 Needs Summary

Two near-term needs have been identified in the study area, and are summarized in Table 6-3 below.

Table 6-3: Summary of Needs in Pickering-Ajax-Whitby Sub-region

Area	Need	Description	Need Date
North Pickering	Transformation Capacity	Need for additional 27.6 kV transformation capacity to supply growth	2019
GTA East Region	Restoration	Need to conducted analysis to assess the economic justification for addressing the restoration shortfall for the 30 minute and 4 hour timelines	Now

7. Near-Term Plan

This section describes the alternatives considered in developing the near-term plan for the Pickering-Ajax-Whitby Sub-region, provides details of and the rationale for the recommended plan, and outlines an implementation plan. The capacity and restoration needs identified above are discussed in separate sections below.

7.1 Alternatives for Meeting the Near-Term Transformation Capacity Need

In developing the near-term plan for the capacity need in the sub-region, the Working Group considered a range of integrated options. The Working Group specifically considered technical feasibility, cost and consistency with longer-term needs and priorities in the sub-region when evaluating alternatives. Solutions that maximize the use of existing infrastructure were also given priority, where they were determined to be cost effective.

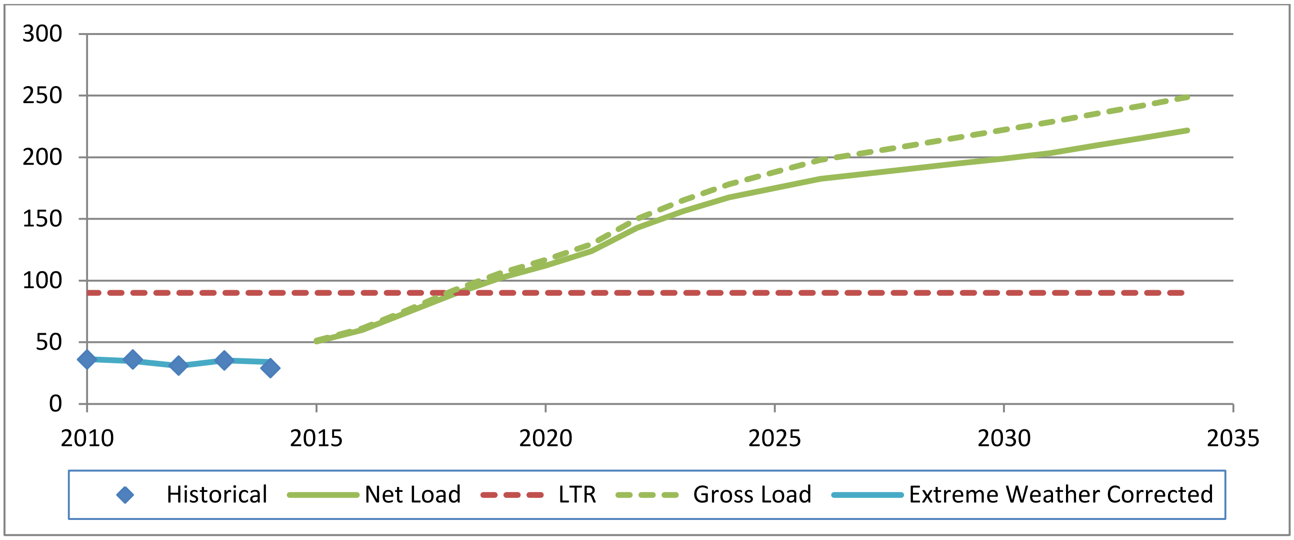
As mentioned previously, the transformation capacity need in the sub-region is mainly influenced by the forecast demand from the Greenfield development of Seaton in north Pickering. This development is being planned for residential capacity for up to 70,000 people and 35,000 jobs. Veridian is also planning to supply this community via 27.6 kV supply.

The following sections detail the alternatives considered. The alternatives are grouped according to three major solution categories: (1) conservation, (2) local generation and (3) transmission and distribution.

7.1.1 Conservation

Conservation was considered as part of the planning forecast, which includes the local peak-demand effects of the provincial conservation targets. Achieving the estimated peak demand reductions associated with the provincial conservation targets does not, however, result in deferring any of the near-term capacity needs. Achieving these conservation targets does however significantly reduce the magnitude of the 27.6 kV transformation capacity required over the long term by 27 MW, from 249 MW to 222 MW by 2034. It also effectively offsets new demand growth at Whitby TS (the only station providing supply at the 27.6 kV level in the sub-region) until 2034. The Whitby TS 27.6 kV load under both the gross and planning load forecasts is shown in Figure 7-1.

Figure 7-1: Effect of Conservation Targets on 27.6 kV Demand in the Sub-region



As explained in Section 5.4 provincial conservation targets are achieved over an entire year, while transmission needs are triggered by peak demand (single highest observation in a year). As a result, in order to reduce, defer, or address transmission capacity needs, conservation programs must have an impact during the hour of peak demand. In the case of this study area this typically means late afternoon on the hottest weekdays of summer.

The peak demand impact shown in the planning forecast represents the Working Group's estimate of how meeting the sub-region's allocation of provincial energy targets will translate into peak demand reductions. There is uncertainty in this estimate, arising both from whether the sub-region is able to meet provincial energy conservation targets and how energy conservation, in fact, translates to corresponding peak demand reductions. As a result, there is a wide range of demand impacts which could be experienced (both higher and lower than forecast).However, higher or lower demand impacts due to conservation achievement are not a significant factor in this sub-region, because 60% of the capacity need is due to greenfield growth in the new community of Seaton. Without this Greenfield growth, it is expected that there would be sufficient 27.6 kV capacity until the end of study period with the achievement of conservation targets for the localized 27.6 kV electrical demand.

7.1.2 Generation

Since the need for LMC in this area stems from residential growth served at the 27.6 kV voltage level, transmission-connected bulk generation is not a viable option. Also, the new Seaton load requires transmission/distribution infrastructure to connect to the existing grid; therefore a bulk generation solution would not avoid the above infrastructure investment.

Standalone local generation could theoretically supply the new community without the need for grid connection; however, without the diverse pool of system resources, the standalone approach would require implementing a portfolio of community based resources, including different types of generation, storage, demand management, transmission, and distribution to meet area needs (capacity, energy, operability) over the entire study period. In order to match the same level of service provided to a grid-connected system and maintain reliable supply to the community, a margin above the base generation requirements is needed to cover planned and forced generation outages. Based on the IESO's understanding of electricity service for the 25 Remote Communities (northern off-grid communities) in Ontario, it is assumed that for a standalone DG option for the Seaton community capacity redundancy would need to be approximately 130% of net-peak demand to provide reliable electricity service in the event of planned or forced generation outages.

The level of local distribution investment required to enable both the standalone option and grid-connected option would be similar in terms of design characteristics and cost. Assuming the standalone portfolio would be a mix of local natural gas generation, renewable generation, and storage, the cost associated with this approach is estimated to be at least three times that of the grid-connected option.

Local small scale generation solutions are better suited to areas with existing wires infrastructure and small incremental resource needs. The potential role of DG to manage long-term growth in the overall study area will be reviewed as part of future regional planning cycles.

7.1.3 Transmission and Distribution

As discussed in the previous sections additional conservation and generation are not feasible options to meet the near-term needs. In parallel with assessing these options, the Working Group developed transmission and distribution options to address the transformation capacity need.

These options provide new or upgraded transmission or distribution system assets, including lines, stations, feeders and related equipment. Solutions of this nature are characterized by high upfront capital costs, but have high reliability over the lifetime of the asset and enable the economic delivery of the incremental capacity and energy requirements from the provincial power system.

As noted previously, Veridian and Hydro One have been monitoring the need for station capacity in this area and given the lead times for development of a new step-down transformer station have initiated EA work for three potential sites to supply the community of Seaton. The preferred site will be determined by this EA process which is currently underway, with results expected in Q1 2017. A new station at any of the three sites will also require an upgrade to the associated 230 kV connecting circuits in the area in order to connect the station to the transmission system; this transmission line upgrade is a necessary feature of all the station alternatives discussed below. For the transformation capacity need, utilization of available station and feeder capacity from proximal stations outside the GTA East Region was also considered as part of the transmission and distribution set of options. Figure 7-2 below shows the relative locations of the infrastructure considered in the alternatives described below.

Figure 7-2: Proposed Station Sites and Related Infrastructure

Source: Data provided by Hydro One Networks Inc.

Copyright: Hydro One Networks Inc. [2016].

The alternatives to meet the transformation capacity need can be found in the Appendix B, and are summarized below. There are two main wires solutions that are suitable for addressing the need: 1. Build new feeders from existing stations, which have available capacity, followed by construction of a new step-down station, once the available capacity is utilized, or 2. Build a new step-down station near the load centre by 2019.

1. Build new 27.6 kV feeders from existing stations followed by a new 230 kV to 27.6 kV step-down station and associated 230 kV transmission line reinforcement at the proposed station sites.

Malvern TS and Sheppard TS already provide 27.6 kV supply to Veridian territory and also have a total of 85 MW of surplus 27.6 kV capacity available until the end of the study period. Combinations of building new feeders from these two stations to the Seaton load centre by 2019 were considered, followed by building a new step-down station and associated 230 kV transmission line reinforcement(see reference to three sites below) in order to meet the remaining capacity need.

2. Build a new 230 kV to 27.6 kV step-down transformer station near the Seaton load centre, with associated 230 kV transmission line reinforcement, by 2019. Three sites for the station are being considered within the EA.

Based on a net present value cost comparison, building a new station at Sites 1 or 2 was determined to be the most economic alternative, as shown below.

Table 7-1: Net Present Value of Alternatives

Alternatives	2016 $M
1. Use Malvern TS capacity and then build Seaton TS at Site 1 or 2	93-109
2. Use Malvern TS capacity and build Seaton TS as Site 3 and associated feeders	104-119
3. Use Sheppard TS capacity and then build Seaton TS-1 or 2	73-84
4. Use Sheppard TS capacity and then build Seaton TS-3 and associated feeders	91-102
5. Use Sheppard TS capacity, then use Malvern TS capacity, then build Seaton TS-1 or 2	105-124
6. Use Sheppard TS capacity, then use Malvern TS capacity, then build Seaton TS-3 and associated feeders	113-130
7 Build Seaton TS-1 or 2	60-68
8 Build Seaton TS-3 and associated feeders	94-108

Building a new step-down station at Sites 1 or 2 is the most cost-effective option[10] for meeting the 27.6 kV transformation capacity need in the sub-region. The EA, which is currently underway, will determine the preferred station site. The EA results are expected in Q1 2017.

Should Site 3 be selected through the EA process more detailed technical and economic analysis[11] is require to determine if a new station should be built only versus building feeders from the Malvern or Sheppard stations followed by a new station.

The detailed economic assumptions and methodology used to assess the options are detailed in Appendix B.

7.2 Alternatives for Meeting the Near-Term Restoration Need for the Region

The other major need identified in the area is the shortfall in meeting restoration timelines following the coincident loss of two transmission circuits to the GTA East Region. Although the IRRP is for the sub-region, the restoration analysis considers the entire GTA East Region, because the loss of two circuits impacts supply to the entire GTA East Region. This was acknowledged by the regional participants during the scoping phase of the regional planning process for the GTA East Region. The restoration analysis considers the loss of a pair of 230 kV circuit in the area, either H24/26C or M29/B23C, and the ability to restore load within the ORTAC prescribed timelines.

7.2.1 Conservation

Meeting restoration criteria requires that the faulted elements (line sections) be isolated, such that customer electrical demand can be restored from a reliable line section or an alternate source. Conservation is not a feasible option for addressing these types of needs.

7.2.2 Generation

Generation was ruled out as a feasible option to address restoration needs in the GTA East Region from both a technical and economic perspective, given the number of facilities that would be required and given the surplus generation capacity available in the province.

---

[10] See Appendix B for details on proposed station Site 3

[11] Further analysis is recommended due to the similar range of costs of the two alternatives-Station at Site 3 or Building feeders from existing stations followed by a station at Site 3

Approximately 93 MW of supply would be required today and 372 MW by 2025 in order to provide back-up in the event of a four hour outage on all four circuits.

Large generation is not a suitable option for addressing restoration needs because multiple facilities are needed in order to address loss of supply along the various line segments. Additionally, these facilities would need to have black start and islanded operation capabilities, a costly generation and system design feature.

Using smaller scale DG was also determined to be infeasible for the same technical and economic reasons as noted above. In order to provide restoration, each of these facilities would also have to be able to supply their local loads in islanded mode. Some high value loads (such as pumping and water purification facilities) are typically developed with onsite gas or diesel generation to ensure they can continue to operate during a power supply outage. While there is benefit to building this type of supply redundancy to ensure restoration capability for some loads, it is impractical on a larger scale to address regional restoration needs.

7.2.3 Transmission and Distribution

Since additional conservation and generation are not feasible options to meet the restoration shortfall, the Working Group considered transmission and distribution options. According to ORTAC[12], where a restoration need is identified, "transmission customers and transmitters can consider each case separately taking into account the probability of the contingency, frequency of occurrence, length of repair time, the extent of hardship caused and cost". Additionally, these parties may also agree on higher or lower levels of reliability for technical, economic, safety and environmental reasons. A preliminary assessment was undertaken to determine high level costs and benefits of transmission and/or distribution options giving consideration to the factors outlined in ORTAC. In carrying out this assessment, the Working Group took into account that many jurisdictions justify costs of this nature by comparing the cost to customers of supply interruption for the low probability/high impact events to the cost of mitigation. These jurisdictions: 1. assess the probability of the failure event occurring; 2. estimate the expected magnitude and duration of outages to customers served by the supply lines; 3. monetize the cost of a supply interruption to the affected customers; and 4. determine the cost of solutions and their impact on supply interruptions to the affected customers. If the cost of meeting the

---

[12] ORTAC Section 7.4 Application of Restoration Criteria - http://www.ieso.ca/documents/marketAdmin/IMO_REQ_0041_TransmissionAssessmentCriteria.pdf

security and restoration criteria exceeds the expected cost of customer supply interruptions, then it is not considered cost-justified.

The Working Group undertook a preliminary costs/benefit analysis (Appendix C) and concluded that there may be value in mitigating these restoration shortfalls. However a more detailed analysis is required to establish specific solutions and determine if these are cost justified. The GTA East regional participants recommended that this further restoration analysis and recommendations be conducted as part of the RIP to be led by Hydro One in collaboration with the affected LDCs and IESO.

7.3 Recommended Near-Term Plan

The Working Group recommends the actions described below to meet the near-term transformation capacity need in the sub-region, and the restoration need identified for the GTA East Region. Successful implementation of this plan will address the region’s electricity needs until the end of the study period in year 2034.

1. Build a new 230/27.6 kV (75/125MVA) step-down station in 2018 and associated circuit upgrade to the new community of Seaton.
2. Undertake detailed restoration analysis and recommend next steps as part of the RIP for the GTA East Region.

7.4 Implementation of Near-Term Plan

To ensure that the near-term electricity needs of the Pickering-Ajax-Whitby Sub-region are addressed, it is important that the near-term plan recommendations be implemented in a timely manner. The specific actions and deliverables associated with the near-term plan are outlined in Table 7-2, along with recommended timing for implementation.

The Pickering-Ajax-Whitby Sub-region Working Group will continue to meet at regular intervals as this IRRP is implemented to monitor developments in the sub-region and to track progress.

Table 7-2: Summary of Needs and Associated Recommendations in the Pickering-Ajax-Whitby Sub-region

Area	Need	Recommendation	Implementation Date
North Pickering	Transformation Capacity	Build a new 230/27.6 kV (175/25MVA) step-down station in 2018 and associated circuit upgrade to provide supply by 2019 to the new community of Seaton.	Veridian and Hydro One to start work on implementing the station and line work as soon as possible
GTA East	Restoration	Undertake further restoration analysis and recommend next steps as part of the RIP for the GTA East Region.	Q3 2016

Veridian and Hydro One are pursuing a combined EA for the proposed station sites and related 230 kV line work. The assessment will determine the preferred site. It is expected to be completed by Q1 2017. Based on the anticipated needs and lead time required for approvals and construction, it is recommended that Veridian complete all work required for implementation of Seaton MTS as soon as possible.

The RIP should be initiated for the GTA East Region upon completion of the IRRP.

The IESO has committed to working with the affected parties to assist with any approval requirements associated with this IRRP.

8. Long-Term Plan

Given the uncertainty in forecasting demand beyond a 10-year timeline, the purpose of the long-term plan is to consider alternate potential demand scenarios in order to facilitate discussions about how the sub-region may need to plan its future electricity supply and to lay the groundwork for the next regional planning cycle. This section describes potential long-term needs, approaches to addressing these needs, and recommended actions.

With the implementation of the proposed new step-down station in North Pickering, the local electricity infrastructure is expected to be capable of reliably supplying the forecast growth in the sub-region over the next two decades. As a result, longer term planning initiatives will focus on monitoring developments associated with factors that could affect longer term electrical service plans for this area. This includes monitoring progress on conservation efforts at the transformer station level.

One of the potential longer term needs identified through discussion with area LDCs is growth in electrical demand exceeding the capacity of existing transmission and distribution infrastructure serving the established areas of Pickering-Ajax-Whitby, including in the lakeshore area. Reviews and updates of Official Plans in this sub-region are expected in the near future. Similar to past Official Plans[13] for the City of Pickering, the lakeshore area is expected to continue to experience intensification through development of high rise multi-unit residential and commercial buildings. Given that this area is south of a major highway-the 401 and approximately 5 km from Cherrywood TS and more than 10 km from Whitby TS, this intensification could drive the need for a new step-down transformer station closer to future growth areas. This new step-down transformer station could be supplied by the transmission lines currently dedicated to delivering bulk power from Pickering GS. When the generation facilities at Pickering GS begin retiring and plans for the site become clearer over the next few years, these transmission lines could be repurposed and used to reliably supply longer term local development.

The provincial growth plan is under review and is expected in late 2016. The plan is expected to consider growth scenarios up to the year 2040. Municipal reviews of growth plans including that of Pickering, Ajax and Whitby will follow the release of the provincial plan and potentially have an impact on the longer term electrical supply for this sub-region. Other initiatives that

[13] https://www.pickering.ca/en/cityhall/resources/op6.pdf

could impact future electricity use are the City of Pickering's corporate energy management plan, the Town of Whitby's sustainability plan and the renewable energy and energy conservation policies in the Town of Ajax Official Plan. Additionally, the upcoming Durham Region Community and Municipal Energy Plans and the projects and initiatives identified by the GTA East Local Advisory Committee could also impact future electricity use. These initiatives will be monitored over the long term (see Section 9).

On a regional and provincial basis, the province's new climate change action plan and the new LTEP is expected to have a significant electrical demand impact through encouraging the electrification of customer end uses and transportation. For instance, the new rail maintenance facility in Whitby is expected to require an incremental demand of 30 MW by 2018 from the regional supply. Such demand requirements are expected to be more frequent in the future as regional transit continues to expand and electrify.

Switching from carbon based fuel sources to electricity to meet provincial or municipal environmental goals are also a factor that could impact the capacity of the existing transmission and distribution systems servicing these developed areas in the longer term.

Monitoring of growth in electricity demand and the achievement of conservation and DG targets in the sub-region will be the key components of ongoing electricity planning in this sub-region and the supply situation will be reviewed in subsequent regional planning studies.

9. Community, Aboriginal and Stakeholder Engagement

Community engagement is an important aspect of the regional planning process. Providing opportunities for input in the regional planning process enables the views and preferences of the communities to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the engagement activities undertaken to date for the Pickering-Ajax-Whitby IRRP and those that will continue to take place to discuss the medium and long-term priorities and initiatives identified by the Local Advisory Committee ("LAC" or "Committee").

A phased community engagement approach was undertaken for the Pickering-Ajax-Whitby IRRP based on the core principles of creating transparency, engaging early and often, and bringing communities to the table. These principles were established as a result of the IESO's outreach with Ontarians in 2013 to determine how to improve the regional planning and siting process, and they now guide IRRP outreach with communities and will ensure this dialogue continues as the plan moves forward.

Figure 9-1: Summary of the Pickering-Ajax-Whitby Sub-region IRRP Community Engagement Process

Creating Transparency: *Creation of GTA East IRRP Information Resources*	• Dedicated GTA East Region IRRP web page created on IESO website providing background information, the IRRP Terms of Reference and listing of the Working Group members • Dedicated web page created on Hydro One website • Self-subscription service established for GTA East for subscribers to receive regional specific updates • Status: complete
Engaging Early and Often: *Municipal & First Nation Outreach*	• Individual meetings and discussions about the Pickering-Ajax-Whitby IRRP with the City of Pickering, Towns of Ajax and Whitby, and Region of Durham (September 2015) • Information provided to First Nation communities (April 2015, September 2015) • Status: initial outreach complete; dialogue continues
Bringing Communities to the Table: *Broader Community Outreach*	• GTA East Region LAC formed in winter 2016; dedicated GTA East engagement page added to IESO website • Two LAC meetings held focused on introducing the regional planning process and initiating a discussion of the medium- and long-term priorities in the area • LAC meetings are open to the public and materials are posted to the GTA East engagement webpage • Status: begun in winter 2016; on-going

Creating Transparency

To start the dialogue on the Pickering-Ajax-Whitby IRRP and build transparency in the planning process, a number of information resources were created for the plan. A dedicated web page[14] was created on the IESO website including a map of the regional planning area,

[14] http://www.ieso.ca/Pages/Ontario%27s-Power-System/Regional-Planning/GTA-East/default.aspx

information on why an IRRP was being developed for the Pickering-Ajax-Whitby Sub-region, the IRRP Terms of Reference and a listing of the organizations involved. A dedicated email subscription service was also established for the GTA East planning region where communities and stakeholders could subscribe to receive email updates about the IRRP.

Engaging Early and Often

The first step in the engagement of the GTA East Region IRRP was to provide information to the municipalities and First Nation communities in the planning area.

In September 2015 individual meetings were held with municipal representatives from the City of Pickering, Towns of Ajax and Whitby and Region of Durham. Key topics of discussion included growth trends, discussion of the near-term needs in the sub-region, a review of the identified near-term projects including those that have already begun due to timing requirements, and a discussion of the possible approaches that can be used to address medium- and long-term needs in regional planning. The regional plan was also discussed in the context of the bulk electricity system in the area, more specifically the upcoming closure of the Pickering Nuclear Generating Station ("NGS") , the refurbishment of the Darlington NGS and the construction of the Clarington TS. The presentations and information were well received and formed the foundation for the broader engagement in the development of the Pickering-Ajax-Whitby Sub-region IRRP.

The IESO continues to work with First Nation communities to arrange a joint information session with all Williams Treaty communities and to jointly develop a plan for their engagement in this and other IRRPs moving forward. It is expected that the session will be held in the summer of 2016.

Bringing Communities to the Table

To continue the dialogue on regional planning, a LAC was established for the GTA East Region in winter 2016. The role of a LAC is to provide advice on the development of the regional plan as well as to provide input on broader community engagement. LACs are generally comprised of municipal, Indigenous, environmental, business, sustainability and community representatives. All LAC meetings are open to the public and meeting information is posted on the dedicated engagement webpage, which in this case is the IESO's GTA East engagement web page[15].

---

[15] http://www.ieso.ca/Pages/Ontario's-Power-System/Regional-Planning/GTA-East/default.aspx

Development of the GTA East LAC was completed through a request for nominations process promoted by the following activities: advertisements in nine local newspapers across Durham Region; localized digital advertising on The Weather Network for a two-week period and promotions through facebook and Twitter; emails sent to municipal representatives across GTA East Region; an e-blast sent to the IESO's GTA East subscribers list which includes over 700 subscribers; and inclusion of the call for nominations in the IESO's weekly Information Bulletin.

Two meetings of the GTA East LAC were held on March 10 and May 4, 2016. At the first LAC meeting, an overview of the regional planning process was presented to the Committee, along with information on the bulk level planning in the area. The Committee was also provided information on the two near-term needs in the Pickering-Ajax-Whitby Sub-region, these being: capacity needs in North Pickering and restoration needs across the entire GTA East Region. Due to the timing of the capacity needs, the Committee was informed that Veridian and Hydro One had already begun the EA process for a new TS and upgraded line in order for these critical pieces of infrastructure to be in-service by their need date of 2019. For the restoration needs, the Committee was presented with an overview of this need and promised additional information at the second LAC meeting once the Working Group undertook additional analysis.

The second meeting of the LAC included an update on the restoration work undertaken by the Working Group and a brainstorming session about the medium- and long-term priorities. For the restoration work, Committee members were informed that, due to the complexity of the required analysis, a Hydro One-led RIP subsequent to the completion of the IRRP will further develop the restoration analysis. For the medium- and long-term priorities, several questions were also posed to the Committee members to generate a group discussion on long-term growth projections and community priorities for inclusion in the plan. This meeting was followed by a two-week comment period for LAC members to provide additional information to inform the long-term portion of the plan. A summary of this discussion and feedback can be found in Appendix D along with the meeting summaries from the GTA East LAC meetings.

Moving forward, engagement will continue on both the near-term projects and the IRRP. For the transformer station and replacement line to meet near-term needs in north Pickering, Veridian and Hydro One will undertake engagement as part of the EA process. For the Pickering-Ajax-Whitby IRRP, the GTA East LAC will be provided with a presentation of the final plan and if requested by LAC members an additional LAC meeting will be held in the fall of 2016 to discuss next steps in the continued development of the long-term priorities.

The IESO is committed to undertaking early and sustained engagement to enhance regional electricity planning. Further information on the IESO's regional planning processes is available on the IESO website[16]. Additional information on outreach activities for the Pickering-Ajax-Whitby IRRP can be found on the GTA East webpage and updates will continue to be sent to all GTA East subscribers.

[16] http://www.ieso.ca/Pages/Participate/Regional-Planning/default.aspx

10. Conclusion

This report documents the IRRP that has been carried out for Pickering-Ajax-Whitby Sub-region. The IRRP identifies electricity needs in the sub-region over the 20-year period from 2015 to 2034, recommends a plan to address near-term needs and identifies actions to monitor long-term developments.

The step-down station solution recommended to meet the near-term need for 27.6 kV transformation capacity in the sub-region is already underway. Veridian and Hydro One have submitted a combined application for an EA of proposed station sites and related 230 kV line work. Results of the EA that is currently underway will determine the preferred station site and are expected in Q1 2017.

In order to further study and analyze the restoration needs and determine a preferred solution it is recommended that a RIP be initiated for the GTA East Region. The RIP is to be led by Hydro One Transmission, and include Veridian, Whitby Hydro, Oshawa PUC, Hydro One Distribution and IESO as Working Group members. It is recommended that this RIP be initiated after the completion of the PAW IRRP in June 2016, with RIP study completion in Q1 2017.

In the longer term, the Pickering-Ajax-Whitby Sub-region Working Group will continue to meet regularly throughout the implementation of the plan to monitor progress and developments in the area and will produce annual update reports that will be posted on the IESO website. Of particular importance, the Working Group will monitor developments focused on the factors described in the long-term section above that could impact electricity infrastructure, along with progress on conservation efforts and DG uptake at the transformer station level.

Oshawa PUC Networks Inc.	Denise Flores / Jayesh Shah
Whitby Hydro Electric Corporation	Kevin Whitehead
Hydro One Networks Inc. (Distribution)	Charlie Lee

Disclaimer

This Local Planning Report was prepared for the purpose of developing wires-only options and recommending a preferred solution(s) to address the local needs identified in the Needs Assessment (NA) report for the GTA East Region that do not require further coordinated regional planning. The preferred solution(s) that have been identified through this Local Planning Report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Local Planning Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Local Planning Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Local Planning Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Local Planning Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Local Planning Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

LOCAL PLANNING EXECUTIVE SUMMARY

REGION	GTA East Region (the "Region") – Oshawa-Clarington Sub-Region		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	October 7, 2014	**END DATE**	May 15, 2015

1. INTRODUCTION

The purpose of this Local Planning (LP) report is to develop wires-only options and recommend a preferred solution that will address the local needs identified in the Needs Assessment (NA) report for the GTA Region. The development of the LP report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

For needs that were identified as requiring further regional planning and coordination, the IESO undertook a Scoping Assessment (SA) to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both were required. Currently, an IRRP is underway to address the following needs: Cherrywood TS T7/T8 station capacity and SC restriction, Whitby TS T1/T2 (27.6 kV Supply) station capacity, and load restoration for the loss of two elements.

2. LOCAL NEEDS ADDRESSED IN THIS REPORT

The Local needs addressed in this report include the following:

- Wilson TS T1/T2 Station Capacity
- Wilson TS T3/T4 Station Capacity
- Thornton TS T3/T4 Station Capacity
- Thornton TS Feeder Capability Utilization

3. OPTIONS CONSIDERED

Prior to the new regional planning process coming into effect, planning activities and interim temporary solution discussions were already underway in the Region to address immediate specific station capacity needs. To address the Wilson TS and Thornton TS station capacity needs, the study team agreed to proceed with the preferred solution identified as follows:

- Add a new 230/44 kV DESN, (previously called "Enfield TS"), at the Oshawa Area Junction site with supply from the two 230 kV Clarington TS busses.

The study team also evaluated options for different transformer sizes and initial number of feeder breaker positions for the proposed new TS.

See Section 3 for further detail.

4. PREFERRED SOLUTION

Based on the load forecast provided by the LDCs, the study team agreed and recommends that the preferred solution is to build a new TS at the Clarington TS site located at Oshawa Area Junction. This will include 2 x 75/125 MVA, 230/44 kV transformers with 6 x 44kV feeder breaker positions (space to be provided for future 2 x 44 kV feeder positions and static capacitor banks).

See Section 4 for further detail.

5. NEXT STEPS

The next steps are summarized in Table 2.

LIST OF FIGURES AND TABLES

1 INTRODUCTION

The Needs Assessment (NA) for the GTA East Region ("Region") was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. Prior to the new regional planning process coming into effect, planning activities were already underway in the Region to address some specific station capacity needs. This Region was subsequently expedited at the request of the affected Local Distribution Companies (LDC) and reprioritized from Group 2 to Group 1. The NA for the GTA East Region was prepared jointly by the study team, including LDCs, Independent Electric System Operator (IESO), Ontario Power Authority (merged with IESO as of January 2015 and herein referred to as IESO), and Hydro One. The NA report can be found on Hydro One's Regional Planning website. The study team identified needs that are emerging in the GTA East Region over the next ten years (2014 to 2023) and recommended whether they should be further assessed through the transmitter-led Local Planning (LP) process or the IESO-led Scoping Assessment (SA) process.

This report was prepared by the GTA East Region LP study team (Table 1) and led by the transmitter, Hydro One Networks Inc. ("HONI"). The report captures the results of the assessment based on information provided by LDCs and HONI.

Table 1: Study Team Participants for GTA East Region

No.	Company
1.	Hydro One Networks Inc. (Lead Transmitter)
4.	Veridian Connections Inc. ("Veridian")
5.	Oshawa Power and Utilities Corporation Networks Inc. ("OPUCN")
6.	Whitby Hydro Electric Corporation ("Whitby Hydro")
7.	Hydro One Networks Inc. (Distribution)

1.1 Oshawa-Clarington Sub-Region Description and Connection Configuration

The GTA East Region comprises the municipalities of Pickering, Ajax, Whitby, Oshawa and parts of Clarington, and other parts of the Durham area. For the purposes of this Local Planning report, the region can be divided into two sub-regions: Pickering-Ajax-Whitby and Oshawa-Clarington. This Local Planning report covers the sub-region of Oshawa-Clarington, which includes the area served by Thornton TS and Wilson TS. The GTA East Region and its approximate sub-region boundaries are shown in Figure 1.

Source: IESO

Figure 1: GTA East Region and Approximate Sub-Region Boundaries

Four 230kV circuits (B23C, M29C, H24C, and H26C) emanating east from Cherrywood TS provide local supply to the Oshawa-Clarington sub-region. Wilson TS is supplied by B23C and M29C and Thornton TS is supplied by H24C and H26C.

It should be noted that a new 500/230kV autotransformer station in the GTA East Region within the municipality of Clarington (called Clarington TS) is being developed and is expected to be in-service in 2017. The new Clarington TS will provide additional load meeting capability in the Region and will eliminate the overloading of Cherrywood autotransformers that may result after the retirement of the Pickering Nuclear Generating Station (NGS). The new autotransformer station will consist of two 750MVA, 500/230kV autotransformers and a 230kV switchyard. The autotransformers will be supplied from two 500kV circuits that pass next to the proposed site. The 230kV circuits supplying the east GTA will be terminated at Clarington TS. Clarington TS will become the principle supply source for the GTA East Region load. The facilities in the GTA East Region, including the connection to Clarington TS, are depicted in the single line diagram shown in Figure 2.

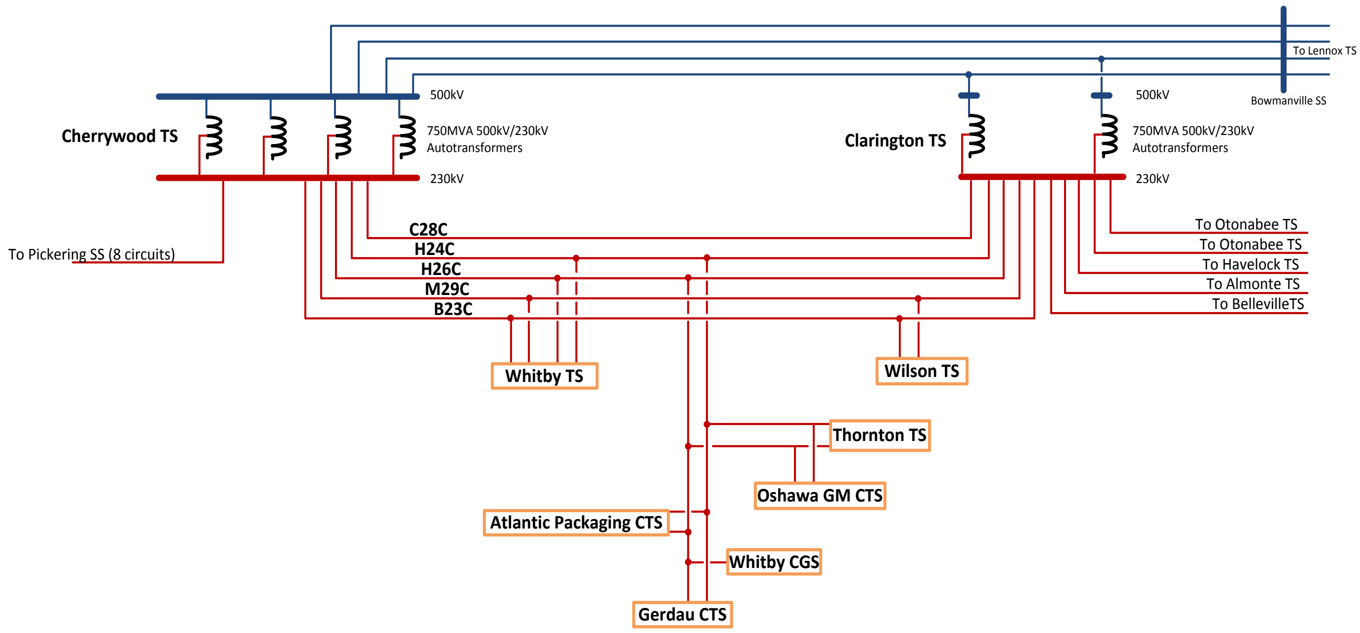

Figure 2: Single Line Diagram – GTA East Region with Clarington TS

2 GTA EAST REGION NEEDS

As an outcome of the NA process, the study team identified several needs in the GTA East Region that require further assessment and planning. The study team recommended that some of the near-term needs required "localized" wires only planning, while others required coordinated regional planning.

Where local planning was recommended to address the needs, Hydro One, as transmitter, with the impacted LDCs, further undertook planning assessments to develop options and recommend a wires only solution(s). For needs that required further regional planning and coordination, the IESO undertook a Scoping Assessment to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both were required.

2.1 Needs Assessed by IESO led Scoping Assessment – Pickering-Ajax-Whitby Sub-Region

The SA reviewed the following needs and determined that they should be addressed by an IRRP, led by the IESO:

2.1.1 Cherrywood TS (230/44 kV)

i. Station Capacity T7/T8: Based on the planned conservation and demand management (CDM) targets, the station capacity is adequate to meet the net demand over the study period, except for years 2014 and 2015. The years 2014 and 2015 may have slight overloads until the planned CDM initiatives offset the expected load.

ii. Short Circuit (SC) Constraint T7/T8: Currently, new distributed generation (DG) is restricted from connecting to Cherrywood TS T7/T8 due to short circuit constraints. Veridian Connections Inc. is supplied by this station and indicated that they have several customers that have expressed interest in connecting DG (over 5MW to date) to Cherrywood TS T7/T8, but have been unable to due to the existing SC restriction. It is worth noting that there is an existing 30 MW landfill gas generation connection at Cherrywood TS T7/T8 contributing to the SC restriction, but has been shut down for the past year.

➢ **Action:** As per the study team's recommendation, the station capacity need and SC restriction at Cherrywood TS T7/T8 is being further assessed by the IRRP study team led by the IESO.

2.1.2 Whitby TS T1/T2 (230/44/27.6 kV)

Station Capacity T1/T2 (27.6 kV): The station capacity is expected to be adequate to meet the net demand up to 2019. The existing stations in the area are not able to supply the entire projected new load. Hydro One and Veridian assessed the station capacity requirements and have discussed plans for a proposed new 230/27.6 kV station called "Seaton TS".

➢ **Action:** As per the study team's recommendation, the station capacity need at Whitby TS T1/T2 (27.6kV supply) is being further assessed by the IRRP study team to assess if CDM/Resource solutions can economically defer the wires investment. Accordingly, the study team will determine and recommend the timing for this new 230/27.6 kV station.

Note that the 230/44 kV supply capacity of Whitby TS T1/T2 and Whitby TS T3/T4 is expected to be adequate during the study period. However, Whitby TS T3/T4 is forecasted to be greater than 90% of the Summer 10-Day LTR from 2015 to the end of the study period. No action is required at this time and the capacity need will be reviewed in the next regional planning cycle.

2.1.3 Load Restoration for the Loss of Two Elements

i. The IESO Ontario Resource and Transmission Assessment Criteria (ORTAC) require loads of 150 MW or more to be restored in 4 hours and 250 MW or more in 30 minutes. For the loss of two elements, the load interrupted by configuration in the GTA East Region may exceed 150 MW and 250 MW.

- **Action:** As per the study team's recommendation, load restoration for the loss of two elements is being further assessed by the IRRP study team.

2.2 Needs Assessed by Hydro One led Local Planning – Oshawa-Clarington Sub-Region

2.2.1 Wilson TS (230/44kV)

i. Station Capacity T1/T2: Wilson TS T1/T2 DESN1 is forecast to exceed its normal supply capacity in 2017 based on the net demand forecast. Transformation capacity relief is needed.

ii. Station Capacity T3/T4: Wilson TS T3/T4 DESN2 is forecast to exceed its normal supply capacity in 2015 based on the net demand forecast. Transformation capacity relief is needed. In the past, overloading at this DESN under certain conditions was significant enough that plans were put in place for emergency rotating load shedding, if and when required.

2.2.2 Thornton TS (230/44kV)

i. Station Capacity T3/T4: Thornton TS T3/T4 is forecast to exceed its normal supply capacity in 2015 based on the net demand forecast. Transformation capacity relief is needed.

ii. Feeder Capability Utilization: OPUCN indicated during the NA process that their four feeders at Thornton TS will exceed their maximum capability by 2015 based on their gross demand forecast. As a result, the study team recommended that feeder capability utilization at Thornton TS required review by the LDCs to ensure the efficient and cost effective use of available feeder capability.

3 OPTIONS CONSIDERED

This section describes the options considered to address the local needs described in section 2.2.

3.1 **Wilson TS and Thornton TS Station Capacity Needs** [refer to sections 2.2.1 (i), (ii) and 2.2.2 (i)]

Prior to the new regional planning process coming into effect, planning activities were already underway in the Region to address specific station capacity needs. Prior to 2010, Hydro One and impacted LDCs were in discussions and developing plans for a proposed new 230/44 kV DESN station that would provide transformation capacity relief to Wilson TS. The proposed station would accommodate the anticipated load growth at the time in Oshawa and Clarington and improve reliability of electricity supply to customers in these areas. As part of the planning process, different options were evaluated and a Class Environmental Assessment for Minor Transmission Facilities ("Class EA") was undertaken. It was determined that the preferred site for the new DESN (called "Enfield TS") would be Oshawa Area Junction. The anticipated load was not materializing to support construction at the time and as a result this plan was put on hold.

Following this and in the past few years, load growth has emerged again in the region. To help manage OPUCN's and Whitby Hydro's load growth and respect 10-Day LTRs at Wilson TS T1/T2 and Whitby TS T3/T4 (during summer peak load conditions), load transfers to Thornton TS were required and the associated distribution investments were made by impacted LDCs. At the time, OPUCN planned to utilize available feeder capability of Hydro One Distribution's (HOD) feeders at Thornton TS where Whitby Hydro is embedded. However, Whitby Hydro was also later required to transfer load from Whitby TS T3/T4 to Thornton TS in order to respect the 10-Day LTR at Whitby TS T3/T4. Currently, the most recent load forecast from LDCs show significant load growth at Thornton TS in the near term, particularly to supply the anticipated load of Metrolinx. Based on the load transfer and updated load forecast for Thornton TS, available feeder capability of HOD's feeders has reduced and consequently OPUCN has limited their load transfer to Thornton TS (see section 3.3 on Thornton TS T3/T4 Feeder Capability Utilization).

As per the current load forecast provided by the study team, transformation capacity relief is needed for both Wilson TS and Thornton TS. To accommodate the load growth of OPUCN and HOD at Wilson TS and Thornton TS, the study team agreed to proceed with the preferred solution identified previously, Enfield TS, with the exception that the current plan supplies the proposed new DESN from Clarington TS as follows:

- Build a new 230/44 kV DESN (name to be determined) at the Clarington TS site located at Oshawa Area Junction, with supply from the two 230 kV Clarington TS busses.

The study team re-emphasized some of the benefits to the preferred option which include:

- Land already acquired at Oshawa Area Junction, where the new TS is proposed to be sited (on a location on the west side of the Clarington TS property). Any location much further east or west to Oshawa Area Junction would adversely affect one or the other LDCs by having to construct longer distribution feeders.

- EA approval previously obtained for building a new TS on Hydro One lands at the Clarington TS site.

The study team also recognized and agreed that, where possible, distribution load transfers to help balance the forecasted load at Wilson TS and Thornton TS would be required in the interim prior to the proposed TS coming into service. However, this would be temporary and unsustainable solution.

3.2 Feasibility Study Results and Budgetary Cost Estimates for Proposed TS

The study team recommended that the following transformer options for the proposed new TS be compared:

a) 2 x 50/83 MVA, 230/44 kV transformers with 6 x 44kV feeder breaker positions

b) 2 x 75/125 MVA, 230/44 kV transformers with 6 x 44kV feeder breaker positions (space to be provided for future 2 x 44 kV feeder positions)

c) 2 x 75/125 MVA, 230/44 kV transformers with 8 x 44kV feeder breaker positions

The preliminary cost estimates for the above options are: $19 million, $23 million, and $27 million for options (a), (b), and (c) respectively (note that this cost does not include the cost for capacitor banks, which may be required if identified in the System Impact Assessment by the IESO).

As per the preliminary estimates, option (a) is not materially less than option (b). If a longer term 25-year forecast is considered for the proposed new station, it will require upgrading the 50/83 MVA transformers (which have an assumed Summer 10-Day LTR of 113 MVA) to 75/125 MVA transformers around 2025 based on the current load forecast. The study team agreed that the typical cost to replace 50/83 MVA transformers with 75/125 MVA transformers would not be cost effective as compared to installing 75/125 MVA transformers initially.

3.3 Thornton TS T3/T4 Feeder Capability Utilization [refer to section 2.2.2 (ii)]

Thornton TS T3/T4 is a 230/44 kV DESN which supplies OPUCN and HOD. This station consists of eight feeders, four of which are owned by OPUCN and the remaining four by HOD. HOD's four feeders solely supply Whitby Hydro's load (embedded customer of HOD).

OPUCN indicated that their four feeders at Thornton TS will exceed their maximum capability for normal operations by 2015 based on their gross demand forecast. HOD's feeders, however, will be adequate to meet Whitby Hydro's gross demand forecast and will also have available feeder capability remaining on their four feeders up to 2023.

The study team considered the following options to address OPUCN's need for additional feeder capability:

A. OPUCN, HOD, and Whitby Hydro to carry out a distribution planning assessment and develop an implementation plan to manage effective and efficient utilization of feeder capability at Thornton TS under both normal and emergency conditions.

B. Add additional feeder breaker positions at Thornton TS.

Option B was rejected for the following reason:

- The station already consists of eight feeders and TS capacity cannot accommodate any additional feeder breaker positions.

  Note: Consistent with the Transmission System Code (TSC) and OEB's regional planning objectives to ensure cost effective and efficient wires expansion without duplication of facility investments, existing feeder capability should be efficiently utilized before investing in new feeders. It should also be noted that as per the TSC transmission facility capacity, if available, cannot be reserved for connecting customers.

4 PREFERRED SOLUTION

4.1 Wilson TS and Thornton TS Station Capacity Needs [refer to section 3.1]

Given the forecasted load growth in the Oshawa-Clarington sub-region, the study team determined that the preferred solution to address this need would be to proceed with option (b): 2 x 75/125 MVA, 230/44 kV transformers with 6 x 44kV feeder breaker positions initially (space to be provided for future 2 x 44 kV feeder positions). This will ensure reliable supply capability for OPUCN and HOD for the medium-to-long term and is a cost effective solution.

The proposed station will be located at the Oshawa Area Junction property (on the right of way of the Bowmanville x Cherrywood transmission line corridor) that HONI owns in the municipality of Clarington. This property is also the site of the new 500/230 kV autotransformer station called "Clarington TS" that will be supplied from 500kV circuits, B540C and B543C. EA approval was previously obtained for building a new TS at the Oshawa Area Junction site on a location on the west side of the property. The new TS will be supplied from the two 230 kV Clarington TS busses. It will consist of 2 x 75/125MVA, 230/44kV transformers with 6 x 44kV feeder breaker positions. Space will be provided for future 2 x 44 kV feeder positions and static capacitor banks.

The proposed in-service date for the new TS will be aligned with the Clarington TS in-service date, currently scheduled for 2017/18.

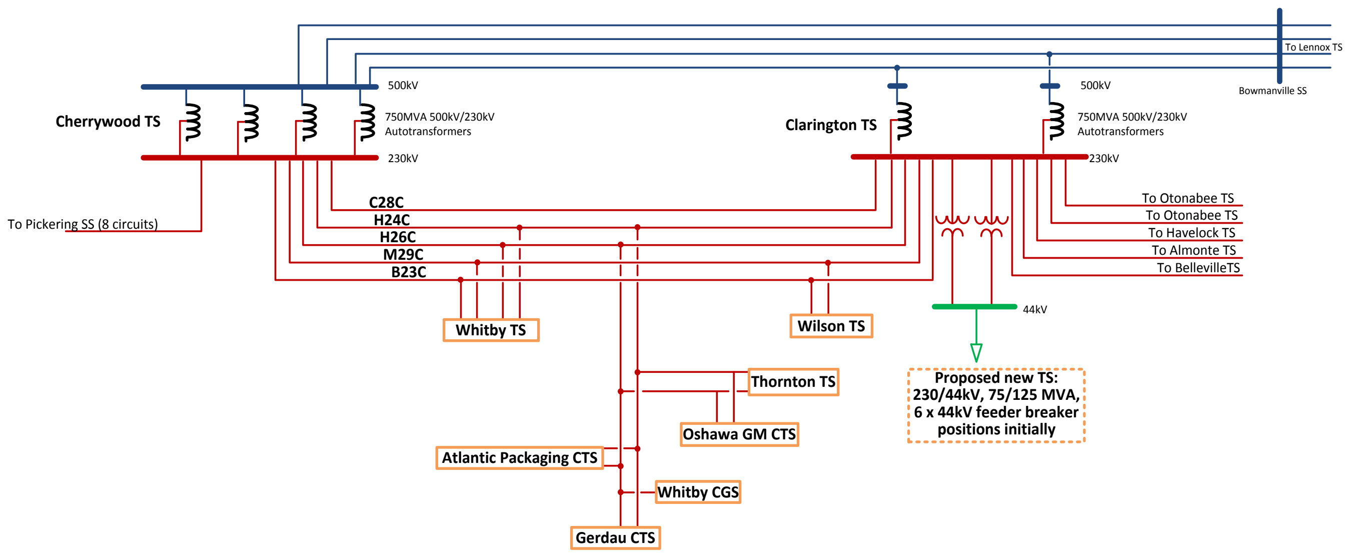

Figure 3: Single Line Diagram – GTA East Region with Proposed New TS

5 NEXT STEPS

A summary of the next steps, actions/solutions and timelines required to address the local needs are as follows:

Table 2: Solutions and Timeframe

Item #	Need	Action / Recommended Solution	Lead Responsibility	Timeframe
1	Wilson TS T1/T2 Station Capacity [Refer to Section 2.2.1 (i)]	• Proposed new 230/44 kV, 75/125 MVA station. This solution will be executed through Hydro One's Transmission Load Connection Process. HOD and OPCUN to initiate the process by contacting Hydro One's Account Executive (AE). • LDCs to assess and confirm if load transfers can partially mitigate forecasted overloading and provide timeline to implement required load transfers.	Affected LDCs and HONI OPUCN, HOD	To be determined (TBD) by LDCs June 2015
2	Wilson TS T3/T4 Station Capacity [Refer to Section 2.2.1 (ii)]	• Proposed new 230/44 kV, 75/125 MVA station. This solution will be executed through Hydro One's Transmission Load Connection Process. HOD and OPCUN to initiate the process by contacting Hydro One's AE. • LDCs to assess and confirm if load transfers can partially mitigate forecasted overloading and provide timeline to implement required load transfers.	Affected LDCs and HONI OPUCN, HOD	TBD by LDCs June 2015

4	Thornton TS T3/T4 Station Capacity [Refer to Section 2.2.2 (i)]	• Proposed new 230/44 kV, 75/125 MVA station. This solution will be executed through Hydro One's Transmission Load Connection Process. HOD and OPCUN to initiate the process by contacting Hydro One's AE. • LDCs to assess and confirm if load transfers can partially mitigate forecasted overloading and provide timeline to implement required load transfers.	Affected LDCs and HONI OPUCN, Whitby Hydro	TBD by LDCs June 2015
7	Thornton TS Feeder Capability Utilization [Refer to Section 2.2.2 (ii)]	• LDCs distribution planning.	OPUCN, HOD, and Whitby Hydro	TBD by LDCs

Regional Infrastructure Plan

February 5, 2016

[This page is intentionally left blank.]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Enersource Hydro Mississauga Inc.
Hydro One Brampton Networks Inc.
Hydro One Networks Inc. (Distribution)
Independent Electricity System Operator
Newmarket-Tay Power Distribution Ltd.
PowerStream Inc.
Toronto Hydro Electric System Ltd.

[This page is intentionally left blank.]

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN (“RIP”) WAS PREPARED BY HYDRO ONE NETWORKS INC. (“HYDRO ONE”) AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE (“TSC”) REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN FACILITIES THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS OF THE GTA NORTH REGION.

The participants of the RIP Working Group included members from the following organizations:

- Enersource Hydro Mississauga Inc.
- Hydro One Brampton Networks Inc.
- Hydro One Networks Inc. (Distribution)Independent Electricity System Operator
- Newmarket-Tay Power Distribution Ltd.
- PowerStream Inc.
- Toronto Hydro-Electric System Limited
- Hydro One Networks Inc. (Transmission)

This RIP is the final phase of the OEB’s mandated regional planning process for the GTA North Region which consists of the York Sub-Region and the Western Sub-Region. It follows the completion of the York Sub-Region’s Integrated Regional Resource Planning (“IRRP”) by the IESO in April 2015 and the Western Sub-Region’s Needs Assessment (“NA”) Study by Hydro One in June 2014.

This RIP provides a consolidated summary of needs and recommended plans for the York Sub-Region over the near-term (up to 5 years) and the mid-term (5 to 10 years). The York Region IRRP has identified the need for additional transformation capacity in Markham, Northern York Region and Vaughan in the mid-term. These mid-term needs are linked to long-term (beyond 10 years) transmission capacity needs.

No needs have been identified over the near-term and mid-term for the Western Sub-Region except for load restoration for the loss of double circuit 230 kV line V43/V44. It is recommended that this need be assessed as part of the IESO led GTA West bulk system planning initiative and as a result is not addressed in this RIP.

The major infrastructure investments planned for the GTA North Region over the near-term, identified in the various phases of the regional planning process, are given in the Table below.

No.	Project	I/S date	Cost
1	Vaughan #4 MTS	Q1 2017	$25M*
2	Holland breakers, disconnect switches and special protection scheme	Q4 2017	$32M
3	Parkway belt switches	Q4 2018	$4-6M

* PowerStream’s station cost. Hydro One line connection cost is currently being estimated

The planning is continuing for the mid-term and long-term needs. These needs, and the options to address these them, are being reviewed by the Working Group as part of the community engagement activities currently being led by the IESO and LDCs through the Local Advisory Committee process. The Working Group expects to finalize recommendations to address these and associated long-term transmission needs in an IRRP update currently scheduled for 2017.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1 INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE GTA NORTH REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") and documents the results of the study with input and consultation with Enersource Hydro Mississauga Inc. ("Enersource"), Hydro One Brampton Networks Inc. ("Hydro One Brampton"), Hydro One Distribution, Newmarket-Tay Power Distribution Ltd. ("NTPDL"), PowerStream Inc. ("PowerStream"), Toronto Hydro-Electric System Limited ("THESL"), and the Independent Electricity System Operator ("IESO") in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The GTA North Region includes most of the Regional Municipality of York and parts of the City of Toronto, Brampton, and Mississauga (see Figure 1-1). Electrical supply to the Region is provided through 230 kV transmission circuits, fifteen step-down transformer stations ("TS"), and the York Energy Centre ("YEC") generating station ("GS").

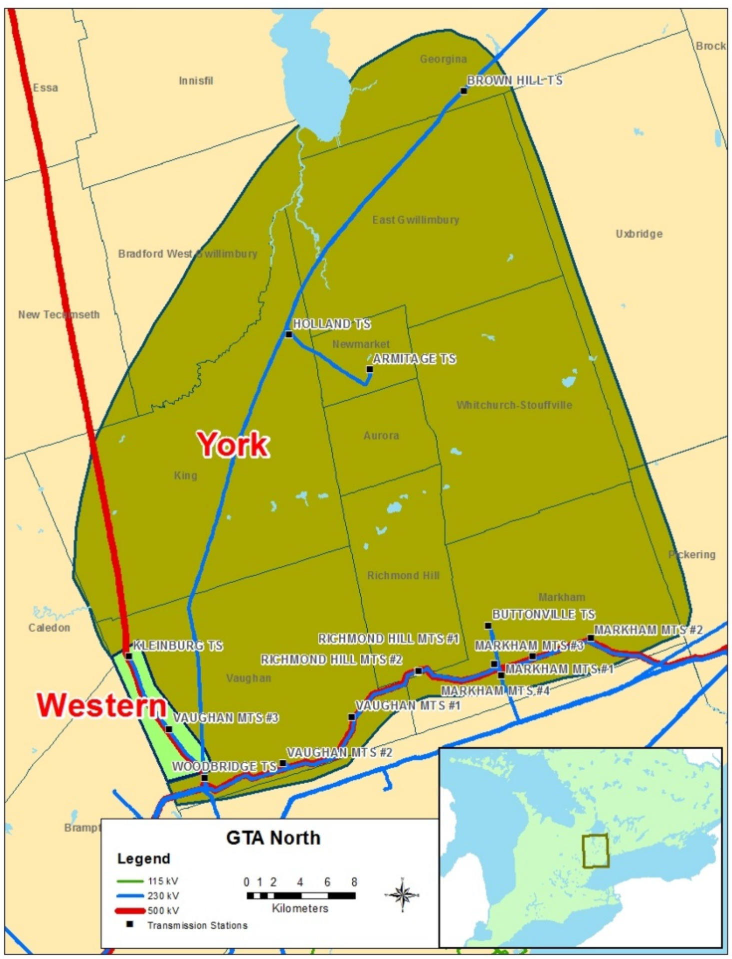

Figure 1-1 GTA North Region

1.1 Scope and Objectives

This RIP report examines the needs in the GTA North Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop a wires plan to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of all the needs and relevant plans to address near and mid-term needs (2015 to 2025) identified in previous planning phases (Needs Assessment and Integrated Regional Resource Plan)
- Identification of any new needs over the 2015-2025 period and a wires plan to address them.
- Consideration of long-term needs identified in the York Region IRRP

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the regional characteristics.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the regional needs.
- Section 7 describes the needs and provides alternatives and preferred solutions.
- Section 8 provides the conclusion and next steps.

2 REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led

[1] Also referred to as Needs Screening.

stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- NA, SA, and LP phases of regional planning; and,
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

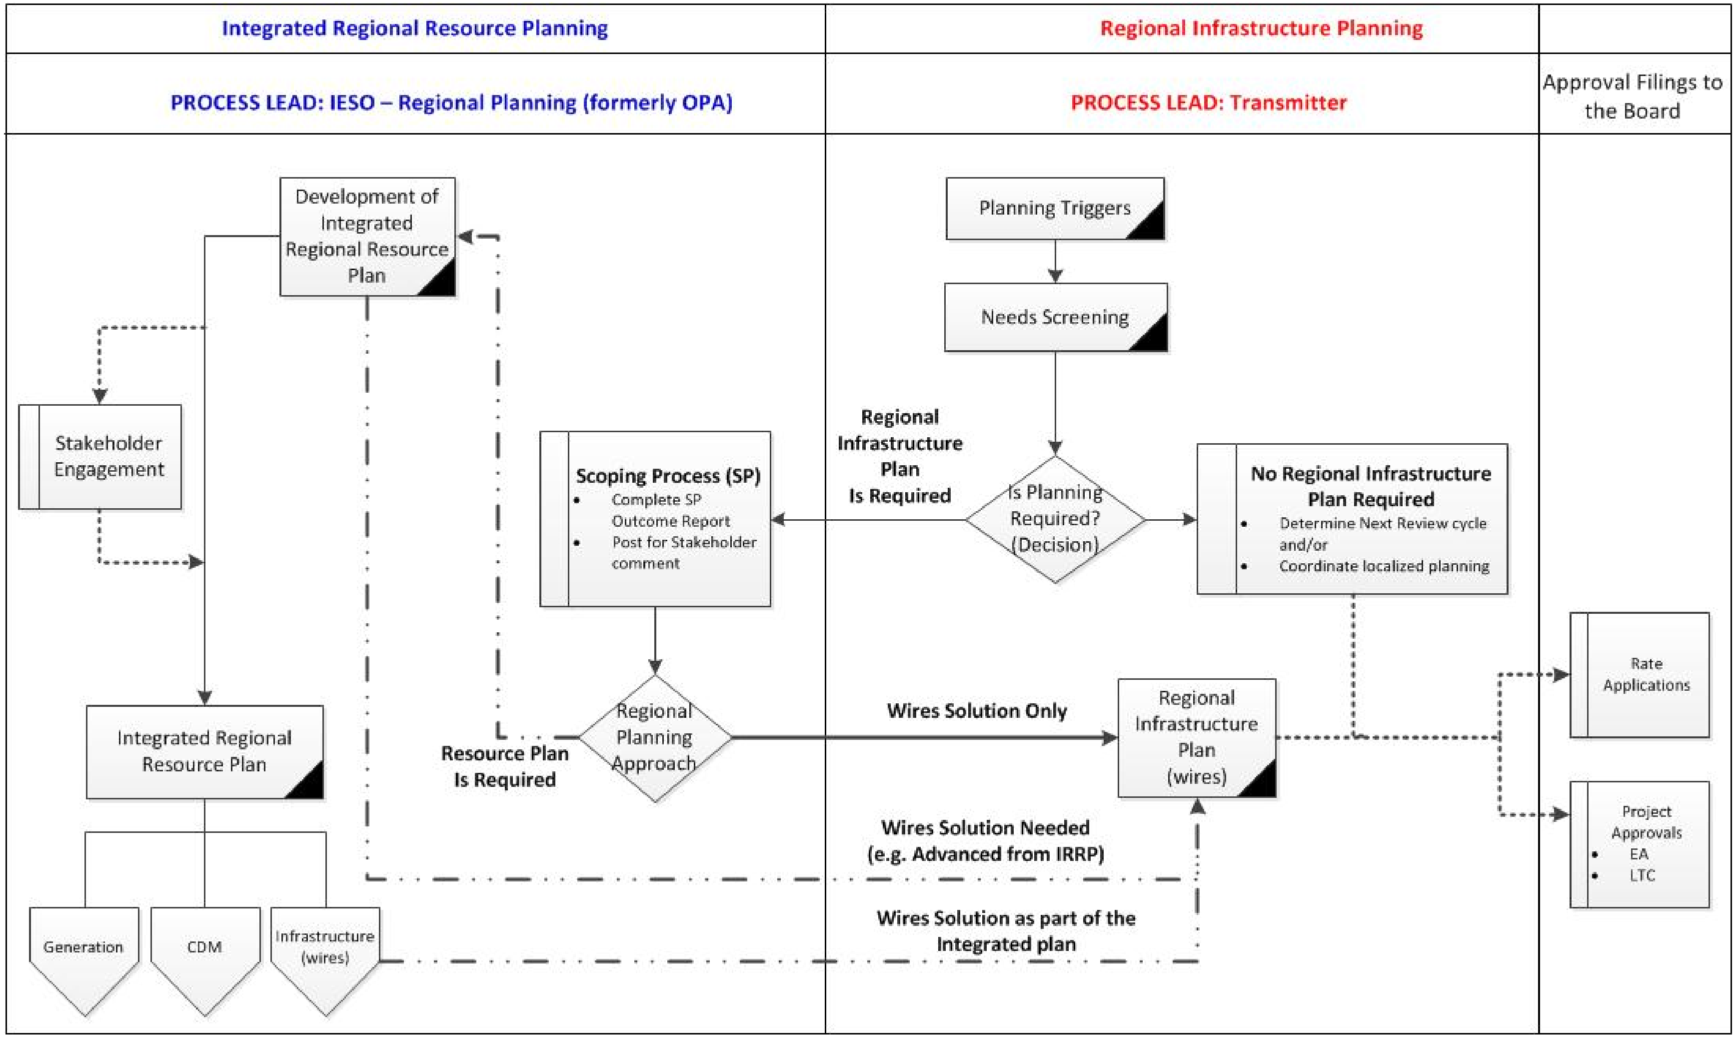

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any DG or CDM programs.
   - Existing area network and capabilities including any bulk system power flow assumptions; and,
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.

2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.

3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

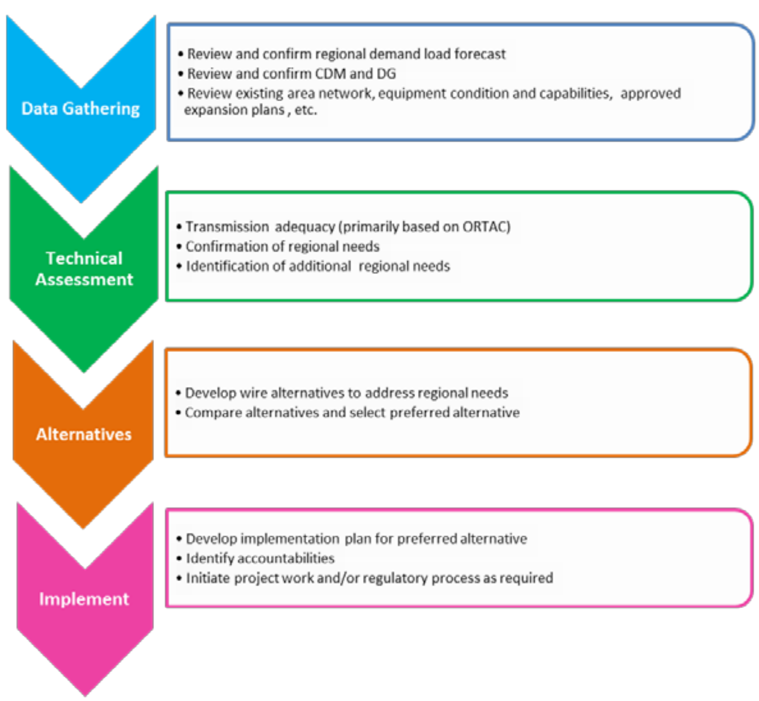

Figure 2-2 RIP Methodology

3 REGIONAL CHARACTERISTICS

THE GTA NORTH REGION IS COMPRISED OF THE YORK SUB-REGION AND THE WESTERN SUB-REGION. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM FIFTEEN 230 KV STEP-DOWN TRANSFORMER STATIONS. THE 2015 SUMMER PEAK AREA LOAD OF THE REGION WAS APPROXIMATELY 1900MW.

Electrical supply to the GTA North Region is primarily provided from three major 500/230 kV autotransformer stations, namely Claireville TS, Parkway TS, and Cherrywood TS, and a 230 kV transmission network supplying the various step-down transformation stations in the region. Local generation in the Region consists of the 393 MW York Energy Centre connected to the 230 kV circuits B82V/B83V in King Township.

The April 2015 York Region Integrated Regional Resource Plan ("IRRP"), prepared by the IESO in conjunction with Hydro One, PowerStream and Newmarket-Tay Power, focused solely on the York Sub-Region. The June 2014 GTA North Western Sub-Region Needs Assessment report, prepared by Hydro One, considered the Western Sub-Region. A map of the GTA North Region is shown in Figure 3-1 and a single line diagram of the transmission system is shown in Figure 3-2.

3.1 York Sub-Region

The York Sub-Region was identified as a "transitional" region, as planning activities in the region were already underway before the new regional planning process was introduced. The NA and SA phases were deemed to be complete, and the regional planning process was considered to be in the IRRP phase. An IRRP for the region was completed in April 2015.

For regional planning purposes, the York Sub-Region is further classified into Northern York Area and Southern York Area to reflect the layout of the region's electricity infrastructure. The Northern York Area encompasses the municipalities of Aurora, Newmarket, King, East Gwillimbury, Whitchurch-Stouffville and Georgina, as well as some load in Simcoe County that is supplied from the same electricity infrastructure. It is supplied by Claireville TS, a 500/230 kV autotransformer station, and three 230 kV transformer stations stepping down the voltage to 44 kV. The York Energy Centre provides a local supply source in Northern York Area. The LDCs supplied in the Northern York Area are Hydro One Distribution, Newmarket-Tay Power Distribution, and PowerStream.

The Southern York Area includes the municipalities of Vaughan, Markham and Richmond Hill. It is supplied by three 500/230 kV autotransformer stations (Claireville TS, Parkway TS, and Cherrywood TS), nine 230 kV transformer stations (includes eight municipal transformer stations) stepping down the voltage to 27.6 kV, and one other direct transmission connected load customer. The LDC supplied in the Southern York Area is PowerStream.

Please see Figure 3-1 and Figure 3-2 for a map and single line diagram of the Sub-Region facilities.

3.2 Western Sub-Region

The Western Sub-Region comprises the Western portion of the municipality of Vaughan. Electrical supply to the sub-region is provided through Claireville TS, a 500/230 kV autotransformer station, and a 230 kV tap (namely, the “Kleinburg tap”) that supplies three 230 kV transformer stations (including one municipal transformer station) stepping down the voltage to 44 kV and 27.6 kV. The LDCs directly supplied in the sub-region are PowerStream and Hydro One Distribution. Embedded LDCs supplied in the sub-region include Enersource, Hydro One Brampton and Toronto Hydro.

During the Needs Assessment phase for the Western Sub-Region, a load restoration need for the loss of V43/V44 was identified. It was recommended that a plan to address this need be included in the IESO led GTA West bulk system planning initiative and therefore this need is not addressed in this RIP.

Please see Figure 3-1 and Figure 3-2 for a map and single line diagram of the Sub-Region facilities.

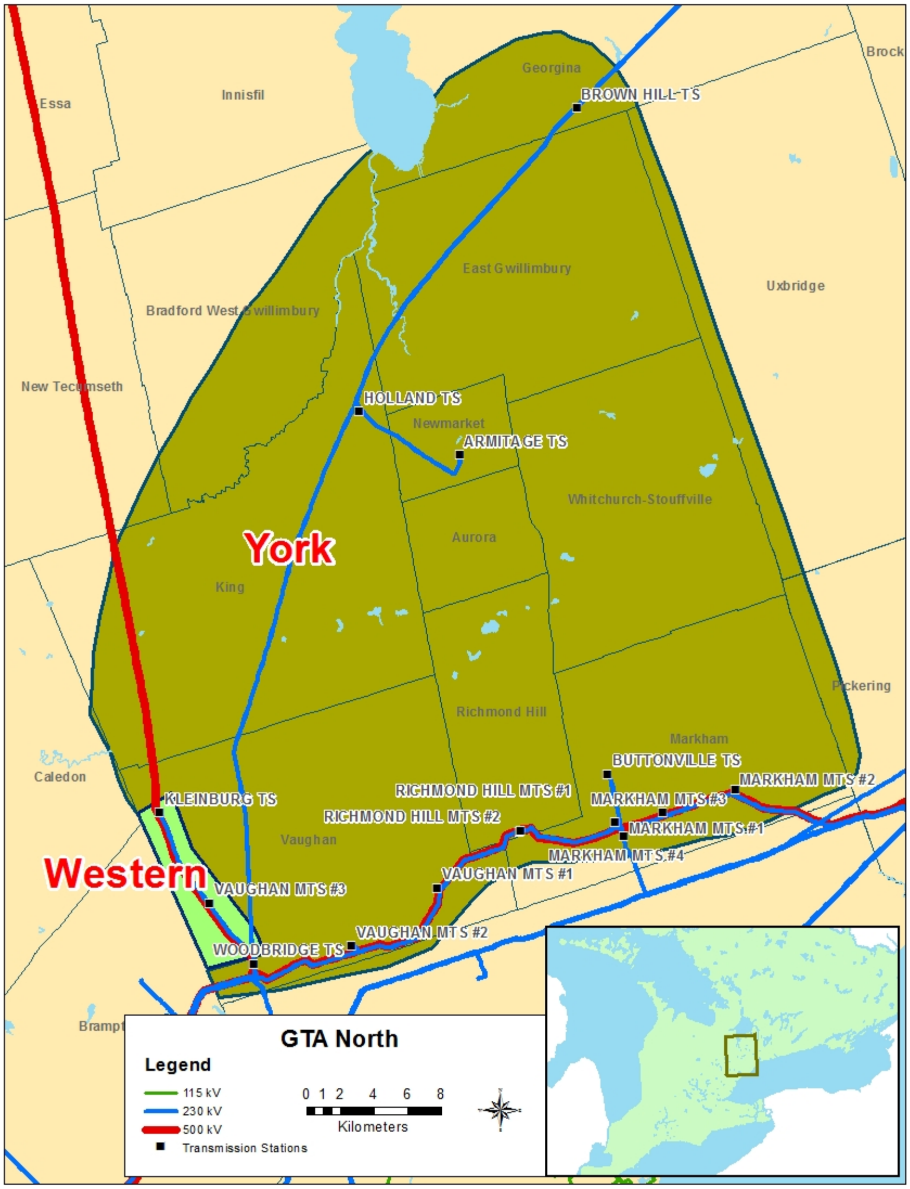

Figure 3-1 GTA North Region – Supply Areas

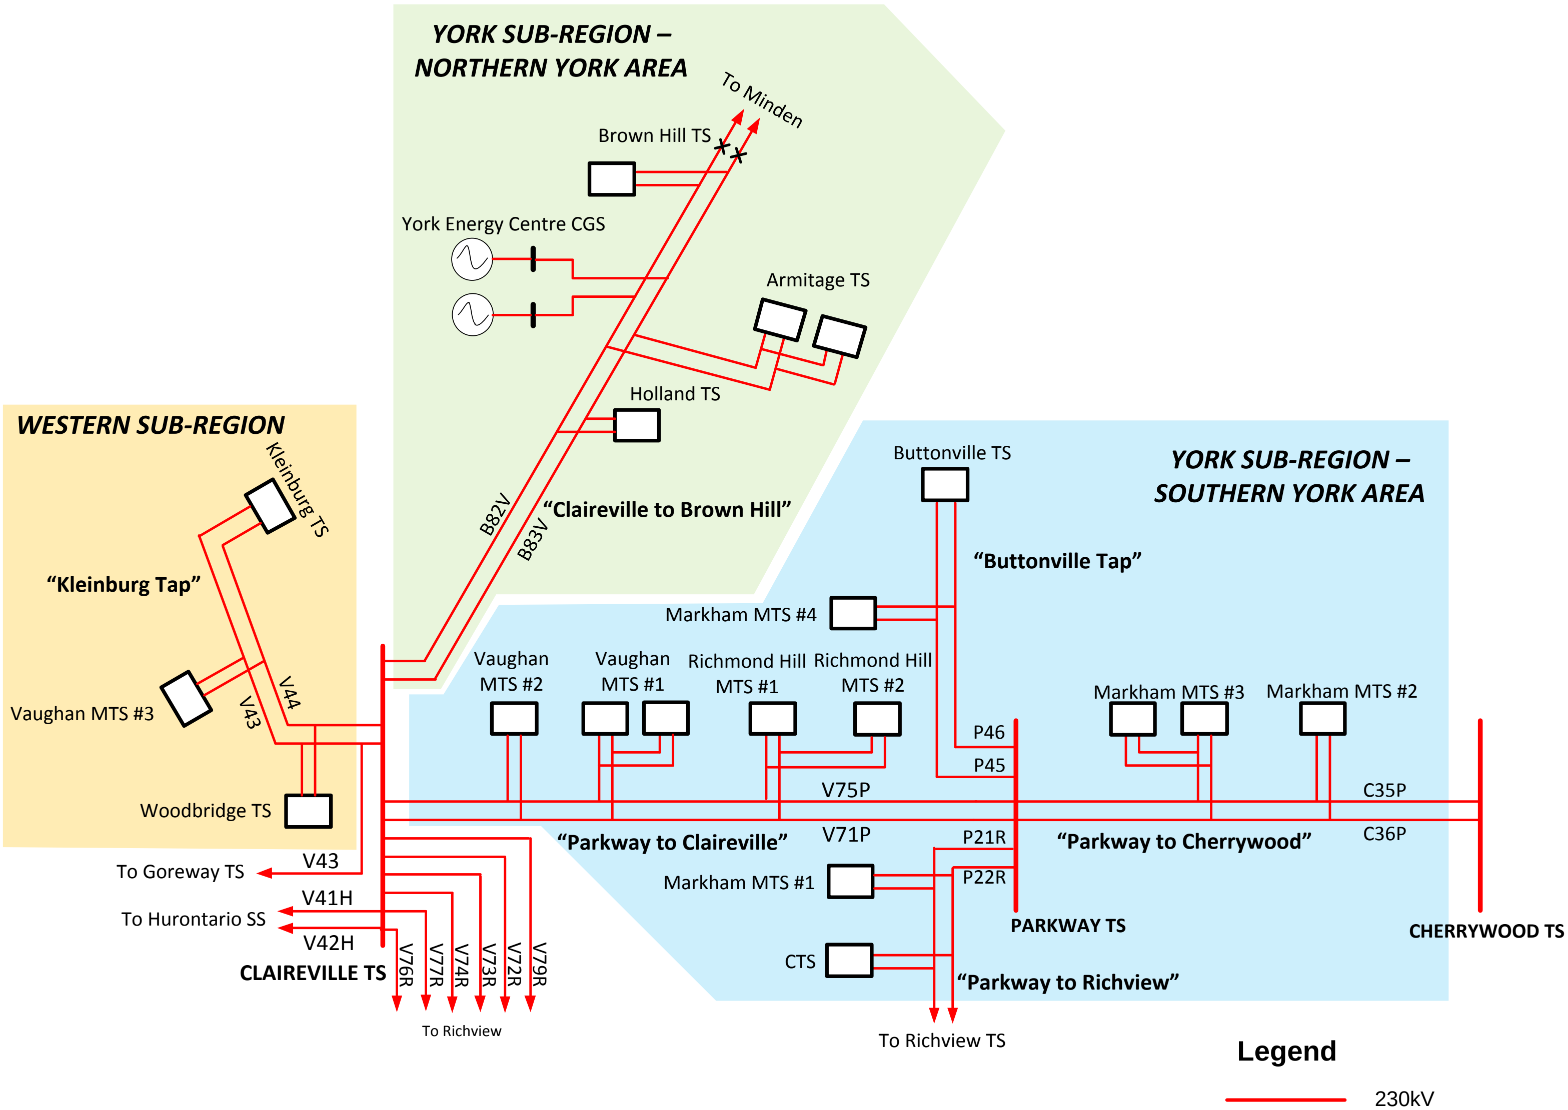

Figure 3-2 GTA North Transmission Single Line Diagram

4 TRANSMISSION FACILITIES COMPLETED OVER THE LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE GTA NORTH REGION.

A brief listing of the completed development projects along with their in-service dates over the last 10 years is given below:

- Holland TS and low voltage capacitor banks (2009) – to increase transformation capacity for the Northern York Area.
- Parkway 500-230kV autotransformer station (2006) – to increase transmission supply capacity to GTA North
- Parkway x Richmond Hill 230kV double circuit line (2006) – to improve reliability of supply to Southern York Area
- Connect Markham #4 MTS (2009) – to increase transformation capacity for the Southern York Area.
- Increased the size of the capacitor banks at Armitage TS (2006) – to improve reliability of supply to the Northern York Area.
- Connect the York Energy Centre generation facility (2012) – to provide a local source of supply for the Northern York Area.

The following development projects are currently underway:

- Vaughan MTS #4 (2017) – to increase transformation capacity for the Southern York Area.
- Holland breakers, disconnect switches and special protection scheme (2017) – to increase the transmission supply capacity and load restoration capability of the York Sub-Region.

5 FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the GTA North Region is forecast to increase at an average rate of approximately 2.1% annually up 2020, and 1.8% between 2020 and 2025. The growth rate varies across the Region.

Figure 5-1 shows the GTA North Region extreme summer weather coincident peak net load forecast. The coincident peak net load forecast for the individual stations in the GTA North Region is given in Appendix D. The net load forecast takes into account the expected impacts of conservation programs and distributed generation resources.

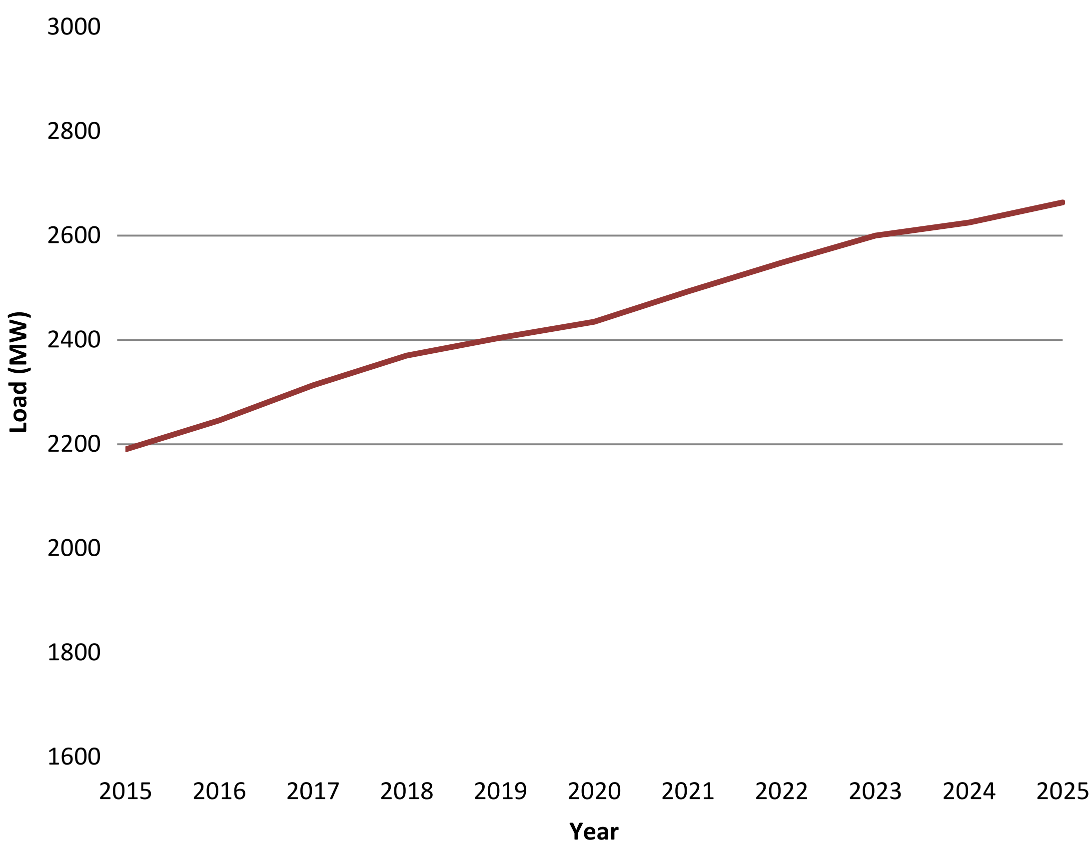

Figure 5-1 GTA North Region Extreme Summer Weather Coincident Peak Net Load Forecast

The station coincident peak net loads used in the RIP are as given in the York Region IRRP for the York Sub-Region[1] and the NA for the Western Sub-Region[2]. RIP Working Group participants confirmed that the load forecast, CDM, and DG information used in the IRRP and NA for the Western Sub-Region was still valid.

5.2 Other Study Assumptions

Further assumptions are as follows:

- The study period for the RIP Assessments is 2015-2025.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor which is consistent with ORTAC[4]. Normal planning supply capacity for transformer stations in this region is determined by the summer 10-Day Limited Time Rating ("LTR").

6 ADEQUACY OF FACILITIES AND REGIONAL NEEDS OVER THE 2015-2025 PERIOD

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND STEP DOWN TRANSFORMATION STATION FACILITIES SUPPLYING THE GTA NORTH REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM.

Within the current regional planning cycle two regional assessments have been conducted for the GTA North Region; the findings of these studies are input to the RIP:

1) IESO's York Region Integrated Regional Resource Plan – dated April 28, 2015[1]
2) Hydro One's Needs Assessment Report – GTA North – Western Sub-Region – June 27, 2014[2]

The York region IRRP identified a number of regional needs to meet the forecast load demand over the near to mid-term. Due to the immediate nature of the needs the Holland TS Breakers project and the Vaughan #4 MTS project were initiated to provide adequate load supply capability for the York Sub-Region while the York Region IRRP study was still underway. A detailed description and status of the Holland TS Breakers project and other work initiated or planned to meet these needs is given in Section 7.

This RIP reviewed the loading on transmission lines and stations in the GTA North Region assuming the Holland TS Breakers project is in-service using the latest Regional Forecast based on the IRRP load growth scenario as given in Section 5. Sections 6.1- 6.4 present the results of this review and Table 6-1 lists the Region's needs identified in both the IRRP and RIP phases.

Table 6-1 Near and Mid-Term Needs in the GTA North Region

Type	Section	Needs	Timing
Step-down Transformation Capacity	7.1.1	Additional transformation capacity in Vaughan (new Vaughan MTS #4 on circuits B82V/B83V)	2017
	7.1.4	Additional transformation capacity in Markham	2022(3)
	7.1.3	Additional transformation capacity in Vaughan(1)	2023(3)
	7.2.2	Additional transformation capacity in Northern York Area(1)	2023
Transmission Capacity	7.2.1	Capacity of the Claireville to Brown Hill (B82V/B83V) transmission line exceeded	2021
Load Security	7.2.1	Claireville to Brown Hill line (B82V/B83V)	2018
	7.1.2	Parkway to Claireville line (V71P/V75P)	Today
Load Restoration	7.2.1	Claireville to Brown Hill line (B82V/B83V)	Today
	7.1.2	Parkway to Claireville line (V71P/V75P)	Today
	7.3.1	Claireville to Kleinburg line (V43/V44) – restoration need only(2)	Today

(1) There are long-term transmission supply needs associated with new transformation capacity
(2) Restoration need to be assessed as part of the IESO led GTA West bulk system planning initiative
(3) PowerStream is currently reviewing their forecast and has advised that the need date for Markham may change to 2023 and the need date for Vaughan may change to 2026.

6.1 Adequacy of York Sub-Region Facilities

6.1.1 500 and 230 kV Transmission Facilities

All 500 and 230 kV transmission circuits in the GTA North are classified as part of the Bulk Electricity System ("BES"). The 230 kV circuits also serve local area stations within the region. The York Sub-Region is comprised of the following 230 kV circuits. Refer to Figure 3-2.

Southern York Area:

a) Parkway TS to Cherrywood TS 230 kV circuits: C35P and C36P.
b) Parkway TS to Claireville TS 230 kV circuits: V71P and V75P.
c) Parkway TS to Buttonville TS ("Buttonville Tap") 230 kV circuits: P45 and P46.
d) Parkway TS to Richview TS 230 kV circuits: P21R and P22R.

Northern York Area:

- Claireville TS to Brown Hill TS 230 kV circuits: B82V and B83V.

The RIP review shows that based on current forecast station loadings and bulk transfers, all 230 kV circuits are expected to be adequate over the study period.

6.1.2 Step down Transformer Station Facilities

There are a total of twelve step-down transformers stations in the York Sub-Region as follows:

Table 6-2 Step-Down Transformer Stations in the York Sub-Region

Northern York Area		
Armitage TS	Brown Hill TS	Holland TS
Southern York Area		
Buttonville TS	Markham MTS#1*	Markham MTS#2*
Markham MTS#3*	Markham MTS#4*	Richmond Hill MTS*
Vaughan MTS#1*	Vaughan MTS#2*	Industrial Customer

*Stations owned by PowerStream

Based on the LTR of these load stations, additional capacity is required in Vaughan in 2017 which will be addressed by Vaughan MTS #4. Based on the forecast in Appendix D, additional capacity is required in Markham as early as 2022, and additional capacity will be needed in both Vaughan and Northern York Area as early as 2023. However, PowerStream has advised that their forecast for Markham and Vaughan is currently under review, and that these need dates may change to 2023 and 2026 respectively.

The station loading in each area and the associated station capacity and need dates are summarized in Table 6-3.

Table 6-3 Adequacy of the Step-Down Transformation Facilities in the York Sub-Region

Area/Supply	Capacity (MW)	2015 Summer Loading (MW)*	Need Date
Northern York Area (Armitage, Holland)	485	430	2023
Northern York Area (Brown Hill)	184	74	-
Southern York Area (Markham/Richmond Hill)	956	833	2022
Southern York Area (Vaughan)	612**	459	2023

* Weather adjusted summer peak as per York Region IRRP

** Includes future capacity provided by Vaughan #4 MTS. It does not include Vaughan MTS #3 which is in the Western Sub-Region

6.2 Adequacy of Western Sub-Region Facilities

The Western Sub-Region is comprised of one 230 kV double circuit line V43/V44 between Claireville TS and Kleinburg TS. Refer to Figure 3-2. The line supplies Kleinburg TS, Vaughan MTS #3, and Woodbridge TS. Loading on the V43/V44 line is adequate over the study period.

6.2.1 Step down Transformation Facilities

There are three step-down transmission connected transformation stations in the York Sub-Region as follows:

Table 6-4 Step-Down Transformer Stations in the Western Sub-Region

Kleinburg TS
Woodbridge TS
Vaughan MTS#3*

*Station owned by PowerStream

The forecast individual station forecast loads are given in Appendix D. Based on the forecast loads these transformer stations are adequate over the study period. The total station capacity and 2015 loads in Western Sub-Region are given in Table 6-5.

Table 6-5 Adequacy of Step-Down Transformation Facilities – Western Sub-Region

Area/Supply	Capacity (MW)	2015 Summer Loading (MW)	2025 Summer Loading (MW)
Western Sub-Region (Vaughan/Kleinburg)	509	394	409

6.3 Other Items Identified During Regional Planning

6.3.1 Load Security and Restoration in the Southern York Area

The York Region IRRP report had identified load security and restoration needs for loss of the Claireville TS to Parkway TS 230 kV double circuit line V71P/V75P. Loading on the Claireville TS to Parkway TS 230 kV double circuit line V71P/V75P exceeds the 600 MW limit as per ORTAC security criteria. Loads in excess of 250 MW cannot be restored in less than 30 minutes as per the ORTAC restoration criteria. The needs and the Working Group recommendations to address the needs are discussed in more detail in Section 7.1.2.

6.3.2 Load Restoration in Western Sub-Region

The Needs Assessment report for the Western Sub-Region had identified a load restoration need for the loss of the Claireville TS to Kleinburg TS 230 kV double circuit line V43/V44. Loads in excess of 250 MW cannot be restored in less than 30 minutes as per the ORTAC restoration criteria. The Working Group has reviewed the need and reaffirmed the NA recommendation that this need be considered as part of the IESO led GTA West bulk system planning initiative.

6.4 Long-Term Regional Needs

As shown in Section 6.1.2 additional transformation capacity is required in the mid-term. With continued demand growth, the transmission system supplying these stations is also expected to reach its limits. The York Region IRRP had identified the need to coordinate the long term transmission needs with plans to address the station capacity needs.

The GO Rail Electrification Project is an initiative by Metrolinx to convert several rail corridors from a diesel to an electric-based system. GO's Barrie and Stouffville corridors are part of this plan and it is expected that parts of these rail corridors will be supplied by transmission infrastructure in the GTA North Region. At the time of this RIP the electrification project is still in the planning phase, but the impact of this project on the electrical infrastructure in the GTA North Region will need to be monitored as the plans are developed.

The options to address the transformation capacity needs are being reviewed by the Working Group as part of the community engagement activities currently being led by the IESO and LDCs through a Local Advisory Committee process. The Working Group expects to finalize recommendations to address these and associated long-term transmission needs in an IRRP update currently scheduled for 2017.

7 REGIONAL PLANS

This section discusses the needs, wires alternatives and the current preferred wires solution for addressing the electrical supply needs in the GTA North Region. These needs are listed in Table 6-1 and include needs previously identified in the IRRP for the York Sub-Region[1] and the NA for the Western Sub-Region.[2] Needs for which work is already underway are also included.

The near-term needs include needs that arise over the first five years of the study period (2015 to 2020) and the mid-term needs cover the second half of the study period (2020-2025).

7.1 Southern York Area

7.1.1 Increase Transformation Capacity in Vaughan

7.1.1.1 Description

The load forecast reflects substantial growth around the City of Vaughan, mainly around the northern boundaries, as new developments are being made in the area. As a result, based on the net demand forecast a new transformer station is needed by 2017 to ensure adequate transformation capacity is available. This need was also identified as a near-term need in the 2015 York Region IRRP.

7.1.1.2 Recommended Plan and Current Status

Due to the need to provide transformation capacity by 2017, work on building a new station was initiated by PowerStream while the York Region IRRP was still under way. The IRRP Working Group recommended that the new station connect to the Claireville to Brown Hill lines (230 kV circuits B82V/B83V) approximately 12 km north of Claireville TS.[5] Refer to Figure 7.1.

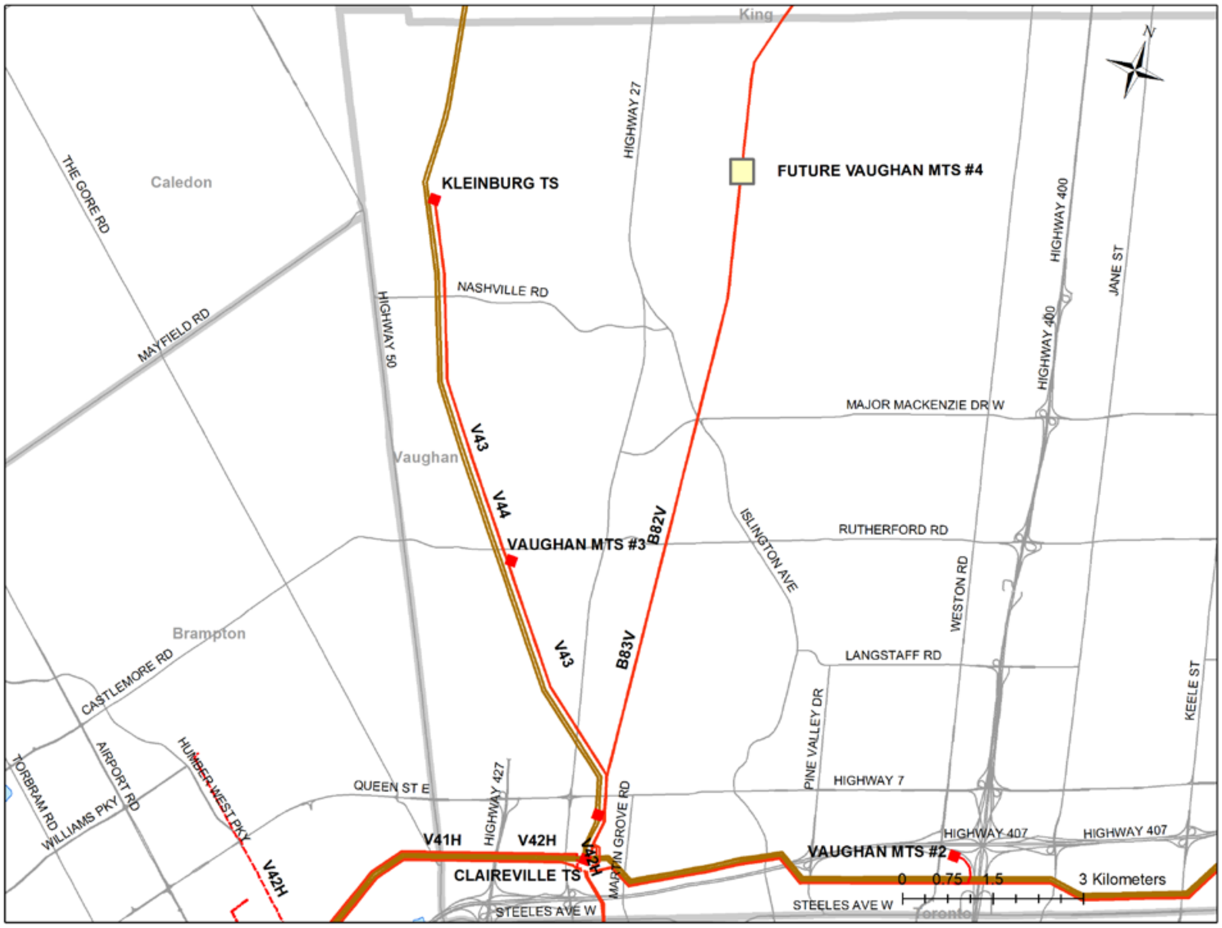

Figure 7-1 Vaughan MTS #4

The new station, Vaughan MTS #4, will provide 153 MW of 27.6 kV transformation capacity and is expected to be in-service by May 2017. Hydro One will construct the line tap to connect the new station to the B82V/B83V circuits.

PowerStream's estimated cost for the station is $25M. The Hydro One line connection cost is currently being estimated. The Hydro One line connection cost will be recovered from rate revenue in accordance with the TSC.

7.1.2 Improve Load Restoration Capability on the Parkway to Claireville Line

7.1.2.1 Description

The Parkway to Claireville line (V71P/V75P) is located on the Parkway Belt and supplies five load stations with a combined load of approximately 700 MW under current summer peak loading conditions. There are two needs identified for this system:

- The load security criteria in ORTAC[4] limits the amount of load that can be interrupted due to the loss of two elements (e.g.: a double circuit line outage) to 600 MW under peak load. On the Parkway to Claireville line, that limit is exceeded.
- The load restoration criteria requires that any load that is interrupted that exceeds 250 MW must be restorable within 30 minutes. At present, this may not be possible on the Parkway to Claireville line under certain operating conditions.

7.1.2.2 Recommended Plan and Current Status

The York Region IRRP recommended the installation of inline switches at the Vaughan MTS #1 junction in order to improve the capability of the system to restore load in the event that both 230 kV circuits V71P/V75P are lost. The switches will not reduce the amount of load that is interrupted, however they will enable Hydro One to quickly isolate the problem and allow the resupply of load to occur expeditiously. This work is covered under the V71P/V75P - Install 230 kV In-line Switches project.

Hydro One has established a project to install the two 230 kV in-line switches onto the V71P/V75P double circuit line with one switch installed on each circuit. The project is currently in the detailed design and estimation phase. The cost of this project is approximately $4-6 million and it is anticipated to be a transmission pool investment. The planned in-service date is May 2018.

7.1.3 Mid-Term Need to Increase Transformation Capacity in Vaughan

7.1.3.1 Description

The planned Vaughan MTS #4 will provide near term transformation capacity for Vaughan beginning in 2017. However, the load forecast shows that additional transformation capacity will be needed in Vaughan as early as 2023. There isn't sufficient transmission capacity available to supply another transformation station on the Claireville to Brown Hill line. Therefore a plan to increase transmission capacity to the area will be required before a plan for a new transformation station can be committed.

7.1.3.2 Recommended Plan and Current Status

Given the time required to build new transmission facilities, the York Region IRRP[1] had advised that it was necessary to identify a preferred alternative no later than 2018 to address both the transformation capacity need as well as the transmission capacity need. However, PowerStream is currently reviewing their load forecast for Vaughan and has advised that the need date for new transformation capacity may change to 2026. An update to the York Region IRRP is currently scheduled for 2017 to review the need date and develop a preferred plan for building and connecting additional transformation capacity in Vaughan.

7.1.4 Mid-Term Need to Increase Step-Down Transformation Capacity in Markham

7.1.4.1 Description

The step-down transformation capacity in Markham will be exceeded as early as 2022. The York Region IRRP has identified that additional transmission facilities will be required to supply the new station. It is expected that the IESO will continue to explore non-wires options, in addition to wires options, through the IRRP process.

New developments attributable to forecasted load growth in the area are generally further north, away from existing transmission facilities. The ORTAC's[4] load restoration criteria will need to be considered in the further development of any detailed wires options. Non-wires options are beyond the scope of this RIP, but there are two main wires options for supplying a new Markham transformer station.

Option 1 - Connect to 230kV circuits C35P/C36P between Parkway TS and Cherrywood TS
The Parkway to Cherrywood line (C35P/C36P) connects two major bulk transmission stations, Parkway TS and Cherrywood TS, and also supplies load stations Markham MTS #3 (2 stations) and Markham MTS #2. There is transmission capacity available on these circuits to connect another transformer station.

Option 2 – Connect to 230kV double circuit line P45/P46 between Parkway TS and Buttonville TS
The Buttonville Tap (P45/P46) currently supplies two stations, Markham MTS #4 and Buttonville TS radially from Parkway TS. The transmission capacity on these circuits is thermally limited by a section less than 1 km long, so it would be necessary to increase the thermal capacity of these circuits in order to fully supply another station.

Extending the transmission circuits discussed would allow the point of supply to be nearer to the area of expected load growth and therefore reduce the amount of distribution facilities that would be needed.

7.1.4.2 Recommended Plan and Current Status

The existing transmission lines are not near the areas of expected load growth so the additional transmission costs to supply a new station nearer to the load need to be considered alongside the distribution costs. PowerStream estimates the incremental distribution costs for a station supplied by existing transmission lines to be on the order of $10-$50M higher than would be required for a station located nearer to the load.

Given that this need is a mid-term need, the York Region IRRP[1] identified a number of non-wires approaches that may address or defer the need for further transformation capacity. Such alternatives include CDM, DG, large generation and other local community initiatives and further monitoring of the load growth was recommended. In order to have facilities in-service to meet a summer 2022 need, it is recommended to continue wires planning, in addition to other non-wires alternatives, to meet this need and to identify a preferred solution by the end of 2017. This timeline allows approximately 4.5 years for detailed estimating, engineering, approvals, construction and commissioning if a wires option is identified as the preferred alternative. However, PowerStream is currently reviewing their load forecast for Markham and has advised that the need date for new transformation capacity may change to 2023. It is expected that the need date will be reviewed and a preferred solution will be identified in the York Region IRRP update process which is currently scheduled for 2017.

7.2 Northern York Area

7.2.1 Increase Capacity and Load Restoration Capability on Claireville to Brown Hill Line

The transmission capacity, load security and load restoration requirements are near-term needs for the Claireville to Brown Hill line (circuits B82V/B83V). These needs were identified in the 2015 York Region IRRP[1]. The Claireville to Brown Hill transmission line and local generation (York Energy Centre) combined are capable of supplying 600 MW of load. This limit is based on the ORTAC[4] load security criteria, which limits the amount of load that can be lost for two elements out of service to 600 MW. This is the most restrictive limit in this system and therefore defines the amount of load that can be supplied. With continued load growth at the stations supplied by this line as well as the future Vaughan #4 MTS (described in section 7.1), it is expected that load security criteria will be exceeded by 2018 based on the net demand forecast.

The load restoration need is based on the ORTAC[4] load restoration criteria that requires any load lost exceeding 250 MW to be restorable within 30 minutes. Based on the current net peak demand forecast, the loss of the Claireville to Brown Hill line will exceed this threshold and there are insufficient transmission and distribution facilities to restore sufficient load within 30 minutes in order to respect the criteria.

7.2.1.1 Recommended Plan and Current Status

Hydro One is expanding the Holland TS station to include two, 230kV inline circuit breakers and six motorized disconnect switches to increase the transmission capacity as well as the load restoration capability of this system. The project includes a load rejection and generation rejection special protection scheme (“SPS”). The purpose of the SPS is to ensure that the transmission system does not get overloaded following respected contingencies. The IESO (formerly the Ontario Power Authority) stated their support for this project in a letter to Hydro One dated June 14, 2013.[5] The planned in-service date for this project is Q4 2017 at an estimated cost of $32 million. This is anticipated to be a transmission pool cost and LDCs are not expected to pay any contribution.

The station service supply to the York Energy Centre is currently supplied from Holland TS. However, a low-voltage breaker failure event at Holland TS or a double circuit 230 kV contingency can result in an interruption to the station service supply to York Energy Centre and therefore the loss of all generation output until the station service can be restored from the alternate source. The IESO intends to develop a plan to address this issue in the York Region IRRP update currently scheduled for 2017.

7.2.2 Mid-Term Need to Increase Transformation Capacity

Based on the growth forecast for the Northern York Area, the combined loading on Armitage TS and Holland TS will exceed their combined summer 10-Day LTR as early as 2023. There is 44 kV transfer capability between these stations on the distribution system so the timing of the need is based on the combined capability of both stations. The IRRP indicated that the Claireville to Brown Hill circuits do not have sufficient capacity to fully supply another transformation station in Northern York Area after the Vaughan #4 MTS connection and Holland breakers project and therefore there is a long-term need to increase transmission capability to supply a new station. However, as noted in the York Region IRRP, under a low growth scenario in the long term, the demand in Northern York Area will stabilize to within the capacity of existing stations to beyond 2033.

7.2.2.1 Recommended Plan and Current Status

The York Region IRRP[1] identified a number of non-wires alternatives that may address or defer the need for further transformation capacity in Northern York Area. Such alternatives include CDM, DG, large generation and other local community initiatives. However, given that the need date for this area may be as early as 2023, it is necessary to identify a preferred alternative by 2018 that addresses both the transformation capacity need as well as the transmission capacity need. The working group expects to finalize a plan and recommendations to address these needs in an IRRP update currently scheduled for 2017.

7.3 Western Sub-Region

7.3.1 Load Restoration Need for the Claireville to Kleinburg Line

The three stations in this sub-region, Woodbridge TS, Vaughan #3 MTS and Kleinburg TS, are supplied by two radial 230kV circuits, V43 and V44, originating from Claireville TS. Inherent to radial configuration, the loss of these two circuits will interrupt supply to loads and consequently load restoration times as per the ORTAC[4] may not be met. This need was identified during the NA for this sub-region and also in the Northwest GTA IRRP[6] and it was subsequently recommended that this need be addressed in the IESO's GTA West bulk system planning initiative.

7.4 Long Term Future Transmission Corridor to the GTA North Region

The GTA West RIP recommended the establishment of a future-use transmission corridor, to address growth-related needs in the GTA West region. In addition to addressing needs in the GTA West region, development of an eastern portion of this corridor through the City of Vaughan is also a possible option that could address the long-term supply needs identified for York Region. It is therefore recommended that, in the development of the long-term plans for the GTA West and GTA North regions, consideration be given to coordinating solutions to meet the needs of both regions when assessing options for each region individually.

8 CONCLUSIONS AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GTA NORTH REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in Table 8-1.

Table 8-1: Regional Plans – Needs Identified in the Regional Planning Process

No.	Need Description
I	Vaughan Transformation Capacity (Near Term)
II	Northern York Area Load Security on B82V/B83V
III	Northern York Area Load Restoration on B82V/B83V
IV	Parkway to Claireville – Load Security on V71P/V75P
V	Parkway to Claireville – Load Restoration on V71P/V75P
VI	Markham Transformation Capacity (Mid-term)
VII	Vaughan Transformation Capacity (Mid-term)
VIII	Northern York Area Transformation Capacity (Mid-term)
IX	Kleinburg Tap – Load Restoration on V43/V44

Next Steps, Lead Responsibility, and Timeframes for implementing the wires solutions for the needs are summarized in Table 8-2 below. Investments to address the needs where there is time to make a decision (Needs No. VI, VII, and VIII), will be reviewed and finalized in the next regional planning cycle. Need No. IX will be addressed in the IESO GTA West bulk system planning initiative.

Table 8-2: Regional Plans – Next Steps, Lead Responsibility and Planned In-Service Dates

Id	Project	Next Steps	Lead Responsibility	I/S Date	Estimated Cost	Needs Mitigated
1	Vaughan #4 MTS	LDC to carry out the work	PowerStream	2017	$25M	I
2	Holland Breakers and SPS	Transmitter to carry out the work	Hydro One	2017	$32M	II, III
3	Parkway Belt Switches	Transmitter to carry out the work	Hydro One	2018	$4-6M	V

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least every five years. Due to the timing of the mid-term needs, the IRRP proposed that the process be updated in advance of the regular 5-year review schedule. The York Region IRRP is currently scheduled to be updated in 2017.

APPENDIX E: LIST OF ACRONYMS

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN (“RIP”) WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE GTA WEST REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Transmission)
- Burlington Hydro Electric Inc.
- Enersource Hydro Mississauga Inc.
- Halton Hills Hydro Inc.
- Hydro One Brampton Networks Inc.
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator (“IESO”)
- Milton Hydro Distribution Inc.
- Oakville Hydro Electricity Distribution Inc.

This RIP is the final phase of the regional planning process and it follows the completion of the Northwest GTA Integrated Regional Resource Plan (“IRRP”) in April 2015; and the GTA West Southern Sub-Region’s Needs Assessment (“NA”) and Scoping Assessment (“SA”) in May 2014 and September 2014, respectively.

This RIP provides a consolidated summary of needs and recommended plans for both the Northern Sub-Region and Southern Sub-Region that make up the GTA West Region.

The major infrastructure investments planned for the GTA West Region over the near and medium-term (2016-2025), identified in the various phases of the regional planning process, are given in the table below with anticipated in-service date and estimated cost. Several long-term needs beyond 2026 have been identified, and further assessments are currently underway as part of the IESO Bulk System Study.

No.	Project	I/S Date	Cost
1	Build new Halton Hills Hydro MTS	2018	\$19M (1)
2	Build new Halton TS #2	2020	\$29M (1)
3	Build new 44/27.6 kV DS to relieve Erindale TS T1/T2	2018-2019	\$5M
4	Upgrade (reconductor) circuits H29/H30 (2)	2023-2026	\$6.5M

Notes:

(1) Excludes cost for distribution infrastructure

(2) The plan will be reviewed and finalized in the next regional planning cycle

The following needs will be considered in the scope of the Bulk System Study led by the IESO:

- Richview x Trafalgar (R14T/R17T & R19TH/R21TH) circuit capacity need;
- Radial supply to Halton TS (T38/T39B) circuit capacity need;
- Supply security and restoration to several load pockets in GTA West Region.

The IESO's Northwest GTA IRRP has identified that Halton Hills, Caledon, Brampton, and Vaughan area is expected to grow by 849-1132 MW by 2031, as forecast by the Province "Places to Grow" program. A new electricity corridor will be required for additional transmission facilities required to meet this long-term need in the area. The RIP Working Group recommends further assessments to be carried out and complete technical details, layout of high voltage electricity infrastructure no later than Q4 2016. Following this, Environmental Approval and acquisition of land rights would be under taken to ensure that the transmission facilities on this corridor can be placed to meet the needs.

As per the OEB mandate, the Regional Plan should be reviewed and/or updated at least every five years. It is expected that the next planning cycle for this region will start in 2018. If there is a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle can be started earlier to address the need.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE GTA WEST REGION.

The report was prepared by Hydro One Networks Inc. (Transmission) ("Hydro One") on behalf of the Working Group in accordance with the regional planning process established by the Ontario Energy Board ("OEB") in 2013. The Working Group included members from the following organizations:

- Hydro One Networks Inc. (Transmission)
- Burlington Hydro Electric Inc.
- Enersource Hydro Mississauga Inc.
- Halton Hills Hydro Inc.
- Hydro One Brampton Networks Inc.
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator ("IESO")
- Milton Hydro Distribution Inc.
- Oakville Hydro Electricity Distribution Inc.

The GTA West Region encompasses the municipalities of Brampton, southern Caledon, Halton Hills, Mississauga, Milton, and Oakville. The region includes the area roughly bordered geographically by Highway 27 to the north-east, Highway 427 to the south-east, Regional Road 25 to the west, King Street to the north and Lake Ontario to the south, as shown in Figure 1-1.

Bulk electricity in the region is supplied by Burlington TS from the west, Claireville TS from the north, Richview TS and Manby TS from the east, and 500/230 kV Trafalgar TS autotransformers, and distributed by a network of 230 kV transmission lines and 17 step-down transformer stations. The summer 2015 peak load of the region was approximately 2900 MW.

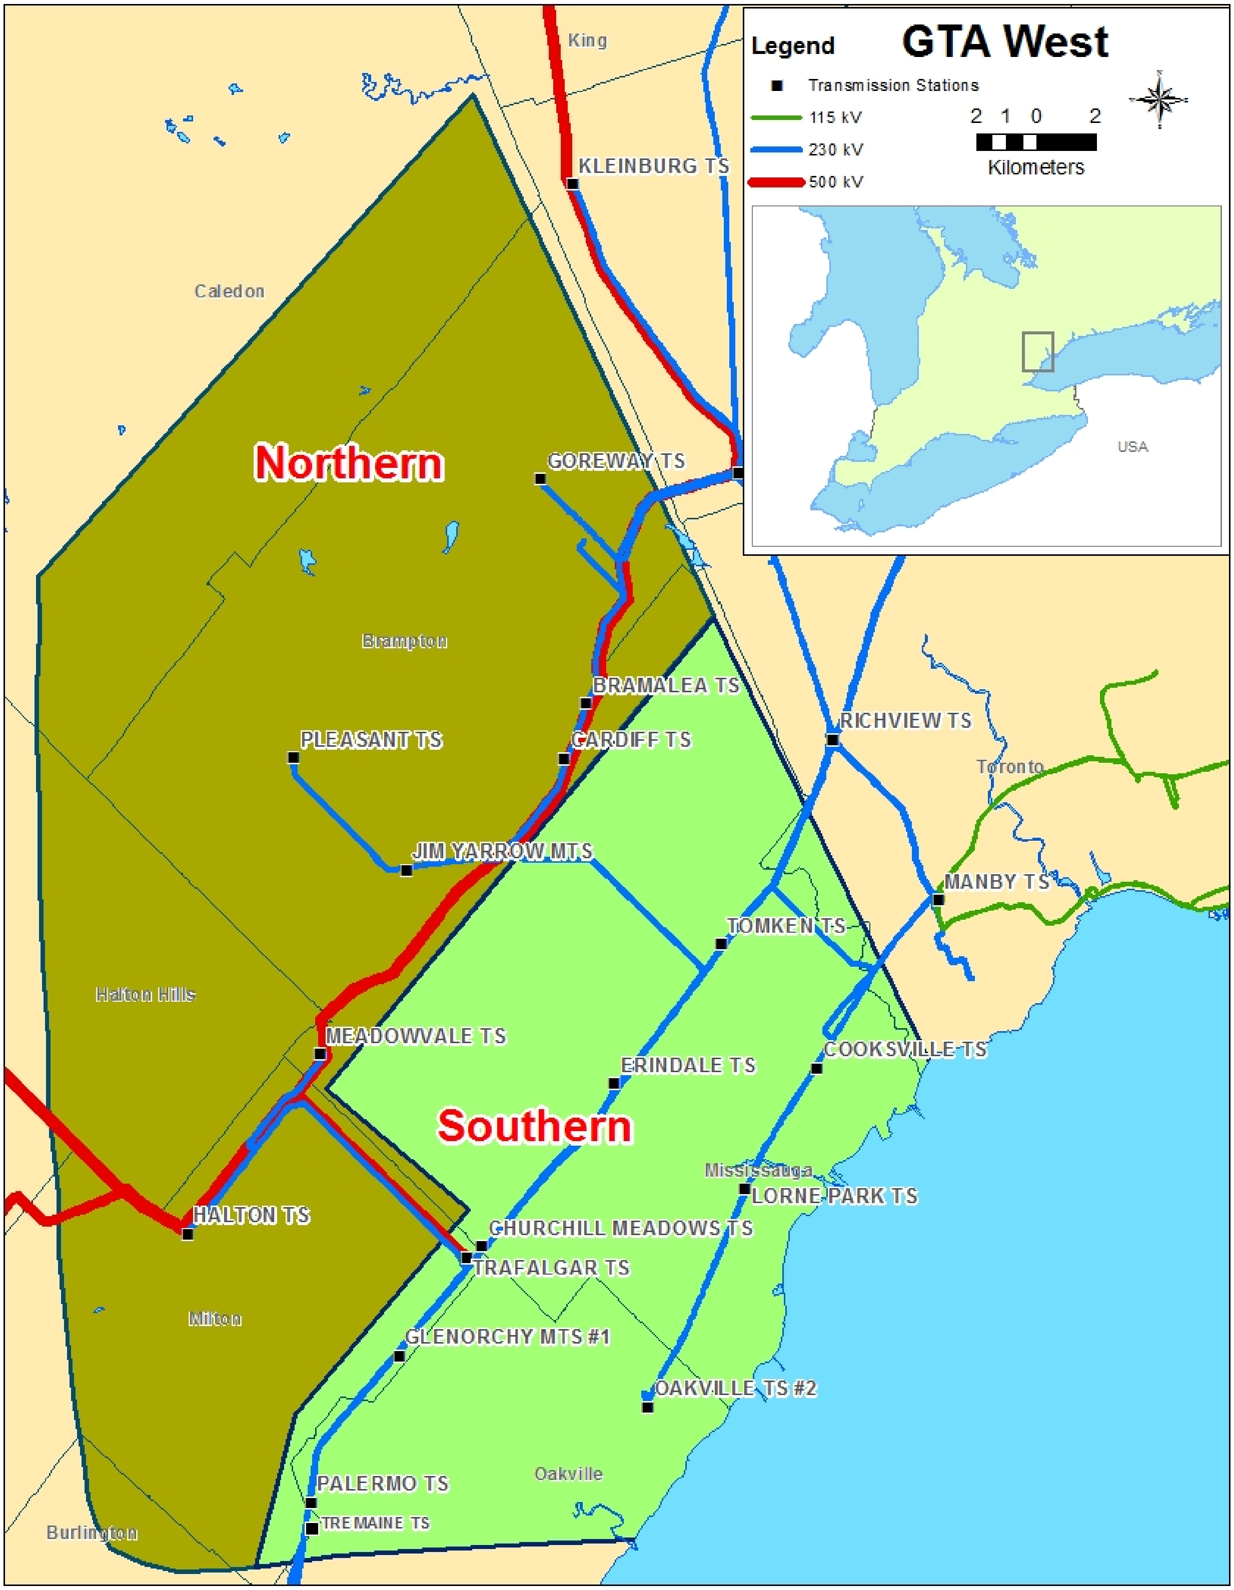

Figure 1-1 GTA West Region Map

1.1 Scope and Objectives

This RIP report examines the needs in the GTA West Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop wires plans to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs (2015-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan, or Integrated Regional Resource Plan);
- Identification of any new needs over the 2015-2025 period and wires plans to address these needs based on new and/or updated information;
- Develop a plan to address any longer terms needs identified by the Working Group.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process;
- Section 3 describes the region;
- Section 4 describes the transmission work completed over the last ten years;
- Section 5 describes the load forecast and study assumptions used in this assessment;
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs;
- Section 7 discusses the needs and provides the alternatives and preferred solutions;
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend

[1] also referred to as Needs Screening

a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee (LAC) in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

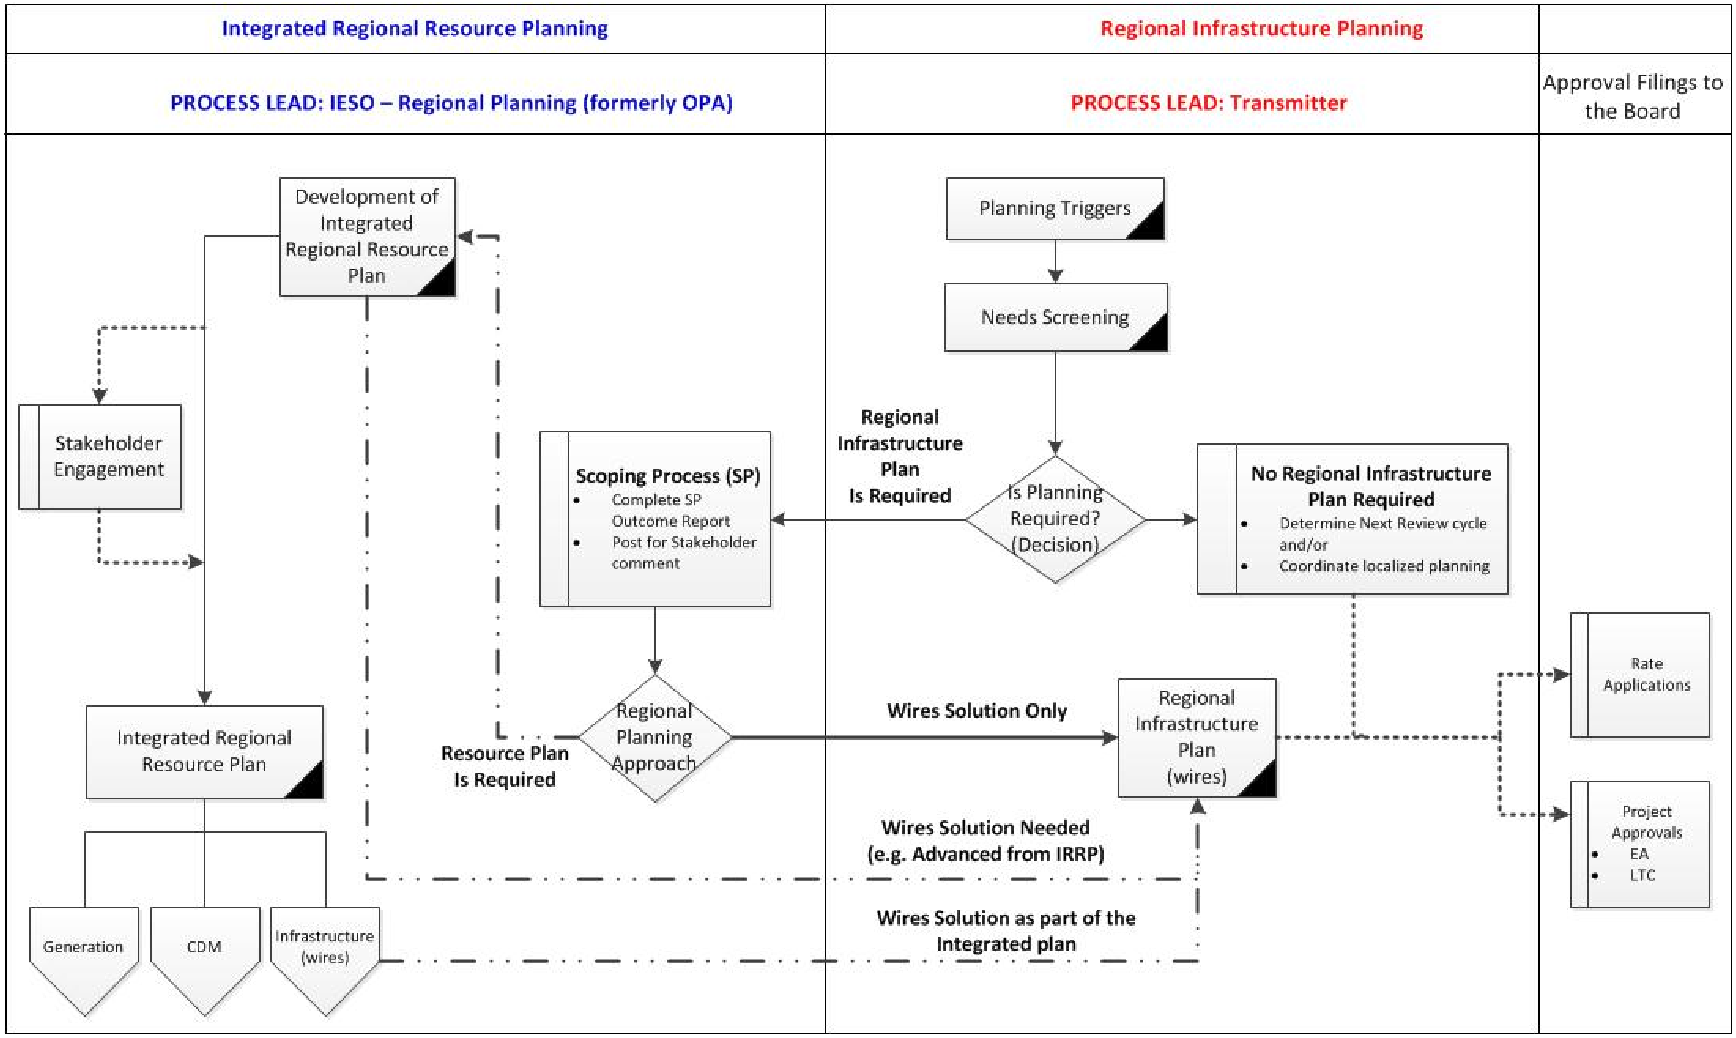

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1. Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions, load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

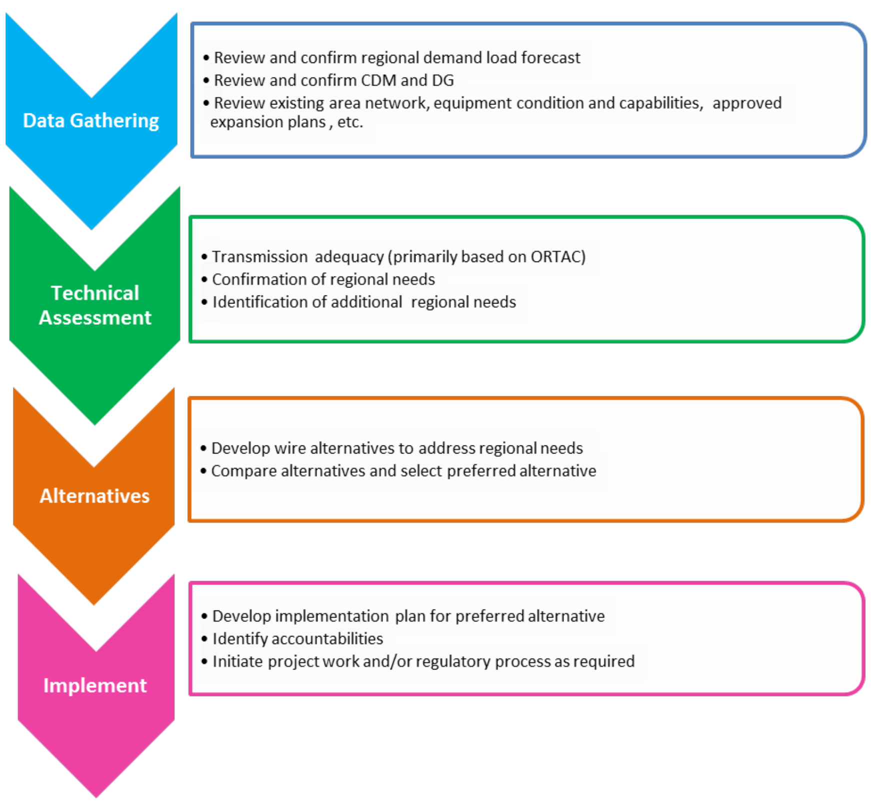

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE GTA WEST REGION ENCOMPASSES THE MUNICIPALITIES OF BRAMPTON, SOUTHERN CALEDON, HALTON HILLS, MISSISSAUGA, MILTON, AND OAKVILLE. THE REGION INCLUDES THE AREA ROUGHLY BORDERED GEOGRAPHICALLY BY HIGHWAY 27 TO THE NORTH-EAST, HIGHWAY 427 TO THE SOUTH-EAST, REGIONAL ROAD 25 TO THE WEST, KING STREET TO THE NORTH AND LAKE ONTARIO TO THE SOUTH.

Bulk electricity in the region is supplied by Burlington TS from the west, Claireville TS from the north, Richview TS and Manby TS from the east, and 500/230 kV autotransformers at Trafalgar TS, and distributed by a network of 230 kV transmission lines and 17 step-down transformer stations. Local generation in the region includes the two gas fired plants: Sithe Goreway CGS (839 MW rated capacity) and TCE Halton Hills CGS (683 MW rated capacity). The summer 2015 regional coincidental peak load of the region is approximately 2900 MW.

LDCs supplied from electrical facilities in the GTA West Region are Burlington Hydro Electric Inc., Enersource Hydro Mississauga Inc., Halton Hills Hydro Inc., Hydro One Brampton Networks Inc., Hydro One Networks Inc. (Distribution), Milton Hydro Distribution Inc., and Oakville Hydro Electricity Distribution Inc. The LDCs receive power at the step down transformer stations and distribute it to the end users – industrial, commercial and residential customers.

The April 2015 Northwest GTA IRRP report, prepared by the IESO in conjunction with Hydro One and the LDC, focused on the Northern Sub-Region which included the 230 kV facilities in the northern part of Region. The May 2014 Southern GTA Needs Assessment report, prepared by Hydro One, considered the remainder of the GTA West Region.

For the purpose of regional planning, the GTA West Region is divided into Northern and Southern Sub-Regions. A single line diagram showing the electrical facilities of the GTA West Region, consisting of the two sub-regions, is shown in Figure 3-1. More details regarding transformer stations and transmission lines in the region are provided in Appendix A and B, respectively.

GTA West – Northern Sub-Region

The Northern Sub-Region covers the GTA West Region area north of Highway 407. It is supplied by 230 kV circuits out of Trafalgar TS, Claireville TS and Hurontario SS through seven 230/44 kV or 230/27.6kV step down transformer stations, local generation consist of the Sithe Goreway GS located in Brampton and the TransCanada Halton Hills GS located in Halton Hills, Generation is also connected to the LV buses of Bramalea TS in Brampton.

Enersource, Hydro One Brampton, Milton Hydro and Halton Hills Hydro are the three main Local Distribution Companies in the Sub-Region. They receive power at the step down transformer stations and distribute it to the end use customers.

The GTA West – Northern Sub-Region was identified as a "transitional" sub-region, as planning activities in this sub-region were already underway before the new regional planning process was introduced. The NA and SA phases were deemed to be complete, and the regional planning process was considered to be in the IRRP phase. The Northwest GTA IRRP was completed for the Northern Sub-Region in April 2015.

GTA West – Southern Sub-Region

The Southern Sub-Region covers the GTA West Region area south of Highway 407. It is supplied by 230 kV circuits out of Trafalgar TS, Richview TS and Manby TS. There are a total of nine steps down 230/44 kV or 230/27.6 kV step down transformer stations serving the area customers.

Enersource Hydro Mississauga and Oakville Hydro are the main LDCs serving the GTA West - Southern Sub-Region. There is one large industrial customer (Ford Motor Company) in Oakville.

The NA and SA for the Southern Sub-Region were completed in May and September 2014, respectively. A Local Plan has also been developed in this sub-region to address a near-term station capacity need at Erindale TS, further discussed in Section 7.2.

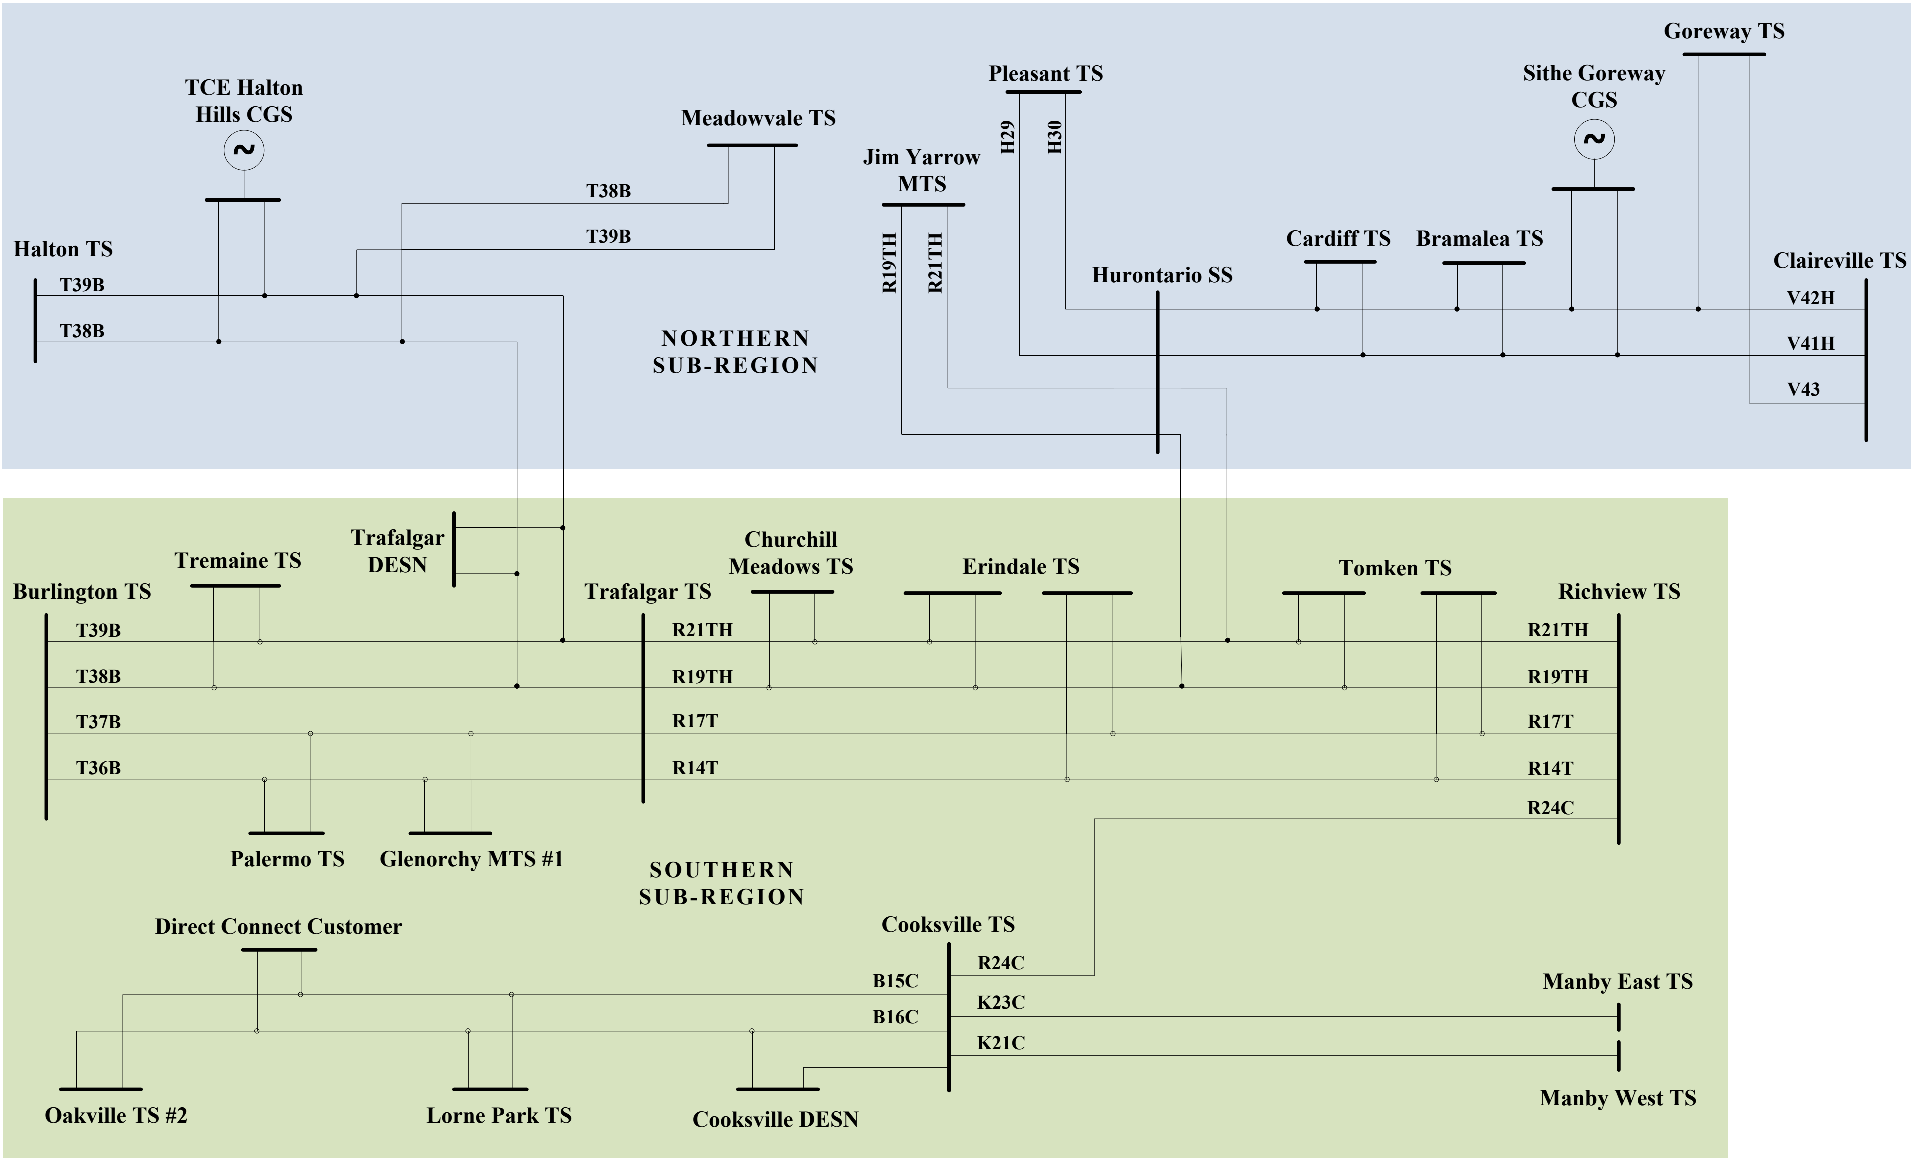

Figure 3-1 GTA West Region Single Line Diagram

4. TRANSMISSION FACILITIES COMPLETED AND/OR UNDERWAY IN THE LAST TEN YEARS

IN THE LAST TEN YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY CAPABILITY AND RELIABILITY IN THE GTA WEST REGION.

A brief listing of those projects is given below:

- Cardiff TS (2005) – built a new step down transformer station consisting of two 50/83 MVA transformers in Brampton supplied from 230 kV circuits V41H and V42H. This station provided additional load meeting capability to meet Enersource Hydro Mississauga Inc. requirements.
- Sithe Goreway CGS (2008) – connect a new 839 MW gas-fired combined cycle generation station in Brampton connected to 230 kV circuits V41H and V42H. This generation station provided necessary local power to supply the GTA West Region.
- Halton TS Shunt Capacitor - installed 43.2 MX of shunt capacitor banks at Halton TS 27.6 kV bus for voltage support (2009).
- Churchill Meadows TS (2010) – built a new step down transformer station consisting of two 75/125 MVA transformers in Mississauga supplied from 230 kV circuits R19TH and R21TH. This station provided additional load meeting capability to meet Enersource Hydro Mississauga Inc. requirements.
- Hurontario SS and underground cable work - built a new switching station Hurontario SS, 4.2 km of double circuit 230 kV Line from Hurontario SS to Cardiff TS and 3.3 km of underground cable from Hurontario SS to Jim Yarrow TS (2010). The new switching station and associated line work connects the R19T/R21T circuits and the V42/V43H circuits to provide relief and improved reliability to Pleasant TS and Jim Yarrow MTS.
- Halton Hills CGS (2010) – connected a new 683 MW gas-fired combined cycle generation station in Halton Hills connected to 230 kV circuits T38B and T39B. This generation station provided necessary local power to supply the GTA West Region.
- Glenorchy MTS (2011) – connected new Oakville Hydro-owned Glenorchy MTS to 230 kV circuits T36B and T37B. This station provided additional load meeting capability to meet Oakville Hydro requirements
- Tremaine TS (2012) – built a new step down transformer station consisting of two 75/125 MVA transformers in Burlington supplied from 230 kV circuits T38B and T39B. This station provided additional load meeting capability to meet Burlington Hydro and Milton Hydro requirements.

5. FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the GTA West Region is expected to grow at an average rate of approximately 0.8% annually from 2015 to 2025, and 0.5% from 2025 to 2035. The growth rate varies across the region ranging from 1.1% in the Northern Sub Region to 0.5% in the Southern Sub Region over the first 10 years. Longer term is a more uniform growth rate of 0.5% across both Northern and Southern Sub Regions. .

Figure 5-1 shows the GTA West Region load forecast from 2016 to 2035. The forecast shown is the regional coincidental forecast, representing the sum of the load in the area for the 17 step-down transformer stations at the time of the regional peak, and is used to determine any need for additional transmission reinforcements. The coincidental regional peak is forecast to increase from approximately 2900 MW in 2015 to 3300 MW in 2035. Non-coincident forecast for the individual stations in the region is available in Appendix A, and is used to determine any need for station capacity relief.

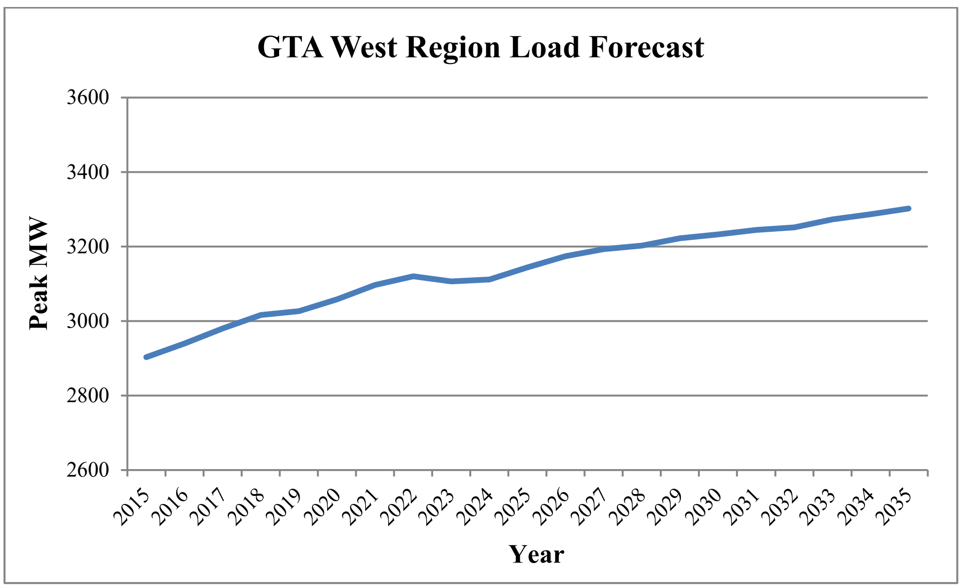

Figure 5-1 GTA West Region Extreme Weather Peak Load Forecast

The regional coincidental load forecast was developed by projecting the 2015 summer peak loads corrected for extreme weather, using the area station growth rates as per the 2015 IESO Northwest GTA IRRP and as per the 2014 Hydro One's Need Assessment Study for the GTA West Southern Sub-Region. The growth rate accounts for CDM measures and connected DG. Details on CDM and connected DG information used in this report are provided in the Northwest GTA IRRP and the Southern Sub-Region's NA, and not repeated in this report.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP assessments is 2015-2035.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is based therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks, or on the basis of historical power factor data.
- Normal planning supply capacity for transformer stations in the region is determined by the summer 10-day Limited Time Rating (LTR).

6. ADEQUACY OF EXISTING FACILITIES AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND STATION FACILITIES SUPPLYING THE GTA WEST REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE 2016-2025 PERIOD.

Within the current regional planning cycle, three regional assessments have been conducted for the GTA West Region. The findings of these assessments are input to the RIP. These assessments are:

1) The Northwest GTA Integrated Regional Resource Plan (IRRP), April 2015 [1]
2) The GTA West Southern Sub-Region's Needs Assessment (NA) Report, May 2014 [2]
3) The GTA West Southern Sub-Region's Scoping Assessment (SA) Report, September 2014 [3]

The IRRP and NA planning assessments identified a number of regional needs to meet the area forecast load demand over the 2016-2025 period. These regional needs are summarized in Table 6-1. Table 6-1 also includes the longer-term needs (up to 2035) that have been identified in the Northern Sub-Region. A detailed description and status of work initiated or planned to meet these needs is given in Section 7.

A review of the loading on the transmission lines and stations in the GTA West Region was also carried out as part of the RIP report. Sections 6.1 to 6.3 present the results of this review.

Table 6-1 Needs Identified in Previous Phases of the GTA West Regional Planning Process

Type	Section	Needs	Timing
Station Capacity	7.1	Halton TS	2018-2020
	7.2	Erindale TS (T1/T2)	Today
Transmission Circuit Capacity	7.3	Richview x Trafalgar (R14T/R17T & R19TH/R21TH)	Within 5 years
	7.4	Radial Supply to Pleasant TS (H29/H30)	2023-2026
	7.5	Radial Supply to Halton TS (T38B/T39B)	2029+
Supply Security	7.6	Supply Security to Halton Radial Pocket (T38B/T39B)	2027
Supply Restoration	7.7	Supply Restoration in Northern Sub-Region [(1)]: - Halton Radial Pocket (T38B/T39B) - Pleasant Radial Pocket (H29/H30) - Cardiff/Bramalea Supply (V41H/V42H)	Today
	7.8	Supply Restoration in Southern Sub-Region: - West of Cooksville (B15C/B16C) - Richview x Trafalgar x Hurontario (R19TH/R21TH) - Richview x Trafalgar (R14T, R17T)	Today
Long-Term Growth	7.9	Pleasant TS (T1/T2) NWGTA Electricity Corridor	2026-2033+

(1) The Northwest GTA IRRP also identified an issue and need to assess "Kleinburg Radial Pocket" supply restoration. This need is being assessed as part of the IESO led Bulk System Study and is not part of this RIP.

6.1 230 kV Transmission Facilities

All 230 kV transmission facilities in the GTA West Region, with the exception of Hurontario SS to Pleasant TS 230 kV circuits H29 and H30 are classified as part of the Bulk Electricity System (BES). A number of these circuits also serve local area stations within the region and the power flow on them depends on the bulk system transfer as well as local area loads. These circuits are as follows (refer to Figure 3-1):

1. Claireville TS to Hurontario SS (230 kV Circuits V41H, V42H, V43) – Supply Bramalea TS, Cardiff TS, and Goreway TS
2. Hurontario SS to Pleasant TS (230 kV Circuits H29, H30) – Supply Pleasant TS
3. Trafalgar TS to Burlington TS, radial tap to Halton TS and Meadowvale TS (230 kV Circuits T38B, T39B) – Supply Halton TS, Meadowvale TS, and Trafalgar DESN
4. Trafalgar TS to Burlington TS (230 kV Circuits T36B, T37B, T38B, T39B) – Supply Glenorchy MTS #1, Palermo TS, and Tremaine TS
5. Richview TS to Trafalgar TS (230 kV Circuits R14T, R17T) – Supply Erindale TS and Tomken TS
6. Richview TS to Trafalgar TS, with tap to Hurontario SS (230 kV Circuits R19TH, R21TH) – Supply Churchill Meadows TS, Erindale TS, Jim Yarrow MTS, and Tomken TS
7. Richview TS and Manby TS to Cooksville TS (230 kV Circuits R24C, K21C, K23C, B15C, B16C) – Supply Cooksville DESN, Ford Oakville CTS, Lorne Park TS, and Oakville TS #2

Based on current forecast station loadings and bulk transfers, the H29/H30 circuits will require reinforcement by 2023-2026. The H29/H30 upgrade will be addressed by Hydro One based on the recommendation stemming from the Northwest GTA IRRP led by the IESO. The Trafalgar to Richview 230 kV circuits (R14T/R17T) will require reinforcement in the near term based on GTA West Southern Sub-Region's NA. This need will be further assessed in the IESO led Bulk System Study.

6.2 500/230 kV Transformation Facilities

All loads are supplied from the 230 kV transmissions system. The primary source of 230 kV supply is the 500/230 kV autotransformers at Trafalgar TS and Claireville TS, as well as 230 kV supply from Burlington TS. Additional support is provided from the 230 kV generation facilities at Halton Hills CGS and Sithe Goreway CGS. Based on the long term forecast in the Northwest GTA IRRP, Trafalgar TS and Claireville TS may require relief in the next 10 years. This need will be studied under the IESO led Bulk System Study.

6.3 Step-Down Transformation Facilities

There are a total of sixteen step-down transformer stations in the GTA West Region. Based on the local station load forecast, Halton TS and Erindale TS would require station capacity relief in the near term, as shown in Table 6-2.

Table 6-2 Step-Down Transformer Stations Requiring Relief

Station	Capacity (MW)	2015 Loading (MW)	Need Date
Halton TS	185.9	176.4	2018
Erindale TS (T1/T2)	181.3	208.3	Now
Pleasant TS (T1/T2)	148.1	124.8	2026-2033 (1)

(1) 2026 under the "Higher Growth" scenario, while 2033 under the "Expected Growth" scenario. Please refer to Northwest GTA IRRP [1]

7. REGIONAL PLANS

THIS SECTION DISCUSSES NEEDS, PRESENTS WIRES ALTERNATIVES AND THE CURRENT PREFERRED WIRES OPTIONS FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS FOR THE GTA WEST REGION. THESE NEEDS ARE LISTED IN TABLE 6-1 AND INCLUDE NEEDS PREVIOUSLY IDENTIFIED IN THE NORTHWEST GTA IRRP AND THE NA FOR THE GTA WEST SOUTHERN SUB-REGION AS WELL AS THE ADEQUACY ASSESSMENT CARRIED OUT AS PART OF THE CURRENT RIP REPORT.

7.1 Halton TS Station Capacity

7.1.1 Description

Halton TS supplies Halton Hills Hydro through 3 feeders and Milton Hydro through 9 feeders at the station. As the load in Halton Hills and Milton continues to grow, the peak load at Halton TS is expected to exceed the station peak load by 2018.

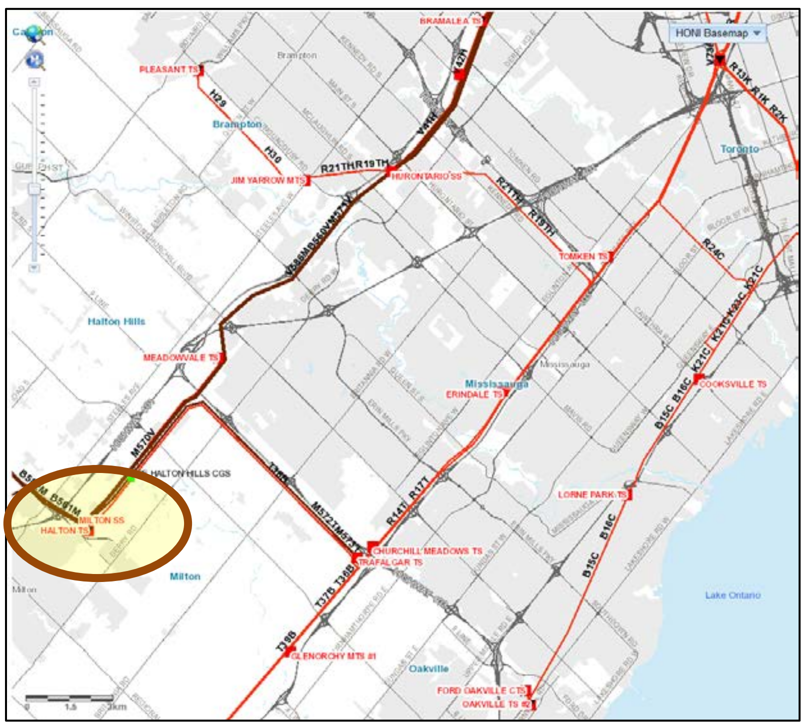

Figure 7-1 Halton TS and Surrounding Areas

7.1.2 Recommended Plan and Current Status

The recommendation of the IRRP is to build two new step-down stations: one to provide supply for Halton Hills Hydro loads and second to supply Milton Hydro load. The Halton Hills Hydro station is expected to be required in 2018, while the Milton Hydro station is expected to be required in 2020.

The IRRP recommends that Halton Hills Hydro proceed to gain the necessary approvals to construct, own, and operate a new step-down station at the Halton Hills Gas Generation facility. Based on technical and economic analysis, the Working Group believes that building this facility is the least-cost option for serving growth within Halton Hills. Currently analysis recommends a targeted in-service date of 2018. Halton Hills Hydro has started a Request for Proposal for the work to construct Halton Hills MTS. The station will consists of two 50/83 MVA transformers with capacity to connect eight distribution feeders. The existing Halton Hills CGS will be expanded to accommodate the HV connection of Halton Hills MTS. There are no transmitter costs for this station. The expected in-service date is spring of 2018. The cost for this station is estimated to be $19 million.

The IRRP recommends Hydro One to initiate engineering work for the development of Halton TS #2 in 2017 (3 year lead-time), at the site of the existing Halton TS, with a tentative in-service date of 2020. The Halton Hills TS #2 will consist of two 75/125 MVA transformers with capacity to connect eight distribution feeders. It will tap to circuits T38B and T39B. The cost for Hydro One to build Halton TS #2 is estimated to be $29 million.

7.2 Erindale TS (T1/T2) Station Capacity

7.2.1 Description

Erindale TS solely supplies Enersource Hydro Mississauga Inc. The existing Erindale TS (T1/T2) DESN load currently exceeds the normal supply capacity. However, there is extra capacity available in the area's 44 kV system that can be utilized by building a step down (44/27.6 kV) distribution station.

Options for providing the required relief were investigated in Local Planning for Erindale TS T1/T2 DESN Capacity Relief [4]. As per the Local Plan, Hydro One and Enersource agreed that this is primarily a distribution planning issue that will involve planning and building a new DS by Enersource to utilize the extra 44 kV station capacity in the area.

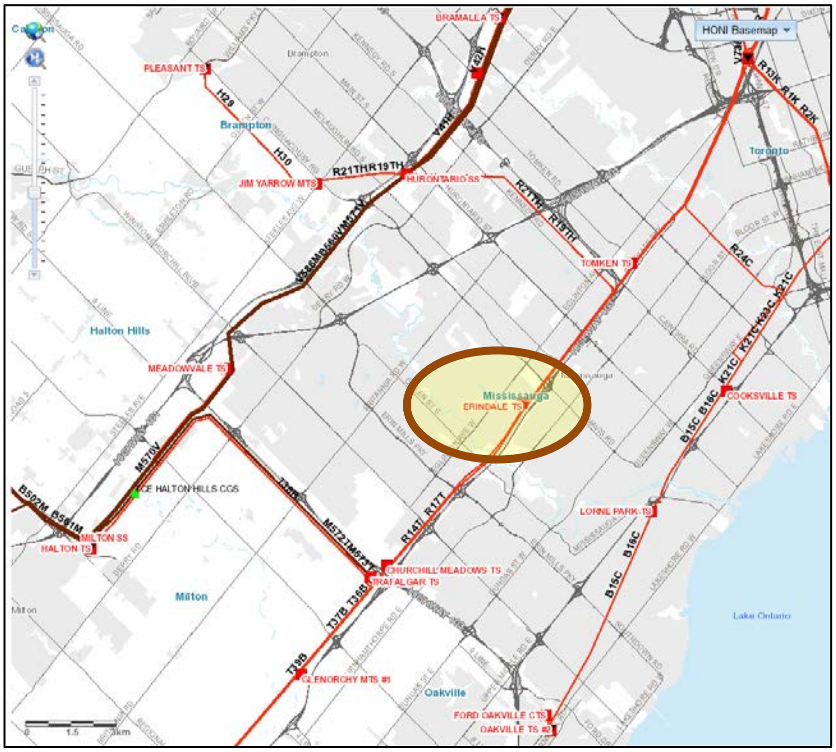

Figure 7-2 Erindale TS and Surrounding Areas

7.2.2 Recommended Plan and Current Status

The proposed DS ("Mini-Britannia MS") is planned to be supplied from Churchill Meadows TS (44 kV system) and provide additional capacity to feed the 27.6 kV load currently supplied by Erindale TS T1/T2. This configuration will reduce over-capacity loading at Erindale TS T1/T2 while balancing the loading capability on 44 kV system via Churchill Meadows TS.

At completion, the substation will house two power transformers (40 MVA capacity), two high voltage switchgears and two low voltage switchgears that will deliver power via four 27.6 kV feeders.

This option is expected to cost $5 million. Under this option, Enersource will build the new DS, own it and recover the costs through the distribution rates. The expected in-service date for the DS is 2018-2019.

7.3 Richview x Trafalgar Transmission Circuit Capacity

7.3.1 Description

As identified in the GTA West Southern Sub-Region's NA, with a single-circuit contingency and high Flow East Towards Toronto (FETT) interface flows, loading on the Richview TS to Trafalgar TS circuits (R14T, R17T, R19TH, R21TH) exceeded their summer long-term emergency ratings in the near-term.

7.3.2 Recommended Plan and Current Status

As these circuits are part of the Bulk Electric System, this need is being further assessed in the IESO-led bulk power system planning.

7.4 Radial Supply to Pleasant TS Transmission Circuit Capacity

7.4.1 Description

Pleasant TS consists of 3 DESNs supplied by 230 kV H29/H30 circuits. Due to growth in load forecasted at Pleasant TS, these circuits are expected to reach their thermal capacity by 2023 at the earliest.

The IRRP process, completed in April 2015, identified the need, discussed alternatives, and recommended a solution to resolve this need.

7.4.2 Recommended Plan and Current Status

The existing conductors used for 230kV circuits H29/H30 going to Pleasant TS are 795.0 kcmil ACSR 26/7 with summer long term emergency rating of 1090 A (at 127°C). They extend 8.5km north from Hurontario SS to Pleasant TS. Based on the study conducted in the Northwest GTA IRRP, this rating limits the maximum load-carrying capacity to approximately 417 MW of load at Pleasant TS.

Preliminary feasibility study shows that the existing towers can support larger conductors. The recommended new conductors would be 1192.5 kcmil ACSR 54/19 with summer long term emergency rating of approximately 1400 A (at 127°C). As per the load flow study conducted in the IRRP, this would supply over 500 MW of load at Pleasant TS. The estimated budgetary cost of this upgrade is about $6.5 million.

The Working Group recommends regularly monitoring the actual load growth and reassessing this issue during the next regional planning cycle.

7.5 Radial Supply to Halton TS Transmission Circuit Capacity

7.5.1 Description

The Northwest GTA IRRP study identified that the thermal capacity of supply circuit to Halton TS from Trafalgar TS to Burlington TS (T38B/T39B) may be exceeded with a single-circuit contingency and Halton Hills GS out of service in the mid-term. However, under this scenario, the ORTAC permits up to 150 MW of load shedding to prevent system overloads. With this control action in place, this need is observed in the long-term in 2029 at the earliest.

7.5.2 Recommended Plan and Current Status

As per the IRRP recommendation, this regional need is being further assessed in the IESO-led bulk power system planning.

7.6 Supply Security to Halton Radial Pocket (T38B/T39B)

7.6.1 Description

As the load connected to T38B/T39B continues to grow, it is expected by 2027 the Halton Radial Pocket will not be able to meet the ORTAC supply security criteria, which states that no more than 600 MW can be interrupted due to a loss of two major power system elements, as shown in Table 7-1.

Table 7-1 Halton Radial Pocket Load Forecast

Year	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026	2027
Halton Radial Pocket Load (MW)	463	471	482	490	491	492	503	512	562	571	585	598	**609**

7.6.2 Recommended Plan and Current Status

The Working Group recommends that the bulk power system study led by IESO account for this supply security issue on T38B/T39B in their planning process.

7.7 Supply Restoration in Northern Sub-Region

The Northwest GTA IRRP study identified that the following circuits are currently at risk of not meeting the supply security and restoration criteria:

Table 7-2 Supply Restoration Need in Northern Sub-Region

Load Pocket	2015 Peak Load (MW)	Load (MW) That Can Be Restored Within 30-min (1)	30-min Restoration Shortfall (MW) (2)
Halton Radial Pocket • Tremaine • Trafalgar DESN • Meadowvale • Halton • Halton Hills Hydro MTS (1) • Halton #2 (1) Supply: T38B/T39B	463	146	**67**
Pleasant Radial Pocket • Pleasant DESNs Supply: H29/H30	359	52	**57**
Bramalea/Cardiff Supply • Bramalea DESNs • Cardiff Supply: V41H/V42H	456	140	**66**

(1) Available 30-min restoration through emergency distribution load transfer following the loss of transmission supply (based on IRRP)
(2) Calculated as follows: Actual Load minus 250 MW minus 30minRestorationCapability. 250 MW is the maximum amount of load not restored within 30-min following loss of two elements.
(3) Halton Hills Hydro MTS and Halton TS #2 are expected to be in-service in 2018 and 2020.

The Northwest GTA IRRP also identified "Kleinburg Radial Pocket" supply restoration need. However, this need will be discussed in more details in the IESO's Bulk System Studies.

As per the IRRP recommendation, all of the above restoration needs are being further assessed in the IESO-led bulk power system planning.

It is expected that with new increased forecasted load at Tremaine TS provided by Milton Hydro and Burlington Hydro, circuitsT38B/T39B Burlington TS to Trafalgar TS will experience higher power flow, and the need date may be moved closer. Therefore, the Working Group recommends that the bulk power system study led by IESO account for this increased flow on T38B/T39B in their planning process.

7.8 Supply Restoration in Southern Sub-Region

The GTA West Southern Sub-Region SA identified that the following circuits are at a risk of not meeting the supply security and restoration criteria in the medium term to long term time frame:

Table 7-3 Supply Restoration Need in Southern Sub-Region

Load Pocket	2015 Peak Load (MW)	Load (MW) That Can Be Restored Within 30-min (1)	30-min Restoration Shortfall (MW) (2)	Load (MW) That Can Be Restored Within 4-hour (1)	4-hour Restoration Shortfall (MW) (3)
West of Cooksville • Oakville #2 • Ford Oakville • Lorne Park Supply: B15C/B16C	304	46	**8**	110	**44**
Richview x Trafalgar x Hurontario • Churchill Meadows • Erindale T5/T6 • Tomken T3/T4 • Jim Yarrow Supply: R19TH/R21TH	555	165	**140**	465	None
Richview x Trafalgar • Erindale T1/T2 • Erindale T3/T4 • Tomken T1/T2 Supply: R14T/R17T	498	115	**133**	390	None

As per the Southern Sub-Region's SA recommendation, all of the above restoration needs are being further assessed in the IESO-led bulk power system planning.

7.9 Long-Term Growth & NWGTA Electricity Corridor Need

Growth projections in the Ontario Governments - Growth Plan for the Greater Golden Horseshoe [5] indicates that the population in Halton Hills, Caledon, Brampton, and Vaughan area is expected to grow significantly over the 20 years period, from 930,000 people in 2011 to 1.5 million people in 2031. Growth plan of this magnitude translates to an overall electrical demand of approximately 849 to 1132 MW by 2031 [1]. Supply electrical demand related to this growth will require new transmission and distribution infrastructure in the area because current electricity infrastructure in the area is limited and at its capacity. Planning and Environmental Approval for a proposed new 400 series Highway, extending from Highway 400 to the Highway 401/407 ETR interchange, has been paused by the Ministry of Transportation. However, opportunities for multi-use transportation/ electricity transmission line corridor must be investigated as new transportation and electricity plans for the area are developed, to maintain consistency with direction outlined in the Provincial Policy Statement.

Existing electricity supply to new developments in the area is technically limited by transmission line and transformer station supply capacity. In addition, there are customer service quality concerns, such as reliability performance and low voltage levels on the LDC's distribution feeders due to the long distance between the locations of new development and existing transformer stations.

Based on the latest load forecast, electrical load at Pleasant TS, which supplies Brampton, is anticipated to exceed its station capacity as early as 2026 [1]. As the result, new station will be required to meet growing electrical needs.

Since a typical 75/125 MVA 230 kV step-down transformer station is capable of supplying up to 170 MW of load, up to 6 new stations in strategic locations could be required to effectively meet load growth in the area over the next 10-20 years. In order to provide adequate supply to these new step-down stations, new 230 kV transmission lines will be required within the general vicinity of the area's load growth centers.

In addition to the need for supply capacity to meet growth, several locations are at risk for not meeting ORTAC criteria following the loss of two transmission elements: Halton radial pocket, Pleasant radial pocket, Bramalea/Cardiff supply, and Kleinburg radial pocket. These needs should also be studied and addressed in a coordinated manner to develop optimal solutions for both GTA North and GTA West Region. As a result, a high degree of integration will be required between regional planning in the two adjacent regions going forward.

Siting a new transmission corridor in the area would provide an alternate supply route to enable continued electrical service when other lines are out of service. Currently it is estimated that over 250 MW of load will not be restored within the timelines prescribed by the criteria. The situation and risk will continue to worsen with continued growth and load will be at higher risk of prolonged power outages following major system contingencies.

An important first phase for providing the required transmission capacity is to identify land / right of ways, which can accommodate economical overhead transmission lines. This includes completing an Environmental Approval followed with an application to the OEB for Leave to Construct (Section 92). The EA process and acquisition of land rights process may take up to five years. Allowing the area to develop without identifying the electricity corridor in municipal plans and not acquiring land rights for transmission corridor now would be significantly arduous after municipal and community development has already taken place without consideration of electricity needs. Identifying and preserving rights-of-way ahead of the forecasted need will help rate payers and municipalities avoid cost associated with underground cables in the future, which is significantly more costly ranging from 5 to 10 times higher than overhead lines.

Continued load growth throughout the GTA, and changing generation patterns across the province, are expected to stress the bulk transmission system's capacity. One option for addressing this need is the addition of a major new 500/230 kV supply point at the existing Milton SS. This new 500/230 kV supply point will provide an additional source to the local network and would need to be supplemented with the incorporation of new 230 kV lines and reconfiguration of the 230 kV system in the area. A new corridor providing new 230 kV transmission lines connecting Milton TS in GTA West and Kleinburg TS in GTA North will allow for better overall bulk system performance in the long-term.

Existing projections of electricity corridor needs can be as early as 2025. The RIP concludes that based on growth projections outlined in the Growth Plan for the Greater Golden Horseshoe [5] a new electricity corridor will be ultimately required to provide additional transmission capacity to meet load growth; provide alternate supply route to various locations to meet restoration criteria; and improve bulk electricity transfer capability.

The RIP Working Group recommends that:

a) The required transmission corridor be identified within the appropriate Regional and Municipal Official Planning documents.

b) Hydro One, the IESO and LDCs undertake immediate action to further assess the location and pace of growth, as well as the related high voltage electrical facilities required for inclusion in a future electricity infrastructure plan. The plan should include but not limited to details with respect to conceptual layout of transmission lines, line terminations, switching stations and the number and approximate location of step-down transformer stations.

c) Following this, Environmental Approval and acquisition of land rights should be under taken to ensure that the transmission facilities on this corridor can be placed to meet the needs.

d) Hydro One, the IESO and LDCs should complete the assessment, technical details, layout of high voltage electricity infrastructure no later than Q4 2016.

8. CONCLUSIONS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GTA WEST REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in the Table 8-1 below.

Table 8-1 Regional Plans – Needs Identified in the Regional Planning Process

No.	Need Description
I	Halton TS station capacity
II	Erindale TS T1/T2 station capacity
III	Radial supply to Pleasant TS (H29/H30) circuit capacity
IV	Richview x Trafalgar (R14T/R17T & R19TH/R21TH) circuit capacity
V	Radial supply to Halton TS (T38B/T39B) circuit capacity
VI	• Supply security to Halton Radial Pocket • Supply restoration to Halton Radial Pocket, Pleasant Radial Pocket, and Bramalea/Cardiff Supply load pockets • Supply restoration to West of Cooksville, Richview x Trafalgar, and Richview x Trafalgar x Hurontario load pockets
VII	Long term need for a new NWGTA electricity transmission corridor

Next steps, lead responsibility, and timeframes for implementing the wires solutions are summarized in the Table 8-2 below. Investments to address the long-term need where there is time to make a decision (Need III) will be reviewed and finalized in the next regional planning cycle.

Table 8-2 Regional Plans - Next Steps, Lead Responsibility and Plan In-Service Dates

Project	Next Steps	Lead Responsibility	I/S Date	Cost	Needs Mitigated
Build new Halton Hills Hydro MTS	LDC to carry out the work	Halton Hills Hydro	2018	$19M (1)	I
Build new Halton TS #2	Transmitter to carry out the work	Hydro One	2020	$29M (1)	I
Build new 44/27.6 kV DS to relieve Erindale TS T1/T2	LDC to carry out the work	Enersource	2018-2019	$5M	II
Upgrade (reconductor) circuits H29/H30 (2)	Transmitter to carry out the work, and monitor growth	Hydro One	2023-2026	$6.5M	III
• R14T/R17T & R19TH/R21TH circuit capacity need • T38/T39B circuit capacity need • Supply security and restoration need	IESO to carry out Bulk System Study	IESO	TBD	TBD	IV, V, VI
Need for a new transmission corridor in NWGTA	Working Group to complete assessments, technical details & layout by Q4 2016	Hydro One, IESO, LDCs	TBD	TBD	VII

Notes:

(1) Excludes cost for distribution infrastructures
(2) The plan will be reviewed and finalized in the next regional planning cycle

As per the OEB mandate, the Regional Plan should be reviewed and/or updated at least every five years. It is expected that the next planning cycle for this region will start in 2018. If there is a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle can be started earlier to address the need.

Notes:

- Northern (N) Sub-Region's stations load forecast is based on the IRRP [1] "Expected Growth" Scenario.
- Southern (S) Sub-Region's stations load forecast is based on the NA [2] non-coincident stations load forecast.
- Halton Hills Hydro MTS and Halton TS #2 are assumed to be in-service in 2018 and 2020, respectively. Some load from Glenorchy MTS will be transferred to the new Halton TS #2 in 2023, as shown by the corresponding increase and decrease at those stations.
- Load forecast were updated for Palermo TS, Tremaine TS, and Glenorchy MTS based on new information provided by Milton Hydro and Burlington Hydro.

Appendix E. List of Acronyms

Acronym	Description
A	Ampere
BES	Bulk Electric System
BPS	Bulk Power System
CDM	Conservation and Demand Management
CIA	Customer Impact Assessment
CGS	Customer Generating Station
CTS	Customer Transformer Station
DESN	Dual Element Spot Network
DG	Distributed Generation
DSC	Distribution System Code
GS	Generating Station
GTA	Greater Toronto Area
HV	High Voltage
IESO	Independent Electricity System Operator
IRRP	Integrated Regional Resource Plan
kV	Kilovolt
LDC	Local Distribution Company
LP	Local Plan
LTE	Long Term Emergency
LTR	Limited Time Rating
LV	Low Voltage
MTS	Municipal Transformer Station
MW	Megawatt
MVA	Mega Volt-Ampere
MVAR	Mega Volt-Ampere Reactive
NA	Needs Assessment
NERC	North American Electric Reliability Corporation
NGS	Nuclear Generating Station
NPCC	Northeast Power Coordinating Council Inc.
NUG	Non-Utility Generator
OEB	Ontario Energy Board
OPA	Ontario Power Authority
ORTAC	Ontario Resource and Transmission Assessment Criteria
PF	Power Factor
PPWG	Planning Process Working Group
RIP	Regional Infrastructure Plan
ROW	Right-of-Way
SA	Scoping Assessment
SIA	System Impact Assessment
SPS	Special Protection Scheme
SS	Switching Station
TS	Transformer Station
TSC	Transmission System Code
UFLS	Under Frequency Load Shedding
ULTC	Under Load Tap Changer
UVLS	Under Voltage Load Rejection Scheme

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE KITCHENER-WATERLOO-CAMBRIDGE-GUELPH ("KWCG") REGION.

The participants of the RIP Working Group included members from the following organizations:

- Cambridge and North Dumfries Hydro Inc.
- Centre Wellington Hydro
- Guelph Hydro Electric System Inc.
- Halton Hills Hydro One
- Hydro One Distribution
- Hydro One Transmission
- Independent Electricity System Operator
- Kitchener Wilmot Hydro Inc.
- Milton Hydro
- Waterloo North Hydro Inc.
- Wellington North Power Inc.

This RIP provides a consolidated summary of needs and recommended plans for the KWCG Region for the near-term (up to 5 years) and mid-term (5 to 10 years). No long term needs (10 to 20 years) have been identified at this time.

This RIP is the final phase of the regional planning process and it follows the completion of the KWCG Integrated Regional Resource Plan ("IRRP") by the IESO in April 2015.

The major infrastructure investments planned for the KWCG Region over the near and mid-term, identified in the various phases of the regional planning process, are given in the table below.

No.	Project	In-Service Date	Cost
1	Guelph Area Transmission Reinforcement	May 2016	$95 M
2	Arlen MTS: Install Series reactors	May 2016	$0.95 M
3	M20D/M21D – Install 230 kV In-line Switches	May 2017	$6 M
4	Waterloo North Hydro: MTS #4	2024	TBD

In accordance with the Regional Planning process, the Regional Plan should be reviewed and/or updated at least every five years. The Region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle may be started earlier to address the need.

[This page is intentionally left blank]

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE KWCG REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") and documents the results of the joint study carried out by Hydro One, Kitchener-Wilmot Hydro Inc. ("Kitchener-Wilmot Hydro"), Waterloo North Hydro Inc. ("WNH"), Cambridge & North Dumfries Hydro Inc. ("CND"), Guelph Hydro Electric Systems Inc. ("Guelph Hydro"), Hydro One Distribution and the Independent Electricity System Operator ("IESO") in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

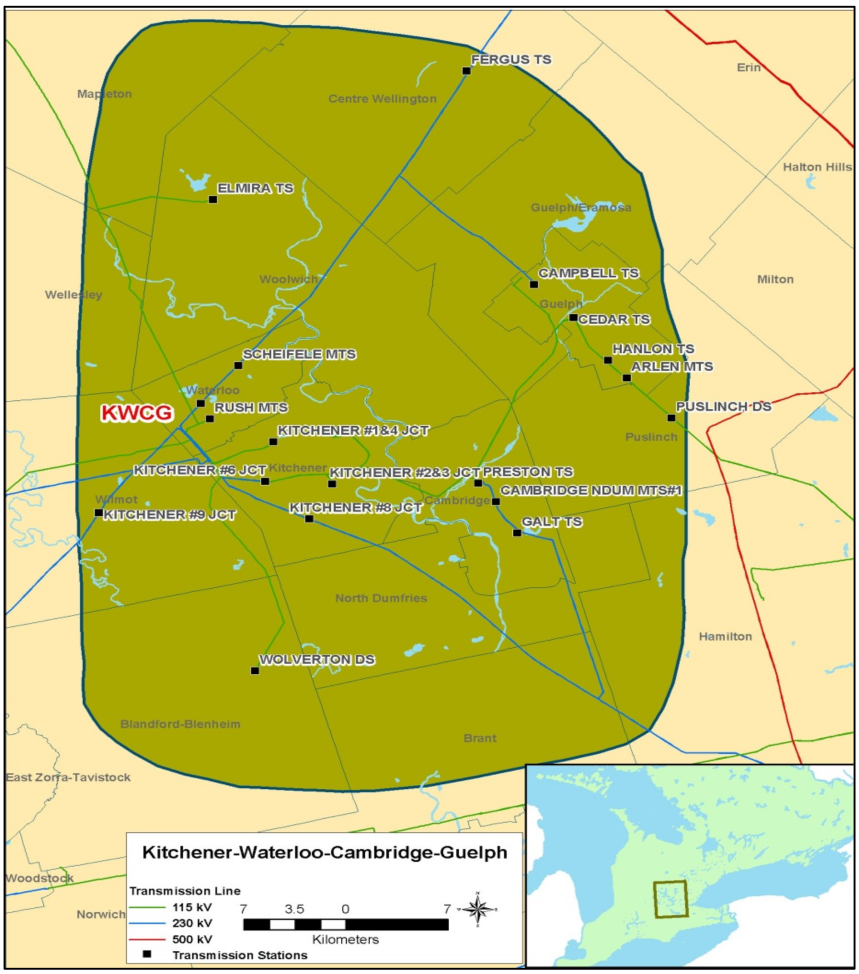

Figure 1-1 KWCG Region

The KWCG Region covers the cities of Kitchener, Waterloo, Cambridge and Guelph, portions of Oxford and Wellington counties and the townships of North Dumfries, Puslinch, Woolwich, Wellesley and Wilmot. Electrical supply to the Region is provided from eleven 230 kV and thirteen 115 kV step-down transformer stations. The summer 2015 coincident regional load was about 1240 MW. The boundaries of the Region are shown in Figure 1-1 above.

1.1 Scope and Objectives

This RIP report examines the needs in the KWCG Region. Its objectives are:

- To identify new supply needs that may have emerged since previous planning phases (e.g. Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan)
- To assess and develop a wires plan to address these needs
- To provide the status of wires planning currently underway or completed for specific needs
- To identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as load forecast, transmission and distribution system capabilities along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of all the needs and relevant plans to address near and mid-term needs (2015-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan or Integrated Regional Resource Plan)
- Identification of any new needs over the 2015-2025 period and a wires plan to address these needs based on new and/or updated RIP phase information
- Develop a plan to address any longer term needs identified by the Working Group

The IRRP or RIP Working Group did not identify any long term needs at this time. If required, further assessment will be undertaken in the next planning cycle because adequate time is available to plan for required facilities.

1.2 Structure

The rest of the report is organized as the follows:

- Section 2 provides an overview of the regional planning process
- Section 3 describes the region
- Section 4 describes the transmission work completed over the last ten years
- Section 5 describes the load forecast and study assumptions used in this assessment
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs
- Section 7 summarizes the Regional Plan to address the needs
- Section 8 provides the conclusions and next steps

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013, through amendments to the Transmission System Code ("TSC") and the Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ('SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation ("DG")) options at a higher or more macro level but sufficient to permit a comparison of options. If the IRRP process identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend the preferred wires solution. Similarly, resource options which the IRRP identifies as best

[1] Also referred to a Needs Screening

suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timeliness provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect
- The NA, SA, and LP phases of regional planning
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region

Figure 2-1 illustrates the various steps of the regional planning process (NA, SA, IRRP and RIP) and their respective phase trigger, lead, and outcome.

Note that as the KWCG Region was identified as a “transitional” region at the onset of the OEB defined Regional Planning process in 2013, the Needs Assessment and Scoping Assessment phases were deemed complete and the region was placed into the IRRP phase of the process.

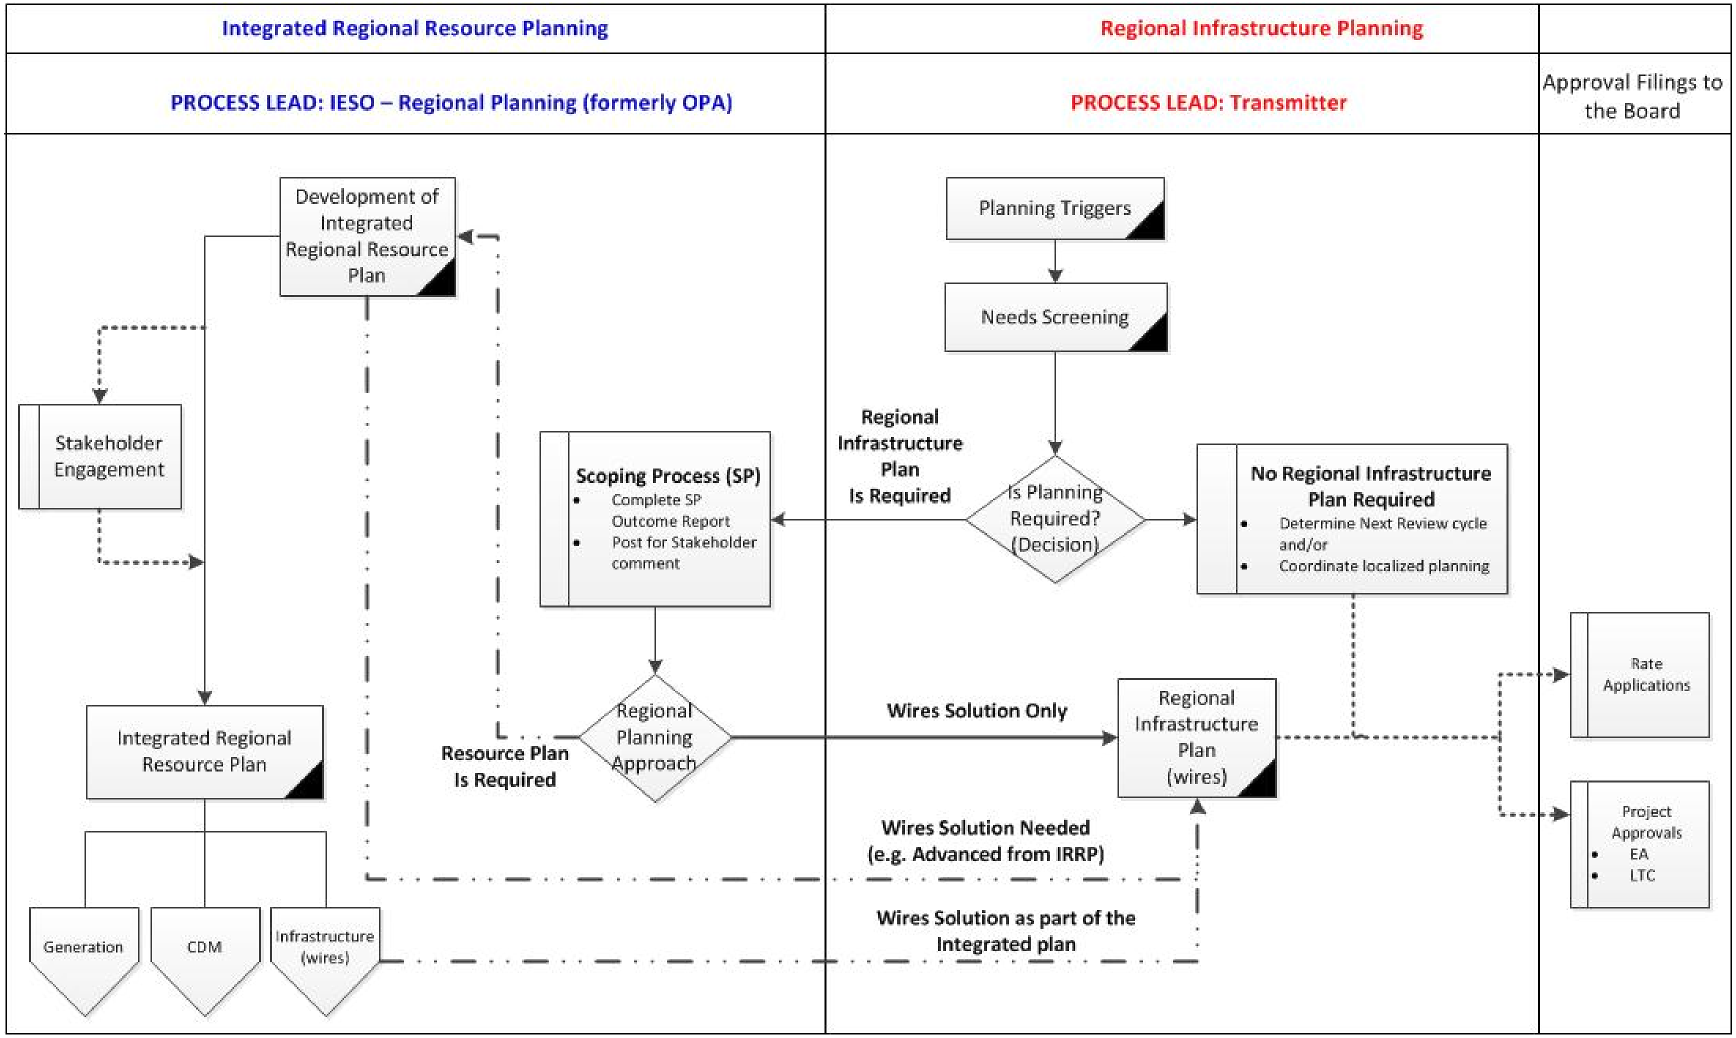

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1) Data Gathering: The first step of the RIP phase is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2) Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3) Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4) Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

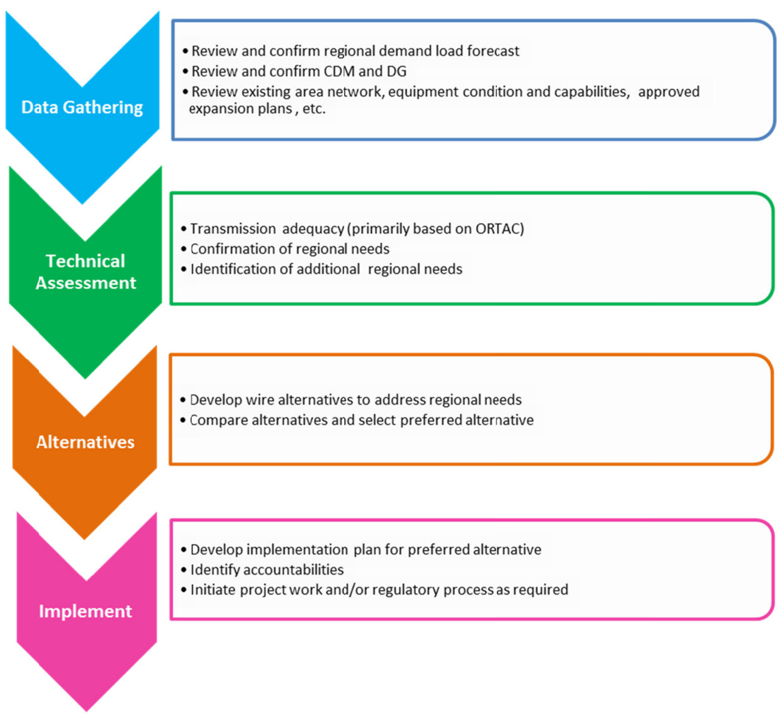

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE KWCG REGION COMPRISES OF THE CITIES OF KITCHENER, WATERLOO, CAMBRIDGE AND GUELPH, PORTIONS OF OXFORD AND WELLINGTON COUNTIES AND THE TOWNSHIPS OF NORTH DUMFRIES, PUSLINCH, WOOLWICH, WELLESLEY AND WILMOT AS SHOWN IN FIGURE 3-1.

The main sources of electricity into the KWCG Region are from four Hydro One stations: Middleport TS, Detweiler TS, Orangeville TS and Burlington TS. At these stations electricity is transformed from 500 kV and 230 kV to 230 kV and 115 kV, respectively. Electricity is then delivered to the end users of LDCs and directly-connected industrial customers by 24 step-down transformer stations. Figure 3-2 illustrates these stations as well as the four major regional sub-systems: Waterloo-Guelph 230 kV sub-system, Cambridge-Kitchener 230 kV sub-system, Kitchener-Guelph 115 kV sub-system and South-Central Guelph 115 kV sub-system. Appendix A lists all step-down transformer stations in the KWCG Region, Appendix B lists all transmission circuits in the KWCG Region and Appendix C lists LDCs in the KWCG Region.

