Figure 6-4 shows the forecast load growth in the Barrie Sub-area under assumptions for the reference scenario. Based on the forecasts provided by the LDCs, the Barrie Sub-area will exceed the combined capacity of Midhurst TS and uprated Barrie TS by 2031. By the end of the study period there is approximately 32 MW of forecast capacity need that cannot be supplied in the Barrie Sub-area assuming optimum load sharing between Midhurst TS and Barrie TS.

Barrie / Innisfil Sub-region

The Barrie/Innisfil Sub-region is defined in Section 4.1 as the area supplied by Midhurst TS, Barrie TS, Alliston TS and Everett TS. This area is supplied primarily by the bulk system, via the 500/230 kV autotransformers at Essa TS. Based on the forecast load growth, the region is primarily limited by the combined transformer capacity of Midhurst TS, Barrie TS, Everett TS and Alliston TS. This recognizes the existing ties used for emergency load transfers and the potential to implement permanent load transfers throughout the area.

Figure 6-5: Summer Demand Forecast Barrie/Innisfil Sub-region - Reference Scenario

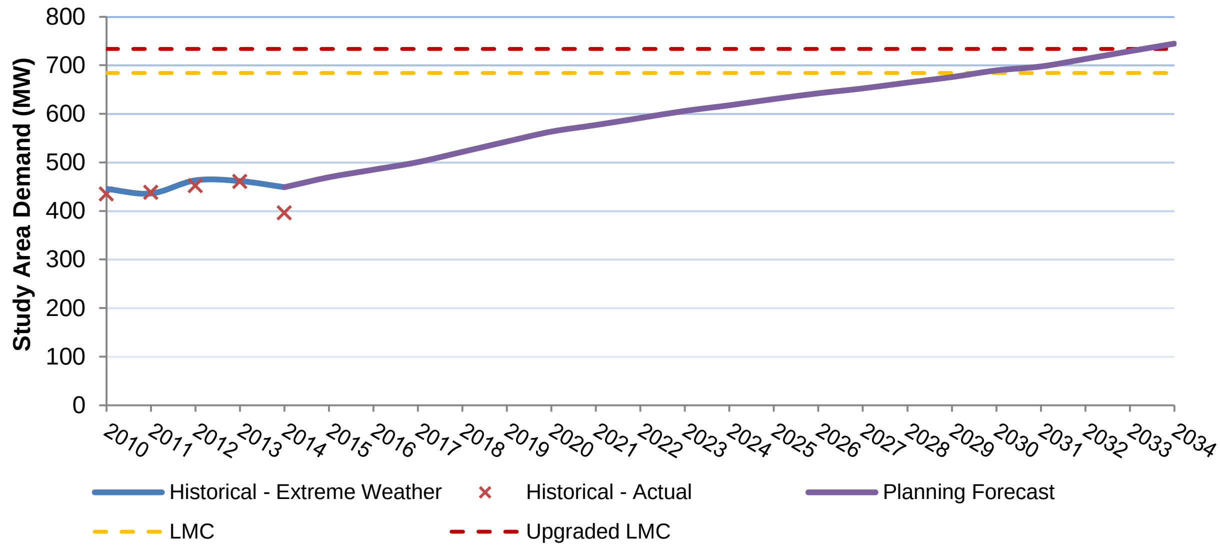

Figure 6-5 shows the forecast load growth in the Barrie/Innisfil Sub-region under assumptions for the reference scenario. Based on the forecasts provided by the LDCs, the Barrie Sub-region will exceed the combined capacity of the transformer stations in the region (accounting for the uprated Barrie TS) by 2034. By the end of the study period there is approximately 14 MW of forecast capacity need that cannot be supplied in the Barrie/Innisfil Sub-region, assuming optimum load sharing between all transformer stations.

The upstream transmission limitation for the sub-region is the 500/230 kV autotransformers at Essa TS. The loading of the autotransformers is also impacted by the load in the Parry Sound/Muskoka Sub-region and, to a certain degree, by the bulk system flow on Ontario's north-south transmission interface. The IESO has studied the impact on the Essa TS autotransformers under different bulk flow conditions and the load forecasts from both the Barrie/Innisfil IRRP and the Parry Sound/Muskoka IRRP. Based on these assumptions, a forecast capacity need, based on the loss of one autotransformer, does not arise until 2034.

In addition to the growth included in the planning demand forecast, the Metrolinx most recent electrification plan has indicated a preference for connecting to the new 230 kV supply extension via the uprated Barrie TS for their traction power station for the Barrie line. This connection could advance the need date for the supply capacity due to the Essa autotransformer limitations. Therefore, this project should be monitored closely by both the IESO (since it has implications for the bulk system) and the Working Group.

6.3 Needs Summary

The majority of needs in the Barrie/Innisfil Sub-region concern various loading limits on Barrie TS, along with the need to address the risk posed by the end-of-life infrastructure at the station.

With the Barrie Area Transmission Reinforcement project, which Hydro One has begun development work for at the request of the IESO and the Working Group, the near-term end-of-life need and the existing capacity need at the station can be addressed. Over the medium and long term, additional capacity needs arise in the area, including InnPower's need for additional 44 kV feeder capacity, additional transformer capacity needs at Everett TS and in the Barrie area, and a need for additional transformer and supply capacity for the sub-region by the end of the study period.

The table below provides a brief summary of needs that will be considered during the development of options for the plan.

Table 6-2: Summary of Needs in Barrie/Innisfil Sub-region

Area	Need	Description	Need Date
Barrie TS	Barrie TS transformer capacity need	There is an existing transformer capacity need at Barrie TS. The incremental capacity provided by the Barrie Area Transmission Reinforcement project should address a large portion of the near- and medium-term capacity need at Barrie TS.	Today
	Barrie TS supply capacity need	The 115 kV circuits currently supplying Barrie TS are forecast to exceed their LMC. By uprating these circuits to 230 kV, the Barrie Area Transmission Reinforcement project addresses this need.	2019

Area	Need	Description	Need Date
	End-of-life for Barrie TS 115/44 kV transformers and station equipment	Significant station components, both at and supplying Barrie TS are nearing end-of-life and require replacement by 2020. The Barrie Area Transmission Reinforcement project should address this need.	2020
	InnPower distribution/feeder supply capacity	Currently InnPower is only allocated one feeder from Barrie TS which is forecast to exceed its normal operating rating in the near to medium term.	2020
	Medium-term transformer capacity need	The uprated Barrie TS is forecast to exceed its new LTR in the medium term, based on the expected load growth in south Barrie and Innisfil.	2022
Everett TS	Everett TS transformer capacity need	Everett TS is forecast to exceed its limited LTR in the long term.	2027
Barrie Sub-area	Transformer capacity need	Load in the Barrie area is forecast to exceed the combined transformer capacity of Midhurst TS and the uprated Barrie TS in the long term, primarily driven by load growth at Barrie TS.	2031

Area	Need	Description	Need Date
Barrie/Innisfil Sub-region	Transformer and supply capacity need	In the long term, the load in the Barrie/Innisfil Sub-region is forecast to exceed both the combined transformer capacity of Barrie TS, Everett TS, Midhurst TS and Alliston TS, and the LMC of the Essa autotransformers.	2034

7. Near- and Medium-Term Plan

The plan to address the near- and medium-term needs identified for the Barrie TS service area is already underway. As described in Section 6.2.1, there are end-of-life and existing station capacity needs at Barrie TS that need to be addressed today. The near-term plan has been developed by the Working Group, with a project to rebuild and uprate Barrie TS (the Barrie Area Transmission Reinforcement project) formally handed off to Hydro One in December 2015. The hand-off letter was issued to ensure that facilities could be in-service in time to meet the identified needs, given the typical lead-time of five to seven years for a transmission project. The rebuild of Barrie TS and E3/4B is currently undergoing the development work (e.g., EA process, Leave to Construct).

This section describes the alternatives considered by the Working Group in developing the near- and medium-term plan for the Barrie/Innisfil Sub-region; provides details of, and rationale for, the recommended plan; and outlines the implementation plan.

7.1 Alternatives for Meeting Near- and Medium-Term Needs

In developing the near- and medium-term plan, the Working Group considered a range of integrated options. The Working Group further considered technical feasibility, cost and consistency with long-term needs and options in the Barrie/Innisfil Sub-region when evaluating alternatives. Solutions that maximize the use of existing infrastructure were given priority.

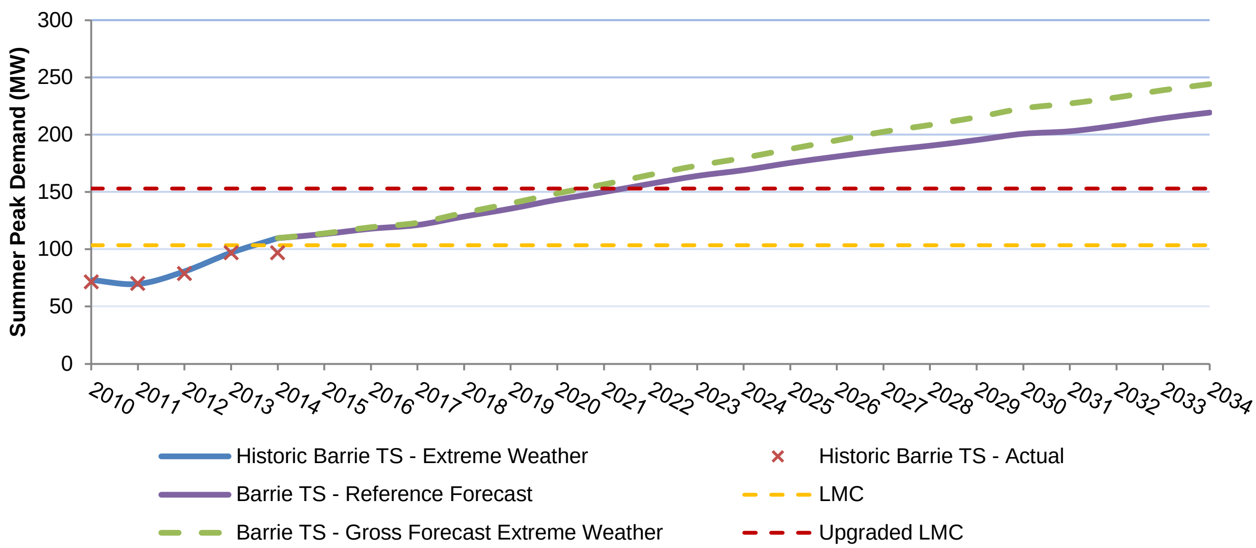
The following sections detail the alternatives considered and evaluates them against the criteria described above. The alternatives are grouped according to three major solution categories: (1) conservation, (2) local generation and (3) transmission and distribution.

7.1.1 Conservation

Conservation was considered as part of the planning forecast, which includes the local peak demand impact of the provincial conservation targets as described in Section 5.4. In the Barrie TS area, the LTEP energy reduction targets account for approximately 10 MW, or 17% of the forecast demand growth during the first 10 years of the study. This is forecast to defer the Barrie TS capacity need by one year from 2021 to 2022.

In Figure 7-1, Barrie TS load is shown under both the gross and net planning (accounts for expected conservation and contracted DG) forecasts. Both forecasts are adjusted for extreme weather conditions.

Figure 7-1: Effect of Conservation Targets on Barrie TS Peak Load



Most conservation targets are energy targets (measured over an entire year). Transmission needs, on the other hand, are triggered based on peak demand (single highest observation of hourly demand in a year). As a result, in order to reduce, defer, or otherwise address needs, conservation programs must have an impact during the hour of peak demand. In the case of the Barrie/Innisfil Sub-region, this typically means late afternoon on the hottest weekdays of summer.

The net planning forecast includes an estimate of how meeting the mostly energy based conservation targets translates into peak demand reductions. There is, however, uncertainty in both meeting energy conservation targets and determining how meeting those targets will translate into peak demand savings. As such, there is a wide range of potential demand impacts that could be experienced (both higher and lower than forecast), while still achieving full conservation targets. Therefore, LDCs are encouraged to focus their Conservation First Framework ("CFF") funding towards measures and programs that can also reduce peak and overall demand–particularly in areas where needs have been identified through regional planning.

As part of the implementation of this plan, the Working Group will annually review actual peak demand, including the impact of conservation. The IESO will support the LDCs in exploring the full potential of conservation for addressing long-term needs, discussed further in the long-term plan in Section 8.

7.1.2 Local Generation

Large transmission-connected generation and small-scale distribution-connected DG options were ruled out as viable alternatives for meeting near-term needs in the Barrie/Innisfil Sub-region. This was primarily due to the end-of-life issues at Barrie TS, which must be addressed now and could not be solved using local generation, since approximately 100 MW of existing customer load would be left without supply if the infrastructure was not replaced at end-of-life.

In addition, because local generation contributes to the overall generation capacity for the province, the generation capacity situation at the provincial level must be considered when assessing options for near- and medium-term needs. Currently, Ontario has a surplus of generation capacity and no new capacity is forecast to be needed until the mid-2020s at the earliest. This was an additional consideration in ruling out local generation for meeting the near-term needs.

7.1.3 Transmission and Distribution

A number of transmission and distribution, or "wires," solutions were considered by the Working Group to meet the near-term needs. "Wires" infrastructure solutions can refer to new or upgraded transmission or distribution system assets, including lines, stations, or related equipment. These solutions are often characterized by high upfront capital costs, but have high reliability over the lifetime of the asset.

7.1.3.1 Transmission-based Solution to Address Near-Term Need

To address the end-of-life need at Barrie TS, the Working Group investigated different transmission-based solutions. Based on the assessment of these options along with the system needs, the rebuild and uprating of Barrie TS and E3/4B to 230 kV, with 75/125 MVA transformers was chosen as the preferred option. A description of the alternatives considered by the Working Group can be found in Appendix B.

7.1.3.2 Distribution-based Solutions to Address Medium-Term Need

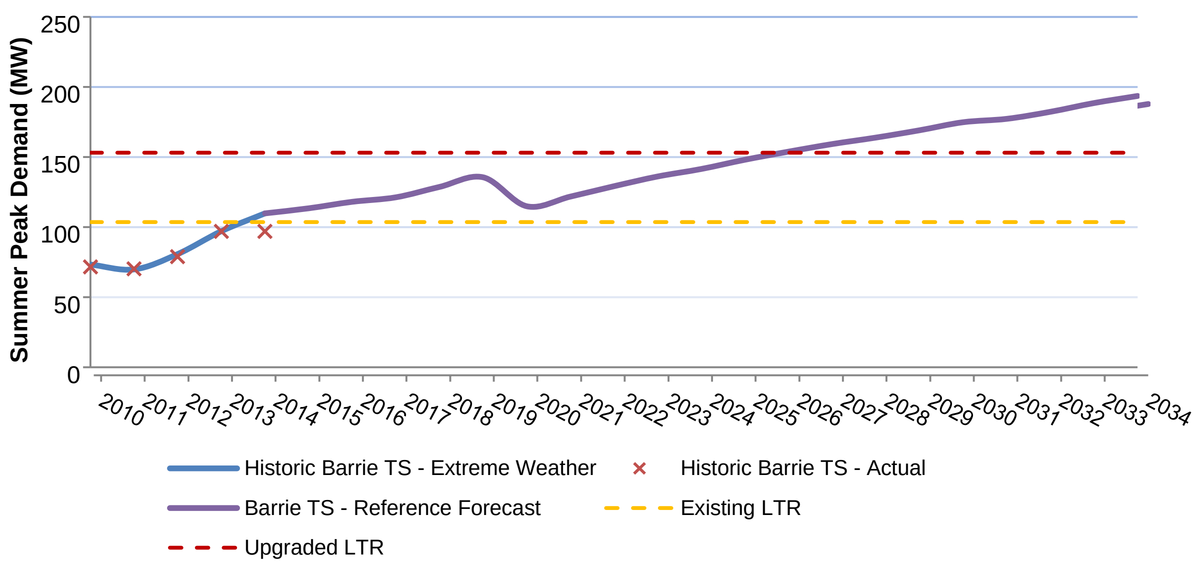
To address the medium-term transformer station and feeder capacity needs at Barrie TS, different distribution-based solutions were investigated. These included load transfers from Barrie TS to Midhurst TS, and new 44 kV feeders from the rebuilt Barrie TS to InnPower's service territory. These are described in more detail below.

Load Transfers

Due to the proximity of Barrie TS and Midhurst TS, and since PowerStream has an existing supply from both stations, load transfers are a feasible option to relieve Barrie TS. By building additional supply feeders from Midhurst TS, PowerStream can transfer up to 27 MW of load from Barrie TS assuming full data center load growth. This load transfer makes use of new feeders PowerStream already planned to construct, primarily due to data center expansion in the area. The available load transfer capacity is based upon normal operating conditions; during feeder outage situations the transfer amount may vary based on the redundancy needs of key customers.

The load transfer defers the capacity need at the uprated Barrie TS from 2022 to 2026 and also provides PowerStream with additional transfer capability between Barrie TS and Midhurst TS during emergency conditions. Figure 7-2 shows the reference scenario demand forecast for Barrie TS accounting for PowerStream's load transfer.

Figure 7-2: Barrie TS Reference Demand Forecast Load with PowerStream 2020 Load Transfer



With PowerStream's load transfer in place, by the end of the study period there is approximately 40 MW of forecast capacity need that cannot be supplied by the uprated Barrie TS.

PowerStream's existing ability to perform temporary load transfers for emergency purposes will also help manage the Barrie TS current capacity need both leading up to the completion of the Barrie Area Reinforcement project and throughout its construction staging. However, depending on Hydro One's contingency plan for the period of construction PowerStream may need to install additional distribution switches to meet their load security requirements during the rebuild of Barrie TS.

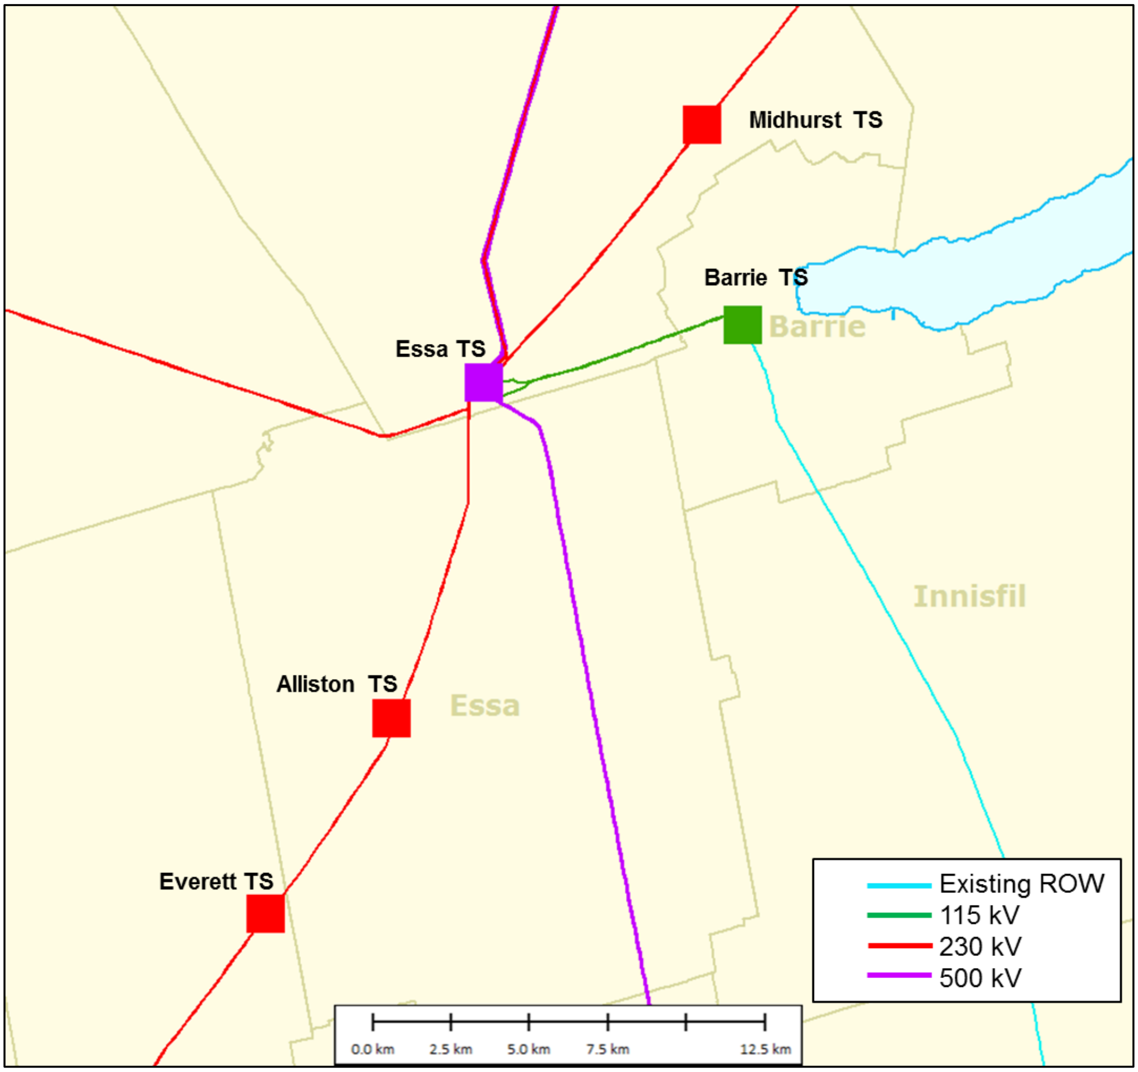
44 kV Feeder Expansion & Relocation

Currently, InnPower is supplied with one feeder from Barrie TS, operated at 44 kV and is considered an embedded customer to Hydro One Distribution. Up until the demarcation point in the Town of Innisfil, the feeder that supplies InnPower, 13M3, is an idle 115 kV line owned by Hydro One Transmission and operated at 44 kV to supply InnPower. The ROW for this 115 kV line extends south, past the existing supply points to InnPower.

This existing feeder can supply approximately 25 MW of capacity, which InnPower is forecast to exceed in 2020. The new Barrie TS will accommodate one additional 44 kV feeder, which can be used by InnPower when their capacity need arises. The additional feeder will require a new route south to Innisfil to service InnPower load.

It is recommended that, when building the new feeder, the line be built as a two circuit 44 kV feeder line and that the 13M3 feeder be relocated to this new line. This will leave the 115 kV ROW idle and will maintain a future option for addressing the long-term capacity needs in the south Barrie and Innisfil areas.

Figure 7-3: Map of the Barrie Area Including the 13M3 115 kV Corridor



Currently, Metrolinx has indicated an interest in utilizing this corridor to extend the 230 kV supply from the uprated Barrie TS to their proposed traction power station site, which sits just south of Barrie TS, adjacent to the ROW. InnPower is also interested in future use of the ROW, recognizing that long-term capacity needs in their service territory may require additional transformer station capacity in the long term.

7.1.3.3 Alternative Transmission Solution to Address Medium-Term Need

To address the need for new transformer station capacity at Barrie TS in 2022 – assuming no PowerStream load transfer – a new station supplied at 230 kV via the 13M3 corridor to south Barrie or Innisfil could provide approximately 150 MW of additional transformer station capacity to the area. This additional capacity would also service the long-term transformer station capacity needs for the Barrie Sub-area and overall Barrie/Innisfil Sub-region.

In this case, the distribution solution (the PowerStream load transfer) is the more cost-effective option and maximizes the use of existing infrastructure, deferring the capacity need to 2026. The lead-time for a new transformer station is five to seven years, so no commitment is needed today to begin development work. The need for new transformer station capacity will be monitored while all options for additional long-term capacity are further explored, as outlined in the long-term plan in Section 8.

7.2 Recommended Near- and Medium-Term Plan

The Working Group recommends the actions described below to meet the near- and medium-term electricity needs of the Barrie/Innisfil Sub-region. Successful implementation of these actions, in addition to achievement of targeted conservation measures, is expected to address the sub-region's electricity needs until the late 2020s /early 2030s.

Rebuild and Uprate Barrie TS and E3/4B to 230 kV

To mitigate challenges posed by both Barrie TS and its 115 kV supply infrastructure reaching end-of-life, and to address the near-term capacity needs at Barrie TS, Hydro One is developing the Barrie Area Transmission Reinforcement project. The project will rebuild the existing Barrie TS and uprate its existing supply from 115 kV to 230 kV, increasing the supply capacity to the area. The existing Barrie TS site is well situated for supplying the near- and medium-term forecast load growth in the south Barrie and Innisfil areas. A Class EA process is currently underway. The targeted in-service date for the project is the end of 2020.

PowerStream Load Transfer – From Barrie TS to Midhurst TS

PowerStream is planning to transfer up to 27 MW of load from Barrie TS to Midhurst TS by 2020 assuming full data centre load growth. This increases the incremental capacity available at Barrie TS, addressing near- and medium-term needs, while providing the reliability benefit of additional transfer points between Barrie TS and Midhurst TS for emergency situations. The PowerStream load transfer allows the need for additional capacity at the uprated Barrie TS to be deferred from 2022 to 2026 under reference case assumptions.

Relocate and Expand InnPower Feeder Supply from Barrie TS

Currently Hydro One Distribution is allocated one feeder from the existing Barrie TS which is used to service InnPower. The capacity of this feeder is forecast to be exceeded in 2020. The rebuilt Barrie TS will include one additional feeder position, which can be used to address this need. Additionally, the existing InnPower supply uses an idle Hydro One Transmission ROW. The use of this ROW for sub-transmission purposes limits future long-term options for additional transmission facilities in the south Barrie and Innisfil areas. It is recommended that Hydro One Distribution and InnPower develop a plan to build a new two circuit 44 kV feeder line to support InnPower's forecast growth and to relocate the InnPower supply to outside of the Hydro One Transmission corridor. The proposed in-service date for these feeders is the end of 2020. The two feeder supply from Barrie TS is forecast to supply InnPower's forecast demand at Barrie TS until 2026 under reference case assumptions.

7.3 Implementation of Near- and Medium-Term Plan

To ensure that the near-term electricity needs of the Barrie/Innisfil Sub-region are addressed, it is important that the plan recommendations be implemented as soon as possible. The specific actions and deliverables are outlined in Table 7-1, along with the recommended timing.

Table 7-1: Summary of Needs and Recommended Actions in Barrie/Innisfil Sub-region

Need	Recommended Action(s)/Deliverable(s)	Lead Responsibility	Timeframe/ Need Date
- Barrie TS is at end-of-life and requires replacement - Barrie TS has reached its firm capacity	Rebuild and upgrade Barrie TS and E3/4B to 230 kV, with 75/125 MVA transformers	Hydro One	In-service by end of 2020
- The uprated Barrie TS has a medium-term capacity need	Transfer up to 27 MW of load from Barrie TS to Midhurst TS assuming full data centre load growth	PowerStream	In-service by 2020 at the latest[10]

[10] PowerStream's 2016-2020 Custom Incentive Rate filing states a proposed in-service date of 2018 based on additional distribution needs their project addresses in the Barrie area. If the project is in-service prior to 2020 it will provide additional ability to mitigate the near-term Barrie TS capacity need until the Barrie Area Transmission Reinforcement project comes in-service.

Need	Recommended Action(s)/Deliverable(s)	Lead Responsibility	Timeframe/ Need Date
- Load growth in south Barrie will require additional feeder capacity for InnPower from Barrie TS - The existing corridor used to supply InnPower is required for future infrastructure development	InnPower will work with Hydro One to relocate out of the 115 kV corridor, constructing two new 44 kV feeders from Barrie TS to Innisfil	InnPower & Hydro One Distribution	Proposed in-service for end of 2020

To implement the recommended near-term actions in a timely manner, a RIP should be initiated for the broader South Georgian Bay/Muskoka planning region upon IRRP completion. This process will allow for detailed design and study of the transmission and distribution infrastructure expansion required to complete the recommended actions. The outcome of the RIP will be a more detailed development plan, including a refined estimate of expected costs and benefits to customers.

8. Long-Term Plan

In the long term, the outlook for the Barrie/Innisfil Sub-region depends on assumptions made in the forecast. Under the low growth scenario, the sub-region has no need for additional transformer station capacity until the end of the study period. Under the reference scenario, the need for new transformer station capacity arises in the mid to late 2020s. With the aggressive load growth assumptions in the high scenario, any new transformer station constructed in the area to address needs throughout the study period would be reaching its LTR by the end of the study period. These three scenarios represent the uncertainty associated with long-term forecasts and are an example of why a different approach is required for long-term versus near- and medium-term planning.

For needs appearing in the long term, there is an opportunity to develop and explore a broader set of options, as specific projects do not need to be committed immediately. This approach is designed to: maintain flexibility; avoid committing ratepayers to investments before they are needed; provide adequate time to assess the success of current and future potential conservation measures in the study area; test emerging technologies; engage with communities and stakeholders; and lay the foundation for informed decisions in the future.

Due to the long-term capacity need forecast for the Barrie and Innisfil areas, PowerStream and InnPower will be undertaking a LAP study for the Barrie TS service area, with support from the IESO's Conservation Fund. This study will help determine the conservation potential, specifically for the Barrie TS area, beyond the LTEP targets already accounted for in the planning demand forecast (e.g., additional incentives and adders to refocus existing CDM programs, new programs, behind-the-meter generation, energy storage, etc.). The study will provide a better understanding of the associated costs and feasibility of CDM measures to address the identified capacity needs in the area, better informing options for the next planning cycle.

PowerStream has also implemented a pilot project in their southern service territory to study the benefits and economics of aggregated customer side generation and storage. The results of this study can be used to inform further discussion and development of non-wires solutions for the long-term needs in the Barrie/Innisfil Sub-region for the next planning cycle.

Broad community and public engagement, including with local Indigenous communities, is essential to develop the long-term plan. It is recommended that engagement involve several phases: addressing public education/awareness of electricity issues, planning, technologies, and regulatory requirements; fostering an understanding of community growth and its relationship to electricity needs; understanding the pros and cons of various alternatives to meeting long-term needs; and obtaining input on community preferences for various approaches to meeting needs.

To provide input and advice on engagement plans for the Barrie/Innisfil Sub-region, the Working Group will establish a LAC consisting of community representatives and stakeholders.

8.1 Recommended Actions and Implementation

A number of alternatives are possible to meet the sub-region's long-term needs. While specific solutions do not need to be committed to today, it is appropriate to begin work now to gather information, monitor developments, engage the community, and develop alternatives to support decision making in the next iteration of the IRRP. The long-term plan sets out the near-term actions required to ensure that options remain available to address future needs if and when they arise.

For some needs, such as the transformer station capacity need at Everett TS, the solution is straightforward (changing the CT ratios) and can be easily implemented by the transmitter when required. For other needs, such as the transformer station capacity needs in the south Barrie and Innisfil areas, the recommended actions focus on monitoring and information gathering, community engagement, and more detailed options development for non-wires solutions prior to the next planning cycle.

The recommended actions and deliverables for the long-term plan are outlined in Table 8-1, along with their recommended timing, and the parties with lead responsibility for implementation.

Table 8-1: Recommended Near-Term Actions for Addressing Long-Term Needs

Recommended Action(s)/Deliverable(s)	Lead Responsibility	Timeframe/ Need Date
Formation of a LAC.	IESO	To be formed early 2017

Recommended Action(s)/Deliverable(s)	Lead Responsibility	Timeframe/ Need Date
Conduct a LAP study to determine cost and feasibility of CDM measures to address capacity needs in the Barrie TS service area.	PowerStream & InnPower	Study to be completed by end of 2017
Coordinate the development work for the Metrolinx traction power station supply to maintain the future supply option for south Barrie and Innisfil utilizing the same corridor.	Hydro One	To be monitored
Change the CT ratios at Everett TS when required.	Hydro One	To be monitored – pre 2027
Monitor, and prepare an annual update to the Working Group, on demand, conservation and DG trends and achievement in the area.	IESO	Annually

The Working Group will work with the local communities to monitor leading indicators for growth in the Barrie/Innisfil Sub-region. This includes monitoring changes to growth targets, the composition and location of specific customer segments (residential, commercial, industrial), and electricity impacts from implementation of community energy plans. If these or other factors affect service reliability or the capacity of the local electricity delivery systems a new IRRP process may be initiated ahead of the five year planning cycle. Examples of developments that could trigger revisiting the plan prior to the next cycle include:

- Critical PowerStream customers reaching 95% of their projected load
- InnPower's expanded feeder supply from Barrie TS reaching 95% of its firm capacity
- Innisfil completing the servicing of their development lands
- Detailed design and development work proceeds for the Metrolinx electrification plans and requires further coordination with the Working Group
- Significant changes to the study area's forecast growth

The Working Group will continue to meet at regular intervals during the implementation phase of this IRRP to monitor developments in the sub-region, progress towards the deliverables in Table 8-1, and developments that would trigger an early return to the IRRP process.

9. Community and Stakeholder Engagement

Community engagement is an important aspect of the regional planning process. Providing opportunities for input in the regional planning process enables the views and preferences of the community to be considered in the development of the plan and helps lay the foundation for successful implementation. This section outlines the engagement principles as well as the engagement activities undertaken to date and next steps for the Barrie/Innisfil IRRP.

A phased community engagement approach is being undertaken for the Barrie/Innisfil IRRP based on the core principles of creating transparency, engaging early and often, and bringing communities to the table. These principles were established as a result of the IESO's outreach with Ontarians in 2013 to determine how to improve the regional planning and siting process, and they now guide IRRP outreach with communities and will ensure this dialogue continues as the plan moves forward.

Figure 9-1: Summary of Barrie/Innisfil Community Engagement Process

Creating Transparency:

Creation of IRRP Information Resources

- Dedicated Barrie/Innisfil IRRP web page created on IESO website providing background information, the IRRP Terms of Reference and listing of the Working Group members
- Dedicated web page created on Hydro One website
- Self-subscription service established for the South Georgian Bay/Muskoka planning region for subscribers to receive regional planning updates
- Status: complete

Engaging Early and Often:

Municipal and Indigenous Outreach

- Posting of South Georgian Bay/Muskoka Scoping Assessment Report for feedback (May-June 2015)
- Group and individual meetings held with municipalities from across the planning region in Barrie, Innisfil, Simcoe County and Springwater (August - November 2015); follow-up meetings held to discuss the draft IRRP recommendations prior to posting the IRRP (November 2016)
- Meeting held with Indigenous communities from across the South Georgian Bay/Muskoka planning region.
- Status: initial outreach complete; dialogue continues

Bringing Communities to the Table:

Broader Community Outreach

- Barrie/Innisfil LAC to be formed in early 2017; dedicated Barrie/Innisfil engagement web page to be added to IESO website
- LAC meetings to discuss longer-term needs in the sub-region, and broader community engagement to help inform the next planning cycle
- LAC meetings will be open to the public; materials will be posted to the engagement webpage
- Status: beginning in early 2017; on-going

9.1 Creating Transparency

To start the dialogue on the Barrie/Innisfil IRRP and build transparency in the planning process, a number of information resources were created for the plan. A dedicated Barrie/Innisfil web page[11] was created on the IESO website including information on why an IRRP was being developed for the Barrie/Innisfil Sub-region, the IRRP Terms of Reference and a listing of the organizations involved. A dedicated email subscription service was also established for the broader South Georgian Bay/Muskoka planning region where communities and stakeholders could subscribe to receive email updates about the IRRP.

9.2 Engage Early and Often

Early communication and engagement activities for the Barrie/Innisfil IRRP included posting the South Georgian Bay/Muskoka Region Scoping Assessment document for comment and undertaking meetings with communities in the planning area to discuss the development of the plan and obtain early input and feedback.

9.3 South Georgian Bay/Muskoka Region Scoping Assessment Outcome Report

The draft South Georgian Bay/Muskoka Region Scoping Assessment Outcome Report was posted to the IESO website in May 2015 for comment, and a final version was posted on June 22, 2015. The Scoping Report identified the need for an IRRP for the Barrie/Innisfil Sub-region and presented the Terms of Reference for the development of the plan.

9.4 Municipal Meetings

Meetings with area municipalities are one of the first steps in engagement for all regional plans. In August through November 2015, the Working Group held individual and group municipal meetings in Barrie, Innisfil, Simcoe County, and Springwater to initiate discussions on the IRRP. Key discussion topics included: the regional planning process and findings in the South Georgian Bay/Muskoka Scoping Report, the need for an IRRP for the Barrie/Innisfil area, municipal growth plans and electricity growth forecasts, the identified electricity needs in the area and future engagement activities. Attendees provided insight on updated municipal growth plans, reinforced the importance of community engagement for project/infrastructure siting, and expressed an interest in having a LAC as a forum to bring local municipalities to the table and engage in a singular dialogue.

---

[11] http://www.ieso.ca/Pages/Ontario%27s-Power-System/Regional-Planning/South-Georgian-Bay-Muskoka/Barrie/Innisfil.aspx

9.5 Bringing Communities to the Table

To continue the dialogue on regional planning, a LAC[12] will be established for the Barrie/Innisfil Sub-region in early 2017. The role of the LAC will be to provide advice and recommendations on the development of options to meet the longer-term electricity needs in the area, as well as to provide input on broader community engagement. LACs are comprised of municipal, Indigenous, environmental, business, sustainability and community representatives. All LAC meetings are open to the public and meeting information and materials will be posted on the Barrie/Innisfil engagement webpage.

Development of the Barrie/Innisfil LAC will be carried out through a request for nominations process promoted by the following activities: advertisements in local newspapers and digital (website) advertising in communities throughout the planning area; emails sent to municipal representatives across the region; meetings with Indigenous communities for the broader region; and an e-blast sent to the IESO's South Georgian Bay/Muskoka subscribers list. Information will also be posted to the dedicated Barrie/Innisfil IRRP webpage.[13]

Meetings were also held with the area municipalities in November 2016 prior to the posting of the IRRP to discuss the recommendations included in the plan as well as future engagement activities such as the development of a LAC.

10. Conclusion

This report documents an IRRP that has been carried out for the Barrie/Innisfil area, a sub-region of the OEB's South Georgian Bay/Muskoka planning region. The IRRP identifies electricity needs in the Barrie/Innisfil Sub-region over the 20-year period from 2015-2034, identifies preferred "wires" solutions to address near-term needs, and lays out actions to monitor, defer, and address needs that may arise in the long term.

Implementation of the near-term plan is already underway. Hydro One is developing the Barrie Area Transmission Reinforcement project, and LDCs are continuing to implement their existing CDM plans. PowerStream and InnPower have also initiated a LAP study for the Barrie TS, which will be used to inform the long-term options discussion for the next planning cycle and discussion with the future LAC.

To further refine and implement the preferred near-term "wires" solutions, it is recommended that an RIP be initiated. The RIP for the broader South Georgian Bay/Muskoka Region is to be led by Hydro One Transmission. For recommendations relating to Barrie/Innisfil, the RIP process should include PowerStream and InnPower as working group members. The IESO will continue to provide support throughout the RIP process, and assist with any regulatory matters that may arise during plan implementation.

To support the development of the long-term plan, a number of actions have been identified to develop alternatives, engage with the community, and monitor load growth in the sub-region. Responsibility for these actions has been assigned to the appropriate members of the Working Group. Information gathered and lessons learned as a result of these activities will inform development of the next iteration of the IRRP for the Barrie/Innisfil Sub-region.

The Barrie/Innisfil Sub-region Working Group will continue to meet at regular intervals to monitor developments in the sub-region and track progress toward the plan deliverables. In particular, the actions and deliverables associated with peak demand reducing initiatives will require annual review of system demand and program achievement to determine whether new initiatives are required. In the event that underlying assumptions change significantly, local plans may be revisited through an amendment, or by initiating a new regional planning cycle sooner than the OEB-mandated 5-year schedule.

1.3 (5.2.2) COORDINATED PLANNING WITH THIRD PARTIES - CUSTOMER ENGAGEMENT

The Renewed Regulatory Framework (RRF) is a comprehensive performance-based approach to regulation that is based on the achievement of outcomes that ensure that Ontario's electricity system provides value for money for customers. One of the main outcomes is *Customer Focus*: services are provided in a manner that responds to identified customer needs and preferences[1]. Hydro One understands that its services are a major driver of long-term success of the Company and its customers and therefore uses various means to obtain feedback from its customers. This feedback is then incorporated into the investment planning process and to inform Hydro One's Business Plan

Customer Engagement was and remains critical to the planning decisions and process that Hydro One follows. Including this information in this chapter demonstrates the up-front commitment to focus on customers and their requirements.

1 Ontario Energy Board, *Renewed Regulatory Framework for Electricity*, October 2012, Page 2

1.3.1 (5.2.2 A) HOW CUSTOMER NEEDS ARE DETERMINED

Hydro One has a three-pronged approach to engaging its distribution customers:

1. formal customer engagement;
2. stakeholder engagement; and
3. other ongoing forums for Hydro One to interact with customers.

Hydro One worked with a consultant to design a formal customer engagement process to assist in engaging customers through a series of meetings to hear their concerns, priorities and preferences. This feedback informed the investment plan that is the basis of this rate application. This customer engagement process is discussed in Section 1.3.2 of this Exhibit.

Hydro One uses a stakeholder engagement process to approach industry stakeholders and OEB staff to receive input from special interest groups and associations that represent Hydro One distribution customers. A total of four stakeholder sessions were held in relation to this Application. They are discussed further in Section 1.3.2.4 of this Exhibit.

Other ongoing initiatives include:

Customer Surveys

Surveys are used to gauge the current satisfaction levels of the distribution customer groups (e.g., residential, local distribution companies, small business, commercial and industrial) and identify issues. Some of these surveys are annual and others are transactional. Transactional surveys are issued after a customer has had direct contact with a Hydro One representative either from the Customer Call Centre or with a field trade group such as Provincial Lines or Forestry.

Focus Groups

Sessions are conducted by a third party on behalf of Hydro One whereby pre-screened groups of people are approached and asked questions about Hydro One and its current practices. The questions can target specific areas of interest for Hydro One and allow for detailed questions.

Direct Personal Contact

Large Distribution Account ("LDA") and Embedded Local Distribution Companies ("LDC") have regular interactions with Hydro One. Zone Superintendents are aligned with LDA customers and Key Account Executives are aligned with Embedded LDCs to better communicate the more complex needs of larger customers.

Call Centre Contact

For Residential and Small Business customers, Hydro One receives ongoing feedback regarding its current performance through its call centre, fax, e-mail, and/or online.

These initiatives are discussed further in Exhibit A, Tab 4, Schedule 1, Customer Service Strategy.

1.3.2 (5.2.2 A) CUSTOMER ENGAGEMENT PROCESS

When the Hydro One investment program is developed, it is guided by the RRF that states that utilities must, "…demonstrate consideration of all relevant factors, including the needs of existing and future customers and the costs to meet them, and that planning has been informed by appropriate engagement…[2]".

Ipsos, an established vendor of record with Hydro One was selected to work on the Distribution Customer Engagement initiative based upon their previously demonstrated ability to deliver the work required and their ability to meet the timelines in support of this Distribution Rate Application. Ipsos is a global independent market research company, ranked third worldwide among research firms, managed and controlled by research professionals through offices in eighty-seven countries.

Ipsos was commissioned by Hydro One, "…to assist with the design, execution, documentation, and analysis of feedback for the customer engagement and engagement process. By engaging Ipsos, a third-party research firm, the Company set out to establish an engagement process that ensured the facilitation, development of research and questions, and report writing provided an unbiased, unvarnished, evidence-based engagement report to support the filing. As a key element of its application for distribution rates, the outcome of this engagement process helped to determine Hydro One's electricity distribution rate application for a five-year period between 2018 and 2022."[3] See Attachment 1 for the Ipsos Report.

The objectives for the distribution customer engagement were to:

---

2 Ontario Energy Board, Renewed Regulatory Framework for Electricity, October 2012, Section 2.5

3 Ipsos, Distribution Customer Engagement Report, August 2016, p.20.

- Establish the process, vehicles, and conditions for effective engagement that captures the feedback of all distribution customer segments;
- Provide every customer with an opportunity to participate;
- Adopt a research-based approach to engagement to gather the data necessary to support an informed and representative view;
- Contribute to unbiased analysis of customer input by engaging external research professionals; and
- Demonstrate flexibility and provide tangible evidence of Hydro One's willingness to listen, learn and establish plans that reflect and respect the needs of its customers.[4]

To achieve these objectives, Ipsos led several efforts on Hydro One's behalf to obtain an impartial understanding of the issues faced today by Hydro One distribution connected customers. Some of the means by which Ipsos approached Hydro One customers to understand their needs and preferences were:

- Phone Surveys - Telephone survey of random and representative sample of Residential and Small Business Hydro One customers;
- On-line Surveys accessing an Ipsos Panel of respondents. An online workbook was used to survey a representative sample of Residential and Seasonal customers drawn from an on-line panel sample;
- Focus Groups for Residential and Small Business customers;
- Open Link Online Survey for Residential/Seasonal, Small Business, Commercial & Industrial customers. For customers who did not wish to complete the survey online, there was an option to complete the survey by phone or a paper copy;
- On-line Survey for Large Distribution Accounts, Local Distribution Companies; and
- In-person Workshops for Large Distribution Accounts, Local Distribution Companies, Commercial & Industrial customers facilitated and recorded independently by Ipsos.

4 Ipsos, Distribution Customer Engagement Report, August 2016, p.5.

1.3.2.1 PRINCIPLES AND DESIGN

The following principles and objectives guided the engagement design and implementation:

- Hydro One entered into the engagement process in good faith with a view to facilitating and streamlining future OEB proceedings related to the application;
- Hydro One received and considered all submissions but retained control over the process of developing its application;
- All engagements were carried out on a without-prejudice basis;
- An independent facilitator documented and reported the discussions and any agreements reached with all or some participants; and,
- Agreements reached are submitted to the OEB as part of the evidence for this application.

The overall goal for the sessions was to create a forum for participants and Hydro One to discuss issues related to the Hydro One Distribution Rate Application and to identify areas of agreement and concern to shape the pre-filed evidence. To further this mandate, participants were asked to:

- Represent the various views of their customers/constituencies; and
- Assist Hydro One to understand their goals and issues through participation in a process of open dialogue and submissions.

The specific objectives for stakeholder engagement included:

- Inform and update key stakeholders about Hydro One’s Distribution business, and the approaches and methodology used to determine revenue requirement and rate design;
- Give stakeholders a range of opportunities to provide input and feedback on aspects of the Application;
- Ensure stakeholder concerns and views are identified, understood and considered in the preparation of the application;
- Act as a forum for the exchange of information and views;

- Assist Hydro One to anticipate and respond to stakeholder and customer views and preferences; and
- Clarify and scope as many issues as possible prior to the Hydro One submission to the OEB.

1.3.2.2 WEBSITE

As part of the engagement process, Hydro One created links to the 2018-2022 Distribution Custom Incentive Rate Application on its Distribution Rates Applications web page on its external website. The intent is to provide interested stakeholders the opportunity to monitor the engagement process and to provide input throughout the engagement.

The web page (http://www.hydroone.com/RegulatoryAffairs/Pages/DxRates.aspx) is updated regularly and contains meeting agendas, presentations made available at the stakeholder sessions and the meeting notes. Hydro One stakeholders were advised by email about the sessions, agendas, and how to participate or follow the proceedings via the regulatory website if they could not attend.

1.3.2.3 CUSTOMER PARTICIPATION

To ensure that as many customers as possible had the opportunity to participate, Hydro One used the following methods to notify customers of its engagement process:

- two press releases;
- bill inserts;
- newspaper advertisements;
- earned media; radio ads;
- eBlasts (English and French);
- posters to MPPs’ offices;
- targeted social media (FaceBook, Twitter);

- printed invitations to participate in the on-line survey (Commercial & Industrial); and
- e-mail invitations with follow-up calls (LDA, LDC/DG).

There were 19,861 residential and small business customer responses through focus groups, an online workbook (Ipsos panel), or by telephone survey. There were also 201 medium and large business customer responses through in-person workshops held in seven locations across the province or on-line workbooks.

Table 7 - Customer Meeting Details

#	Date	Location	Customers	Emerging Themes on Customer Needs and Preferences
1A	June 8, 2016	Hamilton	LDC LDA	• Outage Communication • Power Quality
1B	June 8, 2016	Hamilton	Commercial Industrial	• Awareness of tools and resources • Outage Communication • Customer Service and Relationship • Power Quality • Rate Increase vs. Reliability
2	June 9, 2016	Collingwood	LDC LDA Commercial Industrial	• Planning • Cost Reduction and Efficiencies • Company Culture • Role of Utility • Local Needs
3	June 13, 2016	Timmins	LDA LDC Commercial Industrial	• Cost • Reliability • Capacity and Expansion • Customer Service • Efficiency

#	Date	Location	Customers	Emerging Themes on Customer Needs and Preferences
4	June 14, 2016	Thunder Bay	LDA LDC Commercial Industrial	• Cost • Efficiencies and Optics • Power Quality
5A	June 16, 2016	London	LDA LDC	• Outage Communication • Overall Communication of concerns • Power Quality • Rates • Responsibility to rate payers vs. shareholders
5B	June 16, 2016	London	Commercial Industrial	• Billing • Future of the Grid • Rate Increases and Efficiencies
6	June 17, 2016	Windsor	LDA LDC Commercial Industrial	• Capacity • Power Quality
7	June 24, 2016	Kingston	LDA LDC Commercial Industrial	• Regional Concerns • Sharing of Expertise

See Attachment 2 in Section 1.3.5 for the executive summaries of the customer meetings.

1.3.2.4 STAKEHOLDER SESSION SUMMARY

In the Hydro One Networks Inc. 2015-2019 Distribution Rates Application Decision, dated March 12, 2015, for proceeding EB-2013-0416, the OEB directed Hydro One to perform several productivity studies to be filed with Hydro One's next Distribution Rates application.

Hydro One sought stakeholder feedback on the proposed approach and framework for four separate OEB-directed distribution productivity studies: (i) Vegetation Management Program Study; (ii) Total Factor Productivity Study; (iii) Pole Replacement Program Study and (iv) Distribution Station Refurbishment Program Study.

Hydro One's experience has been that early involvement with stakeholders is critical to developing a submission that reflects the broad interests and concerns of the Ontario Energy Board ("OEB") and Hydro One Distribution's constituencies. Stakeholder groups including intervenors from previous Hydro One rate proceedings, OEB staff, embedded LDCs and large distribution accounts were invited to participate in all of the stakeholder sessions via an invitation letter and a follow-up e-mail. Approximately, forty groups were invited to participate in the stakeholder sessions either in person or via teleconference. Hydro One believes that those invited were representative of the interests of the majority of its stakeholders.

Those stakeholders that were not able to attend were invited to monitor the process through the company's website and to provide input throughout the process. Funding was available to eligible intervenors consistent with the current OEB's Practice Direction on Cost Awards.

Hydro One held four stakeholder sessions in association with this distribution rate application; two sessions addressed the undertaking and preliminary results of four distribution productivity studies; one session to discuss key findings of the Total Compensation Study and how customer feedback and productivity was incorporated into the distribution system plan; and one session was to obtain feedback on the key issues and challenges with Hydro One's 2018 to 2022 Distribution Rate Application.

The overall goal of the stakeholder sessions was to improve the quality and comprehensiveness of the productivity studies and pre-filed evidence and to minimize the issues to be addressed at the OEB hearing. The engagement sessions consisted of presentations to stakeholders followed by facilitated discussions on the issues raised. The presented information and notes of meeting were also made available through Hydro One Networks' website for those stakeholders that could not attend the sessions. In addition, Hydro One staff was available for informal dialogue with stakeholders throughout the process.

All stakeholder sessions were held in accordance with the principles, objectives, participation format, and engagement format described in Section 1.3.2.1.

Session #1 – Productivity Study Proposed Methodology

Session #1 was held on October 22, 2015 at the DoubleTree Hotel in Toronto using Swerhun Facilitation to facilitate the session and produce the minutes of the meeting. Eighteen participants attended, representing eleven stakeholder groups, and OEB staff. In this session, CN Utility Consulting (Vegetation Management Program Study), Power System Engineering Inc. (Total Factor Productivity Study), Navigant Consulting, and First Quartile Consulting (Pole Replacement Program and Distribution Station Refurbishment Program Studies) presented and sought participant feedback on an overview of their respective proposed study methodology, benchmarking approach, peer group selection criteria, and metric selection.

Session #2 – Productivity Study Preliminary Results and Findings

Session #2 was held on October 5, 2016 at the DoubleTree Hotel in Toronto with Hardy Stevenson and Associates Limited acting as the facilitator and scribe for the meeting minutes. Fourteen stakeholders attended, representing eleven stakeholder organizations, and OEB staff. In this session, Power System Engineering Inc., CN Utility, Navigant Consulting and First Quartile Consulting presented and sought participant feedback on preliminary findings and recommendations resulting from their respective studies.

Session #3 – Total Compensation Study, Customer Engagement, Performance Metrics and the Distribution System Plan

Session #3 was held on November 30, 2016 at the DoubleTree Hotel in Toronto with The Fixers Communications Group Inc. acted as facilitator and scribe for the meeting minutes. Fourteen stakeholders attended, representing eleven stakeholder organizations, and OEB staff. In this session:

- Mercer Canada presented the methodology and findings of a comprehensive compensation cost benchmark study, the fourth in a series of such benchmark studies performed by Mercer Canada on behalf of Hydro One (2008, 2011, 2013, and 2016). The Total Compensation Studies are to provide useful and reliable information concerning Hydro One's compensation costs, and how these costs compare to those of other regulated distribution utilities in North America.

- Ipsos Reid presented high-level findings of quantitative and qualitative stakeholder research that they undertook for Hydro One Networks in the summer of 2016. The overall objective of Hydro One's customer engagement process was to obtain a deeper understanding of customer needs and preferences to facilitate the building and managing of strong productive relationships with customers now and in the future.

- Hydro One staff presented the existing and the proposed performance metrics submitted as part of this distribution rate application to demonstrate its commitment to continuous improvement in the areas of productivity and cost efficiency and alignment with the Renewed Regulatory Framework outcomes in the areas of Customer Focus, Operational Effectiveness, Public Policy Responsiveness and Financial Performance. Hydro One was seeking input to ensure the metrics chosen would allow OEB staff and Intervenors to monitor key outcomes and Hydro One's commitment to its distribution system plan.

- Lastly, Hydro One staff delivered a presentation on how the results of the customer engagement process informed Hydro One's DSP and how the proposed metrics would measure and monitor the success of Hydro One's investments and expenditures.

Session #4 – Application Details

Session #4 was held on February 8, 2017 at the DoubleTree Hotel in Toronto with Ehl Harrison Consulting Inc. acting as facilitator and scribe for the meeting minutes. Discussion topics included:

- **2018 to 2022 Custom IR Application Framework –** An overview of the distribution rate application framework. The application is aimed at balancing competing priorities, those being asset needs, customer needs and preferences, and rate impacts. The topic included a review of the 5-year revenue requirements, the estimated rate changes over the period and the contributing factors.

- **Econometric Benchmarking of Total Costs –** This topic included the findings of an econometric study presented by Steve Fenrick of Power Systems Engineering Inc. It included identification and recommendation of an appropriate stretch factor.

- **Distribution Cost Allocation / Rate Design -** A presentation of Hydro One's methodology to forecast load for 2018 to 2022, allocate costs between customer classes, determine customer classes, and implement OEB-approved rate design changes. It includes Hydro One's plan to integrate the acquired utilities with

- respect to rates. The presentation also included the associated bill impacts based upon typical consumption levels.

- **Capital and OM&A Core Work Program -** An overview of the components of the OM&A expenditures; specifically, sustaining, development, operating and customer service details. The primary goal in the management of distribution assets is centred on sound investment strategies to keep costs low and minimize rate impacts. Hydro One demonstrate that the proposed core work projects and programs have been developed to address customer preferences and outcomes.

Detailed notes from the four stakeholder sessions are included in Attachment 3 in Section 1.3.5.

1.3.2.5 FIRST NATIONS ENGAGEMENT SUMMARY

Hydro One serves eighty-eight First Nations communities. A First Nations Engagement Session was held on February 9 and 10, 2017. The main objectives of the discussion session were to hear First Nations' priorities and to solicit feedback on the upcoming Distribution Rates submission to the OEB. To provide the best environment for the engagement session with the First Nations, Hydro One consulted with Hunter Courchene for advice on the logistics to include in the sessions and to create the invitation and contact the First Nations participants on behalf of Hydro One. Hunter Courchene provided the note taking for the sessions. Phil Goulais was hired to act as facilitator. Mr. Goulais has experience with First Nations and is often called upon by First Nations to chair their meetings.

The presentations included an overview of the key features of the distribution system and the rate setting approach for the 2018 to 2022 application This included the general characteristics of the application and the associated rate impacts. There was also a discussion on the approvals sought in the application along with how Hydro One incorporated customer preferences, cost efficiencies and productivity into the application. Hydro One outlined its value proposition for customers that governs the delivery of safe, reliable and affordable service. Additionally, presentations were made on Hydro One's new Customer Care approach and on Hydro One's operations reliability measures.

Session reports from both days of the engagement are provided in Attachment 4 to this Exhibit.

1.3.2.6 METIS DISCUSSION SUMMARY

An engagement session, similar to the First Nations session, was held on May 13, 2017 with representatives of the Métis Nation of Ontario. Hunter Courchene provided the note taking for the session. This discussion included the same topics that were delivered at the First Nations' discussion sessions along with additional information on Hydro One's employment, training and procurement program initiatives.

A session report was not available at the time of filing.

1.3.2.7 CUSTOMER ENGAGEMENT PROCESS SUMMARY

Hydro One's customer and stakeholder engagement process meets the objectives described in Section 1.3.2. Hydro One believes customers and stakeholders have a better understanding of its operations and business practices. More importantly, Hydro One improved its understanding of customer needs and stakeholder issues and concerns through the engagement process. Hydro One has shaped its investment plan and distribution rate application accordingly – by aligning customer preferences, responsible stewardship of assets and impact of rates.

1.3.3 SUMMARY OF CUSTOMER NEEDS AND PREFERENCES

As a result of the customer outreach, Ipsos analyzed the results and wrote a report detailing the results of each of the outreach methods (e.g., open link surveys, phone surveys) by segment, to guide Hydro One distribution investment decisions.

As there were several customer segments involved in the engagement sessions for Hydro distribution-connected customers, the key themes varied by customer segment. The Ipsos report showed the following:

- Cost is definitely the top priority for Residential and Small Business customers, and is one of the top priorities for Large Customers. This preference is influenced by a desire to see Hydro One demonstrate greater fiscal management and operational efficiency before considering rate increases. Many customers believe that total electricity costs are approaching an unaffordable level.

- Maintaining reliable electricity service is consistently second, in terms of priority, compared to cost. Residential and Small Business customers expressed the view that Hydro One should maintain existing levels of power reliability and quality. For Large Customers, improving power quality and reducing the number and duration of sustained outages is a top priority along with cost.

- Willingness to accept a rate increase to maintain and improve service level is limited. The majority of residential and small business customers are unwilling to accept higher rate impacts for better reliability.

- Large customers are more concerned with the reliability of service they currently receive than residential and small business customers and accept that investments are needed. However, although this group of customers is more inclined to value better reliability, it is not willing to entertain the corresponding rate impact.

- Customer service improvements above existing levels are not something for which customers are willing to pay higher rates.

- For large customers, power quality events and unplanned momentary power interruptions of less than one minute, rather than sustained interruptions of one minute or more, are the primary concern. Some customers have capacity challenges and want more access to power in order to grow their enterprises.

- All large customer segments prioritize the renewal program that focuses on replacing equipment that affects reliability ahead of other options for improving reliability. Other options include: tree-trimming, using technology to reduce the chances of losing power, strengthening the grid to better withstand severe weather, better detection of outages and/or remotely responding to outages.

- Commercial and Industrial customers welcomed the opportunity to participate in engagements and are looking for a more active relationship with Hydro One,

- Several Large Customers spoke about a need for greater capacity and want Hydro One to more strongly advocate and support their requests for capacity.

- Large Customers want improved outage customer communications with more accurate estimates of power restoration.

- There is a low awareness of Hydro One's role in the energy industry and negative views of the electrical industry and current government also perform a role.

- Large Customers wanted a greater transparency of Hydro One operations and administration, to include planned investments.[5]

5 Ipsos, Distribution Customer Engagement Report, August 2016, pp. 144-145.

1.3.4 (5.4.1 F) HOW THE PLAN REFLECTS CUSTOMER NEEDS AND PREFERENCES

Hydro One's Distribution System Plan is designed to reflect customers' needs and preferences. Highlights of the specific measures being taken to address the customer engagement information are listed below.

1. Customers indicated that keeping rates low was a priority. Many customers, especially residential customers, asserted that reliability performance is a second priority compared to rates.

Response: Hydro One has deliberately deferred some 2018 capital spending in order to pace investments in such a way as to minimize rate impacts and offset the effects of a reduced load forecast. This includes managing rate of replacement and, where appropriate, accepting short-term, small scale, reliability impacts in order to reduce or defer capital spending requirements and minimize rate impacts.

2. Customers asked that Hydro One demonstrate greater fiscal management and operational efficiency before considering rate increases.

Response: Hydro One has implemented a number of productivity initiatives to reduce unit and operational costs and the associated rate impacts. These productivity initiatives are detailed in Section 1.5.

3. Residential and Small Business customers requested that Hydro One maintain its existing level of reliability.

Response: To sustain reliability performance across the Province, Hydro One has assessed the condition of its key assets and has developed an investment plan that properly paces renewal investments to achieve this outcome. Supporting this are System Renewal projects and programs such as the Pole Replacement Program, Distribution Station Refurbishment Projects, and Line Renewal Projects.

The pole replacement program will be replacing 77,400 poles over the planning period to manage the volume of poles which have been assessed to be in poor condition. Similarly, the number of distribution stations that are refurbished has been established to sustain the condition of the fleet. Reliability performance of specific feeders that have outlier performance will be addressed by correcting the root cause of reliability on a case by case basis. Some feeder performance improvements will be accomplished through remote monitoring and control of switches and breakers as well as fault locating technology and additional protective devices.

4. A top priority for Large Customers is to improve power quality.

Response: Hydro One has created an OM&A program to assist Large Distribution Account customers with investigations to determine the source of the power quality issue that they are experiencing. In addition, a capital power quality program has been incorporated into the plan. This program will install power quality meters, install surge arresters, and/or improve grounding where needed to assist in power quality investigations. Approximately $200k per year has been allocated to this work. Hydro One has also increased the funding for reliability enhancement projects to specifically target LDA and mid-size industrial customers. These projects are selected to improve system reliability where concerns have been raised by Hydro One’s LDA and mid-size industrial customers that a performance issue exists with the network. A lack of action would see existing reliability levels deteriorate. Investments may include installing lightning arrestors, new switches, automatic sectionalizing devices, or creating feeder ties to improve restoration time. The funding for these investments will increase by approximately $3M, starting in 2018, from the current funding level of approximately $1.5M per year.

The investment plan reflected in this Application seeks to meet customers' needs regarding reliability and power quality, in a manner that controls costs. Hydro One recognises that customers are sensitive to the total delivered price of power. Increased investments in the distribution system result in increased cost to customers. As such, Hydro One's focus will be on executing cost control and driving productivity across the organization, as discussed in Section 1.5, in order to align customer preferences, work programs and rate impacts. Ongoing communications with customers to provide information regarding these facts will be another area of focus for Hydro One during the test years in this Application.

TABLE OF CONTENTS

EXECUTIVE SUMMARY

BACKGROUND AND CONTEXT

Hydro One Networks Inc. (Hydro One) engaged Ipsos to assist with the design, execution, documentation and analysis of feedback from distribution-connected customers for its customer engagement process. Ipsos was engaged to facilitate, to develop research questions, and to provide a resulting report that is unbiased, unvarnished and evidence-based. The views contained in this report are the views of Ipsos, based on analysis of research results and views expressed by Hydro One customers.

This report documents and summarizes the feedback and insight from that engagement, and will be considered by Hydro One as it develops its investment plan to support its Distribution Revenue Requirement and Rate Application for 2018–2022. This application is to be submitted to the Ontario Energy Board (OEB) in early 2017.

Hydro One's customer engagement process contemplates the enhanced engagement between utilities and their customers as described in the OEB's Renewed Regulatory Framework for Electricity (RRFE). The RRFE holds the expectation that utilities, "… demonstrate consideration of all relevant factors, including the needs of existing and future customers and the costs to meet them, and that planning has

been informed by appropriate consultation…" The expectation therein, that utilities provide an overview of associated customer engagement and outreach activities in their applications and that they demonstrate how customers' feedback and needs have been reflected and considered, further shaped Hydro One's approach.

By engaging Ipsos, the company set out to establish a best-in-class customer engagement process. The multi-segmented and multi-channel approach undertaken by Hydro One over a period of approximately three months, provided the opportunity for all segments of the company's distribution-connected customers across the province to participate in the process. As a result, 19,904 Hydro One customers provided their input into this process.

CUSTOMER ENGAGEMENT GOALS

- Establish a comprehensive, best-in-class approach to customer engagement.
- Establish an inclusive, accessible, verifiable, and transparent process to secure the input/feedback necessary to prepare an investment plan and Distribution Rate Application that considers Hydro One's customers' needs and preferences.
- Ensure the associated customer and stakeholder research and feedback meets the spirit and the intent of the RRFE.

CUSTOMER ENGAGEMENT OBJECTIVES

- Establish the process and conditions for effective customer engagement that captures the feedback of all distribution customer segments.
- Ensure every customer has the opportunity to participate.
- Take a research-based approach to customer engagement to gather the data necessary to support an informed and representative view.
- Contribute to unbiased analysis of customer input by engaging external research professionals.
- Demonstrate flexibility and provide tangible evidence of Hydro One's willingness to listen, learn and establish plans that reflect and respect the needs of its customers.

OTHER CONSIDERATIONS FOR CUSTOMER ENGAGEMENT

- Hydro One's customers are geographically dispersed, so it is important to reflect this in a multi-channel communications strategy to reach and encourage as many customers as possible to participate.
- Customer engagement should take place as early as possible to build trust and awareness of the process, and more importantly, to ensure time to develop investment plans based on customer input.
- The process must be professional, well-executed and conducted in a manner that clearly and consistently states the aims, rules, process for all involved.
- While investment scenarios were developed for the customer engagement process with Large Customers, the company does not have a recommended scenario, nor will it ask customers to choose from scenarios presented.
- Customer views and input will be reflected in a resulting investment plan.

GLOSSARY OF TERMS

The following terms are used throughout the report.

TERM	MEANING
Directional differences	Refers to comparisons between sub-groups of customers where the differences cannot be said to be statistically significant
'Informed' Customers	Refers to customers who were provided with additional information about Hydro One's network/business
Large Customer	Refers to the aggregate of the following Large Customer segments: Commercial and Industrial (which will be referred to as C&Is), Large Distribution Accounts (which will be referred to as LDAs), Local Distribution Companies (which will be referred to as LDCs), Connected Distributed Generators (which will be referred to as DGs)
Local Distribution Companies (LDCs) and Distributed Generators (DGs)	Throughout the report, the Local Distribution Companies (LDCs) and Connected Distributed Generators (DGs) (>10 kW) have been managed as one segment; both are supported by the same Key Account Executives
Residential and Small Business Customer (R&SB)	Refers to the aggregate of Residential, Seasonal and Small Business customer segments
Small Business Customer	Refers to General Service customers (<50 kW peak demand and 50 to <500 kW peak demand)
'Uninformed' Customers	These customers did not receive the additional information that 'Informed' Customers did

SUMMARY OF FINDINGS

The following summary is based on the collective feedback of 19,904 distribution customers who provided 20,062 responses through the various customer engagement activities. A full detailing of the customer engagement activities are provided in the Methodology section of this report. Detailed findings from each distribution customer segment are also provided in later sections of this report.

The findings of the engagement process are grouped thematically:

1. Costs
2. Customer priorities
3. Level of reliability customers expect
4. Types of reliability improvements customers value
5. Willingness to accept a rate increase to maintain and improve service levels

1. COSTS

Keeping costs as low as possible is customers' top priority. This was evident across most of Hydro One's distribution customer segments, with the exception of local distribution companies who place a greater priority on receiving reliable service, both in terms of the number and duration of interruptions.

"If there is a way to improve both [service and cost], obviously that is ideal, but if I'm going to weigh one over the other, then I'm going to choose the cost."

Among R&SB customers, the preference for keeping costs low is influenced by three factors:

1. The majority of customers indicate that the current level of reliability and service they receive from Hydro One is in line with their expectations, and therefore there is not a strong desire for improved service, particularly if it means raising rates.

"The service is consistent with very few outages."

"I would rather the company not worry about improving the other areas and instead concentrate on keeping costs low for customers."

2. The preference for keeping costs low, for some customers, is influenced by a desire to see Hydro One demonstrate greater fiscal management and operational efficiency before considering rate increases. There is a perception among some customers that Hydro One has not demonstrated this in the past, and thus some customers do not accept that rate increases are necessary.

"If Hydro [One] had ever been well-managed, they would have known years ago that the equipment needed to be dealt with and would have been looking towards that and doing that every year so that their equipment did not become outdated and go beyond its life expectancy. So, now they're saying all this needs to be done and dealt with and they're already in debt and they're already gouging us with hydro rates. And now they're saying this all has to get fixed. This is how they're trying to justify the extra increase so they can deal with this, but why wasn't this dealt with years ago?"

"I think it's unreasonable honestly because I know the company's net assets have increased 13% since 2012, and something like 4,000 employees have made the Sunshine List, earning over $100,000 a year on the public dime. So, I think it's a little unreasonable to be dipping into the customer's pocket to sustain the level of outages that I personally feel is a little unreasonable."

3. The final factor is that for some customers, electricity costs represent a financial challenge, and are approaching being unaffordable. These customers feel that they simply can't afford an increase in rates. The reference to rates is in relation to the overall bill, rather than a specific comment about the distribution delivery rate charge. This was heard primarily in focus groups and in Workshop feedback from C&I customers, rather than arising from survey responses.

"…some months, I have problems paying my hydro bills. So, because of the rates of hydro and all the additional delivery charges and all of that other stuff that comes on your bill, I actually had to go to equal billing in order to be able to pay my hydro, and that's crazy."

"…electricity prices are certainly surpassing my wage [increases]. So, I always think of it that way that I'm definitely paying more out of pocket in proportion to my income."

2. CUSTOMER PRIORITIES

For those who identify cost as their top priority, maintaining reliable electricity service is consistently their second priority. Many Large Customers, particularly C&I businesses, are facing reliability challenges. For many of them, power quality events and unplanned momentary power interruptions of less than one minute, rather than sustained interruptions of one minute or more, is their primary concern and many express that improvements are needed for their businesses to remain competitive and grow. Other customers are facing capacity challenges and want more access to power in order to grow their enterprises.

Customer service improvements, while desired particularly among Large Customers, are not something for which customers are willing to pay higher rates. However, it is clear that customer service issues for C&I and Small Business customers need to be better addressed for these customers to feel heard. The customer service issues raised by these customers during the customer engagement range from those with relatively specific and potentially simple solutions, such as improving the way in which Hydro One communicates with Large Customers during outages/interruptions and doing a better job explaining the charges (such as Global Adjustment) on the bill, as well as correcting outstanding billing errors, to more complex issues such as the need for greater and more prompt support for capacity expansion applications, as well as for incentive programs.

The sentiments expressed by customers indicate that there is a significant opportunity for Hydro One to improve its communication and overall interaction with Large Customers, specifically C&I customers. The customer engagement activities also exposed several areas where customers, both large and small, lack a sufficient level of awareness or have misconceptions of what is within Hydro One's purview, what is mandated by the OEB, what is the responsibility of the Independent Electricity System Operator (IESO), and what is the role of government in setting policy and directing the IESO on the province's fuel mix, the price of electricity, and cost attribution.

3. THE LEVEL OF RELIABILITY THAT CUSTOMERS EXPECT

As outlined in the Methodology section of this report, Hydro One and Ipsos sought to compare the needs and preferences of R&SB customers in two contexts:

- One representing the average 'uninformed' customer (who received no additional information prior to providing input, as noted below); and,
- One representing customers who prior to answering questions have been informed about Hydro One, its service territory, its performance in terms of the average number and length of power outages and why outages occur. This group of customers is referred to as 'informed' customers throughout the report.

'Uninformed' R&SB customers took part in the Telephone Survey, and were not provided with the informational Workbook about Hydro One, unlike 'informed' customers.

The exercise found several similarities between 'informed' and 'uninformed' customers including that both groups indicate that keeping costs low is their top priority and that reducing the number and duration of power outages that they experience today is their second priority. The level of reliability that customers expect appears to be one of the areas where the views of 'informed' customers differ from that of 'uninformed' customers. 'Informed' customers are directionally more likely to say the current number and average length of outages they experience are worse than they expect.

The majority of 'uninformed' R&SB customers indicate that the level of reliability they currently experience is in line with their expectations or better. Residential and Small Business (non-Seasonal) customers report experiencing an average of roughly three outages of at least one minute in duration in the past 12 months, with Seasonal customers averaging about two outages. The largest share of 'uninformed' customers, 48% of Residential and 55% of Seasonal, indicate that this level of reliability (number of outages) is about what they expect. Only 16% of Residential and 17% of Seasonal customers indicate the number of outages they experienced is worse than they expect. Comparatively, among the 'informed' customer group, more customers (25% of Residential and 35% of Seasonal customers) indicate the number of outages they experienced is worse than they expect. This group is also directionally more likely to say the average length of outages is worse than they expect.

Large Customers as a group are much more concerned with the reliability of service they currently receive than represented in the views of R&SB customers. Under the illustrative scenarios presented by Hydro One in Large Customer Workshops, they are much more inclined to value better reliability, but are not willing to entertain the corresponding rate impact.

4. THE TYPES OF RELIABILITY IMPROVEMENTS THAT CUSTOMERS VALUE

Large Customers were provided with six various investment options that Hydro One could prioritize and asked to rank each of them in order from one to six, where one represents the item that would have the greatest positive impact on their organization and where six represents the item that would have the least positive impact. All Large Customer segments, to a lesser extent C&I, prioritize the Renewal Program that focuses on replacing equipment that affects reliability ahead of other options for improving reliability. Other options include: tree-trimming, using technology to reduce the chances of losing power, strengthening the grid to better withstand severe weather, better detection of outages and/or remotely responding to outages.

Views on secondary and tertiary priorities vary somewhat. LDA customers place the second greatest priority on the Smart Grid, that is, using technology to reduce their chances of losing power. They place this slightly ahead of increased tree-trimming and grid strengthening. LDC/DG customers place tree-trimming in the second position – in fact nearly as many of these customers feel this would have the greatest positive impact on them as those favouring the Renewal Program. C&I customers actually place as much of a priority on grid strengthening as the Renewal Program and then place investments in Smart Grid as their tertiary choice.

When it comes to ranking other service-related options, of which there were seven to rank, all Large Customer segments prioritize providing more accurate estimates of when power will be restored. But, this is followed closely by power quality – that is, monitoring and reducing the number of power quality issues (e.g., your lights flickering). LDA customers actually place this slightly ahead of more accurate power restoration estimates.

5. WILLINGNESS TO ACCEPT A RATE INCREASE TO MAINTAIN AND IMPROVE SERVICE LEVEL

A majority of R&SB customers who offer an opinion are willing to accept the rate impact shown during the customer engagement activities – roughly an additional 1% of the total monthly bill each year for five years – that would maintain the current reliability and service levels. 'Informed' customers – particularly among the Seasonal customer segment – are directionally more willing to accept the rate impacts that would maintain the current number and average length of outages than the average 'uninformed' customer. The majority of R&SB customers are unwilling to accept higher rate impacts for better reliability regardless of whether they are 'informed' or 'uninformed'.

Hydro One's Large Customers generally accept that investments are needed to address the company's aging infrastructure and distribution system. However, they expect Hydro One to exhaust all operational efficiencies before raising rates. As such, at present there is limited acceptance of any of the illustrative rate impact scenarios, even to maintain the current levels of reliability and service. Directionally, between the three scenarios posed – one each for improving, maintaining and degrading reliability – Large Customers are more likely to accept larger rate impacts to maintain and improve reliability than smaller rate impacts for declining reliability.

Rate increases are difficult for many Large Customers to accept as they have concerns and need more information about Hydro One's operational efficiencies and its ability to effectively manage costs. Further, they need to be assured the company has sufficiently explored other options. The opinions of some are influenced by negative experiences they have had in the past that they associate with Hydro One's poor decision-making. This is particularly true of those who struggle with their electricity supply, either in terms of reliability and/or capacity, as well as those who have had billing problems and/or difficulty getting the answers they feel they need from the company.

"I do think you have not been efficient in the last 20 years and I think there's a lot of costs you can cut…what do you think is acceptable, 2.5% or 4% increase...How efficient have you become in the last 5 years, do you have that?"

Negative experiences with and poor perceptions of Hydro One have bled into their view of the company's ability to make prudent, cost-efficient investment decisions. They question Hydro One's current operational effectiveness, and believe that maintaining and improving the system can be achieved by managing costs more effectively rather than increasing rates. As well, because customers perceive that Hydro One is a monopoly in its service area, they are reluctant to believe that the company has the desire to get better.

For some Large Customers, the current high cost of electricity means that a rate increase of any size and on any line item of their bill is unaffordable, and a direct threat to the viability and the competitiveness of their businesses in Ontario. Unfavourable comparisons to prices in other jurisdictions were made several times, as participants perceive that Ontario has one of the highest costs of electricity of any jurisdiction in North America. A rate increase by Hydro One needs to include customer-facing, public details on operational efficiencies, as well as information as to how the company has effectively managed costs to date. The investment plan should detail tangible benefits to the customers who struggle most with reliability — addressing power quality concerns and regional concerns. The plan should also detail how Hydro One can address those with additional capacity needs.

"Good for Hydro One. They've been under the radar, [but it is] very brave of [them] to come out and do these sessions."

"How can we see a rate increase of this magnitude in general, but particularly for decreasing service? Why are there seemingly no attempts to maintain service but to reduce YOUR operating costs?"

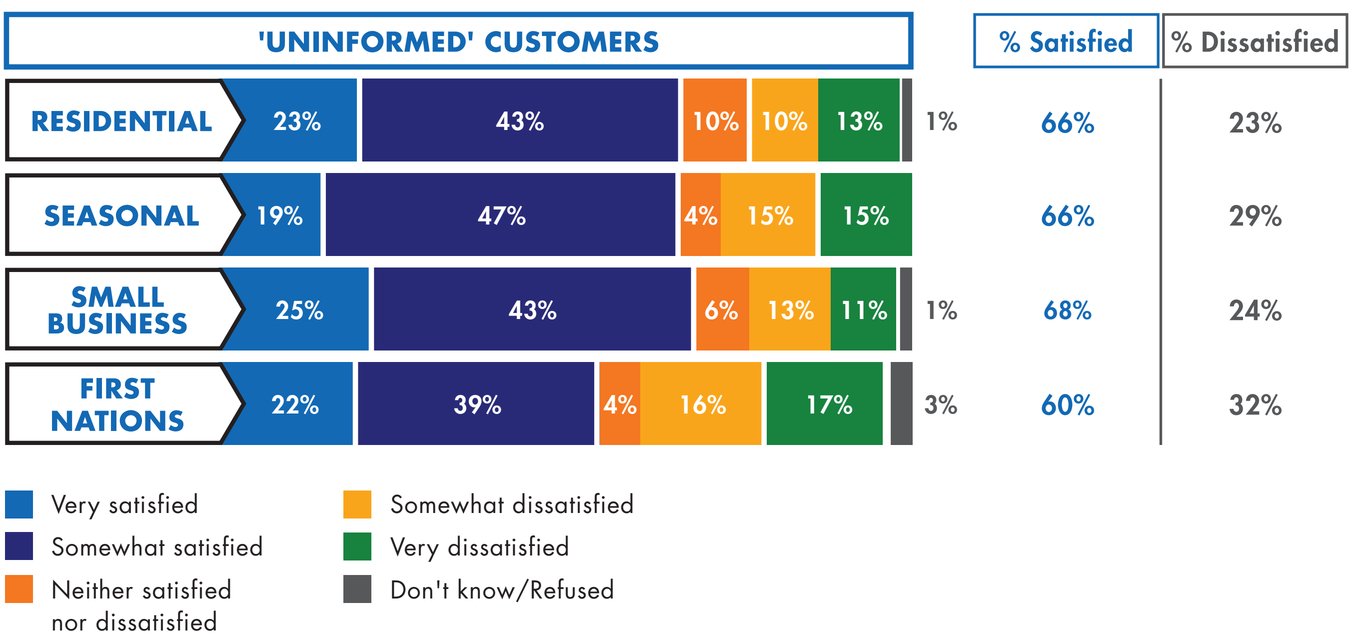
"[I] would have liked to see some slides on what Hydro One is doing internally to identify opportunities to create operational efficiencies and reduce costs internal to the organization."

Overall, as evidenced by the comments and questions raised during the in-person Workshops, the Distribution Customer Engagement was successful in raising awareness of Hydro One's past investment planning and performance, in receiving a wide variety of detailed feedback from all its customer segments, and in positively affecting perceptions of the company by making an effort to engage and listen.

KEY THEMES

Satisfaction with Hydro One does not vary significantly between 'uninformed' customer segments. There is more variation between the 'informed' customer segments including between Large Customer segments. 'Informed' Residential customers report lower satisfaction than 'uninformed' customers.

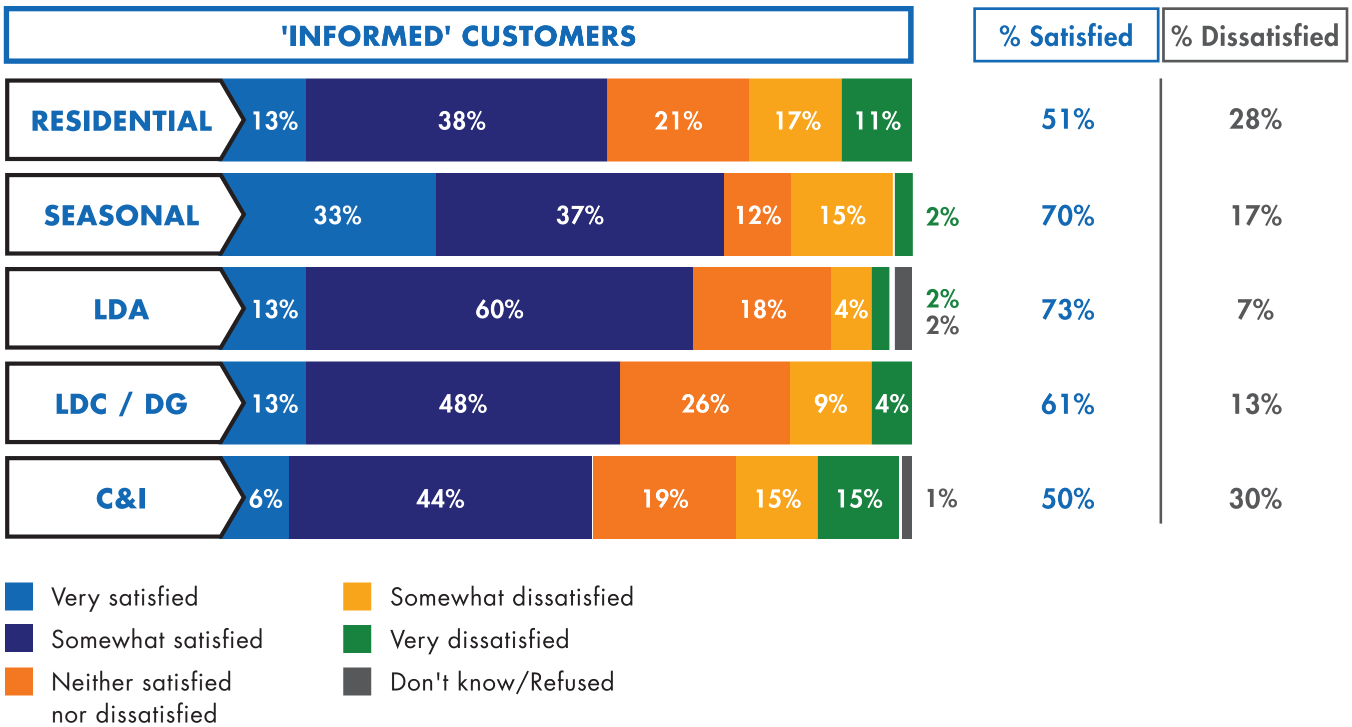
ALL CUSTOMER SEGMENTS
OVERALL SATISFACTION WITH HYDRO ONE



As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices. Q1. How satisfied are you with Hydro One overall? Note: During the first week of fielding the response scale was changed from 1 to 5 to a word scale to be consistent with the Annual Customer Satisfaction survey. Base: All Respondents Post Q change; Telephone Survey: Residential (n=243), Seasonal (n=68), Small Business (n=159), First Nations (n=204)

ALL CUSTOMER SEGMENTS

OVERALL SATISFACTION WITH HYDRO ONE



As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices. Q1. How satisfied are you with Hydro One overall? Note: During the first week of fielding the response scale was changed from 1 to 5 to a word scale to be consistent with the Annual Customer Satisfaction survey. Base: All Respondents Post Q change; Online Workbook: Representative Sample: Residential (n=1384), Seasonal (n=98) / Large Customers: LDA (n=45), LDC/DG (n=23), C&I (n=133)

The largest share of 'uninformed' customers indicate that the current number and average length of outages they experience is about what they expect. 'Informed' customers are directionally more likely to indicate it is worse than they expect.

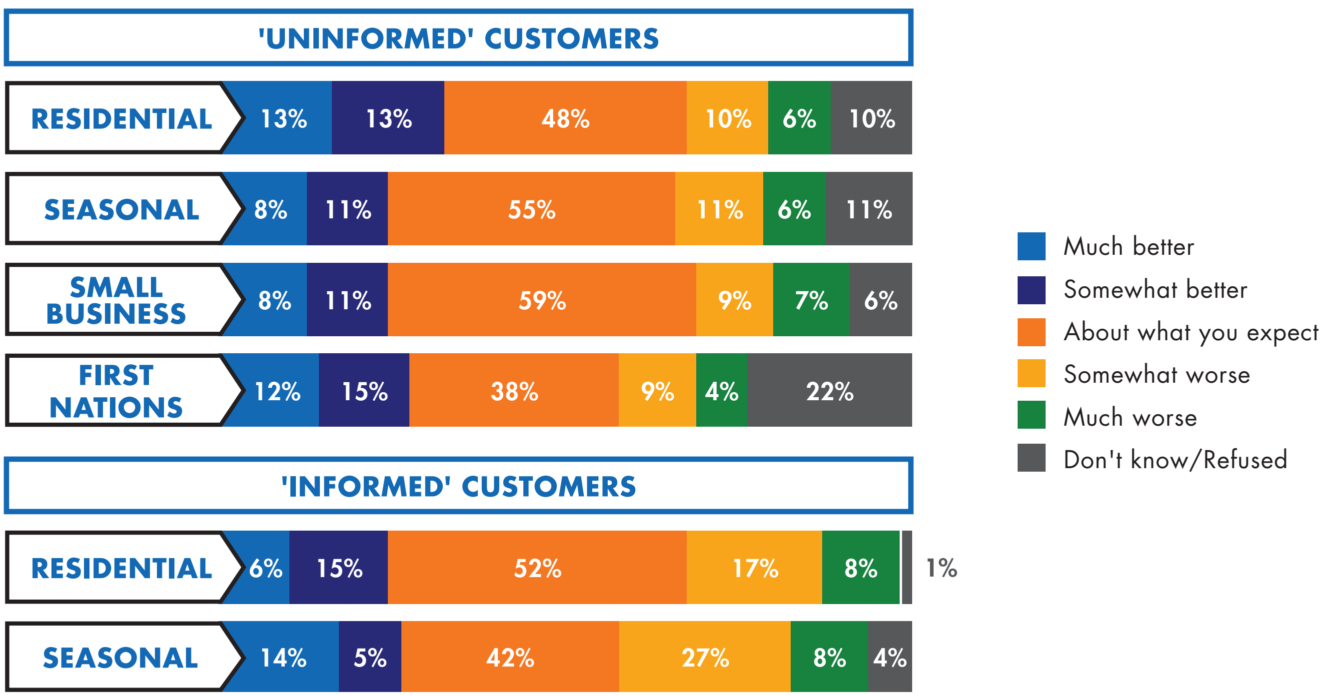
RELIABILITY EXPECTATIONS

NUMBER OF OUTAGES

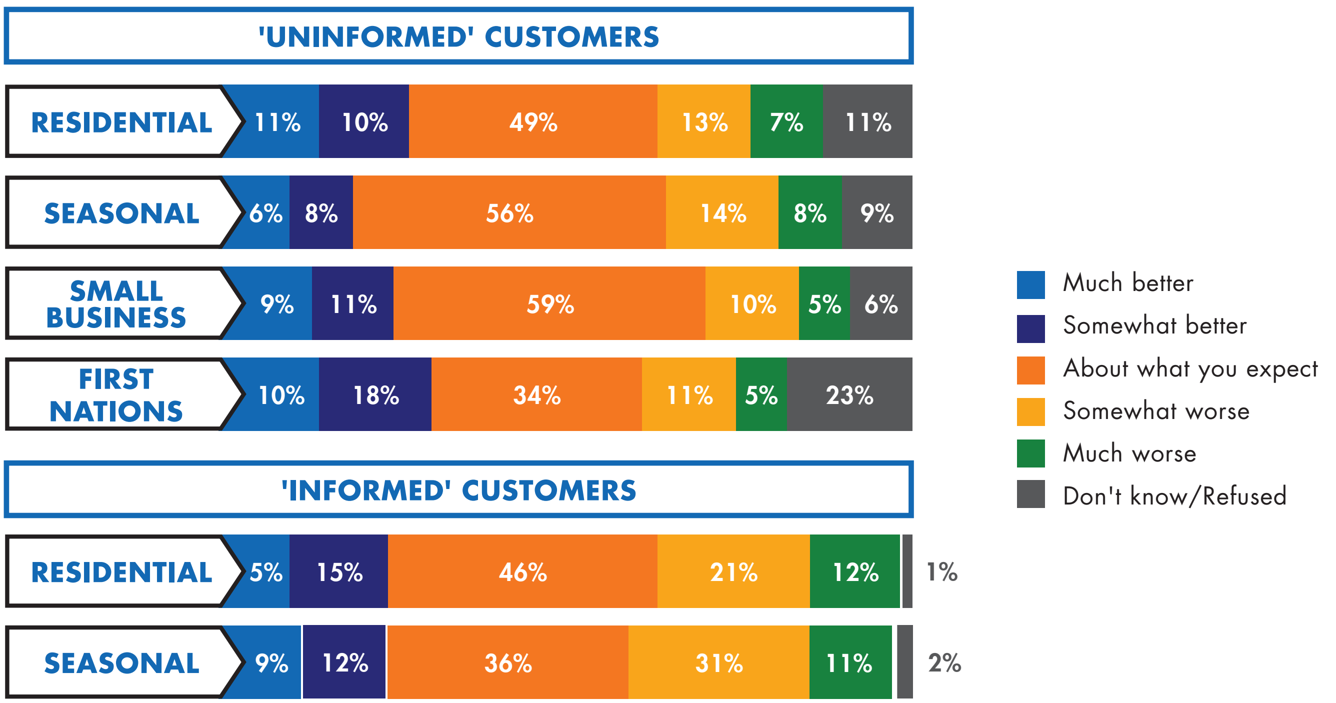


Q8. In general, when you think about how many power outages you experienced over the last 12 months how did it compare to your expectations [READ LIST]? Base: One or more sustained power outages in the past 12 months; Residential (n=314), Seasonal (n=66) Small Business (n=144), First Nation (n=217). Informed: Residential (n=977), Seasonal (n=52)

TELEPHONE SURVEY + ONLINE WORKBOOK REPRESENTATIVE SAMPLE

RELIABILITY EXPECTATIONS

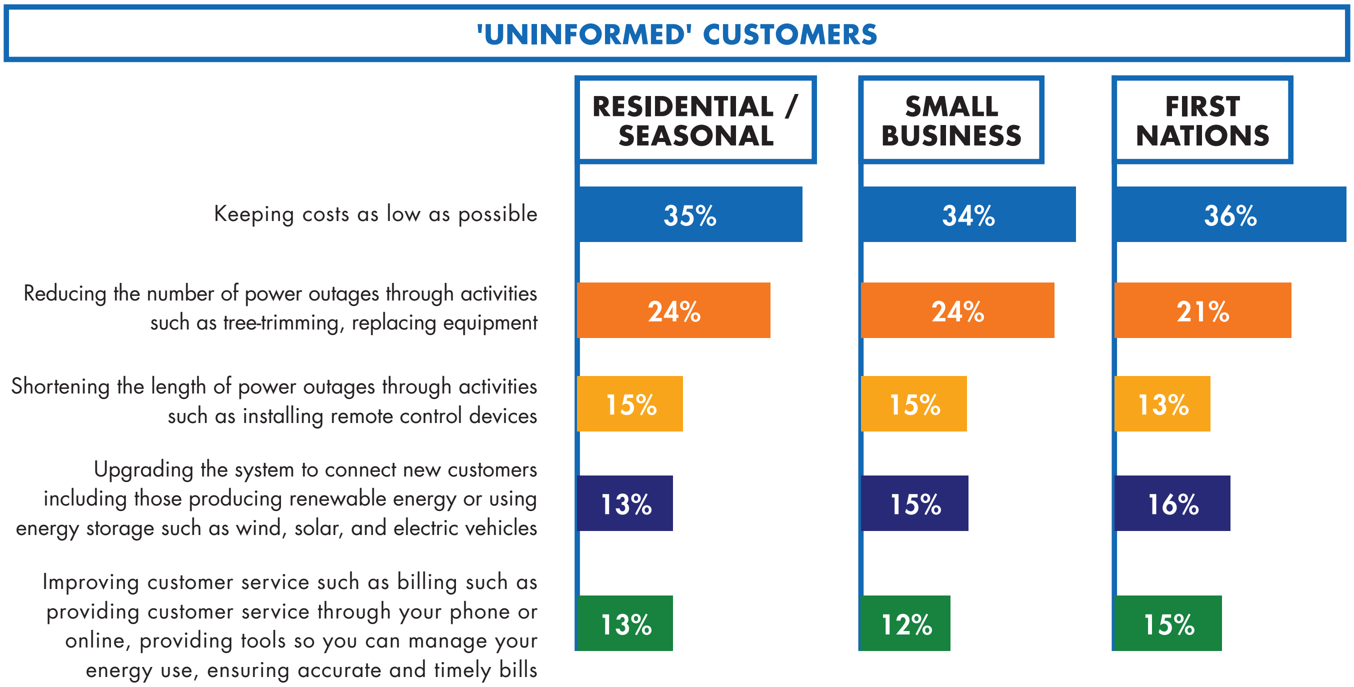
LENGTH OF OUTAGES

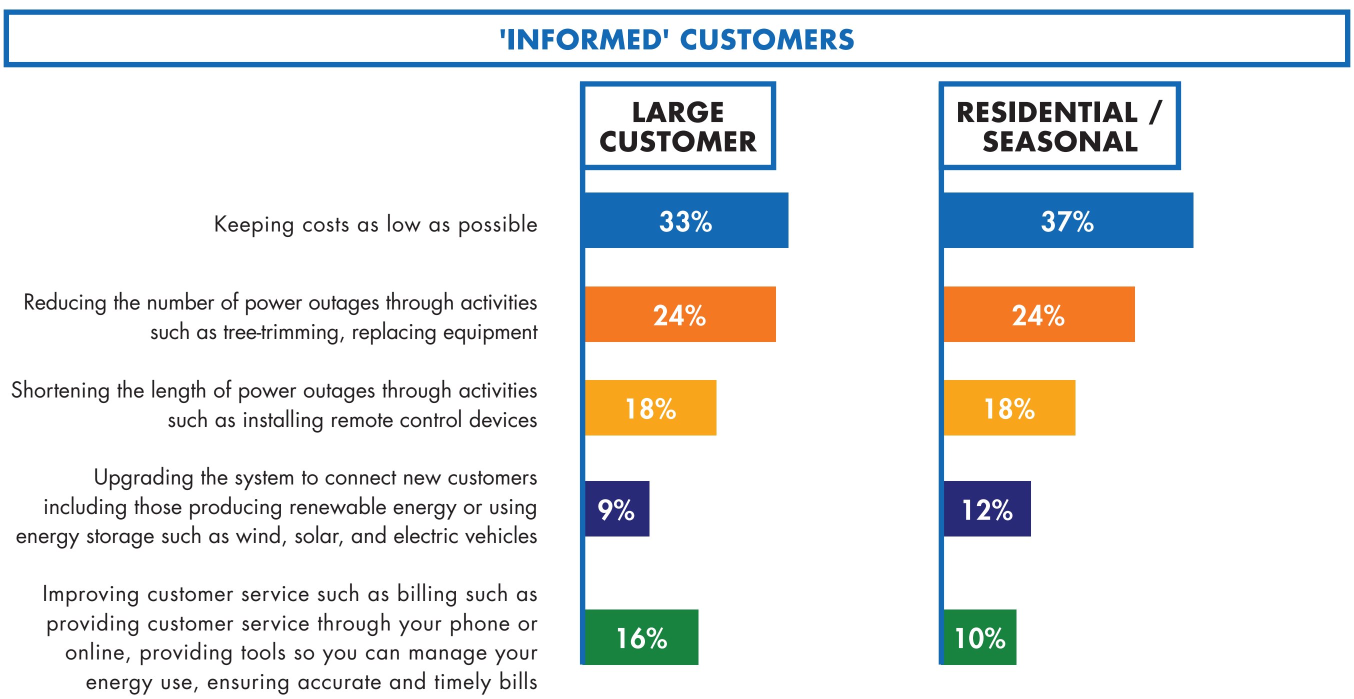


Q10. In general, when you think about the average length of the power outages you experienced over the last 12 months how did it compare to your expectations [READ LIST]? Base: One or more sustained power outages in the past 12 months; Residential (n=314), Seasonal (n=66) Small Business (n=144), First Nation (n=217) Informed: Residential (n=977), Seasonal (n=52)

All customer segments prioritize keeping costs as low as possible over improvements in other areas. Reducing the number of power outages is consistently the second priority among customers.

ALL CUSTOMER SEGMENTS
CUSTOMER PRIORITIES



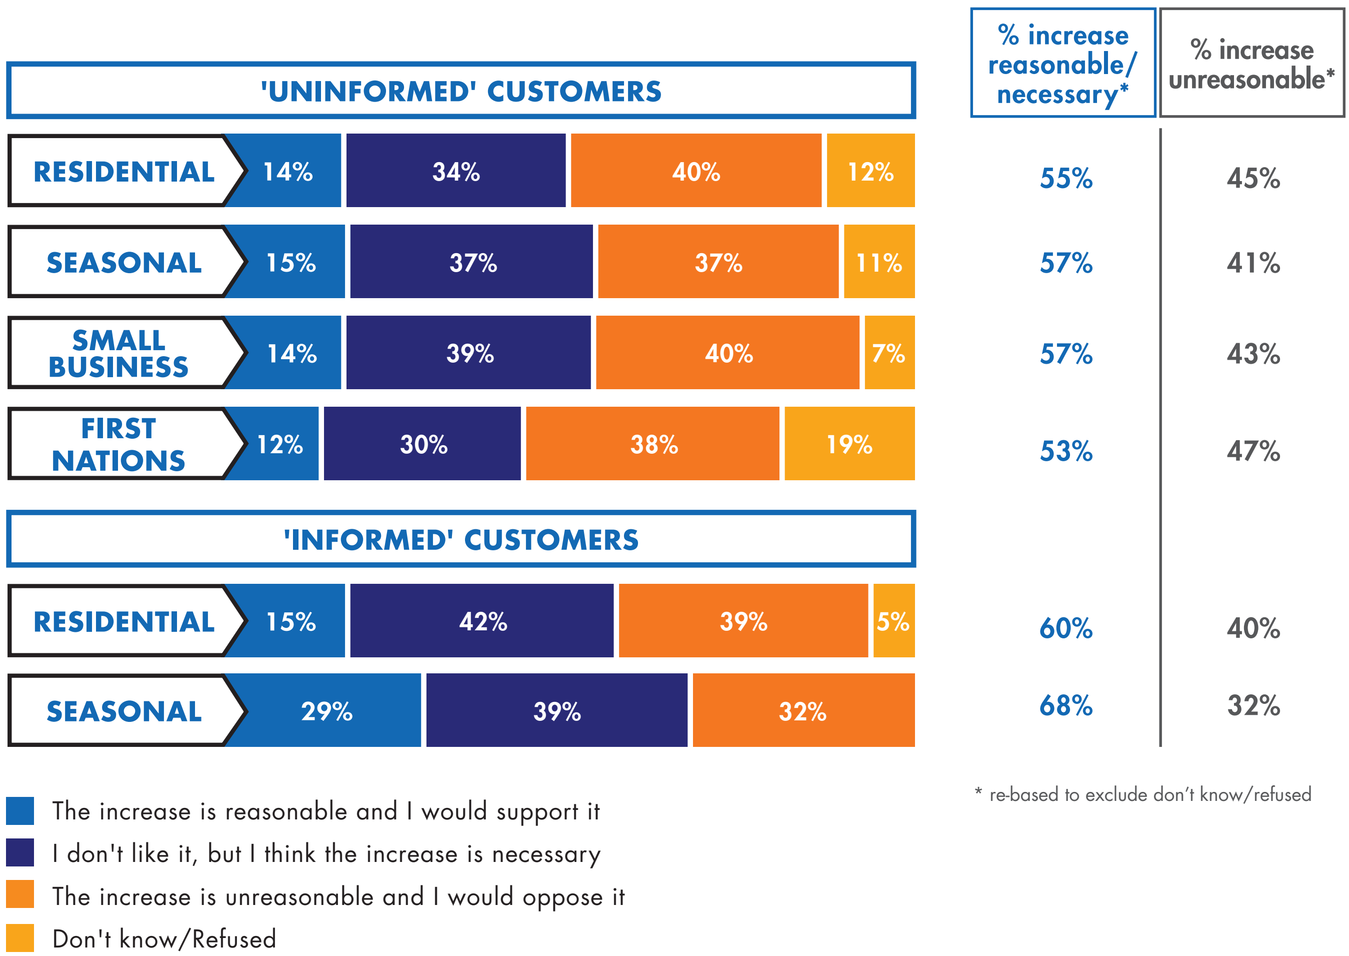


Q5. Hydro One would like to better understand what is important to you as a [insert] customer. [Below is /I am going to read] Hydro One's major expenditures in pairs and for each pair please tell me which one is more important to you. Paired choice preferences relative to other options. Base: Uninformed - Residential/Seasonal (n=499). One respondent opted not to answer, Small Business (n=199). One respondent opted not to answer Q5., First Nations (n=300). Informed - Large Customers (n=87). Base: Residential/Seasonal (n=1604).

When posed with a roughly 1% rate increase on the total monthly bill, per year for five years, acceptance varies from 53% to 57% among 'uninformed' customers who had an opinion (i.e., excluding don't know/refused) and from 60% to 68% among 'informed' customers.

TELEPHONE SURVEY + ONLINE WORKBOOK REPRESENTATIVE SAMPLE

ACCEPTABILITY OF RATE INCREASE TO MAINTAIN LEVELS



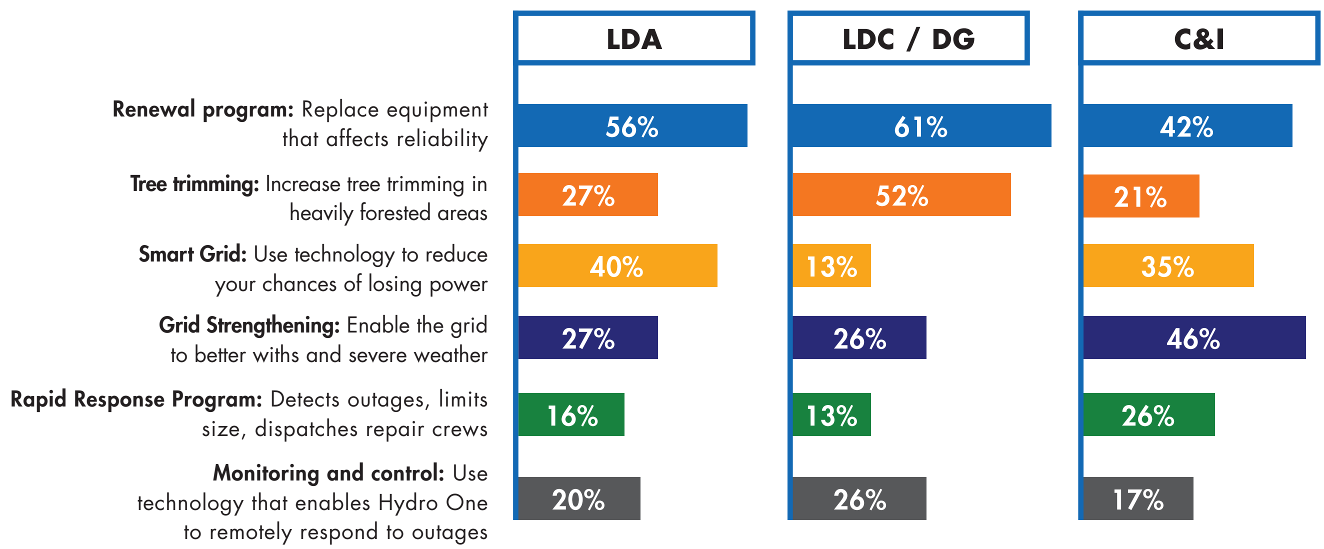
Q17. Hydro One has determined that in order to at least maintain the level of reliability and customer service it currently provides, a typical [residential or seasonal / small business] customer's total monthly bill will need to increase by [IF residential or seasonal 1.1% or the equivalent of $2.00 / IF small business 1% of the equivalent of $5.20]. The increase will be applied each year for the next 5 years. By the fifth year, a typical monthly bill will be roughly [IF residential or seasonal $10.00 / IF small business $26.00] higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability and service to customers. The monthly bill could still increase for other reasons which are outside the control of Hydro One. Would you be willing to accept this increase to maintain the current level reliability and customer service across the electricity system? Note that for the Telephone Survey, this question was posed as Which of the following is closest to your point of view? Base: Uniformed -Residential (n=400), Seasonal (n=100), Small Business (n=200), First Nations (n=300). Informed - Residential (n=1502), Seasonal (n=102)

All Large Customer segments, but to a lesser extent C&I, prefer that Hydro One focuses on replacing equipment that affects reliability ahead of other reliability improvement efforts. LDA customers place the second greatest priority on the Smart Grid, that is using technology to reduce their chances of losing power. They place this slightly ahead of increased tree-trimming and grid strengthening. LDC/DG customers place tree-trimming in the second position – in fact nearly as many of these customers feel this would have the greatest positive impact on them as those who favour the Renewal Program. C&I customers actually place as much of a priority on grid strengthening as the Renewal Program and then place Smart Grid as their tertiary preference.

ONLINE WORKBOOK/WORKSHOP SURVEY BOOKLET

CUSTOMER PREFERENCES FOR WAYS TO IMPROVE RELIABILITY

Percentages shown represent % who ranked the item in the first or second position.



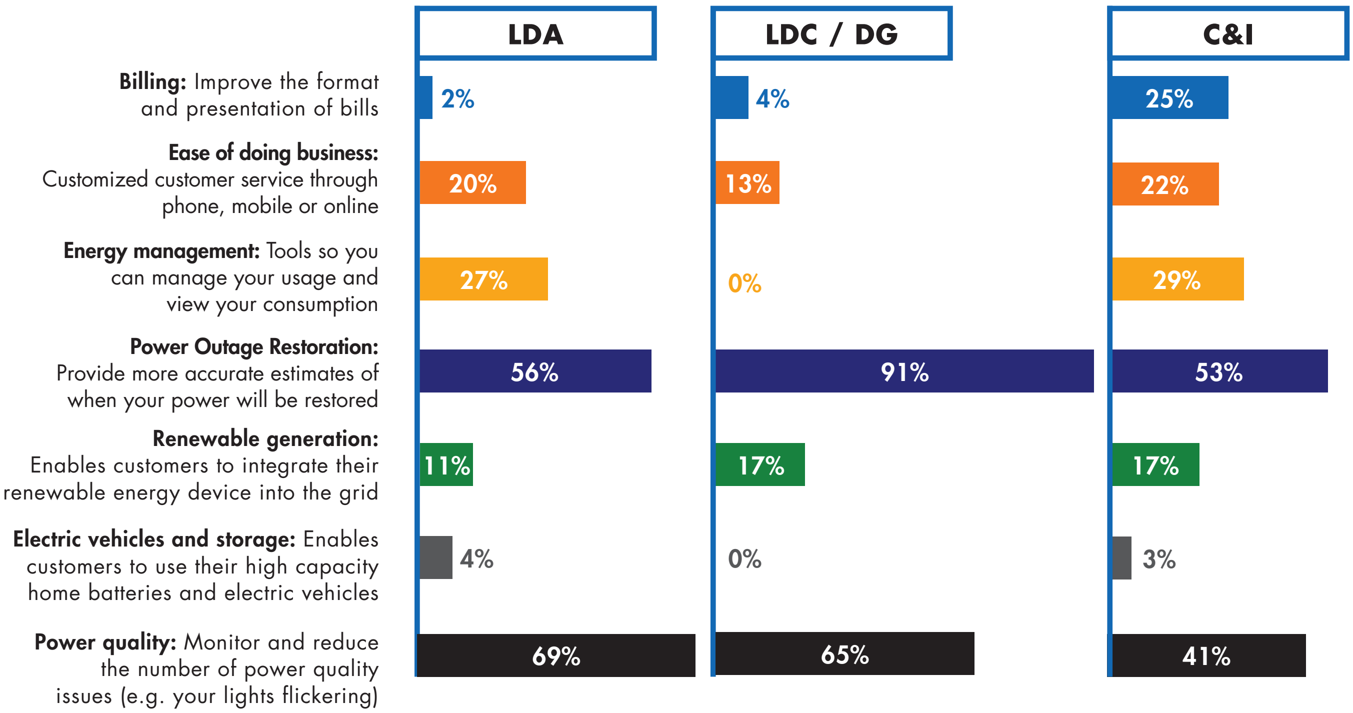
Q11. Please rank the RELIABILTIY items below in the order in which they would have the greatest positive impact on your organization, where 1 represents the item that would have the most positive impact and 6 represents the least positive impact. Base: LDA (n=45), LDC/DG (n=23), C&I (n=133)

When it comes to ranking other service-related options, the top two preferences are more accurate estimates of when power will be restored and for better power quality – that is, monitoring and reducing the number of power quality issues (e.g. your lights flickering).

ONLINE WORKBOOK/WORKSHOP SURVEY BOOKLET

CUSTOMER PREFERENCES FOR WAYS TO IMPROVE SERVICE

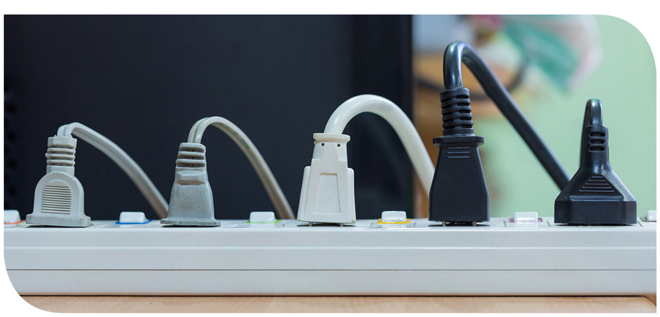
Percentages shown represent % who ranked the item in the first or second position.



Q12. Please rank the SERVICE items below in the order in which they would have the greatest positive impact on your organization, where 1 represents the item that would have the most positive impact and 7 represents the least positive impact? Base: LDA (n=45) , LDC/DG (n=23) , C&I (n=133) Note: for the online workbook, Billing was worded as - Ensure you receive timely and accurate bills, Ease of doing business was worded as - Seamless customer service through phone, mobile or online

CONTEXT AND BACKGROUND

Hydro One's Distribution Customer Engagement process contemplated the enhanced engagement between utilities and their ratepayers as described in the Ontario Energy Board's (OEB) *Renewed Regulatory Framework for Electricity* (RRFE). The RRFE holds the expectation that utilities "…demonstrate consideration of all relevant factors, including the needs of existing and future customers and the costs to meet them, and that planning has been informed by appropriate consultation…" The expectation therein for utilities to provide an overview of associated customer engagement and outreach activities in their application, and to demonstrate how customer feedback/needs have been reflected and considered, further shaped Hydro One's approach. This is in-line with Hydro One's approach and desire to provide customers with the opportunity to provide input into key activities that affect customer service, product offerings and future initiatives.



Ipsos was commissioned by Hydro One to assist with the design, execution, documentation, and analysis of feedback for the customer engagement process. By engaging Ipsos, a third-party research firm, the company set out to establish a best-in-class customer engagement process by ensuring that facilitation, the development of research and questions, and the report writing provided an unbiased, unvarnished, evidence-based report to support the filing. As a key element of its application for distribution rates, the outcome of this customer engagement process will help to determine Hydro One's electricity distribution rate application for a five-year period between 2018 and 2022.

The role of the customer engagement process is to ensure Hydro One's distribution investment plan is informed by customer needs, preferences and priorities.

Customer engagement is critical for the Hydro One Distribution filing with the Ontario Energy Board. To ensure the strongest approach, Hydro One:

- Leveraged lessons learned from its recent Transmission-Connected Customer engagements to create an approach tailored to the unique needs of Hydro One's distribution customers;
- Engaged a third-party vendor to ensure research methodologies and Workshop facilitation were unbiased and thorough;
- Focused the scope of the Workbooks and Workshops such that investment plans can readily incorporate customer input where advisable;
- Used several different approaches to obtain qualitative and quantitative information from customers of all distribution segments (where possible);
- Took advantage of the customer engagement process to begin a conversation with customers about issues and concerns that matter most to them; and,
- Took the necessary steps to ensure the overall process was accessible and transparent.

Further, Hydro One's application filing must demonstrate that services are provided "in a manner that responds to identified customer preferences."

As such the customer engagement objectives were to obtain customer feedback on their following:

- Customers' level of satisfaction with Hydro One and desired improvements;
- Customer expectations of reliable electricity distribution;
- How customers prioritize or trade-off spending on reliability, customer service, upgrades to the system to connect renewable energy customers, and keeping costs low as possible;
- The types of reliability improvements that customers value; and,
- Willingness to accept rate impacts to maintain and/or improve reliability and service levels.

[1] Ontario Energy Board, *Renewed Regulatory Framework for Electricity*, October 2012, Section 2.5

DESCRIPTION OF HYDRO ONE'S DISTRIBUTION CUSTOMER SEGMENTS

As the largest electric distribution utility in Ontario, Hydro One serves several different residential and business segments:

- Residential & Small Business (R&SB) – about 1.3 million customers
- Commercial & Industrial (C&I) – about 8,000 customers
- Large Distribution Accounts (LDA) – 92 customers
- Local Distribution Companies (LDC) – 59 customers (distribution connected)
- Connected Distributed Generators (DG) – 966 connected Hydro One DG projects (projects greater than 10 kW)

RESIDENTIAL & SMALL BUSINESS (R&SB)

At 1.3 million strong, this is Hydro One's largest customer segment by number of accounts, although they are outnumbered by the number of poles that support them (1.6M). Representing 42% of distribution power being used, this segment includes homes, small shops, and local farms. Through previous commissioned research, Hydro One indicates that this customer segment is characterized by the following, relative to the Ontario average:

- Customers are slightly older than the Ontario average;
- They are more likely to own their homes, rather than rent;
- These homes are relatively older, with 18% built before 1946;
- There are fewer homes with central air conditioning;
- More reside in single-detached homes; and,
- Customers spend more, on average, for electricity than the rest of Ontario, with approximately 180,000 using electric heat.

COMMERCIAL & INDUSTRIAL CUSTOMERS

This segment has approximately 8,000 customers and represents 13% of distribution power used (that is, distribution load consumed). This segment includes hospitals, grocery store chains, and other businesses. The Business Customer Centre (BCC) supports this group of customers for billing and business questions. According to Hydro One, historically this customer segment's priorities have been around costs, reliability, billing, and customer service.

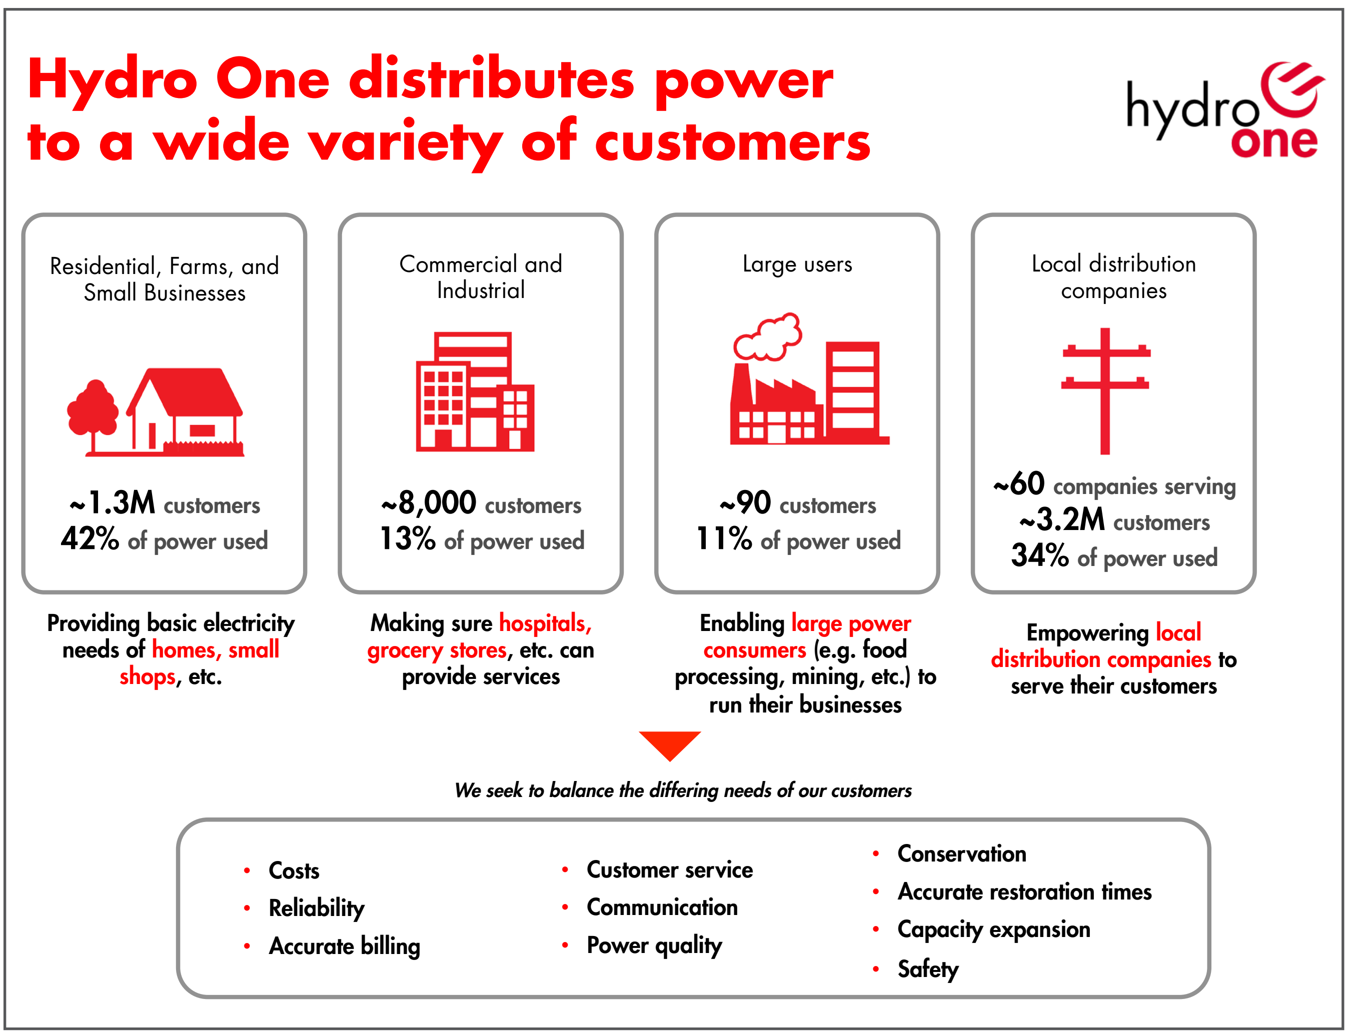
Environics Analytics, EA & Demostats 2016
2 Ibid, Section 1.0

LARGE DISTRIBUTION ACCOUNTS (LDAs)

This segment has 92 customers and represents 11% of all distribution power used. This segment includes food processing plants, automotive and related industries, mining, and other large businesses. The relationship with this customer segment is supported by Hydro One's Zone Superintendents across Ontario. According to Hydro One, historically, this customer segment's priorities have been around communication with Hydro One, conservation and demand management incentives, costs, reliability, power quality, billing, and customer service.

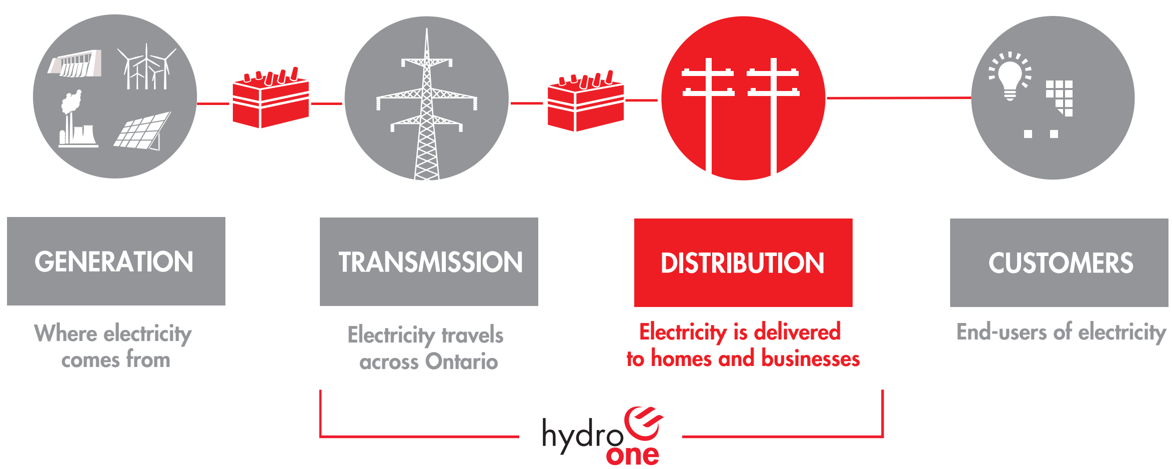
LOCAL DISTRIBUTION COMPANIES (LDCs)

This segment has 59 companies and represents 34% of all distribution power used. This segment represents the utilities connected to Hydro One's distribution system and according to Hydro One, historically, this customer segment's priorities have been around rates, reliability, and capacity expansion. This customer segment is supported by Hydro One Key Account Executives. Hydro One Key Account Executives also support DGs (>10 kW) which are smaller scale energy providers with plants close to the point of energy consumption (e.g., solar, thermal, wind).



DESCRIPTION OF HYDRO ONE'S DISTRIBUTION BUSINESS

Hydro One's operations cover more than 600,000 kilometres and some of the most challenging and diverse geography in Canada. Hydro One's system transmits electricity from generation sources to transmission-connected customers, and indirectly through them, to distribution customers. The Distribution Customer Engagement only addressed the Distribution portion of Hydro One's operations.



GENERATION

- Electricity is produced by generators including Ontario Power Generation, Bruce Power, NextEra and other generators.

TRANSMISSION

- **Transmission assets** convey electricity from generators to distributors and large consumers.
- Hydro One operates 96% of transmission in Ontario

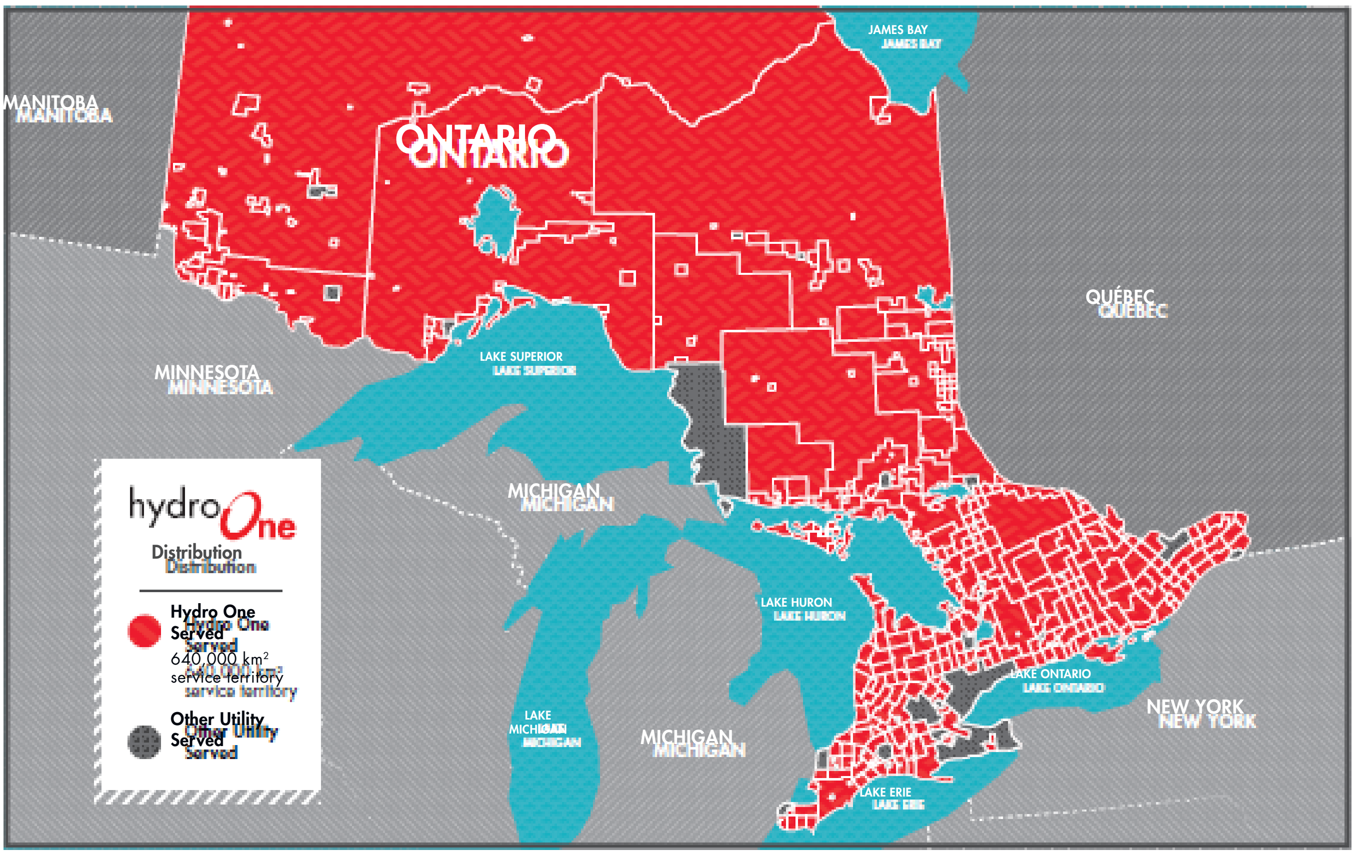
DISTRIBUTION

- **Distribution assets** convey electricity to customers.
- Hydro One distributes electricity to 25% of Ontario's population

CUSTOMERS

- **Residential**
- **Commercial and Industrial**
- **Large Consumers**
- **Other Distributors**

Hydro One's distribution assets include 123,000 kilometres of distribution power lines and approximately 1,000 distribution and voltage regulating stations. Hydro One is accountable to plan, operate, build and maintain an affordable, robust and flexible distribution system that serves Ontario's energy needs.



According to Hydro One, its investment plan will identify, prioritize, and determine pacing of the investments made in their system. On this basis, Hydro One has stated that it aims to create value by:

- Ensuring its investment plan considers and reflects the needs and preferences of its customers by achieving a balance between managing risk, service and cost, while recognizing its customers' needs and maintaining a high standard of quality;
- Recognizing that every dollar spent comes at a cost to its customers and the people of Ontario;
- Making prudent, cost-effective, short and long-term investments in the distribution system so that the electricity needs of Ontario are met now and into the future;
- Addressing emerging risks to the system, and always looking for ways to economically extend the life of existing distribution assets; and,
- Being innovative by adapting new/proven technologies, equipment and processes that contribute to the efficiency of the operation.

CUSTOMER ENGAGEMENT METHODOLGY

A COMPREHENSIVE APPROACH INVOLVING MULTIPLE METHODS OF ENGAGEMENT

In collaboration with Hydro One, Ipsos set out to design a comprehensive customer engagement methodology that is based on scientific method, by ensuring the rules of statistical validity and reliability are followed, and at the same time, is inclusive of any customer seeking the opportunity to voice their opinion. The methodology included both qualitative approaches in the form of Focus Groups and Workshop sessions and quantitative approaches including a Telephone Survey and Online Workbook.

- The qualitative components are useful to uncover the reasons behind customer needs and preferences. These components allow customers to provide open-ended feedback and provide examples to a greater degree than what is possible in a survey format.
- The Online Workbook and Telephone Survey components allow us to quantify opinions, so that Hydro One has a representative and reliable measurement of the magnitude of customer needs and preferences.

AN OPPORTUNITY TO COMPARE AND CONTRAST THE NEEDS AND PREFERENCES OF AN 'INFORMED' CUSTOMER WITH AN 'UNINFORMED' CUSTOMER

Ipsos and Hydro One also sought to explore the extent to which the needs and preferences of R&SB customers differ, if at all, when R&SB customers are provided with information about the energy sector and Hydro One. Understanding the extent to which 'informed input' from customers varies from 'uninformed input' is valuable for a few reasons:

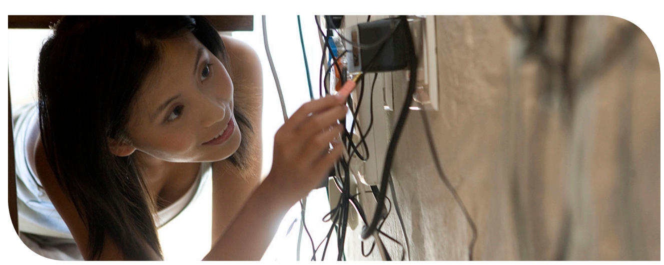
- It improves customer engagement by ensuring that the views Hydro One takes into consideration include the view of customers who are more informed about underlying issues;
- It also provides useful insight to help improve how Hydro One communicates with its customers; and,
- The findings from this approach can inform future customer engagement activities that Hydro One, other utilities, and the OEB may conduct.

Hydro One designed two informative Workbooks to share with customers – one geared toward Residential, Seasonal, and Small Business customers and one geared toward Large Customers. The goal of both Workbooks was to provide customers with background information regarding Hydro One, its service territory, its performance in terms of the average number and length of power outages, and why outages occur. The content of the Workbooks varied between R&SB and Large Customers to ensure that the illustrative examples were reflective of their respective rate classes. Unlike the R&SB customers, where one group of customers did not receive the information, all Large Customers were provided with a Workbook. This Workbook contained detailed, technical information on the ways in which Hydro One currently manages reliability and service, and the ways in which it could approach improving reliability and service for these customers. The creation of the Workbook was handled primarily by Hydro One, who had the final say on its content and design. The questions posed to customers were embedded in the Workbook and followed the relevant information being provided for context for the question. A copy of both the R&SB and Large Customer Workbooks is provided in the Appendix.

As will be described in the following sections, the Online Workbook for R&SB customers was used with two groups of R&SB customers – those who were engaged through Ipsos' online panel and those who were engaged through an Open-Link where any R&SB customer could participate. The former group was recruited to reflect a representative sample of 'informed' R&SB customers and thus could be compared to the representative sample of 'uninformed' R&SB customers who were randomly selected to participate in a Telephone Survey. The sample of customers who completed the Telephone Survey were not provided with the Workbook, and thus represent the 'uninformed' perspective.

WHO WE HEARD FROM AND HOW AND WHEN THEY GAVE THEIR FEEDBACK

Customer engagement process was conducted across all of the Hydro One's distribution customer segments. In total, 19,904 customers participated in the customer engagement. A total of 20,062 responses were received. Please note that customers responding to the Online Workbook Open-Link could answer twice if they are both a Residential/Seasonal and Small Business customer. With respect to Large Customers, some customers sent more than one representative to attend the workshop sessions, resulting in more than one response per customer. A methodology overview and total number of customers from each distribution customer segment who participated in each of the customer engagement components are shown on the next page.



WHO PARTICIPATED

	RESIDENTIAL, SEASONAL AND SMALL BUSINESS CUSTOMERS				LARGE CUSTOMERS		TOTAL NUMBER OF RESPONSES
	Focus Groups	Online Workbook (Representative sample)	Online Workbook (Open-link)	Telephone Survey (Representative sample)	In-person Facilitated Workshop†	Online Workbook	
RESIDENTIAL CUSTOMERS	32	1,502	15,689	400			17,623
SEASONAL CUSTOMERS		102	1,106	100			1,308
SMALL BUSINESS CUSTOMERS	24		406	200			630
FIRST NATIONS CUSTOMERS				300			300
LDA					40	5	45
LDC OR DG					20	3	23
C&I					54	79	133
TOTAL	56	1,604	17,201*	1,000	114	87	20,062

†One-on-one meetings were undertaken with two customers (1 LDC and 1 C&I) *A total of 148 customers who responded to the open-link survey completed the survey twice – once as a residential or seasonal customer and once as a small business customer. Therefore, the total number of responses to the open-link is 17,201 (17,053 unique respondents + 148). A total of 19,904 unique customers participated across all of the consultation components. For Large Customers the numbers provided represent the number of responses received through the Workshop booklet or the Online Workbook, not the number of organizations. Some organizations had more than one person attend the Workshops and not all participants at the Workshop completed the booklet. A total of 129 participants, representing 104 customers attended the Workshops, of which 114 completed the booklet in-person at the session.

The following section describes each customer engagement component in detail. Ipsos was responsible for collecting all of the feedback from the various activities, conducting an analysis of the feedback and writing the report. Ipsos followed its standard internal quality control protocol for data tabulation, analysis and validation to ensure the accuracy of the data. Hydro One was not involved in the data tabulation, analysis or validation process.

PARTICIPATION METHODS

RESIDENTIAL, SEASONAL AND SMALL BUSINESS CUSTOMERS

INFORMED SAMPLE (online workbook)

- A representative sample of n=1,604 Residential and Seasonal customers drawn online panel sample
- An Open-Link of n=17,201 responses representing 17,053 R&SB customers

INFORMED SAMPLE (focus groups)

- Eight online Focus Groups with 56 R&SB customers

UNINFORMED SAMPLE (telephone survey)

- These results are based on a statistically valid and reliable survey and can be projected to broader customer population
- Telephone survey of random and representative sample of n=500 residential and seasonal customers
- Telephone survey of a random and representative sample of n=200 Small Business customers (demand and non-demand)
- Telephone survey of a random and representative sample of n=300 First Nations customers

LARGE CUSTOMERS: LDA, LDC, DG AND C&I

LARGE CUSTOMERS

- Nine in-person Workshop sessions were conducted in seven cities (Collingwood, Windsor, Hamilton, Kingston, London, Thunder Bay and Timmins). A total of 129 people attended representing 104 customers.* In addition to verbal feedback, participants were provided with a Workbook to complete.
- An Online Workbook was completed by 87 customers who did not attend the in-person Workshop sessions.**

*Two one-on-one meetings were conducted with large customers in lieu of attending a Workshop session. In both cases, an Ipsos note-taker was present to record the conversation. ** The Online Workbook presented the same information that was shared at the Workshop and posed nearly identical questions. The only difference in the questions was that the Online Workbook used a statistical technique called paired-choice to quantitatively measure the relative importance customers place on various aspects of service. This technique could not be replicated in hard-copy, thus the Workshop survey booklet used a "pick the most important" approach instead.

DETAILED CUSTOMER ENGAGEMENT FINDINGS

DESCRIPTION OF THE ENGAGEMENT WITH RESIDENTIAL/SEASONAL, SMALL BUSINESS CUSTOMERS

R&SB customers were consulted using both qualitative and quantitative approaches. There were three quantitative components and one qualitative component:

1. **Telephone Survey: Representative Sample.**
   A representative Telephone Survey of Residential, Seasonal, Small Business, and First Nations customers, the results of which can be generalizable to the broader customer base. This sample was not provided with the informational Workbook and thus represents the 'uninformed' view.

2. **Online Workbook: Representative Sample.**
   A representative sample of Residential/Seasonal customers completed an Online Workbook which involved the same questions that were asked in the Telephone Survey, but what makes it a Workbook is that customers were provided with information prior to answering the questions. This sample represents an 'informed' view. The sample was drawn from Ipsos' online panel.

3. **Online Workbook: Open-Link Sample.**
   A publicly available version of the Online Workbook that was distributed broadly through public channels for interested customers subject to qualification rules described in a later section. To distinguish the results of this component from the Online Workbook conducted with the representative sample, it will be referred to as the 'Open-Link' sample.

4. **Focus Groups:**
   Finally, Focus Groups were conducted with R&SB customers to drill down into greater detail on some of the findings from the Telephone Survey.

A full description of each of these components is provided below.

1. TELEPHONE SURVEY: REPRESENTATIVE SAMPLE

Often times public consultations attract the strongest advocates or detractors of a particular policy or initiative and a broad, representative Telephone Survey allows us to put those results in context, reflective of the entire population and not only those who volunteer. By conducting a representative survey, we can have greater confidence that the feedback reflects the broader customer base.

The Telephone Survey was conducted with a random and representative sample of:

- n=500 Residential and Seasonal customers (n=400 Residential and n=100 Seasonal)
- n=200 Small Business customers
- n=300 First Nations residential customers

A stratified, random sampling approach was used to pull each of these from Hydro One's customer database and screened to ensure the respondent was the person in the household or business with primary or shared responsibility for paying the electricity bill.

They also needed to pay the bill directly to Hydro One (as opposed to their landlord or property manager if renting or leasing their home or business property). The table on the next page shows the margin of error associated with each of these samples. The margin of error has been calculated at the 95% confidence level. This means if the survey is repeated 20 times, 19 of those times the results of the survey will be the same within the margin of error. The margin of error will be larger for sub-groups.

TELEPHONE SURVEY: REPRESENTATIVE SAMPLE

	Sample Size	Margin of error (95% confidence level)	Fielding dates	Screening	Quotas	Weighting Variables	Survey length (minutes)	Response Rate
RESIDENTIAL CUSTOMERS	400	±4.9%	June 2–17, 2016	Bill payer, pay to Hydro One	Region, Density	Density (urban, medium, low)	17	13%
SEASONAL CUSTOMERS	100	±9.8%	June 2–17, 2016	Bill payer, pay to Hydro One	Region	None	17	13%
SMALL BUSINESS CUSTOMERS	200	±6.9%	June 2–17, 2016	Bill payer, pay to Hydro One	Region	Region, Demand/ Non-Demand	13	11%
FIRST NATIONS CUSTOMERS	300	±5.7%	June 2–17, 2016	Bill payer, pay to Hydro One	Region and within region urban/rural	None	18	13%

The table also describes any statistical weighting that was applied to the samples to ensure the composition reflects the true proportions in the customer database. Also shown in the table are the interviewing fielding dates, the average survey length and response rate. For all samples, the response rate was calculated using the Marketing Research and Intelligence Association's recommended response rate formula. The survey was available to all respondents in both official languages. A total of two respondents opted to complete the survey in French.

First Nations customers were included as part of the customer survey and over-sampled relative to their size within the total customer base to ensure we reliably captured the needs and preferences of this important customer group.

In some instances, responses to survey questions may total to greater than 100% due to rounding or because respondents were permitted to provide more than one response, such as in open-ended questions. This is in keeping with standard research practice.

2. ONLINE WORKBOOK: REPRESENTATIVE SAMPLE

The primary purpose of conducting the Online Workbook with a representative sample of Residential and Seasonal customers is to have an understanding of the opinions of a representative sample of customers who have been informed about Hydro One, its service territory, its performance in terms of the average number and length of power outages its customers experience, and why outages occur prior to answering questions. A total of n=1,502 Residential customers and n=102 Seasonal customers completed the Online Workbook. The sample was drawn from the Ipsos' online panel. The data was weighted by Residential vs. Seasonal and region/urban/rural customers. A breakdown of the regional/urban/rural sample composition and a copy of the questionnaire is provided in the Appendix.

ONLINE WORKBOOK: REPRESENTATIVE SAMPLE

	Sample Size	Fielding dates	Screening	Quotas	Weighting Variables	Survey length (minutes)
RESIDENTIAL CUSTOMERS	1,502	June 2–23, 2016	Bill payer, pay to Hydro One	Region	Region/ urban/rural	15
SEASONAL CUSTOMERS	102	June 2–23, 2016	Bill payer, pay to Hydro One	Region	Region/ urban/rural	10

The table above describes any statistical weighting that was applied to the samples to ensure the composition reflects the true proportions of Hydro One's customers. Also shown in the table are the interviewing fielding dates and the average survey length. In keeping with industry standards, it is not appropriate to quote a margin of error for non-probability based, opt-in surveys and thus we have not reported a margin of error on the Online Workbook results. The survey was available to all respondents in both official languages. A total of 15 respondents opted to complete the survey in French.

As noted previously, in some instances, the percentages reported may total to greater than 100% due to rounding or because respondents were permitted to provide more than one response, such as in open-ended questions. This is in keeping with standard research practice.

3. ONLINE WORKBOOK: OPEN-LINK SAMPLE

The primary purpose of offering an Open-Link version of the Online Workbook was to provide an avenue by which R&SB customers of Hydro One who were not randomly selected to participate in the Telephone Survey could participate and have their opinions heard.

Since the results contained within this section of the report are based on self-selected or volunteered participation, the results should not be interpreted as a representative sample of Hydro One customers. Further, the Online Workbook was designed to inform customers about Hydro One, its service territory, its performance in terms of the average number and length of power outages, and why outages occur prior to answering questions. This is information to which the average customer would not necessarily have equal access. For both of these reasons, the results of the Online Workbook cannot be said to represent or be generalizable to the opinions of the broader Hydro One customer base. Nonetheless, it is valuable to have feedback from a large volume of interested and now informed customers. Therefore, this section should be given consideration in Hydro One's decision-making. As it is not appropriate to quote a margin of error for non-probability based, opt-in surveys, we have not reported a margin of error on the Online Workbook results.

Respondents who indicated that they are both a Residential or Seasonal customer and a Small Business customer of Hydro One were provided with the opportunity to complete the Online Workbook twice. Those who decided to answer twice count as two responses. Because of this overlap the data in this section is based on the total number of responses, rather than the number of respondents.

PUBLISHING THE WORKBOOK ONLINE

The Open-Link Online Workbook was available in both official languages and was hosted by Ipsos on its secure server at **www.ipsosresearch.com/hydroone**. Upon arriving at the landing page, respondents were able to choose to complete the survey in English or French.

PROMOTING THE SURVEY

The Online Workbook was extensively promoted to customers to encourage as many customers as possible to participate. The objective of Hydro One's communications strategy was to drive maximum customer participation of the Open-Link across customer segments by targeting audiences across multiple channels. A 1-800 in-bound phone number was also promoted across all channels for customers who preferred to participate over the phone. Customers calling in could also request a hard copy of the Workbook be mailed to them (a pre-paid business reply envelope was provided for customers to return the Workbook directly to Ipsos). The call-in line was manned 11 hours a day between 11 a.m. and 10 p.m. EST Monday to Friday, and was available in both official languages. Readers should note that customers requesting to participate over the phone received the Telephone Survey that was used with the representative sample of customers. As such, they were not exposed to the informational Workbook that the customers who responded online would have. There were no requests for a hard copy. A call-back protocol of three call attempts was in place on the in-bound line. For any individual who left a voicemail on the in-bound line if, for example, the line was busy when they called or they were calling off hours, three attempts were made to contact the individual to complete the survey before the number was disposed of as unreachable.

The key messages of the communications strategy were informational in nature:

- Hydro One is looking for feedback from customers to inform the development of tomorrow's electricity system
- Hydro One is looking to learn and understand the level and type of service that customers expect from the company
- Customers' feedback will be considered as Hydro One develops its plan, which in turn will determine electricity delivery rates

The strategy involved two waves of marketing communication which allowed the company to determine the most effective channels for communicating informational messaging. The company was able to determine that the traditional forms of marketing – print and radio – were ineffective in driving participation. The second wave of communications – which was focused on digital media – was more effective, increasing participation by 40%.

Wave One:

- Bill inserts
- Paid traditional advertising: print and online newspaper and radio
- Paid Tweets

Wave Two:

- Facebook ads
- eBlasts

The full channel strategy included the following tactics:

- **Hydro One direct-managed channels:**
  - Link on **www.HydroOne.com** landing page throughout the duration of the campaign
  - Link on **www.HydroOne.com/MyAccount**, which is the authenticated customer portal
  - Use of the company's Twitter account: **@hydroone**
  - Employees to encourage customer participation during customer interactions
  - Bill inserts
  - eBlasts sent directly by Hydro One to customers
- **Earned media**
  - Two press releases
- **Paid advertising**
  - Radio advertisements in local markets
  - Print advertisements in local newspapers
  - Online newspaper advertisements
  - Social media
    - Facebook ads
    - Paid tweets on Twitter
- **Stakeholder engagement**
  - Notification to MPP offices
    - Posters sent to MPP offices
  - Notification to key stakeholder groups

A summary of the total promotional efforts is provided on the next page. The multi-channel strategy garnered more than four million impressions.

R&SB ONLINE WORKBOOK PROMOTION

TOTAL RESPONSE

A total of 18,718 responses were received to the publicly available Open-Link Online Workbook and 379 responses were received over the phone. The phone responses were combined with the online responses for a total of 19,097 responses. On average it took customers 18 minutes to complete the Workbook/Survey. A total of 364 responses were received in French. After removing invalid responses, the final number of valid responses is 17,201. A description of how responses were validated is provided below.

VALIDATING CUSTOMER RESPONSES

Those wishing to participate in the Open-Link Online Workbook were required to self-identify themselves as a R&SB customer. Respondents were also required to indicate that they had at least some responsibility for paying the electricity bill in their household/business and that they pay directly to Hydro One and not through a landlord or property manager. Respondents were also required to enter their postal code to verify their residential, seasonal or business addresses falls within Hydro One's service territory. Any respondent who provided an invalid postal code was removed from the final sample. This removed 703 responses.

Upon closing the survey, the data was scrubbed to accept only one complete per IP address unless the IP was duplicated because the respondent answered the survey twice as they indicated that they are both a Residential/Seasonal and a Small Business customer, and they wanted the opportunity to answer as both. This removed 791 responses. Respondents who indicated that they or someone in their household works for a public relations or market research company, media, a company that provides electricity, an energy regulator or holds an elected office or staff position were also removed from the final sample. This removed 402 responses.

Please note that Ipsos does not ever link to the personal information submitted on the website. All responses are kept anonymous and confidential.

4. R&SB FOCUS GROUPS

Finally, focus groups were conducted following the Telephone Survey. The purpose of the Focus Groups was primarily to dive deeper and probe into more detail the reasons behind why some customers are willing to accept a rate increase and why others are not. Specific customer service and reliability options were probed to understand the level of interest there is among customers for various ways in which Hydro One could improve in these areas.

A series of eight Focus Groups with Residential and Small Business customers of Hydro One were conducted via conference call and using Ipsos' Ideation Exchange online research platform. A total of 31 Residential and 25 Small Business customers attended these sessions. These took place on June 27 & 28, and July 5 & 6. Residential participants received an honourarium of $75 for their participation, and Small Business participants received $150. Providing an honourarium for participation is a standard practice for this type of research.

Residential participants were recruited using a third-party database and Small Businesses were recruited from Hydro One's customer list. Participants in all sessions were the person in their household or business who is primarily or jointly responsible for dealing with paying utility bills. All groups were a mix of gender, age, working status/business type, income, and education levels.

During recruitment, customers were asked their overall perception of Hydro One on a five-point scale. Individuals that selected either end of the scale – either very positive or very negative – were screened out to avoid participants with overly strong views one way or the other from dominating the session.

Participants were able to dial into the conference as well as log in to the platform from their homes or businesses. All sessions were hosted by Ipsos moderators and conducted from Ipsos' Toronto office at 160 Bloor Street East, Suite 300. All were audio recorded for transcription.

A schedule and breakdown of Focus Group session dates, markets, and segments is as follows:

	Residential	Small Business
GTA / HORSESHOE	Monday, June 27, 5:30 p.m.	Tuesday, July 5, 5:30 p.m.
SOUTHWESTERN ONTARIO	Monday, June 27, 7:00 p.m.	Tuesday, July 5, 7:00 p.m.
SOUTHEASTERN ONTARIO	Tuesday, June 28, 5:30 p.m.	Wednesday, July 6, 5:30 p.m.
NORTHERN ONTARIO	Tuesday, June 28, 7:30 p.m.	Wednesday, July 6, 7:00 p.m.

LARGE CUSTOMERS

Hydro One set out to engage as many Large Customers as possible in the customer engagement. In order to maximize participation, customers were provided two methods by which to participate. Feedback was obtained primarily through two qualitative formats:

1. Facilitated, in-person Workshops
2. Online Workbook

In addition to these methods, one-on-one meetings were held with two customers to gather feedback – one with a major grocery chain and one with a Connected Distributed Generator. Ipsos provided a note-taker at both meetings to record the conversation and feedback.

The table below outlines the breakdown of the number of Large Customers that were invited to participate and the number who participated.

BREAKDOWN OF LARGE CUSTOMERS

	LDA	LDC	DG	C&I	TOTAL
Total number of Large Customers	92	59	966	~8,000	~9,117
IN-PERSON FACILITATED WORKSHOPS					
Total number invited to attend an in-person Workshop	81	59	27	881	1,039
Total number who sent back an RSVP	43	18	6	70	137
Total number who attended a Workshop	33	14	3	53	103
ONLINE WORKBOOK					
Total number who were sent the URL to the Online Workbook	46	41	22	5,226	5,335
Total number who completed the Online Workbook	5	3		79	87
CUSTOMERS NOT INVITED					
Did not attend a Workshop and were not sent a survey	11	4	2	2,721	17

Hydro One was responsible for Workshop invitations, and for the outreach and distribution of the Online Workbook URL to Large Customers, the details of which are described next.

LARGE DISTRIBUTION ACCOUNTS (LDAs)

All LDAs were invited to participate in the Workshop sessions through a personalized e-mail which contained an invitation letter from Hydro One's President and CEO Mayo Schmidt requesting their participation. These personalized e-mails were sent out on May 12. Phone calls were made by Hydro One's Zone Superintendents to their customers after May 25, providing information about the purpose of the Workshop as well as the venue and timing for each. After May 25, follow-up calls, visits or e-mails were made to all LDA customers.

For a copy of the invitation e-mail and letter, please refer to the Appendix.

LOCAL DISTRIBUTION COMPANIES (LDCs) AND CONNECTED DISTRIBUTED GENERATORS (DGs)

All LDCs were invited to participate in the Workshop sessions via e-mail sent through a centralized mailbox for RSVP tracking purposes. The initial 'Save the Date' e-mail, inviting customers to attend a Hydro One Workshop location, was sent to all LDCs and a sub-set of Distributed Generators on May 12. A second e-mail which included a registration button with the list of Workshop venues and times (excluding Windsor, which was initially C&I focused), was sent out on May 20, with a reminder sent out again to 33 LDC and DG customers who had not already RSVP'd by June 6. Phone calls were also made by the respective

Key Account Executives to each of the LDC and DG customers that had yet to respond as way of follow-up. On June 17, Hydro One sent out the online Workshop invitations and unique passwords to 41 LDCs who had not been able to participate in the Workshops.

Twenty-two DG customers were invited to participate in the Workshops. The customers selected accounted for a mix of DG types, with input from the Key Account Executives who advised who should be included from their key accounts. Of those, two DG customers participated in the Workshops and the remaining 20 were provided PINs to participate in the online survey.

For a copy of e-mail messages and invitations to participate in the Workshops and Online Survey, please refer to the Appendix.

COMMERCIAL & INDUSTRIAL (C&I) CUSTOMERS

Of Hydro One's total pool of about 8,000 C&I customers, an initial group of 335 customers were selected to be invited to attend one of the Workshops. These C&I customers were selected to ensure there was balanced input accounting for:

- The largest sub-sectors, as well as those known to have specific concerns;
- Representation across zones;
- Representation across size segments; and,
- Customer contact information availability.

Of this initial group of 335 customers, it was determined that Hydro One was able to locate e-mails for 300 of them and these customers were invited to the Workshops. For the remaining 35, the breakdown of additional follow-up for these customers is as follows:

- Left voicemail and did not receive a further response – **9**
- Refused to receive an e-mail and wanted the invitation by mail – **9**
- No answer or unable to find the right person to confirm an email – **17**

An additional 71 customers in Northern Ontario were contacted, for better coverage of these areas in the Workshops. As well, all of Thunder Bay and many Timmins customers were contacted in order to improve participation rates in these markets – 122 and 57 respectively for a total of 179.

To further boost Workshop participation, Hydro One reviewed call logs from the past two years, to source customers likely to be interested in providing feedback at a Workshop. As a result, a total of 150 invitations were sent.

At the beginning of this initiative, Hydro One had spoken with the first person who answered the phone when dialing the number on file. Hydro One staff learned that when they asked to speak with those directly involved with how their company used electricity, they achieved better Workshop acceptance rates. This change in approach to get the 'right' person on the phone resulted in obtaining better targeted contact information for 110 customers, to whom Hydro One then sent a Workshop invitation. As the dates for the workshop were approaching, Hydro One reached out to another 71 customers who were sent invitations, which further improved Workshop participation rates.

In total, 881 C&I Customers were invited by phone and/or e-mail to participate in the Workshops, of which there were 50 customers who participated.

1. FACILITATED, IN-PERSON WORKSHOPS

The Workshop sessions were conducted with LDA, LDC, DG, and C&I customers. The Workshops sought to identify the needs and preferences of these Large Customers. Hydro One was responsible for sending out the invitations as well as the follow-up, reminders and other communication outreach with a broad cross-section of its Large Customers for the Online Workbook. Hydro One's efforts to invite and encourage as many of these customers as possible to the in-person sessions has been documented above.

A total of nine Workshop sessions were conducted in seven locations across Ontario. The locations were chosen by Hydro One in collaboration with Ipsos based on what would be the most convenient and accessible for customers.

Hydro One executives and representatives were present to greet and interact with participants, and to provide local context. Hot breakfast and lunch meals were provided during morning sessions, with a light lunch and refreshments provided during afternoon sessions. In advance of each session, attendees who confirmed their attendance were emailed an advance copy of Hydro One's presentation. Customers who did not RSVP, but showed up on the day of the workshop, did not receive a copy of the presentation in advance.

The Workshop dates, location and times are described in the table below:

LOCATION & DATE	LDA & LDC	C&I
Hamilton: Wednesday, June 8, 2016 Crowne Plaza Hotel and Conference Centre	9:30 a.m. – 12:00 p.m.	2:00 p.m. – 5:00 p.m.
Collingwood: Thursday, June 9, 2016 Blue Mountain Resorts	Combined workshop - 9:30 a.m. – 12:00 p.m.	
Timmins: Monday, June 13, 2016 Cedar Meadows Resort and Spa	Combined workshop - 9:30 a.m. – 12:00 p.m.	
Thunder Bay: Tuesday, June 14, 2016 Thunder Bay Art Gallery	Combined workshop - 9:30 a.m. – 12:00 p.m.	
London: Thursday, June 16, 2016 Four Points by Sheraton	9:30 a.m. – 12:00 p.m.	2:00 p.m. – 5:00 p.m.
Windsor: Friday, June 17, 2016 St. Clair College Centre for the Performing Arts	Combined workshop - 9:30 a.m. – 12:00 p.m.	
Kingston: Friday, June 24, 2016 Delta Kingston Waterfront Hotel	Combined workshop - 9:30 a.m. – 12:00 p.m.	

WORKSHOP AGENDA

Prior to the start of each Workshop, survey booklets were distributed to participants according to their segment (LDA, LDC, DG or C&I), so that they could be filled out during the course of the session. A bound presentation deck was also distributed to each participant to take notes if desired, and to take away with them after the session. The deck included two market-specific slides:

1. Reliability by location within the province, where frequency and duration by local market was provided; and,
2. Examples of improvement projects in the local region were provided.

This presentation was also projected on screen during each Workshop to follow the information as it was presented. An Ipsos note-taker was present at each session, and each session was audio recorded.

Hydro One representatives presented information on the company, and an Ipsos moderator led group discussions after each section of the presentation.

The workshop was conducted in four parts:

1. Introduction: Who we are and what we do

A description of Hydro One, its distribution area, its assets and its customers was provided. Hydro One's role in the electricity system including transmission and delivery was shown, and the purpose of the Workshop focusing on distribution was clarified. The commitment to balance needs of customers, as well as understand previous feedback from Large Customers was also described. A detailed breakdown of a typical customer's monthly bill and a description of line items was provided and disseminated, and it was explained that Hydro One's distribution business only makes a profit through distribution delivery charges. Further, a breakdown of what these charges pay for was shown.

2. Review: Current system performance

Details of Hydro One's previous system performance and historical reliability were shown to participants. A breakdown of reliability by location within Hydro One's service area was provided, including frequency and duration of outages in local markets. Comparison to other distributors with an explanation of Hydro One's mostly rural customer base, as well as reliability variations from customer to customer, were introduced. Causes of equipment failure and reliability challenges faced by Hydro One and other utilities were also shown.

3. Context: Investing in the system

Current efficiencies and productivity, the factors that influence investment decisions, 2016 expenditures, and the current program to maintain reliability were all described during this portion of the Workshops. Regional initiatives to improve reliability and service were also shown.

4. Discussion: What's best for you

Candidate areas for potential improvement for reliability and for service were shown, followed by an introduction to the illustrative investment scenarios. These included three scenarios:

- **Scenario 1:** Maintaining performance scenario
- **Scenario 2:** Declining performance scenario
- **Scenario 3:** Improving performance scenario

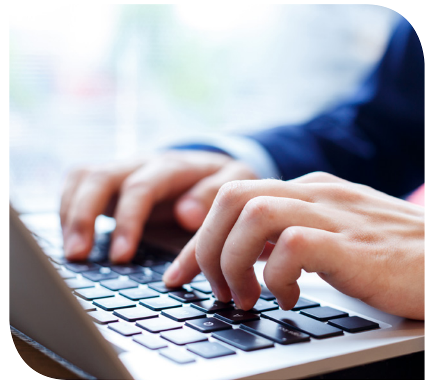
Each Scenario contained information on investment levels, including capital and OM&A expenditures. A summative slide including distribution delivery rate increases was shown, along with reliability and customer service impacts for each Scenario.

Finally, targeting investments to offer differentiated reliability and service to Large Customers, and the metrics to measure reliability performance, were explained to close the Workshops.

2. ONLINE WORKBOOK/ SURVEY BOOKLET

Those invited customers that were not invited to, or were unable to attend, one of the Workshop sessions were e-mailed or mailed the Online Workbook. As with the in-person Workshops, Hydro One was responsible for sending out the invitations as well as the follow-up, reminders and other communication outreach with a broad cross-section of its Large Customers for the Online Workbook.

LDA, LDC, and DG customers received a unique ID to access the Workbook, thus ensuring that once it was completed the customer could not go in and complete it a second time. Because of the size of the C&I customer base that was invited to complete the Online Workbook (5,226), an Open-Link of the Online Workbook was e-mailed or mailed to each customer.



C&I customers were not given a unique ID. IP capture was in place to ensure that only one "complete" per computer was accepted, but it is possible that customers could participate twice since they also attended one of the Workshop sessions.

The Online Workbook presented the same information shared at the Workshops and posed nearly identical questions. The only difference in the questions was that the Online Workbook used a statistical technique called paired-choice to quantitatively measure the relative importance customers place on various aspects of service. This technique could not be replicated in hard-copy, thus the Workshop survey booklet used a, "pick the most important" question in place of the paired-choice question.

A total of 87 customers completed the Online Workbook. This data was merged together with the survey booklets that were completed by 104 participants in the Workshops. As with the R&SB survey results, the percentages reported on this data may total to greater than 100% due to rounding or because respondents were permitted to provide more than one response, as in the case of open-ended questions.

RESIDENTIAL AND SEASONAL CUSTOMERS

SUMMARY

While opinions are mixed, the largest share of Residential and Seasonal customers feel the current number and average length of power outages they experience is in line with their expectations. A majority of Residential and Seasonal customers who offer an opinion are willing to accept the proposed roughly 1% increase on their total monthly bill to maintain the current number and average length of outages, but are not willing to pay more for better reliability.

While on most questions the needs and preferences of Residential and Seasonal customers do not vary greatly regardless of whether they are 'informed' or 'uninformed,' some differences emerge:

- *'Informed' customers are directionally more likely to say the current number and average length of outages they experience is worse than they expect; and,*
- *'Informed' customers, particularly among the Seasonal customer segment, are directionally more willing to accept the rate impacts proposed to maintain the current number and average length of outages than the average 'uninformed' customer.*

TELEPHONE SURVEY

As outlined in the methodology section of this report, the following results are based on a Telephone Survey of a random and representative sample of n=400 Residential and n=100 Seasonal customers. A stratified, random sampling approach was used to pull the sample Residential and Seasonal customers from Hydro One's customer database. With a sample of this size, the results are considered accurate to within ± 4.9 percentage points, 19 times out of 20 for Residential and ± 9.8 percentage points for Seasonal, of what they would have been had all Residential and Seasonal customers been surveyed. That means that if the survey is repeated 20 times, 19 of those times the results of the survey will be the same within the margin of error. The margin of error will be larger within sub-groupings of the survey population. These data were statistically weighted by density (urban, medium, low, seasonal) to ensure the sample composition reflects the true proportions in the customer database. The data was not weighted by region or rural/urban because the unweighted proportions closely match the true proportions.

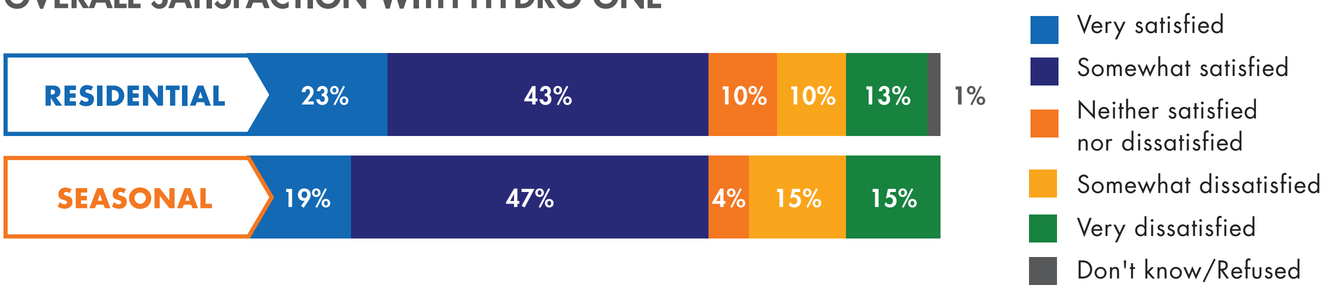
For more information on the survey methodology refer to the Customer Engagement Methodology section of the report. A full breakdown of the sample composition and a copy of the questionnaire are provided in the Appendix.

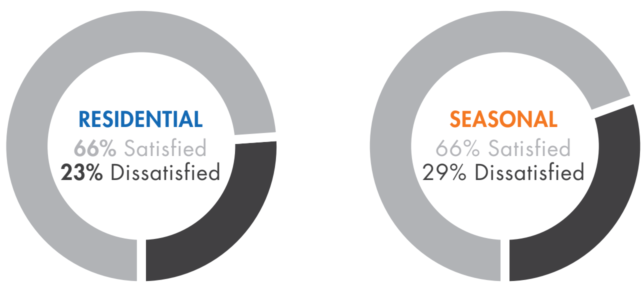
CURRENT SATISFACTION AND WHAT IS IMPORTANT TO CUSTOMERS

Two-thirds (66%) of Residential and Seasonal customers report that they are satisfied with Hydro One overall, one-in-ten (10%) hold a neutral opinion, while one-quarter (23%) are dissatisfied. When asked on an unaided basis what Hydro One can do to improve its service to them, the most frequent answer customers give is to reduce their monthly bills. Some customers mention this in the context of lower prices or lower rates, while others just simply say lower cost.

TELEPHONE SURVEY

OVERALL SATISFACTION WITH HYDRO ONE



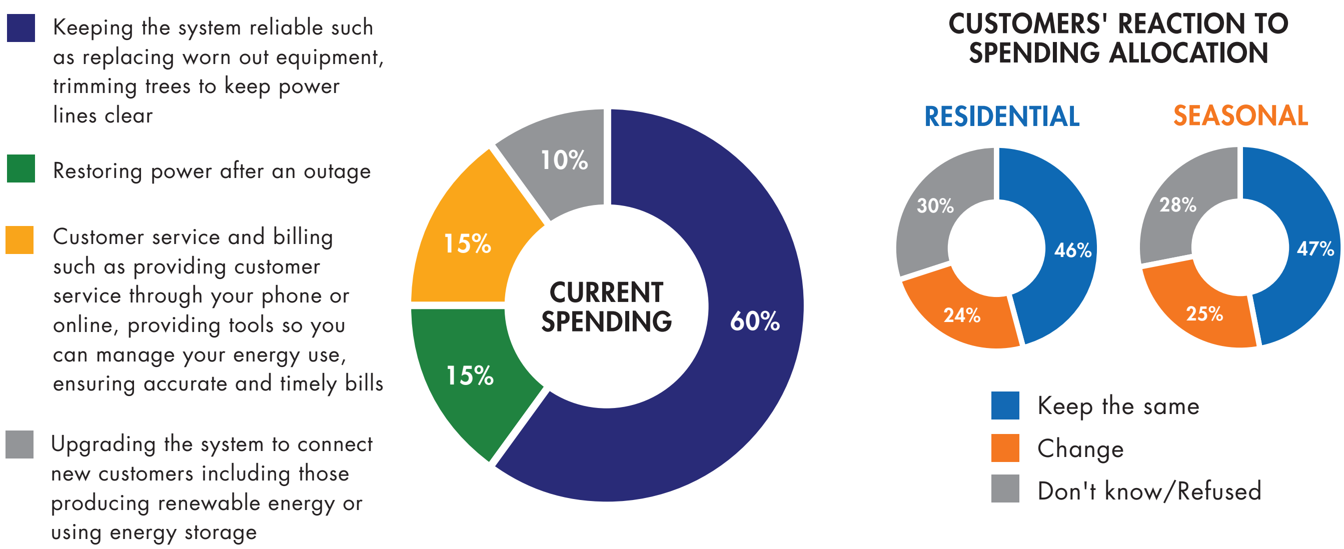


As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices. Q1. Please think about Hydro One as I have just described it to you. How satisfied are you with Hydro One overall? Note: During the first week of fielding the response scale was changed from 1 to 5 to a word scale to be consistent with the Annual Customer Satisfaction survey. Base: All Respondents Post Q change; Residential (n=243), Seasonal (n=68)

Given the opportunity to review a rough breakdown of what Hydro One currently spends on each of its major electricity distribution investments, that is, how the distribution delivery rate is allocated, the majority that offer an opinion (excluding Don't Know/Refused) indicate that they would not change how the money is currently allocated.

TELEPHONE SURVEY

OPINIONS ON CURRENT ALLOCATION OF SPENDING



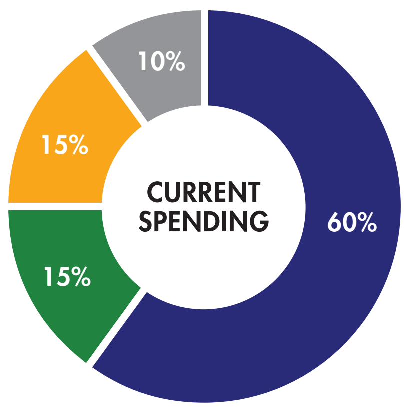
Q3. Please listen carefully as I will be reading out a rough breakdown of what Hydro One currently spends on each of its major electricity distribution investments and will be asking your opinion about the breakdown. Hydro One currently spends [READ LIST]… If you were in charge of Hydro One would you change how spending is allocated or would you keep it about the same as it now? Base: Residential (n= 400) , Seasonal (n=100)

One-quarter of both Residential customers and Seasonal customers indicate that they would change how the money is allocated. In general, these customers allocate more money to restoring power after outages and less money to keeping the system reliable.

TELEPHONE SURVEY

PREFERRED ALLOCATION OF SPENDING

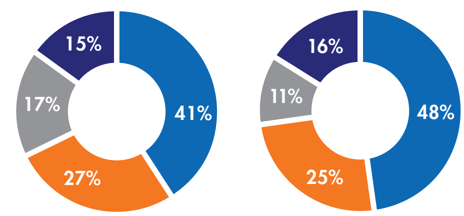
- Keeping the system reliable such as replacing worn out equipment, trimming trees to keep power lines clear
- Restoring power after an outage
- Customer service and billing such as providing customer service through your phone or online, providing tools so you can manage your energy use, ensuring accurate and timely bills
- Upgrading the system to connect new customers including those producing renewable energy or using energy storage



CUSTOMERS' PREFERRED ALLOCATION OF SPENDING

RESIDENTIAL

SEASONAL



- Keeping the system reliable
- Restoring Power
- Customer Service
- Upgrading the system to connect new customers

Q4. Of the 4 distribution investments you just heard, what percentage would you allocate to.. [READ LIST]? Base: Customers who indicated that current spending should be changed. The percentages have been rebased to exclude don't know responses or responses that do not add to 100 % (Residential = n=79) , Seasonal (n=23)

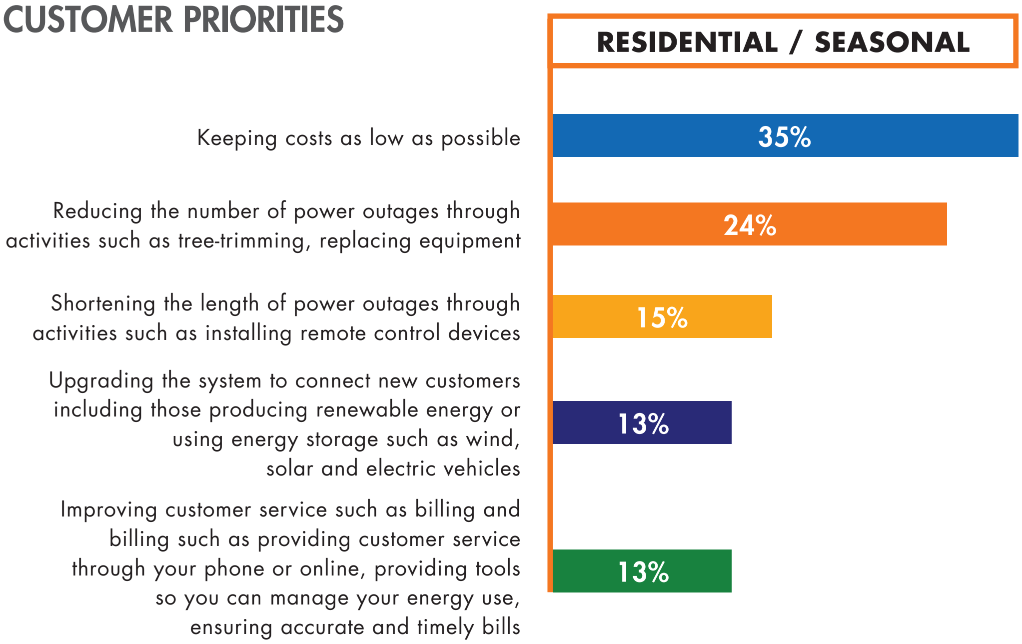
CUSTOMER PRIORITIES

A paired-choice exercise was used to identify customer priorities in order to help Hydro One better tailor its services. Paired-choice is an analytical technique designed to draw out the extent to which respondents prefer each option in relation to every other option. It works by pairing options off so that they are essentially 'competing' against one another. A series of these pairs are presented to respondents, who are asked to choose which of the two options they prefer. Respondents are forced to choose an option and cannot give a 'don't know' answer.

In our survey, there were 10 possible pairs of the five options being evaluated, and each respondent was shown five separate pairs. The rotational design was built by Ipsos' research science team. The results of the exercise are presented as relative preference scores. Relative preference scores reflect the share of total preference each option has, which means we have to imagine that there is a pool of total preference to be allocated across each of the options. Essentially, relative preference reflects a collective strength of feeling towards a particular option in relation to the others – the higher the percentage, the more strongly it is preferred among respondents. For more information on paired-choice, refer to the Appendix.

The chart below shows that keeping costs as low as possible has a relative preference score of 35% among Residential and Seasonal customers, and that this is the largest preference score of the options presented. This indicates that customers prioritize keeping costs as low as possible above the other options (reducing the number of outages, improving restoration times, improving customer service, or upgrading the system to connect new customers). It is more than twice as important to customers as the latter three options (restoration times, customer service and connecting new customers). Reducing the number of outages is the next more preferred option.

TELEPHONE SURVEY
CUSTOMER PRIORITIES



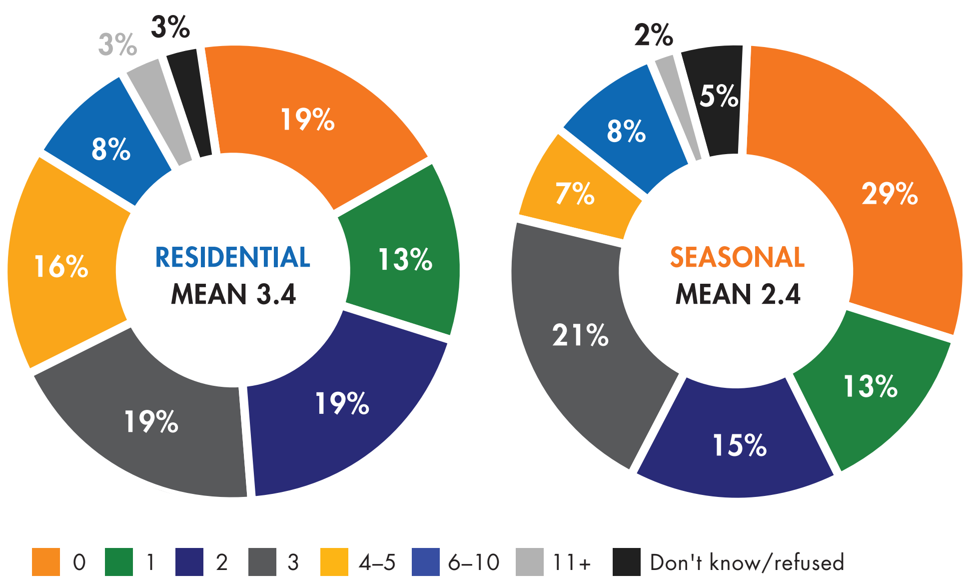
Q5. Hydro One would like to better understand what is important to you as a [Residential or Seasonal customer]. I am going to read Hydro One's major expenditures in pairs and for each pair please tell me which one is more important to you. Paired-choice preferences relative to other options. Base: Residential/ Seasonal (n=499) One respondent opted not to answer Q5.

THE LEVEL OF RELIABILITY THAT CUSTOMERS EXPECT

Most customers indicate that the level of reliability that they currently experience is in line with their expectations. Residential customers report experiencing an average of roughly three outages of at least one minute in length in the past twelve months, Seasonal customers average about two outages. The largest share of customers – 48% of Residential and 55% of Seasonal – indicate that this level of reliability (number of outages they experienced) is about what they expect. Only 16% of Residential and 17% of Seasonal customers who experienced at least one outage indicate the number of outages they experienced is worse than they expect.

TELEPHONE SURVEY

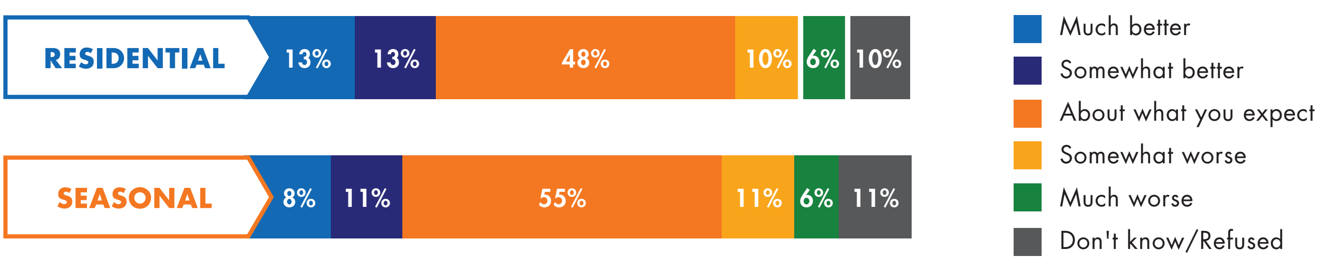
AVERAGE NUMBER OF OUTAGES



Q7. A sustained power outage is one lasting at least 1 minute. How many sustained power outages did you experience in the past 12 months that you were not notified about in advance by Hydro One? Your best guess is fine. Base: Residential (n=400), Seasonal (n=100)

TELEPHONE SURVEY

CUSTOMER EXPECTATIONS

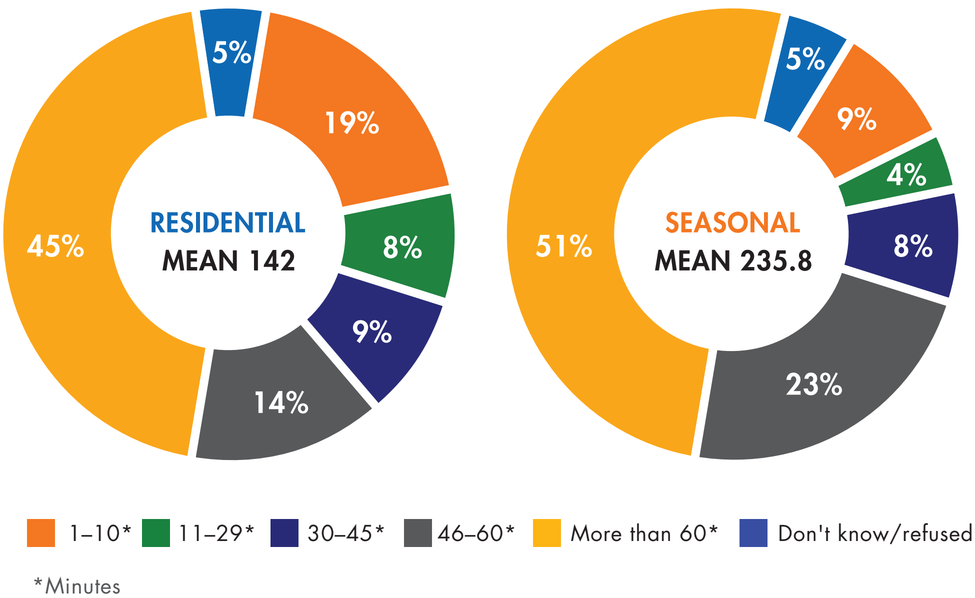


Q8. In general, when you think about how many power outages you experienced over the last 12 months how did it compare to your expectations [READ LIST]? Base: One or more sustained power outages in the past 12 months; Residential (n=314), Seasonal (n=66)

When it comes to length of outages, Residential customers estimate that the outages that they experience last an average of roughly two hours, while Seasonal customers estimate an average of roughly four hours. Similar to opinions of frequency of outage, the largest share of customers indicate that this is about what they expect. Twenty percent say this is worse than they expect.

TELEPHONE SURVEY

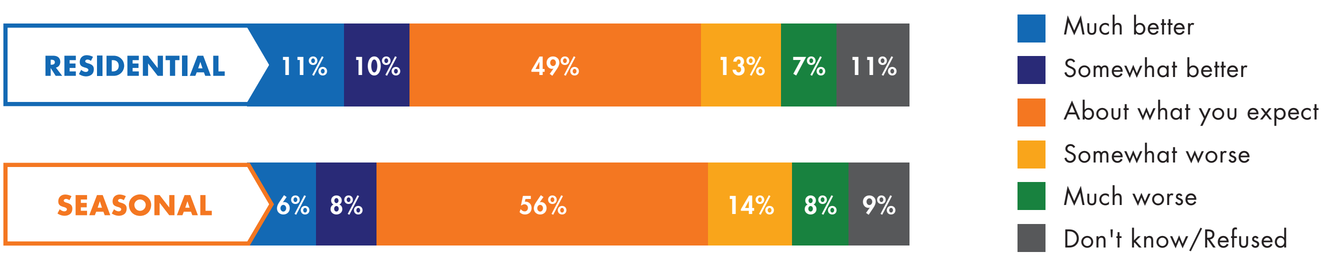
AVERAGE LENGTH OF OUTAGES



Q9. On average, how long did these unplanned outages last? Please answer in minutes. Your best guess is fine. Base: One or more sustained power outages in the past 12 months; Residential (n=314), Seasonal (n=66)

TELEPHONE SURVEY

CUSTOMER EXPECTATIONS



Q10. In general, when you think about the average length of the power outages you experienced over the last 12 months how did it compare to your expectations [READ LIST]? Base: One or more sustained power outages in the past 12 months; Residential (n=314), Seasonal (n=66)

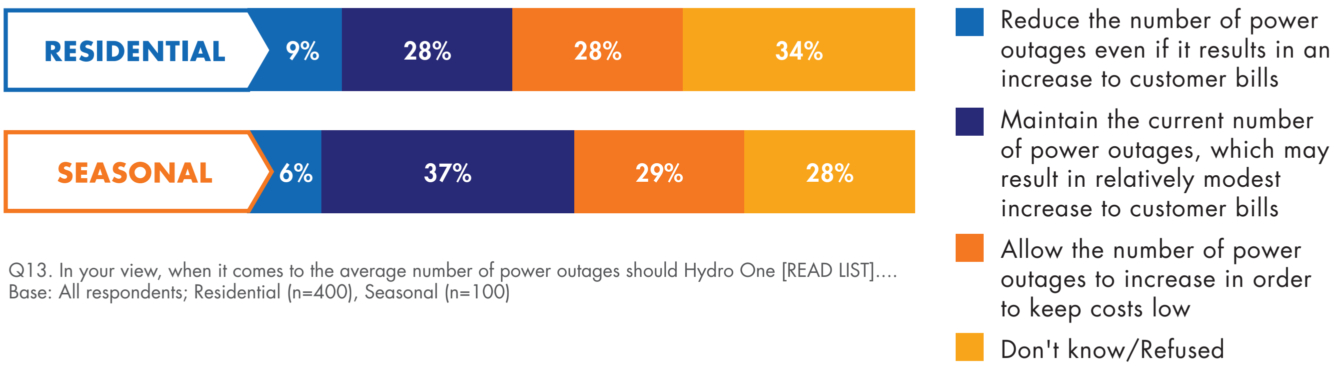
HOW CUSTOMERS REACT TO SERVICE VS. COST TRADE-OFFS

When asked what Hydro One should do on the topic of the number and length of outages, opinions are mixed and a reasonably large minority of customers do not offer an opinion (34% of Residential customers indicate they don't know or refuse to provide an opinion on number of outages and 32% on duration, and 28% and 29% of Seasonal customers respectively). Of those who offer an opinion, 42% of Residential customers would trade off an increase in their monthly bill to keep number of outages to the current level, but 43% would allow the number of power outages to increase in order to keep costs low. Less than two-in-ten customers (14%) would like to reduce the number of outages and would be willing to accept a potential increase in their monthly bill to achieve it.

TELEPHONE SURVEY

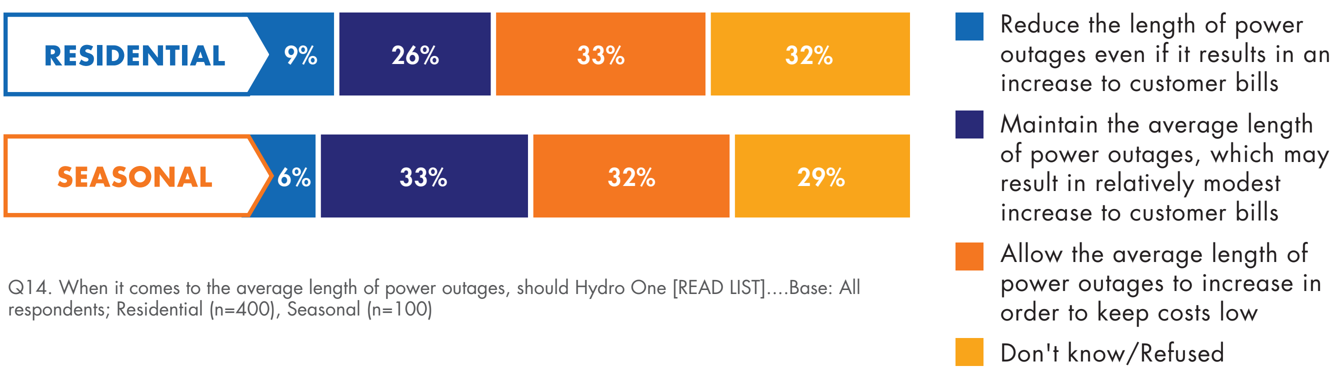
RELIABILITY TRADE-OFF PREFERENCES

NUMBER OF POWER OUTAGES



Q13. In your view, when it comes to the average number of power outages should Hydro One [READ LIST].... Base: All respondents; Residential (n=400), Seasonal (n=100)

LENGTH OF POWER OUTAGES



Q14. When it comes to the average length of power outages, should Hydro One [READ LIST]....Base: All respondents; Residential (n=400), Seasonal (n=100)

As shown in the chart above, customer opinions on the number of outages break out very similarly when it comes to preferences on how to address both the length of outages that they experience as well as the level of customer service they receive. The percentage of Residential customers who would accept a rate increase in order to maintain the status quo is about even with the percentage of customers that would accept worsening levels (including allowing the length of outages to increase or allow for longer wait times and poorer billing accuracy) in order to keep costs low.

There is greater consensus among customers when it comes to their level of interest in upgrades to the system to connect new customers including those producing renewable energy or energy storage. While roughly one-third do not offer an opinion, a majority (65%) of Residential customers with an opinion indicate that given the choice they would prefer to allow a slowdown in Hydro One's ability to connect renewable energy customers, in order to keep costs low.

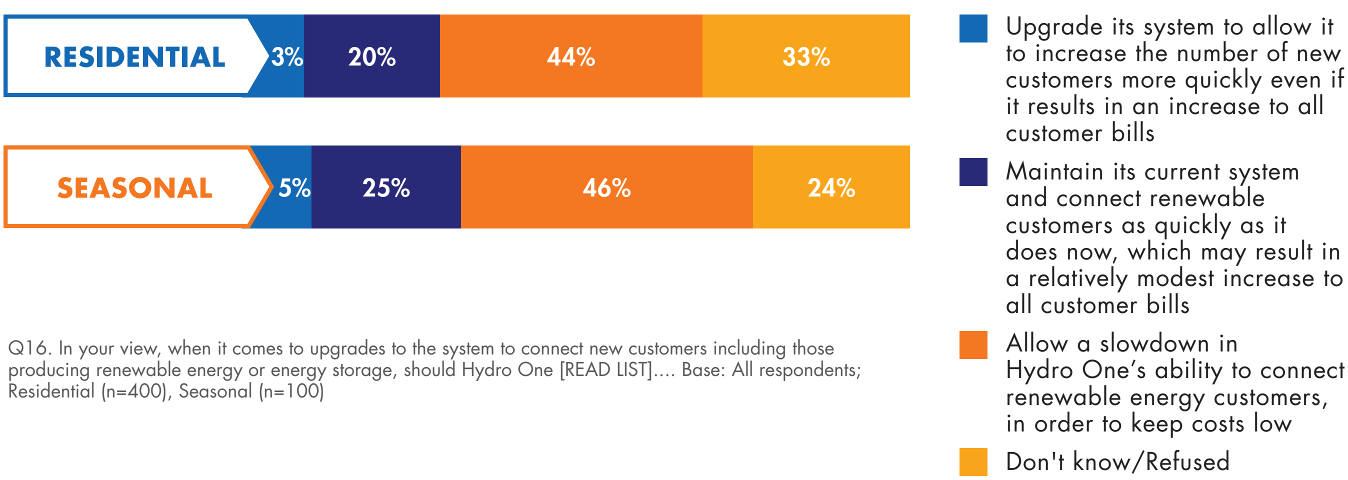
CONNECTING CUSTOMERS PRODUCING RENEWABLE ENERGY



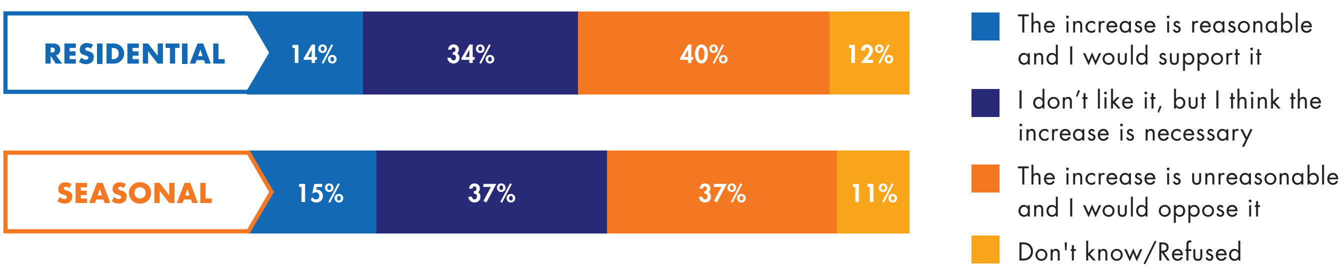
Q16. In your view, when it comes to upgrades to the system to connect new customers including those producing renewable energy or energy storage, should Hydro One [READ LIST]…. Base: All respondents; Residential (n=400), Seasonal (n=100)

WILLINGNESS TO ACCEPT A RATE INCREASE TO MAINTAIN AND IMPROVE SERVICE LEVEL

When customers are informed that Hydro One has estimated that in order to at least maintain the level of reliability and customer service it currently provides, a typical Residential or Seasonal customer's **total monthly bill** will need to increase by 1.1% or the equivalent of $2.00, half of Residential (48%) and Seasonal (52%) customers are willing to accept it, roughly 40% of both segments are opposed, and the remaining 10% do not offer an opinion. Prior to answering this question, customers were informed that the increase of $2.00 would be applied each year for the next five years, and that by the fifth year a typical monthly bill will be roughly $10.00 higher than it is now. Customers were also informed prior to answering that the increase reflects the cost to maintain the current level of reliability and service to customers, and that the monthly bill could still increase for other reasons which are outside the control of Hydro One.

TELEPHONE SURVEY

ACCEPTABILITY OF RATE INCREASE TO MAINTAIN LEVELS



Q17. Hydro One has determined that in order to at least maintain the level of reliability and customer service it currently provides, a typical [Residential or Seasonal customer's total monthly bill will need to increase by [1.1% or the equivalent of $2.00]. The increase will be applied each year for the next 5 years. By the fifth year, a typical monthly bill will be roughly [IF RESIDENTIAL OR SEASONAL $10.00 / IF BUSINESS: $26.00] higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability and service to customers. The monthly bill could still increase for other reasons which are outside the control of Hydro One. Which of the following is closest to your point of view [READ LIST]? Base: All respondents; Residential (n=400), Seasonal (n=100)

This takes into consideration the percentage of customers that do not provide an answer. When these percentages are re-based on only those who offered an opinion, acceptance increases to 55% among Residential customers and 57% among Seasonal customers.

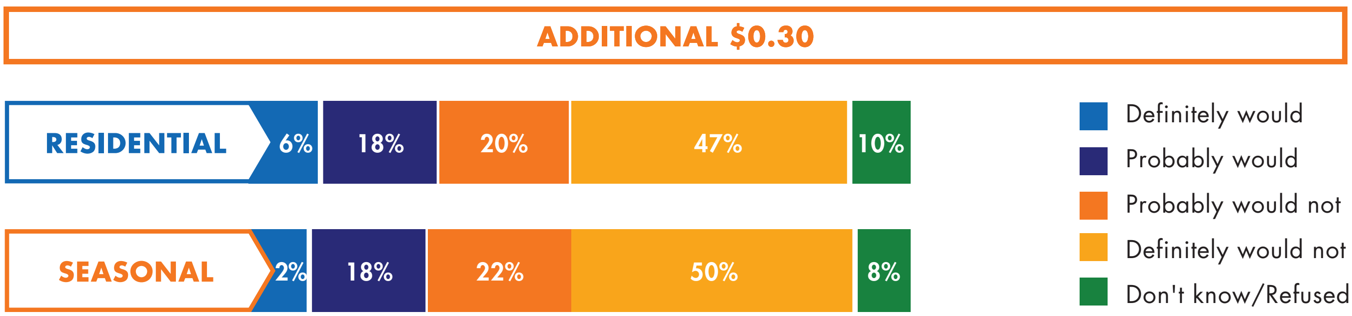
Not surprisingly given the majority of customers feel the current level of reliability falls within their expectations, relatively few customers are willing to pay more for improved reliability or service. Only one-in-ten customers indicate that they would be willing to pay more than the $2.00 (1.1%) increase in order to have **better reliability** than today. An additional 15% of Residential customers and 20% of Seasonal customers would consider it (selecting 'maybe' as their response). Sixty percent would not pay anything more. There is even less interest in paying for an improved level of customer service – only 8% of Residential and 6% of Seasonal customers say that they would be willing to pay extra for improved customer service.

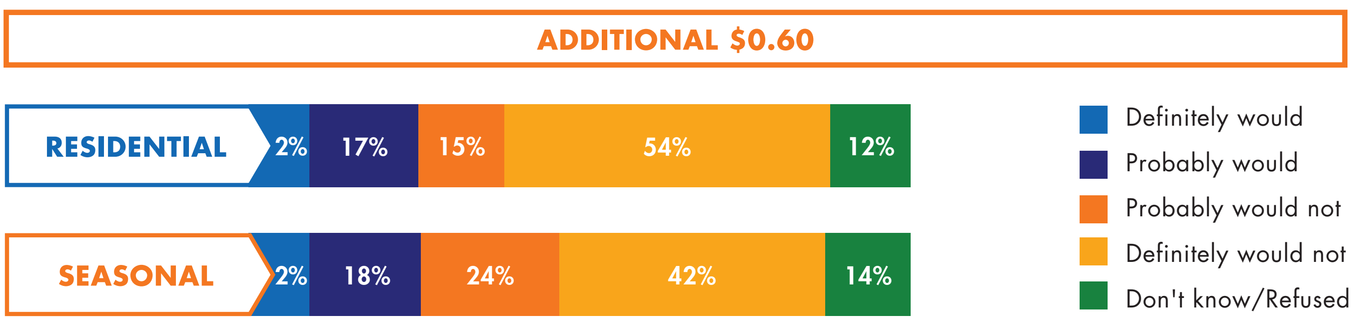
And lastly, customers were asked their level of interest in a 10% reduction in the number and length of future outages, for a specific rate impact. Two additional rate impacts were posed to customers for their reaction. Half of the sample of respondents were asked to consider an additional $.30 per month, or at total of $2.30 more on their monthly bill, and the other half was asked to consider a rate increase of $.60 per month for a total of $2.60 more on their monthly bill.

Only 6% of Residential customers say they definitely would prefer to pay $2.30 more (or $11.50 by the fifth year) instead of the $2.00 (or the $10.00 by the fifth year) and 18% say they probably would. Only 2% of Residential customers say they definitely would prefer to pay $2.60 more (or $13.00 by the fifth year) instead of the $2.00 (or the $10.00 by the fifth year) and 17% say they probably would.

TELEPHONE SURVEY

WILLINGNESS TO PAY FOR IMPROVED LEVELS





Q20A. Would you be willing to pay an additional [HALF OF RESPONDENTS SHOW $0.30 / OTHER HALF SHOW $0.60] per month over and above the $2.00 which would be approximately [SPLIT SAMPLE $2.30 /$2.60] more per month if it meant that Hydro One could reduce the number and length of future power outages by 10%? The increase would be applied annually for the next five years so that by the fifth year your monthly bill will be roughly [$11.50 / $13.00] higher than it is now? [READ LIST] Base: SPLIT SAMPLE (Residential n=200), Seasonal (n=50)

ONLINE WORKBOOK: REPRESENTATIVE SAMPLE

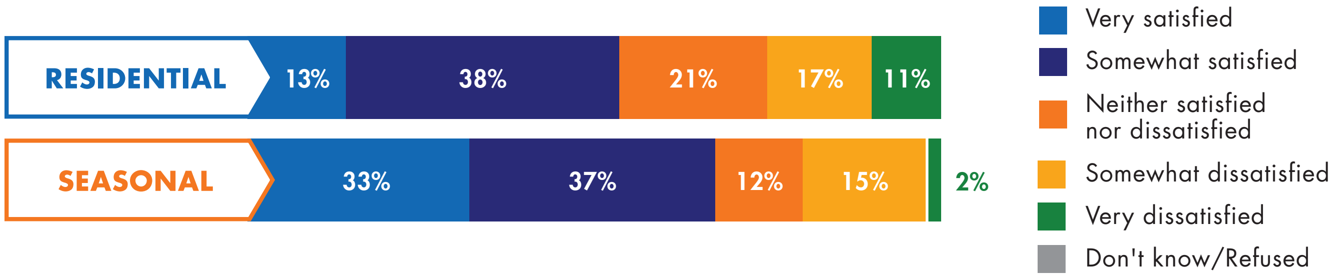
The primary purpose of conducting the Online Workbook with a representative sample of Residential and Seasonal customers is to have an understanding of the opinions of customers who have been informed about Hydro One through the Workbook (the same Workbook that was provided to those responding to the Open-Link). A total of n=1,502 Residential customers and n=102 Seasonal customers completed the Online Workbook. The sample was drawn from Ipsos' panel.

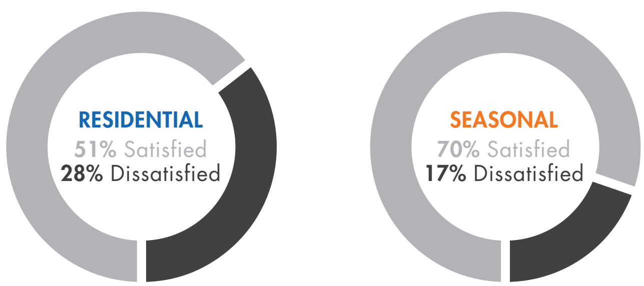
CURRENT SATISFACTION AND WHAT IS IMPORTANT TO CUSTOMERS

Whereas 66% of the representative sample of 'uninformed' Residential customers surveyed by telephone report being satisfied with Hydro One, satisfaction is lower among the 'informed' sample. Only half (51%) of Residential customers are satisfied. Two-in-ten (21%) hold a neutral opinion, while nearly three-in-ten (28%) are dissatisfied. Notably, Seasonal customers report similar levels of being satisfied regardless of being 'informed' or 'uninformed.'

ONLINE WORKBOOK: REPRESENTATIVE SAMPLE

OVERALL SATISFACTION WITH HYDRO ONE



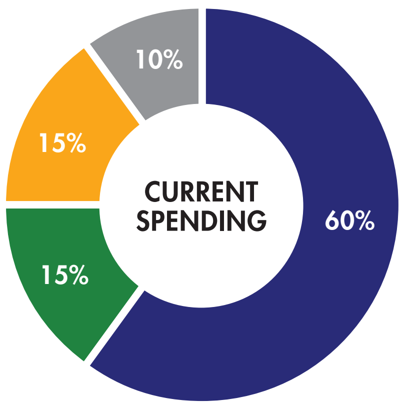


As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices. Q1. How satisfied are you with Hydro One overall? Note: During the first week of fielding the response scale was changed from 1 to 5 to a word scale to be consistent with the Annual Customer Satisfaction survey. Base: All Respondents Post Q change; Residential (n=1,384, Seasonal (n=98)

Given the opportunity to review a rough breakdown of what Hydro One currently spends on each of its major electricity distribution investments, that is, how the distribution delivery rate is allocated, 41% of Residential customers and 56% of Seasonal customers would keep the current spending breakdown the same as it is now. Twenty-seven percent of Residential and 24% of Seasonal indicate that they would change how the money is currently allocated. These results are similar to those of the 'uninformed' telephone sample.

ONLINE WORKBOOK: REPRESENTATIVE SAMPLE

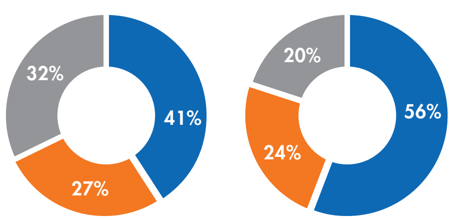
PREFERRED ALLOCATION OF SPENDING



- Keeping the system reliable such as replacing worn out equipment, trimming trees to keep power lines clear
- Restoring power after an outage
- Customer service and billing such as providing customer service through your phone or online, providing tools so you can manage your energy use, ensuring accurate and timely bills
- Upgrading the system to connect new customers including those producing renewable energy or using energy storage

OPINION ON CURRENT ALLOCATION OF SPENDING

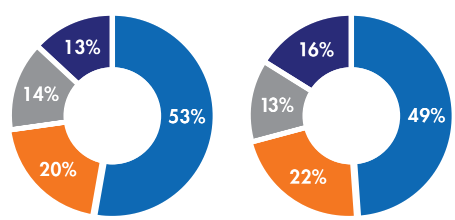
RESIDENTIAL SEASONAL



- Keep the same
- Change
- Don't know/Refused

CUSTOMERS' PREFERRED ALLOCATION OF SPENDING

RESIDENTIAL SEASONAL



- Keeping the system reliable
- Restoring Power
- Customer Service
- Upgrading the system to connect new customers

Q3. The pie chart above shows a rough estimate of what Hydro One currently spends on each of its major electricity distribution investments. If you were in charge of Hydro One would you change how spending is allocated or would you keep it about the same as it now? Base Residential (n=1,502), Seasonal (n=102)
Q4. What percentage would you allocate to...? Base: Customers who indicated that current spending should be changed. The percentages have been rebased to exclude don't know responses or responses that do not add to 100% Base: Residential (n=408), Seasonal (n=25)

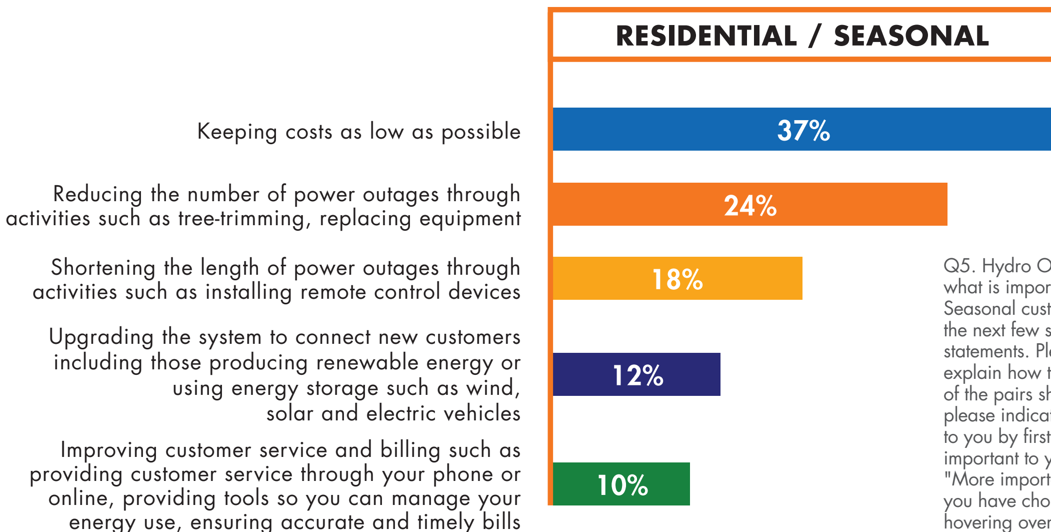
In general, these customers allocate more money to restoring power after outages and less money to keeping the system reliable. This too is consistent with the results of the 'uninformed' Telephone Survey among these customer segments.

CUSTOMER PRIORITIES

As noted in earlier sections, a paired-choice exercise was used to identify customer priorities in order to help Hydro One better tailor its services. For more information on paired-choice refer to the Appendix.

ONLINE WORKBOOK: REPRESENTATIVE SAMPLE

CUSTOMER PRIORITIES



Q5. Hydro One would like to better understand what is important to you as a [Residential or Seasonal customer]. On this screen, as well as the next few screens, you will see rotating pairs of statements. Please read the instructions below that explain how to make your choice between each of the pairs shown. For each of the pairs below, please indicate the one that is more important to you by first clicking the statement that is more important to you and then clicking on the words "More important'. You should see the statement you have chosent with the words 'More important' hovering over it. This indicates the statement that you feel is the more important of the two. Then please click the next button to move to the next screen with the next pair. Base: Residential/ Seasonal (n=1,604). One respondent opted not to answer Q5.

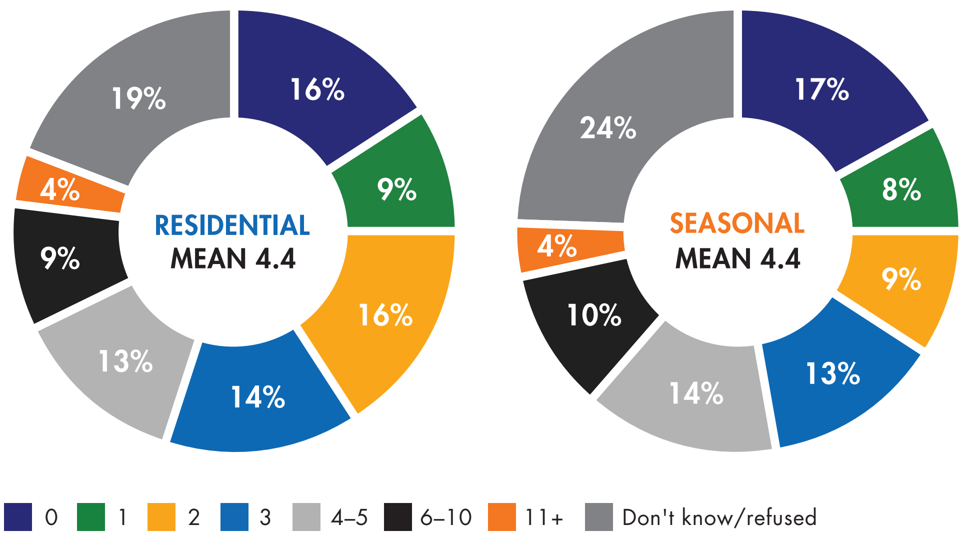
The chart above shows that keeping costs as low as possible has a relative preference score of 37% among Residential and Seasonal customers, and that this is the largest preference score of the options presented. This indicates that customers prioritize keeping costs as low as possible above the other options – reducing the number of outages, improving restoration times, improving customer service, or upgrading the system to connect new customers. It is more than twice as important to customers as the latter three options (restoration times, customer service and connecting new customers). Reducing the number of outages is next more preferred option.

THE LEVEL OF RELIABILITY THAT CUSTOMERS EXPECT

Most customers indicate that the level of reliability they currently experience is in line with their expectations. Residential customers report experiencing an average of roughly 4.4 outages of at least one minute in duration in the past 12 months, Seasonal customers average about the same at 4.4 outages. The largest share of customers – 52% of Residential and 42% of Seasonal – indicate that this level of reliability (number of outages they experienced) is about what they expect. One-quarter of Residential and 35% of Seasonal customers who experienced at least one outage, say it is worse than they expect, comparatively two-in-ten of both Residential and Seasonal customers say it is better than they expect.

ONLINE WORKBOOK: REPRESENTATIVE SAMPLE

AVERAGE NUMBER OF OUTAGES



Q7. A sustained power outage is one lasting at least 1 minute. How many sustained power outages did you experience in the past 12 months that you were not notified about in advance by Hydro One? Your best guess is fine.

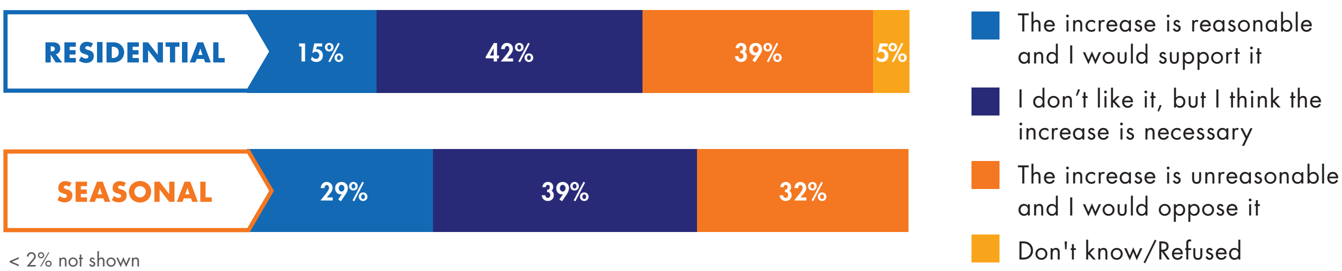
WILLINGNESS TO ACCEPT A RATE INCREASE TO MAINTAIN AND TO IMPROVE SERVICE LEVEL

When customers are informed that Hydro One has estimated that in order to **at least maintain** the level of reliability and customer service it currently provides, a typical Residential or Seasonal customer's **total monthly bill** will need to increase by 1.1% or the equivalent of $2.00, nearly six-in-ten residential (57%) and nearly seven-in-ten Seasonal (68%) customers are willing to accept it. This is directionally higher than the results of the 'uninformed' telephone sample. Prior to answering this question, customers were informed that the increase of $2.00 would be applied each year for the next five years, and that by the fifth year a typical monthly bill would be roughly $10.00 higher than it is now. Customers were also informed prior to answering that the increase reflects the cost to maintain the current level of reliability and service to customers, and that the monthly bill could still increase for other reasons which are outside of Hydro One's control.

ONLINE WORKBOOK: REPRESENTATIVE SAMPLE

ACCEPTABILITY OF RATE INCREASE TO MAINTAIN LEVELS



< 2% not shown

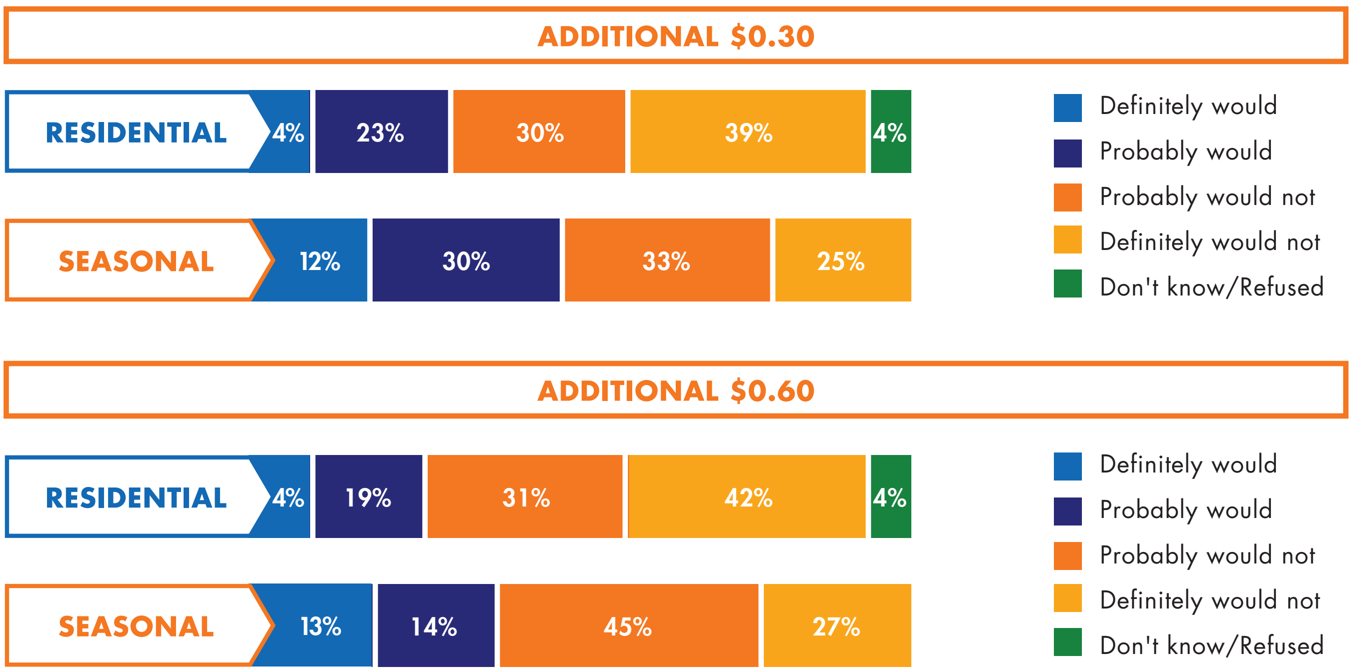
Q17. Hydro One has determined that in order to at least maintain the level of reliability and customer service it currently provides, a typical residential or seasonal customer's total monthly bill will need to increase by [1.1% or the equivalent of $2.00/1% or the equivalent of $5.20]. This increase will be applied each year for the next five years. By the fifth year, a typical monthly bill will be roughly $10.00 higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability and service to customers. The monthly bill could still increase for other reasons which are outside the control of Hydro One. Would you be willing to accept this increase to maintain the current level reliability and customer service across the electricity system? Base: Residential (n=1,502), Seasonal (n=102)

Customers were asked about their level of interest in a 10% reduction in the number and length of future power outages, for a specific rate impact. Two additional rate impacts were posed to customers for their reaction. Half of the sample of respondents were asked to consider an additional $0.30 per month, or a total of $2.30 more on their monthly bill, and the other half was asked to consider a rate increase of $0.60 per month for a total of $2.60 more on their monthly bill.

Only 4% of Residential customers say they would definitely prefer to pay $2.30 more (or $11.50 by the fifth year) instead of the $2.00 (or $10.00 by the fifth year) and 23% say they probably would. Only 4% of Residential customers say they definitely would prefer to pay $2.60 more (or $13.00 by the fifth year) instead of the $2.00 (or the $10.00 by the fifth year) and 19% say they probably would. Interest is directionally higher among Seasonal customers.

ONLINE WORKBOOK: REPRESENTATIVE SAMPLE

WILLINGNESS TO PAY FOR IMPROVED LEVELS



Q20A. Would you be willing to pay an additional [HALF OF RESPONDENTS SHOW $0.30/OTHER HALF SHOW $0.60] per month over and above the $2.00 which would be approximately [SPLIT SAMPLE $2.30/$2.60 more per month if it meant that Hydro One could reduce the number and length of future power outages by 10%? The increase would be applied annually for the next five years so that by the fifth year your monthly bill will be roughly [$11.50/$13.00] higher than it is now? Base: Residential/ Seasonal customer; Residential (split n=756/n=746), Seasonal (split n=50/n=52)

ONLINE WORKBOOK: OPEN LINK

The primary purpose of offering an Open-Link version of the Online Workbook was to provide an avenue by which R&SB customers of Hydro One who were not randomly selected to participate in the Telephone Survey could participate and have their opinions heard.

Since the results contained within this section of the report are based on self-selected or volunteered participation, the results should not be interpreted as a representative sample of Hydro One customers. Further, the Online Workbook was designed to inform customers, prior to answering the survey, about Hydro One and its role within the provincial electricity system such as Hydro One's service territory, reliability, customer service benchmarking, and the challenges it is facing in the future. This is information that the average customer would not necessarily have equal access to. For both of these reasons, the results of the Open-Link survey cannot be said to represent or to be generalized to the opinions of the broader Hydro One customer base.

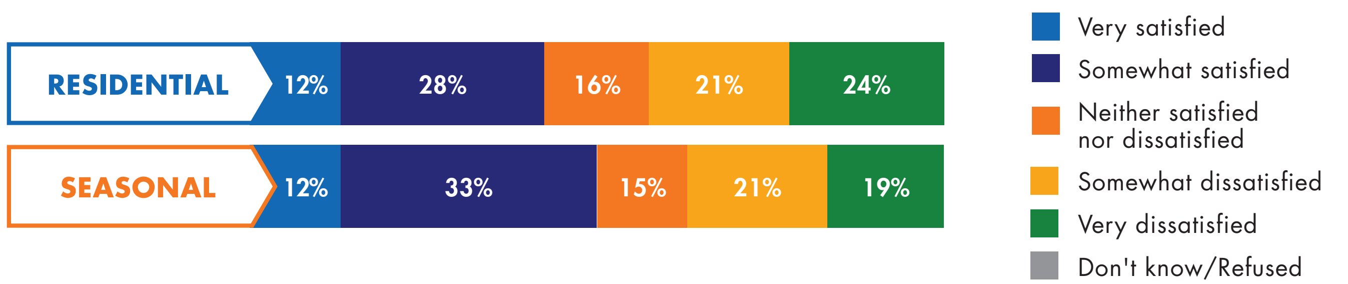
A hard copy of the Online Workbook and Survey is provided in the Appendix. As noted in the Customer Engagement Methodology section of this report, the Online Workbook was extensively promoted to customers to encourage as many customers as possible to participate. A total of 17,201 valid responses were received.

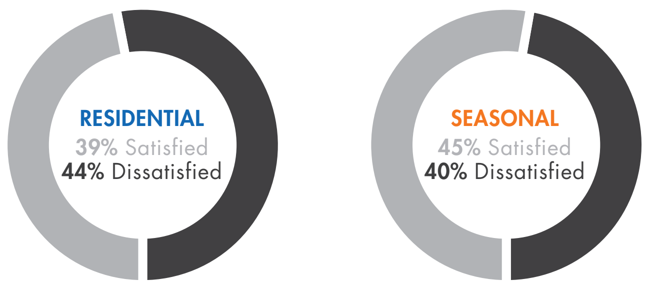
CURRENT SATISFACTION AND WHAT IS IMPORTANT TO CUSTOMERS

Whereas 66% of the representative sample of 'uninformed' Residential customers surveyed by telephone report being satisfied with Hydro One, and half of the 'informed' representative sample report being satisfied, only 39% of those who responded to Open-Link were satisfied. At 45%, satisfaction among Seasonal customers who responded to the Open-Link is also lower than the representative samples (Telephone or Online Workbook).

ONLINE WORKBOOK OPEN-LINK

OVERALL SATISFACTION WITH HYDRO ONE



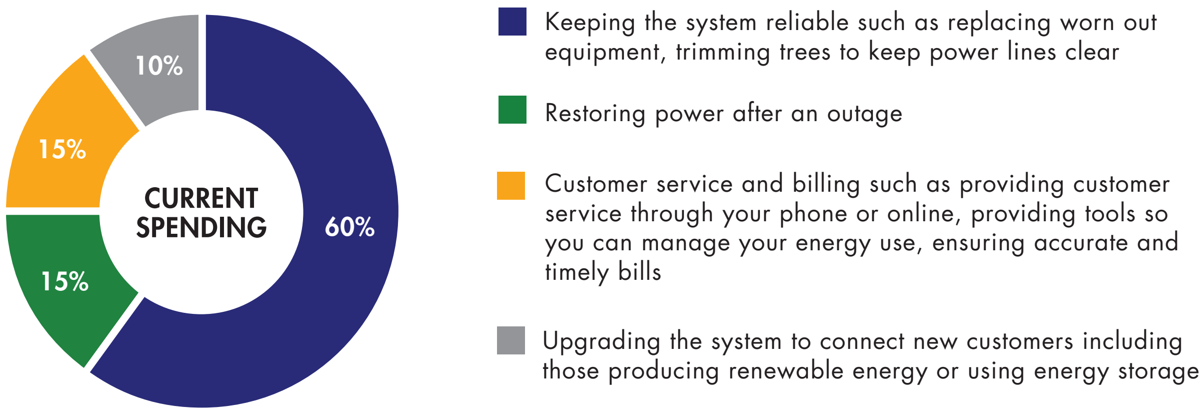


As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices. Q1. How satisfied are you with Hydro One overall? Note: During the first week of fielding the response scale was changed from 1 to 5 to a word scale to be consistent with the Annual Customer Satisfaction survey. Base: All Respondents Post Q change; - Residential (n=15,226), Seasonal (n=1,097)

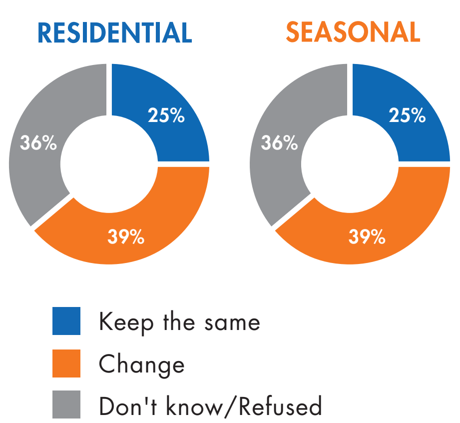
Given the opportunity to review a rough breakdown of how much Hydro One currently spends on each of its major electricity distribution investments, that is, how the distribution delivery rate is spent, 25% Residential and Seasonal customers would keep the current spending breakdown the same as it is now. This is much lower than found in the 'uniformed' Telephone Survey and the 'informed' Online Workbook sample. Four-in-ten indicate that they would change how the money is currently allocated.

ONLINE WORKBOOK OPEN-LINK

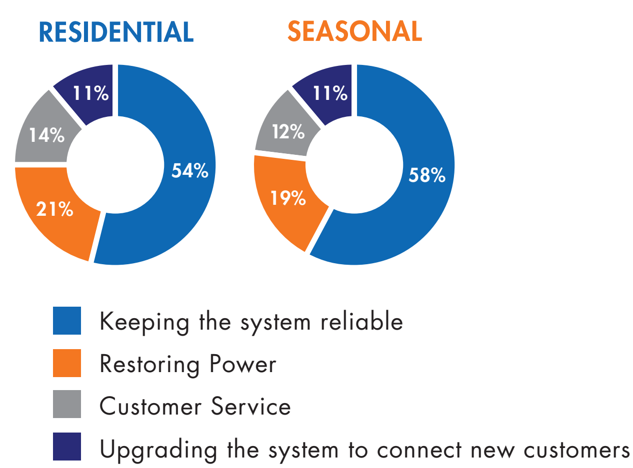
PREFERRED ALLOCATION OF SPENDING



OPINION ON CURRENT ALLOCATION OF SPENDING



CUSTOMERS' PREFERRED ALLOCATION OF SPENDING



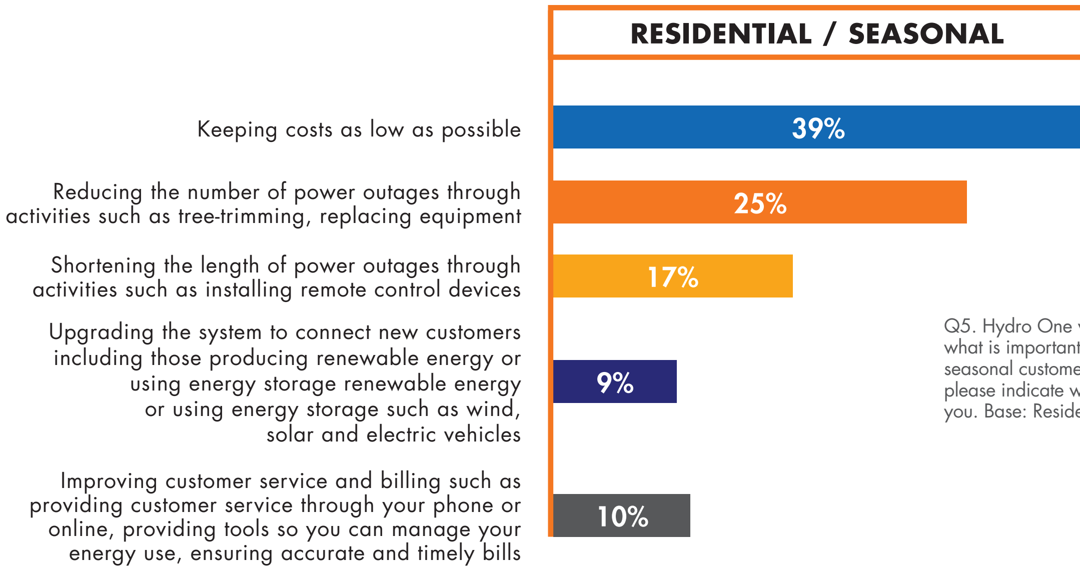
Q3. The pie chart above shows a rough estimate of what Hydro One currently spends on each of its major electricity distribution investments. If you were in charge of Hydro One would you change how spending is allocated or would you keep it about the same as it now? Base Residential (n=15,689), Seasonal (n=1,106)
Q4. Of the 4 distribution investments you just heard, what percentage would you allocate to...? Base: Customers who indicated that current spending should be changed. The percentages have been rebased to exclude don't know responses or responses that do not add to 100% Base: Residential (n=6,095), Seasonal (n=427)

Similar to the results of the other methods, these customers allocate more money to restoring power after outages and less money to keeping the system reliable.

ONLINE WORKBOOK OPEN-LINK

CUSTOMER PRIORITIES

As noted in earlier sections, a paired-choice exercise was used to identify customer priorities in order to help Hydro One better tailor its services. For more information on paired-choice, refer to the Appendix.



Q5. Hydro One would like to better understand what is important to you as a [residential or seasonal customer]. For each of the pairs below, please indicate which one is more important to you. Base: Residential/Seasonal (n=16,675).

The chart above shows keeping costs as low as possible has a relative preference score of 39% among Residential and Seasonal customers, and this is the largest preference score of the options presented. This indicates that customers prioritize keeping costs as low as possible above the other options, such as reducing the number of outages, improving restoration times, improving customer service, or upgrading the system to connect new customers. It is more than twice as important to customers as the latter three options (restoration times, customer service and connecting new customers). Reducing the number of outages is the next more preferred option.

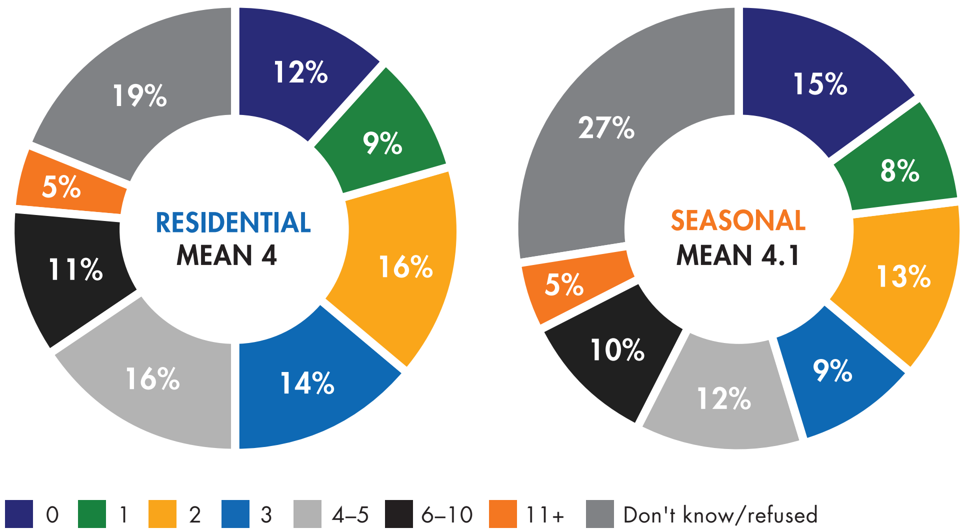
THE LEVEL OF RELIABILITY THAT CUSTOMERS EXPECT

While still the largest share of customers indicate that the number of power outages they experienced in the past 12 months is in line with their expectations, twice as many customers from the 'informed' Open-Link sample indicate the number of outages is worse than they expect compared to those from the 'uninformed' Telephone Sample (Residential customers: 30% Open-Link versus 16% Telephone/Seasonal customers: 34% Open-Link versus 17% telephone).

Both the 'informed' samples from the Online Workbook (Open-Link and representative sample) report they experienced a higher number of power outages in the past 12 months (Residential: 4.4 online representative sample, 4.0 online Open-Link) than those in the Telephone Survey (3.4). The average number of outages is higher among responses from rural customers than those from urban customers (4.4 vs 3.5).

ONLINE WORKBOOK OPEN-LINK

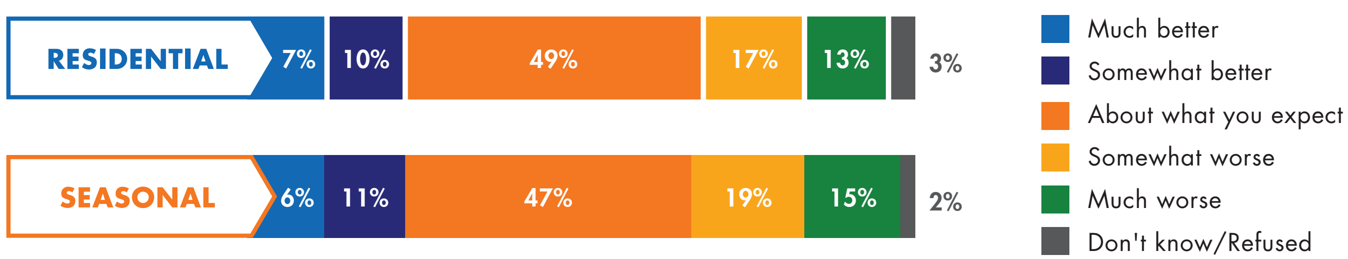
AVERAGE NUMBER OF OUTAGES



Q7. A sustained power outage is one lasting at least 1 minute. How many sustained power outages did you experience in the past 12 months that you were not notified about in advance by Hydro One? Your best guess is fine. Base: Residential (n=15,689), Seasonal (n=1,106)

ONLINE WORKBOOK OPEN-LINK

CUSTOMER EXPECTATIONS



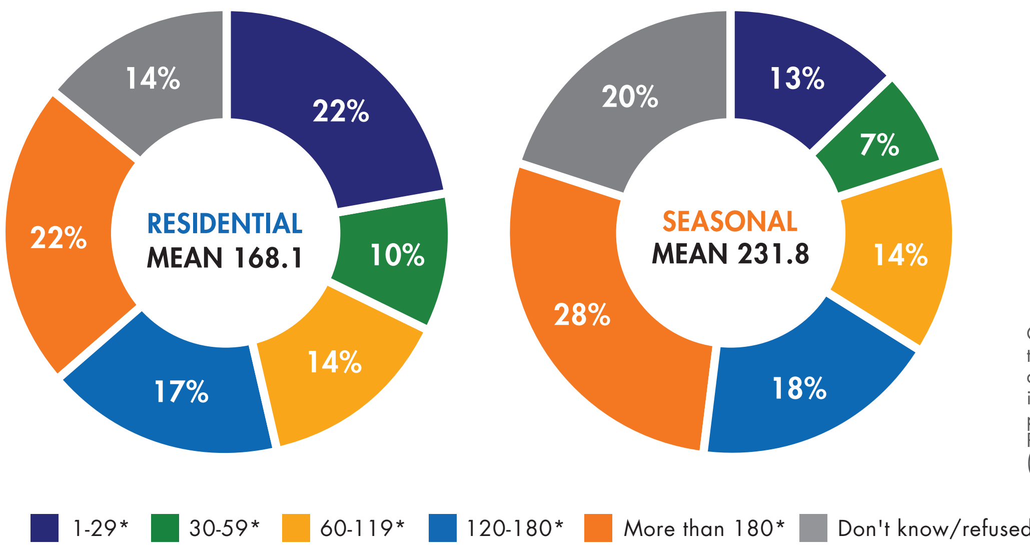
Q8. In general, when you think about how many power outages you experienced over the last 12 months how did it compare to your expectations? Base: One or more sustained power outages in the past 12 months. Residential (n=10,912), Seasonal (n=638)

When it comes to length of outages, 'informed' Residential and Seasonal customers who took the Open-Link survey were twice as likely to say that the average length of outages they experienced is worse than they expect (Residential: 35% versus 20%; Seasonal: 41% versus 22%).

Residential customers who responded to the Open-Link estimate that the average length of the outages they experienced is 2.8 hours, compared to 2.4 hours among the Telephone sample. The estimated average between Seasonal customers to the Open-Link and Telephone are more consistent (3.8 hours and 3.9 hours respectively).

ONLINE WORKBOOK OPEN-LINK

AVERAGE LENGTH OF OUTAGES



Q9. On average, how long did these unplanned outages last? Please answer in minutes. Your best guess is fine. Base: One or more sustained power outages in the past 12 months. Residential (n=10,912), Seasonal (n=638)

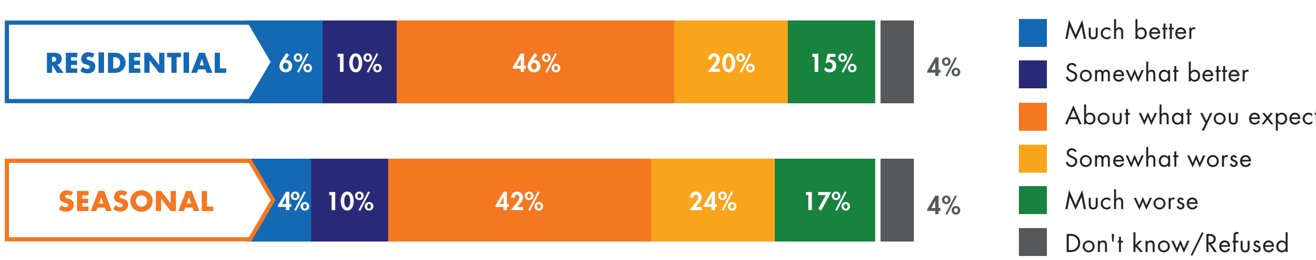
ONLINE WORKBOOK OPEN-LINK

CUSTOMER EXPECTATIONS



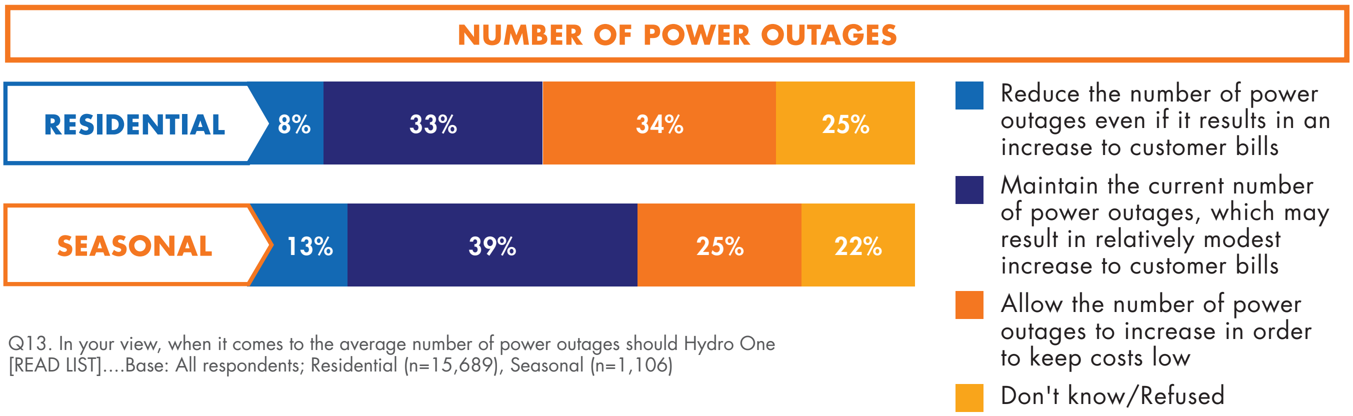
Q10. In general, when you think about the average length of the power outages you experienced over the last 12 months how did it compare to your expectations? Base: One or more sustained power outages in the past 12 months; Residential (n=10,912), Seasonal (n=638)

HOW CUSTOMERS REACT TO SERVICE VS. COST TRADE-OFFS

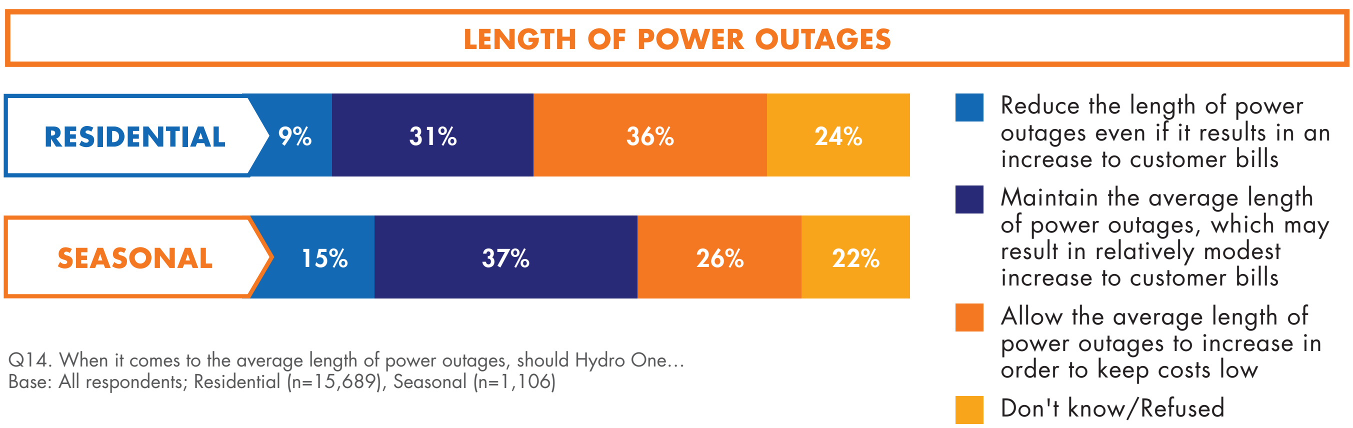
When asked what Hydro One should do on the topic of the number and duration of outages – that is, maintain current levels, improve upon current levels or allow the levels to degrade – opinions are mixed. A reasonably large minority of customers did not offer an opinion (25% of Residential customers indicated they don't know or refused to provide an opinion on the number of outages and 24% on duration, and 22% of Seasonal customers).

ONLINE WORKBOOK OPEN-LINK

RELIABILITY TRADE-OFF PREFERENCE



Q13. In your view, when it comes to the average number of power outages should Hydro One [READ LIST]....Base: All respondents; Residential (n=15,689), Seasonal (n=1,106)



Q14. When it comes to the average length of power outages, should Hydro One…
Base: All respondents; Residential (n=15,689), Seasonal (n=1,106)

Of those who offer an opinion on the number of outages, 44% of Residential customers would trade off an increase in their monthly bill to keep number of outages at the current level, but 45% would allow the number of power outages to increase to keep costs low. One-in-ten customers (11%) would like to reduce the number of outages and would be willing to accept a potential increase in their monthly bill to achieve it. This is consistent with the results of the Telephone Survey. Customers' opinions on the number of outages break out very similarly when it comes to preferences on how to address both the duration of outages as well as the level of customer service.

Customers were asked what they would prefer when it comes to upgrades to the system to connect new customers, including those producing renewable energy or energy storage. While roughly two-in-ten do not offer an opinion, a majority (68%) of those with an opinion indicate that given the choice they would prefer to allow a reduction in Hydro One's ability to connect renewable energy customers in order to keep costs low.

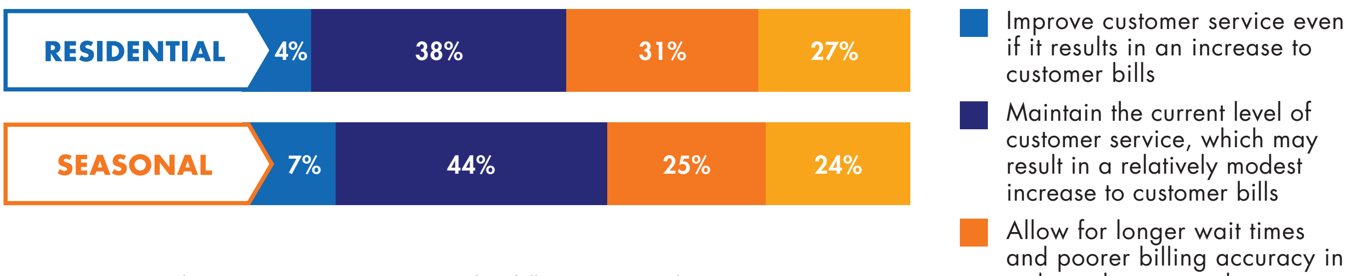
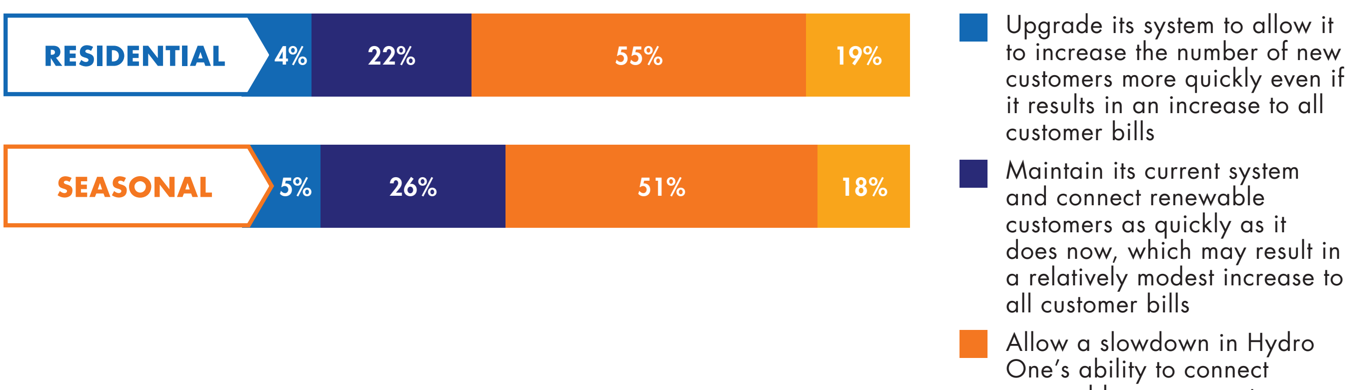
OTHER TRADE-OFF PREFERENCES

CUSTOMER SERVICE



Q15. In your view, when it comes to customer service such as billing accuracy and answering customer questions should Hydro One… Base: All respondents; Residential (n=15,689), Seasonal (n=1106).

CONNECTING CUSTOMERS PRODUCING RENEWABLE ENERGY



Q16. In your view, when it comes to upgrades to the system to connect new customers including those producing renewable energy or energy storage, should Hydro One [READ LIST].... Base: All respondents; Residential (n=15,689), Seasonal (n=1,106)

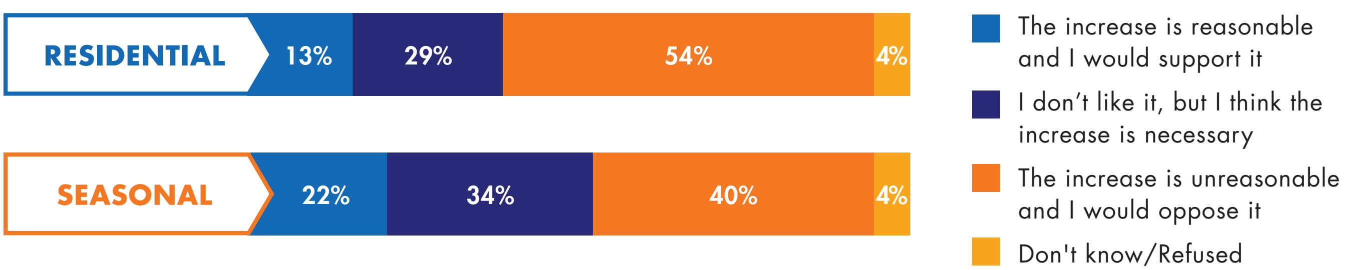
Once re-based on only those who offered an opinion, acceptance increases to 44% among Residential customers and 58% among Seasonal customers. These results are on par with the 'uninformed' Telephone Survey, which was directionally lower than the results of the 'informed' representation sample.

WILLINGNESS TO ACCEPT A RATE INCREASE TO MAINTAIN AND IMPROVE SERVICE LEVEL

When customers are informed that Hydro One has estimated that in order to **at least maintain** the level of reliability and customer service it currently provides, a typical Residential or Seasonal customer's **total monthly bill** will need to increase by 1.1% or the equivalent of $2.00, less than half of Residential (42%), but over half of Seasonal (56%) customers are willing to accept it, while half (54%) of Residential and 40% of Seasonal customers are opposed. The remaining 4% respectively do not offer an opinion. Prior to answering this question, customers were informed that the increase of $2.00 would be applied each year for the next five years, and that by the fifth year a typical monthly bill will be roughly $10.00 higher than it is now. Customers were also informed prior to answering that the increase reflects the cost to maintain the current level of reliability and service to customers, and that the monthly bill could still increase for other reasons which are outside of Hydro One's control.

ONLINE WORKBOOK OPEN-LINK

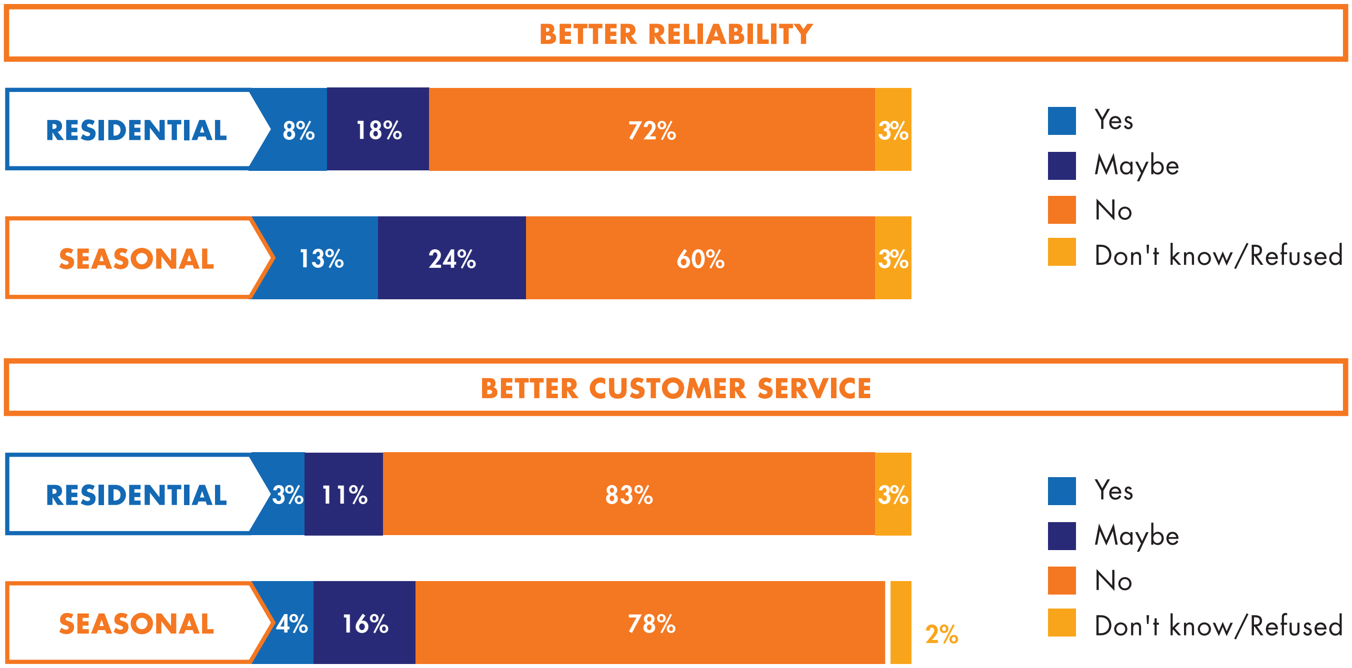
ACCEPTABILITY OF RATE INCREASE TO MAINTAIN LEVELS



Q17. Hydro One has determined that in order to at least maintain the level of reliability and customer service it currently provides, a typical [Residential or Seasonal] customer's total monthly bill will need to increase by 1.1% or the equivalent of $2.00. The increase will be applied each year for the next 5 years. By the fifth year, a typical monthly bill will be roughly [IF RESIDENTIAL OR SEASONAL $10.00] higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability and service to customers. The monthly bill could still increase for other reasons which are outside the control of Hydro One. Would you be willing to accept this increase to maintain the current level reliability and customer service across the electricity system? Base: All respondents; Residential (n=15,689), Seasonal (n=1,106),

ONLINE WORKBOOK OPEN-LINK

WILLINGNESS TO PAY FOR IMPROVED LEVELS



Q18. Would you be willing to pay anything higher than the $2.00 or about 1.1% more on your total monthly bill if it meant you would have better reliability than you have now? Base: Residential (n=15,689), Seasonal (n=1,106) Q19. Would you be willing to pay anything higher than the $2.00 or about 1.1% more on your total monthly bill if it meant you would have better customer service than you have now? than you have now? Base: Residential (n=15,689), Seasonal (n=1,106)

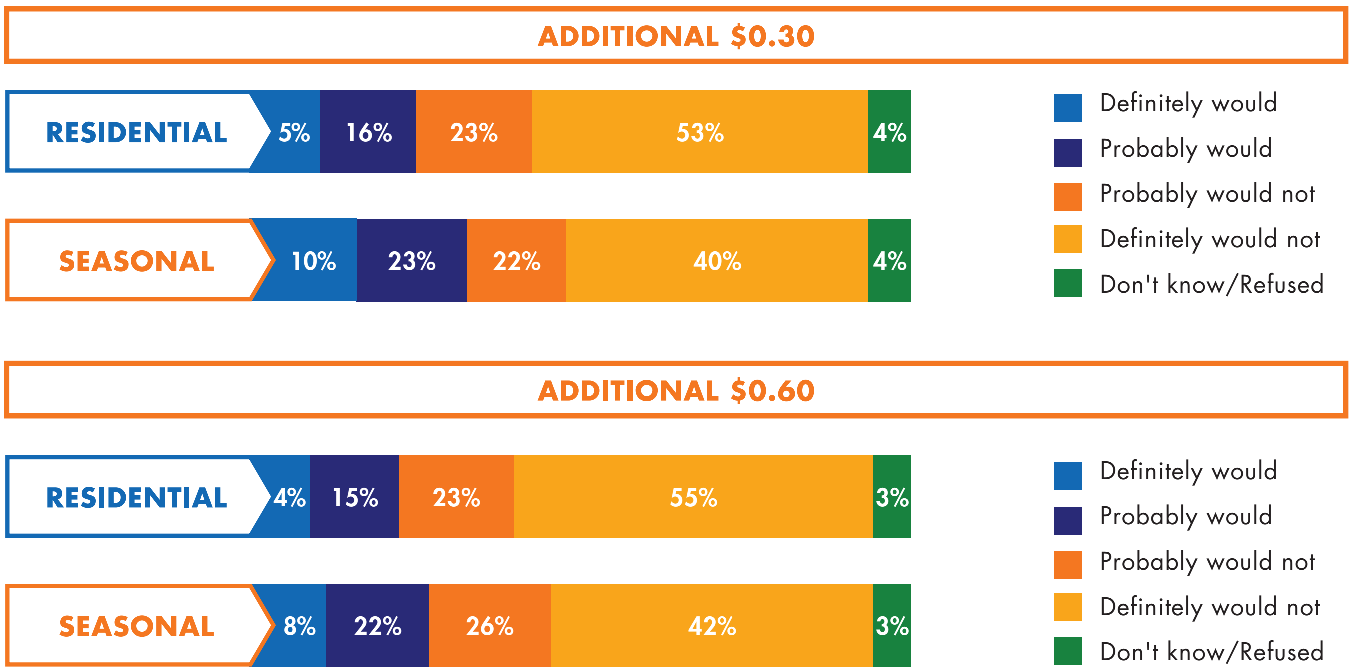
Only one-in-ten Residential customers indicate that they would be willing to pay more than the $2.00 (1.1%) increase in order to have better reliability than they have now. An additional 18% of Residential customers would consider it (selecting 'maybe' as their response) and 72% would not pay anything more. There is even less interest in paying for an improved level of customer service – only 3% of Residential customers are willing to pay more for improved customer service.

Lastly, customers were asked their level of interest in a 10% reduction in the number and length of future outages, for a specific rate impact. Two additional rate impacts were posed to customers for their reaction. Half of the sample of respondents were asked to consider an additional $.30 per month, or a total of $2.30 more on their monthly bill, and the other half was asked to consider a rate increase of $.60 per month for a total of $2.60 more on their monthly bill.

Only 5% of Residential customers say they definitely would prefer to pay $2.30 more (or $11.50 by the fifth year) instead of the $2.00 (or the $10.00 by the fifth year) and 16% say they probably would. This is on par with the telephone sample. Only 4% of Residential customers say they definitely would prefer to pay $2.60 more (or $13.00 by the fifth year) instead of the $2.00 (or the $10.00 by the fifth year) and 15% say they probably would. Willingness to pay the additional cost associated with improved levels is higher among Seasonal customers where 33% definitely or probably would pay the additional $0.30 and 30% would pay the additional $0.60.

ONLINE WORKBOOK OPEN-LINK

WILLINGNESS TO PAY FOR IMPROVED LEVELS



Q20A. Would you be willing to pay an additional [HALF OF RESPONDENTS SHOW $0.30/OTHER HALF SHOW $0.60] per month over and above the $2.00 which would be approximately [SPLIT SAMPLE $2.30/$2.60] more per month if it meant that Hydro One could reduce the number and length of future power outages by 10%? The increase would be applied annually for the next five years so that by the fifth year your monthly bill will be roughly [$11.50/$13.00] higher than it is now? Base: Residential/Seasonal customer; Residential (split n=7,854/n=7,835), Seasonal (split n=567/n=539)

FOCUS GROUPS

A series of four focus groups with Residential customers were conducted to further flesh out early learnings and findings from the Telephone Survey. In particular, understanding the reasons in more detail for why some customers accept and others do not accept rate impacts, were of interest. Furthermore, they were designed to understand general needs and preferences, to provide information about Hydro One and its operations, and to ascertain reaction to this information.

SUMMARY

Residential customers generally had positive overall experiences with and perceptions of Hydro One, as they have satisfactory or high levels of customer service and reliability. For some customers, cost and affordability was the biggest area of concern. Most were unaware that Hydro One only makes a profit on delivery charges.

A distribution rate increase received mixed support, with the majority of customers stating that they didn't like the increase but that they understood why it is necessary. For those who opposed an increase, they disliked the idea in principle. For some this was driven by an information gap as to what the additional funds would be used for, with others citing their negative perceptions of Hydro One and its ability to use the funds wisely.

Opinions were mixed as to what degree Hydro One should be preparing the grid for future needs. While some believed in the forward-looking, long-term benefits of items such as an increase in renewable energy, others stated these types of initiatives would only benefit a select group of individuals and that the cost of these benefits should not be borne by all customers.

Because they do not currently struggle with reliability, seeing this area maintained was of interest, but having it further improved was of little interest. Power restoration during outages was highly satisfactory, with the ability to receive or seek accurate and timely restoration information being of appeal.

Based on the information presented during the Focus Groups, participants stated they had a better understanding of the need to invest in Hydro One's distribution delivery infrastructure, with a few stating their dissatisfaction with its current pace of maintenance and renewal based on the information provided.

Residential participants are the least engaged with and informed about Hydro One and the energy sector. However, they were open and receptive to receiving more information about both their current bill and any future rate increases, which in turn would likely engender a positive influence on their views of Hydro One. Hearing credible information from Hydro One about ways to conserve energy and ideas to save on electricity costs were also of interest to this group. There were multiple channels listed as to how residents would like to hear from Hydro One. Hearing information about planned outages and power restoration, and any rate increase and the reasons for it, through all of these channels were of interest.

DETAILED FINDINGS

COSTS AND RATE INCREASES

The cost of electricity emerged as a theme of concern to many Residential Focus Group participants. There were mentions of issues with the perceived high cost/price of electricity rates and bills, with some participants expressing a desire for overall lower bills or a decrease in rates. A few organic mentions were made of electricity costs being much lower in other jurisdictions.

"Prices could be considerably lower."

"I'm not happy with the overall cost."

> *"Hydro bills are through the roof and it is becoming very unaffordable. Not sure why the States can offer electricity SO much cheaper than Canada."*

Some Residential participants perceive that rate increases are higher than inflation and/or the cost of living. A few who struggle with the cost of electricity state that it is unaffordable and that they are currently unable to pay their electricity bills, with others raising a deep concern that a continued rise in prices would mean being unable to pay their electricity bills in the future.

"…electricity prices are certainly surpassing my wage [increases]. So, I always think of it that way, that I'm definitely paying more out of pocket in proportion to my income."

"…some months, I have problems paying my hydro bills. So, because of the rates of hydro and all the additional delivery charges and all of that other stuff that comes on your bill, I actually had to go to equal billing in order to be able to pay my hydro, and that's crazy."

When it was explained that Hydro One only makes a profit on the transmission, distribution, and delivery charges on an electricity bill, and that other charges on the bill are pass-through only, most participants in the groups were unaware of this. For a few, this positively affected their view of Hydro One, while others stated that their views remain unchanged.

"I guess if the rates seem high I don't have to be mad at Hydro One."

A few mentions were made of delivery charges being billed without having actually used any electricity during that period — participants were puzzled as to the reasons for this.

"[There] hasn't been any electricity or hydro used, and yet they're still got a bill with a delivery charge on it…"

One participant stated her belief that privatization would result in an increase in rates/costs to the ratepayers, as she has observed with other companies who have been privatized.

"I just know that without certain regulation that was in place before, prices of businesses that have moved towards privatization have risen, and that's kind of been the track record in the past, so that's really what I'm basing my prediction on."

When asked about a residential rate increase of 1.1% or $2.00 per month for the average customer:

- Most indicated they don't like the increase, but think that it is necessary
- Several stated that the increase is unreasonable and were opposed to it
- Several indicated they did not know if they support an increase
- Some stated that the increase is necessary and were supportive

Those who indicated that an increase is necessary or supported a rate increase stated they recognize that it is needed to maintain service and reliability levels while others were resigned to rising prices and cost of living.

> *"I actually thought Hydro One was taking much more, but this clarifies a lot. I actually feel more positive towards them now if anything."*

"I feel it does need to be done to sustain maintenance and make sure the power doesn't go out more frequently. Do I like it? No. Because it's going to go up and nobody likes that. But we don't really have a choice, we need the reliability."

"If I see a high quality of reliability over costs I am fine with paying the extra amount."

"Well, the cost of living is going up. Nothing stays at the same rate. Just as your salary is going up, everything else will go up, too. So you can imagine that the bill is going to go up. So nothing to do about that."

For those who were opposed to a rate increase, their opposition was generally not due to a lack of affordability. To them, they opposed it in principle for reasons including:

- A general desire to keep costs low, regardless of maintaining/improving reliability and service
- Skepticism about the "average" amount being $2.00
- A lack of information as to where and how funds are currently used, and how a rate increase would be used
- A perception that funds are currently or will not be used wisely by Hydro One

"I would rather the company not worry about improving the other areas and instead concentrate on keeping costs low for customers."

"If there is a way to improve both [service and cost], obviously that is ideal, but if I'm going to weigh one over the other, then I'm going to choose the cost."

"…the only thing I'd like to see is a decrease in my bill...As far as the bill, I can't think of what they would say that would make me feel an increase at this point in time for anything would be reasonable, because like I said, I honestly feel they should be decreasing our bills."

"…if they increase our percentage on our delivery charge — so yes, maybe our bill will go up maybe $2.00 a month on our delivery charge, but it's not taking into account that our electricity [has] always gone up as well. So, it would be far more of an impact than $2.00…So, having it go up another $2.00 at this point, hypothetically $2.00, is not it. It's going up by 1.1% of whatever the delivery percentage is that they're charging on the electricity they've delivered."

"…I'm unclear on my costs as it is. I pay an awful lot, like everybody else, every year, and I just can't imagine why we need to pay more to maintain reliability…I just don't understand that. So, if I could better understand where the costs are going now, I may have a different answer to this question later."

"…part of that is I see their service trucks sitting on the side of the road for hours on end and their service people taking two-hour lunch breaks all the time…."

"I think it's unreasonable honestly because I know the company's net assets have increased 13% since 2012, and something like 4,000 employees have made the Sunshine List, earning over $100,000 a year on the public dime. So, I think it's a little unreasonable to be dipping into the customer's pocket to sustain the level of outages that I personally feel is a little unreasonable."

One participant stated that she did not understand the relationship between increasing rates, and how it affects outages.

"I just have a hard time understanding how rate increase has to do with power outages, like the length of time or whatever…I mean, do we have to pay money to have a better response time to power outages? I don't understand. So if we pay less, we'll have more frequent power outages or if we pay more, when we have a power outage it will be resolved quicker? I don't understand."

For many participants including those who opposed and those who didn't know whether or not they supported a rate increase, having more information on how the rate would be spent was of interest. Some participants indicated an interest in having this information represented using charts, illustrations or graphics. Some stated that Hydro One should proactively push the information out to its customers via multiple channels, while others indicated they would seek the information out themselves in the event of a rate increase.

"I would like information on why they're going to do a $2.00 increase per month on my bill. So, it could be just something in the mail along with my bill, just to say briefly what it's about and when it would be happening, not that it just appears on my bill."

"I would prefer…a text where it notifies me about the change and where it would lead me to a website where I could find out more information if this is my interest."

"Even a simple pie chart, showing the different areas where they're investing in new infrastructure or maybe even development or their disaster recovery plan, however the money falls out, that would be nice to see. Like a budget."

CURRENT AND FUTURE ASSET MANAGEMENT, AND ASSOCIATED COSTS

Based on the information on Hydro One provided during the Focus Groups, many participants expressed their surprise at the breadth of service the company provides, and stated that it positively affected their view of Hydro One and/or a potential rate increase. Others indicated that the information was new, but did not change their view of Hydro One either positively or negatively.

"More trust. The breakdown helps. We don't normally see what's happening in the background. Helps build confidence in paying that extra amount to them."

"…I had no idea. I definitely have no issues with the increase after seeing this information."

"It improves my view overall of Hydro One."

"This is the kind of information that Hydro One should be sharing with customers so that we better understand the situation."

A few customers expressed their concern and dismay as to the current condition and number of aged assets. They also expressed concern that this would mean an increase in rates in order to fix these issues.

"This impacts my view of Hydro One negatively. I didn't realize the company was so behind on updating their system…"

"These are upgrades that they knew were coming for years and should have budgeted for, not expected the consumer to have to take on additional cost."

Residential participants were polarized as to what degree Hydro One should proactively plan for and manage the grid for future needs. Some participants stated it is Hydro One's responsibility to both proactively plan for items such as renewable energy and energy storage that take the evolution of the grid into account; however, they state costs should be kept low and advocated for a balanced, steady approach to managing these changes. A few stated that although there might be a short-term increase in costs and rates, there would be long-term economic and environmental benefits.

"I think it is important to stay on top of the updates, if we fall behind it could be expensive."

"I believe that Hydro [One] should be continually investing in newer and more reliable ways of delivering and sustaining power overall. I would like Hydro [One] to begin using solar for their own stores of electricity generation."