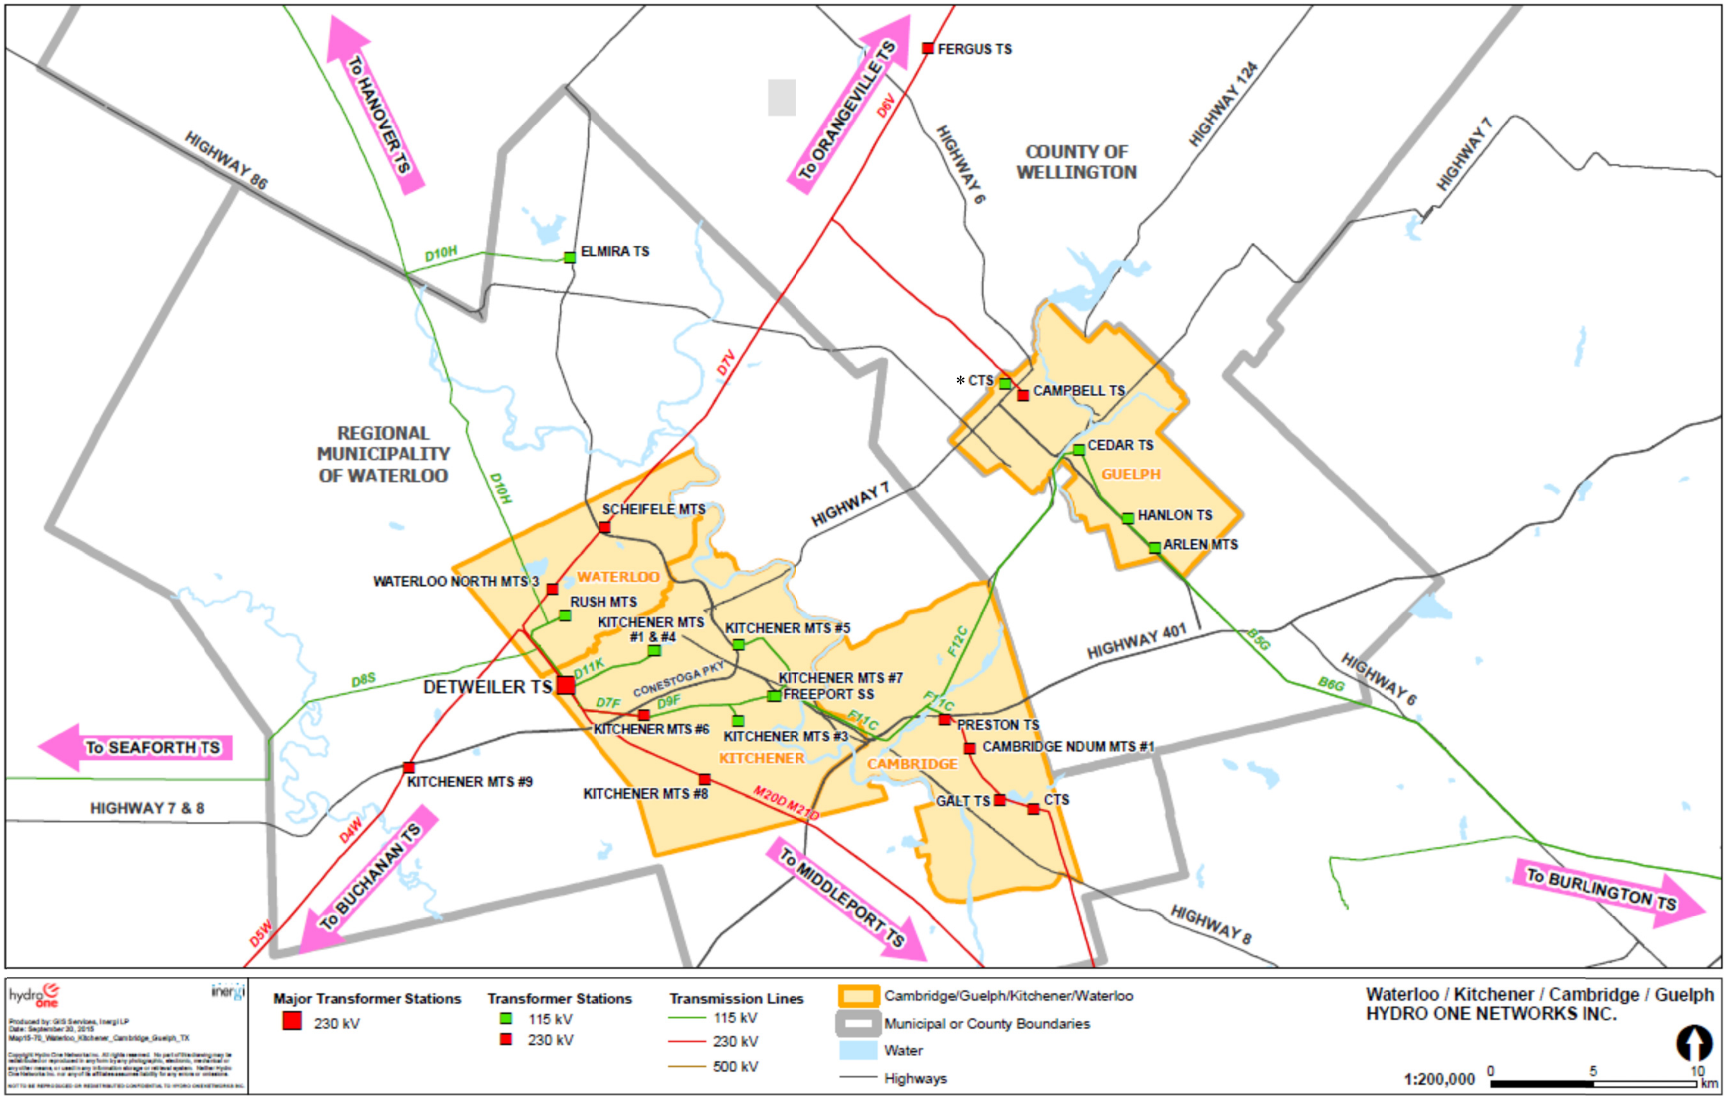

Figure 3-1 Geographical Area of the KWCG Region with Electrical Layout

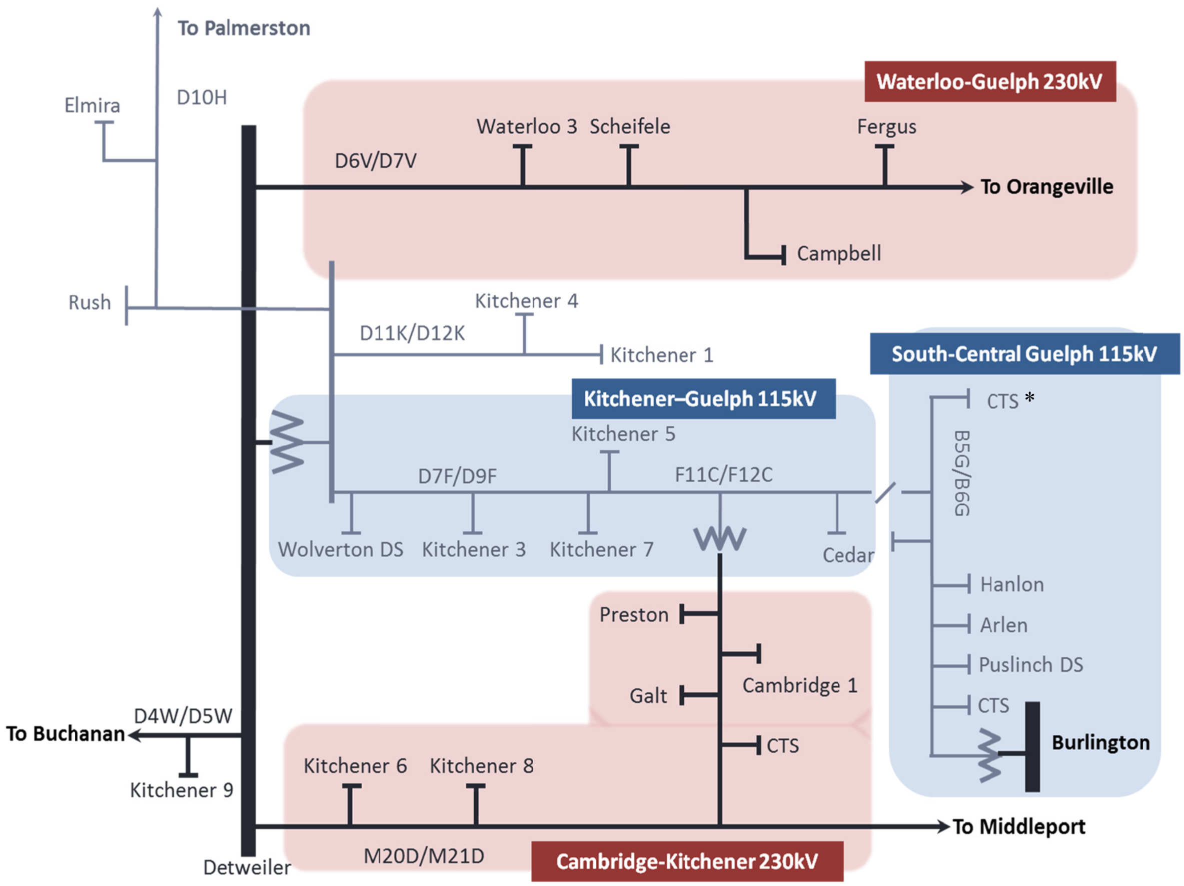

Figure 3-2 KWCG Single Line Diagram

*CTS relocated to the distribution system as part of the GATR project

4. TRANSMISSION FACILITIES COMPLETED OVER LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE KWCG REGION.

These projects were identified as a result of joint planning studies undertaken by Hydro One, IESO and the LDCs; or initiated to meet the needs of the LDCs; and/or to meet Provincial Government policies. A brief listing of the completed projects is given below.

For transmission voltage level transformation capacity needs:

- 250 MVA 230/115 kV autotransformer T4 at Burlington TS replaced in 2006
- 250 MVA 230/115 kV autotransformer T6 at Burlington TS replaced in 2009

For distribution voltage level transformation capacity needs:

- Kitchener MTS#9 connected to replace the Detweiler TS DESN in 2010
- Arlen MTS connected in 2011

For reactive and voltage support needs:

- a 13.8 kV shunt capacitor bank installed at Cedar TS in 2006
- a 230 kV shunt capacitor bank installed at Detweiler TS in 2007
- a 230 kV shunt capacitor bank installed at Orangeville TS in 2008
- a 230 kV shunt capacitor bank installed at Burlington TS in 2010
- a 115 kV shunt capacitor bank installed at Detweiler TS in 2012

For transmission circuit capacity needs:

- M20D/M21D circuit sections capacity increased by sag limit mitigation in 2014

For transmission load security needs:

- Freeport SS installed to sectionalize circuits D7G/D9G (Detweiler TS by Cedar TS) in 2008

For transmission load restoration needs:

- 250 MVA 230/115 kV autotransformer T2 installed at Preston TS in 2007

The following projects are underway:

- Guelph Area Transmission Reinforcement (GATR) project that entails the extension the 230kV circuits D6V/D7V to Cedar TS; the installation of two new 250MVA, 230/115kV autotransformers at Cedar TS; and the installation of two 230 kV in-line switches onto circuits D6V/D7V at Guelph North Junction. This project reinforces the Kitchener-Guelph and South-Central Guelph 115kV sub-systems as well as improves restoration capability to the Waterloo-Guelph 230 kV sub-system. This project is identified in the IESO KWCG IRRP, reference [1].

- The installation of a 13.8 kV series reactor to mitigate short circuit levels at Arlen MTS. This project was identified in the RIP phase.

- The installation two new 230kV in-line switches onto circuits M20D/M21D near Galt Junction to improve restoration capability in the Cambridge-Kitchener 230 kV sub-system. This project is identified in Hydro One's KWCG Adequacy of Transmission Facilities & Transmission Plan 2016-2025 report, reference [2]/Appendix F as well as reference [1].

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the KWCG Region is forecast to increase at an average rate of approximately 1.7% annually between 2015 and 2025. The growth rate varies across the Region with most of the growth concentrated in the cities of Waterloo and Guelph, each at an average rate of 2.5% over the next ten years.

Figure 5-1 shows the KWCG Region's planning load forecast (summer net, regional-coincident extreme weather peak). The regional-coincident (at the same time) forecast represents the total peak load of the 24 step-down transformer stations in the KWCG Region. By 2025 the forecasted coincident regional peak load is approximately 1765 MW.

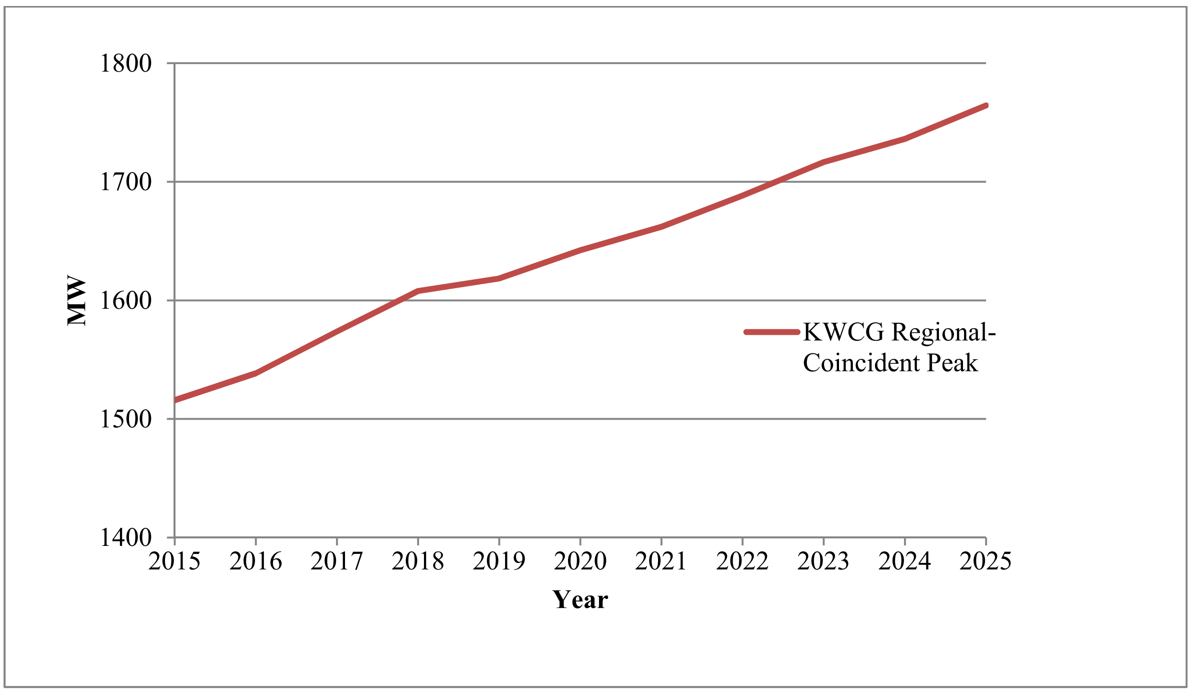

Figure 5-1 KWCG Region's Planning Forecast

The KWCG 2015 RIP planning load forecast is provided in Appendix D and is based upon the KWCG IRRP planning load forecast prepared by the IESO and was reaffirmed by the Working Group upon initiation of the RIP phase. In the IRRP phase, the LDC's provided the IESO with a 10 year gross, normal weather, regional-coincident, peak load forecast in MW. The IESO adjusted the forecast by subtracting the effective CDM capacity, applying an extreme weather factor and then subtracting the effective DG capacity. Further details regarding the CDM and connected DG are provided in reference [1]. The RIP forecast is identical to the IRRP forecast except as otherwise noted in Appendix D.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

1) The Study period for the RIP assessment is 2015-2025.
2) All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
3) Summer is the critical period with respect to line and transformer loadings. The assessment is based therefore based on summer peak loads.
4) Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks.
5) Normal planning supply capacity for Hydro One transformer stations in this Region is determined by the summer 10-Day Limited Time Rating (LTR), while some LDCs use different methodologies for determining transformer station LTR.
6) Adequacy assessment is done as per the Ontario Resource and Transmission Adequacy Criteria ("ORTAC").

6. ADEQUACY OF FACILITIES AND REGIONAL NEEDS OVER THE 2015-2025 PERIOD

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION SYSTEM AND DELIVERY STATION FACILITIES SUPPLYING THE KWCG REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM.

Within the current regional planning cycle two regional assessments have been conducted for the KWCG Region. The findings of these studies are input to the RIP. The studies are:

1) IESO's KWCG Integrated Regional Resource Plan – dated April 28, 2015[1]
2) Hydro One's Adequacy of Transmission Facilities and Transmission Plan 2016-2025 – dated April 1, 2015 with revision 1 – dated October 30, 2015[2] (please see Appendix F)

The IRRP identified a number of regional needs to meet the forecast load demand over the near to mid-term. Due to the immediate nature of the needs the Guelph Area Transmission Reinforcement (GATR) project was initiated to provide adequate load supply capability to the KWCG area while the IRRP study was still underway. A detailed description and status of the GATR project and other work initiated or planned to meet these needs is given in Section 7.

This RIP reviewed the loading on transmission lines and stations in the KWCG Region assuming the GATR project is in-service. Sections 6.1-6.4 present the results of this review and Table 6-1 lists the Region's needs identified in both the IRRP and RIP phases.

Table 6-1 Near and Medium Term Regional Needs

Type	Section	Needs	Timing
Needs Identified in the IRRP [1] and the Adequacy Report [2]			
Transmission Circuit Capacity	7.1.1	South-Central Guelph 115 kV sub-system- Capacity of 115kV circuits B5G/B6G	Immediate
	7.1.2	Kitchener–Guelph 115 kV sub-system – Capacity of 115kV circuits D7F/D9F and F11C/F12C	Immediate
Load Restoration	7.1.3	Waterloo-Guelph 230 kV sub-system	Immediate
	7.2.1	Cambridge-Kitchener 230 kV sub-system	Immediate
Step-down Transformation Capacity	7.3.1	Waterloo North Hydro Inc.	2018
Additional Needs identified in RIP Phase			
Station Short Circuit Capability	7.4.1	Arlen MTS: Short Circuit capability	2016

6.1 230 kV Transmission Facilities

All 230 kV transmission circuits in the KWCG Region are classified as part of the Bulk Electricity System ("BES"). They connect the Region to the rest of the Ontario's transmission system and are also part of the transmission path from generation in Southwestern Ontario to the load centers in the Hamilton, Niagara and GTA areas. These circuits also serve local area stations within the Region and the power flow on them depends on the bulk system transfer as well as local area loads. These circuits are as follows (refer to Figure 3-2):

1) Detweiler TS to Orangeville TS 230 kV transmission circuits D6V/D7V – supplies Fergus TS, Campbell TS, Waterloo North MTS#3 and Scheifele MTS
2) Detweiler TS to Middleport TS 230 kV transmission circuits M20D/M21D – supplies Kitchener MTS #6, Kitchener MTS # 8, Cambridge MTS #1, Galt TS, Preston TS and Customer #1 CTS
3) Detweiler TS to Buchanan TS 230 kV transmission circuits D4W/D5W – supplies Kitchener MTS#9.

The RIP review shows that based on current forecast station loadings and bulk transfers, all 230 kV circuits are expected to be adequate over the study period. Refer to section 3.4.2 of Appendix F for the detailed analysis.

6.2 500/230 kV and 230/115 kV Transformation Facilities

Bulk power supply to the KWCG Region is provided by Hydro One's 500 kV to 230 kV and 230 kV to 115 kV autotransformers. The number and location of these autotransformers are as follows:

1) Two 500/230 kV autotransformers at Middleport TS
2) Four 230/115 kV autotransformers at Burlington TS
3) Three 230/115 kV autotransformers at Detweiler TS
4) Two 230/115 kV autotransformers at Cedar TS
5) One 230/115 kV autotransformer at Preston TS

The RIP review shows that based on current forecast station loadings and bulk transfers, the auto-transformation supply capacity is adequate over the study period. Refer to section 3.4.1 of Appendix F for the detailed analysis.

6.3 Supply Capacity of the 115 kV Network

The KWCG Region contains five pairs of double circuit 115 kV lines. This 115 kV network serves local area load. These circuits are as follows (see Figure 3-2):

1) Detweiler TS to Freeport SS 115 kV transmission circuits D7F/D9F – supplies Wolverton DS, Kitchener MTS #3, Kitchener MTS#7
2) Freeport SS to Cedar TS 115 kV transmission circuits F11C/F12C – supplies Kitchener MTS#5 and Cedar T1/T2 transformers
3) Burlington TS to Cedar TS 115 kV transmission circuits B5G/B6G – supplies Puslinch DS, Arlen MTS, Hanlon TS, Customer #2 CTS and Cedar T7/T8 transformers
4) Detweiler TS 115 kV radial transmission circuit D11K/D12K – supplies Kitchener MTS#1 and Kitchener MTS#4
5) Detweiler TS to Seaforth TS/Hanover TS 115 kV transmission circuit D8S/D10H with Normally Open (N/O) points – supplies Rush MTS and Elmira TS

The RIP review shows that based on current forecast station loadings and bulk transfers, the supply capacity of the 115 kV network is adequate over the study period. Refer to section 3.4.3 of Appendix F for the detailed analysis.

6.4 Step-down Transformer Stations

There are 24 step-down transformer stations within the KWCG Region. Twenty-two supply electricity to LDCs and two are transmission-connected industrial customer stations. These stations are listed within the load forecast in Appendix D. Of those 24 stations, 15 of them are owned and operated by the LDCs.

As part of the IRRP, step-down transformation station capacity was reviewed and resulted in the IRRP forecast which was reaffirmed by the Working Group for use in the RIP phase. According to the load forecast, Waterloo North Hydro anticipates requiring additional step-down transformation capacity in 2018.

6.5 Other Items Identified During Regional Planning

6.5.1 Customer Impact Assessment for the GATR project

Based on the Customer Impact Assessment [3] for the GATR project, Guelph Hydro identified the need to mitigate short circuit levels at Arlen MTS in order to ensure the short circuit levels remain within the TSC limits and equipment ratings. The project need date is May 2016 so as to correlate with the completion of the GATR project.

6.5.2 System Impact Assessment for the GATR Project

A System Impact Assessment ("SIA") [4] was performed for Hydro One's application to the IESO for the Guelph Area Transmission Reinforcement (GATR) project.

Several findings emanated from the SIA report due to conservative assumptions made for the Bulk Power System. The Working Group has reviewed these findings and recommends that the assumptions be looked at in greater detail within a Bulk Power System study. If the Bulk Power System study results in regional needs then an early trigger of the next Regional Planning cycle may occur.

6.5.3 Load Restoration to the Cambridge area

The IRRP recommended Hydro One to continue to explore options with Cambridge and North Dumfries Hydro (“CND”) to further improve the load restoration capability to the Cambridge area. During the RIP phase Hydro One presented to CND a detailed explanation of its capability to restore power to transformer stations that service the Cambridge area. Based on this discussion, CND and Hydro One have agreed that, at this time, no additional infrastructure is required and the restoration capability afforded by the GATR project and the 230 kV in-line switches at Galt Junction is acceptable for the study period.

6.6 Long-Term Regional Needs

The IRRP examined high-growth and low-growth scenarios to identify long-term needs. Under the high-growth scenario, there is sufficient transmission capacity afforded by the GATR project to meet demand in the long-term; however the need for additional step-down transformation capacity may arise. LDC’s to closely monitor their load to determine the timing of potential step-down transformation needs. Under the low-growth scenario, no needs were identified in the long-term.

Consistent with the IRRP, the Working Group did not identify any additional long-term needs during the RIP phase. If new long-term needs were to arise, there is sufficient time to assess them in the next planning cycle which can also be started earlier to make timely investment decisions..

7. REGIONAL PLANS

THIS SECTION DISCUSSES THE ELECTRICAL SUPPLY NEEDS FOR THE KWCG REGION AND SUMMARIZES THE REGIONAL PLANS FOR ADDRESSING THE NEEDS. THESE NEEDS ARE LISTED IN TABLE 6-1 AND INCLUDE NEEDS PREVIOUSLY IDENTIFIED IN THE IRRP AS WELL AS THE NEEDS IDENTIFIED DURING THE RIP PHASE.

7.1 Transmission Circuit Capacity and Load Restoration

7.1.1 South-Central Guelph 115 kV Sub-system

The South-Central Guelph area is supplied by the 115 kV double circuit line B5G/B6G. As per section 6.2.1 of the IRRP, historical peak demand on the B5G/B6G line has already exceeded the 100 MW line Load Meeting Capability ("LMC").

7.1.2 Kitchener-Guelph 115 kV Sub-system

The Kitchener-Guelph area is supplied by two 115 kV double-circuit lines D7F/D9F and F11C/F12C supported by 230/115 kV autotransformers at Detweiler TS and Preston TS. As per section 6.2.1 of the IRRP, the planning forecast peak demand in the Kitchener-Guelph 115 kV sub-system will exceeded the 260 MW line LMC by summer 2014.

7.1.3 Waterloo-Guelph 230 kV Sub-system

As per section 6.2.2 of the IRRP, the transmission infrastructure supplying load in the Waterloo-Guelph 230 kV sub-system does not meet reliability requirements to quickly restore supply in the event of a major outage involving the loss of both transmission circuits, D6V and D7V.

7.1.4 Recommended Plan and Current Status

To address the transmission circuit capacity needs for the South-Central Guelph 115 kV sub-system and the Kitchener-Guelph 115 kV sub-system, the IRRP Working Group recommended reinforcement of the 115 kV transmission system by introducing a new 230 kV – 115 kV injection point. The new injection point is to be located at Cedar TS using two new 230 kV/115 kV autotransformers in conjunction with a 5 km extension of the existing 230 kV double-circuit transmission line, D6V/D7V from Campbell TS to Cedar TS. This reinforcement is covered under the GATR project.

To address the load restoration need of the Waterloo-Guelph 230 kV sub-system, the IRRP Working Group's preferred alternative is to install two new 230 kV in-line switches near Guelph North Junction. The switches will enable Hydro One to quickly isolate a problem and allow the resupply of load to occur expeditiously. This work is also covered under the GATR project.

Current Status of the GATR Project

Hydro One initiated construction on the GATR project in fall 2013 following the OEB approval in September 2013. The project has three components:

- Campbell TS x Cedar TS: Extend the 230 kV D6V/D7V tap from Campbell TS to Cedar TS. This requires replacing approximately a 5 km section of the existing 115 kV double circuit transmission section between CGE Junction and Campbell TS with a new 230 kV double circuit transmission line,
- Cedar TS: Install two new 230/115 kV autotransformers and associated 115 kV switching facilities at Cedar TS. Connect 115 kV switching facilities to the existing B5G/B6G line and the F11C/F12C at Cedar TS.
- Guelph North Junction: Install two in-line 230 kV switches at Guelph North Jct.

This investment will provide for sufficient 230/115 kV autotransformation capacity beyond the study period. The current in-service date of the project is May 2016.

The cost of this project is approximately $95 million. The project is a transmission pool investment as the autotransformers provide supply to all customers in the Region.

7.2 Load Restoration

7.2.1 Cambridge-Kitchener 230 kV Sub-system

As per section 6.2.2 of the IRRP and the section 3.4.8 of the Adequacy of Transmission Facilities report, transmission infrastructure supplying load in the Cambridge-Kitchener 230 kV sub-system does not meet reliability requirements to quickly restore supply in the event of a major outage involving the loss of both transmission circuits, M20D and M21D.

7.2.2 Recommended Plan and Current Status

To address the load restoration need of the Cambridge-Kitchener 230 kV sub-system, the IRRP Working Group's preferred alternative is to install two new 230 kV in-line switches on the M20D/M21D line near Galt Junction. The switches will enable Hydro One to quickly isolate a problem and allow the resupply of load to occur expeditiously. This work is covered under the M20D/M21D Install 230 kV In-line Switches project.

Current Status of the 230 kV In-Line Switches near Galt Junction

Hydro One has established a project to install the two 230 kV in-line switches onto the M20D/M21D double circuit line. One set of switches to be installed onto each circuit. One set of switches to be installed north of the Junction while the other to be installed south of Galt Junction. The switches will enable

Hydro One to quickly isolate a problem on either side of the junction and initiate the restoration of load to the Cambridge-Kitchener 230 kV sub-system.

The project is currently in the detailed design and estimation phase which also includes real estate negotiations. The cost of this project is approximately $6 million and it will be a transmission pool investment. The planned in-service date is May 2017.

7.3 Step-down Transformation Capacity

7.3.1 Waterloo North Hydro

The RIP/IRRP planning load forecast indicates that additional step-down transformation capacity is required by 2018, specifically Waterloo North Hydro's MTS #4.

7.3.2 Recommended Plan and Current Status

To address step-down transformation capacity needs of Waterloo North Hydro, Waterloo North Hydro will, wherever possible, manage load growth by maximizing the utilization of existing stations by increasing distribution load transfer capability between those stations and will continue to explore opportunities for CDM and DG. In addition Waterloo North Hydro will also explore, with other LDCs, opportunities to coordinate possible joint use and development of step-down transformer stations in the Region over the long term. With this in mind, additional step-down transformation capacity is not anticipated prior to 2024. This need will be reviewed in the next cycle of regional planning.

7.4 Station Short Circuit Capability

7.4.1 Arlen MTS

Arlen MTS is a 115/13.8 kV step-down transformer station owned by Guelph Hydro. As a result of the new 230/115 kV injection point afforded by the GATR project, the short circuit levels at Arlen MTS's 13.8 kV bus will exceed the TSC limit and equipment capability.

7.4.2 Recommended Plan and Current Status

To address the station short circuit capability need at Arlen MTS, Guelph Hydro will install series reactors to bring station short circuit levels within TSC limits and within equipment ratings.

Current Status of Short Circuit Mitigation

Guelph Hydro has initiated a project to install series reactors to bring station short circuit levels within TSC limits and equipment ratings. The cost of this project is $0.95 million and the expected completion date is May 2016 so as to correlate with the completion of the GATR project.

8. CONCLUSIONS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE KWCG REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

Six near and mid-term needs were identified for the KWCG Region. They are:

I. Transmission capacity in the South-Central Guelph 115 kV sub-system
II. Transmission capacity in the Kitchener-Guelph 115 kV sub-system
III. Load restoration capability in the Waterloo-Guelph 230 kV sub-system
IV. Load restoration capability in the Cambridge-Kitchener 230 kV sub-system
V. Step-down transformation capacity for Waterloo North Hydro
VI. Station Short Circuit Capacity at Arlen MTS

This RIP report addresses all six of these needs. Next Steps, Lead Responsibility, and Timeframes for implementing the wires solutions for the near and mid-term needs are summarized in the Table 8-1 below.

Table 8-1 Regional Plans – Next Steps, Lead Responsibility and Plan In-Service Dates

No.	Project	Next Steps	Lead Responsibility	I/S Date	Cost	Needs Mitigated
1	Guelph Area Transmission Reinforcement	Construction in the final stages	Hydro One	May 2016	$95M	I, II, III
2	Mitigate Short Circuit Levels at Arlen MTS	Construction underway	Guelph Hydro	May 2016	$0.95M	VI
3	M20D/M21D – Install 230 kV In-line Switches	Transmitter to carry out this work	Hydro One	May 2017	$6M	IV
4	Waterloo North Hydro: MTS #4	LDC to monitor growth	Waterloo North Hydro	2024	TBD	V

In accordance with the Regional Planning process, the Regional Plan should be reviewed and/or updated at least every five years. The region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

Table D1 -is based upon KWCG 2015 IRRP Planning Load Forecast except as noted.

(1) Cambridge and North Dumfries Hydro (“CND”) has confirmed 9.2 MW of cogeneration at a large customer to be accounted for in the Preston TS forecast starting year 2016. The generation plant is expected to run most of the time and would offset the customer's load. This cogeneration was not factored into the KWCG 2015 IRRP Planning Load Forecast.

(2) Both CND and Waterloo North Hydro (“WNH”) are monitoring the load closely to determine the timing of potential transformation needs. For planning purposes, WNH has moved back the in service date of MTS #4 from 2018 to 2024. WNH is closely monitoring the need for additional transformation capacity to determine if the load growth indicated at MTS #4 in the forecast can be managed through a combination of improving transformer station interties, CDM and DG in the Waterloo Region. Where possible, these LDCs are exploring opportunities to coordinate possible joint use and development of step-down transformer station facilities in the KWCG Region over the long term.

(3) Updated to include Hydro One Distribution load

(4) Based on information provided by the transmission-connected customer

Appendix F. KWCG Adequacy of Transmission Facilities and Transmission Plan 2016-2025

Revision 1

KITCHENER/WATERLOO/CAMBRIDGE/GUELPH AREA

ADEQUACY OF TRANSMISSION FACILITIES

AND

TRANSMISSION PLAN 2016 – 2025

October 30, 2015

Prepared by Hydro One Networks Inc. in Consultation with the KWCG Working Group

Foreword

This report is the result of a joint study by KWCG Working Group. It has been prepared by Hydro One Networks in consultation with the Working Group.

The working group members were:

Entity	Member
Kitchener-Wilmot Hydro	Shaun Wang L. Frank G. Cameron
Waterloo North Hydro Inc.	Herbert Haller David Wilkinson Dorothy Moryc
Cambridge & North Dumfries Hydro	Ron Sinclair Shawn Jackson
Guelph Hydro Electric System Inc.	Michael Wittemund K. Marouf Eric Veneman
Hydro One Distribution	Charlie Lee
Ontario Power Authority	Bob Chow Bernice Chan
Independent Electricity Operator	Peter Drury
Hydro One Networks Inc.	Alessia Dawes Farooq Qureshy Emeka Okongwu Qasim Raza

The preferred plan has been selected based on technical and economic considerations. The issue of cost allocation between utilities was not addressed.

TABLE OF CONTENTS

EXECUTIVE SUMMARY

In 2010 an integrated regional planning study was initiated to assess the electricity supply and reliability over a twenty year period for the Kitchener-Waterloo-Cambridge-Guelph (KWCG) areas and continues to be conducted by a Working Group led by the Ontario Power Authority (OPA) and includes staff from the Independent Electricity System Operator (IESO), Hydro One Networks Inc., Kitchener-Wilmot Hydro, Waterloo North Hydro, Cambridge & North Dumfries Hydro, Guelph Hydro Electric Systems Inc. and Hydro One Distribution.

The early results of the integrated regional planning study identified the need to reinforce supply capacity for the South-Central Guelph and the City of Cambridge over the near and medium term. It also identified the need to minimize the impact of double circuit interruptions in the area[1]. As a result, the Working Group recommended two transmission projects in conjunction with conservation and distributed generation:

1. The Guelph Area Transmission Reinforcement (GATR) project – comprising a new 230/115kV autotransformer station at Guelph Cedar TS, upgrading the circuit section between Campbell TS and CGE Junction to 230 kV and in-line switching on the Orangeville TS x Detweiler TS 230kV circuits D6V/D7V – to reinforce supply to South Central Guelph,
2. The Preston TS Autotransformer Project – comprising the installation of a second 230/115kV autotransformer at Preston TS - to reinforce supply to the City of Cambridge.

Work on the GATR project was started in 2014 following approval from the Ontario Energy Board and the Ministry of Environment. The project's planned in-service date is June 2016.

For the Preston project, the OPA issued Hydro One a hand off letter to develop a "Wires" solution to improve the supply to the Cambridge area and to facilitate the connection of a future Cambridge and North Dumfries Hydro transformer station by 2018.

This report presents the results of Hydro One led "Wires" study of the adequacy of supply to the City of Cambridge and the wider KWCG area based on the planned in-service of the GATR project in summer 2016. The main conclusions of the report are as follows:

- The supply capability to the KWCG 115kV area has been significantly increased to meet all 2025 forecast loads by the addition of the GATR project. The need for the Preston autotransformer can be deferred to beyond 2025.
- There is inadequate load restoration capability for load connected to Middleport TS x Detweiler TS 230kV double circuit line M20D and M21D

This report recommends that the most cost effective plan to improve load restoration capability for load connected to circuits M20/21D is to install 230 kV in-line switches onto circuits M20/21D.

[1] OPA Submission to the OEB for the GATR Project – Document EB-2013-0053 dated March 8, 2013 entitled, "Kitchener-Waterloo-Cambridge-Guelph Area

1.0 INTRODUCTION

This transmission adequacy assessment focused on the electrical supply to the municipalities of Kitchener, Waterloo, Cambridge and Guelph and their surrounding areas of Ontario, collectively referred to as the KWCG area in this report. Its primary focus was to confirm the near and mid-term transmission needs for the area and to provide a 10-year transmission plan in order satisfy those Needs.

Geographically, the KWCG area consists of 4 municipalities – Kitchener, Waterloo, Cambridge, Guelph and portions of two counties - Perth and Wellington. Hydro One Networks Inc. is the sole high voltage transmitter in the KWCG area; however the low voltage distribution of electricity in the KWCG area is carried out by Cambridge and North Dumfries Hydro Inc., Guelph Hydro Electric System Inc., Hydro One Distribution, Kitchener-Wilmot Hydro Inc., and Waterloo North Hydro. A geographic map of the area is shown in Appendix A, Map 1 while an electrical map of the area is shown in Appendix A, Map 2.

The KWCG area is a major regional load centre in Ontario. The area has a well-established history in manufacturing and technology. The area peak load is approximately 1400 MW.

This report presents the results of the Hydro One led “Wires” study of the adequacy of supply to the City of Cambridge and the wider KWCG area based on the planned in-service of the GATR project in summer 2016.

2.0 EXISTING TRANSMISSION INFRASTRUCTURE

2.1 TRANSMISSION IN KWCG

Electrical Supply in this area is provided through 230 kV and 115 kV transmission lines and step down transformation facilities (transmission stations, TS) as show in Appendix A, Map 2.

The main sources of electricity into the KWCG Region are Middleport TS, Detweiler TS, Orangeville TS, Cedar TS and Burlington TS. At these stations electricity is transformed from 500 kV and 230 kV to 230 kV and 115 kV, respectively. The KWCG Region transmission system is connected as follows:

- Two 230 kV circuits (D6V/D7V) that run North-East from Detweiler TS to Orangeville TS that supply five load serving stations;
- Two 230 kV circuits (M20/21D) that run South-East from Detweiler TS to Middleport TS that supply five load serving stations and one transmission-connected customer;
- Two 230 kV circuits (D4W/D5W) that run South-West from Detweiler TS to Buchanan TS (in the "London area") that supply one load serving station;
- Four 115 kV circuits (D7F/D9F, F11C/F12C) that run East-West: D7/9F from Detweiler TS to Freeport SS that supply three load serving stations and F11/12C from Freeport SS to Cedar TS that supply one load serving station;
- Two 115 kV circuits (B5G/B6G) that run North-West from Burlington TS to Cedar TS that supply three load serving stations and one transmission-connect customer;
- Two 115 kV radial circuits (D11K/D12K) emanating East from Detweiler TS that supply two load serving stations; and,
- Two 115 kV circuit (D8S and D10H) emanating North from Detweiler TS that supply two load serving stations in the KWCG area.

Voltage support is provided in the area by:

- Four high voltage shunt capacitor banks and one SVC at Detweiler TS
- Four high voltage shunt capacitor banks at Middleport TS
- Three high voltage shunt capacitor banks at Burlington TS
- One high voltage shunt capacitor bank at Orangeville TS
- 43.2 MVar low voltage station shunt capacitor at Galt TS
- 21.6 MVar low voltage station shunt capacitors at Campbell TS
- 59.81 MVar low voltage station shunt capacitors at Cedar TS
- 9.92 MVar low voltage station shunt capacitors at Elmira TS
- Low voltage feeder shunt capacitors were lumped at: C&ND MTS#1, Waterloo North Hydro MTS #3, Scheifele MTS

All stations in the KWCG Region were considered in the analysis to determine the adequacy of the existing transmission system. Transformation capacity at individual load serving stations was previously analyzed by the OPA as part of the Integrated Regional Resource Plan (IRRP). The result of that analysis was a load forecast that included proposed new stations, as shown in Appendix C. Therefore, transformation capacity at individual load serving stations was not considered in this study.

2.2 TRANSMISSION-CONNECTED GENERATION

There are no existing large-scale transmission-connected generation plants in the KWCG area; however two contracted renewable transmission-connected wind farms were included in the study area and are listed in Appendix B.

3.0 ADEQUACY OF EXISTING TRANSMISSION INFRASTRUCTURE IN KWCG AREA

3.1 STUDY ASSUMPTIONS

Assumptions were made in order to assess the effects of contingencies to verify the adequacy of the transmission system. The assumptions used in the study were:

1. A 10 year load forecast: years 2016 to 2025; shown in Appendix C
2. Forecasted loads were provided by the LDC's in MW. The MVAR portion of the load was set to 40% of the MW load which is a reasonable assumption to achieve a power factor of 0.9 at the defined meter point of load serving transformer stations (TS, CTS, MTS)
3. A summer assessment was performed as the KWCG area is summer load peaking while the equipment is at its lowest rating during summer ambient conditions. This was deemed to be the most conservative approach;
4. Equipment continuous and Limited Time Ratings (LTR) were based on an ambient temperature of 35°C for summer and a wind speed of 4 km/hour;
5. The Guelph Area Transmission Reinforcement (GATR) project would be in-service in June 2016;
6. Circuits M20D and M21D are assigned their updated long-term emergency rating (LTE) based on a maximum temperature of 127°C;
7. Simulation of year 2025 load forecast was performed as it was the maximum loading of the area for the duration of the study period; year 2016 was simulated as necessary;
8. Waterloo North Hydro's Snider MTS #4 (MTS #4) will connect to 230 kV circuit D6/7V between Scheifele MTS and Guelph North Jct., projected in-service date 2024 (refer to Note 2 in Appendix C, Table C1)
9. The flows on Ontario's major internal transmission interfaces were assumed as follows:
    - FETT ~ 4500 MW
    - FS ~1250 MW
    - FABCW ~ 5800MW
    - NBLIP ~ 1650 MW (the slightly high NBLIP was offset by the lower FABCW)
    - QFW ~ 1550 MW

3.2 STUDY CRITERIA

The adequacy of the transmission system is assessed as per the IESO Ontario Resource and Transmission Assessment Criteria, Issue 5.0.

3.3 LOAD FORECAST

The load forecast used in this assessment is the KWCG 2015 RIP forecast as shown in Appendix C. This summer forecast is an extreme weather, area coincident, net, peak load forecast.

The KWCG 2015 RIP forecast is based upon the KWCG 2015 IRRP forecast. The LDC's provided the IESO with a 20 year gross, normal weather, area coincident, peak load forecast in MW. The IESO adjusted the forecast by subtracting the effective conservation and demand management (CDM) capacity, applying an extreme weather factor and then subtracting the effective Distribution Generation (DG) capacity.

3.4 SUPPLY CAPACITY NEEDS

Single element contingencies were considered in assessing the adequacy and reliability of the local transmission system that serves the KWCG area. Figure 1 summarizes the local KWCG area Needs for the 10-year period under study. Appendices D, F and G detail the technical study and results.

At stations, within the KWCG area, classified as NPCC Bulk Power System (BPS) additional contingencies were considered to establish their impact to the local KWCG area. Appendix E details the technical study and results.

3.4.1 AUTO-TRANSFORMATION SUPPLY CAPACITY

There is no major generation station in the KWCG area. Hence, the majority of supply to the load is provided by Hydro One's 500 kV to 230 kV and 230 kV to 115 kV auto-transformers. The number and location of these auto-transformers are as follows:

- Two 500/230 kV autotransformers at Middleport TS
- Four 230/115 kV autotransformers at Burlington TS[2]
- Three 230/115 kV autotransformers at Detweiler TS
- Two 230/115 kV autotransformers at Cedar TS
- One 230/115 kV autotransformer at Preston TS

Single autotransformer contingencies were performed to assess the adequacy of the transmission system to supply bulk power into the KWCG area via the autotransformers for year 2025 loading.

The results indicate that there are no thermal overloads and no voltage violations for the loss of a single autotransformer.

[2] The loading of the autotransformers at Burlington TS is mainly driven by the load connected in the Burlington to Nanticoke area. Only a small percentage of the autotransformer load is due to local Guelph load and as such, analysis of the Burlington TS autotransformers was undertaken in the 'Burlington to Nanticoke' Regional Infrastructure Plan.

3.4.2 SUPPLY CAPACITY OF THE 230 KV NETWORK

The KWCG area contains three pairs of double circuit 230 kV lines: M20D/M21D, D6V/D7V and D4W/D5W.

Single circuit contingencies were performed to assess the adequacy of the local 230 kV transmission system for year 2025 loading[3].

As indicated in Appendix D there are no thermal overloads and no voltage violations for the loss of a single 230 kV circuit.

3.4.3 SUPPLY CAPACITY OF THE 115 KV NETWORK

The KWCG area contains five pairs of double circuit 115 kV lines: D7F/D9F, F11C/F12C, B5G/B6G, D11K/D12K and D8S/D10H.

Single circuit contingencies were performed to assess the adequacy of the local 115 kV transmission system for year 2025 loading.

As indicated in Appendix D there are no thermal overloads and no voltage violations for the loss of a single 115 kV circuit. Appendix H details supply capacity on circuit D8S and D10H as request by the LDC.

3.4.4 VOLTAGE PERFORMANCE

Single circuit contingencies as well as single element HV shunt capacitor bank contingencies were performed to determine the overall voltage performance of the KWCG area for year 2025 loading.

As indicated in Appendix D there are no thermal overloads and no voltage violations for these contingencies. Appendix H details voltage performance at Elmira TS and Rush MTS as request by the LDC.

3.4.5 LOAD SECURITY ANALYSIS

The most stringent load security criterion that applies to the KWCG area states that with any two elements out of service:

- Voltage must be within applicable emergency ratings and equipment loading must be within applicable short-term emergency ratings;
- Load transfers to meet the applicable long-term emergency ratings must be able to be made in the time afforded by short-time ratings;
- Planned load curtailment or load rejection in excess of 150 MW is not permissible (except for local generation outages) and;

[3] Note, if another element such as an autotransformer, circuit or capacitor bank shared the same “switching position” and/or zone of protection with the circuit under contingency, both were removed from service.

- Not more than 600 MW of load may be interrupted by configuration and by planned load curtailment or load rejection excluding voluntary demand management with any two transmission elements out of service.

There are three pairs of 230 kV double circuit lines and five pairs of 115 kV double circuit lines in the KWCG area. While one circuit of a double circuit line is out of service, the loss of the companion circuit in the pair would result in the loss of all load stations connected to the pair by configuration. Tables F1 and F2 in Appendix F illustrate the load lost due to configuration in both years 2016 and 2025.

There are five stations in the KWCG area that have autotransformers. Overlapping autotransformer contingencies were taken and Table F3 in Appendix F illustrates any load transfer requirements due to two overlapping autotransformer outages.

As seen in Appendix F, the load forecasted on all circuit pairs is less than 600 MW within the 10-year study period and the loss of two autotransformers within this local area does not result in equipment loading beyond their applicable emergency ratings; therefore there is no concern with Load Security in the KWCG area for the study period.

3.4.6 LOAD RESTORATION CAPABILITY ANALYSIS

The load restoration criteria requires that the transmission system be planned such that following local area design criteria contingencies, the affected loads can be restored within the restoration times indicated below[4]:

- All load lost must be restored within 8 hours;
- Load lost in excess of 250 MW must be restored within 30 min; and
- Load lost between the amount of 150 MW and 250 MW must be restored within 4 hours.

Each pair of double circuit 230 kV and 115 kV lines were assessed to verify their load restoration capability. This assessment is detailed in Appendix G.

The results indicated the existing transmission system can adequately restore load to each circuit pair with the exception of M20/21D. Therefore, improvement to the restoration capability of load connected to circuits M20D and M21D is required.

3.4.7 IMPACT OF CONTINGENCIES ON THE BPS TO THE KWCG AREA

Northeast Power Coordinating Council (NPCC) Bulk Power System stations in the KWCG area are:

- Middleport TS 500 kV bus
- Middleport TS 230 kV bus
- Detweiler TS 230 kV bus

[4] As per ORTAC: “These approximate restoration times are intended for locations that are near staffed centres. In more remote locations, restoration times should be commensurate with travel times and accessibility.”

All elements connected to BPS buses are considered BPS facilities. Elements refer to circuit breakers, transmission lines, generators, transformers and reactive devices (e.g. SVC or capacitor bank).

Appendix E: Technical Results-Bulk Power System Considerations provides a list of BPS contingencies and the results. A *limited* number of BPS contingencies were performed in order to establish the impact of contingencies on the BPS to the local KWCG area.

Three NPCC Directory 1 contingency events were utilized in this study:

1. Simultaneous loss of two adjacent transmission circuits on a multiple circuit tower
2. Loss of any element with delayed fault clearing (a.k.a. Breaker Failure)
3. Loss of a critical element, followed by system adjustment, then loss of a critical element.

These BPS contingency events were applied to BPS buses only. The results can be summarized as follows:

- As per Table E3 and E5 when two of the three auto-transformers at Detweiler TS are not available the remaining auto-transformer may become overloaded. Since the loading of the remaining auto-transformer is within its 15-minute Short-Term Emergency Rating (STE) operational control actions can be taken to reduce the loading to within acceptable limits. Control actions could entail isolation of the faulted element e.g. circuit breaker, bus or transformer, and placing back in-service a healthy auto-transformer (at Detweiler TS and/or Preston TS). Another control action could entail opening of 115kV breakers at Freeport SS to redirect flows through the Cedar TS autotransformers.

3.4.8 Summary of Needs

Figure 1 illustrates the Needs timeline for the KWCG region.

Figure 1: Transmission Needs in the KWCG Area

4.0 Options to Address the Need

Options were considered to address the insufficient load restoration capability for loads connected to circuits M20D and M21D. These options are shown in Table 1. Although there are several metrics that can be utilized to measure and compare options, the simple metric “initial capital cost/MW of load restored” was selected because it compares the unit costs of remedial measures. This was deemed sufficient in order to select the preferred option

Table 1: Options to Improve M20/21D Load Restoration

Option	**Options to Improve Restoration**	**Fault on the Main Line – Restorable Load** (Note 1)	**Fault on the Tap – Restorable Load** (Note 1)	**Initial Capital Cost** (Note 3)	**Initial Capital Cost/ MW Load Restored**
--	Existing (Benchmark)	100 MW (Preston TS only)	100 MW (Preston TS only)	0	$0/MW
1	230 kV in-line switches on M20/21D at **Preston Junction**	100 MW (C&ND load only-Note 2)	100 MW (C&ND load only-Note 2)	$6M	$60k/MW
2	230 kV in-line switches on M20/21D at **Galt Junction** (main line)	368 MW - 484 MW	234 MW (100 MW via existing Preston Auto)	$6M	$12k/MW to $26k/MW
3	One 230 kV cap bank at Preston TS plus 230 kV in-line switches on MxD at **Preston Junction**	140 MW (Note 4) (C&ND load only-Note 2)	140 MW (Note 4) (C&ND load only-Note 2)	$11M	$79k/MW
4	2nd autotransformer at Preston TS plus 230 kV in-line switches on MxD at **Preston Junction**	200 MW (Note 4) (C&ND load only-Note 2)	200 MW (Note 4) (C&ND load only-Note 2)	$21M	$105k/MW
5	2nd autotransformer at Preston TS plus 230 kV in-line switches on MxD at **Preston Junction** plus two 230 kV cap banks at Preston TS	280 MW (Note 4) (C&ND load only-Note 2)	280 MW (Note 4) (C&ND load only-Note 2)	$31M	$111k/MW

NOTE 1 Restorable load values are approximate values only as the actual amount of restorable load will depend on the prevailing system conditions and Operating/Control Centre protocols and priorities

NOTE 2 “C&ND load only” means that only those customers connected to Galt TS, C&ND MTS#1 and Preston TS will benefit. Cambridge and North Dumfries Hydro customers are the sole customers of these three stations.

NOTE 3 All prices are based on historical data: taxes extra, overhead extra, no escalation considered, no assumptions are made to feasibility or constructability, no assumptions made as to space requirements, real estate and environmental cost extra

NOTE 4 Restoration of 230 kV load (Cambridge and North Dumfries load) via the Preston TS auto-transformer may require operational measures on the 115 kV system to secure the transmission system to handle a subsequent contingency e.g. open the low voltage bus-tie breakers/switches at 115kV connected stations

5.0 DISCUSSION OF PREFERRED OPTIONS

5.1 PREFERRED OPTION TO IMPROVE RESTORATION TO M20/21D LOAD

Currently, loads connected to circuits M20/21D do not meet the restoration criteria.

Of the five options, option #2: 230 kV in-line switches on M20/21D at/near Galt Junction is the preferred option to satisfy the Need as it will provide the capability to restore the most load supplied from M20/21D.

Not only does Option #2 allow for more load to be restored, it provides for better operational flexibility; and is the most economical solution. As option 2 substantially meets the need by significantly improving the existing restoration capability, it is therefore the preferred option.

6.0 DEVELOPMENT PLAN

The transmission infrastructure development plan for the KWCG area is as followings:

1) Immediate Action: Install 230 kV In-Line Switches

Install 230 kV Load Interrupter type in-line switches on circuits M20D and M21D on the main line near Galt Junction. Note that load interrupter type switches cannot be used to interrupt fault current.

7.0 CONCLUSIONS

The following conclusions can be reached from the analysis performed by this study.

Local Area Performance

1. Improvement to the load restoration capability of transmission-connected customers on circuits M20D and M21D is required. The preferred option can be implemented by summer 2017.

BPS Performance

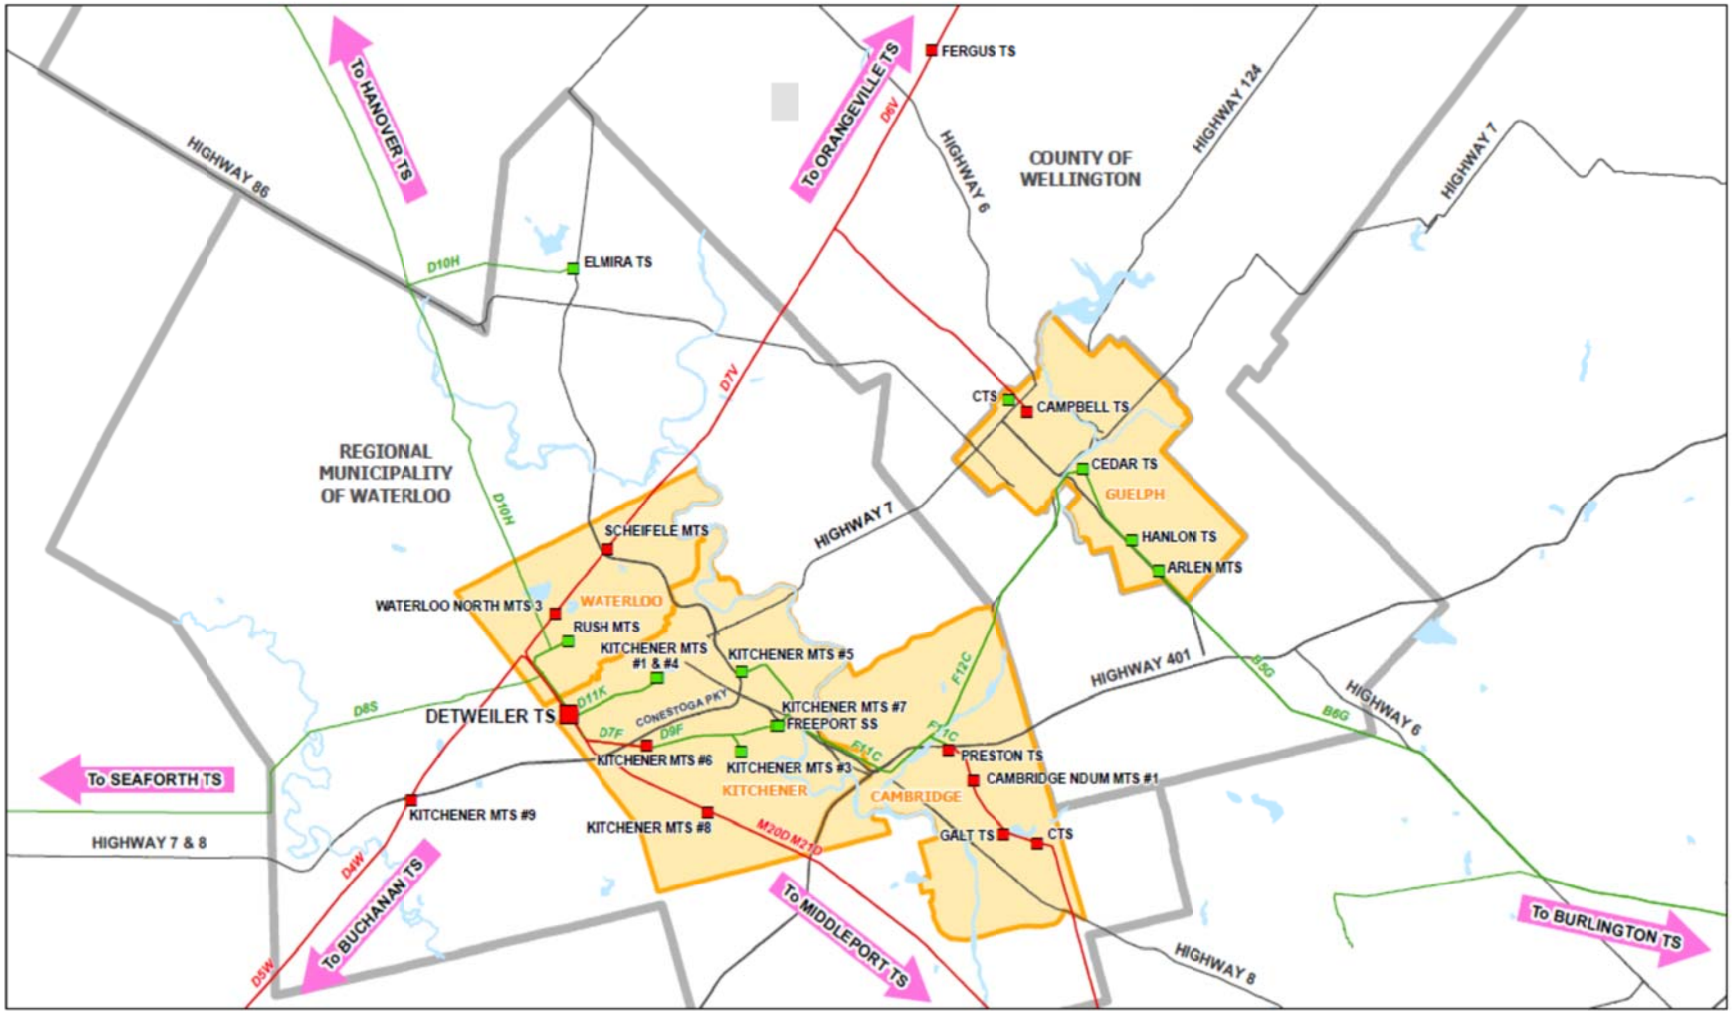
2. Autotransformer T2 at Detweiler TS is expected to be at 104.4% of LTE loading for year 2016 for the following contingency:
   i. Detweiler T4 outage plus Detweiler T3 with M20D (includes Preston T2 via Preston SPS). Since the post-contingency flow is below the auto-transformer STE, operational control actions can be taken to reduce loading to within the LTE rating.

8.0 RECOMMENDATIONS

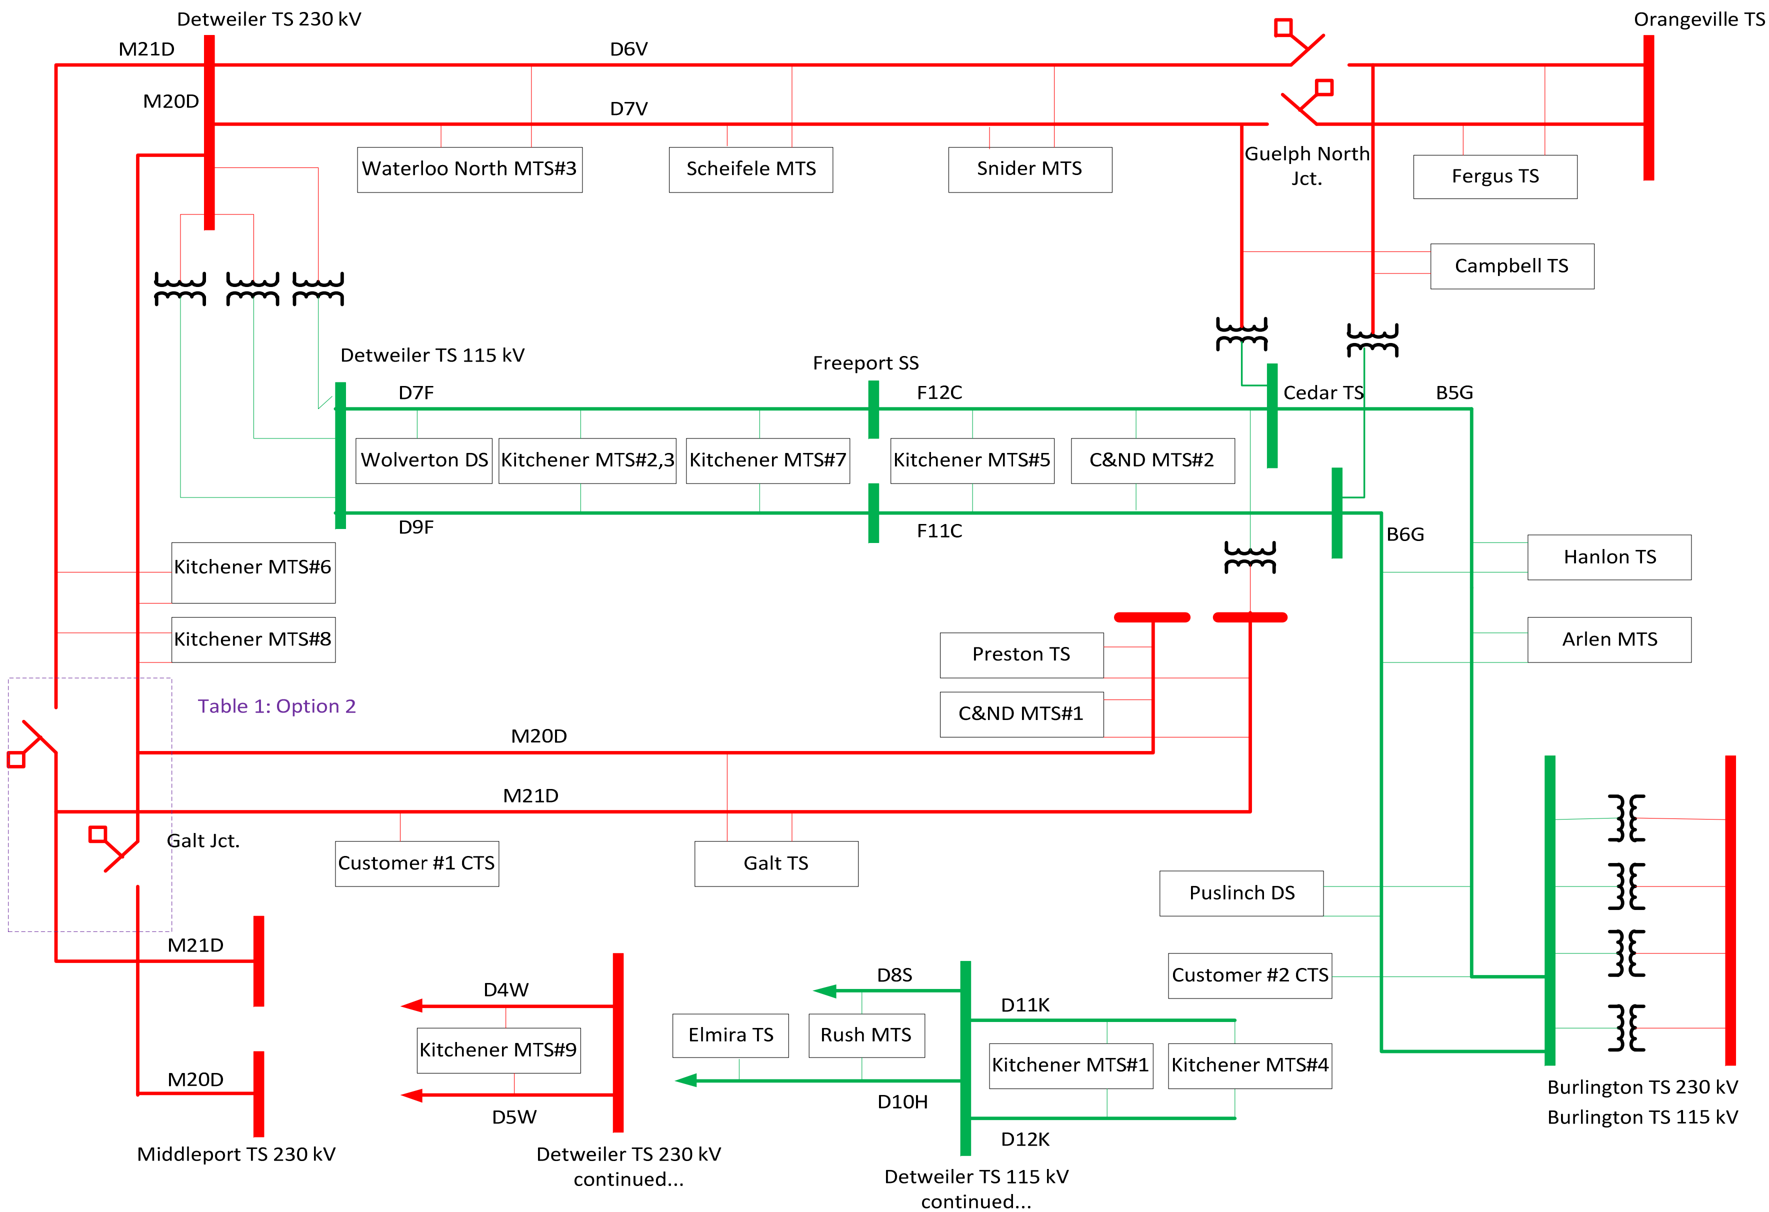
The following recommendations are to address the transmission infrastructure deficiencies within the study period for the KWCG area. These recommendations are:

1. Hydro One Networks to install a set of 230 kV in-line switches onto the main line of circuits M20D and M21D near Galt Junction as soon as possible.
2. Hydro One Networks, the LDCs and the IESO to review the KWCG local area in 2019 with updated KWCG load forecasts to decide on appropriate actions to meet longer-term needs as they emerge.

APPENDIX A: KWCG MAPS



Map 1: Geographical Area of KWCG with Electrical Layout



Map 2: KWCG Electrical Single-Line

APPENDIX B: TRANSMISSION-CONNECTED GENERATION IN THE KWCG AREA

Name	Installed Capacity	Peak Capacity Contribution[5]	Location	Existing or Contracted
Dufferin Wind Farm	97	13.6	Orangeville TS	Existing
Conestoga Wind Farm	67	10.8	D10H	Contracted (future i/s date unknown)

[5] Percentage of installed capacity is 14 % for wind generation

APPENDIX C: KWCG CUSTOMER & LDC LOAD FORECASTS

Table C1: KWCG 2015 RIP Load Forecast*

TS	LDC	Load Forecast	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025

Planning demand (MW) = ((Gross-CDM) x Extreme Weather Factor) – DG

*Based upon KWCG 2015 IRRP Planning Load Forecast except where otherwise noted.

Note 1: The LDC has confirmed 9.2 MW of cogeneration at a large customer to be accounted for in the Preston TS forecast starting year 2016. The generation plant is expect to run most of the time and would offset the customer's load. This cogeneration was not factored into the KWCG 2015 IRRP Planning Load Forecast.

Note 2: The LDC has confirmed that additional transformation capacity (Snider/Bradley TS) would not be required until after 2024. The exact location and timing of these TS's have not been determined at this time. The load growth indicated at Snider and Bradley in the forecast can be managed by existing TS's/impact of CDM/DG in the Waterloo Region. LDCs are monitoring the load closely to determine the timing of potential transformation needs. Where possible, these LDCs are exploring opportunities to coordinate use and development of TS facilities in the KWCG Region over the long term. Cambridge #2 is assumed to be supplied off the KWCG 115kV system

Note 3: Slight modification from KWCG 2015 IRRP Planning forecast based on information provided by the transmission-connected customer

Note: Guelph CTS 1 forecast was removed as the LDC confirmed the load was already accounted for within their forecast

APPENDIX D: TECHNICAL RESULTS – LOCAL AREA ANALYSIS

Single element contingencies were considered in order to determine the presence of thermal overload and/or voltage violations.

Table D1: Single Element Contingencies (single zone of protection)

All voltages are within criteria			

APPENDIX E: TECHNICAL RESULTS – BULK POWER SYSTEM CONSIDERATIONS

Applicable contingencies were considered on BPS elements to establish their impact on the local area.

Table E1: N-2 Contingencies

Loss of a Double Circuit Line (N-2) emanating from a BPS station		
B22D and B23D	D4W and D5W	M20D and M21D
D6V and D7V	--	--
Breaker Failure (B/F) Contingencies at BPS station (N-2)		
Detweiler TS 230 kV bus	B/F of AL6	Loss of: D6V, Cedar T3, Detw T4, M21D, Preston T2
	B/F of AL7	Loss of: D7V, Cedar T4, M21D, Preston T2
	B/F of L7L20	Loss of: D7V, Cedar T4, M20D, Detw T3, Preston T2
	B/F of HT1A	Loss of: M21D, Preston T2, SVC1
	B/F of ACS21	Loss of : M21D, Preston T2, SC21
	B/F of HL20	Loss of: M20D, Detw T3, D5W, SC22
	B/F of T2SC21	Loss of: Detw T2, SC21
	B/F of HT2	Loss of: Detw T2, SC21, D5W
	B/F of DL22	Loss of: B22D, D6V, Cedar T3, Detw T4
Middleport TS 500 kV bus	Covered under Loss of Middleport T3 and T6 autotransformers for the local area analysis (Appendix D)	
Middleport TS 230 kV bus	There are no B/F conditions that would be critical to the supply to the KWCG area.	

Table E2: N-1-1 Contingencies

Loss of a Critical Element, System Adjustment, Loss of a Critical Element (N-1-1)
Loss of: Detw T4 plus Detw T3 (plus M20D by configuration which also includes the loss of Preston T2 via Preston SPS)
Loss of: Preston T2 plus D7V (plus Cedar T4 by configuration)

Note that during the simulations no System Adjustment was afforded; this is considered a conservative approach.

Results: Thermal Overloads and Voltage Violations

As per Table E3 and E5: Detweiler TS 230/115 kV autotransformer T2 will become overloads when Detweiler TS autotransformer T4 is out-of-service followed by the loss of Detweiler TS autotransformer T3 in conjunction with circuit M20D by configuration. Preston TS autotransformer T2 is also removed from service via the Preston SPS.

Table E3: Thermal Analysis (>95% LTE), year 2016

Element	**Contingency**	**%LTE**
Detweiler TS T2 autotransformer	Detweiler T4 plus Detweiler T3 with M20D (includes Preston T2 via Preston SPS)	104.4 (74.2% STE*) %

*STE rating of Detweiler T2 auto-transformer is 396 MVA.

Table E4: Voltage Analysis, year 2016

Element	**Contingency**	**%Voltage Decline**	**Voltage kV**
All voltages are within criteria			

Table E5: Thermal Analysis (>95% LTE), year 2025

APPENDIX F: LOAD SECURITY ANALYSIS

Load connected to each circuit pair that is lost by configuration following an [N-2] double circuit contingency is:

Table F1: Load Lost Due to Configuration, year 2016

Circuit Pair	MW
M20/21D	420
D6/7V	482
D4/5W	34
D7/9F	131
F11/12C	74
B5/6G	105
D11/12K	98
D8S/D10H	89

Table F2: Load Lost Due to Configuration, year 2025

Circuit Pair	MW
M20/21D	489
D6/7V	571
D4/5W	36
D7/9F	141
F11/12C	78
B5/6G	128
D11/12K	103
D8S/D10H	95[6]

Table F1 illustrates that none of the double circuit contingencies result in more than 482 MW of load lost in year 2016.

Table F2 illustrates that none of the double circuit contingencies result in more than 571 MW of load lost in year 2025.

[6] D8S and D10H emanate out of Detweiler TS as a double circuit line however after ~ 5 km they each become a single circuit 115 kV line. Based on their N/O open points, the loss of the double circuit line within the 5 km span out of Detweiler TS, will results in approximately 95 MW of load lost.

Table F3: Two Elements Out of Service

Loss of a Double Circuit Line		
D7F and D9F	F11C and F12C	B5G and B6G
D4W and D5W	M20D and M21D	D11K and D12K
D6V and D6V		

Loss of Two Autotransformers[7]

Station	**Detweiler Auto**	**Preston Auto**	**Cedar Auto**	**Burlington Auto**
Detweiler Auto	N/A	Detweiler T3 + Preston T2	Cedar T3 + Detweiler T4	Burlington T6 + Detweiler T3
Preston Auto	Detweiler T3 + Preston T2	N/A	Cedar T4 + Preston T2	Burlington T6 + Preston T2
Cedar Auto	Cedar T3 + Detweiler T4	Cedar T4 + Preston T2	Cedar T3 + Cedar T4	Burlington T6 + Cedar T3
Burlington Auto	Burlington T6 + Detweiler T3	Burlington T6 + Preston T2	Burlington T6 + Cedar T3	N/A

Results: Thermal Overload and Voltage Violations

Table F5: Thermal Analysis (>100% STE), year 2025

Element	**Contingency**	**%STE**
All circuits and auto-transfers are within ratings		
Element	**Contingency**	**%LTE**
All circuits and auto-transfers are within ratings		

Table F6: Voltage Analysis (> emergency ratings), year 2025

Element	**Contingency**	**%Voltage Decline**	**Voltage kV**
All voltages are within criteria			

[7] For stations that have three or more autotransformers connected in parallel typical operating practice after the loss of one autotransformer is to make load transfers to other interconnected autotransformer station(s) such that the remaining load at the affected station would be at or below the station's reduced Limited Time Rating (LTR). It is assumed the in this case that sufficient time between single autotransformer contingencies is available for such load transfers to be carried out by operator response.

APPENDIX G: LOAD RESTORATION ANALYSIS

Restoration of Load Connected to M20/21D

By year 2025 the total forecasted load connected to circuits M20/21D is 489 MW. Loss of this double circuit line would result in the loss of all 489 MW. In order to restore load to these stations at least one circuit would have to be placed back in service**,** noting that to restore Customer #1 CTS circuit M21D must specifically be placed back in service due to the customer's single-circuit transmission-connection

Based on criteria:

Load Required to be Restored	Duration
239MW	30 min.
100 MW	Within 4 hrs.
150 MW	Within 8 hrs.

Existing infrastructure allows for only the restoration of 100 MW of load in approximately 30 min. This can be accomplished by opening the M20/211D line disconnect switches at Preston TS and back-feed Preston TS T2 230-115 kV autotransformer to supply load at Preston TS only.

Therefore, the existing restoration capability to loads connected to M20/21D does not meet criteria for the duration of the study period.

Restoration of Load Connected to D6/7V

By year 2025 the total forecasted load connected to D6/7V is 571 MW. Loss of this double circuit line would result in the loss of all 571 MW. As part of the Guelph Area Transmission Reinforcement project, two 230 kV in-line switches will be installed in year 2016 on the main line between Detweiler TS and Orangeville TS at Guelph North Junction. To restore load to these stations, the operator will utilize these switches to isolate the problem and return to service the remaining healthy circuit sections. These switches allow for more flexibility to restore load to the affected stations in a timely fashion.

Based on criteria:

Load Required to be Restored	Duration
321MW	30 min.
100 MW	Within 4 hrs.
150 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and

3. the relative distance from the nearest field maintenance centre[8]

the load restoration criterion is substantially met. Therefore, no additional transmission restoration capability is warranted at this time.

Restoration of Load Connected to D4/5W

By year 2025 the total forecasted load connected to D4/5W is 36 MW. Loss of this double circuit line would result in the loss of all 36 MW. To restore load to this station at least one circuit would have to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
36 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

Restoration of Load Connected to D7/9F

By year 2025 the total forecasted load connected to D7/9F is 141 MW. Loss of this double circuit line would result in the loss of all 141 MW. To restore load to these stations at least one circuit would have to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
141 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

[8] The KWCG area is considered an urban area and as such, access to transmission facilities, repair materials and personnel in order to make a repair within 8 hours is realistic. A Hydro One field maintenance centre is located in Guelph.

Restoration of Load Connected to F11/12C

By year 2025 the total forecasted load connected to F11/12C is 78 MW. Loss of this double circuit line would result in the loss of all 78 MW. To restore load to these stations at least one circuit would have to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
78 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

Restoration of Load Connected to B5/6G

By year 2025 the total forecasted load connected to B5/6G is 128 MW. Loss of this double circuit line would result in the loss of all 128 MW. To restore load to Enbridge Westover CTS's circuit B5G must be placed back in service due to the CTS's single-circuit transmission connection. To restore load at the other stations at least one circuit would to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
128 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

Restoration of Load Connected to D11/12K

The total forecasted load serviced by radial circuits D11/12K will not exceed 103 MW by 2025. Loss of this double circuit line would result in the loss of all 103 MW. To restore load to these stations at least one circuit would have to be placed back in service.

Based on criteria:

Load Required to be Restored	Duration
103 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

Restoration of Load Connected to D8S/D10H

The total forecasted load serviced by these radially operated 115 kV circuits will not exceed approximately 95 MW by year 2025. Loss of this double circuit line would result in loss of all 95MW. To restore Rush MTS either circuit can be placed back into service or the station could possibly be fed via circuit L7S out of Seaforth TS; however to restore Elmira TS circuit D10H must be placed back in service due to Elmira TS's single-circuit transmission-connection.

Based on criteria:

Load Required to be Restored	Duration
95 MW	Within 8 hrs.

Depending on:

1. the severity of the double circuit contingency;
2. the prevailing system conditions and
3. the relative distance from the nearest field maintenance centre

the load restoration criteria can be met. Therefore, no additional transmission restoration capability is warranted at this time.

APPENDIX H: SUPPLY TO ELMIRA TS AND RUSH MTS

Study Results:

Table H1: Station Capacity: Summer Ratings and Summer Load Forecast

Station	**Transformer Capacity (10-day LTR)**	**Year 2025 Load Forecast**
Rush MTS	69 MVA*	61.3 MW / 69.9 MVA (0.88 pf** at defined meter point, 115 kV side)
Elmira TS	58.5 MVA	33.6 MW / 37.1 MVA*** (0.91 pf at defined meter point, 115 kV side)

*The limiting component is a low voltage cable; when required the limiting component will be modified and the rating to be 75 MVA

** Power factor at the defined meter point improves to 0.92 when 5.4 MVar of installed feeder capacitor banks assumed lumped at the LV bus and results in 66.8 MVA loading

*** A 9.2 MVar @ 27.6 kV shunt capacitor bank is installed at Elmira TS not in-service; when in-service power factor improves and loading through the transformers decrease.

Table H2: Transmission Capacity of circuits D8S and D10H

Year	**Contingency**	**D10H – Detweiler TS x Waterloo Jct.**	**D8S – Detweiler TS x Leong Jct.**
		590 A Continuous *640 A Long-Term Emergency (LTE)* *660 A Short-Term Emergency (15-min.)*	*590 A Continuous* *640 A Long-Term Emergency (LTE)* *660 A Short-Term Emergency (15-min.)*
2016	Pre	287 A	285 A
	Loss of D8S	454 A	--
	Loss of D10H	--	459 A
2025	Pre	319 A /	302 A
	Loss of D8S	511	--
	Loss of D10H	--	500 A

-assume all St. Mary's TS load is supplied by D8S (as this is more conservative for the study), assume Conestogo Wind Farm not-service (as it would displace load on D10H) and the normally-open point on D10H is between Elmira TS and Palmerston TS

Table H3: Voltage Profile at Rush MTS and Elmira TS

Year	Contingency	Rush MTS 115 kV D8S	Rush MTS 115 kV D10H	Rush MTS 13.8 kV	Elmira TS 115 kV	Elmira TS 27.6 kV

	Loss of D8S	--	121.8	13.7	120.6	27.1
	Loss of D10H	121.5	--	13.7	--	--
2025	Pre	123.2	123.1	14.2	121.6	27.3
	Loss of D8S	--	122.6	13.6	121.1	27.2
	Loss of D10H	122.4	--	13.6	--	--

-assume all St. Mary's TS load is supplied by D8S (as this is more conservative for the study), assume Conestogo Wind Farm not-service (as it would displace load on D10H) and the normally-open point on D10H is between Elmira TS and Palmerston TS

Analysis:

D8S

Circuit D8S has a normally open point at St. Mary's TS separating the circuit from circuit L7S. D8S normally supplies half the load at Rush MTS and half the load at St. Mary's TS. The other half of the load at Rush MTS is normally supplied by circuit D10H and the other half of the load at St. Mary's TS is normally supplied by L7S. Referring to Table H2, for the loss of circuit D10H, circuit D8S has sufficient capacity to supply all load at Rush MTS and St. Mary's TS for year 2025 and beyond.

D10H

Circuit D10H runs between Detweiler TS and Hanover TS and has a normally open point between Elmira TS and Palmerston TS. Elmira TS is normally supplied from Detweiler TS while Palmerston TS is normally supplied from Hanover TS. Referring to Table H2, D10H has sufficient capacity to supply all load at Elmira TS for year 2025 and beyond. When circuit D8S is out of service, D10H has sufficient capacity to supply all load at Elmira TS and Rush MTS (while St. Mary's TS is supplied by circuit L7S).

Rush MTS

Since this station is a Municipal owned station, Waterloo North Hydro is to ensure there is sufficient transformation capacity to accommodate load growth. According to load forecasts and referring to Table H1, over the next 10-years load will fluctuate above and below the year 2025 forecast but will be remain within the station's Limited Time Rating (LTR). Waterloo North Hydro is to inform Hydro One if the connection requires modification and/or if a new station connection is required in order to accommodate load growth. Waterloo North Hydro has already incorporated their future Snider MTS and Bradley MTS into the KWCG regional plan to cater for load growth.

Rush MTS is supplied by two 115 kV circuits, D8S and D10H. Referring to Tables H2 and H3, when one of these circuits is out of service, the voltage profile at Rush MTS is healthy and the other circuit has sufficient capacity to supply all load to Rush MTS.

Elmira TS

According to the forecast and referring to Table H1, transformers at Elmira TS have sufficient capacity for year 2025 loading and beyond.

Elmira TS is supplied by one 115 kV circuit, D10H. Referring to Tables H2 and H3, the voltage profile at Elmira TS is healthy and the circuit has sufficient capacity to supply load to Elmira TS for year 2025 loading and beyond.

When circuit D10H out of Detweiler TS is unavailable, Elmira TS may also be supplied by D10H out of Hanover TS (by closing the normally open point between Palmerston TS and Elmira TS). Assuming Palmerston TS is at its forecasted year 2025 normal weather peak load, approximately 25 MW of load at Elmira TS may be supplied out of Hanover TS. The limiting factor being the 115 kV voltage profile on D10H as Elmira TS is nearly 80 circuit km from Hanover TS.

Metro Toronto

REGIONAL INFRASTRUCTURE PLAN

January 12, 2016

[This page is intentionally left blank]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Enersource Hydro Mississauga
Hydro One Networks Inc. (Distribution)
Independent Electricity System Operator
PowerStream Inc.
Toronto Hydro-Electric System Limited
Veridian Connections Inc.

[This page is intentionally left blank]

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address electrical supply needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE WITH SUPPORT FROM THE WORKING GROUP IN ACCORDANCE TO THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE METRO TORONTO REGION.

The participants of the RIP Working Group included members from the following organizations:

- Enersource Hydro Mississauga
- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator ("IESO")
- PowerStream Inc.
- Toronto Hydro-Electric System Limited ("THESL")
- Veridian Connections Inc.
- Hydro One Networks Inc. (Transmission)

This RIP is the final phase of the regional planning process and it follows the completion of the Central Toronto Sub-Region's Integrated Regional Resource Plan ("IRRP") by the IESO in April 2015 and the and Metro Toronto Northern Sub-Region's Needs Assessment ("NA") Study by Hydro One in June 2014.

This RIP provides a consolidated summary of needs and recommended plans for both the Central Toronto Sub-Region and Metro Toronto Northern Sub-Region that make up the Metro Toronto Region.

The Central Toronto IRRP has identified longer term needs beyond 2025. These longer term needs are also reviewed and discussed in this report. However, as the need dates are beyond 2025, adequate time is available to develop a preferred alternative in the next planning cycle expected to be started in 2018.

The major infrastructure investments planned for the Metro Toronto Region over the near and mid-term, identified in the various phases of the regional planning process, are given in the Table below.

No.	Project	I/S date	Cost ($M)
1	Manby Autotransformer Overload Protection Scheme	2018	$2
2	Runnymede TS Expansion & Manby x Wiltshire Corridor Upgrade	2019	$90
3	Horner TS Expansion	2020	$53
4	Richview x Manby Corridor Upgrade	2020	$20-40
5	Copeland MTS Phase 2	2020+	$46

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered at least every five years. As mentioned above, the next planning cycle is expected to be started in 2018. However, the Region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the regional planning cycle will be started earlier to address the need.

LIST OF FIGURES

LIST OF TABLES

[This page is intentionally left blank]

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN (“RIP”) TO ADDRESS THE ELECTRICITY NEEDS OF THE METRO TORONTO REGION.

The report was prepared by Hydro One Networks Inc. (“Hydro One”) on behalf of the Working Group that consists of Hydro One, Enersource Hydro Mississauga, Hydro One Networks Inc. Distribution, the Independent Electricity System Operator (“IESO”), PowerStream Inc., Toronto Hydro-Electric System (“THESL”), and Veridian Connections Inc. in accordance with the new Regional Planning process established by the Ontario Energy Board in 2013.

The Metro Toronto Region is comprised of the City of Toronto. Electrical supply to the Region is provided by thirty five 230kV and 115kV transmission and step-down stations as shown in Figure 1-1. The eastern, northern and western parts of the Region are supplied by eighteen 230/27.6kV step-down transformer stations. The central area is supplied by two 230/115kV autotransformer stations (Leaside TS and Manby TS) and fifteen 115/13.8kV and two 115/27.6kV step-down transformer stations. The summer 2015 area load of the Metro Toronto region was about 4700MW.

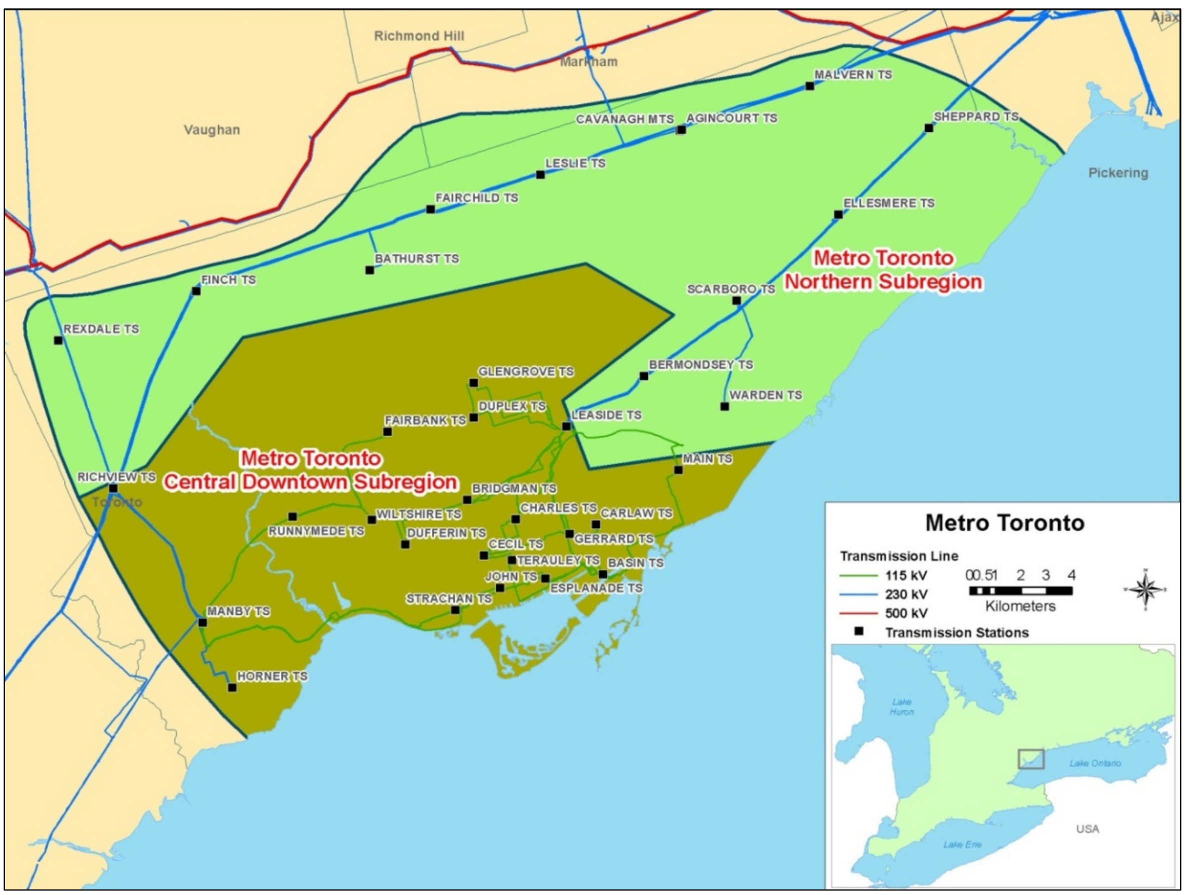

Figure 1-1 Map of Metro Toronto Region

1.1 Scope and Objectives

This RIP report examines the needs in the Metro Toronto Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop a wires plan to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant wires plans to address near and medium-term needs (2015-2025) identified in previous planning phases (Needs Assessment, Local Plan or Integrated Regional Resource Plan);
- Identification of any new needs over the 2015-2025 period and a wires plan to address these needs based on new and/or updated information;
- Develop a plan to address any longer term needs identified by the Working Group.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process;
- Section 3 describes the region;
- Section 4 describes the transmission work completed over the last ten years;
- Section 5 describes the load forecast used in this assessment;
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the needs;
- Section 7 discusses the needs and provides the alternatives and preferred solutions;
- Section 8 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend

[1] Also referred to as Needs Screening.

a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee (LAC) in the region or sub-region. For the Metro Toronto Region, community engagement through a formal LAC is on-going.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

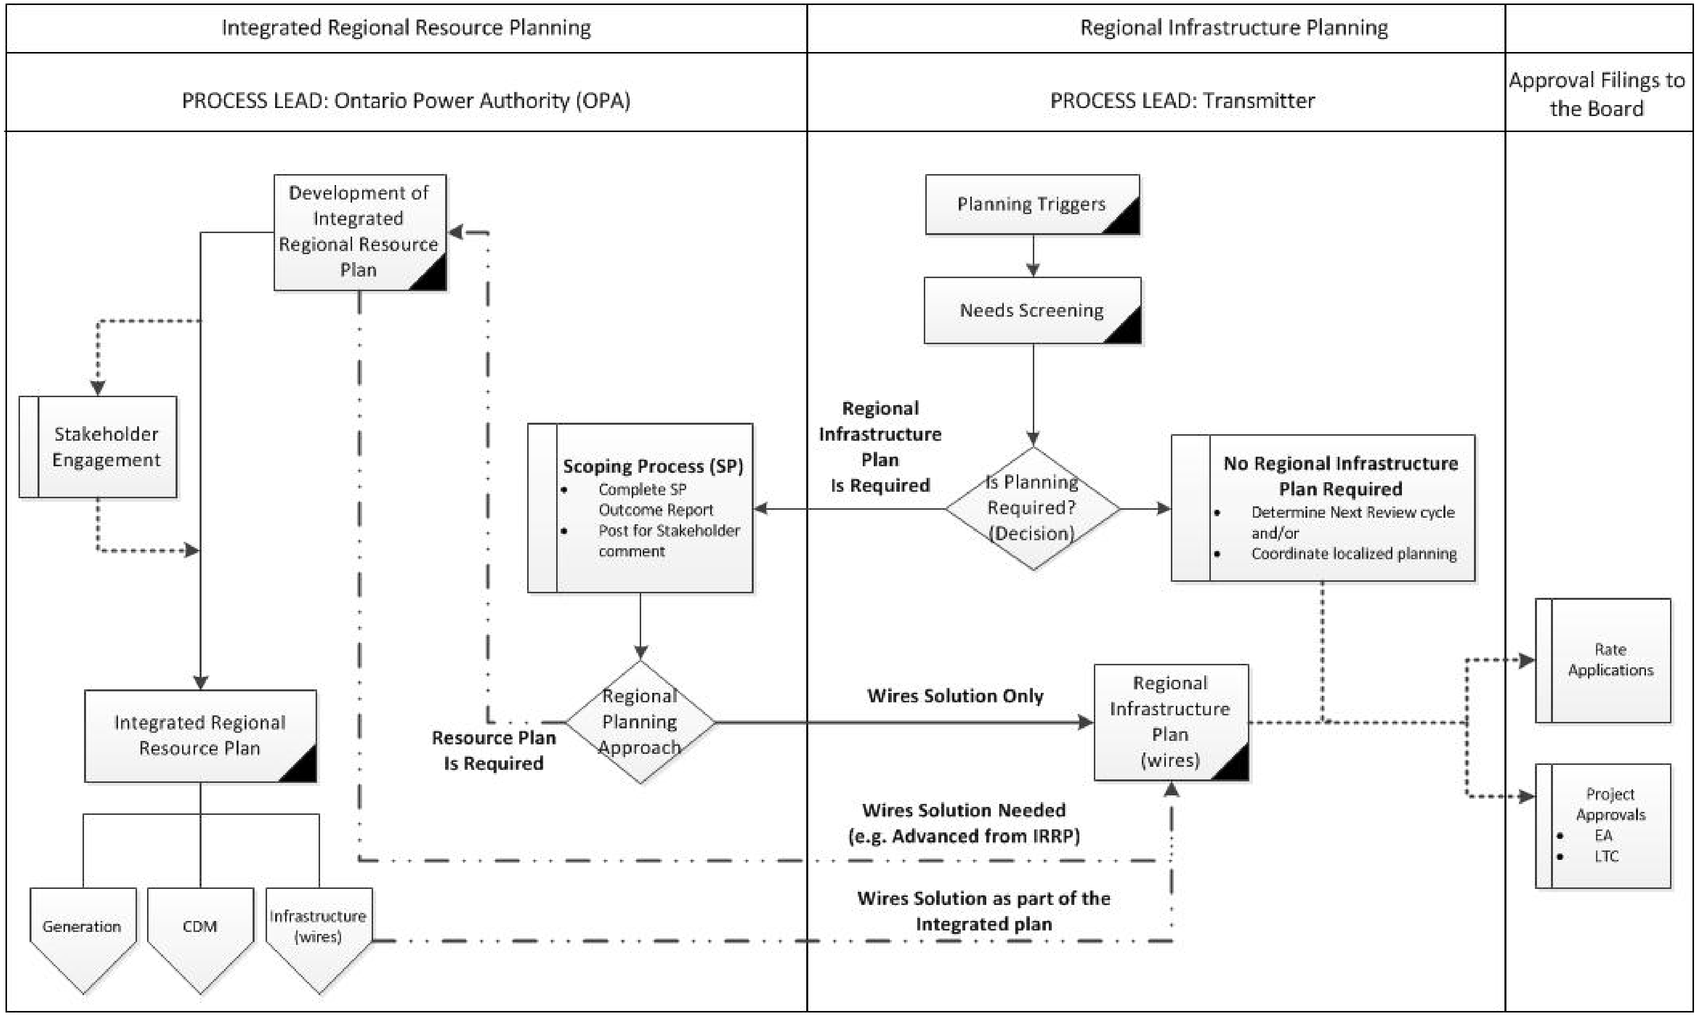

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of four steps (see Figure 2-2) as follows:

1) Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2) Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3) Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4) Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

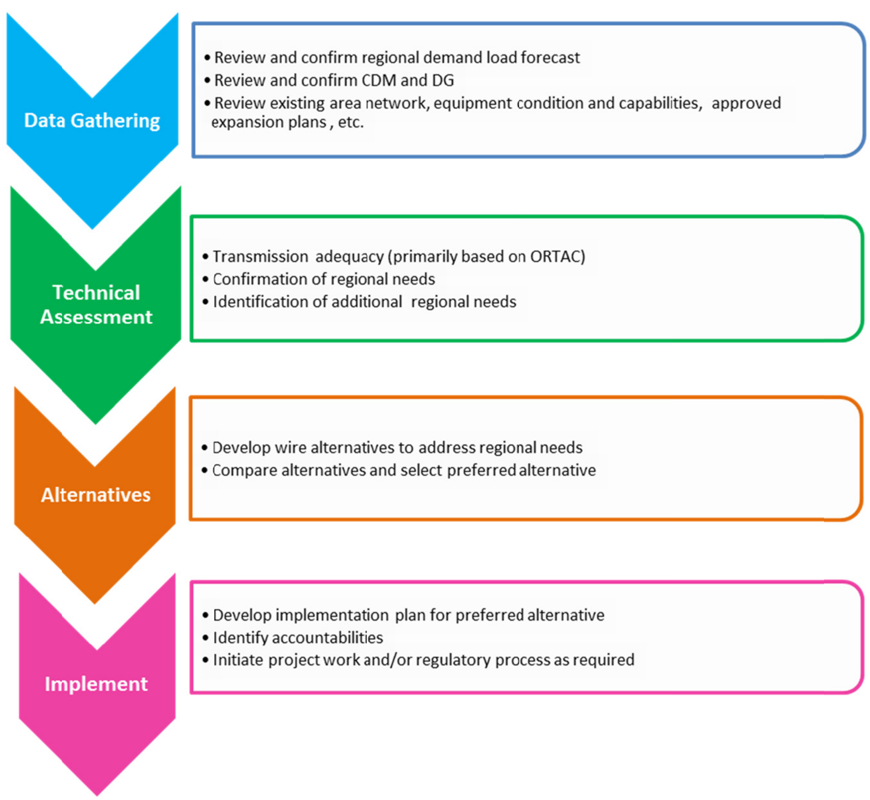

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE METRO TORONTO REGION INCLUDES THE AREA ROUGHLY BORDERED GEOGRAPHICALLY BY LAKE ONTARIO ON THE SOUTH, STEELES AVENUE ON THE NORTH, HIGHWAY 427 ON THE WEST AND REGIONAL ROAD 30 ON THE EAST. IT CONSISTS OF THE CITY OF TORONTO, WHICH IS THE LARGEST CITY IN CANADA AND THE FOURTH LARGEST IN NORTH AMERICA.

Bulk electrical supply to the Metro Toronto Region is provided through three 500/230 kV transformers stations - Claireville TS, Cherrywood TS and Parkway TS and a network of 230 kV and 115 kV transmission lines and step-down transformation facilities. Local generation in the area consists of the 550 MW Portlands Energy Centre located near downtown area and connected to the 115 kV network at Hearn Switching Station. The Metro Toronto Region 2015 peak summer demand was about 4700MW which represents about 20% of the gross electrical demand in the province.

Toronto Hydro-Electric System Limited ("THESL") is the Local Distribution Company ("LDC") that serves the electricity demands for the city of Toronto. Other LDCs supplied from electrical facilities in the Metro Toronto Region are Hydro One Networks Inc. Distribution, PowerStream Inc., Veridian Connections Inc., and Enersource Hydro Mississauga. The LDCs receive power at the step down transformer stations and distribute it to the end users – industrial, commercial and residential customers.

The April 2015 Integrated Regional Integrated Regional Resource Plan ("IRRP") report, prepared by the IESO in conjunction with Hydro One and the LDC, focused on the Central Toronto Area which included the 115kV network and the 230kV facilities in the western part of Region. The June 2014 Metro Toronto Northern Sub-Region Needs Assessment report, prepared by Hydro One, considered the remainder of the Metro Toronto region. A map and a single line diagram showing the electrical facilities of the Metro Toronto Region, consisting of the two sub-regions, is shown in Figure 3-1 and Figure 3-2 respectively. Please note that the facilities shown include the new Leaside TS to Bridgman TS 115kV circuit L18W and the new Copeland MTS. The L18W circuit is being built as part of the Midtown Transmission Reinforcement Project and Copeland MTS is a new THESL owned transformer station to serve the downtown area. Work on these projects is in the advanced stage and both are expected to come into service in 2016.

3.1 Central Toronto Sub-Region

The Central Toronto Sub-Region includes the area extending northward from Lake Ontario to roughly Highway 401, westward to Highway 427 and Etobicoke Creek, and eastward to Victoria Park Avenue.

The Central Toronto Sub-Region was identified as a "transitional" region, as planning activities in the region were already underway before the new regional planning process was introduced. The NA and SA phases were deemed to be complete, and the regional planning process was considered to be in the IRRP phase. An IRRP for the region was completed in April 2015.

The Central Toronto Sub-region is further subdivided into two areas:

- The Richview Manby 230kV area: This includes the former borough of Etobicoke and is served by the Richview TS to Manby TS 230kV circuits. The area has two 230/27.6kV step-down transformer stations. The coincident peak summer 2015 area load was about 320 MW.
  The Richview TS to Manby 230kV circuits together with the Richview TS to Cooksville TS circuit R24C supply a number of stations in the GTA West Southern Sub-Region. These stations while outside the Metro Toronto Region have therefore been included in Figure 3-2.

- The Central 115kV Area: The central area is supplied by two 230/115kV autotransformer stations (Leaside TS and Manby TS), fifteen 115/13.8kV and two 115/27.6kV step-down transformer stations. The area includes the downtown core including the financial, entertainment and educational districts. The 2015 summer coincident area load was about 1900MW.

Please see Figure 3-1 and 3-2 for a map and single line diagram of the Sub-Region facilities.

3.2 Metro Toronto Northern Sub-Region

The Metro Toronto Northern Sub-Region comprises the remainder of the Metro Toronto region. It includes the area roughly bordered geographically by Highway 401 on the south, Steeles Avenue on the north, Highway 427 on the west and Regional Road 30 on the east in addition to the area east of the Don Valley Parkway and north of O'Connor Dr.

Electrical supply to the Metro Toronto Northern Sub-Region is provided through 230 kV transmission lines and step-down transformation facilities. Supply to this sub-region is provided from a 230 kV transmission system consisting of the Richview TS to Parkway TS, the Richview TS to Cherrywood TS, the Richview TS to Claireville TS, as well as the Cherrywood TS to Leaside TS 230kV transmission system. The area is served primarily at 27.6kV by fifteen step-down transformer stations with a pocket of 13.8kV load supplied from Leaside TS and Leslie TS. The 2015 summer coincident area load was about 2500 MW.

Please see Figure 3-1 and 3-2 for a map and single line diagram of the Sub-Region facilities.

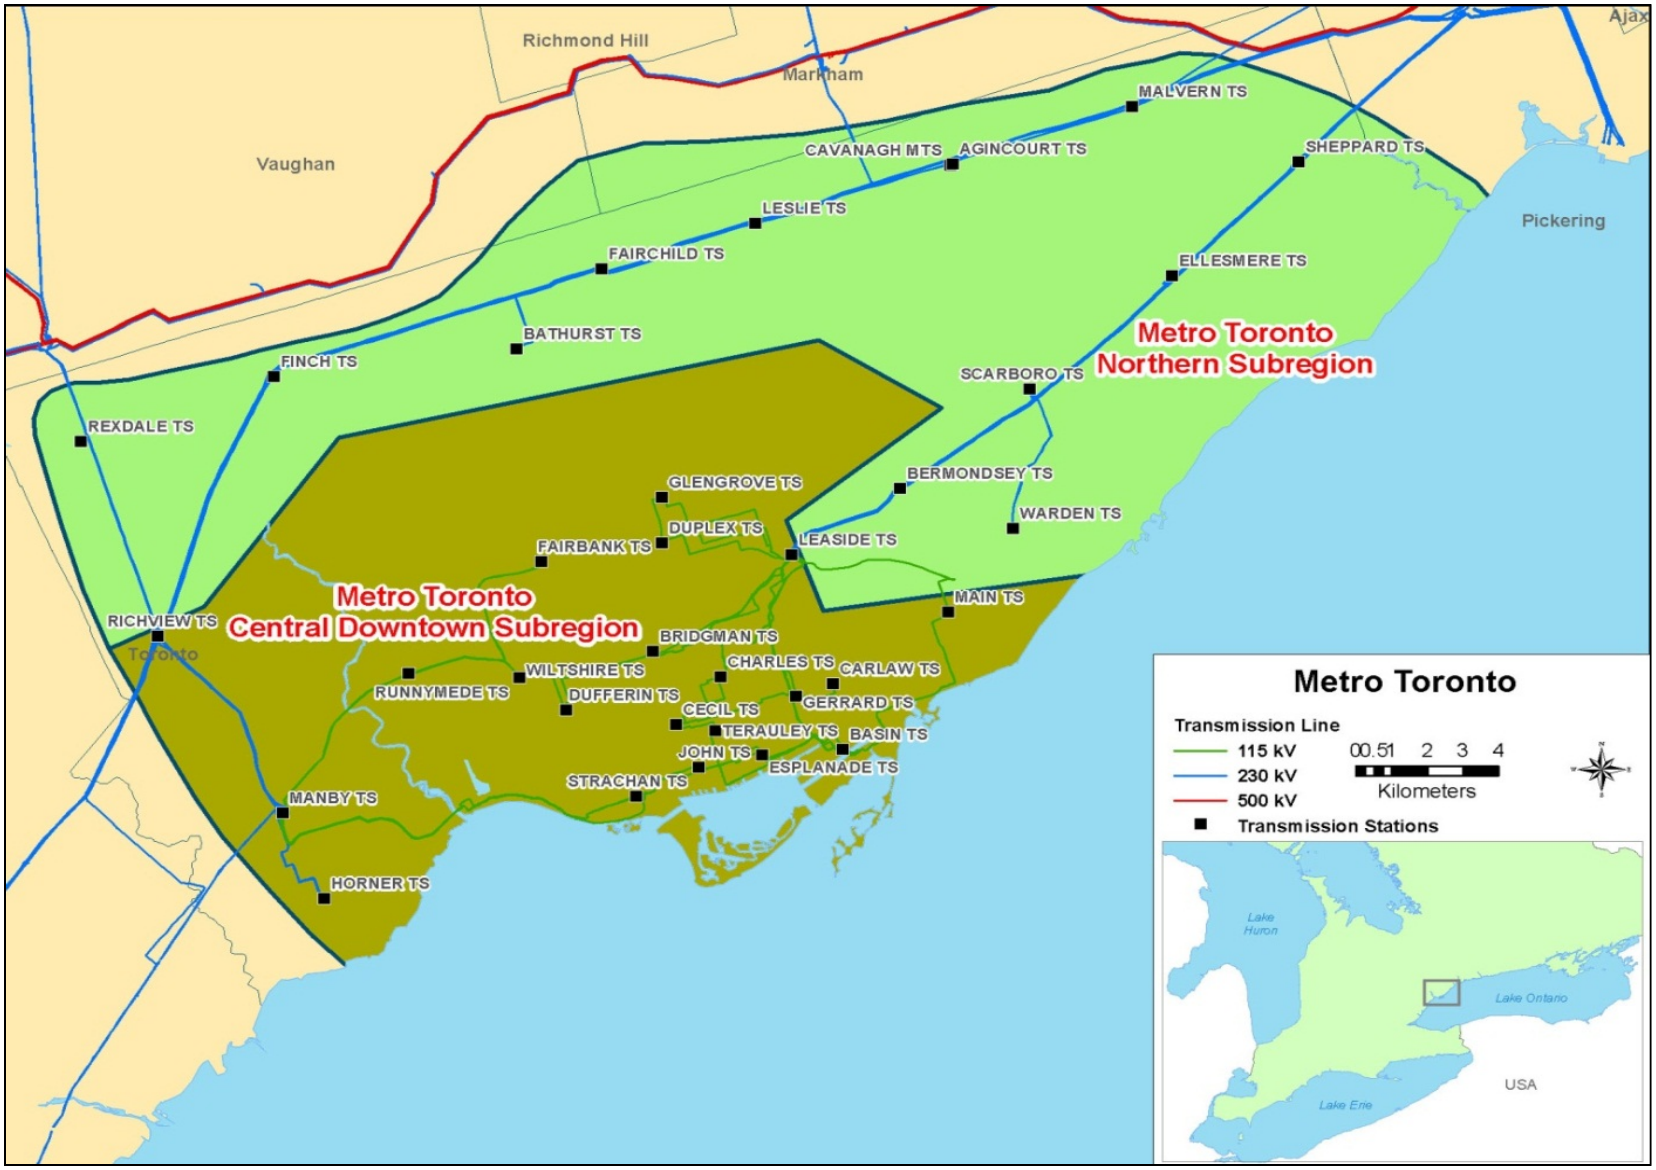

Figure 3-1 Metro Toronto Region – Supply Areas

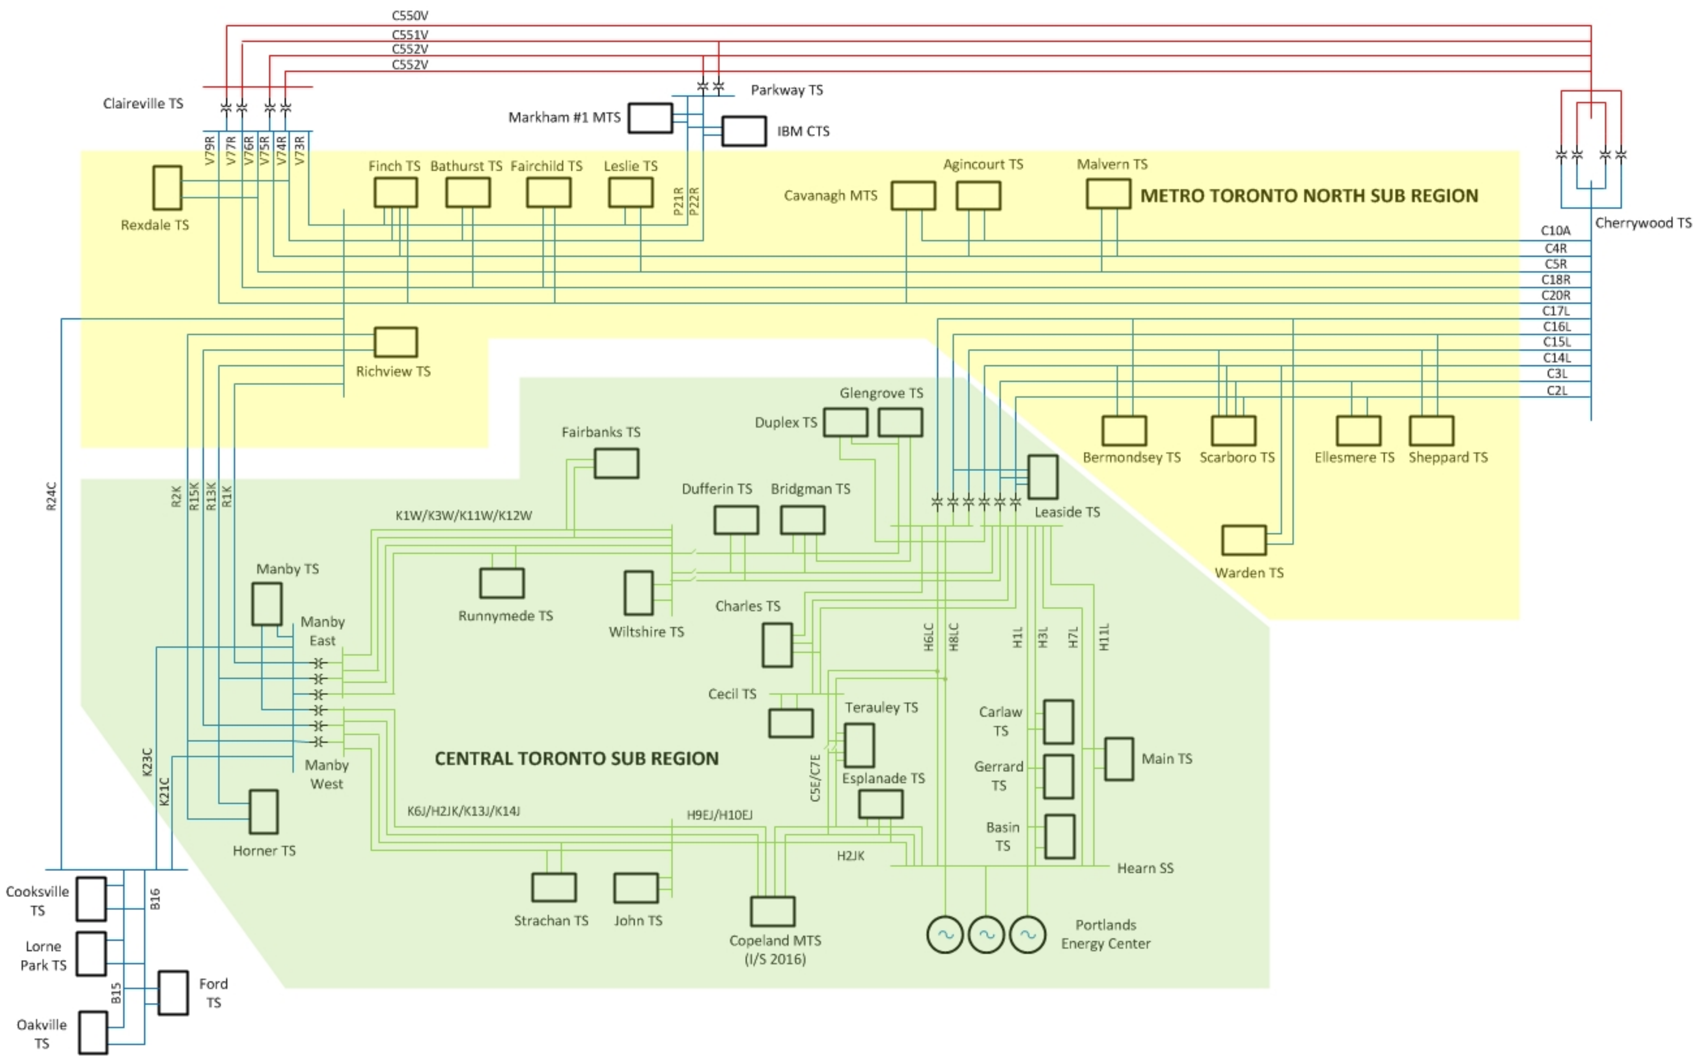

Figure 3-2 Metro Toronto Region – Single Line Diagram

4. TRANSMISSION FACILITIES COMPLETED AND/OR UNDERWAY OVER THE LAST TEN YEARS

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN PLANNED AND COMPLETED BY HYDRO ONE, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE METRO TORONTO REGION IN GENERAL AND THE TORONTO 115 KV NETWORK IN PARTICULAR.

These projects together with the new 550 MW Portlands Energy Centre that went into service in 2009 have ensured that the City continues to receive adequate and reliable supply. A brief listing of these projects is given below:

- Parkway 500/230 kV TS (2005) – built to provide adequate 500/230 kV transformation capacity following the retirement of Lakeview GS. The station while just outside the Metro Toronto Region is a key contributor in ensuring supply adequacy to the Region.
- John TS to Esplanade TS underground cable circuits (2008) – built to provide transfer capability between the Leaside TS and the Manby TS 115 kV areas.
- Incorporation of the 550 MW Portlands Energy Centre (2009) – covered modification to the Hearn 115kV switchyard to connect the new generation.
- 115 kV Switchyard Work at Hearn SS, Leaside TS & Manby TS (2013 & 2014) – covered replacement of the aging 115 kV switchyard at Hearn SS with a new GIS switchyard and replacement of all 115 kV breakers at Leaside TS and Manby TS.
- Manby 230 kV Reconfiguration (2014) – re-tapped Horner TS from the circuit R15K to R13K at Manby TS to balance / improve the distribution of loading on the 230 kV Richview TS to Manby TS system.
- Lakeshore Cable Refurbishment project (2015) – covered replacement of the aging K6J/H2JK 115 kV circuits between Riverside Jct. and Strachan TS.
- Midtown Transmission Reinforcement Project (expected completion by 2016) – covered replacement of the aging L14W underground cable and building an additional fourth 115 kV circuit between Leaside TS and Bridgman TS.
- Clare R. Copeland 115kV switching station (expected completion by 2016) – built to connect a new THESL owned 115/13.8 kV step-down transformer station in the downtown district.

5. FORECAST AND OTHER STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the Metro Toronto Region is forecast to increase at an average rate of approximately 0.9% annually up to 2020, at 0.67% between 2020 and 2025 and at 0.61% beyond 2025. The growth rate varies across the region – from about 0.35% in the Northern Sub-Region to 1.07% in the City's downtown area over the 20 years.

Figure 5-1 shows the Metro Toronto Region's planning load forecast (summer net, non-coincident and regional-coincident extreme weather peak) under the IRRP high growth scenario. The regional-coincident (at the same time) forecast represents the total peak load of the 35 step-down transformer stations in the Metro Toronto. The coincident regional peak load is forecast to increase from 5176 MW in 2015 to 6196 MW by 2035.

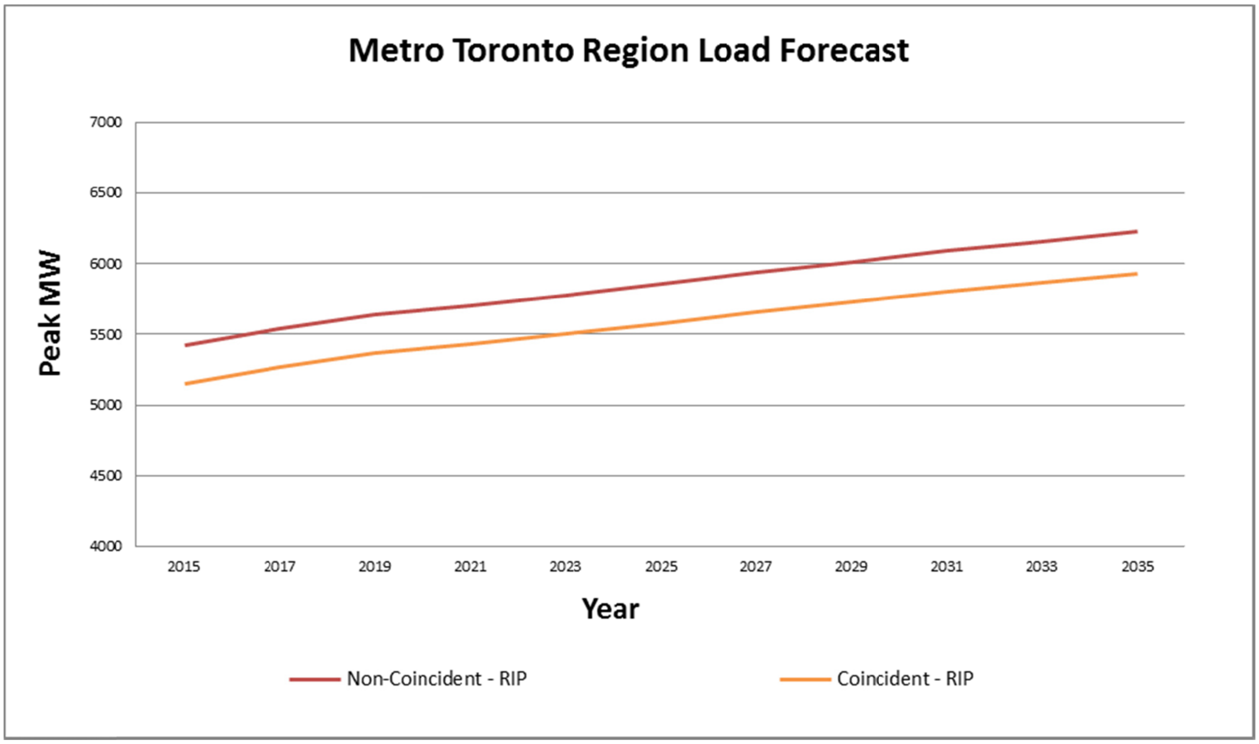

Figure 5-1 Metro Toronto Region Summer Extreme Weather Peak Forecast

The coincident and non-coincident extreme weather peak load forecast for the individual stations in the Metro Toronto Region is given in Appendix D. The coincident forecast represents the sum of the area stations peak load at the time of Metro Toronto Region peak demand and represents loads that would be seen by transmission lines and autotransformer stations and is used to determine the need for additional line and auto-transformation capacity. The non-coincident forecast represents the sum of the individual stations peak load and is used to determine the need for station capacity.

The individual station forecasts were developed by projecting 2015 summer peak loads, corrected for extreme weather, using the area stations growth rates as per the 2015 IESO's IRRP study (High Demand Scenario) for the Central Toronto Sub-Region [1] and as per the 2014 Hydro One's Need Assessment study [2] for the Metro Toronto Northern Sub-Region. The growth rates from [1] only account for existing Distributed Generation ("DG"), and do not include any new CDM and DG. The growth rates from [2] are the net growth rates seen by station equipment and account for CDM measures and connected DG. Details on the CDM and connected DG are provided in [1] and [2] and are not repeated here.

Impact of Metrolinx Go Transit Electrification

In June 2015, Metrolinx advised Hydro One that they are planning to proceed with the electrification of the Go transit rail system. This information was provided after the IRRP was completed in April 2015. Under their plan three Traction Power Stations (TPS) are proposed to be built in the Metro Toronto Region. These stations are as follows:

- Mimico TPS – For the Lakeshore West Go Transit Line (2020)
- Cityview TPS – For the Pearson Airport and Kitchener Go Transit lines (2020)
- Warden TPS – For the Lakeshore East Go Transit Line (2020)

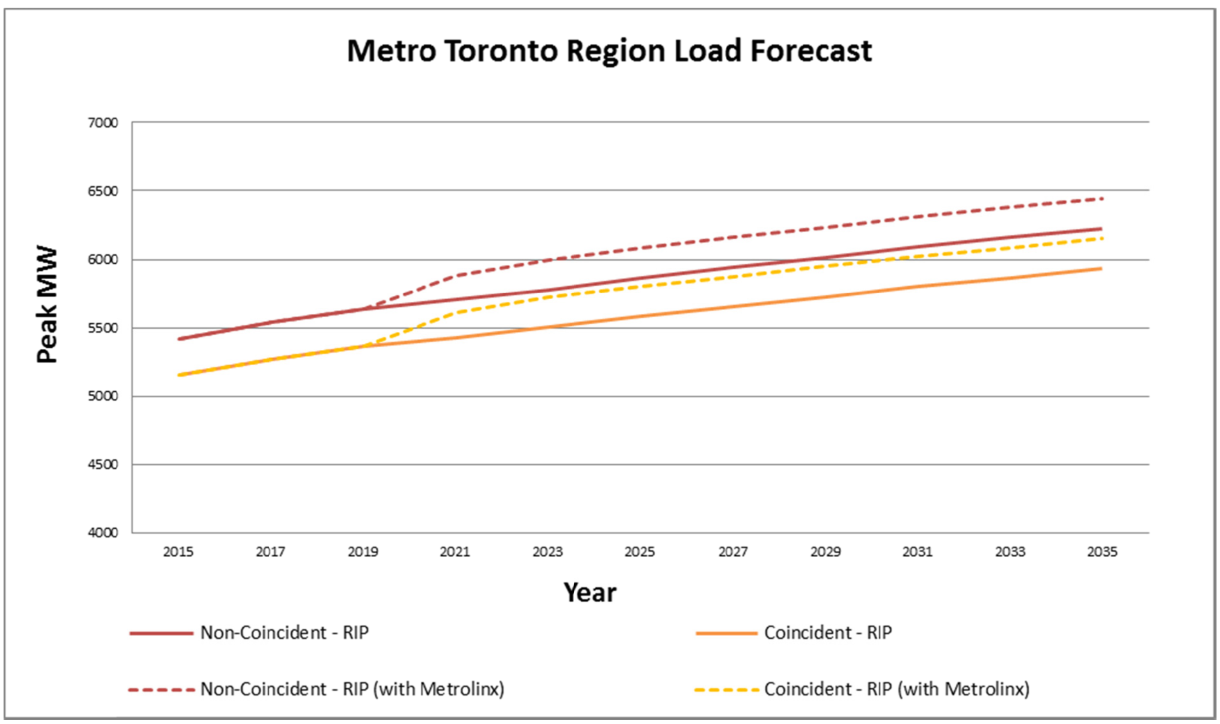

Figure 5-2 Effect of Metrolinx Electrification on the Metro Toronto Region Summer Peak Load

The impact of the Metrolinx load on the regional forecast is shown in Figure 5-2. Each of the three Metro area stations is expected to have an initial load of 40MW increasing to 80MW in 4 years. The net result is to increase the Region peak load by 240MW.

5.2 Other Study Assumptions

The following other assumptions are made in this report.

- The study period for the RIP Assessments is 2015-2035.
- All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
- Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low voltage capacitor banks. Normal planning supply capacity for transformer stations in this Sub-Region is determined by the summer 10-Day Limited Time Rating (LTR).
- For THESL 13.8kV stations, an additional 95% factor is applied to the normal planning supply capacity in this study. This is to reflect the fact that all the capacity cannot be effectively utilized due to the large relative size of the individual customer loads.

6. ADEQUACY OF EXISTING FACILITIES

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND DELIVERY STATION FACILITIES SUPPLYING THE METRO TORONTO REGION OVER THE 2015-2035 PERIOD. IT ASSUMES THAT ALL PROJECTS CURRENTLY UNDER WAY ARE IN SERVICE.

Within the current regional planning cycle two regional assessments have been conducted for the Metro Toronto Region. The findings of these studies are input to the RIP. The studies are:

1) IESO's Central Toronto Integrated Regional Resource Plan – dated April 28, 2015[1]
2) Hydro One's Needs Assessment Report – Metro Toronto – Northern Sub-Region – June 11, 2014[2]

The IRRP and NA planning assessments identified a number of regional needs to meet the area forecast load demands. These regional needs are summarized in Table 6-1 and include needs for which work is already underway and/or being addressed by a LP study. A detailed description and status of work initiated or planned to meet these needs is given in Section 7.

A review of the loading on the transmission lines and stations in the Metro Toronto Region was also carried out as part of the RIP report using the latest Regional Forecast based on the IRRP high load growth scenario and as given in Section 5. The impact of Metrolinx Electrification on the regional infrastructure has been included.

For cases where a need was identified in the near or mid-term by the high growth scenario, a sensitivity analysis was done using the IRRP low growth scenario to get a range on the need date. Sections 6.1 to 6.2 present the results of this review. Additional needs identified as a result of the review are also listed in Table 6-1.

Table 6-1 Needs identified in Previous Stages of the Regional Planning Process

Type	Section	Needs	Timing
Station Capacity	7.1	West Toronto (Runnymede TS & Fairbank TS)	Today
	7.2	Southwest Toronto (Manby TS & Horner TS)	2020-2027
	7.3	Downtown District (JETC[1] Area)	2020+[2]
Transmission Line Capacity	7.4	230 kV Richview TS to Manby TS Corridor	2020-2023
	7.5	Circuit C10A (Duffin Jct. to Agincourt Jct.)	Completed
Supply Security, Reliability and Restoration	7.6	Breaker failure contingencies at Manby W and Manby E TS	2018/2021
	7.7	Breaker failure contingency at Leaside TS	Today
	7.8	Double circuit contingencies C2L/C3L or C16L/C17L (Cherrywood TS to Leaside TS)	2021
	7.9	Load Restoration – Northern Sub-Region (Bathurst TS, Fairchild TS, Leslie TS)	Today
Long-Term	7.10	115 kV Manby West To Riverside Jct. Lines	2035+
		230/115 kV Manby TS transformer capacity	2035+
		230/115 kV Leaside TS transformer capacity	2026+
Additional Long-Term Need Identified in RIP	7.10	Leaside TS x Wiltshire TS circuits	2034

[1] JETC denotes John TS, Esplanade TS, Terauley TS, and Copeland MTS which jointly supply the Downtown District.
[2] The need date will be around 2027 based on the station capacity consideration alone for the Downtown District stations. However, a need date of 2020+ was established by the WG based upon other considerations, such as requirements for spare feeder position. More details are given in Section 7.3.

6.1 Metro Toronto Northern Sub-Region

6.1.1 230kV Transmission Facilities

The Northern 230kV facilities consist of the following 230kV transmission circuits (Please refer to Figure 3-2):

a) Claireville TS to Richview TS 230kV circuits: V72R, V73R, V74R, V76R, V77R and V79R.
b) Cherrywood TS to Richview TS 230kV circuits: C4R, C5R, C18R and C20R.
c) Parkway TS to Richview 230kV circuits: P21R and P22R
d) Cherrywood TS to Agincourt TS 230kV circuit C10A.
e) Cherrywood TS to Leaside TS 230kV circuits: C2L, C3L C14L, C15L, C16L and C17L.

The Claireville TS to Richview TS circuits, the Cherrywood TS to Richview TS circuits and the Parkway TS circuits to Richview TS circuits carry bulk transmission flows as well as serve local area station loads within the Sub-Region. These circuits are adequate over the study period.

The Cherrywood TS to Agincourt TS circuit C10A is a radial circuit that supplies Agincourt TS and Cavanagh TS. The Need Assessment for the Metro Toronto Northern Sub-Region had identified that line capacity was restricted due to inadequate clearance from underbuilt street lighting and distribution line. Field surveys carried out by Hydro One have confirmed that the limiting underbuilds have been removed. The circuit is adequate over the study period.

The Cherrywood TS to Leaside TS 230kV circuits supply the Leaside TS 230/115kV autotransformers as well as serve local area load. Loading on these circuits is adequate over the study period.

6.1.2 Step-Down Transformer Station Facilities

The Sub-Region has the following step down transformer stations:

Agincourt TS	Leaside TS
Bathurst TS	Leslie TS
Bermondsey TS	Malvern TS
Cavanagh MTS	Rexdale TS
Ellesmere TS	Scarboro TS
Fairchild TS	Sheppard TS
Finch TS	Warden TS

The Metro Toronto Northern Sub-Region Needs Assessment Report had identified that the gross load was approaching station capacity at Cavanagh MTS and the Leslie TS (T1/T2, 27.6kV windings) and the Sheppard TS (T3/T4) DESN units. No action was recommended as the net load after considering the CDM and DG program is within ratings. The RIP report has reviewed the station loading and confirms that station capacity is adequate over the study period. However, the station loads will be monitored to ensure facility ratings are not exceeded.

6.2 Central Toronto Sub-Region

6.2.1 230kV Transmission Facilities

The 230kV transmission facilities in the Central Toronto Sub-Region are as follows (Please refer to Figure 3-2):

a) Richview TS x Manby TS 230kV circuits: R1K, R2K, R13K and R15K
b) Cooksville TS x Manby TS 230kV circuits: K21C/K23C
c) Manby TS 230/115kV autotransformers
d) Leaside TS 230kV/115kV autotransformers

The Richview TS to Manby TS circuits and the Cooksville TS to Manby TS circuits supply the Manby 230/115kV autotransformer station as well as Horner TS. Please note that the K21C and K23C circuits connect back to Richview TS through Cooksville TS and 230kV circuit R24C.

Table 6-2 summarizes the result of adequacy studies and gives the need date for transmission reinforcement for each of the above facilities.

Table 6-2 Adequacy of 230kV Transmission Facilities

Facilities	2015 MW Load(1)	MW Load Meeting Capability (LMC)	Limiting Contingency	Need Date
Richview x Manby 230kV Corridor	1456	1540	R2K	2020-2023(2)
Manby E. 230/115kV autos	330	560	T2	2035+
Manby W. 230/115kV autos	397	612	T9	2035+
Leaside 230/115kV autos + Portlands GS(1)	1340	1525-1915(3)	None	2026+(4)

(1) The loads shown have been adjusted for extreme weather.

(2) The 2020 and 2023 need dates correspond to the high growth and low growth rate scenarios without considering Metrolinx Mimico TPS. Assuming Metrolinx Mimico TPS comes into service in 2020, the need date will become 2020 under both scenarios.

(3) The Leaside 115kV area is supplied by the Leaside TS 230/115kV autotransformers and the 550MW Portlands GS. Load Meeting capability is dependent on the generation from Portlands GS which backs up the flow through the Leaside autotransformers. The 1525MW LMC assumes only 160MW generation at Portland GS while the 1915MW LMC assumes the full 550MW generation at Portland GS.

(4) The need date is based on the 1525MW LMC which assumes that two of the three units are out at Portlands GS and total plant generation is 160MW.

6.2.2 115kV Transmission Facilities

The 115kV facilities in the Metro Toronto Region (see Figure 3-2) can be divided into five main corridors:

1. Manby TS East x Wiltshire TS – Four circuits K1W, K3W, K11, K12W. Forecast loading can exceed corridor rating under certain conditions. More details are provided in Section 7.1.2.
2. Manby TS West x John TS – Four circuits H2JK, K6J, K13J and K14J. These circuits are adequate over the study period.
3. Leaside TS x Hearn TS – Six circuits H6LC, H8LC, H1L, H3L, H7L and H11L. These circuits are expected to be adequate over the study period. .
4. Leaside TS x Cecil TS – Three circuits L4C, L9C, and L12C. These are expected to be adequate over the study period.
5. Leaside TS x Wiltshire TS – Four circuits L13W/L14W/L15/L18W. The L18W circuit is expected to go into service in summer 2016. Loading will exceed corridor rating by 2034 for loss of the L18W circuit. More details are provided in Section 7.10.4.

The loading on the limiting sections is summarized in Table 6-3.

Table 6-3 Overloaded Sections of 115kV circuits

Facilities	2015 MW Load	MW Load Meeting Capability	Limiting Contingency	Need Date
Manby TS x Wiltshire TS 115kV Corridor	330	348/410(1)	K11W	2019-2023(1)
Leaside TS x Wiltshire TS	310	350	L18W	2034

(1) The Manby x Wiltshire corridor provides emergency backup for Dufferin TS load under Leaside area contingencies. Assuming that a 100MW of back up capability is provided, the maximum load that can be supplied in the Fairbanks/Runnymede area is 348MW and the need date for upgrading the corridor is 2019. If 75MW of back up capability is required, the need date will become 2023. However, if back up capability during peak is not considered, maximum load meeting capability is 410MW. The need in this case would be beyond 2035.

6.2.3 Step-Down Transformer Facilities

There are a total of 20 step-down transformers stations in the Central Toronto Sub Region.as follows:

Basin TS	Esplanade TS	Fairbank TS
Bridgman TS	Gerrard TS	Copeland MTS
Carlaw TS	Glengrove TS	John TS
Cecil TS	Main TS	Strachan TS
Charles TS	Terauley TS	Horner TS
Dufferin TS	Wiltshire TS	Manby TS
Duplex TS	Runnymede TS	

The stations non-coincident loads are given in Appendix D Table D-1. The areas and the stations requiring relief are given in Table 6-4.

Table 6-4 Adequacy of Step-Down Transformer Stations - Areas Requiring Relief

Area/Supply	Capacity (MW)	2015 Loading (MW)	Need Date
West Toronto: Fairbanks TS and Runnymede TS	285	291	Now
Southwest Toronto : Manby TS and Horner TS area	400	376	2020-2027 (1)
Downtown Toronto: John TS, Esplanade TS, Terauley TS and Copeland MTS (JETC)	739	632	2020+ (2)

(1) The need dates are based on high and low demand growth rates scenario

(2) The need date will be around 2027 based on the station capacity consideration alone for the Downtown District stations. However, a need date of 2020+ was established by the WG based upon other considerations, such as requirements for spare feeder position. More details are given in Section 7.3.

7. REGIONAL NEEDS AND PLANS

THIS SECTION DISCUSSES THE ELECTRICAL SUPPLY NEEDS FOR THE METRO TORONTO REGION AND SUMMARIZES THE REGIONAL PLANS FOR ADDRESSING THE NEEDS. THESE NEEDS ARE LISTED IN TABLE 6-1 AND INCLUDE NEEDS PREVIOUSLY IDENTIFIED IN THE IRRP FOR THE CENTRAL TORONTO SUB-REGION [1] AND THE NA FOR THE METRO TORONTO NORTHERN SUB-REGION [2] AS WELL AS THE ADEQUACY ASSESSMENT CARRIED OUT AS PART OF THE CURRENT RIP REPORT.

7.1 West Toronto Area

7.1.1 Station Capacity - Runnymede TS & Fairbank TS

Runnymede TS and Fairbank TS are 115/27.6 kV transformer stations that supply the load demand in the west end of Toronto. The two stations are connected to the 115 kV Manby East transmission system and have been operating at or near their capacity limits for the last five years. THESL has managed growth by transferring loads to adjacent area stations.

The area 2015 extreme weather peak load was 291 MW and exceeded the stations capacity of 285MW. The area is experiencing some re-development and the proposed Eglinton Crosstown Light Railway Transit (“LRT”) project by MetroLinx will add an additional 14 MW of load to Runnymede TS in 2021. Additional step down transformation capacity is required now to provide relief and be able to meet the forecast load demand.

7.1.2 Line Capacity - Manby TS x Wiltshire TS 115kV circuits

The Manby TS x Wiltshire TS four circuit 115kV tower line carries circuits K1W, K3W, K11W and K12W. These circuits supply Fairbanks TS, Runnymede TS and well as Wiltshire TS. Under Leaside area outage conditions, these circuits are also used to pick up all or parts of Dufferin TS and/or Bridgman TS loads. The total corridor capability is dependent on the Fairbanks TS and Runnymede TS load and the load picked up and is given in table below:

Table 7-1 Manby x Wiltshire Corridor Capability

Year	Fairbanks TS, Runnymede TS, and Wiltshire TS Load Forecast (MW)	Amount of Dufferin TS and Bridgman TS Load that can be picked up (MW)	Total Corridor Capability (MW)
2015	330	120	450
2019	349	97	446
2023	375	68	443
2027	390	46	436
2031	399	25	424
2035	406	10	416

The timing of the Manby TS x Wiltshire TS circuits upgrade is dependent on the backup capability desired. If backup capability is not considered, the upgrade can be deferred to beyond 2035. However, if at least 70MW of back up capability - equal to about half of Dufferin TS load - is deemed appropriate, the upgrade would be deferred to about 2023.

Figure 7-1 West Toronto Area - Fairbank TS and Runnymede TS

7.1.3 Recommended Plan and Current Status

The Working Group has considered and reviewed several options to provide additional transformation capacity in West Toronto area as part of the Central Toronto IRRP. Based upon the review, and consistent with the IRRP Working Group recommendation is to expand Runnymede TS by adding two 115/27.6 kV 50/83 MVA transformers and a 27.6kV switchyard with six feeders. This work is required to be completed as early as possible.

The Working Group also recommends that the Manby TS to Wiltshire TS tower line carrying circuits K1W/K3W/K11W/K12W be also upgraded at the same time. This option would maintain the load transfer capability between Leaside TS and the Manby TS under emergency or outage conditions in addition to supplying future load growth in the West Toronto Area.

The estimated total cost of the work is approximately $90 M, which includes $34 M for the station work at Runnymede TS, $16 M for the upgrade of four 9.5 km long circuits between Manby TS and Wiltshire TS and $40 M for distribution facilities by THESL. The transmission cost of $50M is expected to be recovered in accordance with the TSC.

Hydro One has initiated development work on the project covering preparation of estimates and obtaining of EA approvals. The estimate is expected to be completed by the end of Q2 2016. It will also confirm if the targeted in-service date of May 2019 for this project is achievable. A Section 92 application will be submitted in 2016.

7.2 Southwest Toronto Area

7.2.1 Station Capacity – Southwest Toronto (Manby TS & Horner TS)

Manby TS and Horner TS are two 230/27.6 kV transformer stations supplying the load demand in the southwest end of Toronto (see Figure 7-2). Based on the current RIP forecast the 400MW combined station capacity of the stations is forecast to be exceeded by summer 2020. Additional step down transformation is required to provide relief.

Figure 7-2 Horner TS and Manby TS Supply Area

7.2.2 Recommended Plan and Current Status.

To address the need for additional step down transformation capacity in the Southwest Toronto area, the Working Group's recommended building a second 230/27.6 kV DESN at the existing Horner TS site. Two 75/125MVA transformers will be installed at the station along with a new 27.6kV switchyard. Load transfer out of Manby TS to Horner TS is required to relieve Manby TS as the loading at that station exceeds its capacity. New distribution feeder ties are required to be built between Manby TS and Horner TS by THESL.

The estimated total cost of the work is about $53M, which includes $34 M for the station work at Horner TS and $19M for THESL distribution facilities. The transmission cost of $34M is expected to be recovered in accordance with the TSC.

Hydro One has initiated development work on the project covering preparation of estimates and obtaining of EA approvals at the request of THESL. The current in-service date for the project is expected to be May 2020.

7.3 Downtown District

7.3.1 Station Capacity – JETC[2] Area

The Toronto Downtown Core area is mainly supplied by the three existing 115/13.8 kV stations: John TS, Esplanade TS, and Terauley TS. John TS is connected to the Manby West system while Esplanade TS and Terauley TS are fed from the 115 kV Leaside / Hearn system. (see Figure 7-3)

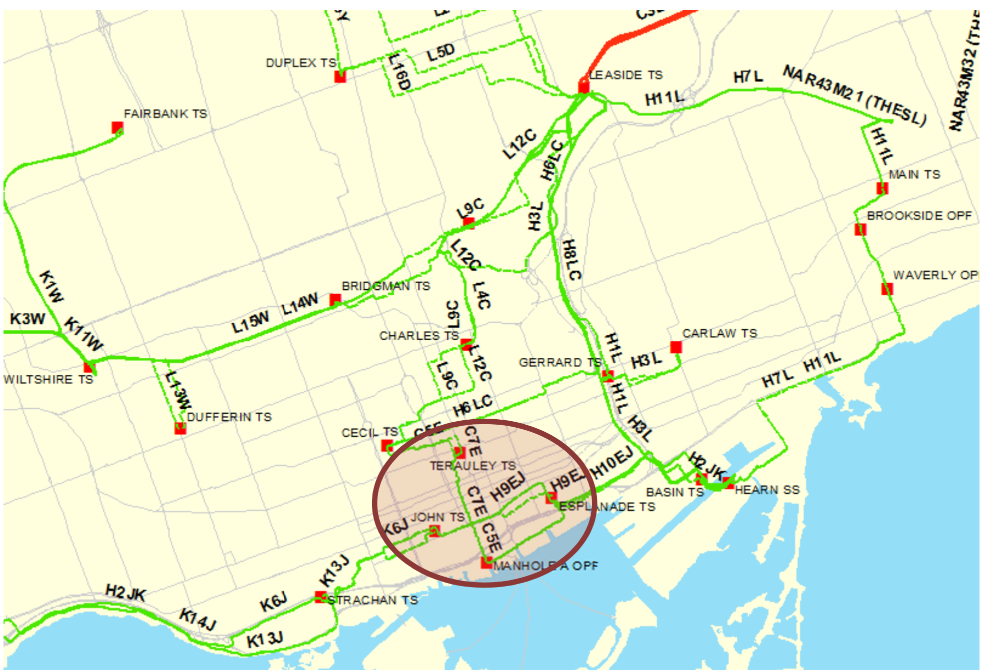

Figure 7-3 Toronto Downtown Supply Area

John TS was built in the 1950's and the THESL switchgear at the station is approaching end of life. THESL is building a new 115/13.8kV owned transformer station, Copeland MTS in the Downtown

[2] JETC denotes John TS, Esplanade TS, Terauley TS, and Copeland MTS which jointly supply the Downtown District.

District near John TS with normal supplied from the 115 kV Manby West system. The station first phase capacity will be around 130 MVA and it is expected to be in service in 2016. Copeland MTS will provide a new source of supply to the area customers and facilitate the replacement of end of life switchgear at John TS.

With the new Copeland MTS in-service in 2016, adequate transformation capacity will be available in the Downtown District till 2027. However, most of this capacity will be at John TS as 13.8kV buses at both Terauley TS and Esplanade TS are at or approaching capacity limits. THESL anticipates that the need for new transformation facility is more advanced due to limited spare feeder positions available at John TS for new customer connection and load transfer required to facilitate the refurbishment work at John TS. At the current pace of development in these areas, both bus and feeder position in the Downtown Core area are expected to be at or near capacity within five to ten years[3]. Specific issues identified by THESL Hydro are as follows:

- By 2019 THESL forecasts that two busses will be overloaded (ie. loaded beyond 10 Day LTR) at George and Duke MS and two busses overloaded at John/Windsor TS.
- By 2025 THESL forecasts that one bus will be overloaded at Copeland TS, two busses overloaded at George and Duke MS and three busses overloaded at John/Windsor TS.
- At John/Windsor TS, four out of six busses have no spare feeder positions to connect new customers. One bus has a single spare feeder position and one bus has two spare feeder positions.
- At George and Duke MS, one bus has no spare feeder positions and one bus has six spare feeder positions.
- At Esplanade TS, there is only one bus with three spare feeder positions.
- Once in service, Copeland TS is forecasted to have six and three spare positions on each its two busses, respectively.

7.3.2 Recommended Plan and Current Status

Based on the current information, the need to relieve the stations in Downtown District is expected to be beyond 2020. However, the need date may get delayed or brought forward if the load growth in this area is slower or faster than currently anticipated. The Working Group recommends that this need and timing should be further refined by THESL through their distribution planning process and included in updates to the IRRP and RIP. The uptake of CDM and DG should be preserved and re-assessed.

In the case where CDM and DG are deemed insufficient, building Copeland Phase 2 and installing additional transformers and two new buses at Copeland MTS site is the most cost effective way to meet the required THESL needs. The site and the high voltage switching facilities required to accommodate this expansion (Copeland Phase 2) are already included as part of the Copeland MTS Phase 1 project.Copeland MTS is an underground station and is not located adjacent to residential land uses. The THESL estimated cost for Copeland MTS Phase 2 to be approximately $46 M.

---

[3] Further information may be found in THESL's rate application EB-2014-0116 to the Ontario Energy Board

7.4 Transmission Line Capacity – 230 kV Richview TS to Manby TS Corridor

7.4.1 Description

The 230 kV transmission corridor between Richview TS and Manby TS is the main supply path for the Western Sector of Central Toronto Sub-Region. It also supplies the load in the southern Mississauga and Oakville areas via Manby TS. Along this Corridor there are two double circuit 230kV lines R1K/R2K and R13K/R15K. In addition the corridor contains an idle double circuit 115kV line. Figure 7-4 shows the area supplied by Richview TS x Manby TS circuits.

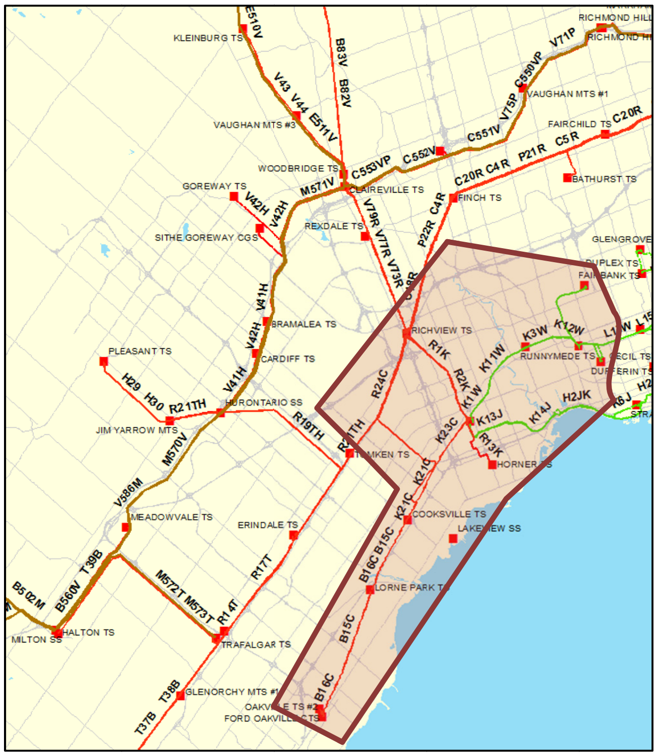

Figure 7-4 Richview x Manby Supply Area Map

The forecast loading on the Richview TS to Manby TS circuits is given in Table 7-2 below for both the high growth and low growth scenarios. The loads include the 115 kV Manby East, 115 kV Manby West, 230 kV Manby, and 230 kV Oakville-Cooksville loads. The need date for providing relief is 2020 for the high growth scenario and 2023 for the low growth scenario.

Table 7-2 also shows the effect of Metrolinx Mimico TPS on the need date for relief. In both scenarios, relief is required by 2020. The magnitude of Metrolinx load is large enough to trigger the reinforcement.

Again, due to the large incremental load from Mimico TPS, CDM will not be sufficient to help eliminate or even defer the need date for the transmission reinforcement. Transmission reinforcement is required to be implemented before the Mimico TPS can be connected.

Table 7-2 Coincident RIP MW Load Forecast for Richview TS x Manby TS Area

	Limit	2015	2017	2019	2021	2023	2025	2027	2029	2031	2033	2035
Base - Without Metrolinx Mimico TPS load												
High Growth	1540	1456	1488	1536	**1580**	1617	1646	1674	1698	1722	1742	1763
Low Growth	1540	1456	1481	1503	1530	**1544**	1557	1566	1572	1577	1597	1617
With Metrolinx Mimico TPS load												
High Growth	1540	1456	1488	1536	**1640**	1697	1726	1754	1778	1802	1822	1843
Low Growth	1540	1456	1481	1503	**1590**	1624	1637	1646	1652	1657	1677	1697

7.4.2 Alternatives Considered

The following alternatives are currently under consideration:

Upgrade four existing 230kV Richview TS x Manby TS circuits: Re-conductor with higher-capacity conductors on existing towers. Hydro One will check the feasibility of this option without major tower modifications and also in terms of outages arrangement. The estimated total cost of this option is about $16M, assuming that no major tower modifications and no bypass lines during re-conductoring are required.

Rebuild existing 115kV Richview TS x Manby TS line: Rebuild the existing idle 115 kV double-circuit line as a 230kV double-circuit line. The new 230 kV line is to share the existing terminations for circuits R2K and R15K at Richview TS and Manby TS. The ampacity of the new conductors are to be equal to or better than that of the existing circuits, effectively doubling the ampacity of R2K and R15K. This alternative requires the replacement of all the existing 115 kV towers with 230 kV towers. The estimated total cost of this option is about $19.5M.

Build two new 230 kV Richview TS x Manby TS circuits: Similar to the second alternative above, rebuild the two existing idle 115 kV double-circuit line as a 230kV double-circuit line. New terminations for these circuits are required at Richview TS and Manby TS. The ampacity of the new conductors are to be equal to or better than that of the existing circuits. This alternative not only provides higher transmission capacity but also increases the supply reliability to the Central Downtown and Southwest GTA area. The estimated total cost of this option is around $39.5M due to the extra station work required at the Richview TS and Manby TS.

Extend the Cooksville TS x Oakville TS line to Trafalgar TS: Extend the Cooksville TS x Oakville TS 230kV double circuit line B15C/B16C about 8km to Trafalgar TS where new 230kV switching facilties are also required. This alternative increases supply capacity and reliability to Southwest GTA area from Trafalgar TS, and thus alleviates the loading on the Richview x Manby corridor. The total estimated cost of this line and station work is around $54M.

CDM & DG: According to Central Toronto IRRP report, the potential DG development, targeted demand response and the potential incremental demand response in these areas supplied by Manby TS may defer the need for this transmission reinforcement by several years, depending on the load growth rate. However, with Mimico TPS connected near Horner TS, these targeted and potential incremental demand response will not be adequate due to the size of the extra load added by the TPS.

The Maintain Status Quo or Do Nothing alternative was not considered as it does not provide relief for the Richview x Manby transmission lines.

7.4.3 Recommended Plan and Current Status

The Metrolinx Mimico TPS information is new and was provided as part of the RIP after the IRRP was completed in April 2015. If this TPS is going to be in-service as planned in 2020, CDM initiatives will not effectively defer the need date for this transmission corridor because of the size of the additional load. Therefore, upgrading the existing Richview x Manby corridor or new supply path for the areas served by Manby TS will be required before the Metrolinx Mimico TPS can be connected.

The Trafalgar x Oakville line alternative, at $54M, is the highest cost alternative ($14.5M higher than the next most expensive alternative) and there is a risk that it may not be able to be completed in time to connect the the Metrolinx Mimico TPS in 2020. This alternative may also trigger the need for additional transformation facilities and thus would incur additional costs.

As a result, Working Group recommends that Hydro One proceed with the development and estimate work on the first three alternatives listed in Section 7.4.2 in 2016. Both EA and Section 92 approvals will be required and it is expected to take at least 3-4 years for the implementation of a wire solution. The Working Group will select the preferred alternative by December 2016. Hydro One will then plan to initiate project execution by summer 2018 in order to enable the connection of MetroLinx Mimico TPS by summer 2020.

7.5 Transmission Line Capacity – Circuit C10A (Duffin Jct. to Agincourt Jct)

C10A is a 20 km long radial circuit in Metro Toronto Northern Sub-Region from Cherrywood TS supplying Agincourt TS and Cavanagh MTS. The Metro Toronto Northern Sub-Region NA identified that the capacity of this circuit was thermally limited by a section approximately 4 km long between Duffin Jct. and Agincourt Jct. The flow on this section of the circuit might exceed its long-term emergency (LTE) rating under summer peak load conditions following certain contingencies.

A preliminary study based on the old field survey data was done in July 2015. The old record showed that the LTE rating was limited by some underbuilds along the line section. A new field survey was then carried out in October 2015. It was discovered that the aforementioned underbuilds had been previously removed, and the LTE rating of this line section should be 840A. The record is being updated. No further action is required.

7.6 Breaker Failure at Manby TS

7.6.1 Description

The failure of any of the Manby TS breakers A1H4 and H1H4 in the Manby West 230kV yard and the breaker H2H3 in the Manby east 230kV yard can cause the outage of any two of the three 230/115kV autotransformers at either the west or east yard of Manby TS. This may result in the overload of the remaining autotransformer. Based on the Coincident RIP Forecast the need date for the work is summer 2018 and summer 2021 for Manby West and Manby East respectively.

7.6.2 Recommended Plan and Current Status

The Working Group has recommended that installation of a Special Protection Scheme (SPS) is the most cost effective means to mitigate the breaker failure risk.

Hydro One is working on the development and estimate work for the SPS at Manby TS. The preliminary estimate for this work is approximately $2M and this will be updated when the development work is complete by summer 2016. The planned in-service of this work is summer 2018.

7.7 Breaker Failure at Leaside TS

The failure of breaker L14L15 at Leaside TS can cause the outage of two of the Leaside TS to Bridgman TS circuits. This may result in the loss of Transformers T11, T12, T14 and T15 at Bridgman TS. Under this scenario, two of the four LV buses will be lost by configuration. Only transformer T13 remains in service and supplies buses HLA1 and HLA7.

The 15 minute LTR for the X and Y windings of Transformer T13 is 55MVA. Therefore, as long as the loading on the HLA1 and HLA7 does not exceed the 15 minutes LTR, the operator can take action to reduce load to within transformer LTE ratings.

A new normally open switch is being installed at Bridgman TS as part of the Leaside-Bridgman Transmission Reinforcement project. This new switch can be closed remotely following the loss of the circuit L15W to resupply the two Bridgman transformers from the circuit L13W. This will alleviate the loading of the transformer T13 and the circuit L18W. and any possible voltage issue at Bridgman TS. Therefore, no investment is recommended.

7.8 Cherrywood to Leaside (CxL) Double Circuit Contingencies

Double circuit contingencies involving the lines C2L/C3L or C16L/C17L from Cherrywood TS to Leaside TS (CxL) can result in the loss of two of the three 230/115kV autotransformers on the same half of Leaside TS. The long-term emergency rating of the remaining autotransformer may be exceeded if only a single combustion unit at the Portland Energy Centre (PEC) is available, coincident with either of the abovementioned double contingencies during peak load condition.

The Working Group recommends that no further work is required in the near- and mid-term as there is already an existing operating instruction in place to cover the overload issue of the remaining Leaside autotransformer by closing the 115kV bus-tie at Leaside TS.

7.9 Load Restoration – Northern Sub-Region (Bathurst TS, Fairchild TS, Leslie TS)

Bathurst TS, Fairchild TS, and Leslie TS are supplied by the 230 kV Richview x Cherrywood x Parkway system in the Metro Toronto Northern Sub-Region. Following two circuit contingencies, approximately 240-300 MW of load during summer peak time could be lost during each contingency scenario, as follows:

Table 7-3 Maximum Load Loss during Two Circuit Contingencies

Double Element Contingency	Station Connected	Non-Coincident Load Forecast (MW)	
		2015	2025
P22R + C18R	Bathurst TS	271	279
C18R + C20R	Fairchild TS	292	301
P21R + C5R	Leslie TS	239	249

There are currently no existing transmission switching facilities to allow load restoration immediately. Partial load could be restored via distribution transfer to the nearby stations.

For Bathurst and Leslie cases, the stations are supplied by circuits on separate transmission lines for all or most sections. The probability of occurrence of overlapping outages on circuits on different tower lines is extremely low. The supplied circuits for Fairchild TS are on common tower for two-third of the line (approximately 32km).

Based on the outage records in the past 25 years there has been no incidence of any double contingencies described above.

A single transformer station would require four motorized disconnect switches to be useful. Typical cost for installing these transmission switching facilities per station would be between $8-10M.

Based on the low probability of frequency of such events versus the high mitigation cost, the Working Group recommendation is that no further action is required.

7.10 Long Term Needs

Four longer term needs had been identified in the Central Toronto IRRP as follows:

- Transmission Line Capacity – 115 kV Manby West To Riverside Junction
- Transformation Capacity – 230/115 kV Manby TS
- Transformation Capacity – 230/115 kV Leaside TS
- Leaside TS x Wiltshire TS 115kV circuits

Loading on Manby TS and the Manby TS x Riverside Junction circuit are within ratings over the study period under the Coincident RIP forecast. The Working Group recommendation is that no further action is required.

The Leaside TS transformer and the Leaside TS x Wiltshire circuits will require relief in the long term. This issue will be considered in the next planning cycle. The Working Group recommendation is that no further action is required. However, Hydro One and IESO will continue to monitor loads and initiate necessary relief measures, if required.

8. CONCLUSIONS AND NEXT STEPS

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE METRO TORONTO REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in the Table 8-1 below.

Table 8-1 Regional Plans – Needs Identified in the Regional Planning Process

No.	Need Description
I	Supply Security – Breaker Failure at Manby West & East TS
II	West Toronto Area - Station Capacity and Line Capacity
III	Southwest Toronto - Station Capacity
IV	Downtown District - Station Capacity
V	230 kV Richview x Manby Corridor– Line Capacity
VI	Leaside Autotransformers
VII	Line Capacity – 115 kV Leaside x Wiltshire Corridor

Next Steps, Lead Responsibility, and Timeframes for implementing the wires solutions for the near-term and mid-term needs are summarized in the Table 8-2 below. Investments to address the long-term needs where there is time to make a decision (Need No. VI & VII), will be reviewed and finalized in the next regional planning cycle.

Table 8-2 Regional Plans – Next Steps, Lead Responsibility and Plan In-Service Dates

Id	Project	Next Steps	Lead Responsibility	I/S Date	Est. Cost	Needs Mitigated
1	Manby SPS	Transmitter to carry out the work	Hydro One	2018	$2M	I
2	Runnymede Expansion & 115 kV Manby x Wiltshire Corridor Upgrade	Transmitter to carry out the work	Hydro One	2019	$90M	II
3	Horner Expansion	Transmitter to carry out the work	Hydro One	2020	$53M	III
4	230 kV Richview x Manby Corridor Upgrade	Transmitter to carry out the work	Hydro One	2020	$20-40M	V
5	Copeland Phase 2	LDC to carry out work & monitor growth	THESL	2020+	$46M	IV

In accordance with the Regional Planning process, the Regional Planning cycle should be triggered every five years. The next planning cycle for the Metro Toronto Region is expected to be started in 2018. However, the Region will continue to be monitored and should there be a need that emerges due to a change in load forecast or any other reason, the regional planning cycle will be started earlier to address the need.

NORTH OF DRYDEN INTEGRATED REGIONAL RESOURCE PLAN

Part of the Northwest Ontario Planning Region | January 27, 2015

ieso
Independent Electricity System Operator

Explanatory Note Regarding January 1, 2015 OPA-IESO Merger

On January 1, 2015, the Ontario Power Authority (OPA) merged with the Independent Electricity System Operator (IESO) to create a new organization that will combine the OPA and IESO mandates. The new organization is called the Independent Electricity System Operator.

This report was largely completed prior to January 1, 2015. Any mention of the activities performed by the former OPA or the former IESO in this report refers collectively to the new IESO.

*Administrative change on April 1, 2015, page 22 , to correct timeframe of the Conservation Firs Framework Directive.

Contents

Table of Figures

Summary of Plan Highlights

- Drivers for increased electricity demand in the areas surrounding Red Lake, Pickle Lake and Ring of Fire include *connecting remote First Nation communities and growth in the mining sector*.

- The OPA recommends a new single-circuit 230 kV line from Dryden/Ignace to Pickle Lake and upgrades to existing lines between Dryden and Red Lake for immediate implementation to address near- and medium- term needs for the Pickle Lake and Red Lake areas.

- Incremental longer term solutions to supply Ring of Fire and Red Lake are not required at this time. Longer term options will be re-evaluated in the next planning cycle (1-5 years).

- Options to supply the Ring of Fire include transmission utilizing an East-West or North South corridor, or on-site generation. East-West and North-South transmission options are comparable in cost under the high demand scenario and the potential need for a transmission line should be considered in the planning of a common infrastructure corridor to the Ring of Fire.

- Long-term options for the Red Lake area include local gas generation or new transmission.

Summary of Updates from August 2013 draft IRRP

- Revised demand forecast used different methodology, includes updated data and is represented by three scenarios – reference, high and low; August 2013 draft included high and low scenarios, but did not include a reference scenario.

- Revised demand forecast indicates relatively higher forecasted demand in the Pickle Lake subsystem, and relatively lower forecasted demand in the Red Lake subsystem than in the August 2013 draft.

- Recommendation is for new 230 kV line to Pickle Lake in this version; voltage recommendation was not specified in the August 2013 draft.

- Recommended line upgrades from Dryden to Red Lake are expected to be sufficient to the end of the planning period for the reference and low forecast scenarios, and to 2030 for the high forecast scenario. The August 2013 draft indicated that the upgrades may be insufficient in the medium-term for the high scenario.

- Recommendation to discuss reactive services of Manitou Falls GS with OPG, as per OPG's written submission.

- Revised economic analysis methodology – refer to Appendices 10.6, 10.7, and 10.8 for details.

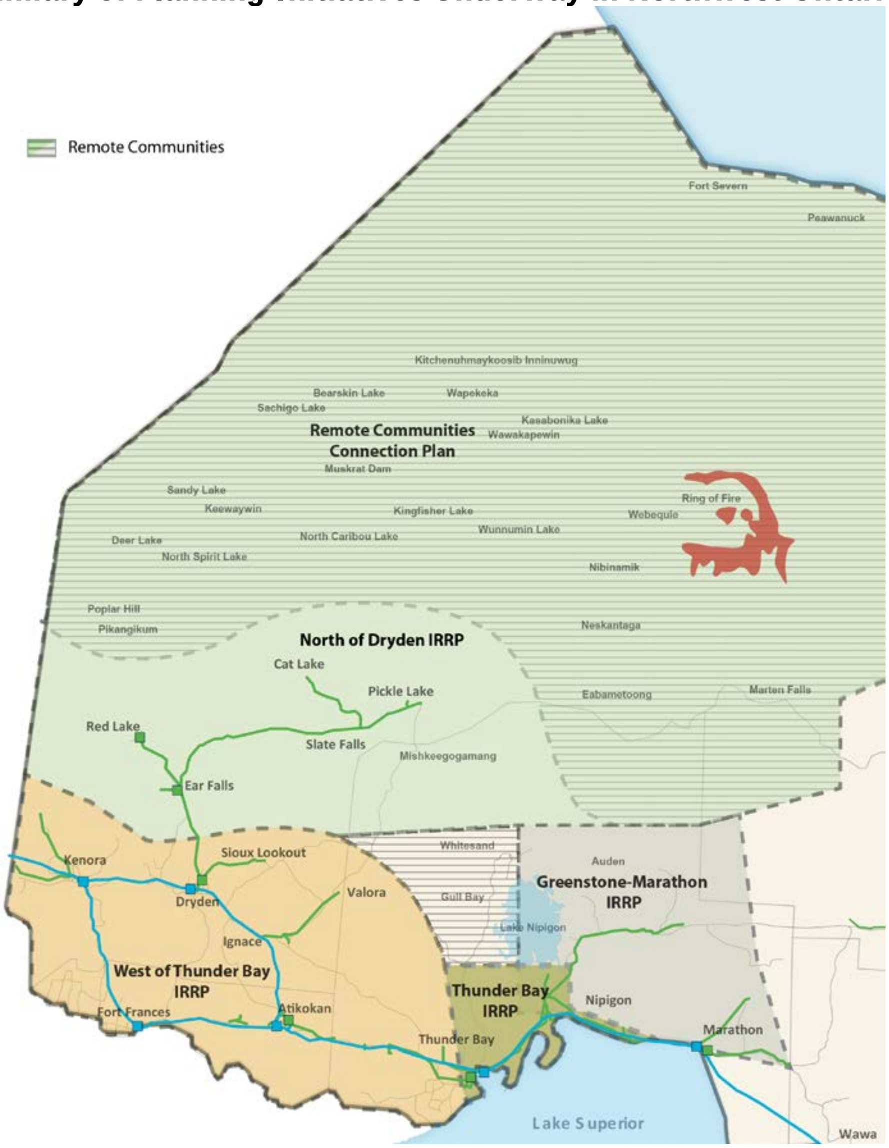
1 EXECUTIVE SUMMARY

Context and Purpose

The purpose of the North of Dryden Integrated Regional Resource Plan (“regional plan”, “North of Dryden IRRP”, or “IRRP”) is to identify the near-term and medium- to long-term electricity supply needs of the area and assess options that are available to address the needs in a timely, reliable and cost-effective manner. The IRRP is intended to provide the overall planning context to address regional supply adequacy and reliability needs.

The North of Dryden IRRP is one of several electricity planning initiatives that the the Ontario Power Authority (“OPA”) is undertaking for the Northwest Ontario region. Figure 1 identifies the IRRP initiatives currently being undertaken by OPA in the Northwest Ontario region. The North of Dryden IRRP accounts for the demand requirements in the North of Dryden sub-region. This includes requirements at Pickle Lake and Red Lake related to the connection of the 21 remote First Nation communities (“remote communities”) that are economic to connect, as outlined in the Remote Community Connection Plan as well as new mining developments forecasted in the area. It also coordinates with the West of Thunder Bay IRRP, ensuring that the West of Thunder Bay transmission system is able to accommodate the expected growth north of Dryden. The North of Dryden IRRP will also coordinate options related to supply to the Ring of Fire with the Greenstone-Marathon IRRP.

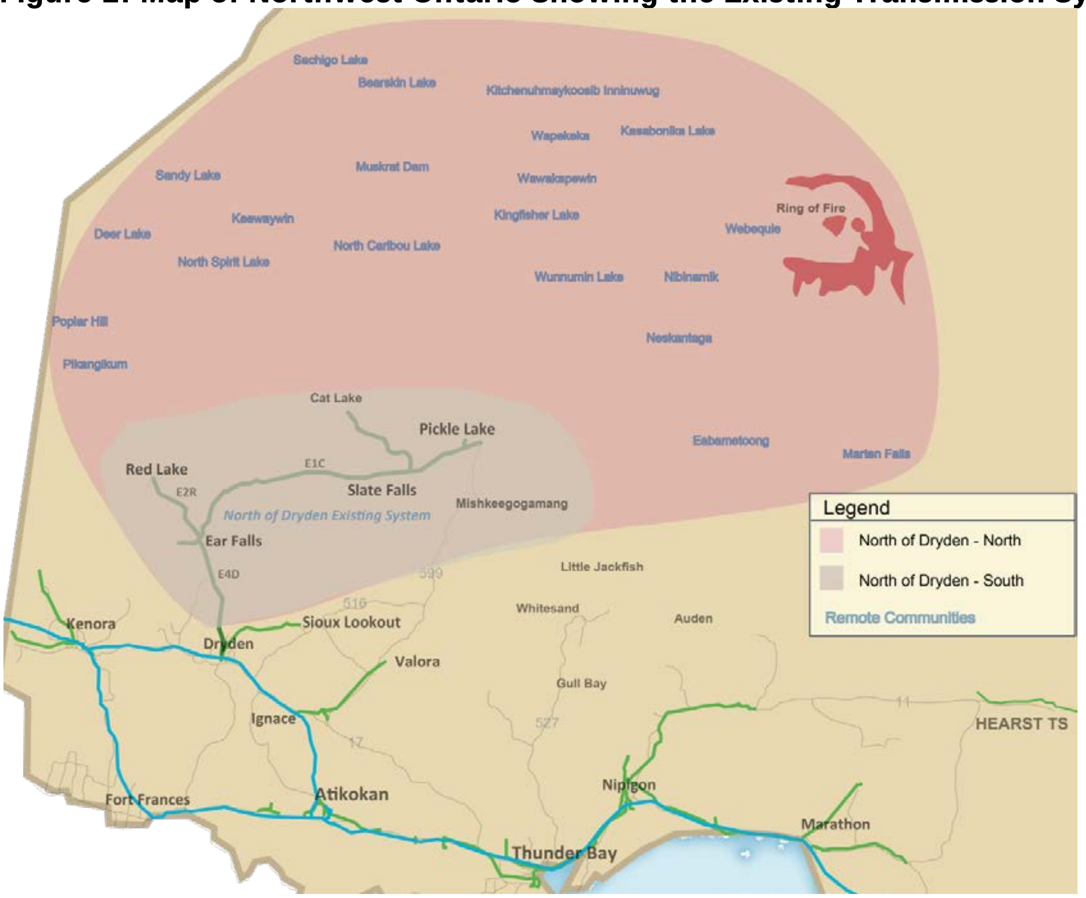
Figure 1: Summary of Planning Initiatives Underway in Northwest Ontario



The North of Dryden sub-region is contained within First Nation Treaty areas 3, 5, 9 and the Robinson-Superior Treaty area. It also includes portions of Region 1 and Region 2 of the Métis Nation of Ontario ("MNO"). The southern portion of the sub-region (shown in Figure 2) is currently served by Ontario's transmission grid and is bounded by Dryden to the southwest, Red Lake to the northwest and Pickle Lake to the northeast. Existing mining activity is primarily located in this southern portion of the North of Dryden sub-region and is largely focused around the towns of Ear Falls, Red Lake and Pickle Lake. The northern portion of the North of Dryden sub-region (shown in Figure 2) contains the

21 remote First Nation communities which are economic to connect, one operating mine, and the mine development area known as the Ring of Fire. At present, only one mine north of Pickle Lake is connected to the transmission grid through a privately owned transmission line.

Figure 2: Map of Northwest Ontario Showing the Existing Transmission System



The North of Dryden sub-region is forecast to experience some of the highest growth in electrical demand in Ontario. Currently the electricity transmission system serving the area is at capacity and is unable to accommodate demand growth.

Mining sector expansion is the primary driver of electricity demand growth in the area; through the expansion of existing mines and the development of new mines, as well as growth in the industries and communities that support the mining sector. Remote

11

communities in the North of Dryden sub-region are currently supplied by diesel generation, however the draft Remote Community Connection Plan[1] developed jointly by the remote communities and the OPA indicates that there is an economic case for connecting the majority of these communities to Ontario's transmission system. The Remote Community Connection Plan is the OPA's primary planning document for these communities, however, the connection would put additional demand requirements on the local transmission system in the areas of Red Lake and Pickle Lake, which is considered in this IRRP.

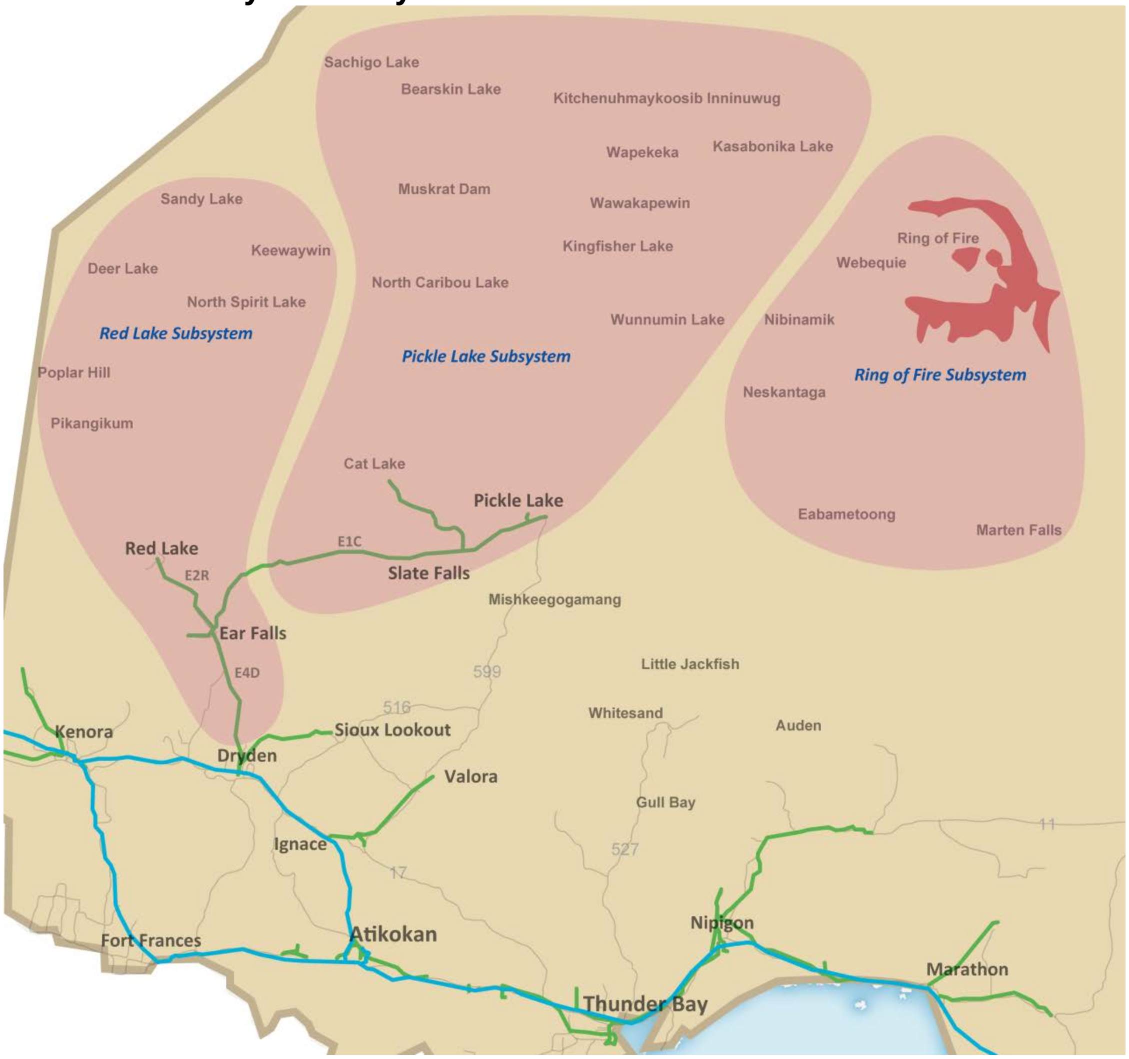
Need Identification

Over the past decade, the annual electricity demand growth in the North of Dryden sub-region has averaged about 1.9%. Growth plans of existing and future customers that are expected to be supplied from the local transmission system indicate that there will be a significant increase in electricity demand over the next 20 or more years.

For study purposes, the area has been segmented into three subsystems generally surrounding Red Lake, Pickle Lake and the Ring of Fire.

[1] A report entitled "Technical Report and Business Case for the Connection of Remote First Nation Communities in Northwest Ontario" was developed by the Northwest Ontario First Nations Transmission Planning Committee and the OPA. The document can be found at this website: http://www.powerauthority.on.ca/sites/default/files/planning/OPA-technical-report-2014-08-21.pdf

Figure 3: North of Dryden Subsystems



Where growth in electricity demand identified in these subsystems cannot be met by the existing system, technically feasible conservation, local generation, and transmission options are identified and compared based on their ability to cost effectively meet the needs.

The OPA produced high and low forecast scenarios to capture the range of variability in future electrical demand and a reference forecast to reflect a likely scenario of future demand based on the information available at the time.

This regional plan has identified that there is a near-term (2014 to 2018) need for additional Load Meeting Capability[2] ("LMC") in the transmission system currently serving the Red Lake and Pickle Lake subsystems. The regional plan has also identified that the majority of the forecasted growth is expected to occur during the medium term between 2019 and 2023. This is the period when remote communities and new mines are expected to develop and connect to the transmission system. The long term is characterized by steadily increasing demand over the remainder of the planning period (to 2033). The need for incremental LMC by subsystem is summarized in Table 1 below.

Table 1: Incremental Capacity Needs by Subsystem

Sub-system	Near-term Capacity Needs (Present to 2018 in MW)			Medium-term Capacity Needs (2019-2023 in MW)			Long-term Capacity Needs (2024-2033 in MW)		
	High	Reference	Low	High	Reference	Low	High	Reference	Low
Pickle Lake	20	18	15	36	28	17	59	47	11
Red Lake	30	30	30	62	44	36	75	48	39
Ring of Fire	22	22	4	67	27	5	73	29	7

Given the magnitude of the increase in electrical demand associated with expanding an existing mine or opening a new mine, as well as growth in electricity demand from growing communities, the area is currently deficient in supply capacity and is expected to become increasingly deficient over the near, medium, and long term.

Options Analysis

The technically feasible options available to meet needs in the Red Lake, Pickle Lake and Ring of Fire subsystems and their implementation timing are outlined in Table 2 below. All costs are net present cost in 2014 dollars, unless stated otherwise (a detailed description of costing methodology can be found in Appendices 10.6, 10.7, and 10.8):

[2] Existing system is thermally limited.

Table 2: Summary of Options

Implementation Timing	Pickle Lake Subsystem	Red Lake Subsystem	Ring of Fire Subsystem
	Conservation and DG Options		
Near term and medium to long term (2014-2033)	Customers may investigate opportunities for additional conservation beyond targets and DG resources to suit their own electrical requirements; Industrial Accelerator Program ("IAP"), Aboriginal Conservation Program, Aboriginal Community Energy Plans Program, remote renewable opportunities after grid expanded to supply remote First Nation communities.		
	Transmission Options		
Near term (2014-2018)	Build a new 115 kV OR 230 kV transmission line from the Dryden/Ignace area to Pickle Lake **Cost: $80 M - $114 M**	Upgrade existing transmission lines serving Red Lake (E4D and E2R) **Cost: $11 M**	East-West Corridor Option: Build a new 115 kV transmission line from Pickle Lake to Ring of Fire for demand up to 67 MW, or build a new 230 kV line if greater than 67 MW. **Cost: $106 M - $156 M** OR North-South Corridor Option: Build a new 230 kV transmission line from either Marathon or a point east of Nipigon to Ring of Fire **Cost: $175 M**
Medium to long term (2019-2033)		If load in the Red Lake subsystem exceeds 109 MW: Install additional voltage support **Cost: $1 M** If load in the Red Lake subsystem exceeds 130 MW: Build a new 115 kV or 230 kV transmission line between Dryden and Ear Falls **Capital Cost: $91 M - $132 M**[3]	
	Generation Options		
Near term (2014-2018)	Gas-fired generator at Pickle Lake fuelled by compressed natural gas, sized and expanded to meet demand growth of up to 31 MW in medium term and up to 76 MW in long	Gas fired generator utilizing up to 30 MW of available gas pipeline capacity at Red Lake **Cost: $51 M**	On-site generation fuelled by compressed natural gas or diesel, **Cost: $209 M - $946 M**[4] Separately connect remote communities
Medium to long term (2019-2033)		Gas-fired generator utilizing up to 30 MW of available gas pipeline	

[3] For comparison with other options, the long-term Red Lake options are presented as capital costs. The NPV of transmission in the long term is $10-15 M. This number is low as the majority of costs are not incurred in the 20 year planning period of this IRRP and the NPV is expressed in 2014 dollars (multiple years of discounting). A fuller description of costing methodology can be found in Appendices 10.6, 10.7, and10.8.

[4] Range indicates variation in cost of diesel and compressed natural gas as well as sizing of the generation facility to accommodate the low, reference or high forecast scenarios.

	term **Cost: $158 M - $317 M**	capacity at Red Lake, followed by additional 30 MW at Ear Falls if a new gas pipeline is built **Capital Cost: $95 M - $ 153 M**[5]	**Cost: $ 62 M** **Total Cost: $ 272 M - $1,009 M**

This regional plan considers overall societal costs[6] in determining the least-cost options for supplying the study area. The analysis in this regional plan does not consider the allocation of costs that are attributable to individual customers in the area or how this may affect individual customer decisions on pursuing the societal least-cost options. The final determination of cost allocation between parties will be made through the applicable regulatory process and/or through commercial agreements. For example, cost allocation of transmission and distribution infrastructure is made by the Ontario Energy Board ("OEB"), benefitting customers, and/or transmitters and distributors in the area in accordance with rules set out in the Transmission System Code ("TSC") and Distribution System Code ("DSC").

Summary of Aboriginal, Stakeholder, and Public Feedback

Aboriginal Consultation

The Ministry of Energy delegated the procedural aspects of consultation to the OPA and identified 44 First Nation communities and four Métis communities to be consulted on

[5] For comparison with other options, the long-term Red Lake options are presented as capital costs. The NPV of generation in the long term is $6-8 M. This number is low as the majority of costs are not incurred in the 20 year planning period of this IRRP and the NPV is expressed in 2014 dollars (multiple years of discounting). A fuller description of costing methodology can be found in Appendices 10.6, 10.7, and10.8.

[6] Societal costs include direct electricity project costs associated with real incremental goods and services (capital cost of engineering, equipment, operations and maintenance, fuel, etc.) but excludes the cost of land, taxes and potential impact benefit agreements that may be reached with affected First Nations, which proponents may be required to pay. Governments (and their agencies) undertake projects of infrastructural, environmental or health and safety enhancements in the wider public interest, assessing project merits in terms of the long-term return to current and future generations of society as a whole, using a social discount rate ("SDR"). The OPA uses a four-percent SDR to determine the present value of options over the planning period.

the Draft North of Dryden IRRP. The OPA and Ministry of Energy provided written notice to each community. The OPA also followed up by telephone to each community and sent all presentation material to each community in advance of the sessions.

The OPA held consultation sessions for the First Nation communities in Thunder Bay on June 18, 2014, June 25, 2014, and October 16, 2014, and in Dryden on June 26, 2014. The OPA met with Red Sky Métis Independent Nation on June 19, 2014 at Red Sky’s office in Thunder Bay.

The OPA was in contact with the Métis Nation of Ontario (“MNO”) on a number of occasions via telephone and email to set up appropriate times for regional consultation meetings with MNO’s member communities. The OPA endeavoured to meet with the MNO and its chartered communities and remains open to such meetings.

To date there have not been any specific concerns expressed regarding potential impacts of the regional plan on any Aboriginal or treaty rights.

Municipal Engagement

The OPA met with municipal representatives in person to solicit feedback on the Draft North of Dryden IRRP to be incorporated into the North of Dryden IRRP. The OPA met with municipal representatives from Pickle Lake, Greenstone, Red Lake, Sioux Lookout, Marathon, Dryden and Ignace in December 2013 and February 2014.

Following the municipal engagement meetings, several common themes emerged from the various municipalities and mainly centered on option preference, cost responsibility, and urgency for development.

Written Feedback

Since the posting of the Draft North of Dryden IRRP, the OPA has received written feedback and has followed up with those who contributed written submissions. Written feedback was submitted from the Common Voice Northwest Energy Task Force

(“CVNW”), the township of Pickle Lake, Imperium Energy on behalf of the municipality of Greenstone, the Ontario Waterpower Association, Ontario Power Generation (“OPG”), Gold Canyon Resources Inc., Energy Acuity, and an independently represented stakeholder.

In general, written submissions asked clarifying questions regarding the content in the draft report. It should be noted that CVNW submitted a 51-page report of comment covering topics across the entire Northwest. The OPA has considered the input in this report, has met with CVNW since publishing the draft report, and will continue to consider their feedback for regional planning initiatives across northwestern Ontario.

Based on written feedback provided by OPG on the Draft North of Dryden IRRP, submitted November 8th, 2013, OPG identified that Manitou Falls units G1, G2, and G3 all have condense features which could be contracted to provide reactive power during drought conditions. The contracting of these units could avoid some of the station investments at Ear Falls Switching Station (“SS”) associated with the installation of voltage control devices. The OPA has considered this feedback in finalizing the plan.

Webinar

The first draft of the North of Dryden IRRP was posted to the OPA’s website in August 2013 and a webinar was held on November 21, 2013 to present the draft IRRP and solicit feedback. Main points of feedback were consistent with that received in written submissions and engagement and consultation meetings.

Recommended Solutions/Actions to be initiated in the near term

The OPA recommends the following solutions for implementation as soon as possible:

1. Building a new single circuit 230 kV transmission line from the Dryden/Ignace area to Pickle Lake (for the Pickle Lake subsystem), installing a new 230/115 kV autotransformer, related switching facilities, and the necessary voltage control

devices at Pickle Lake, and transferring the existing load on the line between Ear Falls and Pickle Lake (E1C) to be supplied by this new line;

2. Upgrading the existing 115 kV lines from Dryden to Ear Falls (E4D) and from Ear Falls to Red Lake (E2R) (for the Red Lake subsystem) and install the necessary voltage control devices; and

3. Having the Independent Electricity System Operator ("IESO")/OPA initiate discussions with OPG for new reactive power services provided by Manitou Falls Generating Station ("GS") if it is confirmed to be beneficial to the ratepayer.

These recommendations are the most cost-effective options that can be implemented in a timely manner and provide flexibility for meeting a broad range of long-term forecast scenarios.

The estimated combined present value cost of recommendations (1) and (2) during the planning period is about $124 million[7]. Recommendation (3) may reduce the estimated cost further. Together these projects increase the LMC of the Pickle Lake subsystem from 24 MW to 160 MW, and increase the LMC of the Red Lake subsystem from 61 MW to 130 MW.

The OPA understands that near-term actions for implementing a new line to Pickle Lake have been initiated by two proponents. Additionally, the OPA understands that Hydro One and various customers in the Red Lake area have initiated discussions to implement the upgrades from Dryden to Red Lake. Implementation of the new 230 kV line to Pickle Lake and the 115 kV line upgrades from Dryden to Red Lake continue to be supported by the OPA.

[7] The August 2013 draft identified this cost as $234-271 million. This change in cost is due to a change in methodology for the NPV economic analysis – treating avoided system generation as a benefit of generation options, rather than a cost to transmission options (as in the 2013 draft). NPV economic analysis is an analysis tool to compare costs over a time horizon, and is not the same as the total project cost for the option being investigated.

Options for the medium to long term period

Pickle Lake Subsystem

The recommendation to build a new single-circuit 230 kV line from Dryden/Ignace to Pickle Lake in the near term would be sufficient under all forecast scenarios for the medium to long term.

Red Lake Subsystem

Following the completion of the near-term recommendations, the 130 MW LMC is expected to be sufficient beyond the planning period for the low and reference forecast scenarios, and until 2030 for the high scenario as shown in Table 1. Therefore, the near-term recommendations are expected to be sufficient to meet the needs of the Red Lake subsystem for the long term.

As shown in Table 2, two options have been investigated for the Red Lake subsystem to address any forecasted load in excess of 130 MW. The OPA recommends that these options, incremental natural gas-fired generation at Red Lake and a new transmission line, be retained as viable long term options and re-evaluated in the next planning cycle (1-5 years) for this IRRP. Re-evaluating plans up to every 5 years is consistent with OEB requirements in the TSC, DSC and the OPA license.

Ring of Fire Subsystem

There are several options for supplying the Ring of Fire subsystem depending on the load growth scenario. The analysis indicates that the Ring of Fire subsystem can be cost-effectively served by a 115 kV transmission connection from Pickle Lake (serving five remote communities and mines at the Ring of Fire), if demand over the long term is 67 MW or less. If demand is reasonably certain to exceed 67 MW in the subsystem, a 230 kV transmission line utilizing an East-West corridor from Pickle Lake, or a 230 kV transmission line utilizing a North-South corridor from either Marathon or east of Lake Nipigon would be required, where these alternatives have approximately equal cost.

The 230 kV transmission options are also expected to be more cost-effective from a societal perspective than the combined cost of developing local generation to serve the total mining load and separately connecting remote communities to Pickle Lake.

The OPA is aware of ongoing work for infrastructure development for the Ring of Fire. Common infrastructure corridors serving multiple uses provide synergies for cost and environmental approvals, and may reduce environmental impacts. The OPA therefore recommends that development of an infrastructure corridor to the Ring of Fire should consider the potential need for a transmission line.

Conservation Options

Recently, the OPA has received new direction[8] from the Minister of Energy pertaining to the framework for conservation programs moving forward. Directives from the Minister of Energy set conservation targets, which Local Distribution Companies ("LDC") will plan to meet through the development of conservation plans and programs for their service area. The spirit of this new direction is to provide more opportunity for LDCs, communities, and industry to participate in conservation initiatives so a broader scope of programs is expected to be tailored to the local needs of the region. For remote communities, conservation opportunities are considered in the Remote Community Connection Plan.

Furthermore, the following programs are available through the OPA to Aboriginal Communities:

- Aboriginal Conservation Program, with the aim to provide customized conservation services designed to help First Nation communities, including remote and northern communities, reduce their electricity use in residential housing, and in commercial and institutional buildings, like stores, schools and

[8] *2015-2020 Conservation First Framework (March 31, 2014), Continuance of the OPA's Demand Response Program under IESO management (March 31, 2014), and Industrial Accelerator Program (July 25, 2014).*

band offices. This program will be offered for one additional year (ending December 31, 2015) until such time as LDCs are able to develop a CDM program which recognizes the specific requirements of on-reserve First Nation communities as per the 2015-2020 Conservation First Framework Directive.

- Aboriginal Community Energy Plans program to support Aboriginal participation in Ontario's energy sector by providing up to $90,000 per community in funding to First Nation or Métis communities for local energy planning activities, with remote communities being eligible for an additional $5,000.

Electricity demand of the industrial sector is quite significant in this area. The Industrial Accelerator Program ("IAP") is available to industrial customers as a means of achieving conservation savings with financial assistance from the OPA.

Given the large component of industrial demand and number of First Nation and Métis communities in the area, the above mentioned programs should be pursued.

Generation Options for the Medium- to Long-term Period

On May 30, 2014, the OPA closed submissions for the Northwest Ontario Request for Information ("NW RFI"). The purpose of the NW RFI was to gather information on the potential availability of diverse resource options in northwestern Ontario, with particular focus on the interim period to 2020. As part of the NW RFI, the OPA received submissions totaling over 4000 MW for the entire Northwest region. Of the over 4000 MW, a few potential projects were identified in the North of Dryden sub-region and were consistent with the generation options investigated as part of this IRRP.

Procurement of generation is not recommended to be pursued at this time for meeting needs in the North of Dryden sub-region. However, if a generation solution is required for other areas of the Northwest, local benefits of these options to the North of Dryden sub-region will be re-evaluated.