"…I think it's good to stay on top of the technology, so when it comes to your electric cars and stuff, that finally becomes the thing to have, it's not all at once we end up with a great big fee. Maybe slowly introducing things might be a smarter idea than us being hit with some other kind of fee on top of our regular hydro."

"…it does need to remain a balance between infrastructure improvement and affordability."

"There needs to be progress in all areas, but I think to have sole focus or a disproportionate focus is only going to in the long run not pay the dividends and it's going to spike cost, it's going to potentially focus on areas that may not in the long run pan out to be the definitive answer."

The advantages of having customers and small generators send power back to the grid were also debated, with one participant citing net metering as a positive program/benefit.

"Hydro One needs to improve access to allow small renewable energy producers (households) to flow their electricity back into the electrical system. We had considered installing solar but there was almost no capacity to do so in our area. Considering there are not a lot of rooftop solar panels in our area, I don't see why capacity is so low."

Those who are opposed to proactively preparing the grid state this is a low priority area that should be of concern only to those who are directly benefiting, or as the need arises in future. They stated that Hydro One should not be responsible for passing these costs to other customers, as they perceive only a small group would benefit — for example, only those who drive electric vehicles, or those who can afford to install solar panels on their roofs.

"I feel it's a personal choice…Why does everybody have to pay for the very, very small percentage of people who [own] electric vehicles, renewable energy at their own home, and making adjustments to their homes and their power systems that Hydro One is then going to pass on to everybody who doesn't have any of that. That would really upset me."

RELIABILITY AND POWER RESTORATION

Most Residential customers stated they do not have issues with reliability and experience an expected/acceptable number of outages. They understand the reasons for outages and state that Hydro One provides great service in restoring power in a timely way. Participants in remote areas were more likely to experience more frequent outages.

"The service is consistent with very few outages."

"I am satisfied with Hydro One because they are always there. For example, when we had the ice storm. They were working 24/7 to make sure everyone's needs were met."

"We are in a fairly remote area, and I would say our power is out maybe once every one or two months, and sometimes it's for a significant period of time, like this week, it was out for three hours, three and one half hours."

Several participants stated they do not believe customers should have to accept a trade-off in terms of choosing reliability versus keeping costs low, and that they should not have to choose one over the other. They stated it is Hydro One's role as a utility to balance reliability and cost.

"…it does need to remain a balance between infrastructure improvement and affordability."

"…I don't think that I would be willing to accept an increase in price for a decrease in outages. I feel as a distributor of electricity, that's kind of Hydro One's responsibility to ensure that people have access to electricity for an agreed upon price. When outages still occur, I don't get a refund on my bill, so I don't feel that I should be charged a premium to reduce outages."

Many participants indicated that because they do not experience a high number of or any outages, they could not comment on power restoration. For those who did experience outages, they reported mixed satisfaction with power restoration — many were satisfied with restoration times, with others stating that they experience longer outages. Impacts were minimal and mostly considered a minor inconvenience.

"We recently had one [power outage] about a month ago due to weather conditions. The outage lasted for about five minutes tops. Swift resolution. I was very impressed."

"I'm pretty happy with the reliability, but when it does happen, it's like four days sometimes, and it's kind of unfortunate."

Most participants call in to the number on their bill or visit Hydro One's website for restoration information. Others rely on news sources or neighbours for information. The information provided by Hydro One on restoration times was often not timely or accurate. Having restoration information proactively pushed out to them by Hydro One was of interest, particularly in the event of longer outages.

"I think communication during an outage could be improved. Often, a customer has to look to secondary news sources to find out [an] ETA for restoring power."

"Hydro One seems to have a delay in posting affected areas on their website, so that information is not always up-to-date."

"Communication during the outage could be improved in the event that power has been out for several days."

Awareness of Hydro One's outage app was low, with some expressing interest in it — particularly for nimble, timely and accurate outage restoration information. One participant mentioned being able to track their usage on the app as being of interest.

"I think it should probably have a specific explanation in terms of which zone is being affected, or maybe just a quick update on what the developments are, minute-by-minute or so of what they are actively doing or working on, on-the-go."

"…how much is my bill [going to be], basically, at the end of the day? …if I can track my own expenses biweekly or whatever."

CUSTOMER SERVICE AND BILLING

Residential customers are generally satisfied with Hydro One's customer service, and most are able to receive satisfactory closure on any issues they have with Hydro One. Having little to no need for contact with Hydro One is considered a positive, as it means that the customer is not having any issues or outages. For many, their monthly bill is their main point of interaction.

"Their customer service is always wonderful, and I can honestly say I have not had an encounter with them where I was not fully satisfied."

"[I am] very satisfied with Hydro One, as they are very prompt with their services — answering questions and onsite visitation."

"…they called back. They [said] they would call back when I phone to say that we lost power here. I phoned them. They phoned right back…They said we'll call you by this time. They called when they were supposed to call. They showed up when they said they were going to show up. And the problem was fixed, so no complaints at all."

"I've lived in my apartment for over a year and I've never once had any outages or had to contact Hydro One for anything. I've been pretty lucky."

Wait times on the phone when calling into the customer service centre was the main area of dissatisfaction for Residential participants — they would like to have wait times minimized. However, this was not an area participants believed should require more investment/ higher costs. While phone is still a preferred contact option for many participants, some also expressed interest in contacting Hydro One in other ways — such as a live chat option on its website — as participants believe this would minimize wait times.

"…recently I had a customer service experience through a direct chat window from the company's website…So, it might be nice just for a quick question that doesn't require a lot of explanation to have a chat window on [Hydro One's] website."

"I think live chat would de-clog lines, so we don't have to spend so much time waiting on a line for a customer rep."

Billing is a satisfactory area for most participants. A few participants indicated that they find their bills confusing, and wished to receive clarity around charges. For some, this meant a more simplified bill while for others it was more information, or information in a more graphic or illustrative format. The ability to see information separate from the bill — either through an insert, or online — were also mentioned as being of interest. One participant mentioned the desire to see digital bills move away from e-post.

"…there is a lot of information on the bills and it seems like the comparative usage and rates and the price and per unit and all that stuff…that might be something that you could go drill down to online through an online account versus all on the bill every month…"

"I always think that when you want to show something visually, graphics always help… It's better than straight numbers."

COMMUNICATION AND AWARENESS

As a group, Residential customers are less aware of the energy sector in general and are the least actively engaged with Hydro One. As a result, they are receptive to hearing more information and less likely than other segments to have negative perceptions.

Some participants indicated their interest in having

Hydro One provide ideas and information on ways to save and conserve energy and ultimately, the cost of their electricity bill. This might be through programs, coupons, or simply being able to track their detailed usage between bills. Having this information come directly from Hydro One would lend credibility to the information. A few customers spoke of positive experiences with energy/cost saving programs with Hydro One, with others stating that they are unable to get recommendations and information on programs.

"I think in a sense they would be a great vehicle to inform their customers how to save…for them to offer their customers suggestions on how to be more efficient users, interesting, unique strategies, I think goes hand in hand. In my opinion, I would value them even more by offering this as opposed to other individuals or companies saying you can do better by using energy in other ways that…I have not been able to do myself."

The means through which Hydro One can effectively communicate with its customers was discussed during the Focus Groups. Relevant information to include in any communication includes planned outages, rate increases, and service restoration.

Participants expressed interest in a number of different channels and some indicated that they would like to hear from/about Hydro One via multiple channels, including:

- Directly on the bill
- Bill inserts
- App
- Social media
- Separate letter
- E-mail
- Advertising
- Texts
- Website

Seeing more information during the groups had an overall positive impact on perceptions of Hydro One. Hearing directly from Hydro One is of high interest and would instill confidence and trust in Residential participants as to Hydro One's efficacy as a service provider.

"The visuals gave me a new understanding of Hydro One and the challenges that they face. They should be sharing this with their customers…"

"What they are doing in more detail. Maybe a breakdown of what each thing cost and is not just maintaining but before more effective in the long run."

"A letter from upper management and an explanation with graphics would be great to assume confidence and trust from our side."

SUMMARY

In general, compared to Residential customers, Small Business customers indicate they are more inclined to accept some type of an increase in their monthly bill to see a reduction in the number and average length of outages, but back track at the size of the increase in rates that is required. When posed with a 1% increase on their total monthly bill to ***maintain*** *the current level of reliability and service they receive, 57% of those who offer an opinion would accept it (53% across all Small Business customers surveyed). This is on par with the response of Residential customers. When posed with higher increase for a reduction in the number of outages, Small Business customers react more negatively than Residential customers.*

TELEPHONE SURVEY

As outlined in the methodology section of this report, the following results are based on a Telephone Survey of a random and representative sample of n=200 Small Business customers. A stratified, random sampling approach was used to pull the sample Small Business <50 kW peak and 50 to <500 kW peak customers from Hydro One's customer database. With a sample of this size, the results are considered accurate to within ±6.9 percentage points, 19 times out of 20, of what they would have been had all Small Business customers been surveyed. That means that if the survey is repeated 20 times, 19 of those times the results of the survey will be the same within the margin of error. The margin of error will be larger for sub-groups of the population. The data was statistically weighted by Demand/ Non-Demand and by region to ensure the sample composition reflects the true proportions in the customer database.

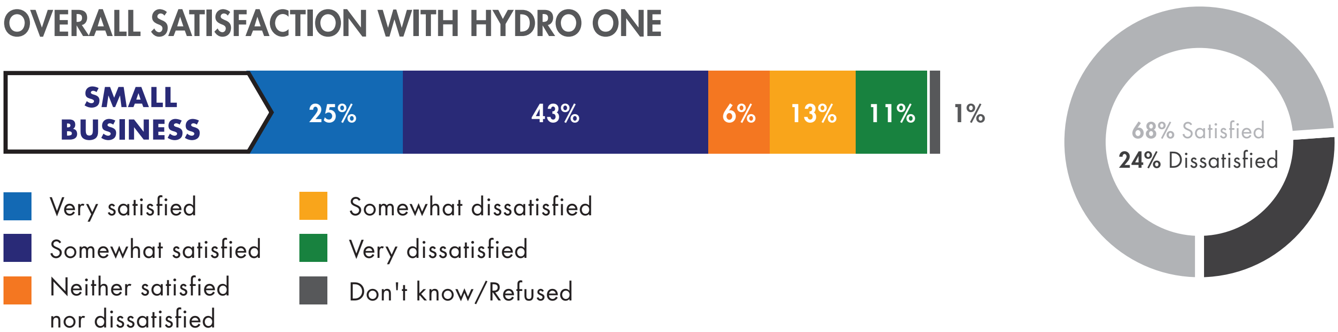
For more information on the survey methodology refer to the Customer Engagement Methodology Section of the report.

CURRENT SATISFACTION AND WHAT IS IMPORTANT TO CUSTOMERS

Roughly two-thirds (68%) of Small Business customers report they are satisfied with Hydro One overall, while one-quarter (24%) are dissatisfied. When asked on an unaided basis what Hydro One can do to improve its service to them, the most frequent answer customers give is to reduce their monthly bills. Some customers mention this in the context of lower prices or lower rates, while other just simply say lower cost.

TELEPHONE SURVEY

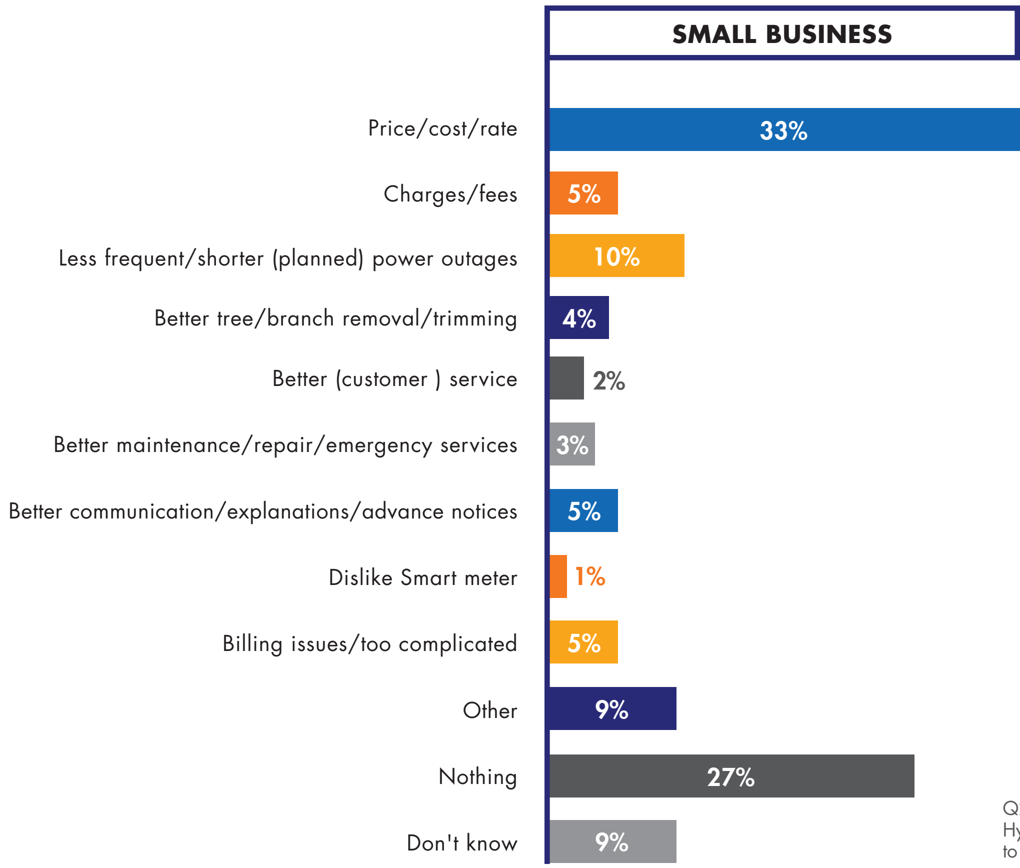
OVERALL SATISFACTION WITH HYDRO ONE



As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices. Q1. Please think about Hydro One as I have just described it to you. How satisfied are you with Hydro One overall? Note: During the first week of fielding the response scale was changed from1 to 5 to a word scale to be consistent with the Annual Customer Satisfaction survey. Base: All Respondents Post Q change; Small Business (n=159)

TELEPHONE SURVEY

HOW HYDRO ONE CAN IMPROVE ITS SERVICE

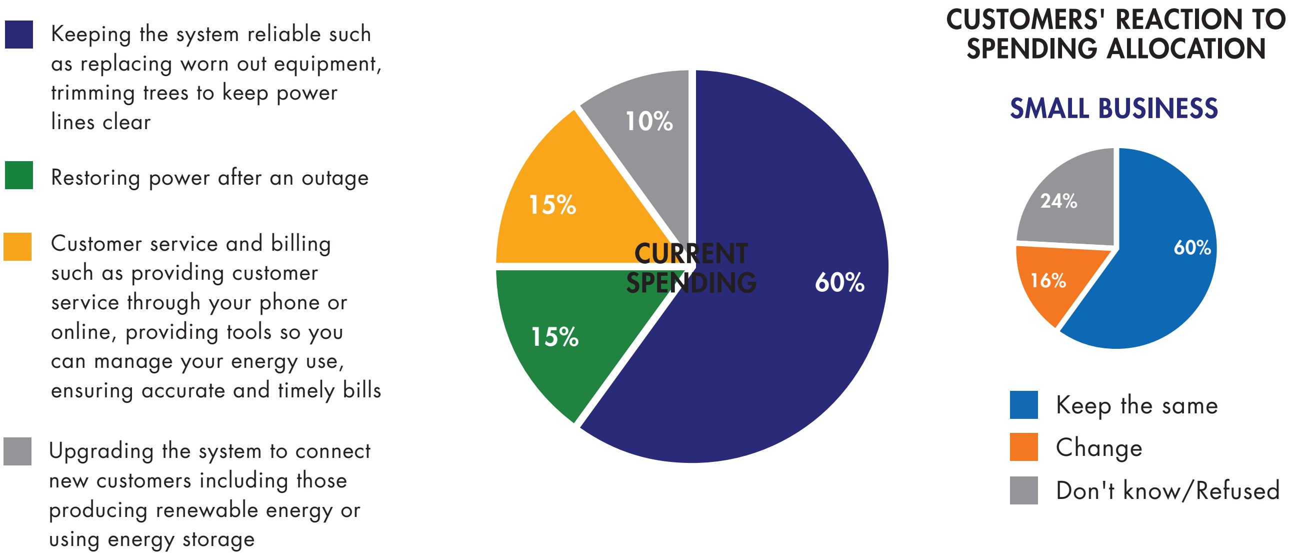


Q2. Is there anything in particular that Hydro One can do to improve its service to you? Base Small Business (n=200)

Given the opportunity to review a rough breakdown of what Hydro One currently spends on each of its major electricity distribution investments, that is, how the distribution delivery rate is allocated, the majority (60%) indicate that they would not change how the money is currently allocated. Sixteen percent of customers indicate that they would change how the money is allocated. In general, these customers allocate more money to restoring power after outages (increasing the current amount by about two-thirds) and money for upgrading the system to connect new customers including those producing renewable energy (by about 50%) and less money to keeping the system reliable (about 20% less).

TELEPHONE SURVEY

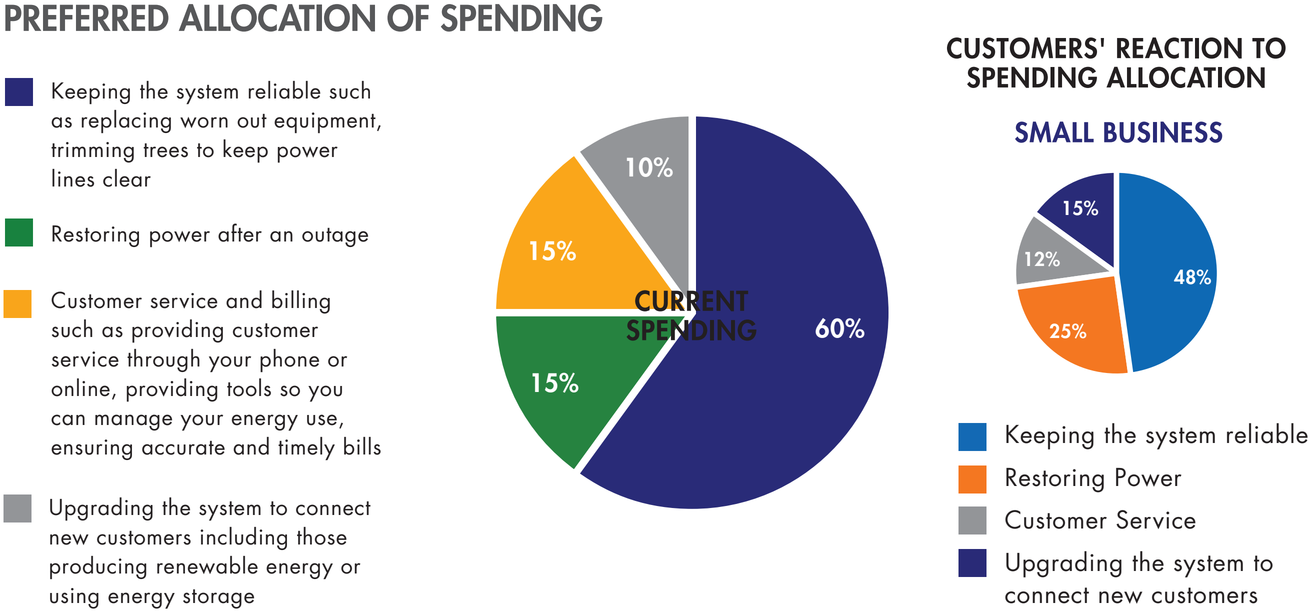
OPINIONS ON CURRENT ALLOCATION OF SPENDING



Q3. Please listen carefully as I will be reading out a rough breakdown of what Hydro One currently spends on each of its major electricity distribution investments and will be asking your opinion about the breakdown. Hydro One currently spends [READ LIST]… If you were in charge of Hydro One would you change how spending is allocated or would you keep it about the same as it now? Base: Small Business (n= 200)

TELEPHONE SURVEY

PREFERRED ALLOCATION OF SPENDING



Q4. Of the 4 distribution investments you just heard, what percentage would you allocate to…? Base: Customers who indicated that current spending should be changed. The percentages have been rebased to exclude don't know responses or responses that do not add to 100% (Small Business n=26)

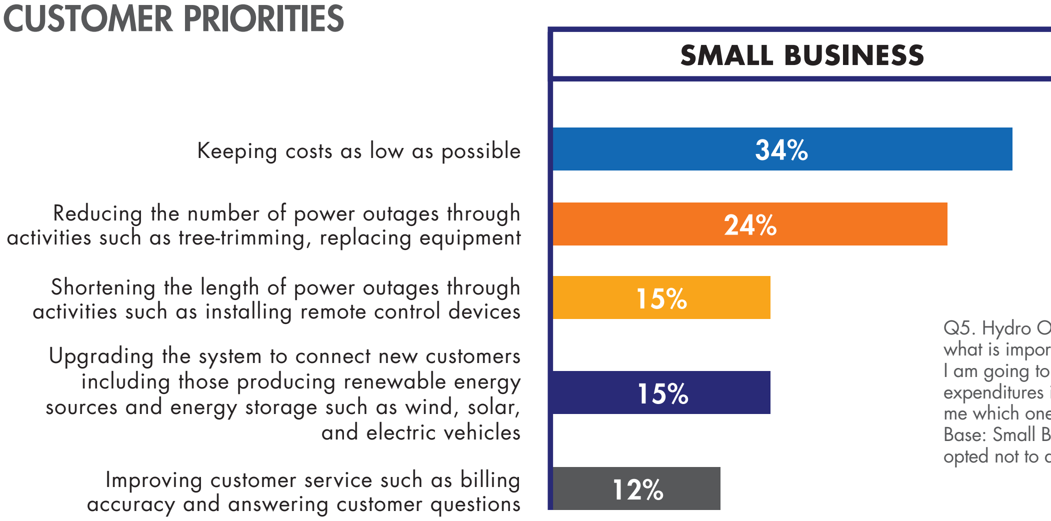
CUSTOMER PRIORITIES

A paired-choice exercise was used to identify customer priorities in order to help Hydro One better tailor its services.

The chart below shows that keeping costs as low as possible has a relative preference score of 34% among Small Business customers, which is the largest preference score of the options presented. This indicates that customers prioritize keeping costs as low as possible above the other options – reducing the number of outages, improving restoration times, improving customer service, or upgrading the system to connect new customers. It is more than twice as important to customers as the latter three options (restoration times, customer service and connecting new customers). Reducing the number of outages is the next most preferred option.

TELEPHONE SURVEY

CUSTOMER PRIORITIES



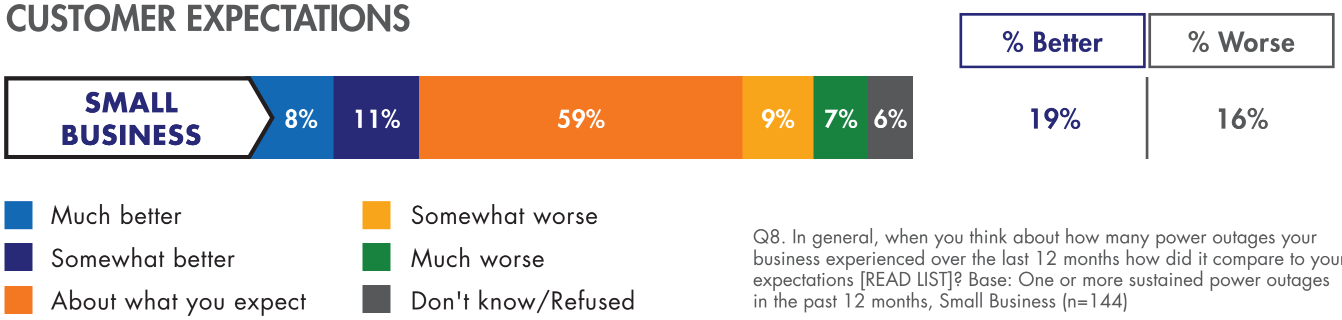
Q5. Hydro One would like to better understand what is important to you as a customer. I am going to read Hydro One's major expenditures in pairs and for each pair please tell me which one is more important to you.
Base: Small Business (n=199). One respondent opted not to answer Q5.

THE LEVEL OF RELIABILITY THAT CUSTOMERS EXPECT

Most customers indicate that the level of reliability that they currently experience is in line with their expectations. Small Business customers report experiencing an average of roughly three outages of at least one minute in duration in the past 12 months. The largest share of customers – 59% – indicate that this level of reliability (number of outages they experienced) is about what they expect. Only 16% of customers who experienced at least one outage indicate the number of outages they experienced is worse than they expect.

TELEPHONE SURVEY

CUSTOMER EXPECTATIONS

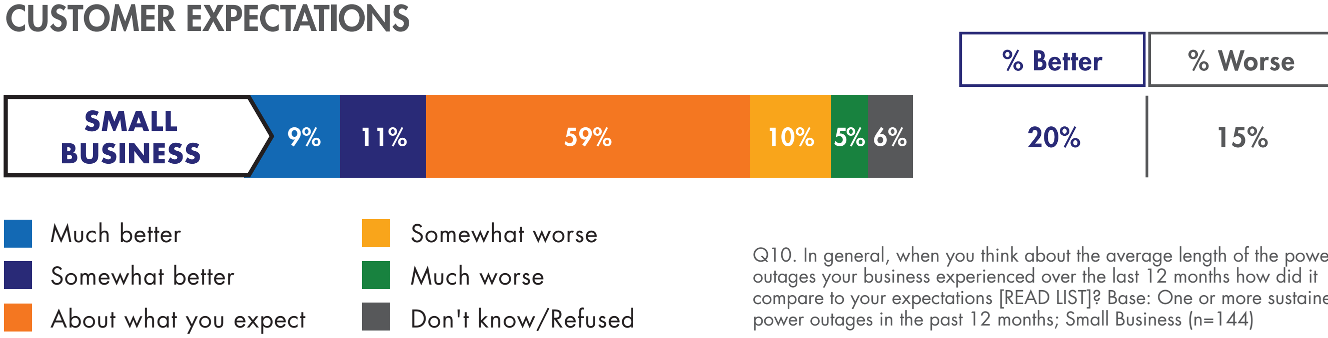


Q8. In general, when you think about how many power outages your business experienced over the last 12 months how did it compare to your expectations [READ LIST]? Base: One or more sustained power outages in the past 12 months, Small Business (n=144)

When it comes to length of outages, Small Business customers estimate the outages they experience last an average of two hours. Similar to opinions of frequency of outage, the largest share of customers indicate that this is about what they expect. Fifteen percent of those who experienced at least one outage say this is worse than they expect.

TELEPHONE SURVEY

CUSTOMER EXPECTATIONS

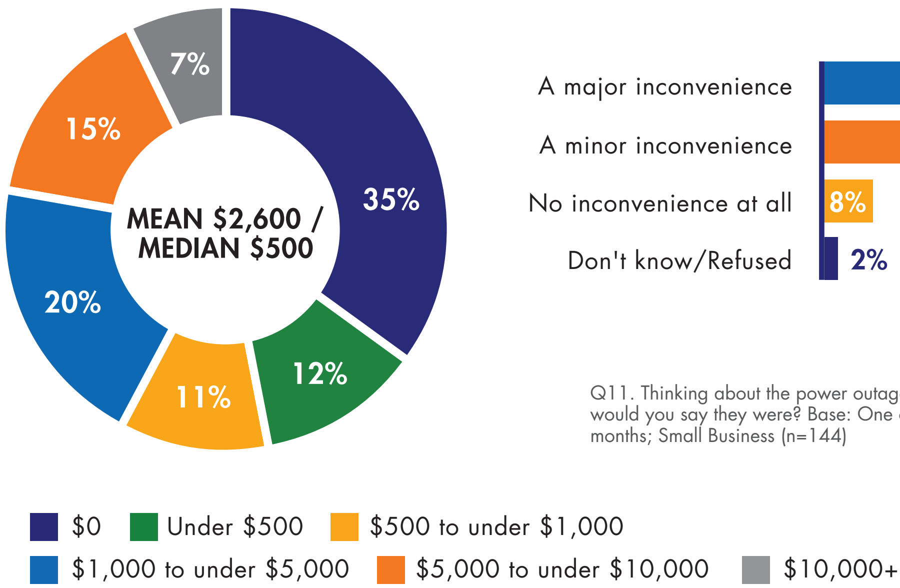


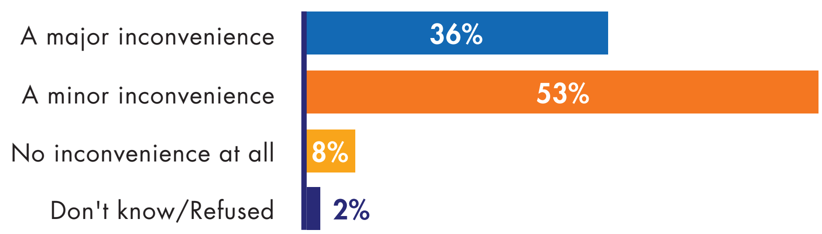
Q10. In general, when you think about the average length of the power outages your business experienced over the last 12 months how did it compare to your expectations [READ LIST]? Base: One or more sustained power outages in the past 12 months; Small Business (n=144)

Half (53%) of Small Business customers who have experienced an outage in the past 12 months indicate that the outage(s) were a minor inconvenience and nearly four in 10 (36%) describe the impact as being a major inconvenience. On average, customers indicate that these outage(s) cost their business $2,600.

TELEPHONE SURVEY

IMPACT OF POWER OUTAGES ON BUSINESS





Q11. Thinking about the power outages your business experienced in the past 12 months, would you say they were? Base: One or more sustained power outages in the past 12 months; Small Business (n=144)

Q12. How much, if any, would you say the outages your business experienced in the past 12 months collectively cost your business? Please answer in whole dollars, do not include cents. Base: Those who faced a major and minor inconvenience in business due to power outages in past 12 months, don't knows excluded (n=117)

HOW CUSTOMERS REACT TO SERVICE VS. COST TRADE-OFFS

Small Business customers are significantly more likely than Residential/Seasonal customers to support a rate increase in order to reduce the number of outages. More Small Business customers offer an opinion than Residential customers (24% don't know or refuse vs. 34% among Residential), and of those, 22% would like to reduce the number of outages and would be willing to accept a potential increase in their monthly bill to achieve it compared to only 14% among Residential customers. The largest share of Small Business customers (31%) would trade off an increase in their monthly bill to keep number of outages to the current level (41% among those that offer an opinion). Nearly four-in-ten (37%) would allow the number of power outages to increase in order to keep costs low. Customers' opinions on the number of outages break out very similarly when it comes preferences on how to address the length of outages they experience.

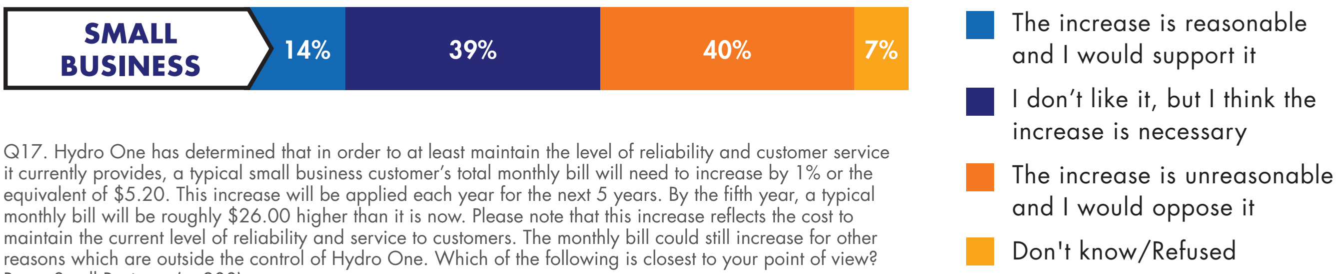
WILLINGNESS TO ACCEPT A RATE INCREASE TO MAINTAIN AND IMPROVE SERVICE LEVEL

When customers are informed that Hydro One has estimated that in order to **at least maintain** the level of reliability and customer service it currently provides, a typical Small Business customer's **total monthly bill** will need to increase by 1% or the equivalent of $5.20, half (53%) of customers are willing to accept it, roughly 40% are opposed and the remaining 7% do not offer an opinion.

TELEPHONE SURVEY

ACCEPTABILITY OF RATE INCREASE TO MAINTAIN LEVELS



Q17. Hydro One has determined that in order to at least maintain the level of reliability and customer service it currently provides, a typical small business customer's total monthly bill will need to increase by 1% or the equivalent of $5.20. This increase will be applied each year for the next 5 years. By the fifth year, a typical monthly bill will be roughly $26.00 higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability and service to customers. The monthly bill could still increase for other reasons which are outside the control of Hydro One. Which of the following is closest to your point of view?
Base: Small Business (n=200)

Prior to answering this question, customers were informed that the increase of $5.20 would be applied each year for the next five years, and that by the fifth year a typical monthly bill will be roughly $26.00 higher than it is now. Customers were also informed prior to answering that the increase reflects the cost to maintain the current level of reliability and service to customers, and that the monthly bill could still increase for other reasons which are outside of Hydro One's control.

Despite being initially more inclined to pay more for better reliability as compared to Residential/Seasonal customers, Small Business customers are less willing to pay what is required to achieve it. Few customers are willing to pay more for better reliability. Only one in 10 customers indicate they would be willing to pay more than the $5.20 (1%) increase in order to have better reliability than they have now. An additional 13% would consider it (selecting 'maybe' as their response). Seventy-three percent (73%) would not pay anything more. There is even less interest in paying for an improved level of customer service – only 6% say that they would be willing to pay extra for improved customer service with 82% saying they would not.

Lastly, customers were asked about their level of interest in a 10% reduction in the number and length of future power outages, for a specific rate impact. Two additional rate impacts were posed to customers for their reaction. Half of the sample of respondents were asked to consider an additional $0.80 per month, or a total of $6.00 more now (or $30.00 by the fifth year) on their monthly bill, and the other half was asked to consider a rate increase of $1.60 per month for a total of $6.80 more now (or $34.00 by the fifth year) on their monthly bill.

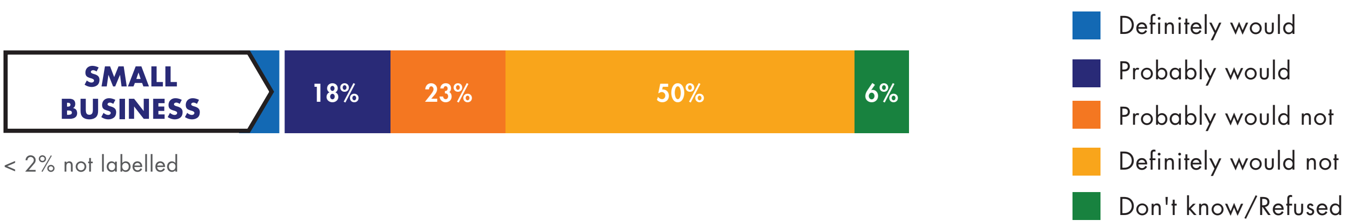
Of those who were asked about paying an additional $0.80, only 20% of customers say they would prefer to pay more, whereas 73% say they would not, including half who say they 'definitely' would not.

Of those who were asked about paying an additional $1.60, only 14% of customers say they would pay and 77% say they would not.

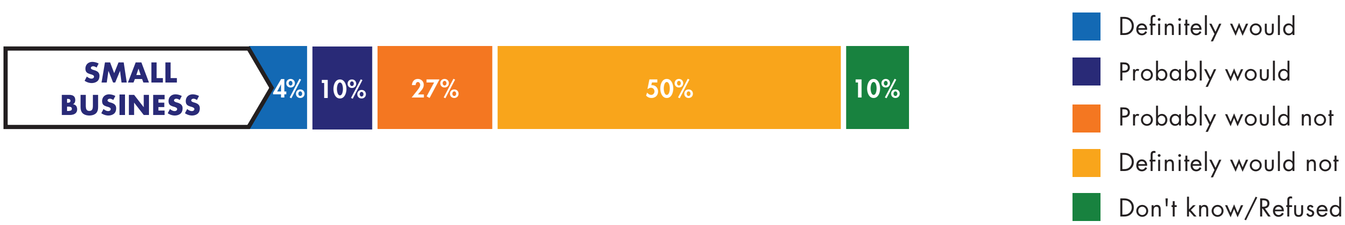
TELEPHONE SURVEY

WILLINGNESS TO PAY FOR IMPROVED LEVELS

ADDITIONAL $0.80



ADDITIONAL $1.60



20B. Would you be willing to pay an additional [HALF OF RESPONDENT SHOW $0.80/OTHER HALF SHOW $1.60] per month over and above the $5.20 which would be approximately [SPLIT SAMPLE $6.00 /$6.80] more per month if it meant that Hydro One could reduce the number and length of future power outages by 10%? The increase would be applied annually for the next five years so that by the fifth year your monthly bill will be roughly [$30.00/$34.00] higher than it is now. Base: SPLIT SAMPLE (Small Business n=100)

Given the opportunity to review a rough breakdown of what Hydro One currently spends on each of its major electricity distribution investments, that is, how the distribution delivery rate is allocated, the largest share of customers would change how it is spent (42%). This compared to only 16% from the 'uninformed' Telephone Survey. In general, these customers allocate more money to restoring power after outages, but how much more customers would spend on this is fairly marginal (up to 19%), particularly compared to how much the 'uninformed' sample, who would allocate up to 25% of the total.

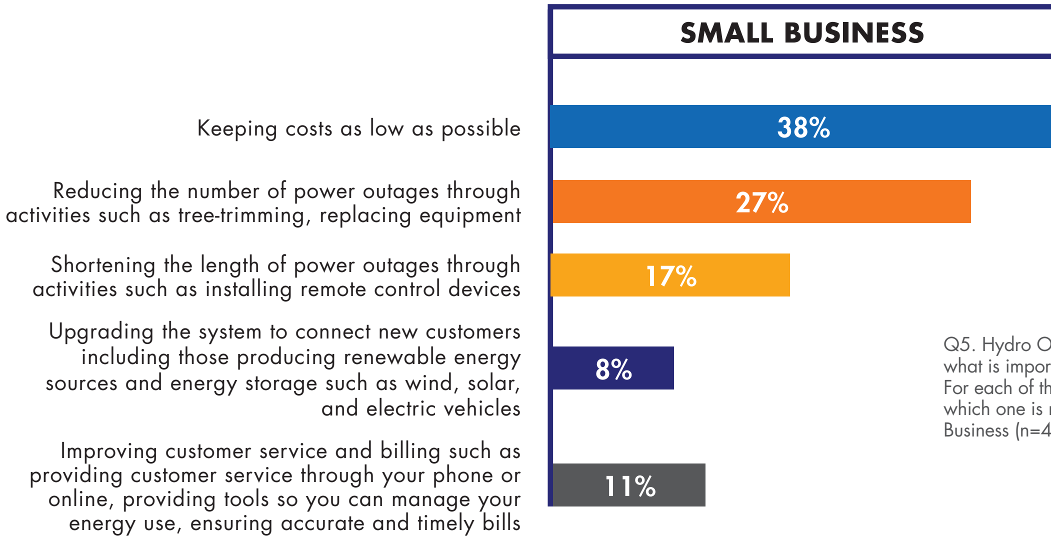
CUSTOMER PRIORITIES

As noted in earlier sections, a paired-choice exercise was used to identify customer priorities in order to help Hydro One better tailor its services. For more information on paired-choice refer to the Appendix.



Q5. Hydro One would like to better understand what is important to you as a business customer. For each of the pairs below, please indicate which one is more important to you. Base: Small Business (n=406).

The chart above shows that keeping costs as low as possible has a relative preference score of 38% among Small Business customers, and is the largest preference score of the options presented. This indicates that customers prioritize keeping costs as low as possible above the other options – reducing the number of outages, improving restoration times, improving customer service, or upgrading the system to connect new customers.

It is more than twice as important to customers as the latter three options (restoration times, customer service, and connecting new customers). Reducing the number of outages is the next most preferred option.

THE LEVEL OF RELIABILITY THAT CUSTOMERS EXPECT

Most customers indicate the level of reliability they currently experience is in line with their expectations. Small Business customers who responded to the Open-Link report experiencing an average of roughly 4.6 outages of at least one minute in length in the past 12 months, directionally higher than the average of three outage reported by the 'uninformed' sample. The largest share of customers, 46%, indicate this level of reliability (number of outages) is about what they expect. But, 37% indicate that it is worse than they expect, which is double the 'uninformed' sample (16%).

When it comes to length of outages, Small Business customers estimate the outages that they experience last an average of roughly two and half hours. Forty percent of customers indicate that the average length of outages they experience is worse than they expect.

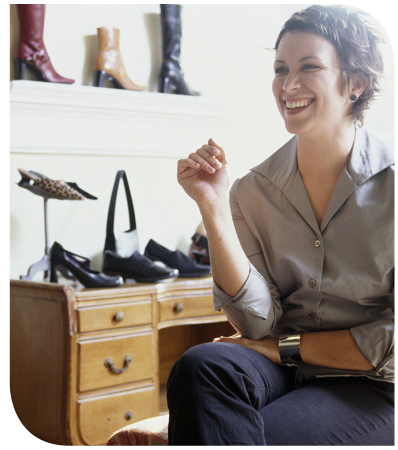
FOCUS GROUPS

SUMMARY

A series of four focus groups with Small Business customers of Hydro One were conducted to further flesh out early learnings and findings from the Telephone Survey. In particular, gauging support or opposition to a rate increase, and understanding reasons in more detail for why some businesses accept and other do not accept rate impacts, were of interest. Furthermore, they were designed to understand general needs and preferences, for providing information about Hydro One and its operations, and to ascertain reaction to this information.

Small Business customers are seeking value and accountability as it relates to their services from Hydro One. Although participants in most regions except northern Ontario generally report satisfactory reliability, many have concerns about the cost of electricity, as well as ensuring the funds being paid to Hydro One are being spent prudently to both maintain reliability and plan for future needs of the grid.



An equal number of participants state they don't like an increase but believe it is necessary, along with those who are opposed to a rate increase. Those who are opposed have questions about how funds are currently being spent as well as how a rate increase would be spent. Others state they have concerns about Hydro One's accountability in their expenditures for items such as staff salaries and workers out in-field. Some are concerned about affordability and have a general sense that rising rates make them feel unsupported as businesses in Ontario.

Knowledge provided in the groups about the level of service was interesting and relevant for some to hear, with others stating that the information reflected their expectation of how Hydro One would need to plan and maintain their assets and services as any business would.

Many participants cited a range of customer service concerns which are in need of improvement including account set-up, billing accuracy, power restoration information, and call centre issues.

Small Business customers have more general awareness and knowledge of the energy sector than their Residential counterparts. They stated concerns with items such as exporting power to the U.S., the Debt Retirement Charge, and the rising cost of commodity prices to offset low load. Given these concerns, they are very interested in communications resulting in accountability and transparency to help them understand how value is being provided to them by Hydro One.

DETAILED FINDINGS

COSTS AND RATE INCREASES

Small Business customers expressed their concern with the cost of electricity. It is one of many expenses that need to be balanced with other needs and expenses of their operations. They stated a concern that rates will continue to rise with maintaining service being used as a justification.

"…we kind of get hit on every side of it, right? As business owners with taxes. There are so many other expenses, that you would hope that certain things would either level out, stay the same or not increase dramatically."

"I don't want in two years for them to come back with the same story that the money that they took from us, well, it just didn't fix what they promised they would, and here's another rate increase."

One participant made an organic mention of their belief that privatization would have a positive impact on Hydro One. Another participant stated their belief that the sector is entirely run by the government, who has made a number of unwise decisions as it relates to the energy sector.

"…my opinion is [hydro] should be privatized, because privatized is the only thing that keeps it fair. It keeps people from taking advantage of the system. And privatized is just better."

"…you really have to realize that Hydro is run by the government, and that should say everything about why stuff isn't done…they have no qualms about wasting money profusely. That's why, as you said, do I trust, and I say, no, because it's the government that runs the whole Hydro thing…"

RATE INCREASE: SMALL BUSINESS: 1% OR $5.20 FOR AVERAGE CUSTOMER

Small Business participants were polarized as to their acceptance of a rate increase. While the majority indicated they don't like the increase but think it is necessary, an equal number stated the increase is unreasonable and that they would oppose it.

For those who were opposed to a rate increase, their reasons included:

- Skepticism about the "average" amount being $5.20, or their own bills are much higher than average
- A lack of information as to where and how funds are currently used, and how a rate increase would be used
- A perceived lack of, or desire for, efficiencies instead of rate increases
- A perception that the funds are currently or will not be used wisely by Hydro One — for example, that the funds would go to wages and salaries, and not improving reliability
- A rise in electricity costs, or any costs, are a risk to their businesses' viability
- An inability to pass along the rate increase to their customers in the form of higher prices
- For those in Northern Ontario with poor reliability, paying more for already poor service is unacceptable

"The average person doesn't exist. So, I am absolutely against it just because it's the percentage. If they said to me, we're adding $5.00 to your bill and that's $5.00 flat rate… I would accept that. But this percentage stuff is total BS it never reflects the average."

"…they're saying that the average bill is about $520.00, right? I can tell you that the businesses that I run, our bills are never $520.00. They are double to triple that easily…when you look at it at a little bit of a bigger standpoint of $1,300, $1,500 a month or $2,000 or $2,500, depending, that tends to be quite a bit more than $26.00, and you're looking into the hundreds."

"What is that 1% made up of? Why should I take their word for it that it's 1% What are they going to spend this 1% on? Why can't they save money somewhere else…Are there no efficiencies to be gained anywhere else?"

"The only problem is, we keep on seeing horrendous mistakes being made, a tremendous amount of money being spent on things that are cancelled, and we constantly have to pay for debt retirement, where we seem to be paying for incompetence. That's what upsets us."

"I would like to see the money spent on infrastructure rather than wages and salaries."

"For a minor increase like that to go up…for just the delivery of our hydro never mind the actual hydro costs themselves, it could be a big difference in making my business able to survive. Small things like that add up big time, and I don't see why we should have to keep taking all these kinds of hits here and there…I can't raise my product prices any more than they really are."

"As a business owner, it comes down to being in the red or being in the black, and any things that a business owner can do to leverage profits, I would say is his or her benefit. So anything that ends up costing us more, would eventually be more prohibitive to us."

"…if we as a business raised our prices as much as our Hydro bill has gone [up], I think we would probably be out of business."

"...what it would take to keep the outages at their current level…we don't feel is acceptable at this point either… if it's going to stay at the same unacceptable level, then I wouldn't be prepared to pay extra for that."

A few indicated that they feel unsupported as Small Businesses in Ontario due to the number of expenses they incur.

"…in general of these increases, they come at the expense of the business owner. The business owner is the one in terms of when there's inflation and things…who end up making comparatively less, and the people on the unions, like Hydro One unions, are the ones who are protected or who just keep making more. The work to reward ratio for the small business owner, it just keeps going down and down and down and down."

"The increase is across the board, they're all claiming they're all separate entities, and then you get one bill with a price increase, and then they don't give you an explanation of it. Then you have the situation where they say, oh, we're just responsible for distributing power. But at the end of the day, when you get your bill, it doesn't matter, the price increase, whether it comes from one company or five companies, it doesn't matter altogether…the small companies are the ones that are getting shafted, primarily."

For Small Business participants who struggle with reliability, they would like to see a concrete improvement in reliability in the event of a rate increase.

"…if you're not seeing value for your money, then it really is increase for the sake of increase, and that's what I have found. There needs to be a plan put forward, to show exactly what they're going to do, for the money that they're going to be spending, in order for us to feel justified by that increase."

"…if there's going to be actual, tangible results…I think most of us concur that reliability of service is a relatively large stumbling block…I don't think they could guarantee it."

"Clearly, it's a matter of value for investment. If we are all saying there are issues with outages, supply, forestry and equipment deficiencies, that are affecting our reliable supply, can you guarantee that there will be an improvement in service and reliable supply for the increase. In our experience, here, we have not seen significant or any improvement related to additional investment and increase[s] in billing."

CURRENT AND FUTURE ASSET MANAGEMENT, AND ASSOCIATED COSTS

When provided with information about current asset management and asset conditions, some participants stated the information provided was in line with their expectations around managing the company's assets and the distribution delivery infrastructure.

However, many expressed deep concern over Hydro One's historical management of assets and infrastructure, and their planning or perceived lack of planning. Some Small Business participants stated that a wait-and-see approach typified one that many service companies have towards making improvements, to the point that it is almost too late. Problems are exacerbated as a result, and the increase in costs for resolving these issues are then passed on to customers.

"It makes me question as to why the poles etc. [weren't] kept up. Why are we having to increase all of a sudden to maintain now? What happened to our funds in previous years?"

"In any business — equipment replacement should be part of the budget. I have always wondered why this was not considered on an ongoing basis rather than under crisis management. 50–60 year life cycle is very long."

"…why haven't these things been maintained sooner so that this increase doesn't have to hit you at once. Maybe instead of a $5.20 increase, if they maintained it a little more appropriately, maybe we'd only have a $1.00 increase every year or something like that."

"…why weren't these anticipated, and why was this not done over a period of time. If you have aging equipment, there should be phases…Now if that was the case, then… [the rate increase] wouldn't be so significant…There was no planning in place, there was no project management in place, there's no assessment of the infrastructure. This is just like, last minute, things start to fail, and then they're like, oh crap. "

Planning and preparation of the grid for future needs was actively debated during the Small Business Focus Groups. Participants had mixed reactions to the notion of proactively anticipating and building infrastructure now, as opposed to responding to needs as they arise, as well as the role of renewable energy in the future of the grid.

For those who supported increased renewable energy being added to the grid, they believe there is a long-term economic benefit, although some acknowledge there may be a short-term rise in costs and subsequently, rates. As well, a few participants stated they would like the environmental benefits of renewables. One participant stated their belief that having new sources of electricity would help mitigate any electricity shortfall experienced by the province.

"I would get behind Hydro One for doing more to help us change, shift the landscape on renewables and alternate ways of generating, storing, distributing, that are more efficient, that are more mindful of the climate crisis. So I'm behind that, and I'm willing to invest in it, and I kind of expect I'm going to."

"…emphasizing lowering rates at a time when all these new technologies and changes to the grid are happening, I don't see is a wise investment. We should be spending money on handling the changes to the grid."

"I definitely think they should start preparing now for it just because I don't think the electricity that they're using at the moment is going to last forever…you may as well get on it before things get any worse or something happens or we're not prepared at all."

Some participants asked questions and expressed skepticism as to the value and benefit of adding renewable sources to the grid. Those who are opposed to proactively preparing the grid state this is a low priority area and have concerns about the costs associated with making or supporting these types of investments.

"It just seems, in general, that they continue to increase the volume [of electricity], but it's more than is required for the system…It just seems counter-productive, at the same time as we're subsidizing these incredibly high returns to these people for setting up the system. So I just think, when are they going to decide that this doesn't need to continue to be feasible."

"We've seen that with windmills and various things that we thought were the ultimate answer and now there are questions from anything from health to noise to all kinds of things."

"Currently, the programs to generate alternative forms of energy appear not to be working and, in fact, are costing the system and users more in higher rates."

A few participants opposed to proactively preparing the grid expressed concern about obsolescence of technology. That is, if Hydro One installs new technology today, it is possible for the technology to be outdated before it is used to its maximum potential. There were also concerns cited that any new technology implemented would fail entirely, as with their perception of Smart Meters.

"Just like if you bought a really fast computer 10 years ago or 20 years ago you thought you were going to use right away, you wouldn't buy a computer to use two years in the future because by then the computers are all new and all different anyway. So, if nobody is going to be filling up these electric vehicles and contributing with these solar panels, then don't spend the money now, because you're going to have to spend it all again in two years or three years or ten years whenever those people are driving the electric vehicles and using the solar panels. Because by then the technology is probably going to be completely different and/or your infrastructure is going to need to be redone anyway. I just think respond to demand."

"The smart meters weren't an effective program, which is why they have pulled it out. There were way too many errors. It was determined through an investigation that it was actually costing customers money because they were not working correctly from day one. So, they implemented something that ended up costing us in the long-run, which we are paying for as customers."

RELIABILITY AND POWER RESTORATION

Many Small Business participants are highly satisfied or satisfied with their service from Hydro One. Most do not struggle with reliability, with the notable exception of participants in northern Ontario, for whom reliability is a significant issue. For these participants, their experience impacts their productivity or the satisfaction of their own customers. Their perception is that Hydro One is insensitive to these impacts when they call into customer service.

"Reliable electricity is a requirement for my business. I get reliable power with almost no outages. When there is an outage, it is fixed promptly. I am satisfied."

"As far as maintaining the supply I have no problem."

"Living in rural central Ontario we face outages relatively frequently. Responses are generally prompt, although we are at times waiting many hours without service."

"Quite often businesses have to close during the day on weekdays, and several of them throughout the community…woe is me [at Hydro One] because we have such a big system to look after, but no sympathy at all for the person who has to close, and send their staff home for the day."

A few businesses have backup generators onsite to mitigate the impacts of any outages. Minimal contact with Hydro One is generally considered a positive as it means that the customer does not have any issues with the company.

"…I am fairly happy with their services in terms of the fact I do not have to deal with them often."

In terms of power restoration, information by phone or on the Hydro One website is often inaccurate — with estimated restoration times being both too short and too long. Sometimes it is difficult for customers to get through on the phone.

"Often they say it's going to be longer than it actually is, in our area…it seems sometimes they go overboard to make sure they're not wrong. [However] a more accurate measure could help production."

"I think that calling in is always a frustration for probably a lot of people."

"…when I have looked online and even called Hydro One to just see what the estimated time of getting everything back up was, they were usually longer than anticipated for most of them, quite a bit longer."

CUSTOMER SERVICE AND BILLING

For Small Business customers who participated in the Focus Groups, customer service from Hydro One is an area in need of significant improvement. They struggle with customer service in a number of different ways, including:

- Not having a dedicated account person or contact. They rely on publicly available information in the event of an outage, and call into the number on their bill in order to have ask questions or have issues addressed.
- When calling the call centre, they mention being passed around from one person or department to another on the phone and often not receiving a satisfactory answer to their questions or resolution on their issues.
- The process of resolving issues can take an excessive amount of time - months or years - if at all.
- Having a third party answering calls and managing the call centre creates the perception is that these individuals can't make decisions or provide concrete help to customers.

Participants stated the more complicated the issue, the more difficult it was to resolve. Some participants believe customer service representatives need better training in order to mitigate these issues.

"I find basic customer service reps are only good if it's a really basic question, because even when they did the bills wrong, they still couldn't help. They still had to get someone else. It's frustrating."

Participants spoke of billing irregularities such as being charged for the wrong meter or not receiving bills regularly. There were mentions that participants would like Hydro One to move away from e-post third party billing, and that the bills should come from Hydro One directly.

"We have a couple of times that we haven't received bills regularly and I've called to discover that our bills were being reviewed and redone. This took up to six months and then we had an extremely large bill that we had to negotiate payment arrangements for."

PERCEPTIONS, COMMUNICATION AND AWARENESS

Small Business Focus Group participants are generally more aware of the energy sector than their Residential counterparts. Several hold negative perceptions of Hydro One as a large and inefficient company.

"I see guys who work hard in the cold for 10 or 15 years, then everybody gets moved up into some type of cushy position. They hire new guys for the lines and the older guys don't have to work the lines and they get paid really, really, really well."

One participant expressed deep skepticism and rate increase fatigue, with any conservation efforts by businesses and concerns not having any positive impact on costs. There were also mentions of having commodity electricity prices increase at times of low load, which was disappointing to participants. Others stated that the information being presented was to justify a distribution rate increase by Hydro One.

"I don't think as a consumer, business or residential, we can ever see where any proactive move that we participate in as consumers help to keep the price down, or from going up. In fact, if you listen to the media, because we conserved, and too much power was being generated for use, we're going to see the price go up again...none of these initiatives that seem to be what they feel is going to make a better system, is impacting on rates at all."

> *"Now I see the tears. Sounds like they are trying to justify the prices."*

The Debt Retirement Charge was also mentioned by participants, with one participant stating his belief that the debt has been paid off, and yet consumers are still being charged for it. Customers are resentful that they are responsible for paying the Debt Retirement Charge, and point out that in any other business, paying off debt by raising prices would not be an option.

"...in any other business...I can't just charge because of other things, I can't charge more for my product, to make up for the difference that I'm losing somewhere else. So while I understand maybe where they're coming from, it's just not fair."

Some participants stated that they would like to experience better communication during outages. The majority call in to the number on their bills, with some checking Hydro One's website on their smartphones. Awareness of Hydro One's outage app is low.

Participants expressed interest in a number of different channels and some indicated that they would like to hear from/about Hydro One via multiple channels, including:

- Directly on the bill
- Bill inserts
- App
- Social media
- Separate letter
- E-mail
- Advertising
- Texts
- Website

When asked to give Hydro One a final piece of advice, participants were forthright about the need for increased transparency and accountability. Several stated that the information provided during the groups was a positive first step in this direction, and more information about Hydro One would continue to positively impact perceptions.

"The entire system and all its partners ha[ve] a massive PR problem — and broken trust is hard to mend, particularly when times like these demand innovation, reinvention, transparency and real accountability."

"Hydro One gets a lot of bad PR about wages, mismanagement and other difficulties which doesn't instill confidence. We need more information to convince us that we're getting good value for money."

"This was informative for me to learn more about Hydro One and see where the money is spent. Thanks."

> *"More or better communication from Hydro One would be beneficial — I feel a lot of issues we have with hydro are not Hydro One specific as they are just distributors."*

FIRST NATIONS CUSTOMERS

SUMMARY

There is a greater amount of dissatisfaction among First Nations residential customers when compared to Residential customers overall. Of all of the R&SB segments, First Nations customers are most sensitive to cost and place the greatest importance on cost over improvements in the service they receive. However, First Nations customers are as likely to accept the proposed 1% increase on the total monthly bill to maintain the current level of reliability and customer service.

TELEPHONE SURVEY

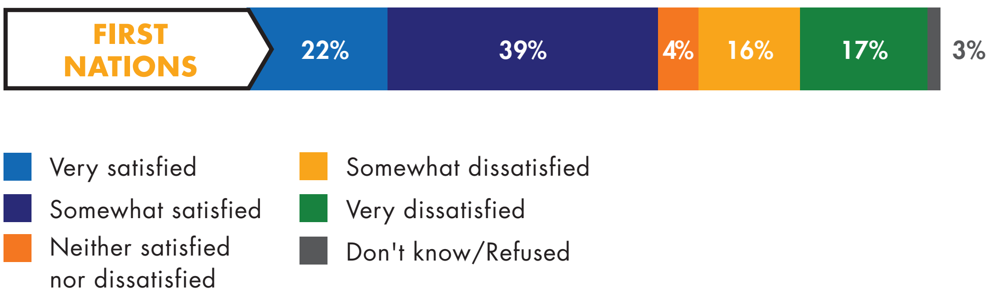
As outlined in the methodology section of this report, the following results are based on a Telephone Survey of a random and representative sample of n=300 First Nations customers. A stratified, random sampling approach was used to pull the sample from Hydro One's customer database. With a sample of this size, the results are considered accurate to within ± 5.7 percentage points, 19 times out of 20, of what they would have been had all First Nations customers been surveyed. That means that if the survey is repeated 20 times, 19 of those times the results of the survey will be the same within the margin of error. The margin of error will be larger for sub-groups of the population. This data was not statistically weighted because the unweighted sample composition closely matches the true regional and urban/rural proportions in the customer database. For more information on the survey methodology refer to the Customer Engagement Methodology Section of the report.

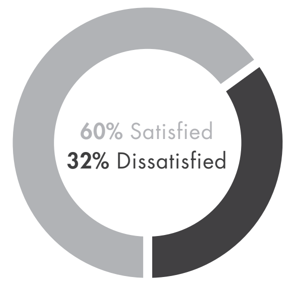
CURRENT SATISFACTION AND WHAT IS IMPORTANT TO CUSTOMERS

Six-in-ten (60%) of First Nations customers report they are satisfied with Hydro One overall, while one-third (32%) are dissatisfied. When asked on an unaided basis what Hydro One can do to improve its service, the most frequent answer customers give is to reduce their monthly bills. Some customers mention this in the context of lower prices or lower rates, while other just simply say lower cost.

TELEPHONE SURVEY

OVERALL SATISFACTION WITH HYDRO ONE





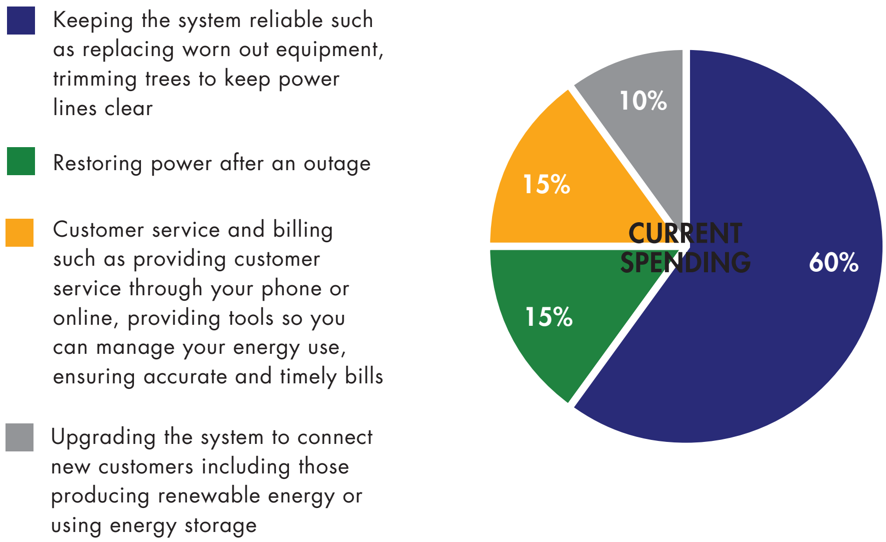
As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices. Q1. Please think about Hydro One as I have just described it to you. How satisfied are you with Hydro One overall? Note: During the first week of fielding the response scale was changed from1 to 5 to a word scale to be consistent with the Annual Customer Satisfaction survey. Base: All Respondents Post Q change, First Nation (n=204)

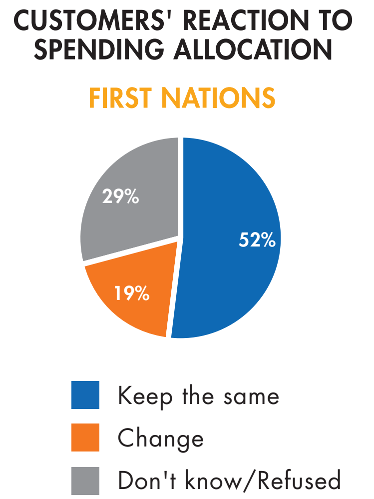
Given the opportunity to review a rough breakdown of what Hydro One currently spends on each of its major electricity distribution investments, that is, how the distribution delivery rate is allocated, half (52%) indicate they would not change how the money is currently allocated. Two-in-ten customers indicate they would change how the money is allocated.

In general, these customers allocate more money to restoring power after outages, doubling the amount of spending on it. They allocate more money for upgrading the system to connect new customers, including those producing renewable energy, by about 50%. They allocate less money to keeping the system reliable, reducing the amount by nearly half.

TELEPHONE SURVEY

OPINIONS ON CURRENT ALLOCATION OF SPENDING

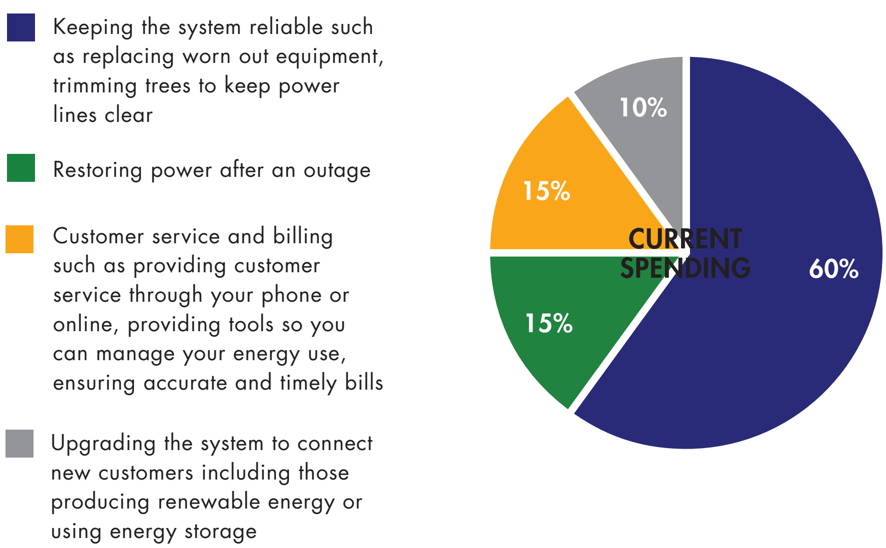


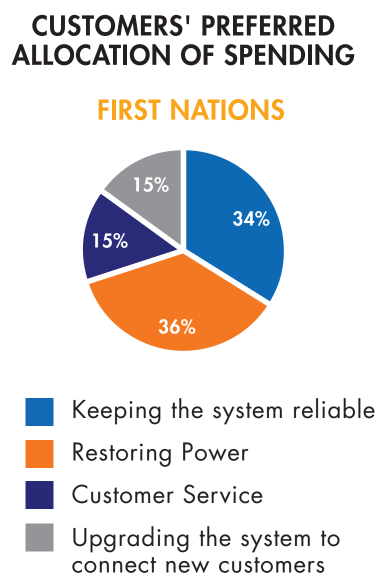


Q3. Please listen carefully as I will be reading out a rough breakdown of what Hydro One currently spends on each of its major electricity distribution investments and will be asking your opinion about the breakdown. Hydro One currently spends [READ LIST]… If you were in charge of Hydro One would you change how spending is allocated or would you keep it about the same as it now? Base: First Nations (n=300)

TELEPHONE SURVEY

PREFERRED ALLOCATION OF SPENDING





Q4. Of the 4 distribution investments you just heard, what percentage would you allocate to…? Base: Customers who indicated that current spending should be changed. The percentages have been rebased to exclude don't know responses or responses that do not add to 100% (First Nations n=54)

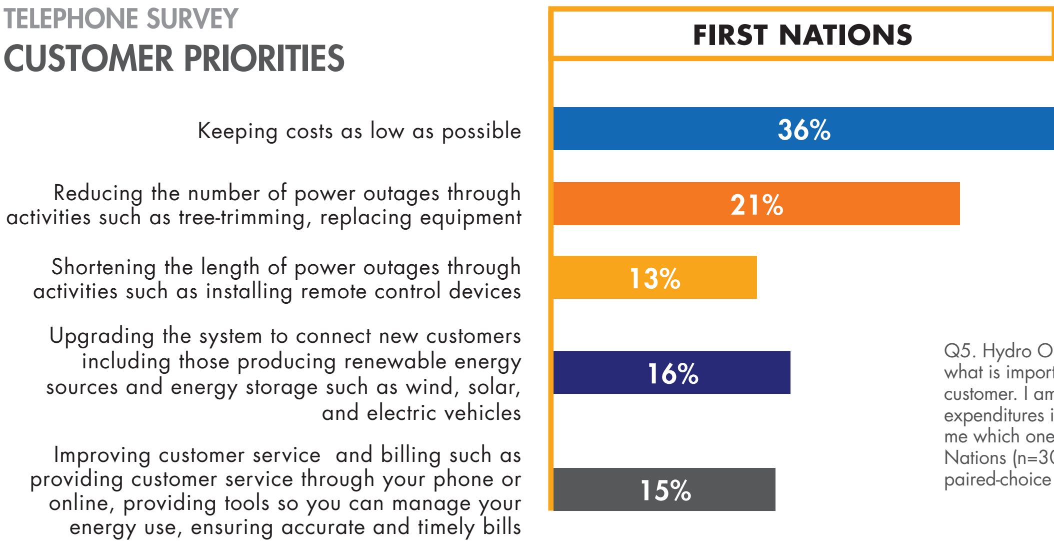
CUSTOMER PRIORITIES

The chart below shows that keeping costs as low as possible has a relative preference score of 36% among First Nations customers, which is the largest preference score of the options presented.

This indicates that customers prioritize keeping costs as low as possible above the other options – reducing the number of outages, improving restoration times, improving customers service, or upgrading the system to connect new customers. It is more than twice as important to customers as the latter three options (restoration times, customer service and connecting new customers). Reducing the number of outages is the next more preferred option.

TELEPHONE SURVEY

CUSTOMER PRIORITIES



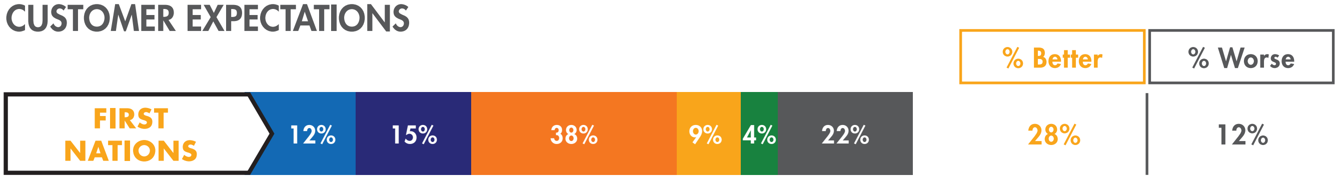
Q5. Hydro One would like to better understand what is important to you as a residential customer. I am going to read Hydro One's major expenditures in pairs and for each pair please tell me which one is more important to you. Base: First Nations (n=300) Pair-choice analysis paired-choice preferences relative to other options.

THE LEVEL OF RELIABILITY THAT CUSTOMERS EXPECT

Most customers indicate the level of reliability they currently experience is at least in line with their expectations. First Nations customers report experiencing an average of roughly three outages of at least one minute in length in the past 12 months. The largest share of customers (38%) indicate that this level of reliability (number of outages they experienced) is about what they expect. Only 12% of customers who experienced at least one outage indicate the number of outages they experienced is worse than they expect.

TELEPHONE SURVEY

CUSTOMER EXPECTATIONS



Q8. In general, when you think about how many power outages you experienced over the last 12 months how did it compare to your expectations [READ LIST]? Base: One or more sustained power outages in the past 12 months; First Nation (n=217)

When it comes to length of outages, First Nations customers estimate that the outages they experience last an average of 3.7 hours. Similar to opinions of the frequency of outages, the largest share of customers indicate that this is about what they expect. Sixteen percent say this is worse than they expect.

HOW CUSTOMERS REACT TO SERVICE VS. COST TRADE-OFFS

Half (57%) of First Nations customers do not offer an opinion on how Hydro One should approach the issue of outages. Of those that do, opinions are generally split, with one-half willing to accept more outages and longer outages to keep rates as low, while the other half are willing to accept a modest increase to maintain the current number of outages or a larger increase to see fewer outages.

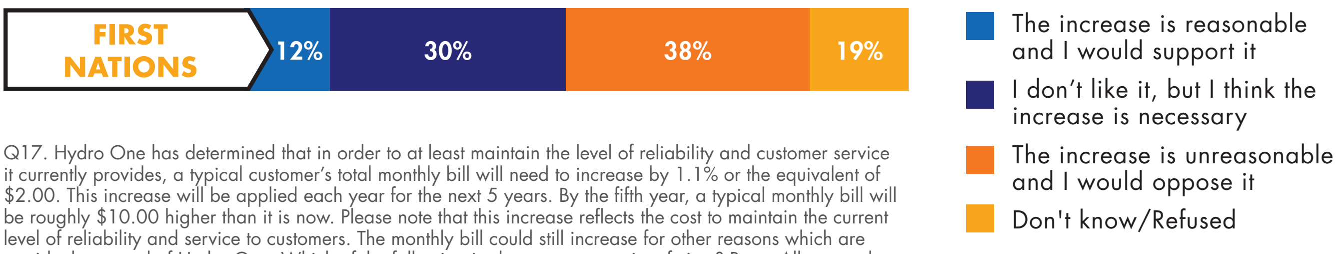
WILLINGNESS TO ACCEPT A RATE INCREASE TO MAINTAIN AND IMPROVE SERVICE LEVEL

When customers are informed that Hydro One has estimated that in order to **at least maintain** the level of reliability and customer service it currently provides, a typical Residential customer's **total monthly bill** will need to increase by 1.1% or the equivalent of $2.00, 42% of First Nations customers are willing to accept it, 38% are opposed and the remaining 19% do not offer an opinion.

TELEPHONE SURVEY

ACCEPTABILITY OF RATE INCREASE TO MAINTAIN LEVELS



Q17. Hydro One has determined that in order to at least maintain the level of reliability and customer service it currently provides, a typical customer's total monthly bill will need to increase by 1.1% or the equivalent of $2.00. This increase will be applied each year for the next 5 years. By the fifth year, a typical monthly bill will be roughly $10.00 higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability and service to customers. The monthly bill could still increase for other reasons which are outside the control of Hydro One. Which of the following is closest to your point of view? Base: All respondents; First Nation (n=300)

Prior to answering this question, customers were informed that the increase of $2.00 would be applied each year for the next five years, and that by the fifth year a typical monthly bill will be roughly $10.00 higher than it is now. Customers were also informed prior to answering that the increase reflects the cost to maintain the current level of reliability and service to customers, and that the monthly bill could still increase for other reasons which are outside of Hydro One's control.

First Nations customers are more willing than others to pay more than $2.00 to have better reliability than they have now, although those holding this opinion still represent a minority. Two-in-ten (19%) customers indicate they would be willing to pay more than the $2.00 (1.1%) increase in order to have **better reliability** than they have now. An additional 22% would consider it (selecting 'maybe' as their response).

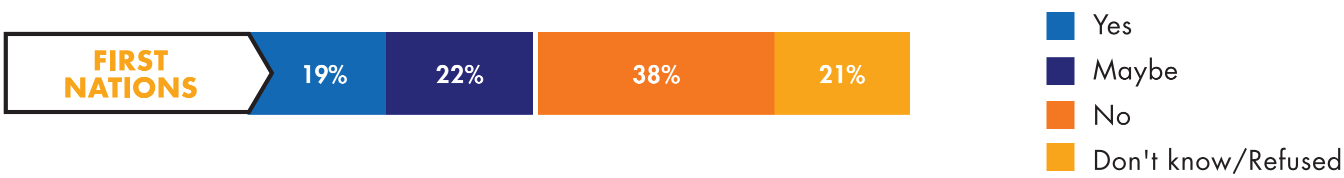
Unlike the 73% of Small Business customers who would not pay anything more or even Residential (off-reserve) customers where 64% would not, 38% of First Nations customers oppose, and 21% say they don't know/ refuse to answer. There is less interest in paying for an improved level of customer service, with only 16% saying they would be willing to pay extra for improved customer service, 16% saying maybe and 49% saying they would not.

Lastly, customers were asked about their level of interest in a 10% reduction in the number and length of future power outages, for a specific rate impact. Two additional rate impacts were posed to customers for their reaction. Half of the sample of respondents were asked to consider an additional $0.30 per month, or a total of $2.30 more (or $11.50 in the fifth year) on their monthly bill, and the other half was asked to consider a rate increase of $0.60 per month, or total of $2.60 more (or $13.00 by the fifth year) on their monthly bill.

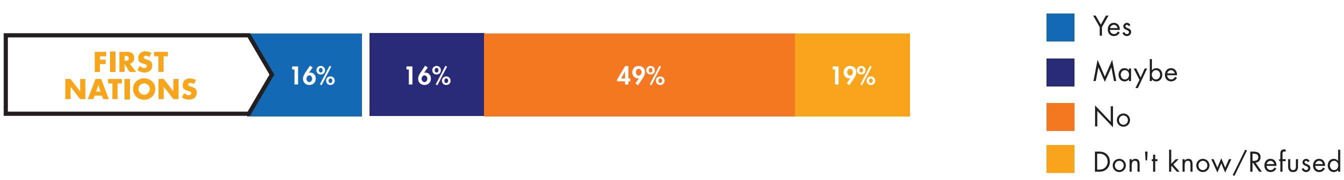
TELEPHONE SURVEY

WILLINGNESS TO PAY FOR IMPROVED LEVELS

BETTER RELIABILITY



BETTER CUSTOMER SERVICE



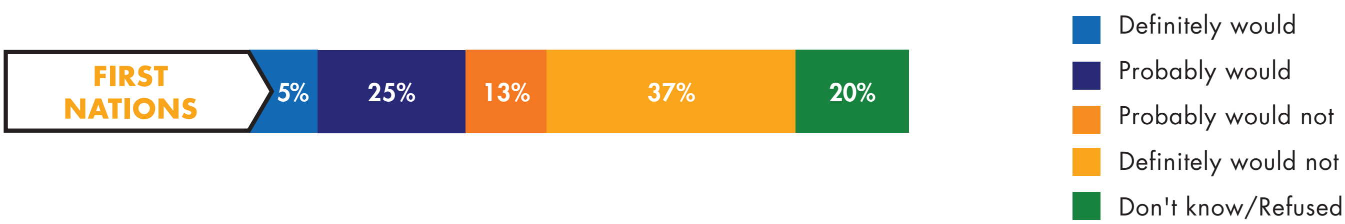
Q18. Would you be willing to pay anything higher than the $2.00 or about 1.1% more on your total monthly bill if it meant you would have a better reliability than you have now? Q19. Would you be willing to pay anything higher than the $2.00 or about 1.1% more on your total monthly bill if it meant you would have better customer service than you have now? Base: All respondents; First Nation (n=300)

Of those who were asked to pay an additional $0.30, only 30% of customers say they would prefer (definitely or probably would) to pay more, while 50% say they definitely or probably would not. Of those who were asked about an additional $0.60, 20% definitely or probably would and 58% definitely or probably would not.

TELEPHONE SURVEY

WILLINGNESS TO PAY FOR IMPROVED LEVELS

ADDITIONAL $0.30



ADDITIONAL $0.60

Q20A. Would you be willing to pay an additional [HALF OF RESPONDENTS SHOW $0.30/OTHER HALF SHOW $0.60] per month over and above the $2.00 which would be approximately [SPLIT SAMPLE $2.30/$2.60] more per month if it meant that Hydro One could reduce the number and length of future power outages by 10%? The increase would be applied annually for the next five years so that by the fifth year your monthly bill will be roughly [$11.50/$13.00] higher than it is now? Base: SPLIT SAMPLE FIRST NATIONS (n=150 were asked about each impact level)

LARGE CUSTOMERS

SUMMARY

There are some key differences between the various Large Customer segments. C&I customers prioritize keeping costs as low as possible, well ahead of other priorities such as reducing the number of outages or shortening the duration of outages. LDA customers strike more of a balance between reducing the number of outages and cost, and LDC/DG customers actually place equal importance on shortening the duration of outages and reducing the number of outages. Both of these are considered more important than simply keeping costs as low as possible.

These segments also vary fairly substantially in their preferences with how Hydro One invests in maintaining and reducing reliability and service. However, what is common among them is that all express a preference for Hydro One to improve power quality as they feel this would have a positive impact on their organization.

ONLINE WORKBOOK + WORKSHOP BOOKLET RESPONSES

As described in the Customer Engagement Methodology section, all of Hydro One's Large Distribution Accounts (LDAs) and Local Distribution Companies (LDCs) and a sub-set of Distributed Generators (DGs) were invited to participate in the facilitated in-person Workshops held in seven locations across the province. Hydro One invited all LDAs and LDCs that did not attend a Workshop to review the presentation and offer their feedback through an Online Workbook — the results of which are presented in this section. A stratified sampling of Commercial and Industrial customers was also invited to participate in the in-person Workshops. The remaining 5,000+ customers were invited (via e-mail or mail) to complete the online workbook. Refer to the Customer Engagement Methodology section for more details on the execution of the Workshops and Online Workbook.

Each Workshop session began with a presentation from Hydro One staff. After presenting specific information, participants were provided an opportunity to ask questions or offer comments and then given time to complete a survey booklet that was provided to each of them. The Online Workbook contained the same presentation that was delivered at the sessions and posed all but one of the same questions. The paired-choice questions on customer priorities could not be asked effectively in a hard copy and so it was asked as "pick the most important priority" in the survey booklet.

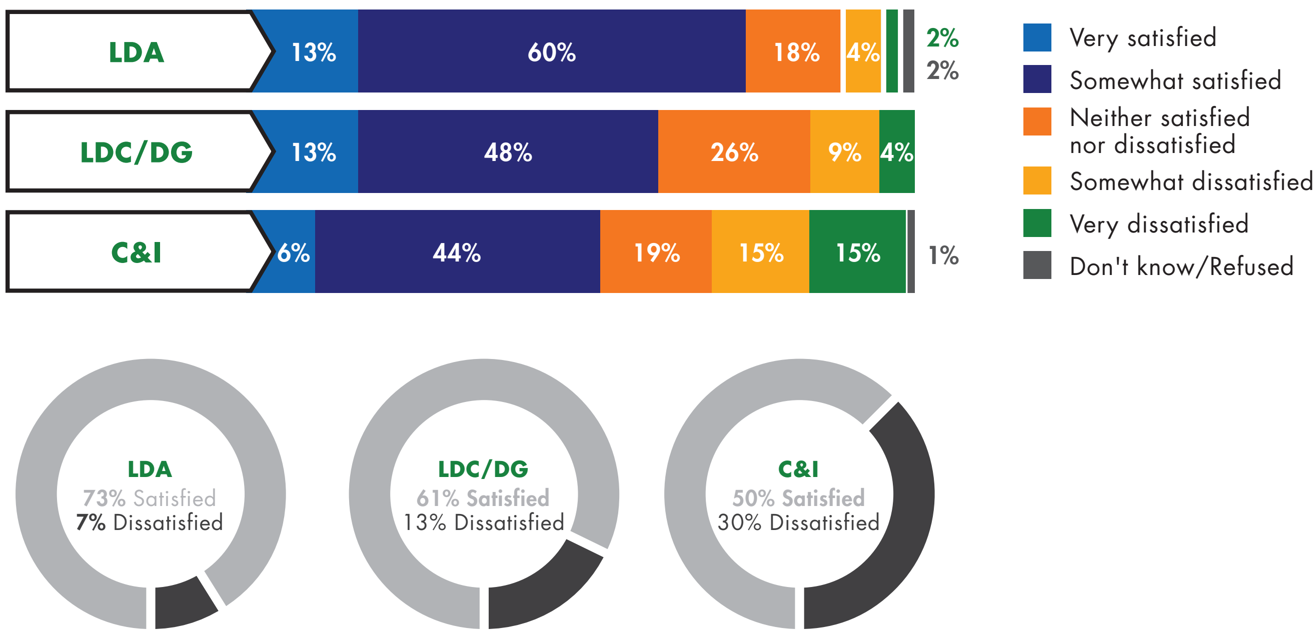
The results in this section combine the results of the completed survey booklets with the completed online workbook. The combined sample sizes are LDAs n=45, LDCs/DGs n=23, C&I n=133. The results of Large Customers are directional only.

CURRENT SATISFACTION AND WHAT IS IMPORTANT TO CUSTOMERS

The majority of LDA and LDC/DG customers are satisfied with Hydro One. Satisfaction is directionally lower among C&I customers, of which half are satisfied and 30% are dissatisfied.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

OVERALL SATISFACTION WITH HYDRO ONE

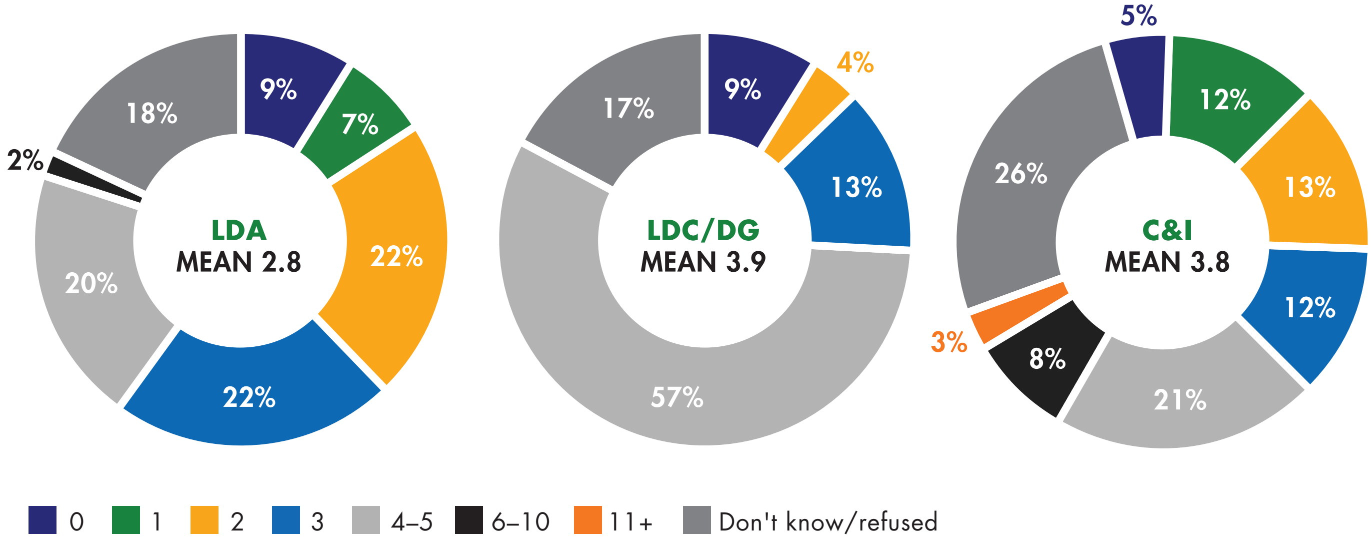


Q1. As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices. How satisfied are you with Hydro One? Base: LDA (N=45), LDC/DG (n=23), C&I (n=133)

The number of sustained power interruptions that Large Customers experience is similar to that experienced by R&SB customers – ranging from three to four interruptions over a 12-month span. Notably, half of LDC/DG are experiencing four to five per year, directionally higher than LDAs or C&I, albeit 8% of C&I customers are experiencing 6–10, and 3% experience 11 or more.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

AVERAGE NUMBER OF INTERRUPTIONS

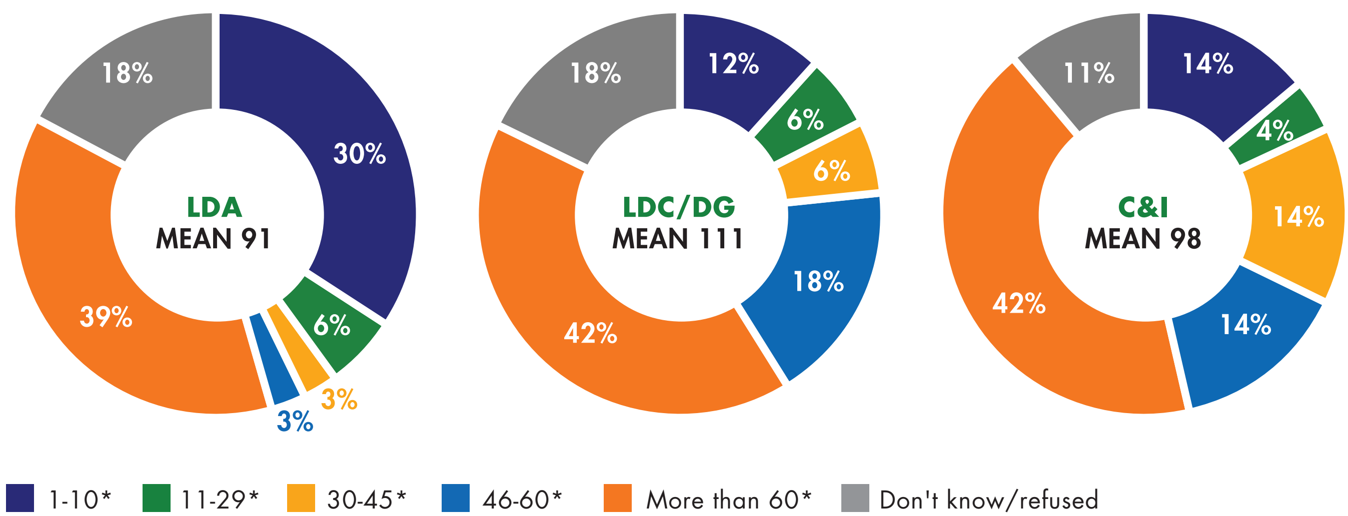


Q5.The term interruption refers to a complete loss of electric power and outage refers to the disabling of a component's capability to deliver power (planned or unplanned). An outage may or may not cause an interruption of service to customers. A sustained power interruption is one lasting at least 1 minute. How many did your organization experience in the past 12 months that you were not notified about in advance by Hydro One? Your best guess is fine. Base: LDA (n=45), LDC/DG (n=23), C&I (n= 133). Note: One C&I customer answered 99. It is unclear if this is correct information or a mistake. The mean above for C&I excludes this person's answer. If it is included the mean increases to 4.7

LDAs who experienced an interruption indicated the average length was roughly 1.5 hours. LDC/DG report an average of 1.9 hours and C&I report an average of 1.6 hours.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

AVERAGE LENGTH OF INTERRUPTIONS



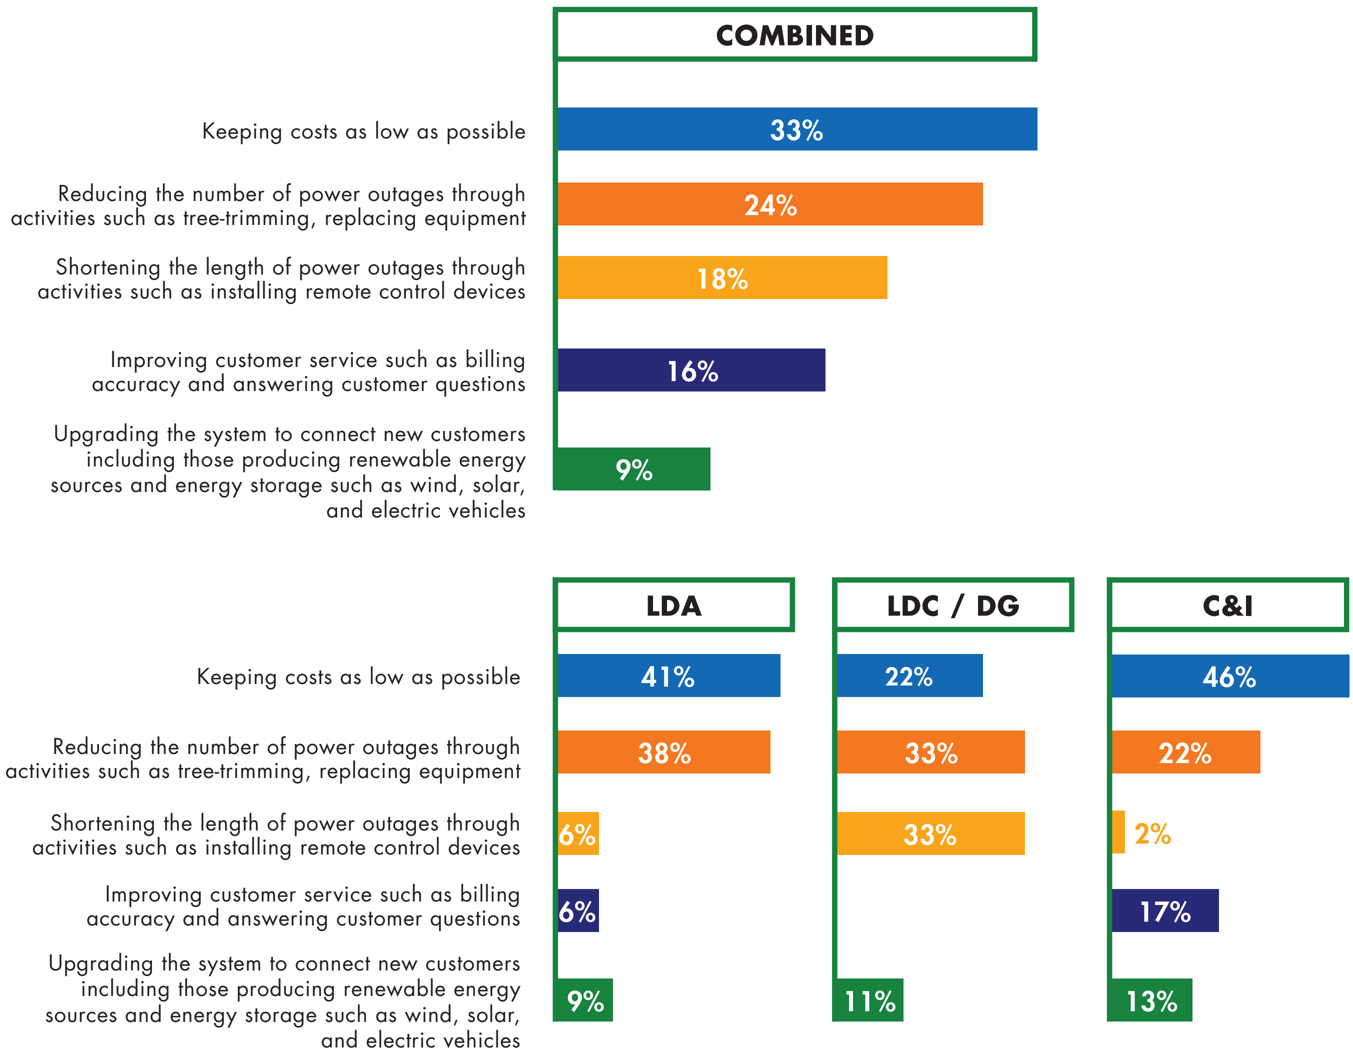
*Minutes

Q6. On average, how long did these unplanned interruptions last? Your best guess is fine. Base: Customesr who experienced at least one interruption. Base: LDA (n=33), LDC/DG (n=17), C&I (n=91) Note: Three customers gave answers that could be considered outliers 1,200 (20 hours) and 2,880 (48 hours). We have removed these 3 responses from the mean calculation. If they are included the mean change as follows: LDA = 194 instead of 91, C&I = 146 instead of 98.

CUSTOMER PRIORITIES

Large Customers, with the exception of LDC/DG customers, also prioritize keeping costs as low as possible over improved reliability, customer service or upgrades to the system to connect new customers including those producing renewable energy. LDC/DG customers prioritize better reliability, as well as both fewer and shorter outages ahead of all else.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET
CUSTOMER PRIORITIES



Q3. Hydro One would like to better understand what is important to you as a large customer. From the following list, which would you say is most important to your organization? (select one only) Base: Excludes don't know/refused. LDA (n=34), LDC/DG (n=18), C&I (n=46) Note: the online workbook asked this question in the form of a paired-choice and the analysis was conducted on the combined response (due to smaller base sizes) Base: LDA/LDC/DG/C&I (n=87).

THE TYPES OF RELIABILITY IMPROVEMENTS THAT CUSTOMERS VALUE

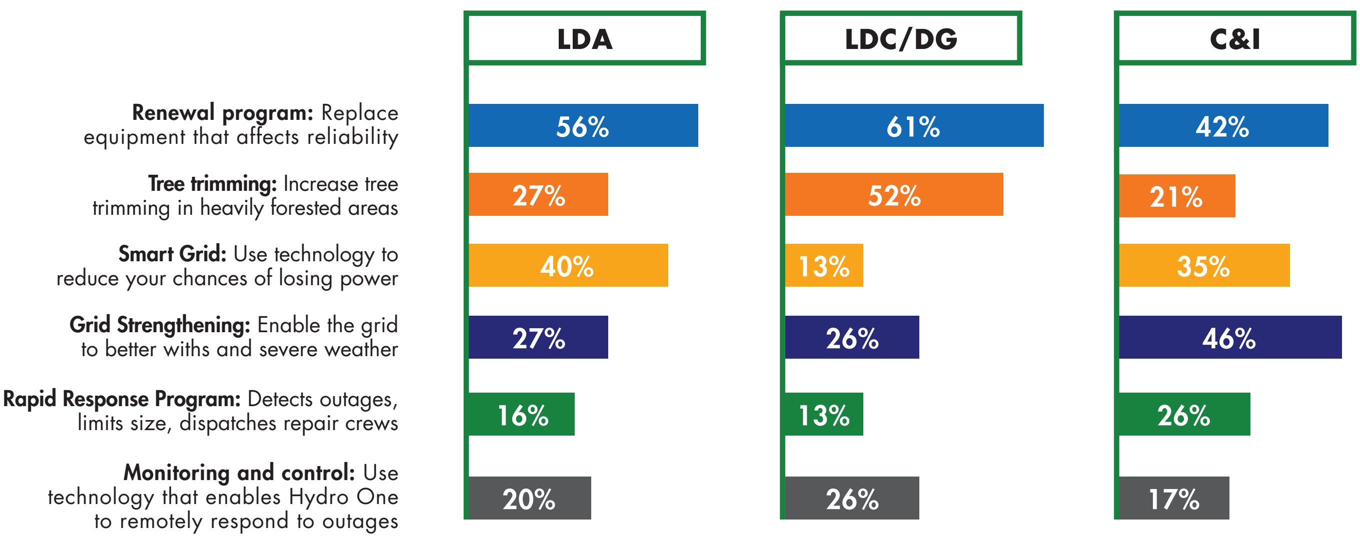
Large Customers were provided with various reliability investment options that Hydro One could prioritize and were asked to rank them in order from one to six, where one represents the item that would have the greatest positive impact on their organization and where six represents the item that would have the least positive impact. All Large Customer segments (LDA, LDC/DG and to a lesser extent C&I) prioritize the Renewal Program that focuses on replacing equipment that affects reliability ahead of others.

Views on the second and tertiary priorities vary somewhat. LDA customers place the second greatest priority on the Smart Grid, that is, using technology to reduce their chances of losing power. They place this slightly ahead of increased tree-trimming and Grid Strengthening. LDC/DG customers place tree-trimming in the second position – in fact nearly as many customers feel this would have the greatest positive impact on them as the Renewal program. C&I customers actually place as much of a priority on Grid Strengthening as the Renewal Program and then place Smart Grid as their tertiary choice.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

CUSTOMER PREFERENCES FOR WAYS TO IMPROVE RELIABILITY

Percentages shown represent % who ranked the item in the first or second position.



Q11. Please rank the RELIABILITY items below in the order in which they would have the greatest positive impact on your organization, where 1 represents the item that would have the most positive impact and 6 represents the least positive impact. Base: LDA (n=45), LDC/DG (n=23), C&I (n=133).

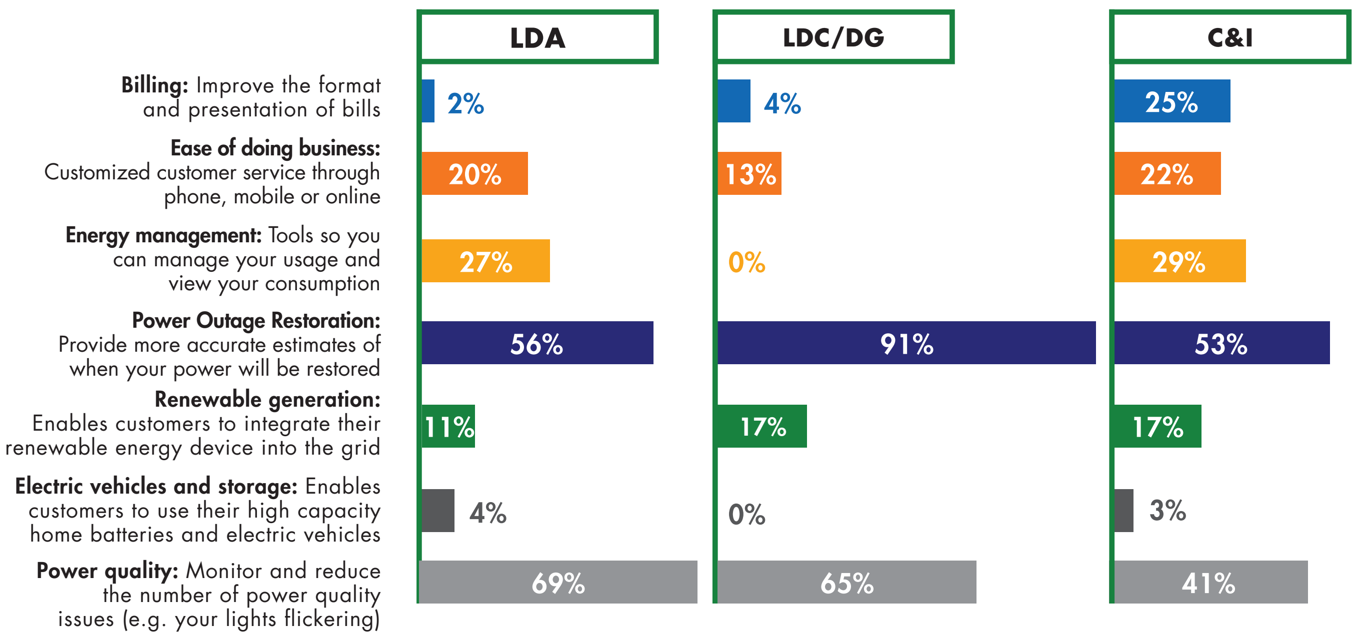
THE TYPES OF SERVICE IMPROVEMENTS THAT CUSTOMERS VALUE

When it comes to ranking seven service-related options, all three Large Customer segments prioritize Power Outage Restoration –providing more accurate estimates of when power will be restored. This is followed closely by Power Quality –monitoring and reducing the number of power quality issues (e.g., your lights flickering), and LDA customers actually place this slightly ahead of Power Outage Restoration.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

CUSTOMER PREFERENCES FOR WAYS TO IMPROVE SERVICE

Percentages shown represent % who ranked the item in the first or second position.



Q12. Please rank the SERVICE items below in the order in which they would have the greatest positive impact on your organization, where 1 represents the item that would have the most positive impact and 7 represents the least positive impact. Base: LDA (n=45), LDC/DG (n=23), C&I (n=133).

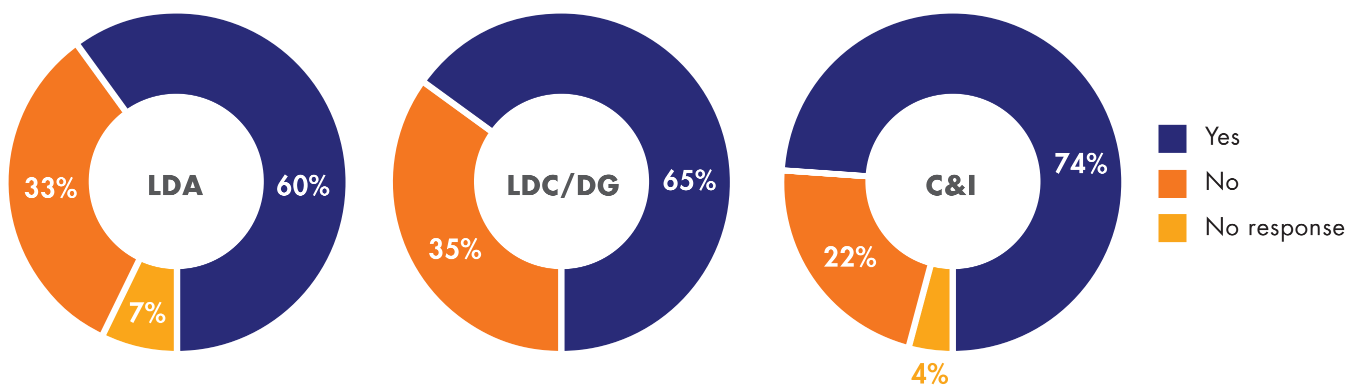
Note: for the online workbook, Billing was worded as - Ensure you receive timely and accurate bills, Ease of doing business was worded as - Seamless customer service through phone, mobile or online.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

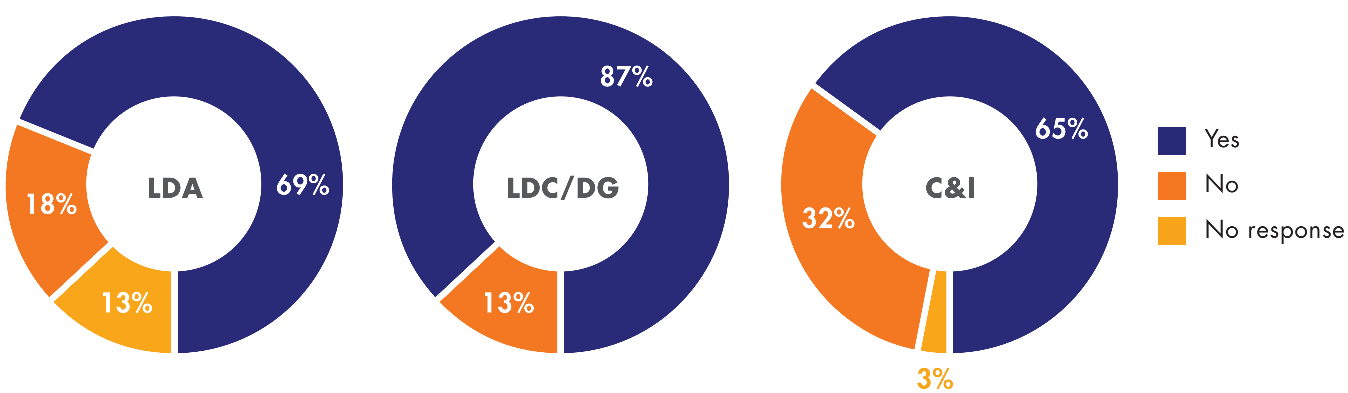
CUSTOMER REACTION TO HYDRO ONE'S CURRENT INVESTMENTS

The majority (60% and higher across the Large Customer segments) indicate that based on what they heard/read in the presentation by Hydro One, the investments that Hydro One is making today to maintain and improve the current level of reliability and service make sense.

TO MAINTAIN CURRENT LEVEL OF RELIABILITY AND SERVICE



TO IMPROVE THE LEVEL OF RELIABILITY AND SERVICE



Q9. Based on what you just heard/read in the presentation, do the investments to maintain the current level of reliability and service that Hydro One is making today make sense to you? Base: LDA (n=45), LDC/DG (n=23), C&I (n=133). Q10. Based on what you just heard/read in the presentation, do the investments to improve the current level of reliability and service that Hydro One is making today make sense to you? Base: LDA (n=45), LDC/DG (n=23), C&I (n=133).

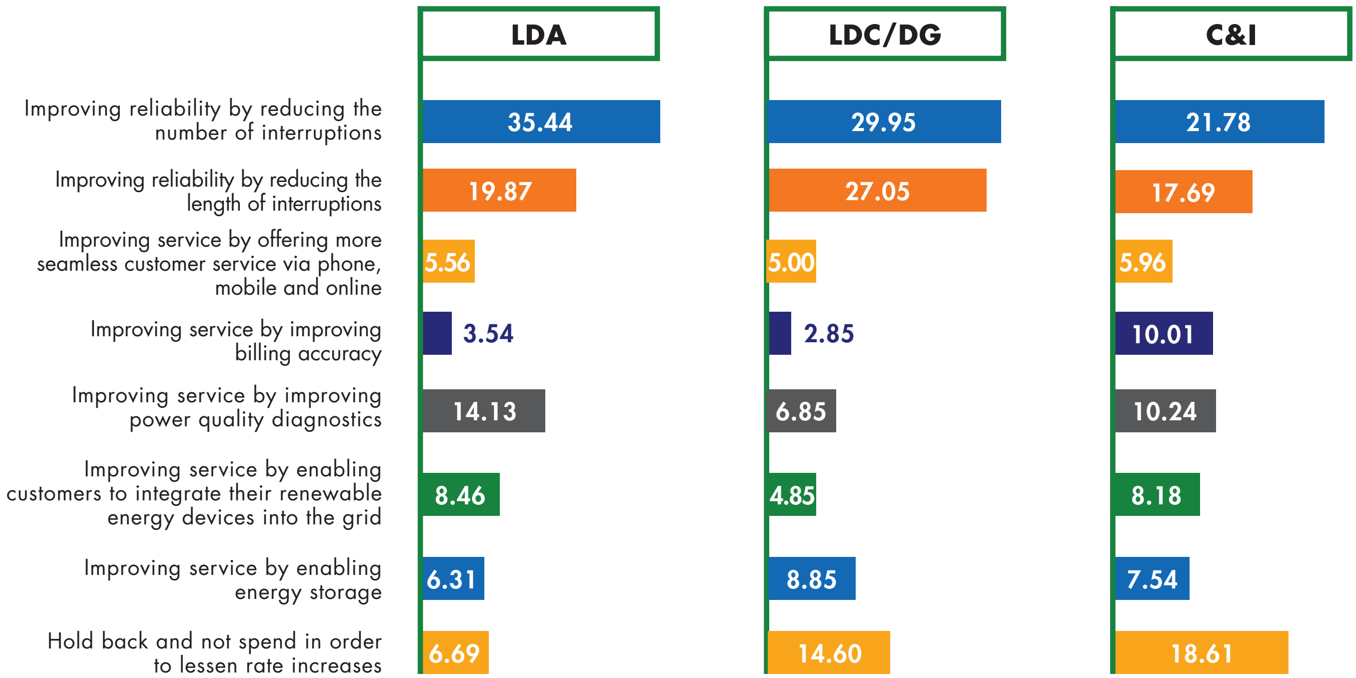
HOW CUSTOMERS WOULD ALLOCATE INVESTMENTS

Large Customers were provided with the opportunity to allocate $100 based on their preferences. All three customer segments allocate the most to reducing the number of interruptions (averaging from roughly 22% of spending to 35% of spending). LDA and LDC/DG customers allocate the next largest share to reducing the length of interruptions (LDA customers allocate an average of roughly 20% and LDC/DG allocate 27%).

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

HOW LARGE CUSTOMERS WOULD ALLOCATE SPENDING

Data shown below is the mean score – representing the average amount ($) customers would spend on these items.



Q13. To explore your preferences for reliability, service and level of rates, please complete the following exercise. If you had $100 to spend on the following, how would you allocate the money? Note that for the workshop survey booklet, the wording was "let's do a simple exercise". The data shown above excludes customers who do not answer the question or whose answer did not total $100. Base: LDA (n=39), LDC/DG (n=20), C&I (n=121).

For C&I customers the next largest share is allocated to savings, i.e. hold back and not spend in order to lessen rate increases (roughly 19%). LDC/DG customers would hold back an average of 15%, while LDA customers would hold back 7%. LDA customers allocate more to improving power quality (at roughly 14%) than LDC/DG or C&I customers.

CUSTOMER REACTION TO ILLUSTRATIVE INVESTMENT SCENARIOS

Large Customers were presented with the following illustrative investment scenarios and asked for their feedback. The three scenarios reflect the estimated rate impacts for declining reliability, maintaining the current level of reliability and improving reliability. The slide below was shown to Large Customers prior to introducing the three illustrative scenarios.

Introduction to investment scenarios

hydro one

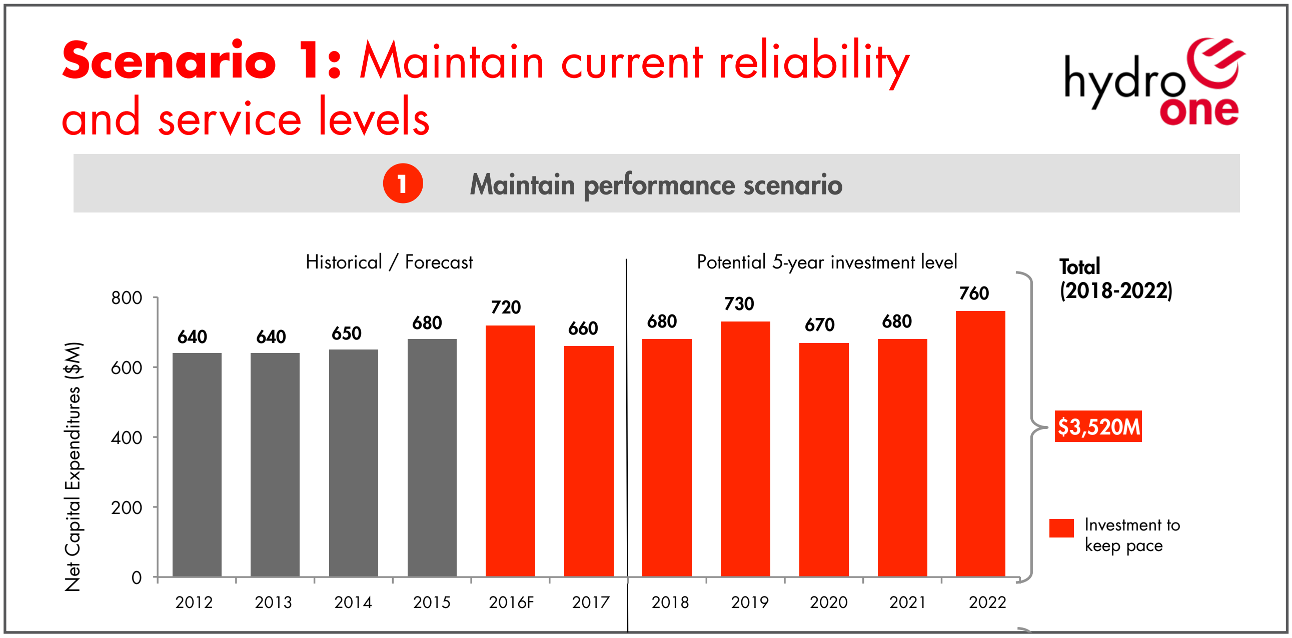
Illustrative scenarios have been developed for various levels of capital investment.

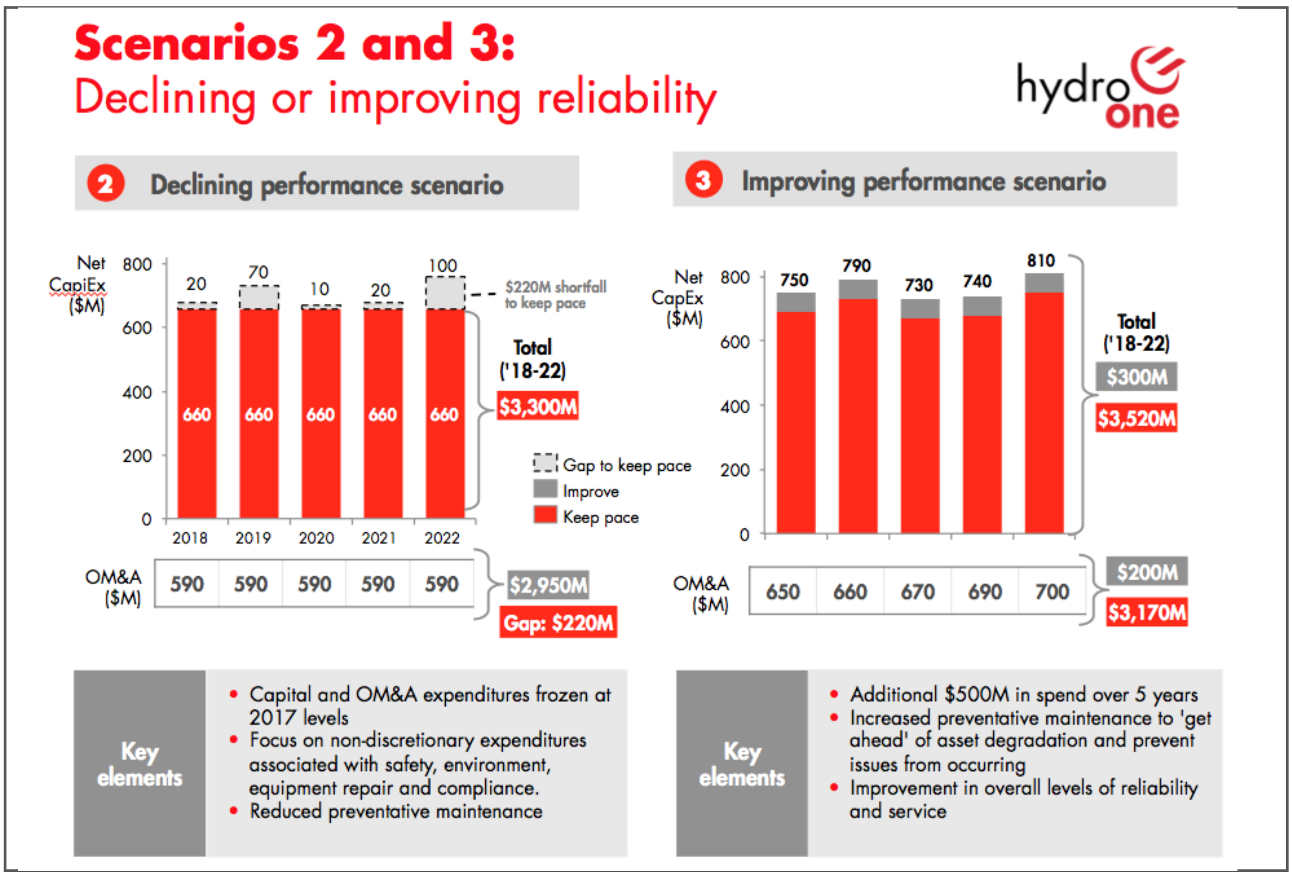
These in turn, result in different impacts on rates, reliability, and service levels.

These scenarios are meant to represent a spectrum of potential investment levels.

We do not have a recommended scenario, nor are we asking you to choose from the scenarios presented.

Through this conversation, we would like to better understand your business needs and preferences to inform our 5-year Distribution Investment Plan.

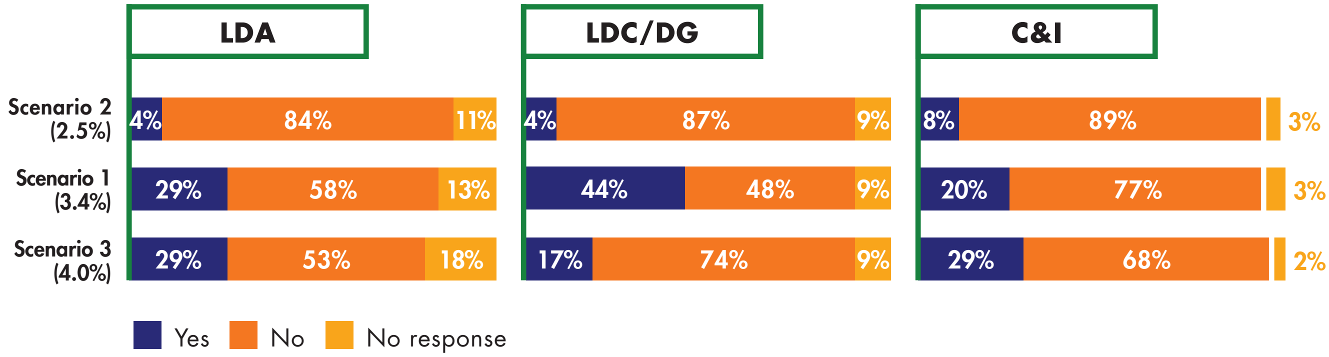




Overall, the majority of Large Customers are not willing to accept any of the rate impacts proposed in the illustrative examples (ranging from 2.5% - 4.0% on the distribution delivery rate). As shown in the chart, the vast majority of customers will not accept a rate increase (2.5% on the distribution rate delivery) where reliability declines. Customers are more likely to accept the larger rate impacts of 3.4% or 4.0% on the distribution delivery rate where reliability is at least maintained or improved. As shown in the qualitative section that follows, customers take issue with the idea that they would be asked to pay more for worse service.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

WILLINGNESS TO ACCEPT INVESTMENT SCENARIOS

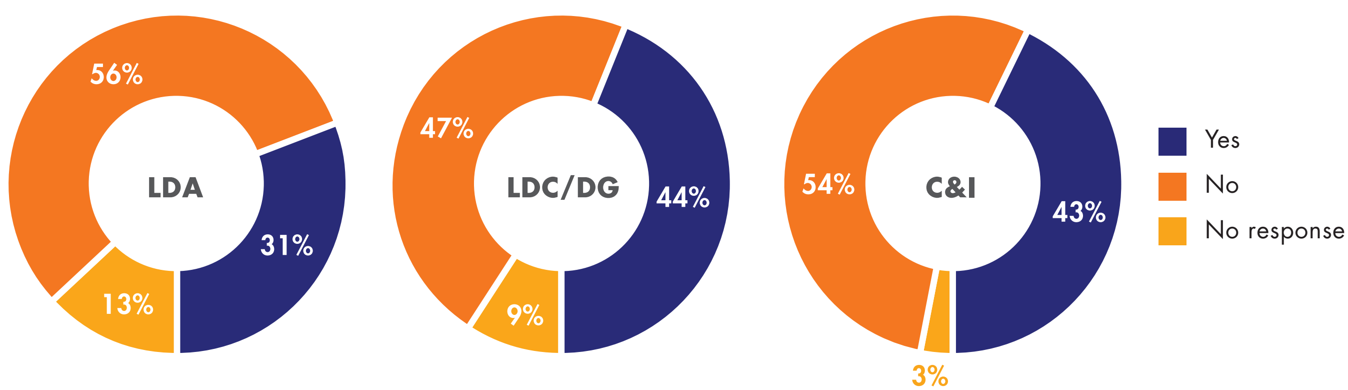


Q15. Would you be willing to accept a 2.5% distribution delivery rate increase where reliability and service performance declines (Scenario 2)? Base: LDA (n=45), LDC/DG (n23), C&I (n= 133) Q16. Would you be willing to accept a 3.4% distribution delivery rate increase where reliability and service performance remains the same as it is now (Scenario 1)? Base: LDA (n=45), LDC/DG (n23), C&I (n= 133). Q17. Would you be willing to accept a 4.0% distribution delivery rate increase where reliability and service performance improves (Scenario 3)? Note that for the online workbook, this was a 4.1% distribution delivery rate increase. Base: LDA (n=45), LDC/DG (n23), C&I (n= 133).

As part of the customer engagement, Large Customers were asked if they expect significantly higher or differentiated service than they receive today from Hydro One. After responding yes or no, there was a place for customers to explain their answer. The response was quite mixed. While a large minority of LDC/DG and C&I customers indicate yes, half or more say no.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

EXPECTATION OF SIGNIFICANTLY HIGHER OR DIFFERENTIATED SERVICE



"Service should be more highly scrutinized and held to a higher expectation. Does not always require more money."

"Service must be maintained and improved by offset internally by savings (just like in private business). Customers in LDA segment cannot keep absorbing huge, over inflation, cost increases."

"I [expect higher, differentiated service because] we are spending money to improve reliability in our manufacturing facilities."

"Our current service is quite good."

"If I will see an increase, I'd like to ensure there is "bang of my buck."

"Better balanced service at points near the end of the distribution grids, better communication of planned outages and better system of informing customers of anticipated return to power times."

"Our business should have a different rate plan since they operate only during peak hours."

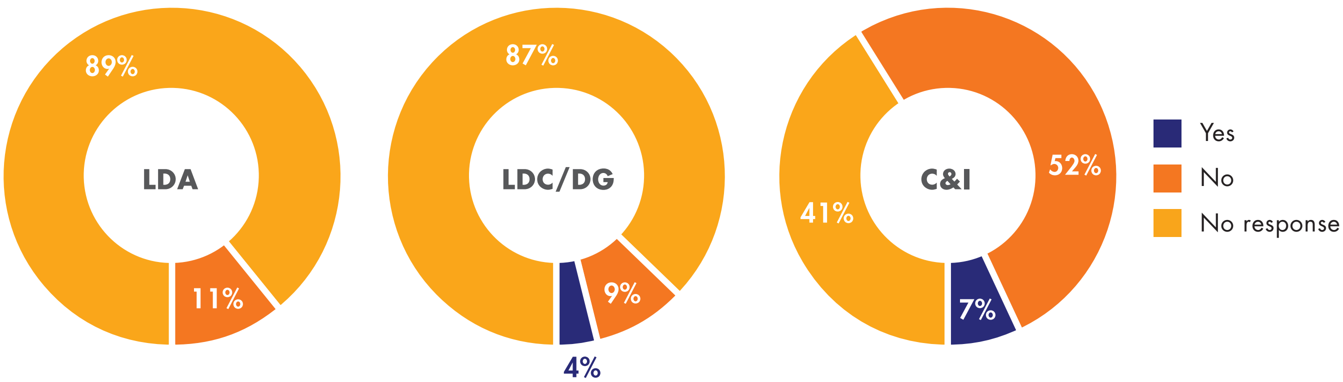
"I think everyone including Hydro One needs to learn how to do more with less just the like the rest of the market place."

Q18. Do you expect significantly higher or differentiated service than you have today from Hydro One? Yes, please explain/ No, please explain. Base: LDA (n=45) , LDC/DG (n23), C&I (n=133)

When asked if they would be willing to accept a distribution delivery rate increase greater than 4.0% in order to have customized reliability and/or service improvements, the majority of LDA and LDC/DG customers do not offer an opinion. More C&I customers answered the question with 7% indicating they would accept this increase for customized improvements.

ONLINE WORKBOOK/ WORKSHOP SURVEY BOOKLET

WILLINGNESS TO ACCEPT A RATE INCREASE ABOVE 4.0% FOR CUSTOMIZED IMPROVEMENTS?



"Power outages have a significant impact on our business. Any small extra investment to protect against this would be positive."

"We are continuously managing improvements at our facilities with little increases in our budgets so we believe Hydro One should as well."

"I don't fully understand 'customized' reliability."

"I feel the rate can be reduced with better usage of the existing assets."

"No. We are installing generators in the next few weeks and are going to be completely or almost completely eliminating our hydro use as a result of skyrocketing costs."

"Our live animals need constant heat, food, and water thus, having customized service that could guarantee perfect service would be ideal."

"We really need more detail but in principle it could put the cost where there is benefit."

Q19. Would you be willing to accept a distribution delivery rate increase greater than 4.0% in order to have customized reliability and/or service improvements? Yes, please explain/No, please explain. Base: LDA (n=45), LDC/DG (n23), C&I (n=133). Note: for the online workbook, this was a Rate Increase Above 4.1%.

FACILITATED, IN-PERSON WORKSHOPS

As noted in the Customer Engagement Methodology section of this report, the Workshop sessions were conducted with LDA, LDC/DG and C&I customers. The Workshops sought to serve Hydro One's customer goals of educating customers, and allowing for a two-way dialogue to have customer questions immediately answered. Hydro One was responsible for sending out the invitations as well as the follow-up, reminders and other communication outreach with a broad cross-section of its Large Customers for the Online Workbook. Hydro One's efforts to invite and encourage as many of these customers as possible to the in-person sessions has been documented.

A total of nine Workshop sessions were conducted in seven locations across Ontario involving 103 Large Customers and 129 participants. The locations were chosen by Hydro One in collaboration with Ipsos based on what would be the most convenient and accessible for customers.

The feedback provided across the Workshop sessions has been organized into six themes.

THEME #1: COST

SUMMARY

While most customers recognize the need for investments in Hydro One's aging infrastructure and distribution system, the majority of participants across the Large Customer Workshops do not accept a rate increase of any size, whether reliability remains the same or improves.

IMPACT OF ELECTRICITY COSTS

The rising/high cost of electricity in Ontario emerged as a theme of great interest and concern throughout the Workshops. For some Large Customers, they stated that the continued rise in electricity prices is a direct threat to the viability and competitiveness of their businesses. It is an expense that is one of or the highest after labour. As well, it is perceived as being higher than in other jurisdictions and participants have observed anecdotally that business is being lost to these other regions as a result — for example, manufacturing plants in Ontario have closed and moved to the United States and Mexico.

"How can a business afford to pay more? We are paying the most in North America. More increases [are] driving business to the US."

For a few participants, natural gas is an alternative energy source which is considered to be more reasonably priced and one participant stated that his organization is considering making a permanent switch to natural gas should the cost of electricity rise again.

"If we get a wee bit more [of an] increase, we will move, go off grid, very close. That's the bottom line. I only have to switch the switch. If you're hooked up on natural gas between 8 and 12 cents. We're very close."

UNDERSTANDING ELECTRICITY COSTS

Clarification was provided on the breakdown of costs and line items on customers' bills and this generated a large amount of discussion about each aspect of an electricity bill. While it was explained that Hydro One only makes a profit on the transmission and distribution delivery charges, and that other charges are pass-through only, participants were eager to share their thoughts and opinions on all line items.

As it relates to electricity conservation efforts, participants were incredulous that they are encouraged to conserve energy, only to have commodity prices rise to offset this, when load in Ontario is lower than expected. Although it was clarified they would still see savings in terms of reduced quantity, participants were nevertheless discouraged and dis-incentivized from trying to conserve energy as a result.

"The OEB did us all a big disservice by the last rate increase. We didn't use enough electricity, and that is why our rates are going up. We're trying to sell to our [LDC] customers that conservation is good: if you conserve, you'll save money. And then the regulator turns around now the rates are going up."

Several participants expressed their frustration with the fluctuating amount of the Global Adjustment charge each month. The lack of predictability makes budgeting and planning extremely difficult. The fluctuation can be very high, as much as tens of thousands of dollars each month, and participants questioned the reasons for this.

"Just looked at my electricity bill last month, the price was around $1,400, the Global Adjustment was $21,000. So that was pretty significant."

The Debt Retirement Charge was also mentioned by participants as being a source of dissatisfaction and confusion. One business participant stated she has heard several times over the years that the charge would be coming off the bill — which it hasn't. In general, customers are resentful that ratepayers are responsible for paying the Debt Retirement Charge, and point out that in any other business, paying off debt by raising prices would not be an option.

"The debt retirement [is] completely ridiculous, we all have our own business here. You know what happens if your business has too much cost and no income, you go broke."

Variations in distribution charges by Rate Class were brought up at times throughout the Workshops and clarification was provided as to how rate classes are determined. A few participants in northern Ontario indicated that their delivery charge exceeds their commodity costs and expressed their confusion and frustration over this.

"We got our hydro bill, $500 electricity, delivery charge was $1,500. That's the biggest issue I think all of us are having...Three times to deliver to the same pole standing there now for 20 years."

IMPACT OF PRIVATIZATION AND ROLE OF GOVERNMENT

Some participants made organic mentions of their belief that privatization would have a positive impact on Hydro One and ultimately ratepayers, as it would result in increased accountability of the organization, and in decision-making based on financial prudency.

"I'm really happy that Hydro [One] is privatized more and more, I think like any government organization just giving out money left right and centre, and not looking at costs, cause they never had to."

One participant stated his strong belief that the government should not have any influence on the electricity sector, and that prices should be subject to a user-driven open market, as with natural gas.

"Just get it completely out of the government's hands, right from top to bottom the whole way through."

Other participants stated their concern with privatization creating a conflict between shareholders and ratepayers, and pointed out the contradiction of Hydro One being both financially beholden to shareholders, as well as being accountable to ratepayers.

"The shareholder's interest is to make money, if you're the only game in town to go to my transmission for, I'm not sure that reliability is the shareholder's mind as being profitable."

COST EFFICIENCIES

Participants repeatedly inquired in all markets about efficiencies in operational and maintenance costs — and asked if Hydro One could improve in these areas in order to save money and re-invest in capital expenditures, instead of raising rates.

"…talking about a distribution delivery rate impact, revenue requirement, those include administration costs, when you're talking about improving performance, a lot of things in that mix, today [is about] only reliability and we don't know anything about cost efficiencies in a lot of other areas."

"Would have liked to see some slides on what Hydro One is doing internally to identify opportunities to create operational efficiencies and reduce costs internal to the organization."

"Efficiencies are not mentioned and need to be part of the consideration. Final scenarios need to include efficiency input."

"Look for ways to find the revenue needed within Hydro One BEFORE you increase rates for customers. Cut pay 5–10% for anyone over $100k. Show costs (budget)."

There were concerns both that Hydro One is mismanaging the funds it currently receives, and/or that funds were being misdirected into corporate needs such as promotions, salaries and payouts, instead of focusing on good customer service and reliability for its customers.

"…three million dollar payout, paying a president is not keeping [the] system reliable, not the best investment moving forward."

Customers expressed interest in seeing further details on the historical and current efficacy of maintenance programs, and capital expenditures already spent on improvements. They inquired as to whether Hydro One is using best practices and technological innovations in their maintenance and asset management. A few customers challenged the expenditure cost related to specific line items, while others stated they needed more information in order to gauge if the expenditures are prudent.

"…you've got $500M capital side, $450M on the operating side, these seem like awfully high numbers to the return on what investment is, the cost of maintaining is at the sacrifice of moving forward. Is there a plan to reduce these operating costs over time…$150M for vegetation management seems awfully high…looking for cost savings on those particular [items] not directly related to distribution itself."

With regard to OM&A costs, a few participants are of the belief that there should be a beneficial curve over time with an increase in capital improvements. That is, once assets have been replaced and would in theory require less maintenance, participants would like to know if there is benefit over time/in the long-term to OM&A costs that could eventually be passed onto customers in the form of lower rates. They wanted to know if there is a formula that can be used to calculate this.

"Investment dollars related to improving service levels is out of perspective, $60M to $1,250M to maintain more focus on improvement will reduce maintenance costs. Repair vs replace analysis — spending more to repair when replace will improve maintenance costs."

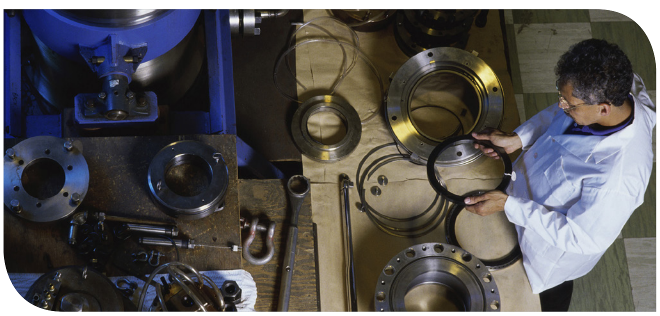
SCENARIO FEEDBACK AND RATE INCREASES

Rate increases are difficult for many customers to accept as they have serious concerns and numerous questions about Hydro One's operational efficiency, its ability to effectively manage costs, and its corporate integrity.

Some participants stated that it is difficult to know which scenarios they would accept in the absence of more detailed information.

"It's really difficult to answer this, because I don't know what's happening with the money that you receive now. So I can't say it's being well managed, give us 2.5% more and have declining performance. 3.4% to maintain. 4.0%. Why are those the only options?"

"Without seeing benchmarks without knowing if Hydro One is as efficient as it should be…another 2.5% or 3.5% to keep things as they are. Would like to see the study, even with the 2.5% increase in expenditures, reliability is going to decline. There had to be a major study would like to see that before I vote."



DECLINING SCENARIO ($3.3B CAPEX, $2.95B OM&A, 2.5% RATE INCREASE)

The vast majority of Workshop participants indicated that they would not accept an increase in rates for declining performance.

"Another 2.5% increase and service will decline — that's scary. Declining service will only result in deteriorating service as time passes — this is not acceptable. Power is an essential service."

"None of our customers would accept a 2.5% increase in price for less product. Why should we?"

"…it is hard to take a price increase to experience declining performance. In this day and age it is unacceptable. This is a difficult scenario to answer."

A few participants stated that a Scenario depicting a rise in rates with a decline in performance is unacceptable, and that presenting the Scenario to customers as an option speaks negatively to issues within Hydro One's company culture.

"How can we see a rate increase of this magnitude in general, but particularly for decreasing service? Why are there seemingly no attempts to maintain service but to reduce YOUR operating costs?"

MAINTAIN ($3.52B CAPEX, $3.17B OM&A, 3.4% RATE INCREASE) AND IMPROVEMENT SCENARIOS ($3.52B CAPEX, $3.17M OM&A, 4.0% RATE INCREASE)

The majority of participants across the Workshops indicated they do not accept a rate increase of any size, whether reliability remains the same or improves. Many participants stated their belief that Hydro One could and should increase efficiencies and improve maintenance programs rather than raising rates. They are looking for more drilled-down, detailed historical and current information on capital sustainment and improvement expenditures, as well as OM&A expenditures. In the absence of these details, participants were unsure of Hydro One's ability to make prudent investment decisions, which in turn made them skeptical of the company's ability to make good decisions as it relates to future investments.

"Investment scenarios are good in principle. However, [these] need to be funded by offsetting savings in other areas. LDA are already taxed significantly and increases between 2.5–4% are hard to accept. Combined with Global Adjustment increases, hard to stay cost competitive to U.S. and Mexico manufacturing sites."

"I think Hydro One needs to figure out how to deliver better service by maintaining their costs like the rest of the businesses have to."

Those in the minority who supported a rate increase would like to see a tangible improvement in reliability, including power quality. Their need for reliability outweighs their concerns about a rate increase. One participant indicated that based on his rate class he would support an even bigger rate increase.

"I would support extra customer costs as long as there is a benefit to the end user, e.g. reliability."

"I guess reliability is about quality of power. We want it all the time and we don't want bumps, we want quality. If we get that we're 100% satisfied, we'll likely bitch a little less about paying for it."

"I think those [scenarios] will be significant to increase reliability and much needed for quality performance and would be beneficial to all customers."

"If my bill is $100K a month, 2% category — so that's $2,000 a month. If I'm in the 2% distribution category, it's 2% of 25 which is like nothing. So the answer's pretty easy for us."

One participant expressed his concern with the proposed pacing of investments, as five years seems like a short period of time to be remedying it entirely.

"Can you spread it over a longer period of time…[it has been] 60 or 70 years [but are you] trying to solve it overnight. Look forward for 10, 15, 20, 30 years — do a proper study with life cycles and all the other components and spread out the capital costs over a greater period of years. "

THEME #2: CONSISTENCY

SUMMARY

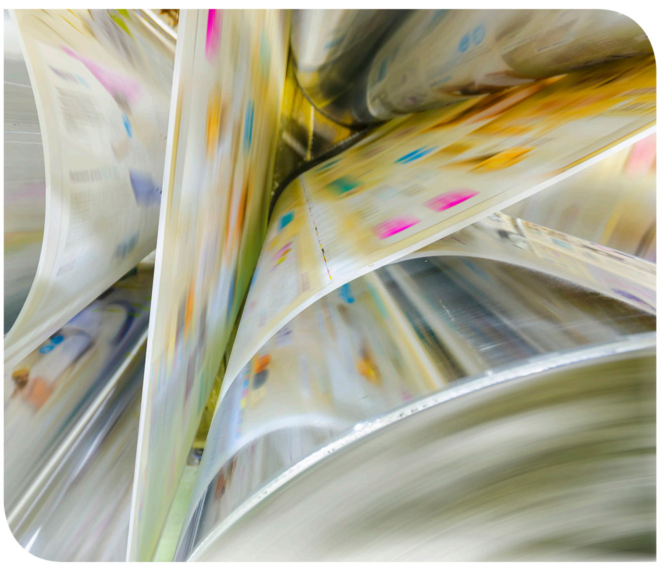
Power quality emerged as being the reliability issue of most concern to participants in the Large Customer Workshops. It was mentioned as being a significant and pressing priority for many customers in all markets.

Dips or spikes in voltage, brownouts, and interruptions of only a few seconds all have the same negative impacts as longer interruptions. Consequently, several participants throughout the customer engagement process challenged the fact that interruptions lasting less than one minute are not being tracked by Hydro One.

"Need to measure and benchmark type of interruptions. Complete outage is one issue, but surges and spikes are an impact on LDAs that use sensitive equipment."

"Need to be able to detect momentary outages. Just as much of an issue as prolonged outages."

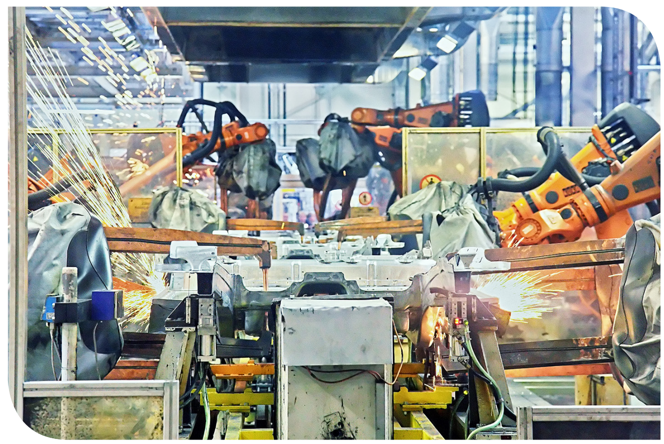
"Monitor outages [of] less than one minute or [allow us to] report bumps to Hydro [One]."



IMPACTS OF POOR POWER QUALITY AND RELIABILITY

The consequences of the impacts due to poor power quality were discussed in detail by participants. These include:

- Lost productivity
- Equipment failure — both temporary, and permanent
- Labour impacts — i.e., the uncertainty of sending workers home or keeping them at the facility
- Health and safety issues
- Financial impacts
- For LDCs, the whole municipality is without power
- Installing backup generation
- Technology / IT impacts



"Severely [impacted]. Food processes involving baking and cooking. Work in progress must be discarded and the line sanitized resulting in extra cost and lost production, i.e., $1,000/minute downtime including time to restart, one minute outage could result in 180 minutes of downtime."

"The 40 per year interruptions are shutting down our assets for one to two hours (even a blip of 100 sec). Annual loss of production $1.2 million."

"In our industry a one minute interruption results in a one to two hour downtown to reset pumps, fans, etc. and then there is cleanup [of] slime, rocks."

"Some are merely seconds but cause hours of downtime. Equipment loss, production loss. Morale issues in employees."

"Lost power in a whole town which is approximately 5–10 thousand customers."

"Has required the installation of a backup generator at major facilities (5)."

"Large cost due to downtime of highly automated and computerized systems."

"Safety risk due to sudden stoppage of processes that generate heat and cannot be sequentially shut-down and cooled. A recent outage cause a fire at our facility."

Participants were mostly unaware that Hydro One relies on its customers to give them feedback and information about power quality incidents. When it was mentioned that it is possible to have Hydro One help customers with their internal power quality capabilities and issues, this suggestion was of great interest.

CURRENT ASSET MANAGEMENT

Most participants in the Workshops recognized the need for continued investment in the system in order to maintain and improve assets and reliability. The current level of investments to maintain and improve reliability and service — as outlined in the presentation — made sense to most customers.

"It makes sense to monitor the current assets based on their expected service life and replace, as needed. It's important to replace aging equipment regularly to avoid having complete system failure, or having to replace all on emergency basis."

"I'm glad to hear that Hydro One performs sort of test/diagnosis on assets that are beyond their useful life prior to decide any needs of investment, optimizing this way budget and resources."

"Absolutely important to maintain and replace equipment as end of useful life approaches. Also good to hear that some high performing equipment may be operated beyond useful life to achieve balance in capital dollars spent."

Based on the information provided during the presentation, some customers expressed their concern as to the current condition of assets. They questioned whether Hydro One is maintaining and improving the system at a pace that mitigates the risk posed by poor asset conditions. The number of poles and stations approaching or beyond their service life were of particular concern. In spite of clarification around condition and not age being the main replacement consideration, these participants were still dismayed by the quantity of older assets.

"Why is the infrastructure so aged? [Has there been] improper spending of capital in the past."

FUTURE ASSET MANAGEMENT AND IMPROVEMENT

Planning and preparation of the grid for future needs was actively debated during the customer engagements. Participants had mixed reaction to the notion of proactively anticipating and building infrastructure now, as opposed to responding to needs as they arise. Additionally, they were divided as to whether the associated costs should be through a rate increase to all ratepayers, versus having only those who benefit directly pay for these changes.

Those participants who supported proactively preparing the grid believe it is important for Hydro One to effectively manage the grid as new technologies and power sources emerge. Some participants stated that it is Hydro One's responsibility to both proactively plan for, and include in their investment plans, items that take future needs and growth of the grid into account.

"To me it's not just about 10 kW and Tesla, [it is] having some grid management benefit as well."

"We're a producer and a user, certainly strengthening the grid is a key concern, to be able to supply, also the smart grid would add efficiency to that…increasing capacity from our perspective is important, and the efficiencies you get out of a smart grid system."

Those who are opposed to proactively preparing the grid state that this is a low priority area that should be of concern only to those who are directly benefiting, or as the need arises in the future. There were also concerns cited that any new technology implemented would fail entirely or not add value.

"My concern is [that we say] rah rah with technology, [and then] rush ahead with very expensive technology [which is] not doing the job."

Several participants stated their belief that underground lines would be a more economical and/or reliable method than overhead lines.

"When are you going to think about putting lines underground…nowadays you have good machinery and equipment to drill in even though it goes five feet down, wouldn't it be smart to start doing that?"

It was clarified by Hydro One that underground lines cost four to ten times more over the life of the line to both install and maintain, and as such, is currently considered cost prohibitive. As well, they are not more reliable than overhead lines, as they are subject to damage and decay. It was further clarified that subdivisions who installed underground lines did so as this was mandated by municipalities. The cost associated with the underground lines was then charged to homeowners by developers through the cost of the new home.

Participants inquired about use of alternate materials for poles other than wood, as well as condition testing for poles, and it was clarified that pilot programs are in place for composite poles, and that a benchmarking study has been commissioned by Hydro One for pole replacement.

REGIONAL CONCERNS

Regional reliability concerns were brought up as being of particular interest to some participants. For those in the Muskoka area, they were concerned about reliability issues caused by the dense forestry in their region, and questioned why trees in their area are not more proactively trimmed. For those in the northern markets, they expressed their concern that capital investments would be focused on areas of greater population density, i.e., in southern Ontario, and that they would not see the benefits of improved reliability. As such, they stated that they would like to see a detailed capital plan that included investments and benefits specific to the north. In general, participants also indicated an interest in seeing more region-specific investment details, to better understand reliability performance in their area of the province.

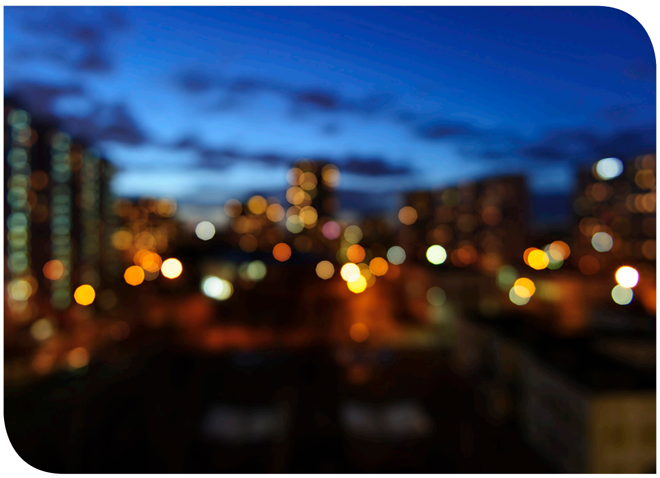
"Breakdown of historical CAPEX spent across Ontario. Are the 84% rural customers receiving proper allocation of CAPEX? Northern ON/Southern ON CAPEX breakdown."

"…province-wide management and cost per capita is not aligned. Popul[ation] in Southern Ontario is higher; more infrastructure repair is done there; rural should have a greater focus."

THEME #3: CUSTOMER SERVICE

SUMMARY

For most LDA/LDC customers, they stated that customer service is generally satisfactory. However, for many C&I customers as well as some LDA/LDCs, customer service from Hydro One is an area in need of significant improvement.



SATISFACTION WITH SERVICE

C&I participants who struggle with service cite a number of issues:

- Not having a dedicated account person or contact. They are reliant on publicly available information or the Ontario Grid Control Centre in the event of an outage, and call the number on their bill in order to have ask questions or have issues addressed.
- When calling the call centre, they mention being passed around from one person or department to another on the phone and often not receiving a satisfactory answer to their questions or resolution on their issues.
- The process of resolving issues can take an excessive amount of time — months or years, if at all.
- Receiving rebates can also take a long time.
- Bills and information on planned outages are sent to a corporate head office, instead of employees on the ground who need the information for planning and budgeting.
- Being unable to receive trustworthy advice. For example, whether or not participating in an energy-saving program is worth the risk.
- Making web meeting appointments with Hydro One employees who do not show up.
- Navigating complicated and time-consuming application processes for incentives and programs.

"…every time we deal with someone, it's someone different…They pass it down the line, [but] who do I contact, it's frustrating. Hydro [One] has a lot of different divisions, and I understand that, but one's not talking to another."

"…on several occasion of reaching out to Hydro One, either emails went unreturned or twice we set up meetings with our President and Vice-President and the gentlemen just never showed up for the teleconferences…"

"Normally I get [the bills] four months later, what good is that to me four months later. As these bills in larger corporate end up with some accountant as opposed to the people trying to run it."

BILLING

In general, participants were looking for two key elements on their bills: accuracy and clarity.

Some participants spoke of receiving estimated bills instead of those based on actual meter readings. They are puzzled as to why this is necessary, and object to paying a Hydro One employee to read meters if the bills are based on estimates.

"We have a couple of times that we haven't received bills regularly and I've called to discover that our bills were being reviewed and redone. This took up to 6 months then we had an extremely large bill that we had to negotiate payment arrangements for."

A few participants also mentioned challenges with consolidating bills if one company is receiving multiple bills for its different buildings/meters/ locations. This process was long, complicated, and difficult to resolve for these participants.

"From our perspective specifically attempting to get consolidated bills, has been brutal."

Several participants indicated that they find their bills confusing or the information provided is incomplete, and wished to receive clarity around charges. The ability to see information separate from the bill — either through an insert, or online — were also mentioned as being of interest. One participant indicated they have not been able to receive a satisfactory explanation of their bill from Hydro One.

"The one line that's not on the bill that should be, what the cost per kW hour is. The total cost…100 lines on this bill, nothing telling me [what the cost per kW hour is] — unless I do a lot of work to find it."

"Do you have the ability to further clarify that bill separately, we find it very confusing to understand it. Is there a way for you to clarify, do you have the ability to do that, [for example through] an insert?"

A few participants mentioned challenges around billing related to capital work fulfilled by Hydro One. One customer was unclear as to why it was necessary to pay in advance for capital work, with another receiving a bill for capital work months after the work was complete.

"…Hydro One is the only contractor I have to pay upfront before they do anything — design and implementation — [they] generally do a good job, [but they're] the only guys to pay upfront. Why is that?"

THEME #4: CONNECTIONS AND CAPACITY

SUMMARY

Customers in certain regions and industries state that a lack of sufficient power capacity is a hindrance to their ability to grow their businesses, that the process of applying for more capacity with Hydro One and the OEB is protracted and unsatisfactory, and that the rules and regulations around adding capacity through the beneficiary payment system are confusing.

CONNECTING NEW CUSTOMERS

Hydro One clarified that it is mandated by the OEB to connect any customer wishing to be connected to the distribution system. The rules around the associated costs were explained in detail, with some participants observing that they found the system confusing. A few participants stated their belief that the utility should be responsible for additional capacity as it helps industry and businesses create jobs and be more competitive in Ontario, while others stated their belief that only those who benefit directly should be paying for new connections.

"The other part is expansion which doesn't seem like you have the capital dollars to build things in rural areas. If the province believes about stimulating and getting people to build things, and they're gonna be partners, then there has to be cash."

"If someone wants to build a gold mine in the middle of nowhere, then is it our responsibility to pay for their power line for this gold mine or is it the gold mine's responsibility to bring the gold mine in…for a gold mine do we need to pay for power lines so there can be a gold mine there."

Hydro One clarified that under the beneficiary payment system, the cost of the connection over a period of 25 years is calculated and if Hydro One is able to recover their costs over that period, the beneficiary does not need to pay any out-of-pocket costs. Should another load customer connect to that same line, the original customer would receive a rebate. A few participants indicated that these costs are prohibitive to expansion. One customer expressed concern that their company is not able to increase load quickly enough to take advantage of the incentive. Furthermore, there is poor communication between customers, municipalities, and utilities — with one customer expanding their business within a municipality, only to discover there isn't power capacity to support its needs.

"We don't use it all at once, our growth is gradually coming up, are we going to hit that max that we have to hit by 2016, are they going to take [the incentive] away from us?"

"[The expense] is not communicated properly to the municipalities, because I meet with the municipality and say, I want to build the plant, do I have everything I need including utilities. Answer? No problem. My building's built, [then you] discover you're not going to get the power you need unless you bring it to you [by paying for it]…I find that really strange."

PROVIDING ADDITIONAL CAPACITY

Several participants stated their urgent need for additional power capacity in their region/industry and this was generally cited as being a highly unsatisfactory area. Participants expressed frustration that expansion in their regions has been extremely slow, with one participant stating that their region has been waiting for 20 years for additional power. One participant mentioned that his organization's application for additional power capacity has not been reviewed by Hydro One after five years. Participants also expressed frustration at the OEB's policy of only meeting current needs, versus planning for capacity expansion.

"Areas designated for industrial development have insufficient utility support and this will stop or slow growth. More needs to be spent on providing necessary services at competitive costs."

"…I think you're limited by the OEB that is ineffective in my opinion. For everything you gotta go back and ask for their permission and they only give you they have a view of 24 hours in terms of forecast, allow this, tomorrow another request and then we'll allow something else for the day after, that process takes nine months, you can imagine the automatic lag as a result of the process…"

A few participants expressed a desire to be more involved in the regulatory and rate filling process. They had concerns about the timeliness of the process to address their power needs, and wanted to actively engage in order to have their voices and concerns directly heard by the OEB, and not just through the customer engagement process.

"…do we have to direct our attention someplace else instead of Hydro One?...Can we help you, we're talking about billions of dollars every year, hundreds if not thousands of jobs going away if not being reduced because of this [lack of power capacity]. How can we help [Hydro One]."

RENEWABLE ENERGY

Participants were polarized as to their opinions on the role of renewable energy in the future of the grid: who would benefit from additional renewable sources, to what degree Hydro One should socialize costs, and to what degree Hydro One should set up/support infrastructure for both large-scale and individual renewable generators.

Some participants expressed skepticism as to the benefits of renewable energy, particularly in the context of power being sold to the U.S. at a loss. The success of renewable sources in adding value to the grid was also debated, with participants asking questions and expressing skepticism as to their benefit. They are reluctant to adopt renewable green energy sources if it means higher rates/prices or less reliable power. In their view, green energy should be used in areas where lines are expensive or difficult to run, and renewable energy generators should not receive an incentive at the expense of ratepayers.

"Why are we investing in infrastructure to connect green energy when we are currently dumping excess power."

"…I'm all for green power as far as the environment, but when it comes to cost it's hugely expensive…I don't agree the price we're paying for solar and wind…put them where it makes sense, where there's issues with the lines, rather than randomly dropping them where people don't need or want them."

The perceived advantages and drawbacks of microgrids, and of having consumers and small generators send power back to the grid, were also discussed. A few participants expressed their dissatisfaction with line loss charges for generators adding power back to the grid.

"Line loss as it relates to people who are supplying their own power…Hydro One will give a credit back to the individuals for producing their own power, but then they charge a line loss charge on that credit…you're being penalized by Hydro One for your own power."

EXPORTING POWER

The sale of electricity at a loss to the U.S. also emerged as a topic of discussion during some of the Large Customer Workshops. Hydro One explained some of the technical and economic considerations involved, including the role of contracts with renewable generators. It was further clarified that this is an area outside of Hydro One's control. Participants expressed concern and dismay that this is happening when rate increases are being considered. In one Workshop, participants from the greenhouse industry indicated their strong interest in using this excess energy to meet their needs, as they require lighting for their greenhouses overnight.

"We are going to take electricity. When you're paying to get rid of it, we're going to take it. We use a crazy amount of electricity right now [summer months], but the real load is from November till March and mostly at night. We're your best customer, we're your best friend and you've ignored us."

ROLE OF THE UTILITY IN SOCIALIZING COSTS OF OTHER POWER NEEDS

There was a debate among participants about whether or not it is within Hydro One's mandate to provide specialized power quality service to a small group of customers, or if their role is as a basic socialized service to all its customers. Some participants stated that ratepayers should not be paying for energy storage and renewables that benefit only a few.

"With a small percentage of customers that might have a specialized need, their tolerances are much higher or stringent than what they would be for the average customer. Really the bill should be on them. It shouldn't be socialized. Why should I pay for someone else's special need?"

Specific aspects of what costs should be socialized through a rate increase to all ratepayers, versus having only those who benefit pay for these improvements, were debated throughout the in-person sessions. Some indicated their belief that improvements benefit the overall economy of Ontario, with others stating that only those who benefit directly should be responsible for paying.

THEME #5: CREDIBILITY

SUMMARY

Hydro One's reputation including areas such as perceptions of workers, concerns with salaries and wages, and overall efficacy as an organization were discussed during the Workshops. As well, clarifying the role of regulators and the effect of a low understanding or misinformation as to what is regulated versus what are decisions by Hydro One were also explored during the Workshops.

ROLE OF REGULATORS

Many participants were unaware of the OEB and the IESO, and their respective roles in the energy sector. For C&I participants in particular, there was a lower understanding of the various players in the energy sector.

Numerous points of clarification were made throughout the customer engagements as to what is mandated and controlled by the respective regulators, including:

OEB:

- Information contained on electricity bills
- Commodity price of electricity as a pass-through charge only, and Hydro One's inability to profit from it
- Capacity expansion
- Beneficiary payment system for capital work
- Non-advisory customer service role – that is, that Customer Service representatives are disallowed from providing advice on the phone as to whether or not an external program is in the customer's best interest.

IESO:

- Global Adjustment
- Environmental incentive programs
- Contracts for generators, including renewable sources

As Hydro One is the customer-facing entity responsible for billing, customers' perceptions are negatively impacted by all aspects of the electricity bill and any poor perceptions of the sector in general.

"General public…paints you all [in the sector] with the same brush."

PERCEPTIONS OF HYDRO ONE AND ITS WORKERS

There was commentary made by some participants on perceptions of Hydro One and its workers. There were mentions of seeing Hydro One workers in coffee shops during working hours, or having too many workers show up to a job. These perceptions of poor productivity and management are particularly difficult to accept with the perception that electricity costs in Ontario are very high and a threat to the economic well-being of the province's businesses.

"People notice these things because it's hurting on the bill. If people felt like they were paying something that was fair, they wouldn't notice it, [but] because people feel like they're being bled dry those things are going to stand out."

They also challenged the idea of efficiency based on their own observations and experiences of working with Hydro One — in terms of customer service, or having negative perceptions of workers and management based on their own interactions.

"Those kinds of things don't make us feel happy like customers [such as] very elaborate vehicles, in the olden days [they] used a ladder, now there's four bucket trucks. That's what I see as we drive through… [I] know it's for safety don't get me wrong, [it's] just a matter of the perception."

COMPANY CULTURE

Some participants expressed their concern that Hydro One was presenting a scenario with a rate increase which depicted declining performance. A few stated their belief that this was an unacceptable approach that spoke negatively to Hydro One's culture. Others stated their belief that the information being presented was to justify a distribution rate increase by Hydro One.

Comparisons were made unfavourably to private companies in several ways: private companies deliver a better product for less money by finding efficiencies, and by being innovative without raising prices. Many participants pointed out that electricity rates have continued to climb for many years and their belief is that there is no end in sight as it relates to rate increases, thanks to poor management and decision-making by Hydro One.

"[Hydro One] is a little bit different than other companies, in that there's little incentive to get better. In the end if you can cover your costs by increasing the rate."

"…seems like Hydro One always has the luxury of asking for more. The reality is all the companies, we can't just add 10% to the end product, you guys it's always give a bit more, get a bit more, get a bit more, a bit more becomes a lot at the end of the line…The rate is out of control, doesn't seem like it's going to be better in the near future."

SHAREHOLDERS VS. RATEPAYERS

Participants inquired about Hydro One's profits, and it was clarified that Hydro One has a regulated rate of return on equity and that they generally come close to making this return. Based on this information, a few participants expressed deep concern and dismay that profits were given to shareholders, and not returned to the company in order make capital improvements, and/or reduce costs for ratepayers. They stated that this is a situation unique to Hydro One, and that other companies would not have the same option available to them — instead, they would put profits back into the company in order to maintain or reduce prices for their end-users, or profits are put back into making a better product. One participant called the approach of giving profits to shareholders while raising rates for ratepayers unethical.

"…you want to take another 2.5% to maintain your profit to shareholders. It's unethical."

"…should Hydro [One] take some of their money and maintain business? Yeah they should, every other company that's publicly or privately owned has to do that to maintain business."

ACCOUNTABILITY AND TRANSPARENCY

The themes of accountability and transparency for Hydro One emerged throughout the in-person sessions. Participants indicated concern at a lack of both, and a desire to see Hydro One undergo an organizational transformation. This would positively impact customers by being more informed, providing reassurance of reliability and service, and responsible stewardship of rates paid in the form of operational and maintenance efficiencies and prudent decision-making in future capital investment planning. While many customers cited deep concerns around rate increases, many were also open and receptive to understanding how and why Hydro One uses its funds.

"…when you have a monopoly sometimes wages can get out of line, and money can get spent without true accountability. It all starts with how transparent you want to be."

THEME #6: COMMUNICATION

SUMMARY

For many, a communication disconnect with Hydro One exacerbates grievous situations during an outage. There is much uncertainty around when power will be restored. The information provided is often inaccurate. There is low awareness of any available tools or resources, such as Hydro One's outage app.

COMMUNICATION DURING OUTAGES

Numerous participants throughout all customer engagement methods stated they would like to experience better communication during outages. The majority call in to the number on their bills or the OGCC, with a few checking Hydro One's website. Most stated that the information they receive or view is inaccurate, and this is a source of frustration in particular for businesses — many of whom stated that communication is an area in which Hydro One could help reduce the impact of outages. Participants indicated that they would like timely, accurate information on outages specific to their region or area.

"Better communication re: anticipated timing to restore power would help us with operational plans."

"Automated notification system to LDA accounts to quickly update, email or text type messages."

"Regional northwestern Ontario specific storm centre reporting with local knowledge."

ROLE OF UTILITY IN COST-SAVING STRATEGIES AND PROGRAMS

A few customers made organic mentions of positive experiences with energy/cost saving programs with Hydro One. One participant stated that he was unable to get recommendations or advice from Hydro One on external programs, which he found frustrating.

"…I'm taking advantage of a 50% audit program at our facilities…customers might benefit from knowing the programs out there."

"…called into the number on my bill, very helpful, introduced me to the portal, none of us had seen it until yesterday. It's brilliant. I got fantastic comparative by site, given me a very good understanding of the savings that we're generating. I would say, maybe little bit more awareness, a little section on the bill to tell me about this, a lot of people would really appreciate that. I thought it was fantastic."

"…why Hydro One can't give a clear answer and advice to people who are considering these options that come by e-mail telephone, clients say I didn't know anything about energy, this company sounds great but is it, if you phone Hydro One and ask you don't get an answer, you get a lot of talking around it."

For Large Customers eligible for cost-saving programs and incentives, awareness was generally low. For those who applied for these programs, the application process is frustrating and complicated, with one organization going so far as to hire an outside company to help them with the application process.

"…I was having coffee, talking to one guy [about] ERIP program, not knowing anything about it…they changed us to LED Lights, there was nobody ever knocked on [our] door here's what we can offer you. I was having coffee in the morning at a local restaurant when I found out about it."

"…when we did an energy audit a few years ago, my application this thick and had to re-submit three times, because it was missing a little piece of information."

CHANNELS

The means through which Hydro One can effectively communicate with its customers was discussed throughout the customer engagement process. Relevant information includes planned outages, rate increases, and service restoration.

Participants expressed interest in a number of different channels and some indicated that they would like to hear from/about Hydro One via multiple channels, including:

- Directly on the bill
- Bill inserts
- Texts
- For C&I customers a dedicated relationship with an account person, a local contact, or a dedicated business (non-residential) call centre line were all of interest.

GENERAL INFORMATION ON HYDRO ONE

While participants acknowledged that the information provided during the Workshops was helpful, in general, participants observed that there was insufficient detail provided. Many participants stated that in order to make decisions around which areas of investment would be of most benefit, as well as whether or not they would support an increase in rates, they would require more comprehensive information including specific costs, historical data, and cost efficiencies. This in turn would lead to trust that Hydro One is focused on efficiency and productivity.

More information on the company, its operations, and its future plans were viewed as being key to positively impacting perceptions of Hydro One — with the customer engagement process being a good start.

CONCLUSIONS

Ipsos has grouped the collective feedback from customers on their needs and preferences into six key themes based on its review and analysis of customer research and the views expressed by customers during the customer engagement process.

1. COST

Cost is the top priority for R&SB customers and among the top priorities for Large Customers. In the context of potentially degrading reliability, a majority of R&SB customer will accept the proposed rate increase to maintain the current levels of service. Although most don't like rate increases, they accept that they are necessary to avoid declining service. Large Customers are more focused on reliability and in some cases less sensitive to cost, but are unwilling to accept the illustrative rate impacts without greater understanding and assurances that Hydro One will improve its operational efficiencies.

2. QUALITY

Reliability and quality electricity service emerged as the second most important priority. For Large Customers improving power quality is as important as reducing the number and duration of sustained outages. Their preference is for Hydro One to invest in improving power quality ahead of several other service improvements. For R&SB customers, in the context of rate impacts, their preference is for Hydro One to maintain the current number and duration of outages rather than improve it.

3. CUSTOMER SERVICE

Customer satisfaction varies substantially across distribution customer segments. Of them, C&I customers appear to be the most under-served and express this in many ways. The feedback suggests that Hydro One should consider establishing a similar key account system as it does for LDA customers so that C&I customers can have their inquiries resolved more promptly and with greater ease.

4. CONNECTIONS AND CAPACITY

Several Large Customers expressed a desire for greater capacity and would like Hydro One to more strongly advocate and support their requests. There was some debate around whether or not the costs of capacity-building should be borne exclusively by the customers or whether in some circumstances the cost should be socialized across Hydro One's ratepayers.

5. CREDIBILITY

It is evident that many customers have negative perceptions of Hydro One that are not necessarily based on their service experience. In part these perceptions are influenced by the fact that customers have a low awareness of Hydro One's role in the energy sector and ultimately their bill. For some negative views of the industry and/or government bleed-into their views of Hydro One. For others their perceptions are influenced by what they believe to be an excessively large and inefficient organization. Large Customers expressed a desire for greater transparency of the organization's operations and administration including OM&A investments.

6. COMMUNICATION

Large Customers indicated they would like to see Hydro One improve their communication with customers during outages. They would like to Hydro One to provide more accurate estimates of when power will be restored.

APPENDIX FOR HYDRO ONE DISTRIBUTION REPORT

GENERAL PUBLIC SURVEY COMMUNICATIONS

We'd like your feedback.

We're planning tomorrow's electricity system and we'd like to hear what matters most to our customers.

MPP OFFICE CONSTITUENT POSTERS
EMAIL

Dear MPPs and Constituency Staff,

Hydro One is currently in the process of developing a five-year plan for Ontario's electricity distribution system. As part of this process, we are conducting a customer survey, which will inform Hydro One's plans to meet the future needs of our 1.3 million customers in Ontario and help ensure their voices are heard.

Hydro One would like your feedback and your constituents' feedback regarding the level and type of service that you expect from Hydro One. This feedback will be included in the process that the Ontario Energy Board uses to set electricity delivery rates for our customers.

In the next few days you will be receiving a small poster to each of your constituency offices, which will invite members of your community to participate in a confidential customer survey.

We would appreciate it if, given the room, you could post this notice on your office wall for the next few weeks, as we are hoping to hear from as many customers as possible.

Thank you in advance. Please let us know if you have any questions or concerns.

Warm regards,

Simmer Anand

NEWS RELEASE

Hydro One Asks its Customers for Feedback on Five-Year Distribution System Plan; Customers' Input Will Help Shape Future Investments

TORONTO, June 3, 2016 - Hydro One announced today that it has launched a province-wide consultation process to seek input from its customers on the development of a five-year electricity distribution plan. The plan will help shape the company's future investments in Hydro One's electricity distribution system, so the Company can deliver its mandate to provide safe, reliable and efficient electricity.

The purpose of the consultation process is to understand whether Hydro One customer needs are being met by the current system and which types of reliability and service improvements customers value most.

"All of our distribution customers will have the opportunity to provide their input through workshops, focus groups, surveys, and/or one-on-one discussions," said Rob Quail, Vice President, Customer Service, Hydro One. "We look forward to hearing our customers' views concerning the future service levels they expect from our electricity delivery system."

In addition to meeting customers' needs, the plan will also address:

- aging electricity infrastructure; some of which was built in the 1950s and 1960s;
- responding to power outages and repairing the electricity system, particularly following significant weather events;
- power quality and reliability enhancements; and,
- offering new products, se vices and web-enabled tools to make it easier for customers to do business with Hydro One.

All feedback concerning customer needs and preferences will in turn influence plans that the Company will submit to the Ontario Energy Board. The Ontario Energy Board will examine the plan in a full public hearing and will ultimately determine new rates to be paid by Hydro One's customers between 2018 and 2022.

To learn more about Hydro One's five-year plan and to complete the online survey, please visit **www.ipsosresearch.com/hydroone**.

Quick Facts

- Hydro One's distribution rates are approved by the Ontario Energy Board. The rate setting process is open and transparent, with opportunities for public participation.
- Hydro One must submit evidence to demonstrate the amount of funding it needs to safely and reliably distribute electricity to its customers.

- Distribution costs are contained in the delivery line of the bill. On average, electricity distribution services account for 29 per cent of a Hydro One bill covers the costs of electricity distribution services. This is the amount collected by Hydro One to pay for the costs of poles, lines, transformers and other equipment that makes electricity delivery possible.
- Hydro One is the largest electricity distribution company in Ontario, providing electricity to 25 per cent of the province – more than 1.3 million customers.
- With the largest and most vast service territory, Hydro One is the only utility in Ontario with more distribution poles (1.6 M) than customers, Hydro One is planning tomorrow's electricity distribution system for its 1.3 million customers and would like to hear what matters most to its customers.

About the Company

Hydro One Limited is Ontario's largest electricity transmission and distribution company headquartered in Toronto, Ontario with approximately $24.3 billion in assets and 2015 revenues of over $6.5 billion. The company delivers electricity safely and reliably to over 1.3 million customers across the province of Ontario, and to large industrial customers and municipal utilities. Hydro One owns and operates Ontario's approximately 29,000 km circuit high-voltage transmission network and an approximately 123,000 circuit km primary low-voltage distribution network. Hydro One Limited common shares are listed on the Toronto Stock Exchange (TSX: H).

PRESS RELEASE 2

NEWS RELEASE

If You Were in Charge of Hydro One Would You Change How Spending is Allocated?

Customer Consultation on Five-Year Distribution System Plan

Toronto – June 21, 2016 – Hydro One is asking its customers to complete an online survey at **www.ipsosresearch.com/hydroone**. The purpose of the survey is to obtain customer input necessary to shape future investments in electricity assets as the Company begins to build a five-year plan for its electricity distribution system. Hydro One is encouraging all customers to have their say in its investment plan by completing the survey by July 18, 2016.

All feedback concerning customer needs and preferences will influence plans the Company will submit to the Ontario Energy Board. The Ontario Energy Board will examine the plan in a full public hearing and will ultimately determine new distribution rates for Hydro One's customers between 2018 and 2022.

"The purpose of the consultation process is to understand whether Hydro One customer needs are being met and which types of reliability and service improvements customers value most," said Warren Lister, VP, Customer Service, Hydro One. "Our customers' point of view is critical to this process and we hope they will take a few minutes to have their say."

In addition to the survey, the Company's distribution customers have had the opportunity to provide their input through workshops, focus groups, and/or one-on-one discussions.

In addition to meeting customers' needs, the plan will address:

- aging electricity infrastructure; some of which was built in the 1950s and 1960s;
- responding to power outages and repairing the electricity system, particularly following significant weather events;
- power quality and reliability enhancements; and,
- offering new products, services and web-enabled tools to make it easier for customers to do business with Hydro One.

Quick Facts

- Hydro One's distribution rates are approved by the Ontario Energy Board. The rate setting process is open and transparent, with opportunities for public participation.
- Hydro One must submit evidence to demonstrate the financial investment needed to distribute safe and reliable electricity to its customers.
- Distribution costs are contained in the delivery line of the bill. On average, electricity distribution services account for 29 per cent of a Hydro One bill. This amount is collected by Hydro One to pay for poles, lines, transformers and other equipment that makes electricity delivery possible.

- Hydro One is the largest electricity distribution company in Ontario, providing electricity to 25 per cent of the province – more than 1.3 million customers.
- With the largest and most vast service territory, Hydro One is the only utility in Ontario with more distribution poles (1.6 M) than customers.

[Introduction]

Customer Segment	CSEG	
Residential Customers	1	n=400
Seasonal Customers	2	n=100
Business	3	n=200
First Nation	4	n=300

Good morning/afternoon/evening. This is ——- calling from IPSOS, a public opinion research firm. We are conducting a survey of [CSEG=1: Residential customers CSEG=2: seasonal customers CSEG=3: business customers CSEG =4 Residential customers] on behalf of Hydro One. This call may be recorded or monitored for quality assurance purposes. (IF NECESSARY) Would you be so kind as to answer some questions? All of your answers will be kept strictly confidential.

Bonjour/Bonsoir. Je m'appelle __________ et je vous téléphone de la part d'IPSOS, une entreprise de recherche sur l'opinion publique. Nous menons un sondage [CSEG = 1 : clients résidentiels CSEG = 2 : clients saisonniers CSEG = 3 : clients commerciaux CSEG = 4 : clients résidentiels] au nom d'Hydro One. Cet appel peut être enregistré ou surveillé aux fins d'assurance de la qualité. (AU BESOIN) Auriez-vous la gentillesse de répondre à quelques questions? Toutes vos réponses resteront strictement confidentielles.

(IF NECESSARY) The survey will last about 15 to 20 minutes and I think you will find it quite interesting.

(AU BESOIN) Le sondage durera de 15 à 20 minutes et je crois que vous le trouverez assez intéressant.

(IF YES) Thank you.

(SI LA RÉPONSE EST OUI) Merci.

(IF NO) When is a better time for me to call back? (SCHEDULE APPOINTMENT)

MAIN QUESTIONNAIRE

[Only read CSEG=2]

For this survey please think about your seasonal property even if Hydro One is also your electricity provider on your primary residence.

[LIRE CE TEXTE SEULEMENT SI CSEG=2]

Pour ce sondage, veuillez penser à votre résidence secondaire même si Hydro One est également le fournisseur d'électricité de votre résidence principale.

[READ TO ALL]

As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices.

Comme vous le savez peut-être, Hydro One construit et entretient des lignes électriques, des pylônes et des poteaux, fournit de l'électricité en toute sécurité, relève les compteurs, calcule vos frais, répond à vos appels, intervient lors d'interruptions de service et élague les arbres et la broussaille autour des lignes électriques. Hydro One ne produit pas d'électricité ni ne fixe le prix de l'électricité.

1. Please think about Hydro One as I have just described it to you. How satisfied are you with HYDRO ONE overall? Would you say you are… ? (READ LIST, RECORD ONE ONLY)

Veuillez penser à Hydro One comme je viens de vous décrire. Dans quelle mesure êtes-vous satisfait(e) d'Hydro One dans son ensemble? Diriez-vous que vous êtes…?

Very satisfied
Très satisfait(e)
Somewhat satisfied
Plutôt satisfait(e)
Neither satisfied nor dissatisfied
Ni satisfait(e) ni insatisfait(e)
Somewhat dissatisfied
Plutôt insatisfait(e)
Or, very dissatisfied
Ou , très insatisfait(e)

2. Is there anything in particular that Hydro One can do to improve its service to you? (ACCEPT ALL MENTIONS)

Y a-t-il quelque chose en particulier qu'Hydro One peut faire pour améliorer le service qu'elle vous offre? (ACCEPTER TOUTES LES RÉPONSES)

3. Please listen carefully as I will be reading out a rough breakdown of what Hydro One currently spends on each of its major electricity distribution investments and will be asking your opinion about the breakdown. Hydro One currently spends…

(READ AND RANDOMIZE)

Veuillez écouter attentivement, car je donnerai le pourcentage approximatif des dépenses que Hydro One fait dans divers aspects de la distribution d'électricité. Je vous demanderai ensuite ce que vous pensez de cette répartition. Des sommes qu'elle investit, Hydro One en consacre...

(LIRE ET CHANGER L'ORDRE DES ÉNONCÉS D'UN RÉPONDANT À L'AUTRE)

60% on Keeping the system reliable (such as replacing worn out equipment, trimming trees to keep power lines clear)

60 % à l'entretien du réseau pour garantir la fiabilité de ce dernier, notamment en remplaçant l'équipement usé et en taillant des arbres pour dégager les lignes électriques)

15% on Restoring power after an outage

15 % au rétablissement du service après une panne

15% on Customer service and billing (such as providing customer service through your phone or online, providing tools so you can manage your energy use, ensuring accurate and timely bills)

15 % au service à la clientèle et à la facturation (par exemple, offrir un service à la clientèle par téléphone ou en ligne, fournir des outils vous permettant de mieux gérer votre consommation d'énergie, établir des factures exactes et en temps opportun)

10% on Upgrading the system to connect new customers including those producing renewable energy or using energy storage

10 % à la modernisation du réseau afin de raccorder de nouveaux clients, notamment ceux qui produisent de l'énergie renouvelable ou ceux qui stockent de l'énergie

If you were in charge of Hydro One would you change how spending is allocated or would you keep it about the same as it is now?

Si vous étiez en charge d'Hydro One, modifierez-vous la répartition des dépenses ou la garderiez-vous telle qu'elle est maintenant?

Change
La modifierait
Keep the same
La garderait telle quelle
Don't know

[SI « MODIFIERAIT » DEMANDER Q4, AUTREMENT PASSER À Q5]

4. Of the 4 distribution investments you just heard, what percentage would you allocate to…?

Veuillez indiquer quel pourcentage des dépenses vous alloueriez à chacun des quatre aspects de la distribution d'électricité suivants.

(READ IN THE SAME ORDER USED IN Q3)

(LIRE DANS LE MÊME ORDRE QU'À LA Q3)

Keeping the system reliable (such as replacing worn out equipment, trimming trees to keep power lines clear)

Garantir la fiabilité du réseau, notamment en remplaçant l'équipement usé et en taillant des arbres pour dégager les lignes électriques)

Restoring power after an outage

Rétablir le service après une panne

Customer service and billing (such as providing customer service through your phone or online, providing tools so you can manage your energy use, ensuring accurate and timely bills)

Assurer le service à la clientèle et la facturation (par exemple, offrir un service à la clientèle par téléphone ou en ligne, fournir des outils vous permettant de mieux gérer votre consommation d'énergie, établir des factures exactes et en temps opportun)

Upgrading the system to connect new customers including those producing renewable energy or using energy storage

Moderniser le réseau afin de raccorder de nouveaux clients (par exemple, utiliser des sources d'énergie renouvelable et stocker de l'énergie)

[TOTAL MUST ADD TO 100% UNLESS DON'T KNOW OR REFUSED ANSWERED]

[LA SOMME DOIT ÊTRE ÉGAL À 100% SAUF S'IL/ELLE RÉPONDAIT « JE NE SAIS PAS/REFUSE DE RÉPONDRE ».]

5. Hydro One would like to better understand what is important to you as a [IF CSEG = 1, 2, OR 4: residential or seasonal customer / IF CSEG =3: business customer]. I am going to read Hydro One's major expenditures in pairs and for each pair please tell me which one is more important to you.

Hydro One aimerait mieux comprendre ce qui est important pour vous ENT TANT QUE [SI CSEG = 1, 2, OU 4: CLIENT RÉSIDENTIEL OU CLIENT SAISONNIER/ SI CSEG =3: CLIENT COMMERCIAL]. Je vais vous lire les dépenses majeures d'Hydro One par paire. Pour chacune, veuillez m'indiquer laquelle des deux dépenses est la plus importante pour vous.

Reducing the number of power outages through activities such as tree-trimming, replacing equipment

Réduire le nombre de pannes de courant grâce à des mesures comme tailler les arbres et remplacer l'équipement

Shortening the length of power outages though activities such as installing remote control devices

Réduire la durée des pannes de courant grâce à des mesures comme installer des appareils contrôlés à distance

Improving Customer service and billing (such as providing customer service through your phone or online, providing tools so you can manage your energy use, ensuring accurate and timely bills)

Améliorer le service à la clientèle et la facturation (par exemple, offrir un service à la clientèle par téléphone ou en ligne, fournir des outils vous permettant de mieux gérer votre consommation d'énergie, établir des factures exactes et en temps opportun)

Upgrading the system to connect new customers including those producing renewable energy or using energy storage such as wind, solar, and electric vehicles

Moderniser le réseau afin de raccorder de nouveaux clients, notamment ceux qui produisent de l'énergie renouvelable ou ceux qui stockent de l'énergie (par example, l'énergie éolienne, l'énergie solaire, et les véhicules électriques)

Keeping costs as low as possible

Garder les coûts aussi bas que possible

6. Is there anything else that is important to you that was not read out? (PROBE UP TO 2 TIMES)

Y a-t-il autre chose qui est important pour vous que je ne vous ai pas lu à voix haute? (RELANCER AU PLUS DEUX FOIS)

The next few questions are about your experience with power outages. Please think about your experience in terms of how frequently they occur and how long they last.

Les quelques questions suivantes portent sur les pannes de courant que vous avez subies. Veuillez réfléchir à la fréquence et à la durée des pannes.

7. A sustained power outage is one lasting at least 1 minute. How many sustained power outages did [IF CSEG = 1, 2, OR 4: you / IF CSEG =3: your business] experience in the past 12 months that you were not notified about in advance by Hydro One? Your best guess is fine.

Une panne de courant soutenue est une panne qui dure au moins une minute. Combien de pannes soutenues [SI CSEG = 1, 2, OU 4 : avez-vous / SI CSEG = 3 : votre entreprise a-t-elle] subies au cours des 12 derniers mois et à propos desquelles vous n'aviez pas été informé(e) à l'avance par Hydro One? Veuillez fournir la meilleure estimation.

[RECORD NUMERIC] [RANGE ZERO TO 99]

Improve customer service even if it results in an increase to customer bills

Améliorer le service à la clientèle, même si cela entraîne une augmentation des coûts pour les clients

Maintain the current level of customer service, which may result in a relatively modest increase to customer bills

Maintenir le niveau actuel de service à la clientèle, ce qui pourrait entraîner une augmentation relativement modique des coûts pour les clients

Allow for longer wait times and poorer billing accuracy in order to keep costs low.

Permettre les temps d'attente à augmenter et l'exactitude des factures à baisser, pour maintenir les coûts bas pour les clients

Don't know

Ne sait pas

16. In your view, when it comes to upgrades to the system to connect new customers including those producing renewable energy or energy storage, should Hydro One…. (READ LIST) (ACCEPT ONE RESPONSE)

À votre avis, lorsqu'il s'agit de moderniser le système pour raccorder de nouveaux clients, notamment ceux qui produisent de l'énergie renouvelable ou ceux qui stockent de l'énergie, Hydro One devrait-elle…? (LIRE LA LISTE. ACCEPTER UNE SEULE RÉPONSE.)

[ROTATE 1 TO 3 / 3 TO 1]

[ROTATE 1 TO 3 / 3 TO 1]

Upgrade its system to allow it to increase the number new customers more quickly even if it results in an increase to all customer bills

Moderniser le réseau, et ainsi augmenter plus rapidement le nombre de nouveaux clients, même si cela entraîne une augmentation des coûts pour l'ensemble des clients

Maintain its current system and connect renewable customers as quickly as it does now, which may result in a relatively modest increase to all customer bills

Maintenir le réseau actuel et raccorder les clients d'énergie renouvelable au même rythme qu'en ce moment, ce qui peut entraîner une augmentation relativement modique des coûts pour l'ensemble des clients

Allow a slowdown in Hydro One's ability to connect renewable energy customers, in order to keep costs low.

Permettre un ralentissement de la vitesse à laquelle Hydro One raccorde de nouveaux clients à des sources d'énergie renouvelable, pour maintenir les coûts bas pour les clients

Don't know

Ne sait pas

(INTERVIEWER TO READ SLOWLY)

(LIRE LENTEMENT.)

The percentages and equivalent dollar amounts that I am going to read out to you in the next few questions are estimates and are subject to change.

Les pourcentages et les montants équivalents en dollars que je vais vous lire dans les questions suivantes sont des estimations et sont susceptible d'être modifiés.

17. Hydro One has determined that in order to at least maintain the level of reliability and customer service it currently provides, a typical [IF CSEG = 1, 2 OR 4: residential or seasonal / IF CSEG =3: small business] customer's total monthly bill will need to increase by [IF CSEG = 1, 2 OR 4: 1.1% or the equivalent of $2.00 / IF CSEG =3: 1% or the equivalent of $5.2O.

Hydro One a déterminé que pour maintenir, au minimum, le niveau de la fiabilité et le service à la clientèle qu'elle offre actuellement, la facture mensuelle type [SI CSEG = 1, 2 ou 4 : d'un client résidentiel ou saisonnier / SI CSEG = 3 : d'une petite entreprise] devra augmenter de [SI CSEG = 1, 2 ou 4 : 1,1 % ou l'équivalent de 2,00 $ / SI CSEG = 3 : 1 % ou l'équivalent de 5,20 $].

This increase will be applied each year for the next 5 years. By the fifth year, a typical monthly bill will be roughly [IF RESIDENTIAL OR SEASONAL $10.00 / IF BUSINESS: $26.00] higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability and service to customers. The monthly bill could still increase for other reasons which are outside the control of Hydro One.

Cette augmentation sera appliquée chaque année pendant les cinq prochaines années. À la cinquième année, une facture mensuelle sera d'environ [SI CLIENT RÉSIDENTIEL OU SAISONNIER 10,00 $ / SI CLIENT COMMERCIAL : 26,00 $] plus élevée qu'elle ne l'est maintenant. Veuillez prendre note que cette augmentation reflète le coût de maintenir les niveaux de fiabilité et de service actuels. La facture mensuelle pourrait tout de même augmenter pour d'autres raisons qui sont hors du contrôle d'Hydro One.

Which of the following is closest to your point of view? (READ LIST) [ACCEPT ONE RESPONSE]

CONFIDENTIAL INFORMATION

In this presentation, "Hydro One" or "the Company" refers to Hydro One Networks Inc. and its affiliates, taken together as a whole.

Hydro One is providing the information contained in the following presentation on a confidential basis in order to solicit your feedback. The feedback from this customer consultation will be considered when making regulatory filings. Any information concerning Hydro One provided as part of this presentation should not be disclosed except as necessary within your corporation in order to provide meaningful feedback.

You should not trade in securities of Hydro One Limited or Hydro One Inc. based on any of the information contained within this presentation and should not use the information for any other purpose.

In this presentation, all amounts are in Canadian dollars, unless otherwise indicated. Any graphs, tables or other information in this presentation demonstrating the historical performance of Hydro One is intended only to illustrate past performance and is not necessarily indicative of future performance.

Forward-Looking Information

This presentation contains "forward-looking information" within the meaning of applicable Canadian securities laws. Forward-looking information in this presentation is based on current expectations, estimates, forecasts and projections about Hydro One's business and the industry in which Hydro One operates and includes beliefs of and assumptions made by management. Such statements include, but are not limited to: statements regarding how Hydro One can improve reliability and other aspects of customer service, including the status of various initiatives; the use of customer feedback from the consultation process and its impact on the Company's investment plans; statements regarding upcoming rate applications: and statements about monthly bill impacts.

Words such as "aim", "could", "would", "expect", "anticipate", "intend", "attempt", "may", "plan", "will", "believe", "seek", "estimate", "goal", "target", "project" and variations of such words and similar expressions are intended to identify such forward-looking information. These statements are not guarantees of future performance and involve assumptions and risks and uncertainties that are difficult to predict. Therefore, actual outcomes and results may differ materially from what is expressed, implied or forecasted in such forward-looking information. Hydro One does not intend, and it disclaims any obligation to update any forward-looking information, except as required by law.

The forward-looking information in this presentation is based on a variety of factors and assumptions. Actual results may differ materially from those predicted by such forward-looking information. While Hydro One does not know what impact any of these differences may have, Hydro One's business, results of operations and financial condition may be materially adversely affected if any such differences occur. Factors that could cause actual results or outcomes to differ materially from the results expressed or implied by forward-looking information are: the risk that previously granted regulatory approvals may be subsequently challenged, appealed or overturned; the risk of public opposition to and delays or denials of requisite approvals and accommodations for the Company's planned projects; the risk that the Company is not able to arrange sufficient cost-effective financing to fund capital expenditures; the risk that the Company may not be able to execute plans for capital projects necessary to maintain the performance of the Company's assets or to carry out projects in a timely manner; the risk that the Company's Board of Directors may not approve the projected expenditures; and the risk that the regulator may alter or deny approval for requested investments and recoverability in rates.

[IF THE RESPONDENT SELECTED MULTIPLE RESPONSES IN B AND ONE OF THE RESPONSES WAS BUSINESS, SHOW QI, ALL OTHERS PROCEED TO Q1]

I. You indicated that you would like to respond to the survey as both a residential/seasonal customer as well as a business customer. You will have the opportunity to go through the survey twice. For the first go around, would you prefer to complete the survey as a…

Residential /seasonal customer
Small business customer

[IF RESIDENTIAL/SEASONAL USE THAT MARKER FOR SURVEY, IF SELECT SMALL BUSINESS USE BUSINESS MARKER FOR SURVEY]

[BUSINESS 'For the first go around, please keep your organization's electricity services in mind, not your residential or seasonal electricity service.']

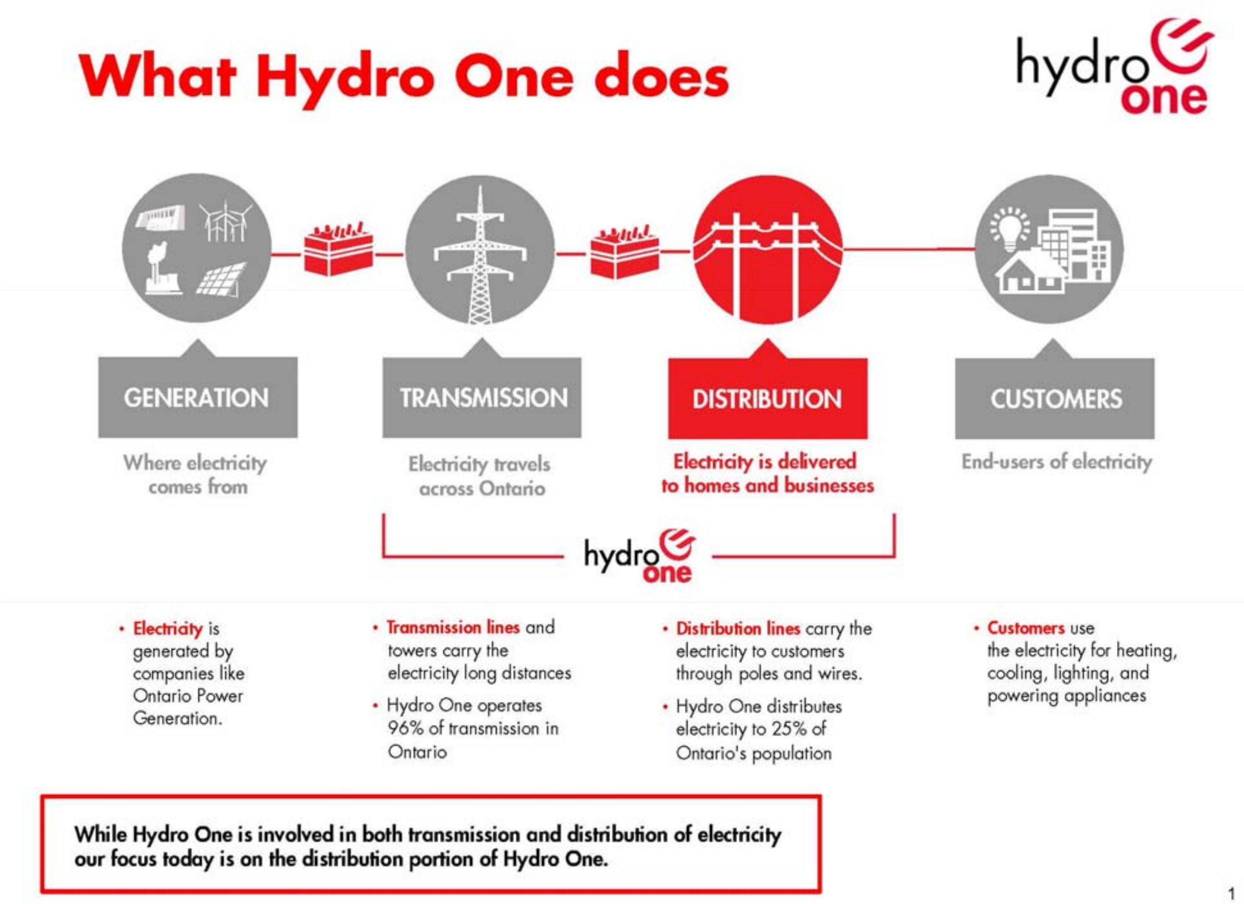
[RESIDENTIAL/SEASONAL 'For the first go around, please keep your residential or season property's electricity services in mind, not your organization's electricity service.']

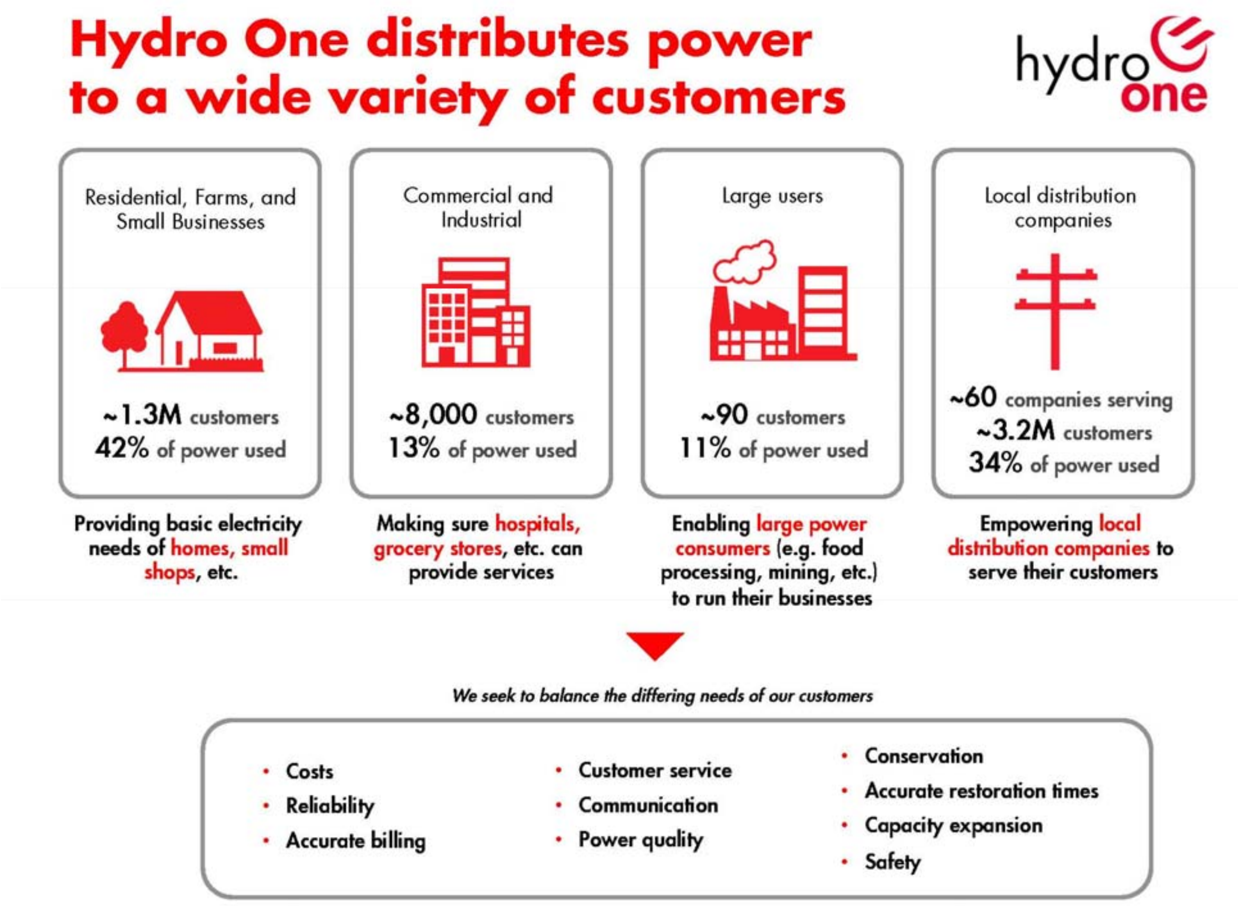
[Ask all]

We'll begin by showing you some information. Then we'll ask you some questions so we understand what you value most when it comes to the level and type of service that you expect from Hydro One.

Every utility in Ontario submits a rate application to the Ontario Energy Board. Hydro One's application will outline its plans and costs to achieve particular outcomes. It will be reviewed by the Ontario Energy Board and they will decide whether the plans are sensible and in customers' interests. The Ontario Energy Board determines what rates utilities are allowed to charge customers to recover the costs of these plans.

Hydro One is currently preparing their rate application and that's the reason why they're asking for their customers' opinions – to help inform the plans contained in this rate application. The application will explain the money that's required by Hydro One in order to maintain the safe and reliable distribution of electricity.





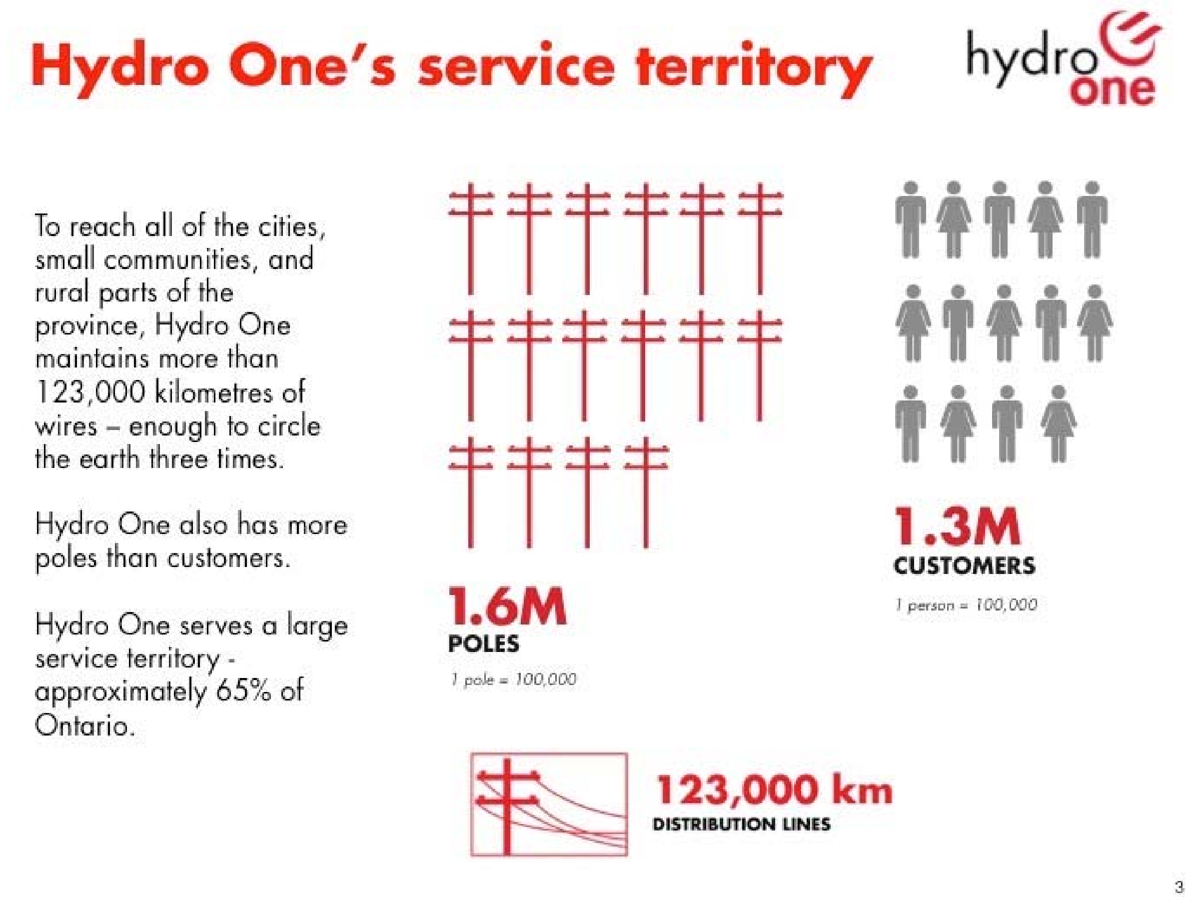
As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices.

1. How satisfied are you with Hydro One overall?

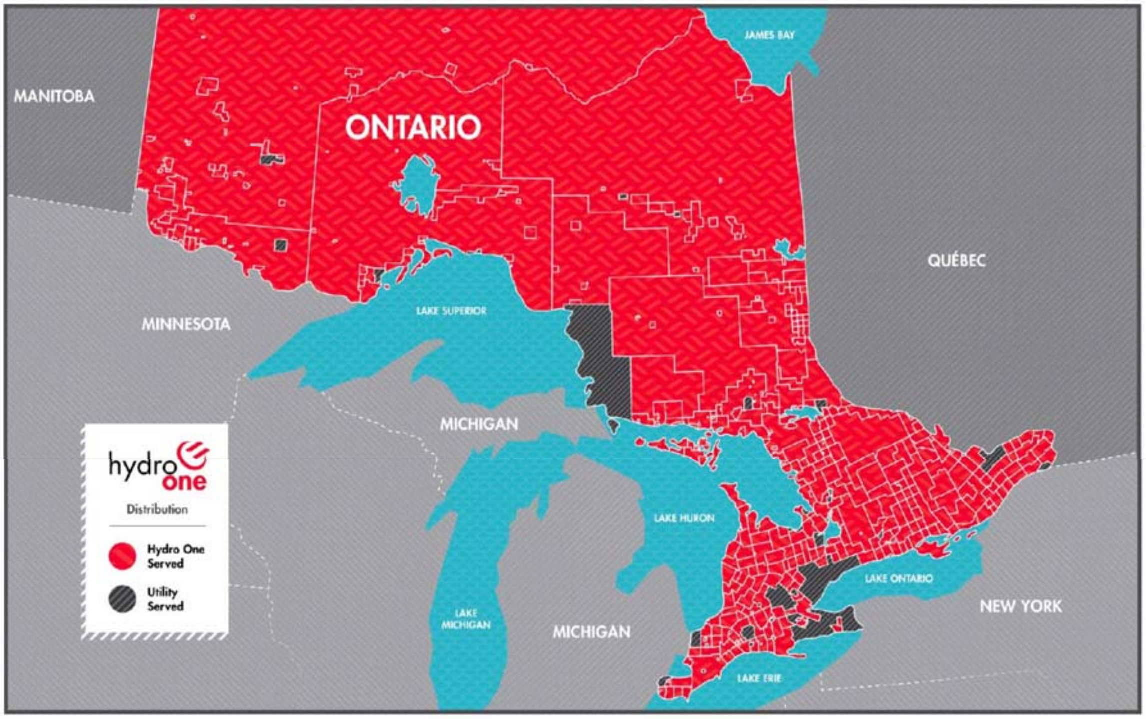
Very satisfied
Somewhat satisfied
Neither satisfied nor dissatisfied
Somewhat dissatisfied
Very dissatisfied

2. Is there anything in particular that Hydro One can do to improve its service to you?

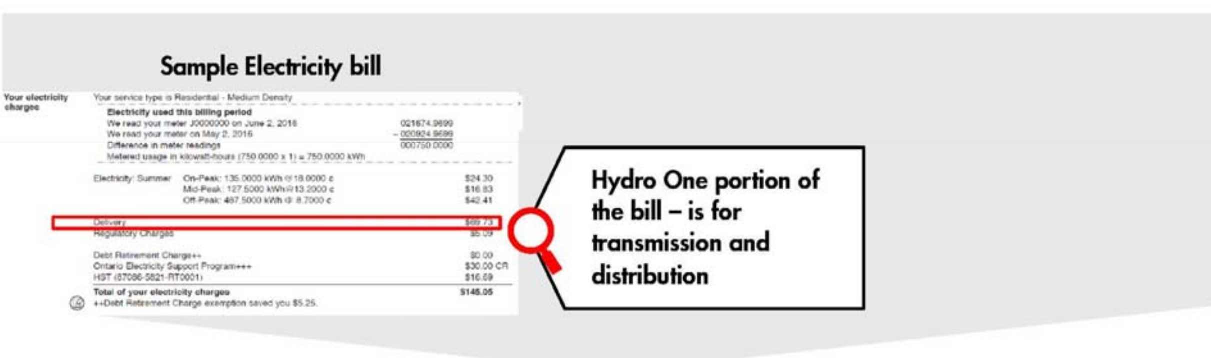
[Open-end]



Hydro One's service territory

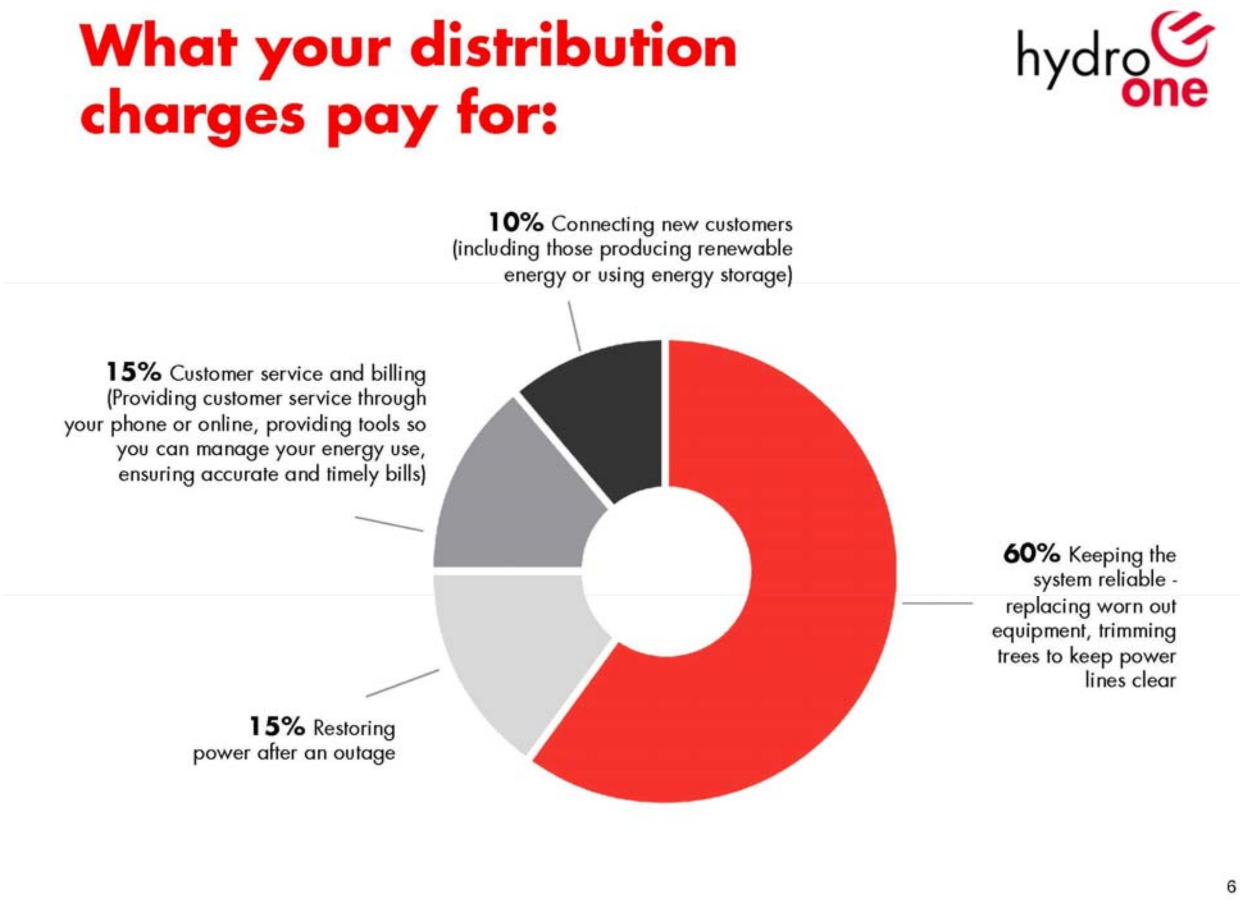


Sample Electricity Bill



The portion of the bill that goes directly to Hydro One is what you see on the delivery line of the bill. Most of this amount is for distribution.

The rest is collected by Hydro One on behalf of generators and other electricity entities.



3. **[Info screen]** The pie chart above shows a rough estimate of what Hydro One currently spends on each of its major electricity distribution investments.

   If you were in charge of Hydro One would you change how spending is allocated or would you keep it about the same as it now? [Single punch]

Change
Keep the same
Don’t know

[IF CHANGE ASK Q4, OTHERWISE SKIP TO Q5]

4. What percentage would you allocate to…?

[RANDOMIZE]
Keeping the system reliable (such as replacing worn out equipment, trimming trees to keep power lines clear)
Restoring power after an outage
Upgrading the system to connect new customers including those-producing renewable energy or using energy storage
Customer service and billing (such as providing customer service through your phone or online, providing tools so you can manage your energy use, ensuring accurate and timely bills)

5. Hydro One would like to better understand what is important to you as a [IF RESDIENTIAL/SEASONAL; residential or seasonal / IF SMALL BUSINESS: business customer. For each of the pairs below, please indicate which one is more important to you. [PAIRED CHOICE EXERCISE PROGRAMMING]

Reducing the number of power outages (through activities such as tree-trimming, replacing equipment)
Shortening the length of power outages (through activities such as installing remote control devices)
Improving customer service and billing such as providing customer service through your phone or online, providing tools so you can manage your energy use, ensuring accurate and timely bills)
Upgrading the system to connect new customers including those producing renewable energy sources and using energy storage (such as wind, solar, and electric vehicles)
Keeping costs as low as possible

6. Is there anything else that is important to you?
[Open-end]

The following few questions are about your experience with power outages. Please think about your experience in terms of how frequently they occur-and how long they last.

7. A sustained power outage is one lasting at least 1 minute. How many sustained power outages did [IF RESIDENTIAL/SEASONAL: you / IF BUSINESS: your business] experience in the past 12 months that you were not notified about in advance by Hydro One? Your best guess is fine. [Single punch]

None
Don't know/can't recall

[IF NONE, DON'T KNOW/CAN'T RECALL SKIP TO INSTRUCTION BEFORE Q13]

8. In general, when you think about how many power outages [IF RESIDENTIAL /SEASONAL: you / IF BUSINESS: your business] experienced over the last 12 months, how did it compare to your expectations? [Single punch]

Much better
Somewhat better
About what you expect
Somewhat worse
Much worse
Don't know

9. On average, how long did these unplanned outages last? Please answers in minutes. Your best guess is fine. [Single punch]

Don't know/can't recall

10. In general, when you think about the average length of the power outages [IF RESIDENTIAL/SEASONAL: you / IF BUSINESS: your business] experienced over the last 12 months, how did it compare to your expectations? [Single punch]

Much better

Somewhat better
About what you expect
Somewhat worse
Much worse
Don't know

[ASK Q11-Q12 TO SMALL BUSINESS ONLY]

11. Thinking about the power outages your business experienced in the past 12 months, would you say they were? [Single punch]

A major inconvenience
A minor inconvenience
No inconvenience at all
Don't know/recall

[IF MAJOR OR MINOR ASK Q12 OTHERWISE SKIP TO Q13]

12. How much, if any, would you say the outages you experienced in the past 12 months collectively cost your business? Please answer in whole dollars, do not include cents. [Single punch]

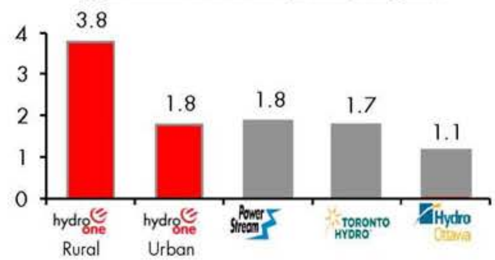
Don't know

Reliability explained

Reliability is measured in two ways - how many times the power goes out, and how long the power is off.

Hydro One trails peer utilities in Ontario on both metrics

An average rural Hydro One customer has about 4 outages per year. Urban customers experience about 2 outages per year.



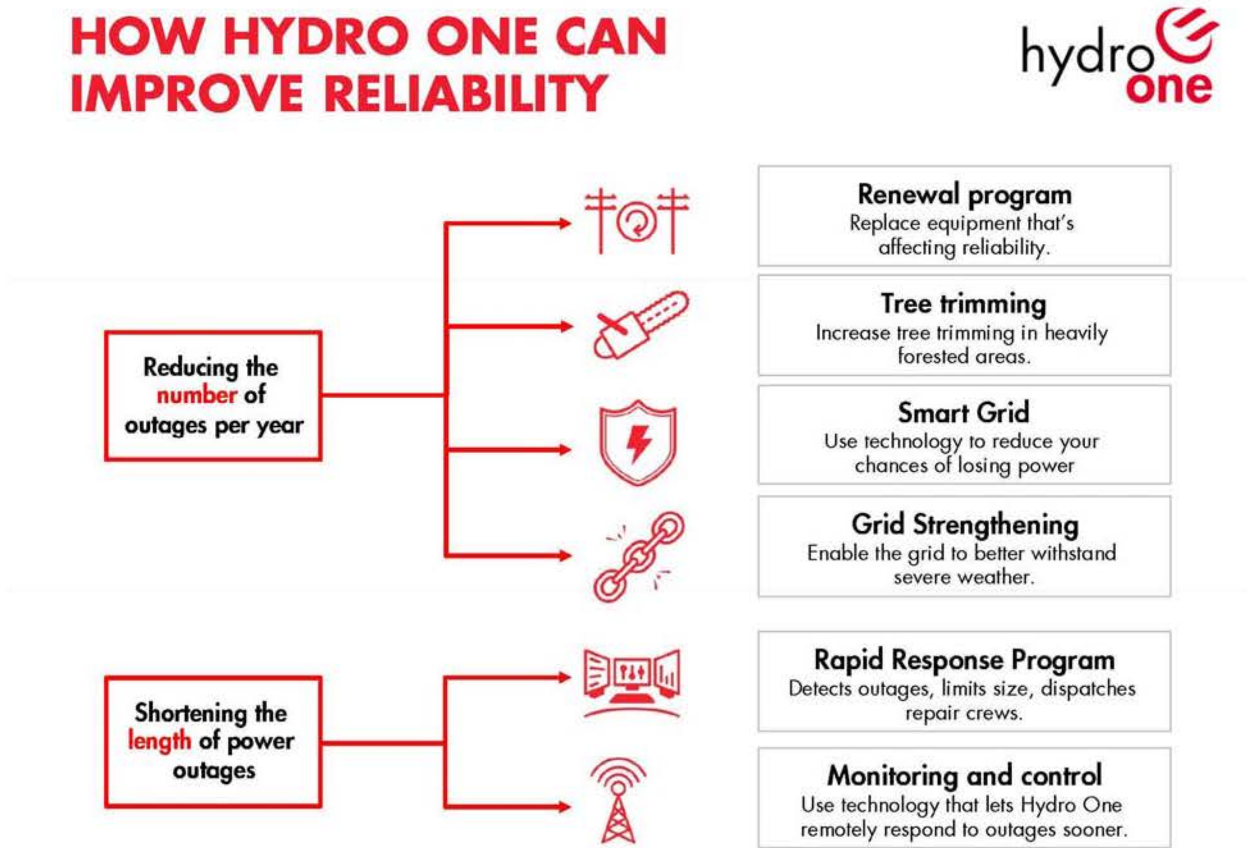
An average rural Hydro One customer's outage lasts about 4 hours. Urban customers' outage is about 3 hours.

1. Metrics for Hydro One based on average from 2013-2015; metrics for other distributors based on average from 2011-2013. Numbers below are approximate. Source: OEB distributor handbook, peer utility rate filings

WHAT CAUSES YOUR POWER TO GO OUT

Power outage causes (2013-2015)

Trees	**24%**	Trees fall on lines during storms.
Equipment failure	**24%**	Poles, transformers, lines failures can cause an outage.
Unconfirmed causes	**19%**	Sometimes Hydro One crews can't determine the exact cause of an outage.
Scheduled outages	**16%**	Occasionally, Hydro One needs to schedule power outages to safely replace or update equipment.
Loss of power supply	**12%**	Issues relating to the larger grid like damage to transmission lines.
Animal or vehicle damage to equipment	**5%**	Animal contacts with Hydro One's equipment and car accidents that damage poles.



KEEP Q13/Q14 TOGETHER AND KEEP Q15/Q16 TOGETHER BUT ROTATE THE ORDER OF THE SETS]

13. In your view, when it comes to the **average number of power outages** should Hydro One…. [select one one]

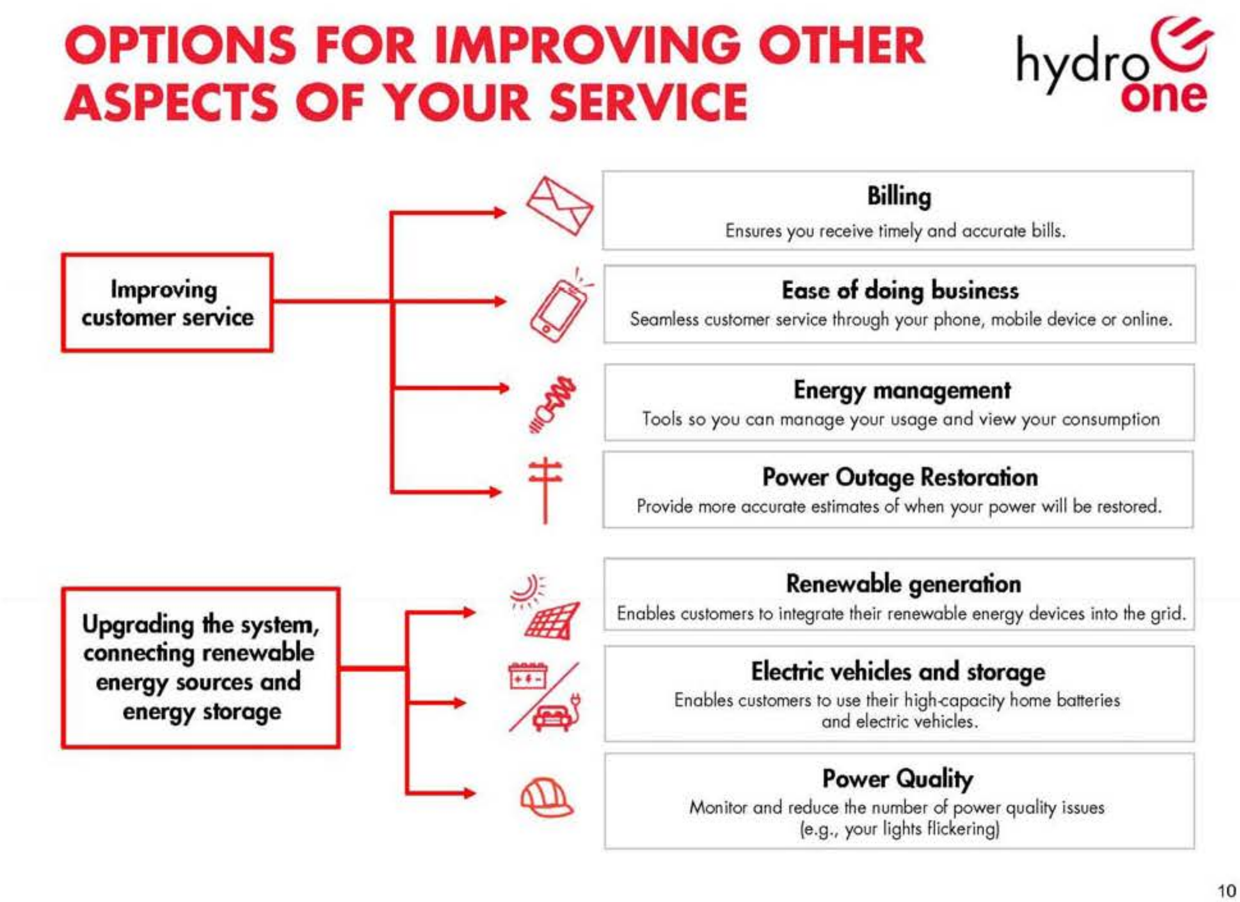
[ROTATE 1 TO 3 / 3 TO 1]

Reduce the number of power outages even if it results in an increase to customer bills
Maintain the current number of power outages, which may result in a relatively modest increase to customer bills
Allow the number of power outages to increase in order to keep costs low
Don't know

14. When it comes to the **average length of power outages**, should Hydro One…. [select one one]

[ROTATE 1 TO 3 / 3 TO 1]

Reduce the length of power outages even if it results in an increase to customer bills
Maintain the average length of power outages, which may result in a relatively modest increase to customer bills
Allow the average length of power outages to increase in order to keep costs low
Don't know



15. In your view, when it comes to **customer service (such as billing accuracy and answering customer questions)** should Hydro One…. [Select one only]

[ROTATE 1 TO 3 / 3 TO 1]

Improve customer service even if it results in an increase to customer bills
Maintain the current level of customer service, which may result in a relatively modest increase to customer bills
Allow for longer wait times and poorer billing accuracy in order to keep costs low
Don't know

16. In your view, when it **comes to upgrades to the system to connect new customers (including those producing renewable energy or energy storage)**, should Hydro One…. [select one only]

[ROTATE 1 TO 3 / 3 TO 1]

Upgrade its system to allow it to increase the number new customers more quickly even if it results in an increase to all customer bills
Maintain its current system and connect renewable customers as quickly as it does now, which may result in a relatively modest increase to all customer bills
Allow a slowdown in Hydro One's ability to connect renewable energy customers, in order to keep costs low
Don't know

Please read the following information carefully. Feel free to re-read the question more than once if necessary to provide a response. The percentage increases and equivalent dollar amounts shown in the next few questions are estimates and are subject to change.

17. **[Info screen]** Hydro One has determined that in order to **<u>at least maintain</u>** the level of reliability and customer service it currently provides, a typical [IF RESIDENTIAL/SEASONAL: residential / seasonal / IF BUSINESS: small business] customer's total monthly bill will need to increase by [IF RESIDENTIAL/SEASONAL: 1.1% or the equivalent of $2.00/ IF BUSINESS: 1% or the equivalent of $5.20].

    This increase will be applied each year for the next 5 years. By the fifth year, a typical monthly bill will be roughly [IF RESIDENTIAL OR SEASONAL $10.00 **/** IF BUSINESS: $26.00] higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability and service to customers. The monthly bill could still increase for other reasons which are outside the control of Hydro One.

Would you be willing to accept this increase to maintain the current level reliability and customer service across the electricity system? [Single punch]

The increase is reasonable and I would support it
I don't like it, but I think the increase is necessary
The increase is unreasonable and I would oppose it
Don't know

[ROTATE THE ORDER OF Q18 AND Q19]

18. Would you be willing to pay anything higher than [IF RESIDENTIAL/SEASONAL: $2.00 or about 1.1.% / IF BUSINESS: $ 5.2O or about 1%] more on your total monthly bill if it meant you would have better reliability than you have now? [Single punch]

Yes
Maybe
No
Don't know

19. Would you be willing to pay anything higher than [IF RESIDENTIAL/SEASONAL: : $2.00 or about 1.1.% / IF BUSINESS: $ 5.2O or about 1%] more on your total monthly bill if it meant you would have better customer service than you have now? [Single punch]

Yes
Maybe
No
Don't know

[IF RESIDENTIAL / SEASONAL ASK 20A. BUSINESS SKIP TO Q20B]

20A. Would you be willing to pay an additional [HALF OF RESPONDENTS SHOW $0.30 / OTHER HALF SHOW $0.60] per month over and above the $2.00 which would be approximately [SPLIT SAMPLE $2.30 /$2.60 more per month if it meant that Hydro One could **<u>reduce the number and length of future power outages by 10%</u>**? The increase would be applied annually for the next five years so that by the fifth year your monthly bill will be roughly [$11.50 / $13.00] higher than it is now.

Definitely would
Probably would
Probably would not
Definitely would not
Don't know

[Q20B SHOWN TO BUSINESS ONLY]

20B. Would you be willing to pay an additional [HALF OF RESPONDENT SHOW $0.80 / OTHER HALF SHOW $1.60] per month over and above the $5.20 which would be approximately [SPLIT SAMPLE $6.00 /$6.80 more per month if it meant that Hydro One could **<u>reduce the number and length of future power outages by 10%</u>**? The increase would be applied annually for the next five years so that by the fifth year your monthly bill will be roughly [$30.00 / $34.00] higher than it is now.

Definitely would
Probably would
Probably would not
Definitely would not
Don't know

Please answer a few more classification questions.

20. Which of the following best describes the area in which [IF RESIDENTIAL/SEASONAL: you live IF BUSINESS: you have your business]? [Single punch]

In a rural or country area or a reserve
In a small town of less than 2,000 people

In a small town of about 2,000 to less than 5,000 people
In a town of about 5,000 to 20,000 people
In a town of about 20,000 to less than 50,000 people
In a city of 50,000 to less than 100,000 people
In a large city of 100,000 or more people

[IF RESIDENTIAL CONTINUE OTHERWISE SKIP TO THANK YOU]

[For all]
THANK YOU MESSAGE: Thank you for taking part in our survey and providing Hydro One with your opinion on keeping the electricity delivery system strong and ready for the future.

APPROACH SPRING 2011
THE SOCIAL RESEARCH NEWSLETTER FROM IPSOS MORI SCOTLAND www.ipsos-mori.com/scotland

Identifying Priorities with Paired Choice Analysis

Identifying people's priorities can help organisations better tailor their services. We have previously discussed qualitative methods for gauging public priorities in local authority budget setting (Approach, autumn 2010). However, there are a range of quantitative methods available and one of the most effective of these is 'paired choice'.

Say we want to measure public preferences for the following ten options available to the Scottish Government to reduce the budget deficit.

1. Raise Council Tax
2. Cut spending on the NHS
3. Freeze public sector pay
4. Cut public sector jobs
5. Cut public sector pensions
6. Increase the free bus travel qualifying age from 60 to 65
7. Charge older people on higher incomes for their personal care
8. Increase prescription charges
9. Introduce tuition fees
10. Charge drivers for using major roads

We could ask them to rate each option on a scale of one to ten in terms of how strongly they feel that it should or shouldn't be adopted, from which we can calculate mean scores. However, meaningful interpretation is limited because it is possible for respondents to indicate that every option should or shouldn't be adopted and most options tend to become clustered around the same score.

Alternatively, we can ask respondents to rank the options from most to least preferred. However, while ranking is effective with a small number of options, it becomes less reliable when respondents are asked to rank longer lists. Respondents tend to find it relatively easy to identify the one or two options they prefer and one or two they like least, but find it difficult to discriminate between middle ranking items. As a result, neither rating nor ranking exercises give us a clear indication of the public's relative preferences.

Paired choice is designed to draw out the extent to which respondents prefer each option in relation to every other option. It works by pairing options off so that they are essentially 'competing' against one another. A series of these pairs are presented to respondents, who are asked to choose which of the two options they prefer. Respondents are forced to choose an option and cannot give a 'don't know' answer.

The number of pairs presented to respondents will depend on the number of options being tested and the methodology used to administer the questionnaire. In this example, 10 options would create 45 pairs[1], which is too many to present to every respondent. The most we would recommend is 15 pairs if conducting the survey via telephone and only slightly more if conducting it face-to-face or online (self-completion paper questionnaires are less suitable for paired choice). However, providing the sample size is large enough, respondents do not have to be shown all possible pairs to obtain reliable results. In this example, the 45 pairs are divided into five groups of nine pairs (see table 1 below), with each respondent given one group. Thus a sample of 1,000 will ensure each pair is put to 200 respondents, while nine is a comfortable number of pairs for respondents to complete.

Relative preference scores are used to estimate the extent to which each respondent prefers each option over each of the other options. The position of each option in the ranking and its overall score is calculated by taking an average of the score for each option across all respondents (see Figure 1 below). In addition, with a large sample we can examine how preferences differ between specific groups.

Reporting the results of this analysis can be tricky. Relative preference scores reflect the share of total preference each option has, which means we have to imagine that there is a pool of total preference to be allocated across each of the options. For

1 Calculated by multiplying the number of options (10) by the number of options it will be paired against (9) and then dividing by 2 (to account for the fact that each pair is used only once)

Table 1

	Group 1	Group 2	Group 3	Group 4	Group 5
Pair 1	3 v 6	1 v 5	7 v 2	2 v 4	9 v 6
Pair 2	1 v 4	5 v 7	9 v 10	10 v 3	8 v 4
Pair 3	7 v 9	6 v 10	8 v 7	1 v 7	10 v 2
Pair 4	4 v 7	2 v 8	3 v 5	9 v 1	2 v 9
Pair 5	2 v 1	8 v 3	5 v 9	4 v 6	7 v 3
Pair 6	5 v 2	7 v 6	4 v 3	5 v 8	1 v 10
Pair 7	10 v 5	4 v 9	6 v 1	7 v 10	6 v 8
Pair 8	9 v 3	3 v 2	1 v 8	6 v 5	4 v 5
Pair 9	8 v 10	10 v 4	2 v 6	8 v 9	3 v 1

example, figure 1 shows that raising the free bus travel qualifying age has a relative preference score of 31%, which means that 31% of the total preference would be allocated to this option. Essentially, relative preference reflects a collective strength of feeling towards a particular option in relation to the others – the higher the percentage, the more strongly it is preferred among respondents.

Analysing the data in this way allows us to reflect the public's preferences in-line with the decisions facing the Scottish Government. After all, the Scottish Government can introduce several of the options at once – they do not have the restriction of having to choose just one of the options. Therefore, the relative preference scores provide a general measure of the Scottish public's preference across all of the options. In other words, it reflects how likely they are to accept each option. This allows us to say that raising the free bus travel qualifying age is over three times more preferred than charging drivers for using major roads or charging older people on higher incomes for their personal care.

Paired choice does have limitations. It relies on respondents making instant decisions based on relatively abstract concepts which they may know little or nothing about. For example, respondents are not given information on the net saving each option is likely to generate, what proportion of the required savings this would be or the impact of the option on them. Knowing any of these may alter their preferences. Paired choice also requires a lot of specialist input, both prior to fieldwork, in scripting the complex routing required for the questionnaire, and after fieldwork, in conducting the analysis, which can make it more expensive than rating or ranking methods.

Overall, paired choice is an effective method that can be used to gauge respondents' priorities on anything from government policy and public spending to service provision and journey planning.

WORKSHOP INVITATION EMAIL
COMMERCIAL AND INDUSTRIAL

Dear Customer:

We are about to begin planning for the future of our electricity system and I would like to hear what matters most to you.

Investment is needed to ensure the reliability of electricity delivery for you, but there are some choices as to how, when, and in what we invest. The feedback that you provide regarding your needs and preferences will be considered as part of the process with the Ontario Energy Board that determines the rates to deliver electricity to you.

You have been selected to participate in one of the workshops, and we would ask you to please read the attached invitation from Hydro One's President and CEO, Mayo Schmidt, for more details about this process. Please let us know which workshop venues you would prefer to attend, listed below, by **Friday, June 3rd, 2016**.

This is a new approach for us at Hydro One and we look forward to your participation.

Sincerely,

Rob Quail
Vice President – Customer Service
Hydro One Networks

Hamilton –June 8th , 2 PM – 5 PM
Crowne Plaza Hotel and Conference Centre - 150 King Street East, Royal Pavilion B, Hamilton, ON

Collingwood—June 9th, 9:30 AM - 12:30 PM
Blue Mountain Resorts LP - 218 Jozo Weider Blvd., Blue Mountains, ON

Timmins—June 13th, 9:30 AM - 12:30 PM
Cedar Meadows Resort & Spa - 1000 rue Norman Street, Salon Cartier, Timmins, ON

Thunder Bay—June 14th, 9:30 AM - 12:30 PM

Kingston—June 24th , 2 PM – 5 PM
Delta Kingston Waterfront Hotel - 1 Johnson Street, Lakeview Room, Kingston, ON

WORKSHOP INVITATION EMAIL
LARGE DISTRIBUTION ACCOUNT

Subject: Large Distribution Account Workshops

Hello (Customer's name),

As part of the preparations for our 2017 Distribution Rate Filing, we are reaching out to our customers to better understand your needs and preferences so that we can incorporate them into Hydro One's investment plan over the next several years. To do so, we are holding workshops for selected customers around the province as well as making an online survey available to all. We have brought on Ipsos Reid, an independent firm, to collect your input and prepare a report documenting your feedback.

You have been selected to participate in one of the workshops, and we would ask you to please read the attached invitation from Hydro One's President and CEO, Mayo Schmidt, for more details about this process. Please let us know which workshop you would prefer to attend by **Friday, June 3rd, 2016**.

This is a new approach for us at Hydro One and we look forward to your participation.

Sincerely,

On behalf of (Superintendent's name)

Mayo Schmidt
President and CEO

May 27, 2016

Dear Sir or Madam,

I am writing to you today as Hydro One Networks Inc. is embarking on the process of developing its Distribution asset investment plan and we would like to receive your input to attain optimum results.

Following a successful Initial Public Offering (IPO) last fall, Hydro One is now operating as a public company. Consistent with our new reality, we are seizing a more proactive and disciplined approach in all aspects of the company. We are fully focused on increasing efficiencies, delivering improved business performance, and targeting our customers by placing a deeper focus on you. We will also continue to make prudent, cost-effective, short and long-term investments in our structure to ensure the electricity needs of Ontario are met now and well into the future.

The Distribution Investment Plan that we develop will, in turn, inform our Distribution Rates Application to the Ontario Energy Board for 2018 to 2022. In the course of developing this Investment Plan, we will identify, confirm and incorporate your needs and preferences into the Plan and ultimately our rate filing.

For this reason, we are asking you to participate in a consultation session with our planning and operations staff. We will hold these sessions across the province in the month of June so that we may:

- hear your views about your specific needs and preferences
- informed decisions will be made about balancing service levels versus cost; and,
- reflect your feedback in the development of an asset investment plan that achieves a balance linking managing reliability, service and cost.

During the course of the meeting, we will:

- provide an overview of our system and describe our historic approach to developing, maintaining and sustaining our distribution assets
- discuss system improvement priorities including their cost and rate implications
- discuss customer preferences for system and service improvements; including their cost and rate implications
- outline our approach to reducing costs and targeting efficiencies in our business
- obtain customer input on rates; striking the right balance between service and costs
- discuss how customer feedback will be considered in the development of our investment plan
- track and document customer feedback.

Ultimately, our aim is to ensure our investment plan identifies, prioritizes and schedules the precise investments in our distribution system so that your electricity needs are met.

Once you confirm your interest in participating, we will provide you with background information to prepare for our discussion. In the meantime, if you have any questions, please contact the Hydro One Business Customer Centre at HydroOneBCC@HydroOne.com or 1-866-922-2466.

We're eager to hear your insights and look forward to your confirmation that you will participate in this important process.

Please join us at one of the following locations:

- Hamilton – June 8th
- Collingwood – June 9th
- Timmins – June 13th
- Thunder Bay – June 14th
- London – June 16th
- Windsor – June 17th
- Kingston – June 24th

My best,

Mayo Schmidt
President & CEO

- Collingwood – June 9th
- Timmins – June 13th
- Thunder Bay – June 14th
- London – June 16th
- Kingston – June 24th

My best,

Mayo Schmidt
President & CEO

WORKSHOP MATERIALS

Dx CUSTOMER ENGAGEMENT

WORKSHOP MATERIALS

June 2016

Agenda for today's conversation

1	Introduction: Who we are and what we do	*30 minutes*
2	Review: Current system performance	*30 minutes*
	Break: ~15 min	
3	Context: Investing in the system	*30 minutes*
4	Discussion: What's best for you?	*75 minutes*

Agenda

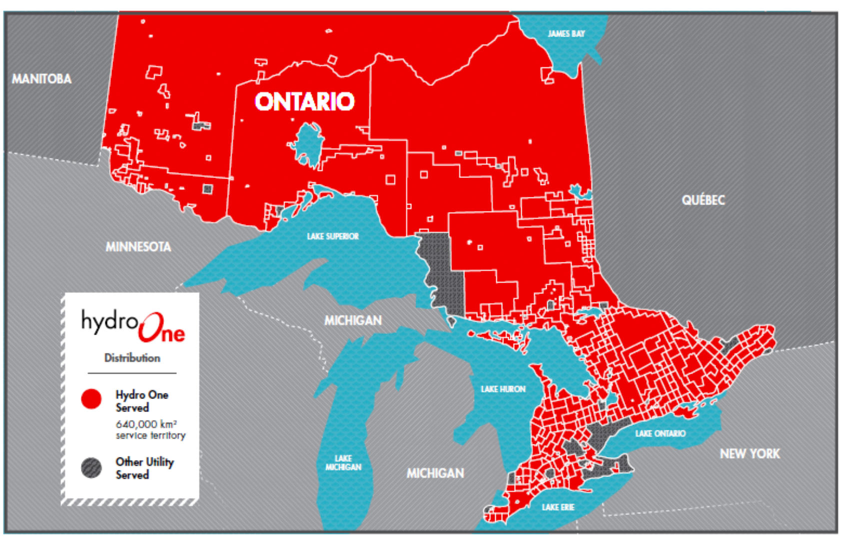
1. **Introduction:** Who we are and what we do

2

Hydro One: Who we are and what we do

Hydro One is the **largest electric power distributor in Ontario**. Hydro One serves 25% of Ontarians — more than **1.3 million customers** across the province.

The distribution service territory covers vast areas and the majority of the province.

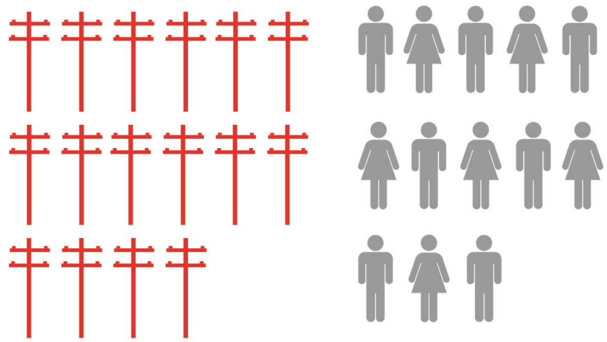


3

Hydro One: How we serve you

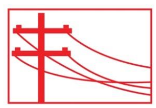
Hydro One's assets include **123,000 kilometres of lines** (enough wire to circle the earth 3 times) and approximately **1,000** distribution and voltage regulating stations.

Hydro One also has more poles than customers.



1.6M
POLES

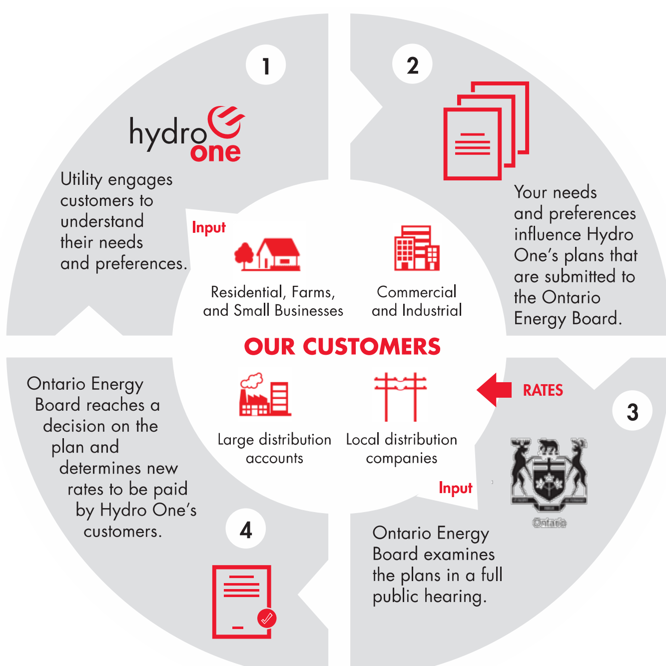
1.3M
CUSTOMERS



123,000 km
DISTRIBUTION LINES

4

Hydro One wants your input



5

Further context for this workshop

The Ontario Energy Board (OEB) ensures that all customers have the opportunity to provide input in its process to set utility rates in Ontario.

Hydro One is currently **preparing a distribution rate application** which will be filed in early 2017.

- The application will explain Hydro One's investment plan that the OEB will assess to determine electricity distribution rates from 2018-2022.

All of Hydro One's distribution customers will have the opportunity to provide input into the investment plan through workshops, focus groups, surveys, and one-on-one discussions.

Hydro One's objective is to provide its customers with safe and reliable electricity.

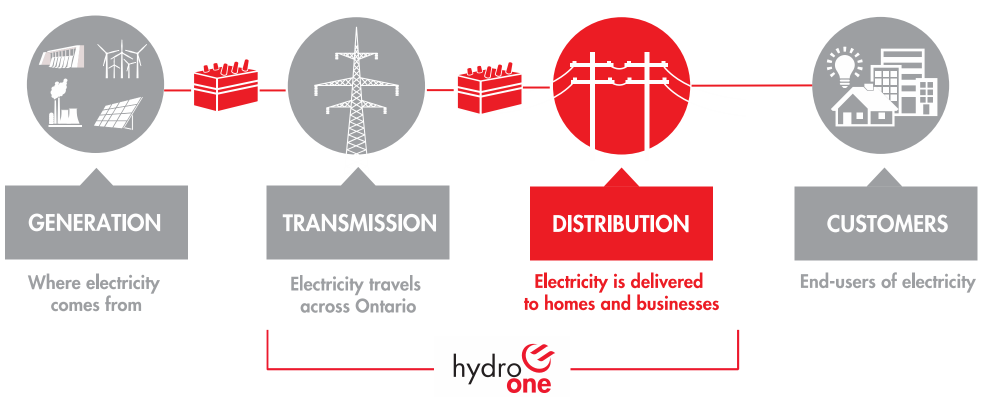
- In pursuing this goal, Hydro One must make tradeoffs between cost impacts, reliability and other services they provide to you.

Hydro One wants to understand whether your needs are being met by the current system and **which types of reliability and service improvements you value most.** Hydro One will also share information and request your feedback on **potential rate impacts.**

Your input will be considered as Hydro One develops its plans, along with other considerations including its mandatory obligations, asset condition assessments and the ability to resource, schedule and execute the plan.

6

Hydro One's role in the electricity system



- Electricity is produced by generators including Ontario Power Generation, Bruce Power, NextEra and other generators.

- The **transmission system** conveys electricity from generators to distributors and large consumers.
- Hydro One operates 96% of transmission in Ontario

- The **distribution system** conveys electricity to customers.
- Hydro One distributes electricity to 25% of Ontario's population.

- Residential
- Commercial and Industrial
- Large Consumers
- Other Distributors

While Hydro One is involved in both transmission and distribution of electricity our focus today is on Hydro One's distribution system.

7

Hydro One's customers are diverse

hydro one

Residential, Farms, and Small Businesses	Commercial and Industrial	Large users	Local distribution companies
~1.3M customers 42% of power used	~8,000 customers 13% of power used	~90 customers 11% of power used	~60 companies 34% of power used
Homes, small shops, local farms	Hospitals, grocery stores and other businesses	Food processing, mining, and other large businesses	Smaller utilities

Hydro One seeks to balance the differing needs of customers

- Costs
- Reliability
- Accurate billing
- Customer service
- Communication
- Power quality
- Conservation
- Accurate restoration times
- Capacity expansion

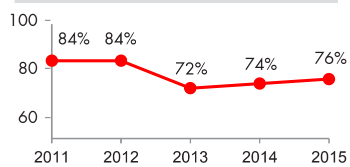
8

What Hydro One has heard from larger customers

hydro one

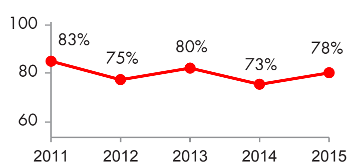
Customer Segment	Recent Customer Satisfaction Surveys	Customer Priorities

Commercial and Industrial



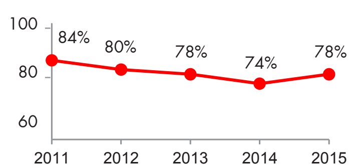
- Customer service, rates, and billing

Large Distribution Account



- Communication with Hydro One, reliability / power quality, customer service, and rates

Local Distribution Company



- Rates, reliability, and capacity expansion

9

What part of your monthly bill goes to Hydro One for distribution?

hydro one

Bill breakdown for typical customer profiles

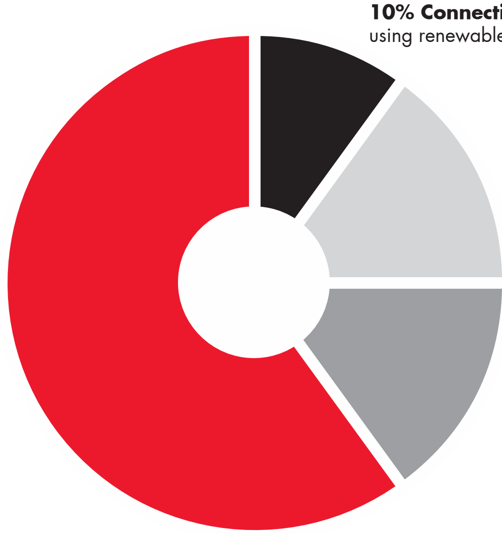
	Commercial and Industrial				Large Distribution Accounts & Local Distribution Companies	
	Rural		Urban			
	Typical	Large	Typical	Large	Typical	Large
Energy consumption (kWh)	35,000	200,000	35,000	200,000	1,450,000	5,000,000
Peak energy use (kW)	150	500	150	500	3,000	10,000
Total Bill with GST/HST ($)	**7,800**	**36,900**	**6,700**	**33,300**	**217,100**	**748,100**
– Commodity	47%	57%	54%	62%	69%	69%
– Distribution delivery charge	30%	20%	20%	13%	3%	2%
– Transmission delivery charge	5%	4%	8%	5%	8%	8%
– Other (Regulatory, Debt Retirement, GST/HST)	18%	19%	18%	20%	20%	21%

10

What do distribution rates pay for?

hydro one

Breakdown of Hydro One's 2016 distribution Capital and Operating, Maintenance and Administration (OM&A) costs



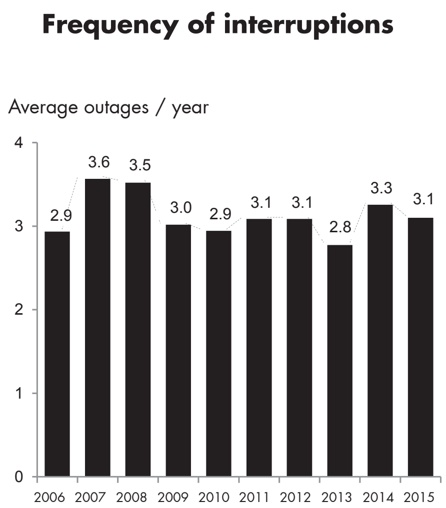
11

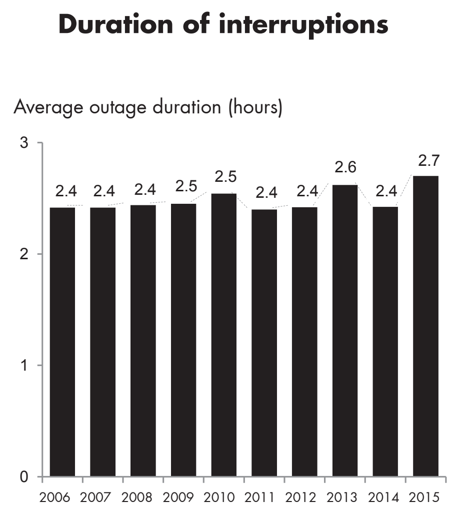
Agenda

2. **Review:** Current system performance

12

Over time, Hydro One's provincial reliability performance has remained consistent





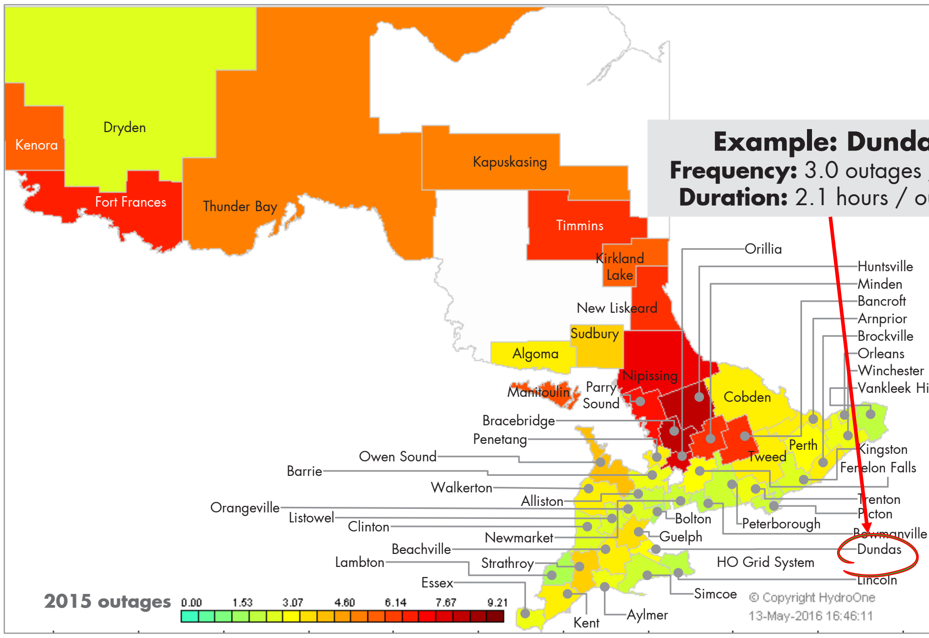
13

Reliability varies by location within the province

hydro one

Hamilton

Example: Dundas
Frequency: 3.0 outages / year
Duration: 2.1 hours / outage



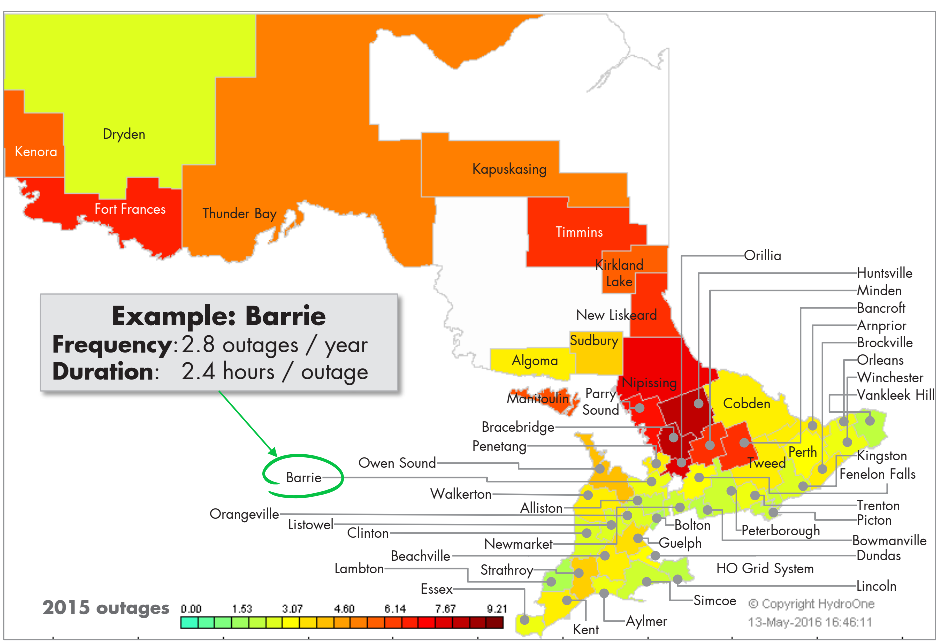
Note: Includes force majeure outages

16

Reliability varies by location within the province

hydro one

Example: Barrie
Frequency: 2.8 outages / year
Duration: 2.4 hours / outage

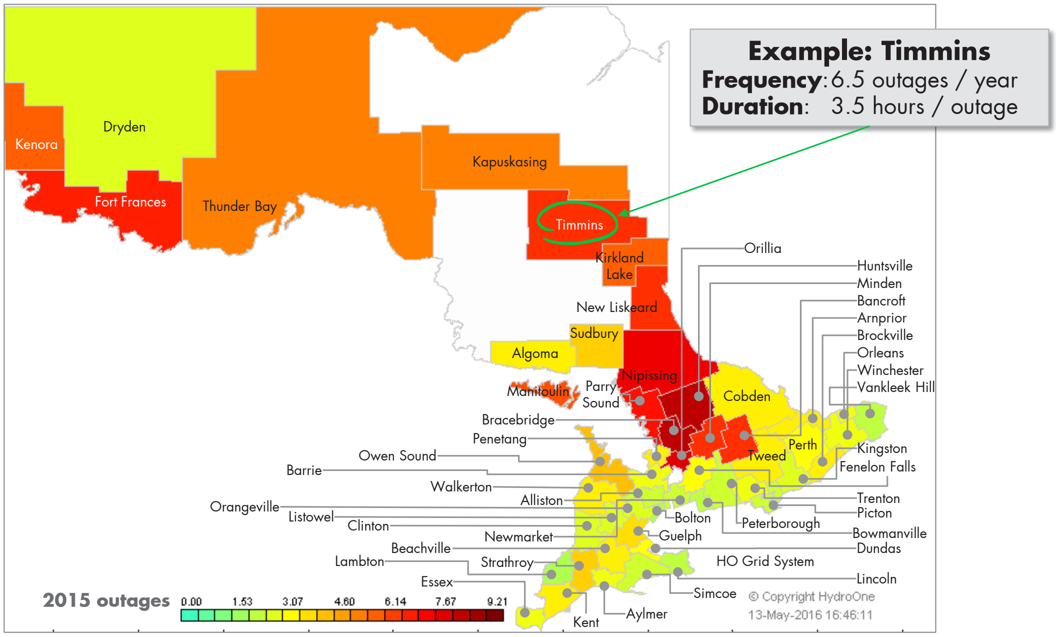


Note: Includes force majeure outages

14

Reliability varies by location within the province

hydro one

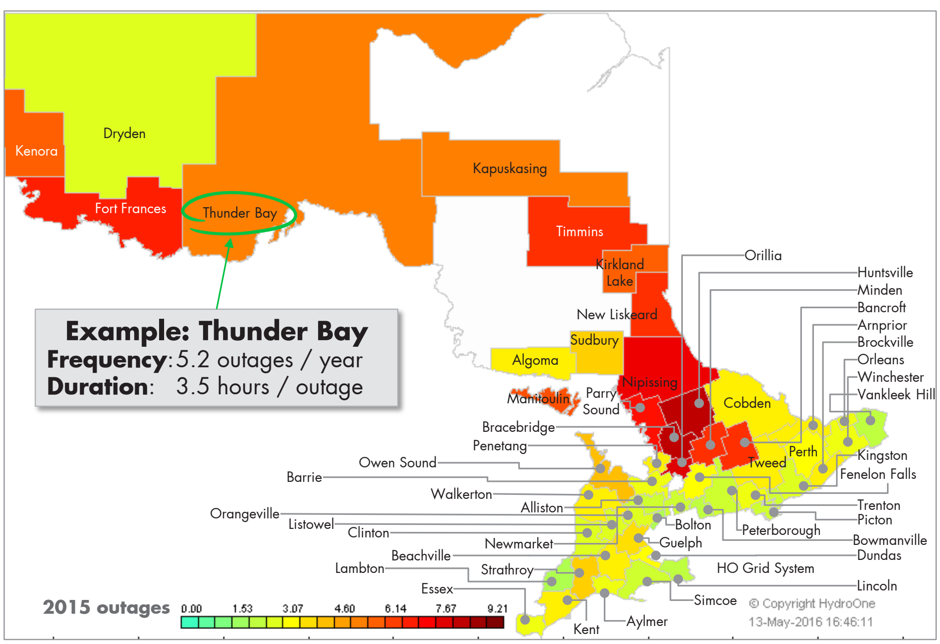


Note: Includes force majeure outages

16

Reliability varies by location within the province

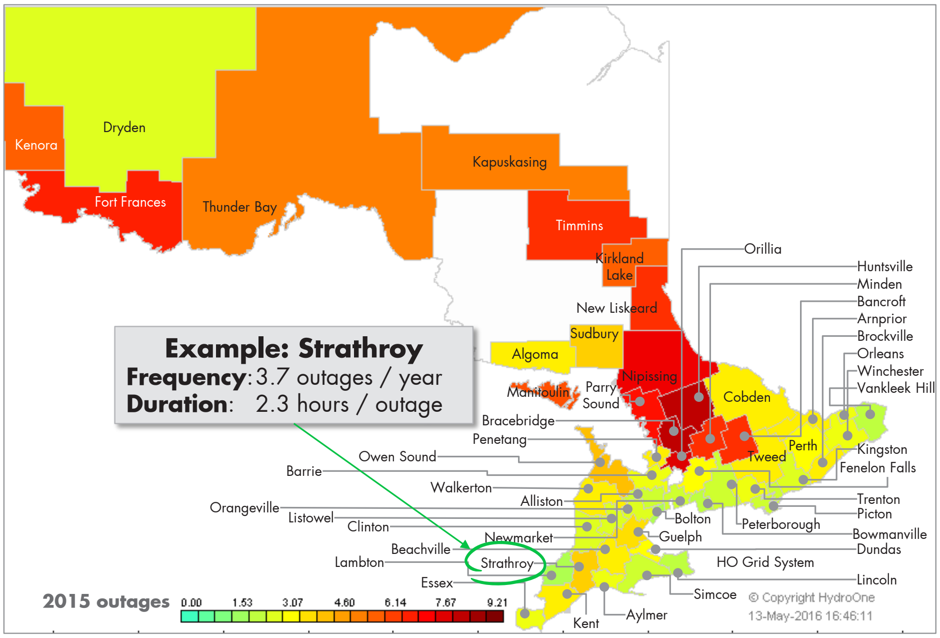
hydro one



Note: Includes force majeure outages

16

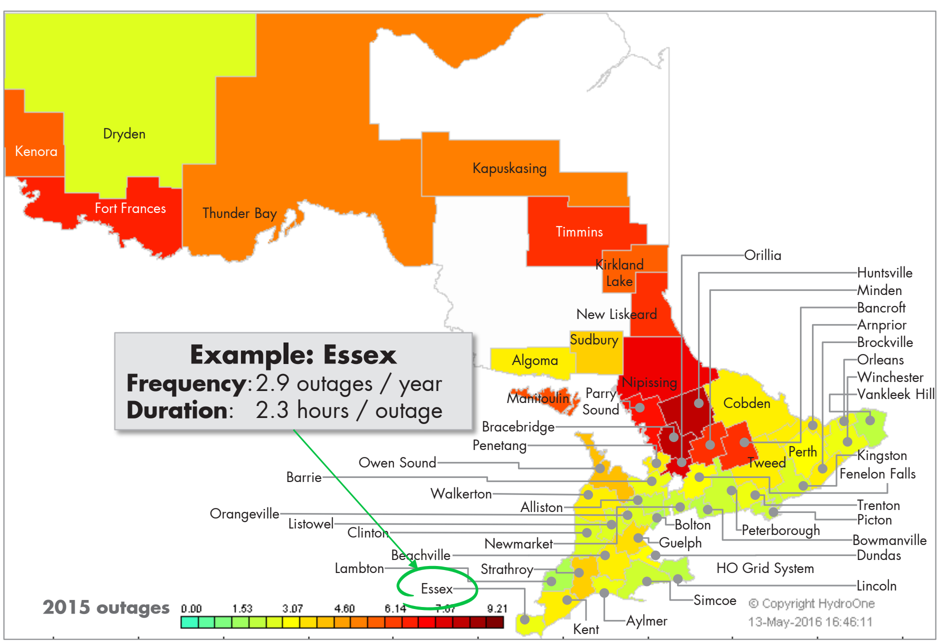
Reliability varies by location within the province



Note: Includes force majeure outages

16

Reliability varies by location within the province

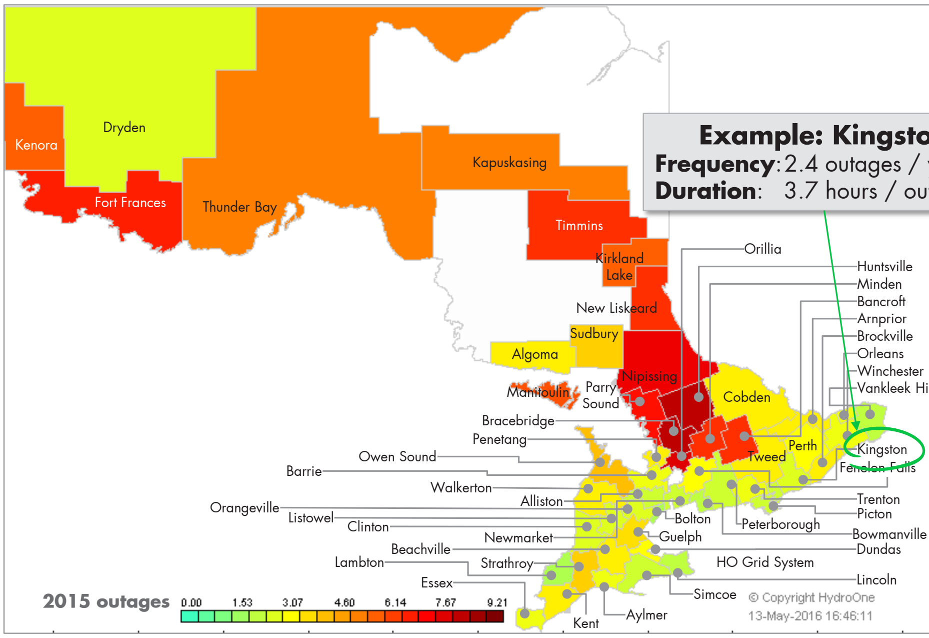


Note: Includes force majeure outages

16

Reliability varies by location within the province

hydro one



Note: Includes force majeure outages

16

Hydro One serves both rural and urban customers

hydro one

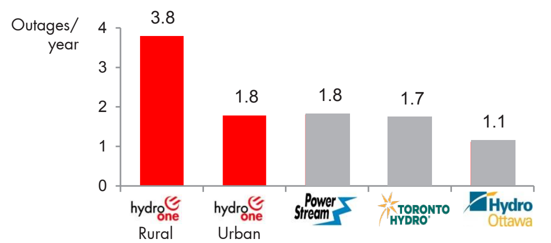
Hydro One's system is larger and more rural than other Ontario utilities'

	Utility	# of customers	Service area (km²)	Km of power lines
hydro one	**Hydro One**	1,300,000 Rural: 84% Urban 16%	640,000	123,000
TORONTO HYDRO	Toronto Hydro	740,000	630	10,000
PowerStream	PowerStream	350,000	800	7,600
Hydro Ottawa	Hydro Ottawa	320,000	1,100	5,500

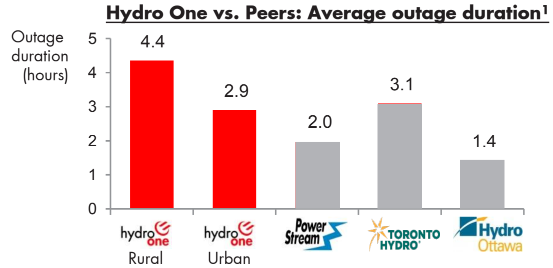
Reliability performance is affected by factors such as: system design, vegetation, equipment performance, geography, exposure to adverse weather.

Hydro One's urban customers experience reliability comparable to other urban utilities'

Hydro One vs. Peers: Average outages / year[1]



Hydro One vs. Peers: Average outage duration[1]



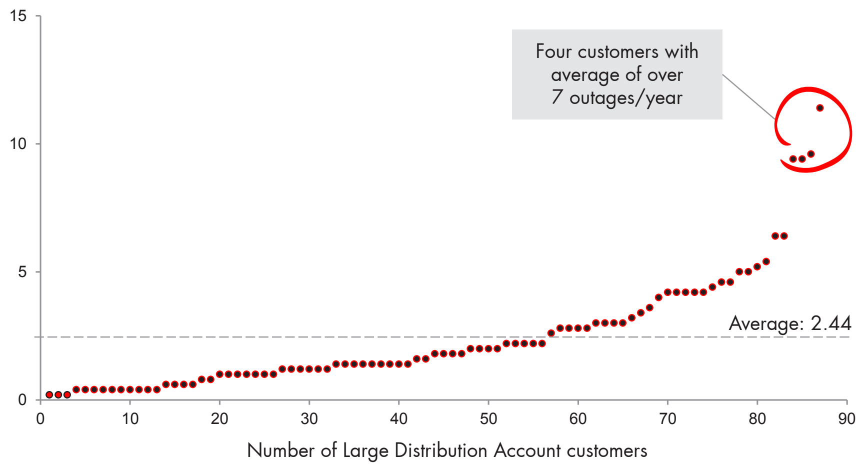
1. Outage metrics based on average from 2012-2014. Includes force majeure, excludes loss of supply.
Source: Ontario Energy Board electricity distributor scorecards. Hydro One outage data.

15

Reliability varies from customer to customer

hydro one

Large Distribution Account (LDA) Outages / year (average 2011-2015)



Hydro One is looking at options to target poor-performing areas

16

Trees and equipment failures cause almost half of Hydro One's power outages

hydro one

Power outage causes (2013-2015)

Tree damage	**24%**	Trees fall on lines during storms.
Equipment failure	**24%**	Poles, transformers, lines failures can cause an outage.
Unconfirmed causes	**19%**	Sometimes Hydro One crews can't determine the exact cause of an outage.
Scheduled outages	**16%**	Occasionally, Hydro One needs to schedule power outages to safely replace or update equipment.
Loss of power supply	**12%**	Issues relating to the larger grid, like damage to transmission lines.
Animal or vehicle damage to equipment	**5%**	Animal contacts with Hydro One's equipment and car accidents that damage poles.

17

Reliability challenges

Challenges all utilities face	Issues specific to Hydro One
Geography: Forested service territories are prone to outages caused by tree contact. In order to restore power, repair crews must locate and travel to source of an outage.	Much of Hydro One's service territory is heavily forested compared to other utilities'.[1] In 2014, Hydro One cleared over 9,000 km of distribution line. Hydro One's large service area means outages are longer and are more costly to locate and repair. Hydro One's network uses a radial circuit design to cover a large area, which does not provide redundant power supplies common in urban areas.
Weather: Major storms inevitably cause damage to power lines.	Hydro One's large service territory exposes it to all of Ontario's most challenging weather conditions.
Infrastructure: Most electric power grids were built up over many years with a huge volume of equipment and a mix of different technologies.	Hydro One's system serves an average of 10 customers per kilometre of power line while other utilities serve about 70 customers per kilometre. This requires Hydro One to maintain a large number of assets per customer.

1. Hydro One 2009 Vegetation Management Benchmarking Study by CN Utility Consulting, Inc.

Agenda

3. Context: Investing in the system

Hydro One is focused on efficiency and productivity

hydro one

Between 2014-2015 unit costs declined by:

- 4% for brush control
- 10% for line clearing
- 12% for wood pole replacement

This has been accomplished through the use of:

- A large, seasonal, mobile, contingent workforce
- Increased use of mechanical harvesting equipment to fell trees
- Targeted herbicide application, where feasible, reducing brush control costs
- Improved planning to prioritize and execute work
- Technology deployment that improves operational monitoring and control

Hydro One is contributing in a material way by reducing its costs.

20

Factors that influence Hydro One's investments

hydro one

Investments are identified, prioritized and scoped to manage risks associated with:

Safety	Keeping the public and employees safe is Hydro One's number one priority
Customer	Meeting customers' service quality expectations
Reliability	Maintaining reliability
Productivity	Achieving efficiencies
Continuous innovation	Adopting proven and effective technologies
Environment	Protecting the environment and complying with regulations
Shareholder Value	Complying with laws and regulations, earning public trust, achieving financial targets

21

2016 expenditures

Approximately $1,250M is spent to maintain reliability and service levels

	Largest investment programs include:	Budget (2016, $M)
	Replacing and refurbishing assets	320
	Connecting new customers	150
	Mandatory system upgrades	30
OM&A	Managing vegetation near lines	150
OM&A	Planned asset maintenance	110
OM&A	Responding to outages	100
OM&A	Customer service	90

$60M is spent to improve reliability and service levels

Outcomes

1. Reducing the number of outages
2. Shortening the length of power outages
3. Improving customer service
4. Improving power quality
5. Upgrading the system to connect renewable energy sources and energy storage

Your input will help Hydro One determine how to invest going forward

22

Maintain: Largest programs involve replacement and refurbishment of assets in poor condition

Wood poles

- **240,000** wood poles (15% of the fleet) are currently beyond their expected service life of 60 years.
- **400,000** wood poles (25% of the fleet) would be beyond their expected service life by 2022 if no replacements are made.

Distribution stations

- Approximately **144** station transformers (12% of the fleet) are currently beyond their expected service life of 50 years.
- Approximately **360** station transformers (30% of fleet) would be beyond their expected service life by 2022 if no replacements are made.

Much of the system was built in the 1950s and 1960s. Consequently many assets are approaching or beyond the end of their expected service lives. Replacement decisions are based on actual asset condition.

23

Improve: There are several outcomes Hydro One can pursue

hydro one

Outcomes	Enabling expenditures
1 Reducing the number of outages 2 Shortening the length of power outages 3 Improving customer service 4 Improving power quality 5 Upgrading the system to connect renewable energy and energy storage	**Improving system design** • Example: Where practical, providing backup capability as old lines are replaced **Vegetation Management** • Example: Trimming trees more frequently, on a selective basis, to reduce consequences of tree-related outages **Improving Monitoring and Control** • Example: Enhancing the capabilities at Hydro One's operating centre and installing equipment that can be controlled remotely • Example: Installing power quality monitoring equipment

26

Improve: There are several outcomes we can pursue

hydro one

Ways we can improve

1. Reducing the number of outages
2. Shortening the length of power outages
3. Improving customer service
4. Improving power quality
5. Upgrading the system to connect renewable energy and energy storage

Examples of improvement projects in Central Ontario

Project	Customer benefits	Details
Muskoka forestry initiative	• Improved reliability	• More aggressive vegetation clearing program on targeted power lines • Timing 2016 • **Cost: ~$20 M**
Algonquin Park tie line	• Improved reliability • Improved power quality	• 12 km tie line to connect two power lines together • Timing 2013-14 • **Cost: ~$3 M**
Rosseau DS	• Improved reliability • Increased capacity • Improved power quality	• New distribution station built to provide load relief to 3 neighboring stations • Timing 2011-12 • **Cost: ~$9 M**

24

Improve: There are several outcomes we can pursue

hydro one

Ways we can improve

1. Reducing the number of outages
2. Shortening the length of power outages
3. Improving customer service
4. Improving power quality
5. Upgrading the system to connect renewable energy and energy storage

Examples of improvement projects in Northeastern Ontario

Project	Customer benefits	Details
City of Timmins voltage conversion	• Improved reliability • Reduction in future maintenance costs	• Replace obsolete distribution stations and lines and standardize city voltage • Completed in 2015 • **Cost: ~$11 M**
Manitouwadge TS M2 rebuild	• Improved reliability • Improved power quality	• Rebuild 80 km long line and replace with larger size standard conductor • Timing 2014-18 • **Cost: ~$18 M**
Martindale TS M5 relocation	• Improved reliability • Reduction in future maintenance costs	• Relocate 45 km long line at end of life to roadside • Timing 2012-16 • **Cost: ~$16 M**

27

Improve: There are several outcomes we can pursue

hydro one

Improvement priorities

1. Reducing the number of outages
2. Shortening the length of power outages
3. Improving customer service
4. Improving power quality
1. Upgrading the system to connect renewable energy and energy storage

Examples of improvement projects in Northwestern Ontario

Project	Customer benefits	Details
• **Barwick TS**	• Improved reliability • Increased capacity • Connection of solar farms	• New transmission station divided 100 km long feeder into two 50 km long feeders • Completed in 2014 • **Cost: ~$20 M**
• **Nipigon Town voltage conversion**	• Improved reliability • Increased capacity	• Voltage feed of Nipigon Town being converted to allow integration with areas north of town • Est. 2017 completion • **Cost: ~$2 M**
• **New Keewatin DS**	• Improved reliability • Increased capacity	• New distribution station built to permit addition of new load, allowing growth in the community • Completed in 2013 • **Cost: ~$5 M**

27

Improve: There are several outcomes we can pursue

hydro one

Ways we can improve

1. Reducing the number of outages
2. Shortening the length of power outages
3. Improving customer service
4. Improving power quality
5. Upgrading the system to connect renewable energy and energy storage

Examples of improvement projects in Southwestern Ontario

Project	Customer benefits	Details
Palmerston TS M2 extension	▪ Improved reliability ▪ Increased capacity	▪ Extend power line by 11 km to provide source of supply to the town of Mount Forest ▪ Timing: 2016 ▪ **Cost: ~$2 M**
Edgeware TS M3 relocation	▪ Improved reliability ▪ Increased capacity	▪ New feeders built from Duart TS to sectionalize Kent TS and St Thomas TS feeders ▪ Timing: 2013 ▪ **Cost: ~$2 M**
Commerce Way TS	▪ Improved reliability ▪ Increased capacity	▪ New transmission station to provide load relief to neighboring station ▪ Completed in 2015 ▪ **Cost: ~$13 M**

27

Improve: There are several outcomes we can pursue

hydro one

Ways we can improve

1. Reducing the number of outages
2. Shortening the length of power outages
3. Improving customer service
4. Improving power quality
5. Upgrading the system to connect renewable energy and energy storage

Examples of improvement projects in Southwestern Ontario

Project	Customer benefits	Details
Leamington TS feeder	• Improved reliability • Increased capacity	• Construction of new power line • Timing 2016-18 • **Cost: ~$60 M**
Lauzon / Belle River TS feeder reconfig	• Increased capacity	• Power line reconfiguration to provide load relief to neighboring power line • Completed in 2013 • **Cost: ~$2 M**

27

Improve: There are several outcomes we can pursue

hydro one

Ways we can improve

1. Reducing the number of outages
2. Shortening the length of power outages
3. Improving customer service
4. Improving power quality
5. Upgrading the system to connect renewable energy and energy storage

Examples of improvement projects in Southeastern Ontario

Project	Customer benefits	Details
Orleans TS	• Improved reliability • Increased capacity	• New transmission station to provide supply for future growth in east end of Ottawa and surrounding area • Timing 2015-16 • **Cost: ~$17 M**
St. Lawrence submarine cable	• Improved reliability • Increased capacity • Improved power quality	• Replace end of life submarine cables from mainland to nearby islands • Timing 2013-16 • **Cost: ~$7 M**
44kV relocation	• Improved reliability • Reduction in future maintenance costs	• Relocate off-road line at end of life to roadside • Complete 10-yr project • **Cost: ~$20 M**

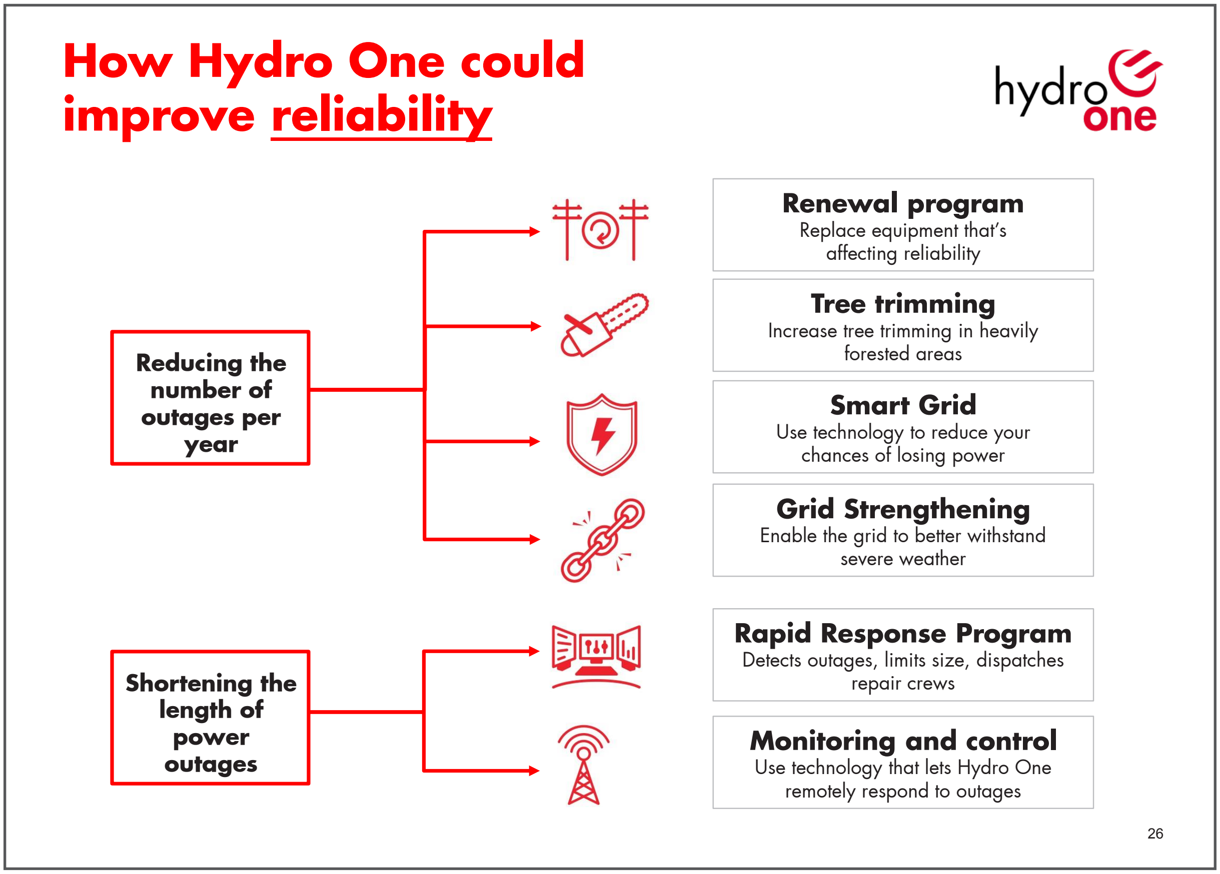
27

Agenda

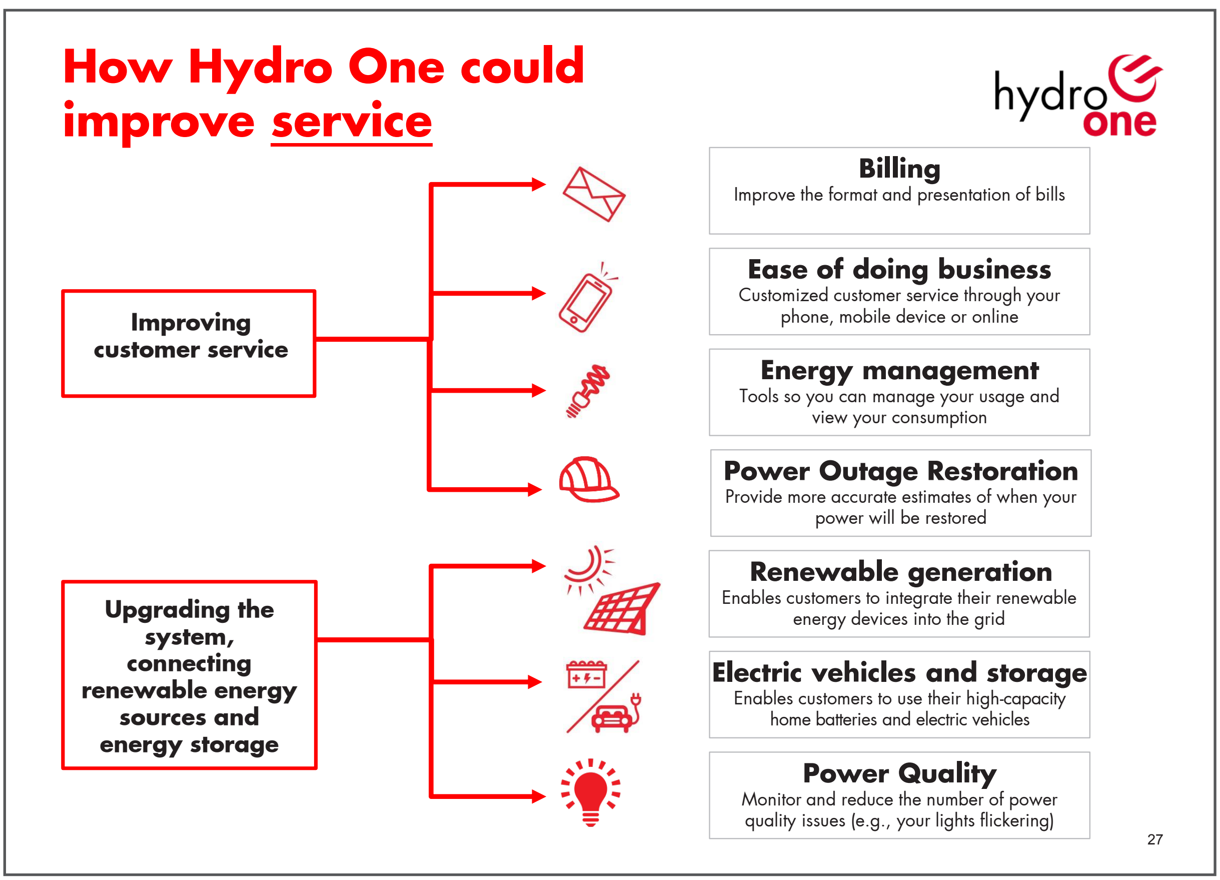
hydro one

4. Discussion: What's best for you?

25



How Hydro One could improve reliability
hydro one
Reducing the number of outages per year
Renewal program
Replace equipment that's affecting reliability
Tree trimming
Increase tree trimming in heavily forested areas
Smart Grid
Use technology to reduce your chances of losing power
Grid Strengthening
Enable the grid to better withstand severe weather
Shortening the length of power outages
Rapid Response Program
Detects outages, limits size, dispatches repair crews
Monitoring and control
Use technology that lets Hydro One remotely respond to outages
26



How Hydro One could improve service
hydro one
Improving customer service
Billing
Improve the format and presentation of bills
Ease of doing business
Customized customer service through your phone, mobile device or online
Energy management
Tools so you can manage your usage and view your consumption
Power Outage Restoration
Provide more accurate estimates of when your power will be restored
Upgrading the system, connecting renewable energy sources and energy storage
Renewable generation
Enables customers to integrate their renewable energy devices into the grid
Electric vehicles and storage
Enables customers to use their high-capacity home batteries and electric vehicles
Power Quality
Monitor and reduce the number of power quality issues (e.g., your lights flickering)
27

Introduction to investment scenarios

Illustrative scenarios have been developed for various levels of capital investment.

These in turn, result in different impacts on rates, reliability, and service levels.

These scenarios are meant to represent a spectrum of potential investment levels.

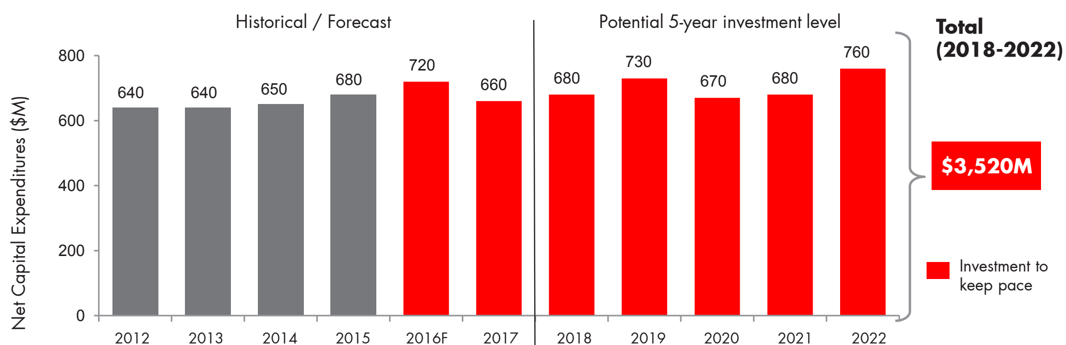
We do not have a recommended scenario, nor are we asking you to choose from the scenarios presented.

Through this conversation, we would like to better understand your business needs and preferences to inform our 5-year Distribution Investment Plan.

28

Scenario 1: Maintain current reliability and service levels

1 Maintain performance scenario



OM&A ($M)	2012	2013	2014	2015	2016F	2017	2018	2019	2020	2021	2022	Total (2018-2022)
	550	610	680	570	590	590	610	620	630	650	660	$3,170M

Key elements

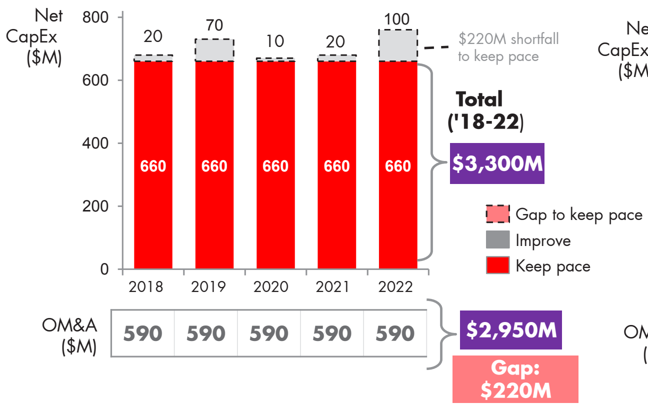
- Increased capital expenditures to keep pace with need to renew aging / deteriorating infrastructure and continue proactive investments to prevent issues
- OM&A growth limited to rate of inflation
- Reliability and service levels unchanged

29

Scenarios 2 and 3:
Declining or improving reliability

hydro one

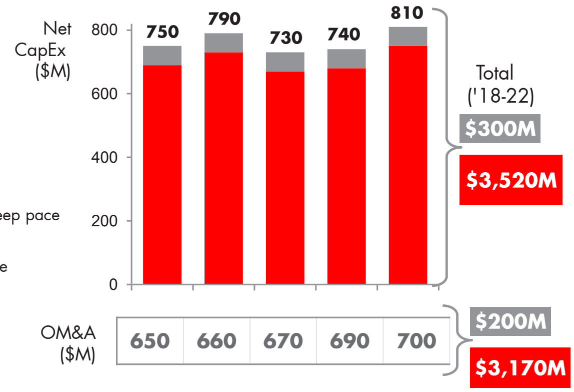
2 Declining performance scenario



Key elements

- Capital and OM&A expenditures frozen at 2017 levels
- Focus on non-discretionary expenditures associated with safety, environment, equipment repair and compliance
- Reduced preventative maintenance

3 Improving performance scenario



Key elements

- Additional $500M in spend over 5 years
- Increased preventative maintenance to 'get ahead' of asset degradation and prevent issues from occurring
- Improvement in overall levels of reliability and service

Preferred levels of reliability and service will affect rates

hydro one

	2 Declining performance	1 Maintain performance	3 Improving performance
Distribution delivery rate impact	Increase: **2.5%** [1]	Increase: **3.4%**	Increase: **~4.0%**
	Average across all customers – could be higher or lower if investments are specifically targeted towards customers in certain rate classes		
Reliability impact	• Average number of outages increases ⟷	• Average number of outages remains the same ⟷	• Average number of outages decreases ~10%
	• Average duration of each outage increases ⟷	• Average duration of each outage remains the same ⟷	• Average outage duration decreases by ~8% (~15 minutes)
Customer Service impact	• Longer response times to customer inquiries ⟷	• Continued focus ⟷	• Increased customized customer service offerings and tools

Assumes full capital expenditure improvement budget allocated to reliability

[1]Hydro One's asset base will continue to increase as old assets are replaced with new ones.

31

Hydro One could target investments to offer differentiated reliability and service to large customers

hydro one

Context	• Many large customers have unique needs and have asked for much higher reliability and/or service levels, beyond the "improve" scenario • Certain portions of the distribution system provide differing levels of performance by virtue of geography and design • Hydro One recognizes that power delivery issues have a significant effect on some customers' businesses • Hydro One wants to support customers' business needs and help them be successful in the face of competition • We would like to open a discussion around customer requirements and what Hydro One could do to better meet your needs

32

HYDRO ONE DISTRIBUTION CONSULTATION

C&I WORKSHOP SURVEY BOOKLET

INTRODUCTION

This survey booklet is organized into sections that correspond with the flow of the workshop today. You will be provided time after each section of the workshop presentation today for you to answer the survey. Feel free to refer back to the Hydro One Presentation/Workbook as needed in deciding your opinion.

Please answer all of the questions in the survey.

If you require more space, please write on the back of your survey. If you have any questions, please ask one of the IPSOS staff present at the session today.

WHO WE ARE AND WHAT WE DO

As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices.

1. How satisfied are you with Hydro One overall?

- ☐ Very satisfied
- ☐ Somewhat satisfied
- ☐ Neither satisfied nor dissatisfied
- ☐ Somewhat dissatisfied
- ☐ Very dissatisfied

Is there anything in particular that Hydro One can do to improve its service to you?

2. Hydro One would like to better understand what is important to you as a large customer. From the following list, which would you say is most important to your organization? (select one only)

- ☐ Reducing the number of power outages (through activities such as tree-trimming, replacing equipment)
- ☐ Shortening the length of power outages (through activities such as installing remote control devices)
- ☐ Improving customer service and billing (such as billing accuracy and answering customer questions)
- ☐ Upgrading the system to connect new customers including those producing renewable energy sources and using energy storage (such as wind, solar, and electric vehicles)
- ☐ Keeping costs as low as possible

If something is more important to you than these five items, please write it into the text box below.

REVIEW: CURRENT SYSTEM PERFORMANCE

3. Is there anything unclear about what has been presented in Current System Performance section of the presentation/workbook today?

The following few questions are about your experience with unplanned power interruptions.

The term interruption refers to a complete loss of electric power and outage refers to the disabling of a component's capability to deliver power (planned or unplanned). An outage may or may not cause an interruption of service to customers.

4. A sustained power interruption is one lasting at least 1 minute. How many did your organization experience in the past 12 months that you were not notified about in advance by Hydro One? Your best guess is fine. Circle your choice.

None 1 2 3 4 5+ Don't know /Can't recall

5. On average, how long did these unplanned interruptions last? Please answer in minutes. Your best guess is fine.

- ☐ No unplanned interruptions
- ☐ Don't know/can't recall

6. How, if at all, did these unplanned interruptions impact your organization?

7. What, if anything, would you like Hydro One to do to manage unplanned interruptions?

CONTEXT: INVESTING IN THE SYSTEM

8. Based on what you just heard/read in presentation, do the investments to maintain the current level of reliability and service that Hydro One is making today make sense to you?

- ☐ Yes, please explain below
- ☐ No, please explain below

9. Based on what you just heard/read in presentation, do the investments to improve the current level of reliability and service that Hydro One is making today make sense to you?

- ☐ Yes, please explain below
- ☐ No, please explain below

5

What's best for you? How Hydro One could improve reliability and service

10. Please rank the RELIABILITY items below in the order in which they would have the greatest positive impact on your organization, where 1 represents the item that would have the most positive impact and 6 represents the least positive impact.

Write in your ranking from 1 to 6 in the column to the left

	Renewal program - Replace equipment that affects reliability
	Tree trimming - Increase tree trimming in heavily forested areas
	Smart grid - Use technology to reduce your chances of losing power
	Grid strengthening - Enable the grid to better withstand severe weather
	Rapid response program - Detects outages, limits size, dispatches repair crews
	Monitoring and control – Use technology that enables Hydro One to remotely respond to outages

11. Please rank the SERVICE items below in the order in which they would have the greatest positive impact on your organization, where 1 represents the item that would have the most positive impact and 7 represents the least positive impact.

Write in your ranking from 1 to 7 in the column to the left

	Billing - Improve the format and presentation of bills
	Ease of doing business – Customized customer service through phone, mobile or online
	Energy management - Tools so you can manage your usage and view your consumption
	Power outage restoration – Provide more accurate estimates of when your power will be restored
	Renewable generation – Enables customers to integrate their renewable energy devices into the grid

6

	Electric vehicles and storage – Enables customers to use their high-capacity home batteries and electric vehicles
	Power quality – Monitor and reduce the number of power quality issues (e.g. your lights flickering)

12. To better understand your preferences for reliability, service, and level of rates, please complete the following. If you had $100 to spend on the following, how would you allocate the money?

Write in how much money you would allocate to each in the column to the left

$	Improving reliability by reducing the number of interruptions
$	Improving reliability by reducing the length of interruptions
$	Improving service by offering more seamless customer service via phone, mobile and online
$	Improving service by improving billing accuracy
$	Improving service by improving power quality diagnostics
$	Improving service by enabling customers to integrate their renewable energy devices into the grid
$	Improving service by enabling energy storage
$	Hold back and not spend in order to lessen rate increases

$100

INTRODUCTION TO INVESTMENT SCENARIOS

13. What's your overall reaction to the investment scenarios presented?

14. Would you be willing to accept a 2.5% distribution delivery rate increase where reliability and service performance declines (Scenario 2)?

- ☐ Yes
- ☐ No

15. Would you be willing to accept a 3.4% distribution delivery rate increase where reliability and service performance remains the same as it is now (Scenario1)?

- ☐ Yes
- ☐ No

16. Would you be willing to accept a 4.0% distribution delivery rate increase where reliability and service performance improves (Scenario 3)?

- ☐ Yes
- ☐ No

17. Do you expect significantly higher or differentiated service than you have today from Hydro One?

- ☐ Yes, please explain below
- ☐ No, please explain below

8

18. Would you be willing to accept a distribution delivery rate increase greater than 4.0% in order to have customized reliability and/or service improvements?

- ☐ Yes, please explain below
- ☐ No, please explain below

19. What metrics and targets should these programs be based on?

9

20. Which of the following industry classifications most closely represents your organization? (select one only)

- ☐ Agriculture, forestry, fishing, and hunting
- ☐ Arts, entertainment, and recreation
- ☐ Educational services
- ☐ Health care and social assistance
- ☐ Manufacturing
- ☐ Mining, quarrying, and oil and gas extraction
- ☐ Other services (except public administration)
- ☐ Public administration
- ☐ Retail trade
- ☐ Utilities
- ☐ Wholesale trade
- ☐ Other (specify)____

21. What are the first three characters of the postal code of your organization's main/corporate office? (example, L5M)

22. What is your title/position within your organization?

Thank you for your feedback!

Please return your survey to an IPSOS staff member.

VP, Customer Service
Hydro One Networks Inc.

June 17, 2016

Dear Customer:

We are in the early stages of building our five-year plan for our electricity distribution system and I would like to invite you to share with us what you believe our priorities should be and what matters most to you in the development of this plan.

Our development plan will form part of our distribution rate application which we will file in the spring of 2017 with the Ontario Energy Board (OEB). Our application will explain our investment plan that the OEB will assess to determine our electricity rates from 2018-2022.

Our objective is to provide our customers with safe and reliable electricity, so we want to understand whether your needs are being met by our current system and which types of reliability and service improvements you value most. Your input will be considered as we develop our plans, along with other considerations including our mandatory obligations, asset condition assessments and our ability to resource, schedule and execute our plan.

All of our distribution customers will have the opportunity to provide input into our investment plan through workshops, focus groups, surveys, and one-on-one discussions. You can participate in this important process by filling in a confidential Customer Survey by June 30, 2016 at: www.ipsosresearch.com/hydrooneC&I.

Thank you in advance for taking part in our online survey and providing your views on how we should keep the electricity delivery system strong and ready for the future.

Sincerely,

Warren Lister
Vice President – Customer Service
Hydro One Networks

WORKSHOP NON-ATTENDEE SURVEY INVITATIONS

SURVEY EMAIL TO WORKSHOP NON-ATTENDEE
COMMERCIAL AND INDUSTRIAL

Good afternoon,

We recently contacted you about a Hydro One Workshop, although you were unable to attend this year's session, we would appreciate you filling out our online survey for Commercial & Industrial Customers.

Please see the attached communication from our Vice President, Warren Lister, for more details and the link to the survey (also found here: http://www.ipsosresearch.com/hydrooneC&I/).

We are looking forward to hearing from you.

Best Regards,

Hydro One Business Customer Centre
1-866-922-2466

SURVEY EMAIL TO WORKSHOP NON-ATTENDEE
LOCAL DISTRIBUTION COMPANY

Dear [redacted]

We are in the early stages of building our five-year plan for our electricity distribution system and I would like to invite you to share your priorities with us and your views regarding the measures that should be included in our plans.

Our development plan will form part of our distribution rate application which we will file in the Spring of 2017 with the Ontario Energy Board (OEB). The OEB will assess our application to determine our electricity rates from 2018-2022.

Our objective is to provide our customers with safe and reliable electricity, so we want to understand whether your needs are being met by our current system and which types of reliability and service improvements you value most. Your input will be considered as we develop our plans, along with other considerations including our mandatory obligations, asset condition assessments and our ability to resource, schedule and execute our plan.

All of our distribution customers will have the opportunity to provide input into our investment plan through workshops, focus groups, surveys, and one-on-one discussions. You can participate in this important process by filling in a confidential Customer Survey by June 30, 2016 at: **www.ipsosresearch.com/hydrooneLDC** using your ID **# 685**.

Thank you in advance for taking part in our online survey and providing your views on how we should keep the electricity delivery system strong and ready for the future.

Sincerely,

Mike Penstone

Dear Customer:

We are in the early stages of building our five-year plan for our electricity distribution system and I would like to invite you to share with us what you believe our priorities should be and what matters most to you in the development of this plan.

Our development plan will form part of our distribution rate application which we will file in the spring of 2017 with the Ontario Energy Board (OEB). Our application will explain our investment plan that the OEB will assess to determine our electricity rates from 2018-2022.

Our objective is to provide our customers with safe and reliable electricity, so we want to understand whether your needs are being met by our current system and which types of reliability and service improvements you value most. Your input will be considered as we develop our plans, along with other considerations including our mandatory obligations, asset condition assessments and our ability to resource, schedule and execute our plan.

All of our distribution customers will have the opportunity to provide input into our investment plan through workshops, focus groups, surveys, and one-on-one discussions. You can participate in this important process by filling in a confidential Customer Survey by June 30, 2016 at: **www.ipsosresearch.com/hydrooneC&I**.

Thank you in advance for taking part in our online survey and providing your views on how we should keep the electricity delivery system strong and ready for the future.

Sincerely,

Warren Lister
Vice President – Customer Service
Hydro One Networks

FOCUS GROUP MATERIALS

DISCUSSION GUIDE FOR HYDRO ONE ONLINE FOCUS GROUPS

RESIDENTIAL AND SMALL BUSINESS CUSTOMERS

Version 3, July 5 2016

SESSION BREAKDOWN

Welcome and Introduction	5 Minutes
Section 1: Satisfaction with Hydro One and improvement expectations	25 Minutes
Section 2: Trade-off between reliability and cost	25 Minutes
Section 3: Trade-off between customer service and cost	10 Minutes
Section 4: Communication and open floor	10 Minutes
SESSION TOTAL	**75 Minutes**

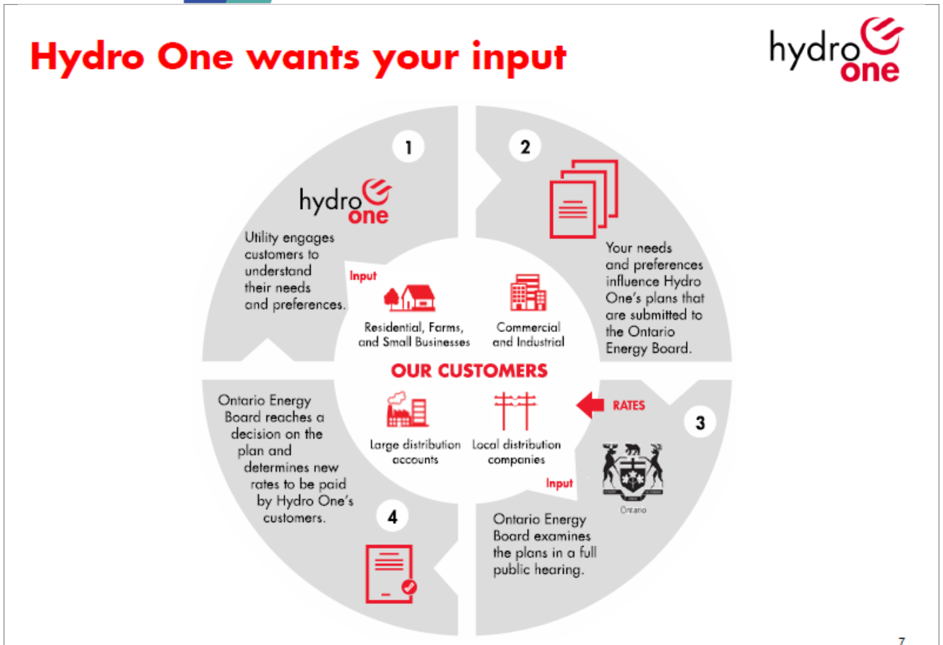
DETAILED SESSION AGENDA

MODERATOR Welcome	• Welcome & thanks for attending • Overview of the session purpose • Overview of technology and how session will work, inputting data into your computer • Good engagement practices • Rules of engagement - informed, passionate, and respectful dialogue • Audio taping for notetaking purposes and report • Importance of being in a quiet room with a closed door

WHY WE'RE HERE TODAY

Hydro One is looking for customer input to shape future investments in electricity assets as the Company begins to build a five-year plan for its electricity distribution system. These focus groups are a part of a larger consultation process that Hydro One is undertaking. They are speaking to both residential / small business customers like you, as well as all the other types of customers they provide electricity to.

Screen grab below will appear in Ideation platform. Moderator to provide brief description.



Unless otherwise noted, all questions are open-ended responses in the Ideation Exchange platform, followed by a Group Discussion.

SECTION 1: SATISFACTION WITH HYDRO ONE AND IMPROVEMENT EXPECTATIONS
25 MINUTES

As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices.

Q1. Thinking about Hydro One as I have just described it to you, please tell us about how satisfied or not satisfied you are with Hydro One overall, and why?

How could Hydro One improve its service to you / your household / business or are you happy with the service as it is now?

Q2. I would like you to consider the following four areas as it relates to Hydro One:

- Keeping the system reliable - avoiding power outages.
- Restoring power quickly after an outage and communicating with customers when the power is out.

2

- Customer service and billing – such as being able to interact with Hydro One through your phone or online, providing tools so you can manage your energy use, ensuring accurate and timely bills.
- Upgrading the system to connect new customers including those producing renewable energy or using energy storage. Here we are talking about how well Hydro One is proactively preparing the electricity system and grid for more electric vehicles, or allowing more customers with solar panels on their roofs to send power back into the system.

Would you say that Hydro One needs to make improvements in any or all of these areas, or would you prefer that Hydro One not worry about improving in any of these areas and instead focus on keeping costs as low as possible for customers? Please tell us about your view.

Moderator to probe:

Keeping the system reliable
- How many outages do you estimate you experience per year?
- What's an acceptable number of outages, to you?
- What do you think is the most common cause of power outages?
- Restoring power quickly after an outage and communicating with customers when the power is out

Restoring power after an outage
- Has anyone ever downloaded Hydro One's app? What do you think of it? What would you expect to do/see on the app?
- Has anyone accessed Hydro One's website during an outage? What's your experience been like?

Customer service and billing
- Would you like to be able to interact with Hydro One more easily? For example, would you like to be able to text or email Hydro One with a question rather than phoning the call centre?

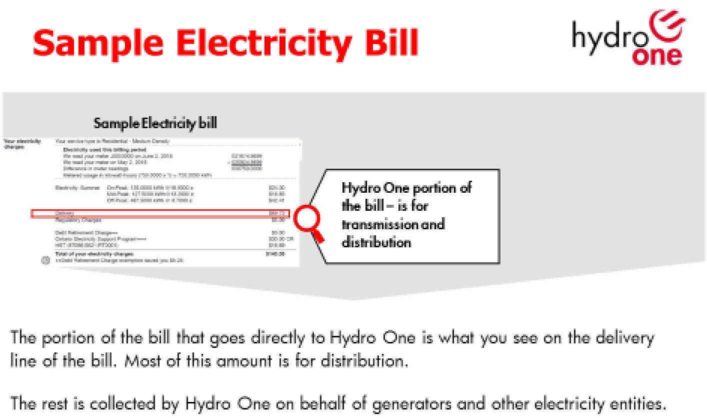
Upgrading the system to connect new customers
- Do you have a view of how well Hydro One is doing in this area?
- Do you have a sense of how many people are producing renewable energy or using energy storage? Do you think it is going to increase slowly or increase quickly over the next few years?

Moderator to probe:
- Is there anything missing from this list in terms of what you would like Hydro One to improve upon?

SECTION 2: TRADE-OFF BETWEEN RELIABILITY AND COST
25 MINUTES

As mentioned at the start of the session, Hydro One is responsible for the safe and reliable delivery of electricity, not the price of electricity. Hydro One does not make any money on the commodity or supply of electricity – Hydro One bills you the cost of electricity as a pass-through. Hydro One only makes a profit on the delivery charge portion of your bill.

Screen grab below will appear in Ideation platform. Moderator to provide brief description.



Q3. How much of this did you know about Hydro One?

In preparing for future planning, Hydro One has determined that in order to **at least maintain** the level of reliability and customer service it currently provides, a typical residential / business customer's total monthly bill will need to increase by 1.1% or $2.00 residential / 1% or $5.2O business.

Moderator to clarify as needed:
The increase is on the delivery charge only, but we have expressed the increase as a percentage of the total bill because it is simpler for customers to think about what they typically pay on each month.

This increase will be applied each year for the next 5 years. By the fifth year, a typical monthly bill will be roughly $10.00 residential **/** $26.00 business higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability - meaning in order to maintain the frequency of outages to its current level. The monthly bill could still increase for other reasons which are outside the control of Hydro One.

Q4. Before we get into a discussion on this, can we start by having you indicate your view.
Please tell us which of the following statements most closely matches your view.
IDEATION PLATFORM - ACCEPT ONE RESPONSE

- The increase is reasonable and I would support it
- I don't like it, but I think the increase is necessary
- The increase is unreasonable and I would oppose it
- Don't know

Moderator to probe (focus on don't know and opposed):

4

- If don't know, what do you need to know?
- If opposed – why?
- Is it that it is unaffordable? - the $2 residential / $5.20 business now, or the $10 residential / $26.00 business in the future
- Can afford it, but feel on principle that it's too big of an increase - the $2 residential / $5.20 business now, or the $10 residential / $26.00 business in the future
- Don't mind worsening reliability (without a rate increase, reliability will worsen, acceptable?)
- Trust/distrust Hydro One to spend the money well?
- Would more information on how the money will be spent to improve reliability help?

Probe if necessary (if many opposed):
Q5. There is a trade-off between what is the desired level of reliability and cost. For everyone, what would you be willing to accept in terms of more frequent and/or longer power outages to avoid the rate increase?

Q6. What would you need to hear or see from Hydro One in order to feel that a $2.00 residential / $5.20 business increase per month on your bill is reasonable?

Moderator to probe:
- Would it make any difference knowing how the money will be invested?

Q7. If instead of paying $2.00 / $5.20 more per month as we have discussed for the same level of reliability that you experience now, would you be willing to pay $2.30 residential / $6.00 business for **better reliability**? Why or why not?

If clarification required: "Better" refers to a reduction in the number and length of future power outages by 10%. Remember it is $2.30 each year for 5 years, so by the fifth year it will be $13.00 more per month (as compared to $10.00 to maintain current reliability).

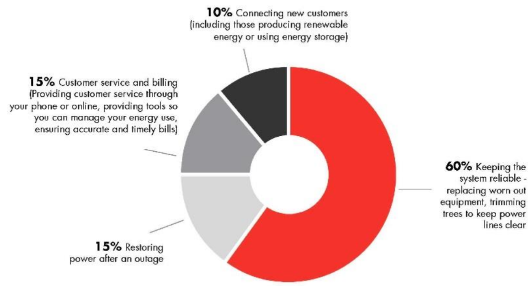
Here is some general information about Hydro One - the type of service they provide, some of the challenges they have, as well as the condition of their poles and lines.

Screen grabs below will appear in Ideation platform. Moderator to provide brief description

hydro one Ipsos

What your distribution charges pay for:

hydro one



6

WHAT CAUSES YOUR POWER TO GO OUT

hydro one

Power outage causes (2013-2015)		
Trees	24%	Trees fall on lines during storms.
Equipment failure	24%	Poles, transformers, lines failures can cause an outage.
Unconfirmed causes	19%	Sometimes Hydro One crews can't determine the exact cause of an outage.
Scheduled outages	16%	Occasionally, Hydro One needs to schedule power outages to safely replace or update equipment.
Loss of power supply	12%	Issues relating to the larger grid like damage to transmission lines.
Animal or vehicle damage to equipment	5%	Animal contacts with Hydro One's equipment and car accidents that damage poles.

6

Reliability challenges

Challenges all utilities face	Issues specific to Hydro One
Geography: Forested service territories are prone to outages caused by tree contact. In order to restore power, repair crews must locate and travel to source of an outage.	Much of Hydro One's service territory is heavily forested compared to other utilities'.[1] In 2014, Hydro One cleared over 9,000 km of distribution line. Hydro One's large service area means outages are longer and are more costly to locate and repair. Hydro One's network uses a radial circuit design to cover a large area, which does not provide redundant power supplies common in urban areas.
Weather: Major storms inevitably cause damage to power lines.	Hydro One's large service territory exposes it to all of Ontario's most challenging weather conditions.
Infrastructure: Most electric power grids were built up over many years with a huge volume of equipment and a mix of different technologies.	Hydro One's system serves an average of 10 customers per kilometre of power line while other utilities serve about 70 customers per kilometre. This requires Hydro One to maintain a large number of assets per customer.

1. Hydro One 2009 Vegetation Management Benchmarking Study by CN Utility Consulting, Inc.

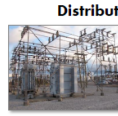
20

Maintain: Largest programs involve replacement and refurbishment of assets in poor condition

Wood poles

- **240,000** wood poles (15% of the fleet) are currently beyond their expected service life of 60 years.
- **400,000** wood poles (25% of the fleet) would be beyond their expected service life by 2022 if no replacements are made.

Distribution stations



- Approximately **144** station transformers (12% of the fleet) are currently beyond their expected service life of 50 years.
- Approximately **360** station transformers (30% of fleet) would be beyond their expected service life by 2022 if no replacements are made.

Much of the system was built in the 1950s and 1960s. Consequently many assets are approaching or beyond the end of their expected service lives. Replacement decisions are based on actual asset condition.

26

Q8. Does this impact your view of Hydro One at all? If so, how?

Moderator to probe: Do you trust Hydro One to make appropriate decisions on when and how to refurbish and replace aging equipment?

7

SECTION 3: TRADE-OFF BETWEEN CUSTOMER SERVICE AND COST 10 MINUTES
Let's talk a little more about customer service and billing. We heard some feedback on this earlier. Q9. For those of you who would like to see some improvements in customer service and billing, what kind of investments would you like to see Hydro One make? **Moderator to probe:** • Is that something you would be willing to pay for? Why/why not? • How much? $2.30 more per month? • What about more accurate estimates of when power will the restore when it is out? • What about tools to help you better keep track of your electricity consumption?
SECTION 4: COMMUNICATION AND OPEN FLOOR 10 MINUTES
I would like to understand from you how you would like to hear about information from Hydro One such as planned outages, rate changes, or improvements being made by Hydro One in your region. Q10. Is there an ideal way you would like to receive information? How about ask questions? **Moderator to probe:** • Would you ever proactively seek information from Hydro One? For example, go to their website, or follow them on social media such as Twitter or Facebook? Why or why not?
Q11. Before we conclude this session - are there any final thoughts or feedback you'd like to give to Hydro One?
SESSION CONCLUSION AND WRAP-UP

Ipsos Public Affairs

Hydro One Ideation Sessions
Recruitment Screener

Recruitment Strategy:

10 participants per residential group; 40 residential participants total

Session	Region	Other demographics	Date/Time	Time
1	GTA / Horseshoe L FSAs	Residential	Monday, June 27	5:30 pm (EST)
2	Southwestern Ontario N FSAs	Residential	Monday, June 27	7:00 pm (EST)
3	Southeastern Ontario K FSAs	Residential	Tuesday, June 28	5:30 pm (EST)
4	Northern Ontario P FSAs	Residential	Tuesday, June 28	7:00 pm (EST)

All should be Hydro One customers

Exclude those who hold very positive or very negative views of Hydro One

In each group, recruit good mix of: gender, age, working status, income & education level

INTRODUCTION

Hello, this is _________________ calling from Ipsos, a professional public opinion research firm. Today we are contacting individuals to invite them to participate in an online research session. This study will involve participation in an online group discussion lasting approximately **75 minutes**. You will be required to log on to our secure website using your personal computer, as well as call in to a toll-free conference line to participate in the group discussions. If you qualify and are able to participate in the session, you will receive an honorarium for your time. ($75)

Would you be interested in participating in this study?

Yes **CONTINUE**
No **THANK & GOODBYE**

1. Have you or any member of your household ever worked for: [**READ. CIRCLE AS MANY AS APPLY**]

AIM FOR A MIX

9. What is the highest level of education that you have completed? Please select one response only.

Grade school or some high school
Completed high school
Technical or trade school/Community college
Some university
Complete university degree
Post-graduate degree

RECRUIT GOOD MIX

10. To take part in the session, we need you to log into a website and dial-in via a telephone line. You therefore need access to a computer (pc/laptop NOT tablet or smartphone), an internet connection and telephone line. Can you please confirm that you have all that?

Yes **CONTINUE**
No **THANK AND TERMINATE**

11. And how often do you do the following…

Check email
Upload & download documents/pictures from email (word/excel/powerpoint etc)
Shop online (Amazon, ebay etc)
Use online banking
Use social media (Facebook, Imgur, a Blog, Reddit …etc.)
Download or Stream Videos (Netflix, Hulu, Sidereel, Fastpasstv, etc.)

Every day
2/3 times a week
Once a week
2/3 times a month
Once a month
Less often than once a month
Never

CONTINUE IF AT LEAST ONCE A WEEK TO 2 OR MORE ITEMS

We would like to invite you to participate in an online research session on [INSERT DATE]. As a token of our appreciation for your time, we are offering each participant **$150**

Are you interested in participating? (DO NOT READ. CIRCLE ONE ANSWER)

Interested in participating
Not interested in participating

Excellent! In order to participate in this session you will need access to the internet via a PC/Mac (not via smart phone) and telephone line. Because there is a conference call component, and the discussion we will have is equally as important as your input via the online tool, we ask that you participate from a quiet room so there is less background noise on the call. We will provide you with a unique URL and toll-free 1-800 number for you to log in.

Date:

Time:

Place:

PLEASE LOG ON 5-10 MINUTES BEFORE THE SCHEDULED START TIME SO WE CAN MAKE SURE EVERYONE IS PROPERLY SET UP

WHEN COLLECTING PERSONAL DETAILS, PLEASE MAKE SURE YOU RECORD EMAIL ADDRESSES SO THAT WE CAN SEND OUT LOG IN DETAILS IN ADVANCE.

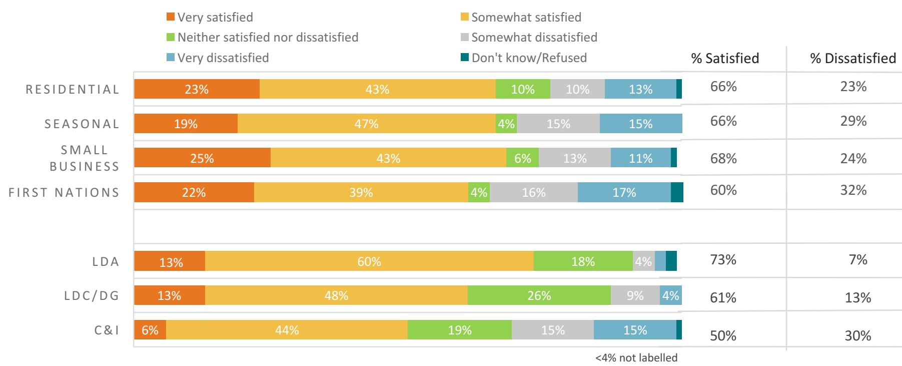
SURVEY RESULTS

SATISFACTION IS GENERALLY CONSISTENT ACROSS SEGMENTS – C&I DIRECTIONALLY LOWER

2

ALL CUSTOMER SEGMENTS

Overall satisfaction with Hydro One



As you may know, Hydro One builds and maintains power lines, towers and poles, safely delivers electricity, reads meters, calculates your charges, answers your calls, responds during outages, and clears trees and brush from power lines. Hydro One does not generate electricity or set electricity prices. Q1., How satisfied are you with Hydro One overall? Note: During the first week of fielding the response scale was changed from 1 to 5 to a word scale to be consistent with the Annual Customer Satisfaction survey. Base: All Respondents Post Q change; Residential (n=243), Seasonal (n=68), General Service (n=159), First Nations (n=204), LDA (N=45), LDC/DG (n=23), C&I (n=133)

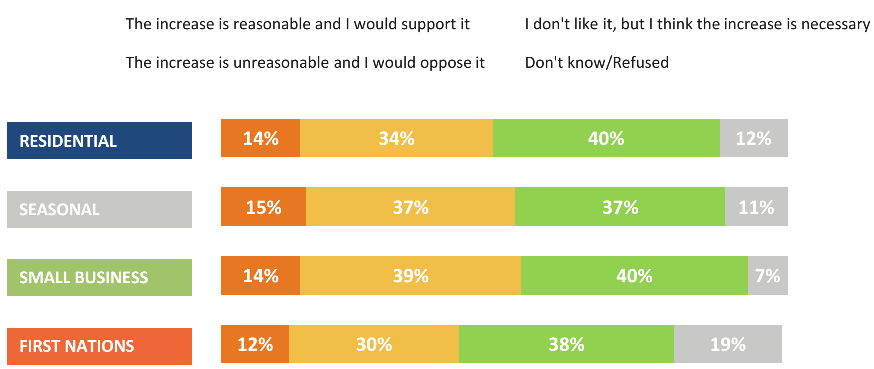
Q12. Please rank the SERVICE items below in the order in which they would have the greatest positive impact on your organization, where 1 represents the item that would have the most positive impact and 7 represents the least positive impact? Base: LDA (n=45), LDC/DG (n=23), C&I (n=133)

SURVEY RESULTS

R&SB CUSTOMERS HAVE MIXED OPINIONS ON RATE IMPACTS, BUT SLIM MAJORITY ACCEPT THE IMPACT NECESSARY TO MAINTAIN RELIABILITY/SERVICE LEVELS (EXCLUDING DKS)

TELEPHONE SURVEY

Acceptability of rate increase to maintain levels



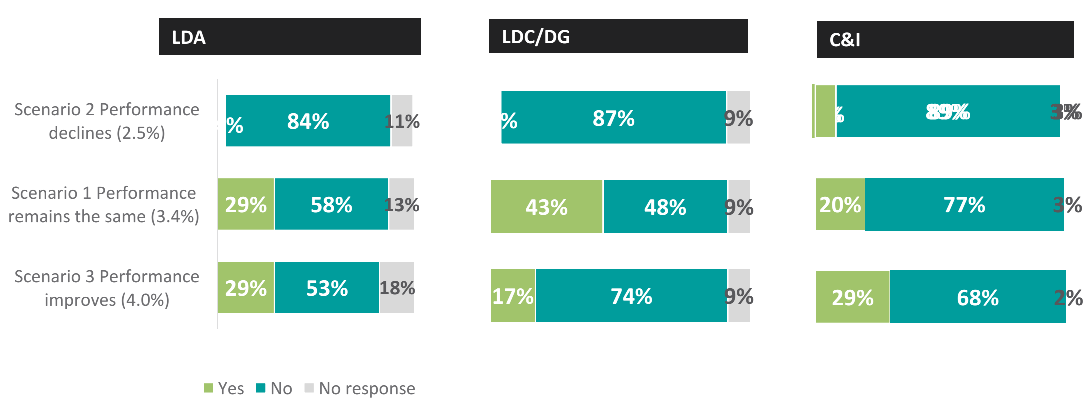
Q17. Hydro One has determined that in order to at least maintain the level of reliability and customer service it currently provides, a typical [residential or seasonal / small business] customer's total monthly bill will need to increase by [1.1% or the equivalent of $2.00 / 1% or the equivalent of $5.2O]. The increase will be applied each year for the next 5 years. By the fifth year, a typical monthly bill will be roughly [residential or seasonal $10.00 / small business $26.00] higher than it is now. Please note that this increase reflects the cost to maintain the current level of reliability and service to customers. The monthly bill could still increase for other reasons which are outside the control of Hydro One. Would you be willing to accept this increase to maintain the current level reliability and customer service across the electricity system? Base: All respondents; Residential (n=400), Seasonal (n=100), Small Business(n=200), First Nations (n=300)

SURVEY RESULTS

LARGE CUSTOMERS ARE NOT WILLING TO ACCEPT A RATE INCREASE, PARTICULARLY FOR DECLINING RELIABILITY

ONLINE WORKBOOK/WORKSHOP SURVEY BOOKLET

Willingness to accept investment scenarios



Q15. Would you be willing to accept a 2.5% distribution deliver rate increase where reliability and service performance declines (Scenario 2)? Base: LDA (n=45), LDC/DG (n=23), C&I (n= 133)
Q16. Would you be willing to accept a 3.4% distribution delivery rate increase where reliability and service performance remains the same as it is now (Scenario 1)? Base: LDA (n=45), LDC/DG (n=23), C&I (n=133)
Q17. Would you be willing to accept a 4.05% distribution delivery rate increase where reliability and service performance improves (Scenario 3)? Base: LDA (n=45), LDC/DG (n=23), C&I (n= 133)

FOCUS GROUP & WORKSHOP

THEMES

THEMES

Overview

- Cost
- Consistency
- Customer Service
- Connections and Capacity
- Credibility
- Communication

THEMES

COST

COST

Impact of hydro costs and affordability

- For residents, many are interested in lowering the cost of hydro. For a few, it is already unaffordable or approaching being unaffordable
- For small businesses, it is one of many expenses of their operations and a threat to their profitability. Small businesses feel squeezed from many sides, and unsupported in Ontario
- For some large business customers, they stated that the continued rise in hydro prices is a direct threat to the viability and competitiveness of their businesses.
  - it is an expense that they state is one of or the highest after labour
  - it is perceived as being higher than in other jurisdictions and participants have observed anecdotally that business is being lost to these other regions as a result - for example, manufacturing plants in Ontario have closed and moved to the United States and Mexico

COST

Understanding hydro bills

- For residents, many are interested in seeing more information about their bills, particularly in a graphic or illustrative format
- For Large Customers, clarification was provided on the breakdown of costs and line items on customers' bills and this generated a large amount of discussion about each aspect of a hydro bill
- Participants in the small business and large workshops were incredulous that they are encouraged to conserve energy, only to have commodity prices rise to offset this when load in Ontario is lower than expected
- The Debt Retirement Charge and Global Adjustment were also mentioned by participants as being a source of dissatisfaction and confusion

COST

Privatization

Several organic mentions of the benefits and drawbacks of privatization

- Benefits: better accountability and transparency, better decision-making
- Drawbacks: conflict between ratepayers and shareholders, a perception of higher prices

COST

Efficiencies

- Large customers inquired repeatedly in all markets about efficiencies in operational and maintenance costs - and asked if Hydro One could improve in these areas in order to save money and re-invest in capital expenditures, instead of raising rates
- They expressed interest in seeing further details on the historical and current efficacy of maintenance programs, and capital expenditures already spent on improvements. This would help them determine if efficiencies are being achieved

COST

Rate increases

- For residents, most don't like the rate increase but understand that it is necessary, several oppose or don't know if they support a rate increase, with a few supporters
- For small businesses, several don't like the rate increase but understand that it is necessary, with an equal number who oppose it
- For large customers, overall the majority are unwilling to accept a rate increase of any size, whether reliability remains the same or improves
- All segments express a desire for more detailed information as to how the rate increases would be spent, so that they can determine if the investments are truly impacting reliability - rather than going to wages, salaries, or payouts to Hydro One employees

THEMES

CONSISTENCY

CONSISTENCY

Power quality and reliability

- Power quality emerged as being the reliability issue of most concern to participants in the large workshops - it was mentioned as being a significant and pressing priority for many customers in all markets.
- Several participants throughout the consultation process challenged the fact that interruptions lasting less than one minute are not being tracked by Hydro One
- The consequences of the impacts due to poor power quality were disseminated in detail by participants during the consultations. These include:
  - Lost productivity
  - Equipment failure - both temporary, and permanent
  - Labour impacts - i.e. the uncertainty of sending workers home or keeping them at the facility
  - Health and safety issues
  - Financial impacts
  - For LDCs, the whole municipality is without power
  - Installing backup generation
  - Technology / IT impacts

CONSISTENCY

Current asset management

- A few residents and in particular small businesses expressed concern at infrastructure not being managed at a pace that mitigates the risk of aging assets
  - They expressed concern that this was as a result of poor planning and maintenance
- Many large customers were satisfied with the current level of asset management

CONSISTENCY

Future asset management

Preparing the grid for future needs - including the role of renewable energy and technology - was debated by participants in all groups and workshops

- Some believe that more renewable energy would benefit the grid and ultimately ratepayers in the long term by being more economical than other forms of generation, although they acknowledge that costs may go up in the short term
- For those who advocate for proactively preparing the grid, the pace of adapting the grid should be measured and the approach balanced
- Detractors are concerned that technology will be obsolete before it is beneficial to the maximum number of people
- They believe that associated costs should be borne by the few who benefit, rather than all ratepayers

CONSISTENCY

Regional concerns

Regional reliability concerns were brought up as being of particular interest to some participants

- For those in the Muskoka area, they were concerned about reliability issues caused by the dense forestry in their region, and questioned why trees in their area are not more proactively trimmed
- For those in the northern markets, they expressed their concern that capital investments would be focused on areas of greater population density, i.e. in southern Ontario, and that they would not see the benefits of improved reliability. As such, they stated that they would like to see a detailed capital plan that included investments and benefits specific to the north
- In general, participants indicated an interest in seeing more region-specific investment details, to better understand reliability performance in their area of the province

THEMES

CUSTOMER SERVICE

CUSTOMER SERVICE

Satisfaction with service

- Most residential customers are satisfied with customer service, with long wait times on the phone being the biggest issue
- For most LDA/LDC customers, they stated that customer service is generally satisfactory
- For many C&I customers, some LDA/LDCs, and small businesses, customer service from Hydro One is an area in need of significant improvement
  – Not having a dedicated account person or contact.
  – Being passed from one person or department to another instead of receiving a satisfactory resolution to issues
  – The process of resolving issues can take an excessive amount of time - months or years, if at all. Receiving rebates can also take a long time.
  – Bills and information on planned outages are sent to a corporate head office, instead of employees on the ground who need the information for planning and budgeting.
  – Being unable to receive trustworthy advice - for example, whether or not participating in an energy-saving program is worth the risk.
  – Making web meeting appointments with Hydro One employees who do not show up.
  – Navigating complicated and time-consuming application processes for incentives and programs.

CUSTOMER SERVICE

Billing

In general, participants were looking for two key elements on their bills: accuracy and clarity.

- Accuracy challenges included:
  – receiving estimated bills instead of those based on actual meter readings
  – consolidating bills if one company is receiving multiple bills for its different buildings/meters/locations
- Clarity challenges included:
  – finding their bills confusing
  – feeling that the information provided is incomplete
  – format issues: wanting a more visual format such as a chart, pie or graph

THEMES

CONNECTIONS & CAPACITY

31

CONNECTIONS AND CAPACITY

Providing additional capacity

Customers in certain regions (northern Ontario) and industries (mining, greenhouses) state:

- that a lack of sufficient power capacity is a hindrance to their ability to grow their businesses
- the process of applying for more capacity with Hydro One and the Ontario Energy Board is protracted and unsatisfactory
- the rules and regulations around adding capacity via the beneficiary payment system are confusing

32

CONNECTIONS AND CAPACITY

Exporting power

- The sale of electricity at a loss to the US also emerged as a topic of discussion during some of the large workshops and focus groups.
- Participants expressed concern and dismay that this is happening when rate increases are being considered
- In one workshop, participants from the greenhouse industry indicated their strong interest in using this excess energy to meet their needs, as they require lighting for their greenhouses overnight.

THEMES

CREDIBILITY

CREDIBILITY

Role of regulator

Because Hydro One is the customer-facing entity responsible for billing, customers' perceptions are negatively impacted by all aspects of the hydro bill and any poor perceptions of the industry in general.

There was low awareness of the role of regulators and numerous points of clarification were made throughout the consultations as to what is mandated and controlled by the respective regulators, including:

- OEB:
  - Information contained on hydro bills
  - Commodity price of electricity and inability to profit on it
  - Capacity expansion
  - Beneficiary payment system for capital work
  - Non-advisory customer service role
- IESO:
  - Global Adjustment
  - Environmental incentive programs
  - Contracts for generators, including renewable sources

CREDIBILITY

Perceptions of Hydro One

- There was commentary made by some participants on perceptions of Hydro One and its workers
  - There were mentions of seeing Hydro One workers in coffee shops during working hours
  - Having too many workers show up to a job
  - Linesmen who are promoted to “cushy”, high-paying jobs within the organization
  - Perception of excessively high quality of working vehicles
- These perceptions of poor productivity and management are particularly difficult to accept with the perception that hydro costs in Ontario are very high, and a perceived threat to the economic well-being of the province’s businesses

CREDIBILITY

Company culture

- Some participants in all segments stated their belief that the information being presented was to justify a distribution rate increase by Hydro One.
- Comparisons were unfavourably made to private companies:
  - private companies deliver a better product for less money, by finding efficiencies, and by being innovative without raising prices
  - many participants pointed out that hydro rates have continued to climb for many years and their belief is that there is no end in sight as it relates to rate increases, thanks to poor management and decision-making by Hydro One.
- Small businesses and large customers pointed out that they are unable to raise their own prices to offset an increase in hydro prices

37

CREDIBILITY

Shareholders vs. ratepayers

- A few participants expressed deep concern and dismay that profits were given to shareholders, and not returned to the company in order make capital improvements, and/or reduce costs for ratepayers.
- They stated that this is a situation unique to Hydro One, and that other companies would not have the same option available to them - instead, they would put profits back into the company in order to maintain or reduce prices for their end-users, or profits are put back into making a better product
- The inherent contradiction between keeping costs low and reliability high for ratepayers, versus making profits for shareholders, was pointed out by participants

38

CREDIBILITY

Accountability and transparency

- The themes of accountability and transparency for Hydro One emerged throughout the in-person consultations.
- Participants indicated concern at a current lack of both, and a desire to see Hydro One undergo an organizational transformation that would positively impact customers in terms of:
  - helping them become informed consumers
  - providing reassurance of reliability and service
  - providing reassurance responsible stewardship of rates paid in the form of operational and maintenance efficiencies, and prudent decision-making in future capital investment planning
- While many customers cited deep concerns around rate increases, many were also open and receptive to understanding how and why Hydro One uses its funds.

THEMES

COMMUNICATION

COMMUNICATION

Communication during outages

- Numerous participants throughout all consultation methods stated that they would like to experience better communication during outages
  - The majority call in to the number on their bills or the OGCC, with a few checking Hydro One's website.
- Most stated that the information they receive or view is inaccurate, and this is a source of frustration in particular for businesses - many of whom stated that communication an area in which Hydro One could help reduce the negative impact of outages
- Participants indicated that they would like timely, accurate information on outages specific to their region/area
- Awareness of other tools and resources for outage information, including Hydro One's app, is low

COMMUNICATION

Cost saving ideas and programs

- Some residents indicated their interest in having Hydro One provide ideas and information on ways to save and conserve energy and ultimately, the cost of their hydro bill
  - This might be through programs, coupons, or simply being able to track their detailed usage between bills
  - Having this information come from Hydro One would lend credibility to the information.
- For large customers, a few customer made organic mentions of positive experiences with energy/cost saving programs with Hydro One.
  - For those who are eligible for cost-saving programs and incentives, awareness was generally low.
  - For those who have already applied for these programs, the application process is frustrating and complicated

COMMUNICATION

Channels

Participants expressed interest in a number of different channels and some indicated that they would like to hear from / about Hydro One via multiple channels, including:

- Directly on the bill
- Bill inserts
- App
- Social media
- A separate letter
- Email
- Advertising
- Texts
- For business customers: a dedicated relationship with an account person, a local contact, or a dedicated business (non-residential) call center line were all of interest.

COMMUNICATION

General information on Hydro One

- Participants in all segments expressed an interest in learning more detailed information about Hydro One
- Many participants stated that in order to make decisions around which areas of investment would be of most benefit, as well as whether or not they would support an increase in rates, they would require more comprehensive information including specific costs, historical data, and cost efficiencies
  - This in turn would lead to trust that Hydro One is focused on efficiency and productivity.
- For many, the information provided during the consultations had a positive impact on their perceptions of the company

ABOUT IPSOS

Ipsos ranks third in the global research industry. With a strong presence in 87 countries, Ipsos employs more than 16,000 people and has the ability to conduct research programs in more than 100 countries. Founded in France in 1975, Ipsos is controlled and managed by research professionals. They have built a solid Group around a multi specialist positioning Media and advertising research; Marketing research; Client and employee relationship management; Opinion & social research; Mobile, Online, Offline data collection and delivery.

Ipsos is listed on Eurolist NYSE Euronext. The company is part of the SBF 120 and the Mid 60 index and is eligible for the Deferred Settlement Service (SRD).

GAME CHANGERS

At Ipsos we are passionately curious about people, markets, brands and society. We deliver information and analysis that makes our complex world easier and faster to navigate and inspires our clients to make smarter decisions.

We believe that our work is important. Security, simplicity, speed and substance applies to everything we do.

Through specialisation, we offer our clients a unique depth of knowledge and expertise. Learning from different experiences gives us perspective and inspires us to boldly call things into question, to be creative.

By nurturing a culture of collaboration and curiosity, we attract the highest calibre of people who have the ability and desire to influence and shape the future.

"GAME CHANGERS" – our tagline – summarises our ambition.

Wave 2 Distribution Consultation – Hamilton LDC/LDA Session

June 8, 2016

Attendees and the company they work for	• Rosso Parra, Grimsby Power Inc. • Keith Vanderwood, Air Canada Products Canada • Grant Nopper, Canadian Gypsum Company (CGC) • Kristen Montague, Canadian Gypsum Company (CGC) • Kevin Hodgins, St. Mary's Cement Inc. • Denis Yeung, Oakrun/Aryzta • Randy Gao, Royal Canin
Mood / tone in the room **Level of engagement**	• Mood in the room was quiet and subdued, but participants arrived open and willing to hear what was being presented, and were thoughtful and engaged. Most had a high level of understanding of the energy sector and had a detailed knowledge of their own electricity needs and challenges. • Oded Hubert was present to greet the participants in addition to presenters Graham Henderson and Paul Brown. • Other Hydro One account persons and staff were present to provide local context and engage with customers.
Quotes to summarize the general conversation	• Customers spoke of challenges due to service interruptions and the subsequent impact on their organizations. • For one LDA, communication during interruptions is the key concern. They state that although it's apparent why the interruption is occurring, i.e. severe weather, they would like communication as to when service will be resumed, including clarification on timing of any necessary repairs. • For other LDAs, they state that communication and customer service from Hydro One is outstanding. For these, their issue is around unreliable service from feeders, stations and transformers not controlled by Hydro One. These are poorly managed and create power issues without an apparent means of recourse for the customer. • For the LDAs who face interruptions, regardless of the cause and communication experience, there are significant impacts as it relates to labour and safety. Manufacturers are unsure as to whether they should send their workers home or keep them onsite. Additionally, there are safety hazards associated with service interruptions (e.g. working with volatile materials). *"A little more communication or availability to answers as to estimated time of outages. Is it 2 hours, is it 8 hours…That's a big difference. Unplanned outages. What's the repair going to take."* *"We schedule the labour force. Do we undertake this undertaking or not? Are we*

	going to be up and running in 5 minutes or 10 hours? For labour reallocation we need to know that – do we send people home or keep them here?" • In terms of ranking areas to improve reliability, there was no clear winner with various participants choosing different areas as being of importance. One participant indicated it's difficult to make a choice between reducing the number of outages or lessening the frequency, as they both have different consequences associated with them. Rather, they felt that it was important to strike a balance in addressing both. *"I think it's good to keep a good balance of both, because any power flicker 5 seconds we have to restart our production lines. But then duration is very important too, every hour you can bring the power back on earlier, is a lost time you can save. It's really a mix of both, one not more important than the other."* • For the improving service ranking, power quality was by far the most pressing concern - in fact, a couple of participants feel that it's more important than reducing frequency or duration of interruptions - to them, reliability equals power quality. However these participants recognize Hydro One is not always responsible for these interruptions, as it's a flaw within the grid. *"Power quality is probably the biggest. Above all."* *"The basic flaw is you're looking at interruptions and duration…for us reliability is quality not interruption and duration. It's not that we don't have power, it's that quality isn't what we need and it's causing us problems."* • For the Scenarios, participants asked for clarification around their specific rate class on delivery distribution charges. Once ascertained that their rate is 2%, a 4% increase was considered very reasonable, with one participant indicating he would be willing to pay a 10% rate increase. *"If my bill is $100K a month, 2% category – so that's $2000 a month. if I'm in the 2% distribution category, It's 2% of 25 which is like nothing. So the answer's pretty easy for us."*
Any follow-ups or points of concern / consideration	• With power quality being a concern, participants indicated interest in having Hydro One manage it on their behalf. • The suggestion by Hydro One that there are ways to minimize impact internally within their organization's infrastructure, i.e. its ability to mitigate the effects of drops in voltage - was of great interest to participants.
Emerging Themes on Customer Needs and	• **Communication**: Providing timely information about outages and repairs to drive decision-making for customers. • **Power Quality**: Having power quality managed by Hydro One as well as working to improve internal capacity/ability to deal with PQ incidents.

Preferences	

Hydro One Distribution Consultation – Hamilton C&I Session

June 8, 2016 - 2pm

Attendees and the company they work for	• Vern Mills and Paul McCoy, McCoy Foundry • Sara Peckford and Caitlin McFadyen, Town of Caledon • Fidel Reijerse, RESco Energy (generator) • Carl Loewith, Joe Loewith & Sons • Joe Lannan, Great Lakes Elevator • Dave Sabola, Pepsico Canada • Stephen Hart, HK Travel Centre • Bob Burlakoff and Abu Sanneh, Hamilton Airport • Natasha Murray and George Bougiouklis, Chartwell Mastercare • Linda Campbell, City of Hamilton
Mood / tone in the room Level of engagement	• Mood in the room was engaged and lively. Participants were eager to ask questions and provide their thoughts and perceptions on a wide range of topics related to Hydro One. • Participants included those with a more basic understanding of the energy sector and Hydro One's role specifically, as well as those with a more sophisticated understanding of the electricity system, including detailed technical knowledge of their own challenges and needs. • Hydro One VP of Regulatory, Oded Hubert, was present to greet the participants in addition to Hydro One presenters Graham Henderson and Paul Brown. • Other Hydro One account persons and staff were present to provide local context and engage with customers.
Quotes to summarize the general conversation	Throughout the discussion, several points of clarification were made about factors/concerns not controlled by Hydro One, including: • **Energy Retailers:** Participants asked about the energy salesperson who knock at their door. It was clarified that these are companies with whom consumers sign a contract for a fixed price on the commodity portion of their bill (electricity or natural gas) • **Bill Format:** Based on feedback by participants on the current bill format not being as detailed as they would like, it was clarified that the format and breakdown included in Hydro One's bills to customers is prescribed by the OEB. • **Global Adjustment Charge:** It was clarified in response to customer questions and comments that this charge includes payment of contracts that the IESO has with generators. As well, any conservation incentive programs that consumers participate are funded through GA. • **Wi-Fi:** One participant inquired as to whether Hydro One is a potential provider of Wi-Fi. It was clarified that this misconception may be related to

	Hydro One's smart metering network but that they are not a provider of Wi-Fi. • **Payment Terms:** One participant remarked that they were required to pay upfront for requested capital work. It was clarified that these payment terms are prescribed by the OEB for any capital work requested by a customer and fulfilled by Hydro One. • **Commodity Price of Electricity**: It was clarified that the commodity price of electricity, which comprises the majority of a customer's overall bill, is a pass-through charge by Hydro One which they are not allowed by law to make a profit on. Feedback specific to Hydro One included: <u>Billing Concerns and Feedback:</u> • Positive experiences as well as challenges faced related to billing were voiced at various times throughout the session. • A couple of participants had positive experiences as it relates to billing, including one who observed that billing accuracy has improved significantly over the past few years. *"…as somebody who looks at bills every single day, [accuracy] has improved significantly, would like to see it improve further, but it has gotten a lot better. "* • One participant stated that they would like a more detailed breakdown of their bill to understand usage and kw/hour. • Another participant had a billing issue where they were charged 3 years later for work in the tens of thousands of dollars. *"Hydro One did the work, the bill came in about 3 years later. That was no longer in our books, 30 or 40 or 50K, it was substantial, fell through the cracks."* <u>Unplanned interruptions:</u> • Service interruptions of less than one minute in duration are a major concern to one manufacturing customer. For this customer a short interruption is just as impactful as a longer one. They stated that a 10-second interruption can close their plant for 5 hours, which costs them thousands of dollars a minute. They asserted that interruptions less than 1 minute should be tracked. *"…a 10 second blip takes the entire factory down, then has to be purged, sanitized, and lack of production could be thousands of dollars a minute. For certain manufacturers, it can be extreme, those [interruptions of] less than 1 minute should absolutely be tracked."* • For a participant who manages a long-term care facility, duration of interruptions was of particular concern with hydro service restoration taking as long as 72 hours in a facility with a vulnerable population (seniors with

medical issues). They do not have a contact person or relationship with an account representative and are instead reliant on publicly available information to contact Hydro One. Finding a person within the organization to provide specific answers is an ongoing challenge.

"In some cases you can't determine how long it's going to be - getting that information is pulling teeth, having some contact for medium [size] businesses with huge impact, next level customer service…my power interruption at home is different than a long-term care home."

Communication and Customer Service

- Customers state that they have faced challenges in trying to receive information and resolution as it relates to both immediate (service interruption and repair) and longer term (clearing brush, billing for LED lights) needs.
- Information on planned outages, as well as bills, are often sent to a customer's head office instead of directly to the employees on the ground who are directly affected. For unplanned outages, this means that employees are unable to plan ahead accordingly. For bills, employees receive bills from their head office months later which affects their ability to plan and budget.
- Some of the issues and challenges faced have been ongoing, with resolution of issues such as billing errors being a long process. A couple of participants had positive experiences with Hydro One staff but in general, finding the right person to help is a challenge.
- A couple of customers spoke of positive experiences with tools and programs offered by Hydro One, including...
    - A 50% funding audit program at a participant's facility.
    - An energy management billing portal recommended through customer service to a participant. They are able to see comparative kw/hr, compare to last year/month, and understand their savings.
    - These were identified as being awareness opportunities for Hydro One.

"I had the same challenge, I got Hydro One to send me the bill because it never comes to me...Normally I get them four months later, what good is that to me four months later. All these bills in larger corporate end up with some accountant as opposed to the people trying to run it."

"As a municipal client we do have some challenges with Hydro One staff in cleaning up the brush…residents come to us first, especially when it has to do with trees…that was challenging to get answers to communicate to our residents."

Planning and Efficiencies

- A municipality pointed out the inherent contradiction in wanting to create a tree canopy for their region, while Hydro One is actively trimming trees.
- Participants asked about the potential to bury lines underground vs. having the poles and line aboveground. It was clarified that for developers, if the

municipality mandates that developers bury their lines underground, Hydro One fulfills the work, and the developer is the one to pay for it. For municipalities, should they request that their lines be buried underground, they are also required to pay for it.

- Hydro One's role in providing capacity and flexibility to consumers for renewable energy sources, such as in-home charging for electric cars, was debated. This was perceived as being a lower priority by one participant with another seeing it as a high priority because it is important for Hydro One to effectively manage the grid as new technologies and power sources emerge.

"How are your costs for these things distributed? Are the costs of doing business in Timmins maybe higher than that of say down in here [Southern Ontario]. So is there a cost base distribution of rates, or is it a big pot, everybody pays the burden of whatever the cost of maintaining the system?"

"…I have put electric vehicles and storage lower down…to me it's individual homeowner, charging station in garage, as opposed Hydro One additional service."

"To me it's not just about 10 kw and Tesla, having some grid management benefit as well."

Power Quality

- Power quality was voiced as a significant issue with severe consequences for affected businesses. One customer defined power quality as a drop in voltage, which could occur as many as 15 times an hour. These drops in voltage have the same impact as a service interruption.

"For us, power quality is bigger…when I think of reliability, I don't think of power outages. But when you drop the power and the generator goes on and comes off 15 times in an hour, you can't run the business that way."

Reliability and Rates

- In response to participant questions, clarification was provided on urban vs. rural rate classes. Participants wanted to know how Hydro One ensures that customers have been correctly assigned to the appropriate rate class. It was clarified that rate classes are determined by the density of customer base, i.e. customer load per kilometre of line.
- One large industrial expressed frustration at the continuously rising cost of electricity in Ontario. For them the rising cost is a barrier to remaining competitive. Another participant stated that they have struggled with fluctuating bill amounts without any way of predicting or understanding why their bill amount changes so much, thus making budgeting extremely challenging. Although these remarks were based on the overall bill and not specifically the delivery distribution charge, they expressed the belief that Hydro One should have a vested interest in facilitating success for businesses

	or better communicating available programs to customers. • A participant inquired as to how being a public company would affect investment plans, and expressed concern that capital investments resulting in improved reliability might not be in the shareholder's best interest. • Questions were raised about whether or not improved technology and the associated increased efficiency/benefits are being considered and calculated into the investment plan. • Some participants are willing to accept a rate increase if there is a demonstrable benefit to their hydro service, customer service and efficiency. *"…what does the consumer need to be more successful, if you don't make them more successful, what have you accomplished."* *"In general, we're all willing to pay more if we receive more, and if the outcomes we can visualize are very tangible."* *"…being out of hydro for 72 hours is unacceptable, Hydro One has known about this problem for 3 years and is unwilling to do anything about it."*
Any follow-ups or points of concern / consideration	• Tools, resources and programs that work in conjunction with municipalities and businesses to improve coordination, provide better customer service, and locate specific information such as a breakdown of their bills, are of great interest to participants.
Emerging Themes on Customer Needs and Preferences	• **Awareness:** Make customers more aware of available tools and resources for billing and service, as well as any programs that may be of benefit to them. • **Communication**: Providing information about outages and repairs, as well as a better understanding what is within Hydro One's domain/control and what isn't. • **Customer Service and Relationship**: Provide timely, efficient, and customer-specific service. For C&I customers, they face challenges in receiving answers and resolution from the call centre and central numbers with their issues often being bounced from person to person. • **Power Quality**: Improve power quality by mitigating frequency of drops in voltage. • **Rate Increase vs. Reliability:** Guarantee a tangible improvement in reliability and service in the event of a rate increase.

Hydro One Distribution Consultation – Collingwood LDA, LDC and C&I Session

June 9, 2016 - 9:30am

<table>
<tr><td>Attendees and the company they work for</td><td><u>LDA/LDC</u>
Bill Koniuch, Honda of Canada Manufacturing
Shawn Plowright and Adem Nezirevic, KTH Shelburne MFG.

Doug Wansborough, Devils Glen Country Club
Randy Fielder, Bonaire Golf & Country
Nick Levangie, JW Marriott
Sean, Owen Sound Ledgerock Ltd.
Ken Rounds, Simcoe County
Jeff Struewing, Grey Standard Condo Corp 75
Ian, Energy Plus</td></tr>
<tr><td>Mood / tone in the room
Level of engagement</td><td>Mood in the room was thoughtful and serious, with many participants contributing to the discussion.
Participants had a high level of knowledge of the energy industry as well as the needs and challenges of their own organizations.
Graham Henderson from Hydro One was present to greet the participants and provide an introduction to Hydro One, in addition to co-presenter Paul Brown.
Other Hydro One account persons and staff were present to provide local context and engage with customers.</td></tr>
<tr><td>Quotes to summarize the general conversation</td><td><u>Reliability</u>
Commercial/industrial participants struggle with the frequency of unplanned interruptions, with some customers experiencing as many as 50 unplanned interruptions per year.
Once an interruption has occurred at a manufacturing plant, their processes need to be re-started and that can take hours to get back-up and running.
Financial consequences can be dire, costing $1.2 million per year for one participant and hundreds of thousands per outage for another.</td></tr>
</table>

	"...Every time [an unplanned interruption] happens re-starting takes hours. Our [cost] impact is $1.2 million a year of repairing parts..." <u>Location/Area specific</u> • Participants from this session were particularly interested in maintenance and outage prevention activities specific to their area. The Muskoka region was identified as being one of the most tree-dense areas in Ontario, and as a result there is a high concentration of power interruptions caused by trees. They would like to see an investment plan that addresses their region-specific concerns with more pro-active tree-trimming, to reduce the number of interruptions and improve reliability performance. • Participants had questions and concerns around future load capacity for their area, which is an area that they indicate is growing exponentially. • Because of the seasonal nature of the businesses in the Muskoka region (i.e. busy ski resorts in winter, and vacationers in the summer months), an unplanned interruption can have serious financial and customer service consequences. *"For us in ski season [interruptions] have a big impact on our business. Imagine a day where we have 2500-3000 people in area and at restaurants, and the power goes out. Our customers are wanting refunds. We can't operate washrooms."* <u>Communication</u> • At various times during the session, a few participants stated Hydro One does not do a good job communicating when power will be restored after an interruption occurs. In their experience it is difficult to get an accurate estimate of when power will be restored. *"During major storm… OGCC only gives ballparks and they're pushing out information they get from local guys. I don't know if there's a better way to tighten up those restoration times, but we want [power restoration times] to be accurate."* <u>Planning, Efficiencies and Accountability</u> • The general consensus in the room was that participants are sensitive to investments that will result in higher costs to them. Customers accept that Hydro One is making efforts to manage and reduce costs, but want greater reassure that in preparing its investment plan Hydro One is maximizing efficiencies and making prudent decisions with an eye toward long-term financial benefits (lower costs) to customers. • Concerns were raised around the fact that Hydro One is a monopoly in their distribution area and that because of this there may not be sufficient accountability of Hydro One. One participant stated that he would like to see Hydro One be more transparent, so that it can be held accountable for its decisions and actions more than it is now.

	"…when you have a monopoly sometimes wages can get out of line, and money can get spent without true accountability. It all starts with how transparent you want to be." <u>Energy Storage and Conservation</u> • A participant questioned whether stored energy was being exported to the US at a loss. • A few participants indicated that in their view the regulator (OEB) is allowing rates to go up to off-set lower consumption among customers. This is incredulous to them given that consumers are being encouraged to reduce their consumption. *"The OEB did us all [of us] a big disservice by the last rate increase. We didn't use enough electricity, and that is why our rates are going up. We're trying to sell to our customers that conservation is good: if you conserve, you'll save money. And then regulator turns around now the rates are going up."* <u>Scenario Feedback</u> • Some participants stated that a Scenario in which there is a rate increase for declining performance was unacceptable, and that having such a Scenario reflected negatively on Hydro One's mindset and culture as an organization. • A few participants drew an analogy between Hydro One and private industry and indicated that their customers would not accept an increase in price for a poorer product. In fact, their customers expect them be more innovative and improve their technology in order to provide a <u>better product</u> at a reduced price. *"I think that it is ingrained in the mindset of the company to give us the same as what we had yesterday, [yet] we gotta pay 3.4% more. None of our customers are going to accept that. Most of our customers expect that we have found improvements [so that we can] sell our product to them for less money next year or have found ways to make it better, and not to ask them for more money for the same product."* • There was debate amongst participants about whether or not it is within Hydro One's mandate is to provide specialized power quality service to a small group of customers, or if their role is as a basic socialized service to all its customers. *"Power quality -- you can add those elements, but they're on the market. You can see specifications of what you can buy, and specifically say what quality of electricity that you need to put in. You should look at that, as a specification. This is what you can buy across the world."* *"With a small percentage of customers that might have a specialized need, their*

	tolerances are much higher or stringent than what they would be for the average customer. Really the bill should be on them. It shouldn't be socialized. Why should I pay for somebody else's special need?"
Any follow-ups or points of concern / consideration	• Participants would like to see more specific historical system performance (reliability and power quality) data from Hydro One as well as a historical breakdown of Hydro One's performance that goes back further than what was shown in the presentation. • Some participants stated that Hydro One needs to improve power quality as well as be more innovative in how it maximizes productivity and efficiency, and in providing value to customers, but participants also stated that it would be irresponsible of Hydro One to expect to be able to socialize the costs of customized needs across all rate payers.
Emerging Themes on Customer Needs and Preferences	• **Planning:** Participants stated that they would like Hydro One to be more pro-active in its asset management, in particular more pro-active with its tree-trimming program. • **Cost Reduction and Efficiencies**: Participants expect that through prudent investments and good planning, Hydro One can over time reduce OM&A costs. • **Company Culture**: Participants believe that Hydro One needs to become more innovative and manage costs better, before or rather than, raising rates. And they believe that raising rates for declining performance unacceptable. • **Role of Utility**: While some expressed a desire for Hydro One to be more actively involved in, and responsible for, power quality, others feel this is a specialized need that should be paid for by the specific end user, and that these needs should not be paid for by all end users on an aggregate level. • **Local Needs**: Participants would like better service and better communication that addresses their needs as seasonal business, and would like to see the investment plan include more tree-trimming.

Hydro One Distribution Consultation – Timmins LDA, LDC and C&I Session

June 13, 2016 - 9:30am

Attendees and the company they work for	LDA/LDC • Ross Byron, Imerys Talc Canada Inc • Eric Buteau, Lecours Lumber Co Ltd. • Dan Gagnon and Harvey Dasti, Primero Gold • Shoaib Zia and Lori Smith, Goldcorp • Sue Howson, Northern College of Applied Arts and Tech • Eric St-Pierre, French Catholic School Board • Carole Horton, District School Board Ontario • Travas Hack, Eacom Timber Corp C&I • Ron Wink and Scott Tam, City of Timmins
Mood / tone in the room Level of engagement	• Mood in the room was thoughtful and serious, with many participants contributing to the discussion. • Participants were generally knowledgeable about the energy industry as well as the needs and challenges of their own organizations, and of other businesses in their region. • Vice President Construction Services Brad Bowness from Hydro One was present to greet the participants and provide an introduction to Hydro One, in addition to co-presenters Graham Henderson and Paul Brown. • Other Hydro One account persons and staff were present to provide local context and engage with customers.
Quotes to summarize the general conversation	• Participants asked for details on Hydro One's rate of return. It was clarified that Hydro One has a regulated return on equity of 9.4% for distribution. • They asked for information on Hydro One's recent transmission rate filing, and a brief description was provided at the outset of the session. It was clarified that there was a transmission rate increase Scenario in the application of approximately 5%. Participants observed that with 94% of the transmission in Ontario there are few comparators, to which it was clarified that comparator transmitters are in BC Hydro and Manitoba Hydro, as well as other transmitter utilities in the US. • Participants observed that Ontario has one of the highest electricity rates compared to other provinces, Quebec in particular. Details and clarification were provided as to the reasons for this difference, that are mainly based on the different type of generation, i.e. mostly hydro-electric generation in QC vs. nuclear in Ontario. As well, Hydro Quebec is a structurally distinct organization from Hydro One with its generation, transmission and distribution all being fully vertically integrated, and therefore more cost

	efficient. • Participants received clarification that the commodity portion of their electricity bill is a pass-through cost by Hydro One and that Hydro One does not having any control over who it buys electricity from or at what price. As with all distributors in Ontario, price and suppliers are dictated by the IESO. • Details on Global Adjustment were provided including details on the contracts between generators (OPG and others) and the IESO. • In spite of the explanations of the differences in commodity price, one participant expressed skepticism that this was the sole reason for the considerable difference in electricity prices in Ontario compared to Quebec. *"…say you have a cottage in Quebec, 100 km from here - completely different bill. So there's more to it than just commodity cost, what is it."* • Cost and reliability were the two most pressing concerns cited by session participants. • The cost of hydro was mentioned as being a major expense for the businesses in the room, and for one participant, the cost of hydro is the business' second-highest cost after labour. *"From my perspective in managing an operation, hydro is [the] number two cost, labour is one, hydro is number two. Cost is important for us to remain competitive."* • Reliability and power quality are viewed interchangeably by this group. Interruptions of less than one minute - even just a few seconds - can have a profound impact on their operations. • The implications of power interruptions vary from one business or another: for municipalities it affects the airport, sewage and water plants, while for mining companies and manufacturing plants it means shutting down production with significant financial implications. Technology and IT systems also fail as a result of power interruptions. With momentary interruptions, backup generators don't kick in. • It was suggested that Hydro One and its customers could work cooperatively to track power quality issues. *"Asking us to tell you how many one-minute interruptions is pointless. [More important is] how many one-second interruptions do we have? Two summers ago I had 40 [one-second interruptions]. And we have at least one or two [of those] a month. Taking the plant down for one-second, I lose $5,000 per hour. If you take me out [4 times] I'm losing $20,000. It's significant."* *"We did talk a lot about small interruptions that Hydro can't see, [those that are] one-minute duration. So what about Hydro teaming [up] with customers, putting meters at customer facilities to see those bumps and those issues a lot better?"*

- Hydro One clarified that the current beneficiary-payer system for capital work is regulated and mandated by the OEB. Some participants felt that these costs should be socialized/shared across all rate payers.
- At least one participant stated that he expects Hydro One's profits be reinvested into capital improvements, rather than to shareholders.

"Every other business takes capital expenditure and either has a way of getting payback for it by the money they put out, or it's the cost of doing business. So what you're saying is, should Hydro take some of their money and maintain business? Yeah they should, every other company that's publicly owned or privately owned has to do that to maintain business."

- Some participants commented positively about the communication that they receive from Hydro One during interruptions, while others stated that Hydro One does not do a good job of this.
- Customer service was cited as an issue for several participants, who spoke of specific incidents such as being passed around from one person to another when calling into the call centre, having emails unreturned, or having Hydro One representatives miss pre-booked phone calls.
- Some participants commented that Hydro One does not resolve customer problems quickly enough and stated that in their experience issues they encountered took a long time to resolve.
- In particular, problems with estimated bills, and problems with requesting to have multiple bills across an organization consolidated were mentioned.
- There is low awareness of incentives and other programs. Those who have experience with them indicated that the application process is frustrating and complicated, with one organization going so far as to hire an outside company to help them with the application process.
- One participant indicated that in their mind, improving customer service should not cost additional money for Hydro One and should just mean better training. Another suggested having a local and/or dedicated contact for their organization as a potential workaround.

"…on several occasions of reaching out to Hydro One, either emails went unreturned or twice we set up meetings with our President and Vice President and the gentlemen just never showed up for the teleconferences… "

"…every time we deal with someone, it's someone different, [so answers questions with] I don't know. They pass it down the line, [but] who do I contact, it's frustrating. Hydro has a lot of different divisions, and I understand that, but one's not talking to another."

"…when we did an energy audit a few years ago, my application this thick and had to re-submit three times, because it was missing a little piece of information."

- Participants expressed concern that southern Ontario would be the main

	beneficiary of any capital expenditures. They would like to see investments in the North that would have a direct benefit to the area. • A few mentioned that they would like to see capacity expanded in the North without the restrictions placed on them by incentives and cost sharing. They argue that limited capacity translates into an inability to expand their businesses, and therefore, they are not in turn helping Ontario's economy. *"…looking at us Kirkland Lake, because of the upgrade of equipment, money not put into Northern Ontario as Southern Ontario."* *"…how you distribute that, does money go north?"* *"that may not be enough money for growth for industry, the industry has to foot the bill, couple of other stories, generators and stuff, we thought maybe someone would help us but there was no money. To help with growth that may not enough money."* • Some participants stated that they are willing to accept a distribution rate increase as long as it results in improved reliability (specifically better power quality), while others stated that they would require more information as to how money is currently being managed by Hydro One in order to comment on the Scenarios. *"I guess reliability is about quality of power. We want it all the time and we don't want bumps, we want quality. If we get that we're 100% satisfied, we'll likely bitch a little less about paying for it."* *"…you're already getting a lot of money, how efficient are you with that money, [and what is the] operational effectiveness of Hydro One as a group to deliver the product? If we give you $100 and it's mismanaged, [then instead] I'll give you $120 [and] it's still mismanaged. That's where I think you were headed."* • Participants indicated that Hydro One is generally viewed as a large and inefficient operation that does not properly manage its labour force and assets. • Some participants expressed an interest in understanding and learning more about what "Hydro One 2.0" looks like, and how its management and efficiency has improved based on all the recent changes it has undergone. *"…I could bring you to a coffee shop here at 10 o'clock, a lot of hydro trucks there, that doesn't look good, they should go back to the shop and hide…That is bad for your own reputation. You're going to get bashed."* *"…there is this general tendency to think of Hydro One as being inflated in terms of its management. What I would like to hear is what this new management is doing making [the organization] a leaner meaner machine, which ultimately*

	translates into better value for customers. Was hoping to hear New Hydro One 2.0. To the contrary, I think what I heard the same continuation of that old story."
Any follow-ups or points of concern / consideration	• Power quality incidents of less than one minute should be tracked and how participants can work together with Hydro One about these incidents should be made clear. • Participants would like to see a more detailed breakdown of how Hydro is currently spending its money in order to make an informed decision about the Scenarios. Although they acknowledge that Hydro One does have an aging asset infrastructure, they state that if money is currently being mismanaged, there is little point in giving Hydro One even more money via a rate increase.
Emerging Themes on Customer Needs and Preferences	• **Cost:** This is the top-of-mind and most pressing issue for most participants. • **Reliability:** Power quality is the most significant reliability issue faced by participants' organizations. Duration of interruption as little as a few seconds can have a profound impact. • **Capacity and Expansion:** Participants in this region would like to see additional capacity in order to stay competitive. However, there is some debate as to whether funding should be a shared cost by all ratepayers, or come from Hydro One's profits. • **Customer Service**: Participants have struggled with poor customer service and have expended time and resources in order to receive resolution on their issues with Hydro One. • **Efficiency**: Demonstrating efficiencies in Hydro One as an organization and as it relates to managing costs is of great interest to this group.

Hydro One Distribution Consultation – Thunder Bay LDA, LDC and C&I Session

June 14, 2016 - 9:30am

Attendees and the company they work for	LDA/LDC • Dale Kosie, Goldcorp C&I • Cody Randle, Azgard Solar • Harold Harkonen, Pure Gold Mining Inc./Laurentian Goldfields Ltd • Carol Maki, Hacquoil Construction • Peter Tillberg, Gordon Trailers • Wayne Chiupka, Nakina District School Area Board • Linda Chiupka, Corporation of the Township of Terrace Bay
Mood / tone in the room Level of engagement	• The mood in the room was engaged and thoughtful, with most participants contributing to the discussion. • Participants had a range of awareness and knowledge of the energy industry, as well as a detailed understanding of the needs and challenges of their own organizations. • Graham Henderson from Hydro One was present to greet the participants and provide an introduction to Hydro One, in addition to co-presenter Paul Brown. • Other Hydro One account persons and staff were present to provide local context and engage with customers.
Quotes to summarize the general conversation	• As a group, participants were particularly sensitive to cost both in relation to the bills they are paying (specifically the delivery charge being too high), as well as how well Hydro One is managing its costs. They would like to see Hydro One better manage costs in order to keep their rates low. • Participants offered a few examples of ways in which it appears to them that Hydro One is not managing costs effectively. These included: seeing too many trucks in use, more workers doing tasks than may be required, elaborate employee vehicles, higher quality paper and printing of bills than is necessary, as well as what is perceived to be inflated CEO and COO salaries. • One participant commented that their distribution delivery charge is three times the commodity cost (see quote below). • According to one participant, Hydro One's brand and reputation are inextricably linked to government policies and IESO decisions. Disagreement with government policy direction and IESO decisions reflects negatively on Hydro One as well. *"We got our hydro bill, 500 electricity, delivery charge was 1500. That's the biggest issue I think all of us are having."*

	"Keep escalating out of proportion, one of our highest costs is electricity, doing everything we can in efficiencies, only way to reduce cost is to shut process down and lose more money that way." *"People notice those things because it's hurting on the bill. If people felt like they were paying something that was fair, they wouldn't notice it, because people feel like they're being bled dry those things are going to stand out."* *"I am] physically seeing the waste that's happening. We had 5 trucks show up to fix a transformer on our property. That's just overkill. You can't tell me it takes that many. Things like that - the public has had enough."* • Power quality was mentioned by participants as being a significant concern and is seen to be synonymous with reliability. • There was consensus among participants that frequency of interruption is a greater concern than duration. *"[My comments have to do] with voltages and frequencies being out of our spec, [I] believe it should be incorporated, they've been out of spec in certain areas - the outlying areas of Thunder Bay. It put us down for a few months."* *"Power quality is almost as big an issue as a power outage to a large industrial client, but that seems to be minimized all the time. Voltage is lights flickering, but it's more. It's motors shutting down that same as an outage."* *"For a large industrial 30 second outage that causes an 8-hour production outage. Sometimes just keying in on outage duration misses big picture."* Throughout the session Hydro One offered statements to clarify comments and answer questions that were raised. These included: • Tree growth. One participant mentioned a concern about municipalities and homeowners planting trees along power lines. It was clarified that Hydro One is working closely with municipalities on vegetation management. • Materials used for poles. A question was raised about the use of alternate materials for hydro poles. Hydro One stated that although there is interest in using materials other than wood - which can be damaged by woodpeckers and beavers - composite material poles cost 2.5 times more than wood poles. Hydro One indicated that composite material is currently being tested and piloted in a number of locations. • The cost of hydro in Ontario compared to other provinces. Hydro One clarified that Ontario's power generation is mostly based on nuclear and renewable energy, whereas in Quebec and Manitoba, power generation is hydro-electric, which is less expensive to generate. • Excess power being shipped out of province and power separation by region. One participant expressed a desire to see power separated from other jurisdictions. Hydro One clarified that participating in the larger North

	American grid is important for the overall stability of the grid. Even if there is a generator close by, there needs to be a power source from elsewhere should the generator shut down. • One participant indicated that because their business is located close to a generating plant their business should see cost savings because the delivery point is so close. *"…take Ontario and divide it based on where power is generated and pro-rate the cost of the grid to those areas."* • One participant commented that new equipment he received from Hydro One was obsolete only a few years later. • One participant suggested that smart metering should be extended to hot water heaters in homes in order to help customers save money on their electricity costs. • One participant expressed frustration that increases in rates are cancelling out the benefits of their efforts and investments to reduce their consumption. *"… [According to the news] hydro rates increase due to loss of profit. We implemented energy savings measures, LED lights, and the rates go up because hydro didn't make enough money based on consumption. It felt like a punch in the gut. What reward do we get with 25% variation in consumption."* • For those participants that have had poor experiences with Hydro One's call centre, customer service is a concern and needs improvement. • Participants object to paying a Hydro One employee to read meters because the bills are based on estimates. *"The customer service is just terrible."* *"…we have a problem with estimated billing. We have found errors in the estimated billing that negatively impacted our budget by thousands of dollars. We refuse to pay. We call, we get a random person with one name, promise that it will has never happen again. Next month another estimated bill - it goes on and on and on…no vested interest in long term."* • One participant stated that the Scenarios are how Hydro One is justifying rate increases. They would prefer to have the profits from Hydro One fund proposed capital investments, rather than raise rates. • A participant from the mining sector stated that given the choice, their business would opt to move out of province. Hydro costs in Ontario are cost prohibitive. *"…With the amount of profits Hydro One has generated, why would they not be looking at their reserves for capital replacement rather than [doing it] on the backs of consumers. I don't think we have any more money to give."*

	"…it's the rates that are killing everybody. We're shutting businesses down [due to] high labour rates and hydro." • Hydro One was applauded for their customer consultation process. *"Good for Hydro One. They've been under the radar, [but it is] very brave of [them] to come out and do these sessions."*
Any follow-ups or points of concern / consideration	• Participants reiterated that Hydro One needs to carefully review its operations and whether or not there is wasteful spending. Their operations are expected to reflect Hydro One's commitment to cost savings and efficiency.
Emerging Themes on Customer Needs and Preferences	• **Cost:** Participants in this market are struggling with the perceived high cost of their electricity bills, including the distribution delivery charge. In their view, the cost they pay for electricity is a real barrier to the viability and profitability of their businesses. • **Efficiencies and Optics:** In order to mitigate negative perceptions of Hydro One, consideration need to be given to optics – the things that people see out in the market and in their area with respect to workers, vehicles etc. Customers want to see evidence of how Hydro One is working hard to manage costs, and proof that they are operating effectively. • **Power Quality:** In this session participants did not view power quality any differently than reliability. To them they are one in the same. When it comes to duration vs. frequency, for this group frequency is the greater concern.

Hydro One Distribution Consultation – London AM LDA, LDC Session

June 16, 2016 - 9:30am

Attendees and the company they work for	• Leslie Dugas, Bluewater Power Sarnia • John Vankerhoven, Blue Water Power • Sheraz Mustafa, Westario Power Inc. • Jeff Graham, Festival Hydro Inc – Stratford • Wayne Dyce, Centre Wellington Hydro • Josh Smith and Scott Brooks, Erie Thames Powerlines • Jim Klujber, Wellington North Power Inc. • Jim Hamilton, First Solar • Tim Prescott, Formet Industries • Pragnesh Shah, Rothsay • Jeff Simpson, Westcast Industries • Matthew Wright, Halton Hills Hydro Inc. • Jared Rowntree and Jodi Dellemonache, Superior Essex • Vicky Hammell, Wallensteinskup Feed Ltd.
Mood / tone in the room Level of engagement	• The mood in the room was engaged but mostly quiet, with a few vocal participants enthusiastic to share their views of Hydro One and the energy industry. • Participants had a high level of knowledge the energy industry, as well as a detailed understanding of the needs and challenges of their own organizations. • Graham Henderson from Hydro One was present to greet the participants and provide an introduction to Hydro One, in addition to co-presenter Paul Brown. • Other Hydro One account persons and staff were present to provide local context and engage with customers.
Quotes to summarize the general conversation	• The Global Adjustment - in particular, the unpredictability of the percentage amount of Global Adjustment - was raised as a concern by more than one participant in the session. • One participant inquired about whether or not Hydro One has looked into electronic billing and whether or not Hydro One believes that it would generate cost-savings that could be passed along to customers. • Some participants in this session indicated that they have difficulty making sense of their bills. Although it was clarified by Hydro One staff that the information on the bill is prescribed by the Ontario Energy Board, the participant indicated that Hydro One staff should still to able to explain the information on the bill. This participant has not been able to get a sufficient explanation from Hydro One staff to date. *"Is anyone able to forecast it [Global Adjustment], forecast our global adjustment?*

	Is it going to be 20, [but] comes out as 30. As a manufacturing plant we should know exactly it's going to be. It's a huge problem you can't forecast." *"We had some folks from Hydro One come to our plant and [they] couldn't explain the bill to us."* • When asked about impact of outages, both a solar generator and an auto industry manufacturer indicated that they experience significant negative impacts from outages. • A few participants spoke about concerns that they have with Hydro One's power quality. For them, power quality is as much of a concern for them as outages. • One participant indicated that he would like to see better reporting of momentary interruptions. He would like to see a reporting of momentary interruptions, as well as the causes of the interruption, within 24 hours. • One participant said that his organization is willing to work with Hydro One and to share in the cost of addressing their specific issues with reliability. A loss of service has severe financial consequences, and thus they are willing to pay for what it will take to improve their specific reliability issues. *"A flicker causes the same impact as an outage."* *"What I want, if possible is if there's a flicker within an hour or two hours, a specific report… a quick 24 hour report if there's a tree branch."* *"…is there any way we can help come up with cost sharing [arrangement with Hydro One to address our concerns]? This week alone it was $500,000 in financial losses just from outage time. Shift over and put protections back, have some redundancy. [We are]willing to invest in that."* Several clarifying questions were asked throughout the presentation, including: • One participant inquired about the process that Hydro One uses to restore service when there is an outage. It was clarified that there are priority areas that are addressed first, such as critical feeders to the area, followed by the lines that serve the highest number of people. • A few participants inquired about the pace at which poles and transformers are being replaced, as well as if the decision to replace assets is primarily based on age, as they would like to understand if the pace at which assets are being replaced is fast enough. It was clarified that Hydro One actively monitors and tests the condition of assets and that recently their testing has been ramped up to meet the levels need for sustainment. • Hydro One also clarified that the best channel for LDCs to provide information back to Hydro One with regard to distribution feeds is through the OGCC. General comments that arose spontaneously during the session:

	• There were times during the session when one participant expressed strong concerns about the way Hydro One is being run. He was incredulous that the previous Hydro One CEO received a $3 million payout, indicating that these fund would have been better directed to improving system reliability. He also stated that any increase in rates, related to the distribution delivery charge or otherwise, would result in the closure of his plant in Simcoe, which would be moved to a location where hydro costs are cheaper.This participant is of the opinion that Hydro One does not operate efficiently and indicated that not putting profits back into capital costs and investments is unethical. Hydro One indicated that they would follow up with him at a meeting already scheduled to address his concerns. • Another participant expressed concern that in their view there was no option for them to answer "no" to each of the scenarios. Ipsos clarified that the participant could in fact answer "no" to each of the scenarios and indicated that each question about willingness to accept the rate increase offered a yes, no or don't know option for the participants to choose from. This participant also stated that there should be a 0% rate increase option, or a rebate option offered to participants. *"Shouldn't that slide have a 3 million dollar payout. Paying a president is not keeping system reliable, [and] not the best investment moving forward."* *"Voicing facts of where I live today. Ontario government, OPG, Bruce Power continue the onslaught on manufacturing. The plant will not exist."* *"You're telling us 2.5% [rate impact], private is taking 0% to maintain jobs here, you want to take another 2.5% to maintain your profit to your shareholders. It's unethical… It's unethical, it's unethical, it's unethical."* *"Why [is there] not an option with 0% [rate increase] or 5% rebate."*
Any follow-ups or points of concern / consideration	• Participants in this session, of all of the sessions, spoke with the greatest frustration and concern about hydro costs and the impact the perceived high cost of electricity is having on the manufacturing plants in the region. They feel that their long-term viability would be directly at risk should Hydro One raise rates.
Emerging Themes on Customer Needs and Preferences	• **Communication:** Two main communications related points where made by participants. The first was to desire for Hydro One to implement a process of immediate (24 hour) reporting of momentary interruptions. The report should include the cause of the interruption. The second is related to making it easier for customers to provide or share information about reliability issues and concerns with Hydro On, so that Hydro One has an accurate understanding of power quality and reliability. The benefit would be that both Hydro One and the customer can therefore more promptly and effectively mitigate and/or address reliability or power quality issues.

	• **Power Quality:** It was articulated during the session that momentary interruptions affect customers as much as longer interruptions, so duration is less of an issue than power quality. • **Rates**: Increasing rates are perceived as direct and real threat to the manufacturing industry. • **Responsibility to ratepayers vs shareholders**: One participant felt strongly that Hydro One's profits should re-invested into the system for the benefit of customers, not shareholders.

Hydro One Distribution Consultation – London PM C&I Session

June 16, 2016 - 2:00pm

Attendees and the company they work for	• Dirk Nauwelaerts, Belleview Acres Ltd. • Tony Di Nardo, Cooper Standard Automotive • Erica Kiestra, Kie Farms • Howard Lucas, Lambton County Admin Office • Adrian Roelands, Roeland Plant Farms Inc. • Garry Fortune, Stanton Bros Ltd. • Linda MacDonald, Walker Dairy Inc.
Mood / tone in the room Level of engagement	• The mood in the room was largely thoughtful, with a few vocal participants enthusiastic to share and discuss their views of Hydro One and the energy industry. • Knowledge of Hydro One and the energy industry was mixed, but most had an understanding of the needs and challenges of their own organizations. Participants asked many questions throughout the session on a broad range of topics related to energy. • Graham Henderson from Hydro One was present to greet the participants and provide an introduction to Hydro One, in addition to co-presenter Paul Brown. • Other Hydro One account persons and staff were present to provide local context and engage with customers.
Quotes to summarize the general conversation	Several points of clarification were made at the outset of the session with regard to the following items: • A participant expressed her dissatisfaction with the debt retirement charge, and said that she understood that it was supposed to have come off the bill multiple times in the past several years, but that her organization is still being charged for it. It was clarified that the decision to remove the charge is one that the government makes. It is not influenced by Hydro One. • A participant shared his experience with getting a new connection. He explained that the cost of the connection was paid for upfront by his organization. He stated that it is unfair for his organization to pay for part of the connection charge for generators via the distribution delivery charge, when his own organization paid for all of their connection charge. It was clarified that his understanding that his organization still is charged the distribution delivery charge is accurate. While generators have a certain amount of their connection charge paid by all ratepayers, in the case of load customers, the expected revenue is calculated over a certain period to see if it will cover the cost of the connection. If not, the customer has to pay for the incremental cost. • A participant asked who the Ontario Energy Board is and it was clarified that this is a quasi-judicial independent regulator run by the provincial

government.

- When asked about whether or not Hydro One should be burying lines underground, Hydro One clarified that it costs 10x over the life of the line to bury lines underground versus having them overhead.
- One participant inquired about Hydro One's rate of return and it was clarified that Hydro One's return on equity is 9.4% and that this amount as prescribed by the Ontario Energy Board.
- There was a discussion about rate classes and how LDA customers are distinguished from Commercial, and what the three qualifying criteria for LDA are. It was clarified that in order to qualify as an LDA, the customer must have a minimum load, supply their own transformation, and have a minimum voltage.

Feedback was heard throughout the session on other issues as well. This is described below:

Billing

- One participant asked if Hydro One intends to move to e-billing away from e-post. It was clarified that this is of interest to Hydro One and is currently in development. However, there has been resistance from Hydro One's customers to electronic forms of communication as their customer base is an older demographic.
- One participant mentioned that he finds the current billing format very confusing. Although he is aware that the information contained is prescribed by the regulator, he wondered if it would be possible to have Hydro One provide further explanation on charges separately - for example, as a bill insert. Hydro One indicated that this would be within their ability to do, however they are sensitive to the cost of such initiatives.
- Another participant mentioned that he is having difficulty in consolidating his bills, calling the process "brutal".

"Do you have the ability to further clarify that bill separately…we find it very confusing to understand it. Is there a way for you to clarify, do you have the ability to do that, an insert [that says] this is what [the charge] actually means…That would be helpful."

Privatization

- A few participants believe that privatization will have a positive impact on Hydro One and ultimately ratepayers, as there will be increased accountability of the organization, and that decisions will be made based on financial prudency. One participant stated his strong belief that the government should not have any influence on the electricity industry, and that prices should be subject to a user-driven open market, as with natural gas.

"[Before privatization] I think that like any government organization [Hydro One was] just giving out money left right and centre, and not looking at costs because

they never had to."

"…our entire power system right from the top to bottom, the whole thing, should have nothing to do with the government… I would really like to see the entire thing privatized and moved the same way natural gas is. Just get it completely out of the government's hands, right from top to bottom the whole way through."

Renewables and Microgrid

- Participants posed two questions to Hydro One regarding renewable energy. The first was about how reliable power generation from renewable sources (such as wind) is and the second was whether green/renewable energy should be incentivized and promoted by the government and regulator instead of focusing on giving customers the power capacity they need from non-renewable sources. In addition, at least one participant said that they disagree with the premium cost/price associated with renewable sources of energy.
- Hydro One clarified that this is studied before the generator (such as a wind power generator) is connected. If the generator meets all of the technical requirements, then it is considered a reliable source of power quality.
- Another participant asked if Hydro One has a positive view of renewables and microgrids. Hydro One responded that there are potential benefits for customers as well as themselves. These benefit relate to not having to run a long line to remote customers. However, one of the potential drawbacks is that customers may choose to leave the grid entirely as a result.

  "I'm all for green power as far as the environment, but when it comes to cost it's hugely expensive…I don't agree the price we're paying for solar and wind, just drop things all over where we don't need the power…it would be nice to say focus this wind and solar to these remote communities put them there [as it] makes sense, where there's issues with the lines, rather than randomly dropping them where people don't need or want them."

Power Quality

- Power quality is a significant concern for participants.
- For one customer, poor power quality also meant spikes in voltage which damages equipment.
- There is a time lapse between the outage and when a generator kicks in.
- Even a very short interruption shuts down production for manufacturers.
- When it was clarified that Hydro One is dependent on their customers for power quality feedback, and participants indicated they were unaware of this.
- It was also clarified that power quality issues are usually internal to the customer's operations/facilities.

"…the interruptions are very disruptive. Us a manufacturing plant, not even the outages, quality of power, if it's a split second it shuts entire plant down. Takes a couple of hours to recover, [it] happened twice this year. [Then you] get it up and

running power fluctuates again, and it is down for a couple more hours."

Proactive Asset Management

- Participants were in general agreement that proactively managing and strengthening the grid makes more sense than fixing problems after they happen, particularly as it relates to preparing for more electric vehicles and energy storage needs.

"…logic would suggest that money you invest in preventing an outage as opposed to fixing it would make more sense."

"We're a producer and a user, certainly strengthening the grid is a key concern, to be able to supply, also the smart grid would add efficiency to that."

Other forms of electricity generation

- At different times throughout the session, participants talked about their ability to generate their own power as either a primary or secondary source. One farming operator spoke about having a bio digester onsite. Hydro One recommends to greenhouses and livestock farms to have sufficient backup generation onsite.
- Some participants also use natural gas as a source of energy for their operations. For one, in the event that hydro costs go up further, they may make the decision to switch to natural gas entirely.

"If we get a wee bit more increase, we will move, go off grid, very close. That's the bottom line. I only have to switch the switch. If you're hooked up on natural gas between 8 and 12 cents. We're very close."

Cost and Scenarios

- Despite the concerns about power quality and reliability that participants raised during the session, it became clear that cost is the most important and pressing concern for this group. Rate increases of any kind, even on the distribution delivery charge only, were viewed negatively.
- Even in a "run-to-failure" scenario for Hydro One/the grid, there were questions about the efficiency of Hydro One's operations. The perception is that Hydro One does not operate as efficiently as its peers.
- A few participants stated would like Hydro One to demonstrate how it is operating efficiently before commenting on the Scenarios.

"You've heard manufacturing, all of that is about reducing our costs and improving our efficiencies, what's Hydro One doing to do more with less how are you getting more efficient so that we don't have a 2.5% increase."

"I do think you have not been efficient in the last 20 years and I think there's a lot of costs you can cut. This yeah, what do you think is acceptable, 2.5 or 4% increase? … How efficient have you become in the last 5 years, do you have that?

	What efficiency rate do you go on, 43% or 30 or 50 plus, what efficiency rate are you at?"
Any follow-ups or points of concern / consideration	• Participants indicated a desire to see more detailed information on the bill, specifically explanations of the various components and charges on the bill. • A few participants said that they would like to better understand the activities and programs that Hydro One has undertaken in the past to make its operations more efficient before they are able/willing to render an opinion about whether or not the rate increases presented in the session are justified. • One participant expressed the desire for an opportunity to provide electricity at night to greenhouse operators based in southwestern Ontario, who are currently building facilities in Michigan and Ohio in order to take advantage of available capacity and cheaper hydro rates. He suggested that this would be a fortuitous opportunity and fit, given that Ontario currently exports power to the US at a loss at night.
Emerging Themes on Customer Needs and Preferences	• **Billing:** Understanding the bill, as well as ease of having billing issues resolved, was of interest to participants in this session. • **Future of the Grid:** While participants stated their opinion that Hydro One should be proactively managing the grid, they are reluctant to adopt renewable green energy sources if it means higher rates/prices or less reliable power. In their view, green energy should be used in areas where lines are expensive or difficult to run, and generators should not receive incentivization at the expense of ratepayers. • **Rate Increases and Efficiencies:** The scenarios were received negatively, with participants expressing their unwillingness to offer an opinion until they have a good sense of whether there have been sufficient efficiencies by Hydro One in recent years to justify rate increases. For those with other potential sources of energy such as natural gas to draw on to run their operations, a rate increase is a potential reason for attrition.

Hydro One Distribution Consultation – Windsor LDA, LDC and C&I Session

June 17, 2016 - 9:30am

Attendees and the company they work for	• Robert Saroli, Canadian Art Aluminum Extrusion Inc. • Terry Attewell, Canadian Department of Agriculture • Louis Chibante and Paul Mastronardi, Golden-Acres Inc. • Kathleen Qenneville, Greater Essex City • Todd Brophy and Peter Quiring, Nature Fresh Green Houses • George Dekker, Southshore Greenhouses Inc. • Mazin Naim, TRQSS Inc. • Dale Hodgins and Mark Stephens, AP Plasman • Howard Huy, Huy Greenhouses • Justin Martens, Johno Foods • Pat Fleming, Milofais • Wanda Juricic, Union Gas • Guido van het Hof, Great Northern Hydroponics
Mood / tone in the room Level of engagement	• The mood in the room was highly engaged and participants were eager to voice their thoughts on the information being presented. • Participants had a high level of sophisticated and detailed technical knowledge about the energy industry, and brought forward the needs and challenges of their own organizations and industry sector. • Graham Henderson from Hydro One was present to greet the participants and provide an introduction to Hydro One, in addition to co-presenter Paul Brown. • Other Hydro One account persons and staff were present to provide local context and engage with customers.
Quotes to summarize the general conversation	• A major concern for participants is the Global Adjustment charge. The fluctuation in price of this charge is extremely frustrating and puzzling. The unpredictability of Global Adjustment makes scheduling and budgeting a challenge. • Because of the direct inverse relationship of commodity price to Global Adjustment, participants stated that they feel dis-incentivized from attempting to conserve their power consumption. Although it was clarified by Hydro One that reducing overall quantity - i.e. units of power - as a way to save costs, in terms of the price of electricity, the Global Adjustment appears to discourage customers from conservation activities. *"There's no incentive to save. My electricity bill goes down, but my Global Adjustment goes up. I thought it was a joke at first."* Beneficiary Payer System • Clarification was provided as to the beneficiary-payer system as prescribed by

	the Ontario Energy Board after participants spoke of their experiences with the process of getting new connections/lines built to service their needs. • Hydro One stated that the potential cost to a new connection customer is calculated on a 25-year basis using forecasting on estimated load. If the cost of the connection over 25 years cannot be recovered, the beneficiary is asked to pay upfront before the work commences. • Additional clarification was provided about new users on a line that a customer has paid for out-of-pocket. The customer is eligible for a rebate in situations when another user uses the line on a pro-rated basis. • Participants expressed their discontent around this system, stating the belief that they should not have to pay the cost of connection, and/or that they shouldn't then also have to pay for ongoing distribution charges once they have paid for a connection. *"I'm dealing with Hydro One and what they're telling me is, I have to pay for poles and infrastructure where I have to pay to bring that power to my plant. I'm also going to pay again for distribution after I've paid the capital cost for bringing that to me?"* Customer Service and Communication • One participant stated that their new connection request forms have gone unanswered. When he met with staff from Hydro One's head office, they said that there is sufficient capacity in his area for his power needs, although he strongly disagrees. • A participant stated that he has received conflicting responses to inquiries from different departments at Hydro One. • Communication between municipalities and Hydro One was also cited as a concern. One participant was encouraged by a municipality to build a plant in their region, only to discover that there was no available power capacity. • Communication during power outages was mentioned as being a concern for participants. They would like to see Hydro One employ technology (such as their website or an app/texting) to communicate to customers the reason for the outage, as well as the estimated restoration time. This in turn would empower the customers to make decisions accordingly. It would also help to understand if the problem is from Hydro One or internal to the customer's facility. *"…there are apps where it goes right to your phone. If you guys are giving information to your line crews, feed us in on that…we're not [going to wait] on the phone, sitting there 20 mins waiting for somebody. We just need some information to make relevant decisions on our part. Those types of things are cheap to implement and they are very helpful for us. That would be a huge thing for us."* *"Planning is very important [for example when you have to] call in a shift or cancel in a shift. If you bring them in and the power is still down you've got to pay them or maybe you call everybody to say don't come in because we're going to be down.*

	[Either way] we need to know as quick as possible." *"[When the power is down] we're not sure if it was Hydro One or our internal power. It would help to say it is your problem, not ours and stop trying to troubleshoot."* <u>Regulatory Concerns</u> • One participant stated that they are strongly concerned with the current energy regulatory environment. He stated that in the case of natural gas, the process to get the line approved and built can take several years and by the time the pipe is actually put in, it is too small. He stated his belief that the Ontario Energy Board needs to be more forward-looking rather than only responding to current needs. In his view, this is a threat to the expansion of industry in Ontario. • As it relates to the upcoming Leamington TS, participants expressed frustration that it has taken over 20 years to get this project off the ground and that it has been promised in the past without actually being built. They also expressed concern that the capacity provided would not be sufficient for current needs. *"…the Ontario Energy Board will only approve the current demand, no expansion. Can you imagine the insanity? They put a gas line in the ground which takes, 2 or 3, 4 years to approve. So by the time they put it in, the information is 4-5 years old, they're putting it in based on [information] 5 years ago. It's too small the day they put it in. Can you imagine how little it would cost to put a bigger pipe in? It would cost virtually no more money. Yet in the wisdom of the Ontario Energy Board that's not possible. We keep paying and paying and paying to put more and more pipes in the ground, which environmentally and in every other way that makes no sense. This is no different. You're going to put a power line in that's too small the day you put it in."* <u>Power Quality</u> • Power quality was cited as an issue both in terms of voltage spikes and dips. Spikes and surges have the potential to damage equipment, while dips cause outages that have negative impacts on operations such as plants going down. • When a manufacturing plant's power goes down, decisions need to be made around sending staff home and/or asking the next shift of staff to come in. *"Power quality, low voltage electronics, where we don't have the life expectancy in Ontario as where we would use that piece of equipment somewhere else in the world because of the power flickers that they have, surges, now we're down to installing through a third party diodes to make sure power quality is filtered."* <u>Investment Planning and Consultation Process</u> • Rather than commenting on the specific ranking and scenarios presented, participants raised concerns that they are being asked to provide feedback on

	areas in which they don't have enough information and an understanding of what the key issues are. All areas asked about in the survey booklet are considered important to participants and some stated that they would like all issues to be resolved, rather than give permission to Hydro One to prioritize one or another. • Participants raised questions about Hydro One's efficiencies and productivity, and if/how they are incentivized to improve in these areas, as they are a monopoly. *"Our answer is simple, we want all those issues to be resolved. All of them have [to be] priority number one."* *"[Since Hydro One is] basically a monopoly why is there an incentive to then improve?* <u>Capacity</u> • For participants in this session, which was comprised mostly of greenhouse growers, the need for additional power capacity to facilitate growth and expansion of their businesses is extremely high and of the utmost importance. • Participants stated the belief that their power needs exceed that of other industries including automotive. • They stated repeatedly that they have electricity needs not currently being met by the grid in their region and expressed frustration that investments are not being made to meet them. • One participant stated that there are currently 2600 acres of greenhouses in Ontario, with 50% of those having lights at half a Megawatt per acre. *"We are going to take electricity. When you're paying to get rid of it, we're going to take it. We use a crazy amount of electricity right now [summer months], but the real load is from November till March and mostly at night. We're your best customer, we're your best friend and you've ignored us."* <u>Future of the Grid</u> • One participant inquired as to whether Hydro One would have the capacity to deal with the additional demand that would be created should natural gas be phased out. Hydro One responded that the grid would not currently be able to support that scenario. Further, their investment scenarios do not take government climate change policy into consideration, as they are unaware as to what the policy is/will be. *"…it seems that your boss, the Ontario government, wants to switch the whole power spectrum from gas to hydro, implying that Hydro One has the infrastructure in place to take on this increased demand."*
Any follow-ups or points of	• Participants in this session were quite vocal and asked repeatedly if there was a way for them to convey their frustrations around the issue of capacity with

concern / consideration	either the Ontario Energy Board or the Ministry of Energy. It was clarified that they are able to register as an intervenor during the rate application process, participate via an industry association such as AAMCO, or write a letter of comment directly to the Ontario Energy Board. • The Greenhouse Growers in this session indicated an interest in using (and paying for) excess power - which is currently being exported to the States at a loss - during the months of the year when load on the grid is not being maximized, i.e. November - March. Further, they would use the power at night when load is low. This is made possible thanks to the flexibility of their needs. They expressed frustration that they are Hydro One's best customer, who use more power than automotive manufacturers, who feel as though their needs have been forgotten.
Emerging Themes on Customer Needs and Preferences	• **Capacity:** For this group, the most pressing issue far and away is power capacity. They state that they are a neglected group of potential high volume customers whose needs are not currently being met, or even listened to. Further, they state that the regulatory environment of only meeting current needs, rather than planning for future need, is a barrier to expansion. • **Power Quality:** Participants face challenges with power quality in both surges/spikes and dips, with significant impacts for their facilities. A lack of communication, and their inability to find information, makes decision-making during an outage difficult for them and they also want this improved by Hydro One.

Hydro One Distribution Consultation – Kingston LDA, LDC and C&I Session

June 24, 2016 - 9:30am

Attendees and the company they work for	LDC • Jerick Astejada and Deonnie Macabales, Great Circle Solar • April Barrie and Matthew McGrath, Hydro Ottawa • Charles Watson and Jane Donnelly, Ottawa River Power • Mike Ploc, Peterborough Distribution Inc. • Bill Nippard, Renfrew Hydro • John Walsh, Rideau St. Lawrence Distribution Inc. LDA • Rod Moffatt, Strathcona Paper LP (Paper Works) • Edward Kalinowski, Gagan Gill and Steve Hughes, Invista Canada Company (Maitland) • Brent Quennell, IKO Industries Ltd. • Brent Williams, Goodyear Canada • Audrey Wood, Norampac • Bill Smith, Nestle Enterprises Ltd. • Habib Arshad, Pembroke MDF • Brian Reil, Kraft Foods Ltd. • Tom Horvath and Dominic Phaneuf, Greenfield Johnstown Limited Partnership C&I • Megan Jessup, Graves Eng. and Finishing • Ross Burt and David LaMontagne, Moose Creek Tire Recycling • Ricki Campbell and Richard Baccari, Crystal Springs • Bob Smith, Assurance Solutions
Mood / tone in the room Level of engagement	• The mood in the room was engaged with participants thoughtfully filling out their survey booklets with lengthy comments. • Participants had a mixed level of technical knowledge about the energy industry. • Vice President Planning Mike Penstone from Hydro One was present to greet the participants and provide an introduction to Hydro One, in addition to co-presenters Graham Henderson and Paul Brown. • Other Hydro One account persons and staff were present to provide local context and engage with customers.
Quotes to summarize the general	• One participant mentioned his experience in dealing with energy retailers, and stated that he turned to Hydro One for advice as to whether the program was worthwhile. However, he was unable to get an answer or a

conversation	recommendation from Hydro One. It was clarified that due to licensing conditions from the Ontario Energy Board, Hydro One is unable to direct customers or offer advice on retail energy programs. • In spite of this clarification, the participant stated his belief that Hydro One should use their technical expertise to help customers make decisions on whether or not to participate in programs. He does not feel it is right for the customers to accept all of the risk associated with this decision because customers are less knowledgeable about the benefits and drawbacks of programs than Hydro One. • This same customer also raised a concern and expressed disappointment about the amount of time his organization has had to wait to receive his rebate/payment back. He would like to see customers receive rebates more promptly. *"…[the risk in retailer programs] is not clear and I think Hydro One has the technology and expertise .. and should be able to say that is a good application of technology for that project. A little bit disappointing."* Clarifying questions were asked about the following topics: • A participant inquired about whether or not Hydro One's surplus profit is re-invested into the business so that future rate impacts are lower for customers. Hydro One clarified that it comes close to the regulated rate of return, and that this is the first rate filing application under the incentive mechanism which is intended to put more of an emphasis on performance. • Participants inquired about Hydro One's flat reliability performance over the past ten years and what spending that reflects. Hydro One clarified that the spend level and strategy over the past ten years has been to spend the minimum amount necessary to maintain the same reliability performance. • One participant inquired about the 19% of interruptions where the cause is unknown. They asked whether there is technology that can help Hydro One find the underlying causes of these outages. Hydro One clarified that it is possible that there is technology that could help this, and the decision to invest in this kind of technology in investment plan as not been made yet. The decision would be informed by customer need and preferences for reliability. • One participant asked why Hydro One does not run underground/bury lines and whether or not this approach would generate efficiencies and savings. It was clarified that underground lines cost approximately 4-10 times more over the life of the line compared to overhead lines. In municipalities and developments where there are underground lines, the developer pays the premium for them. • One participant inquired about whether or not Hydro One has looked into using composite poles. Hydro One clarified that composite poles are being piloted in areas that get a significant animal damage to wood poles; however the long-term life expectancy of composite poles has yet to be determined, because they are relatively new and haven't been around long enough to

determine the longevity of them.

Other areas of feedback included:

Maintenance and Monitoring

- A participant inquired about standards around tree-trimming and asset condition testing. They wanted to know whether the standards are mandated for, or decided by, Hydro One. Hydro One clarified that the decisions are made by Hydro One. It decides how and in what pacing to conduct condition testing and vegetation management, although the Ontario Energy Board does set some minimum requirements, for example, pole testing every 3-6 years.
- Participants inquired about whether Hydro One uses best practices and technological innovations, in its maintenance and asset management (e.g. maximizing asset life vs. premature replacement). The participant asked to see this information and wondered if it should be shared with other LDCs as well. Hydro One clarified that a benchmarking study has been commissioned by Hydro One on pole replacement. Assets are replaced not just on age, but also condition. Age is only one indicator.

"…[Referring to one study the participant had reviewed] The average transformer life is 21 years, but some in the sample were 85 years old. Replacement also depends on the loading which impacts condition over time."

"Just with the amount of trees a covered conductor would seem to be a good standard."

Region-Specific Investments and Reliability

- A couple of LDC participants spoke about the need for more load and improvement in the duration of outages (for example the Village of Lakefield and as well in eastern Ottawa) and asked that their needs be considered in Hydro One's investment plans.
- One participant expressed concern that slide showing the breakdown of reliability across Ontario that Hydro One showed in the presentation (slide 16) was insufficient. More specific location breakdowns should be used to better understand varying reliability performance. Hydro One clarified that the Ontario Energy Board is now requiring a higher level of detail in investment plans that are region-specific.

"[In my answer to this question in the survey booklet] I wrote about the Village of Lakefield and had a specific comment about reducing the duration of outages…. They're on a 44KV radial feeder, the line has been improved to bring it to roadside and add a re-closure, but the outstanding issue is that duration of outages is quite long… the cost for providing a feed there was considered cost prohibitive. It is going to continue to come up as time goes on. If there is anything you can do to build it into your long-term plan as you build the system, that would be appreciated."

	"…Eastern Ontario one of the worst in terms of loss of supply." *"When you spread out [reliability performance reporting] across the whole province [the differences] gets watered down. The geographic disparity in reliability seems to be informational. Reporting one number for Ontario to the OEB [Ontario Energy Board] doesn't provide any useful information."* <u>Efficiencies and Scenarios</u> • A participant expressed concern that there is no incentive for Hydro One to encourage conservation among customers. *"…you're a supplier, are you really interested in efficiency…, because that [will] reduce the volume you have to supply. What incentive is there for you to tell an end-user customer to replace their lighting because it's more efficient. It seems counter-productive."* • Participants stated that they need more information in order to comment on the scenarios. They need more information about how Hydro One builds in efficiencies, and stated that it is difficult to know what the best decisions are in the absence of the whole rate application and the broader picture. *"Today is only [about] reliability and we don't know anything about cost efficiencies in a lot of other areas."* *"I'd like to see the whole rate application and your capital in order to make some of those decisions. I want to see capital, operating, billing, admin, same things all other utilities are judged on and we have to present to our customers when we're asking them do you think we're doing a good job."* • Another participant had a concern with the proposed pacing of investments. Although they acknowledged that Hydro One's asset infrastructure is aging, five years seems like a short period to be remedying it entirely. *"Can you spread it over a longer period of time… [it has been] 60 or 70 years [but are you] trying to solve it overnight. Look forward for 10, 15, 20, 30 years - do a proper study with life cycles and all the other components and spread out the capital costs over a greater period of years."* • One participant stated that they do not have reliability issues, but if they did, they would be willing to pay for improved reliability. *"… we don't have a problem with reliability, if it were [a problem] we would pay for it. We've got good reliability, [there is] not much more [for us] to gain."*
Any follow-ups	• Participants would like to see more information on current efficiencies and a

or points of concern / consideration	more detailed breakdown of investment plans in order to comment on Scenarios. In the absence of this information, especially given that some participants do not have reliability issues, this was of particular importance to this group and stressed more than once.
Emerging Themes on Customer Needs and Preferences	• **Regional Concerns:** Participants have concerns about poor reliability in their region that they would like to see reflected in Hydro One's investment plan. • **Sharing of Expertise**: LDCs would like to understand best practices and innovations as it relates to maintenance of assets.

Distribution Productivity Studies
Hydro One Stakeholder Session
Thursday October 22, 2015
DoubleTree Hotel by Hilton – The Toronto Ballroom
108 Chestnut Street
8:30am – 4:30pm

Overview

On October 22, 2015 Hydro One Networks Inc. hosted a stakeholder session with intervenors and OEB staff. The purpose of this meeting was to present and seek feedback on the proposed approach and framework for four separate distribution productivity studies: Vegetation Management Program Study; Total Factor Productivity Study; and Pole Replacement Program Study and Distribution Station Refurbishment Program Study.

The stakeholder session included:

- Welcoming remarks from Maxine Cooper (Senior Regulatory Advisor, Hydro One Networks);
- A presentation on the proposed approach and framework of the Vegetation Management Program Study delivered by William Porter (CN Utility Consultants);
- A presentation on the proposed approach and framework of the Total Factor Productivity Study by Steve Fenrick (Power Systems Engineering); and
- Two presentations on the proposed approach and framework of the Pole Replacement Program and Distribution Station Refurbishment Program Study by Benjamin Grunfeld (Navigant Consulting) and Ken Buckstaff (First Quartile Consulting).

The draft summary was written by Matthew Wheatley and Bianca Wylie, who provided independent facilitation services for the stakeholder session. It provides a high level summary of the main points shared by participants as captured in the "live" notes written during the meeting, and is not intended as a verbatim transcript of the meeting.

This summary was shared in draft with participants for their review prior to being finalized.

Note that there are three appendices to this summary (attached separately), including:

Appendix 1. List of Participants
Appendix 2. Submissions Received After the Meeting
Appendix 3. Presentation Slides

NOTE: This summary reflects what happened during the meeting and does not attempt to integrate the written feedback received after the meeting. Please see Appendix 2 for the additional feedback received.

Part 1 – Vegetation Management Program Study

William Porter from CN Utility Consultants delivered an overview presentation that described the overall framework and proposed approach for the Vegetation Management Program Study. Following William's presentation participants asked questions of clarification and provided feedback. A summary of the questions and feedback is provided below.

Please note that responses provided to questions and comments are noted in *italics* immediately following each question or comment.

Suggestions and Comments on Study Methodology & Outcomes

- **Make comparisons between Hydro One's regions and comparable companies.** It seems possible that a company like Southern Georgia would look a lot like Hydro One's southern region but nothing like Hydro One in its entirety. Therefore, it would be useful to compare Hydro One's southern region to Southern Georgia. Then, where it makes sense you could compare all of Hydro One to other companies such as Manitoba Hydro. *We will be looking for the comparisons between Hydro One's different regions and their comparators.*
- **The study should be able to demonstrate how Hydro One's different regions are being managed**, including where there are differences among the regions, in terms of cost, and why these differences exist. If the study is not able to do demonstrate this, to me, this study will have failed.
- **What we want to understand from this study is whether or not Hydro One costs more, in terms of vegetation management, on a comparable basis and secondly, why this would be the case.** The fact that some utility companies may have inexperienced workers is a reason their costs are different but not a reason to adjust their comparability. Our main concern is where this study is making adjustments and we feel they should not be made for comparability. You will need to be very clear which adjustments are being made for comparability as we may disagree on these.
- **Measuring SAIFI and SAIDI comingles other factors that make it difficult to draw any conclusions from**. SAIFI and SAIDI are going to have other problems that make it difficult to measure actual effectiveness. *The first time we did this study we looked at SAIDI and SAIFI, for this study we are going to down play SAIDI and SAIFI. We are asking companies to report their tree related SAIFI separate from their system SAIFI.*
- **Identify the top-performing comparators.**
- **If you are going to measure Hydro One, you need to measure on hard things, not soft.** The average percentage of trees in contact at time of maintenance is not a useful indicator. Three things have to happen for an accident: there has to be a tree; there has to be a person and there has to be a line.
- **Stay away from speculative measures that are not established in data**. Speculative safety measures are not established in data pertaining to Hydro One. If you are going to come back with a benchmark study that says Hydro One is spending a lot of money but it is the right thing to do because they are avoiding a lot of accidents, I won't buy it.

Suggestions and Comments on Productivity and Resource Utilization

- **The OEB wants to know if Hydro One is getting more productive and whether it is doing best practices.** It is also looking for metrics that tell you whether Hydro One is doing a good job and if it is getting better at it. I looked at some of the things CN is proposing to do - it has by in large been done before and most of it is pretty good.
- **A huge thing that is missing is resource utilization.** Hydro One has a lot of workers and there is a lot of money invested in training professionals that are highly paid. They also have

a lot of very expensive equipment and minor fixed assets that are dedicated to their forestry program. Hydro One is running their forestry program about six months of the year and once it stops all the assets are parked.

- **Resource utilization has to be addressed if you are comparing with peer utilities**. If peer utilities are either running a 12 month a year program or are hiring contractors that can redeploy resources they will have a natural advantage over a utility that doesn't run its program 12 months a year.

- **It would be worthwhile for CN to look at other utilities to see which ones treat productivity as a function of how the program is treated by the utility.** If Hydro One is managing dollars as opposed to kilometres they are going to have a big problem if they spend all the money in their budget but don't get the kilometres.

Suggestions and Comments on Performance Measures and Objectives

- **Looking at the UVM objectives, be careful that you only focus on objectives that you can reasonably measure.** I do not know that you can reasonably measure how many fires can be prevented or how much you can preserve in terms of environmental quality. As for the one on safety, I would suggest you break that out into results for employees and results for public, they are different.

Suggestions and Comments on Clearing Sites and Cycles

- **The Board will be interested in information about the clearing cycles.** The Board has heard in the past that the length of the clearing cycle is a major driver of current costs when measured on a per kilometre basis. There are different clearing cycles historically; this is something that is going to need to be addressed and something that you control for when doing cross utility cost comparisons.

Questions of Clarification

Benchmarking Methodology

- My understanding of a benchmark study is that you compare different companies to see what their performance is. This sounds like you are doing a study to see how Hydro One can spend more money on vegetation management by doing it better. The theme appears to be "spend more". Can you help me on this? *What we are charged with doing here is understanding performance and improvement performance. We want to look at those metrics that we think indicate where there are areas for improvements independent of how much work is done, where the work is done or why the work is done. One of the objectives that has been brought up is should we look at SAIFI and SAIDI as metric of performance, do we look at how many outages there are per kilometre as a measure of performance. We want to determine this and we want to compare Hydro One with other companies to measure their performance.*
- Then the study is not benchmarking the cost of vegetation management, it is benchmarking only the areas? *The cost of vegetation management is the outcome. We are going to ask lots of questions about cost and productivity. We do not think it is fair to simply compare the raw numbers side by side. So much of what we do is try to figure out how these comparisons are comparing apples to apples as opposed to apples to oranges and those are productivity factors that may not be just the raw numbers of cost. For instance, if you are working with instances of dense forest, terrain, limited ability to access other logistics your cost may be greater than if you are just going from one tree to another tree.*

- How is worker turnover an independent variable? *My experience in the industry is that a worker may be on the job for weeks and find themselves in a tree and may not really know what they are doing and the productivity in that situation may not be the same as in an instance with someone that has been through a six-year apprenticeship program.*

Study Outcomes

- Is it correct to say that this study will do two things: measure the cost of vegetation management and make adjustments because not every company that does vegetation management is comparable; and measure the outcome of that vegetation management program to see if it is effective. *Yes, that is correct.*

Measuring Reliability

- With respect to reliability you say that this is a longitudinal study, however, it appears that you are doing a cross section study of a lot of companies. Will you also examine Hydro One's performance over time against itself, along with a comparison to other companies? *Yes, with the exception that we also have time over time data on the other companies going back to 1997 so we have an ability to do a longitudinal study across not only Hydro One over time but inclusive of the other companies.*
- Your intent is to report on both Hydro One's performance over time against itself and other companies? *Yes.*
- In Ontario every utility reports outages by Cause Code and one of these is tree contact. This is a direct output of vegetation management. Will this study look at the Cause Code outages used, in terms of reliability? *Most assuredly, in fact we have data already on the causes and how much relative to the total number of outages by the system versus vegetation management. Within vegetation management we know that the vast majority of outages are caused by trees and/or branches that fail into lines, as opposed to trees that are simply growing into lines. There is a direct correlation to the time at which maintenance is performed and the number of outages that occur. We also see a relationship between maintaining the space around conductors and the number of outages that occur.*
- Does your study try to create a relationship between outages as recorded by cause code and how will you demonstrate whether the money spent on vegetation management has an effective outcome? *Yes, one of the ways that we normalize cost is by looking at how many labour hours are expended on a project. This is a way to understand across a lot of different factors of compensation that we won't be looking at. This allows you to judge whether company X or company Y is getting more from their productivity based on how many labour hours they are spending. Our main measurement for reliability is the number of outages that occur and we look at that on a per kilometre basis as opposed to reliability metrics that are based on customer densities.*
- Can you tell us briefly about 101 for Reliability Centred Maintenance (RCM) - where is it in terms of is best practices, is that a framework that you will be using in your report to bring together best practices? *I believe that RCM has great value in the delivery of electricity. I do not think that RCM is necessarily the route a vegetation management program should take in order to meet its objectives. That being said, we ask questions about reliability. If companies are performing vegetation management according to RCM ideas, it is going to come out in the study.*
- We now hear a lot more about RCM being the approach to vegetation management, are you going to push in that direction as far as this study? *I think that ultimately our recommendation in terms of innovation will be to seek clarity in measurement performance and if that can be achieved through some reliability measurement than that is what we will advise.*

Overall Comparisons

- Which utilities, in your experience, are the best at vegetation management, just at a high level? *This is a very difficult question to answer because we use a lot of different measurements to determine this. The methodology within Canada, which is to eliminate vegetation within a required zone then maintain a corridor, is best in class.*
- Why can't you tell us the best three on the list of comparators you have provided? *We have discussed giving an award for the best company overall. However, we haven't done this, simply because the evidence isn't in that any company has mastered the problem.*

Peer Group Selection Criteria

- You have some Canadian peers that from my perspective would probably be useful like Manitoba Hydro, are you able to confirm which of these on the list are in the upcoming study? *No, not at this time.*
- How did you pick your comparators and is Hydro One helping you do that? *No, Hydro One is not helping us pick our comparators. The lists provided are all companies we have already done studies with and they will be the companies we invite first. We will also invite additional companies. The final list is our choice, not Hydro One's.*
- Is the final list based on some empirical analysis? *The final list is based on a list of companies that meet the criteria we are looking for. We have a peer group and we have a general group. For the peer group we are going to look at several factors. The most important factors will be the tree density and customer density. The other factors we are going to look at are the region of North America they are in and some of the individual characteristics that match up with Hydro One.*
- Is workforce one of the factors you will be looking at when selecting the peer group? *Hydro One is unique in their workforce to almost all of the companies that we have studied.*
- In your presentation you list the criteria that will be used to choose future comparators, are these the criteria that you will use? *Yes, this is how we are going to divide up the peer group from the general group.*
- Is Total Factor Productivity a factor being used to choose peers? *No, total productivity factors are all of the different parts of the programs that distinguish the different parts from one another. We are trying to match up what we think are good comparators based on the types of programs they have.*
- I understand the independent variables; I don't understand the other ones. *The other variables are independent in that these companies have made particular choices or are driven by particular regulatory rules. We are going to make this completely clear in our study, which companies are included and which types of company are not included. For example, if one company is a complete outlier we may take them out.*

Comparing Hydro One's different regions to other companies

- Why have you added one more region within Hydro One in this study versus the previous study? *Simply because this is the structure that Hydro One is operating under.*
- Are you going to look at Hydro One's different regions separately when making comparisons? *Yes, Hydro One's different regions will be treated like single companies. A lot of the other comparators are doing the same thing, they have different groups and they report data for each operating group separately so they are able to see each of those internal operations as compared to the other companies in the study.*
- When the study is complete will we be able to see Hydro One's southern region compared to other comparable southern region companies to determine whether Hydro One performed well or indifferent under this comparison? *Yes.*

- Are you going to have different peer groups for Hydro One's five regions? *The short answer is no. The comparisons are inclusive, if the southern region of Georgia Power is one comparator and if the southern region of Hydro One is one comparator they will both be in the comparison so you can evaluate that one with the other one. They are included, however, the rest of the comparators will also be included in the comparison.*

Performance Measures and Objectives

- You mentioned other program efficiencies should include other stated objectives, what would other program efficiencies be? *Generally, when we evaluate programs, we look at your objectives and you need to show the metrics which are showing that you are achieving those objectives.*
- Is there an industry standard or metric for cost effectiveness? *In terms of cost effectiveness there is not a standard metric for vegetation management. One of the outcomes of the study is being able to inform the company if there is an improvement they can make and whether they will be able to generate a return on this improvement by looking at how much it would cost to mitigate versus not mitigating.*

Clearing Sites and Cycles

- Aren't clearing sites and cycles controlled by cut back protocols from municipalities, the province or what the local residents say is an acceptable cutback for aesthetic or other reasons? *There are constraints on every utility company for maintaining their clearing and cycle objectives. There are issues in achieving these that relate to municipal rules or customers themselves so compromises are made along the way. We do ask questions about the company's greatest constraints in terms of clearing, these are part of what we call a productivity factor.*

Other Questions of Clarification

- Was Hydro Quebec included in the 2009 study. *Yes, Hydro Quebec was in the 2009 study.*
- Are you going to compare the results from this study with the results from the 2009 study, which you completed? *Yes.*
- Will you also be identifying changes in the methodology between the 2009 study and this study? *Yes.*

Part 2 – Total Factor Productivity Study

Steve Fenrick from Power Systems Engineering delivered an overview presentation that described the overall framework and proposed approach for the Total Factor Productivity Study. Following Steve's presentation participants asked questions of clarification and provided feedback. A summary of the questions and feedback is provided below.

Please note that responses provided to questions and comments are noted in *italics* immediately following each question or comment.

Suggestions and Comments on Study Methodology

- **Find out if the financial data from Hydro One is available by region. It would be interesting to do the outputs by region,** even without the financial data, to determine if reliability is being improved by region.

Suggestions and Comments on Measuring Reliability and Cost Efficiencies

- **Use tried and true ways of calculating the lag related to the timelines of investments and identifying with empirical evidence what the lag is.** I don't believe that a 20-year trend would capture the lag, you would have to know what the lag is. *We can certainly take that under consideration as far as something we think is useful.*
- **Measuring Productivity should include keeping wages at a reasonable level.** *This is certainly important for cost levels. However, I think this would be captured by a different study as this is not traditionally a TFP measure.*
- **Include the incremental cost of units of improved outputs in your report.** *We can certainly take that under consideration.*

Suggestions and Comments on Comparisons to Peer Companies

- **It is good to have TFP improving but you need to know how Hydro One relates to their peers.** On the TFP study the most obvious input is the lack of any comparison to any 3rd part peer/peer group comparison on a TFP basis is a big flaw. *In the OEB Decision, the OEB stated it saw value in Hydro One measuring its own productivity over time and directed Hydro One to determine its own study method. An external comparison is therefore outside of the scope of this study.*

Questions of Clarification

Measuring Reliability and Cost Efficiencies

- How do you address timelines related to investments? Costs in one year may produce outputs 3 years down the road; will this report look holistically at the time period or simply put all the numbers in columns on a spreadsheet? *The report will likely produce columns on a spreadsheet. You are correct that there tends to be a lag in terms of investments and outputs. The fact that we are doing a 20-year trend will hopefully capture some of this lag. We could also do a 3 year rolling average in an effort to capture any lag.*
- *For a well-managed stable operation it is true that you need to increase inputs for reliability to improve. However, for a business where things are not optimally managed you don't necessarily need to incur more costs to get better outputs.*
- Will inflation, which is one of your TFP drivers, include the cost of Hydro One's union contracts? *Yes, it should. It is independent but it also a resource that Hydro One is using related to outputs.*
- In terms of the correlation between reliability and cost, will your study measure the incremental cost of these units, that is, how much more we would pay for each unit of safety, for example? *The TFP measurement should quantify an x percentage improvement in reliability leads to an x percent drop in TFP. Those could then be translated into costs, however, we are primarily concerned with TFP trends.*
- Am I correct that the TFP will go down if Hydro One spends more to keep reliability at the same level? *All else being equal that would drive down the TFP. This is why it will be important to look at TFP over a 20-year time period so that we can see if investments made in one year will increase productivity 2, 3 or even 4 years later.*

Measuring Independent Variables

- My understanding is that the industry sample you are performing will identify and measure independent variables and will not compare Hydro One to anyone else, is this correct? *Yes, that is correct.*

Using the TFP Study for other purposes

- Will this TFP study also be used by Hydro One to develop adjustment mechanisms for rates?
  (Hydro One) Every one of these studies will be reviewed and where possible incorporated into the business plan that support the distribution application to be filed in the first quarter of 2017.
- Will the outputs from this study be used by Hydro One in the design of the next IRM? *(Hydro One) The outputs will be considered as an input.*
- *(Power Systems Engineering) The TFP trends that are likely to come out of this study really should not be used in an I – X formula because they should be revenue weighted. Outputs should be based on what drives revenues which is how PEG did the 4th generation IR, which is the proper approach for rate setting. We are going to be evaluating performance trends for Hydro One.*
- This is a productivity study and therefore the outputs should be included in your application. *(Hydro One) The outputs will be reflected in some way, whether it is done strictly mathematically or qualitatively is yet to be determined.*

Ontario Energy Board's decision regarding PEG

- Will you be able to respond to the Ontario Energy Board's decision, should they decide they support the way PEG performed their benchmarking study, particularly in terms of reliability? *Yes, we would likely be in the first two steps of our study and would be able to incorporate the OEB's feedback. Additionally, these previous studies were benchmarking comparisons, whereas we are only comparing Hydro One to itself over time.*

Regions

- Does this study in any way deal with Hydro One's different regions as an output? *Currently, this study was going to look at Hydro One as a whole company. It is our understanding that the financial data is available on a company wide level.*
- Is the financial data available on the regional level or company wide level? *(Hydro One) We can't speak to finance right now but this is something we can definitely look into.*

Additional Cost Drivers

- You mentioned that you might be considering additional cost drivers, can you give us some examples? *We listed additional cost drivers because we are looking for feedback as we talk with Hydro One and stakeholders. If anyone here has any ideas we would be open to considering these.*

Measuring Outputs

- How will your study normalize the weather component for outputs including SAIDI and SAIFI? *We are going to exclude the major weather event days.*
- What do you mean by environmental output? *These include energy efficiency type activities that may increase costs. We are aware that we will need to be careful to the extent that these costs are calculated in the CDM and are outside the distribution system. However, we are going to look at indirect costs that could be included in the TFP measure.*
- How do you measure customer service levels? *By looking at the score card metrics and looking at how that's changed on TFP trends at different utilities. To the extent that we can come up with an empirical model we will try to do that. This has never been done before so we are not certain we can correlate customer service levels to TFP trends but we will have a better answer to this in the second quarter.*
- Can you explain the output you have listed as system capacity at peak demand? *This refers to the output used in the 4th generation IR proceeding, which was a measure that took the*

maximum peak demand in a year and used it going forward until that demand was an exceeded. It would stay the same until peak demand exceeded its maximum of the past.

- One of the cost issues over time for Hydro One is that capacity continues to increase while basic demand does not. *If Hydro One is doing that that would tend to drive down their TFP, if they are making extra investments and increasing their capacity without a requisite increase in peak demand that is going to drive down their TFP.*

Study Timeline

- When will we see a draft of the TFP report? *The preliminary results will be presented during the next stakeholder session, which is scheduled for Q2 of 2016.*

Part 3 – Pole Replacement and Distribution Station Refurbishment Program Study Approach

Ben Grunfeld from Navigant and Ken Buckstaff from First Quartile delivered an overview presentation that described the overall framework and proposed approach for the Pole Replacement Program and the Distribution Station Refurbishment Program Studies. Following their presentation participants asked questions of clarification and provided feedback on the proposed approach. A summary of the questions and feedback is provided below

Please note that responses provided to questions and comments are noted in *italics* immediately following each question or comment.

Suggestions and Comments on Peer Selection

- **Explain your method to address the quality of your selected group in the report**. There are tests you can do to address the quality of your selected group - do you do this? *In our annual study we run results of our annual studies against what we can get publicly available, primarily on cost (using FERC data). We find that the average for our group is right about the same as the overall average, there is no apparent bias.*
- **Select additional peers with more similarities to Hydro One and be aware of some of the major differences with the ones already on the list.** As far as criteria go for the peer group – there are companies on the map that don't seem to be similar to Hydro One in any way. Texas, for example, with weather patterns, is significantly different than Ontario. Same with SoCal Ed. You don't have Wisconsin, Michigan, and Minnesota, which are much more similar in terms of geography and density. *We have a couple of others that we will be approaching; we started with the list that is in our benchmarking group. Texas, for example, you would be surprised how similar they are, in service territory - densities are different but if you take out Dallas they are quite similar. They have ice storms too. One of the ones we are going to approach is NorthWestern – they cover South Dakota and Montana - it's not on this list yet because they are not in our panel. They have similar wide-open spaces and similar bad weather. They have a number of similarities. And if there are other utilities that are perceived to be good for this sample we are happy to reach out to folks, that's part of the feedback we'd like to get from you today.*

Suggestions and Comments on Study Format & Outputs

- **Use econometrics for benchmarking.** You are doing peer group benchmarking rather than econometric benchmarking. If you have a diverse group of utilities that you want to compare then one way to do it is to use econometrics to get at the relationship between your independent variables and your outputs. *No, we're not planning on doing that*.
- **If you don't use econometrics for benchmarking, provide a rationale in the report.** Yet because you have a diverse group, it would seem that using econometrics would be the

obvious way to do it, it's unclear to me why you're not doing it. *Part of the challenge is defining all of the drivers and not having to deal with admitted variable biases and things of that nature. You can't necessarily trust the outcome of the econometric study unless you are comfortable with the formulas and you have identified all the major drivers. To your point, this is a panel benchmarking exercise. We are not doing regressions; we hadn't planned to do that.*

- **Provide correlation data**. I thought you were going to do regressions with labour costs so we could see if there is a true correlation that goes with labour costs. *We can provide some correlation data but correlation is different from a full regression analysis.*

Suggestions and Comments on Regional Analysis

- **Be consistent in doing regional analysis across all of the studies.**
- **Do peer analysis based on regions.** Regarding the peer group analysis – have you considered splitting up to the various regions of Hydro One and comparing regions where they have regional data to comparators that are similar to those regions. Take SouthWestern Ontario for example - it will be similar to certain other utilities, whereas Northern Ontario won't be similar to those same utilities. Can you add that in to ensure you have better comparability? *We are talking to Hydro One about that - to the extent to which the data is available and we can do these comparisons.*
- Hydro One divides itself up corporately into regions and they run it regionally and some of those regions are run better than others. If one were to test that theory, it would be helpful to have this study done regionally. *What you are really trying to get at are the drivers. What you really want to know is what is causing a cost difference. If there is no difference in driver other than geography than there is not a great level of value to this data. Part of the analysis for us, when we ask questions about and look at practices, as to how they are different in different parts of the province. It is reflected, even if we're not able to get down to that granular level of cost data. Some of the studies do regional studies and some don't so this will be an issue when looking at all of the studies.*
- **Highlight drivers and the impacts of drivers that Hydro One can control**. By splitting up into regions you can identify the operational differences, the reasons why Hydro One is more expensive in the same geography. Get rid of the independent drivers because those you can easily measure and get to the ones where there is a difference that Hydro One can control. *You are going to see that whether you are comparing SouthWestern operations to Integris or whether you are comparing Hydro One generally to another utility. The distinctions around operating practices aren't that varied that you don't see it even when you look at the utility as a whole relative to other utilities as a whole.*
- **Consider comparing what type of pole is being taken out versus what is being put in**. E.g. 35 foot pole to a 50 foot pole

Questions of Clarification

Study Format & Outputs

- The presentation says that the peer group will be confidential - will we know who is on the list or not? *Yes, you will know who is on the list but you won't know the performance of the entity, other than Hydro One.*
- Regarding the limitations on who can be in the group – if you have approximately 21 companies on this list, and then if you only get 60% that's 12 companies - does that affect the statistical quality of your results? *It's always a case of "the more the better" in terms of statistics. In terms of who self-selects to participate, it is companies that have some interest in the area or who are willing to do it for us as a favour – they work with us in our annual studies and get a lot out of that. They help the community by participating in these kinds of*

one-off studies. *The companies that self-select are not at the bottom or top of the performance spectrum, we get a range.*

- Did you talk to Hydro One about regional analysis? I don't see it anywhere here. *We are talking to Hydro One about that.*
- One of the variables is the results of one approach versus another approach. What we saw from the other studies is that one of the things you have to look at are impacts on reliability, maintenance cost, and others' results. I didn't see how other variables such as these will be factored in to this study. *We have been asked to look at the cost of replacement or refurbishment, the cost of the action once that decision has been made.*
- So you are not providing any input on whether there should be a higher rate of replacement or different cycles? Are you not going to be evaluating reasons for replacement/refurbishment? *No, we are not looking at recommending changes to decisions around reasons for replacement and/or refurbishment.*
- The Hydro One mantra for years has been we are a unique utility and you can't compare us to anyone else and now you're saying no, no problem, we can do it. *What I'm saying is that you can identify where those differences come from.*

Terms of Reference

- Regarding the Terms of Reference for this study: If you read the board's decision and look at the six points in the second slide about the benchmarking studies (plural) – the board says you will carry out an internal trend analysis to show the variability of these unit costs over time year over year. In the last rate proceeding EB-2013-0416, they filed that data on some basis, certainly for the poles. So let's start with poles, what are you going to add, other than the data that they've already filed, to comply with the Terms of Reference? *We are looking over a historical period of time and Hydro One data over a historical period of time, as well to some extent, the peer group and the peer utilities over a historical period of time. The one aspect that is completely brand new is where Hydro One sits relative to others on these. That's one new element. On the same metrics we are reporting comparisons against peers we can also provide a trend for what Hydro One has done based on what they have reported over a period of time.*
- Are you going to redo the cost analysis that Hydro One has previously done with the same format and same assumptions as the peer group? *I wouldn't say we'll redo it. We'll do trend analysis in addition to the benchmarking study.*
- How do we compare the two, what they filed last time with what they'll file next time, assuming the data will be different? *Where there are differences we'll identify those.*

Study Methodology – Pole Replacement and Construction Standards

- Can you just do cost per pole? *Once you get into the nuances of what is included and what's not included in that cost of pole replacement there are a lot of differences to what is included*.
- As for unit cost analysis, will you be differentiating between proactive and reactive pole replacement? *It's still uncertain as to whether we can get sufficient data to benchmark this across utilities separately. We recognize it's a potential driver of variation in cost, so we'll have this in the questionnaire where it plays in and how it plays into the data we collect. We will be trying to do this.*
- Regarding construction standards – these are changing over time, in terms of the height of the pole you are putting in. Will this be considered in the study? *Yes, there is consideration for the way demographics are shifting. You can have varied construction standards for poles but more so for stations, particularly for Hydro One and also for peer groups companies.*

Understanding exactly what you're getting for the money you're spending on assets is definitely part of this. There are still some questions about how much you can benchmark these differences, given how many differences there are. At the minimum we will have an understanding of relative contributions.

- Pole replacements programs tend to be the most expensive way to replace poles. How are you going to capture this with the different utilities? A utility with a high-growth rate will have a very low pole replacement program, per se. Do you bundle them all together or separate them out? *One of the questions we ask in the questionnaire is what is the reason for replacement. To the extent that people can give us that data, it's very useful. For the standard proactive replacement (because they got old) there tends to be good data. In the case of other reasons (such as road widening) there is not as much data. We will try to get the different drivers for that.*
- Does the type of pole impact the cost? *We will ask that question and collect that data. Hydro One is predominantly wood. We want to make sure that the peer groups we look at are also predominantly wood, and if they're not, then we adjust for it.* Does the type of wood matter? *Not really.*
- Are you going to be looking at the size of the pole replacement program in its totality relative to the demographics of the pole population? Does Hydro One cut off at 30 or 40 years and someone else cuts off at 50? Curious to know how it affects unit cost. *We don't know whether it affects unit costs - this is something we are going to check, find out the pole replacement rates at the utilities*

Study Methodology – Labour Costs

- How is the labour cost of these utilities considered as an input, how does one understand if there is a correlation between the labour cost and final unit cost of the replacement or if there is no such correlation? *That is one of the open questions. We will ask about the total cost of the program, then we will ask if they can break that down into labour, etc. For the respondents that can give us this we will include it. We will likely get this information from about half of the utilities we ask, many won't be able to give us that level of detail.*
- Why is that? The utilities have labour costs for the type of work that is done on poles. It would let you understand if there a correlation of the unit labour cost vs. labour cost of utilities – then you can say the labour cost is actually driving the difference. *The question is whether people are willing to give us this data. Part of the reason you can only get half of this data is that companies that outsource the work just have a single large number.*
- Will we be able to see the differences between the utilities that outsource the work vs. those that do it in house? *Yes, this is the type of and level of data that we are going to work to get.*

Other Questions of Clarification

- What do you mean by a panel? *A panel is a collection of comparators.*

Part 4A – DISTRIBUTION STATION REFURBISHMENT PROGRAM STUDY METRICS

Ken Buckstaff from First Quartile delivered a presentation that described the proposed program metrics for the Distribution Station Refurbishment Program Study. Following his presentation participants asked questions of clarification and provided feedback on the proposed program metrics. A summary of the questions and feedback is provided below. Please note that responses provided to questions and comments are noted in *italics* immediately following each question or comment.

Suggestions and Comments on Methodology

- **Consider who does the work, not just outside versus inside.** In the case of Hydro One distribution systems, overhauls are done by transmission station workers, who aren't the cheapest labour. You might be able to find difference between utilities to help guide Hydro One to a better practice
- **Consider environmental drivers of refurbishment.** Hydro One used to use arsenic trioxide so some of the costs may be due to environmental drivers. *Great advice, thank you.*

Questions of Clarification

Cost Analysis

- Are you measuring the units of property cost or the program cost? *We will end up with the total program cost divided by the number of units when we're done – so you will end up with the cost per substation refurbished, with some definitions alongside this as to what's in this cost.*
- So these costs will be controlled by the strategy, right? *It will be affected by the strategy, which is why we're asking these questions at the front end, as to what the strategy is and how does it work. And in terms of unit cost, we'll be doing it per station, but we'll also do it per KVA or MVA of capacity, to be able to compare the difference between companies.*
- You have the same issue with pole replacement, where you have a program cost at the bottom and the unit cost at the side [of the presentation slide]. *In this case as well, the total cost will be compared.*

Peer Group Selection

- How are you going to be sure you are going to get like for like in the Hydro and peer definitions? As a subset of that, Hydro One is moving to IMDS - how will you control for that? *We have IMDS in the methods section, it is quite different from doing a more traditional refurbishment and we are going to try to get the data for both. We've spent some time in the past couple days to try to understand how much of a difference there is between the practices when you using one system versus the other.*
- Do you think you will be able to find a peer group that does it the same way? *We will get some. We will also find a number who don't do it that way, who do it purely by components. What we do there, we have to take what they do and try to modify it to fit what Hydro One does.*

Other Questions of Clarification

- What is IMDS? *IMDS is a modular station.*

Part 4B – POLE REPLACEMENT PROGRAM STUDY METRICS

Ben Grunfeld from Navigant and Ken Buckstaff from First Quartile delivered a presentation that described the proposed program metrics for the Pole Replacement Program Study. Following their presentation participants asked questions of clarification and provided feedback on the proposed approach. A summary of the questions and feedback is provided below.
Please note that responses provided to questions and comments are noted in *italics* immediately following each question or comment.

Suggestions and Comments on Methodology

- **Treatments of the poles is not relevant to this context.** It's unlikely that Hydro One is doing treatment on the poles. e.g. injections, this is not relevant to our context.
- **Be careful when considering differences in the phases**. When you are looking at demographics such as single phase versus three phase. 80% of the lines at Hydro One are

single phase, not sure that 80% of the replacements are single phase – may be replacing with more than you think.

- **Consider the type of programs being used for pole replacement**. There are 5 different programs that replace poles. For example, service upgrades can be part of this if the pole is replaced as part of the service upgrade because of its condition. Line refurbishment is where you rebuild the whole line because you bypass the threshold for the amount of poles on the line that need to be replaced, so this is a different program. All poles on the line need to be replaced whether each individual one needs to be replaced or not. Other things that may drive the replacement program include the engineering standards between the old pole and the new pole e.g. the height of the old pole vs. the existing pole. If you don't create this kind of context for the analysis, the cost of pole replacement may look artificially high, because it does not take into account all the pole replacement that was pushed into other programs.
- **Consider adding other criteria that appear to missing, such as density, remoteness, and the median distance between the pole replaced and the service centre**. Given that the end product of the exercise is the unit cost for pole replacement, a lot of these criteria seem to be more related to what drives the number of poles that get replaced in a particular time frame, which is not relevant to the key metric (unit cost).

Questions of Clarification

Cost Drivers

- 90% of Ontario is either rural or really remote - how have you factored this in as a cost driver? Or is the cohort selection process going to take care of that? *We intend to gather the information about what is being replaced, such as whether they are in the urban or rural area. In terms of the drivers, some of those make a difference in the sense that if you are replacing 4% a year you're not going to let them get very old versus if you are replacing 1% a year you're likely to have a lot more failures.*
- I thought you weren't measuring cost of pole replacements? *It's not the core function, but we will be asking for those volumes.* You can rest assured that we'll be 1% or less, not 4%.
- I don't think that's correct that the whole system is remote, there are towns like Ancaster and Kingston, and all sorts of places like that served by Hydro One, you need to let the data tell you about this.
- I want to confirm what you are studying: The question is: How efficiently is Hydro One replacing the poles in total, not the crews individually – you are looking at the entire strategy, there are a lot of different drivers in there in terms of cost impact. *Correct, this is what we are measuring, including all the factors outside of the crew replacing the pole.*

Next Steps in the Study

Ben Grunfeld from Navigant and Ken Buckstaff from First Quartile reviewed the final slides regarding Next Steps for their study. Following their presentation participants asked questions of clarification and provided feedback on the proposed approach. A summary of the questions and feedback is provided below. Please note that responses provided to questions and comments are noted in *italics* immediately following each question or comment.

Questions of Clarification

- Looking at the previous version of the presentation – where your second bullet says finalize peer group selection metrics and identify candidate. Have you finalized your peer group selection metrics? It was my understanding that what was presented here was a sample, as some factors to consider, not the final list, but now I think you're saying that this is your final list. *Yes, that's the primary criteria, but it will be updated based on some of what we heard today.*

- Is the list from presentation your list of candidates? *Yes, this is the final list, plus any that are suggested today.*
- Do you have a list or table somewhere that maps your candidates to your criteria? *Yes.* Can you share it? *Yes.*
- From the first version of the presentation, it says schedule first round of "local practice workshops" - what are those? *That's with Hydro One, to understand what their practices are.* Have you held them yet? *No, we have scheduled them, but we have not had them yet.*
- (To Hydro One) – When are you filing your rate application? (Hydro One) *We currently plan on filing Q1 2017 for 2018-2022 distribution rates. Transmission, we plan filing Q2 2016, for two years, 2017 and 2018 rates.*

Process Next Steps

The facilitator thanked all participants for their input and reviewed the process feedback received throughout the session, which is summarized below and followed by participant questions about next steps for the process.

Comments and Suggestions on the Meeting Process

- **Provide the meeting content (for the next meeting, the detailed results) a week to 10 days prior to the meeting.** When we are looking at actual results, getting detailed content like these results at the meeting is not helpful. We need to get it a week or 10 days in advance so we can do some analysis and ask some questions in advance, send them along before the meeting. *Yes, we can do this.*
- **Indicate the time allocated for feedback in the agenda**.
- **Create separate worksheets per presentation.** For example, this session would have had four worksheets (one per presentation).
- The facilitator noted the adjustment made to enable a better flow of questions between the participants and the presenter and took this as helpful advice for future meetings.
- **Thanks to Hydro One and to Swerhun for your work**. Really appreciate that you included the OEB Decision information in the package, helped a lot.

Questions of Clarification

- Will there be a follow-up session when the consultants put their work together for the intervenor groups to ensure that it matches up with the direction from the OEB? *Yes, this will be the next stakeholder session. Preliminary results and recommendations will be shared before they're finalized.*
- At the next stakeholder meeting are your going to provide drafts of the reports? *We will be sharing the preliminary results and findings.*

Wrap Up – Maxine Cooper, Hydro One

Maxine thanked participants for their feedback and encouraged them to share additional input and feedback via email/the soft copy of the worksheet. She also encouraged participants to be in touch at any point between this session and the next if they had any topics they wanted to discuss. Maxine noted that participants will have until October 30th for written feedback, and will receive the soft-copy of the feedback worksheet on the following day (October 23rd).

Hydro One Stakeholder Session
October 5th, 2016
DoubleTree Hotel by Hilton – The Toronto Ballroom
108 Chestnut Street
8:30am – 4:30pm

OVERVIEW

On October 5th, 2016 Hydro One Networks Inc. hosted a full-day stakeholder session. The purpose of this meeting was to present and discuss the preliminary findings and recommendations of the following studies:

1. Total Factor Productivity
2. Vegetation Management Program
3. Pole Replacement Program
4. Distribution Station Refurbishment Program.

The stakeholder session included:

- Opening Remarks from Oded Hubert (Vice President, Regulatory Affairs, Hydro One Networks);
- Welcoming remarks from Maxine Cooper (Senior Regulatory Advisor, Hydro One Networks);
- A presentation on the Preliminary Findings and Recommendations of the Total Factor Productivity Study, delivered by Steve Fenrick (Power Systems Engineering); and
- A presentation on the Preliminary Findings and Recommendations of the Vegetation Management Program Study, delivered by William Porter (CN Utility Consultants);
- Two presentations on the Preliminary Findings and Recommendations of the Replacement Program and Distribution Station Refurbishment Program Study by Benjamin Grunfeld (Navigant Consulting) and Ken Buckstaff (First Quartile Consulting).

This summary was written by Dave Hardy and Jeremiah Pariag, who provided independent facilitation services for the stakeholder session. It provides a high level summary of the main points shared by participants as captured in the "live" notes written during the meeting, and is not intended as a verbatim transcript of the meeting.

Note that there are two appendices to this summary (attached separately), including:

Appendix 1. List of Participants
Appendix 2. Presentation Slides

Presentation #1 – Total Factor Productivity Study

Steve Fenrick from Power Systems Engineering delivered an overview presentation that described the Preliminary Findings and Recommendations of the Total Factor Productivity Study. Following Steve's presentation, Dave Hardy facilitated a discussion during which participants asked questions of clarification and provided feedback. A summary of the questions and feedback is provided below.

Please note that responses provided to questions and comments are noted in *italics* immediately following each question or comment.

Questions of Clarification

- How much have the Electric Utility Construction Price Index (EUCPI) and Handy-Whitman Index (HWI) varied from each other? *They vary over time. Handy-Whitman has escalated faster than the EUCPI, but from year to year, it is dependent on interest rates. EUCIP is sensitive to interest rates, whereas Handy-Whitman does not incorporate rates.*
- In regards to slide 11, are the numbers shown adjusted or unadjusted? *The numbers shown on this slide are unadjusted.*
- If the utility was selling less power, would this decrease the Total Factor Productivity (TFP)? *Yes, this is possible.*
- Would the TFP be lowered if costs were fixed and less power was sold? *Yes, but in the output index, customers are given more weight than sales. Note: Weights have been determined by the OEB study.*
- Does conservation spending go towards the capital budget? *No.*
- In the consultation leading to the 4th gen, Toronto Hydro and Hydro One were significant outliers. Moving to 2015, were Toronto Hydro and Hydro One pulled out? *The numbers presented do not include Toronto Hydro and Hydro One*
- Both the System Average Interruption Frequency Index (SAIFI) and the Customer Average Interruption Duration Index (CAIDI) are being used in the presentation, why is the System Average Interruption Duration Index (SAIDI) not included? *SAIDI is implicitly included in the two overall components. (SAIDI = average duration time of outages in time for a customer, SAIFI = frequency of outages, CAIDI = average duration time per outage)*
- Have any adjustments been made to the figures presented? *Loss of supply was not included. Major event days were also not included because this could skew the index. Power supply outages were not included.*
- What are you measuring for outputs for safety? *Outputs for safety are measured by the number of recordable injuries per 200,000 hours worked.*
- Lots of things are outputs, safety is different. How prevalent is including a variable like this in the US? Much of the data is not public. *This may be the first application of incorporating safety and reliability into the TFP trend.*
- What justification do you have for using the Lawrence Berkeley National Laboratory paper as opposed to others? *The Lawrence Berkeley National Laboratory paper was used for the US Department of Energy and seems very reliable. It provides a good starting point for pricing outages and reliability for the TFP.*
- In the report that will be produced, will a more detailed analysis be done in regards to interpretation of negative TFP and how other factors are assessed, like the impact of distributed generation (DG)? *Many costs directly related to the cost of DG are not*

included because it is not part of the 4th Generation Incentive Rate-setting method (4GIR), but it is difficult to calculate the cost.

- Are scheduled outages included? *Yes, scheduled outages are included because the customer's experience would be the same for both planned and unplanned outages.*
- Why was EUCPI discontinued? *EUCPI was discontinued because, according to Stats Canada, the methodology that was being used needs to be verified. It is currently under review and it may or may not return.*
- The OEB is asking utilities to use the Pacific Economics Group (PEG) model in their forecasts. Is that in this scope? *This study just looks at the TFP trends, it does not do any total cost benchmarking for Hydro One. This study only looks at how Hydro One's TFP has changed over time.*
- As stated, between 2002 and 2015, the average annual TFP trend declined by 0.9%. What would this do to the Board's current X-Factor? *It should lower the X-Factor.*
- During the presentation, it was noted that Hydro One spends 6% on safety. What is this percentage in reference to? *It is 6% of the total cost of Hydro One*
- If you are spending this money on safety, is the result included in the output index? *Injury data is incorporated into the output index with predetermined weights. It is represented by the change in injuries per 200,000 hours worked.*
- Why is safety an output? It seems to be a common element of running a business? *Output may not be the best word – performance measure or metric is better. It is not a profit function to make a safety a priority because it is the right thing to do, so it can be thought of a society output. Customers don't experience this output, but if it were to be excluded as part of the cost function, it would be giving an advantage to utilities that are not focusing on safety.*
- About 75% of outages are caused because of factors that are out of the control of utilities, e.g. weather and human contact. Could you measure outages that are caused mainly by failure of equipment? *Within that 75%, there are some factors that are tied back to how the utility performs in regards to tasks such as tree trimming. Having said that, one main reason why major event days were removed was because the statistics skewed the numbers, and we also focus on a three-year rolling average, which gives a better indication of the impacts on customers.*
- Conceptually, could you adjust the SAIDI and CAIDI by a factor due to weather? *Yes, it is possible. There have been wind variables used in the past. Toronto Hydro makes a case for reliability benchmarking.*
- Could you take the Ontario industry and measure it over a 10 year wage rate for a utility vs. a wage rate for the province as a whole to understand the impact? *The industry will have its own provision of required employees and there will be a different composition in that industry, so it is hard to compare*
- If you were to take Hydro One's forecasted costs, could you determine the TFP for the next five years? *Yes, but assumptions would need to be made on pricing changes.*
- Are the costs associated with reliability increasing over time? *This is one possible explanation, but it could be the opposite. A utility could be getting worse on its reliability because it is cutting costs. At some point, reliability is likely to worsen. So we should include the worsening of reliability into the TFP as well.*
- Does spending money on safety and reliability lead to better performance for Hydro One? *Typically, more money is spent to improve an outcome. For Hydro One, the reliability factor adjustment really is not improving things, reliability has stayed flat. It is difficult to determine what the exact costs of reliability are.*
- Was using an overall construction index considered to compare Hydro One capital spending to other industries? *No.*

- Are the numbers consistent with the 4GIR up to 2012? *Yes.*
- Will the HWI figures for 2016 be updated for the upcoming application filing? *It is unlikely because the 2016 data will probably not be available.*
- Are the Canadian indexes and the Handy-Whitman index moving in the same direction? *Yes, they are both increasing over time.*
- Is the Handy-Whitman index the only one that could be used? *It seems to be. This is the only index that is utility specific and looks at capital assets – there is not currently a Canadian equivalent, but if there was, it would be used. The current index being used is the best available.*
- Was there any other data that was adjusted other than what was mentioned? *A minor change was made to a Hydro One value for peak demand in 2013 because it looked inconsistent.*

Presentation #2 – Vegetation Management Program Study

William Porter from CN Utility Consultants presented the Preliminary Findings and Recommendations of the Vegetation Management study. Following William's presentation participants asked questions of clarification and provided feedback. A summary of the questions and feedback is provided below.

Please note that responses provided to questions and comments are noted in *italics* immediately following each question or comment.

Questions of Clarification

- What does the term "managed kilometer" mean? *This is a kilometer that was managed by vegetation management staff per year.*
- The techniques surrounding vegetation management have not changed. Why is the number of labor hours going up per tree? *Recent events, such as fires can affect how many labor hours are used. This creates a more strategic and targeted approach towards vegetation that often requires more time. This is also dependant on cycle lengths.*
- Hydro One has much higher costs per kilometer. Is this because Hydro One staff is being paid more? *There is an increase of overall cost on an hourly basis, but the labor burden, equipment costs, and administrative costs can drive up the cost per kilometer.*
- Is it recommended that Hydro One employees conduct the work instead of contractors? *Usually, yes. The full time employee system has led to low turnover and better safety. Substitution of low cost contractors can hurt these outcomes.*
- What does "Establish flexible variable cycles of inspection and maintenance to achieve objectives" mean? It means e*stablishing flexibility to be more strategic to look at areas of the company and determine whether or not there needs to be a more dynamic approach instead of a standardized cycling approach.*
- What "additional metrics" are being referred to? *This refers to an area of metrics that are able to define the objectives that are harder to quantify and measure such as, safety, environmental stewardship and customer service.*
- During an outage, would a vegetation management employee be sent in? *Hydro One has an outage investigation that is performed by a non-vegetation management employee based on a very limited number of data entries.*
- Would a metric that correlated vegetation-caused outage and vegetation management visits make sense? *Yes.*
- Should there be a metric to test the effectiveness of vegetation management procedures? *No answer provided, as the questioner moved on to another question before allowing William to answer*
- "Labor hours per tree treated" is a term used. How is this number determined? *Companies are asked to report how many trees they have treated.*
- In regards to cost per tree treated, how has Hydro One only increased costs by 3% while the rest of the industry has shown an increase of 97%? *Hydro One still has the highest cost per managed kilometer of all the peers. This is done by managing ingrowth effectively and how long the cycle length is.*
- Regarding cycle length, are regional differences taken into account? *Yes, but these are not planned cycle lengths. The m class is on target to be managed at 6.5 years. Much of the system is in a backlog. A minimum of 8 years would be more appropriate.*

- If you change the cycle length, what does it do to the cost? *It is hard to determine this exactly. If you look at example X9 on the productivity slide, lower cycle length does not necessarily mean lower costs. To get feeders to 6.5 years will take six years.*
- In regards to the peer group, how many are Canadian? How many are in Ontario? *There are five Canadian utilities in the peer group. There are none from Ontario.*
- Is data available to determine if contractors are more efficient than Hydro One in regards to their labor metric? *All of the peers except for one are contractors. When looking at labor statistics per tree and per kilometer, Hydro One seems to be more productive than the peers. There is no data for in-house management. Hydro One is an outlier.*
- Regarding outsourcing, are the prices fixed or is it based on an hourly cost? *The largest component is time and material, but the unit price has substantially grown over the last 5-10 years. Due to this, it is mostly based on a unit price cost because lump sums can lead to inaccuracies because of the number of variables present.*
- Is there ability to monitor branches and hit lines? *Theoretically, it is possible.*
- Could you data mine trends for outages? *Don't know if it is possible, but the science is there and it is improving, but setting up a reactive system might create an increased cost.*
- How is tree density determined? *It is the total number of trees managed.*
- Is it possible to clearly identify what data is needed from distributors in Ontario for them to be used as part of the peer group? *The cost of managing a tree in a town and in rural areas is different. If the Ontario distributors are primary suburban/urban distributors, their data will look much different than Hydro One's.*
- Is the ratio of management staff measured between Hydro One and the peer group? *There are comparative labor rates that are compared. The charge out rate, labor burden, and wage are all compared, but there is no conclusive data for quantity of staff.*
- Two of the goals listed were maintaining 100% clearance of ROW (Right of Way) and achieving ROW conversion over time. Is information available about the percentage of ROW converted for the peer group or the amount of ROW they targeted or achieved? *The peer group was not asked this question.*

Presentation #3 – Pole Replacement and Distribution Station Refurbishment Program Studies

Ben Grunfeld from Navigant and Ken Buckstaff from First Quartile presented the Preliminary Findings and Recommendations of the Pole Replacement Program and the Distribution Station Refurbishment Program Studies. Following their presentation, participants asked questions of clarification and provided feedback on the study. A summary of the questions and feedback is provided below.

Please note that responses provided to questions and comments are noted in *italics* immediately following each question or comment.

Questions of Clarification

- How was currency adjusted? *All currency was converted to Canadian Dollars.*
- Why was it converted to Canadian dollars when operations and purchasing is done in Canada? *This is done to directly compare Hydro One to American companies.*
- Does it make sense to weigh the currency change based on the influence it actually has? *If the exchange rate keeps moving, yes, but for the majority of the comparisons in this study, a majority of the data predates 2014, so it does not have a major impact on this study.*
- How does Hydro One conduct physical inspections? *Hydro One only does limited physical testing.*
- When estimating life time costs, did you adjust the cycles? *No, they are actual inspection cycles used.*
- It would be nice to know the breakdown and cost of equipment in regards to tree maintenance.
- In cost per pole 'touched', what does 'touched' mean? *Inspected, replaced, or refurbished this year. This includes visual inspections.*
- There is a recommendation for a vigorous refurbishment program. Would this be more cost effective? *The recommendation is for Hydro One to consider introducing a vigorous refurbishment program. The cost effectiveness depends on a number of factors. If a pole is too old, then replacement makes sense, but for newer poles that are failing prematurely, there could be a case for refurbishment instead. Other utilities do have a refurbishment program. This is only applicable to a small percentage of poles.*
- Who determines the useful life of poles? *The utilities.*
- So many Hydro One poles are at end of life or past useful life. How important is the useful life statistic? *The useful life may not be reflective of the actual life of the poles.*
- Is it valid to examine looping and redundancies knowing that it will be cost effective? *This would not be effective across the board, but it would work in some instances. However, there are no written recommendations regarding this.*
- Is there specific data for each of the peer group members, such as how many poles each peer touched, and does this have any impact on the cost of poles touched? *This data is present, but as a percentage of their system, the cost is similar.*
- Did you draw any conclusions regarding trend and unit cost between 2012 and 2014? *There is a slight increase, but not for all criteria. Inflation was not measured, but it was not dramatically out of line when compared to the peer group.*
- Did you assess quantity of assets replaced? *The information is present, but this was assessed across the comparison group.*

- Did you assess the condition of assets? *No.*
- Did you find that as companies increase the amount of poles they were replacing, that they became more efficient? Did they decrease costs through economies of scale? There are generally economies of scale with this type of activity; however, across the comparison panel we did not perceive clear evidence of incremental economies of scale.
- How were replacement costs calculated? *Total dollars/total poles.*

Notable Themes and Discussion Points

Following the end of the final presentation, Dave Hardy noted the main themes and discussion points that arose during the presentation.

Total Factor Productivity

- Safety was a theme noted as a measure of TFP
  - Safety index; whether or not safety should be an output
- Whether TFP includes an appropriate value for reliability
- Whether there is scope for more detailed correlation of factors and effects to measure TFP
- Weight given to outages caused by weather and major events

Vegetation Management

- Exploring administration and overhead costs
- Additional metrics – safety, environment quality, customer service
- Cycle length and relation to cost and performance
- What data should and should not be part of the peer group comparisons
- When Hydro One should or should not be compared to the peer group

Pole replacement

- Data gathering and ROW maintenance
- Definition of useful life vs. actual life

Distribution Station

- Looping and redundancy
- Economies of scale

Final Comments

Following the final presentation and recap of notable themes, Dave Hardy provided time for each participant to note additional comments and questions they had regarding any of the sessions. The following comments and questions were noted.

TFP

- Have another other outputs been tested other than safety and reliability? If so, what were the results? *Unanswered during session.*

Vegetation Management

- Weather impact should have been considered more because Hydro One has some volatile regions. Vegetation Management cycle might need to be altered for areas with more volatile weather.
- Was the CN study adjusted for currency? *Yes*.

Pole Replacement Study

- Clarify terminology (i.e. "touched")

Miscellaneous

- When is Hydro One planning on filing the application? *At the end of the first quarter of 2017.*
- Who can further questions be directed to? *The worksheets will be sent out electronically following the meeting. Please submit any additional questions on the worksheet by October 12th.*

Wrap Up – Maxine Cooper, Hydro One

Maxine Cooper thanked participants for their feedback and encouraged them to share additional input and feedback via email/the soft copy of the worksheet. She also encouraged participants to be in touch at any point between this session and the next if they have any topics they want to discuss. Maxine noted that participants will have until October 12th, 2016 for written feedback.

PARTICIPANT LIST

The following is a list of participants that attended the meeting and the organizations they represent.

Stakeholders & Consultants

- Bayu Kidane, *Power Workers Union*
- Benjamin Grunfeld, *Navigant Consulting (Presenter)*
- Bohdan Dumka, *The Society of Energy Professionals*
- Brady Yauch, *Energy Probe Research Foundation*
- Chris Codd, *Ontario Energy Board*
- David MacIntosh, *Energy Probe Research Foundation*
- Dmitry Balashov, *Toronto Hydro-Electric System Limited*
- Harold Thiessen, *Ontario Energy Board*
- Ian Nokes, *Ontario Federation of Agriculture*
- Jane Scott, *Ontario Energy Board*
- Jie Han, Canadian *Niagara Power*
- Ken Buckstaff, *1st Quartile (Presenter)*
- Mark Garner, *Vulnerable Energy Consumer Coalition*
- Mark Rubenstein, *School Energy Coalition*
- Mike Jessop, *Ontario Power Generation*
- Rob Earle, *1st Quartile*
- Shelley Grice, *Association of Major Power Consumers in Ontario*
- Steve Fenrick, *Power System Engineering (Presenter)*
- William Porter, *CN Utility (Presenter)*

Hydro One Networks Inc.

- Erin Henderson, *Hydro One Networks Inc.*
- Maxine Cooper, *Hydro One Networks Inc.*
- Oded Hubert, *Hydro One Networks Inc.*
- Paul Brown, *Hydro One Networks Inc.*
- Jody McEachran, *Hydro One Networks Inc.*
- Karen Taylor, *Hydro One Networks Inc.*

Hardy Stevenson and Associates Limited

- Dave Hardy, *Facilitator*
- Jeremiah Pariag, *Note taker*

DISTRIBUTION RATE APPLICATION

Summary Report for Participant Review
Stakeholder Session #3
Wednesday November 30, 2016
DoubleTree Hotel by Hilton – The Toronto Ballroom
108 Chestnut Street
9:00am – 1:45pm

SESSION OVERVIEW

On November 30, 2016, Hydro One Networks Inc. hosted a third stakeholder session to discuss its upcoming Distribution System Plan (DSP) application. The purpose of this meeting was to present information on various aspects of that DSP application, including a high-level summary of extensive qualitative and quantitative stakeholder research undertaken by Ipsos, and to seek stakeholder comment on those presentations and research. Hydro One Networks will host a subsequent stakeholder meeting in February 2017 on its DSP, which, like this meeting in November, will inform Hydro One Network's final DSP application, to be submitted by March 12, 2017.

The stakeholder session included welcoming remarks from Oded Hubert [Vice President, Regulatory Affairs, Hydro One Networks] and facilitator Ted Griffith [The Fixers Group] in advance of presentations by Iain Morris [Partner, Human Capital Business Leader, Mercer Group], Sandy Guiry [SVP, Quantitative Research, Ipsos] and Brad Griffin [SVP, Qualitative Research, Ipsos], Jody McEachran [Senior Regulatory Advisor, Hydro One Networks], and Paul Brown [Director, Distribution Asset Management, Hydro One Networks]. Ted Griffith closed the stakeholder session in asking for any subsequent questions or comments, and thanking everyone for attending.

This summary was written by Ted Griffith and Steven Bright of The Fixers Group, who provided independent facilitation services for the stakeholder session. This report provides a high-level summary of the main points discussed by the participants as captured in "live" notes written during the meeting. It is not meant to be a verbatim transcript of the meeting.

Note that there are two appendices to this summary (attached separately), including:

Appendix 1. Individual Submissions Received After the Meeting
Appendix 2. Presentation Slides

Note: This summary reflects what happened during the meeting and does not include written feedback received after the meeting. Please see Appendix 1 for the additional feedback received.

FEEDBACK SUMMARY

The presentation from Iain Morris described key features of a comprehensive compensation cost benchmark study, the fourth in a series of such benchmark studies. He also presented the study's methodology and its findings. Sandra Guiry and her Ipsos colleague Brad Griffin presented high-level findings of quantitative and qualitative stakeholder research that they undertook for Hydro One Networks in the summer of 2016. Jody McEachran of Hydro One Networks spoke to slides on the Performance Metrics that Hydro One Network proposes to use in their upcoming DSP application. Lastly, Paul Brown of Hydro One Networks spoke to slides that outlined customer engagement impacts on the DSP.

Following each presentation, stakeholders asked questions of clarification and provided feedback. These questions and feedback are reflected in this summary. Each of the following sessions begins with key messages, which are intended to be read together with the more detailed feedback that immediately follows. Please note feedback from participants is in **bold**, while the responses by presenters (and in some cases a Hydro One Networks employee in the audience who answered many questions) are in *italics*.

Part 1 – Total Compensation and Benchmarking Study (Iain Morris, Mercer)

KEY MESSAGES

1. The 2016 study mirrors similar benchmark studies done in 2013, 2011 and 2008, thus allowing for reasonable comparisons and trend analysis across the time horizon of these four reports.
2. Many factors impact the results, among them long-term incentives and headcount reductions.
3. Overall, the compensation of Hydro One Networks is a multiple of 1.14 compared to the 50th percentile of the study group.

QUESTIONS OF CLARIFICATION

<u>Benchmark Methodology</u>

- **The "regional maintainer" position was pulled from the research. How many positions were previously in the study?** *I don't have those exact numbers but can follow up if you like.*
- **Enersource and Horizon are not in the current study, but they were in earlier benchmark studies, while PowerStream is in the current study. Any impact on the current review of not having Enersource or Horizon?** *We looked at the overall sample, and not having these two organizations is not a material change. What we found is representative, but there would be some effect in not having them.*

- **On slide 9, was overtime considered in base wage?** *No.*
- **On slide 18, what is total number of incumbents?** *Total number of employees captured is around 5,200.*
- **Does Hydro One own the survey data, or can others use the data?** *All participants get the data, not sure what they do with it*
- **Will share grants be incorporated in next study?** *The current study was a point in time study and share grants were not included this time, but they will be part of next study.*
- **Which is better, using the 50% percentile figures or an average?** *Percentile is better, more stable, less impacted by extreme values. Others may have other views ... this is our view at Mercer … but percent rank is standard way across the industry research.*

Variability in Findings

- **In looking at slide 15 we see different positions, some are up and some are down. Why the variance?** *There have been some changes within Hydro One, but sample group differences might better explain variances as these can have a bigger effect than other factors.*
- **What is the relative impact of short-term incentives on overall comp? Does this contribute to variability?** *Short term tends to vary with jobs (i.e., level of job) and across different organizations. There are many factors, and these vary. In the aggregate, short-term incentives vary less than what you might think.*

Hydro One Compared to Industry

- **In the "Represented" groups, the universe is primarily small companies, yet Hydro One surrounds them. So I think smaller utilities is the actual comparator in many cases.** *We try to balance everything, which is why we include LDCs. We could re-define and broaden the competitive market in this regard in terms of the survey, which would give us a somewhat different answer. But I'm confident that what we did in this survey is a good picture of what's happening.*
- **I realize you're replicating the study year over year, but the universe of Hydro One itself is significantly broader than other organizations. Are we really getting accurate assessment of those with whom Hydro One is competing for labour?** *Confident we're getting some good results in this survey. We could look more broadly, but the single panel approach we're taking in this survey was the better approach in terms of repeatability*
- **Am I correct that Hydro One is moving away from the industry benchmark? Are compensation and incentives at Hydro moving farther away from the overall average than Hydro One pensions are moving from the average?** *We didn't look at data that way, so the effects of pension changes don't show up here in the data set.*

- **Do you poll other industries? My concern is that our industry is moving away from other industries? Can we break out industry data?** *Different industries do different things. The energy sector pays well, but there is no hard data in our study on whether the energy sector is paying more and more compared to other sectors.*

Pensions

- **In terms of pension comparison, how did you actually do the comparisons with changes in pensions?** *We looked at plans for each incumbent. DC plans applied to only 6 out of almost 3,000 people surveyed. We used similar approach to all organizations involved.*
- **Do you have historical data to break out pensions?** *Yes.*

Part 2 – Customer Preferences (Sandra Guiry and Brad Griffin, Ipsos)

KEY MESSAGES

1. The role of this stakeholder research is to ensure that Hydro One's distribution investment plan is informed by customer needs, preferences and priorities.
2. The research reflects a total of nearly 20,000 customers and more than 20,000 responses between June and July 2016.
3. Overall, keeping costs as low as possible is customers' top priority.
4. More specifically, small and residential customers would accept a small tradeoff of increase costs for current reliability, while large customers have limited acceptance of rate increases.

QUESTIONS OF CLARIFICATION

First Nations

- **Referring to slide 7, what's the definition of First Nations?** *Ipsos received a list from Hydro One for modeling, and took names flagged as First Nations from that list.*
- **Referring to slide 9, do the residential and small business numbers include members of First Nations?***Theoretically, but not identified as such.*

Residential and Small Business

- **Asking about the Appendix slides, does the full report also focus on residential and small business customers?** *Yes it does.*
- **Relative to slide 7, why was the quota for small business customers not based on density?** *We can't answer that now and will get back to you.*

- **Looking at slide 21, you probed distribution impacts for larger customer but not for residential customers. Why?** *We thought residential customers would be more familiar with their overall bills than the specific delivery charge portion of their bills. But larger customers have a better understanding of that delivery portion, so we included that specific part in asking them about this.*
- **In the online workbook, did you ask residential customers about the delivery charge?** *No, as we feel they better understand their total bill.*
- **Were residential and small business participants in the eight online focus groups in same room such that they could ask their own clarification questions?** *These were online platforms with participants also on a conference call, which allowed for some discussion. Telephone and online surveys did not feature that sort of interaction.*

<u>Definitions and Methodology</u>

- **What's the definitional difference between C&I and large?** *We will default to Hydro One for detail, with Hydro then confirming that they would get back an answer on that question.*
- **Are results from the two one-on-one sessions included in the report?** *Yes.*
- **The survey said some customers were not invited. Why was that?** *Ipsos said Hydro One handled the recruiting, at which point a Hydro One representative said that they have 8,000 C&I customers, and many of those have multiple meters.*
- **Did the survey, in talking about the component parts of customer bills, specifically outline who is responsible for what?** *We gave respondents in the online workbooks, focus groups and workshops some detail of the bill, saying they could check their telephone script for details on how much detail this particular method gave on the issue.*
- **What is the definition of DG as used in the survey? Does it mean commercial operators?** *Ipsos said they weren't certain of the precise definition in this context. At which point, a Hydro One representative clarified that DGs are a wide range of embedded generators, and that they would have different points of view than traditional residential customer. They promised to follow-up with more details on this issue, which they did at the meeting's conclusion.*
- **Did participants in the qualitative interviews understand distribution portions?** *Mostly yes. And when they were not clear on specifics they spoke with Hydro One representatives in the meetings to provide clarity.*
- **How did the focus groups actually work?** *With members of the general population and small business customers we ran surveys and focus groups. For large business customers we ran consultative workshops. Ipsos ran these workshops with Hydro One speaking briefly and Ipsos facilitating the discussion for two to three hours. Hydro One representatives could address any detailed questions. Having Hydro One in the room did not prevent participants from speaking their minds.*

- **Did participants in the survey understand the full context of a proposed $1 increase?** *The wording of the question defines the increase as a percentage of the total monthly bill and the equivalent average dollar amount. It also states how much higher the total monthly bill would be at the end of the fifth year. The question also states that the monthly bill could still increase for other reasons which are outside the control of Hydro One.*
- **Ipsos ran nine in-person sessions but only seven cities?** *London and Hamilton had two sessions each due to large demand to participate.*
- **Do the illustrative scenarios in the research report use historical levels?** *Hydro One said they would follow up, which they did at the end of the meeting.*
- **How many investment years were embedded in the various scenarios?** *Five years.*

<u>Reliability</u>

- **With respect to power quality as outlined on slide 14, can Hydro One track power interruptions of under 1 minute?** *A Hydro One representative at the table answered at this point, saying yes, they do have that capability.*
- **Were reliability performance figures included in the survey questions?** *Yes, we gave information on average outages to both residential and large customers in the "informed" surveys.*

<u>Costs</u>

- **This survey was in field in this summer, in June/July. It appears that energy now (i.e., late November) is more on their minds now than six months ago. Does that affect the results?** *Surveys are snapshots, representing the feelings of respondents at the time. We couldn't say if results would be different now. A Hydro One representative added that price dominated the results in the full research report, findings that broadly align with current news and feelings on energy prices.*
- **Slide 11 is matter of fact in talking about cost. How intensely do people feel about cost?** *Cost, in one qualitative session in London session, was most the contentious issue. This is consistent with other findings, as cost was contentious in other cities, but to various degrees of intensity. Similarly, in the quantitative research, cost and rates were the most prominent issues. They were particularly evident when respondents were asked to trade off cost to other factors. Keeping costs low was the number one preference in these trade-off questions.*
- **In looking at slide 12 and the wording about "willing to accept" rate changes, what size majorities did the research find?** *Results for question 17, shown on slide 20, show that acceptances were "a little bit over" the majority.*

- **How does the 1.1% increase equate to Hydro's portion of the increase?** *A Hydro One representative said information given to the "informed" group showed Hydro One's increase in the scenarios. She added that there are many different customer classes, and it can be challenging to use the same messaging in asking the same questions in trying to get statistically valid responses that can be generalized across Hydro One's broad customer range.*

Part 3 – Performance Metrics

KEY MESSAGES

1. OEB set out four categories of customer outcomes: Customer Focus; Operational Effectiveness; Public Policy Responsiveness; and Financial Performance. Hydro One will provide information on all four, plus additional metrics relating to Customer Focus and Operational Effectiveness.
2. Hydro One proposes to cease reporting on four metrics from previous applications: Number of Replaced Poles; Number of Pole Top Transformers with PCB Oil; Residential and Small Business Satisfaction; Estimated Bills Issued as % of Total Issued.

QUESTIONS OF CLARIFICATION

Targets and the scorecard

- **Will the Hydro One application have rewards or targets?** *Only targets.*
- **Will Hydro One link these targets to its corporate scorecard?** *We're working on that scorecard now.*
- **Is residential satisfaction included on scorecard?** *This is a combined scorecard, so it's mixed.*

Reliability

- **In looking at slide 5, what is a distribution outage?** *Paul Brown of Hydro One answered this question, saying a distribution outage is an unplanned outage of more than one minute, and the lights are out. He added that transmission systems have built-in redundancies, but these back-ups don't existing in distribution systems.*
- **Does operational effective and system reliability, as outlined on slide #7, consider SAIDI and SAIFI?** *No, they are a work in progress on the momentary outages.*

Poles

- **In referencing slide #9, is the number of poles replaced covered elsewhere?** *Yes.*

- **What did you previously report on poles with PCB poles?** *We reported on the number actually replaced, but this is not large component of our overall performance metrics program. We're focusing more on work throughput than replacement.*

Billing

- **What does the fourth metric on slide 9, (i.e., "estimated bills issued as % of total issued) refer to?** *We look at this as a way to drive a reduction in the number of bills that are estimated and not meter-read. Our billing accuracy metric on correct meter reads will replace this metric. So it's a duplication, which is why we propose to cease reporting.*

Methodology

- **Are the findings on slide 5 based on surveys?** *Yes.*

Industry Comparisons

- **In looking at slide 6, are other utilities reporting on these five values such that you can compare against them?** *Factors 7 and 8 (i.e., OM&A per customer and OM&A per km of line) are standard industry comparators. However, factors 4, 5 and 6 (i.e., pole replacement – cost per pole; vegetation management – cost per cyclical km; and station refurbishment – cost per MVA) are not standard across the industry.*

Part 4 – Customer Preferences, Metrics and the Distribution System Plan

KEY MESSAGES

1. Customers told Hydro One four main things: keep costs low; maintain reliable service; large customers are more concerned about reliability and capacity; and overall willingness to accept a rate increase is limited.
2. Hydro One has implemented a number of productivity initiatives to reduce unit and operating costs.
3. Hydro One is executing on various productivity and efficiency enhancements to change and reduce its cost structure.

QUESTIONS OF CLARIFICATION

Risk Models and Demographics

- **Does distribution use the same risk model as transmission?** *No, distribution is performance based.*
- **In looking at "Plan B Modified" in 2022, will demographics be worse than now?** *We don't focus as much as demographics. Rather, we want our fleet to be the same, which we means we focus on condition more than demographics. Our investment plan is being driven by performance of the network, which is correlated to condition more than demographics.*

We replace defective assets, and we use demographic information to look ahead to volume requirements.

Rates and Capital Spending

- **Can Hydro One quantify its costs savings by the respective approaches?** *Yes, we could show how effective we're being in our upcoming rate application.*
- **In looking at slide 28, will rates go up after 2018? And why is the dip in that graph important?** *We will have some fixed, non-discretionary expenditures in 2017-18 that will impact our 2018 numbers.*
- **Is the aim of Plan B Modified to reduce capital expenditure or rates?** *A Hydro One representative said Hydro One went through a very iterative process that included several levels of the organization – including up to the Board of Directors – to try and find a balance between rates, preferences and assets in 2018 and throughout the full five-year period. So when talking about the investment plan, we're talking about capital spending and the OM&A envelope interacting to create outcomes that are valued by the customer. In other words, we're trying to find a balance of capital and OM&A and a rates profile for 2018 and the full five years that is consistent with regulatory and customer expectations. A lot of that is found in productivity improvements and in doing the most we can with money we already get before we ask for more.*
- **Will rates go down in 2018?** *No. Capital spending may go down, but not rates.*
- **In looking at slide 22 (i.e., power quality initiatives), will there be incremental spending over the next five years on this quality issue?** *Yes, but these will not be material costs in grand scheme. Rather, it will be extra funding within the existing envelope, as we know there's a quality issue to be addressed.*
- **In referencing station improvements and pole replacements, what accounts for the uptick at end of planning session?** *Our estimates are tempered until 2018, then flat in 2019-2021 to allow for large transmission capital improvements. The 2022 uptick is to account for the planned smart metering re-fresh.*

Reliability

- **Is the use of "reliability" on slide 27 a judgment or a calculation comment?** *We're getting better at forecasting the reliability impact of things such as pole failures as an example. For example, in looking at the condition of our asset fleet, we're getting better at saying that if it degraded by X, then it will have X impact.*

<u>Productivity</u>

- **Looking at Hydro One's productivity initiatives on slides 7-10, are recently undertaken initiatives already embedded, or will you undertake them in the upcoming planning period?** *Some initiatives are in the future, with their respective benefits accruing early in the 2018-2022 time period. Various investments are built into our plan in various stages of implementation in 2017, with a bias towards driving for cost savings early on in that planning cycle.*

CLOSING COMMENTS

After discussion on all of the presentations, Ted Griffith went around the table asking every stakeholder if he/she had any further questions. He added that they would all receive a follow-up email the next day to see if they had any subsequent questions and, if so, they would have an additional seven days to submit those questions.

<u>Process going forward</u>

- *In these closing questions, one stakeholder asked about the process going forward with respect to Hydro One's DSP and stakeholdering. In response, a Hydro One representative said that the OEB suggested Hydro One consider third-party input into the DSP to ensure that it meets best practices. Hydro One therefore contracted an external firm to do exactly that, which Hydro One will share with stakeholders on a meeting scheduled for February 8, 2017. Input from that meeting will be incorporated into Hydro One's final filing.*

<u>Definition of DG</u>

- *A Hydro One representative provided answers to a question posed earlier in the stakeholder session about the definition of a DG customer, saying that a residential and/or small business customer could in fact be included in this DG definition in the research.*

<u>Base case scenarios</u>

- *As a follow-up to an earlier question, a Hydro One representative provided all attendees with more information on the base figures used in the investment scenarios previously discussed. She said that scenario #1 was the "status quo", scenario #2 was "improve", and scenario #3 was "degrade", adding that the first of these scenarios aligned with Plan B Modified as outlined in Paul Brown's slides. Maxine Cooper of Hydro One agreed to confirm that with a follow up email.*

PARTICIPANT LIST

The following is a list of all attending participants and their respective organizations:

Stakeholders
1. Andrew Blair – *Power Workers' Union*
2. Kim McKenzie – *Power Workers' Union*
3. Bimbola Ayo – *Toronto Hydro*
4. Brady Yauch – *Energy Probe*
5. David MacIntosh – *Energy Probe*
6. Bill Harper – *VECC*
7. Harold Thiessen – *OEB*
8. Mark Rubenstein – *SEC*
9. Matthew Higgins – *Toronto Hydro*
10. Michael Jessop – *OPG*
11. Patrick McMahon – *Union Gas*
12. Scott Pollock – *CME*
13. Shelley Grice – *AMPCO*
14. Vicki Power – *Society of Energy Professionals*

Hydro One and Consultants
1. Iain Morris – *Mercer (Presenter)*
2. Sandra Guiry – *Ipsos (*Presenter)
3. Brad Griffin – *Ipsos (Presenter)*
4. Oded Hubert – *Hydro One Networks (HONI)*
5. Jody McEachran – *Hydro One Networks (HONI)*
6. Paul Brown – *Hydro One Networks (HONI)*
7. Karen Taylor – *Hydro One Networks (HONI)*
8. Maxine Cooper – *Hydro One Networks (HONI)*
9. Erin Henderson – *Hydro One Networks Inc. (HONI)*

The Fixers Group
1. Ted Griffith – *Facilitator*
2. Steven Bright – *Note taker*

Hydro One Networks Inc.
2018-2022 Distribution Rate Application

Stakeholder Session #4

Summary Report

Doubletree Hotel by Hilton
Toronto Ballroom, 2nd Floor
108 Chestnut Street
Toronto, Ontario

February 8, 2017

Session Overview

Hydro One Networks Inc. hosted a series of stakeholder sessions with the purpose to exchange information with its stakeholders regarding the 2018-2022 Distribution Rate Application. This summary report is a synthesis of the information and discussion from the fourth, and final, session. Additional meetings with Metis and First Nations communities will also be held. Hydro One is aiming to submit the application at the end of March with an update in June 2017.

Oded Hubert, Vice Present, Regulatory Affairs, Hydro One Networks, welcomed stakeholders to the event and provided introductory remarks. Mr. Hubert highlighted the importance of early and ongoing engagement with stakeholders. The full-day session was facilitated by Tracey Ehl of Ehl Harrison Consulting Inc. and included four presentations:

1. 2018 to 2022 Custom Incentive Rates Application Framework (Oded Hubert)
2. Econometric Benchmarking of Hydro One's Total Distribution Costs (Steve Fenrick)
3. Cost Allocation Methodology, Rate Design and Bill Impacts (Henry André)
4. Core Capital and OM&A Work Programs (Paul Brown)

A facilitated discussion followed each of the presentations. This summary report reflects the questions asked, the responses provided, information requested and any additional comments and advice provided by stakeholders during the session. Stakeholder questions are generally shown in bold text, with the responses directly following. Comments and questions received after the session are not reflected in this report.

A list of participants can be found in Appendix A. These notes also include links to additional information requested by participants such as the results of the customer engagement process, benchmarking studies, a previous executive compensation study, and notes from previous stakeholder sessions.

Stakeholder Discussions

A. 2018 to 2022 Custom Incentive Rates Application Framework (Oded Hubert)

Summary:
Prior to commencing, Mr. Hubert provided and explained a Disclaimer regarding Forward Looking Information for participant review. Mr. Hubert then provided an overview of the distribution rate application framework. He emphasized that the application is aimed at balancing competing priorities, those being asset needs, customer needs and preferences, and rate impacts. He provided a review of the 5-year revenue requirements, the estimated rate changes over the period and the contributing factors. Mr. Hubert also provided an overview of proposed Earnings Sharing Mechanisms (ESM) and Capital In-Service Variance Account (CISVA).

Key messages:

- Acquired LDCs will be fully integrated in 2021.
- The load forecast is still being finalized.
- There will be a load forecast update in 2020 for setting 2021 and 2022 rates.
- The Hydro One Board of Directors approved the Transmission Business Plan and the Distribution Business Plan in December 2016.

Discussion:

1. **Costs are going up but consumption is going down (referencing 3Q report). Why aren't costs reduced when consumption drops?**
   Declining consumption is a contributing factor to the rate increase. Customers are looking to Hydro One to cut costs and increase efficiency. However, a number of our costs are fixed and most are unrelated to the consumption, such as customer service and our call center. This application builds in a number of approaches to increase productivity and efficiency.

2. **Should there be a variable component built into the forecasted OM&A?**
   No. It is recommendation that this question be parked at this time.

3. **When you take over a local distribution company (LDC) are there any benefits to ratepayers? Does this ever result in reduced rates?**
   Acquiring LDCs can result in a number of synergies and these synergies can be passed on to customers.

4. **Is there a business plan/strategic plan underpinning this application?**
   Yes, on December 2, 2016, the Board approved the Transmission Business Plan and the Distribution Business Plan. The latter is the basis for this application. The OEB Handbook is also a guiding document for this application.

5. **What is the basis for the addition of the custom capital factor? Will it be adjusted to reflect 2017 OEB's ACM/ICM parameters?**
   A similar approach was taken in the Toronto Hydro application. The custom capital factor will be applied in all four years (following the initial cost of service year).

6. **For the acquired LDCs, will rates be harmonized? What will the impact be on rates of the acquired LDCs?**
   Most customers of the acquired LDCs will be assigned to new "acquired" rate classes. The impact on their rates is still being finalized. It appears that rates for residential customers of the acquired LDCs will see an increase commensurate with that of other Hydro One customers.

7. **Why did you decide on a deadband of 100 basis points to trigger the ESM?**
   This threshold number was selected as it is commonly used and has been accepted by the OEB and intervenors in other filings. It seems to be reasonable for aligning the customers' and the utility's interests in this application. It was not derived using any special analysis.

8. **Will this application include a capital forecast for the acquired LDCs?**
   Yes, this will be included. Also, the load forecast will be updated for 2021 and 2022.

9. **For the Capital In-Service Variance Account (CISVA), how was the 2% deadband determined? It appears that the stretch factor is already included.**
   It may be very difficult to hit 100% of forecasted in-service additions in any given year. 2% seems reasonable as it provides flexibility in work program execution and allows for a small carry over from year end to the beginning of the next year, where needed.

10. **Is there any interaction between the Earnings Sharing Mechanism (ESM) and CISVA?**
    The ESM will be structured in consideration of the CISVA to avoid double counting of over-earnings.

11. **Is there a financial incentive to reduce energy losses?**
    The losses are a pass through, so incentives would come from planning processes, and are not tied to revenue requirement.

12. **Would you be willing to consider making Line Losses part of revenue requirement?**
    This wouldn't be consistent with our revenue model or how the revenue requirement is established, using the OEB's current methodology. Hydro One does take actions and make investments in phase balancing and through re-conductoring that reduce losses.

13. **Is your intention to apply an annual rate adjustment?**
    No, except as required by the OEB for the purpose of rate setting (e.g. to derive new rates each year that reflect the predetermined load forecast adjustment). However, there will be a number of rate adjustments in 2021 to reflect the ROE, Load Forecast and OM&A associated with the acquired LDCs.

14. **Will the capital factor apply for all five years?**
    Yes, it will apply for all four years, following the initial rebase year.

15. **Is Hydro One comfortable with the inflation rate? Should a different inflation index apply to a Revenue Cap than to a Price Cap? The inflation rate should be applied to the overall rate.**
    Yes, Hydro One is comfortable. We had not contemplated that a different inflation factor would apply for a Revenue Cap.

16. **There is still confusion as to how acquired LDCs fit into the application? Are they licensed until 2021?**
    Operationally, the three acquired LDCs have been integrated but each had a five-year rate freeze in place. For two LDCs, this rate freeze is until 2021. We are proposing to extend the rate freeze for Norfolk by an additional year (i.e. 6 years), so that all three LDCs will be integrated in 2021 for rate setting purposes.

17. **How will Hydro One demonstrate that some of its ISVA shortfall was the result of productivity?**
    We have not determined the specifics for demonstrating this, but we believe it is an appropriate adjustment. The onus will be on Hydro One to demonstrate such savings to the OEB's satisfaction.

18. **Are all of the rate riders included in the rate impacts shown here, or will there be additional ones in the application?**
    Yes, they are all included here and shown in the rate impacts.

19. **Regarding the regulatory process, 2018, would you utilize a mechanistic adjustment for OM&A, and a capital factor that emulates a cost of service approach (not intended to sound derogatory) for Capital.**
    Yes, as applicable.

20. **Are senior managers going to continue to be rewarded for exceeding the OEB-approved level of in-service additions? The targets should be aligned with OEB-approved levels.**
    Hydro One will align these targets with OEB approved levels.

21. **Do you have your Capital Factor stated as a % for each year?**
    This number isn't available at this time.

22. **Why does OM&A increase at a greater pace in 2021?**
    The incremental OM&A of the acquired LDCs will be added in 2021.

23. **Is the line loss factor included in the scorecard?**
    No, it isn't included.

24. **Could you incorporate an incentive to reduce the line loss factor? If possible, this could be part of the score card.**
    It is possible to identify specific economic investments required to reduce line losses. This will be taken under consideration.

25. **You have identified costs over 5 years including the capital factor. Is there a separate mechanism to capture Other revenue?**

    A forecast of Other Revenue is provided for each of the 5 years in the application term.

B. Econometric Benchmarking of Hydro One's Total Distribution Costs (Steve Fenrick)

Summary:
Mr. Fenrick presented the findings of an econometric study conducted to identify an appropriate stretch factor for upcoming rate application. The presenter highlighted the robust data set compiled as part of developing the benchmarking model. The data variables, results from model, and recommendation were provided.

Key messages:

- Hydro One has a unique service territory.
- Distribution costs are not really sensitive to energy sales.
- One challenge is a lack of comparable data sets in Canada. To overcome this, US examples were utilized.
- Stakeholders identified interest in incorporating additional data sets (such as BC Hydro and Québec Hydro), and possibly removing some data sets that are not as similar to Hydro One as others.
- The recommendation can be updated if new data becomes available

Discussion:

1. **With a sample of 380 utilities, checking quality of the data seems very challenging. How do you address this?**
   We conducted a screening process of the entire data set to identify any outliers in terms of peak demand, customers, and costs. Outliers were disregarded.

2. **Did you consider narrowing the sample size?**
   No, narrowing the sample size was not considered. Typically, a larger sample size is more desirable. We looked at all utilities with 10,000 customers and above. No other limiting factors were applied. This was done so as to be inclusive rather than arbitrary.

3. **Your sample size is 380 utilities. Are all of them in the United States?**
   Yes, all of the utilities in the sample are American. American municipal utilities were not included as they do not have standard reporting.

4. **Do you know the percentage of the rate paying population that were sampled?**
   This number is likely high, although the exact number is not known.

5. **Why were Ontario utilities left out?**
   Comparative data is not readily available. Each utility would have to be approached individually.

6. **Was a variable to account for transmission incorporated into the model?**
   No, this variable was not used as it was not significant. Rural utilities are distribution only, and this could potentially skew results.

7. **How are differences related to Canadian and US currency addressed?**
   The differences are addressed through having both the costs and input prices in the same and original currency of the utility. This enables the comparison to be in real numbers and accounts for the differences between Canadian and U.S. currencies.

8. **In your sample, was there an attempt to come up with a balance of urban/rural similar to Hydro One?**
   Yes, the data sample encompasses a range of both urban and rural utilities. PSE accomplished this through including both the U.S. investor-owned utilities and U.S. rural electric cooperatives. This allows us to design model variables/estimates and then the compare against Hydro One. The sample is not meant to exactly mimic Hydro One, but rather to correlate variables to costs (i.e. if one customer is added, this is the resulting cost impact) and identify cost relationships.

9. **The large sample size used for Hydro One is different than the approach used for Toronto Hydro. Why?**
   Generally, more (relevant) data is better. For Toronto Hydro, 150 large utilities were sampled. There were no highly rural utilities in that dataset.

10. **Are you able to forecast productivity for the five year revenue period?**
    Yes, this is possible if the required inputs are available. This was done for both Toronto Hydro and Hydro Ottawa.

11. **Is this data being used in many studies?**
    Both the IOU and rural electric cooperative data sets have been utilized separately for previous studies. This is the first time that we have combined the urban and rural data sets.

12. **What does the range of benchmark scores look like for rural utilities?**
    There is a natural bell curve with a cluster around 0%. The range is usually around +/- 40 or 50%.

13. **A better measure of cost would be to use kilometre of line per customer instead of square kilometre per customer.**
    While this has been tried, a choice had to be made between variables and it is felt that square kilometer per customer is a stronger variable.

14. **Hydro One has a challenge with long lines which result in reduced efficiency. Is it possible to look at particular companies that are 'most like' Hydro One?**
    It is recognized that Hydro One has a unique service area with some areas of very low density. It was felt that the range of utilities in the data set was appropriate because this analysis was performed to derive a correlation between distribution costs and various independent variables. For this reason, similarity to Hydro One is not necessary for the correlation to be determined. It is possible to run other comparators if data is available.

15. **Please confirm that the +28% difference from the benchmark includes consideration of the difference in currencies (Canadian vs US)?**
    Yes it does, as each is considered in its own currency for both the costs and the input prices and therefore considered in real and comparative values.

16. **How is a 0.6% stretch factor derived when productivity is 28% above the benchmark?**
    The stretch factor is based on the OEB decision. Since the Ontario distribution industry has been found to have negative productivity, the 0.6% productivity target for Hydro One is a target that requires the company to outpace the industry productivity by an amount

far beyond the 0.6% target. The 0.6% stretch factor amounts to a very challenging target.

17. **It appears that Hydro One's delivery costs are twice that of other utilities in the study.**
    Hydro One serves a far more challenging service territory that necessitates higher cost levels than its peers. Reliability and customer service performance also factor in to this.

18. **There are other methods that could have been utilized for this study. Why did you choose this econometric benchmarking?**
    Economic benchmarking is superior because it is rigorous in that more variables are utilized than in other methods and it is Board tested and accepted.

19. **Hydro One has never participated in the annual client rate survey (survey of 62 companies)? Why?**
    Hydro One indicated they are not familiar with the study and therefore have no comment.

20. **Hydro One has a challenge with long lines in vast rural areas. Can we look at particular companies that are 'most like' Hydro One like BC Hydro and Hydro Quebec?**
    To explore further the 'density' characteristic, companies like BC Hydro and Hydro Quebec could be considered in the future. Making sure the cost reporting is able to provide the same cost definitions may be a challenge. Comparing directly would be problematic because Hydro One is unique in their service territory.

21. **Why were case studies from Hydro BC and Hydro Québec not included? The service areas may be more similar than many of the utilities in the data set utilized.**
    Data reporting and availability is the issue. If the data was available, it could be utilized as well.

22. **Did study results show any trending over time related to costs and productivity?**
    Similar to the TFP study findings, there was some decline in performance since 2002. Also similar to the TFP study findings, this decline in performance has leveled off in recent years.

C. Cost Allocation Methodology, Rate Design and Bill Impacts (Henry André)

Session description:
Mr. André discussed four broad areas: load forecast; cost allocation; rate design; and, bill impacts. Mr. André noted that 2018 to 2022 will continue to include the seasonal class as part of rate design. The presentation highlighted changes in 2021 including the proposed 6 new acquired rate classes.

Key messages:

- Lower than forecast customers and consumption, relative to 2017 approved levels, are largely due to the negative economic situation in 2015 and 2016.
- The bump up in 2021 reflects acquired customers/rate classes.
- All R/C ratios for existing Hydro One rate classes are within Board approved ranges except for the Dgen class.
- Some R/C ratio adjustments for new acquired general service classes are anticipated
- Bill impacts across rate classes will vary from the average values shown

Discussion:

1. **Do the new LDCs have any seasonal class customers? Why?**
   No we have not identified seasonal customers within acquired utilities. To be consistent with Board decisions, we also haven't broken out the acquired service territory into Hydro One density zones. Hydro One has had a seasonal class since the 1960s and the Board has agreed with this. The Board has initiated a new proceeding to eliminate this rate class and there is a report before the Board on this matter.

2. **There are rebates for conservation. Isn't this counterproductive to Hydro One's bottom line?**
   This is a fair point. These targets are established by the IESO and Government. To the extent that load declines due to conservation, Hydro One must increase rates in order to collect its revenue requirement. However, for an individual consumer, the assumption is that the costs saved through CDM (lower consumption) should at least offset rising rates, and hence result in total lower energy costs for the consumer.

3. **Is the fourth quarter forecast available?**
   We are not aware of what the fourth quarter results are at this time.

4. **Are Hydro One CDM forecasts different than provincial forecasts?**
   My understanding is that the forecasts and historical values used for load forecasting are consistent with IESO data. This will be confirmed.

5. **Is it correct that the Dgen rate will go up?**
   Yes, Dgen customers were severely underpaying. To address this gap, further R/C ratio adjustments will be needed until 2020.

6. **Can we expect year-end 2016 updates in the June update submission? Will load forecasts be available at the same time?**
   Hydro One will use the latest forecast, including 2016 updates, as part of its filing at the end of March. The June 'blue-page update' will reflect audited 2016 numbers for the purpose of finalizing deferral and variance account disposition and riders.

7. **How much consideration was given to doing bump up of rates across years to smooth impacts?**
   Moving revenues across years to smooth impacts was considered in Hydro One's last distribution customer IR application, but the Board did not accept this approach.

8. **How do rates for acquired LDCs compare with other rates?**
   Residential customers of acquired LDCs will see an increase over current distribution rates similar to what all customers are experiencing. General Service acquired customers may see larger impacts as a result of needing to adjust R/C ratios.

9. **How long do you expect to keep 6 new rate categories?**
   Hydro One is hoping to minimize the addition of new rate classes. It is uncertain at this point how long the new categories will be maintained, but we expect to use them for other acquisitions, such as Orillia, as appropriate. (It was clarified that the Orillia application is not yet approved.)

10. **Are the rates lower in LDC territories?**
    Typically, yes they are.

11. **Can you provide an update on the seasonal class? Will it be eliminated? (directed to OEB staff)**
    OEB response: The Board has indicated that it would be eliminated. The procedures to do so have not been established yet. The Board has initiated a proceeding to review Hydro One's updated report on this matter. This proceeding will get under way over the next month or two.

    Hydro One response: Until the outcome of the Board proceeding is known, Hydro One will not include the elimination of the seasonal class in its filing.

12. **Will you have the ability to update any aspect of the load forecast over the 5 year period?**
    The same load forecast as proposed in the application will be utilized over the 2018-2020 period. The load forecast will be updated as part of annual 2020 submission for 2021-2022.

13. **Clarify the factors developed to adjust fixed assets allocated to acquire rate classes.**
    At a high level, factors have been developed to true up the amount of assets allocated by the cost allocation model to the new acquired classes with the amount of acquired utility assets at the time of acquisition plus any in-service additions to 2021. This will be detailed in the application.

14. **Will the LDC customers permanently stay in these new rate classes?**
    Yes, that is the thinking right now.

15. **Do you have any classes where the expected impact is 10% or more?**
    Potentially, however we will adjust using a phased approached so impacts won't be higher than 10%.

16. **How does the 5.8% rate increase for 2018 compare to other companies?**
    To our knowledge, this comparison hasn't been done.

17. **Could you clarify whether the revenues are going up by same %? (slide 8)**
    Yes, this is consistent with the revenue cap approach. We will assess rate impact disparities, which may prompt a look at alternatives that take into account the impact of changing load forecast by rate class.

18. **Have you done a re-fresh of the rate classifications?**
    Yes, a rate class review has been completed and it will be implemented in January 2018. Only a relatively small number, 12,000, customer will be impacted.

19. **There are two sets of Guidelines for Revenue-to-Cost Ratios, the generic requirements, and the OEB's decision for Hydro One. Which are you referring to?**
    Hydro One will be using the broader Board ranges if it helps mitigate bill impacts.

20. **Does the update to class load profiles include smart meter data?**
    Yes, it does.

21. **Is there a gap where hourly metering is not available?**
    There are some customers for whom hourly data is not available, but these will be few in number and not expected to impact the load shapes. This will be confirmed.

22. **Did you notice an impact on revenue - cost ratios as a result of updating load shapes?**
    None of Hydro One's R/C ratios are getting driven outside of the range, so there hasn't been a prompt to look in greater detail. Given Hydro One has historically updated our load shapes, a large impact would not be expected.

23. **When a new utility is acquired, should Hydro One, through policy, be required to apply the same rate setting methodology as it does for its legacy customers? The Hydro One costs to deliver services seems to be higher than that of other rural utilities.**
    This is not the approach Hydro One has adopted for this application. Hydro One is trying to accommodate the Board decision to align rates with costs to serve acquired LDC customers.

    Stakeholder comment: During a previous proceeding support was expressed for reflecting the true cost of service to newly acquired LDC customers.

D. Core Capital and OM&A Work Programs (Paul Brown)

Session description
Mr. Brown provided an overview of the Distribution System Plan (DSP). Mr. Brown highlighted key findings from the recent (July 2016) customer engagement and how this has informed areas of priority for the application. In addition, a number of cost management strategies to reduce rate impacts were presented.

Key Messages
- Through customer engagement, the number one priority identified is keeping costs low. This is followed by maintaining (not improving) reliability levels.
- This application aligns with customer preferences: keep costs low; maintain reliable service; address reliability and capacity concerns raised by large customers; and, manage rate impacts.

Discussion
1. **Do you have a target for SAIFI?**
   Yes. This will be included in the rate application.

2. **For investments that target improvements for large customers, will costs be directly allocated to them?**
   Yes they will. In most cases, these customers are served by the sub-transmission system, and the costs will be recovered from the ST rate class.

3. **Will there be a reliability risk model in the application? You mention it, but it doesn't seem as integral?**
   That is correct. Reliability performance, rather than reliability risk, is more clearly linked with our distribution investments. This is because the distribution system does not have the same level of redundancy as the transmission system. As a result, equipment failures lead directly to interruptions and reflect in lower reliability performance. We look at investments across classes and will largely base investment decision on condition and performance.

4. **Have the four customer preferences impacted this rate application?**
   Yes, the customer preferences and priorities shaped the approach to this application.

5. **Will you be following normal Board filing format?**
   Yes, the application will be aligning more closely to this format.

6. **In previous sessions, we were talking about benchmarking studies. How do they fit into the current plan?**
   There were three studies: pole benchmarking; distribution station benchmarking; and, the vegetation benchmarking study. The outcomes of the studies either validated or challenged unit costs to undertake work. For example, the costs are slightly high regarding station costs. For poles, we gained a sense of the impact of technologies we are investing in to potentially extend the service life. The vegetation benchmarking study also had impacts that we are looking at.

   For additional information, please visit the information posted for the October 5, 2016 session at http://www.hydroone.com/RegulatoryAffairs/Pages/DxRates.aspx .

7. **Are you proposing to adjust depreciation rates for any assets? It would seem to me that you should adjust. In the application, there should be an explanation as to why the current depreciation rate is still appropriate.**
   Hydro One is proposing to keep the same rates as in the previous application. Hydro One has found that (some) older assets are still useful beyond their service life as they were either over-built or running at lower capacities. Comparatively, some newer assets aren't performing as well as expected. Overall, on a fleet basis, the performance remains aligned with past expected service life numbers. Also note that useful life for depreciation is not the same as the useful life for assessing condition.

8. **Provide additional details regarding the customer engagement process.**
   Ipsos was contracted to undertake an in-depth engagement process that included customer surveys (online and by phone), focus groups, and workshops (with LDCs, large distribution account customers, and Commercial/Industrial customers). [Also see Question 24.]

9. **Is there going to be a more robust quantification of efficiency savings?**
   This will be given further consideration. There will be a new approach to this in the application with solid ability to quantify the efficiency savings.

10. **Is the customer power quality program new?**
    This is new for distribution customers. Hydro One is working with customers to address power quality issues through on-site monitoring. Some businesses are quite sensitive to changes to power quality. In certain facilities, audits have been conducted to identify approaches to becoming more resilient. This initiative has been well received by large customers.

11. **Toronto Hydro subcontracts pole replacements. Does Hydro one do this?**
    Some components of pole replacement (i.e. digging, drilling) are subcontracted, but full pole replacement is not.

12. **What is the operational metric for "greatest value for customers" so that we can understand in the future if we are hitting it? (slide 5)**
    This is correlated with the customer preferences shown on slide 3. There are a number of related metrics in the application.

13. **A lot of money is being spent on vegetation management, with the intent of hitting a 7 year cycle. Why was this not achieved?**
    This is partly due to the catch-up that is necessary.

14. **Are you going to have a metric to get costs in-line?**
    Yes, there is plan to address cost efficiencies through proposed metrics.

15. **Can some of the line care be contracted out?**
    This is not currently in the investment plan from a work implementation perspective.

16. **Clarify the slide regarding asset condition and use of an age proxy.**
    In the 5-year plan, Hydro One has specifically identified assets with health issues based on condition. Asset condition (not age) is driving the plan.

17. **Is the pole replacement program driven by the condition of the pole or are there other reasons for replacement? Are the majority of pole replacements a result of the pole itself as opposed to circuits etc.?**
    Poles are replaced for a variety of reasons such as putting taller poles in for new feeders or moving them for roadway widening. In the process of these other drivers, some poles that are in poor condition get replaced. The pole replacement program, however, is to manage the remaining fleet of poles whose condition has been assessed and that need replacement as a result of their poor condition.

18. **Is there a reliability metric that deals with outage impacts that will be included in the application?**
    Yes, there is a metric that addresses this.

19. **With metrics, the difficulty is how they take on meaning. How will they drive behavior? It would be helpful to be as specific as possible regarding the purpose of specific metrics within the application (i.e. how is it expected to be implemented, monitored etc**.).
    In addition to the OEB's Distribution score card measures, there will also be outcome measures. It is a good point. Performance measures always have to be balanced, as there are tradeoffs involved, and one of the benefits of a robust set of performance measures is the further discussion that can result from them.

20. **Do municipalities contribute to the cost of poles replaced as a result of municipal road widening projects?**
    Yes, there is a formula for cost sharing.

21. **Do you have a third party review the condition of the assets?**
    No, however a third party did review the distribution system plan.

22. **Is Hydro One considering burying the lines?**
    This has been looked at it, but the economics aren't really there.

23. **Has a study been done regarding the executive compensation package?**
    Yes. The compensation studies can be found with the following links.
    - Hugessen Consulting: Preliminary CEO/CFO Pay Benchmarking
    - Towers Watson: Hydro One Executive Compensation Benchmarking
    - Towers Watson: Hydro One Competitive Compensation Review

24. **Please provide additional information about the customer engagement process, as well as the results.**
    This information can be found in the November 30, 2016 presentations at www.hydroone.com/RegulatoryAffairs/Pages/DxRates.aspx.

Session Wrap-up

As a summary of the day's discussion, participants were asked to provide their 'top' priority for Hydro One to consider as the Company finalizes the distribution rate application, or feedback on the stakeholder process. These ideas are summarized below.

1. Act more like a private corporation, less like public service. Take ownership of results.
2. Connect the executive compensation with benchmarks in reaching results and realizing efficiencies (i.e. lower rates).
3. Consider contracting out major expenses.
4. Consider comparing more closely with 'like' companies such as BC Hydro and Québec Hydro.
5. Get the rate levels down.
6. There is a marked improvement in this application. Building from the transmission rate application, it is suggested that Hydro One prepare a proper presentation for compensation (2K).
7. Include meaningful compensation schedules to help our assessment.
8. Be transparent in what is being proposed by making clear and direct linkages to explain how outcomes were derived.
9. Prepare and include a succinct guide to the filing for inclusion in part 1 of the application.
10. The studies by Mercer are circular in that they have no relationship to what others are making. A study of compensation should include consideration of how Hydro One wages and wage changes compare both to other companies and also within Hydro One. Horizontal studies should be completed to understand how executive compensation compares to that of people in the field.
11. Hydro One is doing good work on metrics, but this needs to be supported by the specific reasons "why", otherwise, they are just metrics. It needs to be explained why these metrics are useful for change making.
12. Appreciation was conveyed to Hydro One for including other utilities into the process, as it helps the entire sector to move forward. The courtesy will be returned for future applications.

All stakeholders were thanked for their participation. Additional questions and/or comments were invited within seven days following the session.

Appendix A: List of Participants

The following is a list of all attending participants and their respective organizations:

Stakeholders
Shelley Grice – AMPCO
Nicholas Copes – Balsam Lake Coalition
Bill Cheshire – Balsam Lake Coalition
Marion Fraser – BOMA
Marion Fraser – BOMA
Julie Girvan – CCC
Scott Pollock – CME
Cary Ferguson – DeMarco Allan LLP
Brady Yauch – Energy Probe Research Foundation
David MacIntosh – Energy Probe Research Foundation
Ian White – Federation of Ontario Cottagers Associations
Jack Gibbons – Ontario Clean Air Alliance
Harold Thiessen – OEB
Jane Scott – OEB
Andrew Bodrug - OEB
Saba Zadeh – OPG
Andrew Blair – Power Workers' Union
Kim McKenzie – Power Workers' Union
Mark Rubenstein – SEC
Alison Fraser – Shared Value Solutions
Bohdan Dumka – The Society of Energy Professionals
Vicki Power – The Society of Energy Professionals
Andrew Sasso – Toronto Hydro
Daliana Coban – Toronto Hydro
Patrick McMahon – Union Gas
Bill Harper – VECC
Mark Garner - VECC

Hydro One and Consultants
Steve Fenrick – Power System Engineering Inc.
Uri Akselrud - Hydro One Networks
Henry André – Hydro One Networks
Oren Ben-Schlomo - Hydro One Networks
Paul Brown – Hydro One Networks
Erin Henderson – Hydro One Networks
Oded Hubert – Hydro One Networks
Jody McEachran – Hydro One Networks

Tracey Ehl – Facilitator
Jodi Ball – Note taker

Hydro One and First Nations Engagement Session
Mandarin Room, DoubleTree by Hilton
Thursday, February 9, 2017

SESSION REPORT

TABLE OF CONTENTS

Note Taking Summary of Hydro One Key Messages

- There is a new team at Hydro One who is committed to working with First Nations through honest and respectful engagement.
- Hydro One is working to improve service, responsiveness, and reliability of the power system.
- Hydro One committed to finding solutions to address the affordability challenges faced by First Nations.

Note Taking Summary of First Nations Key Messages

- Hydro rates are burdensome for many First Nations, in particular for Elders and vulnerable people. There needs to be immediate and significant action to mitigate the high costs.
- First Nations are interested in exploring the idea that a unique rate for First Nations should apply to First Nations people both on and off reserve.
- First Nations must enjoy the benefit of resources that are drawn from their territories.
- Hydro One staff working in First Nations communities needs some level of cultural awareness training. This should include knowledge about land regimes and treaty relationships.
- Many First Nations are willing to engage with Hydro One in order to achieve results for First Nations communities and people.

WELCOME

Mr. Phil Goulais, Session Facilitator: Mr. Goulais began the meeting by introducing Elder Andrew Wesley who provided an opening prayer and a smudge. Chief Reginald Niganobe, of Mississauga #8 First Nation, welcomed the participants on behalf of the Mississauga Nation, the host territory for the meeting, thanked the Elder for the prayer and acknowledged the sacred items in the room.

Mr. Goulais introduced himself to the room as a member of the Nipissing First Nation, where he was the Chief for many years. He is currently working part time on a contract with Hydro One, which has allowed him to work in many First Nations communities. He thanked the participants for sharing their knowledge and welcoming contractors into their communities with kindness. This work was part of a commitment to relationship building, which is still ongoing. Mr. Goulais shared that he expected many of the topics discussed on those community visits would be discussed at this session: Hydro One billing system sessions; career opportunities at Hydro One; and, procurement workshops for First Nations businesses.

Mr. Goulais reflected that in their conversations with communities, First Nations leaders have expressed an interest in impacting policy development and/or change with Hydro One. Both First Nations and Hydro One leadership are seeking to establish how to work together better. This engagement session is a response to that shared goal of working together better. With this in mind, Mr. Goulais expressed the goal of the engagement session: to hear First Nations' priorities; to share current thinking; and, to solicit feedback on the upcoming Distribution Rates submission to the Ontario Energy Board. The agenda attempts to balance information sharing from Hydro One and discussion.

Mr. Goulais thanked the Hydro One staff for working hard to make the engagement session happen. He also thanked the Chiefs, Councillors and other participants. He also noted the presence of the Ontario Regional Chief, Isadore Day and Grand Chiefs in the room.

Mr. Goulais concluded by noting the participation of senior leadership at Hydro One, which demonstrates a clear willingness to work with First Nations. It was noted that notes of the meeting are being taken and participants would receive the written notes of the session for review.

INTRODUCTIONS

The participants were asked to provide their name, where they are from and their expectations for the gathering.

Lisa Kooshet, Councillor, Wabigoon Lake First Nation: Ms. Kooshet came to the meeting looking for information to inform the development of the Wabigoon Lake First Nation community energy plan

Chief Brian Perrault, Couchiching First Nation: Chief Perrault was attending the meeting with an expectation of talking about on-reserve hydro rates and the potential for eliminating the distribution rate on hydro bills. He noted that, in many of communities, Elders and others have to decide between paying the hydro bill or putting food on the table. He noted that his community is close to Fort Frances, which has low hydro rates because of the n which generates power. However, reserve lands had to be flooded to build that dam. First Nations have paid a price for the low energy rates that Fort Frances enjoys. Chief Perrault came to this session to identify how we can lessen the financial burden on Elders and others.

Jerry Fontaine, Hydro One Contractor: Mr. Fontaine noted that he has been involved with Hydro One for many years. He reiterated the comments from Chief Perrault related to the struggle to sustain basic standards and the need to decide between food and light. This is a struggle alongside the struggle for housing, economic development and employment opportunities. Mr. Fontaine recognized Ms. Lee Anne Cameron (Hydro One's Director of First Nations and Metis Relations), for initiating this discussion and saw the meeting as an opportunity for change. He concluded that he is part of Treaties 1 and 3, and that historically Treaty 3 did not recognize the border.

Phil Goulais, Hydro One Contractor: Mr. Goulais shared that he was looking forward to network throughout the day and was also acting as the Master of Ceremonies for the dinner in the evening.

Mayo Schmidt, President and CEO of Hydro One: Mr. Schmidt welcomed everyone and thanked them for their participation and openness to dialogue. He also thanked Ms. Cameron for organizing the event. He suggested that hearing from participants presents a great opportunity to act on the things that they, as Hydro One, learn through the discussion.

Lee Anne Cameron, Director, First Nations and Metis Relations, Hydro One: Ms. Cameron thanked the participants for attending the session today.

Chief Reginald Niganobe, Mississauga #8 First Nation: Personal introduction

Chief Gerry Duquette Jr., Dokis First Nation: Personal introduction

Darryl Hill, Community Energy Planner, Six Nations of the Grand River Territory: Personal Introduction

Chief Warren Tabobondung, Wasauksing First Nation: Chief Tabobondung noted that they have many issues around Hydro One in his area, including development and power generation dams. These have a significant impact on the hunting, fishing and gathering for his people. Flooding was identified as a challenge. He shared his expectation of the meeting to exchange information about whom his people are and how they are impacted. He also noted that he wanted to talk about the high cost of hydro, which put their Elders in a position to choose between food and light. The Elders are the people who have persevered through so much change. Chief Tabobondung noted that the issue is also about land and the fact that Crown assets (i.e.- transmission lines) are sitting on Treaty territories. Reducing hydro rates by a few percentage points is not going to solve these bigger issues. He noted that he would like the discussion to get to these bigger issues. He also recognized that things have changed including the increasing voice of First Nations since the 1960s. He is optimistic and willing to exchange information and ideas and work together to resolve the issues facing his community.

Karen Taylor, Hydro One: Ms. Taylor stated she was attending the meeting to listen and l

Chief Tom Bressette, Kettle and Stony Point First Nation: In attending today, Chief Bressette shared his hope to examine ways through government engagements. He suggests looking at the Treaties; his is from pre-Confederation. He continues to observe political leaders, Trudeau and Wynne, making commitments about partnerships. However, in reality there does not seem to be much going on. There are a lot of promises but little financial commitment. Chief Bressette reiterated the earlier comments about economic insecurity and the impact on communities including Elders and youth. This is particularly challenging in the winter and impacts mental wellness. He noted that he has seen promises from governments before and challenges them to move from talk to action. He also noted that he sees Hydro One going through challenges, trying to sell off assets, with human resources issues and aging infrastructure. These things cost money and are the reason why hydro rates are so high. However, Chief Bressette reminds attendees that the Treaty talks about sharing resources, yet he sees everyone but his people benefitting from First Nations resources. This is also part of honouring the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP). He also expressed frustration over having to go back to his community without an answer for high hydro rates. He is no longer “asking” for a response, he is “demanding” a response. It is time to share these resources.

Ferio Pugliese, Executive VP, Customer Care and Corporate Affairs, Hydro One: Mr. Pugliese expressed thanks to Mr. Goulais, Mr. Fontaine, Mr. Kakeway and everyone who worked on this event. He noted that Hydro One wants to list en an act on the things that they can and capture the attendees’ comments.

Councillor Ted Williams, Chippewas of Rama: Chief Williams stated he was attending to listen and hear some other issues out there. He said he was pleased for the opportunity to dialogue, but that action is best.

Chief Greg Nadjiwon, Chippewas of Nawash Unceded First Nation: Chief Nadjiwon noted he shared many of the previous comments from Chief Tom Bressette. He stated that he was attending to find out how to collectively move forward in true partnerships, true resources sharing and open and transparent communication. He notes that three decades ago the corporate mindset was flood the lands and deal with the rest after; however, the corporate mindset has changed towards Indigenous relations. For his community it has been a success story; they have a contact and the results happen quite quickly. The results are not always positive, but they get answers more quickly. He views this engagement as an opportunity to move the yardstick, to have a constructive day and network.

Chief Daniel Miskokomon, Bkejwanong Territory (Walpole Island): Chief Miskokomon notes that the Minister of Energy asked how we can change thinking. However, from his perspective Crown corporations do not listen to First Nations. Crown corporations must remember that they are accountable to First Nations and citizens, meaning they need to be more transparent in the way activities are undertaken and services delivered in his territory. He notes the changing tide, as evidenced by the Truth and Reconciliation Commission of Canada (TRC). There must be meaningful partnerships. Hydro distribution costs are very high. The Chief also identified the need for Hydro One staff to undertake cultural sensitivity training. Working with First Nations requires getting to know First Nations. In addition, Chief Miskokomon cited the need to look at alternative energy. This also means supporting First Nations in becoming educated on what is out there and ensure capacity within First Nations. This requires professional support in establishing First Nations owned and run utility companies on-reserve that will not include redistribution costs. All of these ideas require people to be more creative. The Chief reminded the group that non-Indigenous people are still visitors in the territory. Partnerships must be built based on trust.

Chief James R. Marsden, Alderville First Nation: Chief Marsden also shared support for the words of Chief Bressette. As far as this meeting, he was interested in discussing “blanket agreements.” What is it? He notes that in the ‘Addition to Reserve’ process, Indigenous and Northern Affairs Canada (INAC) asked for blanket agreements. They have never had a blanket agreement with Hydro One and asked if this type of agreement was required for his reserve.

Marlene Stiles, Manager of Economic Development, Chippewas of Georgina Island: Ms. Stiles commented that she was attending to listen, learn and take information back to her community.

Marvin Sinclair, Elk Clan, Band Manager, Washagamis Bay Obashkaandagaang: Mr. Sinclair noted that he has previously been on Council and been the Chief of his community. He also shared that his brother was the Chief of his community and passed on last week. The First Nations in the room all share the same challenges, including broken promises and poor people. Mr. Sinclair recently moved back to his community from Sault Ste. Marie and can see the difference in hydro rates between the reserve and the urban centre. He notes this will be a common theme of the day. He also articulated that when people talk about "resource" they are actually talking about the source of life, which is worth much more than a dollar sign. First Nations have a connection to the land. If even a fraction of the Treaty promises were honoured there would be no need to have these discussions. Rather, First Nations would be financially independent and stable. Mr. Sinclair suggested it was a privilege to be a part of the conversation and hoped that Hydro One officials would heed what they heard.

George Kakeway, Hydro One Contractor, Rat Portage: Mr. Kakeway stated that it was nice to see many old friends at the engagement event. He noted the importance of the session in terms of engagement. In addition, he shared that most of his work is done in Treaty 3 communities. He noted that there was diversity between communities, but there were also universal issues including delivery charges. He saw this session as an opportunity to engage, move forward and see how the communities could be helped.

Joe Cheechoo, Elder Councillor, Moose Cree First Nation: Elder Cheechoo shared that he was attending the session to better understand how the hydro system works.

Chief Patricia Faries, Moose Cree First Nation – Chief Faries began as Chief last August and was happy to attend the meeting. She sees engagement as the important first step. A meeting was held in her community on January 10, 2017and the primary concern that was raised related to hydro was outrageous delivery charges. She shared that she is on a fixed income and wants to understand what can be done to address these charges. She sees people suffering under the delivery charges. She notes that her community signed an agreement with Ontario Power Generation (OPG). She also wonders what is the fiduciary duty Hydro One has to her community and all First Nations. She also notes that she expected to hear clarity at this meeting because her time is precious, and hydro is just one of the many issues she needs to address. She suggests that reconciliation means that there must be a discussion about the benefits that Hydro One enjoys at the cost of First Nations land use. She sees Hydro One using Indigenous land only to sell hydro back to Indigenous people. She notes that she has to have tangible things to report back to her people and is expected to report back on February 21, 2017. She also reminded the room of the Lower Mattagami project, right in her community's back yard that included four (4) dams built from 1960 to 1966. Former leaders signed an agreement. Yet today these dams have to be fixed. She suggested that the conversation focus on what is possible from Hydro One and how Hydro One can help her people right now.

Chief Leslee White-Eye, Chippewas of the Thames: Chief White-Eye echoed the words of the previous speakers. She noted the need for some discussion on the corporate history of Hydro

One. She also expressed that there is a need for the federal government to participate in these discussions because of permitting and issues related to lands. She was also seeking a contact person within Hydro One who could discuss negotiating this new payment and who will pay for it.

Errnol Gray, Councillor, Aamjiwnaang First Nation: Councillor Gray noted he was participating to listen, but also to discuss the line crossing at the St. Clair river, which goes through First Nations and the Treaty area. He also noted that he is on a fixed income and has trouble paying his high hydro bills. His community signed an agreement in 1953 and the payments have not increased since. He suggests a new agreement needs to be negotiated.

Chief Melvin Hardy, Biinjitiwaabik Zaaging Anishinaabek: The Chief thanked the host for allowing them on their traditional lands as well as thanking his friend Elder Andrew Wesley. Related to the importance of land, the Chief noted that the youth go out on the land and sustain a relationship with, and right to, the land. He described his First Nation, which is found on the southeast side of Lake Nipigon. He suggested that Hydro One officials needed to spend some time living in some of the homes in his community. He wondered, if the government does not give First Nations authority over their own lands, why would Hydro One do it? He noted that it is cold in First Nations communities, which contributes to Elders and children getting sick. This is exacerbated when the power goes out. There is no compensation when the power goes out and communities are forced to collect their own wood and go without. Chief Hardy noted that his community is constantly in deficit because of high costs of hydro. He also identified that there had not yet been an engagement session in his community and that it needed to happen.

Oded Hubert, Vice President, Regulatory Affairs, Hydro One: Mr. Hubert welcomed the kinds of comments that attendees had been sharing as it is important for him, as a Hydro One official to understand the issues.

Edward Skeid, Councillor, Wauzhushk Onigum First Nation: Councillor Skeid asked that Hydro One staff stake the comments made by the attendees seriously and take them to their superiors.

Deputy Chief Fabian Blackhawk, Ochiichagwe'babigo'ining Nation (Dalles): Deputy Chief Blackhawk began by acknowledging the sacred items in the room and the prayer from the Elder. He noted that he certainly relates to the comments made so far. He was looking for some direction on what this meeting is supposed to accomplish. He also shared that leaders and youth have told him many of the things that were already mentioned. It is tough to see all these people making money off First Nations resources and lands with First Nations people in poverty. His community signed an agreement for the hydro lines and cannot make any adjustments. Of the session, he expected an open dialogue to make good decisions to take back to his people.

Harold Thiessen, Ontario Energy Board: Mr. Thiessen expressed his intention to listen and learn.

Gary Schneider, Vice President of Shared Services, Hydro One: Mr. Schneider shared that he works on procurement as well as land matters. When it comes to the issue of land he has heard the frustration in the room and agrees that agreements with First Nations need to move forward.

Amy Lickers, Chiefs of Ontario: Ms. Lickers introduced herself as coming from Six Nations and works with the Chiefs of Ontario Chiefs Committee on Energy. She noted she attended the session to listen.

Yvette Maiangowi, Energy Planner, Wikwemikong Unceded First Nation: From her perspective, Ms. Maiangowi notes that nothing has changed; in fact the situation in her community has worsened. She also asked those in the position to negotiate agreements with First Nations to stand up. She noted a need for a clear path forward including timelines. She concluded by saying that the time for talking has passed.

Craig Aldred, Wahgoshig First Nation (Abitibi #70): Mr. Aldred noted a need to address distribution costs, as these high costs negate their efforts to build sustainable communities when the costs end up being covered by the bands. He expressed a need to develop long term solutions.

Rob Globocki, Director, Customer Care, Hydro One: He expressed to the participants that he was also here to listen and learn.

Sara Mainville, Associate, Olthuis Kleer Townshend LLP: Ms. Mainville introduced herself as an advisor to Regional Chief Day. She also does work with Grand Chief Peters on Hydro One opportunities. Ms. Mainville expressed that she was happy to attend and see many Chiefs in attendance.

Grand Chief Gord Peters, Association of Iroquois and Allied Indians: Grand Chief Peters noted that the Hydro One process has been a long process that they have been involved in for some time. He also acknowledged Chief Ava Hill from Six Nations for working on this issue. At the last All Ontario Chiefs Conference (AOCC), there was a meeting attended by the new Minister Thibeault who committed to developing a First Nations rate. This commitment was made 8-9 months ago. This remains the issue for the discussion at this session. He posed a number of questions including, what is the rate going to look like and how will that be brought to our communities? He heard that the distribution charge is one of the easier things to change, so wanted a commitment on that. He noted that should Ontario continue to privatize beyond 60% of Hydro One, the province would remain liable for all the damages that continue to flow. His community is the same as Alderville in that there are no agreements in place. They are dealing with the Additions to Reserve process and are 12 years in. He reminded the attendees that “you have to have full permit or cannot move ahead”. His community is still in the talking stages. He suggested that these are the things that become irritants in the process. In order to move forward, Grand Chief Peters says that we have to learn how to get along and there will have to be a better arrangement for First Nations.

Chief Jim Leonard, Rainy River First Nation: Chief Leonard describes his community as between Thunder Bay and Winnipeg near the American border. His community had engaged with Hydro One a number of years ago where they talked about past grievances and decided they need to set those aside to move forward. They acquired, constructed and commissioned a solar farm. Without technical support or shared engagement with Hydro One it is difficult to make these things happen. He was attending the engagement session to advance that process. He saw it as important for Hydro One to listen to the grievances shared because they still impact First Nations, but also recognize that First Nations are ready to move forward. There is the potential for this to be a revenue stream and support to communities.

Deputy Grand Chief Derek Fox, Nishnawbe-Aski Nation (NAN): Deputy Grand Chief Fox began by thanking the Elder for the prayer. He described NAN as being comprised of 49 First Nations and 7 tribal councils. NAN communities extend from the Manitoba border to James Bay. This is a huge land mass and most communities are remote. People in these communities are passionate about their hunting, culture, water, river systems and language. Deputy Grand Chief Fox noted that he is from Treaty 3, Shoal Lake 40 where there are profound water issues. When he was younger he was driven to become a lawyer and learn the systems that govern. He expressed concern over claims to jurisdiction over Indigenous lands. He concluded by sharing that he was participating in the session to support NAN Chiefs, to listen, to talk about NAN initiatives and hoped to have a meaningful discussion.

Jamie Scarlett, Executive Vice President, Chief Legal Officer, Hydro One: Mr. Scarlett commented that he was attending the session primarily to listen and learn. Within his duties, he has some involvement in rates so hearing from the First Nations participants was impactful for him. He noted that he is appalled at how long it takes for Hydro One to deal with these issues. He offered his personal commitment to drive these issues forward to be dealt with in a clear, open, transparent and timely way. He reflected that he had heard the message that 'these are just words, but First Nations want actions.

Chief Ted Roque, Wahnapitae First Nation: Chief Roque began by thanking the Elder and acknowledging the land where the meeting was held. He was attending the meeting to hear more about new rates. He noted that it would be great to see lowered rates and it would make a huge difference for his people. He recognized that there is only one year left in the Wynne government's mandate and he does not want to see these discussions get lost; whether the next Premier is Wynne or someone else, these negotiations must continue. He noted that there must be more sharing of resources and opportunities and true partnership.

Andrew Wesley, Elder: The Elder introduced himself as hailing originally from Fort Albany, but has been living in Toronto for many years. He shared that traditionally electricity was known as Thunderbird Fire. This demonstrates the close relationship between First Nations and mother earth.

Deputy Chief Kevin Mossip, Zhiibaahaasing First Nation (Cockburn): Deputy Chief Mossip shared that in his community hydro rates increased 72% in two years and this increase has caused hardships. He brought a message from his Council that the engagement session was in no way, shape or form to be considered consultation. In addition, his community would not agree to anything unless the hydro rates were lowered by 72%

Warren White, Councillor, Naotkamegwanning First Nation: Councillor White came to the meeting to speak for his community and see the faces of Hydro One. He notes that his Elders, the ones who are struggling, are paying the wages of Hydro One staff. He provided a welcome to the Chiefs, Grand Chiefs and Councillors. He noted that he knows how it feels to be accountable to the Chiefs and the community. He met with 35 Elders in his community last week. They told him that the HST rebate does not impact their hydro bills. Each of those Elders was paying over $1,000. He notes that he burns wood and his bill is still $1,000. He states that he did not want to attend the meeting and did not want to hear the same rhetoric from Hydro One. There is a lack of trust with Hydro One. The delivery charges in his community average out to about $250 each month, which amounts to $50,000 a month for the whole community. Councillor White suggested that he plans to charge Hydro One double that amount to enter his community; this includes any hydro trucks. When Prime Minister Trudeau had his town hall recently there was a woman crying about hydro and the media was all over that. Yet when it comes to First Nations and their hydro rates, there is no media. He said something has to be done. He suggests that his community does not support Hydro One dealing through the Chiefs of Ontario as there are too many grievances that need to be dealt with including the dams in Treaty 3 and the flooding. He asked what Hydro One was willing to do about it. He expressed skepticism as he views Hydro One as only being motivated by money. He concluded by reaffirming that something has to be done otherwise his community would start charging Hydro One to come in.

Annette Currie, Technician, Pic Mobert First Nation: Personal Introduction

Deanna Major, Councillor, Animakee Wa Zhing #37: Councillor Major expressed that she would like to see the salary disclosure for Hydro One and an explanation of how those salaries are justified.

Gary Allen, Executive Director, Grand Council Treaty #3: Mr. Allen introduced himself and that he was attending on behalf of Grand Chief Francis Kavanagh, who is travelling with Minister Zimmer in Treaty 3 territory. Last year, prior to a meeting between Hydro One and Grand Chief White, Treaty 3 citizens were asked to send their hydro bills. They brought a binder full of these bills that demonstrated the exorbitant costs faced by his people. He also noted that he checked the sunshine list for Hydro One and saw over 600 employees earning more than $100K. He found this incredible considering the suffering in First Nations communities. He shared his support for the Great Earth Law, the Sacred Law, and also the laws of the 28 First Nations in Treaty 3.

Lance DeCaire, Technician, Wahta Mohawks: Mr. DeCaire noted that the most pressing issue facing his community is the delivery charges and the impact that those high delivery charges have on the success of the community's economic development initiatives.

Chief Rodney Noganosh, Chippewas of Rama First Nation: Chief Noganosh began by reiterating the comments of previous speakers that there are many people that are upset with the situation. He also expressed concern that there was not a great deal of time on the agenda for discussion, which was upsetting given that Chiefs travelled far to attend. He noted the need to see results very quickly. First Nations should be exempted from delivery charges. People cannot pay those delivery charges and the communities always have to step in and help. He referred to an economic development project in Barrie and his expectation to receive information on that project so that they would be able to bid on those types of projects. He also expressed interest in learning about the 'blanket agreement' idea, because there has not been much information shared to date.