2 INTRODUCTION

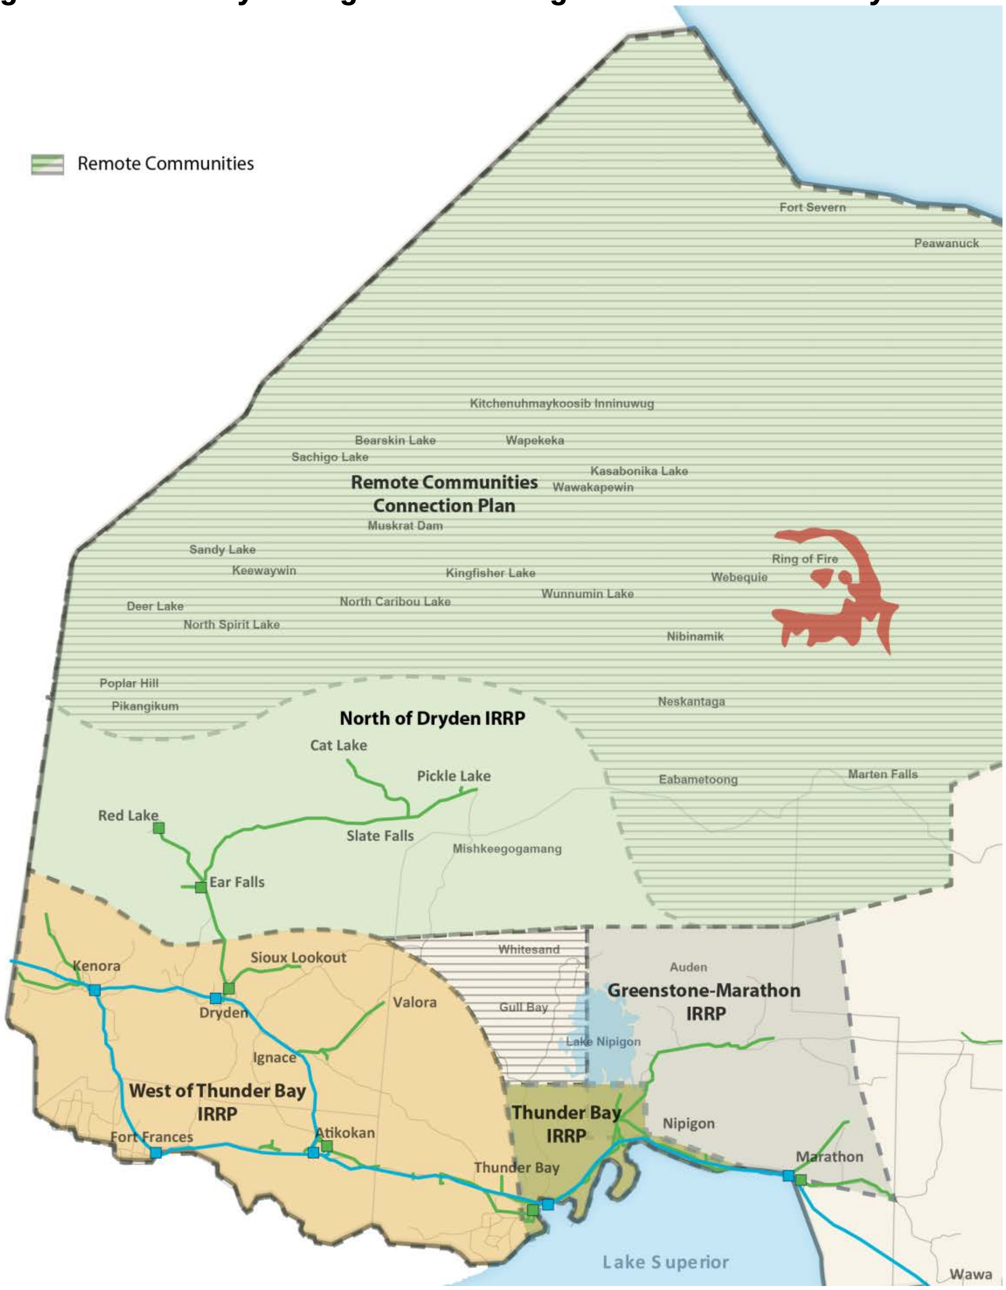
2.1 The North of Dryden Sub-Region

The North of Dryden Integrated Regional Resource Plan (“IRRP”) is one of several electricity planning initiatives that the Ontario Power Authority (“OPA”) is undertaking for the Northwest Ontario region. Figure 4 identifies the IRRP initiatives currently being undertaken by the OPA in the Northwest Ontario region. The North of Dryden IRRP accounts for the demand requirements in the North of Dryden sub-region.

The Thunder Bay IRRP, West of Thunder Bay IRRP and Greenstone-Marathon IRRP were initiated fall 2014. A Scoping Outcome Assessment Outcome Report for northwestern Ontario, which includes the Terms of Reference for three new IRRPs, is available on the OPA’s website, consistent with Ontario Energy Board (“OEB”) requirements. The Terms of Reference for the West of Thunder Bay IRRP and the Greenstone-Marathon IRRP include considerations for relationships with the North of Dryden IRRP.

The North of Dryden sub-region is a natural resource rich area in northwestern Ontario, with existing mining, forestry, and hydroelectric generation operations, as well as potential for substantial new resource development. Mining sector expansion, including expansion of existing mines as well as the development of new mines, is a major driver for electricity demand growth in the area, both at mine sites and through growth in industries that support the mining sector. Another major driver for electricity demand growth in the area is the economic connection of remote First Nations communities (“remote communities”) to the provincial transmission grid, which are currently served by isolated diesel generation systems.

Figure 4: Summary of Regional Planning Initiatives Underway in Northwest Ontario



The transmission system supplying the North of Dryden sub-region is currently at capacity. This IRRP recommends options to provide new high voltage electrical capacity to meet near-term growth, while providing options to meet future growth as it becomes more certain. These near-term recommendations are presented as action items for immediate or early deployment. Options to address potential longer-term needs are also identified, but the OPA does not make a recommendation on a preferred option at this time, as the longer term still remains uncertain and adequate time is available to continue to monitor the situation closely. The OPA will continue to monitor demand growth and reevaluate longer-term options in future planning cycles for the North of Dryden sub-region. When a decision for the longer-term is required, the OPA will make a recommendation for solutions to be implemented.

The North of Dryden sub-region (shown in more detail in Figure 5) is contained within First Nation Treaty areas 3, 5, 9 and the Robinson-Superior Treaty area. It also includes portions of Region 1 and Region 2 of the Métis Nation of Ontario ("MNO"). The southern portion of the area (as shown in Figure 5) is currently served by Ontario's transmission grid and is bounded by Dryden to the southwest, Red Lake to the northwest, and Pickle Lake to the northeast. Current mining activity is mostly contained in this portion of the area, and broadly focused around the Towns of Ear Falls, Red Lake and Pickle Lake.

The northern portion of the North of Dryden sub-region (as shown in Figure 5) is comprised of 21 remote communities, one operating mine and the mine development area in the Hudson Bay lowlands known as the Ring of Fire. At present, the mine north of Pickle Lake is connected to the transmission grid by a privately owned transmission line. There are 25 remote First Nations communities that are distant from the existing provincial transmission system and are currently supplied electricity by local diesel generation facilities. On August 21, 2014, an updated draft Remote Community Connection Plan was made available on the OPA website.[9] The Remote Community Connection Plan demonstrates a business case to connect 21 of 25 remote communities that currently rely on diesel generation, to the provincial transmission grid. The business case is based on the avoided cost of diesel fuel. For the purpose of this regional plan, 21 of the 25 communities are assumed to connect to Ontario's transmission system as per the OPA's Remote Community Connection Plan. Communities are expected to begin connecting in the early 2020s.

Figure 5: Map of Northwest Ontario Showing the Existing Transmission System

Distribution connected customers in the North of Dryden sub-region are served by Hydro One's distribution system. There are also a number of large industrial customers that are connected directly to the transmission system in the area and served by Hydro One's transmission system.

2.2 Purpose and Scope of the IRRP

This regional plan assesses the near-term and medium- to long-term electricity supply needs of the North of Dryden sub-region and identifies the options which are available to address these needs in a cost-effective, reliable, and timely manner. The regional plan is intended to identify alternatives and recommended options to local customers, proponents, and local government so development work may proceed. Proponents may also choose to use this regional plan to support the regulatory proceedings they will undertake to seek approval for their projects.

Regional planning for the North of Dryden sub-region began before the OEB's formalized regional planning process was developed as part of the Renewed Regulatory Framework for Electricity ("RRFE"). Consequentially the North of Dryden IRRP does not have a corresponding Scoping Assessment Outcome Report. The North of Dryden IRRP is considered a "transition plan" as per the Planning Process Working Group ("PPWG") report on Regional Planning to the OEB. This version of the North of Dryden IRRP has transitioned and aligned with OEB requirements for the IRRPs as per the OPA's license.

In 2010, the OPA, Hydro One and the Independent Electricity System Operator ("IESO") began working together to assess the ability of the electricity system in the North of Dryden sub-region to meet forecast growth over the near, medium and long term, and to develop integrated plans to address needs that have been identified. Since beginning this planning work, the OPA has engaged existing and potential customers in the area to identify the size and scope of their future electricity needs in the North of Dryden sub-region. The IESO has also completed a number of System Impact Assessments ("SIAs") and feasibility studies for customers requesting additional capacity.

In addition to the regional planning requirements outlined by the OEB, the Minister of Energy identified in the 2010 Long-Term Energy Plan ("LTEP") that the OPA would develop plans to enable the connection of remote First Nations communities, and identified the development of a new transmission line to Pickle Lake to be a priority transmission project, with the scope and timing to be determined by OPA. In February 2011, the OPA received an updated Supply Mix Directive ("SMD") from the Minister of Energy. The updated SMD requires that the OPA develop a plan to connect remote First Nation communities north of Pickle Lake. In December 2013, the Ministry of

Energy released the second LTEP which reiterated that connecting remote First Nation communities in northwestern Ontario is a priority.

Since 2009, the OPA has been working with remote First Nations communities through the Northwestern Ontario First Nation Transmission Planning Committee ("NWOFNTPC") to identify communities that are economic to connect to the provincial transmission system. Through this partnership, planning is underway for connecting most of these communities to the grid and for developing local solutions for the remaining communities to cost-effectively reduce their reliance on diesel fueled generation.

The North of Dryden IRRP is affected by connection of remote communities in two primary ways:

1. The transmission facilities serving the area must be capable of supplying the electrical demand resulting from the connection of these remote communities; and

2. Options for coordinating connection with mining developments, especially in the Ring of Fire area, must be investigated in accordance with assumptions in the Remote Community Connection Plan.

As new information on the connection of the remote communities becomes available, the North of Dryden IRRP will be updated accordingly and consistent with the regional planning process and PPWG report.

It should also be noted that regional plans consider overall societal costs[10] in determining the least cost options for supplying a study area. This analysis does not

---

[10]Societal costs include direct electricity project costs associated with real incremental goods and services (capital cost of engineering, equipment etc, operating and maintenance, fuel etc.), but excludes the cost of land, taxes, and potential Impact Benefit Agreements that may be reached with affected First Nations, which proponents may be required to pay. cont'd...

consider how the allocation of costs attributable to individual customers in the area may affect their decision to pursue the societal least cost options. The final determination of cost allocation between parties will be determined by the appropriate regulatory process or commercial agreement. For example, cost allocation of transmission and distribution infrastructure is made by the OEB, benefitting customers, and/or transmitters and distributors in the area in accordance with the rules set out in the Transmission System Code (“TSC”) and Distribution System Code (“DSC”).

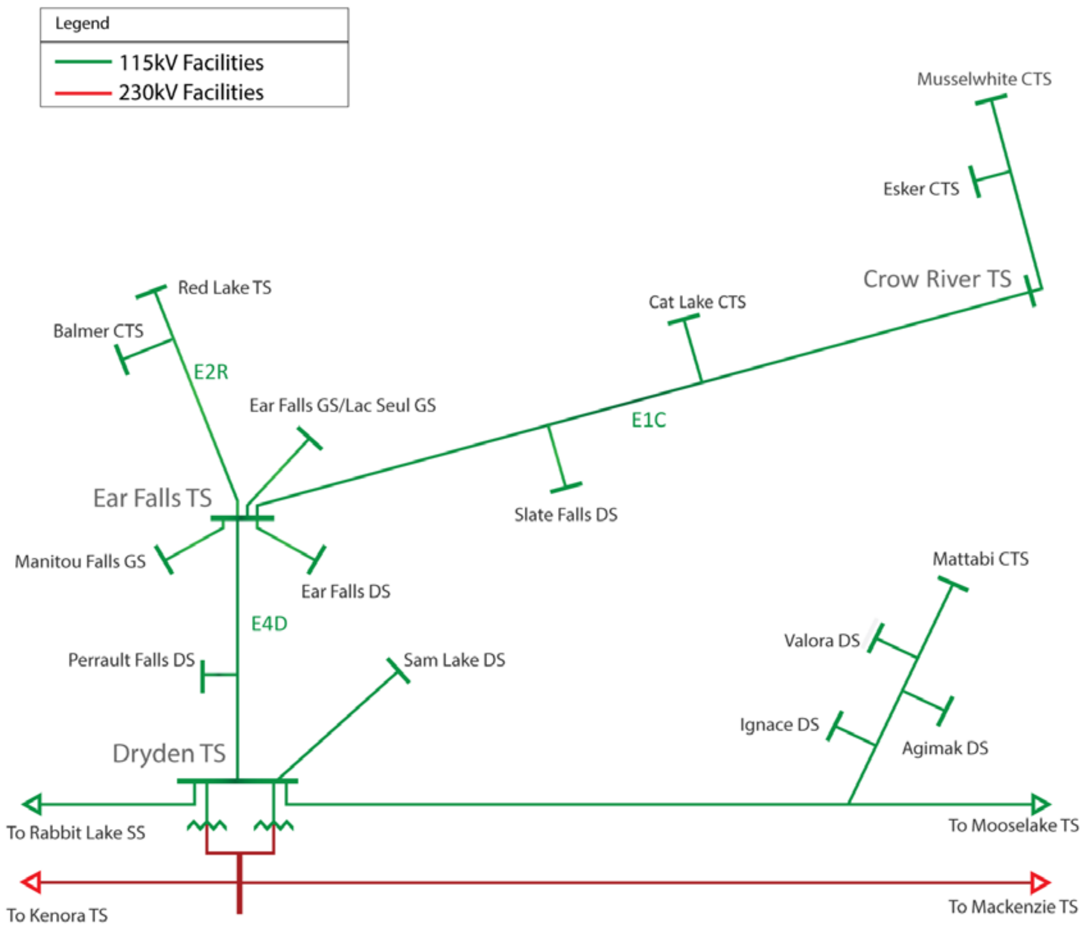
Other planning activities for the region will consider supply needs to the Dryden area for supply of expected load growth in the North of Dryden sub-region. Some of the planning and development work that is underway to ensure an adequate supply is available in the overall Northwest region includes development work being undertaken by NextBridge Infrastructure for an expanded East-West Tie (“EWT”), the May 30, 2014 Northwest Request for Information (“NW-RFI”), and the regional planning initiatives summarized in Figure 4.

...Governments (and their agencies) undertake (or mandate) projects of infrastructural, environmental, or health and safety enhancement in the wider public interest, assessing project merit in terms of the long-term return to current and future generations of society as a whole, using a Real Social Discount Rate (Real “SDR”). The OPA uses a 4% Real Social Discount Rate for determining the present value of options over the planning period.

3 NORTH OF DRYDEN TRANSMISSION AND GENERATION FACILITIES

Currently, electricity customers in the North of Dryden sub-region are supplied by a single-circuit 115 kV radial transmission line (“E4D”) emanating from Dryden TS and by local hydroelectric generation. Dryden TS is a major supply station for this area, where the voltage is stepped down from the regional 230 kV system to 115 kV to serve local community and industrial customers as shown in Figure 6 below.

Figure 6 Existing North of Dryden Transmission System



30

At Ear Falls TS, the 115 kV supply branches to the north, east, and west to supply customers and incorporate generation in the area. Hydroelectric generation is connected to the transmission system at Ear Falls generating station (“GS”) (17 MW Ear Falls + 12.1 MW Lac Seul) and at Manitou Falls GS (73.1 MW). To the north of Ear Falls, the E2R transmission line (“E2R”) supplies Red Lake area mining and community customers. East of Ear Falls, the E1C transmission line (“E1C”) supplies the Town of Pickle Lake, Cat Lake First Nation, Slate Falls First Nation, Mishkeegogamang First Nation, as well as a mine via a privately-owned 115 kV transmission line (“M1M”).

For the purposes of this regional plan, the North of Dryden sub-region is divided into three main subsystems, as shown in Figure 7, the Pickle Lake subsystem, the Red Lake subsystem, and the Ring of Fire subsystem. At present, the Ring of Fire subsystem has no transmission infrastructure and is not connected to the provincial transmission grid, and the Pickle Lake subsystem is supplied downstream of the Red Lake subsystem from Ear Falls via E1C.

The Pickle Lake subsystem includes all demand planned to be served by E1C at Cat Lake CTS, Slate Falls DS, Crow River DS, as well as a mine north of Pickle Lake and any new customers that may connect in the Pickle Lake area in the future. The Pickle Lake subsystem also includes 10 remote communities north of Pickle Lake that are identified to connect to Pickle Lake in the 2014 Remote Community Connection Plan.

The Red Lake subsystem includes all load and generation connected and planned to be served by E4D and E2R, at Perrault Falls DS, Ear Falls TS, Red Lake TS, Balmer CTS, and the six remote communities north of Red Lake that are identified as being economic to connect to Red Lake TS in the 2014 Remote Community Connection Plan. As mentioned previously, there is 102.2 MW of hydroelectric generation at Ear Falls GS and Manitou Falls GS.

Figure 7: North of Dryden Subsystems

The Ring of Fire subsystem does not include any existing transmission facilities. The subsystem includes five remote communities that are identified for connection in the 2014 Remote Community Connection Plan as well as potential future industrial customers at the Ring of Fire mine development area.

Due to the current system configuration, when a transmission line in the North of Dryden sub-region is forced out of service all load connected to it is lost. In the event that E4D is removed from service, some of the North of Dryden system can be restored by islanded[11] hydroelectric generation in the Ear Falls area until E4D is returned to service. While the area is islanded from the system and supplied by local generation, the amount of load that can supplied is limited to the available generation output.

Historically, the reliability of electricity supply to some customers in the North of Dryden sub-region has been worse than the average for other customers in northwestern Ontario. Specifically, customers in the Pickle Lake subsystem (currently supplied by E1C) have experienced, on average, 14 unplanned outages per year over the past 10 years.[12] This compares to an average of about three unplanned outages per year for customers served by the other 115 kV lines in northwestern Ontario.[13] Planning for the north of Dryden system includes consideration of this historical performance.

---

[11] Islanded: when one part of the system is disconnected and operated separately from the rest of the Ontario electricity system.

4 HISTORICAL ELECTRICITY DEMAND

4.1 Historical Electricity Demand

Demand for electricity in the North of Dryden sub-region is driven by a number of factors including mining and forestry activity, as well as local community growth. Mining sector expansion is the primary driver of growth in electricity demand in the area. The north of Dryden area is currently winter-peaking. As shown in Figure 8, peak demand in the North of Dryden sub-region has been growing by approximately 1.9% since 2004. Historical demand includes only the Pickle Lake and Red Lake subsystems, since the Ring of Fire subsystem has not yet developed beyond the five remote communities located east of Pickle Lake. Historical demand figures also do not include remote community demand, since they are not currently connected to the provincial transmission system.

Figure 8: North of Dryden Historical Transmission Connected Demand

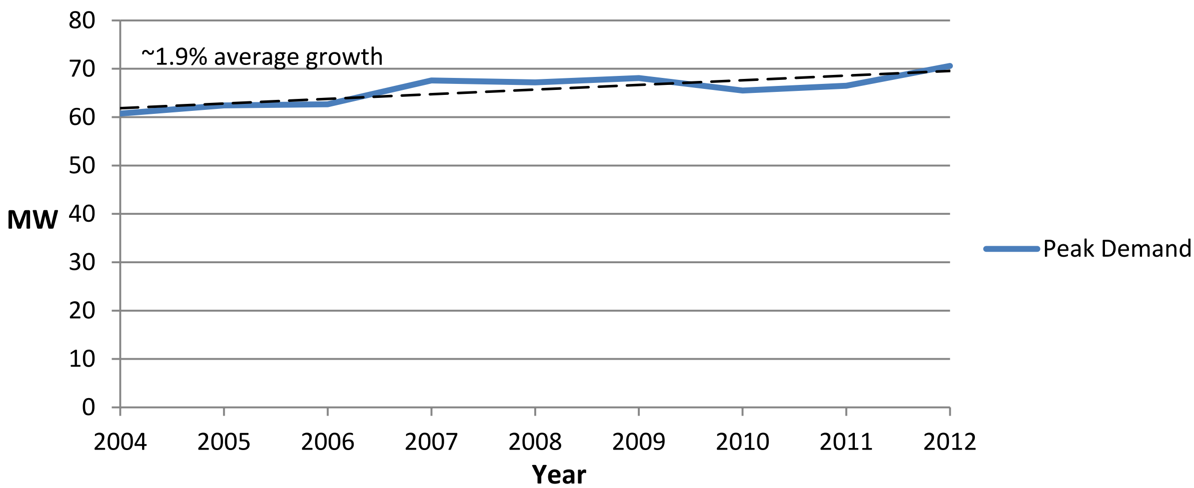

Figure 9 shows that growth in electricity demand has also varied between the Red Lake and Pickle Lake subsystems, with annual growth in electricity demand averaging 1.6% in the Red Lake subsystem and 2.6% in the Pickle Lake subsystem between 2004 and 2012.

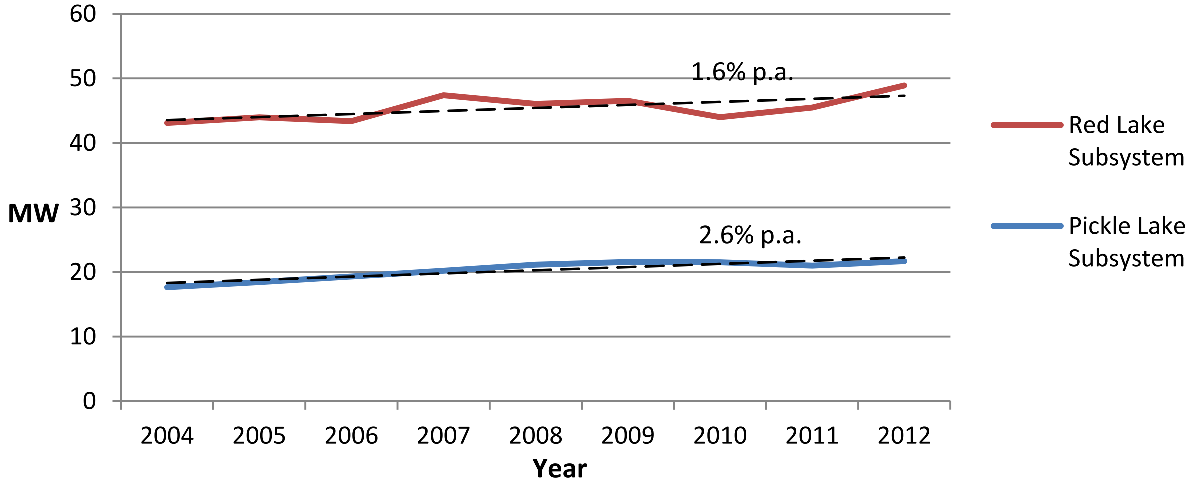
Figure 9: North of Dryden Historical Demand by Subsystem



In 2012, 61 MW of capacity was allocated to customers in the Red Lake subsystem, while 24 MW of capacity was allocated to customers supplied in the Pickle Lake subsystem. When the load of the remote communities in each subsystem are added to the connected load, the total load in 2012 increases to 67 MW in the Red Lake subsystem and 31 MW in the Pickle Lake subsystem. At present, no customers in the Ring of Fire subsystem are connected to the provincial grid; however, the combined demand of the five remote communities in the subsystem was about 3 MW in 2012.

4.2 Existing Distributed Generation Resources

Distributed generation is small-scale generation sited close to load centers; it helps supply local energy needs while at the same time contributing to meeting provincial demand. Along with other OPA procurement processes, the introduction of the *Green Energy and Green Economy Act, 2009* and the associated development of the Feed-in Tariff ("FIT") program have encouraged the development of distributed generation resources in Ontario. These procurements take into consideration the system need for generation as well as cost.

Presently, there are five contracted microFIT projects, and one contracted FIT project in the North of Dryden sub-region. All of these projects are located in the Red Lake subsystem. Of these projects, four microFIT solar projects are located in Red Lake with a total contract capacity of 39.3 kW and one microFIT solar project is in Ear Falls with a contract capacity of 10 kW. Analysis of the ability of solar resources in the North of Dryden sub-region to contribute to meeting local demand during the fall months has been estimated to be 5% of contract capacity. Therefore, these units are expected to contribute 2.5 kW to the LMC of the Red Lake subsystem. The FIT project is the Trout Lake River FIT small hydro project, a run of river hydroelectric project near Ear Falls, with a contract capacity of 3.75 MW[14]. The dependable generation level for this project (see Appendix 10.3.2) and its contribution to the LMC of the Red Lake subsystem is assumed to be 0 MW.[15] In total, the contribution of these DG units to the LMC of the Red Lake subsystem is expected to be 2.5 kW (0.0025 MW).

Currently, there are a number of diesel generators that provide backup/emergency supply at mine sites, which are required for health and safety purposes. Generally, these units are not configured for grid connection and thus are not currently available to supply the system. Even if they were configured to connect to the grid, there may be other limitations on their ability to reliably supply load customers on a regular basis including: their age, efficiency, level of emissions, prescribed limits in their operating approvals and their operating and maintenance costs. These units may have some potential to operate as short-term demand management resources, but given the available information they cannot be relied upon to provide the capacity and energy required to meet the needs of the North of Dryden sub-region. Therefore, they have not been considered further in this regional plan.

The Request for Information for Electricity Resources in Northwestern Ontario ("NW-RFI") was issued to better understand the availability of all potential resources in northwest Ontario including the North of Dryden sub-region, with particular focus on the

[14] Trout Lake River GS, is a contracted FIT small hydro project currently under development, with an expected commercial operation date of Q1 2015.

[15] The performance of the facility during drought conditions has not yet been determined, however, the anticipated contribution based on similar facilities in the area, is much less than the tolerance of the modelling software used for this study.

interim period to 2020. The OPA has received submissions to the NW-RFI. Generation options in this plan have considered the relevant NW-RFI submissions. Should new information become available it will be included at the next update of this regional plan.

5 FORECAST ELECTRICITY DEMAND

To develop the demand forecast the OPA worked with Hydro One (the transmitter and local distribution company serving the North of Dryden sub-region), existing and potential transmission connected industrial customers around Ear Falls, Red Lake, and Pickle Lake[16] and the Ring of Fire, municipalities, business associations, as well as remote First Nations communities in northwest Ontario.

5.1 New Demand from Connection of Remote First Nation Communities

The findings of the Remote Community Connection Plan indicate that due to the high and growing cost of diesel fuel as well as the high cost of operating and maintaining remote diesel generation systems, transmission connection of up to 21 remote communities can avoid substantial future costs of about $1 billion over 40 years and therefore economically justifies the connection of the corresponding 21 remote communities to the provincial transmission grid. For the purposes of this IRRP, it has been assumed that these communities will pursue a connection and therefore includes the demand of the corresponding remote communities in the North of Dryden IRRP forecast. The Remote Community Connection Plan indicates that communities may begin connecting between 2018 and 2020, following the development of required capacity in the North of Dryden sub-region transmission system.

5.2 Residential and Commercial Forecasted Demand

The OPA worked with Hydro One to establish the Residential and Commercial component of the demand forecast in the North of Dryden sub-region. The OPA then removed the industrial component of the load that is connected to the distribution system to determine the forecasted residential and commercial forecasted demand. Hydro One Distribution supplies electricity to customers at the following transformer

[16] The load growth is based on information provided to the OPA by Hydro One Networks Inc. and industrial customers in the North of Dryden sub-region. Hydro One provided information relating to existing distribution facilities North of Dryden; this includes existing community loads and some industrial loads. The OPA worked with existing and potential industrial customers to determine their expected near and long-term electricity needs. The forecast has been shared with Common Voice Northwest's Energy Task Force among other interested stakeholders.

stations: Perrault Falls DS, Ear Falls DS, Red Lake TS, Crow River DS, and Slate Falls DS. Cat Lake CTS is owned by Cat Lake Power Utility Ltd., and is supplied by Hydro One's transmission system from circuit E1C.

5.3 New and Expanding Mining Projects

The majority of forecasted demand growth in the North of Dryden sub-region is anticipated to be primarily driven by the mining sector.

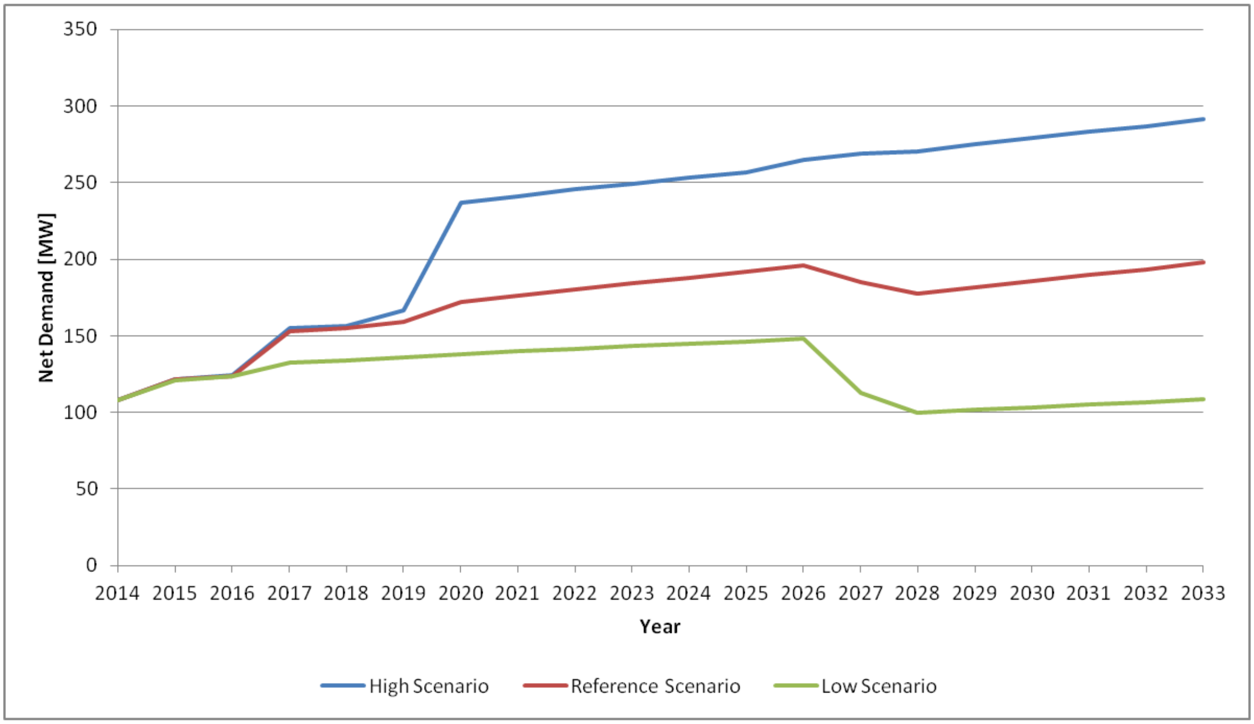
Numerous projects have been proposed in the region, representing a variety of mineral resources, stages of feasibility and development and potential environmental impacts. As mining is a commodity-based industry, there is uncertainty with the timing of mining projects, especially those that are in the relatively early stages of development. This corresponds to uncertainty in the forecasted electrical demand for the area. Recognizing the risk associated with uncertainty in the forecasted demand, the OPA produced three load scenarios. The OPA produced high and low forecast scenarios to capture the range of variability in future electrical demand and a reference forecast to reflect a likely scenario of future demand based on the information presently available.

Through engagement with the mining companies, mining associations and other stakeholders in the region, and by reviewing available technical documents produced by the mining companies regarding their proposed projects, the OPA categorized projects according to the likelihood that they will be developed within their proposed timelines. The projects have been categorized based on several factors, including:

- Stage of development (e.g. under construction, undergoing an Environmental Assessment ("EA"), still in exploration, etc.)
- Financial feasibility (e.g. results of publically available economic assessments)
- Potential environmental impacts
- Existing infrastructure and accessibility
- Global markets (e.g. commodity prices, customers and demand)

Figure 10 shows the forecast range over the planning period.

Figure 10: North of Dryden sub-region Net Demand Forecast

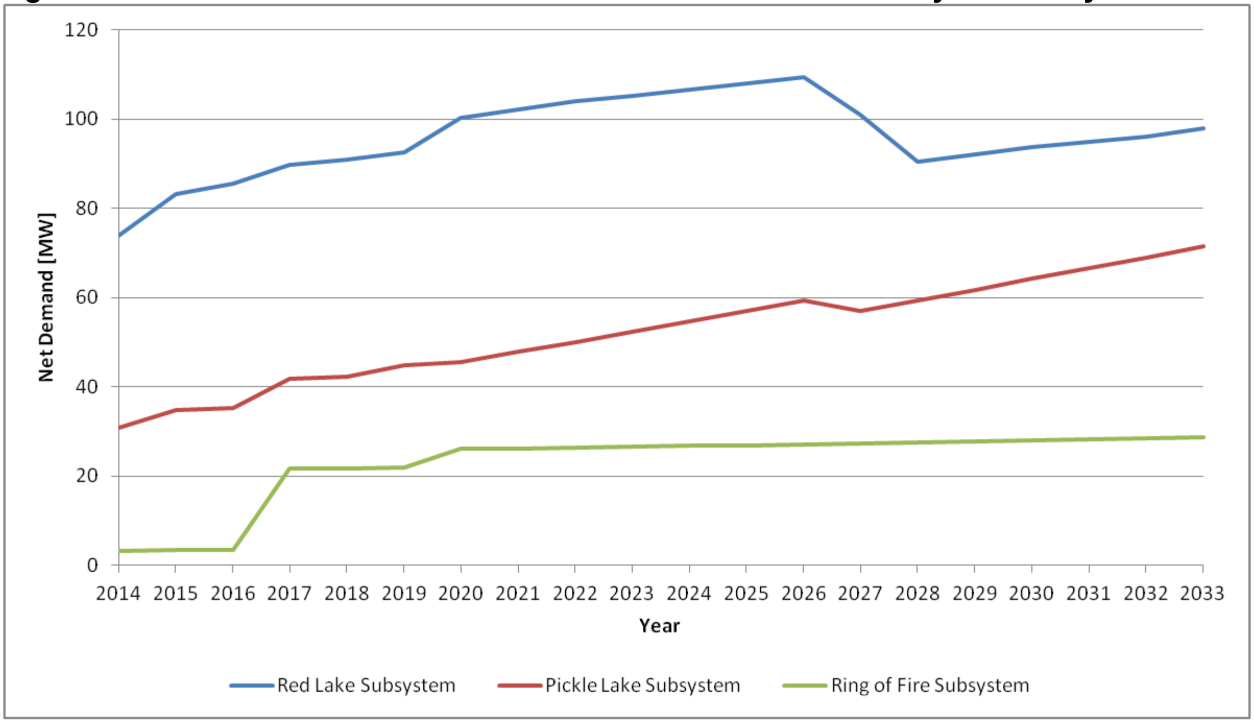


The following descriptions provide the scope of regional activity under the three scenarios.

5.4 Reference Scenario Demand Forecast

Under this scenario, it is assumed that projects currently under construction will be completed and commissioned on schedule. It is assumed that projects with high grade mineral deposits and positive economic assessments will be developed by the timelines specified in their project descriptions with relatively high probability. Projects with potential for extensive environmental impacts are assumed to be unlikely to proceed in the near term as well as projects which are still in the exploration phase. Furthermore, the reference scenario assumes that modest electrical demand driven by the mining sector in the Ring of Fire area is likely to appear before 2024.

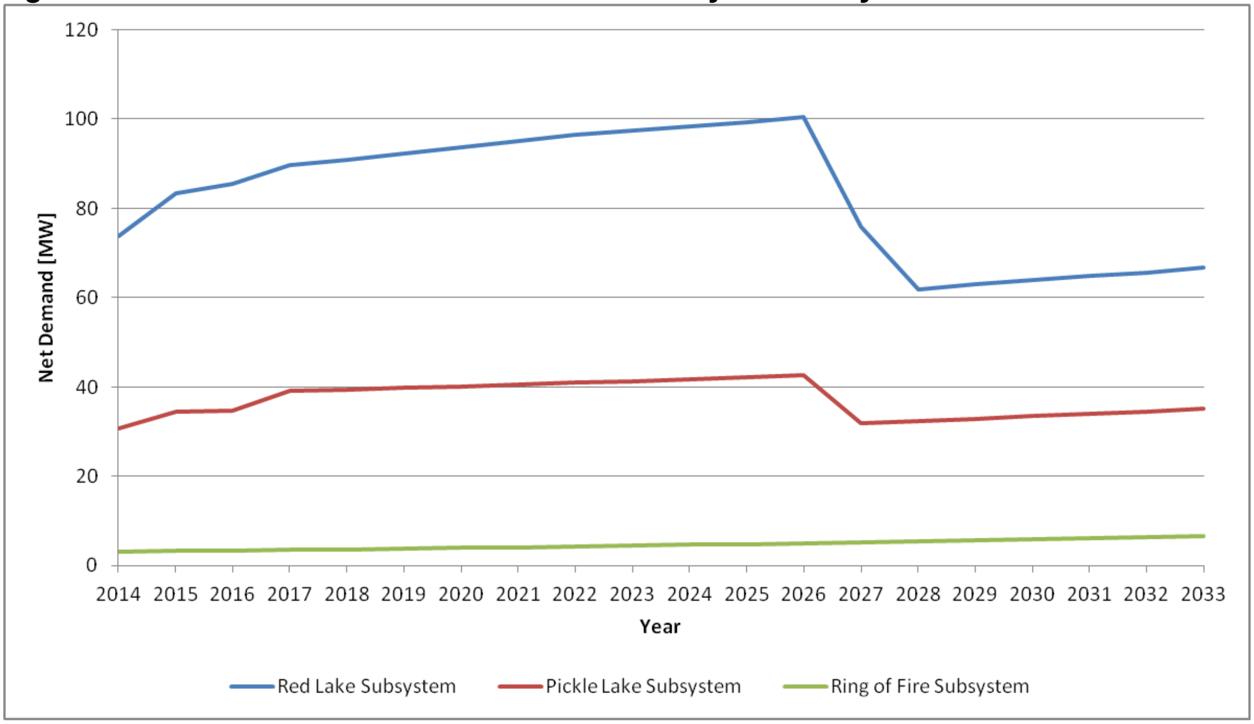
Figure 11: Reference Scenario Demand Forecast for North of Dryden Subsystems



5.5 Low Scenario Demand Forecast

This scenario assumes only the most mature and developed projects (e.g. currently under construction or applying for a leave to construct) are likely to be developed before 2024. It is assumed that other projects with a positive economic assessment will be fully developed with a 50% probability. Early stage exploration projects and projects with marginal economics or environmental, infrastructure and/or accessibility hurdles are assumed to not be developed. This scenario also assumes the Ring of Fire will not be developed before 2034.

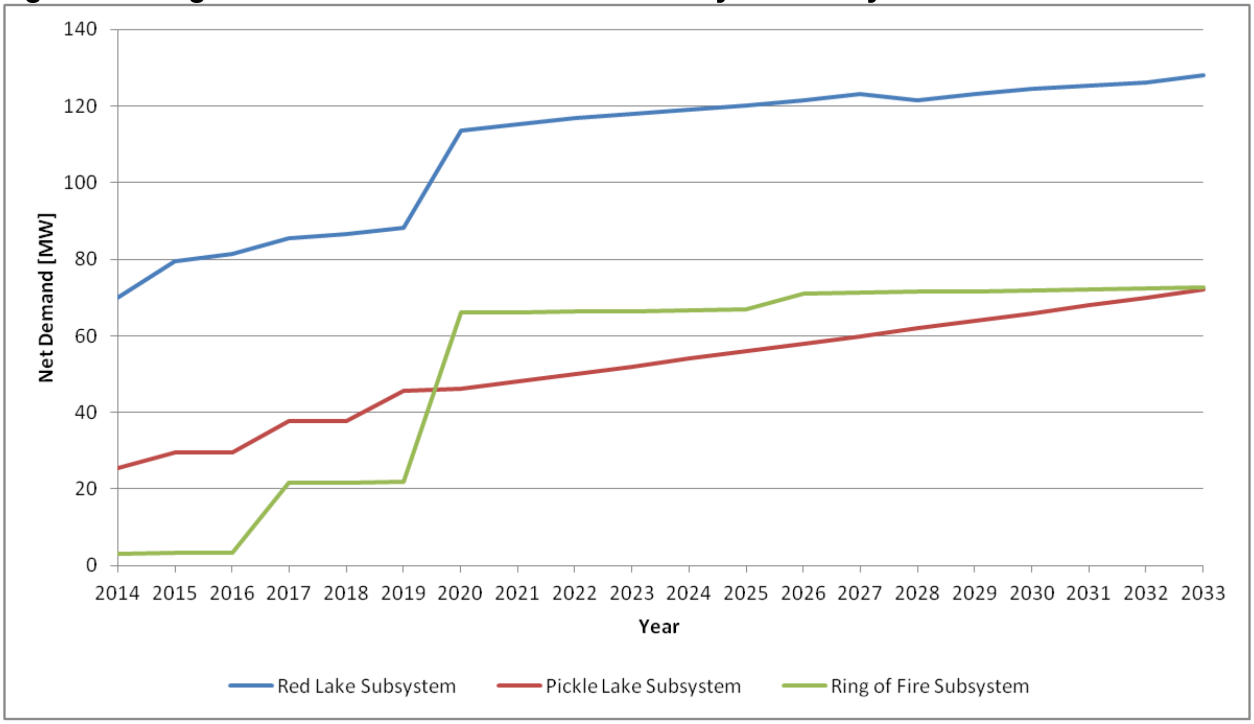
Figure 12: Low Demand Forecast for North of Dryden Subsystems



5.6 High Scenario Demand Forecast

Under the high scenario, most proposed projects are considered likely to be developed and commissioned in the near term. This scenario assumes sufficiently high commodity prices will provide financial feasibility to many projects that may otherwise be considered marginal or uneconomic. The high scenario also assumes an extensive, near- to medium-term build out of the Ring of Fire area, and that multiple mines will be operating in the region by 2020. The expansion of the mining sector is assumed to result in additional expansion of the residential sector in the region, which is also captured in this scenario.

Figure 13: High Demand Forecast for North of Dryden Subsystems



The OPA will continue to monitor electricity demand growth and work with existing and potential customers to maintain up to date electrical demand forecasts for the area. This information will be used to develop regular updates to the North of Dryden IRRP as per the formalized OEB Regional Planning Process.

5.7 North of Dryden Sub-Region Net Electricity Demand

A summary of the net demand forecast scenarios for the North of Dryden sub-region is presented in Table 3.

6 NEEDS IN THE NORTH OF DRYDEN SUB-REGION

Planning for the reliable supply of electricity requires anticipating potential equipment outages before they occur and designing a power system that limits the impacts to consumers, based on good utility practices as outlined in the OEB's TSC. This is accomplished through the application of planning criteria. In Ontario, the criteria for planning the transmission system are specified in the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC")[18].

In accordance with ORTAC, the transmission system shall have sufficient capability under peak demand conditions to withstand specific outages while keeping voltages, and equipment loading within applicable limits. The maximum demand that can be supplied by an electricity system in a defined area is known as the load meeting capability ("LMC") of that area. Where an area is served by a single transmission line and local generation, the LMC is determined as the capability of the transmission line during normal operation, with the dependable level of local generation respecting the loss of the largest generating unit. If the area is served by a single transmission line without local generation, the LMC is determined as the capability of the transmission line during normal operation since the loss of the single line will result in the total loss of all connected load. The following factors are considered when determining the LMC of a transmission system serving an area:

- the configuration of the system;
- the capabilities of individual elements comprising the system, for the north of Dryden system, this includes the limits of the transmission lines and the dependable levels of hydroelectric generation;[19] and

[18] http://www.ieso.ca/imoweb/pubs/marketadmin/imo_req_0041_transmissionassessmentcriteria.pdf
[19] the dependable level of the existing run of river hydroelectric generation (that is available during drought water flow conditions) is assumed to be available. Details regarding the method for determining the dependable level of hydroelectric and other renewable generation resources for the IRRP are provided in Appendix 10.3.2. Drought conditions are expected to occur about one year in every 10 years and can persist for several months at a time, when watersheds are at their lowest levels in the late summer, fall and early winter months.

- the distribution of demand in the area being supplied.

In general, the greater the distance a given electrical load is located from the inter-regional transmission system (bulk system) supply point (Dryden and/or Marathon or east of Nipigon), the lower the LMC of the system will be. This is due to losses and the need to maintain system voltages within criteria.

6.1 Capability of the Existing North of Dryden System to Supply Forecast Electricity Demand

At present the entire North of Dryden system is supplied from Dryden TS (via E4D) and supported by hydroelectric generation at Ear Falls. The application of ORTAC to the 115 kV transmission system serving the North of Dryden results in an LMC of 85 MW, based on the current line ratings and available dependable hydroelectric generation resources in the Ear Falls area. Existing customers have been allocated 85 MW of capacity on the system and thus the area has reached its capacity limit or LMC. Of this LMC, 24 MW is allocated to the Pickle Lake subsystem and the remaining 61 MW serves the Red Lake subsystem. Mining load in the Ring of Fire subsystem has yet to develop, and the five remote communities in the subsystem are currently supplied by isolated diesel generation. Since the Remote Community Connection Plan identifies that it is economic to connect these communities and there is currently no transmission system serving the Ring of Fire subsystem, the corresponding LMC of the existing provincial power system is 0 MW.

For new customer load to be connected and served in any of the subsystems, additional supply capacity is required. The new capacity needed in order to meet forecast demand growth as provided by Hydro One Distribution, existing and future industrial customers, and the Remote Community Connection Plan (net of planned conservation), is summarized in Table 4 below.

Table 4: Summary of Capacity Needs to Meet the Net Demand Forecast for each Subsystem

There is a near-term (present to 2018) need for additional capacity (incremental LMC) in each subsystem. The summary of capacity needs indicates that there will be need for 18 MW and up to 20 MW in the Pickle Lake subsystem, 30 MW in the Red Lake subsystem and 22 MW in the Ring of Fire subsystem in the near term.

The majority of forecast demand growth for the North of Dryden sub-region is expected to occur in the medium-term period between 2019 and 2023. This is the period when remote communities and most new mines are expected to connect their load to the system. The long term is characterized by steadily increasing demand over the remainder of the forecast period (2024 to 2033).

In the medium term, capacity needs in the Pickle Lake subsystem are forecast to be 28 MW and up to 36 MW, and up to 59 MW by the end of the planning period in 2033. In the Red Lake subsystem needs are forecast to be 44 MW and up to 62 MW in the medium term, and up to 75 MW by the end of the planning period in 2033.

The capacity need for the Ring of Fire subsystem, which includes potential mines at the Ring of Fire and the connection of five remote communities east of Pickle Lake, is driven by when and if mines connect to the transmission system. If the mines do not connect, then only the demand of the five remote communities will need to be supplied by the system. This is forecast to be 4 MW at the time of connection and up to 7 MW by the end of the planning period in 2033. If the potential Ring of Fire area mines that are considered in the load forecast develop, the capacity need for the Ring of Fire subsystem is forecast to be up to 73 MW by the end of the planning period.

The near-, medium- and long-term capacity needs of each subsystem are summarized in Table 5 below.

Table 5: Summary of Incremental Capacity Needs by Subsystem[20]

Subsystem	Near-term Capacity Needs (Present to 2018 in MW)			Medium-term Capacity Needs (2019-2023 in MW)			Long-term Capacity Needs (2024-2033 in MW)		
	High	Reference	Low	High	Reference	Low	High	Reference	Low
Pickle Lake	20	18	15	36	28	17	59	47	11
Red Lake	30	30	30	62	44	36	75	48	39
Ring of Fire	22	22	4	67	27	5	73	29	7

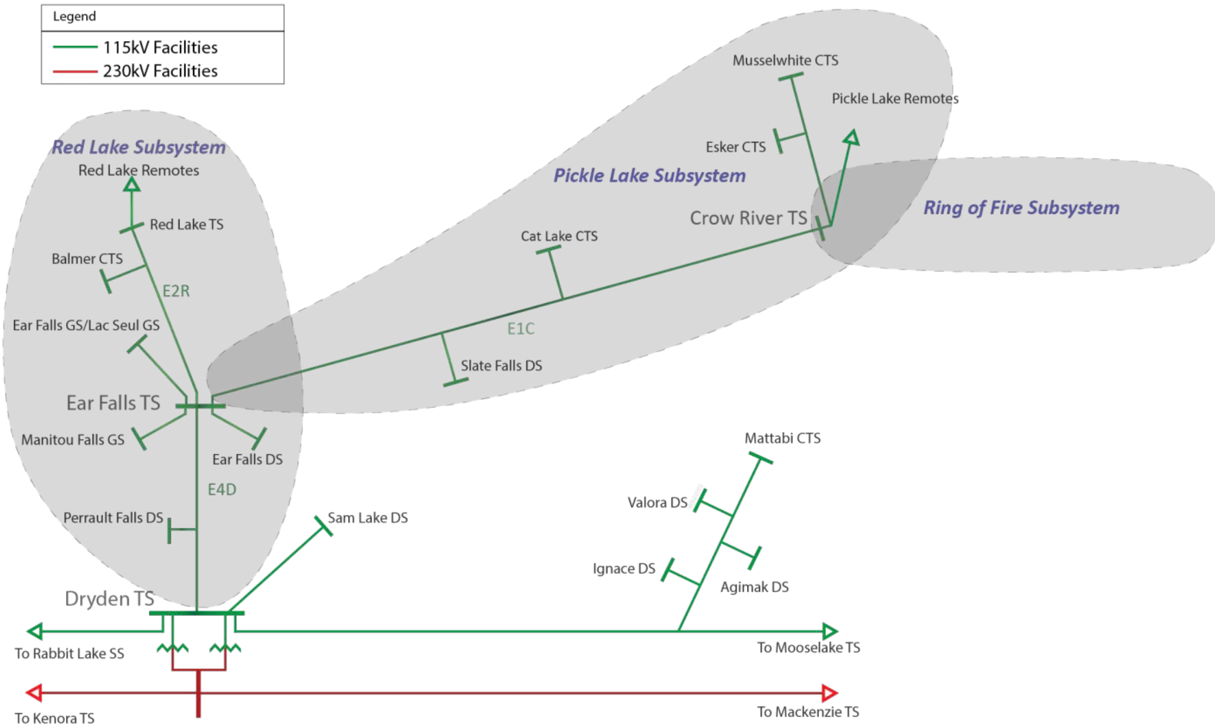
[20] Includes LMC required to supply remote communities that are economic to connect.

6.2 Interdependence between Subsystems

Due to the existing connection of the Pickle Lake subsystem to the Red Lake subsystem at Ear Falls, there is an existing interdependency between these subsystems. Identifying the interrelationships between subsystems is necessary because the supplying subsystem will need to have sufficient capacity to serve the needs of both subsystems. If the Pickle Lake subsystem is supplied completely by a new dedicated transmission connection, then it would be possible (and advantageous during drought conditions) to open the connection between Pickle Lake and Ear Falls (on E1C) and remove this interdependency.

Further, if the Pickle Lake subsystem has sufficient capacity in the future and the Ring of Fire subsystem is connected to Pickle Lake, then a new interdependency between the Pickle Lake and Ring of Fire subsystems would be created. These relationships are highlighted on the map below in Figure 14, which shows the amount of load in the dependent subsystem that is or would be served from the supplying subsystem. The ultimate capacity needed in the Red Lake and Pickle Lake subsystems will depend on the how the Pickle Lake and Ring of Fire subsystems are supplied in the future.

Figure 14: North of Dryden Subsystems and Points of Intersection



51

7 OPTIONS AND ALTERNATIVE DEVELOPMENT

This section identifies and evaluates options for developing integrated solutions that meet the needs identified in Section 6. Options applicable for all subsystems are described first, subsystem-specific options are then discussed. The options for the Pickle Lake subsystem are then evaluated,[21] followed by those of the Red Lake subsystem and the Ring of Fire subsystem. The options for addressing the needs of the North of Dryden sub-region are divided into those that can meet near-term needs (present-2018) and those which can meet the medium- and long-term needs (2019-2033) for each subsystem. Technically viable options are identified and evaluated in the context of their ability to meet the needs of each subsystem based on cost,[22] ability to meet reliability criteria, incremental capacity enabled, and in-service date.

7.1 Conservation, Renewable and Distributed Generation

Opportunities for Further Cost Effective Conservation in the North of Dryden sub-region

Conservation is important in managing the demand in the North of Dryden sub-region. However, the high levels of load growth anticipated for the sub-region, resulting from connection of new industrial customers and the remote communities require the incorporation of supply-side solutions such as new transmission, distribution and/or generation facilities in the near term. New industrial facilities are assumed to install relatively efficient equipment from the beginning given the inherent economic benefits and the improved codes and standards.

[21] The Pickle Lake subsystem is assessed first because of its interdependence with both Red Lake and Ring of Fire subsystems. Decisions for serving the Pickle Lake subsystem will impact the capacity needs for the Red Lake subsystem and available options for the Ring of Fire subsystem.

[22] The costs represented in this report are incremental to costs that would have otherwise been incurred for the overall Ontario power system generation capacity needs. The Ontario electricity system will require incremental generation capacity to reliably serve all Ontario customers during peak demand periods by about 2018. Generation resources developed in the North of Dryden sub-region would contribute to meeting this provincial need. Cost for generation in the North of Dryden area is represented as the incremental cost above the least-cost generation option for Ontario. Details of costing methodology can be found in Appendix 10.4.

The OPA evaluates, measures and verifies ("EM&V") conservation program savings. Moving forward, the OPA will continue to monitor conservation achievement in the North of Dryden sub-region and look for opportunities for further cost effective conservation to address supply capacity needs of the area over the medium and long term.

In Achieving Balance: Ontario's Long-Term Energy Plan ("LTEP 2013"), the government established a provincial Conservation and Demand Management ("CDM") target of 30 TWh in 2032. To assist the government in achieving this target, LTEP 2013 also committed to establishing a new six-year Conservation First Framework beginning in January 2015. Meeting these targets was included in establishing the needs described in Section 6. These targets apply to currently grid-connected communities and customers. The Conservation included in the net demand forecast for each subsystem is provided in Table 6 below. For remote communities, conservation opportunities are considered in more detail in the Remote Community Connection Plan.

Table 6: Forecasted Conservation Savings in North of Dryden Sub-Region

	2014	2019	2024	2029	2033
Pickle Lake Subsystem	0.1 MW	0.5 MW	1.2 MW	2.0 MW	2.6 MW
Red Lake Subsystem	0.2 MW	1.1 MW	2.6 MW	4.0 MW	5.3 MW
Ring of Fire Subsystem	0.0 MW	0.2 MW	0.4 MW	0.7 MW	0.9 MW

It is anticipated that the energy efficiency savings identified in Table 6 above will be achieved mainly through measures aimed at the current load base and the load added through connection of the remote communities. The 9 MW in reduced peak demand represents about a 7% reduction of load in this area. The additional mining load is expected to be built using current codes and standards and will be operating at better energy efficiency compared to older facilities. Thus it is not anticipated that the new mining load will be able to contribute much more to energy efficiency programs. Conservation forecast in the region is derived from the provincial target and is consistent with LTEP 2013.

Given the anticipated electricity demand growth, there are opportunities in the medium to long term for proponents to pursue conservation savings. The following tools and programs could be used to achieve conservation savings in the sub-region.

Recently, the OPA has received direction from the Minister of Energy pertaining to the framework for Conservation programs[23] moving forward:

1. *2015-2020 Conservation First Framework (March 31, 2014):* To remain on track to achieve Ontario's 2013 LTEP CDM target, it is forecasted that 7 TWh needs to be achieved between 2015 and 2020 through Distributor CDM programs enabled by the Conservation First Framework. In addition, transmission-connected customers will continue to have access to OPA CDM programs. The OPA is directed to coordinate, support and fund the delivery of CDM programs through Distributors to achieve a total of 7 TWh of reductions in electricity consumption between January 1, 2015 and December 31, 2020.

2. *Continuance of the OPA's Demand Response Program under IESO management (March 31, 2014):* In LTEP 2013, Ontario signaled that responsibility for existing demand response ("DR") initiatives and introduction of new DR initiatives will be transferred from the OPA to the IESO.

3. *Industrial Accelerator Program (July 25, 2014):* The 5-year Industrial Accelerator Program ("IAP") established through the March 4, 2010 ministerial direction, will conclude on June 23, 2015. The Minister has directed the OPA to deliver the IAP for the period commencing June 23, 2015 through December 31, 2020, with a CDM target of 1.7 TWh for the period.

The spirit of the directive is to provide more opportunity for Local Distribution Companies ("LDCs"), industry, and communities to participate in conservation initiatives

[23] The current framework for Conservation programs does not apply to remote communities. These communities are anticipated for connection post-2020, which is the end of the existing framework.

so a broader scope of programs is expected to be tailored to the local needs of the region.

Each LDC will develop their conservation plans and programs to demonstrate. In assisting LDCs, the OPA has launched an online Tool Kit to provide LDCs with the information and planning resources needed to design an effective CDM plan to serve their customers. One of these resources is the Regional Achievable Potential Calculator which assists the utilities in estimating potential Conservation savings in their service regions. Use of this tool can also achieve an understanding of the potential for further conservation specific to the North of Dryden sub-region.

The IAP is available to industrial customers as a means of achieving conservation savings with financial assistance from the OPA. Given that electricity demand of the industrial sector is significant in the area, this could be a good opportunity for conservation in the sub-region. Also, the IAP program expanded the eligibility to allow commercial and institutional customers. These customers can be directly connected to the grid or connected via an LDC.

Furthermore, the following programs are available to Aboriginal Communities:

- Aboriginal Conservation Program, with the aim to provide customized conservation services designed to help First Nation communities, including remote and northern communities, reduce their electricity use in residential housing, and in commercial and institutional buildings, like stores, schools and band offices. This program will be offered for one additional year (ending December 31, 2015) until such time as LDCs are able to develop a CDM program which recognizes the specific requirements of on-reserve First Nation communities as per the 2015-2020 Conservation First Framework Directive.

- Aboriginal Community Energy Plans program to support Aboriginal participation in Ontario’s energy sector by providing up to $90,000 per community in funding to First Nation or Métis communities for local energy planning activities, with remote communities being eligible for an additional $5,000.

Opportunities for Renewable and Distributed Generation in the North of Dryden sub-region

A high level assessment of the cost of renewable and distributed generation resources to meet the capacity needs of the North of Dryden sub-region was completed, estimating the dependable capacity of hydroelectric (run of river), wind, and solar resources. Dependable capacity refers to the portion of the total installed capacity that can be relied upon to meet local or system peak capacity needs. This refers to 98-percentile output. Based on the dependable capacity, costs were developed for these renewable resources. Based on the cost of other local generation and transmission options that are discussed in the following sub-sections, run of river hydroelectric, wind, and solar are not cost effective solutions for meeting the needs of the North of Dryden sub-region in the near and medium-term periods.

Details of these alternative generation resources are provided in Appendix 10.3.2 and summarized below in Table 7.

Table 7: Summary of Alternative Generation Options

Resource Type	Dependable Capacity	Capital Cost per MW of Dependable Capacity	Levelized Unit Energy Cost[24]	Development Duration
Hydroelectric (Run of River)	15-30%	$16 M-$66 M /MW	$60-$110/MWh	5 to 10 Years
Intermittent Renewables	5-28%	$7.5 M -$100M /MW	$80-$400/MWh	3 Years

While run of river hydroelectric or renewable resources are not cost-effective to meet the North of Dryden sub-region peak capacity needs, there may be opportunity for proponents to develop such projects for broader Ontario supply needs in accordance

[24] Levelized Unit Energy Cost (LUEC) is a method to compare electricity system resources on a $/MWh basis, considering the costs incurred (capital, fixed, variable, fuel, etc.) and the production of energy over the lifetime of the resource, discounted appropriately. LUEC assumes that all energy generated can be delivered without transmission constraints.

with renewable policy objectives for the provincial supply mix as set in the 2013 LTEP. Additionally, the connection of remote communities may provide the opportunity to explore development opportunities in the far north, in the longer term.

The remainder of Section 7 will assess the generation and transmission options that can cost effectively meet the identified capacity needs of the North of Dryden sub-region.

7.2 Summary of Recommended and Assessed Options for Meeting Pickle Lake Subsystem Needs

Based on the following analysis, the OPA recommends that a new 230 kV single circuit line to Pickle Lake be built as soon as possible in order to meet the needs of the Pickle Lake subsystem. Building the new line to 230 kV standards is the most economic option to meet the reference forecast scenario, which is regarded as the most-likely scenario. A line built to 230 kV standards also mitigates the long-term risk associated with higher forecasted demand scenarios and maintains the flexibility to supply the Ring of Fire mining development from Pickle Lake. The OPA also recommends that circuit E1C be opened at Ear Falls as an operational measure when the local system is capacity constrained. This operational measure maximizes the capability of the transmission system in the area, resulting in incremental LMC to the Red Lake subsystem. The capacity constraint is expected to occur during high demand periods coincident with drought hydroelectric conditions.

The following section summarizes the analysis and comparison of options.

Within the context of the North of Dryden IRRP, the Pickle Lake subsystem is assessed first because of its interdependence with both the Red Lake subsystem and the Ring of Fire subsystem as discussed in Section 5.2. Decisions made for serving the Pickle Lake subsystem will impact the capacity needs for the Red Lake subsystem at Ear Falls TS and the options for serving the Ring of Fire subsystem.

As mentioned previously, the Pickle Lake subsystem is currently supplied by the 115 kV line E1C from Ear Falls TS and the subsystem has reached its LMC. The forecasted near-term growth and medium- to long-term growth cannot be met by the existing system and other supply options are required. Identified needs for the Pickle Lake subsystem are summarized in Table 8, below.

Table 8: Needs for Pickle Lake Subsystem

Timing	Needs	Required Load Meeting Capability [MW]		
		Low	Reference	High
Near term (Present-2018)	***Near term Total 1:*** *Supply Mining and Community Demand in the Pickle Lake Subsystem, and Supply the 5 Communities in the Ring of Fire Subsystem*	***43***	***46***	***48***
	Near term Total 2: *Supply Mining and Community Demand in the Pickle Lake Subsystem and in the Ring of Fire Subsystem*	***43***	***64***	***66***
Medium and long term (2019-2033)	***Medium and long term Total 1:*** *Supply Mining and Community Demand in the Pickle Lake Subsystem, and Supply the 5 Communities in the Ring of Fire Subsystem*	***48***	***78***	***90***
	Medium and long term Total 2: *Supply Mining and Community Demand in the Pickle Lake Subsystem and in the Ring of Fire Subsystem*	***48***	***100***	***156***

The following generation and transmission options have been identified to fully or partially meet these needs.

Table 9: Summary of Options to Meet the Needs for Pickle Lake Subsystem[25]

Options	Capital Cost	PV Option Cost	Incremental Load Meeting Capability [MW]	PV Unit Cost of Utilized Capacity
CNG Generation at Pickle Lake[26,27]	$132 M	$294 M	54	$5.44 M/MW
115 kV line to Pickle Lake[28]	$126 M	$80 M	18 + 35	$1.31 M/MW
230 kV line to Pickle Lake[18]	$167 M	$106 M	54 + 35[29]	$1.07 M/MW
Pre-build 230 kV line to Pickle Lake, Stage 1: operate at 115 kV[18] Stage 2: upgrade to 230 kV	$155 M $14 M	$98 M $5 M	46 + 35 114	$1.08 M/MW $0.63 M/MW

The 115 kV transmission line option would not be adequate to meet the needs of the Pickle Lake subsystem, with or without the Ring of Fire mining load supplied from Pickle Lake under the reference scenario forecasted load. The reference scenario forecast is considered the most likely scenario. The only scenario assessed that the 115 kV transmission line option would be adequate for the long term is the low scenario. The reference and high scenarios with and without the Ring of Fire mining load supplied from Pickle Lake would require a new 230 kV line.

Based on the following factors, the OPA recommends that a single circuit 230 kV line be developed as soon as possible:

- There is currently insufficient capacity to supply existing electrical demand; and
- A 115 kV line is insufficient to meet the reference scenario forecast demand, which is considered most likely, and therefore there is material risk in not meeting the long-term demand of the Pickle Lake subsystem with a 115 kV line; and

[25] Description of the method for calculating costs is provided in Appendix 10.7.1 and 0. Note all costs include reactive compensation required to meet stated LMC.
[26] Requires continued supply of 24 MW of load via E1C from Ear Falls TS
[27] Generation could be developed in 2-3 years
[28] Transmission options cannot be developed before 2016
[29] 35 MW are in the Red Lake subsystem. System is voltage limited and can reach a higher LMC with additional reactive compensation. Costing does not include reactive compensation required to supply Ring of Fire.

- A 230 kV line to Pickle Lake is required to preserve the option of supplying the Ring of Fire utilizing an East-West corridor; and
- An East-West infrastructure corridor to the Ring of Fire continues to be a viable option being considered by mining developers.

Decisions made regarding a common infrastructure corridor (e.g. transportation, etc.) to the Ring of Fire should be monitored and reflected in updates to this IRRP.

7.2.1 **Discussion of Options to Meet the Needs of the Pickle Lake Subsystem**

Both generation and transmission options are considered for meeting the needs of the Pickle Lake subsystem. In developing these options, the economic connection of remote communities and maintaining supply options to the Ring of Fire are key planning factors.

The five remote communities in the Ring of Fire subsystem have been determined to be economic to connect in accordance with the conclusions of the Remote Community Connection Plan. The lowest cost transmission connection option for the five remote communities in the Ring of Fire subsystem, independent of the Ring of Fire mines, is to connect to Pickle Lake. Therefore, for the purposes of the IRRP, sufficient capacity would need to be made available in the Pickle Lake subsystem to connect up to five remote communities in the Ring of Fire subsystem as a minimum. Given the uncertainty around other infrastructure development plans for the Ring of Fire area, there is also long-term value in maintaining the option for Ring of Fire mines to connect at Pickle Lake. This connection could be realized utilizing an East-West multi-use corridor, which is being promoted by some mining developers in the area. Details are discussed in the following sections.

7.2.1.1 Reference Scenario Options Analysis for Pickle Lake Subsystem and Connection of Communities in the Ring of Fire Subsystem

From Table 8, this scenario requires an LMC of 46 MW for the near term, and 78 MW for the medium and long term.

Generation Options

There is no existing supply of natural gas in the Pickle Lake subsystem and the OPA is not aware of any plan to expand natural gas pipeline service to Pickle Lake. However, generators fueled by Compressed Natural Gas (“CNG”) could be developed in the Pickle Lake area, as CNG could be produced and transported from the TransCanada Pipelines Limited (“TCPL” or “TransCanada”) mainline near Ignace to Pickle Lake along Highway 599 and beyond as needed. The cost of developing a CNG production facility at Ignace and transporting CNG from Ignace to Pickle Lake is significant and results in a much higher delivered cost of natural gas than in areas that are served by natural gas pipelines, such as Red Lake. To minimize generation costs in this option, it is assumed that the Pickle Lake subsystem will remain connected to Ear Falls TS and 24 MW of load in the Pickle Lake subsystem will continue to be served from Ear Falls TS.

The remaining 22 MW of LMC for the near term and 54 MW of LMC for the medium and long term (which includes the remote communities in the Ring of Fire subsystem), would be served by CNG fueled generation at Pickle Lake.

To make available 22 MW of incremental LMC in the Pickle Lake subsystem with local generation, a total installed generation capacity of 47.5 MW would be required with a maximum unit size of 9.5 MW (i.e. 5x9.5 MW). Similarly, to make available 54 MW of incremental LMC in the Pickle Lake subsystem with local generation, a total installed generation capacity of 76 MW would be required with a maximum unit size of 9.5 MW (i.e. 8x9.5 MW).

This arrangement of units would ensure that load could be supplied with up to two units unavailable by either forced or planned outages, while maintaining flows on E1C and at Ear Falls TS within thermal and voltage limits consistent with requirements outlined in ORTAC. Table 10 summarizes the gas generation capacity required and the increase in the Pickle Lake LMC it will provide.

Table 10: Capacity of Generation Option

Option	Incremental LMC [MW]	Pickle Lake Subsystem LMC [MW]	Near term Reference Forecast Demand[30] [MW]	Medium and Long term Reference Forecast Demand[20] [MW]
Near term: 47.5 MW CNG Generation at Pickle Lake[31]	28.5	52.5	46	78
Medium and Long term 76 MW CNG Generation at Pickle Lake[21]	57	81	46	78

The cost (summarized in Table 11) of supplying the growth needs of the Pickle Lake subsystem with CNG fueled generation includes any additional required voltage control devices at Pickle Lake.

Table 11: Costs and Timing for Generation Option

Option	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
47.5 MW CNG Generation at Pickle Lake	1-2 Years	$75 M	$158 M	$6.59 M/MW
76 MW CNG Generation at Pickle Lake[32]	1-2 Years	$132 M	$294 M	$5.44 M/MW

Generation resources in the Pickle Lake subsystem would be operated to serve local demand in the Pickle Lake subsystem in the event that load exceeds 24 MW and would likely not be dispatched in the Ontario market for supplying provincial system load due to relatively high cost of operation. At present the Ontario system has sufficient generation capacity to meet system peak and energy needs; however, by 2018 a need for additional peak capacity is forecasted. Local generation at Pickle Lake would serve demand that would otherwise be served by generation somewhere else in the system and would help to offset some of this Ontario system need.

Transmission Options

[30] Includes demand for Ring of Fire remote communities (7 MW).
[31] Requires continued supply of 24 MW of load via E1C from Ear Falls TS.
[32] Size is cumulative.

The OPA has identified three transmission options for reinforcing the supply to the Pickle Lake area.

The transmission options are:

1. A new 115 kV single circuit line tapping the 115 kV line 29M1 near Valora with an in-line breaker on the tap line and terminating at Crow River DS in Pickle Lake.

2. A new 230 kV single circuit line tapping D26A east of Dryden with an in-line breaker on the tap line and running to Pickle Lake terminating at Crow River DS or a new TS in the Pickle Lake area with a new 230/115 kV autotransformer.

3. A new single circuit line pre-built to 230 kV standards (230 kV structures, and hardware) and initially operated at 115 kV by connecting it to M2D on the 115 kV system near Dryden with an in-line breaker on the tap line. When additional capacity is required the line would be operated at 230 kV by re-terminating on the 230 kV system near Dryden (D26A) and a 230/115 kV autotransformer would be installed at Pickle Lake.

The 230 kV line options, Options 2 or 3, are capable of supplying the reference scenario forecasted demand for the Pickle Lake subsystem including the five remote communities in the Ring of Fire subsystem until the end of the planning period.

The 115 kV line option is capable of supplying the Pickle Lake subsystem, including the five remote communities in the Ring of Fire subsystem up to a demand of 70 MW, which is the LMC of the option. This corresponds to year 2030 for the reference scenario forecasted demand.

By opening E1C at Ear Falls TS, the Red Lake subsystem no longer supplies the Pickle Lake subsystem. Under this arrangement the capacity that was allocated to the Pickle Lake subsystem (24 MW, which corresponds to 35 MW at Ear Falls due to losses), is offloaded. In other words, a new line to Pickle Lake also provides 35 MW of incremental LMC to the Red Lake subsystem. This occurs because the new line would serve the entire load along E1C. This benefit must be accounted for in the analysis.

Details of these options have been summarized in Table 12 and Table 13 below.

Table 12: Capacity of Transmission Options

Transmission Options	Incremental LMC for Pickle Lake Subsystem [MW]	Incremental LMC for Red Lake Subsystem [MW]	Total Incremental LMC for Option [MW]	Pickle Lake Subsystem Load Meeting Capability [MW]	Pickle Lake Subsystem Near term Reference Forecast Demand[33] [MW]	Pickle Lake Subsystem Medium and Long term Reference Forecast Demand[33] [MW]
115 kV line to Pickle Lake[34]	46	35	81	70	46	78
230 kV line to Pickle Lake[35]	136	35	171	160	46	78
Pre-build 230 kV line to Pickle Lake[35] Stage 1: operate at 115 kV Stage 2: upgrade to 230 kV[35]	 46 136	 35 35	 81 171	 70 160	46	78

[33] Includes demand for Ring of Fire remote communities (7 MW).
[34] Transmission options cannot be developed before 2016.
[35] Upgrade completed in 2023 when three Ring of Fire mines are forecast to be operating

To serve the forecasted electrical demand of the reference scenario to the end of the planning period, without any additional investments, transmission options 2 or 3, a new 230 kV single circuit line to Pickle Lake would be required.

Transmission Option 1, a 115 kV single circuit line to Pickle Lake is insufficient to meet the identified needs of the Pickle Lake subsystem, including connection of up to five remote communities in the Ring of Fire subsystem, for the reference forecast scenario beyond 2030. The reference forecast scenario load exceeds the LMC of a 115 kV single circuit line by 8 MW at the end of the planning period, in 2033.

The OPA recommends that the new line be operated at 230 kV from the onset. Deferring 230 kV operation to when the incremental capacity is required for load supply is not expected to incur any cost savings relative to initially operating at 230 kV. This is due to the fact that some additional voltage control equipment required for 115 kV operation would no longer be required after converting the line to 230 kV operation. This results in a stranded cost which is approximately equal to the deferral value.

Transmission Option 3 is the development of a 230 kV line that is staged to provide additional capacity with deferral of some capital cost to when and if the capacity is needed. This would be done by pre-building the line to 230 kV specifications but initially operating it at 115 kV. When additional capacity is required the line would be reterminated on the bulk 230 kV system on circuit D26A and a 230/115 kV autotransformer would be installed either at Crow River DS or at a new TS in Pickle Lake. As indicated above, this option is not expected to result in any relative savings compared to Transmission Option 2.

In order to properly compare costs of transmission options (which also provide incremental capacity to the Red Lake subsystem) to generation options (which do not provide incremental capacity to the Red Lake subsystem) the unit costs consider the total incremental LMC for both the Pickle Lake and Red Lake subsystems that is made available by the option. Table 13 provides a summary of costs and timing for these options.

Table 13: Costs and Timing of Transmission Options

	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
115 kV line to Pickle Lake	Not technically feasible			
230 kV line to Pickle Lake	3-5 Years	$167 M	$106 M	$1.07 M/MW
Pre-build 230 kV line to Pickle Lake Stage 1: operate at 115 kV Stage 2: upgrade to 230 kV[36]	 3-5 Years 1-2 Years	 $155 M $14 M	 $98 M $5 M	 $1.08 M/MW $0.63 M/MW

From the above tables, the following conclusions can be made for the forecasted load under the reference scenario *with the Ring of Fire subsystem communities supplied from Pickle Lake*:

1. A line built to 115 kV standards would be insufficient to meet the medium- and long-term need.
2. A line pre-built to 230 kV standards with staged 115 kV and 230 kV operation is approximately as cost effective as initially operating at 230 kV. While cost is the same, initially operating at 115 kV will require the installation of voltage control devices that will no longer be useful when the line operates at 230 kV.
3. A line built and initially operated at 230 kV is also a cost effective option that meets the medium- and long-term need, and will not result in stranding of transmission devices. This is the recommended solution option.

7.2.1.2 Reference Scenario Options Analysis for Pickle Lake Subsystem and Connection of Mines and Communities in the Ring of Fire Subsystem to Pickle Lake

The Ring of Fire subsystem reference forecasted load from mines and communities is 22 MW in the near term and 29 MW in the medium and long term. Options to supply the Ring of Fire subsystem mines include on-site generation consistent with the Environmental Assessment cases for the mining developments, as well as building a new transmission line utilizing a North-South corridor and originating from either

[36] Upgrade assumed to be completed in 2023 when three Ring of Fire mines are forecast to be operating.

Marathon or east of Nipigon, or utilizing an East-West corridor originating from Pickle Lake. Detailed analysis of these options is included in 7.4. As indicated in 6.2, if the Ring of Fire subsystem is supplied from Pickle Lake utilizing an East-West corridor, interdependency between the Pickle Lake subsystem and the Ring of Fire subsystem is introduced.

The following assesses the requirements for supply to the Pickle Lake subsystem under the reference forecast scenario if the mines and communities in the Ring of Fire subsystem are supplied from Pickle Lake. The corresponding LMC required for the Pickle Lake subsystem under this reference scenario is 64 MW in the near term and 100 MW in the medium and long term as indicated by the reference scenario "*Total 2*" in Table 8.

Generation Options

Generation options from the Pickle Lake subsystem to supply Ring of Fire mining load were screened out as they are less cost effective than self-generation options at the mining sites within the Ring of Fire subsystem to supply Ring of Fire mining load (which is investigated in 7.4). Therefore, only transmission options are investigated for this scenario.

Transmission Options

The LMC and costs for the respective transmission options are repeated below:

Table 14: Capacity of Transmission Options

Option	Incremental LMC for Pickle Lake Subsystem[1] [MW]	Incremental LMC for Red Lake Subsystem [MW]	Total Incremental LMC for Option [MW]	Pickle Lake Subsystem Load Meeting Capability[37] [MW]	Pickle Lake Subsystem Near term Reference Forecast Demand[27] [MW]	Pickle Lake Subsystem Medium and Long term Reference Forecast Demand[27] [MW]
115 kV line to Pickle Lake[38]	46	35	81	70	64	100
230 kV line to Pickle Lake[28]	136	35	171	160	64	100
Pre-build 230 kV line to Pickle Lake[28] Stage 1: operate at 115 kV Stage 2: upgrade to 230 kV[39]	46 136	35 35	81 171	70 160	64	100

[37] Includes Ring of Fire subsystem.
[38] Transmission options cannot be developed before 2016.
[39] Upgrade assumed to be completed in 2023 when three Ring of Fire mines are forecast to be operating.

Table 15: Costs and Timing of Transmission Options

Option	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
115 kV line to Pickle Lake[40]	Not technically feasible			
230 kV line to Pickle Lake	3-5 Years	$167 M	$106 M	$1.07 M/MW
Pre-build 230 kV line to Pickle Lake Stage 1: operate at 115 kV Stage 2: upgrade to 230 kV[41]	 3-5 Years 1-2 Years	 $155 M $14 M	 $98 M $5 M	 $1.08 M/MW $0.63 M/MW

From the above tables, and consistent with the analysis in 7.2.1.1, the following conclusions can be made for the forecasted load under the reference scenario *with the Ring of Fire subsystem supplied from Pickle Lake*, including the community and mining load:

1. A line built to 115 kV standards would be insufficient to meet the medium- and long-term need.
2. A line pre-built to 230 kV standards with staged 115 kV and 230 kV operation is the approximately as cost effective as initially operating at 230 kV. While cost is the same, initially operating at 115 kV will require the installation of voltage control devices that will no longer be useful when the line operates at 230 kV.
3. A line built and initially operated at 230 kV is also a cost effective option that meets the medium- and long-term need, and will not result in stranding of transmission devices. This is the recommended solution.

This analysis reinforces the need to build a new 230 kV line to Pickle Lake, rather than a new 115 kV line.

7.2.1.3 Low Scenario Options Analysis for Pickle Lake Subsystem and Connection of Communities in the Ring of Fire Subsystem

Under the low scenario forecasted load, the LMC required is 43 MW for the near term, and 48 MW for the medium and long term as indicated by the low scenario "*Total 1*" in Table 8.

---

40 Sufficient for near term, insufficient for medium to long term.
41 Upgrade assumed to be completed in 2023 when three Ring of Fire mines are forecast to be operating.

Sensitivity Analysis for Generation Options

Similarly to what was done with the Reference Scenario analysis, in order to minimize generation cost, it is assumed that 24 MW of load in the Pickle Lake subsystem will continue to be served by the Red Lake subsystem from Ear Falls TS via the circuit E1C.

The remaining 19 MW of LMC for the near term and 24 MW of LMC for the medium and long term (which includes the remote communities in the Ring of Fire subsystem), would be served by CNG fueled generation at Pickle Lake.

To make available 19 MW or 24 MW of incremental LMC in the Pickle Lake subsystem with local generation, a total generation capacity of 38 MW and 47.5 MW would be required, respectively, with a maximum unit size of 9.5 MW (i.e. 4x9.5 MW and 5x9.5 MW).

Table 16: Capacity of Generation Option

Option	Incremental LMC [MW]	Pickle Lake Subsystem LMC [MW]	Near term Low Forecast Demand[42] [MW]	Medium and Long term Low Forecast Demand[32] [MW]
Near term: 38 MW CNG Generation at Pickle Lake[43]	19	43	43	48
Medium and Long term 47.5 MW CNG Generation at Pickle Lake[33]	28.5	52.5	43	48

Table 17: Costs and Timing for Generation Option

Option	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
38 MW CNG Generation at Pickle Lake	1-2 Years	$57 M	$131 M	$6.89 M/MW
47.5 MW CNG Generation at Pickle Lake	1-2 Years	$75 M	$158 M	$6.59 M/MW

[42] Includes demand for Ring of Fire remote communities (7 MW).
[43] Requires continued supply of 24 MW of load via E1C from Ear Falls TS.

Based on the low forecast demand scenario, the initial near-term generation option does not change. However, less capacity is needed to meet the medium- and long-term needs compared to the reference scenario.

Sensitivity Analysis for Transmission Options

Under the low forecast scenario, the LMC required for the Pickle Lake subsystem is 43 MW in the near term and 48 MW for the medium and long term. Consistent with the reference scenario, building a new line to Pickle Lake allows for a capacity increase to the Red Lake subsystem of 35 MW by opening circuit E1C from Ear Falls during capacity-constrained conditions, where peak demand is coincident with drought hydroelectric generation output.

In order to supply 43 MW in the near term and 48 MW in the medium and long term, a new line to Pickle Lake at 115 kV would be required as a minimum and would be the most economic. It should be noted that the low scenario forecast is the only scenario that the 115 kV line option is feasible; the 115 kV line option is not feasible for all other demand scenarios.

Table 18: Capacity of Transmission Options

Option	Incremental LMC for Pickle Lake Subsystem [MW]	Incremental LMC for Red Lake Subsystem [MW]	Total Incremental LMC for Option [MW]	Pickle Lake Subsystem Load Meeting Capability [MW]	Pickle Lake Subsystem Near term Low Forecast Demand[44] [MW]	Pickle Lake Subsystem Medium and Long term Low Forecast Demand[34] [MW]
115 kV line to Pickle Lake[45]	46	35	81	70	37	41
230 kV line to Pickle Lake[35]	136	35	171	160	37	41
Pre-build 230 kV line to Pickle Lake[35] Stage 1: operate at 115 kV Stage 2: upgrade to 230 kV[46]	46 136	35 35	81 171	70 160	37	41

[44] Includes demand for Ring of Fire remote communities (7 MW).
[45] Transmission options cannot be developed before 2016.
[46] Upgrade assumed to be completed in 2023 when three Ring of Fire mines are forecast to be operating.

Table 19: Costs and Timing of Transmission Options

Option	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
115 kV line to Pickle Lake	3-5 Years	$126 M	$80 M	$1.31 M/MW
230 kV line to Pickle Lake	3-5 Years	$167 M	$106 M	$2.12 M/MW
Pre-build 230 kV line to Pickle Lake Stage 1: operate at 115 kV[47]	3-5 Years	$155 M	$98 M	$1.85 M/MW

7.2.1.4 Low Scenario Options Analysis for Pickle Lake Subsystem and Connection of Mines and Communities in the Ring of Fire Subsystem to Pickle Lake

The low scenario does not include any additional load within the planning period from the Ring of Fire area mines compared to 7.2.1.3 and therefore this scenario is identical to 7.2.1.3 and not considered further.

7.2.1.5 High Scenario Options Analysis for Pickle Lake Subsystem and Connection of Communities in the Ring of Fire Subsystem

Under the high scenario forecasted load, the LMC required is 48 MW for the near term, and 90 MW for the medium and long term as indicated by the high scenario "*Total 1*" in Table 8.

Sensitivity Analysis for Generation Options

Similarly to what was done with the Reference Scenario analysis, in order to minimize generation cost, it is assumed that 24 MW of load in the Pickle Lake subsystem will continue to be served by the Red Lake subsystem from Ear Falls TS via the circuit E1C.

[47] Stage 2 would not be required for the low forecast scenario without the Ring of Fire

The remaining 24 MW of LMC for the near term and 66 MW of LMC for the medium and long term (which includes the remote communities in the Ring of Fire subsystem), would be served by CNG fueled generation at Pickle Lake.

To make available 24 MW of incremental LMC in the Pickle Lake subsystem with local generation, a total generation capacity of 47.5 MW would be required in the near term with a maximum unit size of 9.5 MW (i.e. 5x9.5 MW). To make available 66 MW of incremental LMC in the Pickle Lake subsystem with local generation, a total generation capacity of 85.5 MW would be required in the near term with a maximum unit size of 9.5 MW (i.e. 9x9.5 MW).

Table 20: Capacity of Generation Option

Option	Incremental LMC [MW]	Pickle Lake Subsystem LMC [MW]	Near term High Forecast Demand[48] [MW]	Medium and Long term High Forecast Demand[38] [MW]
Near term: 47.5 MW CNG Generation at Pickle Lake[49]	28.5	52.5	48	90
Medium and Long term: 85.5 MW CNG Generation at Pickle Lake[39]	66.5	90.5	48	90

Table 21: Costs and Timing for Generation Option

Option	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
47.5 MW CNG Generation at Pickle Lake	1-2 Years	$75 M	$158 M	$6.59 M/MW
85.5 MW CNG Generation at Pickle Lake	1-2 Years	$140 M	$317 M	$4.80 M/MW

[48] Includes demand for Ring of Fire remote communities (7 MW).
[49] Requires continued supply of 24 MW of load via E1C from Ear Falls TS.

Sensitivity Analysis for Transmission Options

Under the high forecast scenario, the LMC required for the Pickle Lake subsystem is 48 MW in the near term and 90 MW for the medium and long term. Consistent with the reference scenario, building a new line to Pickle Lake allows for a capacity increase to the Red Lake subsystem of 35 MW by opening circuit E1C from Ear Falls during capacity-constrained conditions, where peak demand is coincident with drought hydroelectric generation output.

In order to supply 48 MW in the near term and 90 MW in the medium and long term, a new line to Pickle Lake built to 230 kV standards would be required.

Table 22: Capacity of Transmission Options

Option	Incremental LMC for Pickle Lake Subsystem [MW]	Incremental LMC for Red Lake Subsystem [MW]	Total Incremental LMC for Option [MW]	Pickle Lake Subsystem Load Meeting Capability [MW]	Pickle Lake Subsystem Near term High Forecast Demand[50] [MW]	Pickle Lake Subsystem Medium and Long term High Forecast Demand[1] [MW]
115 kV line to Pickle Lake[51]	46	35	81	70	48	90
230 kV line to Pickle Lake[41]	136	35	171	160	48	90
Pre-build 230 kV line to Pickle Lake[41] Stage 1: operate at 115 kV Stage 2: upgrade to 230 kV[52]	46 136	35 35	81 171	70 160	48	90

[50] Includes 7 MW of forecast demand for the remote communities in the Ring of Fire subsystem

[51] Transmission options cannot be developed before 2016

[52] Upgrade completed in 2023, when 3 Ring of Fire mines are forecast to be operating

Table 23: Costs and Timing of Transmission Options

Option	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
115 kV line to Pickle Lake	Not technically feasible			
230 kV line to Pickle Lake	3-5 Years	$180 M	$114 M	$1.20 M/MW
Pre-build 230 kV line to Pickle Lake Stage 1: operate at 115 kV Stage 2: upgrade to 230 kV[53]	 3-5 Years 1-2 Years	 $155 M $14 M	 $98 M $5 M	 $1.29 M/MW $0.25 M/MW

From the above tables, and consistent with the analysis for the reference scenario, the following conclusions can be made for the forecasted load under the high scenario *with the Ring of Fire subsystem communities supplied from Pickle Lake*:

1. A line built to 115 kV standards would be insufficient to meet the medium- and long-term need.
2. A line pre-built to 230 kV standards with staged 115 kV and 230 kV operation is approximately as cost effective as initially operating at 230 kV. While cost is about the same, initially operating at 115 kV will require the installation of voltage control devices that will no longer be useful when the line operates at 230 kV.
3. A line built and initially operated at 230 kV is also a cost effective option that meets the medium- and long-term need, and will not result in stranding of transmission devices. This is the recommended solution option.

7.2.1.6 High Scenario Options Analysis for Pickle Lake Subsystem and Connection of Mines and Communities in the Ring of Fire Subsystem to Pickle Lake

Under the high scenario forecasted load, the LMC required is 66 MW for the near term, and 156 MW for the medium and long term as indicated by the high scenario "*Total 2*" in Table 8.

---

53 Upgrade completed in 2023, when 3 Ring of Fire mines are forecast to be operating

Sensitivity Analysis for Generation Options

Consistent with the reference scenario analysis, generation options from the Pickle Lake subsystem to supply Ring of Fire mining load were screened out as they are less cost effective than generation options from the Ring of Fire subsystem to supply Ring of Fire mining load (which is investigated in 7.4). Therefore, only transmission options are investigated for this scenario.

Sensitivity Analysis for Transmission Options

In order to supply 66 MW in the near term and 156 MW in the medium and long term, a new line to Pickle Lake built to 230 kV standards would be required. This may be achieved by either Transmission Option 2 or Option 3.

Table 24: Capacity of Transmission Options

Option	Incremental LMC for Pickle Lake Subsystem [MW]	Incremental LMC for Red Lake Subsystem [MW]	Total Incremental LMC for Option [MW]	Pickle Lake Subsystem Load Meeting Capability [MW]	Pickle Lake Subsystem Near term High Forecast Demand[1] [MW]	Pickle Lake Subsystem Medium and Long term High Forecast Demand[1] [MW]
115 kV line to Pickle Lake[2]	46	35	81	70	66	156
230 kV line to Pickle Lake[2]	136	35	171	160	66	156
Pre-build 230 kV line to Pickle Lake[2] Stage 1: operate at 115 kV Stage 2: upgrade to 230 kV[3]	46 136	35 35	81 171	70 160	66	156

(1) Includes 7 MW of forecast demand for the remote communities in the Ring of Fire subsystem
(2) Transmission options cannot be developed before 2016
(3) Upgrade completed in 2023, when 3 Ring of Fire mines are forecast to be operating

Table 25: Costs and Timing of Transmission Options

Options	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
115 kV line to Pickle Lake	Not technically feasible			
230 kV line to Pickle Lake	3-5 Years	$180 M	$114 M	$1.20 M/MW
Pre-build 230 kV line to Pickle Lake Stage 1: operate at 115 kV Stage 2: upgrade to 230 kV[54]	 3-5 Years 1-2 Years	 $155 M $14 M	 $98 M $5 M	 $1.29 M/MW $0.25 M/MW

From the above tables, and consistent with the analysis for the reference scenario, the following conclusions can be made for the forecasted load under the high scenario *with the Ring of Fire subsystem supplied from Pickle Lake*, including the community and mining load:

1. A line built to 115 kV standards would be insufficient to meet the medium- and long-term need, and is only marginally sufficient to meet the near term need.
2. A line pre-built to 230 kV standards with staged 115 kV and 230 kV operation is approximately as cost effective as initially operating at 230 kV. While cost is the same, initially operating at 115 kV will require the installation of voltage control devices that will no longer be useful when the line operates at 230 kV.
3. A line built and initially operated at 230 kV is also a cost effective option that meets the medium-and long-term need, and will not result in stranding of transmission devices. This is the recommended solution option.

7.2.2 Pickle Lake Subsystem Recommended Solutions

The OPA recommends that a new 230 kV single circuit line to Pickle Lake be built as soon as possible in order to meet the needs of the Pickle Lake subsystem. Building the new line to 230 kV standards is the most economic option to meet the reference forecast scenario, which is regarded as the most-likely scenario, and mitigates the long-term risk associated with higher forecasted demand scenarios and maintains the flexibility to supply the Ring of Fire mining development from Pickle Lake. The OPA also recommends that circuit E1C be opened at Ear Falls as an operational measure when

[54] Upgrade completed in 2023, when 3 Ring of Fire mines are forecast to be operating

the local system is capacity-constrained. This operational measure maximizes the capability of the transmission system in the area, resulting in incremental LMC to the Red Lake subsystem. The capacity constraint is expected to occur during high demand coincident with drought hydroelectric conditions.

It is recommended that development work on a new 230 kV single circuit line to Pickle Lake is completed as soon as possible. The OPA understands that preliminary development work has been started by two First Nations-owned transmission development companies. This work was initiated after the project was identified as a priority transmission project in the Government of Ontario’s 2010 and 2013 Long-Term Energy Plans, and was identified for inclusion in future power system plans in the Minister of Energy’s 2011 SMD to the OPA.

Implementation of the new line to Pickle Lake continues to be supported by the OPA. The OPA is following the development process for the two development companies closely. The OPA expresses urgency in the need for a new 230 kV single circuit line to Pickle Lake and will support this project to obtain the necessary approvals as soon as possible.

7.3 Summary of Recommended and Assessed Options for Meeting Red Lake Subsystem Needs

The OPA recommends the upgrading of circuits E4D and E2R from a summer ampacity of 470 A to 660 A and 420 A to 610 A, respectively. The upgrading of E4D and E2R, in addition to a new line to Pickle Lake coupled with operating circuit E1C open at Ear Falls would provide an additional 70 MW of LMC, bringing the LMC for the Red Lake subsystem to 130 MW. The LMC of 130 MW meets the needs of the Red Lake subsystem for the long term for all the OPA’s forecast scenarios, beyond the planning period for the low scenario and reference scenario (which is considered the most likely), and until 2030 for the high scenario.

In addition, the OPA recommends that the IESO and Ontario Power Generation ("OPG"), with assistance from the OPA, negotiate a new contract for amended reactive services contract for Manitou Falls GS if it is beneficial to the rate payer. Based on information provided by OPG on the Draft North of Dryden IRRP, submitted November 8th, 2013, the Manitou Falls units G1, G2, and G3 all have condense features which could be contracted to provide reactive power during drought conditions. The contracting of these units could avoid some of the station investments at Ear Falls SS associated with the installation of voltage control devices. Table 62 in Appendix 10.6 outlines the cash-flows associated with the circuit upgrades including the station costs being referred to above.

The OPA also recommends that the potential long-term options of incremental natural gas-fired generation at Red Lake or a new transmission line be re-evaluated in the next planning cycle (1-5 years) for the North of Dryden sub-region of the Northwest region. This analysis will consider an updated forecast. The economics of additional gas-fired generation compared to a new transmission line will depend on the amount of load that materializes – gas generation is scalable, while transmission has greater economies of scale if enough demand is present for a sufficient level of utilization. Re-evaluating options in future planning cycles is consistent with OEB requirements in the Transmission System Code, Distribution System Code and the OPA license.

The following section summarizes the analysis and comparison of options.

As mentioned previously, the Red Lake subsystem is currently supplied by the 115 kV line E4D from Dryden TS as well as local run of river hydroelectric generation around Ear Falls. At present the subsystem has reached its LMC. Therefore, forecasted near term growth and medium and long term growth cannot be met by the existing system and other supply options are required. Identified needs for the Red Lake subsystem are summarized in Table 26, below.

Table 26: Needs for Red Lake Subsystem

Timing	Needs	Required Load Meeting Capability [MW]		
		Low	Reference	High
Near term (2014-2018)	• Supply of mining and community demand in the Red Lake subsystem	91	91	91
	Total Near term	***91***	***91***	***91***
Medium and long term (2019-2033)	• Supply of mining and community demand in the Red Lake subsystem	100	109	136
	Total Medium and Long term	***100***	***109***	***136***

The following near term generation and transmission options have been identified for meeting these needs.

Table 27: Summary of Options to Meet the Near-term Needs of the Red Lake Subsystem

Options to Meet Near-term Needs	Capital Cost	PV Cost	Incremental Load Meeting Capability	PV Unit Cost of Utilized Capacity
Red Lake Gas Generation (30 MW)	$89 M	$51 M	30 MW	$1.94 M/MW
Off Load E1C to New Line to Pickle Lake[55]	$66 M	$42 M	35 MW	
Upgrade E4D and E2R	$16 M	$11 M	34 MW	$1.11 M/MW[56]
Off Load E1C to New Line to Pickle Lake	$66 M	$42 M	35 MW	

The OPA recommends upgrading E4D and E2R, as this option has the lowest NPV cost for meeting the near-term needs of the Red Lake subsystem. This option also has the shortest lead time and the highest incremental capacity.

[55] Costs assumed for transfer of E1C load to new line to Pickle Lake are pro-rated based on LMC for Red Lake subsystem and the LMC for Red Lake subsystem plus the LMC for Pickle Lake subsystem.
[56] Note that utilized capacity is 30 MW in the near term.

Table 28: Summary of Options to Meet the Medium- and Long-Term Needs of the Red Lake Subsystem

Options to Meet Medium- and Long-Term Needs	Capital Cost	PV Cost[57]	Incremental Load Meeting Capability	PV Unit Cost of Utilized Capacity
Red Lake Gas Generation (30 MW)[58]	$95 M	$6 M	30 MW	$0.20 M/MW
Ear Falls and Red Lake Gas Generation (60 MW)	$153 M	$8 M	60 MW	$0.13 M/MW
Install Voltage Compensation at Ear Falls and Red Lake (130 MW)	$9 M	$1 M	21 MW	$0.05 M/MW
New 115 kV line to Ear Falls (160 MW)	$91 M	$10 M	30 MW	$0.34 M/MW
New 115 kV line to Ear Falls (190 MW)	$108 M	$12 M	60 MW	$0.20 M/MW
New 230 kV line to Ear Falls (190 MW)	$132 M	$15 M	60 MW	$0.25 M/MW

Once the upgrades to E4D and E2R are complete and the new line to Pickle Lake is in service, the Red Lake subsystem will have an LMC of 130 MW, which is sufficient to meet the supply needs of the Red Lake subsystem for the long term.

Costs do not need to be incurred at this time for additional enhancements for the Red Lake subsystem beyond E4D and E2R upgrades. Under the low scenario and reference scenario (which is considered most likely) no incremental LMC is required beyond 130 MW. Only under the high scenario is incremental LMC forecasted to be required in 2030. The lead times for the long-term incremental options allow for re-evaluation of the demand forecast and options in future planning cycles. Future planning cycles will contain more certainty in the demand forecast as mines and related development materialize. The next planning cycle for the North of Dryden sub-region is between 1-5

[57] Present Value costs for long-term options consider only the costs incurred within the 20 year planning horizon. These numbers appear low because costs are assumed to be incurred when a need is forecasted. Costs are not expected to need to be incurred until about 2030 at earliest, and therefore only 3 years of costs discounted over 17 years are included. Present Value costs are a method of comparison and should not be misinterpreted as total project costs.

[58] Same as the near term option, with install date of 2030 and therefore cannot be combined with the near term option.

years, as per the OEB-sanctioned regional planning process. The prudent course of action for the long term is monitoring load growth and re-evaluating in a timely manner.

7.3.1 **Discussion of Options to Meet the Needs of the Red Lake Subsystem**

Both generation and transmission options are considered for meeting the needs of the Red Lake subsystem.

The following sub-sections will outline the evaluation of various integrated options to meet the near-term and medium-to long-term needs of the Red Lake subsystem for the reference, low, and high load forecast scenarios.

7.3.1.1 Reference Scenario Options Analysis for Red Lake Subsystem

Under the reference scenario, the LMC required is 91 MW for the near term, and 109 MW for the medium and long term as indicated by the reference scenario in Table 26. The existing LMC for the Red Lake subsystem is 61 MW, which is not sufficient.

In establishing the need for incremental LMC for the Red Lake subsystem, it is assumed that, consistent with the recommendations for addressing supply needs for the Pickle Lake subsystem, a new line to Pickle Lake will be implemented and circuit E1C will be operated open at Ear Falls SS. Opening circuit E1C from Ear Falls SS relieves circuit E4D of 35 MW.

Generation Options

At Red Lake, there is a limited supply of natural gas on the existing Union Gas pipeline. This pipeline was extended to serve the needs of an industrial customer at Red Lake and the Town of Red Lake. Based on information provided by the industrial customer, there is sufficient pipeline capacity to increase the LMC by 30 MW from gas-fired generation at Red Lake.

The OPA studied the costs and benefits of implementing gas fired generation to provide incremental LMC in the Red Lake subsystem. The generators could operate both as a local area resource and as a system resource to support growth in northwest Ontario, by reducing loading on the bulk transmission system at Dryden TS. Gas generators in the Red Lake subsystem would be expected to operate for local area needs primarily during periods when run of river hydroelectric generation near Ear Falls is low and when the demand in the area is high.

Due to the availability of gas on the pipeline and the distribution of load in the Red Lake subsystem, gas generation at Red Lake would increase the LMC of the Red Lake subsystem by 30 MW. Table 29 summarizes the capability and Table 30 summarizes the cost and timing associated with the gas generation option.

Table 29: Capacity for Generation Options

Option	Incremental LMC [MW]	Red Lake Subsystem LMC [MW]	Near term Reference Forecast Demand [MW]	Medium and Long term Reference Forecast Demand [MW]
Red Lake Gas Generation (30 MW) and Transfer of Pickle Lake load to new line to Pickle Lake	30 MW	91 MW	91	109
	35 MW	126 MW		

Table 30: Costs and Timing for Generation Options

Option	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
Red Lake Gas Generation (30 MW)	2 Years	$89 M	$51 M	$1.94 M/MW
Transfer of E1C load to new line to Pickle Lake[59]	3-5 Years	$66 M	$42 M	

It is important to note that the transfer of Pickle Lake load from E1C to relieve the Red Lake subsystem can be made once a new line to Pickle Lake is in service. This again

[59] Costs assumed for transfer of E1C load to new line to Pickle Lake are pro-rated based on LMC for Red Lake subsystem and the LMC for Red Lake subsystem plus the LMC for Pickle Lake subsystem.

emphasizes the urgent need to implement the new line to Pickle Lake, as it has broader benefits for incremental LMC for the Red Lake subsystem.

Transmission Options

Hydro One Networks Inc. owns and operates transmission lines E4D and E2R and has confirmed that they can be upgraded from a summer ampacity of 470 A to 660 A and 420 A to 610 A, respectively. This upgrade increases the LMC of the Red Lake subsystem by 34 MW. To enable this higher transmission capability, additional voltage control would also be required at Ear Falls TS. Hydro One has indicated that upgrading E4D and E2R and the installation of the required voltage control devices would take two years and could be completed within the near-term period.

Table 31: Capacity of Transmission Option

Option	Incremental LMC [MW]	Red Lake Subsystem LMC [MW]	Near term Reference Forecast Demand [MW]	Medium and Long term Reference Forecast Demand [MW]
Near-term Option				
Upgrade E4D and E2R	34	95	91	109
and Transfer of Pickle Lake load to new line to Pickle Lake	35	130		

Upgrading the transfer capability of E4D and E2R and installation of the required amount of voltage control is the recommended solution for the Red Lake subsystem. This option satisfies the reference scenario forecasted demand at the least cost. When E4D and E2R are upgraded and the required amount of voltage control is installed at Ear Falls TS, there will be 95 MW of capacity at Ear Falls TS to serve load in the Red Lake subsystem and 35 MW available to continue to serve the Pickle Lake subsystem. Once a new line to Pickle Lake is implemented and circuit E1C is operated open at Ear Falls SS, an additional 35 MW of LMC is provided to the Red Lake subsystem because currently the Pickle Lake subsystem currently requires 35 MW of supply from Ear Falls to serve 24 MW of load (due to losses). This brings the total LMC for the Red Lake subsystem to 130 MW. The combination of the line upgrades to E4D and E2R as well as a new line to Pickle Lake is expected provide enough LMC for the Red Lake subsystem until the end of the study horizon for the reference forecast scenario.

It should be noted that the incremental LMC of 35 MW provided to the Red Lake subsystem from transferring E1C load to the new line to Pickle Lake requires the E4D and E2R upgrades to be completed. Without the upgrades, E2R would limit the supply into Red Lake because E2R is not relieved from transferring E1C load (E1C transfer only relieves E4D).

This again emphasizes the urgent need to implement both the upgrades to circuits E4D and E2R, as well as the new line to Pickle Lake, as combined these solutions provide a significant increase in LMC for the Red Lake subsystem.

Table 32: Cost and Timing of Transmission Option

Options	Time to Complete	Capital Cost[60]	PV During Planning Period	PV Unit Cost of Utilized Capacity
Upgrade of E4D and E2R	1-2 years	$16 M	$11 M	$1.11 M/MW
Transfer of E1C load to new line to Pickle Lake[61]	3-5 years	$66 M	$42 M	

Based on the above analysis of Generation and Transmission Options for the reference scenario, the upgrading of circuits E4D and E2R in combination with the relief provided by transferring E1C demand to a new line to Pickle Lake is the most economic solution to meet the needs of the Red Lake area. This solution would be sufficient to meet the electrical demand in the Red Lake subsystem until beyond the planning period.

[60] Capital cost does not include the capital cost for new system generation
[61] Costs assumed for transfer of E1C load to new line to Pickle Lake are pro-rated based on LMC for Red Lake subsystem and the LMC for Red Lake subsystem plus the LMC for Pickle Lake subsystem.

The IESO recently completed SIAs for three customers in the Red Lake subsystem that are interested in increasing their demand on the system. Upgrading of E4D and E2R was also identified by the IESO as the preferred solution to meet the load increase requests. The IESO's analysis is consistent with the OPA's findings.

7.3.1.2 Low Scenario Options Analysis for Red Lake Subsystem

Under the low scenario, the LMC required is 91 MW for the near term, and 100 MW for the medium and long term as indicated by the low scenario in Table 26.

Consistent with the analysis performed for the reference scenario, it is assumed that a new line to Pickle Lake will be implemented and circuit E1C is operated open at Ear Falls SS, which relieves circuit E4D of 35 MW.

Sensitivity Analysis for Generation Options

In order to meet the required LMC for the Red Lake subsystem under the low scenario, the generation option assessed for the reference scenario remains unchanged and is therefore not sensitive to the low scenario demand. A summary of capacity and costs are repeated in the following tables for convenience:

Table 33: Capacity for Generation Options

<table>
<tr><th>Option</th><th>Incremental LMC [MW]</th><th>Red Lake Subsystem LMC [MW]</th><th>Near term Low Forecast Demand [MW]</th><th>Medium and Long term Low Forecast Demand [MW]</th></tr>
<tr><td rowspan="2">Red Lake Gas Generation (30 MW)
and
Transfer of Pickle Lake load to new line to Pickle Lake</td><td>30 MW</td><td>91 MW</td><td rowspan="2">91</td><td rowspan="2">100</td></tr>
<tr><td>35 MW</td><td>126 MW</td></tr>
</table>

Table 34: Costs and Timing for Generation Options

Option	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
Red Lake Gas Generation (30 MW)	2 Years	$89 M	$51 M	$2.38 M/MW
Transfer of E1C load to new line to Pickle Lake[62]	3-5 Years	$66 M	$42 M	

Sensitivity Analysis for Transmission Options

In order to meet the required LMC for the Red Lake subsystem under the low scenario, the transmission options assessed for the reference scenario remain unchanged and are therefore not sensitive to the low scenario demand. A summary of capacity and costs are repeated in the following tables for convenience:

Table 35: Capacity of Transmission Option

Option	Incremental LMC [MW]	Red Lake Subsystem LMC [MW]	Near term Low Forecast Demand [MW]	Medium and Long term Low Forecast Demand [MW]
Near-term Option				
Upgrade E4D and E2R	34	95	91	100
and Transfer of Pickle Lake load to new line to Pickle Lake	35	130		

Table 36: Cost and Timing of Transmission Option

Options	Time to Complete	Capital Cost[63]	PV During Planning Period	PV Unit Cost of Utilized Capacity
Upgrade of E4D and E2R	1-2 years	$16 M	$11 M	$1.36 M/MW
Transfer of E1C load to new line to Pickle Lake[64]	3-5 years	$66 M	$42 M	

[62] Costs assumed for transfer of E1C load to new line to Pickle Lake are pro-rated based on LMC for Red Lake subsystem and the LMC for Red Lake subsystem plus the LMC for Pickle Lake subsystem.
[63] Capital cost does not include the capital cost for new system generation
[64] Costs assumed for transfer of E1C load to new line to Pickle Lake are pro-rated based on LMC for Red Lake subsystem and the LMC for Red Lake subsystem plus the LMC for Pickle Lake subsystem.

7.3.1.3 High Scenario Options Analysis for Red Lake Subsystem

Under the high scenario, the LMC required is 91 MW for the near term, and 136 MW for the medium and long term as indicated by the high scenario in Table 26.

Consistent with the analysis performed for the reference scenario, it is assumed that a new line to Pickle Lake will be implemented and circuit E1C is operated open at Ear Falls SS, which relieves circuit E4D of 35 MW.

Sensitivity Analysis for Generation Options

In order to meet the required LMC for the Red Lake subsystem under the high scenario, additional gas generation at Ear Falls or Red Lake would be required in the long term compared to the reference scenario. However, it should be noted that based on information from the existing industrial customer gas pipeline capacity is not available to support gas-fired generation beyond 30 MW.

The option of incremental gas generation has been assessed assuming that industrial customers may require additional natural gas supply to serve their industrial processes.

A summary of capacity and costs are summarized in the following tables:

Table 37: Capacity for Generation Options

<table>
<tr><th>Option</th><th>Incremental LMC [MW]</th><th>Red Lake Subsystem LMC [MW]</th><th>Near term High Forecast Demand [MW]</th><th>Medium and Long term High Forecast Demand [MW]</th></tr>
<tr><td rowspan="2">Red Lake Gas Generation (30 MW)

and

Transfer of Pickle Lake load to new line to Pickle Lake</td><td>30</td><td>91</td><td rowspan="2">91</td><td rowspan="2">136</td></tr>
<tr><td>35</td><td>126</td></tr>
<tr><td colspan="5">Incremental Long term Options</td></tr>
</table>

Incremental Potential Gas Generation at Red Lake or Ear Falls (30 MW)[65]	30	156	91	136

Table 38: Costs and Timing for Generation Options

Option	Time to Complete	Capital Cost	Total PV During Planning Period	PV Unit Cost of Utilized Capacity
Red Lake Gas Generation (30 MW)	2 Years	\$89 M	\$51 M	\$1.36 M/MW
Transfer of E1C load to new line to Pickle Lake[66]	3-5 Years	\$66 M	\$42 M	
Incremental Potential Gas Generation at Red Lake or Ear Falls (30 MW)[67]	TBD[1]	\$95 M[68]	\$6 M[69]	\$1.00 M/MW

From the above, the option of 30 MW of gas-fired generation at Red Lake using existing pipeline capacity in combination with relieving circuit E4D of the E1C load following the installation of a new line to Pickle Lake would result in an LMC of 126 MW for the Red Lake subsystem. This LMC would be forecasted to be exceeded by 2027 under the high scenario.

The sensitivity analysis does not impact the decisions that are required during this planning cycle. Demand forecasts and long term options will be re-evaluated in the next planning cycle (1-5 years) for the North of Dryden sub-region of the Northwest region.

Sensitivity Analysis for Transmission Options

In order to meet the required LMC for the Red Lake subsystem under the high scenario, the transmission options assessed for the reference scenario remain unchanged and

[65] Contingent on new gas pipeline to serve new electricity and gas customers
[66] Costs assumed for transfer of E1C load to new line to Pickle Lake are pro-rated based on LMC for Red Lake subsystem and the LMC for Red Lake subsystem plus the LMC for Pickle Lake subsystem.
[67] Contingent on new gas pipeline to serve new electricity and gas customers
[68] Capital Cost does not include pipeline costs. It is assumed that if the pipeline was needed anyway, there would be no incremental pipeline costs to incorporate generation
[69] Present Value costs for long-term options consider only the costs incurred within the 20 year planning horizon. These numbers appear low because costs are assumed to be incurred when a need is forecasted. Costs are not expected to need to be incurred until 2026 at earliest, and therefore only 3 years of costs discounted over 13 years are included. Present Value costs are a method of comparison and should not be misinterpreted as total project costs.

are therefore not sensitive to the high scenario demand. A summary of capacity and costs are repeated in the following tables:

Table 39: Capacity of Transmission Option

<table>
<tr><th>Option</th><th>Incremental LMC [MW]</th><th>Red Lake Subsystem LMC [MW]</th><th>Near term High Forecast Demand [MW]</th><th>Medium and Long term High Forecast Demand [MW]</th></tr>
<tr><td colspan="5">Near-term Option</td></tr>
<tr><td rowspan="2">Upgrade E4D and E2R
and
Transfer of Pickle Lake load to new line to Pickle Lake</td><td>34</td><td>95</td><td rowspan="2">91</td><td rowspan="2">136</td></tr>
<tr><td>35</td><td>130</td></tr>
<tr><td colspan="5">Incremental Long-term Options</td></tr>
<tr><td>New 115 kV line to Ear Falls (160 MW LMC)</td><td>30</td><td>160</td><td>91</td><td>136</td></tr>
<tr><td>New 115 kV line to Ear Falls (190 MW LMC)</td><td>60</td><td>190</td><td>91</td><td>136</td></tr>
<tr><td>New 230 kV line to Ear Falls (190 MW LMC)</td><td>60</td><td>190</td><td>91</td><td>136</td></tr>
</table>

Table 40: Cost and Timing of Transmission Option

<table>
<tr><th>Options</th><th>Time to Complete</th><th>Capital Cost[70]</th><th>PV During Planning Period[71]</th><th>PV Unit Cost of Utilized Capacity</th></tr>
<tr><td>Upgrade of E4D and E2R</td><td>1-2 years</td><td>$16 M</td><td>$11 M</td><td rowspan="2">$0.78 M/MW</td></tr>
<tr><td>Transfer of Pickle Lake load to new Line at Pickle Lake[72]</td><td>3-5 years</td><td>$66 M</td><td>$42 M</td></tr>
<tr><td>New 115 kV line to Ear Falls (160 MW LMC)</td><td>4-7 years</td><td>$91 M</td><td>$10 M</td><td>$1.72 M/MW</td></tr>
<tr><td>New 115 kV line to Ear Falls (190 MW LMC)</td><td>4-7 years</td><td>$108 M</td><td>$12 M</td><td>$2.04 M/MW</td></tr>
<tr><td>New 230 kV line to Ear Falls (190 MW LMC)</td><td>4-7 years</td><td>$132 M</td><td>$15 M</td><td>$2.5 M/MW</td></tr>
</table>

[70] Capital cost does not include the capital cost for new system generation

[71] Present Value costs for long-term options (i.e. all except E4D and E2R upgrades, and Transfer of Pickle Lake load to new Line at Pickle Lake) consider only the costs incurred within the 20 year planning horizon. These numbers appear low because costs are assumed to be incurred when a need is forecasted. Costs are not expected to need to be incurred until 2030 at earliest, and therefore only 3 years of costs discounted over 17 years are included. Present Value costs are a method of comparison and should not be misinterpreted as total project costs.

[72] Costs assumed for transfer of E1C load to new line to Pickle Lake are pro-rated based on LMC for Red Lake subsystem and the LMC for Red Lake subsystem plus the LMC for Pickle Lake subsystem.

From the above, upgrading lines E4D and E2R (Dryden to Red Lake) in combination with relieving circuit E4D of the E1C load following the installation of a new line to Pickle Lake, an LMC of 130 MW would result for the Red Lake subsystem. This LMC would be forecasted to be exceeded by 2030 under the high scenario forecasted demand, but not under the reference scenario (which is considered most likely). Incremental transmission options are available if forecasted demand consistent with, or greater than, the high scenario is realized. This is not expected to occur until 2030 under the high scenario and beyond the planning period for the reference scenario. A recommendation for incremental enhancements in addition to the line upgrades and the new line to Pickle Lake does not need to be made at this time. Demand forecasts and long-term options will be re-evaluated in the next planning cycle (1-5 years) for the North of Dryden sub-region of the Northwest region.

7.3.2 Cost Saving Opportunities Utilizing Existing Facilities

OPG provided information to the OPA on voltage control capabilities of the generating units at Manitou Falls as part of their comments on the Draft North of Dryden IRRP. This information was submitted in writing on November 8th, 2013. Part of this submission indicated that the Manitou Falls units G1, G2, and G3 all have condense features which could be contracted to provide reactive power for voltage control during drought conditions. The contracting of these units could avoid some of the station investments at Ear Falls SS associated with the installation of voltage control devices. Total station costs for upgrading E4D and E2R are referenced in Table 62 of Appendix 10.6.

OPA recommends that the IESO and OPG, with assistance from the OPA, negotiate a new contract or amended reactive services contract for Manitou Falls GS if it is of benefit to the rate payer.

7.3.3 Red Lake Subsystem Recommended Solutions

The OPA recommends the upgrading of circuits E4D and E2R from a summer ampacity of 470 A to 660 A and 420 A to 610 A, respectively. The upgrading of E4D and E2R, in addition to a new line to Pickle Lake coupled with operating circuit E1C normally open at

Ear Falls would provide an additional 70 MW of LMC, bringing the LMC for the Red Lake subsystem to 130 MW. The LMC of 130 MW meets the needs of the Red Lake subsystem for the long term for all the OPA's forecast scenarios; beyond the planning period for the low scenario and reference scenario (which is considered the most likely), and until 2030 for the high scenario.

In addition, the OPA recommends that the IESO and OPG, with assistance from the OPA, negotiate a new contract or amended reactive services contract for Manitou Falls GS if it is beneficial to the rate payer. Based on information provided by OPG on the Draft North of Dryden IRRP, submitted November 8th, 2013, the Manitou Falls units G1, G2, and G3 all have condense features which could be contracted to provide reactive power during drought conditions. The contracting of these units could avoid some of the station investments at Ear Falls SS associated with the installation of voltage control devices.

The OPA also recommends that the potential long-term options of incremental natural gas-fired generation at Red Lake or a new transmission line be re-evaluated in the next planning cycle (1-5 years) for the North of Dryden sub-region of the Northwest region. This is consistent with OEB requirements in the Transmission System Code, Distribution System Code and the OPA license.

7.4 Summary of Options to Meet Ring of Fire Subsystem Needs

The Ring of Fire subsystem is a large geographic area on the edge of the Hudson Bay Lowlands approximately 350 km north of Long Lac and approximately 300 km east of Pickle Lake. There are five remote First Nations ("FN") communities in the area (Eabametoong FN, Neskantaga FN, Marten Falls FN, Nibinamik FN and Webequie FN) and a proposed mine development area called the Ring of Fire, where a number of companies are developing mining claims. At present the five remote First Nations communities are supplied electricity by local diesel generators.

The OPA recommends that electricity infrastructure to supply the Ring of Fire subsystem, including the connection of the remote communities, be coordinated with other infrastructure being investigated or planned, such as transportation corridors to the communities and potential mining development. Mining development companies have indicated different transportation corridor preferences for the Ring of Fire. The OPA understands that a transportation corridor may be developed in an East-West orientation from the Pickle Lake area, or in a North-South orientation from the Nakina area. Transmission options may also utilize either an East-West corridor (originating from Pickle Lake) or a North-South corridor (originating from either Marathon or a point east of Nipigon). The OPA therefore recommends that development of an infrastructure corridor to the Ring of Fire should consider the potential need for a transmission line.

The OPA has included transmission supply options for the Ring of Fire subsystem that are consistent with these general corridor orientations identified by mining proponents. A shared East-West or North-South transmission corridor, in alignment with a transportation corridor, could be a way to reduce overall cost and environmental impact. Mining development companies have also indicated self-generation as their electrical supply base case in their EA documentation. Consistent with the EA documentation of mining development companies, the OPA has considered self-generation as a possible option for the forecasted mining load in the Ring of Fire subsystem. The decision as to whether the mining load in the Ring of Fire subsystem is supplied by transmission or generation will ultimately lie with the mining companies as they will be the beneficiaries of a direct transmission supply. The OPA has already indicated in the Remote Community Connection plan that there is a business case for connecting the five remote communities in the vicinity of the Ring of Fire on their own merit, without the connection of the mining development. The connection of the mining development with the five remote communities creates a stronger business case for the connection of the remote communities. The OPA will continue to support the economic connection of remote communities.

The relative economics of generation versus transmission to supply mining load in the Ring of Fire subsystem depends on the amount of electrical demand that materializes. The reason for this is because transmission is generally more economic for relatively large electrical demand, while generation is scalable and generally more economic for lower levels of electrical demand. Details of the various options are explained further later in this section.

The OPA also recognizes that there may be potential for further utilization of a North-South transmission supply to the Ring of Fire subsystem through integration with supplying new growth in the Greenstone area. The detailed needs and supply options specific for new growth in the Greenstone area will be assessed as part of the Greenstone-Marathon IRRP, which may be used to supplement the findings in this IRRP.

The needs identified for the Ring of Fire subsystem are to connect the five remote communities to the provincial transmission system and to supply the potential future mines. The connection of the five remote communities cannot be completed until at least 2018, as indicated in the Remote Community Connection Report. Also, mines at the Ring of Fire are not expected to start up until 2017 at the earliest. A summary of the needs is provided in Table 41.

Table 41: Needs for the Ring of Fire Subsystem

Timing	Needs	Required Load Meeting Capability [MW]		
		Low	**Reference**	**High**
Near term (2014-2018)	• Connect 5 remote communities and supply mining demand in the Ring of Fire subsystems	4	22	22
	Total Near term	***4***	***22***	***22***
Medium and long term (2019-2033)	• Connect 5 remote communities and supply mining demand in the Ring of Fire subsystems	7	29	73
	Total Medium and Long term	***7***	***29***	***73***

An assessment developed for the Remote Community Connection Plan determined that up to five remote First Nation communities in the subsystem are economic to connect to the grid (see Appendices 11.2 and 11.4). As a result, all options identified for this subsystem include the connection of the five remote communities included in this subsystem.

Options to meet these requirements include:

- Connection of mines and remote communities to the transmission system; or
- Connection of the remote communities and on-site generation fueled by diesel or natural gas for the mines.

Transmission supply options being considered for the Ring of Fire subsystem include a new supply from Pickle Lake, a point east of Nipigon, or Marathon. These options were developed with the understanding that both East-West and North-South transportation corridors are being considered and linear corridor planning with electricity may provide greater economic efficiencies and reduce environmental impacts. It should also be noted that 230 kV supply to Pickle Lake is the minimum technical requirement for connecting any mining load at the Ring of Fire to Pickle Lake.

Options for supply to the Ring of Fire subsystem are summarized in Table 42 below.

Table 42: Summary of Options to Meet the Medium- and Long-Term Needs of the Ring of Fire Subsystem[73]

	Capital Cost[74]	PV Cost	Utilized Capacity	PV Unit Cost of Utilized Capacity
Diesel Generation + Remote Connection	Low: $186 M High: $277 M	Low: $456 M High:$1,009 M	29 MW 73 MW	$15.7 M/MW $13.8 M/MW
CNG Generation + Remote Connection	Low: $240 M High: $421 M	Low: $272 M High: $480 M	29 MW 73 MW	$9.37 M/MW $6.58 M/MW

[73] Transmission options routed from Pickle Lake include a prorated portion (based on the relative amount of load that would be supplied to each party) of the cost for a new 230 kV transmission line to Pickle Lake.
[74] Description of capital costs can be found in the following tables: Generation, Table 26; Transmission, Table 27

115 kV Line from Pickle Lake to Ring of Fire	$189 M	$106 M	29 MW	$3.64 M/MW
230 kV Line from Pickle Lake to Ring of Fire	$277 M	$156 M	73 MW	$2.14 M/MW
230 kV Line from Marathon to Ring of Fire	$327 M	$175 M	73 MW	$2.40 M/MW
230 kV Line from east of Nipigon to Ring of Fire	$327 M	$175 M	73 MW	$2.40 M/MW

Options that are developed for the scenario that the Ring of Fire subsystem mining developments and remote communities are supplied from a transmission connection to the provincial power system assumes the cost for the transmission option with road access. The option for connecting only the remote communities from a transmission connection to the provincial power system assumes the cost for the transmission option without road access. Road access may be provided from the development of a multi-use corridor.

7.4.1 **Discussion of Options to Meet the Needs of the Ring of Fire Subsystem**

Currently, the electric supply of the five remote communities in the Ring of Fire subsystem is provided by local diesel generators. As discussed previously, up to five of these communities have been shown to be economic to connect to the transmission system in the Remote Community Connection Plan. Hence, for the purpose of the North of Dryden IRRP, these five communities are assumed to connect to the transmission system.

Given the timelines required to obtain approvals and to design and construct transmission facilities of this scale, the OPA has assumed that transmission options for serving remote communities would not be in service until 2018 at the earliest.

7.4.1.1 Reference Scenario Options Analysis for Ring of Fire Subsystem

Under the reference scenario electrical demand forecast, the LMC required is 22 MW for the near term, and 29 MW for the medium and long term as indicated in Table 41. The existing LMC for the Ring of Fire subsystem is 0 MW, as it is currently not connected to the provincial power system.

Generation Options

Two Environmental Assessment Terms of Reference published by mining developers in the Ring of Fire have included electricity supply options for on-site generation for their particular mining projects. They have identified that diesel or CNG fueled generation plants can provide sufficient capacity and energy to reliably meet their needs and can be brought into service within their mine development timelines. Assuming that a proposed all-season road would connect the Ring of Fire to the provincial highway system, the transportation of the large volumes of fuel required to operate on-site generation of this scale would be enabled.

As mentioned earlier, the five remote communities in the Ring of Fire subsystem have been identified as economic to connect to the transmission system at Pickle Lake. Should the Ring of Fire mines choose the self–generation option for their electricity needs, it is assumed that the remote communities will connect to Pickle Lake through a separate remote community connection project. This option is discussed in detail in the Remote Community Connection Plan. The cost of serving the remote communities by transmission and the Ring of Fire area mines with on-site generation are considered together as an integrated option for serving the Ring of Fire subsystem.

The OPA evaluated the feasibility and relative economics of various on-site generation options to supply the mining load. Findings indicated that reciprocating engines fueled either by diesel or natural gas could power future mines at the Ring of Fire, which is consistent with the respective EA Terms of Reference of developers. These units are available in a large range of sizes which allows for capacity to be scaled to meet a wide range of needs for individual mines initially and over time. Mine developers at the Ring of Fire have plans for transportation systems that would connect the Ring of Fire to the provincial transportation network, by either road or rail. One of these options is an all-season road from the Ring of Fire to the railway near Nakina. In order to develop cost estimates for this regional plan it is assumed that fuel would be transported to the Ring of Fire via the provincial road network to Nakina and then from Nakina to the Ring of Fire via the proposed all-season road[75].

Supplying diesel fuel to mine sites for power generators is common practice. Diesel fuel can be purchased at a number of bulk storage facilities in northwest Ontario and transported to mine sites. CNG also appears to be feasible though there are no direct examples that the OPA could reference for remote mining applications. The OPA has leveraged available public information and worked with industry to establish a reasonable set of assumptions and inputs that were used to develop cost models for both remote diesel and CNG fueled DG. The cost of fuel transportation infrastructure (trucks and trailers) required to transport both diesel and CNG to the mine sites has been included in the cost analysis.

The infrastructure required to fuel a natural gas generation facility at the Ring of Fire would include a compression station located along the TCPL mainline with road access to the proposed all-season road to the Ring of Fire beginning near Nakina. Due to the complexities and permitting required to build a CNG storage facility at the mine site, the OPA understands that no CNG storage facilities are planned for the mine sites and that fuel would be delivered on a just in time basis, with allowance for only a few trailers to be kept on site. Each trailer stores approximately 2 hours supply of fuel.

While the process is not substantially different from the transport and use of diesel, there are more steps and facilities required to compress, transport and decompress the gas before it can be used. Without significant on-site storage facilities, natural gas transportation logistics will be more challenging particularly during inclement weather when the all-season road may be closed for extended periods. To account for such challenges, it is likely that the generators will have to be capable of using both diesel and natural gas. Mines will have large scale diesel storage on site to fuel their vehicles and heavy equipment which could be used to fuel the generators when natural gas

---

[75] The OPA does not have expertise in transportation planning; this assumption is solely for developing cost estimates for generation OM&A and does not indicate a preference of the OPA.

supply is interrupted. The OPA has also discussed the results of its CNG cost model with industry to ensure the findings are reasonable.

Liquefied natural gas (“LNG”) may also be a feasible option to fuel generators. However, it is not clear what minimum production volume is required to establish a natural gas liquefaction facility in northwest Ontario or what the economics of such facilities would be. As a result, the OPA does not have sufficient information to assess either the feasibility or the economics of LNG at this time.

Table 43: Generation Options at the Ring of Fire Mines

Options for Mining Load	Mining Generation [MW]	Near term Reference Forecast Demand (Mines Only) [MW]	Medium and Long term Reference Forecast Demand (Mines Only) [MW]
Diesel Generation	22	18	22
CNG Generation	22		

From the above, in order to meet the reference scenario demand for the Ring of Fire mining load, up to 22 MW of diesel or CNG generation are considered.

The costs for supplying the forecasted Ring of Fire subsystem mining load by either 22 MW of diesel or CNG generation at the Ring of Fire mines are summarized in Table 44.

Table 44: Generation Options at the Ring of Fire Mines

Options for Mining Load	Mining Generation [MW]	Initial Capital Cost	Average Annual Fuel and O&M	Total PV
Diesel Generation	22	$72 M	$39 M	$393 M
CNG Generation	22	$127 M	$20 M	$209 M

As discussed above, the integrated options for serving the needs of the remote communities and the mines in the Ring of Fire subsystem includes a transmission connection option to serve the five remote communities from Pickle Lake in the case where the Ring of Fire mines opt for self-generation. This option would consist of a 115 kV transmission line from Pickle Lake to an end point near Webequie FN, passing near Neskantaga FN. Transformer stations to serve the communities would be sited near Neskantaga FN and at the end of the line near Webequie FN. Neskantaga FN, Eabametoong FN and Marten Falls FN would be connected via distribution lines and stations to the transformer station near Neskantaga FN, while Webequie FN and Nibinamik FN would be connected by distribution lines and stations to the transformer station near Webequie FN. Figure 36 in Appendix 11.4 shows this planned connection system for the five remote communities.

The OPA has estimated the cost of connecting the five remote communities in this subsystem to be $64 million, consistent with the 2014 Remote Community Connection Plan. The costs of the integrated options for mine site generation and transmission connection of remote communities are summarized in Table 45.

Table 45 Integrated Options for the Ring of Fire Subsystem: Mine Generation and Remote Community Connection to Pickle Lake

Integrated Options	PV of Mine Site Generation	PV Remote Connection	Total PV of Integrated Option
Diesel Generation + Remote Connection	$393 M	$62 M	$456M
CNG Generation + Remote Connection	$209 M	$62 M	$272 M

Therefore, in order to supply the entire need for the Ring of Fire subsystem – connection of remote communities and generation supply to mines – a new 115 kV connection for remote communities and 22 MW of generation would be required and would total $273-$457 M, depending on fuel.

Transmission Options

Transmission options for supplying the five remote communities and mining load at the Ring of Fire together include the following:

1. East-West corridor
    a. A new 115 kV single circuit line from Crow River DS or a new station at Pickle Lake to the Ring of Fire
    b. A new 230 kV single circuit line from a new 230/115 kV station at Pickle Lake to the Ring of Fire, and new 230/115 kV TS near Neskantaga FN
2. North-South corridor
    a. A 230 kV single circuit line from Marathon TS to a new transformer station at the Ring of Fire and a new 230/115 kV station near Marten Falls FN
    b. A 230 kV single circuit line from east of Nipigon to a new transformer station at the Ring of Fire and a new 230/115 kV station near Marten Falls FN

The LMC of these options are summarized in Table 46 below

Table 46: Capacity of Transmission Options

Options	Ring of Fire Subsystem Load Meeting Capability [MW]	Ring of Fire Subsystem Near term Reference Forecast Demand [MW]	Ring of Fire Subsystem Medium and Long term Reference Forecast Demand [MW]
East-West corridor			
115 kV line from Pickle Lake	67	22	29
230 kV line from Pickle Lake	78	22	29
North-South corridor			

230 kV line from Marathon TS	78	22	29
230 kV line from east of Nipigon	78	22	29

Power flow studies show that a single circuit 115 kV line from Pickle Lake could supply up to 67 MW of load at the Ring of Fire (60 MW of mining load plus 7 MW of remote community load). Figure 36 in Appendix 11.4 shows a potential configuration of the North of Dryden system with a 115 kV connection to the Ring of Fire from Pickle Lake. This would be sufficient and would be the least-cost option to supply the reference scenario forecasted demand.

It is not economic under the reference scenario forecasted demand to supply the Ring of Fire subsystem by a 230 kV transmission line.

If mining and remote community load exceeds 67 MW a new 115 kV supply would no longer be sufficient and a 230 kV connection to the Ontario transmission system is required for the Ring of Fire subsystem.

The North-South options will be assessed in further detail in the Greenstone-Marathon IRRP by considering possible economic synergies with potential load growth in the Greenstone area.

As mentioned in Section 7.4.1, the five remote communities in the Ring of Fire subsystem have been identified in the Remote Community Connection Plan as being economic to connect on their own. It is therefore assumed that if the Ring of Fire mines do not connect to the grid, then the five remote communities will continue to pursue a connection to the transmission system at Pickle Lake. The lowest cost transmission connection for these communities is a single circuit 115 kV line from Pickle Lake to a new 115/44 kV transformer station near Webequie FN.

A summary of the cost and capabilities of these options is provided in Table 47.

Table 47: Capacity and Costs of Transmission Options

Options	Capital Cost	Prorated Capital of Line to Pickle Lake	Total Capital	Total PV During Planning Period
Remote Community Only Connection from Pickle Lake (115 kV)	$101 M	$13 M	$114 M	$62 M
New 115 kV line from Pickle Lake to Ring of Fire	$146 M	$44 M	$189 M	$106 M
New 230 kV line from Pickle Lake to Ring of Fire	$196 M	$35 M	$231 M	$127 M
New 230 kV Line from Marathon to Ring of Fire	$327 M	N/A	$327 M	$175 M
New 230 kV Line from east of Nipigon to Ring of Fire	$327 M	N/A	$327 M	$175 M

The cost responsibility for the new line to Pickle Lake and any connection line to the Ring of Fire shared by mines and remote communities would be determined through commercial agreements and/or through the OEB's Leave to Construct application process.

7.4.1.2 Low Scenario Options Analysis for Ring of Fire Subsystem

Under the low scenario forecasted load, the LMC required is 4 MW for the near term, and 7 MW for the medium and long term as indicated by the low scenario in Table 41. This scenario corresponds to the load associated with only the five remote communities in the Ring of Fire subsystem.

Therefore, under this scenario, only the connection of the five remote communities is considered. As indicated in the previous section, the lowest cost transmission connection for these communities is a single circuit 115 kV line from Pickle Lake to a new 115/44 kV transformer station near Webequie FN. This is expected to cost $115 M net-present value over the planning period.

Details are included in the Remote Community Connection Report. This scenario does not require any additional consideration.

7.4.1.3 High Scenario Options Analysis for Ring of Fire Subsystem

Under the high scenario forecasted load, the LMC required is 22 MW for the near term, and 73 MW for the medium and long term as indicated by the high scenario in Table 41. Of the 73 MW, 66 MW is mining load and 7 MW is community load. The existing LMC for the Ring of Fire subsystem is 0 MW, as it is currently not connected to the provincial power system.

Sensitivity Analysis for Generation Options

In order to meet the required LMC for the Ring of Fire subsystem under the high scenario, the high generation option would be required. The tables outlining the generation options are repeated for convenience:

Table 48: Generation Options at the Ring of Fire

Options for Mining Load	Mining Generation [MW]	Initial Capital Cost	Average Annual Fuel and O&M	Total PV
Diesel Generation	71	$163 M	$102 M	$946 M
CNG Generation	71	$307 M	$46 M	$418 M

Table 49: Integrated Option for the Ring of Fire Subsystem: Mine Generation and Remote Community Connection to Pickle Lake

Integrated Options	PV of Mine Site Generation	PV Remote Connection	Total PV of Integrated Option
Diesel Generation + Remote Connection	$946 M	$62 M	$1,009 M
CNG Generation + Remote Connection	$393 M	$62 M	$456 M

Sensitivity Analysis for Transmission Options

In order to meet the required LMC for the Ring of Fire subsystem under the high scenario, the transmission options assessed for the reference scenario remain unchanged. A summary of capacity and costs are repeated in the following tables for convenience:

Table 50: Capacity of Transmission Options

Options	Ring of Fire Subsystem Load Meeting Capability [MW]	Ring of Fire Subsystem Near term High Forecast Demand [MW]	Ring of Fire Subsystem Medium and Long term High Forecast Demand [MW]
East-West corridor			
115 kV line from Pickle Lake	67	22	73
230 kV line from Pickle Lake	78	22	73
North-South corridor			
230 kV line from Marathon TS	78	22	73
230 kV line from east of Nipigon	78	22	73

Table 51: Capacity and Costs of Transmission Options

Options	Capital Cost	Prorated Capital of Line to Pickle Lake	Total Capital	Total PV During Planning Period
Remote Community Only Connection from Pickle Lake (115 kV)	$101 M	$13 M	$114 M	$62 M
New 115 kV line from Pickle Lake to Ring of Fire	Not Technically Feasible for medium to long term			
New 230 kV line from Pickle Lake to Ring of Fire	$196 M	$35 M	$231 M	$127 M
New 230 kV Line from Marathon to Ring of Fire	$327 M	N/A	$327 M	$175 M
New 230 kV Line from east of Nipigon to Ring of Fire	$327 M	N/A	$327 M	$175 M

As indicated previously, a 115 kV line to the Ring of Fire subsystem could supply up to 67 MW, and a 230 kV line would be required to serve demand greater than 67 MW.

Based on the high demand scenario, a 230 kV supply to the Ring of Fire subsystem would be required. A recommendation for a specific solution is not required at this time. The magnitude and timing of the potential mining load is still very uncertain, and decisions regarding transportation infrastructure to the Ring of Fire have not yet been made. A common corridor to the Ring of Fire should consider the potential need for a transmission line.

7.4.2 **Ring of Fire Subsystem Recommendations**

The OPA recommends that electricity infrastructure to supply the Ring of Fire subsystem is coordinated with other infrastructure being investigated, such as transportation. Transmission may also utilize either an East-West corridor (originating from Pickle Lake) or a North-South corridor (originating from either Marathon or east of Nipigon). The OPA therefore recommends that development of an infrastructure corridor to the Ring of Fire should consider the potential need for a transmission line.

The lowest cost option for meeting the medium- and long-term identified needs is a transmission connection from either Pickle Lake, Marathon, or east of Nipigon to the Ring of Fire. The incremental cost of developing a transmission connection capable of serving mines and remote communities is substantially lower than the cost of generation to serve mines and separately connect the remote communities.

8 FEEDBACK FROM ENGAGEMENT AND CONSULTATION

8.1 Aboriginal Consultation

The OPA recognizes the importance of engaging with First Nation and Métis communities and carrying out the procedural aspects of Aboriginal consultation where delegated by the Crown.

The Ministry of Energy delegated the procedural aspects of consultation to the OPA and identified 44 First Nation communities and four Métis communities to be consulted on the Draft North of Dryden IRRP. The Ministry of Energy wrote to each community on the consultation list by letter dated April 25, 2014 to provide notice of the consultation and the delegation of the OPA's role as a delegate of the Crown. The OPA then wrote to each community by letter dated May 26, 2014 to provide the dates and locations of the consultation sessions scheduled for June 2014. The letters included the OPA's commitment to cover the cost of travel and accommodation expenses associated with attending a consultation session. OPA staff then phoned each community to follow up and to answer questions about the North of Dryden IRRP consultation and provided presentation materials in advance of all sessions. The OPA sent additional invitation letters by registered mail on September 26, 2014 for the consultation session that occurred on October 16, 2014. The OPA followed up by phoning each community to ensure that leadership and/or band staff were aware of the North of Dryden consultation.

The OPA held consultation sessions for the First Nation communities in Thunder Bay on June 18, 2014, June 25, 2014, and October 16, 2014, and in Dryden on June 26, 2014. Representatives from 15 communities attended the sessions. Two communities informed the OPA that the North of Dryden IRRP is outside their area of interest. Representatives from the Chiefs of Ontario, Grand Council Treaty 3, and Nishnawbe Aski Nation also attended the sessions but did so for informational purposes only. Notes of these sessions were prepared by the OPA and posted in the regional planning section of the OPA's website.

The OPA was in contact with the Métis Nation of Ontario ("MNO") on a number of occasions via telephone and email to set up appropriate times for regional consultation meetings with MNO's member communities. The OPA endeavoured to meet with the MNO and its chartered communities and remains open to such meetings.

The OPA met with Red Sky Métis Independent Nation on June 19 at Red Sky's office in Thunder Bay. OPA staff delivered a presentation on the North of Dryden IRRP and answered questions posed by Red Sky's representatives.

To date there have not been any specific concerns expressed regarding potential impacts of the regional plan on any Aboriginal or treaty rights. Some clarifying questions were asked during the sessions, and there were some non-consultation related questions regarding electricity rates following the connection of the remote communities identified in the Remote Community Connection Plan. At this point in time, it is not yet known how the distribution service would be structured and therefore it is not possible to determine the impact to rates in a detailed manner. Rates similar to other rural distribution customers in northwestern Ontario are believed to be expected. Other general comments included:

- the need for capacity building in communities to facilitate greater participation in consultation sessions
- some communities wish to focus on project-level consultation with proponents due to the more immediate potential impacts.

8.2 Municipal Engagement

Following the publication of the Draft North of Dryden IRRP, the OPA travelled across the northwest to meet with various municipal representatives from affected municipalities. The following summarizes these meetings:

Table 52: Municipal Engagement Summary

Meeting Date	Municipality
December 10, 2013	Pickle Lake
December 10, 2013	Greenstone
December 12, 2013	Red Lake
December 12, 2013	Sioux Lookout
December 13, 2013	Marathon
February 12, 2014	Dryden
February 13, 2014	Ignace

Following the municipal engagement meetings, several themes emerged as common feedback from the various municipalities and mainly centered on option preference, cost responsibility, and urgency for development.

Various municipal representatives provided input that any new transmission being contemplated in northwestern Ontario should be built to 230 kV standards in order to accommodate potentially high growth and encourage economic development. In general, the OPA agrees with this philosophy if there is sufficient justification to spend the incremental cost associated with a more expensive 230 kV option compared to a less expensive 115 kV option.

The OPA considered this feedback in updating the Draft North of Dryden IRRP that was released on August 16th, 2013. In the draft IRRP, the OPA indicated that it had no preference to the voltage for the recommended new line to Pickle Lake. In this version of the IRRP, the OPA was able to find sufficient justification for initially building and operating the recommended new line to Pickle Lake to 230 kV. The justification is based on the fact that the reference scenario forecast exceeds the capability of a 115 kV line in the longer term, and the provision of option flexibility for supplying the Ring of Fire as described in Section 7.2.

Cost responsibility was another common point of feedback. Generally the municipal representatives communicated that the infrastructure being contemplated in the North of Dryden IRRP is to enable economic development. Economic development was said to provide broader benefits than the local customers and costs should therefore be shared more broadly. Cost responsibility for new transmission and distribution infrastructure will be determined by the OEB during the appropriate regulatory process. For example for applicable transmission lines, cost responsibility would be determined during the leave to construct application.

Another common theme communicated by municipal representatives was the sense of urgency to develop the near term recommendations of a new line to Pickle Lake and the line upgrades from Dryden to Red Lake. The OPA agrees that the recommendation of building a new 230 kV single circuit line to Pickle Lake and upgrading the lines between Dryden and Red Lake are required as soon as possible, and will continue to support their development within the capacity of the OPA.

8.3 Other Engagement Activities

Prior to the publication of the Draft North of Dryden IRRP, the OPA engaged with remote communities, municipalities, stakeholder groups and industry to better understand the needs of the North of Dryden sub-region and communicate options that the OPA was considering for the North of Dryden IRRP. Presentations were made to the following groups and events:

- Ontario Mining Conference – June, 2013
- Common Voice Northwest – May, 2013
- Kenora District Municipal Association AGM – February, 2013
- Central Corridor Energy Group/Wataynikaneyap Power – various meetings 2011-2014
- Sagatay Transmission L.P. – various meetings 2012-2014

- Sioux Lookout Aboriginal Advisory Management Board - Trades Conference Fall 2012
- Aboriginal Energy Forum – December 2012
- Keewaytinook Okimakanak Chiefs Annual Meeting – December 2012
- Red Lake Mining Forum – October 2012
- NWOFNTPC - various meetings 2011-2012

With the release of draft IRRP in August 2013, the OPA hosted a webinar on November 21, 2013 to provide a high-level overview of the plan and to start the dialogue on further developing and refining the plan. An archive of the webinar was posted to the OPA website for stakeholders and communities who were not able to participate.

The OPA also established a dedicated email address – northofdryden@powerauthority.on.ca – to receive written feedback on the draft IRRP and for correspondence about the plan.

9 SUMMARY OF RECOMMENDATIONS

The existing North of Dryden sub-region has met its load meeting capability. In order to accommodate the economic connection of remote First Nation communities and to enable forecasted growth in the mining sector, it is prudent to develop and implement the following recommended solutions as soon as possible:

1. Building a new single circuit 230 kV transmission line from the Dryden/Ignace area to Pickle Lake (for the Pickle Lake subsystem) and installing a new 230/115 kV autotransformer, related switching facilities, and the necessary voltage control devices at Pickle Lake;

2. Upgrading the existing 115 kV lines from Dryden to Ear Falls (E4D) and from Ear Falls to Red Lake (E2R) (for the Red Lake subsystem) and install the necessary voltage control devices; and

3. IESO/OPA to initiate discussions with OPG for new reactive power services provided by Manitou Falls GS if it is confirmed to be beneficial to the ratepayer

These recommendations are the most cost-effective options that can be implemented in a timely manner and provide flexibility for meeting a broad range of long term forecast scenarios.

The estimated combined cost of recommendations (1) and (2) during the planning period is about $124 million (net present value). Recommendation (3) may reduce the estimated cost further. Together these projects increase the LMC of the Pickle Lake subsystem from 24 MW to 160 MW, and increase the LMC of the Red Lake subsystem from 61 MW to 130 MW.

Based on the reference scenario forecast, the recommended solutions are expected to satisfy the forecasted demand requirements for the Pickle Lake and Red Lake subsystem until beyond the end of the planning period. The high scenario forecast indicates that additional investments for the Red Lake subsystem may be required by

2030. The transmission and generation options available have relatively short lead times compared to the 2030 need date, based on the high scenario forecast. As a result, no further action needs to be taken at this time.

The OPA has also shown that under all forecast scenarios assessed in this version of the North of Dryden IRRP, transmission supply options to supply the Ring of Fire subsystem are more economic than remote generation options. The OPA therefore recommends that common infrastructure corridor planning to the Ring of Fire should include the consideration of the potential need for a transmission line to ensure economic and regulatory efficiencies. The OPA will monitor developments in the Ring of Fire subsystem to ensure potential customers, stakeholders and Aboriginal groups are aware of these findings.

The OPA will continue to monitor developments in the North of Dryden sub-region, such as: progress on the recommendations in this version of the plan, demand growth, conservation activities, and progress on developments at the Ring of Fire.

As developments in the North of Dryden sub-region reach new milestones, a new planning cycle for the sub-region will be initiated. The next planning cycle will take place within the next 1-5 years, consistent with the TSC, DSC, and the OPA's license, depending on if and when currently uncertain developments take place.

When the long-term needs for the Red Lake and Ring of Fire subsystems become more certain, reinforcement projects can be triggered in the next planning cycle with appropriate lead times to ensure that the needs will be met.

Some projects may require funding by customers, in accordance with the TSC. In these cases the projects cannot proceed until customers have committed the required resources and funding for development work to be completed. Therefore, the timing of these facilities may be dependent on when customers can identify their needs and provide commitment to the project.

Additionally, conservation and distributed generation resources are important contributors to the integrated solution for addressing the needs of the North of Dryden sub-region. The OPA has and will continue to actively work with existing and future customers in the North of Dryden sub-region to pursue conservation and DG. The OPA will continue to work with interested customers to understand the availability of potential resources including conservation and customer based DG in the North of Dryden sub-region.

The recommended solutions in the North of Dryden sub-region are consistent with the broader planning and development work that is underway to ensure an adequate supply is available in the Northwest as a whole.

TSC	Transmission System Code

10.3 Study Methodologies

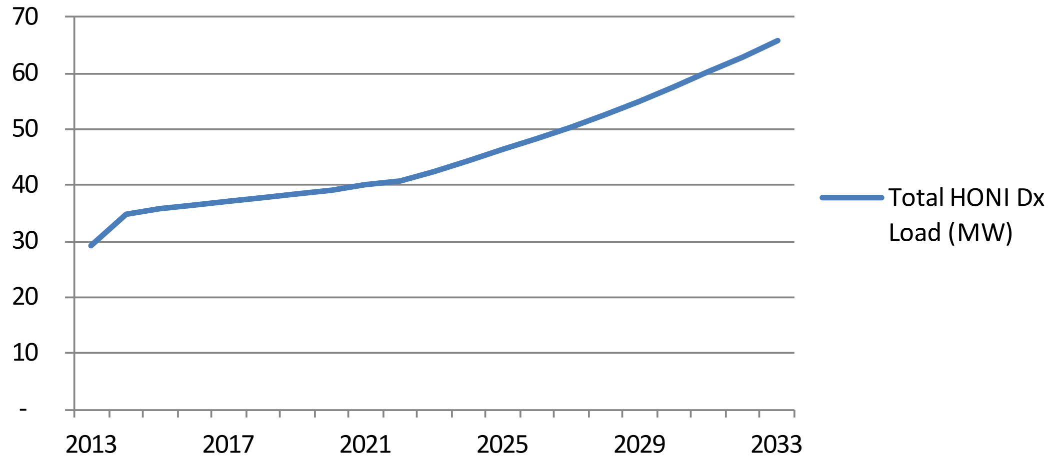
10.3.1 Hydro One Distribution - Reference Demand Forecast Methodology

Hydro One Distribution services the North of Dryden sub-region via six step-down stations:

- 115/12.5 kV Perrault Falls DS supplied by circuit E4D
- 115/44 kV Ear Falls TS supplied by 115 kV circuit E4D
- 115/44 kV Red Lake TS supplied by 115 kV circuit E2R
- 115/24.9 kV Cat Lake CTS supplied by 115 kV circuit E1C
- 115/24.9 kV Slate Falls DS supplied by 115 kV circuit E1C
- 115/27.6 kV Crow River DS supplied by 115 kV circuit E1C

The Hydro One reference demand forecast was developed using macro-economic analysis, which takes into account the growth of demographic and economic factors. Thus historical relationships between actual load growth and economic/demographic factors were utilized in preparing the forecast. In addition, local knowledge, as well as information regarding the loading in the area within the next two to three years, is utilized to make minor adjustments to the forecast. The forecast is net of the load impact of conservation so that it is consistent with actual load for the base-year and expected load in the future in a manner consistent with the on-going provincial conservation efforts. It also reflects the expected weather impact on peak load under average peak-time weather conditions, known as weather-normal. Furthermore, the forecast is unbiased such that there is an equal chance of the actual peak load being above or below the forecast.

Figure 15: North of Dryden sub-region Reference Distribution Demand Forecast (Net of Conservation)



10.3.2 **Methodology for Dependable Renewable Generation Assumptions**

Determining Dependable Wind and Solar Generation

For planning purposes, the dependable capacity of generation is the prorated amount of installed generation capacity that can be relied on to meet demand during peak need hours. Since each type of distributed generation exhibits unique behavior, specific capacity contribution assumptions were used for wind and solar to determine the dependable capacity of these resource types in the North of Dryden sub-region.

Table 53: Capacity Contributions from Wind and Solar

Resource Type	Capacity Contribution	Data Source
Wind	30%	Wind Profiles from AWS Truepower
Solar	5%	Solar Profiles from AWS Truepower

The capacity contribution of solar generation depends on both random and predictable elements, such as weather conditions, latitude, and sunrise/sunset times. The capacity contribution of wind generation depends on weather conditions and can vary significantly. To achieve an accurate representation of these resources, hourly solar and wind profiles for the Northwest zone were estimated by AWS Truepower for the years between 2004 and 2008.

The fall period is typically the most constrained supply period for the North of Dryden sub-region as it is when hydroelectric generation in the Ear Falls area is at its lowest. To calculate the expected solar and wind output in the area, hourly capacity factors from the AWS data corresponding to the top 10% of historical demand hours during October and November were averaged. This result provides a dependable level of output that can be reasonably expected from solar and wind resources in the North of Dryden sub-region during the period of peak need.

Determining Dependable Hydroelectric Generation

The hydroelectric generators located in the North of Dryden sub-region are listed below in Table 54. Lac Seul GS is an expansion of the Ear Falls GS that was undertaken by OPG with the Lac Seul First Nation.

Table 54: Existing and Contracted Hydroelectric Generation

Name	Owner	No. Unit (Total)	Unit Size (MW)	Circuit
Manitou Falls GS	Ontario Power Generation	5	4x14.9 + 1x13.5	M3E
Ear Falls GS	Ontario Power Generation	4	2x5.4 + 2x3.1	Ear Falls TS bus
Lac Seul GS	Ontario Power Generation	1	12.1	Ear Falls TS bus
Trout Lake River GS	Horizon Hydro Inc.	1	3.75	E1C

Northern hydroelectric generation is an energy limited resource known to have significantly reduced output and availability during drought conditions of the river system supplying these generating units. Neither Manitou Falls nor Ear Falls/Lac Seul are currently configured to condense. The OPA has met with OPG and are aware that configuring some select units for condense mode under drought conditions may be a low cost option to provide voltage support.

Dependable generation is defined in ORTAC as the level of generation that is available for at least 98% of hours during the evaluation period. At Manitou Falls GS, output has been at least 14.4 MW 98% of the time, while at Ear Falls GS output has been at least 6.7 MW, 98% of the time.

At Manitou Falls GS, four of the five units are connected on the secondary of one step up transformer (T1), with the fifth unit having its own transformer (T2). Because of this configuration, if T1 is unavailable, only one Manitou Falls GS unit (G5) can remain operational during the duration of the outage of T1.

The units at Manitou Falls GS units are also much larger (13.5 MW and 14.9 MW) than the Ear Falls GS units (3.1 MW and 5.4 MW), therefore the presence of one additional Ear Falls GS unit (assuming sufficient water is available during the outage of Manitou Falls T1) does not significantly improve the transfer limits in the subsystem. The single Lac Seul unit is of a similar size to the Manitou Falls GS units and its operation does significantly improve the transfer capability of the Red Lake subsystem, when it is available.

However, the performance of the Lac Seul unit and the future Trout Lake River GS during drought conditions is not yet known. Until drought condition performance is determined at these units they are assumed to be unavailable during drought conditions. The dependable generation assumptions for hydroelectric units in the Ear Falls area that have been used in this plan are summarized in Table 55.

Table 55: Existing and Contracted Hydroelectric Generation

Name	No. Units (Total)	Unit Size (MW)	Dependable Output (MW)
Manitou Falls GS	5	4x14.9 + 1x13.5	14.4
Ear Falls GS	4	2x5.4 + 2x3.1	6.7
Lac Seul GS	1	12.1	0
Trout Lake River GS	1	3.75	0

High Level Cost Assessment of Renewable Generation

The seasonal and annual variations of run of river hydroelectric generation and the intermittent output of potential wind and solar resources in the North of Dryden sub-region lead to dependable capacities for these resources that are between 5% and 30% of their nameplate capacity, as described above. If these types of resources were used to meet capacity needs for the North of Dryden sub-region, then their dependable capacity would be used to assess their contribution to meeting peak demand. To be an alternative to other generation resources or transmission reinforcements, the nameplate capacity of these renewable resources would have to be built to a level substantially greater than the capacity required for the subsystem. Furthermore, because of this over-sizing, during times of high renewable output, these resources may be partially constrained by limited existing transmission capability connecting them to the rest of the Ontario system.

Developing these resources to serve capacity needs would require between 3 MW and 20 MW of nameplate capacity to dependably supply 1 MW of load.

It is estimated that the capital cost of dependable run of river hydroelectric capacity ranges from $15 million to $65 million per MW, while wind and solar range from $15 million to $100 million per MW. The curtailment of generation would have an associated cost, or alternatively, new implementation of transmission to deliver excess energy would also have societal costs and is an alternative to renewable generation for meeting the needs of the North of Dryden sub-region. Neither of these additional costs were considered in this high level cost analysis. A summary of the results of this cost analysis is in Table 56, below.

Table 56: Summary of Renewable Generation Options

Resource Type	Firm Capacity	Capital Cost per MW of Firm Capacity	Levelized Unit Energy Cost[76]	Development Duration
Hydroelectric (Run of River)	15-30%	$16 M - $66 M /MW	$60-$110/MWh	5 to 10 Years
Intermittent Renewables	5-28%	$7.5 M - $100M /MW	$80-$400/MWh	3 Years

10.4 Technical Studies and Analysis Methodologies

The following section outlines the assumptions and methodology used for performing the technical analysis for determining the load meeting capability of the existing system, and the options being considered. The load meeting capability for options being considered are mostly limited by acceptable voltage performances. Consequently, a significant portion of the costs for options being considered is for the installation of voltage control devices. When developing cost estimates, planning level unit costs were used, which typically have an accuracy of +/-50%.

10.4.1 Base Case Setup and Assumptions

The system studies for this plan were conducted using PSS/E Power System Simulation software. The reference PSS/E case was adapted from the base case that was produced by the IESO for the 2012 North of Dryden Feasibility Study.

Bulk System Assumptions

The North of Dryden sub-region is connected to the bulk transmission system at Dryden TS. The forecasted capacity requirements for the North of Dryden sub-region are coordinated with the West of Thunder Bay IRRP. Therefore, for the purpose of this assessment, it is assumed that the bulk system supply to the North of Dryden sub-

[76] Levelized Unit Energy Cost (LUEC) is a method to compare electricity system resources on a $/MWh basis, considering the costs incurred (capital, fixed, variable, fuel, etc.) and the production of energy over the lifetime of the resource, discounted appropriately. LUEC assumes that all energy generated can be delivered without transmission constraints.
.

region will be stable. A healthy supply voltage from the bulk 230 kV (nominal) system of 245 kV has been assumed.

Local Area Assumptions

These load flow cases include the following assumptions:

- Dependable (drought) level hydroelectric generation, which totals 21.1 MW in the Ear Falls area (Manitou Falls GS (14.4 MW), Ear Falls GS (6.7 MW))
- Summer ambient temperature of 30°C and 0-4 km/hr wind for ampacity of overhead transmission circuits
- Peak forecasted load corresponding to the reference, high, and low scenarios for the near term and medium to long term
- All proposed 115 kV circuits had line characteristics equivalent to that of a 477 kcmil ACSR conductor (similar to existing M2D), and all proposed 230 kV circuits had line characteristics equivalent to that of a 795 kcmil ACSR conductor (similar to existing circuit D26A)
- The 115 kV step-down transformers at Mc Faulds (Ring of Fire mines) were assumed to be similar to the existing transformers at Red Lake TS. Other 115 kV step-down transformers were assumed to be similar to the existing transformers at Crow River DS for loads greater than 3 MVA, or the Slate Falls transformer for loads smaller than 3 MVA. The Pickle Lake 230/115 kV autotransformer was assumed to be similar to the existing Lakehead autotransformers.
- Dependable capacity at Trout Lake River GS is assumed to be 0 MW
- 5% of installed solar capacity is assumed to be dependable. This includes four microFIT projects in Red Lake providing capacity of 39.3 kW and one microFIT project in Ear Falls with an capacity of 10 kW, providing a 2.5 kW of dependable output
- For steady state and voltage assessment, the loads are modeled as constant megavolt-ampere (MVA)
- All new voltage control devices are assumed to be Static Var Compensation (SVC) devices

- It was assumed that the loss of voltage control devices connected at load stations (McFaulds, Esker, Musselwhite, Red Lake, Balmer, Sandy Lake, Pickle Lake area Mine) would also result in the loss of the associated load.

10.4.2 **Application of IESO Planning Criteria**

In Ontario, the criteria for planning the transmission system are specified in the IESO's Ontario Resource and Transmission Assessment Criteria (ORTAC)[77]. In accordance with ORTAC, the transmission system supplying a local area shall have sufficient capability under peak demand conditions to withstand specific outages prescribed by ORTAC while keeping voltages, line and equipment loading within applicable limits. In determining the load meeting capability for each subsystem, ORTAC requires certain conditions to be respected. The supply options that are discussed for the North of Dryden sub-region assume that where new lines are built parallel to existing lines, some or all of the incremental load that is enabled for connection to the system, may be curtailed in the event of a forced outage of either line. This following is an excerpt from Section 7.1 of ORTAC which states:

> "The *transmission system* must be planned to satisfy *demand* levels up to the extreme weather, median-economic forecast for an extended period with any one transmission element out of service. The *transmission system* must exhibit acceptable performance, as described below, following the design criteria contingencies defined in sections 2.7.1 and 2.7.2. For the purposes of this section, an element is comprised of a single zone of protection.
>
> With all transmission *facilities* in service, equipment loading must be within continuous ratings, voltages must be within normal ranges and transfers must be within applicable normal condition stability limits. This must be satisfied coincident with an outage to the largest local generation unit.
>
> With any one element out of service3, equipment loading must be within applicable long-term *emergency* ratings, voltages must be within applicable *emergency* ranges, and transfers must be within applicable normal condition stability limits. Planned load *curtailment* or load rejection, excluding voluntary *demand* management, is permissible only to account for local generation outages. Not more than 150MW of load may be interrupted by configuration and by planned load *curtailment* or load rejection, excluding voluntary *demand* management. The 150MW load interruption limit reflects past planning practices in Ontario."

Additionally, the following were assumed in this study to comply with ORTAC:

- Run of river hydroelectric generation should be assumed at a level that is available 98% of the time (ORTAC Section 2.6);

[77] http://www.ieso.ca/imoweb/pubs/marketadmin/imo_req_0041_transmissionassessmentcriteria.pdf

- Load power factors is assumed to be 0.95 at the low voltage busbar to comply with the Market Rule of 0.9 at the defined meter point at the HV busbar (ORTAC Section 2.4);
- Voltage operating range of 113 kV to 132 kV for the 115 kV nominal system, and 220 kV to 250 kV for the 230 kV nominal system (ORTAC Section 2.4);
- Pre-contingency voltage maintained to the greater of (ORTAC Section 4.2):
  - At least 10% margin above the instability point
  - Minimum continuous voltage pre-contingency: 113 kV for 115 kV nominal system, and 220 kV for 230 kV nominal system
  - That which results in a post-contingency voltage of at least 108 kV for 115 kV nominal system, and 207 kV for 230 kV nominal system
- All line and equipment loading is within the continuous ratings with all elements in service and within their long-term emergency ratings with any one element out of service (ORTAC Section 4.7.2 and 7.1); and
- If the subsystem has transmission connected generation, the largest generator unit is assumed to be on outage pre-contingency and not available post-contingency.

The load meeting capability for each subsystem and each option are determined with the aid of PSS/E simulation, which represents a full model of the system, accounting for active and reactive power flows, losses, voltage drops, etc.

Table 57: Conditions for Determining Subsystem LMC

Local Area Supply	Conditions for LMC
Single Radial Line	Limit of the line during normal operating conditions.
Single Radial Line + Local Generation	Limit of the line during normal conditions; and Loss of the largest generating unit.

10.4.3 **Technical Study Procedures**

Once the needs for the subsystems were determined based on an assessment of the existing system and forecast net demand growth, the technical study identified how various options could meet the identified needs. From these needs, a range of generation and transmission options were developed that are capable of partially or fully meeting the identified needs. The capability of the options to serve the needs including the amount of voltage control required to meet the required LMC was determined.

Contingencies Considered in Option Assessment

A detailed list of the contingencies considered for the North of Dryden sub-region is outlined below in Table 58. All contingencies are limited to the loss of a single element (N-1) considering pre-contingency outage conditions consistent with ORTAC.

Table 58: Contingencies Considered in the Technical Study

Subsystem	Supply Option	Contingencies
Pickle Lake	CNG generation at Pickle Lake	Loss of single generating unit (10 MW) at Pickle Lake
		Loss of Manitou Falls GS
	New Line to Pickle Lake	N/A
Red Lake	NG generation at Red Lake	Loss of single generating unit (10 MW) at Red Lake
		Loss of Manitou Falls GS
	New Line to Ear Falls	Loss of New Line
		Loss of Manitou Falls GS
Ring of Fire	All	N/A

Determining Voltage Control Requirements

For each option in each subsystem, base cases were developed for both peak and light load conditions. Each subsystem was considered independently, and the effects of each option on the bulk system around Dryden TS and/or at Marathon TS were included.

Location and size of the voltage control devices for each test case was determined under the following load scenarios to satisfy the assumptions listed above.

1. Peak load conditions, all elements in service: This test determined the voltage control devices are required to ensure sufficient margin from the voltage collapse point. Voltage control devices were used to maintain the voltage within the ranges stated in the assumptions.

2. Zero load conditions: This test determined the amount of voltage control required to manage high voltages.

3. Light load conditions, all elements in service: This test was used to determine the required switching size and range of the voltage control devices.

4. Peak load conditions, largest local element out of service: In areas where contingencies were tested, voltage control device requirements before tap changing were determined.

Determining Load Meeting Capability of Options

This study uses the base cases that were developed for the peak load scenario in determining voltage control requirements, as stated above. For each subsystem, the LMC of the option following the installation of all facilities and voltage control devices that are required to meet the peak load forecast was determined for each option for each forecast scenario.

The LMCs for each option were determined using the following procedure:

1. The range of voltage control that was determined in the previous analysis was assumed to be available.

2. Peak load was assumed as a base. Thermal loading of transmission equipment was assessed.

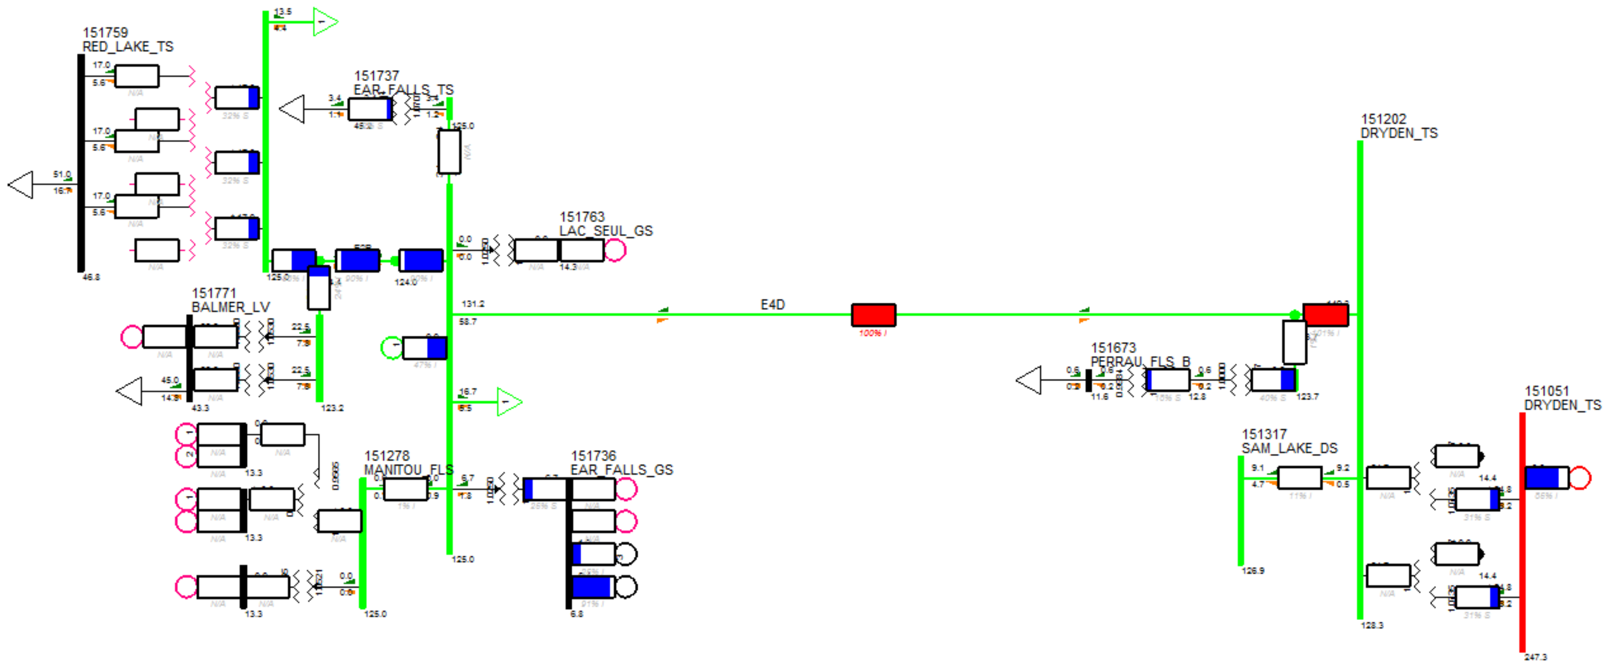
3. Where there was existing thermal capacity on transmission equipment, load was increased and new voltage control requirements were established, to determine the LMC. Load was increased at a central system bus within the subsystem (Pickle Lake area TS for the Pickle Lake subsystem, Ear Falls TS for the Red Lake subsystem, Mc Faulds TS for the Ring of Fire subsystem).

4. Following this, the system was tested allowing voltage control requirements to increase within reasonable limits.

More detailed studies for particular reinforcements may determine that voltage control devices can be located in alternative places closer to large loads, which may be found to optimize their value and reduce the overall cost. Specific connection requirements for individual customers, including requirements for additional voltage control devices will be identified by the IESO in future System Impact Assessments (“SIA”).

A sample load flow case that was used to determine the LMC of the Red Lake subsystem after the upgrade of E4D and E2R is provided in Figure 17 below. In this case, the LMC for subsystem is 130 MW.

Figure 17: Sample of Methodology – Determining Post-Upgrade LMC of E4D and E2R Upgrade

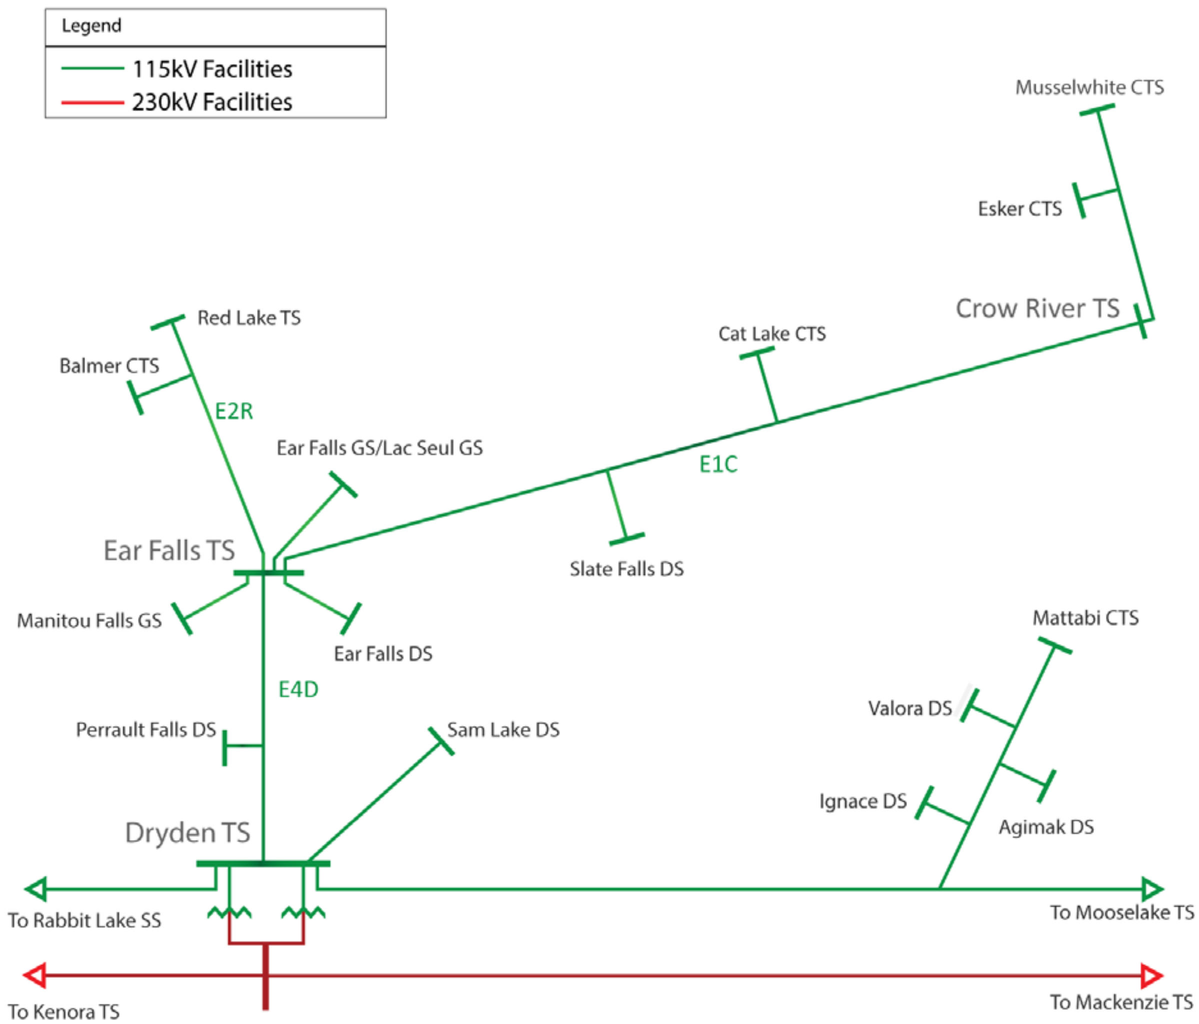


136

10.5 Existing System Description and Load Meeting Capability

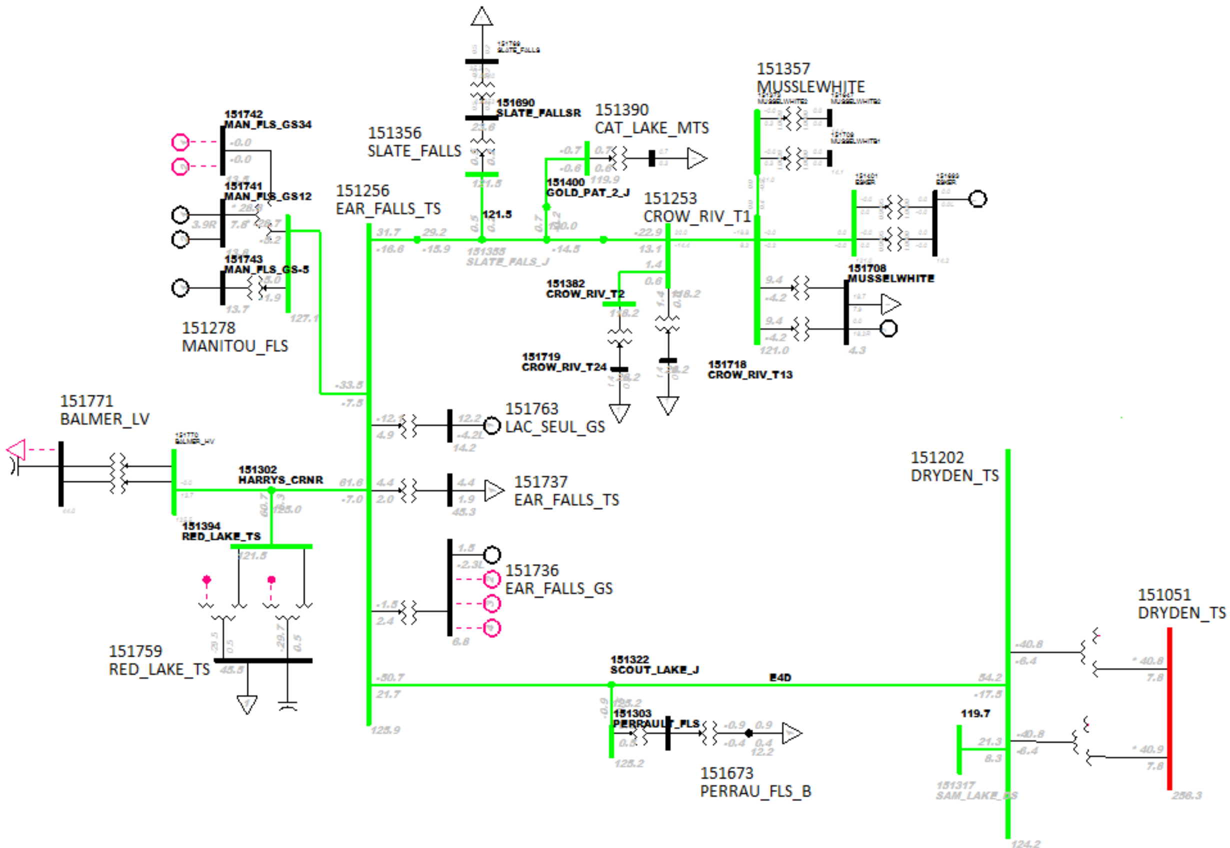
The North of Dryden electricity system is shown in Figure 18.

Figure 18: Existing North of Dryden Transmission System



137

Figure 19: Existing North of Dryden Transmission System Load Flow Plot



Pickle Lake Subsystem

The Pickle Lake subsystem includes all load currently and planned to be served by E1C at Cat Lake CTS, Slate Falls DS, Crow River DS, as well as Musselwhite mine. The Pickle Lake subsystem also includes 10 remote communities north of Pickle Lake that are planned to connect to Pickle Lake via a transmission line to Crow River DS.

Currently, the Pickle Lake subsystem has an LMC of 24 MW. Due to losses on the line E1C, supply of close to 35 MW is required from Ear Falls TS to serve this load along the line and at Pickle Lake. The LMC for the Pickle Lake subsystem is determined by the load that can be met during normal operating conditions.

138

Red Lake Subsystem

The Red Lake subsystem includes all load and generation connected and planned to be served by E4D and E2R, at Perrault Falls DS, Ear Falls TS, Red Lake TS, Balmer CTS, and the six remote communities that lie north of Red Lake that are planned to connect to Red Lake TS. There is 102.2 MW of hydroelectric generation at Ear Falls/Lac Seul GS and at Manitou Falls GS.

Currently, the E4D and Ear Falls area generation is capable of supplying 85 MW from Ear Falls TS, which includes 61 MW in the Red Lake subsystem and 24 MW in the Pickle Lake subsystem.

Ring of Fire Subsystem

The Ring of Fire subsystem includes five remote communities that are planned for connection to the provincial transmission system as well as potential future industrial customers at the Ring of Fire. This subsystem may be connected to the provincial transmission system either at Pickle Lake, Marathon TS, or east of Nipigon.

The Ring of Fire subsystem is not currently supplied from the IESO-controlled grid and thus has a load meeting capability of 0 MW. However the 5 remote communities are currently served by local diesel generation in their communities.

10.6 Analysis of Recommended Options

As indicated in Section 0, the recommended options for the North of Dryden sub-region are:

1. Building a new single circuit 230 kV transmission line from the Dryden/Ignace area to Pickle Lake (for the Pickle Lake subsystem) and installing a new 230/115 kV autotransformer, related switching facilities, and the necessary voltage control devices at Pickle Lake;

2. Upgrading the existing 115 kV lines from Dryden to Ear Falls (E4D) and from Ear Falls to Red Lake (E2R) (for the Red Lake subsystem) and install the necessary voltage control devices; and

3. IESO/OPA to initiate discussions with OPG for new reactive power services provided by Manitou Falls GS if it is confirmed to be beneficial to the ratepayer

   For the list of assumptions and procedure pertaining to the assessment of generation options, refer to Section 10.7. For a list of assumptions and procedure pertaining in the assessment of transmission options, refer to Section 10.8

Recommendation 1: New single circuit 230 kV line to Pickle Lake and supporting facilities

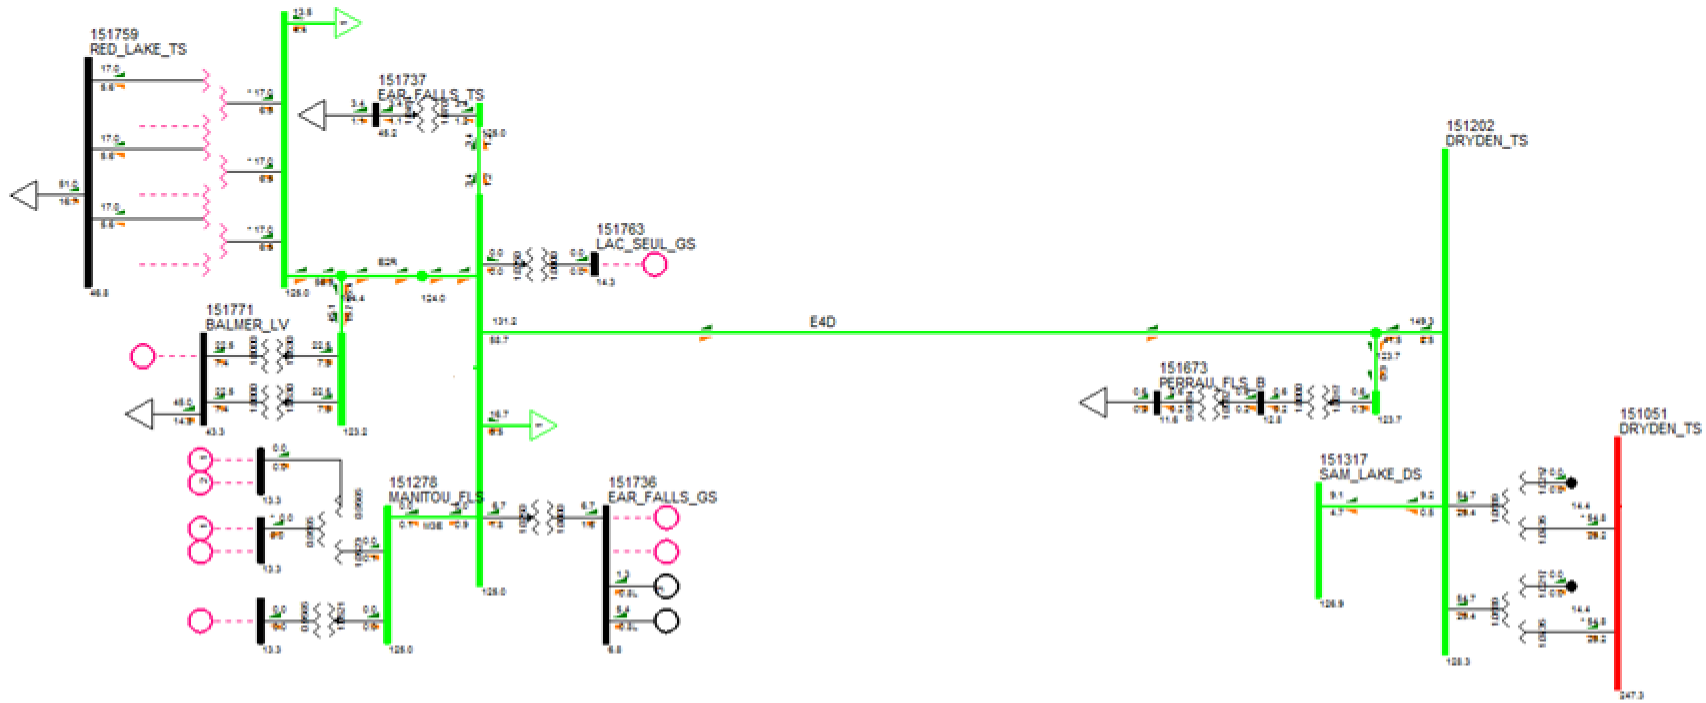
146

Figure 23: E4D and E2R Upgrade Red Lake Subsystem Configuration



147

Recommendation 3: Manitou Falls condense operation during drought conditions

In order to accommodate future growth in the Red Lake subsystem, new voltage control devices would need to be installed in the Ear Falls and Red Lake areas. New voltage control devices would be required in order to release the thermal capability provided to the Red Lake subsystem from the system upgrades being recommended.

OPG has informed the OPA that Manitou Falls units G1, G2, and G3 could be made to condense with minor maintenance work. Units G1, G2, and G3 would have a capability of approximately +/-14 MVar each, for a total of +/- 42 MVar. The OPA anticipates that the NPV cost associated with enabling and operating the condense features over the planning period is likely to be significantly less than the NPV cost of installing new voltage control devices.

10.7 Generation Options

For each of the three subsystems, at least one generation option was studied in detail. However, due to the different nature of each system, and thus the differing needs, each system was approached with a unique methodology to ensure that the generation option/s studied reflect the need of the subsystem.

The assumptions and methodologies used for developing the generation options are described below.

10.7.1 Pickle Lake Subsystem

Assumptions

The following assumptions were used to estimate the cost of CNG electricity generation in the Pickle Lake subsystem:

- Pickle Lake subsystem will remain connected to Ear Falls TS and 24 MW of load in the Pickle Lake subsystem will be served from Ear Falls TS

- Forecasted demand greater than 24 MW in the Pickle Lake subsystem (including remote communities in the Ring of Fire subsystem connecting at Pickle Lake) would be served by CNG fueled generation at Pickle Lake
- Generators will be dual fuel CNG/Diesel reciprocating engines. Engines will be capable of running predominantly on CNG, but can run on pure diesel as needed
- Generation would be fueled mainly by CNG, which would be compressed and transported from TCPL pipeline in the Ignace area via Highway 599
- Decanting stations would be required to decompress the natural gas for use
- CNG fuel delivery would be on a just in time basis due to challenges with large scale on-site CNG storage
- If CNG is unavailable generators will run on diesel, cost of supplying diesel and storage has not been included
- A sufficient number of trailers would be required to transport CNG as well as provide for some limited on-site storage to ensure a stable flow of fuel
- A Special Protection System triggered by the loss of more than one generator in the new facility, may be required to automatically shed load sufficient to maintain operation of E1C within appropriate limits
- Discrete generator unit sizes of 9.5 MW

Study Procedure

To determine the feasibility and estimate the cost of implementing a CNG generation facility in the Pickle Lake subsystem, the following procedure was undertaken:

1. Load flow assessment in PSS/E (provided in this Section) was done to find the installed generation capacity at Pickle Lake that would be required to meet the peak forecast demand of the subsystem.
2. Using established transmission limits, hydroelectric generation profiles and load profiles for the subsystem, the capacity and energy that would need to be served by new CNG generation resources was estimated.
3. Using energy requirements estimate number of trucks and trailers (size of fleet) required to transport fuel based on a) trailer volume assumptions, b) fuel requirements and c) one day round trip;

4. Using generator capacity, number of trailers and annual energy requirements, capital, operations and maintenance, and fuel costs of the system were calculated.
5. These capital, operations and maintenance costs, were levelized over the project life and the present value over the planning period (2013-2033) was calculated.

Planning Level Assessment

A summary of the technical capability of the generation options that were considered for the Pickle Lake subsystem is summarized below.

Table 63: Summary of Capacity for Gas Generation at Pickle Lake

Option	Incremental Capacity	Load Meeting Capability	Low Forecast Demand	Reference Forecast Demand	High Forecast Demand
CNG Generation at Pickle Lake (38 MW)	19 MW	43 MW	41 MW	78 MW	90 MW
CNG Generation at Pickle Lake (47.5 MW)	23.5 MW	47.5 MW			
CNG Generation at Pickle Lake (76 MW)	57 MW	81 MW			
CNG Generation at Pickle Lake (85.5 MW)	66.5 MW	90.5 MW			

*Requires continued supply of 24 MW of load via E1C from Ear Falls

**Includes demand for Ring of Fire remote communities (7 MW)

The cost of supplying the growth needs of the Pickle Lake subsystem with CNG fueled generation are shown in Table 64 through Table 69. Figure 24 shows operation of the Pickle Lake subsystem with this option in the peak load case. Voltage profiles throughout the subsystem remain healthy in the general range of 118 kV to 125 kV. The installation of generation at Pickle Lake also provides some voltage control to the Pickle Lake subsystem.

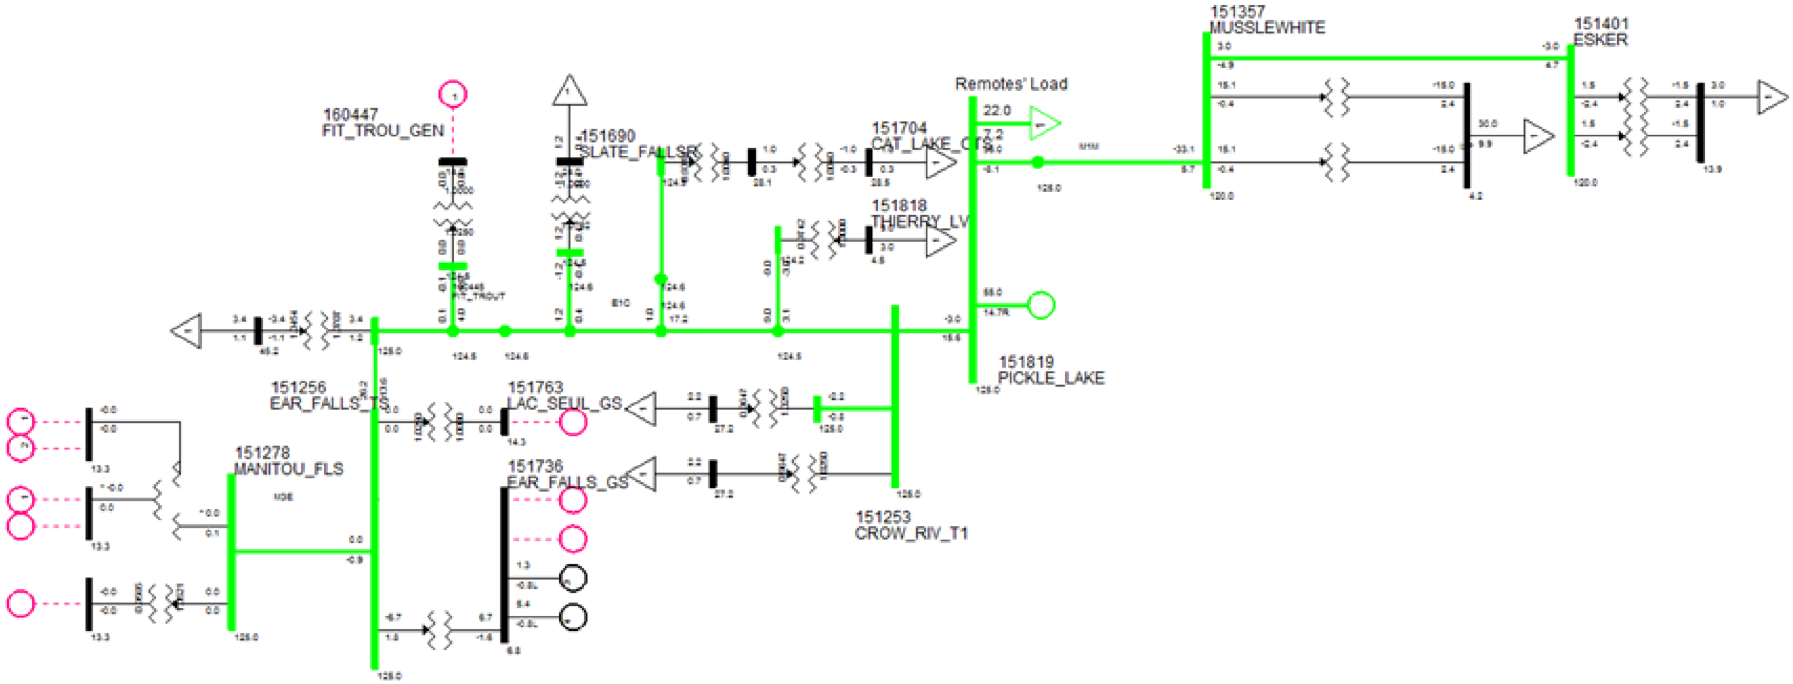
Figure 24: Generation Option Pickle Lake Subsystem Configuration



10.7.2 Red Lake Subsystem Generation Options

Assumptions

The following assumptions were used to estimate the cost of natural gas electricity generation in the Red Lake subsystem:

- Natural gas would be supplied via the existing Union Gas pipeline in the Red Lake area for 30 MW generation (near-term) option;
- Natural gas would be supplied via the existing Union Gas pipeline in the Red Lake area and a new gas pipeline to future customer(s) for the 60 MW (long-term) option;
- Pipelines are assumed to be available and associated costs are not included in this analysis (except gas management charges). New pipeline capacity required for the second 30 MW of gas generation at Ear Falls is assumed to be linked to a future potential load customer, therefore if the incremental gas capacity is not developed neither will the load be present in the subsystem; and
- Discrete generator unit sizes of 9.5 MW.

Study Procedure

To estimate the cost of implementing natural gas generation in the Red Lake subsystem, the following procedure was taken:

1. Load flow assessment in PSS/E (provided in this Section) was done to find the installed generation capacity required to meet the need of the Red Lake subsystem;
2. Using established transmission limits, hydroelectric generation profiles and the identified need for the subsystem, determine the capacity and energy that new generation resources would need to served;
3. Using established unit costs, capital, operations and maintenance, and fuel costs of the new generation resources were calculated;
4. Using capacity size, gas management charges for a peaking facility in the area were estimated; and
5. These capital, operations and maintenance costs, were levelized over the project life and the present value over the planning period (2014-2033) was calculated.

Planning Assessment of Near-Term Option

Table 70 summarizes the incremental capacity provided by this option as well as the total LMC of the Red Lake subsystem with this option, while Table 71 summarizes the cost of the option in the Red Lake subsystem.

Table 70: Capacity and LMC Summary for Generation Options at Red Lake

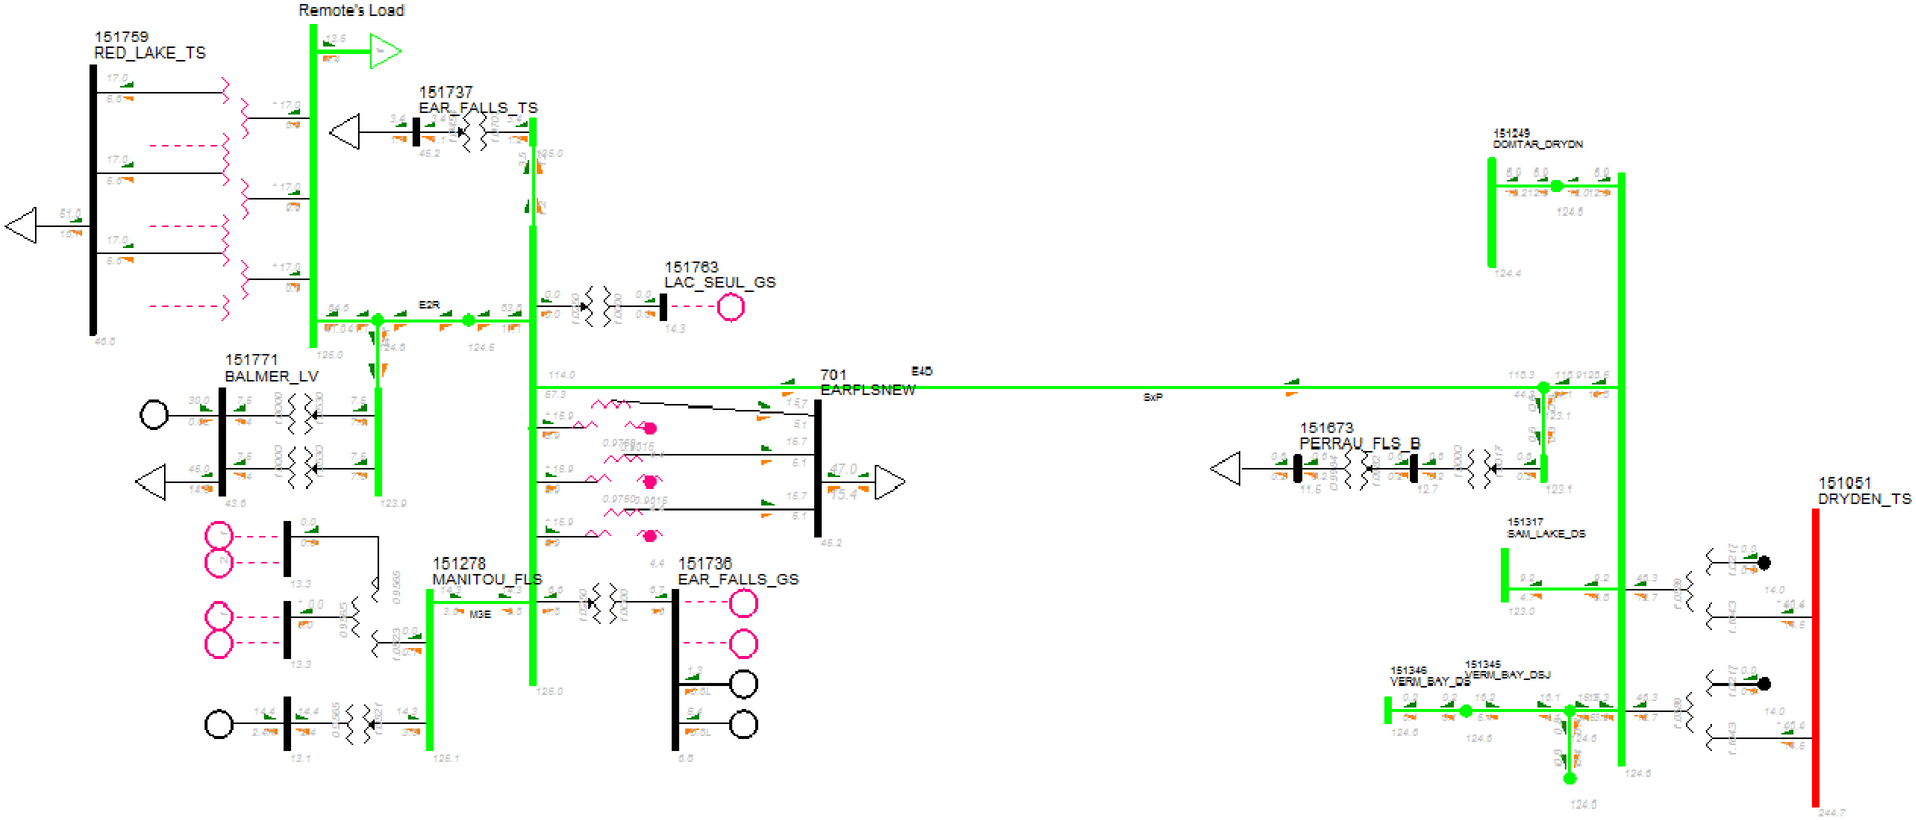
Figure 25: 30 MW Generation Option Red Lake Subsystem Configuration



157

Given the existing opportunity for 30 MW of gas generation at Red Lake, a second gas generator at Ear Falls could be sized to serve the remaining capacity needs of the Red Lake subsystem. With a total of 60 MW of gas generation in the Red Lake subsystem, the LMC of the subsystem would increase by 60 MW to 190 MW (assuming all Pickle Lake subsystem load on E1C is transferred to the new line to Pickle Lake). Table 73 summarizes the capacity provided by a single 30 MW facility at Red Lake as well as two facilities in the subsystem.

Table 73: Summary of Incremental Capacity and LMC

Option	Incremental Capacity	Load Meeting Capability*	Low Forecast Long-term Demand	Reference Forecast Long-term Demand	High Forecast Long-term Demand
NG Generation at Ear Falls (30 MW)	30 MW	160 MW	100 MW	109 MW	136 MW
NG Generation at Ear Falls (60 MW)	60 MW	190 MW			

*Includes the capability of E4D and E2R after upgrading

Figure 25 and Figure 26, show the state of the Red Lake subsystem with each of these options implemented, while Table 74 to Table 77, provide a detailed summary of the costs for each option. The generators at Red Lake and/or Ear Falls help to maintain the voltages at those buses to a healthy range of 120 kV to 125 kV.

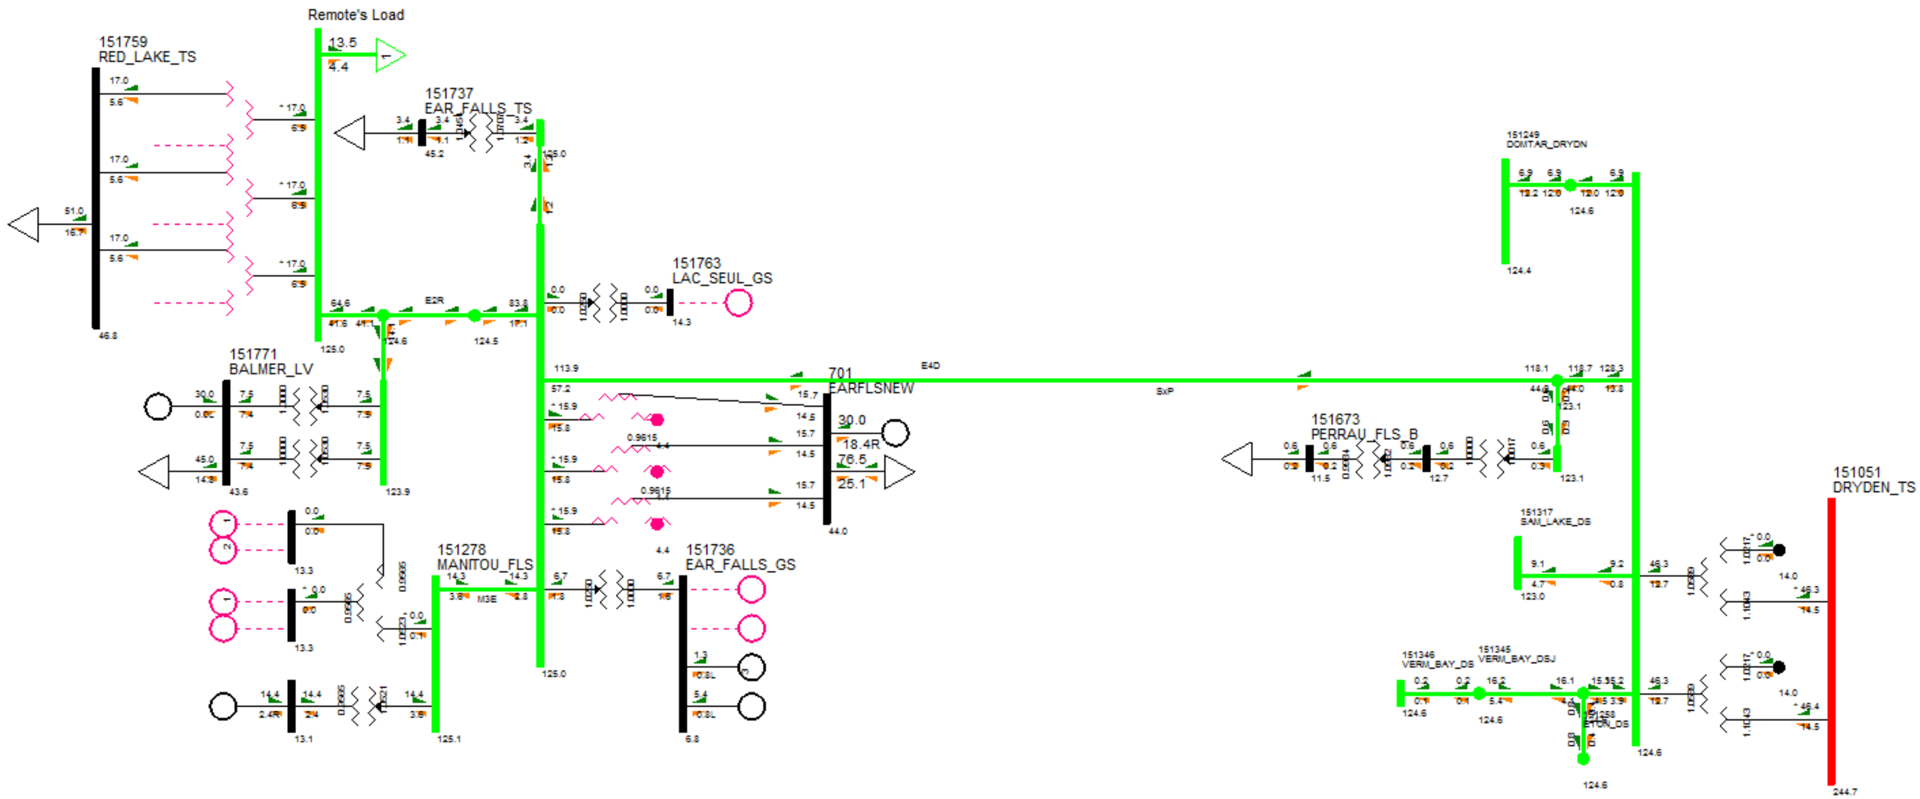
Figure 26: 60 MW Generation Option Red Lake Subsystem Configuration



10.7.3 **Ring of Fire Subsystem Options**

Assumptions

The following assumptions were made to determine the infrastructure required to implement diesel and CNG fueled generation at the mine-sites and its costs. Based on the infrastructure requirements, costs for capital, operating and maintenance and capital sustainment were estimated to determine the total cost of generating electricity at Ring of Fire mine-sites. For both fuel options, generators are assumed to not be connected to the Ontario electricity system.

Assumptions for CNG Fueled Mine-site Generation:

- Generators will be dual fuel CNG/Diesel reciprocating engines. Engines will be capable of running predominantly on CNG, but can run on pure diesel as needed;
- CNG would be compressed at a new compressor station in the Nakina area and transported on specialized high pressure transport trailers via the proposed road to the mine-sites;
- Decanting stations near the generators would be required to decompress the natural gas for use;
- CNG fuel delivery would be on a just in time basis due to challenges and additional cost of large scale on-site CNG storage;
- If CNG is unavailable generators will run on diesel;
- A sufficient number of trailers would be required to both transport fuel as well as provide for some limited on-site storage to ensure a stable flow of fuel; and
- Discrete generator unit sizes of 9.5 MW.

Assumptions for Diesel Fueled Mine-site Generation:

- Generators will be diesel fueled reciprocating engines;

- Diesel would be supplied from the Thunder Bay area and transported to the mine-sites via the proposed all-weather road, stored on site and used for in-mine equipment as well as for electricity generation;
- On-site diesel storage is available due to the variety of uses for diesel at the mine-sites, therefore timing and logistic challenges with fuel transport and delivery will not be as significant as for CNG; and
- Discrete generator unit sizes of 9.5 MW.

Study Procedure

To estimate the cost of implementing a CNG or diesel electricity generation facility at the Ring of Fire mine-sites, the following procedure was undertaken:

1. Determine forecast peak load for the Ring of Fire mines based on the demand forecast;
2. Determine the required amount of generation capacity based on peak load;
3. Calculate the energy requirements (total kWh per year) by applying a estimated load factor to the peak load;
4. Calculate fuel required daily based on energy requirements;
5. Estimate number of trucks and trailers (size of fleet) required to transport fuel based on a) trailer volume assumptions, b) fuel requirements and c) one day round trip;
6. (CNG option only) Determine number of compressor and decanting stations based on amount of fuel required per day; and
7. Use the calculated values (generator capacity, number of trucks, annual fuel requirements, and decanting/compressing stations) to calculate initial capital costs, refurbishment costs, operation and maintenance costs, and fuel costs of the system.
8. These capital, operations and maintenance costs, were amortized over the project life and the present value over the planning period (2013-2033) was calculated.

Planning Level Assessment

The generation options considered for supplying the Ring of Fire subsystem would only supply the mining load. The five remote communities in the Ring of Fire subsystem have been determined to be economic to connect as per the findings of the Remote Community Connection Plan. Backup generation capacity is considered to use consistent reliability criteria specified under ORTAC. Table 78 outlines the generation solution options considered for the Ring of Fire subsystem mining demand.

Table 78: Summary of Incremental Capacity and LMC

Option	Incremental Capacity	Load Meeting Capability for Mining	Low Forecast Long-term Mining Demand	Reference Forecast Long-term Mining Demand	High Forecast Long-term Mining Demand
38 MW of CNG	22 MW	22 MW	0 MW	22 MW	66 MW
38 MW of Diesel	22 MW	22 MW			
57 MW of CNG	44 MW	44 MW			
57 MW of Diesel	44 MW	44 MW			
85.5 MW of CNG	71 MW	71 MW			
85.5 MW of Diesel	71 MW	71 MW			

Table 79 through Table 83 below summarize the cost profiles for each option.

10.8 Transmission Options

Assumptions

In determining the cost of transmission options, the following were assumed:

- Unit cost estimates for new facilities were provided by a study conducted for the OPA by SNC Lavalin T&D. The report has been included in Section 11.3;
- Operations and maintenance costs were estimated as a percentage of the capital cost of the project, and would be incurred every year from the in-service date to the end of the projects useful life;
- Land cost was not included. Land costs are difficult to determine given the types of land and the variety of land holders that certain options described in this report may occupy; and
- Impact Benefit Agreements that may be negotiated between future projects proponents and impacted First Nations have not been estimated or included in the costs of options.

Procedure

To estimate the cost of transmission options to supply the North of Dryden sub-region, the following procedure was taken:

1. Load flow assessment in PSS/E (provided in this Section) was done to determine the capability of each option and the amount of capability of voltage control devices required to achieve the LMC;
2. Using unit costs for lines and stations, line lengths, number and types of new stations and/or station upgrades and voltage control requirements, capital, operations and maintenance costs of the system were calculated;
3. The amount of system generation that could be displaced after 2018, by associated local generation options for the subsystem was calculated; and
4. These capital, operations and maintenance costs and attributed costs for incremental system generation beginning in 2018, were levelized over the project life and the present value over the planning period (2013-2033) was calculated.

10.8.1 **Red Lake Subsystem Transmission Options**

Near-term Option - Upgrade of E4D and E2R

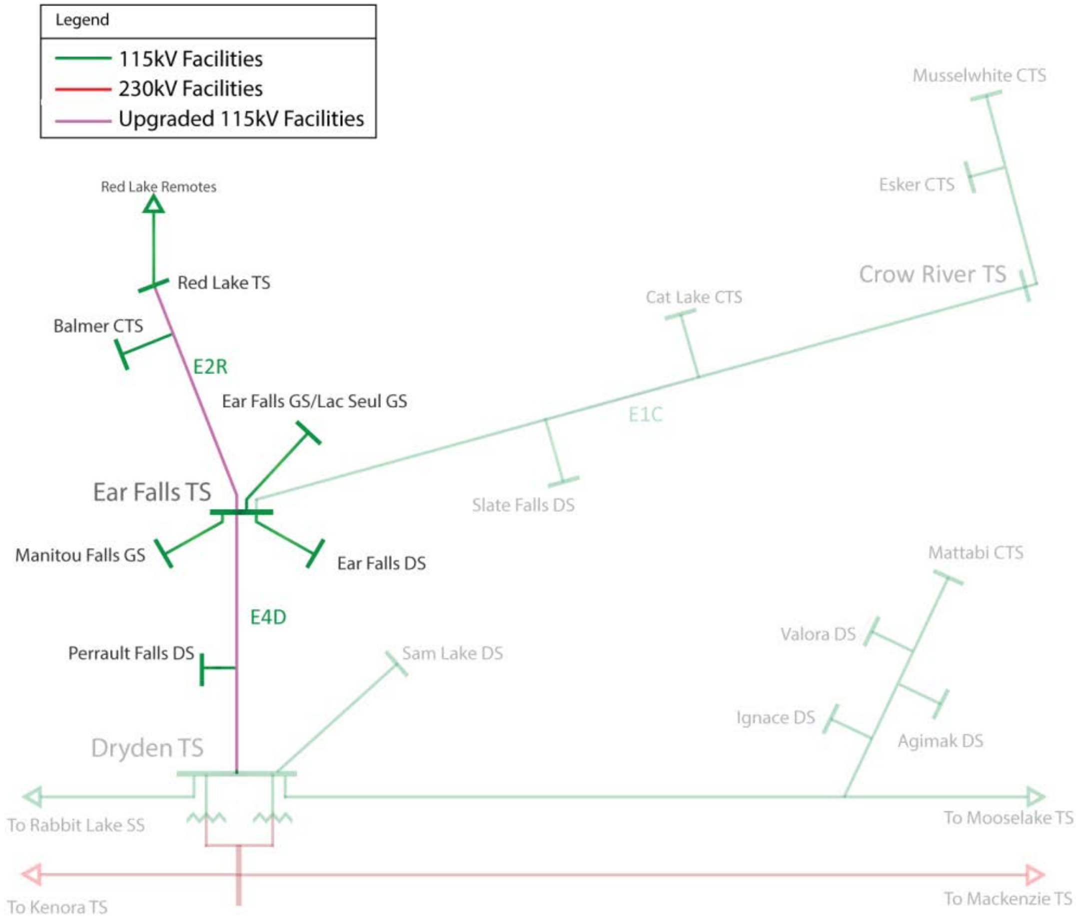
The existing lines serving the Red Lake subsystem are E4D, from Dryden to Ear Falls, and E2R, from Ear Falls to Red Lake. E4D has a thermal rating of 470 amps, and a transfer capability of 100 MVA (at 125 kV nominal voltage), while E2R a thermal rating of 420 amps, and a transfer capability of 91 MVA (125 kV nominal voltage). Based on dependable hydroelectric generation at Manitou Falls GS, Ear Falls GS and Lac Seul GS, and the current summer transmission line ratings, 85 MW of load can be served from Ear Falls TS. The Red Lake subsystem has an LMC of 61 MW, while the Pickle Lake subsystem has an LMC of 24 MW.

Hydro One has identified that E4D can be upgraded to a thermal rating of 670 amps, while E2R can be upgraded to 620 amps. After these line upgrades and the installation of an appropriate amount of voltage control at Ear Falls TS the Red Lake subsystem LMC will rise to 95 MW, assuming the Pickle Lake subsystem continues to be supplied solely from Ear Falls via circuit E1C and the LMC remains at 24 MW. A diagram of the upgrade of E4D and E2R is provided in Figure 27.

Table 85: Summary of Load Meeting Capability

Option	Incremental Capacity	Load Meeting Capability	Low Forecast Demand	Reference Forecast Demand	High Forecast Demand
Upgrade E4D and E2R	34 MW	95 MW	100 MW	109 MW	136 MW
and Transfer of Pickle Lake load to new line to Pickle Lake	35 MW	130 MW			

Figure 27: E4D and E2R Upgrade Diagram



Hydro One has indicated that upgrading these lines as well as the installation of required voltage control devices could be completed within the near-term period. Table 86 below shows the cost breakdown of the upgrade option which includes the required voltage control devices. Figure 28 shows the load flow case during peak load. Ear Falls TS and Red Lake TS voltage is maintained in a healthy range of 120 kV to 125 kV.

169

Medium- and Long-term Option - 115 kV Line from Dryden TS to Ear Falls TS

This option is to build a new 115 kV single circuit line connecting at Dryden TS running to Ear Falls TS. A diagram of this option is provided in Figure 29. Because there are two local generation options for the Red Lake subsystem (30 MW, 60 MW), the 115 kV transmission option has been developed for an LMC of 160 MW and 190 MW. The option designed to have an LMC of 160 MW is comparable to the capability of the 30 MW Red Lake generation option and 190 MW LMC option is comparable to the 60 MW gas generation option, which meets the needs of the high scenario demand forecast. This difference in transmission LMC is determined by the voltage control requirements at Ear Falls TS.

Table 87: Summary of Load Meeting Capability

Option	Incremental Capacity	Load Meeting Capability	Low Forecast Demand	Reference Forecast Demand	High Forecast Demand
New 115 kV line from Dryden to Ear Falls with less compensation (160 MW)	30 MW	160 MW	100 MW	109 MW	136 MW
New 115 kV line from Dryden to Ear Falls with more compensation (190 MW)	60 MW	190 MW			

Figure 29: New 115 kV line to Ear Falls Diagram

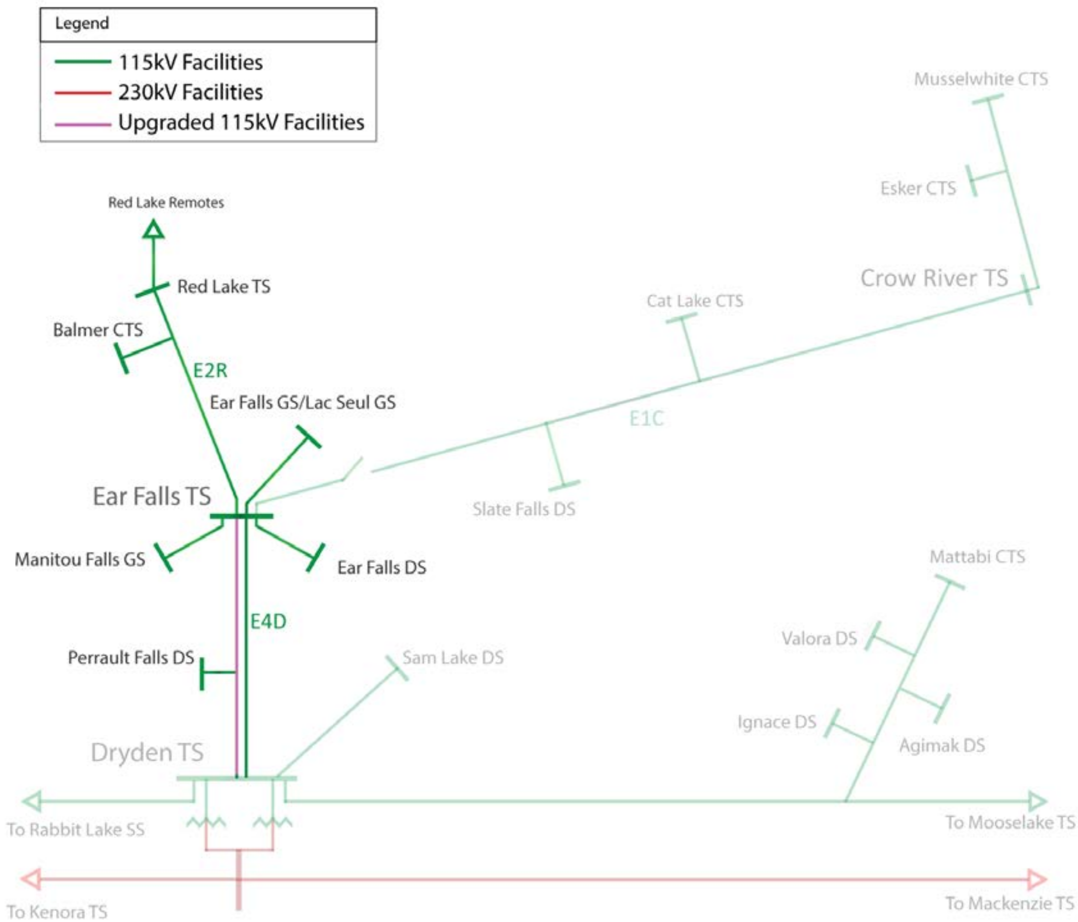

Figure 30, shows the peak load flow case for this option. Voltage at Ear Falls TS is maintained within a healthy range of 120 kV to 125 kV.

Table 88 and Table 89 summarize the annual cashflows and cumulative NPV cost for the options.

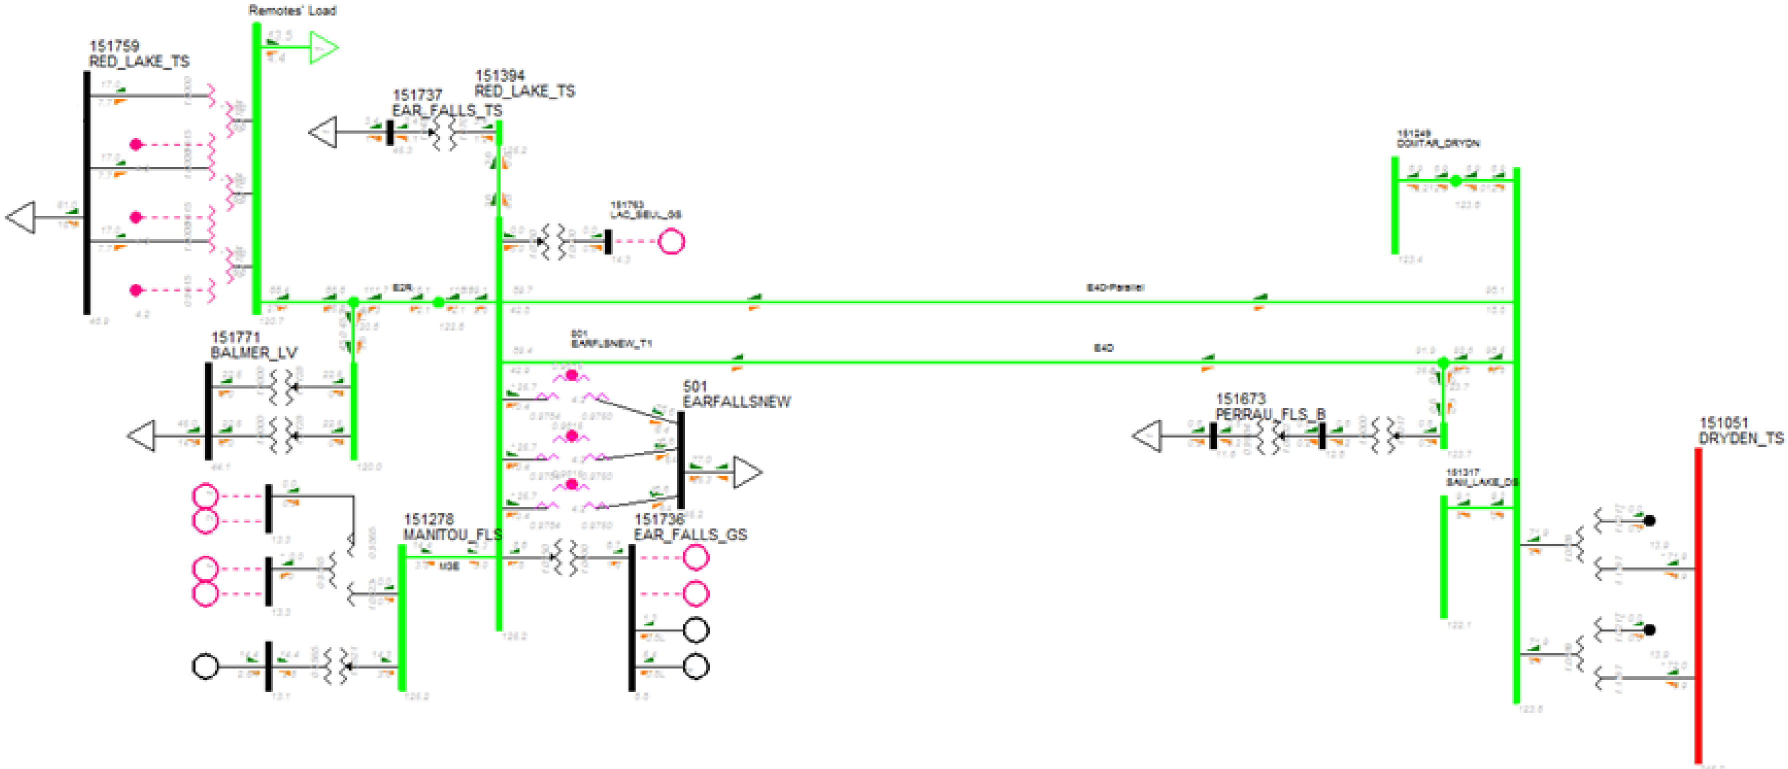
Figure 30: 115 kV Line Option Red Lake Subsystem Configuration



173

10.8.2 Pickle Lake Subsystem Transmission Options

The transmission options for the Pickle Lake subsystem include:

1. A new 115 kV single circuit line tapping the 115 kV line 29M1 near Valora with an in-line breaker on the tap line and terminating at Crow River DS in Pickle Lake;

2. A new 230 kV single circuit line tapping D26A east of Dryden with an in-line breaker on the tap line and running to Pickle Lake terminating at Crow River DS or a new TS in the Pickle Lake area with a new 230/115 kV autotransformer at Crow River DS or a new station; and

3. A new single circuit line pre-built to 230 kV standards (230 kV structures, and hardware) and connecting it to M2D on the 115 kV system east of Dryden with an in-line breaker on the tap line. When additional capacity is required the line would be reterminated on the 230 kV system near Dryden (D26A) and a 230/115 kV autotransformer would be installed at Crow River DS or a new station in Pickle Lake.

For all of these transmission options, it is assumed that following the installation of a new line to Pickle Lake, the line E1C, connecting Ear Falls TS to Crow River DS (at Pickle Lake), would be normally open at Ear Falls. As a result, all customers in the Pickle Lake subsystem would be normally supplied by the new line to Pickle Lake. During sustained outages of the new line to Pickle Lake, some load in the Pickle Lake subsystem may be able to be restored by closing the normally E1C at Ear Falls TS and serving load in the Pickle Lake subsystem from Ear Falls TS. The amount of load that can be restored in the Pickle Lake subsystem from Ear Falls TS will be limited by the available capacity of circuits E4D and E1C.

115 kV Line to Pickle Lake

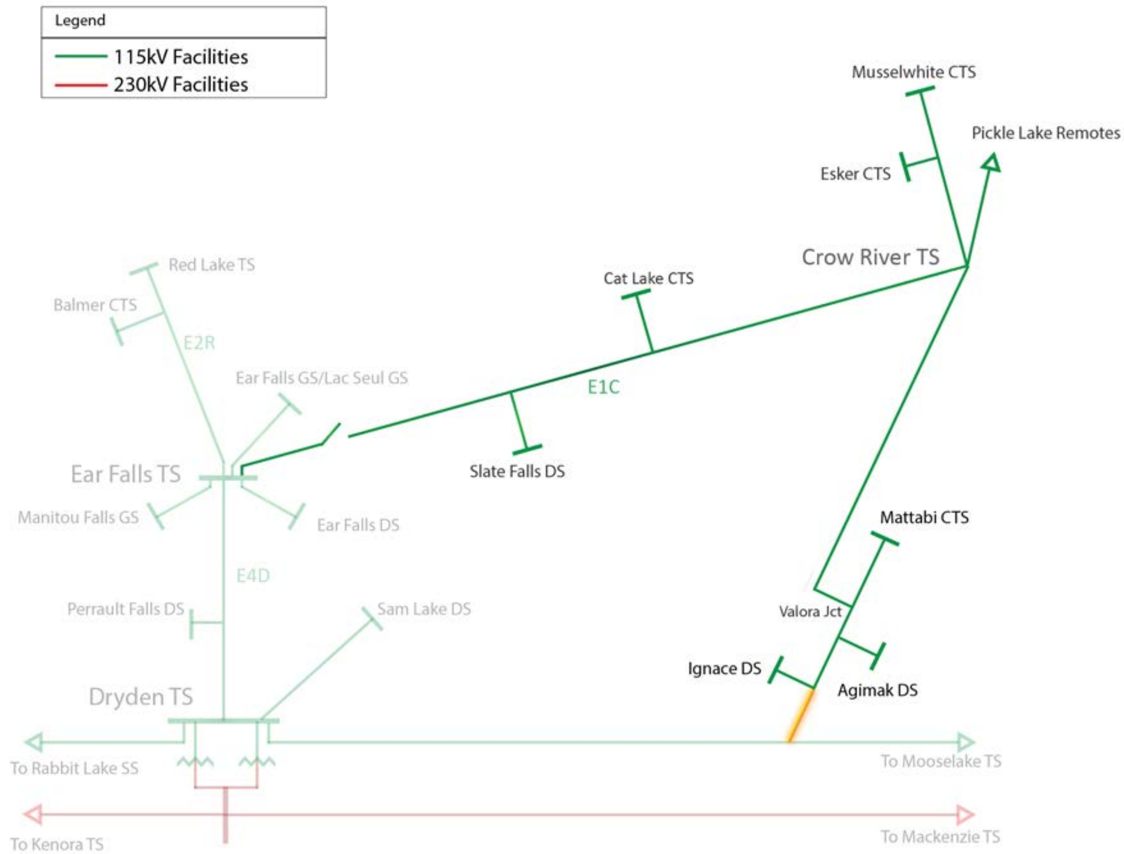
This option is to install a new 115 kV single circuit line tapping the 115 kV line 29M1 near Valora with an in-line breaker and terminating at Crow River DS in Pickle Lake. Currently, there are a number of short sections of 29M1 between Ignace and Valora which have thermal ratings which are lower than the rest of the line. These sections will need to be upgraded to a thermal rating of at least 500 amps to allow the new line to Pickle Lake to have the required transfer capability.

Table 90: Summary of Load Meeting Capability

Option	Incremental Capacity	Load Meeting Capability	Low Forecast Demand	Reference Forecast Demand	High Forecast Demand
New 115 kV line from Valora to Pickle Lake	46 MW	70 MW	48 MW	78 MW (100 MW)	90 MW (156 MW)

Figure 31 shows the Pickle Lake subsystem with this option, highlighting the section of 29M1 that would require upgrading.

Figure 31: New 115 kV line to Pickle Lake Diagram



A summary of the cost for this option can be found in Table 91 below.

176

Figure 32 shows the load flow case during peak load. The Pickle Lake bus voltage is maintained in a healthy range of 120 kV to 125 kV.

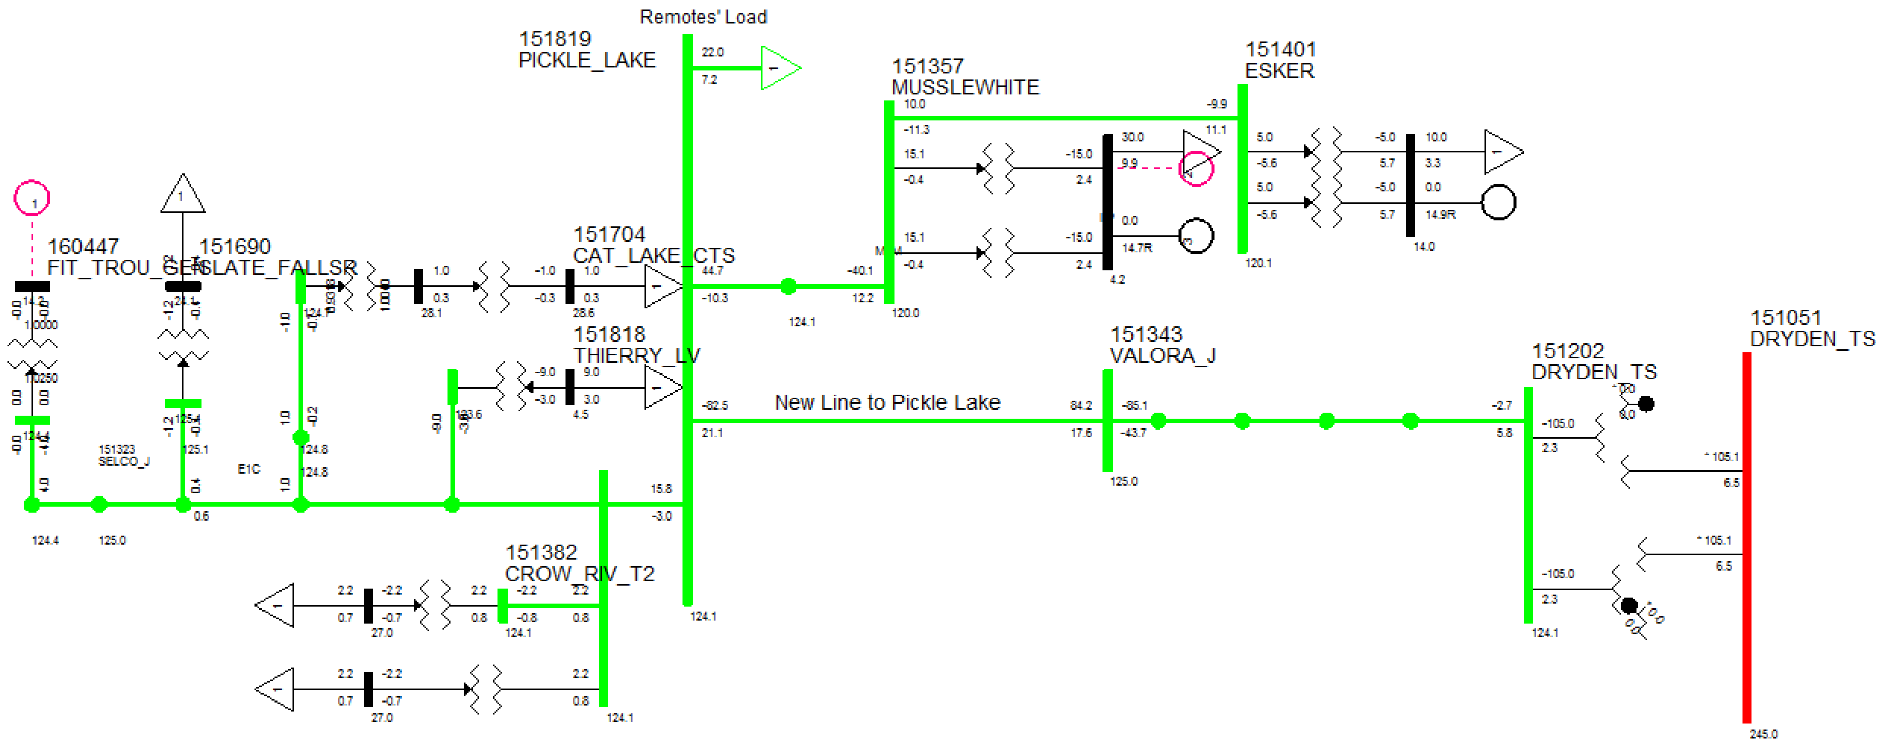
Figure 32: 115 kV Line Option Pickle Lake Subsystem Configuration



230 kV Line to Pickle Lake

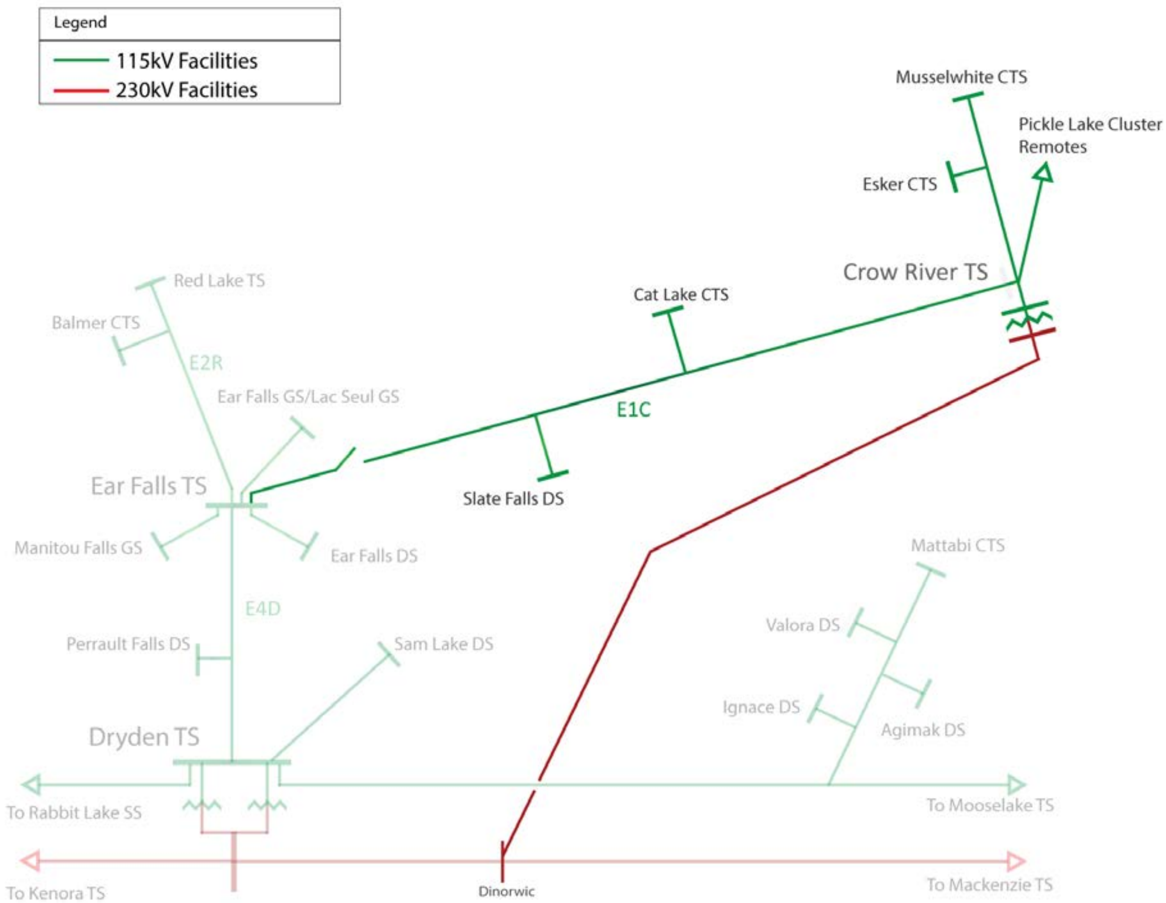
This option is to install a new 230 kV single circuit line tapping D26A east of Dryden with an in-line breaker running to Pickle Lake terminating at Crow River DS or at a new 230 kV station where a new 230/115 kV autotransformer will be installed.

Table 92: Summary of Load Meeting Capability

Option	Incremental Capacity	Load Meeting Capability	Low Forecast Demand	Reference Forecast Demand	High Forecast Demand
New 230 kV line from Dryden/Ignace to Pickle Lake	136 MW	160 MW	48 MW	78 MW (100 MW)	90 MW (156 MW)

A diagram of this option is shown in Figure 33 below.

Figure 33: New 230 kV line to Pickle Lake Diagram



A summary of the cost for this option can be found in Table 93 and Table 94 below.

Table 94 shows an illustration of the peak load flow case for the new 230 kV line to Pickle Lake option. The voltage in the Pickle Lake area is maintained in a range of 240 kV to 245 kV, which helps to maintain voltages on existing and planned facilities within a healthy range.

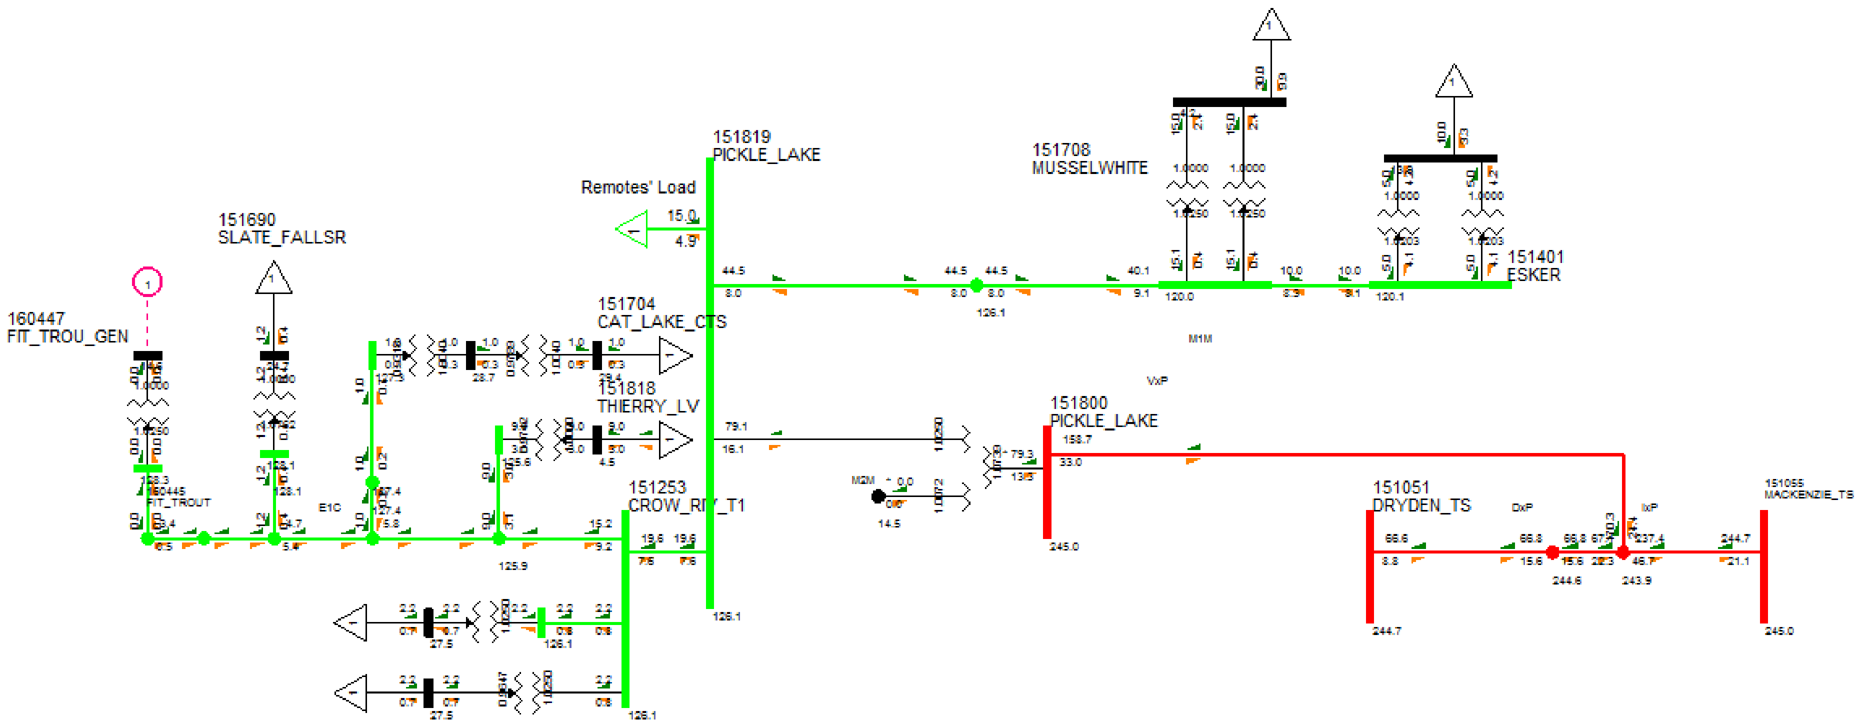
Figure 34: 230 kV Line Option Pickle Lake Subsystem Configuration



183

Pre-build 230 kV Line to Pickle Lake

This option would pre-build a new single circuit line to 230 kV standards (230 kV structures and hardware) and connect it to the 115 kV system on M2D east Dryden with an in-line breaker and running to Pickle Lake where it would terminate at Crow River DS. When additional capacity is required, the line would be reterminated on the regional 230 kV system (D26A) east of Dryden and a 230/115 kV autotransformer would be installed either at Crow River DS or at a new TS in Pickle Lake.

Option	Incremental Capacity	Load Meeting Capability	Low Forecast Demand	Reference Forecast Demand	High Forecast Demand

10.8.3 Ring of Fire Subsystem Transmission Options

The following table summarizes the capability of various transmission options to meet the forecasted demand levels for the Ring of Fire sub-system for the reference, high, and low scenarios:

Option	Incremental Capacity	Load Meeting Capability	Low Forecast Demand	Reference Forecast Demand	High Forecast Demand
East-West corridor			7 MW	29 MW	73 MW
115 kV line from Pickle Lake	60 MW	60 MW			
230 kV line from Pickle Lake	78 MW	78 MW			
North-South corridor					
230 kV line from Marathon TS	78 MW	78 MW			
230 kV line from east of Nipigon	78 MW	78 MW			

The options and costs of the options are discussed in further detail below.

115 kV Line Connection for Ring of Fire Remote Communities from Pickle Lake

In a scenario where mines at the Ring of Fire do not connect to the transmission system, it has been assumed that the 5 remote communities in the Ring of Fire subsystem would develop a connection to Pickle Lake, based on the findings of the draft Remote Community Connection Plan. This option is to build a 115 kV line from Pickle Lake to a point near Webequie FN passing near Neskantaga FN. Neskantaga FN, Eabametoong FN and Marten Falls FN would connect by distribution lines to a new transformer station near Neskantaga FN, while Nibinamik FN and Webequie FN would connect by distribution line to a transformer station near Webequie FN.

Figure 36, provides an illustrative schematic of this option, while costs are provided in Table 98.

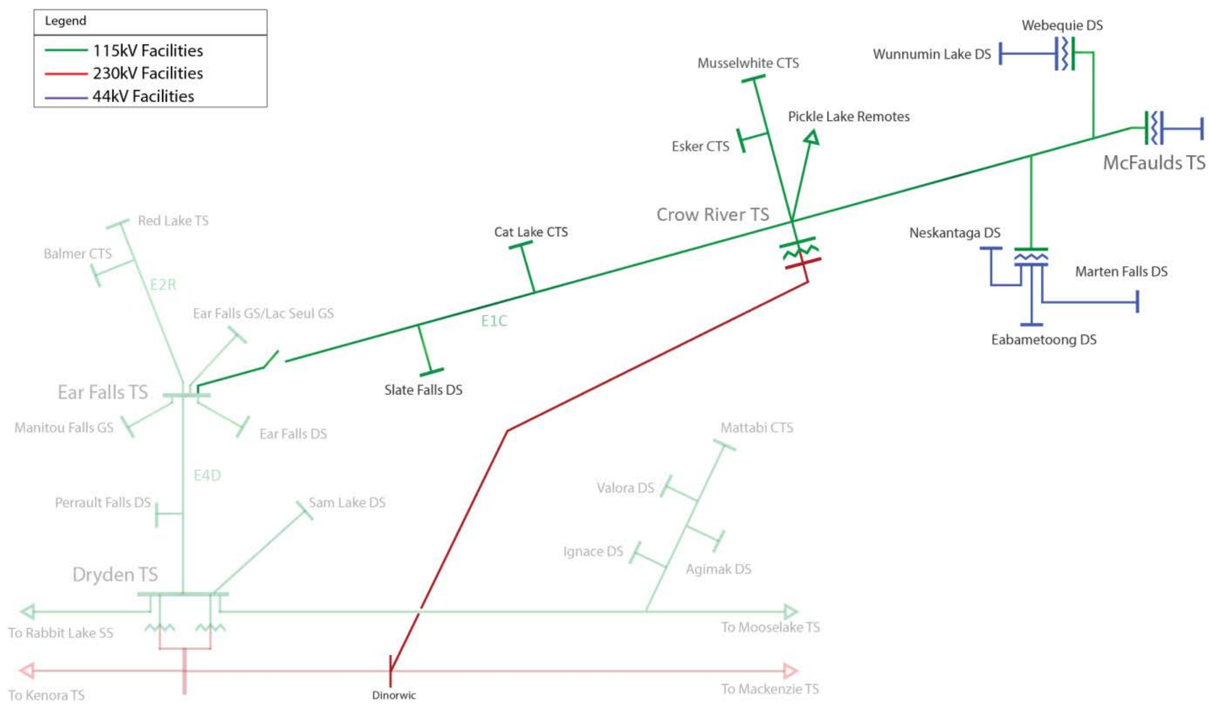
115 kV Line from Pickle Lake to Ring of Fire

This option considers building a new 115 kV line from Pickle Lake to the Ring of Fire mining development area, and connecting the five remote communities in the Ring of Fire subsystem. The feasibility of this option is contingent on the completion of a new 230 kV line from east of Dryden to Pickle Lake. Power flow studies show that a single circuit 115 kV line from Pickle Lake could supply up to 60 MW of mining load at the Ring of Fire plus 7 MW of remote community load.

Figure 37, shows this option with the Pickle Lake subsystem.

Figure 37: 115 kV Line from Pickle Lake to Ring of Fire



A prorated portion of the costs for new a 230 kV transmission line and 230/115 kV transformer station from the Dryden area to Pickle Lake is included in the cost of this option because it is required for this option to be undertaken as is shown in the cost summary in Table 99.

191

Figure 38 provides the peak load flow for the North of Dryden sub-region, illustrating that voltages throughout the subsystem are maintained in a healthy range of 120 kV to 125 kV.

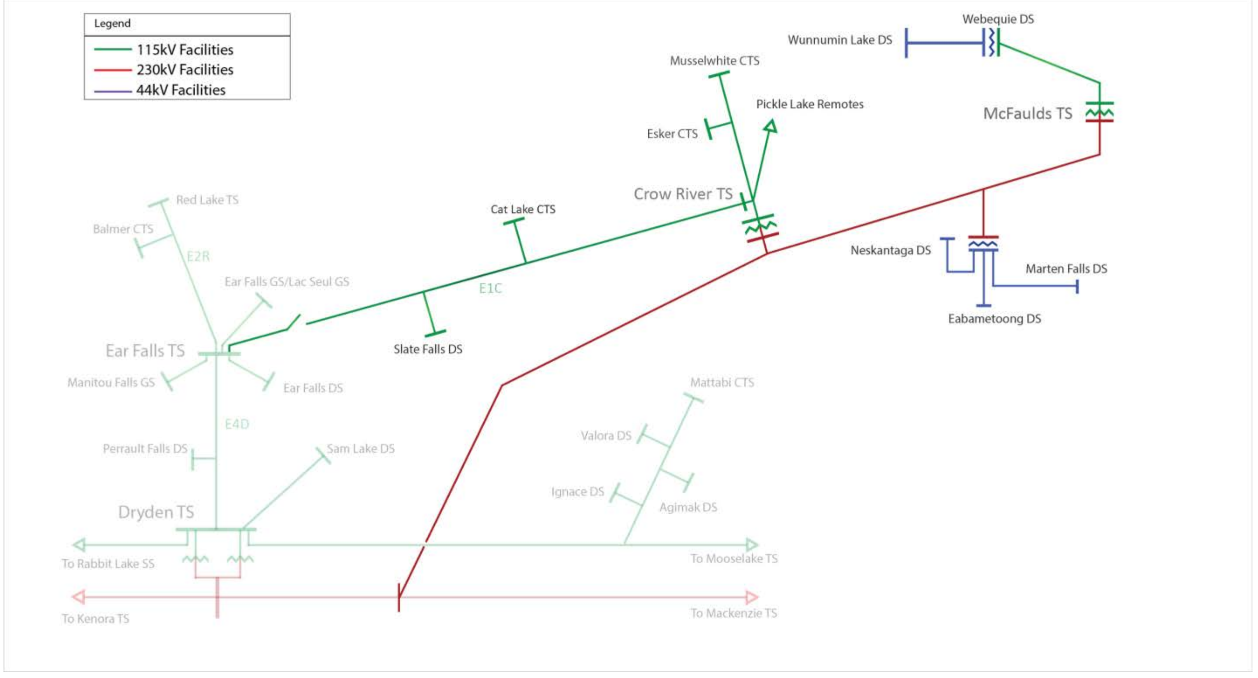
194

230 kV Line from Pickle Lake to Ring of Fire

This option considers building a new 230 kV single circuit line from a new 230 kV station at Pickle Lake to the Ring of Fire, and a new 230/115 kV TS near Neskantaga FN and at the Ring of Fire. The feasibility of this option is contingent on the completion of a new 230 kV line from east of Dryden to Pickle Lake. This line would enable the connection of the five Matawa remote communities in the Ring of Fire subsystem as well as serve the high growth scenario (MW) for mining load at the Ring of Fire. Figure 39 shows the Pickle Lake and Ring of Fire subsystems with a new 230 kV line from the Dryden area to Pickle Lake and this option for a new 230 kV line from Pickle Lake to the Ring of Fire. Figure 39, shows this option implemented with the Pickle Lake subsystem.

Figure 39: 230 kV Line from Pickle Lake to Ring of Fire



A prorated portion of the costs for new a 230 kV transmission line and station from the Dryden area to Pickle Lake is included in the cost of this option, as shown in the cost summary in Table 101 below.

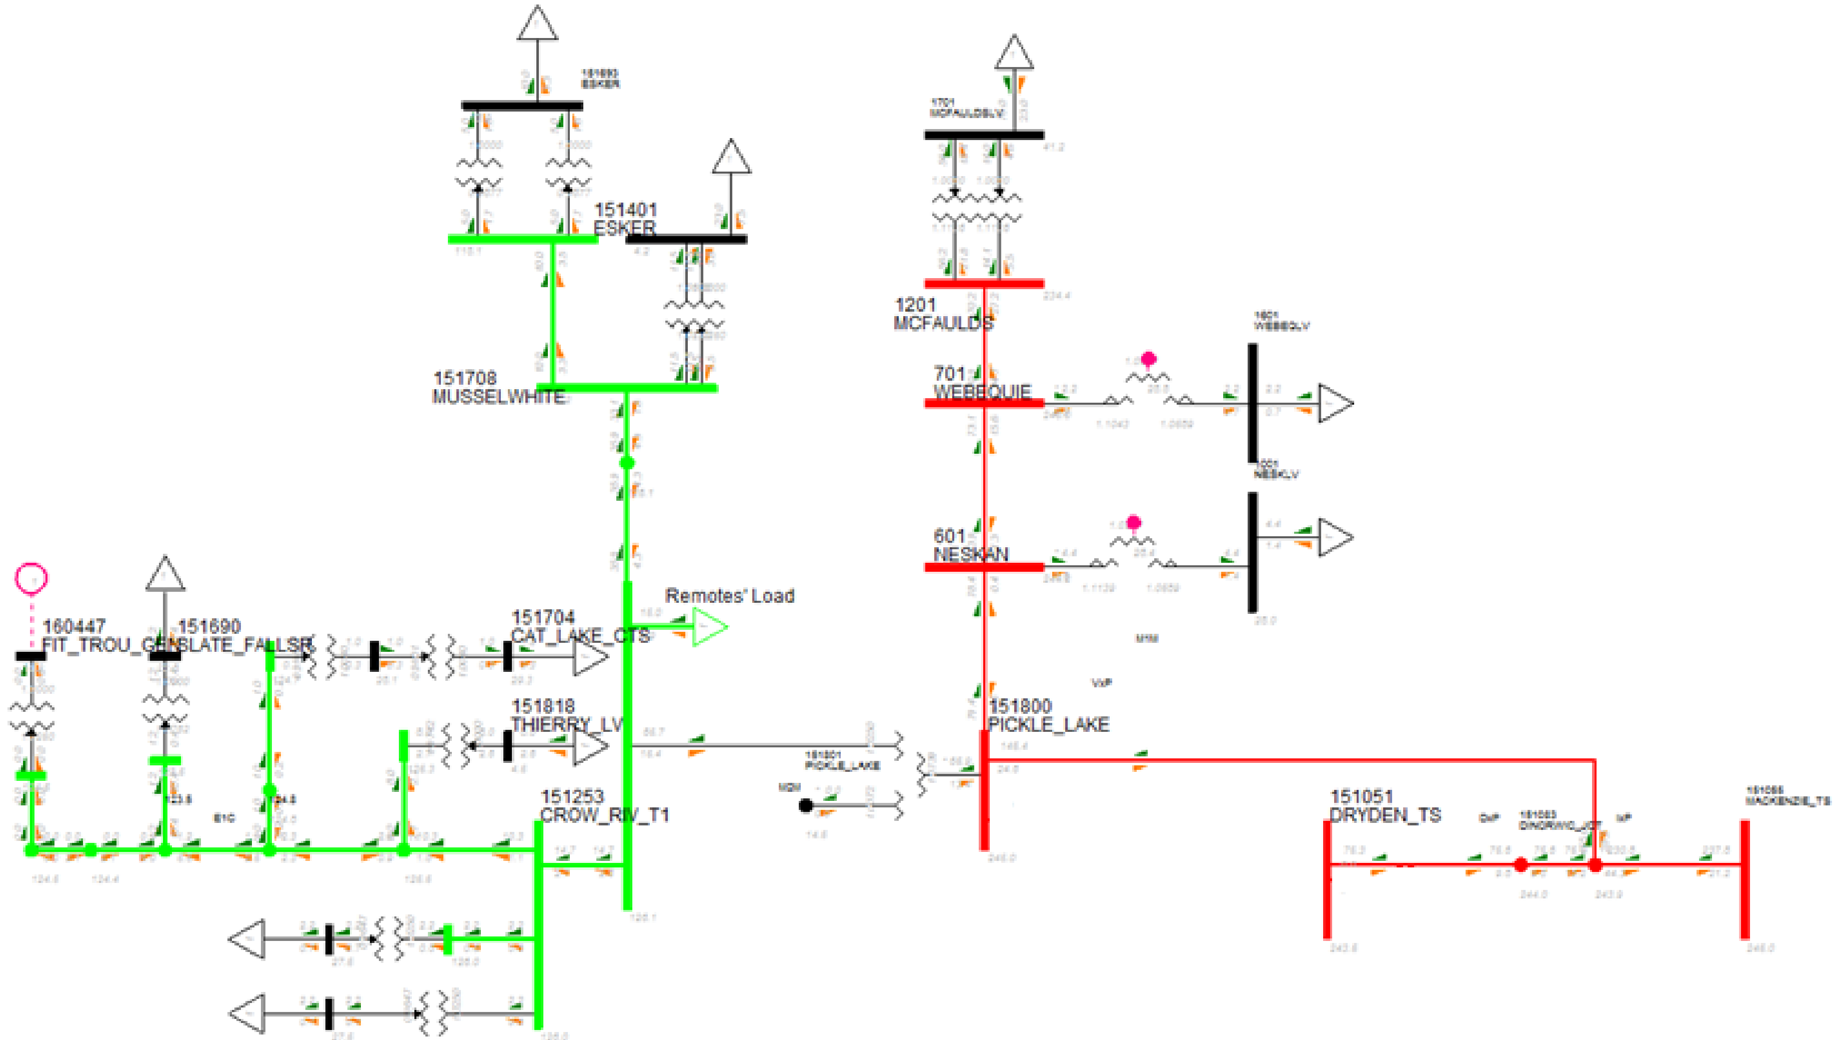
Figure 40: 230 kV Line from Pickle Lake Option Ring of Fire Subsystem Configuration

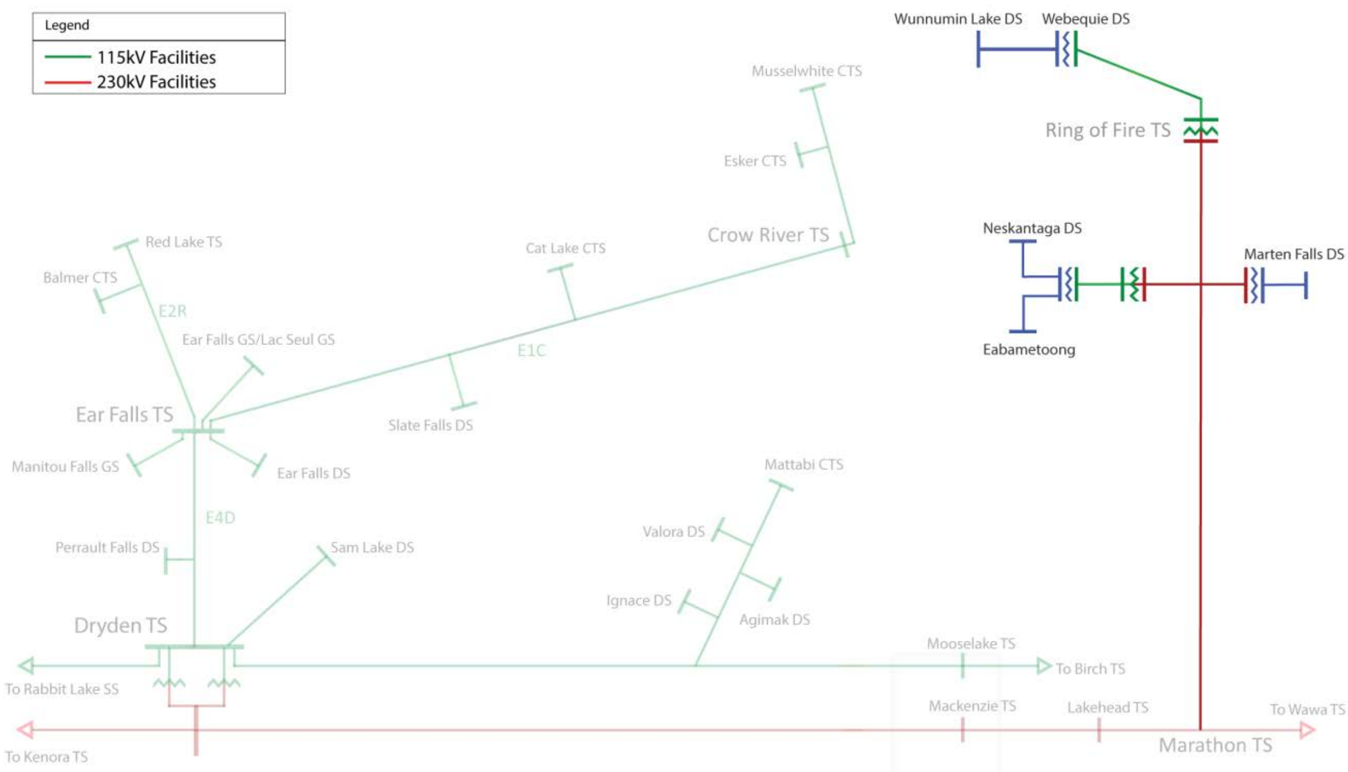


197

230 kV Line from Marathon TS or east of Nipigon to Ring of Fire

Given the potential for a new all season road to serve the Ring of Fire mining development area from around Nakina, this option was developed to leverage the availability of the all season road assuming they can share a common right of way from Nakina. The existing transmission supply serving the Long Lac\Nakina area is the single circuit 115 kV line A4L, which has insufficient capability to serve the forecast load growth of the Ring of Fire subsystem. Therefore, a new 230 kV single circuit transmission line from either Marathon TS or east of Nipigon would be required for this option. These options have similar line lengths and are expected to have approximately the same costs. A diagram of this option is provided in Figure 41 below.

Figure 41: 230 kV Line from Marathon or East of Nipigon to Ring of Fire



The LMC of the Ring of Fire subsystem for this option is 77 MW. This includes 7 MW for the communities on the line as well as 70 MW at the Ring of Fire. A summary of the cost for this option can be found in Table 102 below.

GREENSTONE-MARATHON INTEGRATED REGIONAL RESOURCE PLAN

Part of the Northwest Ontario Planning Region | June 30, 2016

ieso
Connecting Today. Powering Tomorrow.

Integrated Regional Resource Plan

Greenstone-Marathon Area

This Integrated Regional Resource Plan (“IRRP”) was prepared by the IESO pursuant to the terms of its Ontario Energy Board licence, EI-2013-0066, and was prepared by the IESO on behalf of the Greenstone-Marathon Sub-region Working Group (“Working Group”), which included the following members:

- Independent Electricity System Operator (IESO)
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)

The preparation of the IRRP included extensive discussions with industrial developers, as well as engagement with communities who may have interest in the potential industrial developments or options for providing the required electrical supply. The Working Group would like to acknowledge and thank the members of two Local Advisory Committees which were established to provide community input into the development of the IRRP. Their input provided valuable guidance in shaping the electrical supply options.

The Working Group assessed the adequacy of electricity supply to customers in the Northwest Ontario Region over a 20-year period; developed a flexible, comprehensive, integrated plan that considers customer needs, community input, opportunities for coordination in anticipation of potential demand growth scenarios and varying supply conditions. Based on all the planning information provided, an implementation plan was developed. The implementation plan seeks to maintain flexibility in order to accommodate changes in key assumptions over time.

The Working Group members agree with the IRRP’s recommendations and support implementation of the plan through the recommended actions. As the recommendations are directly related to a few large industrial developments, the onus lies with those developers to initiate the implementation of the plan. Working Group members cannot commit to any capital expenditures until the necessary commercial agreements, regulatory and other approvals to implement recommended actions are obtained by the appropriate parties.

In addition to the requirements set out in the IESO's licence, analysis that was requested from communities and was determined by the IESO to provide value to the overall context of electricity planning for the Greenstone-Marathon Sub-region, has also been included in this report.

1. Introduction

This Integrated Regional Resource Plan ("IRRP" or "Plan") for the Greenstone-Marathon Sub-region addresses the electricity needs for the sub-region over the next 20 years. The IRRP was prepared by the Independent Electricity System Operator ("IESO") on behalf of the Technical Working Group for the Greenstone-Marathon Sub-region composed of the IESO, Hydro One Distribution and Hydro One Transmission[1] (the "Working Group").

The Greenstone-Marathon Sub-region includes several First Nation communities: Red Rock Indian Band, Bingwi Neyaashi Anishinaabek ("BNA"), Biinjitiwaabik Zaaging Anishinaabek ("BZA"), Animbiigoo Zaagi'igan Anishinaabek ("AZA"), Long Lake #58, Ginoogaming, Aroland, Pays Plat, Ojibways of the Pic River and Pic Mobert. The area also encompasses the Town of Marathon, the Municipality of Greenstone, and the Townships of Nipigon, Manitouwadge, Schreiber, Terrace Bay, Hornepayne and White River. The area covered by the Greenstone-Marathon IRRP is a sub-region of the Northwest Ontario Region identified through the Ontario Energy Board ("OEB" or "Board") regional planning process.

The regional planning process considers the local needs of a region over a 20-year planning horizon, and seeks to ensure cost-effective, reliable electricity supply to Ontario's communities over the long term. An IRRP takes into consideration, among other things, existing electricity infrastructure in an area, anticipated growth, and electricity requirements. The IRRP then establishes a guide for electricity infrastructure investments, resource development, and procurement decisions for a region, and may include conservation, generation, transmission and/or distribution.

In early 2015, the Municipality of Greenstone and the electricity customers in the area advised the Working Group that the 18-month timeline for IRRPs established by the OEB could not satisfy the timeline of industrial developments anticipated in the area. Given that the forecast growth in the sub-region is driven by the potential for large industrial development, the Municipality and the electricity customers requested that an interim planning report be developed to align with near-term development timelines. The Greenstone-Marathon Interim IRRP ("Interim IRRP") was released June 22, 2015 for the purpose of facilitating critical decision making for customers in a manner that accommodates near-term development timelines,

---

[1] For the purpose of this report, "Hydro One Transmission" and "Hydro One Distribution" are used to differentiate the transmission and distribution accountabilities of Hydro One Networks Inc., respectively.

considers electricity supply needs in the area, and ensures that the electricity system can support the pace of development.

This IRRP for the Greenstone-Marathon Sub-region updates the options and recommendations established for the near term in the Interim IRRP, and extends the analysis to include the medium term (5-10 years) and long term (10-20 years). This IRRP is organized as follows:

- A summary of the recommended plan for Greenstone-Marathon is provided in Section 2;
- The process used to develop the IRRP is discussed in Section 3;
- The context for electricity planning in Greenstone-Marathon and the study scope are discussed in Section 4;
- Demand forecast scenarios, and conservation and demand management ("CDM" or "conservation") and distributed generation ("DG") assumptions are described in Section 5;
- Needs in Greenstone-Marathon are presented in Section 6;
- Alternatives and recommendations for meeting near-term needs are addressed in Section 7;
- Near-term plan recommendations are set out in Section 8;
- Options for the medium and long term are described in Section 9;
- A summary of community and stakeholder engagement to date is provided in Section 10; and
- A conclusion is provided in Section 11.

2. The Integrated Regional Resource Plan

The Greenstone-Marathon IRRP addresses the area's electricity needs over the next 20 years. The IESO prepared the IRRP based on consideration of integrated planning criteria (reliability, cost, feasibility, flexibility, and social and environmental considerations), and based on the application of the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC"). The IRRP uses a scenario-based analysis to identify requirements based on major industrial development for the near term (present-5 years), medium term (5-10 years) and long term (10-20 years). These planning horizons are distinguished in the IRRP to reflect the different level of commitment required. In the near term, it seeks to maximize the use of the existing electricity system, where it is economic to do so.

The IRRP identifies least societal cost options to assist customers and proponents in near-term decision making for meeting the overall electricity needs of the Greenstone-Marathon Sub-region. The IRRP identifies specific investments that respect development lead times, while meeting the various needs in the area and considering feedback from local communities.

For the medium and long term, the IRRP identifies a number of alternatives to meet needs. The medium and long-term needs identify developments that may materialize in the future and could result in cost, environmental, and societal synergies with the identified near-term options. For needs that are forecast to occur in the long term, it is not necessary (given forecast uncertainty and the potential for technological change) to commit to specific projects at this time. Instead, near-term actions are identified to develop alternatives and engage with local communities, to gather information and lay the groundwork for future options. Actions identified for the near term will be directionally consistent with and inform the actions for the medium to long term.

Below is a summary of needs and recommended actions.

2.1 Near-Term Plan Summary

The plan to meet the near-term needs of electricity customers in the Greenstone-Marathon Sub-region was developed considering the planning criteria, including reliability, cost, feasibility, and maximizing the use of the existing electricity system where it is economic to do so.
The near-term needs for the area consist of providing additional capacity to supply industrial development, while considering reliability and service quality requirements for the individual industrial developments.

The recommended elements of the near-term plan depend primarily on the outcome of two potential industrial customers: a mining development in Geraldton (the "Geraldton mine"), and a major gas to oil pipeline conversion project. The Geraldton mine developers have publically communicated an in-service date of 2019, and the major gas to oil pipeline conversion project developers have publically communicated an in-service date of 2020. A scenario-based planning approach has been taken in order to provide recommendations that address the different potential development scenarios that may arise in the area.

2.2 Recommended Actions for the Near Term

Since publishing the Interim IRRP in June, 2015, the Geraldton mine developers notified the IESO of adjustments to their project schedule and scope. Specifically, they now expect to commission in a single stage in 2019, as opposed to two stages in 2018 and 2020 (which was considered in the Interim IRRP). The IESO's recommendations have been revised accordingly.

The IESO recommends a staged approach to accommodate forecast demand from the Geraldton mine and the pumping stations from the gas to oil pipeline conversion project. Stage 1 economically maximizes the use of the existing system to supply the Geraldton mine, while Stage 2 recommends the incremental infrastructure expansion necessary to accommodate the additional demand from the pumping stations.

Stage 1 – Coincident with the Geraldton mine in-service

- Install +40 MVar of reactive compensation at the Geraldton mine
- Install a customer-based grid-connected gas-fired generation plant of sufficient redundancy to meet the risk tolerance of the mining company. A 2x10 MW reciprocating engine plant was used for costing, and would meet North American standards.[2]

[2] The IESO has assumed N-1 reliability of the plant (single redundant unit), consistent with North American electricity reliability standards. If the generation can operate in island-mode, it may be advantageous to pursue due to the inherent supply diversity that it offers. The customer may also wish to investigate the applicability of conservation incentives that the IESO offers to compliment this option.

Figure 2-1: Recommended Actions – Stage 1

Stage 2 – Coincident with the gas-oil pipeline conversion project

- Install a new 230 kV single-circuit line from the East-West Tie near Nipigon or Marathon to Longlac, and a new 230/115 kV auto-transformer and related switching and voltage control facilities at Longlac Transformer Station ("TS") to be in-service coincident with the pumping stations loads.
- Install a new 115 kV single-circuit line from Longlac TS to Manitouwadge TS and related switching and voltage control facilities, to be in-service coincident with the incorporation of the pumping stations as part of the major pipeline conversion project.

Figure 2-2: Recommended Actions – Stage 2

The following should be noted:

- If the Geraldton mine and the major gas to oil pipeline conversion project do not materialize or do not choose to connect to the power system, no new system enhancements are required to supply distribution customer growth.[3]
- If the Geraldton mine materializes, but the major gas to oil pipeline conversion project does not materialize or does not choose to connect to the power system, only Stage 1 is required.
- If the Geraldton mine and the major gas to oil pipeline conversion project choose to connect to the power system, Stage 1 and Stage 2 are required.

[3] It should be noted that even with growth in population and employment due to the industrial customer developments, the distribution customer demand does not increase to the point where the existing system would require a capacity increase.

- If the Geraldton mine and the major gas to oil conversion project choose to connect to the power system, it may be advantageous to the Geraldton mine to advance the new 230 kV line from Stage 2 to reduce or avoid its gas generation costs associated with Stage 1.
- The implementation of Stage 1 and Stage 2 of the near-term plan requires a commercial agreement to be established between the future service provider and the new customers before development work can proceed.
- Further changes to timelines that have been communicated to the IESO by industrial developers may alter the timing and scope of near-term recommendations.

2.3 Medium- and Long-Term Plan Summary

In the medium and long term, the likely drivers of future electricity demand for the Greenstone-Marathon planning area are:

- Additional mining claims in the Greenstone area, specifically near Beardmore (the "Beardmore mine"),
- The potential supply option of utilizing a north-south corridor to supply the Ring of Fire and remote communities of Eabametoong, Marten Falls, Neskantaga, Nibinamik, and Webequie, and
- Community-level energy efficiency opportunities in the Town of Marathon to reduce electric heating demand.

A scenario-based planning approach has also been taken for the medium and long term to address the different potential development scenarios for the area.

2.4 Actions to Maintain Flexibility for the Medium and Long Term

The following actions are proposed to maintain flexibility for accommodating additional growth, within the study area:

- Mine developers in Greenstone retain the option of upgrading circuit A4L from Alexander Switching Station ("SS") to Beardmore TS as an economic alternative for supplying the Beardmore mine and additional mining in Greenstone. Mine developers should engage Hydro One, the transmission owner of circuit A4L, recognizing that a lead-time of approximately five years is required if they wish to pursue this option.
- Those investigating a multi-use infrastructure corridor to the Ring of Fire consider the need for a new transmission line, as outlined in this Plan. The IESO is available to provide planning advice associated with a new transmission line on this corridor. The

IESO will also update electricity plans associated with this corridor as additional information becomes available.

- The Town of Marathon conduct a detailed study of community energy options related to cogeneration. The IESO can support studies within the context of electricity planning, demand, and reliability, as well as IESO-coordinated conservation programs and funding, if applicable.

The IESO does not have the authority to direct or implement these actions on behalf of the indicated parties. These actions are documented to provide customers, communities, and stakeholders with the IESO's independent assessment of the technically feasible and least societal cost options for meeting the various needs in the area.

3. Development of the Integrated Regional Resource Plan

3.1 The Regional Planning Process

In Ontario, planning to meet the electricity needs of customers at a regional level is done through regional planning. Regional planning assesses the interrelated needs of a region—defined by common electricity supply infrastructure—over the near, medium, and long term and develops a plan to ensure cost-effective, reliable electricity supply. Regional plans consider the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluate options for addressing needs, and recommend actions.

Regional planning has been conducted on an as needed basis in Ontario for many years. Most recently, the former Ontario Power Authority ("OPA") carried out planning activities to address regional electricity supply needs. The OPA conducted joint regional planning studies with distributors, transmitters, the IESO and other stakeholders in regions where a need for coordinated regional planning had been identified.

In the fall of 2012, the Board convened a Planning Process Working Group ("PPWG") to develop a more structured, transparent, and systematic regional planning process. This group was composed of industry stakeholders including electricity agencies, utilities, and stakeholders, and in May 2013, the PPWG released its report to the Board[4] ("PPWG Report"), setting out the new regional planning process. Twenty-one electricity planning regions were identified in the PPWG Report, and a phased schedule for completion was outlined. The Board endorsed the PPWG Report and formalized the process timelines through changes to the Transmission System Code ("TSC") and Distribution System Code ("DSC") in August 2013, as well as through changes to the OPA's licence in October 2013. The OPA's licence changes required it to lead a number of aspects of regional planning. After the merger of the IESO and the OPA on January 1, 2015, the regional planning responsibilities identified in the OPA's licence were transferred to the IESO.

The regional planning process begins with a Needs Screening performed by the transmitter, which determines whether there are needs requiring regional coordination. If regional planning is required, the IESO then conducts a Scoping Assessment to determine whether a comprehensive IRRP is required, which considers conservation, generation, transmission, and

---

[4] http://www.ontarioenergyboard.ca/OEB/_Documents/EB-2011-0043/PPWG_Regional_Planning_Report_to_the_Board_App.pdf

distribution solutions, or whether a straightforward "wires" solution is the only option such that a transmission and distribution focused Regional Infrastructure Plan ("RIP") can be undertaken instead. The Scoping Assessment assesses what type of planning is required for each region. There may also be regions where infrastructure investments do not require regional coordination and so can be planned directly by the distributor and transmitter outside of the regional planning process. At the conclusion of the Scoping Assessment, the IESO produces a report that includes the results of the Needs Screening process and a preliminary Terms of Reference. If an IRRP is the identified outcome, the IESO is required to complete the IRRP within 18 months. If an RIP is the identified outcome, the transmitter takes the lead and has six months to complete it. It should be noted that an RIP may be initiated after the Scoping Assessment or after the completion of all IRRPs within a planning region; the transmitter may also initiate and produce a RIP report for every region. Both RIPs and IRRPs are to be updated at least every five years. The draft Scoping Assessment Outcome Report is posted to the IESO's website for a 2-week comment period prior to finalization.

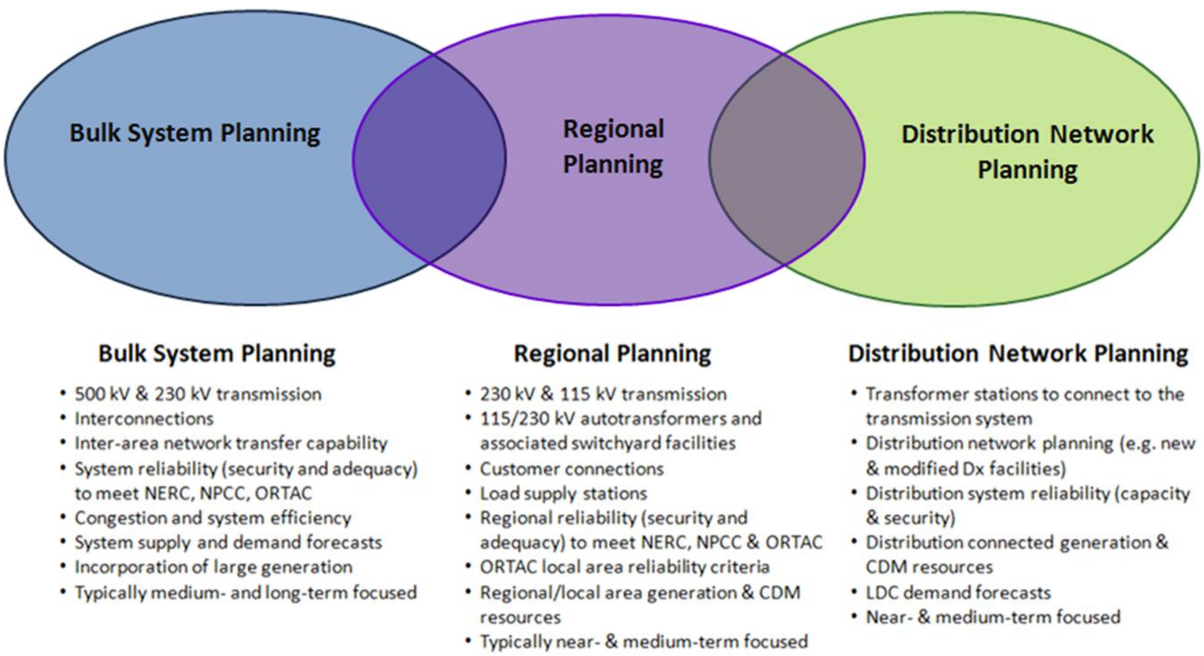
The final IRRPs and RIPs are posted on the IESO's and relevant transmitter's websites, and may be referenced and submitted to the Board as supporting evidence in rate or "Leave to Construct" applications for specific infrastructure investments. These documents are also useful for municipalities, First Nation communities and Métis community councils for planning, conservation and energy management purposes, as information for individual large customers that may be involved in the region, and for other parties seeking an understanding of local electricity growth, CDM and infrastructure requirements. Regional planning is not the only type of electricity planning that is undertaken in Ontario. As shown in Figure 3-1, there are three levels of planning that are carried out for the electricity system in Ontario:

- Bulk system planning
- Regional system planning
- Distribution system planning

Planning at the bulk system level typically considers the 230 kV and 500 kV network and examines province-wide system issues. Bulk system planning considers not only the major transmission facilities or "wires", but it also assesses the resources needed to adequately supply the province. This type of planning is typically carried out by the IESO pursuant to government policy. Distribution planning, which is carried out by Local Distribution Companies ("LDCs"), considers specific investments in an LDC's territory at distribution level voltages.

Regional planning can overlap with bulk system planning. For example, overlaps can occur at interface points where there may be regional resource options to address a bulk system issue. Similarly, regional planning can overlap with the distribution planning of LDCs. For example, overlaps can occur when a distribution solution addresses the needs of the broader local area or region. Therefore, it is important for regional planning to be coordinated with both bulk and distribution system planning as it is the link between all levels of planning.

Figure 3-1: Levels of Electricity System Planning



By recognizing the linkages with bulk and distribution system planning, and coordinating multiple needs identified within a region over the long term, the regional planning process provides a comprehensive assessment of a region's electricity needs. Regional planning aligns near- and long-term solutions and puts specific investments and recommendations coming out of the plan in perspective. Furthermore, regional planning optimizes ratepayer interests by avoiding piecemeal planning and asset duplication, and allows Ontario ratepayer interests to be represented along with the interests of LDC ratepayers, and individual large customers. IRRPs evaluate the multiple options that are available to meet the needs, including conservation, generation, and "wires" solutions. Regional plans also provide greater transparency through engagement in the planning process, and by making plans available to the public.

3.2 The IESO's Approach to Integrated Regional Resource Planning

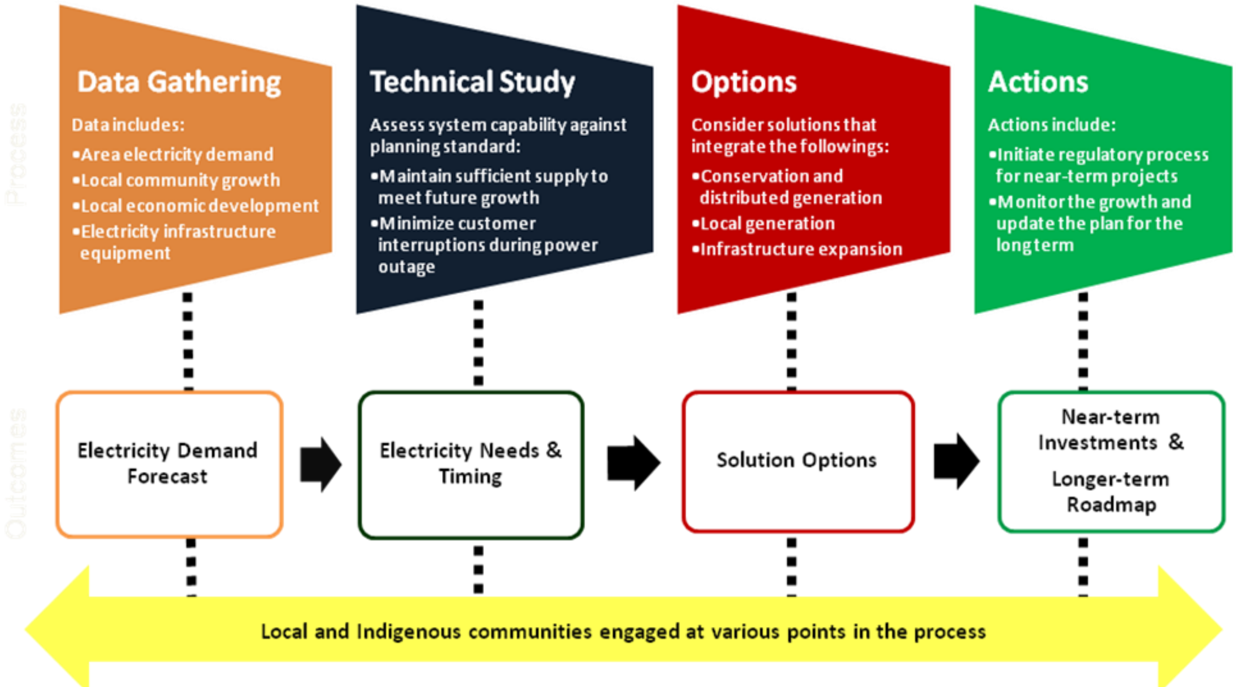
IRRPs assess electricity system needs for a region over a 20-year period. The 20-year outlook anticipates long-term trends in a region, so that near-term actions are developed within the context of a longer-term vision. This enables coordination and consistency with the long-term plan, rather than simply reacting to immediate needs.

Planning in northwestern Ontario requires a unique approach. In southern Ontario, most of the forecast load growth is driven by growth in the LDC customer base. In northwestern Ontario the majority of the forecast load growth is driven by new or expanding large transmission-connected industrial customers, most of which are in the resource sector or are unique development projects. Therefore, when establishing the need for electricity enhancements and developing integrated alternatives, industrial customers generally drive the nature and magnitude of the electrical demand requirements.

The IRRP describes recommendations for system enhancements based on different scenarios, including staging options to mitigate reliability and cost risks related to demand forecast uncertainty associated with individual large customers. The recommendations in this report seek to ensure flexibility is maintained in order to accommodate changing long-term conditions.

In developing this IRRP, the Working Group followed a number of steps including: data gathering, including development of electricity demand forecasts; technical studies to determine electricity needs and the timing of these needs; the development of potential options; and, preparation of a recommended plan including actions for the near and longer term. Throughout this process, engagement was carried out with local municipalities, First Nation communities, Métis community councils and local stakeholders. These steps are illustrated in Figure 3-2 below.

Figure 3-2: Steps in the IRRP Process



This IRRP documents the inputs, findings, and recommendations developed through the process described above, and provides recommended actions for the various entities responsible for plan implementation.

3.3 Greenstone-Marathon Sub-region Working Group and IRRP Development

The Working Group consists of representatives from the IESO, Hydro One Transmission, and Hydro One Distribution.

The IESO also met regularly with potential transmission-connected load and generating customers in the area and the IRRP was informed by these meetings. In particular, important information related to changes in electrical demand and generation production was provided by these potential customers.

3.4 Community and Stakeholder Engagement

Meaningful engagement with all communities in northwestern Ontario was an important element in developing this IRRP report. Early engagement meetings were held in October 2014 and were attended by a broad range of stakeholders and First Nation and Métis community members. In addition, the IESO attended meetings with municipalities, the Northwestern Ontario Municipal Association (“NOMA”), Common Voice Northwest (“CVNW”), and met with the board members of Waaskiinaysay Ziibi Inc. (“WZI”) and a number of the Chiefs of the represented First Nations, and separately visited and met with Ojibways of Pic River First Nation and Pic Mobert First Nation, Constance Lake First Nation, Aroland First Nation, Ginoogaming First Nation, and Long Lake #58 First Nation. The IESO also met with the two Greenstone-Marathon Local Advisory Committees (“LAC”). Greater detail regarding community and stakeholder engagement activities is provided in Section 10 of this report.

4. Background and Study Scope

In 2014, the lead transmitter – Hydro One – initiated a Needs Screening process for the Northwest Ontario Region. The North of Dryden IRRP[5] and Remote Community Connection Plan[6] were already underway prior to the formalization of the regional planning process and were therefore not included within the scope of the Needs Screening process.

The Northwest Ontario Region Needs Screening study team determined that the need for coordinated regional planning had already been established and that a formal Needs Screening process was not required for the Northwest Ontario Region. A Scoping Assessment was then initiated.

4.1 Study Scope

On December 12, 2014, a draft Scoping Assessment Outcome Report ("Scoping Report") was posted for public comment. The Scoping Report[7] was finalized on January 28, 2015 incorporating feedback from communities, stakeholder, and First Nation and Métis community meetings.

The Scoping Report identified three new planning sub-regions for coordinated regional planning: Thunder Bay, West of Thunder Bay, and Greenstone-Marathon.

Regional planning initiatives in northwestern Ontario are illustrated in Figure 4-1.

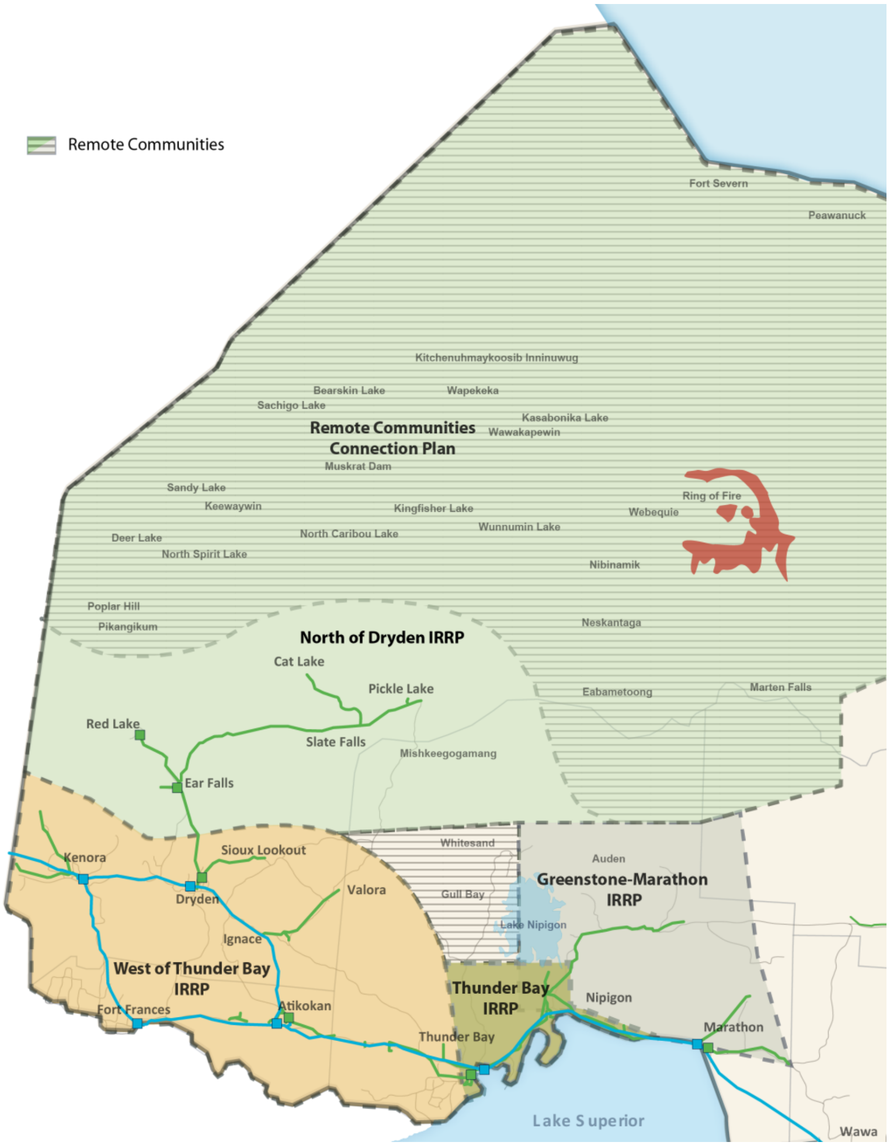
Figure 4-1: Northwest Ontario Planning Region and Sub-regions



4.2 The Greenstone-Marathon Area Electricity System

Electricity is supplied to the Greenstone-Marathon Sub-region from two main sources: Marathon TS and Alexander SS. Marathon TS is located in the Town of Marathon and is a 230/115 kV station supplied at 230 kV from the East-West Tie which connects the northwest system near Thunder Bay and at Marathon to the northeast system at Wawa. At Marathon TS, power is then transformed from 230 kV to 115 kV for transmission customers. Alexander SS is located outside of the Township of Nipigon and is a large switching station where a number of hydroelectric generators south of Lake Nipigon - Alexander Generating Station ("GS"), Cameron Falls GS, and Pine Portage GS - inject power into the system.

The Municipality of Greenstone and surrounding communities are supplied via a single-circuit 115 kV line (A4L) that connects from Alexander SS. Circuit A4L is approximately 150 km and generally follows the Highway 11 corridor. The natural gas-fired Nipigon GS, which holds a non-utility generator ("NUG") contract, is also connected to A4L.

The Town of Marathon and surrounding area is supplied via a single-circuit 115 kV line (M2W) that originates at Marathon TS and branches north to Manitouwadge and east to White River. Circuit M2W has a total distance of approximately 200 km. Hydroelectric generation at Umbata Falls GS and Wawatay Customer Generating Station ("CGS") also contributes to the electricity supply of the local area.

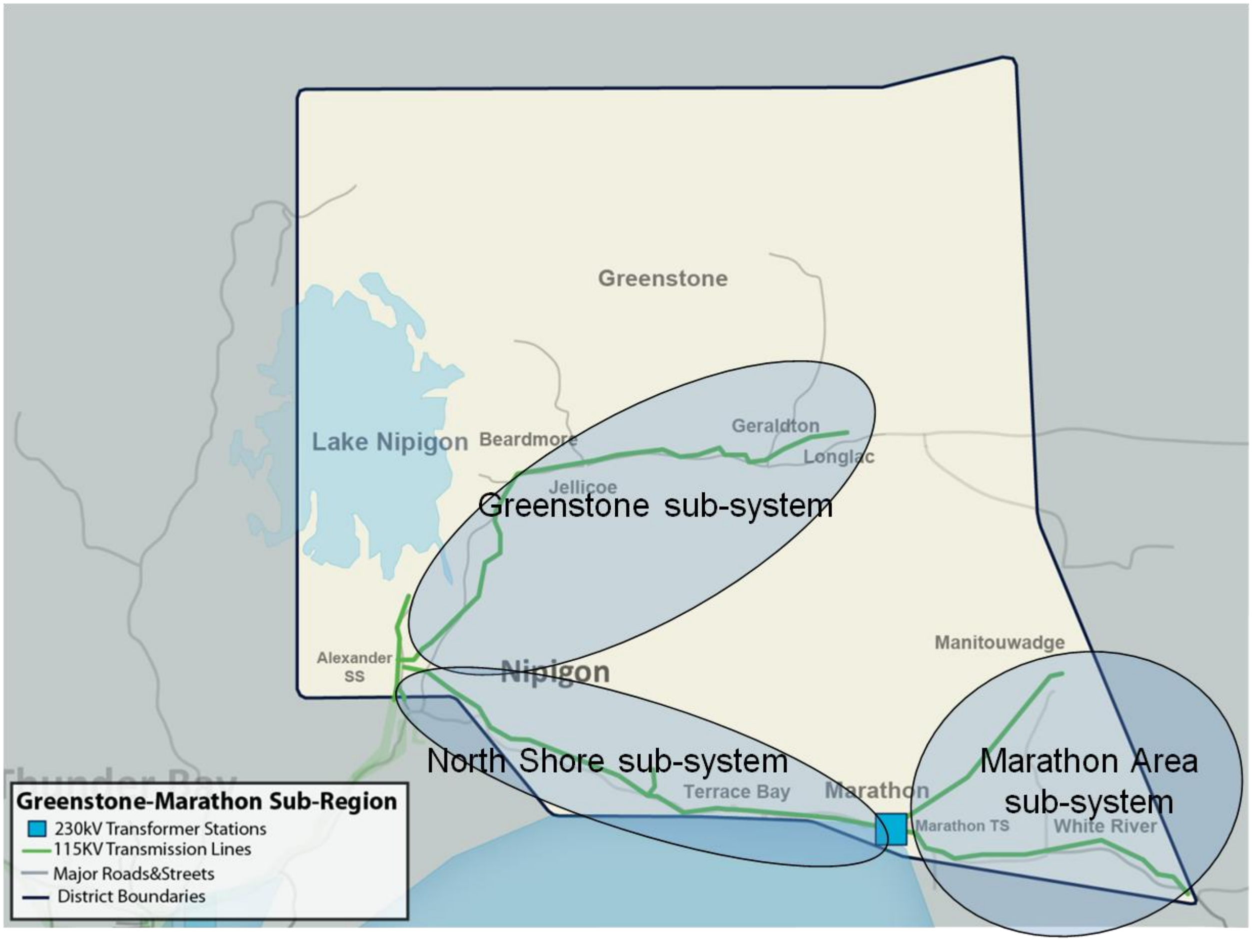
The communities along the north shore of Lake Superior between Nipigon and Marathon are supplied from three circuits in series (A5A / A1B / T1M) that terminate at Marathon TS and Alexander SS. The three circuits generally follow the Highway 17 corridor and have a total distance of approximately 170 km. Hydroelectric generation at Aguasabon GS is connected at Aguasabon SS, which is the terminus for circuits A5A and A1B, and also contributes to the supply of the local area.

4.3 Greenstone-Marathon Area Sub-systems

Within the Greenstone-Marathon Sub-region, there are three electrical sub-systems: Greenstone, North Shore, and Marathon Area.

The facilities supplying each sub-system are illustrated in Figure 4-2.

Figure 4-2: Greenstone-Marathon Sub-Region and Sub-systems



4.3.1 Greenstone Sub-system

The Greenstone sub-system is defined as being comprised of the existing and potential customers serviced from circuit A4L from Alexander SS to Longlac TS. Circuit A4L generally follows Highway 11 from Nipigon to Longlac. Circuit A4L serves the communities comprising the Municipality of Greenstone and serves as connection for Nipigon GS.

4.3.2 North Shore Sub-system

The North Shore sub-system is defined as being comprised of the existing and potential customers serviced from circuits A5A, A1B, and T1M, from Alexander SS to Marathon TS. Circuits A5A, A1B, and T1M are in series and generally follow the Highway 17 corridor. Together, these circuits interconnect Alexander SS to Marathon TS, however, each circuit comprises its own protection zone such that a fault on any one of the three circuits will not interrupt supply on the other two. Hydroelectric generation at Aguasabon GS is connected to the system at Aguasabon SS which is the interconnection between A5A and A1B.

4.3.3 Marathon Area Sub-system

The Marathon Area sub-system is defined as being comprised of the existing and potential customers serviced from circuit M2W, radial from Marathon TS to Manitouwadge TS and White River DS. Hydroelectric generation at Umbata Falls GS and Wawatay CGS is also connected to the system by circuit M2W.

5. Demand Forecast

5.1 Methodology for Establishing a Planning Forecast

The first step in developing an IRRP is establishing a planning forecast. A planning forecast is developed from a compilation of electrical demand data collected from LDCs and potential large customers connected directly to the transmission system. The effects of weather and coincidence factors are considered. Also, the demand reduction from CDM and DG are accounted for when developing the planning forecast.

As part of the lead transmitter's Needs Screening, LDCs are required to submit 10-year gross station demand forecasts. Consistent with the PPWG Report, LDC demand forecasts are further refined and a long-term (10-20 years) projection is also produced. Hydro One Distribution is the sole distributor in the Greenstone-Marathon Sub-region and it provided the Working Group with the gross station demand forecast and related assumptions. The effects of DG and expected conservation from LDC conservation targets were then applied.

The IESO regularly communicates with existing and potential transmission-connected industrial customers to ensure there is an understanding of their future electricity demand requirements. In the Greenstone-Marathon Sub-region, new industrial customers account for the majority of the forecast demand growth. However, the magnitude and timing of the electrical demand growth associated with large industrial customers, especially those in the natural resource sector (e.g., mining, oil, forestry) depend on a number of external factors such as the commodity price of the resource, the economic viability of the industrial project, and the ability to secure capital. In order to account for uncertainty of natural resource-based customers, the IESO developed multiple demand scenarios for potential and existing transmission-connected industrial customers by considering a number of factors, including:

- Customer plans
- Stage of development (e.g., under construction, undergoing an Environmental Assessment ("EA"), still in exploration, etc.)
- Financial feasibility (e.g., results of publically available economic assessments)
- Potential environmental impacts
- Existing infrastructure and accessibility
- Global markets (e.g., commodity prices, customers and demand)

Planning forecasts were developed based on LDC station demand forecast, the impact of CDM and DG, and the forecast scenarios of transmission-connected industrial customers.

5.2 Forecast Elements

The forecast developed for the Greenstone-Marathon IRRP includes quantitative and qualitative contributions from a number of parties including Hydro One Distribution, individual existing and potential industrial customers, local municipalities, First Nation communities and Métis community councils, industry associations, and interest groups.

5.2.1 Local Distribution Company Gross Demand Forecast

To support the regional planning process, the DSC requires that the LDCs provide gross station demand forecasts representing distribution customer demand projections. Hydro One Distribution has provided gross forecast projections for the step-down supply stations within the Greenstone-Marathon Sub-region indicated in Table 5-1 below.

Table 5-1: Step-down Stations by Sub-system

Greenstone Sub-system	North Shore Sub-system	Marathon Area Sub-system
Beardmore DS #2	Marathon DS	Manitouwadge DS #1
Jellicoe DS #3	Schreiber Winnipeg DS	Manitouwadge TS
Longlac TS		Pic DS
		White River DS

LDC forecasts also include small industrial customers, such as saw mills connected to the distribution system. One notable inclusion is the re-start of two saw mills in the Municipality of Greenstone.

5.2.2 Conservation Assumed in the Forecast

In developing planning forecast scenarios, the Working Group also considered the extent to which planned CDM may impact peak demand.

In the report "Achieving Balance: Ontario's Long-Term Energy Plan" ("2013 LTEP"), the Ontario government established a provincial CDM target of 30 TWh in electricity reduction by 2032. To assist in achieving this target, the 2013 LTEP also committed to establishing a new 6-year Conservation First Framework beginning in January 2015. In order to represent the effect of provincial conservation targets within regional planning, the IESO developed an annual forecast for peak demand savings based on the provincial energy savings target which it expressed as a percentage of demand in each year. These percentages were apportioned to the

LDC demand forecast to develop an estimate of the peak demand impacts from the provincial targets in the Greenstone-Marathon Sub-region. The CDM targets included in developing the net demand forecast are provided in Table 5-2 below.

Table 5-2: Conservation Targets by Sub-system

Sub-system	Peak Reduction due to Conservation [MW]				
	2015	2020	2025	2030	2035
Greenstone	0.1	0.4	1.4	2.2	2.5
North Shore	0.1	0.6	1.2	2.0	2.3
Marathon Area	0.2	1.0	1.9	3.0	3.5

5.2.3 Transmission Connected Customer Demand Forecast

The majority of forecast demand growth in the Greenstone-Marathon Sub-region is anticipated to be driven by potential large industrial customers that may connect directly to the transmission system. In the near term, potential industrial projects include a gold mine near Geraldton, and the pumping stations associated with a portion of a large gas to oil pipeline conversion project that generally follows the Highway 11 corridor. The life extension of an existing mine near Marathon, and a precious metals mine near Marathon are also considered.

In the medium and long term, a gold mine near Beardmore, and potential new supply to mining and remote communities in the Ring of Fire area using a North-South corridor are considered in the forecast scenarios.

5.3 Planning Forecast

To address peak electricity demand requirements for the sub-region, a scenario-based planning approach was used to account for uncertainty in demand forecast. As a result, the Greenstone-Marathon planning forecast consists of a number of scenarios which account for different possible industrial development outcomes. The scenarios all represent plausible outcomes that must be considered in planning for the electricity needs of the sub-region.

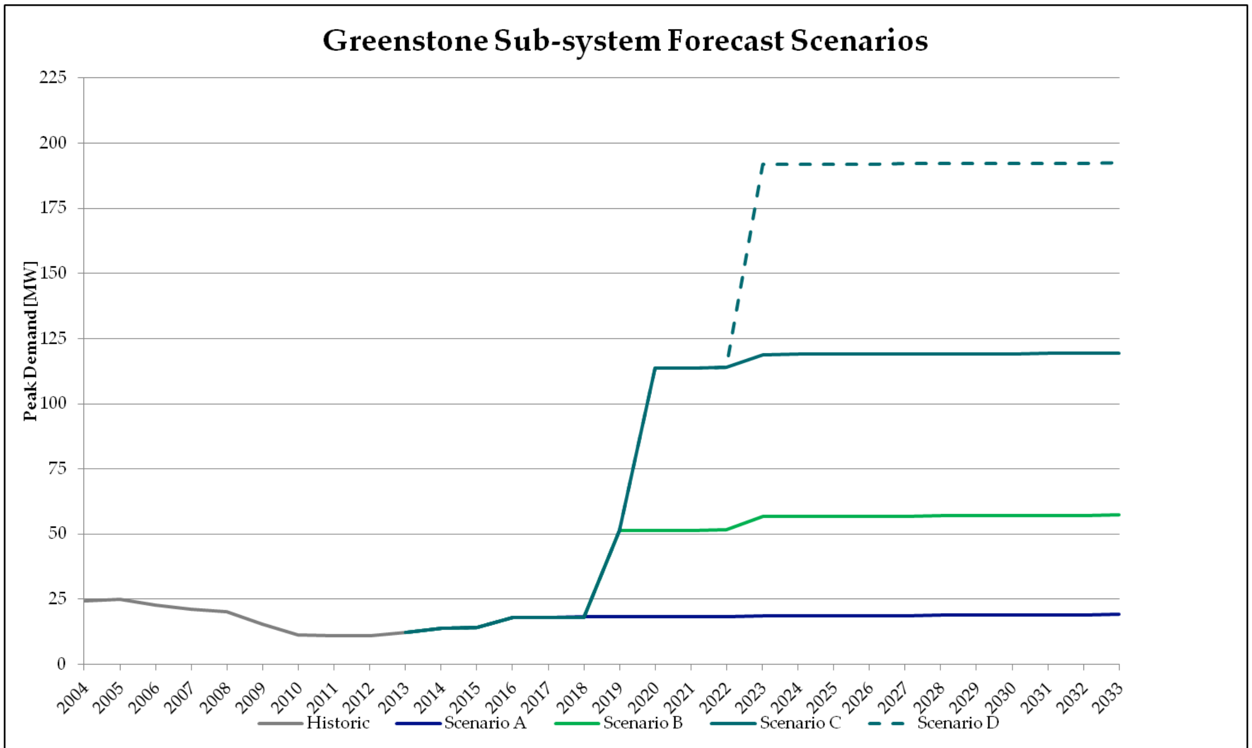
5.3.1 Greenstone Sub-system Forecast Scenarios

The following summarizes the forecast scenarios considered for the Greenstone sub-system. Since publishing of the Interim IRRP, scenarios have been updated to reflect the latest timelines and include medium and long-term developments, including the Beardmore mine and Ring of Fire.

Table 5-3: Greenstone Sub-system Forecast Scenarios

Scenario	Description
A	Hydro One Distribution customer growth (including two saw mill re-starts)
B	Hydro One Distribution customer growth (including two saw mill re-starts), Geraldton mine materializes, and Beardmore mine materializes
C	Hydro One Distribution customer growth (including two saw mill re-starts), Geraldton mine materializes, Beardmore mine materializes and gas to oil pipeline conversion project materializes
D	Scenario C with the Ring of Fire area fully developed by 2023

Figure 5-1: Greenstone Sub-system Forecast Scenarios



Impacts to population and employment from potential industrial customers are considered in the respective scenario. It should be noted that the Greenstone sub-system forecast Scenarios B and C are equivalent until 2020, at which point they diverge. This is important when considering staging of options and will be discussed further in Section 7.2.2.

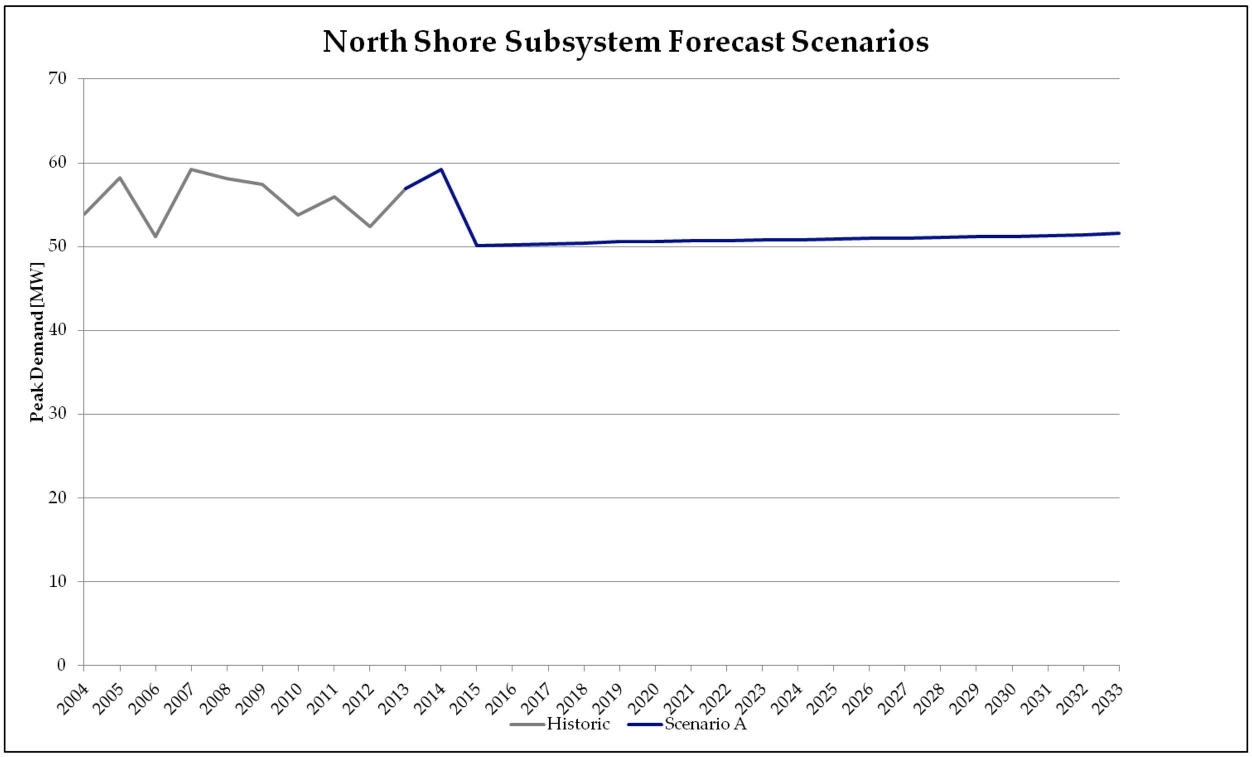
5.3.2 North Shore Sub-system Forecast Scenarios

Since the publishing of the Interim IRRP, the industrial customer is no longer considering behind-the-meter generation and so the accompanying scenarios that were included in the Interim IRRP have been removed from the IRRP analysis. Therefore, a single scenario is used for analysis in this IRRP for the North Shore sub-system and is summarized in Table 5-4 and Figure 5-2, below.

Table 5-4: North Shore Sub-system Forecast Scenarios

Scenario	Description
A	Hydro One Distribution customer growth

Figure 5-2: North Shore Sub-system Forecast Scenarios



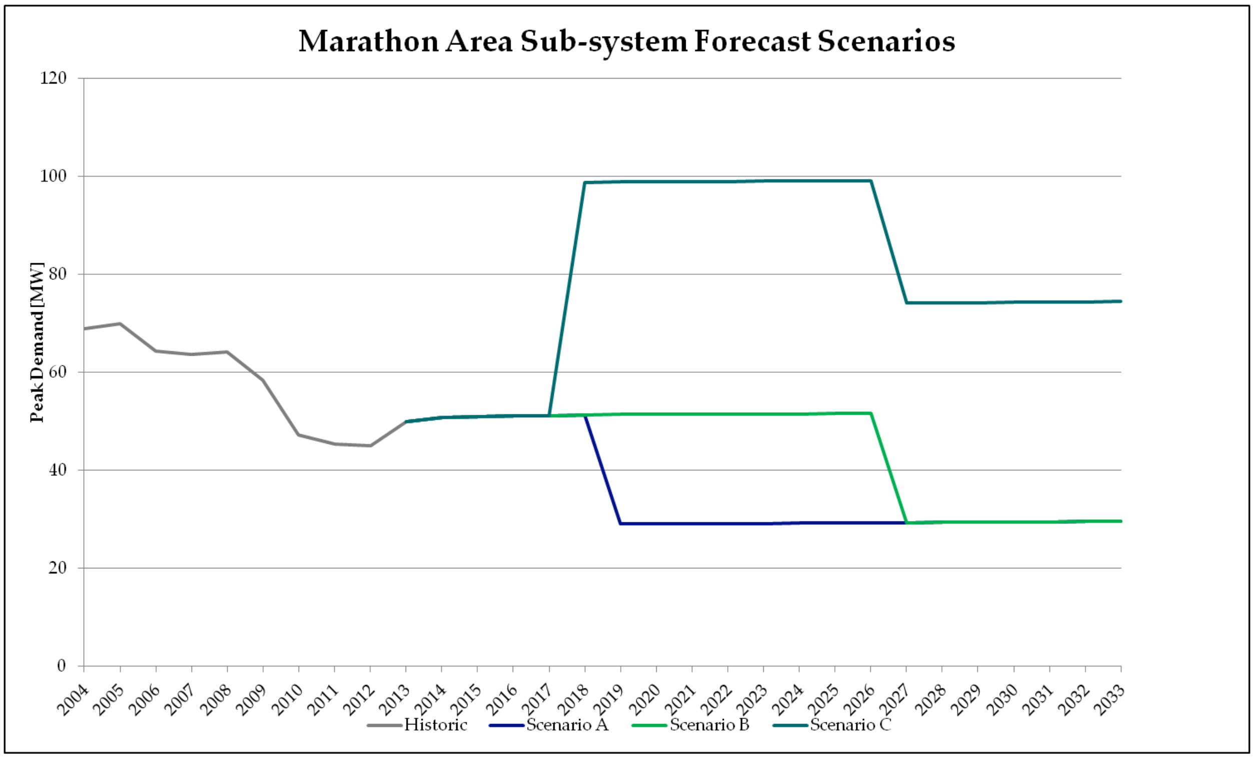
5.3.3 Marathon Area Sub-system Forecast Scenarios

The following summarizes the forecast scenarios considered for the Marathon Area sub-system, which have remained unchanged since the publishing of the Interim IRRP.

Table 5-5: Marathon Area Sub-system Forecast Scenarios

Scenario	Description
A	Hydro One Distribution customer growth, no life extension of existing Marathon Area mine
B	Hydro One Distribution customer growth, with life extension of existing Marathon Area mine
C	Hydro One Distribution customer growth, with life extension of existing Marathon Area mine, and new Marathon Area precious metals mine materializes

Figure 5-3: Marathon Area Sub-system Forecast Scenarios



6. Electricity System Needs

For the purpose of this IRRP, the following section details the near-, medium-, and long-term needs established by the Working Group.

6.1 Methodology for Establishing Power System Needs

Once the planning forecast is developed, power system needs are established by determining the load meeting capability ("LMC") of the power system and determining if a shortfall exists between the electricity that can be supplied by the system in comparison to the forecast demand.

In order to determine the LMC of the power system supplying the Greenstone-Marathon Sub-region, Ontario and North American electricity planning standards are applied consisting of: the ORTAC, the Northeastern Power Coordinating Council ("NPCC") Directory #1 Standards, and the North American Electric Reliability Corporation ("NERC") Transmission Planning Standards ("TPL-001-4"). These documents outline power system planning and design standards and all are publically available.[8]

ORTAC represents the compilation of standards and best-practices in Ontario for long-term electricity plans, including IRRPs. ORTAC identifies certain system conditions, including contingencies, and the required level of performance under those conditions. The performance of the system is categorized based on equipment loading, voltage performance, load security and restoration (acceptable time periods for restoring customers after specified contingencies). Appendix A details the criteria applied in this IRRP.

The IESO recognizes that ORTAC, NERC, and NPCC planning criteria may not necessarily align with customer risk tolerances or their ability to pay for system reinforcement. Ultimately the decision of electric power supply resides with the benefitting customers so long as the reliability of the bulk system is not negatively impacted.

6.2 Existing System Load Meeting Capability

In order to establish electricity supply requirements for the Greenstone-Marathon Sub-region, it is necessary to determine the LMC of each of the Greenstone, North Shore and Marathon Area sub-systems. The LMC of each sub-system is largely dependent on the connection point of the new customers forecast to connect. This is especially true in northwestern Ontario where the LMC of long circuits may be limited by voltage.

6.2.1 Greenstone Sub-system Load Meeting Capability

The Greenstone sub-system is limited by voltage for new customers near the Longlac area. The existing system, consisting of the A4L transmission line, has a total LMC of approximately 25 MW assuming the majority of load is concentrated in the Geraldton and Longlac areas near the end of the circuit. Based on demand forecast Scenario A, the Greenstone sub-system is not expected to be limiting, however all other scenarios are forecast to exceed the 25 MW limit in the near term. It should be noted that although circuit A4L is currently limited by voltage, it has a summer thermal rating of 260 A, or approximately 45 MW.[9]

6.2.2 North Shore Sub-system Load Meeting Capability

In addition to supplying customers, the North Shore sub-system also serves as the bulk system underlay for the East-West Tie. The North Shore sub-system can accommodate a total of approximately 100 MW of load and through-flow (from bulk transfers) during normal conditions. Flow along the North Shore sub-system is not expected to exceed 100 MW during normal conditions, even when the East-West Tie is loaded to its fair weather transfer limit and under a variety of local hydroelectric conditions.

Under the post-contingency condition where the double-circuit line M23L/M24L (which is a portion of the East-West Tie) between Marathon to Lakehead is lost, flows may exceed 100 MW along the North Shore sub-system during high transfer conditions. Overloading is mitigated and reliability is maintained by ensuring load is continuously supplied pre-contingency by the availability of the Northwest Remedial Action Scheme ("RAS"). Following the reinforcement of the East-West Tie between Wawa TS and Lakehead TS, currently planned to be in-service for 2020, reliability to the Northwest will be improved and the North Shore sub-system will also be

[9] In order to release the full thermal capability of facilities that are limited by voltage, reactive compensation of sufficient amounts to address the voltage limit would need to be installed. This is considered further in the Alternatives section of the report.

able to accommodate further growth. Therefore the North Shore sub-system is not expected to be limiting for new customers during this planning cycle.

6.2.3 Marathon Area Sub-system Load Meeting Capability

The Marathon Area sub-system is limited by voltage performance. Incremental reactive compensation may be required to connect additional customers. The further customers are from Marathon TS, the more reactive compensation will be required. The maximum load that the Marathon Area sub-system can accommodate based on the ORTAC load security limit for a single-circuit line is 150 MW. Based on existing forecasts, the Marathon Area sub-system is not expected to be limiting for new customers during this planning cycle.

6.3 Near-Term Needs

The near-term needs are described below by sub-system for each planning forecast scenario.

6.3.1 Near-Term Needs: Greenstone Sub-system

Capacity

The near-term capacity needs have been determined by comparing the near-term demand forecast, driven by the Geraldton mine and the gas to oil pipeline conversion project, to the LMC of the sub-system, and are tabulated below:

Table 6-1: Summary of Near-Term (present-5 years) Capacity Needs for the Greenstone Sub-system[10]

Demand Forecast [MW]	2015	2016	2017	2018	2019	2020
Scenario A	14	18	18	18	18	18
Scenario B	14	18	18	18	51	51
Scenario C	14	18	18	18	51	114
Greenstone LMC[11] [MW]	**25**					
Capacity Need [MW]						
Scenario A	0	0	0	0	0	0
Scenario B	0	0	0	0	26	26
Scenario C	0	0	0	0	26	89

[10] Scenario D is not considered for the near-term, as it is identical to Scenario C from 2015-2023

[11] Based on the capability of circuit A4L without any additional reactive compensation.

Power flow studies are included in Appendix B.

Load Security and Restoration

All demand forecast scenarios being considered up to 2020 remain less than 150 MW. This complies with the load security criteria outlined in ORTAC for a single-circuit line, which requires that no more than 150 MW be lost due to an outage on that line. Also, restoration from a normal outage should remain under eight hours, consistent with ORTAC.

Restoration from forced outages has generally performed within ORTAC. In the last five years, forced outages have been restored within eight hours with the exception of three sustained outages. These outages required crews to perform restoration work into the overnight period. The intent of the 8-hour criterion is that all non-catastrophic forced outages can be restored within a working day. Provisions exist in ORTAC to account for outages that take place outside of normal working hours and away from staffed centres; "approximate restoration times are intended for locations that are near staffed centres… [and] restoration times should be commensurate with travel times and accessibility"[12] (ORTAC 7.2). Therefore, no load security or restoration needs have been identified in the near term. A comprehensive reliability analysis is included in Appendix E.

Additional Customer Requirements

Fault analysis indicates that the available short-circuit at the end of circuit A4L is about 140 MVA[13] at the Longlac TS 115 kV bus. A potential mining customer near Geraldton has indicated that it requires at least 150 MVA available short circuit at 13.8 kV supply to ensure the functioning of its equipment. It has been estimated that the available short circuit would be about 105 MVA at 13.8 kV at the proposed Geraldton mine. Therefore, solutions for the area that consider the Geraldton mine scenarios must increase the available short circuit level, for example: through the use of generators, synchronous condensers or static synchronous compensators ("STATCOM"). Passive devices such as capacitors or Static Var Compensators ("SVCs") cannot provide the required short circuit level.

As well, for forecast scenarios that include the large gas to oil pipeline conversion project, the developer has informed the IESO that adjacent pumping stations cannot be lost for the same

---

[12] ORTAC: http://www.ieso.ca/documents/marketAdmin/IMO_REQ_0041_TransmissionAssessmentCriteria.pdf

[13] Assuming the outage of Nipigon GS, representing a scenario that short-circuit availability is low

contingency. Therefore, provisions for appropriate supply diversity must be included for these relevant scenarios.

6.3.2 Near-Term Needs: North Shore Sub-system

The existing electrical system supplying the North Shore sub-system is expected to be sufficient for the planning horizon, given the latest information made available to the IESO. As indicated in Section 5.3, the North Shore sub-system is not forecast to experience net demand growth. Power flow study results are included in Appendix B for reference, and indicate that facilities are expected to perform within ratings with sufficient reliability.

6.3.3 Near-Term Needs: Marathon Area Sub-system

The existing electrical system supplying the Marathon Area sub-system is expected to be sufficient for the near-term.

This is also supported by the Stillwater Canada Inc. System Impact Assessment ("SIA") Report for the Marathon Platinum Group Metals (PGM) Copper Project, available on the IESO website.[14]

Power flow study results are included in Appendix B, and indicate that facilities are expected to perform within ratings with sufficient reliability.

6.4 Medium- and Long-Term Needs and Initiatives

The medium- and long-term needs for the Greenstone-Marathon Sub-region are discussed below in the context of four medium- and long-term initiatives including: additional mining claims in Greenstone, the possibility of an infrastructure corridor to the Ring of Fire, the Little Jackfish hydroelectric project, and community energy efficiency activities.

6.4.1 Additional Mining Claims in Greenstone

Other mining claims, beyond the Geraldton mine, exist along the Highway 11 corridor in the Greenstone area and additional local system reinforcement may be required if mines develop. Of particular interest is a potential gold mine near Beardmore that may be operational within the medium term. The mining developer's preliminary economic assessment results[15] indicate

---

[14] http://www.ieso.ca/Documents/caa/CAA_2012-476_Final_Report.pdf
[15] http://www.premiergoldmines.com/i/pdf/2014-01-28_NR.pdf

that it would be economically advantageous for the Beardmore mine if processing and gold recovery were performed at the Geraldton mine.

Therefore, it has been assumed for purposes of this IRRP, that the Beardmore mine is included in scenarios that also include the Geraldton mine.

6.4.2 Infrastructure Corridor to the Ring of Fire

A North-South multi-use infrastructure corridor from near Nakina to the Ring of Fire continues to be a possibility for developers. As concluded in the 2015 North of Dryden IRRP, transmission supply for mining and remote communities is economic and the need for a new 230 kV transmission line to the Ring of Fire should be considered when developing an infrastructure corridor to the Ring of Fire. The 2015 North of Dryden IRRP also concluded that an East-West corridor from Pickle Lake or a North-South corridor from East of Nipigon or Marathon were comparable in cost if the Ring of Fire fully develops.

This IRRP report extends the analysis of a new 230 kV North-South transmission line to the Ring of Fire to consider the extent of possible economic efficiencies from multiple customers.

6.4.3 Little Jackfish Hydroelectric Project

The Little Jackfish hydroelectric project would require a new 180 km 230 kV connection line in order to provide power to the provincial electricity grid. The details of the connection line are included in Ontario Power Generation's ("OPG") project description[16] (pursuant to the Canadian Environmental Assessment Act).

The purpose of all IRRPs is to provide plans to reliably serve electricity demand, not to develop plans to connect system generation. However, potential transmission options exist that are detailed in Section 7 that may result in economic efficiencies for connecting the Little Jackfish hydroelectric project. Section 9.3 quantifies the economic efficiencies under the specific system expansion scenario that such efficiencies may result.

6.4.4 Community Energy Efficiency Activities

In a number of communities within the IRRP study area, electricity is the primary source for heating because there is no natural gas pipeline infrastructure. During municipal engagement

---

[16] http://www.opg.com/generating-power/hydro/projects/little-jackfish/Documents/LJF_Project_Description.pdf

activities, the Town of Marathon communicated that electric heating has resulted in budgetary pressures and that the town is investigating the potential for cogeneration options. Section 9.4 provides a high-level avoided cost analysis for cogeneration. Similar solutions may also be a consideration for other communities without access to natural gas pipeline infrastructure. The IESO is including this planning-level economic analysis to provide communities with a methodology that they may use to determine planning-level feasibility.

7. Alternatives for Meeting Near-Term Needs

7.1 Methodology for Alternatives Development and Comparison

Once needs are identified, alternatives are developed that are technically feasible and are then compared on a relative basis against planning criteria. If a decision is required, given the forecast timing of needs and lead times for implementing feasible alternatives, a recommendation is made.

Alternatives may consist of one or a combination of CDM, generation, transmission, and/or distribution. Integrated alternatives that are capable of satisfying criteria for the forecast system condition and for the applicable scenario being assessed are then considered. Alternatives that are not capable of satisfying criteria are screened out and not considered further.

An economic analysis of the technically feasible alternatives is performed and the net present value ("NPV") of each option is determined based on the amortized costs that are incurred within a 20-year planning horizon.[17] The IESO used a real social discount rate of 4% in this analysis.[18] Generation and conservation options that contribute to provincial system supply needs are appropriately credited with the related economic benefit to ensure consistent comparison with all other options. Other factors such as environmental impact and social acceptance are considered, including information obtained from the engagement process. Detailed environmental impact analysis is performed by proponents during the implementation phase for projects requiring environmental assessment.

7.2 Alternatives Considered

7.2.1 Conservation

Conservation is important in managing demand in Ontario and plays a key role in maximizing the useful life of existing infrastructure and maintaining reliable supply. Conservation is achieved through a mix of program-related activities including behavioral changes by customers and mandated efficiencies from building codes and equipment standards. These approaches complement each other to maximize conservation results.

---

[17] This is not the total project cost.

[18] The real social discount rate may be different than individual customer discount rates which account for the individual customer's own return on equity, risk, tax, etc.

However, within the Greenstone-Marathon Sub-region, the majority of the forecast load growth is anticipated to come from new industrial development, which is assumed to include relatively efficient equipment given the inherent economic benefits and latest codes and standards. Conservation expected to be achieved through provincial targets has already been included in the net demand forecast. Therefore, the potential for an additional amount of significant conservation that could address needs is limited.

Two of the available programs that transmission-connected industrial customers could be eligible for are the Industrial Conservation Initiative ("ICI") and the Industrial Accelerator program ("IAP"). The ICI encourages Class A customers to reduce their peak demand contributions, by providing a means to reduce their Global Adjustment charges.[19] IAP is geared to reducing electricity consumption on the provincial system, and to helping companies become more competitive by providing financial incentives that encourage investment in innovative process changes and equipment retrofits.[20] Opportunities for energy savings will continue to be explored for new and existing transmission-connected customers in the Greenstone-Marathon Sub-region.

7.2.2 Renewable Distributed Generation

A high level assessment of the cost of renewable DG resources to meet capacity needs in the Greenstone-Marathon Sub-region was conducted. This was performed by estimating a range of dependable capacity values for run-of-river hydroelectric, wind, and solar resources, based on median historical and simulated data for facilities in the Northwest Ontario Region. Dependable capacity refers to the portion of the total installed capacity that can be relied upon to meet local or system peak capacity needs. Consistent with ORTAC, this refers to the 98-percentile output of the resource. Based on the dependable capacity, unit costs were developed for these renewable resources. These unit costs are summarized in Table 7-1, below and range from $16 M/MW - $100 M/MW. Compared to the unit costs of detailed local generation and transmission options that are considered later in this report that range between $1.4 M/MW - $7.3 M/MW, renewable DG is not economic and can be screened out of further assessment.

---

[19] More information on how Global Adjustment is calculated for Class A customers is available at http://www.ieso.ca/Pages/Participate/Settlements/Global-Adjustment-for-Class-A.aspx
[20] More information on IAP available: http://www.ieso.ca/Pages/Participate/Industrial-Accelerator-Program/default.aspx

Table 7-1: Summary of Analysis of Renewable DG

Resource Type	Dependable Capacity [%]	Unit Capacity Cost [M$/MW-dependable]	Levelized Unit Energy Cost [$/MWh]
Run of River Hydroelectric	15-30	16-66	60-110
Wind and Solar	5-28	7.5-100	80-400

It should be noted that storage systems may be effectively sized to increase the overall dependable capacity of an integrated renewable DG - storage system, though the unit costs of such system are expected to also increase due to the added battery systems. It is also expected that given the magnitude of the needs described in Section 6 of up to 89 MW of incremental LMC by 2020, and the dependability of the resources required, renewable DG options would be of impractical physical size. For example, a solar facility with a dependable capacity of 28% would need to be rated at approximately 320 MW to provide an LMC of 89 MW. Typical solar facilities can require over 5 acres of land per 1 MW.[21]

Although renewable DG is neither economic nor practical to meet the regional needs identified in the Greenstone-Marathon Sub-region, customers connected to the provincial power system have access to renewable energy programs which they may be eligible to participate. From a customer perspective, these programs may be effective in offsetting their individual electric utility costs. Ultimately, this is a customer decision that includes adherence to the corresponding program and connection availability rules.

7.2.3 Greenstone Sub-system Alternatives

The following sections describe the analysis of the different alternatives considered for each of the Greenstone sub-system forecast scenarios.

As indicated earlier, the Greenstone sub-system consists of one single-circuit 115 kV transmission line (A4L) with limited capacity and the near-term need for new capacity is driven by two specific industrial developments. Given that the options must account for a number of

[21] http://www.nrel.gov/docs/fy13osti/56290.pdf

factors such as the limitations of the existing system, the identified needs, and the staging of industrial customer electrical demand increases, a single transmission, generation, or DG alternative may not fulfill the range of customer requirements. In order to develop options that provide for the full scope of existing system limitations and customer capacity requirements, combinations of transmission, large generation, and DG facilities are considered. Off-grid alternatives are also considered for the purpose of cost comparisons. These alternatives include the following scenarios:

Table 7-2: Summary of Alternatives Considered for Scenarios

Scenario	Alternative	NPV Cost [M$]
A	"A0" – Continued sustainment of existing transmission system	0[22]
B	"B1" – Install reactive compensation and distributed generation	65
	"B2" – Install off-grid generation	190
	"B3" – Install reactive compensation and replace sections of circuit A4L	40
C	"C1" – Install reactive compensation, new 230 kV transmission supply and off-grid generation	170
	"C2" – Install reactive compensation, new 230 kV transmission supply and 115 kV connection line	160
	"C3" – Install new grid-connected gas generation and 115 kV connection line	340
	"C4" – Install off-grid generation	530

The result of the scenario-based alternative analysis is summarized below.

Scenario A does not result in the need for any new facilities. As a result, the continued sustainment of existing transmission infrastructure is adequate.

Analysis of Scenarios B and C indicates that a staged approach for recommended capacity enhancements best aligns with the timing of industrial developments. Stage 1 would economically maximize the existing system, while Stage 2 outlines the infrastructure expansion

[22] There is a cost of sustainment and maintenance programs. However, in the context of this option those costs would have been undertaken anyway as regular and good utility practice.

to accommodate a substantial increase in demand. Recommended Stage 1 and Stage 2 are summarized below.

Recommended Stage 1 – to accommodate the Geraldton mine
• Install +40 MVar of reactive compensation in the form of either a synchronous condenser or STATCOM at the Geraldton mine, to be in-service coincident with the mine • Install a customer-based grid-connected gas-fired generation plant of sufficient redundancy to meet the risk tolerance of the Geraldton mine [23]

In 2020, Scenarios B and C diverge. Scenario B includes only the demand from the Geraldton mine, whereas Scenario C includes both the mining demand and the demand from the gas to oil pipeline conversion project.

If, in addition to the Geraldton mine, the gas to oil pipeline conversion project proceeds and commits to electricity service according to schedule (2020), and consistent with Scenario C, the recommendation is:

Recommended Stage 2 – to accommodate the gas to oil pipeline conversion project
• Install a new 230 kV single-circuit line from the East-West Tie near Nipigon or Marathon to Longlac, new 230/115 kV auto-transformer and related switching and voltage control facilities at Longlac TS to be in-service coincident with the connection of the pumping stations loads • Install a new 115 kV single-circuit line from Longlac TS to Manitouwadge TS and related switching and voltage control facilities, to connect the pumping station loads

If the gas to oil pipeline conversion project does not proceed or does not commit to grid supply, consistent with Scenario B, Stage 1 is sufficient to meet forecast demand. The following sections provide a detailed analysis of the alternatives listed in Table 7-2.

[23] The IESO has assumed N-1 reliability of the plant (single redundant unit), consistent with North American electricity reliability standards. If the generation can operate in island-mode, it may be advantageous to pursue this option due to the inherent supply diversity that it offers in comparison to replacing circuit sections of A4L (Option B3). The customer may also wish to investigate conservation incentives that the IESO offers, such as the ICI and IAP, to compliment this option.

7.2.3.1 Continued Sustainment of Existing System ("Option A0")

Under forecast Scenario A, no new industrial customers are supplied from the transmission grid. Under this scenario, the existing transmission system is sufficient to meet electrical capacity requirements in the Greenstone sub-system. No new facilities are required.

A comprehensive reliability analysis is included in Appendix E.

To maintain the reliability of circuit A4L, continued routine maintenance and sustainment activities consistent with Hydro One's maintenance practices and sustainment plans are expected to be adequate and meet planning criteria. Customers may choose to pursue further reliability investments independently.

7.2.3.2 Install Reactive Compensation and Distributed Generation ("Option B1")

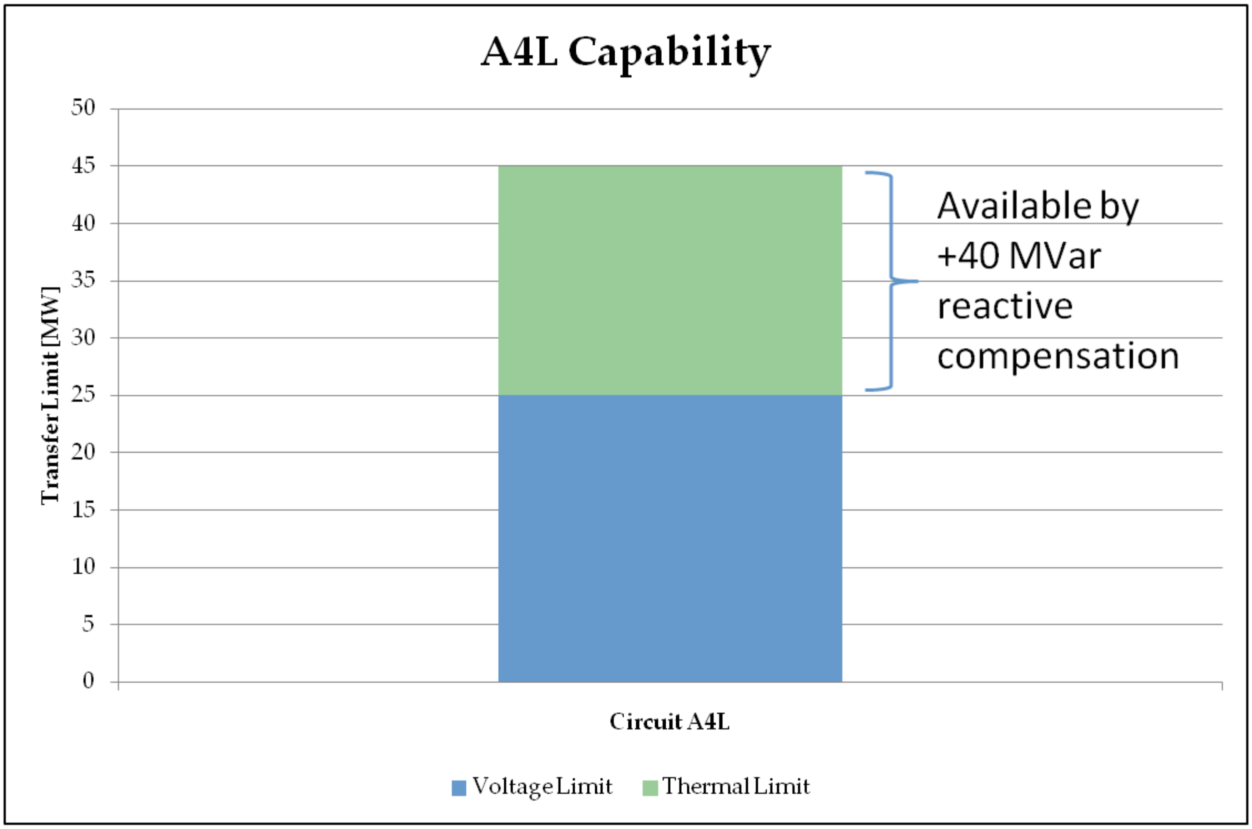
This option considers the needs based on load forecast Scenario B.

This alternative consists of installing additional reactive compensation totaling approximately +40 MVar in the form of either synchronous condenser(s) or STATCOM(s).[24] This would make available the full thermal capability of the circuit of 260 A, or approximately 45 MW (i.e. incremental LMC of 20 MW). As indicated in Section 6.3.1, considering motor starting requirements of the Geraldton mine, reactive compensation solutions would need to increase short circuit levels to 150 MVA at the mine site. Devices such as synchronous condensers or STATCOMs would be able to increase the available short circuit level, but passive devices such as capacitor banks or SVCs would not. This has been considered in the economic analysis by assuming the planning level capital cost estimate of the reactive compensation consistent with that of a synchronous condenser, which is approximately $7.5 million (or $5 M NPV).[25] It should be noted that STATCOMs are expected to be comparable in cost, based on information available to the IESO.

[24] In order to accommodate planned and unplanned outages, a RAS is also recommended.

[25] Estimate provided by Hydro One, based on information received from ABB.

Figure 7-1: Increase in A4L Capability with +40 MVar of Reactive Compensation



In order to accommodate the remaining capacity deficiency associated with the Geraldton mine, two 10 MW gas-fired generators may be installed.[26] For costing purposes, these generators are expected to produce about 43 GWh per year, which corresponds to the electricity that the mine is expected to require in excess of the 25 MW of capacity that may be grid-supplied.

A major benefit of using a combination of grid supply and local generation compared to Options B2 and B3 is the supply diversity. A contingency involving the grid or the on-site generators would still allow the mine to continue with some degree of production.[27] The customer may also wish to investigate conservation incentives that the IESO offers, such as the ICI and IAP, to complement this option and further reduce their costs.

[26] The IESO has assumed N-1 reliability of the plant (single redundant unit), consistent with North American electricity reliability standards.

[27] The level of supply security described for Option B1 would require that provisions are made such that the on-site generators being described can operate in island mode.

Power flow study results are included in Appendix C, and indicate that facilities are expected to perform within ratings with sufficient reliability.

The related economic analysis is included in Appendix D for reference.

The details of Option B1 are summarized below:

Table 7-3: Summary of Option B1

Option B1[28]	
Incremental Utilized Capacity [MW]	26
Undiscounted Capital Cost [M$]	65
Net Present Value Cost [M$]	65
Net Present Value Cost per Utilized Capacity [M$/MW]	2.5
Meets Forecast Scenario A:	Yes
Meets Forecast Scenario B:	Yes
Meets Forecast Scenario C:	No

7.2.3.3 Install Off-Grid Generation ("Option B2")

This option considers the needs based on load forecast Scenario B.

Circuit A4L, which serves the Greenstone sub-system, runs parallel to a portion of the TransCanada natural gas pipeline. A possible option is to continue to serve LDC demand with the existing electricity infrastructure, and for the Geraldton mine to supply their entire facility with on-site natural gas generation (i.e. not interconnected with the IESO-controlled grid). This option is included to provide existing and future customers with the full range of available options. It should be noted that the IESO does not generally procure generation to meet future demand that is not connected to the IESO-controlled grid.[29]

[28] Using cost estimates for 9.5 MW gas engines as a representative cost.
[29] An exception is the December 16, 2013 ministerial directive which directed the former OPA to work with those remote First Nation communities where transmission connection is not economic and implement solutions for on-site renewable generation projects that reduce their dependency on diesel fuel and promote the use of renewable energy sources. http://www.powerauthority.on.ca/sites/default/files/news/December-16-2013-Directive-Renewable-Energy.pdf

The publically available draft EA Terms of Reference[30] for the Premier Gold Mines Ltd. Hardrock Mine indicates that 56 MW of generation capacity is anticipated to be required to meet demand with necessary redundancy.

For the purpose of the economic comparison, the installation of a 6x9.5 MW gas-fired engine power plant with dual-fuel capability is assumed. This arrangement would provide the required capacity indicated and account for N-2 redundancy, and address gas delivery risks. The on-site generation would produce approximately 260 GWh per year to supply the mine's energy needs.

The related economic analysis is included in Appendix D.

The details of the option are summarized below.

Table 7-4: Summary of Option B2

Option B2	
Installed Capacity [MW]	57 (6x9.5)
Incremental Utilized Capacity [MW]	26
Undiscounted Capital Cost [M$]	173
Net Present Value Cost [M$]	190
Net Present Value Cost per Utilized Capacity [M$/MW]	7.3
Meets Forecast Scenario A:	Yes
Meets Forecast Scenario B:	Yes
Meets Forecast Scenario C:	No

7.2.3.4 Install Reactive Compensation and Replace Sections of Circuit A4L ("Option B3")

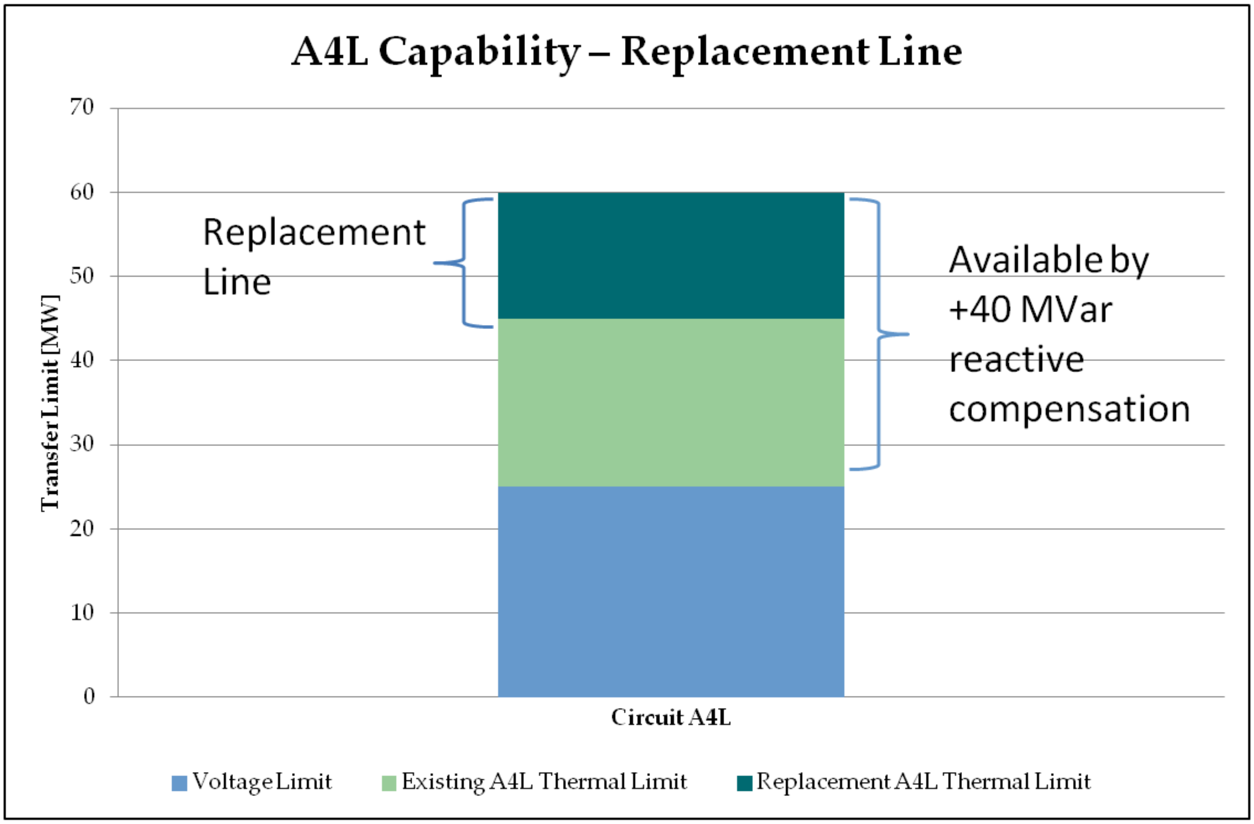
This option considers the needs based on load forecast Scenario B.

This option consists of installing additional reactive compensation of approximately +40 MVar in the form of either a synchronous condenser or STATCOM, and replacing the sections of circuit A4L between Nipigon and Longlac with a new 115 kV line using 477 kcmil Aluminum Conductor, Steel Reinforced ("ACSR") conductors. This would increase the ampacity of the

[30] http://www.premiergoldmines.com/i/pdf/HRTOR/EN/Main_ToR_fnl.pdf

circuit from 260 A to 310 A. If the circuit is fully compensated, this would increase the LMC to about 60 MW[31] which would accommodate the full 51 MW forecast for Scenario B.

Figure 7-2: Increase in A4L Capability with Nipigon to Longlac replaced with a new line equipped with 477 kcmil conductors and with +40 MVar of Reactive Compensation



This option would be optimally staged by first installing +40 MVar of compensation to provide an LMC of 45 MW to accommodate 25 MW of new demand. This would be followed by building the new line sections. The line sections may be constructed while the existing line serves customers, if right-of-way space is available. Otherwise, a bypass would be needed to allow for replacement of the existing line, which may increase costs by approximately 20%. Once the new line sections are constructed, existing facilities can be re-tapped on the new line sections. Following the installation of the new line sections, no additional reactive compensation

[31] The limiting section following the replacement of A4L between Nipigon Junction and Longlac is the section between Alexander SS and Nipigon Junction, which is 310 A. If this section was also replaced, the ampacity of the circuit could increase up to 620 A, which corresponds to an LMC of up to about 120 MW fully compensated. However, since forecast Scenario B only requires an LMC of 51 MW, upgrades were only considered from Longlac TS to Nipigon Junction and a full replacement of A4L was not considered further.

would be required to meet forecast demand beyond the +40 MVar as the larger conductors result in a reduced voltage drop across the line.

Power flow study results are included in Appendix C and indicate that facilities are expected to perform within ratings with sufficient reliability.

The related economic analysis is included in Appendix D.

The details of the option are summarized below.

Table 7-5: Summary of Option B3

Option B3	
Incremental Utilized Capacity [MW]	26
Undiscounted Capital Cost [M$]	62
Net Present Value Cost [M$]	40
Net Present Value Cost per Utilized Capacity [M$/MW]	1.4
Meets Forecast Scenario A:	Yes
Meets Forecast Scenario B:	Yes
Meets Forecast Scenario C:	No

The result of the analysis is that Options B1 and B3 (the grid-connected options) are comparable in cost based on the degree of accuracy of planning cost estimates, and are more economic than Option B2 (the off-grid generation option). Option B1 is recommended over Option B3 due to lead-time constraints. On-site compensation and gas-fired generation typically has a lead time of 1-2 years, while replacing a transmission line with a new line equipped with higher capacity conductors typically has a lead time of approximately five years due to required approvals, including Leave to Construct. However, if the in-service date of 2019 communicated to the IESO by the Geraldton mine developer is delayed, Option B3 is the most economic option and should therefore be pursued. Ultimately this decision rests with the Geraldton mine developer.

An additional consideration for the Geraldton mine developer is that the NPV cost of a new 230 kV line from the East-West Tie over the planning period, as recommended in Stage 2 to meet incremental demand in Scenario C, is approximately $70 million. The $70 million is comparable in cost to Option B1. Although a new 230 kV line may not be technically required immediately, and may require a similar lead time as Option B3 of five years, a new 230 kV source would provide greater reliability to the Geraldton mine customer and the existing

Greenstone customers. A new 230 kV line has been communicated by the LAC to be the preferred supply option by the local community. There may therefore be merit in the Geraldton mine developer pursuing a new 230 kV line immediately, considering the benefits of reliability and community support, while being mindful of the required lead times.

7.2.3.5 Install New 230 kV Transmission Supply to Longlac and Off-Grid Generation ("Option C1")

This option considers the needs based on load forecast Scenario C.

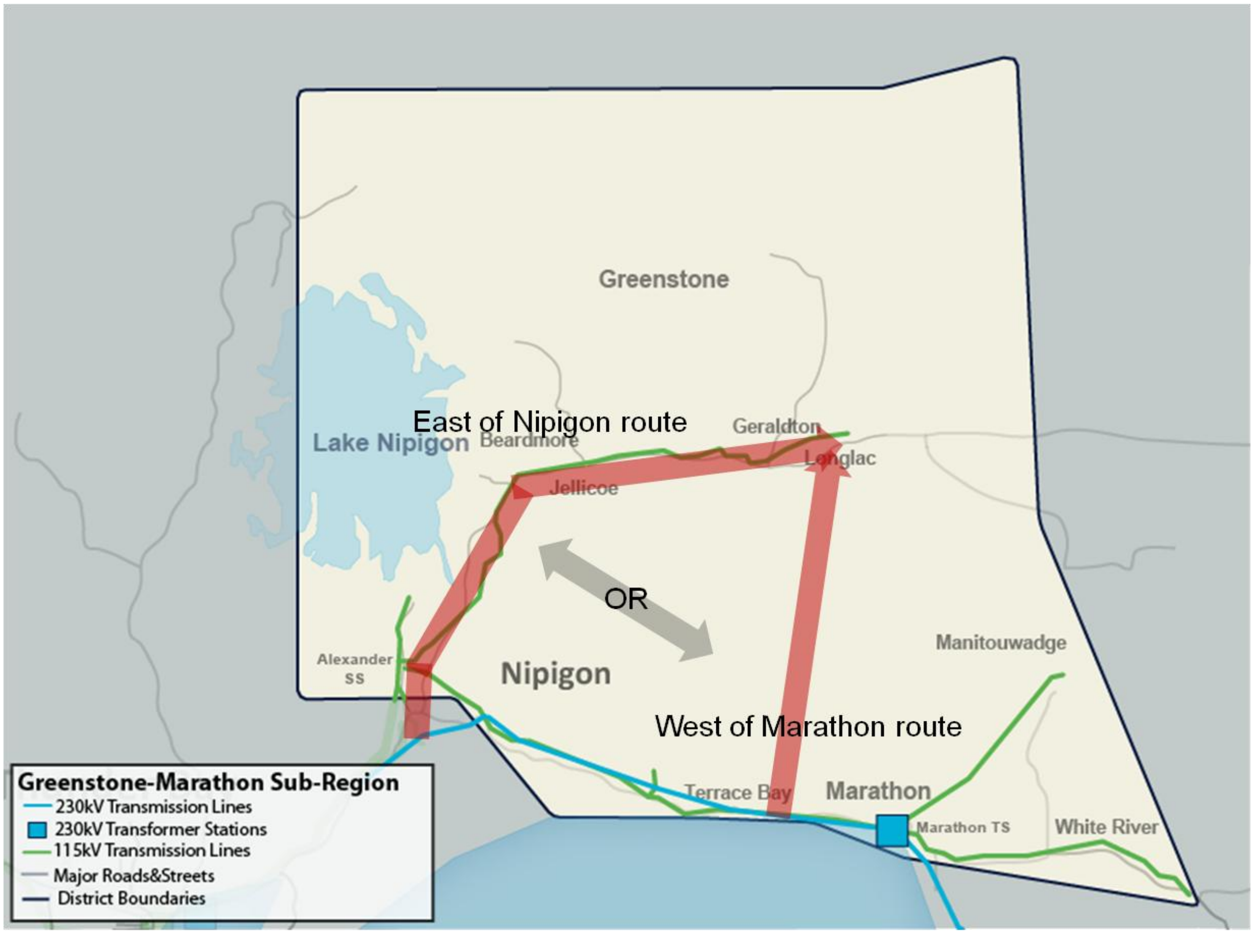
In order to accommodate an incremental capacity deficiency of about 60 MW, (associated with the Geraldton mine and connecting two large oil pumping stations that are located within the vicinity of the existing transmission system), an additional 230 kV supply would be required. The 230 kV supply option would consist of a new single-circuit 230 kV line, a new 230/115 kV auto-transformer located at or near Longlac TS, the associated protection and switching facilities, and reactive compensation (including +40 MVar of reactive compensation at the Geraldton mine consistent with Options B1 and B3). Detailed routing for the 230 kV line option can only be determined through an EA process. However, for planning purposes this report has considered two conceptual routing options for cost comparisons.[32] These two routing options are generally consistent with the routing options that have been communicated to the IESO by interested development groups and consist of an "East of Nipigon" route option, and a "West of Marathon" route option.

The East of Nipigon routing option is based on utilizing the existing Highway 11 corridor, generally running parallel with circuit A4L to Longlac TS and tapping M23L and/or M24L (the existing East-West Tie) between Marathon TS and Lakehead TS, near Nipigon. The length of the East of Nipigon route option would be approximately 150 km. The costing of this option considers single-circuit 230 kV H-frame wood poles with road access in northwestern Ontario.

The West of Marathon routing option is based on utilizing a least-distance, straight line route from the existing East-West Tie, tapping M23L and/or M24L west of Marathon, near Terrace Bay. The length of the West of Marathon route option would be approximately 100 km. The costing of this option considers single-circuit 230 kV H-frame wood poles without road access in northwestern Ontario (since it is considered to be on relatively undeveloped land).

[32] A 230 kV transmission line routing other than the two concepts listed may be considered by proponents if the proposed arrangement provides equivalent or relatively better technical, economic, environmental, and social performance.

Figure 7-3: Option C1 illustrative[33] route map



The East of Nipigon route has the benefit of utilizing an existing corridor with highway access, and a lower per-distance cost (associated with road access), but is longer. The West of Marathon route option has the benefit of being more secure (since common mode failures of both A4L and a new line would be significantly reduced by a separate corridor) and is shorter. However, this option is more costly per-distance (since it has limited road access), and may have greater environmental impact. Details of environmental impacts would be considered during an EA process, where different routes would be considered by the project proponent.

Finally, the two pumping stations to the east of Longlac would be supplied from dedicated gas-fired generation (i.e. not interconnected with the IESO-controlled grid). This would account for the final approximately 30 MW (to total 89 MW) incremental capacity for this scenario. These

[33] The routes depicted are for illustrative purposes only and are not an indication of suggested routing for project developers. The routing depicted was used to establish line lengths to develop planning level cost estimates.

stations are geographically distant from the existing transmission system. As noted earlier, the IESO does not generally procure generation to meet future demand that is not connected to the IESO-controlled grid. This option is included to provide existing and future customers with a broader range of options for comparison.

Power flow study results are included in Appendix C.

The related economic analysis is included in Appendix D.

The details of Option C1 are summarized below:

Table 7-6: Summary of Option C1

Option C1	
East of Nipigon Route Option	
Incremental Utilized Capacity [MW]	89
Undiscounted Capital Cost [M$]	235
Net Present Value Cost [M$]	175
Net Present Value Cost per Utilized Capacity [M$/MW]	2.0
Meets Forecast Scenario A:	Yes
Meets Forecast Scenario B:	Yes
Meets Forecast Scenario C:	Yes
West of Marathon Route Option	
Incremental Utilized Capacity [MW]	89
Undiscounted Capital Cost [M$]	225
Net Present Value Cost [M$]	170
Net Present Value Cost per Utilized Capacity [M$/MW]	1.9
Meets Forecast Scenario A:	Yes
Meets Forecast Scenario B:	Yes
Meets Forecast Scenario C:	Yes

Under this scenario, the N-1 load security would be 45 MW. This accounts for the loss of the new circuit. In considering the N-1 contingency scenario where the 230 kV line (option) is lost, the remaining system would consist of circuit A4L, which is all that exists today. Fully compensated, circuit A4L can accommodate 45 MW.

In order to remain within facility ratings, load would need to be reduced to 45 MW following the loss of the new circuit.[34] The resulting N-1 load security does not satisfy ORTAC requirements. Provisions exist in ORTAC to allow for a customer to agree to higher or lower levels of reliability, provided the bulk system is not negatively impacted. This provides flexibility to customers in the event that ORTAC required enhancements are not cost-effective for them.

Option C2 and Option C3 result in N-1 load security that is greater than Option C1 and satisfies ORTAC.

7.2.3.6 Install New 230 kV Transmission Supply to Longlac and New 115 kV Line from Longlac to Manitouwadge ("Option C2")

This option considers the needs based on load forecast Scenario C.

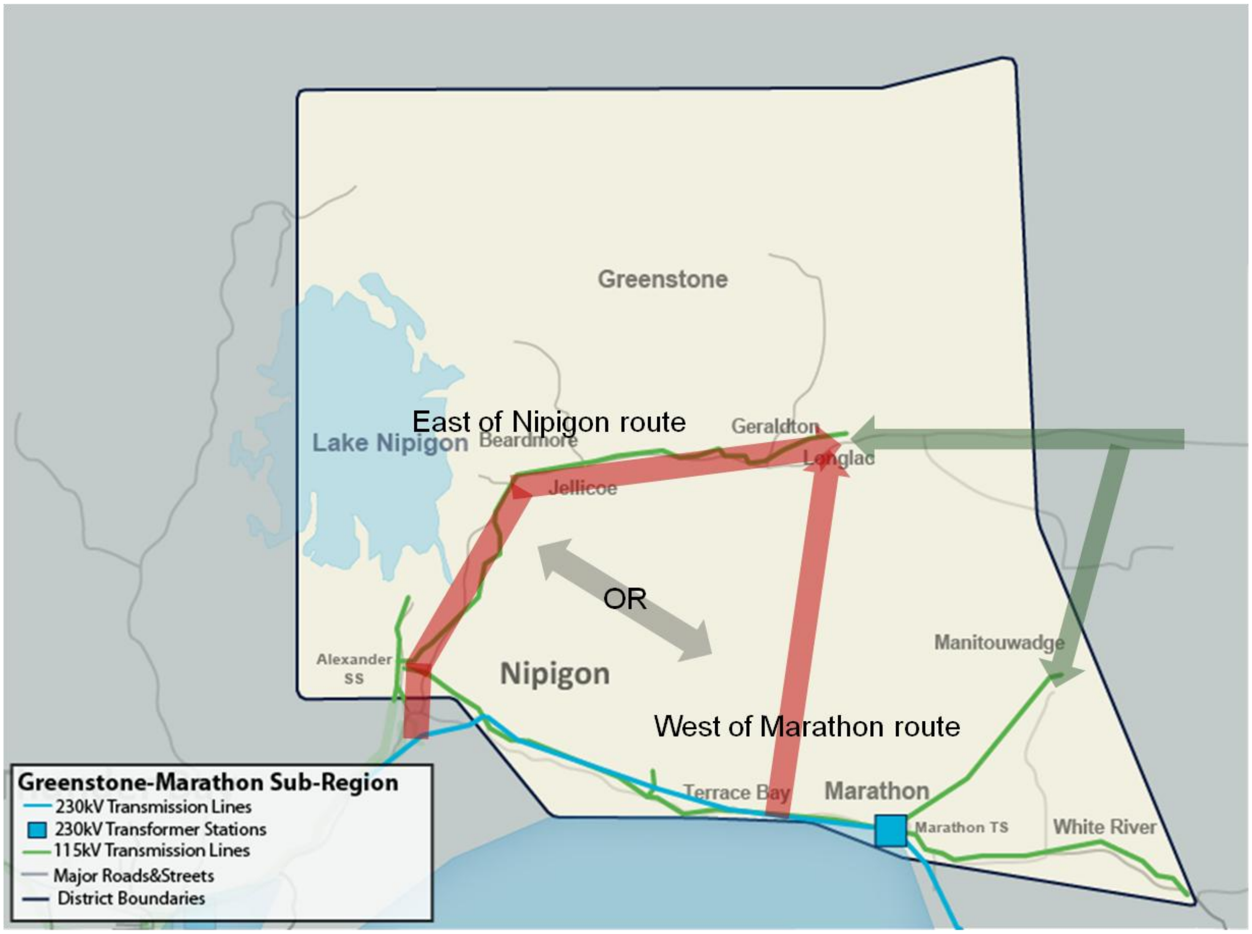
Option C2 builds on Option C1 and consists of installing a new 230 kV supply to the Greenstone area as well as installing reactive compensation (including +40 MVar reactive compensation at the Geraldton mine consistent with Option B1 and Option B3).

In addition, there are two pumping stations that are distant from the existing transmission system and would therefore require a new line if connection is preferred. This option considers installing a new 115 kV single-circuit line from Longlac TS to Manitouwadge TS, as well as the associated protection, voltage control, and switching facilities.

This option also considers the re-termination of the Longlac TS load station on the 230 kV terminal, which would be installed to terminate the 230 kV line option. This is to reduce the overall risk of load loss by distributing load supply stations across different protection zones. The cost of the re-termination has been accounted for by including the cost of new step-down transformers.

[34] To reduce loading to 45 MW, considerations may be built into design configuration, or a Remedial Action Scheme may be installed.

Figure 7-4: Option C2 illustrative[35] route map



Installing switching facilities with appropriate redundancy to separately protect each pumping station can allow all four pumping stations in the area to be supplied from an expanded transmission system. The cost of this protection arrangement has been incorporated by including the cost of new in-line breaker facilities.

Power flow study results are included in Appendix C.

The related economic analysis is included in Appendix D.

The details of the option are summarized below:

[35] The routes depicted are for illustrative purposes only and are not an indication of suggested routing for project developers. The routing depicted was used to establish line lengths to develop planning level cost estimates.

Table 7-7: Summary of Option C2

Option C2	
East of Nipigon Route Option	
Incremental Utilized Capacity [MW]	89
Undiscounted Capital Cost [M$]	270
Net Present Value Cost [M$]	160
Net Present Value Cost per Utilized Capacity [M$/MW]	1.8
Meets Forecast Scenario A:	Yes
Meets Forecast Scenario B:	Yes
Meets Forecast Scenario C:	Yes
West of Marathon Route Option	
Incremental Utilized Capacity [MW]	89
Undiscounted Capital Cost [M$]	260
Net Present Value Cost [M$]	160
Net Present Value Cost per Utilized Capacity [M$/MW]	1.8
Meets Forecast Scenario A:	Yes
Meets Forecast Scenario B:	Yes
Meets Forecast Scenario C:	Yes

Option C2 would satisfy ORTAC and is comparable to the cost of Option C1 based on the degree of planning cost estimates.

7.2.3.7 Install New Generating Plant Near Longlac and New 115 kV Line from Longlac to Manitouwadge ("Option C3")

This option considers the needs based on load forecast Scenario C.

An alternative to Option C2, is to develop a generation-based option to provide a secure supply. Option C3 includes installing a new large grid-connected generation facility near Longlac TS, and building a new 115 kV single-circuit line to connect the two distant pumping stations. The generation plant would provide the required voltage support and short-circuit level to the area. Studies indicate that SVCs would still be required to address credible outage conditions, which have been factored into the costing of this option.

The available capacity of the generating plant would need to be 80 MW at a minimum to provide a secure supply under applicable criteria. For a natural gas-fired generation plant, this would correspond to the summer capability of the plant of 80 MW with at least one unit out of service, a substation with at least two step-up transformers, and a RAS to automatically shed load in the event of additional outage and/or contingency conditions. For the purpose of establishing planning level cost estimates, a 6x18 MW arrangement has been assumed. Other feasible arrangements may be considered.

This option is depicted in Figure 7-5 below.

Figure 7-5: Option C3 illustrative[36] route and generation map

The generating facility would need to be dispatched-on to at least minimum loading whenever the load in the area is expected to exceed 25 MW. The generation facility would also require an output level that ensures the local transmission facilities are able to respect N-1 conditions,

[36] The routes and generation sites are for illustrative purposes only and are not an indication of suggested routing/siting for project developers. The routing depicted was used to establish line lengths to develop planning level cost estimates.

which is limited by the 45 MW thermal capability of A4L. Based on the forecast energy profile of the area, the generation is expected to operate due to local constraints 100% of the time, and would need to produce on average approximately 85 GWh per year in 2019 and 425 GWh per year in 2020 and onward.

Power flow study results are included in Appendix C.

Related economic analysis is included in Appendix D.

Table 7-8: Summary of Option C3

Option C3	
Incremental Utilized Capacity [MW]	89
Undiscounted Capital Cost [M$]	466
Net Present Value Cost [M$]	340
Net Present Value Cost per Utilized Capacity [M$/MW]	3.8
Meets Forecast Scenario A:	Yes
Meets Forecast Scenario B:	Yes
Meets Forecast Scenario C:	Yes

7.2.3.8 Install Off-Grid Generation ("Option C4")

This option considers the needs based on load forecast Scenario C.

Similar to Option B2, a possible option is to serve LDC demand with the existing electricity infrastructure, and for the Geraldton mine and the major pipeline project to supply their own facilities with on-site natural gas generation.

As indicated in Section 7.2.2.3, Option B2 would include provisions for 56 MW of power generation capacity at the Geraldton mine. Additionally this option would include provisions to supply each pumping station with on-site power generation that would not be interconnected with the IESO-controlled grid. For the purpose of establishing cost estimates, 9.5 MW units are assumed.

As noted earlier, the IESO does not generally procure generation to meet future demand that is not connected to the IESO-controlled grid. This option is included to provide existing and future customers with a broader range of options for comparison. Based on the average annual energy forecast for the Geraldton mine and the pumping stations, the energy production is expected to be approximately 260 GWh per year in 2019, and 555 GWh in 2020 and onward.

Table 7-9: Summary of Option C4

Option C4	
Installed Capacity [MW]	57 (6x9.5) + 76 (8x9.5)
Incremental Utilized Capacity [MW]	89
Undiscounted Capital Cost	403
Net Present Value Cost [M$]	530
Net Present Value Cost per Utilized Capacity [M$/MW]	6.0
Meets Forecast Scenario A:	Yes
Meets Forecast Scenario B:	Yes
Meets Forecast Scenario C:	Yes

The result of the analysis is that Options C1 and C2 are more economic than Options C3 and C4. Option C2 is recommended based on economics and reliability. It should also be noted that given the recent timeline change for the Geraldton mine to a single stage in 2019, there may be economic merit in developing a new 230 kV line, consistent with Option C1 and Option C2, in advance of the pipeline project proceeding. This would result in avoiding some or all costs associated with the customer generation at the Geraldton mine described in Option B1 (section 7.2.2.2) for the years that a new 230 kV line may be advanced. Implementation will still require the necessary customer agreements to be in place to ensure the future transmitter can recover prudent costs.

7.3 Near-Term Plan Implementation Considerations

The near-term needs identified in the Greenstone area are driven by a few potential large industrial loads that may develop and choose to connect to the transmission system.

7.3.1 Implementation of Local Transmission Options

Local transmission serves the purpose of reliably supplying specific customer demand. Consistent with the current rules in the TSC, beneficiaries of transmission facilities must pay for the facilities. This is an established requirement and applies to all customers province-wide.

When developing new local transmission, as defined by the OEB, transmitters require financial commitment for capital recovery before incurring any costs associated with developing transmission. This commitment is usually in the form of an agreement between the transmission company and the customer. Customers are typically required to commit to a Connection Cost Recovery Agreement ("CCRA") with the transmitter before the transmitter commits investments for development work. This report therefore does not provide any implementation authority, but simply documents the Working Group's assessment of need and options available for these customers.

Note, on January 11, 2016 the OEB issued a letter stating that it will be holding a Regional Planning and Cost Allocation Review (EB-2016-0003) aimed at ensuring that cost responsibility provisions for load customers under the TSC and DSC are aligned to facilitate regional planning and implementation of regional infrastructure plans. This process may result in changes to the current cost allocation rules contained in the TSC and DSC.

7.3.2 Implementation of Grid-Connected Generation Options

The IESO procures generation resources when needed to supply the Ontario system demand. When doing so, the IESO seeks to minimize marginal energy costs for all Ontario ratepayers. In considering local generation options, the IESO takes into account system needs, feedback from the local community, whether the lowest marginal cost resource can be sited in that local area and whether that option could defer or completely address local needs.

The IESO does not generally procure new generation resources to supply a set of customers in a particular local area if there is no need for system generation, or if that local generation option results in a relatively higher marginal cost compared to other available generation options. If the benefitting customers wish to establish a capacity and energy agreement directly with a local merchant generation company for grid-connected generation, as opposed to other potential supply options (e.g., local transmission or off-grid generation), then they may do so. The local merchant generator would still be subject to all the requirements to connect to the IESO-controlled grid.

The onus is on the customer to engage the electricity service provider that meets its needs. This report therefore does not provide any implementation authority, but simply documents the Working Group's assessment of need and options available for these customers.

7.3.3 Implementation of Off-Grid Generation Options

The IESO does not generally procure generation to meet future demand that is not connected to the IESO-controlled grid. Therefore, it is the responsibility of the customer to develop these options.

To inform customers and local communities of the technical viability and expected costs, some off-grid generation options have been developed for the purpose of illustrating a planning-level cost comparison with grid-connected options.

8. Recommended Near-Term Plan

The following elements of the Greenstone-Marathon IRRP are recommended for near-term development to address demand forecast Scenarios A, B, or C. These scenarios are based on the Working Group's understanding of the various long-term opportunities, and on feedback from the community.

Since publishing the Interim IRRP in June, 2015, the Geraldton mine developers notified the IESO of adjustments to their project schedule and scope. Specifically, they now expect to connect in a single stage in 2019, as opposed to two stages in 2018 and 2020 (which was considered in the Interim IRRP[37]). The IESO's recommendations have been revised accordingly.

The IESO recommends a staged approach to accommodate forecast demand from the Geraldton mine and the pumping stations from the gas to oil pipeline conversion project.

Demand Scenario A

The existing system is sufficient to meet the demand requirements presented in Scenario A. To maintain the reliability of circuit A4L, continued routine maintenance and sustainment activities consistent with Hydro One's maintenance practices and sustainment plans are expected to be adequate and meet planning criteria.

Demand Scenario B

Demand requirements for Scenario B considers the Geraldton mine proceeding in 2019. The Working Group therefore recommends the following to address Stage 1 requirements for Scenario B:

Recommended Stage 1 – to accommodate the Geraldton mine
• Install +40 MVar of reactive compensation in the form of either a synchronous condenser or STATCOM at the Geraldton mine, to be in-service coincident with the mine • Install a customer-based grid-connected gas-fired generation plant of sufficient redundancy to meet the risk tolerance of the Geraldton mine.

[37] http://www.ieso.ca/Documents/Regional-Planning/Northwest_Ontario/Greenstone_Marathon/Greenstone-Marathon-Interim-IRRP-Report-only-Final-20150622.pdf

Figure 8-1: Recommended Near-Term Plan: Stage 1

By initially installing reactive compensation, this maximizes the use of the existing system. The associated NPV cost of +40 MVar of compensation is estimated at approximately $5 million.

Incremental electrical demand needs would be met by customer-based generation. The associated NPV cost of this generation is estimated at approximately $60 million.

The recommendation for customer-based grid-connected gas generation is due to the lead-time requirements communicated to the IESO by the Geraldton mine developer of 2019. However, it should be noted that if the in-service date of 2019 is delayed, Option B3 – upgrading of circuit A4L – is the most economic option under Scenario B and should therefore be pursued. Ultimately this decision rests with the Geraldton mine developer.

Demand Scenario C

If, in addition to the Geraldton mine, the gas to oil pipeline conversion project proceeds and commits to electricity service, and consistent with Scenario C, the Working Group recommends:

Recommended Stage 2 – to accommodate the gas to oil pipeline conversion project
• Install a new 230 kV single-circuit line from the East-West Tie near Nipigon or Marathon to Longlac, new 230/115 kV auto-transformer and related switching and voltage control facilities at Longlac TS to be in-service coincident with the connection of the pumping stations loads • Install a new 115 kV single-circuit line from Longlac TS to Manitouwadge TS and related switching and voltage control facilities, to connect the pumping station loads

Figure 8-2: Recommended Near-Term Plan: Stage 2

Under Scenario C, a new 230 kV transmission supply to Longlac is the most economic option. The associated NPV cost of a new 230 kV supply to the area including associated line, transformation, switching, and terminations is estimated at approximately $70 million.

This option maintains long-term flexibility for a North-South corridor to the Ring of Fire. From a long-term perspective, it is advantageous to develop a transmission supply to Longlac, rather than installing large grid-connected generation. This is because in order to develop a new North-South transmission supply to the Ring of Fire, a 230 kV line to Longlac would be required, and therefore developing large generation would represent an added cost. A North-South corridor option to the Ring of Fire is discussed further in section 9.2.

Should the pipeline developer decide to connect all pumping station loads in the Greenstone-Marathon Sub-region to the transmission system with N-1 supply security, it is recommended that a new 115 kV transmission line linking Longlac TS and Manitouwadge TS be developed. The associated NPV cost of the new 115 kV single-circuit line, compensation, in-line breaker stations and switching facilities is estimated at approximately $90 million.

The total NPV cost of Stage 2 is estimated at approximately $160 million.

It should also be noted that given the recent timeline change for the Geraldton mine, now planned as a single stage in 2019, there may be economic merit for the Geraldton mine in the development of a new 230 kV line in advance of the pipeline project proceeding. This would result in avoiding some or all costs associated with the customer generation at the Geraldton mine described in Stage 1 for the years that a new 230 kV line may be advanced. Implementation would still require the necessary customer agreements to be in place to ensure the future transmitter can recover prudent costs.

9. Options for Meeting Medium- and Long-Term Needs

This section describes approaches, alternatives, and recommendations for the medium- and long-term planning periods. Specific options and initiatives are described in detail related to the medium- and long-term as indicated in Section 6.4 and include: additional mining claims in Greenstone, infrastructure to the Ring of Fire, Little Jackfish hydroelectric project, and community energy efficiency initiatives. Recommended actions and implementation considerations for the medium- and long-term plan are discussed.

The specific alternatives considered for the medium and long term depend on the level of growth that materializes in the near term, as well as the extent to which the local electricity system is reinforced in the near term to accommodate that growth. The specific scenarios being considered are described below for the respective medium and long-term initiatives.

9.1 Additional Mining Claims in Greenstone

A number of mining claims exist along the Highway 11 corridor in the Greenstone area. Of particular interest is a potential gold mine near Beardmore that may be operational in the medium term. As indicated in the Beardmore mine developer's preliminary economic assessment results[38], it would be economically advantageous for the Beardmore mine if processing and gold recovery were performed at the Geraldton mine.

Therefore, for planning purposes, it has been assumed that the Beardmore mine is included in Geraldton mine scenarios. The Geraldton mine is considered in all scenarios except Scenario A.

The recommended near-term plan to meet forecast demand outlined in Scenario C consists of Stage 1 and Stage 2. If Stage 1 and Stage 2 are implemented by the respective developers and service providers, then sufficient capacity would be available to accommodate the Beardmore mine. Power flow analysis is included in Appendix F.

If the Geraldton mine and the major gas to oil pipeline conversion project proponents decide to pursue off-grid options, which are not recommended by the Working Group, then the existing system would have sufficient margin to accommodate the Beardmore mine.