Ted Snache, Councillor, Chippewas of Rama First Nation: Councillor Snache began by thanking the Elder for the prayer. He noted that if he had a wish, it would be to have elections on the same day to build unity. He expressed the strength in First Nations communities, with young people getting education and women who are water keepers. He expressed that the Ontario Energy Board (OEB) hides behind legalese, but because First Nations are getting educated, that strategy will not work for long. He concluded by asking when the delivery charges will be eliminated for First Nations.

Dave Mowat, Technician, Mississaugas of Scugog: Mr. Mowat notes that the Ontario Energy Board said that if they can focus on the delivery charge, that will have the most impact on the consumer. He would like to know what is going on with that. He also asked what Hydro One is doing about a security plan.

Chief Mary McCue-King, Beausoleil First Nation: Chief McCue-King suggests that First Nations should not be talking to Hydro One because it is not the organization that sets the rates. Hydro One only makes a submission to the Ontario Energy Board; therefore, First Nations should be talking to the Ontario Energy Board before they approve the rates. The Ontario Energy Board should be consulting with First Nations.

Chief [Name Not Heard]: The Chief shared the belief of the previous speaker that First Nations are meeting with the wrong people. The Chief asked now that Hydro One has heard their concerns, what do they propose as the fix? He expressed frustration based on the belief that there are no decision-makers attending the meeting and there will therefore be no deliverables from the meeting. He would like to know the next steps? When can First Nations expect action?

Chief Kevin Tangie, Brunswick House First Nation: Chief Tangie noted that his community experiences the same issues identified by previous speakers and wants to hear answers, solutions and ideas.

Jason Batise, Executive Director, Wabun Treaty Council: Mr. Batise echoed the comments of previous speakers and shared a desire to hear practical solutions. He notes that a First Nations hydro rate was committed to, but that there is no mention of that and the elimination of the delivery charges in the Hydro One submission. He expressed that they had given practical solutions in earlier engagement sessions and they are not reflected in the submission.

Warren Lister, Vice President, Customer Care, Hydro One: Mr. Lister introduced himself as a new member of the Hydro One team and shared his commitment to changing the way they do business. He stated that he intended to listen and welcomed the opportunity to dialogue.

John Onabigon, Councillor, Long Lake No.58 First Nation: Councillor Onabigon shared that he was trying to get resource development for his community. He recounted that in the 1930s and 1940s; Hydro One built their dam and flooded his traditional territory without any regard for the impact on the community. However, he noted that the voice of his people is getting stronger and it is not acceptable that others get the benefits from resources taken from the land of his people. He stated that there is only one square mile left for his reserve and the rest has been flooded. There are many grievances and his people live below the poverty line. He stated that the message from his community has been consistent for years: that there must be a balance of sharing. In his community there is a high level of dependence on Ontario Works and the unemployment level is 85%. He sees this as a game or cycle with people dependent on Ontario Works who pay their excessively high Hydro One bills to keep the lights on to the detriment of other things. Hydro One never feels the pain, but the First Nations do. He notes that his community maintains and asserts the right to their own resources; yet have to battle to get any benefits from them. He then asked why some have so much and some have so little? He also mentions that First Nations are overwhelmed with engagements, and yet nothing has changed for his people. He has seen nothing change over 25 years of doing this work. He added that talking about procurement sounds good but communities do not even have the capacity to be a part of procurement processes.

Cesar Martinez, Customer Care at Hydro One: Mr. Martinez mentions the tools that were brought to the meeting today and encourages participants to bring them to the communities.

Sarah Bruggeman, S. Burnett and Associates Ltd.: Ms. Bruggeman is participating as she is working with a community on an energy plan.

Lisa Johnson, S. Burnett and Associates Ltd.: Ms. Johnson works with Ms. Bruggeman.

Cynthia Jamieson, Executive Director, Mississaugas of the New Credit First Nation: Ms. Jamieson expressed some confusion over the process. She notes that they were expecting a letter from the Minister of Energy to the Ontario Energy Board to hold those sessions. She wonders if that is what this meeting was about. She notes that there were already engagement sessions last fall and wonders if those participants wasted their time. She was seeking clarity on the process.

Chief Tom Bressette, Kettle and Stony Point First Nation: Chief Bressette wanted to add to his earlier statement. He notes that Hydro One is being talked about related to the Bruce Nuclear Power Plant, and burying nuclear waste near the Great Lakes. He was astounded that the Canadian government would consider burying nuclear waste near the Great Lakes. Related to the North America Free Trade Agreement (NAFTA), he notes that First Nations better not be left out of the next rounds. He again expressed disappointment that Hydro One considered that waste facility near the Great Lakes and asked, when it cracks where are we going to get more water?

Chief Simon Fobister, Grassy Narrows First Nation: Chief Fobister described being born and raised on the trap line, where there was no hydro and they carried water. They did not need those things. He was elected Chief in 1976, when he was 21. At that time his community members spoke about a time when water was so clear, but then people came in exploring for hydroelectricity. Now you cannot even see your hand in the water around his community. His community did receive compensation. In Grassy Narrows, hydro bills are high, around $1,000 a month. He notes the need to find ways to cut those rates. He attended the meeting to hear Hydro One tell him their plans to cut the rates. He expressed concern that 60% of hydro comes from nuclear power. Like it or not, the nuclear waste will be buried, and the question is whose backyard will that be in?

Introductory Remarks from Hydro One

Presentation from Mr. Mayo Schmidt, President and CEO, Hydro One

Mr. Schmidt expressed a warm welcome to all of the attendees who committed their precious time. He noted the importance of this engagement for Hydro One. He also provided a warm thank you to Elder Wesley, acknowledged the Mississaugas of New Credit and thanked Chief Niganobe for the welcome.

Mr. Schmidt noted that the work that he does at Hydro One is not the kind of work he has traditionally been involved in. He grew up on a farm and his life's work has been in agriculture. He was approached to work at Hydro One from the prairies and worked to identify a leadership team that could effect change. There was not one Hydro One leader in attendance that does intend to commit to change.

Mr. Schmidt lists three (3) things he is hopeful will come out of this session:

1. To listen and learn;
2. Provide some education on who is responsible for what, what we each do, how can we as a company can to advocate for you and your community; and,
3. Commit to action. The hope is to move this conversation to an outcome (educate/advocate/action).

Background: There are a lot of names out there with involvement in this area. The producer of the power is Ontario Power Generation, which also owns Bruce Nuclear Generating Stations, but leased them to Bruce Power. The Ontario Energy Board approves the rates that Hydro One charges to operate and maintain Hydro One's transmission and distribution systems and sets the price of power. Independent Electricity Systems Operator is responsible for real time operations – the ebbs and flows of power and where electricity goes or comes from.

Hydro One collects from customers for the cost of power (electricity price), and delivery of the power, and delivers the bill. The name Hydro One is on all bills. While Hydro One is the party that bills the party that bills the consumer, the electricity pricing comes from someone else, and Hydro One passes those revenues on.

Hydro One recognizes that they need to address their costs and get them down, and apply to have costs reduced. They also have to do their part to ensure that there are no brown-outs or power outages.

Mr. Schmidt suggests that the feedback that they get from the engagement sessions will go into their upcoming distribution rates submission to the OEB. The information will be collected as part of the application and the First Nations participants' voices will be heard there.

Hydro One is transitioning with a new leadership team with a purpose to put customers first. Hydro One is a publicly listed company with lots of opportunity but everyone must act together. In this there is a need to build and maintain relationships with First Nation communities. Hydro One serves 88 First Nation communities.

Mr. Schmidt recognized that consultation is a protected right and First Nations have a unique cultural relationship with the land. While First Nations are not the only customers, they do have a special relationship. The rising cost of electricity is a concern for all of us, so we will redouble our efforts.

In terms of how billing is structured, 51% of the costs that consumers pay comes from nuclear, hydroelectric, wind or solar producers (will fluctuate, but this is the average), 12% sales taxes and 37% is payable to Hydro One for delivery of power through the network of wires, poles and transmission stations. There is a cost to maintaining this infrastructure, and as an example, Mr. Schmidt mentioned the example of a recent transformer fire, where in replacing that asset, Hydro One recognized that it was built in 1962, so there is a need for continual maintenance of aging assets.

On the question of how do we keep the costs down, Hydro One intends to have a customer presence in local offices; the customer bill was redesigned because customers need to understand the bills; Hydro One has reinforced the commitment to service and of responding in a timely manner.

There was a recent meeting with the province to talk about the cost of power where Hydro One advocated for lower power costs; Hydro One had also proposed to the Ontario Energy Board that the delivery charge to First Nations be lowered as part of the First Nations rate being studied by the Minister.

Hydro One has met with many First Nations over the last 8 years, including over 200 community visits. Mr. Schmidt suggested that communities interested in inviting Hydro One to visit, attendees should introduce themselves to Ms. Cameron and she will get a team out there.

The Hydro One First Nations and Métis Relations team demonstrates an appreciation for the concerns of First Nations communities. They want your feedback on how that works.

Hydro One is committed to making a change as demonstrated by offering additional regional outreach on procurement, by participating in First Nations employment, training and career fairs and through the First Nations Conservation Program.

Mr. Schmidt notes that Hydro One has come far with communities and individuals, by taking issues and solving them one-on-one. If session participants are looking for that attention, then Hydro One is willing to work with them.

Question from the audience: How about eliminating the reconnection fee?

- Mr. Schmidt responded that it costs Hydro One money to send trucks out to turn off and turn on power and that there is a better way to do this -- whether it is giving people who need it more time to pay their bills, getting them on to access programs to assist them, and work with Hydro One to provide guidance on these things.

Comment from the audience: A Chief noted that the connection fee is attached to bills in payment of arrears and is a stumbling block for community members.

* **Response:** Mr. Schmidt responded Hydro One launched a new Winter Relief Program to reconnect customers prior to the winter. This was a practice that started in November 2016 and asked participants to let Hydro One know when people are in that situation.
* **Follow up audience comment:** People are paying this now, sometimes two or three times per year.
* **Response**: Mr. Schmidt responded that if a customer is disconnected, they have to take some hardware off after six months and there are costs associated with that.
* **Follow up audience comment:** Hydro One gets all their fees paid.
* **Response:** Mr. Schmidt responded that in the past this might have been the case, but to participate in the Winter Relief Program, Hydro One needs the names on those accounts and there would be no fees. In general, those fees go into maintaining the system.

Mr. Schmidt: Mr. Schmidt noted that it is important for Hydro One to hear from the participants and focus on things that can be changed. He committed to listen, but also committed to meeting again in the future to work on some of the things we want to accomplish together. It will take bold action by all of us to effect change. It is a complicated industry, with complicated pricing. For these reasons Mr. Schmidt encouraged everyone to focus on what is within their power to change and set priorities. Hydro One is accountable to customers including the meeting participants. The team in place is a new team, and Mr. Schmidt encouraged meeting participants to place their trust and work with the team.

Chief Perrault: The Chief shared that last fall he received a call from a community member who had a Hydro One truck at their door ready to disconnect. He went down there and had to drag the guy off the hydro pole and asked him to leave the community or risk his boss getting a call. There is a perception that there is a push to cut people off before the snow flies. He believed this had to be addressed.

Mr. Schmidt**:** Mr. Schmidt shared that he cannot speak to what has happened in the past, but going forward, the focus is on getting people connected rather than disconnected. He also committed to dealing with the issue of cut-offs himself, along with Hydro One legal counsel. The time frames will be addressed, but in general there is no gain for anyone by cutting people off. The larger issue is that we need the cost of power to be reasonable.

Councillor Warren White: Councillor White commented that he has heard many of these promises before from government officials, but respectfully, he will believe it when he sees it. Further, he identifies a fundamental difference between how connections and disconnections are treated. For example, Hydro One is quick to disconnect but is slow to reconnect clients. There is often a long waiting period, even if the bill is paid. Related to procurement, Councillor White recognizes that there are procurement arrangements with some communities, but the only thing he sees by way of procurement opportunities is cutting brush. He thinks there must be more to offer than that. Councillor White noted that while there may be an Ontario-wide Engagement process, there are different issues; the grievances are different in Treaty 3 and therefore he strongly encouraged Hydro One to have more regional-type meetings. In addition, given geography, it is challenging for community representatives to get to meetings in Toronto, for example. Councillor White commented that February and March are stressful months for Elders because of the accumulation of bills that they cannot pay, and they know they will be cut off. Councillor White notes that Hydro One activities constitute a breach of the Treaties (through flooding, etc.). In addition, there is supposed to be a relationship and a partnership that is not yet realized. Councillor White concluded by sharing a personal story related to disconnection. He had an overdue bill of $1,200, and received a disconnection notice. The bill was paid on Friday and yet his power was cut off on Monday. He attempted to demonstrate to Hydro One that the bill was paid, but was told that the payment had not reached Hydro One's bank yet, so the disconnection went ahead. These situations are real.

Mr. Schmidt: Mr. Schmidt stated that he agreed with Councillor White, that Hydro One needed to be reasonable and to rethink previous behaviours that were practiced. He notes that there are a lot of attitudes to change throughout the organization and hopes to do better.

Chief Patricia Faries: Reflecting on Mr. Schmidt's previous comment about constitutionally protected rights, Chief Faries affirms that this is an important point to set the context. She stated unequivocally that the engagement is in no way to be considered consultation and accommodation between Hydro One and the Moose Cree First Nation. She emphasizes that action is key, and she wants a definitive answer on how to move forward. There are power lines going through her land that are intrusive. She expected a response on how her community would be engaged and compensated.

Mr. Schmidt: Mr. Schmidt assured participants that the engagement session was not consultation and they did not view it as such. Related to engagement and compensation at a community-level, Mr. Schmidt introduced Jamie Scarlett and Gary Schneider who can sit and meet with communities to work through their issues.

Jamie Scarlett, Hydro One, provided his email address (Jscarlett@hydroone.com) in order to set up future conversations.

Chief Nadjiwon: Chief Nadjiwon sought an update on the discussions around the delivery charge.

Mr. Schmidt: It was noted that industry was in conversation with government last week on this issue and discussions are ongoing. Mr. Schmidt notes that Hydro One is advocating for changes related to the delivery charge issue. He invited other Hydro One staff to comment.

Hydro One Representative, Oded Hubert: The Minister has asked the Ontario Energy Board to develop a First Nations rate, and the Ontario Energy Board has prepared a recommendation that has gone back to the Minister for consideration. Chief Ava Hill provided comments on the recommendations and Hydro One supplied data. It is with the Minister now.

Question from the audience: Is there a timeframe for an answer?

Hydro One does not have a time frame at this time, as this is the Minister's initiative.

Comment from Chief [Name Not Heard]: The Chief has attended many meeting over the years, some of which were classified as consultation. The Chief noted that the Hydro One Board of Directors was joining the meeting for dinner, and the CEO is accountable to the board, which gives the organization direction [Mr. Schmidt indicates this is correct]. The Chief commented that having the board at the dinner is fine, but they should have been at the engagement session to hear First Nations' concerns firsthand.

Mr. Schmidt**:** Mr. Schmidt clarified that the Board of Directors does not run the company or specifically direct the CEO. Rather, Mr. Schmidt's team determines a plan, which is presented to the Board for comment. This is different than being instructed by the Board. It is not a decision-making group on an operations level body. In addition, plans that are developed by Hydro One must be approved by the regulator.

Chief Tom Bressette: Chief Bressette suggested that Hydro One must have come up with a proposed First Nations rate, given that they engaged with First Nations last year. He questioned why that rate was not presented to the engagement session. In addition, he felt as though the meeting was centrally about politics. He noted that it may be the same old song and dance and First Nations are growing frustrated without little reason to believe anything has changed.

Mr. Schmidt**:** Mr. Schmidt responded that the reason Hydro One felt that this engagement was important was the need to have a respectful conversation. Hydro One does not set the price of power; however, Hydro One can advocate alongside First Nations to address the price of power. He notes that it comes down to whether or not the participants are prepared to give Hydro One a chance.

Customer Care: Vision, Strategy and Key Initiatives

Presentation from Ferio Pugliese, Executive VP, Customer Care and Corporate Affairs, Hydro One

Mr. Pugliese is the Executive responsible for customer care and Indigenous relations. He noted his appreciation for the openness of the conversation. As the company changes direction from a Crown corporation to a public company, there is an opportunity. The electrical system in Ontario is complicated. In this shift there are three (3) things they have embarked on:

- The first is education, to help explain this complicated system including its regulation, etc. Hydro One has started to uncover what can be addressed and asked for the opportunity to first understand and then work on the things that they can change.
- The second task is related to advocacy. Hydro One owns the hydro bills and holds custody of the relationships with communities and customers. Hydro One has an impactful voice in advocacy similar to the loud voice that First Nations have.
- Mr. Pugliese reiterated that the session was not designed to be a consultation; rather, it was the first step in a series of discussions that will lead to change. He also recognized, like Mr. Schmidt, that change is indeed required, particularly in the area of affordability.

Mr. Pugliese recounted a meeting from the previous week between himself, Mr. Schmidt, the Chair of the Board and Premier Wynne. The Hydro One representatives shared stories similar to those that were heard at this engagement session. He noted that he has been to communities where the distribution charges are more than the power charges themselves and recognized the burden that this places on people like retirees.

He noted that he does not expect the participants to trust Hydro One at its word, but rather, to judge the new Hydro One team on their actions. They committed to visiting First Nations communities, reconnect those who are disconnected, and waive the fees. He asked that the participants let them know which of their community members need this assistance.

Mr. Pugliese recognized, once again, that the primary issue is around affordability, and noted that if Hydro One could control the rates, that the rates would be reduced. However, these changes require advocacy and lobbying. Their conversation with Premier Wynne was for that very purpose.

Mr. Pugliese asked the participants to trust that the information shared at the engagement session would not fall on deaf ears. Some action has been taken such as reconnections and winter relief. Previously, the collection process lacked flexibility and was unforgiving and that has changed. He encouraged participants to speak with Hydro One staff about these issues. The engagement session is one step in a new direction and changes will continue.

Mr. Pugliese left his email address and encouraged participants to hold him accountable to his promises (ferio.pugleise@hydroone.com).

Warren Lister VP Customer Care Hydro One**]:** Hydro One has indicated that they had solutions and ideas to give to the Minister. Many of the short-term solutions that are needed in the communities can be acted on immediately. Hydro One is willing to visit communities that they have not yet visited. For people having difficulty with payments, there can be new payment plans set up. In addition, the winter reconnection program can help get people connected and stay connected. There are still things Hydro One can learn regarding changes that need to be made for communities. The Hydro One staff present were there to answer specific questions and the Minister would be available during the evening dinner. The dinner is an opportunity for both Hydro One and First Nations to use their strong voices for change.

Grand Chief Gordon Peters: Grand Chief Peters noted that his organization has been involved in the process for some time beginning in 1989 around the grievance process. Since that time there has been a lot of work done in the communities and grievances were settled. Issues including billing and grievances arose again within the privatization process. The Hydro One customer care was terrible and did nothing to support communities. Grand Chief Peters was pleased to hear that things would be different; however, he warned that expectations are now high. Grand Chief Peters participated in the engagement process in the fall of 2016. He notes that Hydro One should have laid out the plan at that time; that Hydro One was looking at short-term and immediate changes while looking forward to a longer term plan. It needs to be laid out ahead of time and made less complex. First Nations are seeking how to participate effectively.

Warren White, Councillor: Councillor White shared that he met with Premier Wynne recently. He also met with her two years ago and raised the issue of high hydro bills. He took her his hydro bill, which was $4,200 at the time. The Premier has known about this issue for a long time.

Mr. Pugliese reaffirmed Hydro One's commitment and assured the participants that the commitment will be ongoing. He reaffirmed the need for a partnership with First Nations to get the required changes made. That is the reason why they invited the Minister to participate at the dinner, as he is the policy maker that can affect the changes that are needed.

Chief [Name Not Heard]: The Chief described that when a hydro truck pulls up to a house it dehumanizes the residents. He asked that hydro come to the band office first before disconnecting people. In the past, First Nations had the same experience with archaeologists. The Chief also noted that governments had left it to companies to do that engagement themselves, but that can be traumatizing to communities. The Chief asked what Hydro One is prepared to do when the power goes out in order to get people reconnected in a reasonable time.

Mr. Pugliese responded that the situation described by the previous speaker is not how Hydro One wants to do business. He noted that a colleague, Mr. Greg Kiraly, the Chief Operating Officer, would be joining in the afternoon and would like Mr. Kiraly to hear these concerns as well, as he is looking at the operations side of the business. They want to ensure that in the case of outage that restoration occurs in a timely manner.

Councillor Lisa Kooshet: A participant asked for a recap of the new positions within communities. She asked if there were going to be new Hydro One offices and how those would benefit First Nations communities. She notes that she worked for Ontario Hydro in the past and as a single mom, even while working, had a hard time paying the hydro bill. She expressed that this was disheartening.

Mr. Pugliese noted that Hydro One has launched "Get Local" and written letters to all customers. They are in the process of re-establishing regional or community business offices. They are currently building plans to reinstate regional/community offices to resolve customer issues. In addition, Hydro One is putting a great deal more emphasis on Indigenous Affairs and building more of a strategy around that builds on the good work of Mr. Cameron. This engagement session is the beginning of how Hydro One wants to move forward in doing business. They want to go to the community and regional level on a regular basis.

Distribution Rate Filing (2018-2022)

Presentation by Mr. Oded Hubert, Vice-President, Regulatory Affairs, Hydro One [Distribution Rate PowerPoint]

Mr. Hubert began by explaining what a Distribution Rate Filing means, which is a submission that seeks Ontario Energy Board approval of distribution rates for a five-year period [2018-2022]. The application has not gone in yet, but Hydro One is currently preparing the application and is planning to file at the end of March, 2017.

Hydro One conducted many customer engagements, including 300 First Nations customers, in developing the application. However, Hydro One is still seeking input, and this engagement is a good opportunity to inform the submission.

The distribution rate will apply to all Hydro One customers. There has been discussion on a First Nations rate; there is a request from the Minister of Energy to the Ontario Energy Board to develop an on-reserve rate or rate mitigation for reserves. The Ontario Energy Board responded that they would work on that and in doing so consulted both with Hydro One and First Nations representatives.

Question from the audience: Why is there a discussion on something that is not complete? The commentator shared the worry that this is creating false expectations.

- Mr. Hubert responded that the discussion was taking place in order to hear back on what they are proposing as part of the distribution rate filing, before the Company submits it, so that the input can be included in the Application.

Question from Chief Rick Allen, Constance Lake First Nation: Chief Allen wondered as to the extent of First Nations input on the plan?

- Mr. Hubert responded that there has been some First Nations customer input.
- Mr. Hubert clarified that there are three different initiatives underway, which is leading to some confusion,
- The proposal by Hydro One to the Ontario Energy Board is an Application for distribution rates for the next 5 years.
- There is also working underway on a First Nations rate, which is being reviewed by the Minister.
- The other issue of hydro affordability is one for all customers, and especially for rural customers in Ontario, and this issue is being examined by the Premier .
- Hydro One is here to seek feedback on the first item, the proposed Distribution Rates Application.

Comment from Chief Bressette: Chief Bressette commented that in areas where there are wind turbines, First Nations people could not hunt. This is a violation of Treaty rights. They have found that there are very sudden restrictions based on hydro applications to the Ontario Energy Board.

- Mr. Hubert provided an overview of the generation, transmission and distribution system that serves industrial/residential/commercial customers. Related to Chief Bressette's question, Mr. Hubert notes that Hydro One's only role is to connect generators to the system. Hydro One does not have anything to do with land rights for generating facilities.
- **Chief Bressette:** Chief Bressette responded that First Nations own the land and expressed frustration at the common narrative that First Nations do not own the land and that Canada has rights to the land and resources. First Nations do not beg for "help"; rather, First Nations have a right to benefit from the resources drawn from First Nations land.

Question from Chief Allen: Chief Allen asked why Hydro One is talking about a specific distribution rate for First Nations. Given what Hydro One heard form participants already, why would there even be a distribution cost for First Nations.

- Mr. Hubert responded that Hydro One is not in a position to simply tell the Ontario Energy Board that First Nations will not be charged anything for distribution; however, there is an opportunity to do something, and Hydro One has made some recommendations to inform the OEB's review of the First Nations Rate. The Minister mentioned a First Nations rate or rate mitigation and asked the OEB to prepare a recommendation. At the same time, Hydro One is preparing for an Distribution Rates application that applies to all customers. It is up to the Ontario Energy Board to approve it or not. In addition, the Minister may be able to make changes related to a First Nations rate, but that decision is with the Minister alone.

- **Chief Allen:** The Chief pushed back on the idea that Hydro One is still applying a distribution charge to First Nations and he recommended that Hydro One just tell the Ontario Energy Board that they are eliminating the charge for First Nations.
- Mr. Hubert noted that they are working on this as part of Hydro One's advocacy role around the rates for First Nations customers and affordability issues in general. They have asked the Ontario Energy Board to adjust the distribution charge.

Comment from Chief Bressette: Chief Bressette noted that the Ontario Energy Board has never invited First Nations to discuss this issue with them.

- Mr. Hubert noted that he believed that the Ontario Energy Board spoke with First Nations representatives about the First Nations Rate Report, but he was not aware of who was involved on behalf of the First Nations.
- **Chief Bressette:** Chief Bressette reminded the room that there is more than one Chief in Ontario and more than one First Nations provincial/territorial organization as well.
- Mr. Hubert stated he was not entirely sure about the Ontario Energy Board process.
- **Chief Bressette:** The Chief noted that the Ontario Energy Board gives other groups a lot of authority over First Nations land without the involvement from First Nations. It is very powerful as evidenced by breaking up Ontario Hydro and making changes without speaking to First Nations. He reiterates that First Nations own the land and are not reported to at all. He states that this way of operating has to change.
- In response, Mr. Hubert notes that forums such as this are intended to drive change. He also committed to finding out about the Ontario Energy Board process when it comes to the discussions that the OEB held on the First Nations Rate.
- **Chief Bressette:** The Chief reiterated that the Ontario Energy Board should be talking to First Nations; OEB should talk to First Nations.

Question from Amy Lickers: Ms. Lickers, in relation to the information on the PowerPoint, what is the difference between the transmission and distribution area in Hydro One

- Mr. Hubert explained that transmission is above 50,000 volts, and typically involves the larger, steel towers and large transformer stations, whereas distribution is below 50,000 volts. He likened the system to the highway and roads systems in the Province.
- **Follow up question from Chief Faries:** Chief Faries asked if that means Moose Factory First Nation were in distribution then, and if that was why the delivery fees are so high.
- Mr. Hubert explained that there is a delivery charge in both, but the majority of the delivery charge is for distribution. Mr. Hubert referred to his PowerPoint [Slide 6] and noted that electricity makes up the majority of the charge. He also committed to provide both hard and electronic copies of the presentation to the attendees.
- **Follow up by Chief Faries:** The Chief asked if it was the Ontario Energy Board who proposed a credit for remote communities. Also, she posed a question to the Chiefs of Ontario, who helped coordinate the engagement session, around whether or not the engagement needed to be with the Ontario Energy Board. In general, what is the

strategy and is meeting with Hydro One the best way to spend our energy. She also asked where Regional Chief Day was.

- Mr. Hubert suggested that the participants were indeed at the right forum and while there were many issues Hydro One cannot deal with, such as nuclear power for example, it is Hydro One who puts together the bill and delivers it to customers. So Hydro One, plays a role in explaining the system to customers. Hydro One proposes rates, but the Ontario Energy Board approves the rates. Mr. Hubert again invited a constructive conversation.

Grand Chief Gord Peters,: Grand Chief Peters noted that it was not Hydro One, but rather the Ontario Energy Board that did the visit last fall, to discuss the First Nations Rate. . He also mentioned again that Chief Ava Hill worked on this and at the time they could not get anyone else to sit on the committee with her. He acknowledged her for taking on that work. He also noted that other people got involved in the process and as that went forward only a handful of other people came to participate. He stated that the participants were there because they had been invited into the process. He did, however, note that Hydro One should have been clearer about what was going to be discussed and the goals of the meeting.

- Mr. Hubert recognized that they were not clear on the invitation that this is a discussion on the Distribution Rates Application by Hydro One, not the First Nations rate; however, they are not a stage where they can give an answer on the First Nations rate, nor are they in a position to do so, as this is the Minister's initiative.

Chief Daniel Miskokomon: Chief Miskokomon noted the need for cultural sensitivity training for Hydro One staff working within First Nations communities.

Councillor Ted Snache: Councillor Snache asked for clarity. From his understanding, power generation was from the Bruce Power plant, and then Hydro One buys the power and then distributes the power. He also noted that Bruce Power makes so much power that they sell it to the United States at a reduced rate.

- Mr. Hubert clarified that Hydro One does not buy the energy; rather they just deliver the power and issue the bills. Hydro One collects the money and then sends it to the Independent Electricity System Operator (IESO, a Crown agency) which then remits it to the power generators. The IESO is responsible for the market and the system operation. Related to shipping power to the United States, the IESO decides at certain times that it is more economical to ship to other jurisdictions at a lower price than to shut down the nuclear plant and start it back up again.

Cynthia Jamieson: Ms. Jamieson asked for additional clarity on the distribution rate application to the Ontario Energy Board. She asked if the three rates were: First Nations rate, regular rate, and an affordability issue.

- Mr. Hubert clarified that there were three independent issues: the First Nations rate, a Hydro One Distribution l rate application, and energy affordability, in general.
- **Follow up question from Ms. Jamieson**: Sought more explanation of the rural rate.
- Mr. Hubert noted that there was a separate discussion going on with government related to energy affordability.

Chief Brian Perrault: Chief Perrault reflected that the primary role of Hydro One is transmission and the business side of energy. He noted that the CEO spoke about trying to support First Nations. He reiterated that the expectation is to get rid of the distribution charge. He wondered why it would be in Hydro One's interest to get rid of that distribution charge. He ended by sharing some cynicism related to Hydro One's commitment to First Nations issues given that it would seem to go against their own business interests.

- Mr. Hubert assured the Chief that these two goals are compatible. He noted that Hydro One needs to collect the total revenues it needs to operate and maintain the distribution system, but rates for different groups could be different, although getting rid of a distribution rate is not an option that Hydro One was looking at. The reduced rate for First Nations, if implemented, will have to be made up somewhere else to fund the business operations.
- **Follow up from Chief Perrault:** The Chief shared that for some homes in his community, the delivery charge is more than half of the bill. He asked what is the percentage of the bill for delivery charge that Hydro One is comfortable with and going to the Ontario Energy Board with.
- Mr. Hubert explained that Hydro One does not have a percentage in mind. When the application is put together, they advise the OEB how much money it takes to run the system, and then developed a budget for five years for the OEB to approve. Once it is approved, Hydro One can recommend different rates for different classes. The Minister can ultimately make that recommendation and adjust through other income sources the rates for other groups..
- **Chief Perrault:** The Chief advised Hydro One against raising the rates of power itself to make up funding from the (potentially lower) distribution rates.
- Mr. Hubert noted that setting the electricity prices was beyond his control but he would not like to see that happen as it would essentially lead to a vicious cycle.

Councillor John Onabigon: Councillor Onabigon asked Hydro One to define a First Nations customer. Is it only on reserve? He noted that First Nations maintain the same rights no matter where they reside.

- Mr. Hubert noted that the letter from the Minister referred to exploring a rate for First Nations on reserve only.

Chief Rick Allen: Chief Allen asked who was involved in developing the First Nations rate. Was it the Chiefs of Ontario?

- Mr. Hubert responded that ultimately it is in the hands of the Minister however, there was an earlier discussion run by the Ontario Energy Board that did not involve Hydro One.
- **Chief Allen followed up:** The Chief asked Mr. Hubert if he knew who ran it.
- Mr. Hubert reiterated that the process was the OEB's and he did not know much more than that about the discussions that the OEB with First Nations. He then further explained the distribution system map in the PowerPoint [slide 4]. He noted that some First Nations are also serviced by Hydro One Remotes who have their own rates, separate from the Hydro One Distribution rates.
- Mr. Hubert elaborated on how the Hydro One distribution charges are spent: preventing outages (47%); upgrading the system (21%); customer service (12%); responding to power outages (10%) [Slide 7].

Chief Reginald Niganobe: Chief Niganobe stated that he participated in one of the sessions between the OEB and the Chiefs of Ontario. He shared a concern noted by an earlier speaker related to off reserve First Nations people. He noted that First Nations know who the members of their communities are. He concluded by asking Hydro One officials if there would be an opportunity to work towards considering off reserve First Nations for the special rate as well.

- Mr. Hubert stated that Hydro One is open to hearing that idea and, in fact, this was the kind of feedback they were hoping to get from this session. He hopes to find a way to work together on issues.

Councillor Skied: Councillor Skied asked about the loss ratio, how the loss is calculated and why customers are burdened with that loss [Slide 6].

- Mr. Hubert explained that line loss represents 4% of electricity costs to customers. He notes that line loss is an expenditure for Hydro One and has to be paid for by someone. The electricity generator produced it, but some of the power is lost as heat during delivery on the distribution system, and the losses have to be paid by someone. He noted that he understand the frustration over end users paying for something they did not get, so Hydro One is always trying to minimize those losses and costs.

Grand Chief Gord Peters: Related to First Nations people in urban areas, distribution charges go down in areas of higher density. He suggested that these reforms could be made in phases; first address First Nations on reserve and then move to urban areas.

- Mr. Hubert restated that the letter from the Minister only mentioned an on reserve rate or mitigation.

Chief Tom Bressette: Chief Bressette sees the on-reserve/off-reserve issue as an attempt to divide First Nations rights. He notes that those living off reserve have never given up their rights. It is called the principle of portability of rights. First Nations were never to be locked on to a little piece of land forever. The OEB should have an answer to the on-reserve/off-reserve issue. It is about Treaty rights and human rights. Canada recognizes human rights. The Chief reiterated that people who live off reserve have portability of rights and can come and go as they please in their own territory.

Councillor John Onabigon: Councillor Onabigon shared that if there are different rates for on and off reserve people it will mean that his Chief and Council will have to discriminate against their own people; however, they were elected by all of the First Nations membership no matter where they reside.

Chief Leslee White-Eye: Chief White-Eye inquired about the cost structure; specifically, what charges the OEB approves for Hydro One.

- Mr. Hubert clarified that Hydro One was responsible for operating the Transmission and Distribution systems. Further, IESO gets a small part of that bill as well.
- **Follow up from Chief White-Eye:** The Chief asked if there was a transportation levy to enter her community, the operating system is where it would fall?
- Mr. Hubert sought clarity on the question. Was the Chief asking who would pay a levy set by a community?
- **Chief White-Eye:** The Chief asked if a company would have to pay a levy.

- Karen Taylor, Hydro One, responded that there is sometimes a charge from communities for access and the presence of Hydro One facilities. This is included in the distribution portion of the bill and is also included as part of the company's revenue requirements.
- **Chief White-Eye:** The Chief asked if that is from the First Nation or the OEB.
- Ms. Taylor clarified that when Hydro One sets the rates they add up all of the costs and it is passed on within the rate. Any fees paid to First Nations for access are passed on through customer bills.
  Chief White-Eye: The Chief suggests that those costs should be passed on to the distributors and generators.
  Gary Schneider, Hydro One, clarified that Hydro One pays for land use, for the value of land and also payment in lieu of property taxes. He noted that they might be able to make unique payments to First Nations, depending on the situation.

Chief Mary McCue-King: The Chief expressed surprise to hear that the year-end amount was $6.5B with costs of $1.1B. There is quite a lot of profit, so she expressed frustration of being told Hydro One cannot afford to lower rates.

- Mr. Hubert noted that the proposed rate increases within the five year application does not take into account a First Nations rate yet. He notes that the majority of the increases are due to the costs of maintaining infrastructure and upgrades.
- **Chief McCue-King:** The Chief noted that in the annual report ending in 2015, Hydro One's debt to capital ratio was 50%. She stated that Hydro One could afford to lower rates as they profited $620M in net earnings. She stated that she listened to what everyone is saying and that Hydro One can afford to eliminate the delivery rate for First Nations communities or both that and profit sharing on the transmission lines going through our communities.
- Mr. Hubert responded that Hydro One had an 8.87% Return on Equity allowed by the OEB, which is the profit and that we are allowed to earn, but if we significantly exceed it we can return some of it to customers as part of the Hydro One's Earning Sharing proposal.

Chief Tom Bressette: Chief Bressette reminded Hydro One that they do not own the land neither does Canada, Ontario or the Ontario Energy Board. Yet Hydro One is taxing it. He wondered what the First Nations' portion of those profits is.

- Mr. Hubert responded that this is a broader question.
- **Follow up from Chief Bressette:** The Chief reiterated that Hydro One is taxing First Nations and he wanted to know where the First Nations' share is. He noted that Hydro One and First Nations are partners. The land is First Nations land, and First Nations people are generous to share it and help non-Indigenous people on these lands. First Nations did their part of fairness and goodness within a partnership and are asking for their half in return.
- Mr. Hubert suggested that the issue of partnership is a broad question. There are some partnerships developed with First Nations already and he hoped that more discussions on partnerships come out of the engagement session.

Councillor Ted Snache: Councillor Snache asked about the potential for breaks related to peak time rates.

- Mr. Hubert said that related to peak rates, this is a challenge because those rates are determined by the OEB. Therefore, any adjustment would have to be explored with the OEB. The Hydro One recommendation was a limited to a change in the delivery charge.

Councillor Warren White: Referring to the Ontario map in the PowerPoint presentation, Councillor White noted that he is a Treaty person, as part of Treaty 3. He asked the Hydro One team if they are willing to honour and respect the Treaty 3 Sacred Law. He asked if Hydro One knows the Sacred Law, or Treaty 3 Resource Law? He suggests that Hydro One needs to learn First Nations laws within Treaty 3. He noted that it is a land base of 55,000 square miles. Hydro One does not have a territory. He notes that education is an important part of any partnership and within regional engagements, and that Chiefs should be educating Hydro One about First Nations resource laws. With this in mind, Councillor White recommended changing the PowerPoint slide with the map of Ontario, which refer to Hydro One's Service Territory, because Hydro One does not have a territory.

Councillor [Name Unknown]: The Councillor wondered if Hydro One staff could explain rate classes. In addition the Councillor mentioned that there are seasonal customers and wonders why they cannot have their own class.

- Mr. Hubert said that in regards to rate classes, when Hydro One applies to the OEB, they develop proposals for specific rates including: urban, two rates for rural, seasonal, and commercial/industrial. He notes that they could also add a First Nations rate. These rates are based on the cost of the assets that serve them. A proposed rate that is not cost-based is therefore a policy decision of the Government and the OEB and is not an arbitrary process.

System Investments

Presentation by Mr. Greg Kiraly, Chief Operating Officer, Hydro One

Mr. Greg Kiraly provided personal background information. He is in charge of operations and is responsible for the Transmission and Distribution System (T&D system) along with Mike Penstone, Vice President of Planning, and Gary Schneider, Vice President of Shared Services.
In his role, Mr. Kiraly is responsible for safety and reliability of the system (including the number of outages and duration of outages). He noted that his job is also to keep costs low or lower costs. This essentially means trying to improve productivity and decrease costs, decrease vendor costs. Essentially, his aim is to keep the system safe, reliable and affordable.

Mr. Kiraly also acknowledged that he does not know much about First Nations and this has been an education for him. He noted that his job is to achieve operational excellence. To identify where Hydro One is at, identify where they can get to and to put a plan into place to get Hydro One there.

Representative from the Chippewas of Rama [No Name Provided]: The speaker questioned what Mr. Kiraly's presentation has to do with hydro rates. They noted that they had to cancel some important meetings to attend this engagement session.

- Mr. Kiraly responded that he will get to a discussion about reliability and how that affects everyone within the system.

- Referring to the PowerPoint [slide 8] he noted that within the transmission system the primary causes of interruptions is equipment failure and weather. Other causes are major environmental events (tornados, fires, etc.) and animal/vehicle/tree contacts.

Chief Patricia Faries: Referring to Slide 9, she noted the green dots, which indicate issues with reliability. She wondered why there were no lines identified on the slide in those areas.

- Mike Penstone, Vice President of Planning, Hydro One, explained that not all Hydro One lines are represented on the map as it would be too cluttered. He noted that they are monitoring those lines within the distribution system where there are system disruptions. Where Hydro One sees deterioration or degradation, there will need to be repairs and costs associated with those improvements.
- Mr. Kiraly added that it costs more in northern and remote areas to service the system.

Chief Gerry Duquette Jr.: The Chief suggested this is just a reality in Canada. Further, he noted that his community was not represented by a dot on the map within the slide.

- Mr. Penstone clarified that the dots represent hydro stations, not communities.
- **Follow up from Chief Duquette:** The Chief noted that his community had created their own energy project, where the band paid for the line in the 1950s. He suggested that it is discouraging when he hears about the costs. He also suggested that Hydro One should provide their employees a lunch box as many times they are working close to restaurants and so once they leave to get lunch, it takes a long time and things do not get done. In his community they had outages for 11 days; also during Christmas time. Chief Duquette suggests that he is looking forward to change and that his community has been asking what was going to happen. He needs to take the information back and share it with his community.
- Mr. Kiraly responded that Hydro One does not rest until every customer has their power back on but recognizes that it is more challenging in the remote north.

Chief Melvin Hardy: The Chief suggested that Hydro One look at repairing the transmission lines around Lake Nipigon. There is a station near his community and there is still trouble. He also asked a question around when the lines break and are repaired, would the rates go up.

- Mr. Penstone responded that, in order to ensure transmission networks provide reliable service, investments need to be made. He notes that Hydro One is spending money to sustain its networks and those investments are recovered through hydro rates.
- **Follow up from Chief Hardy:** The Chief asked that if it breaks do customers pay for it?
- Mr. Penstone responded that Hydro one anticipates that there will be repairs and costs
- **Chief Hardy:** Responds by saying that there are lots of hours with power and when Hydro One equipment fails, do customers pay for it?
- Mr. Penstone answers that, yes, but all rate payers pay for the repairs.
- **Chief Hardy**: Notes that there is greater density in the south and thus they have lower rates. He noted that Hydro One should have some statistics that are First Nations specific.

Mr. Kiraly noted that Hydro One is looking at getting coverage around the clock and is working with the unions on that. He notes that they have good reliability on the transmission system but less so on the distribution system as it does not have the same technology. Mr. Kiraly notes that

Hydro One workers sometimes have to check an entire line; that could be 100 miles long. Hydro One needs to upgrade this to avoid these delays. These upgrades will take years of investment and changing labour agreements, all aimed at improving reliability.

Chief Brian Perrault: The Chief recounts an incident last spring where there was a Hydro One crew in his community clearing trees around the lines. The crew came right into his yard where he had 5 trees. Instead of trimming the trees, they cut them all down. The Chief's wife's grandfather planted those trees and he felt like he should have been spoken to about it before they were cut.

- Mr. Penstone said that Hydro One has not trimmed in a long time. There are OEB standards related to dying and diseased trees. However, Mr. Penstone felt that he could not comment any further because he did not know about the specific situation. In addition, he committed to following up.

Councilor Ted Snache: Councillor Snache noted that the cost saving measures were part of what Hydro One does and it makes sense to redo the lines as quickly as possible.

- Mr. Kiraly noted that it is about balance. That Hydro One can ask the OEB to make these kinds of investments that are needed, but if we ask for that there needs to be an increase in the rates.

Chief Mary McCue-King: The Chief noted that there were issues with the lines in her area and asked if this is that going to impact the hydro rates in her community. She noted that Hydro One had proposed a change from a single phase to three phase power. She wonders if that is necessary and if it were more expensive.

- Mr. Kiraly responded that it would be more expensive. What you are talking about is a submarine cable and the cost would be borne by all rate-payers. Referring to slide 10, Mr. Kiraly describes the line performance for First Nations in 2016.

Chief Leslee White-Eyes: The Chief thanked the presenters and noted that the information was helpful. She was wondering about the relationship to community emergency planning. Specifically, she asked if Hydro One develops relationships in the community or is it more reactive. For example, can there be collaborative work to develop poles that have street lights on them. In this, Hydro One would be giving back to the community. She asks if there are other details of potential relationships going forward including sponsorships, career fairs, developing community protocols for when Hydro One comes into First Nations.

- Mr. Kiraly responded that Hydro One is open to any of the ideas the Chief just mentioned.
- Mr. Penstone said that related to the street lights, there is a legacy of sentinel lighting, but Hydro One is open to any suggestions.
- Mr. Kiraly mentioned that related to emergency planning, there are some relationships with communities around that, but he recognized that there is certainly not enough of that going on. He continued that they are open to any protocol that the Chiefs feel is most appropriate, for example, Hydro One workers stopping at the band office to let the leadership know what is going on. Mr. Kiraly concluded by saying that many of the items that Chief White-Eye mentioned were possible to achieve.

hydro One

WRAP UP

Mr. Goulais indicated that as heard from the participants, Hydro One should be providing the wrap-up.

Mr. Ferio Pugliese, Executive VP, Customer Care and Corporate Affairs, Hydro One, began by thanking Mr. Goulais and calling up the Hydro One Executive Team to the front. He noted that the conversations were captured visually and in notes. He reminds participants that these are the beginning of more discussions in order to lead to action. Mr. Pugliese identifies the main themes of the discussion.

1. The short-term, immediate economic issues including affordability: There is the additional rural burden and hefty delivery charges. There needs to be serious attention paid to the economic realities faced by First Nations and identify how to provide relief.
2. The need for policy change: A First Nations rate is beyond the power of Hydro One to change, but the Minister will be attending the dinner and may have more insight into the First Nations rate.
3. Longer term issues: There is a need to address longer term issues including outstanding agreements around access, rights, land use, assets on the land. There have been fruitful agreements in the past and Hydro One will continue to work on agreements with First Nations.
4. Relationships and Engagement: Hydro One needs to work with First Nations to develop a long term strategy on engagement. This was the first of many meetings. Hydro One is willing to come to your communities, regions, and tribal councils. These are opportunities to share information and educate both ways.

Mr. Jamie Scarlett, Executive Vice President, Chief Legal Officer, Hydro One, noted that the executive team members see working with First Nations as an overlapping mandate across their areas of focus. He noted that they understand it is critical to deal with costs and rates and Hydro One needs help from the government on that. Senior management understands how acute the issue is for First Nations. Regarding land use and resources, the team learned about how long negotiations have gone on and how this has been unacceptable for First Nations. They do not want these kinds of delays to continue. In order to achieve this, he encouraged direct, open and energized conversations. He encouraged a principled and fact-based method of moving forward. Thirdly, he noted the need to move forward on partnerships and co-ventures and working with First Nations more in the area of procurement.

Mr. Greg Kiraly, Chief Operating Officer, Hydro One, expressed gratitude for being at the engagement session. He thanked the crowd for good questions, comments and providing an education for him. He also noted that the participants could count on him and his team to improve the reliability of the system and get costs under control.

Mr. Pugliese asked for any questions or final comments?

Councillor Ted Williams: Councillor Williams shared an appreciation for the meeting and noted that he learned a few things. He stated that it was a difficult day and he appreciates that Hydro One heard their community issues. He noted that he does not want to come back in a year with nothing changed for the better regarding power. He commended the senior officials for facing a tough crowd.

Mr. Pugliese noted that he wants to be back here celebrating success in one year. The comments will be shared with board members. He concluded by noting that the meeting will end but the conversation will not. He encouraged participants to reach out to Hydro One if there is something you would like to add, and Hydro One will be happy to come to your communities for similar meeting. Thank you.

Meeting Adjourned

Hydro One and First Nations Engagement Session
Mandarin Room, DoubleTree by Hilton
Friday, February 10, 2017

SESSION REPORT

Table of Contents

WELCOME

Mr. Phil Goulais, Session Facilitator, called the meeting to order and introduced Elder Andrew Wesley. Elder Wesley provided the opening prayer and a smudge. Mr. Goulais noted that on the previous day, the session was welcomed by the Mississaugas of New Credit First Nation and he thanked them for continuing to allow the attendees to meet on their territory.

Mr. Goulais provided background information from the previous day and thanked participants for letting him share the day with them. He noted that he was pleased to see his own Chief present, Chief McLeod. In his work with Hydro One, Mr. Goulais has built relationships with communities and has travelled to communities to give procurement workshops and share career opportunities at Hydro One. He noted that Chiefs were asking how to work with Hydro One and effect change, particularly around hydro rates. At the same time, Hydro One was asking how to work with First Nations. This came from an understanding of the need to work better together. This was part of the motivation for hosting the engagement session.

Mr. Goulais shared the message from the invitation related to the objective of the session: "*Our most important objective is to hear from you and the issues that matter to your community. We will also be pleased to share our current thinking and solicit feedback on the application for Distribution Rates and the distribution system plan that we are preparing for submission to the Ontario Energy Board.*" He reassured participants that these discussions did not constitute consultation, and that it was just meant as a discussion. He noted that it was an honour to work with the Chiefs and Councillors, Grand Chiefs, Deputy Grand Chiefs and the Regional Chief. It was an honour to hear firsthand what community members are saying.

Mr. Goulais noted three senior executives from Hydro One in the room, noting that they are the decision-makers and the engagement is an opportunity to draw from their experience and knowledge. They were attending to hear the views of First Nations. He concluded by stating that the engagement is an important first step. He commended the participants for venturing out and taking that step. He shares his hope for a productive day of information sharing and discussion as well as establishing a plan going forward to continue the discussions and strengthen the relationship further. He asks that everyone consider what they will collectively leave as a legacy for their young people and generations to come.

As far as the morning's agenda, Mr. Goulais asked that participants introduce themselves, state where they are from and any early comments. Mr. Ferio Pugliese, Executive Vice President, Customer and Corporate Affairs will give a presentation on customer service. He asked participants to speak to what they would like to get out of the session, and what great customer service means to them. It was noted that notes of the meeting are being taken and participants would receive the written notes of the session for review. In addition, a graphic artist is capturing comments in a graphic way.

INTRODUCTIONS

Chief Barron King, Moose Deer Point First Nation: Personal Introduction

Jerry Fontaine, First Nations and Métis Relations, Hydro One: His work with Hydro One involves travelling to communities and conducting relationship-building work. He is from Treaty 1 in Manitoba, Sagkeeng First Nation. He is also party of Treaty 3, as the treaties did not recognize provincial borders. He noted that at the session yesterday there was some confusion on the point the purpose of the meeting, so he clarified that it is about building a relationship, trying to do things right, and identify where there can be changes at Hydro One. The company is seeking how to do things differently.

George Kakeway, First Nations and Métis Relations, Hydro One: Mr. Kakeway introduced himself as from Rat Portage, Treaty 9. He noted that he works with Treaty 3 communities and has been doing this work for Hydro One for about three years. In doing so he follows the traditional spiritual protocols before entering each community.

Chief Tom Johnson, Seine River First Nation: Chief Johnson noted that in his community when they see a Hydro One truck it is only for one thing [presumably to cut off service]. He notes that it has been a long process of negotiations and he would like to walk out of the engagement session feeling good about the process. He recognized that one day would not solve everything; there will need to be more time. However, he was looking for something to look forward to regarding hydro rates.

Rob Globocki, Director, Customer Service, Hydro One: This Customer Care Director noted the desire to establish connections with customers. They do not want to be seen as just people who come to cut people's power off. He suggests that Hydro One wants to work with First Nations, provide information and ask about First Nations' needs and priorities.

Ferio Pugliese, Executive Vice President, Customer and Corporate Affairs, Hydro One: Mr. Pugliese noted that he has only been with Hydro One for five months. He is originally from Ontario. He describes his responsibility as being about customer care and Indigenous Relations. He thanked the participants for coming and noted that the previous day had been a frank and honest discussion. He suggested that the Hydro One executive team were forging a new commitment to relationship building. He reiterated that Hydro One appreciates the presence of the attendees and recognized that they were busy. He reaffirmed that the session is a conversation and is not a consultation. He saw this as the first chance to meet and get to know the new team and answer participant questions. He also mentioned that they wanted to do more community visits.

Steven Nootchtai, Councillor, Atikameksheng Anishnawbek: Personal introduction.

Chief Alex Batisse, Matachewan First Nation: Chief Batisse noted that he was attending to voice his concerns about the very high delivery rates.

Amy Lickers, Chiefs of Ontario: Ms. Lickers introduced herself and said that she works with the Chiefs of Ontario Chiefs Committee on Energy.

Sherrylyn Sarazin, Councillor, Algonquins of Pikwakanagan: Councillor Sarazin noted that her community has a long-held grievance with the energy sector. Dams took away their food; the eels disappeared. Energy lines were brought through in 1954 without permission. They are only now almost at an agreement. She noted the need for more cross-cultural sensitivity training for the staff dealing with First Nations. They should know the Seven Grandfather Teachings. She wondered how her community members could see relief directly on the bills, given the rising cost of living and high hydro bills with delivery fees costing more than the energy. She is seeking a solution.

Chief William Diabo, Magnetewan First Nation: The Chief noted that he is in his third term in office. He thanked the organizers for putting together the gathering to bring his community's concerns to the table. His concerns are primarily about the relationship, the services and the high rates faced by his community. He noted his hope to achieve a solution, not just hear more words.

Chief Greg Peters, Delaware Nation (Moravian of the Thames): The Chief noted he is in his fifth term in office. He was attending the meeting for similar reasons to everyone: the standard of living for his people is in jeopardy. They have lower standards of living than other communities. To address this, they need to come up with a plan.

Chief Dean Sayers, Batchewana First Nation: Chief Sayers notes that the government of Ontario compels Hydro One to work with First Nations. His Elders make sure he expresses the fact that First Nations in Ontario pay the highest taxes of anyone. They had to give up 50% of their revenues and their quality of life. In the 1800s they were managing the resources but that was taken away. They refused to pay taxes to the government because they already paid with the violations on the land. Any tax that is paid today (PST, GST, etc.) is a violation of their Treaty. He notes that one measure that Ontario could do is point of sale exemptions for all First Nations in Ontario for any tax. If First Nations, no matter where they live, show a status card in paying a Hydro One bill, all taxes should be removed. The delivery charge should also be removed because of the lines going across their lands. Chief Sayers notes that there are many other issues that he would like to bring forward. He thanked Hydro One for inviting him and the other Chiefs for attending as well.

Tausha Esquega, First Nations and Métis Relations Team, Hydro One: Personal introduction.

Cesar Martinez, Customer Care, Hydro One: Mr. Martinez was attending the session to find solutions that are mutually agreeable.

Chief Scott McLeod, Nipissing First Nation: The Chief shared that he was encouraged to hear that Hydro One wants to hear the issues faced by First Nations. The situation is tough. His community just signed a bunch of cheques to help seniors make it through the winter. Most of the homes in his community are heated by electricity, so people have to choose between food and heat. He also echoed the comments from Chief Sayers regarding the constant struggle with the government to honour their Treaty obligations. He notes that hydro is a resource that is taken from the land, and instead of sharing; First Nations have to pay huge costs for it. Energy is generated from Mother Earth, and we have agreed to share it in the Treaties. The Chief hopes he can start seeing the government live up to their obligations.

Kathleen Naponse: Ms. Naponse noted that she is from Whitefish Lake but is attending on behalf of Thessalon First Nation. She would like to know what is happening with the rates and where there are plans for more lines to go. She sees this as impacting her Treaty rights.

Imran Merali, Interim Director, First Nation and Métis Relations, Hydro One: Personal introduction.

Karen Taylor, Senior Director of Regulatory Affairs, Hydro One: Ms. Taylor noted that she worked on the application to the Ontario Energy Board (OEB) and she was also a member of the Ontario Energy Board at one time. From the meeting, she hoped to take away sustainable and actionable items.

Chief R. Donald Maracle, Mohawks of the Bay of Quinte: Chief Maracle described his vast traditional territory that extended to both sides of the river. This territory was never surrendered nor was any of the rights within that territory surrendered. The Niagara Power Generation Station is within that territory and his community is looking for benefits from that. First Nations' resources have led to a comfortable life for the colonizing nation to the detriment of First Nations quality of life. People on reserves are paying the highest rates. These people are further away from big cities, have lower incomes, can only find part-time jobs and often work minimum wage. He notes that the dynamics within the province were not considered in developing the current rates. In addition, municipalities have collected royalties from power lines that cross First Nations land. Sometimes there are land claims or lands that have not been surrendered at all and First Nations should be compensated. He notes that First Nations have contributed resources to the country and have also contributed in times of war. Rates are a political decision, and thus can also be changed by politicians. The rural rate is not properly applied to First Nations. From the meeting, Chief Maracle was looking for some kind of commitment. The OEB will do what the Minister tells it to do. If the Minister was committed to developing a First Nations rate, they should have already had their discussion and told the Chiefs what the decision is. He noted that he hopes this happens. He also hopes that First Nations can build a better working relationship with Hydro One and Ontario, based on the actions that are taken in response to First Nations' concerns.

Art Jacko, Manager of Lands and Resources, Whitefish River First Nation: Mr. Jacko noted that Chief Shining Turtle could not attend, so he was attending in his place, primarily to find out more information. His territory encompasses Treaty 3. None of the promises were ever fulfilled. Fast forward here today, Ontario has created a huge regulated monster. He stated that he was glad to see there is a new management group and will be watching to see how things change. He noted that the process is about the Hydro One application to OEB. He agrees that the infrastructure needs to be addressed. He noted that he knows the cost of running a business however, it is hard to understand and to explain to his people the rationale and reason for the rates that are being contemplated. While there are huge profits at Hydro One, First Nations communities continue to suffer and have not seen any breaks. In the 1853 treaty, First Nations were promised $4 at that time. Today it is still $4. He noted that he looked forward to seeing the application that Hydro One will submit and how they intend to deal with those Treaty issues.

Peter Nahwegahbo, Consultation Officer, Aundeck Omni Kaning First Nation (Sucker Creek): Mr. Nahwegahbo noted that he was attending on behalf of the Chief, and will be taking information back for the Chief. He noted that he was looking forward to this meeting, as it was his first session with Hydro One. He recalled that, 15 years ago, he went to his Chief about his hydro bill and then followed up 10 years ago. The Ombudsman of Ontario is finally hearing his case.

Chief Edward Wawia, Red Rock Indian Band: The Chief noted that 15 years ago his mother was Chief and she was saying the same things being said at this engagement session. His community has three dams in their back yard. They are close to Nipigon and yet their bills are 2 or 3 times higher. He would like an answer for why that is. He explained that they teach their young people to conserve energy and pay their bills, but when their bills are so high and the delivery charge is so high, they have troubles paying. He suggested that the delivery charge is so high because First Nations cannot be taxed. He concludes with a comment on maintaining the hydro lines; he would like to see a manual way of tending the lines and an end to spraying the lines.

Gary Schneider, Vice President of Shared Services, Hydro One: Mr. Schneider explained that procurement and land matters falls under his area of responsibility.

Chief Dwight Sutherland, Takwa Tagamou Nation: Personal introduction.

Peter Archibald, Councillor, Takwa Tagamou Nation: Councillor Archibald cited a number of issues that needed to be discussed with Hydro One. He mentioned a transmission agreement process they are hoping to start and they need to know who to speak with and where to go from here. He reflects that delivery charges are another issue. These charges are sometimes three times the electricity charge. There are also transmission problems despite there being several generating sites in his territory. One was just built at New Post Creek. They have also been impacted by not being able to fish out of their river anymore. There are well-documented impacts of sewage dumping, including damage to the environment, and the animals cannot drink there either. This is not being monitored. They are also impacted by Highway 101 and mining in the area. There was no regulation on these activities prior to the Environmental Assessment process. He shares that there is no doubt that people got sick and died from the contamination. He concludes by inviting Mr. Cesar Martinez to meet with him and discuss these issues further.

Oded Hubert, Vice President, Regulatory Affairs, Hydro One: Mr. Hubert noted that he would be giving a presentation later in the afternoon.

Devi Shantilal, First Nations and Métis Relations, Hydro One: Personal introduction.

Lucy Trudeau, Band Manager, Sheguiandah First Nation: Ms. Trudeau noted that she would like to bring back to her community real world solutions to the many issues they face related to hydro.

Daniel Charbonneau, First Nations and Métis Relations, Hydro One: Personal introduction.

Erin Henderson, Regulatory Affairs, Hydro One: Ms. Henderson noted that she had been working with the First Nations and Métis groups at Hydro One in relation to this session.

Valerie George, Consultation Coordinator, Chippewas of Kettle and Stony Point First Nation: Ms. George noted that she wanted to follow up on a point made earlier by Chief Sayers around transmission lines. She also raised the point around an off-reserve exception because sometimes people have to move off-reserve but that does not mean they have forgone their right. She ended by reminding Hydro One that this is not a consultation and Hydro One was not provided consent for anything.

Chief Paul Eshkakogan, Sagamok Anishnawbek First Nation: The Chief expressed his desire to talk more about solutions and the work that needs to be done to achieve those solutions. He noted that the Premier could impact the rates. He added that there was a need in his community for employment and training. He recalled, years ago, when Hydro One was building the 250kV line from Sudbury to Sault Ste. Marie; they were recruiting community members across the North Shore. He noted that now, we need to go back and look at how First Nations can participate in the business and create employment in his community. He would also like to look at partnering with Hydro One to look at creating energy efficient communities. He notes that there are many energy sources in First Nations that should be considered. He shared that he was looking forward to the discussion.

Warren Lister, Vice President of Customer Care, Hydro One: Mr. Lister explained that his role is everything to do with billing and energy conservation. He noted that they are waiting to hear about rate relief from the Minister, but that in the meantime, Hydro One can do some things to assist First Nations and that is what he was interested in speaking about. He noted that he knows Hydro One has work to do as it relate to policies and procedures and committed to taking action on those.

Chief Wayne Pamajewon, Shawanaga First Nation: The Chief explained that he was attending the session out of a concern for where we are headed and how we get there. He also affirmed the words of Chief Sayers. He notes that the issues with Hydro One have been around for a long time. His community signed an agreement on hydro in 1951, which clearly points out that power would be delivered, to his community and three other communities at no cost. The interpretation of the agreement is not done from the First Nations perspective. His band members are telling him that they cannot pay their hydro bills and have to choose between food, power or rent. He notes that he came from a time where they would study using a coal oil lamp and when they ran out of oil they borrowed or got creative. Today people need power. We must find a way to make it better for his people. He notes the treaty, which begins at the Severn River and goes to Batchewana Bay. Those lands belong to his community and Hydro One has not paid for crossing those lands. That Treaty said that the First Nations would get benefits. This has not happened. According to that Treaty, his people should not be paying for hydro. They have paid enough. The Chief noted that his community needs three-phase power. They have upgraded the lines a little bit in the community but they still have lower electricity costs and very high delivery charges. The Chief had asked his community members to hand in their bills in order to record the total costs his people were facing. He suggested that all the leadership in the room do that. As Chief, in 2012, he sat at a huge table with First Nations on one side and Hydro One lawyers on other. They did not get very far. He questions how Bell Canada can be paying Hydro One for the use of the poles with no agreement from the First Nations. He noted that he wished some Hydro One policy people had to live on the reserves before making policy for First Nations. He concluded by saying he wanted to talk about the future for his community.

Mary Ann Giguere, Councillor, Thessalon First Nation: Councillor Giguere noted that she has concerns about the high hydro costs, and was attending the meeting to take information back to her people.

Chief Patricia Big George, Anishnaabeg of Naongashiing: Chief Big George began by stating her community was part of Treaty 3. Many of the issues that had already been brought up, resonated with her. She described that her community is at the end of Highway 21. She notes that the delivery charges are usually way more than the hydro charges. She asked if anyone sits at a negotiation table with Hydro One. She described a substation about 35 km from her community that was built when a mine came in. She thought that hydro rates would go down, as a result, but they actually went up. She viewed Hydro One as catering to the mine as there is an economic incentive coming from the mine. Regarding procurement, she noted that the only contract work for First Nations seems to be cutting trees around the line. She asked if that was the only work available. She asserted that First Nations are worth more than menial tasks. She noted that about 60% of her community members are taking their hydro bills to the band office because they cannot afford to pay them. They should not have to rely on band funds to pay those astronomical rates.

Chief Lorraine Crane, Slate Falls First Nation: Chief Crane noted that she wanted to come to the meeting to discuss the many issues with Hydro One. She describes being born and raised on the land. Hydro One entered the area in 1930. There were agreements between Hydro One and six bands signed in the 1990s. She notes that they have never received reserve status, partly, she believes, because of Hydro One. They have been fighting for decades. The Chief recalled talking to a woman at Hydro One and the woman said Hydro One held the pen. This was both frustrating and offensive. In addition, her community shares many of the same struggles with Hydro One as others have mentioned. Hydro One can just drive in any time and disconnect people, and the community struggles to get people connected so the pipes do not freeze. The hydro bills are high and there is not a lot of employment in her community. They have annual contracts with Hydro One for clearing the land around the lines. She noted that when she was growing up, she always respected the hydro line going through the land. They always let people go through the land. This adds to her frustration alongside no reserve status, high costs of hydro and Hydro One can just come in whenever they want. She wants this to stop.

Chief Dorothy Towedo, Aroland First Nation: Chief Towedo noted that their concerns were many of the same already stated. She is new as a Chief and is learning. Her community is about four hours from Thunder Bay. They also do not have reserve status. She noted the outrageous cost of hydro while her people live in poverty. It makes it hard to pay for heating in winter. Many in her community are unemployed. Many families are forced to choose between power and food. This is also a challenge for Elders and people on fixed income. They also face challenges with interruptions to power that sometimes last days. As a result food gets spoiled and these are people who cannot afford to waste any food. Many people come to the band office for help with food or the hydro bill. The Chief concluded by stating that she was attending to learn how the system works and how these rates are determined.

Chief Elaine Johnston, Serpent River First Nation: Chief Johnston expressed gratitude for attending the session. She supported the comments of Chief Sayers regarding the Treaties. Her community is part of the Robinson Huron treaty area. The political conversation around 'Canadian Values' from Kellie Leitch reminds her that everyone who came to Canada is an immigrant. She posed the question: what are Canadian values? How did settlers treat First Nations people? She reminded the room that First Nations people treated newcomers well but that was not reciprocated. The way that First Nations have been treated for 500 years has been abysmal. Regarding relationships, the Chief notes that each side has to understand one another. She was pleased for the opportunity to open up a conversation; however, there is a need for some cultural understanding and an understanding of First Nations history, in order to understand where First Nations are coming from. The fathers of confederation gave First Nations people the residential school system. Hydro One needs to know the history of this country. Regarding energy, the Chief noted three things: 1) the Minister of Energy is the one making decisions; 2) there is confusion around Hydro One and the OEB. Who is doing what? and, 3) there needs to be some cultural recognition within Hydro One from the bottom to top. In addition, there needs to be designated staff as part of the call centres that can respond to land issues and taxation issues, etc. The Chief noted that when members call the call centre they get nowhere. Chief Johnston concluded by sharing appreciation to Hydro One for hosting this event because relationships start with dialogue. While Hydro One is sharing information, First Nations should share their perspectives too.

Deborah Wetzel, Councillor, Big Grassy First Nation: Councillor Wetzel concurs with everything previously said.

Lee Anne Cameron, First Nation and Métis Relations, Hydro One: Personal introduction.

Chief Wayne Smith, Naicatchewenin First Nation: Chief Smith noted that it was a pleasure to attend the engagement session. He came hoping to know more about delivery charges, as it is the biggest issue facing his First Nation. He recounted a personal anecdote that was instructive of what his community members deal with related to Hydro One. He shared that he had a rental unit that he paid the hydro for monthly. His tenant moved out in October, so he closed off the account. When a new tenant moved in, he transferred the bill to the new tenant. He received an excellent letter of recommendation from Hydro One, but also received a $126 bill from the month before. He forgot about it and missed the due date by a week and a half. Ultimately he paid the bill online. However, when he came back from vacation it had been sent to collections by Hydro One. The Chief noted that First Nations members are badly treated by Hydro One customer service and there is a real need for a change in attitude. He also agreed with the issues brought up by the other participants. Out of this meeting, the Chief was hoping to learn more about Hydro One and also move from talking to action.

Jason Laronde, Director of Lands and Resources, Union of Ontario Indians: Mr. Laronde shared that he was attending the meeting to listen.

Brendon Huston, Economic Development Coordinator, Union of Ontario Indians: Mr. Huston noted that he was also attending to listen.

Chief Wayne Pamajewon, Shawanaga First Nation: The Chief noted that when it comes to submersible lines, that First Nations never gave up rights to the water.

CUSTOMER CARE

Mr. Ferio Pugliese, Executive Vice President, Customer and Corporate Affairs, Hydro One
Mr. Pugliese began by thanking the participants for the frank discussion and open dialogue. He noted that Hydro One was undergoing a lot of changes, including a new system in Ontario. There are a lot of moving parts. For its part, Hydro One is undergoing profound changes, because of the shift towards a private company with shareholders. Providing some clarity, Mr. Pugliese noted that Hydro One was not in the power generation business, but in the Transmission and Distribution businesses. Hydro One does manage the delivery charges. He admitted that the new team at Hydro One recognizes that things had happened in the past when it came to First Nations land and communities. While they cannot change what happened in the past, the new Hydro One team is making a commitment to work differently, in partnership with First Nations. He asked the attendees to judge the new team on their actions. He noted that in a year from now, or sooner, Hydro One will be able to share insights and progress on closing out past grievances, in helping community members with bills, and making movement on

affordability. He recognized that this meeting was the first step in a long journey of building relationships.

Mr. Pugliese provided information on four points: the First Nations rate, affordability, calls to action, and understanding the distribution rate filing. Regarding the First Nation rate: in Ontario hydro bills are generally made up of the following: 50% for generation costs (nuclear, hydro, gas, wind, solar, biofuel) and 37% of the bills are distribution costs. These costs vary based on density (more poles than people in rural areas). Hydro One applies for, but does not set the distribution rates; those are set by the OEB. However, Hydro One is trying to influence change related to those distribution rates. Mr. Pugliese recalled seeing bills where the delivery charge is larger than the consumption charge. He noted that he views this as a serious problem. He recognized that in remote communities, where there is electrical heat combined with poorly insulated homes (not on gas lines for forced air), the result is high consumption charges plus even higher delivery charges.

Regarding the potential for a First Nations rate; this is an issue being managed by the Minister of Energy. In developing the proposed First Nations rate, there were meetings with the Chiefs of Ontario and five (5) sessions that included 48 communities. The First Nations consultation was completed last fall in 2016. Mr. Pugliese shared that the final paper was filed by the OEB with the Minister on December 29, 2016 and he believes an announcement on the First Nations rate is imminent.

Hydro One does not want those high rates for communities and has teams working on affordability issues. Once those are resolved, then they can move on to system issues. Hydro One has been focused on education, advocacy and responsiveness. The need for education is acute because not many people understand the hydro system in Ontario. Customers, communities and even decision makers/policy makers need to understand the breakdown of costs and why they are so high. There was a cost increase once Ontario got off coal, for example, which was transferred to the cost to consumers. Hydro One can watch its costs, save money in different ways, and defer expenditures, where possible. Hydro One operates on the cost recovery system, and there are costs associated with maintaining that system which requires capital investments. These plans all have to be submitted to OEB.

Mr. Pugliese noted that Hydro One also plays an important role in advocacy that includes going to policy meetings at the Minister's office and also with the OEB. Hydro One met with the Premier last week and presented an advocacy position on behalf of customers. In that meeting, Hydro One described the situation as a crisis that needed radical redesign of policy in order to address the affordability issue. At that meeting, Hydro One shared information on how the redesign might look to reduce costs on the power generation side, etc. Mr. Pugliese noted that it was not just Hydro One who brought this message to the Premier, although Hydro One probably feels the most pressure because their name is on the bill. Hydro One owns that relationship with customers. Hydro One needs to start listening to the impact that high bills are having. The message was well received by the Premier and the level of engagement and knowledge of the Premier and her staff was impressive. Mr. Pugliese commented that Hydro One saw it as time to act as the voice for their customers, but this advocacy is not something that they can do alone. Hydro One believes that the voice of First Nations on this issue is strong. Hydro One and First Nations sharing the same message on affordability would be powerful. Related to improving Hydro One's responsiveness, Mr. Pugliese noted that they have heard First Nations speak about empty promises from the past. The new team at Hydro One will improve on this performance.

Mr. Pugliese notes that there are some actions that are beyond their ability to change, however, where they can; there are some actions that can be taken to respond to First Nations concerns. Recently they have taken some steps such as waiving reconnection fees. A customer was in arrears and had failed in the payment plan, but in working with the customer they learned that, it was not that the customer could not pay, they just could not follow the plan exactly. Hydro One recognized that they must be more flexible to meet customers' realities. Payment plans can be worked out to better suit customers. Also related to 'taking action', Mr. Pugliese asked participants to let Hydro One know what they wanted in terms of training programs for communities. They are willing to go to communities to work on individual bills, explain the bills, and get clients on plans; however, these activities take many visits. Another option is training people within communities to host these meetings and provide this service within the community. These programs are just getting started, but Hydro One will continue to work with communities in this area.

Chief R. Donald Maracle: The Chief noted that some councils loan monies to community members for bills in arrears. He asked what Hydro One could do for communities in this situation. Some people have had to go to high interest rate companies to borrow, which is a hard cycle for people to get out of.

- Mr. Pugliese responded that people would generally have to rely on social service agencies and that Hydro One does not have a policy on this issue, but can potentially look into it. In addition, he noted that they spoke with the Premier on affordability funding. The current program qualifiers are stringent but perhaps Hydro One can use the surpluses in cases such as this.
- **Follow up from Chief Maracle:** The Chief notes that in smaller communities there are no service agencies and have to depend on the band council.
- Mr. Martinez, Hydro One, noted that when they come to the community in March they will bring the United Way with them. Community members can apply for relief from the United Way. He has done this with First Nations communities before.
- Mr. Pugliese noted that this issue has come up before and is something that they want to look at. They are looking to support an adjudication process in order to address it. This is a potential suggestion for action going forward.

Chief Elaine Johnston: Chief Johnston noted that a lot of her people are living in poverty, so a payment plan will not help them. They are having a hard time paying for food. There are other social service programs, but those have a limit.

- Mr. Pugliese commented that Hydro One cannot address poverty in a general sense. It is a very broad, complex social issue. However, Hydro One can focus on the bills as part of their own social responsibility. Also related to community social services, perhaps Hydro One can support those through Hydro One's community giving program.

Peter Archibald, Councillor: Regarding Hydro One coming into communities and turning off power, Councillor Archibald asked if it was possible to put a load limiter on these houses. He reiterated that when the power is turned off pipes freeze causing unnecessary renovations that cost even more money. He also expressed frustration that Hydro One staff go on reserve to shut people's power off and do not even stop at the band office first. If this does not change, Councillor Archibald suggested that Hydro One staff would no longer be welcome in his community. He reiterates that concerns must be addressed, especially the delivery charges. He shared his position that the delivery charge should be removed altogether.

- Mr. Pugliese responded that Hydro One supports Councillor Archibald's position on the delivery charge; however, it is not Hydro One that controls that. Regarding Hydro One staff entering the community, Hydro One has heard this concern previously and believes that their staff must respect the community protocols. They should first visit the band office. Finally, with respect to the disconnection and whether there could be load limiters, Mr. Pugliese noted that there are resources on this that Hydro One is willing to share through their outreach activities.

Chief Wayne Pamajewon: Chief Pamajewon brought back the conversation on the agreement from 1951, which was signed by four communities. He inquired about how much revenue was generated through that agreement over the years. He would like to see the historical numbers. He also suggested the conversation on submersible cables should move forward.

- Mr. Pugliese responded that he is sure there must be information on the revenues generated through those agreements. He noted that he and the Chief Legal Officer had been going through all of the agreements to identify what had gone wrong in the past and where there are fixable issues. Hydro One wants to re-evaluate all of those agreements and resolve outstand issues. Regarding submersibles, Mr. Pugliese noted that they are happy to sit and meet to have a discussion. In addition, the Chief Operations Officer would be presenting later and would be better suited for that discussion.

Chief William Diabo: Chief Diabo spoke about delivery costs. He shared that they have houses in his community that they rent. They turn the breakers off in the summer and yet they still receive bills with an astronomically high delivery charge. He is seeking an explanation for that. In addition, he asked for more details about the First Nations rate and the consultation with First Nations on that issue.

- Mr. Pugliese noted that consultation has not started for Hydro One on that issue. Regarding the First Nations rate, that was a consultation conducted by the OEB last year.
- **Response from Chief Diabo:** The Chief noted that his community was not consulted and added that the Chiefs of Ontario does not consult for his community; rather, they only advocate for his community.
- Mr. Pugliese noted that Hydro One can provide more information on that consultation initiated by the OEB and on the request for a First Nations rate.

WELCOME REMARKS FROM THE PRESIDENT

Mr. Mayo Schmidt, President and CEO, Hydro One

Mr. Schmidt provided a warm welcome to the Grand Chiefs and Chiefs. He recognized that the participants were looking for action and outcomes. He noted that the Hydro One team was learning more about the issues that are facing First Nations. Many of the issues identified the previous day were brought up again at this session. Hydro One is going through a period of transition. As part of the transition, the company has taken a renewed focused on customer service. He assured participants that their voices are being heard, not just by the leadership team in attendance, but also the entire Board of Directors. Hydro One, being a publicly listed company, opens up an opportunity to advocate on behalf of customers, whereas before Hydro One just took instructions from the province. The leadership team has come to understand how painful the delivery charge is for First Nations and they are speaking with the province to try to address that. Hydro One serves 88 different First Nation communities, which represent a great deal of diversity. He noted the need to account for constitutionally protected rights and unique cultural connection to the land.

Mr. Schmidt shared that Hydro One met with the majority of the First Nations communities that they serve, which included over 200 community visits. He noted that they are looking to expand community visits and welcomed the participants to let Hydro One know if they were interested in a community visit. He appreciated the goals and aspirations, as well as the needs of First Nations rights-holders and landowners, in terms of business development and community relationships.

The rising cost of power is a serious concern and Hydro One would like to see lower rates. He assured the room that Hydro One staff were listening and taking notes which they will use to advocate First Nations concerns when meeting with the Premier and Minister of Energy, in making those points about affordability. Mr. Schmidt noted that Hydro One has information about how the rate increases occurred and plans for how they can be addressed. They will use this information to try and influence better outcomes for customers. Hydro One met with the OEB on the First Nations rate and supported reducing the delivery charge for First Nation communities. They also met with the Premier. Mr. Schmidt shared his optimism in seeing a policy change in the near future.

Regarding high bills and high arrears Mr. Schmidt noted that they are expanding the delivery of a new service model in First Nations communities. The new model centres on sitting down with customers face-to-face to review accounts and provide assistance where possible. To date, they have met with over 600 customers and are seeking to expand. Mr.. Schmidt stated that if this is of interest to participants, to let Hydro One staff know. He noted that in the coming months they will be developing new programs for sustainable relationships. He views this as not only good business but also the right thing to do.

Mr. Schmidt concluded by thanking attendees for participating, as well as thanking the Minister of Energy and Regional Chief Day for working together towards building a strong and sustainable relationship.

Chief Dean Sayers: The Chief began by thanking Mr. Schmidt for attending the meeting. He explained that Indigenous people in Ontario pay the most taxes of anyone. There was an agreement to share the economy with settlers based on the understanding that First Nations people do not have to pay taxes. In Ontario, this is largely unrecognized. Chief Sayers asked if Hydro One would be willing to honour the point of sales tax exemption for all Indigenous people in Ontario no matter where they live. This was his formal request. The Chief's second point is on working for mutual benefit; he wondered how working together would look, and what would be the benefits, in general.

- Mr. Schmidt asked his staff member, Ms. Lee Anne Cameron [First Nations and Metis Relations], to make a note on the issue of taxes. He stated that given the complexity of the tax system there would have to do some analysis on that. He committed to going back to Chief Sayers on that topic.
- Ms. Cameron sought to clarify Chief Sayers' statement; that the tax can be removed for customers on reserve once Hydro One receives a status number, but she believes what Chief Sayers is referring to is eliminating the taxes even for those First Nations who are not living on reserve.

- **Chief Sayers:** The Chief clarified that at the time the agreement was made, there was no differentiation between on-reserve or off-reserve.
- Ms. Cameron said that Hydro One would go back to their tax group to discuss as well as talk to the province. She noted that they had been audited several times by the Canadian Revenue Agency related to tax collection. She also noted that, on a personal level, she agreed with Chief Sayers.

Mr. Schmidt described recent conversations with the province where they sought to provide solutions to the challenge of high delivery charges. The Province is currently looking at those issues. Hydro One is seeking to make progress on the big issues, and is trying to get away from disconnecting customers; rather, they are seeking to turn the power back on and work with customers one-on-one to try and solve the challenges.

Chief Scott McLeod: Chief McLeod shared that his band council had to issue 220 cheques to Elders to assist them in paying their hydro bills. That is $88,000 in one month. He notes that it is not just the financial burden; they view it as insulting and immoral. The Chief shared that there are two major lines running through his First Nation, and yet leadership has to explain why citizens who are struggling are getting delivery charges. He noted that his community members are outraged, particularly because Hydro One does not pay anything to the community for the lines running through their territory and then Hydro One turns around and charges outrageous rates. They view this as money that is owed to them, and they need a conversation about that.

- Mr. Schmidt noted that Hydro One staff needed to meet with Chief McLeod on this issue and wondered if the contract lapsed or was ever renewed? He committed to reviewing these agreements.
- Ms. Cameron suggested that Mr. Gary Schneider, Hydro One, can talk with the Chief on this issue.
- **Chief McLeod:** The Chief explained that the issue cannot be resolved because the land is the First Nations' land, it was unsold and un-surrendered. It took 50 years to get the land back from the federal government. In the meantime, the delivery charges keep rising.
- Mr. Schmidt commented that Hydro One could work with the First Nations as a partner in approaching the federal government when these things are taking so long to resolve.

Peter Archibald, Councillor: Councillor Archibald noted that when it comes to projects in their area, the First Nations should be contacted for employment. He noted the case of Otter Rapids specifically. They had sent permits for the band council to review, and when the band signed off, the contractor said "oh sorry, no jobs." Councillor Archibald's second point is related to disconnections. He does not believe that Hydro One staff are aware of the new policies around working with people one-on-one to avoid disconnections because in his community they just cut people off. He noted that he sent a letter to Mr. Schmidt's office and received no response.

- Mr. Schmidt assured Councillor Archibald that he responds to every note that comes into his office. He asked that he resend a copy and he will respond. In terms of employment, Mr. Schmidt stated that he could not agree more and wants First Nations employees to participate in projects. He committed to putting people in touch with Ms. Judy McKellar, Executive Vice President, Chief Human Resources Officer. In regards to disconnection, Mr. Schmidt asked participants to let Hydro One know of anyone living without power. Hydro One wants to get them connected. If any community has people headed in that direction, Mr. Schmidt asked them to let Hydro One know and they will try and find a way to manage. In addition, if your community would like Hydro One to make a community visit, just ask.

- **Councillor Archibald:** He commented that Hydro One comes to the community and does not want to hire his people.
- Mr. Schmidt noted that this might have something to do with Ontario labour law, and they will look into it.
- Mr. Martinez, Hydro One, announced that they would pass around a note and for participants to identify any preferred dates for community visits.

Chief Edward Wawia: The Chief shared that he did not get anything out of the presentations today. He felt that he needed to return to his community with answers for the Elders and young people about why their bills are so high. Based on this meeting he noted that nothing will be done about the high bills except another group of people will come to the community to show them how to manage their bills. That is degrading for his community members. The solution on offer is just extending their payments for a longer period of time. The Chief noted that what is actually required is getting serious about profit sharing so First Nations can deal with the huge bills.

- Mr. Schmidt clarified that Hydro One is in the transmission and distribution business, and it is the regulators who set the prices. Hydro One is indeed advocating getting better rates, but they cannot control the rates themselves. However, Hydro One can control certain things and make some changes such as infrastructure repairs and such. Hydro One can also provide assistance before a disconnection. He again encouraged people to approach Hydro One to see what they can do on that end. He reiterated that Hydro One is just one part of a much larger system. He also reiterated that the organization is undergoing a culture shift and asked that they be given a chance.

Steven Nootchtai, Councillor: Councillor Nootchtai began by thanking the organizers of the event. He noted that many of the concerns raised were also concerns for his community. Councillor Nootchtai provided a recommendation: that Hydro One uses their influence with their suppliers, because he views externalized costs as a Treaty issue. Hydro One has much more power than First Nations to influence change.

- Mr. Schmidt was in agreement with the speaker. He noted that Hydro One went from a Crown corporation to a commercial operation and in doing so has a greater influence on their suppliers. In addition, they are asking the province to make adjustments where necessary. He noted that, as a company, Hydro One has to get costs down as well. They are doing more work with less people and are reinvesting the savings back into stabilizing the system.

Chief R. Donald Maracle: Chief Maracle reminded the room that land was never surrendered to the Crown, yet the Crown gave letters of patent to others for some of his reserve land. Some members of his community live on that land part time. He wondered if their bills could be tax exempt, as their rights are being infringed on.

- Mr. Schmidt offered to talk to legal counsel on the issue and help investigate the situation. He noted that, if necessary, Hydro One could advocate the community's position with the provincial and federal governments as well.
- Mike Penstone, Vice President of Planning, Hydro One suggested that what the Chief was describing was a federal jurisdictional issue. The land was not surrendered. Secondly, the status of First Nations as it relates to tax is also a federal issue that would have to be determined by the Canadian Revenue Agency.

- **Chief Maracle**: The Chief restated that the land was not surrendered.
- Mr. Penstone responded that he understands the Chief's argument, but it is an argument that needs to be made to the federal government.
- **Chief Maracle**: Chief Maracle asked why Hydro One does not just try it and see what the Canada Revenue Agency says.
- Mr. Penstone responded that this might be an option for the Chief.

Chief Wayne Pamajewon: The Chief began by describing an issue his community had related to a road. The province was involved, and the First Nations took them to task on that. Cottagers were pushing the province to build a road west of his community. The community knew that those lands were still theirs. All the blasting required to build that road affected the aquifer and wells dried up. The community had to fight INAC on that issue. His community drilled the well and successfully negotiated with the Ministry of Transportation. Now the community has a water station, which requires power to operate. The Chief noted that there are many power outages and as a result, the community had to purchase generators for the well and the facility. There are a number of outstanding expenses related to power failures.

- Mr. Schmidt commented that Hydro One formed a group specifically to deal with water station outages. On occasion they have supplied the province with generators and fuel in the past. Mr. Schmidt suggested that perhaps Hydro One could support First Nations in this way, with the support of the province and the OEB.
- **Chief Pamajewon:** The Chief responded that his community had already expended that money
- **Lee Anne:** Ms. Cameron suggested that they would ask Mr. Penstone to speak to this point in the next presentation.

SYSTEM INVESTMENTS

Mr. Mike Penstone, Vice-President, Planning, Hydro One

Mr. Penstone explained the power system within the PowerPoint presentation. He explained that the transmission system map shows the system that takes the power from the generation to "load centres" through high-voltage transmission lines. The Hydro One distribution system (map) does not support the entire province. It mostly supports the rural part of Ontario. So, for example, Toronto uses Toronto Hydro for a distribution system rather than Hydro One. Most First Nations are in rural areas and are served by the Hydro One distribution system. The number of assets within the transmission and distribution systems is enormous and Hydro One are one of the larger transmitters in North America.

Question from Chief Elaine Johnston: The Chief asked how Hydro One does not service Toronto and if there is some type of agreement.

- Mr. Penstone responded that within their transmission network, Hydro One brings power to Toronto's boundaries and then Toronto uses its own distribution network to reach customers. There are operational agreements in place, as the operations and investment need to be coordinated.
- Mr. Penstone noted that the primary causes of interruption are equipment failure (49%) and weather (18%). Hydro One has to spend money to maintain or replace equipment. This costs roughly $1.4B annually. He added that a lot of the equipment is from the 1950s and 1960s and is reaching end of life. It will need to be replaced and Hydro One needs to ensure there is the money to do that.

Chief McLeod: The Chief asked if the rates covered the delivery and upgrades

- Mr. Penstone responded positively.
- **Chief McLeod:** Chief McLeod noted that he runs a business and when upgrades are required it comes out of his profit. He wondered why Hydro One did not operate that way.
- Mr. Penstone responded that Hydro One collects money to cover ongoing costs of operating the business and providing reliable service is their business and requires upgrades. He also noted that Hydro One does have a net income and Mr. Hubert, Hydro One, would be able to explain that more in the next presentation.

Steven Nootchtai, Councillor: Councillor Nootchtai questioned whether there were investments in innovation or research in order to replace the old equipment.

- Mr. Penstone responded that yes, Hydro One invests in finding better, less costly ways of delivering reliable service. One potential innovation is drones. Utility companies can use them, but there is a lot of resource and development work that goes into determining how they could be used. Specialized drones can be used to inspect the lines for example. . Also they are looking at technology that can identify failures in the system to address them quickly.
- Mr. Penstone noted that Hydro One is maintaining reliability in the transmission system by increasing capital investments (lines) and leveraging technology. He noted that disruptions to the distribution system are most often caused by trees (24%) and equipment failure (24%).
- Vegetation management is a sensitive issue for customers and landowners all across the province because it involves cutting down trees. Hydro One recognizes that it is controversial but the company's focus is on reliability. However, Hydro One workers should not be surprising homeowners with action taken on their trees. They are working to notify homeowners prior to cutting.
- Related to First Nations distribution connections, they are often long, heavily treed lines. There is an impact on reliability for those reasons.

Question from Ms. Amy Lickers: Ms. Lickers wondered if these distribution connections are less likely to get three phase power.

- Mr. Penstone responded that he is referring only to the performance of the wire. It is a separate issue related to the demands for electricity. Converting lines from single to three phases is because of high consumption.
- Related to maintaining reliability of the distribution system, Mr. Penstone is looking to reduce the number of outages per year through the renewal program, tree trimming and the smart grid and shortening the length of outages through improved outage response, monitoring and control.
- Mr. Penstone noted that Hydro One asked customers about their priorities and they responded that the priority should be minimizing costs and less of a priority on improving reliability. The survey included 300 customers in First Nations communities.
- In order to control costs Hydro One is pacing expenditures, undertaking vegetation management and moving to mobile technology. He noted that Hydro One spent $100 million this year on vegetation management.

Chief Paul Eshkakogan: The Chief noted that this morning a Hydro One representative said that they could not do anything about poverty in First Nations communities, yet the company spent $1.4 billion on equipment. He asked what percentage of that goes into First Nations communities in terms of contracts and employment. He suggested that there should be more effort in integrating First Nations communities and business and helping them get a piece of that $1.4 billion. When it comes to procurement, terms like “best efforts” are not effective. He referred to the use of “set asides” or sole source contracts. He also noted that training is an important component. Communities are getting better at drafting and negotiating Impact Benefit Agreements (IBAs) with industry. He did, however, observe that Ontario and its Crown corporations are lagging behind other sectors when it comes to meaningful and capacity building opportunities for First Nations. The Chief would like to see a table developed to move this work around contracts and employment/training forward. As an example of his frustration, the Chief noted that even on the issue of vegetation management, they could not get anyone on the project because of a union issue. He reiterated that they need jobs in his community to pay the bills. The Chief expressed a desire to come to an agreement to continue the dialogue related to unlocking job and contracting opportunities for First Nations.

- Mr. Penstone agreed with the Chief and noted that there have been instances where First Nations communities provided material and services for projects. Mr. Penstone directed the comment to his colleagues in procurement.
- A Hydro One representative agreed with the Chief and suggested that they do a workshop with the community and their businesses in order to participate in the Hydro One sourcing events. He also commented that he supported the idea of a table for dialogue and is considering what that would look like from a strategic perspective. He agreed that they needed to start those discussions.
- **Chief Eshkakogan:** The Chief noted that that was pretty weak language and something they are used to hearing. He noted that he does not believe any company is going to work with First Nations, despite their best efforts. Rather, what will work is when communities have something of value like contract work in their hands, businesses will come to them. Hydro One can choose the company that they want to work with and allow the community to build capacity through that relationship. There is a lot that can be learned from each other. His community established the Lake Huron Transmission Company and participated in a procurement process on the east/west line. It was ultimately not successful but it was a good learning process. Hydro One should be unbundling larger contracts to support First Nations, as they likely do not have enough capacity to do the full contracts. The Chief concludes that there are many things that can be done and companies that could partner with First Nations. In addition, he offered to make himself available to work on this issue with Hydro One.

Chief Patricia Big George: The Chief asked why Hydro One does not move forward on sole source processes for First Nations. Also, related to the work around vegetation control, the Chief asked where to find out more information.

- Mr. Penstone noted that a description of where they spend their money and how is included in all applications to the OEB. They are on the OEB website and they are also on the Hydro One website. The descriptions go into a great deal of detail. Hydro One staff would provide the links to those websites.

Chief Elaine Johnston: Chief Johnston expressed some concern about the survey, which determined that cost was more important than reliability. She noted that clearly they needed to deal with the high bills, but they also need reliable lines. Reliable lines are needed for economic development initiatives to work; it is how the community functions. She asked what plan was in place for those lines that are unreliable. She suggests perhaps a pilot project for other initiatives to deal with reliability.

- Mr. Penstone responded that the customer survey was only to determine customer priorities. Hydro One is not using the survey to justify ignoring the reliability aspects of the lines. He reassured the attendees that Hydro One continually monitors performance and where it is bad or degrading they will make investments. When lights go out in the community there are health and safety impacts. This is also part of determining where investments in reliability are made.

DISTRIBUTION RATE FILING (2018-2022)

Mr. Oded Hubert, Vice-President, Regulatory Affairs, Hydro One

Mr. Hubert described how Hydro One is going to the OEB with a distribution rate application that, if approved, would provide the necessary Revenue Requirement to operate the system for the next five years (2018-2022). This is the standard application that Hydro One has to complete (from now on, every five years). It is completely separate from the policy decision around a First Nations rate that the Minister will decide on.

To assist the OEB's work on a First Nations rate,

- Hydro One has given the OEB a significant amount of information to make their determination including the size of bills and the amount of the delivery charge compared to the commodity charge.

Also, the Premier asked Hydro One, among others, for advice on providing relief to rural customer, given that the delivery charge is often higher than the commodity charge.

Chief Elaine Johnston: wondered what was the difference between the All-Ontario rate and the First Nations rate.

- Mr. Hubert responded that the general distribution delivery rate is for all Hydro One customers. The Minister will decide the First Nations rate and then the Minister will tell the OEB what the First Nations rate will be. The general rates (other than the First Nations rate) are determined by the OEB, through Hydro One's application.
- Hydro One is filing this submission at the end of March and is looking for input before it is completed. Included in the submission will be results from the customer engagement surveys, and also the notes from this meeting. There are some First Nations that have actually represented themselves at the OEB, so there is a voice for First Nations at the hearings.

Chief R. Donald Maracle: thanked Hydro One for advocating for a reduction in the rates paid by First Nations. He asked if First Nations would benefit from the rural/remote reduction.

- Mr. Hubert responded that everyone within the R2 classification already receives a subsidy on their bills automatically.
- **Chief Maracle:** The Chief inquired as to the total profits for Hydro One last year.

Mr. Hubert responded that this figure is available online (Hydro One Limited's consolidated Net Income for 2016 was $721 M).

First Nations Representative [name unknown]: The participant wondered about the implications for members that do not live on reserve.

- Mr. Hubert noted that the Minister's letter which asked them to explore the idea of a First Nations rate specified on-reserve customers only.

- **First Nations Representative:** First Nations leadership has a responsibility for all of their members, no matter where they live.
- **Chief McLeod:** The Chief noted that it is a huge concern, if the rates for off-reserve First Nations go up; while on-reserve it goes down.

Chief R. Donald Maracle: Chief Maracle asked if hydro rates overall are going up 10% next year

- Mr. Hubert responded that not according to Hydro One's numbers. The PowerPoint presentation will explain further.
- Slide 6 showed the breakdown of electricity costs to customers. The diagram represents an average customer: 51% goes to electricity generation, 37% goes to Hydro One delivery charges, 5% is a sales tax, 3% is regulatory charges and line losses represent 4%.

Chief Elaine Johnston: Chief Johnston wondered why rates had increased so much.

- Mr. Hubert responded that the increase is due to a few factors: the increased cost of electricity, the move to eliminate coal, renewable energy and infrastructure costs.
- Slide 7 showed how distribution charges are spent by Hydro One: preventing outages (47%), upgrading the system (21%), customer service (12%), responding to power outages (10%), and information technology (7%) and, administration (3%).
- The next slide details how distribution rates are set by the OEB.
- Mr. Hubert explained that this year Hydro One could earn an allowed profit (Return on Equity) of about 8.78%.
- Slide 10 identifies the stages in developing and submitting an application to the OEB including preliminary matters (3-4 months), issues and discovery (2-3 months), hearing (3-4 weeks), and decision and approvals (2-4 months). In total, the process usually takes 8-12 months.
- Slide 11 shows that the Hydro One application must balance key considerations including customer needs and preferences, rate impact and asset needs.
- Related to customer needs and preferences, Hydro One called about 800 customers including 300 First Nations people. In general, First Nations had greater levels of dissatisfaction, more cost sensitivity and placed greater importance on keeping costs low. In general, the First Nations surveyed would accept a 1% bill increase if they saw some improvement in service. Many findings were similar with the non-First Nations respondents.
- Mr. Hubert's presentation also noted that shrinking consumption so the cost serving each consumer has to go up.

First Nations Representative [Name Not Heard]: The participant asked if the seasonal rate is more than the rural rate 2 (The R2 rate).

- Karen Taylor, Hydro One**,** explained that the charge is based on how much a customer consumes. She noted that the OEB is looking at moving those into fixed monthly charges and eliminating the variable component.
- Mr. Hubert noted that Hydro One is asking the OEB for rates for five years and will not be going back except for minor adjustments. However, over the five years, Hydro One can continue to search for productivity savings, innovations, and better technology and reduce costs. This could lead to more profit, but Hydro One has committed that if it were

more than a 1% increase above the allowed ROE, the additional profit would be shared 50/50 with customers.

Chief Patricia Big George: Chief Big George asked if this would affect the First Nations rate.

- Mr. Hubert responded that it would not change the First Nations rate and that they would all have to see how the First Nations rate unfolds.

Chief Elaine Johnston: Chief Johnston asked what is causing the decreasing consumption.

- Mr. Hubert responded that it was mostly due to conservation activities and economic conditions.
- Mr. Hubert concluded that the participants can send any additional questions via email.

WRAP UP

The Facilitator closed the meeting by mentioning that the PowerPoint presentations would be available. In addition, pictures of the artwork and copies of the notes will be distributed.

Summary points:

- Where they went from here will be determined by relationship building that will continue. There will be ongoing meetings set up including community meetings.
- Please judge Hydro One based on actions and results over the next five years.

The closing prayer was done by Elder Andrew Wesley.

Meeting Adjourned.

1.4 (5.2.3) PERFORMANCE MEASUREMENT AND OUTCOME MEASURES

The Renewed Regulatory Framework (RRF) is an outcomes-based approach to regulation. Hydro One recognizes the need to demonstrate how it will achieve the four RRF outcomes: customer focus, operational effectiveness, financial performance and public policy responsiveness. The Electricity Distributor Scorecard, including the targets (Exhibit A, Tab 5 Schedule 1), shows Hydro One's success achieving these outcomes and the performance levels that Hydro One expects to achieve over the 2018 to 2022 rate setting period.

In addition to the measures already reported through this scorecard, Hydro One is proposing to report on several additional performance measures in its Distribution Scorecard that also demonstrate the distribution system outcomes the Company provides. Hydro One is committed to both sets of performance measures as it evaluates its progress executing its 2018 to 2022 investment plan that aligns the needs and preferences of customers, compliance and condition needs of Company assets, and rate impacts. Hydro One's plan has a number of initiatives that control costs, increase productivity and maintain levels of reliability in rural and urban areas. These are all outcomes that customers have indicated they value, are central to Hydro One's Business Objectives, and the OEB's Renewed Regulatory Framework.

1.4.1 (5.2.3 A AND B) METHODS AND MEASURES

In considering outcome measures to be included in scorecards, Hydro One identified potential metrics drawn from internal and external sources that include Hydro One's past performance management metrics, benchmarking studies, and scorecards and metrics of other utilities in the public domain. The selection process was also guided by the OEB's

Handbook for Utility Rate Applications, which indicates the OEB will evaluate proposed outcomes and performance metrics using the following key considerations:

- A focus on strategy and results, not activities;
- The need to demonstrate continuous improvement;
- Outcomes that are demonstrated to be of value to customers; and
- Performance metrics that will accurately measure whether outcomes are being achieved, and that include stretch goals to demonstrate enhanced effectiveness and continuous improvement.

The Distribution OEB Scorecard provided in the table below, includes the metrics that Hydro One is proposing to report on and includes targets for 2018. Hydro One proposes to report the results on an annual basis or as determined by the OEB. As described in the attached Productivity Reporting Governance Document (DSP Section 1.4, Attachment 1), Hydro One operations managers and the Executive Leadership Team will be reviewing progress on these metrics on a regular basis. This reporting and governance structure will allow Hydro One's management to assess progress towards targets and determine corrective action, when warranted, to help ensure that a performance or outcome measure is effective and does not result in unintended consequences. Hydro One will be considering these metrics in its business planning processes and will be setting new targets on an annual basis.

Table 8 – Distribution OEB Scorecard

			Historical Results						Target	
RRF Outcomes		Measure	2011	2012	2013	2014	2015	2016	2017	2018
Customer Focus	Customer Satisfaction	Customer Satisfaction - Perception Survey %	77%	78%	80%	67%	70%	66%	72%	74%
		Handling of Unplanned Outages Satisfaction %	81%	79%	78%	75%	76%	75%	76%	77%
		Call Centre Customer Satisfaction %	85%	84%	82%	81%	85%	86%	86%	87%
		My Account Customer Satisfaction %	81%	84%	64%	75%	78%	79%	81%	83%
Operational Effectiveness	Cost Control	Pole Replacement - Gross Cost Per Unit in $	8,541	8,441	7,824	8,928	8,392	8,350	8,640	8,733

Customer Focus Measures

Customer Satisfaction – Perception Survey %

Hydro One included this metric for reporting as part of its previous distribution rates application (EB-2013-0416), referred to as 'Residential and Small Business Satisfaction' at that time. Hydro One proposes to continue reporting this metric as part of this Application. Hydro One measures customers' perception of the Company as a whole, whether they have interacted with Hydro One recently or not. The survey indicates how well the Company meets customers' expectations. The perception surveys are conducted twice per year by an external service provider, who contacts randomly selected customers. The reported results reflect what customers have indicated as their overall satisfaction with Hydro One. Although the results may be influenced by the overall price of electricity on a customer's bill, Hydro One still seeks to improve its score on this measure.

Handling of Unplanned Outages Satisfaction

Hydro One began reporting this metric as part of its previous distribution rates application (EB-2013-0416) and proposes to continue reporting it as part of this Application. This metric measures customers' satisfaction of Hydro One's handling of a customer's last unplanned outage. The Handling of Unplanned Outages was indicated as a source of frustration for customers during recent customer consultation, as described in Section 1.3 of the Distribution System Plan. Satisfaction is measured through the results of a survey that Hydro One conducts in two segments per year, targeting 1,200 interviews per segment. The telephone survey contacts a random sample of customers that have called into Hydro One's customer centre over the previous 12 months. Customers are asked if they have experienced an unplanned outage over the last 6 months. Those respondents that answer "yes" are then asked how satisfied they are with the way Hydro One handled the most recent unplanned outage.

Call Centre Customer Satisfaction

This metric is newly proposed as part of this Application and is intended to measure customer satisfaction with services provided by Hydro One's call centre, which is often the first point of contact Hydro One has with a customer when they have a question or an issue that needs to be resolved. Customer satisfaction after the call is a strong indication of whether or not a customer inquiry has been addressed appropriately. This metric demonstrates that services are being provided in a manner that is responsive to customer needs. The call centre customer satisfaction survey occurs shortly after the phone call, which allows the call centre to capture timely and accurate information and to address any areas for improvement.

My Account Customer Satisfaction

This metric is newly proposed as part of this Application and is intended to measure customer satisfaction with services delivered by Hydro One's My Account web portal. My Account allows customers to find the information they need so that they can manage their bills and electricity usage. With My Account, Hydro One is able to provide customers with the information and services they are seeking in a convenient, efficient manner. This measure will demonstrate whether the services are being provided in a manner consistent with customer expectations. The satisfaction level is determined by using an online survey, which is emailed to customers through a third party and contains a link inviting them to take part in the survey. This email is sent out to customers who have accessed and logged on to My Account within the past two days.

Operational Effectiveness Measures

Hydro One's customers have indicated that effective cost management and efficiency are outcomes that they value. The following metrics are designed to measure and track Hydro One's operational effectiveness.

Pole Replacement – Cost per Pole

This metric is newly proposed as part of this Application. This cost per unit metric will demonstrate how successful Hydro One is in delivering productivity improvement in this area. In addition, the pole replacement program has been an area of interest in previous applications, with the OEB directing Hydro One to complete a benchmarking study to support this Application. Hydro One completed this study through Navigant and First Quartile, which can be found in Section 1.6 of the Distribution System Plan. This metric will allow for benchmarking over time and will allow for cost per unit comparisons with other distributors. There are many factors that could impact the average cost per pole such as whether it is going into earth or rock, or the height and type of pole required. These circumstances will change the cost of poles and will cause fluctuations within the program, which is why the programs cost per unit should be viewed as a trend versus an individual year. In addition to providing useful information on cost trending, variances in performance between periods will also inform management on factors affecting costs and enable corrective actions and improvements to be made.

$$= \frac{Total\ Cost\ of\ Pole\ Replacement\ Program}{Number\ of\ Poles\ Replaced}$$

Vegetation Management – Cost per KM

This metric is newly proposed as part of this Application. This cost per unit metric will demonstrate how successful Hydro One is at delivering productivity improvement in its vegetation management program. In addition, this program has been an area of interest in previous applications, with Hydro One directed by the Board to complete a benchmarking study to support this Application. Hydro One has completed this study through CN Utility Consulting, Inc., which can be found in Section 1.6 of the

Distribution System Plan. This metric will allow for benchmarking over time and will allow for cost per unit comparisons with other distributors.

There are many factors that affect the average cost per unit for vegetation management, including the density of vegetation and the remoteness of the location. These factors have a significant impact on the costs related to the program which is why the average cost per unit should be viewed as a trend rather than an individual year. This measure is the dollar cost per km of cyclical line cleared.

$$= \frac{Cost\ of\ Forestry\ Cyclical\ Line\ Clearing}{KM's\ of\ Line\ Cleared}$$

Station Refurbishment MVA – Cost per Unit

This metric is newly proposed as part of this Application. This cost per unit metric will demonstrate how successful Hydro One is in delivering productivity improvement in its station refurbishment projects. This has been an area of interest in previous applications. As a result, the OEB directed Hydro One to complete a benchmarking study to support this Application. Hydro One has completed this study through Navigant and First Quartile, which can be found in Section 1.6 of the Distribution System Plan. Every station refurbishment project has a different scope of work that will change the total cost per project. As a result this metric should be viewed as a trend over a number of years. This metric will allow for benchmarking over time and will allow for cost per unit comparisons with other distributors, as well as inform management of the potential for improvements and aid in setting improvement targets.

$$= \frac{Total\ Cost\ of\ Station\ Refurbishment\ Program}{Total\ Stations\ MVARefurbished}$$

Note that the cost per MVA only considers projects which have a station MVA of less than 10 MVA. Including projects greater than 10 MVA would cause large cost fluctuations from year to year depending on how many were included due to the significantly lower per MVA cost. The smaller MVA category shows the most potential for improvement as it has the highest historical cost per MVA. This covers approximately 75% of the station refurbishment projects in 2018.

<u>OM&A cost per Customer</u>

This metric is newly proposed as part of this Application. Through the customer consultation process, residential and small business customers indicated that cost is their top priority and Large Customers indicated it was among their top priorities. This metric will help demonstrate how successful Hydro One is in delivering productivity improvement through OM&A reductions. This metric will also allow for benchmarking and cost comparison over time for Hydro One as well as comparisons with other comparable utilities.

$$= \frac{Total\ OM\&A}{Number\ of\ Customers}$$

<u>OM&A Expense per km of Line</u>

This metric is newly proposed as part of this Application. Through the customer consultation process, residential and small business customers indicated that cost is their top priority and Large Customers indicated it was among their top priorities. This metric will help demonstrate how successful Hydro One is in delivering productivity improvement through OM&A reductions. This metric will also allow for benchmarking and cost comparison over time for Hydro One as well as comparisons with other comparable utilities.

$$= \frac{Total\ OM\&A}{Number\ of\ line\ km's}$$

Witness: Michael Vels/Greg Kiraly/Darlene Bradley

<u>Line Equipment Caused Interruptions</u>

Hydro One began reporting this metric as part of its previous distribution rates application (EB-2013-0416) and proposes to continue reporting it as part of this Application. This metric is a count of the total number of outages caused by line equipment failures on an annual basis. Customers indicated, in general, that they value sustaining current reliability levels while managing rate impacts and effective cost management. This metric demonstrates the outcome of Hydro One's capital and maintenance programs in terms of line equipment caused outages. Benchmarking, over time, will demonstrate Hydro One's success in maintaining reliability and how effective Hydro One has been in the spending of resources on areas of the system that are in need.

$$= Line\ Equipment\ Caused\ Outages$$

<u>Vegetation Caused Interruptions</u>

Hydro One previously agreed to report this metric as part of EB-2013-0416. This metric is a count of the total number of vegetation-caused outages on line equipment on an annual basis. Visibility to the vegetation-caused outages allows for focus to be placed on those areas with less than optimal performance while ensuring Hydro One's on-cycle program for critical feeders is delivering good performance. Ultimately, the expected outcome and customer benefit of the vegetation management program is a reduction in vegetation-caused outages. This metric is directly impacted by the number of kilometres that were managed over many years and is not immediately impacted by the number of kilometres managed in the current or previous year. As a result this is a lagging indicator of the outcomes of the vegetation management program.

$$= Total\ Vegetation\ Caused\ Interruptions$$

Substation Caused Interruptions

Hydro One previously agreed to report this metric as part of EB-2013-0416. This metric is a count of the total number of substation equipment failure outages. Substation equipment failures often cause outages that are significantly longer in duration compared to vegetation-caused outages. This, in part, is due to limitations in transfer capabilities on Hydro One's network. Hydro One will manage these events by tracking these failures and adjusting the pace of substation refurbishment programs to align with customer expectations on system reliability. This metric is intended to measure the effectiveness of Hydro One's distribution station refurbishment program, through which Hydro One is endeavoring to reduce the cost per unit as demonstrated in the Station Refurbishment MVA Cost per Unit metric.

$$= Total\ Substation\ Caused\ Interruptions$$

SAIDI – Urban

This metric is newly proposed as part of this Application. Distinguishing between rural and urban reliability provides a better basis for benchmarking to other utilities and a higher quality metric for internal comparison. The Electricity Distributor Scorecard includes the Hydro One System Average Interruption Duration Index ("SAIDI") for the overall system. The SAIDI-Urban metric tracks the duration of interruptions for Hydro One's urban areas only and Hydro One is targeting to keep the performance of this measure consistent with historical results in the medium term, which aligns with customer expectations.

$$= \frac{Total\ Urban\ Customer\ Hours\ of\ Interruption}{Total\ Urban\ Customers\ Served}$$

Witness: Michael Vels/Greg Kiraly/Darlene Bradley

SAIFI – Urban

This metric is newly proposed as part of this Application. The Electricity Distributor Scorecard includes the Hydro One System Average Interruption Frequency Index ("SAIFI") for the overall system. The SAIFI – Urban metric tracks the frequency of interruptions for the urban areas only. Hydro One is targeting to keep the performance of this measure consistent with historical results in the medium term, which aligns with customer expectations.

$$= \frac{Total\ Urban\ Customer\ Interruptions}{Total\ Urban\ Customers\ Served}$$

SAIDI – Rural

This metric is newly proposed as part of this Application. The Electricity Distributor Scorecard includes the Hydro One SAIDI for the overall system. The SAIDI-Rural metric tracks the duration of interruptions for the rural areas only and Hydro One is targeting to keep the performance of this measure consistent with historical results in the medium term, which aligns with customer expectations.

$$= \frac{Total\ Rural\ Customer\ Hours\ of\ Interruption}{Total\ Rural\ Customers\ Served}$$

SAIFI – Rural

This metric is newly proposed as part of this Application. The Electricity Distributor Scorecard includes the Hydro One SAIFI for the overall system. The SAIFI-Rural metric tracks the frequency of interruptions for the rural areas only. Hydro One is targeting to keep the performance of this measure consistent with historical results in the medium term which aligns with customer expectations.

$$= \frac{Total\ Rural\ Customer\ Interruptions}{Total\ Rural\ Customers\ Served}$$

Large Customer Interruption Frequency Large Distribution Accounts (LDAs)

This metric is newly proposed as part of this Application. During the customer engagement process, Large Distribution Accounts ("LDA") informed Hydro One that their top priority was interruption frequency as even a short outage could have major financial impacts to their operations. Hydro One will track this new measure to address this specific reliability concern. The goal is to improve performance compared to historical results. This metric tracks the total number of sustained interruptions to all LDA customers connected to Hydro One.

$$= \frac{Total\ Interruptions\ for\ Large\ Distribution\ Customers}{Total\ Large\ Distribution\ Customers\ Served}$$

1.4.2 OUTCOME MEASURES: EB-2013-0416

In its previous distribution rate Application (EB-2013-0416), Hydro One submitted a list of outcome measures for future reporting. The measures and the results have been captured in Table 9 below. From the measures listed in the table below, Vegetation Caused Interruptions, Substation Caused Interruptions, Distribution Line Equipment Caused Interruptions, Handling of Unplanned Outages Satisfaction, and Residential and Small Business Satisfaction are metrics that Hydro One proposes to continue reporting in the future.

Table 9 – Outcome Measures from EB-2013-0416

Year	Actual		
	2014	2015	2016
Vegetation Caused Interruptions	6,540	6,944	7,674
Substation Caused Interruptions	158	141	103
Distribution Line Equipment Caused Interruptions	8,311	8,164	7,439
Number of Replaced Poles	11,179	11,837	12,355
Number of Pole Top Transformers with PCB Oil	NA	34	347
Residential and Small Business Satisfaction (%)	67%	70%	66%
Handling of Unplanned Outages Satisfaction (%)	75%	76%	83%
Estimated Bills Issued as % of Total Issued*	NA	4%	NA

***No longer measured, replace by bill accuracy measure**

Hydro One proposes to cease reporting the Number of Replaced Poles and Number of Pole Top Transformers with PCB Oil, as these measures are activity-based, which is not consistent with the intent of the RRF. Hydro One has replaced these measures with cost per unit metrics, which are consistent with the intention of the RRF in terms of demonstrating continuous productivity improvement. Hydro One proposes to cease reporting the Estimated Bills Issued as a % of Total Bills Issued as it believes this is adequately covered under the Billing Accuracy metric already reported on Hydro One's Electricity Distributor Scorecard.

Witness: Michael Vels/Greg Kiraly/Darlene Bradley

1.4.2.1 RELIABILITY RESULTS

This section contains the reliability statistics for the historic period from 2012 to 2016.

Customer interruptions are analyzed and reported internally throughout the year. Interruption data is collected and recorded in the Distribution Operations and Maintenance Centre (part of Ontario Grid Control Centre) through communications with field staff involved in the interruption restoration. It is input into a database system called Outage Response Management System, which provides data for in-depth performance analysis to drive strategy and business investment decisions.

Interruption data is used to calculate the OEB reliability indices monthly, and results are reported internally. There is ongoing analysis of approximately 40,000 annual interruptions. Trends of frequency, duration, cause of interruptions, feeders, location, and other factors, are analyzed to allow prioritization of maintenance and capital programs on the distribution system.

Measures

Reliability is measured in terms of the duration of outages (SAIDI), the frequency of outages (SAIFI) and the average interruption time ("CAIDI"). The SAIDI, SAIFI and CAIDI statistics for the last five years are included in the tables below. For the distribution system as a whole, both SAIDI and SAIFI are reported with and without Loss of Supply ("LOS") and Force Majeure ("FM") events. In addition, details of the outages in terms of outage cause are also included. These statistics are reported including LOS and FM.

Duration of Interruptions (SAIDI)

The average numbers of hours that distribution customers served by Hydro One were without power in the year.

Frequency of Interruptions (SAIFI)

The average number of times that distribution customers served by Hydro One were interrupted in the year.

Average Interruption Time (CAIDI)

The average interruption duration (in hours) of Distribution customers who were interrupted. $(CAIDI = SAIDI \div SAIFI)$

The above reliability indices measure all interruptions caused by planned and unplanned interruptions of one minute or more.

Force Majeure

Hydro One deems a *force majeure* to have occurred when a storm or other event(s) causes the interruption of 10% of customers or more and causes a change in normal restoration business processes. All Hydro One customers interrupted throughout the duration of the event while normal restoration business processes are suspended are counted in the determination of the numerator of the percent interrupted. The denominator is the total number of customers served at the end of the month when the force majeure occurred. Details of all *force majeure* events that have occurred from 2012 to 2015 are provided below.

2012 Force Majeure Events

In 2012, there were four force majeure events.

- From March 2 to 4, an early spring storm that tracked up from Texas across Lake Huron and Georgian Bay to Lake Nipissing dragged a sharp cold front with strong winds from east to west across Southern Ontario. The winds reached up to 105 km/h along the Niagara Peninsula. This event affected 173,000 or about 14% of customers.
- From July 23 to 26, a strong lightning/thunderstorm, with hail and winds gusting up to 110 km/h moved through southeast Ontario and crossed over the Northeast areas. This storm caused widespread damage and affected 158,000 or about 13% of customers.
- From October 29 to 31, remnants of Hurricane Sandy, including winds moving up to 100 km/h, moved across Southern Ontario from the lower Great Lakes passing through Sarnia, Georgian Bay and the Niagara region. The combination of strong winds and residual leaves on trees caused power outages due to falling limbs and downed trees snapping power lines. This event affected 258,000 or about 21% of customers.
- From December 21 to 23, Environment Canada issued a weather warning for Eastern and Northern Ontario when up to 30 cm of snow fell in these regions. This winter storm caused severe damage to the distribution system; heavy wet snow and high winds caused trees to contact distribution lines. This event affected 147,000 or about 12% or customers.

These storms resulted in a contribution to the annual SAIDI of 3.9 hours and annual SAIFI of 0.6 interruptions per customer.

2013 Force Majeure Events

In 2013, there were seven force majeure events.

- From April 12 to 16, Environment Canada issued a weather warning when a slow moving low pressure system combined with Artic air to produce a mix of snow, rain, ice pellets and freezing rain over Southern Ontario. It laid down a blanket of 2 to 4 cm of snow and ice pellets in a band from Toronto to Lake Huron. The storm was accompanied by gusting winds of up to 65 km/h that caused downed tree limbs resulting in widespread power outages. This event affected 419,000 or about 34% of customers.
- From May 21 to 24, a tornado warning was issued by Environment Canada when two clusters of thunderstorms made their way through Southern Ontario. Both tornadoes were accompanied by intense lightning, hail, heavy downpours and wind gusts of up to 100 km/h that caused broken poles and downed trees. This event affected 147,000 or about 12% of customers.
- From May 31 to June 3, a line of thunderstorms with winds up to 90 km/h moved through Southern and Central Ontario. Hail, heavy rain and frequent lightning accompanying the storm caused widespread outages. This event affected 121,000 or about 10% of customers.
- From July 19 to 23, scattered thunderstorms moved over Northwestern Ontario accompanied by wind gusts of 90 km/hour, hail greater than 2 cm in diameter and downpours of up to 50 mm. At the same time, isolated thunderstorms moved over Southern and Central Ontario that were also accompanied with high winds, hail and heavy rain. Both incidents resulted in power interruptions to 434,000 or about 35% of customers.
- From November 1 to 3, a Colorado low pressure system bought rain and high winds to much of Southern Ontario. The winds reached speeds of up to 100 km/h in areas near Lake Erie and Lake Ontario. This event affected 315,000 or about 25% of customers.
- From November 17 to 19, another low pressure system from Colorado caused a strong cold front with heavy winds of up to 90 km/hour for much of South Western

and South Central Ontario. This event impacted both the distribution and transmission system and caused interruptions to 367,000 or about 28% of customers.

- From December 21 to 29, a low pressure system originating in Texas collided with a warm front causing up to 40 mm of freezing rain, snow and ice pellets to spread into Southern and Southwestern Ontario. As a result, ice accumulated on tree branches causing wide spread outages from downed trees. After the storm passed, light rain continued with extreme cold temperatures causing ice accumulation of up to 30 mm on surfaces and tree branches. The ice storm was followed by a windstorm of up to 55 km/hr that caused the ice-covered tree branches to contact distribution lines. This ice storm affected 585,000 or about 46% of customers.

The effect of these storms resulted in a contribution to the annual SAIDI of 20.1 hours and annual SAIFI of 1.8 interruptions per customer.

2014 Force Majeure Events

In 2014, there were two force majeure events.

- From September 5 to 6, a thunderstorm with large hail, high winds greater than 75 km/h, and heavy rain moved over Northwestern Ontario, Northeastern Ontario, Georgian Bay, Central Ontario, and Southern Ontario. This event affected a total of 137,000 or about 11% of customers.
- From November 24 to 25, strong wind storms passed through Southern Ontario with sustained wind speeds of 60 to 70 km/h. Gusts of 90 to 100 km/h passed through north of Lake Erie and Lake Ontario, Central Ontario, Grey /Bruce area and the GTA. Northeastern Ontario experienced freezing rain and snow with accumulations of up to 30 cm. This event affected a total of 238,000 or about 18% of customers.

The effect of these storms resulted in a contribution to the annual SAIDI of 2.0 hours and annual SAIFI of 0.3 interruptions per customer.

2015 Force Majeure Events

In 2015, there were three force majeure events.

- From August 1 to 4, a severe thunderstorm with wind speeds of up to 55 km/h, lightning and heavy downpours passed through Southern Ontario causing tree branches to fall on various portions of the power lines. This event caused interruptions to 144,000 or about 11% of customers.
- From November 6 to 9, a strong wind storm passed through Southwestern Ontario, Northwestern Ontario and Georgian Bay with wind speeds of up to 100 km/h. The high speed winds damaged poles and caused broken tree branches to fall on the lines causing power outages. This event caused interruptions to 277,000 or about 21% of customers.
- From December 24 to 26, a strong wind storm passed through Southwestern Ontario along the shores of Lake Huron with wind speeds of 70 to 90 km/h, damaging poles and causing tree branches to fall on various portions of the lines, which resulted in severe widespread outages. This event caused interruptions to 189,000 or about 14% of customers.

The effect of these storms resulted in a contribution to the annual SAIDI of 4.6 hours and annual SAIFI of 0.5 interruptions per customer.

2016 Force Majeure Events

In 2016, there were three force majeure events.

- From February 24 to 25, a winter snow storm with freezing rain and wind gusts between 60 and 80 km/h, travelled from Southern and Western Ontario towards Eastern Ontario. This late winter storm caused several power interruptions, affecting approximately 135,000 or 10% of Hydro One customers.
- From March 24 to 28, a severe ice storm with freezing rain and wind gusts of 70 to 90 km/h, hit Ontario causing wide-spread damage. Damage from the ice and wind, as well as fallen trees and branches caused several outages. In total this event impacted approximately 371,000 or 28% of Hydro One customers.
- From July 8 to 9, a severe thunderstorm moved across Ontario from the west to the east, causing extensive power interruptions. This event impacted approximately 143,000 or 11% of Hydro One customers.

Reliability Summary

The historical results for the past five years for SAIDI, SAIFI and CAIDI are provided below in Tables 10, 11, and 12, respectively. Results have been provided including and excluding both Loss of Supply (LOS) and Force Majeure (FM). From 2012 to 2016, reliability performance (SAIDI and SAIFI) excluding FM and LOS has generally been constant at 7.3 hours and 2.6 timers per customer per year. SAIDI and SAIFI for the overall system have generally deviated by less than 6% from the five-year average for the period. Force Majeure events increased these statistics, on average, by 90% for SAIDI and 25% for SAIFI. Loss of Supply also increased these statistics, on average, by 5% for SAIDI and 15% for SAIFI. As highlighted above, a number of storms in 2013 dramatically increased the frequency and duration of outages as can be seen in the tables and figures below. CAIDI is derived by dividing SAIDI by SAIFI. As a result, the performance of this measure is largely explained by the performance of SAIDI and SAIFI, as discussed above.

SAIDI and SAIFI by outage cause is provided in Tables 13 and 14. Tree contacts were the most common cause of outages for most years, followed by defective equipment.

Table 10 - Historical SAIDI Summary

Outage Cause	2012	2013	2014	2015	2016
Including LOS and Including FM	11.3	27.4	9.9	12.9	13.2
Including LOS and Excluding FM	7.5	7.3	7.9	8.3	8.3
Excluding LOS and Including FM	10.6	26.6	9.4	12.2	12.6
Excluding LOS and Excluding FM	7.0	6.9	7.4	7.6	7.8

1.4.3 (5.2.3 C) HOW THE PLAN REFLECTS PERFORMANCE MEASUREMENT AND OUTCOME MEASURES

The productivity and outcome measures discussed above are used to drive continuous improvement in asset management planning, work execution, and in customer oriented performance. The table below summarizes the alignment of Hydro One's performance measures with its Business Objectives and the corresponding RRF Outcomes.

Table 16 - Hydro One Business Objective Alignment with Performance Measures

RRF Outcomes	Hydro One Business Objectives	Performance Measures
Customer Focus Services are provided in a manner that responds to identified customer preferences	Improve current levels of customer satisfaction	• Handling Unplanned Outages Satisfaction % • Call Centre Customer Satisfaction % • My Account Customer Satisfaction % • New Residential/Small Business Services Connected on Time • Scheduled Appointments Met On Time • Telephone Calls Answered On Time • First Contact Resolution • Billing Accuracy • Customer Satisfaction Survey Results
	Engage with our customers consistently and proactively	• Used to inform outcomes
	Ensure our investment plan reflects our customers' needs and desired outcomes	• Used to inform outcomes
Operational Effectiveness Continuous improvement in productivity and cost performance is achieved; and distributors deliver on system reliability and quality objectives	Actively control and lower costs through OM&A and capital efficiencies	• Total Cost per Customer • Total Cost per km • OM&A per Customer • OM&A per km of Line • Pole Replacement –Cost per Unit • Vegetation Management – Cyclical Cost per km Line Clearing • Station Refurbishments – Cost per MVA

RRF Outcomes	Hydro One Business Objectives	Performance Measures
	Achieve and maintain employee engagement	• Drives company culture leading to improved Operational Effectiveness
	Drive towards achieving an injury -free workplace for employees and the public	• Drives company culture leading to improved Operational Effectiveness • Level of Public Awareness • Level of Compliance with Reg 22/04 • Number of General Public Incidents
	Provide reliability consistent with customer requirements.	• Average Number of Times that Power to a Customer is Interrupted • Average Number of Hours that Power to a Customer is Interrupted • Rural and Urban SAIFI • Rural and Urban SAIDI • Large Customer Interruption Frequency • Number of Substation Caused Interruptions • Number of Vegetation Caused Interruptions • Number of Line Equipment Caused Interruptions • Distribution System Plan Implementation Progress
Public Policy Responsiveness Distributors deliver on obligations mandated by government (e.g., in	Ensure compliance with all codes, standards, and regulations	• Monitored by the applicable business unit(s)
	Partner in the economic success of Ontario	• Monitored by the applicable business unit(s)

RRF Outcomes	Hydro One Business Objectives	Performance Measures
legislation and in regulatory requirements imposed further to Ministerial directives to the Board).	Sustainably manage our environmental footprint	• Net cumulative energy savings • Renewable Generation Connection Impact Assessments completed on time • New Micro-embedded facilities connected on time
Financial Performance Financial viability is maintained; and savings from operational effectiveness are sustainable.	Achieve the ROE allowed by the OEB	• Current Ratio (Current Assets/Current Liabilities) • Return on Equity (deemed) • Return on Equity (achieved) • Total Debt to Equity

INVESTMENTS DRIVING BUSINESS PERFORMANCE

The following sections demonstrate how the planned investments will enable Hydro One to achieve its Business Objectives and the corresponding targets set for its productivity and outcome measures. The impact of each material investment within the DSP is summarized below by OEB Performance Outcome and corresponding Hydro One Business Objectives.

1.4.3.1 CUSTOMER FOCUSED PROJECTS

The RRF Customer Focus Outcome aligns with Hydro One's business outcomes to improve current levels of customer satisfaction, engage with our customers consistently and proactively, and ensure our investment plan reflects the Company's customers' needs and desired outcomes. Hydro One has historically measured the degree to which it is meeting the objective of increasing customer satisfaction with the OEB scorecard measures:

- New Residential/Small Business Services Connected on Time;
- Scheduled Appointments Met on Time;
- Telephone Call Answered on Time;
- Customer Satisfaction Survey Results;
- First Contact Resolution; and
- Billing Accuracy.

In addition to the OEB scorecard measures, Hydro One has added four additional measures to better measure the level of customer satisfaction:

- Customer Satisfaction – Perception Survey %;
- Handling of Unplanned Outages Satisfaction;
- Call Centre Customer Satisfaction; and
- My Account Customer Satisfaction.

The following investments are targeted at improving customer satisfaction and are expected to positively impact the measures used to monitor customer satisfaction.

Worst Performing Feeders ISD SS 06.

This investment will facilitate capital works to improve performance on Hydro One's feeder performance outliers. The strategy for this investment is to focus on distribution system areas that are reliability performance outliers. This approach will keep system performance statistics stable and control capital costs by deferring other investments with less impact on performance. This investment is expected to increase the reliability of the distribution network for customers that have been experiencing poor performance by reducing the average frequency and duration of power outages. This is expected to positively impact the **Customer Satisfaction Survey Results**.

Customer Self Service Technology ISD GP 16.

This investment addresses the need to enhance customer experience through additional self-service tools and functionality. This investment is expected to improve customer engagement by providing a convenient mechanism through which customers can interact with Hydro One. This investment also provides customers with a streamlined online experience that allows them to better understand their bills. This investment is expected to improve the **My Account Customer Satisfaction** and **Customer Satisfaction Survey Results** measures.

Call Centre Technology ISD GP 28.

This investment addresses the need to replace a system that has reached end-of-life. The investment also addresses the need to improve customer satisfaction and operational efficiencies at the call centre, especially for commercial and Industrial customers. This investment is expected to positively impact the **Customer Satisfaction Survey Results, Call Centre Customer Satisfaction, First Contact Resolution** and **Telephone Call Answered on Time** measures.

Customer Service Billing Investments ISD GP 29.

This investment will provide Non-Energy Billing Integration and will also produce a redesigned and improved bill for customers in 2022. This investment is expected to improve **Customer Satisfaction Survey Results**.

Customer Data and Analytics ISD GP 32.

This investment will upgrade several customer analytic tools provided by Hydro One. This investment is required to improve customer satisfaction through implementing alerts and analytics functionality. This investment is expected to improve **Customer Satisfaction Survey Results** as customers would have access to tools to help them manage energy usage.

Customer Service Complaint Management Tool ISD GP 33.

This investment will integrate the Complaint Management System with our SAP Customer Information System. This investment addresses the need to improve customer satisfaction through better handling, tracking and resolution of customer complaints. This investment is expected to improve **Customer Satisfaction Survey Results** and **Call Centre Customer Satisfaction.**

Smart Meter Network Investments ISD GP 34.

This investment will upgrade several meter reading systems and processes. This investment will reduce the number of customers who receive estimated bills, thereby improving **Customer Satisfaction Survey Results** and support Hydro One's efforts to meet the Ontario Energy Board's **Bill Accuracy** target of 98%.

1.4.3.2 OPERATIONAL EFFECTIVENESS INVESTMENTS

The OEB Operational Effectiveness Outcome aligns with Hydro One's Business Objectives as illustrated in Table 16. The measures that align with these business objectives and the material investments that impact the performance of these measures are discussed below.

Actively Control and Lower Costs Through OM&A and Capital Efficiencies

Hydro One has historically measured the degree to which it is meeting the objective to actively control and lower costs through OM&A and capital efficiencies with the following productivity measures:

- Cost/customer
- Cost/km
- OM&A/customer
- OM&A/km

- Pole replacement -unit cost
- Vegetation Management - unit cost
- Station refurbishments transformer bank- unit cost

The following investments are intended to actively control and lower costs through OM&A and capital efficiency gains and are expected to positively impact the measures used to monitor cost efficiency.

Remote Disconnection / Reconnection Program ISD SS 01.

The investment will result in the installation of meters with Remote Disconnect/Reconnect ("RDR") capabilities. Installing RDR capable meters will reduce the number of truck rolls required for disconnection and reconnection of service, required for customer needs such as move in and move out. Over the period 2018to 2022 planning period, 55,625 RDR capable meters will be installed.

Collection Enhancements ISD GP 31

This investment will enhance Hydro One's collections processes and functionality and implement pre-paid metering. This investment will improve collections and reduce bad debt expense at Hydro One leading to an increase in operational efficiency.

Corporate Performance Reporting ISD GP 07

The new Corporate Performance Reporting ("CPR") application will replace third-party software that requires support from an external vendor. The new application will be internally supported leading to reduced vendor costs. It will also be integrated with Hydro One's SAP system allowing for greater flexibility to meet reporting requirements.

Transport and Work Equipment (TWE) Capital Requirements ISD GP 01

This investment will replace transport and work equipment that is deemed to be at the end of its expected service life resulting in an optimal fleet composition that meets industry standards. This investment will maintain or improve operational efficiency by minimizing maintenance costs, shortening vehicle downtime, and increasing fleet availability.

Work Management & Mobility ISD GP 10

This investment will result in a refresh of the mobile technology used by Hydro One Distribution. The investment will eliminate or automate a significant amount of manual work and improve workforce effectiveness through better scheduling. In addition to the overall cost measures, this investment will have a positive impact on several distinct measures including pole replacement unit cost, vegetation management unit cost and station refurbishments – cost per transformer bank.

Business Process Consolidation ISD GP 12

This investment will allow the expanded use of the SAP Business Planning and Consolidation tool to add functionality such as integrated investment planning, business planning and forecasting capability. The added functionality will improve accountability and planning accuracy, shorten cycle times and allow for period books to be closed faster. This investment will yield operational and process efficiencies and improved decision-making capabilities.

Human Resource (HR) & Pay Related Technology Investments ISD GP 13

This investment will implement various process and tool enhancements to Hydro One's HR and Pay operations. This investment will improve efficiency/productivity in the HR & Pay area. These tool and process enhancements will increase operational efficiency.

Warehouse Scanning Device Replacement ISD GP 14

This investment will upgrade the bar coding devices used to manage warehouse inventory. This investment will enable Hydro One to monitor its inventory more efficiently, accurately and at reduced cost, all outcomes that increase operational efficiency.

SAP Treasury ISD GP 15

This investment will replace the Treasury system that has reached the end of its useful life and will no longer be supported by the vendor. The investment will implement the SAP Treasury & Risk Management System. Integration with enterprise SAP self-service tools results in savings attributable to better processes and more timely financial data. This investment improves business performance through using standard SAP automated processes for cash management, reducing manual entries for wire and ETF payments, and providing timely updates of bank data and transactions.

S4 HANA for Finance and Enterprise Asset Management ISD GP 17

This investment involves the replacement the SAP enterprise reporting platform with a new system, S4 HANA for Finance and Enterprise Asset Management. Implementation of the new system will improve decision-making with real time reporting, process simplification, better data quality, and a more effective interface. The new system will also increase processing speed and system performance. This investment will yield operational efficiencies.

Station Spare Transformer Purchases, ISD SR 03

This investment will result in the purchase of spare transformers for distribution stations as needed to support the in-service population. Operating with current proposed Mobile Unit Substation (MUS) fleet size requires spare transformers to be available to eliminate the 6 to 12 month transformer lead time. Hydro One has optimized its inventory of spare transformers required by moving toward a more standardized fleet of in-service transformer banks. This investment will also lower cost by reducing the need for expansion of the MUS fleet that would otherwise be necessary to support long transformer lead times.

Manage Public Safety Risk

Managing Public Safety Risk involves assessing the risks to the public from Hydro One's business operations, assessing the probability of an event and the severity of that event, and assessing the costs to mitigate identified risks. The following investments are expected to have a positive impact on Hydro One's Business Objective to manage public safety risk and are expected to drive improvement in the measures used to monitor this objective.

Station Security Upgrades, ISD GP 24

This investment provides for the installation of upgraded security measures at distribution stations to mitigate break and enter occurrences and prevent thieves from stealing copper grounds and neutral conductors. This investment is expected to improve public safety by mitigating the public's exposure to compromised grounding systems and station perimeters, positively impacting the number of general public incidents. In addition, this investment is expected to reduce maintenance costs associated with repairing the damage caused to distribution stations as a result of break and enters.

Component Replacement – Submarine Cable ISD SR 11

This investment will replace or refurbish submarine cables that are damaged or exposed at the shoreline and present a risk to public safety and are at an increased risk of failure. The public expects Hydro One to manage these safety risks. This investment is expected to mitigate public safety risks posed by damaged submarine cables and positively impact number of general public incidents.

Providing Reliability Consistent with Customer Requirements

Most of Hydro One's customers expect the level of system reliability to be maintained while large customers expressed a desire for improved reliability and a reduction in the frequency of outages. Hydro One will measure the degree to which it is meeting the objective of providing reliability consistent with customer requirements with the following measures:

- Substation-caused interruptions;
- Vegetation-caused interruptions;
- line equipment-caused interruptions;
- OEB Scorecard SAIDI;
- OEB Scorecard SAIFI;
- Rural SAIFI;
- Rural SAIDI;
- Urban SAIFI; and
- Urban SAIDI.

The following investments are targeted at providing reliability consistent with customer expectations and are expected to positively impact the measures used to monitor Hydro One's reliability performance.

Distribution Station Component Planned Replacements Program ISD SR 04

This investment replaces station equipment components that are at the end of their useful life and are not otherwise planned to be addressed by the station refurbishment program. By replacing these components before they fail, this investment will help maintain the substation-caused interruptions measure.

Distribution Station Recloser Upgrades ISD SR 05

This investment, which is part of an ongoing program, proactively installs new station reclosers at feeders where the existing protective device has become insufficient to meet electrical requirements. The new reclosers have lower maintenance costs, can be monitored and controlled remotely and have a longer service life. The quantity and funding for recloser upgrades is expected to be in line with historical levels to help maintain substation-caused interruptions within the historical range.

Distribution Station Refurbishments ISD SR 06

This investment, which is part of an ongoing program, replaces or refurbishes distribution stations at the end of their useful life before they fail. This investment is expected to help maintain substation-caused interruptions within the historical range.

Pole Replacement Program ISD SR 09

This program addresses replacement of wood poles and associated hardware that are at the end of their useful life. By replacing these poles before they fail, this investment is expected to maintain line equipment-caused outages within the historical range.

Distribution Line Component Replacements ISD SR 10

Hydro One performs assessments to identify distribution line components that are near the end of their useful life. This program addresses replacement of those line components. By replacing these components before they fail, this investment is expected to maintain line equipment-caused interruptions within the historical range.

Reliability Improvements ISD SS 03

This investment provides targeted reliability improvements in areas where customers have expressed concerns about the performance of the existing distribution network. Based on the currently identified projects targeted for reliability improvement in this DSP, overall SAIDI and SAIFI numbers are not expected to change materially from the historical range due to the local and limited size of these projects relative to Hydro One's system. However, this investment is expected to positively impact the Large Customer Interruption Frequency measure.

Worst Performing Feeders ISD SS 06

The strategy for this investment is to focus on distribution system areas that are reliability performance outliers and defer investments with less impact on performance. This investment aligns with customer preferences to sustain reliability and positively impact costs. This investment is expected to positively impact reliability of the feeder performance outliers and sustain the proposed SAIDI and SAIFI measures.

1.4.3.3 PUBLIC POLICY RESPONSIVENESS INVESTMENTS

The OEB Public Policy Responsiveness Outcome aligns with Hydro One's Business Objectives to ensure compliance with all codes, standards and regulations, partner in the economic success of Ontario and sustainably manage our environmental footprint. A significant portion of Hydro One's material investments are non-discretionary and are driven by the need to adhere to these business objectives. These investments do not directly align with specific performance measures but are critical to Hydro One's compliance with OEB Public Policy Responsiveness outcomes and the Company's corresponding Business Objectives. These non-discretionary investments are listed below.

- Life Cycle Optimization & Operational Efficiency Projects ISD SR 13;
- Distribution Lines Trouble Calls & Storm Damage Response Program ISD SR 07;
- AMI Network Expansion ISD SA 03;
- System Upgrades Driven by Load Growth ISD SS 02;
- Joint Use and Line Relocation Program ISD SA 01;
- Meter Inventory Sustainment ISD SA 02;
- AMI Hardware Refresh ISD SR 14;
- New Load Connections, Upgrades and Cancellations and Metering ISD SA 04;
- Generation Connections ISD SA 05;
- Enterprise Content Management (ECM) - Phase C ISD GP 09;
- Customer Service Regulatory Changes and Pricing Options ISD GP 30;
- Distribution Line PCB Equipment Replacement Program ISD SR 08;
- Leamington TS Capital Contribution ISD GP 25;
- Hanmer TS Capital Contribution ISD GP 26;
- Enfield TS Capital Contribution ISD GP 27;
- Demand Investments ISD SS 04;
- Distribution Station Demand Program ISD SR 01; and
- Distribution System Modifications ISD SS 05.

Details on each of the investments listed are available in the corresponding ISD in Section 3.8.

1.4.4 ATTACHMENTS: PERFORMANCE MEASURES AND OUTCOME MEASURES

Productivity Reporting Governance Document

February 17th, 2017

Contents

Productivity Reporting at Hydro One

Hydro One's goal is to be a best-in-class customer-centric commercial utility with a culture of continuous improvement and excellence in execution. Successful execution and performance measurement are critical to achieving this goal and will allow Hydro One to deliver incremental Value to customers in the coming years.

Hydro One will track and document the collective effort of all organizations to improve the Value provided to customers for program spending. The reporting of these efforts will drive increased accountability for management to achieve Productivity gains and will provide a transparent view for the regulator and our customers that Hydro One has adopted a culture of continuous improvement.

Definitions

Value

Value for the purposes of Productivity reporting can be defined as the service level provided to customers relative to the cost they pay through electricity rates. Customers assign different levels of importance to the services provided by Hydro One but it is clear through customer engagement that customers place the most Value in having a low cost electricity distributor without sacrificing performance in maintaining a safe, reliable electricity system. Creating Value for customer's means improving the service level provided while lowering the relative cost to provide those services.

Productivity

Productivity gains are the result of improved planning or execution of work that increases Value to the customer. This Value can be measured through output/input metrics which often are based on the cost per unit of output in a given work program. These metrics are measured over time to show the increasing Value to customers for program spending. Savings from new technologies and process innovations will naturally impact these metrics as they reduce costs to the customer while providing consistent or improved service levels. Productivity is quantifiable and can be measured through dollars or other numerical units.

Savings

There are many initiatives in place or under development that specifically target cost reductions in work programs and corporate support services. These Savings are tracked and reported to gauge the success of the initiatives and to find new ways to build upon their success. However, ultimately Productivity will be measured using metrics that demonstrate increasing Value to the customer rather than total Savings achieved.

Avoided Cost

Through Hydro One's business planning process, future cost increases can be identified in time to develop a strategy to mitigate or eliminate the increase. Avoided Costs are by their nature difficult to quantify as the conditions that would have caused the cost increase were prevented from occurring. These avoided costs will not be included in Savings tracking or Productivity reporting, but do impact the Value being generated for customers.

Performance Outcomes

In order to ensure that Hydro One is achieving its Productivity and cost efficiency goals it has aligned its planning, execution and reporting functions around performance outcomes. These outcomes are based upon the Renewed Regulatory Framework (RRF) that the Ontario Energy Board (OEB) has implemented for use in both Transmission and Distribution regulatory proceedings. The RRF outcomes are designed to provide additional transparency into the performance of Hydro One in these four areas:

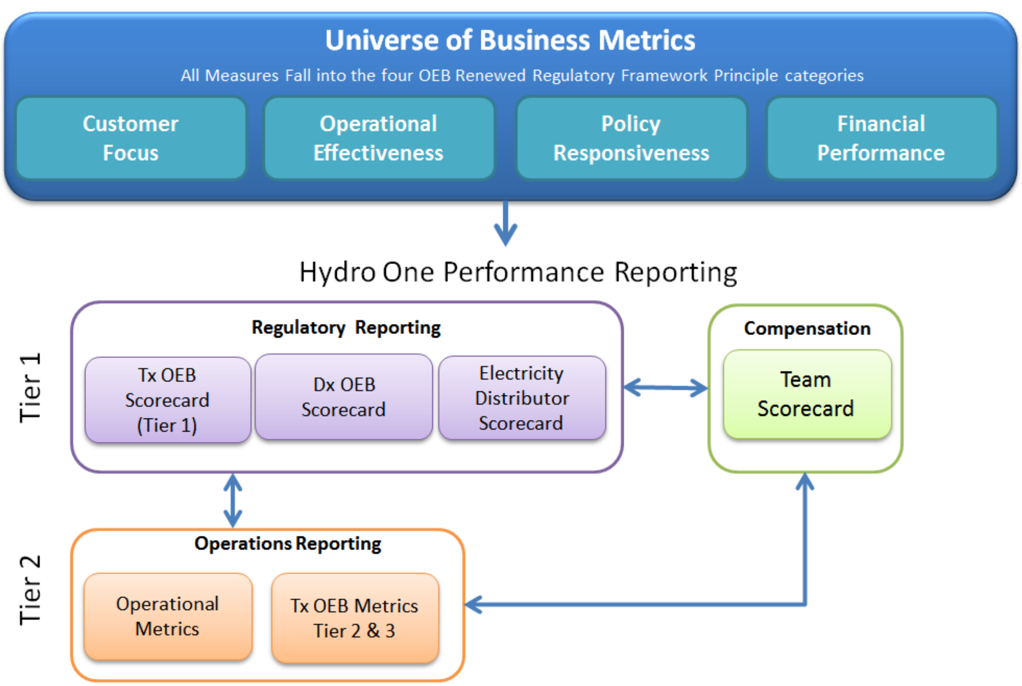
1. Customer Focus,
2. Operational Effectiveness,
3. Policy Responsiveness, and
4. Financial Performance

A direct correlation can be drawn between Hydro One's business objectives and the RRF performance outcomes.

Performance Scorecards

Hydro One primarily reports its performance through regulatory scorecards and the Team Scorecard which is used for the Short Term Incentive Plan award. These four scorecards comprise the Tier 1 scorecards that are reported internally and externally. The Tier 2 scorecards were designed for operational reporting to help managers effectively run the business. The measures on these scorecards often overlap, and at a minimum support the achievement of the Tier 1 goals, to ensure management at all levels are working towards the same goals.

The illustration below provides a view of the relationship between the RRF principles, the universe of business metrics and the scorecards used for reporting.



Performance Metrics

The regulatory scorecards and the Team Scorecard are composed of metrics that are designed to demonstrate the increasing Value to customers for program spending. The most evident of these are the cost per unit metrics that aim to reduce the cost of putting a standardized unit into service. Cost per unit metrics are impacted by both a reduction in costs (inputs) as well as the total number of units put into service (outputs). Increasing the number of units put into service will provide Value to the customer by improving service levels such as reliability. By showing an improvement in these metrics over time, Hydro One is demonstrating that it is providing an improved service level relative to the cost of providing the service.

For example cost per unit for the Wood Pole Replacement program is a metric where Value for the customer can be generated by maintaining service through reliability while reducing the cost of the pole through labour and material efficiencies. If the same standardized unit of pole is being replaced at a lower total cost then the customer will realize the Value through their electricity rates.

The reliability and customer service metrics on the scorecards are examples of metrics that are focused on the service level side of the equation (outputs). Since these service levels are very broad and cover many work programs and customer service efforts, they must be measured relative to other cost metrics (inputs) included on the scorecards such as OM&A per customer and OM&A per line km. These high level metrics will show the trend in spending that when viewed with the service level performance metrics will illustrate the Value that customers are receiving relative to spending over time.

Authorities & Accountabilities

Lines of Business

Each line of business is accountable for developing a Productivity strategy including targets and forecasts for the business planning period. This strategy should be aligned with Hydro One's business objectives and will focus on providing additional Value to customers. Lines of business will be responsible for executing their Productivity strategy and achieving the targets that are imbedded in the Productivity plan.

Business Planning

Business Planning will support LOB's in designing Productivity metrics to measure the effectiveness of the organizations Productivity strategy. The Productivity team will also review the data governance and reporting methodology for all metrics used in reporting (both internal and external).

Finance

Finance is the owner of the Team Scorecard and is accountable for reporting the results based on the internal reporting schedule.

Regulatory

Regulatory is the owner of the regulatory scorecards and is accountable for reporting based OEB requirements.

Deliverables and Stakeholders

Productivity reporting has two primary customers, including the Executive Leadership Team and the OEB. The OEB requires annual reporting to ensure performance levels are being maintained as well as for rate setting purposes during regulatory proceedings. The Executive Leadership Team requires monthly and quarterly reporting in order to successfully manage the business and achieve the business objectives.

Scorecard	Ontario Energy Board	Executive Leadership Team	Operations Managers
Regulatory			
Tx OEB – Tier 1	Annual	Quarterly	Monthly
Dx OEB	Annual	Quarterly	Monthly
Electricity Distributor Scorecard	Annual	Quarterly	Monthly
Compensation			
Team Scorecard	Upon Request	Monthly	Monthly
Operational Reporting			
Tx OEB – Tier 2 & 3	Not Provided	Quarterly	Monthly
Operational Reporting	Not Provided	Not Provided	Monthly

1.5 (5.2.3) PRODUCTIVITY AND CONTINUOUS IMPROVEMENT

As reflected in its Business Objectives, Hydro One is committed to continuous improvement and achieving Distribution system outcomes that are valued by customers, including cost efficiency. This commitment is central to the planning and execution of work programs across the Company.

Hydro One has undertaken a number of initiatives to reduce costs while maintaining service quality and work outputs. Quantifiable improvements are included in the business plan with clear accountabilities for delivering the savings.

Hydro One will use the performance metrics described in Section 1.4 to establish a baseline of its historical performance, track current progress, and establish new targets for future periods. These performance measures provide visibility to the progress of initiatives to deliver outcomes valued by customers.

1.5.1 PRODUCTIVITY SAVINGS IN THE PLAN

The key to providing customers with value is creating a business plan that aligns customer preferences, responsible stewardship of the system and rate impacts. Developing initiatives and approaches that make the Company more productive and more efficient define Hydro One's plan. The savings driven by these initiatives have been included in detailed OM&A and Capital plans. A summarised forecast of productivity savings for 2018-2022 is outlined in Table 17.

Table 17 – Detailed Productivity Savings Forecast

$Millions	**2018**	**2019**	**2020**	**2021**	**2022**
Move to Mobile	10.3	10.5	10.7	10.7	10.7
Procurement	14.2	15.3	19.1	20.2	20.8

Total Savings	**63.5**	**70.8**	**78.9**	**82.8**	**87.8**

1.5.1.1 MOVE TO MOBILE

When Hydro One crews are working in the field, they could be anywhere inside a 640,000 sq. km area. Equipping these crews with technological resources that will help them perform work more effectively and find solutions faster will lead to savings. The goal of the Move to Mobile ("M2M") project is to improve operational efficiency in the field by using technology. The project is designed to apply industry best practices to Provincial Lines major business processes in the areas of Customer, Maintenance and Project work in addition to integrating mobile technology with the Company's existing suite of work management tools. An upgrade to the existing PCAD Scheduling Tool and associated process improvements will result in a 5% increase in field productivity and a reduction of eight clerical/administrative positions managed through attrition. The elimination of the current paper-based processes will result in an additional 21 clerical/administrative positions, also managed through attrition.

Other significant benefits that are realised by linking the Company's scheduling to real-time data that can be accessed by field crews via mobile devices will include improved Customer Service through timely and accurate meter setup, improved data accuracy and additional supervisory time in the field, which is critical to improving both safety and productivity. Implementation will be completed on a staged approach with completion scheduled for April 2017. Following successful implementation of this program to Provincial Lines, expansion to Forestry Services will be considered.

1.5.1.2 OPERATIONS

Hydro One forecasts productivity savings of over $120 million in Operations over the course of the 2018-2022 planning period. These savings demonstrate Hydro One's commitment to identifying and implementing efficiencies and minimizing expense before passing on costs to customers. Many of these savings have been realized by initiatives that leverage new technologies and processes, and in some cases drive a significant change to the way that Hydro One completes work. Cable Locates and Forestry are two significant sources of Operations savings.

Cable Locates

Hydro One forecasts $39.6 million in savings over the 2018-2022 planning period as a result of changes to execution of cable locates work. Beginning in September 2015, a pilot area was selected to source underground distribution locates through external service providers. The scope was expanded across the province over the following six months so that the majority of locates, excluding emergencies and some remote areas of the province, are outsourced. Savings are now being realized due to a competitive price and a multi-utility discount from these locate service providers that also perform the same service for other infrastructure owners.

To achieve the savings, Hydro One joined the Locate Alliance Consortium (LAC) to facilitate the transition to outsourced locates. LAC utilizes a One Call One Locate model in which multiple utilities use the same Locate Service Provider and share in the costs. This allows a decrease in the cost of an individual locate for each facility owner depending on the number of LAC members included on the locate request. Since Hydro One's territory is shared with a number of other LAC members this method has been successful in reducing the cost per locate.

A further initiative to lower locate costs is through reducing locate volumes through the implementation of Alternate Locate Agreements ("ALA") between Hydro One and excavators. An ALA outlines specific terms and conditions determined by the utility and agreed to by the excavator that allow the excavator to dig without receiving a traditional marked field locate. Improved GIS mapping in conjunction with planned system upgrades at Ontario One Call in late 2017 will result in further savings by avoiding locate requests where Hydro One does not have infrastructure within, or in close proximity to, the excavation area.

The overall savings forecast from changes to the Cable Locates work is provided in the Table 18.

Table 18 – Cable Locates Savings Forecast

$**Millions**	**2018**	**2019**	**2020**	**2021**	**2022**
OM&A Savings	7.6	7.8	7.9	8.1	8.2

Forestry

Hydro One forecasts $69 million in savings over the 2018-2022 planning period as a result of savings in vegetation management related work on the Distribution system. The Forestry Services department ("Forestry") is continuously looking to reduce costs and increase productivity. The following initiatives have been included in the business plan:

Inclement Weather Initiative: Forestry utilizes a significant amount of temporary staff to complete its annual work program. Changes to work practices and management of shifts have allowed for increased flexibility of staff levels during inclement weather. The cost savings expected as a result of this change have been included in the business plan.

Brush Control Optimization: Historically, brush control has been achieved through multiple approaches of manual cutting and herbicide application in the same location. A review of the program has concluded that costs can be reduced through operational changes without compromising the results of the program. These changes include a reduction of multiple treatment methods and instead utilize a one-touch approach wherever possible. Herbicides are now applied to standing brush to reduce follow-up cutting and processing. In locations where herbicide or mechanical brush cutting cannot take place, the brush will be trimmed at a reasonable height. This results in less aggressive re-growth and costs considerably less than trimming at ground level as previously done.

Customer Notification Optimization: Forestry is using various means to reduce the costs of notifying customers on upcoming work. This includes utilizing automated technology and BASC staff to make preliminary notification phone calls and having technicians collect field data on feeders scheduled for vegetation management within a three-year period. This approach would cover 60-70% of work plan requirements and would be more efficient, freeing technician time to notify customers where exceptions are necessary on the feeder. Forestry is also considering other measures to reduce expense including leveraging GIS and SAP data for feeder length calculation, reducing tree counting to determine density by using various sampling techniques, reducing marking of trees slated for removals and, when considering large removals, determining if trimming would suffice to minimize time without compromising safety and reliability.

Muskoka / Parry Sound Initiative: The Muskoka/Parry Sound region is a high priority region in terms of vegetation management, especially in light of frequent storm activity. Work volume in this area requires resources to be temporarily relocated from various areas across the province. Hydro One has created a broader project-based approach, integrating Forestry and Lines projects in planning and execution. This approach allows for the achievement of synergies in crew mobilization, project oversight and work reporting. This approach is expected to continue throughout the Application period.

Forestry Switching and Grounding: Currently, Forestry Regional Maintainers are required to wait for qualified Lines staff to switch and ground lines before commencing work activities. However, by employing a number of qualified foresters, who are trained to open switches and apply grounds in certain voltage and line configuration situations, forestry work can proceed without delays. This will result in more efficient utilization of Lines and Forestry resources as well as improved storm restoration times.

Labour Optimization: Forestry is working to optimize the number of high-skilled regular work staff to the level required to complete core work programs. Temporary workers will be utilized to perform the additional work in the applicable areas, allowing for additional flexibility in Hydro One's labour expense. In addition, Forestry is working to outsource low skilled brush control work at reduced expense to Hydro One. Both of these initiatives are expected to develop throughout the Application period (2018-2022).

Table 19 – Forestry Savings Forecast

$**Millions**	**2018**	**2019**	**2020**	**2021**	**2022**
OM&A Savings	10.0	12.9	13.8	14.9	17.4

Additional operational savings of approximately $2.4 million per year are included in the plan, primarily from two programs related to trouble calls and meter reading. The planned reduction in trouble call expense is the result of the deployment of Fault Current Indicators, which allow for faster identification of the location of outages, which aides in reducing in restoration time and expense. Planned reductions in meter reading expenses are the result of the Flexible Bill Window program, which was created to extend the billing window in order to obtain actual meter reads and reduce estimated bills. As part of that program, Hydro One's SAP system can update manual meter read schedules for unanticipated electronic meter reads, thereby eliminating the manual meter read expense. In addition, meter reading routes are adjusted on a real time basis to ensure that routes are optimized for driving distance, demand and resource constraints in order to reduce drive time.

1.5.1.3 PROCUREMENT

Subsequent to the Company's IPO, Hydro One's Supply Chain division has made several changes to its sourcing processes to increase productivity and reduce expenses, as described in Exhibit C1, Tab 3, Schedule 1. Hydro One forecasts more than $100 million in embedded savings over the 2018-2022 planning period as a result of procurement enhancements. The following enhancements are under development:

- **Bundling/Volume Discounts** – Renewed view of sourcing categorization by grouping materials/services supplied by like-suppliers to maximize savings and volume discount opportunities, and addressing multiple sub-categories at once. Bundling multiple contracts with a single supplier, and negotiate volume discounts across multiple categories and contracts.
- **Feedback Rounds** – Maximize competitive pressure through multiple feedback rounds on rates, with an opportunity for vendors to improve their proposals.
- **'Lean' RFPs** – Emphasize leaner, "bidder-friendly" scope and value in RFP formats with fewer onerous requirements and redundancies.

- **Standardization of Specifications** – Standardize requirements to allow direct, like-for-like comparisons across bidders. Move towards industry-standard specifications where reasonable, rather than Hydro One specifications, to reduce unnecessary costs.
- **Streamlined Evaluation** – Compress timelines and streamline evaluation process to meet business needs and accelerate the realization of negotiated savings.
- **Cost Transparency** – Increase knowledge of bidders' prices and composition to improve Hydro One's ability to challenge and negotiate competitive pricing.
- **Transition Pricing** – Where contracts are being renegotiated with incumbent vendors, implement new negotiated rates before the renegotiated contract execution.

Table 20 lists spending categories and the forecast procurement savings that have been embedded in the business plan over the 2018-2022 planning period.

Table 20 – Distribution Procurement Productivity – Category Overview

Category	Embedded Savings 2018-2022	Potential Approach/Levers
IT Software & Hardware	$13 M	• Renegotiate IT software contract(s) • Conduct broad RFP with telecoms and networks carrier services spend to leverage scale
Professional Services	$44 M	• Conduct RFP's to establish competitive rate cards and preferred suppliers(s) through multiple feedback rounds • Lock-in prices with preferred suppliers including volume discount agreements
Materials & Equipment	$23 M	• Conduct broad RFP's to consolidate spend with preferred suppliers with provincial capacity using multiple feedback rounds, thus increasing volume discount potential • Conduct RFP's to lock-in equipment rental rates while bundling other services as part of the RFP process
Back Office	$4 M	• Evaluate market alternatives and renegotiate office supplies

Category	Embedded Savings 2018-2022	Potential Approach/Levers
Telecom	$5 M	• Consolidate bulk of spend with fewer preferred suppliers to lower cost
Fleet	$22 M	• Renegotiate Fleet Management contract, including a broad RFP with multiple feedback rounds

1.5.1.4 CUSTOMER SERVICE

As Hydro One strives to become a customer-centric commercial entity focussed on improving customer satisfaction, the Company's business plan includes a number of initiatives that forecast Customer Service savings over $16 million.

Hydro One's new eBilling solution, launched in December 2016 via Hydro One's self-service website, is expected to increase ebilling penetration. Over 500,000 customers are expected to sign up for e-billing by 2022, reducing the volume of paper bills and associated expenses, including postage.

1.5.1.5 TELEMATICS

Telematics integrates telecommunications, including global positioning systems (GPS) and informatics systems that provide location of vehicles, and live vehicle operation and performance data. The Telematics project was successfully rolled out to all fleet vehicles and equipment at the end of 2016 and provides analytics that will allow Hydro One to realize productivity efficiencies for the 2018-2022 investment planning period. In 2017, Fleet Services will leverage the telematics vehicle data to define the baseline metrics with respect to equipment utilization, non-productive idling and reduction in speeding. The data gathered will enable Fleet Services to reallocate resources to other areas to prevent the need to purchase additional resources and reduce spending without compromising service quality to operating divisions. By using 2017 as the baseline year, targets for the specific metrics will be established for the 2018-2022 investment planning period. Please refer to Exhibit C1, Tab 3, Schedule 1, Attachment 2 for additional Telematics project information.

1.5.1.6 INFORMATION TECHNOLOGY

The following OM&A initiatives are designed to reduce costs without impacting the services provided.

Backup and Storage Optimization

Based on an assessment of industry best practices and project and application support requirements, Hydro One has identified opportunities to change its practices regarding frequency of full and incremental backups. This improvement has resulted in savings of disk space and staff time. For no material change in risk profile, this change resulted in a decrease of Hydro One's monthly storage requirement.

Environment Optimization and Decommissioning Initiatives

Hydro One has consolidated IT environments and, in some cases, decommissioned them. This has resulted in a reduction in monthly service fees paid to its third-party service provider. Also, after an assessment of IT infrastructure components and databases, Hydro One began decommissioning servers and databases that had low utilization. To date, 138 servers and 38 databases have been decommissioned, with plans to decommission an additional 67 servers and three databases by early 2017. This has reduced Hydro One's monthly server and database fees. An ongoing review process has been implemented to ensure that unused infrastructure is decommissioned in a timely manner.

Implementation of Cloud Infrastructure

Hydro One is implementing secure, cloud-based platforms into its IT environment. This will result in reduced costs due to a reduction in infrastructure resources, ongoing management and support.

IT Contract Renegotiation

A comprehensive review of all third-party contracts, including Hardware, Software, Personnel, and Telecom/Network Assets, was performed to determine opportunities for renegotiation based on overall cost and current contract renewal timelines. Hydro One is continuing its analysis of other third-party contracts and opportunities for renegotiation.

1.5.1.7 ADMINISTRATIVE

Hydro One has renewed its focus on reducing administrative and back office costs and plans, through a mixture of staff optimization and leveraging new technology, to reduce costs by $7.5 million over the Application period.

One of the drivers of these savings is implementing a new SAP-based expense management tool that allows for a reduction of corporate charge cards and optimization of the expense management processes leading to a reduction in costs of $5.4 million over the planning period.

1.6 (5.2.3) BENCHMARKING

In the Decision in Hydro One's last Distribution Rate Application for the 2015 to 2019 rates (EB-2013-0416), dated March 12, 2015, the OEB found that the proposed plan showed limited prospects for continuous improvement, lacked externally imposed improvement incentives, included limited cost and productivity benchmarking support, and failed to demonstrate value to customers commensurate with the forecast spending. To address the perceived shortcomings in the application, the OEB directed Hydro One to undertake several studies and submit reports.

The undertaking of these studies and reports presented Hydro One with the opportunity to demonstrate continuous improvement by different means: comparison to self; comparison to others; and unit cost trending analysis. This will assist Hydro One align its performance outcomes with those of the RRF.

Hydro One also challenged itself, venturing further ahead than just undertaking the studies and reports asked of it by the OEB. Hydro One identified other studies that would help it perform more efficiently, develop a culture of continuous improvement and stay on the path to excellence in execution.

1.6.1 (5.2.3 A) BENCHMARKING STUDY OVERVIEW

Benchmarking is increasingly being referenced as a means of monitoring company performance, especially when used in combination with specific cost drivers and other sources of utility performance information, as these allow for an overall assessment of a utility's cost and outcome performance. These studies address the expressed interest to better understand the cost of Hydro One's work by providing a high-level set of benchmarks that compare Hydro One's relative position to other North American utilities.

To secure the most technically qualified proponents with in-depth knowledge of the industry, market experience, and the ability to perform quality studies, Hydro One issued Requests for Proposal ("RFP") in accordance with the company's competitive bid process. Hydro One held stakeholder sessions for the productivity studies to gain input and endorsement from stakeholders and OEB staff regarding the study approach, peer comparators and metrics. Further information on the stakeholder sessions is available in Section 1.3.

The studies also presented Hydro One with a baseline to allow assessment of its own performance year over year. Exploration of cost variations and associated best practices will be beneficial for Hydro One to analyze potential cost efficiencies within its distribution business and will provide an opportunity to investigate industry best practices for the company's lines of business. Hydro One therefore also added its own objectives to the studies. The sections below outline the specific objectives for each of the studies.

Pole Replacement and Station Refurbishment Program Studies

The Pole Replacement and Station Refurbishment Programs were areas where Hydro One requested significant increases in Capital and OM&A expenditures over the three year test period of 2015 to 2017. Studies were directed to conduct a trend analysis of year over year unit costs, investigate variations, and explore best practices that can be adopted to realize value.

The Pole Replacement and Distribution Station Refurbishment Program Studies were awarded to Navigant Consulting in partnership with First Quartile Inc.

Vegetation Management Program Study

Vegetation Management was another area where Hydro One had increased expenditure levels in the test years. The OEB directed Hydro One to undertake a comprehensive trend analysis of the vegetation management program to show year over year comparisons in unit costs and a best practices study similar to the 2009 CN Utility study. The Vegetation Management Program Study was awarded to CN Utility Inc.

IT Budget Assessment Study

Hydro One conducted its own benchmarking study to collect relevant input that would craft a five-year strategy for its IT organization with sustainable efficiencies and continuous improvements. The study, which was not mandated by the OEB, was awarded to Gartner Consulting

Total Factor Productivity Study

In the *"Productivity and Benchmarking Research in Support of Incentive Rate Setting in Ontario: Final Report to the Ontario Energy Board"* issued on November 21, 2013 and as corrected on December 19, 2013, the OEB's expert, Pacific Economics Group (PEG), performed, *"TFP "backcasts" and statistical tests which showed that Hydro One and Toronto Hydro were having a statistically significant impact on the industry's TFP trend, thereby providing the empirical rationale for eliminating these companies from the sample used to set the productivity factor for the electricity distribution industry"*.

In Hydro One's Distribution Rate Decision (EB-2013-0416), all parties saw value in Hydro One measuring its TFP over time to be able to demonstrate improvement in productivity to its customers and the OEB. Therefore, Hydro One was directed to determine its preferred TFP study methodology and subsequently awarded the contract to undertake a TFP Study to Power System Engineering Inc.

Total Compensation Study

Hydro One was directed by the OEB to undertake a compensation study similar to the study filed as part of the last distribution rate application to allow benchmarking to comparable companies. The study showed that on an overall weighted basis, compensation was fourteen per cent higher than industry comparators at the market median. Details and discussion regarding the findings of this study are contained in Exhibit C1, Tab 2, Schedule 1.

Total Cost Benchmarking Study

Hydro One conducted a further study in order to measure the Company's total cost performance relative to its peer group. The study showed that Hydro One is above the market median on an overall basis. Details and discussion regarding the findings of this study are contained in Exhibit A, Tab 5, Schedule 2.

1.6.2 (5.2.3 A) SUMMARY OF BENCHMARKING FINDINGS AND RECOMMENDATIONS

This section summarizes the key findings and recommendations from the benchmarking studies. How these key findings and recommendations are reflected in the Distribution System Plan can be found in Section 1.6.3.

1.6.2.1 POLE REPLACEMENT PROGRAM STUDY

The primary findings of the Pole Replacement Program Study are found in Table 21. The best practice recommendations are summarized in Table 22. The study report can be found as Attachment 1 in Section 1.6.4.

Table 21 - Pole Replacement Program Study Primary Findings

#	Primary Finding	Study Reference
1	Hydro One's costs are in line with the average of the comparison group, with low unit costs for inspections and average costs for replacement of poles.	Section 3.1
2	Hydro One inspects its poles more frequently than most utilities, using mostly visual inspections with some light physical inspections, while the others typically perform more rigorous physical inspections and testing.	Section 3.2
3	The replacement rate for Hydro One is slower than for the comparison utilities, with the result that Hydro One's pole inventory is the oldest; on average, eight years older than the rest of the utilities in the comparison group. This matches the planned life of poles, which is also about 10 years longer for Hydro One than for the comparison group.	Section 3.3

#	Primary Finding	Study Reference
4	Hydro One does not employ a formal pole refurbishment program, whereas 13 of 17 companies in the comparison group do in an effort to postpone premature replacement of poles.	Section 3.4

Table 22 - Pole Replacement Program Study Recommended Actions

#	Recommended Actions
1	Consider modifying the pole replacement program to include more complete pole inspections (sound, bore, excavation) and a longer (approximately 10-year) inspection cycle – the OEB would need to approve the change in inspection cycle.
2	Expand the existing centralized program management and pole selection approach to cover 90-95% of the replacement / refurbishment work on poles in a given year, leaving the remainder to be guided by the local staff while still meeting the centralized strategy and replacement criteria.
3	Where geography and/or pole density permit, consider the use of dedicated pole replacement crews.
4	Consider modifying the program to include a rigorous pole refurbishment option, when appropriate.

1.6.2.2 DISTRIBUTION STATION REFURBISHMENT PROGRAM STUDY

The primary findings of the Distribution Station Refurbishment Program Study are included in Table 23. The best practice and implementation recommendations are summarized in Table 24. The contents of the study report can be found in Attachment 1 of Section 1.6.4.

Table 23 - Distribution Station Refurbishment Program Study Primary Findings

#	Primary Finding	Study Reference
1	Station refurbishment activities are varied within and across utilities.	Section 4.1
2	Hydro One's costs for individual substation refurbishments are within range observed across the comparison utilities.	Section 4.1
3	As with most utilities, the cost of individual Hydro One refurbishment projects ranges from first to fourth quartile.	Section 4.1
4	Navigant and First Quartile Consulting believe Hydro One's station-centric approach is appropriate, given the system configuration and density within the service territory; Hydro One has the highest percentage of single transformer substations, higher than average transformer loadings, older age profile for in-service transformers, and more rural locations.	Section 4.2
5	Use of testing results and maintenance history records could be improved in making replace versus repair decisions for certain substation equipment.	Section 4.3
6	Use of performance measures for tracking success of individual programs, in addition to the overall refurbishment program could be enhanced.	Section 4.4

Table 24 - Distribution Station Refurbishment Program Study Recommended Actions

#	Recommended Actions
1	Consider implementing a formal data governance process for equipment performance and maintenance data and incorporating that information into the asset condition scoring and project planning process.
2	Enhance cost and work completion reporting for individual projects and implement a formal change control process.

Witness: Darlene Bradley / Lyla Garzouzi

#	Recommended Actions
3	Develop and implement more comprehensive key performance indicators, including in-progress project cost performance measures, assessments of project/program impacts on substation reliability, maintenance costs, and overall asset health.

1.6.2.3 VEGETATION MANAGEMENT PROGRAM STUDY

The best practice and implementation recommendations found in the Vegetation Management Program Study are summarized in Table 25. The study report can be found as Attachment 2 of Section 1.6.4.

Table 25 - Vegetation Management Program Study Recommendations

#	Recommendation	Study Reference
1	Bring the whole distribution system to a four to eight-year flexible cycle that is trued up each year to ensure backlogs do not creep back into the schedule. This will enable a more effective herbicide program, better off-ROW tree risk management, and reduce workload over the long term. Reduce the current backlog over the next decade through innovations, automation and changes in labour mix. See Recommendations 2, 3, 4, 6, and 9 (below).	Sections 4.1 - 4.3, 4.6, 4.8
2	Improve through innovation the mechanization and automation of the Utility Vegetation Management ("UVM") program. This will improve understanding of the workload and it will enable more effective work planning and cost/resource predictions.	Sections 4.3, 4.4
	Improve data analytics and predictive modeling through automated data collection of key UVM activities.	Sections 4.3.1, 4.3.2
	Use technology such as LiDAR to improve measurements, condition assessments, and accuracy of data collection.	Sections 4.3.2

Witness: Darlene Bradley / Lyla Garzouzi

#	Recommendation	Study Reference
	Increase ROW clearing capacity and safety through innovations in mechanical equipment and routing technology.	Section 4.4.1
	Improve customer knowledge, communication, and involvement by merging UVM data with the customer service system.	Sections 4.3.3 – 4.3.5
3	Improve productivity and control costs by utilizing higher percent of Hiring Hall and contract workers to perform lower safety and liability risk activities such as work planning, herbicide applications, and brush-clearing. This will lower unit costs.	Section 4.4.2
4	Strategically increase herbicide usage for cost-effective results. This will ensure ROWs stay clear between shorter cycles of management and lower the long term cost.	Sections 4.1.3, 4.2.5, 4.2.7, and 4.3.1
5	Develop a vegetation management outage investigation protocol that expands on the current cause codes and utilizes UVM personnel. This will improve capability to predict tree failure modes and guide future tree risk mitigations.	Section 4.5.3
6	Synchronize the annual asset inspections with the UVM work planning program to quantify system vegetation conditions based on performance metrics for maintaining air space around conductors. This will improve workload understanding and provide annual performance metrics for system conditions.	Section 4.3.1
7	Improve and increase the Tree Risk Assessment Program to reduce outages caused by off-ROW trees. This will, with the help of lessons learned through outage investigations, improve reliability by reducing outages caused by trees or branches falling into overhead lines.	Sections 4.3.1, 4.5.3, 4.7 and Appendices F and G

#	Recommendation	Study Reference
8	Identify fixed cost increases and overheads allocated to UVM to ensure cost effects of changes to the program are portrayed accurately. This will enable a better understanding of improvements to production and other cost reduction measures.	Sections 4.1 (4.1.1, 4.1.3, 4.1.4) and 5
9	Improve equipment and personnel utilization. This will lower unit costs by improving efficiency and optimizing equipment availability.	Section 4.4 (4.4.1, 4.4.2)

1.6.2.4 IT BUDGET ASSESSMENT

Hydro One conducted its own benchmarking study to collect relevant input that would craft a five-year strategy for its IT organization with sustainable efficiencies and continuous improvements. The study, which was not mandated by the OEB, shows Hydro One's commitment to increasing productivity before asking customers to pay more. Awarded to Gartner Consulting, the "**IT Budget Assessment"** analyzed enterprise-level metrics and the distribution of IT spending relative to industry peer groups. The study showed that Hydro One spends a similar amount on IT compared to the peer group, but there are differences in how the dollars are spent.

The IT Budget Assessment's key findings are summarized in Table 26. The best practice recommendations are summarized in Table 27. More details and discussion regarding the findings and recommendations of the IT Budget Assessment are available in Section 1.6.4. The study report can be found in Attachment 3 to Section 1.6.4.

Table 26 - IT Budget Assessment Key Findings

#	Key Findings	Study Reference
1	Hydro One uses more outsourcing than the peer group.	Sections - Summary of Metrics
2	Hydro One spends half of the peer group average on hardware and software.	Sections - Summary of Metrics
3	Capital IT spending is lower. Significant factor is Hydro One's minimum capitalization threshold of $2M compared to the peer group average of $250K-$500K	Sections - Summary of Metrics
4	Hydro One expenses are higher for Enterprise Computing (Servers and Storage), End User Computing (laptops and desktops) and applications support. Voice and data are both lower than the peer group.	Sections - Summary of Metrics
5	Hydro One in-house and contractor full-time employees ("FTE") are focused primarily in management and applications roles.	Sections - Summary of Metrics

Table 27 - Assessment Recommended Actions

#	Recommended Actions
1	Optimize enterprise computing and storage costs and increase server virtualization.
2	Reduce materiality threshold for IT capital expenditure.
3	Review IT organization structure and identify any duplication between roles and responsibilities of retained staff and outsourced service provider.

1.6.2.5 TOTAL FACTOR PRODUCTIVITY STUDY

Hydro One's Total Factor Productivity study can be found at Exhibit A, Schedule 3, Tab 2, Attachment 1. The key findings regarding that studied are summarized in Table 28.

Table 28 - Key Findings - Total Factor Productivity Benchmarking Study

#	Key Findings	Study Reference
1	2002-2015 TFP without safety or reliability adjustments declined by 1.4% per year.	Sections 6.1 and 8
2	2002-2015 TFP with adjustments declined by 0.9% per year which is the same as the Ontario industry decline from 2002-2014 of 0.9%.	Sections 6.1, 6.2.3, 7.1 and 8
3	Hydro One's TFP has been improving since 2010. After adjustments, Hydro One has shown positive TFP of 0.5% from 2010-2015, compared to -1.8% from 2002-2010	Section 6.2.3
4	With no adjustments, using only billing determinants as outputs, TFP was -0.4% in the recent period and -2.1% in the earlier period	Section 6.1
5	Based on the empirical evidence of declining industry TFP and the OEB's 4th Generation IR decision to set the productivity factor at 0.0%, PSE recommends setting Hydro One's productivity factor no higher than 0.0%.	Section 1.3

1.6.3 (5.2.3 C) HOW THE PLAN REFLECTS THE BENCHMARKING FINDINGS AND RECOMMENDATIONS

The pole replacement and station refurbishment benchmarking studies generated findings and recommendations that have had an impact on DSP investments. This section summarizes impacts of the benchmarking studies on the distribution system plan stemming from some key recommendations and findings.

The key recommendations from the Total Factor Productivity study are included in Exhibit A, Schedule 3, Tab 2.

Listed below, by recommendation/finding, are the actions currently being taken by Hydro One in response to the results of the benchmarking studies.

1.6.3.1 POLE REPLACEMENT PROGRAM STUDY

Recommendation 1: Pole Inspection Process

The benchmarking study recommended performing more comprehensive but less frequent pole inspections. The study recommended extending the inspection frequency from the current three and six years mandated by the Distribution System Code to a more comprehensive but less frequent 10-year inspection cycle. As a result of the recommendation, Hydro One will re-evaluate its pole inspection program frequency and comprehensiveness.

The study recommended approaching the OEB to extend the inspection frequency. Once potential changes to the frequency and comprehensiveness of the pole inspection process have been formalized, Hydro One may redesign the pole inspection process and approach the OEB for approval to implement a new inspection frequency.

Recommendation 2: Program Management

The study recommended expanding the centralized pole replacement selection reducing the amount of pole replacements identified by the local operations centres. Hydro One has implemented a centralized pole selection process with all pole replacements being selected based on identical criteria with data inputs from the inspection results of the Line Patrol Program. From the list of poor condition poles a subset of poles is selected and released to the field for replacement. When releasing these poles to the field, a timeline of one to three years is given for completion. If a pole is in urgent need of replacement, the field will be asked to replace it within the next year. For all other poles the field will be given the flexibility to replace it within the next one to three years to optimize the work execution.

There are currently a large number of poles that are in poor condition. These poor condition poles will take at least five years to be replaced.

The flexible replacement schedule allows the field to optimally schedule replacement in conjunction with other work in the area for increased efficiency. In order to determine the appropriate pole replacement design and technical requirements, Hydro One's field staff visit the pole replacement sites. During this visit, field staff may identify additional poles that have deteriorated since the last condition data was collected. Once members of field staff identify a pole that is deteriorating, they are required to submit updated condition data such that those poles are considered for inclusion in the pole replacement program. If they are deemed to require replacement, then they are replaced in conjunction with the previously identified poles.

Recommendation 3: Pole Replacement Crew

The study recommended considering use of dedicated pole replacement crews when geography and/or pole density permit. When geography and pole density conditions make the use of dedicated crews desirable, Hydro One will consider this option.

Recommendation 4: Pole Refurbishment Program

The study found that most of the peer group perform pole refurbishment. The study recommended refurbishing poles where possible. Hydro One will investigate the feasibility and cost benefit analysis of this option and its impact on work methods. The results of this analysis will determine if Hydro One will implement a pole refurbishment program.

Recommendation 5: Pole Replacement Rate

The benchmarking study found that Hydro One's pole replacement and maintenance costs are approximately average for the North American industry, with low unit costs for inspections and average costs for pole replacement. The study also found that the replacement rate has been slower than for the peer panel and, as a result, Hydro One's pole inventory is the oldest in the comparison group. This finding supports the need to increase the pole replacement rate as proposed in the DSP, see ISD SR-09 for more details on proposed pole replacement rates.

1.6.3.2 DISTRIBUTION STATION REFURBISHMENT PROGRAM STUDY

Recommendation 1: Project Planning Process

The study recommended implementing a formal data governance process for equipment performance and maintenance data, and to incorporate that information into the asset condition scoring and project planning process. The study also recommended incorporating test results and maintenance history data for switching and protection equipment and relays into the asset condition scoring and project planning process.

Hydro one is working towards improving its data governance process for equipment performance. Hydro One Station refurbishment projects are driven by major component replacement needs, (e.g., transformers, breakers, reclosers, and structures). Asset condition data on these major components drives station asset condition scoring and subsequently determines station refurbishment projects. Switching and protection equipment, and relays do not drive this program, however they are addressed under the station centric refurbishments.

Recommendation 2: Project Management Execution

The study recommended enhancing cost and work completed reporting for individual projects, and implementing a formal change control process. Hydro One currently employs cost and work completed reporting for individual projects, but has moved to improve it going forward. Substation refurbishment projects will now be managed individually with comprehensive tracking of costs, progress and a formal change control process for each project.

Recommendation 3: Key Performance Indicators (KPIs)

The study recommended developing a more comprehensive set of key performance indicators, including project cost performance measures and assessments of project impacts on substation reliability, maintenance costs and overall asset health. Hydro One is exploring the development of KPIs for station projects to incorporate aspects of cost and system impact measures.

Recommendation 4: Station Refurbishment Approach and Rate

The study found that Hydro One's station-centric approach is appropriate, given the system configuration and density within the service territory. This finding supports Hydro One's approach to continue the expansion of its station-centric refurbishment investments as proposed in the DSP. For more details, see Distribution Station Refurbishments (ISD SR-06) and Station Spare Transformer Program (ISD SR-03).

The study found that Hydro One's power transformer age profile ranks in the older end of the peer group distribution. The study also found that Hydro One's "Expected Service Life" for power transformers is somewhat higher than the peer group average. Given that Hydro One's expected service life is reasonable and given its relatively old transformer age profile, this supports the level of station refurbishment investment as per the DSP, which is expected to maintain the current condition profile and corresponding reliability over the DSP period. Based on Hydro One's station service life profile and supported by the benchmarking study finding, it is expected that there will be an increased rate of distribution station deterioration that will require an increase in the level of station refurbishment investment beyond 2022. Complete details on the proposed increase in Hydro One's station-centric refurbishment programs can be found in Distribution Station Refurbishments (ISD SR-06) and Station Spare Transformer Program (ISD SR-03).

1.6.3.3 VEGETATION MANAGEMENT PROGRAM STUDY

Hydro One Forestry Services is committed to demonstrating improvements in the areas of productivity and cost efficiency. Hydro One is addressing some key recommendations made in the Vegetation Management Program Study as follows:

Recommendation 1: Technology Innovation Project

Hydro One is currently engaged in the early stages of a technology innovation project that is focused on upgrading the systems and processes that manage the vegetation programs. This project will consider options to address the following recommendations:

- Improvement through innovation and the mechanization and automation of the UVM program to enable more effective work planning and cost/resource predictions;
- Improve data analytics and predictive modeling through automated data collection of key UVM activities;
- Improve customer knowledge, communication, and involvement by merging UVM data with the customer service system;
- Synchronize the annual asset inspections with the UVM work planning program to quantify system vegetation conditions based on performance metrics for maintaining air space around conductors to improve workload understanding;
- Identify fixed cost increases and overheads allocated to UVM to ensure cost effects of changes to the program are portrayed accurately to enable a better understanding of improvements to production and other cost reduction measures; and
- Improve equipment and personnel utilization to lower unit costs by improving efficiency and optimizing equipment availability.

In 2016, Hydro One Distribution completed a pilot study on using LiDAR technology to improve program planning. LiDAR and other remote sensing technologies are in scope of the technology innovation project.

Recommendation 2: ROW Clearing Productivity

Hydro One is exploring and integrating new mechanical equipment into their work practices to improve productivity. The use of Feller Bunchers and Kershaw Sky Trimmers, and the introduction of a greater variety of grinding equipment are having a significant impact on backlog feeder clearing and brush control efficiencies. Further productivity improvements in the areas of vehicle telematics usage, route optimization, and schedule optimization are being investigated in the scope of the technology innovation project. Storm restoration efficiencies have also been gained through Forestry staff becoming qualified to provide their own work protection to provide safe work conditions.

To improve unit prices, Hydro One strives to optimize resource allocation while abiding by the terms of its Collective Bargaining Agreements. Current approaches include utilization of Hiring Hall Technicians for work planning and additional seasonal workers.

Recommendation 3: Increased Herbicide Usage

Herbicide is one tool used in Hydro One's integrated vegetation management program. The use of herbicides is sought where appropriate. Advances in the herbicide industry are closely tracked by our Herbicide Advisory Committee. Hydro One will continue to pursue the judicious use of herbicide where appropriate, including current and expanding mid-cycle application programs to control regrowth after manual control.

Recommendation 4: Outage Investigation Protocol

Hydro One has implemented a detailed outage investigation process to collect more root cause data and drive improvements in mitigating outages through planned investments.

Recommendation 5: Tree Risk Assessment Program

All programs within the vegetation management program contain elements of tree risk assessment. However, to reduce outages caused by off-ROW trees, Hydro One will be conducting a review of the International Society of Arboriculture's Tree Risk Assessment program to identify improvements in current assessment protocols and will apply these findings to the outage investigation process.

More discussion on the incorporation of the findings and recommendations of the Vegetation Management Program Study are in the exhibit entitled Sustaining OM&A, Exhibit C1, Tab 1, Schedule 2.

1.6.3.4 IT BUDGET ASSESSMENT

Recommendation 1: Rationalize Enterprise Computing Costs

The study recommended Hydro One work with internal stakeholders and an outsourcer to rationalize enterprise computing costs and review opportunities to increase server virtualization. The study also recommended Hydro One evaluate data management policies and roles at the business level to optimize storage costs.

As a result of the recommendation, Hydro One has developed a detailed 2017-2022 costs savings program, listed as IT Productivity Initiative. Included in the program are initiatives to increase server virtualization, enhance existing data management policies, optimize storage and reduce storage costs.

Recommendation 2: Reduce Capitalization Policy

The study recommended Hydro One work with internal business leadership and Finance to review the current capitalization minimum threshold of $2M and determine whether there is an opportunity to align with the peer group capitalization threshold of $250K-$500K.

As a result of the recommendation, Hydro One Finance is reviewing the current capitalization policy of $2M and will be making a decision in the near future on a potential reduction of the minimum threshold.

Recommendation 3: Review Current Organization Design

The study recommended Hydro One review the organization design to understand roles and responsibilities of retained in house IT staff and identify any overlaps (or duplication) with the service provider. The study also recommended determining whether roles should be retained or outsourced and reviewing how work is managed among the parties.

As a result of this recommendation, Hydro One is in the process of reviewing the current IT organizational structure and the roles and responsibilities of internal staff and the main outsourcer.

TABLE OF CONTENTS

LIST OF FIGURES

EXECUTIVE SUMMARY

In the Ontario Energy Board's (OEB's) decision in EB-2013-0416/EB-2014-0247 on Hydro One's distribution rates for 2015 to 2019, the Board directed Hydro One to "to conduct an external benchmarking study on the unit cost of its pole replacement and station refurbishment programs against other utilities as well as carry out an internal trend analysis to show the variability of these unit costs over time (year over year)". Hydro One was also directed to "report on the results of this work with the corresponding analysis as part of its next rates application". Through a competitive procurement process, Hydro One Networks Inc. (Hydro One) engaged the consortium of Navigant Consulting Ltd. (Navigant) and First Quartile Consulting (1QC) to conduct this benchmarking study.

This report provides an overview of the approach, including the processes of selecting and recruiting utilities to participate in the study, assembling appropriate performance metrics, and gathering and analysing the data. The study provides insights into both the costs incurred by Hydro One and the practices used for the execution of pole replacement and substation refurbishment. Primary findings from the study for both the pole replacement and station refurbishment activities are presented below.

Pole Replacement

1. Hydro One's costs are in line with the average of the comparison group, with low unit costs for inspections and average costs for replacement of poles.
2. Hydro One inspects its poles more frequently than most utilities, using mostly visual inspections with some light physical inspections, while the others typically perform more rigorous physical inspections and testing.
3. The replacement rate for Hydro One is slower than for the comparison utilities, with the result that Hydro One's pole inventory is the oldest; on average, eight years older than the rest of the utilities in the comparison group. This matches the planned life of poles, which is also about 10 years longer for Hydro One than for the comparison group.
4. Hydro One does not employ a formal pole refurbishment program, whereas 13 of 17 companies in the comparison group do in an effort to postpone premature replacement of poles.

Substation Refurbishment

1. Station refurbishment activities are varied within and across utilities.
2. Hydro One's costs for individual substation refurbishments are within range observed across the comparison utilities.
3. As with most utilities, the cost of individual Hydro One refurbishment projects ranges from first to fourth quartile.
4. Navigant and First Quartile Consulting believe that Hydro One's station-centric approach is appropriate, given the system configuration and density within the service territory; Hydro One has the highest percentage of single transformer substations, higher than average transformer loadings, older age profile for in-service transformers, and more rural locations.
5. Use of testing results and maintenance history records could be improved in making replace versus repair decisions for certain substation equipment.
6. Use of performance measures for tracking success of individual programs, in addition to the overall refurbishment program could be enhanced.

Recommended Actions

In its request for proposals, Hydro One indicated that the study should produce recommendations that Hydro One could act upon to close gaps to best practice and improve the efficiency of its operations. Several recommendations were developed for each of the two areas under study.

Pole Replacement

The key recommended actions for pole replacement are outlined below.

1. Consider modifying the pole replacement program to include more complete pole inspections (sound, bore, excavation) and a longer (approximately 10-year) inspection cycle – the OEB would need to approve the change in inspection cycle.
2. Expand the existing centralized program management and pole selection approach to cover 90-95% of the replacement / refurbishment work on poles in a given year, leaving the remainder to be guided by the local staff while still meeting the centralized strategy and replacement criteria
3. Where geography and/or pole density permit, consider the use of dedicated pole replacement crews.
4. Consider modifying the program to include a rigorous pole refurbishment option, when appropriate.

Substation Refurbishment

The key recommended actions for substation refurbishment are outlined below.

1. Consider implementing a formal data governance process for equipment performance and maintenance data, and incorporating that information into the asset condition scoring and project planning process.
2. Enhance cost and work completion reporting for individual projects, and implement a formal change control process.
3. Develop and implement a more comprehensive set of key performance indicators including in-progress project cost performance measures and assessments of project/program impacts on substation reliability, maintenance costs and overall asset health.

1. INTRODUCTION

In the OEB's decision in EB-2013-0416/EB-2014-0247 on Hydro One's distribution rates for 2015 to 2019, it directed Hydro One to "to conduct an external benchmarking study on the unit cost of its pole replacement and station refurbishment programs against other utilities as well as carry out an internal trend analysis to show the variability of these unit costs over time (year over year)". Hydro One was also directed to "report on the results of this work with the corresponding analysis as part of its next rates application".

1.1 Study Objectives

Hydro One engaged Navigant and First Quartile Consulting to design and implement a robust and replicable benchmarking study of Hydro One's distribution costs.

The benchmarking study was designed to:

- Include an appropriate group of utilities to compare Hydro One against, taking into account a number of characteristics, including asset demographics, geography, customer characteristics, etc.;
- Quantify and evaluate Hydro One's practices and unit costs for distribution pole replacement and distribution substation refurbishments and substation replacements relative to the comparison utilities, taking into account cost drivers and differentiating characteristics;
- Ensure a common understanding of the comparison criteria through the use of clear definitions;
- Make recommendations on practices that could be augmented or adopted to improve efficiency; and
- Engage stakeholders in regards to the comparison group selection criteria, comparison metrics, and preliminary findings and recommendations.

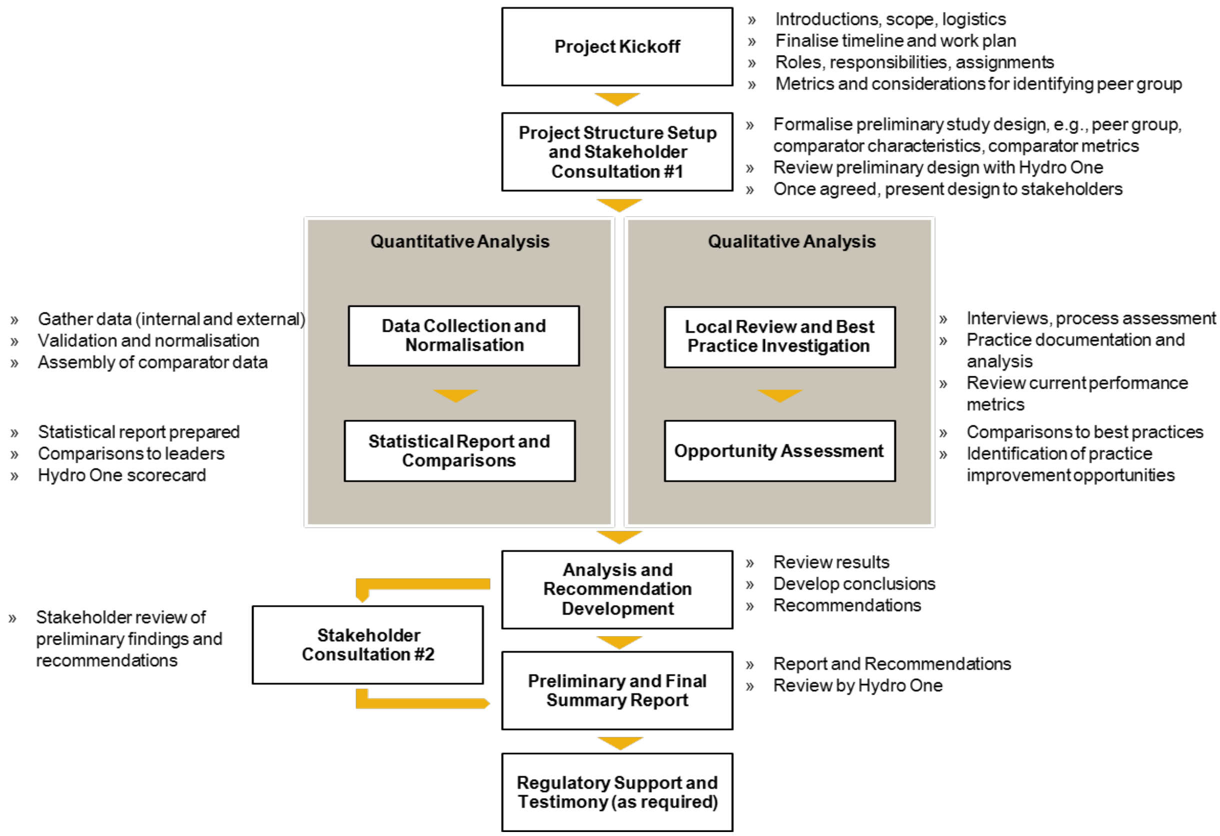
1.2 Overview of Approach

The approach to the engagement included two analyses: a quantitative analysis and a qualitative analysis. Figure 1 provides a pictorial overview of the approach used for the project. As part of the study, the evaluation team determined which business and operational demographics were relevant to identify a representative comparison group given Hydro One's vast and disparate service territory. This work leveraged First Quartile Consulting's existing transmission and distribution benchmarking program participants as well as additional companies recruited specifically for this study.

Through the quantitative analysis, the evaluation team identified and collected the necessary data from Hydro One and the comparison utilities, normalised the data, and assembled statistical reports and comparisons. Through the qualitative analysis, the evaluation team explored cost variations, identified current and best practices, and identified gaps that ultimately led to recommendations on processes and practices that Hydro One could adopt to realise efficiency gains.

The study engaged and included stakeholders. Hydro One consulted with stakeholders regarding the terms of reference for this study. Stakeholders then had the opportunity to review and provide comments at the beginning of the study on the proposed methodology and selection of the comparison group. Finally, they commented on the preliminary results, prior to the evaluation team finalising the study.

Figure 1. Overview of Benchmarking Approach



1.3 Content of Report

This report is organised into five sections and two appendices.

- Section 1: Introduction, provides an overview of the study objectives, and approach.
- Section 2: Benchmarking Process, provides an overview of the process, information collected, comparison group selection, and normalising factors used.
- Section 3: Pole Replacement Benchmarking Results, summarises cost performance, along with details associated with replacement and refurbishment of poles.
- Section 4: Substation Refurbishment Benchmarking Results, summarises the results for refurbishment and rebuilding of distribution substations
- Section 5: Recommendations, identifies practices that could be augmented or adopted to realise efficiency gains.
- Appendix A: Detailed Comparison Group Statistics, provides demographic data for the utilities that participated in the study.

2. BENCHMARKING PROCESS

The benchmarking process is the means by which data is collected and analysed in a standardised fashion. This process provides transparency into Hydro One practices and lends itself to identifying strengths as well as areas for improvement. This section covers four topics.

1. **Overview:** Outline of the benchmarking process from start to finish.
2. **Information Collected:** Description of the data collected.
3. **Comparison Group Selection:** Characterisation of the Canadian and U.S. distribution utilities included in the study.
4. **Normalising Factors:** Normalising factors were chosen to allow comparison of costs across utilities on a common basis. In the case of poles, the normalising factor most often was the number of poles or the number of poles touched (i.e. inspected, refurbished, and/or replaced). For substations, MVA of capacity, number of transformers, and number of substations were all used as normalisers.

2.1 Overview

This benchmarking study provides a balanced evaluation of Hydro One's pole replacement costs and approach versus other utilities, and a similar comparison of the unit costs for substation refurbishment. This analysis considers total cost and operations across the company's operating territory, rather than examining regional variations or providing regional recommendations. The benchmarking process consisted of the following steps for each of the two areas of study:

1. **Project structure setup:** Determine comparison group, comparator characteristics and comparator metrics, and present design to stakeholders.
2. **Quantitative analysis:** Gather data (internal and external), validate and normalise, and assemble the data; create a statistical report; and create a Hydro One scorecard.
3. **Qualitative analysis:** Review performance metrics, interview Hydro One staff, compare Hydro One practices to comparison utility and industry best practices, and identify practice improvement opportunities.
4. **Analysis and recommendation development:** Review results, develop conclusions and recommendations, and present them to stakeholders.

2.2 Information Collected

To best characterise Hydro One's costs and operating practices, the project team collected data about demographics, overall and unit cost performance, program performance and replacement/refurbishment rates for Hydro One and the comparison utilities. This data and the areas covered by the data that was collected for 2012, 2013, and 2014 operation years (the most recent complete periods), are summarised in Figure 2 and Figure 3.

Figure 2. Data Collected from Hydro One and Comparison Utilities for Pole Replacement

Demographic Information	Practice Information	Cost Performance Data
• Service territory square miles/km • Number of in-service poles by material type and age profile • Pole footing conditions (soil vs. rock vs. swamp) • Pole accessibility (on-road vs. off road) • Pole framing (single phase vs. multi-phase/circuits) • Average crew travel time to pole work sites	• Planned Service Life for different pole types • Inspection methods, trigger ages and time cycles • Average months to complete non-urgent pole inspection recommendations • Refurbishment methods used • Replacement process information (# trips, crew sizes, equipment complements, person-hours required) • Cost categorization (O&M vs. Capital) for different work activities • Regulatory requirements • Agreements with joint-use utilities regarding pole removals	• 2012 to 2014 pole inspection volumes, costs and hours • 2012 to 2014 results of inspections • 2012 to 2014 pole refurbishment volumes, costs and hours • 2012 to 2014 program pole replacement volumes, costs and hours • 2012 to 2014 emergency pole replacement volumes, costs and hours • Breakdowns of 2012 to 2014 labor costs for inspection, refurbishment and replacement by type (company vs. contractor)

Figure 3. Data Collected from Hydro One and Comparison Utilities for Substation Refurbishment

Demographic Information	Practice Information	Cost Performance Data
• Service territory square miles/km • Number of distribution substations by size (# power transformers) and service territory density served (urban vs. suburban vs. rural) • Number of distribution power transformers by high side and low side voltage • Current in-service age profiles of major substation components • Average power transformer loading at non-coincident peak % for past 12 months	• Planned Service Life for major substation components • Criteria for using different substation refurbishment approaches (component-focused vs, station-centric vs. full station rebuild) • 2010 to 2019 number of actual and planned refurbishment projects by approach • Component evaluation processes to determine need for replacement or repair/reconditioning • Component replace vs. repair/recondition criteria • Use of integrated (multi-component) modules • Regulatory support for refurbishment program funding	• Data on recently completed distribution substation refurbishments including: • Refurbished substation demographics • Refurbishment project type (component-focused vs. station-centric vs. full station rebuild) and high level work scope • Detail on major components replaced/installed • Total project costs and costs associated with major component installations • Year when majority of work was performed • Breakdowns of labor resource costs by function (engineering & design vs. construction vs. commissioning) and type (company vs. contractor)

2.3 Comparison Group Selection

The goal of the comparison group selection is to find utilities that represent the industry, with both similarities and differences from Hydro One. Similar utilities provide the opportunity for direct comparisons of outcomes (costs, service levels, etc.) while dissimilar utilities offer the opportunity to investigate a broader array of practices that might be beneficial for Hydro One. Companies across North

America were identified and evaluated for their usefulness as part of the comparison group. As a result, 29 North American Utilities were approached to participate in the study.

Figure 4. Comparison Utilities Targeted for Participation

8 Canadian Utilities	21 U.S. Utilities
• Large provincial utilities from across Canada • Mix of local distribution companies in Ontario	• Large utilities • Previous willingness to participate in similar studies

Responses (combined) were received from 20 organizations. Those not responding cited various reasons for not participating:

- Lack of interest;
- Insufficient resources; and
- Competing priorities.

Not all of the utilities agreed to participate in both parts of the study. A few contributed data only for the pole replacement part of the study, a few participated only in the substation refurbishment part, while the majority participated in both portions. Together, they provide a reasonable representation of the North American utility industry, and a viable comparison group for Hydro One.

A concerted effort was made, as requested by stakeholders, to include more Canadian utilities. However, because there is no requirement for them to participate, and the effort for them to participate is significant, only a few Canadian utilities agreed and provided data for the study. As shown in Figure 5, the utilities in the comparison group are located throughout Canada and the U.S. There are several large companies, some smaller ones, with regulatory circumstances and weather patterns similar and different from Ontario. The net result is a reasonably representative and useful comparison group.

Figure 5. Comparison Utility Service Territories

Appendix A provides a list of the comparison group companies, along with some demographic details, including number of customers, number of poles, and number of distribution substations.

2.4 Normalising Factors

Because the comparison group includes both U.S. and Canadian utilities, the first normalisation step was to convert all cost figures into Canadian currency. All charts and tables showing dollar values are based on Canadian dollars. The conversion rate used for data submitted by U.S. companies was the average currency exchange rate in effect during the year in which the work was performed. The shift in the exchange rate in 2014, the Canadian companies look slightly more cost effective, despite any change in their actions. All values are presented in nominal dollars, and costs were not adjusted for inflation when taking an average or aggregating across multiple years.

The figure below shows the exchange rates used for this study.

Figure 6. Exchange Rates Used in the Study

	2010	2011	2012	2013	2014
CAD:USD	0.9700	0.9987	0.9995	1.0300	1.1043

Source: http://www.federalreserve.gov/releases/g5a/current/

Within the individual areas of focus, different normalising factors were appropriate. In particular, for the pole replacement investigation, the number of poles served as the primary normalising factor. It varied depending on what the team was considering, meaning the total number of poles on a company's system was used for lifecycle cost analysis for all poles, and the number of poles touched (or treated) was used as the normaliser for the unit costs of specific activities (i.e., inspections, replacement, and/or refurbishment).

For substation refurbishment, unit costs were built around the total number of stations, the number of transformers, transformer banks, and the capacity in terms of MVA. No single normalising factor is ideal for comparing the unit costs, so a portfolio of normalisers was used to reach the appropriate conclusions. Additional comparisons were made using breakers and switches as normalisers, where the subject of cost analysis was the breakers or switches, to provide a comparison point for those companies who do component-based replacements/refurbishment rather than station-based work.

3. POLE REPLACEMENT BENCHMARKING RESULTS

The key findings of the pole replacement benchmarking study are provided below.

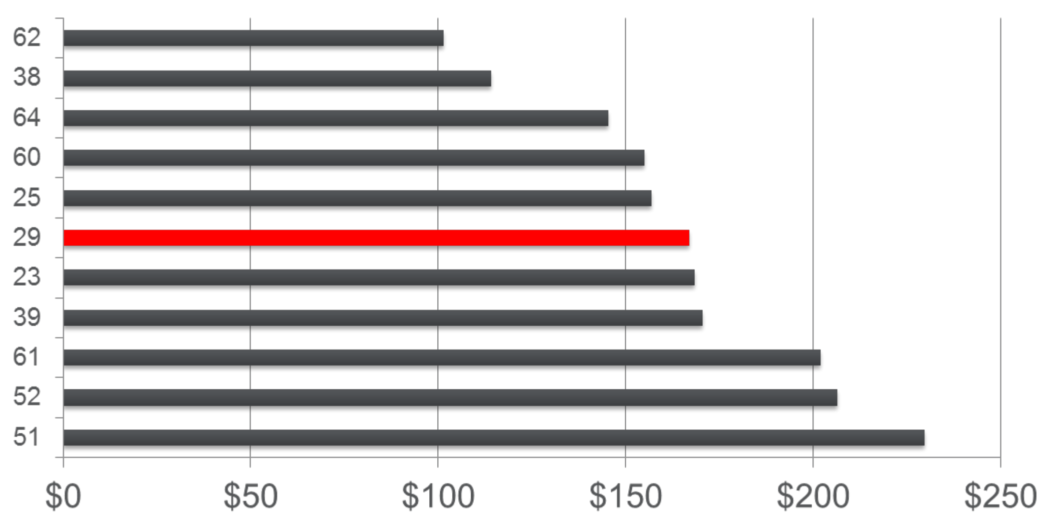
1. Hydro One's costs are in line with the average of the comparison group, with low unit costs for inspections and average costs for replacement of poles
2. Hydro One inspects its poles more frequently than most utilities, using mostly visual inspections, while the others typically do more rigorous physical inspections
3. The replacement rate has been slower than for the comparison utilities, with the result that Hydro One's pole inventory is the oldest, and on average, eight years older than the rest of the utilities in the comparison group. This matches the planned life of poles, which is also about 10 years longer for Hydro One than for the comparison group
4. Hydro One does not employ a formal pole refurbishment program, whereas 13 of 17 companies in the comparison group do in an effort to postpone replacement of poles, and reduce lifecycle costs.

3.1 Cost Comparisons

The cost analysis portion of the study looked at pole replacement from several aspects – lifecycle costs per pole across all poles, unit costs per pole worked on in a year, and then costs of individual aspects of the pole program such as inspection costs, replacement costs, and refurbishment costs. Each of these is summarized below in a series of charts showing the resulting cost figures.

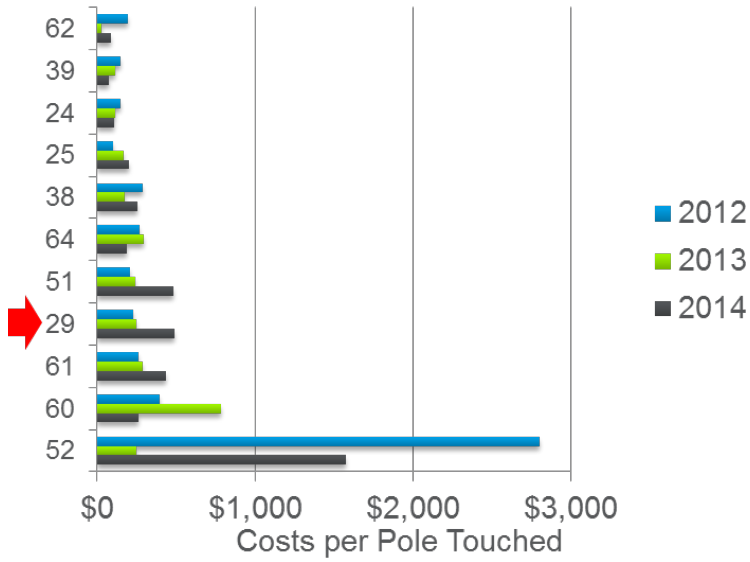
As shown in Figure 7, Hydro One demonstrates average life cycle costs. The most important factor in the life cycle cost is the original installation cost, but other factors such as the cost of inspections, the time between inspections, expected pole life, and others have influence as well.

Figure 7. Actual Annualized Life Cycle Costs per Pole per Year



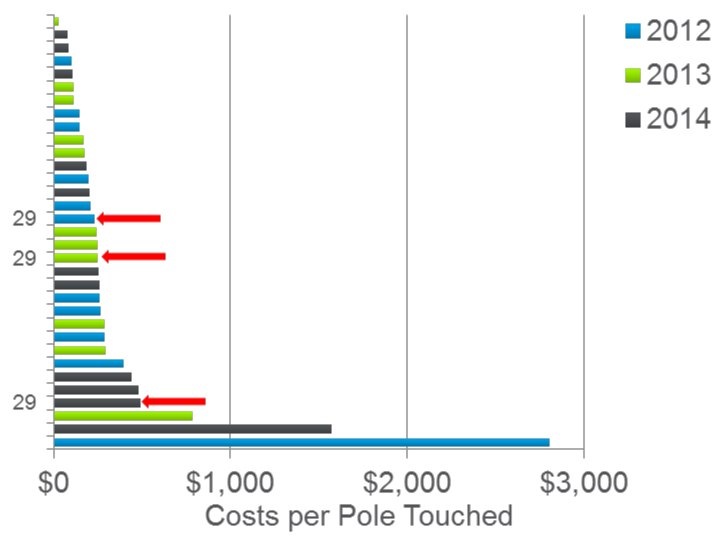
Another way to view pole program costs is through the unit cost of the poles touched (or treated) during an individual year. This is affected by the choices of how many poles to work on during a year, and what is done to those poles. "Poles touched" in this case is those inspected, refurbished, or replaced during the year, so depending on the mix of work done, the costs can vary year to year for an individual company. Three years of data were gathered for each of the participating companies, to allow understanding of these potential shifts from year to year. As with the life-cycle costs shown above, in this comparison, Hydro One again falls very near the mean of the comparison group.

Figure 8. Pole Program Costs Per Pole Touched Grouped by Company



Note: In this comparison, pole touched means the total number of poles inspected, replaced, and refurbished.

Figure 8. Pole Program Costs Ranked by Annual Spend



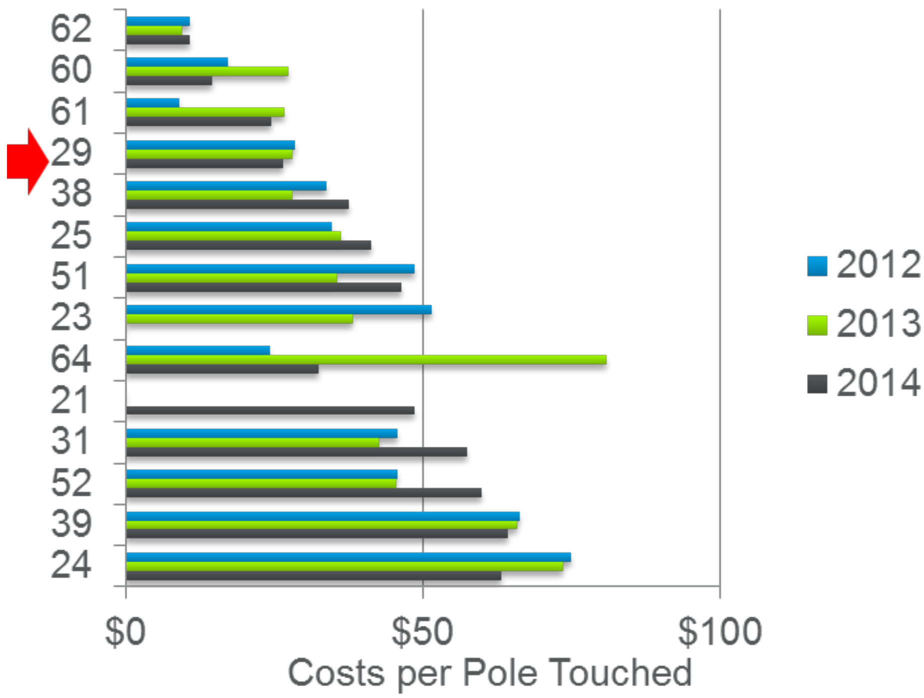
Note: In this comparison, pole touched means the total number of poles inspected, replaced, and refurbished.

3.2 Pole Inspection Costs and Frequency

Inspection costs are a function of what is done during the inspection. For example, is it a visual inspection, sound and bore, or other more complex physical inspection. Hydro One performs visual and light physical inspections on a shorter interval than most other companies (three to six years compared to 10 for the panel). Hydro One is the only company that does not use bore, excavation or ultrasonic methods on a dedicated schedule (seven to 20 years).

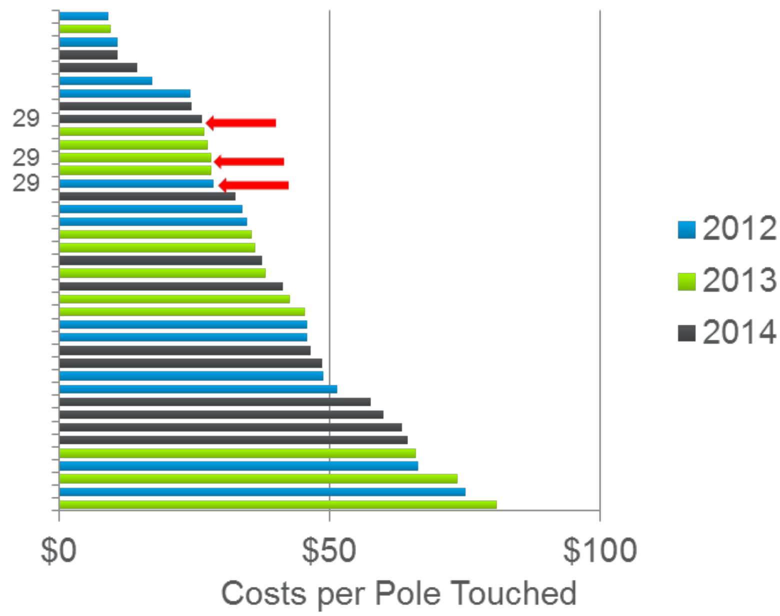
Overall, Hydro One conducts its inspections at a cost that is below the average of the comparison group. Hydro One costs are $27.60 per pole inspected, which is 29% lower per inspection compared to the mean of the panel.

Figure 9. Pole Inspection Costs Grouped by Company



Note: In this comparison, pole touched means the total number of poles inspected.

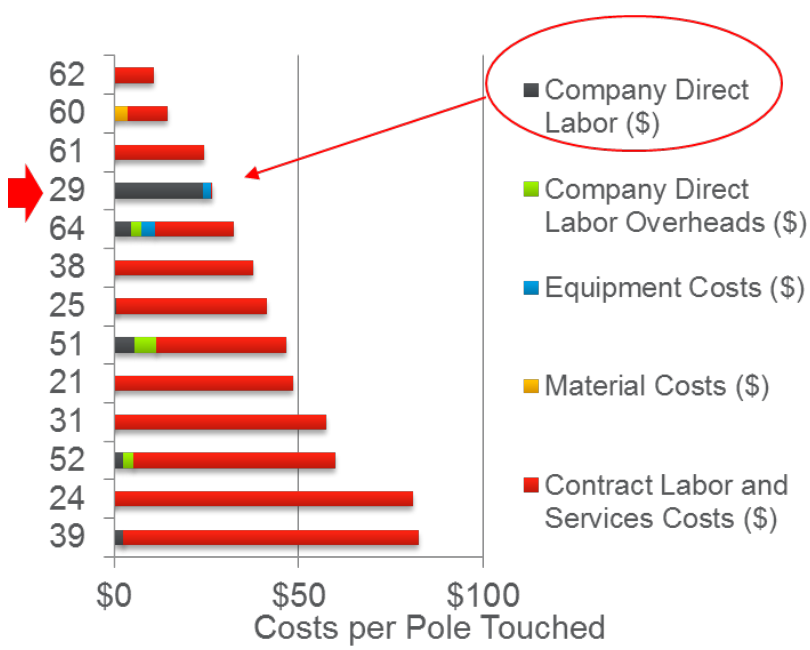
Figure 10. Pole Inspection Costs Ranked by Annual Spend



Note: In this comparison, pole touched means the total number of poles inspected.

Hydro One is the only company that performs more than 95% of inspections with in-house crews as compared to near 100% outsourced in other companies.

Figure 11. Pole Inspection Costs by Category

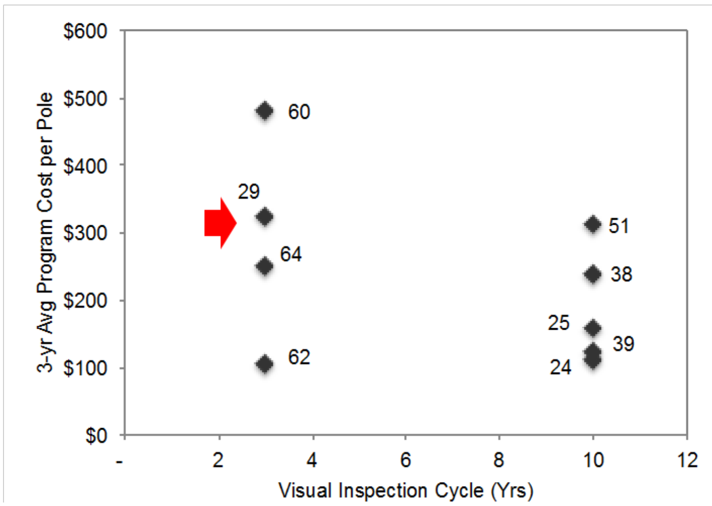


Note: In this comparison, pole touched means the total number of poles inspected.

3.2.1 Visual Inspection Cycle Time

Figure 12 shows the relative frequency of visual inspections and its impact on total pole replacement program costs. Where companies provided a range, the lower end of the range is represented in the figure. The frequency of inspections has only a modest impact on total program costs, since the majority of program costs are driven by pole replacements.

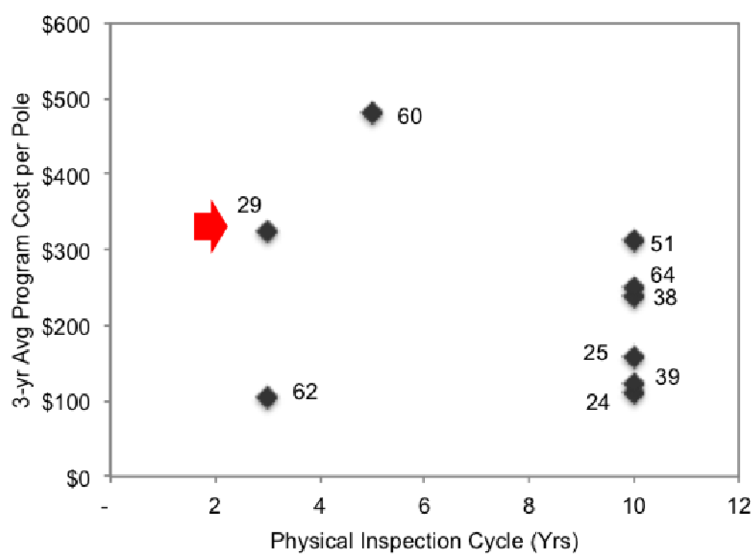
Figure 12. Visual Inspection Cycle Frequency



3.2.2 Physical Inspection Cycle Time

Though Hydro One doesn't have a comprehensive program for physical inspections, for those that are done, the cycle time is relatively short in comparison to the benchmark panel.

Figure 13. Physical Inspection Cycle Frequency



3.3 Replacement Rates and Pole Age

Hydro One has historically replaced its poles at a slower rate than other utilities. This fits with its planned longer life of the poles than other utilities in the comparison group. The net result is that the average age of Hydro One's wood poles is the oldest in the panel, at 37 years.

Figure 14. Age Profile of Wood Poles

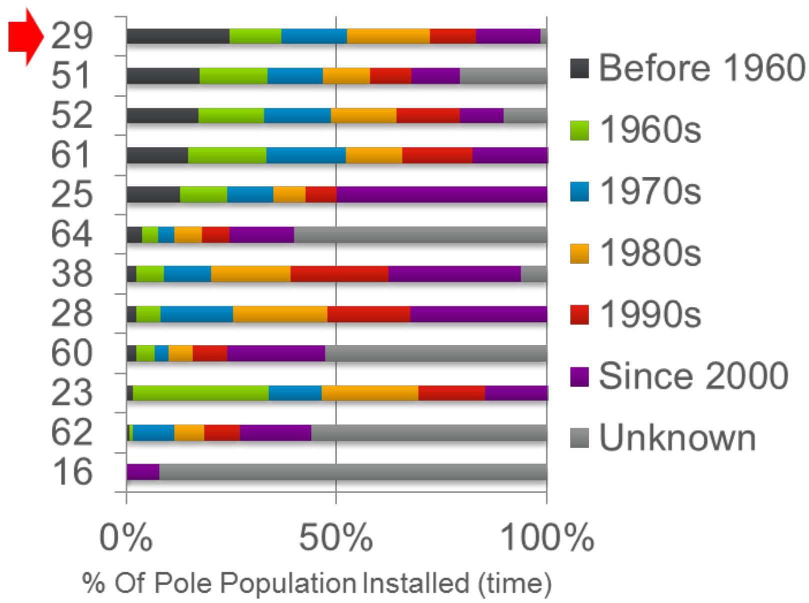


Figure 15. Average Age versus Planned End of Life

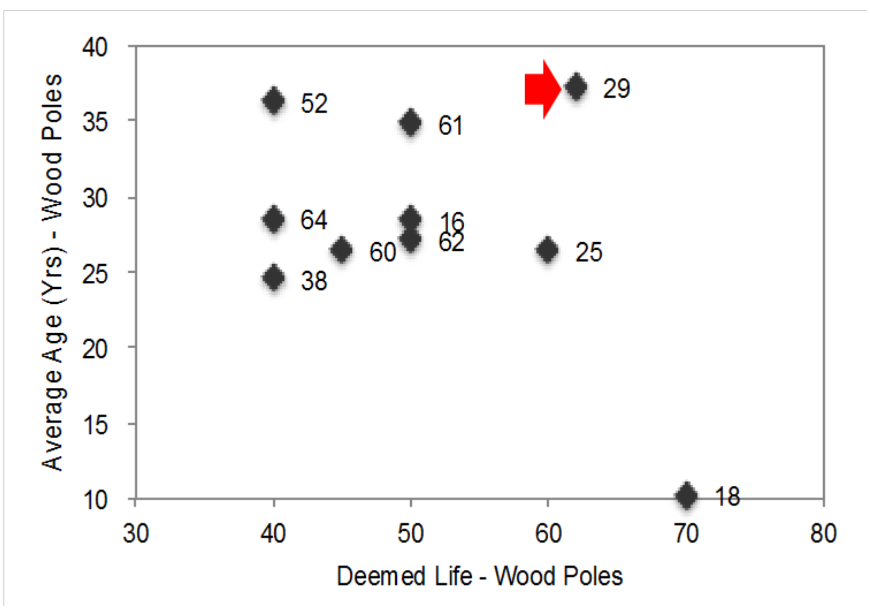
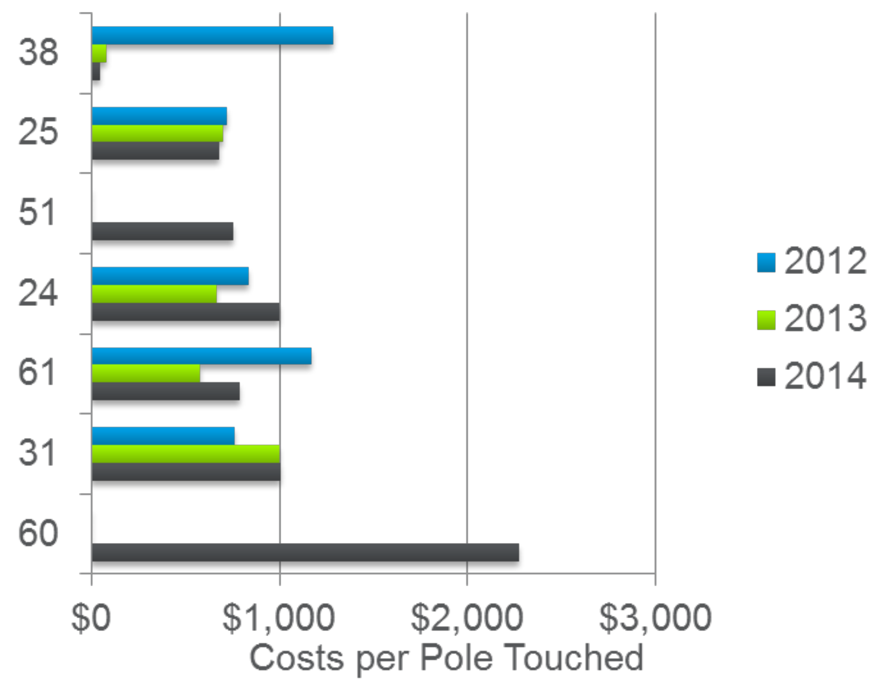


3.4 Pole Refurbishment Costs

Most North American utilities (13 of 17 in the study) have a formal distribution pole refurbishment practice in place to deal with poles that fail prematurely. Hydro One currently does not have such a refurbishment program, electing to replace poles that fail, rather than refurbish them. The fact that Hydro One has experienced a long life for its poles is one indicator of the reasonableness of this approach. At the same time, organizations with refurbishment practices in place are able to demonstrate that their lifecycle costs have improved due to the refurbishment practice.

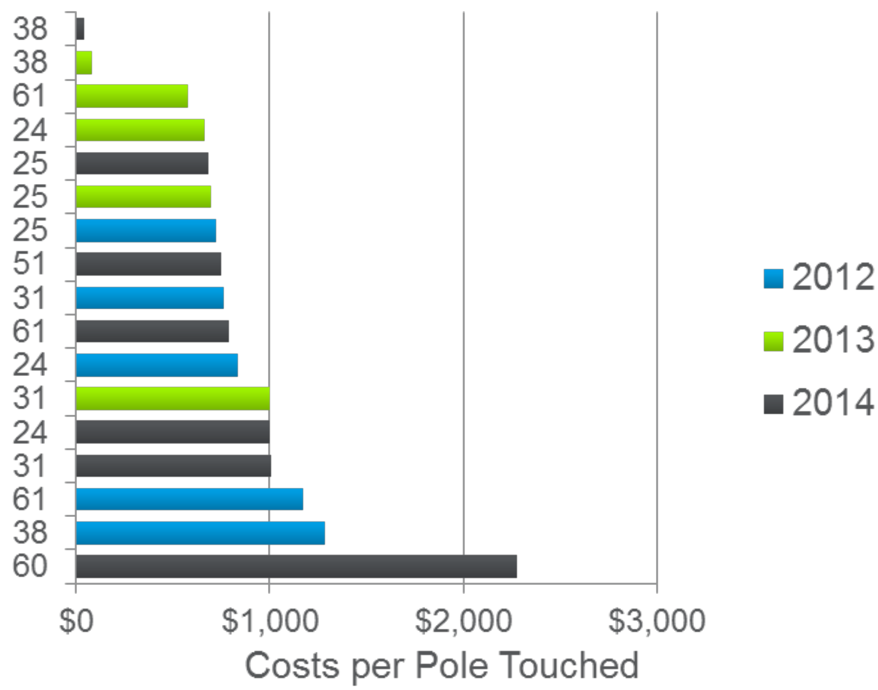
Figure 16 and Figure 17 show the unit costs for pole refurbishment for those companies who track and could report those costs. The mean cost to refurbish a pole is $947.

Figure 16. Pole Refurbishment Costs Grouped by Company



Note: In this comparison, pole touched means the total number of poles refurbished.

Figure 17. Pole Refurbishment Costs Ranked by Annual Spend



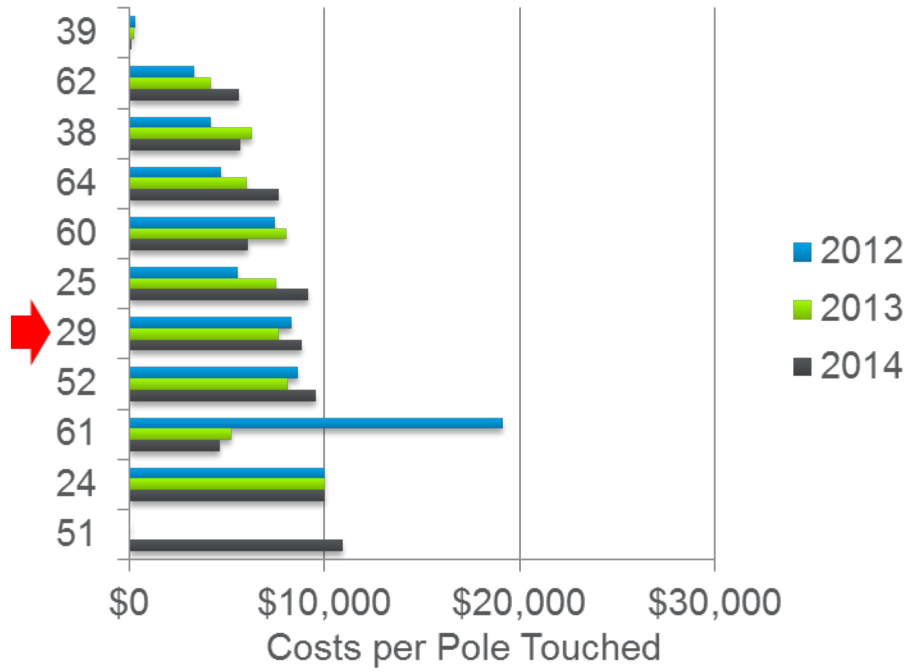
Note: In this comparison, pole touched means the total number of poles refurbished.

3.5 Pole Replacement Costs

As poles reach the end of their useful life, they must be replaced. All utilities have systematic programs for replacing those poles, with the goal of getting the longest useful life without allowing the poles to stay in service until their failure. Across the comparison group, the average cost to replace a pole is $7,105. For Hydro One, that cost is $8,266, or 16% higher than the mean.

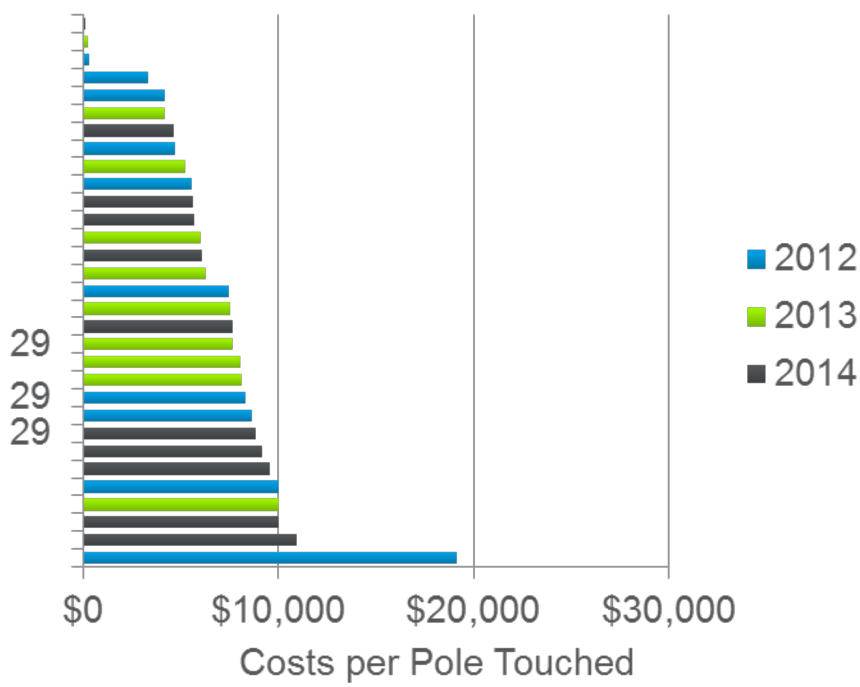
In the course of the study, a number of factors were investigated for their impact on the cost of replacing poles. This analysis revealed that these demographics had little impact on the overall results. Elements investigated include the planned life of the poles, the percent of poles installed off-road, the percent of poles installed in soft soil, the average travel time to get to poles, and average age of poles.

Figure 18. Pole Replacement Costs Grouped by Company



Note: In this comparison, pole touched means the total number of poles replaced.

Figure 19. Pole Replacement Costs Ranked by Annual Spend



Note: In this comparison, pole touched means the total number of poles replaced.

3.6 Refurbishment versus Replacement Costs

The cost of replacing a pole is substantially higher than the cost to refurbish a pole, with replacement being approximately 7x more expensive, where refurbishment is an option. Refurbishment is not an option in all cases. For example, it wouldn't make sense to refurbish a 50-year-old pole when its useful life is planned for 60 years. Refurbishment makes the most sense when a pole is found to be failing early in its planned life. Refurbishment has the possibility of extending the life of the pole by 20 to 40 years. In any scenario where a refurbishment can extend the life of the pole by over 20 years, then the economic benefit of refurbishment tends to be clear.

4. SUBSTATION REFURBISHMENT BENCHMARKING RESULTS

The six key findings of the station refurbishment benchmarking study are provided below.

1. Station refurbishment activities are varied within and across utilities.
2. Hydro One's costs for individual substation refurbishments are within range observed across the comparison utilities.
3. As with most utilities, the cost of individual Hydro One refurbishment projects ranges from first to fourth quartile.
4. Navigant and First Quartile Consulting believe that Hydro One's station-centric approach is appropriate, given the system configuration and density within the service territory; Hydro One has the highest percentage of single transformer substations, higher than average transformer loadings, older age profile for in-service transformers, and more rural locations.
5. Use of testing results and maintenance history records could be improved in making replace versus repair decisions for certain substation equipment.
6. Use of performance measures for tracking success of individual programs, in addition to the overall refurbishment program could be enhanced.

4.1 Cost Analysis

The analysis compared costs of substation refurbishment and rebuilding in several different ways. Since companies take different approaches to substation refurbishment, it was necessary to group the refurbishment work into several categories – full station rebuild projects, substation-centric projects, and component-based projects.

Hydro One's costs for station centric and full substation rebuild refurbishment projects fall within a reasonable range compared to comparison utilities. As with other companies, Hydro One's unit costs for individual projects vary from first quartile to fourth quartile.

Across all types of projects, Hydro One's per unit installation costs for major substation components are generally lower than those of other comparison utilities due to Hydro One' s use of less expensive, lower capacity equipment.

4.1.1 Full Substation Rebuild Projects

A limited number of companies completed a full station rebuild in the past three years. The costs associated with these projects were compared on a per-transformer bank basis and a per-MVA basis.

Figure 20. Cost per Transformer Bank Refurbished

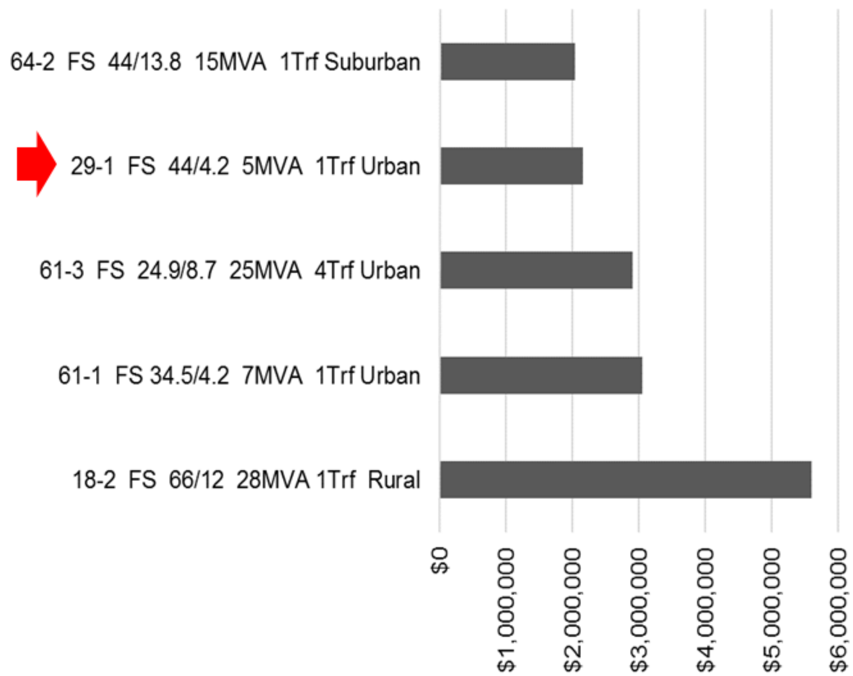


Figure 21. Cost per Substation MVA Refurbished

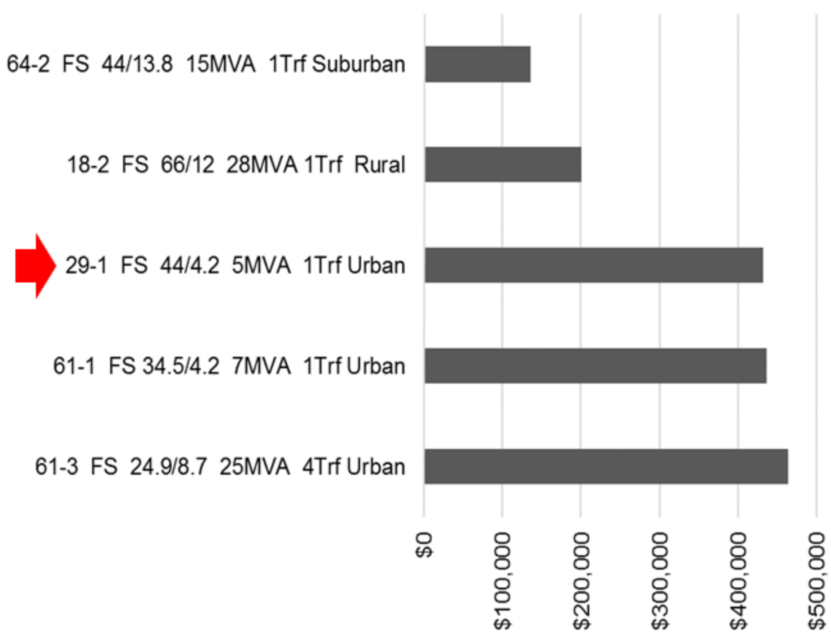

4.1.2 Substation-Centric Projects

A higher volume of substation-centric projects was available for analysis. As shown in Figure 22 and Figure 23, Hydro One's projects represent several of these, and they fall at different points within the comparative cost spectrum, whether measured on a per-transformer or a per-MVA basis. As before, all of the Hydro One stations in the comparison are single-transformer stations, typically at a distance from a work site.

Figure 22. Cost per Transformer Bank Refurbished for Substation-centric Projects

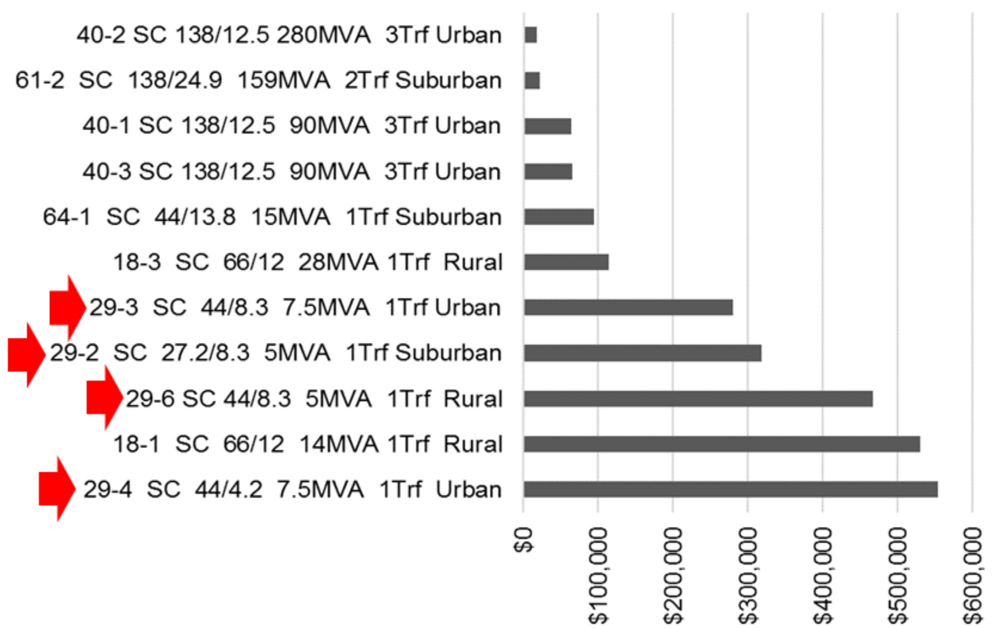

Figure 23. Cost per Substation MVA Refurbished

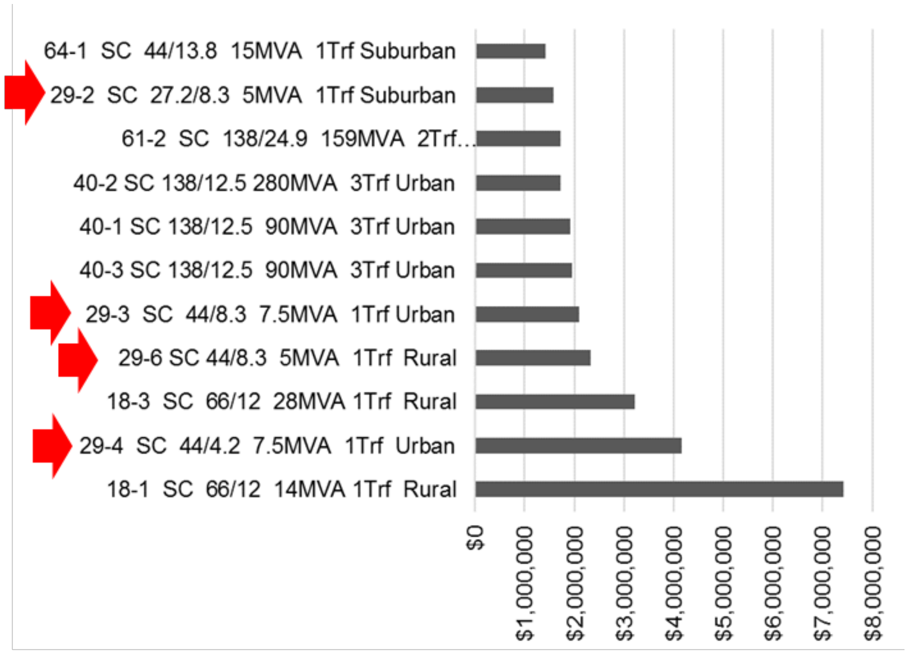


4.2 Operating Approach to Refurbishment

Hydro One's current emphasis on station centric and full station rebuild projects is not unique within the comparison group and is related to several demographic factors that distinguish Hydro One:

- Higher than average transformer loadings at non-coincident peak;
- An older age profile for in-service power transformers;
- Highest percentage of single transformer substations; and
- Second highest percentage of rural substations (substations serving areas with 50 or fewer customers per square mile).

The demographics of the electric system, and specifically the substations, help drive the decision-making with respect to refurbishment activities. Age, condition, and planned life all influence what type of maintenance and refurbishment activities are appropriate, for individual components and for entire stations. Also important is the configuration of the system, i.e. the range of stations that have multiple transformers (or not), whether or not they are looped or structured with a radial design.

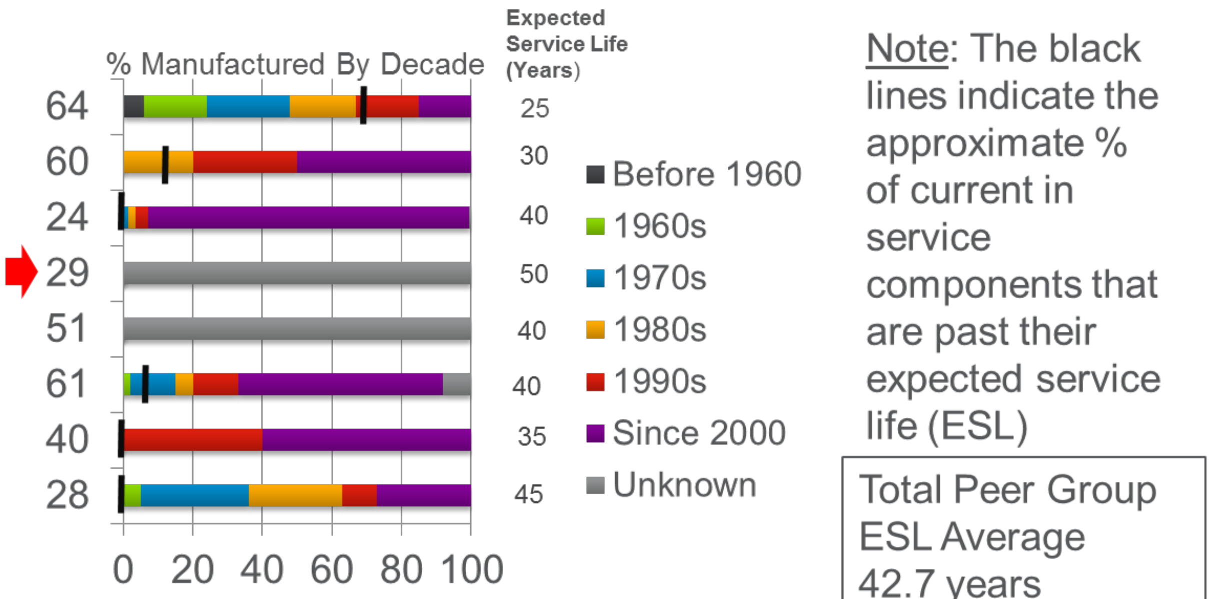
In this section, we present information about the age of the various station components, along with some information about the system configuration. While these findings aren't a measure of performance, they do have an impact on the costs and appropriate practices associated with the substation refurbishment activities.

While Hydro One's focus on station-centric and full-station refurbishment is not unique, several of the comparison companies primarily or exclusively rely on component-based refurbishment programs.

4.2.1 High Side Switching and Protection Equipment

Hydro One's expected service life for high side switching and protection equipment is higher than the comparison group average. It's actual age profile for these components is unknown.

Figure 24. Expected Service Life for High Side Switching and Protection Equipment

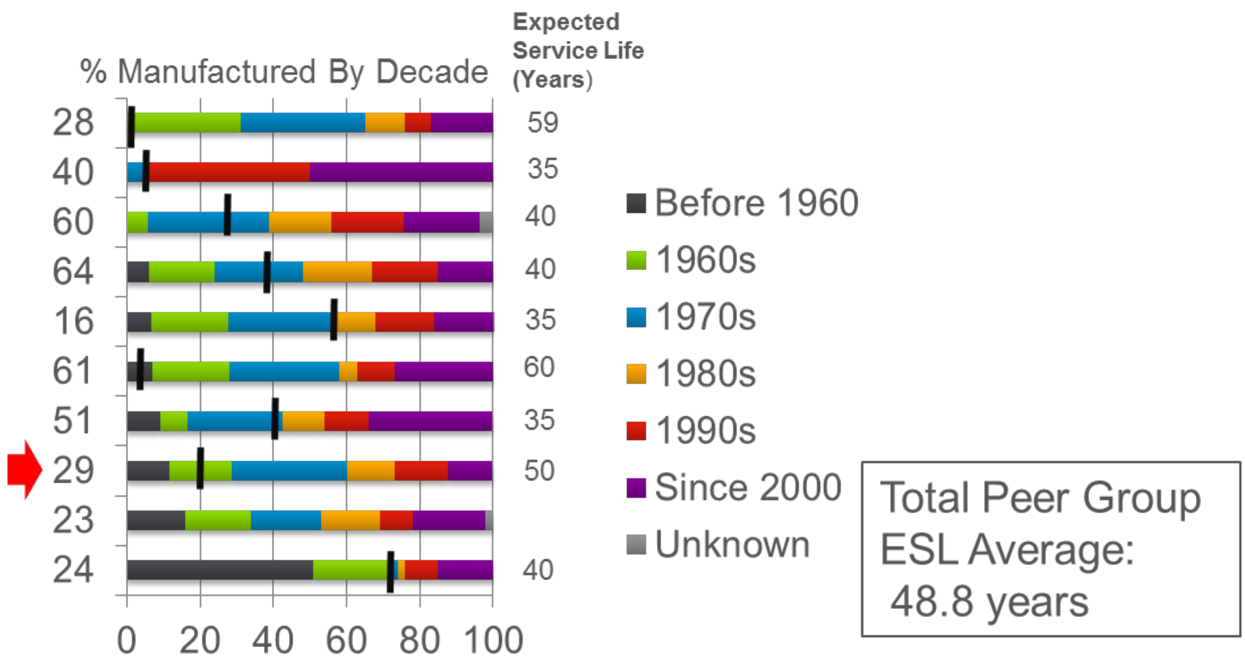


Source: Questions A3 and A4

4.2.2 Power Transformer Demographics

Hydro One's power transformer age profile ranks in the older end of the comparison group distribution. It's expected service life for power transformers is also somewhat higher than the group average, as shown in Figure 25.

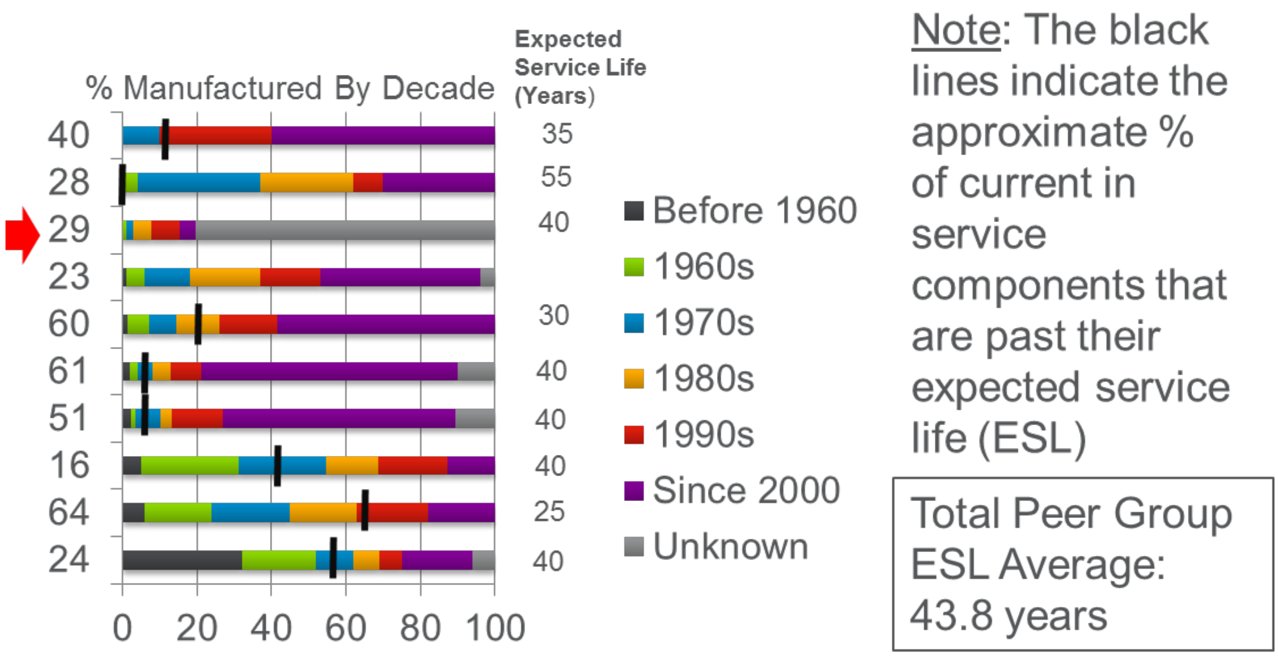
Figure 25. Expected Service Life of Power Transformers



4.2.3 Low Side Switching and Protection Equipment

Hydro One's expected service life for low side switching and protection equipment is somewhat lower than the comparison group average. Most of its actual age profile for these components is unknown.

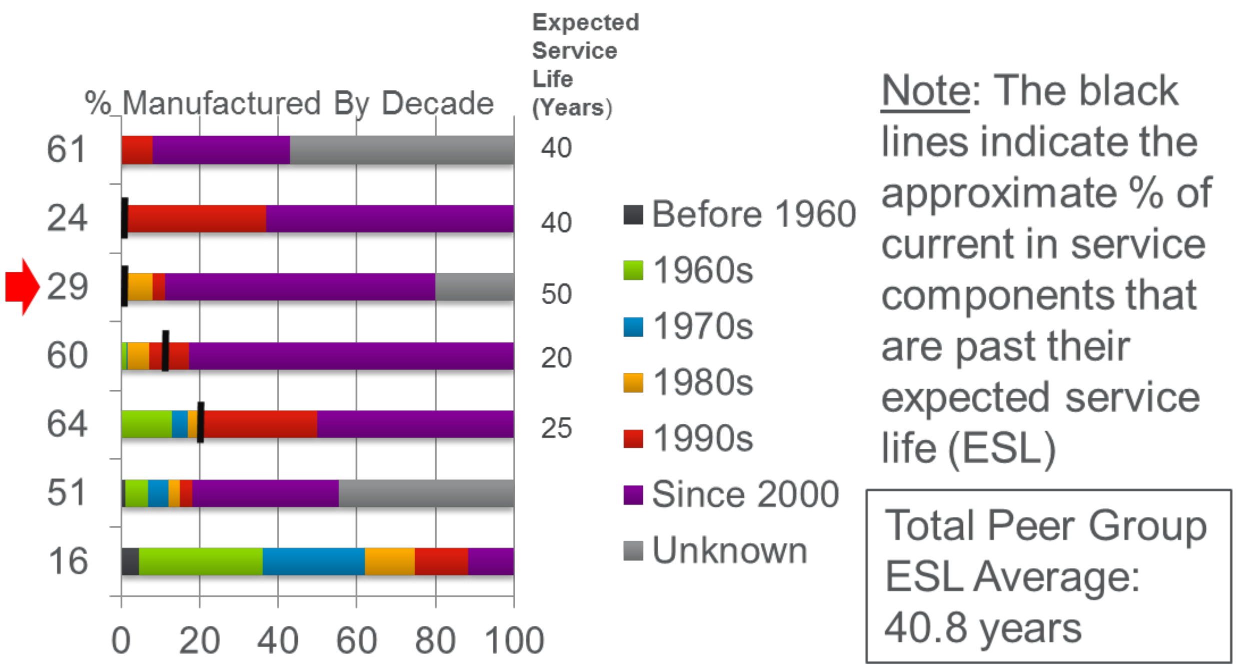
Figure 26. Expected Service Life for Low Side Switching and Protection Equipment



4.2.4 Relays and Control Wiring Demographics

Hydro One's Expected Service Life for in-service relays and control wiring is higher than the comparison group average. Most companies were not able to furnish a complete age profile for these components.

Figure 27. Expected Service Life for In-service Relays and Control Wiring



4.2.5 Substation Profiles

Hydro One has the highest percentage of single transformer substations within the comparison group. It also has a very high % of rural stations (stations serving areas that have 50 or fewer customers per square mile), meaning there are many stations with single transformers in remote locations.

Figure 28. Percent of Substations by Number of Power Transformers

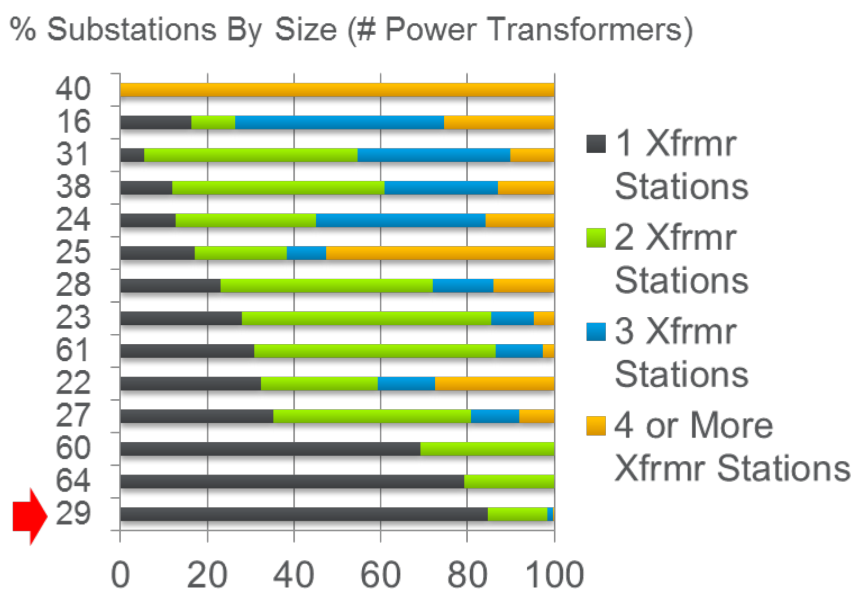


Figure 29. Percentage of Substations by Area: Rural, Urban and Mixed

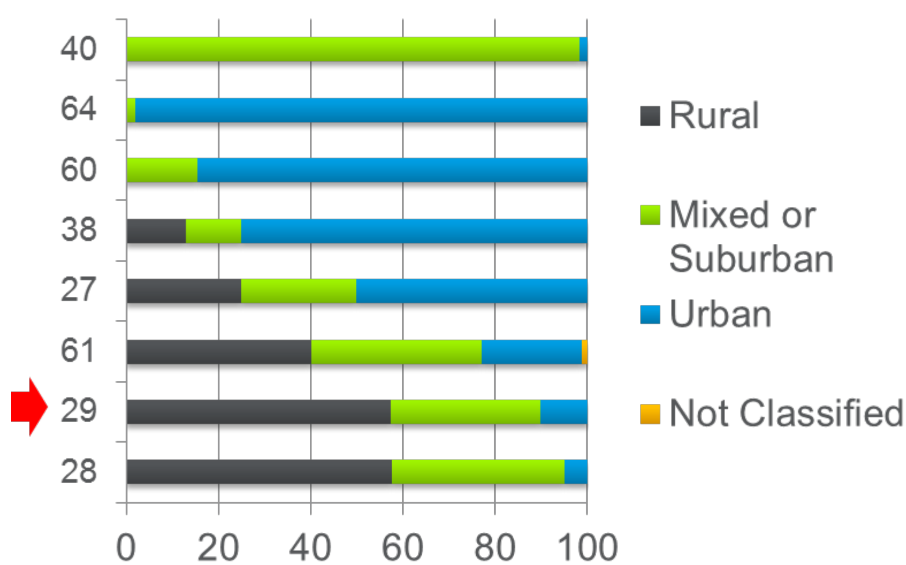

4.3 Use of Testing Results and Maintenance History Records

The processes that Hydro One follows to evaluate the condition of switching equipment, protection equipment and relays appear to differ from those of most other comparison utilities.

Equipment Type	Hydro One Practice	Leading Practice
Switchgear	Visual inspections, or safety concerns	Visual inspections, testing, current and forecasted loading, maintenance history & costs
Breakers and Bus Ties	Visual inspections, current and forecasted loading, inoperable or poor performance, safety concerns	Visual inspections, testing, current and forecasted loading, maintenance history & costs
Relays and Control Wiring	Poor Performance	Visual inspections, testing, maintenance history & costs

The key difference between most comparison utilities and Hydro One is that Hydro One does not evaluate testing results and/or maintenance history records as a primary driver when making replace versus repair decisions for switching and protection equipment or relays.

Hydro One is one of only two companies in the comparison group that listed safety concerns as an important evaluation factor when evaluating switching and protection equipment.

4.4 Performance Measurement

Hydro One's performance measurement and reporting is limited, focusing only on the numbers and average costs of completed projects by type (conventional refurbishment projects versus refurbishment projects using an integrated modular substation).

Subject Area for Tracking	Hydro One Practice	Leading Practice
Age and usage history data for existing equipment	Limited tracking and available data	Complete data, including installation dates, maintenance activities, other investment
Periodic reporting of progress on individual projects while ongoing.	Reporting of program costs across year, but not individual station projects	Regular reporting of individual station project costs, completion % by work type (advanced practice is Earned Value)

5. RECOMMENDATIONS

The four key recommended actions for pole replacement are:

1. Consider modifying the pole replacement program to include more complete pole inspections (sound, bore, excavation) and a longer (approximately 10-year) inspection cycle – the OEB would need to approve the change in inspection cycle.
2. Expand the existing centralized program management and pole selection approach to cover 90-95% of the replacement / refurbishment work on poles in a given year, leaving the remainder to be guided by the local staff while still meeting the centralized strategy and replacement criteria
3. Where geography and/or pole density permit, consider the use of dedicated pole replacement crews.
4. Consider modifying the program to include a rigorous pole refurbishment option, when appropriate.

The three key recommended actions for substation refurbishment are:

1. Consider implementing a formal data governance process for equipment performance and maintenance data, and incorporating that information into the asset condition scoring and project planning process.
2. Enhance cost and work completion reporting for individual projects, and implement a formal change control process.
3. Develop and implement a more comprehensive set of key performance indicators including in-progress project cost performance measures and assessments of project/program impacts on substation reliability, maintenance costs and overall asset health.

APPENDIX A. DETAILED COMPARISON GROUP STATISTICS

A total of 29 Canadian and U.S. utilities were contacted to participate in the comparison group. These companies include those summarized in Figure 30, as well several others who declined to participate. The Navigant and First Quartile Consulting team followed up with the utilities multiple times to clarify the data needed, and answer questions about reporting. The comparison group is a good cross section of the North American electric utility industry.