The recommended near-term plan to meet forecast demand outlined in Scenario B consists of only Stage 1. If Stage 1 is implemented by the respective developers and service providers, then

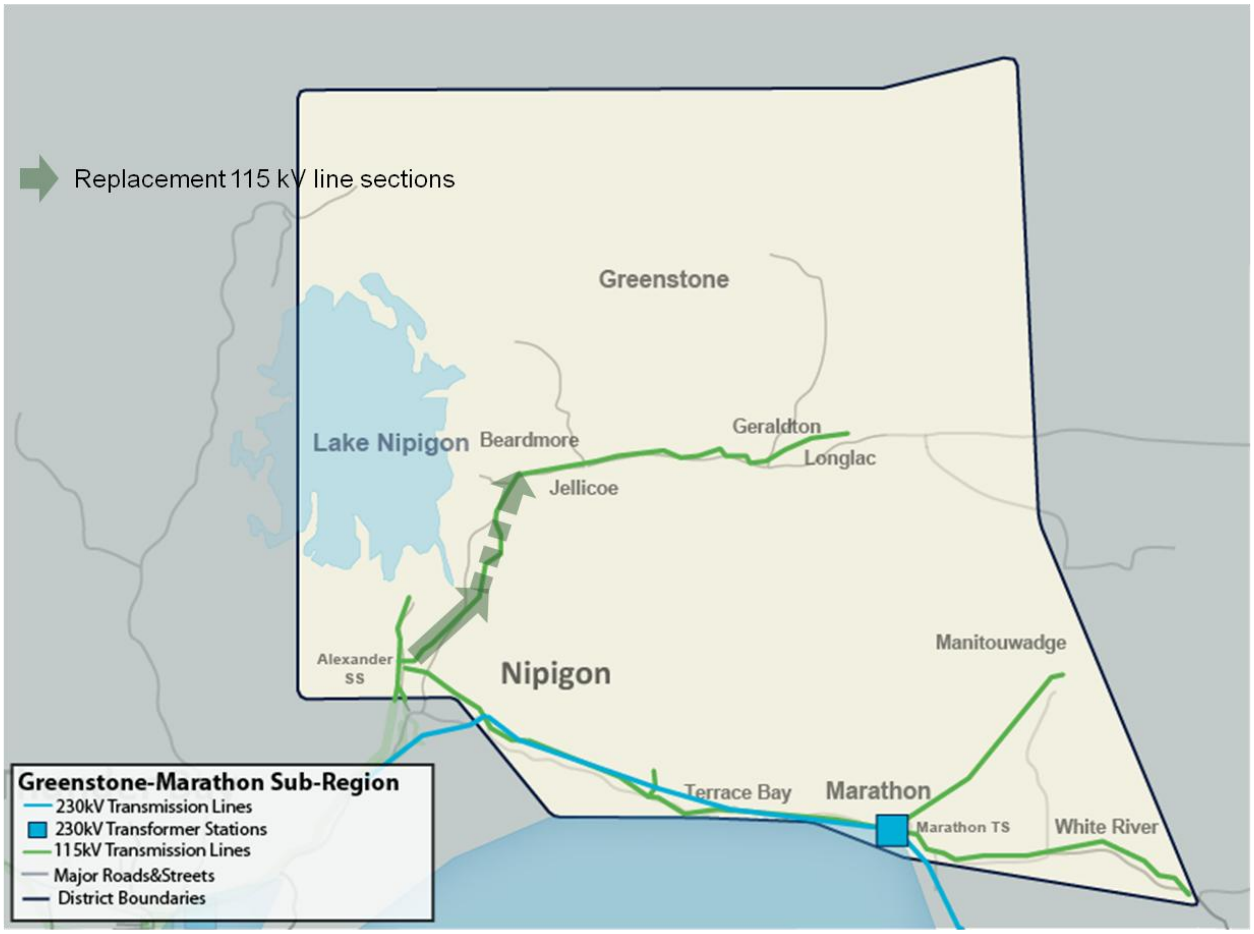
[38] http://www.premiergoldmines.com/i/pdf/2014-01-28_NR.pdf

additional capacity enhancements would be required to accommodate additional customer demand. Power flow analysis is included in Appendix F, which illustrates the need for additional enhancements. Therefore, this analysis of additional mining is focused on Scenario B. As indicated in sections 9.1.1 and 9.1.2, transmission upgrade options and new or expanded local generation options are available. Analysis indicates that the transmission upgrade options available are more economic than generation options to supply the Beardmore mine under Scenario B.

9.1.1 Transmission Upgrade

Incremental capacity to accommodate additional mining development may be in the form of transmission system enhancements to deliver power to the Beardmore mine customer. This would be economically achieved by upgrading or replacing sections of circuit A4L from Alexander SS to the Beardmore mine. If this option is combined with replacing A4L from Nipigon Junction to Longlac TS in Option B3 (i.e. replacement of all of A4L), then the Greenstone sub-system would be capable of supporting up to approximately 120 MW, fully compensated.

Figure 9-1: Transmission Upgrade Option for Additional Mining in Greenstone



It has been estimated that the NPV cost associated with this option is $10-15 M.[39]

9.1.2 Local Generation

Incremental capacity to accommodate additional mining development may be in the form of new or expanded local generation resources. Two possible generation options to provide capacity to supply the demand from the Beardmore mine have been considered: a new 2x10 MW gas generating facility near Beardmore, or 1x10 MW expansion of a gas generating facility in Geraldton (considered if 2x10 MW gas generating plant is implemented for Stage 1).

---

[39] The cost associated with this option depends on the decision by the customer. If this option is combined with replacing A4L from Nipigon Junction to Longlac TS as in Option B3, then only the sections from Alexander SS to Nipigon Junction of 35 km need to be upgraded ($8 M NPV), as opposed to from Alexander SS to Beardmore TS of 65 km ($15 M NPV).

Figure 9-2: Local Generation Option for Additional Mining in Greenstone

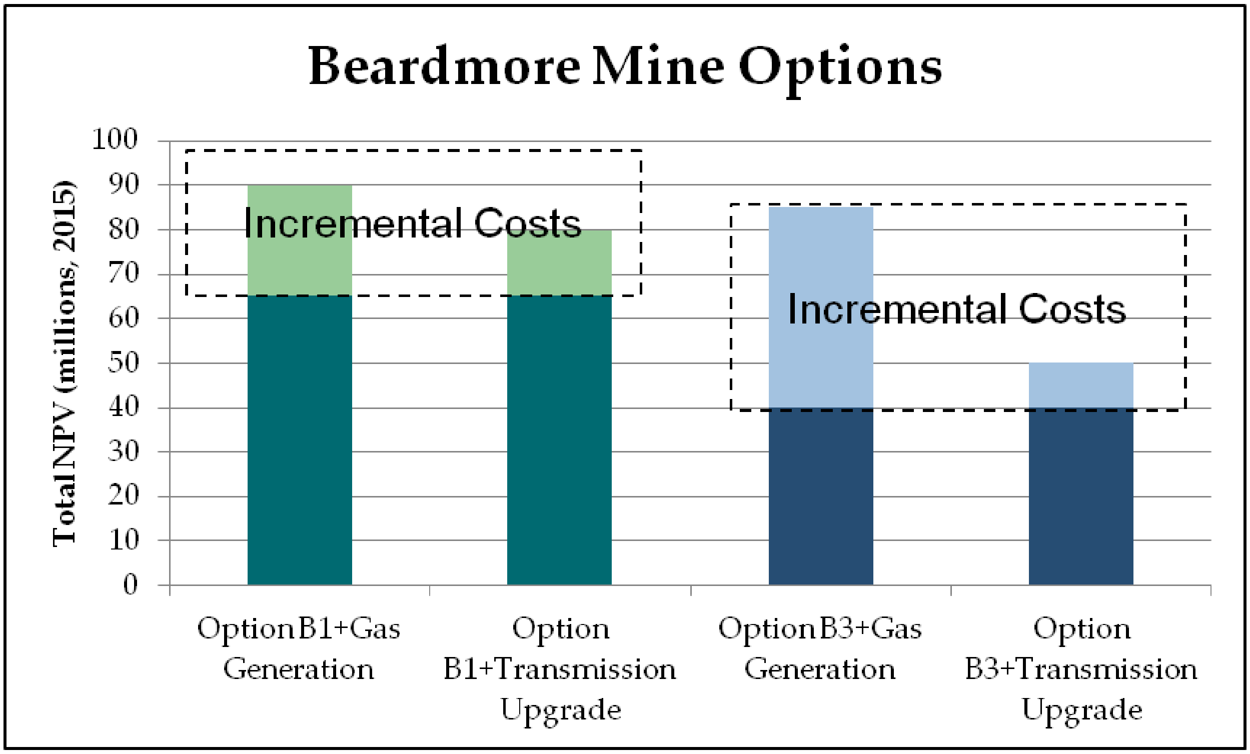
It has been estimated that the NPV cost associated with this option is $25-45 M.[40]

9.1.3 Comparison of Options

As indicated, depending on the solution selected for supplying the Geraldton mine, different incremental costs may result. This is illustrated in Figure 9-3 below.

[40] The cost associated with this option depends on the decision by the customer. If this option is combined with a 2x10 MW gas generating plant at the Geraldton mine as in Option B1, the facility could be expanded by one gas genset ($25 M NPV), as opposed to the installation of a separate facility with at least two gas gensets ($45 M NPV).

Figure 9-3: Comparison of Options for Additional Mining in Greenstone



9.2 Infrastructure Corridor to the Ring of Fire

The 2015 North of Dryden IRRP included an analysis that considered the supply to the Ring of Fire. This analysis included a planning-level cost-comparison between the following options: mine self-generation and separately connect remote communities, an East-West transmission corridor from Pickle Lake, and a North-South transmission corridor from either east of Nipigon or Marathon.

The analysis contained in this report expands the work completed as part of the 2015 North of Dryden IRRP to consider potential cost savings by the potential customers in the Ring of Fire area and Greenstone-Marathon Sub-region. This analysis is based on typical cost allocation principles consistent with the TSC, namely that capital contribution is generally determined based on the relative proportions of non-coincident peak demand of individual customers to that of other customers benefitting from the facility.[41]

[41] Ultimately cost allocation is determined by the OEB. This report simply presents a reasonable assumption to illustrate the potential for cost savings and communicate that it is advantageous for multiple customers to share the utilization of new facilities.

The greatest potential cost savings to benefitting customers results when the new infrastructure is highly utilized by a large number of customers. This is consistent with the following scenario illustrated in Table 9-1.

Table 9-1: Scenario Assumed for Ring of Fire Cost Sharing Evaluation

Timing	New Customers	Infrastructure
Near Term (0-5 years)	Geraldton mine, gas to oil pipeline conversion project	Recommended Stage 1 and Stage 2
Medium and Long Term (5-20 years)	Beardmore mine, Ring of Fire mines and remote communities	North-South transmission line to Ring of Fire

Table 9-1 describes the forecast Scenario D presented in section 5.3.1. It is important to note that Recommended Stage 2 consists of a new 230 kV transmission line from the East-West Tie to Longlac TS. This facility could also serve as the southern sections of a new North-South transmission line to the Ring of Fire, if that option is pursued. Therefore, it would be reasonable to suggest that all new customers under this scenario would contribute to the 230 kV transmission line from the East-West Tie to Longlac TS (southern section), as per recommended Stage 2. This greater utilization and cost-sharing could reduce costs for all new customers in the area.

The remaining northern sections of a new North-South transmission line from Longlac TS to the Ring of Fire would only serve customers in the Ring of Fire area, and no additional cost-sharing is expected.

Table 9-2: Relative Utilization of a 230 kV Line to Supply Greenstone and the Ring of Fire

Customer Group	New Customer Peak Demand	230 kV Line – Southern Section Utilization	230 kV Line – Northern Section Utilization
All	170 MW	170 MW	75 MW
Greenstone sub-system	95 MW	56%	0%
Ring of Fire sub-system	75 MW	44%	100%

Table 9-2 indicates that a significant potential for cost-sharing could result for all new customers from shared utilization of a 230 kV transmission line being recommended as part of Stage 2 (referred to as 230 kV line – southern section in Table 9-2).

9.3 Little Jackfish Hydroelectric Project

Similar to the potential cost savings outlined in the previous section related to the Ring of Fire, recommended Stage 2 could also result in some connection cost savings to the Little Jackfish hydroelectric project. Although analysis of individual generation projects is not within the typical scope of IRRPs, following discussion with the proponents it was agreed that assessing the potential connection cost savings would be valuable information.

The 230 kV transmission line recommended as part of Stage 2 could utilize the East of Nipigon route option, as described in sections 7.2.3.5 and 7.2.3.6. Most notably, the southern routing of this option from the East-West Tie to near Beardmore is largely consistent with the southern routing of the 230 kV connection line routing that OPG considered as part of the EA for the project. This section of the East of Nipigon 230 kV line route option as part of recommended Stage 2 would result in a reduction in the length of the connection line for the Little Jackfish project by approximately one half. During earlier economic evaluations of Little Jackfish, it was believed that the cost of the connection line significantly impacted its viability. The IESO has included updated economic analysis based on the possible development of a new East of Nipigon 230 kV line.

This results in a reduction in the connection line cost by about half and a reduction in the Levelized Unit Energy Cost ("LUEC") from $150/MWh to $144/MWh, or about a four percent reduction. With the reduced LUEC, the Little Jackfish project is $50- $80/MWh[42] more than the cost of system supply. Additional details are included in Appendix H.

Therefore, further analysis has found that the potential reduction in connection cost for the Little Jackfish project does not result in a significant reduction in the overall project LUEC. The IESO is cognizant of the potential for anticipated carbon policies in the province of Ontario to positively impact the business case for new hydroelectric generation development. It should be noted that the IESO is not currently active in procuring provincial generation resources for capacity or energy needs. As capacity needs are forecast to arise in the mid-2020s, and as carbon policy is further clarified, alternatives will be evaluated and compared at the appropriate time.

[42] Depending on cost of carbon scenarios

9.4 Community Energy Efficiency Activities

A large number of communities in the Greenstone-Marathon Sub-region do not have access to natural gas delivery infrastructure, and rely on electricity as their primary source of heating. During early engagement activities, the Town of Marathon identified their interest in developing cogeneration to supply some of their community facilities which require a significant amount of heat load thereby creating budgetary constraints for the community.

The electricity infrastructure serving the North Shore sub-system, and Marathon Area sub-system has been determined to be sufficient. The analysis of individual proposals in the absence of power system need is not typically within the scope of an IRRP. However, from discussions with the local community and as part of the IESO's authority to coordinate provincial and regional conservation programs, it was agreed that a high-level analysis to help demonstrate the feasibility of cogeneration opportunities would be valuable within the context of this IRRP.

An analysis is described below to demonstrate the feasibility for cogeneration in the Town of Marathon. A similar methodology may be applied by other communities with no access to pipeline natural gas infrastructure. Details of the step-by-step methodology and analysis are included in Appendix I.

It was determined from the publicly available data reported for the Broader Public Sector regulation for public sector facilities in Marathon that the three largest municipal electricity consumers in Marathon are the hospital, arena/theatre, and high school. These total nearly 50% of the municipal electrical energy use. These facilities and others are also located within a 150 m radius, making logical candidates for a shared cogeneration solution.

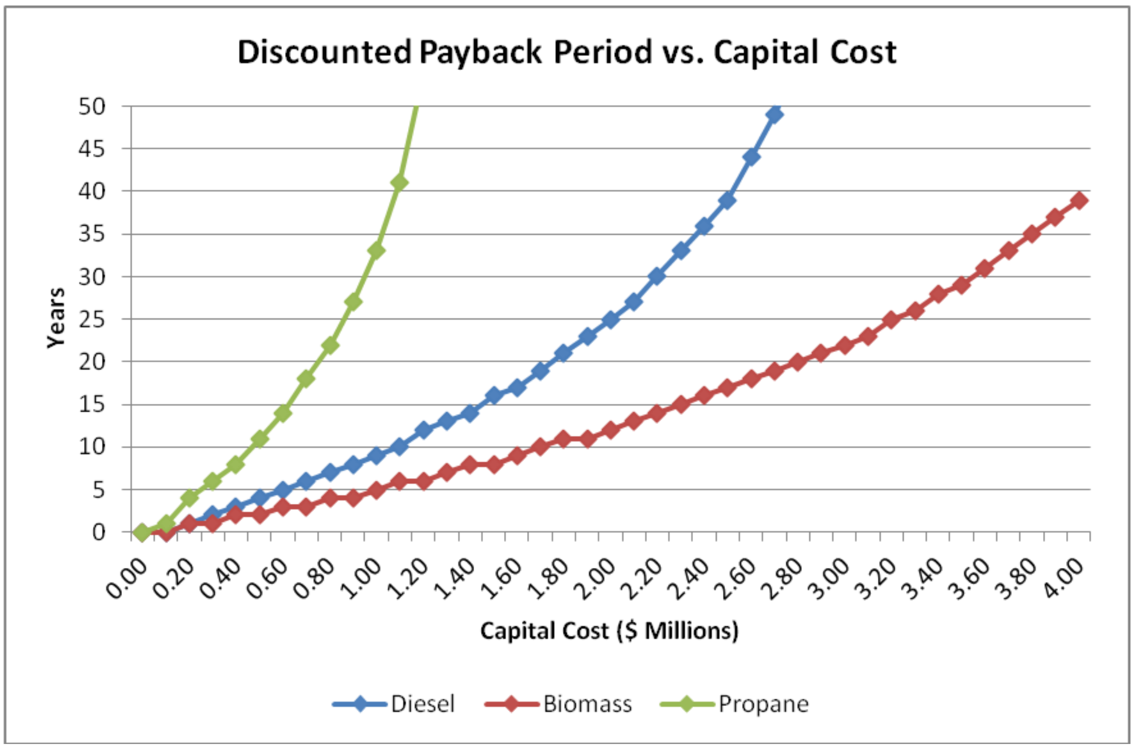
This analysis did not consider the sale of cogeneration services to facilities not reported by the Broader Public Sector regulation (e.g., private businesses), which may help to improve the business case.

Depending on the capital cost of the facility and the type of fuel being considered, a range of payback scenarios may result which are illustrated in Figure 9-4.

It is cautioned that this analysis has been done at a planning-level and investments should not be made solely based on this high level analysis. Furthermore, a number of development projects, regulatory proceedings, and legislative processes are underway that may impact this analysis. This includes the possible development of Liquefied Natural Gas infrastructure and delivery, the possible expansion of natural gas service to Ontario communities that are currently not served, the impact of cap and trade regulation, and the evolution of carbon policy.

Therefore, the Town of Marathon may find value in undertaking a detailed study of cogeneration solutions in the community, considering public and private customers, and the associated risks. Noteworthy, is that the IESO has funded engineering studies to support cogeneration initiatives through the "Save on Energy" program which are accessible through its website.[43]

Figure 9-4: Marathon Cogeneration Discounted Payback Period Analysis



9.5 Actions to Maintain Flexibility for the Medium and Long Term

The following actions are proposed to maintain flexibility for accommodating additional growth, within the study area for the medium and long term:

- Mine developers in Greenstone retain the option of upgrading circuit A4L from Alexander SS to Beardmore TS as an economic alternative for supplying the Beardmore mine and additional mining in Greenstone. Mine developers should engage Hydro One,

[43] https://saveonenergy.ca/Business/Program-Overviews/Process-and-System-Upgrades/Engineering-Studies.aspx

the transmission owner of circuit A4L, recognizing that a lead-time of approximately five years is required if they wish to pursue this option.

- Those investigating a multi-use infrastructure corridor to the Ring of Fire consider the need for a new transmission line, as outlined in this plan. The IESO is available to provide planning advice associated with a new transmission line on this corridor. The IESO will also update electricity plans associated with this corridor as additional information becomes available.
- The Town of Marathon conduct a detailed study of community energy options related to cogeneration. The IESO can support studies within the context of electricity planning, demand, and reliability, as well as IESO-coordinated conservation programs and funding.

The IESO does not have authority to direct or implement these actions on behalf of the parties indicated. These actions are documented to provide customers, communities, and stakeholders with the IESO's independent assessment of the technically feasible and least societal cost options for meeting the various needs in the area.

10. Community and Stakeholder Engagement

Community engagement is an important aspect of the regional planning process. Providing opportunities for input in the regional planning process enables the views and preferences of the community to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the engagement activities undertaken to date and next steps for the Greenstone-Marathon IRRP.

A phased community engagement approach was undertaken for the Greenstone-Marathon IRRP based on the core principles of creating transparency, engaging early and often, and bringing communities to the table. These principles were established as a result of the IESO's outreach with Ontarians in 2013 to determine how to improve the regional planning and siting process, and they now guide IRRP outreach with communities and will ensure this dialogue continues as the plan moves forward.

Figure 10-1: Summary of the Greenstone-Marathon Community Engagement Process

Creating Transparency: ***Creation of Greentone-Marathon IRRP Information Resources***	• Dedicated Greenstone-Marathon IRRP web page created on IESO website providing background information, the IRRP Terms of Reference and listing of the Working Group members • Dedicated web page created on Hydro One website • Self-subscription service established for the Northwest Ontario planning region for subscribers to receive regional planning updates • Status: complete
Engaging Early and Often: ***Municipal & First Nation Outreach***	• Early engagement on regional planning and the draft Northwest Ontario Scoping Assessment Report (October - December 2014) • Two group meetings held with municipalities from across the planning region held in Greenstone and Marathon (April 2015) • Meetings held with First Nation communities throughout the planning region (May 2015 -February 2016) • Status: initial outreach complete; dialogue continues
Bringing Communities to the Table: ***Broader Community Outreach***	• Greenstone-Marathon Local Advisory Committees (LAC) formed in spring 2015; dedicated Greenstone-Marathon engagement page added to IESO website • Three LAC meetings held to discuss the Interim IRRP released June 2015, further development of the near-term options and priorities for the long-term, as well as a review of draft IRRP • LAC meetings are open to the public and broadcast via live webinar; materials are posted to the engagement webpage • Status: begun in spring 2015; on-going

10.1 Creating Transparency

To start the dialogue on the Greenstone-Marathon IRRP and build transparency in the planning process, a number of information resources were created for the plan. A dedicated web page was created on the IESO website including a map of the regional planning area, information on why an IRRP was being developed for the Greenstone-Marathon Sub-region, the IRRP terms of reference and a listing of the organizations involved. A dedicated email subscription service was also established for the broader Northwest Ontario planning region where communities and stakeholders could subscribe to receive email updates about the IRRP.

10.2 Engage Early and Often

Early communication and engagement activities for the Greenstone-Marathon IRRP were initiated in October 2014 as part of a series of meetings with communities and stakeholders to discuss electricity planning initiatives across Northwest Ontario. The main objective of the meetings from a regional planning perspective was to introduce attendees to the regional planning process. This included the Northwest Ontario Scoping Assessment process for the regional planning studies being initiated in the area, as well as discussions of upcoming engagement activities. Various meetings were held with a broad range of attendees including municipal representatives, First Nation and Métis community members, federal and provincial representatives, electricity customers, CVNW, transmission and generation project developers, and others.

10.2.1 Northwest Ontario Scoping Assessment Outcome Report

The draft Northwest Ontario Scoping Report was posted to the IESO website in December 2014 for comment. Feedback on the draft report was received from the Municipality of Greenstone indicating the need for an accelerated timeline for the Greenstone area plan. In response, the Working Group added an interim document on the near-term elements to the Terms of Reference for the Greenstone-Marathon IRRP. The Interim Greenstone-Marathon IRRP was released June 22, 2015 in response to this request.

10.2.2 Municipal Meetings

Meetings with area municipalities are one of the first steps in engagement for all regional plans. In April 2015, the Working Group held group municipal meetings in Marathon and Greenstone to discuss the findings and options developed to date. Attendees were generally pleased with the progress of the plan, and indicated that planning needs to be cognizant of the implementation risks involved and the need to ensure electricity prices do not increase unnecessarily.

10.2.3 First Nation and Métis Community Meetings

On May 11, 2015 the IESO met with the Board members of WZI and Chiefs Pelletier, Gustafson and Nelson of Red Rock Indian Band, Whitesand First Nation and AZA, respectively. WZI is an economic development corporation established by five First Nations: Red Rock Indian Band, BNA, BZA, AZA, and Whitesand First Nation. The feedback received from WZI focused on the desire for infrastructure to be planned so that environmental disturbance is minimized. WZI requested that, when possible, existing infrastructure corridors are optimally utilized before developing a new corridor resulting in a new disturbance.

On May 11, 2015 the IESO met with Chief Duncan Michano of Ojibways of Pic River First Nation. A follow-up discussion with additional community members may be required. The IESO remains open to additional meetings to support further engagement of the IRRP.

On May 12, 2015 the IESO met with a Councilor and staff of Pic Mobert First Nation. The feedback from this meeting was that decisions regarding electricity should not result in unnecessary price increases and the need for greater community-level economic development opportunities for First Nation communities in general.

On July 7, 2015 the IESO met with the Highway 11 First Nations Energy Working Group, which consisted of representatives from the following First Nation communities: Aroland, Constance Lake, Long Lake #58 and Ginoogaming. The feedback shared was that there is a preference by the Highway 11 First Nations Energy Working Group that grid-connected solutions be pursued by the customers. The Highway 11 First Nations Energy Working Group also expressed an interest in developing some solutions consistent with the IRRP recommendations. Finally, the Group emphasized their support for long-term supply options to the Ring of Fire and the need to coordinate planning efforts.

On November 11, 2015 the IESO met with Chief Richard Allen and representatives from Constance Lake First Nation, as well as representatives of Long Lake #58 First Nation. The feedback shared by some representatives was that they would like to see a connection from Longlac TS (Greenstone) to Hearst TS (interconnected to the Northeast power system). The IESO responded that this would not be technically feasible because the respective 115 kV systems are equipped with relatively small conductors and by effectively shorting the connection between the Northwest and Northeast along a new 115 kV link would result in overloading of that connection and possible stability concerns. The IESO indicated that reinforcement of the connection between the Northwest and Northeast systems is being considered through the planning of the expanded East-West Tie. There was also discussion around the possible option of connecting the remote Matawa communities via a north-south corridor option from near Geraldton to the Ring of Fire via a logging road that passes by

Eabametoong First Nation. The IESO will investigate this option as part of its continued support for the economic connection plan for remote First Nation communities.

On February 3, 2016 the IESO met with representatives of Long Lake #58 First Nation. Updates were shared by the IESO and Long Lake #58 regarding the progress made, and confirming the IESO's opinion regarding options and recommendations.

The IESO invited all other local First Nations communities and Métis councils to similar meetings and remains open to further engagement with those communities on the plan.

The IESO has been made aware of a Matawa Chief's resolution and a WZI Board resolution. Both these resolutions indicate support for grid-connected electric supply solutions for the region, and opposition to off-grid solutions. The WZI Board resolution specifically supports the new 230 kV East of Nipigon line option identified in the IRRP. The IESO will continue to work with the local First Nations and Métis in future planning initiatives.

10.3 Bringing Communities to the Table

To continue the dialogue on regional planning, two Local Advisory Committees - a general LAC and a First Nations LAC - were established for the Greenstone-Marathon regional planning area in spring 2015. The role of LACs is to provide advice and recommendations on the development of the regional plan as well as to provide input on broader community engagement. General LACs are comprised of municipal, Indigenous, environmental, business, sustainability and community representatives. First Nations LACs are comprised of representatives from the First Nation communities in the planning area. All general LAC meetings are open to the public and meeting information is posted on the dedicated engagement webpage, which in this case is the IESO's Greenstone-Marathon engagement webpage.[44] The Greenstone-Marathon general LAC meetings are also broadcast as live webinars to allow participation from across the planning region.

Development of the Greenstone-Marathon general LAC was completed through a request for nominations process promoted by the following activities: advertisements in five local newspapers across the planning area and one Thunder Bay newspaper; digital (website) advertising in eight communities throughout the planning area; emails sent to municipal representatives across the region; and an e-blast sent to the IESO's Northwest Ontario

[44] http://www.ieso.ca/Pages/Participate/Regional-Planning/Northwest-Ontario/Greenstone-Marathon.aspx

subscribers list. Each Métis council in the Greenstone-Marathon area appointed a member of their community to the General LAC. The development of the Greenstone-Marathon First Nation LAC was established through a letter to the leadership of each First Nation in the Greenstone-Marathon area inviting them to appoint a representative to the First Nations LAC. The First Nations LAC then appointed members to the general LAC.

On June 29, 2015, following the release of the Interim Greenstone-Marathon IRRP, the IESO held the first LAC meetings in Nipigon. The focus of these meetings was to introduce the regional planning process to the newly formed LACs and review the newly released Interim IRRP. Material from the two LAC meetings and a web archive of the general LAC meeting can be accessed online.[45]

On November 24-25, 2015 the IESO held the second LAC meetings at the Red Rock Indian Band Lake Helen Reserve. The focus of these meetings was to discuss and receive feedback on the development of the medium and long-term options for the IRRP. Material from the two LAC meetings and a web archive of the general LAC meeting can be accessed online.

On May 11-12, 2016 the IESO held the third LAC meetings at the Red Rock Indian Band Lake Helen Reserve. The focus of these meetings was to discuss and receive feedback on the full set of recommendations to be included in the IRRP prior to finalizing the plan. The LAC members decided to produce a report outlining the local socio-economic impacts of the electricity solutions being explored in this IRRP and compliment the Working Group's technical and economic analyses. Material from the two LAC meetings and a web archive of the general LAC meeting can be accessed online.

Copies of the meeting summaries from the Greenstone-Marathon general LAC meetings can be found in Appendix K.

Moving forward, the Working Group will present the final IRRP to both of the Greenstone-Marathon LACs and discuss with members how they would like to continue the dialogue on regional planning in the area following the completion of the plan.

The IESO is committed to undertaking early and sustained engagement to enhance regional electricity planning. Further information on the IESO's regional planning processes is available on the IESO website. Additional information on outreach activities for the Greenstone-

---

[45] http://www.ieso.ca/Pages/Participate/Regional-Planning/Northwest-Ontario/Greenstone-Marathon.aspx

Marathon IRRP can be found on the webpage and updates will continue to be sent to all Northwest Ontario email subscribers.

10.4 Additional Meetings and Presentations

The IESO recognizes CVNW's unique mandate that includes investigating and making recommendations to NOMA on issues related to energy in the Northwest Ontario Region. The IESO continues to meet regularly with CVNW to discuss the status of electricity planning for northwestern Ontario.

The IESO also presents regularly at the NOMA Spring Annual General Meeting and Fall Regional Conference, the Association of Municipalities of Ontario ("AMO") conference, as well as the Ontario Mining Association ("OMA") Conference, among others. These presentations have included high-level status updates on the development of the Greenstone-Marathon IRRP, along with other electricity topics.

11. Conclusion

This report documents an IRRP that has been carried out for Greenstone-Marathon, a sub-region of the OEB's Northwest Ontario planning region. The IRRP identifies electricity needs in the Greenstone-Marathon Sub-region over the 20-year period from 2015-2035, recommends a plan to address near-term needs, and identifies actions to retain economic alternatives for the medium and long term.

Implementation

Implementation of the near- and medium-term plan requires action from the industrial developers. This action consists of customers establishing a commercial agreement for the facilities required to provide the required electrical service. These agreements may include the following elements.

Stage	Recommended Near-Term Facilities	Implementation Agreement
Stage 1	Synchronous condenser or STATCOM	Relevant agreements such as, but not limited to, Reactive Power Service and/or Capacity Agreement
	New 2x10 MW gas engine generating facility	Relevant agreements such as, but not limited to, Capacity and Energy Agreement
Stage 2	New 230 kV line, 115 kV line, 230/115 kV autotransformer station, switching, and voltage control devices	Detailed planning as appropriate, Connection Application, Connection Assessment and Approvals, Cost Recovery, and other agreements consistent with TSC
Medium-Term Actions		**Implementation Agreement**
Mine developers in Greenstone should retain the option of replacing sections of A4L[46]		Detailed planning as appropriate, Connection Application, Connection Assessment and Approvals, Cost Recovery, and other agreements consistent with TSC

[46] This facility is not required if Stage 2 is developed.

The IESO will provide support to individual customers and proponents within the context of the Working Group's recommendations as documented in the IRRP. The IESO does not have the mandate to procure on behalf of individual customers.

The IESO will continue to participate in planning activities related to long-term initiatives such as supply to the Ring of Fire, and community energy efficiency projects.

First Nations and Métis, Community, and Stakeholder Engagement

This report documents the engagement that has been conducted to support the development of the Greenstone-Marathon IRRP.

The IESO will continue to engage First Nation communities, Métis community councils, as well as municipalities and other major interest groups through the LAC and individual meetings as requested.

The LAC meetings and engagements with First Nation communities, municipalities, industry, and stakeholders have provided valuable feedback on the 2015 Interim Plan and input in the development of this IRRP. The Greenstone-Marathon LACs have undertaken a complimentary socio-economic document. The IESO looks forward to subsequent meetings with the two Greenstone-Marathon LACs and continued engagements with communities and stakeholder in the area to discuss the recommendations included within this IRRP, and the future implementation of this plan.

WEST OF THUNDER BAY SUB-REGION INTEGRATED REGIONAL RESOURCE PLAN

Part of the Northwest Ontario Planning Region | July 27, 2016

ieso
Connecting Today. Powering Tomorrow.

Integrated Regional Resource Plan

West of Thunder Bay

This Integrated Regional Resource Plan ("IRRP") was prepared by the Independent Electricity System Operator ("IESO") pursuant to the terms of its Ontario Energy Board electricity licence, EI-2013-0066.

This IRRP was prepared on behalf of the West of Thunder Bay Sub-region Working Group (the "Working Group"), which included the following members:

- Independent Electricity System Operator
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Fort Frances Power Corporation
- Atikokan Hydro Inc.
- Kenora Hydro Electric Corporation Ltd.
- Sioux Lookout Hydro Inc.

The Working Group assessed the reliability of electricity supply to customers in the West of Thunder Bay Sub-region over a 20-year period; developed a flexible, comprehensive, integrated plan that considers opportunities for coordination in anticipation of potential demand growth scenarios and varying supply conditions in the West of Thunder Bay Sub-region; and developed an implementation plan for the recommended options, while maintaining flexibility in order to accommodate changes in key assumptions over time.

The Working Group members agree with the IRRP's recommendations and support implementation of the plan, subject to obtaining necessary regulatory approvals. Where growth in the sub-region is directly related to potential large industrial developments, the onus lies with those developers to initiate the implementation of the plan.

1. Introduction

This Integrated Regional Resource Plan ("IRRP") for the West of Thunder Bay Sub-region addresses the electricity needs for the sub-region over the next 20 years ("study period") from 2015-2034. The IRRP was prepared by the Independent Electricity System Operator ("IESO") on behalf of the Technical Working Group (the "Working Group") for the West of Thunder Bay Sub-region composed of the IESO, Hydro One Networks Inc. (Hydro One Distribution and Hydro One Transmission[1]), Atikokan Hydro Inc. ("Atikokan Hydro"), Kenora Hydro Electric Corporation Ltd. ("Kenora Hydro"), Fort Frances Power Corporation ("Fort Frances Power"), and Sioux Lookout Hydro Inc. ("Sioux Lookout Hydro").

The area covered by the West of Thunder Bay IRRP is a sub-region of the Northwest Ontario Region identified through the Ontario Energy Board ("OEB" or "Board") regional planning process. This sub-region is defined as the area bordered to the south and west by the United States and Manitoba borders respectively, and extending north to include the City of Kenora, the City of Dryden and the Municipality of Sioux Lookout, and east as far as (but not including) the City of Thunder Bay, and does not include the area North of Dryden. This sub-region is characterized by:

- **Diverse communities**: In addition to the "unorganized areas"[2] in the Kenora and Rainy River Districts, there are 26 First Nation communities and 16 municipalities included in this sub-region, all of which are listed in Section 4.1. Each community has local priorities and distinct electricity needs. Many of these communities are engaging in community energy planning activities.

- **Mining, pulp and paper and other industrial developments:** Industrial customers are major electricity consumers in this sub-region and are sensitive to varying economic conditions, such as commodity price and changes in economic growth. Often these factors can lead to material changes in their annual electricity demand and uncertainty in the sub-region's electricity demand forecast.

- **Large geographical area:** Long and expansive transmission and distribution infrastructure is required to bring electricity supply to the various communities and customers across this sub-region. The geography and sparsely populated areas make it challenging and costly to develop and maintain infrastructure.

---

[1] For the purpose of this report, "Hydro One Transmission" and "Hydro One Distribution" are used to differentiate the transmission and distribution accountabilities of Hydro One Networks Inc., respectively.

[2] Unorganized areas are parts of the province where there is no municipal level of government. Services in these unorganized districts are typically administered by local service boards.

- **Complex electricity infrastructure network:** The sub-region's electricity system is comprised of a 230 kilovolt ("kV") bulk system, 115 kV regional system, local distribution networks and variable, local generation resources. The system is interconnected with Manitoba and Minnesota. This system not only supplies the communities and customers in the West of Thunder Bay Sub-region, it also provides an important source of supply to the North of Dryden Sub-region. The interactions between these interconnections and the bulk, regional and distribution network will have an impact on the reliability of supply for the West of Thunder Bay Sub-region.

This IRRP took into consideration the characteristics discussed above. Given the uncertainties associated with the timing and magnitude of potential industrial developments, the Working Group identified regional electricity needs and solutions under three demand forecast scenarios (Reference, High and Low) as described in Section 5.3.4., and developed a flexible, comprehensive, integrated plan to accommodate these potential scenarios. The challenges, costs and lead times required to develop and maintain infrastructure in this sub-region were also taken into consideration in the development of the plan.

The primary focus of this IRRP is to identify and address electricity reliability needs on the 115 kV regional transmission systems in the sub-region. Given the complex nature of the electricity system and the diverse needs in this sub-region, bulk, distribution and community energy planning activities are also underway. To facilitate coordination of the various electricity planning activities in this sub-region, this IRRP also documents and considers bulk and distribution system needs and community planning activities. Section 3 describes the types of electricity planning in Ontario and the linkages between them, as well as, how important it is to coordinate regional planning with bulk and distribution system and community energy planning.

This IRRP fulfills the requirements for the sub-region as required by the IESO's OEB electricity licence. IRRPs are required to be reviewed on a 5-year cycle so that plans can be updated to reflect the changing electricity outlook. This IRRP will be revisited in 2021, or earlier if significant changes occur relative to the current forecast.

This IRRP report is organized as follows:

- A summary of the recommended plan for the West of Thunder Bay Sub-region is provided in Section 2;
- The process used to develop the plan is discussed in Section 3;

- The context for electricity planning in the West of Thunder Bay and the study scope are discussed in Section 4;
- Demand forecast scenarios, and conservation and demand management ("CDM" or "conservation") and distributed generation ("DG") assumptions are described in Section 5;
- Needs in West of Thunder Bay are presented in Section 6;
- Options to address regional and local needs are addressed in Section 7;
- Recommended actions are set out in Section 8;
- A summary of community, indigenous and stakeholder engagement to date is provided in Section 9; and
- A conclusion is provided in Section 10.

2. The Integrated Regional Resource Plan

The West of Thunder Bay IRRP addresses the sub-region's electricity needs over the next 20 years, based on application of the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC"). The IRRP was developed in consideration of a number of factors, including reliability, cost, technical feasibility and also the diverse needs and unique characteristics of the sub-region. Given the uncertainty associated with the demand forecast, the Working Group identified regional electricity needs and solutions under various demand scenarios and developed a flexible, comprehensive, integrated plan for these varying conditions.

In addition to regional planning, bulk, distribution and community energy planning activities are also underway in the sub-region. While these activities are beyond the scope of the regional planning process, they were identified and taken in consideration in the development of this IRRP.

The needs and recommended actions are summarized below.

The 20-Year Plan (2015-2034)

Aside from the potential need for additional supply on the 230 kV bulk transmission system, the Working Group did not identify any major regional 115 kV supply and reliability needs in the West of Thunder Bay Sub-region under Low and Reference scenarios. Under the High scenario, there is the potential need for an additional 50 MW of supply on the Dryden 115 kV sub-system.

Given the uncertainty with the location, timing and magnitude of demand growth, early development work for major infrastructure projects is not required at this time. Instead, the Working Group has sought to lay the ground work for the next planning cycle by exploring potential options for the Dryden 115 kV sub-system and monitoring demand growth closely to determine if and when an investment decision on the Dryden 115 kV sub-system would be required. End-of-life replacements/sustainment activities and transformer station capacity needs were also identified in this area, but these are not expected to have regional implications. Options to address the 230 kV bulk transmission system needs are being considered as part of the bulk system planning process led by the IESO.

In this sub-region, many communities and customers are supplied by long transmission and distribution networks and rely on a single supply source. They are concerned about service reliability and performance. The transmission and distribution service reliability performances of the West of Thunder Bay Sub-region are within the provincial service reliability and performance standards. Communities and customers may consider working with Hydro One Transmission and local distribution companies ("LDCs") to explore opportunities to further improve transmission and distribution service reliability and performance. Cost-benefit and cost-responsibility for investments will need to be considered.

A number of communities in this sub-region are also in the process of developing community-energy plans ("CEPs"). While regional planning focuses on maintaining reliability of electricity supply, CEPs takes into consideration other energy uses, such as transportation, natural gas and electricity. CEPs also have different goals, including net zero energy, electrification, and reducing emissions. Since CEP and regional planning processes have different objectives and scope, greater coordination between community energy planning and regional planning processes is required to help provincial system and municipal planners develop a common understanding of growth and local developments and to identify opportunities to develop community-based energy solutions.

Recommended Actions

1. Monitor electricity demand growth closely to determine if and when an investment decision for the Dryden 115 kV sub-system is required

On an annual basis, the Working Group will review electricity demand growth in the West of Thunder Bay and the North of Dryden Sub-regions with the members of the Local Advisory Committees ("LACs"). This information will be used to determine if and when an investment decision for the Dryden 115 kV sub-system is required.

2. Ensure communities are informed of bulk and distribution planning activities in the West of Thunder Bay Sub-region

The Working Group will provide a status update at LAC meetings on bulk and distribution planning activities and associated projects.

3. Explore opportunities to further improve service reliability and power quality in consideration of cost-benefit and cost allocations

Communities and customers who are looking to further improve service reliability and performance may work with Hydro One Transmission and LDCs to develop transmission, distribution and community energy solutions. The cost and benefit of improvements and how costs would be allocated will need to be considered.

4. Coordinate regional and community energy planning activities

Greater coordination between community energy planning and regional planning processes can inform dialogue on energy issues and can assist provincial system planners and local communities in developing a common understanding of the growth and local developments and in identifying opportunities to develop community-based energy solutions. Going forward, LAC meetings can be used as an opportunity to facilitate discussions on: (1) status of local growth and developments, (2) local planning priorities, (3) energy planning activities, (4) impact of supply interruptions, and (5) the potential, feasibility and challenges of implementing community-based energy solutions. Due to the unique energy planning challenges in northwestern Ontario, it would be helpful to identify initiatives to facilitate knowledge sharing and coordinate community energy planning activities in northern Ontario (e.g., a community energy planning webinar or workshop for communities in northern Ontario).

3. Development of the Integrated Regional Resource Plan

3.1 The Regional Planning Process

In Ontario, planning to meet the electricity needs of customers at a regional level is done through regional planning. Regional planning assesses the interrelated needs of a region—defined by common electricity supply infrastructure—over the near, medium, and long term and develops a plan to ensure cost-effective, reliable electricity supply. Regional plans consider the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluate options for addressing needs, and recommend actions.

Regional planning has been conducted on an as needed basis in Ontario for many years. Most recently, the former Ontario Power Authority ("OPA") carried out planning activities to address regional electricity supply needs. The OPA conducted joint regional planning studies with distributors, transmitters, the IESO and other stakeholders in regions where a need for coordinated regional planning had been identified.

In the fall of 2012, the Board convened a Planning Process Working Group ("PPWG") to develop a more structured, transparent, and systematic regional planning process. This group was composed of industry stakeholders including electricity agencies, utilities, and stakeholders, and in May 2013, the PPWG released its report to the Board[3] ("PPWG Report"), setting out the new regional planning process. Twenty-one electricity planning regions were identified in the PPWG Report, and a phased schedule for completion was outlined. The Board endorsed the PPWG Report and formalized the process timelines through changes to the Transmission System Code and Distribution System Code in August 2013, as well as through changes to the OPA's licence in October 2013. The OPA's licence changes required it to lead a number of aspects of regional planning. After the merger of the IESO and the OPA on January 1, 2015, the regional planning responsibilities identified in the OPA's licence were transferred to the IESO.

The regional planning process begins with a Needs Screening performed by the transmitter, which determines whether there are needs requiring regional coordination. If regional planning is required, the IESO then conducts a Scoping Assessment to determine whether a comprehensive IRRP is required, which considers conservation, generation, transmission, and

---

[3] http://www.ontarioenergyboard.ca/OEB/_Documents/EB-2011-0043/PPWG_Regional_Planning_Report_to_the_Board_App.pdf

distribution solutions, or whether a more limited "wires" solution is the only option such that a transmission and distribution focused Regional Infrastructure Plan ("RIP") can be undertaken instead. The Scoping Assessment assesses what type of planning is required for each region. There may also be regions where infrastructure investments do not require regional coordination and so can be planned directly by the distributor and transmitter outside of the regional planning process. At the conclusion of the Scoping Assessment, the IESO produces a report that includes the results of the Needs Screening process and a preliminary Terms of Reference. If an IRRP is the identified outcome, the IESO is required to complete the IRRP within 18 months. If an RIP is the identified outcome, the transmitter takes the lead and has six months to complete it. It should be noted that a RIP may be initiated after the Scoping Assessment or after the completion of all IRRPs within a planning region; the transmitter may also initiate and produce a RIP report for every region. Both RIPs and IRRPs are to be updated at least every five years. The draft Scoping Assessment Outcome Report is posted to the IESO's website for a 2-week comment period prior to finalization.

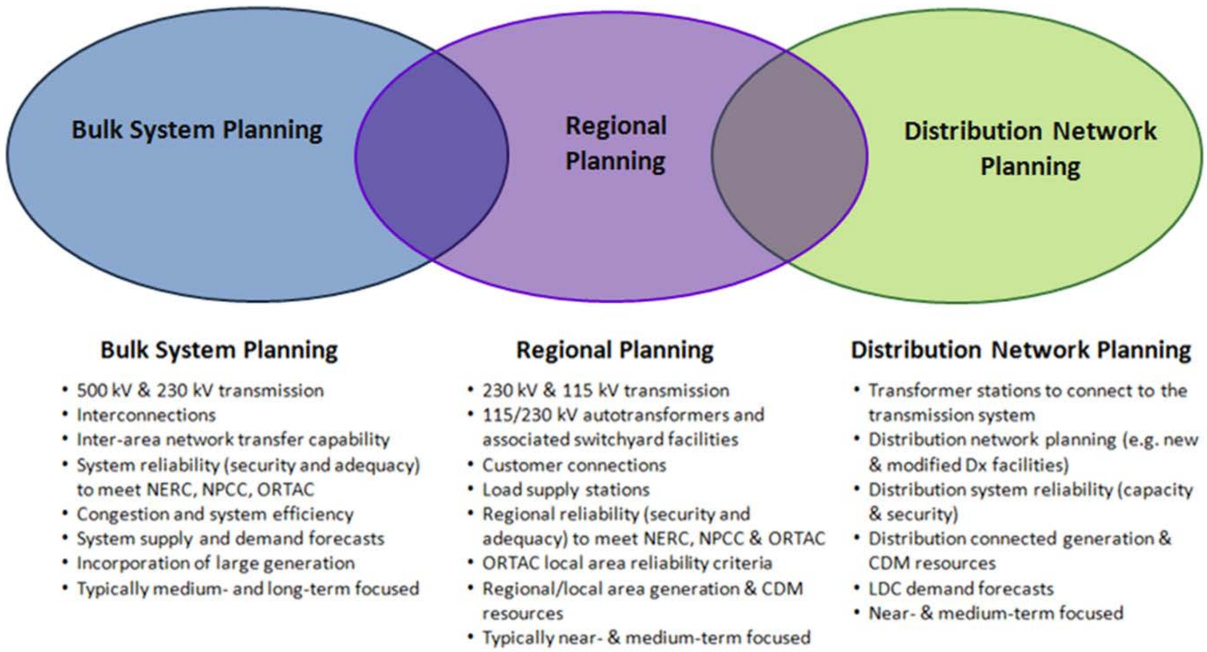
The final IRRPs and RIPs are posted on the IESO's and relevant transmitter's websites, and may be referenced and submitted to the Board as supporting evidence in rate or "Leave to Construct" applications for specific infrastructure investments. These documents are also useful for municipalities, First Nations communities and Métis community councils for planning, conservation and energy management purposes, as information for individual large customers that may be involved in the region, and for other parties seeking an understanding of local electricity growth, CDM and infrastructure requirements. Regional planning is not the only type of electricity planning that is undertaken in Ontario. As shown in Figure 3-1, there are three levels of planning that are carried out for the electricity system in Ontario:

- Bulk system planning
- Regional system planning
- Distribution system planning

Planning at the bulk system level typically considers the 230 kV and 500 kV network and examines province-wide system issues. Bulk system planning considers not only the major transmission facilities or "wires", but it also assesses the resources needed to adequately supply the province. This type of planning is typically carried out by the IESO pursuant to government policy. Distribution planning, which is carried out by LDCs, considers specific investments in an LDC's territory at distribution level voltages.

Regional planning can overlap with bulk system planning. For example, overlaps can occur at interface points where there may be regional resource options to address a bulk system issue. Similarly, regional planning can overlap with the distribution planning of LDCs. For example, overlaps can occur when a distribution solution addresses the needs of the broader local area or region. Therefore, it is important for regional planning to be coordinated with both bulk and distribution system planning as it is the link between all levels of planning.

Figure 3-1: Levels of Electricity System Planning



By recognizing the linkages with bulk and distribution system planning, and coordinating multiple needs identified within a region over the long term, the regional planning process provides a comprehensive assessment of a region's electricity needs. Regional planning aligns near- and long-term solutions and puts specific investments and recommendations coming out of the plan in perspective. Furthermore, regional planning optimizes ratepayer interests by avoiding piecemeal planning and asset duplication, and allows Ontario ratepayer interests to be represented along with the interests of LDC ratepayers, and individual large customers. IRRPs evaluate the multiple options that are available to meet the needs, including conservation, generation, and "wires" solutions. Regional plans also provide greater transparency through engagement in the planning process, and by making plans available to the public.

3.2 The IESO's Approach to Integrated Regional Resource Planning

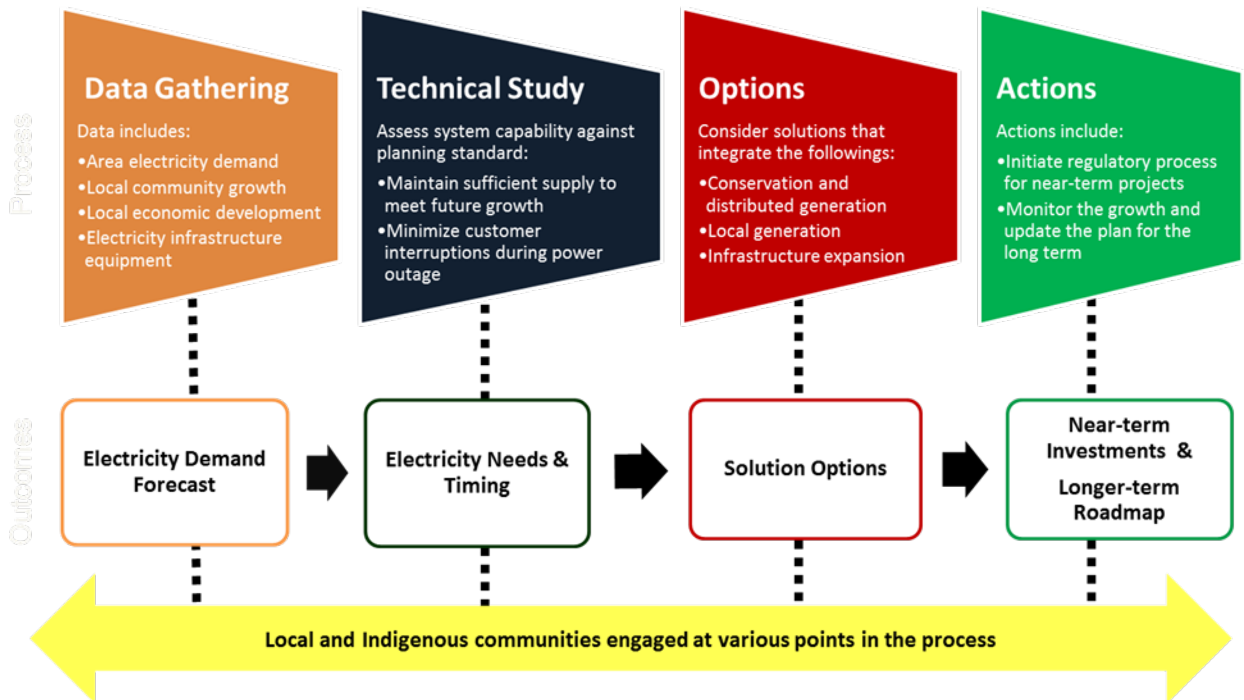
IRRPs assess electricity system needs for a region over a 20-year period. The 20-year outlook anticipates long-term trends in a region, so that near-term actions are developed within the context of a longer-term vision. This enables coordination and consistency with the long-term plan, rather than simply reacting to immediate needs.

Planning in northwestern Ontario requires a unique approach. In southern Ontario, most of the forecast load growth is driven by growth in the LDC customer base. In northwestern Ontario the majority of the forecast load growth is driven by new or expanding large transmission-connected industrial customers, the majority of which are in the resource sector or are unique development projects. Therefore, when establishing the need for electricity enhancements and developing integrated alternatives, industrial customers generally drive the nature and magnitude of the electrical demand requirements.

The IRRP describes the Working Group's recommendations for system enhancements based on different scenarios. The Working Group also recommends staging options to mitigate reliability and cost risks related to demand forecast uncertainty associated with individual large customers. The recommendations of the IRRP seek to ensure flexibility is maintained such that changing long-term conditions may be accommodated.

In developing this IRRP, the Working Group followed a number of steps. These steps included: data gathering, including development of electricity demand forecasts; technical studies to determine electricity needs and the timing of these needs; the development of potential options; and, preparation of a recommended plan including actions for the near and longer term. Throughout this process, engagement was carried out with local municipalities, First Nation communities, Métis community councils and local stakeholders. These steps are illustrated in Figure 3-2 below.

Figure 3-2: Steps in the IRRP Process



This IRRP documents the inputs, findings, and recommendations developed through the process described above, and provides recommended actions for the various entities responsible for plan implementation.

3.3 West of Thunder Bay Sub-region Working Group and IRRP Development

In 2014, the lead transmitter – Hydro One Transmission– initiated a Needs Screening process for the Northwest Ontario Region. The North of Dryden IRRP[4] and Remote Community Connection Plan[5] were already underway prior to the formalization of the regional planning process and were therefore not included within the scope of the Needs Screening process. The Northwest Ontario Region Needs Screening study team determined that the need for coordinated regional planning had already been established, and that a formal Needs Screening process was not required for the Northwest Ontario Region. A Scoping Assessment was then initiated to identify new planning sub-regions within the Northwest Ontario Region that were not already identified in previous planning studies.

[4] http://www.ieso.ca/Pages/Ontario's-Power-System/Regional-Planning/Northwest-Ontario/North-of-Dryden.aspx
[5] http://www.ieso.ca/Pages/Ontario's-Power-System/Regional-Planning/Northwest-Ontario/Remote-Community-Connection-Plan.aspx

On December 12, 2014, a draft Scoping Assessment Outcome Report ("Scoping Report") was posted for public comment. The Scoping Report was finalized on January 28, 2015, and it incorporated feedback from community, stakeholder, and First Nation and Métis community meetings. The Scoping Report identified the West of Thunder Bay Sub-region as one of three new planning sub-regions for coordinated regional planning, as illustrated in Figure 3-3.

Figure 3-3: Northwest Ontario Region and Sub-regions

Subsequently, the Working Group was formed to carry out the IRRP for the West of Thunder Bay Sub-region.

For the purpose of regional planning, two LACs have been established for this sub-region: a General LAC and a First Nation LAC. The LACs were informed of the planning activities in the area and provided their input on the status of local growth and developments, local planning priorities, energy planning activities (e.g., community energy planning), local electricity concerns, and opportunities to implement community-based energy solutions. Greater detail regarding community and stakeholder engagement activities is provided in Section 9 of this report.

4. Background and Study Scope

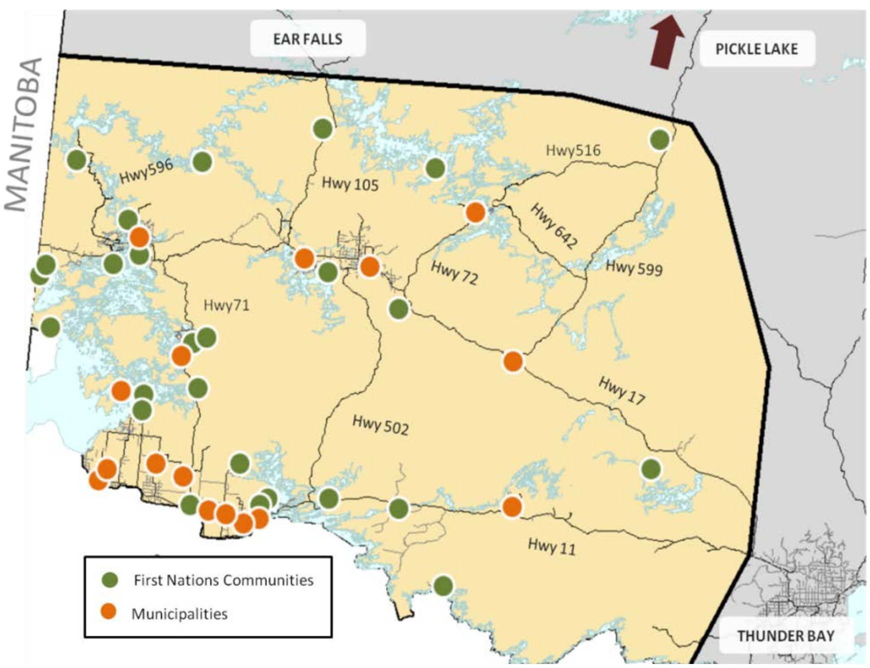
The sub-region and the scope of the IRRP are described in Section 4.1. Section 4.2 details the electricity system supplying the West of Thunder Bay Sub-region.

4.1 West of Thunder Bay - Study Scope

The West of Thunder Bay IRRP assesses the reliability of the regional electricity system supplying the West of Thunder Bay Sub-region and identifies integrated solutions for the 20-year period from 2015 to 2034.

The West of Thunder Bay Sub-region is defined as the area bordered to the south and west by the United States and Manitoba borders; it extends north to include Kenora, Dryden and Sioux Lookout, and east as far as (but not including) the City of Thunder Bay; the study area does not include the area north of Dryden[6]. The approximate geographical boundaries of the sub-region are shown in Figure 4-1.

Figure 4-1: Geographical Boundaries of the West of Thunder Sub-region



[6] The North of Dryden IRRP published in 2015 addresses the reliability of the electricity system supplying the North of Dryden sub-region (see http://www.ieso.ca/Documents/Regional-Planning/Northwest_Ontario/North_of_Dryden/North-Dryden-Report-2015-01-27.pdf)

The West of Thunder Bay Sub-region includes the following First Nations:

- Anishinabe of Wauzhushk Onigum
- Anishinaabeg of Naongashiing
- Big Grassy
- Couchiching
- Eagle Lake
- Grassy Narrows
- Iskatewizaagegan #39
- Lac Des Mille Lacs
- Lac La Croix
- Lac Seul
- Mitaanjigamiing
- Naicatchewenin
- Naotkamegwanning
- Nigigoonsiminikaaning
- Northwest Angle #33
- Northwest Angle #37
- Obashkaandagaang
- Ochiichagwe'Babigo'Ining
- Ojibway Nation of Saugeen
- Ojibways of Onigaming
- Rainy River
- Seine River
- Shoal Lake #40
- Wabaseemoong
- Wabauskang
- Wabigoon Lake Ojibway

The sub-region also includes the following municipalities:

- Township of Alberton
- Town of Atikokan
- Township of Chapple
- Township of Dawson
- Township of Emo
- Town of Fort Frances
- Township of Lake of the Woods
- Township of La Vallee
- Township of Morley

- Town of Rainy River
- City of Dryden
- City of Kenora
- Municipality of Machin
- Municipality of Sioux Lookout
- Township of Ignace
- Township of Sioux Narrows-Nestor Falls

In addition, there are a number of unorganized areas[7] in the Rainy River and Kenora Districts.

This IRRP addresses the reliability of the 115 kV regional transmission systems. The reliability of the 230 kV bulk transmission system and distribution systems supplying the area is beyond the scope of the regional planning process and this IRRP. 230 kV Bulk system and distribution system related concerns are for context referenced in Section 6.3, but they will be formally addressed through the bulk system and distribution systems planning processes.

It is important to note that connection assessment of generation resources for procurement programs, such as the Feed-in-Tariff and, the Large Renewable Procurement, are beyond the scope of this IRRP. Generation projects participating in procurement programs will be assessed according the rules and specifications of the procurement programs.

4.2 West of Thunder Bay Electricity System

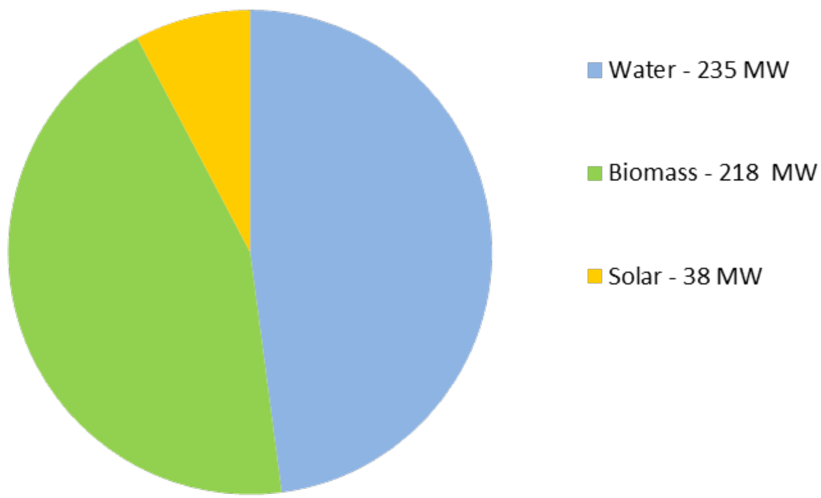
The West of Thunder Bay electricity system consists of local generation resources, 230 kV bulk transmission, 115 kV regional transmission and low voltage distribution networks. Local generation resources provide important sources of electricity supply to the communities and customers in this sub-region. However, under certain system conditions (e.g., generation outages or if electricity demand exceeds the capability of local generation), local generation sources would need to be supplemented with power delivered to the sub-region from the rest of the province through the 230 kV bulk transmission system. From the 230 kV bulk transmission system, power is then delivered to various communities and customers through the regional 115 kV and low-voltage distribution networks. The following sub-sections discuss these components in more details.

[7] Unorganized areas are parts of the province where there is no municipal level of government. Services in these unorganized districts are typically administered by local service boards.

4.2.1 Local Generation Resources

There are three types of generation resources totaling to about 491 Megawatts ("MW") in the West of Thunder Bay Sub-region: hydroelectric (water), biomass and solar, as shown in Figure 4-2.

Figure 4-2: Installed Capacity of Generation Resources in the West of Thunder Bay Sub-region (MW)



In Ontario, the electricity system is designed to meet regional coincident peak demand – i.e., the 1-hour period each year when total demand for electricity in the region (or sub-region) is the highest. While hydroelectric, biomass and solar resources are a potential source of energy, only a certain amount of power can be relied upon at the time of peak due to the variable nature of these resources. In the West of Thunder Bay Sub-region, electricity demand typically peaks during the evening in the winter season. For the purposes of infrastructure planning, the installed capacity of distributed and variable generation is adjusted to reflect the reliable power output at the time of the local winter peak.

Below is a description of local generation resources in the West of Thunder Bay Sub-region.

- **Hydroelectric (Water):** Hydroelectric resources account for almost 50 percent of the installed capacity in the sub-region (about 235 MW). While there are a number of small scale hydroelectric generators, the major facilities, Caribou and Whitedog Generating Stations, are situated in the Kenora area. All hydroelectric resources in this sub-region are run-of-river facilities and have limited storage capability. As such, hydroelectric output is highly variable and is dependent on water conditions. During drought and low water conditions, power output is reduced to less than a third of the installed capacity. In some cases, high waters and flooding conditions may also reduce the power output from these facilities.

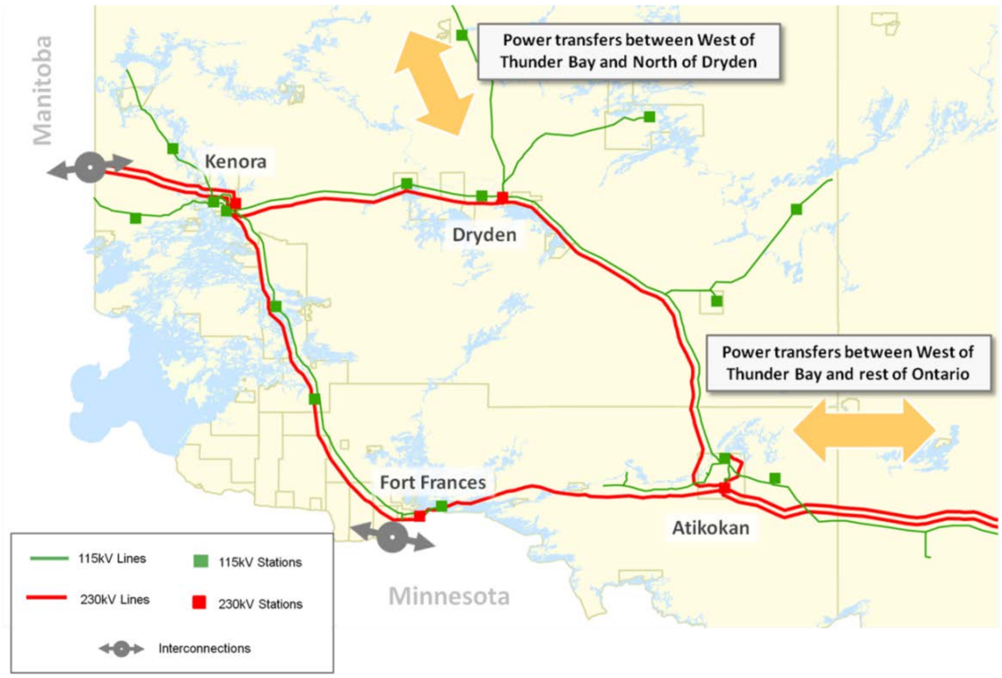
- **Biomass:** In 2014, the coal-fired generation facility at Atikokan was converted to burn biomass (wood pellets). This facility currently is contracted with the IESO until 2024 and has the capacity to generate up to 200 MW. Based on the current contract terms, the facility purchases up to 90,000 tonnes of biomass fuel annually. The forecast fuel availability will limit energy production to 140 GWh per year and may limit the amount of hours it can operate at the maximum capacity. For the purpose of this IRRP, it is assumed that Atikokan facility may operate as a merchant facility upon expiration of the contract. There are currently two merchant biomass generation facilities near Dryden and Fort Frances.

- **Solar:** A 25 MW transmission-connected solar facility is in operation in the Rainy River area. Many communities have also installed small-scale, distribution-connected solar facilities. Today, solar resources account for a small portion of the local, installed capacity. Solar is an intermittent resource and power output can vary depending on factors such as cloud cover, location, time of day, and season. As the local peak typically occurs during the evening in the winter, solar resources are not expected to contribute to the reduction of the local peak demand.

4.2.2 Transmission System

The transmission system in the sub-region consists of 230 kV and 115 kV lines and stations, as shown in Figure 4-3.

Figure 4-3: West of Thunder Bay Sub-region – Transmission System



The West of Thunder Bay transmission system is interconnected with Manitoba at Kenora and with Minnesota at Fort Frances. The interconnections with Manitoba and Minnesota handle transfers scheduled on an economic basis to address provincial needs and are not relied upon for maintaining local reliability. As the electricity system in this area is a source of supply to the North of Dryden Sub-region, its electricity requirements are affected by the potential growth in the area north of Dryden.

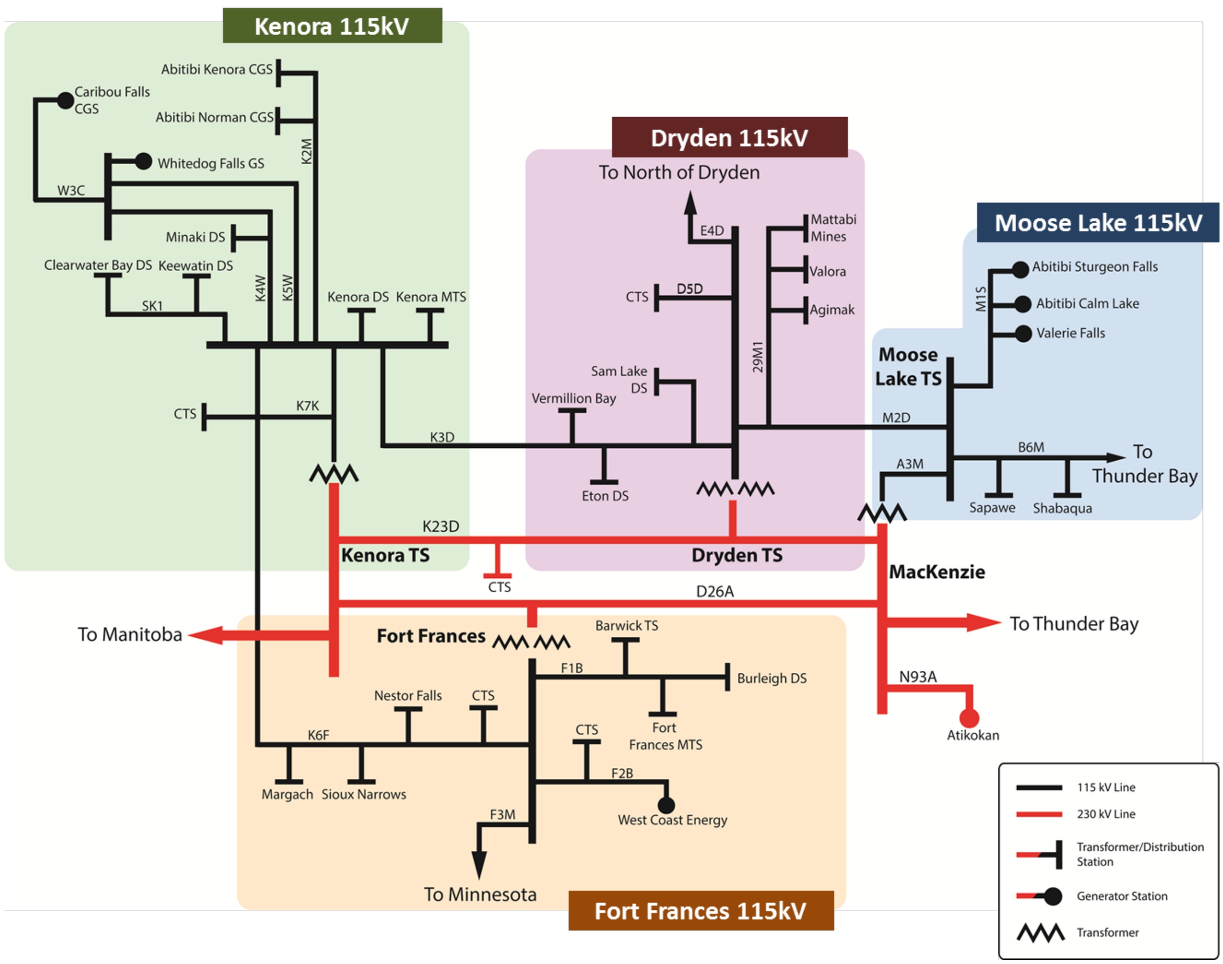
The West of Thunder Bay transmission system can be broken down into two components: 230 kV bulk transmission system and 115 kV regional sub-systems. These components are described in more detail below.

__230 kV Bulk Transmission System__

The bulk transmission system consists of a double circuit 230 kV line and a single-circuit 115 kV line between Thunder Bay and Atikokan. These lines bring power into the West of Thunder Bay Sub-region to supplement local generation resources. To the west of Atikokan, a diamondshaped, 230 kV bulk transmission network connects to Fort Frances, Dryden and Kenora. There are step-down stations that connect to local 115 kV networks at Kenora, Fort Frances, Dryden and Atikokan. Issues related to the bulk system are for context discussed in this IRRP, but these issues will be addressed as part of bulk transmission system planning.

Regional 115 kV Sub-systems

Figure 4-4: Regional 115 kV Sub-systems in the West of Thunder Bay Sub-region



The regional 115 kV sub-systems (as shown in Figure 4-4) enable power to be delivered to communities and customers in the West of Thunder Bay Sub-region. There are four 115 kV sub-systems in the sub-region:

- **Dryden 115 kV sub-system:** Today, this sub-system provides up to 65 MW of power to customers and communities in the Dryden and surrounding areas and supplies up to 68 MW to the North of Dryden Sub-region through the 115 kV line from Dryden to

Ear Falls. The two 230 kV/115 kV autotransformers at Dryden are the primary sources of supply into this sub-system. This sub-system also includes 115 kV connection lines to the Kenora and Atikokan areas.

- **Kenora 115 kV sub-system**: The Kenora and surrounding areas are supplied by this 115 kV sub-system. Today, this sub-system has a winter peak demand of about 60 MW. In addition to the 230 kV/115 kV autotransformer at Kenora, this sub-system relies on local hydroelectric facilities, including Norman, Caribou and Whitedog, as the main sources of electricity supply. This sub-system also has 115 kV connections to Fort Frances and Dryden.

- **Fort Frances 115 kV sub-system:** During the winter season, this sub-system provides up to 75 MW of supply to customers and communities in the Fort Frances and surrounding areas. This sub-system is supplied by local hydroelectric facilities and the two 230 kV/115 kV autotransformers at Fort Frances and has 115 kV connections to Kenora and Minnesota.

- **Moose Lake 115 kV sub-system:** Today, this sub-system provides up to 13 MW of electricity supply to customers and communities in the Atikokan and surrounding areas. While this sub-system is primarily supplied by the two 230 kV/115 kV autotransformers near Atikokan, the 115 kV connections to Dryden and Thunder Bay and the small hydroelectric facilities also provide electricity supply.

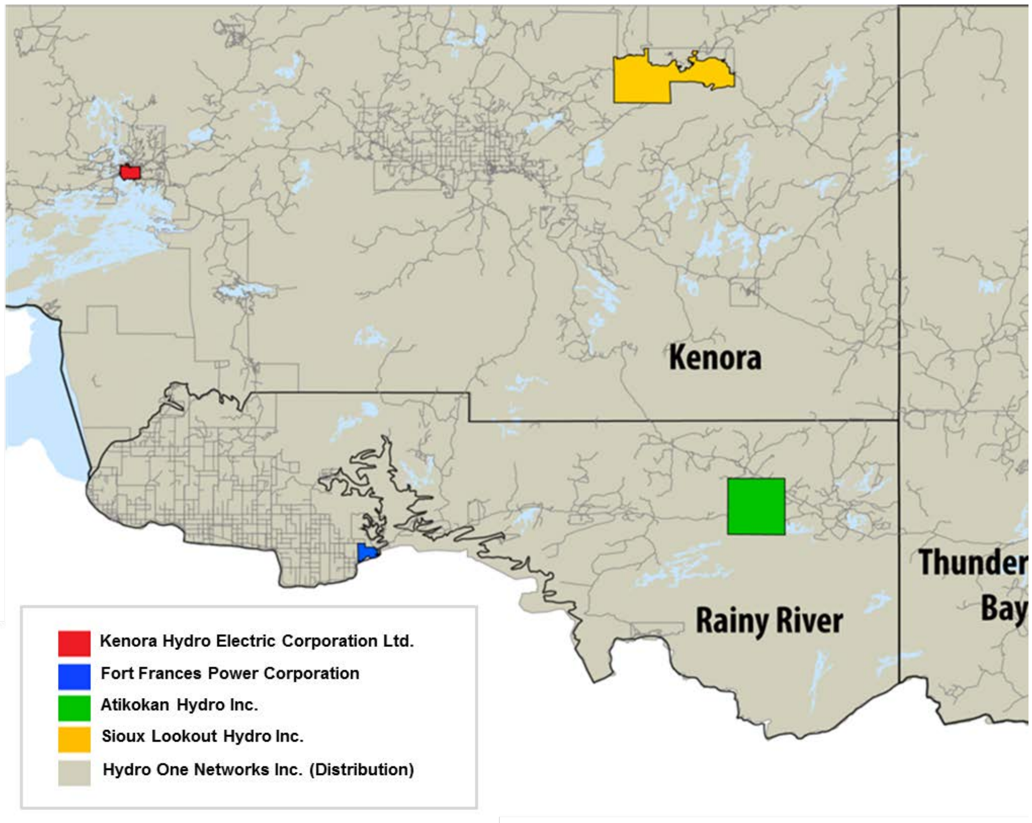
The focus of this IRRP will be on the reliability of the 115 kV regional sub-systems in the West of Thunder Bay Sub-region.

4.2.3 Distribution System

From the regional 115 kV sub-systems, power is delivered through transformer stations to the low-voltage distribution systems. There are 36 customer and utility-owned transformer stations that service the various communities and industrial customers in this sub-region. Given the large geographic and sparsely populated areas, many communities and customers in the West of Thunder Bay Sub-region are supplied by long distribution lines and a single source of supply.

The low-voltage distribution system is managed and operated by five LDCs: Atikokan Hydro, Fort Frances Power Corporation, Kenora Hydro, Sioux Lookout Hydro, and Hydro One Networks (Distribution), as shown in Figure 4-5.

Figure 4-5: Local Distribution Companies (LDCs) Service Area



Distribution system planning is beyond the scope of the regional planning process. Issues related to the distribution system may for context be discussed in this IRRP, but they will be addressed as part of the distribution planning process led by the LDCs.

The details regarding the characteristics of the LDC service areas can be found in Appendix A.

5. Demand Forecast

Regional electricity systems in Ontario are designed to meet regional coincident peak demand – the one-hour period each year when total regional demand for electricity is the highest.

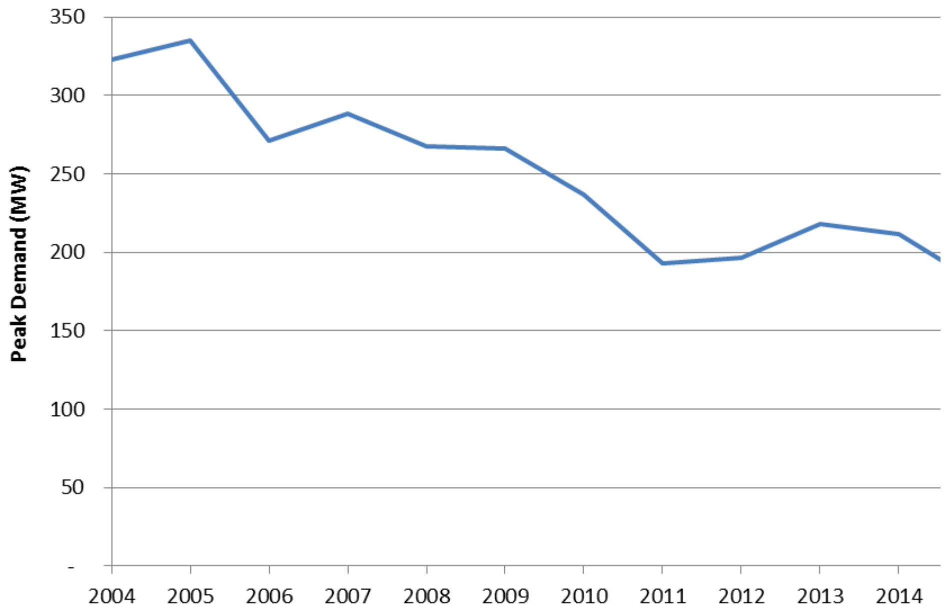
This section describes the development of the regional electricity demand forecast for the West of Thunder Bay Sub-region. Section 5.1 describes electricity demand trends in the sub-region from 2004 to 2014. Section 5.2 provides an overview of the demand forecast methodology used in this study, and Section 5.3 summarizes the various demand scenarios.

5.1 Historical Electricity Demand 2004-2014

The West of Thunder Bay Sub-region's peak electrical demand typically occurs during the evening in the winter. This is driven by a large electrical heating demand in the residential sector as access to natural gas in the area is limited.

In addition to the heating requirements from the residential sector, there are a number of large industrial customers in the pulp and paper and forestry sectors. These industrial customers consume a large amount of energy on a continuous basis; however, they are sensitive to changing economic conditions (e.g., commodity prices, changes in economic growth) which can have material impacts on annual energy demand. As shown in Figure 5-1, historical winter peak demand in the sub-region has decreased from a high of 335 MW in 2005 to a low of 210 MW in 2014. This decline in electrical load is primarily due to the closure of numerous large industrial customers in the pulp and paper sectors.

Figure 5-1: West of Thunder Bay Sub-region Historical Peak Demand (2004-2014)



5.2 Methodology for Establishing Planning Forecast Scenarios

Demand forecast scenarios were developed to assess reliability of the West of Thunder Bay electricity system over the planning period. For the purpose of regional planning, these demand scenarios take into consideration a number of components:

- Gross winter demand forecast scenarios for distribution-connected and transmission-connected customers,
- Estimated peak demand savings from meeting provincial energy conservation targets, and
- Expected peak capacity contribution from DG.

Gross demand forecast scenarios were developed based on the expected peak demand projections for distribution-connected and transmission-connected customers in the West of Thunder Bay Sub-region. For each scenario, these growth projections are modified to reflect the estimated peak demand savings from meeting provincial energy conservation targets and from existing and contracted DG.

Using a planning forecast that is net of provincial conservation targets is consistent with the province's Conservation First policy. However, this assumes that the targets will be met and that the targets, which are energy-based, will produce the expected local peak demand impacts.

An important aspect of plan implementation will be monitoring the actual peak demand impacts of conservation programs delivered by the local LDCs and, as necessary, adapting the plan accordingly.

The methodology and assumptions used for the development of the demand forecast scenarios are described in detail in Appendix A.

5.3 Development of Planning Forecast

5.3.1 Gross Demand Forecast Scenarios

The gross demand forecast is based on the gross electricity requirements for distribution-connected customers and transmission-connected customers in the sub-region.

Distribution-Connected Customers

The gross demand forecast for distribution-connected customers is provided by the five LDCs in the West of Thunder Bay Sub-region. Overall, the growth in electricity demand forecast from distribution-connected customers is expected to remain relatively modest. Most of the growth is attributed to requirements from small industrial customers, such as biomass pellet plants and saw mills, community development associated with the new gold mine near Rainy River and population growth in First Nations communities. Descriptions of the LDCs' forecast assumptions and methodology can be found in Appendix A.

Transmission-Connected Customers

The gross demand forecast for transmission-connected customers is developed based on information gathered from transmission-connected industrial customers. The IESO and Hydro One Transmission regularly communicate with existing and potential transmission-connected industrial customers to understand their electricity demand requirements and their operation and development status.

Over the planning period, the demand growth in the West of Thunder Bay Sub-region will be primarily driven by large, transmission-connected industrial customers, including gold mines near Rainy River and Dryden, and the proposed gas to oil pipeline development. New transmission-connected industrial customers could potentially add up to 300 MW of incremental electricity demand by 2034. As discussed, industrial customers are particularly sensitive to the changes in economic conditions. The timing, location and scale of industrial developments is uncertain and will depend on a number of external factors, such as the commodity price of the resource, the economic viability of the industrial project, and the ability to secure capital. Often these factors can lead to material increases or decreases in annual demand. For example, due to declining gold prices, the development of a prospective, large gold mine near Atikokan, with peak demand requirements of up to 125 MW, was suspended in 2014. Other developments, by contrast, are proceeding. For example, a new gold mine near Rainy River, with a peak demand requirement of up to 60 MW, is currently under construction and should be in operation by 2017.

Since these changes are often difficult to anticipate, a scenario based approach was used to ensure the sub-region's electricity system is able to adequately supply electricity to industries and communities under various assumptions and conditions. Three scenarios (Reference, High and Low) are described in Section 5.3.4.

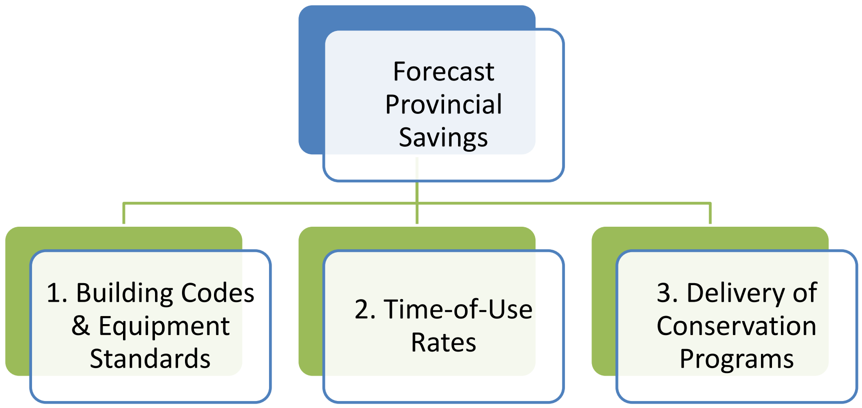
The specific forecasting methodology and assumptions for the gross demand forecast scenarios can be found in Appendix A.

5.3.2 Expected Peak Demand Savings from Provincial Conservation Targets

Conservation is the first resource considered in planning, approval and procurement processes. It plays a key role in maximizing the utilization of existing infrastructure and maintaining reliable supply by keeping demand within equipment capability. Conservation is achieved through a mix of program-related activities, rate structures, and mandated efficiencies from building codes and equipment standards. The conservation savings forecast for the sub-region have been applied to the gross peak demand forecast, along with DG resources (described in Section 5.2), to determine the planning forecast for the sub-region.

In December 2013 the Ministry of Energy released a revised Long-Term Energy Plan ("LTEP") that outlined a provincial conservation target of 30 terawatt-hours ("TWh") of energy savings by 2032. A portion of this province-wide energy conservation target was allocated to the West of Thunder Bay Sub-region, and, as further described below, it was further converted to an estimated peak demand reduction for the sub-region. To estimate the impact of the conservation savings in the area, the forecast provincial savings were divided into three main categories, as shown in Figure 5-2:

Figure 5-2: Categories of Conservation Savings



1. *Savings due to Building Codes & Equipment Standards*
2. *Savings due to Time-of-Use Rate structures*
3. *Savings due to the delivery of Conservation Programs*

The 2013 LTEP committed to establishing a new 6-year Conservation First Framework ("CFF") beginning in January 2015 to enable the achievement of all cost-effective conservation. In the near term, Ontario's LDCs have an aggregate energy reduction target of 7 TWh, as well as individual LDC specific targets. These targets are to be achieved between 2015 and the end of 2020 through LDC conservation programs enabled by the CFF. In 2015, each LDC submitted a CDM plan to the IESO describing how the targets will be achieved. LDCs are also required to provide updates to their CDM plans.

As part of the Conservation First policy, the provincial government has adopted a broad definition of conservation that includes various types of customer action and behind-the-meter generation. This means that conservation includes any programs or mechanisms that reduce the amount of energy consumed from the provincial electricity grid. Conservation initiatives, including behind-the-meter generation projects and on-site generation, are expected to reduce customers' reliance on the provincial electricity grid and contribute to peak demand savings in the sub-region. Conservation initiatives, including behind-the-meter generation projects and on-site generation, are expected to reduce customers' reliance on the provincial electricity grid and contribute to peak demand savings in the sub-region.

For the purpose of this IRRP, the allocation of the 7 TWh of provincial energy savings target to the West of Thunder Bay Sub-region is estimated to offset approximately 14 MW of the forecast peak demand between 2015 and 2034. Savings from potential future demand response ("DR") resources are not included in the forecast. Instead, the development of locally targeted DR projects may be considered as potential solutions to address future needs.

The estimated annual peak demand savings from the provincial energy conservation targets in the West of Thunder Bay Sub-region are summarized in Appendix A.

5.3.3 Expected Peak Demand Contribution of Existing and Contracted Distributed Generation

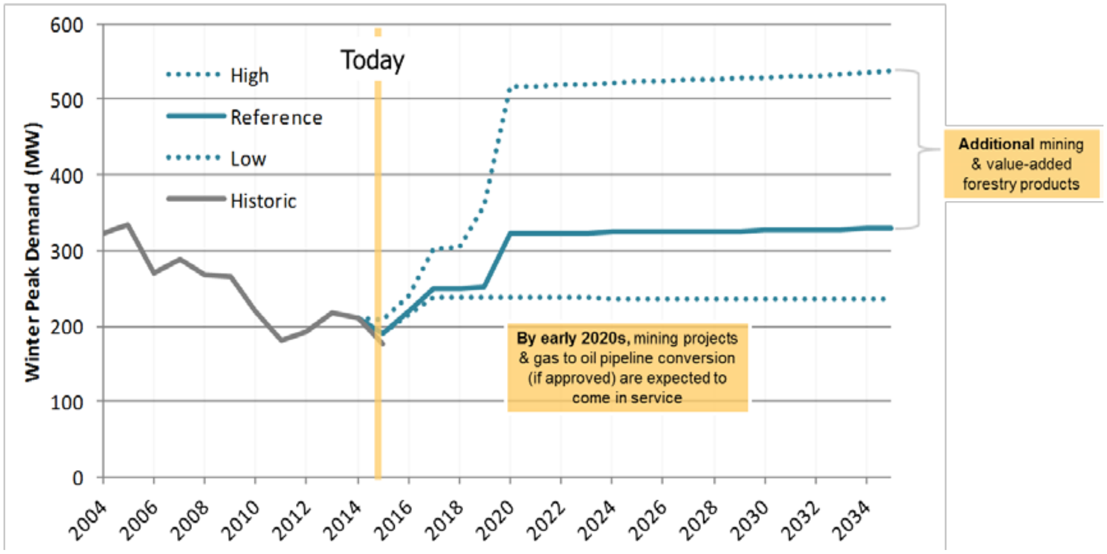
As of 2015, about 38 MW of DG was contracted in the West of Thunder Bay Sub-region. For the purpose of developing the planning forecast, contracted DG is expected to reduce the regional peak demand by about 1.5 MW over the next 20 years. Future DG uptake was, as noted, not included in the planning forecast and is instead considered as an option for meeting identified needs.

The expected annual peak demand contribution of contracted DG in the West of Thunder Bay Sub-region can be found in Appendix A.

5.3.4 Planning Forecast

A scenario-based approach was used to account for the uncertainty in the demand forecast. Figure 5-3 shows planning demand scenarios for the West of Thunder Bay Sub-Region (2015 to 2034, using a base year of 2014). The scenarios represent plausible outcomes that must be considered in planning for the electricity needs of the sub-region. The demand forecast scenarios shown below take into consideration the gross demand forecast scenarios, estimated peak demand savings from provincial energy conservation targets, and existing and contracted DG.

Figure 5-3: Planning Forecast Scenarios [8]



Reference scenario

Under the Reference scenario, the winter peak electricity demand in the West of Thunder Bay Sub-region is expected to increase to 330 MW over the planning period. As shown in Figure 5-3, by the mid-2020s, the peak demand will be similar to 2004 levels. The growth includes two transmission-connected mining developments near the Dryden and Rainy River areas. Together, these developments could increase regional electricity demand by up to 70 MW.

For the purpose of regional planning, it is also assumed that the proposed gas to oil pipeline development will be approved and that four oil pumping stations will be supplied from the West of Thunder Bay transmission system under the Reference scenario. The pumping stations would each require approximately 15 to 18 MW of electricity supply by 2020.

High scenario

In addition to the growth identified in the Reference scenario, the High scenario assumes more transmission-connected mining developments and the recovery of the local pulp and paper industry, for example the restart of the mill in the Fort Frances area. The electricity demand from the proposed gas to oil pipeline development is expected to increase as a total of six oil pumping stations will be supplied from the West of Thunder Bay transmission system under

---

[8] West of Thunder Bay Sub-region demand forecast does not include growth in the North of Dryden Sub-region. The demand forecast for the North of Dryden Sub-region is discussed in Section 5.4.

this scenario. With these additional developments, the total demand could grow to 540 MW by the end of the study period.

Low scenario

Aside from the above-mentioned mining development in the River Rainy area, no additional mining development is expected to materialize under the Low scenario. It is assumed that the proposed gas to oil pipeline development will not proceed. This scenario results in a relatively flat electricity demand growth over the planning period.

Further details related to the demand forecast scenarios can be found in Appendix A.

5.4 Potential Growth in the North of Dryden Sub-region

The West of Thunder Bay electricity system is a major source of supply to the North of Dryden Sub-region, capable of transferring up to 85 MW via through the 115 kV line from Dryden to Ear Falls. In 2015, the winter peak demand in the North of Dryden area was about 68 MW.

Based on the North of Dryden IRRP published in 2015[9], up to 170 MW of additional demand growth could materialize in the North of Dryden Sub-region and would require supply from the West of Thunder Bay 230 kV bulk transmission system. Depending on the location, magnitude and timing of these potential developments in the North of Dryden Sub-region, this could have an impact on the 115 kV Dryden regional sub-system.

The North of Dryden IRRP recommends building a new 230 kV line to Pickle Lake to support the potential developments in the North of Dryden Sub-region including connection of 21 remote First Nation communities. With the new 230 kV line to Pickle Lake, up to 120 MW of incremental demand from new mining developments and remote communities north and northeast of Pickle Lake would be supplied directly from the 230 kV West of Thunder Bay bulk transmission system. The remaining growth in the Red Lake and Ear Falls area (up to 50 MW of incremental demand), which includes the remote communities north of Red Lake, would be supplied directly from the Dryden 115 kV sub-system. To ensure that the West of Thunder Bay electricity system has sufficient capacity to serve growth in the West of Thunder Bay and North of Dryden Sub-regions, the potential growth and development in the area north of Dryden is taken in to consideration in the development of this IRRP.

---

6. Needs

This section outlines the needs assessment methodology and identifies regional electricity supply and reliability needs over the 20-year planning period. In addition, other electricity needs and considerations at the bulk, distribution and community levels are also discussed in this section.

6.1 Needs Assessment Methodology

The IESO's ORTAC,[10] the provincial standard for assessing the reliability of the transmission system, was applied to assess supply capacity and reliability needs. ORTAC includes criteria related to the assessment of the bulk transmission system, as well as the assessment of local or regional reliability requirements (see Appendix B for more details).

Through the application of these criteria, three broad categories of needs can be identified:

- **Transformer Station Capacity** is the electricity system's ability to deliver power to the local distribution network through the regional transformer stations. This is limited by the load meeting capability ("LMC") of the step-down transformer stations in the local area, which is the maximum demand that can be supplied from the transformer stations based on their combined transformer station ratings.
- **Supply Capacity** is the electricity system's ability to provide continuous supply to a local area. This is limited by the LMC of the transmission line or sub-system, which is the maximum demand that can be supplied on a transmission line or sub-system under applicable transmission and generation outage scenarios as prescribed by ORTAC; it is determined through power system simulations analysis (See Appendix B for more details). Supply capacity needs are identified when peak demand on a transmission line or sub-system exceeds its LMC.
- **Load Security and Restoration** is the electricity system's ability to minimize the impacts of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the amount of load susceptible to supply interruptions in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within

[10] http://www.ieso.ca/imoweb/pubs/marketadmin/imo_req_0041_transmissionassessmentcriteria.pdf

reasonable timeframes. The specific load security and restoration requirements prescribed by ORTAC are described in Appendix B.

In addition, the needs assessment may also identify needs related to transmission service reliability performance, equipment end-of-life and planned sustainment activities. Service reliability performance describes the frequency and probability of major outages on an electricity system, which can be affected by various factors such as exposure to elements, age and maintenance of equipment, and length and configuration of the transmission or distribution networks. Equipment reaching the end of its life and planned sustainment activities may have an impact on the needs assessment and options development. Transmission assets reaching end-of-life are typically replaced with assets of equivalent capacity and specification. The need to replace aging transmission assets may present opportunities to better align investments with evolving power system priorities. This may involve up-sizing equipment in areas with capacity needs, or downsizing or even removing equipment that is no longer considered useful. Such instances may also present opportunities to enhance or reconfigure assets for infrastructure hardening to improve system resilience.

6.2 Regional Electricity Reliability Needs

For the purpose of regional planning, this IRRP focuses on identifying and addressing needs on the regional 115 kV sub-systems, as defined in Section 4.2.2. It is important to note that there may be a potential need for additional supply on the West of Thunder Bay 230 kV bulk system. This bulk system need is not within the scope of this IRRP, but for contextual reasons is discussed in Section 6.3.1.

Results from the needs assessment show all the regional 115 kV sub-systems are adequate over the planning period under Reference and Low scenarios. Under the High scenario, strong growth in the Dryden and North of Dryden Sub-region may exceed the Dryden 115 kV sub-system capacity over the planning period. End-of-life replacements, transmission service reliability and transformer station capacity needs were also identified in the West of Thunder Bay Sub-region. The following section describes these needs in more detail.

6.2.1 Potential Supply Capacity Need on the Dryden 115 kV Sub-system

The Dryden 115 kV sub-system can provide up to 240 MW of continuous supply to the Dryden area and North of Dryden Sub-region (Dryden 115 kV System LMC = 240 MW). Today, the Dryden 115 kV sub-system supplies 130 MW to the Dryden area and North of Dryden Sub-region. Under the Reference scenario, electricity demand supplied by the Dryden 115 kV sub-system is expected to grow to about 240 MW by 2034. There will be sufficient capacity on the existing system to support this growth over the planning period.

Under the High scenario, however, the electricity demand on Dryden 115 kV sub-system can potentially increase to about 290 MW. The existing Dryden 115 kV sub-system therefore does not meet the ORTAC supply capacity under this particular scenario. If the forecast demand growth materializes under the High scenario, 50 MW of additional supply capacity may be required on the Dryden 115 kV sub-system in the mid-2020s. Given that the timing, magnitude and location associated with potential developments in the Dryden area are uncertain, it is important to monitor these potential developments before proceeding with an investment decision. Section 7.1 will provide a high-level discussion of potential options to address these concerns under the High scenario.

Details related to the assessment can be found in Appendix B.

6.2.2 Transformer Station Capacity Needs in the Kenora area

The transformer station supplying the City of Kenora and surrounding areas ("Kenora MTS") can supply up to 25 MW at the time of peak. Today, this transformer station currently supplies up to 20 MW. There is therefore about 5 MW of supply margin remaining on the transformer station. Since the residential and commercial growth in the Kenora area is forecast to be modest over the planning period, the remaining margin will be adequate to support commercial and residential developments in the area.

Recently, a large industrial customer in the Kenora area that has historically been supplied from a local dam is looking to Kenora MTS for alternative supply. Depending on the needs of the industrial customer, the requirement for additional transformer station capacity may be triggered in Kenora over the next few years. Potential developments at the former Abitibi mill site may also require additional transformer station capacity in the Kenora area. However, the timing and magnitude of these developments are uncertain at this time. Kenora Hydro will monitor these developments closely to determine if and when a new transformer station will be required. If a new transformer station is required to supply the industrial customers, it may potentially provide a second source of supply to the City of Kenora and surrounding areas. As this is a customer-driven need, it is not expected to have major regional implications.

6.2.3 Transmission End-of-Life Replacements and Sustainment Activities

The Dryden TS 115 kV/44 kV transformers and Moose Lake 115 kV/44 kV transformers are due for end-of-life replacements within the next five years. The Dryden 115 kV/44 kV transformers are scheduled to be replaced in 2016, with assets of equivalent capacity and specification based on current standards. This sustainment decision was made prior to the initiation of this IRRP.

The Moose Lake 115 kV/44 kV transformers and associated 44 kV distribution lines are scheduled to be replaced in the early 2020s. The refurbished transformer station, with equally sized equipment and station reconfiguration, will improve the supply security to the customers and communities in Atikokan and the surrounding areas. As part of the IRRP, Atikokan Hydro and Hydro One Transmission examined potential sustainment options, including potential relocation of the transformer station, based on cost-benefit and cost allocation considerations. The details related to the end-of-life replacements for the Moose Lake 115 kV/44 kV transformers can be found in Appendix E.

Hydro One Transmission will be replacing wood pole structures on a number of aging 115 kV transmission lines in the Kenora, Sioux Lookout and Dryden areas and the 230 kV transmission lines in the Fort Frances and Atikokan areas. During the wood pole structure replacements, the electricity supply to local communities will be temporarily rerouted to other circuits. As a result, no service interruption is expected during construction. This sustainment decision was made prior to the initiation of this IRRP.

Going forward, the Working Group will need to better understand the timing and scope of upcoming sustainment activities in this sub-region, as sustainment activities may provide opportunities to replace these aging assets in a manner that also addresses broader regional needs.

6.2.4 Transmission Service Reliability and Performance

Many communities and customers in the sub-region are supplied by long transmission lines and rely on a single supply source. A few customers have expressed concerns regarding service reliability and performance. Service reliability and performance is measured based on customers' exposure to power outages on the distribution and transmission system, which is expressed in terms of *frequency* (i.e., number of outages a year) and *duration* (e.g., length of time before the power is restored). Transmission customer delivery point standards are used to measure the service reliability and performance of the electricity system in Ontario.

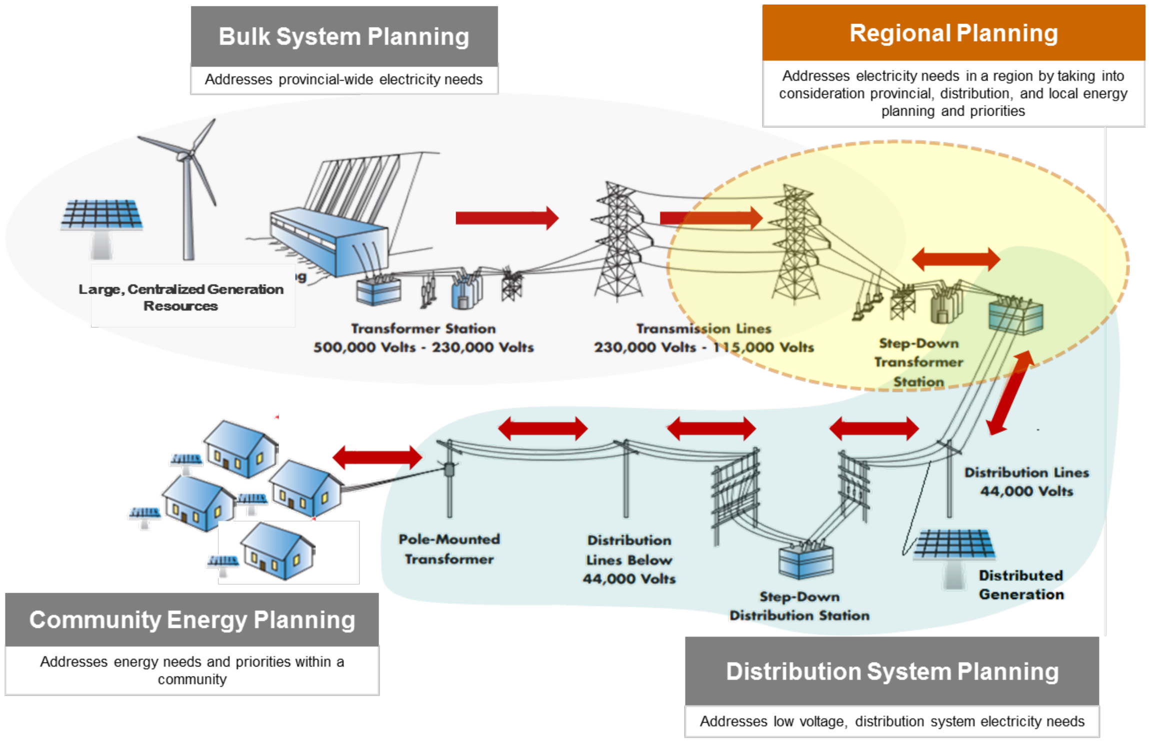
In response to service reliability and performance concerns raised by communities and LDCs, the Working Group assessed the reliability performance of the transmission system in the West of Thunder Bay Sub-region, in particular, the 115 kV sub-systems supplying Town of Sioux Lookout and Town of Fort Frances. These sub-systems are supplied by a single transmission supply and have recently experienced outages. Based on historical reliability performance statistics, the 115 kV transmission system supplying Sioux Lookout and Fort Frances is within the provincial service reliability and performance standards. However, Hydro One Transmission indicated that during a recent maintenance outage, switching equipment failure resulted in a prolonged outage for customers in the Fort Frances area. Customers and communities may work with Hydro One Transmission to explore options to avoid similar incidents in the future.

A summary of transmission reliability performance assessment can be found in Appendix C. Section 7.2 will discuss the potential opportunities to further improve transmission service reliability and the associated cost implications.

6.3 Other Electricity Needs and Considerations

As discussed in Section 3, electricity planning is conducted at various levels: bulk, regional, local, and community (Figure 6-1). In addition to regional planning, bulk, distribution and community energy planning activities are also underway in the West of Thunder Bay Sub-region. While these needs are beyond the scope of regional planning process, bulk, distribution and community energy needs were taken into consideration in the development of the plan.

Figure 6-1: Electricity Planning at the Bulk, Regional, Distribution and Community Levels

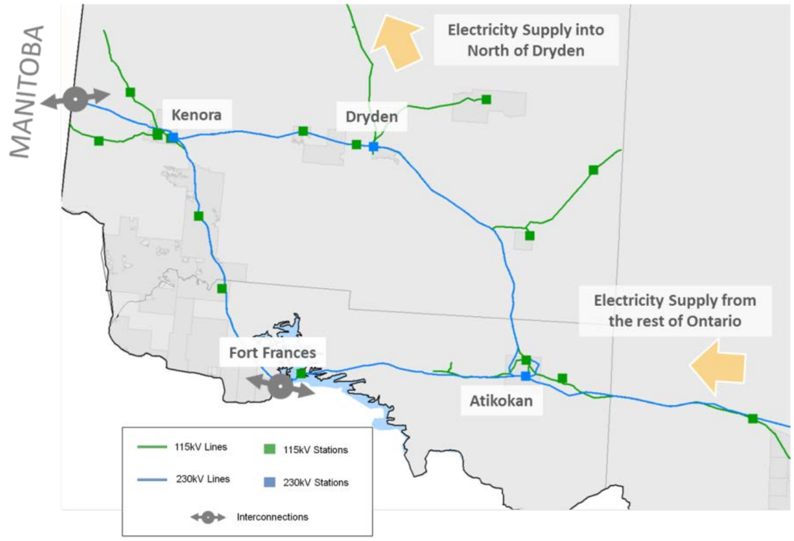


To provide the broader context, issues and considerations related to 230 kV bulk transmission system, the local distribution systems, and community energy planning activities and their implications on the West of Thunder Bay Sub-region will be discussed in the following sections.

6.3.1 230 kV Bulk System Needs

The 230 kV bulk transmission system supplying the West of Thunder Bay and North of Dryden Sub-regions is adequate today. As a result of potential industrial developments and remote community connections in the West of Thunder Bay and North of Dryden Sub-regions, the West of Thunder Bay 230 kV bulk transmission system may need to serve up to 500 MW of additional electricity demand over the planning period. The 230 kV bulk transmission system will require sufficient supply capacity to deliver power into the West of Thunder Bay and North of Dryden Sub-regions as shown in Figure 6-2.

Figure 6-2: 230 kV Supply into West of Thunder Bay and North of Dryden Sub-regions



12

Given the limited supply margin remaining on the 230 kV bulk transmission system, potential demand growth and changes in the regional supply mix may lead to bulk system reliability needs in the sub-region. These needs are discussed below:

- **230 kV supply into the Dryden area:** The existing 230 kV bulk transmission system can supply a total of 175 MW of load in Dryden area and North of Dryden Sub-region. There is 50-100 MW of additional capacity remaining to support growth in the Dryden area and North of Dryden Sub-region.

- **230 kV supply into the West of Thunder Bay Sub-region:** The existing 230 kV bulk transmission system is adequate today, assuming generation at Atikokan is available. Currently, there is approximately 150 MW of supply margin remaining to support growth in the West of Thunder Bay and North of Dryden Sub-regions. If the Atikokan generation is unavailable, either because of biomass fuel limitations or contract termination (in 2024), the supply margin may be further reduced.

A bulk transmission system study is currently underway to assess the reliability of the 230 kV bulk transmission system supplying the West of Thunder Bay and North of Dryden Sub-regions. As part of the study, the IESO is exploring potential supply options including generation, transmission and firm imports from Manitoba.

In order to maintain the viability of the transmission option, the IESO has issued a hand-off letter to Hydro One to undertake early development work. To facilitate the development work, Hydro One has been engaging Infrastructure Ontario in exploring ways to ensure that the project is developed and delivered in a cost-effective manner and results in value for Ontario electricity customers. The preliminary scope of the transmission option ("Northwest Bulk Transmission Line Project"[11]) consists of a new double-circuit 230 kV line between Thunder Bay and Atikokan and a single-circuit 230 kV line from Atikokan to Dryden. However, alternate routes may be considered as part of the development work.

6.3.2 Distribution System Needs

A number of distribution system needs were identified through engagement with communities and LDCs, including issues related to service reliability and performance, power quality and end-of-life replacements and sustainment activities. A summary of these issues is provided below. However, these needs will be formally addressed as part of the distribution planning process carried out by LDCs.

Distribution Service Reliability

In response to the service reliability and performance concerns raised by communities and LDCs, the Working Group assessed the reliability performance of the distribution systems in the West of Thunder Bay Sub-region. Results from the assessment show that the majority of distribution lines in this area perform well relative to other distribution lines in the province. However, there are two distribution lines supplying electricity to areas near Shabaqua and Margach that are performing below the provincial distribution system average. These distribution lines are three to four times longer than other distribution lines across the province. Long distribution lines typically exhibit lower levels of reliability because they are more exposed to tree and wildlife contact, and they sustain more damage from poor weather. Outages in rural areas with difficult terrain, also limits access by repair crews leading to increased restoration time. A summary of distribution reliability performance assessment can be found in Appendix D.

Section 7.2 will discuss the potential opportunities to further improve distribution service reliability and the associated cost implications.

---

[11] For more information on Northwest Bulk Transmission Line: http://www.ieso.ca/Pages/Ontario's-Power-System/Regional-Planning/Northwest-Ontario/Bulk-Planning-Initiatives.aspx

Power Quality

Some industrial customers in the sub-region are experiencing issues related to power quality. Power quality issues are defined as disturbances to the customer's supply as a result of voltage-related issues. These voltage issues can be driven by a combination of customers' equipment and/or system voltage performances. The solutions and the cost responsibility of investments to address power quality issues may vary depending on the root causes of the problem. The Working Group agreed that there needs to be a better understanding of power quality issues in this sub-region and that they should be examined on a case-by-case basis by the LDCs, transmitter and customers.

End-of-Life Replacement and Sustainment Activities

Based on information provided by Hydro One Distribution, three distribution stations ("DS") were refurbished over the last couple of years: Nestor DS, Sioux Narrows DS, and Burleigh DS.

6.3.3 Community Energy Planning

A number of communities in the sub-region are in the process of developing community energy plans. At the time of this report, 16 of the 26 First Nations communities have received funding from the IESO through the Aboriginal Community Energy Plan program to develop community energy plans. The City of Kenora, City of Dryden and Town of Sioux Lookout have also expressed interest in developing community energy plans and some plans are in the early stages of development. The Municipal Energy Plan Program[12] administrated by the Provincial government supports municipalities in their efforts to develop a community energy plan.

Through community energy planning activities, communities will have a better understanding of their local energy needs and emissions footprint, will identify opportunities for energy efficiency and emissions reduction, and will develop plans to meet their goals in consideration of local economic development. These community energy plans examine broader energy needs, such as transportation, natural gas and electricity, and consider other objectives including net

---

[12] For more information on the Ministry of Energy MEP Program: http://www.energy.gov.on.ca/en/municipal-energy/

zero energy, electrification, and emissions reductions. The development of these plans is being led by communities.

Given the growing concern with climate change and the move toward a low carbon economy, a CEP may include recommendations to promote electrification and other forms of fuel switching, such as shifting from natural gas to electric-power heat pumps, to achieve a goal of reducing greenhouse gas ("GHG") emissions. As such, the outcomes from CEPs may drive additional requirements on the electricity system and should be monitored closely as part of the regional planning process. Furthermore, with the increased access to distributed energy resources, community energy plans may identify opportunities for community-based energy solutions, such as district energy, combined heat and power ("CHP"), or microgrids. Depending on the timing, location and magnitude of the needs, community-based energy solutions can be considered as potential options to address regional electricity needs.

6.4 Needs Summary

Table 6-1 provides a summary of the regional supply and reliability needs in the West of Thunder Bay Sub-region. These needs are within the scope of the regional planning process.

Table 6-1: Summary of Regional Supply and Reliability Needs

Regional Electricity Reliability Needs	Components	Status
Supply Capacity	Dryden 115 kV sub-system	50 MW of additional supply may be required around the mid-2020s under the High scenario
Transformer Station Capacity	The transformer station supplying the City of Kenora and surrounding areas (Kenora MTS)	Limited supply margin remaining on the transformer station. Additional capacity may be required in the next few years as a result of a distribution connection-request from industrial customers in the Kenora area.

Transmission Service Reliability	Transmission supply to Town of Sioux Lookout and Town of Fort Frances	Based on historical outage statistics, the regional transmission system is within provincial service reliability and performance standards. During a recent maintenance outage, switching equipment failure resulted in a prolonged outage for customers in the Fort Frances area.
End-of-Life Replacements and Sustainment Activities	Dryden 44 kV/115 kV transformers	Scheduled to be replaced in 2016
	Moose Lake 44 kV/115 kV transformers	Due for end-of-life replacements in early 2020s
	Aging 115 kV structures in Kenora, Fort Frances and Dryden area	These structures will be replaced within the next five years

Table 6-2 provides a summary of the issues and considerations related to 230 kV bulk transmission system, local distribution systems, and community energy planning activities in the West of Thunder Bay Sub-region. Although these issues are beyond the scope of the regional planning study, the Working Group will continue to monitor these needs closely and keep LAC members informed of bulk, distribution and community planning activities in the sub-region.

Table 6-2: Other Electricity Needs and Considerations in the area

Type	Needs	Status
Bulk	A potential need for additional supply on the 230 kV bulk system supplying the West of Thunder Bay and North of Dryden Sub-regions	Potential growth in the North of Dryden and West of Thunder Bay Sub-regions may exceed capability on the 230 kV bulk transmission system

Distribution	Reliability Performance	Majority of distribution lines in this area perform well relative to other lines in the province, with the exception of the two distribution lines supplying to areas near Shabaqua and Margach.
	Power Quality	Some industrial customers are experiencing power quality issues, which could be driven by a combination of customers' equipment and/or system voltage performances. This will need to be investigated on a case-by-case basis.
	End-of-Life and Sustainment Activities	Nestor DS, Sioux Narrows DS, and Burleigh DS were refurbished over the last couple of years
Community	Greater coordination is required	A number of communities have expressed interest and some plans are in the early stages of development.

7. Options to Address Potential Regional and Local Needs

In developing the 20-year plan, the Working Group considered a range of integrated solutions for addressing needs, including a mix of conservation, generation, transmission and distribution facilities, and other electricity system initiatives. When evaluating alternatives, the Working Group considers a number of factors, including technical feasibility, cost, flexibility, alignment with planning policies and priorities and consistency with long-term needs and options. Solutions that maximized the use of existing infrastructure were given priority, where they were otherwise determined to be cost effective.

Although investing in new electricity infrastructure, such as a new transmission line or a generation facility, can be a potential solution to address the electricity needs within a community, it requires substantial capital investment, has environmental/land-use impact and has a long-service life. As such, it is important to take into the consideration the longer-term cost implications, value and potential risks (e.g., stranded or underutilized assets) when recommending investment. Furthermore, these facilities typically require a long lead time to complete development, obtain approvals and complete construction. For this reason, commitment of these facilities must be made with sufficient lead time to ensure they are available when needed. When assessing the need for infrastructure investments, it is important to strike a balance between overbuilding infrastructure (e.g., committing to infrastructure when there is insufficient demand to justify the investment) and under-investing (e.g., avoiding or deferring investment despite insufficient infrastructure to support growth in the region). Typically, conservation solutions can be implemented within six months, or up to two years for larger projects, whereas transmission and distribution facilities can take five to seven years to come into service. The lead time for generation development is typically two to three years, but could be longer depending on the size and technology type.

Given the uncertainty with the location, timing and magnitude of the electricity demand growth in the West of Thunder Bay Sub-region, as discussed in Section 5, it is important to monitor development closely and create a flexible, comprehensive, integrated plan in anticipation of potential demand growth scenarios and varying supply conditions in the sub-region. At this time, early development work for major electricity infrastructure projects to address potential regional needs is not required. However, to lay the ground work for the next planning cycle, the Working Group has explored potential options to address the potential supply capacity needs on the 115 kV Dryden sub-system under the High scenario. There are opportunities for communities and customers to work with LDCs and Hydro One Transmission to explore opportunities to further improve transmission and distribution service reliability and to assess the associated cost implications. Finally, the Working Group, with input from the LACs, has identified areas to facilitate greater coordination between community energy planning activities and regional planning.

These options and the opportunities to address these local and regional needs are discussed in the following section.

7.1 Options to Address Supply Capacity Needs on Dryden 115 kV Sub-system under the High Scenario

As discussed in Section 6.2.1, about 50 MW of additional supply capacity will be required on the Dryden 115 kV sub-system under the High scenario. Given the uncertainty with the demand growth, early development work for major electricity infrastructure projects is not required at this time. However, it is important to continue to monitor demand closely to determine if and when an investment decision for the Dryden 115 kV sub-system is required.

To lay the groundwork for the next planning cycle, the Working Group examined three conceptual approaches to address potential supply capacity needs on the Dryden 115 kV sub-system: conservation and distributed energy resources, delivering provincial resources ("wires" planning); and, large localized generation. In practice, certain elements of electricity plans will be common to all three approaches, and some overlap may be necessary. It is likely that all plans will contain some combination of conservation, local generation, transmission, and distribution elements. The following section describes the attributes, benefits, risks and implementation requirements associated with each of the three approaches.

As discussed in Section 6.3.1, additional reinforcements may be required to address the 230 kV bulk transmission needs in the West of Thunder Bay Sub-region and will be addressed separately as part of the bulk transmission planning process.

7.1.1 Conservation and Distributed Energy Resources

Conservation is important in managing demand in Ontario and plays a key role in maximizing the useful life of existing infrastructure and maintaining reliable supply. Conservation is achieved through a mix of program-related activities including behavioural changes by customers and mandated efficiencies from building codes and equipment standards. These approaches complement each other to maximize conservation results.

However, within West of Thunder Bay Sub-region, the majority of the forecast load growth is anticipated to be driven by new industrial development, which is assumed to include relatively efficient equipment given the inherent economic benefits and the latest codes and standards. Conservation expected to be achieved through provincial targets, including time-of-use, codes and standards, and program delivery, has already been included in the planning forecast scenarios. Therefore, the potential for an additional amount of significant conservation that could address needs is limited.

Two of the available programs that transmission-connected industrial customers could be eligible for are the Industrial Conservation Initiative ("ICI") and the Industrial Accelerator Program ("IAP"). The ICI encourages Class A customers to reduce their peak demand contributions, by providing a means to reduce their Global Adjustment charges.[13] IAP is geared to reducing electricity consumption on the provincial system, and to helping companies become more competitive by providing financial incentives that encourage investment in innovative process changes and equipment retrofits.[14] Opportunities for energy savings will continue to be explored for new and existing transmission-connected customers in the West of Thunder Bay Sub-region.

7.1.2 Large, Localized Generation Resources

Siting localized generation based on the size and location of the electricity requirements can be an effective means for addressing major regional supply and reliability needs over the long term. While this approach is similar to distributed energy resources in that it shares the goal of providing supply locally, the emphasis is on large, transmission-connected generation facilities rather than smaller, distributed resources. In the context of the West of Thunder Bay Sub-region, a 50 MW generation facility connected to the Dryden 115 kV sub-system can address the potential supply capacity needs under the High scenario.

There are a number of factors that need to be considered when siting localized generation, and any decisions would need to align with the recommendations found in the August 2013 report

[13] More information on how Global Adjustment is calculated for Class A customers is available at http://www.ieso.ca/Pages/Participate/Settlements/Global-Adjustment-for-Class-A.aspx
[14] More information on IAP is available at: http://www.ieso.ca/Pages/Participate/Industrial-Accelerator-Program/default.aspx

entitled “Engaging Local Communities in Ontario’s Electricity Planning Continuum”[15] that was prepared for the Minister of Energy by the OPA and the IESO.

As the requirements in the West of Thunder Bay Sub-region are for additional capacity during times of peak demand, a large, transmission-connected generation solution would need to be capable of being dispatched when needed, and operate at an appropriate capacity factor. In some cases, additional transmission reinforcements may also be required. In addition, siting may be a challenge if the generation is to be located in populated or environmentally sensitive areas.

The cost of a large, localized generation resource depends on the size, fuel type, technology and the degree to which it can contribute to the local and provincial system capacity or energy needs. The fuel availability will also need to be taken in consideration. For example, there is limited natural gas storage capacity in northern Ontario, and the commitment timeframes for gas and electricity are not aligned. As such, procuring “firm” service in the northwest is expected to be more costly than in southern Ontario. The lead time for generation development is typically two to three years, but it could be longer depending on the size and technology type.

7.1.3 Delivering Provincial Resources (“Wires” Planning)

Delivering provincial resources, or “wires” planning, reflects the traditional regional electricity planning approach associated with the development of centralized electric power systems. This approach involves using transmission and distribution infrastructure to supply a region’s electricity needs by taking power from the provincial electricity system. This model takes advantage of generation that is planned at the provincial level, along with generation sources typically located remotely from the region. Utilities, both transmitters and distributors, play a lead role in the development of this approach.

Installing an additional 115/230 kV autotransformer in the Dryden and surrounding area can enable more power to be delivered from the 230 kV bulk transmission system to the 115 kV Dryden sub-system. A 115/230 kV autotransformer typically costs in the range of $15 million to $20 million and the lead time to develop a transformer is typically three to five years. These enhancements may be subject to regulatory approvals, such as a Class Environmental Assessment and utilities’ rate filings. The costs of “wires” solutions would depend not only on

[15] http://www.ieso.ca/Pages/Participate/Regional-Planning/Local-Advisory-Committees.aspx

the specific infrastructure involved, but also on the cost of providing energy at the provincial system level. Cost responsibility for the transmission and distribution infrastructure would be determined as part of the regulatory application review process.

7.2 Opportunities to Further Improve Service Reliability

As discussed in Section 6.2.4 and Section 6.3.2, the reliability performance of the West of Thunder Bay Sub-region is generally within the provincial service reliability and performance standards. Communities and customers may consider working with LDCs and transmitter to explore opportunities to improve transmission and distribution service reliability and performance. Cost-benefit and cost allocation for investments will need to be considered.

At the distribution level, communities and customers may work with LDCs to identify mitigation measures to improve distribution service reliability, where applicable. Similarly, at the transmission-level, LDCs or transmission-connected customers may work with Hydro One Transmission to look at potential transmission improvements (e.g., switching facilities) to reduce the risk and impact of supply interruptions, especially during maintenance outages. Furthermore, many communities are interested in developing distributed energy resources. Communities may wish to explore opportunities for community-based solutions and emerging technologies, such as on-site generation and storage facilities, to minimize the impact of potential power outages.

Whether customers are looking at incremental distribution, transmission or community–based energy solutions to improve service reliability, consideration must be given to the cost–benefits and cost responsibility issues. According to the OEB's proposed "beneficiary pays" principle for cost-allocation, the responsibility to pay for higher reliability would likely be borne by the customers in the area. The issue of how much is appropriate to invest and who pays for the investments will need to be addressed.

The cost of improving service reliability varies depending on geography, the nature of the issue and the local system configuration. In the case of the West of Thunder Bay Sub-region, given the large geographical area and sparse population, solutions for improving system reliability performance may be very costly (e.g., a transmission line covering hundreds of kilometers), while the benefiting customer base may be relatively small. The Working Group has heard from communities and customers in this sub-region that below-average reliability is an impediment to economic development, while the investments necessary to improve the situation are not affordable. However, minor improvements, such as switches and outage mitigation and maintenance measures (e.g., tree trimming and relocations of off-road distribution lines), and distributed energy resources, may be more cost-effective alternatives. In any case, the cost-benefit and responsibility of investments to further improve service reliability will need to be examined on a case-by-case basis.

7.3 Potential Areas for Coordination: Community Energy Planning and Regional Planning Activities

As discussed in Section 6.3.3, a number of communities are currently in the process of developing community energy plans. Greater coordination between community energy planning and regional planning processes can help provincial system planners and local communities develop a common understanding of the growth and local developments, identify opportunities to develop community-based energy solutions and have an informed dialogue on related energy issues.

With the input from the LACs, the Working Group identified potential areas for greater coordination:

- Status of local growth and developments
- Local planning priorities
- Local energy planning activities (e.g., community energy plan)
- Impact of potential supply interruptions or outages
- Potential, feasibility and challenges of implementing community-based energy solutions in consideration of cost-benefit and cost responsibility

LAC meetings can be used as a forum to facilitate the discussion on these energy and planning issues at the community, distribution, regional and bulk system levels. More importantly, these meetings can provide an opportunity for communities to share lessons learned and best practices from community energy planning activities across a region.

A number of coordination efforts are underway in Ontario to facilitate the development of community energy planning, such as the Quality Urban Energy Systems of Tomorrow ("QUEST") initiative. Due to the unique energy planning challenges in the northwest, it would be helpful to identify initiatives to facilitate knowledge sharing and coordinate community energy planning activities in northern Ontario (e.g., a community energy planning webinar or workshop for communities in northern Ontario).

8. Recommended Actions

While specific solutions do not need to be committed to today, it is appropriate to begin work to gather information, monitor developments, continue to engage communities and develop alternatives to support decision-making for the next iteration of the IRRP for this sub-region. The plan sets out the actions required to ensure that options remain available to address future needs, if and when they arise.

Supply capacity needs on the Dryden 115 kV sub-system may emerge under the High scenario, but these potential needs do not require any immediate action. The Working Group will monitor demand growth closely to determine if and when an investment decision for the Dryden 115 kV sub-system is required. In the meantime, the Working Group will keep the communities informed about any developments at the bulk, regional and distribution levels. For communities and customers who are looking to further improve service reliability, they may consider working with LDCs and Hydro One Transmission to develop transmission, distribution and community-based solutions. However, cost-benefit and responsibilities will need to be taken into consideration. Communities in the West of Thunder Bay Sub-region have become increasingly involved in community energy planning activities. The results of early community energy planning initiatives, energy conservation initiatives, and achievable potential studies will be an important input to the next iteration of the plan for the West of Thunder Bay Sub-region. The LAC meetings can be an opportunity to help facilitate greater coordination between the local and regional electricity planning activities.

The recommended actions and deliverables for the plan are outlined in Table 8-1, along with the proposed timing and the parties assigned lead responsibility for implementation. The West of Thunder Bay Working Group will continue to meet regularly during the implementation phase of this IRRP to monitor developments in the West of Thunder Bay Sub-region and track progress of these deliverables.

Table 8-1: Recommended Actions

Recommendations		Action(s)/Deliverable(s)	Lead Responsibility	Timeframe
1	Monitor electricity demand growth closely to determine if and when a decision on Dryden 115 kV sub-system is required	Review electricity demand growth in the West of Thunder Bay and the North of Dryden Sub-regions with the members of the LACs	Working Group	Annually
2	Ensure communities are informed of bulk and distribution planning activities in the West of Thunder Bay Sub-region	Provide a status update on bulk and distribution planning activities at LAC meetings	Working Group	On-going
3	Explore opportunities to further improve service reliability and power quality in consideration of cost-benefit and cost allocations	Examine cost benefit and cost responsibility of distribution, transmission and/or community-based energy solutions	Customers, local distribution companies, and transmitter	On-going
4	Coordinate regional and community energy planning activities	Use LAC meetings as an opportunity to share best practices and to coordinate regional and local energy planning activities Identify opportunities to facilitate knowledge sharing and to coordinate community energy planning activities in northern Ontario, such as webinars on community energy planning in northern Ontario	Working Group and Communities	On-going

9. Community and Stakeholder Engagement

Community engagement is an important aspect of the regional planning process. Providing opportunities for input in the regional planning process enables the views and preferences of the community to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the engagement activities undertaken to date and next steps for the West of Thunder Bay IRRP.

A phased community engagement approach was undertaken for the West of Thunder Bay IRRP based on the core principles of creating transparency, engaging early and often, and bringing communities to the table. These principles were established as a result of the former OPA and the IESO's outreach with Ontarians in 2013 to determine how to improve the regional planning and siting process, and they now guide IRRP outreach with communities and will ensure this dialogue continues as the plan moves forward.

Summary of the West of Thunder Bay Community Engagement Process

Creating Transparency: *Creation of West of Thunder Bay IRRP Information Resources*	• Dedicated West of Thunder Bay IRRP web page created on IESO website providing background information, the IRRP Terms of Reference and listing of the Working Group members • Dedicated web page created on Hydro One Network Inc's website • Self-subscription service established for the Northwest Ontario planning region for subscribers to receive regional planning updates • Status: complete
Engaging Early and Often: *First Nation & Municipal Métis Outreach*	• Early engagement on regional planning and the draft Northwest Ontario Scoping Assessment Report (October - December 2014) • Meetings held with First Nations communities from across the planning region in Dryden, Fort Frances and Kenora (June - July 2015) • Group meetings held with municipalities from across the planning region in Dryden, Fort Frances and Kenora (June - July 2015) • Status: initial outreach complete; dialogue continues
Bringing Communities to the Table: *Broader Community Outreach*	• West of Thunder Bay Local Advisory Committees (LACs) formed in fall 2015; dedicated West of Thunder Bay engagement page added to IESO website • Two LAC meetings held in November 2015 and April 2016 to discuss and obtain feedback on the development of the IRRP • General LAC meetings are open to the public and broadcast via live webinar; materials are posted to the engagement webpage • Status: begun in summer 2015; on-going

9.1 Creating Transparency

To start the dialogue on the West of Thunder Bay IRRP and build transparency in the planning process, a number of information resources were created for the plan. A dedicated web page was created on the IESO website including a map of the regional planning area, information on why an IRRP was being developed for the West of Thunder Bay Sub-region, the IRRP Terms of Reference and a listing of the organizations involved. A dedicated email subscription service was also established for the broader Northwest Ontario planning region where communities and stakeholders could subscribe to receive email updates about the IRRP.

9.2 Engage Early and Often

Early communication and engagement activities for the West of Thunder Bay IRRP were initiated in October 2014 as part of a series of meetings with communities and stakeholders to discuss electricity planning initiatives across northwest Ontario. The main objective of the meetings from a regional planning perspective was to introduce attendees to the regional planning process. This included the Northwest Ontario Scoping Assessment process for the regional planning studies being initiated in the area, as well as discussions of upcoming engagement activities. Various meetings were held with a broad range of attendees including municipal representatives, First Nation community members, Métis council members, federal and provincial representatives, electricity customers, Common Voice Northwest, transmission and generation project developers, and others.

9.2.1 Northwest Ontario Scoping Assessment Outcome Report

The draft Northwest Ontario Scoping Report was posted to the IESO website in December 2014 for comment. Following this comment period, the final scoping report was posted on January 27, 2015.

9.2.2 First Nation and Métis Community Meetings

Meetings with First Nation communities are one of the first steps in engagement for all regional plans. Initial meetings were held in Dryden, Fort Frances and Kenora in June and July 2015. The purpose of these meetings was to discuss the development of the IRRP and share the initial findings. During these meetings, community members indicated their participation in community energy planning as well as interest in local small renewable projects. Communities also gave information about developments in their community and the growing population. Concern was also raised about service outages and the cost of electricity.

On April 18, 2016, the IESO met with Dalles (Ochiichagwe'Babigo'Ining) Ojibway Nation to discuss the status of planning and the identified needs in the West of Thunder Bay area. The community also raised concerns about high electricity costs and the impact of hydroelectric power and other electricity infrastructure on their community.

The IESO invited all other local First Nations communities and Métis councils to similar meetings and remains open to further engagement on the plan.

9.2.3 Municipal Meetings

Meetings with area municipalities are also one of the first steps in engagement for all regional plans. In June and July 2015, the Working Group held group municipal meetings in Dryden, Fort Frances and Kenora to discuss the development of the IRRP as well as the findings to date. Attendees were generally pleased with the meetings and the opportunity to offer a local perspective, and they looked forward to the development of the LACs. During these meetings, many communities also indicated they were interested in developing community energy plans and wanted to find out more about how these plans and the IRRP could work together.

9.3 Bringing Communities to the Table

To continue the dialogue on regional planning, two LACs – a general LAC and a First Nations LAC - were established for the West of Thunder Bay regional planning area in fall 2015. The role of LACs is to provide advice and recommendations on the development of the regional plan as well as to provide input on broader community engagement. General LACs are comprised of Indigenous, municipal, environmental, business, sustainability and community representatives. First Nations LACs are comprised of representatives from the First Nation communities in the planning area. All general LAC meetings are open to the public and meeting information is posted on the dedicated engagement webpage, which in this case is the IESO's West of Thunder Bay engagement web page[16]. The general LAC meetings are also broadcast as live webinars to enable participation from across the planning region.

Development of the West of Thunder Bay general LAC was completed through a request for nominations process promoted by the following activities in July/August 2015: advertisements in local newspapers across the planning area and in Thunder Bay newspapers; localized digital advertising; emails sent to municipal representatives across the region; and an e-blast sent to the IESO's Northwest Ontario subscribers list. Two Métis Councils in the West of Thunder Bay area appointed a member to the general LAC. The development of the West of Thunder Bay First Nations LAC was established through a letter to the leadership of each First Nation in the

[16] http://www.ieso.ca/Pages/Participate/Regional-Planning/Northwest-Ontario/West-of-Thunder-Bay.aspx

West of Thunder Bay area inviting them to appoint a representative to the First Nations LAC. The First Nations LAC then appointed members to the general LAC.

The first meetings of the West of Thunder Bay LACs were held on November 18-19, 2015 in Dryden. The focus of these meetings was to introduce the regional planning process to the newly formed LACs, highlight key electricity supply issues and considerations in the West of Thunder Bay area, and determine the purpose and scope of the LACs. Material from the two LAC meetings and a web archive of the general LAC meeting can be accessed online.[17]

On April 19-20, 2016, the second general and First Nation LAC meetings were held in Dryden. The focus of these meetings was to provide an update on electricity planning activities in the area, review the draft outcomes of the West of Thunder Bay IRRP and determine key areas of focus for future LAC meetings. Material from the two LAC meetings and a web archive of the general LAC meeting can be accessed online.

Copies of the meeting summaries from the West of Thunder Bay general LAC meetings can be found in Appendix F.

Moving forward, the Working Group will present the final IRRP to both of the West of Thunder Bay LACs and discuss with members how they would like to continue the dialogue on regional planning in the area, as well as other electricity issues brought up by the LAC members, but that are outside the scope of regional planning.

The IESO is committed to undertaking early and sustained engagement to enhance regional electricity planning. Further information on the IESO's regional planning processes is available on the IESO website. Additional information on outreach activities for the West of Thunder Bay IRRP can be found on the IESO webpage and updates will continue to be sent to all Northwest Ontario Region email subscribers.

9.4 Additional Meetings and Presentations

The IESO recognizes Common Voice Northwest's unique mandate that includes investigating and making recommendations to the Northwest Ontario Municipal Association ("NOMA") on issues related to energy in the Northwest Ontario Region. The IESO continues to meet regularly

[17] http://www.ieso.ca/Pages/Participate/Regional-Planning/Northwest-Ontario/West-of-Thunder-Bay.aspx

with Common Voice Northwest to discuss the status of electricity planning for northwestern Ontario.

The IESO also presents regularly at the NOMA Spring Annual General Meeting and Fall Regional Conference, the Association of Municipalities of Ontario conference, as well as the Ontario Mining Association conference, among others. These presentations have included high-level status updates on the development of the West of Thunder Bay IRRP, along with other electricity topics.

10. Conclusion

This report documents the IRRP that has been carried out for the West of Thunder Bay Sub-region and fulfills the OEB's regional planning requirement for the sub-region. The IRRP identifies electricity needs in this sub-region over the 20-year period from 2015 to 2034.

Aside from the potential need for additional supply on the 230 kV bulk transmission system, there are no major regional needs identified in the West of Thunder Bay Sub-region under the Low and Reference scenarios. An additional 50 MW of supply may be required on the Dryden 115 kV sub-system under the High scenario. However, early development work for major electricity infrastructure projects is not required at this time given the uncertainty with the demand forecast. The Working Group will monitor demand growth closely to determine if and when an investment decision for the Dryden 115 kV sub-system is required. Although the transmission and distribution reliability performance of the West of Thunder Bay Sub-region is within the provincial service reliability and performance standards, communities and customers may consider working with LDCs and Hydro One to explore opportunities to further improve transmission and distribution service reliability with consideration given to cost-benefits and responsibility for investments. In the meantime, a number of communities in this sub-region are currently developing community energy plans. LAC meetings can be used as an opportunity to share best practices and to coordinate regional and local energy planning activities.

The West of Thunder Bay Working Group will continue to meet regularly throughout the implementation of the plan to monitor progress and developments in the sub-region, and will produce annual update reports that will be posted on the IESO website. To support development of the plan, a number of actions have been identified to develop alternatives, engage with the community, and monitor growth in the area, and responsibility has been assigned to appropriate members of the Working Group for these actions. Information gathered and lessons learned from these activities will inform development of the next iteration of the IRRP for the West of Thunder Bay Sub-region. The plan will be revisited according to the OEB-mandated 5-year schedule.

DISCLAIMER

This Regional Infrastructure Plan (“RIP”) report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and also any additional near and mid-term needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, “the Authors”) make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared (“the Intended Third Parties”), or to any other third party reading or receiving the RIP report (“the Other Third Parties”), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN (“RIP”) WAS PREPARED BY HYDRO ONE AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS WITHIN THE WINDSOR-ESSEX REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Transmission)
- Independent Electricity System Operator
- E.L.K. Energy Inc.
- Entegrus Powerlines Inc.
- EnWin Utilities Ltd.
- Essex Powerlines Corporation
- Hydro One Networks Inc. (Distribution)

This RIP provides a consolidated summary of needs and recommended plans for Windsor-Essex Region. No long-term needs (10 to 20 years) and associated plans have been identified.

This RIP is the final phase of the regional planning process and it follows the completion of the Windsor-Essex Region Integrated Regional Resource Plan (“IRRP”) by the IESO in April 2015 [1].

The major infrastructure investments planned, or being planned, for the Windsor-Essex Region over the near and medium-term identified in the various phases of the regional planning process are given in the table below.

No.	Project	I/S Date	Cost
1*	Supply to Essex County Transmission Reinforcement (SECTR TX) Project	June 2018	$77.4M
2*	Supply to Essex County Transmission Reinforcement (SECTR DX) Project	June 2018	$19.3M
3	Replacement of Keith end-of-life autotransformers	2020	$45M
4	Replacement of Kingsville end-of-life transformers	2018	$12M
5	230kV/115kV circuit and 27.6kV feeder reconfiguration at Keith TS due to Gordie Howe International Bridge (GHIB) Project	2018	$63M
6	Additional feeder position at Malden TS	TBD	TBD
7	Decommission of Tilbury TS	2019	TBD
8	Decommission of T1 Transformer at Keith TS	TBD	TBD

* These projects address the needs identified in the Windsor-Essex IRRP study for the region in the near and medium-term.

In accordance with the Regional Planning process, the Regional Plan should be reviewed and/or updated at least every five years. Should there be any new needs that emerge due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

LIST OF TABLES

[This page is intentionally left blank]

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN (“RIP”) TO ADDRESS THE ELECTRICITY NEEDS OF THE WINDSOR-ESSEX REGION.

The report was prepared by Hydro One Networks Inc. (Transmission) (“Hydro One”) and documents the results of the joint study carried out by Hydro One, EnWin Utilities Ltd. (“EnWin”), Essex Powerlines Corporation, E.L.K. Energy Inc. (“E.L.K Energy”), Entegrus Inc. (“Entegrus”), Hydro One Networks Inc. (Distribution) (“Hydro One Distribution), and the Independent Electricity System Operator (“IESO”) in accordance with the regional planning process established by the Ontario Energy Board (“OEB”) in 2013.

The Windsor-Essex Region comprises the City of Windsor, Town of Amherstburg, Town of Essex, Town of Kingsville, Town of Lakeshore, Town of LaSalle, Municipality of Leamington, Town of Tecumseh, the western portion of the Municipality of Chatham-Kent and the Township of Pelee Island. The map of the region is shown in Figure 1-1 below.

The Windsor-Essex area is supplied from a combination of generation located in the region and from the Ontario grid via a network of 230 kV and 115 kV transmission lines and stations. The region peak electricity demand of about 800 MW is provided from three 230 kV and fourteen 115 kV step-down transformer stations.

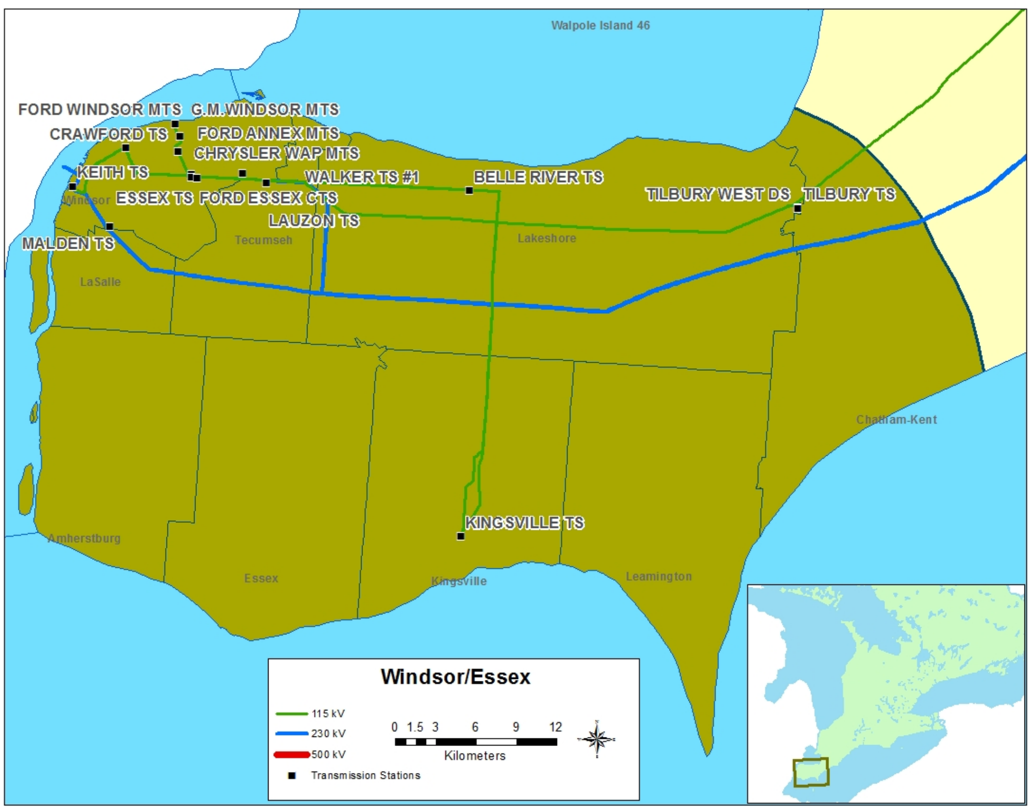

Figure 1-1 Geographical Map of Windsor-Essex Region

1.1 Scope and Objectives

This RIP report examines the needs in the Windsor-Essex Region. Its objectives are to: identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment ("NA"), Scoping Assessment ("SA"), Local Plan ("LP"), and/or Integrated Regional Resource Plan ("IRRP")); assess and develop wires plans to address these needs; provide the status of wires planning currently underway or completed for specific needs; and identify investments in transmission and distribution facilities or both that should be developed and implemented to meet the electricity infrastructure needs within the region.

Planning activities for the Windsor-Essex Region were already underway before the new regional planning process was introduced. The NA and SA phases were deemed to be complete and the Windsor-Essex Region was identified as a "transitional" region. The planning status for the region was considered to be in the IRRP phase of the regional planning process. An IRRP for the region was completed in April 2015.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant plans to address near and mid-term needs (2015-2025) identified in previous planning phases (NA, SA, LP, and/or IRRP).
- Identification of any new needs over the 2015-2025 period and a wires plan to address these needs based on new and/or updated information.
- Develop a plan to address any longer term needs identified by the Working Group.

The IRRP or RIP Working Group did not identify any long term needs at this time. If required, further assessment will be undertaken in the next planning cycle because adequate time is available to plan for required facilities.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process.
- Section 3 describes the region.
- Section 4 describes the transmission work completed over the last ten years.
- Section 5 describes the load forecast and study assumptions used in this assessment.
- Section 6 describes the regional needs.
- Section 7 provides a summary of regional plans.
- Section 8 provides summary of other projects.
- Section 9 provides the conclusion and next steps.

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115 kV and 230 kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment [1] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, further planning is undertaken by the transmitter and the impacted local distribution company ("LDC") or customer and develops a Local Plan ("LP") to address them. These needs are local in nature and can be best addressed by a straight forward wires solution.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. The approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options which the IRRP identifies as best suited to meet a

[1] Also referred to as Needs Screening

need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee in the region or sub-region. Since the Windsor-Essex Region was in transition to the new regional planning process, the IESO led IRRP engagement for this region was initiated after the completion of the IRRP.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

The regional planning process specifies a 20 year planning assessment period for the IRRP. The RIP focuses on the wires options and, given the forecast uncertainty and the fact that adequate time is available to identify and plan new wire facilities in subsequent planning cycles, a study period of 10 years is considered adequate for the RIP. The exception would be the case where major transmission infrastructure investments are required. In these cases the RIP would review and assess longer term needs and develop a longer term plan.

To efficiently manage the regional planning process in the region, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect.
- Participating in and conducting wires planning as part of the IRRP for the region.
- Working and planning connection capacity requirements with the LDCs.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

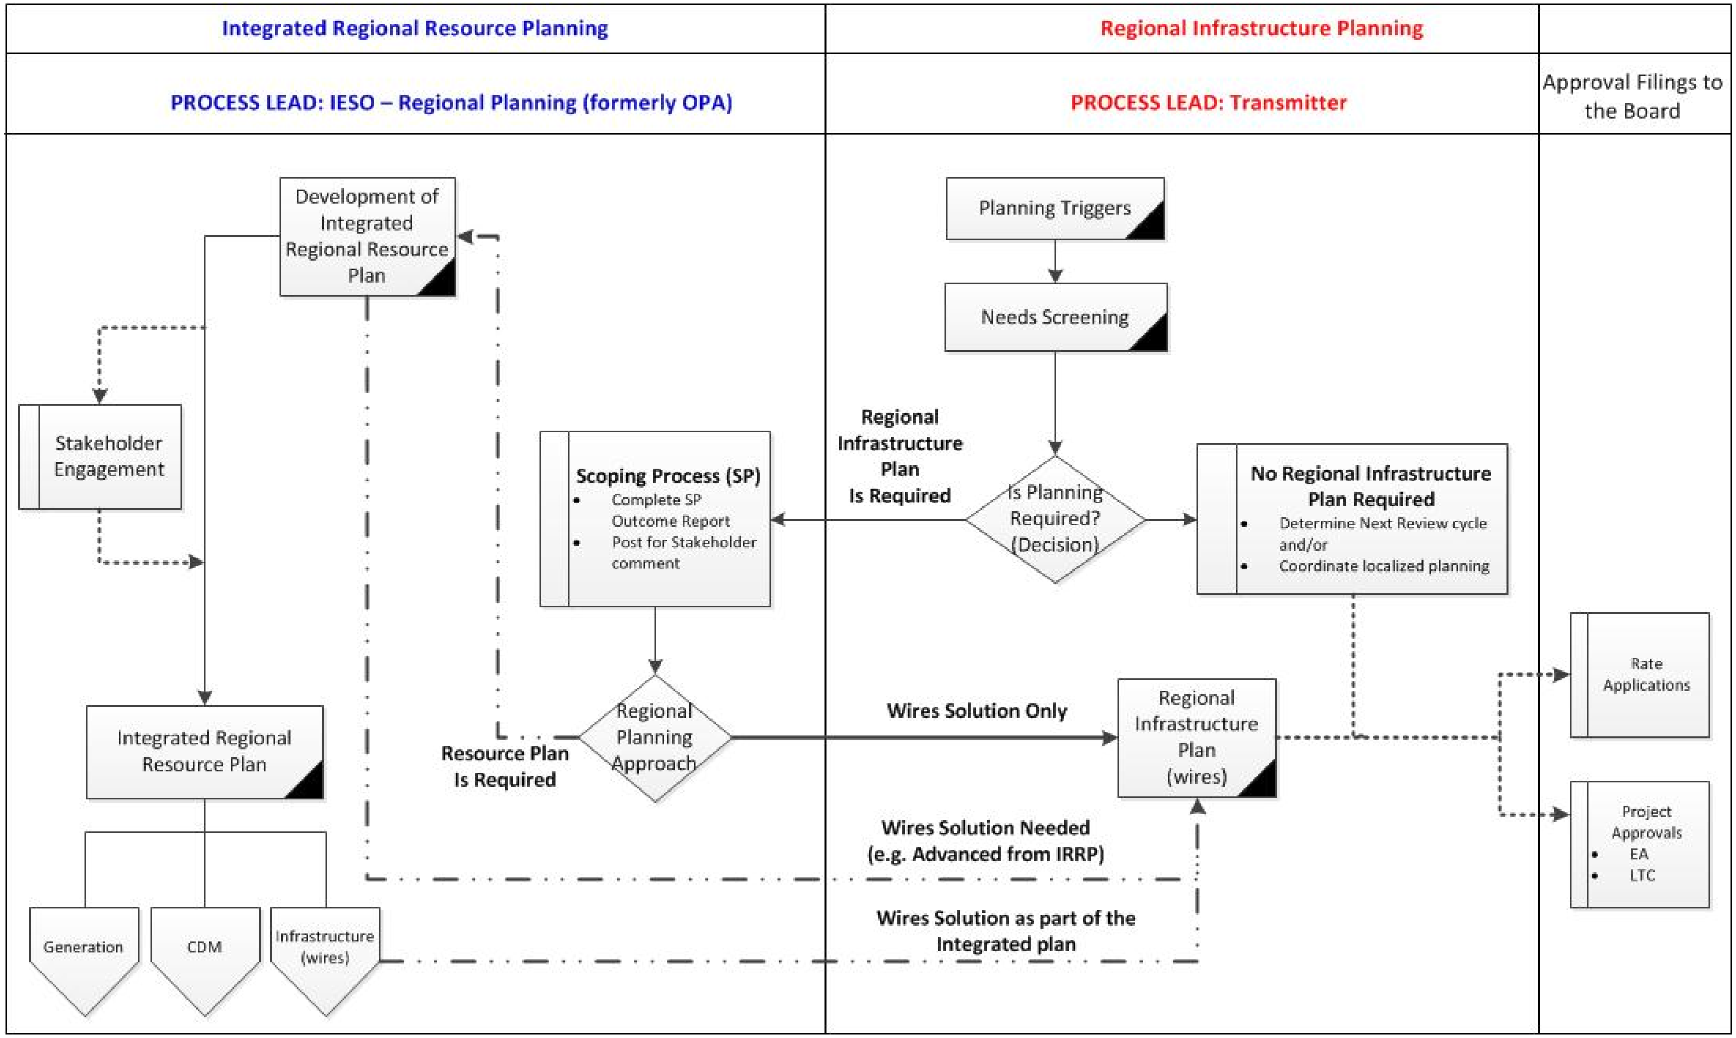

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP process is a four step process as shown in Figure 2-2 below.

1. Data Gathering: The first step of the RIP process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects this information and reviews it with the Working Group to reconfirm or update the information as required. The data collected includes:
   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation or conservation and demand management programs.
   - Existing area network and capabilities including any bulk system power flow assumptions.
   - Other data and assumptions as applicable such as asset conditions; load transfer capabilities, and previously committed transmission and distribution system plans.
2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.
3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact and costs.
4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

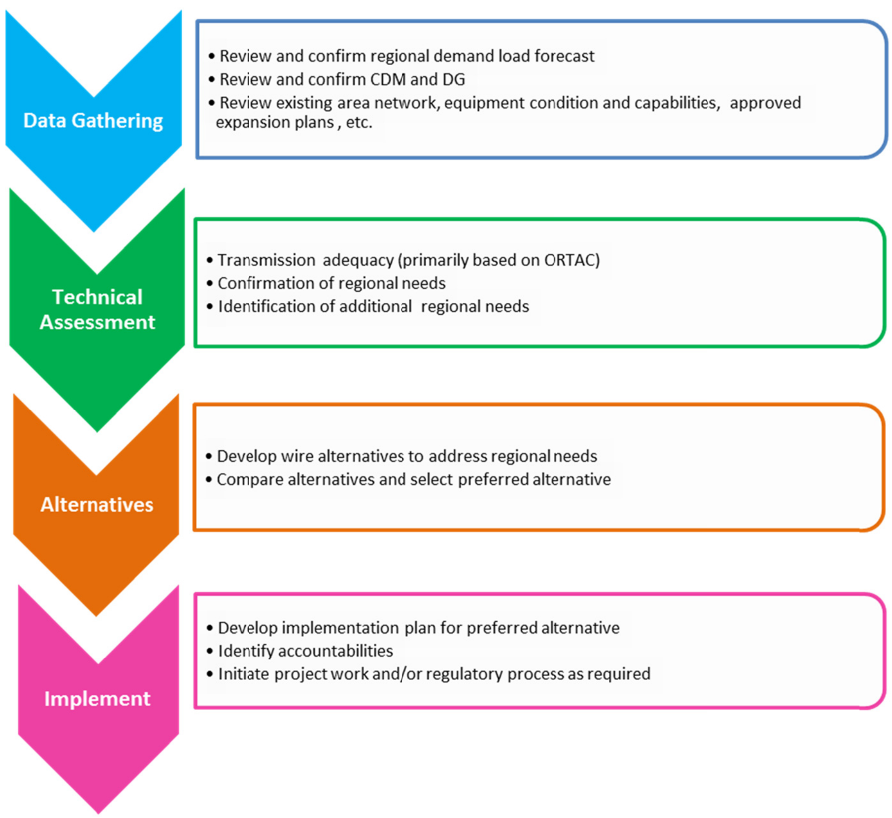

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE WINDSOR-ESSEX REGION COMPRISES THE CITY OF WINDSOR, TOWN OF AMHERSTBURG, TOWN OF ESSEX, TOWN OF KINGSVILLE, TOWN OF LAKESHORE, TOWN OF LASALLE, MUNICIPALITY OF LEAMINGTON, TOWN OF TECUMSEH, THE WESTERN PORTION OF THE MUNICIPALITY OF CHATHAM-KENT AND THE TOWNSHIP OF PELEE ISLAND.

The region is served by five LDCs: EnWin, Essex Powerlines Corporation, E.L.K. Energy, Entegrus, and Hydro One Distribution, whose service territories are shown in Figure 3-1. EnWin and Hydro One Distribution are directly connected to the transmission system, while the three other LDCs have low voltage connections.

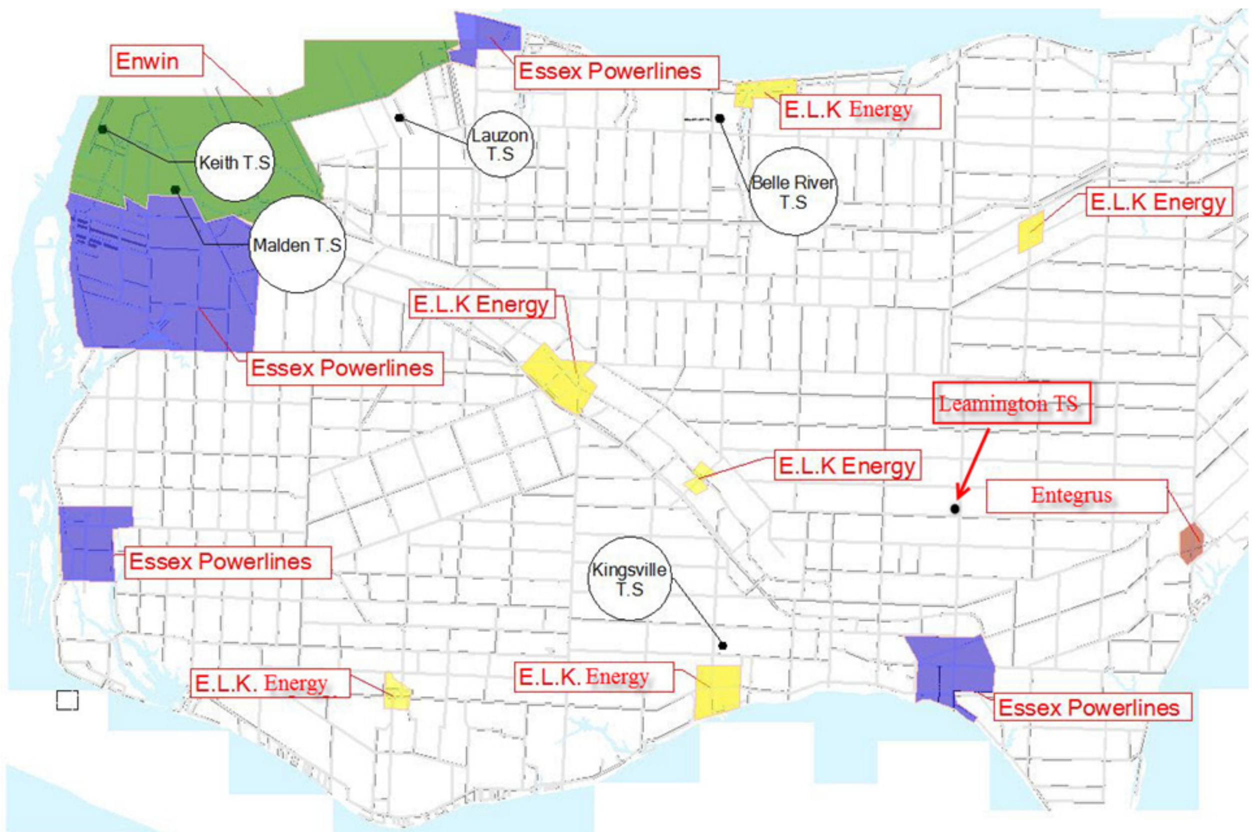

Figure 3-1 LDC Service Territories

The region peak electricity demand of about 800 MW is supplied from a combination of local generation and from connection to the Ontario grid via a network of 230 kV and 115 kV transmission lines and stations shown in Figure 3-2 below.

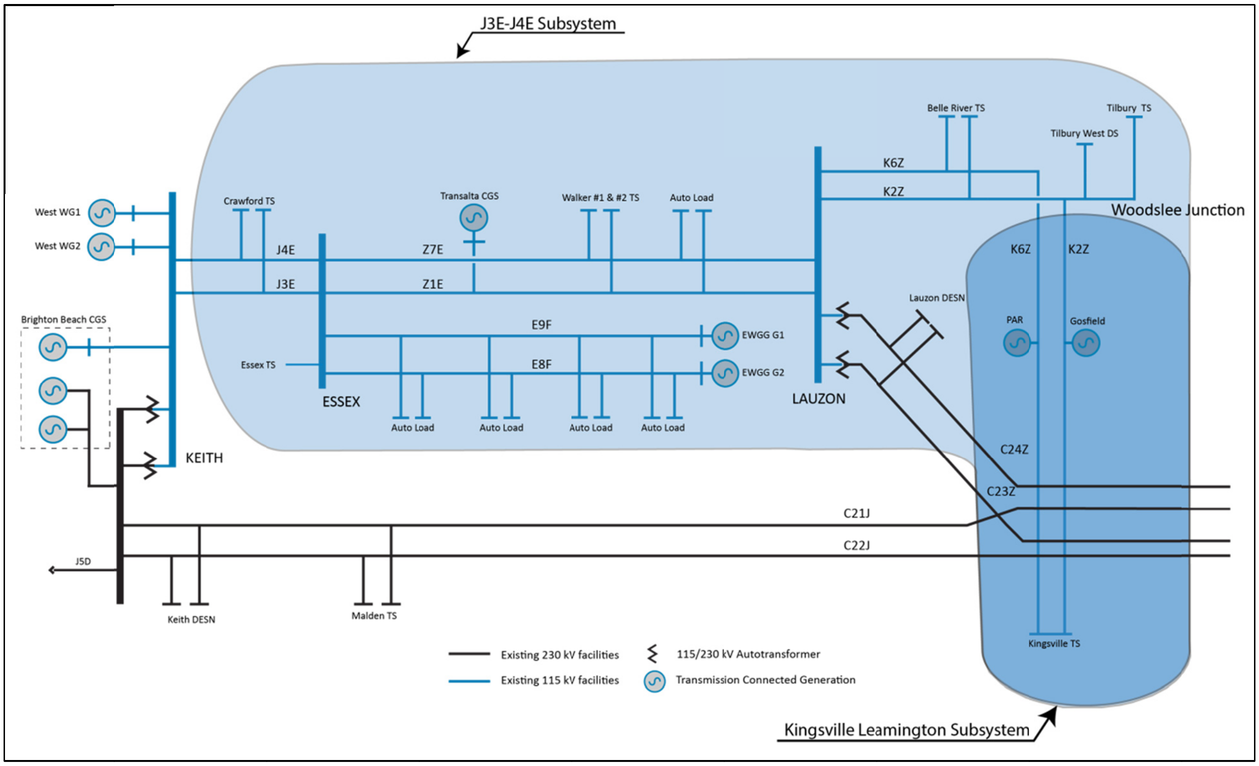

Figure 3-2 Windsor-Essex Area Subsystems/Single Line Diagram

The main transmission corridor in the region connects with the rest of the Hydro One system at Chatham Switching Station ("SS") and connects the Ontario transmission system with the Michigan transmission system at Keith TS.

The region's 115 kV network connects to the 230 kV transmission system at Keith TS and Lauzon TS via two auto-transformers in each station. About 65% of the area load is supplied by fourteen step-down transformers stations connected to the 115 kV network, while the balance is supplied by three step-down transformer stations connected to the 230 kV network. Table 3-1 lists the region's step-down transformer stations.

There are six customer-owned generating plants in the region connecting at the 230 kV and 115 kV levels with a combined contract capacity of 927 MW. In addition, the distributed generation connected at various locations to low-voltage ("LV") feeders in the region account for about 65 MW of effective capacity. Table 3-1 list the region's transmission connected generations.

The transmission system in the region can be divided into two "nested" sub-systems:

- The Kingsville-Leamington subsystem: customers supplied from Kingsville TS and
- The J3E-J4E subsystem: customers supplied from stations connected to the Windsor-Essex 115 kV system, as well as customers supplied from the 230/27.6 kV Lauzon DESN.

As can be noted in Figure 3-2 below, the Kingsville-Leamington subsystem is nested within the J3E-J4E subsystem. Therefore, increasing supply to the Kingsville-Leamington subsystem or transferring load from the existing Kingsville TS to a new 230 kV TS will impact the supply and demand balance in the J3E-J4E subsystem.

Table 3-1 Stations Included in the Windsor-Essex Region

Station (DESN)	Voltage Level (kV)	Supply Circuits	Connected Customer(s)
Belle River TS (T1/T2)	115/27.6	K2Z/K6Z	Hydro One Distribution
Kingsville TS (T1/T2/T3/T4)	115/27.6	K2Z/K6Z	E.L.K. Energy Essex Powerlines Corp. Hydro One Networks Inc.
Lauzon TS (T5/T6/T7/T8)	230/27.6	C23Z/C24Z	EnWin Utilities Ltd. Hydro One Distribution
Tilbury West DS	115/27.6	K2Z	Hydro One Distribution
Tilbury TS (T1)	115/27.6	K2Z	Hydro One Distribution
Chrysler WAP MTS	115/27.6	E8F/E9F	EnWin Utilities Ltd.
Crawford TS (T3/T4)	115/27.6	J3E/J4E	EnWin Utilities Ltd.
Essex TS (T5/T6)	115/27.6	Z7E/	EnWin Utilities Ltd.

Malden TS (T1/T2)	230/ 27.6	C21J/C22J	EnWin Utilities Ltd. Essex Powerlines Corp. Hydro One Distribution
Walker MTS #2	115/27.6	Z1E/Z7E	EnWin Utilities Ltd.
Walker TS #1 (T3/T4)	115/27.6	Z1E/Z7E	EnWin Utilities Ltd.

Table 3-2 Transmission Connected Generation Facilities in the Region

Technology	Station Name	Contract Expiry Date	Connection Point	Contract Capacity (MW)	Summer Effective Capacity (MW)
Combined Cycle Generating Facility	Brighton Beach Power Station	Dec. 31, 2024	Keith TS	541	526
Combined Heat and Power (CHP)	West Windsor Power	May 31, 2031	J2N (Keith TS)	128	107
	TransAlta Windsor	Dec. 1, 2031	Z1E	74	74
	East Windsor Cogeneration Centre	Nov. 5, 2029	E8F/E9F	84	80
Renewables	Gosfield Wind Project	Jan. 12, 2029	K2Z	51	8
	Point Aux Roches Wind Farm	Dec. 5, 2031	K6Z	49	8

4. TRANSMISSION FACILITIES COMPLETED OVER THE LAST TEN YEARS OR CURRENTLY UNDERWAY

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED OR ARE UNDERWAY BY HYDRO ONE, AIMED AT IMPROVING THE SUPPLY TO THE WINDSOR-ESSEX REGION. A BRIEF LISTING OF THE COMPLETED PROJECTS OVER THE LAST 10 YEARS IS GIVEN BELOW:

- Belle River TS (May 2006): Built a new 2-25/33/42 MVA 115/27.6 kV transformer station in the Town of Lakeshore supplied from 115 kV circuits K2Z/K6Z. The station provides additional load supply capability to meet the load requirements of Hydro One Distribution customers in the Town of Lakeshore. The connection of new station required the untwining of K6Z to obtain two circuits (K2Z and K6Z) with K6Z on the north side of the towers. The new K2Z circuit section which only extends to Belle River TS was then connected to the then existing K2Z circuit just outside of Lauzon TS.

- Essex TS (October 2008): The station was refurbished with new 2-50/66/83 MVA 115/27.6 kV transformers. The 115 kV supply circuits were reconfigured to mitigate exposure to customer load loss for loss of a single transmission element under certain system conditions.

- Malden TS: Transformer T2 75/100/125 230/27.6 kV was replaced (July 2010) and T1 was replaced (December 2011).

- Keith TS: T23 transformer 50/67/83 MVA 230/27.6 kV was replaced (October 2008) and T22 transformer 50/67/83 MVA 230/27.6 kV was replaced (December 2013).

- Walker TS #1: Reactor installation for short circuit mitigation (June 2011).

- Kingsville TS: Reactor installation for short circuit mitigation (November 2011).

- Keith TS: Reactor installation for short circuit mitigation (April 2012).

- Lauzon TS: Three breakers were replaced: SC2Q (June 2012), SC3E (April 2012) and SC4J (April 2012).

- Keith TS: Six breakers were replaced: SC11K (May 2014), SC11SC (May 2014), SC1B (June 2014), T11P (August 2014), T12P (October 2014), SC2Y (January 2015).

The following projects are currently underway:

- Crawford TS: is a 115/28 kV, with two 50/67/83 MVA units in Windsor. It supplies the downtown Windsor area with a current peak load of 60 MW. The existing T3 transformer is at the end-of-life with leaky fittings and headboard. The T3 fire suppression system and separation wall also needs to be upgraded to current standards. The current plan is to replace T3 transformer and install neutral grounding reactors on the T3 and T4 transformer units. The project includes protection and control upgrades and relocation of battery, necessary spill containment facilities at Crawford TS. The project is under execution for $8.46 million with an in-service date of December 15, 2016. There are no cost implications for the LDCs. Once this project is complete the station will meet the current design standards.

5. LOAD FORECAST AND OTHER ASSUMPTIONS

THE FORECASTS REFLECT THE EXPECTED PEAK DEMAND AT EACH STATION UNDER EXTREME WEATHER CONDITIONS, BASED ON FACTORS SUCH AS POPULATION, HOUSEHOLD AND ECONOMIC GROWTH, CONSISTENT WITH MUNICIPAL PLANNING ASSUMPTIONS.

5.1 Historical Demand

The peak demand in the Windsor-Essex Region has declined from a high of 1060 MW in the summer of 2006 to approximately 800 MW in both 2013 and 2014.

Figure 5-1 shows the historical summer peak demand observed in the region from 2004 to 2014. A noticeable peak in 2006 is coincident with the all-time peak in Ontario power demand, while a dip in 2008 and 2009 shows the area's response to the global recession. There is a large concentration of automotive manufacturing facilities in the City of Windsor. The sector is a major economic driver and electricity user within the region. The decline in Ontario's manufacturing sector and the 2008/09 economic downturn have both contributed to a decline in electricity use in the region.

While the manufacturing sector continues to face challenges in recovering, economic diversification is changing the region's growth and electricity use. The five-year Windsor-Essex Regional Economic Roadmap, released in 2011, identifies nine industry groups that hold growth potential for the region, including advanced manufacturing, tourism, and agri-business.

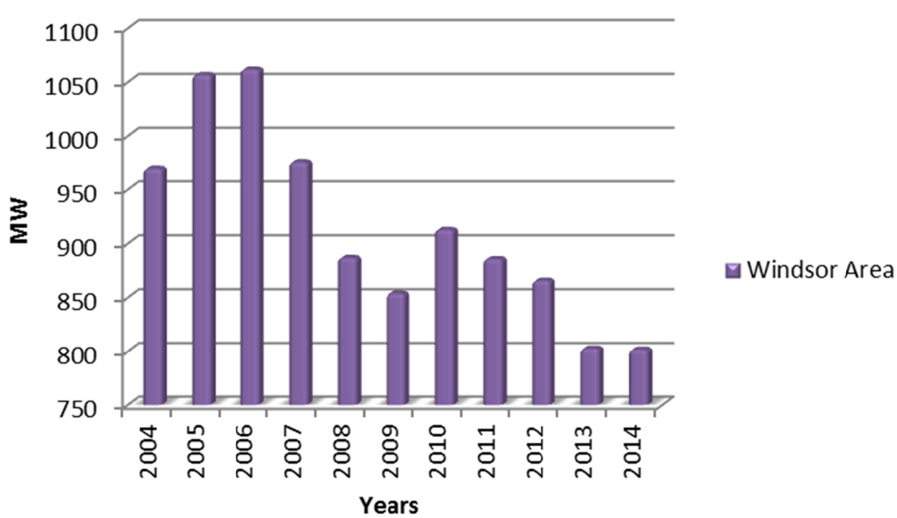

Figure 5-1 Historical Load Demand in Windsor-Essex Region

The peak demand in the Kingsville-Leamington area has also experienced fluctuations over the 2004-2014 period as shown in Figure 6-1.

5.2 Contribution of CDM and DG

In developing the planning forecast, the following process was used to assess the Windsor-Essex Region:

a) First, "gross demand" is established. Gross demand reflects the forecast developed and provided by the area LDCs and is influenced by a number of factors such as economic, household and population growth.
b) Second, "net demand" is derived by reducing the gross demand by expected savings from improved building codes and equipment standards, customer response to time-of-use pricing, and projected province-wide CDM programs. This information is provided by the IESO.
c) Lastly, a "planning forecast" is determined by reducing net demand by the contribution in the area from existing, committed and forecast DG. This information is provided by the IESO.

5.3 Gross and Net Demand Forecast

Summer peak gross non-coincident demand forecasts for the 20-year planning horizon were provided by EnWin and Hydro One Distribution, the two LDCs which are directly connected to the transmission system, for each of the transformer stations in the area. The forecasts from Hydro One Distribution include forecasts provided by the appropriate embedded LDCs.

The development of the load forecast for this RIP report followed a two-stage process:

(a) Using the forecast provided by the LDCs, the year by year growth rate for each station was first developed.
(b) The 2014 summer actual peak load, corrected for extreme weather, for each station was obtained.
(c) The growth rates from (a) were then applied to the 2014 summer peak load of (b) to obtain the gross load forecast for each station for extreme weather conditions.

The gross load forecasts, for extreme weather conditions, by station and by subsystem are shown in Appendix A. This load forecast reflects the following:

- A shift of load, commencing in 2016, from Walker TS #1 and #2 to Essex TS and GM MTS.
- Reduction in Kingsville TS load.
- Increase in loads at Keith TS, Crawford TS and Lauzon TS.

The gross load forecasts, for extreme weather conditions, by station and by subsystem are shown in Appendix A. Figure 5-2 is a graph of the Windsor – Essex Region extreme weather peak summer non-coincident load forecast. The overall region will experience an average annual growth rate of just less than 1%, while the Kingsville-Leamington area average growth rate would be about 1.6%.

Figure 5-2 also shows the load forecast from the IRRP report. The two forecasts are not materially different; hence the load forecast in this RIP report will not alter the conclusions of the IRRP.

The Reference Planning forecast (Appendix D) for each station is obtained by reducing the gross load forecast for the station by the amount of forecast conservation and DG. The conservation forecast (Appendix B) and the DG forecast (Appendix C) are the same as used in the IRRP report.

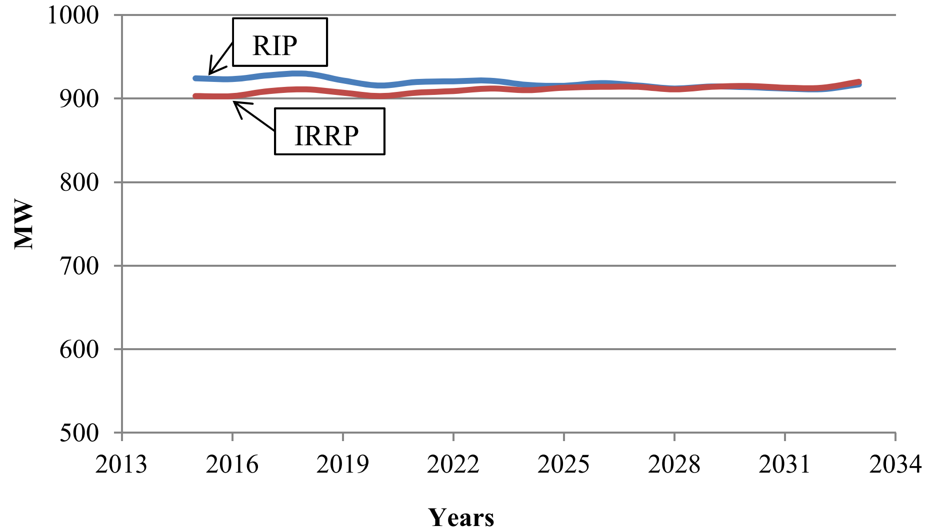

Figure 5-2 Reference Forecast in Windsor-Essex Region

5.4 Other Study Assumptions

The following other assumptions are made in this report.

1) The Study period for the RIP assessment is 2015-2025.
2) All planned facilities for which work has been initiated and are listed in Section 4 are assumed to be in-service.
3) Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on summer peak loads.
4) Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity. Load is assumed at 90% lagging power factor, unless known.
5) Normal planning supply capacity for Hydro One transformer stations in this Region is determined by the summer 10-Day Limited Time Rating (LTR), while some LDCs use different methodologies for determining transformer station LTR.

6. REGIONAL NEEDS

THIS SECTION SUMMARIZES THE WINDSOR-ESSEX REGION NEEDS OVER THE NEAR AND MID TERM. NO LONG TERM NEEDS HAVE BEEN IDENTIFIED.

Earlier studies by the IESO, ("Windsor-Essex Region Integrated Regional Resource Plan" - April 28, 2015, Supply to Essex County Transmission Reinforcement Project, January 2014) identified two near-term needs in the region. These needs are:

- **Minimize the Impact of Supply Interruptions in the J3E-J4E Subsystem:**
  The existing system lacks the capability to restore power to customers in the J3E-J4E subsystem in accordance with the ORTAC criteria, i.e., restoration of all loads within 8 hours. Based on current and forecast demand, up to 170 MW 0f the load interrupted cannot be restored by 2017.

- **Additional Supply Capacity in the Kingsville-Leamington Area:**
  Demand in the Kingsville-Leamington subsystem has already exceeded the load meeting capability of 120 MW in recent 3 years and is expected to continue to exceed the supply capacity over the forecast period. Figure 6-1 below shows the historical and forecast demand and supply capabilities in the Kingsville-Leamington subsystem after conservation and DG are taken into consideration.

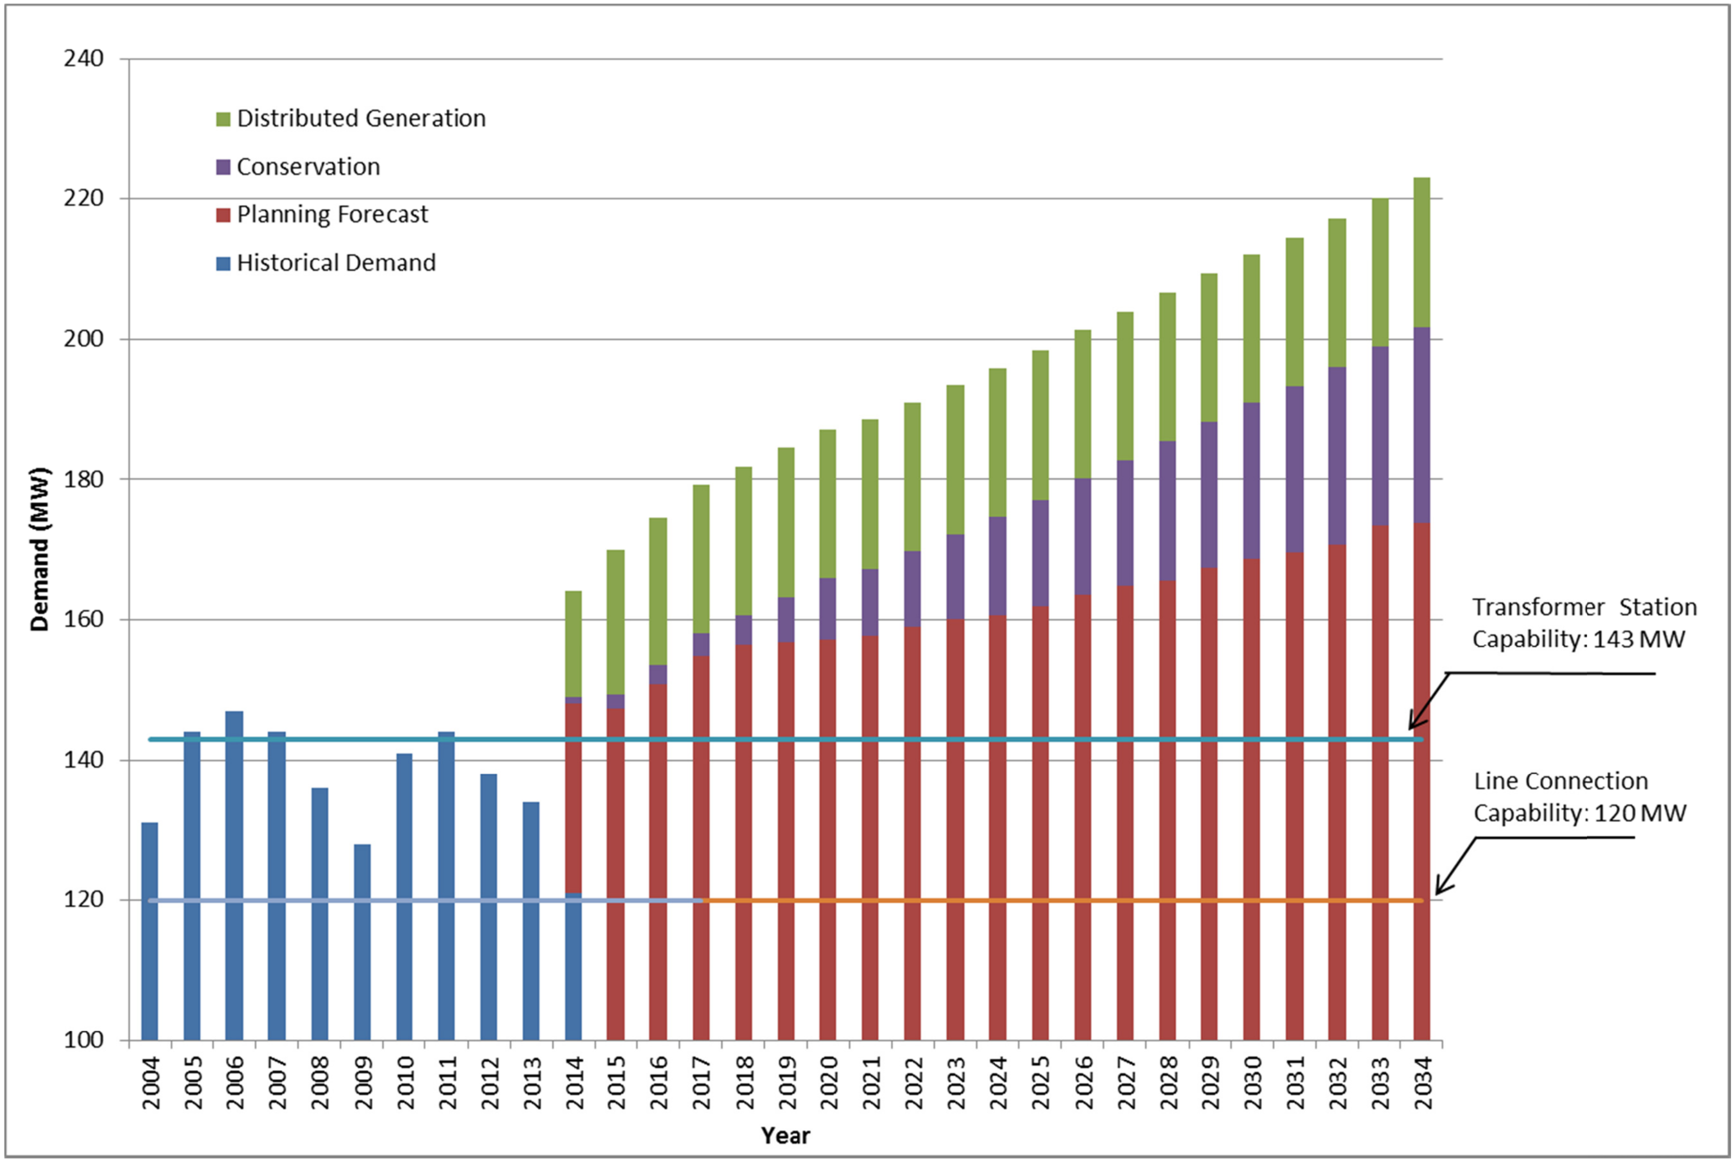

Figure 6-1 Historical and Forecast Demand of Kingsville-Leamington Subsystem

In addition, Hydro One has also identified infrastructure and major equipment which need replacement during the study period. The current plan is essentially a like-for-like replacement of 3 step-down transformers at Kingsville TS and 2 auto-transformers at Keith TS.

These regional needs are summarized in Table 6-1 and include needs for which work is already underway and/or being addressed. A detailed description and status of work initiated or planned to meet these needs is given in Section 7.

Table 6-1 Summary of Needs

Type	Needs	Timeline	Process
Capacity to Meet Demand	Kingsville-Leamington Subsystem	2018	**IRRP**
Minimize the Impact of Interruption	J3E-J4E Subsystem	2018	**IRRP**
Aging Equipment Replacement	3 transformers at Kingsville TS are at end-of-life	Near-Term	**RIP**
Aging Equipment Replacement	2 autotransformers at Keith TS are at end-of-life	Near-Term	**RIP**

7. REGIONAL INFRASTRUCTURE PLANS

THIS SECTION PRESENTS WIRES ALTERNATIVES AND THE CURRENT PREFERRED WIRES SOLUTION FOR ADDRESSING THE ELECTRICAL SUPPLY NEEDS FOR THE WINDSOR-ESSEX REGION.

7.1 Supply to Essex County Transmission Reinforcement (SECTR) Project

7.1.1 Description

The SECTR project as presented in the IRRP is an integrated solution to address both the J3E-J4E subsystem restoration need and the Kingsville – Leamington capacity need. As illustrated in Figure 7-1 the project consists of the installation of a new 230 kV supplied transformer station near Leamington connected to the existing C21J/C22J circuits via a new 13 km double-circuit 230 kV connection line on a new right-of-way.

The total cost of this project is $96.7M made up of:

(a) Build 230/27.6 – 27.6 kV 75/100/125 MVA Leamington TS with six LV breaker positions, plus other required switchgear: $32.1M
(b) Build a 13 km 2-circuit 230 kV line on a new right-of-way tapping into existing 230 kV circuits C21J/C22J plus Optical Ground Wire: $45.3M.
(c) Carry out distribution work for Leamington TS: $19.3M. Other additional distribution work includes two additional feeder positions at Leamington TS, and protection upgrades for in-service Kingsville DG transferred to Leamington TS.

With the establishment of Leamington TS, load will be transferred from Kingsville TS to the new station, such that the Kingsville TS load will be reduced to about 50 MW. As discussed in the IRRP report, this presents an opportunity to downsize the station from four transformers to two transformers, and would result in a combined supply capability in the Kingsville-Leamington area of 210 MW.

Figure 7-2 is a preliminary plan for the transfer of Kingsville TS feeders to Leamington TS. Feeders which are shown in blue will be completely transferred to Leamington TS, and the ones shown in green will be partially transferred to Leamington TS.

7.1.2 Recommended Plan and Current Status

Hydro One filed an application on January 22, 2014 with the OEB under Section 92 of the OEB Act for an order granting leave to construct approximately 13 km of new 230 kV transmission lines on steel lattice towers on a new right of way in the Windsor-Essex area and the installation of optic ground wire for system telecommunication purposes on existing C21J/C23Z towers near Leamington Junction and on new 230 kV towers. The application included a request for OEB approval of the methodology for allocating project cost to Hydro One Distribution, embedded LDCs and Sub-Transmission class customers.

On February 12, 2015, Hydro One filed an updated application that included the new 230/27.6 kV Leamington Transformer Station (Leamington TS). The OEB decided that the proceeding would be addressed in two phases. Phase 1 would only deal with the leave to construct application and Phase 2 of the proceeding would deal with cost allocation. Phase 1 of the SECTR S.92 proceeding has concluded and the "Leave to Construct" approval was granted by the OEB on July 16, 2015. The expected in-service date for the SECTR Project is June 2018. Phase 2 of the proceeding is continuing via an OEB policy review rather than the originally planned adjudicative process.

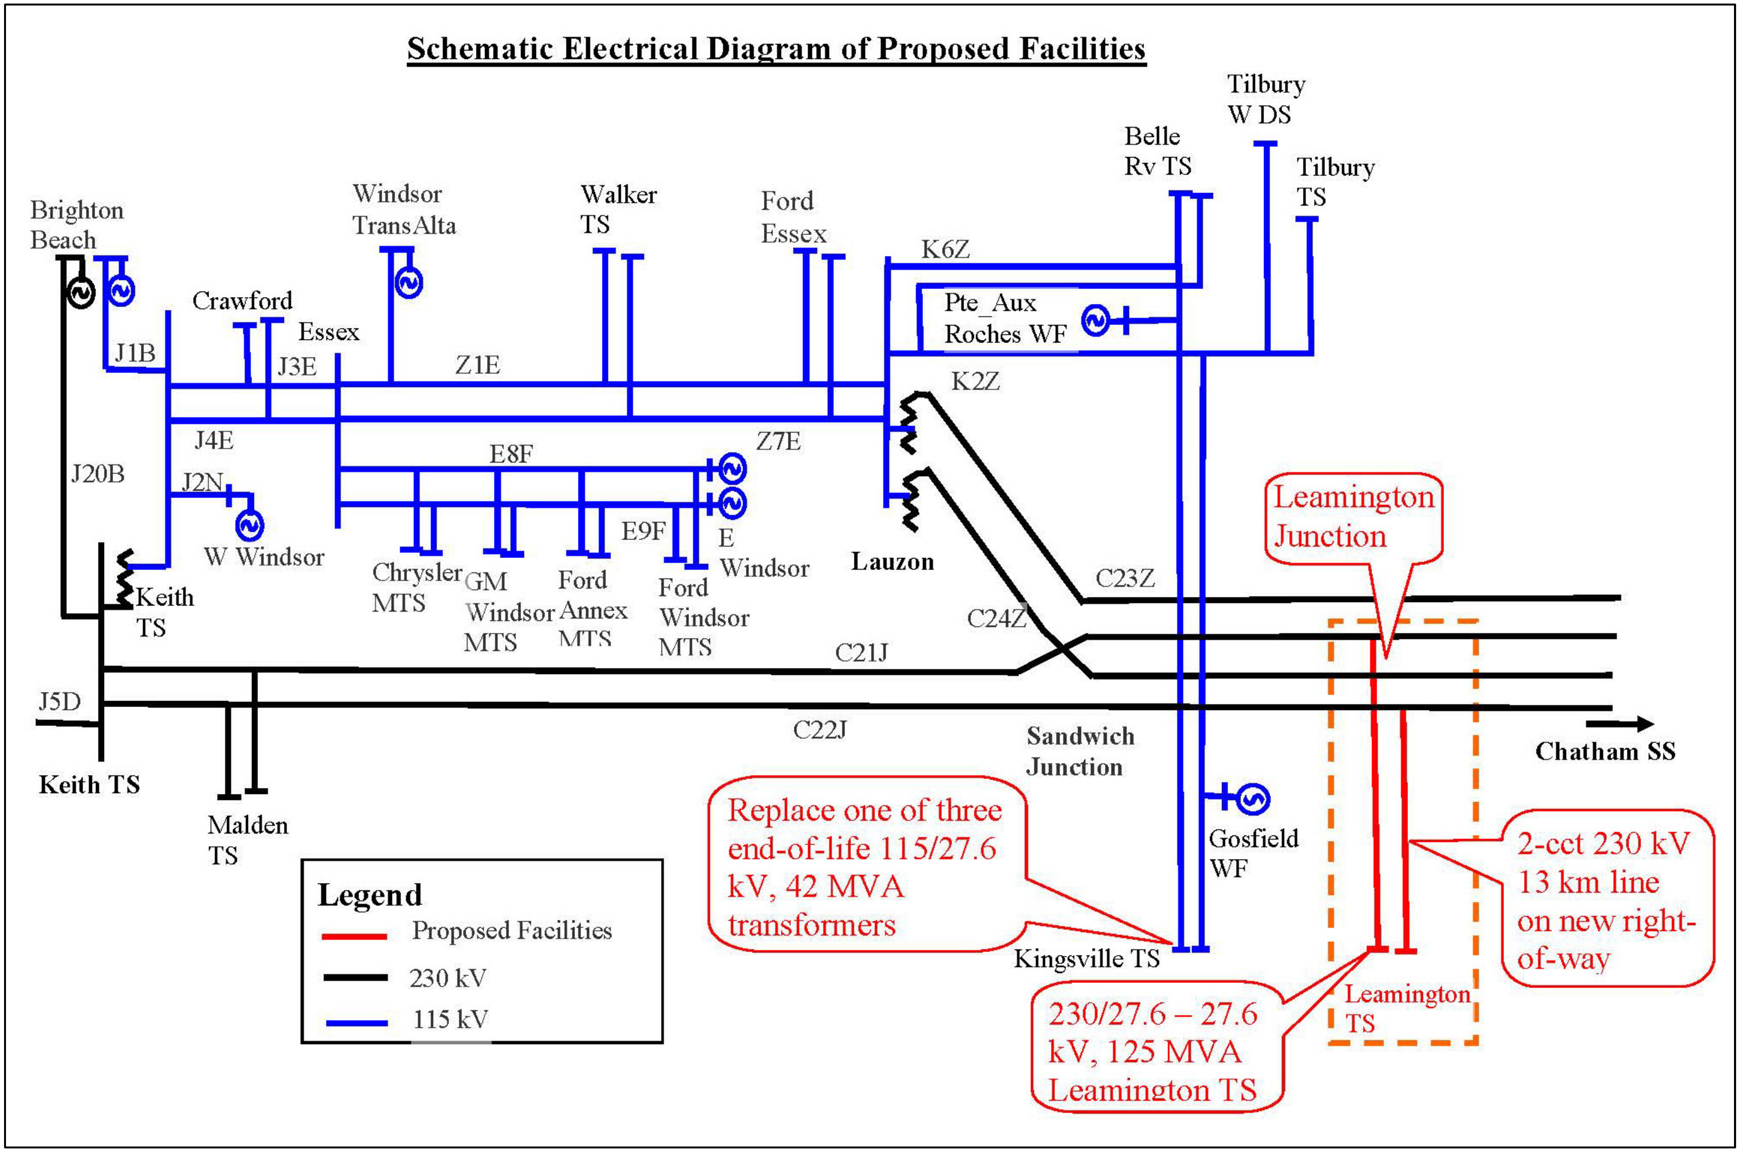

Figure 7-1 Schematic Electrical Diagram of the Proposed Facilities

Figure 7-2 Preliminary Distribution Feeder Plans for SECTR Project

7.2 Keith TS End-of-Life Auto-Transformer Replacement

7.2.1 Description

Keith TS is equipped with 2-230/115 kV 115 MVA autotransformers. These autotransformers are 1950's vintage and near end-of-life and require replacement.

7.2.2 Recommended Plan and Current Status

Due to SECTR project additional capacity will not be required and the end-of-life autotransformers at Keith TS will be replaced with equivalent like-for-like 125 MVA units. The expected in-service date is 2020. There are no cost implications for the LDCs.

7.3 Kingsville TS End-of-Life Transformer Replacement

7.3.1 Description

Kingsville TS is equipped with 4-115/27.6 kV 25/33/42 MVA transformers. One of these transformers was recently replaced, but the other three are 1950's vintage and will require replacement in the near future.

Due to SECTR project and the associated reduction in load at Kingsville TS, the station may be downsized and reconfigured as a two-transformer station. Hydro One Distribution is further reassessing to justify retaining the four-transformer arrangement if they receive additional request for connections at Kingsville area.

7.3.2 Recommended Plan

Hydro One Distribution to complete their connection capacity assessment as part of distribution system planning before Q3 2016 so that replacement and reconfiguration plan can be finalized by Hydro One in a timely manner.

7.4 Gordie Howe International Bridge (GHIB)

7.4.1 Description

The Gordie Howe International Bridge (GHIB) is a construction project under a bi-lateral agreement between the federal governments of Canada and the USA, and the governments of Ontario and Michigan, to construct a new border crossing between Windsor and Detroit. It will comprise a 12 km westerly extension of Hwy 401 to a site near Keith Transformer Station, where a new customs plaza and a new bridge over the Detroit River will be constructed. The highway will be extended by the Ministry of Transportation of Ontario (MTO), while the customs plaza and the bridge will be constructed by Transport Canada.

The GHIB project is multi-faceted in its impacts on Hydro One facilities and operations at Keith TS including: transmission lines, fiber lines and feeders relocation; insulation contamination due to salt spray effects from new bridge; relocation of access routes; possible security issues for staff accessing and working at the station; impacts on existing utilities (water/sewer/gas). In addition, the GHIB project will reduce the footprint of the station and encumber egress from the station. Consequently, this project will impact future expansion work at the station and possibly limit the extent to which the station can be developed relative to its ultimate plan development over the long term.

7.4.2 Recommended Plan and Current Status

In order to mitigate these impacts, as illustrated in Figure 7-3 below, additional real estate is required for future expansion to the north of McKee Rd. The existing transmission lines and feeders will also need to egress the station via underground cables so as not to interfere with the bridge operations.

The cost of this project will be fully recovered from the Windsor Detroit Bridge Authority (WDBA). A Transmission Assets Modification Agreement (TAMA) with the WDBA is expected to be finalized by early January 2016. Approvals for executing the project are expected by March 2016 for a planned in-service date by the end of 2018.

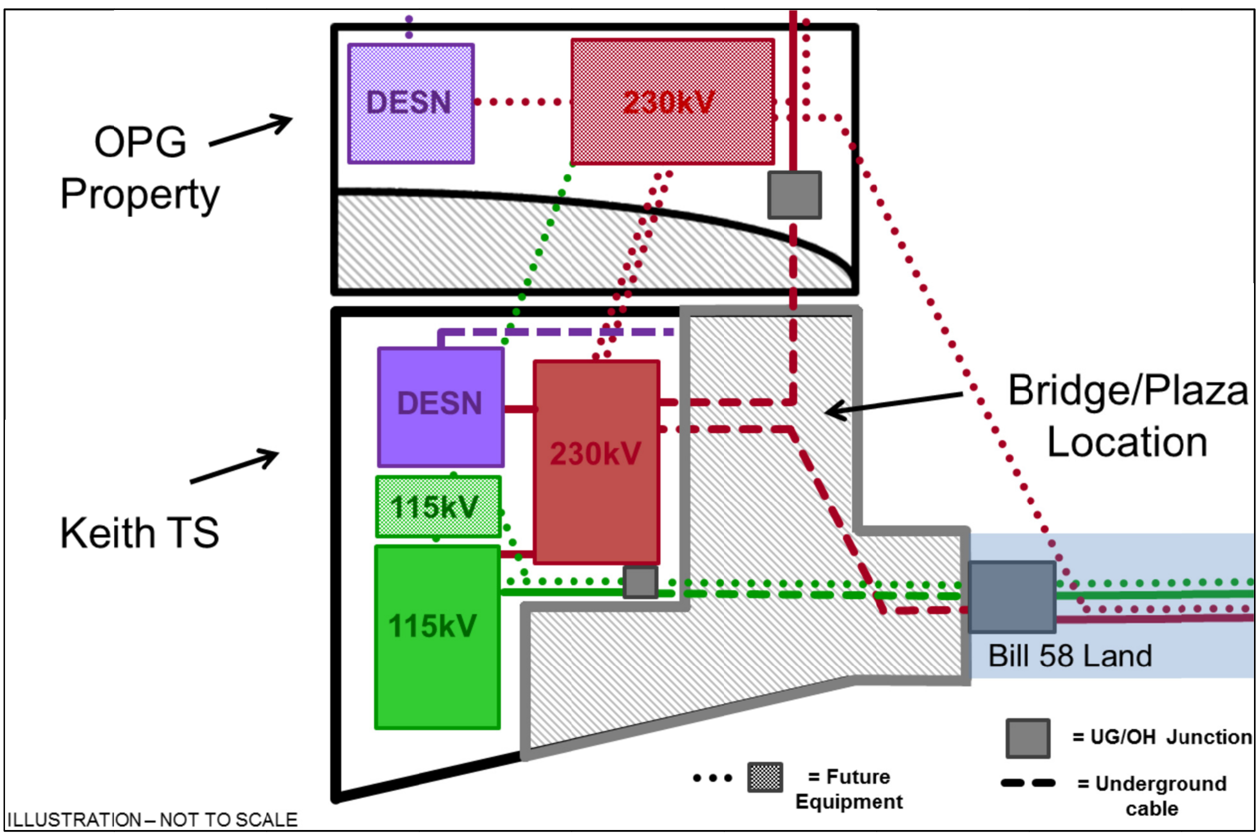

Figure 7-3 Gordie Howe International Bridge (GHIB) Project

8. OTHER PROJECTS

There are other wires projects that are currently under development and pending decision in the Windsor-Essex Region. These projects are local in nature and being planned and developed by Hydro One and relevant LDC as discussed below.

8.1 Malden TS Additional Feeder Positions

8.1.1 Description

Due to the load increase that's expected from the planned Detroit River International Crossing work and local highway construction, Essex Power has identified a need for two additional 28 kV feeder positions to be constructed at Malden TS.

The Malden transformer station is currently equipped with two 75/125 MVA transformers, 12 feeder positions and two capacitor banks and this plan involves expanding the station to 14 feeders. The two transformers at Malden TS were recently replaced, and there is additional capacity available at the station to meet the load requirement of the customer.

Based on a preliminary estimate the following will be the cost for the different layouts:

- Installation of two 28kV feeder breaker positions with feeder tie with underground feeder egress to outside station fence by 1 meter. Estimated cost of about $1.1M
- Installation of one 28kV feeder breaker position with no feeder tie with underground feeder egress to outside station fence by 1 meter. Estimated cost of about $875k
- Installation of one 28kV feeder breaker position with a break before make connection to alternate bus with underground feeder egress to outside station fence by 1 meter. Estimated cost of about $925k

8.1.2 Recommended Plan and/or Current Status

The above options have been provided to Essex Powerlines Corp. Hydro One is awaiting its decision on the preferred option expected to be made in 2016.

8.2 Tilbury TS Transformer End-of-Life Replacement

8.2.1 Description

Tilbury West HVDS and Tilbury TS are both supplied from 115 kV circuit K2Z and are adjacent to each other. The two stations supply the Town of Tilbury and surrounding area. Tilbury West HVDS consists of 2 x 15/20/25 MVA, 115/27.6 kV transformers of 1980's vintage with two feeder positions; and Tilbury TS consists of 1 x 6/8 MVA 115/27.6 kV transformer of 1950's vintage with one feeder position. The

2014 peak load at Tilbury TS was 1.0 MW, and 16 MW at Tilbury West HVDS. The future load levels over the next 10 years at these stations are not expected to grow significantly.

Tilbury TS is near its end-of-life, and a decision to replace or retire should be made by 2017. Following three options are under consideration for Tilbury TS:

(1) Transfer Tilbury TS load (M1 feeder) to Tilbury West DS and decommission Tilbury TS at a cost of about $1.7M. This option is feasible as there is sufficient capacity at Tilbury West HVDS to accommodate both the Tilbury West HVDS forecast load and the Tilbury TS forecast load into the long term. Further, Tilbury West HVDS has sufficient capacity to accommodate its existing DG connections plus the existing 5 MW solar DG currently connected to Tilbury TS.

(2) Refurbish Tilbury TS at a cost of about $5M. This option would retain the supply capacity level and supply diversity that currently exists.

(3) Build a new DESN station at Tilbury TS with dual 115kV circuit supply from the K2Z and K6Z for an expected cost of about $20M. This would include building the 115kV line out from Tilbury Junction to the TS and a complete new station.

8.2.2 Recommended Plan and Current Status

Option 1 is the least cost alternative. It is recommended that Hydro One will have further discussions with the LDCs regarding these options and associated costs. These discussions are expected in 2016, and a decision is expected to be made by no later than 2017. Project construction is planned to commence in 2018 for an expected in-service in 2019. Depending on the option selected, costs may have to be recovered from the LDCs consistent with the TSC.

8.3 Keith TS T1 Transformer End-of-Life Replacement

8.3.1 Description

Keith TS transformer T1 (25/33/42 MVA 115/27.6 kV) is of 1950's vintage and it is approaching end-of-life. EnWin is the only LDC supplied from this Keith T1 and exclusively serves a single customer Nemak. The peak load was 8 MW in 2014. The load growth is expected to remain at this level in the long-term.

There is sufficient capacity at the Keith DESN station to accommodate both the forecast at Keith DESN load plus the forecast Keith TS T1 load over the next 10 years.

Following three possible options are considered to address the end-of life issue for Keith TS T1:

(1) Replace Keith TS T1.
(2) Transfer Keith TS T1 load to Keith T22/T23 DESN station.
(3) Resupply Nemak from another EnWin feeder connected to Keith T22/T23 DESN.

8.3.2 Recommended Plan and Current Status

It is recommended to develop cost estimates for each of the option. Following that Hydro One will initiate discussions with EnWin to review the options and decide on a preferred option.

Cost estimates are expected in Q1 of 2016 and selection of a preferred option is expected before the end of 2016. Discussions will then ensue with Hydro One and EnWin regarding planned construction dates.

9. CONCLUSION

THIS REGIONAL INFRASTRUCTURE PLAN REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE WINDSOR-ESSEX REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report provides a single consolidated source of information for infrastructure plans in the Windsor-Essex Region. It develops and outlines a plan for investments in transmission and/or distribution facilities to meet the electricity needs within the region. The RIP report was developed in collaboration of a Technical Working Group consisting of representation from the LDCs in the region, the IESO, and led by Hydro One consistent with the requirements set out in the TSC, DSC and the PPWG report.

This report highlights several near-term needs in the region for which implementation plans have already been developed and are planned for completion in the next five years. Table 9-1 provides a status of these projects along with their cost and timelines. Projects requiring further planning on scoping and pending decisions on the preferred alternative are provided in Table 9-2. Over the next five years, the total transmission and distribution investments associated with these projects is approximately $215M - $225M.

Table 9-1 Project Under Development

Project/Plan	Cost	I/S	Performed by
Supply to Essex County Transmission Reinforcement “SECTR TX”	$77.4 Million	March 2018	Hydro One
Supply to Essex County Transmission Reinforcement “SECTR DX”	$19.3 Million	March 2018 (first stage)	Hydro One Distribution
Replacement of Keith end-of-life autotransformers	$45 Million	2020	Hydro One
Replacement of Kingsville end-of-life transformers	$12 Million	2018	Hydro One
230kV/115kV circuit and 27.6kV feeder reconfiguration at Keith TS due to Gordie Howe International Bridge (GHIB) Project	$63 Million	October 2018	Hydro One
Transformer replacement and station refurbishment at Crawford TS	$8.46 Million	December 2016	Hydro One

Table 9-2 Project Pending Decision

Project/Plan	Cost	I/S	Performed by
Additional feeder position at Malden TS	TBD	TBD	Hydro One
Replacement of Tilbury end-of-life transformer	TBD	2019	Hydro One
Keith TS end-of-life T1 Transformer	TBD	TBD	Hydro One

There are no long-term needs in this region that requires plans to be developed at this time. As with any region, the Windsor-Essex Region is monitored as part of Hydro One and LDC operations. Should there be a need that emerges earlier due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

Tillsonburg Hydro Inc.	Stephen Gradish
Woodstock Hydro Services Inc.	Jay Heaman
Hydro One Networks Inc. (Distribution)	Alexander Hamlyn

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the London Area and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	London Area		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	February 2, 2015	**END DATE**	April 3, 2015

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the London Area and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the London Area was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is completed and has been initiated for Group 2 Regions. The London Area belongs to Group 2. The NA for the London Area was triggered on January 30, 2015 and was completed on March 31, 2015.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was conducted for the next 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2023.

Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning.

This NA included a review of transmission system connection facilities capability, which covers station and line loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the IESO, and Hydro One Transmission provided information for the London Area. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life. In this region, asset utilization is at the capacity threshold even when LDCs CDM forecast is taken into account. Accordingly, further assessment is required to determine possible targeted CDM activities by feeders and station(s) to ensure CDM will meet load reduction forecasts. See Section 4 for further details.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs in the London Area over the study period (2014 to 2023). The assessment reviewed available information and load forecasts and included single contingency analysis to confirm needs, if and when required. See Section 5 for further details.

6. RESULTS

Transmission Capacity Needs

A. 230/115 kV Autotransformers

- The 230/115 kV autotransformers (Buchanan TS and Karn TS) supplying the London Area are adequate over the study period for the loss of a single 230/115 kV autotransformer.

B. 230 kV Transmission Lines

- The 230 kV circuits supplying the London Area are adequate over the study period for the loss of a single 230 kV circuit.
- Under high eastwardly flows and or high generation conditions, W44LC, W45LS, N21W, N22W and S47C may be overloaded under pre-contingency conditions. This issue will be further assessed by IESO as part of bulk system planning.

C. 115kV Transmission Lines

- The 115 kV circuit W8T reaches its continuous rating pre-contingency in 2014 based on the gross load forecast.
- The remaining 115 kV circuits supplying the London Area are adequate over the study period for the loss of a single 115 kV circuit.

D. 230 kV and 115 kV Connection Facilities

- Loadings at Aylmer TS, Strathroy TS and Wonderland TS exceed their transformer 10-Day Long Term Rating (LTR) in 2014 based on the net load forecast. The limitation at Aylmer TS will be addressed through the currently planned sustainment investment. Tillsonburg TS is forecasted to exceed its 10-Day LTR by the end of near term. Clarke TS is forecasted to exceed its 10-Day LTR in 2014 based on the gross load forecast, but is expected to be adequate to meet the net load forecast for the remainder of the study as planned CDM targets and DG contributions continue to offset the load growth.
- Historical data shows that Buchanan DESN power factor may be below Ontario Resource and Transmission Assessment Criteria under peak load conditions.

System Reliability, Operation and Restoration Review

Based on the net and gross load forecast, the 115 kV voltages at Tillsonburg TS were found to be less than minimum requirements under pre-contingency conditions in the near term.

Based on the gross and net load forecast, the loss of one element will not result in load interruption greater than 150MW in the London Region. The maximum gross and net load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period.

For the loss of two elements on the 230kV system, the gross and net load interrupted by configuration at peak conditions will exceed 150 MW and 250 MW.

Under peak load conditions with the Buchanan 115 kV capacitor in-service, the 115 kV voltage reaches its maximum limit. Accordingly, switching in any additional 230 kV capacitors at Buchannan becomes challenging. This is an operational issue and will be discussed between IESO and Hydro One.

Aging Infrastructure / Replacement Plan

During the study period, plans to replace or add equipment do not affect the needs identified.

7. RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends that:

a) The following needs should be further assessed as part of the Scoping Assessment to determine if CDM/DG can fully or partly address them or wires planning should be undertaken:

- Transformation capacity limitations at Strathroy TS, Tillsonburg TS, Wonderland TS, Clarke TS and Talbot TS
- Thermal and voltage limitations along the 115kV circuit W8T
- Load restoration concerns following the loss of two elements as described in section 6.2

b) No further regional coordination is required and following needs should be further assessed as part of local planning :

- Low power factor at Buchanan DESN

TABLE OF CONTENTS

List of Figures and Tables

1 INTRODUCTION

This Needs Assessment (NA) report provides a summary of needs that are emerging in the London Area between 2014 – 2023. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the London Area to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. The SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs.

This report was prepared by the London Area NA study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, and the IESO.

Table 1: Study Team Participants for London Area

10.	Hydro One Networks Inc. (Distribution)

2 REGIONAL ISSUE / TRIGGER

The NA for the London Area was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The London Area belongs to Group 2. The NA for this area was triggered on January 30, 2015 and was completed on March 31, 2015.

3 SCOPE OF NEEDS ASSESSMENT

This NA covers the London Area over an assessment period of 2014 to 2023. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station and line thermal capacity and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

3.1 London Area Description and Connection Configuration

The London Area includes the municipalities of Oxford County (comprising Township of Blandford-Blenheim, Township of East Zorra-Tavistock, Town of Ingersoll, Township of Norwich, Township of South-West Oxford, Town of Tillsonburg, Township of Zorra), City of Woodstock, Middlesex County (comprising Municipality of Adelaide Metcalfe , Municipality of Lucan Biddulph, Municipality of Middlesex Centre, Municipality of North Middlesex, Municipality of Southwest Middlesex, Municipality of Strathroy-Caradoc, Municipality of Thames Centre, Village of Newbury), City of London, Elgin County (comprising Municipality of Town of Aylmer, Municipality of Bayham, Municipality of Central Elgin, Municipality of West Elgin, Municipality of Dutton/Dunwich, Township of Malahide, Township of Southwold), City of St. Thomas. In addition, the facilities located in the London Region supply part of Norfolk County. The boundaries of the London Area are shown below in Figure 1.

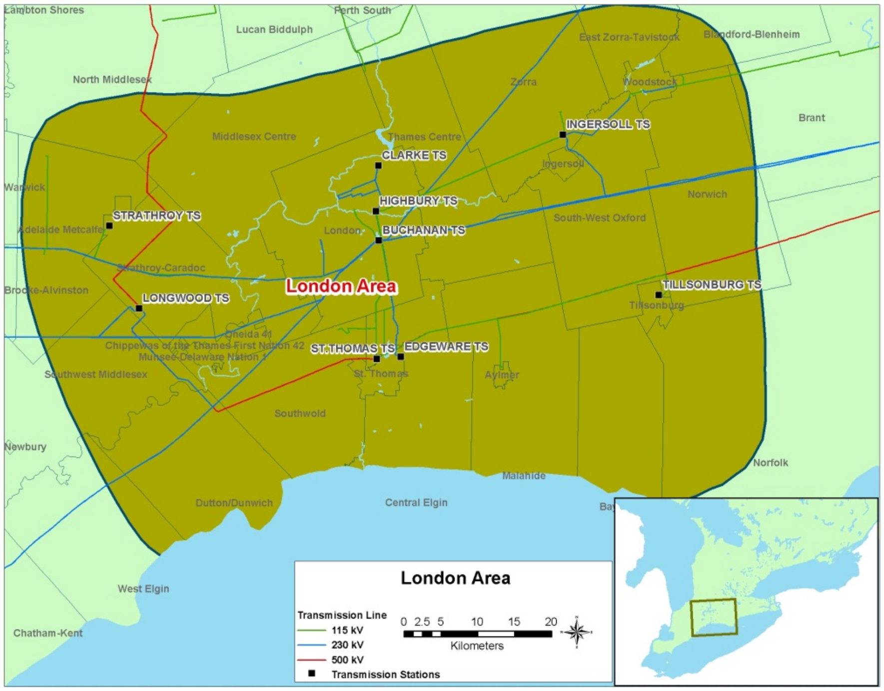

Figure 1: London Area Map

Electrical supply to the London Area is provided through a network of 230 kV and 115 kV circuits supplied by 500/230 kV autotransformers at Longwood Transformer Station (TS) and 230/115 kV autotransformers at Buchanan TS and Karn TS. There are fourteen Hydro One step-down TS's, four direct transmission connected load customers and three transmission connected generators in the London Area. The distribution system consists of voltage levels 27.6 kV and 4.16kV.

The existing facilities in the London Area are summarized below and depicted in the single line diagram shown in Figure 2. The 500kV system is part of the bulk power system and is not studied as part of this Needs Assessment. Also, although depicted, Duart TS is not included in the London Area study and will be studied as part of the Chatham Area Regional Infrastructure Plan.

- Longwood TS is the major transmission station that connects the 500kV network to the 230kV system via two 500/230 kV autotransformers.
- Buchanan TS and Karn TS are the transmission stations that connect the 230kV network to the 115kV system via 230/115 kV autotransformers.
- Fourteen step-down transformer stations supply the London Area load: Aylmer TS, Buchanan TS, Clarke TS, Commerceway TS, Edgeware TS, Highbury TS, Ingersoll

TS, Nelson TS, Strathroy TS, St. Thomas TS, Talbot TS, Tillsonburg TS, Wonderland TS, and Woodstock TS.

- Four Customer Transformer Stations (CTS) are supplied in the London Area: Ford Talbotville CTS, Enbridge Keyser CTS, Lafarge Woodstock CTS, and Toyota Woodstock CTS.

- There are 3 existing Transmission connected generating stations in the London Area as follows:
    - Suncor Adelaide GS is a 40 MW wind farm connected to 115 kV circuit west of Strathroy TS
    - Port Burwell GS is a 99 MW wind farm connected to 115kV circuit near Tillsonburg TS
    - Silver Creek GS is a 10 MW solar generator connected to 115kV circuit near Aylmer TS

- There are a network of 230 kV and 115 kV circuits that provide supply to the London Area, as shown in Table 2 below:

Table 2: Transmission Lines in London Area

Voltage	Circuit Designations	Location
230 kV	N21W, N22W	Scott TS to Buchanan TS

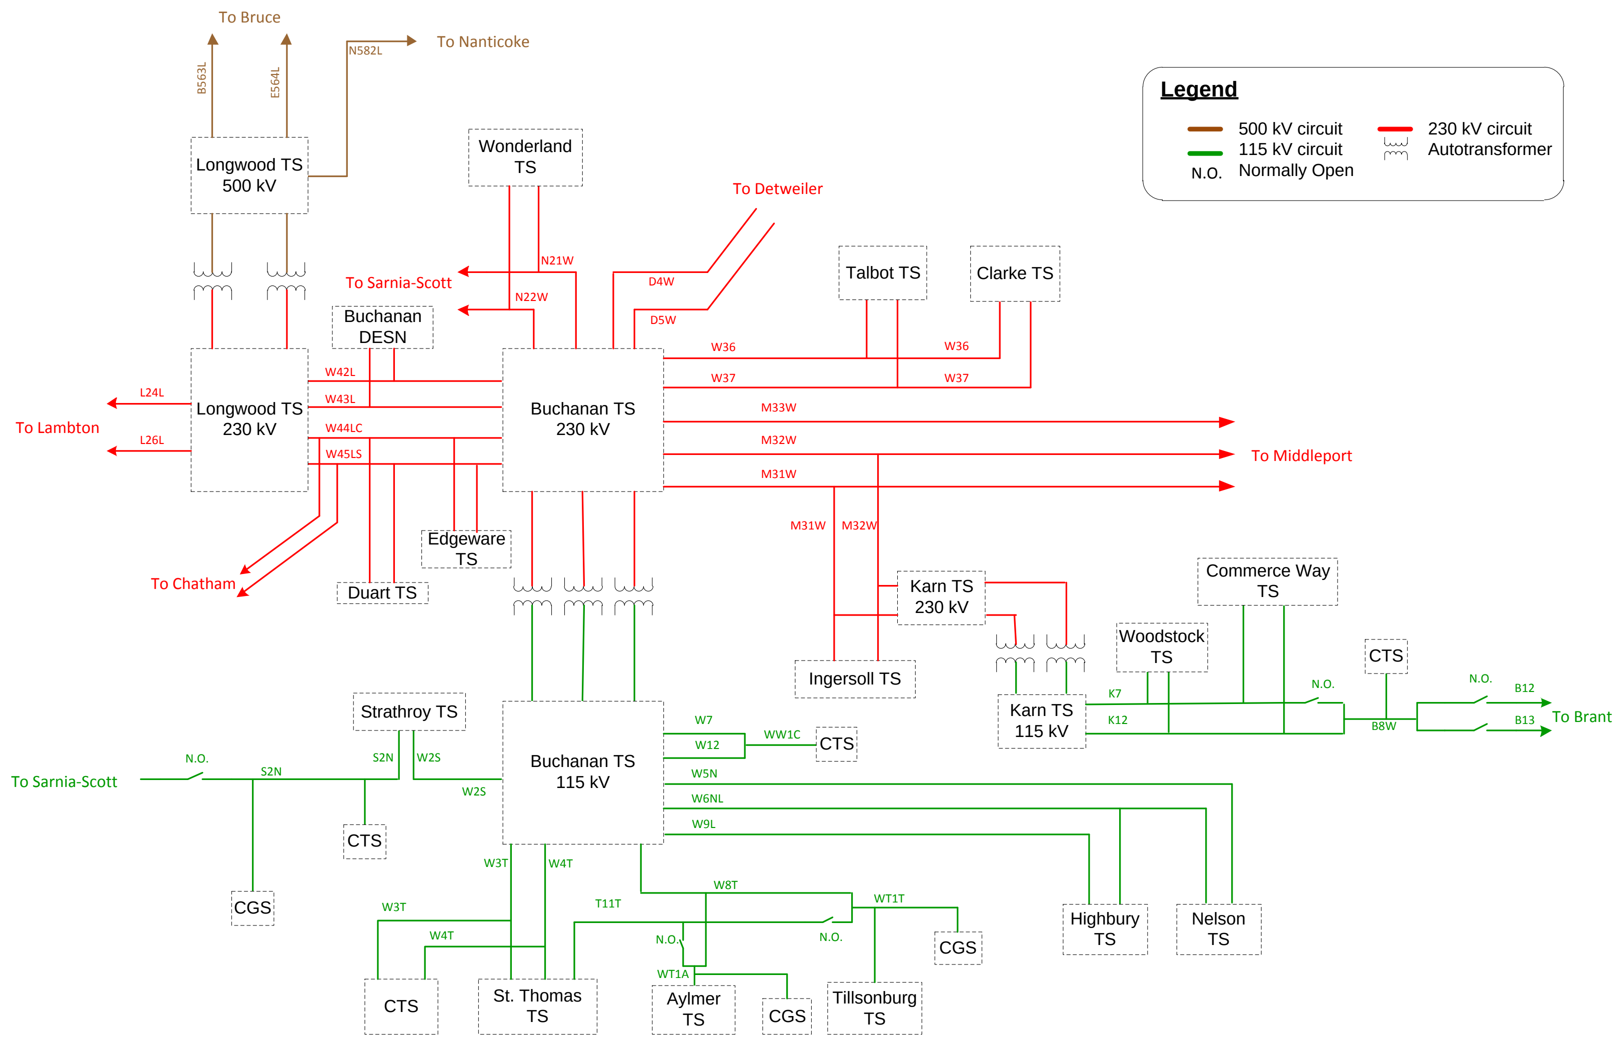

Figure 2: Single Line Diagram – London Area

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information and data to Hydro One:

- IESO provided:
    i. Historical 2013 regional coincident peak load and station non-coincident peak load
    ii. List of existing reliability and operational issues
    iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2011-2013) net load, and gross load forecast (2014-2023)
- Hydro One (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

4.1 Gross Load Forecast

The gross load forecast describes the total forecast electrical consumption in the area without considering the combined impact of CDM and DG. As per the data provided by the study team, the gross load in the London Area is expected to grow at an average rate of approximately 0.9% annually from 2014 – 2023.

4.2 Net Load Forecast

The net load forecast builds from the gross load forecast and includes the planned CDM targets and DG contributions. For the London Area, the net load is expected to grow at an average rate of approximately 0.2% annually from 2014 – 2023.

5 NEEDS ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The assessment is based on summer peak loads.

2. Load data for transmission connected industrial customers in the region was assumed to be consistent with historical peak loads.

3. The LDC's load forecast is translated into load growth rates and is applied onto the 2013 summer peak load as a reference point.

4. Accounting for (2) and (3) mentioned above, the gross load forecast and a net load forecast were developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast which accounts for CDM and DG is analyzed to determine if needs can be deferred.

   A coincident version of the gross and net load forecast was used to assess the transformer capacity needs (section 6.1.1), 230 kV transmission line needs (section 6.1.2), 115 kV transmission line needs (6.1.3) and system reliability operation and restoration needs (6.2).

   A non-coincident version of the net load forecast was used to assess the station capacity as presented in section 6.1.4.

   A coincident peak load forecast and a non-coincident peak load forecast were produced for each gross load and net load forecasts.

5. Review impact of any on-going and/or planned development projects in the London Area during the study period.

6. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.

7. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer 10-Day Limited Time Rating (LTR).

8. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.

9. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:

- With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
- With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings and transformers within their summer or winter 10-Day LTR, as appropriate.
- All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) (Section 4.2) criteria.
- With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
- With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC (Section 7.2) criteria.

6 RESULTS

This section summarizes the results of the Needs Assessment in the London Area.

6.1 Transmission Capacity Needs

6.1.1 230/115 kV Autotransformers

The 230/115 kV autotransformers (Buchanan TS and Karn TS) supplying the London Area are adequate over the study period for the loss of a single 230/115 kV autotransformer.

6.1.2 230 kV Transmission Lines

Overall, the 230 kV circuits supplying the London Area are adequate over the study period for the loss of a single 230 kV circuit in the Region.

Under high eastwardly flows and/or high generation conditions, W44LC, W45LS, N21W, N22W and S47C may be overloaded under pre-contingency conditions. This issue will be further assessed by IESO as part of bulk system planning.

6.1.3 115 kV Transmission Lines

The 115 kV circuit W8T from Buchanan TS to Edgeware JCT reaches its continuous rating under pre-contingency conditions in the near term based on the gross load forecast. Such thermal overload is deferred to the medium term based on the net load forecast. In addition, the 115kV system is also restricted for any new DG connections at Tillsonburg TS because of capacity limitation.

The remaining 115 kV circuits supplying the London Area are adequate over the study period for the loss of a single 115 kV circuit in the area.

6.1.4 230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and 115 kV TSs in the London Area using the summer station peak load forecasts provided by the study team. The results are as follows:

Aylmer TS
Aylmer TS T2/T3 is forecasted to exceed its 10-Day LTR in 2014 based on the net load forecast (approximately 113% Summer 10-Day LTR in 2014).

Buchanan TS

Historical data shows that Buchanan DESN power factor is below ORTAC criteria under peak load conditions.

Clarke TS

Clarke TS T3/T4 exceeds its 10-Day LTR in 2014 based on the net load forecast (approximately 101% of Summer 10-Day LTR). Although based on the planned CDM targets and DG contributions, the station capacity for Clarke TS T3/T4 is adequate to meet the net forecasted demand over the remainder of the study period, loading at Clarke TS is above its LTR based on gross load.

Strathroy TS

Strathroy TS T1/T2 is forecasted to exceed its 10-Day LTR in 2014 based on the net load forecast (approximately 125% of Summer 10-Day LTR in 2014)

Talbot TS

Talbot TS T1/T2 and T3/T4 DESN is near its 10-Day LTR rating in the near term based on the net load forecast and is above its LTR based on gross load. The load forecast for Talbot TS increases significantly in year 2015 by 17MW based on the ongoing planning activities of the LDC to convert and transfer Nelson TS load to Talbot TS to accommodate the redevelopment plans of Nelson TS. The load transferred to Talbot TS in 2015 is temporary in nature, and will be transferred back to Nelson TS when the redevelopment is expected to be complete in 2019.

Tillsonburg TS

For the loss of T3, Tillsonburg TS T1 is forecasted to exceed its 10-Day LTR towards the end of the near term based on the net load forecast (approximately 102% of Summer 10-Day LTR in 2018) and is above its LTR based on gross load

Wonderland TS

For the loss of T6, Wonderland TS T5 is forecasted to exceed its 10-Day LTR 2014 based on the net load forecast (approximately 112% of Summer 10-Day LTR in 2014).

All the other TSs in the London Area are forecasted to remain within their normal supply capacity during the study period.

6.2 System Reliability, Operation and Restoration Review

Based on the net load forecast, the pre-contingency voltage at Tillsonburg TS 115kV is expected to be less than the minimum voltage level as established in Section 4.3 of the ORTAC.

Under peak load conditions with the Buchanan 115 kV capacitor in-service, the 115 kV voltage reaches its maximum limit. Accordingly, switching in any additional 230 kV capacitors at Buchannan becomes challenging. This is an operational issue and will be discussed between IESO and Hydro One.

Based on the gross and net coincident load forecast, the loss of one element will not result in load interruption greater than 150MW in the London Region. The maximum gross and net load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period.

Based on the gross coincident load forecast at Buchanan TS, the load interrupted by configuration will exceed 150 MW for the loss of double-circuit line W42L and W43L. However, based on the net coincident load forecast, which accounts for CDM and DG, the load interrupted by configuration does not exceed 150 MW. Therefore, no action is required at this time and this will be reviewed in the next planning cycle.

Based on the gross and net coincident load forecast for Ingersoll TS and stations connected along the 115 kV circuits K7/K12/B8W, the load interrupted by configuration at peak will exceed 150 MW for the loss of double-circuit 230kV line M31W and M32W. Similarly, based on the gross and net coincident load forecast at Clarke TS and Talbot TS, the load interrupted by configuration will exceed 250 MW for the loss of double-circuit 230kV line W36 and W37. Furthermore, based on the gross and net coincident load forecast at Wonderland TS and Modeland TS, the load interrupted by configuration will exceed 150 MW for the loss of double-circuit 230kV line N21W and N22W.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Hydro One reviewed the sustainment and development initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables. These sustainment plans do not affect the results of this NA study. During the study period:

- The existing Aylmer TS will be replaced with a new DESN with two 25/33.3/41.7 MVA transformer and four feeder positions and is scheduled to be completed in 2019. The replacement plan will address the transformer capacity need identified in section 6.1.4.
- The existing Nelson TS DESN will be redeveloped to maintain supply to the area. Final arrangement will depend on the ongoing discussions between the Hydro One and the LDC. This NA study assumes the LDC's plan to redevelop Nelson TS and convert the station LV from 13.8kV to 27.6kV.

- As part of the Burlington-Nanticoke Area Regional Infrastructure Planning, there is an ongoing plan to replace existing switches on B12/B13 with 115 kV breakers to address the voltage and capacity issue in the Brant area. This project will allow the existing normally-open points on B12/B13 to be operated normally-closed. The breakers cause no adverse impacts to the London Region. As the project is still in its planning phase, the ability to provide backup to the Woodstock area has not yet been confirmed.

7 RECOMMENDATIONS

Based on the findings and discussion in Section 6 of the Needs Assessment report, the study team recommends that the following needs should be further assessed as part of the Scoping Assessment to determine if CDM/DG can fully or partly address them or Wires Planning should be undertaken:

- Transformation capacity limitations at Strathroy TS, Tillsonburg TS, Wonderland TS, Clarke TS and Talbot TS
- Thermal and voltage limitations along the 115kV circuit W8T
- Load restoration concerns following the loss of two elements as described in section 6.2

The following need should be further assessed as part of local planning by Hydro One and relevant LDCs:

- Low power factor at Buchanan DESN

8 NEXT STEPS

IESO and Hydro One will initiate a SA and Local Planning process to address the relevant needs as per the recommendations in Section 7.

Peterborough to Kingston Region

Regional Infrastructure Plan ("RIP")

July 8th, 2016

Kingston Hydro
Hydro One Networks Inc. (Distribution)

The Peterborough to Kingston Region includes Frontenac County, Hasting County, Northumberland County, Peterborough County, and Prince Edward County.

The Needs Assessment ("NA") report for the Peterborough to Kingston region was completed in February, 2015 (see attached). The report concluded that there were only two needs in the region and that they should be addressed as follows:

a) Transformation capacity relief for Gardiner TS T1/T2 DESN1: to be addressed by a Local Plan ("LP").
b) Loading constraints on circuit Q6S: to be addressed by Bulk System Planning and not as part of Regional Planning.

An LP was undertaken by Hydro One Networks Inc. (Transmitter), Hydro One Networks Inc. (Distribution) and Kingston Hydro to address the transformation capacity relief for Gardiner TS T1/T2 DESN1 . The LP recommended re-distributing the load at Gardiner TS by transferring one feeder from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2. The estimated cost of this project is approximately $1.5M. An LP report was prepared and published by the Working Group for the Peterborough to Kingston region in October, 2015 (also attached).

There are no other major development projects planned for the Peterborough to Kingston Region over the near and mid-term

Consistent with a process established by an industry working group[1] created by the OEB the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no further regional coordination was required, the attached NA and LP reports will be deemed to form the ("RIP") for the Sudbury/Algoma Region.

The next planning cycle for the region will take place within five years of the start of this cycle (2014) or earlier, should there be a new need identified in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Peterborough to Kingston Region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	Peterborough to Kingston Region (the “Region”)		
LEAD	Hydro One Networks Inc. (“Hydro One”)		
START DATE	December 12, 2014	**END DATE**	Feb 10, 2015

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the Peterborough to Kingston Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a “localized” wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the Peterborough to Kingston Region was triggered in response to the Ontario Energy Board’s (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario’s 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Peterborough to Kingston Region belongs to Group 2. The NA for this Region was triggered on December 12, 2014 and was completed on Feb 10, 2015.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to the next 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2023.

Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning.

This NA included a study of transmission system connection facilities capability, which covers station and line loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the IESO, and Hydro One transmission provided information for the Peterborough to Kingston Region. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life. See Section 4 for further details.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment’s primary objective was to identify the electrical infrastructure needs in the Region over the study period (2014 to 2023). The assessment reviewed available information and load forecasts and included single contingency analysis to confirm needs, if and when required. See Section 5 for further details.

6. RESULTS

Transmission Capacity Needs

A. 230/115 kV Autotransformers

- The 230/115 kV autotransformers (Dobbin TS and Cataraqui TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

B. 230 kV Transmission Lines

- The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.
- Under high Transfer East of Cherrywood and low water conditions in the east, P15C may be loaded near its continuous rating under pre-contingency conditions. This issue will be further assessed by the IESO as part of bulk system planning.

C. 115kV Transmission Lines

- With the loss of 230 kV circuit P15C, the 115 kV circuit Q6S may reach its LTE ratings in the near term based on the gross load forecast. The net load in the area is forecasted to decrease from 2014-2023 with the inclusion of DG and CDM. No action is required at this time and the capacity need will be reviewed in the next planning cycle.
- The remaining 115 kV circuits supplying the Region are adequate over the study period for the loss of a single 115 kV circuit in the Region.
- With the loss of 230 kV circuits P15C and C27P and expected load additional loading in Renfrew area in 2018, the circuit Q6S may be loaded beyond its LTE rating. This issue will be further assessed by the IESO as part of bulk system planning.

D. 230 kV and 115 kV Connection Facilities

- Gardiner TS T1/T2 DESN1 (summer peaking station) is forecasted to exceed its normal supply capacity from 2014 to 2023 based on the gross load forecast (approximately 112% and 117% of Summer 10-Day LTR in 2014 and 2023 respectively). However, based on the net load forecast with planned CDM targets and DG contributions, the station capacity for Gardiner TS T1/T2 DESN1 is adequate to meet the net forecasted load over the study period. It should be noted that Gardiner TS T3/T4 DESN2 is lightly loaded. Hydro One transmission will undertake an assessment of the need for load transfers as a local planning initiative and work with LDCs to develop a plan to balance load between the two DESNs

System Reliability, Operation and Restoration Review

Generally speaking, there are no significant system reliability and operating issues identified for this Region. Based on the gross coincident load forecast, the loss of one element will not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period.

For the loss of two elements, the load interrupted by configuration may exceed 150 MW based on the gross coincident load forecast. However, based on the net coincident load forecast, the load interrupted by configuration does not exceed 150 MW. No action is required at this time.

Aging Infrastructure / Replacement Plan

During the study period, plans to replace major equipment do not affect the needs identified.

7. RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends that

- "localized" wires only solutions be developed in the near-term to adequately and efficiently address the needs associated with transformation capacity relief for Gardiner TS T1/T2 DESN1 as indicated above through planning between Hydro One Networks Inc. and the impacted distributors. See Section 7 for further details, and
- IESO to assess loading constraints on circuit Q6S for the loss of two elements, and P15C under high transfers as part of their bulk system planning

TABLE OF CONTENTS

LIST OF FIGURES AND TABLES

1 INTRODUCTION

This Needs Assessment (NA) report provides a summary of needs that are emerging in the Peterborough to Kingston Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the Peterborough to Kingston Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. The SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs.

This report was prepared by the Peterborough to Kingston Region NA study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, and the IESO.

Table 1: Study Team Participants for Peterborough to Kingston Region

No.	Company
1.	Hydro One Networks Inc. (Lead Transmitter)
3.	Independent Electricity System Operator ("IESO")
4.	Kingston Hydro Corporation ("Kingston Hydro")
5.	Peterborough Distribution Inc. ("Peterborough Distribution")
6.	Veridian Connections Inc. ("Veridian")
7.	Hydro One Networks Inc. (Distribution)

2 REGIONAL ISSUE / TRIGGER

The NA for the Peterborough to Kingston Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Peterborough to Kingston Region belongs to Group 2. The NA for this Region was triggered on December 12, 2014 and was completed on Feb 10, 2015.

3 SCOPE OF NEEDS ASSESSMENT

This NA covers the Peterborough to Kingston Region over an assessment period of 2014 to 2023. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station and line thermal capacity and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

3.1 Peterborough to Kingston Region Description and Connection Configuration

The Peterborough to Kingston Region includes Frontenac County, Hasting County, Northumberland County, Peterborough County, and Prince Edward County. The boundaries of the Peterborough to Kingston Region are shown below in Figure 1.

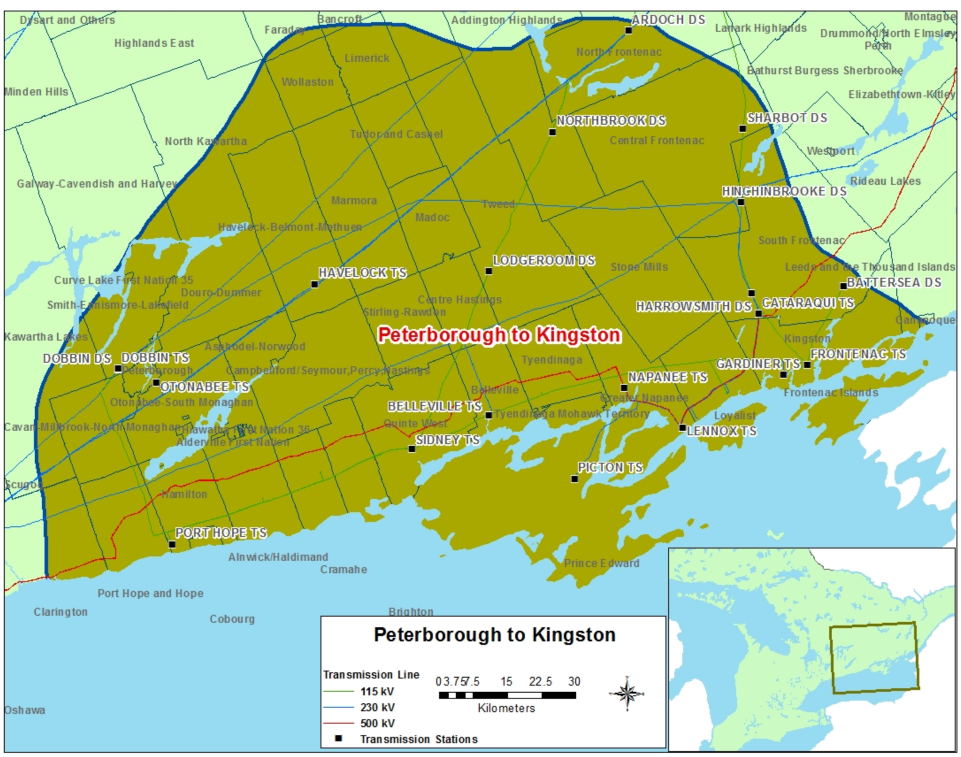

Figure 1: Peterborough to Kingston Region Map

Electrical supply to the Peterborough to Kingston Region is provided through a network of 230 kV and 115 kV circuits supplied by 500/230 kV autotransformers at Lennox Transformer Station (TS) and 230/115 kV autotransformers at Cataraqui TS and Dobbin TS. There are ten Hydro One step-down TS's, eight high voltage distribution stations (HVDS), and five other direct transmission connected load customers in the Region. The distribution system consists of voltage levels 44 kV, 27.6 kV, 12.5 kV, 8.32kV, and 4.16kV. The main generation facility in the Region is the 2000 MW Lennox Generation Station (GS) connected to Lennox TS.

The existing facilities in the Region are summarized below and depicted in the single line diagram shown in Figure 2. The 500kV system is part of the bulk power system and is not studied as part of this Needs Assessment:

- Lennox TS is the major transmission station that connects the 500kV network to the 230kV system via two 500/230 kV autotransformers.

- Cataraqui TS and Dobbin TS are the transmission stations that connect the 230kV network to the 115kV system via 230/115 kV autotransformers.

- Ten step-down transformer stations supply the Peterborough to Kingston load: Dobbin TS, Port Hope TS, Sidney TS, Picton TS, Otonabee TS, Havelock TS, Belleville TS, Napanee TS, Gardiner TS, and Frontenac TS. There are also eight HVDS that supply load in the Region: Dobbin DS, Ardoch DS, Northbrook DS, Lodgeroom DS, Hinchinbrooke DS, Harrowsmith DS, Sharbot DS, and Battersea DS.

- Five Customer Transformer Stations (CTS) are supplied in the Region: TransCanada Pipelines Cobourg CTS, TransCanada Pipelines Belleville CTS, Enbridge Pipelines Hilton CTS, Lafarge Canada Bath CTS, and Novelis CTS.

- There are 3 existing Transmission connected generating stations in the Region as follows:
    - Lennox GS is a 2000 MW natural gas-fired station connected to Lennox TS
    - NPIF Kingston GS is a 130 MW gas-fired cogeneration facility that connects to 230 kV circuits X1H and X2H near Lennox TS
    - Wolfe Island GS is a 198 MW wind farm connected to circuit X4H near Gardiner TS

- A 910 MW gas-fired plant (Napanee GS) is expected to connect to Lennox TS at the 500kV level in 2018.

- Up to 535 MW of additional transmission connected renewable generation could be in service in the Region by the year 2023.

- There are a network of 230 kV and 115 kV circuits that provide supply to the Region, as shown in Table 2 below:

Table 2: Transmission Lines in Peterborough to Kingston Region

Voltage	Circuit Designations	Location
230 kV	X1H, X2H, X3H, X4H	Hinchinbrooke SS to Lennox TS
	X21, X22	Picton TS to Lennox TS
	H23B	Belleville TS to Hinchinbrooke SS
	H27H	Hinchinbrooke SS to Havelock TS
	X1P	Dobbin TS to Chenaux TS

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information and data to Hydro One:

- IESO provided:
  i. Historical 2013 regional coincident peak load and station non-coincident peak load
  ii. List of existing reliability and operational issues
  iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2011-2013) net load, and gross load forecast (2014-2023)
- Hydro One (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

4.1 Gross Load Forecast

As per the data provided by the study team, the gross load in the Peterborough to Kingston Region is expected to grow at an average rate of approximately 0.4% annually from 2014-2023.

4.2 Net Load Forecast

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. The net load is expected to decrease at an average rate of approximately 0.6% annually from 2014-2023.

5 NEEDS ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The Region consists of both winter and summer peaking stations. Therefore, this assessment is based on both winter and summer peak loads, as appropriate.

2. Forecast loads are provided by the Region's LDCs. LaFarge Canada had provided a load forecast for LaFarge Canada CTS. Load data was not received by the other industrial customers in the region (Enbridge Pipeline Inc, TransCanada Pipeline Ltd.). For these stations, the load was assumed to be consistent with historical loads.

3. The LDC's load forecast is translated into load growth rates and is applied onto the 2013 summer/winter peak load as a reference point.

4. The 2013 summer/winter peak loads are adjusted for extreme weather conditions according to Hydro One's methodology.

5. Accounting for (2), (3), (4) above, the gross load forecast and a net load forecast were developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast which accounts for CDM and DG is analyzed to determine if needs can be deferred.

   A coincident version of the gross and net load forecast was used to assess the transformer capacity needs (section 6.1.1), 230 kV transmission line needs (section 6.1.2), 115 kV transmission line needs (6.1.3) and system reliability operation and restoration needs (6.2).

   A non-coincident version of the gross and net load forecast was used to assess the station capacity as presented in section 6.1.4.

   A coincident peak load forecast and a non-coincident peak load forecast were produced for each gross load and net load forecasts.

6. Review impact of any on-going and/or planned development projects in the Region during the study period.

7. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.

8. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer or winter 10-Day Limited Time Rating (LTR), as appropriate.

9. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.

10. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings and transformers within their summer or winter 10-Day LTR, as appropriate.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) (Section 4.2) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
    - With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC (Section 7.2) criteria.

6 RESULTS

This section summarizes the results of the Needs Assessment in the Peterborough to Kingston Region.

6.1 Transmission Capacity Needs

6.1.1 230/115 kV Autotransformers

The 230/115 kV autotransformers (Dobbin TS and Cataraqui TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

6.1.2 230 kV Transmission Lines

The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

Under high Transfer East of Cherrywood and low water conditions in Eastern Ontario, the 230 kV circuit P15C may be loaded near its continuous rating under pre-contingency conditions. This issue should be further assessed by the IESO as part of bulk system planning.

6.1.3 115kV Transmission Lines

With the loss of 230 kV circuit P15C, the 115 kV circuit Q6S from Invista Jct to Sidney TS may reach its LTE rating in the near term based on the gross load forecast. The net load forecast in the area is forecasted to decrease from 2014-2023 with the inclusion of DG and CDM. No action is required at this time and the capacity need will be reviewed in the next planning cycle.

With the loss of 230 kV circuits P15C and C27P and expected additional loading in the Renfrew region in 2018, the circuit Q6S may be loaded beyond its LTE rating. This issue should be further assessed by the IESO as part of bulk system planning.

The remaining 115 kV circuits supplying the Region are adequate over the study period for the loss of a single 115 kV circuit in the Region.

6.1.4 230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and 115 kV TSs and HVDSs in the Region using either the summer or winter station peak load forecasts as appropriate that were provided by the study team. The results are as follows:

Gardiner TS

Gardiner TS T1/T2 DESN1 (summer peaking station) is forecasted to exceed its normal supply capacity from 2014 to 2023 based on the gross load forecast (approximately 112% and 117% of Summer 10-Day LTR in 2014 and 2023 respectively). However, based on the planned CDM targets and DG contributions, the station capacity for Gardiner TS T1/T2 DESN1 is adequate to meet the net forecasted demand over the study period.

It should be noted that Gardiner TS T3/T4 DESN2 is lightly loaded. Hydro One transmission will undertake an assessment of the need for load transfers as a local planning initiative and work with LDCs to develop a plan to balance load between the two DESNs

All the other TSs and HVDSs in the Region are forecasted to remain within their normal supply capacity during the study period. Therefore, no action is required at this time and the capacity needs will be reviewed in the next planning cycle.

6.2 System Reliability, Operation and Restoration Review

Generally speaking, there are no significant system reliability and operating issues identified for this Region.

Based on the gross coincident load forecast, the loss of one element will not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period.

For the loss of circuits X2H and X4H, the load interrupted by configuration at Gardiner TS may exceed 150 MW based on the gross coincident load forecast. However, based on the net coincident load forecast, which accounts for CDM and DG, the load interrupted by configuration does not exceed 150 MW. Therefore, no action is required at this time and this will be reviewed in the next planning cycle.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables.

During the study period:

- Replacement (like-for-like) of both transformers (T1 and T2) at Gardiner TS DESN1 is scheduled in 2020. The replacement plan does not affect the results of this NA study.

- Replacement of two autotransformers, T2 and T5 (78 MVA and 115 MVA respectively), at Dobbin TS with a single 150/250 MVA autotransformer is scheduled in 2019. The third autotransformer (T1) will remain the same. The replacement plan does not affect the results of this NA study.

- There are no significant lines sustainment plans that will affect the results of this NA study.

7 RECOMMENDATIONS

Based on the findings and discussion in Section 6 of the Needs Assessment report, the study team recommends that no further coordinated regional planning is required.

Rather the study team recommends the following to address the identified needs:

a) Hydro One transmission will lead the assessment and develop a local plan ("Gardiner TS Load Balancing") with the relevant LDCs to balance load between the two DESNs at Gardiner TS; and,

b) IESO to assess and develop a plan for the contingencies associated with circuit Q6S for the loss of two elements and loading constraints on circuit P15C under high transfers within the context of a bulk planning study for the area.

8 NEXT STEPS

Hydro One Transmission and impacted LDCs will address the recommendation in Section 7a and develop a local plan.

IESO to initiate a bulk planning study for the area.

Hydro One Networks Inc. (Distribution)
Kingston Hydro (Embedded LDC)

DISCLAIMER

This Local Planning Report was prepared for the purpose of developing wires-only options and recommending a preferred solution(s) to address the local needs identified in the Needs Assessment (NA) report for the Peterborough to Kingston Region that do not require further coordinated regional planning. The preferred solution(s) that have been identified through this Local Planning Report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Local Planning Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Local Planning Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Local Planning Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Local Planning Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Local Planning Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

LOCAL PLANNING EXECUTIVE SUMMARY

REGION	Peterborough to Kingston (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	April 10, 2015	**END DATE**	October 7, 2015

1. INTRODUCTION

The purpose of this Local Planning (LP) report is to develop wires-only options and recommend a preferred solution that will address the local needs identified in the Needs Assessment (NA) report for the Peterborough to Kingston Region. The development of the LP report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

2. LOCAL NEED ADDRESSED IN THIS REPORT

The Needs Assessment (NA) report for the Peterborough to Kingston Region indicated that Gardiner TS T1/T2 DESN1 is forecasted to exceed its normal supply capacity in the near term. Gardiner TS T3/T4 DESN2 is lightly loaded. The local need addressed in this report will be how to best alleviate the station capacity issue at Gardiner TS T1/T2 DESN1.

3. ALTERNATIVES CONSIDERED

The alternatives considered were:

1) Transfer load from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN
2) Do Nothing

4. PREFERRED ALTERNATIVE

Transferring load from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2 is the preferred alternative as it addresses the station capacity issue at Gardiner TS T1/T2 DESN1. Transferring some of the existing load at Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2 is the most straight forward and cost effective option.

5. RECOMMENDATIONS

Hydro One Distribution will proceed with a detailed estimate for the load transfer work at Gardiner TS. The detailed estimate for the load transfer work is expected to be completed mid-2016. The expected in-service date for this work is end of 2018.

Table of Contents

1 Introduction

The Needs Assessment (NA) for the Peterborough to Kingston Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 and 2 Regions is complete and will be initiated for Group 3 Regions later this year. The Peterborough to Kingston Region belongs to Group 2. The NA for this Region was triggered on December 12, 2014 and was completed on Feb 10, 2015. The NA for the Peterborough to Kingston Region was prepared jointly by the study team, including Local Distribution Companies (LDC), Independent Electric System Operator (IESO), Ontario Power Authority (merged with IESO as of January 2015 and herein referred to as IESO), and Hydro One. The NA report can be found on Hydro One's Regional Planning website. The study team identified needs that are emerging in the Peterborough to Kingston Region over the next ten years (2014 to 2023) and recommended whether they should be further assessed through the transmitter-led Local Planning (LP) process or the IESO-led Scoping Assessment (SA) process.

This report was prepared by the Peterborough to Kingston Region LP study team (Table 1) and led by the transmitter, Hydro One Networks Inc. (Hydro One). The report captures the results of the assessment based on information provided by LDCs and Hydro One.

Hydro One Networks Inc. (Lead Transmitter)
Hydro One Networks Inc. (Distribution)
Kingston Hydro (Embedded LDC)

2 Regional Description

The Peterborough to Kingston Region includes Frontenac County, Hasting County, Northumberland County, Peterborough County, and Prince Edward County. Please refer to the NA Report for further details. The Peterborough to Kingston Region and its approximate boundaries are shown in Figure 1. The facilities in the Region are depicted in the single line diagram shown in Figure 2.

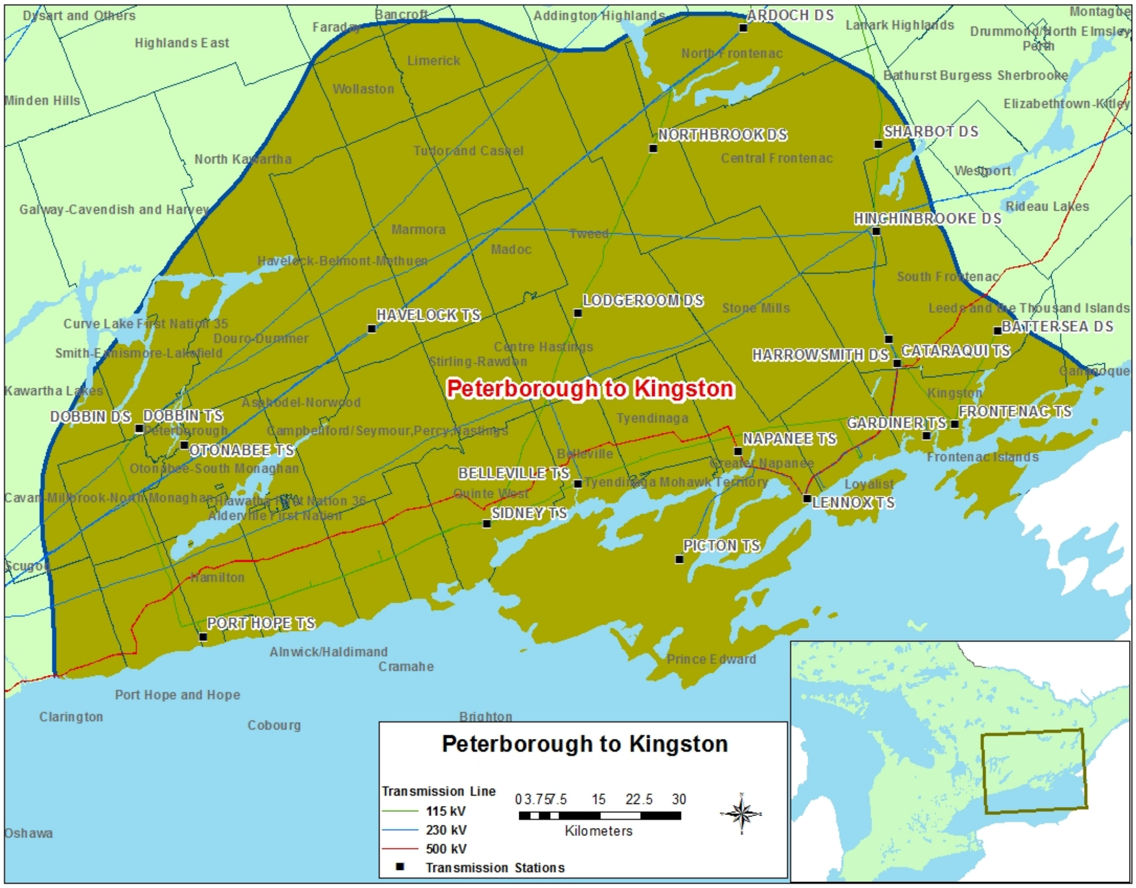

Figure 1: Peterborough to Kingston Region Map

5

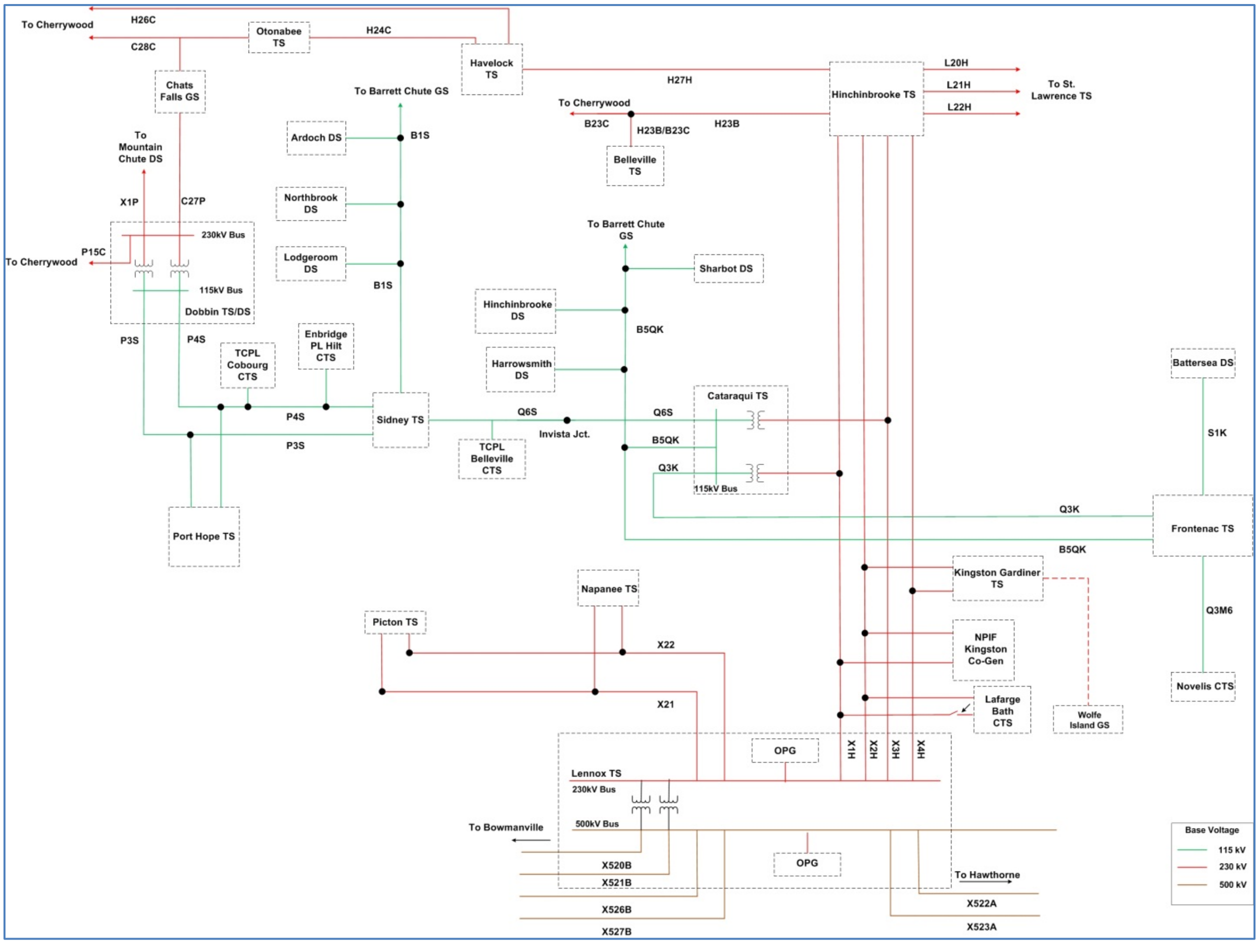

Figure 2: **Single Line Diagram – Peterborough to Kingston Region**

3 Peterborough to Kingston Region Needs

As an outcome of the NA process, the study team identified a need to address the normal supply capacity at Gardiner TS T1/T2 DESN1. Since this need can be clearly addressed by a straightforward wires solution, the study team agreed that it should be further planned directly by the impacted LDC and the transmitter through the LP process and that further coordinated regional planning was not required. Hydro One with the impacted LDCs further undertook planning assessments to develop options and recommend a wires only solution(s). Gardiner TS (230/44 kV)

3.1 Gardiner TS (230/44kV)

Gardiner TS T1/T2 DESN1 is forecasted to exceed its normal supply capacity from 2014 to 2023 based on the gross load forecast (approximately 112% and 117% of Summer 10-Day LTR in 2014 and 2023 respectively). However, based on the net load forecast which takes planned CDM targets and DG contributions into consideration, this issue will be avoided. Nevertheless, the station will still be loaded at 100% of its thermal capacity at that time. The load forecast provided by LDCs and the CDM and DG forecast provided by the IESO are attached in Appendix A.

4 Options Considered

This section describes the options considered to address the local need described in section 3.1.

4.1 Gardiner TS Load Balancing

Prior to the regional planning process, Hydro One Distribution had already planned on re-distributing the load at Gardiner TS by transferring one feeder from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2. This would alleviate the loading concerns at Gardiner TS T1/T2 DESN1 for this study period. The preliminary budgetary cost estimate for this project is about $1.5M.

4.2 Do Nothing

Do nothing is not a viable option since it could result in the violation of transformer ratings at Gardiner TS T1/T2 DESN1, which is not acceptable.

5 Recommendation

The study team agreed that transferring one feeder from Gardiner TS T1/T2 DESN1 to Gardiner TS T3/T4 DESN2 would relieve the thermal loading at Gardiner TS T1/T2 DESN1. This is a cost effective solution that will ensure that any additional load growth during the study period at Gardiner TS can be accommodated without exceeding the station thermal limit. Hydro One Distribution will be proceeding with the development of a plan to transfer the load along with a cost estimate for the work by the end of 2015. The expected in-service date for this feeder load transfer is end of 2018.

Veridian Connections Inc.	Craig Smith

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the South Georgian Bay/Muskoka Region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	South Georgian Bay/Muskoka Region		
LEAD	Hydro One Networks Inc.		
START DATE	January 2, 2015	**END DATE**	March 3, 2015

1. INTRODUCTION

The purpose of this Needs Assessment report is to undertake an assessment of the South Georgian Bay/Muskoka Region ("the Region") and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One Networks Inc. (HONI) and other parties as required.

For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE/TRIGGER

The Needs Assessment for the South Georgian Bay/Muskoka Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The Needs Assessment for Group 1 Regions is complete and has been initiated for Group 2 Regions. The South Georgian Bay/Muskoka Region belongs to Group 2 and the Needs Assessment for this Region was triggered on January 2, 2015 and was completed on March 3, 2015.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the Needs Assessment study was limited to the next 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2023.

Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA process, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning.

This Needs Assessment included a study of transmission system and connection facilities capability, which covers station and line loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the IESO and HONI transmission provided information for the Region. The information included historical load, load forecast, Conservation and Demand Management (CDM) and Distributed Generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful-life. See Section 4 of the report for further details.

5. ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs in the Region over the study period (2014 to 2023). The assessment reviewed available information and load forecasts, and included single contingency analysis to confirm needs, if and when required. See Section 5 of the report for further details.

6. RESULTS

Transmission Capacity Needs

A. 115/230kV Transmission Lines and Auto-Transformers

- With the 230/115kV auto-transformer T1 or T2 at Essa TS out-of-service, the companion transformer is expected to exceed its summer 10-Day Limited Time Rating (LTR) during the study period based on gross summer demand forecast. T1 is expected to exceed its summer 10-Day LTR in the near-term and T2 in the medium-term. The net summer demand forecast is not expected to significantly defer the need due to the high growth rate at Barrie TS.
- With one element out of service, the 115 kV circuit E3B is expected to exceed its summer Long-Term Emergency (LTE) rating in the near-term based on gross summer demand forecast. The net summer demand forecast is not expected to significantly defer the need due to the high growth rate at Barrie TS.

B. 115/230kV Transmission Stations

- Barrie TS is a summer peaking station and currently exceeds its normal supply capacity based on both gross and net summer demand forecast.
- Muskoka TS is a winter peaking station and will exceed its normal supply capacity in near-term based on both gross and net winter demand forecast.
- Parry Sound TS is a winter peaking station and currently exceeds its normal supply capacity based on both gross and net winter demand forecast.
- Midhurst TS T1/T2 DESN may exceed its normal supply capacity in the medium-term based on gross and net summer demand forecast if potential new commercial operations in the city of Barrie materialize.

System Reliability, Operation and Restoration Needs

Based on the gross and net coincident demand forecast, the loss of one element will not result in load interruption greater than the limit of 150MW. The loss of two elements will not result in load interruption greater than the limit of 600MW.

For the loss of two elements, based on gross and net region-coincident demand forecast the load interrupted by configuration may exceed 150MW and 250MW. The loss of 230kV circuits M6E+M7E may require some load to be restored within 4 hours and 30 minutes; the loss of 230kV circuits M80B+M81B may require some load to be restored within 4 hours; and the loss of 230kV circuits E8V+E9V may require some load to be restored within 4 hours during the study period. 230kV circuit M6E+M7E may not meet the 30 minutes restoration criteria. Further assessment is required.

Due to the increase generation within the Bruce Area, 115kV circuit S2S and Stayner T1 auto-transformer may be overloaded under pre-contingency conditions during high flow eastward from the Bruce Area. One possible solution would be to operate S2S open loop. This issue was identified by IESO as part of this assessment. Further assessment is required.

With Essa TS 500/230kV auto-transformer T3 or T4 out of service, the loss of the remaining 500/230kV Essa TS auto-transformer, may result in excessive post-contingency voltage declines under high loads conditions within the Essa area. This issue was identified by IESO as part of this assessment. Further assessment is required.

Aging Infrastructure / Replacement Plan

- Replacement of 115-44kV transformers (T1 and T2) at Barrie TS is scheduled for 2018.
- Replacement of 230-44kV transformers (T1 and T2) and possible rebuild of low voltage switchyard at Minden TS is scheduled for 2019.
- Replacement of dual windings 230-44/27.6kV transformers (T1 and T2) and associated low voltage equipment at Orangeville TS is scheduled for 2017.
- Ground clearance on several sections of the 230kV circuits M6E and M7E are planned to be increased in 2015. This may increase the current thermal rating of the lines.

7. RECOMMENDATIONS

Based on the findings of this Needs Assessment, the study team's recommendations are as follows.

Study team recommends that a Scoping Assessment should be undertaken to address the near-term transmission and system reliability, operation and restoration needs as listed in Section 6, taking into consideration where appropriate the aging infrastructure/replacement plans identified.

These near-term needs require coordinated regional planning and development of a regional and/or sub-regional plan as soon as possible. The Scoping Assessment will determine whether the IESO-led IRRP process and/or the transmitter-led RIP process (for wires solutions) should be further undertaken for one or more of these needs. The assessment may also recommend that local planning of wires only option between the transmitter and affected LDCs may be undertaken to address certain needs.

TABLE OF CONTENTS

LIST OF FIGURES AND TABLES

1 INTRODUCTION

This Needs Assessment report provides a summary of needs that are emerging in the South Georgian Bay/Muskoka Region ("the Region") over the ten-year period from 2014 to 2023. The development of the Needs Assessment report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements, and the Planning Process Working Group (PPWG) Report to the Board.

The purpose of this Needs Assessment report is to undertake an assessment of the South Georgian Bay/Muskoka Region to identify any near-term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One Networks Inc. (HONI), as transmitter, with Local Distribution Companies (LDCs) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. The SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs.

This report was prepared by the South Georgian Bay/Muskoka Region Needs Assessment study team (Table 1) and led by the transmitter, HONI. The report captures the results of the assessment based on information provided by LDCs, the OPA and the Independent Electricity System Operator (IESO).

2 REGIONAL ISSUE/TRIGGER

The Needs Assessment for the South Georgian Bay/Muskoka Region was triggered in response to the OEB's RIP process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The Needs Assessment for Group 1 Regions is complete and has been initiated for Group 2 Regions. The South Georgian Bay/Muskoka Region belongs to Group 2. The Needs Assessment for this Region was triggered on January 2, 2015 and was completed on March 3, 2015.

3 SCOPE OF NEEDS ASSESSMENT

This Needs Assessment covers the South Georgian Bay/Muskoka Region over an assessment period of 2014 to 2023. The scope of the Needs Assessment includes a review of transmission system connection facility capability which covers transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this Needs Assessment.

3.1 South Georgian Bay/Muskoka Region Description and Connection Configuration

The South Georgian Bay/Muskoka Region is the area roughly bordered by West Nipissing to the northwest, Algonquin Provincial Park to the northeast, Peterborough County and Hastings County to the southeast, Lake Scugog, York and Peel Regions to the south, Wellington County to the southwest and Grey Highlands to the west. The boundaries of the Region are shown in Figure 1 below.

Electrical supply to the Region is provided through two (2) 500/230kV auto-transformers at Essa TS, the 230kV transmission lines connecting Minden TS to Des Joachims TS, the 230kV circuits E8V and E9V coming from Orangeville TS, and the single 115kV circuit S2S connecting to Owen Sound TS. There are sixteen (16) HONI step-down transformer stations in the Region, most of which are supplied by circuits radiating out from Essa TS, and the majority of the distribution system is at 44kV, except for Orangeville TS which has 27.6kV and 44kV feeders.

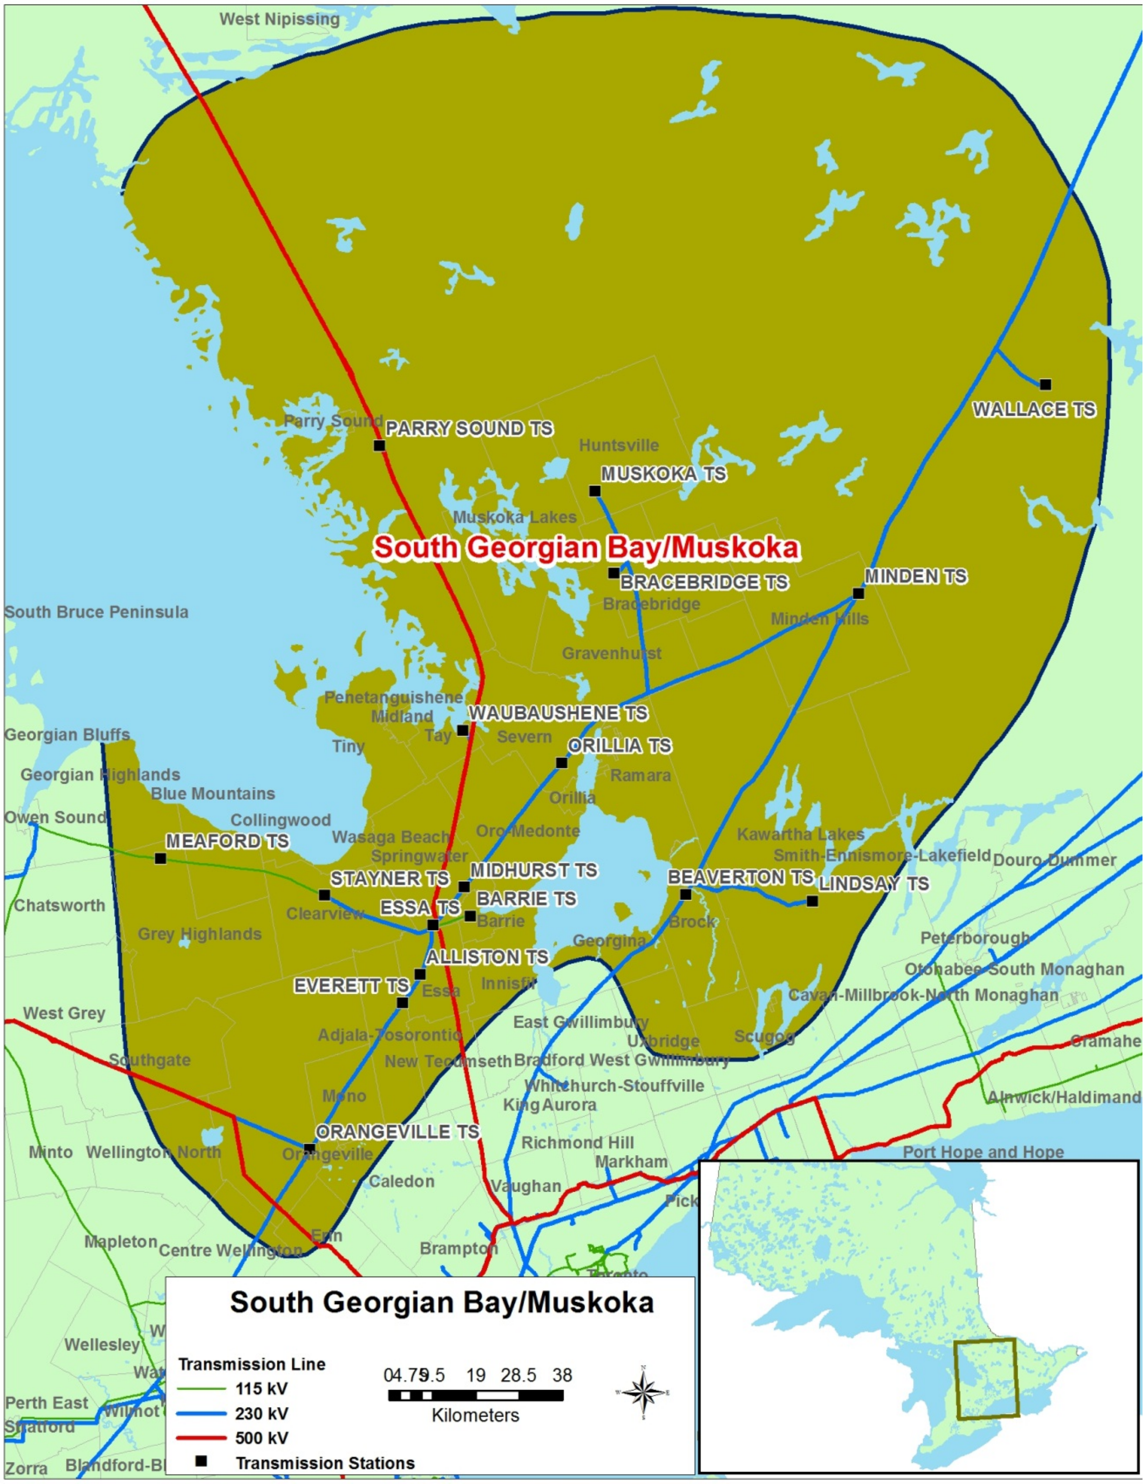

Figure 1: South Georgian Bay/Muskoka Region Map

The following circuits are not included in the South Georgian Bay/Muskoka Region:

- The 230kV circuits, B4V and B5V, and all stations which they supply. These circuits and stations are included in the Greater Bruce/Huron Region.

- The 230kV circuits, D6V and D7V, and all stations which they supply. These circuits and stations are included in the Kitchener/Waterloo/Cambridge/Guelph Region.

The existing facilities in the Region are summarized below and depicted in the single line diagram shown in Figure 2. The 500kV system is part of the bulk power system and is not studied as part of this Needs Assessment:

- Essa TS is the major transmission station that connects the 500kV network to the 230kV system via two 500/230kV auto-transformers. Essa TS also supplies the 115kV system towards Barrie TS via two 230/115kV auto-transformers.

- Eleven step-down transformer stations supply load to the north and east areas of the Region (north and east of Essa TS): Barrie TS, Beaverton TS, Bracebridge TS, Lindsay TS, Midhurst TS, Minden TS, Muskoka TS, Orillia TS, Parry Sound TS, Wallace TS, and Waubashene TS.

- Five step-down transformer stations supply load to the south and west areas of the Region (south and west of Essa TS): Alliston TS, Everett TS, Meaford TS, Orangeville TS, and Stayner TS.

- Eight 230kV circuits (E8V, E9V, E20S, E21S, E26, E27, M6E, and M7E) radiating outward from Essa TS provide local supply to the Region. These circuits are essential to the Region and will be included in the study to ensure long-term reliability. Four 230kV circuits (D1M, D2M, D3M, and D4M) entering the region from the east are also a major supply path for the Region and will be analyzed in this study.

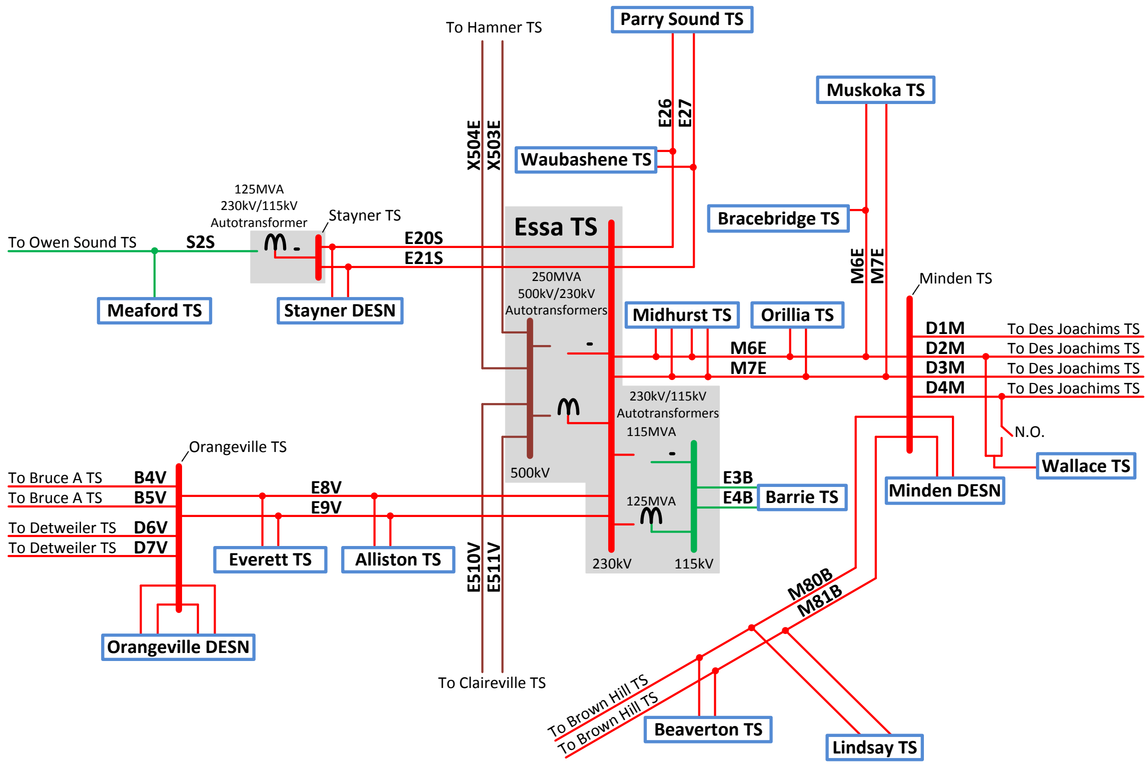

Figure 2: Single Line Diagram – South Georgian Bay/Muskoka Region

Table 2 below provides a list of LDCs in the South Georgian Bay/Muskoka Region.

Veridian Connections Inc.
Wasaga Distribution Inc.

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information and data to HONI:

- IESO provided:
    1. Historical 2013 regional coincident peak load and station non-coincident peak load
    2. List of existing reliability and operational issues
    3. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2011-2013) net load and gross load forecast (2014-2023)
- HONI (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

4.1 Load Forecast

As per the data provided by the study team, the load in the South Georgian Bay/Muskoka Region is expected to grow at an average gross rate of approximately 2% annually from 2014-2018 and 1.8% annually from 2019-2023.

Most of the load growth is attributed to the southern portion of the region, with the highest approximate annual growth rate occurring at the following stations: Barrie TS (4.1% from 2014-2018 and 5.9% from 2019-2023); Alliston TS (4.7% from 2014-2018 and 3.3% from 2019-2023); Midhurst TS (3.5% from 2014-2018 and 2.9% from 2019-2023) and Everett TS (3.2% from 2014-2018 and 2.9% from 2019-2023).

5 ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment report:

1. The Region is winter peaking, however five out of sixteen stations in the Region are summer peaking (Alliston TS, Barrie TS, Everett TS, Midhurst TS and Orangeville TS T1/T2 DESN). Therefore, this assessment is based on both winter and summer peak loads, as appropriate.

2. Forecast winter/summer loads are provided by the Region's LDCs. There are no customer loads within this region.

3. The LDC's load forecast is translated into load growth rates and is applied onto the 2013 winter/summer peak load as a reference point.

4. The 2013 winter/summer peak loads are adjusted for extreme weather conditions according to HONI's methodology.

5. Accounting for (2), (3), (4) above, the gross load forecast and a net load forecast were developed. The gross demand forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast, which accounts for CDM and DG, is analyzed to determine if needs can be deferred.

   A gross and net non-coincident peak load forecast was produced for both winter and summer and were used to perform the analysis for Section 6.1.2 of this report.

   A coincident region peak load forecast was used to perform the analysis for sections 6.1.1 of this report. A gross and net-region coincident peak load forecast was developed for winter conditions. As for summer conditions, only a gross coincident forecast was developed for conservatism but also due to the high load growth relative to CDM and DG in the summer peaking portion of the region. The gross summer coincident peak load forecast was developed based on projected percentages of the winter historical loading.

6. Review impact of any on-going and/or planned development projects in the Region during the study period.

7. Review and assess impact of any critical/major elements planned/identified to be replaced at the end-of-their-useful-life such as auto-transformers, cables, and stations.

8. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity, assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer/winter 10-Day Limited Time Rating (LTR).

9. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.

10. Transmission adequacy assessment considers, but is not limited to, the following criteria:
    - Region-coincident peak load forecast is used.
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their Long-Term Emergency (LTE) ratings and transformers within their summer/winter 10-Day LTR.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC).
    - With one element out of service, no more than 150MW of load is lost by configuration. With two elements out of service, no more than 600MW of load is lost by configuration.
    - With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC.

6 RESULTS

This section summarizes the results of the Needs Assessment in the South Georgian Bay/Muskoka Region.

6.1 Transmission Capacity Needs

6.1.1 115/230kV Transmission Lines and Auto-Transformers

The 115/230kV transmission line and auto-transformer needs identified during the study period include, but may not be limited to the following:

- With the 230/115kV auto-transformer T1 or T2 at Essa TS out of service, the companion auto-transformer at Essa TS is expected to exceed its summer 10-Day LTR in the near-term based on gross summer demand forecast. T1 is expected to exceed its summer 10-Day LTR in the near-term (approximately 104% and 142% of summer 10-Day LTR by 2018 and 2023 respectively) and T2 in the medium-term (approximately 106% and 113% of summer 10-Day LTR by 2022 and 2023 respectively). The net summer demand forecast is not expected to significantly defer the need due to the high growth rate at Barrie TS.
- With one element out of service, the 115kV circuit E3B is expected to exceed its summer LTE rating in the near-term based on gross summer demand forecast (approximately 106% and 137% of summer LTE rating by 2019 and 2023

respectively). The net summer demand forecast is not expected to significantly defer the need due to the high growth rate at Barrie TS.

- With one element out of service, the voltage after tap-changer action at the Muskoka TS 230kV bus drops slightly below minimum continuous voltage limit in the medium-term based on gross winter demand forecast. With net winter demand forecast, the voltage remains within acceptable limits. This will be monitored and reassessed in the next regional planning cycle.
- With one element out of service, the voltage declines immediately following a contingency at Muskoka TS 44kV exceeds the limit of 10% after 2020 based on gross winter demand forecast. With the net winter demand forecast, the voltage remains within acceptable limits. This will be monitored and reassessed in the next regional planning cycle.

6.1.2 115/230kV Transformer Stations

The connection capacity needs identified during the study period include, but may not be limited to the following:

Barrie TS T1/T2 DESN (115-44kV):

- Barrie TS is a summer peaking station and currently exceeds its normal supply capacity based on both gross and net summer demand forecast (approximately 103% and 150% of summer 10-Day LTR in 2014 and 2023 respectively).

Everett TS T1/T2 DESN (230-44kV):

- Everett TS is a summer peaking station and will exceed its normal supply capacity at the end of the study period based on the gross summer demand forecast. With the net summer demand forecast, the station remains below its normal supply capacity. This will be monitored and reassessed in the next regional planning cycle.

Minden TS T1/T2 DESN (230-44kV):

- Minden TS is a winter peaking station and will exceed its normal supply capacity in the near-term based on the gross winter demand forecast. With the net winter demand forecast, the station remains below its normal supply capacity until the end of the study period. This will be monitored and reassessed in the next regional planning cycle.

Muskoka TS T1/T2 DESN (230-44kV):

- Muskoka TS is a winter peaking station and will exceed its normal supply capacity in near-term based on both gross and net winter demand forecast (approximately 100% and 103% of winter 10-Day LTR in 2016 and 2023 respectively). The station capacity is currently limited by the low voltage current transformers (CTs). If this limitation is non-existent, the power transformer winter LTR would remain above the gross winter demand forecast for the study period.

Parry Sound TS T1/T2 DESN (230-44kV)

- Parry Sound TS is a winter peaking station and currently exceeds its normal supply capacity based on both gross and net winter demand forecast (approximately 117% and 119% of winter 10-Day LTR in 2014 and 2023 respectively). Using a historically more reasonable winter power factor of 0.95, the station still exceeds its normal supply capacity (approximately 111% and 113% of winter 10-Day LTR in 2014 and 2023 respectively).

Waubaushene TS T5/T6 DESN (230-44kV)

- Waubaushene TS is a winter peaking station and will exceed its normal supply capacity at the end of the study period based on the gross winter demand forecast. With the net winter demand forecast, the station remains below its normal supply capacity. This will be monitored and reassessed in the next regional planning cycle.

Several load customers are planning new commercial operations in the City of Barrie during the study period. The forecast used for capacity assessment is the 'median' load growth projection for the City of Barrie, which reflects the historical load growth. Using the 'high growth scenario', where new commercial operations may materialize and achieve their projected loading by 2018, the following additional capacity needs emerge:

Midhurst TS

- Both T1/T2 and T3/T4 DESN stations at Midhurst TS are summer peaking and remain within their normal supply capacity based on gross 'median' summer demand forecast.
- T1/T2 DESN may exceed its normal supply capacity in the medium-term based on both net and gross 'high growth scenario' summer demand forecast (approximately 102% and 104% of summer 10-Day LTR in 2021 and 2023 respectively).
- T3/T4 DESN may exceed its normal supply capacity in the medium-term based on gross 'high growth scenario' summer demand forecast. With the net forecast, the station remains within its normal supply capacity until the end of the study period. This will be monitored and reassessed in the next regional planning cycle.

6.2 System Reliability, Operation and Restoration Review

Based on the gross and net coincident demand forecast, the maximum load interrupted by configuration due to the loss of one element is below the load loss limit of 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW.

For the loss of two elements, the load interrupted by configuration may exceed 150MW and 250MW based on gross and net coincident demand forecast. The loss of 230kV circuits M6E+M7E may require some load to be restored within 4 hours and 30 minutes; the loss of 230kV circuits M80B+M81B may require some load to be restored within 4 hours; the loss of 230kV circuits E8V +E9V may require some load to be restored within 4 hours during the study period. 230kV circuit M6E+M7E may not meet the 30 minutes restoration criteria. Further assessment is required.

Due to the increase generation within the Bruce Area, 115kV circuit S2S and Stayner T1 auto-transformer may be overloaded under pre-contingency conditions during high flow eastward from the Bruce Area. One possible solution would be to operate S2S open loop. This issue was identified by IESO as part of this assessment. Further assessment is required.

With an Essa TS 500/230kV auto-transformer T3 or T4 out of service, the loss of the remaining 500/230kV Essa TS auto-transformer, may result in excessive post-contingency voltage declines under high load conditions within the Essa area. This issue was identified by IESO as part of this assessment. Further assessment is required.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

HONI reviewed the sustainment initiatives that are currently planned for the replacement of any auto-transformers, power transformers and high-voltage cables.

During the study period:

- Replacement of 115-44kV transformers (T1 and T2) at Barrie TS is scheduled for 2018.
- Replacement of 230-44kV transformers (T1 and T2) and possible rebuild of low voltage switchyard at Minden TS is scheduled for 2019.
- Replacement of dual windings 230-44/27.6kV transformers (T1 and T2) and associated low voltage equipment at Orangeville TS is scheduled for 2017.
- Ground clearance on several sections of the 230kV circuits M6E and M7E are planned to be increased in 2015. This may increase the current thermal rating of the lines.

7 RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team's recommendations are as follows.

Study team recommends that a Scoping Assessment should be undertaken to address the following needs:

- Barrie TS 115kV transmission and transformation capacity – this includes the 230/115kV auto-transformer needs at Essa TS, the 115kV circuit E3B supplying Barrie TS (first three points of section 6.1.1) and the transformation capacity need at Barrie TS (first point of section 6.1.2). Coordination is also required with the existing sustainment initiative at Barrie TS.
- Muskoka TS T1/T2 DESN transformation capacity (fourth point of section 6.1.2).
- Parry Sound TS transformation capacity (fifth point of section 6.1.2).
- Midhurst TS T1/T2 DESN potential transformation capacity need based on 'high growth scenario'.
- System reliability, operation and restoration needs (section 6.2).

These near-term needs require coordinated regional planning and development of a regional and/or sub-regional plan as soon as possible. The Scoping Assessment (SA) will determine whether the IESO-led IRRP process and/or the transmitter-led RIP process (for wires solutions) should be further undertaken for one or more of these needs. The assessment may also recommend that local planning of wires only option between the transmitter and affected LDCs may be undertaken to address certain needs.

8 NEXT STEPS

IESO will initiate a SA process for the region as soon as possible for the needs identified in the region.

Hydro One Networks Inc. (Distribution)

Disclaimer

This Local Planning Report was prepared for the purpose of developing wires-only options and recommending a preferred solution(s) to address the local needs identified in the Needs Assessment (NA) report for the South Georgian Bay / Muskoka Region that do not require further coordinated regional planning. The preferred solution(s) that have been identified through this Local Planning Report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Local Planning Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Local Planning Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Local Planning Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Local Planning Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Local Planning Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

LOCAL PLANNING EXECUTIVE SUMMARY

REGION	South Georgian Bay / Muskoka (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	October 14, 2014	**END DATE**	May 27, 2016

1. INTRODUCTION

The purpose of this Local Planning (LP) report is to develop wires-only options and recommend a preferred solution that will address the local needs identified in the Needs Assessment (NA) report for the South Georgian Bay / Muskoka Region dated March 3, 2015. The development of the LP report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

Based on Section 6 of the NA report, the study team recommended that coordinated regional planning is required to address the majority of needs in the South Georgian Bay / Muskoka region. The NA report also indicated that there are end-of-life needs at Orangeville TS and it was determined that these needs are local in nature and will be addressed by wires options through local planning led by Hydro One with participation of the impacted LDCs.

2. LOCAL NEEDS ADDRESSED IN THIS REPORT

There are no capacity needs identified for Orangeville TS over the next ten years. Hydro One has identified that transformers and associated protection, control and telecom equipment at Orangeville TS will be reaching the end of their useful life over the study period. The replacement of this end-of-life equipment is a local area need and is addressed in this report.

3. OPTIONS CONSIDERED

Hydro One (Transmitter) and Hydro One Distribution (LDC) have considered addressing the above need with the following options;

Alternative 0 – Status Quo.
Alternative 1 – Like-for-like replacement of non-standard end-of-life equipment at Orangeville TS.
Alternative 2 – Replacement of non-standard end-of-life equipment at Orangeville TS with standard equipment, and reconfiguration of Orangeville DESN.

See Section 3 for further detail.

4. PREFERRED SOLUTION

The preferred solution at this time is Alternative 2 – Replacement of non-standard end-of-life equipment at Orangeville TS with standard equipment, and reconfiguration of Orangeville DESN. See Section 4 for details.

5. NEXT STEPS

Hydro One will proceed with end-of-life replacement of non-standard equipment based on conditions assessment. Currently, it is planned to be replaced in 2023.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1 Introduction

The Needs Assessment (NA) for South Georgian Bay / Muskoka ("Region") was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. Prior to the new regional planning process coming into effect, planning activities were already underway in the Region to address some specific station capacity needs. The NA report can be found on Hydro One's Regional Planning website. The study team identified needs that are emerging in the South Georgian Bay / Muskoka Region over the next ten years (2014 to 2023) and recommended whether they should be further assessed through the transmitter-led Local Planning (LP) process or the IESO-led Scoping Assessment (SA) process.

1.1 South Georgian Bay / Muskoka Region Description and Connection Configuration

The South Georgian Bay / Muskoka Region is the area roughly bordered by West Nipissing to the northwest, Algonquin Provincial Park to the northeast, Peterborough County and Hastings County to the southeast, Lake Scugog, York and Peel Regions to the south, Wellington County to the southwest and Grey Highlands to the west. The boundaries of the Region are shown in Figure 1 below.

Electrical supply to the Region is provided through two (2) 500/230kV auto-transformers at Essa TS, the 230kV transmission lines connecting Minden TS to Des Joachims TS, the 230kV circuits E8V and E9V coming from Orangeville TS, and the single 115kV circuit S2S connecting to Owen Sound TS. There are sixteen (16) HONI step-down transformer stations in the Region, most of which are supplied by circuits radiating out from Essa TS, and the majority of the distribution system is at 44kV, except for Orangeville TS which has 27.6kV and 44kV feeders. Table 1 below lists the major transmission circuits and Hydro One stations in the subject region. Figure 2 shows the single-line diagram of the transmission network in the Region.

This region has the following two local distribution companies (LDC):

- PowerStream Inc.
- Hydro One Networks Inc. (Distribution)

There are several other LDCs in this region embedded into the Hydro One Distribution system. Although invited, many of them opted not to directly participate as part of the Study Team. However, the interests of all embedded LDCs were communicated and considered through Hydro One Distribution as a host LDCs.

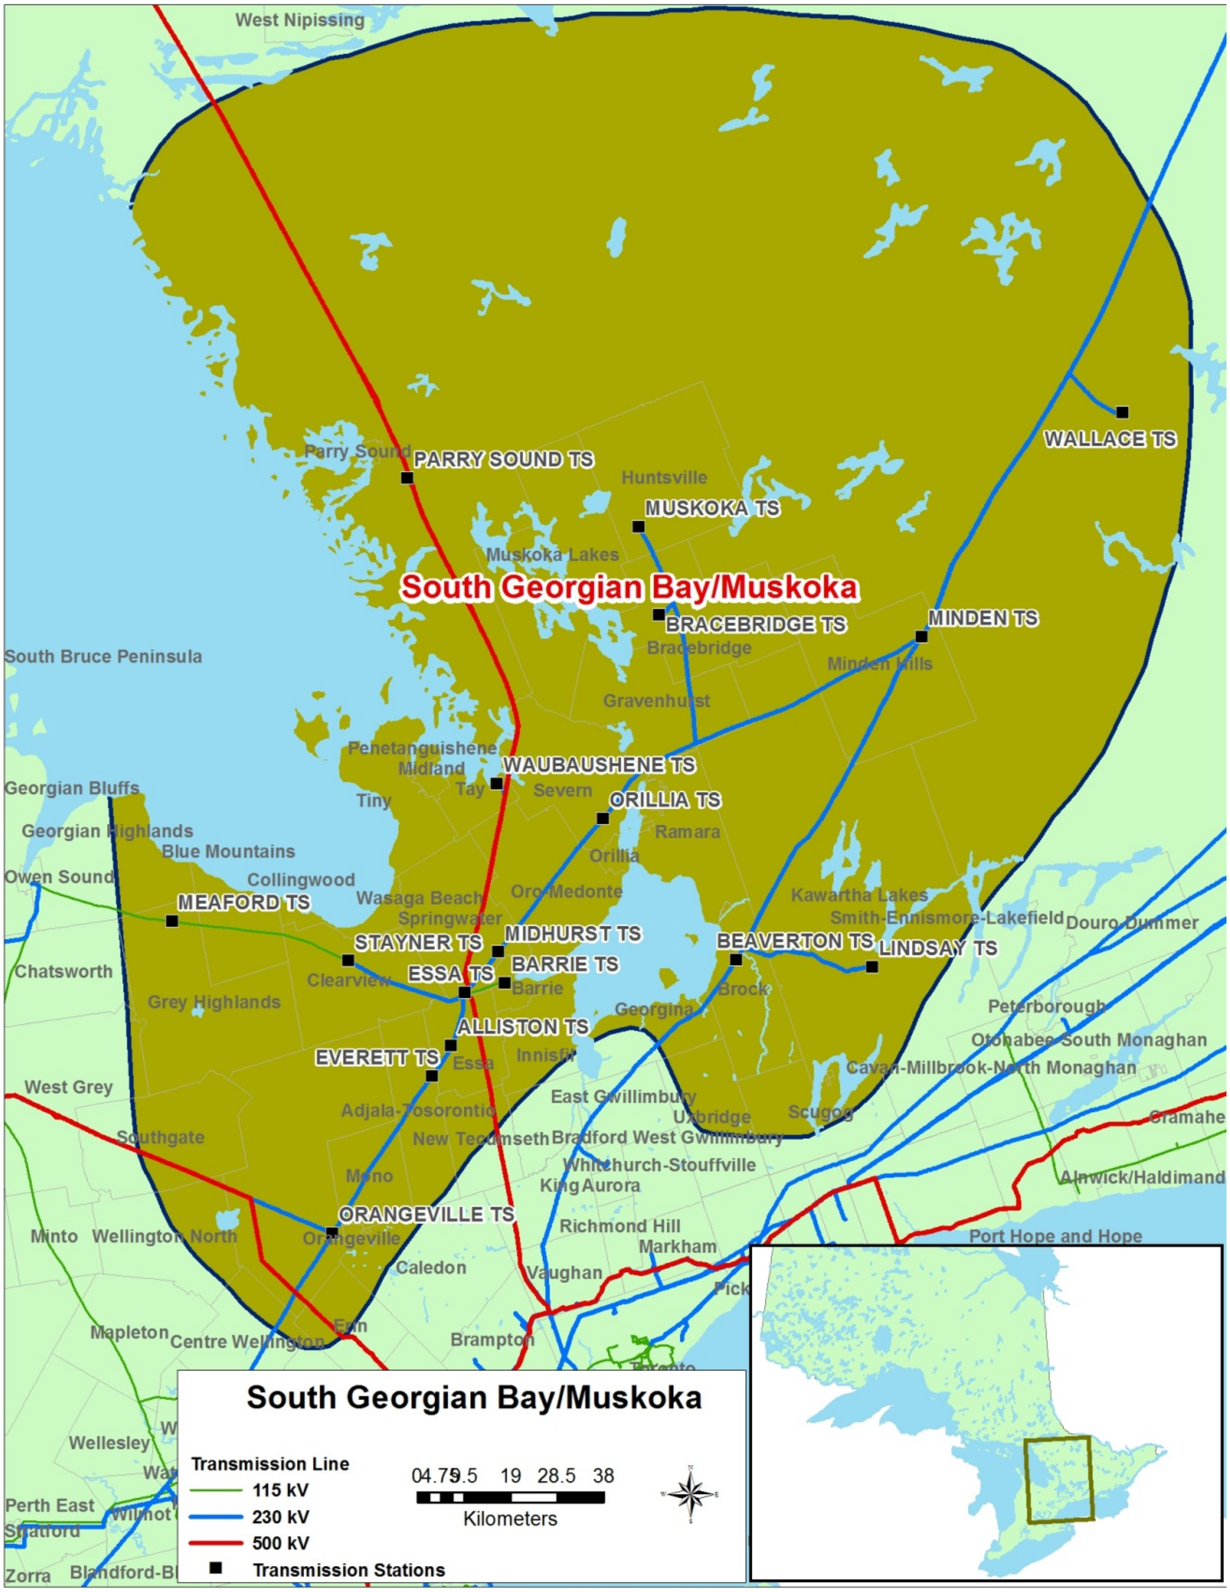

Figure 1: South Georgian Bay / Muskoka Region Map

Distribution connected loads of embedded LDCs in the South Georgian Bay / Muskoka region form a large percentage of the overall demand. Although these LDCs are not explicitly participating in the regional planning process, Hydro One considered their impact in this analysis.

Table 1: Transmission Lines and Stations in the South Georgian Bay / Muskoka Region

115kV circuits	230kV circuits	Hydro One Transformer Stations
E3B, E4B, S2S	E8V, E9V, E20S, E21S, M6E, M7E, D1M, D2M, D3M, D4M, M80B, M81B, E26, E27	ALLISTON TS, BARRIE TS, BEAVERTON TS, BRACEBRIDGE TS, EVERETT TS, LINDSAY TS, MEAFORD TS, MIDHURST TS, MINDEN TS, MUSKOKA TS, ORANGEVILLE TS, ORILLIA TS, PARRY SOUND TS, STAYNER TS, WALLACE TS, WAUBAUSHENE TS

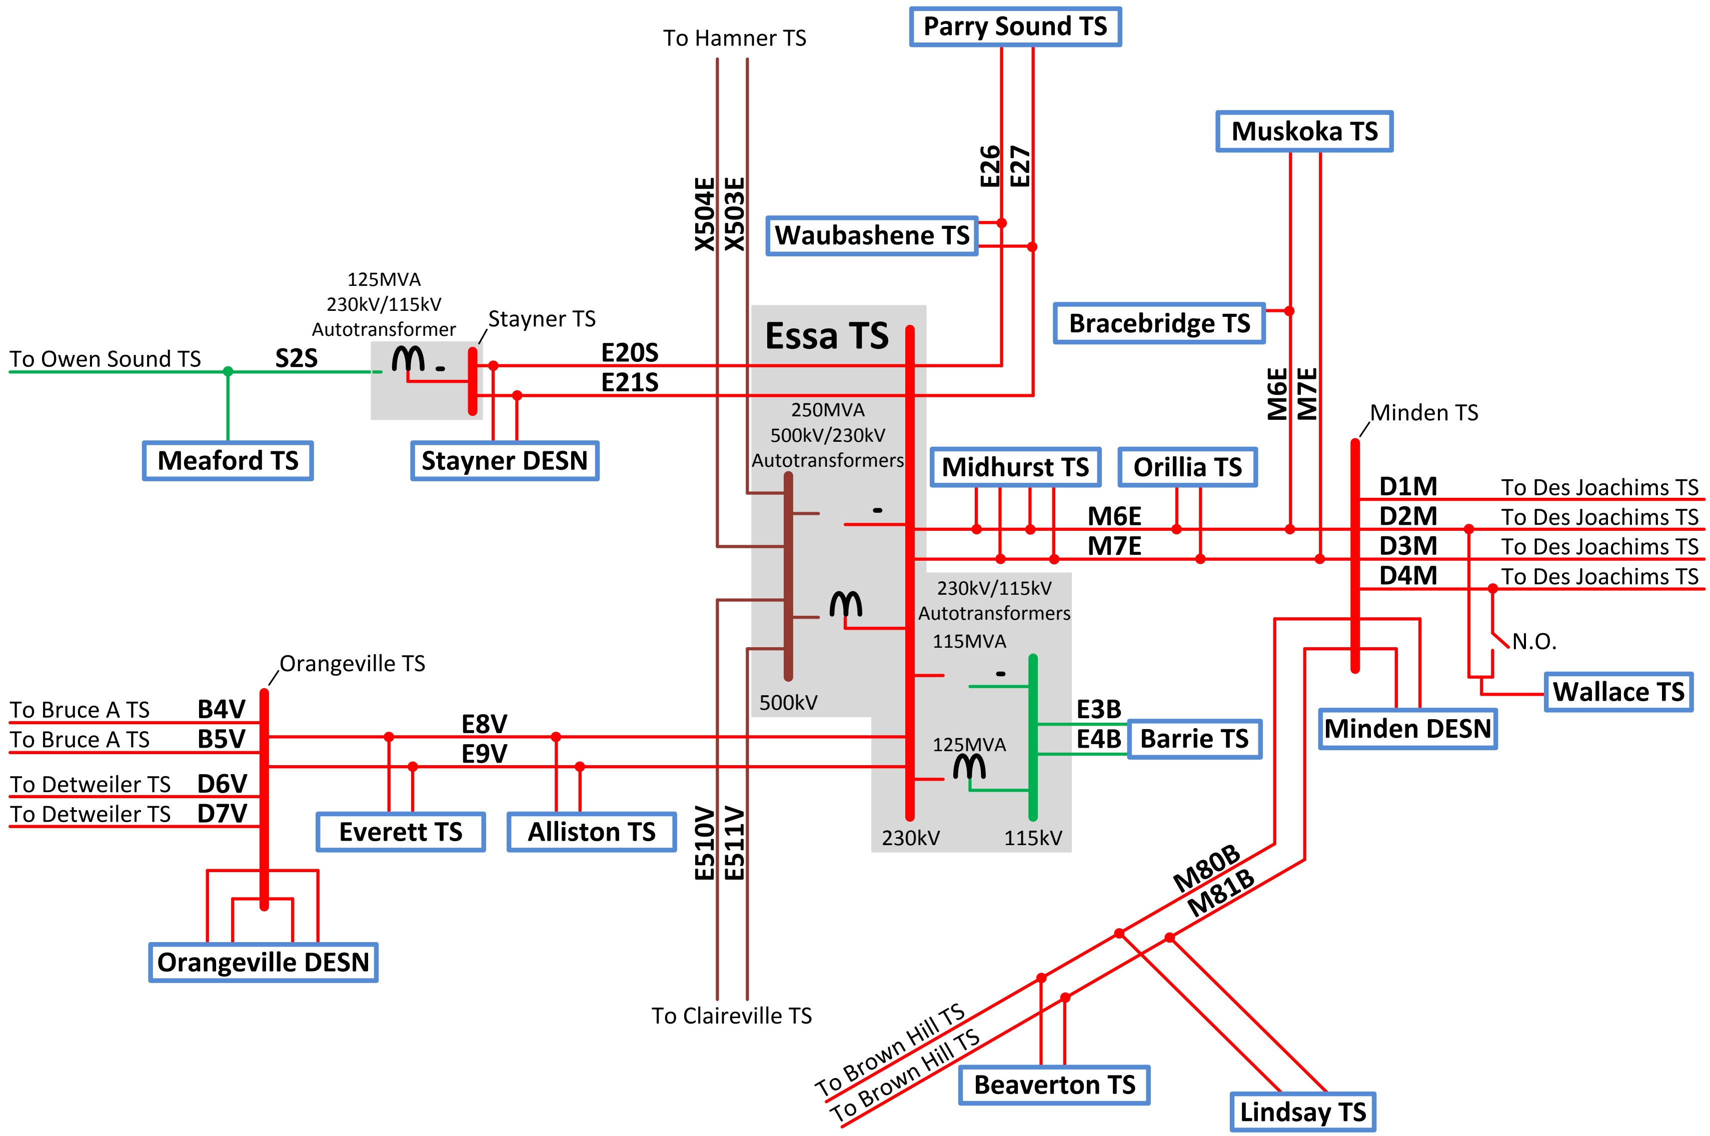

Figure 2: Single Line Diagram – South Georgian Bay / Muskoka Region

2 Area needs

2.1 South Georgian Bay / Muskoka Region Needs

As an outcome of the NA process, the study team identified six transformer stations with medium-term (5-10 years) capacity needs based on LDCs net load forecast which are not part of this Local Plan and will be addressed through the IRRP or RIP processes. It also identified a near-term end-of-life need at Orangeville TS in the South Georgian Bay / Muskoka Region to be addressed by developing a "Local Plan". To address this need, Hydro One Transmission undertook planning assessments with the impacted LDC, to address the need.

2.1 Needs Assessed by Hydro One Led Local Planning

- Orangeville TS End-of-Life Replacements – The 27.6 kV and 44 kV switchyards at Orangeville TS were placed in-service in late 1960s and several of the assets are at the end of their useful life. Previous assessments have identified that all four transformers T1, T2, T3, and T4 and associated equipment are candidates for replacement over the next few years. In addition, the existing 210-44-28 kV winding configuration on T1 and T2 is non-standard, which introduces challenges with maintenance, spare parts and future replacement strategies.

3 Alternatives Considered

Hydro One Transmission reviewed the above need and determined that Hydro One Distribution is the sole transmission-connected LDC impacted by the end-of-life replacements at Orangeville TS. Orangeville Hydro Limited (OHL), which supplies power to the Orangeville area, is an embedded LDC connected to the Hydro One-owned distribution system at Orangeville TS. OHL is also impacted by the end-of-life replacements and its interests were taken into consideration in determining the preferred alternative. Following options were considered to address the needs identified in Section 2.

Alternative 0 – Status Quo.

No further action taken at this time. Hydro One and LDC will monitor the aging equipment over the next three years and perform maintenance as issues arise. Further review will be undertaken in the next planning cycle or earlier and aging equipment will be replaced as failures arise.

Alternative 1 – Like-for-like replacement of non-standard end-of-life equipment at Orangeville TS

End-of-life transformers T1 and T2 will be replaced like-for-like by customized 75/125MVA transformers with non-standard 210-44-28kV three-winding configuration. A customized spare transformer would also be required in case T1 or T2 is removed from service for an extended period of time. End-of-life transformers T3 and T4 will be replaced like-for-like by standard 50/83MVA 220/44kV transformers. All associated end of life protection, control and telecom assets will be replaced as well as station service equipment. See figure 3 and figure 5.

Alternative 2 – Replacement of non-standard end-of-life equipment at Orangeville TS with standard equipment, and reconfiguration of Orangeville DESN

End-of-life transformers T1 and T2 (non-standard) will be replaced with two standard three-phase transformers sized 215.5-28 kV, 50/66.7/83.3 MVA units and T3 and T4 will be replaced with standard 215.5-44 kV, 75/100/125 MVA units. To standardize the configuration, the T1/T2 switchyard will be reconfigured as a single 230-28 kV switchyard and the two existing 44 kV feeders, M45 and M46, will be relocated and supplied from the T3/T4 DESN. All associated end-of-life protection, control and telecom assets will be replaced as well as station service equipment. See figure 4 and figure 6.

Table 2 provides a budgetary cost summary of a cost of all options.

Table 2: Budgetary Estimates for Alternatives

Options Considered	Cost
Alternative 0 – Monitor aging equipment over the next 3 years and perform maintenance as issues arise.	Will result in poor reliability not acceptable
Alternative 1 – Like-for-like replacement of non-standard end-of-life equipment at Orangeville TS.	$35-40M
Alternative 2 – Replacement of non-standard end-of-life equipment at Orangeville TS with standard equipment, and reconfiguration of Orangeville DESN.	$30M

4 Preferred Alternative Selection

A recent station assessment has confirmed that transformers T1, T2, T3, T4 and associated equipment as well as associated end of life protection, control and telecom assets will be approaching end of their useful life. Integration of the replacement of multiple end-of-life components into a single investment allows additional efficiencies to be realized during the design, construction, and commissioning stages of the work.

Orangeville Hydro Limited (OHL) has also expressed their intent to further increase their use of the 27.6 kV feeders supplied from Orangeville TS. Consequently, OHL also intends to reduce the number of customers and stations connected to the 44 kV feeders M3 and M5. Therefore, in an effort to standardize the configuration in the T1/T2 switchyard it can be reconfigured as a single 230-28 kV switchyard and the two existing 44 kV feeders, M45 and M46, relocated and supplied from the T3/T4 DESN. In this option, transformers T3 and T4 will be replaced, increasing capacity to maintain overall available capacity on the 44 kV network.

Hydro One Transmission and the LDCs reviewed all alternatives and concluded that Status Quo and Alternative #1 are not preferred options. It recommends to proceed with Alternative 2 – Replacement of non-standard end-of-life equipment at Orangeville TS with standard equipment, and reconfiguration of Orangeville DESN.

The study team's recommendation to replace end-of-life equipment at Orangeville TS will also improve the level of reliability and quality of service. Currently, it is expected that the these equipment will be replaced in 2023. The cost of this investment is expected to be a transmission pool investment and LDCs are not expected to pay to replace the transmission equipment.

5 Next Steps

A summary of the next steps, actions/solutions and timelines required to address the local needs are as follows:

Table 3: Solutions and Timeframe

Need	Action / Recommended Solution	Lead Responsibility	Timeframe
End-of-life replacements at Orangeville TS	• Alternative 2 – Replacement of non-standard end-of-life equipment at Orangeville TS with standard equipment, and reconfiguration of Orangeville DESN.	Hydro One Networks	Expected In- Service 2023

Sudbury/Algoma Region

Regional Infrastructure Plan ("RIP")

June 10th, 2016

Greater Sudbury Hydro Inc.
Hydro One Networks Inc. (Distribution)

The Sudbury to Algoma Region includes Greater Sudbury Area, Manitoulin Island, and townships of Verner, Warren, Elliot Lake, Blind River and Walden.

The Needs Assessment ("NA") for the Sudbury/Algoma region was completed in March, 2015 (see attached) and the report recommends that no further coordinated regional planning is required to address needs in the Sudbury-Algoma Region.

To address local needs, local planning was undertaken by Hydro One Networks Inc. (Transmitter) and Hydro One Networks Inc. (Distribution) to address the "Manitoulin TS Low Voltage Regulation" need. A Local Planning ("LP") report was prepared and published by the Working Group for the Sudbury/Algoma region in September, 2015 (also attached).

The only major project planned for the Sudbury/Algoma Region over the near and mid-term is

- New 230/44kV station at Hanmer Ts to replace Coniston Ts (115/22kV). As part of this project, Coniston loads will be converted from 22kV to 44kV (2019). The approximate cost of this work is $25M. This is a pool funded investment.

Consistent with a process established by an industry working group[1] created by the OEB the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no further regional coordination was required, the attached NA and LP reports will be deemed to form the ("RIP") for the Sudbury/Algoma Region.

The next planning cycle for the region will take place within five years of the start of this cycle (2013) or earlier, should there be a new need identified in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks

LOCAL PLANNING REPORT

Manitoulin TS Low Voltage Regulation
Region: Sudbury-Algoma

Revision: Final
Date: September 30, 2015

Prepared by: Hydro One Networks Inc (Transmission & Distribution)

Study Team	
Organization	Name
Hydro One Networks Inc. (Lead Transmitter)	Kirpal Bahra
Hydro One Networks Inc. (Distribution)	Richard Shannon

Disclaimer

This Local Planning Report was prepared for the purpose of developing wires-only options and recommending a preferred solution(s) to address the local needs identified in the Needs Assessment (NA) report for the Sudbury-Algoma Region that do not require further coordinated regional planning. The preferred solution(s) that have been identified through this Local Planning Report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Local Planning Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Local Planning Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Local Planning Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Local Planning Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Local Planning Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

Local Planning Executive Summary

Region	Sudbury to Algoma (the "Region")		
Lead	Hydro One Networks Inc. ("Hydro One")		
Start Date	October 20, 2014	**End Date**	September 30, 2015

1. INTRODUCTION

The purpose of this Local Planning (LP) report is to develop wires-only options and recommend a preferred solution that will address the local needs identified in the Needs Assessment (NA) report for the Sudbury-Algoma Region dated March 12, 2015. The development of the LP report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

Based on Section 6 of the NA report, the study team recommended that no further coordinated regional planning is required to address the needs in the Sudbury-Algoma region. These needs are local in nature and will be addressed by wires options through local planning led by Hydro One with participation of the impacted LDC.

2. LOCAL NEEDS ADDRESSED IN THIS REPORT

The Manitoulin TS Voltage Regulation is a local need addressed in this report.

3. OPTIONS CONSIDERED

Hydro One (Transmitter) and Hydro One Distribution (LDC) have considered addressing the above need with the following options;

Alternative 0 – Status Quo.
Alternative 1 - Install 44kV Capacitor Bank at Manitoulin TS
Alternative 2 - Install 115kV Capacitor Bank at Manitoulin TS

See Section 3 for further detail.

4. PREFERRED SOLUTION

The preferred solution at this time is Alternative 0 – Status Quo. See Section 4 for details.

5. NEXT STEPS

The next steps are summarized in section 5

TABLE OF CONTENTS

1 INTRODUCTION

The Needs Assessment (NA) for the Sudbury/Algoma ("Region") was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. Prior to the new regional planning process coming into effect, planning activities were already underway in the Region to address some specific station capacity needs. The NA report can be found on Hydro One's Regional Planning website. The study team identified needs that are emerging in the Sudbury-Algoma Region over the next ten years (2014 to 2023) and recommended whether they should be further assessed through the transmitter-led Local Planning (LP) process or the IESO-led Scoping Assessment (SA) process.

1.1 Sudbury to Algoma Region Description and Connection Configuration

The Sudbury to Algoma Region includes Greater Sudbury Area, Manitoulin Island, and townships of Verner, Warren, Elliot Lake, Blind River and Walden. The boundaries of the Sudbury to Algoma Region are shown below in Figure 1.

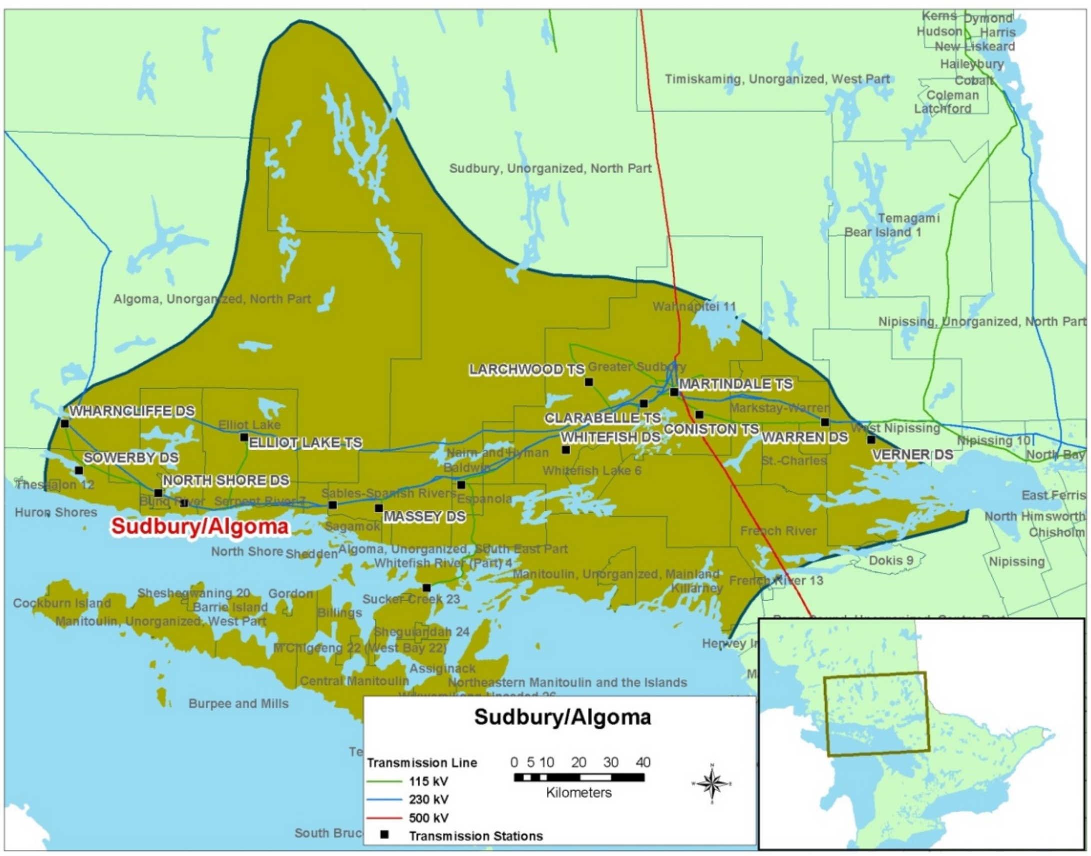

Figure 1: Sudbury to Algoma Region Map

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits supplied by autotransformers at Hanmer TS, Algoma TS and Martindale TS. This area is further reinforced through the 500kV circuits (P502X and X504/503E) connecting Hanmer TS (Sudbury) to both Porcupine TS (Timmins) and Essa TS (Barrie). It is also connected to Northwest Ontario through Mississagi TS. Table 2 below lists the major transmission circuits and Hydro One stations in the subject region.

This region has the following two local distribution companies (LDC):

- Greater Sudbury Hydro Inc.
- Hydro One Networks Inc. (Distribution)

Espanola Regional Hydro Distribution is a third LDC in this region embedded into the Hydro One Distribution system. Although invited, this LDC opted not to participate in the Study Team. However, the interests of this LDC were communicated and considered through Hydro One Distribution as a host LDC.

Transmission connected loads in the Sudbury to Algoma region form a large percentage (approximately 50%) of the overall demand. Although these customers are not explicitly participating in the regional planning process, Hydro One considered their impact in this analysis.

115kV circuits	230kV circuits	Hydro One Transformer Stations
S6F,S5M	X74P, X27A	ALGOMA TS
S2B,B4B	A23P, A24P	MARTINDALE TS
T1B, B3E	X23N, S21N	HANMER TS
B4E, L1S	X25S, X26S	CONISTON TS
	S22A	CLARABELLE TS
		ELLIOT LAKE TS
		ESPANOLA TS
		LARCHWOOD TS
		MANITOULIN TS

Table 1: Transmission Lines and Stations in Sudbury to Algoma Region

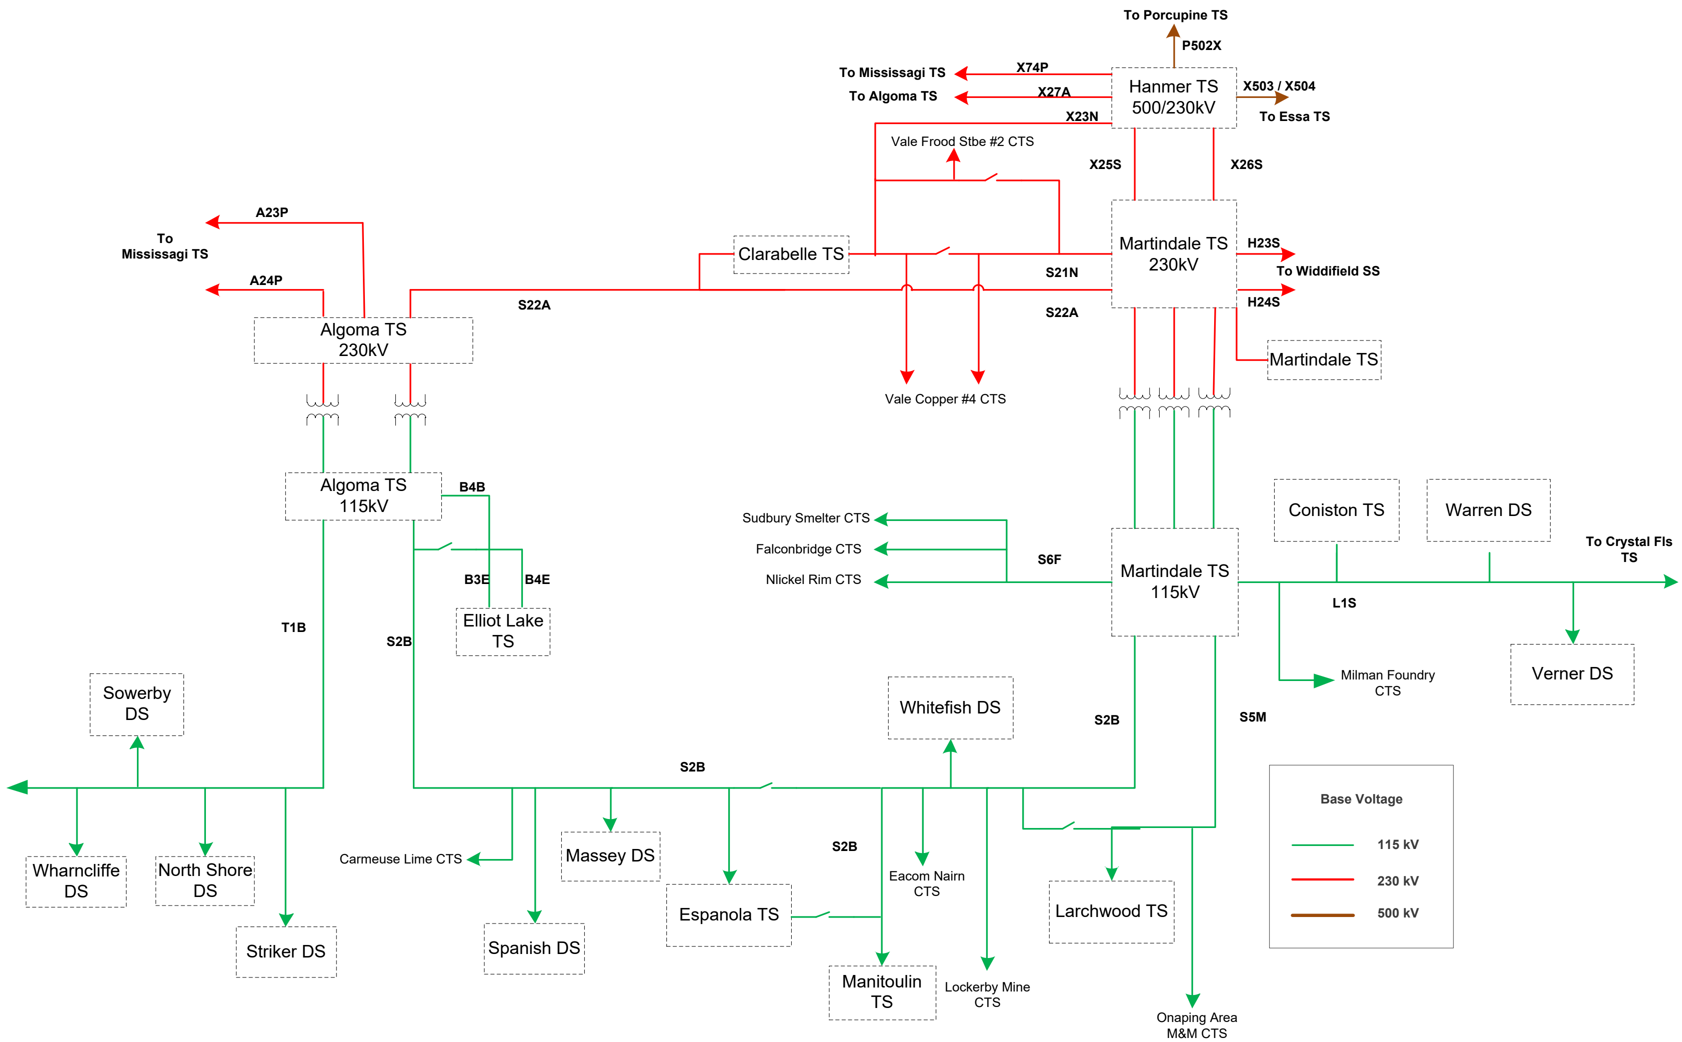

Figure 2: Single Line Diagram – Sudbury to Algoma Region

2 AREA NEEDS

2.1 Sudbury-Algoma Region Needs

As an outcome of the NA process, the study team did not identify any capacity needs based on LDCs load forecast. Only need identified was an issue with potential voltage regulation at Manitoulin TS in the Sudbury-Algoma Region to be addressed by a “localized” wires planning. Where local planning was recommended to address the needs, Hydro One, as transmitter, with the impacted LDC, further undertook planning assessments to address the need.

2.2 Needs Assessed by Hydro One led Local Planning

- Manitoulin TS Voltage Regulation – pre-contingency voltages at Manitoulin TS 115kV can at times fall below the ORTAC criteria of 113kV. Without McLean’s mountain wind farm in service, and under peak load conditions, pre-contingency voltage at Manitoulin TS high voltage bus can be as low as 110kV when supplied from Algoma TS, and 112kV when supplied from Martindale TS.

3 ALTERNATIVES CONSIDERED

Hydro One transmission reviewed the above need and determined that the only LDC impacted by a low voltage at Manitoulin TS is Hydro One distribution which is directly supplied at the stations’ 44kV bus. Following options were considered to address the needs identified in section 2 above.

Alternative 1 – Status Quo.

No further action is required at this time. Hydro One and LDC will monitor the load and voltages over the next three years. Further review will be undertaken in the next planning cycle or earlier if there is any evidence where load cannot be served or system cannot be operated in a safe, secure and reliable manner.

Alternative 2 – Install 44kV Capacitor Bank at Manitoulin TS

A 7MX low voltage capacitor bank can help improve high voltages regulation at Manitoulin TS. Manitoulin TS has a non-standard low voltage switch yard arrangement whereby each of the two feeders is supplied from a dedicated bus and associated transformer. There is currently no tie breaker between the two 44kV buses and thus, two 5.4MX capacitor banks will be required (for each of the busses). See figure 3.

Alternative 3 – Install 115kV Capacitor Bank at Manitoulin TS

A high voltage capacitor bank would also regulate the high voltage bus at Manitoulin TS. This alternative would require two high voltage breakers, and a motorized disconnect switch. See figure 4. Further investigation into this alternative indicated that 96MX capacitor bank is the smallest size available at this voltage. This large capacitor size would cause large voltage changes during switching and would violate operational criteria. Although this aspect would rule out this alternative it is shown illustration purposes in Table 3.

Table 3 below provides a budgetary cost summary of a cost of all options.

Options Considered	Cost
Alternative 1 – Hydro One to assess voltage performance of 115kV and 44kV bus with no immediate investment.	--
Alternative 2 – Install 44kV Capacitor Bank at Manitoulin TS	\$4M
Alternative 3 – Install 115kV Capacitor Bank at Manitoulin TS	\$6M

Table 2 – Budgetary Cost for Alternatives

4 Preferred Solution and Reasoning

Hydro One Networks and the LDC have reviewed all alternatives and the preferred solution at this time is, Alternative 1 – Status Quo.

The study team acknowledges that the Manitoulin TS HV bus may experience voltages below ORTAC requirements only during limited operating scenarios. These scenarios are infrequent and the impacts of a low voltage at this point does not affect system stability or result in low voltages issues beyond the Manitoulin TS and Hydro One Distribution (LDC)

Manitoulin TS power transformers (T3/T4) are presently equipped with under load tap changers which have the ability to maintain 44kV bus voltages for wide array of voltage variations on the 115kV bus. ULTC ratings for both T3 and T4 are 44kV +/- 20% on 115.5kV at 42MVA load. These ratings are sufficient to maintain a customer delivery point performance within the rules of the Transmission System Code. The 44kV bus voltage will be maintained within 1.06 and 0.98pu for a 110kV (or lower) voltage.

Manitoulin TS voltage is constantly monitored by Hydro One's Ontario Grid Control Centre (OGCC) . OGCC's records will be reviewed regularly to ascertain the system conditions during peak load and its ability to operate the system and supply load to Manitoulin TS at acceptable voltage.

Voltage history will be reviewed with the LDC to determine if 44kV supply voltage remains within acceptable range for all distributed connected customers. The next planning cycle will take place within five years and an investment can be triggered at any time should there be a situation where load cannot be served or system cannot be operated safely and reliably.

5 NEXT STEPS

A summary of the next steps, actions/solutions and timelines required to address the local needs are as follows:

Need	**Action / Recommended Solution**	**Lead Responsibility**	**Timeframe**
Low Voltage at Manitoulin 115kV bus	• Status Quo –standard five year cycle	Hydro One Networks	Maximum five years

Table 3: Solutions and Timeframe

Independent Electricity System Operator	Phillip Woo Angelina Tan Kun Xiong
Greater Sudbury Hydro	Brian McMillan
Hydro One Networks Inc. (Distribution)	Richard Shannon

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Sudbury Algoma region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	Sudbury to Algoma (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	October 20, 2014	**END DATE**	March 20, 2015

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the Sudbury to Algoma Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, IESO will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the Sudbury Algoma Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Sudbury Algoma Region belongs to Group 2. The NA for this Region was triggered on October 20, 2014 and was completed on March 20, 2015.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to the next 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2023. Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning. This NA included a study of transmission system connection facilities capability, which covers station loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the Independent Electricity System Operator (IESO), and Hydro One transmission provided information for the Sudbury Algoma Region. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs and system performance issues in the Region over the study period (2014 to 2023). The assessment reviewed available information and load forecasts and included single contingency analysis to confirm needs, if and when required. See Section 5 for further details.

6. RESULTS

Transmission Needs

A. 230/115 kV Autotransformers

- The 230/115 kV autotransformers (Algoma TS, Martindale TS, Hanmer TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

B. 230 kV Transmission Lines

- The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

C. 115kV Transmission Lines

- The 115 kV circuits supplying the Region are adequate over the study period for the loss of a single 115 kV circuit in the Region.
-

D. 230 kV and 115 kV Connection Facilities

- The 230k and 115kV connection facilities in this region are adequate over the study period.

E. Pre-contingency voltages at Manitoulin TS

- Under peak load conditions, pre-contingency voltages at Manitoulin TS 115kV bus can be below 113 kV.

System Reliability, Operation and Restoration Review

Based on the gross coincident load forecast, the loss of one element will not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period. For the loss of one or two elements, the load interrupted by configuration does not exceed 150 MW or 250 MW. In addition,

- As identified by the IESO, under peak load conditions, the loss of two Martindale TS 230/115kV transformers may result in the overload of the third Martindale transformer.
- As identified by the IESO, With either X25S or X26S is out of service, the loss of the companion circuit may result in voltage declines at Martindale 230kV and 115kV buses below acceptable ORTAC limits.

The above issues will be further assessed as part of bulk system planning outside of the regional planning process.

Aging Infrastructure / Replacement Plan

Replacement of the autotransformers at Martindale is currently in Hydro One's 5yr sustainment business plan. As part of this replacement, T21/T23 autotransformer replacement at Martindale TS may result in higher emergency ratings.

7. RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends that no further regional coordination is required and following needs identified in Section 6 be further assessed as part of Local Planning:

Manitoulin TS Voltage Regulation

- Low pre-contingency voltages at Manitoulin TS 115kV bus.

TABLE OF CONTENTS

LIST OF FIGURES

1 INTRODUCTION

This Needs Assessment (NA) report provides a summary of needs that are emerging in the Sudbury to Algoma Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the Sudbury to Algoma Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. If localized wires only solutions do not require further coordinated regional planning, the SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs.

This report was prepared by the Sudbury to Algoma Region NA study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, and the Independent Electricity System Operator (IESO).

Table 1: Study Team Participants for Sudbury to Algoma Region

No.	Company
1.	Hydro One Networks Inc. (Lead Transmitter)
2.	Independent Electricity System Operator
3.	Greater Sudbury Hydro Inc ("Sudbury Hydro")
4.	Hydro One Networks Inc. (Distribution)

2 REGIONAL ISSUE / TRIGGER

The NA for the Sudbury to Algoma Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Sudbury to Algoma Region belongs to Group 2. The NA for this Region was triggered on October 20, 2014 and was completed on March 20, 2015

3 SCOPE OF NEEDS ASSESSMENT

This NA covers the Sudbury to Algoma Region over an assessment period of 2014 to 2023. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

3.1 Sudbury to Algoma Region Description and Connection Configuration

The Sudbury to Algoma Region includes Greater Sudbury Area, Manitoulin Island, and townships of Verner, Warren, Elliot Lake, Blind River and Walden. The boundaries of the Sudbury to Algoma Region are shown below in Figure 1.

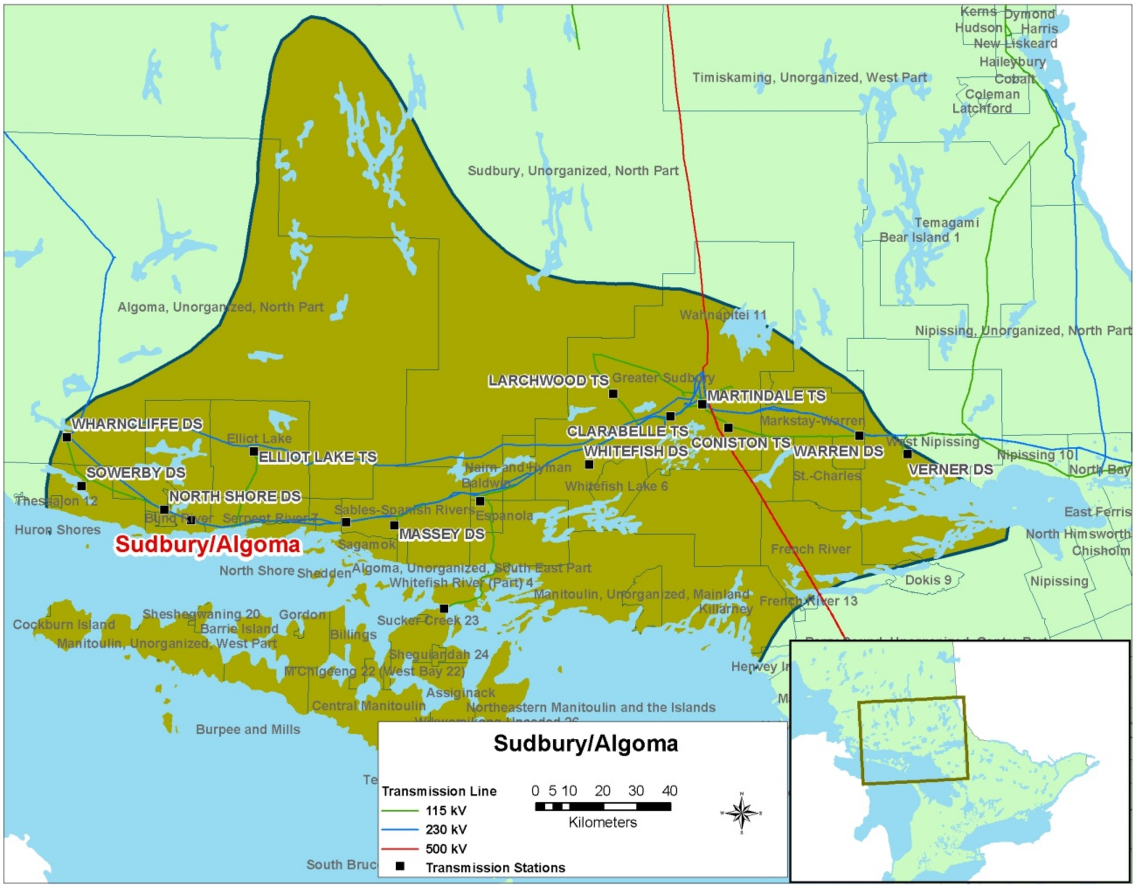

Figure 1: Sudbury to Algoma Region Map

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits supplied by autotransformers at Hanmer TS, Algoma TS and Martindale TS. This area is further reinforced through the 500kV circuits (P502X and X504/503E) connecting Hanmer TS (Sudbury) to both Porcupine TS (Timmins) and Essa TS (Barrie). It is also connected to Northwest Ontario through Mississagi TS. Table 2 below lists the major transmission circuits and Hydro One stations in the subject region.

This region has the following two local distribution companies (LDC):

- Greater Sudbury Hydro Inc.
- Hydro One Networks Inc. (Distribution)

Espanola Regional Hydro Distribution is a third LDC in this region embedded into the Hydro One Disribution system. Although invited to participate in the Study Team, the interests of this LDC was communicated through Hydro One Distribution.

Tranmission connected loads in the Sudbury to Algoma region form a large percentage (approximately 50%) of the overall demand. Although these customers are not explicitly participating in the regional planning process, Hydro One will consider their impact in the NA of this region.

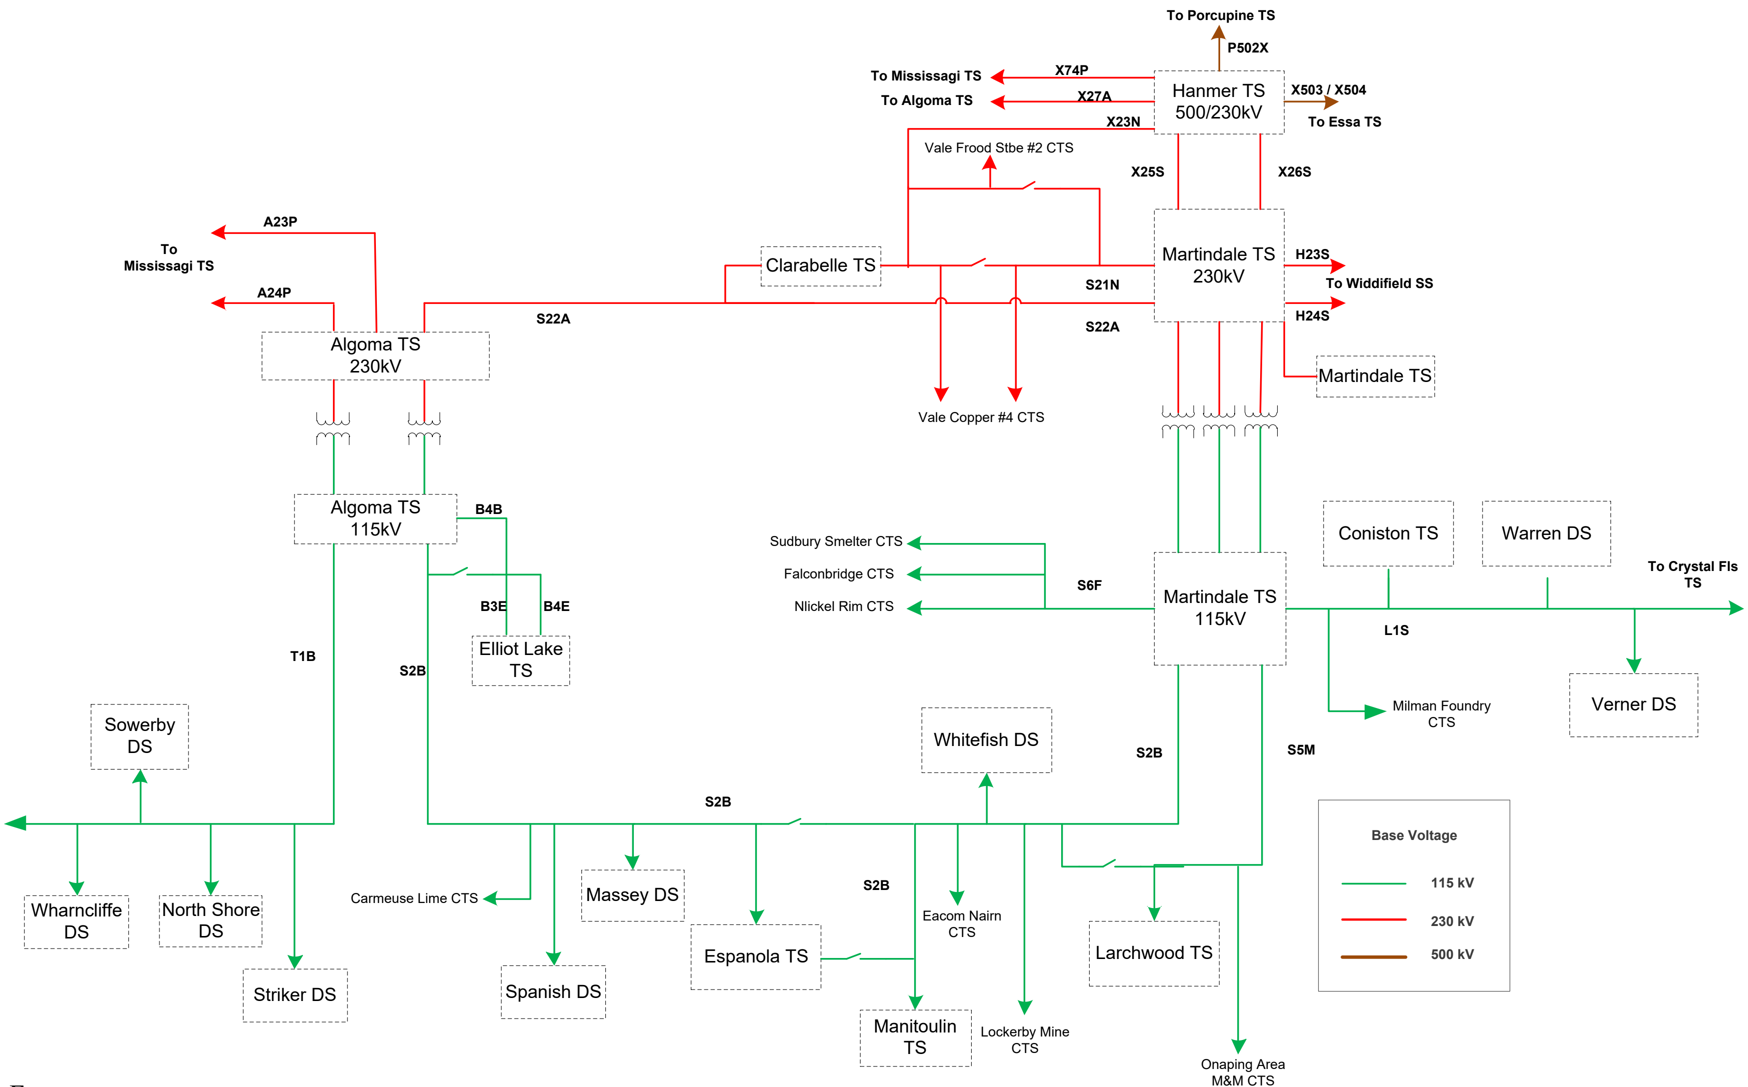

Figure 2: Single Line Diagram – Sudbury to Algoma Region

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information and data to Hydro One:

- IESO provided:
    i. Historical 2013 regional coincident peak load and station non-coincident peak load
    ii. List of existing reliability and operational issues
    iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2011-2013) net load and gross load forecast (2014-2023)
- Hydro One (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

4.1 Load Forecast

As per the data provided by the study team, the gross load in region is expected to grow at an average rate of approximately 0.3% annually from 2014-2023.

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. The net load is expected to decrease at an average rate of approximately 0.2% annually from 2014-2023.

5 NEEDS ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The Region is winter peaking so this assessment is based on winter peak loads.
2. Forecast loads are provided by the Region's LDCs (Greater Sudbury Hydro Inc, Hydro One Distribution).
3. Load data was provided by industrial customers in the region. Where data was not provided, the load was assumed to be consistent with historical loads.
4. The LDC's load forecast is translated into load growth rates and is applied onto the 2013 winter peak load as a reference point.
5. The 2013 winter peak loads are adjusted for extreme weather conditions according to Hydro One's methodology.

6. Accounting for (2), (3), (4) above, the gross load forecast and a net load forecast were developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast which accounts for CDM and DG is analyzed to determine if needs can be deferred. A gross and net non-coincident peak load forecast was used to perform the analysis for Section 6.1.3 of this report.

   A gross and net region-coincident peak load forecast was used to perform the analysis for sections 6.1.1 and 6.1.2.

   Review impact of any on-going and/or planned development projects in the Region during the study period.
7. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.
8. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer or winter 10-Day Limited Time Rating (LTR), as appropriate.
9. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.
10. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their winter long-term emergency (LTE) ratings. Thermal limits for transformers are acceptable using winter loading with winter 10-day LTR.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
    - With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC criteria.

6 RESULTS

This section summarizes the results of the Needs Assessment in the Sudbury to Algoma Region.

6.1 Transmission Capacity Needs

6.1.1 230/115 kV Autotransformers

The 230/115 kV autotransformers (Algoma TS, Martindale TS, Hanmer TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

6.1.2 Transmission Lines & Ratings

The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

The 115 kV circuits supplying the Region are adequate over the study period.

6.1.3 230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and 115 kV transformer stations in the Region using the station winter peak load forecast provided by the study team. All stations in the area have adequate supply capacity for the study period (2014-2023).

6.1.4 Pre-contingency voltages at Manitoulin TS 115kV

Pre-contingency voltages at Manitoulin TS 115kV bus can be below the ORTAC criteria of 113 kV. This issue has been also identified by the IESO as part of their System Impact Assessments.

6.2 System Reliability, Operation and Restoration

Based on the gross coincident load forecast, the loss of one element will not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to The loss of two elements is below the load loss limit of 600MW by the end of the 10-year Study period. For the loss of one or two elements, the load interrupted by configuration does not exceed 150 MW or 250 MW. Review of the power network in the area indicates that all loads in the Sudbury-Algoma area can be restored within the 8 hour requirement.

6.2.1 Post contingency voltage declines at Martindale TS

With either X25S or X26S is out of service, the loss of the companion circuit may result in voltage declines at Martindale 230kV and 115kV buses below acceptable ORTAC limits. This issue has been presented in the IESO System Impact Assessment Victoria

Advanced Exploration Project (CAA 2013-512). In this assessment, voltage declines at the Martindale 230kV and 115 kV buses were found to be greater than the 10% limit.

6.2.2 Post Contingency Thermal Overload of Martindale Autotransformers

Under peak load conditions, the loss of two Martindale 230/115kV transformers may result in the overload of the third Martindale transformer. This issue has been presented in the IESO System Impact Assessment Process Gas (CAA 2012-488).

The double element contingency presented here occurs on the premise that all 115kV area loads would be supplied from one remaining autotransformer at Martindale TS. The worst case would be with Martindale T23 transformer remaining as it has the lowest STE (Short Term Emergency) rating.

Replacement of the autotransformers is listed in Hydro Ones 5yr sustainment business plan. T21/T23 autotransformers at Martindale TS may result in higher emergency ratings. In addition, loads connected to S2B (from Martindale) can also be transferred to S2B from Algoma, reducing Martindale 115kV load.

The above issues (6.2.1, 6.2.2) will be further assessed as part of bulk system planning outside of the regional planning process.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables.
During the study period:

- Replace T21/T23 230/115kV autotransformers at Martindale TS
- Build a new 230/44kV station at Hanmer TS to replace Coniston TS (115/22kV). As part of this project, Coniston loads will be converted from 22kV to 44kV
- Replace 115/44kV power transformers at Espanola TS (T1/T2) and Larchwood TS (T2)

7 RECOMMENDATIONS

Based on the findings and discussion in Section 6 of the Needs Assessment report, the study team recommends that no further coordinated regional planning is required. It is further recommended that following needs identified be best addressed by wires options thru local planning led by Hydro One:

Manitoulin TS - Pre-contingency voltages

- Low pre-contingency voltages at 115kV Manitoulin TS.

8 NEXT STEPS

Following the Needs Assessment process, the next regional planning steps, based on the evaluation conducted by this assessment is for Hydro One Transmission and impacted LDCs to carry out the local planning studies identified in Section 7

NEEDS ASSESSMENT REPORT

Region: Chatham-Kent/Lambton/Sarnia

Date: June 12, 2016

Prepared by: Chatham-Kent/Lambton/Sarnia Study Team

This report is prepared on behalf of the Chatham-Kent/Sarnia/Lambton regional planning study team with the participation of representatives from the following organizations:

Organizations
Hydro One Networks Inc. (Lead Transmitter)
Independent Electricity System Operator
Bluewater Power Distribution Corporation
Entegrus Inc.
Hydro One Networks Inc. (Distribution)

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Chatham-Kent/Lambton/Sarnia and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

NAME	Chatham-Kent/Lambton/Sarnia Study Team		
LEAD	Hydro One Networks Inc.		
REGION	Chatham-Kent/Lambton/Sarnia		
START DATE	April 13, 2016	**END DATE**	June 12, 2016

1. INTRODUCTION

The purpose of this Needs Assessment report is to undertake an assessment of the Chatham-Kent/Lambton/Sarnia Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a “localized” wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE/ TRIGGER

The Needs Assessment for the Chatham-Kent/Lambton/Sarnia Region was triggered in response to the Ontario Energy Board’s (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario’s 21 regions were assigned to one of three groups - Group 1 Regions are being reviewed first. The Chatham-Kent/Lambton/Sarnia Region belongs to Group 3. The Needs Assessment for Chatham-Kent/Lambton/Sarnia Region was triggered on April 13, 2016 and was completed on June 12, 2016.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this Needs Assessment was limited to the next 10 years as per the recommendations of the Planning Process Working Group Report to the OEB.

The scope of the Needs Assessment includes a review of transmission system capability which covers transformer station capacity, transmission circuit thermal capacity, voltage performance and load restoration. System reliability, operational issues and asset replacement plans were also briefly reviewed as part of this Needs Assessment.

Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led Scoping Assessment and/or IRRP, or in the next planning cycle. If required, an IRRP will develop a 20-year strategic direction for the Region

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the IESO, and Hydro One transmission provided information for the Chatham-Kent/Lambton/Sarnia Region. The information included: planning activities already underway, historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, system reliability performance, operational issues and major equipment approaching end-of-life.

5. ASSESSMENT METHODOLOGY

The assessment’s primary objective was to identify the electrical infrastructure needs in the Region over the study period (2015 – 2024). The assessment reviewed available information and load forecasts and included single contingency analysis to identify needs.

6. RESULTS

Transmission Capacity Needs

A. 230/115 kV Autotransformer Capacity

- Based on the gross regional-coincident load forecast, the 230/115 kV autotransformers capacity (Scott TS) supplying the Region is adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

B. 230 kV Transmission Lines

- Based on the gross regional-coincident load forecast, the 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

C. 115 kV Transmission Lines

- Based on the gross regional-coincident load forecast, the 115 kV circuits supplying the Region are adequate over the study period for the loss of a single 115 kV circuit in the Region.

D. 230 kV and 115 kV Connection Facilities

- Loadings at Kent TS exceed their transformer 10-Day Long Term Rating (LTR) in 2016 based on the net load forecast.

System Reliability, Operation and Restoration Needs

A. Load Security

- Based on the gross regional-coincident load forecast and the existing transmission configuration, load security criteria can be met over the study period.

B. Load Restoration

- Based on the gross regional-coincident load forecasts with the use of existing transmission infrastructure, restoration criteria can be met over the study period.

C. Voltage Performance

- Under gross regional-coincident peak load conditions, post-contingency voltage at all transformer stations in the region meet Market Rule requirements.

D. Bulk Power System Performance in the Region

- Based on the assumed system study conditions, no bulk power system issue was identified in the Region. The IESO might undertake planning study to access the adequacy of the bulk power system with different system conditions.

Aging Infrastructure / Replacement Plan

During the study period, plans to replace aged equipment at stations and several transmission circuits will take place. Further details of these investments can be found in Section 6.3 of this report.

7. RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends Hydro One transmission and the relevant LDCs to develop a local plan to address thermal overload of transformer T3 at Kent TS.

LIST OF TABLES

1 INTRODUCTION

This Needs Assessment report provides a description of the analysis to identify needs that may be emerging in the Chatham-Kent/Lambton/Sarnia (the Region) over the next ten years. The development of the Needs Assessment report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the Planning Process Working Group (PPWG) Report to the OEB.

The purpose of this Needs Assessment report is to: consider the information from planning activities already underway; undertake an assessment of the Chatham-Kent/Lambton/Sarnia Region to identify near term and/or emerging needs in the area; and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with LDCs or other connecting customer(s) will further undertake planning assessments to develop options and recommend solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (the IESO) will initiate the Scoping Assessment process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required.

This report was prepared by Hydro One (Lead Transmitter) with input from the Chatham-Kent/Lambton/Sarnia Region Needs Assessment study team listed in Table 1. The report captures the results of the assessment based on information provided by LDCs and the IESO.

2 REGIONAL ISSUE / TRIGGER

The Needs Assessment for the Chatham-Kent/Lambton/Sarnia Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups, where Group 1 Regions are being reviewed first. The Region falls into Group 3. The Needs Assessment for this Region began on April 13, 2016 and was completed on June 12, 2016.

3 SCOPE OF NEEDS ASSESSMENT

This Needs Assessment covers the Chatham-Kent/Lambton/Sarnia Region over an assessment period of 10 years, from 2015 to 2024. The scope of the Needs Assessment includes a review of transmission system connection facility capability which covers transformer station capacity, transmission circuit thermal capacity, voltage performance and load restoration. System reliability, operational issues and asset replacement plans were also briefly reviewed as part of this Needs Assessment.

3.1 Chatham-Kent/Lambton/Sarnia Region Description and Connection Configuration

The region includes the municipalities of Lambton Shores and Chatham-Kent, as well as the townships of Petrolia, Plympton-Wyoming, Brooke-Alvinston, Dawn-Euphemia, Enniskillen, St. Clair, Warwick, and Villages of Oil Springs and Point Edward. The area is bordered by the London area to the east and Windsor-Essex to the southwest.
Figure 1 illustrates the approximate study area.

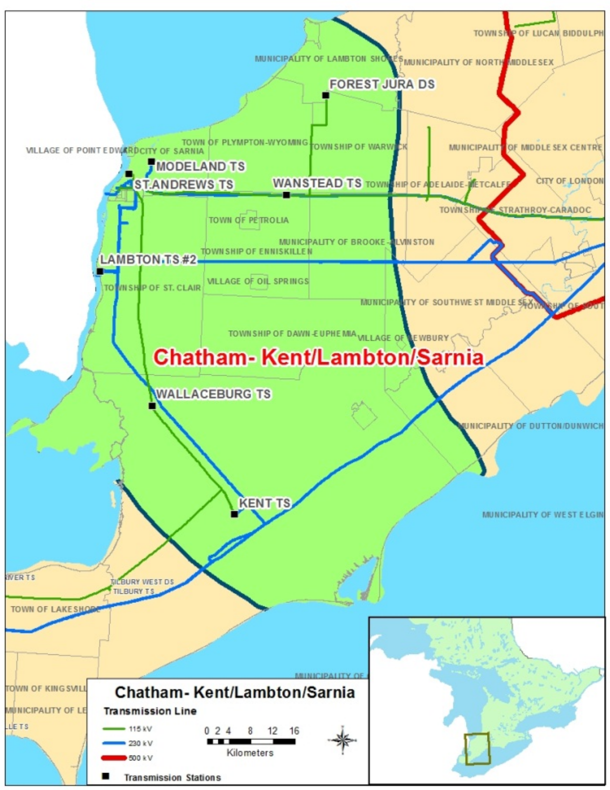

Figure 1: Map of Chatham-Kent/Lambton/Sarnia Region

Electricity supply for the Region is provided through a network of 230 kV and 115 kV transmission lines. The bulk of the electrical supply is transmitted through 230 kV circuits (N21W, N22W, L24L, L26L, W44LC and W45LS) towards Buchanan TS. This Region also contains a number of interconnections with neighboring Michigan State (B3N, L4D and L51D)

Listed in Table 2 and shown in Figure 2 are Hydro One transmission and transmission-connected customers' assets in the Chatham-Kent/Lambton/Sarnia Region.

Table 2: Hydro One and customer assets in Chatham-Kent/Lambton/Sarnia Region

115 kV Circuits	230 kV Circuits	Hydro One Transformer Stations	Customer Transformer Stations
N1S, N4S, N6C, N7C, S2N, N5K, K2Z	N6S, N7S, V41N, V43N, L23N, L27V, L25V, L37G, L38G, L28C, L29C, C31, W44LC, W45LS, S47C, L24L, L26L, N21W, N22W	Scott TS, Lambton TS, Kent TS, Duart TS, Modeland TS, Wanstead TS, St. Andrew TS, Wallaceburg TS	Forest Jura HVDS, Customer CTS #1, Customer CTS #2, Customer CTS #3, Customer CTS #4, Customer CTS #5, Customer CTS #6, Customer CTS #7, Customer CTS #8

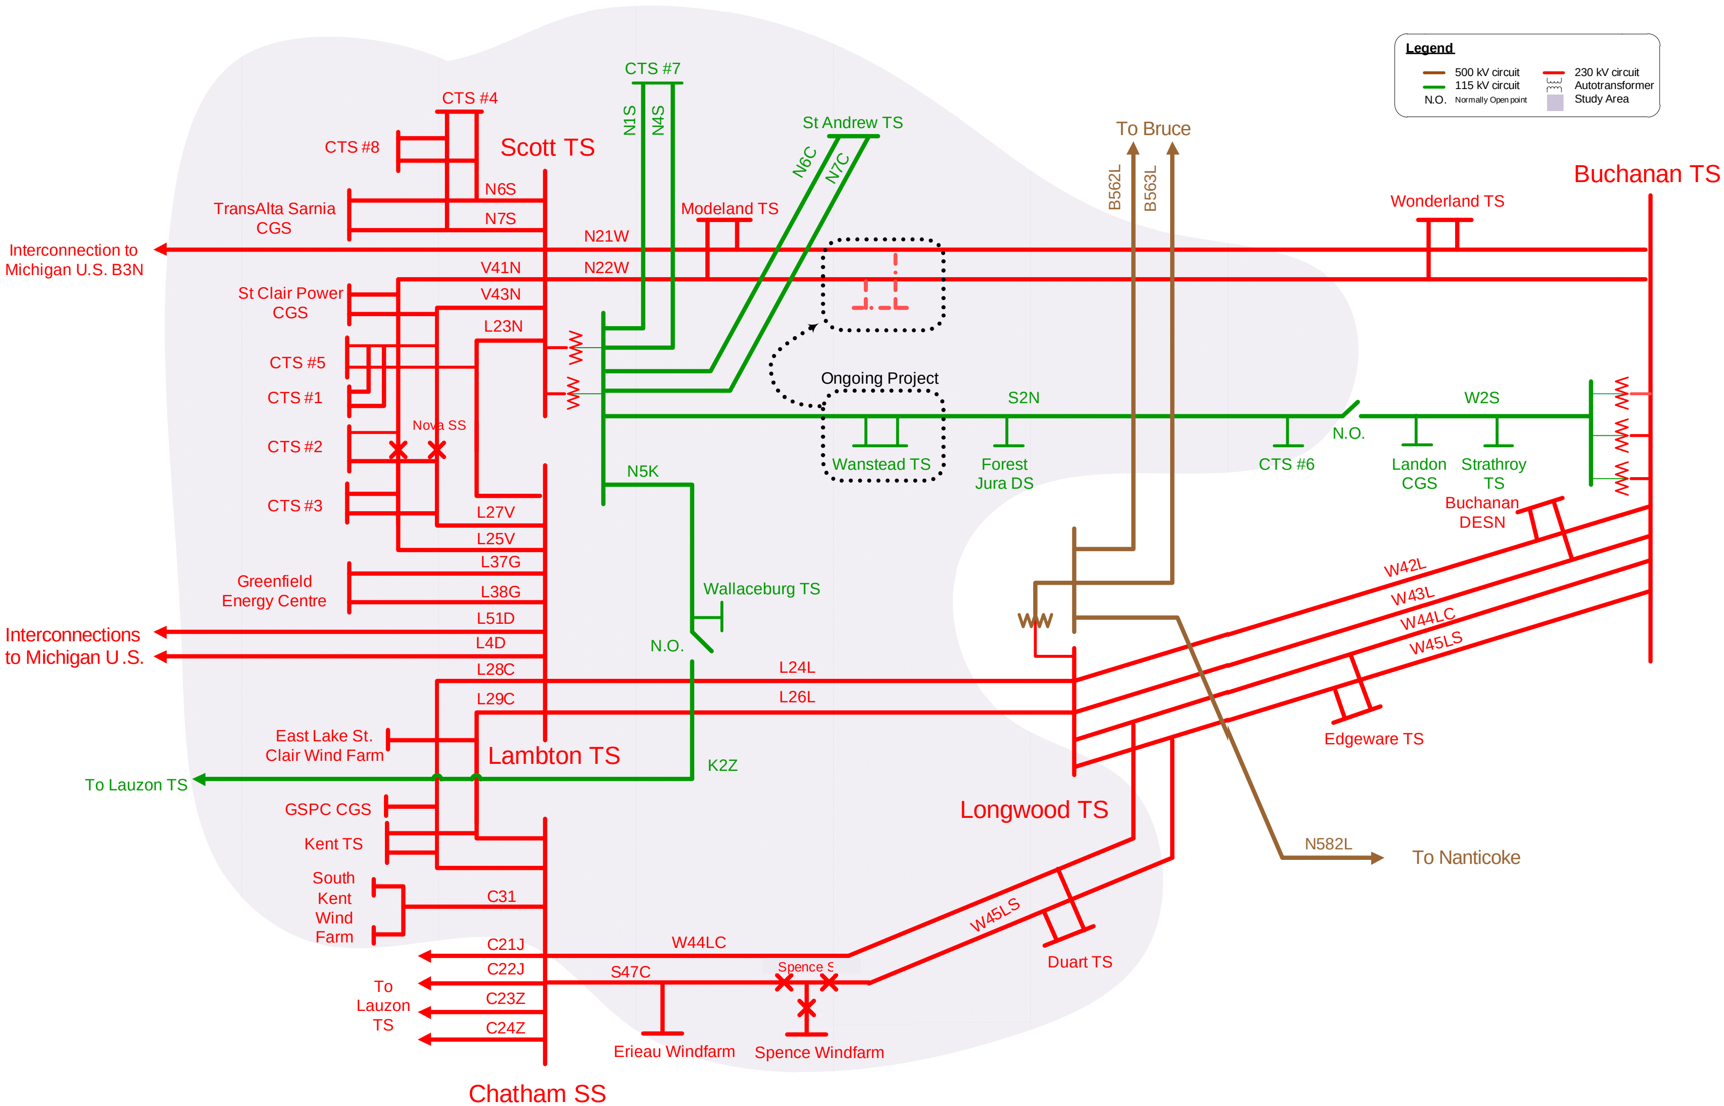

Figure 2: Single-Line diagram – Chatham-Kent/Lambton/Sarnia Region

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information to Hydro One:

- LDCs provided historical summer (2012 – 2014) as well as summer gross load forecast (2015 – 2024)
- IESO provided:
  a. Historical regional coincident peak load and station non-coincident peak load
  b. List of existing reliability and operational issues
  c. Gas generation assumptions (See Table 3)
  d. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- Hydro One (Transmission) provided transformer, station and circuit ratings
- Hydro One (Transmission) provided existing reliability and operation issues
- Any relevant planning information, including planned transmission and distribution investments are provided by Hydro One (Transmission) and LDCs

Table 3 : Gas-fired generation output levels assumed for Needs Assessment

Gas Generators in Chatham-Kent/Lambton/Sarnia area	Maximum continuous summer outputs (MW)
Greenfield Energy Centre	1001
TransAlta Sarnia	435
St. Clair Power CGS	484
Greenfield South Power Corporation (GSPC)	283

Based on the historical information provided, Chatham-Kent/Lambton/Sarnia Region is a summer peaking region. As such, the Needs Assessment was conducted based on summer peak load and studies conditions. Further, as part of Hydro One's regular sustainment assessment, Wanstead TS has been identified as reaching end-of-life and is scheduled for a complete station rebuild. Prior to launch of the Needs Assessment study, LDCs connected to the existing Wanstead TS and Hydro One had committed to rebuilding the existing Wanstead TS from the current 115 kV supply to 230 kV supply. The project is currently being assessed by the IESO as part its System Impact Assessment process (CAA ID 2015-545). As such, the Needs Assessment assumed Wanstead TS will be converted to a 230 kV station. Please refer to Section 6.3 for more details about this conversion project.

4.1 Load Forecast

Based on data provided by the study team, the summer gross coincident load in the Region is expected to grow at an average rate of approximately 1.3% annually from 2015 – 2024. Factoring in the contributions of CDM and DG, the summer net coincident load in the Region is expected to grow at an average rate of approximately 0.2% annually from 2015 – 2024.

Please refer to Appendix A for the load forecasts utilized for this Needs Assessment.

5 Assessment Methodology

The following methodology and assumptions are made in this Needs Assessment:

1. The assessment is based on summer peak loads.
2. Load forecasts are provided by the Region's LDCs using historical 2015 summer peak loads as reference points.
3. For the purpose of Needs Assessment, 2014 historical load levels were assumed for transmission connected industrial customers throughout the study period.
4. The historical peak loads at Hydro One's stations are adjusted for extreme weather conditions according to Hydro One methodology.
5. The LDC's load forecast is translated into load growth rates and is applied onto the historical, extreme weather adjusted, reference points.
6. Accounting for (2), (3), (4), and (5) above, a gross load forecast and a net load forecast are developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net forecast, which accounts for CDM and DG, is analyzed to determine if the needs can be deferred.
   - A gross and net non-coincident peak load forecast was used to perform the analysis for sections 6.1.4
   - A gross and net regional coincident peak load forecast was used to perform the analysis for sections 6.1.1 to 6.1.3, 6.2.1, 6.2.2 and 6.2.4
7. Review impact of any on-going and planned development projects in the Region during the study period.
8. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as transformers, cables, and stations.
9. Station capacity adequacy is assessed by comparing the non–coincident peak load with the station's normal planning supply capacity by assuming a 90% lagging power factor for stations without low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer 10 – Day Limited Time Rating (LTR).

10. Transmission adequacy assessment is primarily based on the following criteria:
    - Regional load is set to the forecasted regional coincident peak load.
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long term emergency (LTE) ratings and transformers within their 10 – Day LTR.
    - All voltages must be within pre and post contingency ranges as per the Ontario Resource and Transmission Assessment Criteria (ORTAC).
    - The system to meet load security criteria as per the ORTAC, specifically, with one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
    - The system is capable of meeting the load restoration timeframes as per the ORTAC.

6 RESULTS

This section summarizes the results of the Needs Assessment in the Chatham–Kent/Lambton/Sarnia Region.

6.1 Transmission System Capacity Needs

6.1.1 230 kV and 115 kV Autotransformers

The 230/115 kV autotransformers (Scott TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

6.1.2 230 kV Transmission Lines

The 230 kV circuits are adequate over the study period for the loss of a single 230 kV circuit in the Region.

6.1.3 115 kV Transmission Lines

The 115 kV lines supplying the Region are radial single circuit lines. These 115 kV circuits have adequate capacity over the study period.

6.1.4 230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and

115 kV transformer stations in the Region using the summer station non- coincident peak load forecasts.

Kent TS T3/T4 is forecasted to exceed its 10 – Day LTR in 2016 based on the net load forecast (approximately 119% Summer 10 – Day LTR in 2016).

All the other TSs in the Chatham-Kent/Lambton/Sarnia Region is forecasted to remain within their normal supply capacity during the study period.

6.2 System Reliability, Operation and Restoration Review

6.2.1 Load Security

Based on the gross regional coincident peak load forecast, with all transmission facilities in–service and coincident with an outage of the largest local generation units, all facilities are within applicable ratings. The largest local generation unit is a 230 kV–connected Greenfield Energy Centre unit on the 230 kV.

Based on the gross regional-coincident load forecast, the loss of one element will not result in load interruption greater than 150 MW by configuration, by planned load curtailment or by load rejection. In addition, under these conditions, all facilities are within their applicable ratings.

Based on the gross regional coincident load forecast, the loss of two elements will not result in load interruption greater than 600 MW by configuration, by planned load curtailment or by load rejection. In addition, under these conditions, all facilities are within their applicable ratings.

Therefore, load security criteria for the Region are met.

6.2.2 Load Restoration

Based on the gross coincident load forecast at Modeland TS, Wanstead TS and Wonderland TS, by the end of study period, the load interrupted is expected to approach 240 MW for the loss of double-circuit 230 kV line N21W and N22W. Presently, N21W can be sectionalized and load can be restored from either Scott TS or Buchanan TS by use of existing switches on N21W. With the switching capabilities, magnitude of load loss can be reduced from the peak level of over 240 MW to less than 150 MW within 4 hours. The remaining load can be resupplied within the 4-8 hours timeframe by means of load transfers and/or switching alternate feeder supplies to neighbouring, unaffected transformer stations. Hydro One will continue to monitor load growth at stations connected to N21W/N22W and update the restoration plan on an ongoing basis as appropriate.

Based on the assumed load levels for the transmission-connected industrial customers connected to N6S and N7S, the load interrupted will exceed 150 MW for the loss of double-circuit 230kV line N6S and N7S. Hydro One crews located in Sarnia will be able to respond as quickly as possible to restore load to meet the 4 hours and 8 hours restoration criteria. It is the customer's accountability to ensure that there is onsite emergency supply for essential load or arrange for backup supply from other sources.

Therefore, load restoration criteria for the Region are met.

6.2.3 Voltage Performance

Under gross regional coincident peak load conditions, post-contingency voltage at all transformer stations in the region meet Market Rule requirements.

6.2.4 Bulk Power System Performance in the Region

Based on the study assumptions listed in Section 4, no issue was identified for bulk power system in the Region. It is noted that, however, there are a number of large scale combined-cycle gas plants in the Sarnia-Lambton area and gas-fired generation output could vary depending on broader system conditions such as expected load growth in the province or availability of other generation resources. Moreover, as previously noted in Section 3.1, the Chatham-Kent/Lambton/Sarnia Region is connected to the US market through interconnections in Sarnia and Lambton. Import and export generation levels on the interties have a significant impact on the bulk transmission system. Recognizing gas-fired generation output and import/export levels are important parameters for the bulk system performance for this Region, the IESO might undertake further study to assess the bulk system adequacy under different system conditions. At the launch of the said study, Hydro One will work with the IESO and solicit inputs from other entities such as large transmission connected industrial customers as required.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Hydro One reviewed the sustainment and development initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables. As mentioned in earlier section, the existing Wanstead TS will be refurbished, with standard 50/66/83 MVA transformers and is scheduled to be completed in 2018. Prior to launch of this study, the LDCs connecting to Wanstead TS and Hydro One had discussed and committed to converting the station from 115 kV to 230 kV connecting to 230 kV circuits N21W and N22W. The Needs Assessment study had included this committed project in the area network setup.

The following sustainment plans do not affect the results of this Needs Assessment study, but are included for completeness:

- The existing St Andrews TS will be refurbished with standard 50/66/83 MVA transformers and is scheduled to be completed in 2023.
- The existing Scott TS will be refurbished, autotransformer T5 will be replaced like-for-like with a 250MVA unit and is scheduled to be completed in 2022.

7 RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team agrees that Scoping Assessment is not required at this time.

For thermal overload of transformer T3 at Kent TS, considering there is adequate regional supply capacity to accommodate expected load growth, it is the study team's recommendation that no further regional coordination is required. Further, the study team recommends Hydro One transmission and the relevant distributors to develop a local plan ("Kent TS – T3 Capacity Limitation") for this need.

APPENDIX A: LOAD FORECASTS

As noted in Section 5, conservation and demand management (CDM) and distributed generation (DG) projects forecast information provided by the IESO were used to determine the net load forecast. The forecasted CDM achievement in the Chatham – Kent/ Lambton/Sarnia area is summarized in Table 4 and it represents the percentage reduction applied to gross peak demand at each station.

Table 4 : CDM forecast for the Chatham- Kent/Lambton/Sarnia Region

	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
CDM	0.96%	2.04%	2.74%	3.84%	4.86%	5.68%	6.25%	6.83%	7.22%	7.72%

The DG information shown in Table 5 and Table 6 reflects all generation contracts with the IESO in the Chatham – Kent/Lambton/Sarnia area: FIT, microFIT and CHPSOP. Further, the DG information represents the cumulative, effective capacity to meeting area peak demand.

Table 5: Chatham-Kent/Lambton/Sarnia regional coincidental load forecast

APPENDIX B: KEY TERMS AND DEFINITIONS

Key terms and definitions associated with this Needs Assessment are cited here.

Normal Supply Capacity
The maximum loading that electrical equipment may be subjected to continuously under nominal ambient conditions such that no accelerated loss of equipment life would be expected.

Coincident Peak Load
The electricity demand at individual facilities at the same point in time when the total demand of the region or system is at its maximum.

Contingency
The prevalence of abnormal conditions such that elements of the power system are not available.

Conservation and Demand Management (CDM)
Programs aimed at using more of one type of energy efficiently to replace an inefficient use of another to reduce overall energy use, and influencing the amount or timing of customers' use of electricity.

Distributed Generation (DG)
Electric power generation equipment that supplies energy to nearby customers with generation capacity typically ranging from a few kW to 25 MW.

Gross Load
Amount of electricity that must be generated to meet all customers' needs as well as delivery losses, not considering any generation initiatives such as CDM and DG. It is usually expressed in MW or MVA.

Limited Time Rating (LTR)
A higher than nameplate rating that a transformer can tolerate for a short period of time

Load Forecast
Prediction of the load or demand customers will make on the electricity system

Net Load
Net of generation (e.g. CDM and DG) deducted from the Gross load

Non-Coincident Peak Load
The maximum electricity demand at an individual facility. Unlike the coincident peak, non-coincident peaks may occur at different times for different facilities.

Peak Load
The maximum load consumed or produced by a unit or group of units in a stated period of time. It may be the maximum instantaneous load or the maximum average load over a designated interval of time.

Weather Corrected Data
Load data that is adjusted to account for extreme weather conditions using an adjustment factor.

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Greater Bruce-Huron Region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	Greater Bruce-Huron Region (the Region)		
LEAD	Hydro One Networks Inc. (Hydro One)		
START DATE	February 29, 2016	**END DATE**	April 28, 2016

1. INTRODUCTION

The purpose of this Needs Assessment report is to undertake an assessment of the Greater Bruce-Huron Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE/ TRIGGER

The Needs Assessment for the Greater Bruce-Huron Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups - Group 1 Regions are being reviewed first. The Greater Bruce-Huron Region belongs to Group 3. The Needs Assessment for this Region was triggered on February 29, 2016 and was completed on April 28, 2016.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this Needs Assessment was limited to the next 10 years as per the recommendations of the Planning Process Working Group Report to the OEB.

The scope of the Needs Assessment includes a review of transmission system capability which covers transformer station capacity, transmission circuit thermal capacity, and voltage performance. System reliability, operational issues and asset replacement plans were also briefly reviewed as part of this Needs Assessment.

Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led Scoping Assessment and/or IRRP, or in the next planning cycle. If required, an IRRP will develop a 20-year strategic direction for the Region.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the IESO, and Hydro One transmission provided information for the Greater Bruce-Huron Region. The information included: planning activities already underway, historical load and power factor, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, system reliability performance, operational issues and major equipment approaching end-of-life.

5. ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs in the Region over the study period (2016 to 2025). The assessment reviewed available information and load forecasts and included single contingency analysis to identify needs.

6. RESULTS

Transmission System Capacity Needs

A. 230/115 kV Autotransformer Capacity

- Based on the gross regional-coincident load forecast, the 230/115 kV autotransformer capacity (Seaforth TS, Hanover TS) supplying the Region is adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

B. 230 kV Transmission Lines

- Based on the gross regional-coincident load forecast, the 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

C. 115 kV Transmission Lines

- Based on the gross regional-coincident load forecast, thermal limits for 115 kV circuit L7S between Seaforth Junction and Kirkton Junction will be exceeded in the near term (summer 2019) for the loss of 115 kV circuit D8S.
- Based on the net regional-coincident load forecast, the need date is expected to be deferred to the end of the study period.
- Due to the limited recorded effectiveness of CDM uptake in this Region, further study is required to identify an action plan.
  - The Need will be managed via Local Planning with the Region's study team.

D. 230 kV and 115 kV Connection Facilities

- Based on the gross non-coincident load forecast, the capacity of the 230 kV and 115 kV connection facilities in the Region are adequate over the study period.

System Reliability, Operation and Restoration Needs

A. Load Security

- Based on the gross regional-coincident load forecast and the existing transmission configuration, load security criteria can be met over the study period.