Figure 30. Comparison Group Demographics

Company	Number of Distribution Customers	Service Territory (sq. km)	Number of Distribution Poles	Number of Distribution Substations
Atlantic City Electric	547,145	7,166	226,111	61
Austin Energy	439,402	1,131	153,375	190

Disclaimer

The information collected through benchmark surveys and other data sources is offered as guidance to the readers of this report. How this data is interpreted is subject to many variables and potential biases. CNUC reviews benchmark data for errors and omissions and analysis is performed to advance positive recommendations and outcomes but makes no claims and does not take responsibility for interpretation or submitted survey information that is inaccurate or incomplete.

1 EXECUTIVE SUMMARY

1.1 STUDY PURPOSE

Hydro One was instructed by the Ontario Energy Board (OEB) in March 2015 to perform a trend analysis of the utility vegetation management (UVM) program. Specifically, the Ontario Energy Board (OEB) requested:

> *• A comprehensive trend analysis of the vegetation management program showing year over year comparisons in unit costs.*
> *• A best practices study, if undertaken, for vegetation management similar to the CN Utility study filed in EB-2009-0096.* (OEB, March 2015, p. 61)

In response, Hydro One contracted CN Utility Consulting (CNUC) to conduct a benchmark survey of North American UVM programs and perform trend analysis.

1.2 OVERVIEW OF THE HYDRO ONE SERVICE TERRITORY

Operating one of the largest North America distribution systems in vast remote and rural areas, dense forests and harsh winters, Hydro One maintains over 100,000 kilometres of rights-of-way (ROW) to keep trees away from powerlines. The service territory includes most of Ontario with the exception of the metropolitan areas around Lake Ontario and rural communities served by local distribution companies. The extreme northwestern region of the province (the Hudson Bay Lowlands) is also not included in the service territory.

Hydro One's geography presents several challenges to vegetation management. Although the majority of the powerlines are along roadways, one-third of the lines are off-road. These are rigorous to work and require special equipment, including heavy equipment, all-terrain vehicles, and boats. In addition, the system is large, sprawling and dense with vegetation as well as prone to ice-storms and wind events. In many areas the customers are scattered and separated by long distances. The number of customers per square kilometre is one of the lowest for all utilities compared and the number of trees managed per customer is one of the highest. On a cost per customer basis, these facts express the need for a highly efficient vegetation management program.

In general, electric systems start with high-voltage supply lines that divide and step-down into networks of lower voltage lines. For the Hydro One distribution system, the highest voltage lines are called M-Class feeders and are operated at 44,000 volts (44kV), 27,600 volts (27.6kV) and 25,000 volts (25kV) depending on the area. The rest of the network is comprised of F-Class feeders operated at lower voltages that consist of three-phase, two-phase, and single-phase lines. Of the 102,000 km of overhead line, 52,000 km are lower voltage feeders and two-phase and single-phase lines. The higher the voltage, the more customers are affected by an outage. M-Class feeders are a high priority for vegetation management. However, all overhead lines are managed to prevent vegetation encroachments. Although the higher voltage lines are more important to the system, vegetation needs to be managed for safety and reliable service, down to the lowest voltage.

There are three main forestry eco-zones within Hydro One's service area:

- The Boreal is mainly conifers
- The Great Lakes/St Lawrence Forest Zone is mixed conifer/deciduous forests
- The Deciduous Forests Zone has the greatest diversity of tree species

Hydro One's distribution system is divided into four forestry management regions: North, South, Central and East. The Central and East Regions have similar dense forestry conditions and require the greatest amount of vegetation management on the system. The North Region has dense forests, is mostly conifer, and has the least amount of line. In contrast, the South has scattered forests, is predominately agricultural, and has the most kilometres of line.

Expansive and large forests, harsh winters, frequent storms, and rugged and remote ROWs with long travel distances are realities that characterize forestry management for Hydro One.

1.3 Progress and Performance of Hydro one's Vegetation Management Program

Over the period of this study, 2011-2015, Hydro One increased their efforts to reduce the number of trees managed on their system. However, when the number of trees managed is almost eight million, it takes more than five years to experience a significant reduction in the workload. Since work is performed infrequently, a cycle of 9.5 years on average, it is difficult to make progress as trees are growing faster than they are managed. Until the backlog of work and the cycle length are reduced, Hydro One needs to continue to improve progress.

Hydro One has maintained the high level of efficiency that was discovered in the 2009 study. More trees are managed per hour than most peer utilities. In spite of all their challenges, Hydro One has fewer outages per kilometre of line than most peer companies. Even though the conditions are rugged and sometimes harsh, Hydro One has an excellent safety record in comparison to peers. Overall, Hydro One ranks high for performance in safety, reliability, and productivity.

Hydro One's costs per unit of work are very high in comparison to peers. Although many of Hydro One's costs are fixed costs, such as wages, benefits, equipment depreciation and overhead costs, there are some opportunities to decrease spending. Hydro One has been diligent at finding ways to improve efficiency and to lower labour costs. Continued efforts to employ new technologies, automation, mechanization, routing and scheduling, and outsourcing more of the labour will result in lower overall costs.

Hydro One's record shows a serious effort to reduce production costs and improve performance and progress. They have shown measurable headway in their performance over time. However, this progress has not been sufficient to effectively decrease the total workload.

Although most of the peer group has lower costs than Hydro One, it is not always due to better performance than Hydro One. This is because fixed costs are higher. Some companies do show that cost per unit can be lower. In fact, one company maintains their system three times during the same time period that Hydro One maintains their system once and the cost for three cycles is still less than Hydro One's single cycle. (See p. 39 for more details)

1.4 Best Management Practices

The following examples of vegetation best management practices (BMP) are based on industry standards and current industry practices.[1]

1.4.1 Best Management Practice Strategies

1. Perform consistent, compliant, and cost-effective ROW corridor management to maintain clearances between conductors and vegetation using industry-approved practices targeted to ensure reliable electric service, environmental quality, customer satisfaction, and safety for workers and the public.
2. Provide sufficient funding and resources to measurably achieve UVM program objectives. “A stable and consistently funded circuit pruning program minimizes the risks of public and worker electrocution as well as wild fire events and is a utility best practice (National Grid 2015).”
3. Build greater safety awareness and education for anyone who enters a ROW zone for any reason and measure success by using leading performance indicators, such as safe ROW environment metrics, safe work place metrics, and program features.
4. Define, measure, and audit the barrier space between conductors and vegetation.
5. Establish a cycle of inspection and maintenance that is sufficiently flexible to address a variety of vegetation management conditions but regular enough to anticipate conflicts before they occur.

1.4.2 Best Management Practice Tactics and Key Measures

1. Maintain 50-75% of distribution ROWs using industry-approved herbicides.
2. Cultivate and measure positive customer involvement with UVM.
3. Automate the UVM Program. See 4.3.2 for details
    a. Improve routing, deployment and management of crews through telematics technology and scheduling.
    b. Use predictive analytics and modeling to improve performance and achieve best management practices.
4. Perform detailed outage investigations by forestry personnel and model data to promote understanding of tree conditions and failure modes.
5. Convert the majority of distribution ROW to low-growing shrubs and herbaceous plants.
6. Assess ROW edge trees routinely for risk and replace hazardous trees with appropriate vegetation.
7. Improve adjacent off-ROW vegetation to ensure desired percent of tree cover to provide appropriate benefits and protections. Trees provide vital ecosystem services and having the right trees adjacent to powerlines requires appropriate planting and maintenance strategies.
8. Establish common goals and maintain action-based relationships with various provincial and community forestry units that foster a reduction in necessary line clearing activities: Align various vegetation management activities in province of Ontario

[1] Industry practices were derived from the benchmark survey conducted for this project and a literature review

9. Develop wood utilization programs as an organizing principle for sustainable harvesting and recycling of off-ROW trees before they become hazards. Trees provide many products and utility clearing can be a source of raw materials for wood products.
10. Develop land use programs such as food crops, pollinator habitats, recreational, emergency access, transportation, and other various land uses that are appropriate and beneficial for distribution ROWs.

1.5 Peer Group Criteria and Selection

The study included five Canadian companies, Hydro One and its four regions, and thirty-one US utilities for a total of forty-one companies. Based on selection criteria, four Canadian companies and twenty-three US companies were used in peer group comparisons. The remaining nine companies were used only in general industry comparisons. Peer companies were selected on the basis of geographic region, tree density, customer density and territory demographics, and whether the utility was a peer in the 2009 Hydro One Study.

All companies in the peer group have UVM programs aligned with the objective to deliver safe and reliable electricity. They have formal vegetation management programs, are directed by an employee of the utility, and operate year-round. Practices include aerial hand-pruning and tree removal with bucket trucks and climbing arborists, mechanical pruning and clearing with heavy equipment, and the application of herbicides to prevent stump sprouting and to terminate small trees and whips.

See Appendix C for further details on Peer Selection

1.6 Benchmarking and Year-over-Year Trending Metrics

For this project commonly collected performance and progress metrics were analyzed. In general, benchmarking are comparisons between Hydro One and the peer companies. Year-over-year trends (time-studies) for Hydro One and its regions were compared to the peer-average trends. System kilometres are the total number of overhead (OH) right of way kilometres in the distribution system. Managed kilometres are the number of overhead (OH) lines managed on an annual basis.

1.6.1 Unit Costs

Unit costs provides a basis for comparison and year-over-year analysis

1. **Cost per system kilometre:** Normalizes costs differences caused by variable cycle lengths
2. **Cost per managed kilometre**: Measures cost-efficiency and ability to control fixed costs
3. **Cost per tree:** Measures cost-efficiency and workload prioritizations

1.6.2 Labour Hours Expended

Labour Hours (LH) expended normalizes differences in fixed costs

1. **Labour Hours per system kilometre:** Normalizes LH differences caused by variable cycle lengths
2. **Labour Hours per managed kilometre:** Measures work-efficiency and workload reduction
3. **Labour Hours per tree:** Measures work-efficiency and workload prioritizations

1.6.3 Workload and Performance

Measuring workload is a baseline for improving performance

1. **Tree Density and Ingrowth:** Reductions indicate workload management improvements. Increases occur when the cycle of management is long. Disturbance from mowing and manual cutting can influence density of ingrowth especially in the absence of herbicide controls and long cycles.
2. **Tree Risk Assessment and Extent of Implementation:** Measures off-ROW risk reduction efforts
3. **Percent of System Kilometres Managed Annually:** Measures improvements on management cycles and enables industry comparisons

1.6.4 *Cost Efficiency*

Measures control over fixed costs

1. **Personnel Costs and Labour Mix**: Changes in labour costs were analyzed and compared to peers
2. **Equipment Costs and Usage:** Fleet management, usage rates and right-sizing were analyzed

1.6.5 *Reliability*

Measures the effect of UVM on electric reliability (See Appendix B for discussion on appropriate use of reliability metrics)

1. **Tree related outages per system kilometre:** Effective measure of UVM reliability performance
2. **IEEE Tree-Related Reliability Metrics:** SAIDI, SAIFI are customer density biased
3. **Storm Impact Prevention and Response:** Measures the impact of UVM on storm resiliency
    - **Major Event Day (MED) outages:** Changes indicate performance of UVM program
    - **Non-MED outages:** Helps to distinguish between asset improvement need vs UVM

1.6.6 *Safety*

Safety and reliability are ranked the most important UVM objectives by utility companies. Safety has a lack of leading indicator metrics. Accident incident rates are unevenly reported and are lagging indicators.

1. **Annual OSHA Incident Rates:** Rate of recordable accidents reported per 100 workers
2. **Annual Lost-Time Incident Severity Rate:** Rate of lost days per 100 workers
3. **Employee Turnover Rates:** High severity rates correlates well with employee turnover rate in this study and across industries

1.7 Key Findings

Each finding is followed by a section number where detailed discussion can be found.

1.7.1 *Unit Cost*

Hydro One reports high unit costs compared to the peer group. The high costs are due to heavy workloads associated with long cycle lengths, higher cost of labor and equipment, and better reporting of overhead costs by Hydro One as a result of having an in-house vegetation management program. (4.1).

1.7.1.1 System Unit Cost

UVM costs are increasing across the industry. Hydro One’s costs, in contrast, are remaining relatively steady with a decrease in 2015. (4.1.2)

1.7.1.2 Managed Unit Cost

Hydro One's cost per managed kilometre and per managed tree was high compared to the peer group, but the percent increase in cost from 2011-2015 was not as high as the peer average increase for both units. This statement also holds true when comparing 2011-2015 averages to 2006-2008 averages (2009 study). (4.1.3)

1.7.2 Labour Efficiency

As shown in the 2009 study for the OEB, Hydro One continues to perform UVM at or below the average for number of labour hours expended per managed kilometre of overhead line. The result is a decade of efficient UVM performance. See Section (4.2)

1.7.2.1 Labour Hours per System Kilometre

All of the Hydro One regions performed better than the peer average in this measurement. Rather than demonstrating work-efficiency, this metric is an indicator that Hydro One is under-resourcing their program and more work needs to be done. This is true because tree density, the number of trees managed per kilometre, is increasing and Hydro One has not been able to decrease the length of its cycle. (4.2.1)

1.7.2.2 Labour Hour per Managed Unit

Hydro One outperforms the peer group with low labour hours per tree and is close to the average for labour hours per kilometre for 2011 - 2015. (4.2.2)

- **Labour hours per managed km:** In spite of increasing tree densities and long cycle lengths, Hydro One's tree crews have been able to stay close to the peer average of labour hours per managed kilometre for 2011-2015. (4.2.2.1 - 4.2.2.2)
- **Labour hours per tree:** Hydro One's labour hours per tree has stayed relatively constant from 2006 – 2015, while the peer group has increased by 60%. (4.2.3)

1.7.3 Tree Density, Ingrowth and Tree Risk Controls

Tree density has increased on Hydro One service territory over the last decade. This increase is the result of a program on a long cycle, which increases in-growth, workload, and off-ROW risk. (4.2.4)

Insufficient management controls include:

- Herbicide control of ROW in-growth
- Tree risk assessment for off-ROW edge trees
- Removal and pruning of hazardous off-ROW trees

(4.2.5 - 4.3.1)

1.7.4 Work Planning (4.3)

1.7.4.1 Automation

Hydro One has a comprehensive work planning program, and it performs well especially in regards to customer communication and the sheer size of the territory. However, it is insufficient in the areas of technological innovation and automation of data collection, data analysis, work management, auditing and predictive modeling. Hydro One has initiated digital automation to the UVM program, but, like its peers, is challenged by transitions, knowledge transfers and change management that accompany new technologies. For detailed discussion see 4.3.1-4.3.2

1.7.4.2 Customer Service

Hydro One provides better customer service and communication than the industry at large. For detailed discussion see Sections 4.3.3 – 4.3.5.

1.7.5 *Equipment and Personnel (4.4)*

1.7.5.1 Equipment

- Hydro One's utilization rate of their equipment is lower than their peers.
- Hydro One has a continuous improvement program for the efficient use of equipment through logistics and mechanization.

(4.4.1)

1.7.5.2 Personnel (4.4.2)

- Hydro One's labour burden for in-house employees is double the cost of Hiring Hall employees and is more than three times the average of the peers' contractor charge-out rates.
- Hydro One employees on average have more than double the years of experience of peer contractor employees.
- The increase in UVM cost is not a matter of efficiency or increased workload; rather it is a result of increases in cost per labour hour, including wages, benefits, equipment, fuel expenses, and other overhead and administrative costs.

(4.1.4 and 4.4.2)

1.7.6 *Reliability (4.5 and Appendix B)*

- Hydro One is well below the peer group average for tree-related outages per system kilometre and this measurement has been improving since 2003 (See Appendix J analysis). This metric is preferred for measuring the performance of UVM over the standard reliability metrics because it is more closely related to the system workload and it more appropriately measures the performance on downstream facilities.
- Hydro One compares unfavorably with peers in the area of the standard reliability metrics, SAIDI and SAIFI. These metrics are biased when applied to Hydro One where there are no high customer density areas on a very large service territory. Low customer density, as well as six other factors common to Hydro One, is known to negatively impact reliability metrics. (4.5.1-4.5.2)

1.7.6.1 Storms are Hydro One's Greatest Challenge

- Hydro One's outage per system kilometre metric is an achievement given the length of management cycles, high tree densities, system size, and the propensity for storms in the South, Central, and East Regions.
- A high percent of outages, especially during storms are caused by trees on the Hydro One system.

(4.5.1-4.5.4 and Appendices B, E, and J)

1.7.7 Safety as a Priority (4.6)

- Hydro One is distinguished from the peer group by having a more experienced and stable workforce that is in-house and is more directly connected to safety monitoring and initiatives promoted within the company.
- Hydro One's lost-time safety incident severity annual rate (SR) for 2013-15 is 7.90 lost days/100 FTE compared to the peer group average of 31.36. Compared to the industry-wide fatalities over the past three years and the peer group's incident SR, Hydro One shows clear evidence of a more successful record of tree worker safety.
- Hydro One's safety incident average rate for 2013-15 is 3.90 incidents/100 FTE compared to the peer group average of 2.46. It should be noted that there are problems with accident under-reporting and OSHA has instituted a new rule effective in 2017 to improve accident reporting.

(4.6.1 & 4.6.2)

1.7.8 2022 Model Cost Projections

Four models with varying degrees of risk and workloads are proposed by CNUC with projections of cost out to 2022. The initial 2017 costs are Current Risk Model A, $150.2 million; Moderate Risk Model B, $166.5 million; Lowest Risk Model C, $174.9 M; and Best Management Practice Model D, $192.9 M. It is expected that SAIDI and SAIFI will improve under all three models. Under Model A outages per kilometre will likely increase and public and worker safety risks will increase. With Model B the number of outages per kilometre will probably not increase but reductions are likely to be minimal. The workload will improve at a slow pace. Model C would be the most likely model to secure some reductions to the workload, to long-term cost, and to safety risk. Model D would move Hydro One towards a cycle closer to best management practices in the industry and secure significant reductions to the workload. These predictions assume resource cost will be reduced by employing Hiring Hall or contracted labour for all work on one and two-phase lines and it does not account for improvements from innovations and new technology. The recommended labour mix, employing contracted labour for only lower risk activities, would increase all modeled estimates by approximately 10 – 15%.
The assumptions behind these models are discussed in Section 4.8 and in Appendix D.

1.8 Recommendations: Improvements, Best management practices and Innovation

The following are recommendations in the order of importance:

*ST means Short-Term and indicates a onetime change; LT means Long-Term and will require continuous improvement or will take many years to implement. When both LT and ST are indicated, periodic improvements will be needed to update a short-term improvement

1. **Bring the whole distribution system to a four to eight-year flexible cycle that is trued up each year to ensure backlogs do not creep back into the schedule. This will enable a more effective herbicide program, better off-ROW tree risk management, and reduce workload over the long term.** (LT)* See Sections 4.1 - 4.3, 4.6, 4.8

   a. **Reduce the current backlog over the next decade through innovations, automation and changes in labour mix** (LT)* See Recommendations 2, 3, 4, 6, and 9 (below), Section 4.1 (intro)
2. **Improve through innovation the mechanization and automation of the UVM program. This will improve understanding of the workload and it will enable more effective work planning and cost/resource predictions.** See Sections 4.3, 4.4
   a. **Improve data analytics and predictive modeling through automated data collection of key UVM activities.** (ST, LT)* See Sections 4.3.1, 4.3.2
   b. **Use technology such as LiDAR to improve measurements, condition assessments, and accuracy of data collection.** (ST,LT)* See Sections 4.3.2
   c. **Increase ROW clearing capacity and safety through innovations in mechanical equipment and routing technology** (ST,LT)* See Sections 1.4.2 and 4.4.1
   d. **Improve customer knowledge, communication, and involvement by merging UVM data with the customer service system**. (ST)* See Sections 4.3.3 - 4.3.5
3. **Improve productivity and control costs by utilizing higher percent of Hiring Hall and contract workers to perform lower safety and liability risk activities such as work planning, herbicide applications, and brush-clearing. This will lower unit costs.** (LT)* See Section 4.4.2
4. **Strategically increase herbicide usage for cost-effective results. This will ensure ROWs stay clear between shorter cycles of management and lower the long term cost** (LT)* See Sections 4.1.3, 4.2.5, 4.2.7, and 4.3.1
5. **Develop a vegetation management outage investigation protocol that expands on the current cause codes and utilizes UVM personnel. This will improve capability to predict tree failure modes and guide future tree risk mitigations.** (ST)(LT)* See Section 4.5.3
6. **Synchronize the annual asset inspections with the UVM work planning program to quantify system vegetation conditions based on performance metrics for maintaining air space around conductors**. **This will improve workload understanding and provide annual performance metrics for system conditions.** (ST)* See Section 4.3.1
7. **Improve and increase the Tree Risk Assessment Program to reduce outages caused by off-ROW trees. This will, with the help of lessons learned through outage investigations, improve reliability by reducing outages caused by trees or branches falling into overhead lines.** (LT)* See Sections 4.3.1, 4.5.3, 4.7 and Appendices F and G
8. **Identify fixed cost increases and overheads allocated to UVM to ensure cost effects of changes to the program are portrayed accurately. This will enable a better understanding of improvements to production and other cost reduction measures.** (ST)* See Sections 4.1 (4.1.1, 4.1.3, 4.1.4) and 5
9. **Improve equipment and personnel utilization**. **This will lower unit costs by improving efficiency and optimizing equipment availability.** (LT)* See Section 4.4 (4.4.1, 4.4.2)

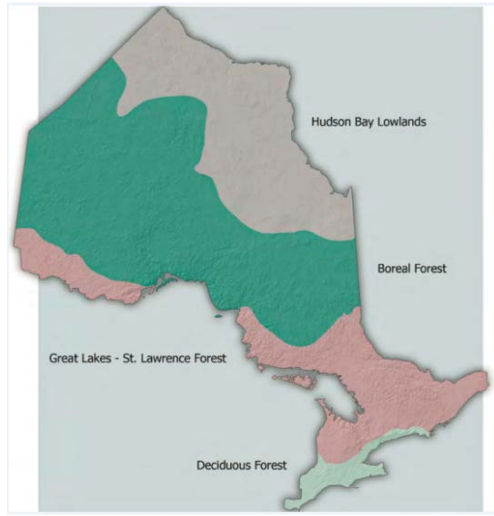
1.9 Conclusion

Hydro One has established over the last decade the capacity for safely managing dense vegetation on one of the largest service territories of the peer comparators. This accomplishment is highlighted above and is noteworthy considering the long cycles of management and financial constraints. Hydro One has achieved a below average number of outages per kilometre, but has high SAIDI and SAIFI. Budgetary constraints on UVM resources, insufficient innovation, incomplete digital automation of work management, and a long cycle have limited Hydro One's ability to convert ROWs to compatible plant communities. This has resulted in high costs of mechanical and manual intervention throughout the system. However, Hydro One has demonstrated improvements in numerous areas such as increased usage of herbicides, mechanization, and automation of planning and work management processes. To expand and sustain these efforts, longer-range goals for improving the management of the 52,000 kilometres of single and two-phase lines should be studied. Without this effort, the probability that outage numbers will increase should be expected. While the IEEE reliability metrics may show improvement under the current scheduling, they should not be viewed as a definitive performance metric for UVM. A minimum percent of tree-related outages should be investigated by arborists using root-cause analysis. Reliability is the center of UVM performance and there is a plethora of reliability data to gauge it. In the discipline of quality management, too much reliance on a single set of data can be misleading and the UVM program currently relies heavily on IEEE reliability metrics. Conversely, Hydro One's low accident severity rate and low employee turnover rate are evidence of a successful program, but the dataset is limited and is composed of lagging indicators. Equally important UVM objectives, such as safety, compliance to regulations, environmental quality, and customer satisfaction should be measured through improved data collection and included as key performance indicators, both leading and lagging.

2 INTRODUCTION

2.1 STUDY BACKGROUND

Hydro One was instructed by the Ontario Energy Board (OEB) in March 2015 to perform a study similar to the *Hydro One 2009 - Vegetation Management Benchmark Study*, which analyzed Hydro One's relative efficiency. Central to the current project is a distribution utility vegetation management (UVM) survey conducted by CN Utility Consulting (CNUC) in February, March and April of 2016 with Hydro One and 35 electric utility companies throughout North America. The following statements by the OEB and the Ontario Auditor General have influenced this project:



MAP 1: FOREST REGIONS OF ONTARIO

> *The OEB also directs Hydro One to present in its next rates application a comprehensive trend analysis of its vegetation management program showing year-over-year comparisons in unit costs. Further, the OEB encourages Hydro One to explore best practices in vegetation management with other distributors and transmitters, similar to the CN Utility Study filed with the OEB in the EB-2009-0096 proceeding, and file any resulting study in its next rates application.* (OEB, March 2015)
>
> *Explore best practices in vegetation management, considering changes in labour mix and innovation opportunities, as well as conduct a trend analysis of the vegetation management program showing year-over-year variations in unit costs.* (Office of the Auditor General of Ontario, 2015)

2.2 BENCHMARK STUDY PURPOSE AND LIMITATIONS

This report is for the purpose of determining the level of efficiency that Hydro One has achieved in carrying out its mission to manage vegetation that impairs or potentially could impair the reliable and safe operation of their expansive distribution system, which serves over 1.3 million customers and requires management of over 7 million trees. The efficiency level is determined by comparing the productivity, costs, and measurements of reliability and safety for each Hydro One business unit (region) and Hydro One with a group of peer utilities across North America. Analysis includes longitudinal studies of the different metrics, particularly for Hydro One. Given the peer group level of efficiency, the question can be asked whether enough work is being performed by Hydro One to meet a standard of care. Regulations, policies and behaviors that establish a performance standard include the various decisions made by the utility and the regulator, the normative behavior of the industry at large, and the industry consensus standards that are applied to UVM. These are the gauges to determine whether the efficiency of Hydro One's performance is sufficient to manage the UVM workload and whether it meets a best management practice criteria.

2.3 Goals and Objectives of the Benchmarking Study

Based on the five obstacles to success in business enterprise (Deming, 1984), this project:

- Looks for inconsistencies, especially in the UVM planning process
- Evaluates whether long-term goals are receiving adequate attention
- Reviews the performance evaluation system with a focus on whether some metrics are relied on too heavily because the data are the easiest to obtain
- Looks at whether the customer is driving the quality of the program
- Examines the safety and liability risks and whether they are managed adequately

It is hoped that some changes can be implemented that will streamline processes and ease burdens. For utilities to succeed in the 21st century, they will have to create a new philosophy for UVM by envisioning it in a new framework that customers will appreciate. With the customer on board, improvements can move forward with leadership inspired to empower an advanced culture of positive and freely-exchanged knowledge, whether it is for productivity, technology, safety, reliability, customer service or the environment.

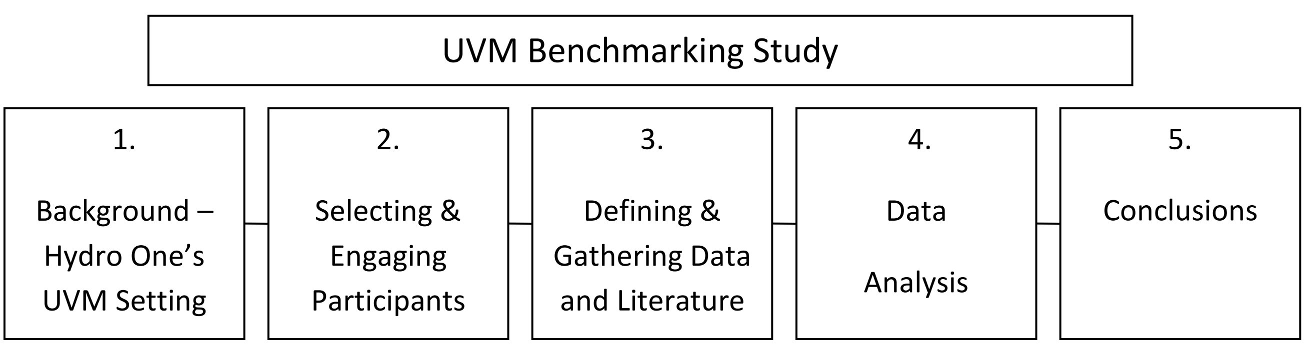
2.4 The Benchmark Report Team

CNUC was selected as an independent third-party consulting team to execute Hydro One's 2016 Vegetation Management Benchmarking Study. CNUC has extensive experience in both Utility Vegetation Management (UVM) and in benchmarking. This combination of expertise is unique in North America and is evidenced by experiences and achievements that CNUC brings as a consulting team.

Details about CNUC's project team can be found in Appendix A of this report.

3 Benchmark Study Framework

3.1 Benchmark Study Data Collection and Analysis Methodology

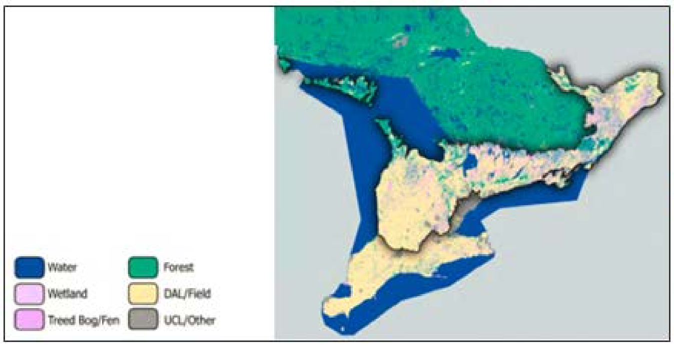


See Appendix I: Benchmark Study Process Chart for details

See Appendix D: Statistical Methodology and Model Development for details on analysis

3.2 Forests in Ontario

The South is mostly agriculture and has a small percent of deciduous forests scattered throughout. The East and South and Central are predominantly privately owned. Parts of the East and Central Regions, however, are heavily forested with large conifer, deciduous and mixed forests. The concentration of forested areas, particularly conifer, is the greatest in the North in the boreal forest. The land north of Lake Superior and Lake Huron/Georgian Bay is another ecoregion within the North Region that also contains many mixed and deciduous forests. It is in the East and Central where the density of customers is greater than the North but there are heavy and scattered forests. The Central incurs more tree-related reliability issues than the other regions, having many settlements in forested areas. The East is not far behind, but has more agricultural areas that reduce the tree populations in some areas and risks of tree-related outages.



Map 2 Urban Agriculture and Dense Forests

Map 3 Hydro One Regions Map

By comparing the yellow and green areas in Map 2 with the Hydro One regional boundaries in Map 3, one can see that about fifty percent of the Central and East Regions are densely forested. The North region (only partly shown in Map 2) is practically all dense forests. The East and Central regions also have significant areas that are agriculture, wetlands, scattered forests and many populated areas.

Forestry and customer demographics play a key role in UVM program implementation and performance results. The North Region is the largest area but only contains 18% of the system kilometres and 14% of the customers. The North Region is heavily forested and has the highest percent of kilometres (29%) that have limited or difficult access. The North region of Hydro One is roughly 512,600 km^2 with 190,000 customers. This vast area contains only 18,000 km of line. The South region has the largest number of distribution lines at 32,000 km and Central and East regions are roughly equal at 26,000 km.

3.3 Hydro One's UVM Environment and System Attributes

Peer Stats: Customers per Square Km					Peer Stats: Customers per OH System Km			
Sample Size	27	Q3	74.5		Sample Size	27	Q3	42.2
Average	57.1	Min	0.9		Average	37.7	Min	6.7
Q1	11.0	Max	293.9		Q1	21.2	Max	141.1
Median	27.5	SD	71.3		Median	28.9	SD	27.7
Hydro One Networks					Hydro One Networks			
Hydro One	2.1	HO Central	8.8		Hydro One	13	HO Central	14.3
HO North	0.4	HO East	8.7		HO North	10.6	HO East	15.3
HO South	9.2				HO South	11.3		

Table 1: Customers per Square Kilometre and Customers per Distribution Overhead System Kilometre

With the exception of one other North American company, Hydro One has the lowest average customer density by land area. Even the South Region, the most densely populated of the four Hydro One regions, has only 9.2 customers per square kilometre (km^2) (Table 1, above left). *This is six times less dense than the average of the peer group*. Of the twenty-seven companies in the peer group, only three have fewer customers per overhead (OH) system kilometre than the East region, which has 15.3 customers per km, the highest of Hydro One's four regions (See Table 1, above right). Hydro One manages forty-one percent of the electric distribution equipment in Ontario, while it only serves twenty-five percent of the customers (OEB, 2015). All Hydro One Regions are in quartile 1 (Q1) for lowest customer density per km of line.

Customer density is important when analyzing the cost to the customer and reliability. In 2011-2015 each Hydro One customer spent on average $99.36 for UVM. Although this is above the average ($35.13 in 2015) for utilities in their peer group, it is important to note some extenuating circumstances that contribute to higher cost for Hydro One customers:

- Hydro One manages 76 trees per system km compared to the average for the peer group at 68 trees per km.
- Hydro One has nearly the lowest number of customers per km^2 and per km of line; therefore it has fewer customers to pay for the cost of UVM.
- On Hydro One's system there are significantly greater distances between customers than peer companies. Low customer density contributes to higher logistical costs for maintenance and longer response times for emergencies.
- Low customer density increases the difficulty of prioritizing work to achieve consistent reliability performance improvements uniformly across the system.
- Low customer density reduces the reliability improvement impact of any single UVM effort
- Wages are higher for Hydro One than for most of the peers.
- Hydro One's service territory has a higher than average number of storms, especially in winter, that damage the distribution system on a regular basis.
- Vegetation management is performed infrequently (9.5 year intervals).
- 30% of Hydro One's system is difficult to access because of terrain, lack of roads, water and other access issues. In the North and East regions, 75% of off-road locations are difficult to access.
- With the exception of the South Region, Hydro One has one of the coldest minimum average winter temperatures in the peer group, making winter time work challenging and sometimes less cost-effective. Lake-effect snow accumulations and snow that persists for much of the winter makes forestry work difficult to perform in some areas. Additionally, the window for applying herbicides is limited.

3.4 Selection of Peer Utilities

The study had a total of forty-one companies, including six Canadian companies as well as Hydro One's four regions. Twenty-seven peers were selected to be comparators to Hydro One and are referred to as the peer group. The peer group includes four Canadian companies and twenty-three US companies. In some comparisons, non-peer companies are included. The response sample size of each question is noted with each graph and if the non-peer group is included it is noted under the graph title. Peer companies were selected on the basis of geographic region, tree density, customer density and territory demographics, and whether the utility was a peer in the 2009 Hydro One Study.

All companies in the peer group have UVM programs aligned with the objective to deliver safe and reliable electricity. They have formal vegetation management programs, are directed by an employee of the utility, and operate year-round. Practices include aerial hand-pruning and tree removal with bucket trucks and climbing arborists, mechanical pruning and clearing with heavy equipment, and the application of herbicides to prevent stump sprouting and to terminate small trees and whips.

See Appendix C for further details on Peer Selection

3.5 Differences between 2009 study and 2016 study

- In 2009 CNUC distributed the survey only to companies who were deemed to be potential peers. In 2016 companies were invited to participate regardless of their peer potential and the peer group was selected after preliminary analysis of several factors, which resulted in a larger peer group sample size (14 peers in 2009 vs. 27 in 2016).
- Non-peer companies were included in the analysis for some industry-wide comparisons in 2016, whereas in 2009 all of non-peer data was discarded.
- Survey questions were changed, revised and clarified. The scope of the survey was expanded to ensure coverage of target areas and to include some topics not covered in the past.
- More intensive literature review was performed on laws and regulations, reliability and climate impacts on UVM.
- More correlational and predictive analysis was used to draw conclusions. A future UVM cost model for Hydro One was developed.

4 Findings and Discussion

4.1 Unit Cost Introduction

Cost is relative to production, efficiency, labour and equipment management, program stability, sufficiency, and risk acceptance. Cost is a measurement that incorporates many variables when making comparisons. It represents regional and local economics, monetary exchange rates, union membership costs and wage agreements, taxation differences, and the scope and interval of work. It is difficult to always know what is included in cost. Differences may be arbitrary, based on perceptions of valuation and where overhead costs are assigned. Cost comparisons in this report shouldn't be taken necessarily as a measure of efficiency or productivity but rather a measure of cost variables.

Annual cost is usually understood as an annual input that can positively or negatively influence future annual inputs. Variations in annual cost over the long-term are influenced by the frequency of maintenance. A stable annual UVM cost is achieved by having an optimum interval of maintenance that comports with the workload. The workload is determined by ingrowth, the annual accumulations of growth on existing trees, and the desired reductions in risk associated with off-ROW tree and branch failure.

UVM workload is managed through vegetation clearing activities and logistics. If the interval of maintenance is too short, then long-term logistical cost will increase unnecessarily. If the interval of maintenance is too long, then risk will rise above the acceptable level and annual vegetation-clearing cost will increase. If quality of work and duration of vegetation clearances aren't specified and audited, then financial constraints on a UVM program can result in a longer cycle of routine maintenance. At some point, as the cycle length increases, it will become more and more difficult or impossible to maintain acceptable risk including safety, reliability, adequate storm response, and fire protection. At some point when a long cycle is getting longer, a workload barrier is formed in which it will take extraordinary short-term measures to achieve even minor reductions to cycle length, and improvements to reliability and efficiency. Achieving a stable, consistent and desirable cycle length with maximum cost efficiencies is a long-term project. *In Hydro One's case it will take at least a decade of accelerated and highly productive UVM to reduce the cycle of management by two to four years.*

4.1.1 Routine UVM Maintenance Cost per System Kilometre

Long-term cost comparisons with the peer group are made by normalizing the cycle lengths and comparing the annual cost per kilometre. The term for this is **cost per system kilometre** and it compares what companies spend annually on UVM relative to the size of their system:

Routine UVM Cost per system kilometre = Annual Routine UVM expenditures ÷ Number of OH kilometres in the system

Cost per system kilometre compares what companies spend per kilometre regardless of the frequency of management. Hydro One spends more per system kilometre than the average of the peer group. This is because its annual clearing costs are significantly higher than the entire peer group. Hydro One's long cycle length is driving up the annual unit cost increment. However, there are more variables that affect cost and Hydro One would still spend more per system kilometre than their peers if the cycle was shortened.

In combination with other variables, such as tree density, labour burden, or overhead/administrative costs, system kilometre cost is a way to compare productivity costs. The following graph (Figure 1 below) compares Hydro One's system km cost with its peers.

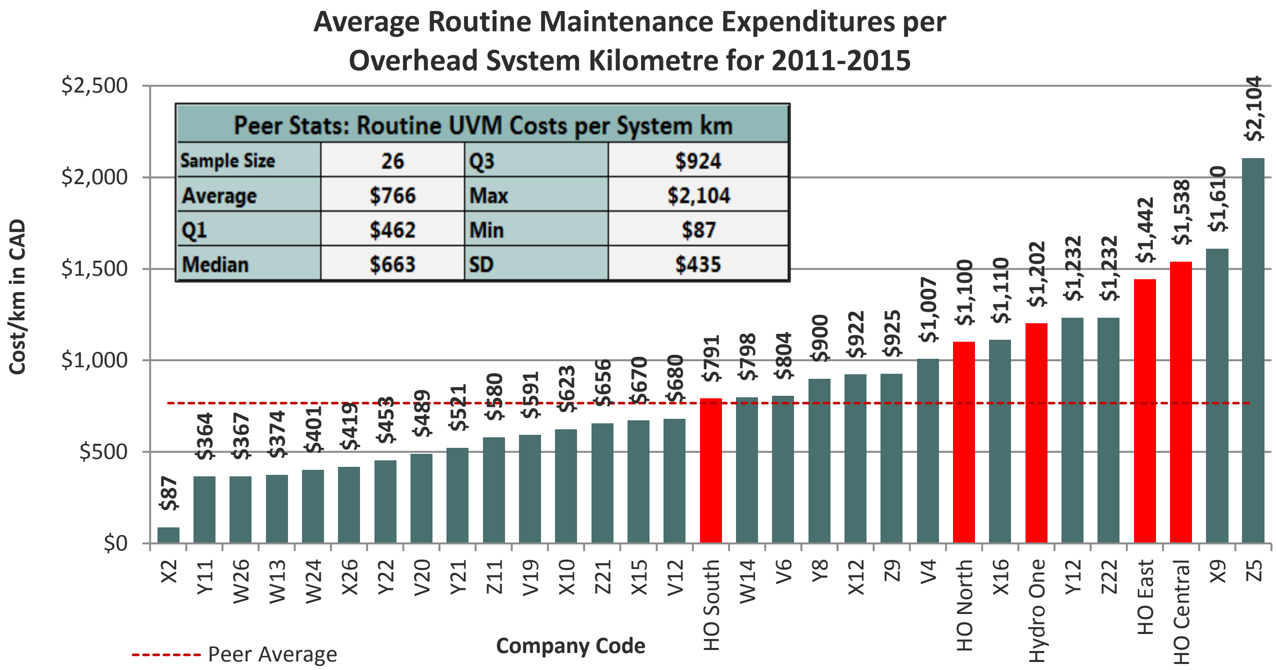


FIGURE 1: ROUTINE MAINTENANCE COSTS PER SYSTEM KILOMETRE

Hydro One is in quartile four for average cost per system km for routine maintenance 2011-2015. Hydro One is paying a high rate per km of UVM and the cost must be spread over one of the lowest number of customers per km. This makes the cost evaluation problematic and sensitive. Routine maintenance system kilometre costs at Hydro One are one standard deviation *above* the peer average.

In 2006-2008 Hydro One's routine system kilometre costs were also much higher than the peer average and it was attributed to significantly higher wages and benefits than the peer group. The current study finds that higher routine system kilometre cost is still a matter of hourly costs but is not solely a matter of higher wages and benefits. In fact, the cost of UVM per labour hour has increased significantly since 2011, while the number of labour hours actually decreased after 2012. System kilometre cost increases were due to hourly cost escalations which include administrative and equipment costs as well as labour burden. Hourly cost increases are discussed further in 4.1.4 below.

The peer group has a consistent ratio between labour burden and basic wage rates (about *17:10* for line clearance personnel). This ratio is much larger for Hydro One (about *29:10* for line clearance personnel). Hydro One UVM personnel are company employees who earn a higher wage than contract workers employed by peer companies. Furthermore, Hydro One includes significant administrative costs in their total UVM spend, whereas the peer companies outsource UVM and do not include administrative costs other than the personnel costs for the UVM department. Hydro One UVM hourly costs increased between 2011 and 2015 by $14 for line clearing, $18 for Brush Clearing and $25 for work planning. These increases represent fixed costs unrelated to efficiency and productivity and only a part of the increases are due to increases in wages and benefits. These increases are discussed further in the following sections.

4.1.2 *Total UVM Cost per System Kilometre Year over Year*

Another cost per system kilometre that can be compared is the total cost for UVM, which includes routine, reactive and storm costs. From 2011 to 2014, Hydro One increased the UVM expenditures by $130/system kilometre. In 2015, the cost per system kilometre was scaled back by $221/system kilometre. This reduction was achieved by modifying the work scope and schedule, which resulted in a $22.5 million budget decrease, only $3 million above the average spend in 2006-2008. In contrast, the peer group average system kilometre cost *increased* by $272/km from 2011 to 2014, more than double the increase of Hydro One during this time period. In 2015 Hydro One's system kilometre cost was only $42 above the peer average. Figure 2, below, highlights this fluctuation dynamic between Hydro One and the peer group. Hydro One's cost is split between high cost per system km in the East and Central Regions and low cost per system kilometre in the North and South Regions.

	2011	2012	2013	2014	2015
HO Central	$1,525	$1,717	$1,725	$1,764	$1,544
HO East	$1,552	$1,528	$1,521	$1,720	$1,379
Hydro One	$1,248	$1,338	$1,323	$1,378	$1,157
HO North	$1,170	$1,304	$1,200	$1,183	$932
HO South	$822	$895	$904	$898	$788
Peer Average	$850	$905	$965	$1,122	$1,115
Peer Q1	$604	$649	$632	$680	$714
Peer Median	$862	$854	$947	$1,072	$1,090
Peer Q3	$1,046	$1,087	$1,157	$1,354	$1,286

Figure 2: Year over Year System Kilometre Cost Comparisons

4.1.3 Routine Cost per Managed Kilometre

4.1.3.1 Average Cost 2011-2015 Comparisons

Another ratio for comparing cost is calculating the cost per managed kilometre. Managed kilometre is different from system kilometre. System kilometres are the number of overhead (OH) kilometres in the distribution system. Managed kilometres are the number of OH lines managed on an annual basis. The high cost for Hydro One vegetation management is apparent when measured by the cost of a managed kilometre (Figure 3, below). The routine average cost per managed km in the Central Region is nearly double that of the South Region and over four times the cost of the peer average. These costs are the result of:

- The accumulated biomass and heavy workload after a long interval between maintenance cycles. The management of in-growth after a long cycle is more expensive than treating a converted ROW on a short cycle with herbicides to prevent ingrowth.
- A higher cost of labour and equipment compared to the peer group, nearly all of which outsource UVM program implementation. A qualified line clearance arborist at Hydro One earns \$5/hour more than the highest paid peer company contract arborist. The labour burden is \$55 more. For the peers the average labour burden is 1.7 times greater than base wage. For Hydro One the labour burden is 3.0 times greater than the wage for field personnel, except for trainees (2.6 times) and temporary employees (1.6 times), which is closer to the contract crews. Hydro One's labour burden is loaded with associated UVM costs such as equipment and indirect administrative costs. The peer group labour burden is lower because wages and benefit costs are lower, but also because administrative/overhead costs are lower or they are not fully reported.
- Hydro One reports administrative/overhead costs better than their peers, since they are completely in-house. The peer group does not report indirect costs on the UVM program. They only report the direct costs to run the UVM department plus the cost of the contractor.

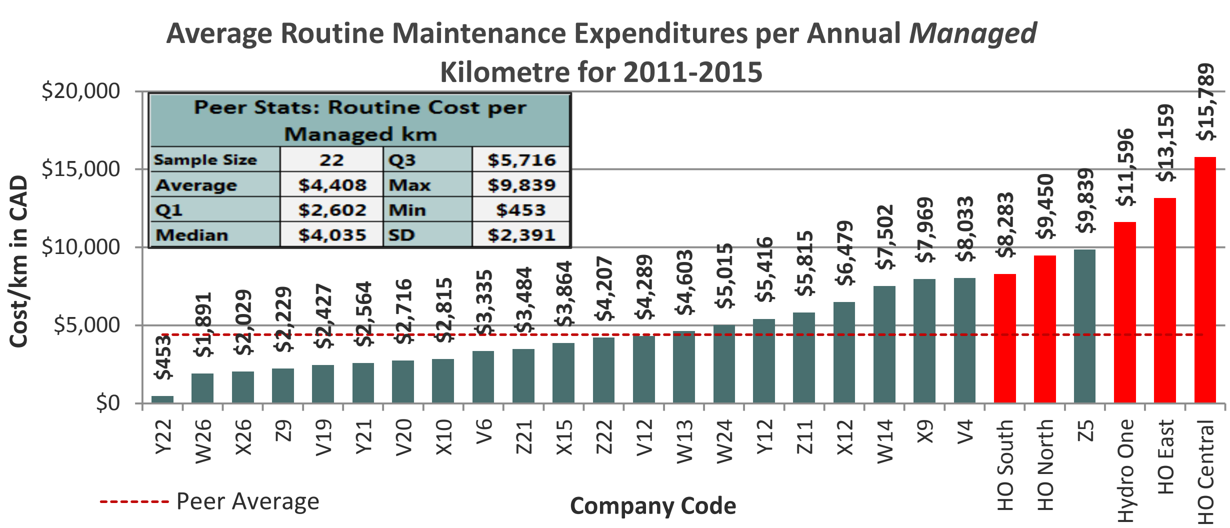

Figure 3: Routine Maintenance per Managed Kilometre

4.1.3.2 Longitudinal Cost per Managed Kilometre

Hydro One's 2011-2015 average cost per managed kilometre was a 22% increase over its average cost in 2006-2008 compared to a 25% increase for the peer group. Hydro One's 2015 cost per managed kilometre was only 13% over its 2006-2008 average compared to the 49% increase for the peer group. Also, Hydro One significantly reduced the cost per managed kilometre in 2015 over 2014 by 25% compared to the peer group average which was reduced by only 5% (See Figure 4, below). This reduction in cost was a result of targeting the 2015 schedule on M-Class feeders which are managed on a shorter cycle 6-8 years. The cost reduction in 2015 illustrates the cost savings possible when work is performed on-cycle and on a shorter cycle than in the past. It does not, however, show the cost reductions that could be achieved through herbicide use which requires a shorter cycle length to be effective.

	2011	2012	2013	2014	2015
HO Central	$13,483	$14,172	$18,084	$18,901	$14,303
HO East	$12,986	$13,087	$12,515	$15,487	$11,717
Hydro One	$10,721	$10,875	$12,163	$13,807	$10,417
HO North	$9,297	$7,795	$11,245	$11,112	$7,800
HO South	$7,388	$8,568	$8,150	$9,688	$7,624
Peer Average	$3,725	$4,034	$4,169	$5,547	$5,265
Peer Q1	$2,311	$2,633	$2,719	$2,688	$2,986
Peer Median	$3,326	$3,573	$3,756	$4,265	$4,391
Peer Q3	$5,107	$5,307	$5,092	$7,148	$7,370

Figure 4: Annual Routine Cost per Managed Kilometres for 2011-2015

4.1.4 Hydro One UVM Cost Increases are due to rates more than production

Total cost increases over time at Hydro One can be explained in part by variations in the number of trees treated per km or the amount of brush treated. Much of the cost increase is independent of tree densities or numbers of kilometres completed. It is the annual cost per unit of labour that has increased steadily since 2011 by nearly $20/hour (Figure 5, below). The number of labor hours increased in 2012 but decreased each year 2013-2015. The largest decrease was in 2015. The UVM cost increase is not a matter of efficiency or increased workload. It is due to increases in wages, benefits, equipment, fuel expenses, and other overhead and administrative costs. By reviewing Figure 5, the extent of the annual labour burden increase from 2011-2015 can be seen, irrespective of labour hours expended. In mid 2014 the labour pool was reduced by a large percent. When Hydro One was questioned about the increase in cost per labour hour, the following explanations were provided:

- $9 million cost centre administration costs
- $4.5M health and safety costs
- $1.5M BASC Costs
- $0.2M Central tools
- $0.35M shared services
- Wage increases
- Changes in the mix of full time employees and temporary hiring hall employees.
- Other labour burden increases

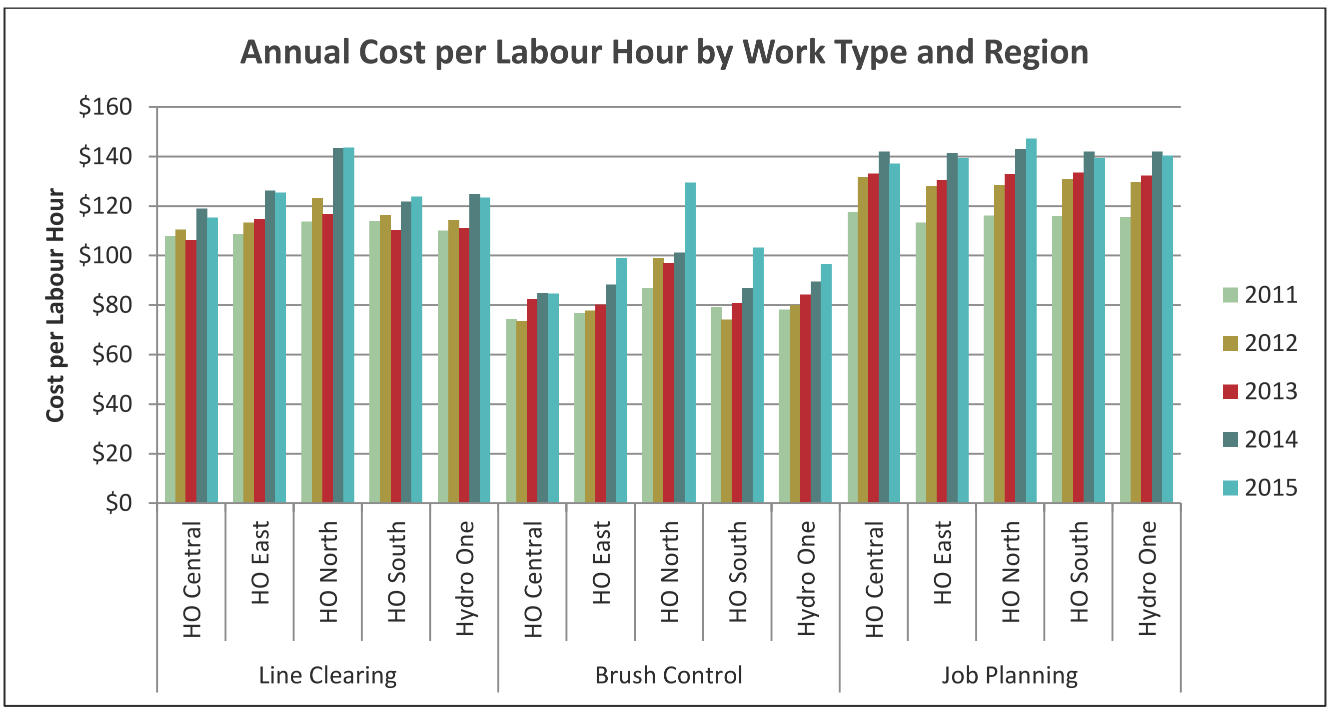

Figure 5: Hydro One Annual Cost per Labour Hour by Work Type and Region

The increases in hourly costs should be separated from the variations in productivity costs. The peer group typically reports less than 1% of costs related to administration or overhead compared to Hydro

One whose administrative costs are closer to 8%. This is a significant difference. The peer group may not report all in-house costs associated with the UVM department.

4.1.5 Cost Per Tree Treated

Trees treated are the same as managed trees and include both prunes and removals. Hydro One has maintained an above average cost (third quartile) per tree treated (Figure 6, below). This ratio is moderate in comparison to the cost per managed kilometre, which is high for Hydro One due to high tree density. The average cost per tree increased by $11 for the peer group and $12 for Hydro One over the five years. For Hydro One the rise in cost per tree represented increases in fixed cost rather than changes in work scope or productivity. In contrast, the peer group's cost increase was due to a greater emphasis on off-ROW tree risk, mitigating emerald ash borer (EAB), and hardening distribution systems against more frequent and intense storms, all of which require more off-ROW removals of larger trees. The average labour hours per tree did increase for the peer group by 9%. Labour efficiency is analyzed in section 4.2.

Hydro One's average cost per tree treated in 2011-2015 increased by only 3% over the 2006-2008 average compared to the peer group which rose by 97%.

Annual Cost per Tree Treated for Routine UVM for Years 2011-2015

	2011	2012	2013	2014	2015
Hydro One Central	$90.37	$104.22	$88.51	$111.31	$97.74
Hydro One North	$76.37	$81.39	$69.07	$73.85	$104.43
Hydro One	$106.26	$105.28	$94.47	$106.55	$118.33
Hydro One East	$113.18	$112.76	$90.01	$100.55	$135.03
Hydro One South	$178.76	$118.66	$155.89	$157.11	$155.48
Peer Average	$80.51	$77.68	$79.58	$85.62	$91.54
Peer Q1	$48.96	$52.69	$52.84	$57.94	$59.14
Peer Median	$65.82	$63.34	$68.07	$77.29	$76.01
Peer Q3	$97.58	$104.22	$91.07	$106.55	$118.33

Figure 6: Year over year Changes in Cost per Tree Treated

4.1.6 COST AND TREES PER CUSTOMER

"The OEB notes that the 2011-2012 CN Utility Benchmarking analysis showed that Hydro One had the highest vegetation management cost per customer relative to its peers. This benchmarking comparison emphasizes the need for Hydro One to provide detailed and thorough evidence substantiating its spending requirements and how it intends to continuously improve in this activity (OEB, March 2015)." Figure 7, Annual UVM Cost per Customer, below, confirms Hydro One's high relative cost that was discovered in 2012. This measurement is an average. It does not account for the variations in electric usage which affects cost per customer, but it does show that a Hydro One customer has a measureable stake in the performance of the UVM program, and that there may be a customer expectation that costs should be closer to that of peers.

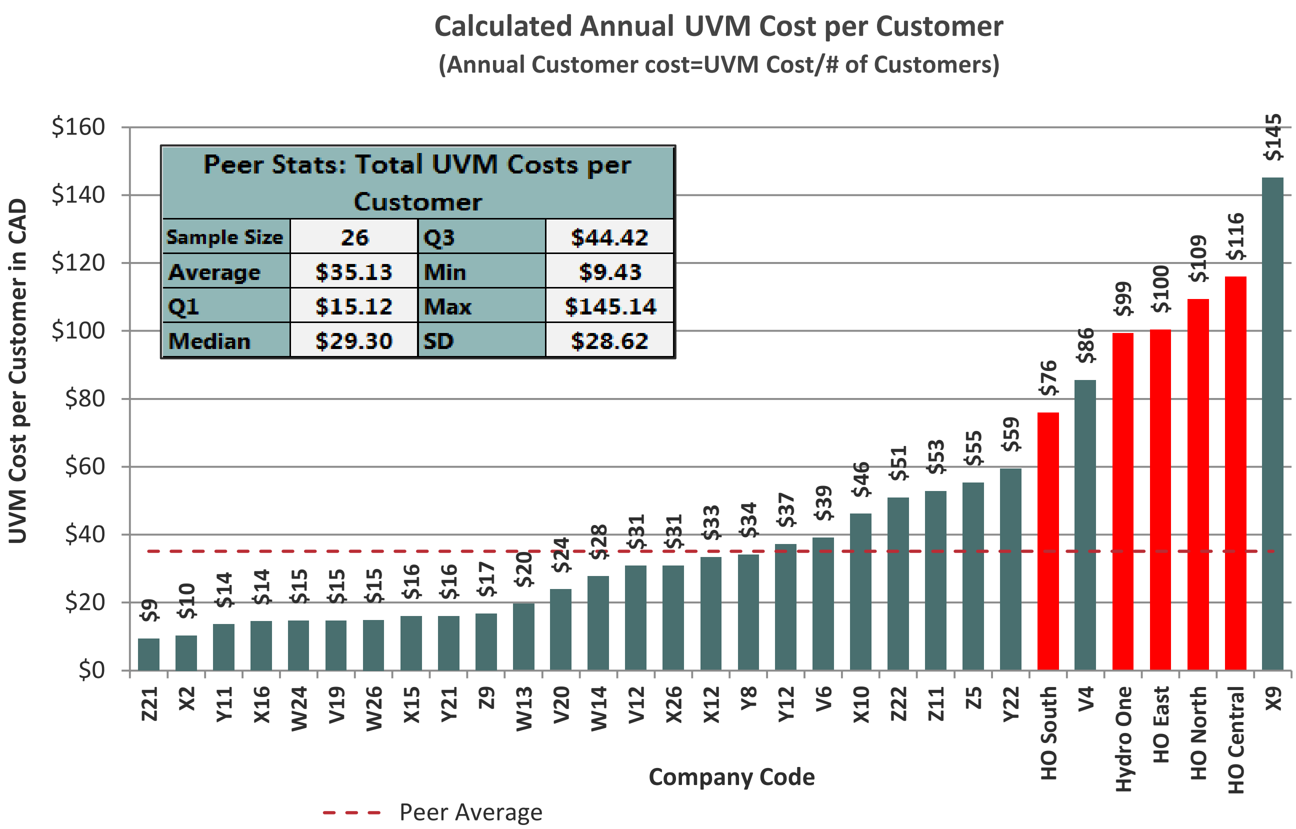

FIGURE 7: ANNUAL UVM COST PER CUSTOMER

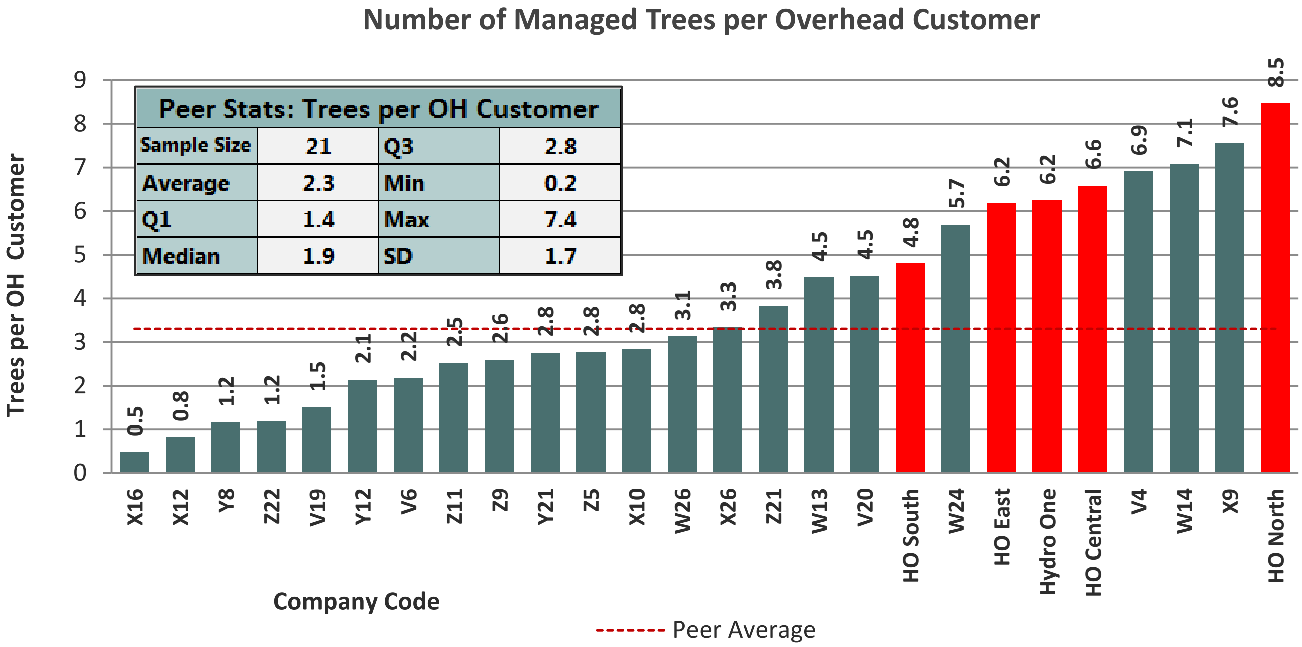

Figure 8: Number of Managed Trees per OH Customer

Another way to compare the customer's cost is to compare the workload per customer. The average number of trees per customer is calculated by dividing the total number of trees managed by the total number of customers. Since residential customers make up 90% of the total customer base, the calculations for trees per customer in Figure 8 (above) should be close the actual average (unlike the cost per customer, which is weighted to the industrial and commercial customers). There are wide variations of trees from one property to the next, but each Hydro One customer on average have 6.2 trees that must be managed compared to the peer and non-peer group average of 2.3. This is a cost factor that helps to explain a higher cost for Hydro One in terms of total cost and cost per customer.

4.2 Labour Efficiency

Another way to compare companies is to focus on the time units required to perform UVM. This is a more universal measurement (hours) for comparing the relative efforts of each company in the peer group. Hydro One compared favorably with the peer group in the 2009 study and again in the current study.

4.2.1 *Routine Labour Hours per System Kilometre*

When routine labour hours per system km are compared, a different picture of relative efficiency emerges in comparison to cost (Figure 9, below). Hydro One's labour hours per system km is nearly one standard deviation *below* the average. This could indicate the work is being performed as or more efficiently than the majority of companies in the comparison group. All of the Hydro One regions performed better than the peer average labour hours per system kilometre. However, rather than demonstrating work-efficiency, this metric is an indicator that Hydro One is under-resourcing their program and more work needs to be done. This is true because tree density, the number of trees managed per kilometre, is increasing and Hydro One has not been able to decrease the length of its cycle.

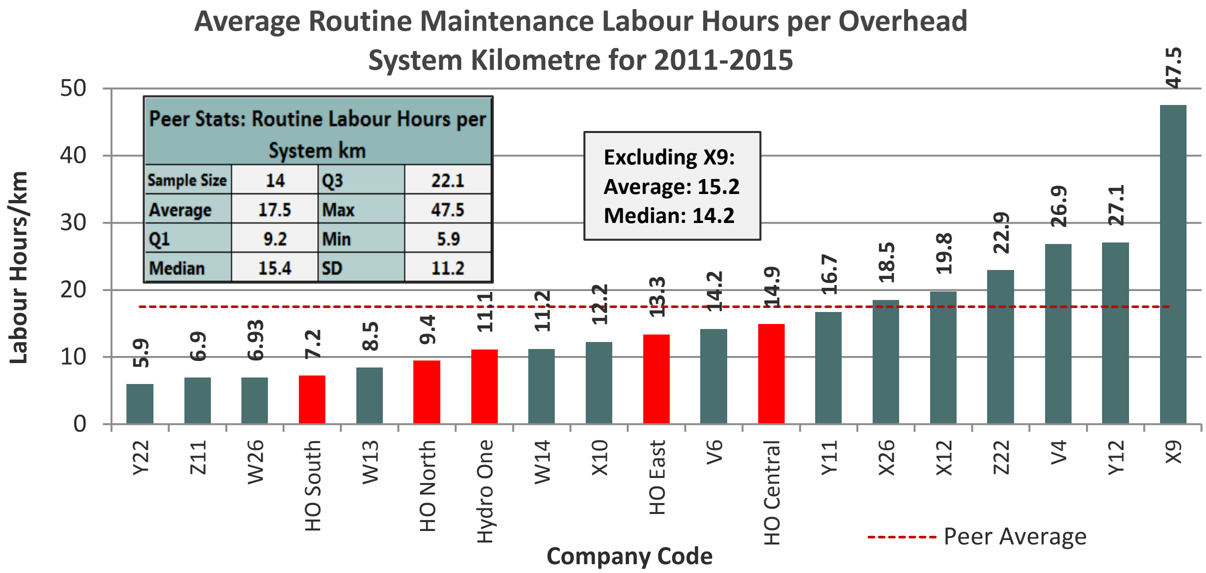

FIGURE 9: ROUTINE MAINTENANCE LABOUR HOURS PER SYSTEM KILOMETRE

4.2.2 LABOUR HOURS PER MANAGED KILOMETRES

4.2.2.1 Establishing Work Efficiency

The following discussion will establish that Hydro One has an efficient workforce relative to the peers. Figure 10, below more accurately depicts Hydro One's performance in labour hours per managed kilometre (LH/managed km) in comparison to peers by including tree density and cycle length for each company. Hydro One, W13 and W14 show similar measurements for all three metrics. All three have high tree densities, long cycle lengths and similar labour hours per kilometre. (**Gray bars = labour hours per km**; **Blue dots = trees per km**; **Green squares = calculated cycle length**). W13 and W14 have better ROW access than Hydro One regions with the exception of Hydro One South. This comparison with three different metrics lined up together shows how Hydro One compares evenly with other companies. Given a fourth metric, ROW accessibility, Hydro One compares more favorably with W13 and W14 because of the greater amount of access issues challenging the work at Hydro One.

The other companies with high tree densities, V4 and X9, expend significantly more labour hrs/managed km than Hydro One. Although their systems are on a shorter cycle than Hydro One, both V4 and X9 are under recent regulatory mandates that require increases in vegetation management. The remaining companies in Figure 9 have lower tree densities and shorter cycle lengths than Hydro One.

Work efficiency is reinforced by the higher tree density found on much of Hydro One's system. Hydro One also has a significant number of access issues to their system and it is typically in a state of heavy growth after nine to ten growing seasons. In conclusion, although Hydro One is close to the average for LH/km, they are in fact working UVM at a higher rate of efficiency in comparison to the peer group.

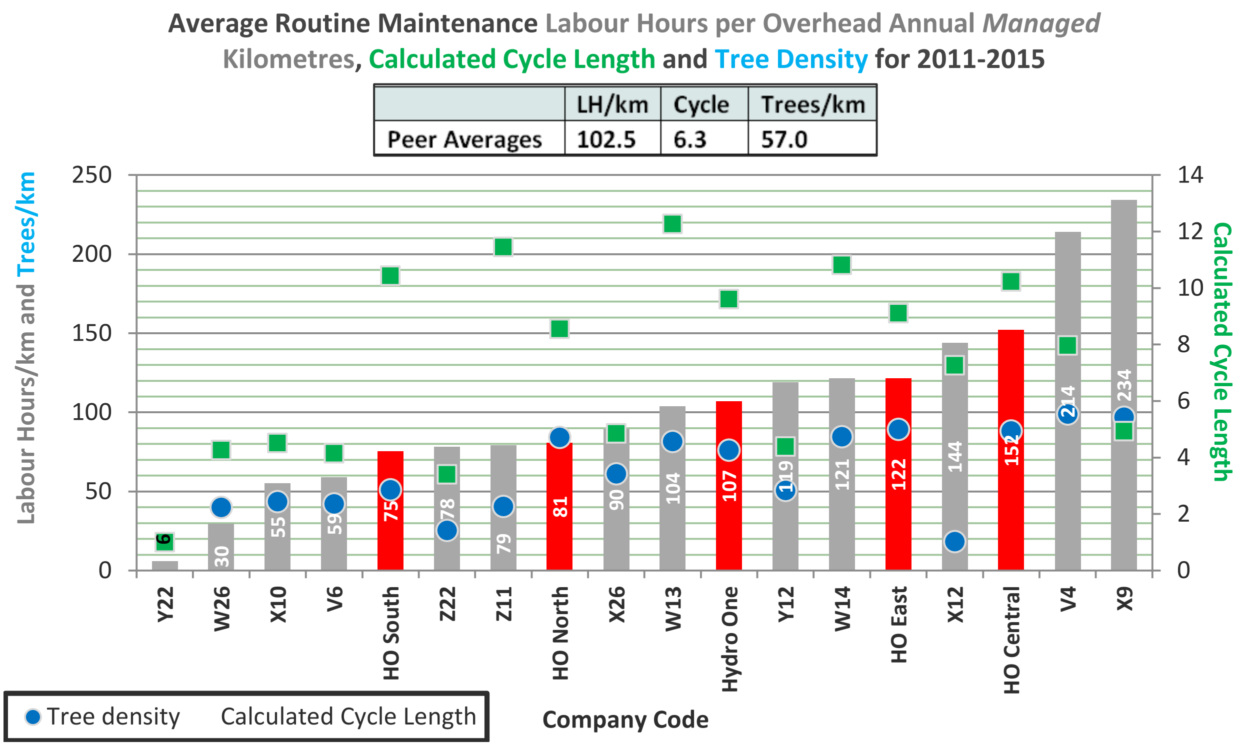

Figure 10: Routine Maintenance LH/Managed km, Cycle Length, and Tree Density

4.2.2.2 Tree Density and Managed Labour Hours

Figure 10, above is also a visual representation of the relationship between tree density and labour hours. In fact, there is a good correlation ($R= 0.66656$, $p < 0.005$) between tree density and labour hours for the peer group. As is expected, labour hrs/managed km increase as tree density increases. Hydro One's managed tree population has been enlarging for many years as a result of a long cycle length. Hydro One has had to work more efficiently to meet this rising demand. Hydro One's policy is to clear the ROW thoroughly in hopes of reducing outages, reactive work, and future workloads. When applied to circuits that have not been managed for many years (more than eight years), it is difficult to maintain efficiency. In order to sustain efficiency and reliability, in 2015 Hydro One modified the schedule to achieve shorter cycle lengths on M-Class feeders. At the same time, fewer kilometres of single phase and two-phase were worked. The change in labour hours per managed kilometre in 2015 can be seen in Figure 11 (below). This is evidence that shorter cycles will result in lower tree densities and less work and longer cycles will result in higher tree densities and more work.

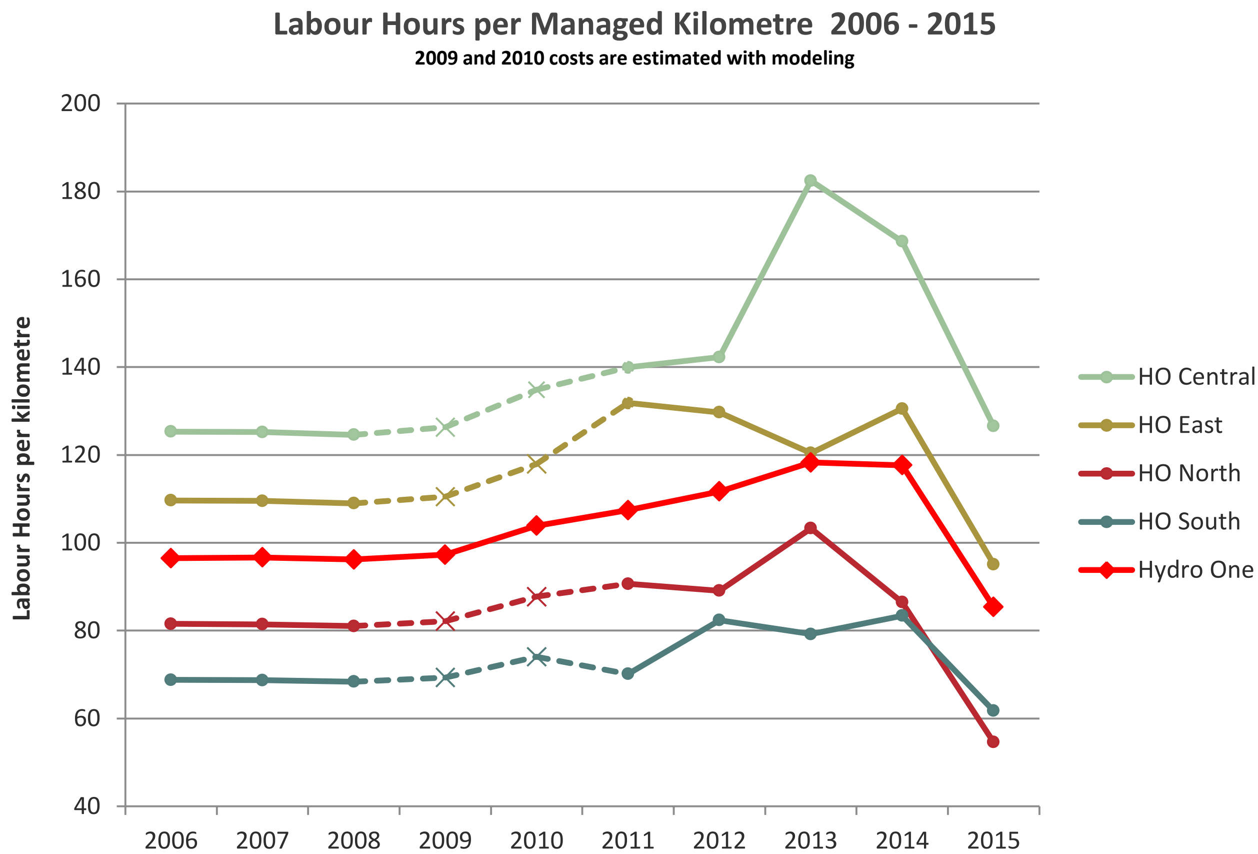

FIGURE 11: HYDRO ONE LABOUR HOURS PER MANAGED KILOMETRE 2006-2015

The following graph (Figure 12) is the same as the one above but it is limited to the labour hours per managed km of 2011-2015. The peer group average, median and 1st and 3rd quartiles are also represented. The peer average surpassed Hydro One in 2014 when both were at the highest number of labour hours per managed kilometre over the five years. It is easy to see in this graph that tree densities of the East and Central Regions are driving the annual labour hr/managed km output for the whole company. The North is managing a similar tree density with a much smaller labour output per km.

	2011	2012	2013	2014	2015
HO Central	139.96	142.26	182.41	168.63	126.56
HO East	131.83	129.68	120.43	130.79	95.09
Hydro One	107.42	105.52	118.30	117.67	85.40
HO North	90.66	68.91	103.29	86.30	54.60
HO South	70.14	82.38	79.23	83.26	61.74
Peer Average	92.7	93.1	93.7	129.3	110.7
Peer Q1	51.0	62.5	58.1	49.0	55.0
Peer Median	88.9	90.2	86.2	93.6	84.7
Peer Q3	115.8	129.7	118.3	152.2	134.6

Figure 12: Annual Labour Hours Expended per Managed Kilometres for Routine UVM 2011-2015

4.2.3 Labour Hours per Tree Treated

In contrast to the cost per tree treated, Hydro One's labour hours per tree treated are near the best-in-class (see Figure 13, below). In fact, the North Region is best-in-class all five years. If tree density was not so high, Hydro One could also be best-in-class at labour hours per kilometre. The South, which has the lowest labour hours per managed kilometre and per system kilometre of Hydro One's four regions, has the highest labour hours per tree. As previously mentioned, this is due to a longer growing season, a greater number of large trees, greater species diversity, and lower tree density. These conditions require moving personnel and equipment more frequently. The tree density in the North, Central and East Regions should be reduced to a level closer to the South Region, where possible.

	2011	2012	2013	2014	2015
Hydro One Central	0.84	0.94	0.83	0.94	0.85
Hydro One East	1.04	1	0.78	0.8	1.08
Hydro One	0.96	0.92	0.85	0.86	0.96
Hydro One North	0.67	0.66	0.59	0.52	0.73
Hydro One South	1.57	1.03	1.41	1.3	1.26

Peer Q1	1.11	1.17	1.19	1.16	1.20
Peer Median	1.48	1.39	1.46	1.53	1.50
Peer Q3	1.87	1.68	1.78	1.96	1.85

FIGURE 13: YEAR OVER YEAR LABOUR HOURS PER TREE TREATED FOR 2011-2015

4.2.4 TREE DENSITY IS A FUNCTION OF CYCLE LENGTH

In general, tree density is a natural phenomenon of the environment. For the purposes of UVM and this study, tree density is the average number of trees treated per kilometre each year. Consequently, tree density is not an independent variable. For example, although forested areas tend to have higher tree density than agricultural areas, tree density for UVM is still a function of management. Less management allows tree density to become a function of the environment. Consequently, companies with long UVM cycles (less management) tend to have higher tree densities (Figure 14 below). When Hydro One changed the UVM scheduling in 2015 and began focusing on M-Class, the tree density decreased because these lines have been managed more frequently. Hydro One's data shows that other non-M-Class backlogged circuits have greater tree density.

In Figure 14 the cluster of companies that have shorter cycles (left side of scatter plot) follow the correlation between tree density and cycle length more closely, because tree density increases with minor increases in cycle length. Companies with long cycle lengths correlate less well and the points are more scattered across both cycle length and tree density. The probable reason for this is that when the management cycle is long, environmental conditions begin to influence tree density more and changes in cycle length have a weaker relationship with changes in tree density. In other words, the shorter cycle UVM programs are lined up with a steep slope of tree density against the cycle length axis, whereas the long cycle companies are spread out and tree density is less oriented to the length of the cycle. Only one company in the long cycle group has less tree density than the short cycle group. Since Hydro One's cycle is already long, there is not as much change in tree density if the cycle is extended by another year or two. New trees, re-sprouted stumps, and increased growth from existing trees have already saturated the space.

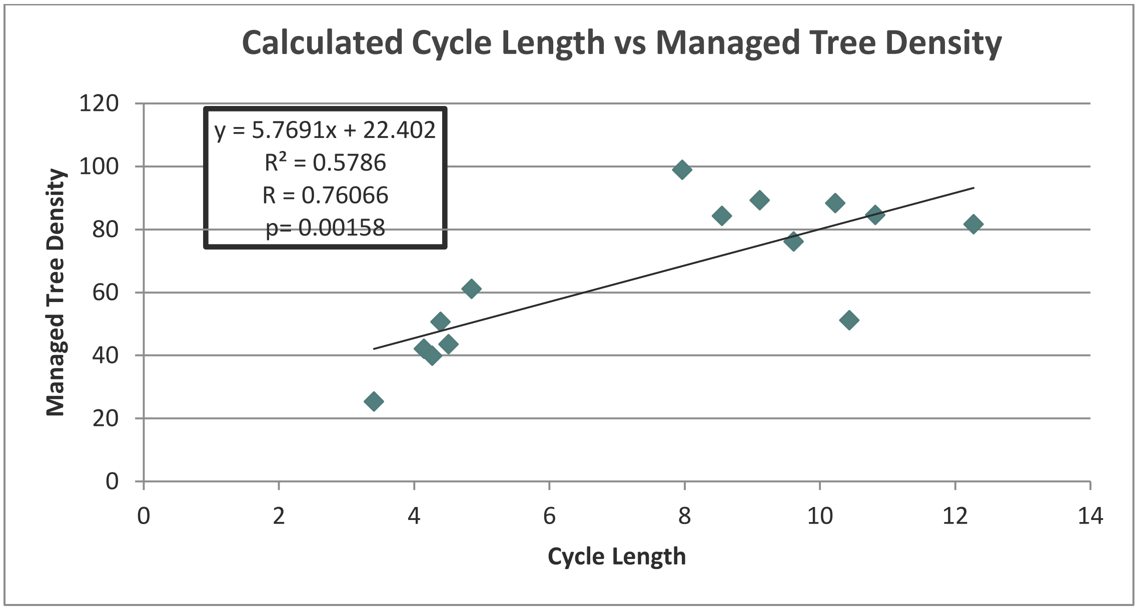

Figure 14: Tree Density is a Function of Cycle Length

The measuring and definition of tree density is also changing. Traditionally, tree density has been defined as the number of trees managed for UVM. Some companies have come to recognize that off-ROW trees cause many, if not the majority of reliability risks. A few companies have begun collecting data that expands the scope of their management to off-ROW risk trees. If this trend continues, the measurements of tree density will be higher than in the past for reasons other than long cycle lengths. Like Hydro One, the field of peer companies has not established a best management practice that balances cost, cycle length and tree density. This is evident in the wide range of tree densities matched to a wide range of cycle lengths and labour outputs.

4.2.5 *Tree Density Controls*

The conditions on parts of the Hydro One system at the time of maintenance are a considerable challenge to workers faced with multitudes of trees that are in contact or nearly contacting conductors and with trees that are overhanging conductors that must be roped down or pruned one small piece at a time. Tree workers are also faced with ROWs that are overgrown with dense invasive plant growth. Utility companies have a certain amount of control over tree density:

- If on-ROW trees are removed;
- If ROWs are treated with herbicides frequently enough to prevent ingrowth

- If off-ROW trees are removed where possible according to tree-risk assessment

Another term for controlling tree density is "controlling in-growth" and this control is natural for a maturing UVM program. Programs on long cycles such as Hydro One may *not* be controlling in-growth. Such programs are accumulating biomass in the ROW faster than it is managed. Several years can pass in this condition if there is not a programmatic effort to limit how many tree are encroaching conductors. This long cycle approach increases safety and reliability risks, but by applying selective tree work and having a well trained workforce as well as making other technical improvements to the distribution system, reliability metrics can improve in spite of increasing in-growth, at least in the short-term (See Appendix B).

The path to a shorter cycle is blocked by high costs to reclaim ROWs and the added cost in subsequent years of reworking ROWs with herbicides to get a stable plant conversion established. Figure 11 (p. 27) shows the increased effort to reclaim ROWs, particularly in the Central Region, where labour hours per km went from 124 in 2008 to 140 in 2011 to 182 in 2013. The effort to reclaim ROWs will result in vigorous regrowth without a follow-up herbicide program.

4.2.6 *Regional Costs Indicate Varied Forestry Conditions and Management Challenges*

The following are a few facts that illustrate the varied conditions in the Hydro One regions for the years 2011-2015:

- The Central, East and North Regions have similar tree densities, which are approximately 1.7 times greater than the South
- The South has nearly one-third of Hydro One's line kilometres
- The cost per tree treated in the South is 30% higher than in the Central Region
- The need to improve forestry conditions is the greatest in Central Region, followed by the East
- The Central Region's reliability performance is the worst of the four regions, having the highest number of outages/km
- North is removing over 70% of the trees managed

The above facts indicate Hydro One UVM program needs varied approaches in order to reduce and control the workload. For example, the South needs to devise strategies to reduce cost per tree treated. This could be accomplished with specialized equipment, pruning practices, scheduling and routing. The East and the Central need to decrease the tree density. This might be accomplished by educating customers, tree risk assessment to identify higher risk trees, and similar tactics recommended for the South could be used. The North, and where applicable in the other three regions, could reduce tree density by applying herbicides on a shorter cycle than the line-clearing cycle. Each region needs a customized approach to reducing the workload.

4.2.7 *Integrated Vegetation Management (IVM)*

Integration Vegetation Management or IVM's ". . . ultimate goal is to maintain a desirable plant community with available tools, emphasizing biological and ecological control (Miller, 2014)." Using IVM to make planning decisions, Hydro One should endeavor to convert ROWs to more appropriate plant communities. Initially, it is recommended treat a higher percent of distribution kilometres with industry-approved herbicides or other land management applications that effectively reduce or eliminate mechanical-cutting. Treating 50 – 75% of ROWs is recommended, although this amount may vary depending on property owner acceptance.

IVM is considered the most universal of Best Management Practices by system foresters, vegetation managers, academic research, the Environmental Protection Agency, and many other environmental groups. It has been championed by the *ROW Stewardship Accreditation Program* and is the chosen methodology of many in the arboricultural, forestry, and landscape industries. It is also known as integrated pest management (IPM). IVM advocates a rational approach to managing vegetation that is environmentally beneficial, cost-effective and meets the approval of various stakeholders, such as property owners, regulators and other involved parties. A key component in current IVM methodology is the use of approved herbicides to control inappropriate plant species early, before more invasive and expensive manual and mechanical methods are necessary. This means the vegetation must be treated when it is small brush and before it reaches the smallest class size of tree. This is not possible when the cycle of management is too long. IVM also encourages conversion of the ROW to appropriate low growing plant communities. IVM is a best management practice for achieving safety, reliability and customer satisfaction objectives of UVM while reducing the workload and environmental impacts. In general, IVM prevents substantial in-growth in a cyclical management program.

One of the primary tools advocated in IVM is the use of herbicides to prevent ingrowth. Table 2 (below) provides the percent of distribution kilometres that are treated with herbicides by utility companies. IVM is one of the most effective tools for managing vegetation, but it is the most inconsistently applied tool. In a six-year study, EPRI determined herbicide control could reduce stem counts of trees in the ROW by 70% compared to manual cutting methods which increased stem counts and mowing which didn't significantly reduce stem counts. (EPRI 2000)

Peer Group Herbicide Use					
Sample: 21	**GENERAL (Foliar, Basal)**	**STUMP**		**GENERAL**	**STUMP**
Hydro One	**14%**	**7%**	**Q3**	75%	98%
Average	35%	66%	**Max**	100%	99%
Q1	9%	21%	**Min**	0%	0%
Median	20%	93%			

TABLE 2: HERBICIDE USE

The Ontario Pesticide Act is designed to provide safety to the applicator, the public and the environment. However, it is used as a constraint by many who do not understand its benefits and who are more comfortable with traditional mechanical controls or favor the absence of control. Consequently, Hydro One compares poorly with many of the peer group in the percent of distribution system managed with herbicides through IVM. Only about 14% of the Hydro One system is managed with general herbicide methods such as foliar or basal treatments. Only 7% of stumps are treated. A more widespread use of herbicides would be necessary for Hydro One to reduce the cost, equipment, and human resources currently required to provide management of distribution ROWs. Once a succession of appropriate stable plant communities is allowed to populate ROWs, the volume of needed herbicide applications would decrease. This is the ultimate goal of IVM- stable plant communities in the ROW that suppress ingrowth of incompatible tree species. Estimates for an IVM cost benefit ratio over traditional manual and mechanical treated ROW are 3:1 or better (Finley Engineering 2010).

Hydro One's best effort to utilize herbicides is in the North Region, where 22% of the managed kilometres are treated with herbicide. Although this is a higher percent than the other Hydro One regions, it is not nearly enough to be cost-effective. If a decade passes before the ROWs are treated again, they will need to be fully cleared before herbicides can be reapplied, which is not cost-effective. The Central Region is the furthest from ROW conversion to appropriate and stable plant communities. Only 6% of Central ROW kilometres are treated with herbicides. For much of Hydro One, applying herbicides is not cost-effective because the interval between applications is so long that the ROW must be re-cleared. Hydro One currently is increasing their use of herbicides.

4.3 Work Planning, Customer Notification and Scheduling

4.3.1 *Work Planning and Cycle Length*

The following (Figure 14) is a representation of the consequence of not being on cycle as cited by survey respondents. Overwhelmingly, UVM managers believe that getting behind in the maintenance schedule has negative effects on cost, reliability, and safety.

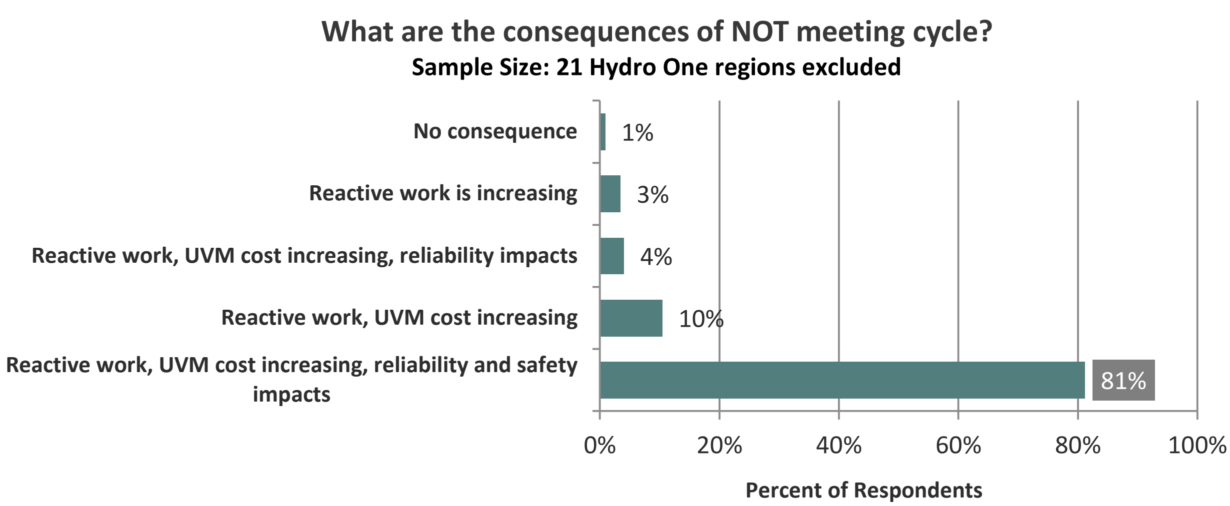

Figure 15: Consequences of NOT Meeting UVM Cycle Targets

The following are recommended practices for work planning at Hydro One. Included are some features that would enhance Hydro One's cyclical management of distribution corridors:

- **Cyclical survey of vegetation:** Document beneficial and unwanted vegetation conditions on the ROW. Hydro One only documents offending vegetation. 17% of system is inspected each year by non-vegetation management personnel trained to recognize the most obvious vegetation issues. Approximately 12% of the system is inspected by a qualified vegetation management pre-inspection planner. The 17% may overlap with the 12%. These inspection programs could be strategically synchronized to better capture tree risk that is out of reach of the routine program and to audit the success of the program. Improve, consolidate, and synchronize the current required asset inspections and the UVM work-planning inspections to add value and economies of scale to the planning program. Workload documentation should be more thorough at the circuit level to improve cost-planning, productivity, and quality management.
- **Cyclical survey of specific tree hazards off-ROW (Tree Risk Assessment) followed by prescribed work:** Hydro One has a formal Tree Risk Assessment Program that is a part of the pre-inspection program. The funding for this program is a small percent of the routine maintenance. It could be a more integral part of the UVM program if the responsibility was more clearly defined regarding trees off-ROW.
- **Management interval that is flexible based on actual conditions in the field and regular enough to prevent vegetation encroachment:** The M-Class and three-phase feeders are on a target for 4-8 years. The rest of the system should be managed similarly (See Table 3, below).
- **Establish performance metrics for maintaining air space around conductors**. Employ innovative data collection and leading performance indicators, such as safe ROW environment metrics, safe work place metrics, tree-risk assessment data, advanced outage investigation documentation, and other program features. These metrics will enhance and build greater safety awareness and education for anyone who enters and performs activities in a ROW zone for any reason.
- **Quality-driven IVM program that ensures ROWs are populated with beneficial plants and kept clear of inappropriate vegetation with a minimum of cutting, chemical application and soil disturbance:** Hydro One cannot cost-effectively apply herbicides until the cycle of UVM including herbicide applications is a shorter interval. The six-year cycle for M-Class and three-phase are sufficiently short if the herbicide applications are timed properly (Table 3).
- **Involvement of significant stakeholders, such as electric customers, regulators, governing jurisdictions, property owners, land agencies, media and the public:** Under equitable conditions the burden of liability risk would not be 100% on the utility company as they do not own the trees. Some stakeholder actions, such as property owners who are opposed to vegetation management, constrain the utility from performing UVM at standard industry levels. The pre-planners and utility foresters should be trained in customer communications and regulatory matters in order to build a future where carefully crafted incentives shift some of the financial and legal responsibility for trees away from the utility and toward property owners and local jurisdictions.

- **Database documentation of activities and favorable outcomes:** Hydro One has electronic data capture. Data transfers from paper to electronic and across various electronic formats should be streamlined so there is a seamless automation.
- **Use of innovation and technology to enhance effectiveness and efficiency of UVM program to achieve stated measureable objectives for reliability, safety, customer satisfaction and environmental quality:** Hydro One has a continuing commitment to innovation. More emphasis should be placed on R&D.

Variable Cycle Statistics [Peers plus Hydro One Networks]								
Cycle Type	General Target	General Actual	Urban & Suburban Target	Urban & Suburban Actual	Rural Target	Rural Actual	Remote Target	Remote Actual

STDEV	1.7	2.0	1.4	2.0	2.5	2.5	1.8	1.9

Table 3: Variable UVM Cycle Statistics

In Table 3 (above), target cycles and actual cycles are listed for demographic divisions. Descriptive statistics of the responses are given, including standard deviation from the norm. This table illustrates how the majority of the distribution UVM industry operates behind schedule, and has for many decades. The yellow highlighted numbers are recommended cycle lengths for Hydro One based on what is realistic for the average company and given the fact that a majority of Hydro One' system is rural or remote and that the North, Central and East Regions have harsher climates than most of the peers in this study. The variation in cycle lengths could be applied to the different regions or as needed to reduce risk. Similar cycle lengths have been cited by personnel at Hydro One during interviews about ideal cycle lengths.

Can a company, that is on schedule, has a proactive reliability program to reduce the risk of tree failures, and has a history of top-tier reliability, be spending less than Hydro One on a per km basis? A simple comparison of cost per system km shows the difference. One company (Y8) that is at the minimum cycle length (one-year inspection cycle and a three-to-four-year maintenance cycle) spends $900/system km for routine maintenance while Hydro One Central spends $1,538 per system km and is on a 9.5-year cycle (Figure 1, p.17). In other words, it is costing the Central Region almost twice as much to manage a km of line one time as it costs Y8[2] to manage a km of line three times. Even for the complete Hydro One system it cost more to manage it once than it does for Y8 to manage its system 3-4 times. Y8 inspects

[2] Y8 did not supply their labour hours which would have provided a more normalized comparison

their entire system once every year and only manages what is necessary. Hydro One Central may be clearing the full width of the ROW, but since the interval of maintenance is so long the workload stays the same. With a more frequent management, the workload (cost) could be reduced because vegetation is managed at a smaller stage of growth. This is not to say a three to four-year interval would be cost-effective for Hydro One, but it does establish that a more frequent interval could be more efficient. Inspecting the system more frequently than it is maintained also ensures a quality of management and increases the ability to discover hazardous trees.

4.3.2 *WORK PLANNING AUTOMATION*

Survey participants were asked to name three technologies they have introduced into their program. The most frequently mentioned technology was software for planning, work management, and mapping. This technology adoption is not immediate or without challenges. Planning UVM work is less standardized than line clearance maintenance work, so software automation projects are unique and emergent. Only about 27% of companies have comprehensive work planning over 100% of their distribution system. Another 15% are formally planning at least 50% of the system. 36% of companies are conducting less formal summary planning over their entire system. The variations in data collection present challenges to adding value with electronic systems.

Hydro One conducts comprehensive work planning over 100% of their distribution system. There are 48 notifiers and five work planners. Although every tree is not documented and evaluated for treatment, tree-counts are estimated through samples and all customers are notified. Herbicide treatments require a signed permit. Although Hydro One has introduced custom software to the UVM program, there are still many challenges to effectively improving the efficiency of the program with data.

Hydro One administers the UVM program using several formats. Most of Hydro One’s UVM administrative activities are done partly on paper, with the exception of the workload inventory database. Mapping is electronic but crews do not have access to it. Many activities are done in multiple formats such as paper, Microsoft office products, and various types of in-house or vendor software. Activities such as crew dispatch or work plans are done purely on paper. Time sheets are done on paper and in-house enterprise software. Production is on paper, on excel, and on in-house custom software. Invoices are on paper and electronic.

UVM administration and documentation activities performed in multiple formats are likely to have extra layers of data input and opportunities for error. Much of modern life is conducted electronically and increasingly outmoded paper formats are reviewed and verified less than in the past, making them more dysfunctional than when they were the primary transaction format. Paper today presents fewer opportunities to create summaries, because most calculations are currently performed in databases. Therefore, paper information has to be input to the database before calculations can be made. A best management practice (BMP) is to fully automate administration and documentation of the UVM program with the least amount of data input repetition and maximum integration within the UVM department and across other departments and stakeholders.

The following are work planning automation statistics with 33 companies providing data:

- 42% of companies reported that they use more than one format to collect work planning data.
- 55% use one format
- 18% use paper *only*
- 54% use paper
- 36% use paper with another format such as excel or a proprietary software
- 21% use excel, word or pdf only
- 9% use in-house software only
- <1% use vendor software only

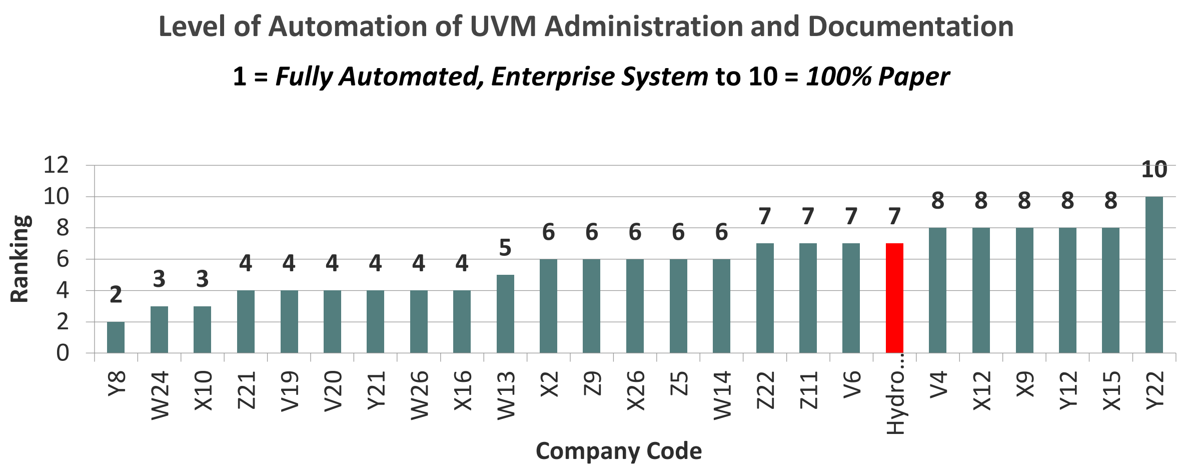

Figure 16: Level of Automation of UVM Administration and Documentation

A rough scoring was devised to compare Hydro One with other utilities based on how well each company has adopted electronic processes and how far they have progressed through transitions that require multiple formats. Figure 16 (above) shows the scores for each company. A fully automated and integrated UVM system would receive a score of one and a system that still performs all administrative and documentation activities on paper received a score of ten. No company received a one and only one company was scored at ten. The majority of companies is attempting to transition away from paper and has been since the last time a similar survey question was posed in 2009. The progress can be seen in how much paper has been transitioning to electronic processes, but it is more difficult to see how efficient the various electronic systems are performing, particularly in transition with multiple formats in use. Full transition to the field crew level is likely to take a few more years for many companies.

Automation should continue to be pursued and improved on all fronts. For example, the following work management activities would benefit from automation:

- Electronically documented measurements and assessments of ROW conditions
- Professional prescriptions
- Electronic work order transmission to crews
- Crew electronic time keeper submitted back with verification that work plan was completed with any modifications
- Documentation of production

- Records automatically generated for audits, payroll, invoicing, data analysis, and financial planning.
- Monthly and quarterly reports tracking progress and exceptions to plans
- Statistical process control calculator to determine weekly production that is two and three standard deviations above norm with investigative follow-up and corrective action when appropriate
- Data collected from the above activities can be used to develop predictive models

The use of remote sensing such as LiDAR to quantify and accurately measure vegetation conditions will improve Hydro One's ability to model appropriate, economical, safe, environmentally beneficial, climate-change aware UVM programs that help deliver optimum electric reliability.

4.3.3 *Customers and UVM*

Hydro One reported their "Customers are becoming more aware of their trees and more environmentally conscious, while not very aware of the hazards of powerlines and trees." The path to a rational and sustainable distribution ROW management begins with customers, who need to take some responsibility for their vegetation encroachments and their vegetation-caused damages to the infrastructures they depend on. This is no easy task since the ROW crosses over or is at the edge of customer property. If the utility is willing to manage the problem, then the customer should be willing to accept cost-effective management or plan to pay for management that is customized for their purposes. A rule such as this exists in Illinois where communities that require costlier UVM practices than what the utility prescribes have to pay the difference. Is reliability and the customer a *Catch-22* or an opportunity to know your customer? Most companies don't know much about their customers and rely on field workers to be good representatives for the company. Data on the customer is not impactful to decision making and policy. An improved UVM program would do a better job of understanding and educating the customer.

4.3.4 *Company Customer Service*

Hydro One is more customer service oriented compared to the peer and non-peer group. Hydro One personnel:

- negotiate with customers on work specifications
- negotiate with customers who refuse work
- get permission to remove trees
- notify every customer of impending work
- respond to focus groups
- get permission access property
- get permission to apply herbicides
- respond to complaints
- call property owners who don't live on the property

Hydro One does most of these customer service activities using multiple resources, including notifiers and other supervisory personnel. Although many companies provide these services, not as many do it at multiple levels and often the core of customer communication is conducted by the same people who are cutting the trees.

4.3.5 *How well are UVM departments connected to the utility customer service equation?*

The key to knowing the customer from a planning perspective is dependent on the data collected and how that data is leveraged in future customer services. 58% of companies, including Hydro One, keep a record on customers who respond to notifications. 92% of companies said they think there is 'a disconnect' between industry standards and what customers/property owners and local agencies require when UVM is performed on their properties. Hydro One has a customer refusal tab in their Tech notification software (*Forestry Application Production*), where information about customer refusals is captured. Figure 17 (below) illustrates the lack of knowledge about customers that may be at the root of why there is a disconnect between customers and the industry standards. Only 5% of companies store vegetation data on the customer service system (CSS) and less than half of UVM departments and/or UVM planners/notifiers can access the CSS database. As one survey respondent commented, one of the most important factors for UVM efficiency is customer relations.

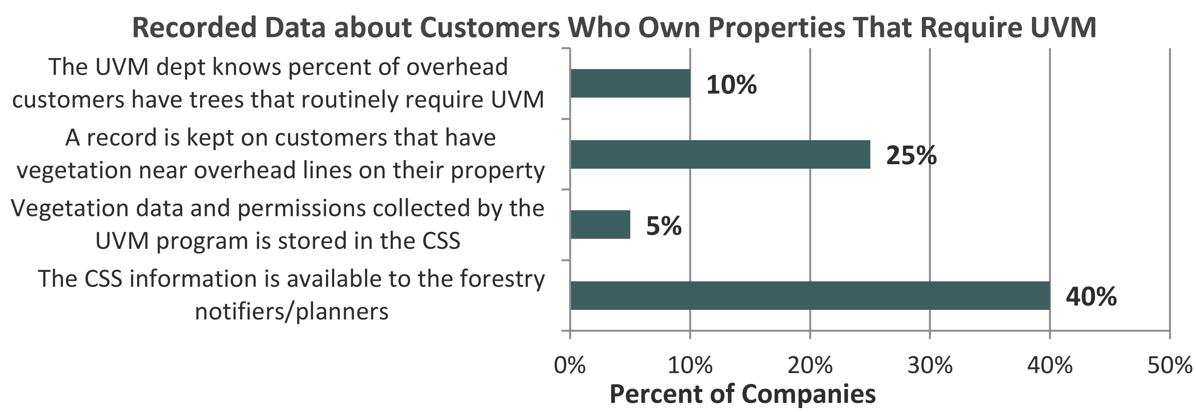

Figure 17: Knowledge about Customers Who Own Property Where UVM Is Required

4.4 Equipment and Personnel

4.4.1 *Equipment*

Hydro One named three items that are key to the efficiency of their UVM program:

- Logistics
- Labour Rates
- Mechanization

Two of these: logistics and mechanization, involve equipment. One is for transportation and the other is equipment for performing work. Under logistics a subcategory of utilization could be included that maximizes the efficiency related to having the right equipment and people in the right place at the right time. Hydro One expects each local area to develop strategies based on local geographical knowledge. Beyond the prioritization of circuits, there isn't a company-wide approach for scheduling crews or pooling resources. Hydro One is developing GIS telematics to monitor crew locations, manage fleet maintenance and enhance emergency response. This technology could be used to improve routing of crews to minimize drive times and fuel consumption. This is an area of technology R&D that should be coordinated centrally to ensure high level planning prioritization feeds into routing optimization and to ensure storm response is enabled to decrease the current high number of MED SAIDI minutes.

To economize fuel and travel time, crews meet at temporary work headquarters that are remote from the local operations centres. Training is conducted on inclement days and in the winter to ensure blue sky days are utilized. Hazard trees are managed at the same time that routine work is performed to eliminate duplicate trips. Hydro One spends on average 6.4% (of routine + reactive work) on travel intensive reactive work to correct emergency system problems. This is lower than the peer average of 8.8% reactive expenditures. 40% of customer calls are resolved without a crew site visit. The UVM department only receives 15,000 calls per year out of the 2M customer calls made annually to the Hydro One call center. If this ratio were to increase, the productive utilization of labour and equipment would decrease. Customer satisfaction is important to the level of efficiency for a UVM program.

Hydro One made the following statement in the 2013 rate proceeding: "Equipment utilization averages have increased from approximately 65 percent in 2001 to approximately 80 percent in 2012. The 2012 average equipment rate is $21.38 per hour; this is established by averaging total annual fleet equipment costs over total annual fleet utilization hours." (EB-2013-0416 Exhib. C1 Tab 4, 2013) Hydro One reported in the benchmark survey that on average equipment is utilized 63% of the time. On average 60% of Hydro One employees are stood-off for at least three months of the year, which idles equipment. The savings in lost productivity due to weather extremes and short days and the winter wear on equipment may offset some of the utilization losses. Hydro One depreciates equipment at standard rates, which are based on year around utilization and this may prolong the time it takes to fully depreciate equipment. The excess pool enables equipment to be replaced when taken out of service for repairs and it enables quicker deployment to locations where the equipment is needed. The forestry department meets with the fleet department to decide the future equipment needs and which pieces to sell and replace. *This process could be incentivized to maximize utilization and optimize the life-cycle of useful equipment, while replenishing and rightsizing the fleet for maximum productivity, safety and environmental quality.*

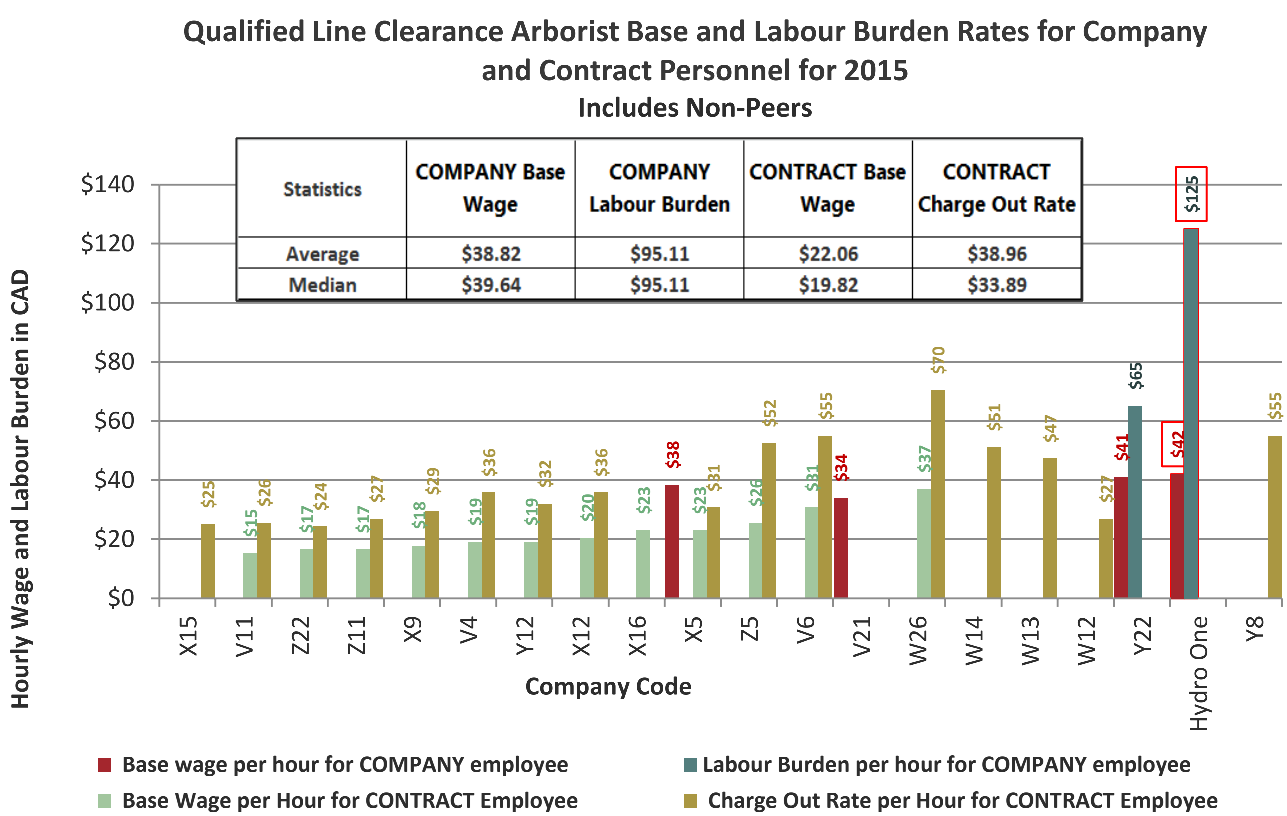
The peer and non-peer groups did not report equipment utilization percent except for one company that reported 95%. Most companies (83%) said they rely on their contractor to have serviceable equipment. 22% of 36 companies reported they require contractor equipment to be not older than five years on average. 66% of companies said their contractors' trucks are tracked with GPS locators (Telematics). 36% of companies said crews are allowed to add workers whose equipment is being repaired.

Although an argument can be made for lack of utilization of equipment throughout some periods of the year, having a consistent and adequate budget to accomplish clearly established objectives is a more effective way to ensure a fleet is optimized and rightsized than simply penalizing a department for underutilizing equipment purchased when funds were more available. The increases in cost of equipment accounted for only a small percent of the increase in expenditures for UVM over the 5 years. Mechanization and new technology is necessary for forestry services as its importance grows.

Improvements can be made by focusing more resources in the North during the warmer months of the year and shifting resources to the South Region during the coldest months of the year. Productivity could be improved and labor costs reduced by increasing the deployment of crews when working conditions are optimal and discontinuing deployments during the harshest weeks/months of the year. Forestry staff deployment strategies and technology should also be tailored and coordinated to improve preparedness and restoration response to reduce outage durations.

Customers are becoming more aware of the value of their trees. Provided the right messages they will become more aware of the efforts and effective forestry practices required to have power system corridors crossing through many forests.

4.4.2 *Personnel*



Statistics	COMPANY Base Wage	COMPANY Labour Burden	CONTRACT Base Wage	CONTRACT Charge Out Rate
Average	$38.82	$95.11	$22.06	$38.96
Median	$39.64	$95.11	$19.82	$33.89

Figure 18: Line Clearance Arborists Base Wages and Labour Burden Comparison

The primary driver for the cost of UVM at Hydro One is the cost of labour. The base wages for Hydro One are in the fourth quartile (Figure 18 above) and they are about 1.9 times higher than the average of the peer group contract labour. The $125 charge-out rate for a Hydro One crew leader or qualified line clearance arborist combined with $67 for an apprentice is also about 1.9 times higher than the cost of a two-person aerial lift contract crew including typical line clearance equipment.

There are large differences between labour burden rates for in-house arborists, Hiring Hall line-clearance workers and contractors (Figure 18, above). Changes in the labour mix could improve productivity and control costs. These improvements can be made by utilizing a higher percent of Hiring Hall and contract workers to perform lower safety and lower liability risk activities such as work planning, herbicide applications, and brush-clearing. To maintain current level of lower safety risk, the more experienced and highly-trained in-house arborists who perform line-clearing activities should not be replaced with less experienced and less trained workers common to contractors and the Hiring Hall.

The turnover rate at Hydro One is at 5% compared to 32% for the peers. The table below shows the result of low turnover rates. For example, on average, Hydro arborists have 20 years of experience compared to 6.5 years for peer group companies that contract out line clearance activities (See Highlighted cells in Table 4, below). Since these are averages per company, it is evident some peer group contractors employ more people with minimal experience.

Number of Years Line Clearance Employees Have Been Working at the Utility					
Average, Max, and Min Exclude Hydro One		Peer Average	Hydro One	Peer Max	Peer
Supervisor	Company	13	25	24	5

	Contract	5.5		15	1

TABLE 4: EMPLOYEE TENURE COMPARISONS

4.5 RELIABILITY PERFORMANCE

As a measure of performance, reliability metrics have been developed to help utilities prioritize work to provide optimum improvements to the expansive and aging overhead electrical grids that matured many decades ago and are now in various stages of renewal, rebuild and replacement. The metrics commonly known as the IEEE 1366 methodology have provided a way to triage complex systems that are vulnerable to dozens of minor and major interrupting events each year. It is not uncommon for large utilities to experience in excess of 10,000 outages every year, but most utilities have reduced the frequency that feeder lines fail and they have reduced the number of affected customers by inserting loops and breaks to isolate interruptions down to the fewest possible number of customers. Much of this effort has been the answer to storm events that are increasing in frequency and intensity. However, these efforts, while mitigating impacts, do not reduce the vegetation management workload. If anything they have allowed utilities to postpone UVM and to reallocate funds to other efforts that are more successful at improving the reliability metrics. Appendix B offers more details about the impact of IEEE 1366 reliability metrics on UVM programs.

A majority, 54%, of companies, are using SAIFI (System Average Interruption Frequency Index) as a measure of performance in their UVM programs. Other indexes are used to a lesser extent. Recently, over the past decade, regulators started requiring utilities to report reliability metrics as a way to measure the performance of regulated utilities. 83% of utilities in the CNUC survey are reporting SAIFI to their regulator. Of particular interest to UVM are the separation of customer interruptions into Major Event Days (MED) and Non-MED. The threshold for MED is T_{MED} which is calculated with the Beta Method equation which involves the average of MED over a five-year period. Not all companies use this method, including Hydro One, who uses 10% of customers interrupted as the threshold for a MED. The following variables have a negative influence on reliability metrics and(Pacific Economics Group 2010) are all very common to Hydro One:

- **Weather**— South, East and Central regions are in path of common storm tracks in all seasons
- **Vegetation density**— 76 trees per km, which is above the peer average, nearly highest number of trees per customer (6 trees/customer)
- **Low percent of underground**—94% overhead
- **Low customer density**—lowest in peer group
- **Difficult terrain** –20-30% off road and 55% of off road is difficult to access
- **Industrial and Commercial Customer Influence** – Lowest percent of commercial and industrial customers in peer-group. Larger commercial and industrial commercial customers will pay a premium for better reliability and thus improve reliability of the system
- **Age of network**—high percent is beyond replacement age

This section provides comparisons of reliability metrics with peer groups, but any reliance on these comparisons should bear in mind the disadvantage that Hydro One has in regards to reliability metrics and that reliability metrics are a lagging indicator for performance in vegetation management, which is less cost effective to address after trees have encroached conductors and are causing more outages.

4.5.1 Tree-Related Outages per System Kilometre

The following graph, Figure 19, below, shows a less common reliability measurement that is more appropriate to UVM, although it is still a lagging indicator: outages per kilometre.

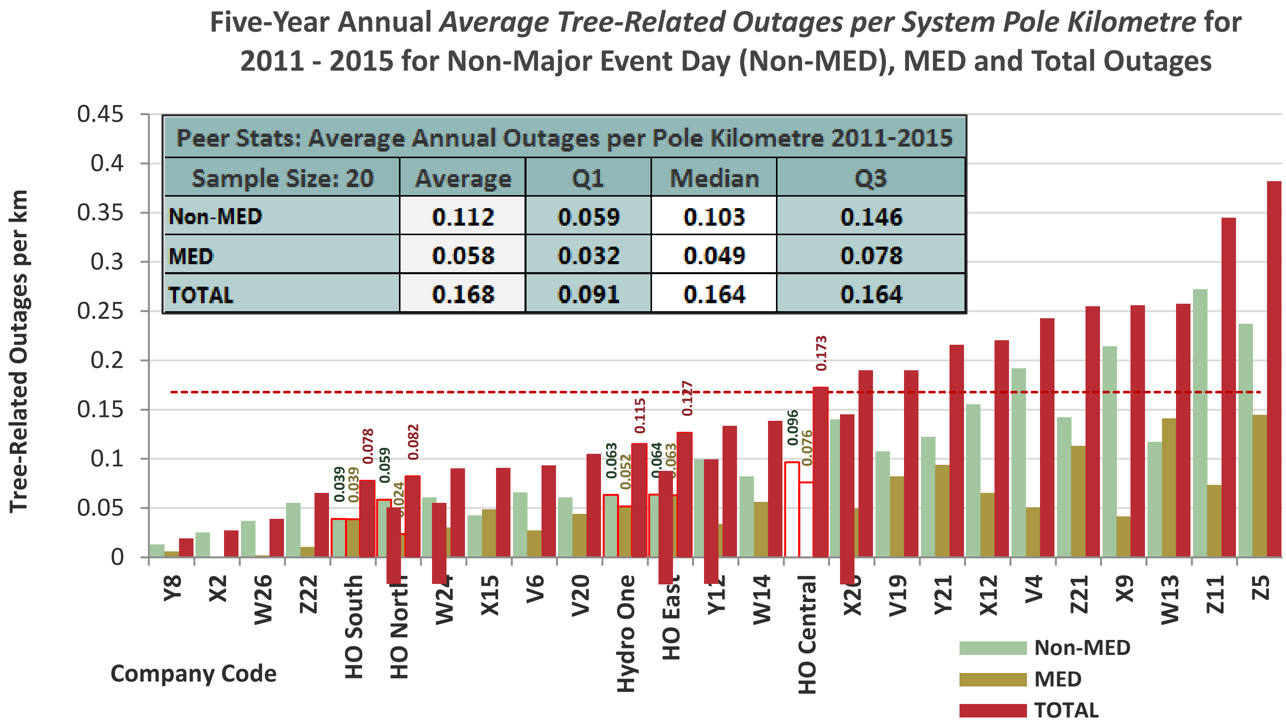

FIGURE 19: TREE-RELATED OUTAGES PER SYSTEM KILOMETRE

This measurement indicates Hydro One is doing a better than average job of reducing the risk of trees causing outages across the Hydro One System. This Figure is analyzed and discussed further in Appendix E.

4.5.2 *IEEE RELIABILITY METRICS FOR TREE-RELATED OUTAGES*

The measurements for tree-related SAIDI (Figure 20 and Figure 21) and SAIFI are not as reassuring. Hydro One is in the fourth quartile in both non-MED SAIFI and SAIDI. Hydro One has improved from 2.9 hours (174 minutes) in 2003 to 2.3 hours (138 minutes) in 2015 for Non-Major Event Day (Non-MED) tree-related System Average Interruption Duration Index (SAIDI). This improvement has remained relatively steady since 2008 with a 2009-2015 average of 2.1 hours (126 minutes). In spite of improvements Hydro One still compares unfavorably with peers in the area of standard reliability metrics. Hydro One's 126 minute SAIDI average is more than twice as high as the peer average of 50 minutes for 2011 -2015.

Hydro One is currently scheduling UVM work to improve tree-related SAIDI and SAIFI. However, the prioritization of workload to accomplish reliability metrics improvement will not necessarily improve total UVM performance. See Appendix B for in-depth analysis of relationships between reliability metrics and UVM.

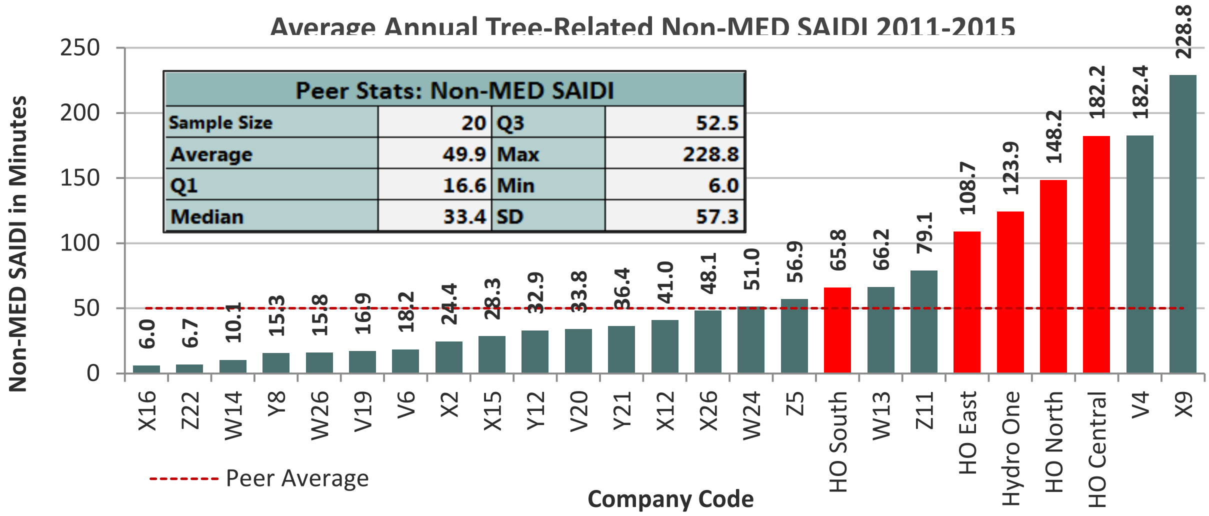

FIGURE 20: TREE-RELATED NON-MED SAIDI

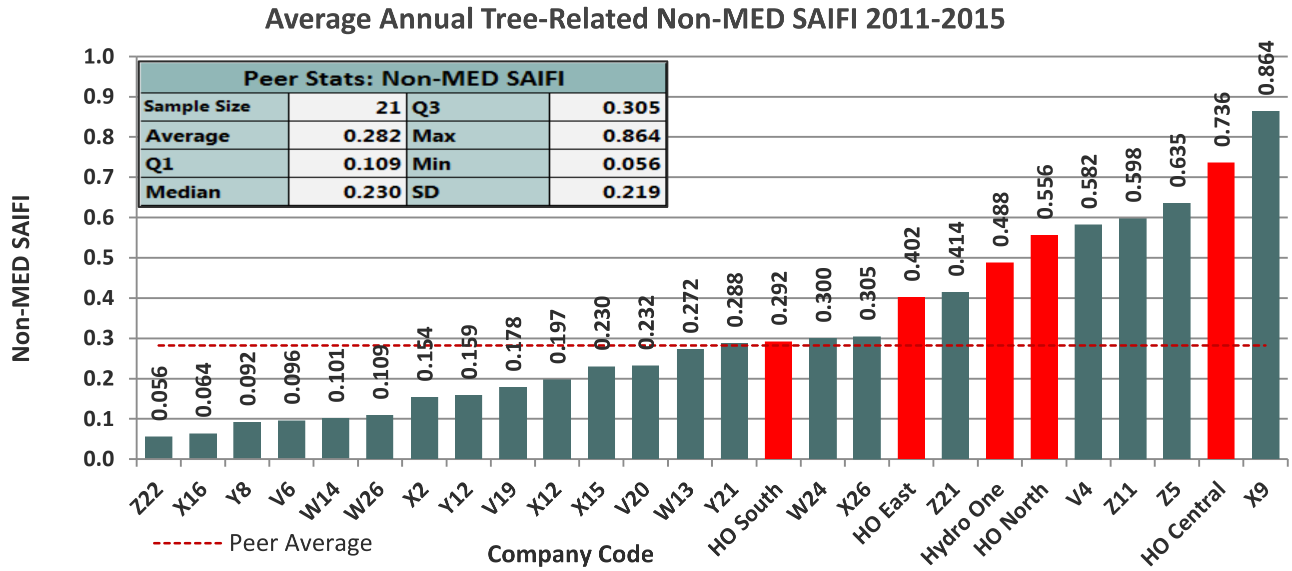

FIGURE 21: TREE-RELATED NON-MED SAIFI

There are other metrics that can be used as indicators of the reliability performance of a UVM program. For example, utility companies were asked whether they record what percent of trees are in contact. Few companies could produce this data. Trees in contact and trees overhanging conductors are condition-based metrics. Most companies estimate these measurements, but a few utilities record locations where trees are in contact or overhanging the conductors to better understand their workload and to measure the performance of the cyclical clearing work. This data also provides information about the growth characteristics associated with species, time of year pruning, local site differences and eco-regions, failure modes etc. Tree condition data can be correlated with reliability data to better understand proximity influences on reliability, particularly during ice and wind events. Lidar has been introduced most recently to provide tree condition data on distribution systems. Unmanned Aircraft Systems (UAS) hold promise for collecting Lidar data on distribution networks which have many times more kilometres than linear transmission, where Lidar measurement data has been collected with helicopters for nearly a decade.

The following graph (Figure 22) shows how important it is to recognize that vegetation management could be the leading edge in any program that seeks to reduce the reliability risk during storms. This is especially dramatic when comparing with the percent of Non-MED outages that are tree-related -- a dramatically lower percent of total outages (Figure 23 below). These are five-year averages and clearly the Central Region has a significant influence on both metrics. The effect of each region can be seen in the next section with longitudinal measurements (Section 4.4.3). The most striking finding in this is how vegetation becomes so much more relevant to reliability when there is a major event day. It suggests that better strategies should be developed for UVM resiliency against storms.

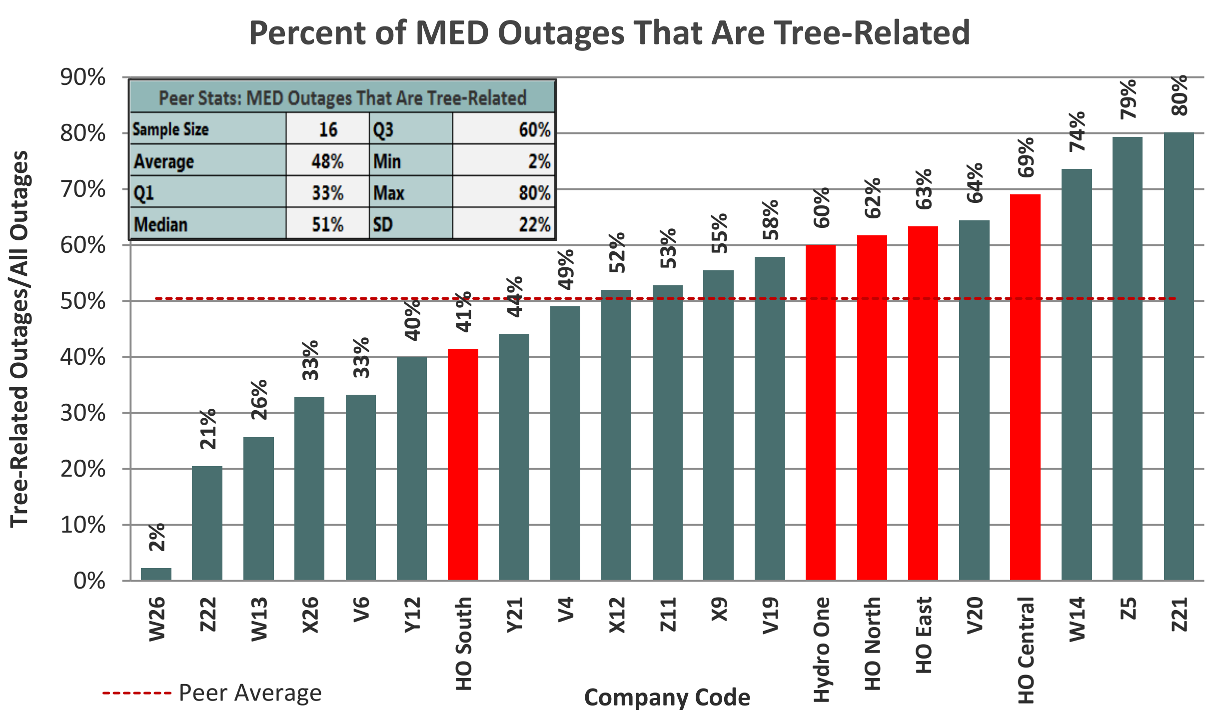

FIGURE 22: PERCENT OF MED OUTAGES THAT ARE TREE-RELATED

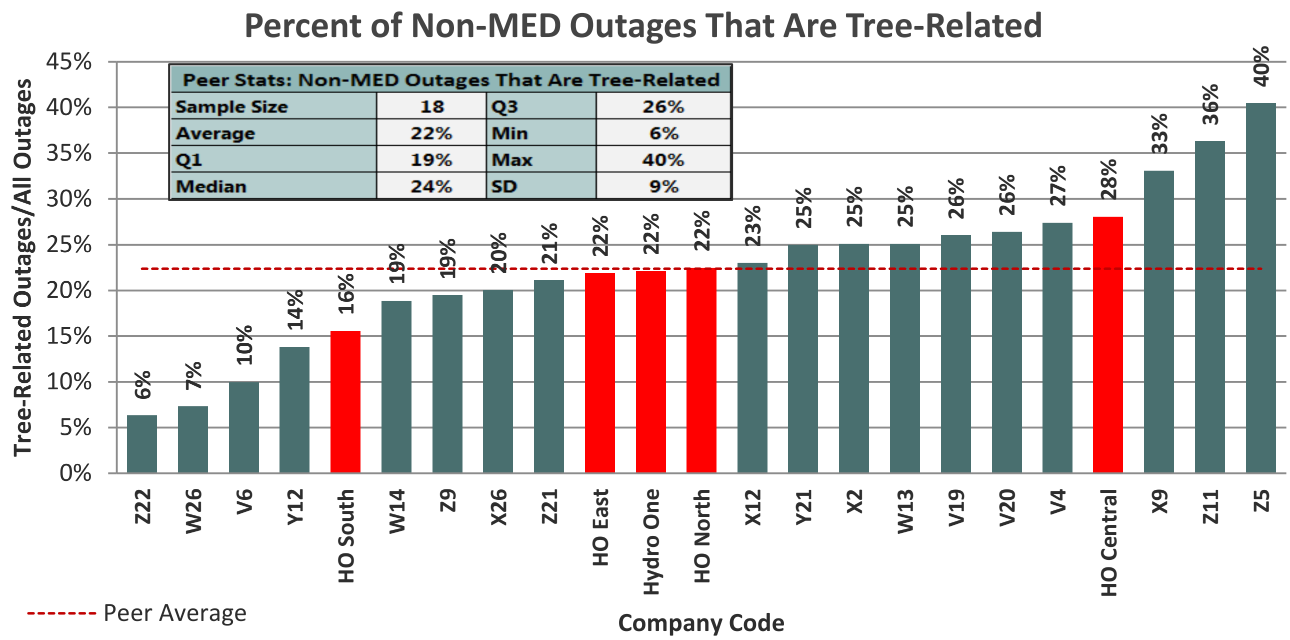

FIGURE 23: PERCENT OF NON-MED OUTAGES THAT ARE TREE-RELATED

4.5.3 INDUSTRY AND LONGITUDINAL COMPARISONS

Figure 24 (below) shows that the ratio of Non-MED tree-related outages to company outages has remained relatively static from 2011 to 2015. Although Hydro One and the peer average are similar performances in this metric, the Hydro One regions are not very consistent, with the exception of the South Region which has done well to keep the company at the average. Central is consistently a poor performer in regards to reliability and it would do well to fully evaluate its strategy for vegetation management.

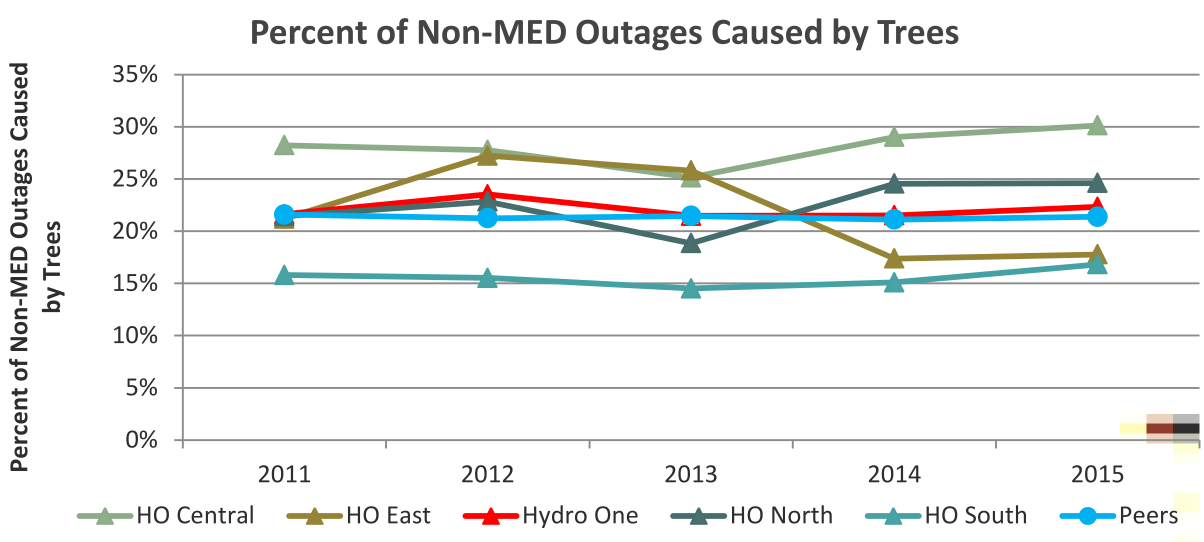

FIGURE 24: PERCENT OF NON-MED OUTAGES CAUSED BY TREES ON THE HYDRO ONE SERVICE TERRITORY 2011-2015

The percent of MED outages caused by trees (Figure 25 below) has also remained constant at Hydro One. It is an indicator that when a storm blows through the majority of restoration will involve distribution facilities damaged and interrupted by trees. In this measurement the peer group on average is improving from 51% down to 40% --an 11% improvement over the five-year period. Hydro One stayed much higher than the peer group at 64% of MED outages caused by trees. Central region has not been able to improve over the five years and nearly 70% of MED outages in the Central region are caused by trees. None of the regions are below the 2015 level of the peer group. Although Hydro One has a below average percent of outages per km caused by trees and the Non-MED tree-related outages are close to the peer average, MED tree-related outages are a high percent of the total and they are not improving. Major Event Day (MED) outages have dominated the worst years of Hydro One's tree-related outages, which escalated to as many as 17,200 in 2006 and 2013. In years with low MED outages, Hydro One has not been able to drop below 8,000 outages. Since Hydro One does not compare favorably with peers in either MED or Non-MED reliability metrics SAIDI and SAIFI, but has below average outages per km compared to peers, it will need to adjust its program to build more resiliency to storms while keeping the raw number of outages per km from increasing.

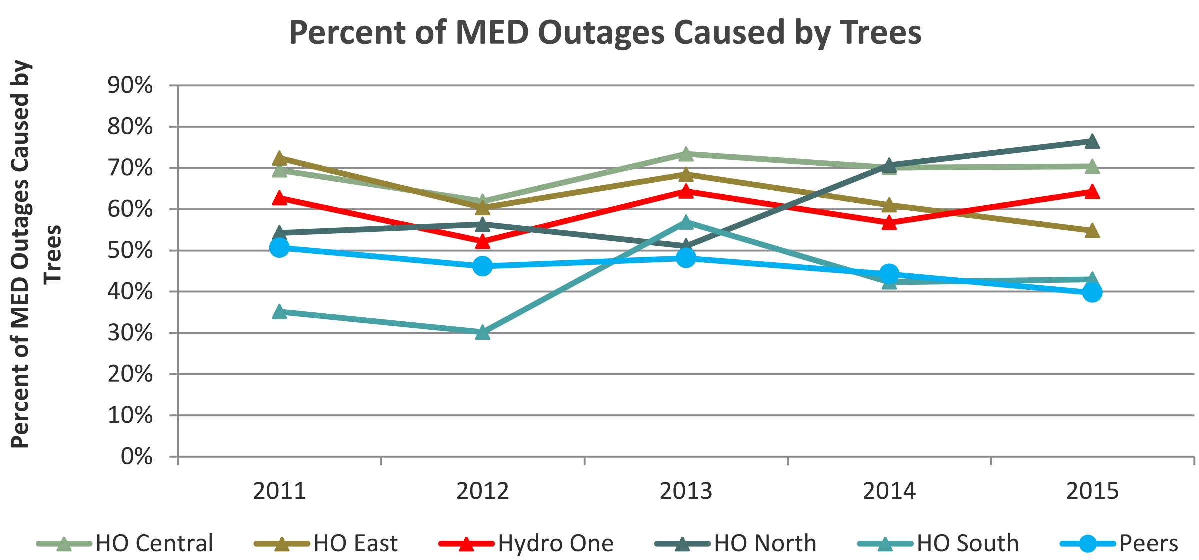

Figure 25: Percent of MED Outages Caused by Trees on the Hydro One Service territory 2011-2015

Although Hydro One compares favorably using the metric of outages per kilometre, it will have to make improvements in reliability performance for the foreseeable future. First and foremost, the *UVM department* should be investigating tree-caused outages. Hydro One is the only utility in the survey where the vegetation management department does not investigate tree-related outages. It is also unknown how many tree-related outages are categorized as unknown or weather-related.

Outage investigations should be performed by trained forestry personnel and should be stored in a database. Areas of data capture and database development should include species, age, size, site conditions, tree failure modes beyond whole tree, branch and growth, measurements of ROW, whether tree is on or off ROW, description and condition of adjacent vegetation, investigation and analysis of external causes such as local weather and wind information. This program could be piloted on a stratified random selection of outages to limit costs and accentuate the focus on both high priority feeder outages and the variety of outage settings found on infrequently managed single and two-phase lines. A modeling program based on the outage investigation database will help identify tree failures before they happen and this will be more effective than removing all suspected trees in and off the ROW. The models should be used to improve the tree risk assessment program.

4.5.4 Reliability Improvement Targets

Hydro One was asked to explain the poor relative reliability performance in Central Region and they supplied the following response:

- The Central Region is covered by heavy tree density.
- Most of operation centers in the Central Region have radial distribution lines, which means lack of alternate feeding and switching capability compared to other regions
- The Central Region is in the path of normal storms that goes through Ontario
- Other design, planning, protection, and control issues

Given the metrics provided are accurate; Hydro One should focus on resiliency improvements to the Central Region where reliability issues are more prevalent.

4.6 Safety as a Priority

For the purposes of this report safety is evaluated as a performance metric and as elements of program design. Hydro One's performance in the field is compared with the peer group and the industry at large. Hydro One's UVM program is also compared to peers for how well safety risks are minimized to the public and line clearance workers.

4.6.1 Safety Performance

In general Hydro One's performance over the past five years falls short of the perfect incident rate (0 accidents) recorded in 2008 when CNUC performed a benchmark survey. However, some indicators suggest Hydro One's program is less likely to incur lost time accidents than other programs. Hydro One maintained a low accident severity rate and zero fatalities. Hydro One has one of the lowest employee turnover rates of the peer group. An extensive training program also is evidence that Hydro One reduces the risk of accidents occurring. Several studies have found that accidents increase proportionally to employee turnover and disproportionally to employee tenure: "[T]he weight of research evidence seems to overwhelmingly show a relationship between job tenure and accidents (Burt, 2015)." A high percent of incidents involves employees in their first year and many leave the line clearance industry because they perceive it to be too unsafe.

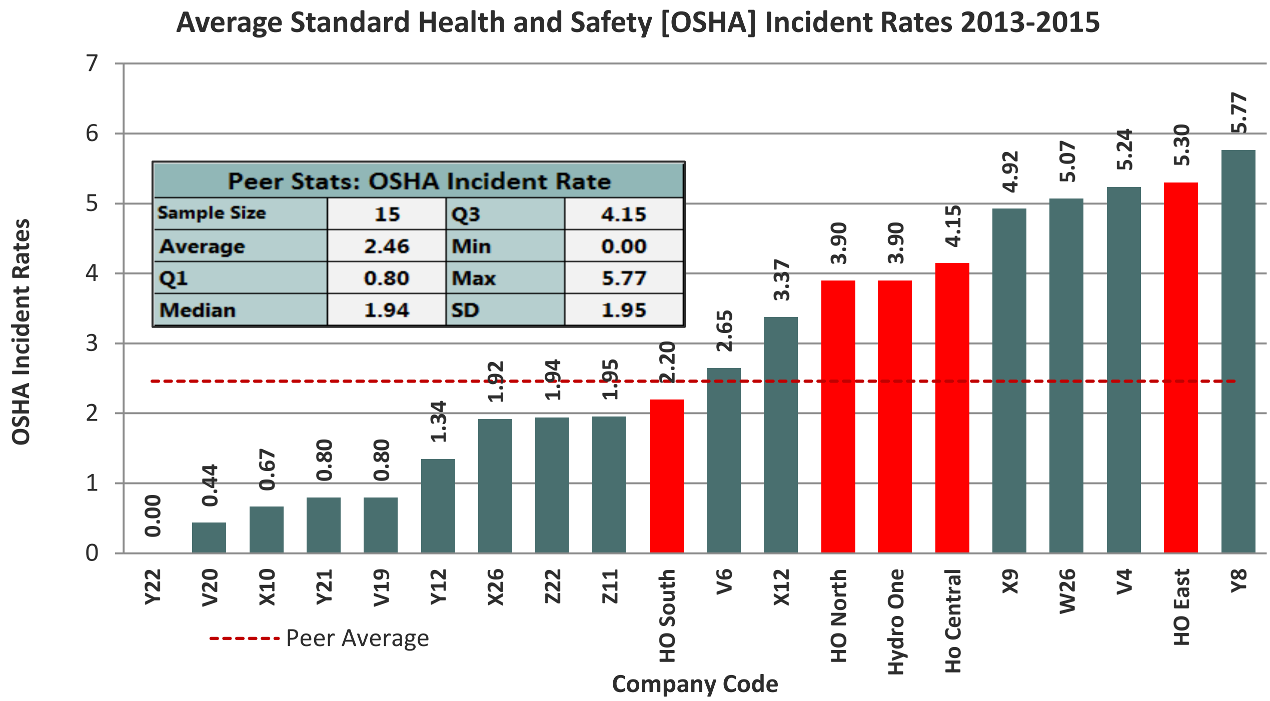

FIGURE 26: OSHA INCIDENT RATE COMPARISONS 2013-2015

Hydro One has succeeded in minimizing the turnover rate and this can be associated with the zero accident frequency and severity rates that were reported in the 2009 study for the OEB. The current survey found the average turnover rate for the peer group is 32% for line clearance personnel compared to Hydro One which is 5%. Hydro One's incident rate was 3.90 incidents/100 FTE for 2013-15 (East region reported 5.30 incidents/100 FTE) (Figure 26 above). The average for the peer group was 2.46 incidents/100 FTE. However, recent statements and actions by OSHA in the US indicate incident rates may not be accurate for the tree care industry, which includes line clearance. Beginning in November 2016, new rules apply to incident reporting that are designed to improve accuracy of reporting. Accident Severity Rates were not reported by many survey participants. Of the nine peer companies who did report, the average severity rate 2013-2015 was 31.36 lost days/100 FTE (Figure 26 below). If companies reported rates for multiple contractors the worst rate was used for this comparison. Hydro One's severity rate was 7.9 lost days/100 FTE average for 2013-2015. It should be noted that regression analysis of employee turnover rate and incident severity rate for these nine companies showed a high correlation ($R^2 = 0.643$, $R = 0.802$, $p < 0.001$). This finding is also supported by multi industry studies which have found high correlations between accident rates and employee tenure.

Combined, the Hydro One incident rate and severity rate indicate some need for improvement at achieving the benchmark for limiting injury accidents. However, the low severity rate at Hydro One indicates there is still a high level of safety on the job. The accident frequency rate for the South region is below the average for the peer group and North Region is above average and is at the low-end of the third quartile. More problematic for Hydro One is the Central Region accident frequency and severity rates. The Central Region severity rate, 21.6 lost days/100 FTE, is below the peer average, 31.36 lost days/100 FTE, but it is still an indicator that safe work improvements are needed. The incident rate for

Central Region is at the upper end of the third quartile and the East Region, which is the second highest on the chart. Why has there been an increase in the incident rate over the period of this study,

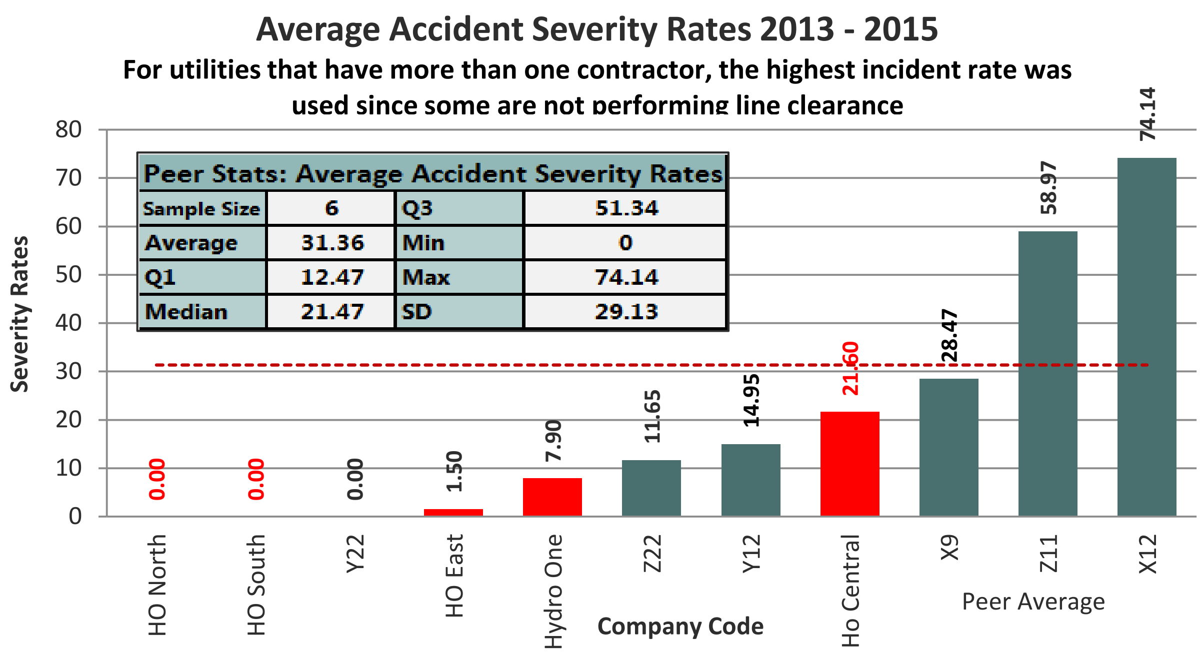

FIGURE 27: AVERAGE ACCIDENT SEVERITY RATES 2013-2015

particularly for the East and Central Regions? First, there has been greater reliance on temporary employees and a decreased reliance on in-house trained personnel. However, the safety data is not comprehensive or conclusive. Second, Hydro One stepped up the effort to decrease the cycle length through greater numbers of inexperienced employees and higher expectations for production, particularly in the Central and East regions. Fluctuating budgets changes the employee count and increases potential for some employees not to consider the employment permanent, which may have a negative influence on the safety culture. Higher stress levels with employees who are required to move around the province to maintain M and F class feeders on a more frequent basis. Increases in the number of backlogged kilometers worked each year that are past the target cycle length. Worker safety is affected by program changes. We recognize program improvements designed to improve safety in the work place, but we are not always cognizant of the unintended consequences of program changes that affect safety.

Hydro One is required to report the number of serious electrical incidents that occur on their system each year. An average of six per year was reported to the OEB for 2010-2014. Although the survey requested information related to vegetation and electrical contacts, only two peer companies could provide information. One company stated 0 incidents occurred over the past five years. Another stated no more than one to two per year and that these incidents are usually the fault of the victim, not the result of poor maintenance or system defects. Hydro One could not state whether contacts involving vegetation occurred on their system. 67% of peer companies report the rate of occurrence is unknown. 71% of companies, like Hydro One, do provide many public service announcements that discourage removing trees or branches near powerlines. 19% of companies provide electrical hazards awareness training to non-line clearance arborists. Hydro One did not report they provide this service. Another 19% said they do not frequently and/or effectively communicate safety concerns of trees and powerlines. Hydro One was not in this group.

Many companies in the survey consider safety to be the business of their contractors and a few said they supplement the contractor's programs with company-initiated safety training. Hydro One has 40-50 hours of safety training for their employees, which is more training hours than any participant in the survey reported for in-house or contractor employees.

92% of peer utilities plus Hydro One reported that they track safety metrics. The following are metrics tracked:

- All companies: Accidents, contractor-caused outages, vehicle incidents, and non-reportable incidents are included in their statistics
- Six companies: Web-based program that contractors use to enter incidents and calculate safety statistics
- Most companies: have quarterly meetings and contractors submit accident logs
- Two companies: Utilize near-miss reports.

Three companies in the survey (Hydro One, one peer, and one non-peer) had more extensive monitoring. These include frequent safety audits, internal safety specialists, and frequent departmental safety meetings. Hydro One is distinguished by having an in-house workforce that is more directly connected to safety monitoring and initiatives promoted within the company.

4.6.2 UVM Program Safety

The most important safety monitoring metrics and arguably a best management practice for documenting a successful program are leading indicators that measure safety in performance. Documented completion of specific task-oriented and performance-based training programs are an example of a leading indicator. Other examples could be certification and continuing education units through a third-party administered safety training program; new employee apprenticeship programs that audit the trainers and ensure new employees receive consistently adequate hands-on training and documented proficiency measurements; ongoing hazards and skills training that is specific for the work that the employee performs and appropriate training provided when an employee changes job duties.

Other leading indicator safety metrics are policies that specify the activities of the UVM program. Based on the responses of the peer group and a few of the non-peer group, there is a direct and positive relationship between UVM program policies regarding clearances between vegetation and conductors and the safety of the public and utility arborists.

Is a tree in contact with a powerline a safety issue? The following language is from Ontario Infrastructure Health and Safety Association (IHSA) of which a Hydro One employee was a board member at the time of this publication.

> ***The Line Clearing Operations Safe Practice Guide*** *(Infrastructure Health and Safety Association 2008)*
> *Should a limb still attached to a tree be found in contact with a conductor energized above 750V:*
> - *the tree should not be climbed directly from the ground*
> - *clearing should be done using live line equipment from the ground, from an aerial device or portable non-conductive ladder*
> - *the circuit should be isolated and de-energized prior to limb removal*

From a safety and economic perspective, preventing trees from being in contact with conductors should be a best management practice. The alternative is that trees *could* be climbed by a line clearance worker or someone else, when it is in contact, that a utility tree worker's electrical hazard exposure is increased by trees in contact, and that to follow proper protocols by de-energizing the line would be more expensive.

The topic of maintaining clearances is discussed in several places in this report with compelling arguments for why it is important, but there is probably no data that is as compelling as the 90% of survey respondents reporting that they believe a required airspace around conductors would be a *significant* improvement to the safety of the distribution system. A third of these UVM experts, who collectively manage a significant percent of the kms of distribution lines in North America, stated they have a requirement for airspace and it has improved worker safety significantly. A smaller percent, but a solid majority, 64%, of respondents said that clearance duration requirements play a role in over-all program safety. Multiple commenters stated that longer cycle lengths increase the probability of an incident.

4.7 Recommendations for Measuring and Determining a Risk Acceptance Level

In the future, it is recommended that a standard of care be documented that provides the acceptable level of risk reduction from vegetation conflicts with powerlines. It is also recommended that customers be notified of what responsibilities they have relative to the risk reduction. Some metrics should be introduced that measure the performance of UVM in achieving objectives. The following are suggestions for metrics, analysis, data collection, and databases:

- Create a tree-related outage database and analyze types of tree failure and weather conditions to support annual reliability report.
- Set a target percent limit for trees in contact found during annual audit inspections with corrective action measures.
- Create a customer vegetation transaction record that defines workload per customer.
- Keep a record of customers who refuse standard UVM work for pruning, removing trees or applying herbicides.

- Use a statistical process control calculator to continuously monitor km productivity with corrective action plans for work that falls outside of two standard deviations.
- Have a target percent reduction of tree density measured for each km (or by circuit) over each cycle of management with a corrective action plan if density is increasing.
- Create an annual reliability report for tree-related outages delineated by outage risk. Metrics such as tree-related SAIDI and SAIFI that are biased to customer densities should be evaluated cautiously because Hydro One's system has very a low customer density, which biases IEEE reliability metrics, and reliability performance is also related to other measures. Outage data statistics could include at-risk customers, heavy load circuits, outages on circuits with a long duration response time, time since last UVM maintenance for each tree-related outage, frequency and interval averages for outages by circuit. The report should be scored as 'improved' or 'not improved' over previous year(s) based on a variety of metrics.
- Publish an annual report of innovation and initiatives which is effective at bringing stakeholders and customers into partnership with UVM objectives. There should be a net reduction of tree density involved plus an enhanced environmental quality and a customer satisfaction metric.
- Document the Tree Risk Assessment Program that targets hazardous trees at the edges and beyond the ROW with target outage reductions by circuit and voltage class.

4.8 2022 Model Cost Projections

See Appendix D: Statistical Methodology and Model Development - Projections of Unit Costs for Hydro One for details on model development

Three different budget projections were developed based on levels of risk.

- **Risk Model A:** This model is at the *highest risk* level. It is a model built on the current scheduling methodology, which targets M-Class feeders and three-phase (3Ø) lines. This methodology will get the high priority lines on schedule, but the single and double phase will fall farther behind resulting to a 14.9 year cycle on average for this part of the distribution system.
- **Risk Model B:** This model is a *moderate risk model*. This model expands the Risk Model A by continuing the backlog and cyclical work on the M-Class and 3Ø lines, but will also increase the work on the single-phase and double-phase lines to keep this part of the system closer to the 9.5 year (on average) cycle.
- **Risk Model C:** This model carries the *least risk* and produces a more storm resilient system. It gets all of circuits on target cycles by obtaining an eight-year cycle (ten in the North region) for single and double-phase circuits.
- **BMP Model D:** This model produces a more storm resilient system with greater returns. It gets all of circuits on target cycles by obtaining a six-year average cycle for single and double-phase circuits.

4.8.1.1 Budget Projections for Each Model

MODEL	Risk Model A Highest Risk Model		Risk Model B Mid-Risk Model		Risk Model C Lowest Risk Model		Model D BMP Model	
	Annual Cost Projections	Annual Kilometres Completed	Annual Cost Projections	Annual Kilometres Completed	Annual Cost Projections	Annual Kilometres Completed	Annual Cost Projections	Annual Kilometres Completed
2017	$150,217,259	12,000	$166,458,286	13,973	$174,912,181	15,000	$192,914,780	17,167
2018	$152,725,887	12,000	$169,238,140	13,973	$177,833,215	15,000	$196,136,456	17,167
2019	$155,276,410	12,000	$172,064,417	13,973	$180,803,029	15,000	$199,411,935	17,167
2020	$157,869,526	12,000	$174,937,892	13,973	$183,822,440	15,000	$202,742,115	17,167
2021	$160,505,947	12,000	$177,859,355	13,973	$186,892,275	15,000	$206,127,908	17,167
2022	$163,186,396	12,000	$180,829,606	13,973	$190,013,376	15,000	$209,570,244	17,167

TABLE 5: BUDGET PROJECTIONS THROUGH 2023 FOR RISK MODELS A, B, C, AND D

Note: All four models were developed using exclusively Hiring Hall or contract labour for single and double-phase work. It is recommended that the lower safety risk work (planning, brush, and herbicide) be performed by contracted labour and that the higher safety risk work continue to be performed by in-house crews. *The costs for Risk Models B-D would increase by between 10% - 15% with the suggested labour mix.*

5 CONCLUSIONS

Hydro One's routine maintenance costs measured by system kilometre are one standard deviation *above* the peer average. Hydro One's expended labour hours per system km is nearly one standard deviation *below* the peer average. This differential is the result of the following factors (the first three explain the cost deviation and the last three explain the labour efficiency):

- The accumulated biomass and heavy workload after a long interval between maintenance cycles.
- A higher cost of labour and equipment compared to the peer group, all of which outsource UVM program implementation, with the exception of one other company.
- Hydro One reports overhead/administrative costs better than their peers, since they are completely in-house. The peer group does not report indirect costs on the UVM program. Comparators only report the direct costs to run the UVM department plus the cost of the contractor.
- Hydro One management organizes work and crews perform ROW maintenance more efficiently than the majority of the peer companies.
- Hydro One's long cycle of maintenance has resulted in fewer labour inputs per system kilometre than shorter cycle programs.

- The historical practice of clearing the full width of the ROW, a shorter growing season in 50-75% of the system, and a third of the system is in agricultural areas where tree density is low are all factors that contribute to a more labour efficient management.

The result of Hydro One's UVM program is 32% fewer outages per kilometre than the average of the peer group. Hydro One did not report a history of fires caused by powerline contacts, electrocution accidents involving trees and power lines, or other incidents related to the close proximity of powerlines and trees. The absence of such incidents and the employee safety record are testaments to the success of their program.

Despite the positive results of Hydro One's UVM program, there are areas that are in need of improvements, because:

- Some aspects of the program are not sustainable over the long-term
- Risk is increasing on parts of the system, and
- The environment and the customer are driving UVM programs to a higher level of performance than the past.

The positive outlook is that 50% of the system is targeted for a consistent schedule (4-8 year cycle) of maintenance that includes the highest priority and largest load kilometers on the system, M-Class and non-M-class feeders. Over the next six years all of the backlog of work for this half of system will be brought up to date. This requires 8,500 kilometres of M-Class and non-M-class feeders to be managed each year.

The areas that are in need of improvement are the other half of the system, which is composed of single and two-phase lateral primaries and associated secondary lines that feed residential and commercial customers. Under the current plan only 3,500 kilometres of these lines will be managed each year for the next six years. This will put the second half of the system further behind and the annual increment of work will be the equivalent of a 15-year cycle of management. This is a rational approach to cope with a reduced budget. Although greater efficiencies can improve the execution of the program, it will not be enough to offset the reductions in program expenditures. Additionally, the new schedule will increase the risk of outages occurring on the single and two-phase lines.

The highest priority recommendation from this study is that Hydro One should strive to bring all of its system to a 4-8 year flexible cycle that is trued up each year to ensure backlogs do not creep back into the schedule. The current plan to prioritize the M-Class and feeder system is appropriate if sufficient attention can be given to the rest of the system. This may require greater expenditures in the future and an increase in the number of lower cost hiring hall or contract personnel. In the short-term, the single and two-phase system should be worked on an eight to nine-year cycle of management instead of a 15 year cycle. This would require increasing the annual increment from 3,500 to approximately 6,000 kilometres. The program could be ramped up 500 kilometres each of the six years after which additional resources can be reassigned from the M-Class and feeders. These will be managed under a six-year IVM cycle and require fewer resources to keep cleared.

NERC: National American Electric Reliability Corporation

Non-MED: Non-Major Event Days

O&M: Operation and Maintenance

OEB: Ontario Energy Board

OH: Overhead

PIM: Performance Incentive Mechanism

PPE: Personal Protective Equipment

R&D: Research and Development

ROW: Right-of-Way, Rights-of-Way, Right-of-Ways

SAIDI: System Average Interruption Duration Index

SAIFI: System Average Interruption Frequency Index

T_{MED}: Major Event Day Threshold

TRA: Tree Risk Assessment

UG: Underground

USD: United States Dollars

UVM: Utility Vegetation Management

7.2 GLOSSARY

Barriered: "Barriered" means separated by clearances, burial, separations, spacings, insulation, fences, railings, enclosures, structures and other physical barriers, signage, markers or any combination of the above (OEB, 2004)

Cause code: Code for reporting the initiating condition for electrical interruption

CAIDI: Customer Average Interruption Duration Index

$$\text{CAIDI} = \frac{sum\ of\ all\ customer\ interruption\ durations}{total\ number\ of\ customer\ interruptions} = \frac{SAIDI}{SAIFI}$$

DBH: Diameter Breast Height as a measurement of the size of a tree

FAC-003: Electric Transmission Vegetation Management Regulation in North America

F-Class: 27.5 kV, three-phase feeders

In-growth: The volume of new trees growing into the minimum dbh size class during the measurement period [cycle]

IVM: A systematic integrated approach to managing vegetation, which includes controlling vegetation in the ROW by removal of inappropriate species, discouraging re-growth or in-growth, and planting and maintaining of appropriate tree species

OSHA RECORDABLE INCIDENT RATE (IR): a mathematical calculation that describes the number of employees per 100 full-time employees that have been involved in a recordable injury or illness.

$$\text{OSHA RECORDABLE INCIDENT RATE} = \frac{Number\ of\ OSHA\ Recordable\ Cases\ x\ 200{,}000}{Number\ of\ Employee\ Labour\ Hours\ Worked}$$

M-Class: 44kV feeders, sub-transmission

Managed kilometres: The number of overhead (OH) lines managed on an annual basis.

Trees treated: The same as trees managed and includes both trees pruned and trees removed

SAIDI: System Average Interruption Duration Index

SAIDI= $\frac{sum\ of\ all\ customer\ interruption\ durations}{total\ number\ of\ customers\ served}$

SAIFI: System Average Interruption Frequency Index

SAIFI= $\frac{sum\ of\ all\ customer\ interruptions}{total\ number\ of\ customers\ served}$

System kilometres: The number of overhead (OH) kilometres in the distribution system.

Tree Density: Tree density = Average number of trees managed per kilometre each year.

Work Planning: Same as Pre-Planning

APPENDIX A: CNUC TEAM QUALIFICATIONS AND EXPERIENCE

PROJECT TEAM MEMBERS:

William Porter, Project Lead and Chief Consultant

Nina Cohn, Data Analyst

Both project team members participated in the Hydro One 2009 UVM benchmark project

WILLIAM PORTER, PROJECT LEAD AND CHIEF CONSULTANT

- Director of Research, Development and Industry Intelligence (RDII) at CN Utility Consulting, Inc. (CNUC)
    - CNUC consults internationally with utility companies, vendors, lawmakers and regulators on all issues related to utility vegetation management (UVM)
- With more than 25 years of experience in the utility vegetation management (UVM) industry, Porter has direct knowledge of all aspects of UVM work
- Directed program and compliance reviews and special projects
- Performed analysis on a wide range of UVM metrics
- Principal author of the 2010 *CN Utility Consulting Utility Vegetation Management Benchmark and Industry Intelligence*
- Often presents on UVM benchmarking and LIDAR projects and other industry topics in the U.S. and abroad.
- Continuously monitors and evaluates legal and regulatory changes, as well as issues and trends related to UVM around the world.
- Led a research project for the Centre for Energy Advancement through Technological Innovation (CEATI) on *Data Analytics and Modeling Tools Applied to UVM Programs.*
- Serving on a task group to revise the ANSI Standard Z133, the *American National Standard for Arboricultural Operations – Safety Requirements*.
- Provides support to legal cases for CN Utility Consulting, tracks legal cases involving UVM in the U.S. and has participated in several legal cases as a witness.
- Has 15 years of line clearance experience, starting as a ground-person and advancing to supervising crews for 11 of those years. He was employed for Davey Tree and Wright Tree Service in Colorado and Iowa for most of these years, as well as supervising storm restoration throughout the US.

EDUCATION AND TRAINING

Education

Attended arboricultural and utility vegetation management seminars over the last 22 years

2003	General Foreman's School, Wright Tree Service
1997	Davey Institute of Tree Sciences
1976-1986	Post Graduate Studies at University of Illinois and University of Colorado
1975	Bachelor's Degree, University of Illinois, Urbana, Illinois

Certifications

1997-2009	Certified Pesticide Applicator
2006	Certified Proctor of ISA Certification Exams

2003	ISA Certified Utility Specialist
1996	ISA Certified Arborist International Society of Arboriculture: Certification # MW-0620AU

NINA COHN, DATA ANALYST

- Nina Cohn, Senior Analyst for CN Utility Consulting, provides data and statistical analysis for reports.
- Cohn earned degrees in Mathematics and Sciences with work experience in entomology research, biochemistry research, and mathematics instruction.
- She taught Mathematics for over 14 years at Community Colleges in Denver, Colorado and Des Moines, Iowa.
- Cohn began working in the utility vegetation management field in 2009 by analyzing benchmark data for the publication, *"CN Utility Consulting Utility Vegetation Management Benchmark and Industry Intelligence."*
- The current benchmark report, *2011-2012 Cumulative Distribution CN Utility Consulting Benchmark Survey Report,* is co-authored by Nina Cohn and William Porter.
- Her statistical analysis has also been utilized in a Canadian rate case, consulting projects, numerous utility vegetation management (UVM) program reviews, and reports conducted for CNUC.
- Cohn co-authored a 2014 research project for the Centre for Energy Advancement through Technological Innovation (CEATI) on *Data Analytics and Modeling Tools Applied to UVM Programs.*
- Cohn's background in the math and sciences lends a distinctive skill-set to the UVM industry.

EDUCATION AND TRAINING

- University of Illinois, 1975
  Bachelor of Science in Physiological Psychology, Minor in Chemistry

- University of Colorado at Denver,1987
  Mathematics Degree and Teacher Certification in Mathematics and Sciences

Utility Vegetation Project Portfolio (Partial List)

William Porter was the Lead on all these projects. All Projects Included a Written Report.

1. Hydro One
   - Performed benchmark analysis for *Hydro One 2009 - Vegetation Management Benchmarking Study.* Retrieved from http://www.hydroone.com/RegulatoryAffairs/Documents/EB-2009-0096/Exhibit%20A/A-15-02_Attachment_1.pdf
2. United Illuminating
   - Sorted and cleaned LIDAR data supplied by LIDAR acquisition company to make field ready. These sorts were done to desired clearances and rights-of-way (ROW) widths
   - Developed methods to determine how many trees were represented and to eliminate duplicate LIDAR information
   - Developed methods to input data into field software to aid inspectors in organizing field work
3. Connexus Energy
   - Organized and analyzed data supplied by Connexus to answer specific questions posed by the utility
   - Analysis proved crucial to presenting a business case to increase the UVM budget
4. Reports for Internal and External Stakeholders
   - Produced numerous statistical reports on specific topics for utilities and for use by CNUC personnel
5. The Centre for Energy Advancement through Technological Innovation (CEATI)
   - Co-author and co-researcher of *A Study of Data Analytics and Modeling Tools Applied to UVM Programs,* a research project funded by CEATI (William Porter primary author)
   - Performed a Literature Review for the research project
   - Helped develop a survey for the project
   - Analyzed the data collected from the survey
   - Developed a template for UVM managers to aid in the incorporation of data analytics into UVM programs
6. Greencoat Capital
   - Benchmark Study of LiDAR use in North America and the United Kingdom
   - Helped develop a survey for the project.
   - Analyzed the data collected from the survey.
   - Performed market research.
   - Co-authored final report (William Porter primary author)
7. Ameren Illinois (AIC) Project One
   - Benchmark Study of UVM programs in North America
   - Helped develop a survey for the project.
   - Analyzed the data collected from the survey.
   - Secondary author of final reports (William Porter primary author)
8. Ameren Illinois (AIC) Project Two
   - Researched and analyzed data for three white papers for AIC's UVM program
   - Modeled return on investment and capitalization of UVM program enhancements
   - Secondary author of final reports (William Porter primary author

Appendix B: A Study of Reliability Metrics' Influence on UVM Programs

A decade ago, utility vegetation management (UVM) subject matter experts were encouraging utility executives to realign their UVM programs for measureable reliability benefits. It was suggested this realignment would result in lower costs and bring UVM out of the industrial age and into the technological realities of modern business management. The most significant and clearest measure of reliability improvement has been with extra high voltage transmission, because the internationally mandated FAC-003 standard has spurred utilities to achieve specific results. FAC-003 affected transmission lines, which account for about 3% of the total miles of overhead power lines in the US, but what about the other 97% of miles of overhead T&D electric lines in the US?

Although the bright light of business models, including economies of scale and process management, has been shined into the voids of UVM performance, there is no consensus that the industry has given birth to the golden age of utility arboriculture. Young arborists, some freshly trained on UVM, are still put to daily task to work around lethal conductors engulfed in vegetation. Utility arborists, scolded by the public for being butchers, continue to wonder why the industry does things the way it does them. Every year, a few go to work and never return. Many more tree workers lose their lives or are injured because they made contact with electrical energy, often not knowing the wires were there.

Studies conducted to evaluate how UVM has conformed to reliability data revealed several interesting findings:

- Reliability improvement is correlated with increases in customer density .
- Reliability-centered maintenance (RCM) applied to UVM may shift focus away from other objectives, such as safety, fires, environment and the customer.
- When UVM programs are prioritized to improve reliability metrics, long-term UVM workloads are likely to increase
- An increase in tree-related outages can occur at the same time reliability is improving.

The need to apply computer-enabled technology to UVM has coincided with the adoption of IEEE-1366. The Interruption Cost Estimate (ICE) calculator designed by the Department of Energy (DOE) reinforces the nexus between data-driven UVM and a burgeoning growth of reliability data. It would be imprudent to discourage actions that prevent outages that affect large electric loads. However, it is also important to recognize that the priorities of electric system reliability are not the only motivation for performing UVM. The consequences of applying electric system reliability metrics to UVM should be fully vetted. Is it okay that RCM encourages UVM policies that increase the frequency that outages occur? Improvements for relative reliability and improvements for absolute reliability are two separate outcomes that both require adequate planning and resources to achieve.

The following discussion demonstrates the theory, the logic, and the empirical evidence that the industry should be supporting UVM beyond the current reliability-centered maintenance (RCM).

Theory:
In *theory*, UVM programs operate upon a set of objectives that are established to support a mission and vision for a utility company. These objectives are collectively the driver and benchmark upon which the program is measured and implemented in a continuous spiral of improvements. Objectives provide the theoretical framework behind UVM. Without such a framework UVM would be reactions to system failures and liability. The cost alone of reactive UVM has driven UVM programs to become more preventative. To be preventative one must have a plan based on a theory of objectives, strategies and results.

Logic:
Once the theory behind UVM is established, then logical steps are taken to achieve the framework of objectives. Theory may be the the lodestar, but logic is the navigation system and it has to adjust to stay on course. For example, a UVM program must show a return on investment, but what logic gets you there? UVM has sought cost-effective ways to manage high risk, but in order to maximize return on investment, it has bypassed managing smaller risks and made compromises and adjustments. This strategy has allowed UVM departments to show success by using IEEE reliability metrics. Managers can report success if the system average interruption duration index (SAIDI) and the system average interruption frequency index (SAIFI) are reduced. For upper management, this provides a reduced cost burden achieved through reliability improvements.

Unfortunately, the marriage of UVM risk and reliability metrics has also meant performance for other objectives and risks could be reduced, ignored or transferred away from UVM departments. Worker safety liability has been shifted to contractors. Reliability performance shows UVM is performing what is reasonable and shields utilities from public liabilities. State regulatory compliance validates this idea by requiring reliability metrics. Other objectives like fire prevention, environmental quality, and customer service have become weak objectives.

Regardless of relative ranking, each objective should have key performance indicators. Strategies and tactics should be formulated to support measureable achievements and improvements. Some objectives, such as reliability and safety, may be more important, but a program ought to be balanced. A single objective, such as reliability, should not be the only characteristic of quality service. For example, UVM, from a customer perspective, is an inconvenient intrusion onto private property where vegetation is negatively altered in order to complete an electric system correction. Asset corrections protect equipment and ensure reliability, which is misconstrued as the primary if not only element of customer service. Why shouldn't UVM be a customer service activity in which the customer perceives they are receiving a benefit to their property or vegetation and their community? Perhaps we have come to accept adversarial relationships with rate-paying customers.

Empirical Evidence:
While logic is necessary to navigate, we need empirical evidence - an analysis of readings from our instrument cluster - to support and measure the performance of our logic. The following four sets of data are readings from the current era of UVM, and they suggest that there is a need to change our theoretic lodestar or reevaluate the logic used to navigate our UVM programs.

1. **Reliability is a UVM problem, but Reliability-Centered Maintenance is an asset management strategy**

   Reliability-centered maintenance (RCM) from an asset perspective is designed to address the vast majority of failure modes that are likely to occur during normal operating conditions. RCM is integral to the life-cycle of assets, which includes constructing, maintaining, extending, and finally replacing. Since abnormal conditions are usually an "event" such as weather, IEEE devised a statistical method to exclude certain outages in reliability performance metrics.

   The IEEE- 1366 2012 defines a Major Event as one *"that exceeds reasonable design and or operational limits of the electric power system. A Major Event includes at least one Major Event Day (MED)."* A T-MED is a calculated threshold for excluding outages in reliability metrics. It provides a limit beyond which a utility should not be expected to perform within expected reliability parameters.

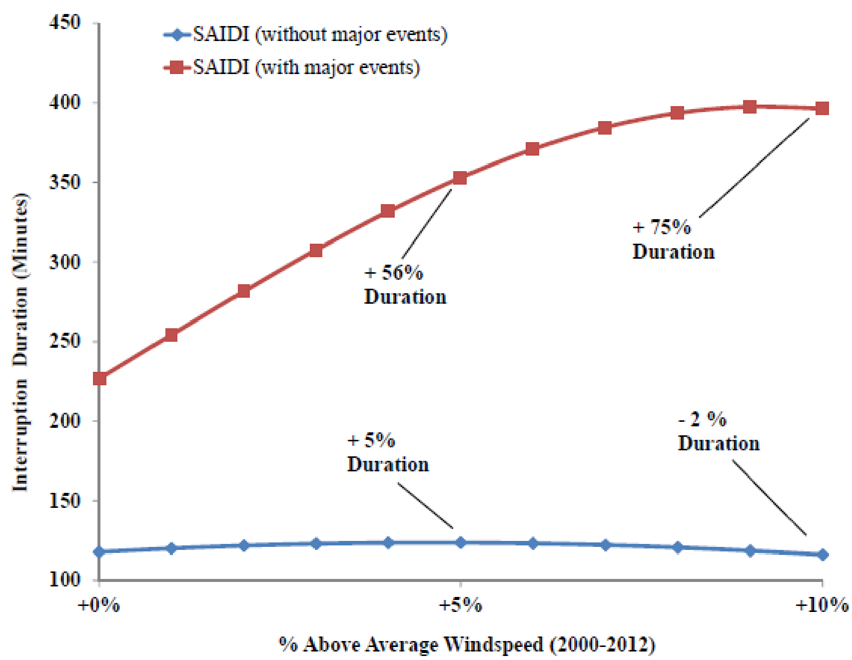

Figure 28: Above-average wind speed and duration of interruptions (SAIDI) (Larsen, 2015)

Berkeley National Laboratory (BNL) has performed cumulative statistical research on utility reliability data collected over the past thirteen years. Some specific variables are associated with measureable improvement in SAIDI and SAIFI. T&D expenditures, percent of underground, hot weather, and increases in customer density were found to correlate with lower SAIDI and SAIFI. Other variables such as wind are associated with increases in SAIDI and SAIFI (Larsen, 2015). Although the BNL research does not differentiate wind-caused outages between tree and equipment failures, CN Utility Consulting (CNUC) benchmark surveys have found at least 43% of outages during major event days (MED) are tree-related (CNUC, 2015). Wind-event data were studied at BNL, including and excluding MED. If MED are included, a 10% increase in average annual wind speed is correlated with a 75% increase in SAIDI. In contrast, if MEDs are excluded, a 10% increase in average annual wind speed is correlated with only a 2% increase in SAIDI (Larsen, 2015) (See Figure 1). This data analysis is significant to UVM since the majority of tree-related outages are caused by wind and other loading events. Without actionable knowledge of the life-cycle of trees and their failure modes and without a reliability system designed around the effective management of right-of-way (ROW) land and nearby trees, RCM is not likely to address tree-related reliability nearly as well as it can guide asset management.

2. Reliability Performance is not measured the same from one company to the next

The CNUC benchmark surveys found that 88% of responding companies track tree-related SAIFI, SAIDI and CAIDI, and 74% of companies are using this information to make planning and resourcing decisions for the UVM department (CNUC, 2014). Additionally, 59% of companies have not strictly used the IEEE-1366 guidelines for separating major event days (MED) from non-MED (CNUC, 2014). In fact, the 1366-2012 revisions left the door open for companies to adopt their own specific definition of a catastrophic storm. Some companies may have to comply with a state commission definition. Differences in MED definitions and thresholds may effectively increase or decrease the number of events which become MEDs and subsequently influence the threshold for determining MED. When one major event is excluded, the average used to determine the T-MED is also lowered, which causes additional events to be classified as major. Consequently, the measurement of reliability performance is inconsistent and possibly misleading, because SAIFI and SAIDI numbers vary significantly depending on whether outage events are included or excluded.

3. Reliability is worsening, according to SAIDI

Despite the reported improvements to non-MED SAIDI, the most current research into reliability data indicates that distribution system SAIDI measurements are worsening by 10% annually over the 13-year period of study (Larsen, 2015). In recent years, major storm events have become a critical reliability issue, and tree-related outages are the chief contributor. A comparison of the ratios of tree-related to system SAIFI revealed Non-MED tree-related SAIFI was, on average, 24% of system non-MED SAIFI. In contrast, MED tree-related SAIFI was 43% of the system MED SAIFI (CNUC, 2015). This difference underscores the significance of the SAIFI amplitude that vegetation causes during MEDs compared to other distribution system failure modes.

The risk factor for MEDs is greater for UVM than it is for equipment failure in the absence of tree damage. The Larsen study, which has many interesting findings, also found a 10% decrease in precipitation is correlated with a 3% increase in SAIFI (Larsen, 2015). It has been thought that drought conditions may contribute to tree-related outages.

4. **A Case Study**

The following is a comparison study between SAIFI, SAIDI, and tree-related outages per pole mile between three companies (X, Y and Z). The UVM programs for these utilities represent a reliability-centered maintenance program (Company X), a compliance-based program (Company Y) and a company (Company Z) that had favorable reliability performance but was dissatisfied with its UVM program. All three companies were excellent performers based on SAIDI and SAIFI. Company Z initiated the study with CNUC by asking the question, “How is it possible that we achieve best-in-class reliability when we know the UVM program is not meeting best management practices?”

By comparing the metrics from the three companies within a field of other companies, CN Utility Consulting (CNUC) found several revealing facts that demonstrate the limitations for using reliability metrics as a measure of the standard of care for UVM.

Company X almost doubled the number of tree-related outages on its distribution system in five years (2008-2012) and still showed significant improvements in SAIFI (31%) for the same years (See Figure2, below). By focusing UVM efforts on high customer density feeder lines while deferring maintenance on single-phase lines with lower customer density, X was able to report almost best-in-class metrics in 2012. An increase in SAIFI in 2011 could have been an anomalous year given the return to dropping SAIFI values in 2012. Subsequent years, 2013 and 2014, suggest something else is happening. Potentially, there is an upper limit of tree-related outages at which point SAIFI will also increase (2012-2014 in Figure 2).

	2006	2007	2008	2009	2010	2011	2012	2013	2014
Outages	8,906	12,194	13,918	14,865	16,197	18,379	16,636	18,774	21,633
SAIFI	0.08	0.11	0.13	0.12	0.10	0.12	0.09	0.1	0.12

Figure 29: SAIFI improves whilevegetation-related outages increase

Another interesting aspect of the reliability metrics occurs when SAIFI increases faster than SAIDI, then customer average interruption duration index (CAIDI) will actually improve, in spite of an overall worsening of the other metrics. This is another example of how reliability metrics may be misleading. A company could show exemplary reliability - in comparison to industry averages - by only focusing on non-major events, even while vegetation-related SAIDI, SAIFI and outages are increasing.

Outstanding reliability is a product of interpreting statistics and focusing on the bigger picture of utility reliability, which include other failure modes such as equipment failure and generic categories such as non-major weather events. If asset improvements are made – such as replacing equipment, adding isolating fuses, monitoring with sensors and making equipment more resistant to weather, vegetation, and animals – then reliability will improve and vegetation appears to be under better control. In reality, it is the asset that is improved, not the vegetation management.

In a comparison of reliability indices for the three companies of interest (X, Y, and Z), all three utilities show excellent metrics when compared with the UVM industry in general (See Figures 3 and 4, below). If the graphs only included peer utilities (companies with similar key characteristics), all three companies are best-in-class among their comparators. These two figures also show that X and Z, RCM companies, compare well with Y, the compliance-based program. Of note, a majority of the other companies that are in the first quartile have cycle-mandated programs (regulatory-based programs).

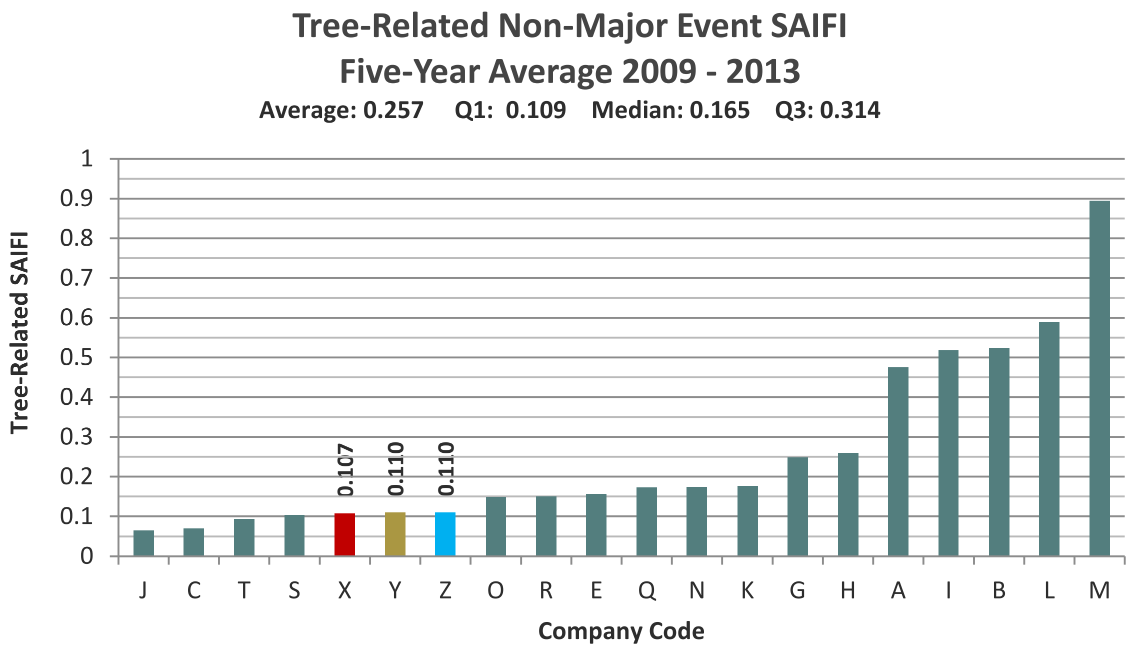

Figure 30: Utilities X, Y, and Z have different UVM strategies but similar SAIFI

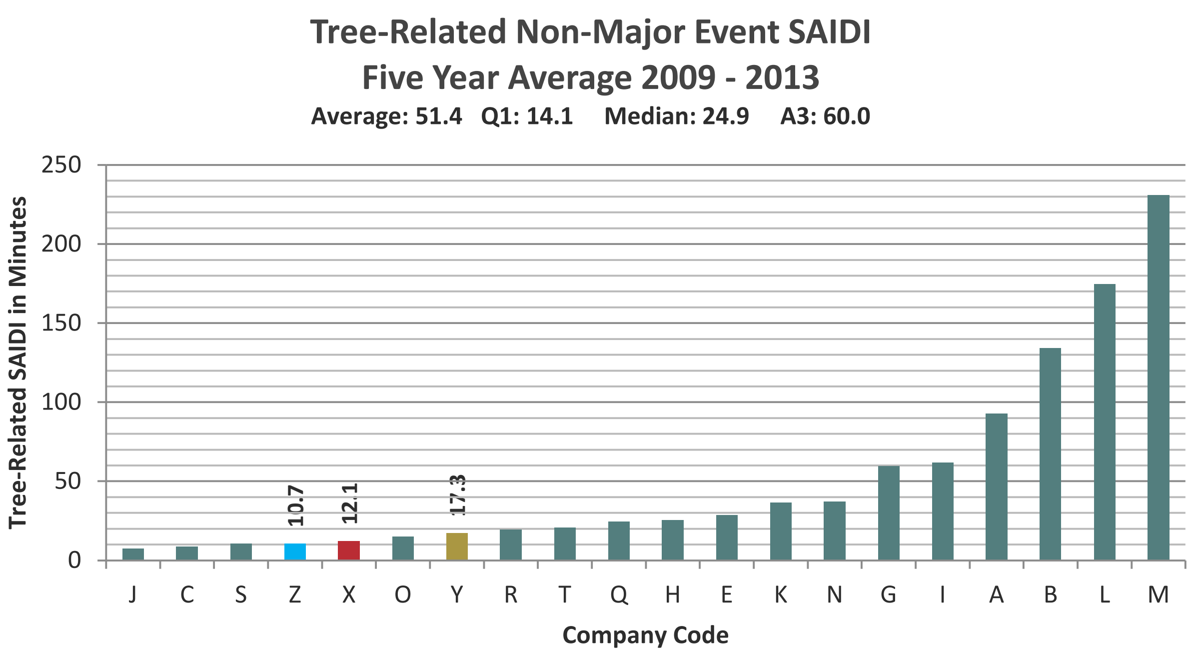

Figure 31: Company Y has a slightly higher SAIDI byt program is focused on the bigger picture

As noted above in Figure 2, company X is able to achieve a high reliability performance as measured by SAIFI, while the absolute number of outages has increased 143% over a nine-year period. Company Z knew that there was something misleading about their best-in-class tree-related reliability metrics, because the increases in the percent of trees in contact with powerlines and the increases in the percent of reactive maintenance were not represented by these measurements.

What was unclear to company Z was the relative value of SAIFI and SAIDI. In other words, IEEE metrics are customer-density dependent and UVM is tree-density dependent. When comparing companies X, Y and Z with peers using an absolute rate (outages per mile), a different picture emerges (Figure 5, below). Company Y, which is focused on regulatory mandates, achieves similar SAIDI/SAIFI but much better outage prevention performance that the RCM utility, X, while meeting other objectives as well. These objectives include public and worker safety, fire risk reduction, and environmental quality. As figure 5 shows, this inclusive strategy also results in best-in-class reliability when measured as an absolute rate.

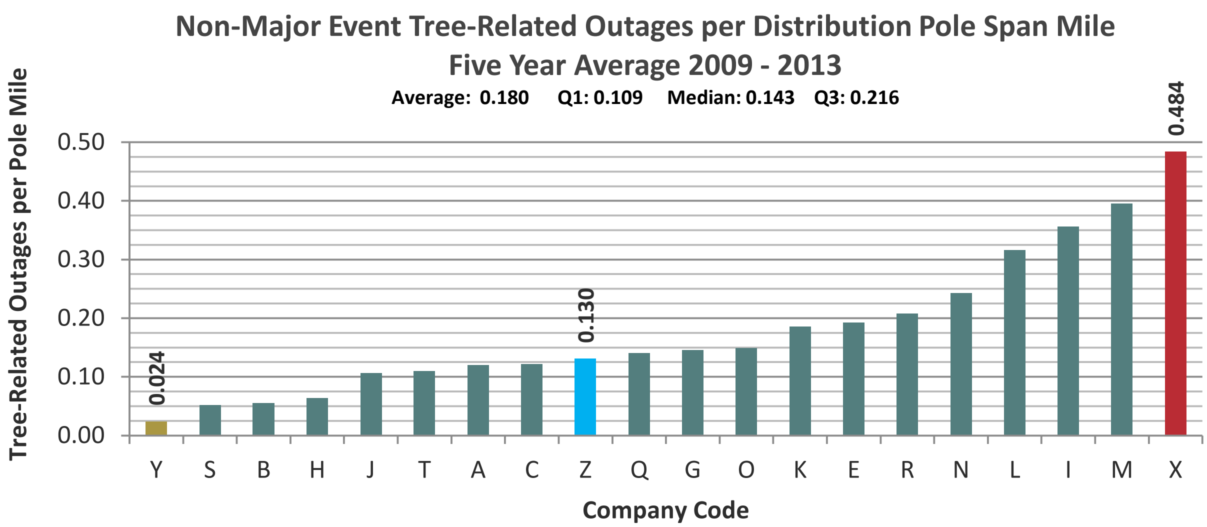

Figure 32: Absolute Reliability Rates

Conclusion:

Reliability is a major objective, especially as we enter into an era when climate changes are a significant threat to utility operations. However, effective vegetation management is not a direct response to conditions that negatively impact reliability. The reliability metrics that currently guide vegetation management do not measure or recognize the full extent of the UVM workload or forestry conditions. It is not the incremental tree growth that impacts reliability but rather the accumulative growth which leads to branch and tree failure. Nonetheless, it is still growth that UVM must control in order to prevent interruptions. This growth component must be managed in a cost-effective way and UVM must be performed to satisfy other objectives besides reliability. The use of reliability metrics as a measurement of UVM efficacy is pressuring utilities to practice reliability-measured UVM rather than sustainable

UVM that adheres to principles of forestry and urban arboriculture. All vegetation near power-lines must be managed at some point, regardless of its impact on reliability. Delaying maintenance to serve improvements to reliability metrics compromises all of the objectives and creates a greater long-term risk. This research was performed to demonstrate the shortcomings of reliability-centered maintenance and offer some alternatives to steer UVM in the direction of a more balanced approach that includes multiple objectives.

APPENDIX C: PEER SELECTION

In 2009 CN Utility Consulting (CNUC) conducted a Distribution Vegetation Management Benchmark Survey for Hydro One and performed a comparative analysis of program efficiencies with utilities that had been selected as peers. The current study is a continuation of this analysis.

The selection of peer utilities in 2009 was based on the following criteria:

- Vegetation Cover and Density
- Weather Considerations
- Distribution System Characteristics (i.e. Customer Density, Size of Service Territory, Percent of Overhead (OH) Lines and Off-Road Lines)

The current peer selection expanded upon the 2009 criteria. There are several departures in the 2016 study design that allowed CNUC to select peers based on a larger set of criteria and to limit bias. These departures were:

- The survey was distributed to utilities that wanted to participate regardless of whether they were perceived as a possible peer to Hydro One.
- Comparative analysis of system characteristics and vegetation cover was performed on all survey participants before selecting peers.

Once the preliminary analysis was done, CNUC gave weights to the importance of each characteristic. These weights were assigned partly on regression analysis and correlational studies. The order of importance is as follows:

1. Peer in the 2009 study
2. Geographic location and proximity to Hydro One
3. Tree density and managed tree characteristics
4. Customer Density (i.e. Customers per sq km, customers per system km, customers per OH km and OH customers per OH km, Urban versus Remote)

Peer in 2009:

2009 peers were automatically selected as peers to give the current study continuity to the previous study. A majority of the 2009 peer utilities are represented in the current study.

Geographic location and proximity to Hydro One:
Utilities in Northern United States as well as Canada had similarities to Hydro One in several areas. Canadian companies not only had geographical proximity to Hydro One, they had comparable regulatory oversights that may vary from US utilities. Canadian utilities were given greater scrutiny for this reason. Most of the survey participants that are Canadian companies were chosen as peers, although not all. Northern US, excluding the Northern Great Plains utilities, has comparable climate and tree populations.

Tree density and managed tree characteristics:
Tree density and tree characteristics are of major importance, since it is really trees that are managed by the UVM department, not kilometres of line. A kilometre of line that is heavily treed will require more work than one with few trees. The tree species make-up will also affect the amount of time required for management.

Customer density:
Customer density was the last factor that was used for peer selection. Customer density was viewed from several perspectives, since each viewpoint gave insights into comparability of different utilities.

Customer density was calculated as followed:

- *Customer density by land area*: customers per square kilometre
- *Customer density per system circuit kilometre*: customers per overhead (OH) and underground (UG) distribution system circuit kilometre
- *Customer per pole kilometre*: Customer per OH distribution system kilometre
- *Service Territory Descriptions*: Percent of Urban, Suburban, Rural and Remote

This selection process allowed a larger sample set than the 2009 study and afforded the different territories comparators that had similar characteristics. It also eliminated some assumptions about comparability of UVM programs.

APPENDIX D: STATISTICAL METHODOLOGY AND MODEL DEVELOPMENT

UNIT CONVERSION

NUMERICAL DATA

All numerical data was converted to metric if necessary. Survey participants stated the units they used and appropriate conversions and calculations were done.

FINANCIAL DATA

United States dollars (USD) were converted to Canadian dollars (CAD).

- Statistics on financial graphs that used five-year averages or year-over-year trends were converted using the average of the annual exchange rates for years 2011 – 2015. This rate is: 0.9343524 (USD to CAD). This method was selected to smooth out the anomalous variation in the exchange rate.
- Statistics that only used only 2015 financial information (e.g. wages) employed the 2015 exchange rate (0.782992)

NORMALIZATION

Data was normalized by:

1. Filtering by peer group selection
2. Dividing by distribution system overhead (OH) kilometres
3. Dividing by annual managed kilometres
4. Dividing by number of electric customers
5. Focus on labour hours expended as a proxy for cost
6. Using percents
7. Selective comparisons of peer group

Given the complexity of the utility vegetation management (UVM) industry, calculations using weighted adjustments were not employed since they would mostly likely introduce bias. If there had been only one or two variables affecting differences between UVM programs, it would have been an appropriate approach. Multivariate analysis proved one factor could not be selected for weighted adjustment over another. Therefore, root-cause analysis was used to explain variability.

EXPLORATORY DATA ANALYSIS

Comparative investigation was based on an exploratory data analysis (EDA) approach. Simply put, the key data was summarized visually and by descriptive statistics before hypotheses were formulated.

REGRESSION AND MULTIVARIATE ANALYSIS

The relationship between UVM program cost and productivity components was explored using graphical visualization and by regression analysis. For example, tree density (trees/managed km), cycle length, and cost per managed kilometre were charted on one graph using the secondary axis to view all three variables simultaneously.

Regression analysis was done with some of the variables to see if relationships exist between factors. When more than two variables were being explored, multivariate analysis was done. Analysis was performed using JMP software, which is an exploratory statistical software. JMP allowed the researchers to perform a variety of tests and provided best fit analysis.

This exploration was done to build hypotheses about efficiencies, especially when identifying best management practices (BMP).

PROJECTIONS OF UNIT COSTS FOR HYDRO ONE

Hydro One is unique in three major ways with regard to the peer group:

- Line clearance, brush control, and job planning is performed by in-house crews using company-owned equipment
- The UVM program costs include administrative costs that other utilities do not include
- Hydro One employs seasonal workers that are hired from the Hiring Hall at lower labour burden rates

These differences make it difficult to use information from peer utilities to estimate costs for the model. Therefore, all projections were made using Hydro One's past spending records as a basis for setting cost estimates.

Hydro One experienced a major funding cut in 2014. This compelled them to change their UVM program in terms of equipment utilization, scheduling, and labour mix. Therefore, historical data of costs and production took a sharp turn beginning in 2014. Long-term cost modeling had to be based on the current budget, which has a larger cost per labour hour, but total expenditures are similar to pre-2011. This decision was determined through consultations with Hydro One UVM strategists.

Variables that affect the predictions:

- Fixed Variable Cycle Lengths

- Number of kilometres managed annually
- Annual Inflation
- Tree Density
- Cost per Labour Hour
- Employee Resource Mix (Hiring Hall vs FTE)

Three models were built:

1. **Risk Model A:** This model is at the highest risk level. It is a model built on the current scheduling methodology, which targets M-Class feeders and three-phase (3Ø) lines. 8,500 km of 3Ø (~one-sixth of the 3Ø system) will be done annually, including approximately 7,083 km of backlog work. Only 3,500 km of single-phase (1Ø) and double-phase (2Ø) will be done annually on a case-by-case basis and will be performed by Hiring Hall employees. There are 52,000 kilometres in this category and this will put this part of the distribution system on a 14.9 year cycle. 1Ø, 2Ø scheduling will be triggered by reliability problems. This scheduling methodology will take approximately six-years to get all the M-Class and the 3Ø feeders on the desired target variable cycles (four, six, and eight-year dependent on reliability considerations). This approach will get the high priority lines on schedule, but the single and double phase will fall farther behind.
2. **Risk Model B:** This model is a mid-risk model. This model expands the Risk Model A by continuing the backlog and cyclical work on the M-Class and 3Ø lines, but will also increase the work on the single-phase and double-phase lines to keep this part of the system closer to the 9.5 year (on average) cycle. This will increase the number of km for 1,2Ø lines to 5,473 km/year (13,973 total km managed annually). This increased work on the 1Ø will be done by Hiring Hall or contracted labor.
3. **Risk Model C:** This model carries the least risk and produces a more storm resilient system. It gets all of circuits on target cycles by obtaining an eight-year cycle (ten in the North region) for single and double-phase circuits. This requires that 6,500 km (1,2Ø) and 8,500 km (3Ø) be managed annually for the next six-years, a total of 15,000 km a year. The single and double – phase circuits will again be performed by Hiring Hall or contracted labor.
4. **BMP Model D:** This model produces a more storm resilient system with greater returns. It gets all of circuits on target cycles by obtaining a six-year average cycle for single and double-phase circuits. This requires that 8,687 km (1,2Ø) and 8,500 km (3Ø) be managed annually for the next six-years, a total of 15,000 km a year. The single and double –phase circuits will again be performed by Hiring Hall or contracted labor.

Once these models have cycled through the six-years, it is anticipated that the cost of maintenance on the scheduled work will decrease due to improved forestry conditions. Anticipated cost savings in each model:

- **Risk Model A** will see improvements only for the M-Class and 3Ø. At the same time, the single-phase will have accumulated a greater workload. This model will possibly see little to no improvements in the cost of maintenance due to half the system falling into greater arrears. In fact, it may make the work on the single-phase circuits more expensive and time-consuming. The time and money saved on the three-phase system will need to be funneled into the single-phase work after six-years.

- **Risk Model B** will see improvements only for the M-Class and 3Ø, but the single-phase system will have maintained its present conditions. This should produce reduced costs and labour hours for work done on the 3Ø. This will allow concentration on the single-phase. Once again, the time and money saved on the three-phase system will need to be funneled into the single-phase work.
- **Risk Model C** will see improvements on all circuits in the system and there should be a reduction in costs. These savings will not only come from reduction in workload, but also from increased storm resilience and a decrease in reactive work. It will take many years beyond the six year time-frame to establish an appropriate plant community and ROW conditions and to realize cost-savings.
- **BMP Model D** will see improvements on all circuits in the system and there should be a reduction in costs. These savings will not only come from reduction in workload, increased storm resiliency, and a decrease in reactive work. There will also be a reduction in the need for line clearance personnel and an increase in the herbicide and planning personnel. This change in labour mix will also be a cost-savings. It will take many years beyond the six year time-frame to establish an appropriate plant community and ROW conditions and to realize cost-savings. The long-term gains for this model will be greater than Risk Model C, since cycle lengths will be closer to best management practices.

The following elements and assumptions were built into all models:

- Units completed for Line Clearing, Brush Control, and Job Planning were equalized to account for the large differentials experienced in 2014 and 2015.
- 2015 costs were projected to be the best indicator of labour burden rates for the future by Hydro One. These unit rates were adjusted to include equal units completed for all three work types.
- The South's 2015 costs per managed km were thought to be a target for a system in control by Hydro One. The cost per kilometre was adjusted to include equal units completed for all three work types. Since all the regions in the Hydro One territory vary in terms of what will be required once on schedule, it is possible that this may need to be adjusted after several years of data has been collected on the new scheduling and work-force implementation.
- The M-Class feeders are mostly in control. It was assumed that the rest of the three-phase and F-Class feeders would get on schedule by 2022-2023
- East's costs per km were used to represent costs when circuits are in arrears or backlogged. Although the Central region has higher costs, the East was chosen to be a better estimate to account for regional differences. . Since all the regions in the Hydro One territory vary in terms

of what will be required to address backlog, it is possible that this may need to be adjusted after several years of data has been collected on the new scheduling and work-force implementation.

- An annual inflation rate of 1.67% - calculated from the current ten-year average for Canada.
- Hiring Hall/Apprentice and FTE mix is unpredictable at present. An approximation of the effect this mix will have on costs was established in the following way. Since, on average, the labor burden for hiring hall/apprentice personnel runs about 59% of a FTE, this ratio was used to model costs on the single and two-phase circuits. Presently, Hydro One will dedicate the use of hiring hall employees to the single and two-phase work. Since this mix has not been established and will change due to attrition, all calculations using this variable are subject to variation.
- An average of approximately $10M was added on each year to the projected costs. This represented the difference between routine maintenance and total cost of UVM. This includes reactive and administrative cost and was calculated using the five-year average from 2011-2015.

Model Set-ups

Risk Model A: 8,500 kilometres were set for the M-Class and 3Ø, and the single and double-phase lines were set at 3,500 km. 1,417 km of M-Class/3Ø will be circuits already on cycle and it will be predicted that UVM costs (Planning, Brush and Line Clearance) could be approximated by the 2015 cost for the South Region. The rest of the 3Ø will uses an equalized 2015 rate for Hydro One East, since the brush control and job planning were decreased in 2015.

Risk Model B: 8,500 kilometres completed were set for the M-Class and 3Ø, and the single and double-phase lines were set at 5,473 km. The same costing rates were used for projections as Risk Model A.

Risk Model C: 8,500 kilometres completed were set for the M-Class and 3Ø, and the single and double-phase lines were set at 6,500 km. The same costing rates were used for projections as Risk Model A.

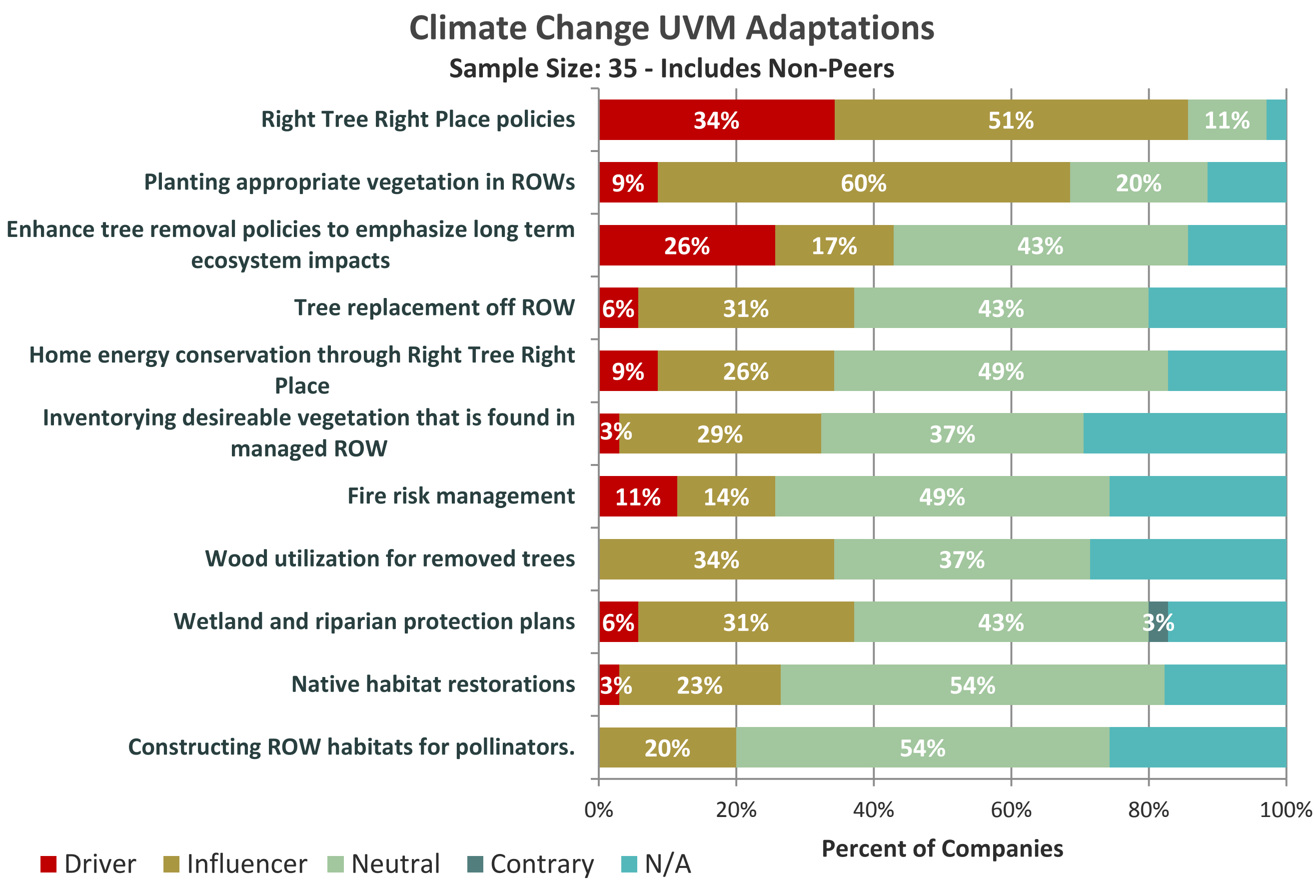
Model D: 8,500 kilometres completed were set for the M-Class and 3Ø, and the single and double-phase lines were set at 8,667 km. The same costing rates were used for projections as Risk Model A.

APPENDIX E: CLIMATE CHANGE AND STORMS

INTRODUCTION

This appendix addresses *Climate Change and Storms.* Of importance is not only the current storm severity but the impact on vegetation conditions due to climate change. A proactive approach to utility vegetation management (UVM) will most likely result in a long-term savings and mitigation of heightened risk from climate change.

Climate change adaptation will have its most aggressive opportunities in cycling trees out of the system before they become hazardous and entering trees into the system early enough to provide a sustainable canopy. UVM has to make this their mission in order to integrate with more global forestry efforts.



Graph 1: Climate Change Adaptation

Graph 1 (above) provides an analysis of how UVM policies are aligned with climate adaptive behavior. This is not an exhaustive listing of how UVM policy is or can adapt to climate change.

The models for climate change in Ontario indicate there may be significant increases in temperatures with the number of high temperature days (>30°C) doubling by 2050. Consider what this means to UVM at Hydro One. 2016-2050 is roughly 3.5 cycles of UVM for Hydro One. Heat waves are predicted to increase from the current “moderate/possible” (0-2.5 days) to “often” (1-5 days). The number of winter cold waves (≥ 3 days of <-10°C) will decrease from occasional to remote. Heavy rain days (>50mm/24hr) in southern Ontario are expected to increase from “moderate/possible” to “often.” Summertime precipitation is predicted to decrease by as much as 10-25% by 2050 in southern ON. The predictions for beyond 2050 escalate (CIMA 2014). Will the UVM department be able to respond effectively to a much different future, when it is challenged by the present growth conditions?

Adaptation to climate change could be a positive influence on UVM programs efficacy, efficiency and knowledge of the evolving conditions. Opportunities for the forestry and utility industries have already been manifested in a multitude of ways. Utilities have decreased their use of coal and other fossil fuels in favor of cleaner and ultimately cheap sources of energy such as wind and solar. Regulators are discovering ways to keep utilities successful while generating and distributing less electricity. End-users are getting more benefits while using less energy. Western Canadian timber companies have already salvaged the majority of useable lost timber from the Mountain Pine Beetle (MPB) devastation. These are winning, “no-regrets” adaptations that are helping to solve a problem. UVM could follow a similar pattern, by strategically planning for a future in which fewer resources will be needed to bring solutions for adapting to climate changes and improving electric reliability.

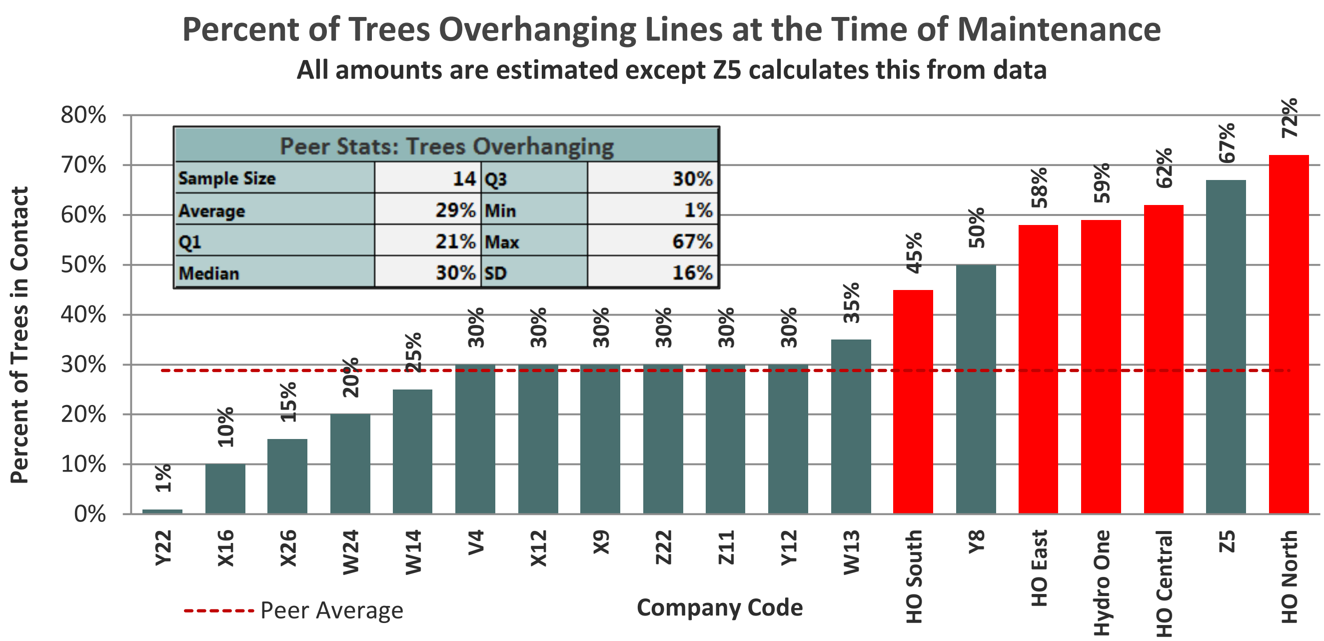
STORMS

CLIMATE CHANGE AND THE UVM RESPONSE TO STORMS

Reliability is the number one UVM objective for Hydro One. This is because Hydro One has been in the fourth quartile for system average interruption duration index (SAIDI) in peer performance comparisons for many years. Storms are a tree problem. Strategies for reducing damages that occur from storms are a priority for Hydro One’s UVM programs, because customers have come to expect electricity to be highly resilient to storms. Customers, the public, the media, elected officials, and regulators will judge utilities when major storms interrupt power for prolonged periods. Climate change has begun to cause catastrophic storms to happen more frequently and with greater intensity than in the past. Major storms have been happening ever since the first overhead system was built. In many ways storms already represent climate change because they are never the normal and they have always set new records. Distribution grids typically sustain heavy damage and require resources many times the size of the routine workforce that are brought in from long distances to work incredible hours in often dangerous conditions of unstable trees and broken equipment. Unfortunately for

UVM programs, the history of violent storms bringing down trees has not inspired society to want the utility to scientifically and effectively manage for reductions in damage. Perhaps for a short time, customers want to give up a tree to protect their part of a circuit, but soon the major event is historical and the risk of losing power again is not as important as the tree.

A realistic equation between tree benefits and cost-effective utility forestry strategies and best management practices has to become a part of the future environmental zeitgeist of the larger society that Hydro One serves. Not until overhead electrical equipment is afforded an appropriate space without vegetation will Hydro One be able to effectively manage the risk of failing trees during storms, particularly storms in the 21st century of climate change. Hydro One's *estimated* percent of managed vegetation that overhangs conductors is higher than nearly all of its peer group (Graph 2 below).



Graph 2: Percent of Trees Overhanging Lines at the Time of Maintenance

Without effectively managing to achieve a low percent of overhanging trees, particularly susceptible species, storm risk will remain dangerously high. This situation is likely to collide fatefully with the catastrophic storms predicted for the coming decades.

Proactive initiatives to increase system resiliency are happening at several utilities. Hydro Quebec, Manitoba Hydro, Consolidated Edison, Connecticut Light and Power, PSEG, FPL, and Entergy are a few utilities that have experienced multiple events over the last few years that have inspired them to respond to perceived impacts of climate change (CIMA 2014). They have implemented programs to harden their distribution systems against more frequent and more intense storms. Hydro Quebec has ramped up its efforts with a special pruning program in areas that are prone to freezing rain over 25mm. Identifying and removing hazardous trees is a key component to hardening a system.

The benchmark survey performed for this project probed whether UVM departments have linked their efforts to climate change prevention/adaptation policies and strategies adopted by the generation and grid operators they serve. The survey and literature review shows that while UVM departments are aware that climate change is already affecting their programs, there aren't strategies for adapting beyond meeting the current urgencies. 85% of companies view Right-Tree Right-Place policies as a driver or influencer to their program (see Graph 1, p.85), but it is unclear whether such policies and initiatives are being applied in a strategic response to climate change or if programs passively apply it because it would effectively reduce workloads. Right-tree right-place is the ultimate solution to UVM and many other urban forestry problems and it has been trending since the term was coined in the 1940's. However, unless it is applied more faithfully, right-tree right-place becomes little more than a wish and any place a tree grows is the right place. In the past we managed forests with fire to regenerate new forests and provide new food for wildlife. It is in a similar spirit of stewardship and benefits that a utility should maintain networks to provide reliable modern "fire" that powers our homes, cities and towns. 43% of companies who responded to the survey are adopting more assertive climate change adaptation by enhancing their UVM program tree removal policies to emphasize long-term ecosystem benefits (Graph 1). This is an alignment of UVM objectives, such as reliability, with more global forestry urgencies.

Storms and the Reliability

Out of the last thirteen years, Hydro One finished ten of them with greater than 60% of Major Event Day (MED) outages caused by trees (Graph 4, p.90). This poor performance during storms is a great challenge. When climate change effects intersect with long-term poor reliability performance, there is likely to be a catastrophic outcome.

Hydro One has had numerous ice storms and wind events that have resulted in a high number of outages. While lightning strikes and tornadoes may happen less frequently than in parts of the US, Hydro One faces many logistical challenges in managing storms that other companies in the study are better suited to handle. These challenges are evident in reliability data over the past decade. A few facts emerge when you look at the reliability (SAIDI) of the Hydro One Networks on Non-MEDs (Graph 3, p.89):

- Tree-related Non-MED SAIDI has improved for Hydro One since 2008. The improvement since 2003 is less significant.

- Other (non tree-related) causes of non-MED failure have been increasing steadily since 2009 so that SAIDI has increased nearly an hour during the last 6 years while tree-related SAIDI has remained relatively steady since 2009.
- *2011 through 2015 was the lowest five- year period of non-MED tree-related SAIDI for the last thirteen years*.
- Non-MED tree-related SAIDI has ranged between 26-38% of the company non-MED SAIDI for the last thirteen years.
- Non-MED SAIDI is probably a higher priority for asset improvements since on average more than two-thirds of it is not tree-related.
- The percent of SAIDI that is caused by trees during non-major event days (non-MED) is average in comparison to peers (see reliability section in main report).
- The contrast between non-MED performance and MED performance is striking and emphasizes the need for making the system more resilient (See Graph 4,below).

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
% Tree-Related	36%	28%	31%	27%	31%	38%	31%	33%	26%	30%	27%	26%	27%
Total Non-MED	8.0	6.5	8.0	7.1	8.2	8.1	7.0	7.1	7.3	7.5	7.2	7.9	8.2
Tree-Related	2.9	1.8	2.5	1.9	2.5	3.1	2.1	2.4	1.9	2.2	1.9	2.1	2.3

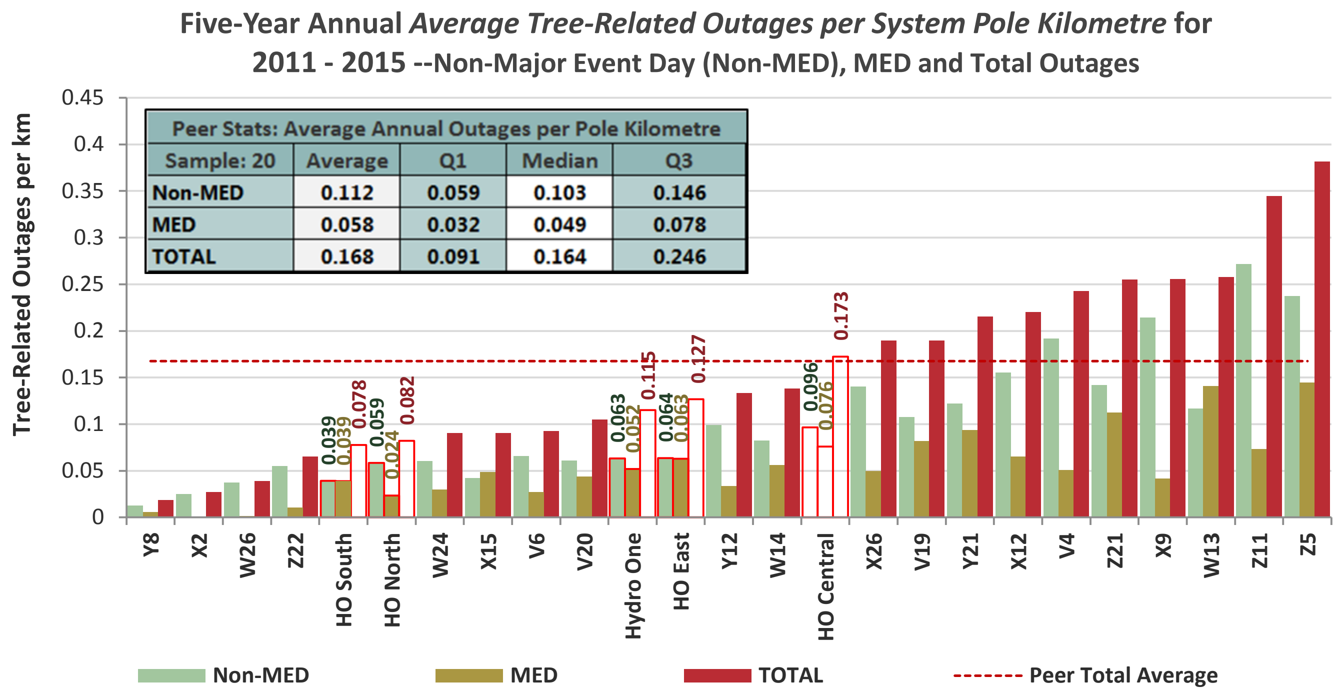
Graph 3: Hydro One Time Study of Non-MED SAIDI from 2003 – 2015

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014	2015
% Tree-Related	84%	39%	83%	76%	49%	84%	65%	75%	68%	55%	63%	66%	70%
Total MED	7.1	0.4	6.5	21.3	2.7	12.8	2.3	1.9	14.7	3.8	20.0	2.0	4.6
Tree-Related	6.0	0.2	5.4	16.2	1.3	10.7	1.5	1.4	10.0	2.1	12.7	1.3	3.3

Graph 4: Hydro One Time Study of MED SAIDI from 2003 – 2015

MED SAIDI is a different puzzle and trees are the culprit for the majority of cases. MED tree-related SAIDI was 70% of total MED SAIDI in 2015 (See Graph 4, above). The significant fact to recognize with these measurements is how much the ratio of tree related outages to asset failure increases during storms. A Department of Energy (DOE) study has noted that SAIDI is increasing throughout the US particularly when measured with major events. Even a slight increase in average annual wind speed of 10% correlates with a 75% increase in SAIDI (Larsen et al, 2015). The 2014 CNUC distribution benchmark survey found tree-related SAIFI accounted for more than 43% of total SAIFI during MED compared with 24% during non-MED. What this tells us is that UVM will have much greater success if it can reduce the outages that happen during major event days. It is the duration of interruptions during major events that have caught the attention of the public, the media and high level officials (White House 2013).

Hydro One performs relatively well when total outages are measured per kilometre of overhead line (See Graph 5, below). With the exception of the Central region, the five-year average of *total* outages per kilometre is below the average of their peers. The South and the North are in the first quartile. The whole company, performing at 0.115 outages per kilometre, is well below the average of 0.168. The ratio of Non-MED to MED outages is on average about 2:1 for the peer companies. However, for Hydro One East and South it is 1:1, Central is 5:4, and North is 5:2. With the exception of North, the ratio of MED to Non-MED outages is significantly less than peer companies. Since 2003, the majority of storm outages have been caused by trees nearly every year (See Graph 4, above).



Graph 5: Hydro One Comparison with Peers for Non-MED, MED and Total SAIDI 2011 - 2015

Hydro One's relative performance with outages in MED or Non-MED may be somewhat related to methodology in determining the MED, which does not follow the 2.5 Beta Method described in IEEE-1366. However, Hydro One's methodology would tend to keep small scale storm impacts in the Non-MED category because the bar is set sufficiently high for MED—10% of customers are disrupted. Most companies are able to remove catastrophic storms from the metric so that their Non-MED isn't an unrealistically low bar and if a company has no big storms the bar is automatically set at a level to allocate a fair proportion of outages to MED. Additionally, this data is smoothed by averaging over five years. In other words, storm events are frequently severe enough that 40% of Hydro One outages are MED. Hydro One Central is in the high end of the third quartile in peer comparisons of outages per km during storms, East is in the third quartile, and the company as a whole is close to the median (Graph 5 above). *Central and East should make storm resiliency a priority*.

Hydro One and all of its stakeholders would like to see an improvement in the reliability of the system, especially when storms blow through. A definite trend emerges for MED tree-related SAIDI (Graph 4, p.90). The data since 2003 has shown that storms have been worse every second or third year since 2003. The cause is unknown to CNUC, but it is worth noting from a planning perspective. The percent of SAIDI during storms attributable to tree failures is most interesting. From an engineering perspective, the asset failure causes are mostly happening during non-MED and could be solved with system upgrades and other condition-based refurbishments. Equipment failures that happen during storms may be the same failures that happen on non-MED days and the same maintenance processes will solve both reliability issues. The hardening of the system during storms is predominantly a single issue - trees. These are ostensibly not the same issues that are happening during non-MED outages, although a consistently applied improvement in routine maintenance would result in a substantial improvement to MED SAIDI. From a UVM perspective, if the right trees could be removed, then the system would be more resilient during storms, which is when it needs the most improvement (See Appendices F & G Tree Risk Assessment).

Typically on most systems the events that cause the greatest damage are wind events. A map of wind events from the Ontario Ministry of Community Safety and Correctional Services, Hazard Identification Risk Assessment (Figure 1, below) illustrates the relative potential for storms in the four Hydro One Regions. The South has the highest potential, but it has the lowest tree density and lowest number of outages per km. The Central has the second highest risk and it has high tree density and the highest number of outages per mile. The East has the second highest number of outages per km, but it has only a moderate risk of wind events. The North has the least risk in regards to wind events. Similar maps are included for tornadoes and freezing rain. The highest concentration of the most severe tornadoes are in the South (Figure 2, below). The East has the second highest risk for tornadoes and also has the highest risk for freezing rain (Figure 3, p.94). The South has the third highest risk for tornadoes and the southern part of the North region is fourth.

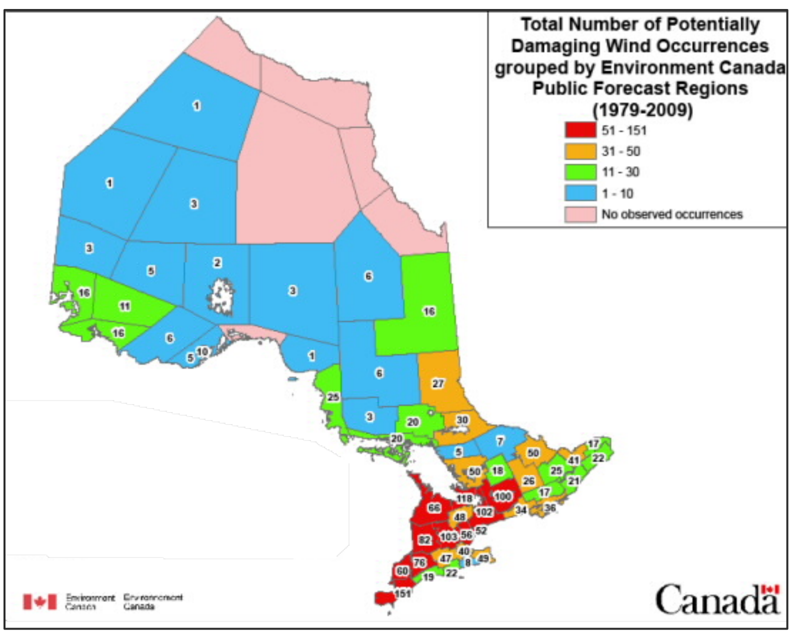


Figure 33: Historical Cumulative Number of Damaging Wind Events 1979-2009 (Hazard Identification Risk Assessment)

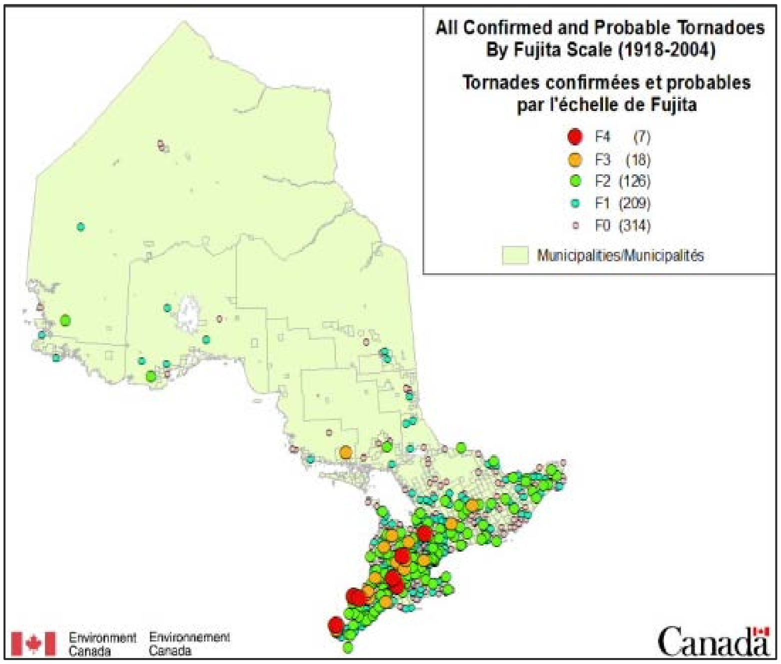

Figure 34: Total Tornado Occurrence in Ontario 1979-2004

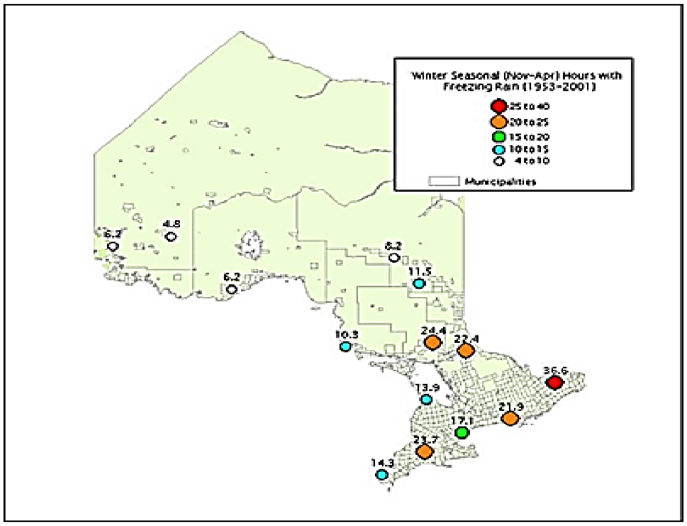
Wind damage has been cited as the largest cause of destruction to forested areas in Europe:

> *Tree species and average tree or stand dimensions, especially height, have been found to be the most important factors controlling [wind] storm damage in the forests typical of central Europe* (Hanewinkel 2013).

Tree defect, which is sometimes difficult to assess, is the most common attribute that an arborist in the US uses to determine the risk of failure. The collection of articles entitled Living with Storm Damage to Forests (Gardiner 2013) suggests there is an attribute elevating wind damage risk - tree heights - that can more easily be evaluated at the stand level instead of individual tree assessments. Other important factors affecting wind damage noted in this study were:

- Types of trees: Conifers are more susceptible than hardwoods
- Waterlogged soils with restricted rooting
- Acidic soils
- High final tree height and high target diameters are key factors for determining risk
- Early thinning at low heights increases diameter and reduces wind risk
- Slopes and valleys exposed to prevailing wind
- Thinning at latest stages of forest rotation increases wind throw risk
- New edges on a upwind side of stands increase wind damage risk
- Trees with highest taper are most wind resistant
- Thinning on exposed sites increases wind risk

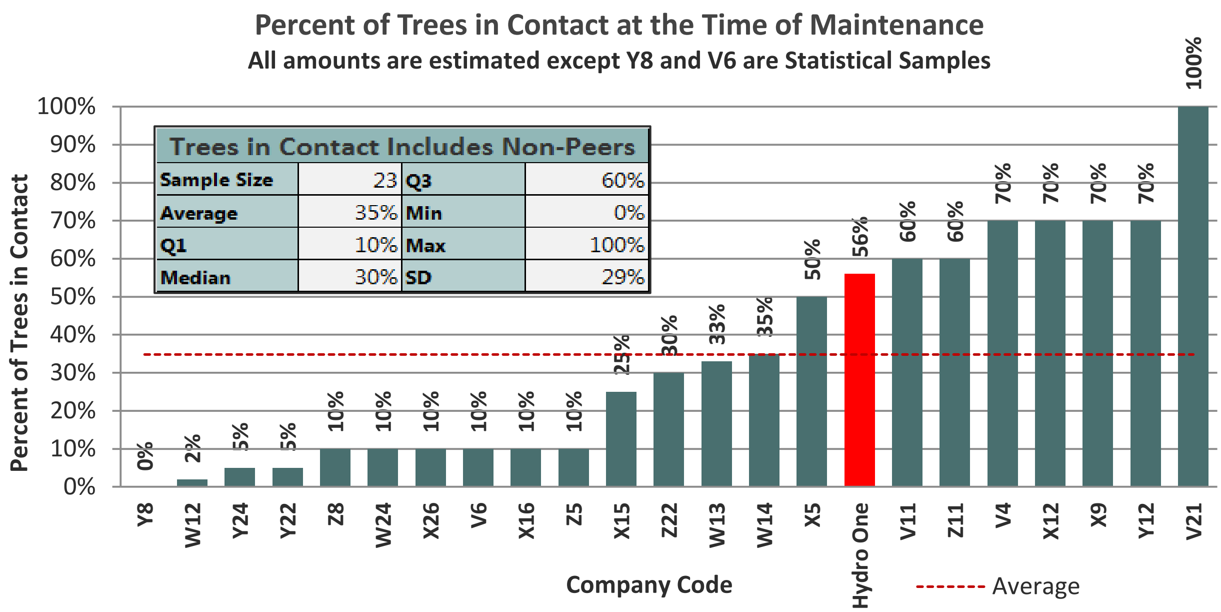
(Hanewinkel 2013)



Freezing rain is a frequent hazard in Ontario. Northern and Central Ontario experience the greatest number of days per year with freezing precipitation (Figure 5) with an average of over 17 days per year. Southern Ontario has fewer days per year with an average of just over 11 days. In Ontario, the most severe ice storms/freezing rain events usually occur from November to March with approximately one half occurring between the last two weeks of December and the first two weeks of January. In general, these have lasted between 12 hours and 1-2 days (Environment Canada, 2009). Freezing rain can be a small scale or a large scale hazard, depending on the size of the storm system.

Figure 35: **Average number of hours per year with freezing rain, based on data form 1953-2001**

Ice storms are not an uncommon occurrence in Ontario and, as noted by the Ministry of Community Safety and Correction, from 17-36 hours of freezing rain can occur annually in Hydro One's South and East regions and the southern part of the North region. Ice storm risk is increased by a considerable margin when trees are overhanging or in close proximity to conductors. The ice brings the branches into the conductors. Until ice-covered, broken, and permanently-bent branches are removed, the power cannot be restored. This is repeated for *every* tree that has not been managed for clearance from conductors. Unlike wind, there is less chance that trees from a further distance will be blown over into the conductor. Managing a system for permanent clearances is the greatest defense against ice storms, which are a frequent cause of disruption on parts of the Hydro One system. A similar case can be made for protection against heavy snows on conifer trees. When the percent of trees overhanging (Graph 2, p.87) and the percent of trees in contact (Graph 6, below) on the Hydro One system is considered, it is not surprising that wind, ice and snow events cause many MED outages for Hydro One.



Graph 6: Percent of Trees in Contact at the Time of Maintenance

Storm Case Study

In 2014 after Nova Scotia Power (NSP) experienced the aftermath of Post-Tropical Storm Arthur, the company entered into an investigative and rule-making proceeding with the Nova Scotia (NS) Utility and Review Board (UARB or "Board"). The jurisdictions of various stakeholders regarding vegetation management and storm hardening were the primary concern of the Board. Like Hydro One, the issue of vegetation management must be handled with stakeholder consultation. Organizations, such as the transportation authority, the union of NS Municipalities and Wood Lot associations, are included in the proceedings. A consulting company was hired to study NSP's preparations and response to the hurricane. The following activities have resulted from the proceeding:

- Improve the capability for weather forecasts on a local level
- Reclaim overgrown distribution ROW including widening of the ROW
- Prioritize three-phase feeders
- Execute multi-year performance evaluation for worst-performing circuits
- Widen ROW of sub-transmission lines (69kV)

Comments from intervenors regarding vegetation management were generally aligned with the independent recommendations, which were nearly all made into policy at NSP. Most of the letters from the public stated NSP should do more vegetation management (UARB 2014).

"*More than 90% of the power outages caused by Post-Tropical Storm Arthur were due to trees contacting lines and other equipment"* (NSPower 2014). In 2015, NSP filed with UARB a follow-up report in which they stated, "*There is approximately 10,875 km of distribution right-of-way remaining to reclaim throughout the province and at the current budget for vegetation management it is estimated to take approximately 32 years (at $3M per year) to get the program to a sustainable level"* (NSPower 2015 p. 18).

For Nova Scotia Power the measure of progress is the percent of ROW kilometres that are classified as sustainable with integrated vegetation management (IVM). NSP has begun widening the sub-transmission corridors and has submitted a plan for widening the remaining 40% of the distribution line kilometres at a cost of $8,500 per km (NS Power 2016). This plan should effectively bring the NSP distribution system to an optimum level of cost efficient management and reduced reliability and safety risk.

One of the issues that was reviewed at length after Post-Tropical Storm Arthur was the weather forecasting capabilities. This is an area of technology that is developing rapidly and many companies are now setting up local weather reporting systems to enable preparations and responses to impending storms. This will enable the utility's response to be more finely tuned to the timing, intensity and actual damages from a storm. These hyper-local forecasts can inform load planning as well as "ensure utilities know what weather will affect a specific point of their service area up to the minute and throughout the entire day, up to 72 hours in advance. They also can determine if high winds or rain will hit a portion of their service area, while other areas will be hit with ice and snow. This allows utilities to plan for outages before they happen and understand where their pain points will be" (Schneider Electric 2015).

CONCLUSION

The human-built world will have to adapt to changes that will not always be predictable. For an electric distribution company, it makes sense to take a "no regrets" approach (Figure 4, below) to protecting the grid against more frequent and more intense weather events. The win-win outcome will be to have a more reliable and safe system regardless of climate change and a more environmentally adaptable, safe and reliable system.

POTENTIAL REGULATORY SOLUTIONS FOR CLIMATE CHANGE ADAPTATION

Common Regulatory Commission Functions	Potential Enabling Roles for Adaptation
Determine the revenue requirement and utility rates	Guidance on eligibility of adaptation-related investments for rate reimbursement; Structure utility rates to enable demand responsiveness (Ex: dynamic pricing)
Set service quality standards and consumer protection requirements	**Require robust storm plans and conduct evaluations and drills.**
Oversee the financial responsibilities of the utility, including reviewing and approving capital investments and long-term planning	**Examine adaptation-related investment and require long-term planning take climate change impacts into account.**
Review and approve comprehensive supply resource plans	Require that resource plans are tested against future scenarios that include climate change projections and uncertainties; Provide opportunities for collaborative decision making.
Approve the entry of competitive retailers into the state's market	Allow microgrids and ESCOs to operate in utility service territory to provide customers with energy management options

Appendix F: Tree Risk Assessment - A Best Management Practice

A Tree Risk Assessment (TRA) standard, ANSI A300 Part 9, has provided a framework for utilities to develop formal TRA programs. In a survey performed in February and March 2016 for Hydro One and the Utility Arborist Association TRA Best Management Practice (BMP) Working Group, 40 utility companies throughout North America gave their opinions and facts on their programs relative to tree risk and hazardous trees. The data from this survey is intended to help determine current practices and what would fairly represent a BMP for publication. This discussion will pose some questions and potential directions for a Best Management Practice as the basis for evaluating Hydro One's current practices. The cornerstones for determining tree risk are inspection, measurement, and record keeping. Some key practices include site and tree inspections, remote sensing, customer education, and data analysis.

An important aspect when making vegetation management decisions is understanding specific hazards in the context of populations of trees. An inspector looking for suspect trees rarely encounters a tree that is ready to fail. Instead, a decision to remove a tree may need to be based on a classification list that comports with a system-wide effort to reduce risk over the entire population of trees. It is different for an arborist about to commence work, who must inspect the tree for hazards as a matter of safe practice. If the tree has some hazards that the arborist considers a compromise to his or her safety, then a decision might be made to adjust the method of working the tree, including a recommendation that the tree be removed. Removal may be recommended if the tree cannot be worked safely, and so that the tree isn't left as a safety risk for the public, the property owners or future arborists assigned to work on the tree. The arborist decision process is valid, because it is vital to weigh out the probability of safety factors that are part of the exigent realities of working in the trees. However, these trees are typically expensive and risky to work on and it is unfair to arborists to expect such conditions to be the normal life-cycle of trees they work on. A better scenario involves deciding to remove trees before they become hazardous. Hence, there are significant benefits to be derived from a formal Tree Risk Assessment program.

There are also social and economic reasons for developing a formal process. The final decision to remove a tree may require assessments based on the probabilities for how many trees will be selected for removal versus how much resource is available to remove the trees. These are calculations that cannot be easily made, even by a trained, experienced inspector, armed with precision measurements and techniques for detecting signs that a tree should be removed.

Removing trees is a product-based event with a dramatic and permanent outcome; i.e. there is no longer a tree standing, there is substantial debris, and there are agreements and communications to make it happen. For these reasons, the process for permitting the removal of a tree, the time it takes to remove, particularly large trees (hazard trees are frequently mature trees), and the challenges related to debris disposal have made tree removals an expensive, onerous business for utilities. Waiting until trees become hazardous before removing them may be the most expensive mistake utilities have made over the last century. The following testimony highlights this assessment:

> *"The fact is that many of our outages that are caused by trees are actually from trees that are outside of our right-of-way. Limbs fall on our equipment or trees fall down: This is just a fact. If you look at our distribution system, the three largest causes of interruptions, in order, are tree contact, tree contact and tree contact. That's a fact."* (Hydro One recorded testimony 2016 Legislature)

There are few incentives for removing large trees adjacent to ROWs beyond a fear the tree is about to fail any minute. Even with the knowledge that a tree may be unsafe, it is unclear whose responsibility sits with a bad tree. In fact, only 11% of utility respondents to the Tree Risk Assessment survey stated their company has a clear idea of where their responsibility for risk ends and the property owner's begins. Consequently, a standard of practice for the utility industry is likely to be somewhat of a lowest common denominator, such as the arborist performing a job site analysis decides the tree is dangerous and the *only* way to work it is to cut it down. Otherwise, leave the tree standing until there is a more definitive assessment that the tree is going to fail. And then maybe the property owner will step up and take responsibility. Many trees are worked by arborists who have doubts about their structural integrity, but the external pressures for them to perform to a standard of productivity in spite of their doubts has led to a culture of risk-taking behavior. A standard or best management practice for evaluating tree risk could alleviate some of the danger of trees failing into high voltage distribution lines. In fact, this is occurring on regulated (FAC-003/NERC) transmission corridors and some distribution and sub-transmission corridors. The TRA survey identified the percent of companies that frequently inspect their lines:

- 18% of companies inspect 100% of their single-phase line annually
- 26% inspect 100% of their multi-phase primary lines annually
- 63% inspect 100% of their non-FAC-003 regulated lines annually
- 100% inspect 100% of their FAC-003 regulated lines annually

Of the companies that have separate TRA programs (17), 65% (11 companies) also have pre-inspection programs. Of the remaining six companies who have a separate TRA program, 83%

do inspections at the time of maintenance (one did not answer this question). These statistics indicate it is probable that formal TRA programs are better implemented as a subset of pre-inspections than added to the highly-focused and risk-intensive activities of aerial arborists. The skill levels of inspection and assessment and capabilities to analyze data are the current limits on how successful a TRA program can effectively pay for itself. Successive inspections and the use of historical data, as well as the growing database of outage root-cause analysis, will bring regular improvements to TRA. The TRA process is likely to remove some trees that in reality would not have failed in the near term. For utility purposes this is not as efficient as cutting down a tree that would have caused a significant amount of service disruption, damage, and customer dissonance. Nevertheless, benefits are derived because the tree does not have to be removed in the future and, since the tree is not fully decadent, it may have value as a wood product. Renewal of trees adjacent to the ROW offers an opportunity for changing the culture of land management to one that is more harmonious with infrastructure. Laura Cooke from Hydro One made the following statement about Hydro One's efforts:

> *Something else that we like to do is we like to work with communities to beautify a section on a right of way after we've done the work. We understand that in some communities, the rights of way and the greenery along the rights of way are the only green space some communities have, so they really, really want to protect that space. What we try to do is manage our obligations to reliability and manage our obligations to the community by trying to do some beautification work following some aggressive tree trimming.* (Hydro One recorded testimony 2016 Legislative Standing Committee)

Since inspections on distribution ROW for the majority of companies, 54-58%, is performed by the crew at the time of maintenance, there is little opportunity to fully engage the customer or plan a ROW conversion that is beneficial to both the customer and the utility. For the 43% of companies that do engage in a pre-inspection process, the most common way utilities make improvements on the properties they impact is to plant a new tree or shrub in an appropriate place. A few companies have begun offering to plant trees that provide energy conservation. Research from the University of Guelph indicates significant value to maintaining a high percent of canopy for human comfort levels to prevent heat islanding (Graham 2012). The peak load needs of summer heat waves are mitigated by tree canopy, thereby relating tree canopy to energy efficiency. It is expected that summer time heat waves in southern Ontario will increase as the effects of climate change intensify. Customer service via utility forestry services may be directly influenced by the nexus of energy, environment and conservation. It is apparent the utilities cannot operate forestry programs without integrating with the larger environmental concerns.

In general, a formal inspection program is a prerequisite for a TRA program. Arborists performing tree work could be expected to implement a formal TRA program, but there are many challenges to manage and it could result in cost escalations in areas where tree removals are indiscriminant or do not bring any reductions in tree-related outages and equipment damages. Utility reaction has been to limit the number of removals and allow only the smallest class trees to be selected without approval from forestry management. There are some questions to consider:

- Should a tree risk assessment program go beyond the effort of trying to find the trees that are imminently in danger of failing?
- Should aerial arborists who are charged with production expectations make decisions whether to remove trees that are not imminently hazardous but carry long-term financial and safety risks that could be mitigated?
- Should a utility have some level of understanding about the inventory of trees that are tall enough to strike distribution lines and have the risk for failure?
- Will the costs of measuring, collecting and analyzing data plus the additional work of removing trees bring a return on investment?

While these questions have been presented, they are exceedingly difficult to quantitatively answer. Studies have shown that deferring maintenance escalates cost and increases safety hazards. The North American UVM standard for transmission (FAC-003), California requirements for permanent airspace around conductors including managing hazardous trees, and a few states and provinces that have initiated reliability performance expectations have compelled utilities to manage hazardous trees. Beyond these regulations, there are few incentives for utilities to spend funds on removing anything other than the most obvious hazardous trees and the smallest class trees (in-growth).

The Auditor General for Ontario has noted the following concerning Hydro One's UVM program:

> *Hydro One's cycle for clearing vegetation (forestry) under, around and above distribution lines is more than twice as long as that of comparable utilities. Because trees are not trimmed back as often, Hydro One experiences more outages caused by fallen trees or tree limbs. We noted that line breaks caused by trees were the main cause of distribution outages from 2010 to 2014, responsible for 31% of all outages.*
>
> (Auditor General 2015)

One could argue that a few select removals on high- priority feeder lines could improve the reliability performance. On the other hand, this type of effort would divert resources from the already escalating problem of ROWs spiraling out of control with growth into the lines. This strategy has been tried and what has been learned is that it does improve reliability if select trees are removed.

While the survey has many measurements to consider and the UAA is in the process of designing a best management practice for the industry, a phased in approach with flexibility is appropriate for Hydro One to begin addressing the reliability, safety, cost, and customer service problems caused by a preponderance of off-ROW tree -related outages. The design of a TRA program could involve discussions with regulators and a public discourse to arrive at consensus of what a long-term approach would look like and where responsibilities and funding would be assigned. A TRA program should begin with baseline expectations for on-ROW management to ensure the effectiveness of the practice is not compromised by on-ROW growth and that the program is efficiently administered. Otherwise, the TRA program would not be a best management practice.

Appendix G: Tree Risk Assessment Best Management Practices Survey Results

TABLE OF CONTENTS

INTRODUCTION

The following report represents the results of the *Tree Risk Assessment Best Management Practices Survey* deployed in March 2016. This report will be used by Utility Arborist Association (UAA) to develop a Utility Best Management Practice (BMP) for Tree Risk Assessment (TRA).

Work is currently underway to develop a Tree Risk Assessment (TRA) Best Management Practice (BMP) specific to the utility industry. The BMP will follow the general format and use the risk assessment constructs included in the current ISA TRA BMP (2012). The utility-specific BMP needs to reflect current practices within the industry and provide useful guidance on contemporary best management practices. The results of this survey will help guide development of the new BMP.

How to Navigate the Report

- The Table of Contents (previous page) has links to each graph and table
- All questions (as written in the survey) are given after the survey question number.
- Graphs and comment tables are shown after each question to report on the survey results.
- Responses to the questions are in brackets on comment tables. In other words, if the respondent answered, “Yes”, [Yes] will appear after their comment. This will be true for most comment tables in this report.
- Each participating utility has been given a unique code (Company Code)

CONFIDENTIAL PARTICIPANT INFORMATION

Question 1: Confidential Information. Results not available for publication

COMPANY AND UVM PROGRAM INFORMATION

All questions as written in the survey are given after the survey question number. Graphs and comment tables are shown after each question to report on the survey results.

Responses to the questions are in brackets on comment tables. In other words, if the respondent answered, “Yes”, [Yes] will appear after their comment. This will be true for most comment tables in this report.

Question 1: Please indicate the *Region* in which the majority of your T&D system is located. Note: Map included in survey to locate region in which the utility operates.

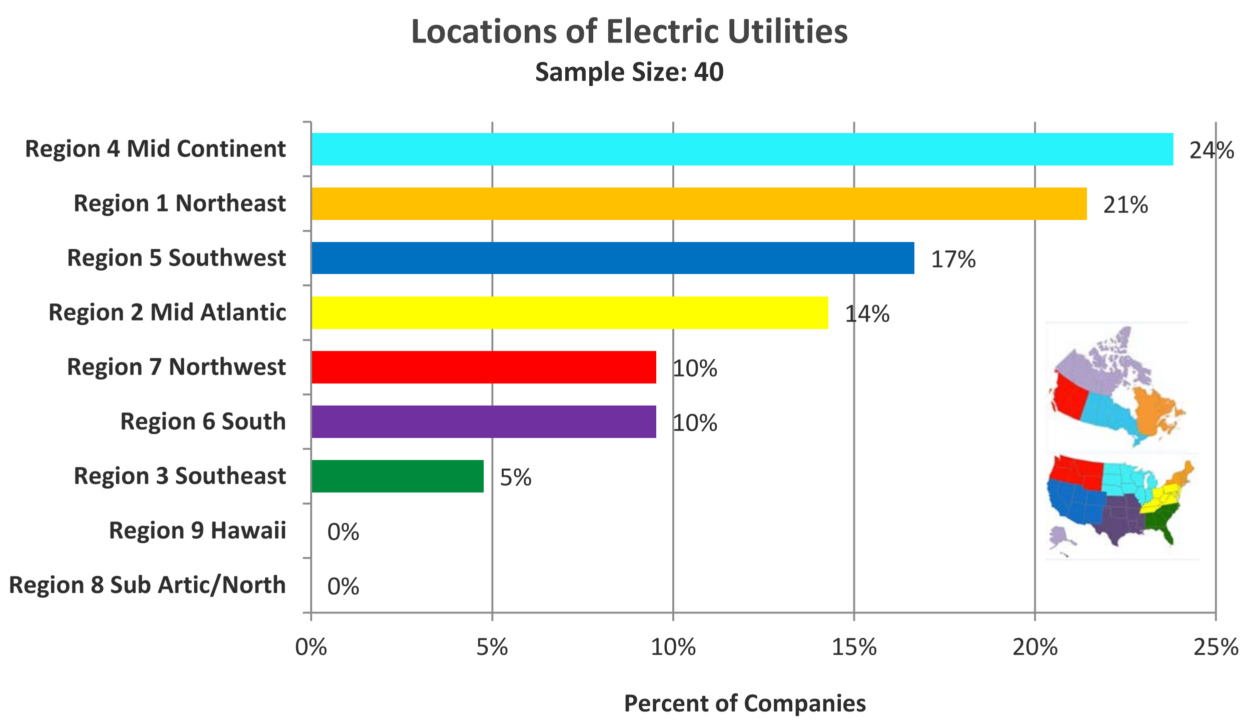

Figure 37: Locations of Electric Utilities

Three participants operated in more than one region and these additional regions are included in the above graph.

Question 2: Please select from your following choices to describe your company type

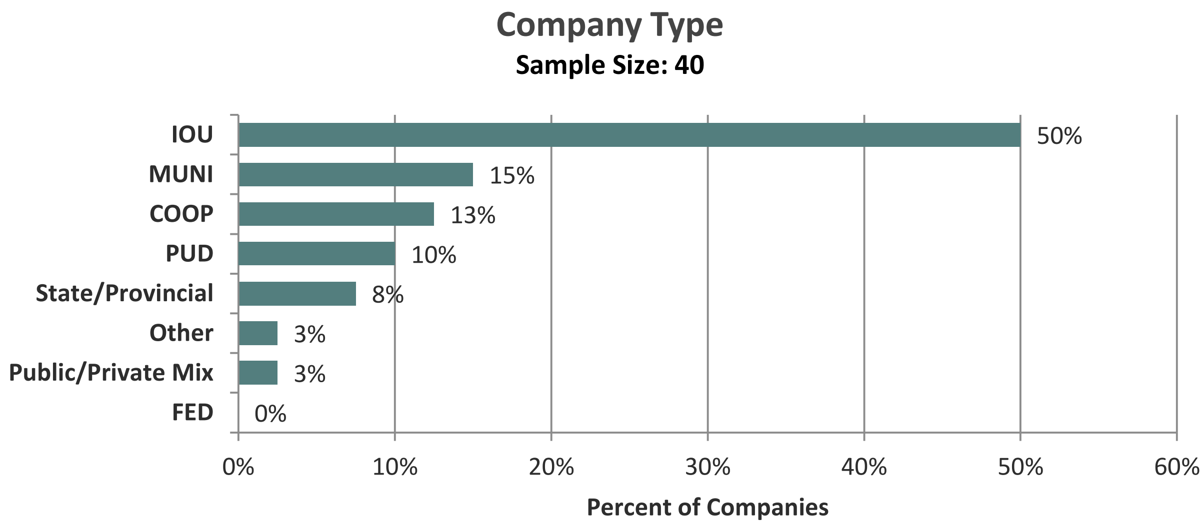

Figure 38: Company Type

Legend:

IOU: Investor Owned Utility

MUNI: Municipal Utility

COOP: Rural Electric Cooperative

PUD: Public Utility District

State/Provincial: State or Provincial Run Utility

FED: Federal Utility

Public/Private Mix: Quasi-Public and Privately Owned Utility

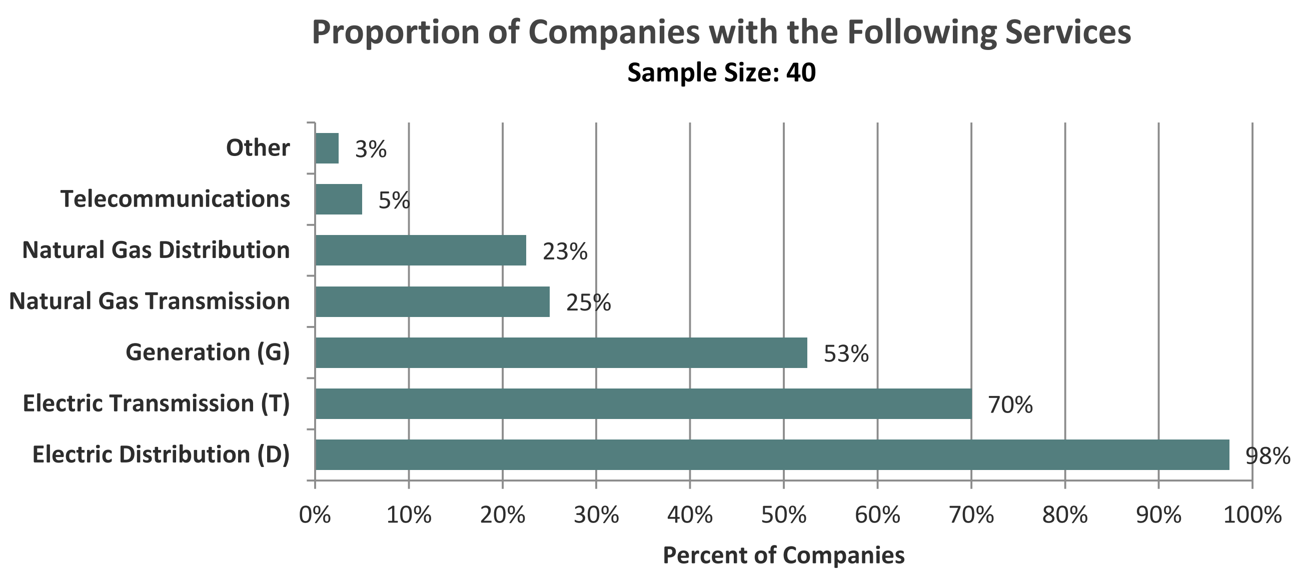

Figure 39: Proportion of Companies with the Following Services

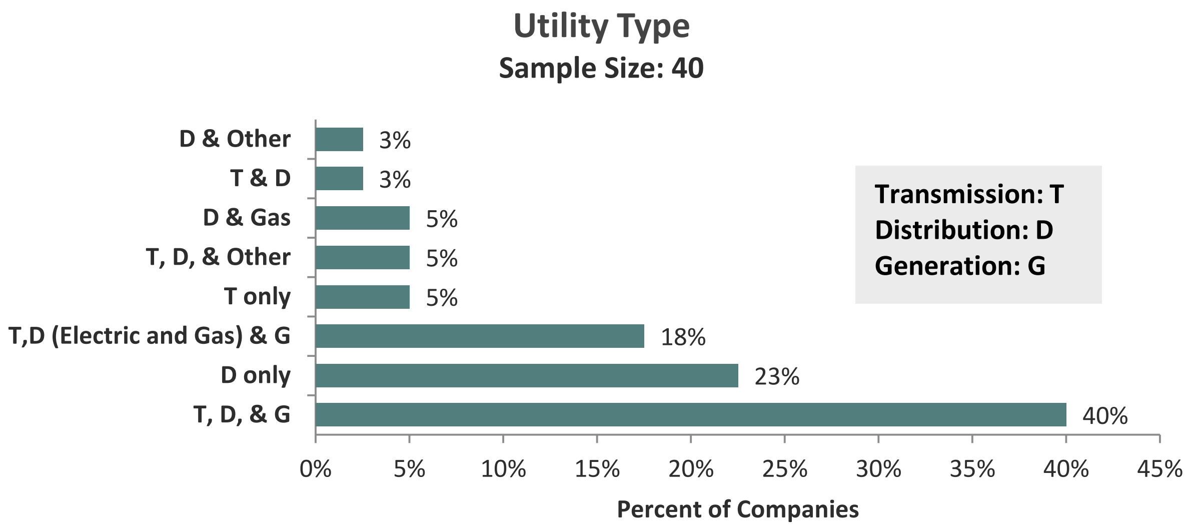

Figure 40: Utility Type

Question 3: How many circuit miles of overhead line in each line type are included on your overhead system within this region?

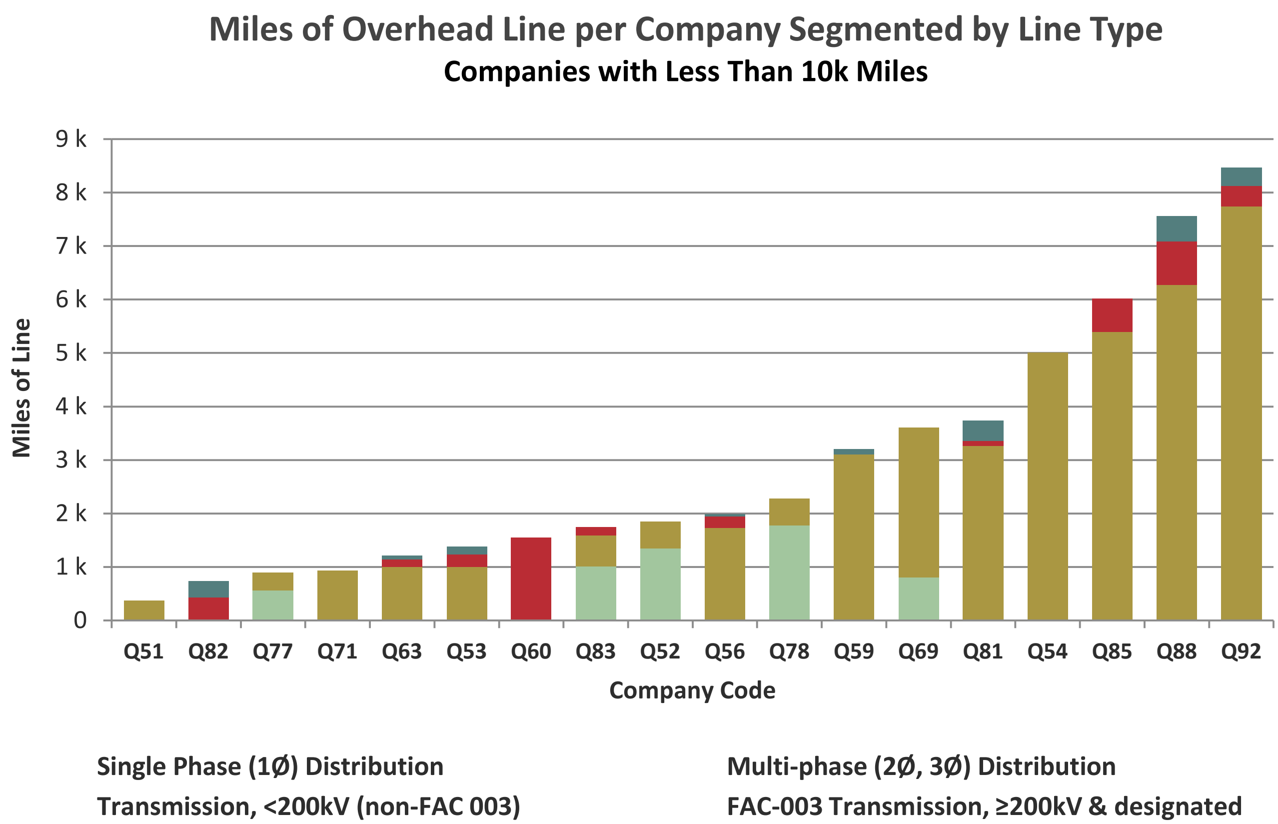

Figure 41: Miles of Overhead Line per Company Segmented by Line Type Companies with Less Than 10k Miles

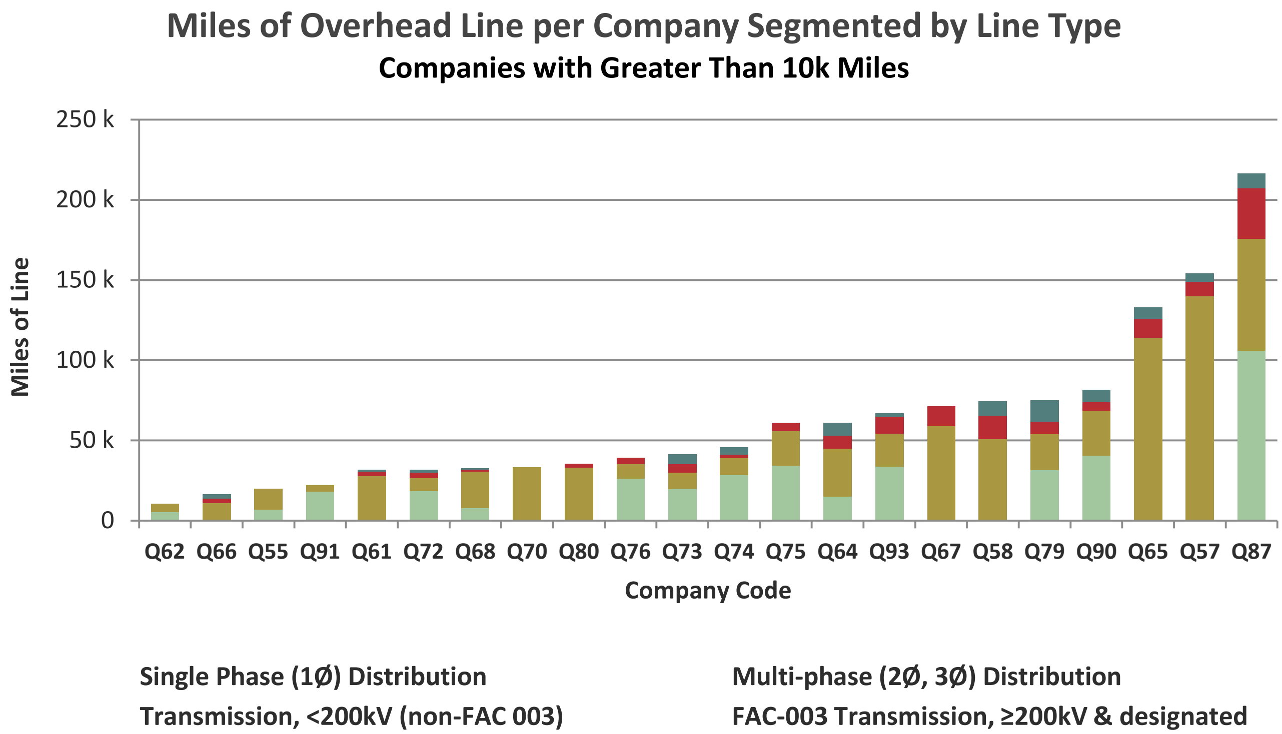

Figure 42: Miles of Overhead Line per Company Segmented by Line Type Companies with Greater Than 10k Miles

	Single Phase (1Ø) Distribution	Multi-phase (2Ø, 3Ø) Distribution	Transmission, <200kV (non-FAC 003)	FAC-003 Transmission, ≥200kV & designated
Miles of Line	398,254	782,276	144,207	80,208

Figure 43: Total Miles of Line Represented by Line Type

Question 4: Do you have a formal Tree Risk Assessment (TRA) program separate from routine maintenance for assessing and managing tree risk involving potentially hazardous trees? Comment on the nature of your Tree Risk Assessment program.