B. Load Restoration

- Based on the gross regional-coincident load forecasts with the use of existing transmission infrastructure, restoration criteria can be met over the study period.

C. Power Factor at Connection Facilities

- Historically, power factor at Wingham TS and Bruce HWP B TS do not meet Market Rule requirements.
  - The Need at Wingham TS will be managed via Local Planning between the transmitter and the affected LDCs.
  - The Need at Bruce HWP B TS will be managed via Local Planning between the transmitter

and the affected customer.

D. Voltage Performance

- Under gross regional-coincident peak load conditions, post-contingency voltage at the Wingham TS 44 kV bus is below 6% of nominal voltage and may result in poor end-of-feeder voltages (winter 2020/2021).
- Based on the net regional-coincident peak load forecast at Wingham TS, the need date may be deferred by 2 years.
- Due to the synergy between voltage performance and power factor, this voltage deficiency Need will be further studied in coordination with Wingham TS's power factor.
  - The Need will be managed via Local Planning between the transmitters and the affected LDCs

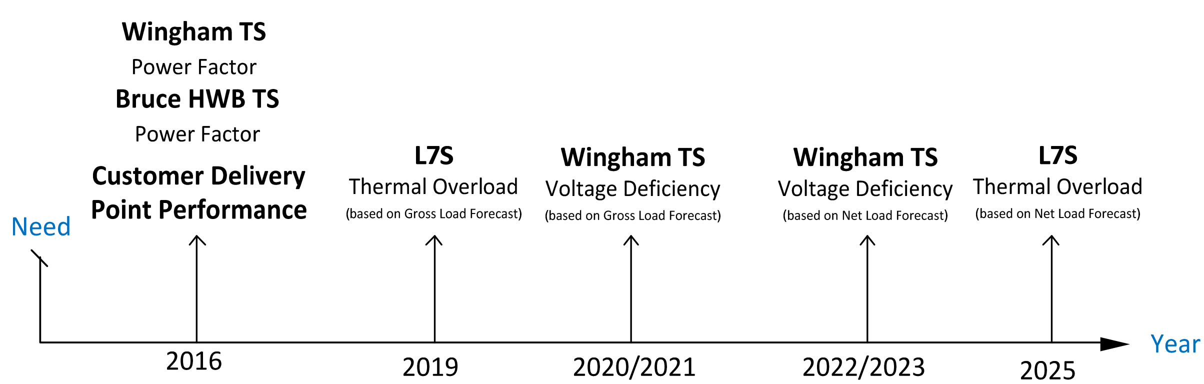
E. Customer Delivery Point Performance

- Based on a review of delivery point performance, several customer delivery points in the Region are below their historical measures.
  - Mitigation measures that align with Hydro One's OEB-approved process for addressing poor performance will be discussed between the transmitter and the affected LDCs and transmission customers.

F. Bulk Power System Performance in the Region

- Based on a limited analysis of the bulk power system in the Region, 230 kV transmission circuit D7V between Detweiler TS and Waterloo North Junction is over its thermal limit near the end of the study period. This result is consistent with the KWCG Regional Infrastructure Plan (RIP) findings.
  - As recommended in the KWCG RIP, this Needs Assessment also recommends further investigation via bulk system planning study.

Needs Timeline Summary



Aging Infrastructure / Replacement Plan

During the study period, plans to replace aged equipment at ten stations and several transmission circuits will take place. The replacement of aged equipment may improve customer delivery point performance. Investigation into customer delivery point performance will take into consideration this replacement work.

Further details of these investments can be found in Section 6.3 of this report.

7. RECOMMENDATIONS

Based on the findings of this Needs Assessment, the study team recommendations:

1. Poor power factor and voltage deficiency at Wingham TS to be managed by Local Planning between Hydro One transmission and Hydro One distribution and may include additional LDC's embedded within Hydro One distribution fed out of Wingham TS

2. Poor power factor at Bruce HWP B TS to be managed by Local Planning between Hydro One transmission and the transmission connected customer.

3. Mitigation of poor delivery point performance to several 115 kV connected customers to be managed according to Hydro One's OEB-approved process between Hydro One transmission, Hydro One distribution, Goderich Hydro and transmission connected customers.

4. Thermal overload on circuit L7S to be managed by Local Planning between Hydro One transmission and the Region's study team.

TABLE OF CONTENTS

LIST OF FIGURES AND TABLES

1 INTRODUCTION

This Needs Assessment report provides a description of the analysis to identify needs that may be emerging in the Greater Bruce-Huron Region (the Region) over the next ten years. The development of the Needs Assessment report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the Planning Process Working Group (PPWG) Report to the OEB.

The purpose of this Needs Assessment report is to: consider the information from planning activities already underway; undertake an assessment of the Greater Bruce-Huron Region to identify near term and/or emerging needs in the area; and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with LDCs or other connecting customer(s) will further undertake planning assessments to develop options and recommend solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (the IESO) will initiate the Scoping Assessment process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required.

This report was prepared by Hydro One (Lead Transmitter) with input from the Greater Bruce-Huron Region Needs Assessment study team listed in Table 1. The report captures the results of the assessment based on information provided by LDCs and the IESO.

Table 1: Study Team Participants for Greater Bruce-Huron Region

No.	Company
1	Hydro One Networks Inc. (Lead Transmitter)
2	Entegrus
3	Erie Thames Power
4	Festival Hydro Inc.
5	Goderich Hydro - West Coast Huron Energy Inc.
6	Hydro One Networks Inc. (Distribution)
7	Independent Electricity System Operator
8	Wellington North Power Inc.
9	Westario Power Inc.

2 TRIGGER OF NEEDS SCREEN

The Needs Assessment for the Greater Bruce-Huron Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups, where Group 1 Regions are being reviewed first. The Region falls into Group 3. The Needs Assessment for this Region was triggered on February 29, 2016 and was completed on April 28, 2016.

3 SCOPE OF NEEDS ASSESSMENT

This Needs Assessment covers the Greater Bruce-Huron Region over an assessment period of 2016 to 2025. The scope of the Needs Assessment includes a review of transmission system connection facility capability which covers transformer station capacity, transmission circuit thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this Needs Assessment.

3.1 Greater Bruce-Huron Region Description and Connection Configuration

The Greater Bruce-Huron Region includes the counties of Bruce, Huron and Perth, as well as portions of Grey, Wellington, Waterloo, Oxford and Middlesex counties. The boundary of the Greater Bruce-Huron Region is shown in Figure 1.

Figure 1: Greater Bruce-Huron Region Map

Electricity supply for the Region is provided through a network of 230 kV and 115 kV transmission lines supplied mainly by generation from the Bruce Nuclear Generating Station and local renewable generation facilities in the Region. The bulk of the electrical supply is transmitted through 230 kV circuits (B4V, B5V, B22D, B23D, B27S and B28S) radiating out from Bruce A TS. These circuits connect the Region to the adjacent South Georgian Bay/Muskoka Region and the adjacent Kitchener-Waterloo-Cambridge-Guelph (KWCG) Region.

Listed in Table 2 and shown in Figure 2, are the transmission and transmission connected assets in the Greater Bruce-Huron Region.

Table 2: Hydro One and Customer Assets Bounded by the Greater Bruce-Huron Region

115 kV Circuits	230 kV Circuits	Hydro One Transformer Stations	Customer Transformer Stations

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information to Hydro One:

- IESO provided:
  i. Historical regional coincident peak load and station non-coincident peak load
  ii. List of existing reliability and operational issues
  iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
  iv. Historical power factor data, MW and MVar for each station in the Region
- LDCs provided historical summer and winter net load (2013-2015) as well as summer and winter gross load forecast (2016-2025)
- Hydro One (Transmission) provided transformer, station and circuit ratings
- Hydro One (Transmission) provided existing reliability and operation issues
- Any relevant planning information, including planned transmission and distribution investments are provided by Hydro One (Transmission) and LDCs

4.1 Load Forecast

As per the data provided by the study team, the winter *gross* coincident load in the Region is expected to grow at an average rate of approximately 1.1% annually from 2016-2025 and the summer *gross* coincident load in the Region is expected to grow at an average rate of approximately 1.0% from 2016-2025.

As per the data provided by the study team, the winter *net* coincident load in the Region is expected to grow at an average rate of approximately 0.5% annually from 2016-2025 and the summer *net* coincident load in the Region is expected to grow at an average rate of approximately 0.3% from 2016-2025.

Based on historical load and on the load forecast, the Regions' winter coincident peak load is larger than its summer coincident peak load. As well, the majority of stations within the Region are winter peaking. The load forecasts utilized for this Needs Assessment are found in Appendix A: Load Forecasts.

5 NEEDS ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The Region contains some stations that are summer peaking and others that are winter peaking. Equipment ratings are normally lower in the summer than winter due to ambient temperature. Based on these factors this assessment is conducted for both summer and winter peak load.
2. Forecast loads are provided by the Region's LDCs using historical 2015 summer and historical 2014/2015 winter peak loads as reference points.
3. Forecast loads are provided by industrial customers in the Region. Where data was not provided, the load is assumed to be consistent with historical loads.
4. The historical peak loads are adjusted for extreme weather conditions according to Hydro One methodology.
5. The LDC's load forecast is translated into load growth rates and is applied onto the historical, extreme weather adjusted, reference points.
6. Accounting for (2), (3), (4), (5) above, a gross load forecast and a net load forecast are developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net forecast, which accounts for CDM and DG, is analyzed to determine if the needs can be deferred.
    a. A gross and net non-coincident peak load forecast was used to perform the analysis for sections 6.1.4 and 6.2.3
    b. A gross and net regional-coincident peak load forecast was used to perform the analysis for sections 6.1.1 to 6.1.3 and 6.2.1 and 6.2.2 and 6.2.4
7. Review impact of any on-going and planned development projects in the Region during the study period.
8. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as transformers, cables, and stations.
9. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity by assuming a 90% lagging power factor for stations without low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer and winter 10-Day Limited Time Rating (LTR), as appropriate.
10. Transmission adequacy assessment is primarily based on the following criteria:
    - Regional load is set to the forecasted regional-coincident peak load
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.

- With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings and transformers within their 10-Day LTR.
- All voltages must be within pre and post contingency ranges as per the Ontario Resource and Transmission Assessment Criteria (ORTAC).
- The system to meet load security criteria as per the ORTAC, specifically, with one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
- The system is capable of meeting the load restoration timeframes as per the ORTAC.

6 RESULTS

This section summarizes the results of the Needs Assessment in the Greater Bruce-Huron Region. The results are based on all 8 Bruce nuclear generating units in-service and no local/renewable generating units in-service in order to verify whether the transmission system has adequate capacity to supply the forecasted regional load.

6.1 Transmission System Capacity Needs

6.1.1 230 kV and 115 kV Autotransformers

The 230/115 kV autotransformers (Seaforth TS, Hanover TS, Detweiler TS, Owen Sound TS) supplying the Region are adequate over the study period for the loss of a single 230/115 kV autotransformer in the Region.

6.1.2 230 kV Transmission Lines

The 230 kV lines supplying the Region are double circuit. The 230 kV circuits are adequate over the study period for the loss of a single 230 kV circuit in the Region.

6.1.3 115 kV Transmission Lines

The 115 kV lines supplying the Region are radial single circuit lines. These 115 kV circuits have adequate capacity over the study period.

115 kV circuit L7S that runs between Seaforth TS and St. Mary's TS is connected to 115 kV circuit D8S that runs between St. Marys TS and Detweiler TS, through the St. Marys TS low voltage bus-tie breaker. For the loss of D8S, L7S will exceed its short-term emergency (STE) and LTE ratings in the near term (summer 2019), under summer *gross*

peak load conditions. Under summer *net* peak load conditions, the flow on L7S decreases to ~97% of its emergency ratings at the end of the study period (summer 2025).

The sections of circuit explicitly over their ratings are: Seaforth Jct. x Goshen Jct., and Goshen Jct. x Kirkton Jct. The emergency ratings of these sections are limited by substandard clearances due to ground topology and a rural distribution line. Due to the limited recorded effectiveness of CDM uptake in this Region, this thermal overload Need will require further study and will therefore be managed by Local Planning with the Region's study team.

6.1.4 230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and 115 kV transformer stations in the Region using the winter and summer station non-coincident peak load forecasts. All stations in the Region have adequate supply capacity for the study period (2016-2025).

6.2 System Reliability, Operation and Restoration Review

6.2.1 Load Security

Based on the gross regional-coincident peak load forecast, with all transmission facilities in-service and coincident with an outage of the largest local generation units, all facilities are within applicable ratings. The largest local generation unit is a 230 kV-connected Bruce nuclear unit on the 230 kV system while on the 115 kV system Goshen wind farm is assumed out of service.

Based on the gross regional-coincident load forecast, the loss of one element will not result in load interruption greater than 150 MW by configuration, by planned load curtailment or by load rejection. In addition, under these conditions, all facilities are within their applicable ratings.

Based on the gross regional-coincident load forecast, the loss of two elements will not results in load interruption greater than 600 MW by configuration, by planned load curtailment or by load rejection. In addition, under these conditions, all facilities are within their applicable ratings.

Therefore, load security criteria for the Region are met.

6.2.2 Load Restoration

Based on the gross regional-coincident peak load forecasts, with the use of existing transmission infrastructure, all load can be restored within approximately 8 hours depending on the severity of the contingency, the prevailing system conditions and the relative distance from the nearest field maintenance centre. Existing transmission infrastructure includes switches that can be operated from the Ontario Grid Control Centre (OGCC), Mid-Span Openers (MSOs) and other isolating devices that require a bucket truck and line crew to open and close.

The largest loss of load in the Region is 325 MW in winter 2024/2025 for the loss of the double circuit line B22D/B23D. By use of existing 61B22D-21 and 61B23D-26 switches at Seaforth TS, the OGCC can quickly resupply, within 30 minutes, approximately 218 MW from Bruce A TS or approximately 268 MW from Detwiler TS. The remaining load can be resupplied in 4-8 hours by opening existing bolted openers along the circuits.

Therefore, load restoration criteria for the Region are met.

6.2.3 Power Factor at Connection Facilities

Based on the analysis of historical power factors at connection facilities under peak load conditions, the power factor at Wingham TS does not meet Market Rule requirements. Based on May 2014 to May 2015 historical data the power factor at Wingham TS does not meet Market Rule requirement of 0.9 lead-lag power factor at the defined meter point at least 60% of the time. This is a Need that will be managed by Local Planning between the transmitter and the affected LDCs.

Based on the analysis of historical power factors at connection facilities under peak load conditions, the power factor at Bruce HWP B TS does not meet Market Rule requirements. Based on January 2014 to December 2015 historical data the power factor at Bruce HWP B TS does not meet Market Rule requirement of 0.9 lead-lag power factor at the defined meter point approximately 80% of the time. This is a Need that will be managed by Local Planning between the transmitter and the affected customer.

6.2.4 Voltage Performance

Under winter 2020/2021 gross regional-coincident peak load conditions, post-contingency voltage at the Wingham TS 44 kV bus is below 6% of nominal voltage and may result is poor end-of-feeder voltages. Under winter *net* regional-coincident peak load conditions, the need is deferred by two years to winter 2022/2023. This is a Need that requires mitigation via Local Planning between the transmitter and the affected LDCs.

6.2.5 Customer Delivery Point Performance

Based on a review of Hydro One's historical delivery point performance statistics, several customer delivery points in the Region are below their historical measures. The delivery points are those fed from the Region's 115 kV system. These statistics are consistent with those provided by IESO. Mitigation measures that align with Hydro One's OEB approved process for addressing poor performance will be discussed between the transmitter and the affected LDCs and transmission customers.

6.2.6 Bulk Power System Performance in the Region

To bridge regional system planning with bulk system planning, a select number of bulk system planning contingencies within the Region are undertaken. With respect to the 230 kV circuits that supply regional load, breaker failure contingencies of these circuit's terminal breakers at BES and BPS station are analyzed to determine their impact. Gross regional-coincident peak load for the Greater Bruce-Huron region was used while a net regional-coincident peak load forecast for the KWCG region was used.

The results showed that 230 kV transmission circuit D7V between Detweiler TS and Waterloo North Junction is at its thermal rating at the end of the study period. This result is consistent with KWCG Regional Infrastructure Plan findings.

As recommended in the KWCG RIP, this Needs Assessment also recommends further investigation via bulk system planning study.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Table 3 lists Hydro One transmission sustainment initiatives that are currently planned for aging and End-Of-Life (EOL) infrastructure.

Table 3: Hydro One Transmission Sustainment Initiatives

Station/Circuit	Description of Work	Planning In-Service Date
Bruce A TS	230 kV breaker replacement	2019
	500 kV breaker replacement	2024
Bruce B SS	500 kV breaker replacement	2020
Goderich TS	Station refurbishment: replace existing 3 transformers (T1/T2/T3) with a typical 50/83 MVA 2 transformer DESN arrangement (T4/T5)	2017
Detweiler TS	Replace AC station service	2017
	Replace T2 and T4 autotransformers	2021
Centralia TS	Station refurbishment: replace existing 3 transformers with a typical 25/42 MVA 2	2018

	transformer DESN arrangement	
Palmerston TS	Station refurbishment: replace existing 3 transformers with a typical 50/83 MVA 2 transformer DESN arrangement	2018
Wingham TS	Station refurbishment	2022
Seaforth TS	Station refurbishment: to include autotransformers and DESN	2023
Hanover TS	Station refurbishment: to include DESN	2023
Stratford TS	Station refurbishment	2023
Circuit L7S	Replacement of 4 wood poles	2016
	Insulator replacements	As required
Circuit S1H	Replacement of shield wire	2016
	Replacement of 9 wood poles	2017
Circuits B4V & B5V	Insulator and U-bolt replacement	As required
Circuits B22D & B23D	Insulator replacements	As required
Circuits B27S & B28S	Insulator replacements	As required
Circuits B20P & B24P	Insulator replacements	As required

The replacement and/or refurbishment of equipment may improve the overall reliability performance at customer delivery points. Further investigation is required to verify.

6.4 Planned Transmission and Distribution Investments

Listed in Table 4 are planned transmission and distribution investments in the Region. Note that other than the currently planned refurbishment work in table 3, Hydro One transmission does not have additional planned investments within the Region other than connecting generation upon request.

Table 4: Planned Local Distribution Company Investments

LDC	**Investment Description**	**Planning In-Service Date**
Wellington North Power	Transfer ~50% of LDC's Mount Forest load fed from Hanover TS to Palmerston TS in 2016. A feeder extension (M2) from Palmerston TS will be used for this load transfer. This transfer has been incorporated into the Region's station load forecast.	2016

7 RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team's recommendations are as follows:

1. To mitigate poor power factor and to prevent against voltage deficiency at Wingham TS, Local Planning between Hydro One transmission and Hydro One distribution (this may include additional LDC's embedded within Hydro One distribution fed out of Wingham TS) is recommended.

2. To mitigate poor power factor at Bruce HWP B TS, Local Planning between Hydro One transmission and the transmission connected customer is recommended.

3. To mitigate poor delivery point performance to several 115 kV connected customers, planning in accordance with Hydro One's OEB-approved process between Hydro One transmission, Hydro One distribution, Goderich Hydro and transmission connected customers is recommended.

4. To prevent against thermal overload on circuit L7S, Local Planning between Hydro One transmission and the Region's study team is recommended.

NEEDS ASSESSMENT REPORT

Region: Niagara

Date: April 30th 2016

Prepared by: Niagara Region Study Team

Niagara Study Team
Hydro One Networks Inc. (Lead Transmitter)
Independent Electricity System Operator
Hydro One Networks Inc. (Distribution)
Canadian Niagara Power Inc.
Grimsby Power Inc.
Haldimand County Hydro Inc.
Horizon Utilities Corp.
Niagara Peninsula Energy Inc.
Niagara on the Lake Hydro Inc.
Welland Hydro Electric System Corp.

DISCLAIMER

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Niagara region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

Region	Niagara (the "Region")		
Lead	Hydro One Networks Inc. ("Hydro One")		
Start Date	October 15, 2015	End Date	April 30th 2016

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the Niagara Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, IESO will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the Niagara Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 and 2 regions is complete and has been initiated for Group 3 Regions. The Niagara Region belongs to Group 3. The NA for this Region was triggered on October 15, 2015 and was completed on April 30th 2016

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2025. Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning. This NA included a study of transmission system connection facilities capability, which covers station loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the Independent Electricity System Operator (IESO), and Hydro One transmission provided information for the Niagara Region. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs and system performance issues in the Region over the study period (2015 to 2024). The assessment reviewed available information, load forecasts and included single contingency analysis to confirm needs, if and when required. See Section 5 for further details.

6. RESULTS

Transmission Needs

A. Transmission Lines & Ratings

The 230kV and 115kV lines are adequate over the study period with a section of 115kV circuit Q4N being the exception.

B. 230 kV and 115 kV Connection Facilities

The 230kV and 115kV connection facilities in this region are adequate over the study period.

System Reliability, Operation and Restoration Review

There are no known issues with system reliability, operation and restoration in the Niagara region.

Aging Infrastructure / Replacement Plan

Within the regional planning time horizon, the following sustainment work is currently planned by Hydro One in the region:

- DeCew Falls SS: Circuit Breaker Replacement (2017)
- Sir Adam Beck SS #1: 115kV Refurbishment Project (2018)
- 115kV Q11/Q12S Line Refurbishment from Glendale TS to Beck SS #1 (2019)
- Carlton TS: Switchgear Replacement (2020)
- Sir Adam Beck SS #2: 230kV Circuit Breakers Replacement (2020)
- Glendale TS: Station Refurbishment and Reconfiguration (2021)
- Stanley TS: Station Refurbishment (2021)
- Thorold TS: Transformer Replacement (2021)
- Crowland TS: Transformer Replacement (2021)

Based on the findings of the Needs Assessment, the study team recommends that thethermal overloading of 115kV circuit Q4N shouldbe further assessed as part of a Local Plan. No further regional coordination or planning is required.

LIST OF TABLES

1 Introduction

This Needs Assessment (NA) report provides a summary of needs that are emerging in the Niagara Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the Niagara Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. The SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain local type of needs if straight forward wires solutions can address a need. Ultimately, assessment and findings of the local plans are incorporated in the RIP for the region.

This report was prepared by the Niagara Region NA study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, and the Independent Electricity System Operator (IESO).

Table 1: Study Team Participants for Niagara Region

No.	Company
1	Hydro One Networks Inc. (Lead Transmitter)
2	Independent Electricity System Operator
3	Canadian Niagara Power Inc.
4	Grimsby Power Inc.
5	Haldimand County Hydro Inc
6	Horizon Utilities Corp.
7	Hydro One Networks Inc. (Distribution)
8	Niagara Peninsula Energy Inc.
9	Niagara on the Lake Hydro Inc.
10	Welland Hydro Electric System Corp.

2 Regional Issue / Trigger

The NA for the Niagara Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The Niagara Region belongs to Group 3.

3 Scope of Needs Assessment

This NA covers the Niagara Region over an assessment period of 2015 to 2024. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

3.1 Niagara Region Description and Connection Configuration

For regional planning purposes, the Niagara region includes the City of Port Colborne, City of Welland, City of Thorold, City of Niagara Falls, Town of Niagara-on-the-Lake, City of St. Catharines, Town of Fort Erie, Town of Lincoln, Township of West Lincoln, Town of Grimsby, Township of Wainfleet, and Town of Pelham. Haldimand County has also been included in the regional infrastructure planning needs assessment for Niagara region. A map of the region is shown below in Figure 1.

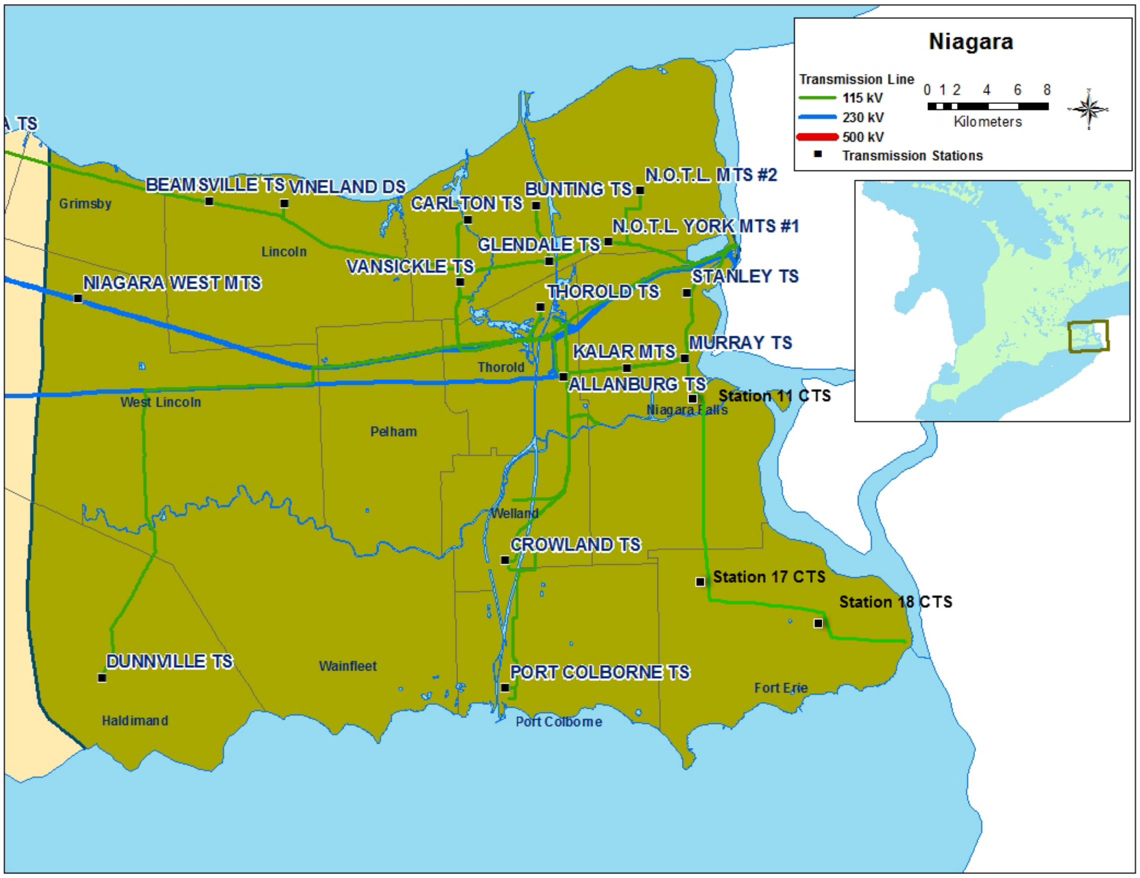

Figure 1: Niagara Region Map

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits supplied mainly by the local generation from Sir Adam Beck #1, Sir Adam Beck #2, Decew Falls GS, Thorold GS and the autotransformers at Allanburg TS.

Bulk supply is provided through the 230kV circuits (Q23BM, Q24HM, Q25BM, Q26M, Q28A, Q29HM, Q30M, and Q35M) from Sir Adam Beck #2 SS. These circuits connect this region to Hamilton/Burlington.

The Niagara Region has the following local distribution companies (LDC):

- Canadian Niagara Power Inc.
- Grimsby Power Inc.
- Haldimand County Hydro Inc.
- Horizon Utilities
- Hydro One Distribution Inc.
- Niagara Peninsula Energy Inc.
- Niagara on the Lake Hydro Inc.
- Welland Hydro Electric System Corporation

Large transmission connected customers in the area will not actively participate in the regional planning process, however their load forecasts will used in determining regional supply needs.

Table 2: Transmission Lines and Stations in Niagara Region

115kV circuits	230kV circuits	Hydro One Transformer Stations	Customer Transformer Stations

4 Inputs and Data

In order to conduct this Needs Assessment, study team participants provided the following information and data to Hydro One:

- Actual 2013 regional coincident peak load and station non-coincident peak load provided by IESO;
- Historical (2012-2014) net load and gross load forecast (2015-2024 provided by LDCs and other Transmission connected customers;
- Conservation and Demand Management (CDM) and Distributed Generation (DG) data provided by IESO;
- Any known reliability and/or operating issues conditions identified by LDCs or the IESO;
- Planned transmission and distribution investments provided by the transmitter and LDCs, etc.

4.1 Load Forecast

As per the data provided by the study team, the gross load in region is expected to grow at an average rate of approximately 0.61% annually from 2015-2024.

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. With these factors in place, the total regional load is expected to decrease at an average rate of approximately 0.26% annually from 2015-2024.

5 Needs Assessment Methodology

The following methodology and assumptions are made in this Needs Assessment:

1. The Region is summer peaking so this assessment is based on summer peak loads.
2. Forecast loads are provided by the Region's LDCs.
3. Load data for the industrial customers in the region were assumed to be consistent with historical loads.
4. Accounting for (2), (3), above, the gross load forecast and a net load forecast were developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast which accounts for CDM and DG are analyzed to determine if the needs can be deferred. A gross and net non-coincident peak load forecast was used to perform the analysis for this report.

5. Review impact of any on-going and/or planned development projects in the Region during the study period.
6. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.
7. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the summer 10-Day Limited Time Rating (LTR). Summer LTR ratings were reviewed to assess the worst possible loading scenario from a ratings perspective.
8. Extreme weather scenario factor at 1.037 was also assessed for capacity planning over the study term.
9. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.
10. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their summer long-term emergency (LTE) ratings. Thermal limits for transformers are acceptable using summer loading with summer 10-day LTR.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.

- With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC criteria.

6 Results

6.1 Transmission Capacity Needs

230/115 kV Autotransformers

The 230/115kV transformers supplying the region are adequate for loss of single unit.

Transmission Lines & Ratings

The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

The 115 kV circuits supplying the Region are adequate over the study period with Q4N as an exception between Sir Adam Beck SS #1 x Portal Junction.

230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and 115 kV transformer stations in the Region using the station summer peak load forecast provided by the study team. All stations in the area have adequate supply capacity for the study period even in the event of extreme weather scenario.

6.2 System Reliability, Operation and Restoration

6.2.1 Load Restoration

Load restoration is adequate in the area and meet the ORTAC load restoration criteria.

The needs assessment did not identify any additional issues with meeting load restoration as per the ORTAC load restoration criteria.

6.2.2 Thermal Overloading on Q4N Section

Under high generation scenarios at Sir Adam Beck GS #1, the loading on the *Beck SS #1 x Portal Junction* section (egress out from the GS) of 115kV circuit Q4N can exceed circuit ratings. Hydro One already has plans to address this issue as part of the Beck SS #1 Refurbishment Project.

6.2.3 Power Factor at Thorold TS

A few instances (<54 hours / year) of power factor below 0.9 (between 0.89 - 0.9) were observed at the HV side of Thorold TS. Hydro One Distribution will investigate these instances and work with Distribution customers to address.

7 Aging Infrastructure and Replacement Plan of Major Equipment

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers and power transformers during the study period. At this time, the following sustainment work is planned at the following stations:

- DeCew Falls SS Circuit Breaker Replacement (2017)
- Sir Adam Beck SS #1 115kV Refurbishment Project (2018)
- 115kV Q11/Q12S Line Refurbishment from Glendale TS to Beck SS #1 (2019)
- Carlton TS; Switchgear Replacement (2020)
- Sir Adam Beck SS #2 230kV Circuit Breakers Replacement (2020)
- Glendale TS; Station Refurbishment and Reconfiguration (2021)
- Stanley TS; Station Refurbishment (2021)
- Thorold TS; Transformer Replacement (2021)
- Crowland TS; Transformer Replacement (2021)

8 Recommendations

Based on the findings and discussion in Section 6 and 7 of this report, the study team recommends that no further regional coordination or further planning is required. The region will be reassessed within five years as part of the next planning cycle.

9 Next Steps

No further Regional Planning is required at this time. The Niagara Region Regional Planning will be reassessed during the next planning cycle or at any time should unforeseen conditions or needs warrant to initiate the regional planning for the region.

NEEDS ASSESSMENT REPORT

Region: North and East of Sudbury

Date: April 15, 2016

Prepared by: North and East of Sudbury Region Working Group

North & East of Sudbury Working Group	
Organization	**Name**
Hydro One Networks Inc. (Lead Transmitter)	Kirpal Bahra Qasim Raza
Independent Electricity System Operator	Chris Reali Philip Woo
Hydro One Networks Inc. (Distribution)	Richard Shannon Daniel Boutros
Northern Ontario Wires Inc	Dan Boucher
Hearst Power Ltd	D Sampson J Richard
North Bay Hydro Distribution Ltd	Matt Payne

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the North & East of Sudbury region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by Working Group participants.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	North & East of Sudbury (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	October 15, 2015	**END DATE**	April 15, 2016

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the North & East of Sudbury Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, IESO will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the North & East of Sudbury Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 and 2 regions is complete and has been initiated for Group 3 Regions. The North & East of Sudbury Region belongs to Group 3, triggered on October 15, 2015 and completed on April 17, 2016

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2026. Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning. This NA included a study of transmission system connection facilities capability, which covers station loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Working Group participants included representatives from LDCs, the Independent Electricity System Operator (IESO), and Hydro One. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective is to identify the electrical infrastructure needs and system performance issues in the Region over the study period (2016 to 2026). The assessment reviewed available information, load forecasts and included single contingency analysis to confirm needs, if and when required.

6. RESULTS - TRANSMISSION NEEDS

A. 500/230kV Autotransfomers

The 500/230kV Autotransformers supplying the regional are adequate over the study period for the loss of a single 500/230kV unit.

B. 500/115kV Autotransfomers

The 500/115kV Autotransformers supplying the regional are adequate over the study period for the loss of a single 500/115kV unit

C. 230/115 kV Autotransformers

The 230/115kV Autotransformers supplying the regional are adequate over the study period for the loss of a single 230/115kV unit

D. Transmission Lines & Ratings

The 500kV, 230kV transmission lines are adequate over the study period.

Sections of the 115kV H9K circuit may experience thermal overloads during high generation scenarios. This is a bulk system issue and will be addressed jointly with the IESO outside of regional planning.

E. 230 kV and 115 kV Connection Facilities

The 230kV and 115kV connection facilities in this region are adequate over the study period.

F. Outage Condition resulting in P15T,P7G and T61S radially connected to Timmins TS

The loss of K1K4 and K1K2 circuit breakers at Porcupine TS can result in excessive voltage declines at Timmins TS 115kV bus

G. Ansonville T2 or D3K Outages

With Ansonville T2 or D3K out of service, the loss of the other can result in excessive voltage decline at the Kirkland Lake TS 115kV bus.

System Reliability, Operation and Restoration Review

Circuit reliability in the region is acceptable, and Hydro One will continue to monitor performance of supply stations and circuits to ensure customer delivery performance criteria are met.

Restoration requirements for the loss of one element can be met by Hydro One.
Restoration requirements for the loss of up to two elements can be met by Hydro One.

Aging Infrastructure / Replacement Plan

Within the regional planning time horizon, the following work is part of Hydro One approved sustainment business plan

Dymond TS (T3/T4) transformers (2016)
Kirkland Lake TS (T12/T13) transformers (2017)
Timmins TS (T63/T64) with single 83MVA (2016)
Otto Holden TS (T3/T4) autotransformers, and 115kV circuit breakers (2019)

7. RESULTS – NEEDS ASSESSMENT REPORT

Based on the findings of the Needs Assessment, the Working Group recommends that no further regional coordination is required and following needs identified be further assessed as part of Local Planning:

Timmins TS / Kirkland Lake TS – Voltage Regulation Issues

TABLE OF CONTENTS

LIST OF FIGURES

1 INTRODUCTION

This Needs Assessment (NA) report provides a summary of needs that are emerging in the North & East of Sudbury Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the North & East of Sudbury Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. If localized wires only solutions do not require further coordinated regional planning, the SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs.

This report was prepared by Hydro One Inc ("Hydro One") on behalf of the North & East of Sudbury Region NA Working Group (Table 1). The report captures the results of the assessment based on information provided by LDCs, and the Independent Electricity System Operator (IESO).

5.	Hearst Power Ltd
6.	North Bay Hydro Inc.

2 Regional Issue / Trigger

The NA for the North & East of Sudbury Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The North & East of Sudbury Region belongs to Group 3.

3 Scope of Needs Assessment

This NA covers the North & East of Sudbury Region over an assessment period of 2016 to 2026. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

North & East of Sudbury Region Description and Connection Configuration
The North & East of Sudbury Region are bounded by regions of North Bay, Timmins, Hearst, Moosonee, Kirkland Lake and Dymond. A map of the region is shown below in Figure 1.

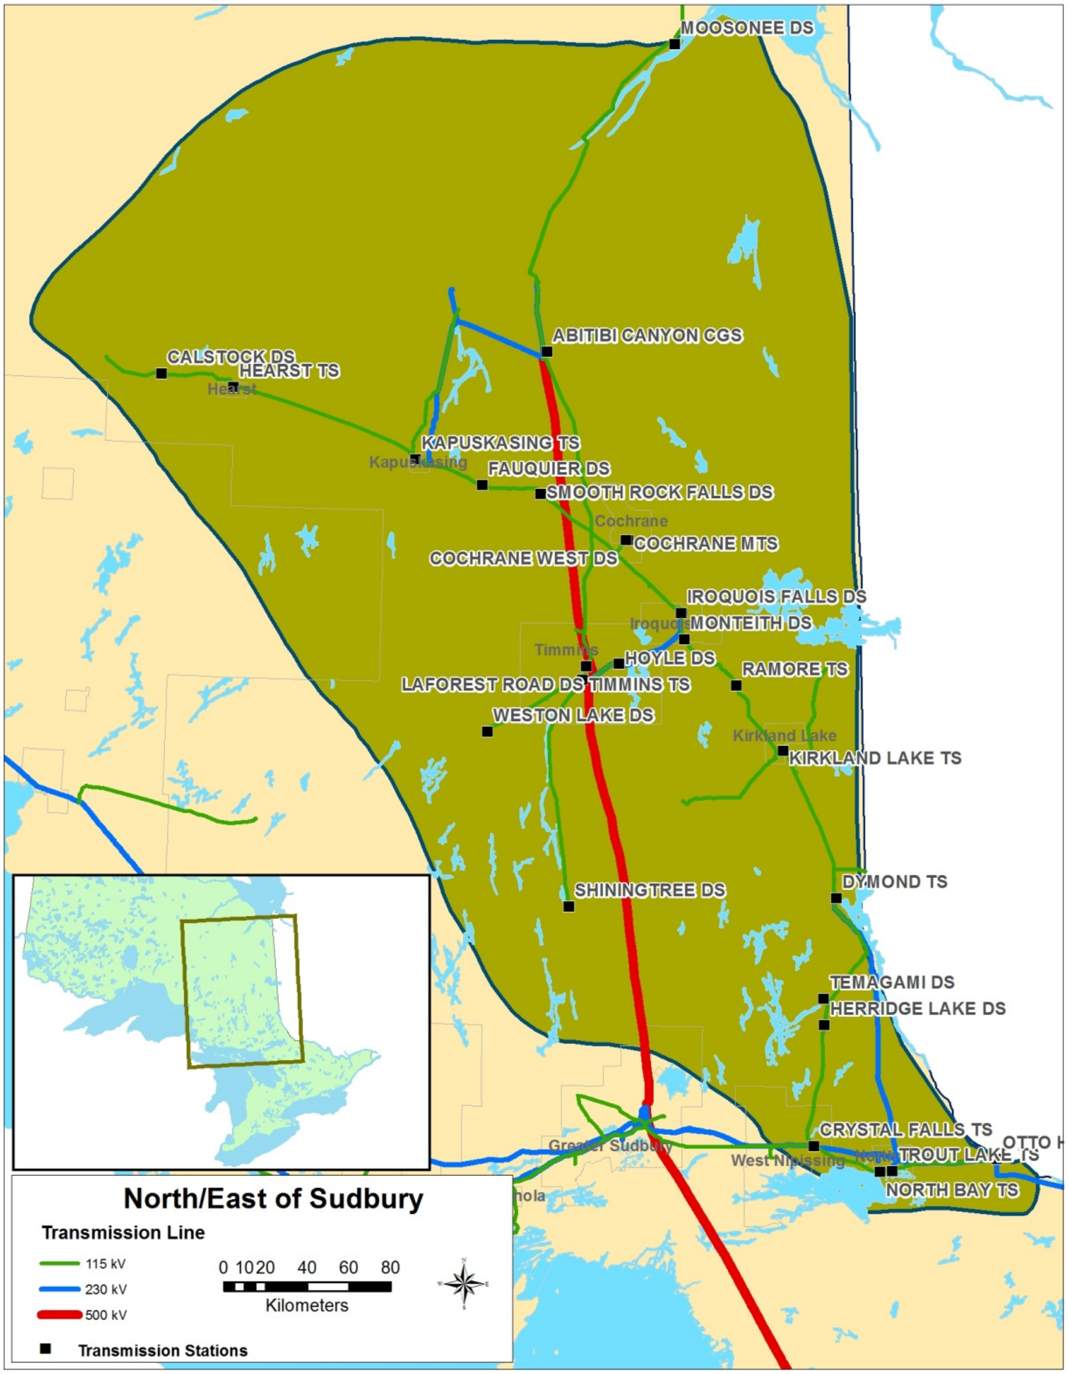

Figure 1: North & East of Sudbury Region Map

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits. This area is further reinforced through the 500kV circuits P502X and D501P connecting Pinard TS to Hanmer TS.

This region has the following four local distribution companies (LDC):

- Hydro One Networks (distribution)
- Northern Ontario Wires Inc
- Hearst Power Ltd
- North Bay Hydro Distribution Ltd.

115kV circuits	230kV circuits	500kV circuits	Hydro One Transformer Stations

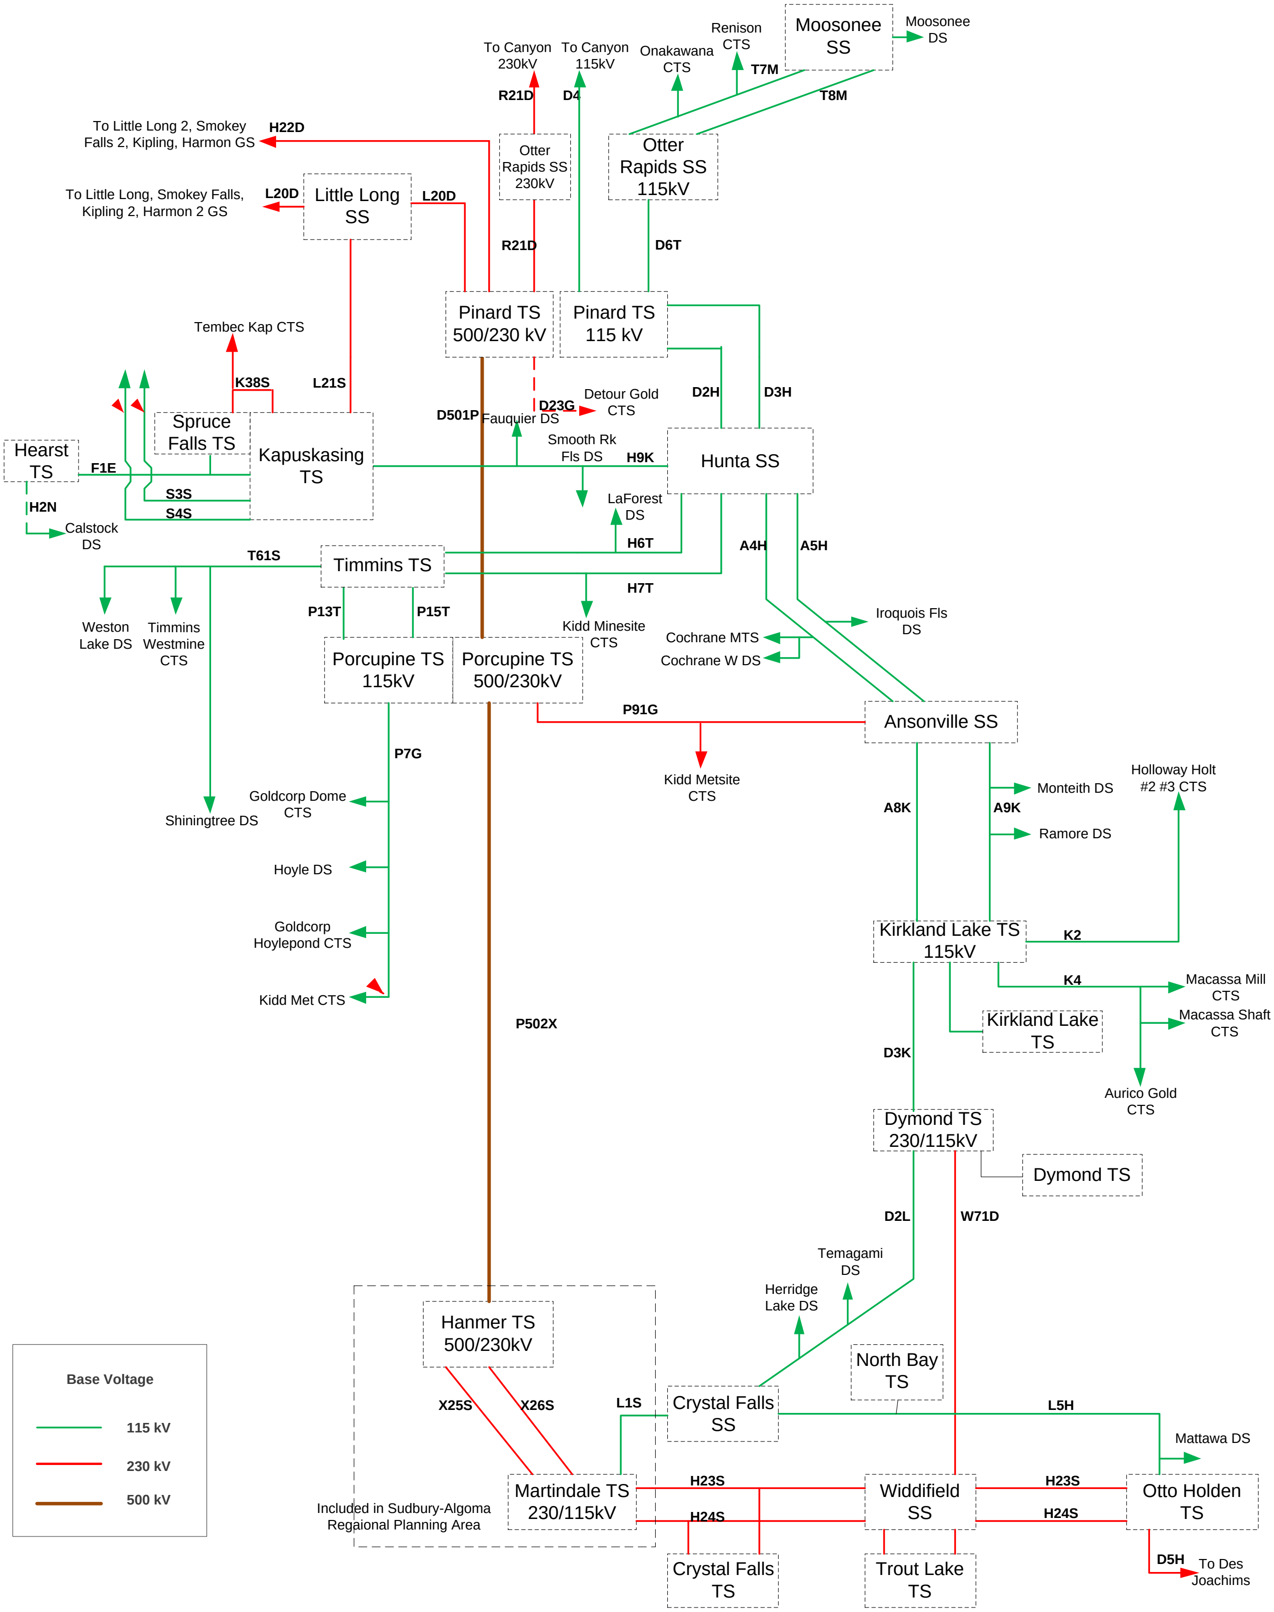

Figure 2 – North and East of Sudbury Regional Planning Electrical Diagram

4 Inputs and Data

In order to conduct this Needs Assessment, Working Group participants provided the following information and data to Hydro One:

- IESO provided:
  - i. Historical Ontario and regional coincident load station peaks, as well as individual station peaks.
  - ii. List of existing reliability and operational issues
  - iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2013-2015) net load and gross load forecast (2016-2026) Note: 2026 gross load values were extrapolated from 2025 if required.
- Hydro One (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

Load Forecast
As per the data provided by the Working Group, the gross load in region is expected to grow at an average rate of approximately 0.7% annually from 2016-2026.

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. With these factors in place, the total regional load is expected to increase at an average rate of approximately 0.04% annually from 2016-2026.
Note: Extreme weather scenario factor at 1.057 assessed over the study term.

5 Needs Assessment Methodology

The following methodology and assumptions are made in this Needs Assessment:

1. The Region is winter peaking so this assessment is based on winter peak loads.
2. Forecast loads are provided by the Region's LDCs
3. Load data was provided by industrial customers in the region. Where data was not provided, the load was assumed to be consistent with historical loads.
4. Accounting for (2), (3) above, the gross load forecast and net load forecast were developed. The gross load forecast is used to develop a worst case scenario to identify needs. Where there are issues, the net load forecast which accounts for CDM and DG are analyzed to determine if needs can be deferred. A gross and net non-coincident peak load forecast was used to perform the analysis for this report. A gross and net region-coincident peak load forecast was used to perform the analysis.

5. Review impact of any on-going and/or planned development projects in the Region during the study period.
6. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.
7. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the winter 10-Day Limited Time Rating (LTR). Summer LTR ratings also were reviewed against the station load forecasts over the study period.
8. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.
9. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. Note: This criterion was put in place after the 500 kV Northeast system was built and as such, the system was not originally designed to respect this criteria for the loss of the 500 kV circuits P502X or D501P. Currently the loss of either these circuits can result in the loss of more than 150 MW.
    - With two elements out of service, no more than 600 MW of load is lost by configuration.
    - With up to two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC criteria.

6 RESULTS

6.1 500/230kV Autotransfomers

The 500/230 kV transformers supplying the region are adequate for loss of single 500/230 kV unit.

6.2 500/115kV Autotransfomers

The 500/115kV transformers supplying the region are adequate for loss of single unit.

6.3 230/115kV Autotransfomers

The 230/115kV transformers supplying the region are adequate for loss of single unit.

6.4 Transmission Lines and Ratings

The 500kV and 230 kV circuits supplying the region are adequate over the study period for the loss of a single 500kV or 230 kV circuit in the Region.
As per section 7.2 below – the 115kV H9K circuit may experience thermal overloads and will be addressed as a bulk system issue outside of regional planning.

6.5 230 kV and 115 kV Connection Facilities

A station capacity assessment was performed over the study period for the 230 kV and 115 kV transformer stations in the Region using the station winter peak load forecast provided by the Working Group. All stations in the area have adequate supply capacity for the study period even in the event of extreme weather scenario

7 SYSTEM RELIABILITY, OPERATION AND RESTORATION

7.1 Performance

The areas of Timmins, Dymond and Abitibi Canyon have experienced severe weather patterns over the last 5 years causing periodic increases of both momentary and sustained outages which have been highlighted by the IESO. The region (including the three mentioned above) does not have circuit performance outliers which would fall below customer delivery point performance standards set forth by the Ontario Energy Board.

Hydro One continually monitors performance of supply stations, and high voltage circuits and will make the necessary steps to address the problem should this issue persist.

7.2 Restoration

Depending on system conditions, the loss of P502X may result in the greatest amount of load lost through North East LR/GR special protection schemes. Based on the load levels in the study period of this assessment, load can be restored within the 30 minute, 4 hour and 8 hour time frames as required by IESO ORTAC Section 7.0. The maximum load which may be interrupted by configuration or load rejection due to the loss of two elements is up to 450MW which is below the ORTAC requirement of 600MW. (loss of P502X with D3K out of service, or vice versa)

7.3 Thermal overloading on H9K section

Under high generation scenarios, IESO has identified pre and post contingency overloads on the 115 kV circuit H9K between *Tembec SRF x H9K 127A* junction.
This is a bulk system issue which will be addressed outside of the scope of regional planning.

7.4 Congestion on D3K, A8K, A9K, H6T and H7T

Under high generation scenarios, IESO has identified there may be congestion on D3K, A8K, A9K, H6T and H7T circuits.
This is a bulk system issue which will be addressed outside of the scope of regional planning.

7.5 Kapuskasing and Calstock Area Generation

Non-utility Generator ("NUG") contracts are reaching end of term for the Kapuskasing and Calstock Generating Stations. The NUG Framework Assessment Report [1] indicated that local reliability and congestion issues may require further study as this pertains to contracted generation facilities. This is a bulk system issue which will be addressed outside of the scope of regional planning.

7.6 Outage Condition Resulting in P15/P7G/T61S radially connected to Timmins

The loss of K1K4 and K1K2 circuit breakers at Porcupine TS can result in excessive voltage declines at Timmins TS 115kV bus.
This scenario will be addressed in the next stage of regional planning.

7.7 Ansonville T2 or D3K outages

With Ansonville T2 or D3K out of service, the loss of the other can result in excessive voltage decline at Kirkland Lake TS. This scenario will be addressed in the next stage of regional planning.

8 AGING INFRASTRUCTURE AND REPLACEMENT OF MAJOR EQUIPMENT

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables. during the study period. At this time the major committed system investments are;

Dymond TS (T3/T4) transformers (2016)
Kirkland Lake TS (T12/T13) transformers (2017)
Timmins TS (T63/T64) with single 83MVA (2016)
Otto Holden TS (T3/T4) autotransformers, and 115kV circuit breakers (2019)

9 RECOMMENDATIONS

Based on the findings and discussion in Section 6 of the Needs Assessment report, it is further recommended that voltage regulation issues at Timmins TS and Kirkland Lake TS be best addressed by wires options solution thru local planning led by Hydro One:

10 NEXT STEPS

Based on the findings of the Needs Assessment, the Working Group recommends that no further regional coordination is required and the two voltage regulation needs identified in Section 7 be further assessed as part of Local Planning to be entitled:

Timmins TS / Kirkland Lake TS – Voltage Regulation Issues

Renfrew Region

Regional Infrastructure Plan ("RIP")

July 22nd, 2016

Independent Electricity System Operator
Renfrew Hydro Inc.
Ottawa River Power Corporation
Hydro One Networks Inc. (Distribution)

The Renfrew Region consists of Renfrew County and it is roughly bounded by the Des Joachims TS on the West and Chenaux TS on the East, and 230kV circuit X1P to the Southeast.

The Needs Assessment ("NA") report for the Renfrew region was completed in March, 2016 (see attached). The report concluded that no regional planning needs were identified for the region at this time although circuit X1P is nearing its capacity and will be monitored on a regular basis over the next three to five years.

There are no other major development projects planned for the Renfrew Region over the near and mid-term.

Consistent with a process established by an industry working group[1] created by the OEB, the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no regional planning was required, this letter and the attached NA report will be deemed to form the ("RIP") for the Renfrew Region.

The next regional planning cycle for the region is expected to be undertaken in five years from the start of this planning cycle (2015) or earlier if there is a new need emerging in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the Renfrew Region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	Renfrew Region (the Region)		
LEAD	Hydro One Networks Inc. (Hydro One)		
START DATE	October 23, 2015	**END DATE**	March 11, 2016

1. INTRODUCTION

The purpose of this Needs Assessment report is to undertake an assessment of the Renfrew Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE/ TRIGGER

The Needs Assessment for the Renfrew Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups - Group 1 Regions are being reviewed first. The Renfrew Region belongs to Group 3. The Needs Assessment for this Region was triggered on October 23, 2015 and was completed on March 11, 2016.

3. SCOPE OF NEEDS ASSESSMENT

The scope of this Needs Assessment was limited to the next 10 years as per the recommendations of the Planning Process Working Group Report to the Board.

Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led Scoping Assessment and/or IRRP, or in the next planning cycle to develop a 20-year IRRP with strategic direction for the Region.

The assessment included a review of transmission system connection facilities capability, which covers station loading, thermal, and voltage analysis, system reliability, and assets approaching end-of--life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the IESO, and Hydro One transmission provided information for the Renfrew Region. The information included: existing information from planning activities already underway, historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-life.

5. ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs in the Region over the study period (2015 to 2024). The assessment reviewed available information and load forecasts and included single contingency analysis to identify needs.

6. RESULTS

Transmission Capacity Needs

A. Station Capacities

- All stations in the region have sufficient capacity to supply the loads in studied period under normal and single contingency condition.

B. Transmission Circuits Capacities

- All transmission circuits have sufficient capacity under normal and single contingency condition.

System Reliability, Operation and Restoration Needs

There are no transmission system reliability issues and no operating issues identified for one element out of service in this Region.

Based on the gross coincident demand forecast, loss of one element will not result in load interruption for more than 150MW by configuration.

All load within the region can typically be restored within eight hours as per the ORTAC requirement for loads under 150 MW.

In recent years, maintenance activity in the region with respect to vegetation management has been enhanced resulting in an improvement in reliability and/or load restoration.

Aging Infrastructure / Replacement Plan

During the study period, plans to replace aged equipment at three stations will increase station capacities. Further details of these investments can be found in Section 3.2 of this report.

7. RECOMMENDATIONS

Based on the findings of this Needs Assessment, the study team's recommendations are as follows:

- Should the performance of X1P fall below adequate levels (as shown by standard OGCC monitoring systems) the Hydro One will undertake to assess and address this issue with the LDCs.

- No further coordinated regional planning is required for this region at this time. The next regional planning cycle for the region is expected to be undertaken in Q1 2019 or earlier if there is a new need emerging in the region.

TABLE OF CONTENTS

LIST OF FIGURES AND TABLES

1 INTRODUCTION

This Needs Assessment report provides a description of the analysis to identify needs that may be emerging in the Renfrew Region (the Region) over the next ten years. The development of the Needs Assessment report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this Needs Assessment report is to: consider the information from planning activities already underway; undertake an assessment of the Renfrew Region to identify near term and/or emerging needs in the area; and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with LDCs or other connecting customer(s) will further undertake planning assessments to develop options and recommend solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (the IESO) will initiate the Scoping Assessment process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required.

This report was prepared by Hydro One (Lead Transmitter) with input from the Renfrew Region Needs Assessment study team. The report captures the results of the assessment based on information provided by LDCs and the IESO.

2 TRIGGER OF NEEDS SCREEN

The Needs Assessment for the Renfrew Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups, where Group 1 Regions are being reviewed first. The Region falls into Group 3. The Needs Assessment for this Region was triggered on October 23, 2015 and was completed on March 4, 2016.

3 SCOPE OF NEEDS ASSESSMENT

This Needs Assessment covers the Renfrew Region over an assessment period of 2015 to 2024. The scope of the Needs Assessment includes a review of transmission system connection facility capability which covers transformer station capacity, transmission circuits thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this Needs Assessment.

3.1 Renfrew Region Description and Connection Configuration

The Renfrew Region includes all of Renfrew County. Fig.1 shows the map of the Region. The 2014 peak load in this Region was 124 MW.

The electricity supply to the region is mainly through one 230kV circuit X1P and three 115 kV radial circuits: D6, X6 and X2Y (Fig.1). The 115kV circuits are supplied by 230/115 kV autotransformers at Chenaux Transformer Station (TS) from the East and Des Joachims TS from the West. A normally opened 115kV switch at Pembroke TS isolates the East and the West sides of the region.

The Renfrew Region is roughly bounded by the Des Joachims TS on the West and Chenaux TS on the East, and 230kV circuit X1P to the Southeast. The distribution system in this region consists of voltage levels 44 kV, 13.8 kV, and 12.5 kV. The main generation facilities in the Renfrew Region are Chenaux Generation Station (GS) of 143.7 MW (according to Transmission Connection Agreement, applicable thereafter), Mount Chute GS of 170.2 MW and Des Joachims GS of 432.5 MW.

Hydro One Networks Inc. (Distribution) is the main customer in the area. Other Local Distribution Companies (LDC) supplied from electrical facilities in the Renfrew Region includes Ottawa River Power Corporation and Renfrew Hydro Inc, both are embedded into Hydro One's distribution system. Major transmission connected customers in the area include Canadian Nuclear Laboratories and Magellan Aerospace.

.

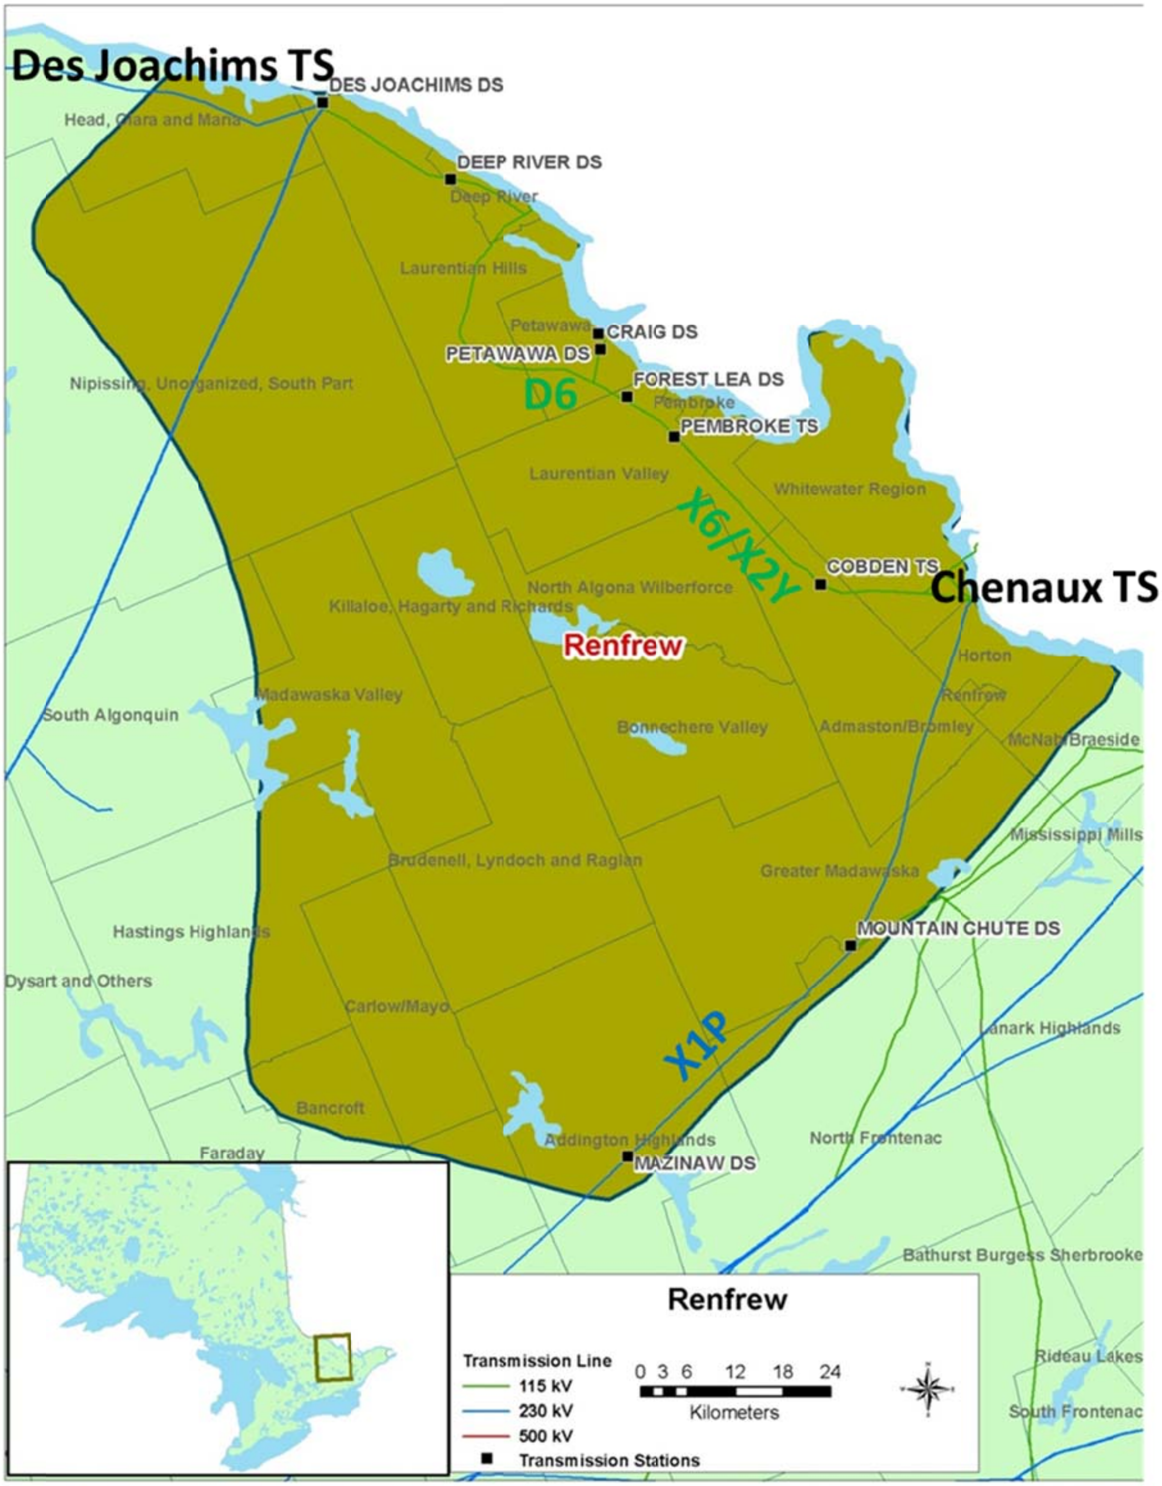

Fig. 1 Renfrew Region Map

The existing facilities in the Region are summarized below and depicted in the single line diagram shown in Fig. 2.

- Des Chenaux TS is a major 230kV station in the region. The station has 143.7MW of hydraulic generation connected to the 230kV bus. The station connects to the bulk system via a single 230kV circuit X1P. Two autotransformers step down the voltage to 115kV to supply two radial circuits X6 and X2Y.

- The 115kV circuits X6 and X2Y from Chenaux TS supply four stations: Pembroke TS, Cobden TS, Cobden DS and Magellan Aerospace CTS. The two circuits are coupled via and only via Pembroke 44kV bus tie breaker

- Des Joachim TS is the other major 230kV transformer station in the Region. There are 432.5MW of hydraulic generation units connecting to the 230kV bus. The station interconnects to the Bulk Electric System (BES) via five 230kV circuits which are not in the scope of this regional assessment. Two autotransformers (one operates as standby) step down the voltage to 115kV to supply one radial circuit D6.

- The 115kV circuit D6 from Des Joachim TS 115kV bus supplies six stations: Des Joachims Distribution Station (DS), Deep River DS, Craig DS, Forest Lea DS, Petawawa DS, and Chalk River Customer Transformer Station (CTS).

- All the 115kV circuits X6/X2Y/D6, all the 115kV stations tapped to the 115kV circuits, and all the autotransformers at Des Joachims TS and Chenaux TS are not NERC BES element.

- Bryson GS of Hydro Quebec can be radially connected to Renfrew region via X2Y.

- The 230kV single circuit X1P from Dobbin TS to Chenaux TS connects two stations in Renfrew Region: Mountain Chute GS (with hydraulic generation of 170.2MW) and Mazinaw DS.

- Mountain Chute DS, a 115kV station adjacent to Mountain Chute GS, is supplied by a circuit W3B from outside of the studied region. The DS typically has load less than 1MW.

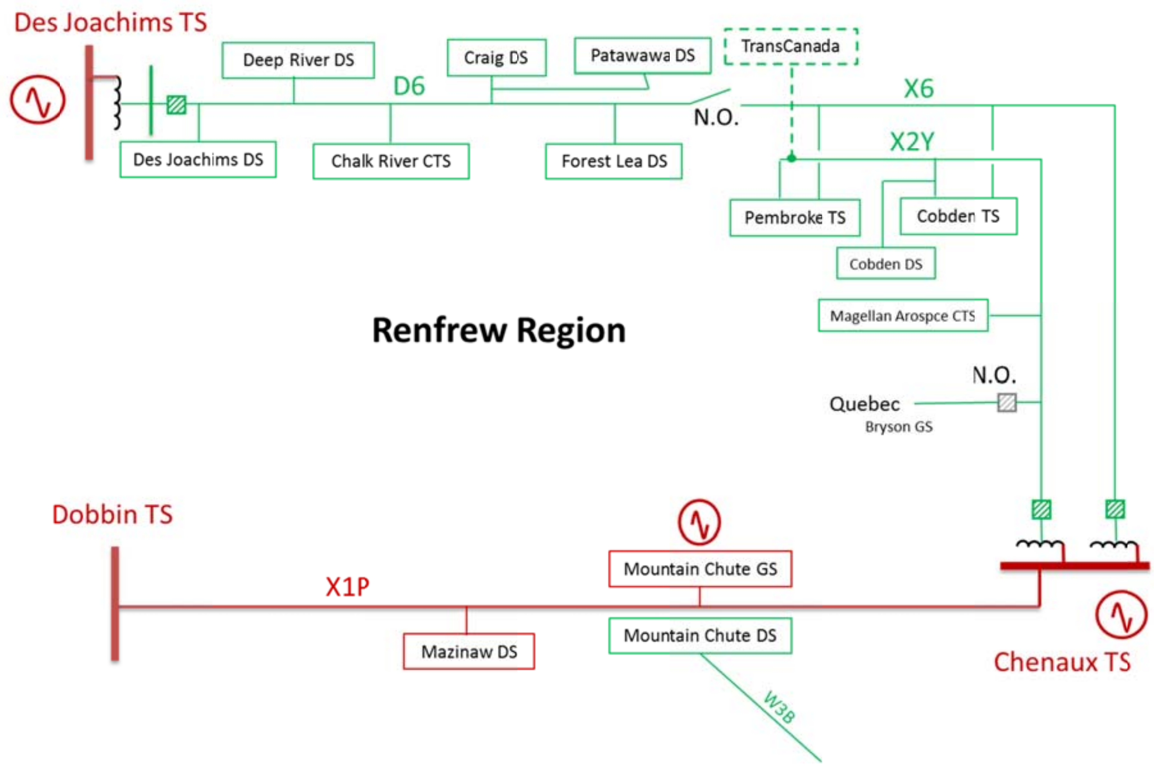

Fig. 2 Single Line Diagram – Renfrew Region

3.2 Planned Work in Renfrew Region

Following work has been planned in Renfrew Region:

- Two step-down transformers at Deep River DS (T1 and T2) will be replaced due to end-of-life for an in service date of end of 2016. This will also result in uprating the transformer capacity from 10MVA to 12.5MVA.
- Mountain Chute DS transformer will be replaced due to end-of-life with an in service date of end of 2016. This will also result in uprating the transformer capacity from 3MVA to 12.5MVA.
- Chenaux TS 230/115kV autotransformers T3 and T4 will be replaced due to end-of-life with an in service date of end of 2018. The existing units are rated 78MVA and 115MVA respectively. The new T3/T4 will both have continuous rating of 125MVA. This is a transmission pool investment and LDCs are not expected to pay.
- A TransCanada pump station is expected to tap to X2Y at Pembroke TS (Fig.2). The peak load of the station is 19.4MW. Two capacitor banks, each rated at 10Mvar, are assumed to be in service with the load. The station is expected to be in service in 2020.

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information to Hydro One:

- IESO provided:
  i. Historical regional coincident peak loads and station non-coincident peak loads between 2012 and 2014
  ii. List of existing reliability and operational issues
  iii. Conservation and Demand Management (CDM) and future Distributed Generation (DG) data
- LDCs provided historical (2012-2014) net loads and gross loads forecasts (2015-2024) for each station.
- The study team could not get response from Chalk River CTS and Magellan Aerospace CTS regarding their load forecasts. It is assumed that the loads at these two stations would not increase over the study period.
- Any relevant planning information, including planned transmission and distribution investments are provided by the transmitter and LDCs.

As per the data provided by the study team, the net load (i.e. after DG and CDM adjustment) in the Renfrew Region is expected to grow at an average rate of approximately 0.6% annually from 2015 to 2024.

5 ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The Region typical typically has winter peak. Fig. 3 plots the load profiles at Pembroke TS and Cobden TS from July 2013 to July 2015, which evidences the winter peaking characteristics. Therefore this assessment is based on winter peak load.

2. Loads forecasts are provided by the LDCs, i.e., Hydro One Networks Inc. (Distribution) in this case.

3. Average gross load growth rate at each station is calculated from the LDC's load forecast. The growth rates are then applied to the 2014 coincidental winter peak load to generate each year's coincidental peak load.

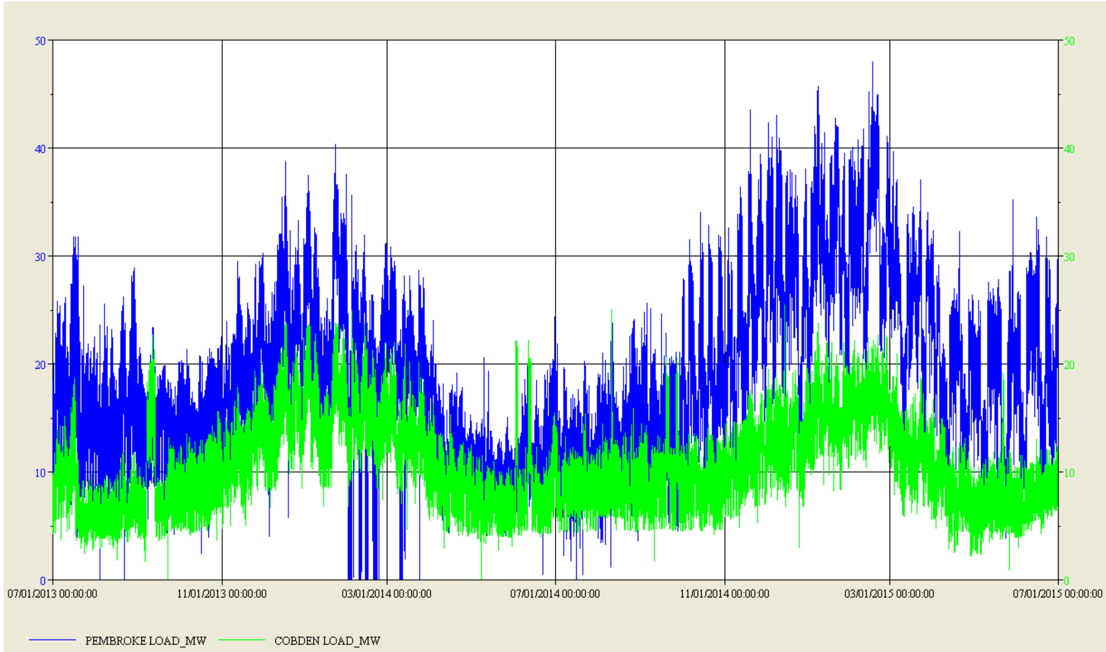

Fig. 3 Pembroke TS and Cobden TS Winter Peak Load Profiles

4. The 2014/15 winter was already extremely cold; therefore no extreme weather adjustment was used.

5. The gross demand forecast is used to develop a worst case scenario to identify needs. Both the gross demand forecast and the net demand forecast (which includes forecasted CDM and DG contributions) were used to determine the timing of the needs.

6. Review impact of any on-going and planned development projects in the Region during the study period. This includes:

   - A new 19.4MW load is expected to connect to circuit X2Y at Pembroke in 2020. This Needs Assessment assumes that the load is in service.

7. Review and assess impact of any major elements planned to be replaced at the end of their useful life such as transformers, cables, and stations.

8. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity by assuming a 90% lagging power factor for stations without low-voltage capacitor banks and 95% lagging power factor for stations with low-voltage capacitor banks. Normal planning supply capacity for transformer stations in this Region is determined by the 10-Day Limited Time Rating (LTR).

9. To identify emerging needs in the Region and determine whether further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.

10. Transmission adequacy assessment is primarily based on the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range. Projected coincidental peak loads are used in such assessment.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their long-term emergency (LTE) ratings and transformers within their summer 10-Day LTR.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC). Des Joachims and Chenaux 115kV bus voltages are maintained between 122kV and 127kV according to established operation practice.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
    - The system is capable of meeting the load restoration time limits as per ORTAC criteria.

11. Full load transfers for restoration purposes are not mandatory requirement. Restorations of load between Chenaux TS and Des Joachims TS via D6-X6 load transfers are performed to the extent possible.

6 RESULTS

This section summarizes the results of the Needs Assessment in the Renfrew Region.

6.1 Transmission Capacity Needs

This is to assess a) adequacy of each station's load supply capacity which is mainly to inspect the step-down transformer ratings; and b) adequacy of transmission facility to deliver the power within the Region under normal and contingency conditions, which is mainly determined by circuit thermal rating and voltage profile.

6.1.1 Station Adequacy Assessment

Non-coincident peak load at each station is compared against corresponding transformer maximum continuous rating or 10-day LTR if the continuous rating is exceeded. The peak loads are all forecasted to happen in 2024. Table 2 compares the net peak load against transformer ratings at each station. It can be seen that all stations are adequate to supply the loads in studied period.

Table 2 Station Adequacy Assessment

Station	Transformers	Net Peak Load (MW)	Transformer Rating/LTR* (MW)
Cobden DS	T3	7.2	11.3
Cobden TS	T1/T2	27.1	37.5
Craig DS	T1/T2	12.2	15.9
Deep River DS	T1/T2/T3	11.1	23.8
Des Joachims DS	T1	3.3	11.3
Forest Lea DS	T1/T2	9.2	9.9
Mazinaw DS	T1	3.4	5.4
Mountain Chute DS	T1	1.0	11.3
Pembroke TS	T1/T2	49.1	49.6
Petawawa DS	T1/T2	14.3	14.8
Chalk River CTS***		10	N/A
Magellan Aerospace CTS***		3.1	N/A
Chenaux TS	T3/T4	101.7**	112.5
Des Joachims TS	T6/T7	57.1	112.5

*: LTR is listed only if the peak load exceeded transformer continuous rating
**: Including 19.4MW new load, all station MVAs add up arithmetically
***: Load customer owned transformers, capacity not assessed in this study

6.1.2 Transmission Facility Adequacy Assessment

Under normal condition with all elements in service and the D6-X6 in-line switch open, the study found that:

- All transmission circuits supplying the Region, namely D6, X6, X2Y and X1P have adequate capacity over the study period.

The projected regional peak loads can be supplied even if the local generations at Des Joachims GS and Chenaux GS are out of service. In the X6/X2Y corridor, loss of one circuit (including breaker failure condition to cause additional loss of Chenaux generation) would not cause overload or under-voltage on the accompanying circuit. .

6.2 System Reliability, Operation and Restoration Review

- The Region’s total coincidental peak load is less than 150MW, therefore load loss violation due to configuration does not apply in this assessment.
- All loads are expected to be restored within 8 hours.
- The most critical contingency in the Region would be loss of 230kV circuit X1P which would produce an island at Chenaux. Stable islanding operation might be

achieved depending on pre-contingency flow and generation rejection arming. Reliability data recorded 13 X1P non-planned outages in past ten years, among which seven events show stable islanding operations before the system was paralleled back to the grid. In another two events the island collapsed after more than one hour of operation. The performance is expected to be unchanged in the study period.

- Studies show that under this contingency, Des Joachims TS may not be able to radially supply all the loads in the Region, under peak load conditions.
- Due to the fact that the loads are supplied via radial circuits and the Region is prone to storms, extended outages on D6 were experienced in the past (in 2011 for example). Further, outage analysis indicated that the most common cause for sustained outages was under severe storm. This issue cannot be addressed by building additional line in the same right-of-way. As a result, improved vegetation management and outage responses have effectively reduced sustained outages considerably in recent years. Table 3 lists sustained outage records of D6 in past five years.

Table 3 Outage Records of D6 from 2011 to 2015

Year	No. of Sustained Outages	Cumulative Duration (min)	Causes
2015	1	367	Conductor Broken
2014	1	5	Human Error
2013	3	1381	Isolated Electrical Storm
2012	1	1341	Tree Contact
2011	4	7792	Tree Contact

Studies show that under D6 terminal outage at the Des Joachims terminal, load can be restored by transferring D6 to Chenaux TS 115kV via X6 supply. Note, there is a maximum limit of 125 MW, which is the peak regional load in 2015, that can be supplied radially from Chenaux.

a) The following potential needs will be monitored and assessed in the next Regional Planning cycle for the Renfrew Region:

- Hydro One and the LDCs will continue to monitor and assess the load restoration performance under X1P and D6 outages.

- Major Hydro One facilities and equipment are continually monitored to ensure their safe and reliable operation. Circuit X1P is one of these facilities and, as such, its performance is monitored by Hydro One's Ontario Grid Control Centre (OGCC) in Barrie. OGCC's records will be reviewed regularly to ascertain the adequate performance of this circuit. The next planning cycle will take place in five years however, if the performance of X1P fall below adequate levels the Hydro One will undertake to assess and address this issue with the LDCs.

6.3 Aging Infrastructure and Replacement Plan of Major Equipment

Section 3.2 lists the sustainment initiatives that are currently planned for the replacement of any aged transformers. There are no major line replacement plans scheduled in the near term in this region.

7 RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team's recommendations are as follows:

> No further coordinated regional planning is required for this region at this time. The next regional planning cycle for the region is expected to be undertaken in Q1 2019 or earlier if there is a new need emerging in the region. Should the performance of X1P fall below adequate levels (as shown by standard OGCC monitoring systems) the Hydro One will undertake to assess and address this issue with the LDCs.

St. Lawrence Region

Regional Infrastructure Plan ("RIP")

July 22nd, 2016

Independent Electricity System Operator
Hydro One Networks Inc. (Distribution)

The St Lawrence Region covers the southeastern part of Ontario bordering the St Lawrence River. The region starts at the Gananoque in the West and extends to the inter-provincial boundary with Quebec in the East..

The Needs Assessment ("NA") report for the St. Lawrence region was completed in April, 2016 (see attached). The report concluded that no regional planning needs were identified for the region at this time.

There are no other major development projects planned for the ST. Lawrence Region over the near and mid-term.

Consistent with a process established by an industry working group[1] created by the OEB the Regional Infrastructure Plan ("RIP") is the last phase of the planning process. In view that no regional planning was required, this letter and the attached NA report will be deemed to form the ("RIP") for the St. Lawrence Region.

The next regional planning cycle for the region is expected to be undertaken in five years form the start of this planning cycle (2015) or earlier if new needs emerge in the region.

Sincerely,

Ajay Garg | Manager, Regional Planning Co-ordination
Hydro One Networks

NEEDS ASSESSMENT REPORT

Region: St Lawrence

Date: April 29, 2016

Prepared by St Lawrence Region Study Team

St Lawrence Region Study Team

Company
Hydro One Networks Inc. (Lead Transmitter)
Independent Electricity System Operator
Hydro One Networks Inc. (Distribution)

Disclaimer

This Needs Assessment Report was prepared for the purpose of identifying potential needs in the St Lawrence region and to assess whether those needs require further coordinated regional planning. The potential needs that have been identified through this Needs Assessment Report may be studied further through subsequent regional planning processes and may be reevaluated based on the findings of further analysis. The load forecast and results reported in this Needs Assessment Report are based on the information and assumptions provided by study team participants.

Study team participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the Needs Assessment Report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the Needs Assessment Report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the Needs Assessment Report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the Needs Assessment Report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

NEEDS ASSESSMENT EXECUTIVE SUMMARY

REGION	St Lawrence (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	March 1, 2016	**END DATE**	April 29, 2016

1. INTRODUCTION

The purpose of this Needs Assessment (NA) report is to undertake an assessment of the St Lawrence Region and determine if there are regional needs that require coordinated regional planning. Where regional coordination is not required, and a "localized" wires solution is necessary, such needs will be addressed between relevant Local Distribution Companies (LDCs) and Hydro One and other parties as required.

For needs that require further regional planning and coordination, IESO will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or whether both are required.

2. REGIONAL ISSUE / TRIGGER

The NA for the St Lawrence Region was triggered in response to the Ontario Energy Board's (OEB) Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 and 2 regions is complete and has been initiated for Group 3. The St Lawrence Region belongs to Group 3. The NA for this Region was triggered on March 1, 2016 and was completed on April 29, 2016.

3. SCOPE OF NEEDS ASSESSMENT

The scope of the NA study was limited to 10 years as per the recommendations of the Planning Process Working Group (PPWG) Report to the Board. As such, relevant data and information was collected up to the year 2025. Needs emerging over the next 10 years and requiring coordinated regional planning may be further assessed as part of the IESO-led SA, which will determine the appropriate regional planning approach: IRRP, RIP, and/or local planning. This NA included a study of transmission system connection facilities capability, which covers station loading, thermal and voltage analysis as well as a review of system reliability, operational issues such as load restoration, and assets approaching end-of-useful-life.

4. INPUTS/DATA

Study team participants, including representatives from LDCs, the Independent Electricity System Operator (IESO) and Hydro One transmission provided information for the St Lawrence Region. The information included: historical load, load forecast, conservation and demand management (CDM) and distributed generation (DG) information, load restoration data, and performance information including major equipment approaching end-of-useful life.

5. NEEDS ASSESSMENT METHODOLOGY

The assessment's primary objective was to identify the electrical infrastructure needs and system performance issues in the Region over the study period (2016 to 2025). The assessment reviewed available information, load forecasts and included single contingency analysis to confirm needs, if and when required. See Section 5 for further details.

6. RESULTS

Transmission Needs

A. 230/115 kV Autotransformers

The 230/115kV Autotransformers at St Lawrence TS are adequate over the study period for the loss of a single 230/115kV unit

B. Transmission Lines & Ratings

The 230kV lines are adequate over the study period. A Special Protection Scheme is in place to reject generation at Beauharnois GS and/or Saunders GS under post contingency conditions to ensure the loading on the St Lawrence to Hinchinbrooke TS 230KV circuits are within ratings.

The 115kV lines are adequate over the study period to supply the forecasted load. The section of the 115kV lines L2M/L1MB between St Lawrence TS and Lunenberg Jct may be overloaded under light load conditions and high DG and Cardinal Power generation, for the loss of the companion circuit. Since 2012, Morrisburg TS has been restricted and no additional generation is accepted. At the same time, this situation is also mitigated using the Cardinal Power CGS run back scheme or by limiting generation dispatch during these light load conditions. No further action is required.

C. 230 kV and 115 kV Connection Facilities

The 230kV and 115kV connection facilities in this region are adequate over the study period.

Inadvertent breaker operation (IBO) at Cardinal Power on either L1MB or L2M can result in Morrisburg TS transformers exceeding their reverse flow limits and/or cause a transformer to be loaded beyond ratings at Dyno Nobel CTS. Morrisburg TS has been restricted and no additional generation is accepted since 2012. This situation is also mitigated by using Cardinal Power runback scheme. No further action is required.

System Reliability, Operation and Restoration Review

Based on the gross coincident load forecast, the loss of one element does not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW by the end of the 10-year study period. No action is required.

Chesterville TS missed its delivery point performance standard in recent years due to momentary outages resulting from severe weather patterns. The delivery point performance at Chesterville TS will be assessed and monitored to determine if corrective actions are required. No further action is required as part of regional planning.

Aging Infrastructure / Replacement Plan

Within the regional planning time horizon, the following sustainment work is currently planned by Hydro One in the region:

- Morrisburg TS: components replacement (2019 in service)
- Smiths Falls TS: components replacement (2021 in service)
- St Lawrence TS: components replacement (2024 in service)

7. RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends that no further regional coordination or further planning is required. The region will be reassessed within five years as part of the next planning cycle.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1 INTRODUCTION

This Needs Assessment (NA) report provides a summary of needs that are emerging in the St Lawrence Region ("Region") over the next ten years. The development of the NA report is in accordance with the regional planning process as set out in the Ontario Energy Board's (OEB) Transmission System Code (TSC) and Distribution System Code (DSC) requirements and the "Planning Process Working Group (PPWG) Report to the Board".

The purpose of this NA is to undertake an assessment of the St Lawrence Region to identify any near term and/or emerging needs in the area and determine if these needs require a "localized" wires only solution(s) in the near-term and/or a coordinated regional planning assessment. Where a local wires only solution is necessary to address the needs, Hydro One, as transmitter, with Local Distribution Companies (LDC) or other connecting customer(s), will further undertake planning assessments to develop options and recommend a solution(s). For needs that require further regional planning and coordination, the Independent Electricity System Operator (IESO) will initiate the Scoping Assessment (SA) process to determine whether an IESO-led Integrated Regional Resource Planning (IRRP) process, or the transmitter-led Regional Infrastructure Plan (RIP) process (wires solution), or both are required. The SA may also recommend that local planning between the transmitter and affected LDCs be undertaken to address certain needs if straight forward wires solutions can address a need. Ultimately, assessment and findings of the local plans are incorporated in the RIP for the region.

This report was prepared by the St Lawrence Region NA study team (Table 1) and led by the transmitter, Hydro One Networks Inc. The report captures the results of the assessment based on information provided by LDCs, and the Independent Electricity System Operator (IESO).

Table 1 Study Team Participants for St Lawrence Region

No.	Company
1.	Hydro One Networks Inc. (Lead Transmitter)
2.	Independent Electricity System Operator
3.	Hydro One Networks Inc. (Distribution)

2 REGIONAL ISSUE / TRIGGER

The NA for the St Lawrence Region was triggered in response to the OEB's Regional Infrastructure Planning process approved in August 2013. To prioritize and manage the regional planning process, Ontario's 21 regions were assigned to one of three groups. The NA for Group 1 Regions is complete and has been initiated for Group 2 Regions. The St Lawrence Region belongs to Group 3.

3 SCOPE OF NEEDS ASSESSMENT

This NA covers the St Lawrence Region over an assessment period of 2016 to 2025. The scope of the NA includes a review of transmission system connection facility capability which covers transformer station capacity, thermal capacity, and voltage performance. System reliability, operational issues such as load restoration, and asset replacement plans were also briefly reviewed as part of this NA.

St Lawrence Region Description and Connection Configuration

The St Lawrence Region covers the southeastern part of Ontario bordering the St Lawrence River. The region starts at the Gananoque in the West and extends to the inter-provincial boundary with Quebec in the East.

The western part of the region is supplied from Hydro One owned stations connected to the 230kV network. The reminder of the region is supplied from Hydro One stations connected to the 115kV network except for St Lawrence TS which is supplied from 230kV.

The City of Cornwall is supplied by Fortis Ontario with transmission lines from Quebec and is not included in this Region. A map of the region is shown below in Figure 1.

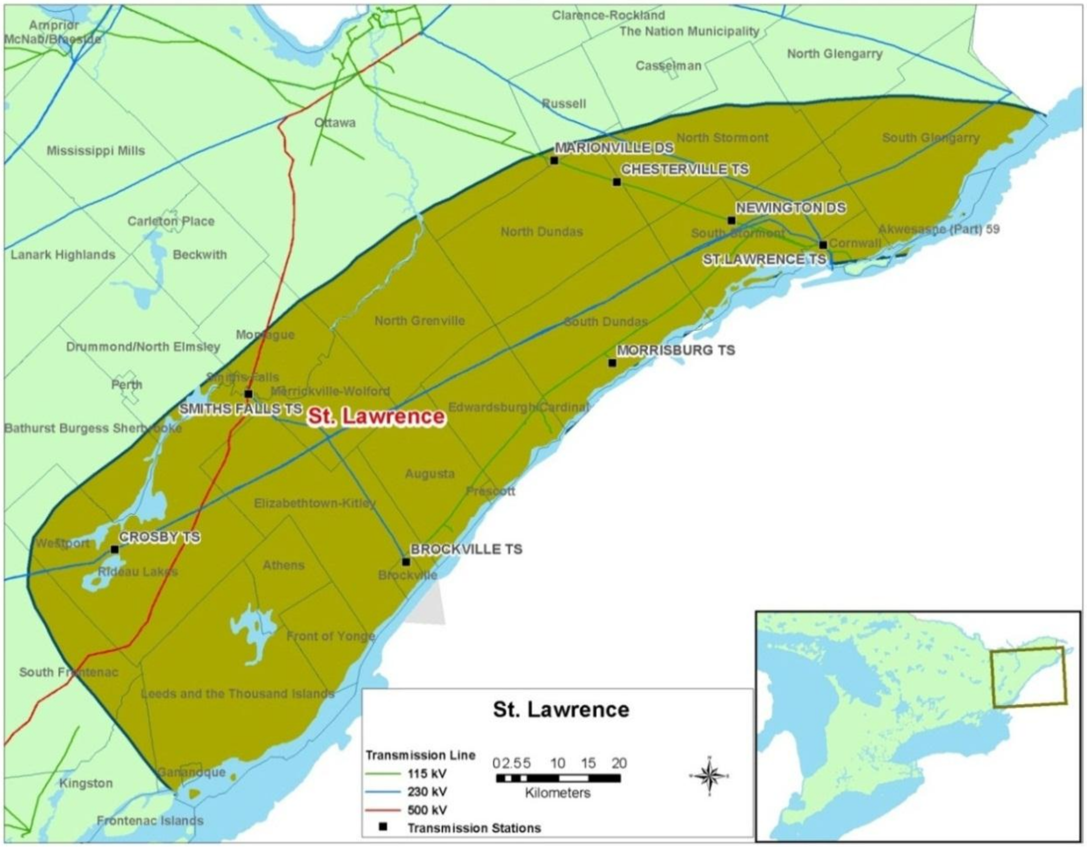

Figure 1 Map of St Lawrence Regional Planning Area

Electrical supply for this region is provided through a network of 230kV and 115kV transmission circuits. The major source of supply for this region is OPG's Saunder Hydro Electric station which connects to St Lawrence TS 230kV yard.

This region has the following three local distribution companies (LDC):

- Hydro One Networks (Distribution)
- Cooperative Hydro Embrun Inc. (embedded in Hydro One Distribution)
- Rideau St Lawrence Distribution Inc. (embedded in Hydro One Distribution)

Table 2 Transmission Lines in the St Lawrence Region

115kV circuits	230kV circuits	Hydro One Transformer Stations
L1MB, L2M, L5C[1]	L20H, L21H, L22H, L24A[2], B31L[2]	Brockville TS, Chesterville TS, Crosby TS Morrisburg TS, Newington DS, Smith Falls TS St Lawrence TS*

*Stations with Autotransformers installed

[1] L5C is normally o/s, and used as a backup supply for the City of Cornwall.

[2] L24A and B31L connect to St Lawrence TS but do not have load customers connection.

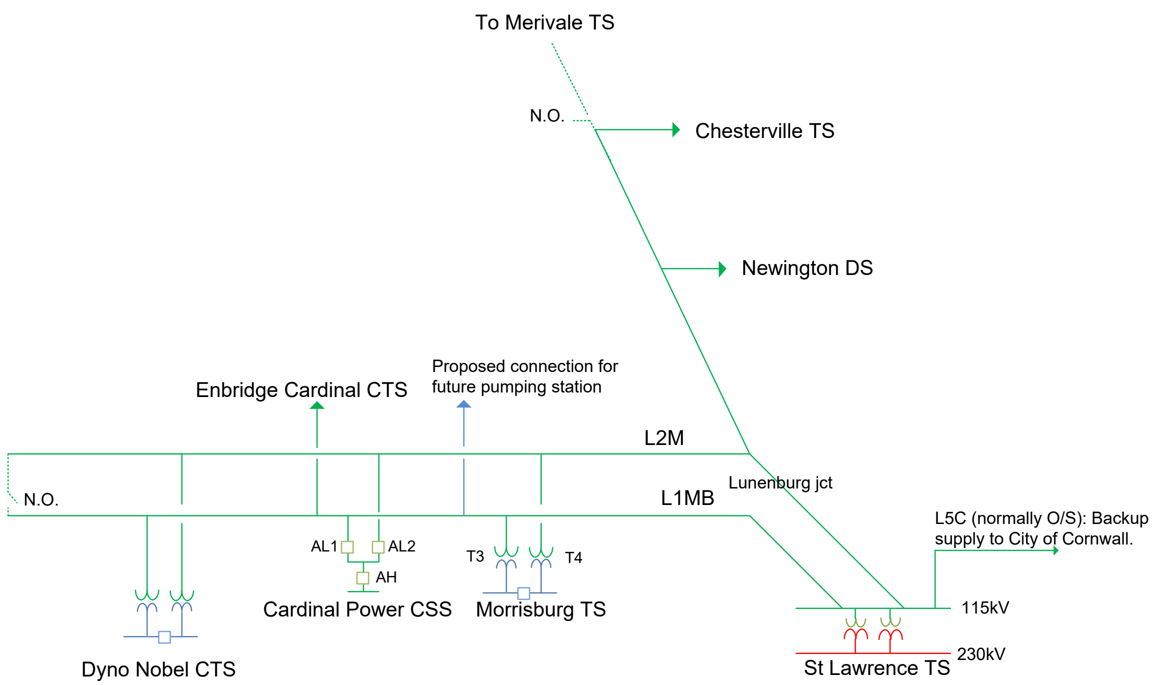

Figure 3 Single Line Diagram 115 kV St Lawrence Regional Planning Area

4 INPUTS AND DATA

In order to conduct this Needs Assessment, study team participants provided the following information and data to Hydro One:

- IESO provided:
  - i. Historical Ontario and regional coincident load station peaks, as well as individual station peaks.
  - ii. List of existing reliability and operational issues
  - iii. Conservation and Demand Management (CDM) and Distributed Generation (DG) data
- LDCs provided historical (2013-2015) net load and gross load forecast (2016-2025).
- Hydro One (Transmission) provided transformer, station, and circuit ratings
- Any relevant planning information, including planned transmission and distribution investments provided by the transmitter and LDCs, etc.

Load Forecast
As per the data provided by the study team, the gross load in region is expected to grow at an average rate of approximately 0.8% annually from 2016-2025.

The net load forecast takes the gross load forecast and applies the planned CDM targets and DG contributions. With these factors in place, the total regional load is expected to increase at an average rate of approximately 0.2% annually from 2016-2025.

Future Project
As shown in Figure 3, there is a proposal to connect a pumping station for the TransCanada Energy East project that will add 18MW of load to the area. The pumping station is planned to be connected to circuit L1MB close to Morrisburg TS. The current in-service date is 2021.

5 NEEDS ASSESSMENT METHODOLOGY

The following methodology and assumptions are made in this Needs Assessment:

1. The Region is winter peaking so this assessment is based on winter peak loads.
2. Saunders GS was assumed to generate at its average 98% of time dependable hydro generation level which is 542MW.
3. Forecast loads are provided by the Region's LDCs

4. Load data was requested from industrial customers in the region. Where data was not provided, the load was assumed to be consistent with historical loads.
5. Accounting for (3), (4), above, the gross load forecast and a net load forecast were developed. The gross load forecast is used to verify each station is within its rating to supply the forecasted load. The net forecast was used for system study.
6. Review and assess impact of any critical/major elements planned/identified to be replaced at the end of their useful life such as autotransformers, cables, and stations.
7. Station capacity adequacy is assessed by comparing the non-coincident peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks or the historical low voltage power factor, whichever is more conservative. For stations having low-voltage capacitor banks, a 95% lagging power factor was assumed or the historical low-voltage power factor, whichever is more conservative. Normal planning supply capacity for transformer stations in this Region is determined by the winter 10-Day Limited Time Rating (LTR). Winter LTR ratings were reviewed.
8. Extreme weather scenario factor at 1.0582 was also assessed for capacity planning over the study term.
9. To identify emerging needs in the Region and determine whether or not further coordinated regional planning should be undertaken, the study was performed observing all elements in service and only one element out of service.
10. Transmission adequacy assessment is primarily based on, but is not limited to, the following criteria:
    - With all elements in service, the system is to be capable of supplying forecast demand with equipment loading within continuous ratings and voltages within normal range.
    - With one element out of service, the system is to be capable of supplying forecast demand with circuit loading within their winter long-term emergency (LTE) ratings. Thermal limits for transformers are acceptable using winter loading with winter 10-day LTR.
    - All voltages must be within pre and post contingency ranges as per Ontario Resource and Transmission Assessment Criteria (ORTAC) criteria.
    - With one element out of service, no more than 150 MW of load is lost by configuration. With two elements out of service, no more than 600 MW of load is lost by configuration.
    - With two elements out of service, the system is capable of meeting the load restoration time limits as per ORTAC criteria.

6 RESULTS

230/115 kV Autotransformers
The 230/115kV Autotransformers at St Lawrence TS are adequate over the study period for the loss of a single 230/115kV unit

Transmission Lines & Ratings

230kV Lines
The 230 kV circuits supplying the Region are adequate over the study period for the loss of a single 230 kV circuit in the Region.

There is a generation rejection scheme in place that can runback Saunders GS and/or Beauharnois GS under post-contingency conditions. This scheme ensures that the St Lawrence to Hinchinbrooke TS lines are not overloaded under peak summer conditions.

115kV Lines
Under the assumptions made for regional planning, the 115kV lines are adequate over the study period for the loss of a single circuit in the Region.

The following operating issues have been previously in the SIA/CIA done for Cardinal Power G3 Expansion [4, 5]:

Under light load condition and with all distributed generation in the area and the Cardinal Power generation at maximum output the section of the L1MB/L2M line between St Lawrence to Lunenburg JCT can be loaded beyond its short time emergency (STE) rating for loss of either circuit.

To manage the situation, Morrisburg TS has been restricted to accept new generation connection since 2012. In addition, there is Cardinal Power's runback scheme will reduce the plant output following the loss of either circuit and hence reduce the post-contingency loading on either of the L1MB/L2M lines. However since the lines could be loaded beyond their STE, measures such generation re-dispatch is implemented by the IESO as per the Cardinal Power G3 Expansion studies [4, 5].

230 kV and 115 kV Connection Facilities
A station capacity assessment was performed over the study period for the 230 kV and 115 kV transformer stations in the Region using the station winter peak load forecast provided by the study team. All stations in the area have adequate supply capacity for the study period even in the event of extreme weather scenario.

Reverse Power Flow
At Morrisburg TS, under light load condition and high distributed and directly connected generation, a reverse power flow issue was identified in the Cardinal Power G3 Expansion SIA/CIA [4, 5]. This situation occurs if one of the line breakers at Cardinal Power has an inadvertent opening (IBO). This IBO results in all of Cardinal Power's generation being sent to one line, which causes reverse power at Morrisburg TS beyond its maximum limit. As noted previously, since 2012, additional generation connection has been restricted at Morrisburg TS to manage the reverse power flow at the station.

Dyno Nobel CTS
Under the same conditions mentioned above, an IBO at Cardinal Power can also result in power flow through the Dyno Nobel CTS to exceed their rating [4, 5].

For Morrisburg TS and Dyno Nobel CTS transformer loading issues, Cardinal Power run back scheme is triggered to reduce the flows to within equipment ratings as it was outlined in the SIA and CIA [4,5]. No further action is recommended within the scope of this regional planning.

7 System Reliability, Operation and Restoration

Based on the gross coincident load forecast, the loss of one element does not result in load interruption greater than 150MW. The maximum load interrupted by configuration due to the loss of two elements is below the load loss limit of 600MW for the duration of the 10-year study period.

Chesterville TS and Newington DS are on single supply from L2M for a combined gross load of 50MW in 2025. If the supply from St Lawrence TS becomes unavailable, these two stations can be supplied from Merivale TS.

All loads in the St Lawrence area can be restored within the 8 hour requirement.

IESO indicated in their unsupplied energy report that the 115kV area did not meet its target in the past. Chesterville TS missed its customer delivery point target (frequency of interruption) in recent years due to momentary outages seen as a result of severe weather patterns. Hydro One will review and monitor its supply point performance at Chesterville TS to determine if corrective measures are required. No further actions required as part of regional planning.

8 AGING INFRASTRUCTURE AND REPLACEMENT PLAN OF MAJOR EQUIPMENT

Hydro One reviewed the sustainment initiatives that are currently planned for the replacement of any autotransformers, power transformers and high-voltage cables during the study period. At this time the following sustainment work is planned for the stations in the area:

Morrisburg TS: Protection upgrade, 44kV breakers (2019 in service)

Smiths Falls TS: Protection replacement, battery and charger, switches (2021 in service)

St Lawrence TS: Replacement of oil breakers at 230kV, 115k, and 44kV; replacement of AC/DC station service supplies; and protection upgrade work. (2024 in service)

The facilities at these stations are adequate and there is no need to increase the equipment rating.

9 RECOMMENDATIONS

Based on the findings of the Needs Assessment, the study team recommends that no further regional coordination or further planning is required. The region will be reassessed within five years as part of the next planning cycle.

10 NEXT STEPS

No further Regional Planning is required at this time. The St Lawrence Region Regional Planning will be reassessed during the next planning cycle or at any time should unforeseen conditions or needs warrant to initiate the regional planning for the region.

REGIONAL INFRASTRUCTURE PLAN

January 9th, 2017

[This page is intentionally left blank]

Prepared by:
Hydro One Networks Inc. (Lead Transmitter)

With support from:

Company
Hydro One Networks Inc. (Distribution)
Independent Electricity System Operator
Oshawa PUC Networks Inc.
Veridian Connections Inc.
Whitby Hydro Electric Corporation

DISCLAIMER

This Regional Infrastructure Plan ("RIP") report was prepared for the purpose of developing an electricity infrastructure plan to address all near and mid-term needs identified in previous planning phases and also any additional needs identified based on new and/or updated information provided by the RIP Working Group.

The preferred solution(s) that have been identified in this report may be reevaluated based on the findings of further analysis. The load forecast and results reported in this RIP report are based on the information provided and assumptions made by the participants of the RIP Working Group.

Working Group participants, their respective affiliated organizations, and Hydro One Networks Inc. (collectively, "the Authors") make no representations or warranties (express, implied, statutory or otherwise) as to the RIP report or its contents, including, without limitation, the accuracy or completeness of the information therein and shall not, under any circumstances whatsoever, be liable to each other, or to any third party for whom the RIP report was prepared ("the Intended Third Parties"), or to any other third party reading or receiving the RIP report ("the Other Third Parties"), for any direct, indirect or consequential loss or damages or for any punitive, incidental or special damages or any loss of profit, loss of contract, loss of opportunity or loss of goodwill resulting from or in any way related to the reliance on, acceptance or use of the RIP report or its contents by any person or entity, including, but not limited to, the aforementioned persons and entities.

[This page is intentionally left blank]

EXECUTIVE SUMMARY

THIS REGIONAL INFRASTRUCTURE PLAN ("RIP") WAS PREPARED BY HYDRO ONE NETWORKS INC. ("HYDRO ONE") AND THE WORKING GROUP IN ACCORDANCE WITH THE ONTARIO TRANSMISSION SYSTEM CODE REQUIREMENTS. IT IDENTIFIES INVESTMENTS IN TRANSMISSION FACILITIES, DISTRIBUTION FACILITIES, OR BOTH, THAT SHOULD BE DEVELOPED AND IMPLEMENTED TO MEET THE ELECTRICITY INFRASTRUCTURE NEEDS OF THE GTA EAST REGION.

The participants of the RIP Working Group included members from the following organizations:

- Hydro One Networks Inc. (Distribution)
- Independent Electricity System Operator
- Oshawa PUC Networks Inc.
- Veridian Connections Inc.
- Whitby Hydro Electric Corporation
- Hydro One Networks Inc. (Transmission)

This RIP is the final phase of the OEB's mandated regional planning process for the GTA East Region which consists of the Pickering-Ajax-Whitby Sub-Region and the Oshawa-Clarington Sub-Region. It follows the completion of the GTA East Region's Needs Assessment ("NA") in August 2014, the Oshawa-Clarington Sub-Region's Local Plan ("LP") in May 2015, and the Pickering-Ajax-Whitby Sub-Region's Integrated Regional Resource Plan ("IRRP") in June 2016.

This RIP provides a consolidated summary of needs and recommended plans for the entire GTA East Region that includes the Pickering-Ajax-Whitby Sub-Region and Oshawa-Clarington Sub-Region. The major transmission and distribution infrastructure investments planned for the GTA East Region over the near and mid-term, as identified in the regional planning process are given below.

No.	Project	I/S Date	Cost
1	Enfield TS; new 230/44kV station	2019	$34M[1]
2	Seaton MTS; new 230/27.6/27.6kV station	2019	$43M-$48M[2]

As per the Regional Planning process, the Regional Plan will be reviewed and/or updated at least once every five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

[1] Considers 6x44kV feeder breaker positions initially without capacitor banks
[2] Class Environmental Assessment (EA) not complete at time of RIP. Range of costs includes all sites under consideration – includes transmission line rebuild costs and all station equipment less capacitor banks for 12x27.6kV feeders and a spare transformer.

1. INTRODUCTION

THIS REPORT PRESENTS THE REGIONAL INFRASTRUCTURE PLAN ("RIP") TO ADDRESS THE ELECTRICITY NEEDS OF THE GTA EAST REGION.

The report was prepared by Hydro One Networks Inc. ("Hydro One") and documents the results of the study with input and consultation with Hydro One Distribution, Oshawa PUC Networks Inc. ("OPUCN"), Veridian Connections Inc. ("Veridian"), Whitby Hydro Electric Corporation ("Whitby Hydro") and the Independent Electricity System Operator ("IESO") in accordance with the Regional Planning process established by the Ontario Energy Board ("OEB") in 2013.

The GTA East Region comprises the municipalities of Pickering, Ajax, Whitby, Oshawa, and Clarington. Electrical supply to the Region is provided through 500/230kV autotransformers at Cherrywood Transformer Station ("TS") and five[3] 230kV transmission lines that supply the four local area step-down transformer stations. The boundaries of the Region are shown in Figure 1-1 below.

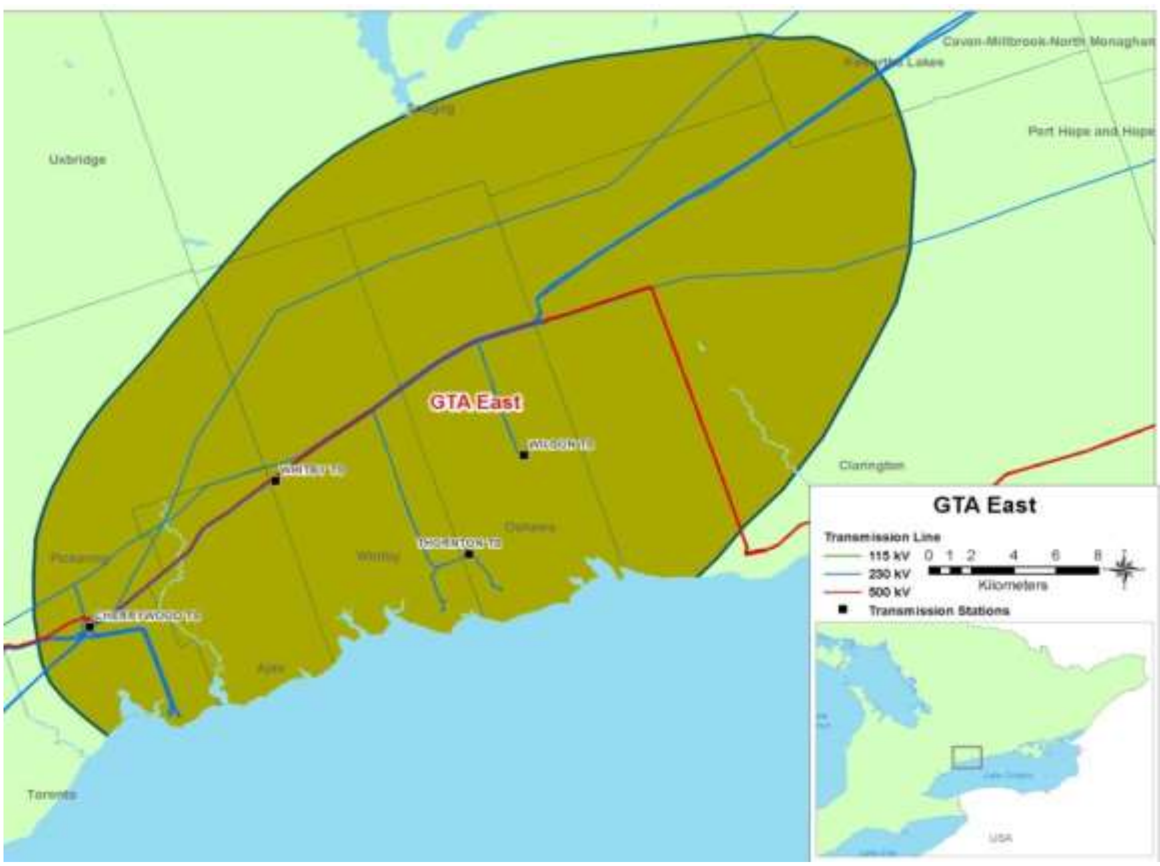

Figure 1-1 GTA East Region

---

[3] Including 230kV circuit C28C (T28C with Clarington TS) which extends 2km north from Cherrywood TS to Duffin Jct. and then extends 26km east to be terminated at Clarington TS in 2018

1.1 Scope and Objectives

This RIP report examines the needs in the GTA East Region. Its objectives are to:

- Identify new supply needs that may have emerged since previous planning phases (e.g., Needs Assessment, Scoping Assessment, Local Plan, and/or Integrated Regional Resource Plan);
- Assess and develop a wires plans to address these needs;
- Provide the status of wires planning currently underway or completed for specific needs;
- Identify investments in transmission and distribution facilities or both that should be developed and implemented on a coordinated basis to meet the electricity infrastructure needs within the region.

The RIP reviews factors such as the load forecast, transmission and distribution system capability along with any updates with respect to local plans, conservation and demand management ("CDM"), renewable and non-renewable generation development, and other electricity system and local drivers that may impact the need and alternatives under consideration.

The scope of this RIP is as follows:

- A consolidated report of the needs and relevant plans to address near and mid-term needs (2016-2025) identified in previous planning phases (Needs Assessment, Scoping Assessment, Local Plan or Integrated Regional Resource Plan);
- Identification of any new needs over the 2016-2025 period and a wires plan to address them;
- Consideration of long-term needs identified in the Pickering-Ajax-Whitby Sub-Region IRRP

As per the Regional Planning process, the Regional Plan for the region will be reviewed and/or updated at least every five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

1.2 Structure

The rest of the report is organized as follows:

- Section 2 provides an overview of the regional planning process
- Section 3 describes the regional characteristics
- Section 4 describes the transmission work completed over the last ten years
- Section 5 describes the load forecast and study assumptions used in this assessment
- Section 6 describes the results of the adequacy assessment of the transmission facilities and identifies the regional needs
- Section 7 describes the needs and provides the alternatives and preferred solutions
- Section 8 provides the conclusion and next steps

2. REGIONAL PLANNING PROCESS

2.1 Overview

Planning for the electricity system in Ontario is done at essentially three levels: bulk system planning, regional system planning, and distribution system planning. These levels differ in the facilities that are considered and the scope of impact on the electricity system. Planning at the bulk system level typically looks at issues that impact the system on a provincial level, while planning at the regional and distribution levels looks at issues on a more regional or localized level.

Regional planning looks at supply and reliability issues at a regional or local area level. Therefore, it largely considers the 115kV and 230kV portions of the power system that supply various parts of the province.

2.2 Regional Planning Process

A structured regional planning process was established by the Ontario Energy Board ("OEB") in 2013 through amendments to the Transmission System Code ("TSC") and Distribution System Code ("DSC"). The process consists of four phases: the Needs Assessment[4] ("NA"), the Scoping Assessment ("SA"), the Integrated Regional Resource Plan ("IRRP"), and the Regional Infrastructure Plan ("RIP").

The regional planning process begins with the NA phase, which is led by the transmitter to determine if there are regional needs. The NA phase identifies the needs and the Working Group determines whether further regional coordination is necessary to address them. If no further regional coordination is required, and needs are local in nature, an assessment is undertaken for any necessary investments directly by the LDCs (or customer) and the transmitter through a Local Plan ("LP"). These needs are local in nature and can be best addressed by a straight forward wires solution. The Working Group recommends a LP undertaking when needs are a) local in nature b) limited investments of wires (transmission or distribution) solutions c) does not require upstream transmission investments d) does not require plan level stakeholder engagement and e) other approvals such as Leave to Construct (S92) application or Environmental Approval.

In situations where identified needs require coordination at the regional or sub-regional levels, the IESO initiates the SA phase. During this phase, the IESO, in collaboration with the transmitter and impacted LDCs, reviews the information collected as part of the NA phase, along with additional information on potential non-wires alternatives, and makes a decision on the most appropriate regional planning approach. If there are needs that do not required regional coordination, Working Group can recommend them to be undertaken as part of the LP approach discussed above. Else, the approach is either a RIP, which is led by the transmitter, or an IRRP, which is led by the IESO. If more than one sub-region was identified in the NA phase, it is possible that a different approach could be taken for different sub-regions.

---

[4] Also referred to as Needs Screening.

The IRRP phase will generally assess infrastructure (wires) versus resource (CDM and Distributed Generation) options at a higher or more macro level, but sufficient to permit a comparison of options. If the IRRP phase identifies that infrastructure options may be most appropriate to meet a need, the RIP phase will conduct detailed planning to identify and assess the specific wires alternatives and recommend a preferred wires solution. Similarly, resource options that the IRRP identifies as best suited to meet a need are then further planned in greater detail by the IESO. The IRRP phase also includes IESO led stakeholder engagement with municipalities and establishes a Local Advisory Committee ("LAC") in the region or sub-region.

The RIP phase is the final stage of the regional planning process and involves: confirmation of previously identified needs; identification of any new needs that may have emerged since the start of the planning cycle; and development of a wires plan to address the needs where a wires solution would be the best overall approach. This phase is led and coordinated by the transmitter and the deliverable of this stage is a comprehensive report of a wires plan for the region. Once completed, this report can be referenced in rate filing submissions or as part of LDC rate applications with a planning status letter provided by the transmitter. Reflecting the timelines provisions of the RIP, plan level stakeholder engagement is not undertaken at this stage. However, stakeholder engagement at a project specific level will be conducted as part of the project approval requirement.

To efficiently manage the regional planning process, Hydro One has been undertaking wires planning activities in collaboration with the IESO and LDCs for the region as part of and/or in parallel with:

- Planning activities that were already underway in the region prior to the new regional planning process taking effect;
- The NA, SA, and LP phases of regional planning;
- Participating in and conducting wires planning as part of the IRRP for the region or sub-region.

Figure 2-1 illustrates the various phases of the regional planning process (NA, SA, IRRP, and RIP) and their respective phase trigger, lead, and outcome.

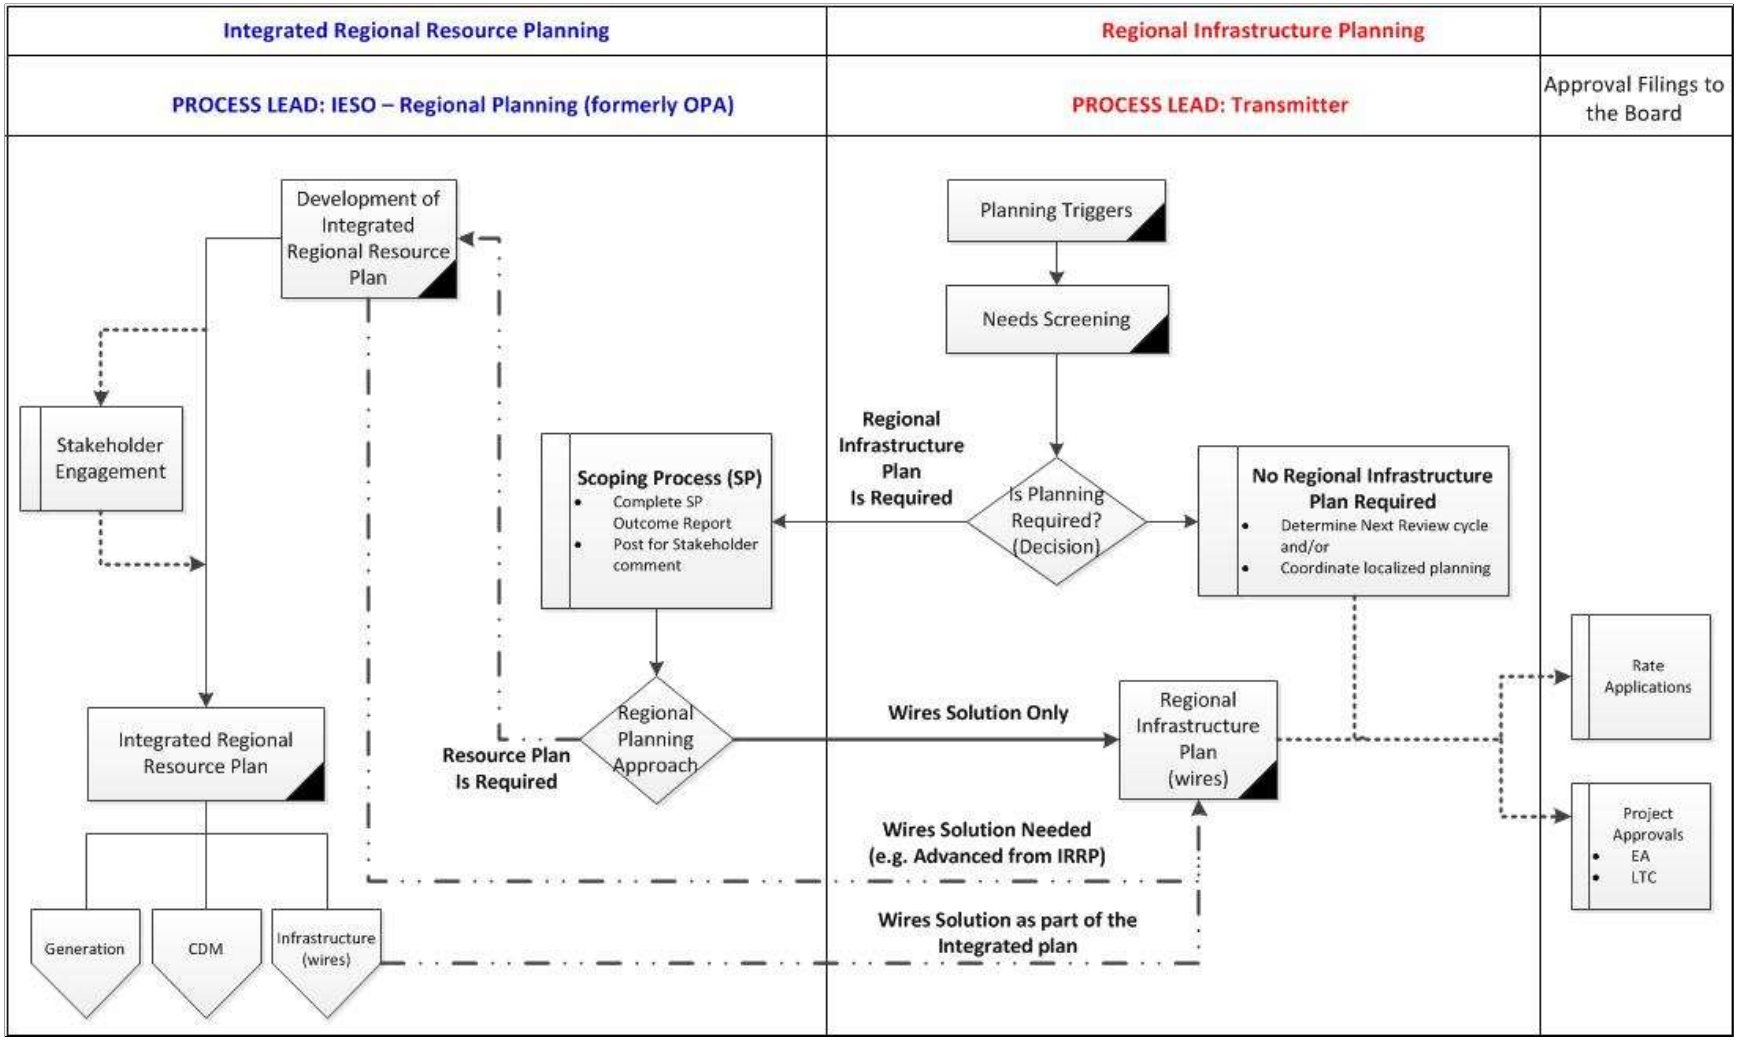

Figure 2-1 Regional Planning Process Flowchart

2.3 RIP Methodology

The RIP phase consists of a four step process (see Figure 2-2) as follows:

1. Data Gathering: The first step of the process is the review of planning assessment data collected in the previous stages of the regional planning process. Hydro One collects the following information and reviews it with the Working Group to reconfirm or update the information as required.

   - Net peak demand forecast at the transformer station level. This includes the effect of any distributed generation ("DG") or CDM programs;
   - Existing area network and capabilities including any bulk system power flow assumptions;
   - Other data and assumptions as applicable such as asset conditions, load transfer capabilities, and previously committed transmission and distribution system plans.

2. Technical Assessment: The second step is a technical assessment to review the adequacy of the regional system including any previously identified needs. Additional near and mid-term needs may be identified at this stage.

3. Alternative Development: The third step is the development of wires options to address the needs and to come up with a preferred alternative based on an assessment of technical considerations, feasibility, environmental impact, and costs.

4. Implementation Plan: The fourth and last step is the development of the implementation plan for the preferred alternative.

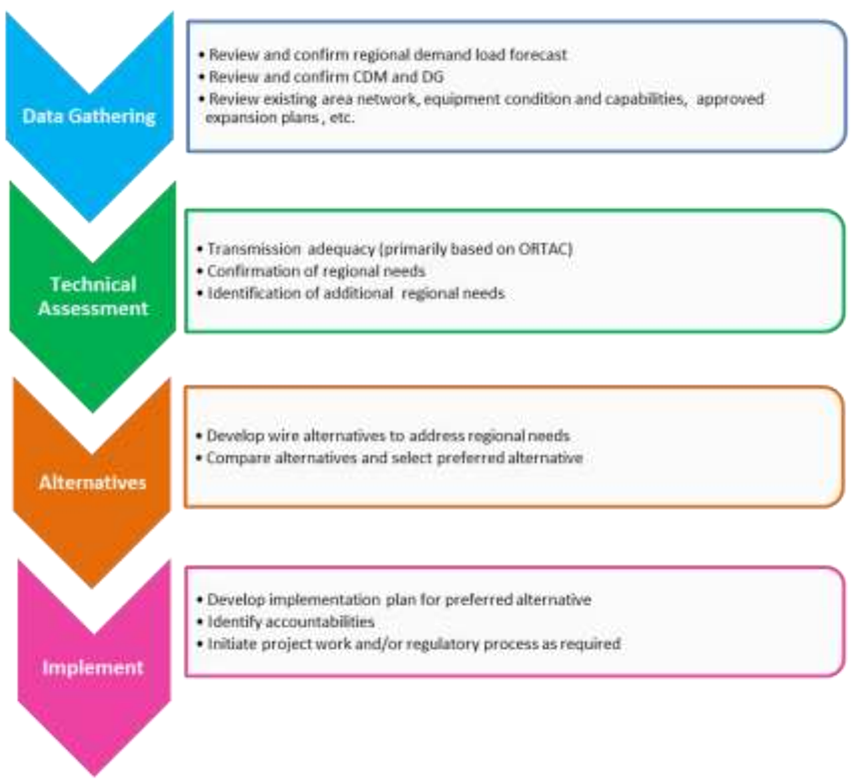

Figure 2-2 RIP Methodology

3. REGIONAL CHARACTERISTICS

THE GTA EAST REGION IS COMPRISED OF THE PICKERING-AJAX-WHITBY SUB-REGION AND THE OSHAWA-CLARINGTON SUB-REGION. ELECTRICAL SUPPLY TO THE REGION IS PROVIDED FROM FOUR 230KV STEP-DOWN TRANSFORMER STATIONS. THE 2015 SUMMER PEAK AREA LOAD OF THE REGION WAS APPROXIMATELY 938.5 MW INCLUDING DIRECT TRANSMISSION-CONNECTED CUSTOMERS.

Bulk electrical supply to the GTA East Region is currently provided through Cherrywood TS, a major 500/230kV autotransformer station in the City of Pickering, and five 230kV circuits emanating east from Cherrywood TS that supply four local area step-down transformer stations and four other direct transmission connected load customers. Major generation in the area includes the Pickering Nuclear Generating Station ("NGS") which consists of six generating units with a combined output of approximately 3000 MW and is connected to the 230kV system at Cherrywood TS.

The August 2014 GTA East Region NA report, prepared by Hydro One, considered the GTA East Region as a whole. Subsequently, the GTA East Region was divided into two sub-regions, Pickering-Ajax-Whitby Sub-Region and Oshawa-Clarington Sub-Region. The IRRP report focused on the needs in the Pickering-Ajax-Whitby Sub-Region. The May 2015 Oshawa-Clarington Sub-Region LP report focused solely on the Oshawa-Clarington Sub-Region. A map of the GTA East Region is shown in Figure 3-1 and a single line diagram of the transmission system is shown in Figure 3-2.

3.1 Pickering-Ajax-Whitby Sub-Region

The Pickering-Ajax-Whitby Sub-Region comprises primarily the City of Pickering, Town of Ajax, part of the Town of Whitby, and part of the Townships of Uxbridge and Scugog. It is supplied by Cherrywood TS, a 500/230kV autotransformer station, two 230kV transformer stations, namely Cherrywood TS DESN and Whitby TS (2 DESNs), that step down the voltage to 44kV and 27.6kV. The LDCs supplied in the Sub-Region are Hydro One Distribution, Veridian, and Whitby Hydro.

3.2 Oshawa-Clarington Sub-Region

The Oshawa-Clarington Sub-Region comprises primarily the City of Oshawa, part of the Municipality of Clarington, part of Whitby, and part of the Township of Scugog. It is supplied by Cherrywood TS, a 500/230kV autotransformer station, two 230kV transformer stations, namely Wilson TS (2 DESNs) and Thornton TS, that step down the voltage to 44kV, and four other direct transmission connected load customers. Local generation in the area consists of the 60 MW Whitby Customer Generating Station ("CGS"), a gas-fired cogeneration facility that connects to 230kV circuit H26C. Thornton TS also supplies some load within the Pickering-Ajax-Whitby Sub-Region. The LDCs supplied in the Sub-Region are Whitby Hydro, Hydro One Distribution, and OPUCN.

A new 500/230kV autotransformer station in the GTA East Region within the township of Clarington (called Clarington TS) is also being developed and is expected to be in-service in 2018. The new Clarington TS will provide additional load meeting capability in the Region and will eliminate the overloading of Cherrywood autotransformers that may result after the retirement of the Pickering NGS. The new autotransformer station will consist of two 750MVA, 500/230kV autotransformers and a 230kV switchyard. The autotransformers will be supplied from two 500kV circuits that pass next to the proposed site. The 230kV circuits supplying the east GTA will be terminated at Clarington TS. Clarington TS will become the principal supply source for the GTA East Region load.

A single line diagram of the GTA East Region transmission system including the connection of Clarington TS is shown in Figure 3-2.

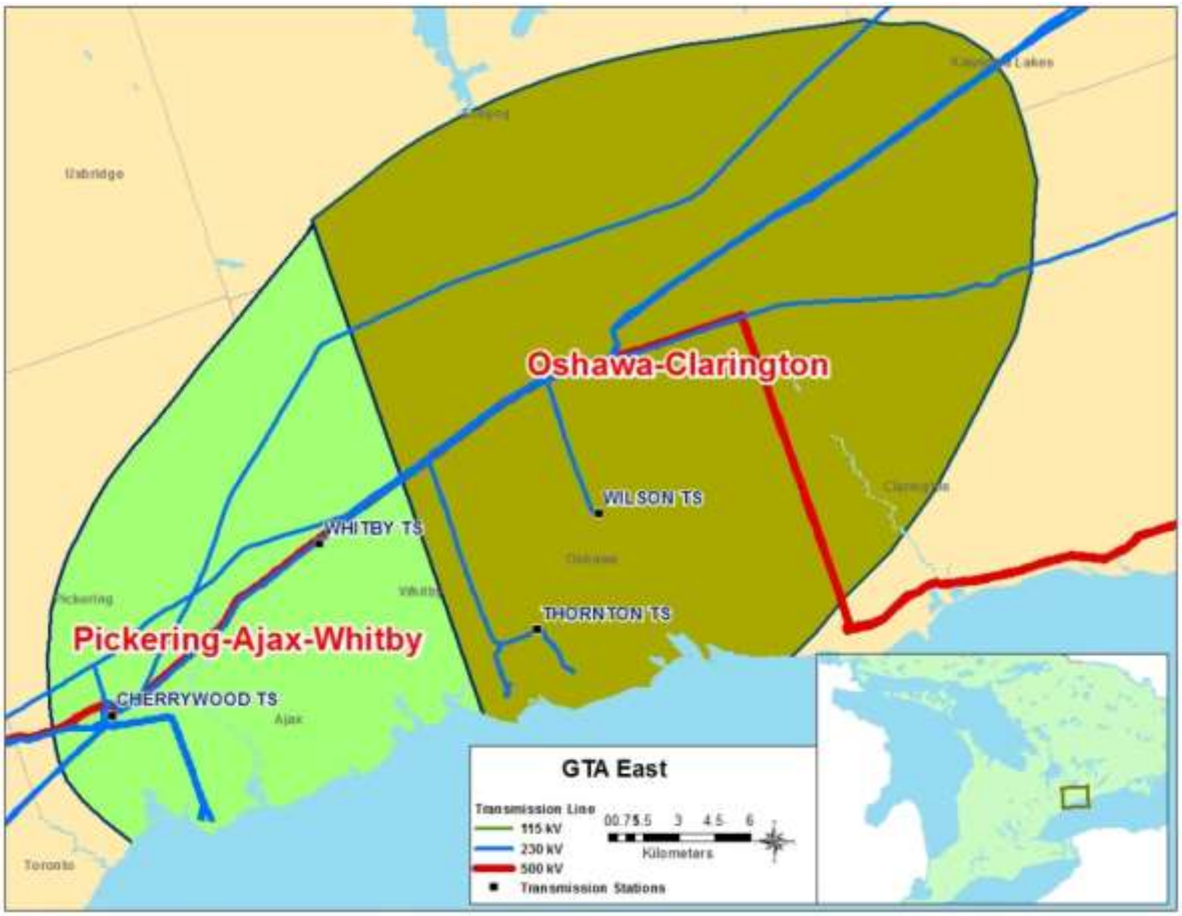

Figure 3-1 GTA East Region – Supply Areas

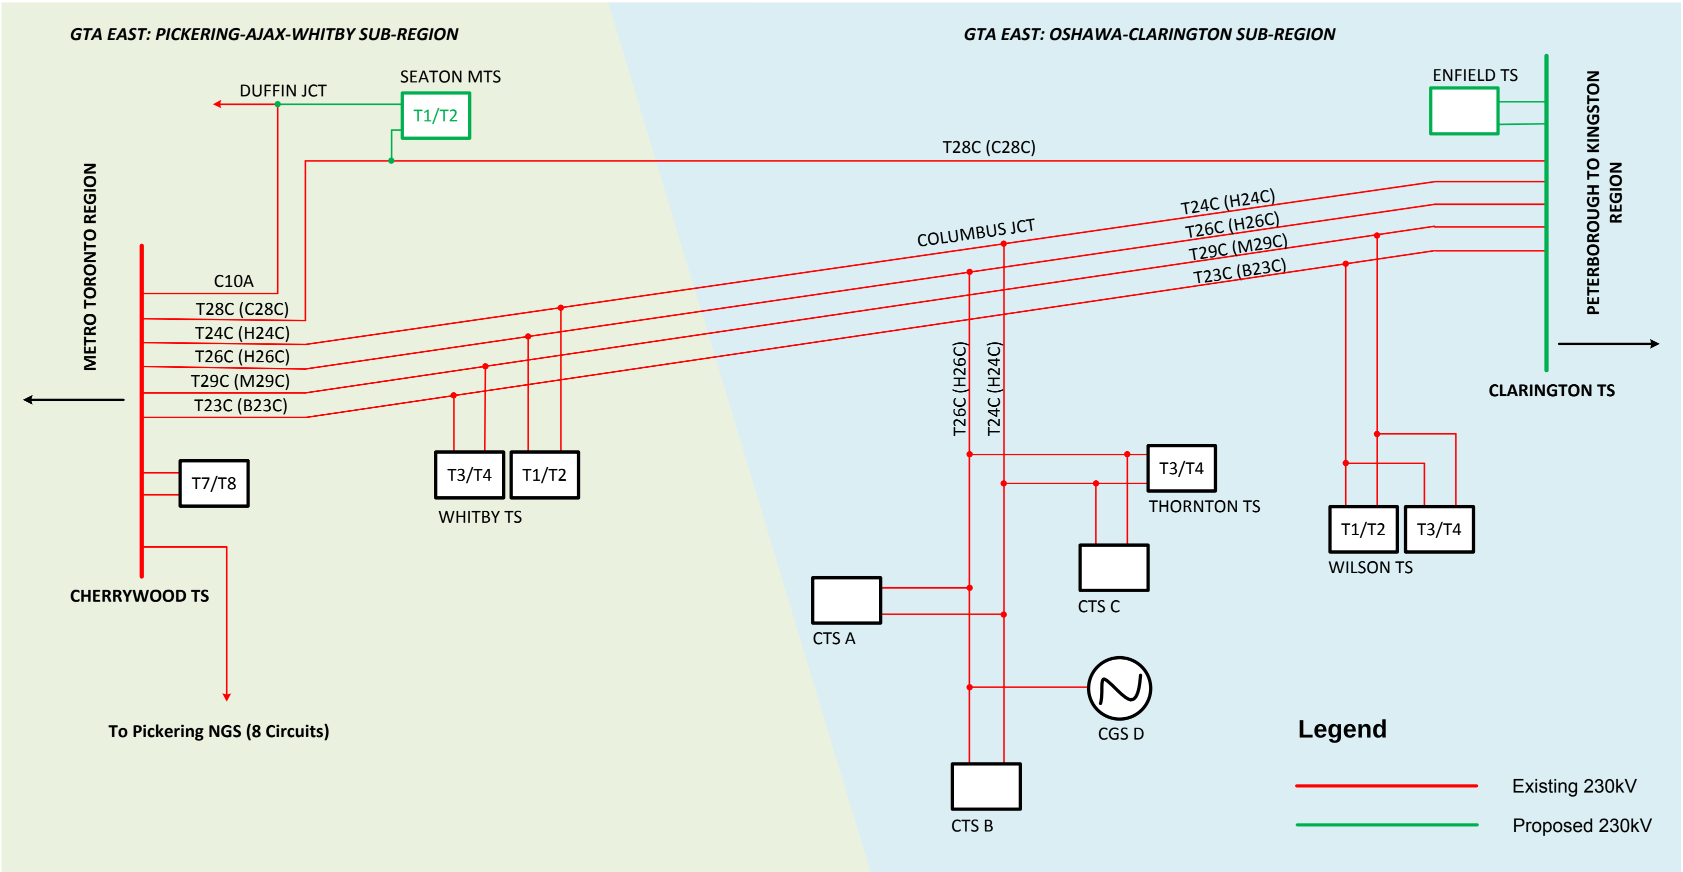

Figure 3-2 GTA East Region Single Line Diagram

Note: Current circuit designations (before Clarington TS is in-service) are provided in brackets

4. TRANSMISSION FACILITIES COMPLETED OR CURRENTLY UNDERWAY OVER LAST TEN YEARS

OVER THE LAST 10 YEARS A NUMBER OF TRANSMISSION PROJECTS HAVE BEEN COMPLETED, OR ARE UNDERWAY, AIMED AT IMPROVING THE SUPPLY TO THE GTA EAST REGION.

A brief listing of the developed projects along with their in-service dates over the last 10 years is given below:

- Whitby TS T1/T2 (2009) – built new step-down transformer station supplied from 230kV circuits H24C and H26C in municipality of Whitby to increase transformation capacity for Whitby Hydro and Veridian requirements.

- Installed LV neutral grounding reactors at Wilson TS T1/T2 DESN1 (2015) – to reduce line-to-ground short circuit fault levels to facilitate DG connections.

- Thornton TS T3/T4 transformer replacements and install LV neutral grounding reactors (2016) – to replace end-of-life transformers and reduce line-to-ground short circuit fault levels to facilitate DG connections.

The following development projects are currently underway:

- Clarington TS (2018) – a 500/230kV autotransformer station at the Oshawa Area Jct. to increase transmission supply capacity to the GTA East Region, eliminate the overloading of Cherrywood TS autotransformers that may result after the retirement of Pickering NGS, and improve supply reliability to the Region. The thermal limits of the 230kV circuits supplying the Region will be upgraded and will be terminated at Clarington TS.

- Seaton MTS (2019) – a 230/27.6/27.6kV municipal transformer station to increase supply capacity in the Pickering-Ajax-Whitby Sub-Region and provide relief to Whitby TS 27.6kV following the development of new community of Seaton. The station will be serviced by two parallel 230kV circuits, C10A and C28C, emanating from Cherrywood TS. C10A will be extended eastward from Duffin Jct. to the site of the station.

- Enfield TS (2019) – a 230/44kV DESN to increase supply capacity in the Oshawa-Clarington Sub-Region and provide relief to Wilson TS. This station will be located at the Oshawa Area Jct. and will be directly connected to Clarington TS 230kV bus.

5. FORECAST AND STUDY ASSUMPTIONS

5.1 Load Forecast

The load in the GTA East Region is expected to increase at an annual rate of approximately 2% between 2016 and 2025. The growth rate varies across the Region but an overall coincident growth in the Region is illustrated in Figure 5-1. The gross and net non-coincident and coincident load forecast, adjusted for extreme weather, CDM, and DG, for each station in the region are provided in Appendix C and D.

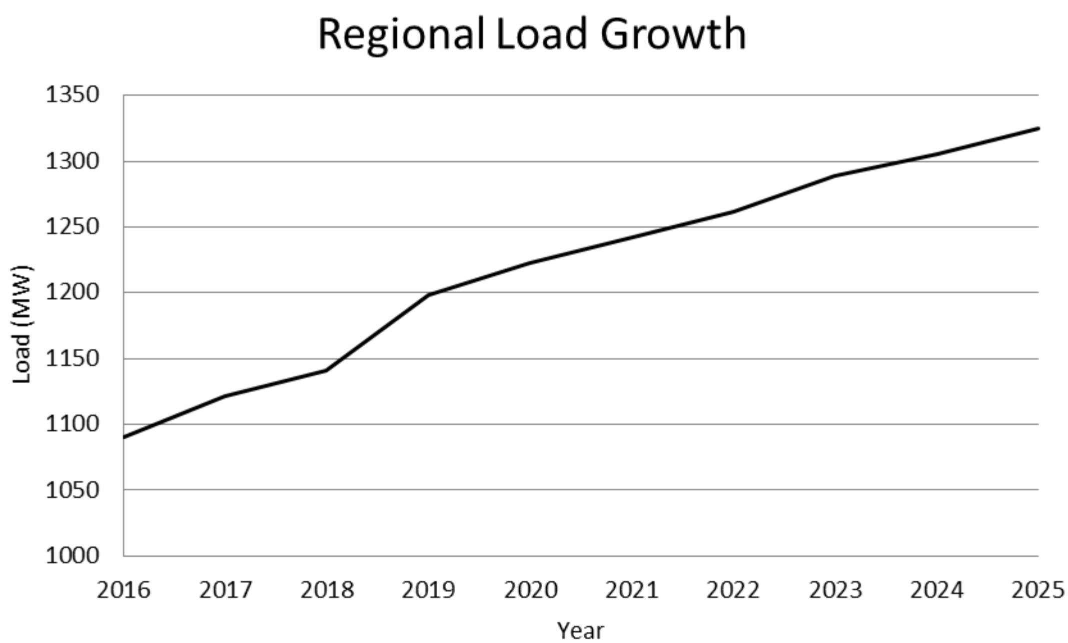

Figure 5-1 GTA East Region Coincident Net Load Forecast

Prior to the RIP's kick-off, the Working Group were asked to confirm load forecast for all stations in the Region provided for previous assessments. The RIP's load forecast for Pickering-Ajax-Whitby Sub-Region did not have a significant revision compared to the IRRP's load forecast. However, the revised forecasted non-coincident stations' peaks for Wilson TS and Thornton TS in the Oshawa-Clarington Sub-Region had a significant increase; therefore, the needs identified in previous assessments were reconfirmed.

5.2 Other Study Assumptions

Further assumptions are as follows:

- The study period for the RIP assessment is 2016 – 2025.
- Pickering NGS is assumed to be out-of-service by 2024.
- Summer is the critical period with respect to line and transformer loadings. The assessment is therefore based on extreme summer peak loads.
- Station capacity adequacy is assessed by comparing the peak load with the station's normal planning supply capacity assuming a 90% lagging power factor for stations having no low-voltage capacitor banks and 95% lagging power factor for stations having low-voltage capacitor banks. Normal planning supply capacity for transformer stations in this region is determined by the summer 10-Day Limited Time Rating ("LTR").

6. ADEQUACY OF FACILITIES AND REGIONAL NEEDS

THIS SECTION REVIEWS THE ADEQUACY OF THE EXISTING TRANSMISSION AND STEP DOWN TRANSFORMATION STATION FACILITIES SUPPLYING THE GTA EAST REGION AND LISTS THE FACILITIES REQUIRING REINFORCEMENT OVER THE NEAR AND MID-TERM PERIOD.

Within the current regional planning cycle, three regional assessments have been conducted for the GTA East Region. The findings of these studies are input to the RIP:

1. IESO's Pickering-Ajax-Whitby Sub-Region Integrated Regional Resource Plan – June 30, 2016[1]
2. Hydro One's Oshawa-Clarington Sub-Region Local Planning Report – May 15, 2015[2]
3. Hydro One's GTA East Region Needs Assessment Report – August 11, 2014[3]

The IRRP, NA, and LP studies identified a number of regional needs based on the forecast load demand over the near to mid-term. A detailed description and status of plans to meet these needs is given in Section 7.

Based on the regional growth rate referred to in Section 5, this RIP reviewed the loading on transmission lines and stations in the GTA East Region assuming Clarington TS will be in-service by 2018, Seaton MTS and Enfield TS by 2019, and Pickering NGS out-of-service between 2018 and 2024.

Sections 6.1 – 6.3 present the results of this review and Table 6-1 lists the Region's near to mid-term needs identified in both the IRRP and RIP phases.

Table 6-1 Near and Mid-Term Needs in the GTA East Region

Type	Section	Needs	Timing
Step-down Transformation Capacity	7.1	Additional transformation capacity for Whitby TS T1/T2 27.6kV in Pickering-Ajax-Whitby Sub-Region	2019
	7.2	Additional transformation capacity for Wilson TS T1/T2 & T3/T4 in Oshawa-Clarington Sub-Region	Immediately
Load Restoration	7.3	Load Restoration for loss of B23C/M29C or H24C/H26C	No action required at this time
Short Circuit Constraint	7.4	Short Circuit Constraint at Cherrywood TS T7/T8	Pending outcome

6.1 500kV and 230kV Transmission Facilities

The GTA East Region is comprised of five 230kV circuits, B23C/M29C, H24C/H26C, and C28C, supplying both the Pickering-Ajax-Whitby Sub-Region and the Oshawa-Clarington Sub-Region. Refer to Figure 3-2 for existing and proposed facilities to be operational in the Region in near future.

Bulk system planning is conducted by the IESO and is informed by government policy such as the long term energy plan ("LTEP"). The next LTEP is expected to be issued in 2017. Any outcomes from this level of planning that impact regional planning are expected to be integrated into the respective regions as necessary.

6.2 Pickering-Ajax-Whitby Sub-Region's Step-Down Transformer Station Facilities

There are two step-down transformer stations in the Pickering-Ajax-Whitby Sub-Region as follows:

Table 6-2 Step-Down Transformer Stations in Pickering-Ajax-Whitby Sub-Region

Station	DESN	Voltage Transformation
Cherrywood TS	T7/T8	230/44kV
Whitby TS	T1/T2	230/44/27.6kV
	T3/T4	230/44kV

Based on the LTR of these load stations, additional 27.6kV capacity is required at Whitby TS T1/T2 in 2019 which will be addressed by the proposed Seaton MTS (see details in Section 7.1). Cherrywood TS T7/T8 may be slightly overloaded initially, however, due to CDM and commissioning of Seaton MTS, the capacity need is expected to be eliminated by 2019. Forecast loads at Whitby TS T1/T2 44kV windings, and Whitby TS T3/T4 44kV windings are adequate over the study period.

The stations' actual non-coincident peaks, the associated station capacity, and need dates are summarized in Table 6-3.

Table 6-3 Transformation Capacities in the Pickering-Ajax-Whitby Sub-Region

Station	LTR (MW)	2015 Summer Peak (MW)	Relief Required By
Cherrywood TS T7/T8 44kV	175	156	-
Whitby TS T1/T2 27.6kV	90	41	2019
Whitby TS T1/T2 44kV	90	56	-
Whitby TS T3/T4 44kV	187	161	-

6.3 Oshawa-Clarington Sub-Region's Step-Down Transformer Station Facilities

There are two step-down transformer stations and four direct-connected customers in the Oshawa-Clarington Sub-Region as follows:

Table 6-4 Step-Down Transformer Stations in Oshawa-Clarington Sub-Region

Station	DESN	Voltage Transformation
Wilson TS	T1/T2	230/44kV
	T3/T4	230/44kV
Thornton TS	T3/T4	230/44kV
Industrial Customer TS x4	-	-

Based on the LTR of these load stations, additional 44kV capacity is immediately required to provide relief to Wilson TS. Under certain conditions, overloading at Wilson TS T3/T4 was significant enough to plan for emergency rotating load shedding, if and when required. Plan to address this need is discussed further in Section 7.2. Thornton TS is adequate to meet the net demand over the study period.

The stations' actual non-coincident peaks, the associated station capacity, and need dates are summarized in Table 6-5.

Table 6-5 Transformation Capacities in the Oshawa-Clarington Sub-Region

Station	LTR (MW)	2015 Summer Peak (MW)	Relief Required By
Wilson TS T1/T2 44kV	161	167	Immediately
Wilson TS T3/T4 44kV	133	146	Immediately
Thornton TS T3/T4 44kV	159	126	-

The non-coincident and coincident load forecast for all stations in the Region is given in Appendix C and Appendix D, respectively.

7. REGIONAL PLANS

This section discusses the needs, wires alternatives and the current preferred wires solution for addressing the electrical supply needs in the GTA East Region. These needs are listed in Table 6-1 and include needs previously identified in the IRRP for the Pickering-Ajax-Whitby Sub-Region and the NA and LP for the Oshawa-Clarington Sub-Region. Needs for which work is already underway are also included.

The near-term needs include needs that arise over the first five years of the study period (2016 to 2020) and the mid-term needs cover the second half of the study period (2021-2025).

7.1 Increase Transformation Capacity in Pickering-Ajax-Whitby Sub-Region

Description

The Pickering-Ajax-Whitby Sub-Region is supplied by Cherrywood TS at 44kV level and Whitby TS at 27.6kV and 44kV levels. Over the next 10 years, the load in this Sub-Region is forecasted to increase at approximately 2.1% annually.

Based on the DG and CDM forecasts in the Sub-Region, adequate 44kV transformation capacity is available at Cherrywood TS T7/T8 and Whitby TS to maintain reliable supply to meet the demand over the study period.

With the proceeding of a new residential and mixed use commercial area in the Sub-Region, called Seaton, significant increase in load demand is expected at 27.6kV level resulting in a shortage transformation capacity by 2019. The gross demand in the new development of Seaton is expected to be 88MW at the end of the study period (2025) and will continue to grow over long term period. The growth resulting from Seaton will have a significant impact on the 27.6kV transformation capacity in the Sub-Region.

Recommended Plan and Current Status

During the regional planning process, the Working Group considered multiple alternatives to address the transformation capacity in the Sub-Region. Preference was given to already existing facilities to ensure system's maximum capacity had been considered in line with the future demand. Other alternatives included CDM, local generation, and transmission & distribution facilities.

After considering estimated DG and CDM targets over the study period, the stations' capacities in the Sub-Region can be relieved to a certain extent. However, existing facilities alone will not be adequate to meet the future demand resulting from the new Seaton community load planned to be supplied at 27.6kV level.

As a result, an investment in wires infrastructure development in the Sub-Region is mandatory to connect and supply the development of Seaton via transmission/distribution facilities. Following the completion of the IRRP, the Working Group recommended Seaton MTS as the best solution to meet the transformation capacity need in the Sub-Region. Veridian Connections Inc. and Hydro One Networks Inc. have jointly submitted an EA application for the proposed station site and related 230kV transmission line work. Consistent with the regional planning studies, Veridian Connections Inc. is developing a plan for a new transformation station called Seaton MTS in northern Pickering. As confirmed by Veridian, the in-service timeline of this transformation station has been deferred to 2019 due to revised 2018 load forecast.

Class Environmental Assessment (EA) is in progress for the three potential construction sites for Seaton MTS illustrated in Figure 7-1.

Figure 7-1 Seaton MTS: Proposed Construction Sites

The project will have the following connection arrangement:

- From Duffin Jct, extend the circuit C10A east to proposed location under EA process
- Connect 2x75/125MVA, 230/27.6/27.6kV transformers to 230kV circuits; C10A and T28C[5]
- Supply 12x27.6kV feeders with a normally open tie-breaker configuration

The total cost of this project is estimated to be \$43M – \$48M. This estimate includes the cost of transmission as well as distribution investments which include the station’s construction, its connection

[5] T28C circuit nomenclature to replace C28C following Clarington TS (2018)

arrangements as defined above, feeder egress to the distribution risers outside of the station, and a spare transformer.

7.2 Increase Transformation capacity in Oshawa-Clarington Sub-Region

Description

The load forecast reflects an annual growth of 1.85% in Oshawa and Clarington area throughout the study period. Based on the 2015 historical demand and station's net demand forecast, Wilson TS T1/T2 and T3/T4 have already exceeded their respective normal supply capacities and will continue to do so over the study period. Overloading at Wilson TS T3/T4 has been significant enough that plans were put in place for emergency rotating load shedding, if and when required. Thornton TS may briefly exceed its transformation capacity in 2018 and 2019 but is adequate over the study period as well as long term period due to CDM contributions and distribution load transfer capability.

Therefore, based on the current load forecasts, additional transformation capacity relief is required for Wilson TS to accommodate the load growth and improve reliability in this sub-region.

Recommended Plan and Current Status

To accommodate the load growth of Hydro One Distribution's and OPUCN's feeders at Wilson TS, a new transformer station, Enfield TS, is recommended to relief the transformation capacity. The proposed transformer options to be evaluated for the DESN are as follows:

1. 2x75/125MVA, 230/44kV transformers with 6x44kV feeder breaker positions, with space for future 2x44kV feeder positions and capacitor banks (Preliminary Cost Estimate: $23 million)
2. 2x75/125MVA, 230/44kV transformers with 8x44kV feeder breaker positions (Preliminary Cost Estimate: $27 million)

The Working Group recommends option 1 to address the transformation capacity need in the Sub-Region. Six feeders will be adequate to supply demand over the study period. Also, option 2 is not considered the best economic solution since option 1 will reserve extra space for 2x44kV feeder positions and capacitor banks for future, when required.

The new DESN, 2x75/125MVA 230/44kV transformers with 6x44kV feeder breaker positions with 2x44kV spare feeder positions, is proposed to be located at the Oshawa Area Junction in the municipality of Clarington. This junction is on the ROW of the Bowmanville and Cherrywood transmission line corridor illustrated in Figure 7-2. The property is already owned by HONI and it is also the site of the new 500/230kV autotransformer Clarington TS supplied by circuits B540C and B543C. The proposed in-service date for the new DESN has a preliminary cost estimate of $34M including feeders egress to the distribution risers outside the station and will be aligned with Clarington TS which is scheduled for 2018.

Figure 7-2 Enfield TS: Proposed Construction Site

Advantages in proceeding with this particular location are as follows:

- The land proposed has already been purchased as part of the property where Clarington TS will be situated resulting in one less station footprint in the Sub-Region.
- Class EA approval has been already obtained for the construction of new TS on Hydro One land at the Clarington TS site.
- The site is also near new development areas which results in minimizing the length of supply feeders from the station.

7.3 GTA East Load Restoration Assessment

Description

GTA East load restoration need was identified in the NA and IRRP reports as the Working Group recommended that further assessment was required to address the supply shortfall during peak load periods. Previous assessments indicated that for the loss of two transmission elements (B23C/M29C or H24C/H26C), the load interrupted with current circuit configuration during peak periods may exceed load restoration criteria and requires further assessment.

Recommended Plan and Current Status

In collaboration with the Working Group, a detailed report[6] was completed to make a recommendation for the load restoration need identified in the Region. The Working Group's assessments in the report, attached in the Appendix F, concluded the following:

- The historical performance of the circuits over the last 15 years has been excellent with little or no impact on supply reliability and security.

- Working Group is recommending that further investment in motorized disconnect switch (MDS) at this time is not a feasible solution to the load restoration need because the risk and/or probability of loss of load is small based on past performances. Therefore, no further action is required at this time.

7.4 Short Circuit Constraint at Cherrywood TS T7/T8

Description

Currently, new DG is restricted from connecting to Cherrywood TS T7/T8 due to short circuit capacity constraints. Veridian Connections Inc., supplied by this station, has indicated that they have several customers that have expressed interest in connecting DG (over 5MW) to Cherrywood TS T7/T8 but are prevented due to the existing restriction. There is an existing 30MW landfill gas generation connection at Cherrywood TS T7/T8 contributing to the short circuit capacity restriction. This generating unit has been shut down and/or has not generated electricity now for more than one year.

Recommended Plan and Current Status

The short circuit capacity is currently held by an earlier landfill generation connection. Although the facility has not been generating and partially dismantled, there is an uncertainty about availability of the short circuit capacity. Hydro One and the IESO will continue to assess this issue to have this capacity reservation released.

[6] GTA East: Load Restoration, Transmission Planning Report, circulated within the Working Group on August 31, 2016

7.5 Long Term Regional Plan

As discussed in Section 5, the electricity demand in GTA East Region is forecasted to grow at 2% annually over the next 10 years. Similar trend is also expected in the long term period where the load is expected to increase by approximately 1.3% annually from year 2026 to 2036. Long term forecast provides a high level insight of how the region may be developing in the future so that near and mid-term plans and ongoing projects in the region are best aligned with potential long term needs and solutions.

No long term needs for the Pickering-Ajax-Whitby Sub-Region were identified in the IRRP. Seaton MTS is expected to supply the Sub-Region's demand adequately over the next two decades. As indicated in the IRRP, official plans by the municipalities expect the lakeshore area in the southern part of Pickering-Ajax-Whitby Sub-Region to grow due to development of high rise residential and commercial buildings. With Pickering NGS expected to retire by 2024, the 230kV transmission lines can be utilized along with a new step-down transformer station to address capacity needs in the southern part of the Sub-Region.

The current forecast did not consider future Pickering Airport which may have an impact on transformation capacity in the long term. Such potential needs will be monitored and system supply capability will be reviewed in the next planning cycle based on the official plans released by the municipalities.

The demand in Oshawa-Clarington Sub-Region is expected to grow over the long term period. The new Enfield TS will mainly provide relief to Wilson TS by supplying the excess load through distribution load transfer capability. As the demand grows in the northern Oshawa area in the long term, additional transformation capacity may have to be planned for in future. Further review and assessment will commence in next Regional Planning cycle to identify and develop alternatives to address new needs.

8. CONCLUSION AND NEXT STEPS

THIS RIP REPORT CONCLUDES THE REGIONAL PLANNING PROCESS FOR THE GTA EAST REGION. THIS REPORT MEETS THE INTENT OF THE PROCESS DESCRIBED IN SECTION 2 WHICH IS ENDORSED BY THE OEB AND MANDATED IN THE TSC AND DSC.

This RIP report addresses regional needs identified in the earlier phases of the Regional Planning process and any new needs identified during the RIP phase. These needs are summarized in Table 8-1.

Table 8-1: Regional Plans – Needs Identified in the Regional Planning Process

Need ID	Needs	Timing
I	Additional transformation capacity for Whitby TS T1/T2 27.6kV in Pickering-Ajax-Whitby Sub-Region	2019
II	Additional transformation capacity for Wilson TS T1/T2 & T3/T4 in Oshawa-Clarington Sub-Region	Immediately
III	Load Restoration for loss of B23C/M29C or H24C/H26C	No action required at this time
IV	Short Circuit Constraint at Cherrywood TS T7/T8	Pending outcome
V	Additional transformation capacity for Oshawa-Clarington Sub-Region	Long term

Projects, lead responsibility, and timeframes for implementing the wires solutions for the above needs are summarized in Table 8-2 below.

Table 8-2: Regional Plans – Projects, Lead Responsibility, and Planned In-Service Dates

#	Project	Lead Responsibility	I/S Date	Estimated Cost	Mitigated Need ID
1	Seaton MTS and associated line work	Veridian and Hydro One	2019	$43M-$48M	I
2	Enfield TS	OPUCN and Hydro One	2019	$34M	II

GTA East load restoration need, Need ID III, has been reviewed in this Regional Planning cycle and “status quo/do nothing” course of action has been recommended (see Appendix F). Further developments in the Region will be monitored and the need will be reviewed again as part of the next planning cycle.

Hydro One is working with the IESO to explore the best course of action to relieve the short circuit constraint at Cherrywood TS, Need ID IV.

Additional transformation capacity for Oshawa-Clarington Sub-Region, Need ID V, will be reviewed as part of the next Regional Planning cycle.

In accordance with the Regional Planning process, the Regional Planning cycle will be triggered at least once within five years. Should there be a need that emerges due to a change in load forecast or any other reason, the next regional planning cycle will be started earlier to address the need.

TRANSMISSION PLANNING REPORT

GTA East: Load Restoration

Revision: Final
Date: August 31, 2016

Prepared by: Hydro One Networks Inc.

[This page is intentionally left blank]

Executive Summary

REGION	GTA East (the "Region")		
LEAD	Hydro One Networks Inc. ("Hydro One")		
START DATE	June 17, 2016	**END DATE**	August 31, 2016

1. INTRODUCTION

The purpose of this Transmission Planning (TP) report is to undertake a comprehensive assessment of the load restoration need identified in the Needs Assessment (NA) and Integrated Regional Resource Plan (IRRP) and develop a preferred recommendation. The recommendations of this TP report will become part of the Regional Infrastructure Plan (RIP) and is intended to facilitate the regional planning process as set out by Ontario Energy Board's (OEB) in the Transmission System Code (TSC) and the Planning Process Working Group (PPWG) report to the Board.

Based on Section 6 of the NA and IRRP report, the study team recommended that further assessment was required to address the load restoration need during peak load in the GTA East region. The NA and IRRP report indicated that for the loss of two transmission elements (B23C/M29C or H24C/H26C), the load interrupted with current circuit configuration may exceed load restoration criteria and requires further assessment. The IESO led IRRP recommended this need be further assessed in the RIP, to be completed in Q4 2016. This report provides a detailed assessment along with options and the WG recommendation to be included in the RIP report.

2. REGIONAL NEED ADDRESSED IN THIS REPORT

The circuits M29C/B23C and H24C/H26C are on the same tower line in the GTA East Region 230kV corridor. The loss of either pair of circuits during peak load may result in load shortfall/outage exceeding the limits of 150MW and 250MW to be restored within 4 hours and 30 minutes, respectively.

3. OPTIONS CONSIDERED

Hydro One Transmission along with the WG members have considered the following options to addressing the load restoration need:

Option 1 – a) Status quo/Current state
b) Commissioning of Clarington TS by 2018

Option 2 – Install 8 Motorized Disconnect Switches (MDS) on circuits B23C, M29C, H24C, and H26C

See Sections 4 & 5 for detailed assessment.

4. PREFERRED SOLUTION

At this time, B23C, M29C, H24C, and H26C are approximately 120km-300km long and the historical performance since 2000 has been excellent with no relevant outages. With the new Clarington TS in 2018, the line exposure in the region will reduce to only 46km including tap sections. The assessment concluded that

a) The annual carrying cost of the switches is not justified compared to the annual outage cost, and
b) The installation of Motorized Disconnect Switches will not result in significant enhancement to the reliability of the system after the Clarington TS is in service in 2018.

Option 1 is the preferred solution recommended by the WG at this time. Further details of the assessment and justification are provided in Sections 4 & 5.

5. NEXT STEPS

There are no further actions required at this time.

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

1 Region Description and Connection Configuration

The GTA East Region comprises the municipalities of Pickering, Ajax, Whitby, Oshawa and parts of Clarington, and other parts of the Durham Region.

Four 230kV circuits (B23C, M29C, H24C, and H26C) emanating east from Cherrywood TS provide local supply to the Region. Whitby TS DESN2, Thornton TS, and other CTS in the Region are supplied by H24C/H26C while Whitby TS DESN1 and Wilson TS are supplied by B23C/M29C.

A new 500/230kV autotransformer station in the GTA East Region within the municipality of Clarington (called Clarington TS) is expected to be in service by 2018. The assessments in this report evaluate the reliability impact of Clarington TS in the region as well as the installation of Motorized Disconnect Switches (MDS). The new Clarington TS will provide additional load meeting capability in the Region and will eliminate any overloading of Cherrywood autotransformers that may result after the retirement of the Pickering Nuclear Generating Station (NGS). The new autotransformer station will consist of two 750MVA, 500/230kV autotransformers and a 230kV switchyard. The 230kV circuits supplying the east GTA will be terminated at Clarington TS. Clarington TS will become the principle supply source for the GTA East Region load. The facilities in the GTA East Region, including the connection to Clarington TS, are depicted in the single line diagram shown in Figure 1[1].

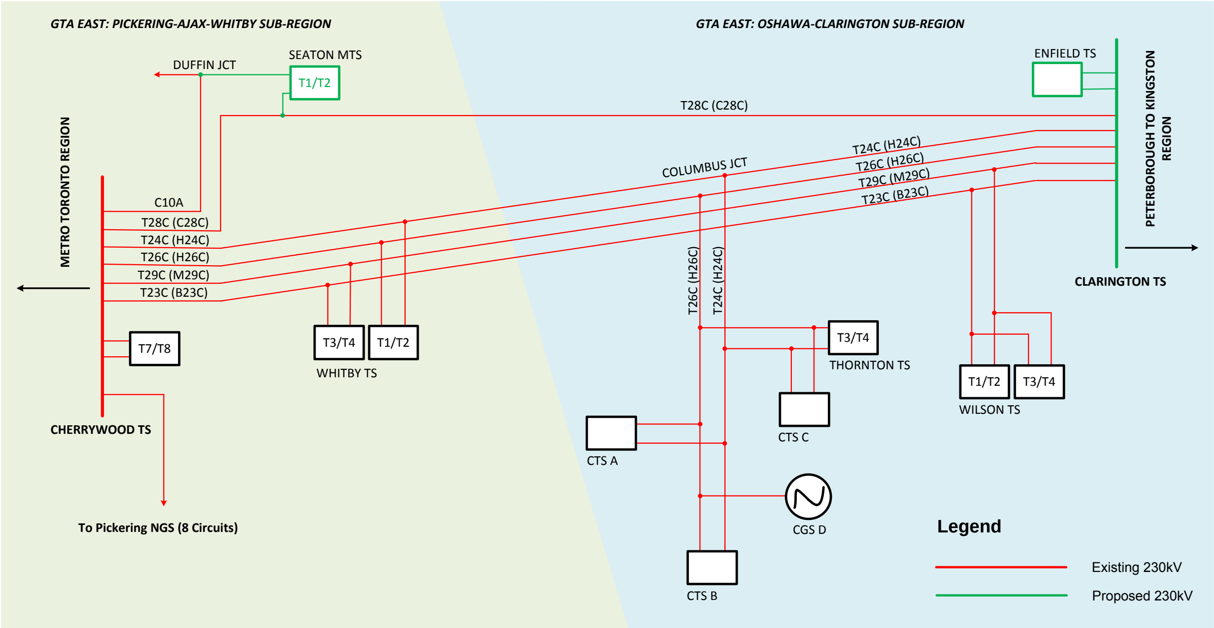

Figure 1 **GTA East Region - Single Line Diagram**

[1] Circuits' nomenclature is shown following the commissioning of Clarington TS (2018) with current convention in parentheses

2 Identified Need

2.1 Load Restoration Criteria

In case of contingencies on the transmission system, the Ontario Resource Transmission Assessment Criteria (ORTAC) provides the load restoration times relative to the amount of load affected. Planned system configuration must not exceed 600MW of load curtailment/rejection. In all other cases, the following restoration times are provided for load to be restored for the outages caused by design contingencies.

a. All loads must be restored within approximately 8 hours.
b. Load interrupted in excess of 150MW must be restored within approximately 4 hours.
c. Load interrupted in excess of 250MW must be restored within approximately 30 minutes.

In addition, ORTAC also provides a provision for exemption from the above restoration criteria on a case-by-case basis.

Figure 2 illustrates the load restoration timelines as discussed above.

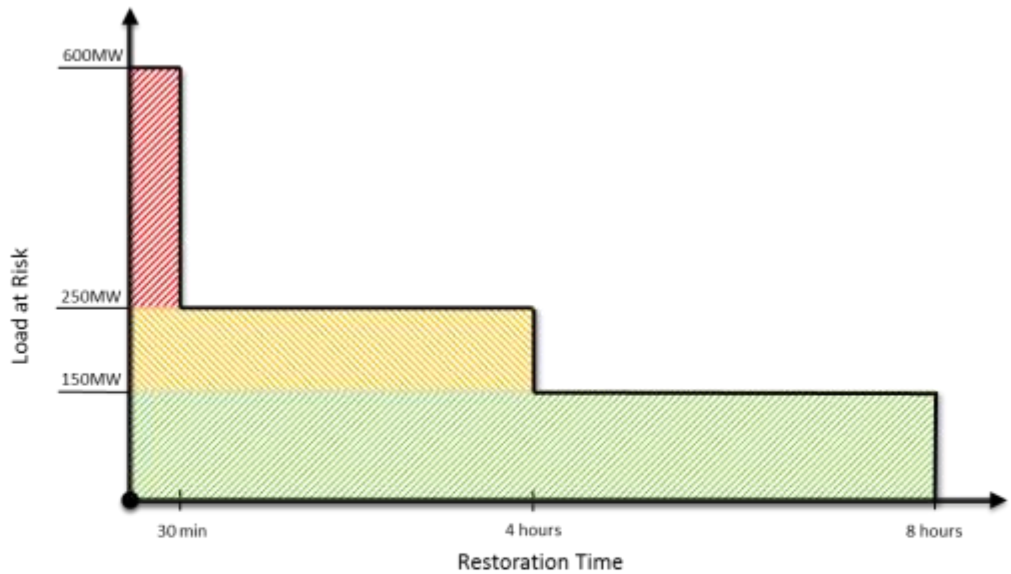

Figure 2 **Load Restoration Criteria**

2.2 Shortfall Need

In 2015, H24C/H26C and M29C/B23C supplied a coincident peak demand of approximately 366MW and 417MW, respectively.

It is expected and assumed that all loads can be restored within 8 hours. However, consistent with the NA and IRRP reports, during peak load periods all loads cannot be restored in the region subsequent of a double circuit contingency between Cherrywood TS and Clarington TS within 30 minutes to 4 hours.

Further findings from the Local Distribution Companies (LDC) in the Region and as reported in the IRRP[2], up to 57MW and 142MW can be restored for customers supplied by H24C/H26C through distribution transfers within 30 minutes and 4 hours, respectively. This leaves the maximum shortfall of 59MW after 30 minutes, and 74MW after 4 hours to be restored from these circuits.

Similarly, for the M29C/B23C, up to 105MW can be restored through distribution transfers within 30 minutes and 257MW within 4 hours for customers supplied by these circuits under the current supply arrangement. This leaves the maximum shortfall of 62MW after 30 minutes, and 10MW after 4 hours to be restored from these circuits.

Table 1 summarizes the 2015 peak demands for each pair of circuit and differentiates between restorable load and the shortage load for 30-minutes and 4-hour periods as discussed above.

Table 1 **Load Restoration/Shortfall in 2015**

2015 Coincident Peak					
Load Pocket	**Actual Demand**	**30-Min Restoration**	**30-Min Restoration Shortfall**	**4-Hour Restoration**	**4-Hour Restoration Shortfall**
H24C/H26C: Whitby TS DESN 1, Thornton TS, and Transmission Connected Customers	366	57	59	142	74
M29C/B23C: Whitby TS DESN2, Wilson TS	417	105	62	257	10

By the end of 2025, the load that cannot be restored increases due to load growth in the region illustrated in Table 2.

Table 2 **Load Restoration/Shortfall in 2025[3]**

2025 Coincident Peak (Net Forecast)					
Load Pocket	**Forecast Demand**	**30-Min Restoration**	**30-Min Restoration Shortfall**	**4-Hour Restoration**	**4-Hour Restoration Shortfall**
H24C/H26C: Whitby TS DESN 1, Thornton TS, and Transmission Connected Customers	445	57	138	142	153
M29C/B23C: Whitby TS DESN2, Wilson TS	425	105	70	257	18

[3] Load forecast is subject to change

2.3 Options considered

An option to build a new 26km of line would have resulted in a cost of more than $75M, obtaining new right-of-way and was not further considered. Following options were further assessed:

Option 1a is status quo and option 1b includes Clarington TS to be in-service by 2018. Accordingly, following two options are further evaluated against each other:

Option 1 – a) Status quo/current state
b) Commissioning of Clarington TS by 2018

Option 2 – Install 8 Motorized Disconnect Switches (MDS) on circuits B23C, M29C, H24C, and H26C

A conceptual configuration of the switches (marked by the red X) is shown for Option 2 in Figure 3.

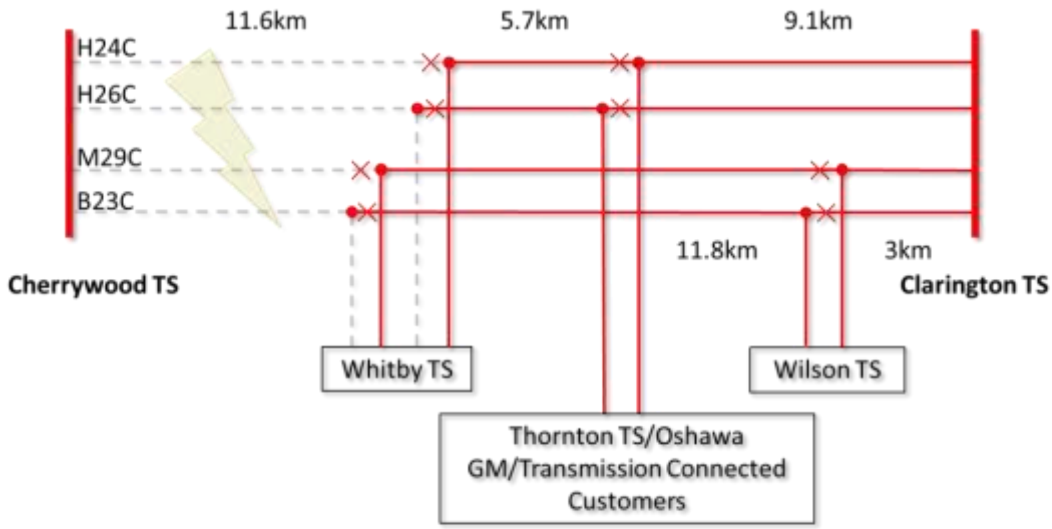

Figure 3 **MDS: Conceptual Configuration**

Similar cases can be shown to isolate faults on other sections of the corridor to restore the loads. It must be noted that although the corridor is protected using 8 MDSs as shown above, the tap offs will still remain unprotected. Further, a common mode fault (refer to section 4) at the tap off line sections will cause an outage regardless of installed switches. With the use of 8 MDS, the optimal locations of the switches are the junction points and 2 switches per circuit as shown in Figure 3.

3 Evaluation Method & Assumptions

The options identified in the previous section were evaluated from the reliability and cost points of view. The reliability indices for overlap outages were evaluated with the help of the AREP Program (Area Reliability Evaluation Program). The reliability for each option is expressed in terms of the frequency and duration of supply interruptions to customers.

Two cost components, one representing the capital cost and one representing the outage cost were evaluated for each option. The two annual costs are given as follows:

Annual cost of carrying charge = C*R,

Where: C – Capital cost of the switches
R – Annual discount rate

The annual outage cost (or risk cost) = F*P*I,

Where: F – Annual duration of load interruption in hours
P – Average kW interrupted including load factor
I – Customer interruption cost ($/KWh)

The following assumptions were made in the assessments:

1. All MDSs are assumed to be perfect (100% reliable).
2. Outages on line tap sections are excluded in common mode outages assessment in section 4.
3. All customer loads are restored within 8 hours for Option 1 and within 30 minutes for Option 2.
4. In case of overlap outages, switching time to isolate the faulted component and restore healthy ones to service is assumed to be one hour.
5. Faults do not occur on lines section where MDSs are located.

The assessment data used in the benefit/cost analysis for all options is provided in Table 3.

Table 3 **Data Used in Reliability Studies**

Assessment Data	
No. of circuit pairs on same towers	27
Total circuit length	551.347km
Circuit years in service	26 years
Distance between Cherrywood TS and Clarington TS	26km
2015 Peak load supplied from B23C and M29C, P	417MW
2015 Peak load supplied from H24C and H26C, P	366MW
Load factor for all load stations	0.6
Customer interruption cost, I	\$10–\$30/kWh[4]
Load restoration time without switches	8 hours
Load restoration time with switches	30 minutes
Cost of one switch (x4 per pair, C)	\$3 Million (\$12 Million)
Annual discount rate, R	5%

[4] Known as Value of Lost Load (VOLL), range is consistent with a Canadian Regulatory Application conducted in 2006 after considering customer composition and provincial GDP – IRRP (2016)

4 Impact of Common Mode Outages

A common mode outage is defined as an event involving two or more outages with the same initiating cause and where the outages are not consequences of each other and occur nearly simultaneously.

4.1 Line Outage Data

The historical common mode outage data for all 230 kV circuits on same structures and east of Cherrywood TS from 1990 to 2015 was used to compute the frequency and duration of common mode line outages. A summary of the common mode line outage events, along with the duration, over the period of 25 years is given in Table 4.

Table 4 **Common Mode Outage Events (from 1990 to 2015)**

Event #	Circuits Involved	Year	Outage Duration	Outage Cause
1	X3H and X4H	1992	927.6h	High winds toppled 16 towers
2	D5A and B5D	1998	0.15h or 9m	Electrical storm
3	B23C and M29C	2008	2.02h	Human error, relay settings
4	L21H and L22H	2011	0.08h or 5m	Relay problems

Only 4 common mode outages have been recorded in eastern Ontario in the last 25 years, of which, only one event is of relevance for this assessment. Hence, Event # 1, in Table 4 is the only one used in calculating the frequency of common mode line outages. This event occurred in November 1992 where adverse weather toppled multiple towers. The other outage events are not relevant to common mode outages because either the outage duration is less than 30 minutes (time assumed for switches to restore power supply to customers) or the outage was preventable or both.

NOTE: Event #1 has never occurred on the GTA East 230kV corridor which is the scope of this assessment but used as a proxy for assessment.

4.2 Reliability Results

The annual frequency of line common mode outages for 230 kV circuits east of Cherrywood TS was calculated by dividing the number of common mode line outages in 25 years by the product of the number of circuit in service years and the total circuit km over the 25 years period. The annual frequency was found to be **0.00007 outages/km** for all of eastern Ontario's 230kV transmission circuits. A low reliability index indicates the circuits in eastern Ontario have performed exceptionally well.

The commissioning of Clarington TS, Option 1b, does not affect the reliability indices for the common mode line outages because of the location of the station at the Oshawa Area Junction. All four 230 kV circuits currently emanate east on single towers from Cherrywood TS to the Oshawa Area junction point. From there on, B23C disperses south towards Belleville TS while the remaining three circuits emanate east on individual towers towards eastern Ontario. Therefore, a common mode line outage on these circuits cannot occur east of Oshawa Area

Junction, future site for Clarington TS.

It is also emphasized that the MDS would have no impact on the frequency of supply interruptions to customers. However, depending upon the location of a permanent fault, the switches can reduce the duration of interruption to customers by isolating the faulted section of the line and restoring the load from the alternative path.

The frequency and duration indices for all options are given in Table 5. The 8 hour restoration time for Option 1a and 1b, without switches, is in accordance with the standard outlined in ORTAC.

Table 5 **Reliability Indices, Common Mode Line Outages**

Options	Annual Frequency of Loss of Supply to any Customer	Duration of loss of Supply in Hours per Occurrence	Annual Duration of Supply Interruptions, F
Option 1a or 1b	0.00182	8	0.01456h or 52.4s
Option 2	0.00182	0.5	0.00091h or 3.3s

4.3 Cost Results

The capital cost and outage cost components were evaluated for all options using the formulae stated earlier. Table 6 shows the results for Circuits B23C and M29C while Table 7 shows the results for Circuits H24C and H26C.

Table 6 **Cost Results, Common Mode Line Outages (B23C/M29C)**

Options	Annual Cost of Carrying Charge in $k	Annual Outage Cost in $k	Total Annual Cost in $k
Option 1a or 1b	$0.00	$36.43-$109.29	$36.43-$109.29
Option 2	$600.00	$2.28-$6.84	$602.28-$606.84

Table 7 **Cost Results, Common Mode Line Outages (H24C/H26C)**

Options	Annual Cost of Carrying Charge in $k	Annual Outage Cost in $k	Total Annual Cost in $k
Option 1a or 1b	$0.00	$31.97-$95.92	$31.97-$95.92
Option 2	$600.00	$2.00-$6.00	$602.00-$606.00

The reliability and cost benefit assessment for the common mode line outages is based on the past 25 years of historical performance of 230kV circuits in eastern Ontario. Based on these findings, the annual reliability index for the GTA East region is only 0.00182 outages. As stated earlier, the installation of switches will not have an impact on the frequency index of events. Rather, as seen in Table 5, the duration of an event is the only dependent variable where the annual duration of an outage is reduced from 52.4s to 3.3s with the installation of switches.

The cost analysis in each option is dependent on the reliability index and is calculated using the assessment data provided in Table 3. Using the cost calculation formulas in Section 3, annual carrying cost of the switches and annual outage costs are calculated for B23C/M29C and

H24C/H26C. The annual carrying cost of the 4 switches per circuit pair is based on the minimum operating period of 20 years while the annual outage costs are based on the duration of outages, calculated from the reliability index, with and without the installation of switches.

The annual cost for just common mode line outages for each pair in the region is approximately $32k-$109k while the annual carrying cost of switches, including cost of outages, for each pair is nearly 5-19 times more, $602k-$607k. Also, the annual outage cost due to a common mode line outage is calculated on a very small probability of an event occurring. The annual frequency of loss of supply to any customer in the region is only 0.00182 outages, 1 in over 549 years, with or without switches as MDS have no impact on the frequency of supply interruptions.

As shown, the annual reliability and cost benefits from the MDS are insignificant compared to the annual carrying costs of the switches. The installation of switches improves the outage duration, if occurred, from 52.4s to 3.3s for a certain annual investment of over $1.2M for both pairs of circuits. The annual benefits will still be lower than the carrying costs even if higher values are used for the frequency of common mode line outages. In addition, MDS are assumed to be 100% reliable in this assessment while they introduce a weak link on the system. The reliability and cost analysis show that the installation of MDS is not justifiable.

5 Impact of Overlap Outages

An overlap outage is referred to an event where two or more components are out of service at the same time. The outage initiating causes are different and outages can start at different time. The overlap outage may occur as one of two types; Forced-Forced or Planned-Forced.

5.1 Line Outage Data

The historical outage data from 1990 to 2014 was used to compute the frequency and duration of H24C/H26C line sections and line terminal indices due to forced and planned outages. A reliability model was developed using Area Reliability Evaluation Program (AREP) for both options. The reliability indices were then used to calculate the annual frequency and annual duration of loss of supply to customers. It is expected that circuits B23C/M29C will have similar reliability indices, if not better, due to comparable characteristics and load as circuits H24C/H26C.

5.2 Reliability Results

Currently, the four circuits collectively supply eastern Ontario for 120–300km. In spite of this long distance, the reliability and security of the transmission lines in this part of the province has been exceptional based on the historical performances. Given that these 230kV circuits will now be terminating at Clarington TS, the exposure will reduce to 26km, the region's security and reliability is expected to improve substantially. Table 8 illustrates the reliability indices for the loss of supply to customers considering both types of overlap events: Forced-Forced and Planned-Forced.

Table 8 **Reliability Indices, Overlap Line Outages**

Options	Annual Frequency of Loss of Supply	Annual Duration of Supply Interruptions
Option 1a	0.01	0.12h or 7.02m
Option 1b	0.0008	0.007h or 26.60s
Option 2, Whitby TS DESN 1	0.0001	0.0003h or 1.26s
Option 2, Thornton TS/CTSs	0.0004	0.002h or 8.47s

For each reliability index above, two sets of reliability indices were considered: one due to the overlap of forced outages (Forced-Forced) only and one with the overlap of planned and forced outages (Planned-Forced). In the course of the overlap outages' assessment, it was observed that the Planned-Forced type outages had the dominant impact on the final reliability indices when compared to Forced-Forced type outages.

Further, two types of outages in each set, namely the permanent outages and the switching outages, were computed. In the permanent outage, the supply to customers is restored after repairing the failed components while in the switching outage; the supply to customers is restored by switching off the failed components and restoring the healthy ones to service. The switching time to isolate the faulted component and restore healthy ones to service is assumed to be one hour except in the case of Option 2 where MDSs are expected to operate within 30 minutes.

It is observed in Table 8 that with the commissioning of Clarington TS in 2018, the reliability improves by over 92% while an additional investment in MDSs of over $24 million yields another increment of only 7% to the system reliability. With Clarington TS in service, Option 1b, the reliability indices improve significantly when compared to the reliability of the existing supply system. Also, the annual duration of supply interruption is reduced to just 26.6 seconds from 7 minutes with Clarington TS in the region.

5.3 Cost Results

The capital (carrying) cost and outage cost components were evaluated for the both options using the formulae stated earlier and the results are shown in Table 9. These costs are mainly dependent on the annual duration of supply interruption in Table 8. Since the annual duration of supply interruption in the region is expected to be reduced to merely 26.6s with Clarington TS soon to be in service, the annual expected outage cost has dropped by almost 94%.

Table 9 illustrates that the annual benefits from the MDS are insignificant compared to the annual carrying costs of the switches. The performance of H24C/H26C is expected to be exceptionally good following the commissioning of Clarington TS with an expected annual cost of $15.37k-$46.12k, a very well improvement from the current system and at least 13 times more economical than the annual cost with the switches. With the inclusion of Clarington TS by 2018, the system is projected to be most cost-effective and reliable.

Table 9 **Cost Results, Overlap Line Outages (H24C/H26C)**

Options	Annual Cost of Carrying Charge in $k	Annual Outage Cost in $k	Total Annual Cost in $k
Option 1a	$0.00	$263.52-$790.56	$263.52-$790.56
Option 1b	$0.00	$15.37-$46.12	$15.37-$46.12
Option 2	$600.00	$3.66-$10.97	$603.66-$610.97

6 Conclusion

6.1 Common Mode Outages

The following concluding remarks can be made regarding the impact of the common mode outages:

i) All options have the same frequency of supply interruptions to customers.
ii) Only one common mode outage, relative to this assessment, has occurred in the eastern Ontario in the past 25 years. This event occurred in 1992 due to high winds toppling multiple towers.
iii) The reliability and cost analysis show that it is not justifiable to invest $24M for marginal improvement.

6.2 Overlap Outages

The following concluding remarks can be made regarding the impact of overlap outages:

i) A significant improvement in reliability is observed after the commissioning of Clarington TS in 2018, Option 1b. However, the installation of MDS, Option 2, does not result in a substantial improvement in the reliability indices for an additional cost of approximately $24M.
ii) The result of reliability/cost analysis for circuits B23C/M29C is expected to be similar to H24C/H26C due to similar regional characteristics and loading conditions, therefore, same conclusion can be drawn for both pairs.

6.3 Summary

Based on historical data and a technical analysis on how outages impact the loads supplied by the GTA East 230kV corridor currently, post-Clarington TS, and with MDS, Table 10 illustrates that Clarington TS alone improves the reliability in the region by 77.8% while with additional investment of $24M in MDS, further reliability improvement is insignificant (less than 4%).