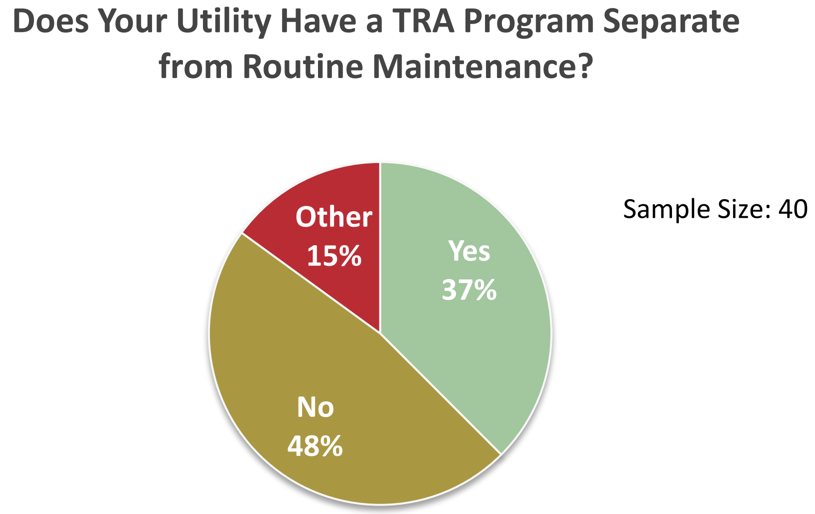

Figure 44: Does Your Utility Have a TRA Program Separate from Routine Maintenance?

Responses to the questions are in brackets on comment tables. In other words, if the respondent answered, "Yes", [Yes] will appear after their comment. This will be true for all comment tables in this report.

TRA Program Descriptions
We have a mid-cycle vegetation patrol for obvious hazard trees [Other]
TRA is conducted as a critical component of routine maintenance [Other]
Yes for mountains of Colorado, focusing on trees killed by Mountain Pine Beetle and other insects in the 'epidemic area'. Otherwise hazard trees are mitigated as part of routine cycle maintenance in all other areas. [Other]
Distribution: Public Safety and Reliability Program addresses live trees with identified failure patterns. 2nd Patrol Program addresses dead or dying trees due to drought, beetle kill. Transmission: [Yes]
Aerial and Ground patrols [Yes]
For our Distribution program [Yes]
We have one of our [ ] foresters [are] train in hazard tree id and dedicate one day per week to looking for hazard trees. [Other]
Trees of a hazardous nature, posing either from limb, branch or tree position or state or decline, or positioning (leaning) are identified during foot patrol of transmission. [No]
We have a hazard tree program on both distribution and transmission systems. [Yes]
Level 2 risk assessment as part of prescriptive work planning [No]
While routine work is being completed, a trained job planner identifies hazard trees/limbs and these are removed at that time. [Other]

TRA Program Descriptions - continued
First we arrange our line in consideration of their outage number per kilometre (poor performing circuit). We patrol the worst fifth (20%) of these lines to detect 10 to 15 trees per km that show imminent risk of failure and we cut 40,000 trees per year. We detect and cut another 10,000 trees per year when patrolling line in the pruning and brush cutting cycle (15% of system about 17,500 Km/per year). We try to obtain owner authorization to cut all of those trees in respect of legal exigence. [Yes]
We complete an annual ground-based patrol and four aerial patrols of which Tree Risk is incorporated. [Yes]
Tree Risk Assessment Protocol built specifically for us based on ANSI Part 9 and TRAQ but modified for utility. [Yes]
Trees may exhibit potential threats to the facilities due to disease, damage, physical location, growth characteristics or environmental problems. Where these trees exist, the utility considers them high priority risks that need to be addressed and remediated. [No]
We have a program but it is very basic. Any dead, dying or significantly leaning trees are identified. We make a filed decision to remove or trim. This is only for our NERC/FERC facilities [Other]
The TRA is completed within the Asset Defect Program. [Yes]
Select potential hazard tree for removals [Yes]
Potential Danger trees identified during routine maintenance of circuits. Have utilized Intern to do Danger tree inventory on distribution. [Yes]
EHTM - Enhanced Hazard Tree Mitigation ranks circuits based upon customer count, miles of three phase bare wire, Tree exposure, & three year average for Customer Impacted per tree event and total customers impacted. Review Intensity is very robust from station breaker to 1st protection device. Intensity of review is reduced as progress moves beyond each protection device further out on a circuit. Customer count from protection device to end also dictates level of review. [Yes]

Comment Table 1: TRA Programs Descriptions

The following graph integrates the answers from Questions 3, 4, and 5.

	Distribution Only Companies: Sample 12	Distribution & Transmission and Transmission Only Companies: Sample 28
Have Separate TRA Program	17%	46%
Do NOT Have Separate TRA Program	58%	43%
Other	25%	11%

Figure 45: Separate TRA Program by Company Type

Question 5: Is your Tree Risk Assessment program modeled after Level 1 Tree Risk Assessment practices as described in ANSI A300 Part 9 and the current ISA TRA BMP?

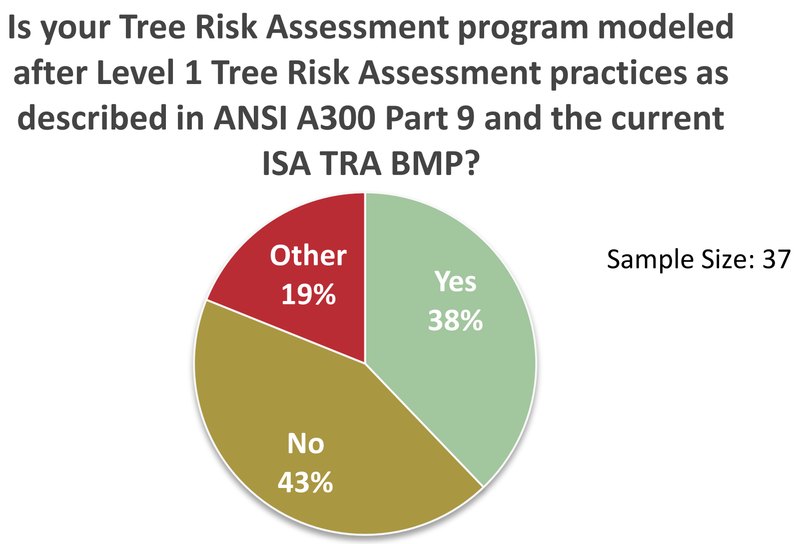

Figure 46: Is your Tree Risk Assessment program modeled after Level 1 Tree Risk Assessment in ANSI A300?

TRA Program Practices in Relation to ANSI A300 Part 9
We employ professional arborists who have qualifications such as college degrees in forestry, ISA arborist certified, utility arborist certified, and/or hold State tree expert certifications plus have on the job experience. Current vegetation management specifications require identification, evaluation and mitigation of trees as described in a Level 1 TRA. Today our current specifications do not reference ANSI A300 Part 9. [Yes]
[Province] has the "[Province] Reliability Standard" which is modeled from the NERC Standards. [Other]
Ours is based on the UAA Utility Best Management Practices Tree Risk Assessment and Abatement for Fire Prone States and Provinces in the Western Region of North America [Other]
To my knowledge our program is not modeled after others, but our guy, [ ], is using principals learned from a week long certification class attended last year. [Other]
Overhead inspection of 33% of the plant each year to identify hazards and high priority actions. [No]
Developed in-house [Other]
ANSIA300 part 9 is unknown here in [Province]. [No]
We use the same terminology for Level 1, visual and limited visual assessment. [Yes]
1. Visual Assessment While performing work on a circuit, contract crews shall conduct a visual assessment to identify trees with imminent and/or probable likelihood of failure inside and outside the right-of-way. The tree should be viewed from some distance away, if possible, to consider crown shape and surroundings. Any tree identified to be a potential imminent threat to a utility line shall be reported to the responsible forester. [Yes]
[Utility]'s Level 1 would be the most intense review including a 360 survey of each tree. This is from the station breaker to the first protection device or beyond depending on calculated customers served on the specific circuit. *** A [Utility] level 3 would equate to a level 1 per ANSI A300

Comment Table 2: TRA Program Practices in Relation to ANSI A300 Part 9

Question 6: Does your company have specified and formally documented procedures to elevate the level of inspection intensity of a tree or site from Level 1 to Level 2 and/ or Level 3?

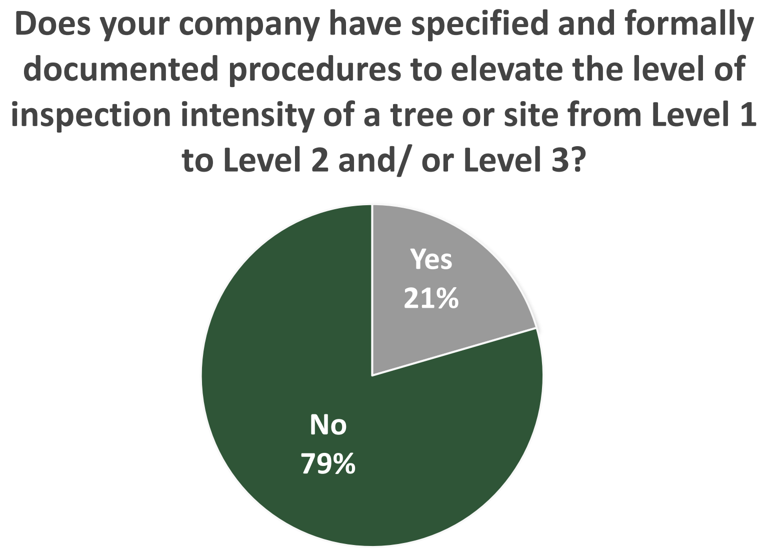

Figure 47: Does your company have procedures to elevate the level of inspection intensity?

TRA Level of Inspection Intensity
Due to the small size of our area, we inspect and complete any work identified in the same year. [No]
If hazard trees are identified in a level one assessment, inspectors are expected to look farther into the issue. [No]
Trees posing an imminent threat are reported immediately and removal is governed by timeline. Formalized program to manage trees of risk. [Yes]
We have developed inboard criteria. [Yes]
We state that we only elevate to Level 2 (we don't have the means for level 3). We have defined required action/assessment based on defect levels. [Yes]
Only to Level 2. Program is conservative and will take any trees that are a threat without the need of a Level 3 evaluation. [Level] 2. Ground Evaluation: If a Hazard Tree is identified during the visual assessment, a 360° ground evaluation shall be required. The evaluations should include an inspection of: * Tree crown * Trunk * Trunk flare * Above-ground roots * Site conditions around the tree in relation to targets. The Contractor shall report risk and mitigation options to the responsible utility forester. [Yes]
Our level 2 is a Moderate Inspection Intensity and is conducted beyond the first protection device out to a calculated customer service point or pre-determined number of customers served. Level 3 is an Imminent Risk Inspection. Again, a calculated customer service point determines the intensity of tree inspection. [Yes]

Comment Table 3: TRA Level of Inspection Intensity

Question 7: Do you use a Visual Tree Assessment (VTA) checklist or risk evaluation form that is intended to assign a numeric score to tree related risk?

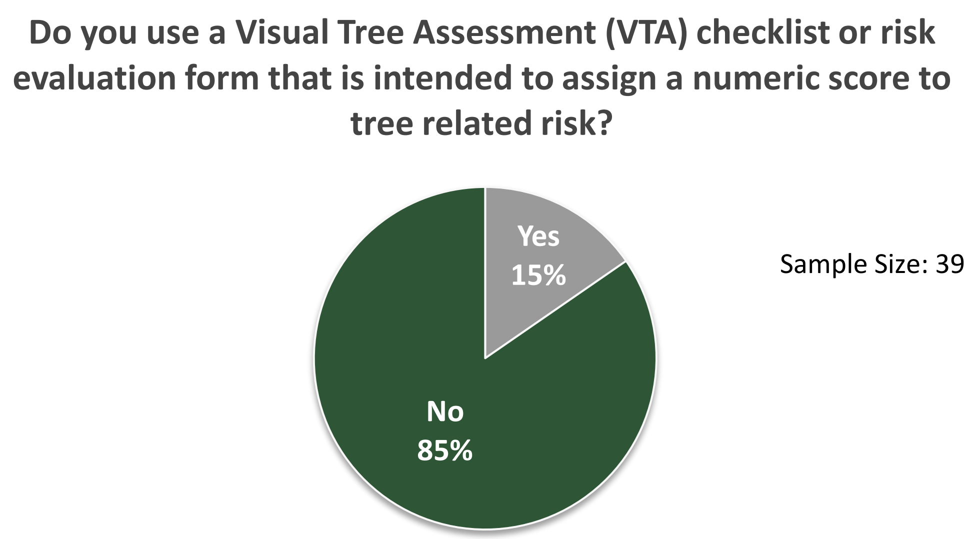

Figure 48: Do you use a Visual Tree Assessment (VTA) checklist intended to assign a numeric score to tree related risk?

Risk Evaluation Descriptions
Derived internally and incorporates circuit information and customer counts, site specific weather patterns, and common failure patterns derived from internal outage investigations. [Yes]
Some of us had the formation and we integrated the principle in our process. [Yes]
We do use a form, but it does not assign a numeric value. It leads you to an action based on a matrix. [No]
Numeric score is just prioritization depending on tree assessment and site conditions (voltage, type of construction etc.) [Yes]

Comment Table 4: Risk Evaluation Descriptions

Question 8: Which best describes the type of vegetation inspection(s) conducted on your system? Please enter an estimated percent (%) of total line miles inspected for each line type. *NOTE: Each graph for Question 8 is arranged by percent of lines inspected annually with the most on the right.*

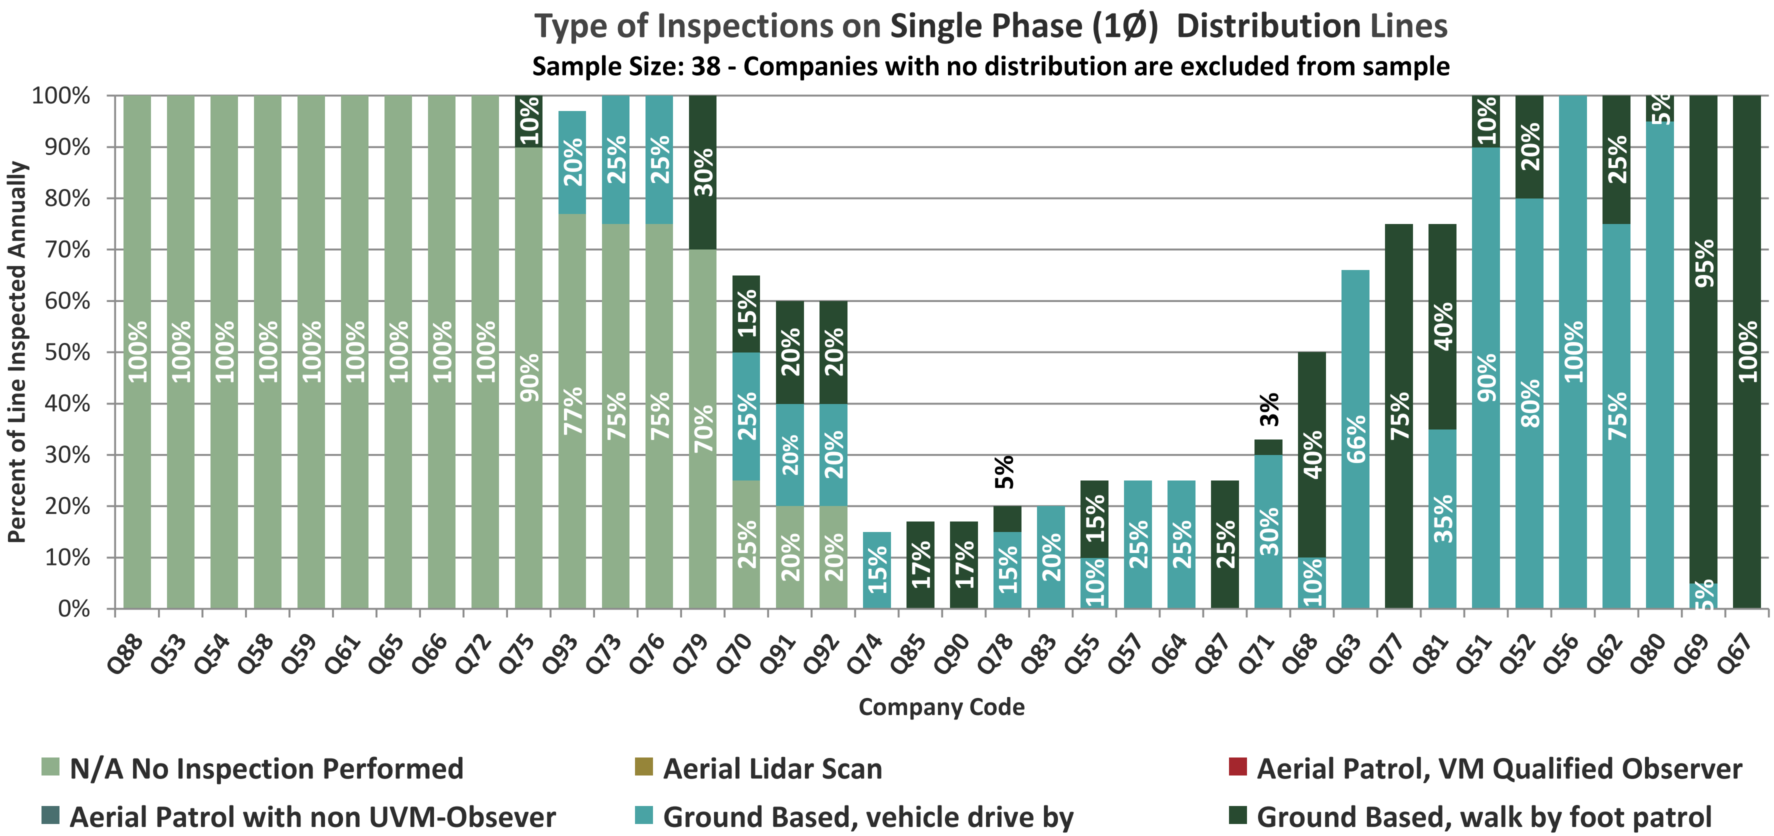

Figure 49: Types of Inspections Performed on Single Phase Distribution Annually

Statistics on Annual Inspection for Single Phase Distribution Lines:

- 18% Inspect 100% of the Single Phase Lines Annually
- 24% Do Not Inspect Any of The Single Phase Lines

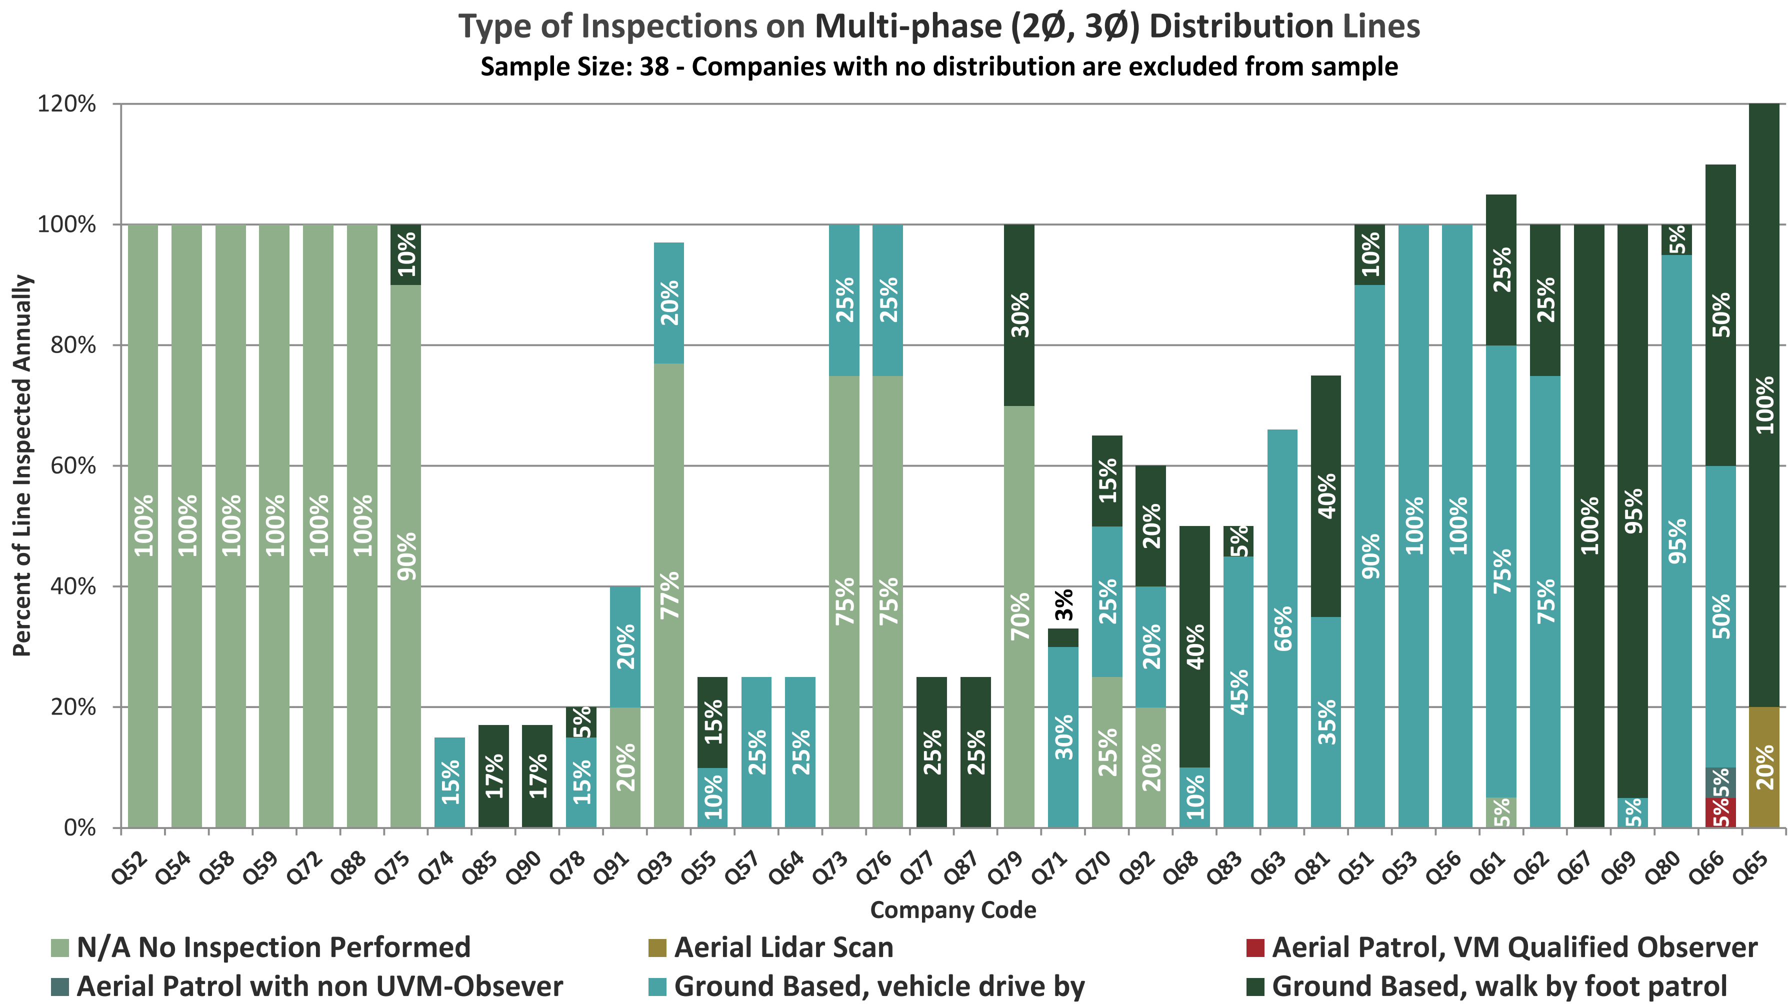

Figure 50: Types of Inspections Performed on Multi Phase Distribution Annually

Statistics on Annual Inspection for Multi-Phase Distribution Lines:

- 26% Inspect 100% of the Multi-Phase Lines Annually
- 16% Do Not Inspect Any of The Multi-Phase Lines

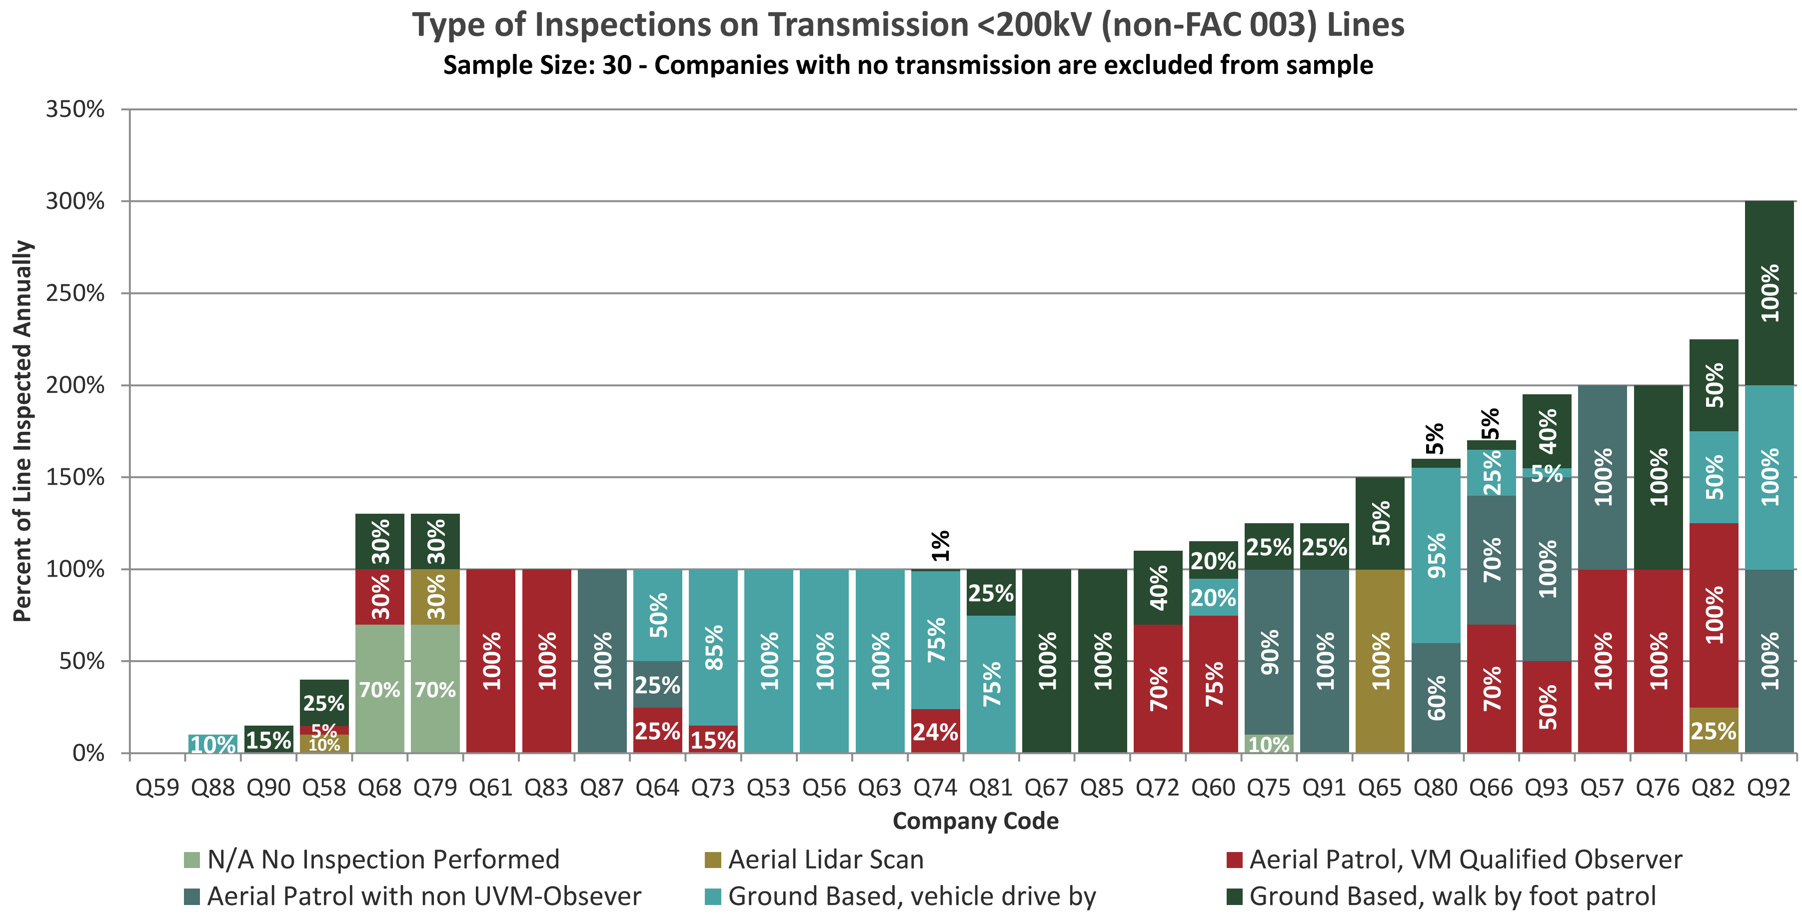

Figure 51: Types of Inspections Performed on Non-FAC-003 Regulated Transmission Lines Annually

Statistics on Annual Inspection for Non-FAC-003 Regulated Transmission Lines:

- 63% Inspect 100% of the Non-FAC-003 Regulated Transmission Lines Annually
- 3% Do Not Inspect Any of The Non-FAC-003 Regulated Transmission Lines

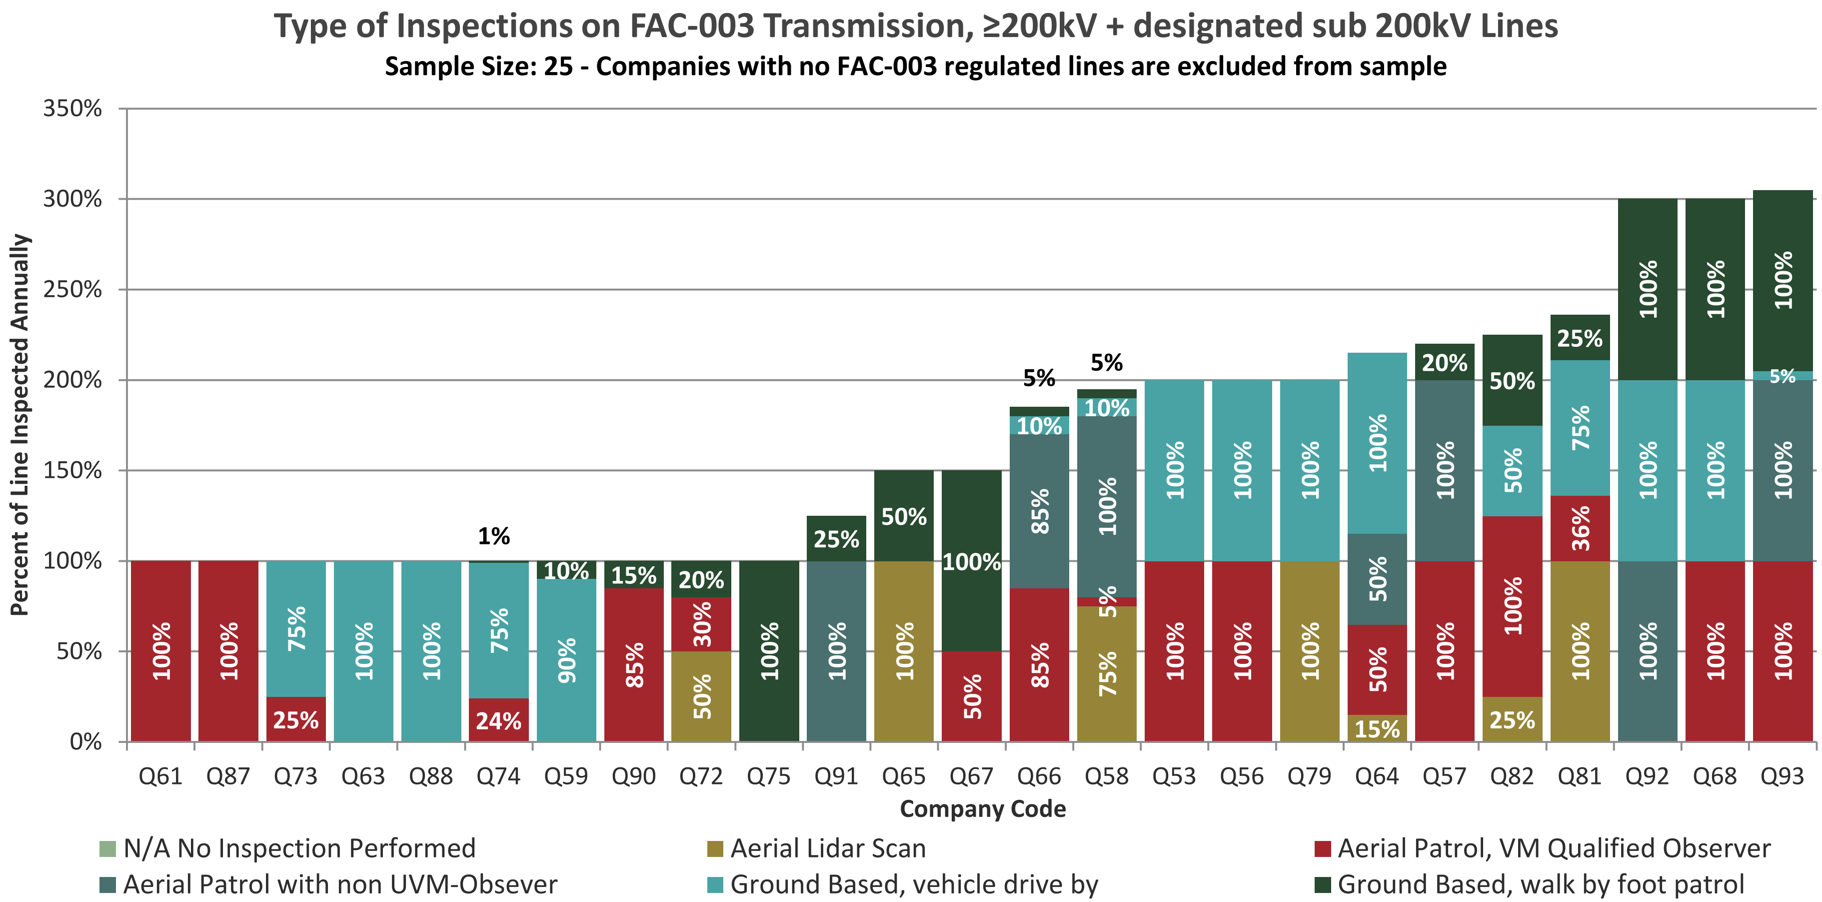

Figure 52: Types of Inspections Performed on FAC-003 Regulated Transmission Lines Annually

Statistics on Annual Inspection for FAC-003 Regulated Transmission Lines:

- 100% Inspect 100% of the FAC-003 Regulated Transmission Lines Annually
- 60% Use Multiple Methods of Inspection for Some of the FAC-003 Regulated Transmission lines

Comments on Types of Inspections
All distribution are patrolled (either vehicle or foot if private property) based on feeder classification. Urban is trimmed every 4 years, rural every 6 with each inspection at mid-point
fixed wing monthly on all BES by non UVM-observer
Some of the foot patrols are followed by aerial patrol.
100% of lines above 200kV are inspected annually
Line patrol for hardware and trees 5-year cycle
LiDAR is once every 5th year.
We patrol all 230kV facilities twice a year, should be 200% in the 230kv category
In 2015 we captured Lidar on all FAC 003-3 lines in one Jurisdiction including pending 115kV IROL circuits. To date it is not an annual inspection tool

Comment Table 5: Comments on Types of Inspections

Percent of Companies That Perform Inspections Annually by Inspection Type

	No Inspection Performed	Aerial Lidar Scan	Aerial Patrol, VM Qualified Observer	Aerial Patrol with non UVM-Obsever	Ground Based, vehicle drive by	Ground Based, walk by foot patrol
1Ø Distribution (Sample 38)	21%	0%	0%	3%	63%	61%
2Ø, 3Ø Distribution (Sample 38)	24%	3%	3%	3%	66%	61%
Transmission, non-FAC 003 (Sample 30)	3%	10%	43%	30%	43%	57%
FAC-003 Transmission (Sample 28)	0%	21%	57%	25%	54%	68%

Figure 53: Percent of Miles Inspected by Line and Inspection Type

	No Inspection Performed	Aerial Lidar Scan	Aerial Patrol, VM Qualified Observer	Aerial Patrol with non UVM-Obsever	Ground Based, vehicle drive by	Ground Based, walk by foot patrol
1Ø Distribution (Sample 38)	12%	0%	0%	0%	23%	17%
2Ø, 3Ø Distribution (Sample 38)	12%	1%	0%	0%	27%	18%
Transmission, non-FAC 003 (Sample 30)	0%	5%	28%	25%	27%	24%
FAC-003 Transmission (Sample 28)	0%	13%	39%	23%	37%	29%

Figure 54: Average Percent of Miles Inspected Annually by Line Type and Inspection Type

Question 9: Which best describe the intended frequency of vegetation inspections completed as part of a deliberate inspection program (rather than informal, incidental inspection). Check all that apply

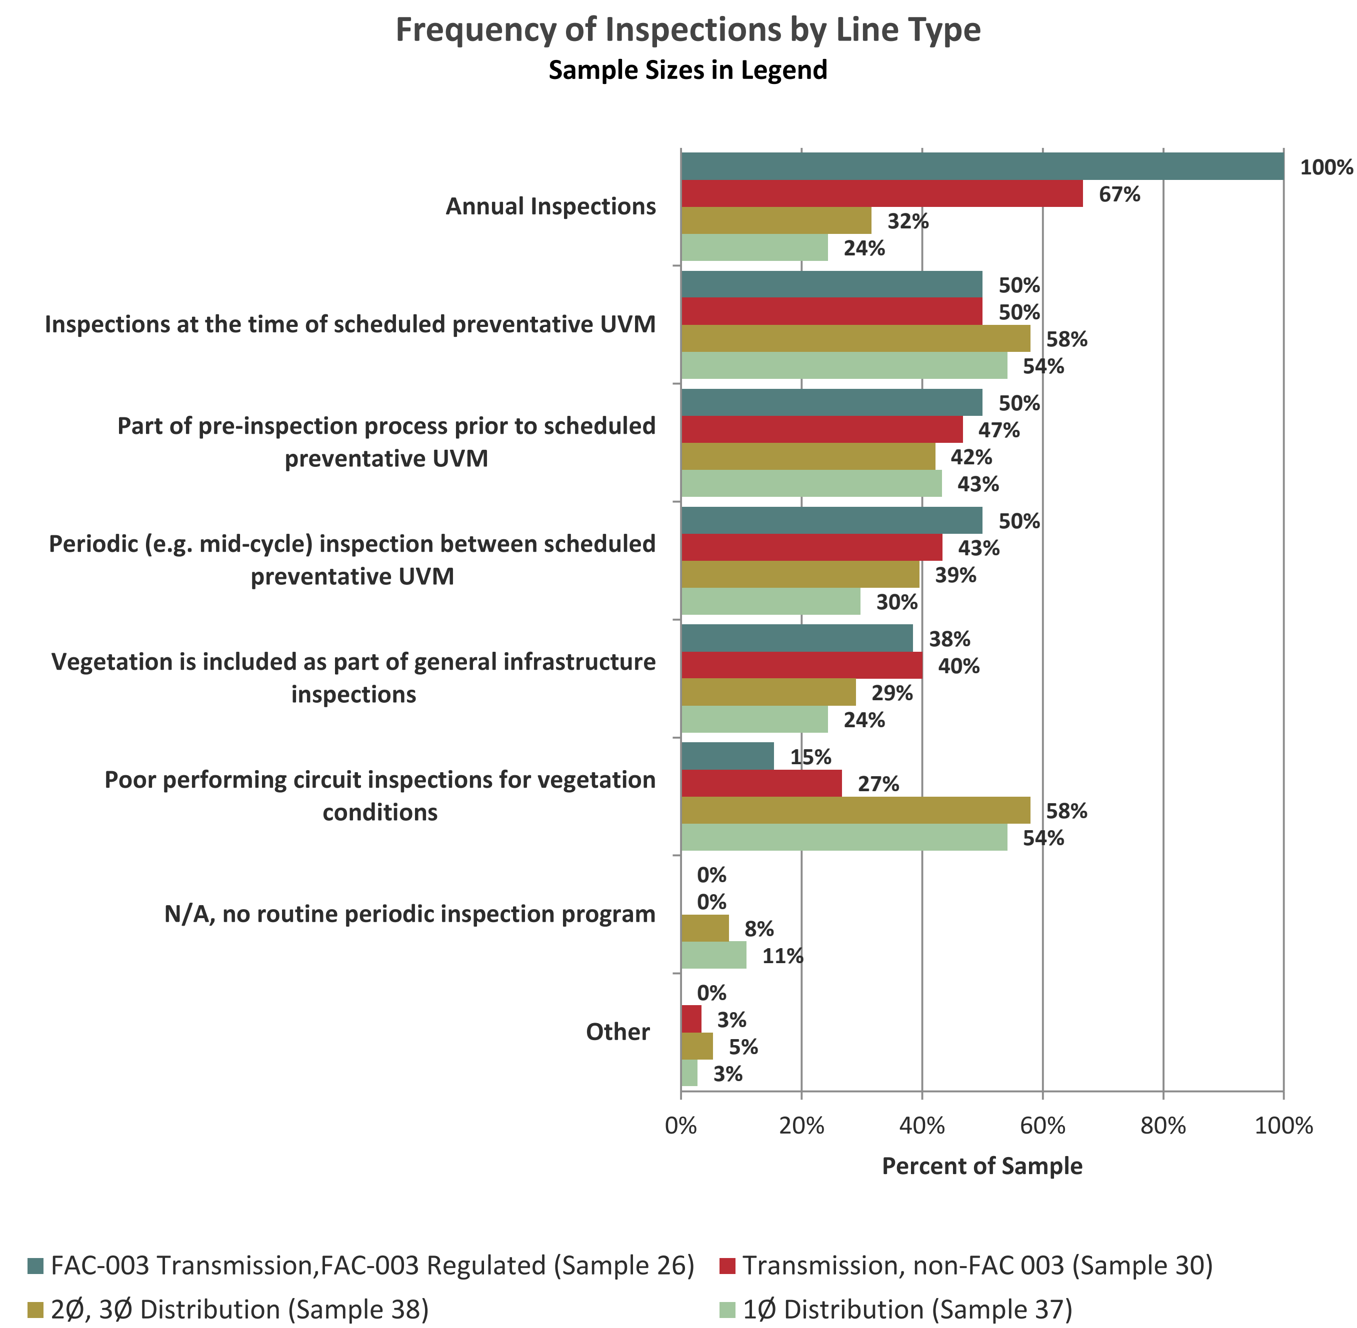

Figure 55: Frequency of Inspections by Line Type

Comments on Frequency of Inspections
For maintenance trimming, typically have a planner do a pre-inspection, crews perform inspections at time of trimming, and General Foreman does a post-trimming quality assessment.
DISTRIBUTION: random inspections by operations personnel for circuits of interest. Level 1 inspections by veg management of circuits experiencing significant general reliability issues or increased customer complaints.
Quarterly aerial patrols with qualified VM personnel of all 200kV and greater transmission corridors.
We added "Post Storm" inspections to our program a couple years. We usually find more risk trees per mile immediately after a major storm event. [Other]
We consider anytime that we are out looking at circuits that we are on inspection/ patrol
Line patrol 5-year cycle
100% post audit for all NERC VM control activities, and 7 to 8% post audit for everything else.
We patrol our 40 miles of 138kV and selected priority 69kV (tie line) facilities.

Comment Table 6: Comments on Frequency of Inspections

Question 10: Which best describes the qualifications of personnel who regularly perform Tree Risk Assessments (TRA)? If more than one category of Assessment Personnel is involved for a line type, please indicate the percent (%) of line miles inspected by each.

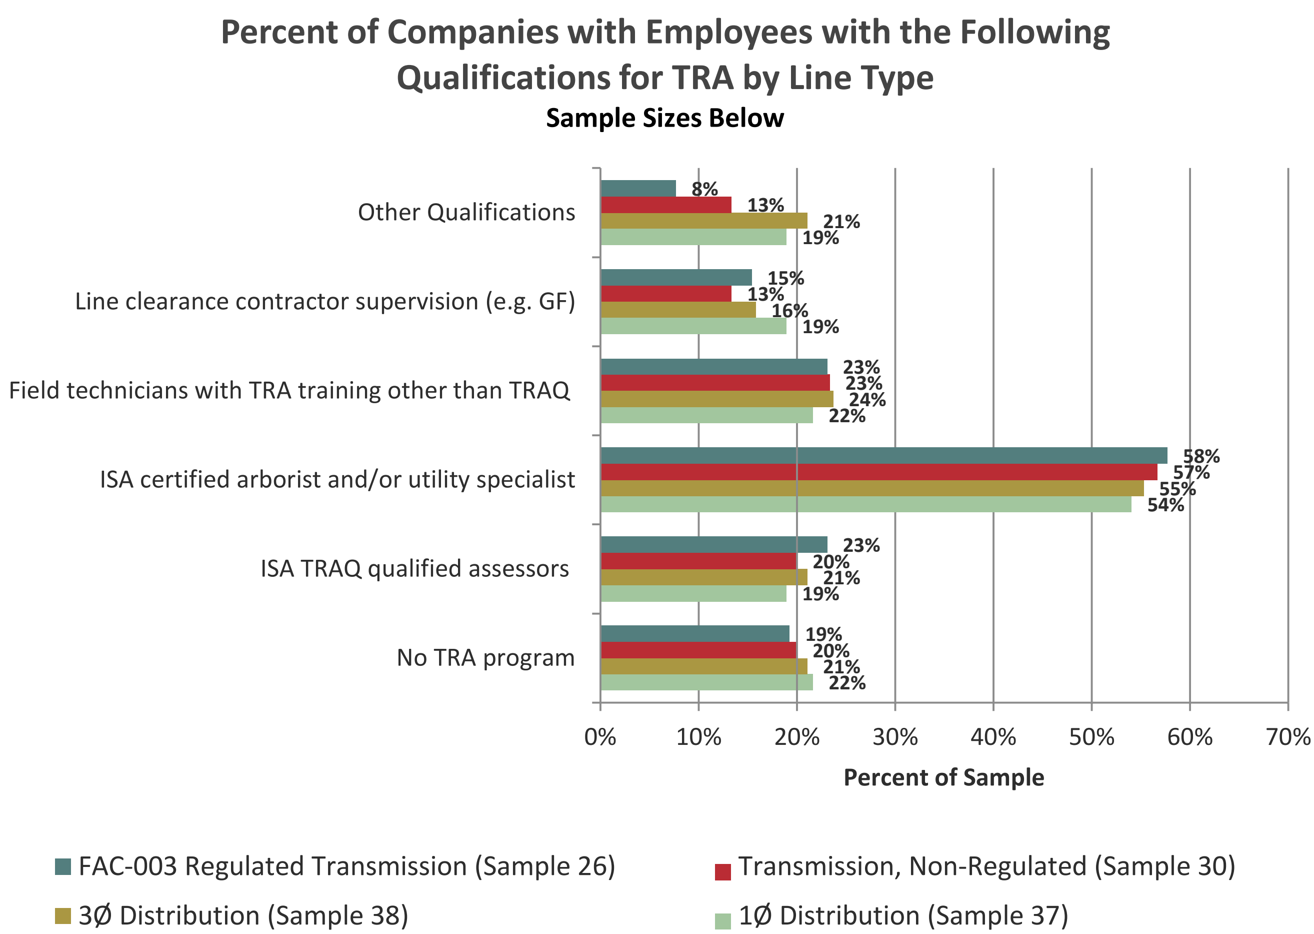

Figure 56: Percent of Companies with Employees with the Following Qualifications for TRA by Line Type

Other Qualifications for Inspectors
Our contract foresters have additional TRA training programs through their parent employer.
Internal risk tree assessment protocol training
Other qualifications are degreed foresters.
We do not have a separate TRA program, but we do have trained planners evaluating and looking for high risk whole tree failures and co-dominate branching during our VM cycle
It's an internal equivalent
We do not currently perform TRA.
Power Lineman
Forestry Technicians
Line clearance contractor supervision is also ISA certified arborists.
UVM contractor personnel with general working knowledge of obvious hazards; administered by dedicated utility forester.
Powerline Technician that is also a Safety Codes Officer

Comment Table 7: Other Qualifications for Inspectors

TRA Inspection Qualifications for 1Ø Distribution

Statistics Table 4: Percent of Miles Inspected By Personnel with Given Qualifications for FAC-003 Regulated Transmission

Question 11: Do you have formal specifications that codify requirements for Tree Risk Assessment?

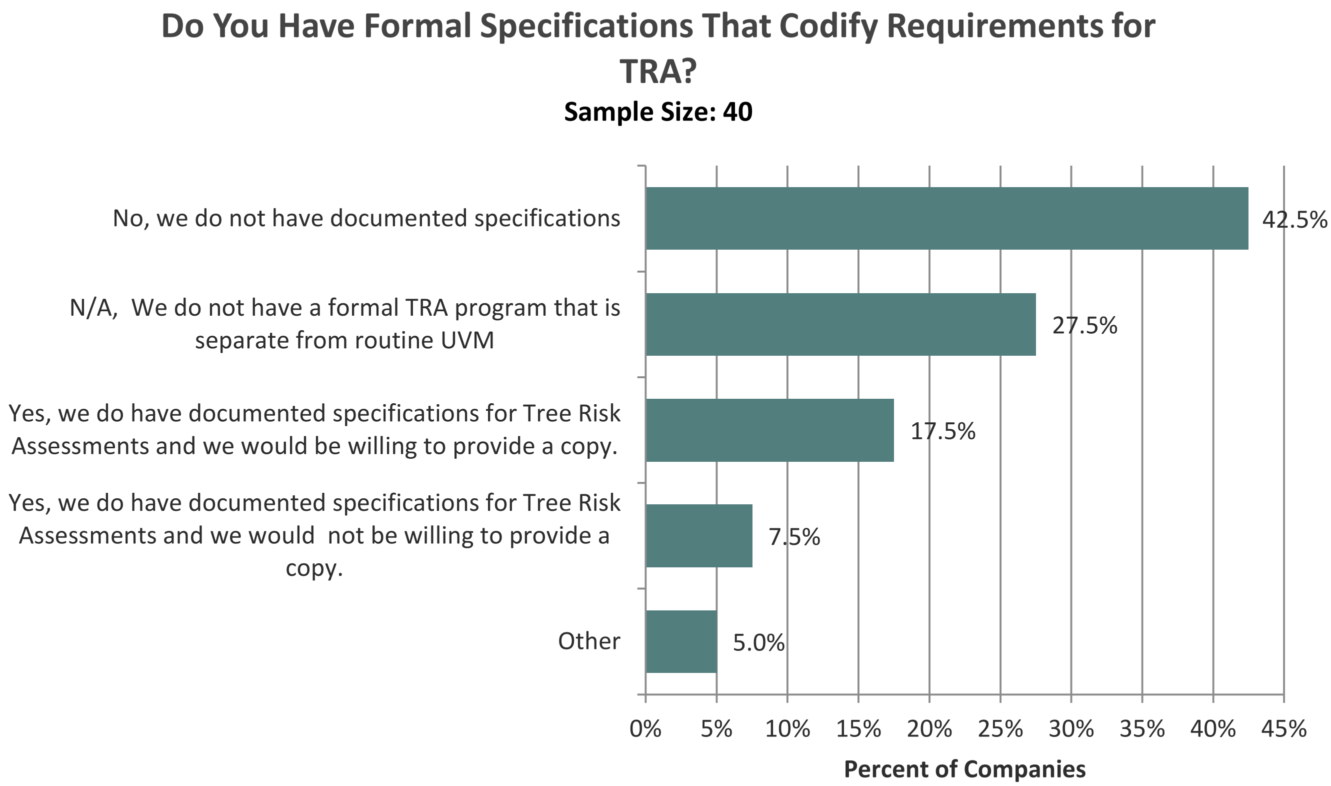

Figure 61: Do You Have Formal Specifications That Codify Requirements for TRA?

Formal Specification for TRA Comments
We have a general approach on risk vs target (voltage/facilities). For example a tree with slight risk for a single phase line would not be acceptable risk for sub-T radial feed [Other]
Experience and common sense is our guide! [N/A, No]
We do not have a formal TRA program that is separate routine UVM [N/A, No]
I would need approval from the vendor who helped us develop the material, as it is copyrighted. [Yes, will provide copy]
Specifications are specific to FAC-003 applicable lines. [Yes, will *not* provide copy]
As [we] gather more data we expect to craft specs. [N/A, No]
Most of TRA program is routine UVM, we are currently doing inspections and collecting danger tree inventory on Distribution. Transmission is done during annual and mid-cycle inspections [Other]
We craft our specs ourselves and we do inform our personnel. And our spécifications are in French. [Yes, will provide copy]
We have a section in our Vegetation Management Guidelines Book that refers to hazard tree expectations (section 2.2). [Yes, will provide copy]

Comment Table 8: Formal Specification for TRA Comments

Question 12: Do you provide or require training for Tree Risk Assessment assessors?

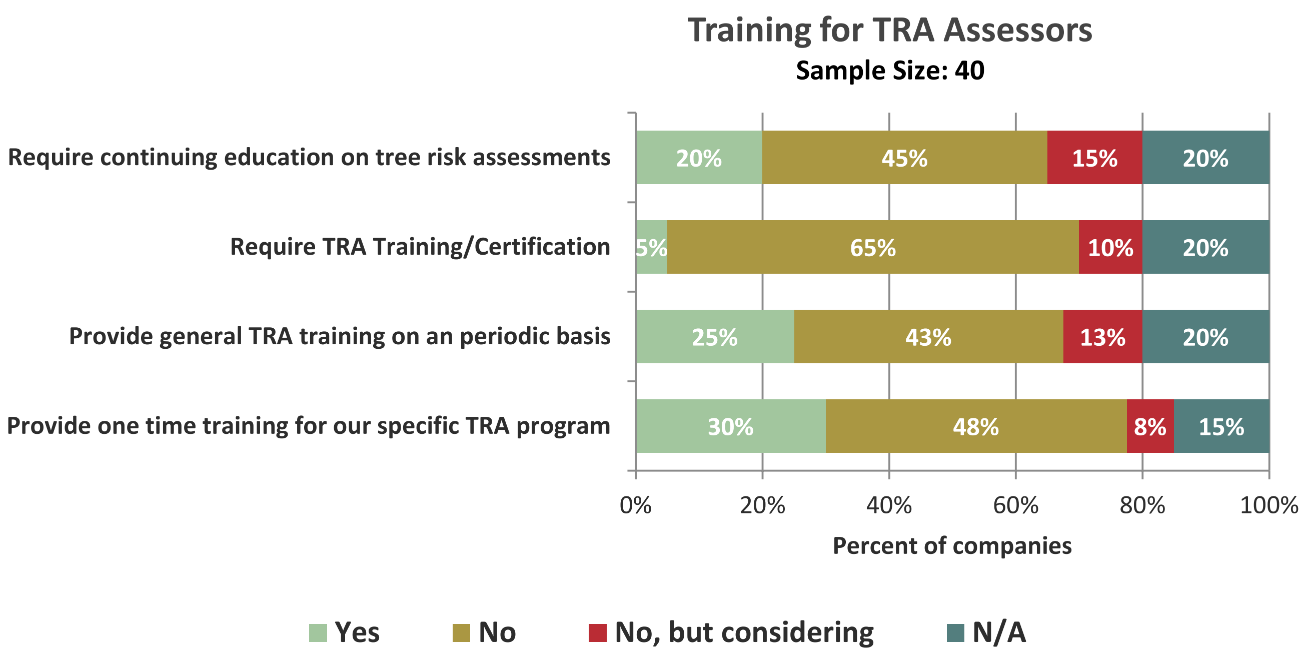

Figure 62: Training for TRA Assessors

Other Training Scenarios
Annual training along with specification review
Transmission specialist with an understanding of the Clearance requirements in the Alberta Reliability Standard.
Distribution: Review general expectations with available UVM contractor inspectors to identify trees that are obviously hazardous (i.e. dead trees, leaning, etc.); Transmission: Utilize experienced internal utility transmission foresters to perform aerial inspections, with subsequent follow-up ground assessments by contractor personnel if needed.
Contractor lead trainings
The ISA TRA requirement of re-testing and no CEUs is ridiculous. I will not be re-certifying when my certification expires.
[Inspection contractor] volunteered to have one of their foresters trained, which has proven very valuable to our informal TRA program
Annual training as an aspect of general orientation
We provide our on specific training for determining hazard trees and profession judgement
MN tree inspector license and MN first pest detector
Annual training for anyone involved with FAC003-3

Comment Table 9: Other Training Scenarios

Question 13: Which best describes the normal/expected location (viewing position) from which routine ground-based Tree Risk Assessment is conducted? Please indicate the one Assessor Location which best describes what is done on each type of line.

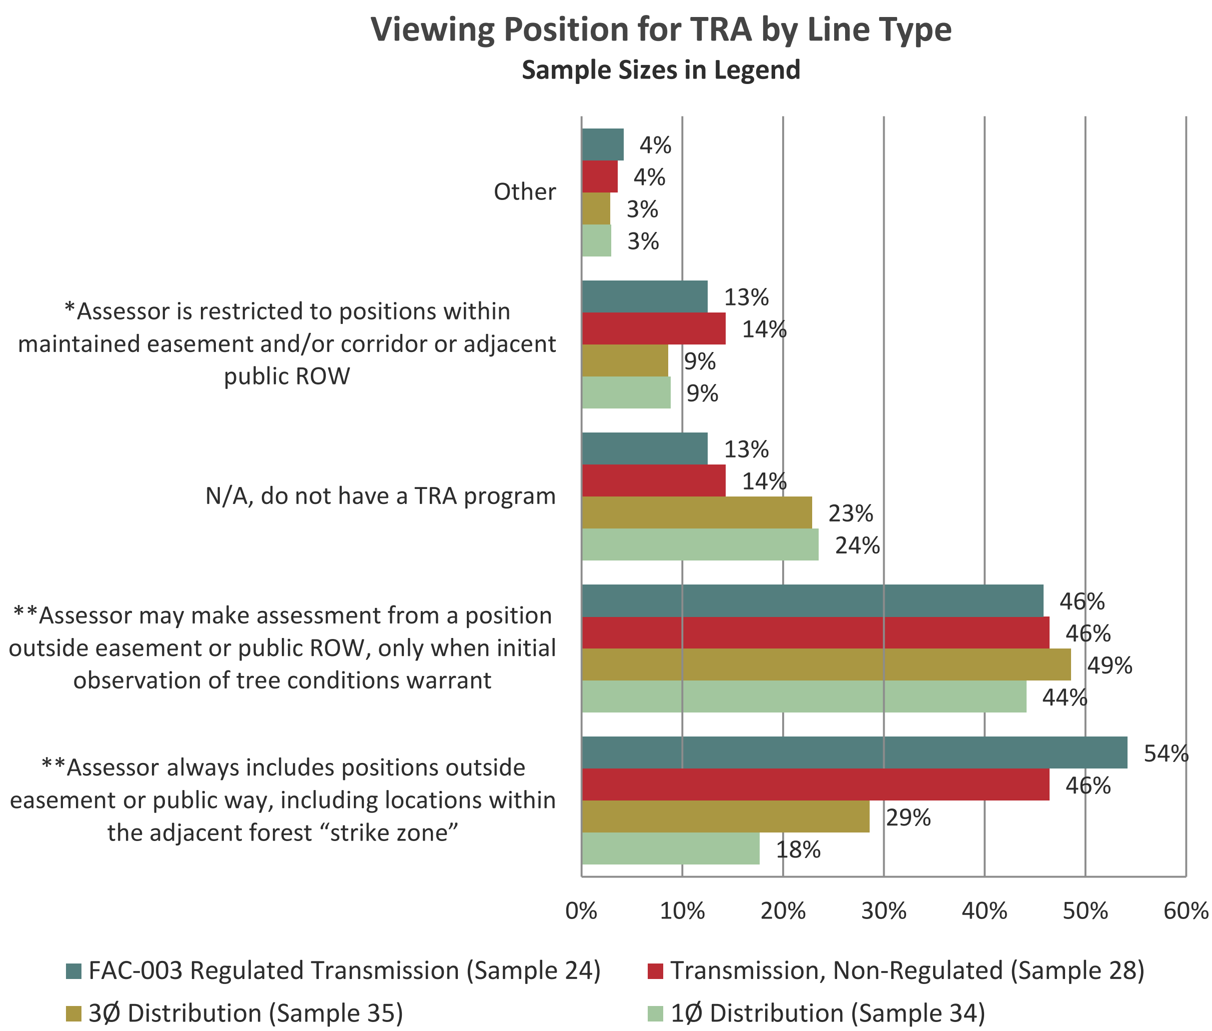

Figure 63: Viewing Position for TRA by Line Type

Three companies chose more than one response per multi-phase and transmission line types:

- *One company chose this response *and* the responses labeled ** and ***
- Two companies chose responses labeled ** and ***
- Therefore, these categories do not add to 100%

Comments

- We do not have any rule on observation positioning for our TRA program
- I don't understand what you're getting at with this question. We can inspect our lines from outside or inside the easement as needed and we do.

Question 14: Which approach best describes the primary area of focus for Tree Risk Assessment (TRA) on each of the four line types?

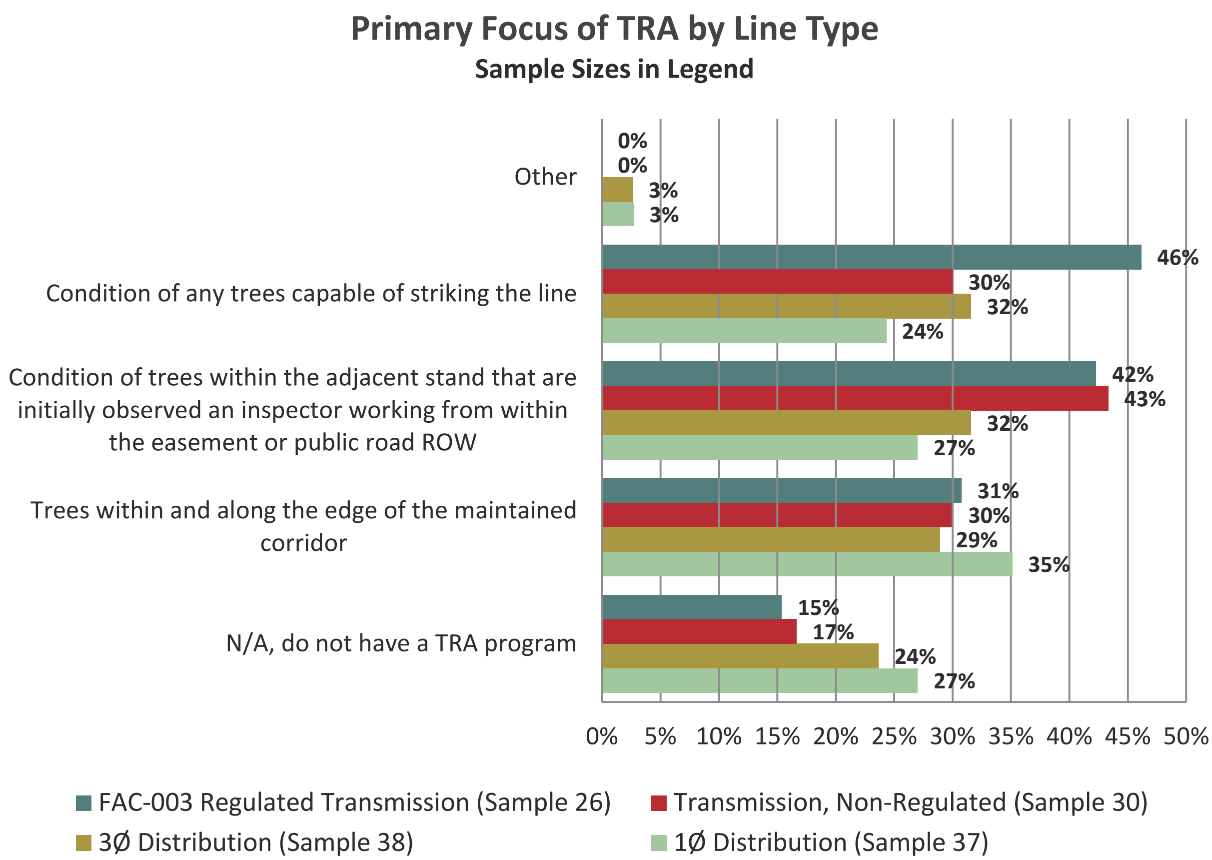

Figure 64: Primary Focus of TRA by Line Type

Other: Risk trees can be mitigated as far away from line as needed

Question 15: Please identify the types of rights you have to inspect and mitigate risks posed by Off ROW trees, by indicating the estimated percentage (% of total line miles) of Off ROW Rights for each line type.

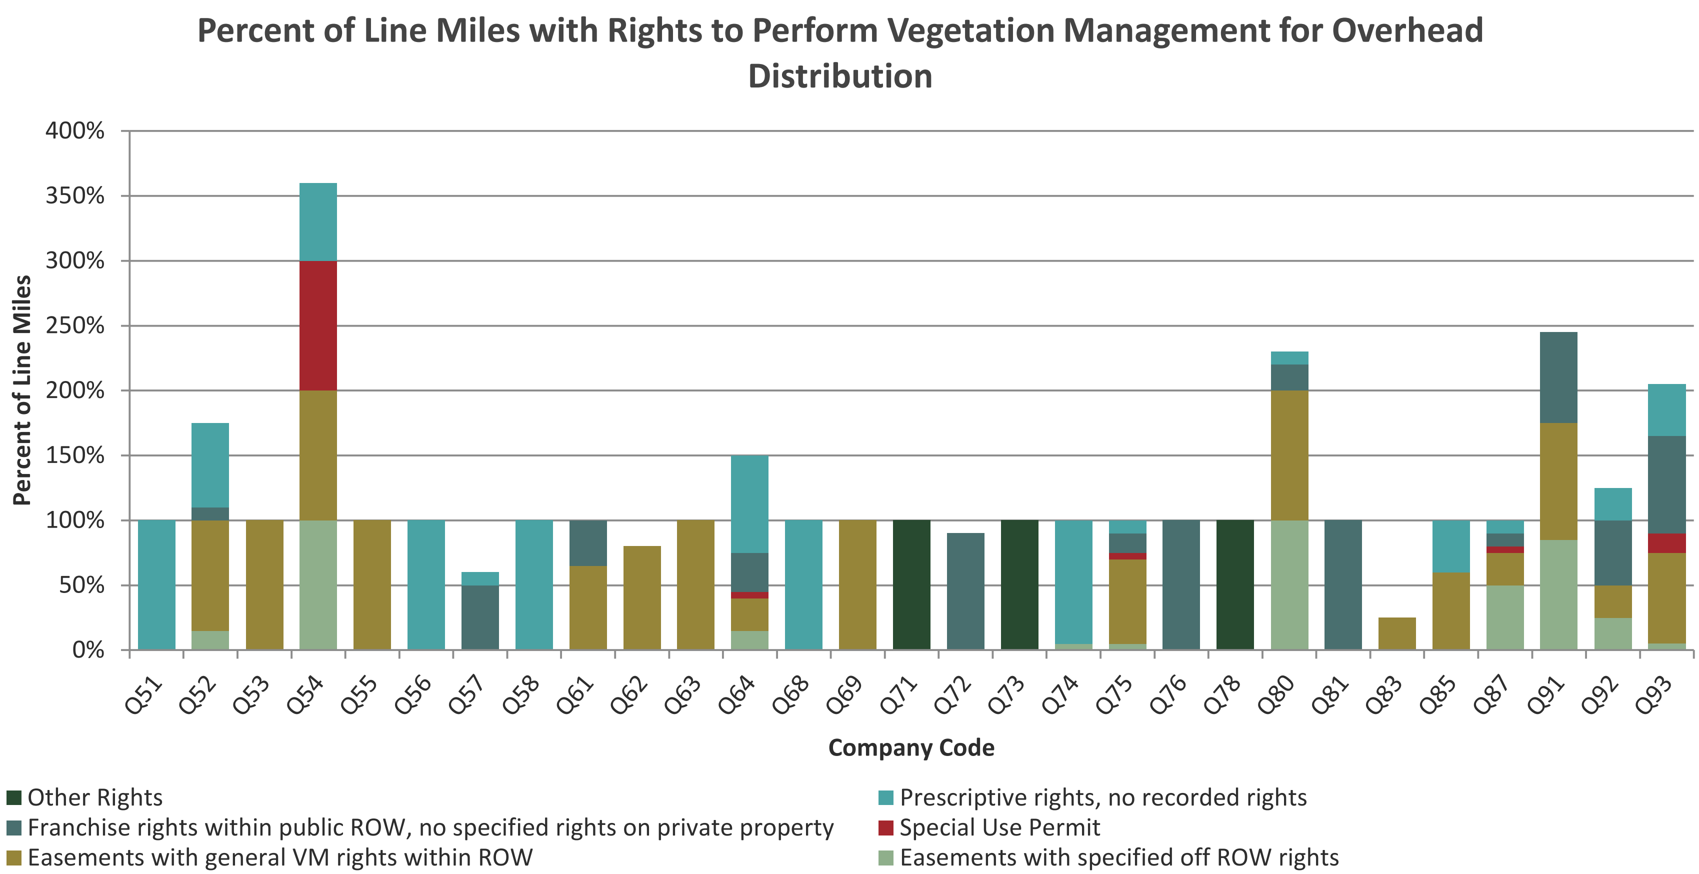

Figure 65: Percent of Line Miles with Rights to Perform Vegetation Management for Overhead Distribution

- **26% Reported 0% in all categories (Total Sample: 34)**

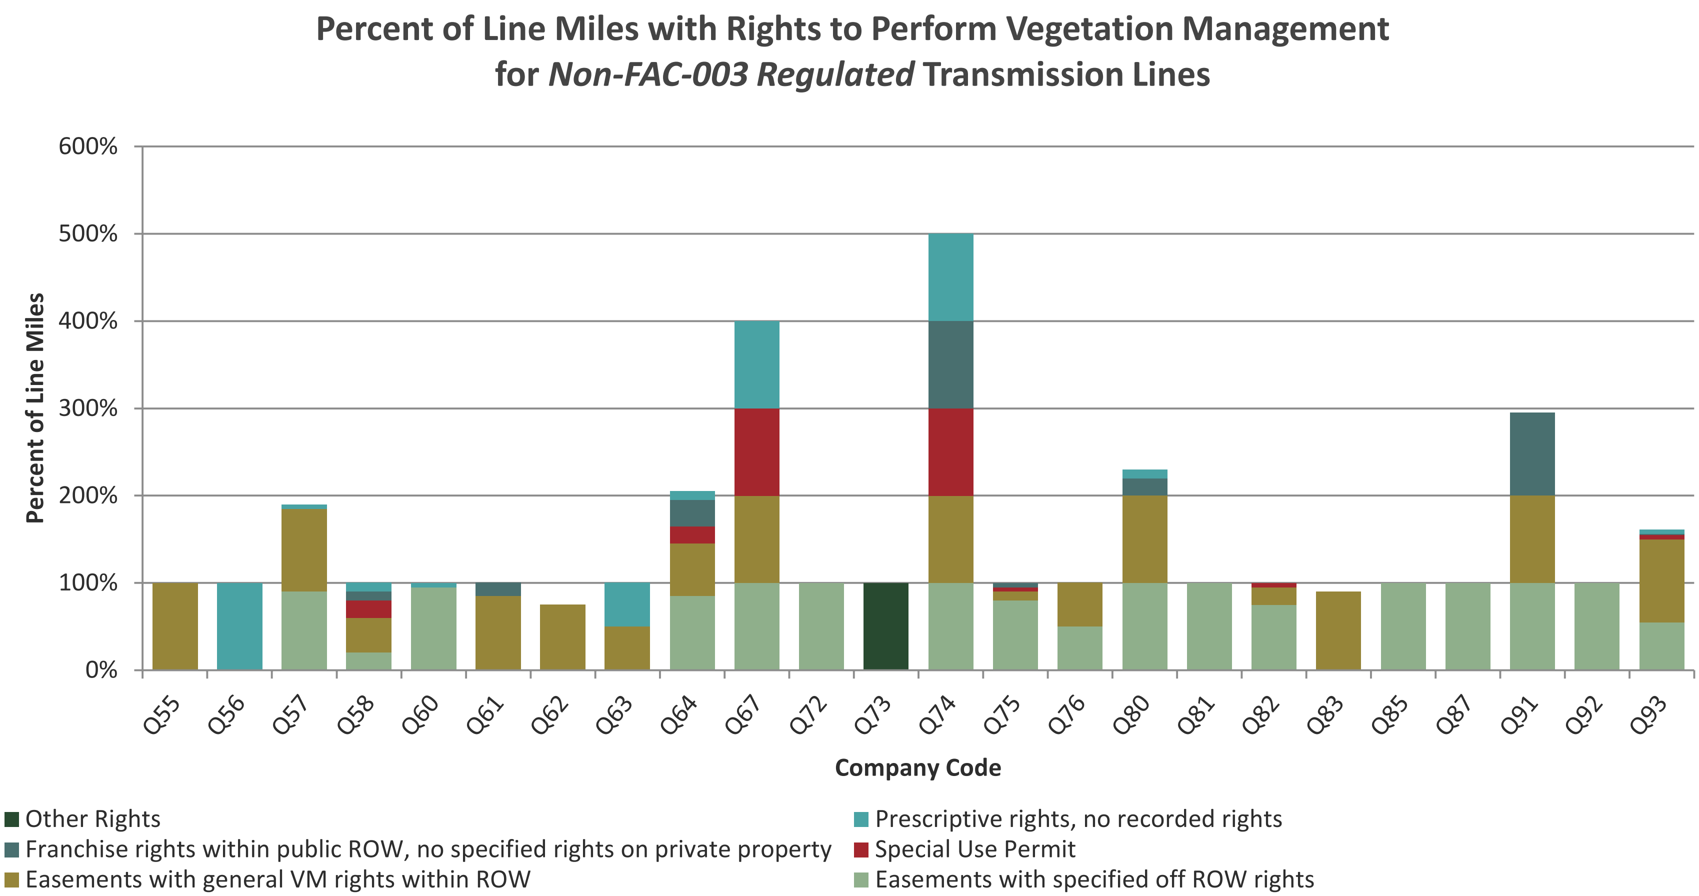

Figure 66: Percent of Line Miles with Rights to Perform Vegetation Management for *Non-FAC-003 Regulated* Transmission Lines

- **24% Reported 0% in all categories (Total Sample: 33)**

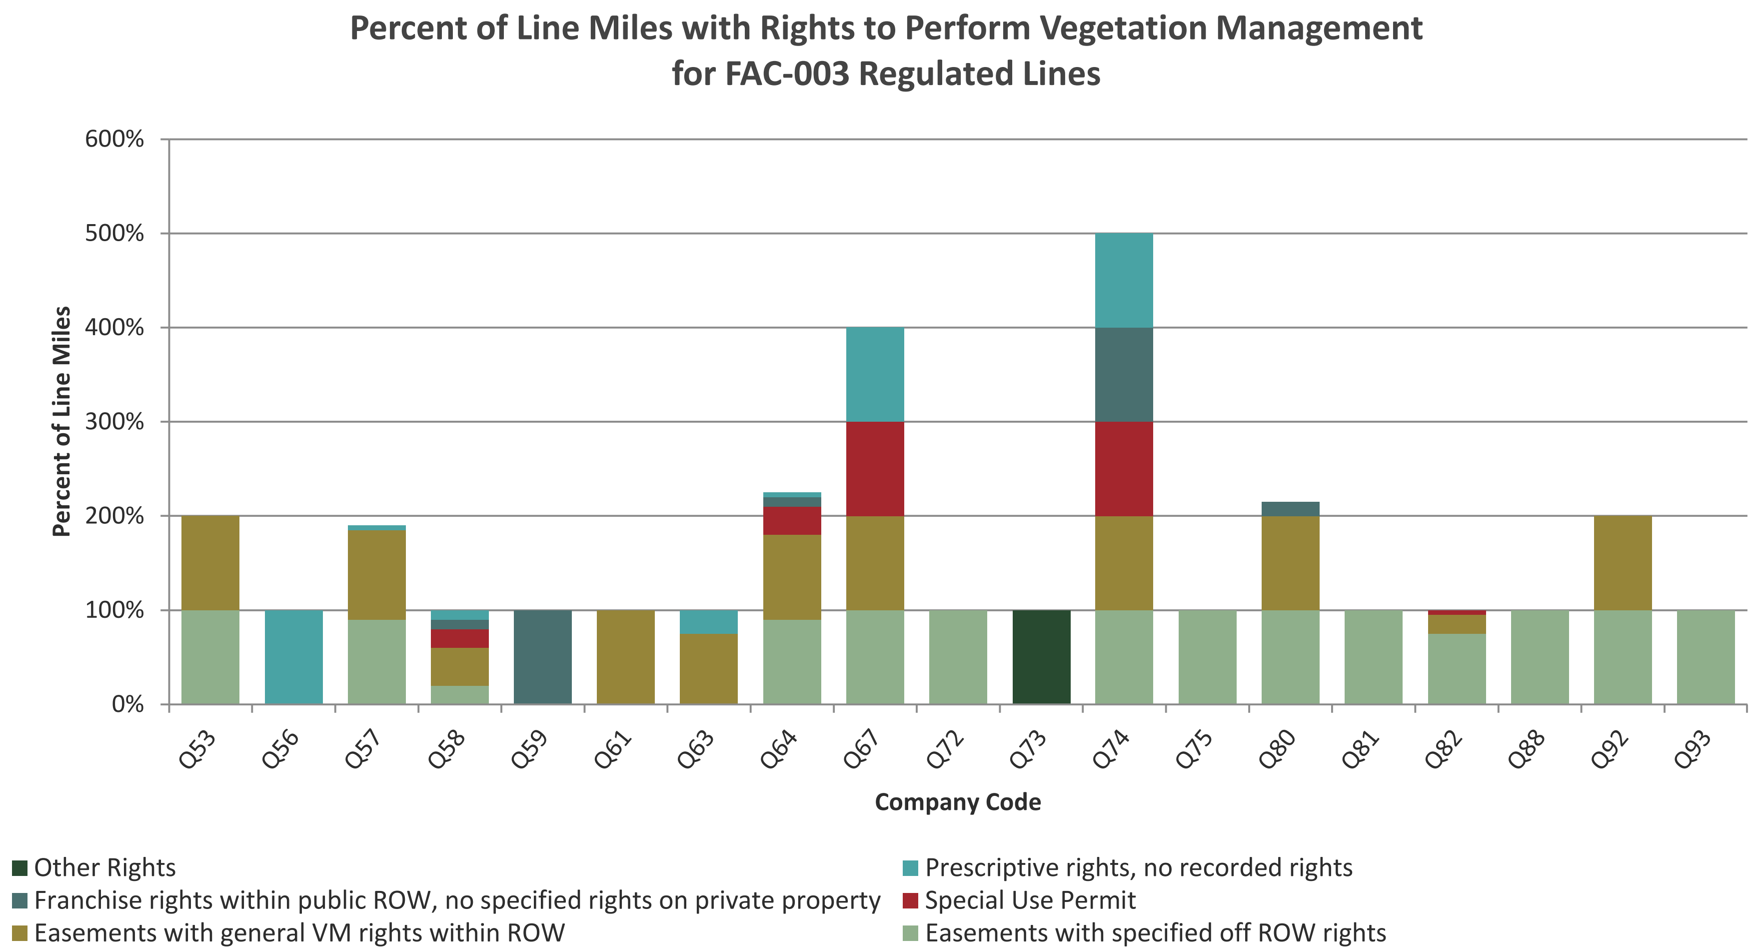

Figure 67: Percent of Line Miles with Rights to Perform Vegetation Management for FAC-003 Regulated Lines

- **34% Reported 0% in all categories (Total Sample: 29)**

Comments Rights on Off-ROW Trees
These are estimates [percent of miles]
We do not have any way to track this information by mileage.
Information not attainable.
We go wherever necessary.
Only cross country distribution line has easement rights but no off-ROW rights.
Under law, we have the authority to remove any vegetation that we deem hazardous to our electrical system
Prescriptive easement with general VM rights
We do not need right to inspect any trees; we need owner's authorization to cut risk trees.
Unknown, really a poor question. Rights or not, if we identify a tree that is a problem we will find a way to purchase the tree, work with the customer, etc. Really do not have all these easement rights categorized in this way.
We do not keep records of this as it relates to line miles.

Comment Table 10: Rights on Off-ROW Tree

Question 16: Are there any regulatory requirements in your service territory that specifically address the need to conduct periodic inspections of vegetation conditions? If so, please cite Regulatory agencies and titles of requirements in the comments box.

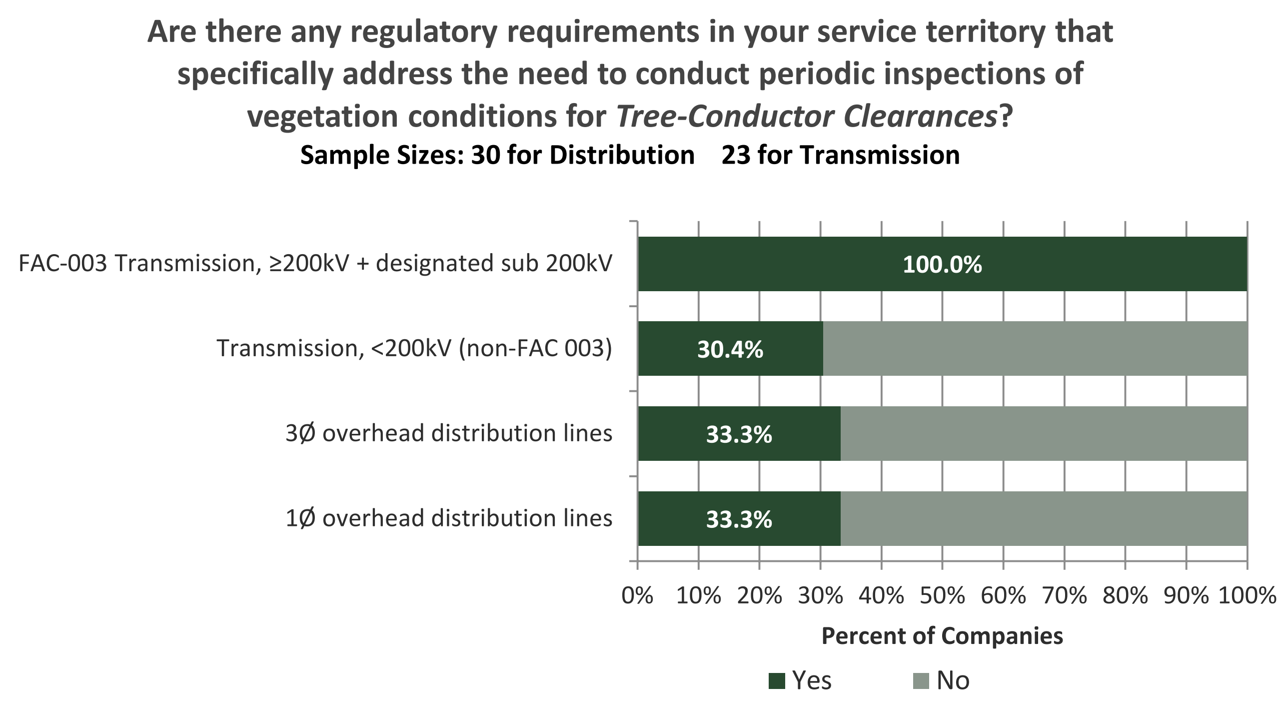

Figure 68: Regulation Requirements for Tree-Conductor Clearances

Are there any regulatory requirements in your service territory that specifically address the need to conduct periodic inspections of vegetation conditions for *Tree Condition, Likelihood of Failing and Striking the Line*?

Sample Sizes: 26 for Distribution

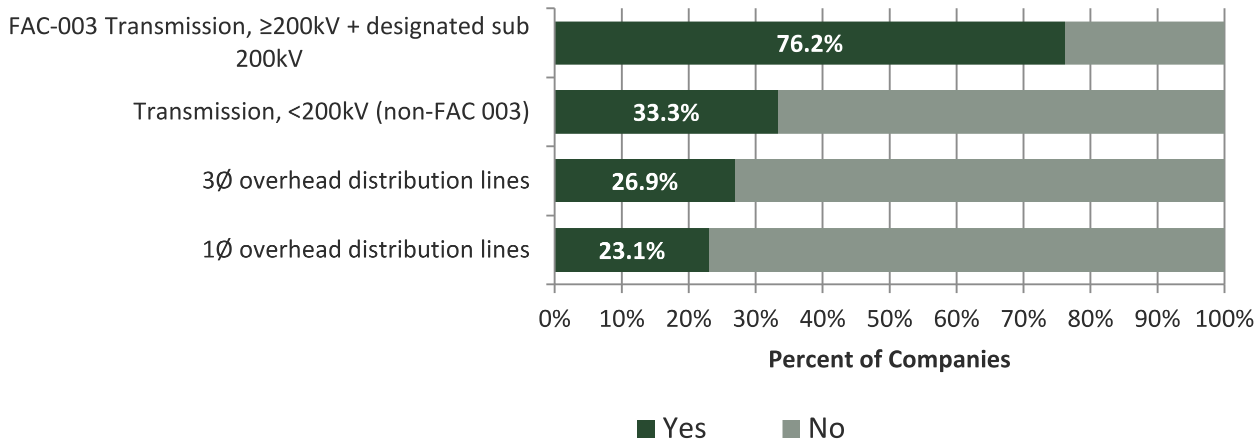

Figure 69: Regulation Requirements for Tree Condition, Likelihood of Failing and Striking the Line

Identify Regulatory Agencies and Titles of Regulations
CPUC NERC
General clearances are contained within PSC rule 4 CSR 240-23 along with all investor own filing of specific clearances for each programs.
New Jersey Administrative Code - 14:5 various Maryland RM43
FAC-003 on NERC lines ***(Cited 8 times as only regulation)***
Alberta Reliability Standard Alberta Utilities Commission
CA GO 95 R35 and PRC 4293 in addition to NERC standards for Transmission
FAC-003 WECC
California Public Utility Commission [CPUC], General Order #95 Rule #35, PRC 4292, and PRC 4293.
only NESC 218
ICC
Ontario Energy Board- Maintain historical practices- inspect 33% of the plant annually.
Manitoba Hydro Distribution Standards / Tree Trimming Clearance and Brush Clearing NERC/FERC
FERC, CT PURA, MA DPU, NH DPUC
NH PUC 3017.10
Régie de l'énergie du Québec
California Public Resource Codes 4292 and 4293
State of New York Public Service Commission, CASE 04-E-0822 Order Requiring Enhanced Transmission Right-of-Way Management Practices By Electric Utilities

Comment Table 11: Identify Regulatory Agencies and Titles of Regulations

Question 17: Do you have different standards or policies for tree risk assessment inspection in areas of potentially elevated risk (e.g. fire prone areas).

Sample Size: 40
Yes 27.5%
No 72.5%

Description of TRA in Areas of Elevated Risk
Extra patrols and clearance is required in [California Department of Forestry] CDF areas [Yes]
Fire [Yes]
Yes, our Mountain Pine Beetle program (this is a general program title which includes hazard trees created by insects other than MPB too) in Colorado. [Yes]
Area very small [No]
Emerald Ash Borer affected areas. Ash trees that shows any degree of decline caused by the Emerald Ash Borer is removed as a hazard tree. [Yes]
No different standards; however, have focused inspections on areas that have historically experienced higher mortality rates during enhanced drought conditions or elevated bark beetle infestations. This may increase the frequency of inspections for those specific areas. [No]
We inspect California Resource areas annually [Yes]
Conducting Redundant patrols in high fire risk areas [Yes]
More aggressive vegetation clearances and proactive tree removals where permitted to mitigate risk in high fire locations. [Yes]
We inspect fire prone or recent fire areas yearly until not needed. [Yes]
We have standards for hazard tree removal that define a process for "worst performing" circuits [Yes]
Higher focus on Backbones (un-fused portion of circuit) [Yes]
No, other than what is required for [inspections]. [No]
We have different standards of tree risk assessment for those circuits that meet our Storm Resiliency Program qualification [Yes]
If we ever did this it would be after the fact/event, after the fire in a specific area, after the storm, etc. [No]
Not a large fire risk [No]

Comment Table 12: Description of TRA in Areas of Elevated Risk

Question 18: Are there any regulatory requirements in your service territory that specifically address the risk of power-line-initiated wildfire, such as tree risk assessment?

Sample Size: 40
Yes 22.5%
No 77.5%

If yes, please cite regulatory agency and requirement title(s).
G.O. #95 and [California Department of Forestry] CDF High fire threat areas [Yes]
State [Yes]
Not applicable to our utility [Yes]
California Public Service Commission [Yes]
CA GO 95 R35 and PRC 4293 specify minimum clearance requirements and mitigation of potentially hazardous trees. [Yes]
California Public Utility Commission [CPUC], and PRC 4292 and PRC 4293. [Yes]
Wildfire Act [Yes]
Provincial Fire Smart Program - to negotiate with Manitoba Conservation [Yes]
Régie de l'énergie du Québec [No]
California Public Resource Codes 4292 and 4293 [Yes]

Comment Table 13: Regulatory Requirements in Service Territory That Address Powerline Initiated Wildfires

Question 19: Do you provide any training to staff specific to wildfires (e.g. prevention, limiting spread, evidence preservation)?

Sample Size: 40
Yes 25.0%
No 75.0%

Description of Fire Risk Training
Extreme dry conditions limit mowing work/all crews have fire extinguishers on vehicle and [are] trained. [Yes]
Monthly safety meeting [Yes]
Contractors conduct their own fire prevention training internally. [No]
Annual Fire Season Kickoff Meeting, training on prevention and practical exercises to familiarize with common tools such as fire rake, shovel, and water pack. [Yes]
Arizona Wildfire Academy [Yes]
General fire prevention and safe operating practices in high fire areas. [Yes]
Utility doesn't provide the training; we have Department of Natural Resources conduct periodic training. [Yes]
Contractors are required to provide annual training on fire prevention and response. [Yes]
Not really just for fire, but it is discussed. We annually review our Imminent threat process, this is general to all threats, but fire damaged tress, dead trees, wind throw trees, etc. [No]
Basic Fire awareness. [Yes]

Comment Table 14: Description of Fire Risk Training

Question 20: When evaluating trees for risk, do your Tree Risk Assessors document fire potential (e.g. fuel build up or the potential for tree wire contacts to occur, which could lead to wild land fire ignition)?

Sample Size: 40
Yes 5.0%
No 95.0%

If yes, could you briefly describe the assessment process?
- DNR & [utility] jointly generated form [Yes]
- Question may be N/A since we have no TRA program. [No]

The following graph compiles the information from questions 18 -21, which all relate to wildfire risk.

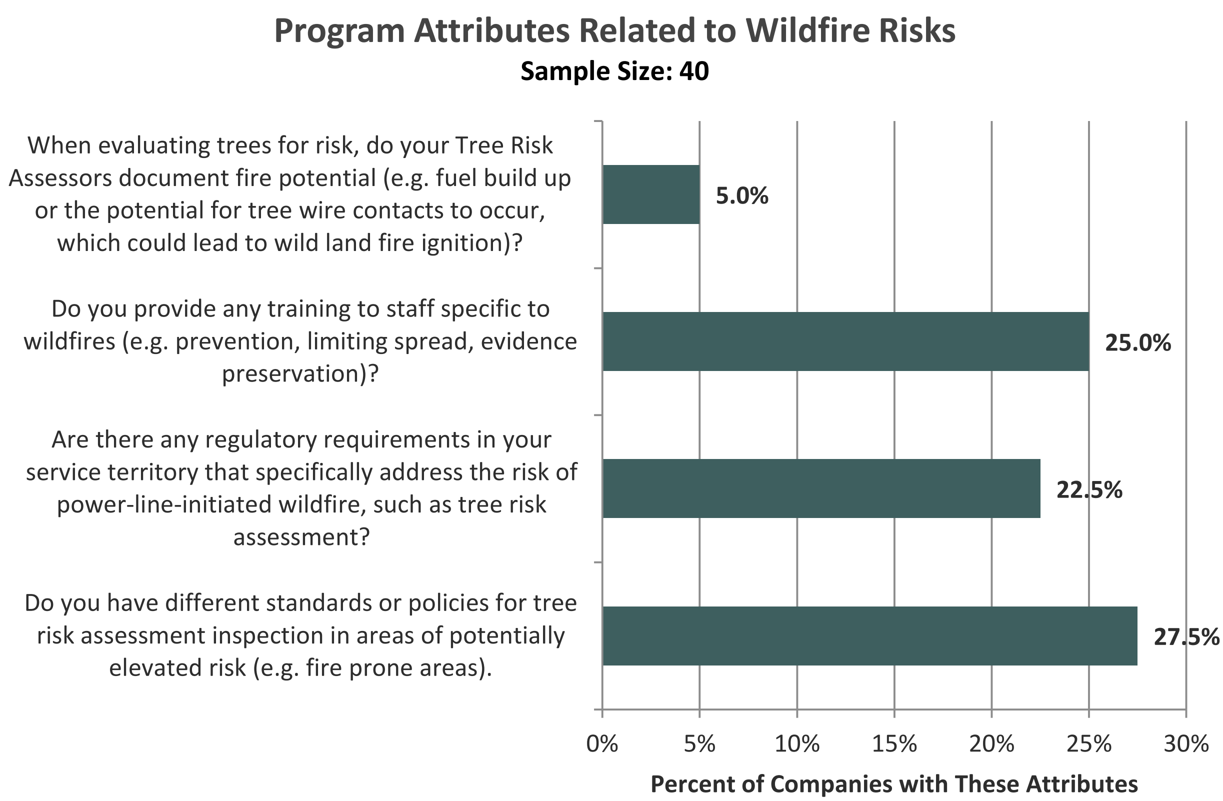

Figure 70: Program Attributes Related to Wildfire Risks

Question 21: Do your hazard tree inspectors pursue removal permits on large trees that appear to be in good health but could impact an important feeder line if they failed in a storm? If yes, how many such trees are removed each year? Choose all that apply

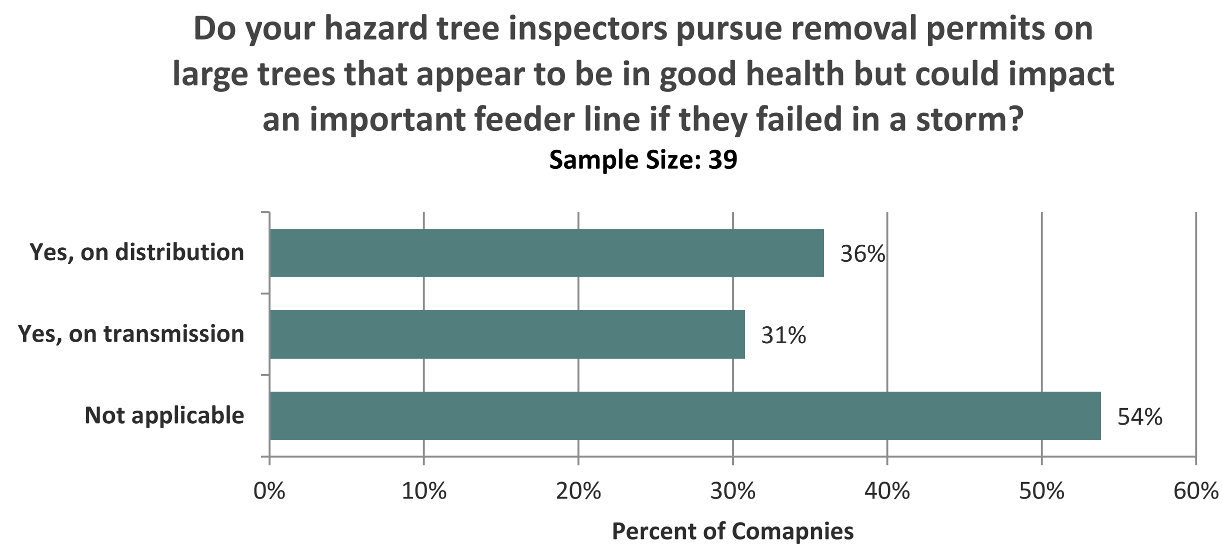

Figure 71: Pursue the Removal of Healthy Trees That Could Impact Important Feeder Lines

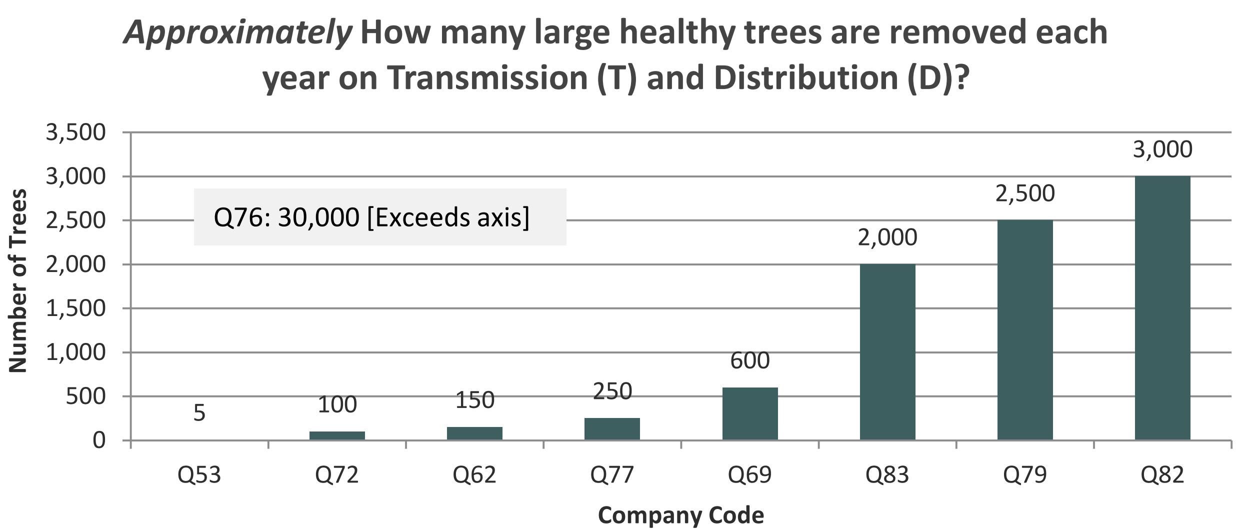

Figure 72: Number of Healthy Trees Removed per Utility

Approximately How many large healthy trees are removed each year on T and D?
Tree count does not distinguish between healthy vs hazard removals [Yes, on T & D]
If they are in good health, why would we take them down? [N/A]
Unknown [Yes, on T & D]
No on Dist. Pursue removals on Trans if on the easement (may or may not need a permit). Transmission off-ROW, if healthy, limited pursuit of removals. [Yes, on Transmission]
Starting with H[azard]&D[iseased] tree survey this year [N/A]
< 100 total; however, we capitalize widening activities on T&D annually. [Yes, on T & D]
5% of our 50 000 removals and it's recent [Yes, on Distribution]
On average 3000 [Yes, on Transmission]

Comment Table 15: Removal of Healthy Trees Comments

Question 22: When trees are assessed for risks, are targets other than powerlines considered (e.g. traffic, pedestrians, playgrounds, and backyards where children are present)?

Sample Size: 40
Yes 47.5%
No 52.5%
Other 0%

Are Other Targets than Powerlines Part of TRA?
NESC 218---we consider any tree on major highway crossings for removals. We consider any tree in school yard or backyard that is readily able to climb an issue. Any tree house within a tree in proximity to electrical wires would be an issue. [Yes]
While we are cognizant of such risks other than to our transmission lines, they do not factor into a decision to remove a tree that is not a threat to our lines. [No]
May observe/assess these risks during the course of normal work to identify any tree, healthy or hazardous, to determine if risk should be mitigated. [No]
We have a lot of internal discussion on how much responsibility lies with the property owner. We don't have an answer, but if we are unsure, we act to remove the tree at our ratepayer's expense. [Yes]
We take in to account the environment in order to prioritize when the work will be done. [Yes]
Public safety and reliability are our highest goals. [Yes]
We notify customers of potential risks from tree houses, playground equipment, etc. that are within minimum approach distances. [Yes]
Not officially part of the removal criteria but if they are a factor they can be used in discussing removal with the tree owner [No]
[We] got no TRA [No]
These factors may influence tree A versus tree B that are otherwise evaluated as a similar risk [Yes]
The potential hazards are articulated to the member [Yes]
We use those risk assessments to obtain owner authorization [Yes]
Public and employee safety [Yes]

Comment Table 16: Are Other Targets than Powerlines Part of TRA?

OPINIONS

Question 1: Please indicate whether you, strongly agree (SA); agree (A); have no opinion (No O); Disagree (D); or Strongly Disagree (SD), with the following statements:

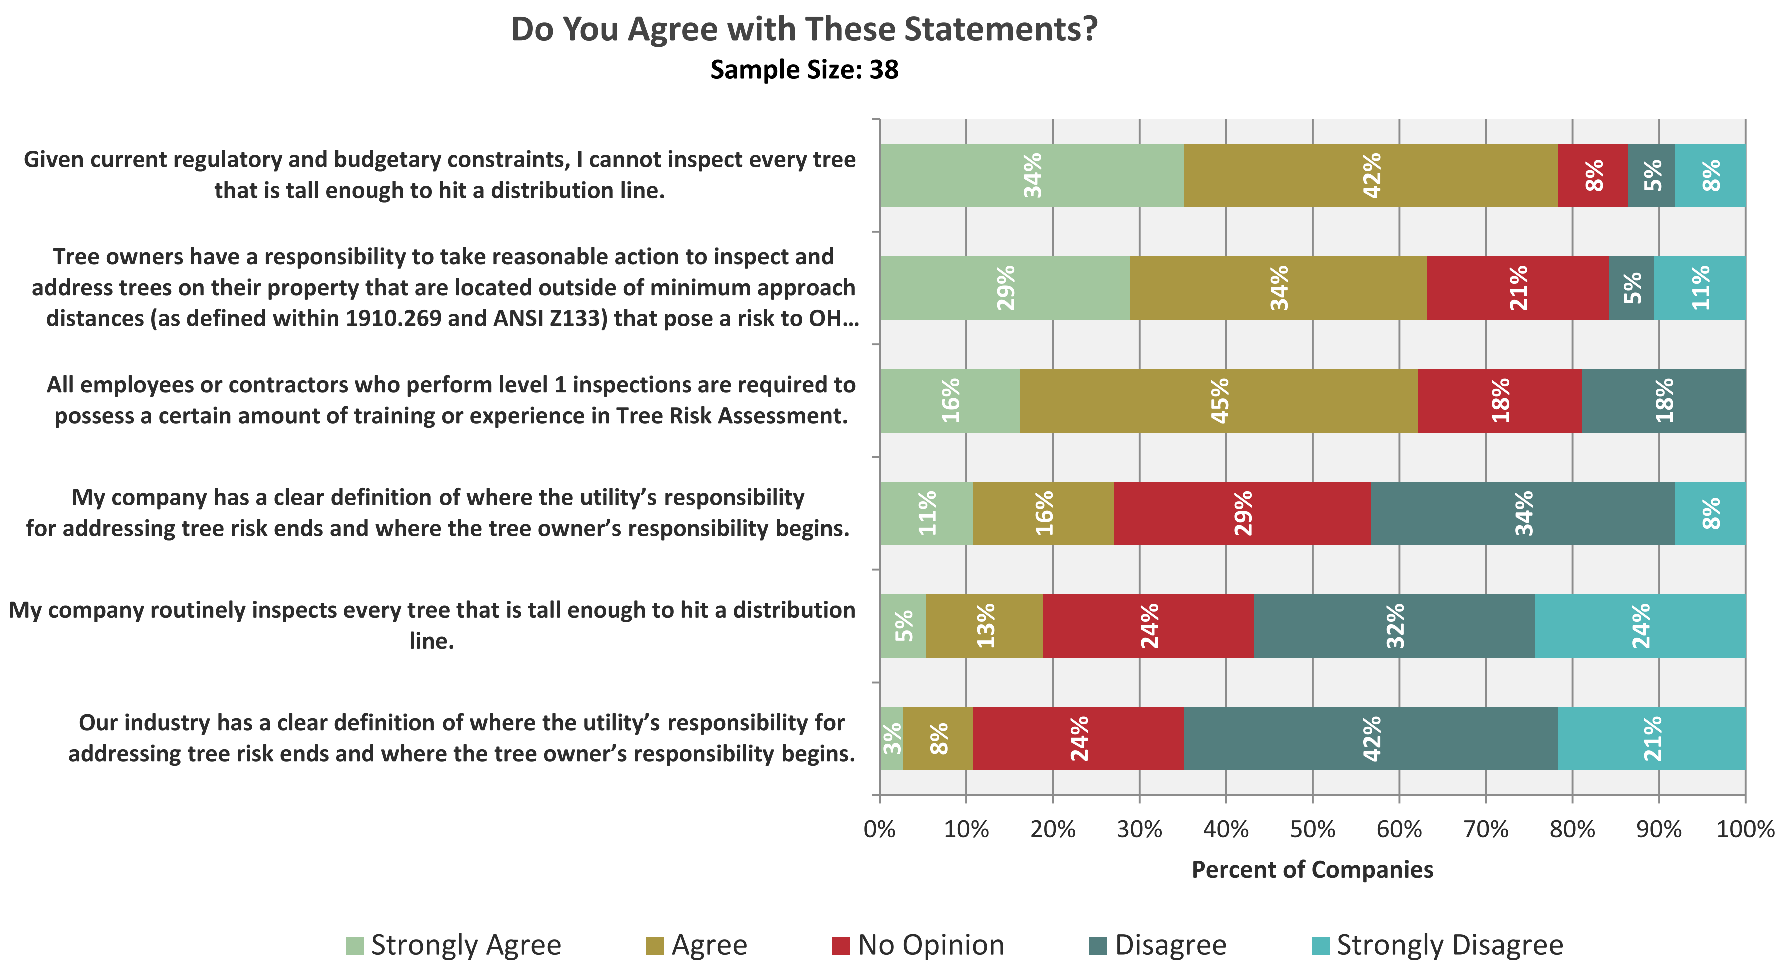

Figure 73: Do You Agree with These Statements?

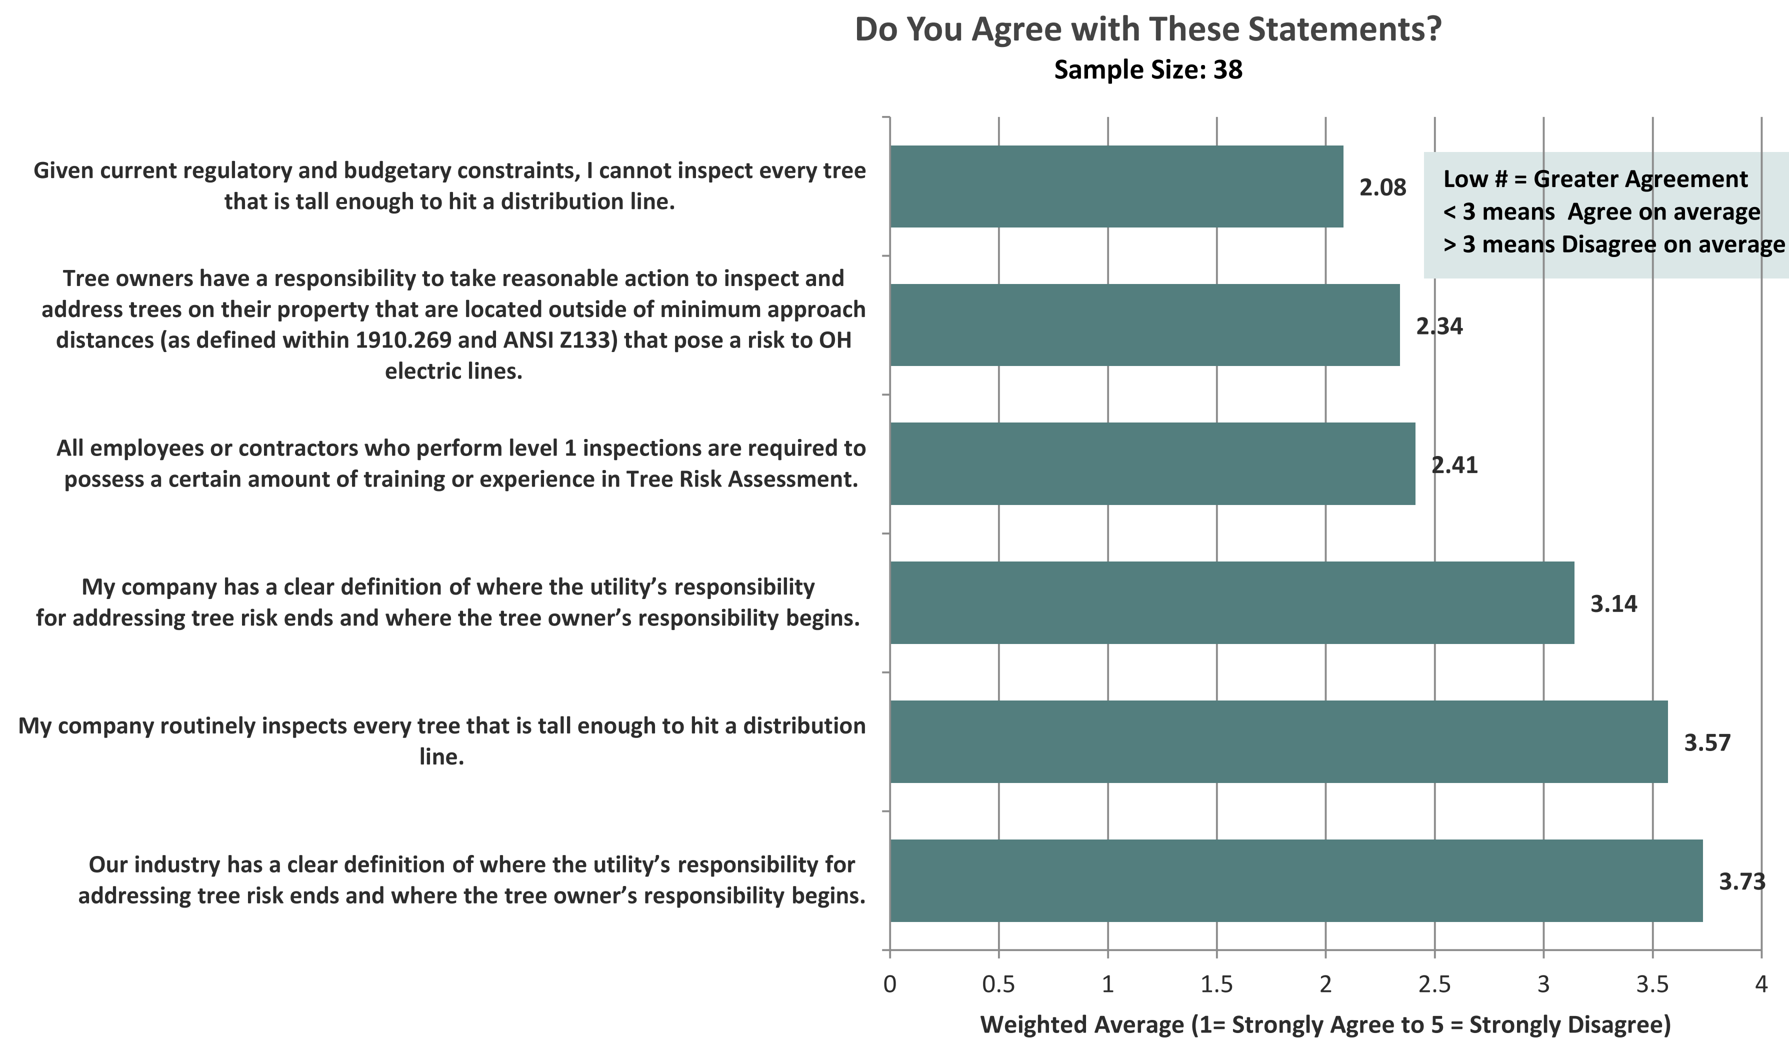

Figure 74: Do You Agree with These Statements? Analyzed with Weighted Averages

How is this Responsibility Established between the Utility and the Customer?
As a public utility we are all about customer service, but we will not remove stumps and [we] leave the wood for the customer whenever possible when removing trees. I would like to place the liability for the tree on the owner of the tree for refusals and danger trees.
Comes down to definition of inspection. Limited vantage point versus intense inspection.
The customer responsibility: it is on the service line from the last pole to the meter Panel and depending on the degree of hazard we may provide the service.
In my opinion, tree maintenance or mitigation responsibility and liability should shift significantly towards the property owner.
Municipal property is utility's responsibility, and private property is the responsibility of the property owner with the exception of easements (i.e. rear lot)
Owner has no responsibility
Distribution up to 14.4/24.9 kV out to 35 feet from centerline; 46 kV out to 80 feet from centerline; 138 kV and 345 kV out 40 feet from edge of cleared ROW
Tree risk assessment should be utility's responsibility, but addressing the risk should be owner's responsibility.
Again, this is a rather difficult question, funding, staffing, corporate value for this service are all factors.

Comment Table 17: How is this Responsibility Established between the Utility and the Customer?

Question 2: Do you have additional thoughts or opinions about a Best Management Practice for Tree Risk Assessment?

Additional Thoughts or Opinions

- Our company does not have an official TRA program in place. We assess risk trees while doing normal routine R.O.W. maintenance. We do offer incentives to property owners for removal of large trees on and off our ROW's that are a danger to our facilities. Our system arborist, (myself) has been certified in Tree Risk Assessment by the ISA for mitigating risk by tree's on and off our ROW.
- Tree risk assessment is an important part of conducting vegetation management to reduce tree related outages to utility facilities. A basic level of TRA should be required; however, [utility is] cautious about requiring high level of TRA on individual trees and on stands due to size of our utility, limited resources, limited qualified personnel etc.
- Due to our small size and limited vegetation, we do not have any additional comments.
- Our utility has chosen to widen distribution circuits to a new standard ROW width as well as 69kV. Trees of risk are removed on an individual basis on all rights-of-way no matter the voltage class.
- Dangerous road to go down as it introduces liability questions that have to be answered in court if something goes awry. Property law says property owner is responsible but development of a risk assessment standard can be used to say the utility has a duty of care beyond their easement rights with no formal permission to perform the work.

Appendix H: Distribution Survey Benchmark Results

INTRODUCTION

CN Utility Consulting conducted a benchmarking survey in January - April 2016. The participants included 36 companies (excluding Hydro One) and of this group 27 were selected as peers to Hydro One Networks. This peer group was used for making comparisons involving costs, reliability, and safety.

Peer companies were chosen to some degree by geographic proximity (see Appendix D for further details on how the peer group was selected). This proximity helps equalize variables that impact the functioning of a utility vegetation management (UVM) program such as tree species populations, economic factors, weather conditions, and regulatory oversight. Although all UVM departments and utilities are unique, benchmarking has value and all efforts have been made to normalize or analyze data to accommodate "fair" comparisons. "Company Profiles of Peer Companies," the first section in this appendix, highlights how the selected group varies on core elements. A list of companies that responded to the survey is shown in Table 1. In order to maintain confidentiality and anonymity, the peer group list will not be distinguished from this group.

List of Participating Utilities

Participating Utilities in the Hydro One Networks 2016 Benchmark Study	
AEP Texas	Liberty Utilities (New Hampshire)
Ameren Illinois Company	Lincoln Electric System
Appalachian Power Company	Manitoba Hydro
Arizona Public Service	Massachusetts Electric (National Grid)
Avista Utilities	Modesto Irrigation District
BC Hydro	Mount Pleasant Power System
City of Tallahassee	Narragansett Electric (RI) (National Grid)
Connexus Energy	Niagara Mohawk (National Grid)
Consumers Energy	Ohio Power Company
CoServ	Omaha Public Power District
Entergy Corporation	Pacific Gas and Electric
EPB (Electric Power Board)	Public Service of Oklahoma
EPCOR	Puget Sound Energy
Hydro Ottawa	Southern California Edison
Hydro-Québec	Southwestern Electric Power Company
Indiana Michigan Power	Tampa Electric (TECO)
Kansas City Power and Light (KCPL)	Turlock Irrigation District (TID)
Kentucky Power	Unitil

Table 6: Participating Companies

The data used to develop this appendix is important to the accuracy of the analysis in the report. In particular, the number of kilometres of overhead line is a key element of many of the calculations and models used for comparing utility vegetation management (UVM) programs. To ensure accuracy of elemental data, survey responses were verified with publically available sources, such as utility websites, legal dockets, the Energy Information Administration (EIA), Platts Directory of Electric Power Producers and Distributors, utility reports to regulatory entities, regulatory reports, and previous CN Utility Consulting (CNUC) survey responses. This process was used to "scrub" the data of erroneous data entry, missing data or misinterpretation of the question. Respondent communication was also a part of this data "cleansing."

Most graphs use data only from the peer group companies. *Data from **all** participants in the survey was used for information that is not regionally or workload dependent, such as what factors influence the utility vegetation management budget (UVM).* **Graphs that include non-peer companies will be indicated next to the sample size.**

Graphical Representation and Highlighting of Hydro One Networks

The graphs in this appendix highlight the data from Hydro One in the following ways:

- On graphs, Hydro one Networks' label is *Hydro One*.
- The South, East, Central and North region labels are *HO South, HO East, HO Central*, and *HO North*, respectively.
- A gray text box surrounding the data label indicates the group to which Hydro One belongs. This applies to bar graphs or pie charts.
- A red highlighted bar indicates Hydro One Networks and its regions for single column graphs, where individual utilities have their data represented with a bar or two variable stacked column graphs.
- Hydro One Networks and its regions are represented with a red outline for stacked or column cluster graphs, unless 'bright" colors can be used without losing clarity.
- All *Statistical Tables* in plot area of graphs are peer statistics and exclude Hydro One and its regions in the calculations.

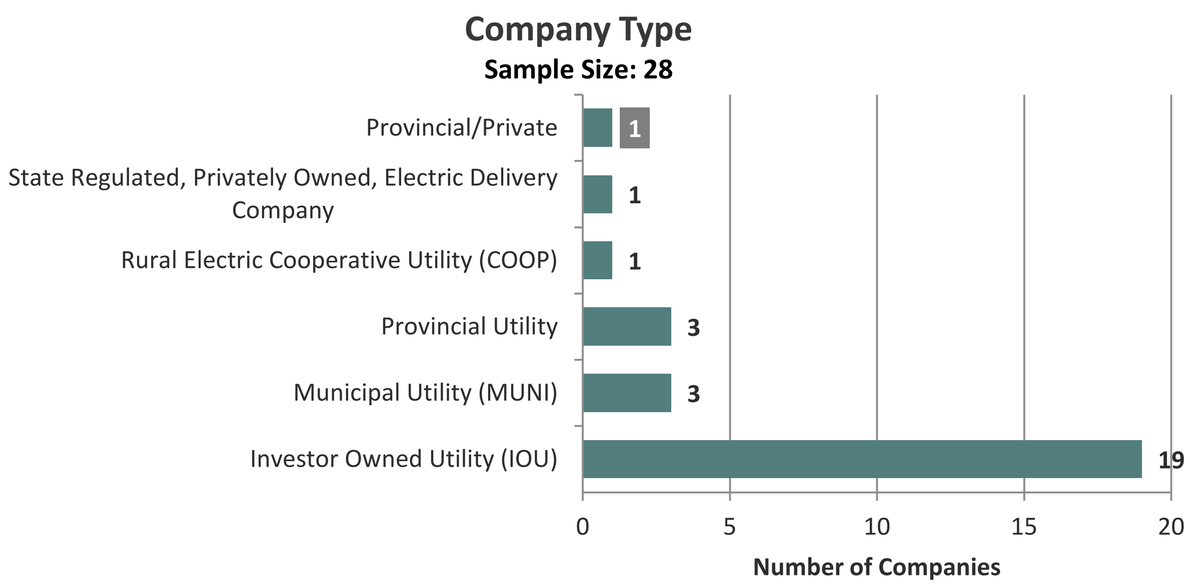
Graph and table numbers in this appendix vary from labels in the main report and other accompanying appendices.

Responses to the question are in brackets on comment tables. In other words, if the respondent answered, "Yes", [Yes] will appear after their comment. This will be true for most comment tables in this report.

COMPANY PROFILES OF PEER UTILTIES

The graphs in this section are comprised of general information about the peer group. They support the efficacy of the choice to include each utility in the target group for comparison with Hydro One.

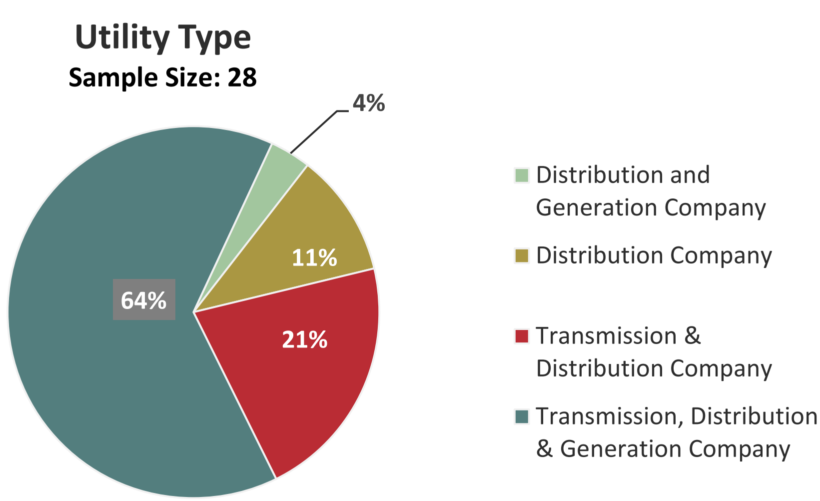
Company Type



Graph 7: Company Type

NOTE: Hydro One only counted as one company (not five) in graph above and below.

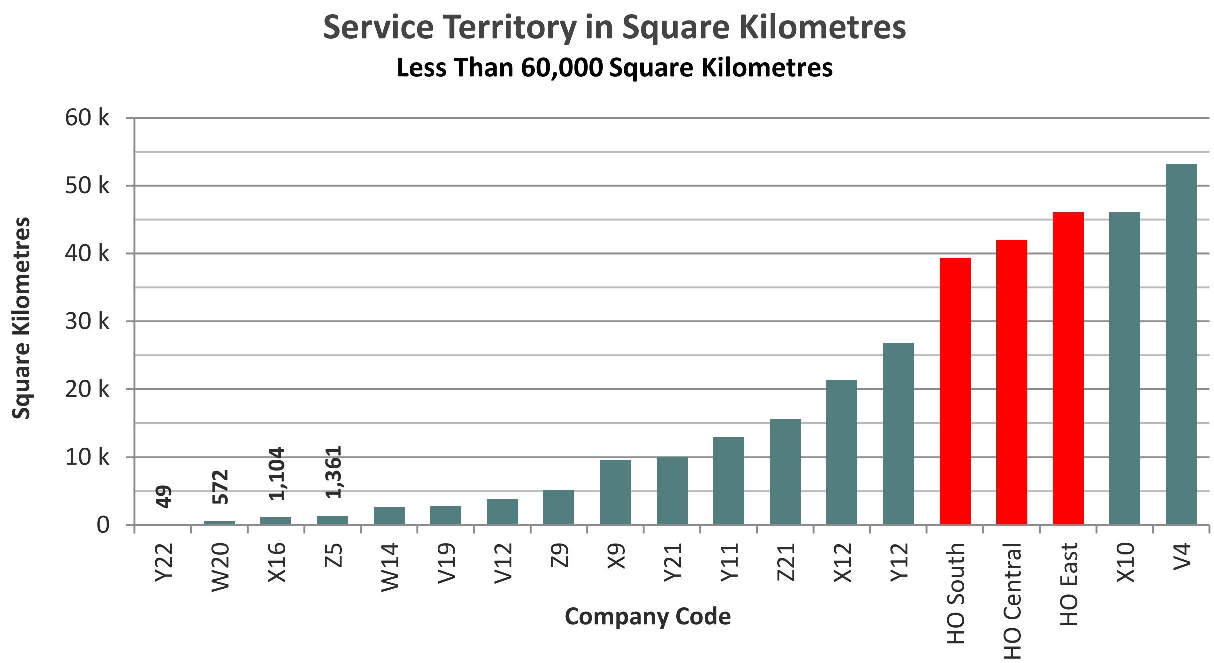
Utility Type



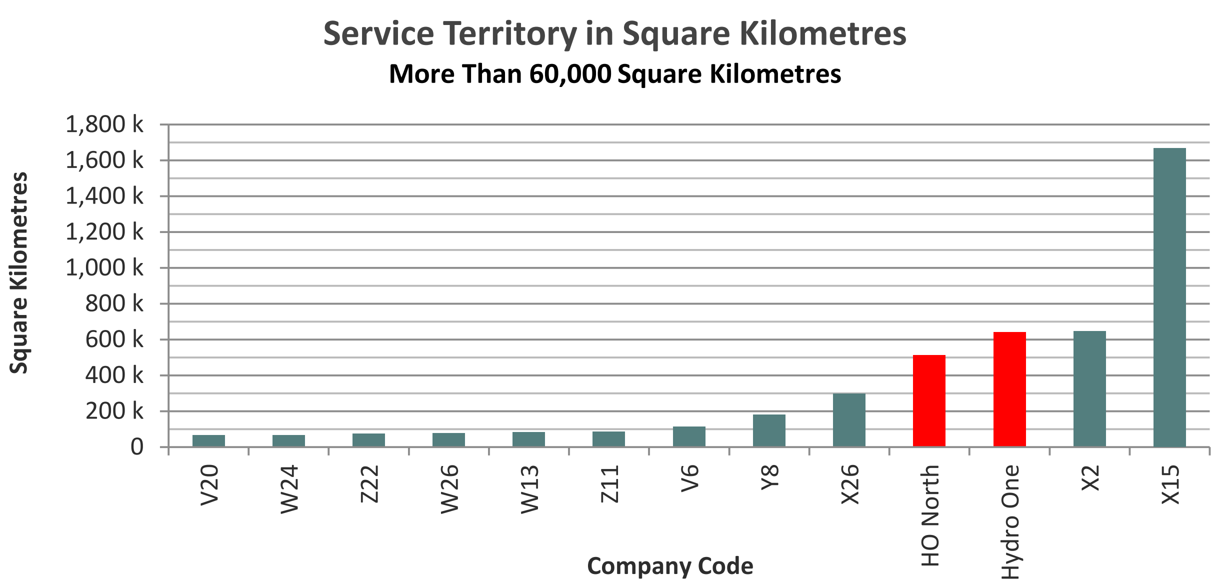
Graph 8: Utility Type

Service Territory in Square Kilometres (Land Area)

The peer group is shown on two graphs (*with different y-axis scales*), so that the range of service territory sizes can be distinguished.



Graph 9: Service Territory in Square Kilometres – Companies with Less Than 60,000 Square Kilometres



Graph 10: Service Territory in Square Kilometres – Companies with More Than 60,000 Square Kilometres

Number of Electric Customers

The peer group is shown on two graphs (*with different y-axis scales*), so that the range of customer count can be distinguished.

Note: Some companies only have the Supervisor/ Forester as the planning personnel

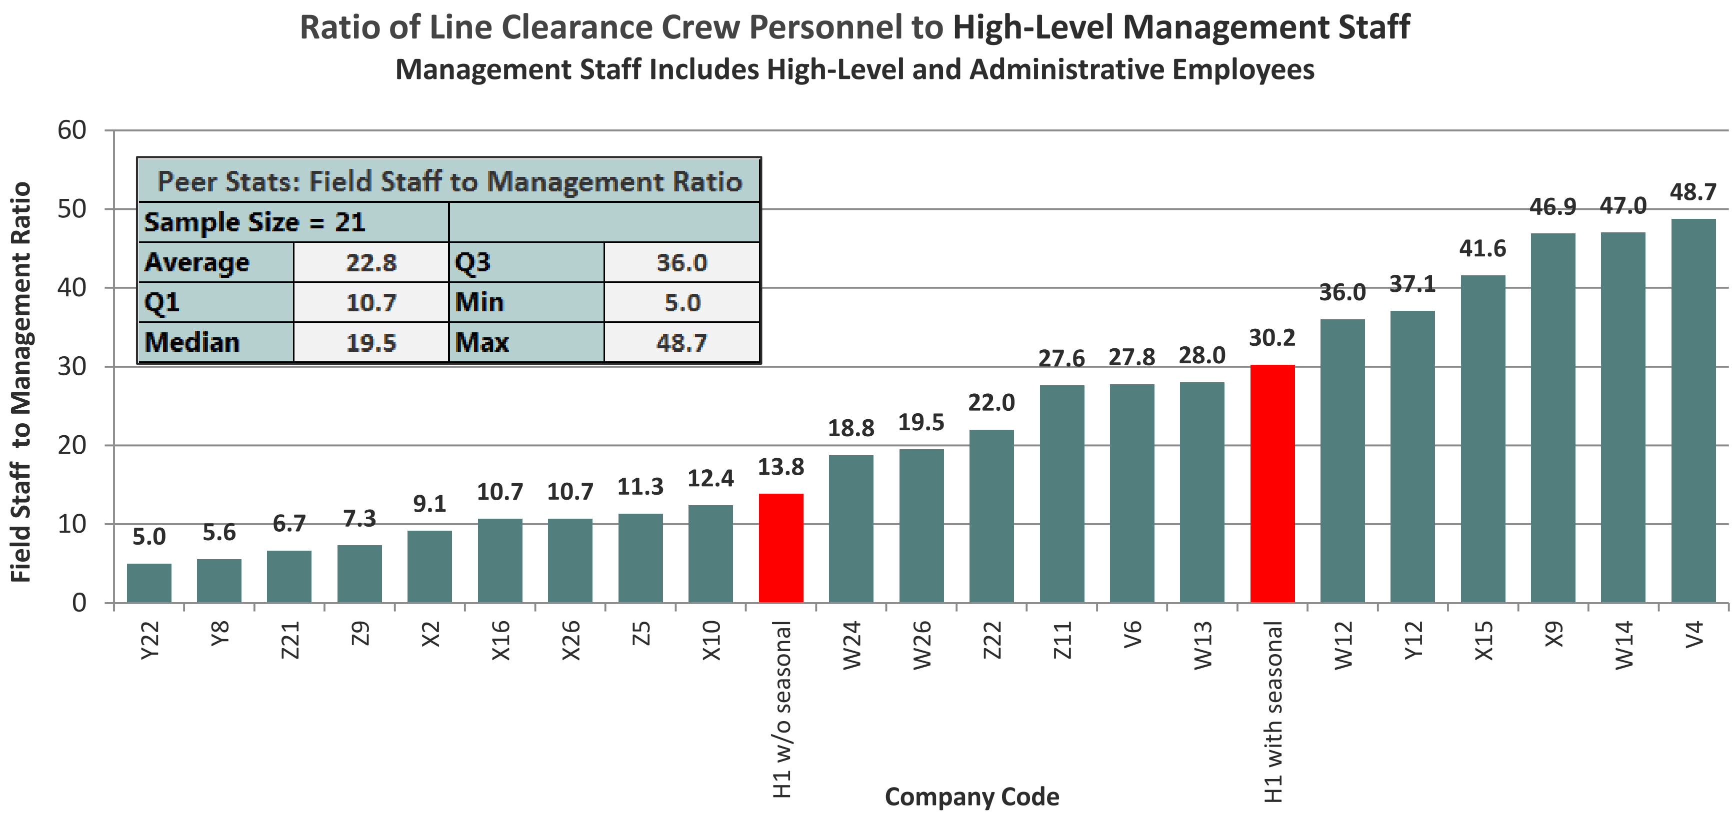
Management Staff to Line Clearance Crew Personnel Ratios

Utilities organize their UVM departments differently. Variations in position titles and duties, in-house to contract personnel ratios, and extent of work planning all impact the following study. It should also be noted that Hydro One is the only company in the peer group that uses temporary labour to any degree. As a result of these differences, Hydro One data are presented as an upper and lower range using the management staff reported and the number of full-time staff with and without seasonal labour.

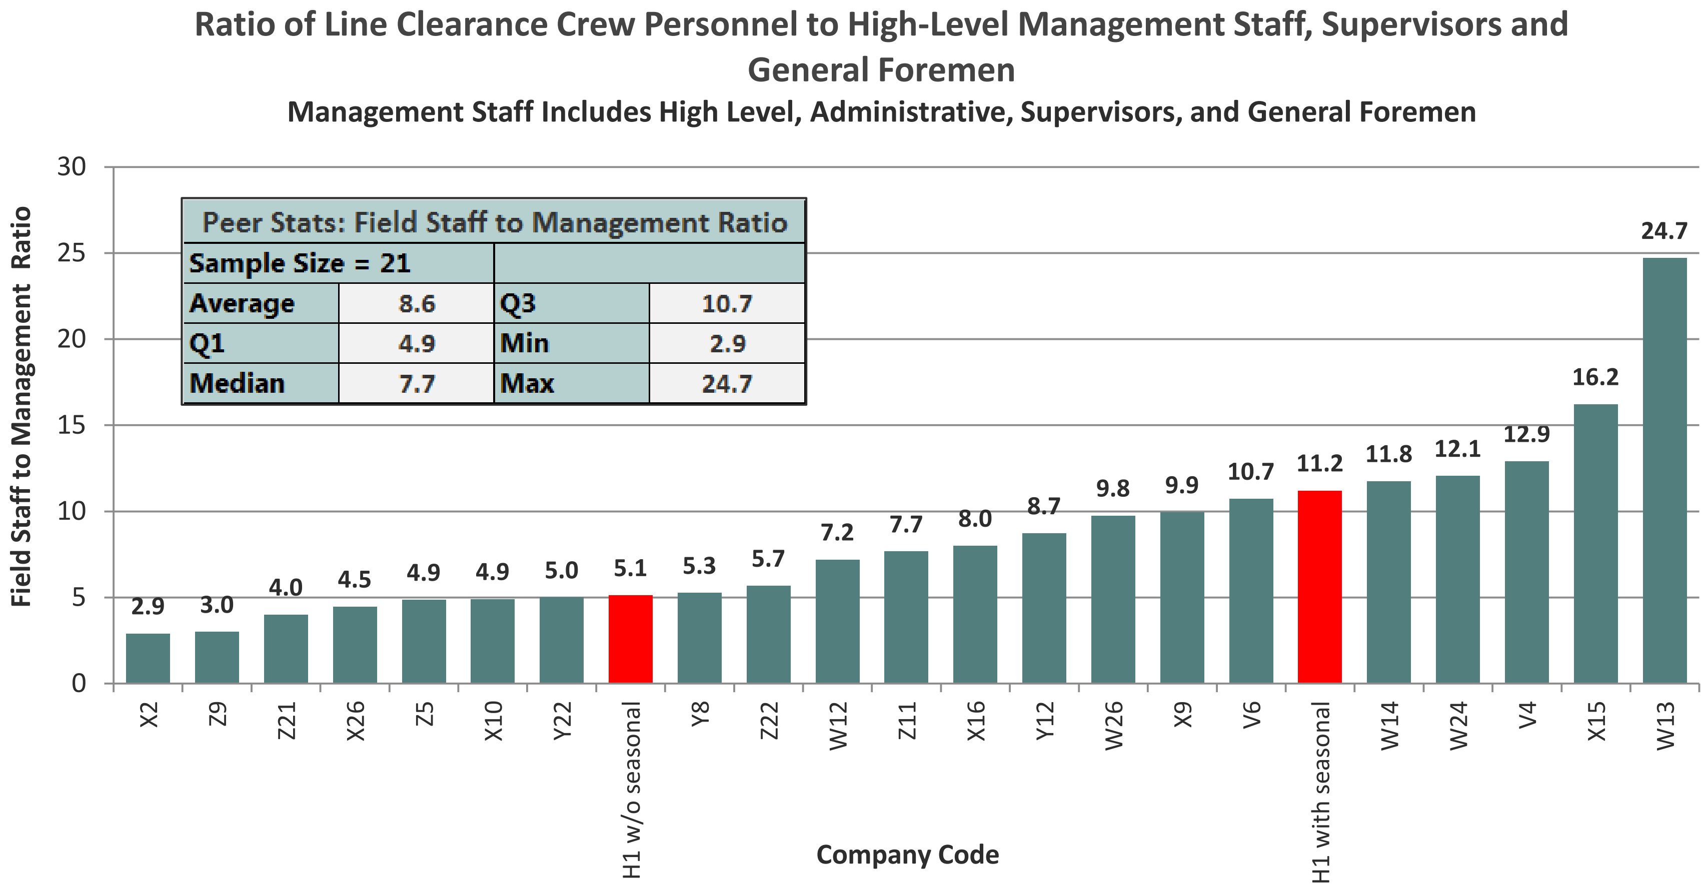
Management Staff was separated into three categories:

1. High-level and administrative
2. Line Clearance Supervisors and General Foremen
3. Work planning staff

Graphically, the above categories were grouped as follows: 1 only; 1 + 2; and 1 + 2 + 3



Graph 36: Ratio of Line Clearance Crew Personnel to High-Level Management Staff



Peer Stats: Field Staff to Management Ratio			
Sample Size = 21			
Average	8.6	Q3	10.7

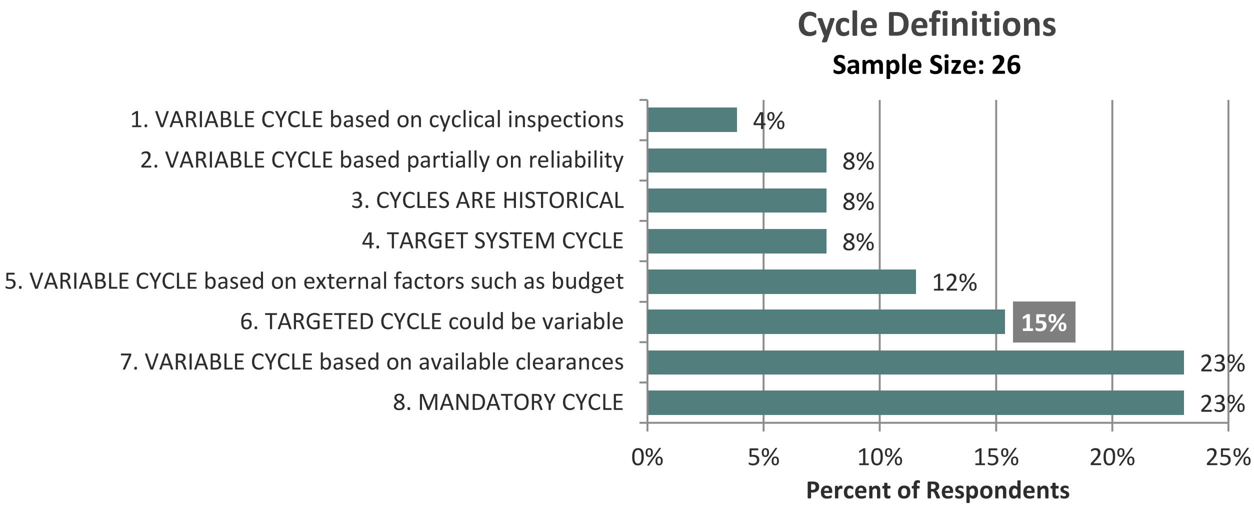
CYCLES OF MANAGEMENT

Cycle Definitions



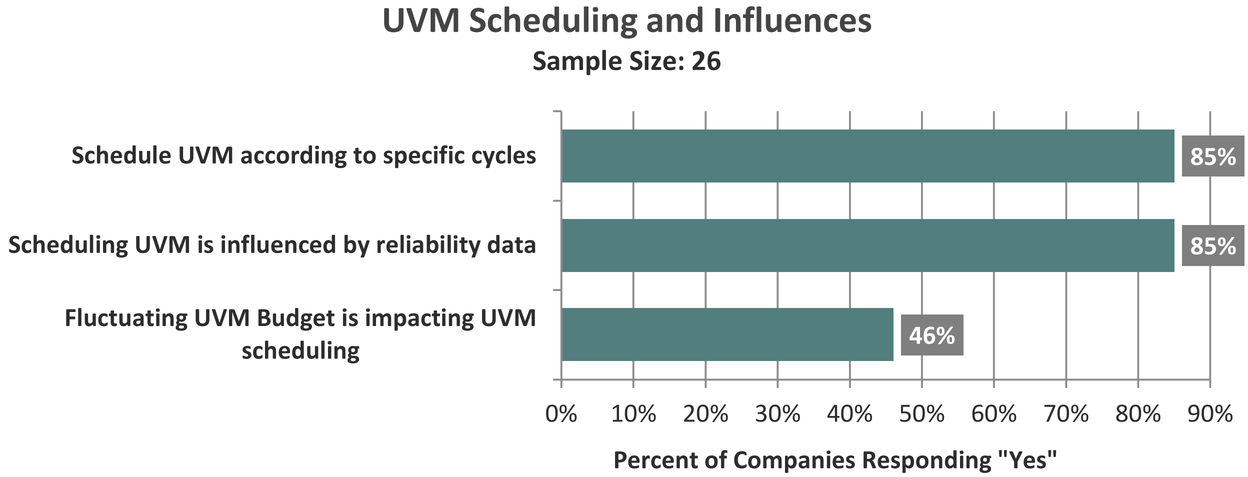
Legend: Complete Definitions
1. VARIABLE CYCLE based on cyclical inspections: A set SCHEDULE OF INSPECTIONS that determines which trees are in need of maintenance
2. VARIABLE CYCLE based partially on reliability
3. CYCLES ARE HISTORICAL: A measure of the time it takes to manage ALL of the trees, spans or miles in your distribution system ONE TIME
4. TARGET SYSTEM CYCLE: A SCHEDULE of maintenance applied to the entire distribution system
5. VARIABLE CYCLE based on external factors such as budget: The time between management of a SINGLE tree, span or mile in your distribution system
6. TARGETED CYCLE could be variable: PLANNED length between vegetation maintenance activities
7. VARIABLE CYCLE based on available clearances: A SCHEDULE based on the amount of clearance that can be realistically obtained as well as the expected growth rates of the trees on any given site
8. MANDATORY CYCLE: A PLANNED length of time that MUST be maintained between vegetation management activities
9. VARIABLE HISTORICAL CYCLES: The amount of time between SCHEDULED pruning operations

Graph 46: Percent of Companies with Given Cycle Definitions

Descriptions of Vegetation Maintenance Cycles
We run 4 and 6 year cycles on distribution. [7]
Working towards a cycle based on inspections [5]
Based on predictive model that forecasts tree related outages per mile of line and impact to SAIFI and SAIDI for the next 12 months [2]
Our UVM cycle is a four-year average (or effective) cycle. For example, we maintain 25% of our overhead UVM system miles annually. This is a reliability based, variable cycle. [2]
We are expected, by [State] Commerce Commission mandate, to perform full maintenance on each of our distribution circuits at least once every 48 months. We are also mandated to perform a mid-cycle patrol of every circuits the second year after full maintenance has taken place. [8]
Utility vegetation cycles are planned lengths of time attributed to every circuit of our system and are based on vegetation response to all factors influencing growth as well as customer density. These cycles should be maintained for each programmed interventions. [5]
Also agree that it is a planned length of time not only looking backwards, but forwards as well. But it is a measure of time to manage all trees, spans, or miles one time. [3]
Our tree program is driven by customer density and budget and reliability. 5-year cycle suburban 10-year cycle Rural [4]

Table 9: Descriptions of Vegetation Maintenance Cycles

Scheduling, Cycles, and Impacts



Graph 47: UVM Scheduling and Influences

Comments on Fluctuating UVM Budget
We set budgets according to the number of miles being maintained in a given year [No]
Due to program underfunding we are experiencing a backlog of work [Yes]
Depends upon the year and the budget. Over the years we have been successful in creating a more stable annual budget [No]
Yes and no. Maintaining 48-month compliance is first priority and we have been successful in achieving this despite budget fluctuations over the past few years. It affects us most in regard to how we approach the work. When resources are limited, we often have to just get by with the necessary clearance and move on. Often times we may not be able to address good removals (trees and brush), off - ROW trees/hazard tree conditions, overhang removal (beyond what our minimum specs require), etc. Essentially, we are not able to do the work that really improves reliability. Also, we sometimes are not able to do full maintenance on the isolated sub-t. We often have just been able to "hot spot" the sub-t. Limited resources also have an effect on fulfilling customer requests and reliability work. [Yes]
Our cycles are based on vegetation response to all factors influencing growth as well as customer density. These cycles should be maintained for each programmed interventions. They can be consider[ed] as objectives. Availability of resources impacted directly our scheduling. [Yes]
Beginning of 2014 we have a stable budget for the next 4-years [Yes]

Table 10: Comments on Fluctuating UVM Budget

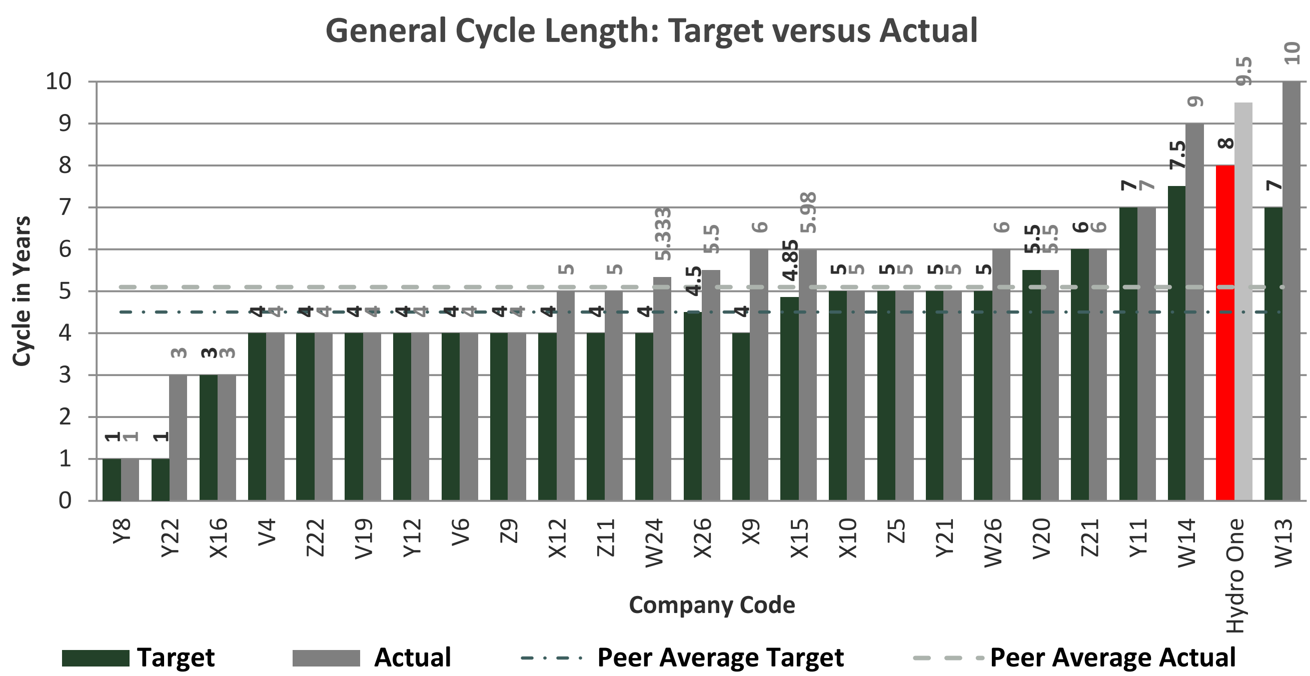
Explain How Reliability Measurements Influences Your UVM Scheduling
We schedule on a yearly basis and we'll often move circuits up in a given year to make sure the reliability benefits are realized as early as possible [Yes]
Priorities are based on targeting worst performing areas and/or feeders [Yes]
Previous 12 month vegetation coded outages have a great impact in the predictive model for forward 12 months [Yes]
[Enhanced Hazard Tree Mitigation] EHTM program is influenced by reliability [Yes - 3 companies]
Our routine operations are not influenced by this however we have a dedicated reliability program that incorporates this data to determine the SSDs that will be worked in a given year. [No]

Explain How Reliability Measurements Influences Your UVM Scheduling [Continued]
[Utility] Power Quality team tracks momentaries on poor performing circuits and will issue trim locations within circuit. [Yes]
Part of our rankings for determining EHTM circuits are based on reliability.
[Utility] utilizes the Davies Consulting Tree Trim Model (TTM), a sophisticated software program that projects a "Bang for Buck" approach, a balance of reliability and cost. [Yes]
Time between UVM activities may be in/decreased based on reliability. [Yes]
All circuits/feeders reliability is monitored throughout the year for vegetation outages. Circuits with poor performing reliability #'s are inspected and if it determined by the Forester/OC that the circuit is performing badly due to grow-in type vegetation outages, then the circuit will be added to the trim list for that coming year. This plays a role in the reliability metrics, but doesn't always effect scheduling. Scheduling the yearly trim plan is determined by the last trim year, distance of vegetation from conductor, and viewing outage data on that feeder. If the feeder is having a lot of grow-in outages it will be a good candidate for trim, where as a feeder that is performing badly from a SAIFI/SAIDI standpoint due to outside ROW Tree fall in's, the forester may not schedule that feeder to be trimmed but instead conduct a danger tree patrol or see if skylining certain parts of the feeder are feasible to alleviate the non-preventable outages. [Yes]
Poorly performing line segments are priority for line clearing [Yes - 6 companies]
Sometimes, but seldom. We may move a circuit up on the schedule (perform work before the circuit is actually due for full maintenance) if there are tree conditions present which warrant addressing, and may be causing reliability issues. In most cases, if there are issues, we will perform some hot-spotting to help alleviate problems before the next cycle trim is due. For worst performing circuits: On the vegetation side, I do not believe that we are actually REQUIRED to do anything. We do, however, take a closer look (through an inspection) at these circuits to see if there is any additional work (beyond what our program guidelines dictate) that could be done to improve reliability. We would look at possibly removing more overhang, removing "problem" trees, addressing off-ROW trees, etc. [Yes]
Reliability data is used as the driving force behind our composite risk index used to prioritize feeders for UVM treatments [Yes- Hydro One]
[Reliability data is used] for the tree removal program only. [Yes]
We do off-cycle trimming to mitigate urgent reliability issues. [No]
Annual work is prioritized in that year based on reliability ranking. Occasionally a cycle can be shortened (other(s) lengthened) to meet a reliability need. [Yes]
If we have a circuit that is having [outages] it will be given priority until reliability is successfully restored. [Yes]
If a section of line or circuit is experiencing an unacceptable amount of outages we will trim out area before the designated UVM cycle. (2013). The 10 worst performing circuits are reviewed and addressed on a yearly basis [Yes]

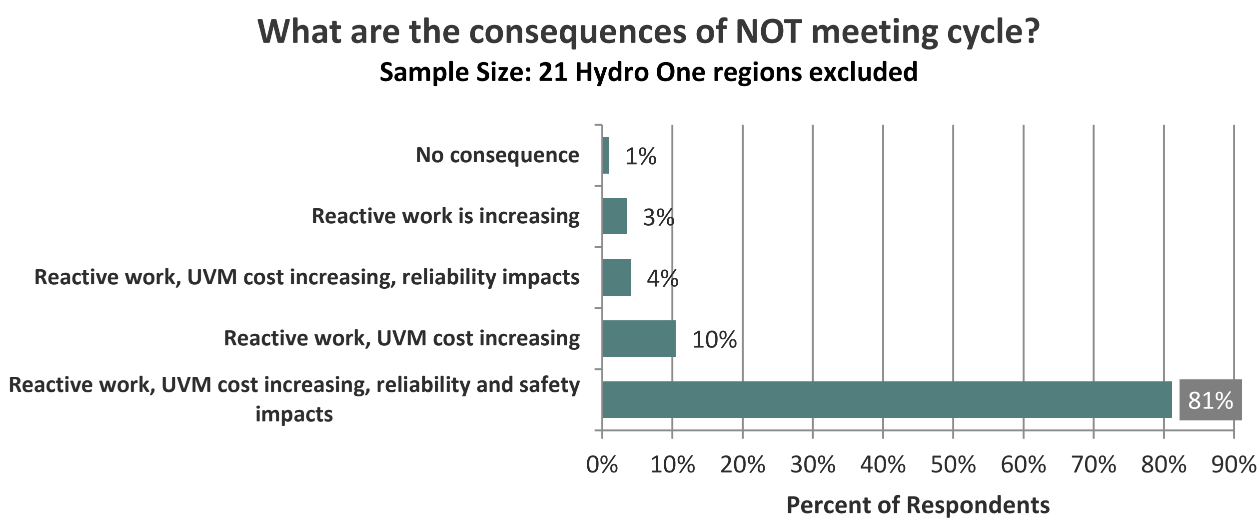
Table 11: Explain How Reliability Measurements Influences Your UVM Scheduling

Responses highlighted in tan prioritize poor or worst performing circuits.
Hydro One highlighted in rose.

General Cycle Lengths



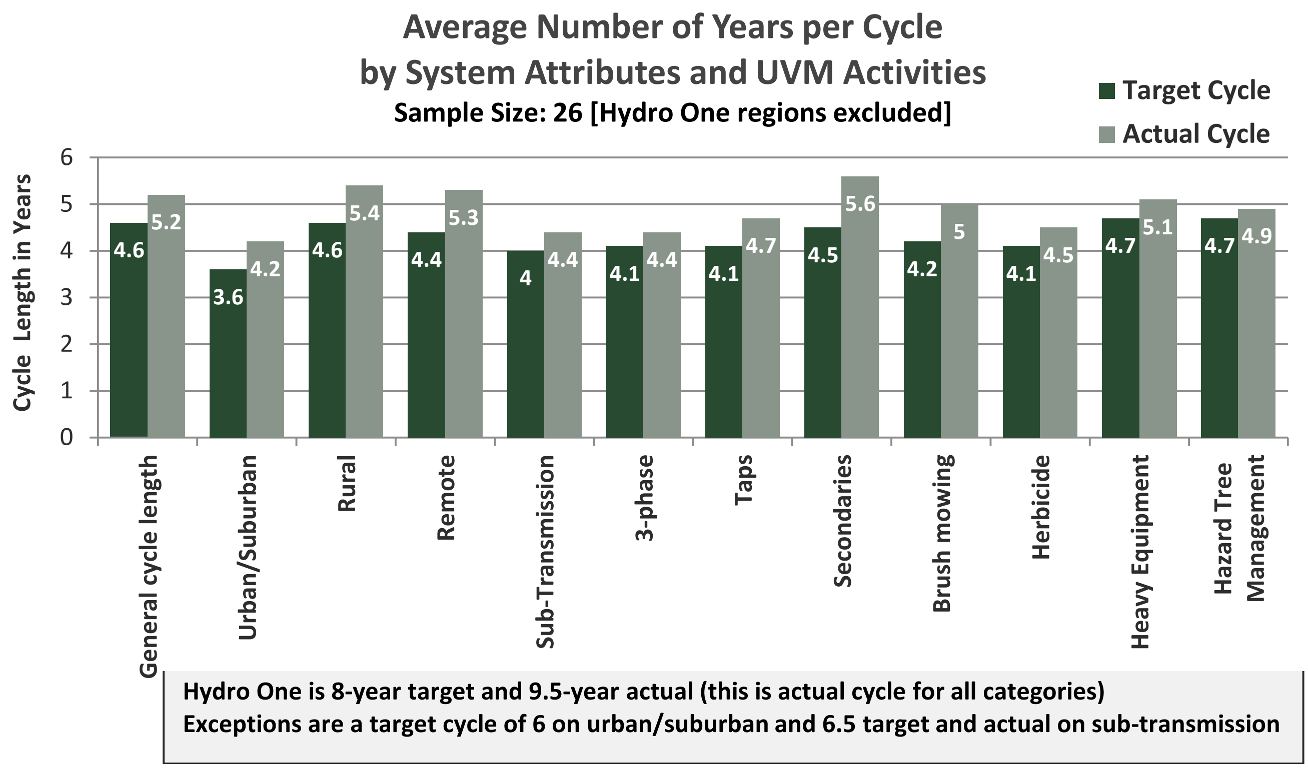
Graph 48: General Cycle Length: Target versus Actual



Graph 49: What are the consequences of NOT meeting cycle?

The graph (Graph 40) above is based on responses from the following twelve cycle categories: General, Urban/Suburban, Rural, Remote, Sub-Transmission, Three-phase, Taps, Secondaries, Brush mowing, Herbicide control, Heavy equipment work, and Hazardous tree management. The variation between the twelve categories was not significant, so all cycle types were averaged to derive the statistics in the graph.

Variable Cycles



Graph 50: Average Number of Years per Cycle by System Attributes and UVM Activities

Variable Cycle Statistics [Peers plus Hydro One Networks]								
Cycle Type	General Target	General Actual	Urban & Suburban Target	Urban & Suburban Actual	Rural Target	Rural Actual	Remote Target	Remote Actual
Sample	25	25	11	11	11	11	8	8
Average	4.6	5.3	3.6	4.5	5.0	6.4	4.9	6.6
Q1	4.0	4.0	3.0	4.0	4.0	5.5	4.0	6.0
Median	4.0	5.0	4.0	4.0	4.0	6.0	4.5	6.5
Q3	5.0	6.0	4.0	4.5	6.0	7.0	6.0	7.3

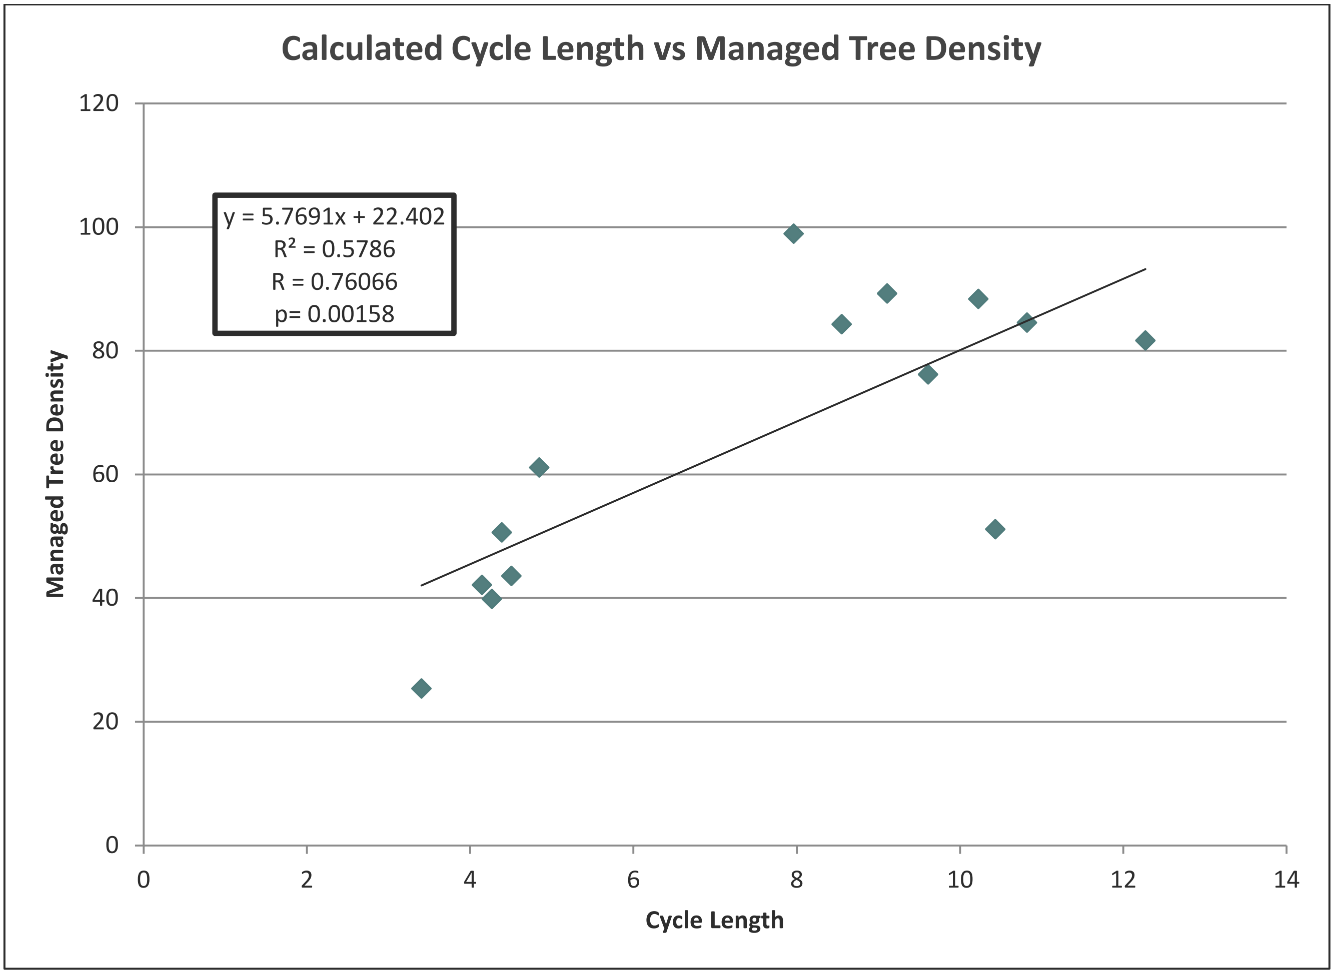
Min	1.0	1.0	1.0	2.0	1.0	3.0	2.0	3.0
STDEV	1.7	2.0	1.4	2.0	2.5	2.5	1.8	1.9

Statistics Table 5: Variable Cycle Statistics

Correlation between Cycle Length and Managed Tree Density



Graph 51: Calculated Cycle Length vs Managed Tree Density

R^2 = 0.5786 or 57.9% of the variance can be accounted for in the model. Simply, this indicates the strength of the model for prediction (This is adequately high)
R = 0.76066 is the correlation coefficient and it is an indication of the strength of the relationship (1 is perfect). This is a good correlation
p = 0.001582 or p-value loosely means 'how significant or repeatable is this result or model?' The smaller the p-value indicates that the probability that this model is a good predictor is high. In this case it is well below 1%

RELIABILITY

Calculating Reliability Metrics

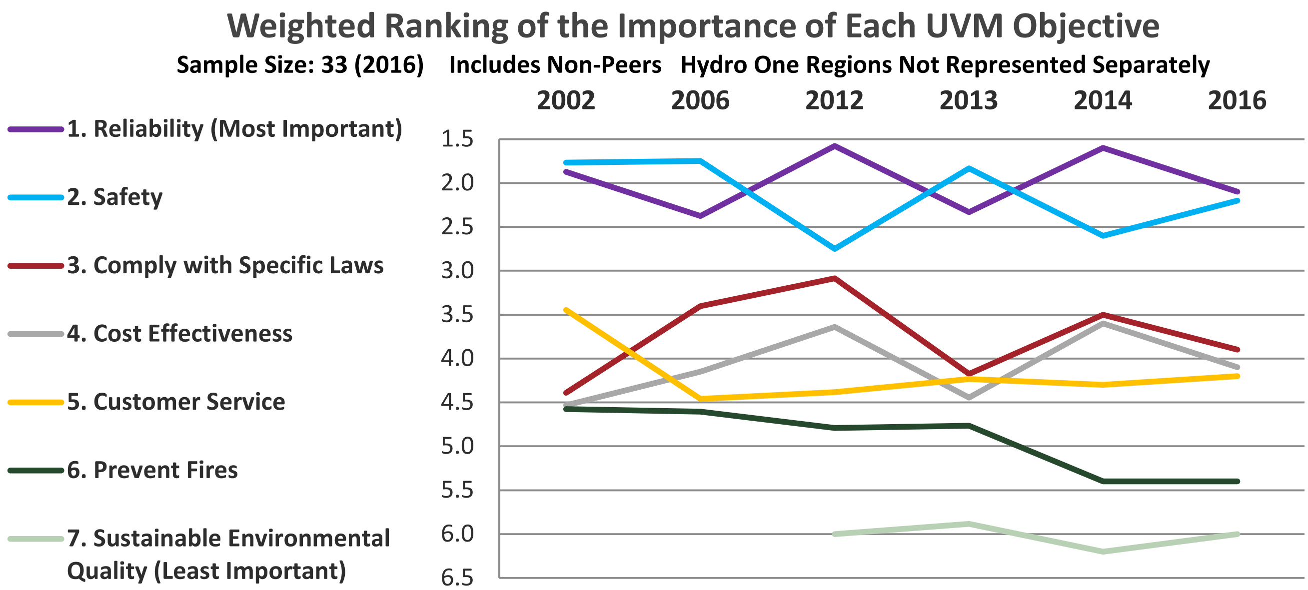
UVM DRIVERS AND FUNDING

UVM Objectives

This graph was created from six different CNUC surveys given in 2002, 2006, 2009, 2014, and 2015 (the survey done for this project). The number of participants varied from year to year and the utilities were not the exact same set, although many participated in all five surveys. The order shown in the legend is the 2016 rankings.



Graph 69: Weighted Ranking of the Importance of Each UVM Objective

Hydro One's Rankings in order of importance were:

- Most Important: Reliability
- Cost-Effectiveness
- Customer Service
- Safety
- Sustainable Environmental Quality
- Comply with Specific Laws
- Least Important : Prevent Fires

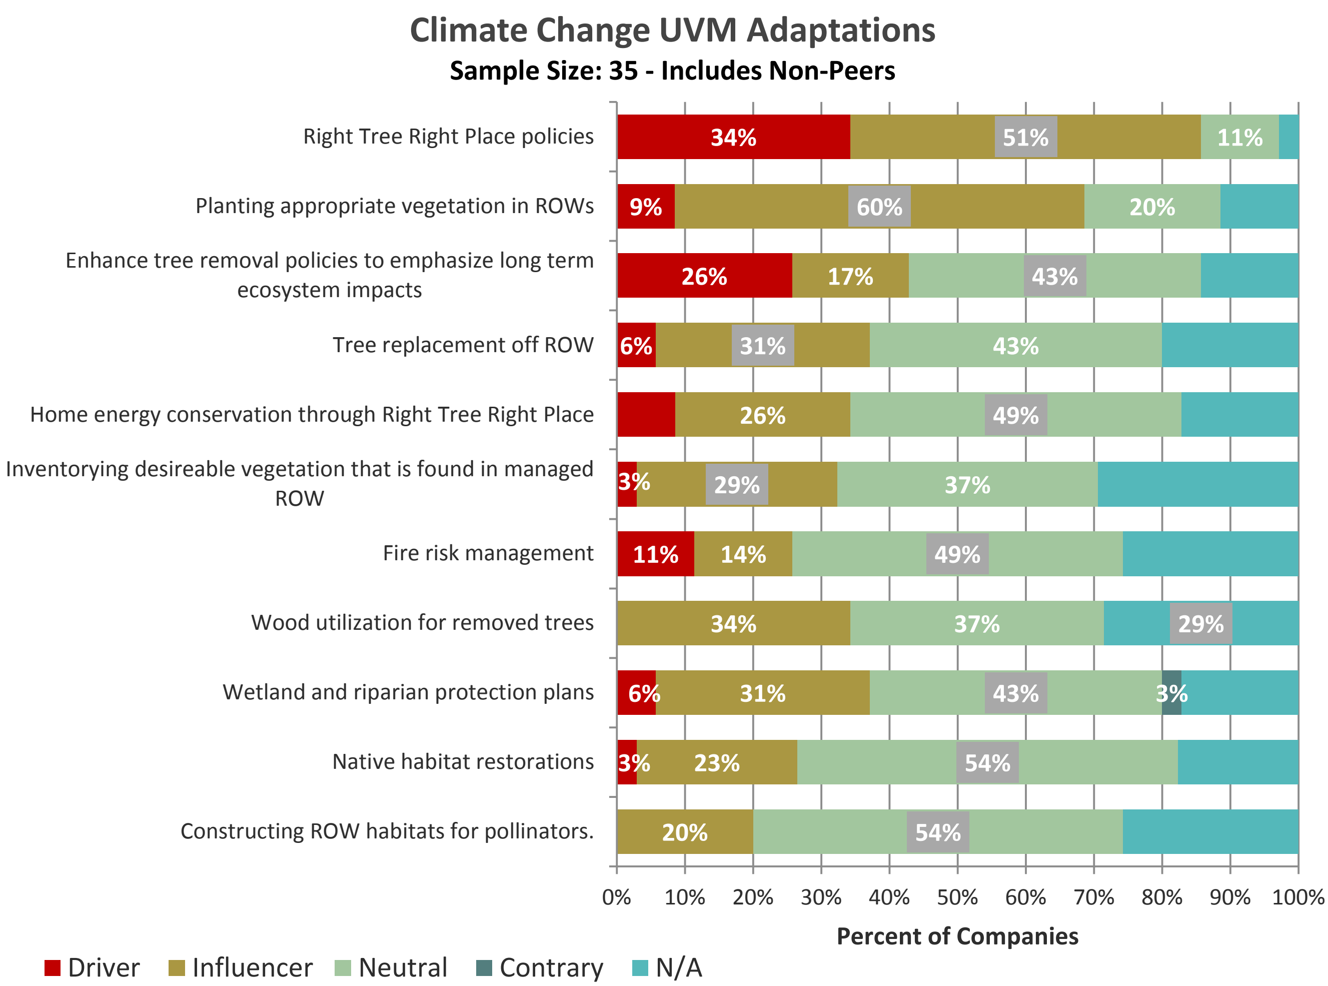
Of note is the Hydro One's ranking for Safety (4th), which is significantly lower than the industry; Compliance - 6th compared to the industry ranking of 3rd; and Cost-Effectiveness, which is significantly higher than the industry. Although much of the industry ranks preventing fires a lower priority, several rank it is as the second most important. These utilities are located in areas of high fire danger. Locations with higher fire danger are changing as changes in climate impact forest health and composition. The fires in Alberta in May 2016 may be an indication that Hydro One should consider incorporating fire prevention into their UVM program.

UVM Programs Contributions to Ecosystem Sustainability

The following question was posed to UVM managers:

OBJECTIVE: To determine the extent that distribution UVM programs are contributing and adapting to carbon free initiatives and ecosystem benefits.

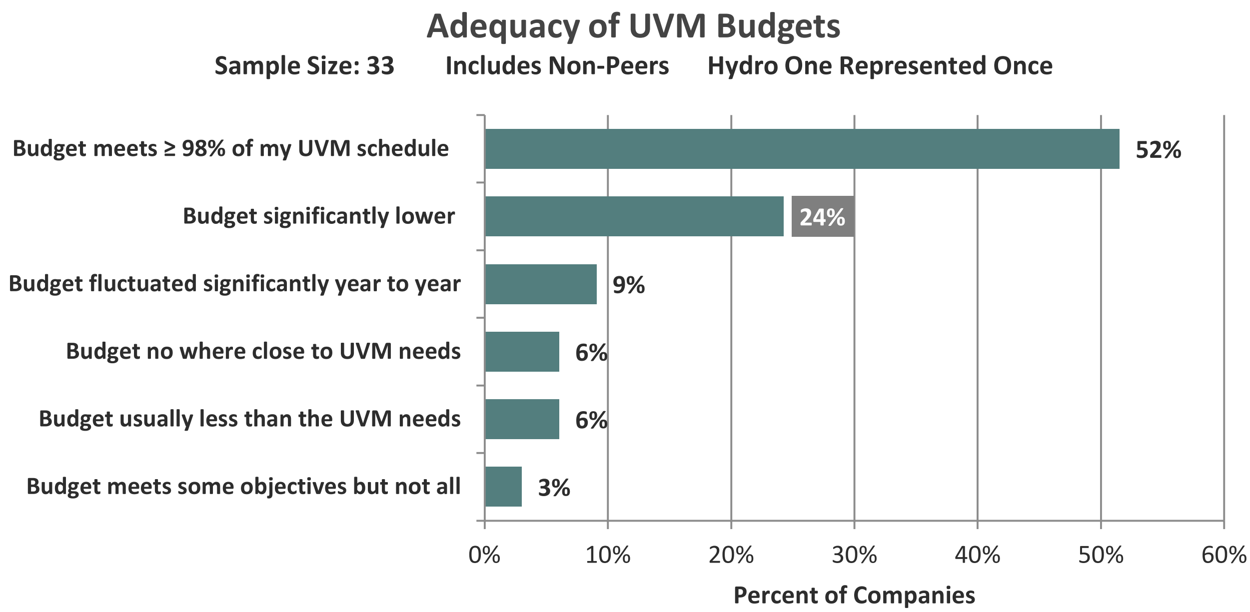
QUESTION: Evaluate whether the activities listed below are driving, influencing, neutral or contrary to your UVM program.



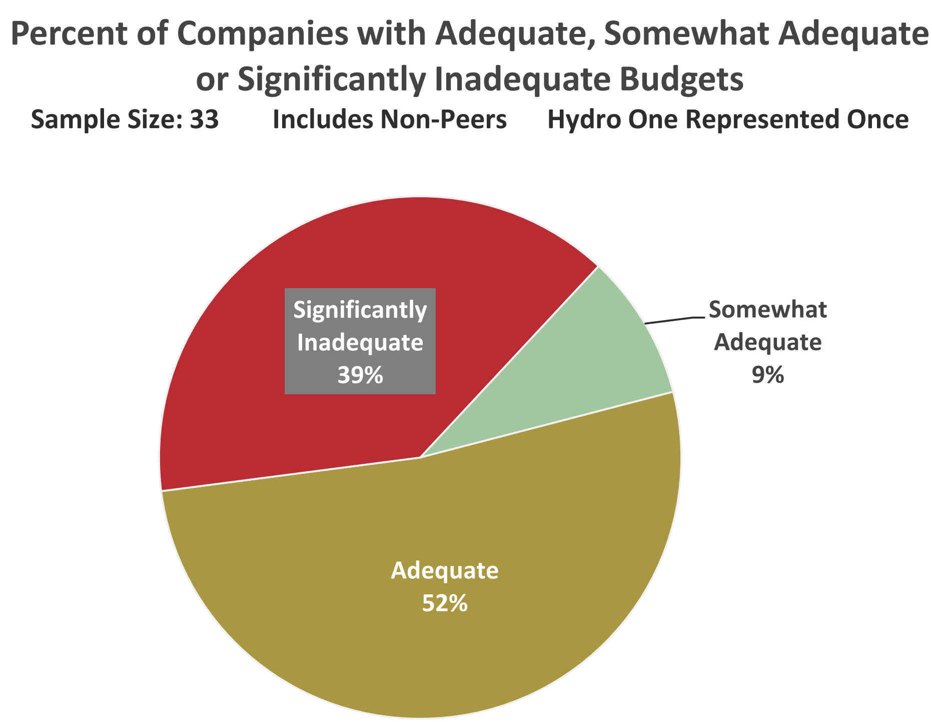
Graph 70: Climate Change UVM Adaptations

- One utility targets invasive species and this influences their UVM activities.

UVM Budget

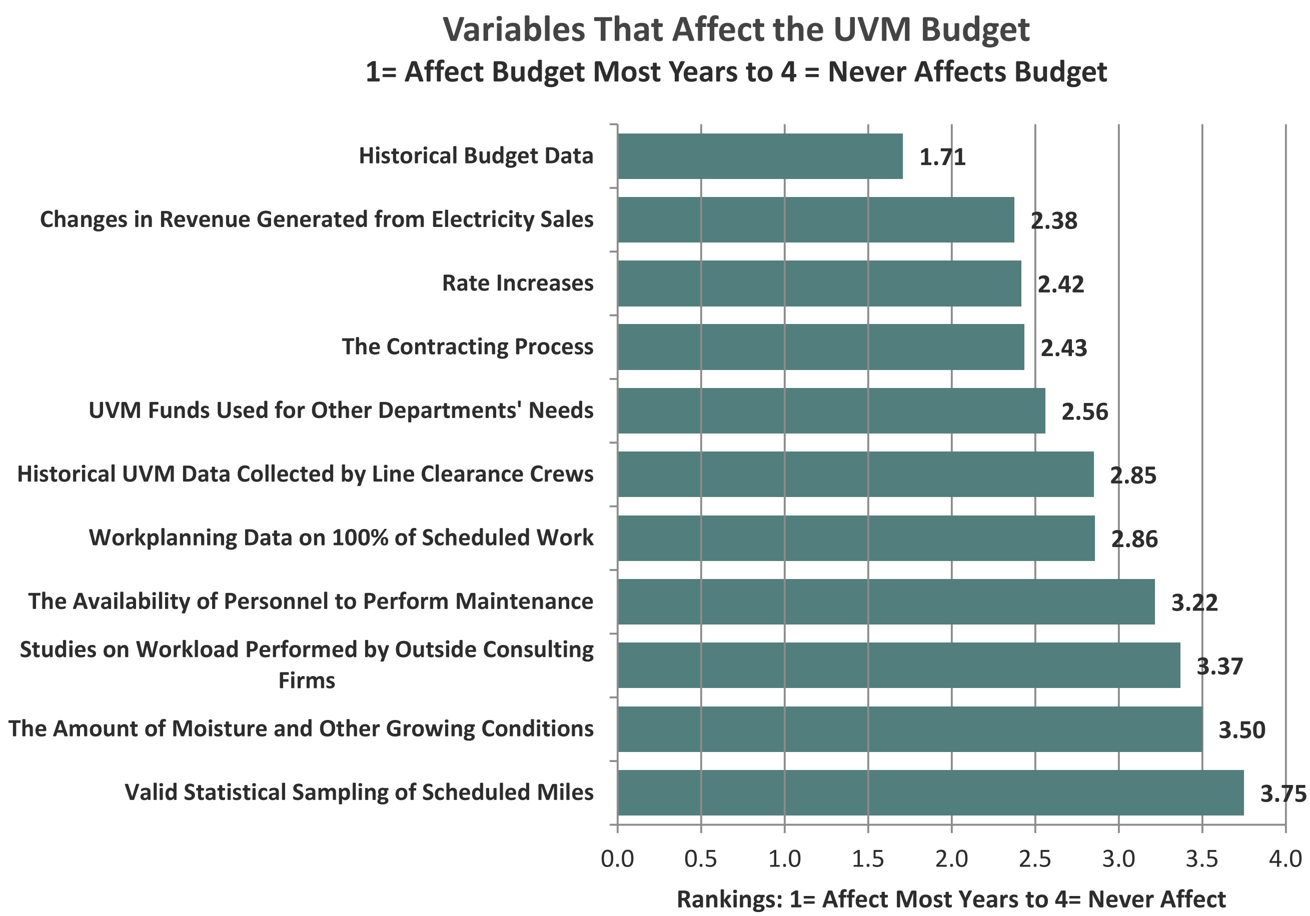


Graph 71: Adequacy of Budgets Meeting UVM Needs



Graph 72: Percent of Companies with Adequate, Somewhat Adequate or Significantly Inadequate Budgets

Variables That Influence UVM Budget



Graph 73: Variables That Affect the UVM Budget

Program Policies to Optimize Efficiency

These responses include **Non-Peer** utilities. 32 companies answered this question.
The survey asked:

> Do you have scheduling strategies or program policies that are designed to optimize efficiency and reduce non-productive costs resulting from transportation and related costs of the mobile work environment?

Included in this question were several sub-categories. A summary of responses follow.

What scheduling strategies are employed?

We ask [our contractor] to schedule work in the most efficient way possible. This is to their benefit as their contract is dependent on meeting quarterly production metrics
Planned feeder cycles, SAIDI, and routine patrols
An annual target for all compliance work is employed.
O&M program clearing work is coordinated with capital line work to maximize efficiency
Planning, inventory to plan maintenance schedule (3 similar responses)
Time of year (Seasons) coordinating work (maintenance and hazard tree programs)
Mainly try to put the right equipment in the right place at the right time. For example, get bucket trucks into farm fields before crops are planted.
Switched to Unit Price contract for planned maintenance work two years ago
Organized at a local level, no overall strategy [Hydro One]
Group circuits of a substation together in an annual plan (or group by local work area)
We try to concentrate all of efforts to a particular location and do all we can in that location until completed.

Table 12: Scheduling Strategies

What program features, such as cycle length, limit unplanned or reactive work?

Our cycle lengths are appropriate for our system, [the] grow[th] in outages are less than 10%. We have also had third party studies confirm that our cycle length is appropriate.
Two- year planned feeder cycles, targeting past outage areas
Cycle length does not affect unplanned/storm/reactive work. We are able to ramp up crews to meet unforeseen events along our powerline systems.
Relatively short and consistent cycle
Managing vegetation maintenance to a cycle (6 Companies)
Cycle length [and] increasing use of technology such as LiDAR.
Our mid-cycle program helps address issues that may result in unplanned work.
We have had to increase our Transmission pruning to stay compliant with NERC requirements and it had a negative impact on our routine pruning so I have implemented the use of topping machines and have been able to keep our regular crews on routine work.
Combine vegetation defect program with regular maintenance to avoid duplicate trips [Hydro One]
[Third party contractor] work inventory and prescriptions
Cycle length, mid-cycle review, Forestry driven reliability assessment work, Engineering driven reliability enhancement work

Table 13: Strategies to Limit Unplanned Work

Clearance and removal policies that limit future reactive work to optimize efficiency

We defer a lot of requested off cycle work, we mainly only do reactive work that really needs to be done.
We remove problem trees as much as possible
Aggressive removal of "cycle busters"
Maximize removals of trees inside and hazardous trees outside of the right-of-way
Aggressive removal policy (7 companies)
Data
Contractor incentives for reducing inventory
Remove if allowed
Remove trees vs just trim to eliminate future issues [Hydro One]
We attempt to clear 10-15' to all sides of the primary conductors to minimize growth into or close before the next cycle is due.
Corrective pruning and certain removals are performed on hourly T&M billing
Remove all dead, dying, defective branches in overhang (regardless of height)
We alter all scheduling for any and all tree removal near our facilities.

Table 14: Policies to Limit Future Work

Tree removal was the primary method to reduce future unplanned work. (53%)

Contract policies on travel time to optimize efficiency

Must be approved by [utility]
None. Our contracts are set up so that there are crews positioned in each respective district.
Contract crews locate pullouts within 15 minute drive of work locations (2 companies)
No charges for travel time.
No requirement - Unit Price contract

Table 15: Travel Time Policies

A vast majority (86%) of UVM departments do not have a policy for travel time.

Technology that monitors transportation to optimize efficiency

68% of the respondents (Hydro One is in this category) use a GPS-based monitoring system for tracking vehicle locations. One company mentioned having a two-way communication system included with their monitoring system.

Two responses that varied were:

- We are in the process of introducing a Work Force Management tool.
- [Contractor] uses Telogis to monitor crew travel and production.

Customer service activities and policies to optimize efficiency

Customer contact is handled by contractor representatives and by [utility] personnel to ensure 100% compliance and satisfaction.
Increased utilization of partnership with internal customer care department.
No debris clean-up after storms or damage from acts of nature, customer responsible for service
We try to do this ahead of time to minimize the impact on time.

Table 16: Customer service and policies

Parking locations for crews to optimize efficiency

This is always a challenge in our Urban areas
None. This is a contractor's responsibility. (2 companies)
At substation or farm or gas station within 15 min of work site (2 companies had 15 minute policies).
Various staging sites based on work plan (7 companies)
Yes we provide places for contractor trucks.
Encourage "show-up" locations close to circuit
Parking/staging locations are set up close to the work to minimize travel times. These are changed frequently to keep contractors close to the work. (3 companies)
Temporary work headquarters for jobs that are remote from the local operations centre. [Hydro One]
At local operating center for reactive work crews (none for bid work crews)

Table 17: Parking locations for crews

Lodging and per diem to optimize efficiency

Must be approved by [utility]
Only during storm work/emergent work
Only for peak workloads when utilizing out-of-state traveling resources
Per diem per designated distance from show-up as defined in contract (7 companies)
Very minimal; considered on a case-by case basis. Seldom utilized except in extreme circumstances.
Limited but union mandated when applicable
None (2 companies)

Table 18: Lodging and per diem

Large crews transported in one vehicle to optimize efficiency

On some jobs, yes
Organized at a local level, no overall policy [Hydro One]
Again, contractor's responsibility.

Table 19: Large crews transported in one vehicle

Training to optimize efficiency

We generally pay time for training, we ask [contractor] to cover the cost of conferences, etc.
Contractor provides training to all crews. We conduct an annual environmental sensitivity training for all contractor personnel.
Focus on winter and inclement weather days for crew training [Hydro One]
At least annual
Training is an ongoing process that we schedule around.
On the job

Table 20: Training

Other methods used to optimize efficiency

If conditions merit we may perform a mid-cycle maintenance cut (basically a planned and controlled hot spot cut)
Incentive/remedy program has increased productivity
Assigning contractors to specific geographic areas to reduce non-productive travel time
Smart phone with email, GPS, mapping for reactive work crews
Work is planned in advance; contractor is responsible for optimizing resources.

Table 21: Other optimizing methods

Compensating for Storm Disruptions

What adjustments to your schedule do you make to compensate for storm disruptions of the routine schedule?
None. If we have a storm the contractors try to add resources to get back on schedule. Not always successful. [8 companies similar responses including Hydro One]
Storms can be a big challenge; they interfere with getting maintenance work done. We will often have crews that are on storm standby go out and do maintenance work so they're not just sitting around.
Bump scheduled work as needed
Compliance tree crews are ramped up after a storm incident to be able to ensure compliance time-frame is on track.
Overtime based on length and severity of the storm (7 companies)
Depending on the severity of the storm and damage
Overtime may be authorized when significantly behind schedule. Work may be shifted from reliability to compliance pruning.
Adding crews, working overtime or both if possible.
We have been able to absorb storm costs without impacting the completion of our annual schedule
We can be flexible on the Target miles that contractors are to complete each quarter if they have worked numerous storm disruptions. In many cases we will not penalize them for being behind target on line mile production.
Circuit completion dates are reported as month/year, not an exact date. This means that you have until the last day of each month to complete a circuit. We schedule each of them to be completed by the 15th however to provide us with some breathing room in case of unforeseen circumstances. For instance, if a storm hit an area the last week of the month, and you had to take your crews of the circuit work to address the storm, you may not meet the end of the month deadline.
Increase Risk Tree assessments post storm to cover all affected areas -push out other maintenance work
Reactively adjust all scheduled activities
Bring in an extra crew or add Saturday work at straight time or OT, if necessary
Being an in house crew, routine UVM is restarted as soon as the disruption is resolved.
Our utility budgets an annual amount for storms
Add on additional crews if possible in order to meet our cycle goals

Table 22: Strategies for Storm Disruptions

Basically, companies use the following two strategies:

- Increase expenditures by adding overtime or extra crews to maintain schedule
- Keep target maintenance schedule flexible or readjust them

Elements of UVM Program That Optimize Efficiency

Name three things that are key to the efficiency of your UVM program:
1: Contractor continuity - [Contractor] has been here so long they know our system intimately. 2: We have several cycles' worth of cost data so we know how much each circuit should cost. 3: We run very low overheads (7.5%) so more funding goes towards tree trimming
Outage tracking, targeting tree type (faster growing to slower growing) and patrols
Accountability of the inventory personnel and tree crews, accurate work of such, and proper oversight and management of all contractors by [utility] personnel throughout the year.
100% audit of all vendor work, vendor flexibility in scheduling to maximize their productivity, incentives for exceptional on-time delivery of quality work.
Weather, Customer Relations, Equipment Reliability
1. Great contractor leaders and trained, dependable personnel; 2.   Small, but excellent internal team; 3. Sufficient budget funds to pay for quality contract help
Mowing the brush/trimming rather than chipping in the rural area mainly. The 55' back yard-lift to reduce manual climbing. Mini skid for removing brush/trimming from back yards and having the clam truck pick up brush rather than chipping. Job planners talking members rather than VM tree crew. -herbicides play a huge role.
1) Field-verify any unknown ticket work prior to crew dispatch. 2) Cycle customized to each VM area. 3) Assess VM areas several months prior to making a scheduled cut to allow for re-prioritizing based on actual field conditions
Targeted RE (time per primary tree unit includes associated brush & secondary) with quarterly payment adjustments Use of mowers and side trimmers where ever possible Backyard buckets and "bigfoot" aerial lifts to increase accessibility
Safety, planning, proper equipment (7 companies)
Adequate funding, quality work audits, resourceful management.
Inventory, safety and square meter contract
Getting consistency in all aspects of the program such as planning, work layout and end product delivery. Effective contracting strategy. Contractors that are committed to supplying resource to our programs.
Consistent workload over a year (number of trees consistent over the year). Long-term contracts (5 years). Incentive for reducing the number of trees that need to be pruned compared to a baseline quantity at start of contract. (reward for removal vs prune)
electronic inventory/prescription, electronic time keeping and invoicing, Google Earth mapping and pictures of work
Budget, inspections of work, and crews regularly
Close communication with the contractor, good supervision and well thought out planning
Adequate funding, quality work audits, resourceful management. (2 companies)
Contractor performance, Staff inspection of the work performed, Management of staff, contractors and budget
Pre-notification Incentive/Remedy Program Consistent workforce

Continued next page
(1) Receiving funding to meet our target Trim cycle, (2) Adequate funding to our Danger Tree Program (3) Knowledge transfer from retirees to new hires.
Logistics, labour rates, mechanization [Hydro One]
Weather, Resources and Planning
1) Accurate estimation of the resources needed to complete the 48-month work. 2) The right contractor management folks in place to make sure the work is managed most effectively/efficiently. 3) Experienced work force in regard to the tree workers themselves.

Table 23: Three things that are key to the efficiency of your UVM program

New Technologies Used in UVM Program

What new technologies have you introduced to your UVM program?
Unfortunately we are not a technology forward company.
Use of SAIDI information and outage tracking
We introduced at the start of the year a new GIS tree inventory program utilizing handheld iPad units that enables the inventory patrolmen to digitally inventory the tree with GPS placement, updated inventory count, pertinent notes related to the site, and GIS mapping capability for QC work of the tree crews in real-time.
Mechanized hazard/danger tree removal, use of Hiring Hall crews, LiDAR trial [Hydro One]
Electronic work planning (7 companies)
GPS data collection for patrol inventory of vegetation
Electronic data (computer and GIS based work management systems.
LiDAR is being used for transmission inspection, and we are testing its use for distribution.
Trying to get away from Paper maps. We are attempting to email all maps to GF's in the field. Many of our Company Forester's can make updates to the map in the field and send directly to our contractors. All OC's have mobile offices in their trucks and we're looking at going to a tablet.
Pilot TGR program. Electronic timesheets and production trackers. New UVM software to be introduced possibly late in 2016.
Electronic inventory/prescription, electronic time keeping and invoicing, Google Earth mapping and pictures of work
Work management system, electronic invoicing, new equipment technology (new type of whole tree chipper, new type of mower, cranes. etc) herbicide application (plus starting TGR in 2016)
Lateral Pruning, Herbicide Treatment
1. Skid-steer with forestry cutter; 2. Mini back yard Jaraffe; 3. Organized herbicide program; 4. Clear, simple expectations
Inventory software - back yard lift 55'- Quick trim where possible

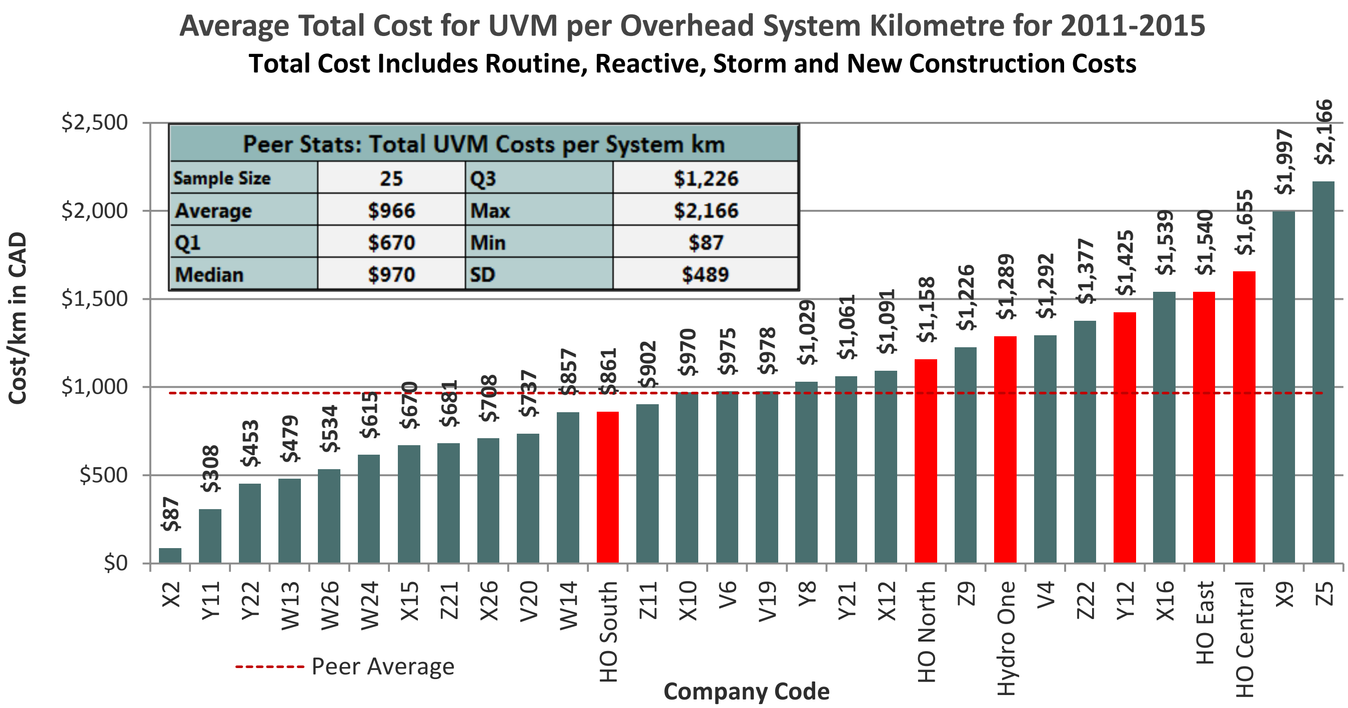
Table 24: New Technologies

Predominate New Technologies in the order of times mentioned:

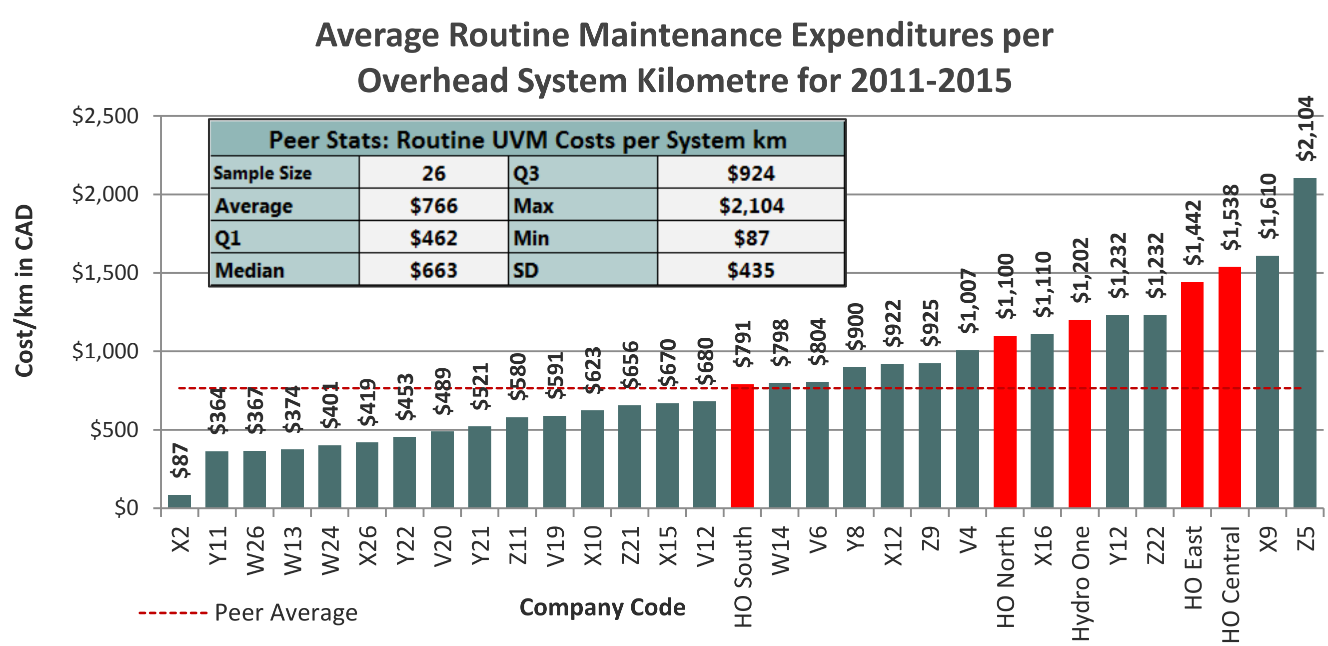
- Software for data collection, inventory, and work-planning, which may also include electronic mapping capabilities
- Mechanization and UVM equipment technologies
- LiDAR and remote sensing technologies
- Herbicide

FINANCIAL AND LABOUR HOUR COMPARISONS

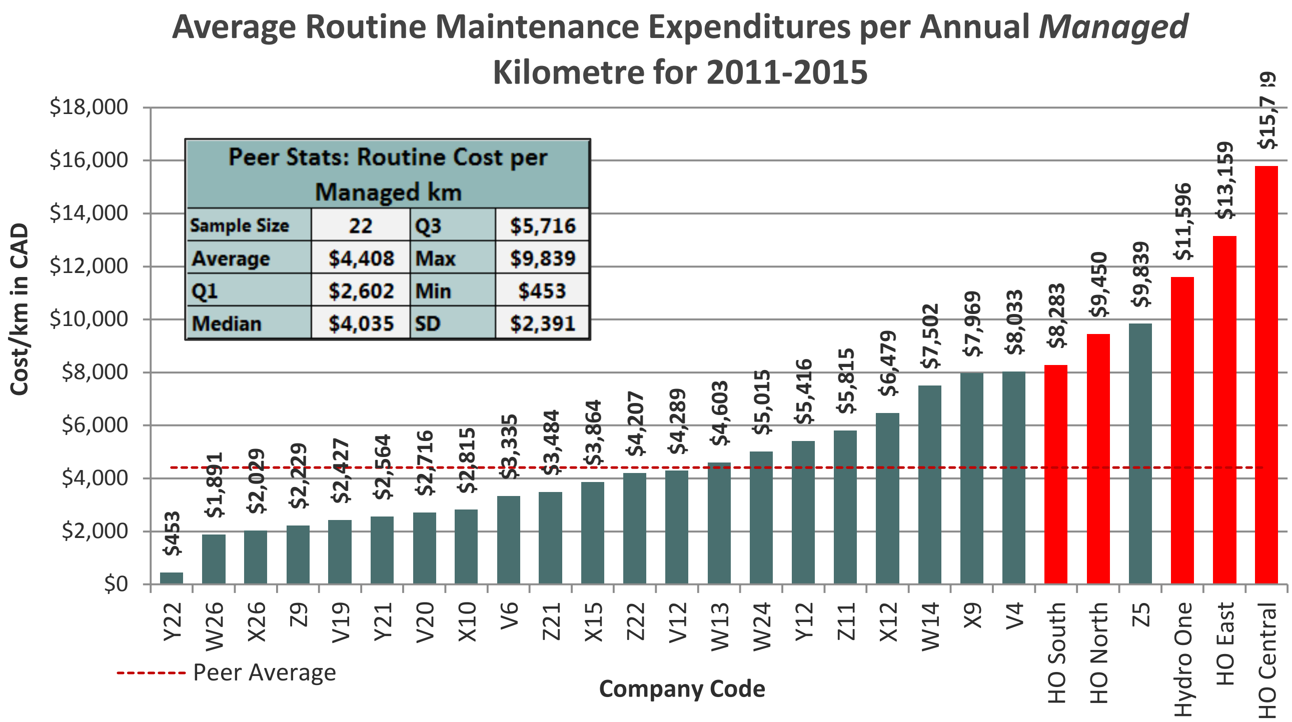
UVM Expenditures



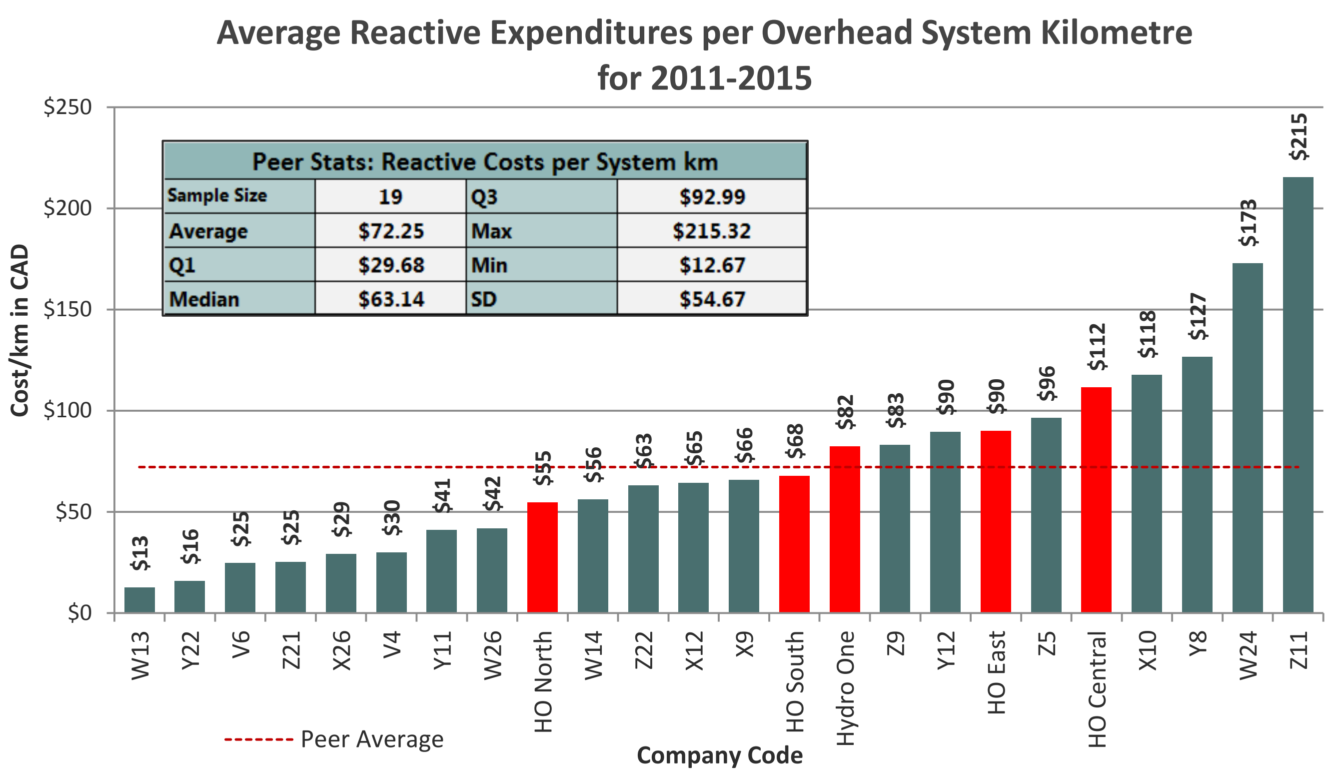
Graph 74: Average Total Cost for UVM per Overhead System Kilometre for 2011-2015



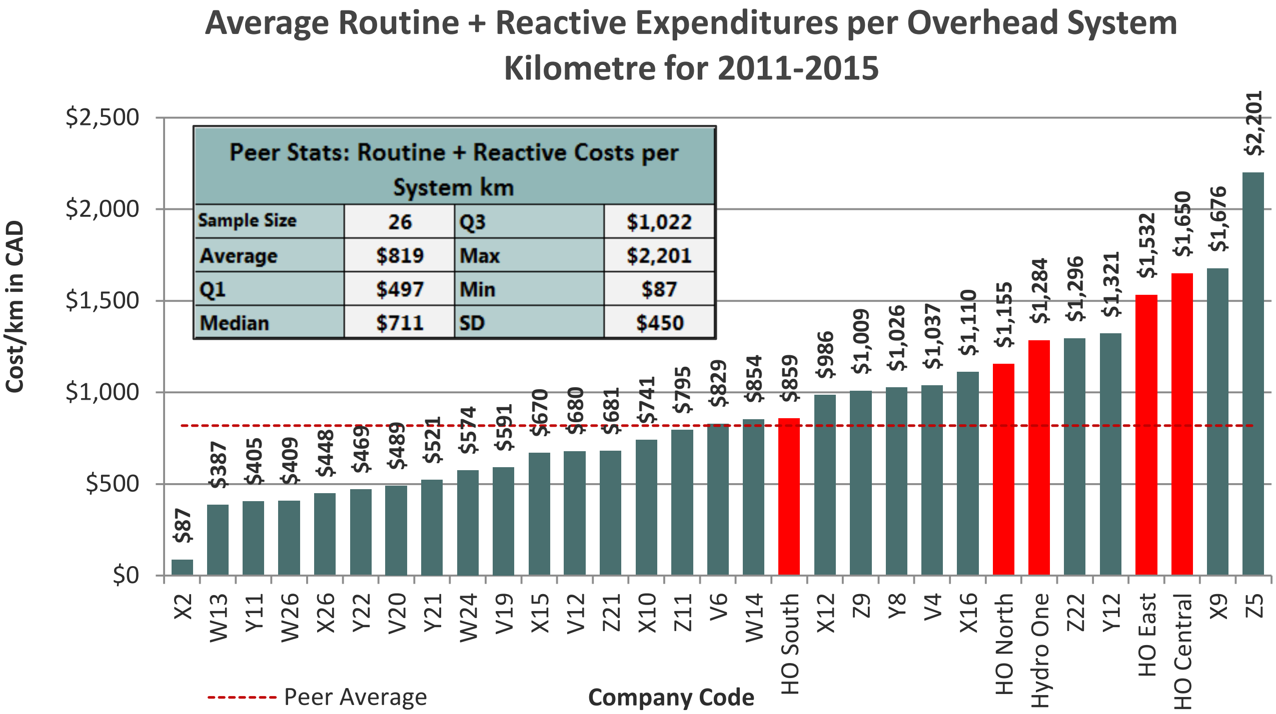
Graph 75: Average Routine Maintenance Expenditures per Overhead System Kilometre for 2011-2015



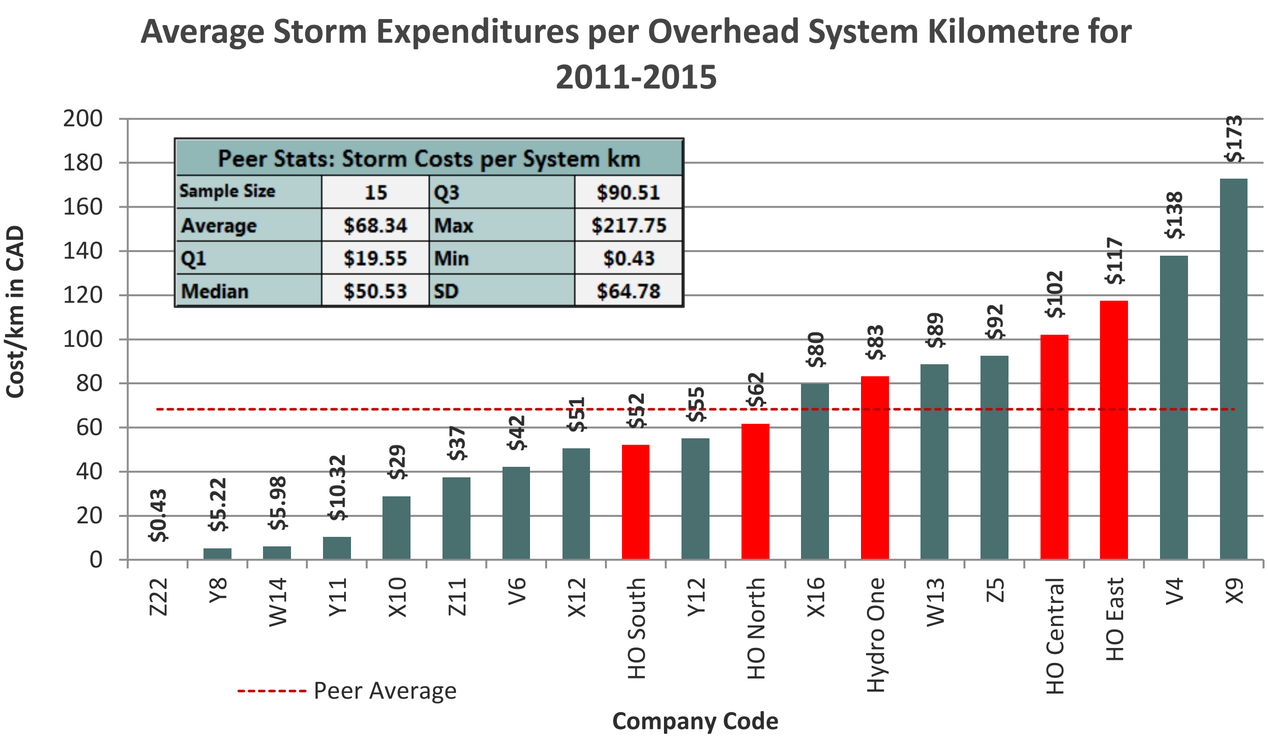
Graph 76: Average Routine Maintenance Expenditures per Annual *Managed* Kilometre for 2011-2015



Graph 77: Average Reactive Expenditures per Overhead System Kilometre for 2011-2015

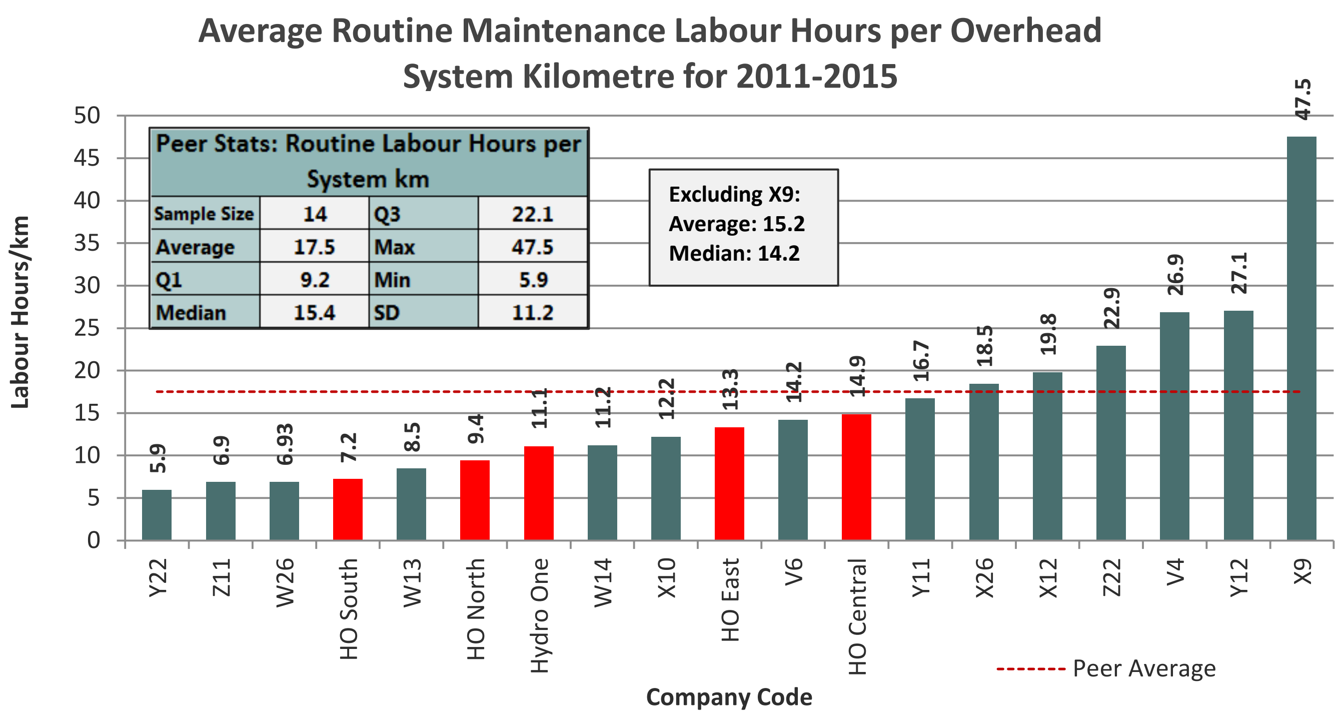


Graph 78: Average Routine + Reactive Expenditures per Overhead System Kilometre for 2011-2015

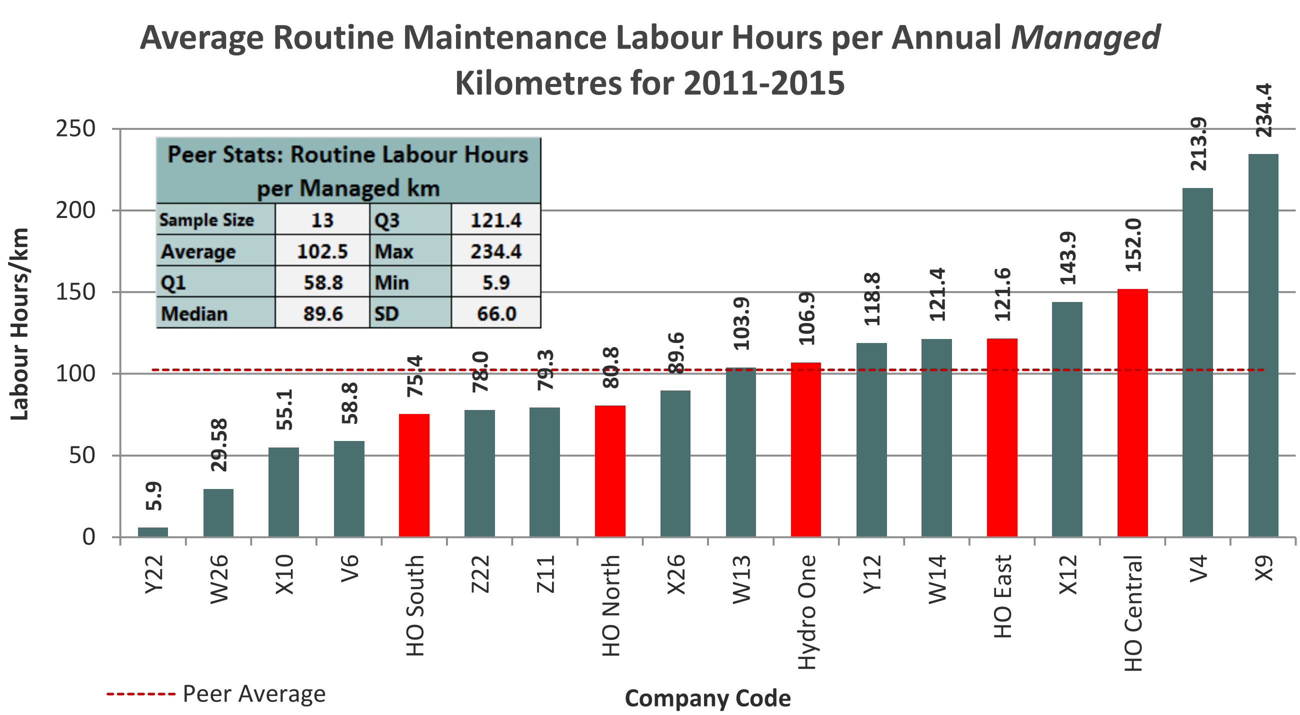


Graph 79: Average Storm Expenditures per Overhead System Kilometres for 2011-2015

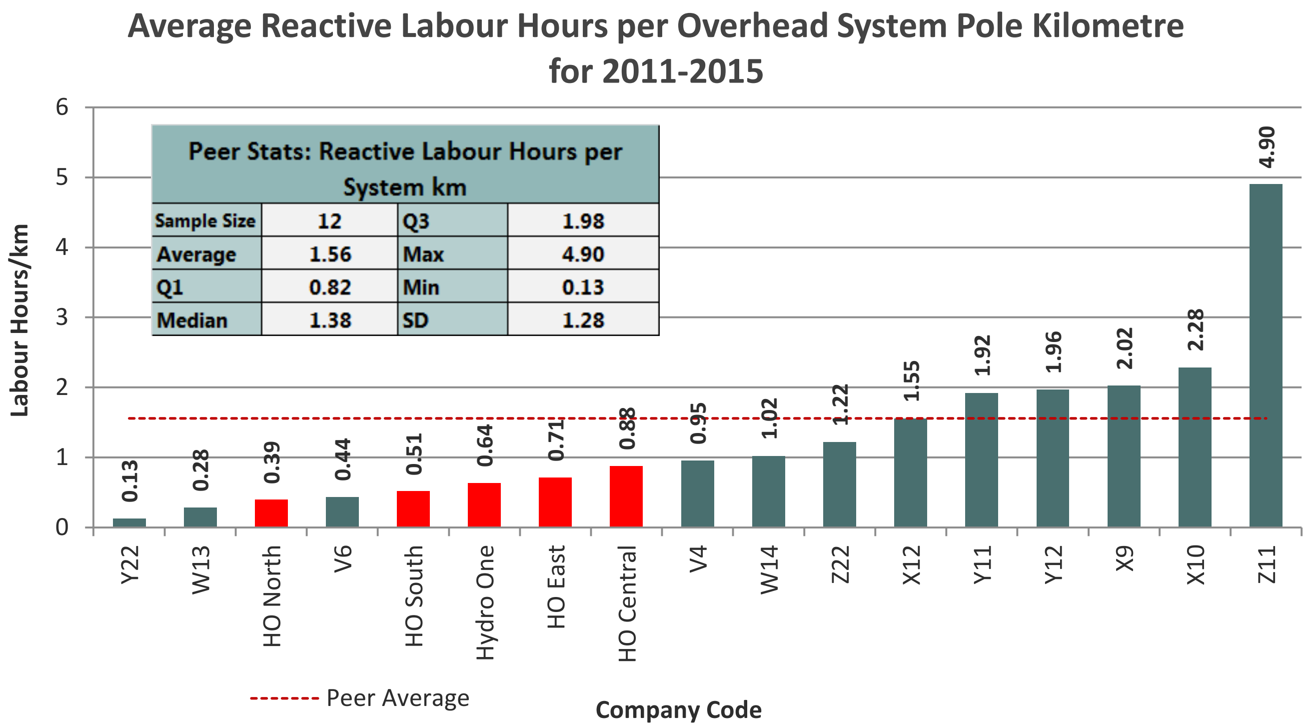
Labour Hours Expended on UVM



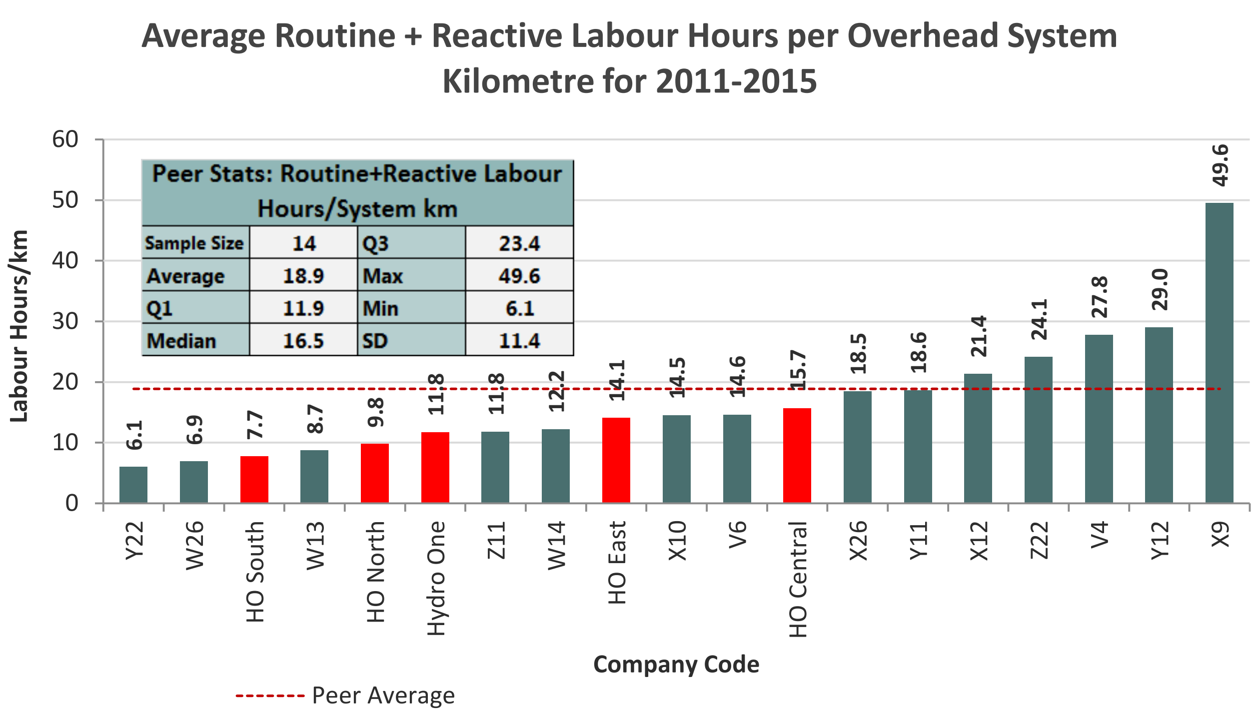
Graph 80: Average Routine Maintenance Labour Hours per Overhead Distribution System Kilometre for 2011-2015



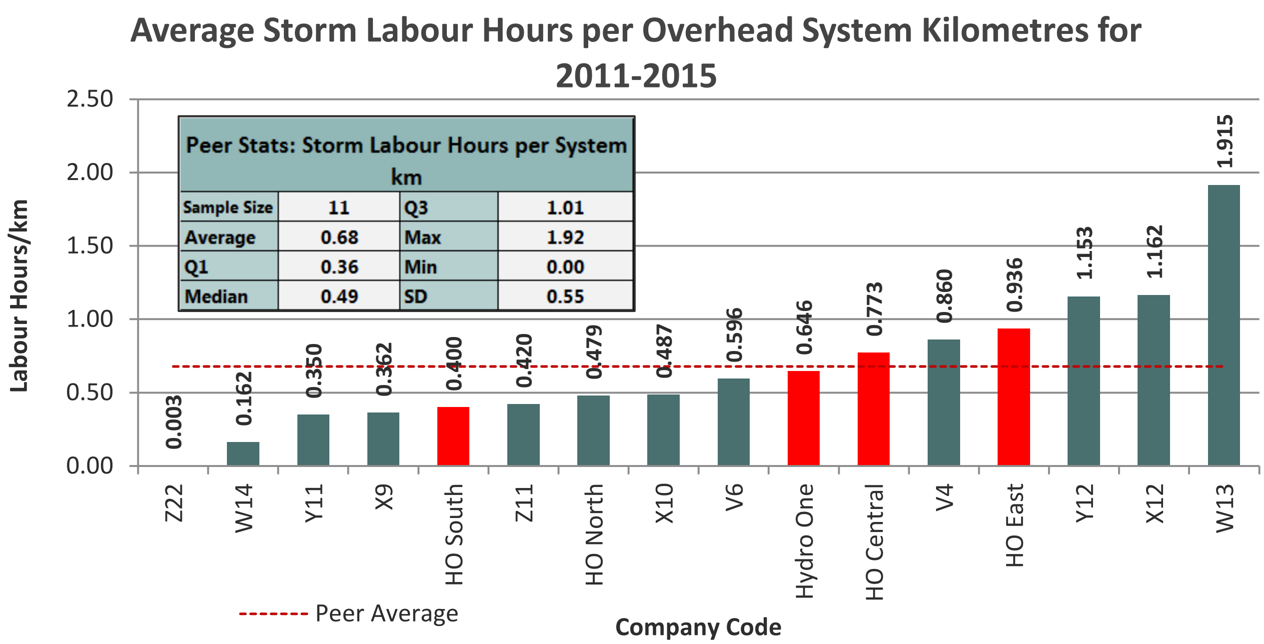
Graph 81: Average Routine Maintenance Labour Hours per Annual *Managed* Kilometres for 2011-2015



Graph 82: Average Reactive Labour Hours per Overhead System Kilometre for 2011-2015

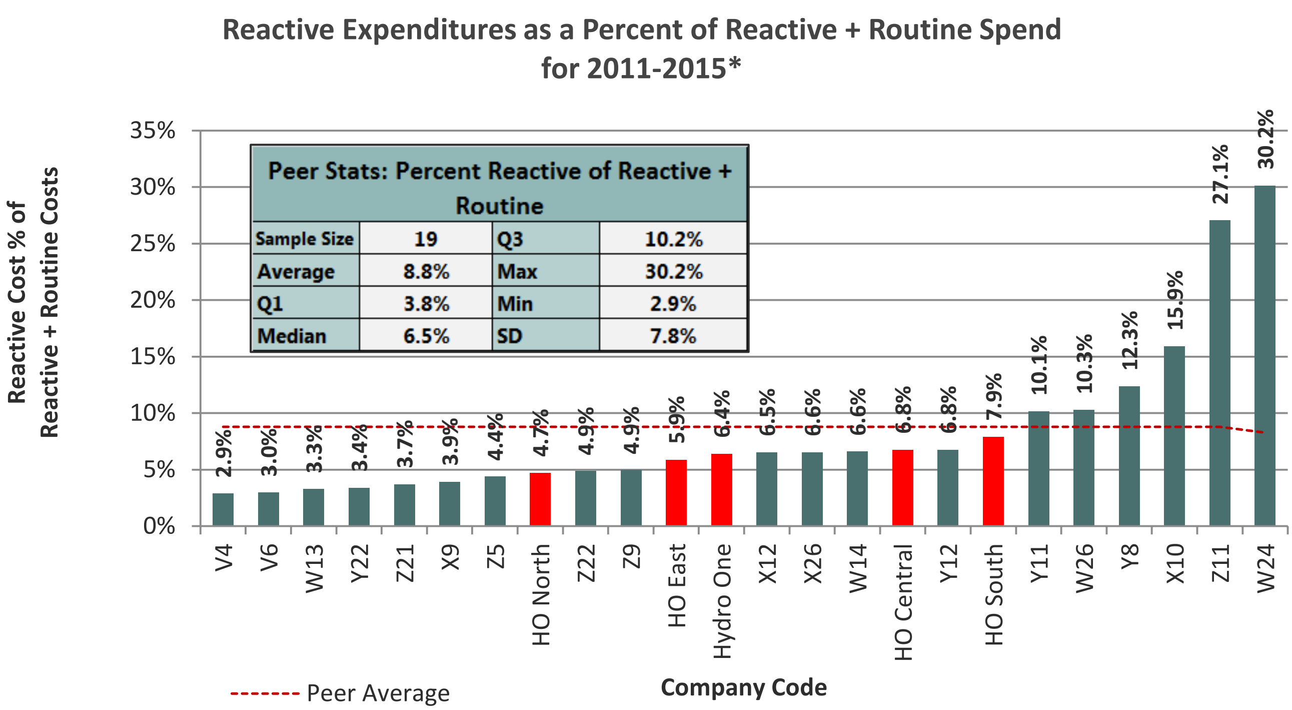


Graph 83: Average Routine + Reactive Labour Hours per Overhead System Kilometre for 2011-2015



Graph 84: Average Storm Labour Hours per Overhead System Kilometres for 2011-2015

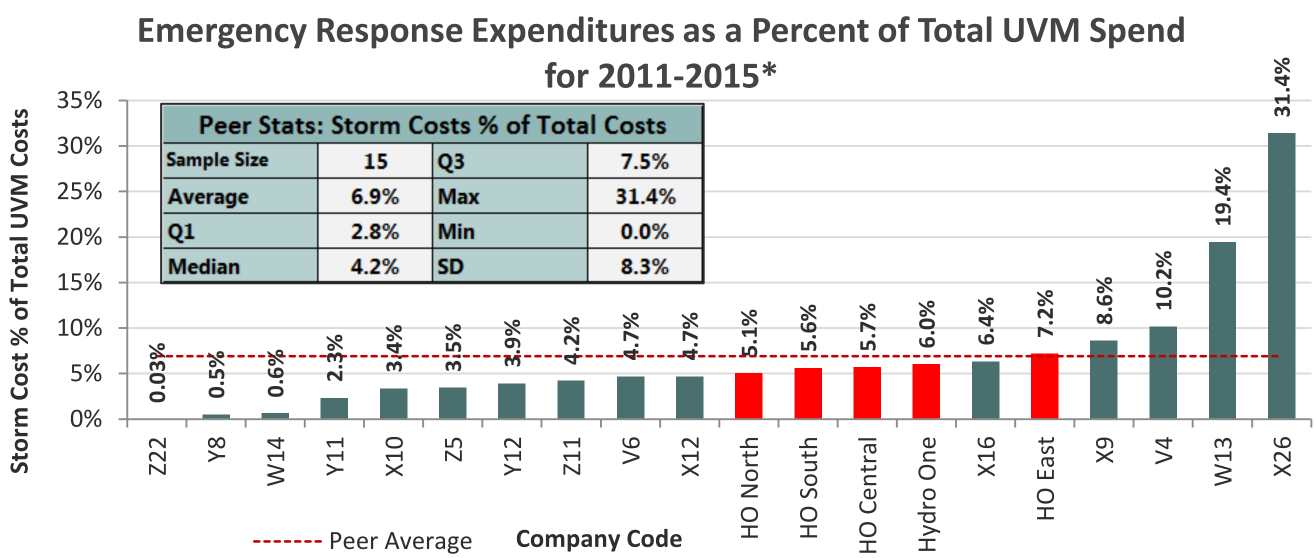
Reactive Work Expenditures as a Percent of Reactive and Routine Maintenance Costs



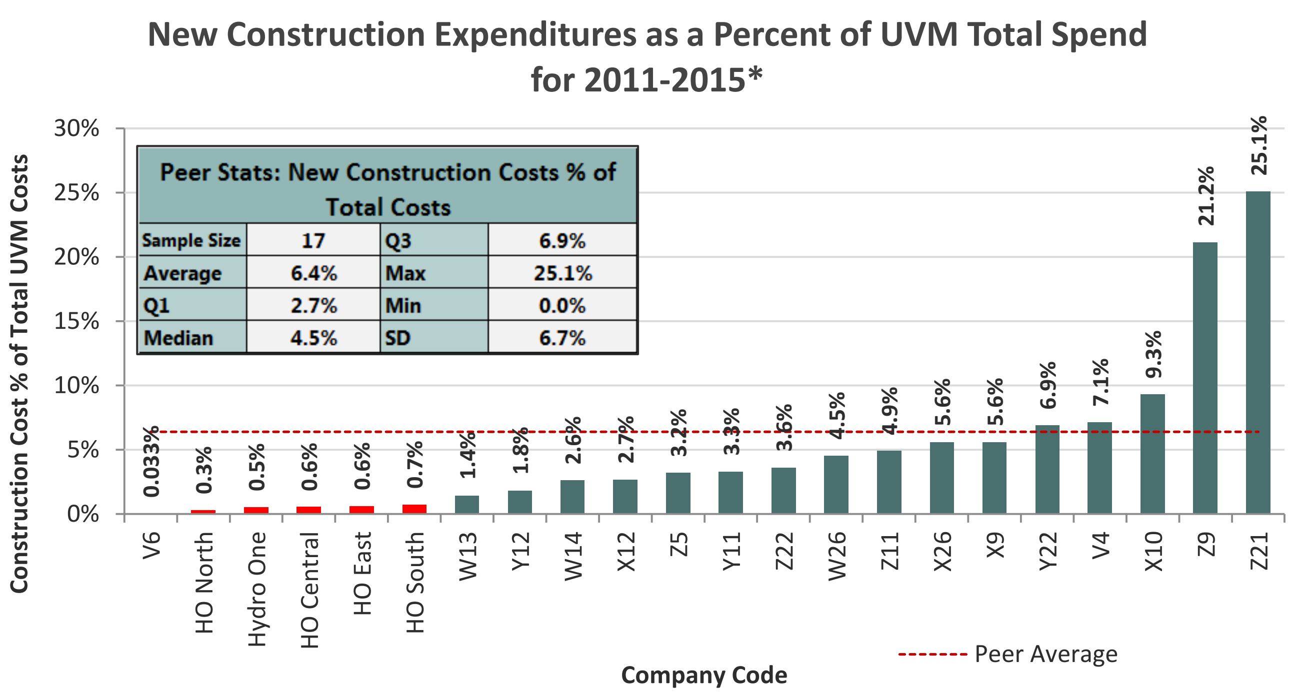
Graph 85: Reactive Expenditures as a Percent of Reactive + Routine Spend for 2011-2015

Percent of Total UVM Spend

*The following graphs were derived by adding the reported expenditures *for Routine Maintenance, Reactive, Emergency Response,* and *New Construction Work* costs to derive the "Total Spend." This "total" may vary from reported *Total UVM Expenditures* reported by the respondents due to the way costs are accounted for each utility. Some utilities included overheads, excluded storm and/or new construction since these expenses are not part of the UVM budget. Therefore, to equalize "Total Spend", CNUC added the costs of each work type.

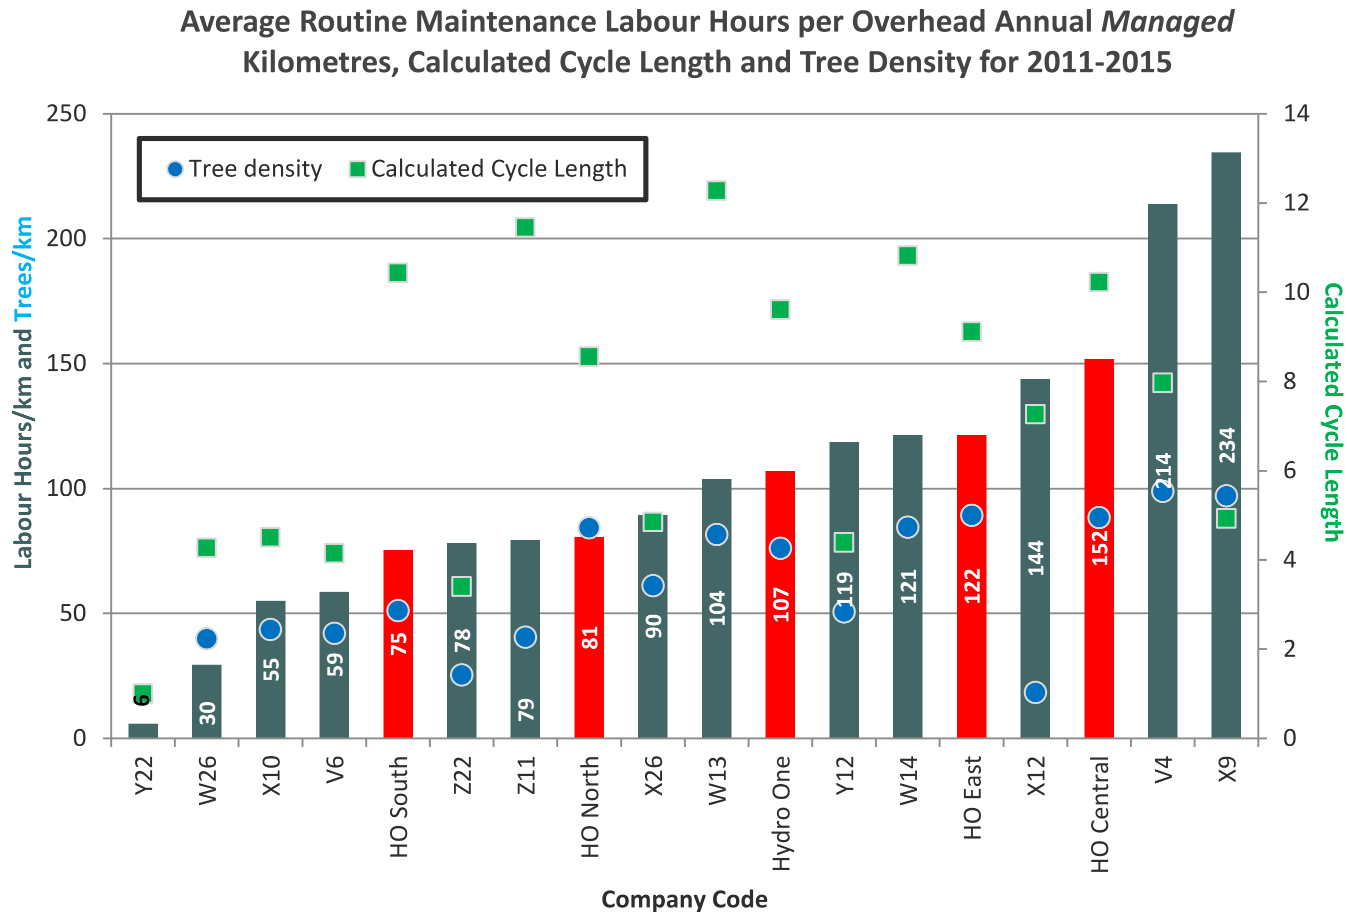


Graph 86: Emergency Response Expenditures as a Percent of Total UVM Spend for 2011-2015*



Graph 87: New Construction Expenditures as a Percent of UVM Total Spend for 2011-2015*

Labour Hours per Kilometre, Tree Density, and Cycle Length



Graph 88: Labour hours per Kilometre, Tree Density and Calculated Cycle Length*

A good correlation (0.7480) exists between tree density and actual cycle length ($p<0.002$). This analysis left-out X12, since this company has high calculated cycle length (143.9) with low tree density (18.3 trees/km). X12 is mitigating a tree mortality epidemic at present, which is affecting management scheduling. Although the reason for this correlation can only be guessed, CNUC believes that the longer cycles are allowing in-growth which produces a larger workload.

A good correlation (0.66656) exists between tree density and labour hours per km ($p<0.005$). This analysis left-out X12, since this company has high labour hour expenditure (143.9) with low tree density (18.3 trees/km). X12 is mitigating a tree mortality epidemic at present, increasing the current workload.

*Cycle length was calculated from information collected for 2011-2015 using the following calculation:

$$Calculated\ Cycle = Average\ \frac{Routine\ Labour\ Hours}{Annual\ Managed\ km} \div Average\ \frac{Routine\ Labour\ hours}{System\ km}$$

PRODUCTIVITY MEASURES

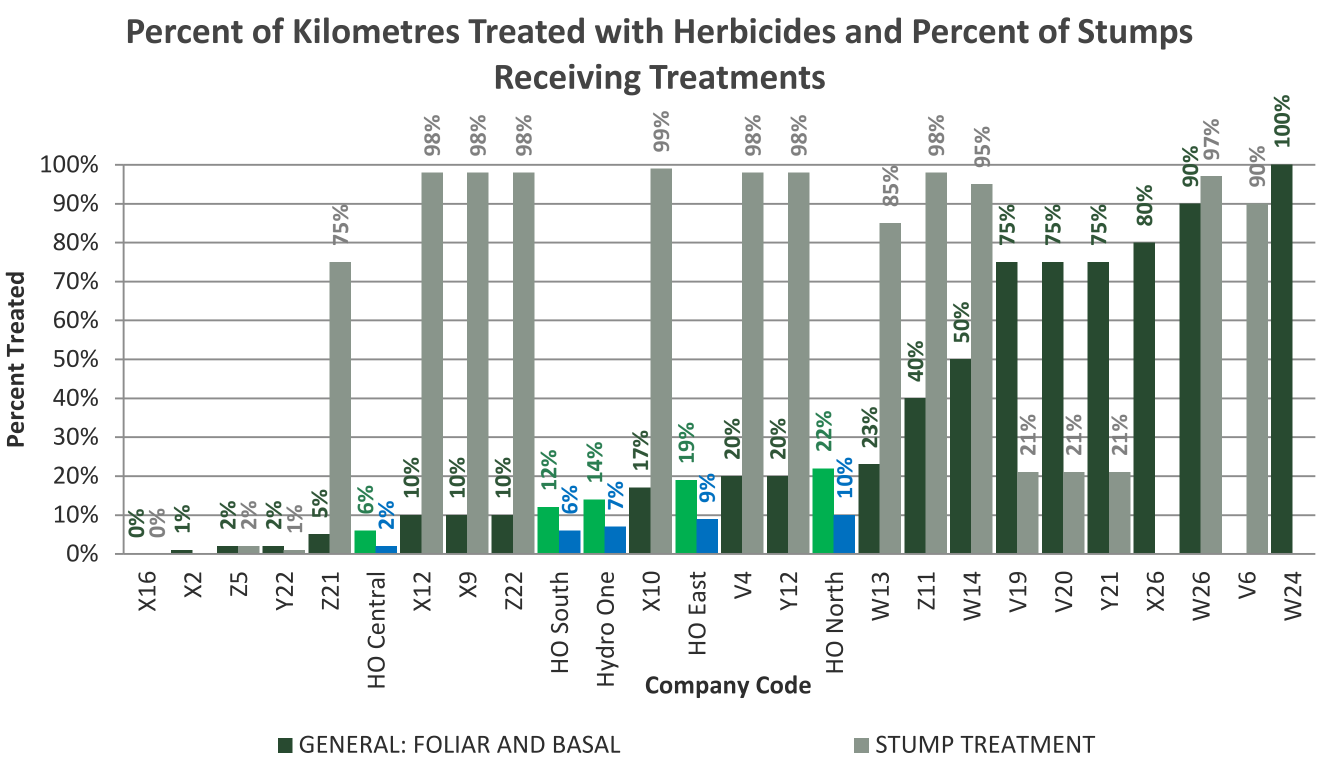
Herbicide Use

Participants were asked, "On average, what percent of the annual managed km (miles) of distribution ROW receive herbicide treatments to eliminate the in-growth incompatible species (excluding stump treatments on established trees)?" for GENERAL application methods (e.g. foliar, basal, etc.). They were also asked, "What percent of stumps from removed trees are treated with an herbicide to prevent re-sprouting?" for STUMP TREATMENTS.

Peer Group Statistics (Sample size: 21):

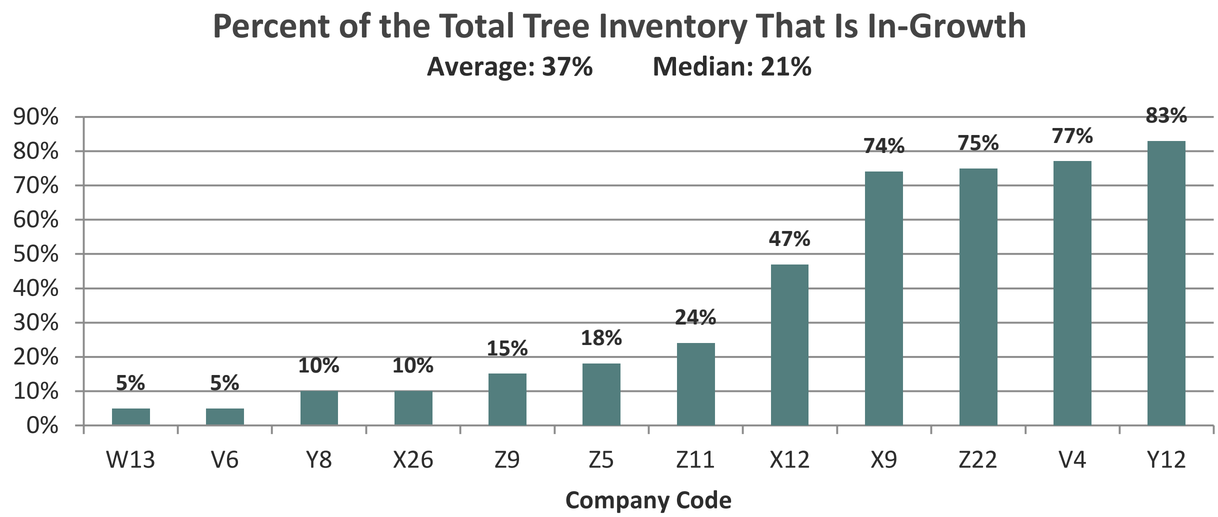
Herbicide Use					
	GENERAL	STUMP		GENERAL	STUMP
Average	35%	66%	**Q3**	75%	98%
Q1	9%	21%	**Max**	100%	99%
Median	20%	93%	**Min**	0%	0%

Statistics Table 6: Herbicide Use - Peer Group Statistics



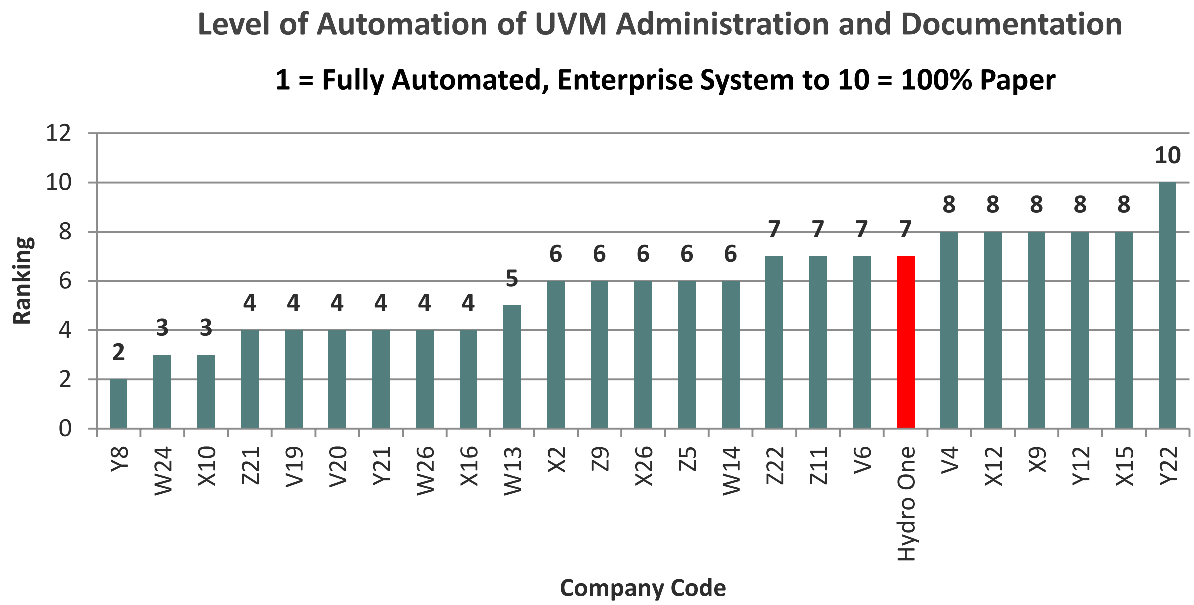
Graph 89: Percent of Kilometres Treated with Herbicides and Percent of Stumps Receiving Treatments

In-Growth Estimates



Graph 90: Percent of the Total Tree Inventory That Is In-Growth

WORK-PLANNING, PRE- INSPECTION AND AUTOMATION



Graph 91: Level of Automation of UVM Administration and Documentation

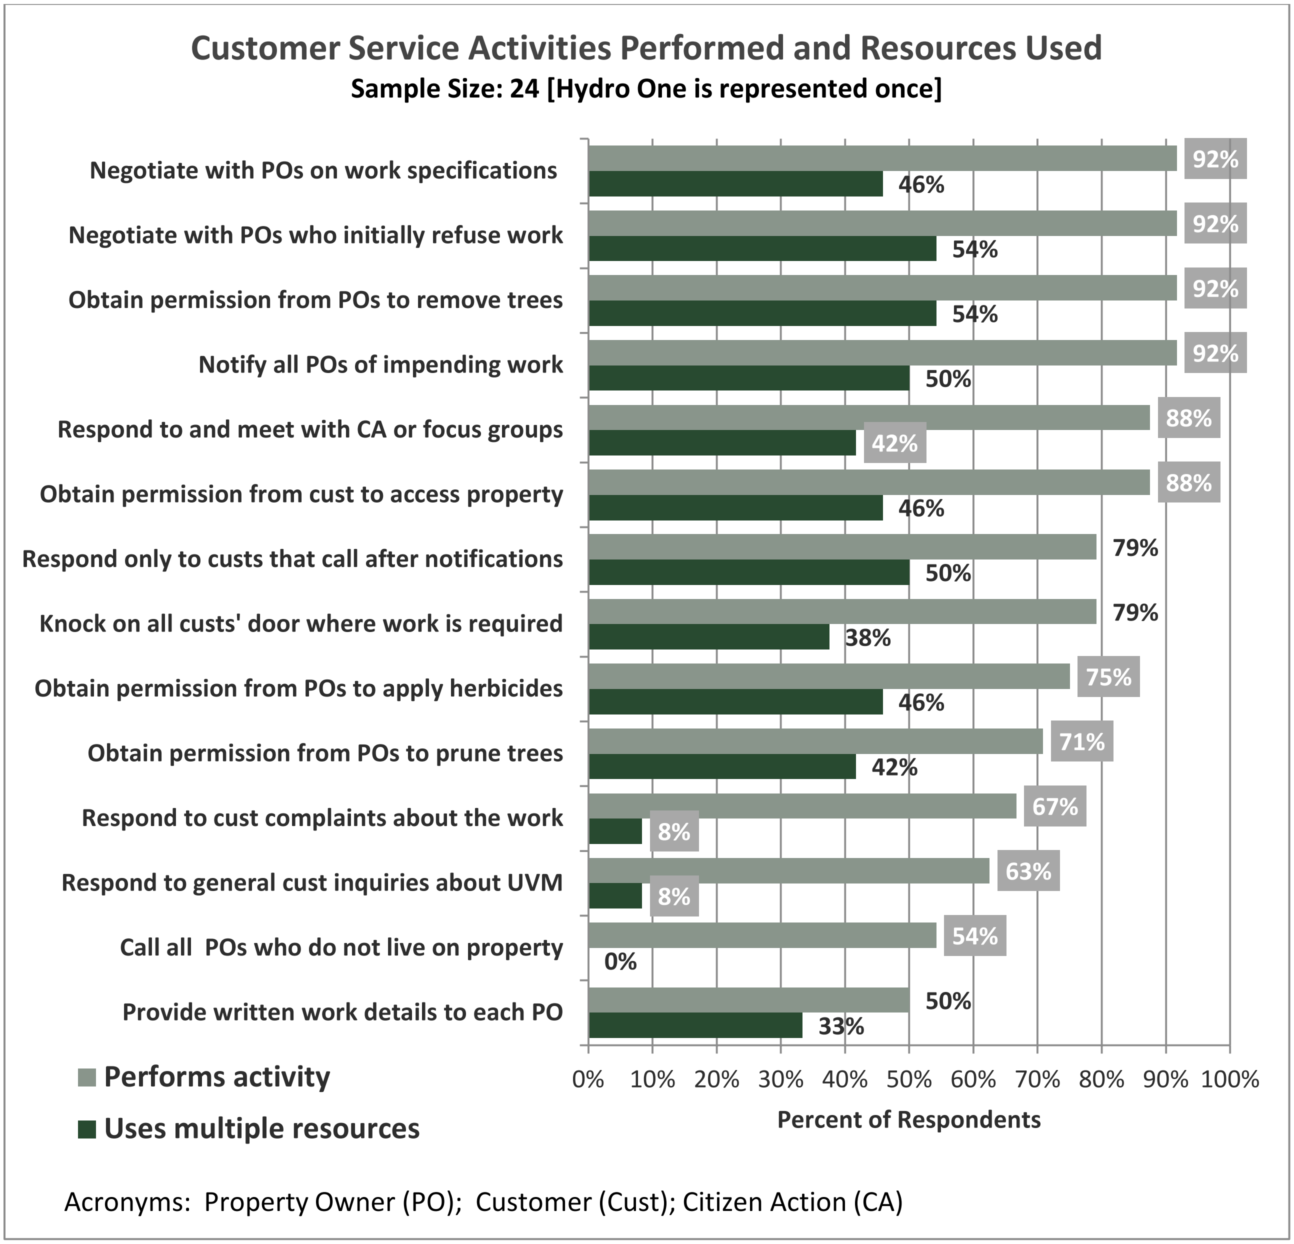
CUSTOMER SERVICE

Customer Service Activities Performed and Number of Resources Used

Survey Participants were asked the following question:

> If you have foresters, preplanners, workplanners, notifiers or auditors included in your distribution UVM program, choose from the following the types of customer communications that these individuals perform as parts of their routine work.

Resource choices were: Notifier, In-House Forester, Consulting Utility Forester (CUF), Line Clearance Planner, Automated Technology or Other. *NOTE: PO = Property Owners*



Graph 92: Customer Service Activities Performed and Resources Used

Customer Relations

Data Collection for Customers that Require UVM on their Property

Peer Utilities and Hydro One networks were asked, "Do you keep records on customers who respond to notification and refuse to allow the planned UVM work?"
Sample Size: 26
Yes 58% [Hydro One responded Yes]
No 42%
One participant said that a database was being developed.

Public Understanding of UVM

Peer Utilities and Hydro One networks were asked, "Do you think there is a "disconnect" (lack of understanding) between industry standards and what your customers/property owners and local agencies require you to do when performing UVM?"
Sample Size: 26
Yes 92% [Hydro One responded Yes]
No 8%

If yes, to what extent and what are the typical issues?
People in [state] love their trees and don't particularly care if we need to remove a tree for reliability or prune a tree to obtain clearance for an entire cycle.
Typically, the opinion of the customer is that we are doing too much work to the tree, or should be leaving the tree / brush alone altogether. Just take a little and come back more often.
General lack of knowledge of state and local guidelines (6 companies)
Only for difficult customers
Most of our customers don't realize there is a service guaranty/contract approved by [PUC] giving us the right to trim/remove trees.
Virtually all utilities operated a dual clearing standard; say 10 feet plus ANSI A-300. It is the ANSI A-300 portion which seems to always lead to misunderstanding.
Don't understand why the tree was trimmed in the manner it was- trimming is performed for clearance from the conductor, not aesthetics.
They do not always understand why we must trim certain trees as we do. Especially the u or v shape cuts made for trees directly under the line. This technique in their eyes is butchering a tree.
Public does not understand the wire-tree conflict issue
It doesn't really affect our operation in terms of getting things done, but the issue continues to be why we trim as much as we do and why we trim using the "natural" method of pruning to direct growth away from the lines.
There is a disconnect regarding the customers don't like the looks of industry standards pruning, but we don't do anything else. They don't "require" us to do something different.
Continued

Customer refusal tab in Tech notification software (Forestry Application Production) where the info about customer refusals is captured. [Hydro One]
It's getting better and better, but in general: Our pruning cycle is often perceived too long, and the result of the activity, too intense. We can also report that our various [customers] grant to trees a very different importance accordingly to their origin, or their culture. As an example: the urbans are more sensitive to the tree than the countryman; the English speaking are more sensitive than French speaking. And urban moved in the countryside wishes a quality of service [as] impeccable as in the city while keeping the forest character of his new environment. Quality of the electric service: the complaints of this nature are among the most numerous but the subject is not carried in the media. Quality of the work done: the aestheticism of the pruning is the object of less numerous complaints but more frequently carried in the media; Also [leaving] debris is the object of complaints.
Typically concerned customers do not want healthy trees pruned to our standards. They do not understand the impact on public safety and reliability when trees are not trimmed to standard. On the other hand when trees are in decline they think it is the Utilities' responsibility to remove the trees at 100% our cost.
Prune to customers often means how they would annually trim their bushes. They don't understand the magnitude of the work. They also don't understand that their small "tree" we call brush. Customers often don't understand how power [electricity] works and that their property's trees can potentially affect thousands of people's power.
Lack of education and public relations by not only the utilities but also by the government agencies themselves.

Table 25: Descriptions of Customer Understanding about UVM

SAFETY AS A PRIORITY

Tracking Safety Metrics

23 peers and Hydro One Networks answered the question, "Do you track safety metrics?

- 92% responded **"Yes"**
- 81% responded **"Yes"** for the industry-wide sample (31 companies)

24 companies (industry-wide sample) *described* how they track safety. The following is a summary of their remarks:

- All utilities monitored *worker* safety by tracking incidents (accidents) and some of the respondents included contractor-caused outages, vehicle incidents, and non-reportable incidents in their statistics.
- Six companies used a web-based program that contractors can access to enter incidents and calculate safety statistics.
- Several have quarterly meetings and have contractors submit logs.
- Two companies ask for near-miss reports.

Only three companies (one of them is Hydro One) had more extensive monitoring. Their comments follow:

- Weekly safety audit are required and tracked through the Supervisor safety and accountability program along with internal Safety specialists and ISN
- We have a safety department within our UVM that tracks incidents and non-compliances of not only our contractors but of our own department as well. Additionally, we conduct monthly safety meetings as an entire department and require annual training of all personnel.
- ***Hydro One- Forestry*** has a number of metrics to track safety of the UVM program. Key focus is reducing High Maximum Reasonable Potential for Harm type incidents and total recordable injuries among other things. The other safety metrics that are constantly monitored are reducing Preventive MVAs, Electrical contact, Musculoskeletal Disorder Injuries, slips, trips, falls, Contact with Sharp Objects, Fall from Heights & Stuck by Falling objects

Other Metrics Applied to Safety

When asked, "**Do you have other measurements that you utilize to measure safety achieved by your UVM program?**" 22 peers and Hydro One Networks responded:

- **43% Yes**
- **57% No**

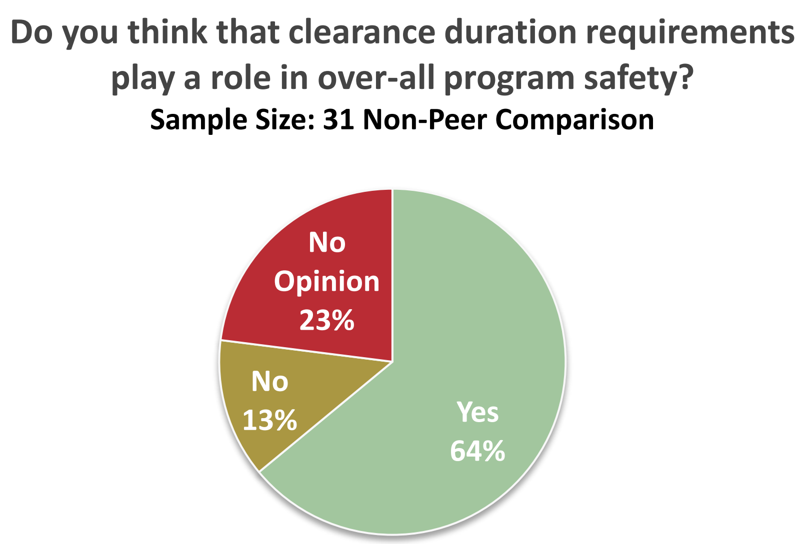
Once again, most of the monitoring was done on incident rate. See comments that follow.

Measuring Safety
We track Total Recordable Injuries per 200,000 hours worked. We also develop on an annual basis Forestry Health, Safety & Environment Initiatives – Prevent Struck by Injuries from lodged tree, Prevent fall from height, eliminate injuries from electrical contacts and off road MVA incidents. We are also meet OHSAS: 18001. [Yes – Hydro One Response]
Any quarter of the year with a lost time recordable injury or a crew caused outage removes that quarter from consideration for Performance Incentives (paid holidays) -Any year with 5 or more injuries or outages (combined) will require a meeting regarding safety process/procedures and an action plan to reduce these incidents [No]
Incident rate, severity rate, DART rate, at fault vehicle accidents [Yes]
We monitor each contractor's RAI [Requests for Additional Information] and have a review with each vendor quarterly to review their safety record and performance records. [Yes]
Track contractor hours, incidents, and TRIRs [Total Recordable Injury Rates] [Yes]

Table 26: Measuring Safety

Safety policies

Clearance Duration Policies and Safety



Graph 93: Clearance Duration Requirements

Comments on the relationship between clearance duration requirements follow.

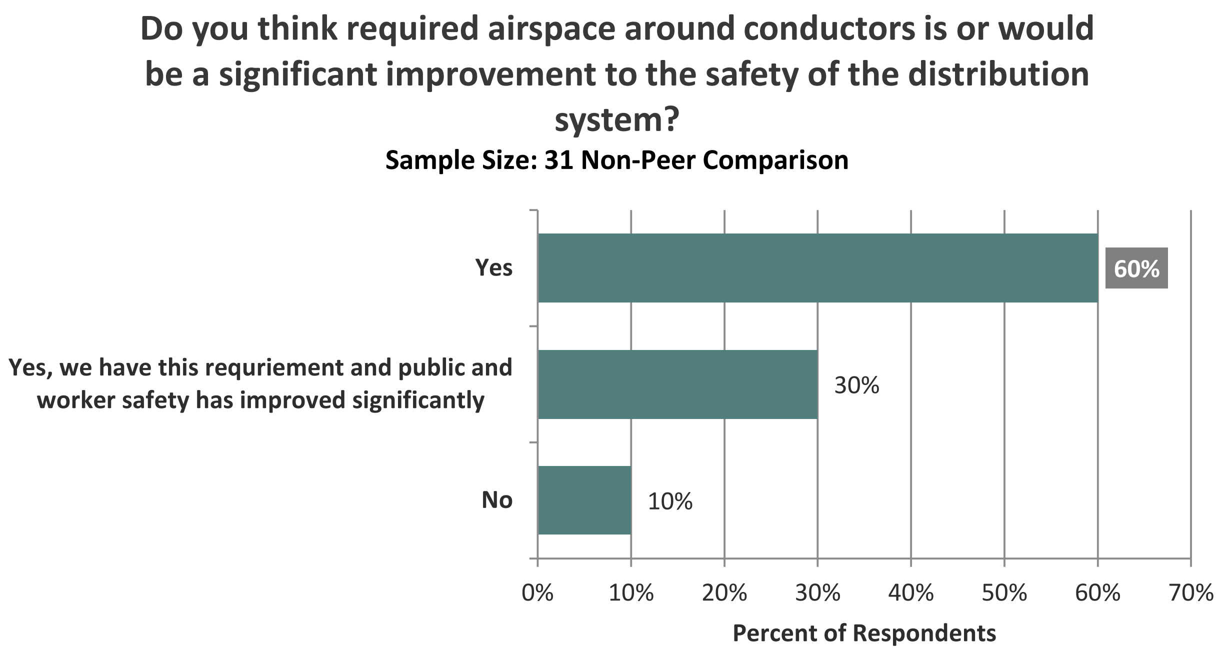
Clearance Duration Requirements and Safety
Longer cycles mean more tree/conductor contact and a higher chance of an incident [Yes]
Increased cycle length means increased exposure. [Yes]
Deferred vegetation maintenance becomes more difficult to deal with. I.E. increased encroachment to energized conductors [Yes]
I do believe that if the ROWs are not kept adequately clear, it can pose safety issues for those who have to work there. [Yes}
Not with our program. Even though we may be behind in cycles, the growth into primary conductors is not significant. The safety concerns (and potential outages) are elevated when it comes to open secondary lines, street light lines, and service drops. [Yes]
If clearance is poor, there is a safety issue with crews working around the wires. The more clearance around the wires at time of pruning, the more visible the wires, and the safer the program is. [Yes]
The farther we can keep our trimmers, vegetation and equipment away from energized lines, the safer all included are. common sense [No]
If safety practices are being thoroughly implemented, there should be no increase in accidents despite clearances. [No]

Table 27: Clearance Durations Requirements and Safety

Required Airspace between Trees and Conductors and Safety

Utilities were asked, **"Do you think required airspace around conductors is or would be a significant improvement to the safety of the distribution system?"**

90% of the industry-wide sample (31) agreed with this statement. See graph below (Each category is exclusive).



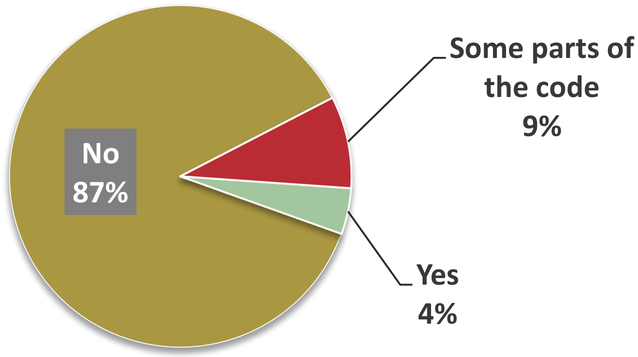
Graph 94: Required Airspace and Safety

Required Airspace and Safety Comments
Mandatory minimum clearances would likely triple our budget but our system would be safer [Yes]
There would be almost no change from what we do now [No]
We have no data to suggest that a required airspace would improve safety. It might increase production if there is less encroachment. There would be a significant increase in costs to achieve a required airspace [No]
I am not in favor of a required amount of clearance. I think clearances should be dependent on species, voltage, site conditions, etc. Maybe there could be a minimum required clearance. [Yes, with modifications]
Certainly couldn't hurt. [Yes]
IHSA requires 3' between conductors and trees to establish safe work areas for climbers. If the tree is within 3' the tree is a hazard. [Yes, Have requirement]
I'm leaning more towards the yes, but before I support it 100% it would be nice to see some research and results on the topic. [Yes]
I think anything coming from the ground, especially wet vegetation which can contact live high voltage conductors, produces a dangerous condition. [Yes]

Table 28: Comments on Required Airspace and Safety Comments

Wildfire-Urban Interface Code

Does your service territory have jurisdictions that have adopted the International Code Council (ICC) Wildland-Urban Interface Code (WUIC) for UVM?
Sample Size: 23 (Hydro One Represented once)



Graph 95: Adoption of the ICC WUIC for UVM

Wildfire Incidents

It should be noted that when peers were asked about fire incidents attributed to fires started by conductor and tree conflicts, several reported none, but they also reported that they had no metrics to track this.

Peers were asked, “Have confirmed tree-wire contact-caused wildfires occurred in your distribution system in the last decade?”
35% Yes
65% No [Hydro One answered **No**]

Fire Incidents in Service Territory Due to Tree-Wire Conflicts
We may have 6-10 small fires per year [Yes]
I know of one small fire contained to the tree and surrounding hedges. [Yes]
No metrics to track wildfires occurring from tree-to-wire contact [No –Hydro One response]
Several small fires (< 2 acres) over the last decade 8 acre fire in 2013 100 (?) acre fire in 2006 No fires the last two years [Yes]
Don't have a firm count, but we know we have caused wildfires in the past. Our climate is not conducive for large wildfires (Our Humidity is high), but during periods of severe drought, this is monitored more closely. [Yes]
We don't have that statistic. Any wild fire resulting from a tree contact is usually a tree fallen (off corridor) tree. We had several of these as a result of the Mountain Pine Beetle epidemic. [Yes]
1. Less than 2 acre grass fire/no structure damage [Yes]

Table 29: Fire Incidents in Service Territory Due to Tree-Wire Conflicts

Safety Training

Safety Training Initiatives Undertaken in Last Three Years
[Contractor] has one of the most intensive safety programs in the country. We allow them to do what they think is needed for safety, we never have to ask them to do more.
100% vendor function
Lodged tree training, heavy equipment training, and Herbicide application training. Foresters receive 30-40 hours of new training annually. [Hydro One response]
Require all contractors to have own safety program, including tailboards and regular safety officer visits. Contract initiation meeting includes review of the program and expected reporting to MH
Contractor KPI impacted by safety numbers, increased safety audits by the utility, training days provided as needed.
Vendors provide basic training, all have different programs.
No information available
We use a 3rd Party company to carry out our Power Safe training. These courses are entry level courses in reviewing the requirements to work for our Utility and we have created some job specific modules that are mandatory for our contractors to take. To take all courses it is about $100 per year per contractor employee and the trainings take about 4-6 hours.
Safety training is handled by the contractors. We do conduct Safety Seminars annually with our contractor's management folks, which cover a variety of safety topics. There is also a steering committee composed of both Ameren and contract employees.
Vendors with a reported caused outage had to undergo company safety mitigation steps to become qualified as a line clearance vendor again, and continue work.

Table 30: Safety Training Initiatives Undertaken in Last Three Years

Public and Non-Utility or Utility-Contracted Tree-Worker Electric Incidents

Survey participants were posed the following question:
OBJECTIVE: To determine the utility's awareness of electrical contacts which occur outside of utility managed line clearance operations. As many as 15-20 on the job electrocutions occur each year in the US that involve non-line clearance tree and landscape workers. It is estimated that there are more that involve the home owners or non-employed tree workers.
QUESTION: Which of the following apply to your company?
Sample: 21 (20 peer utilities and Hydro One Networks)

- The utility provides many public service announcements that discourage pruning or removing trees near powerlines and the utility requires notification to perform or determine approved vegetation management : **71% [Applies to Hydro One]**
- A rate of occurrence is unknown for electrical contacts involving vegetation, powerlines and non-line clearance workers or members of the public: **67% [Applies to Hydro One]**
- The utility company provides electrical hazards awareness training to non-line clearance arborists in the service territory: **19%**

- The utility does not frequently and/or effectively communicate the safety concerns of trees and power lines: **19%**
- The utility is alerted anytime an electrical contact is reported by the media: **0%**
- A study of non-line clearance tree companies has been performed by the utility to determine the percent of tree workers who have had electrical contacts: **0%**

One utility commented: The utility is notified of incidents, but **UVM is not alerted** of all incidents that occur.

State the number of known electrical contacts involving vegetation that have occurred in the utility service territory over the past 5 years:

- One utility stated “**0”**
- I don't know how many electrical contacts we've had in the last 5 years, but we have them occasionally. Probably not more than 1 or 2 per year. They are almost [always] a result of error on the part of the person contacting the system and not a result of poor maintenance or system defects.
- The rest stated that they do not know or the information is not available

Conclusion:
Electrical contact incidents involving non-utility workers or the public is not measured or available to the UVM department.

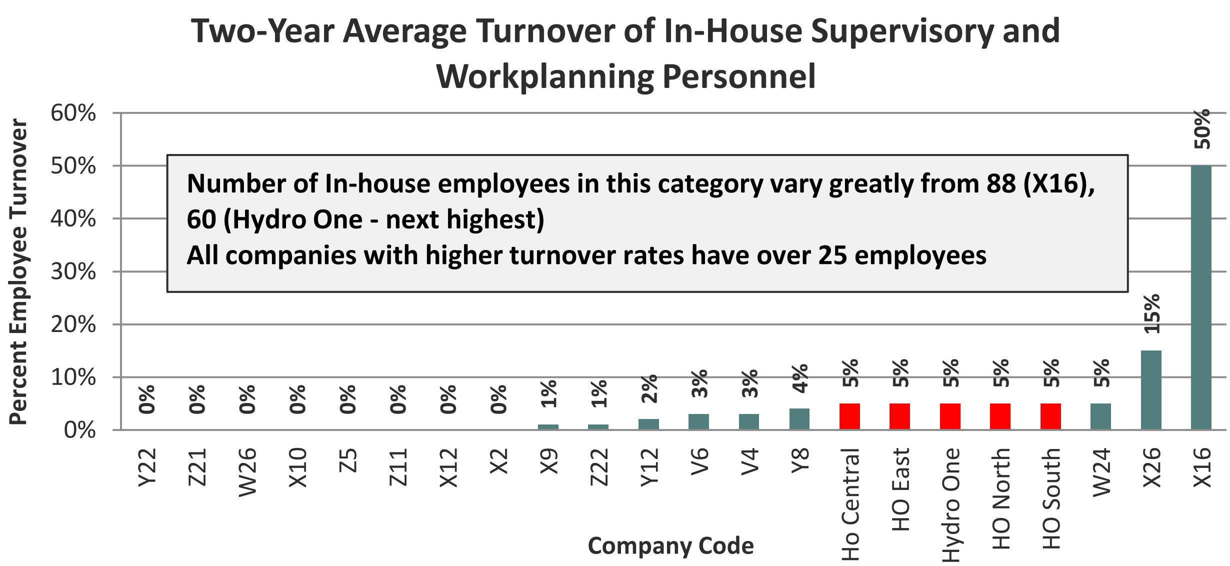
Safety Statistics

Employee Turnover

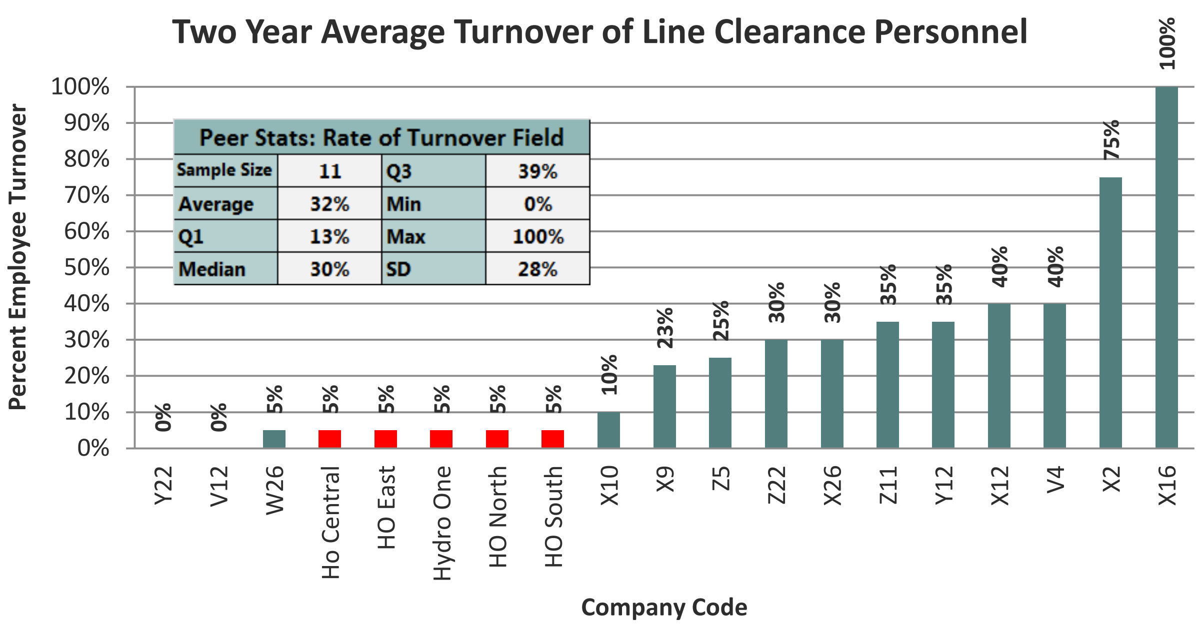
Since there is not a consistent way to measure safety in the UVM industry other than incidents, which are lagging indicators, CNUC looked at employee turnover as an gauge of a safety culture.
The following two quotes identify that employee turnover can be used as a safety measure:

> *While there are certainly more precise and scientific measures of safety culture, I believe that turnover rates provide the best quick, easy, and cheap “snapshot” of an organizations’ culture. — Dave Weber, a former Safety and Environmental Manager and founder of Safety Awakenings*
>
> *When temporary workers have to be continually replaced, their impact on profitability includes: . . .*
>
> - ***Safety** (Bureau of Labor Statistics [shows a correlation between] accidents and safety violations increases proportionately to employee turnover) . . .*
> - ***Training . . .***
> - ***Productivity . . .***
>
> http://www.insourceperforms.com/news/employee-turnovers-impact-on-your-budget

Since Hydro One is the only utility in the survey (and there are very few in the industry as a whole) that performs UVM completely in-house, the turnover rates are divided into in-house (non-clearance activities) and contracted line-clearance personnel. The line-clearance employees are confronted with more safety issues than the non-clearance personnel of the UVM department, so the second graph is of greater significance to the discussion of safety.



Graph 96: Two-Year Average Turnover of In-House Supervisory and Work-planning Personnel



Graph 97: Two-Year Average Turnover of Line Clearance Personnel

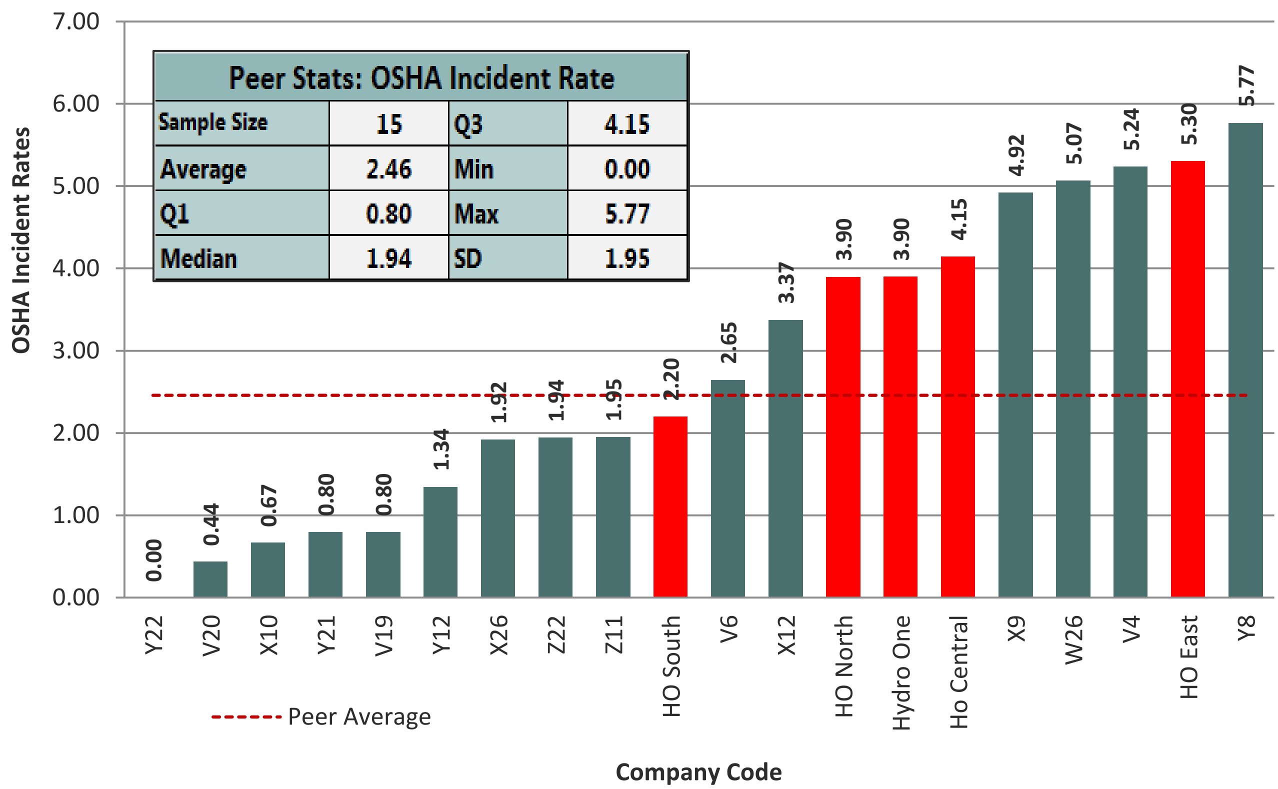
Safety Statistics

Incident rates are shown in the next graph by company. Most of the statistics for this graph have been gathered by the contractors and reported to the utility. Since Hydro One is all in-house employees, the information is gathered by Hydro One.

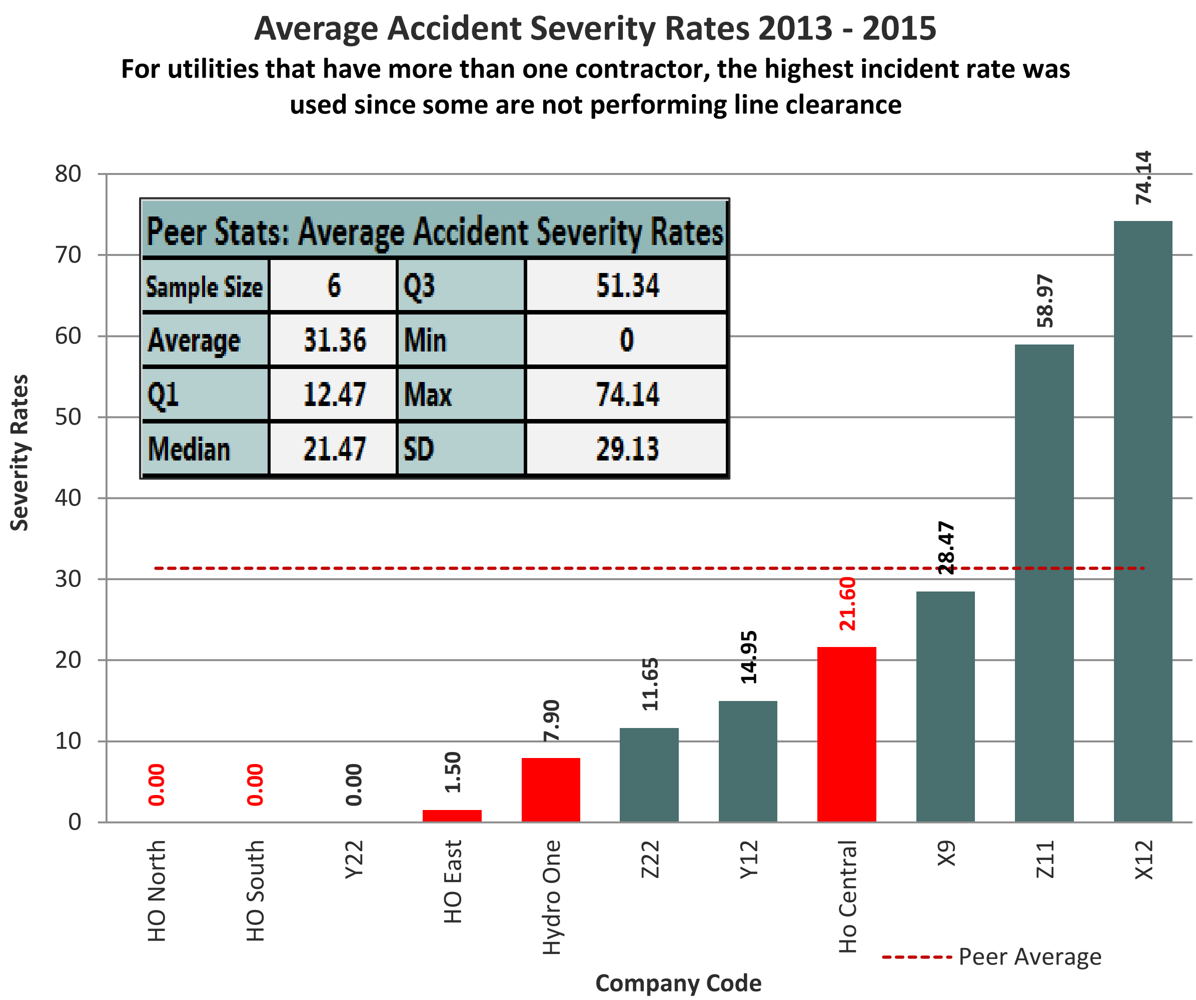
Incident rates vary from severity rates in that an incident may be reported, but very little work time is lost if the incident was not significant to the health of the worker. OSHA incident statistics are the most common form of reporting and only tells part of the story. Unfortunately, the severity rate was not reported by as many utilities, but the sample is adequate to derive some statistics.

Average Standard Health and Safety [OSHA] Incident Rates 2013-2015

For utilities that have more than one contractor, the highest incident rate was used since some contractors are not performing line clearance



Graph 98: Average Standard Health and Safety [OSHA] Incident Rates 2013-2015

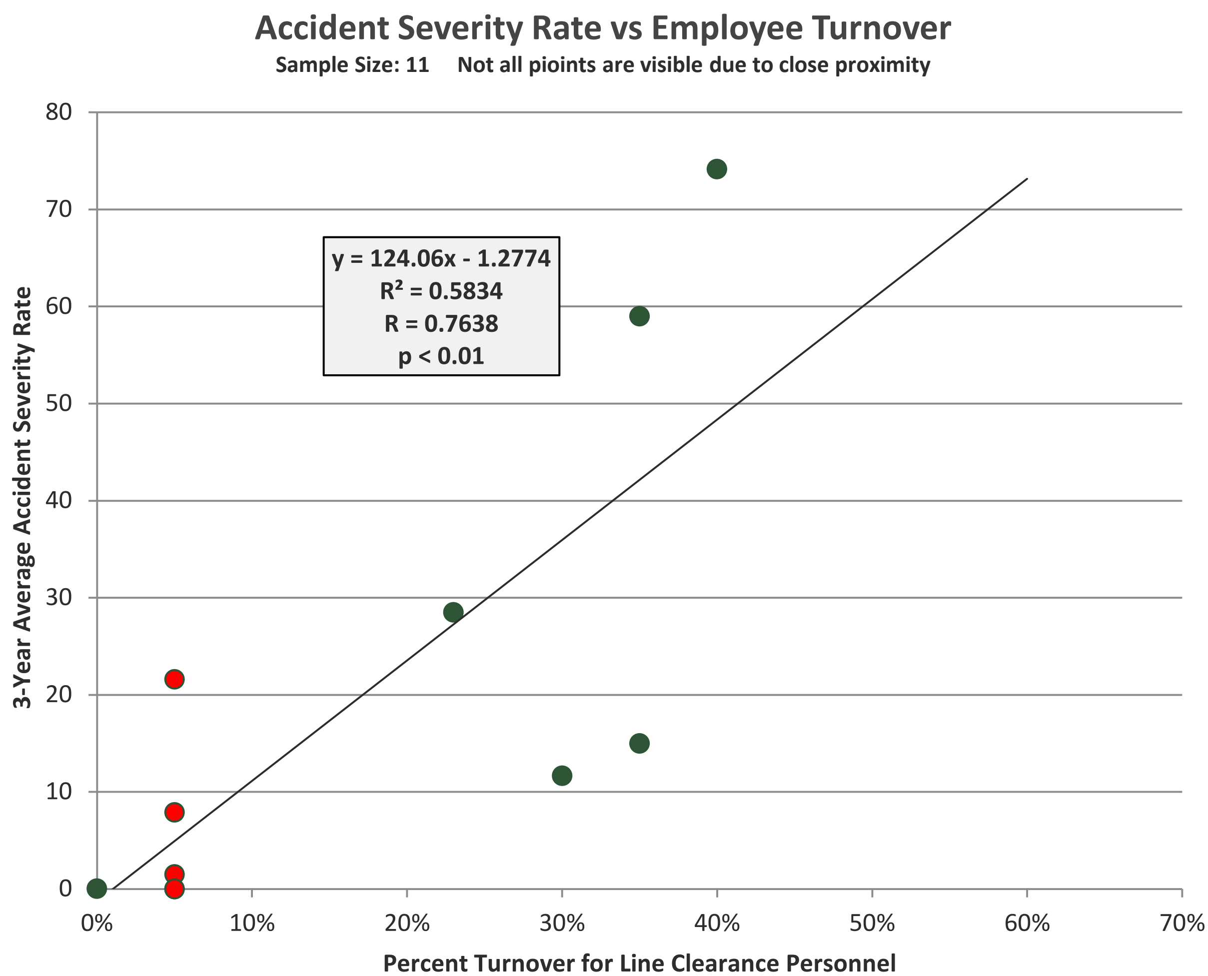


Peer Stats: Average Accident Severity Rates			
Sample Size	6	Q3	51.34
Average	31.36	Min	0
Q1	12.47	Max	74.14
Median	21.47	SD	29.13

Graph 99: Average Accident Severity Rates 2013-2015

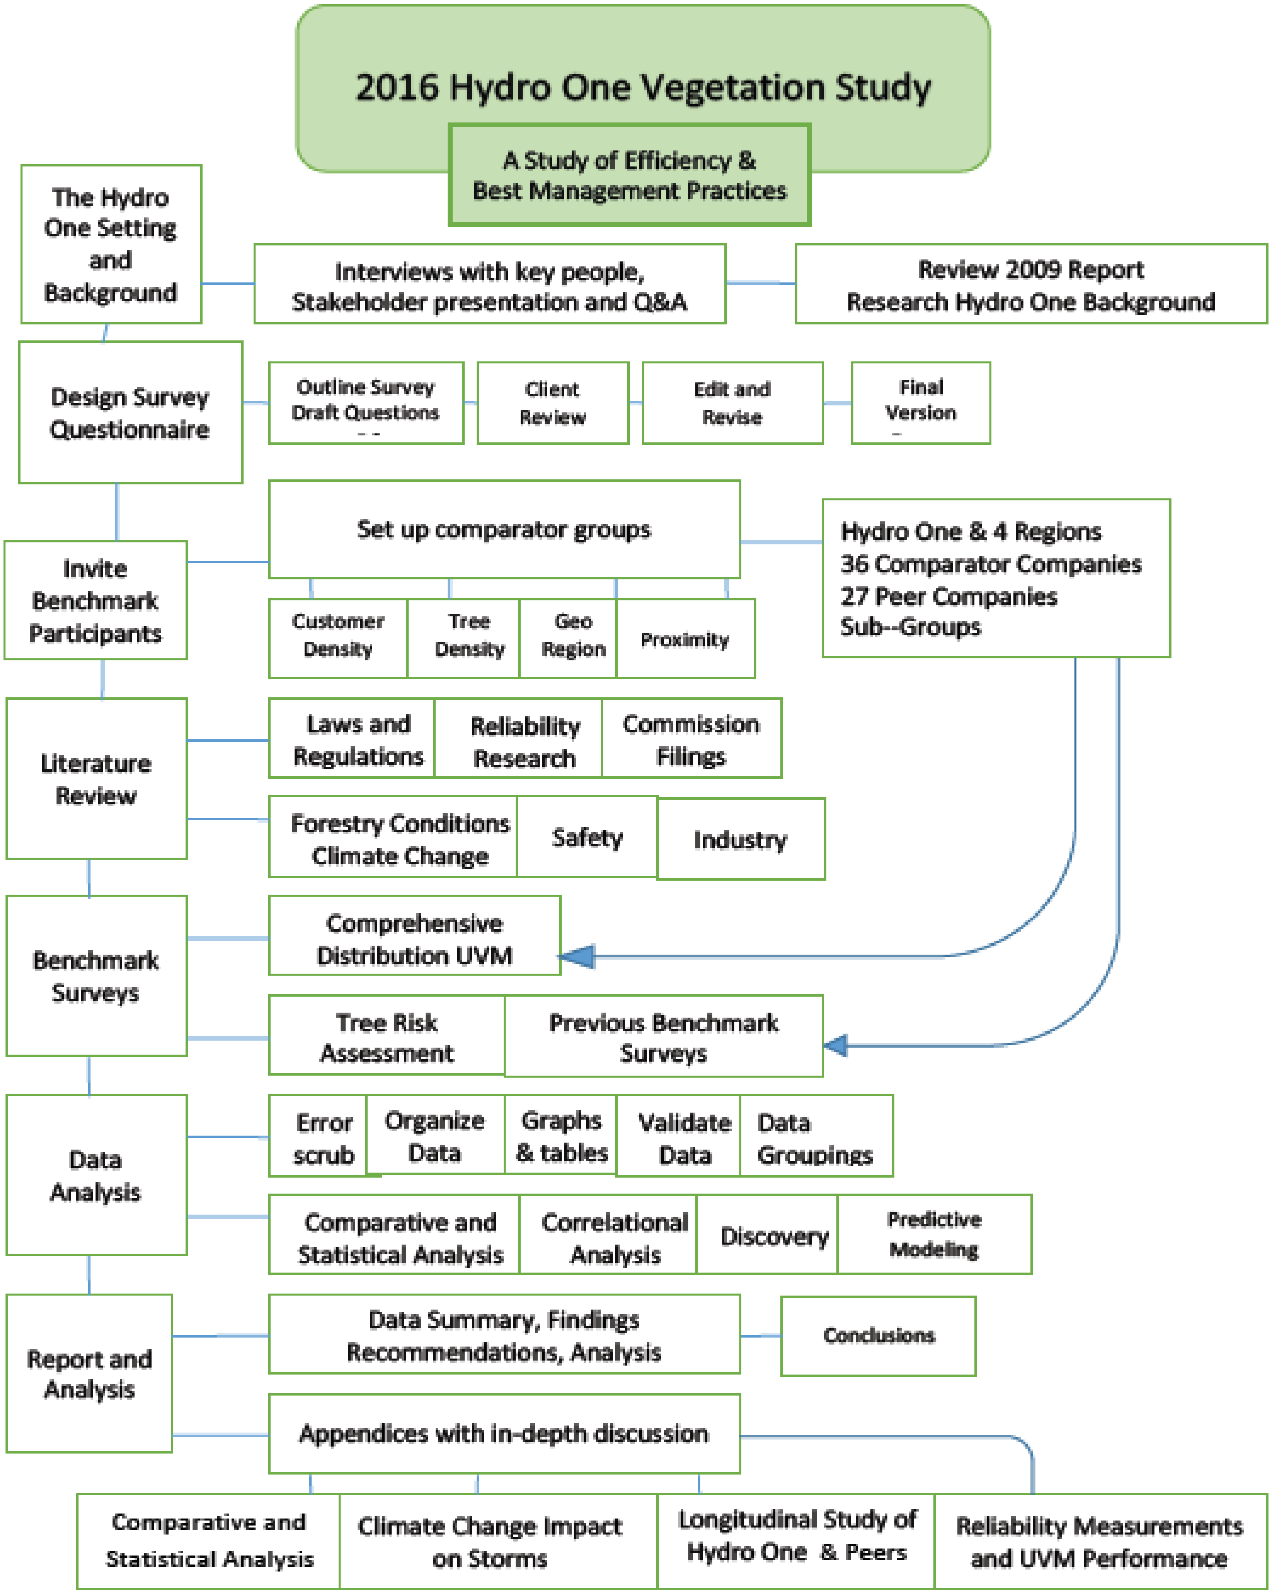
Correlation between Employee Turnover and Safety Severity Rate

A significant correlation can be drawn between employee turnover rates and incident severity rates. Hydro One is identified by red data points. Sample limited to companies that supplied turnover rates and incident severity rates.



Graph 100: Accident Severity Rate vs Employee Turnover

Appendix I: Benchmark Study Process Chart



Appendix J: Longitudinal and Comparative Analysis of Hydro One Regions Data and Peer Data

INTRODUCTION

All the graphical and tabular representations are derived from Hydro One and Peer data collected in the *2015 CNUC Distribution Benchmark Survey*. CNUC has included data from previous CNUC UVM benchmark surveys and from the CNUC *Hydro One 2009 -Vegetation Management Benchmark Study* that was submitted to the Ontario Energy Board in September 2009.

Regional studies of Hydro One's territory include 2009 data, which had separated Hydro One into three regions. The original regions were the South, the North and the East. The current study has four regions with the addition of the Central region. The Central region was created by taking a portion of each of the original three regions. CNUC has taken the percent of the electrical system removed from each of the original three regions to understand trends for the current four divisions. By proportioning regional data from 2009 to the current regional makeup, CNUC was able to compare information dating back to 2008 with a two year gap (2009 and 2010) in these comparisons.

Most of the graphs and tables in this appendix are longitudinal (over time). Some analysis for trends in the data has also been included in this appendix.

The following concepts are important for interpreting the graphical results:

- "Per System Kilometre"
- "Per Managed Kilometre"

Graph and table numbers in this appendix vary from labels in the main report and other accompanying appendices.

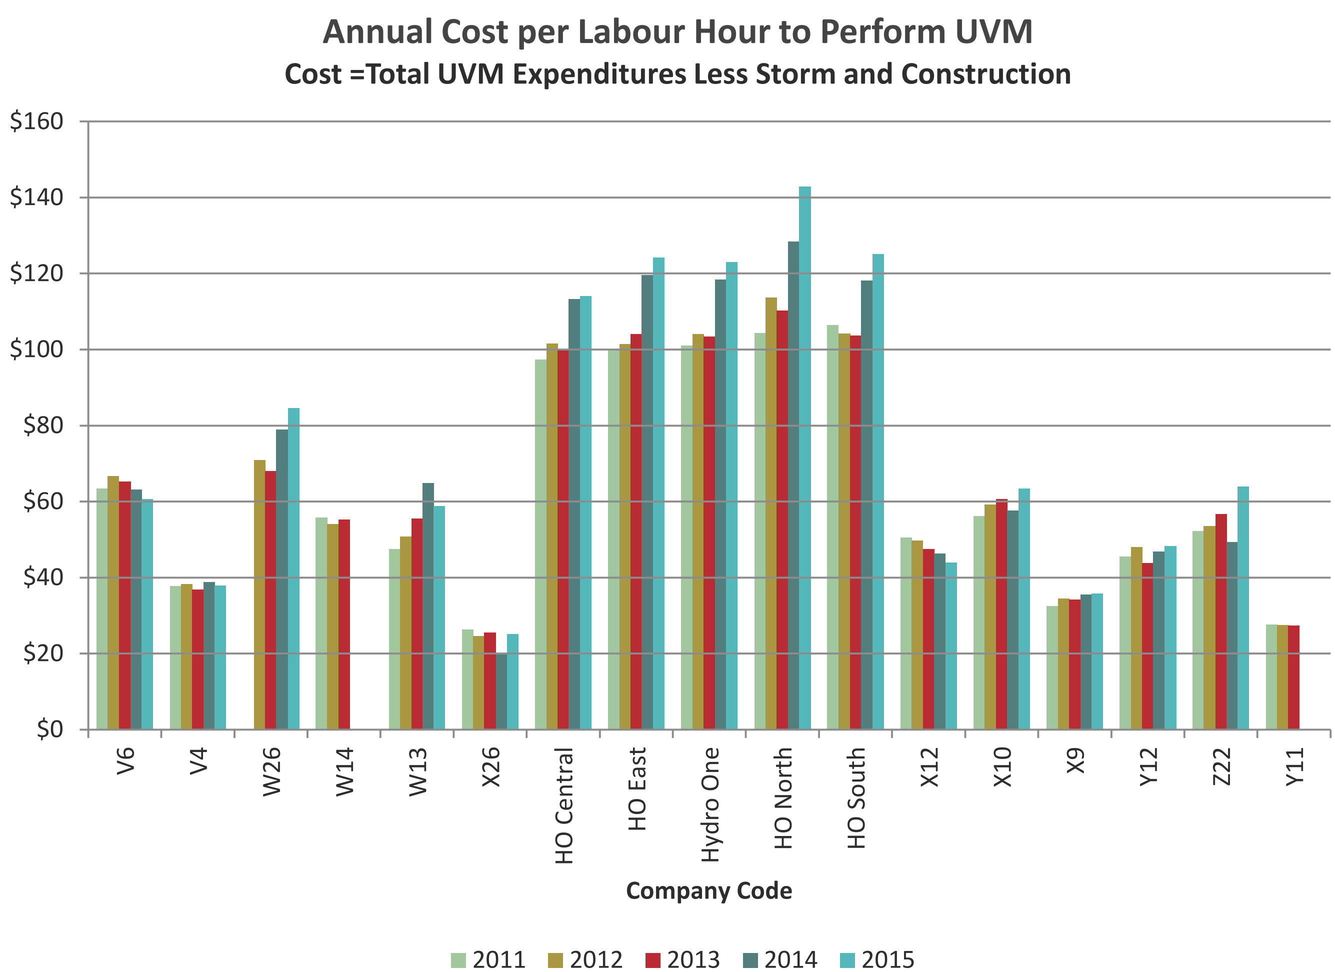
Longitudinal Study of Cost per Labour Hour for Peer Group



Graph 149: Annual Cost per Labour Hour to Perform UVM

This study was done to visualize the change the change in cost per labour hour over time and identify trends in the change. Companies like V6 are actually decreasing their cost per labour hour, while the majority is increasing.

Storm and New Construction were not included in this study for several reasons:

- Some utilities do not capture these costs
- Many companies capitalize these costs or they are paid for by different departments.

	2011	2012	2013	2014	2015

ACKNOWLEDGMENT OF EXPERT'S DUTY

1. My name is William Porter (*name*). I live at Chicago (*city*), in the Illinois (*province/state*) of USA .

2. I have been engaged by or on behalf of Hydro One (*name of party/parties)* to provide evidence in relation to the above-noted proceeding before the Ontario Energy Board.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the Board may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

Methodology and Scope

Project Methodology
Gartner Approach
Scope and Peer Group Profile

Gartner.

Project Methodology

Hydro One engaged Gartner to assess its overall IT spending in terms of enterprise-level metrics and the distribution of IT spending. Using industry, revenue, and employee data, Gartner compared Hydro One to a peer group of similar organizations. The following information was collected from Hydro One:

- IT budget spending (capital and operations)
- Revenue and operating expense
- Number of employees
- IT staffing levels

Metrics available from this analysis include:

- IT Spend as a % of Revenue
- IT Spend as a % of Operating Expense
- IT Spending Per Company Employee
- Distribution of IT Spend – by Category (hardware, software, outsourcing and personnel)
- Distribution of IT Spend – by Domain (data center, end user computing, service desk, voice, data, applications development, applications support, corporate IT management, finance and administration)
- Distribution of IT Support – by Domain (data center, end user computing, service desk, voice, data, applications development, applications support, corporate IT management, finance and administration)
- IT Employees as a % of Company Employees
- IT Contractor Usage
- Capital Vs. Operational Spending
- Run, Grow, Transform Spending

Gartner

Gartner Approach

IT Spending Benchmark Project Plan

1 Project Initiation
- Planning
- Kickoff
- Data collection

2 Data Collection
- IT Spending Metrics Data Collection
- Data Collection Assistance
- Status Meetings

3 Data Validation
- Data Validation Review
- Peer Group Review
- Data correction
- Data Freeze

4 Analysis
- Spending Drivers Analysis
- Discussion of opportunities and findings
- Preliminary Report

5 Deliver Results
- Final Reports
- Presentation of Report

- Using Gartner's Cost Model for IT Spending, Gartner collected IT spending and staffing information and performed a cost analysis report using Gartner benchmarking databases
- This analysis focused on enterprise IT cost compared to industry peer group. The outsourcing contract was not evaluated. This analysis did not assess governance mechanisms, strategy or organization design.

Hydro One Scope and Peer Group Profile

Hydro One Business Information:

- 2015 Annual Revenue: $6.5B
- 2015 Annual Business Operating Expense: $5.3B
- Revenue and Operating Expense include fuel and purchased power
- Company Employees: 5,516

Hydro One IT Information:

- Analysis Period: 2015
- Total IT Budget for:
  - IT Capital Investment: $53,800,000
- IT Operational Budget: $141,136,000
  - Total IT Spending, Capital and Operations: $194,936,000
- Total IT FTEs: 102

Peer Group Profile:

- 9 Energy and Utilities Organizations – 6 Canadian, 3 USA.   7 of the 9 are Utilities and the remaining 2 are Canadian Energy (distribution and energy infrastructure).
- Average Peer Group Revenue: $6.6B
- Average Peer Group Operating Expense: $4.8B
- Average Peer Group Company Employees: 6,336

Gartner

Executive Summary

Business Context
IT Drivers
Summary of Metrics
Observations and Recommendations

Business Context establish the priorities and focus for IT investments and the way the IT organization conducts business

Business Context and External Factors	Implications
Geography	▪ Hydro One is Ontario's largest distribution utility spanning 75 percent of the province. ▪ Requires IT to support users and maintain equipment over a large service territory and in remote areas.
Seasonal Workforce and Other Temporary Labour	▪ While Hydro One employs 5,516 full-time employees, there are an additional 2,237 temporary, contract and part-time employees, some of which are seasonal. ▪ The Gartner benchmark includes only the 5,516 in the employee count and this methodology is consistent for the peer comparison group. The Gartner Benchmarking cost model does not include temporary workers in the company employee total. IT contractors are counted in the IT FTE total. ▪ There are IT costs associated with the seasonal staff. ▪ While there is some outsourcing in the peer group, the percentage of outsourcing is lower than Hydro One. ▪ The peer group on average has 820 more total employees than Hydro One.
Labour Agreements	▪ The workforce is unionized and Hydro One estimates that agreements add 20 percent to the employee cost. ▪ Note: The peer comparison group also includes some organized labour.
Regulatory and Compliance	▪ Hydro One is regulated by the Ontario Energy Board.
Business Accounting Policies Governing IT Investment Capitalization	▪ Hydro One has a minimum capital threshold of $2M (IT assets cannot be capitalized if under $2M). This is a higher threshold than typically observed for IT assets for the peer group. For example, software is often in the $200K-$500K range, some are at $1M.

Gartner

IT Drivers influence the decisions and ability for the IT organization to effectively enable the business

IT Drivers	Implications
Cornerstone Project	▪ From 2007 through 2014, Hydro One was engaged in the Cornerstone project. The Cornerstone project replaced legacy CIS applications and transformed business processes. The project lasted longer and was more difficult to implement than originally anticipated. ▪ By 2015, the current benchmark period, Cornerstone is now part of operating expense and remaining depreciation. ▪ The benchmark period therefore represents a time period of minimal transformation spending at Hydro One. ▪ The peer group members report higher allocation to grow and transform. Some peer group members are undergoing CIS implementations.
Strategy, Governance and Organization	▪ Some IT functions have individual strategic plans but it does not appear that there is a comprehensive enterprise IT strategic plan. ▪ There are FTE and contractor resources that appear to be working along with the service provider based on functional assignment in the benchmarking model. It is unknown if there are overlaps in responsibility or duplicated roles. ▪ Hydro One does not show back or charge back IT costs. Business demand impact on consumption is not formally communicated.
Outsourced IT	▪ Hydro One IT is outsourced to Inergi for services. The Gartner benchmark does not convert the Inergi staff into FTE counts. This reduces the FTE count for Hydro One and also impacts the distribution of FTE by function.

Hardware Assets	▪ Multiple drivers influence hardware assets:
	    ▪ Some assets are kept in service for more than five years, such as Network assets and some server equipment.
	    ▪ SAP architecture is based on Unix and is not virtualized.
	    ▪ End User hardware costs are driven by decisions to outfit users with high performance and ruggedized equipment. 74% of the end user devices are mobile. End User assets are also refreshed more frequently.
	    ▪ Hydro One also provides end user computing equipment to Inergi staff.

Summary of Metrics

	Hydro One	Peer Average
IT Spending, Capital and Operations	$194,936,000	$200,135,986
IT Spending Capital and Operating by Cost Category		
Hardware	$18,129,048	$36,246,851
Software	$20,858,152	$47,810,263
Personnel Salaries & Benefits	$27,291,040	$77,830,661
Outsourcing (including telecom carrier costs)	$128,657,760	$38,248,211
IT Spend/% Revenue	3.0%	3.1%
IT Spend/% OPEX	3.6%	4.1%
IT Spend per Employee	$35,340	$32,911
Percentage of IT Spend - Capital	28%	40%
Percentage of IT Spend - Operating	72%	60%
Percentage of IT Spend - Run	79%	65%
IT FTEs, Excluding Outsourcing	102	513
IT FTEs Excluding Outsourcing by Technology Domain		
Enterprise Computing	3	84
End-User Computing	4	35
IT Service Desk	2	24
Voice Network	2	16
Data Network	1	52
Application Development	30	110
Application Support	15	132
Management,Project Management, Finance & Admin	46	60
IT Expense by Technology Domain		
Enterprise Computing	25%	20%
End-User Computing	14%	6%
IT Service Desk	2%	4%
Voice Network	4%	5%
Data Network	6%	10%
Application Development	13%	19%
Application Support	31%	27%
Management,Project Management, Finance & Admin	5%	10%

- Hydro One spends a similar amount on IT compared to the peer group, but there are differences in how the dollars are spent.
- Hydro One uses more outsourcing than the peer group with outsourcing representing $129M of the IT capital and operating budget.
- Hydro One spends half of the peer group level on hardware and software.
- Software includes capital and operating expenses for all software, for example business functionality software such as SAP. Hydro One is lower than the peer group in software but has a higher expense allocation to Applications Support compared to the peer group.
- Capital IT spending is lower. Hydro One does not capitalize below $2M which is higher than most organizations.
- 2015 represents a time period of Run allocation for Hydro One IT with 79% of IT spending as Run, versus 65% for the peer group.
- Hydro One expenses are focused on Enterprise Computing (servers and storage), End User Computing (laptops and desktops) and applications support. Voice and data are both lower than the peer group.
- Hydro One in-house and contractor FTEs are focused primarily in management and applications roles. It is unclear if there are overlaps with the service provider.

Gartner

Observations & Recommendations

Observations	Recommendations
The benchmark results show a similar IT spend to peers but there are differences in how cost and staffing are allocated. Hydro One spending is also directed toward Run now that Cornerstone is complete, while the peer group is directing more IT dollars to Grow and Transform. This study focused on IT spending and did not measure governance mechanisms or value of IT services. It is unclear if Hydro One has a comprehensive enterprise IT strategy that articulates the vision of IT and its role in enabling the business. Currently Hydro One does not charge back or show back for IT services. Without any type of show back or understanding of where IT dollars are going, it is difficult to enable both groups (IT and the business) to be accountable for investment choices.	• Consider an assessment of the IT strategy, capabilities, governance mechanisms and organization design to better understand IT spending and staffing. The goal is to determine if the IT investments are appropriate for the direction of Hydro One. • Review governance mechanisms to understand how decisions are made for projects and services and the carried out with the service provider. • Analyze the IT spending by business service. Grouping IT spending into business services and capabilities will not only help to communicate IT spending in business terms but also determine if funds are directed in the right areas. Promote a focus on business outcomes in addition to IT efficiency to ensure that there is business value (spending on the right things at the right cost). Multiple views of IT spend can also show the impact of external forces out of the organization's control, such as regulatory and compliance and demand for services, which are within the organization's control. This will allow the business to make informed decisions about IT investments and help to manage internally driven complexity. • Review the organization design to understand roles and responsibilities of retained staff to determine if there are overlaps with the service provider, what roles should be retained and how work is managed.

Hydro One has a high capital threshold for IT investments compared to most organizations. IT cannot capitalize below $2M while other organizations are capitalizing at lower amounts (e.g. $250K-$500K range). The current policy does not book any IT spending below $2M as an asset.
While IT leaders should not be the ones to set accounting policy, there should be discussion of impact of policy on IT decisions. For many organizations, capitalization decisions of IT assets are often based on outdated capitalization policies, or "this is how we have always done it."
	• Work with business leadership to review capitalization policies. The capitalization policy has multiple impacts and will require review and analysis jointly among IT leadership, business leadership, legal and accounting professionals.
	
	    • Capitalization of IT assets has an impact on business balance sheet metrics (e.g. net income, cash flow, assets).
	    • Capitalization has an impact on IT budget planning and funding.
	    • Considerations include variability in the IT budget year over year, managing IT investments as company assets, and changing delivery models for services.

Gartner

Observations & Recommendations

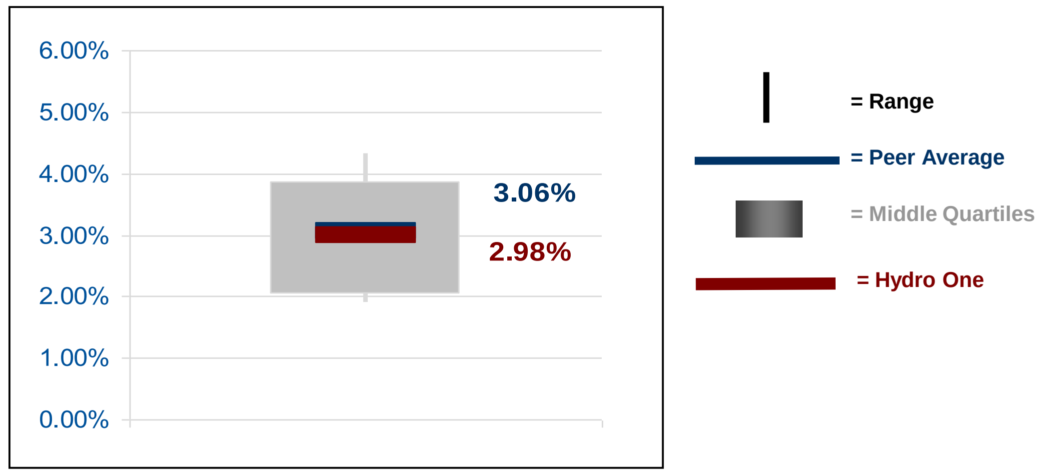
Observations	Recommendations
Benchmark findings indicate variations to the peer group by spending category and in the functional areas (end user computing, enterprise computing, and applications support are higher, network is lower). End user computing and applications support have a more direct business user impact (equipment and applications) and therefore require more business collaboration to balance cost, value and productivity. Hydro One spends differently than the peer group by category, with outsourcing receiving the highest allocation. Hydro One is outsourced with an additional 102 in-house and contractor FTEs. The in-house and contractor FTEs are allocated throughout the functional areas but with higher concentrations in applications development and support and management.	• Perform a deeper-dive analysis on specific areas to better understand cost drivers. • Ensure that outsourcing contract pricing is competitive in the market and services match both business needs and end user behavior. • As mentioned earlier, review roles and responsibilities of retained in-house and contractor staff and the service provider outsourcer. There are some indications of possible overlaps with retained staff and the service provider. For example, Hydro One reported a total of 45 FTEs in Applications Development and Support. The outsourcer also provides applications services and it is unclear if the 45 FTE and the outsourcer are duplicating effort. There are also a number of corporate IT staff including project management staff. Review role specification, processes and handoffs. • Develop a plan to rationalize enterprise computing costs and review opportunities to increase server virtualization. • Evaluate data management policies and roles at the business level to optimize storage costs. • Consider user segmentation strategies for end user computing, carefully analyzing impact on user productivity. • Review software costs in depth - including the application portfolio and other software usage such as tools against the software spending reported in the assessment. Software costs are low, but applications support spending allocation is high. Is this indicative of applications that have a low software cost but require more maintenance? Is Hydro One investing in tools or applications to improve user productivity? • Analyze data network equipment investment levels for review and possible replacement, especially in remote locations.

IT Metrics

IT Spending as a Percentage of Revenue

Assessment Area	Observations
IT Spending	▪ IT Spending as a Percentage of Revenue is similar to the peer group. ▪ The analysis period in the benchmark represents a period of minimal transformational initiatives in the IT budget at Hydro One.

	Hydro One	Peer - Avg
IT Spending as a % of Revenue	3.0%	3.1%



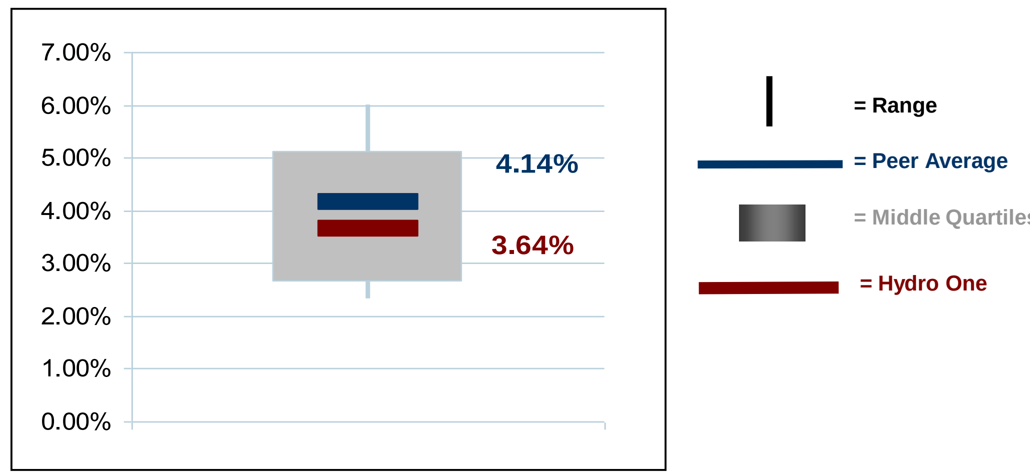
- Definitions:
  - Revenue – includes revenue for business units supported by IT. Includes fuel.
  - IT Spending – includes operations and capital spending (does not include any amortization and depreciation).

Gartner.

IT Spending as a Percentage of Operating Expense

Assessment Area	Observations
IT Spending	▪ IT Spending as a Percentage of Operating Expense is lower than the peer group. Hydro One has a higher business operating expense compared to the peer group average.

	Hydro One	Peer - Avg
■ IT Spending as a % of Opex	3.6%	4.1%



- Definitions:
  - Operating Expense – includes the total expense associated with the business units supported by the IT organization.
  - Includes items such as selling, general and administrative expenses (SGA), cost of goods sold (or cost of revenue), research and development, depreciation, depletion and amortization expenses etc.
  - IT Spending – includes operations and capital spending (does not include any amortization and depreciation).

IT Spending Distribution – Capital and Operations Spending

Assessment Area	Observations
IT Spending	▪ Hydro One has a lower proportion of capital spending compared to the peer group average. ▪ Hydro One does not capitalize any IT investments below \$2M. This is higher than typically observed in Gartner benchmarks (for example, many organizations are in \$250K-\$500K range).

	Hydro One	Peer - Avg
Operations	72%	60%
Capital	28%	40%

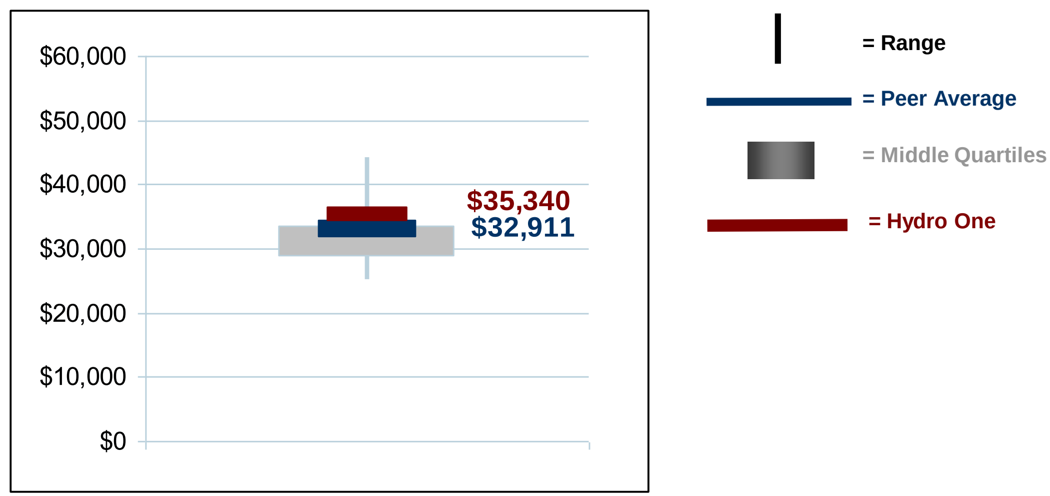
IT Spending Distribution – Capital and Operations

- IT capital expenses vs. operational expenses helps to portray the investment profile for an organization in a given year.
- Definitions:
  - Operational IT Spend: IT Operational expenses: Total day to day operations and maintenance expenses for this fiscal year that have not been capitalized. This does not include any amortization and depreciation.
  - Capital IT Spend: Capital Expenses: Total capitalized IT spending for this fiscal year.

IT Spending per Company Employee

Assessment Area	Observations
IT Spending	▪ IT Spending per Employee is higher than the peer group average. Hydro One has fewer employees than the peer group average (5,516 versus 6,336). In addition to the 5,516 full-time employees, there are an additional 2,237 temporary, contract and part-time employees at Hydro One, some of which are seasonal. ▪ IT Spending per Employee is the IT spending for capital and operations for the number of company employees, which excludes contractors and outsourcing. ▪ Hydro One estimates a 20% premium on labour cost due to their heavily outsourced model.

	Hydro One	Peer - Avg
IT Spending per Company Employee	$35,340	$32,911



- Definitions:
  - IT Spending – includes operations and capital spending (does not include any amortization and depreciation).
  - Company employees.

Gartner.

Run, Grow and Transform

Assessment Area	Observations
IT Spending	▪ Hydro One is allocating the IT budget to Run and Grow activities and nothing in Transform during the current analysis period. The peer group is spending 35% of their IT budget on Grow and Transform compared to 20% for Hydro One.

	Hydro One	Peer - Avg
Run	79%	65%
Grow	20%	26%
Transform	0%	9%

IT Spending Distribution by Run, Grow and Transform

- Definition:
  - Allocation of IT Spending ($) capital and operations by run, grow and transform categories.
  - Run: Run-the-business IT initiatives are aimed at essential (and generally non-differentiated) business processes. The objective of a run-the-business initiative is to improve or maintain the desired balance among cost, quality and risk for these essential processes.
  - Grow: Grow-the-business metrics are about improvements in operations and performance, within current business models.
  - Transform: Transform-the-business value metrics are about new horizons — new markets, new products and new business models.

IT Spending Distribution by Cost Category

Assessment Area	Observations
IT Spending	▪ IT support is outsourced with Hydro One owning the assets. There is a 20% premium on labour due to agreements. There are differences in asset age and type by function. For example, network and server assets are kept in service longer, over five years, while end user assets such as laptops are refreshed more frequently. There is a high concentration of mobile devices (74% of devices). Hardware and software spending is lower than the peer group. ▪ The higher percentage of outsourcing also reduces the number of company employees and IT FTEs, since outsourcing staff are not counted.

	Hydro One	Peer - Avg
Hardware	9%	18%
Software	11%	24%
Personnel	14%	39%
Outsourcing	66%	19%

- Definitions:
  - Allocates the percentage of capital and operations spending into categories.
  - Outsourcing includes voice and data carrier costs as well as service provider contracts.

IT Expense Spending Distribution by IT Functional Area

Assessment Area	Observations
IT Expense Spending	▪ Hydro One has a higher allocation to Enterprise Computing, End User Computing and Applications Support compared to the peer group.

	Hydro One (102)	Peer - Avg (513)
Enterprise Computing and Storage	25%	20%
End-User Computing	14%	6%
IT Service Desk	2%	4%
Data Network	6%	10%
Voice Network	4%	5%
Application Development	13%	19%
Application Support	31%	27%
Corporate IT and Project Management	4%	6%
Finance & Administration	1%	4%

IT Expense Distribution by Functional Area

- The distribution of spending by functional area provides a view of key IT resource consumption. This distribution represents an "expense view" of IT spend which includes current-year operational expense as well as current-year lease, maintenance, depreciation and amortization expense.
- Definitions:
  - Allocates the percentage of expenses into the functional areas.

IT FTEs Distribution by IT Functional Area

Assessment Area	Observations
IT Staffing	▪ This represents In-House and Contractor FTEs and does not include outsourcing. The FTEs are focused on applications and in corporate IT management roles.

	Hydro One (102)	Peer - Avg (513)
Enterprise Computing and Storage	3%	16%
End-User Computing	4%	7%
IT Service Desk	2%	5%
Data Network	1%	10%
Voice Network	2%	3%
Application Development	30%	21%
Application Support	15%	26%
Corporate IT and Project Management	34%	9%
Finance & Administration	11%	3%

IT FTE Distribution by Functional Area

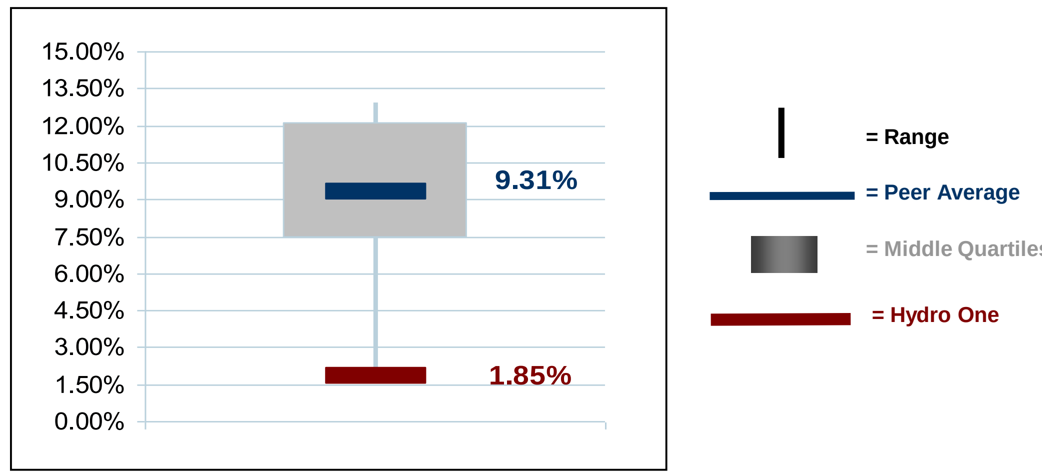
- The distribution of staffing by technology domain provides a view of key IT resource consumption.
- Definitions:
  - This distribution represents FTE allocation.

Gartner

IT FTEs as a Percentage of Total Company Employees

Assessment Area	Observations
IT Staffing	▪ Hydro One has a lower ratio of IT FTEs to Hydro One employees due to the level of outsourcing.

	Hydro One (102)	Peer - Avg (513)
■ IT FTEs as a % of Company Employees	1.8%	9.3%



- Definitions - IT employees includes - In-House IT Full-Time Equivalents (FTEs) and Contractor FTEs:
  - FTEs who are employed by the IT organization and contract FTEs which are supplemental to your staff and "operationally" managed by in-house staff. This includes all full time, part time, and temporary FTEs covered by the IT Spending definitions.
  - Full Time Equivalents (FTEs) Definition: An FTE represents the logical staff to support functions performed by the physical staff, measured in calendar time. This includes all staffing levels within the organization from managers and project leaders to daily operations personnel.

IT Contractor FTE Usage

Assessment Area	Observations
IT Staffing	■ Hydro One uses fewer contractors than the peer group average.

	Hydro One	Peer - Avg
In-House	77%	60%
Contractor	23%	40%

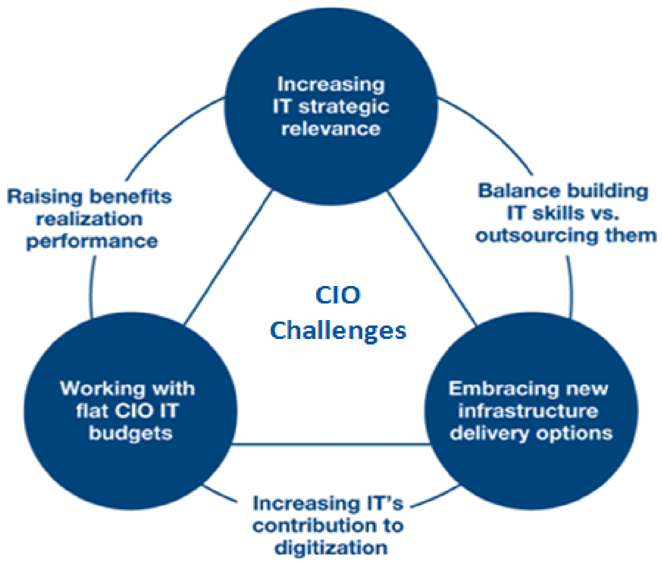
In-House and Contractor Staff Distribution

- Definitions:
  - Contract IT Full-Time Equivalents (FTEs): Total number of contract full-time equivalents, which are supplemental to your staff and "operationally" managed by in-house staff. This includes all full time, part time, and temporary FTEs.

Appendix

IT Strategy
Cost Optimization Model Framework
Data Management
Applications Rationalization

IT organizations run the risk of missing opportunities for longer term business value and strategic impact



IT organizations without a deliberate strategy often describe current capabilities as 'accidental'

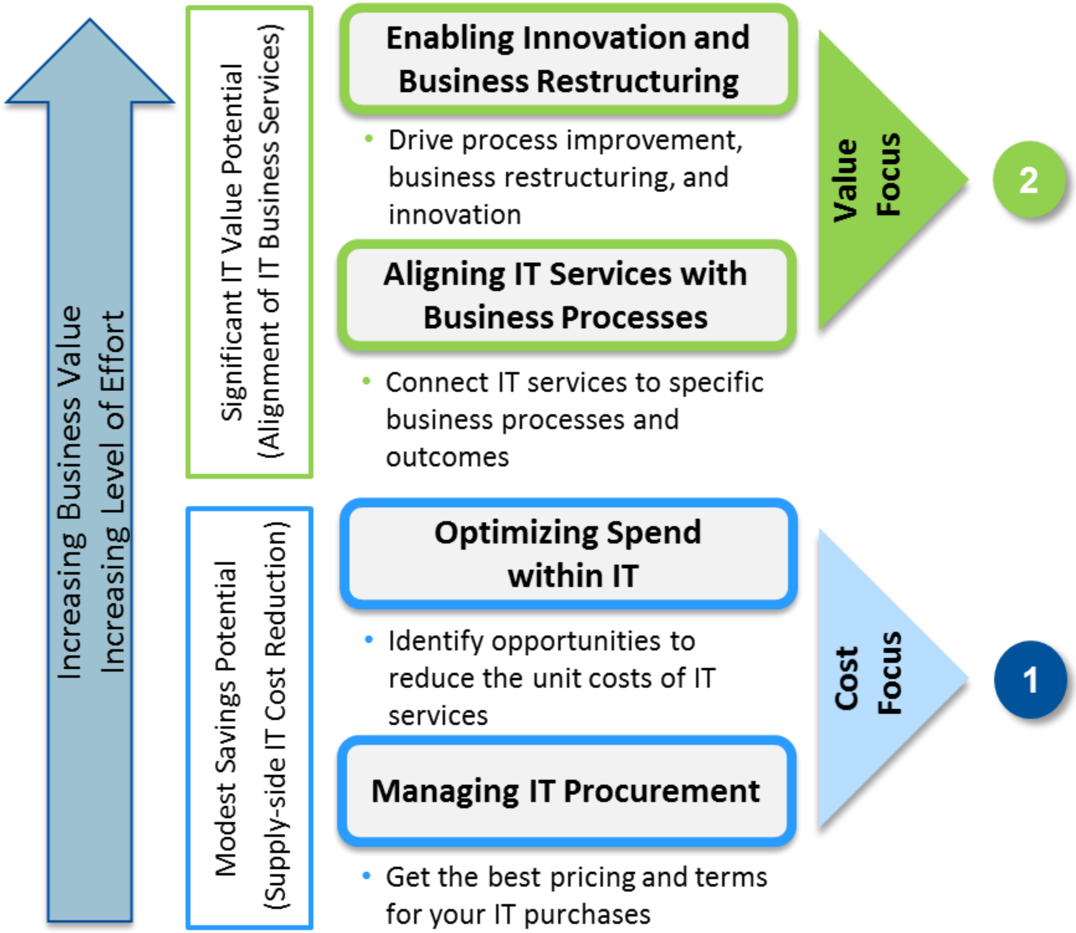
- In the long run, accidental IT strategies are substantially more expensive
- Missed opportunities for growth and differentiation, especially with new emerging technologies
- Carrying costs of low value, high risk projects
- Substantial, real investments to correct, reorganize, modernize, standardize, rationalize, and simplify

- Today more than ever, managing IT performance and delivering IT-intensive projects is necessary but not sufficient to create business, IT and CIO success.
- CIOs must understand that business results and business growth are critical for their success. This means…
  - being more disciplined about benefits realization for new capabilities and investments
  - clarifying business impact of IT contribution to business growth
  - ensuring optimization and reuse of trusted data assets
  - working with the rest of the organization to plan and prioritize IT services and investments based on business priority

Gartner

Gartner Cost Optimization Model

This framework outlines the path to optimization of both value and cost. IT can focus on ensuring that costs under IT control are efficient. Business engagement aligns IT services with business processes in order to ensure investments either contribute to revenue or reduce operating expense through productivity improvements.



- Business involvement is required to maximize the value of IT investments.
- This includes new investments and rationalization of existing applications portfolio.
- IT can manage unit costs but without business involvement cannot change the number of units under IT management or how the business works.

- IT can focus here to harvest any opportunities to improve IT efficiency. This frees up dollars for new investments.
- Measure unit costs to understand price per performance.

Data Management

Review data management and storage volume in light of the higher allocation of expenses to Enterprise Computing. Managing storage growth is a concern for many utilities owing to the large volumes of data. Many organizations have invested more in buying storage, which has a relatively low acquisition cost, than resources, processes and capabilities to manage and use the data. Data management is even more challenging in regulated industries where business requirements govern data retention.

- Barriers to storage optimization often include either a lack of the right resources and/or understanding of the differences between storage management and data management. Storage management and data management are different competencies and the terms are often misinterpreted:
  - Data management is concerned with associating value to data and then creating policies and procedures to determine data retention tiers and safe deletion. This is a business-facing role.
  - IT is a custodian of data and not the data owner, which imposes significant restrictions on IT's ability to discern the business value of data.
- An IT organization can efficiently manage large storage volumes by using products and technologies – which are within IT's direct control. As with applications, IT tools and processes can only be impactful up to a point. Storage optimization requires changing processes, procedures and organizational behavior – determining the value of data – which are out of IT's direct control.
- Review roles and responsibilities for data management and leverage more business self-service to reduce the storage footprint. Ensure that policies and processes around the value of data, such as who owns what data and how it should be retained are developed and followed.

Gartner

Applications Support

Hydro One allocates more of the budget to Applications Support than the peer group at 31%. Spending is lower on software however, suggesting that there is either overlap in support with the service provider or there are applications that require support but do not have a software cost. There could be an opportunity to rationalize the applications portfolio.

Recommendations

- Review the mix of applications spending to determine if the mix of support and development is appropriate for Hydro One.
- Application Development and Support tends to be more difficult to optimize than assets because of the impact on business processes. The IT organization cannot simply turn off applications. IT acting on its own cannot change how the business works.
- Common optimization initiatives include:
  - Rationalizing the current application portfolio. Taking extra care in managing the application portfolio to ensure that costs for maintaining older applications don't "crowd out" spending on new initiatives. This may require that some application is retired for every new one that is brought in.
  - Being sure to build in ongoing costs through one upgrade cycle when building business plans for new initiatives.
- Business executive sponsorship is required to the success of any application optimization effort.
- Divide application rationalization efforts into two teams – one team to focus on large applications (where there are significant cost savings through reductions in complexity and customization) and one to focus on reducing the number of small applications.

Many companies experience the "Piling On" effect of multiple projects that continuously add to baseline costs year over year. Maintenance costs can crowd out funding. This can create competitive risk in an industry dependent on technology.

2.0 (5.3) ASSET MANAGEMENT PROCESS

Infrastructure Asset Management is the combination of management, financial, economic, engineering, and other practices applied to physical assets, with the objective of providing a level of service that aligns customer needs and preferences, asset needs and rate impacts. It includes the management of the entire lifecycle of the asset including planning, design, construction, commissioning, operating, maintaining, repairing, modifying, replacing, decommissioning and disposal.

Hydro One's asset management goal is to identify and scope the optimal timing of capital investments and asset maintenance throughout the life cycle of its assets. This is done to manage risks and to support the achievement of Hydro One's Business Objectives, while managing total cost and customer rate impacts.

This section focuses on information pertaining to the asset management processes employed by Hydro One to manage its distribution assets.

Investment Planning Process

For the planning of capital investments, Hydro One utilizes a comprehensive investment planning process for identification, prioritization and optimization of asset and capital investments. An overview of the planning process is included in Section 2.1.

Overview of Assets Managed

An overview of the system that supports the delivery of service to customers including service area and the fundamental assets is included in Section 2.2.

Asset Component Information and Life Cycle Strategies

For the management of assets deployed, strategies are developed based on the characteristics and requirements of the various assets themselves. A summary of the key distribution components outlining the specific maintenance and replacement strategies for each of these various assets is contained in Section 2.3.

2.1 (5.3.1) INVESTMENT PLANNING PROCESS

Hydro One's planning process is an ongoing cyclical process that develops an annual budget for OM&A and capital investments and a five-year planning forecast consistent with the Board's filing requirement of a consolidated five-year capital plan. All investments follow this same process. The planning process cycle in 2016, which underpins Hydro One's investments in this Distribution System Plan, pertains to the 2017 to 2022 period.

Hydro One's planning process consists of seven stages, as outlined in Figure 9 below.

1. **Strategic Context**: Incorporation of strategic direction from Hydro One's Senior Executives and the OEB that is used to focus the identification of needs and appropriately prioritize the candidate investments;
2. **Planning Assumptions**: Incorporation of load forecast and economic assumptions to guide the development of investments;
3. **Needs Assessment**: Assessment of needs based on the existing assets, customer preferences, system requirements and other influences;
4. **Investment Development**: Development of alternative solutions and selected candidate investments to address the identified needs;
5. **Investment Optimization**: Prioritization of the proposed investments to yield an optimized investment plan;
6. **Investment Approval and Implementation**: Management of the investments within the optimized investment plan from final approval through to project completion; and
7. **Performance Reporting**: Monitoring of the plan through a set of performance metrics.

The following sections will provide further detail on each stage of the planning process.

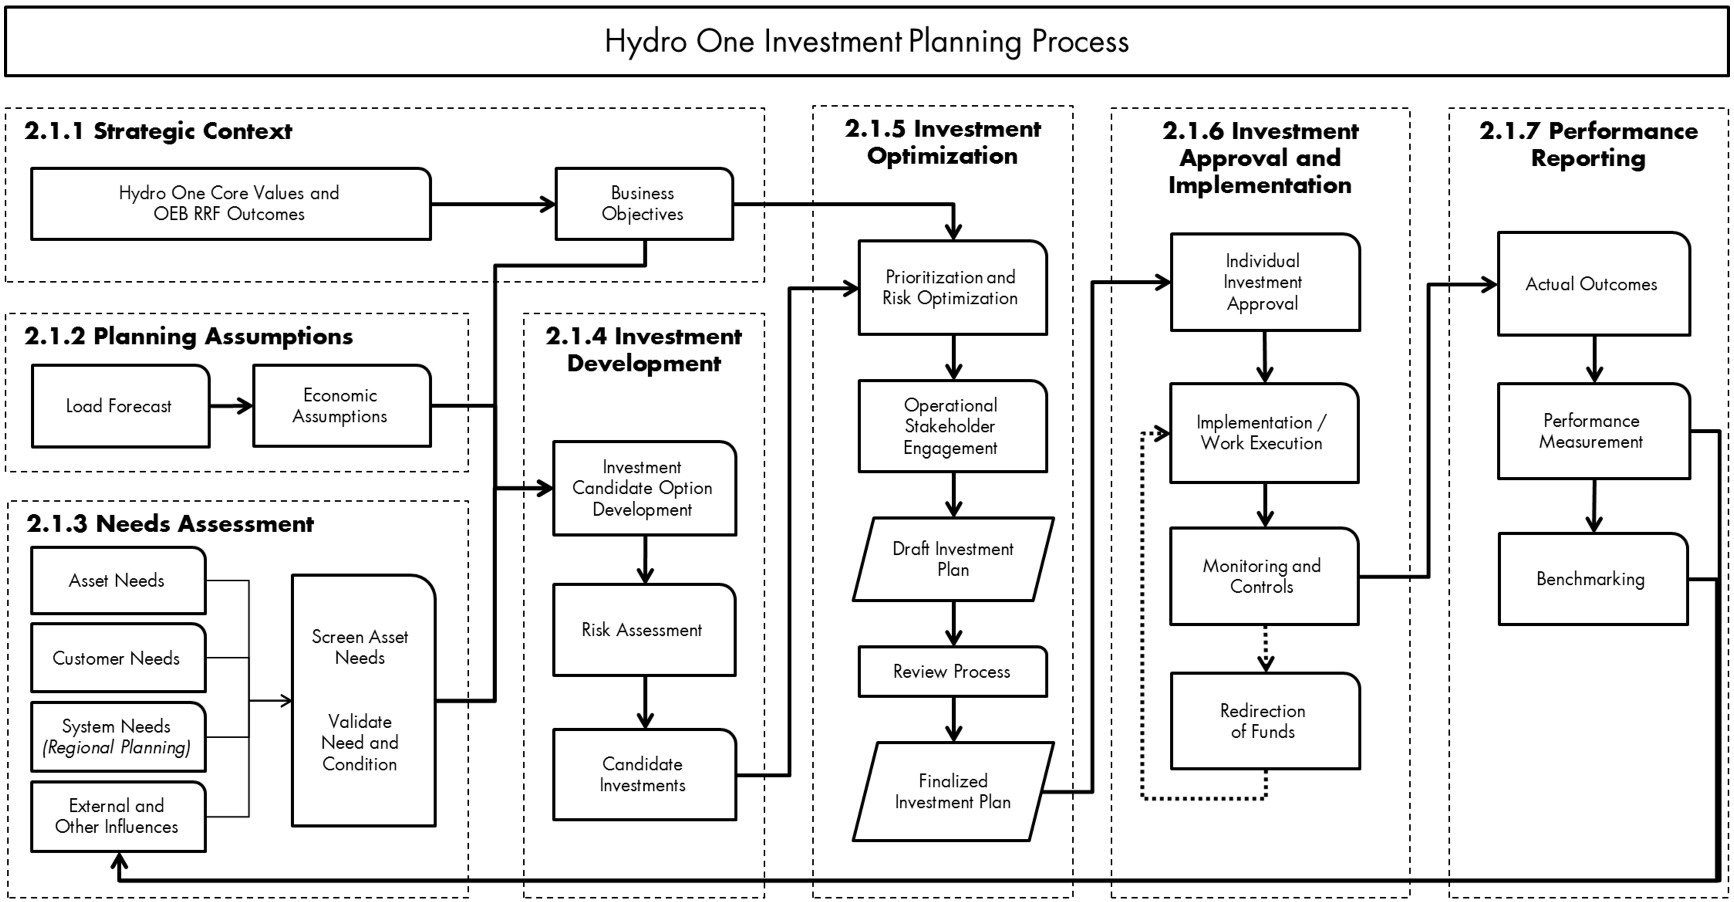

Figure 9 - Hydro One's Investment Planning Process

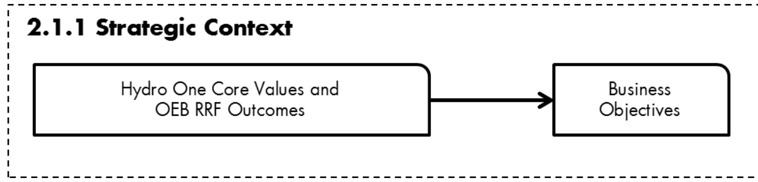
2.1.1 (5.3.1 A) STRATEGIC CONTEXT



Hydro One aspires to be a best-in-class, customer-centric, commercial utility, while remaining committed to delivering safe, reliable power, and supporting the sustainable development of the Ontario economy. This is reinforced by the company's vision which states, Hydro One will become:

> *"an innovative and trusted company delivering electricity safely, reliably, and efficiently to create value for our customers".*

2.1.1.1 HYDRO ONE CORE VALUES AND OEB RRF OUTCOMES

Hydro One is guided by a set of five Core Values promoting:

- a safe workplace for its employees and the public;
- a customer caring environment;
- one company working to meet customer, commercial and shareholder needs with integrity;
- a people-powered business, committed to engaging, developing and retaining the best people; and
- the pursuit of execution excellence in delivering safe, reliable, affordable transmission and distribution services.

Witness: Darlene Bradley

As a steward of assets that are critically important to customers and the provincial economy, Hydro One is committed to delivering the level of service required by customers, safely, in a manner that complies with regulatory requirements and that manages the company's environmental footprint.

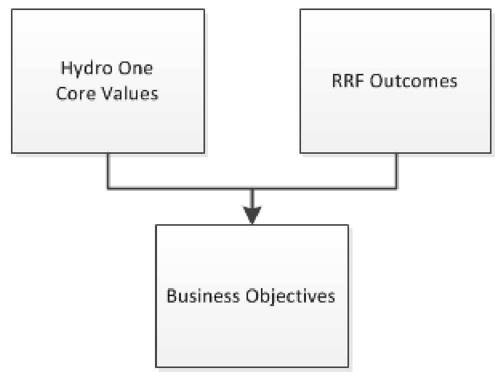
The Renewed Regulatory Framework has a clear set of objectives. To achieve those objectives, the OEB has laid out a series of four RRF Outcomes.

- **Customer Focus** – services are provided in a manner that responds to identified needs and customer preferences;
- **Operational Effectiveness** – continuous improvement in productivity and cost performance is achieved; and distributors deliver on system reliability and quality objectives;
- **Public Policy Responsiveness** – distributors deliver on obligations mandated by government (e.g., in legislation and in regulatory requirements imposed further to Ministerial directives to the Board); and
- **Financial Performance** – Financial viability is maintained; and savings from operational effectiveness are sustainable.

Ultimately, the RRF Outcomes will be used to monitor and measure performance against defined performance outcomes. Hydro One is prepared and ready to meet these outcomes and the expectations of its customers and has integrated the RRF Outcomes into its planning process.

2.1.1.2 BUSINESS OBJECTIVES

Guided by its Core Values and the RRF Outcomes, Hydro One has developed a set of Business Objectives that drive decisions across the Company in the development of an investment plan. Hydro One's Business Objectives are used in the evaluation of asset and other needs in order to inform and guide the development of investment candidates. Moreover, the Business Objectives are further utilized as a basis for the prioritization weightings in the optimization of the investment plan as outlined in Section 2.1.5.

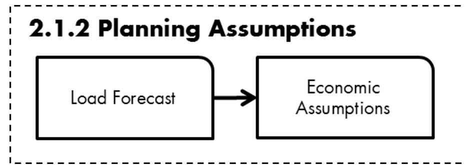


These Business Objectives, outlined in Table 29 below, are aligned with the OEB's RRF Outcomes and provide the layout of how Hydro One intends to measure success to drive continuous improvement as described in Section 1.4.

Table 29 - RRF Outcomes and Hydro One Business Objectives

RRF Outcomes	Business Objectives
Customer Focus	**Customer** • Improve current levels of customer satisfaction • Engage with our customers consistently and proactively • Ensure our investment plan reflects our customers' needs and desired outcomes
Operational Effectiveness	**Safety** • Drive towards achieving an injury -free workplace for employees and the public
	Reliability • Provide reliability consistent with customer expectations
	Productivity • Actively control and lower costs through OM&A and capital efficiencies
	Employees • Achieve and maintain employee engagement
Public Policy Responsiveness	**Shareholder Value** • Ensure compliance with all codes, standards, and regulations • Partner in the economic success of Ontario
	Environment • Sustainably manage our environmental footprint
Financial Performance	**Financial Benefit** • Achieve the ROE allowed by the OEB • Manage planning and spending to mitigate customer impacts

2.1.2 (5.3.1 B) PLANNING ASSUMPTIONS



To facilitate the preparation of Hydro One's investment plan, an economic outlook forecasting key economic statistics and a customer load forecast are developed. The forecasts and assumptions used for Hydro One's investment plan are documented below.

2.1.2.1 LOAD FORECAST

Hydro One uses a number of methods, such as econometric models, end-use models, and customer forecast surveys to produce the load forecast required for its distribution business. This load forecast methodology is the same method that Hydro One has applied in previous Distribution Rate Applications (EB-2005-0378, EB-2007-0681, EB-2009-0096, and EB-2013-0416). Similar methods are used by major utilities throughout North America.

The forecasts presented are weather-normal at the wholesale level unless otherwise specified. Abnormal weather effects are removed from the base year for load forecasting purposes so that the forecast assumes typical weather conditions based on the average of the last 31 years. This weather correction methodology was reviewed and approved by the OEB in the Distribution Cost Allocation Review (EB-2005-0317).

A detailed description of Hydro One's forecasting methodology, models and their elements including: consensus input, updates to changes in economic forecasts, energy prices, population and household trends, industrial development and production, residential and commercial building activities, and efficiency improvement standards are discussed in Exhibit E, Tab 2, Schedule 1.

Using this approved forecasting methodology; the forecast for the test years (2018 to 2022) is presented in the table below.

Table 30 - Forecast Energy Deliveries and Customer Count

Year	Energy Delivery Forecast (GWh)	Change (%)	Distribution Customer Count	Change (%)
2018	36,019	-0.6	1,300,518	0.7
2019	35,680	-0.9	1,309,216	0.7
2020	35,673	0.0	1,317,967	0.7
2021*	36,363	1.9	1,386,522	5.2
2022*	36,373	0.0	1,395,578	0.7

** The figures include the impact of integrating the Acquired Utilities into Hydro One Distribution. Without this, the GWh delivered would have changed by -0.3% in 2021 and 0% in 2022, and the number of customers would have changed by 0.7% in both 2021 and 2022.*

While the Provincial aggregate load growth is expected to decline, the customer count is expected to rise moderately. The decrease in load is mainly due to the impact of Conservation and Demand Management ("CDM") and the current economic conditions. There are also pockets of load and customer growth expected to occur in Hydro One's service territory, primarily in areas that border major urban centres.

Witness: Darlene Bradley

2.1.2.2 ECONOMIC OUTLOOK

Distribution Cost Escalation for Construction, Operations & Maintenance

Hydro One utilized the HIS Global Insight's "Distribution Cost Escalators for Construction, Operations & Maintenance" presented in Table 31 below to forecast expenditure level changes for distribution materials and services. These escalators provide a broad average measure of the industry-wide yearly price changes by tracking a representative basket of equipment and labour comprised of: operation, supervision and engineering, load dispatching, stations, lines, meters, customer installations, maintenance, structures, overhead lines, underground lines, line transformers, and miscellaneous.

Table 31 - IHS Global Insight's June 2016 Forecast

%	Historical Years					Bridge Year	Test Years				
	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022
Distribution Cost Escalation for Construction	2.9	3.5	2.9	2.5	-0.4	1.8	2.5	3.0	3.0	3.0	2.9
Distribution Cost Escalation for Operations & Maintenance	2.3	0.8	0.7	-0.8	-0.7	1.6	2.2	2.4	2.3	2.2	2.0

Consumer Price Index

Hydro One, as an Ontario based distributor, has relied on the Ontario Consumer Price Index ("CPI") presented in Table 32 for its assumptions about inflation and costs. The CPI, published by Statistics Canada, provides a broad measure of the cost of living. Through the monthly CPI, Statistics Canada tracks the change in the retail price of a representative shopping basket of about 600 goods and services from an average household's expenditure: food, housing, transportation, furniture, clothing, and recreation.

Table 32 - Ontario CPI

%	Historical Years					Bridge Year	Test Years				
	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022
CPI-Ontario*	1.4	1.1	2.3	1.2	2.1	1.9	2.0	2.0	2.0	2.0	2.0

** IHS Global Insight's June 2016 forecast.*

Exchange Rates (CDN:USD)

Hydro One utilized historic exchange rates based on the average exchange rates for 2012, 2013, 2014 and 2015 from the Bank of Canada. The exchange rate forecasts for 2016 to 2022 are based on the June 2016 edition of the Global Insight Forecast. These exchange rates, as presented in Table 33, are used to forecast other variables such as Fleet vehicle related costs, forecasts for which are typically obtained in US$. It is an important variable affecting the performance of the Ontario economy.

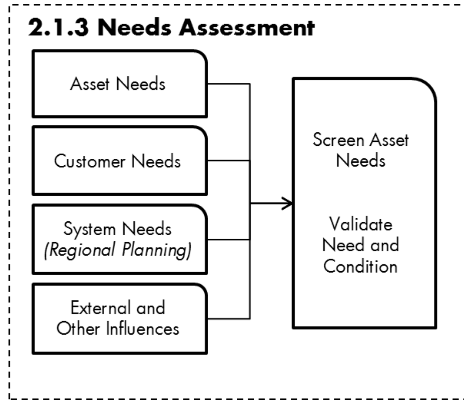
Table 33 - Exchange Rate

USD:CAD	Historical Years					Bridge Year	Test Years				
	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022
Exchange Rate	1.000	0.971	0.905	0.783	0.751	0.770	0.790	0.841	0.872	0.885	0.900

Note. Actual exchange rates for 2013 and 2014 were lower than forecasted due to unexpected decline in price of oil
Source: IHS Global Insight's June 2016 forecast.

Witness: Darlene Bradley

2.1.3 (5.3.1 B) NEEDS ASSESSMENT



Hydro One performs a needs assessment in order to identify the needs that will drive the development of candidate investments. The needs assessment considers the asset needs, customer needs and preferences, system needs (including regional planning) and other external influences. The needs assessment also identified potential hazards, vulnerabilities, threats or other risk sources that could present risks to achieving Hydro One's Business Objectives

2.1.3.1 ASSET NEEDS

Individual asset needs are determined, in part, by performing an asset risk assessment ("ARA"), which relies on various information sources such as asset condition data, asset registry for demographics, system configuration, and system performance and utilization data. SAP is Hydro One's asset registry with some supplemental asset information being extracted from GIS, such as conductor length, secondary circuits, etc.

Each of these different information sources are used to assess risk by their corresponding asset risk category, as described below. This assessment is the same process that Hydro One applied in the previous Distribution Rate Application (EB-2013-0416) and is outlined in Figure 10 below.

Witness: Darlene Bradley

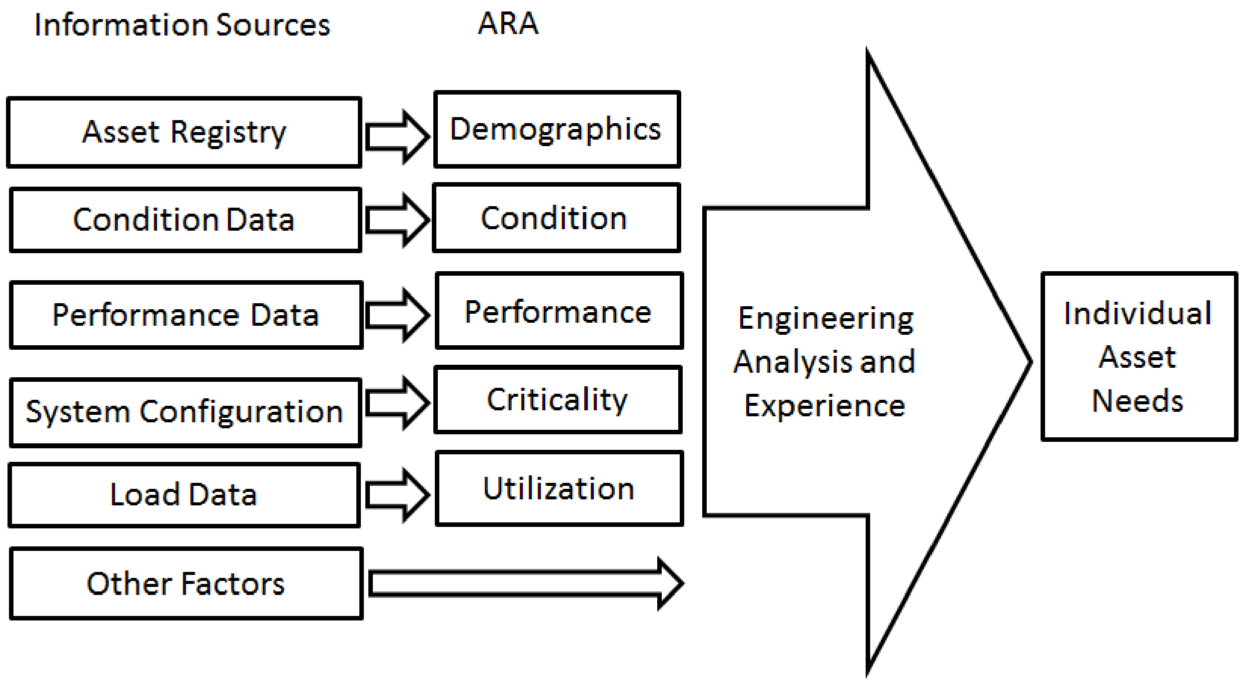


Figure 10 - Asset Need Development Process

Asset Demographic Risk

Asset demographic risk relates to the increased probability of failure exhibited by assets of a particular make, manufacturer, and/or vintage. Asset demographic data by make and manufacturer is contained within Hydro One's asset registry. Typically, the probability of asset failure increases with age. Thus, the asset demographic risk increases as an asset ages.

At times, specific asset makes or models are observed to deteriorate at a markedly different rate than other assets of the same type. For example, Hydro One has observed increased deterioration rates in Red Pine wood poles of specific vintages. Poles of this material and of these specific ages therefore carry a higher asset demographic risk than other wood poles of the same age.

Witness: Darlene Bradley

Assets with relatively high demographic risk are candidates for refurbishment or replacement.

Asset Condition Risk

Asset condition risk relates to the increased probability of failure that assets experience when their condition degrades over time. Asset condition is defined using different criteria depending on the asset. For example, the condition of a distribution station transformer is measured by visual inspection and analysis of the oil within the transformer. The condition of a wood pole is measured by a visual inspection, a sounding test and, if required, a boring test. While methods to evaluate condition vary from asset type to asset type, the condition of all assets of a given type is evaluated consistently.

Asset Performance Risk

Asset performance risk reflects the historical performance of an asset. Performance is defined by any power interruptions that have been caused by failure of the asset. Hydro One tracks the failure of an asset and customer power interruption data using its distribution Outage Response Management System. This risk factor considers the frequency and duration of these interruptions, as well as whether the interruptions are occurring more or less frequently over time. Past performance can be a good indicator of expected future performance.

Asset Criticality

Asset criticality represents the impact that the failure of a specific asset has on the distribution system. Primarily, it is defined by the number, type and size of customers impacted by the failure of a given asset. Assets whose failure would result in an interruption to a higher number of customers or in a larger amount of load would have an asset criticality that is higher than assets whose failure would have a smaller customer impact.

Asset criticality does not directly drive a decision to refurbish or replace an asset. However, it is used to prioritize the refurbishment or replacement of assets whose other risk assessment factors has already resulted in the asset being considered a candidate for refurbishment or replacement.

Asset Utilization Risk

Asset utilization risk represents the increased rate of deterioration (or increased risk of failure) exhibited by an asset that is highly utilized. While not all assets exhibit this increased rate, the deterioration of some assets is highly dependent on the loading placed upon them or the number of operations they experience. For example, transformers that are heavily loaded beyond their nameplate rating deteriorate more quickly than those that are lightly loaded. Therefore, the asset utilization risk for transformers attempts to consider their relative deterioration based on available loading history.

In assessing asset needs, planners also consider other factors such as environmental risk and requirements, compliance obligations, equipment defects, and health and safety considerations. The results of the ARA, in conjunction with the other factors, are analyzed to develop a list of asset needs by major asset type. The specific information and risks utilized to determine asset needs is dependent on the major asset.

2.1.3.2 CUSTOMER NEEDS

Hydro One customer needs are identified through engagement with its customers. On a regular basis, as part of its everyday operations, Hydro One engages with customers, collecting information on customer needs and preferences via customer surveys. In addition to this regular engagement, Hydro One has undertaken a customer engagement process for the purpose of increasing understanding of customer preferences and aligning those preferences, responsible asset stewardship and rate impacts in its distribution system plan. As described in Section 1.3, this plan is consistent with the OEB's RRF framework.

The key messages from the customer engagement process were integrated into the system plan as follows:

- A top priority for all customers was to minimize rate increases. To address this Hydro One will defer early year capital spending to pace investments in such a way as to minimize rate impacts and implemented a number of productivity initiatives to reduce unit and operational costs.
- Residential and Small Business customers requested that Hydro One maintain its existing level of reliability. Hydro One's overall business plan was optimized to maintain current levels of reliability. To provide cost value and manage system wide reliability performance, Hydro One will focus some investments on feeder performance outliers.
- For Large Customers, improving power quality and reducing the number of sustained outages is their top priority. To address this Hydro One has created an OM&A program to assist Large Distribution Account customers with investigations to determine the source of the power quality issue that they are experiencing. Hydro One has increased the funding of reliability enhancement projects to specifically target Large Distribution Accounts and mid-size industrial customers.

Complete details of how Hydro One has integrated the outcomes of the customer engagement process into the distribution system plan are in Section 1.3.4.

Hydro One seeks to continue to engage customers consistently and proactively, leveraging a better understanding of customer needs into improved overall satisfaction with service. An investment plan that provides customers with outcomes that are value for money is critical to achieving this goal.

2.1.3.3 SYSTEM NEEDS

Hydro One's system needs are identified through the regional planning process and by performing regionally focused reviews of the distribution system's remaining capacity.

Hydro One is actively involved in the regional planning process in conjunction with the IESO, the Transmitter, and other LDCs. The regional planning process identifies primarily transmission-level investments that provide supply to more than one distributor. However, distribution-level investments are also identified when such investments can address a regional need more effectively than other transmission or resource options. A detailed description of the Regional Planning process is included in Section 1.2.

Regionally focused reviews of the distribution system's remaining capacity involve a review of the loading on all major assets supplying the area to determine if there are any assets that are at or near loading limits.

2.1.3.4 EXTERNAL AND OTHER INFLUENCES

Other planning considerations include such factors as: results of the performance reporting metrics benchmarking trends and industry best practices. Benchmarking gives Hydro One the opportunity to compare its performance and internal measures to other utilities within the industry. Hydro One conducted external benchmarking studies on the unit cost of its pole replacement and station refurbishment programs, which highlighted potential productivity and efficiency opportunities that were considered in the development of the investment plan.

2.1.3.5 SCREEN AND VALIDATE NEEDS

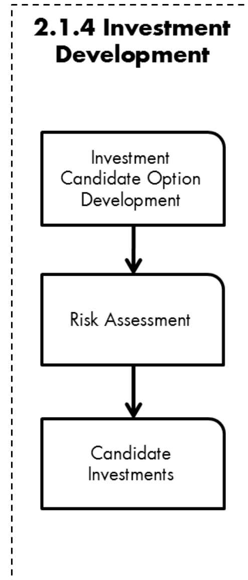
The final step in the Needs Assessment is comprised of three parts.

1. Screening Needs involves prioritizing the needs within the needs categories, e.g., customer expressed a desire for lower rates and improved reliability, but the priority was on rate impacts.

2. Screening Needs also involves grouping the needs identified into logical functional and geographic groups. For instance, a customer need for increased capacity and an asset need to replace a distribution station in deteriorated condition could be grouped together if the same physical assets are involved.

3. Validating Needs entails reconfirming that the need is still present and has not evolved and will not be addressed by other means. For instance, a planned new station may eliminate the need to replace an end of life station and could also provide the additional capacity required by a customer.

2.1.4 (5.3.1 B) INVESTMENT DEVELOPMENT



The process Hydro One undertakes to identify candidate investments entails the development of candidate options and an assessment of risk related to each option.

2.1.4.1 INVESTMENT CANDIDATE OPTION DEVELOPMENT

Hydro One's development of candidate options is driven by three things.

First, Hydro One's Business Objectives act as a filter to determine whether an investment is worth considering. If an investment does not support the achievement of a Business Objective then it is not considered further.

Second, where appropriate, planning assumptions are factored in to ensure that full and unbiased information is available and so that the candidates are ultimately evaluated in a credible fashion.

Finally, investment candidates are chosen by their ability to address the needs identified in the needs assessment. Hydro One classifies investments into one of the four OEB investment categories: System Renewal, System Access, System Service, and General Plant. Each category shares a common investment development process, but the development of investments to address the specific needs is distinct to each category.

System Renewal

System Renewal investments involve replacing and/or refurbishing system assets to extend the expected service life of the assets and thereby minimize life cycle costs and maintain reliability performance.

In general, identifying and selecting System Renewal investments consist of several steps. The first step is to consolidate the risk information identified in the Needs Assessment by major asset type. The next step is to identify options to mitigate risk for assets that are deemed to have a significant increased risk of failure. Hydro One then reviews the needs of assets in close proximity to determine if there are opportunities for an integrated stations or lines centric investment. Hydro One relies upon the factors used to evaluate risk including condition, criticality, performance and demographics as described in Section 2.1.3.1. The aggregate risk is then used to prioritize the assets within an asset type and centric investment types. Following this prioritization, alternative levels of accomplishment and their corresponding levels of risk to which Hydro One will be exposed, are defined. Finally, the preferred option to mitigate the asset risk is selected using the Investment Optimization process described in Section 2.1.5.

System Service

System Service investments are modifications to the distribution system to ensure that it continues to meet distributor operational objectives while addressing anticipated future customer electricity service requirements.

System Service investments are reviewed based on their ability to address the system need in the most cost-effective manner while considering benefits to other Hydro One

Business Objectives. In general, identifying and selecting System Service investments is comprised of the following steps.

First a geographic boundary, based on system needs, is established to determine the extent and scope of the area being considered. Hydro One has a vast service area and thus defining this geographic boundary is necessary to focus the analysis.

Next a series of data reviews for the defined area are undertaken, including:

- A review of the loading on all major assets supplying the area to determine if there are any assets that are at or near their loading limits or if these limits will be exceeded based on expected load growth for the area. The major assets reviewed for remaining capacity include sub-transmission feeders, distribution stations and distribution feeders. Supply capacity from the transmitter is also confirmed. The current peak loading and forecast 10-year peak loading with conservation demand management and without conservation demand management are compared to current loading limits;
- A review of existing and planned Distributed Generators ("DG") in the area for any potential synergies to optimize capital investments as part of the area plan;
- A review of System Renewal and System Access needs in the area to assess opportunities of integrating work into an optimal integrated plan; and
- A review of the system reliability for feeders supplying load in the area. Feeders identified as having a reliability concern will be analyzed to determine if an alternative will improve its reliability.

Based on this information, alternatives are developed to address any issues determined through the analysis described above. These alternatives are compared on economic considerations, efficiency/line losses, reliability and other factors impacted by the alternatives. Finally, a preferred alternative is recommended based on the above analysis.

System Access

System Access investments are non-discretionary in nature and are system modifications that Hydro One is obligated to perform to provide and maintain customer(s) access to electricity services. These investments mainly include:

New Customer Service Requests

Investments are generated in response to customer requests for new connections to Hydro One's distribution system. Hydro One is obligated to connect new customers as per Section 28 of the *Electricity Act* under the conditions specified by the Distribution System Code. To effectively budget for new customer service requests, Hydro One forecasts new customer connections using forecasting methodology described in Exhibit E1, Schedule 2, Tab 1. Specifically, for large customers, new customer service requests are assessed as dictated by the Distribution System Code.

Third-party Infrastructure Development Projects

Investments are generated based on requests from external proponents to relocate Hydro One's assets to accommodate various infrastructure projects, such as a road widening. To effectively identify and budget for third-party infrastructure projects that require plant relocation or modification, Hydro One actively engages in planning and coordination meetings with the Ministry of Transportation, local municipalities and other third party initiated projects that require relocation of Hydro One assets.

Mandated Service Obligations

Investments that Hydro One is mandated to perform by government regulation or policy such as replace/upgrade metering infrastructure, and/or enable distributed generation.

General Plant

General Plant investments are comprised of modification or replacements to distributor's assets that are not part of the distribution system. These include investments related to Hydro One's transport and work equipment fleet, facilities, and information technology. The process to identify and select investments in each of these areas is discussed below.

Transport and Work Equipment Fleet

Transport and work equipment investments are necessary to ensure that crews have the ability and the vehicles required to access and perform the work required. Investments are generally comprised of either new equipment or replacement of existing equipment. The investments are identified and selected based on need which is driven by the following key factors:

- work program requirements;
- industry standards (manufacturer's recommendations) for life cycle expectancy;
- Net Book Value (NBV) to Original Capital Value (OCV) ratios; and
- operating cost drivers.

Based on this information, a preferred alternative is recommended in line with Hydro One's expected Business Plan and Work Programs.

Facilities

Facility investments are necessary to provide appropriate and adequate accommodations for core work programs and changing requirements of the various lines of business. The investments are identified and selected based on need which is driven by the following key factors:

Witness: Darlene Bradley

- aging facilities that are at or near their end of life;
- compliance with legal requirements, such as *Accessibility for Ontarians with Disabilities Act*;
- expanding work programs;
- evolving work practices;
- improved health and safety;
- improved security;
- sustainable development; and
- work efficiency and productivity.

Based on this information, a comparative evaluation of alternatives, which may entail the lease or purchase of existing or green-field developments against status quo condition, is undertaken. A preferred alternative is recommended based on the objective to pursue the most cost-effective strategy that addresses operational requirements and manages risk.

Information Technology

Information Technology ("IT") investments are identified and selected based on the need to address:

- potential end of life information technology systems and determine the point in time to initiate their upgrade or replacement; and
- mandatory Ontario Energy Board Regulatory Compliance changes to our systems, (e.g. billing, rate increases, policy changes).

2.1.4.2 RISK ASSESSMENT

Once investment candidate options are identified, a risk assessment is undertaken. The risk assessment is based on the value that the candidate creates by mitigating risks identified in the needs assessment or the ability of the candidate to enhance productivity.

The risk assessment includes an evaluation of the effectiveness of existing processes and operations to control risk.

The risk assessment is based on a Risk Evaluation Matrix that defines the level of risk as a product of the likelihood of a risk (i.e. probability) and the severity of a risk (i.e. consequence), as illustrated in Figure 11. The “consequence” of a given risk is measured on a five-point risk tolerance scale from “minor” to “catastrophic”. The “probability” that a given risk will materialize is measured on a six-point likelihood scale, from “unexpected” to “very likely”.

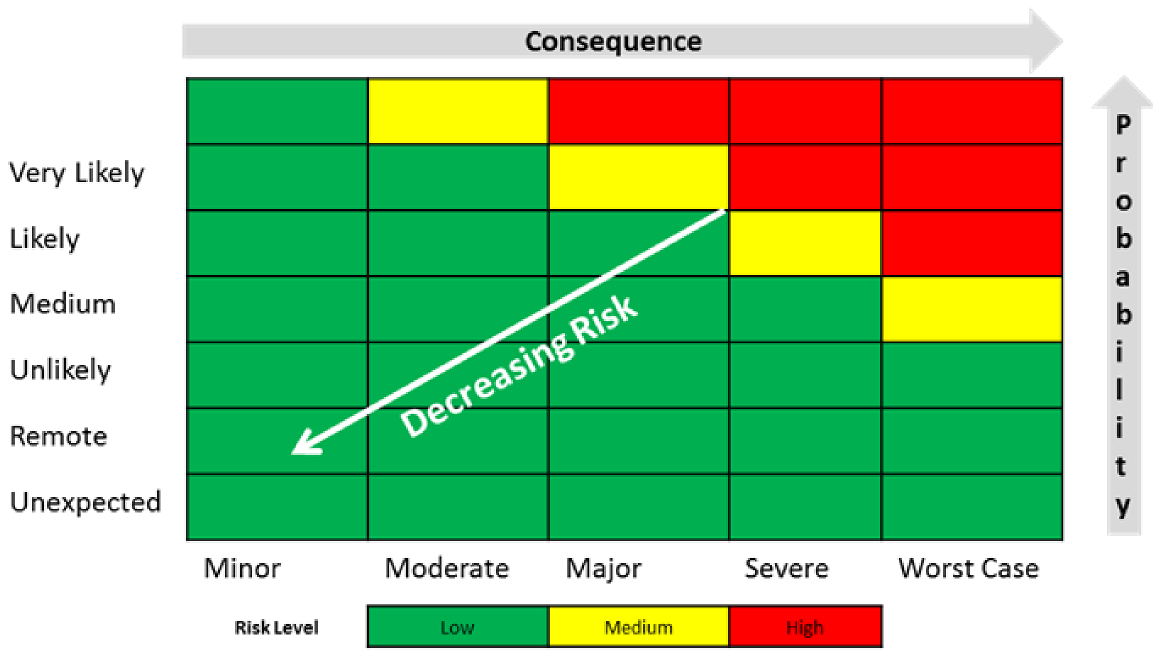


Figure 11 - Risk Evaluation Matrix

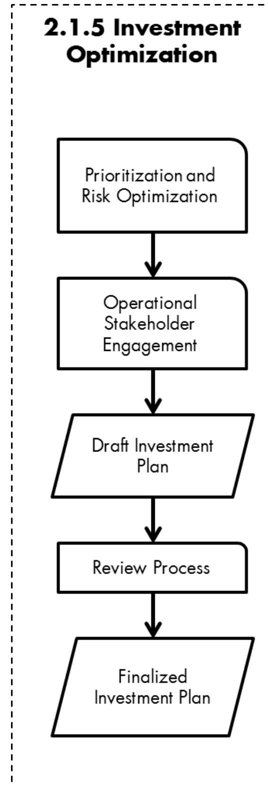
A risk assessment is undertaken for two scenarios: (a) a baseline risk evaluation, representing the risk of not proceeding with the investment; and (b) a residual risk evaluation, representing the remaining risk after the investment is put into service.

These risks assessments form a clear link between the risks and the intended benefit of the candidate investments. The difference between the baseline risk and residual risk is the risk mitigation value created by the investment.

2.1.4.3 CANDIDATE INVESTMENTS

Once the investment candidate options have been through a risk assessment, a structured, multi-level managerial review is conducted. The managerial review is focused on the need justification, the reasonableness of the risk assessment, and the appropriateness of the candidate investment options prior to its inclusion in the investment plan. A decision is made to accept the risk or mitigate the risk. Mitigation is designed to reduce the impact of the risk (consequence) or reduce the likelihood of occurrence (probability). For risks identified for mitigation, a list of recommended candidate investments with associated estimated cost and risk assessment are input into the investment optimization process and used to produce the optimized investment plan.

2.1.5 (5.3.1 B) INVESTMENT OPTIMIZATION



This section details the investment optimization process that takes identified candidate investments and yields a finalized investment plan.

2.1.5.1 PRIORITIZATION AND RISK OPTIMIZATION

All candidate investments are aggregated into a consolidated investment plan for prioritization and optimization. At the core of the process is the multi-variable framework based on the business objectives, which helps decision-makers understand and quantify business risks and uncertainties so that objective decisions can be made respecting investment priorities.

For the purpose of prioritizing investment candidates, the Business Objectives outlined in Section 2.1.1 are translated into a series of prioritization criteria, against which candidate investments are assessed. The prioritization criteria are assigned weights based on their relative importance within the Business Objectives as shown in Table 34.

Table 34 - Hydro One's Prioritization Criteria and Weightings

Prioritization Criteria	Business Objectives	Weighting (Pts)	Weighting (%)
Customer	• Improve current levels of customer satisfaction • Engage with our customers consistently and proactively • Ensure our investment plan reflects our customers' needs and desired outcomes	20	17%
Safety	• Drive towards achieving an injury - free workplace	20	17%
Reliability	• Provide reliability consistent with customer requirements	15	13%
Productivity	• Actively control and lower costs through OM&A and capital efficiencies	15	13%
Employees	• Achieve and maintain employee engagement	10	9%
Shareholder Value	• Ensure compliance with all codes, standards, and regulations • Partner in the economic success of Ontario	10	9%
Environment	• Sustainably manage our environmental footprint	10	9%
Financial Benefit	• Achieve the ROE allowed by the OEB • Manage planning and spending to mitigate customer impacts	15	13%

The prioritization process attempts to find the combination of investment options that maximize investment benefit without exceeding the defined funding constraints. This iterative process is intended to produce an overall plan of appropriately paced investments that achieves an optimal balance between cost effectiveness, timely responsiveness to customer needs, asset requirements and business needs. This iterative process is a key stage in the process and it is what lead to the determination of Plans A, B and C as described in Section 1.1 and Section 2.4

Witness: Darlene Bradley

2.1.5.2 OPERATIONAL STAKEHOLDER ENGAGEMENT

After prioritization, a company-wide review of the investment plan is conducted by all internal Hydro One stakeholders. These cross-functional review meetings are held to review and discuss the investment plan. This review is meant to facilitate the consideration of additional operational and execution considerations such as resourcing, material availability and outage obtainability. Based on these discussions, adjustments may be made to reflect emerging execution risks and financial considerations. The end product is a draft investment plan that is a prioritized and paced six-year plan that aligns customer preferences, asset needs and rate impacts.

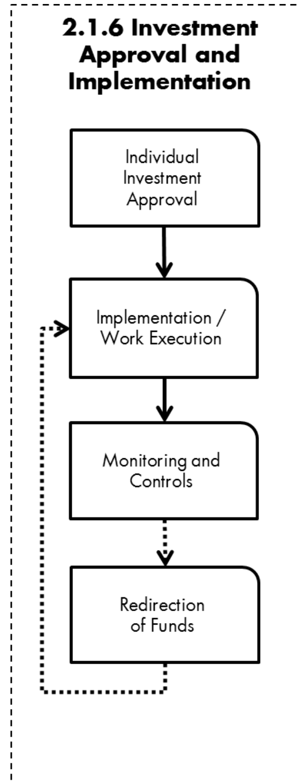
2.1.5.3 REVIEW PROCESS

Following the Operational Stakeholder engagement, the draft investment plan is put forward for review by the Executive Leadership Team ("ELT"). The ELT review is a two-day process that reviews the draft investment plan. The ELT will request additional information on certain investments. Any adjustments to the investment plan, based on input from the ELT review, are completed. A final determination is then made taking into consideration the associated impacts on customer rates, the impact to Hydro One's Business Objectives, and system reliability.

Ultimately, the completed Investment Plan is incorporated into the corporate Business Plan and this is sent to the Board of Directors for approval.

2.1.6 (5.3.1 B) INVESTMENT APPROVAL AND IMPLEMENTATION

Once the overall plan is finalized and approved, individual investments undergo specific individual approvals, are queued for implementation, and monitored during execution.



2.1.6.1 INDIVIDUAL INVESTMENT APPROVAL

Individual projects are reviewed and approved in a series of steps at the senior management and executive levels, consistent with the provisions of the corporate expenditure authority register. This review process entails:

- Verification of the need for the investment and recommended specific investment solution;
- Review of the implications and risks of not executing the investment;
- Review of the anticipated benefits; and
- Review of the estimated costs and execution timing.

Once approval is granted, the individual investments move to the implementation and work execution phase.

2.1.6.2 IMPLEMENTATION/WORK EXECUTION

Hydro One utilizes a fully integrated work execution method that balances and optimizes the use of internal and external resources, costs, system outages, customer needs and material availability in the implementation and execution of its investment plan.

Witness: Darlene Bradley

Hydro One's work execution focus aims to effectively and efficiently execute on its investment plan while focusing on the Company's Business Objectives. Hydro One intends to execute and deliver on its investment plan while maintaining the necessary flexibility to address emergent work and changing priorities.

2.1.6.3 MONITORING & CONTROL

On a monthly basis, year-to-date expenditures and accomplishments as well as projected year-end expenditures are monitored. Variances from plan are identified and presented to senior management for appropriate action.

When it is apparent that an investment will have a material change to scope, schedule or cost from the approved plan, a variance proposal to address the unplanned change is created and presented to the appropriate management level. The approval of the variance proposal is in accordance with the limits set out in the expenditure authority register based on the cost and criticality of the investment. Investments that cannot be re-justified are reprioritized, cancelled or otherwise adjusted to conform to the new condition.

2.1.6.4 RE-DIRECTION OF FUNDS

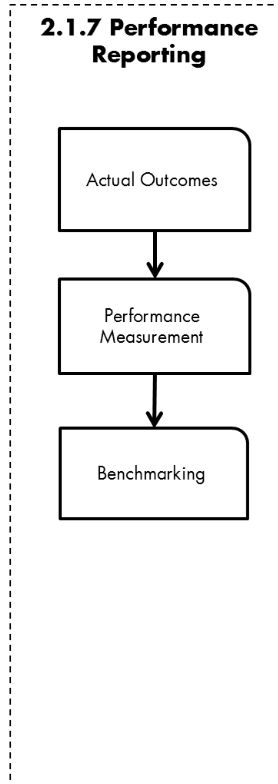
While the investment plan is the product of extensive planning and analysis, implementation of the investment plan must be done in a manner that is dynamic and flexible. Following on the monitoring outlined above, Hydro One may be required to re-direct funds or even authorize additional spending. Depending on the situation, new risks or opportunities could emerge, including:

- Changing customer needs and requirements (e.g., new regional plans, unexpected load growth, etc.);
- Changing asset priorities based on new information;

- Changing external requirements (e.g., new or changing regulatory and/or technical standards, new policy initiatives, etc.); and
- Significant unforeseen events (e.g., extensive storms and equipment failures).

The re-direction or allocation of new funds allows appropriate and prudent adjustments to be made to the work originally identified in the investment plan. For example, the emergency restoration work needed to repair equipment failures or storm damage to distribution lines can be significant and may necessitate the re-direction of funds from other projects.

2.1.7 (5.3.1 B) PERFORMANCE REPORTING



The final stage of the planning process is to monitor performance of the approved investment plan. The performance is monitored through tracking actual outcomes, measuring performance and benchmarking. The results of performance monitoring are utilized to facilitate continuous improvement of the plan in future years.

2.1.7.1 ACTUAL OUTCOMES

Hydro One performs a comparison between the actual investment costs and accomplishments and the proposed investment plan throughout the year and at the end of the investment plan year.

If the plan is projected to miss the planned outcomes within the year, the variance proposal may call for resources to be redeployed to bring the plan back in line with expectations. At year end, the actual investment plan accomplishments and costs are used to adjust future years' expected plan results to allow next year's expected plan to be more accurate.

2.1.7.2 PERFORMANCE MEASUREMENT

In addition to actual outcome monitoring, Hydro One is proposing a set of key performance measures to be incorporated into Hydro One's scorecard to track the company's performance. For more information on how this Performance Measurement is tracked, please refer to Section 1.4.

These performance measures will be evaluated and used to inform future investment plans as part of the feedback to the External and Other Influences portion of the Needs Assessment process.

2.1.7.3 BENCHMARKING

The measurement of selected accomplishments and costs for each investment is used to benchmark Hydro One's performance against other utilities. Complete details for the results of Hydro One's benchmarking activities that informed this DSP can be found in Section 1.6.

Benchmarking for major investment accomplishments serves to identify potential productivity and efficiency gains. Internal review and analysis of Hydro One's work practices and cost structure can lead to new work practices, along with modified productivity and cost efficiency targets. Any future identified productivity gains are used to adjust the plan accomplishments and costs accordingly.

2.1.8 INVESTMENT PLANNING PROCESS SUMMARY

Hydro One's investment planning process begins with its five core values and its vision of becoming a best-in-class, customer-focused utility. Planners navigate through seven important steps, including understanding needs, assessing candidate investments and measuring risk. The ultimate goal is to develop a comprehensive investment plan that embraces the overall Business Objectives, responds to the OEB's Renewed Regulatory Framework and aligns customer needs and preferences, system reliability (asset needs) and rate impact.

2.2 (5.3.2) OVERVIEW OF ASSETS MANAGED

The Hydro One distribution system, one of the largest in North America, has evolved over more than 100 years. Hydro One manages over $7 billion in distribution assets supplying electricity to customers across the province of Ontario. The distribution system delivers electricity at voltages below 50 kV from Ontario's transmission and generation systems to approximately 60 Local Distribution Companies, 90 Large Distribution Accounts, 8,000 Commercial & Industrial customers and 1.3 million Residential and Small Business customers.

A large number of Hydro One's assets have deteriorated in condition and significant investment is required to maintain supply reliability and to mitigate the associated risks to Hydro One's Business Objectives.

Hydro One has a number of proactive investment programs that aim to pre-emptively address critical assets where a failure would impact a large number of customers.

Hydro One has maintenance programs to address less critical assets that individually serve fewer customers, in order to quickly respond to events such as asset failures on a reactive basis.

Finally, Hydro One has demand-driven programs that react to unforeseen incidents that affect the entire system, such as storms or other external factors.

2.2.1 (5.3.2 A) DESCRIPTION OF THE DISTRIBUTION SERVICE AREA

The Hydro One distribution service area is over 99% rural with less than 1% considered to be in urban areas. Hydro One's distribution system includes approximately 1.6 million poles to serve 1.3 million customers. To service these rural areas the distribution system is radial in design, with very little transfer capability in supply to customers. A small part of the distribution system is monitored. M Class Sub Transmission feeders are monitored for volt, current, and status at the station. Smart grid devices have been deployed at the Owen Sound operating centre, including monitoring of line reclosers, capacitors and distribution stations in the operating centre's area. Otherwise, Hydro One has limited monitoring and control of breakers and switches on the system. Furthermore, the majority of the Hydro One distribution system is located overhead, with only about 8% of the system being underground. This design is consistent with other rural systems.

The map below is a representation of Hydro One's distribution service territory.

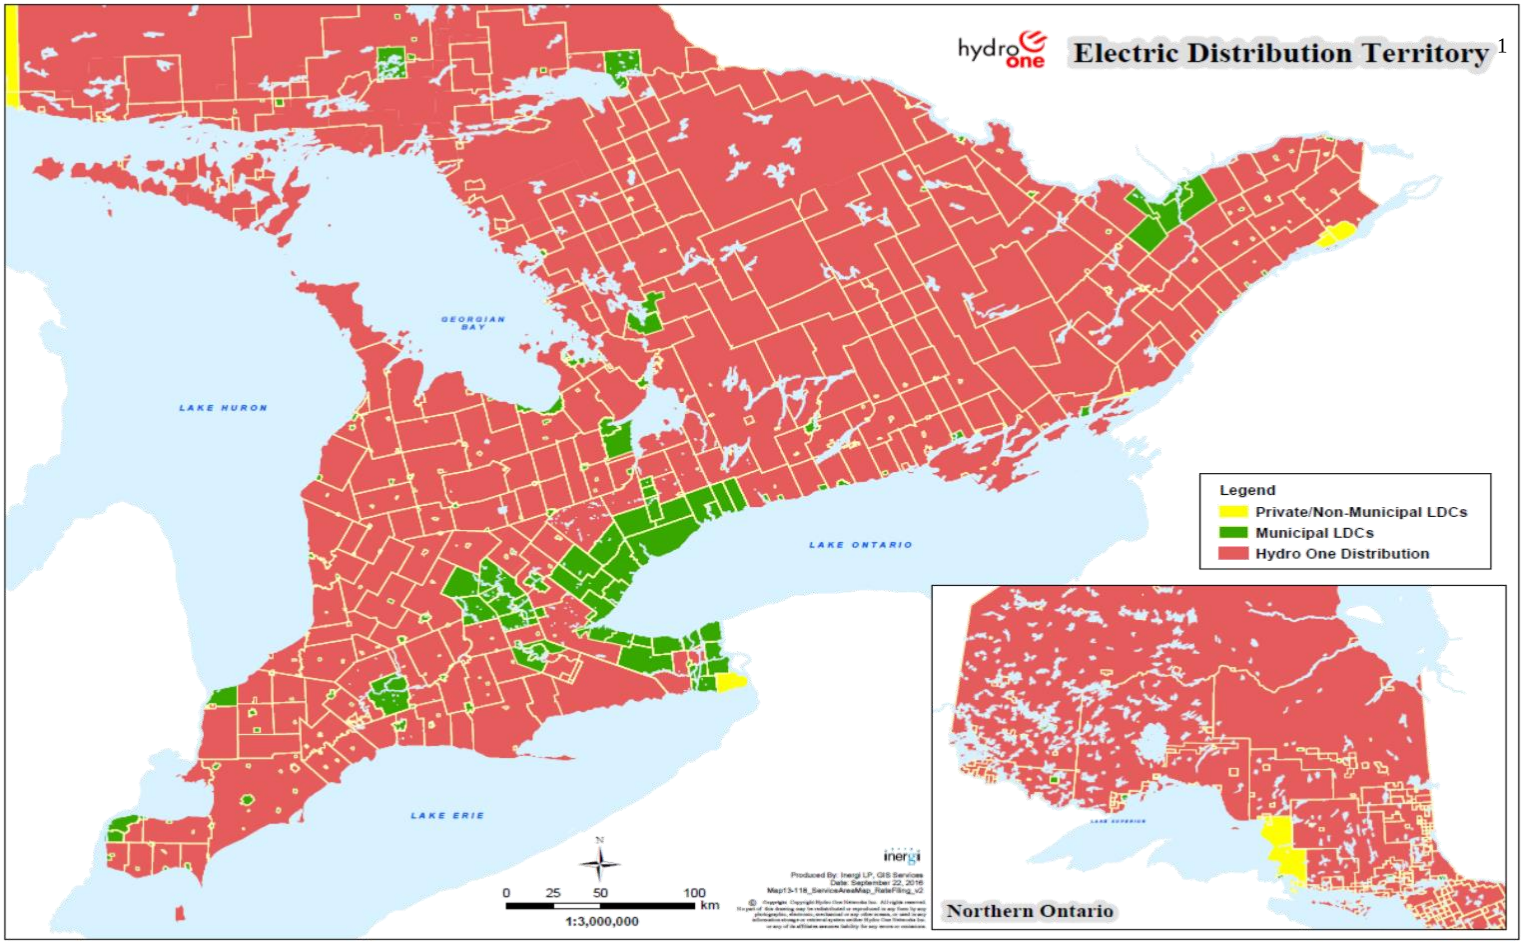


Figure 12 - Hydro One's Distribution Territory

Witness: Lyla Garzouzi

Hydro One's service to its customer is susceptible to a variety of weather conditions. Storms in Ontario include such extremes as blizzards, hail, ice storms, lightning and thunderstorms including tornadoes. Due to the radial configuration in most of the service territory, storm damage almost always results in an outage to customers and requires immediate repair to restore service.

To effectively manage the response to trouble calls from customers, the initial problem assessment and dispatching of a response is handled through a single facility, the Ontario Grid Control Centre ("OGCC"). Hydro One has Service Centres located throughout the province to cost-effectively provide operating, maintenance and restoration services. These Service Centres provide base locations for field crews and related materials, tools and equipment. In storm conditions, additional crews can be brought in from unaffected Service Centres to assist with power restoration.

Hydro One deems a force majeure to have occurred when 10% or more of Hydro One customers have been interrupted by an event. Over the past 3 years, there has been an average of 8 force majeure days per year. These types of events may include severe ice storms in the winter, or major wind and rain events in the summer months.

Another characteristic of Hydro One's service area is Ontario's forests. Southern Ontario is mostly agricultural land, but has some scattered deciduous forests. The eastern and central regions of the Hydro One service area are about fifty percent densely forested with large conifer, deciduous, and mixed forests. The northern zone, is about 74 percent covered with forests. Given that the majority of the Hydro One distribution system is located overhead, with only about 8% of the system being underground, the system is susceptible to vegetation caused outages.

System load growth over the next five years is expected to be in line with historic growth patterns. Overall, load on the Hydro One distribution system is forecast to grow at 0.1 % per year net of CDM initiatives over the next five years. During the same period, the overall increase in the number of customers is anticipated to be about 100,000, or 8.0% of the existing customer base. These figures include the impact of integrating the newly acquired LDCs into Hydro One's distribution system in the year 2021.

The majority of growth and new customer connections are expected to occur in Hydro One's urban service territories which border major urban centres including the City of Ottawa, City of Kingston, northern York and Peel Regions, Durham Region, and the City of Hamilton. For the remainder of Hydro One's service territory, which is mostly rural in nature, load growth and new customer connection activity is expected to be in line with historic growth rates - about 0.7% for new customers.

2.2.2 (5.3.2 B, C, D) DESCRIPTION OF SYSTEM CONFIGURATION AND CAPACITY

The Hydro One distribution system receives wholesale electricity from the transmission system and/or distributed generation facilities and delivers it to consumers at lower voltages. The system consists primarily of the following asset categories:

1. Distribution Stations
2. Distribution Lines
3. Other Assets

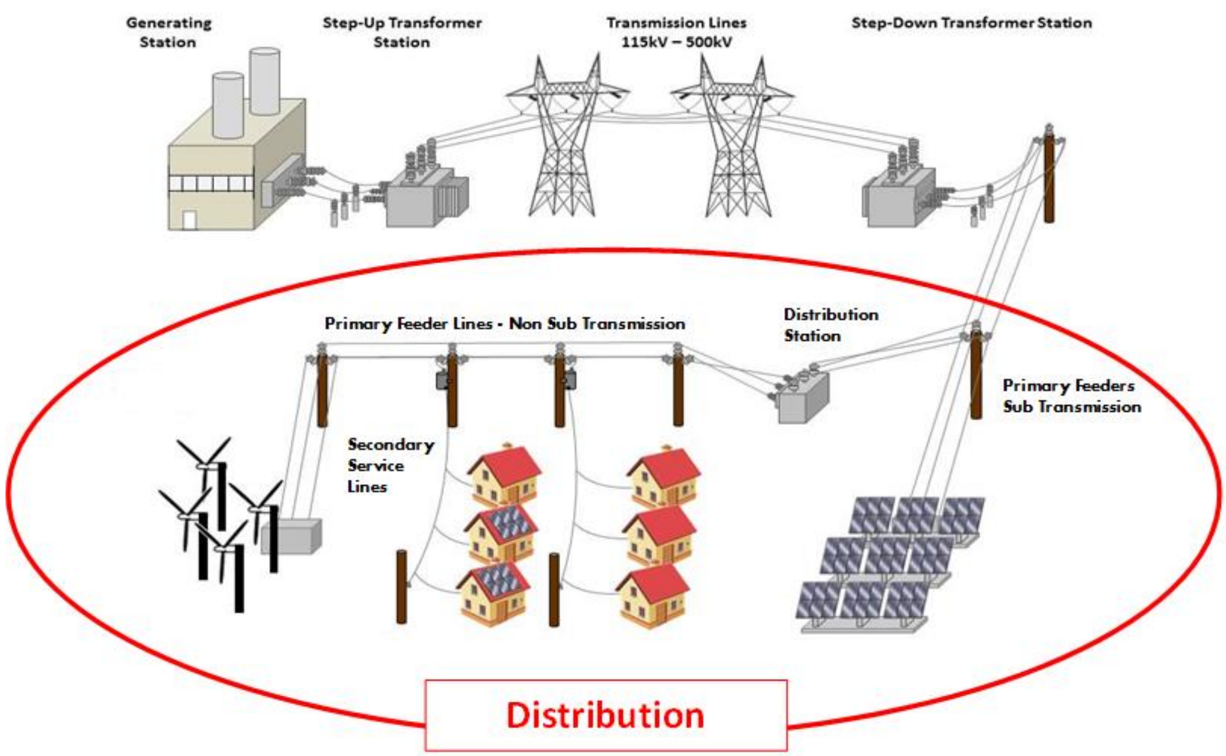

Figure 13 - Hydro One Networks' Distribution System

A description of each of these categories is provided in the following sections.

2.2.2.1 DISTRIBUTION STATIONS

Distribution Stations step down voltage from transmission or sub-transmission levels to primary distribution voltage for distribution to commercial, industrial, farm, year-round residential and seasonal residential customers. Regulating Stations are a special type of station that maintains voltage within the prescribed limits in response to load variations that can cause voltage increases or decreases.

Hydro One owns and operates approximately 1,005 Distribution and Regulating Stations. They typically consist of one or two transformers, depending on the load that needs to be supplied. A loss of any one element (such as a transformer or a breaker) at a distribution station will normally result in the interruption of service to all customers served from that element until the failed component is repaired or replaced, or until an alternate service is enabled.

The capacity of a distribution station is mainly a function of the station's transformers. These can vary from less than 2 MVA to over 15 MVA with the largest percentage of transformers having a nameplate capacity of 5 MVA. Total capacity of Hydro One's Distribution Stations is over 6,500 MVA.

System asset utilization is assessed by Hydro One through planned area studies and system impact assessments. These studies are typically done on a cyclical basis (or on a demand basis if an urgent need arises). When any system assets are identified to approach or exceed Hydro One's established planning limits, corrective scopes of work are issued to address the concern. The source of utilization information for station loading is an annual data collection program through the use of electronic recording ammeters. Meters are installed on each phase of the station feeders and left for a week to record data. This data is then collected and loaded into a system simulation tool called

CYME where the system is then studied in detail. Advancements with Grid Modernization will eventually eliminate this method of data collection and allow asset loading to be sourced from the Distribution Management System ("DMS") using SCADA and DMS state estimation. Modernizing the grid will be key to delivering reliable and cost effective services to our customers going forward. Remote monitoring and control of power system equipment will be undertaken largely in conjunction with asset renewals. Distribution station refurbishment projects (ISD SR-06) will provide such functionality that delivers better determination of fault location and restoration timelines. Further deployment of equipment monitored through the DMS will be implemented through the equipment replaced through the Worst Performing Feeders (ISD SS-06), Distribution Station Reclosers Upgrade (ISD SR-05) and Distribution Lines Planned Component Replacement (ISD SR-10). All of the remotely monitored and controlled devices will be enabled by communication infrastructure implemented in the Advanced Distribution System Project (IS SS-07). As well, another component of this project is the Advanced Metering Infrastructure Analytics ("AMIA") that will leverage the smart metering data to provide transformer, feeder and distribution station information on an asset-by-asset basis and will also allow aggregation at a station level according to the network connectivity model.

Figure 14 represents the percentage of Distribution stations in each capacity category.

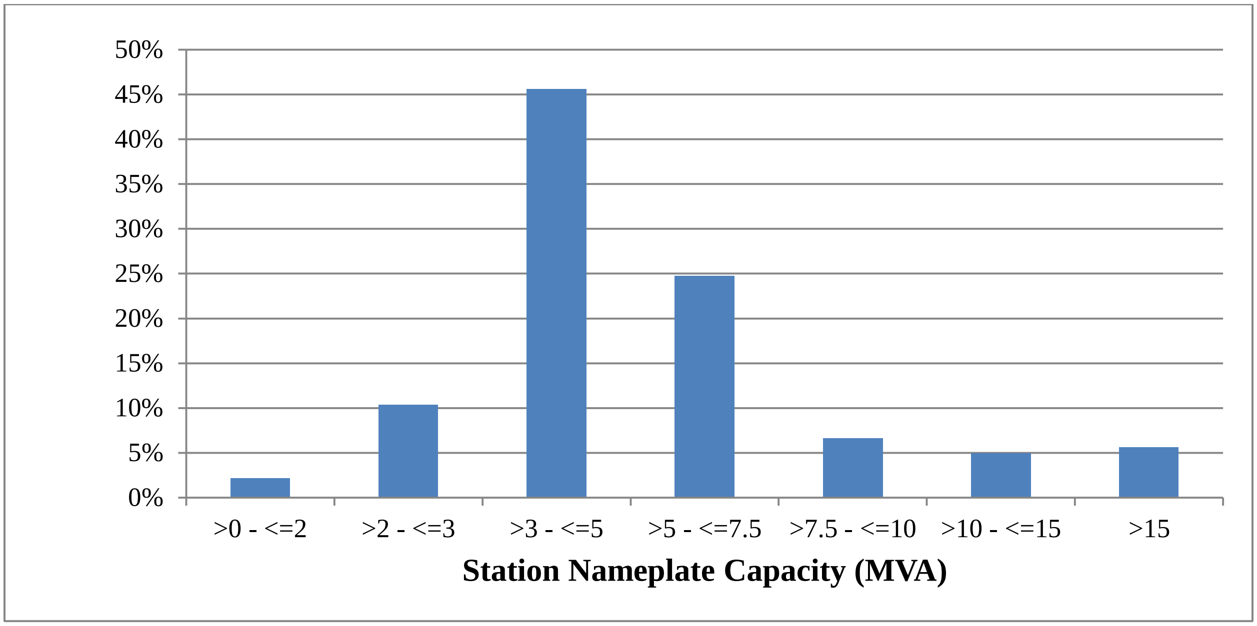

Figure 14 - Station Population by Size

2.2.2.2 DISTRIBUTION LINES

Feeder Lines include the distribution assets necessary to carry power from a station to the customer.

Distribution Feeders are classified into one of the following:

- Primary Feeder – Sub Transmission;
- Primary Feeder – Non Sub Transmission; and
- Secondary Service Lines.

Primary feeders are the lines whose main purpose is to carry electricity from a distribution station to another distribution station or to a line transformer in preparation of final transformation to a voltage that can be utilized by customers. Hydro One owns and operates more than 122,000 circuit kilometres of Primary Distribution feeders across Ontario.

Table 35 - Primary Feeder Length (km) and Count by Voltage Level

Voltage Level (kV)	Overhead (km)	Underground (km)	Submarine (km)	Total Length (km)	Feeder Count
44	9,766	48	16	9,830	343
27.6*	10,849	2,035	95	12,979	377
25*	5,433	99	369	5,901	80
22.8	48	0	0	48	3
Sub-Total Sub-Transmission				**28,758**	**803**
13.8	227	100	0	327	35
12.5	34,731	839	2,907	38,477	619
8.32	50,905	2,023	316	53,244	1,369
4.16	1,359	294	17	1,669	415
Sub-Total Non-Sub Transmission				**93,717**	**2,438**
Total	**113,318**	**5,438**	**3,720**	**122,475**	**3,241**

** Some 27.6 and 25 kV lines function as Non-Sub Transmission feeders but they are grouped together here for simplicity*

Primary Feeders – Sub Transmission

Hydro One has approximately 29,000 circuit kilometers of primary feeders that are considered to be sub-transmission. These feeders originate at transmission transformer stations or high-voltage distribution stations.

Witness: Lyla Garzouzi

Sub-transmission feeders, often referred to as M-Class feeders, typically supply power at 25 kV, 27.6 kV or 44 kV from a high voltage station to other distribution stations. These stations may be owned by Hydro One, other LDCs or large customers. Further voltage transformation takes place at these downstream stations that take power from the M-Class feeders.

In some cases, Regulating Stations are used to maintain voltages on sub-transmission feeders within the prescribed limits. This is needed because the increases or decreases in line voltage depend on load variations at the distribution stations supplied by the sub-transmission feeders.

Primary Feeders – Non Sub Transmission

Hydro One has approximately 94,000 circuit kilometers of primary feeders that operate below sub transmission voltages between 4.16 kV and 13.8 kV.

These feeders, also referred to as F-Class feeders, are circuits that deliver power from distribution stations to line transformers generally in preparation for final transformation to customer voltages. These feeders also connect increasing numbers of distributed generators.

Hydro One’s primary feeder lines are predominately radial in design. As with Stations, a loss of any one element will normally result in the interruption of service to all customers served from that feeder until the failed component is repaired or replaced, or until an alternate service is enabled.

Secondary Service Lines

Hydro One secondary system includes approximately 50,000 kilometers of secondary service lines. This system generally provides a connection from a pole top or pad mounted transformer to an individual customer's demarcation point, which is generally the meter for most residential customers. The Secondary system operates at lower voltage levels that are useable by customers.

The secondary service lines could be either underground or overhead when originating from a pole top transformer. These lines are always underground when originating from a pad mounted transformer.

Secondary service lines generally serve a single customer. Therefore, an outage on a secondary line usually has minimal impact to customers on the system. As such, Hydro One does not perform preventative maintenance on secondary lines. They are repaired as needed on a run to fail basis.

2.2.2.3 OTHER ASSETS

Other Assets are items vital to the continued, effective operation and maintenance of the system but are not necessarily grid-related assets. The significant items in this category include:

- IT Hardware and Applications;
- Real Estate and Facilities;
- Transport and Work Equipment (Fleet); and
- Customer Care Assets.

Each of these assets are significant in size and essential in function. Each undergoes unique asset management strategies designed to optimize the life cycle of the asset. The key component and their relevant strategies are outlined in Section 2.3.3 below.

2.3 (5.3.3) ASSET COMPONENT INFORMATION AND LIFE CYCLE STRATEGIES

During the Customer Engagement sessions, Hydro One's customers said that they want the Company to sustain current levels of reliability. Therefore, maintenance and renewal plans have been designed to manage asset condition across the fleet over the planning period to sustain overall reliability performance. Within each asset category, there are numerous individual components, all of which have different characteristics, requirements and risk factors that are considered from an asset management point of view.

In addition to properly maintaining the assets, these maintenance programs inform the renewal projects and programs for the assets with condition information. Hydro One's asset strategy is the methodology by which Hydro One seeks to maintain its fleet of assets to meet its Business Objectives and customer preferences. Each individual component has a unique asset strategy based on its individual characteristics. Hydro One's asset strategy for each component is summarized in the table below:

Table 36 - Asset Strategy Summary

Section	Component	Asset Strategy
2.3.1.1	Station Transformers and Regulators	Mitigate the risk of failures through predictive testing and, where needed, proactive replacement.
2.3.1.2	Breakers	Perform maintenance every 6 years, and replace those which are obsolete, non-arc resistant, or beyond their service life, with electronic reclosers under station refurbishment investments.

Section	Component	Asset Strategy
2.3.1.2	Reclosers	Maintain based on manufacturer recommended number of operations, and to upgrade to newer technology reclosers when their fault ratings are close to being exceeded, when they demonstrate reliability issues, or when there are opportunities to bundle their replacement under station refurbishment projects
2.3.1.3	Station Switches and Fuses	Inspect during routine station inspections, and bundle preventive maintenance with transformer maintenance to minimize the number of planned outages. When fuses are defective, they are replaced. When switches are defective, they are replaced if they cannot be repaired.
2.3.1.4	Mobile Unit Substations	Address the ageing demographics and deteriorating condition of the MUS fleet by purchasing new MUSs.
2.3.1.5	Other Station Assets	Visually inspect for defects, and address the defects when they are identified. If components are broken and cannot be repaired, then they are replaced.
2.3.2.1	Poles	Asset strategy centres on condition information collected through the line patrol program. Once a pole has been assessed to be in poor condition it is planned for replacement.
2.3.2.2	Rights of Way	Continue with cycle program to address routine vegetation management and augment with a tactical program to focus on poor performing assets for leveraged improvement in reliability.
2.3.2.3	Line Transformers	Replace units upon failure. The exception is PCB contaminated transformers, which are being replaced over the period of 2017-2023.
2.3.2.4	Submarine Cables	Mitigate the risk of failures through visual inspection at the shoreline using the distribution line patrol. Repair/replacement is performed if there is any damage to the cable armour.

Section	Component	Asset Strategy
2.3.2.5	Other Distribution Line Components	Visually inspect all lines assets as part of the distribution line patrol program. Individual assets are assessed and replaced on a "run to failure" basis or on condition-based assessment.
2.3.3.1	IT Hardware and Applications	Hardware: Adhere to the IT industry standard practice of managing assets through a life cycle program ensuring vendor support is available and decreasing the likelihood of failure. Applications: Replace or upgrade where required to ensure continued vendor support and compatibility with the current IT environment.
2.3.3.2	Real Estate and Facilities	Conduct planned maintenance of key facility systems and infrastructure. Undertake inspections at an appropriate frequency to identify and enable corrective maintenance. Undertake annual operational assessments with the various lines of business to confirm facility requirements.
2.3.3.3	Transport and Work Equipment (Fleet)	Provide safe and reliable equipment while balancing the decision to replace or repair equipment based on age, mechanical condition, kilometers traveled and cost per kilometer as well as the current Net Book Value ("NBV").
2.3.3.4	Customer Care Assets	Coordinate the activities of IT and the service provider to maintain customer-facing systems to ensure regulatory compliance while balancing cost and customer satisfaction.

2.3.1 (5.3.3 A, B) KEY COMPONENT SUMMARIES – DISTRIBUTION STATIONS

Hydro One's station maintenance program includes the assets in the Distribution Station. The program inspects and maintains 1,005 distributing and regulating stations. The station asset hierarchy is maintained in SAP. Inspection and maintenance work orders are auto-generated by maintenance plans with asset specific-maintenance frequencies, tasks and unit costs.

Stations and associated asset inspection frequencies are selected to satisfy the DSC – Minimum Inspection Requirements. Rural stations are visually inspected every 6 months, and urban stations are visually inspected monthly. Station transformer and regulator main tanks and oil-filled tap-changer compartments receive an annual oil sample, which is sent to a third party lab for analysis to obtain industry-standard diagnostic test results. In addition, all distribution stations receive an annual infrared thermography inspection of the power equipment in order to identify thermal defects.

The frequencies at which station asset types are removed from service for maintenance is based upon a variety of factors including asset condition data (obtained through inspections and diagnostic testing), equipment performance, maintenance records, manufacturer recommendations, replacement plans, bundling opportunities, and funding constraints.

The main components managed under the Station Maintenance program include:

- Station Transformers and Regulators;
- Reclosers and Breakers;
- Switches and Fuses;
- Mobile Unit Substations; and
- Other Station Assets.

2.3.1.1 STATION TRANSFORMERS AND REGULATORS

Transformers comprise the single largest component of Hydro One's distribution station asset base.

Station transformers convert a high level voltage (typically 115kV, 44kV, or 27.6kV) to a lower distribution voltage (typically 27.6, 25, 13.8, 12.47, 8.32 and 4.16 kV). Regulating transformers are also included in this asset group.

Figure 15 – Picture of Station Transformer

Hydro One owns and operates over 1,200 distribution station transformers. The number of distribution transformers maintained by Hydro One grouped by primary voltage is outlined in Table 37.

Table 37 - Transformer by Voltage Level

Primary Voltage Level	Number of Transformers
230 kV	1
115 kV	141
44 kV	777
27.6 kV	244
< 27.6 kV	59

Witness: Lyla Garzouzi/Lincoln Frost-Hunt/Rob Berardi

Hydro One's distribution asset strategy for transformers is to mitigate the risk of failures through predictive testing and maintenance. Where condition warrants, proactive replacement of these transformers is conducted before they fail to avoid lengthy customer interruptions. Opportunities to integrate transformer replacements with other work required at a distribution station are analyzed in order to improve work efficiency and minimize customer outages.

Preventative Inspection and Maintenance Program

Hydro One utilizes maintenance plans to facilitate distribution station transformer maintenance that is issued and tracked in the SAP system.

The transformer maintenance plans are broken down into the following 7 distinct maintenance activities. Each of the following maintenance activities has an associated frequency, list of tasks, and unit price.

- *Station Visual Inspection* – Station transformers and regulators are visually inspected on a six month cycle for rural stations and monthly for urban stations.

- *Thermovision Inspection* – Annually, each station receives a thermography inspection of all power equipment, at which time the transformer is inspected to identify hot spots in any components.

- *General Oil Test* – Annually, an oil sample is taken from the transformer main tank and sent to a third party lab for analysis to obtain industry-standard diagnostic test results including Dissolved Gas Analysis, Moisture Content and Furan Analysis.

- *Transformer Diagnostic Test* – Following an unsatisfactory oil sample result, the main tank of the transformer may receive diagnostic testing and an internal inspection. This maintenance activity includes the following: Inspection of current carrying parts, bushing oil level check, verification of PCB content in oil, insulation resistance tests, turns ratio and phase angle tests, core loss test, dissipation factor and capacitance test, winding resistance test, inspection of oil conservator breather, repair of minor or moderate oil leaks, function test of pressure vacuum device, check and top-up oil levels, function test of gauges and indicators, and application of touch-up painting to mitigate rust.

- *Under-Load Tap-Changer Oil Analysis* – Annually, an oil sample is taken from tap-changer oil filled compartments and sent to a third party lab for analysis to obtain industry-standard diagnostic test results including Dissolved Gas Analysis, Moisture Content and Furan Analysis.

- *Tap-Changer Selective Intrusive Inspection* – Internal inspection and maintenance of under-load tap-changers with mechanical moving parts is performed every 12 years. If there are unsatisfactory tap changer oil analysis results, inspection and maintenance may be performed earlier in the cycle. This maintenance activity includes the following: filtration of insulating oil, flush and clean oil compartments, visual check for oil leaks and contact wear, inspection of current carrying parts, checks of insulation condition, collector ring, drive chains, pushrod, reversing switch, oil compartment door gaskets, exercise isolation and grounding switch, function test of operating limit switches, gauges and indicators.

- *Power Factor Test* – 115 kV distribution station transformers will receive a power factor test to verify the integrity of the transformer insulation material, and to ensure they are functioning correctly. This is performed when the transformers are removed from service for diagnostic testing or SI maintenance.

The annual budgets are based on the known asset population of transformers and upcoming maintenance schedule based on the maintenance plans.

Optimization, Prioritization and Scheduling

Transformer maintenance is prioritized as follows and within the following four categories:

1. Transformer Condition Based Maintenance (CBM) following high risk oil sample results for transformer main tanks or tap-changers;
2. Maintenance on transformers with unsatisfactory polychlorinated biphenyl ("PCB") content[1], to reduce the content in oil filled compartments down to Environment Canada acceptable levels;
3. Maintenance on leaking transformers to mitigate the leaks; and
4. Tap-changer time-based maintenance for regulators and step-down transformers equipped with under-load tap-changers.

In instances where the visual inspection or diagnostic testing of the transformer identify deficiencies for which the transformer repair cost is relatively high, planners utilize a "repair versus replace" economic model to aid in repair/replace decision-making based on a Net Present Value ("NPV") analysis. In instances where it is more economical to replace the transformer as opposed to repairing it, the transformer is planned for replacement.

In addition to the condition data obtained from the transformer maintenance program and NPV analysis, Hydro One considers other factors such as condition, demographics, performance, utilization, criticality and other influencing factors. Distribution transformers are then ranked based on a composite score which is a combination of the factors.

[1] PCBs were used as an additive to transformer oil up until the late 1970's.

Condition

Many factors lead to the degradation over time of a transformer's internal components. These factors include: transformer loading, switching, lightning surges, moisture contamination, and paper insulation degradation. The internal components degrade over time and the resulting asset condition is one of the leading predictive indicators of the transformer's reliability.

Hydro One assesses a distribution transformer's condition primarily on transformer oil test results by applying industry standard diagnostic testing. Annual oil sample test results are obtained for all transformer main tanks and under-load tap-changer compartments. In addition to annual oil sampling, other aspects of transformer condition identified through preventive inspection and maintenance activities include oil leaks, under-load tap-changer operation, PCB content, and bushing condition.

One of the best ways to determine the health of a transformer is by taking a sample amount of oil and testing its physical properties. Transformers with poor dissolved gas analysis test results, poor moisture content test results, and poor furan test results are given a higher priority for replacement. These poor test results identify transformers that are experiencing internal conditions that will eventually result in permanent electrical failure. Proactive replacement of these transformers before they fail avoids lengthy customer interruptions. Leaking transformers are also given a higher priority for replacement because they pose environmental risk and often are uneconomical to repair.

Based on results gathered, approximately 23% of distribution station transformer condition assessments fall into the high risk category. Figure 16 illustrates which component of the transformer is the main contributing factor to the condition of the 280 high risk distribution station transformers.

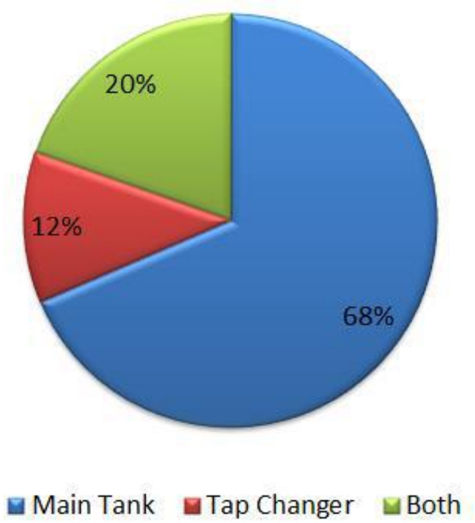

Figure 16 - Reason for Classification of Transformers as High Risk

These units are at a higher risk of failure compared to the transformer population and should be considered for replacement, refurbishment or other remedial action in order to correct significant deterioration or deficiencies. This is required to prevent failures and reduce impacts to Hydro One's distribution customers.

Demographics

The age of the transformer compared to its expected service life is used in 'repair versus replace' decision making. In general, older transformers have a higher probability of failure compared to newer transformers, and therefore older transformers are commonly given a higher priority for replacement. Transformers are not planned for replacement based on age alone. Hydro One monitors the condition of aged distribution transformers through inspections and oil sampling, and plans replacements as needed.

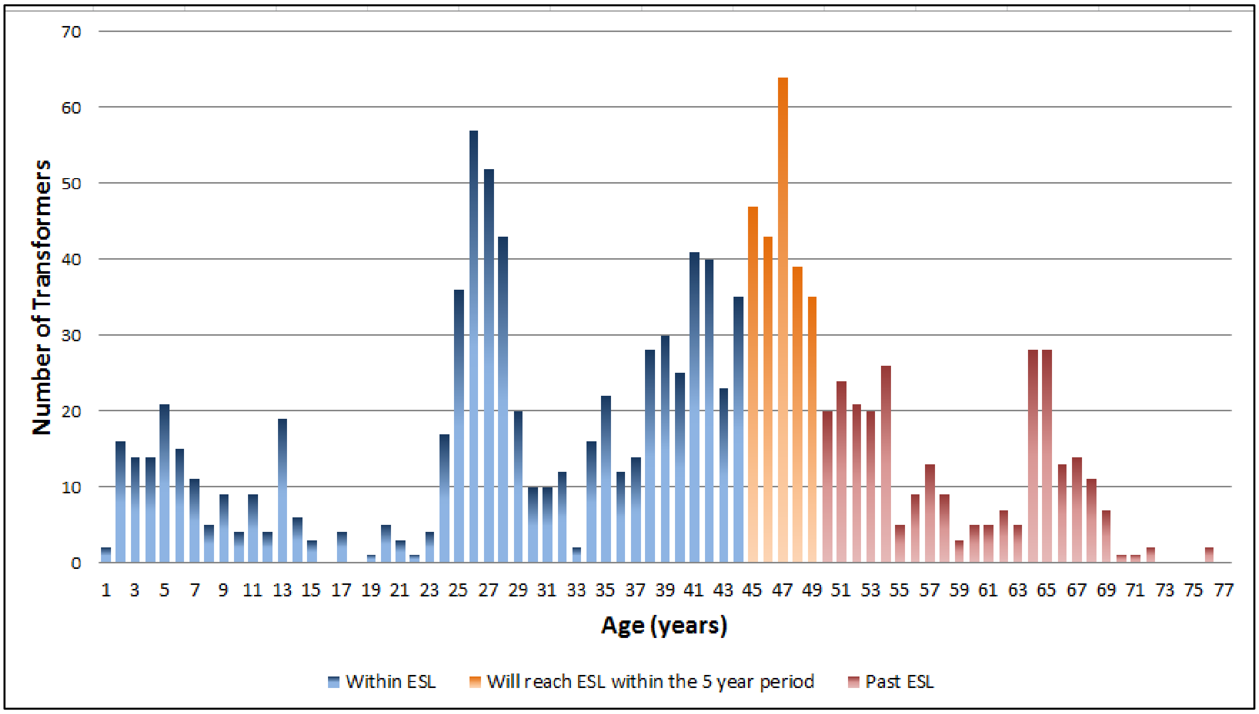

Figure 17 - Demographics of the Distribution Station Transformers

Hydro One utilizes an expected service life of 50 years for its distribution station transformers. The current average age of the transformer fleet is 38 years. Currently 23% of the transformer population is beyond its expected service life, with an additional 19% to reach its expected service life in the next five years. While not all of these transformers require immediate replacement, the long-term management of the high number of transformers reaching expected service life requires increased capital investment. A sustained program targeting a high number of transformer replacements is required to maintain the historical number of transformer failures at a manageable level for customers.

Performance

Distribution station transformer failures are highly impactful. Hydro One's distribution stations typically do not have on-site spare transformers that can be switched into service in the event of a failure, and load cannot be transferred amongst rural stations, which are most often fed from a radial system. In these instances, when a station transformer fails, service restoration requires the installation of a mobile unit substation.

The total number of failures varies from year to year. However, the number of major transformer failures (Class 1) and number of potential major failures avoided by proactively removing transformers from service (Class 2) are shown in Figure 18. Total failures have gone down on the system since 2013.

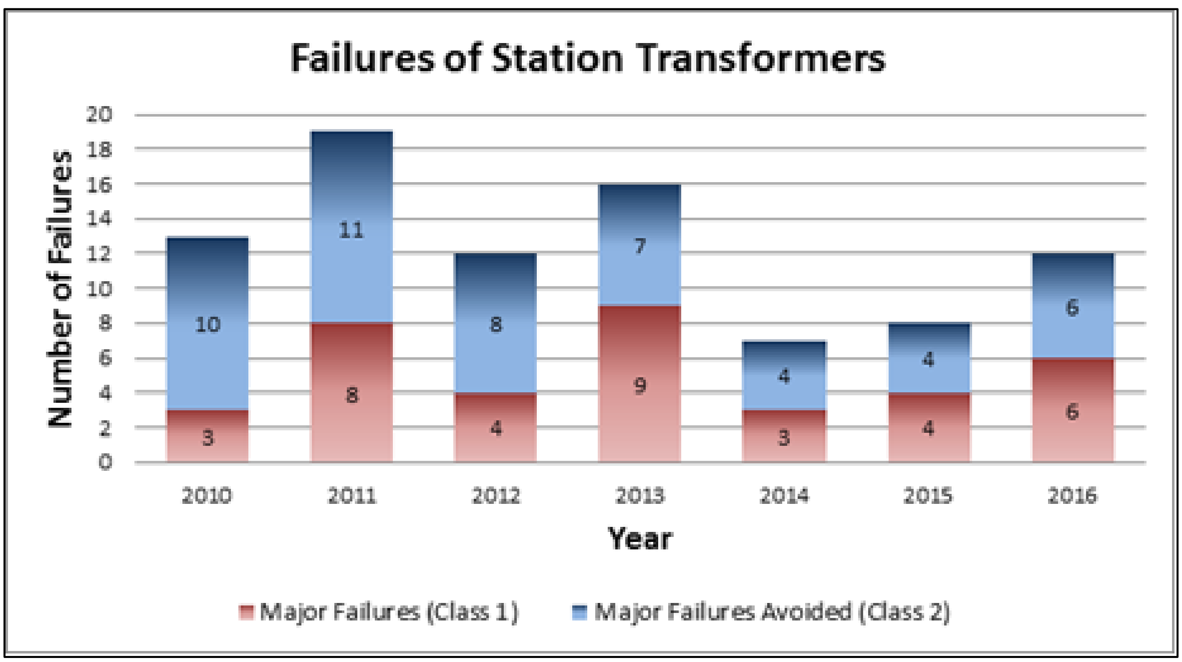

Figure 18 - Failures of Station Transformers

The reason for the decrease in failures in years 2014 and 2015 is the result of an increase in planned replacements of transformers in poor condition. Figure 19 shows a graph of the number of planned and unplanned station transformer replacements from 2010 to 2016. It can be observed that there has been a steady increase in total transformer replacements from 2011 to 2015. Similarly over this period, there has been an overall decrease in transformer failures.

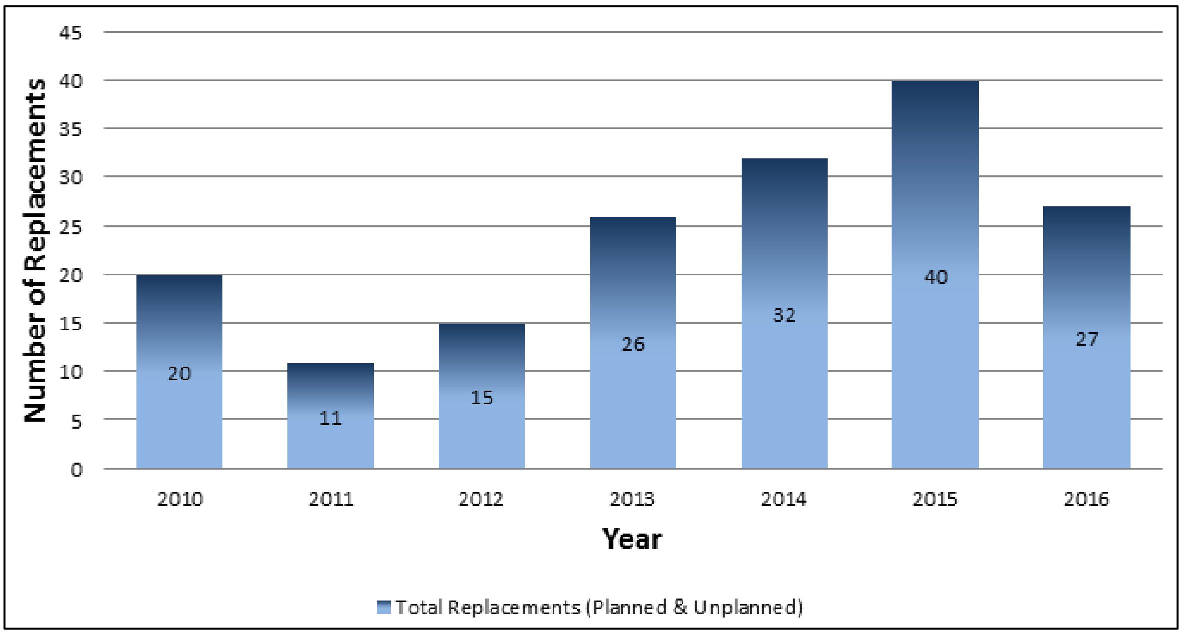

Figure 19 - Number of Transformer Replacements

Utilization

Station transformers that are overloaded, or are more heavily loaded, experience higher winding temperatures which shorten the life of the paper insulation within the transformer. These transformers are given a higher priority for replacement compared to those that are lightly loaded.

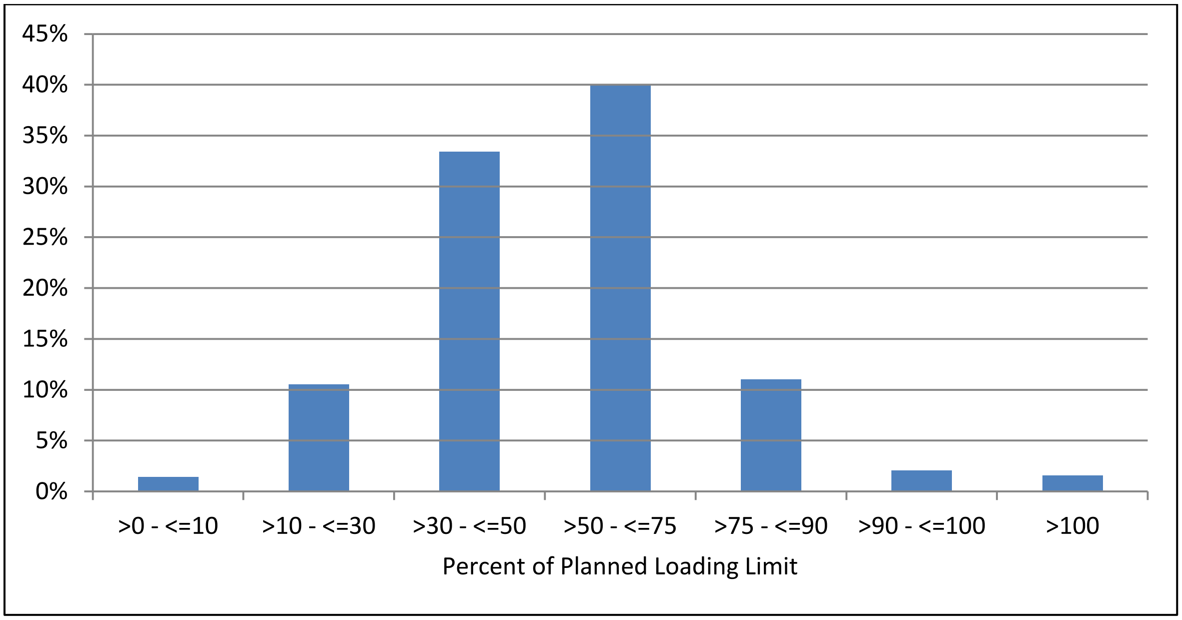

Figure 20 - Station Loading as a Percentage of Total Fleet

Criticality

Transformer replacements are prioritized based on impact on downstream customers and magnitude of downstream load supplied. Higher priority is given to transformers that would impact a higher number of customers and a higher magnitude of load in the event of a failure.

2.3.1.2 STATION RECLOSERS & BREAKERS

Hydro One currently manages approximately 2,263 three-phase equivalent distribution station reclosers and approximately 155 distribution station circuit breakers. Reclosers and breakers are used to remove assets from service under fault conditions. Reclosers are also used to attempt to restore service to customers when faults are temporary or transient in nature.

Hydro One has three main types of reclosers / breakers on its distribution system. The number of devices for each type is shown in Table 38.

To keep pace with manufacturers' change in technology, Hydro One is currently installing new vacuum technology reclosers at its distribution stations.

Figure 21 – Picture of Station Reclosers

Table 38 - Breaker and Recloser by Type

Type	Number of Reclosers	Number of Breakers
Oil	1,758	13
Vacuum	505	4
Metalclad	0	137

The asset strategy for station reclosers is to maintain them based on manufacturer recommended number of operations, and to upgrade them to newer technology reclosers when fault ratings are close to being exceeded, when they demonstrate reliability issues, or when there are opportunities to bundle their replacement under station refurbishment projects. Additional reclosers are planned for upgrade to move towards an advanced distribution system.

Witness: Lyla Garzouzi/Lincoln Frost-Hunt/Rob Berardi

The asset strategy is to perform maintenance on station breakers every 6 years, and replace those that are obsolete, non-arc resistant, or beyond service life, with electronic reclosers under station refurbishment investments.

Preventative Inspection and Maintenance Program

The recloser and breaker maintenance program is primarily triggered based on the number of open and close operations that the device experienced. The annual maintenance budget for reclosers and breakers is based on the known asset population and upcoming maintenance program schedule.

Hydraulically controlled reclosers receive maintenance based on the number of open and close operations that they experience. During station inspections, the number of counter operations is checked and compared with the manufacturer recommended number of operations before required maintenance. Hydraulic reclosers that have exceeded the recommended number of operations are removed from service and replaced with another set of reclosers from inventory. The removed set are then sent to a Hydro One recloser shop for maintenance before being placed into inventory. Hydraulic reclosers are also replaced with units from inventory for other reasons, including observation of cracked or chipped bushing porcelain, corrosion of components, or oil leaks.

Electronically-controlled reclosers equipped with oil interrupters may also be planned for maintenance based on the manufacturer recommended number of operations as well as identification of oil leaks, or identification of hot spots through thermovision inspections. When in need of maintenance work, they are removed from service and receive maintenance at their station location.

Electronically-controlled vacuum interrupter reclosers are the newest technology available. These reclosers have higher fault interrupting ratings compared to hydraulic reclosers and can undergo 10,000 mechanical operations before requiring maintenance or replacement, compared to hydraulic reclosers that are limited to between 58 and 248 operations. Electronically-controlled reclosers equipped with vacuum interrupters are visually inspected and receive thermovision inspections. Hot spots identified through thermovision inspections are addressed by corrective repair. Back-up controller batteries are replaced every five or six years as per OEM instruction.

Most Hydro One distribution station breakers are metalclad air magnetic type breakers. When these breakers are removed from service for maintenance, they undergo the following activities:

- **Diagnostic Test** – The breaker is function tested, manually operated, and undergoes cleaning and lubrication of operating mechanisms; and
- **Selective Intrusive (SI) Inspection** – Inspection of all internal components, insulation condition, contacts and rack-in mechanisms.

Optimization, Prioritization and Scheduling

The upgrade of unserviceable oil reclosers to the newest electronic vacuum recloser technology under capital investments are prioritized as follows:

1. Under station rebuild projects;
2. When the calculated fault levels for the associated feeder are approaching or beyond the fault interrupting rating of the installed recloser;
3. Replacement of electronic reclosers with performance or reliability issues; and
4. Upgrade of hydraulic reclosers with electronically-controlled reclosers to move towards an advanced distribution system.

Most of the metalclad air magnetic breakers on the Hydro One distribution system are approaching or beyond their expected service life. They are technically obsolete (no longer supported by manufacturers for spare parts) and are not arc resistant, which is a safety concern for electrical maintenance staff. As a result, most of these breakers on the distribution system are either planned for replacement with vacuum interrupter, electronically-controlled reclosers under station rebuild projects, or are planned for removal through voltage conversion projects.

Condition

The condition of station recloser and breaker assets is monitored through information gathered during the preventative inspection and maintenance activities. A visual inspection of the reclosers and breakers is completed twice a year to note any defects and to record the number of operations the devices have sustained. The number of recloser and breaker defects Hydro One has noted during inspections is shown in Table 39. Defective reclosers and breakers are addressed either through repair or replacement.

Table 39 - Breaker and Recloser Defects

Year	Number of Recloser Defects	Number of Breaker Defects
2010	431	3
2011	304	9
2012	336	2
2013	323	4
2014	356	9
2015	324	2

Demographics

Hydro One maintains an asset registry of all reclosers and breakers on the Hydro One distribution system.

Reclosers make up the majority of the recloser/breaker asset fleet. The age profile of the 505 station vacuum reclosers in the system range from the early 2000's to present. Station oil filled reclosers in general were purchased prior to the year 2000. Historically, reclosers were removed from service and replaced with overhauled units every six years. Hydro One has adopted a more targeted approach to trigger when reclosers need to be replaced with overhauled units. The number of operations (i.e., fault interruptions) that a recloser performs triggers a recloser replacement with an overhauled unit. The number of operations that trigger a recloser replacement is dependent on the make, model and type of the unit, as explained above. As a result of the utilization based approach, recloser age-based demographic information is no longer relevant in recloser OM&A sustainment planning process.

Breakers comprise a small percentage of the overall breaker/recloser population. These breakers were mainly added to the fleet through Hydro One's acquisition of Local Distribution Companies. Distribution breakers have an expected service life of 50 years. Breakers are replaced if they are obsolete, non-arc resistant, or beyond their expected service life.

Other Influencing Factors

Most metal clad breakers on the Hydro One distribution system are obsolete and replacement parts are not available. These breakers are no longer supported by the manufacturer. As such, when one breaker in a bank of metalclad breakers fails and is not repairable, the entire bank of metalclad breakers must be replaced.

Some of the metalclad breakers were designed in small buildings, which do not meet Hydro One clearance requirements. Hydro One mitigates this risk with safe work practices, removing the breaker from service before the execution of work. Since service interruptions are impactful to customers, this too is considered in the prioritization of upgrades.

2.3.1.3 STATION SWITCHES & FUSES

Hydro One currently manages approximately 2,525 three-phase switches and 1,850 three-phase fuses installed at distribution stations.

Station switches provide a means of isolating pieces of equipment such as transformers, breakers or reclosers so that maintenance work can be performed on them, or for the purpose of isolation for other reasons.

Figure 22 – Picture of Station Switch and Fuse Combination

Station fuses provide a means to protect transformers in stations when a fault occurs. Station fuses also provide a means to by-pass station reclosers; although not all distribution station reclosers are equipped with by-pass fuses. Distribution stations which do not have feeder breakers or feeder reclosers are equipped with fuses to provide a means of protection for the feeder.

The asset strategy is to visually inspect station switches and fuses during routine station inspections and to bundle their preventive maintenance with transformer and regulator maintenance to minimize the number of planned outages. As discussed in Section 2.3.1.1, station transformers and regulators receive maintenance based on unsatisfactory main tank or tap-changer oil sample results, and under-load tap changers have a default 12 year maintenance cycle. Defective fuses are replaced. Defective switches are replaced if not repairable.

Table 40 - Switches and Fuses by Voltage

Primary Voltage Level	Number of Switches	Number of Fuses
230 kV	2	1
115 kV	150	103
44 kV	870	759
27.6 kV	503	225
< 27.6 kV	999	760

Preventative Inspection and Maintenance Program

Switch and fuse inspection costs are embedded in the Station Visual Inspection (“SVI”) unit price, which is reviewed and adjusted annually as required. Switch and fuse maintenance is triggered based on SAP maintenance plans, which have associated frequencies, tasks and unit price. The unit prices are reviewed annually and adjusted as required based on historical expenditure. The annual switch and fuse inspection and maintenance budgets are based on the known asset population of switches and fuses, and upcoming maintenance schedule based on SAP maintenance plans.

The switch and fuse maintenance program is bundled with transformer maintenance in order to reduce the number of planned outages, and to keep switch and fuse maintenance unit costs to a minimum. When stations are removed from service for transformer maintenance, the switches and fuses are tested, current carrying parts are inspected, and hinges are cleaned and lubricated.

Optimization, Prioritization and Scheduling

Station fuses which fail testing are replaced. Transformer or recloser replacements may also trigger the need to replace fuses with those of different continuous current rating and interrupting speed in order to allow for proper protection coordination. Fuses at stations, which act as feeder protection in the absence of reclosers or breakers, are planned for replacement with vacuum electronic reclosers for improved reliability by allowing transient faults to clear and not cause a sustained outage, which likely would be the case with a fuse.

Station switches that fail to operate and are not repairable are replaced. Under station rebuild projects, switches will be planned for replacement based on their condition.

Condition

The condition of the switch and fuse assets are determined during regular station maintenance program activities. A visual inspection of switch and fuse assets are completed twice a year to note any defects. Switches and fuses that fail testing or are found to be in substandard condition are replaced.

Table 41 - Switch and Fuse Defects

Year	Number of Switch Defects	Number of Fuse Defects
2012	118	139
2013	81	135
2014	98	94
2015	110	185

Some of the main failure modes of switches include: seized bearings or load interrupters, and failure of porcelain insulators. Fuses located on the switch/fuse assembly are prone to falling due to hairline cracks in porcelain support insulators. The number of switch and fuse defects Hydro One has noted during inspections are shown in Table 41.

2.3.1.4 MOBILE UNIT SUBSTATIONS

Hydro One currently has a fleet of 30 mobile unit substations ("MUSs"). The MUSs have similar components to a distribution station, however the components are mounted on a trailer. The MUS fleet is utilized for:

- Emergency power restoration in the event of a transformer or other station component failure;
- Carrying the station load during maintenance and capital activities; and
- Load relief for distribution stations, as required.

Figure 23 – Picture of Mobile Unit Substation

Hydro One's asset strategy is to address the aging demographics and deteriorating condition of its MUS fleet by purchasing new MUSs to replace those in need of replacement. The MUS asset strategy also involves expanding the MUS fleet to address a shortfall in MUSs required to support the distribution system and proposed work programs. The appropriate size of MUS fleet is determined based on having MUSs which can be deployed to stations to support failures and restore customers within eight to twelve hours, and to have sufficient MUSs to allow for the completion of planned and unplanned capital and maintenance work. Six MUSs are planned for replacement and three new MUSs will be procured to expand the fleet over the five year period.

The ISD containing details on the investment in new MUS units is SR-02.

Preventative Inspection and Maintenance Program

Because the MUSs are such a critical component of the distribution system (relied upon for emergency restoration, capital projects and maintenance work) each MUS receives an annual inspection and full maintenance of all electrical components each year. The maintenance activities for the MUS transformers, switches, fuses, reclosers and other electrical components are the same as for those installed in stations, other than the higher (annual) frequency. MUS annual maintenance for each unit takes two weeks to complete. When MUSs are deployed for maintenance or capital work, commissioning checks are performed on the MUS trailer and electrical equipment to ensure safe operation and supply voltage with CSA standards.

When MUSs are deployed for emergency restoration, they are typically deployed to stations, installed, and connected within eight to twelve hours, restoring the interrupted load. Depending on the magnitude of work required to repair or replace the failed equipment, the MUS installation time can range from a few days to a year. The replacements of failed insulators, surge arresters or fuses are examples of emergent work where an MUS would be installed for a few days. MUS deployments for failed transformer replacements can take up to a year if the replacements require adjacent land to be procured.

MUS trailers receive a mandated annual inspection. They require an Ontario Ministry of Transportation ("MTO") annual inspection certificate.

Demographics

The MUSs are assessed by focusing on two key components, the transformer and the trailer. The age distribution for these two components of the MUSs is shown in Figures 24 and 25.

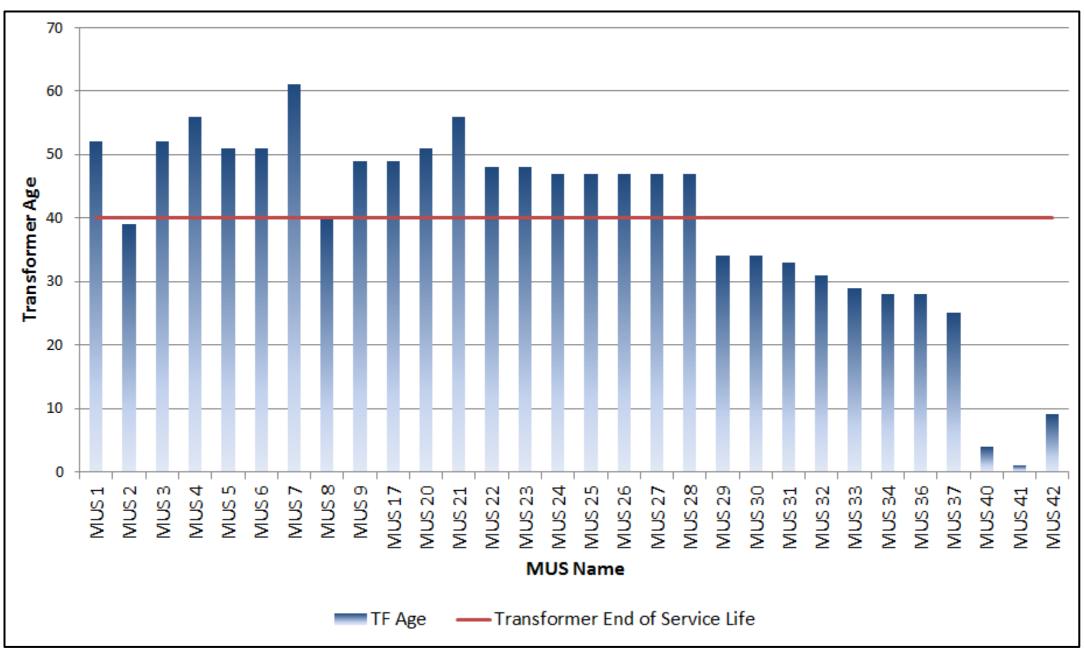

Figure 24 - Demographics of the Mobile Unit Substation Transformers

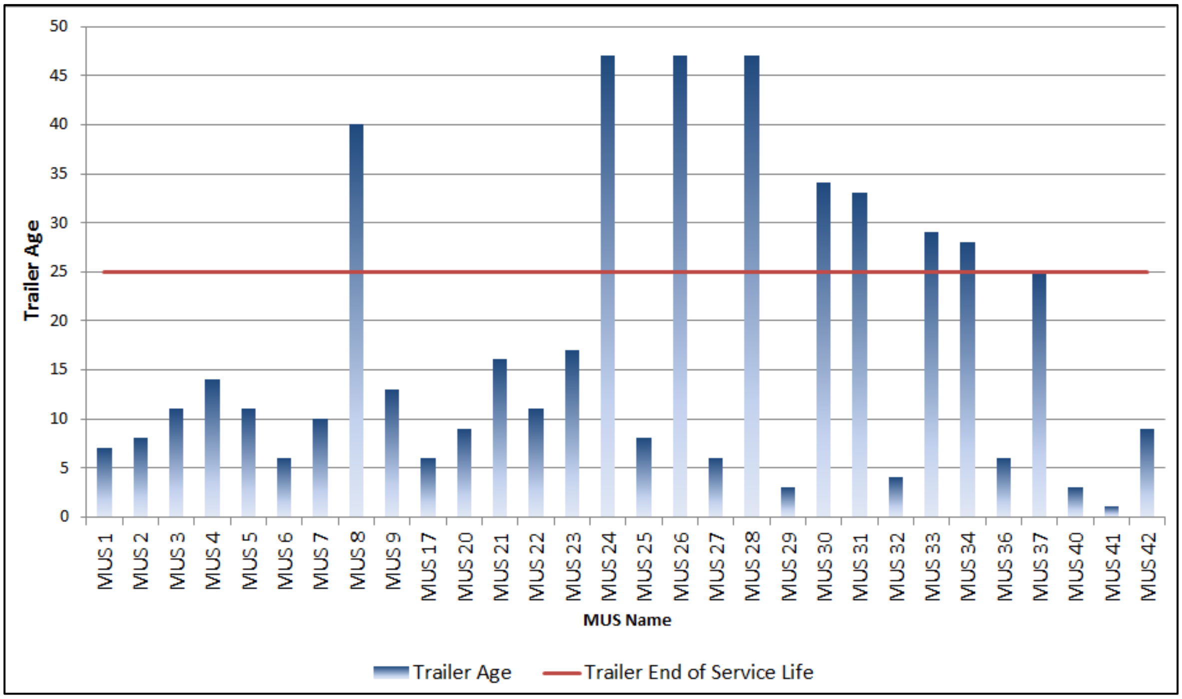

Figure 25 - Demographics of the Mobile Unit Substation Trailers

Hydro One utilizes an expected service life of 40 years for its MUS transformers and 25 years for the MUS trailers. The average age of the MUS transformers is 40 years. Currently, 60% of the MUSs transformers are beyond their expected service life. The average age of the MUS trailers is 17 years. Currently 30% of the MUS trailers are at or beyond their expected service life.

Condition

The condition of the trailer is inspected as required by the Ministry of Transportation and the electrical equipment is inspected in detail on an annual basis. Inspection and maintenance of the MUS electrical equipment (such as, the transformer, reclosers and switches) are identical to that of a distribution station but more frequent as these assets are relied upon during emergency situations. Any significant defects are logged and immediate plans are made to correct them.

Table 42 - MUS Defects

Year	Transformer Defects	Trailer Defects	Switchgear Defects	Cable Defects	Total MUS Defects
2012	8	5	11	5	**29**
2013	7	3	12	7	**29**
2014	18	9	16	10	**53**
2015	17	5	13	8	**43**
2016	14	9	12	16	**51**

Failure modes and condition defects of MUSs include the typical defects that station transformers, switches, fuses and reclosers experience. Additional defects that MUSs can experience compared to that of a station can include trailer rust, and damage to MUS feeder connection cables. The number of MUS defects that Hydro One has noted is shown in Table 42.

Currently, 40% of the MUS transformers and 30% of the MUS trailers fall into the high risk category. Overall, 43% of the MUS fleet is categorized as high risk.

2.3.1.5 OTHER STATION ASSETS

In addition to the assets previously mentioned, Hydro One distribution stations also typically have station structures, fences and gates, grounding systems, station service transformers, insulators and bus. Stations equipped with breakers or vacuum electronic reclosers also have protection relays or intelligent electronic devices (IEDs). Stations identified as having high environmental risk are equipped with spill containment systems.

Station Structures are used in stations for mounting electrical components such as switches, fuses, reclosers, station service transformers, bus, and IEDs. Some station structures are wooden, though most are made of steel. The earliest station structures in Hydro One stations were built in the 1920's.

Fences are used to separate live station equipment from the public to maintain public safety, while *gates* are used as an entry point for Hydro One maintenance vehicles, construction vehicles and staff. Most station fences are chain link, though some are wooden.

Grounding Systems are used in stations to safely dissipate fault currents into the ground in the event of equipment failure, to protect Hydro One employees and the public.

Station Service Transformers are used to transform distribution system voltages to 120 V to supply station equipment such as IEDs and receptacles.

Insulators provide electrical insulation between live equipment and grounded station structures. They are also used to mount the power equipment to the station structures.

Bus work in stations is used to electrically connect the power equipment within the station.

Protection Relays in stations are used to trip feeder breakers in the event of a system fault.

IEDs are used to control electronic vacuum reclosers, directing the reclosers when to open and close during system faults.

Spill Containment Systems are present in stations that have a high spill risk. These spill containment systems contain transformer oil in the event of a transformer tank rupture.

Table 43 - Other Distribution Station Components

Station Component	Units
Station Structures	2,172
Fences[1]	1,005
Station Grounding Systems[1]	1,005
Station Service Transformers	820
Insulators	NA
Bus Work	1,316
Protection Relays[2]	154
IEDs	236
Spill containment systems	88
MUS Structures	788

1. Assumed to match the number of stations
2. Assumed to match the number of breakers

Preventative Inspection and Maintenance Program

These additional station assets are generally inspected for defects during routine station visual inspections. The live electrical components will also undergo a thermovision inspection. If any defects are identified, they are addressed as corrective maintenance work where practical.

Optimization, Prioritization and Scheduling

The strategy for these station components is to visually inspect them for defects, and address the defects when they are identified. If they are broken and cannot be repaired, then they are replaced.

2.3.2 (5.3.3 A, B) KEY COMPONENT SUMMARIES – DISTRIBUTION LINES

The Distribution Lines Maintenance program encompasses all the pole, wire and transformer assets for both M-class and F-class feeders. The purpose of this program is to ensure that the distribution lines are safe and will continue to deliver reliable power to the load and generation customers.

Distribution lines are inspected on a six-year cycle for rural areas and a three-year cycle for urban areas as required by the DSC, Appendix C – Minimum Inspection Requirements. Approximately 350,000 locations are planned for inspection per year. SAP is used to plan these inspections and schedule the feeders and release the work on the applicable cycle. During these inspections, information about the condition and demographics of specific assets is collected.[2] This information informs our maintenance programs and capital renewal projects and programs.

Often, lines are located off-road. Off-road sections of feeders are difficult to access during power interruptions resulting in increased risk of prolonged outages and public safety concerns. When inspections identify significant concerns with the condition of an off-road line, including wood poles, crossarms, and insulators, this poses an elevated risk to reliability and public safety. The most cost-effective option to address these risks is often to rebuild entire feeders or feeder sections to current standards on a nearby road allowance, funded by the Distribution Lines Sustainment Initiatives, ISD SR-12.

[2] Secondary Service Lines are not actively maintained and the assets included in this category are addressed on a Break/Fix basis. Detailed demographic and condition data on Secondary Service Lines is not available.

The main components maintained in the Distribution Lines Management program include:

- Poles;
- Rights of Way;
- Line Transformers;
- Submarine Cables; and
- Other Distribution Line Components.

2.3.2.1 POLES

Poles comprise the single largest component of Hydro One's lines asset base. Poles keep conductor and line equipment at a safe distance from the ground and other objects. Hydro One utilizes poles made from wood, concrete, steel and composite material based on specific situations. However, as shown in Table 44, wood poles make up the vast majority of the pole fleet.

Table 44 – Number and Age by Pole Material

Material	Number of Poles	Average Age
Wood	1,597,000	39.7
Steel	6,000	19.6
Concrete	2,000	29.2
Composite	2,000	6.9

Hydro One's asset strategy for the management of distribution poles centres on condition information collected through the line patrol program. Once a pole has been assessed to be in poor condition it is planned for replacement.

Witness: Lyla Garzouzi/Lincoln Frost-Hunt/Rob Berardi

Preventative Inspection and Maintenance Program

Typical pole inspections begin with a visual assessment of the pole's current condition. Items the inspector would identify are the severity of woodpecker damage, mechanical damage, and insect damage. The inspector would also determine if the pole is severely leaning and report on the amount of surface decay.

The inspector will also perform a hammer test on every pole inspected to ensure the soundness of the pole. In some situations the pole may be bored to measure the remaining shell thickness. All of this condition data is used for prioritizing pole replacements.

During the inspections other defects associated with the line are collected at the pole level such as a broken guy wire. These issues are corrected as part of the defect correction program unless there are capital replacement plans for the pole.

All data collected during these inspections is recorded in SAP and is used for planning replacements and defect corrections. During the data collection, the inspector will confirm all characteristic data about the pole is correct and up to date.

Optimization, Prioritization and Scheduling

Hydro One's asset strategy for the management of distribution poles centres on their condition and the forecast condition using demographics of the population. The condition information is used in the selection and prioritization of specific poles to be replaced annually, whereas the demographic profile enables the projection of long term pole replacement rates. Hydro One endeavours to replace poles before they fail, pose a safety hazard, or cause a service interruption. Where possible, these replacements are made in conjunction with other planned work on the distribution system to increase efficiency and minimize the number of planned outages.

Condition

The condition of the poles, as determined by distribution line patrols, impacts pole replacement, line refurbishment and defect correction investment plans. The condition of wood poles deteriorates over time due to decay and rot, insect and rodent damage, mechanical impact, or other factors that reduce the structural integrity of the pole. The number and type of pole related defects on the distribution system are illustrated in Figure 26. Depending on the severity of the damage the pole may be prioritized for replacement.

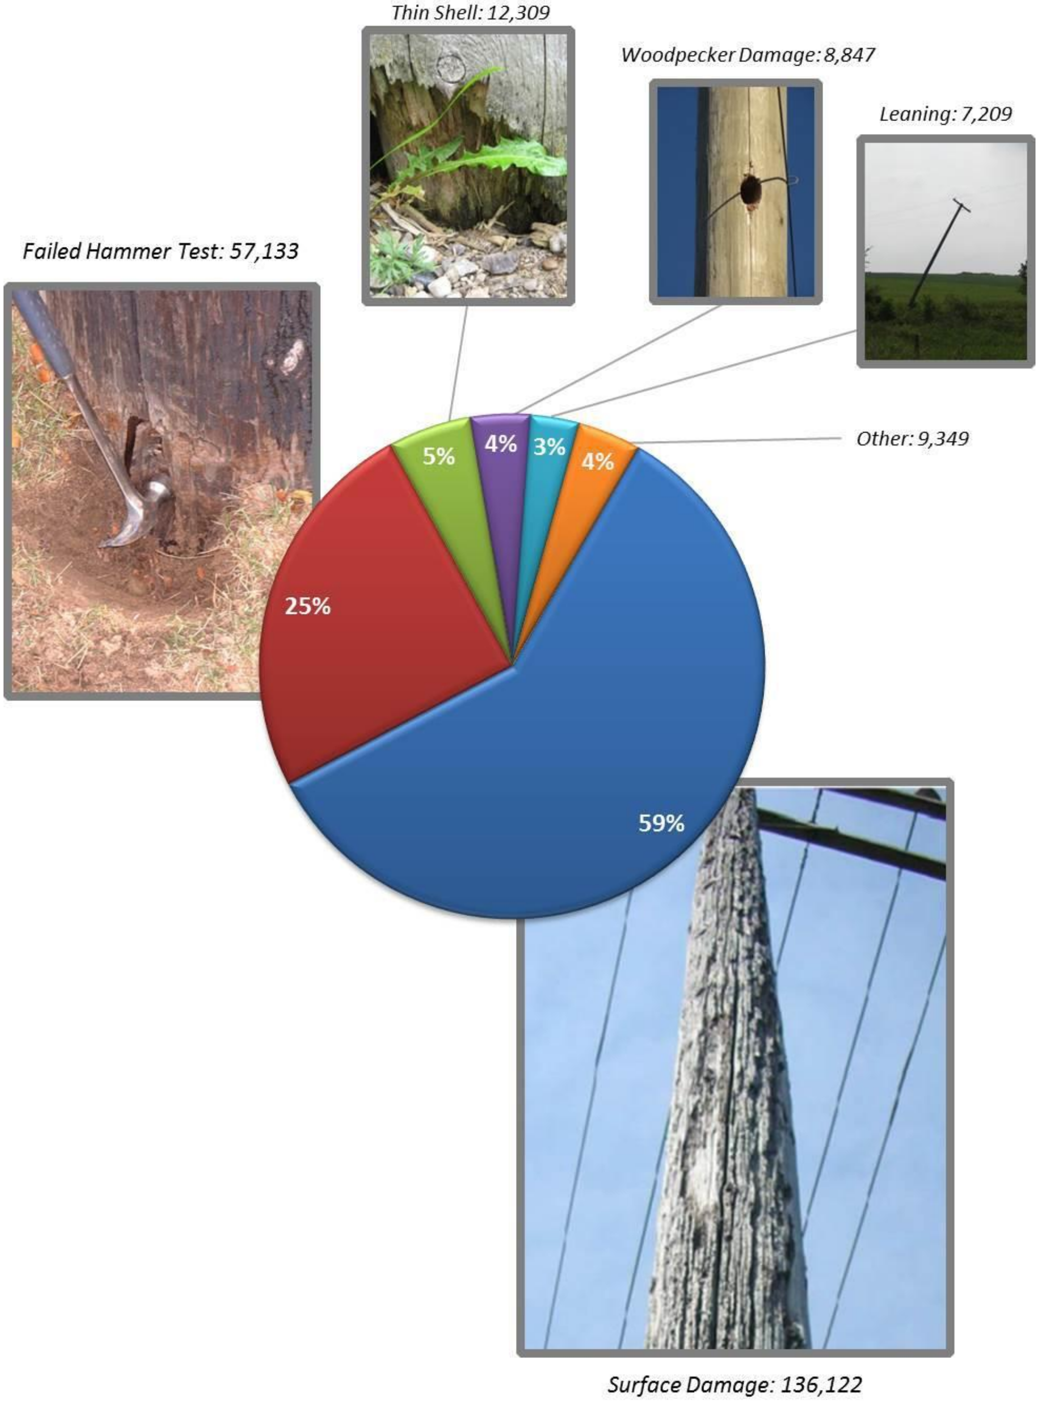

Figure 26 - Pole Defects

Note: Poles in poor condition may have multiple defects and some defects are not severe enough to cause a pole to be classified as poor condition.

Witness: Lyla Garzouzi/Lincoln Frost-Hunt/Rob Berardi

Where other needs are identified, they can be included in large sustainment or development projects and addressed in conjunction with other planned work.

Figure 27 summarizes the current condition of Hydro One's poles based on the results gathered. Poles in poor condition currently require replacement in the next five years. Poles in fair condition have some defects but do not require replacement. Poles in good condition passed their last inspection with no defects recorded.

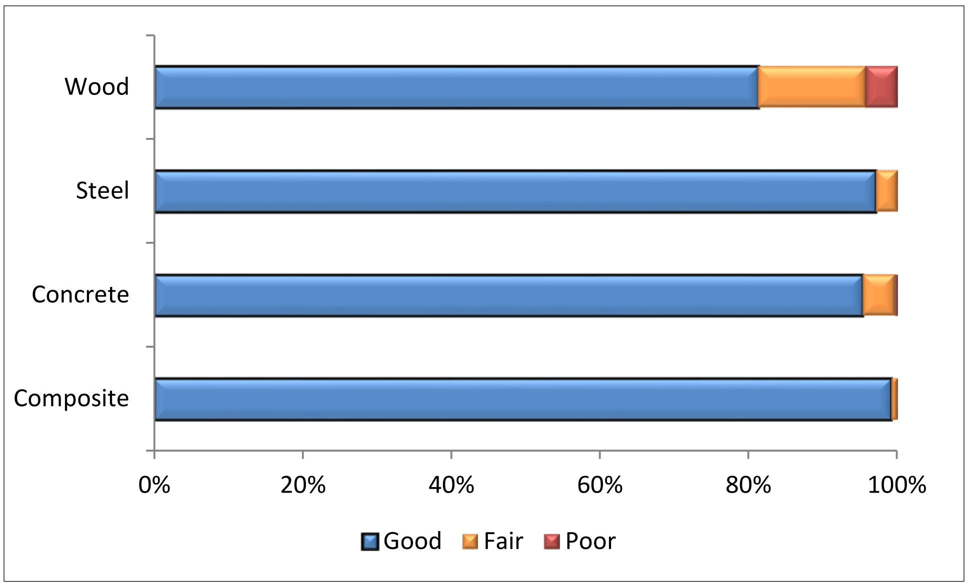

Figure 27 - Pole Condition by Material

Figure 28 details the total poles that are categorized as being in poor and fair condition. The total volume of Red Pine wood poles requiring replacement due to premature degradation is also included.

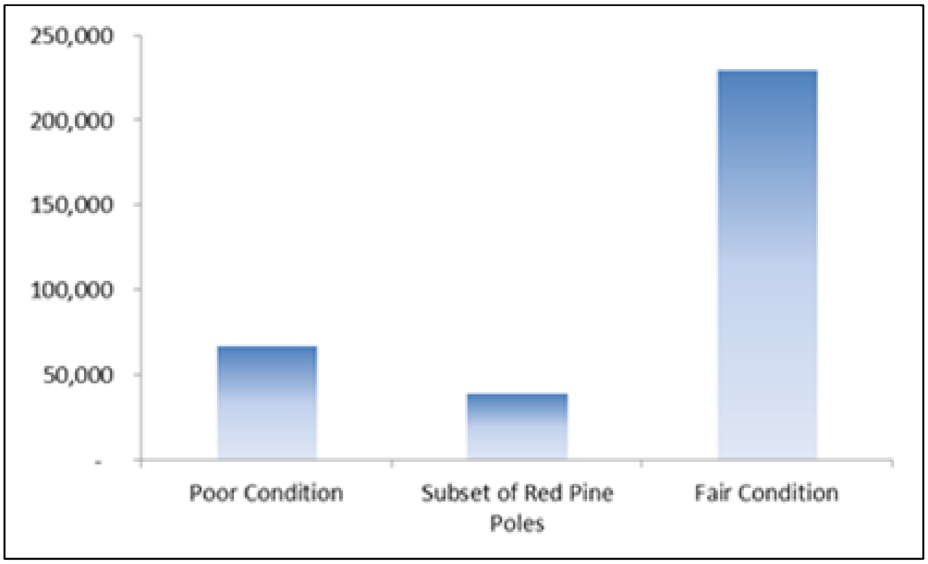

Figure 28 - Poles in Poor or Fair Condition

Demographics

Analysis of wood pole failures has indicated that the expected life of a wood pole is approximately 62 years. Based on the current demographics of the Hydro One wood pole population, 280,000 poles are at least 62 years old, with an additional 120,000 poles reaching 62 over the next five years. To ensure a long-term sustainable pole replacement program, the number of poles being replaced is proposed to increase over historical levels. The age distribution of wood poles owned by Hydro One is shown in Figure 29.

There are currently 37,000 poles with no age information available. This data will be updated over time as the distribution line patrol program inspects poles on a six or three-year cycle. Some of the data will remain unknown because the manufacturer information becomes illegible as a pole ages.

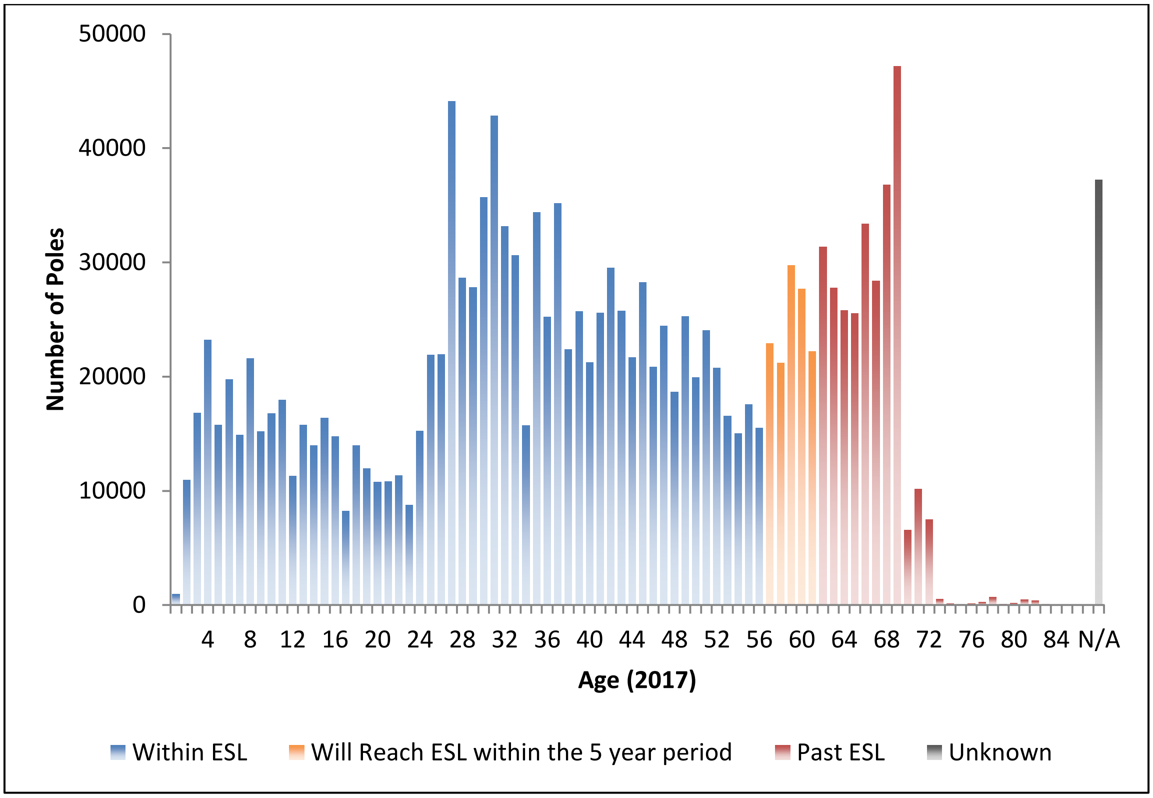

Figure 29 - Wood Pole Demographics

Performance

Another driver of wood pole replacement work is the impact pole failures have on reliability. When poles fail, they are highly impactful and typically require an emergency pole replacement to restore service. These unplanned repairs are more difficult, take longer and are more costly than a planned pole replacement. The average duration of an unplanned outage involving a pole replacement is about nine hours. The average duration of a planned outage involving a pole replacement is about 2 hours. The improvement in outage duration for planned replacements, combined with the benefits of scheduling and notifying customers of work before it is done, drives Hydro One to replace end-of-life poles on a planned basis.

Criticality

Poles are prioritized based on their impact on downstream customers and their potential safety risks. Factors such as number of downstream customers, downstream load, and joint use attachments are considered when determining criticality. These factors are used to give higher priority to poles that have a potentially higher impact on reliability and safety.

Other Influencing Factors

Hydro One continues to address a subset of Red Pine wood poles that are experiencing premature degradation. These poles have a considerably shorter expected service life, and require replacement on a priority basis. Further details on the Red Pine pole issue can be found in proceedings EB-2012-0136 and EB-2009-0096.

2.3.2.2 RIGHTS OF WAY

Hydro One's distribution system is comprised of approximately 112,000 km of right-of-way. Hydro One's rights-of-way are adjacent to approximately 7 million trees, which are the most prevalent cause of distribution power outages. The vegetation management program is the largest budget within operations and maintenance. The program is designed and executed to facilitate the safe and reliable distribution of power to Hydro One customers.

The asset strategy for the management of rights-of-way is to regain control of backlogged maintenance and shorten the average maintenance cycle in order to improve asset condition, asset performance and program costs. This will be accomplished by classifying the right-of-way assets into two groups based on their impact on customers. The first group will be managed in the cycle clearing program, which manages high impact rights-of-way on their optimum cycle length. The second group will be managed in the tactical maintenance program which is focused on the lower impact rights-of-way managed using a risk based approach that considers reliability, asset condition, asset age and feedback from our customers and within the organization. More detailed information on the vegetation management programs can be found in Exhibit C1, Section 1 Tab 2.

Preventative Inspection and Maintenance Program

Right-of-way assets are acquired through capital expansion of the distribution network. Once in service, rights-of-way are managed through the sustaining OM&A budget. Asset maintenance is accomplished through planned and demand investments.

Condition

Right-of-way condition data is collected during the distribution line patrol and is used to prioritize planned and demand vegetation management programs. The condition of a right-of-way deteriorates over time as vegetation grows and the health of over-mature trees adjacent to the right-of-way gradually declines. The number and type of vegetation related defects on the distribution system are illustrated in Figure 30.

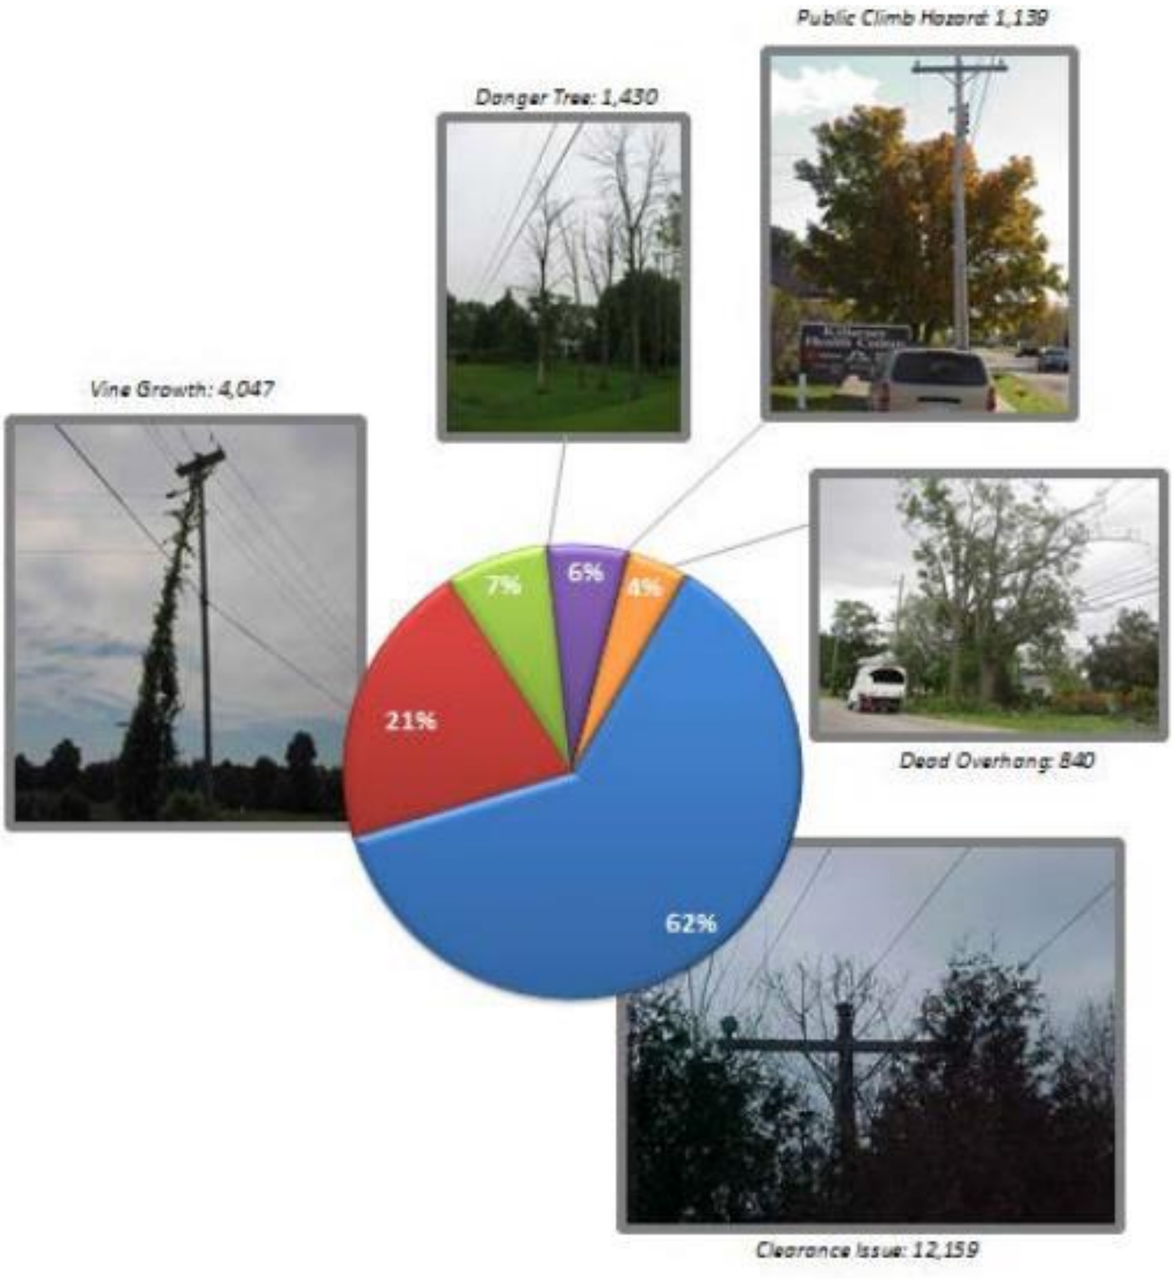

Figure 30 - Vegetation Defects

Demographics

"Asset age" for rights-of-way is a reflection of the number of years since the last planned vegetation management treatment. Asset age and maintenance cycles are important concepts in vegetation management because asset performance tends to deteriorate as vegetation grows. For example, if a tree ages and becomes unstable to the point of falling or if a vine grows and overruns a pole, these are issues where the asset requires protection from the growing vegetation surrounding it. An effective vegetation management program is able to invest in maintenance at the most cost effective time and mitigate sharp increases in vegetation-caused issues on the power system.

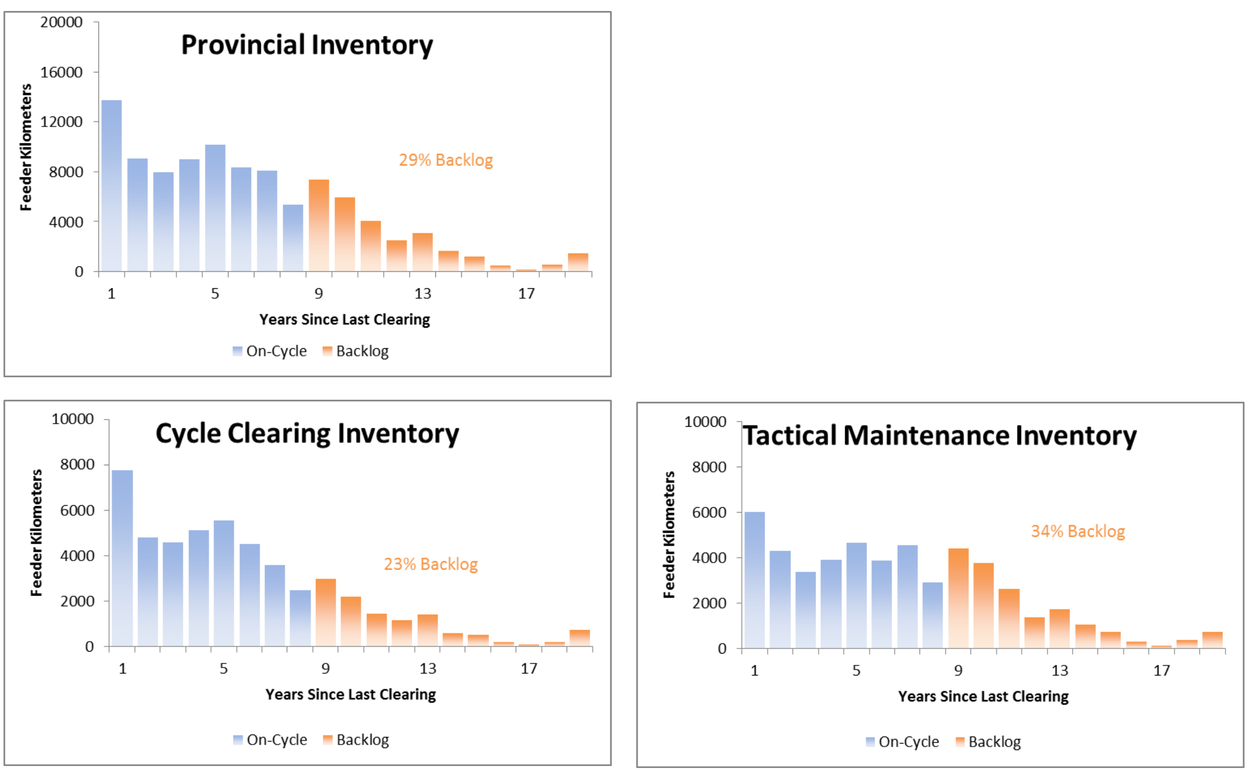

Figure 31 - ROW Vegetation Demographics

Within Hydro One's right-of-way inventory, optimal maintenance cycles vary between four and eight years depending on the feeder specific vegetation conditions and management considerations. The majority of the Province is managed on a six-year cycle which is consistent with the peer average reported in the vegetation benchmarking study summarized in Section 1.6. In Northern Ontario, where the growing season is shorter, cycles are eight years. In select areas of Southern and Eastern Ontario, vegetation growing conditions require a shorter cycle and those areas have been assigned a four-year cycle. Provincially, 29% of Hydro One's right-of-way assets have not been cleared in over eight years (backlog) and the Provincial average right-of-way age is 6.2 years.

Hydro One's strategy for reducing the Provincial backlog is to classify the right-of-way inventory based on impact to customers and to phase in appropriate cycles on the most impactful assets first. The cycle clearing program manages the assets that have the largest impacts on Hydro One's customers and eliminating backlog in this inventory is a primary objective for the 2018 – 2022 planning period. Presently, the assets managed within the cycle clearing program have a backlog of 23% and an average age of 5.7 years.

The tactical vegetation maintenance program manages the lower impact assets in the distribution network (single and two phase lines). Instead of being managed on a cycle, the tactical program is managed using a risk-based approach that considers reliability, asset condition, asset age and feedback from customers and within the organization. Presently the assets managed in the tactical maintenance program have a backlog of 34% and an average age of 6.7 years. Improvements in age demographics (years since last cleared) within the tactical maintenance program will be sought once the assets in the Cycle Clearing inventory have been optimized.

Performance

One driver for continuing to pursue a stable clearing cycle is improving system reliability for Hydro One customers. Annually, vegetation-caused outages account for approximately 16% of non-force majeure distribution outages and those outages contribute to an average of 27% of the annual corporate SAIDI score. The most common root cause of tree caused power outages (see Figure 32) are whole tree failures originating from outside the cleared right-of-way. These are considered hazard trees by the nature of their condition and proximity to lines. Preventing tree fall outages is accomplished through tree removals in the planned and unplanned programs. The newly initiated tree outage investigation process, which is a result of the peer benchmarking exercise, will result in additional insight into hazard tree failures that will be used to improve Hydro One's vegetation maintenance practices.

Table 45 - Total SAIDI and Vegetation Contribution

	All Interruptions (hours)			Force Majeure Events (hours)		
Year	**Total**	**Tree Contribution**	**Tree %**	**Total**	**Tree Contribution**	**Tree %**
2013	27.3	14.6	53%	20.0	12.7	64%
2014	9.9	3.4	34%	2.0	1.3	65%
2015	12.9	5.5	43%	4.6	3.3	72%
Total	**50.1**	**23.5**	**47%**	**26.6**	**17.3**	**65%**

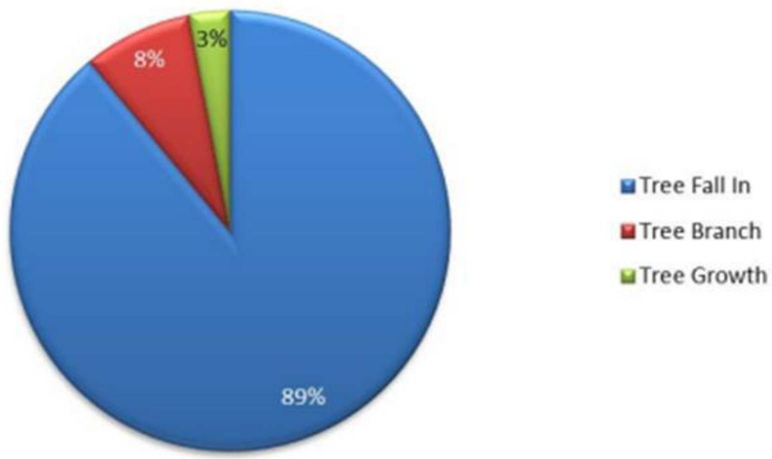

Figure 32 - Root Cause of Vegetation Outages

Criticality

Criticality for rights-of-way is a reflection of the assets housed within the right-of-way and the consequences of tree failure on those assets. Asset criticality has been addressed in the vegetation management program through identifying and managing high impact assets within the cycle clearing program.

2.3.2.3 LINE TRANSFORMERS

Distribution Line Transformers are used to convert electricity from primary distribution voltage levels (e.g., 44kV, 27.6 kV, 14.4 kV, or 8 kV) to secondary voltage levels (e.g., 600 V or 220/110V) so the power can be utilized by residential and small business customers.

Depending on the proximity of adjacent customers, each single-phase pole top or pad mounted transformer may supply one or several customers at 240/120 volts. A three-phase pole top or pad mounted transformer generally supplies a single customer at 600/347 volts or 208/120 volts.

Figure 33 – Picture of Pole-Top Line Transformer

Hydro One maintains a total fleet of approximately 500,000 transformers in overhead (pole mounted) or underground (pad mount or submersible) configurations.

Table 46 - Line Transformer Type

Transformer Type	Quantity
Pole-mounted Transformer	445,500
Pad-Mount Transformers	53,250
Submersible Transformers	121
Transclosures and Pole-Trans Transformer	800

Hydro One's asset strategy for distribution line transformers is to replace units upon failure. The exception is PCB contaminated transformers which are being replaced as part of the PCB removal program over the period of 2017-2023.

Preventative Inspection and Maintenance Program

Historically, the asset data collected for line transformers did not include the manufactured date and, as a result, Hydro One does not possess age data for most of its fleet of line transformers. With this component being a "run to failure" asset, there was no requirement for cataloguing the age information. However, with the introduction of the 2009 Environment Canada legislation, requiring the removal of equipment with a PCB concentration of greater than 50 ppm, the policy of "run to failure" is being modified to address the retirement of PCB contaminated assets in an organized manner. Hydro One has an ongoing initiative to correct and update the lack of data in SAP over time. The immediate need and driver for the collection of this information is the PCB legislation requirements. The methodology for addressing this need is outlined below.

Based on oil sampling results, PCBs in concentrations greater than 50 ppm have been found in distribution line transformers manufactured as late as 1984. Because manufacturer's dates were not readily available to determine the line transformer population demographics, transformer ages were recorded starting with the 2011 Line Patrol data collection program. As outlined in Figure 34, based on the sample population compiled, approximately 53% of line transformers were manufactured before 1985 or have a date of manufacture that is unknown.

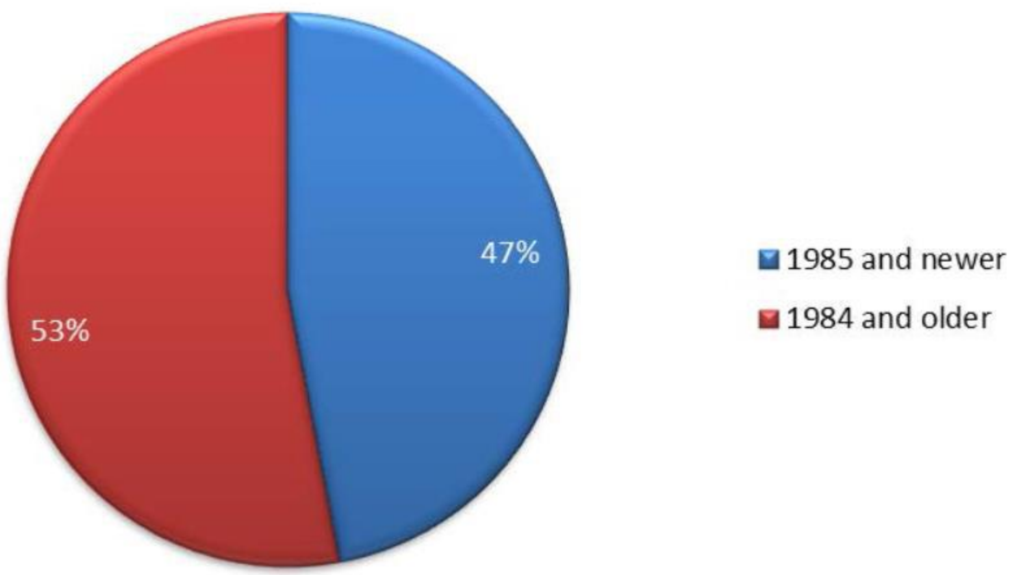

Figure 34 - Line Transformer Age Distribution

Each of the transformers in 1984 or older category will require oil sampling and PCB analysis. During the years 1997 to 2003, Hydro One conducted a Due-Diligence PCB inspection program, involving approximately 87,000 transformers. At that time, the Environment Canada legislation was foreseen, but not yet finalized. Based on past experience with PCB testing, transformers up to 1984 were found to contain PCBs greater than 50ppm. It is this threshold that is being used in the current PCB Inspection and Testing Program. Hydro One predicts that approximately 8% of tested transformers will exceed the 50 ppm threshold and will ultimately require replacement due to PCB contamination.

The OM&A Transformer Inspection and Testing Program commenced in 2009 with the completion of the underground assets – the pad mounted transformer population of 53,250. In 2014, the Overhead Pole Mounted Equipment Inspection and Testing Program started with a pilot program of 5,000 locations. In 2015, inspection and testing expanded to 13,000 locations. In 2016, the full program was rolled out at 30,000 locations per year going forward to completion. The inspection and testing program visits each overhead transformer location, verifies the transformer age and collects an oil sample for any transformer manufactured prior to 1985. Oil samples are analyzed by a third party laboratory and any transformer with PCB content greater than 50 ppm is scheduled for planned replacement.

Optimization, Prioritization and Scheduling

The OM&A Distribution Line Patrol program breaks the province down into six sectors, with one sector being patrolled each year to comply with the DSC requirements. The line patrol program collects distribution system data, including, where possible, the overhead transformer nameplate information. Beginning In 2017, in an attempt to optimize the data collection initiatives, the Overhead Equipment Inspection and Testing program will follow the same sectors by a year lag. For example, overhead equipment inspection and testing in Sector 1 will take place a year after distribution line patrols for Sector 1. This plan will allow for a more efficient targeted approach to the inspection and testing program. The schedule calls for the completion of the inspection and testing program by 2023, to allow a buffer to complete all transformer replacements with greater than 50 ppm to meet Environment Canada's deadline of December 31, 2025.

Asset Condition

The failure of a distribution line transformer is difficult to predict. While a transformer does deteriorate due to exposure to the elements, its life is mainly impacted by the electrical stresses on which it is placed. These stresses include the loading of the transformer and electrical faults or lightning strikes on the feeder supplying the transformer. Transformers are also replaced as a result of distribution feeder rebuilds, traffic accidents or when they pose an environmental hazard due to oil leakage or failure.

Trends and Impacts

In 2014, Hydro One commenced the PCB inspection and testing of pole mounted line transformers. In order to comply with PCB regulations by 2025, Hydro One will perform approximately 35,000 to 40,000 inspections and approximately 20,000 to 25,000 tests annually. As described above, pole mounted transformers with PCB content 50ppm or greater will be replaced.

2.3.2.4 SUBMARINE CABLES

In order to service certain remote customers, Hydro One builds and maintains a number of submarine cable installations. A submarine cable is a distribution conductor, installed under water, to service customers for which overhead crossings are not technically or economically feasible. Submarine cable installations are primarily in Ontario's "cottage country" supplying island residences. Approximately 11,500 such installations are currently in service, with a total circuit length of about 3,750 kilometers.

Figure 35 – Picture of Submarine Cable Entering Entering Water

Table 47 provides a synopsis of the submarine cable based on a 2014 survey.

Table 47 - Number of Cables and Length

Number of Phases	Cable Run Length (km)	Total Cable (km)	Number of Cables
Single-Phase	3,434	3,434	10,913
Two-Phase	13	26	66
Three-Phase	108	324	684
Total	**3,555**	**3,784**	**11,663**

Hydro One’s asset strategy for submarine distribution cables is to mitigate the risk of failures through visual inspection at the shoreline using the distribution line patrol. Repair/replacement is performed if there is any damage to the cable armour.

Preventative Inspection and Maintenance Program

Submarine cables are installed in environmental conditions that are among the harshest experienced by any distribution assets. They are permanently submerged in water and cross shorelines that are subjected to both severe wave action and winter cycles of freezing and thawing, along with ice build-up. Aside from the harsh conditions to which submarine cables may be exposed, their locations make them exceptionally difficult to access. For these reasons, it is challenging to perform effective maintenance on submarine cables. Submarine cables are managed in conjunction with the Distribution Line Patrol Program; all submarine cables are reviewed on a six-year cycle.

Submarine cable assessments are condition based, prioritized by the missing concentric neutral wires and also by the condition/existence of shoreline protection where the cable egresses the water. The Submarine cable program is focused on replacing cables where potential public hazards are found

Demographics

As evidenced by the information in Table 48, the amount of demographic information available for submarine cables regarding installation date and service life is minimal. In the past, similar to Secondary Service Lines, these assets have been installed to connect individual customers and repairs take place based on customer request. Service life plays no part in the decision regarding the replacement of a submarine cable and there has been no program in place regarding preventative maintenance activities with these assets. Therefore, there was no requirement for detailed information and the life of the asset was generally not maintained.

Table 48 - Submarine Cables by Known Decade of Construction

	1960s	**1970s**	**1980s**	**1990s**	**2000s**	**2010s**	**Unknown**	**Total**
Single-Phase	10	36	408	184	120	40	10,115	10,913
Two-Phase				1			227	228
Three-Phase							33	33
Total	**10**	**36**	**408**	**185**	**120**	**40**	**10,375**	**11,174**

Hydro One is changing the practice around maintenance of submarine cable. Primarily to ensure public safety, Hydro One is initiating an assessment program built around a six year cycle. Out of this program, data will be logged and the robustness of the data is expected to improve over time.

Condition

Submarine cables exposed at shorelines are subject to the action of waves and to repeated cycles of freezing and thawing. Many older cables do not have any form of shoreline protection installed. Especially on rocky shorelines, natural processes can lead to significant cable damage.

Distribution patrols show that approximately 25% of cables are exposed at the shoreline with no mechanical protection. Due to natural forces, the protective armour of these exposed cables is more susceptible to deterioration. In many cases it is completely deteriorated or missing, thus leaving the concentric neutral wires exposed and prone to failure. Protective armour damage and the subsequent neutral failure is the predominant failure mode for submarine cables. While not necessarily causing service interruptions, this type of damage can cause power quality issues or potentially dangerous public safety hazards. Cables are repaired or replaced when the armour is found to be compromised.

Trends and Impacts

In order to mitigate the risk associated with cables that are subject to natural processes at the shoreline, Hydro One has revised standards for these installations including a revised cable design and has developed improved mechanical shoreline protection techniques and products – specifying a more rigid PVC protective covering, which will help mitigate the armour damage

Hydro One also developed and tested numerous mechanical protection systems that will lessen the damaging effects as the submarine cable transitions from the water to the pad mount transformer or the overhead connection.

As patrols identify submarine cables at beginning stages of deterioration they will be repaired or replaced under the Submarine Cable Replacement program. Hydro One is proposing to spend $8M per year for the next five years to replace 220 to 250 submarine cables per year to address the number of deteriorating cable installations. Details of this investment can be found in ISD SR-11

2.3.2.5 OTHER DISTRIBUTION LINE COMPONENTS

In addition to the major line components referenced in the previous sections – poles, line transformers and submarine cables – there are a number of other components that contribute to the total Distribution System. The following table provides a list of these components and numbers in service.

Table 49 - Other Distribution Line Components

1 of 2			Voltage Level (kV)									Totals
			44	**16/ 27.6**	**14.4/ 25**	**22.8**	**8/ 13.8**	**7.2/ 12.5**	**4.8/ 8.32**	**2.4/ 4.16**	**Other**	
Conductor	**Overhead (Km)**	3 Phase	9,780	6,785	2,247	48	146	8,761	15,560	856		**44,183**
		2 Phase		25	21			677	1,177	25		**1,925**
		1 Phase		3,282	3,240		81	25,295	33,237	471		**65,606**
	Underground (km)	3 Phase	47	466	21.0		26.9	125.0	416	100		**1,202**
		2 Phase		165	2.6		11.6	27.8	150	19.3		**376**
		1 Phase		1,245	79.5		63.6	676.0	1,433	154		**3,651**
AMI	**Retail Meters**										1,335,000	**1,335,000**
	Collectors										10,400	**10,400**
	Repeaters										38,000	**38,000**

2 of 2

			Voltage Level (kV)									Totals
			44	16/ 27.6	14.4/ 25	22.8	8/ 13.8	7.2/ 12.5	4.8/ 8.32	2.4/ 4.16	Other	
Switches	**Air Break and Load Break**	3 Phase	1,648	1,004	49	7	23	140	103	79	9	**3,062**
Reclosers	**Hydraulic**		40	305	262		32	3,093	8,214	61	28	**12,035**
	Electronic		42	87	4	1		54	37	2	9	**236**
Regulators			1	98	79		3	744	1,346	15		**2,286**
Capacitor Banks			86	263	36		5	230	661	38	2	**1,321**

Hydro One's asset strategy for maintenance of distribution lines assets is to visually inspect all lines assets as part of the distribution line patrol program. Individual assets are assessed and replaced on a "run to failure" basis or on a condition-based assessment.

Distribution lines are inspected on a six-year cycle for rural area and a three-year cycle for urban areas. During these inspections information about the condition and demographics of specific assets is collected. During the line patrols, defects found on any component are recorded and, depending on the nature and seriousness of the defect, repairs are scheduled for correction.

For the components above, all are managed on a "run to failure" basis, with heavy emphasis on the Line Patrol program to identify defects/issues before the components reach the failed state. Several have Capital Component Replacement programs, which replace, like for like, components that are defective or have reached end of life.

The Advanced Meter Infrastructure (AMI) is composed of retail revenue meters, repeaters, collectors and other electronic components. The AMI is used to implement Time of Use electricity pricing and to remotely collect customer billing data. AMI components are currently replaced when they fail. To facilitate timely replacement of AMI components, an inventory of AMI components is maintained to better serve customers.

The vast majority of retail revenue meters are Smart Meters. Smart Meters have a manufacturer-stated service life of 15 years. It is expected that the Smart Meters will exhibit unacceptable performance beyond their expected service life. As a result, Smart meters are planned to be proactively replaced starting in 2021. The replacement schedule will match the historic installation schedule which began in 2006.

Distribution Line Switches – Three Phase Load Break and Air Break – are a vital component during line construction for safety and isolation and during outage restoration. These switches are maintained under an OM&A program for Switch Maintenance. Any switches found under this maintenance program to be un-repairable, are replaced under the Capital Component Replacement program.

Distribution Line Reclosers and Regulators are divided across the province into six sectors and are replaced at a rate of 1,250 per year under the Component Replacement program. The regulators and hydraulic reclosers are replaced with units that have been refurbished at several maintenance shops across the province.

Distribution Line Capacitor Banks are utilized to ensure that the distribution lines voltage performance complies with power quality industry standards. The capacitor banks are part of distribution line patrol inspection program with replacement on a “run to failure” basis.

2.3.3 (5.3.3 A, B) KEY COMPONENT SUMMARIES – OTHER ASSETS

The assets that Hydro One employs to operate the system and its business include some assets not directly related to the provision of electricity, but that are nonetheless critical to ensuring the success of continuing operations.

IT Hardware and Applications are the systems that support all of the grid and administrative operations. Real Estate and Facilities include the numerous physical and locational assets housing assets and crews. Transport and Work Equipment are comprised of the different types of vehicles that transport staff and materials. Customer Care includes the specific assets needed to effectively serve customers.

These assets are as vital to the successful achievement of Business Objectives as are the electrical components described above. Details on these various groups of assets are included below.

2.3.3.1 INFORMATION TECHNOLOGY – HARDWARE AND APPLICATIONS

Background

Information Technology ("IT") refers to computer systems (hardware, software and applications), enterprise data storage and processing systems, and voice communication systems that support business processes and allow employees to perform their work to serve customers effectively. Hydro One currently manages approximately $150 million of IT assets and uses approximately 800 business software applications. IT hardware includes desktop/notebook computing equipment, field tablet computers, storage devices, servers, and telecommunication infrastructure including switches, and computer-telephony interfaces.

IT Minor Fixed Assets ("MFA") programs ensure the continued operation of the IT hardware infrastructure. These programs address equipment needs generated by the growth in demand for IT services, capacity limitations, and the replacement of end-of-life equipment. The replacement of aging hardware is based on the age and the nature of the applications running on the hardware. Equipment may be upgraded, or improvements may be made to extend hardware lifecycle. IT MFA is broken down into the categories shown in Table 50 below and the number of devices currently employed for each type is provided.

Table 50 - IT Minor Fixed Assets

Description	**Quantity**
Number of Enterprise Servers	1,539
Number of Desktops & Laptop computers	7,503
Number of Tablets, Printers and Plotters	2,172
Volume of Enterprise Data Storage(TB)	946.5

Telecommunication infrastructure includes equipment such as Local Area Network ("LAN") switches, Wide Area Network ("WAN") routers, firewalls, Virtual Private Networks ("VPN"), telephony services (dial tone and voice mail), infrastructure cabling and Uninterrupted Power Supplies ("UPS").

The Asset Strategy for Hardware is to adhere to the IT industry standard practice of managing assets through a life cycle program ensuring vendor support is available and decreasing the likelihood of failure. Investment decisions are made based on software life cycles, vendor schedules, reliability requirements, customer requirements, and experience with similar equipment.

Witness: Lyla Garzouzi/Lincoln Frost-Hunt/Rob Berardi

The Asset Strategy for Applications is to replace or upgrade where required to ensure continued vendor support and compatibility with the current IT environment in order to minimize business interruption. Investment decisions are based on return on investments calculations which reflect savings and constraints of software life cycles, vendor schedules and, reliability requirements.

Hardware Maintenance

Investments in servers and storage are required to respond to and manage growth in demand for processing and storage capacity and to address end-of-life issues. In determining when equipment requires replacement, functionality and operating and maintenance costs are assessed. Spending varies depending upon hardware life cycles and business requirements for increased processing capacity. Lifecycles vary due primarily to demand for additional functionality from the applications being hosted or the expected failure rate provided by the vendor; generally expressed as Mean Time Between Failures ("MBTF").

Desktop and laptop computers are used by most Hydro One staff. Rugged tablet computers are used by field staff. Tablets are used with geospatial information systems ("GIS") applications for system design work and asset condition assessments. Plotters are used by engineering and operations staff for design work and to plot system maps.

Hydro One's practice is to replace desktop and laptop computers every three to five years, and printers and plotters, every four to five years. The renewal timeline is consistent with industry practices as outlined by leading technology analytics organizations including Gartner, IDC, Forrester and others. Hydro One strongly values and takes industry insight into consideration for its own IT strategies and practices.

Another factor governing the replacement timelines is that hardware maintenance costs typically increase after the four to five-year expected life cycle period, making it a more appropriate time to refresh. MBTF for physical components is another consideration for refresh. In general terms, as physical components continue to be powered on and active, their reliability and performance (for example, Solid-State Disks and Flash RAM), degrades. This drives more frequent component failures after the four to five-year period. At times, the refresh cycle has been adjusted to accommodate business requirements. Moreover, application upgrade projects performed on broadly used applications, such as Microsoft Windows, may have effects on hardware replacement. For example, the newer versions of Windows tend to have increased hardware requirements. Therefore, an update to Windows may accelerate the refresh cycle on a large number of computers. Hydro One has implemented the refresh cycles it currently has in place in order to minimize the overall life cycle costs of the assets.

The telecom assets of Hydro One are varied with different installation dates and life cycles. The business telecom network transmits data required to run business applications. Voice or data network improvements or replacements improve network efficiency and ensure equipment is current and supported by third party vendors. Projects regularly undertaken include rewiring local area networks, replacing end-of-life data network switches and routers, upgrading voice infrastructure, replacing un-interruptible power source systems, and upgrading security solutions for external network interfaces. For voice and data network equipment, the equipment refresh generally occurs about every five years. Funding for voice and data networks may vary depending upon hardware lifecycles, technology changes, and business needs for increased bandwidth.

Key enterprise systems and their supporting hardware must always be available to customers and to the employees involved with the delivery of customer service programs and work management programs linked to Hydro One's Business Objectives.

Application Maintenance

Hydro One's Enterprise Applications provide the backbone of business operations. Customer Information systems enable effective delivery of call centre, meter reading, billing, collections and settlement services to Hydro One customers. Enterprise Resource Planning ("ERP") systems provide the tools to seamlessly manage administration across multiple lines of business including finance, human resources, supply chain, as well as, asset and work management for field staff upgrading and maintaining the power system. Work Management Systems enable timely connection of customers through demand related activities and effective operations through scheduled plant maintenance or storm restoration activities. The reliability of Enterprise systems is critical to keeping Hydro One running effectively.

The following general architectural principles apply to all Hydro One IT applications:

- Applications will be commercial-off-the-shelf ("COTS") and maintained in a vendor-supported version lifecycle to ensure continued functionality and maximum longevity;
- Custom applications are migrated to COTS solutions where possible to minimize development, integration and maintenance costs;
- Where possible, application rationalization is applied to reduce the number of applications supported and lower support costs; and
- Middleware will be used to facilitate application interconnectivity. Hydro One has invested in implementing middleware or Service Oriented Architecture ("SOA") to enable data integration within and between applications and ensure continued interoperability.

The ongoing maintenance and sustainment of Hydro One IT applications and the supporting infrastructure is outsourced to Inergi LP. Based on support levels established by Hydro One IT operations and the respective business operations, applications are managed through the "IT infrastructure library", a framework focused on incident, problem, and change management.

When an application is placed into service, it is assigned a Support Level ("SL") designation. The SL contains a set of characteristics and expectations which determine the standards to which each application will subsequently be maintained. The uptime expectations are included in Table 51 below.

Table 51 - Uptime Expectations by IT Support Level

Support Level	Expected	Minimum	Hours of Operation*
SL-1	99.91%	99.53%	7x24x365
SL-2	97.30%	95.25%	7x24x365
SL-3	99.55%*	97.15%*	Mon. - Fri. x Business Hours x 6:00 – 18:00

** Higher than SL-2 as Hours of Operation are Business Hours only. No single outage of a SL 1 or SL2 Application shall exceed thirty (30) cumulative minutes during any measurement window.*

There are a number of important and coincident factors that must be considered when determining whether an application should be upgraded. These include:

- age (lifecycle) of the existing application;
- dependencies on other up/downstream applications;
- complexity of the upgrade process;
- cost and duration of application upgrade;
- potential impact to the business (ex. tolerance for downtime);
- risk and potential impacts to other up/downstream applications;
- maintaining vendor supportability;
- providing enhanced business functionality/capability required by Hydro One; and
- integration with other applications, including "cloud-aware" applications that use modern development architectures and authentication/authorization/federation protocols (for example, OpenID, SAML, and OAuth).

IT Development

IT Development projects enable the replacement and/or upgrade of end-of-life applications and may also include investments in new applications to meet changing business and customer requirements. Applications are replaced when they have become inadequate for current functional needs; where the platform is no longer supported by the vendor; to address legislative changes or market driven initiatives; or to significantly modify the application to better support an evolving business capability. New applications are only added when necessary to address business needs and to support existing or new business processes.

The strategic decisions to conduct system upgrades are largely based on industry standard Systems Development Life Cycle ("SDLC") methodologies. An SDLC is composed of a number of clearly defined and distinct work phases which are used to plan for, design, build, test, and deliver information systems. An SDLC aims to produce high-quality systems that meet or exceed customer expectations, based on customer requirements, by delivering systems which move through each phase, according to scheduled time frames and cost estimates.

Business planning is performed on an annual basis with business stakeholders to assess whether investments in business processes and IT technology are required. When a requirement is identified, the details are sent to the Corporate Projects department of IT. This group makes provisions by assessing the need against potential benefits and costs to calculate a return on investment. IT capital projects are required to submit a business case to justify the cost against future savings.

Projects are generally 1 of 3 types:

Investments in new functionality to meet business objectives

These investments include new or upgraded applications designed to improve functionality, customer support and efficiency. The projects may support other Business Objectives. Examples of these projects include:

- Work Management & Mobility (ISD-GP-10);
- S/4 HANA for Finance and Enterprise Asset Management (ISD-GP-17);
- HR and Pay Related Technology Investments (ISD-GP-13);
- Collections Enhancements (ISD-GP-31);
- Customer Data and Analytics (ISD-GP-32); and
- Customer service Complaint Management Tool (ISD-GP-33).

Investments to replace or upgrade end-of-life applications

These investments address hardware deficiencies to support efficiency and performance. Examples of these projects include:

- Enterprise Geographical Information System (ISD-GP-11);
- Call Centre Technology (ISD-GP-28); and
- Smart Meter Network Investments (ISD-GP-34).

Investments to address regulatory (legislative) requirements

In certain cases, a technology solution is required to address a regulatory requirement. An example of this type of project is:

- Customer Service Regulatory (ISD-GP-30).

Other Influencing Factors

Aside from maintaining an up to date and effective IT environment to support employees and customers, the proposed investments also includes items to:

- improve customer service satisfaction based on priority items from the customer engagement sessions described in Section 1.3;
- monitor and implement, where feasible, new and disruptive technologies that can be leveraged to improve business functionality and enhance customer service;
- support the lines of business to improve the cyber security posture of the company assets based on the North American Electric Reliability Corporation (NERC) version 5 and 6 mandatory standards;
- improve safe work practices for Hydro One employees with mobile and GIS investments; and
- create work management efficiencies to improve customer satisfaction and reduce cost per unit measures.

2.3.3.2 REAL ESTATE AND FACILITIES

Background

Hydro One Real Estate Facilities assets include Administrative Centres, Operations Centres, Maintenance/Work Centres, Warehouses, Maintenance Garages, Helicopter Hangars, Material Yards and numerous others. These facilities are vital assets to the company in support of the business operations to fully deliver the prescribed work programs.

Capital investment is periodically required in order to continue to provide appropriate and adequate accommodations for core work programs and changing requirements of the various lines of business.

Hydro One currently manages a total of approximately 136 facilities that exclusively serve the Distribution program or in common with the Transmission program. The key elements of these facilities are 486 buildings of various natures serving the business requirements. These facilities and their related buildings are broadly distributed across the Province as depicted by Figures 36 and 37 below.

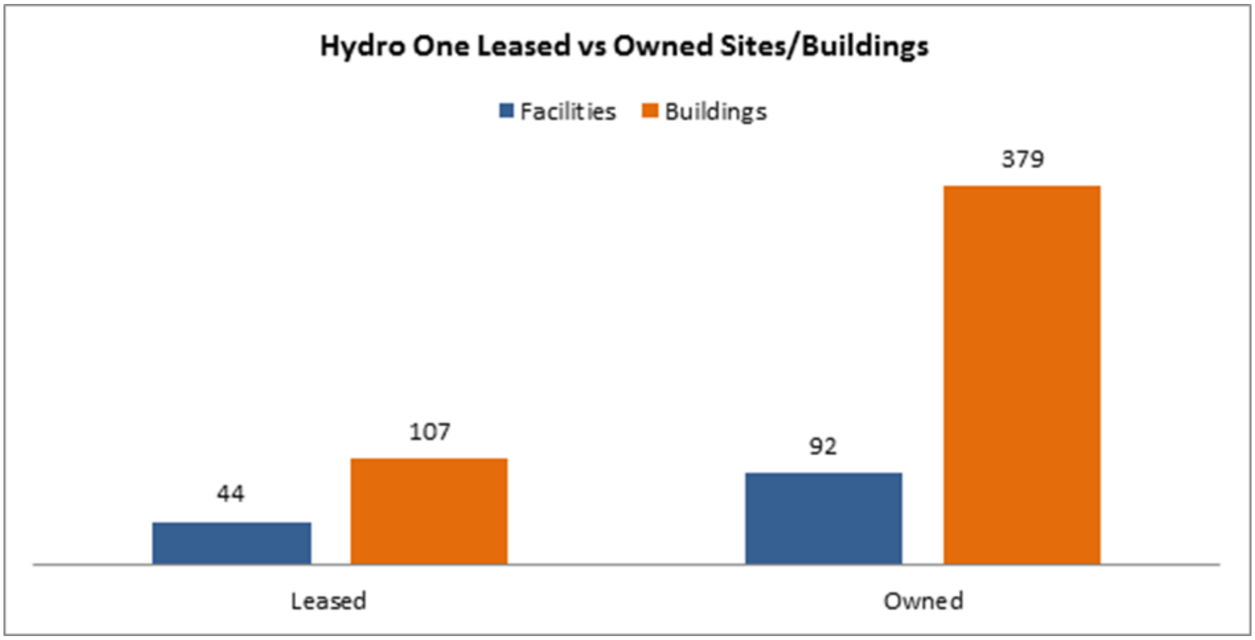

Figure 36 - Leased vs Owned Facilities & Buildings

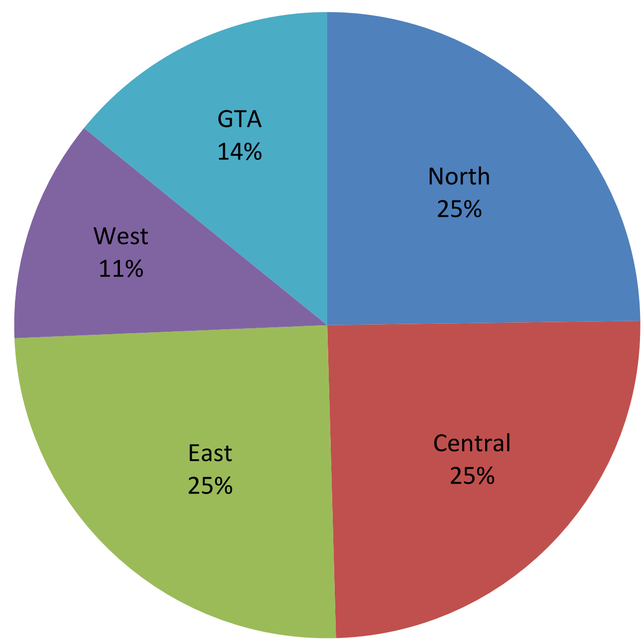

Figure 37 - Distribution of Facilities in Ontario

Hydro One facilities are distributed to align with the configuration and demands of the network and customers as well as the diverse operational requirements of the various lines of business. In addition, the siting of facilities is established against a number of factors, which are balanced and optimized. These factors can be categorized as internal and external.

Internal factors include network demands, which dictate/influence business operations and requisite facility requirements. The aim is to maximize operational effectiveness of the various lines of business operating within their respective regions, which may be incremental or complementary. Furthermore, financial performance will dictate an examination of various alternatives, (e.g. lease versus owned).

External factors also affect the siting and development of facilities. Some of these external factors include regulatory framework, public policy and municipal and economic development. Furthermore, provincial geography and topography influence or dictate the siting of facilities. Finally, market conditions also dictate the availability and feasibility of solutions which can impact a facility's siting.

The asset strategy for Facilities and Real Estate is to maintain facilities that serve operational requirements in accordance to a life cycle approach by conducting planned maintenance of key facility systems and infrastructure and undertake inspections at an appropriate frequency to identify and undertake corrective maintenance. Undertake annual operational assessments with the various lines of business to confirm facility requirements and as necessary complete renovations, additions or replacements for new requirements and/or end of life condition.

Condition

More than 40% of administration and service facilities are greater than 40 years old. These facilities are commonly undersized, ill-configured and, in context of operational requirements, are underperforming. The result is an increase to operating costs for maintenance and repair and inefficiency to business operations. In addition, the facilities program is tasked with addressing corporate growth objectives, such as LDC acquisitions. With past and ongoing resource constraints, the objective is to make timely and prudent investments that address priority requirements that serve operational and condition gaps and align with future plans to upgrade or replace these facilities.

Building condition assessments of all facilities have been initiated to identify condition gaps and required future investments needed for ongoing requirements. To date, assessments have been completed for approximately 60% of the facilities within the current portfolio. These assessments have identified approximately 20% of buildings to be in fair to very poor condition. These assessments are to be completed within two years. In conjunction with operational assessments, corrective plans will be established to address conditions on a priority basis.

Maintenance and Inspection

Hydro One's facilities maintenance program is supported by visual inspections and building condition assessments at planned frequencies. Execution of facility maintenance and inspections is outsourced to Brookfield Global Integrated Solutions in accordance to internal and external guidelines. Hydro One has documented the maintenance and inspection guidelines within its controlled document system. In addition, the service provider through its experience has and continues to provide insight and recommendations for appropriate level of maintenance and repair. These recommendations are typically identified through inspection reporting and building condition assessments.

These guidelines are defined and enforced through contractual obligations with the service provider and service level agreements for the facilities. Guidelines are developed to serve operational and corporate defined requirements, regulatory requirements and general commercial guidelines employed by the facilities industry.

Visual inspections are conducted at all facilities with frequencies ranging from monthly to annual as defined below to optimize performance. Each facility is visually inspected on a monthly basis, which consists of preventative maintenance plans scheduled for various components. The monthly visual inspections are done on various major building systems such as, HVAC, lighting and fences. Bi-monthly, visual inspections of the building envelope and site are completed. Annual inspections address fire systems, building auxiliary, sewage system, and foundation and floor pads. However, Hydro One may carry out additional inspections after storms, earthquakes, fire, vandalism, and public reports, as deemed necessary.

Building condition assessments are performed every five years to provide Hydro One with comprehensive insight of the facility's asset condition. It provides short, medium and long term assessment of the facility and associated levels of required investment with respect to ongoing use. This assessment serves to establish or confirm a facility asset strategy in conjunction with operational requirements.

In line with the facility asset strategy, the results from the visual inspections and building condition assessments either trigger corrective maintenance, capital expenditure for renewal, or replacement, or are documented and re-evaluated in future planning. The results of inspections and assessments are completed and considered on an individual facility basis. Global reporting is currently under development, which will refine the assessment and reporting. The objective will be to update guidelines for planned maintenance and corrective plans.

The level of corrective maintenance at each site, which may vary, is determined by whether the site is owned or leased, the life-cycle standing (i.e., the remaining estimated life of the asset), and the future operational requirement. The exception is Hydro One's leased facilities where the burden of capital repairs and/or replacements resides with the Landlord other than repairs that are specific to Hydro One's operations (i.e., tenant improvements). Building and site elements in fair or good condition resulting from the building condition assessments would be re-evaluated every five years and implemented in context of the facility capital asset strategy.

Identification and Assessment of Operational Requirements

An effective facilities management program is contingent upon identifying and prioritizing business and operational requirements. These requirements can range from minor capital repair or upgrade of existing facilities to establishment of a new work centre to address operational, business or regulatory requirements.

The process entails conducting ongoing operational assessments with each line of business to ensure facilities are fully aligned with operational requirements and to identify and reaffirm planned investments. An annual planning meeting is conducted with each line of business to review their specific portfolio to identify facility requirements to current, planned or operational trends/strategies. As part of this review, opportunities and risks are considered to assist in the prioritization of facility requirements within and amongst the various lines of business. In addition to the annual meeting, broader stakeholder meetings are conducted on a semi-annual basis with all lines of business. This provides each group with operational status of the various facility projects and initiatives in progress to confirm alignment with operational requirements. These stakeholder meetings may lead to identification of operational synergies, such as co-location opportunities, so that different lines of business can leverage common infrastructure and facility elements. Periodic meetings are also conducted as needed to review newly identified corporate initiatives, which may impact the operational and facility requirements of the lines of business.

Corporate and individual lines of business requirements often create competing requirements with respect to timing and resources. Therefore, these requirements are assessed within and amongst each other to establish priorities and timing. The process of prioritization considers a variety of factors, including but not limited to:

- Impact to business (regulatory and operational risks);

- Corporate initiatives (e.g. customer service strategies and LDC acquisitions);
- Life-cycle standing of assets (condition);
- Facility constraints (physical, regulatory and operational)
- Market opportunities (existing and greenfield developments); and
- Financial (corporate, shareholder and ratepayer).

Prioritization often results in gaps to addressing defined operational requirements. This necessitates strategies that recognize these gaps with interim facility solutions that lead or contribute to the preferred strategy. This can be accomplished through maintenance of current facilities with incremental additions, short-term facilities and phased developments.

Identification and Assessment of Facility Alternatives

Based on the established priorities and resulting facility strategy, Hydro One considers a range of potential alternatives available to meet the requirements on a project basis. Alternatives considered include:

- Current location;
- Relocation to another existing Hydro One facility;
- Acquisition (purchase or lease) of existing available facilities in the marketplace; and
- Greenfield developments.

The identification of alternatives in the marketplace entails leveraging municipal economic development departments, local real estate brokerage community, and like resources.

Alternatives undergo a rigorous analysis, which considers risks measured against the continuation of the status quo. Alternatives are assessed on their ability to meet line of business operational requirements, satisfy regulatory requirements, and address financial considerations, such as facility costs (initial capital and ongoing operations) and potential savings to the lines of business. All alternatives are assessed on a comparative basis, supported by input from architects, engineers, cost consultants and real estate consultants/brokers, as well as prior experience. Recommended alternatives are reviewed and approved as part of the investment planning process. Hydro One considers potential risks to ongoing business requirements and a corresponding facility exit strategy for all alternatives.

Other Factors - Divestment of Assets

Periodically, Hydro One determines various facility assets to be surplus to requirements and seeks to divest these properties. However, most facilities are located in smaller markets where low value and demand result in delayed sales, usually below book value.

Hydro One divests itself of its surplus properties through an open and competitive process, generally through a Real Estate Broker listing, with the intention of maximizing exposure and optimizing return on the asset. In cases where a sale of the asset is not possible, Hydro One will attempt to lease the property to a third party or mothball/demolish to offset ongoing cost and liability. To ensure that Hydro One realizes fair market value and as a check in the sale process, surplus properties are independently appraised by qualified real estate professionals.

The decision to declare properties as surplus considers the life cycle standing of the asset and future operational requirements, the latter entailing the input from the lines of business through the operational assessment process.

2.3.3.3 TRANSPORT AND WORK EQUIPMENT (FLEET)

Background

Hydro One Fleet Management Services provides centralized and turnkey services that include maintenance, administration, vehicle replacement and disposal. Transport and Work Equipment ("TWE") consists of a variety of different equipment types including:

1. Light duty (cars, vans, pickups);
2. Heavy duty (service trucks, highway tractors, bucket trucks, Figure 39, and radial boom derricks (RDB), Figure 40);
3. Off-Roads (rubber tire and tracked);
4. Miscellaneous equipment such as trailers, boats, chippers, puller tensioners, manlifts and forklifts; and
5. Helicopters.

Figure 38 summarizes the number of vehicles by equipment type.

Fleet vehicles support the various lines of business, including Provincial Lines, Stations, Forestry and Construction Services. Fleet vehicles must be maintained at an optimum level to ensure public and employee safety and compliance with laws and Ministry regulations. These regulations include, but are not limited to CSA 225, the Highway Traffic Act and the Commercial Vehicle Operator's Registration regulations. The objective is low environmental impacts and optimized line-of-business productivity by minimizing downtime, travel time, and by optimizing technology and continuous improvement opportunities.

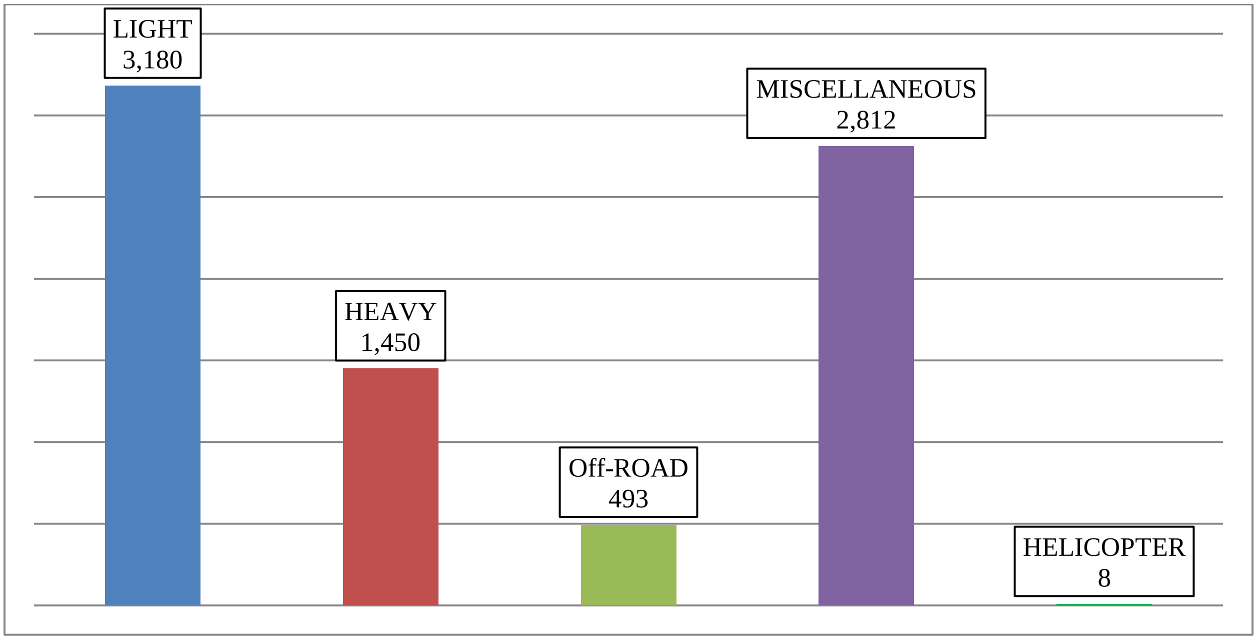

Figure 38 - Fleet Equipment by Type

The asset strategy for TWE assets is to provide safe and reliable equipment for employees to deliver safe, reliable and economical service while balancing the decision to replace or repair equipment. The decision to replace or repair equipment is based on age, mechanical condition, kilometers traveled and cost per kilometer, as well as the current Net Book Value (“NBV”).

Figure 39 – Picture of Heavy Bucket Truck

Figure 40 - Picture of Radial Boom Derrick

Inspection and Maintenance Program

Fleet Management Services has developed a balanced maintenance model for mobile service. Staff can arrange to have local mechanics provide service at the location of the breakdown or they can have it towed to a centralized facility. This model provides for 41 provincial locations and balances geographical customer requirements, travel time, third party vendor support and response time. The locations of the 41 garages are based on the density of equipment and Line of Business ("LOB") work centres. Mobile/satellite repair units provide timely on-site field support for various nomadic work programs, such as vegetation control, new construction and off-road tower maintenance. Services provided to the LOBs meet the requirements of Fleet Management Services' agreements and are structured as a mobile model to meet customer requirements.

Fleet Management Services employs specialized heavy duty mechanics that deal with most heavy, off-road and miscellaneous equipment. If there is an issue with the equipment, the driver will drop the equipment off at their fleet maintenance garage to get the vehicle repaired. If the driver is unable to deliver the equipment, they will call into their fleet maintenance garage where the supervisor will make an assessment of whether the equipment will be towed in or a mechanic will drive out to the equipment and repair it on site. The Fleet Management Services mechanics will also complete inspections of the equipment based on regulation and manufacturers' timelines.

For all light vehicles Hydro One has agreements in place to allow external mechanics to complete all inspections, services and repairs. If there is a service or repair that needs to be completed on a light vehicle, the driver can take it to any non-Hydro One garage for the issue to be addressed. All light vehicle repairs get approved by Fleet Management Services prior to any work being completed.

For all helicopters, Fleet Management Services has a group of experienced Pilots and Air Maintenance Engineers based in five strategic locations across the province to support the LOBs. All Pilots and Air Maintenance Engineers hold Transport Canada licenses and receive annual training and testing to maintain a high level of proficiency.

Demographics, Condition and Performance

Each year, Fleet Management Services and the LOB complete a review of all the equipment that has met the replacement guidelines, stated below. The NBV, age and condition of the vehicles are reviewed against the future work programs and staff needs. Where possible, replacement equipment is pulled from the current inventory based on utilization and transferred to other locations or LOBs. If there is no equivalent equipment available in the current inventory, a requisition will be completed to order a new replacement vehicle. The vehicles that will be replaced are sent back to Fleet Management Services to be sent to auction or disposed of locally.

Fleet Management Services replacement program reviews:

- equipment capital forecast;
- equipment productivity, functionality, and future requirements;
- equipment standards, equipment age, mechanical condition, kilometers traveled and cost per kilometer, downtime, and repair time;
- safety/risk;
- work programs, evaluating staff and equipment complement;
- tendered procurement process;
- fleet's original capital value and net book value;
- historical and future utilization; and
- strategic procurement.

Replacement guidelines per type of equipment are:

- Light vehicles (personnel carriers) are considered for replacement after 6 years or 180,000 km;
- Heavy vehicles:
  - Service Trucks are considered for replacement after 6 years or 300,000 km;
  - Work equipment-single axle (RBDs, buckets, etc.) are considered for replacement after 8 – 10 years or 400,000km; and
  - Work equipment-tandem axle (RBDs, buckets, etc.) are considered for replacement 12-14 years or 400,000km.
- Off-Road and Miscellaneous equipment are specialized and due to a lower utilization can be kept for a longer period of time. Replacement is dependent on availability of parts, the condition of the equipment at the annual inspections, future work program requirement and changes in technology as well as the length of the replacement timeframe and availability of rentals; and
- Helicopters are considered for replacement on a case by case basis depending on utilization, condition of the aircraft and the cost of refurbishment as well as work program requirements.