Table 10 **Summary of Results**

Options	Total Annual Cost ($k)	Annual Frequency of Interruption	% Reliability Improvement
Option 1a, Current System	$632.16-$1,896.49	0.02364	-
Option 1b, post Clarington TS	$101.28-$303.87	0.00524	77.8%
Option 2, MDS post Clarington TS	$1,211.47-$1,234.37	0.00444	81.2%

In conclusion, the performance of all 4 circuits has been very good over the last 20 years. With Clarington TS in service in 2018 the risk exposure on these circuits will be significantly less; therefore, it is not justifiable to further invest $24M.

Finally, these costs will have to be recovered from the customers or rate payers consistent with the TSC. Furthermore, MDS were considered to be ideal and 100% reliable in the course of this assessment but in reality introduce a weak link in the system.

WG is recommending that based on this assessment, Option 1b is considered to be the most economical and reliable state of the system. No further action is required at this time.

7 Next Steps

Hydro One will continue with the Clarington TS and keep the LDCs informed of any delays with the project. The finding of this study will be included in the GTA East RIP report expected to be completed in Q4 2016.

PARRY SOUND / MUSKOKA SUB-REGION
INTEGRATED REGIONAL RESOURCE PLAN

Part of the South Georgian Bay/Muskoka Planning Region | December 16, 2016

ieso
Connecting Today. Powering Tomorrow.

Integrated Regional Resource Plan

Parry Sound/Muskoka

This Integrated Regional Resource Plan ("IRRP") was prepared by the Independent Electricity System Operator ("IESO") pursuant to the terms of its Ontario Energy Board electricity licence, EI-2013-0066.

This IRRP was prepared on behalf of the Parry Sound/Muskoka Sub-region Working Group (the "Working Group"), which included the following members:

- Independent Electricity System Operator
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)
- Lakeland Power Distribution Ltd.
- Midland Power Utility Corporation
- Newmarket-Tay Power Distribution Ltd.
- Orillia Power Distribution Corporation
- PowerStream Inc.
- Veridian Connections Inc.

The Working Group assessed the reliability of electricity supply to customers in the Parry Sound/Muskoka Sub-region over a 20-year period; developed a flexible, comprehensive, integrated plan that considers opportunities for coordination in anticipation of potential demand growth scenarios and varying supply conditions in the Parry Sound/Muskoka Sub-region; and developed recommended actions, while maintaining flexibility in order to accommodate changes in key assumptions over time.

The Working Group members agree with the IRRP's recommendations and support implementation of the plan, subject to obtaining necessary regulatory approvals and appropriate community consultations.

1. Introduction

This Integrated Regional Resource Plan ("IRRP") for the Parry Sound/Muskoka Sub-region addresses the electricity needs for the sub-region over the next 20 years from 2015 to 2034 ("study period"). The IRRP was prepared by the Independent Electricity System Operator ("IESO") on behalf of the Technical Working Group (the "Working Group") for the Parry Sound/Muskoka Sub-region composed of the IESO, Hydro One Distribution and Hydro One Transmission[1], Lakeland Power Distribution Ltd. ("Lakeland Power"), Midland Power Utility Corporation ("Midland PUC"), Newmarket-Tay Power Distribution Ltd. ("Newmarket-Tay Power"), Orillia Power Distribution Corporation ("Orillia Power"), PowerStream Inc. ("PowerStream") and Veridian Connections Inc. ("Veridian Connections").

The area covered by the Parry Sound/Muskoka IRRP is a Sub-region of the South Georgian Bay/ Muskoka Region identified through the Ontario Energy Board ("OEB" or "Board") regional planning process. This sub-region roughly encompasses the Districts of Muskoka and Parry Sound and the northern part of Simcoe County. This sub-region is characterized by:

- **Diverse communities**: In addition to the "unorganized areas"[2] in the Parry Sound District, there are eight First Nation communities and 35 municipalities located in this sub-region, all of which are listed in Section 4.1. The communities have different local priorities and electricity needs. Some communities are engaging in community energy planning activities.

- **Large geographical area:** A mix of long and expansive 230 kilovolt ("kV") transmission, 44 kV sub-transmission and low-voltage distribution infrastructure are required to deliver electricity supply to the various communities and customers across this sub-region. The geography and sparsely populated areas make it challenging and costly to develop and maintain infrastructure.

- **Use of Electric Space and Water Heating:** Due to limited access to natural gas infrastructure in this sub-region, many communities rely on electric space and water heating, especially during the winter season. In addition to electricity, some customers also rely on other fuel types, such as wood, to meet their heating requirements.

---

[1] For the purpose of this report, "Hydro One Transmission" and "Hydro One Distribution" are used to differentiate the transmission and distribution accountabilities of Hydro One Networks Inc. ("Hydro One"), respectively.
[2] Unorganized areas are parts of the province where there is no municipal level of government. Services in these unorganized districts are typically administered by local services boards.

- **Modest Growth:** While relatively slower growth is expected in the manufacturing sector, growing First Nation communities, developments in the tourism and retail sector, and potential local economic development could contribute to higher electricity demand in the sub-region. Seasonal population driven by tourism and recreational activities may also increase electricity requirements over the longer term.

This IRRP fulfills the requirements for the sub-region as required by the IESO's OEB electricity licence. IRRPs are required to be reviewed on a 5-year cycle so that plans can be updated to reflect the changing electricity outlook. This IRRP will be revisited in 2021, or earlier if significant changes occur relative to the current forecast.

This IRRP report is organized as follows:

- A summary of the recommended plan for the Parry Sound/Muskoka Sub-region is provided in Section 2;
- The process used to develop the plan is discussed in Section 3;
- The context for electricity planning in the Parry Sound/Muskoka Sub-region and the study scope are discussed in Section 4;
- Demand forecast and conservation and demand management ("CDM" or "conservation") and distributed generation ("DG") assumptions are described in Section 5;
- Needs in the Parry Sound/Muskoka Sub-region are presented in Section 6;
- Options to address regional and local needs are addressed in Section 7;
- Recommended actions are set out in Section 8;
- A summary of community, Indigenous and stakeholder engagement to date is provided in Section 9; and
- A conclusion is provided in Section 10.

2. The Integrated Regional Resource Plan

The Parry Sound/Muskoka IRRP addresses the sub-region's electricity needs over the next 20 years, based on application of the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC"). The IRRP was developed in consideration of a number of factors, including reliability, cost, technical feasibility, flexibility and also the diverse needs and unique characteristics of the sub-region.

The needs and recommended actions are summarized below.

2.1 Need to Minimize the Frequency and Duration of Power Outages

Customers and communities in the Parry Sound/Muskoka Sub-region experience more frequent and prolonged power outages relative to other communities and electricity customers in the province. Any outage along the 230 kV transmission, 44 kV sub-transmission and low-voltage distribution lines can interrupt the electricity supply to the communities and customers. Results from the service reliability performance assessment show that a number of 44 kV sub-transmission systems in this sub-region are performing below provincial average[3] in terms of frequency and duration of outages. Long 44 kV sub-transmission lines and off-road facilities are the main causes for frequent and prolonged outages for this sub-region. Lengthy distribution lines also typically exhibit lower levels of reliability because of increased exposure to trees and wildlife, and they sustain more damage from poor weather. Limited access to off-road facilities makes it difficult for repair crews to detect early signs of equipment failures, do preventative maintenance and restore power in a timely manner.

While major 230 kV transmission outages have been relatively infrequent in the Parry Sound/Muskoka Sub-region, the existing 230 kV transmission system has limited ability to restore power in a timely manner and minimize the number of customers impacted in the event of a major 230 kV transmission outage and does meet Ontario's planning criteria.

The Working Group has recommended a set of actions to minimize the frequency and duration of 44 kV related power outages and to bring the 230 kV transmission system in compliance with Ontario's planning standards.

---

[3] On average, customers being supplied from a typical 44 kV sub-transmission line in Ontario experience outages about two times a year with outages typically lasting 5 hours or less.

Recommended Actions

1. **Inform communities and Local Advisory Committee ("LAC")[4] members of the 44 kV sub-transmission system service reliability performance and the on-going maintenance and improvement initiatives in the Parry Sound/Muskoka Sub-region.**

   Hydro One Distribution will examine options to improve the reliability performance on the 44 kV sub-transmission system as part of their planning process. Hydro One Distribution will provide an update on measures to improve 44 kV sub-transmission system service reliability performance including any proposed capital plans. This update will be provided by end of 2017.

   The ability to implement any proposed capital investment plans will be contingent on the outcome of Hydro One Distribution's 2018-2022 rate filing application with the OEB.

2. **Examine the cost benefit and cost responsibility of options to resupply customers in Bracebridge, Gravenhurst, Muskoka Lakes and surrounding areas from alternate transformer station**

   Hydro One Distribution, Lakeland Power and Veridian Connections will examine various options to improve service reliability performance of the 44 kV sub-transmission system supplying the Bracebridge/Gravenhurst/Muskoka Lakes and surrounding areas, including the option to resupply customers in Bracebridge, Gravenhurst, Muskoka Lakes and surrounding areas from an alternate transformer station. The cost-benefit and cost responsibility of these options will be considered. The affected LDCs will discuss their assessment and decision with the Working Group through the regional planning process. This action is expected to be completed by the end of 2017. The results will be shared with LAC members and affected communities.

[4] A LAC for the Parry Sound/Muskoka Sub-region was established to allow community representatives to provide input on the status of local growth and developments, local planning priorities, energy planning activities (e.g., community energy planning), and opportunities to implement community-based energy solutions.

3. **Install two 230 kV motorized switches at Orillia TS**

To restore power to customers in a timely manner in the event of a major outage on the Muskoka-Orillia 230 kV sub-system, the Working Group recommends proceeding with the installation of two 230 kV motorized switches at the Orillia Transformer Station ("TS"). The IESO will provide a letter to Hydro One Transmission to initiate project development work for the two 230 kV motorized switches at Orillia TS in 2017. Based on typical development timeline of switching facilities, the project is expected to be in-service by the end of 2020.

4. **Explore opportunities to improve resilience and service reliability at the community level**

Some communities are engaged in community energy planning activities and interested in developing distributed energy resources. The IESO can facilitate discussions with First Nation communities, municipalities and LAC members on the opportunities to improve system resilience and service reliability through community energy planning and distributed energy resources and the cost-benefit of these opportunities.

2.2 Need to Provide Adequate Supply to Support Growth

Despite the relatively slow growth in this sub-region, the transformers supplying the Parry Sound and Waubaushene areas are approaching their maximum capacity in the near term. Additionally, the electricity demand on the 230 kV transmission system supplying the Orillia and Muskoka area may exceed capacity over the longer term.

Actions need to be taken to ensure that the regional electricity system has adequate supply to support growth in this sub-region over the planning period.

Recommended Actions

1. **Resupply some customers in the Parry Sound and Waubaushene areas from neighbouring transformer stations using existing and new distribution facilities to maximize the use of the existing system**

The electricity demand at the Parry Sound TS has already exceeded the transformers' capacity. To manage the near-term demand growth in the area, about 6 Megawatts ("MW") at Parry Sound TS will be resupplied from Muskoka TS. In order to re-supply these customers, it is recommended that Hydro One Distribution seek approval to construct a new 44 kV sub-transmission line between Parry Sound TS and Muskoka TS. The siting and routing of these facilities will be determined as part of the project development process.

Based on the typical project development timeline for 44 kV sub-transmission reinforcements, the project is expected to be in-service by 2020.

The electricity demand at Waubaushene TS is approaching it's transformer's capacity limits. To manage the near-term demand growth in the area, about 4 MW at Waubaushene TS will be resupplied from Orillia TS by 2020. If required, another 7 MW at Waubaushene TS can be resupplied from Midhurst TS upon completion of Barrie Area Transmission Reinforcement in the early 2020s. This can be done using existing distribution system and no new facilities will be required.

Midhurst TS is a major transformer station supplying the Barrie/Innisfil Sub-region. Resupplying some of the customers in the Waubaushene area from Midhurst TS could impact the timing and need for a new transformer station in the Barrie/Innisfil Sub-region over the longer term. As such, the Working Group will need to coordinate with the Barrie/Innisfil IRRP Working Group to monitor and manage the demand growth in the Waubaushene and Barrie/Innisfil Sub-region.

2. **Determine the cost and feasibility of using distributed energy resources and local conservation and demand management options to defer major capital investments in the Parry Sound/Muskoka Sub-region**

With the relatively slow electricity demand growth forecast for this sub-region, there is an opportunity to use targeted local conservation and demand management, distribution-connected generation and/or other distributed energy resources to defer major capital investments that might otherwise be required (e.g., transformer upgrades at Parry Sound TS and Waubaushene TS, reinforcements on the Muskoka-Orillia Sub-system).

The Working Group will initiate a local achievable potential study in the Parry Sound/Muskoka Sub-region to determine the cost and feasibility of using distributed energy resources and local demand management options to defer those major capital investments. A range of distributed energy resources and local demand management options may be suitable, including focused marketing and/or incentive adders to existing conservation programs, new conservation and demand management programs, local demand response, behind-the-meter generation and energy storage. These options will be considered as part of the study. This study will be initiated in early 2017 by the LDCs. The IESO will assist and provide funding for the study.

The Working Group will also work closely with communities to leverage local knowledge and community energy planning activities and to identify opportunities for targeted conservation and energy efficiency programs in First Nation communities and municipalities.

3. **Determine whether it is cost effective to advance the end-of-life replacement and to replace the aging assets with upgraded/upsized facilities at Parry Sound TS and Waubaushene TS**

The transformers at Parry Sound TS and Waubaushene TS were installed in the early 1970's and therefore these transformers could be reaching end-of-life in the early 2030s. On an annual basis, Hydro One Transmission will provide updated information on the condition of aging equipment at the Parry Sound TS and Waubaushene TS. This information will be shared with the LAC and the Working Group. The IESO will continue to monitor the demand growth at Parry Sound TS and Waubaushene TS to determine whether it is cost effective to advance the end-of-life replacement and to replace aging assets with upgraded/upsized facilities. This need will be revisited in the next iteration of the plan.

4. **Monitor electricity demand growth closely to determine the timing of any investment decisions relating to the Muskoka-Orillia 230 kV sub-system**

On an annual basis, the IESO will review electricity demand growth on the Muskoka-Orillia 230 kV sub-system with the Working Group and members of the LAC. This information will be used to determine if and when an investment decision for the Muskoka-Orillia 230 kV is required. This need will be revisited in the next iteration of the plan.

3. Development of the Integrated Regional Resource Plan

3.1 The Regional Planning Process

In Ontario, planning to meet the electricity needs of customers at a regional level is done through regional planning. Regional planning assesses the interrelated needs of a region—defined by common electricity supply infrastructure—over the near, medium, and long term and develops a plan to ensure cost-effective, reliable electricity supply. Regional plans consider the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluate options for addressing needs, and recommend actions.

Regional planning has been conducted on an as needed basis in Ontario for many years. Most recently, the former Ontario Power Authority ("OPA") carried out planning activities to address regional electricity supply needs. The OPA conducted joint regional planning studies with distributors, transmitters, the IESO and other stakeholders in regions where a need for coordinated regional planning had been identified.

In the fall of 2012, the Board convened a Planning Process Working Group ("PPWG") to develop a more structured, transparent, and systematic regional planning process. This group was composed of industry stakeholders including electricity agencies, utilities, and stakeholders, and in May 2013, the PPWG released its report to the Board[5] ("PPWG Report"), setting out the new regional planning process. Twenty-one electricity planning regions were identified in the PPWG Report, and a phased schedule for completion was outlined. The Board endorsed the PPWG Report and formalized the process timelines through changes to the Transmission System Code and Distribution System Code in August 2013, as well as through changes to the OPA's licence in October 2013. The OPA's licence changes required it to lead a number of aspects of regional planning. After the merger of the IESO and the OPA on January 1, 2015, the regional planning roles identified in the OPA's licence were to become the responsibility of the new IESO.

The regional planning process begins with a Needs Screening performed by the transmitter, which determines whether there are needs requiring regional coordination. If regional planning is required, the IESO then conducts a Scoping Assessment to determine whether a comprehensive IRRP is required, which considers conservation, generation, transmission, and

---

[5] http://www.ontarioenergyboard.ca/OEB/_Documents/EB-2011-0043/PPWG_Regional_Planning_Report_to_the_Board_App.pdf

distribution solutions, or whether a more limited "wires" solution is the only option such that a transmission and distribution focused Regional Infrastructure Plan ("RIP") can be undertaken instead. The Scoping Assessment assesses what type of planning is required for each region. There may also be regions where infrastructure investments do not require regional coordination and so can be planned directly by the distributor and transmitter outside of the regional planning process. At the conclusion of the Scoping Assessment, the IESO produces a report that includes the results of the Needs Screening process and a preliminary Terms of Reference. If an IRRP is the identified outcome, the IESO is required to complete the IRRP within 18 months. If an RIP is the identified outcome, the transmitter takes the lead and has six months to complete it. It should be noted that a RIP may be initiated after the Scoping Assessment or after the completion of all IRRPs within a planning region; the transmitter may also initiate and produce a RIP report for every region. Both RIPs and IRRPs are to be updated at least every five years. The draft Scoping Assessment Outcome Report is posted to the IESO's website for a 2-week comment period prior to finalization.

The final IRRPs and RIPs are posted on the IESO's and relevant transmitter's websites, and may be referenced and submitted to the Board as supporting evidence in rate or "Leave to Construct" applications for specific infrastructure investments. These documents are also useful for municipalities, First Nation communities and Métis for planning, conservation and energy management purposes, as information for individual large customers that may be involved in the region, and for other parties seeking an understanding of local electricity growth, CDM and infrastructure requirements. Regional planning is not the only type of electricity planning that is undertaken in Ontario. As shown in Figure 3-1, there are three levels of planning that are carried out for the electricity system in Ontario:

- Bulk system planning
- Regional system planning
- Distribution system planning

Planning at the bulk system level typically considers the 230 kV and 500 kV network and examines province-wide system issues. Bulk system planning considers not only the major transmission facilities or "wires", but it also assesses the resources needed to adequately supply the province. This type of planning is typically carried out by the IESO pursuant to government policy. Distribution planning, which is carried out by Local Distribution Companies ("LDCs"), considers specific investments in an LDC's territory at distribution level voltages.

Regional planning can overlap with bulk system planning. For example, overlaps can occur at interface points where there may be regional resource options to address a bulk system issue. Similarly, regional planning can overlap with the distribution planning of LDCs. For example, overlaps can occur when a distribution solution addresses the needs of the broader local area or region. Therefore, it is important for regional planning to be coordinated with both bulk and distribution system planning as it is the link between all levels of planning.

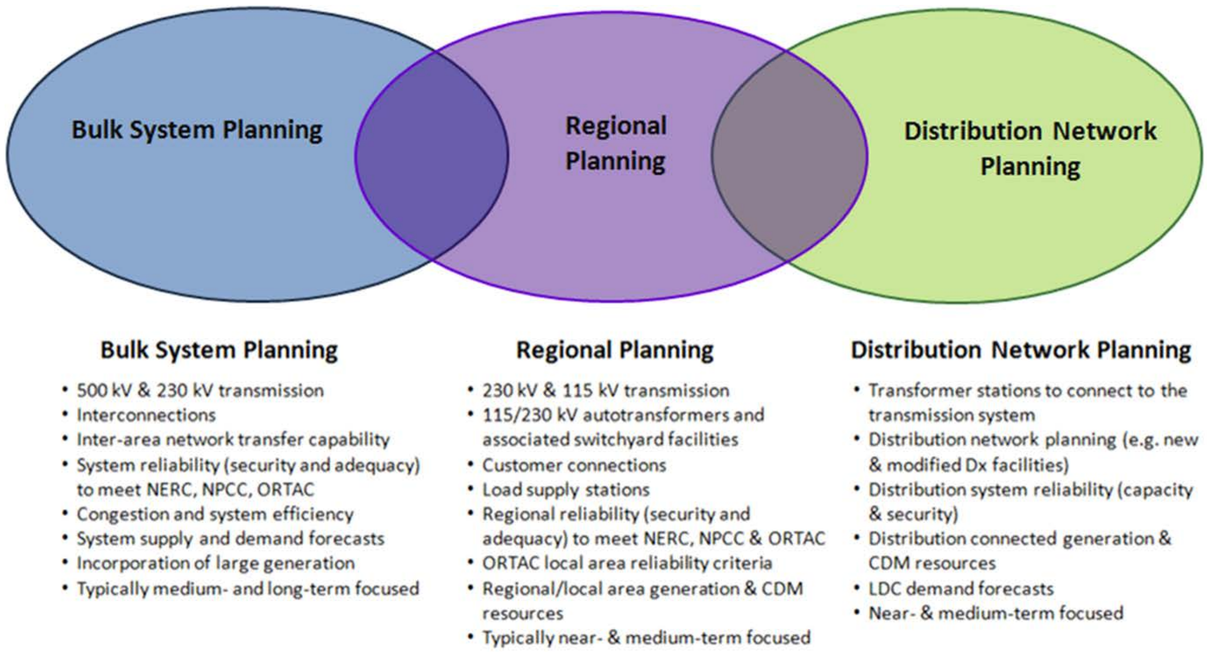

Figure 3-1: Levels of Electricity System Planning

By recognizing the linkages with bulk and distribution system planning, and coordinating multiple needs identified within a region over the long term, the regional planning process provides a comprehensive assessment of a region's electricity needs. Regional planning aligns near- and long-term solutions and puts specific investments and recommendations coming out of the plan in perspective. Furthermore, regional planning optimizes ratepayer interests by avoiding piecemeal planning and asset duplication, and allows Ontario ratepayer interests to be represented along with the interests of LDC ratepayers, and individual large customers. IRRPs evaluate the multiple options that are available to meet the needs, including conservation, generation, and "wires" solutions. Regional plans also provide greater transparency through engagement in the planning process, and by making plans available to the public.

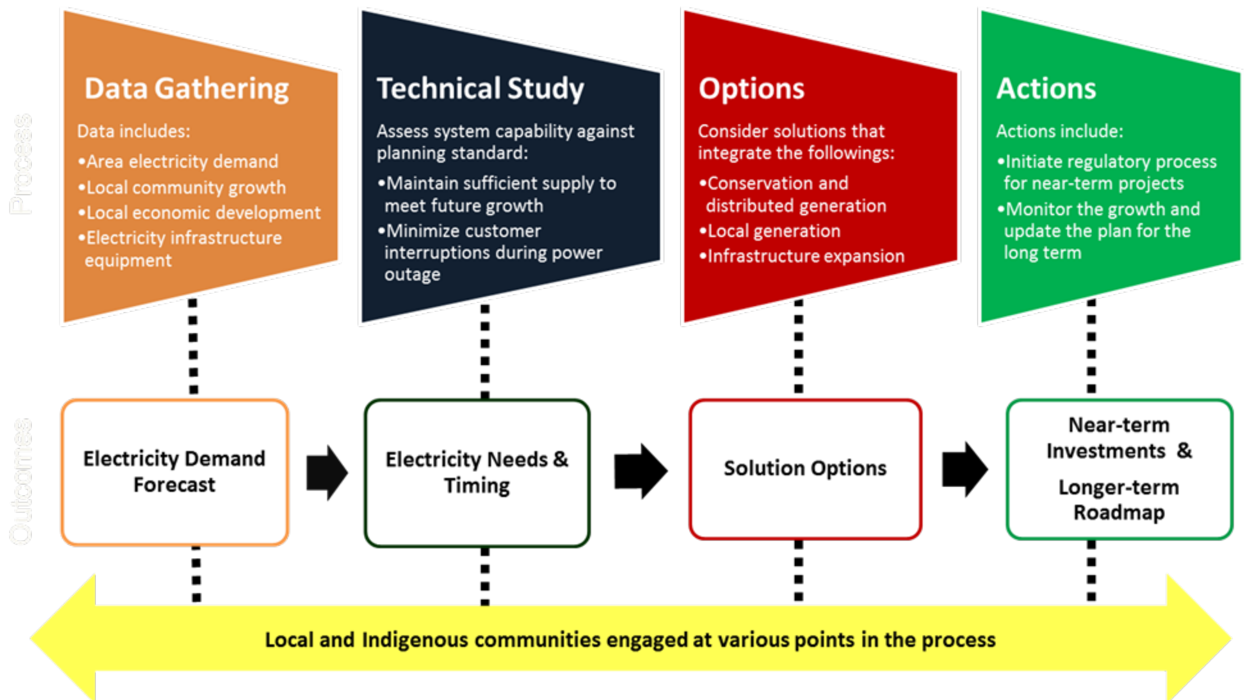
3.2 The IESO's Approach to Integrated Regional Resource Planning

IRRPs assess electricity system needs for a region over a 20-year period. The 20-year outlook anticipates long-term trends in a region, so that near-term actions are developed within the context of a longer-term vision. This enables coordination and consistency with the long-term plan, rather than simply reacting to immediate needs.

The IRRP describes the Working Group's recommendations for system enhancements based on different scenarios. The Working Group also recommends staging options to mitigate reliability and cost risks related to demand forecast uncertainty associated with large individual customers. The IRRP seeks to ensure flexibility is maintained such that changing long-term conditions may be accommodated.

In developing this IRRP, the Working Group followed a number of steps. These steps included: data gathering, including development of electricity demand forecasts; technical studies to determine electricity needs and the timing of these needs; the development of potential options; and, preparation of a recommended plan including actions for the near and longer term. Throughout this process, engagement was carried out with local municipalities, First Nation communities, Métis community councils and local stakeholders. These steps are illustrated in Figure 3-2 below.

Figure 3-2: Steps in the IRRP Process



This IRRP documents the inputs, findings, and recommendations developed through the process described above, and provides recommended actions for the various entities responsible for plan implementation.

3.3 Parry Sound / Muskoka Sub-region Working Group and IRRP Development

In 2014, the lead transmitter – Hydro One Transmission – initiated a Needs Screening process for the South Georgian Bay/Muskoka planning region. The South Georgian Bay/Muskoka Needs Screening study team determined that there was a need for coordinated regional planning, resulting in the initiation of the Scoping Assessment process.

The South Georgian Bay/Muskoka Scoping Assessment Outcome Report [6] was finalized on June 22, 2015 and identified two sub-regions for coordinated regional planning: Parry Sound/Muskoka and Barrie/Innisfil. The two sub-regions are shown in Figure 3-3.

[6] South Georgian Bay/Muskoka Region Scoping Assessment Outcomes report (see IESO website: whttp://www.iemo.com/Documents/Regional-Planning/South-Georgian-Bay-Muskoka/SGBM-Scoping-Process-Outcome-Report-Final-20150622.pdf)

Figure 3-3: South Georgian Bay/Muskoka Region and Sub-regions

Subsequently, the Working Groups were formed to carry out the IRRP for the Parry Sound/Muskoka and Barrie/Innisfil Sub-regions. According to the OEB regional planning process, the Working Groups had 18 months to develop the IRRP.

In addition to the formation of the Working Groups, a LAC for the Parry Sound/Muskoka was established to allow community representatives to provide input on the status of local growth and developments, local planning priorities, energy planning activities (e.g., community energy planning), and opportunities to implement community-based energy solutions. Further detail regarding community and stakeholder engagement activities is provided in Section 9.

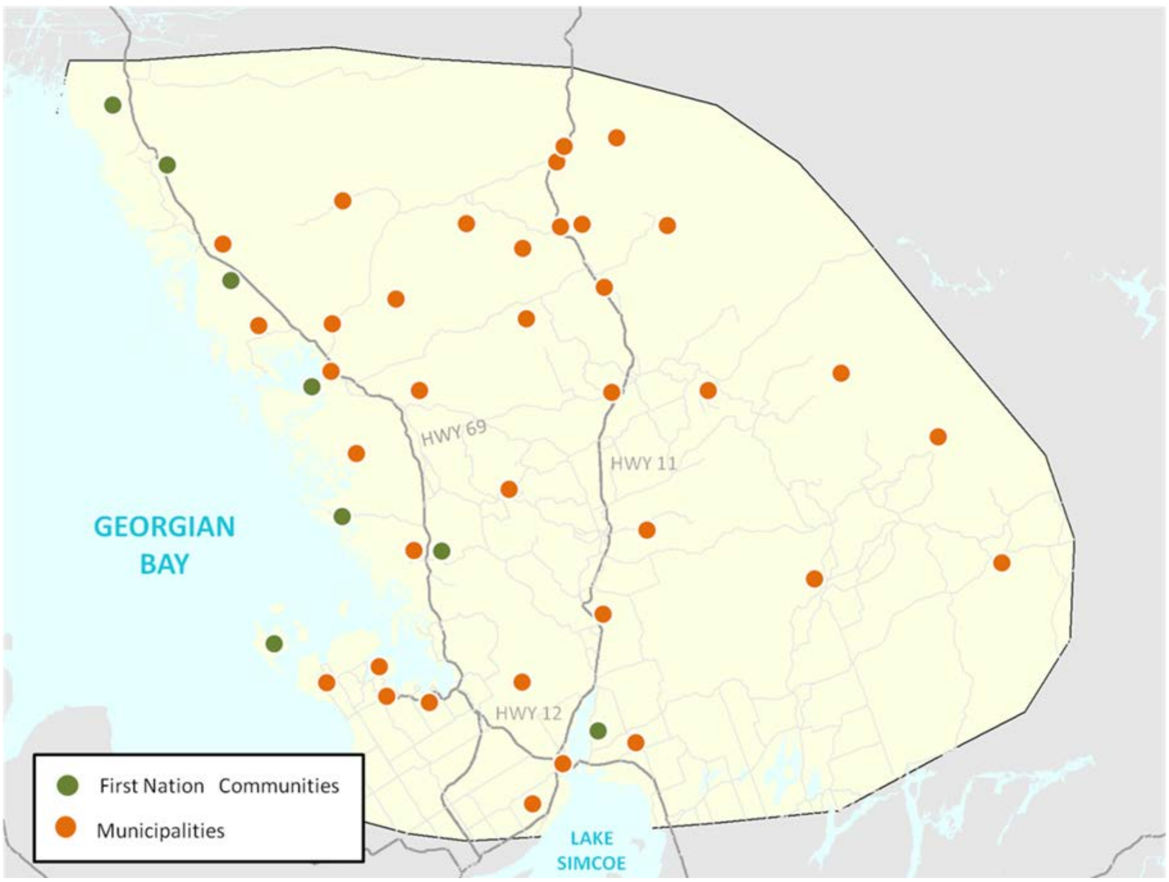
4. Background and Study Scope

The study scope of the IRRP is described in Section 4.1. Section 4.2 describes the electricity system supplying the Parry Sound/Muskoka Sub-region.

4.1 Parry Sound / Muskoka - Study Scope

The Parry Sound/Muskoka Sub-region roughly encompasses the Districts of Muskoka and Parry Sound and the northern part of Simcoe County. The approximate geographical boundaries of the sub-region are shown in Figure 4-1.

Figure 4-1: Geographical Boundaries of the Parry Sound/Muskoka Sub-region



The Parry Sound/Muskoka Sub-region includes the following First Nation communities:

- Henvey Inlet
- Magnetawan
- Shawanaga
- Wasauksing
- Moose Deer Point
- Beausoleil
- Wahta Mohawks
- Chippewas of Rama

The sub-region also includes the following municipalities:

- City of Orillia
- Municipality of Highlands East
- Municipality of Magnetawan
- Municipality of McDougall
- Municipality of Whitestone
- Town of Bracebridge
- Town of Gravenhurst
- Town of Huntsville
- Town of Kearney
- Town of Midland
- Town of Parry Sound
- Town of Penetanguishene
- Township of Algonquin Highlands
- Township of Armour
- Township of Carling
- Township of Georgian Bay
- Township of Joly
- Township of Lake of Bays
- Township of McKellar
- Township of McMurrich-Monteith
- Township of Minden Hills
- Township of Muskoka Lakes
- Township of Oro-Medonte
- Township of Perry
- Township of Ramara
- Township of Ryerson
- Township of Seguin

- Township of Severn
- Township of Strong
- Township of Tay
- Township of the Archipelago
- Township of Tiny
- United Townships of Dysart, Dudley, Harcourt, Guilford, Harburn, Bruton, Havelock, Eyre and Clyde
- Village of Burk's Falls
- Village of Sundridge

In addition, there are a number of unorganized areas in the District of Parry Sound.

The Parry Sound/Muskoka IRRP assesses the reliability and adequacy of the regional electricity system supplying the Parry Sound/Muskoka Sub-region and identifies integrated solutions for the 20-year period from 2015 to 2034. The electricity system supplying the Parry Sound/Muskoka Sub-region is described in more detail in Section 4.2.

It is important to note that connection assessments of generation resources procured under programs, such as the Feed-in-Tariff, are beyond the scope of this IRRP. Generation projects participating in procurement programs will be assessed according to the rules and specifications of those programs. However, the peak demand contribution from generation resources already contracted through such programs are taken into account in the demand forecast as described in Section 5.3.3.

4.2 Electricity System Supplying Parry Sound / Muskoka Sub-region

The electricity system supplying the Parry Sound/Muskoka Sub-region consists of local generation resources, 230 kV regional transmission, 44 kV sub-transmission and low voltage distribution networks. Local generation resources provide important sources of electricity supply to the communities and customers in this sub-region. However, local generation sources are not sufficient and are supplemented with power delivered to the sub-region from the rest of the province through the 230 kV transmission system. From the 230 kV transmission system power is delivered to communities and customers through the 44 kV sub-transmission and low-voltage distribution networks. The following sub-sections discuss these components in more detail.

4.2.1 Local Generation Resources

Local generation in the Parry Sound/Muskoka Sub-region is primarily hydroelectric and solar. The total installed capacity of local generation is approximately 126 MW comprised of approximately 28 MW hydroelectric, 97 MW solar, and 1 MW combined heat and power ("CHP").

In Ontario, the electricity system is designed to meet regional coincident peak demand – i.e., the one-hour period each year when total demand for electricity in the region is the highest. While hydroelectric and solar resources are potential sources of energy, only a portion of their generation capacity can be relied upon at the time of peak due to the variable nature of these resources. In the Parry Sound/Muskoka Sub-region, electricity demand typically peaks during the evening in the winter season. For the purpose of infrastructure planning, the installed capacity of distributed and variable generation is accordingly adjusted to reflect the reliable power output at the time of the local winter peak.

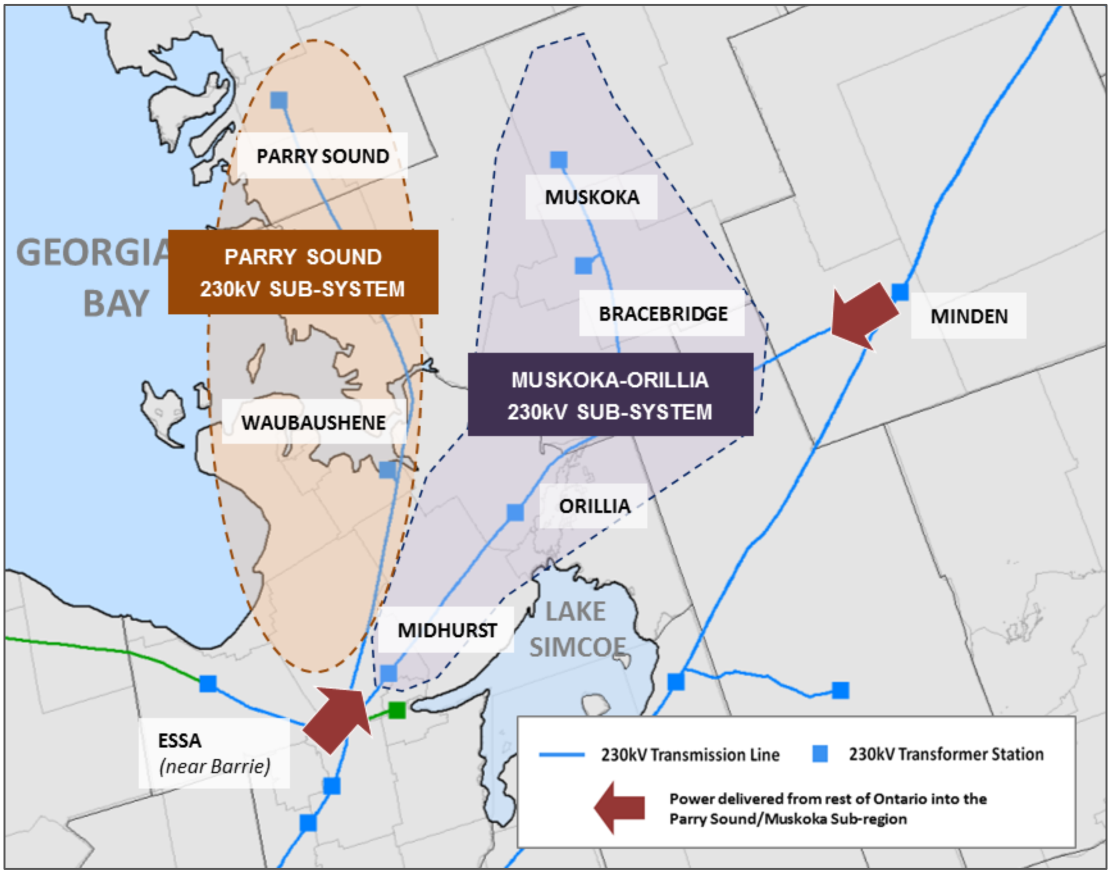
Hydroelectric facilities in the area are relatively small, generally less than 2 MW, however there are a couple facilities as large as 10 MW. The output of these facilities also depends on the availability of water resources and the operation of the facilities. To determine the dependable level of output at the time of peak, historical performance data of the hydroelectric generation facilities in the sub-region were used. The results are an assumed 34% capacity contribution from these resources.

Similarly, the solar facilities in the sub-region are also relatively small, with most being less than 0.5 MW, however there are a couple facilities as large as 10 MW. While the installed capacity of solar is high in the region, there is limited availability of solar power during the time of local peak, which occurs during the evening in the winter. It is assumed that solar would not provide any capacity at the time of local peak.

4.2.2 230 kV Transmission System

Power is delivered from the rest of the province into the Sub-region through the 230 kV transmission system at Essa (near Barrie) and Minden. As shown in Figure 4-2, the 230 kV transmission system supplies seven customers and utility-owned transformer stations. For the purpose of regional planning, the sub-region is further sub-divided into two regional 230 kV sub-systems: Muskoka-Orillia 230 kV sub-system and Parry Sound 230 kV sub-system.

Figure 4-2: Parry Sound/Muskoka Sub-region – 230 kV Transmission System

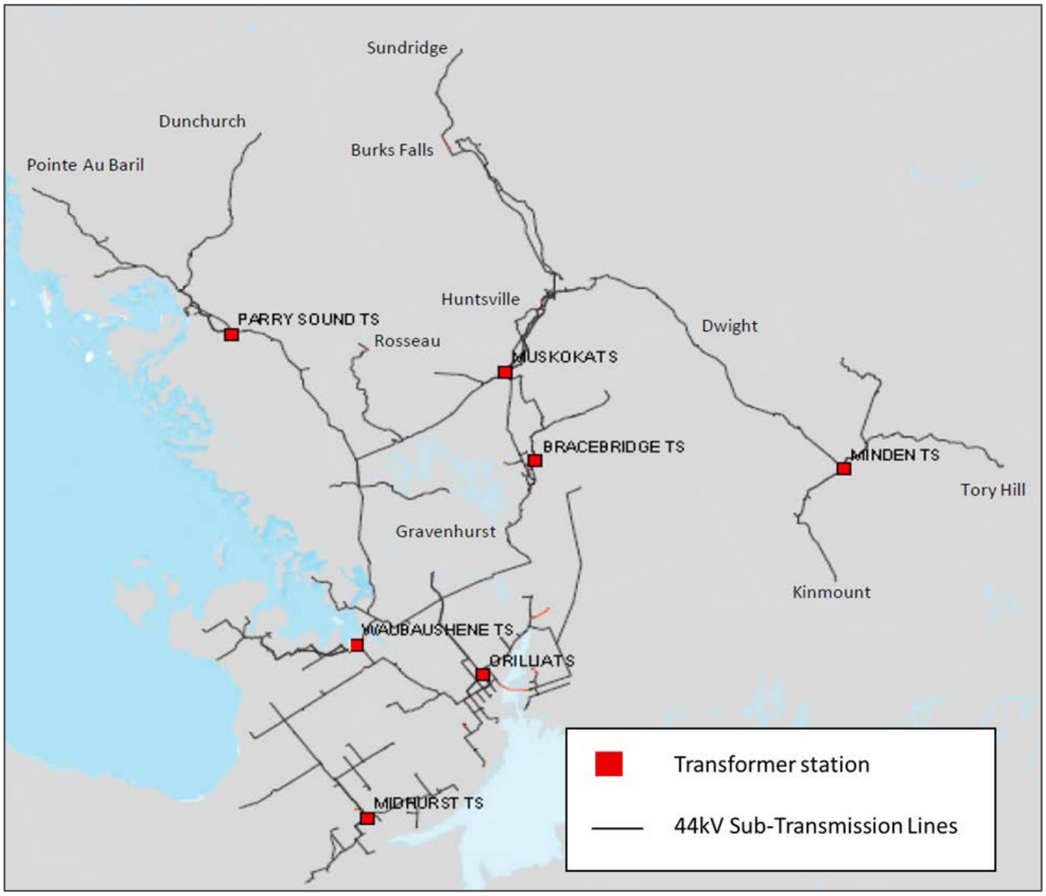


Since Midhurst TS primarily supplies the customers in the Barrie/Innisfil Sub-region, it is considered within the scope of the Barrie/Innisfil IRRP. However, Midhurst TS is supplied by the Muskoka-Orillia 230 kV sub-system and could impact the electricity supply to the Parry Sound/Muskoka Sub-region. Therefore, when assessing the reliability and adequacy of the Muskoka-Orillia 230 kV sub-system, the electricity demand growth at Midhurst TS needs to be considered in this IRRP.

4.2.3 44 kV Sub-transmission and Low-Voltage Distribution System

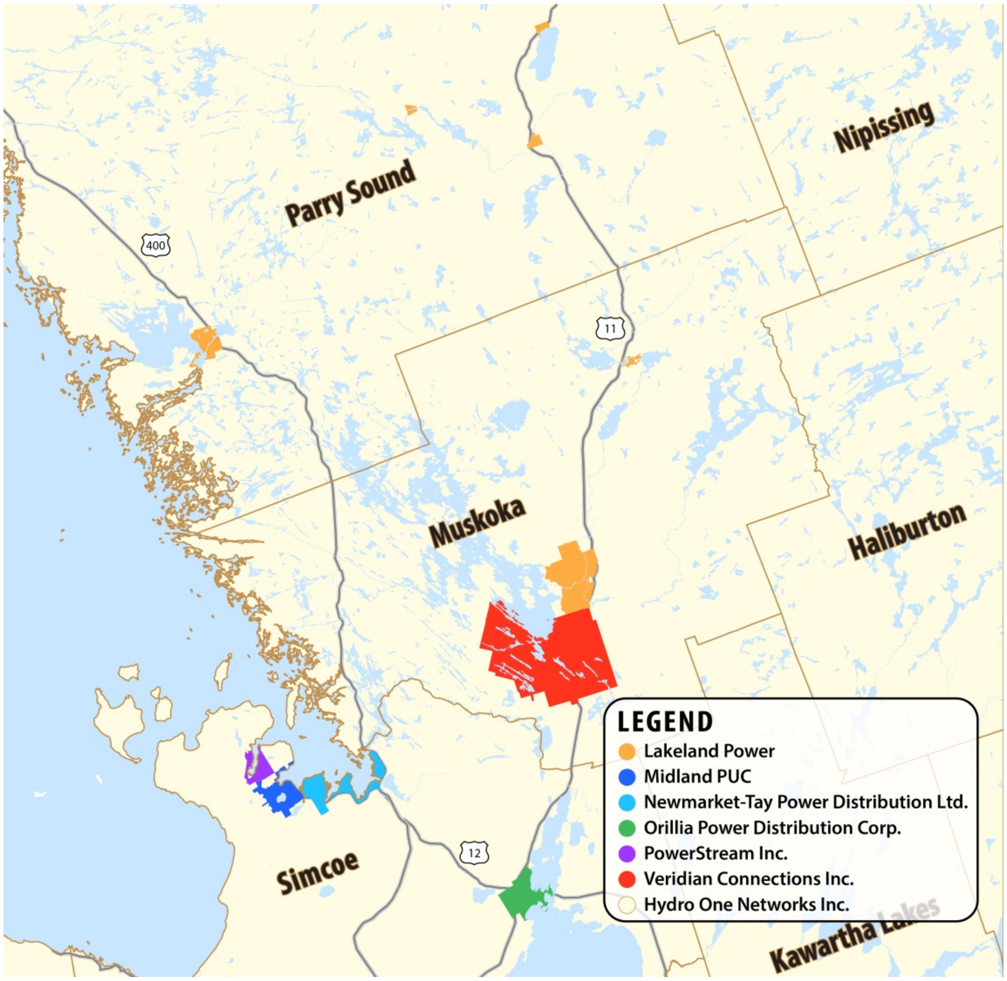
From the 230 kV sub-systems, power is delivered through transformer stations to the 44 kV sub-transmission system majority of which is operated by Hydro One Distribution in the Parry Sound/Muskoka Sub-region. As illustrated in Figure 4-3, given the large geography and sparsely populated areas, many communities and customers in this Sub-region are supplied by long 44 kV sub-transmission lines and a single source of supply.

Figure 4-3: 44 kV Sub-transmission System in the Parry Sound/Muskoka Sub-region



From the 44 kV sub-transmission system, power is delivered to the low voltage distribution network, which supplies various communities across the sub-region. The low-voltage distribution system is managed and operated by seven LDCs: Lakeland Power, Midland PUC, Newmarket-Tay Power, Orillia Power, PowerStream, Veridian Connections, and Hydro One Distribution, as shown in Figure 4-4.

Figure 4-4: Local Distribution Companies Service Areas



Distribution system planning is beyond the scope of the regional planning process. Issues related to the distribution system may be discussed in this IRRP for context, but will be addressed through the local distribution planning process led by the Local Distribution Companies ("LDCs").

Details regarding the characteristics of the LDC service areas can be found in Appendix A.

5. Demand Forecast

Regional electricity systems in Ontario are designed to meet regional coincident peak demand – the one-hour period each year when total regional demand for electricity is the highest.

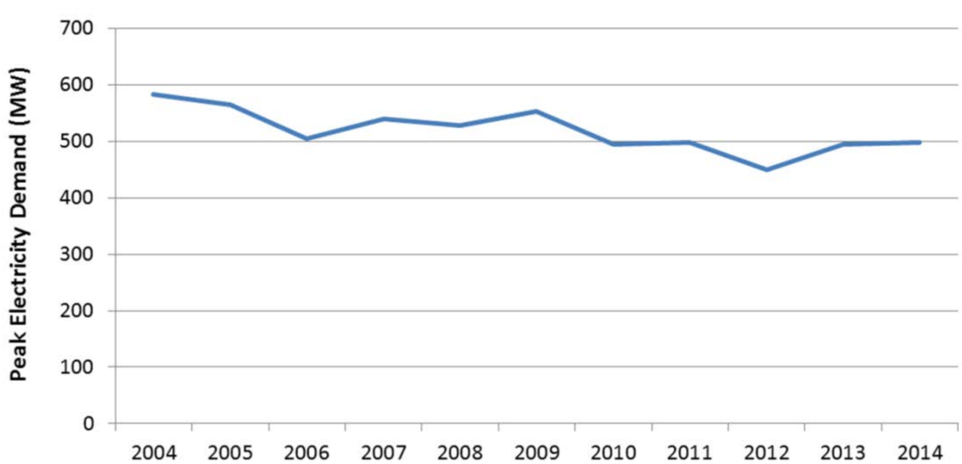
This section describes the development of the regional electricity demand forecast for the Parry Sound/Muskoka Sub-region. Section 5.1 describes historical electricity demand trends in the sub-region from 2004 to 2014. Section 5.2 provides an overview of the demand forecast methodology used in this study, and Section 5.3 summarizes the planning forecast for the sub-region.

5.1 Historical Electricity Demand 2004-2014

Electricity demand in this sub-region is primarily driven by residential and commercial customers. Due to limited access to natural gas infrastructure in this sub-region, many communities rely on electric space and water heating, especially during the winter season. As such, the electricity demand in this sub-region typically peaks during the winter months. This sub-region also supports a mix of economic activities including tourism, retail, healthcare and manufacturing industries. Seasonal population driven by tourism and recreation activities also contributes to the electricity demand requirements in this sub-region.

Demand has declined slightly between 2004 and 2010 but has been relatively stable since then at around 500 MW, as shown in Figure 5-1. The historical demand shown below was adjusted to account for weather-related impacts.

Figure 5-1: Historical Peak Demand - Parry Sound/Muskoka Sub-region (2004-2014)



5.2 Methodology for Establishing Planning Forecast

A planning forecast was developed to assess reliability of the Parry Sound/Muskoka Sub-region electricity system over the planning period (2015 to 2034). For the purpose of regional planning, the planning forecast considers the following components:

- Gross winter demand forecast scenarios for distribution-connected and transmission-connected customers,
- Estimated peak demand savings from meeting provincial energy conservation targets, and
- Expected peak demand capacity contribution from DG.

The gross demand forecast was developed based on the expected peak demand projections for distribution-connected and transmission-connected customers in the Parry Sound/Muskoka Sub-region. To develop the planning forecast, the gross demand forecast was modified to reflect the estimated peak demand savings from meeting provincial energy conservation targets and from existing and contracted DG.

Using a planning forecast that is net of provincial conservation targets is consistent with the province's Conservation First policy. However, this assumes that the targets will be met and that the targets, which are energy-based, will produce the expected local peak demand impacts. An important aspect of plan implementation will be monitoring the actual peak demand impacts of conservation programs delivered by the LDCs and, adapting the plan accordingly.

The methodology and assumptions used for the development of the planning forecast are described in detail in Appendix A.

5.3 Development of Planning Forecast

5.3.1 Gross Demand Forecast

The gross demand forecast was provided by the seven LDCs in this sub-region, based on customer connection requests, local economic development and growth assumptions outlined in Ontario's *Places to Grow Act, 2005*, which are reflected in municipal and regional plans.

A modest increase in electricity demand is forecast in this sub-region over the next 20 years. While slower growth is expected in the sub-region's manufacturing sector, growing Indigenous communities, new residential and commercial developments, seasonal population and potential local economic development such as the Parry Sound Airport Development and

Rama Road Corridor Economic Employment District, will contribute to growing electricity demand in the sub-region. Electric space and water heating requirements from communities, and aforementioned new residential and commercial developments will continue to be a major driver of peak electricity demand in this sub-region. Based on the information provided by the LDCs, gross demand is expected to grow 1.1% annually over the planning period.

Given the diverse communities and geography of this sub-region, electricity demand growth is not uniformly distributed across the sub-region. Only a small increase in electricity demand is expected in the northern Simcoe County, Minden and Parry Sound. Most of the electricity growth is forecast to be concentrated in Muskoka, Orillia and surrounding areas. For example, in Orillia, additional planned developments, including condominium and waterfront development and new retail, commercial, industrial and institutional customers may materialize within the 20-year planning period resulting in as much as an additional 20-22 MW of peak demand. For the purpose of regional planning, this potential load was considered as part of the sensitivity analysis.

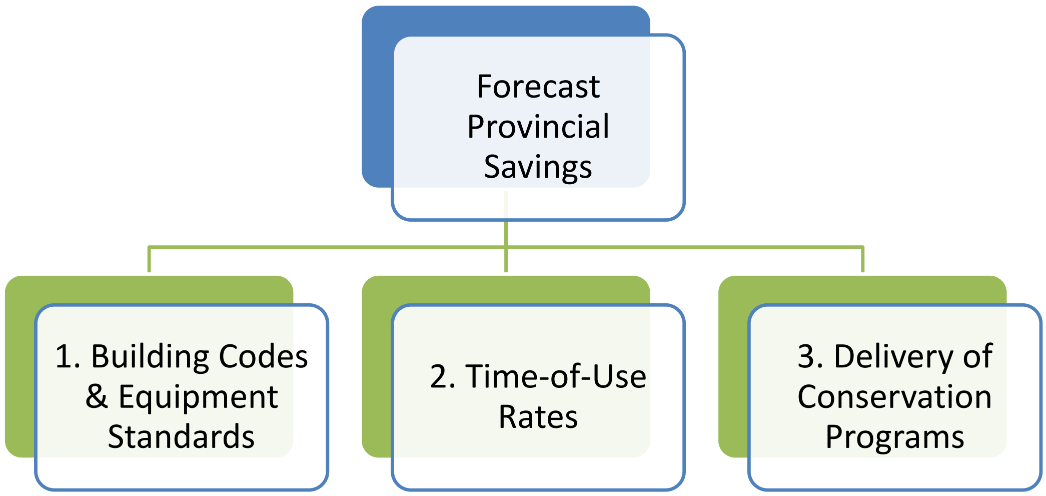
The specific forecasting methodology and assumptions for the gross demand forecast can be found in Appendix A.

5.3.2 Expected Peak Demand Savings from Provincial Conservation Targets

Conservation is incented and achieved through a mix of program-related activities, rate structures, and mandated efficiencies from building codes and equipment standards. Conservation plays a key role in maximizing the utilization of existing infrastructure and maintaining reliable supply by keeping demand within equipment capability. The conservation savings forecast for the Parry Sound/Muskoka Sub-region have been applied to the gross peak demand forecast, along with DG resources (described in Section 5.2), to determine the planning forecast in this sub-region.

In December 2013 the Ministry of Energy released a revised Long-Term Energy Plan ("LTEP") that outlined a provincial conservation target of 30 terawatt-hours ("TWh") of energy savings by 2032. The expected peak demand savings from meeting this target were estimated for the Parry Sound/Muskoka Sub-region. To estimate the impact of the conservation savings in the sub-region, the forecast provincial savings were divided into three main categories, as illustrated in Figure 5-2.

Figure 5-2: Categories of Conservation Savings



1. *Savings due to Building Codes & Equipment Standards*
2. *Savings due to Time-of-Use Rate structures*
3. *Savings due to the delivery of Conservation Programs*

The impact of estimated savings for each category was further broken down for the Parry Sound/Muskoka Sub-region by the residential, commercial and industrial customer sectors. The IESO worked together with the LDCs to establish a methodology to estimate the electrical demand impacts of the energy targets by the three customer sectors. This provides a better resolution of forecast conservation, as conservation potential estimates vary by sector due to different energy consumption characteristics and applicable measures.

For the Parry Sound/Muskoka Sub-region, LDCs were requested to provide breakdowns of their gross demand forecast, and electrical demand by sector for the forecast at each transformer station. For each transformer station where the LDC could not provide gross load segmentation, the IESO and the LDC worked together using best available information and assumptions to derive sectoral gross demand. For example, LDC information found in the OEB's Yearbook of Electricity Distributors was used to help estimate the breakdown of demand. Once sectoral gross demand at each transformer station was estimated, the next step was to estimate peak demand savings for each conservation category: building codes and equipment standards, time-of-use rates, and delivery of conservation programs. The estimates for each of the three savings groups were done separately due to their unique characteristics and available data. The final estimated conservation peak demand reduction, 35 MW by 2034, was then applied to the gross demand to create the planning forecast.

Additional conservation forecast details are provided in Appendix A.

5.3.3 Expected Peak Demand Contribution of Existing and Contracted Distributed Generation

As of 2015, about 123 MW of DG was contracted and/or existing in the Parry Sound/Muskoka Sub-region. The majority of the contracted and installed capacity is solar projects. The sub-region also has several hydroelectric power facilities and one CHP facility.

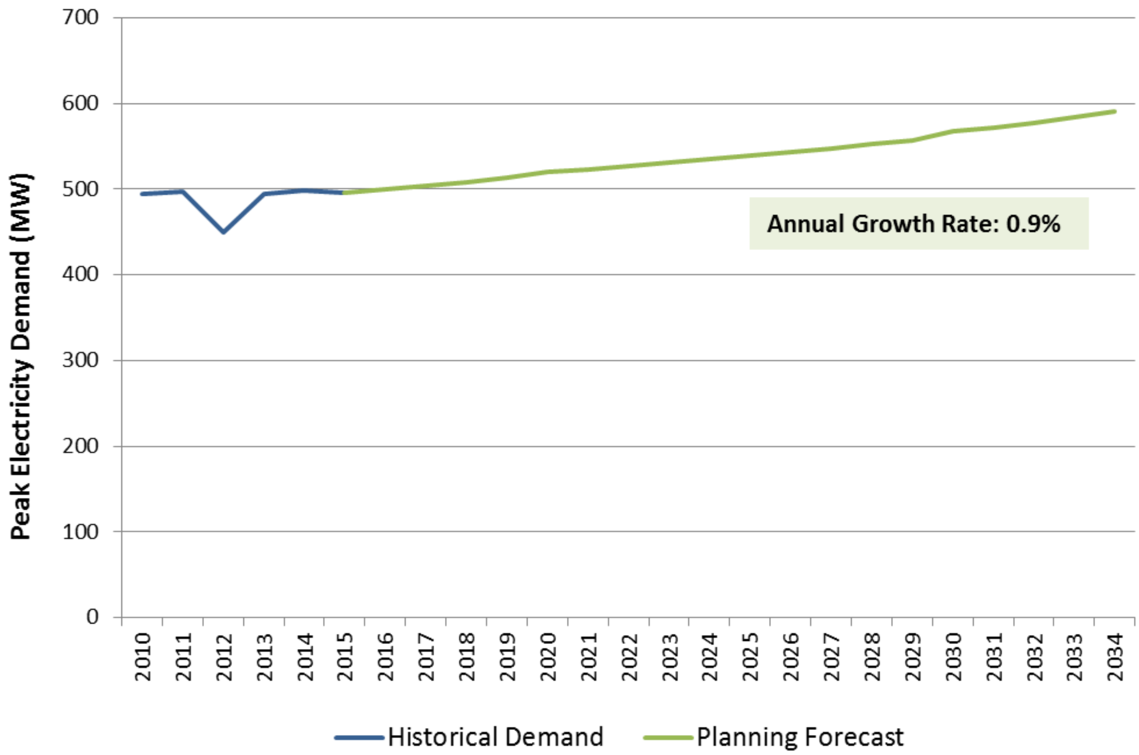
As the peak for the sub-region tends to occur during the winter evening hours, solar resources do not provide capacity contribution, however the other DG resources do have an impact on the peak. For the purpose of developing the planning forecast, contracted DG is expected to reduce the regional peak demand by as much as 11 MW over the next 20 years. Future DG uptake was, as noted, not included in the planning forecast and is instead considered as an option for meeting identified needs.

The expected annual peak demand contribution of contracted DG in the Parry Sound/Muskoka Sub-region can be found in Appendix A.

5.3.4 Planning Forecast

Figure 5-3 shows the planning forecast for the Parry Sound/Muskoka Sub-region for the planning period from 2015 to 2034 (using a base year of 2014). The planning forecast takes into consideration the gross demand forecast scenarios, estimated peak demand savings from provincial energy conservation targets, and existing and contracted DG. Based on the planning forecast, the electricity demand in the sub-region is expected to grow 0.9% annually, with an incremental peak demand growth of 100 MW over the planning period.

Figure 5-3: Parry Sound/Muskoka Sub-region Planning Forecast (2015-2034)



As discussed in Section 4.2.2, Midhurst TS primarily supplies the customers in the Barrie/Innisfil Sub-region. As a result, the Parry Sound/Muskoka Sub-region demand forecast shown above does not include electricity demand from Midhurst TS.

Further details related to the demand forecast scenarios can be found in Appendix A.

6. Needs

This section outlines the needs assessment methodology and identifies regional electricity supply and reliability needs over the 20-year planning period.

6.1 Needs Assessment Methodology

The IESO's ORTAC,[7] the provincial standard for assessing the reliability of the transmission system, was applied to assess supply capacity and reliability needs. ORTAC includes criteria related to the assessment of the bulk transmission system, as well as the assessment of local or regional reliability (see Appendix B for more details).

Through the application of these criteria, three broad categories of needs can be identified:

- **Transformer Station Capacity** is the electricity system's ability to deliver power to the local distribution network through the regional transformer stations. This is limited by the load meeting capability ("LMC") of the step-down transformer stations in the local area, which is the maximum demand that can be supplied from the transformer stations based on equipment rating and outage conditions.
- **Supply Capacity** is the electricity system's ability to provide continuous supply to a local area. This is limited by the LMC of the transmission line or sub-system, which is the maximum demand that can be supplied on a transmission line or sub-system under applicable transmission and generation outage scenarios as prescribed by ORTAC; it is determined through power system simulations analysis (See Appendix B for more details). Supply capacity needs are identified when peak demand on a transmission line or sub-system exceeds its LMC.
- **Load Security and Restoration** is the electricity system's ability to minimize the impact of potential supply interruptions to customers in the event of a major transmission outage, such as an outage on a double-circuit tower line resulting in the loss of both circuits. Load security describes the total amount of electricity supply that would be interrupted in the event of a major transmission outage. Load restoration describes the electricity system's ability to restore power to those affected by a major transmission outage within reasonable timeframes. The specific load security and restoration requirements prescribed by ORTAC are described in Appendix B.

[7] http://www.ieso.ca/imoweb/pubs/marketadmin/imo_req_0041_transmissionassessmentcriteria.pdf

In addition, the needs assessment may also identify needs related to service reliability performance, equipment end-of-life and planned sustainment activities. Service reliability and performance is measured based on customers' exposure to power outages on the distribution and transmission system, and is expressed in terms of frequency (i.e., number of outages a year) and duration (e.g., length of time before the power is restored). Equipment reaching the end of its life and planned sustainment activities may impact the needs assessment and options development. Transmission assets reaching end-of-life are typically replaced with assets of equivalent capacity and specification. The need to replace aging transmission assets may present opportunities to better align investments with evolving power system priorities. This may involve up-sizing equipment in areas with capacity needs, or downsizing or even removing equipment that is no longer considered useful. Such instances may also present opportunities to enhance or reconfigure assets for infrastructure hardening to improve system resilience.

6.2 Regional and Local Electricity Reliability Needs

Through the needs assessments, the Working Group has identified the need: (1) to minimize the frequency and duration of power outages and (2) to provide adequate supply to support growth in the Parry Sound/Muskoka Sub-region. The following sections further describe these needs.

6.2.1 Need to Minimize the Frequency and Duration of Power Outages

As discussed in Section 4.2, while there is local generation in this sub-region, communities and customers primarily rely on the 230 kV transmission, 44 kV sub-transmission and low-voltage distribution lines to deliver power from the rest of the province into the Parry Sound/Muskoka Sub-region. Outages along any of these lines (i.e., 230 kV, 44 kV, low voltage distribution lines) could interrupt the electricity supply to communities and customers in the Parry Sound/Muskoka Sub-region.

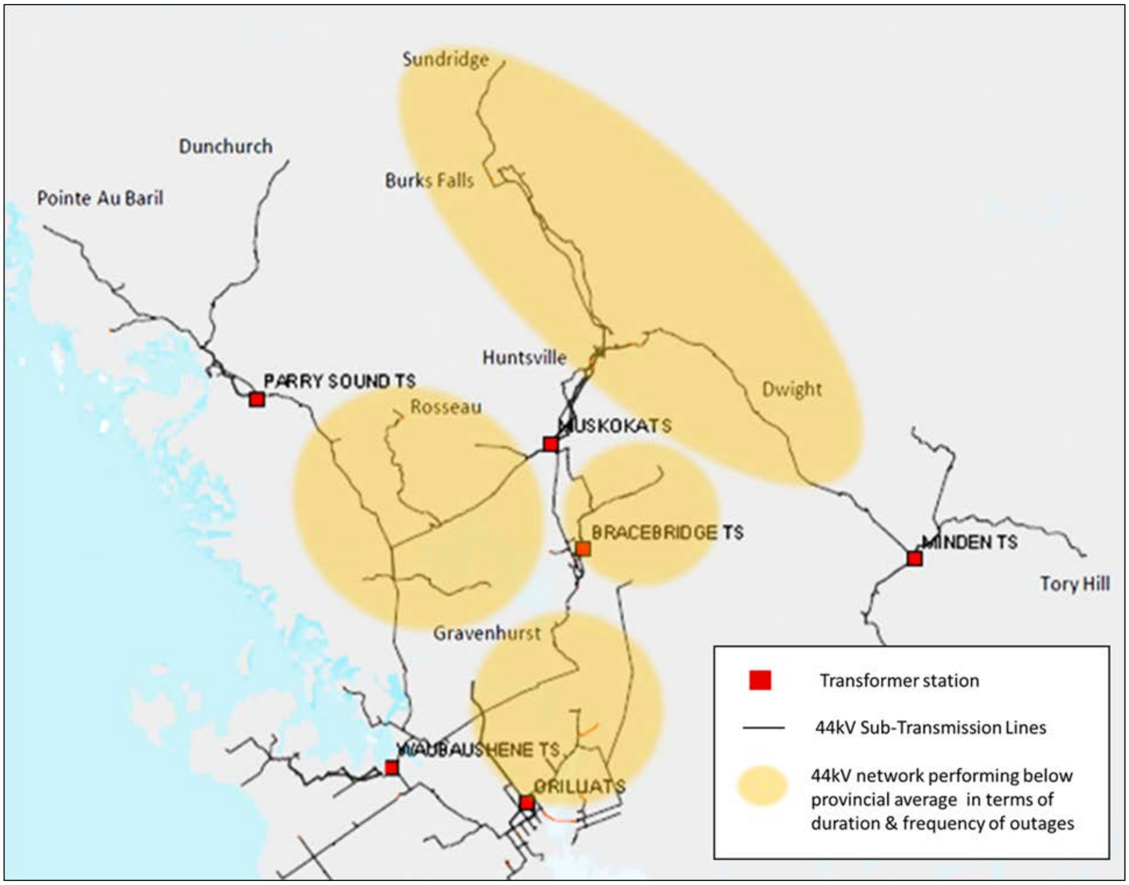
In this sub-region, customers and communities experience more frequent and prolonged power outages in comparison to customers and communities in other areas of the province. The consequences of extended power outages can have impacts for customers and society at large. For example, the Working Group has heard from communities and customers in this sub-region that below-average reliability is an impediment to economic development.

To better understand the causes of these power outages, the Working Group examined the service reliability and performance of the 44 kV sub-transmission system, and the load restoration capability and security of the 230 kV transmission line supplying the Parry Sound/Muskoka Sub-region. The results from the needs assessments are summarized below.

44 kV Sub-Transmission Service Reliability and Performance

In response to community and customers' concerns regarding power outages in this sub-region, the Working Group examined historical service reliability and performance of the 44 kV sub-transmission system over the last five years. Results from the assessment show that a number of 44 kV sub-transmission systems in this sub-region are performing below average in terms of frequency and duration of outages (as shown in Figure 6-1). On average, customers being supplied from a typical 44 kV sub-transmission line in Ontario experience outages about two times a year with outages typically lasting 5 hours or less. Based on the historical service reliability and performance data over the last five years, the outages for many of the 44 kV sub-transmission system in the Parry Sound/Muskoka Sub-region are almost double the provincial average in terms of frequency and duration.

Figure 6-1: 44 kV sub-transmission systems that are performing below provincial average in terms of frequency and duration of outages in the Parry Sound/Muskoka Sub-region



The service reliability and performance of the 44 kV sub-transmission system is impacted by a number of factors, including a facility's exposure to various elements, age and maintenance of equipment, length and configuration of the network, and the repair crew's accessibility to facilities. Lengthy 44 kV sub-transmission lines and off-road facilities are the main reasons for frequent and prolonged outages in the Parry Sound/Muskoka Sub-region.

- **Lengthy 44 kV sub-transmission lines:** As a large and sparsely populated geographical area, this sub-region is supplied by 44 kV sub-transmission lines that are typically longer than other 44 kV sub-transmission lines in Ontario. The average length of a 44 kV sub-transmission line in Ontario is about 45 km. Most of the 44 kV sub-transmission systems in the Parry Sound/Muskoka Sub-region range from 40 to 100 km in length. Long sub-transmission lines typically exhibit lower levels of reliability because of increased exposure to trees and wildlife. Tree contact has been identified as one of the major causes of 44 kV sub-transmission outages in this sub-region. Furthermore, with longer

44 kV sub-transmission lines, repair crews require additional time to identify and isolate causes of any outages.

- **Off-Road Facilities:** Many of the 44 kV sub-transmission systems are located off-roads. Due to limited access to off-road facilities, repair crews have difficulty detecting early signs of equipment failure, performing preventative maintenance and restoring power in a timely manner.

The detailed summary of the reliability performances of these 44 kV sub-transmission systems can be found in Appendix C.

Load Restoration and Security on the 230 kV Transmission System

Outage statistics from Hydro One Transmission indicate that have been three major outages involving the loss of both 230 kV transmission circuits in the sub-region since 1990. These outages lasted no more than 2-3 hours. While major 230 kV transmission outages have been relatively infrequent and short in duration in the Parry Sound/Muskoka Sub-region, the existing 230 kV transmission system supplying the Orillia and Muskoka area has limited ability to restore power in a timely manner and minimize the number of customers interrupted in the event of a major 230 kV transmission outage. As discussed in Section 6.1, the 230 kV transmission system should be designed in accordance with the load restoration and security criteria outlined in ORTAC (see Appendix B).

Based on the needs assessment, the Muskoka-Orillia 230 kV sub-system does not meet the ORTAC load restoration criteria and may violate the load security criteria over the longer term depending on the electricity demand growth in the area. The Muskoka-Orillia 230 kV sub-system is a 171 km double-circuit 230 kV transmission line (M6/7E) between Barrie and Minden. This system currently supplies four transformer stations and supplies about 465 MW of peak demand.[8] In the event of a major outage involving the loss of both transmission circuits on the Muskoka-Orillia 230 kV sub-system, all customers supplied by this transmission line would be interrupted. The existing system cannot restore any power to customers within 30 minutes. As

---

[8] Muskoka-Orillia 230 kV sub-system includes the electricity demand at Orillia TS, Muskoka TS, Midhurst TS, and Bracebridge TS. Although Midhurst is part of Barrie/Innisfil IRRP, it is supplied by the Muskoka-Orillia 230 kV sub-system and could have an impact on the electricity supply to the Parry Sound/Muskoka Sub-region.

a result, the Muskoka-Orillia 230 kV sub-system does not meet the ORTAC 30 minute load restoration criteria.

Based on the planning forecast, the winter demand on the Muskoka-Orillia 230 kV sub-system is expected to increase to 621 MW by 2034. According to ORTAC load security criteria, no more than 600 MW of electricity supply can be interrupted following a major outage. Depending on the electricity demand growth, the Muskoka-Orillia 230 kV sub-system may violate the load security criteria over the longer term.

Action is required to improve the load restoration and security for the Muskoka-Orillia 230 kV sub-system and to bring the 230 kV transmission system in compliance with Ontario's planning standards.

6.2.2 Need to Provide Adequate Supply to Support Growth

To ensure there is an adequate and reliable source of electricity supply for the customers and communities in the Parry Sound/Muskoka Sub-region, the electricity system will need to have sufficient supply to support forecast electricity demand growth and to comply with ORTAC. Results from the needs assessment indicate that transformers at Waubaushene TS and Parry Sound TS are at, or nearing capacity and will be in violation of ORTAC in the near term. Over the longer term, electricity demand growth could also exceed the supply capability of the Muskoka-Orillia 230 kV sub-system. The following sections further discuss these near- and longer-term supply capacity needs.

Demand Exceeds Capability at Parry Sound TS and Waubaushene TS in the Near-Term

The transformers supplying the Town of Parry Sound and surrounding areas can supply up to 52 MW at the time of local peak (Parry Sound TS LMC = 52 MW). The electricity demand in the area has already exceeded the capability of these transformers over the last couple of years. For example, during the winter of 2015, these transformers supplied up to 61 MW at the time of local peak, exceeding the LMC of Parry Sound TS by about 9 MW. Near-term action is required to ensure that the electricity system in the area has adequate supply to support growth. Over the planning period, the electricity demand supplied by Parry Sound TS is forecast to grow less than 1 MW per year so that by 2034 Parry Sound TS would need to supply about 74 MW.

Similarly, Waubaushene TS, supplying Waubaushene and the surrounding area can supply up to 99 MW at the time of local peak (Waubaushene TS LMC = 99 MW). Today, Waubaushene TS supplies about 96 MW of electricity demand. The transformers at this station are nearing capacity and electricity demand growth is expected to exceed capability by 2017. Near-term action is required to ensure that the electricity system has adequate supply to support future growth. The electricity demand supplied by Waubaushene TS is expected grow modestly at less than 1 MW per year. Based on the planning forecast, Waubaushene TS is expected to supply about 111 MW of electricity demand by 2034.

Demand may exceed the capability of Muskoka-Orillia 230 kV sub-system over the longer term

The Muskoka-Orillia 230 kV sub-system can supply up to 600 MW at the time of peak (Muskoka-Orillia 230 kV sub-system LMC = 600 MW). Today, the Muskoka-Orillia 230 kV sub-system supplies up to 454 MW.[9] Given the modest electricity demand growth in this area, electricity demand is not expected to exceed its capability until the early 2030s based on the planning forecast.

Given the uncertainty associated with the long-term electricity demand forecast, it is sufficient to monitor demand growth before proceeding with an investment decision. Section 7.2.2 provides a high-level discussion of options to address this potential need over the longer term.

6.3 Other Electricity Needs and Considerations

In addition to the regional and local electricity reliability needs outlined in Section 6.2, the Working Group identified other electricity needs and considerations that could impact the regional electricity supply. These issues are discussed in more detail below.

6.3.1 End-of-Life Replacements and Sustainment Activities

The Minden 230/44 kV transformers are scheduled for end-of-life replacements within the next five years. Hydro One is preparing a plan to replace all the aging equipment at Minden TS in the next few years. The aging 25/42 MVA transformers are to be replaced with 50/83 MVA transformers to address the capacity needs at the station. This sustainment decision was made prior to the initiation of this IRRP.

[9] Muskoka-Orillia 230 kV sub-system includes the electricity demand at Orillia TS, Muskoka TS, Midhurst TS, and Bracebridge TS. Although Midhurst TS is considered as part of Barrie/Innisfil IRRP, it is supplied by the Muskoka-Orillia 230 kV sub-system and has an impact on the electricity supply to the Parry Sound/Muskoka Sub-region.

In addition to the near-term sustainment activities, the Working Group also identified potential assets that could be reaching end-of-life over the planning period. The expected service life of a transformer is about 60 years. The transformers at Parry Sound TS and Waubaushene TS were installed in the early 1970s and therefore these transformers could be reaching end-of-life in the early 2030s. There may be opportunities to align end-of-life facility replacements with solutions to address longer-term needs in the sub-region.

6.3.2 Community Energy Planning

A number of communities in the sub-region are in the process of developing community energy plans ("CEP(s)"). At the time of this report, seven of the eight First Nation communities have received funding from the IESO through the Aboriginal Community Energy Plan program to develop CEPs. The Municipal Energy Plan Program[10] administrated by the provincial government supports municipalities in their efforts to develop CEPs.

Through community energy planning activities, communities will have a better understanding of their local energy needs and emissions footprint, be able to identify opportunities for energy efficiency and emissions reduction, and develop plans to meet their goals in consideration of local economic development. These CEPs examine broader energy needs, such as transportation, natural gas and electricity, and consider other objectives including net zero energy, electrification, and emissions reductions.

On June 8, 2016, the Ontario government released Ontario's Climate Change Action Plan ("CCAP"), which outlines policy to reduce the use of fossil fuel and to encourage the move toward a low carbon economy. In response to this policy direction, a CEP may include recommendations to promote electrification and other forms of fuel switching, such as shifting from natural gas to electric-power heat pumps and from gasoline to electric vehicles, to achieve a goal of reducing greenhouse gas ("GHG") emissions. As such, the outcomes from CEPs may drive additional requirements on the electricity system and should be monitored closely through the regional planning process. Furthermore, with the increased access to distributed energy resources, CEPs may identify opportunities for community-based energy solutions, such as district energy, CHP, or microgrids. Depending on the timing, location and magnitude of the

---

10 For more information on the Ministry of Energy MEP Program: http://www.energy.gov.on.ca/en/municipal-energy/

needs, community-based energy solutions can be considered as potential options to address regional electricity needs.

6.3.3 Power Quality

A large customer in the sub-region is experiencing issues related to power quality. Power quality issues are defined as disturbances to the customer's electricity supply as a result of voltage. Voltage issues can be caused by customers' equipment and/or system voltage performance. The solutions and cost responsibility of investments to address power quality issues may vary depending on the root causes of the problem. The Working Group agreed that power quality issues need to be better understood and should be examined on a case-by-case basis by the area LDCs, transmitter and customers.

6.4 Needs Summary

Table 6-1 provides a summary of the regional supply and reliability needs in the Parry Sound/Muskoka Sub-region.

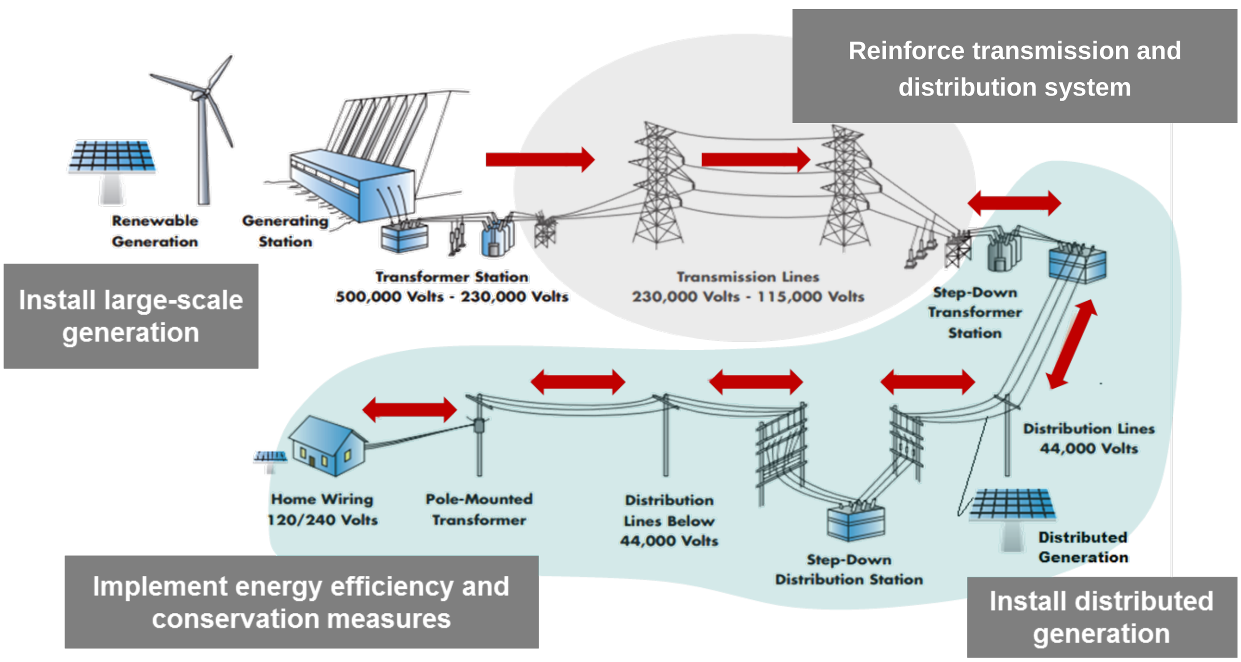
Table 6-1: Summary of Regional and Local Reliability Needs

Local and Regional Electricity Reliability Needs	Components	Status
Need to Minimize the Frequency and Duration of Power Outages	44 kV sub-transmission systems	Performing below provincial average in terms of frequency and duration of 44 kV sub-transmission outages
	Muskoka-Orillia 230 kV sub-system	Limited ability to restore power to customers in a timely manner in the event of a 230 kV transmission outage involving the loss of both transmission circuits. The sub-system does not meet the ORTAC load restoration criteria
		Electricity demand growth may exceed 600 MW and could violate the ORTAC load security criteria in the early 2030s
Provide Adequate Supply to Support Growth	Parry Sound TS	Electricity demand growth already exceeds system capability today
	Waubaushene TS	Electricity demand growth forecast to exceed system capability in 2017
	Muskoka-Orillia 230 kV sub-system	Electricity demand growth could exceed system capability in the early 2030s

7. Options to Address Regional and Local Electricity Needs

As shown in Figure 7-1, traditionally power has been generated from large, centralized generation sources. To provide electricity supply to the various communities across Ontario, power has been delivered through transmission and distribution infrastructure. To address regional and local electricity needs, one approach is therefore to reinforce the transmission and distribution infrastructure supplying the local area. However, in recent years, communities and customers have been exploring opportunities to reduce their reliance on the provincial electricity system by meeting their electricity needs with local, distributed energy resources and community-based solutions. This approach includes a combination of emerging technologies and conservation programs, such as targeted DR and conservation programs, DG and advanced storage technologies, micro-grid and smart-grid technologies, and more efficient and integrated process systems combining heat and power.

Figure 7-1: Options to Address Electricity Needs



Options Evaluation

When evaluating alternatives, the Working Group considered a number of factors, including technical feasibility, cost, flexibility, alignment with planning policies and priorities and consistency with long-term needs and options. Solutions that maximized the use of existing infrastructure were given priority.

Investing in new electricity infrastructure, such as a new transmission line or a generation facility requires substantial capital investment, has environmental/land-use impacts and has a long-service life. As such, it is important to take into the consideration the longer-term cost implications, value and potential risks (e.g., stranded or underutilized assets) when recommending an investment. Furthermore, these facilities typically require long lead times to obtain approvals and complete construction. For these reasons, decisions on new facilities must take into account these considerations and be made with sufficient lead time to ensure they are available when needed.

When assessing the need for infrastructure investments, it is important to strike a balance between overbuilding infrastructure (e.g., committing to infrastructure when there is insufficient demand to justify the investment) and under-investing (e.g., avoiding or deferring investment despite insufficient infrastructure to support growth in the region). Typically, demand management and energy efficiency programs can be implemented within six months, or up to two years for larger projects, whereas transmission and distribution facilities can take five to seven years to come into service. The lead time for generation development is typically two to three years, but could be longer depending on the size and technology type.

Finally, the issue of how much is appropriate to invest and who pays needs to be addressed. In regional planning, depending on the type and classification of assets, the costs may be shared by all provincial ratepayers or recovered only by the specific customers they serve (e.g., LDC, industrial customers). In some cases, a combination of cost-sharing may occur when there are both provincial and local benefits. Notably, the Working Group has heard concerns from communities about affordability. Given the high cost of electricity, it is important consider how investments impact local ratepayers.

<u>Near-Term Actions and Long-Term Planning Considerations</u>

For the near and medium term, the IRRP identifies specific actions and investments for immediate implementation. This ensures that necessary resources will be in-service in time to address more pressing needs. For the long term, the IRRP identifies potential options to meet needs that may arise in 10-20 years. It is not necessary to recommend specific projects at this time (nor would it be prudent given forecast uncertainty and the potential for technological change). Instead, the long-term plan focuses on developing and maintaining the viability of long-term options, engaging with communities, and gathering information to lay the groundwork for making decisions on future options.

As discussed in Section 6, actions need to be taken to (1) minimize the frequency and duration of power outages, and (2) ensure that the regional electricity system has adequate supply to support growth. In developing the 20-year plan, the Working Group examined a wide range of integrated solutions to address these local and regional needs. These options are discussed in the following section.

7.1 Minimize the Frequency and Duration of Power Outages

To minimize the frequency and duration of power outages, the Working Group examined options to improve service reliability and performance on the 44 kV sub-transmission system and to address load restoration and security needs on the 230 kV transmission system.

7.1.1 Options to Improve Service Reliability and Performance on the 44 kV Sub-transmission System

44 kV Sub-Transmission Maintenance and Outage Mitigation Initiatives

Hydro One Distribution owns and operates the 44 kV sub-transmission system in the Parry Sound/Muskoka Sub-region. Currently, Hydro One Distribution has a number of on-going maintenance and outage mitigation initiatives, including vegetation management, line patrols and grid modernization, to help reduce the frequency and duration of outages on the 44 kV sub-transmission system. These initiatives are summarized in Table 7-1.

Table 7-1: Status of Current Maintenance and Outage Mitigation Initiatives in the Parry Sound/Muskoka Sub-region

Initiatives	Status
Vegetation Management Program	▪ Vegetation management was last completed in these areas in 2015/2016 ▪ Full clearing for these areas is planned for 2021/2022 ▪ Hydro One has committed $20 million in 2016 in the districts of Muskoka and Parry Sound to reduce tree-related outages for its customers
Line Patrols	▪ Data is collected to help identify and prioritize the need to replace distribution poles and/or potentially defective equipment ▪ Last line patrolling cycle for these priorities areas occurred between 2010-2012 ▪ The next line patrolling cycle is scheduled for 2016 to 2021

Mid-cycle Hazard Tree Program	▪ Visual inspection to identify potential risk of tree-related contact ▪ This program will be conducted in this sub-region in 2018/2019
Distribution Management System & Grid Modernization	▪ Distribution management system will be implemented in this sub-region by the end of 2016 and will enable operators to have greater grid visibility and to respond to outages in a timely manner ▪ A broader grid modernization initiative is underway to identify opportunities for distribution automation (e.g., remote fault indicators, automated switches), which can help operators diagnose the sources of the outages and respond in a timely manner

In addition to these on-going maintenance programs and initiatives, Hydro One Distribution may take additional measures to further improve service reliability and performance on the 44 kV sub-transmission systems. These include:

- Install distribution automation and fast-acting switching devices to restore power in a timely manner
- Relocate "Off-Road" 44 kV sub-transmission system lines to roadside to facilitate access for maintenance crews
- Strengthen ties within the 44 kV sub-transmission system to allow adjacent 44 kV lines to serve as a back-up supply in the event of an outage

The cost, feasibility and effectiveness of these measures depend on the solution type, geography and nature of the 44 kV sub-transmission system and will need to be examined on a case-by-case basis. Hydro One Distribution will assess these options through the distribution planning process and will provide an update to the communities and LACs on plans to improve 44 kV sub-transmission system service reliability performance, including any proposed capital plans, by the end of 2017. The ability to implement any proposed capital investment plans will be contingent on the outcome of Hydro One Distribution's 2018-2022 rate filing application with the OEB.

<u>Option to Resupply Customers from Bracebridge TS</u>

Currently, the Town of Bracebridge, the Town of Gravenhurst, the Township of Muskoka Lakes, and the Township of Seguin are supplied by lengthy 44 kV sub-transmission system lines (60-100 km in length) from Muskoka TS and Orillia TS. To reduce 44 kV sub-transmission line exposure, new 44 kV sub-transmission lines can be built (~ up to 15 km) to resupply these areas from Bracebridge TS. These new 44 kV sub-transmission lines to Bracebridge TS cost about $3 to $6 million.

Today, Bracebridge TS supplies one industrial customer. The electricity demand from this industrial customer has decreased significantly over several years. Over the longer term, there should be sufficient capacity at Bracebridge TS to supply some of the customers in the Town of Bracebridge, the Town of Gravenhurst, the Township of Muskoka Lakes, and surrounding areas.

As discussed in Section 6.2.1, outages on the transmission system or transformer stations are relatively infrequent in this sub-region. However, due to the current system configuration at Bracebridge TS,[11] all power being supplied by the Bracebridge TS will be interrupted in the event of an outage at the TS or on the 230 kV transmission line.

Operational measures could help mitigate customers' exposure to outages on the 230 kV transmission system supplying Bracebridge TS. In the event of an outage on the 230 kV system, customers could rely on the Muskoka TS or Orillia TS as a backup supply and vice versa. In addition, a second TS and/or a combination of switching facilities could be installed to minimize the impact of potential 230 kV transmission system outages. The cost of these transmission reinforcements could range from $5 to $30 million.

Going forward, Hydro One Transmission, Hydro One Distribution, Lakeland Power and Veridian Connections will examine the cost-benefit and cost-responsibility of options to improve the service reliability performance of the 44 kV sub-transmission system supplying the Bracebridge/Gravenhurst/Muskoka Lakes and surrounding areas and will discuss these findings with the Working Group through the regional planning process. This action is expected to be completed by the end of 2017. The results from these discussions will be shared with LAC members and affected communities.

[11] In Ontario, most transformer stations are designed to have two transformers to provide redundancy during outages on the transmission system. In the event that one transformer is out-of-service, the remaining TS could still provide a continuous supply to the customers. Because Bracebridge TS was originally designed to serve the needs of the specific industrial customer, the station only has a single transformer.

7.1.2 Options to Improve Load Restoration and Security on the Muskoka-Orillia 230 kV Transmission System

Distribution Option

One option to restore electricity supply to customers following a major outage on the Muskoka-Orillia 230 kV sub-system is to resupply these customers from neighbouring 230 kV transmission system (e.g., Parry Sound 230 kV sub-system) using the distribution network. The extent to which these customers can be resupplied through the distribution network is highly variable and depends on various factors such as load level at neighbouring stations, distance between stations, voltage of neighbouring distribution systems, time of day and operating procedures in place on the distribution system. Based on information provided by the LDCs, only about 20 to 30 MW can be resupplied from neighbouring stations within 30 minutes following a major outage on the Muskoka-Orillia 230 kV sub-system. In order to meet the ORTAC load restoration at today's demand level, the system will need to restore at least 200 MW within 30 minutes following the transmission outage. As such, this option is not sufficient to meet the ORTAC load restoration criteria.

Transmission Option

In the event of a 230 kV transmission outage, fast-acting isolating devices can be installed to minimize the impact of supply interruption to customers. There are two types of fast-acting isolating devices: (1) motorized switches and (2) breakers.

Motorized switches can be used to isolate sections of the transmission line within 30 minutes following a major transmission outage and would enable power to be restored to customers in a timely manner. This is particularly important in remote areas, where repair crew may have limited access to the infrastructure. Grid operators can operate these switches remotely to isolate sections affected by an outage in a timely manner. The cost of these switches ranges from $5 to $7 million.

As an alternative solution, breakers can immediately isolate sections of the transmission line that are not directly impacted by the outage. Since breakers can reduce the total number of customers that would be affected by a transmission outage, it can be an effective solution to address the longer-term load security needs on Muskoka-Orillia 230 kV sub-system. Since additional infrastructure and protection and control systems are required for breakers, the cost of breakers is usually 3-4 times more than for motorized switches ($20 to $25 million). Given the uncertainty of the demand forecast over the longer term and the substantial cost of installing breakers, the Working Group agreed that installing breakers on the Muskoka-Orillia 230 kV sub-system is not required at this time. A summary of options to improve load restoration and load security on Muskoka-Orillia 230 kV sub-system can be found in Appendix E.

In consideration of the cost-benefit of these options, the Working Group recommends proceeding with the installation of two 230 kV motorized switches at Orillia TS. With these switches, about 50% of the electricity supply to customers on the Muskoka-Orillia 230 kV sub-system could be restored within 30 minutes in the event of an outage on the 230 kV transmission system, meeting the ORTAC 30 minute load restoration criteria.

To bring the 230 kV transmission system in compliance with Ontario's planning standard, the IESO will provide a letter to Hydro One Transmission to initiate project development work for the two 230 kV motorized switches at Orillia TS. Based on project development timeline for switching facilities, the project is expected to be in-service by the end of 2020.

7.1.3 Opportunities to Use Community-Based Solutions to Improve Resilience and Service Reliability

In addition to the transmission and distribution options discussed above, there may be opportunities to improve system resilience and service reliability at the community level using distributed energy resources and emerging technologies, such as residential solar-storage technology, micro-grids and on-site generation. Many of the community-based solutions are still in the early stages of development. The Working Group needs to better understand the cost and feasibility of these options. Depending on the interest from First Nation communities, municipalities and the LAC, the Working Group can facilitate discussions on the cost-benefit of opportunities to improve system resilience and the service reliability through community-based solutions. A good opportunity for these discussions may be through community energy planning activities.

7.2 Provide Adequate Supply to Support Growth

To ensure that the regional electricity system has adequate supply to support growth, the Working Group examined options to address the near-term needs at Parry Sound TS and Waubaushene TS and the longer-term supply capacity needs on the Muskoka-Orillia 230 kV sub-system.

The following section discusses these options in more detail.

7.2.1 Options to Provide Additional Transformer Station Capacity at Parry Sound TS and Waubaushene TS

Distribution Option

To free up supply capacity at Parry Sound TS and Waubaushene TS, some customers in the Parry Sound and Waubaushene areas can be resupplied from neighbouring transformer stations using existing and/or new 44 kV sub-transmission facilities.

To manage the near-term demand growth in the area, about 4 MW at Waubaushene TS can be resupplied from Orillia TS using the existing 44 kV sub-transmission infrastructure by 2020. If required, another 7 MW at Waubaushene TS can be resupplied from Midhurst TS upon completion of Barrie Area Transmission Reinforcement in the early 2020s. This can be done using existing distribution system and no new facilities will be required. This option would address the needs at Waubaushene TS over the planning period at minimal cost and would maximize the use of existing facilities. Midhurst TS is a major transformer station supplying the Barrie/Innisfil Sub-region. Resupplying some of the customers in Waubaushene from Midhurst TS could have an impact on the timing and need for a new TS in the Barrie/Innisfil Sub-region over the longer term. As such, the Working Group will need to coordinate with the Barrie/Innisfil IRRP Working Group to monitor and manage the demand growth in the Waubaushene and Barrie/Innisfil areas.

Similarly, to manage the near-term growth in the area, about 6 MW at the Parry Sound TS can be resupplied from Muskoka TS. There is sufficient capacity at Muskoka TS to supply these customers over the planning period. To resupply these customers, Hydro One will need to seek approval to construct a new 44 kV sub-transmission line (estimated cost of about $7 million). The siting and routing of these facilities will be determined as part of the project development process. Based on the typical project development timeline for 44 kV sub-transmission reinforcements, the project is expected to be in-service by 2020. These reinforcements would substantially address the near-term supply needs at Parry Sound TS and would also improve service reliability for the Townships of Muskoka Lakes and Seguin.

In the near term, the Working Group recommends resupplying some customers in the Parry Sound and Waubaushene areas from neighbouring transformer stations. This option will fully address the supply needs at Waubaushene TS over the planning period and will help manage near-term demand at Parry Sound TS at a minimal cost. Even after implementing these near-term measures, about 16 MW of additional supply will still be required to address the supply needs at Parry Sound TS over the planning period. As such, other options will need to be considered to address the supply needs at Parry Sound TS over the planning period.

Transmission Option

Transformers at the existing Parry Sound TS and Waubaushene TS can be upgraded to enable more power to be delivered to the Parry Sound and Waubaushene areas. This option costs about $25 to $30 million for each transformer station upgrade.

Transmission-Connected Generation Facilities

Since the need is at the transformer station level, transmission-connected generation facilities would not address the need. The Working Group therefore did not consider it.

Community-Based Solution: Local Demand Management and Distributed Energy Resources

With the relatively slow electricity demand growth forecast for this sub-region, there is an opportunity to use targeted conservation and local demand management, distribution-connected generation and/or other distributed energy resources to defer the transformer upgrade at Parry Sound TS and Waubaushene TS. In order to defer the transformer upgrades, LDCs would need to reduce the electricity demand by about 1 MW annually at each of these transformer stations. Based on economic analysis, the LDCs can save about $2 million for every year of deferred capital. More details related to the capital deferral analysis can be found in Appendix D.

Through discussions with the LDCs and communities, the Working Group has identified a number of potential community-based solutions to address supply needs in the Parry Sound and Waubaushene areas. For example:

- **Heating efficiency:** As discussed in Section 5.1, the electricity demand peak in this sub-region is driven by electric space and water heating. There may be opportunities to reduce the peak demand by improving heating efficiency in the area.

  While a large portion of the communities in this sub-region rely on electric heating, some customers also rely on other fuel types, such as wood, to meet their heating requirements. In some cases, communities may have some access to natural gas infrastructure. Through initiatives, such as home energy audits, retrofit programs and community energy planning activities, the Working Group can work with communities to better understand the heating requirements and energy baseline (e.g., heating fuel, housing insulation) and identify opportunities to improve heating efficiencies in the Parry Sound/Muskoka Sub-region.

- **Local hydroelectric potential:** Based on information provided by the Ontario Waterpower Association ("OWA"), there is about 38 MW of hydroelectric potential in the Parry Sound District. As discussed in Section 4.2.1, many of the hydroelectric resources are run-of-the-river facilities with limited storage capability. As such, only a portion of their installed capacity can be relied upon at the time of local peak. Furthermore, much of these potential hydroelectric resources are located far from existing transmission and distribution infrastructure. To access this potential, additional transmission and distribution infrastructure may be required. More details related to these hydroelectric potential can be found in Appendix F.

- **Pilots and emerging technologies:** Many LDCs are engaging in pilots and studies to better understand the costs and feasibility of community based solutions and **e**merging technologies, such as residential solar-storage technology, microgrids, and thermal energy storage. These emerging technologies can potentially help reduce a community's reliance on the provincial grid during the time of local peak.

At this time, the Working Group has limited information on the cost and feasibility of distributed energy resources and local demand management. More work is needed to determine whether it is cost effective and feasible to rely on these solutions to address the local need. To better understand the cost and feasibility of implementing distributed energy solutions and demand management in the Parry Sound/Muskoka Sub-region, the Working Group recommends initiating a local achievable potential ("LAP") study for the Parry Sound/Muskoka Sub-region in early 2017. The study will examine the cost and feasibility of a range of distributed energy resources and local demand management options including incentive adders to existing conservation programs, new conservation and demand management programs, local demand response, behind-the-meter generation and energy storage. The study may also examine options to manage new demand from increased electrification that may result from Ontario's CCAP. This study will be initiated in early 2017 by the LDCs. The IESO will assist and provide funding for the LAP study.

As well, the Working Group will work closely with communities to leverage local knowledge and community energy planning activities and to identify opportunities for targeted conservation and energy efficiency opportunities in First Nation communities and municipalities.

End-of-Life Replacement Considerations

As discussed in Section 6.3.1, transformers at Parry Sound TS and Waubaushene TS could be reaching their end-of-life in the early 2030s. Depending on the electricity demand growth, it may be cost effective to advance the end-of-life replacement of these aging assets with upgraded/upsized facilities.

To determine if there is an opportunity to align the end-of-life facility replacement with solutions to address supply need at Parry Sound TS and Waubaushene TS, the Working Group will actively monitor and assess the conditions of these transformers and electricity demand growth. The Working Group will revisit this need in the next iteration of the plan.

7.2.2 Options to Provide Additional Supply Capacity on Muskoka-Orillia 230 kV sub-system over the Longer Term

As discussed in Section 6.2.2, about 20 MW of additional supply capacity will be required on the Muskoka-Orillia 230 kV sub-system in the early 2030s. Given the uncertainty with the demand growth and the fact that the need does not arise until late in the planning period, early development work for major electricity infrastructure projects is not required at this time. However, it is important to continue to monitor demand closely to determine if and when an investment decision for the Muskoka-Orillia 230 kV sub-system is required. To lay the ground work for the next planning cycle, the Working Group has explored potential options to address the longer-term needs on Muskoka-Orillia 230 kV sub-system.

Distribution Option

To free up supply capacity on the Muskoka-Orillia 230 kV sub-system, one option is to supply some of customers on the Muskoka-Orillia 230 kV sub-system from the transformer stations on the Parry Sound 230 kV sub-system using existing and/or new 44 kV sub-transmission facilities. However, as discussed in Section 6.2.2 , electricity demand at Parry Sound TS and Waubaushene TS has already exceeded the TS capacity and would not have sufficient capacity to supply additional customers. This option was therefore ruled out by the Working Group.

Transmission Options

Installing switching facilities or upgrading sections of the transmission lines can enable more power to be delivered into the Muskoka-Orillia 230 kV sub-system. These enhancements may be subject to regulatory approvals, such as a Class Environmental Assessment and utilities' rate filings. The lead time to develop these facilities is typically three to five years.

The costs of these transmission reinforcements range from $20 to $30 million depending on the reinforcements requirements. Cost responsibility for the transmission reinforcements would be determined as part of the regulatory application review process.

This option should be considered and revisited in the next iteration of the plan.

Transmission-Connected Generation Option

Siting transmission-connected generation facilities can be effective for addressing supply capacity on Muskoka-Orillia 230 kV sub-system. A 20 MW generation facility connected to Muskoka-Orillia 230 kV sub-system can address the potential supply capacity needs arising in the early 2030s.

There are a number of factors that need to be considered when siting localized generation, and any decisions would need to align with the recommendations found in the August 2013 report entitled "Engaging Local Communities in Ontario's Electricity Planning Continuum"[12] prepared for the Minister of Energy by the former OPA and the IESO.

As the requirements in the Parry Sound/Muskoka Sub-region are for additional capacity during times of peak demand, a large, transmission-connected generation solution would need to be capable of being dispatched when needed, and operate at an appropriate capacity factor. In some cases, additional transmission reinforcements may also be required.

The cost of a large, localized generation resource depends on the size, fuel type, technology and the degree to which it can contribute to the local and provincial system capacity or energy needs. The fuel availability will also need to be taken into consideration. The lead time for generation development is typically two to three years, but it could be longer depending on the size and technology type.

---

[12] http://www.ieso.ca/Pages/Participate/Regional-Planning/Local-Advisory-Committees.aspx

This option should be considered and revisited in the next iteration of the plan.

Community-Based Solutions: Local Demand Management and Distributed Energy Resources

With the modest electricity demand growth in this sub-region, there is an opportunity to use targeted local demand management, distribution-connected generation and/or other distributed energy resources to manage demand on the Muskoka-Orillia 230 kV sub-system and to defer major capital investments and infrastructure development over the longer term. As discussed in Section 7.2.1, the Working Group will initiate a LAP study to determine the cost and feasibility of using distributed energy resources and local demand management options to defer major capital investments (e.g., transmission reinforcements). In conjunction with the study, the Working Group will continue to work closely with communities to coordinate community-energy planning activities and to identify opportunities for targeted CDM opportunities in First Nation communities and municipalities.

This option should be considered and revisited in the next iteration of the plan.

8. Recommended Actions

The recommended actions to minimize the frequency and duration of power outages and to provide adequate supply to support growth in the Parry Sound/Muskoka Sub-region over the planning period are outlined in Tables 8-1 and 8-2, along with the proposed timing and the parties that will lead the implementation.

The Working Group will continue to meet regularly during the implementation phase of this IRRP to monitor developments in the sub-region and to track progress toward these deliverables and this information will be shared and discussed with the LAC.

Table 8-1: Recommended Actions to Minimize Frequency and Duration of Power Outages

	Recommendations	Action(s)/Deliverable(s)	Lead Responsibility	Timeframe
1	**Inform communities and LAC members of the 44 kV sub-transmission service reliability performance and the on-going maintenance and improvement initiatives in the Parry Sound/Muskoka Sub-region**	Provide an update to communities and LAC members on the 44 kV sub-transmission service reliability performance improvements including any proposed capital plans The ability to implement any proposed capital investment plans will be contingent on the outcome of Hydro One Distribution's 2018-2022 rate filing application with the OEB.	Hydro One Distribution	End of year 2017
2	**Examine the cost benefit and cost responsibility of options to resupply customers in Bracebridge, Gravenhurst, Muskoka Lakes and surrounding areas from alternate transformer station**	Discuss findings and decision with the Working Group through the regional planning process Share the results with LAC members and affected communities	Hydro One Distribution, Lakeland Power and Veridian Connections	To be completed by Q4 2017

3	**Install two 230 kV motorized switches at Orillia TS to restore power to customers in timely manner in the event of a major outage on the Muskoka-Orillia 230 kV sub-system**	Prepare a letter to Hydro One Transmission to initiate project development work	IESO	Early 2017
		Design, develop and construct two 230 kV motorized switches	Hydro One Transmission	In-service by end of 2020
4	**Explore opportunities to improve resilience and service reliability at the community level**	Facilitate discussions with First Nation communities, municipalities and LAC members on the cost-benefit and opportunities to improve system resilience and service reliability through community energy planning	IESO	On-going

Table 8-2: Recommended Actions to Provide Adequate Supply to Support Growth

Recommendations		Action(s)/Deliverable(s)	Lead Responsibility	Timeframe
1	**Resupply some customers in the Parry Sound and Waubaushene areas from neighbouring transformer stations using existing and new distribution facilities to maximize the use of the existing system**	Seek approval to construct a new 44 kV sub-transmission line between Parry Sound TS and Muskoka TS	Hydro One Distribution	In-service by 2020
		Transfer up to 4 MW from Waubaushene TS to Orillia TS Transfer up to 6 MW from Parry Sound TS to Muskoka TS	Hydro One Distribution	Prior to 2020
		Transfer up to 7 MW from Waubaushene TS to Midhurst TS (if required)	Hydro One Distribution	Early 2020s upon completion of Barrie Area

				Transmission Reinforcement
		Coordinate with the Barrie/Innisfil IRRP Working Group to monitor and manage demand growth in the Waubaushene and Barrie/Innisfil areas	IESO	On-going
2	**Determine the cost and feasibility of using distributed energy resources and local CDM options to defer major capital investments in the Parry Sound/Muskoka Sub-region**	Initiate a LAP study to determine the cost and feasibility of using distributed energy resources and local conservation and demand management options to defer major capital investments (e.g., transmission reinforcements)	IESO to assist and provide funding LDCs to carry out the study	Initiate study in early 2017
		Work closely with communities to leverage local knowledge and community energy planning activities and to identify opportunities for targeted conservation and demand management opportunities in First Nation communities and municipalities.	IESO	On-going
3	**Determine whether it is cost effective to advance the end-of-life replacement and to replace the aging assets with upgraded/upsized facilities at Parry Sound TS and Waubaushene TS**	Review electricity demand growth at Parry Sound TS and Waubaushene TS with LAC members	IESO	Annually
		Monitor and provide updated information on the condition of aging equipment at Waubaushene TS and Parry Sound TS to the LAC and the Working Group	Hydro One Transmission	Annually

		Determine whether it is cost effective to advance the end-of-life replacement and to replace the aging assets with upgraded/upsized facilities.	IESO	Annually
4	**Monitor electricity demand growth closely to determine if and when an investment decision on the Muskoka-Orillia 230 kV sub-system is required**	Review electricity demand growth on the Muskoka-Orillia 230 kV sub-system with LAC members	IESO	Annually

9. Community and Stakeholder Engagement

Community engagement is an important aspect of the regional planning process. Providing opportunities for input in the regional planning process enables the views and preferences of the community to be considered in the development of the plan, and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the engagement activities undertaken to date and next steps for the Parry Sound/Muskoka IRRP.

A phased community engagement approach was undertaken for the Parry Sound/Muskoka IRRP based on the core principles of creating transparency, engaging early and often, and bringing communities to the table. These principles were established as a result of the IESO's outreach with Ontarians in 2013 to determine how to improve the regional planning and siting process, and they now guide IRRP outreach with communities and will ensure this dialogue continues as the plan moves forward.

Figure 9-1: Summary of the Parry Sound/Muskoka Community Engagement Process

Creating Transparency:

Creation of Parry Sound/Muskoka IRRP Information Resources

- Dedicated Parry Sound/Muskoka IRRP web page created on IESO website providing background information, the IRRP Terms of Reference and listing of the Working Group members
- Dedicated web page created on Hydro One website
- Self-subscription service established for the South Georgian Bay/Muskoka planning region for subscribers to receive regional planning updates
- Status: complete

Engaging Early and Often:

Municipal and Indigenous Outreach

- Early engagement on regional planning and the South Georgian Bay/Muskoka Scoping Assessment Report (September 2015)
- Group meetings held with municipalities from across the planning region held in Huntsville and Parry Sound (September 2015)
- Meetings held with First Nation communities in Rama (September 2015)
- Status: initial outreach complete; dialogue continues

Bringing Communities to the Table:

Broader Community Outreach

- Parry Sound/Muskoka LAC formed in spring 2016; dedicated Parry Sound/Muskoka engagement web page added to IESO website
- Two LAC meetings held in June and September 2016 to discuss and obtain feedback on the development of the IRRP and draft recommendations
- LAC meetings are open to the public; materials are posted to the engagement webpage
- Status: begun in spring 2016; on-going

9.1 Creating Transparency

To start the dialogue on the Parry Sound/Muskoka IRRP and build transparency in the planning process, a number of information resources were created for the plan. A dedicated web page was created on the IESO website including a map of the regional planning area, information on why an IRRP was being developed for the Parry Sound/Muskoka Sub-region, the IRRP terms of reference and a listing of the organizations involved. A dedicated email subscription service was also established for the broader South Georgian Bay/Muskoka planning region where communities and stakeholders could subscribe to receive email updates about the IRRP.

9.2 Engage Early and Often

Early communication and engagement activities for the Parry Sound/Muskoka IRRP were initiated in September 2015 as part of a series of meetings with communities and stakeholders to discuss electricity planning initiatives across the Parry Sound/Muskoka Sub-region. The main objective of the meetings from a regional planning perspective was to introduce attendees to the regional planning process. This included the South Georgian Bay/Muskoka Scoping Assessment process for the regional planning studies being initiated in the area, as well as discussions of upcoming engagement activities. Various meetings were held with a broad range of attendees including municipal representatives, First Nation community members, and local industrial customers.

9.2.1 South Georgian Bay/Muskoka Region Scoping Assessment Outcome Report

The draft South Georgian Bay/Muskoka Region Scoping Report was posted to the IESO website in May 2015 for comment, and a final version was posted on June, 22, 2015. The report was led by the IESO, and developed in collaboration with regional participants, including Hydro One Networks, Lakeland Power, Midland PUC, Newmarket-Tay Power, Orillia Power, PowerStream, and Veridian Connections.

9.2.2 First Nation Community Meetings

On September 24, 2015 the IESO met with Chief Denise Restoule and Councillor Roger Restoule of Dokis First Nation, Chief Barron King of Moose Deer Point First Nation, Chief Warren Tabobondung of Wasauksing First Nation and community representatives. The feedback received focused on the concern that any necessary future infrastructure be planned so that environmental disturbance is minimized and traditional land and space considerations for each community be respected during the planning process. Community members also expressed the preference to have meetings with communities and municipalities at the same time to ensure that everyone is engaged in the same dialogue. Feedback was also shared that communities would like distributed generation proponents to have the same strong relationship with First Nation communities as they do with municipalities to provide communities with a firsthand opportunity to present and protect their needs.

The IESO remains open to additional meetings to support further engagement of the IRRP.

9.2.3 Municipal Meetings

Meetings with area municipalities are one of the first steps in engagement for all regional plans. In September 2015, the Working Group held municipal meetings in Huntsville and Parry Sound to discuss findings for the South Georgian Bay/Muskoka Region and next steps in the process, including identifying potential options to strengthen reliability in the area, increase supply capacity and replaced aging electricity infrastructure nearing end-of-life. Attendees provided insight on population forecasting, challenges with reliability in the area, and the importance of public and community engagement as the planning process develops. It was also indicated that there was a preference for a LAC for each of the two sub-regions instead of one committee for the larger South Georgian Bay/Muskoka Region.

9.3 Bringing Communities to the Table

To continue the dialogue on regional planning, a LAC was established for the Parry Sound/Muskoka Sub-region in spring 2016. The role of the LAC is to provide advice and recommendations on the development of the regional plan as well as to provide input on broader community engagement. LACs are comprised of municipal, Indigenous, environmental, business, sustainability and community representatives. There is currently one general LAC in the planning area, which includes First Nation and Métis representation. The possibility of also forming a First Nation LAC, comprised of representatives from the First Nation communities in the planning area remains, should First Nation communities request an additional forum for community discussions. All general LAC meetings are open to the public and meeting information is posted on the dedicated engagement webpage, which in this case is the IESO's Parry Sound/Muskoka engagement webpage.[13]

Development of the Parry Sound/Muskoka LAC was completed through a request for nominations process promoted by the following activities: advertisements in nine local newspapers across the planning area; digital (website) advertising in communities throughout the planning area; emails sent to municipal representatives across the region; letters to the Chiefs of the First Nation communities in the area inviting them to appoint a representative to the LAC, and an e-blast sent to the IESO's South Georgian Bay/Muskoka subscribers list.

On June 20, 2016, the Working Group held the inaugural LAC meeting in the Town of Gravenhurst. The focus of the meeting was to introduce the regional planning process to the newly formed LAC, provide an overview of the electricity infrastructure supplying the area, and touch upon key electricity needs and issues in the Parry Sound/ Muskoka Sub-region to be discussed in greater detail at subsequent LAC meetings.

The second LAC meeting was held on September 26, 2016 in the Town of Dwight. LAC members were presented with the draft IRRP recommendations, and had the opportunity to provide their feedback following the meeting to help inform the final report. Materials from both meetings can be accessed online on the IESO's website.[14]

Copies of the meeting summaries from the Parry Sound/Muskoka LAC meetings can be found in Appendix G.

At the September 2016 meeting, the members of the Parry Sound/Muskoka LAC expressed their interest in continuing to meet on a regular basis following the posting of the IRRP. As a result, the LAC will continue to meet until the start of the next planning cycle in 2018. Information about LAC meetings will continue to be posted on the IESO Parry Sound/Muskoka Sub-region engagement webpage and email notifications of meetings will continue to be sent to the broader South Georgian Bay/Muskoka email subscriber list.

---

[13] http://www.ieso.ca/Pages/Participate/Regional-Planning/South-Georgian-Bay-Muskoka/Parry-Sound-Muskoka-sub-region.aspx

[14] http://www.ieso.ca/Pages/Participate/Regional-Planning/South-Georgian-Bay-Muskoka/Parry-Sound-Muskoka-sub-region.aspx

10. Conclusion

This report documents the regional planning process that has been carried out for the Parry Sound/Muskoka Sub-region and fulfills the OEB's regional planning requirement for the sub-region. The IRRP identifies electricity needs in this sub-region over the 20-year period from 2015 to 2034 and recommends a set of actions to minimize the frequency and duration of power outages and to ensure that the regional electricity system has adequate supply to support growth.

The Parry Sound/Muskoka Sub-region Working Group will continue to meet regularly throughout the implementation of the plan to monitor progress and developments in the sub-region, and will produce annual updates that will be posted on the IESO website[15]. To support development of the plan, a number of actions have been identified to develop alternatives, engage with communities, and monitor growth in the area. Responsibility has been assigned to appropriate members of the Working Group for these actions. Information gathered and lessons learned from these activities will inform development of the next iteration of the IRRP for the Parry Sound/Muskoka Sub-region. The plan will be revisited according to the OEB-mandated 5-year schedule.

BARRIE / INNISFIL SUB-REGION INTEGRATED REGIONAL RESOURCE PLAN

Part of the South Georgian Bay/Muskoka Planning Region | December 16, 2016

Integrated Regional Resource Plan

Barrie/Innisfil Sub-region

This Integrated Regional Resource Plan ("IRRP") was prepared by the Independent Electricity System Operator ("IESO") pursuant to the terms of its Ontario Energy Board licence, EI-2013-0066.

The IESO prepared the IRRP on behalf of the Barrie/Innisfil Sub-region Working Group (the "Working Group"), which included the following members:

- Independent Electricity System Operator
- PowerStream Inc.
- InnPower Corporation
- Hydro One Networks Inc. (Distribution)
- Hydro One Networks Inc. (Transmission)

The Working Group assessed the adequacy of electricity supply to customers in the Barrie/Innisfil Sub-region over a 20-year period; developed a flexible, comprehensive, integrated plan that considers opportunities for coordination in anticipation of potential demand growth scenarios and varying supply conditions in the Barrie/Innisfil Sub-region; and developed an implementation plan for the recommended options, while maintaining flexibility in order to accommodate changes in key conditions over time.

The Working Group members agree with the IRRP's recommendations and support implementation of the plan through the recommended actions, subject to obtaining all necessary regulatory and other approvals.

1. Introduction

This Integrated Regional Resource Plan ("IRRP") addresses the electricity needs for the Barrie/Innisfil Sub-region over the next 20 years. This report was prepared by the Independent Electricity System Operator ("IESO") on behalf of the technical Working Group composed of the IESO, PowerStream Inc. ("PowerStream"), InnPower Corporation ("InnPower"), Hydro One Distribution and Hydro One Transmission.[1]

In Ontario, planning to meet the electrical supply and reliability needs of a large area or region is done through regional electricity planning, a process that was formalized by the Ontario Energy Board ("OEB" or "Board") in 2013. In accordance with the OEB's regional planning process, transmitters, distributers and the IESO are required to carry out regional planning activities for 21 electricity planning regions at least once every five years. The Barrie/Innisfil Sub-region is within the South Georgian Bay/Muskoka planning region, one of the OEB's 21 identified areas (Figure 1-1).

Figure 1-1: Map of the South Georgian Bay/Muskoka Region

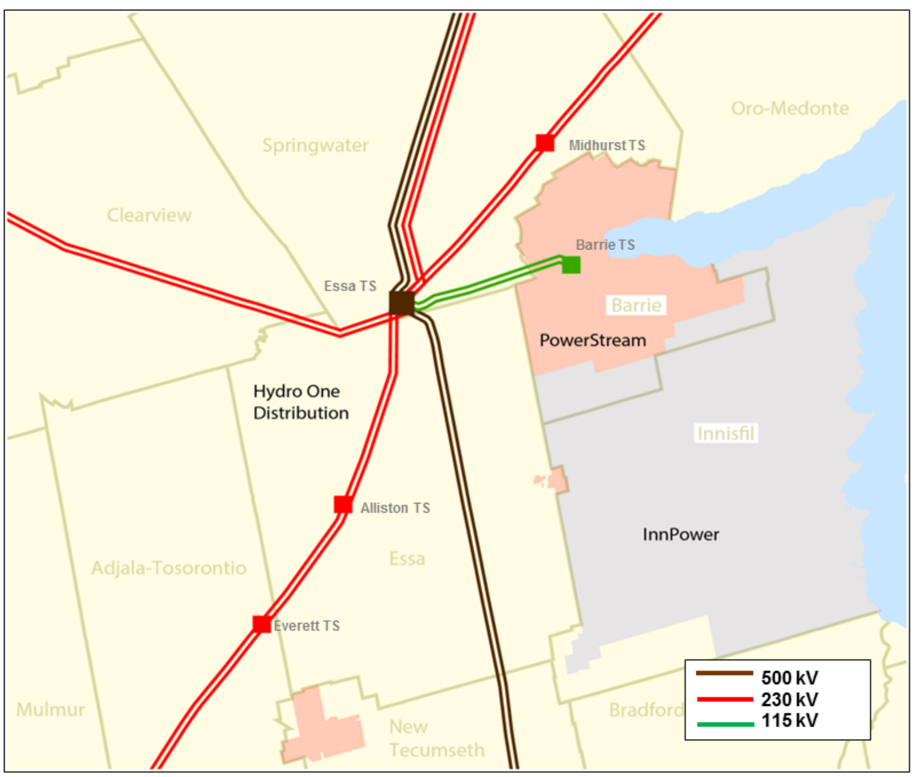
[1] For the purpose of this report, "Hydro One Transmission" and "Hydro One Distribution" are used to differentiate the transmission and distribution accountabilities of Hydro One Networks Inc. ("Hydro One"), respectively.

The Barrie/Innisfil Sub-region roughly encompasses the following municipalities:

- City of Barrie
- Town of Innisfil
- Township of Essa
- Township of Springwater
- Township of Clearview
- Township of Mulmur
- Township of Adjala-Tosorontio
- Town of New Tecumseth
- Town of Bradford West Gwillimbury

The study is focused on addressing the forecast load growth in south Barrie and the Town of Innisfil; however, it considers other needs throughout the sub-region. The study area is shown in Figure 1-2, along with the service area of each local distribution company ("LDC") in the sub-region.

Figure 1-2: Map of Barrie/Innisfil Sub-region



This IRRP identifies power system capacity and reliability requirements, and coordinates the options to meet customer needs in the sub-region over the next 20 years. Specifically, this IRRP identifies immediate investments that are required to meet near- and medium-term needs in the sub-region, respecting the lead time for development.

This IRRP also identifies options to meet long-term needs, but given forecast uncertainty, the longer development lead time and the potential for technological change, the plan maintains flexibility for long-term options and does not recommend specific investments or projects at this time. Instead, the long-term plan identifies near-term actions to consider alternatives, engage with the community, and gather information to lay the groundwork for determining options for future analysis. These actions are intended to be completed before the next IRRP cycle, scheduled for 2020 or sooner, depending on demand growth, so that the results can inform decisions should any be needed at that time.

This report is organized as follows:

- A summary of the recommended plan for the Barrie/Innisfil Sub-region is provided in Section 2;
- The process and methodology used to develop the plan are discussed in Section 3;
- The context for electricity planning in the Barrie/Innisfil Sub-region and the study scope are discussed in Section 4;
- Demand forecast scenarios, and conservation and distributed generation ("DG") assumptions, are described in Section 5;
- Electricity needs in the Barrie/Innisfil Sub-region are presented in Section 6;
- Alternatives and recommendations for meeting needs are addressed in Sections 7 and 8;
- A summary of engagement to date and moving forward is provided in Section 9; and
- A conclusion is provided in Section 10.

2. The Integrated Regional Resource Plan

The Barrie/Innisfil Sub-region IRRP provides recommendations to address the sub-region's forecast electricity needs over the next 20 years, based on the application of the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC"). This IRRP identifies forecast electricity needs in the sub-region over the near term (up to five years, or 2015 through 2019), medium term (six to 10 years, or 2020 through 2024) and longer term (11-20 years, or 2025 through 2034). These planning horizons are distinguished in the IRRP to reflect the different levels of forecast certainty, lead time for development, and planning commitment required over these time horizons. The IRRP was developed based on consideration of planning criteria, including reliability, cost, feasibility and flexibility; and, in the near term, it seeks to maximize the use of existing electricity system assets.

This IRRP identifies and recommends specific projects for implementation in the near term. This is necessary to ensure that they are in-service in time to address the area's more urgent needs, respecting the lead-time for development of the recommended projects or actions. This IRRP also identifies possible long-term electricity needs. However, as these needs are forecast to arise in the future, it is not necessary, nor would it be prudent given forecast uncertainty and the potential for technological change, to recommend specific projects at this time. Instead, near-term actions are identified to gather information and lay the groundwork for future options. These actions are intended to be completed before the next IRRP cycle so that their results can inform further discussion at that time.

The Barrie/Innisfil IRRP includes a near-term project to rebuild Barrie Transformer Station ("TS"). Given the timing of the need, the Working Group issued a hand-off letter in December 2015 to request that Hydro One begin development work on this project.[2] The need and rationale for this near-term project are outlined in Section 6.2.1. The full near-, medium-, and long-term plans are summarized below.

2.1 Near-Term and Medium-Term Plan (2015-2024)

The plan to meet the near- and medium-term needs of electricity customers in the Barrie/Innisfil Sub-region was developed to maximize the use of the existing electricity system in consideration of planning criteria such as reliability, cost, and feasibility, as outlined earlier in

[2] http://www.ieso.ca/Documents/Regional-Planning/South-Georgian-Bay-Muskoka/Barrie/Innisfil_IESO-letter-to-HydroOne-20151207.pdf

Section 2. The near-term plan was also developed to be consistent with the long-term development of the sub-region's electricity system.

To address the near-term end-of-life and capacity needs at Barrie TS, the aforementioned new transmission project to rebuild Barrie TS is underway. The near- and medium-term plan also includes a load transfer to be completed by PowerStream to relieve Barrie TS, and a feeder relocation and expansion project, to be carried out by InnPower and Hydro One Distribution, to increase InnPower's feeder supply capacity from Barrie TS. The elements of the plan are outlined in further detail below.

Recommended Actions

1. Rebuild and Uprate Barrie TS and E3/4B to 230 kV

To mitigate challenges posed by both Barrie TS and related 115 ("kilovolt") kV supply infrastructure reaching end-of-life, and to address the near-term capacity needs at Barrie TS, Hydro One is developing the "Barrie Area Transmission Reinforcement" project. The project will rebuild the existing Barrie TS and uprate its existing supply from 115 kV to 230 kV, increasing the supply capacity to the area. A Class Environmental Assessment ("EA") process is currently underway. The existing Barrie TS site is well situated for supplying the near- and medium-term forecast load growth in the south Barrie and Innisfil areas. The targeted in-service date for the project is the end of 2020.

2. PowerStream Load Transfer – From Barrie TS to Midhurst TS

PowerStream is planning to transfer up to 27 ("megawatt") MW of load from Barrie TS to Midhurst TS by 2020, assuming full data centre load growth. This will increase the incremental capacity available at Barrie TS and provide additional transfer points between Barrie TS and Midhurst TS. This will address near-term capacity needs and provide additional reliability benefits during emergency situations.

3. Relocate and Expand InnPower Feeder Supply from Barrie TS

Currently, Hydro One Distribution is allocated one feeder from the existing Barrie TS, the 13M3 feeder, which is used solely to supply their embedded LDC InnPower. The capacity of this feeder is forecast to be exceeded in 2020. The rebuilt Barrie TS will include one additional feeder position, which can be used to address this need. Additionally, the existing InnPower supply uses an idle Hydro One Transmission right-of-way ("ROW"). The use of this ROW for sub-transmission purposes limits future long-term options for new transmission facilities in the south Barrie and Innisfil area. It is recommended that Hydro One Distribution and InnPower develop a plan to build new 44 kV feeders to support InnPower's forecast growth and enable the existing 13M3 feeder to be relocated out of the Hydro One Transmission corridor. The proposed in-service date for the new feeders is the end of 2020.

2.2 Longer-Term Plan (2025-2034)

In the long-term, the Barrie/Innisfil Sub-region's electricity system is expected to reach its capacity. This is based on the IRRP planning forecast presented in Section 5.6, which is consistent with municipal growth plans and the province's *Places to Grow Act, 2005*. Beginning in the mid to late 2020s, there is a forecast need for new transformer station capacity, particularly in the south Barrie and Innisfil areas. The capacity of the upgraded Barrie TS and the existing Everett TS are forecast to be exceeded in 2026 and 2027, respectively. Transformer station capacity in the Barrie area is forecast to be exceeded in 2031, and the sub-region's transformer capacity is forecast to be exceeded by the end of the study period in 2034. Additionally, in 2034, there is a need for supply capacity for the broader South Georgian Bay/Muskoka Region based on the ratings of the 230/500 kV autotransformers at Essa TS. Any plans to address the station capacity needs must be coordinated with a plan to address this long-term transmission system needs at Essa TS, as they are interrelated.

A number of alternatives are possible to meet the sub-region's long-term needs. While specific solutions do not need to be committed today, it is appropriate to begin work now to gather information, monitor developments, engage the community, and develop alternatives to support decision making in the next iteration of the IRRP.

This IRRP sets out near-term actions required to ensure that options remain available to address future needs, if and when they arise.

Recommended Actions

1. Implement Conservation and Distributed Generation

The implementation of provincial conservation targets established in the 2013 Long-Term Energy Plan ("LTEP") is a key near-term action of the Barrie/Innisfil Sub-region's long-term plan. In developing the demand forecast, peak demand impacts associated with meeting provincial targets were assumed before identifying the residual needs; this is consistent with the province's Conservation First policy.[3] Meeting provincial conservation targets amounts to approximately 37 MW, or 19%, of the forecast demand growth, during the first 10 years, and a total of 82 MW, or 23% of the total forecast demand growth, by the end of the study period.

To ensure these savings materialize, it is recommended that the LDCs' conservation efforts be focused as much as possible on measures that will contribute to meeting the Conservation First energy targets while also maximizing peak demand reductions. The monitoring of conservation success will lay the foundation for the long-term plan by evaluating the performance of specific conservation measures in the sub-region and assessing potential for additional conservation.

Provincial programs that encourage the development of DG can also contribute to reducing peak demand in the sub-region; these will, in part, depend on local interest and opportunities for development. The LDCs and the IESO will continue their activities to support these initiatives and monitor their impacts.

2. Barrie TS Local Achievable Potential Study

Due to the long-term capacity need forecast for the south Barrie and Innisfil areas, PowerStream and InnPower, with support from the IESO's conservation fund, will be undertaking a Local Achievable Potential ("LAP") study for the Barrie TS service area. This study aims to determine demand savings potential through conservation and demand management ("CDM" or "conservation") for the Barrie TS area, above and beyond what is attributed to the LTEP targets already accounted for in the planning demand forecast. The study will also help determine options for acquiring this potential (e.g., incentives and adders to existing CDM programs, new programs, behind-the-meter generation, energy storage, etc.). The study will provide a better understanding of the costs and feasibility of conservation and demand management measures to address capacity needs in the area to better inform options for the next planning cycle. The study may also examine options to manage new demand from increased electrification that may result from Ontario's Climate Change Action Plan.

---

[3] Conservation First: A Renewed Vision for Energy Conservation in Ontario: http://www.energy.gov.on.ca/en/conservation-first/

3. Undertake Community Engagement

Broad community and public engagement, including discussions with local Indigenous communities, is essential to develop the long-term plan. It is recommended that engagement involve several phases addressing: public education/awareness of electricity issues, planning, technologies, and regulatory requirements; fostering an understanding of community growth and its relationship to electricity needs; understanding the pros and cons of various alternatives to meeting long-term needs; and obtaining input on community preferences for various approaches to meeting longer-term needs.

To obtain input and advice on the engagement plans for the Barrie/Innisfil Sub-region, the Working Group will establish a Local Advisory Committee ("LAC") consisting of community representatives and stakeholders.

4. Increase the Limited Time Rating of Everett TS

The existing ratios of the current transformers[4] ("CT") at Everett TS are causing a limitation beyond the limited time rating[5] ("LTR") of the station transformers. Since the minimum station load has increased sufficiently, Hydro One can update the CT ratios, allowing the full LTR of the existing transformers to be utilized. Everett TS is forecast to exceed its existing de-rated LTR in 2027; the Working Group will monitor the station load and request that Hydro One take action to change the CT ratios if necessary before the next regional planning cycle.

5. Explore Conversion of the 13M3 115 kV Corridor to 230 kV

Metrolinx has applied for connection to the transmission system in the Barrie area. They will connect to the new 230 kV transmission lines created as part of the Barrie Area Transmission Reinforcement project. It is recommended that Hydro One works to ensure the development work for the Metrolinx connection project will allow for future expansion of the transmission system south toward Innisfil. The Working Group will monitor the need for additional development work for the corridor between planning cycles.

---

[4] Current transformers are instrument transformers used for measurements for metering/loading data or for generating signals for protective devices. Since the current on the actual system is usually too high to be either economically or practically measured or to supply a signal to a protective device, the current transformer lowers the current to an acceptable level. The ratio between these two current values is the "CT ratio".

[5] The limited time rating is a property of an individual transformer, representing its ability to withstand the thermal stress of short duration use (10 days) at the given capacity, above its standard rating, without experiencing any degradation in asset condition as a result.

6. Develop Community-Based Solutions

There is the potential for emerging technologies and innovative solutions to address the long-term needs in the Barrie/Innisfil Sub-region. These could include combinations of conservation, district heating, local generation, storage, off-grid solutions, and other emerging technologies. However, before such technologies can be relied upon to address regional capacity needs, it is necessary to identify the opportunities available in the Barrie area, test the performance of these technologies, and demonstrate how these technologies can be "bundled" to provide firm capacity resources at the local level. In addition, the cost responsibility and payment mechanisms for these options still need to be assessed.

PowerStream has implemented a pilot project in their southern service territory to study the benefits and economics of aggregated customer-side generation and storage. The results of this study can be used to inform future discussion and the development of non-wires solutions for the long-term needs in the sub-region for the next planning cycle.

7. Monitor Demand Growth, Conservation Achievement and Distributed Generation Uptake

On an annual basis, the IESO, with the Working Group, will review CDM achievement, the uptake of provincial distributed generation projects, and actual demand growth in the Barrie/Innisfil Sub-region. This information will be used to determine when decisions on the long-term plan are required, and to inform the next cycle of regional planning for the area. Information on conservation and DG is also a useful input into the ongoing development of non-wires options as potential long-term solutions.

8. Initiate the Next Regional Planning Cycle Early, if Needed

Along with the indices outlined in point 7 above, the Working Group will monitor changes in growth targets, progress in servicing greenfield lands, transit electrification in the area, results of the LAP study for Barrie TS, and any significant changes in the area's forecast growth. If monitoring activities determine that area growth is on pace with the high forecast scenario, it may be necessary to initiate the next iteration of the regional planning process earlier than 2020 given the lead time for the long-term supply options.

3. Development of the IRRP

3.1 The Regional Planning Process

In Ontario, planning to meet the electricity needs of customers at a regional level is done through regional planning. Regional planning assesses the interrelated needs of a region—defined by common electricity supply infrastructure—over the near, medium, and long term and develops a plan to ensure cost-effective, reliable electricity supply. Regional plans consider the existing electricity infrastructure in an area, forecast growth and customer reliability, evaluate options for addressing needs, and recommend actions.

Regional planning has been conducted on an as needed basis in Ontario for many years. Most recently, the former Ontario Power Authority ("OPA") carried out planning activities to address regional electricity supply needs. The OPA conducted joint regional planning studies with distributors, transmitters, the IESO and other stakeholders in regions where a need for coordinated regional planning had been identified.

In the fall of 2012, the Board convened a Planning Process Working Group ("PPWG") to develop a more structured, transparent, and systematic regional planning process. This group was composed of industry stakeholders including electricity agencies, utilities, and stakeholders, and in May 2013, the PPWG released its report to the Board[6] ("PPWG Report"), setting out the new regional planning process. Twenty-one electricity planning regions were identified in the PPWG Report, and a phased schedule for completion was outlined. The Board endorsed the PPWG Report and formalized the process timelines through changes to the Transmission System Code and Distribution System Code in August 2013, as well as through changes to the OPA's licence in October 2013. The OPA's licence changes required it to lead a number of aspects of regional planning. After the merger of the IESO and the OPA on January 1, 2015, the regional planning roles identified in the OPA's licence were to become the responsibility of the new IESO

The regional planning process begins with a Needs Assessment process performed by the transmitter, which determines whether there are needs requiring regional coordination. If regional planning is required, the IESO then conducts a Scoping Assessment to determine what type of planning is required for each region. A Scoping Assessment explored whether a

---

[6] http://www.ontarioenergyboard.ca/OEB/_Documents/EB-2011-0043/PPWG_Regional_Planning_Report_to_the_Board_App.pdf

comprehensive IRRP is required, which considers conservation, generation, transmission, and distribution solutions, or whether a more limited "wires" solution is the preferable option, in which case a transmission and distribution focused Regional Infrastructure Plan ("RIP") can be undertaken instead. There may also be regions where infrastructure investments do not require regional coordination and so can be planned directly by the distributor and transmitter outside of the regional planning process. At the conclusion of the Scoping Assessment, the IESO produces a report that includes the results of the Needs Screening process and a preliminary Terms of Reference. If an IRRP is the identified outcome, the IESO is required to complete the IRRP within 18 months. If an RIP is the identified outcome, the transmitter takes the lead and has six months to complete it. Both RIPs and IRRPs are to be updated at least every five years. The draft Scoping Assessment Outcome Report is posted to the IESO's website for a two week public comment period prior to finalization.

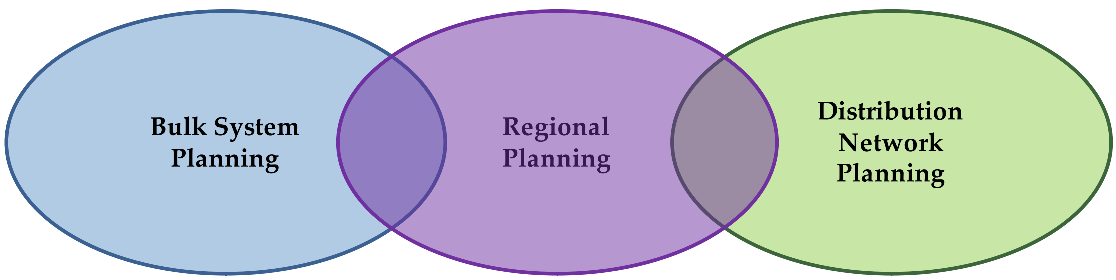
The final IRRPs and RIPs are posted on the IESO's and the relevant transmitter's websites, and may be referenced and submitted to the Board as supporting evidence in rate or "Leave to Construct" applications for specific infrastructure investments. These documents are also useful for municipalities, First Nation communities and Métis community councils for planning, and for conservation and energy management purposes. They are also a useful source of information for individual large customers that may be involved in the region, and for other parties seeking an understanding of local electricity growth, CDM and infrastructure requirements. Regional planning is not the only type of electricity planning that is undertaken in Ontario. As shown in Figure 3-1, there are three levels of planning that are carried out for the electricity system in Ontario:

- Bulk system planning
- Regional system planning
- Distribution system planning

Planning at the bulk system level typically considers the 230 kV and 500 kV network and examines province-wide system issues. Bulk system planning considers not only the major transmission facilities or "wires", but it also assesses the resources needed to adequately supply the province. This type of planning is typically carried out by the IESO pursuant to government policy. Distribution planning, which is carried out by LDCs, considers specific investments in an LDC's territory at distribution level voltages.

Regional planning can overlap with bulk system planning. For example, overlaps can occur at interface points where there may be regional resource options to address a bulk system issue. Similarly, regional planning can overlap with the distribution planning of LDCs. For example, overlaps can occur when a distribution solution addresses the needs of the broader local area or region. Therefore, it is important for regional planning to be coordinated with both bulk and distribution system planning, as it is the link between all levels of planning.

Figure 3-1: Levels of Electricity System Planning



Bulk System Planning

- 500 kV & 230 kV transmission
- Interconnections
- Inter-area network transfer capabilities
- System reliability (security and adequacy) to meet NERC, NPCC, ORTAC
- Congestion and system efficiency
- System supply and demand forecasts
- Incorporation of large generation
- Typically medium- and long-term focused

Regional Planning

- 230 kV & 115 kV transmission
- 115/230 kV autotransformers and associated switchyard facilities
- Customer connections
- Load supply stations
- Regional reliability (security and adequacy) to meet NERC, NPCC & ORTAC
- ORTAC local area reliability criteria
- Regional/local area generation & CDM resources
- Typically near- and medium-term focused

Distribution Network Planning

- Transformer stations to connect to the transmission system
- Distribution network planning (e.g. new & modified DX facilities)
- Distribution system reliability (capacity and security)
- Distribution connected generation and CDM resources
- LDC demand forecasts
- Near- and medium-term focused

By recognizing the linkages with bulk and distribution system planning, and coordinating the multiple needs identified within a region over the long term, the regional planning process provides a comprehensive assessment of a region's electricity needs. Regional planning aligns near- and long-term solutions and puts specific investments and recommendations coming out of the plan into perspective. Furthermore, regional planning optimizes ratepayer interests by avoiding piecemeal planning and asset duplication, and allows Ontario ratepayer interests to be represented along with the interests of LDC ratepayers, and individual large customers. IRRPs evaluate the multiple options that are available to meet the needs, including conservation, generation, and "wires" solutions. Regional plans also provide greater transparency through engagement in the planning process, and by making plans available to the public.

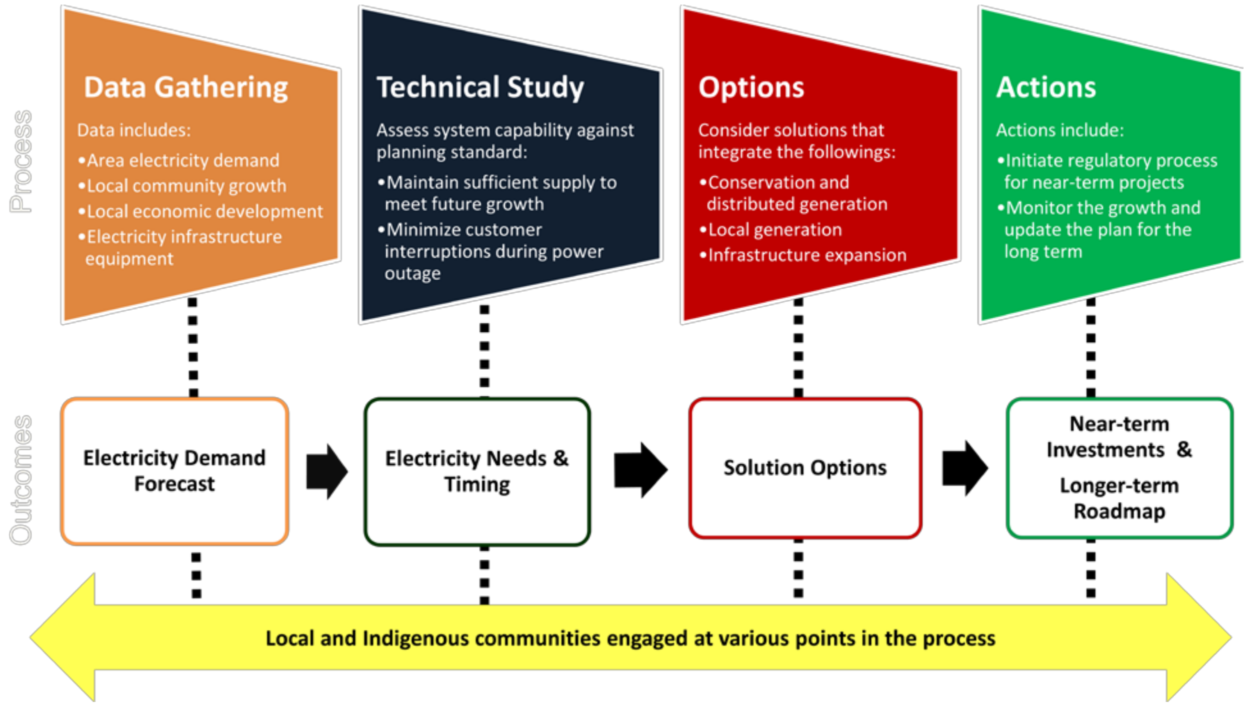
3.2 The IESO's Approach to Regional Planning

IRRPs assess electricity system needs for a region over a 20-year period. The 20-year outlook anticipates long-term trends so that near-term actions are developed within the context of a longer-term view. This enables coordination and consistency with the long-term plan, rather than simply reacting to immediate needs.

In developing an IRRP, a different approach is taken to developing the plan for the first 10 years of the plan—the near and medium term—as compared to the longer-term period of 10-20 years. The plan for the first 10 years is developed based on best available information on demand, conservation, and other local developments. Given the long lead-time to develop electricity infrastructure, near-term electricity needs require prompt action to implement the specified solutions. By contrast, the long-term plan is characterized by greater forecast uncertainty and longer development lead-time; as such solutions do not need to be committed to immediately. Given the potential for changing conditions and technological development, the IRRP for the long term is more directional, focusing on developing and maintaining the viability of options for the future, and continuing to monitor demand forecast scenarios.

In developing an IRRP, the IESO and the Working Group carry out a number of steps. These steps include electricity demand forecasts; technical studies to determine electricity needs and the timing of these needs; the development of potential options; and a recommended plan including actions for the near and long term. Throughout this process, engagement is carried out with stakeholders and Indigenous communities who may have an interest in the area. The steps of an IRRP are illustrated in Figure 3-2, below.

Figure 3-2: Steps in the IRRP Process



The IRRP report documents the inputs, findings and recommendations developed through the process described above, and provides recommended actions for the various entities responsible for plan implementation. Where "wires" solutions are included in the plan recommendations, the completion of the IRRP triggers the initiation of the transmitter's RIP process to develop those options. Other recommendations in the IRRP may include: development of conservation, local generation, community engagement, or information gathering to support future iterations of the regional planning process in the region or sub-region.

3.3 Barrie/Innisfil Sub-region Working Group and IRRP Development

The process to develop the Barrie/Innisfil IRRP was initiated in 2015 with the release of the Needs Assessment report for the South Georgian Bay/Muskoka Region. This product was prepared by Hydro One Transmission with participation from the IESO, PowerSteam, Innisfil Hydro Distribution Inc. ("Innisfil Hydro"),[7] Orangeville Hydro Ltd., Veridian Connections Inc. and Hydro One Distribution. The Needs Screening process was carried out to identify needs

[7] Innisfil Hydro Distribution Inc. became InnPower Corporation on November 4, 2014. This was reflected the OEB's amendment to the licensee name on their electricity distribution licence on December 4, 2014 (EB-2014-0297).

that may require coordinated regional planning in the South Georgian Bay/Muskoka Region. The subsequent Scoping Assessment Report produced by the IESO recommended that the needs identified for the Barrie/Innisfil Sub-region should be further pursued through an IRRP owing to the potential for coordinated solutions and significant assets reaching end-of-life.

In 2015 the Working Group was formed to develop Terms of Reference for this IRRP, gather data, identify near- to long-term needs in the sub-region, and recommend the near- and medium-term actions.

4. Background and Study Scope

Two planning studies have been conducted in the South Simcoe area – now referred to as the Barrie/Innisfil Sub-region – in the last 12 years.

First, in November 2003, a joint utility planning study was initiated by six LDCs in Simcoe County, one large industrial customer, and Hydro One Transmission, to assess the supply and reliability needs of Simcoe County. The study recommended the implementation of two transmission projects to supply forecast growth in the Meaford/Collingwood and South Simcoe areas: the addition of Everett TS, which came into service in 2007 and the Southern Georgian Bay Transmission Reinforcement, which involved upgrading the 115 kV Essa-to-Stayner line to 230 kV and installing a 230/115 kV autotransformer at Stayner TS, which came into service in 2009.

Second, in 2010, Hydro One Transmission initiated a regional supply planning study of the South Simcoe area. Together with the OPA (now merged with the IESO), PowerStream, Innisfil Hydro, and Hydro One Distribution, Hydro One Transmission prepared a study report in 2011 that recommended the installation of low voltage capacitors at Midhurst TS and Orillia TS, completed in 2012, and recommended that Innisfil Hydro (now InnPower) make a formal request to Hydro One for additional transformation capacity.

Building on these past regional studies and taking into account updates to activities in the region and LDCs' load forecasts, this report presents an IRRP for the Barrie/Innisfil Sub-region for the 20-year period from 2015 to 2034. To set the context for this IRRP, the scope of the planning study and the sub-region's existing electricity system are described in Section 4.1.

4.1 Study Scope

This IRRP develops and recommends options to meet the supply needs of the Barrie/Innisfil Sub-region in the near, medium, and long term. The plan was prepared by the IESO on behalf of the Working Group. The plan includes consideration of forecast electricity demand growth, CDM, transmission and distribution system capability, relevant community plans, developments on the bulk transmission system, and generation uptake through the Feed-in Tariff ("FIT") and other province-wide programs.

This IRRP addresses regional needs in the Barrie/Innisfil Sub-region, including adequacy, security, and relevant end-of-life asset considerations.

The following transmission facilities were included in the scope of this study:

- 230/115 kV autotransformers at Essa TS
- Stations—Barrie TS, Midhurst TS, Alliston TS, and Everett TS
- Transmission circuits—E8/9V, E3/4B, M6/7E (Essa to Midhurst section)

The Barrie/Innisfil Sub-region is supplied from the two 500/230 kV autotransformers at Essa TS. These transformers form part of the bulk transmission system, as they are impacted by changes in the broader Ontario electricity system, rather than the local system. Specifically, the autotransformers are impacted by bulk power system flows on the north-south transmission interface, driven by changing generation and load patterns in northern and southern Ontario. Accordingly, the Essa autotransformers were assessed through a separate bulk planning study by the IESO. However, results of the bulk study that have regional implication are discussed in this IRRP.

The Barrie/Innisfil Sub-region and its supply infrastructure are shown in Figure 4-1 and Figure 4-2.

Figure 4-1: Regional Transmission Facilities

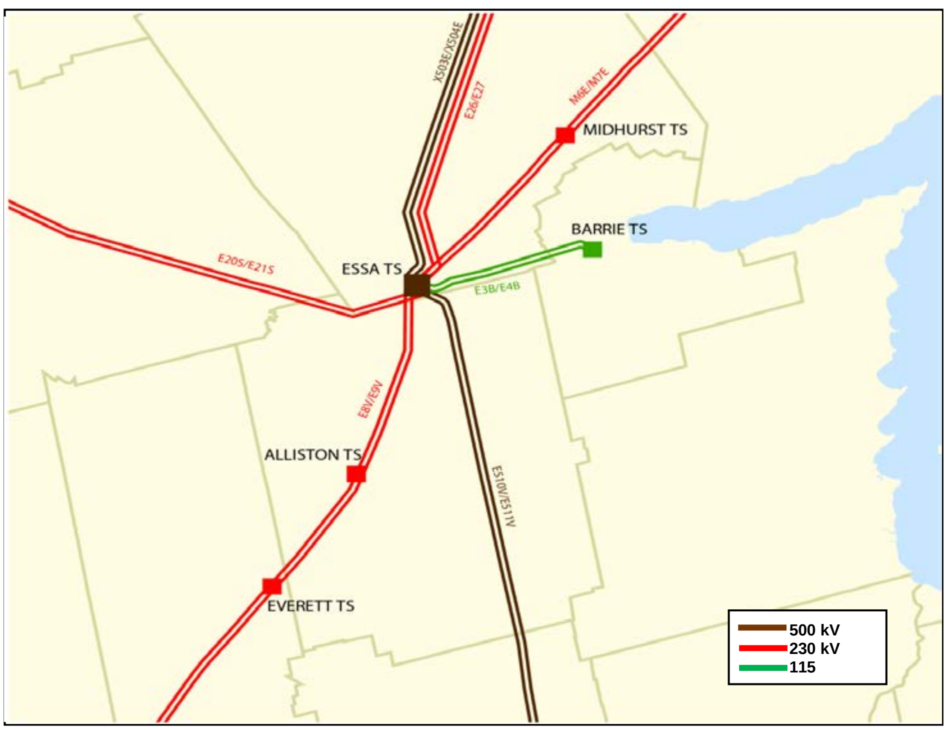


Figure 4-2: Barrie/Innisfil Sub-region Electrical Sub-systems

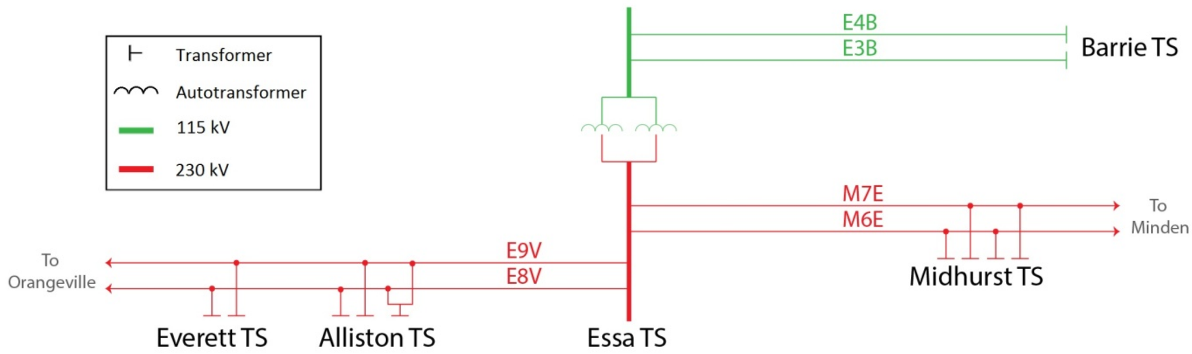


The Barrie/Innisfil IRRP was developed by completing the following steps:

- Preparing a 20-year electricity demand forecast and establishing needs over this timeframe.
- Examining the load meeting capability ("LMC") and reliability of the existing transmission system supplying the Barrie/Innisfil Sub-region, taking into account facility ratings and performance of transmission elements, transformers, local generation, and other facilities such as reactive power devices. Needs were established by applying ORTAC.
- Establishing feasible integrated alternatives to address needs, including a mix of CDM, generation, transmission and distribution facilities, and other electricity system initiatives.
- Evaluating options using decision-making criteria that include: technical feasibility, cost, reliability performance, flexibility, environmental and social factors.
- Developing and communicating findings, conclusions and recommendations.

5. Demand Forecast

This section outlines the forecast of electricity demand within the Barrie/Innisfil Sub-region. It highlights the assumptions made for peak demand load forecasts, and the contribution of conservation and DG to reducing peak demand. The resulting net demand forecast is used in assessing the electricity needs of the area over the planning horizon.

To evaluate the adequacy of the electric system, the regional planning process involves measuring the demand observed at each station for the hour of the year when overall demand in the study area is at a maximum. This is referred to as “coincident peak demand”. Typically this represents the time when assets are most stressed and resources most constrained. This differs from a non-coincident peak, which is measured by summing each station’s individual peak, regardless of whether each station’s peaks occur at a different time than the area’s overall peak.

Within the Barrie/Innisfil Sub-region, the peak loading hour for each year typically occurs in mid-afternoon of the hottest weekday during summer, driven by the air conditioning loads of residential and commercial customers. The Working Group determined the co-incident and non-coincident area peaks for the sub-region are fairly equivalent since they correspond with this weather-related peak. Hence, the non-coincident peak for each station was used as the basis of the load forecast starting point.

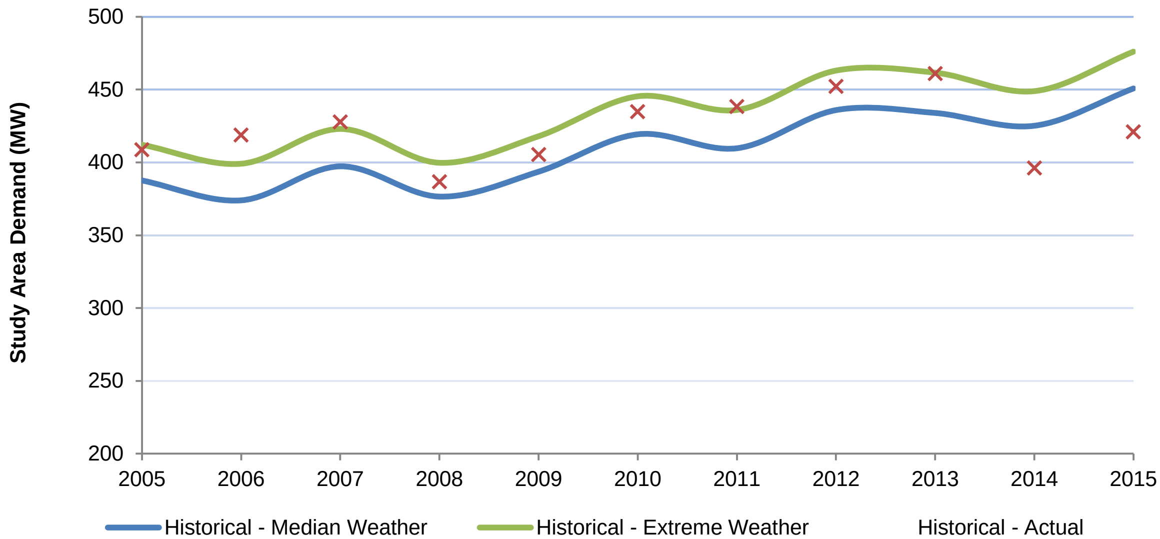
Section 5.1 begins by describing the historic electricity demand trends in the sub-region from 2005 to 2015. Section 5.2 describes the demand forecast used in this study and the methodology used to develop it.

5.1 Historical Demand

The coincident peak electrical demand for the Barrie/Innisfil Sub-region is shown in Figure 5-1. The historical data (in red) shows the coincident peak demand for the year.

The historical demand adjusted for extreme and median weather (in green and blue, respectively) shows the demand at the same hour, but adjusted to reflect the expected behaviour under the applicable weather conditions. Correction factors between historical, median and extreme conditions are produced on a zonal basis by Hydro One, the transmitter in this area.

Figure 5-1: Historical Peak Demand in the Barrie/Innisfil Sub-region



The weather corrected peak shows that demand has been generally increasing since 2005. However, the data for the summer of 2014 and 2015 should be regarded as less reliable due to abnormally cool summer conditions. Although weather correction has been applied in all cases, these methodologies are generally not designed to make such extreme adjustments (i.e., as required for the summers of 2014 and 2015).

5.2 Demand Forecast Methodology

For the purpose of the IRRP, a 20-year planning forecast was developed to assess electricity supply and reliability needs at the regional level.

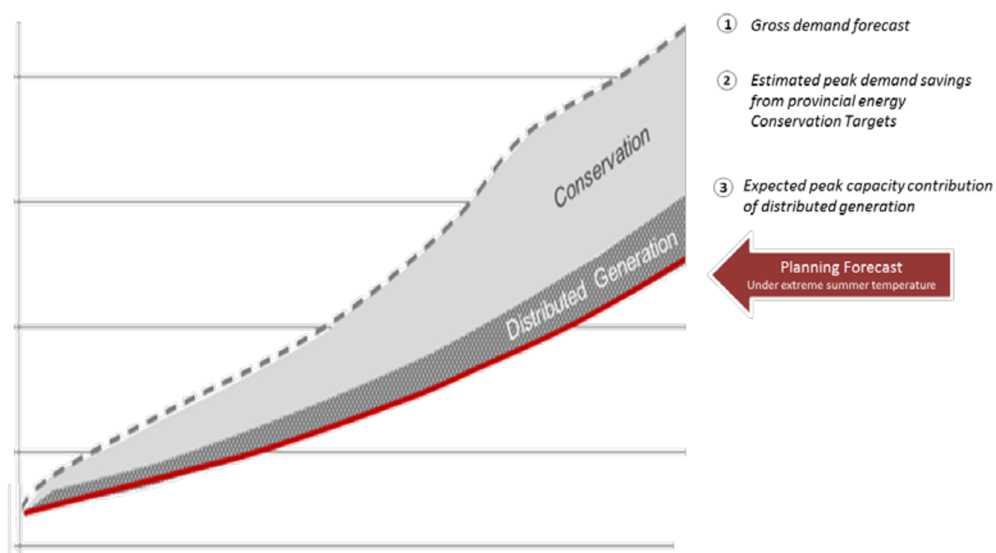
Regional electricity needs are driven by the limits of the transmission infrastructure supplying an area, which is sized to meet peak demand requirements. Regional planning therefore typically focuses on the growth in regional-coincident peak demand.

The 20-year planning forecast is divided notionally into three timeframes. The near term (0-5 years) has the highest degree of certainty; any near-term needs are typically met using regional transmission or distribution solutions as other methods (i.e., DG or CDM) are still being tested to determine if their lead-times will be suitable to meet near-term timelines. The medium term (5-10 years), however, provides more lead time to develop and incorporate DG and CDM options.

The long-term forecast covers the 10-20 year period and has the lowest degree of certainty. It is used for the identification of potential longer-term needs, and for the consideration and development of integrated solutions (including CDM, DG, and major transmission upgrades). To address the relative uncertainty of long-term needs, a high and a low forecast scenario were created. Early identification of potential long-term needs and potential solutions makes it possible to begin engagement with the local community and all levels of government long before the need is triggered. This provides the greatest opportunity to gain input on decision making, and to ensure local planning can account for new infrastructure.

The regional peak demand forecast was developed as shown in Figure 5-2. Gross demand forecasts, assuming normal-year weather conditions, were provided by the LDCs and the transmission-connected customers in each LDC's service territory. The LDC forecasts are based on growth projections included in regional and municipal plans, which in turn reflect the province's Growth Plan for the Greater Golden Horseshoe, 2006, as amended. These forecasts were then modified to produce a planning forecast (i.e., they were adjusted to reflect the peak demand impacts of provincial conservation targets, DG contracted through provincial programs such as FIT and microFIT, and to reflect extreme weather conditions). The planning forecast was then used to assess any growth-related electricity needs in the region.

Figure 5-2: Development of Demand Forecast



Using a planning forecast that is net of provincial conservation targets is consistent with the province's Conservation First policy. However, it also assumes that the targets will be met and that the targets, which are energy-based, will produce corresponding local peak demand reductions. An important aspect of plan implementation will be monitoring the actual peak demand impacts of conservation programs delivered by the area LDCs and, as necessary, adapting the plan. Additional details related to the development of the demand forecast are provided in Appendix A.

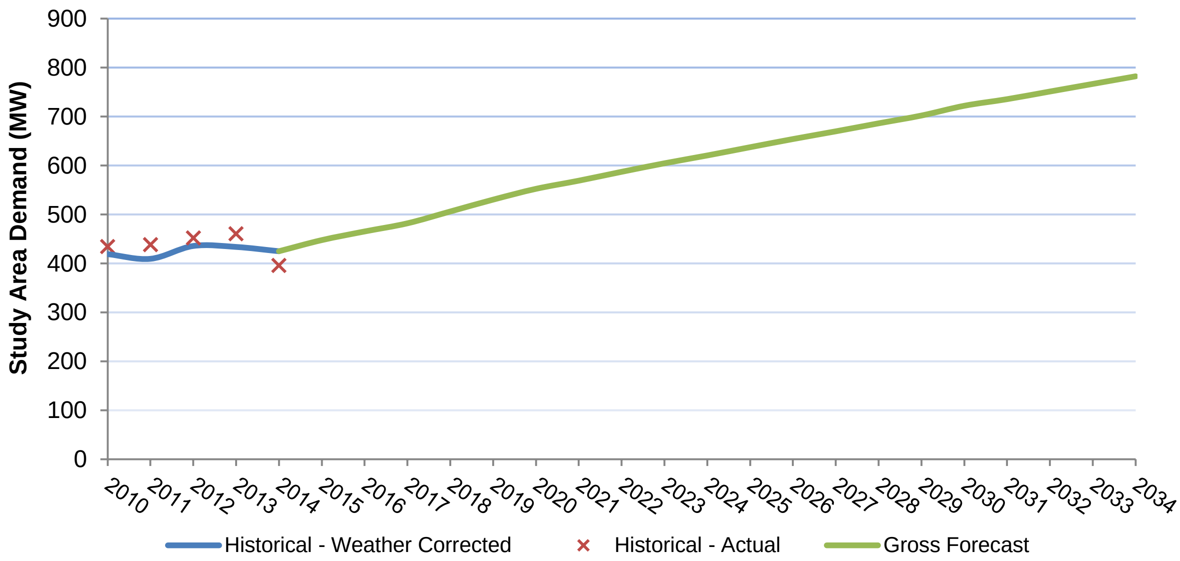
5.3 Gross Demand Forecast

Each participating LDC in the Barrie/Innisfil Sub-region prepared gross demand forecasts at the transformer station level, or at the bus level for multi-bus stations. Gross demand forecasts account for increases in demand from new or intensified development, but they do not account for the impact of new conservation measures such as codes and standards or demand response ("DR") programs. However, LDCs are expected to account for changes in consumer demand resulting from typical efficiency improvements and response to increasing electricity prices, which is termed "natural conservation".

LDCs have the best information on customer and regional growth expectations in the near and medium term since they have the most direct involvement with their customers. Most LDCs cited alignment with municipal and regional official plans as a primary source for input data. Other common considerations included known connection applications and typical electrical demand for similar customer types. More details on the LDCs' load forecast assumptions can be found in Appendix A.

The graph below shows the gross demand forecast information provided by LDCs for the Barrie/Innisfil Sub-region, with historical data points provided for comparison. The gross forecast provided by the LDCs, shown in Figure 5-3, is for median weather conditions.

Figure 5-3: Barrie/Innisfil Sub-region Gross Forecast



Total annual growth averages 3% per year for the study area over the 20-year planning horizon. Growth is highest in the first 10 years at an average of 3.7% per year, before reducing to an average of 2.3% per year for the following 10 years. Although the forecast is shown for the entire study area, individual stations are forecast to experience different growth rates.

To address development uncertainty in the area, the LDCs also produced a forecast for both a high and a low growth scenario. While the needs assessment was conducted based on the reference load growth scenario, the high and low forecasts were used for evaluating the robustness of different medium- and long-term options. The regional gross growth rate ranges from 2.2% per year in the low scenario to 3.9% per year in the high.

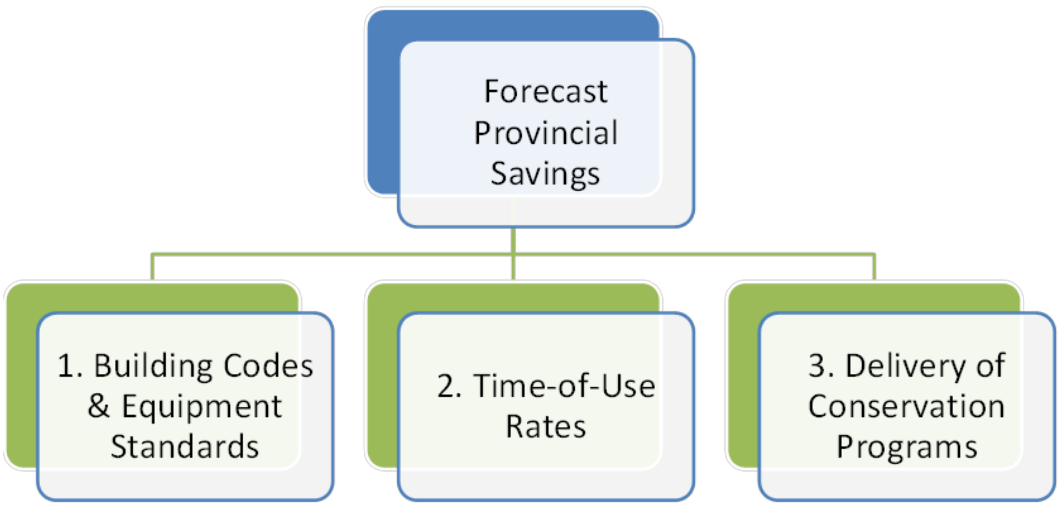
The forecasts were provided based on best available information and, as appropriate, will be updated going forward. The gross demand forecasts by station for the reference, high and low scenarios are provided in Appendix A.

5.4 Conservation Assumed in the Forecast

Conservation is achieved through a mix of program-related activities, rate structures, and mandated efficiencies from building codes and equipment standards. It plays a key role in maximizing the use of existing assets and maintaining reliable supply by offsetting a portion of a region's growth, helping to keep demand within equipment capability. The conservation savings forecast for the Barrie/Innisfil Sub-region have been applied to the gross peak demand forecast for median weather, along with DG resources (described in Section 5.5), to determine the net peak demand for the sub-region.

In December 2013 the Ministry of Energy released a revised LTEP that outlined a provincial conservation target of 30 terawatt-hours ("TWh") of energy savings by 2032. To estimate the impact of the conservation savings in the sub-region, in terms of impact to peak demand, the forecast provincial savings were divided into three main categories:

Figure 5-4: Categories of Conservation Savings



1. *Savings due to Building Codes & Equipment Standards*
2. *Savings due to Time-of-Use Rate Structures*
3. *Savings due to the delivery of Conservation Programs*

For the Barrie/Innisfil Sub-region, the impacts of the estimated savings for each category were further broken down by the residential, commercial and industrial customer sectors. The IESO worked together with the LDCs to establish a methodology to estimate the electrical demand impacts of the energy targets by these three customer sectors. This provides a better resolution for the forecast conservation, as conservation potential estimates vary by sector due to different energy consumption characteristics and applicable measures.

For the Barrie/Innisfil Sub-region, LDCs were requested to provide both their gross demand forecast and a breakdown of electrical demand by sector for each TS. Once sectoral gross demand at each TS was estimated, the next step was to estimate peak demand savings for each conservation category: codes and standards, time-of-use rates, and conservation programs. The estimate for each of the three savings groups was done separately due to their unique characteristics and the available data. The final estimated conservation peak demand reduction, 82 MW by 2034, was applied to the gross demand to create the planning forecast. Table 5-1 provides the conservation peak demand savings for a selection of the forecast years.

Table 5-1: Peak Demand MW Savings from 2013 LTEP Conservation Targets, Select Years

Year	2016	2018	2020	2022	2024	2026	2028	2030	2032
Savings (MW)	5	12	19	28	37	48	60	73	80

Additional conservation forecast details are provided in Appendix A.

5.5 Distributed Generation Assumed in the Forecast

In addition to conservation resources, DG in the Barrie/Innisfil Sub-region is also forecast to offset peak demand requirements. The introduction of the *Green Energy and Green Economy Act, 2009*, and the associated development of Ontario's FIT program, has increased the significance of distributed renewable generation in Ontario. This renewable generation, while intermittent in nature, contributes to meeting the electricity demands of the province.

After applying the conservation savings to the demand forecast as described above, the forecast is further reduced by the expected peak contribution from contracted, but not yet in-service, DG in the sub-region. The effects of projects that were already in-service prior to the base year of the forecast were not included as they are already embedded in the actual demand, which is the starting point for the forecast. Potential future (but uncontracted) DG uptake was not included and is instead considered as an option for meeting identified needs.

Based on the IESO contract list as of June 2015, new DG projects are expected to offset an incremental 3.2 MW of peak demand within the Barrie/Innisfil Sub-region by 2018. Most distribution connected contracted generators included in the forecast are small-scale solar projects (< 500 kW); however, there are some larger FIT (< 10 MW) solar projects connecting at Midhurst TS. A capacity contribution of 22%, to the regional peak, has been assumed to account for the expected output of the local solar resources during summer peak conditions.

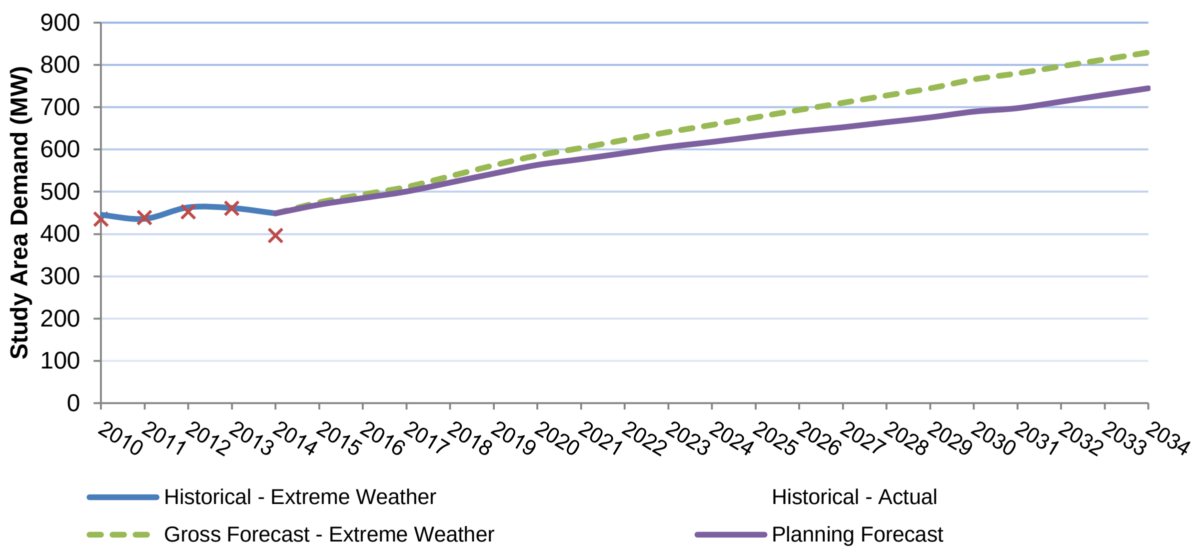
Additional details of the regional demand reductions from province-wide DG programs are provided in Appendix A.

5.6 Planning Forecasts

After taking into consideration the combined impacts of conservation and DG, a 20-year planning forecast was produced.

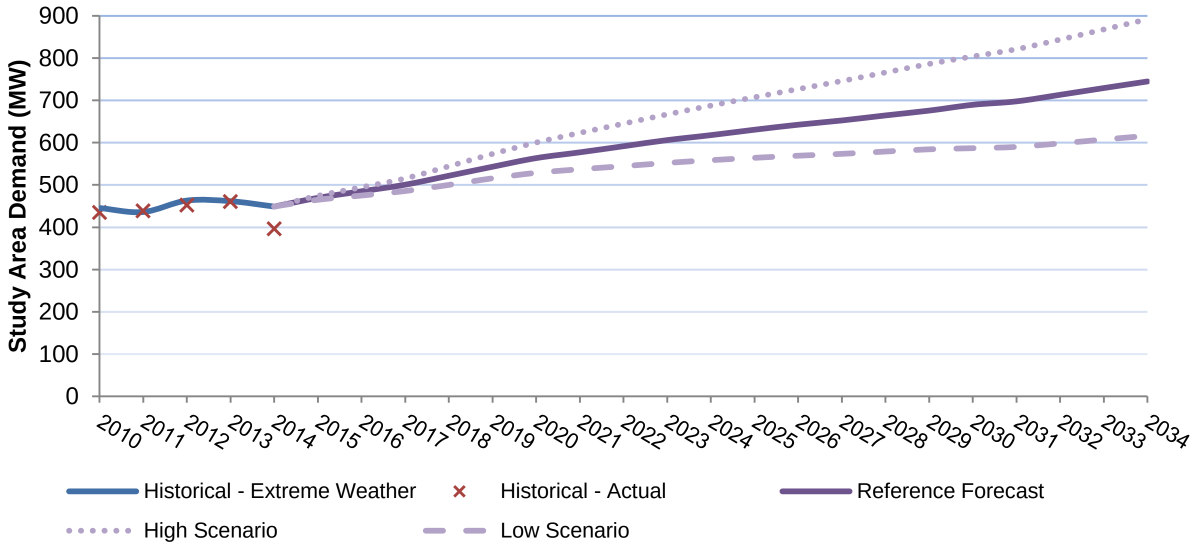
Figure 5-5 below illustrates the planning forecast, along with historic demand in the area. Note that the planning forecast has been adjusted for extreme weather conditions. For comparison in Figure 5-5 the gross forecast has also been adjusted for extreme weather conditions. Further details of the planning forecast scenarios are provided in Appendix A.

Figure 5-5: Barrie/Innisfil Sub-region Planning Forecast



The net forecast for the high, low and reference scenarios are shown in Figure 5-6. Further information on the high and low scenarios and each of the LDC's load forecast assumptions can be found in Appendix A.

Figure 5-6: Barrie/Innisfil Sub-region High and Low Demand Forecast Scenarios



6. Needs

Based on the planning forecasts, system capability, and application of provincial planning criteria, the Barrie/Innisfil Sub-region Working Group identified electricity needs in the near, medium, and long term. This section describes the identified needs for these three time horizons in the Barrie/Innisfil Sub-region.

6.1 Needs Assessment Methodology

ORTAC,[8] the provincial standard for assessing the reliability of the transmission system, was applied to assess supply capacity and reliability needs. ORTAC includes criteria related to the assessment of the bulk transmission system, as well as the assessment of local or regional reliability requirements (see Appendix B for more details).

By applying these criteria, two broad categories of needs have been identified for the Barrie/Innisfil Sub-region IRRP:

- **Transformer Station Capacity** describes the electricity system's ability to deliver power to the local distribution network through the regional step-down transformer stations. The capacity rating of a transformer station is the maximum demand that can be supplied by the station and is limited by the station equipment. Station ratings are often determined based on the 10-day LTR of a station's smallest transformer(s) under the assumption that the largest transformer is out of service.[9]
- **Supply Capacity** is the electricity system's ability to provide continuous supply to a local area. This is limited by the LMC of the transmission supply to the area. The LMC is determined by evaluating the maximum demand that can be supplied to an area accounting for limitations of the transmission element(s) (e.g., a transmission line, group of lines, or autotransformer), when subjected to contingencies and criteria prescribed by ORTAC. LMC studies are conducted using power system simulations analysis (see Appendix B for more details). Supply capacity needs are identified when the peak demand for the area exceeds the LMC.

The needs assessment also identifies requirements related to equipment end-of-life and planned sustainment activities. Equipment reaching end-of-life and planned sustainment activities have

---

[8] http://www.ieso.ca/imoweb/pubs/marketadmin/imo_req_0041_transmissionassessmentcriteria.pdf

[9] A transformer station can also be limited when downstream or upstream equipment (e.g., breakers, disconnect switches, low voltage bus, high voltage circuits, etc.) are undersized relative to the transformer rating. LTR is further defined on page 8.

a significant impact on the needs assessment and option development for the Barrie/Innisfil Sub-region.

6.2 Local Electricity Supply and Reliability Needs

The needs assessment for the Barrie/Innisfil IRRP focused on identifying needs for local transformer stations and related supply infrastructure. The impact of all three demand forecast scenarios (reference, high, and low – see Section 5.6) on the local transmission infrastructure was evaluated. Near-, medium-, and long-term capacity needs were identified for the south Barrie and Innisfil areas for the reference scenario, along with a long-term capacity need at Everett TS. End-of-life infrastructure needs were also identified in the area.

6.2.1 Near- and Medium-Term Needs

The near- and medium-term needs identified for the Barrie TS service area were considered together since the infrastructure impacted is common to all identified needs. The near- and medium-term needs are summarized in Table 6-1.

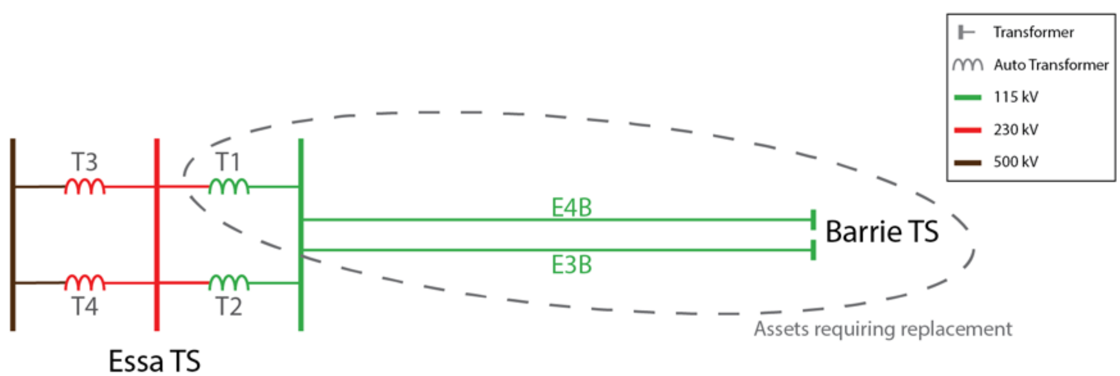
Table 6-1: Barrie/Innisfil Sub-region Near- and Medium-Term Electricity Needs

Need	Description	Timing
End-of-Life	Hydro One has identified Barrie TS and components of its 115 kV supply infrastructure to be nearing their end-of-life.	2020
Transformer Station Capacity	Net demand growth in the southern portion of the City of Barrie and in the Town of Innisfil is forecast to exacerbate the existing transformer station capacity need at Barrie TS. Barrie TS also lacks additional feeder positions to accommodate future growth in Innisfil.	Today
Supply Capacity	The net demand growth is forecast to exceed the LMC of the 115 kV supply to Barrie TS (E3/4B).	2019

Hydro One Transmission identified existing sustainment initiatives at Barrie TS driven by the 115/44 kV station transformers reaching end-of-life, along with the 44 kV switchgear, circuit breakers, disconnect switches and other station equipment.

Barrie TS was placed in-service in 1962. The 44 kV switchyard assets at Barrie TS have been identified by Hydro One as being in need of replacement in the near term. Barrie TS is currently supplied by the 230/115 kV autotransformers at Essa TS via the Essa 115 kV switchyard and 115 kV circuits E3/4B. These assets were built in the 1950s, with many of them already exceeding their expected life and in need of replacement in the near and medium term. Figure 6-1 depicts the significant assets that Hydro One has identified as requiring replacement in the near term.

Figure 6-1: Single Line Diagram Detailing Existing Supply of Barrie TS and Assets Requiring Replacement



The timing and replacement options for Barrie TS were discussed among the Working Group members. It was agreed that based on the existing and forecast station demand, that Barrie TS and E3/4B should be rebuilt to 230 kV, with 75/125 Mega Volt Amp ("MVA") 44/230 kV transformers. This means that the end-of-life replacement of Barrie TS will add approximately 50 MW of incremental supply capacity in the south Barrie and Innisfil area. Details of the alternatives considered by the Working Group can be found in Appendix B.

Barrie TS is forecast to experience the highest average yearly growth rate of any TS in the study area over the 20 year planning period, for all load growth scenarios. This is driven by the large amount of growth set out in the local municipal plans and in the province's Growth Plan for the Greater Golden Horseshoe, 2006, as amended, which identify the City of Barrie as an urban growth centre.

Effective January 1, 2010, the City of Barrie annexed approximately 5,700 acres of land from the Town of Innisfil to accommodate its forecast growth. These annexed lands are within the Barrie TS service area, and their development contributes to a large portion of the station's forecast growth. Barrie TS growth is also influenced by the recent and continued development of data centres in the City of Barrie, and forecast growth in the Town of Innisfil, including the proposed industrial and commercial development of Innisfil Heights near Highway 400.

Barrie TS is currently utilized by two LDCs, PowerStream and InnPower.

Figure 6-2: Forecast Summer Demand for Barrie TS - Reference Scenario

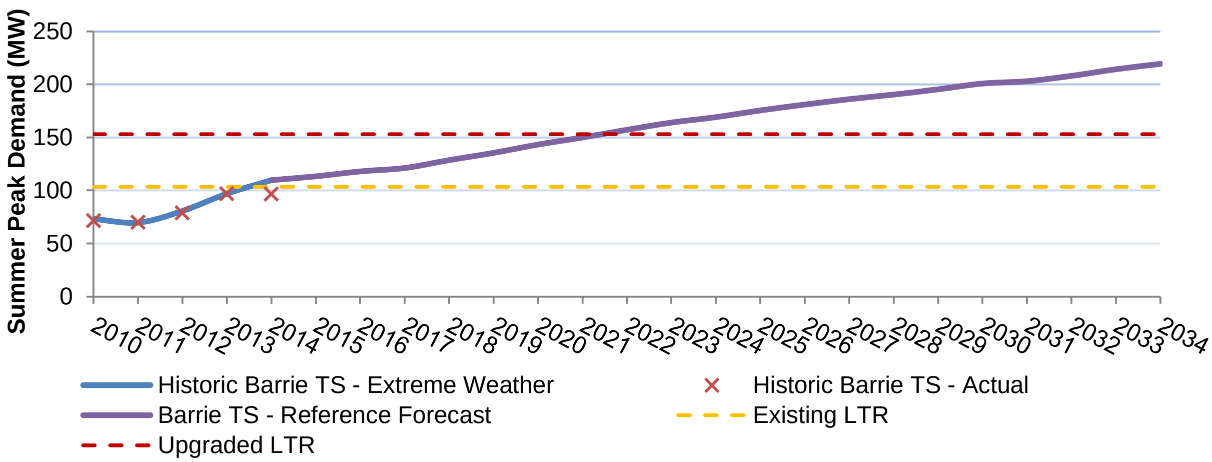


Figure 6-2 shows the forecast load growth for Barrie TS under the assumptions from the reference scenario, along with the existing LTR of Barrie TS and the future LTR of the uprated Barrie TS. Based on the forecast provided by the LDCs, Barrie TS would have exceeded its existing LTR by 2015 and will exceed the uprated LTR by 2022. By the end of the study period, there is approximately 66 MW of forecast capacity need that cannot be supplied by the uprated Barrie TS.

Currently all seven existing 44 kV feeder positions available at Barrie TS have been allocated to an LDC. Six of these feeders are used to supply PowerStream customers and one to supply InnPower. Based on the normal operating rating of the 44 kV feeder supplying InnPower, there will be a need for additional feeder capacity and a new feeder position by 2020 for the reference forecast scenario. The uprated Barrie TS will have a total of eight feeder positions, meaning there will be an additional position available as an option to supply future load growth in both south Barrie and Innisfil.

In addition to the limitation posed by the transformers at Barrie TS, the existing upstream 115 kV transmission supply is forecast to exceed its limit. The 115 kV circuits that supply Barrie TS are E3/4B. E3B is expected to exceed its LMC in 2019. These 115 kV circuits are supplied by two 230/115 kV autotransformers at Essa TS. The most limiting of these transformers is expected to exceed its LTR in 2020. By upgrading the Barrie TS supply to 230 kV, it ensures that future load growth at Barrie TS, up to its new LTR, can be accommodated, and there will be remaining line capacity to accommodate future load customers in the area at 230 kV.

6.2.2 Long-Term Capacity Needs

Long-term capacity needs were identified at both the transformer station level and the sub-area/sub-region level. Two different sub-system levels were defined based on both the ability to transfer load on the distribution system, and on the overall electrical supply to the area. The two areas defined for the purpose of the needs assessment are the "Barrie Sub-area" – defined below – as well as the established "Barrie/Innisfil Sub-region".

In the long term, transformer capacity needs arise for Everett TS and for the broader Barrie Sub-area. At the end of the study period, both a transformer capacity need and a supply capacity need arise for the broader Barrie/Innisfil Sub-region. These needs, along with their timing and influencing factors, are discussed in more detail below.

Everett TS

The transformer station capacity need at Everett TS is a long-term need. Everett TS is a relatively new transformer station, which came into service in late 2007 to address capacity needs in the South Simcoe area, relieving Alliston TS. Everett TS is forecast to supply load growth in the Town of New Tecumseth, primarily Alliston and the surrounding area.

Figure 6-3: Forecast Summer Demand for Everett TS - Reference Scenario

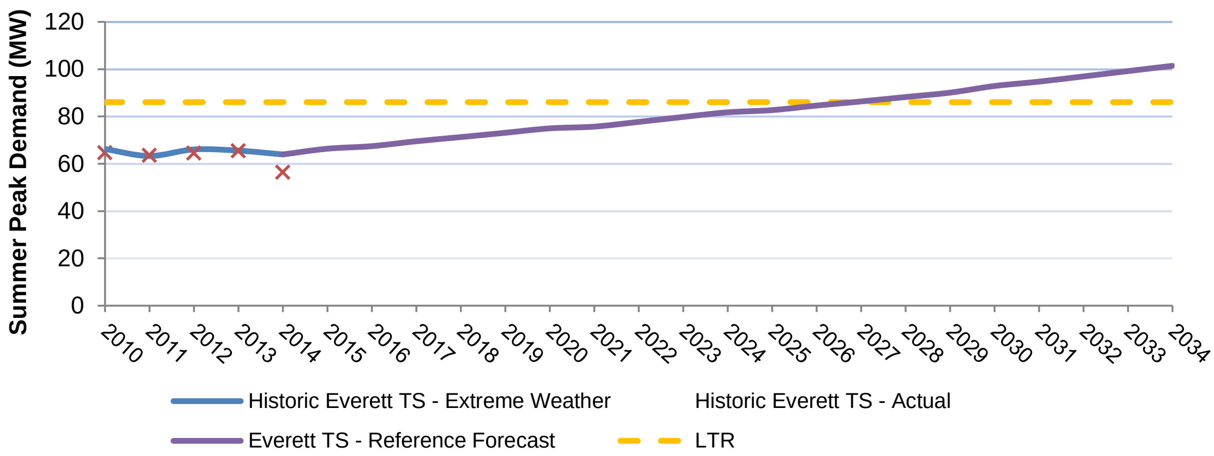

Figure 6-3 shows the forecast load growth for Everett TS under assumptions from the reference scenario. Based on the forecast provided by the LDCs, Everett TS will exceed its current LTR in 2027. By the end of the study period, there is approximately 15 MW of forecast capacity need that cannot be supplied by Everett TS.

A capacity need at Everett TS was identified in both the 2011 South Simcoe study and in the latest Needs Assessment completed by Hydro One for this regional planning cycle. Both studies outlined that this capacity need can be addressed by changing the CT ratios, which are currently limiting the station LTR, once the station's minimum load exceeds 8 MVA. Since 2011, the minimum load at Everett TS has surpassed 8 MVA meaning the CT ratios can now be changed whenever the additional capacity is required. This would defer the capacity need at Everett TS beyond the study period.

Barrie Sub-area

The Barrie Sub-area is defined as the area serviced by both Midhurst TS and Barrie TS, recognizing geographical overlap in their service areas. Ties exist between the stations for emergency load transfers, and there is potential for permanent load transfers or for a choice between the two stations when servicing new load.

The LMC of the Barrie Sub-area is defined as the combined LTRs of Midhurst TS and Barrie TS. The ability to fully utilize this firm capacity, however, is constrained by the feasibility or cost effectiveness of any load transfers or optimization of the distribution system. The available capacity in the Barrie Sub-area is also increased by the uprating of Barrie TS discussed in Section 6.2.1.

Figure 6-4: Summer Demand Forecast for the Barrie Sub-area - Reference Scenario