1 
2 **Figure 41 - Transport and Work Equipment Demographics**

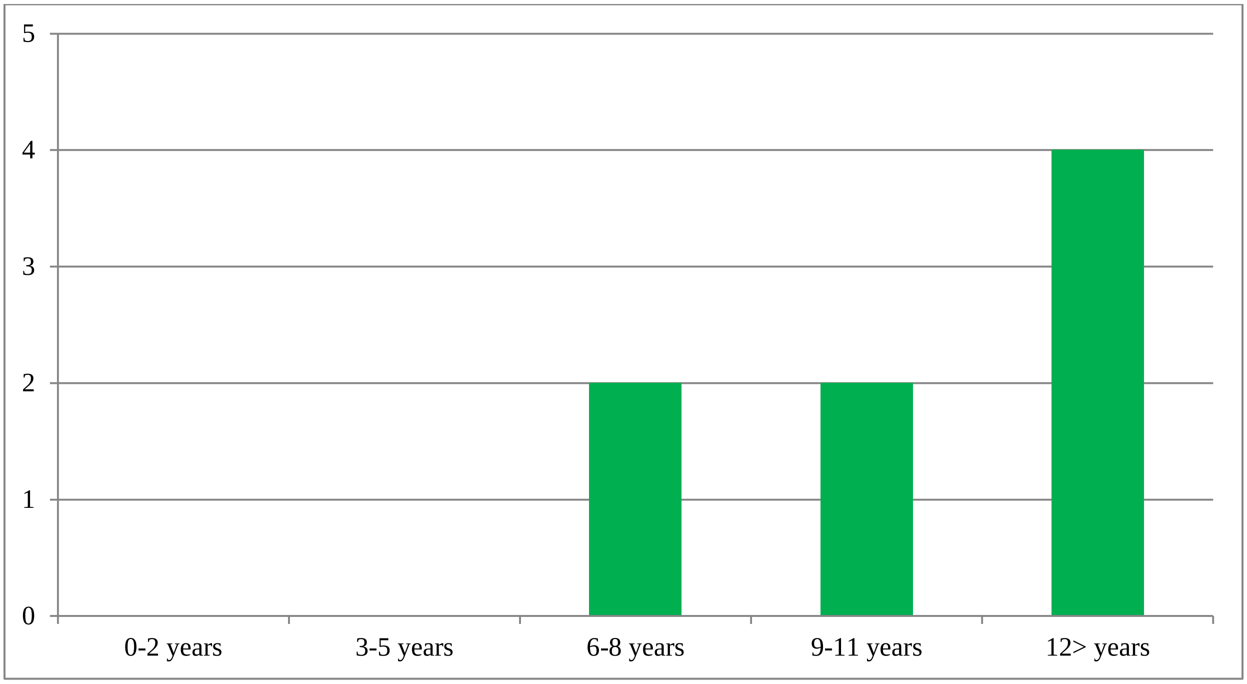

Figure 42 - Helicopter Demographics

Other Influencing Factors

Fleet Management Services has implemented a fleet telematics system for 4,700 fleet vehicles. Integrating telecommunications, global positioning systems (GPS), and informatics systems, Telematics provide location of vehicles and live vehicle operation and performance data. This project was completed at the end of 2016.

The Telematics system provides the following benefits:

- Improves operator safety through awareness of driving habits using Speeding and Harsh Events (hard breaking) reports;
- Provides better visibility to Fleet Management Services regarding vehicles that are not being utilized by a LOB and those vehicles can be redeployed to other work

groups leading to better utilization or possibly a reduction of overall fleet using the Utilization report;

- Allows implementation of fuel efficiency and greenhouse gas reductions by changing driver habits with the Speeding and Idling reports;
- Improve Fleet Management Services response time with live vehicle locations;
- Improved fuel tax credit savings with the Power Take Off (PTO) reports;
- Visibility to the Engine Control Module of the vehicles allow for tracking of vehicle condition, optimization of routine maintenance; and
- Decrease thefts and increase security of the fleet vehicles through the advertisement of on-board GSP telematics systems.

In 2017, Fleet Management Services will leverage the telematics data to institute a framework to define the baseline metrics with respect to equipment utilization and productivity. Savings are forecast to begin in 2017 with $0.3M in OM&A but will ramp up to $3.1 million Capital and $2.2 million in OM&A by 2022. Further details on the productivity savings expected from the Telematics system are included in Section 1.5.1.5.

2.3.3.4 CUSTOMER CARE

Background

Hydro One's Customer Service division services approximately 1.3 million residential, small business, commercial, and industrial customers. The Customer Service department is responsible for responding to customer inquiries when they contact the call centre, obtaining meter readings, and issuing timely and accurate bills. In 2016, the call centre handled over 2.7 million calls from customers and delivered over 14 million bills. As Hydro One pursues its vision of becoming a best-in-class, customer-centric company, managing this large customer base requires a number of large assets and advanced technology.

The Hydro One Customer Contact Centre relies on the following technologies to operate effectively:

- Customer Information System ("CIS") – A billing software that manages customer information, meter data, electricity consumption, billing calculations, service orders, and collection activities. The system also provides customer service representatives a single solution for tracking all interactions with customers and enables interactions with customers, generators and other partners, such as retailers and social services agencies.
- Interactive Voice Response ("IVR") System – An automated telephone system that interacts with callers, gathers information through voice prompts, and routes calls to the appropriate recipient.
- Computer Telephony Integration ("CTI") – Gathers information through voice prompts, routes calls to the appropriate recipient, and coordinates interactions with CIS.

The Customer Service department also relies on Smart Meter technology. Hydro One was one of the first LDCs to introduce smart meters in 2006 and this project delivered the Advanced Meter Infrastructure ("AMI") to 1.2 million customer premises by the 2010 OEB target date. The corresponding smart meter communication network was completed in 2013.

Smart meters measure the total amount of electricity used over a billing period, record how much and when electricity is used (typically hourly), and transmit this information automatically to

Hydro One's CIS. The smart meter will record total electricity consumption and send that information to Hydro One through a wireless communications network. Customers will then receive bills based on automated meter readings. Smart Meters, when teamed with Time-of-Use prices, are energy management tools that help customers manage their electricity use and costs, reduce the need for additional power generation during peak periods, and create real supply and environmental benefits.

The Asset Strategy for customer service capital is to coordinate the activities of IT and the service provider to maintain customer-facing systems to ensure regulatory compliance while balancing cost and customer satisfaction – the latter of which is determined via direct and varied engagement with customers. As outlined in Section 1.3, surveys, focus groups, and customer engagement sessions are used to gauge the current satisfaction levels of customers and identify needs, preferences and issues.

Condition and Performance

Customer Information System

Hydro One's most recent CIS went live May, 2013. The CIS replacement project was designed to address current needs, improve customer value, and enable a customer service delivery vision. Although the system is operating effectively from a billing perspective, the following enhancements are required in order to improve internal operations and customer satisfaction.

Billing – Hydro One's latest survey results indicated that only 62% of customers find their bill easy to understand. In order to help customers better understand their bill, Hydro One plans to redesign the bill. Continued interaction with the technology to help modernize our bills is required. There is also a need to improve billing for non-energy services (whereby Hydro One provides specialized work for non-energy services to external parties). Hydro One's existing tool is inefficient and is not integrated in CIS. As a result, there are inconsistent customer service policies between energy related billing and non-energy related billing.

Data and Analytics – Customers are also concerned about the high cost of electricity, based on feedback received from customers via the Distribution Customer Engagement and detailed in Section 1.3. The feedback indicated that reducing cost is the top priority for Residential and Small Business customers. Many customers believe that total electricity costs are approaching an unaffordable level. CIS is capable of providing analytics to customers to help them manage their consumption. Currently, CIS has minimal interaction opportunities with customers to provide this type of information effectively. Hydro One is planning on implementing a new suite of technology to address the shortcomings of the current CIS in this respect.

Complaint Management – Hydro One receives approximately 3,000 complaints from customers on an annual basis. Complaints are currently managed within an access database. This database is not integrated with CIS and therefore complete and robust customer information is often not available to Hydro One employees addressing the customer's complaint. Plans are in place to implement a tool on top of CIS that will not only track customer complaints from initiation to resolution, but also provide account information, contain workflows to improve productivity, and assist with root cause analyses.

Collections – Hydro One's collections tool within CIS offers customers a variety of payment options and sends reminders to overdue customers. However, the existing collections functionality within CIS requires enhancements in order to reduce overdue receivables and Net Bad Debt for Hydro One. Based on feedback received from customers via the Distribution Customer Engagement (as detailed in Section 1.3), customers have a desire to see Hydro One demonstrate greater fiscal management and operational efficiency before considering rate increases. As such, Hydro One will implement technology and process changes to encourage customers to promptly pay their bills, thereby increasing the likelihood of payment and reducing uncollectable accounts receivables moving forward.

Contact Centre Technology

Hydro One's IVR and CTI systems were last replaced in 2004 and are now past their recommended useful life. As a result, the current IVR is at risk of not being supported by vendors from a break fix perspective. Extended maintenance contracts only address existing defects but will not develop or release new code for legacy versions of software. This introduces a high risk around recovery time when system outages are experienced, thus in turn impacting customer satisfaction. Customers who have billing related inquiries, and more importantly, customers calling to report emergencies on a 7/24 basis, won't be able to reach the call centre. In addition, newer systems offer enhanced call routing, enhanced call monitoring capabilities, and more effective monitoring of agents and call centre performance.

Smart Meter Technology

Hydro One designed a number of custom applications in order to integrate the Smart Meter network, the IESO Meter Data Management and Repository ("MDM/R"), and CIS in order to meet regulatory requirements set by the Ontario Energy Board. However, these systems are no longer supported by the vendor. As such, Hydro One plans to replace the custom applications with commercial-off-the-shelf ("COTS") applications wherever possible, thereby reducing the risk of system failure currently present and gaining vendor support to avoid failure in the future. If the systems were to fail, billing operations would be disrupted, thereby impacting customers.

Other Influencing Factors

Regulatory and government policy play a key role in shaping the decisions made with respect to Hydro One's customer assets.

Capital funding is required to implement system changes to support the Distribution System Code Demand to Interval amendments that came into force August, 2014. Section 5.1.3 requires a distributor to install an interval meter on any installation that is forecast to have a monthly average peak demand during a calendar year of over 50 kW and pay the hourly Ontario energy price from the IESO-administered real-time energy market based on their actual usage by August, 2020.

The Ontario Energy Board also issued its Regulated Price Plan Roadmap: Guideline for Pilot Projects on RPP Pricing in July, 2016. Dynamic Energy Pricing encourages customers to reduce electricity usage and shift usage away from peak hours. Capital funding is required to extend the pilot beyond April, 2017. This investment will provide customers with new pricing options, thereby encouraging energy conservation, making electricity more affordable, and improving customer satisfaction through the new pricing model.

2.4 (5.3.3 B) HOW THE PLAN REFLECTS INVESTMENT PLANNING AND ASSET MANAGEMENT

Starting early in 2016, and informed by work completed on efficiency studies and business objectives described earlier in the DSP, the Investment Management team finalized an asset investment plan that forecast improvement of approximately 6% in SAIDI and 4% in SAIFI related to Hydro One's most significant areas of reliability performance over the five-year period. This "Plan A" was supported by detailed analysis, and the outcomes followed significant iteration and assessment of investment candidates and asset sustainment plans, as described in Section 2.1.

In an effort to explore solutions that align customer preferences, asset investment and rate impacts, Investment Management, as part of its process (see Section 2.1.5.1), also put forward a plan with lower levels of investment known as "Plan B". This plan proposed to deliver a reliability improvement of approximately 3% SAIDI, and 2% SAIFI.

Investment Management also assessed what would be required to achieve the lowest 2018 rate increase without material disruption to Hydro One operations. This "Plan C" scenario forecast a degradation of approximately 2% in both SAIDI and SAIFI.

The final subset of options considered was a scenario labelled "Plan B Modified." This scenario proposed a pacing of investments designed to minimize rate impacts while holding reliability performance constant and in line with customer expectations. Asset replacement rates are reduced for a short but manageable period.

Reliability Performance Impact Estimation

Reliability impacts for the proposed scenarios were modelled using the effect of relative investment impacts for:

- Vegetation Management;
- Pole Replacement; and
- Distribution Stations.

Reliability performance is affected by other factors. Other Line Components are also included in the forecast. However, the three asset areas listed above contribute the majority of reliability impacts, and represent the most significant, predictable drivers of reliability for which Hydro One has meaningful statistical data. The data allowed Hydro One to understand each option before deciding on a solution that aligned customer preferences, asset needs and rate impacts.

Below is a summary of the forecast of the primary sources and impact on reliability of the Distribution system. The SAIDI and SAIFI impacts were calculated on a high level estimate basis, using simplified assumptions and are approximate. The methodology to determine the link between percent changes in SAIDI and SAIFI for poles, distribution station, other line components and vegetation under investment plans A, B, C, and B-Modified is briefly summarized below.

Pole Replacement

Hydro One has extensive condition data on its pole population. Assets in poor condition have a higher probability of failure than assets in good condition. Hydro One's change in asset condition profile for its fleet of wood poles at the end of the planning period was projected under the various proposed investment plans. Current SAIDI and SAIFI reliability contributions due to pole failure were assumed to be indicative of the current asset condition profile for the wood pole fleet. Projected changes in the profile for the wood pole fleet condition were assumed to be directly proportional to improvements in SAIDI and SAIFI arising from changes in pole failure. If the condition of the wood pole fleet improved by a certain percentage then SAIDI and SAIFI would improve by a proportional percentage. This methodology was used to estimate the expected change to SAIFI and SAIDI under the various proposed investment plans.

Hydro One manages a population of 1.6 million poles, of which 106,000 require replacement. Inspections show that 67,000 are in poor condition and 39,000 are in the Red Pine pole set that need to be addressed due to premature failure. Outages due to pole failures average 345 annually, and each outage impacts an average of 185 customers for 10 hours. In total, pole failures contribute approximately 3% to SAIDI and 2% to SAIFI. In addition, as pole failures generally occur in the public domain (i.e., not in a Hydro One enclosed area); they also represent a public health and safety risk.

- Plan A proposed a reduction in the number of poles needing replacement from 106,000 to 93,000 by the end of the planning period (2022). The plan would reduce forced outages to 303 instances per year. Both SAIDI and SAIFI impacts from wood poles would improve by 12%.
- Plan B proposed a reduction in the number of poles needing replacement to 96,000 by the end of the planning period. It would reduce forced outages to 312 instances per year, improving reliability impacts from wood poles by 10%.
- Plan C forecast an increase in the number of poles needing replacement to 126,000 by the end of the period. Plan C would increase forced outages to 409 instances per year, decreasing reliability due to wood poles by 18%.
- Plan B-Modified proposed a reduction in the number of poles needing replacement to 99,000 by the end of the period. Plan B-Modified is forecast to decrease forced outages down to 321 instances per year, forecasting an overall improvement in reliability due to wood poles of 7%.

Distribution Stations

Defective equipment is the leading contributor to distribution station outage frequency and second highest contributor to outage duration. Defective equipment can be directly influenced by proactive asset replacements. The number of distribution stations in poor condition at the end of the planning period was projected under investment plans A, B, C and B-modified. Based on the projected distribution station profile under the various investment plans, Hydro One modelled the effects on reliability to estimate the corresponding impact on SAIDI and SAIFI.

Hydro One operates 1,005 stations, of which 70 are in poor condition. Currently, 16 stations per year, on average (23% of those in poor condition) require a station outage. Each outage affects an average of 1,200 customers for 24 hours and contributes 4% to SAIDI and 3% to SAIFI. Because of the distributed nature of these stations, a failure has consequential impacts. For example, failures often require redirecting a mobile station from a planned replacement underway and increasing cost. Also, a station failure will affect an entire community and that has major impacts if it occurs in cold conditions in Northern Ontario.

- Plan A proposed to replace all stations deemed to be in poor condition (70) by the end of the planning period (2022). SAIDI and SAIFI were forecast to improve by 14%.
- Plan B proposed to reduce the number of stations in poor condition to 40 by the end of the period. SAIDI and SAIFI were forecast to improve by 5% as a result.
- Plan C proposed a scenario that would lead to an increase in the number of stations in poor condition to 90 by the end of the period. SAIDI and SAIFI were forecast to degrade by 4% as a result.
- Plan B-Modified proposed a scenario that would maintain the number of stations in poor condition at 70 by the end of the period. SAIDI and SAIFI were forecast to change by 0% as a result of this factor.

<u>Vegetation Management</u>

Rights-of-way ("ROW") in need of vegetation management are assumed to contribute to a proportion of vegetation caused outages. Hydro One's change in km of ROW in poor condition and in need of vegetation management was projected under the various proposed investment plans. Changes to SAIDI and SAIFI reliability were estimated for the various investment plans based on the proportional change in km of ROW in poor condition.

Hydro One currently maintains 112,000 km rights-of-way that generate approximately 15,530 outages per annum due to tree contact. These outages contribute 27% to SAIDI and 16% to SAIFI. All scenarios include consistent spending on high priority rights-of-way, with targets to eliminate the backlog of off-cycle rights-of-way by 2022 (9% decrease of SAIDI, 9% of SAIFI).

- Plans A and B proposed a scenario wherein the work on medium or low-priority rights-of-way maintenance is reduced by 1,000 km/yr. This is forecast to cause an increase in the backlog of approximately 8%, and a degradation to both SAIDI and SAIFI of 1%. However, this decrease in maintenance is significantly offset by the 9% improvements in high priority rights of way for a total reliability improvement of 8%.
- Plan C would reduce maintenance by an additional 1,000km/yr. The increased backlog causes a forecast decrease in reliability of 2%. After factoring positive impact of rights of way, the net improvement in SAIDI and SAIFI falls to 4% from 8% envisioned in the other plans.
- Plan B-Modified includes the same levels of spending as Plans A and B.

Table 52 - SAIDI Projection for Investment Plan Scenarios

SAIDI[1]:	**Avg. 2013-15: 7.3 hours/year**	**Average Number of Hours that a Customer is Interrupted**					
	Assumptions			**Forecasted Impact on SAIDI by 2022[2]**			
	Failure Rate/Impact	**Contribution to SAIDI**	**SAIDI Contribution** (based on 2013-15)	**Plan A**	**Plan B**	**Plan C**	**Plan B-M[3]**
Poles	• 345 outages/year • 180 customers/outage • 10 hours/outage	3%	0.2	12%	10%	(18)%	7%
Stations	• 16 failures (outages) /year • 1200 customers/outage • 24 hours/outage	4%	0.2	14%	5%	(4)%	0%
Other Line Components	• 2070 outages/year • 180 customers/outage • 4 hours/outage	23%	1.5	10%	0%	(10)%	(5%)
Vegetation	• 15,530 outages/year	27%	1.8	8%	8%	4%	8%
Estimated Impact to SAIDI				**5%**	**2%**	**(2)%**	**0-1%**
Forecasted SAIDI (hours)				**7.0**	**7.1**	**7.4**	**7.3**

1-Excludes force majeure and loss of supply events
2 – These columns reflect the forecasted impact on SAIDI by then end of 2022. Estimated performance improvement is expressed as a positive value; performance deterioration is expressed as a negative value
3 – Impacts for "Plan B-M" refer to Plan "B-Modified" described earlier in this Section.

Table 53 - SAIFI Projection for Investment Plan Scenarios

SAIFI [1]:	**Avg. 2013-15: 2.6 outages/year**	**Average Number of Times a Customer is Interrupted**					
	Assumptions			**Forecasted Impact on SAIFI by 2022[2]**			
	Failure Rate/Impact	**Contribution to SAIFI**	**SAIFI Contribution** (based on 2013-15)	**Plan A**	**Plan B**	**Plan C**	**Plan B-M[3]**
Poles	• 345 outages/year • 180 customers/outage • 10 hours/outage	2%	0.1	12%	10%	(18)%	7%
Stations	• 16 failures (outages) /year • 1200 customers/outage • 24 hours/outage	3%	0.1	14%	5%	(4)%	0%
Other Line Components	• 2070 outages/year • 180 customers/outage • 4 hours/outage	18%	0.5	10%	0%	(10)%	(5%)
Vegetation	• 15,530 outages/year	16%	0.4	8%	8%	4%	8%
Estimated Impact to SAIFI				**4%**	**2%**	**(2)%**	**0-1%**
Forecasted SAIFI (instances)				**2.5**	**2.6**	**2.7**	**2.6**

1-Excludes force majeure and loss of supply events
2 – These columns reflect the forecasted impact on SAIFI by then end of 2022. Estimated performance improvement is expressed as a positive value; performance deterioration is expressed as a negative value
3 – Impacts for “Plan B-M” refer to Plan “B-Modified” described earlier in this Section.

Summary

As described in Section 1.1, Hydro One considered all the options in the context of customer preferences and reliability. The ultimate decision coming out of the planning process was to proceed with a hybrid plan referred to as Plan B-Modified, the plan described in this DSP. The plan's financial details are included in Section 3 below. Hydro One determined that this plan best aligned customer needs and preferences, responsible asset management and rate impacts. This plan adopts lower 2018 spending to minimize near term rate impacts. Reliability performance through the 2018-2022 period is forecast to be stable under this plan and consistent with recent system performance.

3.0 (5.4) CAPITAL EXPENDITURE PLAN

The requested capital expenditures result from the rigorous business planning and work prioritization processes described in detail in Sections 1.1 and 2.1. These processes reflect a risk-based decision-making approach to ensure appropriate and cost-effective investments that meet Hydro One’s Business Objectives and the RRF Outcomes.

Hydro One has right-sized its 2018 capital plan by increasing its efficiency and reducing its OM&A costs before asking customers to pay higher rates. The DSP reflects Hydro One’s plan to appropriately prioritize and pace its capital investments over the 2018 to 2022 period which will align: (a) customer needs to keep rates as low as possible and a preference to maintain current service levels; (b) asset needs driven by condition and compliance requirements; and (c) rate impacts.

The capital expenditures in this Application represent investments that will ultimately become in-service capital assets supporting the Hydro One distribution system. Specifically, these expenditures include:

a) planning, purchase, construction and commissioning of specific assets providing future economic benefits;
b) additions to or replacement of specific assets; and
c) betterments that result in improvement of capacity, efficiency, useful life span, or economy of specific assets.

Section 3.7 includes a list of all Investment Summary Documents (“ISD”) for material projects forecast over the five-year planning period. The materiality limit for ISDs for Hydro One, as listed in the OEB filing requirements, is $1 million in any single year.

<u>Category Descriptions</u>

Investment projects and activities have been grouped into one of the four OEB-defined investment categories:

System Access

System Access investments are modifications (including asset relocations) to the distribution system. Hydro One is obligated to perform to provide a customer (including a generator customer) or a group of customers with access to electricity services via its distribution system.

System Renewal

System Renewal investments involve replacing and/or refurbishing system assets to extend the original service life of the assets and thereby maintain the ability of Hydro One's distribution system to provide customers with electricity service.

System Service

System Service investments are modifications to Hydro One's distribution system to ensure that the system continues to meet operational objectives while addressing anticipated future customer electricity service requirements.

General Plant

General Plant investments are modifications, replacements or additions to Hydro One's distribution assets that are not part of the electricity distribution system; including land

and buildings, tools and equipment, rolling stock, electronic devices, and software to support day-to-day business and operations activities.

The Investment Summary Documents for all categories are included in Section 3.8.

3.1 (5.4.1) CAPITAL EXPENDITURE SUMMARY

Hydro One’s distribution capital expenditures for the historical, bridge and test years by OEB investment categories are summarized in Tables 54 – 57 in Section 3.2. In Hydro One’s last distribution rates application (EB-2013-0416), capital expenditures were summarized using the following categories: Sustainment, Development, Operating and Common Capital. To provide continuity between filings, the capital expenditures in this Application are also summarized by EB-2013-0416 categories. For clarity, a definition of Sustainment, Development, Operating, and Common Capital are provided below.

Distribution sustaining capital represents expenditures required to replace or refurbish existing components of the distribution system to ensure they will continue to function as originally designed. Opportunities to install distribution automation devices are considered and installed, where appropriate. The sustaining capital programs are subdivided into expenditures in three asset categories, Stations, Lines, and Meters

Development capital represents investments required to connect new load and generation customers, and to enhance or construct distribution facilities. These investments ensure the system’s capability to provide a secure and reliable supply of electricity in response to new large load customer connections, cumulative system-wide load growth and system demands associated with new generators.

Operations capital investments are required to implement, enhance, and modify the physical tools, systems and infrastructure used to operate the Hydro One distribution system. These investments provide performance improvements in the form of reduced outage duration, improved customer satisfaction, and accurate information for regulatory reporting as required by the Distribution System Code (DSC).

Corporate Common Costs expenditures support the Sustainment, Development, and Operations work programs of Hydro One Networks Inc. consisting of assets shared by Transmission and Distribution businesses. Corporate Common Costs include information technology, buildings, office equipment, transportation and work equipment, tools, and service equipment.

3.2 (5.4.1 B) CAPITAL EXPENDITURE FORECAST

Table 54 - Historical and Bridge Year Capital Expenditure Summary

Category	Historical and Bridge (previous plan and actual)										
	2013*	2014*	2015			2016			2017 Bridge

3.3 IMPACTS AFFECTING CAPITAL EXPENDITURES

Impacts affecting the capital expenditures that form the DSP are summarized in the list below.

1. The Regional Planning process identifies capital expenditure investments that should be undertaken by Hydro One to meet regional needs.
2. Hydro One's customer consultations identified customer needs and preferences. This customer and stakeholder input informed Hydro One in developing its investment plan, refine and shape the elements of its distribution rate application and helped to ensure that customer and stakeholder concerns were understood and addressed. This included right-sizing the capital expenditure budget for 2018 to specifically address the rate sensitivities of customers pursuant to Hydro One's distribution customer engagement process.
3. Hydro One conducted two benchmarking studies for significant capital investments: pole replacement and station refurbishment investments. These studies have resulted in changes to implementation of these investments, as described in the subsection below and in Section 1.6.
4. Hydro One's investment planning process prioritizes and selects, from a list of candidate investments posed by planners, those investments that best meet identified Business Objectives including those important to customers. The result of this process is the investment plan.
5. Hydro One will implement capital investments that will result in reduced OM&A annual costs. These capital expenditures include replacing old distribution stations with new stations, replacing oil reclosers with vacuum reclosers and moving off-road lines to on-road locations.

Further details on each item are included in the subsections below.

3.3.1 (5.4.1 A) CAPABILITY TO CONNECT NEW LOAD OR GENERATION CUSTOMERS

Hydro One is obligated to provide a connection service to new industrial, commercial, residential, seasonal and generation customers when requested under section 28 of the Electricity Act, 1998.

The division of costs between Hydro One and the customer is determined based on the Company's connection policies, which are in accordance with the DSC requirements. A basic load customer connection consisting of a service layout, overhead transformation, 30 metres of overhead conductor, and standard retail metering is provided free of charge to new customers that lie along the existing network, as per the DSC requirements. For customers that require expansion of the network in order to be connected, a discounted cash flow calculation is used to determine the net customer capital contribution. The capital contribution is based on any shortfall between estimated future revenues resulting from the connection and the cost of the connection and network expansion.

Most of Hydro One's distribution system is radial in design, with limited transfer capability to supply customers. Connections to Hydro One's distribution system are generally constrained by a variety of engineering factors, including but not limited to:

- equipment ratings;
- reverse power flow constraints in the case of generators;
- supply feeder current ratings;
- power quality; and
- remaining short circuit capacity at transmission stations.

Hydro One Distribution assesses system capacity capability to accommodate additional load through participation in the Regional Planning Process (described in Section 1.2.1) and through the following five main local distribution planning activities:

1. load vs. capability screening at the station and feeder levels;
2. planned feeder studies (six-year cycle studies);
3. system impact assessments for large new or increased service size requests for load connections;
4. assessment of field and customer identified issues related to power quality or other operating concerns; and
5. system impact assessments for large new or increased service size for generator connections.

Activities 1 to 4 are expanded in ISD SS-02 System Upgrades Driven by Load Growth and activity 5 is expanded on in ISD SA-05 Generation Connections.

There are two main determinants in the determination of capacity - Station Capacity and Feeder Capacity.

Station Capacity

When investigating the ability to connect additional customers, Hydro One determines the available capacity at a Station asset by considering the thermal capacity of the transformers at the distribution station, as well as protection device ratings and settings. Station upgrade is required if the additional load causes the transformer thermal capacity or protection device ratings to be exceeded. For generation connection investigation, the reverse flow capacity of the transformer and protective device, and short circuit capacity at the distribution station are also considered.

Feeder Capacity

Capacity determinations at a feeder level are made by considering the thermal rating of equipment on the feeder, voltage drop along the feeder as well as the phases on which the loads are connected. Feeder upgrade is required if the additional load causes equipment rating to be exceeded or causes the voltage along the feeder to be outside of the acceptable range of 0.94 to 1.06 p.u. For generation connection, short circuit level, distance from station to the generation, loading vs. generating balance, and interrupt rating of protection devices are also considered.

Outlook

Hydro One's forecasts for load and customer growth (See Section 2.1.2) are relatively flat. Average annual change in load over the planning period is -0.3%. The average change in customers over the planning period is +0.7%[1]. This means that growth is relatively flat on an overall system basis. However, in many areas, especially on the outskirts of urban areas, Hydro One experiences significant growth. These local regions comprise most of the customer increase. Certain assets will require testing to ensure capacity can be met.

Through the Regional Planning Process and local distribution planning activities Hydro One anticipates the need for the following projects to address local capacity limitations.

Regional Planning Projects:

- Dundas TS #2 Feeders, ISD SS 02 Project LG-28
- Enfield TS - capital contribution, ISD GP-27
- Enfield TS Feeder Development, ISD SS-02 Project LG-11
- Leamington TS Capital Contribution, ISD GP-25
- Leamington TS Feeder Development, ISD SS 02 Project LG-14
- Kingston Gardiner TS M26 Feeder Development, ISD SS-02
- Hanmer TS Capital Contribution, ISD GP-26
- Hanmer TS Feeder Development, ISD SR-13 Project LC-10

Identified Through Distribution Planning Activities:

- Cumberland DS F4 Development, ISD SS-02 Project LG-1
- Devlin DS F1 3 Phase Upgrade, ISD SS-02 Project LG-2

[1] Load and customer forecasts provided here exclude Acquired Utilities.

- Kleinburg TS M6 Mayfield Rd Line Extension, ISD SS-02 Project LG-3
- Orangeville TS M3 - Mayfield West Line Extension, ISD SS-02 Project LG-4
- New Bradford North DS, ISD SS-02 Project LG-5
- Caledonia TS M3 Extension, ISD SS-02 Project LG-6
- Alfred DS F2 Feeder Upgrades, ISD SS-02 Project LG-7
- Cameron DS Feeder Improvements, ISD SS-02 Project LG-8
- Armitage TS M22 Extension, ISD SS-02 Project LG-9
- City of Owen Sound Tie-Line Reinforcement, ISD SS-02 Project LG-10
- Grand Bend DS F3 Voltage Conversion, ISD SS-02 Project LG-12
- Kirkland Lake Voltage Conversion – Part 1, ISD SS-02 Project LG-13
- Manotick DS Feeder Development, ISD SS-02 Project LG-15
- Stouffville 10th Line DS New T3 & Feeder, ISD SS-02 Project LG-16
- Town of Shelburne Voltage Conversion, ISD SS-02 Project LG-17
- Twelve Mile Bay DS - New Station & Feeders, ISD SS-02 Project LG-18
- Beckwith DS F3 Feeder Development, ISD SS-02 Project LG-19
- Crilly DS Replacement and Transformer Upgrade, ISD SS-02 Project LG-20
- Kirkland Lake Voltage Conversion-Part 2, ISD SS-02 Project LG-21
- Manotick DS F3 New Feeder, ISD SS-02 Project LG-22
- Margach DS F3 Voltage Conversion - SW676, ISD SS-02 Project LG-23
- Muskoka TS M5 x M1 Feeder Tie, ISD SS-02 Project LG-24
- Rockland DS T2 Transformer, ISD SS-02 Project LG-25
- Barrie TS - Construct New Feeders, ISD SS-02 Project LG-26
- Caledonia TS New Feeders, ISD SS-02 Project LG-27
- King City DS - New Station & Feeders, ISD SS-02 Project LG-29
- New Old School DS, ISD SS-02 Project LG-30
- Town of Dundalk Voltage Conversion, ISD SS-02 Project LG-31
- Greely DS F1 Feeder Development, ISD SS-02 Project LG-32
- Kirkland Lake Voltage Conversion-Part 3, ISD SS-02 Project LG-33
- Midhurst Wilson DS F2 Extend to Doran Rd, ISD SS-02 Project LG-34
- Midhurst Wilson DS F1 Extend to Dobson Rd, ISD SS-02 Project LG-35
- Perth Area Upgrades, ISD SS-02 Project LG-36
- Macville DS - New 27.6kV Station, ISD SS-02 Project LG-37
- Wikwemikong DS & Line Work, ISD SS-02 Project LG-38
- Dunchurch DS F2 - Extend to Magnetawan, ISD SS-02 Project LG-39
- Fairbanks Lake Line Upgrade, ISD SS-02 Project LG-40
- Kleinburg TS M26 extension to Mayfield West, ISD SS-02 Project LG-41

- Lively DS F2 SW142 Upgrade Black Lake Road, ISD SS-02 Project LG-42
- Mar DS – New Station, ISD SS-02 Project LG-43
- Ancaster West DS Transformer Upgrade, ISD SS-02 Project LG-44
- Brockville 44kV System Upgrades, ISD SS-02 Project LG-45
- Manitoulin TS - Add Third 44 kV Feeder, ISD SS-02 Project LG-46
- Point Au Baril DS F2 Extension, ISD SS-02 Project LG-47
- Aspdin DS F1 Feeder Upgrade, ISD SS-02 Project LG-48

Generator Connection Requests:

- Kirkland Lake TS – DX Feeders, ISD SA 05
- Wendover HVDS – DX Feeders, ISD SA 05
- Muskoka TS – DX Feeders, ISD SA 05

Hydro One expects full capability to meet customer needs for connections over the planning period. ISD SA-04 includes the specific capital spending planned on New Load Connections and ISD SA-05 includes the details regarding Generation Connections.

3.3.2 (5.4.1 C) IMPACTS OF INVESTMENT PLANNING PROCESS

Hydro One completes a detailed investment planning process annually to identify and implement a plan that aligns customer needs and preferences, the needs of the system and its assets, and rate impacts. The RRF Outcomes and Hydro One's Core Values lead to a set of Business Objectives that are fundamental to that process. Each objective is assigned a weighting to guide the prioritization of the potential candidate investments. Details regarding the derivation of the Business Objectives and their alignment with the RRF Outcomes are included in Section 2.1.1. Specific details regarding the investment prioritization stage of the process are included in Section 2.1.5.

How these objectives impact investments in each category is discussed below. The impact of customer consultation on the business plan will be expanded upon separately as Hydro One has undertaken extensive customer consultation and has used the results to drive changes to the investment plan so that it more closely aligns with customer expectations and preferences.

System Access

Hydro One will invest more than $100 million per year in new distribution load customer connections and service upgrades for existing distribution customers (ISD SA-04). The investment meets customer needs and fulfills a regulatory requirement to connect new customers. System Access investments do not materially impact reliability.

Line relocation due to municipal, joint use tenant and land owner requests requires more than $20 million annually (ISD SA-01). These requests must be fulfilled to comply with joint use agreements and property owner expectations. The main outcome achieved is public policy responsiveness by complying with requests from land owners and other utilities.

System Renewal

The pole replacement program is the largest investment in the System Renewal category with a plan to invest an average of $115 million annually (ISD SR-09). Hydro One has approximately 1.6 million poles, of which 67,000 poles are currently in poor condition. Furthermore, each year, approximately 9,000 more poles are identified as being in poor condition. Investing in poles that are in poor condition seeks to minimize risks to public safety and improve reliability which improves customer experience. The current level of investment is expected to contribute to maintaining current levels of reliability.

Investments are also made to move poor condition poles that are located in off-road corridors onto road allowances with less vegetation interference thus improving reliability performance and shortening outage times for customers (ISD SR-12). Proactively moving poles onto road allowance also results in productivity benefits that improve operation efficiency as locating and repairing damaged poles in off-road corridors is time consuming.

Another significant program is distribution station refurbishments (ISD SR-06). These investments are prioritized based on asset condition and reliability performance. A new strategy of installing low profile stations with significantly fewer structures is expected to reduce the unit cost of the station refurbishment. The new design is expected to improve reliability as there are fewer components that can fail. The reduced cost and maintenance requirements will improve financial performance in this program.

System Service

Hydro One plans to invest $28 million between 2018 and 2022 to implement remote meter functionality (ISD SS-01). This investment will drive significant productivity gains and improve Hydro One’s operational efficiency as it will reduce the need for staff to physically travel to the meter to perform certain functions. The current level of investment is expected to contribute to maintaining current levels of reliability.

Approximately $50 million has been allocated to improve the reliability of the feeder performance outliers on the Hydro One distribution system (ISD SS-06). One strategy to improve reliability will be to strategically deploy electronic reclosers to reduce outage duration. Electronic reclosers reduce outage duration by sending information about the fault location to the OGCC which reduces the time for repair crews to locate the fault. Other strategies will be deployed such as addressing vegetation encroachment and assets in degraded condition that are contributing to poor reliability.

Hydro One will invest approximately $19 million per year on average to solve power quality and reliability issues that are raised by customers or identified by Hydro One asset inspections or system studies (ISD SS-03, SS-04, SS-05). These investments allow Hydro One to continue to operate the distribution system in compliance with the DSC and provide targeted reliability improvements in areas where customers have expressed concerns about reliability performance.

General Plant

Between 2018 and 2020, $56 million will be allocated to Hydro One Distribution to build an Integrated System Operation Centre ("ISOC") to ensure the continued safe and reliable operation of the Hydro One distribution system (ISD GP-18). The ISOC will provide a backup operation and telecommunication management centre as well as a security operation centre. The existing facilities no longer meet North American Electricity Reliability Corporation ("NERC") standards due to increasing failures of critical infrastructure. The investment will maintain Hydro One's compliance with regulatory standards which contributes to public policy responsiveness. General Plant investments do not materially impact reliability.

Hydro One will invest $200 million between 2018 and 2022 to keep the 7,800 fleet units operating safely (ISD GP-01). Vehicles are maintained at an optimal level to ensure public and employee safety and meet regulations such as the *Highway Traffic Act* which ensures Hydro One is in alignment with public policy. Hydro One has shown a positive trend in fleet utilization over the past 15 years, which reflects productivity and operational efficiency improvements.

3.3.3 (5.4.1 E) IMPACTS OF REGIONAL PLANS

Hydro One actively participates in the Regional Planning process to address supply and reliability issues on a regional level. Distribution-level investments are undertaken when they can address a regional need more effectively than transmission or resource options. A description of how Hydro One engages in the Regional Planning Process is contained in Section 1.2. The major investments that the Regional Planning Process identified are captured below:

Enfield TS Capital Contribution and New Feeders

Significant load growth in the Durham region will cause the existing Wilson TS to be overloaded. Hydro One Distribution will contribute $3 million between 2018 and 2019 towards building Enfield TS to offload Wilson TS (ISD GP-27). Hydro One Distribution will also invest about $7 million in the same time period to build feeders out of the new Enfield TS to pick up the load from Wilson TS (ISD SS-02, LG11).

Leamington TS Capital Contribution and New Feeders

Significant load growth in the municipalities of Leamington and Kingsville will cause the existing Kingsville TS to be overloaded. Hydro One Distribution will contribute $2.2 million in 2018 towards building Leamington TS to offload Kingsville TS (ISD GP-25). Hydro One Distribution will also invest $3.7 million in the same time period to build feeders out of the new Leamington TS to pick up some load from Kingsville TS as well as accommodate new load connections (ISD SS-02, LG-14).

Hanmer TS Capital Contribution and New Feeders

Coniston TS supplies the East Sudbury area and is in poor condition. The Regional Infrastructure Plan for Sudbury/Algoma proposed a new station called Hanmer TS to replace Coniston TS and supply future load growth in the area. Hydro One Distribution will make a $4 million capital contribution between 2018 and 2019 (ISD GP-26).

3.3.4 (5.4.1 F) IMPACTS OF CUSTOMER ENGAGEMENT FEEDBACK

Hydro One recognizes the need to have customer needs and preferences inform the business plan. External consultant Ipsos was retained to develop and lead a customer engagement process. This process included a number of opportunities to interact with Hydro One distribution customers including surveys, focus groups, one-on-one meetings and call centre interactions. The details of this process and full results are detailed in Section 1.3.1.

The results of the Ipsos work and Hydro One's on-going engagement with its customers indicate that they are very sensitive to costs; especially in the residential and small-business segments. Moreover, reliability was also a key concern, along with power quality for large customers.

Hydro One is listening to its customers and, in order to address their concerns, has incorporated a number of initiatives into its investment plan which are described below.

- Hydro One is deliberately deferring early year capital investments to pace investments so as to minimize rate impacts and offset the effects of a reduced load forecast. This includes managing rate of replacement and, where appropriate, accepting decreased levels of reliability performance to minimize rate impacts;
- Hydro One is implementing numerous productivity enhancements, which will ultimately lead to lower costs for customers. These initiatives are detailed in Section 1.5;
- Hydro One is implementing a program to install power quality meters when needed to assist in power quality investigations and improve on-going power quality for large customers with sensitive equipment;
- Hydro One is increasing spending on feeders where sensitive large and mid-size industrial customers are connected in order to improve reliability and reduce costly outages (ISD SS-03); and

- Hydro One is targeting reliability investments on feeder performance outliers (ISD SS-06) in the Hydro One portfolio to improve reliability for customers affected by poor reliability.

3.3.5 (5.4.1 F) IMPACTS OF BENCHMARKING

After Hydro One's last distribution rate application, the OEB directed Hydro One to undertake several benchmarking studies and submit the results. Two of these studies were directly related to capital investment programs: the pole replacement and station refurbishment programs. The complete benchmarking findings are in Section 1.6. The findings relevant to capital investments are summarized below.

Pole Replacement Program

The pole replacement benchmarking study found that Hydro One had a short inspection cycle but completed less comprehensive inspections than industry average. Hydro One plans to seek regulatory approval to lengthen the DSC-mandated inspection cycle and complete more comprehensive inspections.

Station Refurbishment Program

The station refurbishment benchmarking study recommended that Hydro One incorporate test results and maintenance history for switching and protection equipment into the decision-making process for station refurbishment. The study also recommended that Hydro One enhance cost and work completion reporting as well as implement a set of Key Performance Indicators ("KPIs") to track project cost and asset health. These recommendations have been implemented into the station refurbishment program (ISD SR-06)

3.3.6 (5.4.1 G) SYSTEM DEVELOPMENT FORECAST OVER THE PLANNING PERIOD

Hydro One's work programs and upgrades consider future distributed generation plans and load trends. Since the start of the FIT program in 2009, Hydro One has seen a substantial increase in distributed generation connections with over 14,250 connected to date. Various IESO incentive programs drive future growth of distributed generation connections. From 2017 to 2022, Hydro One is forecasting the connection of over 3,400 new distributed generators. More details are available in Section 3.5.2.

Hydro One is continuing its efforts to make the distribution system more efficient and reliable. By investing in its smart grid project, Hydro One is piloting, testing, and validating smart grid capabilities on a larger scale to enable distributed generation integration, improve reliability and operations, and enhance outage restoration and network planning. Work on establishing the foundation for the smart grid project is expected to be completed by 2018.

Hydro One has also started its multi-year program to deploy distribution automation and fault location to its feeders. This program will install devices on the distribution feeders and distribution substations that will be able to be controlled and monitored centrally. These investments are expected to help maintain reliability in the face of aging assets.

New control systems have been established at the Ontario Grid Control Centre that will leverage the new distribution automation and fault location devices on the distribution network. With this foundational technology, Hydro One will be better able to locate faults and reconfigure the distribution network from the control centre. This investment will enable more work to be done in the control centre creating some operational efficiency as well as reduce sustainment effort. This will translate to total annual savings of $4 million of OM&A.

Hydro One is leveraging its investments in smart meters to improve operational decision making. New systems have been established that enable Hydro One to utilize smart meters to identify and isolate outages as well as confirm power restoration. This investment is expected to achieve a fifty percent reduction in unnecessary truck rolls. This will translate to total annual savings of $2 million of OM&A.

With additional intelligent devices on Hydro One's distribution network, new data streams can be leveraged to improve distribution planning and operations. By leveraging data from the existing smart meters and the newly installed distribution automation devices, Hydro One will be able to produce new analytics that enable deeper insights into the distribution system. This includes more granular identification of distribution network loading.

3.3.7 (5.4.1 H) LIST OF PROJECTS PLANNED TO ADDRESS CUSTOMER, TECHNOLOGY, AND INNOVATION

The following is the list of the projects planned in response to Customer Preferences.

Table 58 - Projects in Response to Customer Preferences

ISD #	Name	Total Cost ($M)
SS-06	Worst Performing Feeders	49.9
GP-16	Customer Self Service Technology	12.9
GP-29	Customer Service Billing Investments	10.4
GP-30	Customer Service Regulatory Changes and Pricing Options	14.0
GP-32	Customer Data and Analytics	9.9
GP-33	Customer Service Complaint Management Tool	3.3

The following is the list of the projects planned to take advantage of technology opportunities.

Table 59 - Projects to Take Advantage of Technology Opportunities

ISD #	Name	Total Cost ($M)
SS-01	Remote Disconnection / Reconnection Program	28.5
SA-03	AMI Network Expansion	14.3
GP-12	Business Process Consolidation	2.7
GP-13	HR and Pay Related Technology Investments	5.0
GP-14	Warehouse Scanning Device Replacement	1.8
GP-31	Collection Enhancements	6.1

The following is the list of the projects planned to study or demonstrate innovative processes, services, business models or technologies.

Table 60 - Projects Driving Innovation

ISD #	Name	Total Cost ($M)
SS-07	Advanced Distribution System	5.0
GP-07	Corporate Performance Reporting	3.5
GP-08	PCMIS Modernization and Optimization	1.6
GP-17	S4 HANA for Finance and Enterprise Asset Management	6.5
GP-35	Asset Analytics Risk Factor	2.0

3.4 (5.4.2) CAPITAL EXPENDITURE PLANNING PROCESS OVERVIEW

The capital expenditure planning process is part of Hydro One's Asset Management process. Hydro One's asset management goal is to identify and scope the optimal timing of capital investments and asset maintenance throughout the life cycle of its assets. This is done to manage risks and to support the achievement of Hydro One's Business Objectives, while managing total cost and customer rate impacts.

Investment Planning Process

For the planning of capital investments, Hydro One utilizes a comprehensive investment planning process for identification, prioritization and optimization of asset and capital investments. Details of the planning process are included in Section 2.1.

3.5 (5.4.3) DISTRIBUTED GENERATION CONNECTIONS

Distributed Generation ("DG") refers to small-scale generators that connect to the distribution system and produce electricity to serve local areas. DG Connections include the assets to support over 14,000 DG projects supplying approximately 2,500 MW of generation capacity. These projects are primarily solar and wind installations that range in size anywhere from a few kW to several MW.

Hydro One's asset strategy for distributed generation connections is to meet its distribution license requirements to connect generators that meet the principles set out in the Distribution System Code ("DSC"), and to perform Renewable Enabling Improvements (as defined in the DSC) to allow for the connection of DGs. In addition, all work is done in a timely fashion in order to meet customer schedules and maximize customer satisfaction.

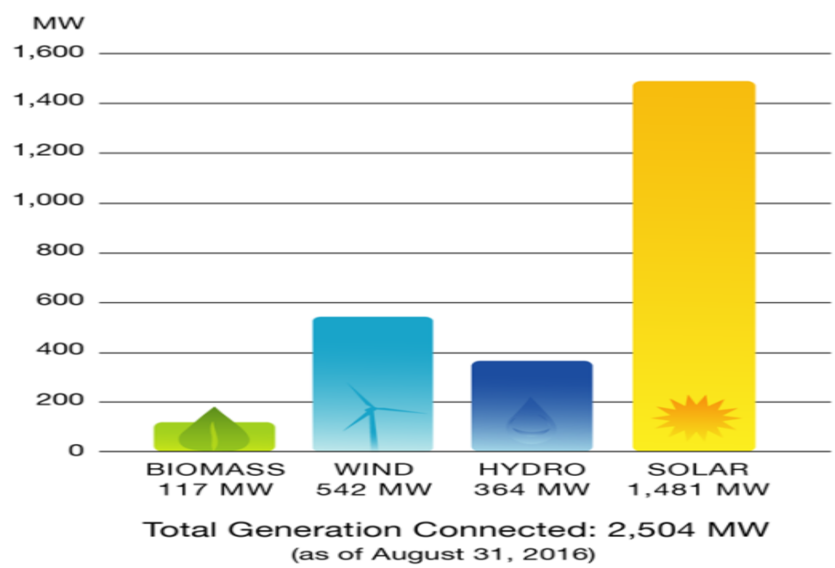

Figure 44 - Renewable Generation Connections

** Approximately 145MW of generation come from various sources other than those listed here for a total of 2,649.*

Witness: Lyla Garzouzi

3.5.1 (5.4.3 A) RENEWABLE APPLICATIONS

The Renewable Energy Standard Offer Program ("RESOP") launched by the Ontario Power Authority ("OPA") in 2006 attracted a tremendous amount of interest in connecting renewable energy generation to distribution systems in Ontario. Hydro One received the majority of the applications under this program in its large, rural service territory. The cost for connecting the RESOP projects to Hydro One's distribution system was 100% recoverable from the generation customer.

In 2009, the OPA launched the Feed-in Tariff ("FIT") program and the OEB amended the Distribution System Code ("DSC") to facilitate the FIT program. The FIT prices paid to developers for the renewable energy produced were higher than RESOP. In addition, there was a change in cost allocation of distribution investment costs to be borne by the generation customers and the distributor. The revised DSC required Hydro One to fund a portion of the expansion cost (up to $90,000/MW) and 100% of Renewable Enabling Improvement ("REI") investments for renewable energy generation projects. The generation customer paid for connection assets, the expansion cost exceeding $90,000 per MW, and upstream station upgrades, if required.

3.5.2 (5.4.3 B) CONNECTION FORECAST - DISTRIBUTED GENERATION

The vast majority of DG and renewable connections are for small, microFit projects. These units possess a generation capacity of 10kW or less per unit and comprise less than 10% of the capacity of the DG connections on the system. At time of writing, Hydro One has received over 13,885 applications and has connected 13,429 with a total capacity of 121.8 MW of generation.

Among the larger generators, since 2010 Hydro One has received over 1,140 applications for connections greater than 10kW. So far 989 generators have been connected with a total capacity of approximately 2,025 MW.

Based on the definitions in the DSC, Hydro One classifies DGs into four categories for planning purposes.

1. Capacity Allocation Required ("CAR"), this includes large DGs, mid-sized DGs and Small embedded DGs that are not capacity allocation exempt;
2. Capacity Allocation Exempt ("CAE");
3. Capacity Allocation Exempt generators that are Net-Metered ("CAE-NM"); and
4. Micro embedded (10kW or less) – including MicroFIT.

Table 61 details the additions to the system in terms of quantity and capacity of generation projects from each of the four segments.

[1] Approximately 502 MW of DG was connected prior to 2010.

The following Government initiatives have recently been put in place through the IESO (formerly OPA) to procure renewable energy for the province of Ontario.

- The FIT 4.0 procurement has concluded as the Independent Electricity System Operator (IESO) prepares to offer 936 new Feed-in Tariff (FIT) renewable energy contracts as per IESO website link given below. These FIT 4.0 contracts represent 241 MW of power.[2] Out of 936 new CAR and CAE contracts assigned by the IESO under FIT 4.0 program, 379 are in Hydro One territory.
- The FIT 5.0 Program was created to procure an additional 150MW of capacity of all capacity allocation types (CAR and CAE). Fit 5.0 will also classify microFIT projects as CAE due to the cancellation of the microFIT program at the end of 2017.[3] The process of assigning contracts under the FIT 5.0 program is complete and its application period opened on October 31, 2016.
- The Hydroelectric Standard Offer Program (HESOP) was developed to procure new hydroelectric capacity in Ontario in two streams. The municipal stream procured a total of 10MW of CAR projects between 500kW and 5MW and 50MW of CAR projects 5MW or larger. In addition the expansion stream had a procurement total of an additional 40MW.[4]
- The Combined Heat and Power Standard Offer Program (CHPSOP) 2.0 was developed to support the efficient use of gas-fired electricity generating facilities that use combined heat and power (CHP) technology. It procured 92MW of CAR projects each up to maximum of 20MW in size.[5]

[4] http://www.powerauthority.on.ca/hesop
[5] http://www.powerauthority.on.ca/combined-heat-power-procurement

- The Energy Storage Procurement Program was developed to explore the use of energy storage on Ontario's grid and has resulted in total of 50.3MW of CAR projects being connected in two phases.[6]
- The Large Renewable Procurement (LRP) I process concluded in April 2016, with the execution of 454.885 megawatts of new wind, solar, and waterpower contracts as per IESO directive.[7] There are nine LRP1 contracts for total of 57.4 MW under Hydro One distribution territory.

Based on the Government directive and procurement targets and DG connection investment carryovers of the previous Renewable Energy Standard Offer Program ("RESOP") and FIT program, the number of projects forecast for 2017 to 2022 is shown in the Table 62. The corresponding data source is listed for each group. Notable in this forecast is the change in volumes for small generation from the microFIT program to a net metering program.

Table 62 - Forecast DG Connections – 2017-2022

		Forecasted					
Year		2017	2018	2019	2020	2021	2022
CAR	Projects	8	6	5	5	5	5
CAE	Projects	200	200	170	160	110	110
CAE Net Metered	Projects	17	295	280	305	335	370
Micro Embedded	Projects	500	200	200	20 0	200	200

3.5.3 (5.4.3 C, D, E) CAPACITY AND CONSTRAINTS – DISTRIBUTED GENERATION

The capacity required to connect the forecasted level of DG connections is available on different distribution stations all across the Hydro One distribution system. Hydro One provides information on station capacity in order to provide potential generation customers with assistance in determining a suitable location for their generation projects.

The Hydro One distribution system is radial in design, with limited transfer capability in the supply to customers. The system was designed with a forward power flow direction with the supply coming from the transmission system flowing downstream to the customers.

When distributed generation is connected to Hydro One's distribution system it may lead to operational issues that must be assessed and addressed before connections can be made. First, under certain conditions, power may flow in the reverse direction leading to required protection system upgrades to ensure effective operation of the protection system in all situations. Second, the reverse power flow may also lead to an unacceptable voltage rise above the Distribution System Code limits, requiring Hydro One to upgrade system equipment. Finally, added generation sources lead to increased fault current levels and may require that protective devices be replaced and upgraded to meet the new fault levels.

Operational issues stem from the DG fault current contribution and potential reverse power flow as a result of the DG connection. Reverse power flow may lead to unacceptable voltage increases in the distribution system, which would necessitate upgrades to the voltage regulating devices or conductor size to mitigate this effect. Reverse power flow through metering devices will require replacement with bi-directional devices. DG fault contribution leads to increased fault levels and may require protective devices to be replaced with higher interrupting ratings. The DG fault contribution may also cause mis-operation of existing protection equipment, requiring bi-directional protective devices be installed.

The amount of generation capacity connected to Hydro One's distribution system is constrained by a variety of engineering factors, including but not limited to:

- Equipment ratings;
- Reverse power flow constraints;
- Supply feeder current ratings;
- Power Quality; and
- Remaining short circuit capacity at TS stations.

The impacts of connecting potential generators are studied on each application. Upgrades to both lines and stations equipment may be required to mitigate the above factors and ensure that unsafe flows do not occur.

A local distributor embedded within Hydro One's distribution system that is seeking to connect a new generator to its system would need to account for the same factors as a generator connecting directly to Hydro One's distribution system. Equipment ratings, power flow constraints, and short circuit impacts on the embedded distributor and Hydro One systems would need to be studied for each connection application. Upgrades may be necessary at both distribution and/or transmission stations to mitigate these factors.

3.6 (5.4.4) CAPITAL EXPENDITURE SUMMARY

Table 63 - (Table 2) Capital Expenditure Summary

CATEGORY	Historical (previous plan and actual)											Forecast (planned)				
	2013 [1]	2014 [1]	2015			2016			2017 Bridge [2]			2018	2019	2020	2021	2022

1) 2013 and 2014 were IRM years and therefore do not have Board-approved capital expenditure figures.

2) Bridge year 2017 is a forecast as of end of 2016

3) System OM&A values include all Operations, Maintenance and Administration expenses.

For explanatory notes on Shifts in Forecast vs. Historical Budgets by Category, please see Section 3.6.1.

For explanatory notes on Plan vs. Actual Variance Trends by Category, please see Section 3.6.2.

3.6.1 (5.4.4 – TABLE 2) SHIFTS IN FORECAST VS. HISTORICAL BUDGETS BY CATEGORY

System Access

System Access investments are expected to modestly decrease from historical levels in 2018 continuing the trend from 2014. The decrease is primarily due to the completion of the advanced meter infrastructure investment for the planned phase out of CDMA technology in meters and collectors in 2017 and a decrease in spending for generation connections (ISD SA-05). From 2018 to 2020 system access investments are expected to increase marginally until 2021 and 2022 where there is an increase due to the incorporation of the Acquired Utilities (Norfolk, Haldimand, and Woodstock) which are incorporated into the investment plan in 2021.

System Renewal

System Renewal spending will gradually increase above historical levels starting in 2019. The additional spending is required to replace end-of-life wood poles (ISD SR-09), relocate off-road feeders that are currently on poles in poor condition (ISD SR-12), and refurbish distribution stations (ISD SR-06). The increased spending is needed to address an aging infrastructure, characterized by a large number of assets in poor condition. The objective over the planning period is to maintain reliability performance and this level of spending is designed to accomplish this objective. In 2022, there is a significant increase forecast in System Renewal spending due to the planned replacement of Hydro One's metering infrastructure that is reaching end of life (ISD SR-14).

System Service

System Service spending will remain within historical spending levels from 2018 to 2022. This represents a decrease as compared to previous budget amounts. This reflects a more realistic stance on the ability to complete the necessary work.

General Plant

General Plant spending increased in 2016 above historical levels and is projected to continue to increase through 2019 before decreasing. The increases from 2017 to 2019 are attributed to: (a) capital contributions to three major transmission projects (ISD GP-25, GP-26, GP-27); (b) an increase in real estate spending to replace end of life operation centres or accommodate an increase in operational activity (ISD GP-02); (c) a major investment in the Integrated System Operating Centre which is required to maintain compliance with several regulatory requirements (ISD GP-18); and (d) IT investments to implement mandated billing changes (ISD GP-30), improve customer service (ISD GP-28, GP-32, GP-33) and improve work efficiency and planning (ISD GP-10, GP-11).

3.6.2 (5.4.4 – TABLE 2) PLAN VS. ACTUAL VARIANCE TRENDS BY CATEGORY

System Access

From 2013 to 2014 there was an increase in System Access spending of about $40 million. This increase was due to unplanned defective meter replacement, the initiation of the phase out of CDMA technology in meters and collectors and an increase in demand driven customer connection requests. Overall spending across System Access investments for 2015 and 2016 was generally in line with plan levels. However, $42 million above planned spending was caused by an accelerated meter replacement investment. Hydro One planned to phase out CDMA technology in meters and collectors over a five-year period, but this was compressed to two years because a vendor declined to support the technology beyond the two-year window. This increase was offset mostly by a reduction in generation connections. Hydro One had forecast $55 million of connection work, but due to the withdrawal of several connection applications, the actual work completed totalled $23 million.

System Renewal

In 2015, System Renewal projects were $58 million above planned spending. Most of that variance is attributable to the following 4 items. A total of $29 million was due to increased spending on distribution station refurbishment projects to address the high number of stations in poor condition. Increased work on line relocation projects, for the purpose of improving access and reliability, contributed $13 million to the overage. Projects from previous years were under construction and had significant portions carry over into 2015. Increased storm damage and trouble call activity contributed another $14 million to the spending above planned levels.

System Renewal investments for 2016 were $23 million above plan. Spending on storm, trouble call and post-trouble response was the largest source of variance at $22 million above planned levels. Distribution station refurbishments and line sustainment projects, for the purpose of improving access and reliability, accounted for $15 million and $4 million of the overage, respectively. Pole replacement program spending was $5 million less than planned. Additionally, station spare transformer purchases and PCB equipment replacement spending were $12 million and $3 million less than planned, respectively.

The current 2017 forecast for System Renewal investments is $33 million below the previous approved plan due to deferral of the PCB Equipment Replacement Program to future years, a decrease in the Pole Replacement Program, a decrease in Distribution Line Sustainment Initiatives and a decrease in Distribution Station Refurbishments as a result of reprioritized spending into General Plant investments, which are elaborated on below.

System Service

System Service investments were $49 million below planned investment levels in 2015 and $26 million below planned spending in 2016. The 2015 variance is due primarily to a $17 million variance attributable to a delay in the start of the Advanced Distribution System project. Several initiatives of this project were delayed to start in 2016 to align with other related investments. Also, $27 million in 2015 and $25 million in 2016 below planned spending levels were due to a reduction in spending on investments related to distribution system expansion. These investments were reprioritized to accommodate unforeseen increases in other areas of capital spending.

The current 2017 forecast for System Service investments is $43 million below the previous approved plan primarily due to a reduction in investments for System Upgrades driven by load growth as a result of reprioritized spending into General Plant investments, which are elaborated on below.

General Plant

The General Plant over spending in 2015 ($15 million) and 2016 ($43 million) was primarily a result of the following investments:

- $8 million of the overage in 2015 is due to the implementation of efficiencies in the Customer Service Organization's (CSO) operations needed to receive reduced pricing specified on the CSO's single source agreement with Inergi LP;
- $8 million above planned spending in 2015 was due to the Telematics Project undertaken by Hydro One Fleet Services. This project was not planned at the time of the rate filing however it was undertaken to realize productivity efficiencies in the fleet operations from 2017 onward. The Telematics Project will allow Hydro One to lower costs related to fleet operation by reducing non-productive idling and speeding as well as increase the overall fleet utilization;
- $9 million above planned spending in 2016 was to implement customer alert and analytics functionalities. Customers will be alerted if their consumption is trending higher than a pre-defined threshold and receive personalized insights and program promotions. Customers will be able analyze their energy usage through an enhanced web portal. As a result of these investments, Hydro One anticipates improved customer experience and satisfaction, increased customer engagement, and ultimately a reduction in calls to the call centre;
- $6 million above planned spending occurred in 2016 to redesign the Hydro One website to make it more user-friendly to address customer concerns about performance, navigability and mobile responsiveness. The customer “My Account” portal will be upgraded to improve customer experience. The intended result is improved customer satisfaction with the portal, increased customer engagement, and a reduction in calls to the call centre;
- $10 million above planned spending occurred in 2016 to make improvements to SAP, Hydro One’s integrated financial planning, work management and billing environment. Several improvements were implemented and are listed below:

- A new testing environment was implemented to simplify bi-annual rate changes and will reduce costs associated with future system updates;
- The financial reporting module was approaching end of support and was updated to the latest version. The new version of the software automates several financial reporting processes and will reduce the time and manual effort to produce reports while increasing reporting accuracy; and
- The billing module was updated to improve the accuracy of monthly bills and to track unbilled revenue. The module was also updated to improve the collections process by enabling security deposit functionality and fraud checking.

- $10 million of the overage in 2016 was due to the construction of a new Bolton operation centre, which provides a permanent location for field crews. This will reduce costs via lower commute times to work sites and increase service response to a high growth area of Hydro One's service territory; and
- $7 million of the overage in 2016 was due to the "Move-to-Mobile" project. This goal of this project is to increase operational efficiency by improving the use of technology by field staff. Field staff and schedulers will have real-time information updates which will reduce manual administrative effort and drive productivity by improving scheduling, dispatching and reporting workflows. In the last distribution rate filing (EB-2013-0416), the project was targeted to take five years to complete. However, during the discovery phase of the project, it was identified that overall project costs could be reduced by shortening the execution timeline to three years with a majority of the spending happening in 2016. The reduction in overall project costs will be achieved through reduced project management and change management costs.

The current 2017 forecast for General Plant investments is $56 million above the previous approved plan primarily due to the following investments:

- $23 million increase in investments for customer centric Information Technology investments such as, Web Redesign, eBilling Customer Usage Analytics, Bill Redesign, Contact Centre – Customer Insight and Data, and CTI Replacement;
- $10 million is due to unplanned Transmission Capital Contributions for Enfield TS (ISD GP-27) Leamington TS (ISD GP-25) and Hanmer TS DESN (ISD GP-26); and
- $12 million is due to an increase in common Information Technology investments that serve both the transmission and distribution business.

3.6.3 (5.4.4) IMPACT OF CAPITAL INVESTMENT ON OPERATIONS, MAINTENANCE AND ADMINISTRATION SPENDING

Hydro One has a number of capital investments that reduce Hydro One Operations, Maintenance & Administration ("OM&A") spending. Several examples of capital initiatives that reduce OM&A costs are listed below.

Hydro One is investing in mobile technology to improve the productivity of the Provincial Lines organization. The investment will reduce inefficiencies, time delays and data inaccuracies in the scheduling, dispatching and execution of work completed by Provincial Lines. The investment will leverage existing technology like SAP and Hydro One's geographical information system. The investment is expected to achieve a five percent productivity gain across the organization which will translate to total annual savings of $13 million, $3 million of this being directly related to OM&A (ISD GP-10).

Hydro One serves approximately 1.3 million customers. To effectively manage customer accounts, there are between 10,000 and 21,000 trips each year to disconnect and reconnect customers. An investment in meters with remote connect and disconnect functionality is planned to eliminate approximately 6,000 of these trips each year. This will result in estimated annual OM&A savings of $4.5 million (ISD SS-01).

Further detailed discussion on OM&A is included in the application throughout Exhibit C1.

Witness: Darlene Bradley

3.7 (5.4.5.1) LIST OF MATERIAL CAPITAL INVESTMENTS PROPOSED

Below is a list of the Investment Summary Documents ("ISD").

Each ISD includes a priority.

- "**Demand**" Priority refers to those projects that are part of Demand Work and are effectively non-discretionary in nature. Not completing these projects is likely to cause or extend failures on the system. Completion of these activities may be necessary to satisfy legislative or regulatory directives.
- **"High"** Priority projects ranked highest in the risk matrix. Failure to complete is expected to have significant impacts on the risk profile of the system in the short term.
- **"Medium"** Priority projects represent the largest group of projects. If reductions are required and sufficient savings are not available from the Low priority group, the Medium items would be reviewed as well for possible decreases in spending.
- **"Low"** Priority is for those projects ranking among the lowest group in the risk prioritization methodology. These projects are important to Hydro One but should a reduction in spending be necessary, Hydro One would look at these projects first for cost savings. Failure to complete Low Priority projects is not expected to have significant detrimental effects on the system in the near term.

3.8. (5.4.5.2) ATTACHMENTS: MATERIAL INVESTMENTS

SA-01 Joint Use and Line Relocations Program

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Program	**Plan Period Cost ($M):**	111.3
Primary Trigger:	Infrastructure Development Requirement		
Secondary Trigger:	Failure Risk		

Investment Need:

Hydro One must meet contractual obligations to joint use partners as per existing Joint Use Agreements. In addition, a growing number of distributed generators have become third parties on poles owned by Hydro One, causing an increase in the number of upgrades required to Hydro One's distribution assets required by other parties.

Hydro One is also obligated to perform line relocation work at the request of Municipal and Provincial road authorities as per the requirements of the *Public Service Work on Highways Act* and associated Ministry of Transportation guidelines, as well as line relocation work requested by customers in accordance with Hydro One's Conditions of Service.

Alternatives:

This investment is non-discretionary. No alternatives are considered, since failure to perform the requested work would place Hydro One in violation of contractual obligations with the third party joint use partners; as well as could jeopardize Hydro One's occupation rights on the public road allowance.

Investment Description:

This investment addresses the externally driven requirements for joint use work and line relocations, as noted below. Due to the demand nature of this work, the total number of joint use and line relocation projects can vary year to year from 250 to 400 projects annually; with the cost of each project being less than $1 million.

<u>Joint Use</u>

Joint Use investments alter or upgrade Hydro One distribution line equipment in order to accommodate the use of this equipment by joint use partners. These partners may include telephone or cable companies (communication circuits), municipalities (street lighting), local distribution companies, or generators connected to the distribution system.

The type of upgrade or change required may involve increasing pole class to accommodate changes in pole loading, and/or increasing pole height to obtain appropriate ground clearances for public safety. These activities may also carry the cost associated with premature retirement of in-service assets.

Cost sharing provisions in joint use agreements allow Hydro One to recover costs resulting from requests to accommodate new attachments to its poles.

Line Relocations

Line relocation investments alter the location of Hydro One distribution line equipment in response to road modifications initiated by road authorities or in response to property development initiated by individual customer requests.

Hydro One occupies road allowances at no cost. However in return, Hydro One is required, on occasion, to install, relocate or reconstruct its facilities in order to accommodate specific road authority or property development requirements. Most commonly, this involves relocating lines to accommodate changes to roads, highways, and bridges.

The cost of the plant relocation is either fully or partially recoverable, depending on the specific circumstances of each project.

Risk Mitigation:

The risk to completion of this investment as planned is the fluctuation and volume of projects which must be completed on annual basis. This program, driven by third party requirements, can be subject to changing requests and additions. These risks are mitigated by maintaining open communication channels with the third party agencies – reviewing priorities and timelines for project completion.

Result:

The joint use and line relocation program will result in:

- Satisfying Hydro One’s contractual and legal obligations with third party joint use partners, road authorities, and customers; and
- Maintaining property rights for distribution lines located on road allowances.

Outcome Summary:

Customer Focus	• Improve customer satisfaction with joint-use customers by providing joint use capabilities. • Deliver on customer requests in a timely manner.
Operational Effectiveness	• Realize reliability improvements, where possible, on upgrades or renewal of the distribution system in response to customer requests.
Public Policy Responsiveness	• Comply with contractual and legal obligations under the *Public Service Work on Highways Act* and Hydro One’s Conditions of Service.
Financial Performance	• Realize cost savings by cost sharing, where possible, on upgrades or renewal of the distribution system in response to customer requests.

Costs:

The average gross investment cost for this program over the five year period is in line with the average historic gross spend over the last 5 years. The factors which affect the costs in this investment are the volume of requests and scope of such requests. The costs for the joint use and line relocation program are based on projections from joint use partners including new generator customers, road authorities and property development customer requests. Provincial government infrastructure initiatives can cause an increased in project volumes. Any significant changes to these projects would affect the overall investment cost.

Controllable costs have been minimized by standardizing the procedure for common activities such as pole and equipment replacement and coordinating joint use and relocation projects with other sustainment programs where feasible.

SA-02 Metering Infrastructure Sustainment Program

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Program	**Plan Period Cost ($M):**	75.9
Primary Trigger:	Mandated Service Obligation		
Secondary Trigger:	Failure Risk		

Investment Need:

Hydro One currently owns, operates, and maintains approximately 1.3 million retail revenue meters. With an asset base of this magnitude, it is reasonable to expect that there will be a number of meters and network devices that will fail to operate as intended and must be replaced in a timely fashion.

With the introduction of smart meters in 2006, customer meters have the capability to provide billing settlement data electronically. However, any disruptions in the electronic communication due to the failure of a meter or network device (i.e., collector or repeater), results in an estimated bill being generated to which customers have routinely indicated their displeasure.

Furthermore, replacement of failed components is critical to maintain a reliable meter infrastructure network and resultant source of billing settlement data to satisfy the OEB Distribution System Code Section 7.11 “Billing Accuracy” requirement to have 98% billing accuracy.

Alternatives:

This investment is non-discretionary. No alternatives were considered, since failure to perform the work to repair and/or replace the meters and associate network would be in violation of the OEB Distribution System Code Section 5.1 "Provision of Meters and Metering Services" and has the potential to negatively impact the reliable source of billing settlement data.

Investment Description:

This investment addresses the like for like replacement of failed metering devices and the maintenance of an adequate level of inventory of metering devices to ensure timely replacement.

The meter inventory consists of meters, repeaters, collectors and other electronic components used in the meter infrastructure network. The required inventory levels are determined based on the population size of particular meter or equipment model, and historical failure rates. The annual inventory purchases are dependent on which categories of equipment were deployed to replace failed equipment each year.

Based on recent operational experience, Hydro One estimates the approximate number of devices, consisting of meters and various network devices, that are required to be removed and replaced each year are as outlined below. The forecasted number of meter devices procured are lower than the number replaced since a portion of failed metering devices may be repairable.

	2018	**2019**	**2020**	**2021**	**2022**
Number of Metering Devices Procured	27,000	25,000	25,000	25,000	27,000
Number of Metering Devices Replaced	29,880	27,000	27,000	27,000	29,000

Risk Mitigation:

The risk to completion of this investment as planned is the potential unavailability of resources in certain locations. This risk is mitigated by managing program resources and hiring temporary staff as required.

Result:

The meter infrastructure sustainment program will result in:

- Ensuring timely availability of meters and network devices;
- Complying with regulatory requirements; and
- Ensuring a reliable source of billing settlement data that increases customer confidence and satisfaction that bills are accurate.

Outcome Summary:

Customer Focus	• Reduce unwanted estimated customer bills. • Reduce customer interruption time by maintaining an adequate level of components to ensure timely replacement of failures.
Operational Effectiveness	• Increase efficiency by reducing number of manual reads. • Maintain meter network reliability to ensure a reliable source of billing settlement data.
Public Policy Responsiveness	• Comply with OEB Distribution System Code requirements to provide accurate and timely billing. • Comply with the *Electricity and Gas Inspection Act* to ensure meter accuracy.
Financial Performance	

Costs:

The costs for this program are projected based on these historic labour costs, material unit costs, and future anticipated needs. The factors which affect the costs in this investment are the following:

- The cost of material and term of procurement contracts;
- The volume and types of meters and network devices requiring replacement; and
- The accessibility conditions of the area in which devices are being replaced. Accessing off road locations to replace network devices can be more costly due to the use of specialized equipment.

Controllable costs have been optimized through standardization of metering device purchasing specifications and issuance of vendor contract to secure unit pricing for procurement of materials.

SA-03 Meter Infrastructure Expansion Program

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Program	**Plan Period Cost ($M):**	14.3
Primary Trigger:	Mandated Service Obligation		
Secondary Trigger:	System Efficiency		

Investment Need:

Hydro One currently owns, operates, and maintains approximately 1.3 million retail revenue meters. With the introduction of smart meters in 2006, customer meters have the capability to provide billing settlement data electronically. Hydro One uses a metering infrastructure network to communicate with these smart meters; which has been constructed to take advantage of Canada and Rogers Communications ("the Carriers") cellular networks. However some of these meters cannot communicate reliably with Hydro One's meter infrastructure network, resulting in manually reading of these meters at specific intervals and estimated billing for the customer.

The OEB's Distribution System Code requires 98% billing accuracy, thereby limiting the use of estimated billing for customers. In the fall of 2015, Hydro One received an exemption from this OEB requirement to allow the use of estimated billing for approximately 170,000 customers with poorly communicating smart meters. This exemption was granted to the end of 2019.

Since that time, Hydro One has been working to establish reliable communication with these customers where economically viable in order to comply with the OEB direction for Hydro One to transition to time of use pricing. This improvement in communication levels is largely due to the success of the Carriers widening the capability of the cellular network. Another factoring contributing to the success was Hydro One's implementation of a flexible bill window, allowing billing data to be based on a meter read within a certain time frame rather than necessarily at a particular moment in time thereby creating a broader time window within which it can obtain a successful read.

Nonetheless, there remains approximately 123,000 meters that the meter infrastructure network still cannot communicate reliably with. By continuing to leveraging onging Carrier upgrades, there exists opportunties to allow more customers to communicate reliably.

Alternative 1: Maintain existing meter infrastructure network

Continue to operate the existing meter infrastructure network as is, and not leverage ongoing Carrier upgrades. This alternative is rejected as it will not improve the communication reliably nor does it align with OEB direction to move customers to time of use pricing and achieve 98% billing accuracy.

Alternative 2: Expand the meter infrastructure network *(Recommended)*

Expand the meter infrastructure network by leveraging the Carriers upgrades by installing collectors, repeaters and executing configuration changes to improve communicate reliably with meters. This alternative is recommended as it will reduce the resource requirements of manual meter reads and improve Hydro One's billing accuracy by reducing the number of meters with unreliable communication to 96,564 from 123,000 by the end of the five year period.

Investment Description:

This investment addresses the expansion of Hydro One's meter infrastructure network by leveraging the Carriers upgrades where economically viable. As the Carriers expand their network, Hydro One will expand their network by executing configuration changes and installing repeaters and/or collectors to enable reliable, remote, meter reading. This will result in a reduction of manual meter reading and the transfer of customers from two-tier billing to time-of-use rate schedules consistent with OEB direction for Hydro One to transition meters to time of use.

Hydro One has estimated that the proposed level of investment in the expansion of the communication network will result in approximately 26,436 customers transitioning from two-tier pricing to time of use over the five year period as outlined in the table below. In addition to meeting OEB guidelines, this will reduce the number of meters requiring manual meter reads.

	2018	**2019**	**2020**	**2021**	**2022**
Number of Customers Transitioned to Time of Use	5,843	5,551	5,273	5,010	4,759

At the end of this period, approximately 96,564 meters (representing 78% of the existing 123,000 meters with unreliable communication) will still not have reliable communication and will remain on two-tier pricing, requiring exemption from the OEB requirement.

Risk Mitigation:

The risks to completion of this investment as planned are that the Carriers may not expand their networks at the forecasted rate or that their network expansion does not match the geographic areas where Hydro One is experiencing unreliable communication. These risks are considered low as there is a very competitive market demand for cellular service availability and performance that continues to drive the Carriers to expand their network.

Result:

The meter infrastructure network expansion program will result in:

- Providing reliable communication for remote reading of an additional 26, 436 meters; and
- Enabling the transition of 26,436 customers from two-tier to time of use pricing in accordance with OEB guidelines to do so where economically viable.

Outcome Summary:

Customer Focus	• Provide reliable remote meter reading enabling time of use pricing in order for customers to manage their electricity usage to reduce costs. • Increase customer confidence and satisfaction by providing a reliable communication network and reducing the number of bills issued on estimated data.
Operational Effectiveness	• Reduce resource requirements of manual meter reads.
Public Policy Responsiveness	• Comply with OEB direction to transition customers to time of use pricing, where economically viable. • Comply with OEB Distribution System Code Section 7.11 “Billing Accuracy” requirements to provide accurate and timely billing.

Financial Performance	• Avoid the cost of manual meter reading by reducing the number of meters with unreliable communication.

Costs:

The factors which affect the costs in this investment are the following:

- The cost of material and term of procurement contracts; and
- The number of meters that can communicate reliably with a newly installed collector or repeater.

Controllable costs have been minimized through issuance of vendor contract to secure unit pricing for procurement of materials and the establishment of a standard on the minimum number of meters required to communicate reliably to justify installing a network device such as a repeater or collector.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

SA-04 New Load Connections, Upgrades, Cancellations and Metering

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Program	**Plan Period Cost ($M):**	581.6
Primary Trigger:	Customer Service Requests		
Secondary Trigger:	Mandated Service Obligations		

Investment Need:

Hydro One is obligated to connect new customers to the distribution network, upgrade services for existing customers, and install meters for new services under Hydro One's Distribution License. These system investments include the following activities:

<u>New Connections</u>**:** As part of its obligations under Hydro One's electricity distribution license and the distributor's responsibilities in the Distribution System Code ("DSC"), Hydro One is required to make an offer to connect all distribution customers on a non-discriminatory basis, upon written request for connection.

<u>Service Upgrades</u>: A service upgrade occurs when a customer requires a larger service entrance. A service upgrade normally requires the preparation of a service layout and replacement of secondary service lines. Transformers may also have to be upgraded, meters replaced and possibly additional transformation installed.

<u>Metering</u>: Installations may be required for new connections and service upgrades. Revenue meters, are funded under this program for new connections and service upgrades.

<u>Cancellations</u>: For cancellations of existing service, Hydro One is required to remove idle assets (such as transformers, poles, wires and meters) for safety and security reasons.

Alternatives:

Not proceeding with these investments would result in non-compliance with Distribution license requirements and with obligations under the DSC. This work is a regulatory requirement.

Investment Description:

Individual investments within these programs are managed on a project basis. Projects include design (service layouts), labour, material and other costs associated with actual physical connection or removal.

New Connections:

To comply with its obligations under section 28 of the *Electricity Act, 1998*, Hydro One is required to provide a connection service to new industrial, commercial, residential, and seasonal customers when requested. The division of costs between Hydro One and the customer is determined based on the company's connection policies, which are in accordance with the DSC requirements. A basic connection consisting of a service layout, overhead transformation, 30 metres of overhead conductor, and standard retail metering is provided free of charge to new customers that lie along the existing network, as per the DSC requirements. For customers that require expansion of the network in order to be connected, a discounted cash flow calculation is used to determine customer contributions. The capital contribution is based on any shortfall between future revenues and the cost of connection and network expansion. Customer contributions for system expansions and other recoverable costs beyond the basic connection are forecasted to be between $32.9 million and $36.7 million between 2018 and 2022. Projected costs for these programs are primarily based on historic demand and forecast load growth.

Service Upgrades:

To comply with its obligations under section 28 of the *Electricity Act, 1998*, Hydro One is required to respond to existing customers who require a larger service to accommodate additional load and/or modify their electrical service entrance. These costs are classified as upgrade costs. A service upgrade normally requires the replacement of secondary service wires and the preparation of a service design. Also, it may be necessary to upgrade transformer(s), replace meters or install additional transformers. For standard service upgrades, Hydro One will provide a service layout, pole-mounted transformer, and the meter installation, if required. Costs for service modifications that exceed the cost of a standard installation would be recovered from the customer on a user-pay basis. Hydro One's customer capital contribution policies adhere to DSC requirements.

Service Cancellations:

Service cancellations are included in this program's "Removals" costs in the cost table in this document. These involve customers who request disconnection from the distribution system. Hydro One removes idle assets, such as transformers, poles, service wires and meters for safety and security reasons. As this work involves the removal of Hydro One owned equipment, these costs are accounted for under depreciation and are not capitalized.

The currently projected volume (number of units) of new connections, service upgrades and service cancellations from 2018 to 2022 is summarized in the table below.

Description	**2018**	**2019**	**2020**	**2021**	**2022**
New Connections	14,724	14,862	15,005	15,148	15,291
Service Upgrades	4,473	4,515	4,558	4,601	4,645
Service Cancellations	5,562	5,614	5,668	5,722	5,776

Risk Mitigation:

Hydro One connects several thousand customers to its distribution system every year. The main risk to this program is volume and timing of the customer requests. Every effort is made to prioritize these projects in order to meet the required service obligations. This prioritization and timing is completed at a service centre level through scheduling of work. Communication is maintained with the customer to ensure expectations are being met.

Result:

- Connect new customers and satisfy the requirements of the DSC and Hydro One’s distribution license;
- Upgrade the services of existing customers;
- Remove assets when services are cancelled and mitigate safety risks; and
- Satisfy the requirements of the DSC and Hydro One’s distribution license.

Outcome Summary:

Customer Focus	• Fulfill customer requests for connections and upgrades within established time frames to improve customer satisfaction.
Operational Effectiveness	• Ensure all new connections or upgrades meet latest standards. • Remove assets when services are cancelled to mitigate safety risks.
Public Policy Responsiveness	• Comply with requirements in the DSC and distribution licence to provide new connections or service upgrades when requested by customers.
Financial Performance	• Leverage financial benefits on company-wide productivity initiatives.

Costs:

Planned costs for the program are based on historic actual costs and a forecast of future load growth, factoring in future savings initiatives. The actual program costs will be comprised of the individual projects (connections, upgrades, cancellations) completed on an annual basis. Controllable costs are minimized by ensuring that all projects are completed using standard processes and within standard unit costs. Any unforeseen issues at a work location, outside the established unit cost, will result in increased costs.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

SA-05 Distributed Generation Connections

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Program	**Plan Period Cost ($M):**	16.6
Primary Trigger:	Customer Service Requests		
Secondary Trigger:	Mandated Service Obligation		

Investment Need:

The Distribution System Code ("DSC") and Hydro One's distribution license obligate it to connect generation facilities that meet the requirements of the DSC. Hydro One's generation connection investments fund additions and modifications required to connect generating facilities to the distribution system. Generators make capital contributions to this work in accordance with Hydro One's connection policy and the DSC. Similar to load customers, Hydro One gives credit to the customer based on the forecasted load for station services of the distributed generator.

Alternatives:

This is a demand-based program for connecting new distributed generation. There are no viable alternatives as not proceeding with these investments would result in non-compliance with the requirements of Hydro One's distribution license and the DSC. This work meets a regulatory requirement.

Investment Description:

Individual investments within these programs are managed on a project basis. Projects involve estimating, design, labour, material and costs associated with actual physical connection of new generators.

Hydro One's investment plans are based on Ministry of Energy ("MOE") directives on distributed generation facilities and the IESO's Feed-in Tariff ("FIT") programs for distributed generators of different sizes, as well as other procurement initiatives from the IESO. The cost allocation requirements are as set out in the DSC. These determine the investments that are presented in this section.

The DSC divides DGs into five size categories: micro, capacity allocation exempt small, small, mid-sized and large. In Section 1.2 – Definitions, each of the five size categories is defined:

- Micro-embedded generation facility – an embedded generation facility with a name-plate rated capacity of 10 kW or less;
- Capacity allocation exempt small embedded generation facility – an embedded generation facility which is not a micro-embedded generation facility and which has a name-plate rated capacity of 250 kW or less in the case of a facility connected to a less than 15 kV line and 500 kW or less in the case of a facility connected to a 15 kV or greater line;
- Small embedded generation facility – an embedded generation facility which is not a micro-embedded generation facility with a name-plate rated capacity of 500 kW or less in the case of a facility connected to a less than 15 kV line and 1 MW or less in the case of a facility connected to a 15 kV or greater line;
- Mid-sized embedded generation facility – an embedded generation facility with a name-plate rated capacity of 10 MW or less and a) more than 500 kW in the case of a facility connected to a less than 15 kV line; and b) more than 1 MW in the case of a facility connected to a 15 kV or greater line; and
- Large embedded generation facility – an embedded generation facility with a name-plate rated capacity of more than 10 MW.

Based on the definitions in the DSC, Hydro One places DGs into four categories for planning purposes:

1. Capacity Allocation Required (“CAR”) DGs which includes large DGs, mid-size DGs and small embedded DGs that are not capacity allocation exempt;
2. Capacity Allocation Exempt (“CAE”) DGs;
3. Capacity Allocation Exempt generators that are Net-Metered (“CAE-NM”); and
4. Micro-embedded DGs (including MicroFIT and Micro-embedded Net-Metered).

Hydro One makes lines and stations equipment upgrades to mitigate the above factors. The numbers of estimated projects are summarized below:

DG Category	Forecasted				
	2018	2019	2020	2021	2022
CAR	6	5	5	5	5
CAE	200	170	160	110	110
CAE -NM	295	280	305	335	370
Micro Embedded	200	200	200	200	200

At the time of writing, the identified material projects for 2018 are set out below.

Project	Name Plate Capacity (kW)	DG Category	Target In-Service
Kirkland Lake TS – DX Feeders	3,000	CAR – FIT project*	2018
Wendover HVDS – DX Feeders	12,000	CAR – Large renewable procurement project*	2018
Muskoka TS – DX Feeders	11,760	CAR – Large renewable procurement project*	2018

**Descriptions of FIT and large renewable procurement projects are provided in Section 3.5 of the Distribution System Plan.*

The connection requirements for each project vary depending on its size. For the CAR and CAE projects, the investments are broken down into three components: (1) Renewable Enabling Improvements ("REI") which are upgrades to existing lines; (2) "Expansions" which are actual line extensions; and (3) Connection Assets. The cost allocation for each component is based on Hydro One's connection policy and is in accordance with the DSC. All project connection costs are recoverable from the customer if the source of energy is non-renewable. If the source of energy is renewable, then a portion of the expansion cost (up to $90,000/MW) and 100% costs under REI is funded by Hydro One pursuant to the DSC. Costs of Expansions exceeding $90,000 per MW and the cost for any upstream station upgrades, if required, are recoverable in full from the customer.

Hydro One's distribution system is radial in design, with limited transfer capability to supply customers. The system was designed to move power from the transmission system downstream towards customers. As a result, the amount of generation capacity connected to Hydro One's distribution system is generally constrained by a variety of engineering factors, including but not limited to:

- equipment ratings;
- reverse power flow constraints;
- supply feeder current ratings;
- power quality; and
- remaining short circuit capacity at transmission stations.

These constraints are addressed on a project-by-project basis with engineering involvement when required. This may entail new line expansions, protection system upgrades, control system upgrades, new voltage regulators, voltage regulator control upgrades, line and station recloser upgrades. Associated costs include procurement, engineering, and project management costs associated with each project. Costs have been minimized through standardized design and procurement processes.

Consistent with the requirements of O. Regulation 330/09 under the *Ontario Energy Board Act*, *1998*, a portion of the costs associated with the connection of renewable generators is allocated to Hydro One ratepayers and a portion of the costs are allocated to all provincial ratepayers. The allocation of costs is explained in Exhibit G1. The allocation of costs to Hydro One ratepayers and provincial ratepayers is different for Expansion assets and for REI assets. Connection assets are paid for by the generator customer.

Risk Mitigation:

Hydro One connects many DGs to its distribution system every year on demand. The main risk to this planned execution of this program is volume and timing of the customer requests.

DG projects are prioritized in order to meet the required service obligations. This prioritization and timing is completed through scheduling of work. Hydro One maintains communications with the customer to ensure that all requirements are met so the parties can complete their connection by the agreed upon in-service date.

Result:

- Connect new generators and satisfy the customers' timelines;
- Upgraded distribution lines as required; and
- Compliance with the requirements of the DSC and Hydro One's distribution license.

Outcome Summary:

Customer Focus	• Improved customer satisfaction by connecting new generators within contractually established time frames.
Operational Effectiveness	• Ensure all upgrades reflect latest standards and future load and generator forecasts.
Public Policy Responsiveness	• Compliance with requirements in the DSC and Hydro One's distribution licence to connect qualifying generators.
Financial Performance	• Lower engineering costs using standardized design and work practices.

Costs:

SR-01 Distribution Stations Demand Capital Program

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Program	**Plan Period Cost ($M):**	12.3
Primary Trigger:	Mandated Service Obligation		
Secondary Trigger:	Safety		

Investment Need:

Service interruptions or unplanned system deficiencies associated with various distribution station assets occur and require an immediate response by Hydro One personnel. Asset failure or extreme weather may result in service interruptions that require restoration of power to maintain reliability. Over the past five years, there has been an average of 59 interruptions per year related to station equipment.

Hydro One also performs station inspections; rural stations every six months and urban stations monthly. These regular inspections may also identify damaged or failed distribution station assets that pose a safety hazard or customers may report power quality issues. Hydro One is obligated to replace these assets in accordance with good utility practice and the requirements of the Distribution System Code.

Alternatives:

This investment is non-discretionary. No alternatives are considered, since failure to quickly respond to service interruptions or other situations where assets have failed would violate the Distribution System Code and result in unacceptable reliability and safety risks.

Investment Description:

This investment addresses the replacement of failing or failed distribution station equipment in a timely manner in order to maintain distribution system reliability, safety, and/or power quality in situations where the assets cannot be repaired, and replacement is the only viable option in compliance with the Distribution System Code. Stations are key critical assets in that a large number of customers are impacted by station related failures. Examples of the most common work that is undertaken under this distribution station demand program include:

- Replacement of power transformers that have failed or are failing, must be replaced immediately to maintain the integrity of the system, also transformers that generate customer complaints with noise levels that exceed the guidelines must be replaced to comply with the requirements set out by the MOECC;
- Replacement of assets that have become significantly overloaded due to unexpected customer loading variations;
- Replacement of failed reclosers, or reclosers whose fault interruption levels have become exceeded or are close to being exceeded; and
- Replacement of failed or failing insulators, switches or poles within the station.

These failures are difficult to predict, but must be addressed quickly because they generally result in customer interruptions or present significant safety risks. Planned expenditures in this investment are projected based on historical trends and adjusted to reflect recent experiences.

Risk Mitigation:

The work in this investment is unplanned in nature. However, there are risks to executing such unplanned work including the availability of the mobile unit substations ("MUSs") and engineering resources. These risks are mitigated by ensuring that there is always at least one MUS available for emergent work in each voltage/capacity category and by having a process to enable reprioritization of engineering resources to support the immediate and emergent work as required.

Result:

From this investment, customers will benefit from sustained reliability resulting from the replacement of failed, failing and overloaded station equipment in a timely manner. The replacement of failing and overloaded station equipment before the failures occur results in fewer customer interruptions. The replacement of failing equipment also mitigates safety issues.

Outcome Summary:

Customer Focus	• Improve customer satisfaction by minimizing the customer interruption duration by carrying out unplanned outages in a timely manner.
Operational Effectiveness	• Maintain distribution system reliability, safety, and/or power quality. Reduce safety risks associated with failed equipment.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system. • Comply with the Distribution System Code requirement to ensure that appropriate follow up and corrective action is taken regarding problems identified during station inspections.
Financial Performance	

Costs:

The costs for this demand program are projected based on these historic costs and future anticipated needs. The average investment cost for this program over the five year period is in line with the average five year historic spending. The factors which affect the costs in this investment are the following:

- The scope of the replacement required to address the failure;
- The type and number of failed assets requiring replacement (i.e. transformers, switches, reclosers, etc.); and
- The ratings of the equipment requiring replacement.

Controllable costs have been minimized through the standardization of station designs and equipment ratings, establishment of unit price contracts with vendors, and maintaining a spare inventory for replacement of failed equipment to minimize outage time.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

SR-02 Mobile Unit Substation Program

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Program	**Plan Period Cost ($M):**	26.9
Primary Trigger:	Failure Risk		
Secondary Trigger:	Operational Functionality		

Investment Need:

Hydro One owns, maintains and operates a fleet of 30 mobile unit substations ("MUS") located across Ontario to support Hydro One's distribution stations that are designed primarily with only one transformer and with very little transfer capability. These MUS's perform an integral role in the operation of Hydro One's distribution system and are utilized for the following purposes:

- To offload distribution stations during maintenance and capital activities;
- For emergency power restoration in the event of a transformer or other distribution station component failure; and
- For load relief for distribution stations.

The management of Hydro One's MUS fleet is required to ensure that an adequate, safe and reliable fleet is available to satisfy these outage requirements noted above. The MUS fleet must adhere to the requirements of the Highway Traffic Act. Under the Highway Traffic Act, each MUS must receive an annual vehicle safety and structural inspection from an approved facility to certify that they meet minimum safety requirements. If an MUS does not pass the annual inspection, it cannot be transported. As a result, it is imperative that high risk MUS trailers are addressed to ensure usability.

As documented in DSP Exhibit 2.3, thirteen of the MUS fleet is in the high risk category resulting from deteriorated trailers, transformers, and other components in failing condition. The prolonged use of high risk MUS's could increase risk to Hydro One employees and the general public. There is also a need for higher MVA capacity MUS's to support heavier loaded stations, and MUS's with under load tap-changers to provide for voltage regulation.

There continues to be strain placed on the MUS fleet resulting from Hydro One's proposed work programs to address ageing infrastructure on the distribution system. Each year, approximately 30% of planned station work is deferred due to an insufficient number of available MUSs. In 2016, there were 121 scheduled MUS deployments to stations to support planned maintenance and capital work. Of the 121 scheduled outages, 31 were cancelled due to MUS unavailability. To ensure there is an adequate number and type of MUSs to accomplish all planned and unplanned station work and to minimize customer outages, additions to the MUS fleet are required. An inadequate MUS fleet has an adverse impact on emergency failure response that would jeopardize customer reliability and would negatively impact the ability of Hydro One to proceed with maintenance and capital work programs.

Alternative 1: Reactive Component Replacements

Wait for MUS transformer and trailer components that are at high risk to fail, and replace the failed MUS transformers and trailer components on a reactive basis. This alternative is rejected for several reasons. When MUS components such as MUS transformers or trailer components fail, the MUSs are unavailable until the failed components are replaced. The lack of availability of appropriate level of MUS fleet would have a negative impact on customer service, emergency power restoration and system reliability. Furthermore, the lead time to replace a failed major MUS component such as the transformer or trailer is expected to be 1.5 years; which would limit the capability of the MUS fleet to support emergency power restoration and/or capital and maintenance activities.

Alternative 2: Planned Component Replacements

Replace individual major MUS assets identified as high risk on a component basis. While this alternative is viable where only one of the major components is at high risk; it is not ideal when multiple MUS assets (i.e., trailers and transformers) are at high risk and in need of replacement. This alternative is rejected as the assessment of the MUS fleet, as documented in DSP Exhibit 2.3, has identified multiple assets in deteriorated condition. The replacement of MUS components on an individual basis will also not allow for higher MVA MUS transformers with voltage regulation capability to be installed on existing MUS trailers due to space and weight limitations. Furthermore, this alternative also does not address the shortfall in the MUS fleet.

Alternative 3: Planned Full MUS Replacements

Replace six MUS's at end-of-life. This alternative addresses the condition of the existing fleet by replacing half of the MUS's identified as high risk, with the remaining seven high risk MUSs to be replaced beyond the planning period. However, like Alternatives 1 and 2, this alternative does not address the shortfall in the MUS fleet. This alternative is rejected as the existing MUS fleet level is insufficient to address demands of the proposed work program and address emergency power restoration.

Alternative 4: Planned Full MUS Replacements and Fleet Expansion *(Recommended)*

Replace six MUS's at end-of-life to address the condition of the existing fleet identified as high risk, and expand the fleet with the procurement of three additional MUS's to address the shortfall in the MUS fleet. This alternative is recommended as it attempts to address the immediate needs identified for the MUS fleet to ensure system reliability is maintained and begins to alleviate backlog by making strategic expansion to the fleet.

Investment Description:

This investment addresses the replacement of MUSs that are at end-of-life, and addresses a shortfall in MUSs required to support the distribution system and proposed work programs.

The MUS fleet identified for replacement is based on MUS trailers and transformers in high risk, and are prioritized based on their level of risk and number of years beyond their expected service life. As outlined in DSP Exhibit 2.3, twelve of the MUS transformer condition assessments fall into the high risk category, while nine of the MUS trailers are in high risk. Also some of the MUS transformers have limited capacity or lack voltage regulation capability, which limits the utilization of the MUS. The appropriate level of MUS fleet is determined based on having MUSs which can be deployed to stations to support failures and restore customers within eight to twelve hours, and to have sufficient MUSs to allow for the completion of planned and unplanned capital and maintenance work.

Based on this assessment, six MUSs are planned for replacement and three new MUSs will be procured to expand the fleet over the five year period as outlined in the table below.

	2018	**2019**	**2020**	**2021**	**2022**
Number of MUS Replaced	2	1	2	1	0
Number of MUS Procured	0	0	0	1	2
Total	2	1	2	2	2

The MUSs will be replaced with units that have higher MVA capacity and will include voltage regulation. The new MUSs will also be equipped with electronic reclosers capable of remote operation and interruption of higher fault conditions. The specification for the replacements is as follows:

- Four MUS's with capacity of 10MVA, and voltage rating of 44kV – 12.5/8.32kV;
- One MUS with capacity of 7.5MVA, and voltage rating of 27.6kV – 8.32kV; and
- One MUS with capacity of 15MVA, and voltage rating of 115kV–27.6/25/12.5/8.32kV.

Of the three planned MUS purchases, two will be 10 MVA capacity with voltage rating of 44kV – 12.5/8.32kV, and one will be 7.5 MVA capacity with voltage rating of 27.6 kV – 8.32kV.

Risk Mitigation:

The risks to completion of this investment as planned are the time required to execute the procurement process, and the availability of vendor to manufacture and deliver the MUSs. Depending on when in the year the manufacturer receives the request for procurement, they may be fully booked and not able to immediately accommodate the request. These risks are mitigated by early evaluation of vendors, and by providing MUS procurement forecasts to vendors in advance to ensure that they will be able to accommodate the requests and issuance of the purchase orders in a timely matter.

Result:

The mobile unit substation program will result in:

- Ensuring a safe and reliable MUS fleet to respond to station failures in a timely manner;
- Obtaining an adequate MUS fleet to support failures with emergency power restoration and offload distribution stations to execute the proposed work program without unacceptable outage impacts to customers; and
- Maintaining the condition of the MUS fleet to mitigate risks to Hydro One staff and the general public.

Outcome Summary:

Customer Focus	• Reduce customer interruption time by ensuring an adequate level of MUSs to provide emergency power restoration to failure events.
Operational Effectiveness	• Maintain the reliability of the distribution system by obtaining an adequate level of MUSs to carry the distribution station load while performing capital and maintenance work to mitigate power disruption to customers.
Public Policy Responsiveness	• Comply with Ministry of Transportation licensing requirements by ensuring the units are roadworthy and electrically functional.
Financial Performance	• Utilization of MUSs provides a cost effective alternative to constructing redundant transformation at distribution stations across the province.

Costs:

The factors which can affect the unit price of each MUS include the following:

- The specification of the MUS requirement replacement (i.e. MVA capacity of the transformer, Primary voltage(s), Secondary voltage(s), etc); and
- The cost of material and term of procurement contracts.

Controllable costs have been minimized through standardization of the MUS purchasing specifications with standardized MVA capacity for given voltage levels (i.e. 10 MVA for the 44 kV – 12.5/8.32 kV MUS's, and 7.5 MVA for the 27.6 kV – 8.32 kV MUS's). A general outline agreement with vendors for MUS unit prices will be established to further control costs.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets	3.5	5.7	5.8	5.9	6.0	26.9

**Includes Overhead at current rates.*

SR-03 Station Spare Transformer Purchases Program

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Program	**Plan Period Cost ($M):**	18.6
Primary Trigger:	Failure		
Secondary Trigger:	Reliability		

Investment Need:

Transformers comprise the single largest component of Hydro One's distribution station asset base. Hydro One owns, maintains and operates 1,222 distribution station transformers. As outlined in DSP Exhibit 2.3, 23% of the distribution station transformer condition assessments fall into the high risk category.

Hydro One's distribution stations are designed primarily with only one transformer without on-site spare transformers that can be switched into service in the event of a failure, and typically have very little transfer capability based on the radial design of the distribution system. Each distribution station transformer supplies approximately 1,200 customers; hence a distribution station transformer failure is highly impactful to customers.

Over the past five years, there has been an average of nine spare transformer deployments per year to support failed transformers, as well as transformers on the verge of failure based on oil samples, demonstrating major oil leaks or violating noise guidelines set by the Ministry of Environment and Climate Change ("MOECC"). In these instances, when a station transformer fails, service is initially restored with the installation of a mobile unit substation ("MUS") until a spare transformer can be transported and installed at the station.

In order to ensure timely response in the event of a failure and maintain system reliability, a sufficient number of spare transformers are required as the lead time to procure transformers can range from 6 to 12 months. If the spare transformer inventory is not maintained, MUSs will be deployed to support failures for prolonged periods of time. Planned project and maintenance work would be deferred, resulting in an increase in failures.

Alternative 1: Reactive Procurement of Replacement Transformer

Deploy spare transformers currently in inventory to support failures, without replenishing the spare transformers which were deployed. Once all the existing spare transformers are depleted, Hydro One would no longer continue to maintain an inventory of spare transformers. Rather, transformer replacements would only be procured after the failure event has occurred. This alternative is rejected as the current fleet of MUSs cannot support this level of utilization. MUSs would be required to remain in service for extended periods of time until a replacement transformer could be purchased (typically 6 to 12 months). This would minimize the MUS's availability to support the proposed maintenance and capital work program, and provide emergency power restoration for other system failures which may occur, resulting in a negative impact on system reliability. Deferral of planned capital and maintenance work will result in an increase in failures. Once the failures exceed the number of available MUSs, system reliability will decrease and customers will be without power for extended periods of time.

Alternative 2: Maintain Sufficient Stock of Spare Transformers *(Recommended)*

Continue to maintain a sufficient inventory of spare transformers to address transformer failures by replenishing the spare transformer inventory when spare transformers are deployed to support failures. This alternative is recommended as it addresses transformer failures in a timely manner; and minimizes the utilization of MUSs for extended periods of time, enabling MUS availability to support the proposed maintenance and capital work program and maintain system reliability.

Investment Description:

This investment addresses the procurement of spare transformers for distribution stations as needed to support the in-service population. These spare transformers are used as replacements for failed units, replacements for transformers with escalated internal heating which must be forced out-of-service, replacements for noisy transformers identified through customer complaints which violate MOECC guidelines, and replacement for transformers with a major unexpected defect identified during routine inspection (i.e. failed tap-changer or significant oil leaks) which are not economical to repair.

The optimal number of spares Hydro One maintains is based on a probabilistic risk analysis model of each transformer category. Transformers are categorized by MVA capacity, primary voltage, secondary voltage, step-down transformers versus voltage regulators, auto voltage regulation capability, 3-phase versus 1-phase and bushing style.

The model determines the optimum number of spares required for each group of transformers by taking into consideration several factors including demographics, failure rates, delivery lead time and repair/replacement time. As outlined in DSP Exhibit 2.3 the failure rate of station transformers is on average 11 transformers per year. To address the failures, there has been an average spare deployment of 9 units per year.

Based on a recent assessment of the spare transformer fleet, and in consideration of previous spare transformer deployments, the proposed level of transformer replacements under the station refurbishment investment, and the optimum level of transformer spares projection of 149 units by 2022, thus the expectation is that 27 spare transformers will be required to be procured over the five year period in order to support failing and failed units as outlined in the table below.

	2018	**2019**	**2020**	**2021**	**2022**
Number of Transformers Procured	4	5	6	6	6
Expected Number of Spares Deployed	9	9	9	9	9
Transformers in Inventory	164	159	155	152	149

The transformers purchased under this investment will vary in size and type, dependent on the spare that is deployed to support a failure event, in order to replenish the spare inventory to support the sizes and types of the in-service transformer fleet. Careful consideration is given to the available number of spares in each group. These spare transformers will be purchased only for instances where spare transformers deployments result in the spare category being below the required stock level.

With an average of 9 spare deployments per year, overall, this investment level will reduce the spare transformer inventory over the planning period from 164 spares to 149 spares, however, system reliability is expected to be maintained as long as planned replacements continue.

Risk Mitigation:

The risk to completion of this investment as planned is the availability of transformer vendors to manufacture and deliver the spare transformers in a timely manner. Manufacturer lead times are typically 6 to 12 months; and depending on when in the year the manufacturer receives the request for procurement, they may be fully booked and not able to immediately accommodate the request. This risk is mitigated by providing transformer purchase forecasts to vendors in advance to ensure that they will be able to accommodate the requests, and issuance of the purchase orders in a timely matter.

Result:

The station spare transformer program will result in:

- Sustaining reliability of the distribution system by replacing failed and failing transformers with new units from the spare inventory in a timely manner; and
- Reducing the number of customer interruptions by replacing transformers identified on the verge of failing.

Outcome Summary:

Customer Focus	• Improve customer satisfaction by replacing failed or failing transformers in a timely manner to maintain system reliability.
Operational Effectiveness	• Maintain safe and reliability operation of the distribution system by maintaining an adequate level of spares. • Minimize the utilization of MUSs for extended periods of time to support failures; thereby ensuring the MUS availability to support maintenance and capital work program.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system. • Comply with the Distribution System Code requirement to ensure that appropriate follow up and corrective action is taken regarding problems identified during station inspections.
Financial Performance	• Realize cost savings through planned replacements of transformers identified as failing prior to failure as the cost of emergency replacements is more expensive.

Costs:

The factors which affect the costs in this investment are the following:

- The actual number of transformer failures and demand transformer replacements which occur in year that require spare deployment; and
- The type of transformer requiring spare deployment, as the costs of the spare transformers can vary based on transformer specifications such as: voltage, capacity and tap-changer requirements.

Controllable costs have been minimized through standardization of transformer purchasing specifications with standardized MVA capacities for given voltage levels, and development of unit pricing with the transformer vendor.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets	2.6	3.4	4.1	4.2	4.3	18.6

**Includes Overhead at current rates.*

SR-04 Distribution Station Planned Component Replacement Program

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Program	**Plan Period Cost ($M):**	11.0
Primary Trigger:	Failure Risk		
Secondary Trigger:	Reliability		

Investment Need:

Hydro One owns, operates, and maintains 1,005 distribution stations across the province. As outlined in DSP Section 2.3, Hydro One performs inspections and preventative maintenance to assess the condition of the assets (i.e., switches, insulators, support structures, station service, fences and grounding) at distribution stations. These assessments identify a number of distribution station components that are in deteriorated condition, as outlined in DSP Section 2.2. Other influencing factors that affect the operation of the distribution station include components that have safety issues, substandard design or manufacturer defects (i.e., certain models of switches which are prone to failure due to seized bearings, seizing load interrupters and failure of porcelain insulators). The management of these components is required to mitigate these safety and environmental risks and maintain the reliability of the distribution system.

Alternative 1: Reactive Replacements

Wait for distribution station components to fail while in service and replace them on a reactive basis. This alternative is rejected as the cost of emergency replacements is more expensive as materials and resources tend to be at a premium cost. Reactive management of the distribution station components will lead to increased failures resulting in increased safety risks given the emergency nature of the work and degraded reliability for Hydro One's customers.

Alternative 2: Planned Component Replacements (*Recommended*)

Planned replacement of distribution station components identified in deteriorated condition or that have deficiencies, safety issues, substandard design, manufacturer defects. This alternative is recommended as it maintains the safe and reliable operation of the distribution stations.

Investment Description:

This program addresses the individual replacement of distribution station components. The components are identified annually for replacement based on the condition of the asset. These replacements are coordinated with maintenance activities, where possible, to minimize the number of outages. Replacements under this program include but are not limited to the following:

<u>Switches</u>
Switches that are prone to failure due to seized bearings, load interrupters, and/or damaged porcelain insulators require replacement to ensure the reliability and operability of the system.

<u>Structures</u>
Mobile unit substation poles and "dead-end" poles identified in deteriorated condition require replacement to maintain the reliability of the system.

<u>Station Service</u>
Batteries and chargers identified in deteriorated condition require replacement to ensure the operation of protection and control devices, breakers, and circuit switchers in the event of a loss of station service power supply. These devices support reliability and protect other assets on the system.

<u>Fences and Grounding</u>
Station fences identified in deteriorated condition or of substandard height as well as damaged or stolen grounding components require replacement to maintain public safety and security.

The proposed plan is to replace an average of 35 distribution station components annually over the five year period, as noted in the table below. The capital investment for each component replacement is below $1 million. This is expected to maintain the overall condition of the station assets.

Component	**2018**	**2019**	**2020**	**2021**	**2022**
Switches	10	10	11	14	15
Structures	15	15	16	21	22
Other	5	5	5	6	5
Total Component Replacements	**30**	**30**	**32**	**41**	**42**

These planned component replacements are limited to cases where no other assets at the station require replacement. If other assets at the station are at the end of their expected service life and in failing condition, then the work is bundled into an integrated Station Refurbishment project as outlined in ISD SR-06.

Risk Mitigation:

The risks to completion of this investment as planned are outage scheduling and mobile unit substation availability. These risks are mitigated by identifying and planning the work in advance and in a timely manner to ensure that work can be coordinated with existing maintenance work.

Result:

The distribution station component replacements program will result in:

- Mitigating the risk of safety concerns with failed or defective assets;
- Maintaining the reliability of the distribution system; and
- Mitigating the risk of lengthy equipment outages from component failures that affect customers.

Outcome Summary:

Customer Focus	• Reduce customer interruption time by minimizing the number of outages at distribution stations.
Operational Effectiveness	• Maintain safe and reliable operation of the distribution station by reducing asset failure incidents.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system. • Comply with the Distribution System Code requirement to ensure that appropriate follow up and corrective action is taken regarding problems identified during a station inspection.
Financial Performance	• Realize cost savings through planned replacements as the cost of emergency replacements is more expensive.

Costs:

The factors which affect the costs in this investment are the number and the type of assets identified for replacement during the routine station inspections and preventative maintenance.

Controllable costs have been minimized by coordinating replacements with regular maintenance schedule, where possible. In situations where a station refurbishment is planned in the near-term, component replacement is bundled with the refurbishment to reduce costs.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

SR-05 Distribution Station Feeder Protection Upgrade

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Program	**Plan Period Cost ($M):**	12.1
Primary Trigger:	Failure Risk		
Secondary Trigger:	Grid Modernization		

Investment Need:

Hydro One's distribution system has about 2,438 non-sub transmission primary feeders. The majority of these feeders (93%) are protected by various types of station reclosers, while the remaining 7% are protected by circuit breakers and station fuses with no reclose capability.

The 7% of distribution feeders that are protected by circuit breakers and fuses with no reclose capabilities have reduced reliability performance for customers. In the event that a fuse experiences a momentary fault resulting in a disconnection, the feeder would be subject to a sustained outage until it is manually re-energized. This situation is avoided when the feeder protection is upgraded to utilize a recloser (with reclose capability) to protect the distribution feeder.

There is also a subset of reclosers that have become technically obsolete and are no longer supported by the manufacturer. Not only are there no spare parts available should repairs be required, but these reclosers are also more prone to failure. Feeders with obsolete recloser types are only 2% of all feeders, however they account for 5% of all defects identified in 2016.

Furthermore, there are concerns that some of the existing reclosers have reached 95% to 100% of the reclosers' ratings and are approaching a point that the reclosers will no longer have sufficient short circuit and/or interrupt capability to meet the distribution station short circuit levels. Short circuit levels at these stations have increased due to several factors, such as: system reconfiguration, addition of generation on feeders, and/or installation of higher rated station transformers. These reclosers need to be replaced prior to short circuit levels reaching beyond 100% of the recloser's rating.

Alternative 1: Reactive Replacements

Wait for the feeder protection to fail while in service and replace them on a reactive basis. This alternative is rejected for several reasons. Reactive management of the feeder protections will lead to increased unplanned outages due to failures of the reclosers and fuses at unexpected times. This may result in safety risks, reduced feeder protection and reduced reliability for Hydro One's customers. Also the existing feeder protection fleet would require a large stock of spares to be maintained as there are various types and voltage levels of reclosers and fuses on the distribution system. In circumstances, where the existing reclosers are obsolete, modification of the existing structure and station design may be required to install a new recloser design which can take up to 12 months.

Alternative 2: Planned Replacements *(Recommended)*

Proactively install new electronic vacuum type reclosers with communication capability, where the existing protective device has become insufficient and at risk of failure due to condition, short circuit capability, or the lack of reclosing capability. This alternative is recommended as it upgrades the feeder protection before a failure occurs and improves reliability on feeders that are being upgraded from fuse protection to recloser protection due to the reclose capability of a recloser. Also the new electronic controlled vacuum type reclosers have a higher operation limit before maintenance is required compared to the traditional oil filled hydraulic type reclosers, and are also equipped with communication capability for remote controllability.

Investment Description:

This investment addresses concerns with the existing feeder protection through the installation of new vacuum type reclosers with electronic control and communication capability.

These new reclosers are designed for up to 10,000 reclose operations with minimal maintenance. This will reduce the maintenance required compared to oil filled hydraulic type reclosers which are only designed with a threshold of 58 to 272 reclose operations before a maintenance cycle is required. These new electronic reclosers also contain multiple protection settings that can be changed without the need for intrusive upgrades to the recloser, making them more flexible and adaptable to system changes than fuses and hydraulic reclosers. Furthermore, these new reclosers also provide remote control and monitoring capability features to allow automation of the distribution system. This capability modernizes the distribution system, which allows for monitoring and remote control of the recloser. This added benefit can reduce the restoration time when an outage occurs.

Feeder protections are identified and prioritized for replacement based on risk assessment of distribution feeders, in consideration of the following:

- Feeders where station short circuit current level and/or fault current is approaching short circuit rating/interrupt rating of the existing feeder protection;
- Feeders currently protected by fuses that provide reduced reliability to customers as this type of feeder protection has no reclose capability; and
- Feeders where the existing feeder protection is technically obsolete and/or historically prone to failure.

Each feeder protection upgrade will vary in scope and duration depending on the type of existing feeder protection and the design of the station. The forecast of the number of feeder protection requiring replacement annually over the five year period is provided in the table below. The capital investment of each feeder protection replacement is below $1 million.

	2018	**2019**	**2020**	**2021**	**2022**
Number of Replacements	13	13	13	12	12

By the end of 2022, approximately 8% of all distribution feeders would have been upgraded to new electronically controlled vacuum type recloser with remote communication capability. These planned feeder protection upgrades are limited to cases where no other assets at the station require replacement. If other assets at the station have deteriorated and require replacement, then the work is bundled into an integrated Station Refurbishment project as outlined in ISD SR-06.

Risk Mitigation:

The risk to completion of this investment as planned is the time required to execute an upgrade if the distribution station has a substandard design or insufficient clearances, to ensure the newly installed recloser meets current standards. This risk is being mitigated by identifying requirements early in the engineering phase such that proper resources can be allocated to complete the feeder protection upgrade.

Result:

The feeder protection upgrade investment will result in:

- Modernizing the distribution system with feeder reclosers that have a higher operation limit and can be monitored and controlled remotely;
- Improving safety to those stations where fault current levels are on the rise, with the installation of new electronic vacuum type recloser that have a higher interrupt capability and rated for higher fault current levels; and
- Improving customer experience by reducing number and duration of potential sustained customer interruptions.

Outcome Summary:

Customer Focus	• Reduce the number of potential sustained interruptions to customers by adding reclose capability.
Operational Effectiveness	• Improve operational efficiency by adding monitoring and remote controllability to feeder protection. • Address rising station short circuit levels by increasing interrupt capability of the feeder protection.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system. • Enable the potential for more renewable generation to be connected by increasing short circuit rating of the feeder protection.
Financial Performance	

Costs:

The factors that impact the cost of a feeder protection upgrade include the station design and the existing type of feeder protection that is being upgraded. These factors determine the complexity of the installation and the amount of alteration required for each station to install new reclosers.

Controllable costs have been minimized through the procurement of new reclosers that have a higher operation limit before maintenance is required when compared to the traditional oil filled hydraulic type reclosers and allow for monitoring and remote control capability that have the added benefit of reducing the restoration time when an outage occurs.

SR-06 Distribution Station Refurbishment

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Program	**Plan Period Cost ($M):**	148.1
Primary Trigger:	Failure Risk		
Secondary Trigger:	Capacity Upgrade		

Investment Need:

Hydro One owns, maintains, and operates 1,005 distribution stations in Ontario. Each distribution station serves an average of 1,200 customers. A vast majority of these stations are a single transformer design with limited transfer capability.

In the event of a failure of the transformer, the supply to the transformer, or the bus work at a distribution station; all customers supplied by that distribution station would experience an interruption of service until power restoration was achieved through either a repair of failed equipment or connection of a mobile unit substation ("MUS"). These power restoration efforts can take 12 to 24 hours depending on the severity of the failure and location of the station. Over the last five years there has been an average of five transformer failures per year which caused interruption of service.

As outlined in DSP Exhibit 2.3, the main power equipment at these distribution stations are transformers and 23% of these transformers are classified as high risk based on condition assessment. There are also concerns with the condition of some of the structural components of distribution stations, including rotting high and low voltage wood structures, failing tube and clamp structures, fence and grounding systems.

Some other factors contributing to the need for the refurbishment of a distribution station are: loading requirements, lack of MUS facilities, obsolete equipment, environmental spill risk mitigation, and safety issues or a combination of all of these factors. Details relating to these factors can be found in DSP Exhibit 2.3.

Alternative 1: Reactive Component Replacements

Wait for distribution station equipment to fail and replace the failed components on a reactive basis. This alternative is rejected for several reasons. Reactive management of stations would lead to degraded reliability for Hydro One's customers as a result of station failure increases and the duration of outages being longer in length (12 to 24 hours). The reactive replacements would be limited to only addressing the failed component and would not address other components in deteriorated condition that are also at risk of failure. The volume of failures would increase and the MUS and spare transformer fleet would need to be expanded in order to address the additional failures in a timely manner to maintain the customer reliability. Where a station requires additional capacity, the increase in capacity cannot be addressed with a reactive component replacements strategy.

Alternative 2: Planned Component Replacements

Replace individual components identified in high risk condition on a planned component basis. This alternative is viable where only one component at a distribution station is in deteriorated condition (as documented in Investment Summary Document SR-04). Planned replacements have the advantage of avoiding customer outages by arranging for an alternative supply (MUS or load transfer) unlike reactive replacements. However, this alternative is not ideal when multiple components are in deteriorated condition, as individual replacements work is not integrated resulting in increased costs due to multiple mobilizations to replace the different assets.

Alternative 3: Planned Station Refurbishments *(Recommended)*

Refurbish entire stations that have multiple assets in high risk condition, before failures occur. This alternative is recommended as it addresses the needs identified at the distribution station to maintain reliability for Hydro One's customers supplied from that station in the most cost effective manner, consistent with the findings of the customer engagement process. Furthermore for distribution stations in high risk condition where a capacity upgrade is required, station refurbishment is the only feasible alternative as an increase in capacity requires several components of the station need to be replaced or modified (i.e. larger transformer, additional reclosers, increase structure size and station footprint, change conductor and cable size).

Investment Description:

This investment addresses the refurbishment of distribution stations to address station equipment in high risk condition where the likelihood of a failure is high. The level of investment has been determined based on this assessment of condition and in consideration of: customer preferences, safety concerns, compliance requirements, and the benchmarking recommendation to incorporate test result data into the condition assessment.

The proposed plan is to refurbish an average of 15 distribution stations per year over the 5 year period, as noted in the table below. This is expected to maintain the current level of transformers in poor condition at 23% (even though the overall age of the fleet will increase) with the goal of maintaining the current level of station reliability in line with customers' preference to balance reliability and rate impacts.

Each station refurbishment will vary in size and scope. The refurbishment will address: aged transformers and structures, defective equipment, site or property issues, customer issues, safety concerns, environmental compliance, and operational issues. The stations will be refurbished to comply with present standards.

Risk Mitigation:

The risks that can impact the completion of a distribution station refurbishment project are: procurement of real estate to accommodate the station configuration, and environmental remediation of the site. These risks are mitigated by determining the requirements of the new station early in the project planning process and requesting a land survey and environmental site survey before detailed design work has started.

Result:

The station refurbishment program will result in:

- Ensuring sufficient capacity to meet customer loading requirements for the foreseeable future;
- Addressing assets in poor condition to reduce customer interruption time; and
- Resolving operational and safety issues and mitigating environmental spill risk where the risk exists.

Outcome Summary:

Customer Focus	• Reduce customer interruption time by minimizing the number of outages at distribution stations.
Operational Effectiveness	• Maintain safe and reliable operation of the distribution station by addressing degrading equipment in an integrated manner.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system.
Financial Performance	• Realize cost savings by addressing multiple degrading components within the station as part of the same project.

Costs:

The factors which affect the cost of this investment are the following:

- The station design and required station capacity;
- The level of environmental remediation required at the distribution stations; and
- The condition of the structure and level of refurbishment required.

Controllable costs have been optimized through consideration of the station load forecast to avoid additional investments due to overloading in the foreseeable future, and the use of a risk based approach when deciding the level of environmental remediation required.

SR-07 Distribution Lines Trouble Call and Storm Damage Response Program

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Program	**Plan Period Cost ($M):**	431.0
Primary Trigger:	Failure		
Secondary Trigger:	Safety		

Investment Need:

Service interruptions associated with distribution lines invariably occur that require immediate response by Hydro One personnel. Extreme weather or asset failures may result in a service interruption that requires restoration of power to customers. Regular patrols and inspections may also identify damaged or failed distribution line assets that pose a safety hazard or customers may report power quality issues. Hydro One personnel must be dispatched to assess and resolve any urgent deficiency in accordance with good utility practice and the requirements of the Distribution System Code.

Alternatives:

This investment is non-discretionary. No alternatives are considered, since failure to respond to service interruptions or other system deficiencies would violate the OEB Distribution System Code and result in unacceptable reliability for customers and safety risks.

Investment Description:

This investment encompasses the capital costs of asset replacements associated with responding to trouble calls, storm damage, power interruptions and other situations that pose reliability or safety risks and require immediate attention in compliance with the Distribution System Code.

The distribution lines trouble call and storm damage response program includes the following activities:

- Emergency pole and line equipment replacements,
- Emergency submarine and underground cable replacements,
- Storm damage response and resolving service interruptions caused by adverse weather conditions,

- Post trouble-call response and providing permanent solutions to any temporary repairs that were required during an emergency or a service interruption,
- Power quality response requiring modifications to the system to resolve unacceptable voltage or frequency levels, and
- Damage claims, including payment for third party damage that Hydro One cannot recover.

All other trouble call and storm damage response costs which cannot be capitalized are allocated to the OM&A work program as documented in Exhibit C, Tab 1, Schedule 2.

Risk Mitigation:

The work in this investment is unplanned in nature. However, there are risks to executing such unplanned work including the number of asset failures and storm events and the availability of qualified resources. This risk is mitigated by diverting qualified resources from other projects to complete restoration activities.

Result:

The distribution lines trouble call and storm damage response program will result in:

- Maintaining reliability of the distribution system by ensuring timely response to trouble calls, service interruptions, and power quality complaints,
- Mitigating safety risks of defective or failed assets, and
- Satisfying customer and regulatory requirements.

Outcome Summary:

Customer Focus	• Improve customer satisfaction by minimizing the customer interruption duration by carrying out unplanned outages in a timely manner. • Mitigate customer complaints related to power quality and reduce public safety hazards.
Operational Effectiveness	• Maintain the safe and reliable operation of the distribution system.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system. • Comply with the Distribution System Code requirement to ensure that appropriate follow up and corrective action is taken regarding problems identified during station inspections.
Financial Performance	

Costs:

Planned expenditures for this demand program are projected based on historical costs, factoring in anticipated needs and inflation over the period. The factors which affect the costs in this investment are the following:

- The volume of the asset failures and storm events which occur on an annual basis.
- The scope of the work required to address asset failures and storm events.

Any significant changes to these would affect the costs.

Controllable costs have been minimized by standardizing the procedure for common activities such as pole and equipment replacements.

SR-08 Distribution Lines PCB Equipment Replacement Program

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Program	**Plan Period Cost ($M):**	72.8
Primary Trigger:	Mandated Obligation		
Secondary Trigger:	Substandard Performance		

Investment Need:

Hydro One owns, operates, and maintains 450,000 pole top transformers, 54,000 pad mount/submersible transformers and 3,000 pole mounted capacitor units; all of which are oil filled equipment. Prior to year 1985, a chemical compound known as a polychlorinated biphenyl (“PCB”) was widely deployed in dielectric and coolant fluids in the manufacturing of oil filled electrical apparatus. However, this manufacturing practice was discontinued in the late 1970’s when it became evident that PCBs build up in the environment and exposure to high levels can cause harmful health effects. In 2008, Environment Canada enacted legislation mandating that all oil-filled equipment whose insulating oil contains greater than 50 ppm of PCBs be removed by December 31, 2025. Therefore Hydro One must remove all such oil-filled equipment. Hydro One’s distribution assets which are oil-filled consist solely of pole top transformers, pad mount mount/submersible transformers and pole mounted capacitor unit.

Alternatives:

This investment is non-discretionary. No alternatives are considered, since failure to remove PCB contaminated distribution line equipment would place Hydro One in violation of Environment Canada regulations and result in increased public health and safety risks.

Investment Description:

This program addresses the removal and replacement of distribution line oil-filled equipment (i.e., pad mount transformers, pole top transformers and pole mounted capacitor banks) whose insulating oil contains PCB contamination levels are greater than 50 ppm. All of Hydro One’s pad mount transformers have already been tested as part of the PCB inspection and testing program, and all units with greater than 50 ppm of PCBs have been replaced.

All of Hydro One's pole-top transformers manufactured prior to 1985 will require inspection and oil sampling testing. To date, approximately 10 to 15% of the transformers have be inspected and tested. Hydro One proposes to inspect and test the remaining transformers at a consistent rate over the period from 2018 to 2024.

From past experience with PCB testing, approximately 8% of these transformers will exceed the 50 ppm threshold and will ultimately require replacement due to PCB contamination. The replacement of the pole-top transformers is slated to lag the PCB inspection and testing program by one year, allowing time for the identification of contaminated transformers and optimization of a plan to replace the transformers that minimizes the impact to customers. Based on historic sampling results this would result in approximately 2,400 to 2,600 replacements per year to ensure that the program will be completed by the 2025 deadline set out by Environment Canada.

Capacitor units cannot be tested for PCBs without causing them significant damage. Therefore, all of Hydro One's capacitors manufactured before 1985, will require replacement. Hydro One proposes to replace the units at a consistent rate over the period from 2018 to 2024.

Risk Mitigation:

The risk to completion of this investment as planned is based on the uncertainty of the volume and exact location of the PCB contaminated equipment exceeding the allowable threshold of 50 ppm. This risk is mitigated by the establishment of an inspection and testing program to identify all oil filled equipment that must be replaced under legislative requirement and an associated process to replacement the identified contaminated equipment.

Result:

The distribution lines PCB equipment replacement program will result in:

- Mitigating health and safety risks associated with PCB contamination by removing the affected line equipment; and
- Ensuring compliance with environmental legislation.

Outcome Summary:

Customer Focus	• Mitigate potential health and safety hazards to customers and the public by removing the contaminated lines equipment.
Operational Effectiveness	• Realize improvement of distribution lines by replacing the old PCB contaminated equipment with new equipment.
Public Policy Responsiveness	• Comply with Environment Canada legislation to remove all oil filled equipment with PCB contamination > 50 ppm by 2025.
Financial Performance	• Avoid non-compliance penalties arising from a failure to complete the mandated PCB elimination by 2025.

Costs:

The costs for this program are projected based on historic sampling results and future anticipated replacement needs which lag the PCB inspection and testing program by one year. The factors which affect the costs in this investment are any unforeseen issues at each work location, for example all new installations must meet Electrical Safety Authority requirements, so where a transformer is to be replaced, minimum pole height standards are mandated which could result in multiple pole and other equipment replacements.

Controllable costs have been minimized by standardizing the procedure for common activities such as equipment replacement, and coordinating with other sustainment programs where possible.

SR-09 Pole Replacement Program

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Program	**Plan Period Cost ($M):**	579.0
Primary Trigger:	Failure Risk		
Secondary Trigger:	Safety		

Investment Need:

The structural integrity of a distribution line is largely dependent on the poles that support the line. Hydro One owns, maintains and operates approximately 1.6 million poles, of which 99% are wood poles.

The condition of wood poles deteriorates over time due to decay and rot, insect and rodent damage, mechanical impact, or other factors that reduce the structural integrity of the pole. Once a pole's condition has deteriorated to the point that it has a significant risk of failure under adverse weather condition, it is deemed to be at end-of-life. During storm conditions, poles that fail can sometimes trigger "cascading failures", which result in the failure of a larger number of distribution system assets.

As outlined in DSP Exhibit 2.3, there are currently approximately 67,000 poles in poor condition that are at high risk of failure. By the end of 2022, it is forecasted that an additional 77,000 poles will be added to this high risk category due to deteriorating condition.

In addition to concerns with condition, there are still a subset of 39,000 red pine poles that are demonstrating premature degradation, as documented in previous proceedings (EB-2013-0416, EB-2012-0136 and EB-2009-0096), that require replacement.

Furthermore, one of the finding of the benchmarking study discussed in DSP Section 1.6 found that Hydro One's poles replacement rate of approximately 10 700 pole per year over the past five years is slower than the comparison utilities. The study also found that the average pole on the Hydro One system is on average eight years older than the comparison utilities.

Alternative 1: Reactive Replacements

Wait for the poles that are at end of life to fail and replace the failed poles on a reactive basis. This alternative is rejected for several reasons. The cost of reactive replacements is more expensive as documented in DSP Exhibit 2.3. Reactive management of the poles will lead to increased failures resulting in a risk to public safety and degraded reliability for Hydro One's customers. Also the volume of poles requiring replacement will quickly increase to the point where the volume of trouble calls will become unmanageable.

Alternative 2: Planned Pole Replacements at Historic Rate

Planned replacement of end of life poles at the historic rate of replacement. This alternative is rejected as it would not address all of end of life poles within the five year period resulting in a backlog of poles which will lead to more frequent and/or longer duration outages for Hydro One customers.

Alternative 3: Planned Pole Replacement at an Increased Rate (Recommended)

Planned replacement of end of life poles at an increased rate (as noted in the following table) that balances asset needs, resource availability, and cost impact to customers. The number of poles at high risk of failure requiring replacement will be slightly reduced over the plan. This alternative is recommended as it will maintain reliability of the distribution system.

Investment Description:

This investment addresses the replacement of poles that are at end-of-life, and addresses the subset of red pine poles demonstrating premature degradation. Poles are inspected on a regular basis, and are identified and prioritized for replacement based on an asset risk assessment that considers factors such as: condition, performance, demographics and criticality.

Hydro One has been gradually ramping up the number of poles replaced each year to a sustainable level of replacement that balances the needs of the asset, resource availability, and the rate impact to customers.

Hydro One is sensitive to customer needs and will manage the population of poles in poor condition that are at high risk of failure over the five year plan so as to reduce cost impacts to customers. There are currently a large number of poles in poor condition that are at high risk of failure and it is forecasted that this number will be slightly reduced to 99,000 poles (including the red pine pole subset) over the plan. Poles are prioritized for replacement based on their impact on reliability and potential safety risks. The table below outlines the planned volume of poles to be replaced throughout the five year period.

	2018	2019	2020	2021	2022
Number of Poles Replaced	9,600	14,300	16,000	16,123	16,128

Pole replacement costs and accomplishments are tracked and reported monthly. Depending on the types of poles requiring replacement (i.e. pole height, pole class, number of circuits, etc.) and the accessibility conditions of the area, the cost of replacement can vary. Where possible, the efficiency of this investment is maximized by bundling work and replacing poles in close proximity to each other. Larger line rebuilds are funded by the "Distribution Lines Sustainment Initiative" program as outlined in ISD SR-12.

Risk Mitigation:

The risk to completion of this investment as planned is the number of major storm events which decreases the availability of qualified resources, as resources are diverted to storm restoration efforts. However, the number of storms in recent years this has not been an issue.

Result:

The pole replacement program will result in:

- Reducing the risk of pole failure by replacing poles in poor condition;
- Reducing safety and reliability risks on the distribution system; and
- Ensuring compliance with Canadian Standards Association standards.

Outcome Summary:

Customer Focus	• Reduce the number of potential interruptions to customers by proactively replacing wood poles prior to failure. • Focus on balancing the rate impact to customers while addressing the replacement need and risks associated with end of life poles.
Operational Effectiveness	• Maintain safe and reliability operation of the distribution system by proactively replacing end of life poles.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system. • Comply with Canadian Standards Association standard by replacing wood poles that have deteriorated to 60% of their design strength.
Financial Performance	• Realize cost savings through planned replacements as the cost of emergency replacements is more expensive.

Costs:

Pole replacement costs and accomplishments are tracked and reported monthly. The factors which affect the costs in this investment are the following:

- The types of poles requiring replacement (i.e. pole height, pole class, number of circuits, etc.);
- The location accessibility conditions of the area in which the poles are being replaced. Accessing off road locations can be more costly due to the use of specialize equipment; and
- The cost of material and term of procurement contracts.

Controllable costs have been minimized through balancing the pole types and locations selected for pole replacements in a given year and by standardization the procurement of materials and procedures for equipment replacement.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

SR-10 Distribution Lines Planned Component Replacement Program

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Program	**Plan Period Cost ($M):**	35.3
Primary Trigger:	Failure Risk		
Secondary Trigger:	Reliability		

Investment Need:

Hydro One's distribution system consists of approximately 122,000 circuit kilometers of primary feeders lines across the province. As outlined in DSP Exhibit 2.3, Hydro One performs line patrols and preventative maintenance programs to assess the condition of line equipment (i.e. cross arms, nest platforms, overhead conductor, regulators, reclosers, sentinel lights, transformers, and switches) on those feeders. These condition assessments have identified a number of distribution line components that due to their condition, are near the end of their expected service life. Additionally, there are a number of components on the system that are substandard or that pose environmental risks. The management of these components is required to mitigate these safety and environmental risks and maintain reliability of the system.

Alternative 1: Reactive Replacements

Wait for the distribution line equipment to fail while in service and replace it on a reactive basis. This alternative is rejected as the cost of emergency replacements is more expensive as materials and resources tend to be at a premium cost. Reactive management of distribution line equipment will lead to increased failures resulting in risks to employee and public safety and degraded reliability for Hydro One's customers.

Alternative 2: Planned Component Replacements (*Recommended*)

Planned replacement of distribution line equipment identified in deteriorated or substandard condition. This alternative is recommended as it mitigates the risk of failure of critical customer service assets and ensures a safe and reliable distribution system.

Investment Description:

This investment addresses the individual replacement or refurbishment of distribution line components when it is not economical to integrate the work into one of the large sustainment initiative projects, as described in ISD SR-12. The program comprises the replacement of the following asset types:

Overhead Conductor

Some types of overhead conductor (i.e., #2 ACSR and #4 ACSR) have been found to pose increased safety risks requiring modified work practices. The presence of this conductor limits Hydro One's ability to work on poles and equipment, and can pose work issues for Joint Use Partners. Replacement is based on the location and joint use status of poles which support these conductor types.

Cross arms

Cross arms are fastened to poles to support insulators and conductors. As these components deteriorate with age, their risk of failure increases, posing increased safety risks to the public and Hydro One personnel. System reliability is also potentially impacted.

Nest Platforms

Bird nests on distribution poles can potentially cause pole fires and damage equipment, impacting safety, asset condition, and system reliability. Nest platforms are constructed to allow bird nests to be relocated from distribution poles, while complying with environmental regulations protecting species at risk. The relocated nest platforms can be installed on existing poles, on taller poles, or on separate adjacent poles.

Lines Regulators and Reclosers

Regulators and reclosers are integral components in the operation of the distribution system. Devices requiring replacement are those which are inoperable and where maintenance is not deemed feasible. Failed or inoperable regulators and reclosers can lead to disproportionately widespread and/or extended outage impacts.

Lines Transformers

Some types of transformers (i.e. pole transformer units and trans closure units) have been found to be substandard as these transformers are housed in enclosures, resulting in sub-standard working clearances. These transformers are in poor condition and provide inadequate operational clearances. As a result, any work on the transformers can only be completed if they are taken out of service, which results in long outages. As these types of transformers are not currently part of Hydro One's standards, limited supplies of spare parts can also result in extended outages if they fail. These substandard transformers are replaced with pad mount transformers to current Hydro One standards.

<u>Lines Switches</u>

Switches are integral components in the operation of the distribution system. Overhead Air Break and Load Break switches requiring replacement are those which have failed or have operational issues that cannot be feasibly repaired. Failed or inoperable switches can lead to reduced operational flexibility as well as disproportionately widespread and/or extended outage impacts.

<u>Sentinel Lights</u>

Sentinel Lights are legacy equipment which provides dusk to dawn lighting for Hydro One's customers. Hydro One is contractually obligated to maintain existing installations, which may include replacing failed fixtures or poles. No new customer contracts for installation of these sentinel lights are being issued. This program also funds the removal of lights that are no longer required.

Planned replacement of these aged, deteriorated or defective assets can greatly reduce these risks of failure thereby ensuring reliability is maintained for Hydro One's customers. Depending on the types of distribution line equipment requiring replacement and the location conditions of the area, the cost of the replacement can vary. The table below outlines the proposed volume of the components to be replaced throughout the five year period. The overhead conductor replacements are project based and can vary year over year based on length and complexity of replacement.

	2018	**2019**	**2020**	**2021**	**2022**
Cross arms	1,780	1,780	1,780	1,780	1,780
Nest Platforms	15	15	15	15	15
Regulators and Reclosers	1,244	1,244	1,244	1,244	1,244
Transformers	100	100	100	100	100
Switches	60	60	60	60	60
Sentinels Lights	1,400	1,400	1,400	1,400	1,400

Risk Mitigation:

The risk to completion of this investment as planned is the number of major storm events which decreases the availability of qualified resources, as resources are diverted to storm restoration efforts. However, the number of storms in recent years this has not been an issue.

Result:

The line component replacement program will result in:

- Mitigating safety risks of defective, substandard or deteriorated assets;
- Maintaining reliability of the distribution system; and
- Satisfying customer and regulatory requirements.

Outcome Summary:

Customer Focus	• Maintain reliability for customers by minimizing the number of interruptions to customers due to equipment failures. • Reduce public safety hazards of deteriorated line components.
Operational Effectiveness	• Maintain safe and reliable operation of the distribution system by proactively replacing equipment.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system. • Comply with the Distribution System Code requirement to ensure that appropriate follow up and corrective action is taken regarding problems identified during a line patrol.
Financial Performance	• Realize cost savings through planned replacements as the cost of emergency replacements is more expensive.

Costs:

The factors which affect the costs in this investment are the following:

- The location in which the equipment is being replaced;
- Unforeseen property/easement issues; and
- Availability of required resources.

Controllable costs have been minimized by standardizing the procedure for common activities such as equipment replacement, and coordinating with other sustainment programs where possible.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

SR-11 Submarine Cable Replacement Program

Start Date:	Q1 2018	Priority:	Medium
In-Service Date:	Program	Plan Period Cost ($M):	39.1
Primary Trigger:	Safety		
Secondary Trigger:	Failure Risk		

Investment Need:

Hydro One's distribution system contains approximately 11,663 submarine cables totaling about 3,300 circuit kilometers in length. These cables are used to traverse water when overhead crossings are technically or economically unfeasible.

Distribution system patrols have found that many cables are deteriorating, particularly at the shoreline. Cables that are exposed at or near the shore can be damaged by the movement of water or ice and by human activity. This damage usually takes the form of abrasion or corrosion of the protective cable armour, which can lead to neutral failure or water ingress.

Cables that are damaged or exposed at the shoreline can pose significant public safety hazards, as well as increased reliability risks.

Alternative 1: Reactive Replacement

Wait for submarine cables to fail while in service and replace them on a reactive basis. This alternative is rejected as it results in an unacceptable safety risk to the general public and employees. Contact with a damaged cable can lead to serious injury or a fatality. Emergency repairs are also more expensive as materials and resources tend to be at a premium cost.

Alternative 2: Planned Replacement (*Recommended*)

Planned replacement or refurbishment of submarine cables approaching end-of-life or demonstrating deteriorating condition. This alternative is recommended as it will mitigate the risk of failure and ensure a safe and reliable distribution system.

Investment Description:

This investment addresses the replacement or refurbishment of submarine cables that are damaged or that are exposed at the shoreline. Cables that meet these criteria are identified during distribution system line patrols. If a cable is found to pose an immediate hazard, it is immediately replaced under the "Trouble Call" program. If immediate replacement is not possible, these cables are temporarily repaired and scheduled for replacement or refurbishment. Depending on the location and extent of damage to a cable, the submarine cable may require either a sectional repair or a full cable replacement. In the case of a sectional repair, damaged locations are identified and a new section is spliced into place. However, if the cable is severely damaged, is obsolete, has exhibited poor performance, or has required repeated repairs, it is completely replaced.

This program will replace or refurbish approximately 220 to 250 submarine cable sections per year. This program also addresses the re-establishment of mechanical shoreline protection (cable covering which protects the submarine cable from deterioration caused by ice and wave damage) and the installation of warning signage for these cables.

Risk Mitigation:

Due to the significant public safety hazards associated with these defective submarine cables, these replacements are treated as a high priority and therefore no risks are foreseen with completing this replacement program as planned.

Result:

The submarine cable replacement program will result in:

- Mitigating the public safety risks of defective submarine cable; and
- Maintaining reliability of the distribution system.

Outcome Summary:

Customer Focus	• Mitigate public safety hazards from defective submarine cable. • Maintain reliability by reducing interruptions to customers from defective submarine cable.
Operational Effectiveness	• Maintain safe and reliable operation of the distribution system by proactively replacing equipment.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system. • Comply with the Distribution System Code requirement to ensure that appropriate follow up and corrective action is taken regarding problems identified during a line patrol.
Financial Performance	• Realize cost savings through planned replacements as the cost of emergency replacements is more expensive.

Costs:

The factor which affects the costs in this investment is the shoreline condition where the cable exits the water; as shoreline protection may be required for the cable.

Controllable costs have been minimized by standardizing the procedure for common activities such as equipment replacement.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

SR-12 Distribution Lines Sustainment Initiatives

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Program	**Plan Period Cost ($M):**	151.7
Primary Trigger:	Failure		
Secondary Trigger:	Reliability		

Investment Need:

Hydro One's distribution system consists of approximately 122,000 circuit kilometers of primary feeder lines across the province with approximately 17% of these feeders lines being located off-road. These off-road sections of feeders are difficult to access during power interruptions and can result in increased risk of prolonged outages.

As outlined in DSP Exhibit 2.3, Hydro One performs line patrols and preventative maintenance programs to assess the condition of its distribution feeder lines. These assessments have identified a number of concerns with the condition of the components on the primary feeders.

In addition to the condition of the distribution feeder line, there are a number of component installations that are of sub-standard design/construction based on changes over time in industry standards and do not meet current Hydro One standards, including conductor sizing, framing, guying, transformer installations and clearance issues. These conditions pose increased safety and reliability risks.

Alternative 1: Reactive Replacements

Wait for the distribution line equipment to fail while in service and replace it on a reactive basis. This alternative is rejected as the cost of emergency replacements is more expensive as materials and resources tend to be at a premium cost. Moreover, reactive management of the distribution line equipment will lead to increased failures resulting in risks to employee and public safety and degraded reliability for Hydro One's customers.

Alternative 2: Planned Components Replacements

Planned replacement of distribution line equipment identified in deteriorated or substandard condition, on a "like for like" component basis. This alternative is viable where an individual component of standard design on a distribution line is in deteriorated condition. However it is not ideal when multiple components are in deteriorated condition or the components are of substandard design, as individual replacement work does not allow for cost efficiencies associated with integration of replacements of assets in close proximity to each other; as well as it would require custom-engineered designs to address substandard equipment. Furthermore, this alternative would not address any accessibility concerns and would result in higher ongoing maintenance costs.

Alternative 3: Planned Lines Sustainment Initiatives (Recommended)

Planned refurbish or rebuild of entire feeders or feeder sections, when multiple components of the distribution line have been identified in deteriorated condition, in order to improve the performance of that distribution line. This alternative is recommended as it addresses the needs identified on the distribution lines in order to maintain the reliability of the distribution system in the most cost effective manner and minimize any safety risks to the public and Hydro One personnel.

Investment Description:

This investment address the refurbishment of entire feeders or feeder sections in an integrated manner to address line equipment with likelihood of failure is high. Distribution line assets deteriorate over time, taking into account the overall condition of poles, conductors and associated components; feeder sections are identified and prioritized for refurbishment or rebuild. Refurbishing or rebuilding an entire feeder section is preferred when the cost of maintaining or replacing individual components on that section becomes excessive.

There are a number projects identified under this program annually; which vary significantly in size and scope. The projects with capital investment exceeding $1 million are provided in the following table.

Year	Project Name	Net Total ($Million)
2018	City of Owen Sound Refurbishment - Part 3 of 4, *Owen Sound*	1.2
	Dundas TS M1 Rebuild Carlisle, *Dundas*	2.0
	Duart TS M6 Relocation, *Strathroy*	4.0
	Dymond TS M3 Rebuild - Part 1 of 2, *New Liskeard*	3.6
	Manitouwadge TS M2 Rebuild - Part 5 of 5, *Thunder Bay*	3.5
	Minden TS M2 - Part 2 of 2, *Minden*	2.5
	Otonabee TS M28 - Part 3 of 3, *Peterborough*	1.5
	Projects Less Than $1M	4.0
2019	Brant TS M21 Relocation, *Simcoe*	1.8
	Brockville TS 24M2-Part 5 of 5, *Brockville*	1.0
	City of Owen Sound Refurbishment-Part 4 of 4, *Owen Sound*	2.2
	Dobbin TS 20M4/6/8 Reconstruction, *Peterborough*	1.3
	Duart TS M5 Relocation, *Kent*	3.9
	Dymond TS M3 Rebuild-Part 2 of 2, *New Liskeard*	3.0
	Errington Street Rebuild—Chelmsford, *Sudbury*	1.6

	Projects Less Than $1M	2.4
2020	Angus 44 kV Backlot Relocate, *Barrie*	1.2
	Augasabon DS F1 & F2 Rebuild (Part 1 of 2), *Thunder Bay*	2.5
	Brant TS M22 Relocation, *Beachville*	2.0
	G3K Towerline Refurbishment, *Kirkland Lake*	1.0
	Ingersoll TS M46 Rebuild, *Beachville*	2.5
	Kent TS M16 Relocation, *Kent*	1.2
	Kleinburg TS M8, *Bolton*	2.0
	Muskoka TS M1 Relocation - Part 2 of 5, *Huntsville*	4.0
	Napanee TS M2 Relocation - Part 1 of 2, *Picton*	3.0
	Owen Sound TS M24 Rebuild - Part 3 of 3, *Owen Sound*	2.8
	Palmerston TS M1 Relocation - Part 1 of 2, *Listowel*	3.0
	Sidney TS M7 Reconductor, *Frankford*	1.3
	Weston Lake DS F1 Relocation, *Timmins*	1.0
	Projects Less Than $1M	3.4

Witness: Lyla Garzouzi

Year	Project Name	Net Total ($Million)
2021	Augasabon DS F1 & F2 Rebuild (Part 2 of 2), *Thunder Bay*	2.5
	Clarke TS M2 Relocation, *Strathroy*	2.5
	Colgan DS Inaccessible Switch 2314 Relocation, *Alliston*	1.0
	Havelock TS M2 Rebuild-Part 1 of 2, *Tweed*	2.5
	Lauzon TS M25 Rebuild, *Essex*	2.0
	Longueuil TS 26M23 Relocate, *Vankleek Hill*	3.5
	Meaford TS M1 Lower Valley Rd Rebuild, *Owen Sound*	1.5
	Muskoka TS 30M1 Relocation-Part 3 of 5, *Huntsville*	1.7
	Muskoka TS M2 Relocate, *Huntsville*	1.4
	Napanee TS M2 Relocation-Part 2 of 2, *Picton*	3.0
	Old E1R Ear Falls DS F3, *Dryden*	2.5
	Palmerston TS M1 Relocation-Part 2 of 2, *Listowel*	1.0
	Tillsonburg M1 Refurbishment, *Beachville*	2.7
	Projects Less Than $1M	6.0
2022	Forest Jura DS F1 Relocation, *Lambton*	2.0
	Geraldton Rebuild-Part 1 of 3, *Thunder Bay*	1.0
	Havelock TS M2 Rebuild-Part 2 of 2, *Tweed*	2.5
	Kirkland Lake TS G3K Relocate-Part 1 of 2, *Kirkland Lake*	4.0
	Mair Mills DS F1 Grey Rd 21 Rebuild, *Stayner*	1.0
	Muskoka TS 30M1 Relocation-Part 4 of 5, *Huntsville*	2.5
	Muskoka TS M3 Relocation, *Bracebridge*	2.0
	Palmerston TS M3 Relocation-Part 1 of 2, *Listowel*	2.5
	Picton TS M5 Rebuild (Part 1 of 2), *Picton*	3.0
	Sidney TS M7 Rebuild-Part 1 of 2, *Frankford*	3.0
	Stayner TS M2 Rebuild, *Stayner*	3.4
	Wanstead TS M1 Rebuild Alvinston, *Lambton*	2.0
	Projects Less Than $1M	4.8

Each of these projects involves equipment that is identified as a concern during the condition assessment. The refurbishment or rebuilding of entire feeders or feeder sections entails replacing all components to the present Hydro One' standard and is done in compliance with Electrical Safety Authority (ESA Reg. 22/04) requirements for new construction.

Risk Mitigation:

The risk to completion of this investment as planned is the number of major storm events which decreases the availability of qualified resources, as resources are diverted to storm restoration efforts. However, due to the lower number of major storms in recent years this has not been an issue. This investment assumes the level of major storms to be in line with historical trends.

Result:

The lines sustainment initiatives will result in:

- Mitigating safety risks of defective, substandard or deteriorated assets;
- Maintaining the reliability of the distribution system; and
- Obtaining operational efficiencies by executing work in an integrated manner and reducing customer interruption time.

Outcome Summary:

Customer Focus	• Maintain reliability for customers by reducing the number of planned outages on distribution lines. • Improve response time by relocating off-road line segments to more accessible locations.
Operational Effectiveness	• Maintain safe and reliable operation of the distribution system by proactively addressing lines equipment in an integrated manner.
Public Policy Responsiveness	• Comply with the Distribution Rate Handbook by maintaining the existing service reliability performance of the system. • Comply with the Distribution System Code requirement to ensure that appropriate follow up and corrective action is taken regarding problems identified during a line patrol.
Financial Performance	• Realize cost savings by addressing multiple degrading components along a section of line as part of the same project.

Costs:

The factors which affect the costs in this investment are the following:

- The location in which the equipment is being replaced;
- Unforeseen property/easement issues; and
- Availability of required resources.

Controllable costs have been minimized by standardizing the procedure for common activities such as pole and equipment replacement.

SR-13 Life Cycle Optimization & Operational Efficiency Projects

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Program	**Plan Period Cost ($M):**	134.0
Primary Trigger:	Failure Risk		
Secondary Trigger:	System Efficiency		

Investment Need:

Assets at the end of their expected service life are typically addressed by system renewal projects and programs that focus on like-for-like replacements. However, in some situations it is more efficient from a cost and operations perspective to address end-of-life assets by other means such as constructing supply facilities at a different location, upgrading nearby assets, or modifying the network configuration in order to eliminate the need for certain assets.

As assets reach end-of-life, the risk of failure under adverse conditions increases, which can lead to lengthy interruptions to customers and can increase the likelihood of exposing the employees and the public to safety hazards. In situations where other issues are also present, such as poor voltage, limited load transfer capability, or multiple/incompatible system voltages, it is often beneficial to address all issues through one project that upgrades or modifies the existing network configuration. As an example, converting feeders fed from an end-of-life station to a higher operating voltage results in higher load meeting capability, better power quality, and reduced line losses.

These investments provide an opportunity to achieve overall cost savings by bundling asset renewal work on stations and feeders and integrating other system capacity and operational needs under a common solution. Eliminating or combining assets reduces future operating and maintenance costs and improves operational efficiency. Other factors which may lead to addressing end-of-life assets by other than like-for-like means may include environmental factors, property issues, and incompatibility of existing assets with surrounding land uses. Project-specific information is provided in Attachment 1.

Not proceeding with this investment would result in higher expenditures, reduced productivity and inefficient operations. The issues addressed under this investment are a mix of urgent needs and good planning practices that improve overall system operations. By executing projects that simultaneously address these items over individual refurbishment or upgrade projects, overall costs are reduced and fewer resources are required.

Alternative 1: Address End of Life Assets only Through Like-for-Like Replacement

Address all end-of-life asset issues only through like-for-like replacements through other system renewal projects or programs.

This alternative is not recommended since it presents a lost opportunity to achieve overall operational efficiencies and customer benefits which can be achieved by identifying more optimal asset replacement approaches.

Alternative 2: Modify The Distribution System to Eliminate Operationally Inefficient Assets that are Nearing End-of-Life *(Recommended)*

Address specific end-of-life asset needs by means other than like-for-like where there are opportunities to reduce costs and achieve increased operational efficiencies. When stations or lines are approaching their end-of-life based on the condition of their individual components, there may be opportunities to implement system changes other than like-for-like replacement of these assets in order to achieve cost savings and long-term operational efficiencies. It may be possible to eliminate stations or consolidate line assets through voltage conversion projects, or transfers to other stations. Reduced upfront capital costs as well as future maintenance savings can be realized using this approach.

Investment Description:

A number of distribution stations are approaching their end of life. For stations where other alternatives may exist to address renewal needs, an integrated planning approach is taken. This involves assessing other potential system renewal needs in the surrounding network, capacity needs, as well as reliability and operational needs. Alternative solutions are evaluated and an optimal plan is developed which addresses all identified needs in the most cost-effective manner. In cases where stations can be completely eliminated, all existing equipment, structures and materials are removed from the property. Any necessary land remediation needed to remove contaminated soil and site restoration is also included.

To improve operational efficiency and optimize asset life cycle costs, there are several types of projects that are commonly executed.

Station Decommissioning through Voltage Conversions: One approach to remove a station from service is to convert the voltage of its feeders to match its upstream voltage. For example, to decommission a 27.6kV - 8.32kV station, the 8.32kV feeders could be converted to 27.6kV, which removes the need for the station. This approach is advantageous because it addresses stations that are near end-of-life, and improves the voltage quality and capacity of the downstream feeders.

Station Decommissioning by Constructing New Station/Feeders: Another approach used to decommission stations is to construct new stations in their place. In some cases, a new station may suffice to replace multiple stations that are near end-of-life. These projects also include the construction of new feeders to take over the loads from stations planned for decommissioning.

The most common type of project addressed under this investment is the elimination of a distribution station that has reached end-of-life by converting the station's low-voltage feeders to a higher distribution voltage. This may involve feeding the station load directly from the upstream TS supply feeder where it is feasible to do so, or by transferring it to another nearby station operating at a higher voltage. Performing a voltage conversion project may involve replacing feeder assets such as poles, transformers, primary and secondary conductors and secondary service connections, which may also be approaching end-of-life.

A listing of all proposed projects under this investment category with costs in excess of $1 million over 2018 to 2022 time frame is provided in Attachment 1. These projects are reprioritized each year based on updated condition assessment and performance data to ensure they are addressed in order of criticality. Additional funding is included in this investment for projects less than $1 million and to cover emergent needs or to coordinate system renewal needs with work initiated by other third parties such as the transmitter, land developers, municipalities, and road authorities. In these cases, planned projects may be postponed to ensure the most efficient use of resources and funding.

Risk Mitigation:

The main risks to completion of this work are lack of labour resources for design and construction, as well as risks around property rights for poles, anchors and tree trimming required for feeder construction. For projects that require the construction of new stations, there are additional risks associated with the acquisition of new property such as the lack of a willing seller, delays due to negotiations with property owners, municipalities, and in some cases First Nation concerns. These risks will be mitigated by ensuring appropriate planning lead times are followed for project scheduling and by considering constructability issues early in the project definition stage.

Result:

- Eliminated end-of-life assets to mitigate reliability, customer dissatisfaction, and safety risks;
- Improved power quality and load meeting capability of the system;
- Provide enhanced operating flexibility to mitigate customer impacts during planned outages or emergency situations;
- Improvement in overall cost effectiveness by implementing integrated solutions that address end-of-life assets, capacity, and operational needs simultaneously; and
- Reduced line losses.

Outcome Summary:

Customer Focus	• Avoided material deterioration in reliability and customer satisfaction. • Reduced outage duration by eliminating obsolete network equipment with non-standard designs/equipment. • Improved load meeting capability of the network. • Large customer needs for enhanced voltage support and other quality of power criteria addressed.
Operational Effectiveness	• Streamlined operations by eliminating multiple operating voltages and the requisite additional inventory, work methods and training needs. • Minimized cost by taking an integrated planning approach based on area supply needs. • Improved long-term operating and maintenance efficiency due to consolidating and reducing the number of system assets.
Public Policy Responsiveness	• Compliance with DSC requirements to maintain and plan the system in accordance with good utility practice. • Reduced overall environmental impact by eliminating stations where feasible.
Financial Performance	

Costs:

Construction costs for voltage conversion work can vary depending on conditions such as ground conditions, customer density, urban vs. rural, and condition of existing feeder assets. Newer lines built to present day standards can be converted to higher operating voltages at minimal cost, while older lines tend to require complete replacement and upgrading to current standards.

Costs are controlled by avoiding costly or complex design solutions where possible, by sub-contracting specialized civil work to external service providers, and by using intermediate step-down transformers where feasible to reduce the amount of line reconstruction work.

Project ID	Project Name	Scope	Need Addressed	Cost $M Net	Year(s)
LC-1	Barrys Bay Voltage Conversion	Convert existing 4.16 kV lines to 12.5 kV and re-supply from adjacent 12.5kV system.	Eliminate end-of-life 4.16kV distribution station and refurbish old 4.16 kV lines.	1.8	2018
LC-2	Burford DS Removal	Convert two 8.32 kV feeders to 27.6kV and remove existing Burford DS.	Eliminate end-of-life station assets.	1.5	2018
LC-3	Margach DS F3 – SD3676 Voltage Conversion	Convert 7.2 kV single-phase line section to 14.4 kV.	Eliminate end-of-life step-down transformer and line equipment.	1.4	2018
LC-4	Beaver Valley RS	Construct New 44 kV Regulating Station & Remove Existing Eugenia RS.	Eliminate End of Life Assets and potential high impact spill risk at Eugenia RS.	1.5	2018
LC-5	Carlton Place DS's Reconstruction	Construct new dual-transformer 27.6 kV station and single-transformer 8.32 kV station with MUS facilities at the site of Carleton Place Bridge DS and Edmund DS. Construct a new 27.6 kV feeder to relieve the existing Carlton Place DS #2 F2 and install step-down transformers to eliminate 4.16 kV station.	Replace end-of-life station assets at Carlton Place DS #2, Carlton Place Bridge DS, and Carlton Place Edmund DS. Improve loop feed capabilities and supply capability in the Town of Carlton Place.	5.9	2018-2019
LC-6	Dresden DS Voltage Conversion	Convert 2-8.32kV feeders to 27.6kV to match incoming supply voltage, and remove Dresden DS.	Elimination of end-of-life station assets at Dresden DS.	2.6	2018-2019
LC-7	Dundas Sydenham DS Voltage Conversion	Convert 8.32kV line section to 27.6kV. Remove existing Dundas Sydenham DS.	Eliminate end-of-life station.	2.9	2018-2019

Project ID	Project Name	Scope	Need Addressed	Cost $M Net	Year(s)
LC-8	Coniston Voltage Conversion	Convert 22 kV 3-wire feeder and 22 kV connected substations to 44 kV operation.	Eliminate obsolete 22 kV system voltage and allow de-commissioning of Coniston TS T1/T2 transformers which are at end of life.	3.9	2018-2019
LC-9	Town of Forest Voltage Conversion	Convert 5-4.16kV feeders to 27.6kV to match incoming supply voltage. Remove Forest Jefferson DS and Forest McNab DS.	Eliminate end-of-life station assets at Forest Jefferson DS and Forest McNab DS.	3.2	2018-2019
LC-10	Hanmer TS Feeder Development	Construct 3 new 44 kV feeders from new Hanmer TS DESN.	Elimination of existing 44 kV off-road line sections fed from Martindale TS which are at end of life.	4.9	2018-2019
LC-11	Lucan Market DS Voltage Conversion	Convert two 4.16 kV feeders to 27.6 kV operation, install 2 x 2.5MVA 27.6-8kV step down transformers to replace existing 5MVA transformers at Lucan Market DS.	Eliminate end-of-life station assets at Lucan Market DS.	3.3	2018-2019
LC-12	Warkworth DS Removal	Offload station by reconfiguring and extending existing feeders from other adjacent stations, and remove Warkworth DS.	Eliminate end-of-life station assets at Warkworth DS.	2.9	2018-2019
LC-13	Grand Bend Downtown Voltage Conversion	Convert loads in downtown Grand Bend currently fed at 8.32 kV to 27.6 kV supply.	Eliminate end-of-life 8.32 kV line assets and reduce line congestion in main business section of Grand Bend.	1.3	2019
LC-14	Brookside DS Removal	Off load Brookside DS by building and reinforcing feeder ties to adjacent stations. Remove Brookside DS.	Eliminate end-of-life station assets at Brookside DS.	1.9	2019-2020

Project ID	Project Name	Scope	Need Addressed	Cost $M Net	Year(s)
LC-15	Drumbo DS Voltage Conversion	Convert two 8.32 kV feeders to 27.6kV to match incoming supply voltage and remove existing Drumbo DS.	Eliminate end-of-life station assets at Drumbo DS.	2.0	2019-2020
LC-16	Lily Lake DS Removal	Off load Lily Lake DS by building and reinforcing feeder ties to adjacent stations including some limited voltage conversion. Remove Lily Lake DS.	Eliminate end-of-life station assets at Lily Lake DS.	3.3	2019-2020
LC-17	Rondeau DS Voltage Conversion	Convert 2-8.32kV feeders to 27.6kV to match incoming supply voltage, and remove Rondeau DS.	Eliminate end-of-life station assets at Rondeau DS.	1.7	2019-2020
LC-18	Thorold Turner DS Voltage Conversion	Replace Thorold Turner DS with padmount transformers.	Eliminate end-of-life station.	1.0	2019-2020
LC-19	Wallaceburg DS Voltage Conversion	Convert 3-8.32kV feeders to 27.6kV to match incoming supply voltage, and remove Wallaceburg DS.	Eliminate end-of-life station assets at Wallaceburg DS.	1.7	2019-2020
LC-20	Devlin DS Rebuild and Voltage Conversion	Refurbish Emo DS and Devlin DS and replace existing 44-12.5 kV transformers with 44-25 kV units. Convert 12.5 kV line sections to 25 kV operation.	Replace end of life station assets including obsolete single phase transformers and standardize to one distribution voltage of 25 kV.	4.0	2020
LC-21	Blind River Voltage Conversion	Convert 12.5 kV feeder to 25 kV to match incoming supply voltage & remove Blind River DS.	Eliminate end of life station assets including obsolete single phase transformers.	1.0	2020
LC-22	Kemptville Area System Upgrades	Upgrade Kemptville West DS from 5 MVA to 7.5 MVA and add new feeder position.	Meet forecast load growth in the Town of Kemptville.	4.2	2020-2021

Project ID	Project Name	Scope	Need Addressed	Cost $M Net	Year(s)
LC-23	Maxville Area System Upgrades	Off load Maxville Prince DS by converting feeders from 4.16 kV to 8.32 kV and transferring to Maxville George DS.	Eliminate end-of-life station assets at Maxville Prince DS and eliminate 4.16 kV system in Town of Maxville.	4.2	2020-2021
LC-24	Prescott Area System Upgrades	Implement system upgrades as per recommendations of pending study.	Eliminate end-of-life system assets and ensure reliable supply.	4.2	2020-2021
LC-25	Wardsville DS Voltage Conversion	Convert 8.32 kV feeder to 27.6kV to match incoming supply voltage and remove existing Wardsville DS.	Eliminate end-of-life station assets at Wardsville DS.	1.1	2020-2021
LC-26	Alexandria Area System Upgrades	Upgrade Alexandria Industrial DS from 5 MVA to 7.5MVA. Remove Alexandria – Margaret DS, East Boundary DS, Kenyon West DS and transfer loads to adjacent DSs. Convert the town 4.16kV feeders to 8.43kV.	Eliminate end-of-life station assets as Kenyon West DS, provide loop feeds for single contingency backup of DS's in the town of Alexandria.	3.8	2021
LC-27	Anderdon DS Voltage Conversion	Convert 2-8.32kV feeders to 27.6kV to match incoming supply voltage, and remove Anderdon DS.	Eliminate end-of-life station assets at Anderdon DS.	1.5	2021
LC-28	Town of Elliot Lake Station Upgrades	Replace Mississauga DS T2 transformer with larger unit and add second transformer at Porridge Lake DS.	Facilitate the elimination of Elliot Lake DS which is at end-of-life and improve load transfer capability in Town of Elliot Lake.	3.5	2021
LC-29	Vanastra DS Voltage Conversion	Convert 8.32 kV lines to 27.6 kV to match incoming supply voltage and install step-down transformers.	Eliminate Vanastra DS which is at end of life.	2.2	2021

Project ID	Project Name	Scope	Need Addressed	Cost $M Net	Year(s)
LC-30	Berwick-Finch Area Upgrades	Offload Crysler DS F2 onto Casselman DS F1 by reinforcing feeder ties.	Crysler DS F2 feeder load is approaching planning guideline.	4.2	2021-2022
LC-31	Brockville Distribution System Upgrades	Upgrade various distribution feeder sections within the Town of Brockville.	Replace end-of-life distribution line assets, including direct buried cable, and eliminate back lot construction.	4.2	2021-2022
LC-32	Chesterville Area Upgrades	Add a second 5 MVA 44-8.32 kV transformer at Frood DS and one with additional feeder. Convert 5 existing 4.16 kV feeders to 8.32kV and remove Chesterville DS#2 & Brennen DS.	Eliminate end-of-life station assets at Chesterville DS #2 and Brennen DS and standardize on a single voltage 8.32 kV in the Town of Chesterville.	4.2	2021-2022
LC-33	Ivy Lea Area System Upgrades	Upgrade Ivy Lea DS station capacity.	Provide load relief to transformer loaded above planned load limit.	4.2	2021-2022
LC-34	Russell Area System Upgrades	Offload Russell DS to the neighbouring stations and Remove Russell DS.	Eliminate end-of-life station assets at Russell DS.	4.2	2021-2022
LC-35	Smiths Falls System Upgrades	System upgrades to allow removal of Smith Falls James DS.	Address end-of-life station assets and reliability risks due to lack of MUS facilities.	4.2	2021-2022
LC-36	Actons Corners Area System Upgrades	Implement system upgrades as per recommendations of pending study.	Eliminate end-of-life system assets and ensure reliable supply.	4.2	2022
LC-37	Sleeman DS Rebuild and Voltage Conversion	Rebuild Sleeman DS at a new location and convert 12.5 kV line sections to 25 kV.	Replace end-of-life station assets including obsolete single phase transformers and standardize to one distribution voltage of 25 kV.	4.4	2022

SR-14 Advanced Meter Infrastructure Hardware Refresh

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Program	**Plan Period Cost ($M):**	79.9
Primary Trigger:	Mandated Service Obligation		
Secondary Trigger:	Failure Risk		

Investment Need:

Hydro One currently owns, operates, and maintains approximately 1.3 million retail revenue meters. There are several factors that can trigger the need to upgrade these meters; some of the key factors are listed below:

- Hydro One Distribution is accountable, based on the market rules, to upgrade wholesale meter installations to a retail revenue meter when customers decide to become a retail customer of Hydro One Distribution at seal expiry;
- Hydro One Distribution has acquired non-standard meter installations due to a boundary change or the outright acquisition of an LDC;
- Hydro One Distribution has a population of 600V self-contained meters that are being replaced with inherently safer 120V transformer rated meters;
- Hydro One Distribution is required by the Distribution System Code, to upgrade existing customer's demand meters to interval meters when the average annual monthly peak demand is equal to or greater than 50 kW. There is also a requirement to install interval meters for customers who exceed 150,000 kWh of energy consumption per year; and
- Hydro One Distribution will require to replace smart meters once these meters reach the end of expected service life.

Alternatives:

No alternatives are considered, since this program represents the minimum level of work to satisfy Hydro One Distribution's operational requirements. Replacement of meters is critical to maintaining a reliable source of billing settlement data.

Investment Description:

This investment provides planned upgrades to address meters that no longer meet current standards, are obsolete, have reached end of service life; and to address regulatory requirements imposed by the Distribution System Code. The work includes, but is not limited to the following:

- Upgrade wholesale meter installations or acquired non-standard retail meter installations to Hydro One Distribution's current retail revenue meter standard;
- Upgrade 600V self-contained meters, with expired seals, with new 120V meters. Replacing these 600V meters with an inherently safer 120V unit increases employee and customer safety, allows Hydro One Distribution to meet expired seal obligations, eliminates a reliance on a single source supply as like-for-like replacements are not readily available on the market, and assists in standardizing inventory;
- Upgrade existing customer's meters to interval meters or demand meters when the energy consumption exceeds the thresholds set out in the Distribution System Code; and
- Replace smart meters which have reached the end of their expected service life. Smart meters have a manufacturer service life of 15 years, therefore, meter replacements will commence in 2021 with 3,621 replacements and another 206,119 replacements in 2022. A similar level of replacements will be required beyond the planning period.

The forecast of the number of meters requiring replacement and upgrade annually over the five year period is provided in the table below. The capital investment of each meter upgrade is below $1 million.

	2018	**2019**	**2020**	**2021**	**2022**
Number of Meter Upgrades/Replaced	341	341	341	4,134	206,632

Risk Mitigation:

The risks to completion of this investment as planned are the availability of the vendor to manufacture and deliver the meters in a timely manner, and the availability of qualified resources to perform the volume of replacements required. These risks are mitigated by providing procurement forecasts upfront to the vendor, maintaining ongoing discussions with vendor regarding future product supply, and managing resources with option to hire temporary staff as required.

Result:

This meter upgrade program will result in:

- Ensuring timely replacement of meters,
- Complying with regulatory requirements, and
- Ensuring a continue reliable source of billing settlement date for customers.

Outcome Summary:

Customer Focus	• Maintain billing accuracy and customer confidence by ensuring reliable meter performance.
Operational Effectiveness	• Maintain reliable operation of the meter and meter infrastructure network by proactively replacing equipment.
Public Policy Responsiveness	• Comply with the OEB Distribution System Code Section 2.10 “Estimated Billing” requirement for no more than 2 estimated meter reads per year and Section 7.11 “Billing Accuracy” requirements.
Financial Performance	• Avoid the cost of manual meter reading through timely replacement of meter and network equipment.

Costs:

The factors which affect the costs in this investment are the following:

- The cost of material and term of procurement contracts; and
- The accessibility conditions of the area in which the meters are being replaced. Accessing off road locations or replacing a meter on a lake cottage can be more costly due to the use of specialized equipment.

Controllable costs have been minimized through standardization of metering device purchasing specifications and issuance of vendor contract to secure unit pricing for procurement of materials.

**Includes Overhead at current rates.*

SS-01 Remote Disconnection / Reconnection Program

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Program	**Plan Period Cost ($M):**	28.5
Primary Trigger:	System Efficiency		
Secondary Trigger:	Customer Service Requests		

Investment Need:

Hydro One currently owns, operates, and maintains approximately 1.3 million retail revenue meters. From time to time, there is a need to have power to these meters disconnected and/or reconnected as a result of customer non-payment and vacant premises.

Hydro One makes every effort to work proactively with customers to address billing issues and adheres closely to all steps mandated in the OEB Distribution System Code. Disconnection is only considered as a last resort; as customers rely on their power and understandably become upset if a decision is made to disconnect power. Hydro One makes every effort to take swift action in the reconnection of power for customers in order to reestablish important electrical services to their home or business.

Hydro One currently implements a manual disconnection and reconnection process, requiring at least two trips to the customer premises. These disconnection and reconnection activities cause between 10,000 and 21,000 on-site visits per year. The costs and associated risks of this manual process can be avoided with the utilization of meters that have the functionality to execute remote disconnection and reconnection.

Alternative 1: Continue Manual Disconnections/Reconnections

Continue to manually disconnect and reconnect customer meters when required in accordance with Section 4.2 of the OEB Distribution System Code. This alternative is rejected as it will not result in improving the customer experience or achieving operational efficiencies.

Alternative 2: Remote Disconnections/Reconnections *(Recommended)*

Install new meters with remote disconnection and reconnection functionality at customer sites where non-payment and/or vacant premises situations exist. This alternative is recommended as it will reduce the number of visits to customer premises resulting in operational efficiencies, and improve customer experience by providing a faster response time for disconnection and reconnection requests. Active and timely actions to address customers in arrears also assists customers in staying current with their invoices and reducing bad debt expenditure.

Investment Description:

This investment addresses the replacement of existing meters at customer premises with new meters capable of remote disconnection and reconnection functionality. Meter replacements will be identified for replacement when disconnection required based on assessment of customer accounts in arrears due to non-payment and/or customer premises with noted vacancy. These replacements are to be rolled out in stages as work orders are authorized and appropriately approved for action of disconnection. The table below is an annual forecast of meter replacements.

	2018	**2019**	**2020**	**2021**	**2022**
Number of Meter Replacements	11,875	11,500	11,125	10,750	10,375

Once the new meters are installed, the actual execution of the reconnection (or disconnection) is accomplished within a few minutes after the customer request has been authorized and appropriately approved for action thereby reducing lost revenue for unbilled power, and providing improved customer service through faster response time.

Risk Mitigation:

The risks to completion of this investment as planned are the availability of the vendor to manufacture and deliver the meters in a timely manner, and the accessibility of the meters required to be replaced. These risks are mitigated by providing procurement forecasts upfront to the vendor, maintaining ongoing discussions with vendor regarding future product supply, and managing coordination with resources required to gain access.

Result:

This remote disconnection/reconnection program will result in:

- Reducing the number of required visits customer premises thereby delivering operational efficiency, and potentially avoiding approximately $4.5 million in costs annually arising from on-site reconnections and disconnections and the safety risks related to driving hours; and
- Improving the customer's experience by providing a faster disconnection or reconnection response time.

Outcome Summary:

Customer Focus	• Improve customer experience by providing a faster response time for disconnection and reconnection requests.
Operational Effectiveness	• Increase operational effectiveness by executing the disconnection/reconnection process in a more efficient manner. • Reduce employee safety risks related to driving hazards by avoiding travel to customer premises.
Public Policy Responsiveness	• Comply with the OEB Distribution System Code Section 4.2 regarding disconnection and reconnection process.
Financial Performance	• Avoid the cost arising from on-site reconnection/disconnection at customer premises by installing new meters with remote reconnection/disconnection functionality.

Costs:

The factors which affect the costs in this investment are the following:

- The cost of material and term of procurement contracts; and
- The accessibility conditions of the area in which devices are being replaced. Accessing off road locations to replace network devices can be more costly due to the use of specialized equipment.

Controllable costs have been minimized through standardization of metering device purchasing specifications and issuance of vendor contract to secure unit pricing for procurement of materials.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

SS-02 System Upgrades Driven by Load Growth

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Program	**Plan Period Cost ($M):**	190.0
Primary Trigger:	Mandated Service Obligation		
Secondary Trigger:	Reliability		

Investment Need:

Over time, new customers connect to the system, and load growth occurs as a result. This also occurs due to increased loading at some existing customers who may increase their service sizes. This places additional stress on the elements of the distribution system. Increases in distribution station and feeder loading can lead to system elements operating at or exceeding their maximum equipment ratings or violate other planning criteria such as voltage or protection limits during periods of heavy load.

In accordance with Section 3.3 of the Distribution System Code ("DSC"), Hydro One Distribution plans and executes enhancement projects on its distribution system to improve system operating characteristics and relieve system capacity constraints. This investment covers major system upgrades that are needed in response to load growth.

Investments with a gross cost less than $300,000 are normally included in either the Distribution System Modifications (ISD SS-05) or Demand Investments (ISD SS-04) capital programs.

The capability of the Hydro One distribution system to accommodate forecast loading needs is determined through the following four main activities:

1. load versus capability screening at the station and feeder levels;
2. planned feeder studies (six-year cycle studies);
3. system impact assessments for large new load connections; and
4. assessment of field and customer identified issues related to power quality or other operating concerns.

Load versus system capability and planned feeder studies (six-year cycle studies) are the main pro-active planning activities carried out to assess the capability of Hydro One's system to accommodate existing and forecast needs. These activities take into account the capability of the network to meet load needs based on normal anticipated load growth. Load growth rates vary for different segments of the system. For example, the growth rates can differ significantly between urban and rural segments. Normal load growth is determined locally within the system based on historical trends, known or planned development in an area, and information from local municipalities including official plan documents and long-term population projections. In some cases, local power quality or reliability issues may be identified by field staff or customers due to specific local loading issues or changes that develop over time and may need to be addressed through system upgrades. If these issues cannot be accommodated under the Demand Investments capital program (ISD SS-04) then a major capital project may be required.

For all new load connections or customer upgrades above 500 KVA, and for new subdivisions with more than fifteen lots, a distribution system impact assessment is conducted in order to determine the impact of the proposed load with respect to equipment ratings, voltage and protection criteria, and planning guidelines. Where planning criteria will be violated, system upgrades may be required. Where an upgrade is required in order to meet the specific loading needs of one individual customer, a customer contribution may be required based on a discounted cash flow evaluation of future revenues and costs.

For distribution feeders, planning guidelines for load-ability have been established based on feeder voltage level. Planning guidelines are used to conduct high-level screening of system capability to maintain loading within equipment ratings, meet system voltage and protection needs, and ensure a reasonable degree of operating flexibility and efficiency. Planning guidelines are based on typical feeder topology and lengths. In some parts of Hydro One's distribution system where feeder distances are significantly long or load centers are far from the supply station, technical considerations such as voltage and system protection needs restrict maximum feeder loading to values, which are less than the planning guidelines.

Where major new capacity upgrades are deemed necessary through load screening or other means, Hydro One uses an integrated planning approach to identify and develop the optimal system development plans for a specific area. This involves assessing other potential system needs in the surrounding network from the perspective of capability, performance, operability, sustainment, and efficiency/effectiveness. Once the full long-term needs for the system are determined, integrated solutions are identified to ensure the long term viability of the network in the most cost-effective manner.

Alternative 1: Allow System Assets to Become Overloaded

Wait until overloaded assets reach critical values such that customers are experiencing significant power quality issues, or a material decrease in reliability is observed.

This alternative was rejected since it does not satisfy the DSC requirement for a distributor to enhance its system in response to normal load growth. Also, due to the long lead times needed to implement effective solutions, there would be significant customer dissatisfaction due to on-going power quality issues and reduced reliability.

Alternative 2: Upgrade System to Meet Normal Load Growth (Recommended)

Pro-actively monitor system loading, conduct system studies for forecast new load connections and develop appropriate investment plans to address system needs based on forecast load.

The recommended plan satisfies section 3.3 of the DSC, which requires distributors to plan and expand their systems in response to normal load growth. Identifying and implementing major projects to maintain loading on assets within design ratings ensures acceptable delivery voltage is provided to customers, that reliability is maintained at acceptable levels, and that system assets are not exposed to undue stress.

Investment Description:

System load growth over the next five years is expected to be in line with recent historic growth patterns. Approximately 90,000 new customer connections and 27,000 service upgrades are forecast for the 2018-2022 time period. Cancellation of about 34,000 existing services is also anticipated for an overall increase in customers of 56,000 or 4.4% of the existing customer base over the next five years.

The majority of growth and new customer connections are expected to occur in Hydro One's urban service territories which border major urban centers including the City of Ottawa, City of Kingston, northern York and Peel Regions, Durham Region, and the City of Hamilton. For the remainder of Hydro One's service territory which is mostly rural in nature, load growth and new customer connection activity is expected to be in line with historic rates which are generally lower.

Proposed investments to address load growth include station upgrades, feeder upgrades and modifications, new feeders, construction of new distribution stations and new voltage regulating stations, and conversion of feeders to higher voltages. Also included are feeder development projects in accordance with recommendations of Regional Infrastructure Plans. A list of all planned system upgrades in excess of $1 million along with their proposed timing is provided in Attachment 1. Additional funding is included to cover projects less than $1 million as well to cover emergent needs due to unforeseen customer connections or upgrades.

There are a variety of ways to relieve overloaded equipment. Each area is unique and the optimal solution varies area to area depending on the existing feeder configuration and the state of surrounding lines and stations.

Feeder Reinforcement: One common solution is to redistribute load through reinforcement projects. In urban areas, this can entail upgrading or creating new radial loops. These projects focus on optimizing load distribution by reconfiguring existing feeders to enable load transfers between phases, and between different feeders. By extending feeders, installing new phases and tie points, and updating feeder protections, lightly loaded feeders can offload heavily loaded sections.

Station Upgrade: Station upgrade projects are executed in areas where the existing configuration cannot be utilized to offload equipment that has reached its planned loading limit. Instead, additional capacity must be added to the system. Station upgrades involve an increase in capacity to existing stations by upgrading transformer sizes; installing additional transformers; increasing the station's secondary voltage (voltage conversion at the station); or installing fan monitoring to cool station transformers. These projects also include adding new feeder positions at the station to increase the number of available feeders.

Construct New Station: In some situations, constructing a new station is more effective from a cost and operating perspective than upgrading an existing station. In these cases, a new distribution station is installed and incorporated into the distribution system. New feeders are also used to provide additional capacity to areas that are overloaded. These feeders may be built to compliment the construction of a new distribution station.

Voltage Conversion: To increase equipment ratings and capacity, feeders may also be converted to higher voltage levels. These upgrades may coincide with a station voltage conversion or may involve a reconfiguration with nearby feeders that operate at higher voltage levels.

Risk Mitigation:

The main risks concerning project execution are real estate/property rights, shortage of qualified labour, customer delays, and delays in finalizing development plans.

Construction of new stations requires acquisition of new property and is subject to delays due the lack of a willing seller, negotiations with property owners, municipalities, and in some cases First Nation concerns. Construction or upgrading of feeders requires occupancy rights on road allowances or private property, as well as cutting rights and anchoring easements on private property. Delays, or the inability in obtaining these rights, can lead to the need for re-design, or route alterations. In some cases, road authorities may have coinciding plans for road widening or other construction, which need to be coordinated with new pole locations resulting in delays to line construction work. These risks are mitigated by providing appropriate lead times during the design and estimating stages to allow sufficient time for obtaining necessary property rights. For new station or station upgrade work, Hydro One has recently implemented a new project planning approach where any new property needed will be determined and acquired prior to commencing engineering/design work.

Execution of the proposed station and feeder construction projects identified in this investment driver requires the coordinated efforts of multiple technical and engineering disciplines some of which are highly specialized. Lack of available resources in these specialties can lead to project delays. These risks are mitigated by establishing appropriate project time lines in conjunction with internal and external service providers to reflect available resources for design and construction.

Projects that are being driven by specific customer requests or by specific development needs are also subject to delays due to changes in the customers’ or developers’ timing.

Projects are reprioritized each year as new loading information and updated forecasts become available to ensure they are addressed in order of criticality. Funding may also need to be reallocated to unplanned projects to serve immediate needs for system capability reinforcement due to unforeseen load growth or specific customer requests. In these cases, planned projects may be postponed to ensure the most efficient use of resources and funding.

Result:

System Upgrades Driven by Load Growth will result in:

- Ensuring there is adequate capacity within the distribution system to meet existing and forecast customer load needs;
- Maintaining acceptable Power Quality throughout the distribution system;
- Ensuring the safe and reliable operation of the distribution system;
- Reducing the risk of lengthy customer outages caused by failure or malfunction of overloaded assets;
- Balancing loads to allow for additional customer connections and to improve voltage and power quality;
- Reducing line losses; and
- Providing additional supply options to relieve overloaded feeders and enable future load growth and customer connections.

Outcome Summary:

Customer Focus	• Meet load needs of existing and new customers. • Ensure acceptable delivery voltage and other quality of power criteria are provided to customers. • Improve customer reliability.
Operational Effectiveness	• Maintain safe and effective operation of the distribution system. • Minimize overall costs by taking an integrated planning approach based on an overall assessment of area supply needs.
Public Policy Responsiveness	• Meet requirements of the Distribution System Code to plan the system to accommodate reasonable forecast load growth. • Comply with equipment standards which include Renewable Energy enabling technologies.
Financial Performance	

Costs:

Costs are primarily affected by design requirements and conditions of construction. Hydro One uses three main styles for new station construction based on rural vs. urban as well as operating requirements. The optimal design solution is based on a number of factors including property availability, capacity requirements, operational needs, compatibility with surrounding land uses, as well as environmental mitigation needs.

Feeder construction costs can vary widely depending on conditions such as ground type (soil vs. rock), tree density where right-of-way clearing or expansion is required, underground vs. overhead, and whether it is green field construction versus upgrading or overbuilding of existing lines. Costs are controlled by avoiding costly or complex design solutions where possible and by sub-contracting specialized civil work to external service providers.

1 **Attachment 1 – System Upgrades Driven by Load Growth**

Project ID	Project Name	Scope	Need Addressed	Cost - $M Net	Year(s)
LG-1	Cumberland DS F4 Development	Extend the lightly loaded F4 feeder from Cumberland DS to meet with the more heavily loaded F2.	Provide a loop feed for the Cumberland urban load area and meet future load needs.	1.2	2018
LG-2	Devlin DS F1 3 Phase Upgrade	Upgrade 3 km of two-phase and 1.5 km of single-phase line to three-phase along Highway 613.	Address single phase line loading above Planning Guidelines.	1.0	2018
LG-3	Kleinburg TS M6 Mayfield Rd Line Extension	Extend 27.6 kV along Mayfield Road, for approximately 4 km, from Airport Rd to Dixie Road.	Improve supply efficiency and reliability and provide capability to supply future loads along Mayfield Road in the Town of Bolton.	1.0	2018
LG-4	Orangeville TS M3 - Mayfield West Line Extension	Extend 44 kV feeder from Chinguacousy Rd, east along Old School Road, for approximately 6 km.	Introduction of 44kV to the Mayfield West area, to facilitate connection of anticipated industrial loads, and to construct a future Old School Road DS.	1.8	2018
LG-5	New Bradford North DS	Construct new 44-27.6 kV DS, as well as associated feeders.	To meet forecast residential and commercial load growth in the Town of Bradford West Gwillimbury.	5.0	2018-2019
LG-6	Caledonia TS M3 Extension	Convert 7.5 km of 4.16 kV line to 27.6kV and transfer load from Jarvis TS M3 to Caledonia TS M3.	Relieve overloaded step-downs and improve reliability to Six Nations.	1.1	2018-2019
LG-7	Alfred DS F2 Feeder Upgrades	Upgrade 6 km of single-phase line to three-phase, balance loads between phases, and between F1 and F2 feeders.	Single phase line section loaded above planning guideline.	2.4	2018-2019
LG-8	Cameron DS Feeder Improvements	Construct new F2 feeder out of Cameron DS and upgrade existing single phase line to three phase along Monarch Road and Hwy 35.	To meet forecast residential load growth in west part of the Town of Lindsay.	1.4	2018-2019
LG-9	Armitage TS M22 Extension	Extend M22 feeder by double circuit with existing M12 feeder, for approximately 6 km. Transfer Wesley DS from M12 to M22.	Provide load relief to Armitage TS feeder M12 which is loaded beyond planning guidelines.	2.0	2018-2019

Project ID	Project Name	Scope	Need Addressed	Cost - $M Net	Year(s)
LG-10	City of Owen Sound Tie-Line Reinforcement	Construct new 4.16 kV tie-lines between 24th St West DS and 2nd Ave West DS, and between 6th Street East DS, and 2nd Ave East DS.	To provide loop feeds for single-contingency back up of DS transformers which do not have MUS facilities.	1.3	2018-2019
LG-11	Enfield TS Feeder Development	Construct two new 44 kV feeders out of Enfield TS consisting of 18 km of new feeder line.	To meet forecast load growth in Durham Region.	7.6	2018-2019
LG-12	Grand Bend DS F3 Voltage Conversion	Convert existing 8.32 kV feeder to 27.6 kV and connect to Grand Bend East DS F2 feeder.	To address substandard voltage being experienced by customers along the Lake Huron shoreline south of Grand Bend.	2.4	2018-2019
LG-13	Kirkland Lake Voltage Conversion – Part 1	Rebuild Goodfish DS and replace 44-4.16 kV transformer with a 44-12.5 kV unit. Convert Goodfish DS F8, F9, F10 feeders from 4.16 kV to 12.5 kV.	Meet future load needs in the Town of Kirkland Lake and eliminate obsolete metalclad switchgear at Goodfish DS.	4.8	2018-2019
LG-14	Leamington TS Feeder Development	Build 8 new 27.6 kV feeders from Leamington TS, transfer load and DG from Kingsville to Leamington TS, and partial 8.32 kV DS conversion to 27.6 kV.	Meet future load needs in the towns of Kingsville and Leamington consistent with Supply to Essex County Transmission Reinforcement (SECTR) work.	3.7	2018-2019
LG-15	Manotick DS Feeder Development	Extend new F3 feeder to off-load existing F1 feeder and to connect to new residential subdivisions.	To connect new residential subdivisions in Manotick to new F3 feeder.	2.6	2018-2019
LG-16	Stouffville 10th Line DS New T3 & Feeder	Construct new DS with 2 x 44 - 27.6 kV and 1 x 44 - 8.32 kV transformer.	Replace existing end-of-life 8.32 kV T1 station assets and add more capacity to meet the load growth in the Town of Stouffville.	6.6	2018-2019
LG-17	Town of Shelburne Voltage Conversion	Convert 4.16 kV feeders to 8.32 kV and rebuild Shelburne DS as a single-transformer station, 44-8.32kV. Remove existing T1 and T2 transformers.	Increase transformer and feeder capacity at Shelburne DS to meet forecast load growth.	8.4	2018-2020

Project ID	Project Name	Scope	Need Addressed	Cost - $M Net	Year(s)
LG-18	Twelve Mile Bay DS - New Station & Feeders	Construct a new 44-12.5 kV station including 1 km of new 44 kV line with 12.5 kV underbuild, and install 11 km of new three-phase submarine cable in Georgian Bay to connect the new station to the Honey Harbour DS F1 feeder.	Provide load relief to Foots Bay DS which is loaded above its PLL, and to the Honey Harbour DS F1 feeder which does not meet system protection requirements.	4.0	2018-2019
LG-19	Beckwith DS F3 Feeder Development	Extend new Beckwith DS F3 feeder to off-load F1 and T1 transformer.	Relieve T1 overloading and create a three-phase loop feed for urban customers.	1.8	2019
LG-20	Crilly DS Replacement and Transformer Upgrade	Construct new Crilly DS 2 km from existing DS site. New Crilly DS will be supplied from Hydro One 115 kV circuit.	Address overloaded transformer and eliminate non-standard supply from privately owned generating station bus.	6.7	2019
LG-21	Kirkland Lake Voltage Conversion-Part 2	Replace 44-4.16 kV transformer at Woods DS with a 44-12.5 kV unit. Convert Woods DS F5, F6, F7 feeders from 4.16 kV to 12.5 kV.	To meet future load needs in the Town of Kirkland Lake.	2.0	2019
LG-22	Manotick DS F3 New Feeder	Add new feeder position and underground egress to connect new F3 Feeder	To meet forecast residential load growth in the Village of Manotick	1.9	2019
LG-23	Margach DS F3 Voltage Conversion - SW676	Extend Keewatin DS feeder F2 for 3.5 km to off-load part of the Margach DS F1 load onto Keewatin DS F2.	Provide load relief to overloaded step-down transformer.	1.4	2019
LG-24	Muskoka TS M5 x M1 Feeder Tie	Extend the Muskoka TS M5 feeder for 14 km from Ullswater DS to the village of Rosseau by overbuilding existing 12.5 kV feeders with 44 kV.	To facilitate off-loading Parry Sound TS through a load transfer to the Muskoka TS M1 feeder and to create a 44 kV loop feed around Lake Rosseau.	5.3	2019
LG-25	Rockland DS T2 Transformer	Install a second transformer at Rockland DS.	Provide load relief to existing T1 transformer and meet forecast load growth.	2.3	2019
LG-26	Barrie TS - Construct New Feeders	Construct 8 km of New 2-circuit 44 kV Line from Barrie TS to Salem Road.	To meet forecast load needs of InnPower embedded LDC.	2.6	2019-2020
LG-27	Caledonia TS New Feeders	Construct 6 km of new 27.6 kV feeders from Caledonia TS.	Relieve Existing Feeders which are loaded above planning guideline.	4.3	2019-2020

Project ID	Project Name	Scope	Need Addressed	Cost - $M Net	Year(s)
LG-28	Dundas TS #2 New Feeders	Construct 2.5 km of new feeders from Dundas TS#2. Construction will be done across the Niagara Escarpment and through a subdivision.	To provide load relieve to Dundas TS T1/T2 DESN.	6.7	2019-2020
LG-29	King City DS - New Station & Feeders	Construct a new 44-13.8kV DS. Build feeder ties with existing 13.8kV feeders from Eversley DS, and balance load between feeders / stations.	Provide a second 13.8 kV source of supply for King City to enable loop feeds and meet future load growth.	4.6	2019-2020
LG-30	New Old School DS	Construct a new 44-27.6kV DS. Construct 27.6kV feeders and tie to Snelgrove DS and Kleinburg TS M6.	Relieve capacity issues at Snelgrove DS, and provide a second 27.6kV source to improve loop feed supply.	7.0	2019-2020
LG-31	Town of Dundalk Voltage Conversion	Construct a new 44-8.32kV DS. Convert existing 4.16kV loads within the town of Dundalk to 8.32 kV, and remove existing 44-4.16kV transformer.	Provide increase station and feeder capacity to meet forecast load growth in Town of Dundalk.	9.5	2019-2021
LG-32	Greely DS F1 Feeder Development	Extend F1 feeder from Greely DS to offload existing feeders.	To meet forecast load growth in south Ottawa.	1.5	2020
LG-33	Kirkland Lake Voltage Conversion-Part 3	Convert Kirkland Lake DS #1 F1, F2, F3 feeders from 4.16 kV to 12.5 kV and re-supply from Goodfish DS and Woods DS. Remove Kirkland Lake DS #1.	Meet future load needs in the Town of Kirkland Lake and eliminate Kirkland Lake DS #1 which has obsolete switchgear and is located inside the Kirkland Lake TS yard.	2.8	2020
LG-34	Midhurst Wilson DS F2 Extend to Doran Rd	Overbuild 6.5km of existing 8.32 kV line with new 27.6 kV feeder from Wilson Road to Doran Road.	To meet future residential subdivision growth in the north-east Midhurst Area (Midhurst Secondary Plan – Neighbourhood 2).	2.2	2020
LG-35	Midhurst Wilson DS F1 Extend to Dobson Rd	Extend Midhurst Wilson DS 27.6 kV feeder for 3.5 km to Dobson Rd by converting existing Grenfel DS F2 feeder from 8.32 kV to 27.6 kV.	Address forecast overloading of Grenfel DS F2 feeder due to residential subdivision load growth.	2.2	2020
LG-36	Perth Area Upgrades	Reconstruct station egress’s with higher capacity underground cable.	Provide back feed capability for single contingency station transformer outage.	2.0	2020

Project ID	Project Name	Scope	Need Addressed	Cost - $M Net	Year(s)
LG-37	Macville DS - New 27.6kV Station	Extend Kleinburg TS M26 44 kV feeder for 2km and construct a new 44-27.6kV DS.	Provide Additional DS capacity to meet forecast load growth in the Town of Caledon.	3.7	2020-2021
LG-38	Wikwemikong DS & Line Work	Build a 15 kV 44 kV feeder extension by overbuilding existing a 12.5 kV line and construct a new 44-12.5 kV station. Upgrade an additional 3 km of existing 12.5 kV line to double-circuit.	To meet forecast load growth at Wikwemikong First Nation on Manitoulin Island.	6.5	2020-2021
LG-39	Dunchurch DS F2 - Extend to Magnetewan	Upgrade 10 km of existing single-phase line to three-phase and build 1 km new line to extend Dunchurch DS F2 feeder to Town of Magnetewan.	Provide load relief to Burks Falls DS F2 feeder which is loaded above planning guidelines and does not meet system protection criteria.	2.8	2021
LG-40	Fairbanks Lake Line Upgrade	Upgrade 2.6 km existing single-phase line to three-phase and build 8.7 km of new three-phase line.	To Address Substandard Feeder Protection on existing Whitefish DS F1.	2.5	2021
LG-41	Kleinburg TS M26 extension to Mayfield West	Extend Kleinburg TS M26 to Mayfield West (approximately 12 km).	Provide load relief to Pleasant TS M21 feeder based on forecast loading.	3.2	2021
LG-42	Lively DS F2 SW142 Upgrade Black Lake Road	Upgrade 5 km of single-phase line to three-phase.	Address single phase line loading above planning guidelines.	1.4	2021
LG-43	Mar DS – New Station	Construct a new 44-12.5 kV station and 2 km of new 12.5 kV feeders.	Provide load relief to Colpoys Bay DS which is loaded above the transformer Planned Load Limit (PLL).	3.0	2021
LG-44	Ancaster West DS Transformer Upgrade	Upgrade Ancaster West DS transformer from 5 MVA to 7.5 MVA.	Provide DS Capacity to meet forecast load growth.	2.0	2021-2022
LG-45	Brockville 44kV System Upgrades	Extend Brockville M7 and Morrisburg M24 feeders to off load B1R and M5 feeders.	Provide load relief to Brockville TS B1R & M5 feeders which are currently loaded above planning guidelines.	10.5	2021-2022

Project ID	Project Name	Scope	Need Addressed	Cost - $M Net	Year(s)
LG-46	Manitoulin TS - Add Third 44 kV Feeder	Add new 44 kV breaker at Manitoulin TS, new feeder tie switches, and construct 1.5 km new 44 kV line to Little Current DS.	To maintain 44 kV feeder loading within protection limits during transformer or breaker outages.	4.6	2021-2022
LG-47	Point Au Baril DS F2 Extension	Extend the Point Au Baril DS F2 feeder for 8.5 km by double-circuit the existing F1 feeder north of Point Au Baril.	To provide load relief to the Point Au Baril DS F1 feeder which has substandard system protection and voltage.	3.6	2021-2022
LG-48	Aspdin DS F1 Feeder Upgrade	Upgrade 5 km of single-phase line to three-phase.	Address single phase line loading above planning guidelines.	1.3	2022

SS-03 Reliability Improvements

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Program	**Plan Period Cost ($M):**	33.1
Primary Trigger:	System Efficiency		
Secondary Trigger:	Reliability		

Investment Need:

The Hydro One distribution system is normally planned based on a radial supply configuration. Due to system growth and development over time, there may be alternate feeds available to certain load centres or specific customer locations. However, alternate feeds may not be capable of supplying the entire load. Also, in many cases, only a single radial supply exists so there are no opportunities to transfer load during outages. Extended outages can be particularly disruptive to commercial and industrial customers due to lost business or lost productivity and in some cases lost/damaged product due to processing interruptions. Some industrial customers may also be sensitive to momentary supply interruptions due to lightning or even to voltage fluctuations which may occur when lightning strikes other parts of the system that do not directly supply them.

To improve reliability and increase customer satisfaction in certain areas, investments focused on improving backup capability, adding new tie-lines, and lightning mitigation may be needed.

Alternative 1: Status Quo

Address customer concerns about poor reliability in sensitive areas on a reactive basis only.

This alternative is rejected since it would lead to decreased customer satisfaction and continued poor reliability in areas where concerns have already been expressed. Not proceeding with this investment would leave customers susceptible to longer and more frequent outages that are characteristic of radially configured lines. The risk of serving customers at unacceptable power quality levels will also increase. If left unaddressed, poor power quality can lead to equipment damage and sustained outages for customers.

Alternative 2: Targeted Reliability Improvements (Recommended)

Implement targeted projects to improve reliability in areas where customer concerns have been raised and where practical system development opportunities exist to meaningfully improve system capability and performance.

Investment Description:

There are a variety of ways to improve system reliability. Each area is unique and the optimal solution varies area to area depending on the existing feeder configuration and the state of surrounding lines and stations.

Examples of projects to improve reliability include building tie lines to provide alternative supply capabilities, installing express feeders to critical load centers, improving sectionalizing capabilities on multi-branch feeders, adding voltage regulators or upgrading conductor to improve capability of existing ties, and installation of lightning arrestors on feeders. These reliability investments typically occur in areas with a high customer density because of the relative cost-benefits (i.e. more customers benefit from improved reliability in comparison to the investment costs).

<u>Constructing Alternative Supply Options & Improving Sectionalizing Capabilities</u>: To minimize the duration of an outage experienced, customers can be temporarily supplied by alternative sources as the faulted section of line is addressed. This is typically achieved by connecting two or more feeder sections through tie-lines and ensuring that appropriate equipment is in place to enable switching over to the alternative supply. Improved sectionalizing capabilities help reduce the number of customers impacted by sustained power interruptions.

<u>Reducing Line Exposure</u>: By decreasing the circuit length of a feeder, the total amount of conductor exposed to the elements is lessened. This reduces the likelihood of that circuit experiencing a fault due to natural elements, such as trees.

<u>Improving Power Quality through Line Upgrades</u>: Power quality can be improved by increasing conductor sizes or installing voltage regulating equipment.

<u>Installing Lightning Arrestors</u>: Lightning arrestors are used to prevent power interruptions due to lightning strikes. These are installed on feeders that experience a high frequency of lightning storms.

The proposed overall expenditure includes placeholder funding of approximately $3 million annually for planned reliability improvements to large distribution account customers based on customer engagement sessions.

A list of planned and scoped projects in excess of $1 million over the 2018-2022 period is provided below.

Project ID	Project Name	Scope	Need Addressed	Cost $M Net	Year(s)
RI-1	Nebo TS Feeder Extension to Binbrook	Construct a new 6 km 27.6 kV feeder and tie to Nebo TS M5.	Provide a loop feed for Binbrook area.	2.8	2019-2020
RI-2	Tilbury DS New Feeder	Add a new 27.6 kV feeder position at Tilbury West DS, construct 0.6 km 27.6kV feeder and transfer Tilbury West DS F2 load to the new feeder position	Provide a loop feed for Town of Tilbury and lighthouse cove area.	1.9	2019
RI-3	Puslinch DS 4th Feeder	Construct a new 27.6kV feeder for 2 km out of Puslinch DS.	Provide a dedicated supply to industrial customers for improved reliability.	2.9	2021
RI-4	Orangeville TS M3-M6 Tie Line	Construct approximately 10km of new 44kV line between Caledon DS and Sleswick DS (along Charleston Road).	Provide a loop feed for to enable backfeed during outages.	2.6	2022
RI-5	Tilsonburg-Norfolk Tie Line	Construct 4 km 27.6kV feeder tie between Tilsonburg TS M1 and Norfolk TS M1.	Provide backup supply for Town of Delhi loads.	1.1	2022

Risk Mitigation:

The main risks to completion of this work are lack of labour resources for design and construction, as well as the usual risks around property rights for poles, anchors and tree trimming. These risks will be mitigated by ensuring appropriate planning lead times are followed for project scheduling and by considering constructability issues early in the project definition stage.

Result:

Reliability Improvement projects will:

- Improve customer satisfaction levels, particularly where customer concerns have been raised;
- Reduce outage durations for specific load centers or customers; and
- May improve operational efficiency and safety through increased system flexibility on projects involving tie-line upgrades.

Outcome Summary:

Customer Focus	• Reduce outage durations/frequency for sensitive customer loads. • Reduce lengthy outages to certain areas by providing an alternate feed capability. • Mitigate voltage fluctuations due to lightning activity for industrial customers.
Operational Effectiveness	• Allow increased operational flexibility to supply some loads by an alternate means in order to perform planned and unplanned maintenance.
Public Policy Responsiveness	
Financial Performance	• Cost saving opportunities such as making provisions for future circuits or tie-lines during routine work such as road relocation, end-of-life pole replacements are pursued when possible. • Maximum benefit/cost outcome is a primary factor taken into consideration when selecting appropriate investments under this category.

Costs:

Cost estimates are based on historical actual costs. Costs are mainly affected by design requirements and conditions of construction. Costs are controlled by avoiding costly and complex design solutions where possible and by sub-contracting specialized civil work to external service providers.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets	5.2	7.9	7.2	8.2	9.2	37.6
Less Removals	0.6	1.0	0.9	1.0	1.1	4.5

SS-04 Demand Investments

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Program	**Plan Period Cost ($M):**	19.9
Primary Trigger:	Service Obligation		
Secondary Trigger:	Reliability		

Investment Need:

Minor distribution system modifications are required to address system needs identified by customer power quality complaints, feeder studies and system impact assessments. These system needs are identified by the Distribution System Code ("DSC") as "enhancements" (section 3.3) and are completed for the purposes of improving system operating characteristics or for relieving system capacity constraints. Responding to these needs ensures an adequate supply of electricity to customers.

Resolution of issues within the individual projects of this investment could include upgrading conductor size, voltage conversion, supplying three phase circuit where a single phase supply would not be adequate, or protection upgrades.

Alternatives:

This investment addresses issues that arise on a demand basis and typically relate to power quality, and feeder protection. As these issues arise on the distribution system, it is imperative for Hydro One to address them in an expedient and efficient manner. Completion is required to comply with the DSC.

Not proceeding with this investment would be a failure to comply with the DSC and result in critical issues remaining on the system, leading to deteriorated service reliability and power quality, decreased customer satisfaction and substandard supply. Damage to distribution system assets could also occur.

Investment Description:

The triggers of the projects within this investment are driven by customer requests to increase loading on the system or to resolve power quality issues. When a request is received, a system impact assessment is performed to investigate possible resolution. Technical criteria are used in assessing system and customer needs.

System enhancements addressed by this plan include items such as protection coordination, and installing new equipment or equipment upgrades.

This investment resolves lower cost, high priority issues identified by customers, feeder studies, or system impact assessments with a short lead-time. These investments generally cost between a few thousand dollars for low cost projects such as fuse upgrades upwards to a few hundred thousand dollars for costly upgrades such as voltage conversion or single to three phase line conversion.

Risk Mitigation:

To ensure customer satisfaction it is important that work is prioritized to avoid catastrophic failure of critical assets supporting large numbers of customers. Projects are prioritized among the work in the queue for a given work centre. Higher priority projects may need to be completed on a faster turnaround causing the lower priority projects to be delayed.

Result:

This investment will address the following:

- Maintain reliability and quality of service within supply standards; and
- Address customer issues in an expedient and efficient manner.

Outcome Summary:

Customer Focus	• Improve customer satisfaction by resolving high priority issues.
Operational Effectiveness	• Improve power quality by ensuring that protection settings are effective and within acceptable levels for customers.
Public Policy Responsiveness	• Adhere to DSC by maintaining reliability and power quality standards. • Address issues identified in feeder studies and/or system impact assessments.
Financial Performance	• Avoided costs by proactively replacing equipment that is causing issues on the system.

Costs:

As the types of issues that need to be resolved in this program are unforeseen, this work is considered non-discretionary and annual costs are based on historic spending.

The costs of the project are affected by the complexity of the work involved to resolve the reported issues. Costs are controlled by avoiding costly/complex design solutions where possible.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets	4.1	4.3	4.4	5.0	5.0	22.6
Less Removals	0.5	0.5	0.5	0.7	0.7	2.7
Gross Investment Cost	**3.6**	**3.7**	**3.8**	**4.3**	**4.3**	**19.9**
Less Capital Contributions	-	-	-	-	-	-
Net Investment Cost	**3.6**	**3.7**	**3.8**	**4.3**	**4.4**	**19.9**

**Includes Overhead at Current Rates.*

SS-05 Distribution System Modifications

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Program	**Plan Period Cost ($M):**	40.1
Primary Trigger:	Mandated Service Obligation		
Secondary Trigger:	Reliability		

Investment Need:

These investments provide adequate supply to accommodate system load growth on the distribution system with new or modified distribution facilities.

These investments focus on correcting feeder load balance, voltage quality and protection coordination, which are issues that arise over time due to variability in feeder load resulting from changes like natural load growth and economic changes. As these changes occur, the distribution of load along feeders can vary significantly. This can affect the voltage quality and conductor loading, cause improper protection operations, and potentially cause equipment ratings to be exceeded.

To identify issues that have arisen, the distribution system is reviewed for load balance and protection coordination on a cyclical basis. To correct issues that arise such as feeder load balance, voltage quality and protection coordination issues, the scope of work involved can include rebalancing and re-phasing feeders, changes to feeder configuration, new or modified protection equipment and voltage regulators, feeder expansions, and construction of new feeders and voltage conversion.

Alternative 1: Do Nothing

Not proceeding with this investment increases reliability and safety risks associated with low feeder end voltages, overloaded equipment, and improper protection operation. It also increases the risk of not adhering to industry standards for voltage regulation and current levels.

Alternative 2: Make Frequent Investments

This alternative would correct feeder load balance and protection coordination issues on a frequent basis driven by any system changes.

Annual investments on each feeder are not recommended because year over year the changes to load distribution are relatively minimal and this alternative does not lead to the most efficient use of resources.

Alternative 3: Infrequent Investments

This alternative would correct feeder load balance and protection coordination based on a cycle greater than six years.

A review cycle longer than six years is not recommended because the investment needs resulting from natural load growth and economic changes would not be addressed in a timely manner. This could cause issues in terms of coordination of the cycle study reviews with the current line patrol frequency. This would significantly increase the risk of operating the distribution system with overloaded equipment, voltage issues and improper protection.

Alternative 4: Planned Six-year Cycle (Recommended)

This alternative would correct feeder load balance and protection coordination based on a six-year review cycle, consistent with the outcomes of the studies described in Section 2.3 of the DSP. The recommended six-year review cycle length aligns with Hydro One's six-year inspection cycle mandated by the Distribution System Code, Appendix C. Acting on information about a feeder that has just been inspected reduces risks arising from data errors or discrepancies.

This represents a balance between addressing natural load growth in a timely manner and effectively applying resources to maintain all distribution feeders at appropriate voltage and protection levels.

Investment Description:

The work performed under this investment is coordinated with feeder studies that will be conducted on a six-year cycle through Development OM&A activities. The investments address the needs identified through the studies and are executed through this program on a priority basis.

Separate scopes of work are developed for each distribution station and their downstream feeders based on the results of feeder studies. Work is prioritized based on the severity and criticality of the issues being addressed.

The investment is expected to complete approximately seventy-five projects annually over the five-year business plan.

Risk Mitigation:

The main risks to completion of this work are lack of labour resources for design and construction. These risks will be mitigated by ensuring that appropriate planning lead times are followed for project scheduling and by considering constructability issues early in the project definition stage.

Implementation timing is dependent on resources available in the work centres where the projects are occurring.

Result:

This investment provides the following results:

- Reliability and safety risks associated with improper protection coordination, overloaded equipment, and non-standard voltage levels are reduced;
- Power quality issues are reduced;
- System voltage and current levels will be maintained within industry standards; and
- Improve operational efficiency with effective protection schemes.

Outcome Summary:

Customer Focus	• Minimize power interruptions to customers by improving voltage levels and power quality with adjusted protection settings.
Operational Effectiveness	• Improve operational efficiency by addressing overloading on parts of the system, proper phase balancing and ensuring effective protection schemes to deal with changes on the system.
Public Policy Responsiveness	• Maintain system voltage and current levels within industry standards.
Financial Performance	

Costs:

As the types of issues that need to be resolved in this program are unforeseen, this work is considered non-discretionary and annual costs are based on historic spending. Final costs of the program are affected by the scope and complexity of the modifications required for each project. Projects that could incur significant costs get released for design and estimate before execution. This gives system planners an opportunity to consider alternatives to the proposed work and include longer term plans where possible. Other projects which are low in cost or have no alternatives available go straight to release for construction.

Controllable costs are minimized by selecting the most cost effective alternative that addresses the issues.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

SS-06 Worst Performing Feeders

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Program	**Plan Period Cost ($M):**	49.9
Primary Trigger:	Reliability		
Secondary Trigger:	Customer Service		

Investment Need:

Hydro One has various programs that deal with asset based sustainment. Most sustainment programs rely on various condition-based and/or time-based data and use various characteristics such as asset condition, demographics, criticality, utilization and others to determine which feeders are most likely to lead to a failure incident over the planning period. Provisions are made to service those assets with immediate maintenance requirements.

Recently, Hydro One has been able to leverage the available reliability data and has come up with a list of the "worst performing feeders" on the system. Rather than using pure asset-based requirements, the identification of these feeders is primarily based on their reliability metrics as a contributor to System Average Interruption Duration Index ("SAIDI") and/or System Average Interruption Frequency Index ("SAIFI"). These metrics are referred to in combination as Customer Average Interruption Delivery Index ("CAIDI"). [$SAIDI \div SAIFI = CAIDI$]. The trending of performance also factors into the determination of the list.

The worst performing feeders program will include those feeders whose contribution to SAIFI/CAIDI is three times the average feeder's contribution. Based on preliminary analysis, this represents approximately 230 feeders whose contribution to SAIFI is three times the average and approximately seventy feeders whose contribution to CAIDI is three times the average. Improving performance of this small number of feeders should improve reliability of the overall system for customers.

Generally, the primary reason for a feeder being on the worst performing list is related to vegetation management. However, solving the issue is not necessarily about more aggressive forestry practices. Modernization can be a significant contributor to improvement as can placement of the line away from pending forestry contacts. Moreover, improved communication would help to address outages more quickly and reduce their duration to the benefit of customers on these lines.

Witness: Lyla Garzouzi

Alternative 1: Status Quo:

This alternative continues to use the current practice of analyzing and addressing feeder components based solely on their individual characteristics. This alternative misses the opportunity of providing targeted reliability improvements to customers.

Alternative 2: Initiate Program to Modernize Worst Performing Feeders (Recommended)

This alternative specifically targets those feeders whose contribution to SAIFI/CAIDI is three times the average feeder's contribution.

The program will invest in communication to open point switches, installed sectionalizers, and feeder breakers. These investments will allow the grid control room to more quickly identify the origin of a fault and perform operational actions in order to improve reliability. Also, this program will address those feeders where an asset-based approach or vegetation management programs cannot eliminate high numbers of momentary outages.

Initial estimates suggest that this program itself could, over time, increase the reliability of the distribution network by approximately one percent.

Investment Description:

This program focuses on overall feeder performance using reliability data. This approach allows Hydro One to upgrade entire feeder sections rather than just underlying components on an individual basis. Recently improved components on these feeders would not be replaced.

This investment program will use feeders' contribution levels to metrics to identify those feeders where proactive action will result in tangible benefits. Analysis of historical SAIFI contribution values will identify those feeders that are experiencing a significant number of interruptions. Analysis of historical CAIDI contribution values will identify feeders where outage duration is the longest.

This investment program will focus on reducing of two key elements of reliability:

1. Reducing the number of system interruptions (SAIFI) – Key causes of interruptions that can be proactively addressed are vegetation encroachment and equipment failure. Off-road to on-road feeder relocations and remote conditions monitoring are all options for reducing momentary outages.
2. Reducing the duration of customer interruptions when they occur (CAIDI) – Use of fault detectors, automation and remote control of switching equipment and "self-healing-grid" solutions are all options for reducing outage duration.

The program will take proactive action to increase the reliability of the distribution network using a number of solutions:

- Equipment monitoring and alerts;
- Adding monitoring and remote control to existing equipment capable of supporting SCADA, which will be done for problematic feeders to support rapid response to outages when they occur;
- Deployment of modern switching equipment that can act autonomously and can also be remotely controlled to provide isolation and sectionalizing (which is particularly important around existing manually operated open points) with integration to the Distribution Management System ("DMS") through high speed wireless communication systems;
- Construction of additional ties between feeders capable of supporting load transfers; and
- Relocating sections of feeders from off-road to on-road.

Risk Mitigation:

Risk associated with completion of the program is minimal and in line with other upgrade programs. Availability of resources and length of outages are the biggest factors to manage.

The level of approved program investment would impact on modernization effort and hence improved reliability.

Result:

This investment will have an impact on the following:

- Reducing the customer hours of outage by an automated system of back-to-back supply for the faulty feeder and improving reliability through SAIFI and CAIDI metrics resulting in increased customer satisfaction;
- Reducing Hydro One outage times by 50% on faults involving main feeder trunks through identifying the location of faults through DMS monitoring and control telemetry system instead of dispatching a crews to drive along feeders to perform the same task; and
- Performance improvement by allowing the grid control room to quickly identify the origin of a fault and perform operational actions to allow back-to-back supply for the faulty feeder.

Outcome Summary:

Customer Focus	• Improved customer reliability through back to back supply from alternative adjacent feeders. • Improved response times to dispatch.
Operational Effectiveness	• Improved efficiency through enablement of back-to-back switching and remote automation through DMS. • Reduced public safety risk by quickly and accurately identifying dangerous faults. • Improved reliability where current programs are not as effective in removing momentary outages.
Public Policy Responsiveness	• Improved compliance with DSC requirements in responding to trouble situations.
Financial Performance	• Reduced unit costs through more accurate and timely location of faults as well as potentially fewer and more targeted truck rolls. • Reduced level of field effort and, therefore cost, dealing with trouble events.

Costs:

Cost estimates are planners' estimates. Individual feeders may have different issues and hence different solutions. Individual estimates will be obtained in order to fully define the volume of work required.

The factors which affect the estimates for this investment are determined by the annual purchase of the smart equipment units. Controllable costs for this program were based on modernization of open points.

SS-07 Advanced Distribution System ("ADS")

Start Date:	Q1 2013	**Priority:**	High
In-Service Date:	Q2 2018	**Plan Period Cost ($M):**	5.0
Primary Trigger:	System Operational Objectives		

Investment Need:

The ADS investments were part of the smart grid investments outlined in Exhibit D1, Tab 3, Schedule 5 (Customer Services Capital) of EB-2013-0416. They were originally planned for completion within the last approved rate period. Investments were delayed due to a later than anticipated release of a version of software that incorporated more functions into one platform.

The current Distribution Management System ("DMS") went in service in 2012. A lifecycle system refresh is planned to replace hardware and software system components. Specifically, two key sub-projects were delayed: (1) the "DMS Upgrade" project; and (2) the Demand Response for Operations project. The DMS Upgrade project will provide the functionality of the following projects identified on pages 5 to 7 of Exhibit D1, Tab 3, Schedule 5 in Hydro One's last distribution application (EB-2013-0416): DMS Enhancements, Selective Load Shedding, Infrastructure Support, Mobility Solutions and Online Operating Diagrams projects.

The DMS is a control system that monitors and controls the distribution system. It provides a platform for distribution supervisory, control and data acquisition (SCADA). It also provides a set of advanced applications that enable proactive management of the distribution system (such as fault location). The new DMS will include new functionality that will improve operations by enabling field crews with a mobile DMS that they can use to have real-time situational awareness of the distribution system.

The DMS Upgrade project was delayed due to a later than anticipated release of a version of the relevant DMS software that accommodates distributed energy resource management and integrates the broad set of distribution modernization functions (such as mobility solutions). This software version was originally thought to be released in mid-2014, but is now scheduled to be released in 2017.

The Demand Response for Operations project will pilot a system that optimizes electric load and supply on a local basis leveraging all of the variable load (electric vehicle, energy storage, residential/commercial demand response) and generation (dispatchable renewable, energy storage) available. The Demand Response for Operations project was delayed to find more cost effective energy storage solutions.

Alternatives:

Not proceeding with the DMS Upgrade project will see the system go out of support. It will also delay the operational benefits associated with the new version of the software which include management of distributed energy resources. Failing to proceed with this investment would result in an increased risk of application failure which would impact Hydro One ability to manage its deployed smart grid assets.

Not proceeding with the Demand Response for Operations project will impact Hydro One's ability to manage the increasing volumes of customer-owned generation and microgrids expected to proliferate in the coming years.

Investment Description:

Planned investments for the DMS Upgrade project include hardware refresh, server operating system upgrade, DMS software upgrade as well as rollout of the DMS to be available for field crews.

Planned investments for the Demand Response for Operations project will see Hydro One install assets that monitor and control customer-side generation and storage assets and integrate them with control systems at the substation and the control centre.

Risk Mitigation:

<u>DMS Upgrade Project</u>

- As with all complex control system upgrade projects, the project entails system integration and technology risks. Hydro One has assigned an experienced team that worked on the original DMS implementation.
- As the DMS is being deployed to field crews for the first time, there are change management risks associated with training and adoption. A comprehensive change management program is planned to mitigate these risks.

<u>Demand Response for Operations Project</u>

- As the project will be piloting the integration of several new technologies (energy storage, solar, home energy management systems, etc.), there are system integration and technology risks. Hydro One will bring in external resources who have implemented similar systems elsewhere to mitigate these risks.

- As the project will be piloting technology on both the customer-side and grid-side of the meter, there are risks with the technology failing or customer expectations not being met. A comprehensive customer communication strategy will be developed that ensures clear communication with customers to set realistic expectations. Technology will be selected, engineered and commissioned to ensure they are reliable and safe.

Result:

DMS Upgrade Project

- Provide further integration of smart grid capabilities into the central control system for operators.
- Equip field crews with new mobile systems they can use to restore power more quickly and execute planned outages more efficiently.
- Enables more surgical load shedding during bulk electric system emergencies that would maintain distributed generation and critical loads (hospitals, water treatment plants, etc).

Demand Response for Operations Project

- Defer local distribution investment by maintain load below a set point by leveraging generation and storage assets.
- Increases the load capacity factor of the distribution system and reduces the variability of load and generation.
- Establish the systems and processes to manage the proliferation of customer-side generation and energy storage systems.

Outcome Summary:

Customer Focus	• Enable customer-side generation and storage assets for the benefit of both customers and the grid.
Operational Effectiveness	• Enhanced reliability of distribution system by providing field crews additional situational awareness on the real-time state of the distribution system and location of faults. • Increase operational efficiencies related to how the distribution system is studied in the planning time frame and provide more tools for the control room and field crews in real-time operations. • Improve the efficiency of distribution cycles studies by leveraging the accurate network topology and the state estimation function. • Improve efficiency of storm management by providing an electronic mimic of the distribution system in the operating centres that can replace the paper pinning.
Public Policy Responsiveness	• Comply with the public policy objectives set out in the OEB *Supplemental Report on Smart Grid* (2013) including: ○ improving customer control; ○ enabling power system flexibility; and ○ building adaptive infrastructure.
Financial Performance	

Costs:

DMS Upgrade Project Costs associated with the DMS Upgrade project are primarily driven by:

- Required testing effort;
- Hardware and software costs; and
- Integrations.

These costs have been minimized through:

- Requiring that all customizations be reviewed for priority and approved by the Steering Committee for their approval before proceeding;
- Utilizing a mixed team of contract and internal resources to perform testing of the system;
- Going to competitive bid for all hardware and software components of the upgraded DMS;
- Minimizing the number of integrations and using resources experienced with the existing integrations to design, build and test the new integrations; and
- Demand Response for Operations Project.

Costs associated with the Demand Response for Operations Project are primarily driven by:

- Cost of solar photovoltaic systems;
- Cost of energy storage systems;
- Cost of onsite installation services; and
- Integrations with utility systems (substation protections and the DMS).

These costs have been minimized through:

- Delaying the project start to find more cost effective solar and energy storage systems as they become more commercially viable;
- Leverage experience in performing onsite installations for conservation programs to minimize install cost; and
- Leverage the resources of the inflight DMS project to perform the integrations required to monitor and control.

GP-01 Transport & Work Equipment

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Q4 2022	**Plan Period Cost ($M):**	201.0
Primary Trigger:	F1-Asset renewal / maintenance		
Secondary Trigger:	Capital Program		

Investment Need:

Hydro One controls and manages approximately 8,000 Fleet vehicles which support the various lines of business, including Provincial Lines, Stations, Forestry and Construction Services. Fleet vehicles must be maintained at an optimum level to ensure public and employee safety and compliance with laws and Ministry regulations. These include, but are not limited to CSA 225, the Highway Traffic Act and the Commercial Vehicle Operator's Registration regulations. This results in minimized environmental impacts and optimized line-of-business productivity by minimizing downtime, travel time, and by optimizing technology and continuous improvement opportunities.

Transport and Work Equipment ("TWE" or "Fleet") expenditures for 2018 through 2022 are primarily required to accomplish the following:

- Replace end of life core TWE;
- Support the growing levels of transmission and distribution capital and OM&A sustainment, development and operations work programs;
- Support the Forestry Mechanical Brushing Program, and Provincial Lines Pole Replacement Program; and
- Replace aging helicopters with newer safer and more capable aircraft.

Alternatives:

TWE plays a wide reaching and integral role in the day-to-day operations, safety and success at Hydro One. Availability of TWE has a direct impact on work programs and this proposal is to maintain the Fleet compliment.

The primary alternative to the proposed plan centres on a reduction in capital spending on TWE in favour of increased use of rental equipment, if the required equipment is available, and extended retention of existing equipment to satisfy work program and staffing requirements. Hydro One employs specialized equipment specifically outfitted to Hydro One safety specifications. Short term rentals are utilized where applicable on light duty vehicles but history has shown that due to the nature of the work, any rental savings is quickly offset by additional costs incurred by the normal wear and tear on the rental vehicles in this type of industry. The result is increased maintenance costs on the retained vehicles, increased vehicle downtime and decreased equipment availability.

Investment Description:

Fleet capital replacement requirements are based on:

1. Industry standards (manufacturer's recommendations) for life cycle expectancy;
2. Net Book Value (NBV) to Original Capital Value (OCV) ratios; and
3. Operating cost drivers which are then linked to the Business Plan and Work Programs.

Currently, the fleet is at 39% NBV to OCV where industry standards, established through a combination of Canadian Utility Fleet Manager workshops, direction from Fleet Management Companies and Industry experts, suggest that 45% as an optimum level. Our present replacement criteria are based on manufacturers' recommendations and repair history.

Key contributors to the 2018-2022 capital program include:

- The replacement of core transport and work equipment (about 8%, approximately 650 vehicles, of Fleet annually);
- Incremental vehicle and equipment requirements to support the increase in the Mechanical Brushing Program and the Provincial Lines Pole Replacement Program; and
- Replacement of aging helicopters.

Table 1 – Forecast of Acquisitions for 2018 to 2022

Equipment Type	2018		2019		2020		2021		2022	
	Cost ($M)	# of Units	Cost ($M)	# of Units	Cost ($M)	# of Units	Cost ($M)	# of Units	Cost ($M)	# of Units
Light[1]	7.3	322	8.4	369	7.9	348	8.3	365	7.4	323
Heavy[2]	14.0	108	15.8	121	16.9	129	17.8	136	21.0	159
Off-Road[3]	6.3	26	7.1	29	7.3	30	7.6	31	8.0	33
Miscellaneous[4]	4.0	173	4.6	197	4.6	201	4.6	198	3.9	166
Helicopter	2.4	0.5	2.4	0.5	2.4	0.5	2.4	0.5	2.4	0.5
Incremental Additions [5]	1.1	9	1.3	12	1.3	12	1.3	12	1.4	12
Total	**35.0**	**639**	**39.5**	**729**	**40.4**	**720**	**42.0**	**743**	**44.1**	**694**

Note: Number of units is based on average unit costs per category of equipment and is subject to change based on specific LOB staff and work program requirements.
Numbers of units are based on the Tx and Dx Capital Investment Costs

[1]Light – cars, SUVs, pickups, vans
[2]Heavy – service trucks, highway tractors, radial boom derricks (RDB), bucket trucks
[3]Off Roads – rubber tire, tracked equipment
[4]Miscellaneous – boats, chippers, tensioners, manlifts, forklifts
[5]Incremental Additions – Tracked and Rubber Tired Grinding/Mulching units, Tag-a-long Chippers, Bulldozers are used for the Forestry Mechanical Brushing Program and RDB for the Provincial Lines Pole Replacement Program.

Risk Mitigation:

Fleet capital requirements are primarily based on industry standards (manufacturer's recommendations) for life cycle expectancy, the remaining capital value, and operating cost drivers.

Light vehicles are replaced after six years or 180,000 km. Heavy vehicles have several replacement guidelines depending on the type of equipment; service trucks are replaced after six years or 300,000 km, and work equipment-single axle is replaced after eight to ten years or 400,000 km. Work equipment-tandem axle is replaced after twelve to fourteen years or 400,000 km. Off-Road and Miscellaneous equipment is replaced on a case by case basis depending on utilization and condition of the equipment and ongoing need.

Helicopters are replaced on a case by case basis depending on utilization, condition of the aircraft and the cost of refurbishment. This asset strategy is designed to address the following risks:

- Equipment failure - Retaining and operating older equipment increases the probability of failure, which creates costly downtime for crews and increases safety risk for employees and the public;
- Scheduled Outages - Customers (especially large industrial) are impacted when equipment is unavailable because the outage must be rescheduled;
- Emergency response - Unplanned work (i.e., storm response, trouble calls) requires timely dispatch and lack of available equipment will impact customers by exacerbating outages;
- Work Schedules - Delay in work programs impact the Line of Business (LOB) project costs and decrease operational effectiveness;
- Increasing costs - Repair time and maintenance costs are reduced since aging equipment requires more maintenance as seen in table 2; and
- Environmental goals - Environmental Impact to the public is affected by operating aging equipment as newer, maintained vehicles tend to have a lower carbon footprint.

Result:

The objective of the TWE Replacement Program is to promote an orderly system of purchasing and funding a standardized fleet replacement process and to plan for future TWE requirements based on work program and staffing forecasts. The TWE Replacement Program annually analyzes its five-year business planning cycles for capital investment requirements and maintains a safe and efficient fleet. It is critical to evaluate and forecast spending requirements to minimize fluctuating spending patterns and to stabilize long term capital investment. The fleet capital replacement program, on an annual basis, is evaluated against the business plan and is subject to the LOB’s work program prioritization and forecasting process.

The objective is to maintain a stable fleet replacement program and minimize capital investment fluctuations year-over-year. A reduction in capital spent in a given year will result in increased operating costs, which could ultimately result in increased equipment rates.

This investment will:

- Ensure compliance with all safety standards, as well as Ministry of Transportation (MTO) and regulatory requirements;
- Allow Hydro One to maintain and improve its present core fleet level of 39% versus the industry standard of 45% NBV. At the end of 2022 it is forecasted to be 41%.

Fleet Services will leverage the telematics data to institute the baseline metrics with respect to equipment utilization and productivity;

- Maximize, productivity efficiencies and utilization; and
- Optimize repair time and fleet size.

Outcome Summary:

Customer Focus	• Optimize Fleet Service levels to mitigate potential delays in response time to unplanned incidents, such as trouble calls and storm response.
Operational Effectiveness	• Fleet vehicles and other specialized equipment at optimal levels of availability reduce human effort and minimize risk of personal injury. • Optimal investment levels allow employees to have the right equipment to do their job, increase employee engagement levels, minimize risk of injury and increase work satisfaction.
Public Policy Responsiveness	• Optimal investment levels allow for maximum equipment efficiencies and minimize Hydro One's carbon footprint. • Ensure compliance with all codes, standards and regulations to maximize shareholder value and sustainably manage our environmental footprint. • Vehicles will be maintained at an optimum level to ensure public and employee safety and to meet Ministry regulations.
Financial Performance	• Ensure savings from operational effectiveness are sustainable. Control maintenance costs (external repair, parts and internal labour), potential rental costs and maintain equipment rates at optimal levels to ensure OEB mandated ROE is achieved.

Costs:

GP-02 Real Estate Field Facilities Capital

Start Date:	Q1 2018	Priority:	High
In-Service Date:	Program	Plan Period Cost ($M):	185.9
Primary Trigger:	Business Operations Efficiency		
Secondary Trigger:	Non-System Physical Plant		

Investment Need:

The Field Facilities Capital work program addresses the accommodation portfolio of administrative and service facilities in terms of improvements, building additions and new facilities as determined by Hydro One's operational requirements and asset condition. This program ensures that essential and supportive improvements are made to administration and service facilities to minimize building and site related risks to the operations; serve operational requirements; and promote efficiencies in the maintenance and operation of the facilities in the longer term.

Capital investment is periodically required in order to continue to provide appropriate and adequate accommodations for core work programs and changing requirements of the various lines of business. The investment need is driven by the following key factors:

- deteriorating facilities that are at or near the end of life;
- compliance with current regulatory requirements, such as Accessibility for Ontarians with Disabilities Act and the Ontario Building Code;
- expanding work programs;
- new accommodation needs;
- evolving work practices;
- improved health and safety;
- improved security;
- sustainable development; and
- work efficiency and productivity.

More than 40% of administration and service facilities are estimated to be more than 40 years old. These facilities are largely undersized, ill configured and underperforming to current operational requirements with resulting increase to operating costs for maintenance and repair and inefficiency to facility and business operations.

The Field Facilities Capital work program focuses on undertaking facility work encompassing improvements, additions or new facilities. Work is undertaken on a priority and timely basis at a level of expenditure required to support the business operations to fully deliver the prescribed various work programs addressing network requirements, customer needs, corporate and government policy and regulatory/licensing directives in a safe, efficient and cost effective manner. This work is conducted on a project basis.

Alternative 1: Status Quo

This alternative is to effectively curtail future investment on a minimal basis in an attempt to operate within the outdated facilities.

This alternative is not sustainable. Without necessary capital repairs, upgrades and replacements, facility conditions will deteriorate to the point where efficiency and safety become impaired. Incidents arising from this alternative will hamper Hydro One's ability to perform its work and serve customers.

This alternative would require additional operating expense for maintenance repairs, which have not been factored into this Application. The risk created by this alternative, and the additional operating maintenance expense it would create, caused it to be rejected without further analysis.

Alternative 2: Update Facilities *(Recommended)*

This alternative would bring field facilities to an acceptable state of repair and make strategic additions or replacements where beneficial.

The spending requested herein is an estimate of the work to be performed over the planning period. The development of field facilities entails an on-going, comparative evaluation of alternatives, which entails the expansion and/or renovation of existing facilities, the lease or purchase of suitable facilities and greenfield developments against maintenance of the status quo condition. The ultimate investment will be dictated by the circumstances in place. The objective is to pursue the most cost effective strategy that addresses operational requirements and manages risk. Operational considerations are for both existing and future requirements; the latter considers changes to the business, e.g., volumes and delivery strategy. Regardless, each substantial investment will be subject to analysis and approval based on its benefit prior to implementation.

The prime consideration throughout is to extract the value of existing facilities through ongoing operations, maintenance and sustainment investments in line with operational requirements. Where facility and/or operational conditions/requirements dictate an examination of facility alternatives, the objective is to derive the greatest net assessable benefit to the company.

Investment Description:
The key program work activities include:

- replacement of major building system/components, including roof structures; windows and cladding; heating, ventilating and air conditioning (HVAC) systems; electrical, lighting and control systems; and other crucial/fundamental structural elements and building systems that are at end of life;
- site replacements and additions, including drainage; asphalt, fencing; and septic/well (servicing); and
- addition and/or renovation of existing facilities and the acquisition or development of new facilities to address existing and/or new accommodation requirements.

The required capital investment for field facilities is outlined in the Costs section below. These amounts are needed to fund required improvements of existing facilities and the development of new accommodation solutions through renovation and/or expansion and the acquisition or development of new facilities as required by the company's work programs. Projects can be multi-year; and the work is contingent in several projects on the successful identification and acquisition of development sites and in all instances obtaining the requisite municipal planning approvals. Furthermore, certain projects are tied to the successful and timely completion of utility acquisitions or others may be adjusted for emerging acquisition opportunities.

The current estimate of the volume of work to be completed annually at individual sites/facilities is as follows:

Work	**Annual Completed Projects**
New Facilities and Major Renovations	2 – 4
Site Improvements (asphalt; drainage; servicing; fencing; security)	20 – 25
Building Envelope (roof; windows/doors; cladding)	20 – 30
Mechanical & Electrical (HVAC; lighting; generators)	15 – 20
Minor Building Renovations and Additions	10 – 15

Witness: Rob Berardi

Benefit is realized through a number of factors, such as lower cost, improved operational performance, regulatory compliance, enhanced health & safety, reduced risk, enriched life cycle management and adaptability to address known or anticipated change.

Risk Mitigation:

Cost certainty for new operating centres is established through the use of a scalable template design and experience from recently completed projects. Developments are completed in accordance to prevailing commercial standards and practices.

Developments of new facilities are in various instances dependent on the availability of suitable sites and requisite municipal approvals, which is managed through advance planning and acquisition. Development interests are cultivated by leveraging municipal officials/departments and utilizing the services of the real estate and development community.

Facilities redundancy and low value investments are managed by conducting regular reviews with the various lines of business to understand and align with current and emerging work programs and identify common requirements and workplace synergies. Furthermore, planning is integrated with utility acquisition strategies and objectives to identify opportunities, create flexibility and manage facilities investments.

Result:

- Field Facilities that serve current operating requirements of the various lines of business.
- Field Facilities commitments and investments aligned with known and emerging operating requirements and corporate business decisions.
- Maintenance of existing Field Facilities through timely replacement of major building systems/components.
- Enhanced health & safety of employees operating within Field Facilities.

Outcome Summary:

Customer Focus	• Improve the ability of the lines of business to address customer needs through facilities that commensurately align with operational requirements.
Operational Effectiveness	• Maintain and improve operational effectiveness of the lines of business through timely and strategic facilities investments.
Public Policy Responsiveness	• Comply with government policy and regulatory/licensing directives.
Financial Performance	• Cost savings realized through the broad consideration of facilities alternatives. • Cost effectiveness realized through regular assessment and timely investment. • Cost efficiency realized through facilities investments that align with current and emergent operating requirements and business decisions.

Costs:

The development of facilities and resulting final cost of a project are influenced by various factors beyond the typical realm of design, such as market, regulatory and site conditions/factors. Regulatory and site conditions are somewhat predictable through assessment, but not overly influenced by design considerations. Whereas, the market is highly influential to final cost for availability of suitable sites, market opportunity and interest and competing demand. These market factors could have a significant negative or positive influence to the cost of the project. Furthermore, existing facility conditions, site and/or building, may have significant latent defects that, irrespective of early assessments, are undetectable until implementation and could contribute to significantly higher costs.

The cost for the development and/or renovation of facilities is controlled where applicable through template design, consistency of application, and the adoption of commercial building standards and practices.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

GP-03 MFA Servers and Storage

Start Date:	Q1 2018	Priority:	High
In-Service Date:	Program	Plan Period Cost ($M):	16.0
Primary Trigger:	System Capital Investment Support		

Investment Need:

Hydro One has made significant investments in Enterprise class technology; most notably SAP, Microsoft and a Geographic Information System ("GIS"). These systems directly enable customer services such as timely and accurate bills and customer contacts through Hydro One's call centre. Hydro One's Enterprise systems also provide the backbone of business operations within finance, human resources, supply chain as well as asset and work management for field staff upgrading and maintaining the power system. The reliability of these systems is critical to keeping the business running effectively. This investment plan maintains the Enterprise systems at service levels aligned with business criticality.

Infrastructure servers are used to run business applications, networks, web services and email. Data storage devices are used by business applications and email to store and retrieve data. Servers and storage devices reach capacity over time and reach their vendor's end-of-support life at which time they require upgrading or replacement to increase capacity or to ensure cost efficient maintenance that minimizes or eliminates down time.

Key systems and the data generated must always be available (99.5%) to customers and employees involved with the delivery of customer service programs and work management programs linked to Hydro One Customer satisfaction goals/KPIs. Customer Information systems enable effective delivery of call center, meter reading, billing, collections and settlement services to Hydro One Customers through reliable and cost effective information systems; Work Management Systems enable timely connection of customers and demand related activities. As more customers are integrated into the SAP landscape and generate more business analytics the need for SAP capability increases. Move-to-Mobile and Customer High Bill Alerts are projects that require new hardware. Merger and Acquisition activity is another component that drives an increase to our server landscape.

Enterprise applications being refreshed (to stay within vendor supported levels) drive refresh of the overall environment. Hardware refresh is also required to support enterprise applications from a performance/capacity and overall availability perspective to meet both customer and business expectations. Without refreshed assets, Hydro One would have difficulty enforcing performance agreements with vendors and could potentially be exposed to large, un-warranted costs. Conversely, refreshing as per vendor requirements allows for sustainment costs due to technology improvements being implemented as part of new deployments to be favourably re-negotiated.

HONI continues to increase its virtualization footprint for any new/existing applications that are refreshed. With virtualization, several operating systems can be run in parallel on a single server. This parallelism and allows Hydro One to better manage updates and changes to the operating system and applications without disrupting the user. Virtualization can improve the efficiency and availability of resources and applications in an organization.

Hydro One continues to explore opportunities to leverage cloud based application/infrastructure services while complying with HONI's corporate data security policies around NERC, CCAI, and PIPEDA.

IT system availability directly impacts the productivity of employees who use the technology. IT availability also has direct impacts on the availability and security of the power network itself given the modern suite of tools that are relied upon to monitor and operate the grid.

Alternative 1: Delay Refresh

This alternative would seek to delay the replacement of equipment past its current life-cycle expectancy.

Not refreshing end-of-life servers or delaying investment in storage devices beyond the current level will impact the reliability of IT systems and increase the incidents of failure. This reduced reliability will impact application uptime and overall system availability for customers and internal users alike. It will also drive additional sustainment costs, as many vendors commonly charge their services at a premium rate to support end of life products. It will remove the ability to build out capacity on-demand capability and will cause hardware to be added frequently and incrementally. This "just-in-time" server add strategy comes at a significant premium due to the lack of bulk buys, multiple complex setup and staging processes and potentially costly delays to important Business IT projects if hardware procurement has any issues.

Alternative 2: Refresh In-line with Life Cycle Guidelines (Recommended)

This alternative would keep assets current and refreshed. This option will support the maintenance of up-time requirements and ensure that data and processing ability is available to customer and employees.

Investment Description:

Wintel servers are refreshed on a three- to five-year cycle and UNIX servers are refreshed on a five- to seven-year cycle. These cycles fall within industry best practices and maintain warranties within an acceptable level. Virtualization technology is being leveraged to further increase the life of our physical servers. The replacement cycle for refresh of Wintel and Unix servers is to maintain vendor-supported levels and includes hardware upgrades, capacity upgrades for core access control and middleware environments in anticipation of increased data processing with SAP-driven processing.

In determining when systems require replacement, the functionality, operating and maintenance (i.e., standard warranty or extended warranty) costs are assessed. The funding for the servers and storage refresh/replacement program varies year over year depending on hardware lifecycles and business requirements for increased processing capacity.

Costs in 2018 to 2022 reflect typical lifecycle refresh of end of life storage hardware.

Risk Mitigation:

Replacement of infrastructure as proposed in this investment is a fairly routine occurrence that has been performed many times within the Hydro One environment by the staff that will be involved in this project. While issues occur, the risk of project failure is very low and most adverse situations can be anticipated and addressed from experience.

Any project risk is mitigated through stakeholders and modification of scope to reach desired business outcome. In the event of hardware failure, defects discovered, or resource constraints the project will work the systems integrator equipment manufactures to resolve issues or modify scope timelines until the issue can be resolved or architected.

Result:

A proactive investment approach reduces the risk of prolonged IT system outages and reduces the costs of unplanned investment for problem resolution. It also reduces the risk to

Hydro One's ability to respond to business requirements and project delivery due to IT system integration and scalability impacts.

Outcome Summary:

Customer Focus	• Support information availability to customers ensuring that systems are supported and reliable. • Improve customer satisfaction around ease of use and experience of our customers when accessing billing information on e-customer.
Operational Effectiveness	• Increase productivity by ensuring that applications / systems function as designed and provide Hydro One employees with the information they require to perform their daily work effectively.
Public Policy Responsiveness	
Financial Performance	• Minimize overall cost by minimizing the potential for costly outages and unplanned refreshes or upgrades. • Maintain vendor support and the ability to enforce performance or availability SLA's thus avoiding increased costs.

Costs:

Historical costs provide a trend and basis for budget estimation, in addition to vendor discussions for future demand management driven by development projects/programs. The market for these products has matured significantly over the last decade. Major cost fluctuations are not anticipated and, in any event, are foreseeable and addressable through sound procurement strategy.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets	3.2	3.2	3.2	3.2	3.2	16.0

Witness: Lincoln Frost-Hunt

GP-04 Minor Fixed Assets - Desktop, Laptop, Printer

Start Date:	Q1 2018	Priority:	High
In-Service Date:	Program	Plan Period Cost ($M):	9.8
Primary Trigger:	System Capital Investment Support		

Investment Need:

Hydro One has made significant investments in Enterprise class technology; most notably SAP, Microsoft and a Geographic Information System (GIS). These systems directly enable customer services such as timely and accurate bills and customer contacts through Hydro One's call centre. The Enterprise systems also provide the backbone of business operations within finance, human resources, supply chain as well as asset and work management for field staff upgrading and maintaining the power system. Minor Fixed Assets ("MFA") are the method by which the information and capability of these enterprise systems are provided to employees. Currency and functionality of the MFA fleet is critical to allowing employees perform their work productively.

Key systems and the data generated will always be available (99.5%) to customers and employees involved with the delivery of customer service programs and Distribution work management programs linked to H1 Customer satisfaction goals/KPIs – Customer Information Systems enable effective delivery of call center, meter reading, billing, collections and settlement services to Hydro One Customers through reliable and cost effective information systems; Work Management Systems enable timely connection of customers and demand related activities.

MFA equipment includes:

- Desktops, Laptops, and Printers used by Hydro One staff to perform their daily work such as accessing email, desktop applications (i.e. Microsoft Office), and enterprise applications;
- Tablets used with, among other things, Geospatial Information Systems ("GIS") applications for undertaking system design work and for asset condition assessments;
- Rugged Tablets and mobile devices used by field staff for entry of work related data; and
- Plotters commonly used by Hydro One engineering and operations staff for design work and to plot system maps.

Witness: Lincoln Frost-Hunt

Replacement of MFA that have reached the end of their useful life is necessary to address warranty considerations and to maintain hardware reliability, as well as to upgrade existing equipment to meet business performance needs.

Equipment refresh maintains or reduces maintenance costs. Hardware costs tend to increase with age, especially when the hardware is no longer supported under vendor warranty.

Alternative 1: Delay Hardware Refresh

This alternative would delay the refresh of assets and address increased failure and performance of the obsolete assets.

A delay in hardware refresh would affect operational effectiveness and our ability to serve customers. Aging hardware impacts application performance which in turn impacts ability to provide timely responses to customers in a call centre environment. In other areas of the business aging PC's perform poorly as new state of the art applications are deployed demanding more processing power and memory.

Delaying the equipment replacement or reducing funding beyond the current level will negatively impact the ability of employees to support the business and customers due to the increased risk of breakdown and lost productivity.

Other investment changes intended to reduce replacement would increase sustainment costs and the time to restore IT services. This is because technology beyond the vendor-supported life is normally outside of service agreements, and parts and labour are difficult and costly to secure.

Alternative 2: Refresh Per Plan (Recommended)

This alternative would strive to purchase and refresh MFA within asset life cycle guidelines.

New models are selected as part of technology refresh to meet user needs based on business requirements (USB Ports, Processing & Memory requirements, indoor versus outdoor usage, etc). Newer models provide additional compatibility with new business applications, operating systems, modern browsers, etc. The hardware refresh allows Hydro One to enforce service levels and performance based SLAs with vendors.

The option of renting/leasing MFA was reviewed. However, most of this equipment is made up of small, relatively inexpensive items whose usefulness is generally exhausted by end of life. Therefore it was deemed not feasible to rent or lease these items on a long term basis since leasing vendor margins would be purely accretive to the cost and would be higher than any cost of capital benefits from leasing. As a result, this alternative was not pursued.

Old equipment that is past the end of its useful life becomes unreliable and negatively impacts the ability of the business to perform their day to day work, thereby increasing costs to Hydro One and its customers. In addition, existing equipment may need to be upgraded to meet the changing needs and applications of the business.

Investment Description:

Hydro One’s practice is to replace desktop and laptop computers every three to five years, and printers and plotters every four to five years. The renewal timeline is consistent with industry practice as identified by Gartner industry benchmarking studies. Historically, Hydro One’s refresh cycle has been slightly longer but has been consistent with maintaining functionality and minimizing maintenance costs.

The estimated units to be replaced over the program are as follows:

	2018	**2019**	**2020**	**2021**	**2022**
Desktop/Laptop	1050	950	950	950	950
Printers	50	47	47	47	47
Other	21	19	19	19	19

Risk Mitigation:

Refresh programs run year over year, assets not deployed in one year are leveraged first the next year. Total number of machines deployed over 3-5 years remains constant.

Issues around software compatibility are addressed as part of certification process where a standard locked down image is deployed to all users with packaged/certified software applications.

Issues around hardware failure are addressed via the warranty process with the vendor.

Result:

The PC and Printer hardware assets will reliably support business needs and the performance of day-to-day work unimpeded by end-of-life computer reliability problems, promoting workforce productivity.

Outcome Summary:

Customer Focus	• Support customer services by ensuring employees have the necessary equipment to meet customer needs.
Operational Effectiveness	• Maintain productivity by ensuring reliability of IT tools required by Hydro One employees to perform their daily work.
Public Policy Responsiveness	
Financial Performance	• Overall costs are minimized by enabling general employee productivity.

Costs:

Estimates are driven by historical costs, which are driven by the inherent lifecycle of the devices.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

GP-05 Hardware/Software Refresh and Maintenance

Start Date:	Q1 2018	Priority:	High
In-Service Date:	Program	Plan Period Cost ($M):	20.1
Primary Trigger:	System Capital Investment Support		

Investment Need:

Hydro One has made significant investments in Enterprise class technology; most notably SAP, Microsoft and a Geographic Information System ("GIS"). These systems directly enable customer services such as timely and accurate bills and customer contacts through Hydro One's call centre. The Enterprise systems also provide the backbone of business operations within finance, human resources, supply chain as well as asset and work management for the field staff upgrading and maintaining the power system. The reliability of these systems is critical to keeping Hydro One's business running effectively. The investment plan maintains the Enterprise systems at service levels aligned with business criticality.

Key systems and the data generated will always be available (99.5%) to customers and employees involved with the delivery of our customer service programs and work management programs linked to Hydro One customer satisfaction goals/KPIs. Customer Information Systems enable effective delivery of call center, meter reading, billing, collections and settlement services to Hydro One Customers through reliable and cost effective information systems; Work Management Systems enable timely connection of customers and demand related activities.

Investments are needed to build contingency so as to ensure that critical systems are available and can survive the failure (result of a manufacturer bug, security patch, etc) of any single supporting technology component. Investments in supporting technology components include telecom, IT hardware and software. Leveraging these investments with effective vendor maintenance means that the assets can be fixed and/or replaced expeditiously in the event of failure. To that end, Hydro One adheres to an IT industry standard practice of managing its assets through a lifecycle program ensuring vendor support is available and decreasing the likelihood of failure. Funding decisions are made based on software lifecycles, vendor schedules, reliability requirements, and experience with similar initiatives/projects.

Alternative 1: Delay Refresh

This alternative would defer replacement of assets due for refresh and address additional issues with higher failure rates of the systems.

Increasing the current life-cycle asset refresh strategy takes Hydro One beyond industry practice and significantly increases risk to the business in the following areas:

- Increases in employee dissatisfaction and decreased productivity due to frequent and/or prolonged service outages;
- Degraded regulatory relationship from disruptions to market operations of IT systems that interact with market participants;
- Decrease in customer satisfaction due to failure of enterprise wide applications such as SAP, ihub/Tivoli, Microsoft Exchange, mobile applications, customer billing, relationship management, and call centre systems; to meet service quality index for customer service; and
- Productivity declines due to the high unit cost of supporting and servicing applications without vendor support.

Alternative 2: Refresh Per Plan (Recommended)

This would replace servers within life cycle guidlelines. A number of factors drive the refresh of an application. Hardware or Applications out of vendor support is one component, while additional application functionality or performance considerations will also drive a refresh. This investment covers the cost to build the new servers along with any data migration activities and decommissioning.

Server hardware is refreshed every 3-7 years based on hardware type. Hardware refresh is required to support enterprise applications from a performance/capacity and overall availability perspective to meet both customer and business expectations. Refreshing per plan allows for sustainment costs to be favourably negotiated due to technology improvements being implemented as part of new deployments.

This investment covers the capital costs, including Professional Services, to build new Web/Database/Application and Infrastructure servers along with all relevant data migration, Operating System, hardening, and decommissioning activities. There are a number of factors that drive hardware refresh – vendor supportability being a primary driver. There are other important considerations as well, including hardware age, and the general availability of supported replacement parts.

From an application perspective, today's business demands performance levels that are only offered by the latest server hardware and network technologies. While from a technology perspective, the entire IT market continues to virtualize and optimize key areas that are common across all data-centres – virtualizing server compute, storage and network. Refreshing this aging hardware allows for greater scalability and higher server densities, since it is possible to run addititional virtual servers with a smaller hardware footprint.

Investment Description:

Included in 2018 to 2022 the planned investments relate to the implementation of enterprise resource planning ("ERP") applications and related tools including SAP, further IT security access control and monitoring capabilities, middleware and databases, productivity tools, and server upgrades to keep the data center infrastructure vendor supported and to make improvements to the disaster recovery platforms. Refreshes for applications in sustainment are funded from this investment. The only exception is if the refresh is going to drive new functionality that can be tied to a Business Case. Lastly, a system being refreshed in order to accommodate its inclusion into the Disaster Recovery Program (DRP) would also be funded by this investment.

Risk Mitigation:

No concerns are foreseen with completing the completing the Hardware/Software refresh program. Any project risk is mitigated through stakeholders and modification of scope to reach desired business outcome.

Any risks around resourcing (specific skillset) will be addressed prior to project award with systems integrators. The award will ensure proper expertise is maintained during the life of the project and is well documented as part of scope execution.

Result:

This proactive investment approach reduces the risk of prolonged system outages and reduces the costs of unplanned investments for problem resolution. This investment in IT system reliability enables general employee productivity because users have access to the tools they require to work, and it enables customer satisfaction through availability of enterprise wide applications, customer call centre and outage management systems.

1 **Outcome Summary:**

Customer Focus	• Ensure IT Hardware / Software is supported and reliable to prevent information gaps for customers. Performance and Stability of IT Hardware / Software directly impact ability to service customers in a timely manner (ie: Outages, Billing Inquiry, Program Enrollment, etc).
Operational Effectiveness	• Maintain the reliability of IT Hardware/Software to allow applications / systems to function as designed and provide Hydro One employees with the information they require to perform their daily work.
Public Policy Responsiveness	• Maintain efficacy of the of IT systems that interact with market participants and support the IESO in its market oversight mandate.
Financial Performance	• Overall costs are minimized serves to reduce the potential for costly outages and unplanned refreshes or upgrades.

2

3 **Costs:**

4 Estimates are driven by historical costs, which are driven by the inherent lifecycle of the
5 devices.

6

7

GP-06 MFA Telecom Infrastructure

Start Date:	Q1 2018	Priority:	High
In-Service Date:	Program	Plan Period Cost ($M):	6.7
Primary Trigger:	System Capital Investment Support		

Investment Need:

Hydro One has made significant investments in Enterprise class technology; most notably SAP, Microsoft and a Geographic Information System ("GIS"). These systems directly enable customer services such as timely and accurate bills and customer contacts through the call centre. The Enterprise systems also provide the backbone of Hydro One's business operations within finance, human resources, supply chain as well as asset and work management for its field staff upgrading and maintaining the power system. The reliability of these systems is critical to keeping Hydro One's business running effectively. The investment plan maintains the Company's Enterprise systems at service levels aligned with business criticality.

Key systems and the data generated will always be available (99.5%) to Hydro One's customers and employees involved with the delivery of the Company's customer service programs and work management programs linked to Hydro One Customer satisfaction goals/KPIs. Customer Information Systems enable effective delivery of call center, meter reading, billing, collections and settlement services to Hydro One Customers through reliable and cost effective information systems; Work Management Systems enable timely connection of customers and demand related activities.

This investment is required to replace end-of-life assets and to maintain service reliability and security, by refreshing network switches and routers, upgrading voice infrastructure, replacing un-interruptible power source system, and upgrading the security solutions for external network interfaces.

Telecom infrastructure is the underlying hardware to support the business telecom network which is used to transmit data required to run business applications. Voice or data network improvements or replacements are undertaken to improve network efficiency and to ensure equipment is current and supported by third party vendors.

Alternative 1: Delay Refresh

This alterative would defer purchase of Minor Fixed Assets ("MFA") and deal with the incremental sustainment issues arising as a result.

Delaying the equipment replacement or reducing funding beyond current level will increase time between hardware refreshes, which may cause degraded voice and data network, reduced capacity to accommodate Move, Adds or Changes activities and poor network performance. Network availability and performance directly impacts customer interaction (ability to respond to customers in a timely manner in a call centre settings) and Lines of Business efficiency (performance from remote field sites will impact end user efficiency on applications as a result of poor network connectivity).

Alternative 2: Refresh Per Plan (Recommended)

This alterative would purchase and refresh equipment purchases according to their life cycle requirements.

Today's business applications demand the higher performance offered by current server and network technologies. The integration of systems, their applications, and sharing and dissemination of underlying data also drive higher complexities in order to fulfill expected business objectives and outcomes. In conjunction with this, from a raw hardware perspective, performance requirements also increase as more and more virtual servers are stacked onto fewer and fewer physical assets. Physical network bandwidth requirements increase proportionately in all these respects. Additionally, today's networking devices offer more mature degrees of network virtualization, and enable network segmentation and micro-segmentation which fulfills security requirements by further securing the data-centre environments.

Refreshing per plan allows HONI to deploy current generation technology in order to meet and exceed the demands put upon the underlying network technologies. For example, Move 2 Mobile project will rely on increased bandwidth from remote sites to ensure work being done is updated in SAP as quickly/timely as possible so the Company can reassign crews to other jobs if they are finished early. As Hydro One introduces new applications into its eco system, the aggregate need for more bandwidth increases. Current network technologies also allow for new functionality to be explored to further optimize network traffic making packet transmission more efficient and helping the prioritization of network traffic.

Investment Description:

The investment in Networks for voice and data is undertaken to replace end-of-life assets and to maintain service supportability, network reliability and network security. The strategy is to replace equipment that is no longer vendor supported. For network equipment, the refresh occurs about every five years for voice and data network related hardware. The funding for voice and data networks varies year to year depending upon hardware lifecycle refreshes, and incrementally as increasing business demands necessitate increased network bandwidth. As more business work flows are introduced and automated, there is generally always an impact to the underlying network. In other cases, additional workloads are pushed to remote field offices, which sometimes require a more efficient network infrastructure. In general terms, as business functionality increases and demand grows at a given Hydro One location (for example, Business Admin Support center (BASC) or an Operations (OPS) centre), network bandwidth is taken into consideration and if warranted, is incrementally increased to support the business. Costs in 2018 to 2022 reflect normalized refresh program covering Voice Networks, Telecom Networks, Data Centers and Perimeter Security.

Risk Mitigation:

All MFA assets are purchased in a just in time approach and in serviced in the same year of purchase. Any risk of assets not being installed will be managed as part of project scope with timelines being reflected in current or following year.

Result:

The Telecom Infrastructure refresh will provide a secure and reliable network to support core business applications, address Hydro One's communication needs and maintain hardware supported levels required by our contractual commitments with vendors and outsourcing partners.

Outcome Summary:

Customer Focus	• Ensures reliable voice and data network to address Hydro One customer's communication needs to service customers.
Operational Effectiveness	• Maintain efficiency of the reliability of voice and data infrastructure to allow all IT applications to function as designed.
Public Policy Responsiveness	
Financial Performance	• Minimize overall cost to maintain its IT environment proactively and minimize the potential for costly outages and unplanned upgrades.

Costs:

Historical costs provide a trend and basis for budget estimation, in addition to vendor discussions for future demand management driven by development projects/programs.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

GP-07 Corporate Performance Reporting

Start Date:	Q3 2018	**Priority:**	Low
In-Service Date:	Q4 2019	**Plan Period Cost ($M):**	3.5
Primary Trigger:	Reliability Enhancement		
Secondary Trigger:	Efficiency Improvements		

Investment Need:

The Corporate Performance Reporting ("CPR") application is required to produce key high-profile, corporate reporting deliverables (e.g. OEB mandated reliability reports, reports to government, customer reports, and industry benchmarking reports) including SAIDI and SAIFI.

The Business has been using a custom, third-party software tool built approximately 7 years ago. It is still being supported by an external vendor. This tool is not supported by Corporate IT processes and Service Agreements.

There are limited knowledgeable resources available. As a result, it continues to incur costs and present unacceptable business reliability and continuity risks, unavailability of IT sustainment processes/agreements, and potential lack of vendor resource stability. There is limited availability of design and functional documentation on the algorithms, data sources and process chains. For a successful migration, any upgrade project must document these algorithms. This makes modifications for new requirements and standards difficult and risky to implement.

With the information contained on a stand-alone, proprietary system, resources in the Performance Management department are typically needed to fulfill other Hydro One Lines of Business ("LOB") with ongoing data requests. These requests can be labour-intensive.

Alternative 1: Maintaining the Status Quo

Maintaining the status quo leads to continued high risk and dependency on a custom, third-party application. In a qualitative sense, tight dependency on the limited vendor resources and limited support for a non-commissioned environment are high Business Reliability and Continuity risks given the importance of the data. Status quo will also keep Performance Management resources engaged in supporting other LOB's versus responding to new OEB requests and focus on core tasks and new LDC reporting requirements.

For quantitative analysis of lost benefits, refer to breakdown of savings indicated below.

Alternative 2: Migrate Existing Servers into Commissioned Environment

The option to migrate the application and data servers used for the current Performance Management tools into the sustainment (commissioned) environment was reviewed. This would place the support for the functioning of the servers and their interconnectivity with Inergi under the Enterprise umbrella for day-to-day operational support. This alternative was rejected because it would not materially reduce risks.

In a qualitative sense, the primary drivers of Business Reliability and Continuity risk are the diminishing availability of qualified resource pool for the existing tool combined with the lack of documentation about the applications. Neither of these would be reduced by this alternative.

For quantitative analysis of lost benefits, refer to breakdown of savings indicated below.

Alternative 3 *(Recommended)*: Integration of CPR with SAP system

The plan is to transition the application and data to an enterprise supported platform (SAP). A Discovery phase was conducted to document the Business requirements and functional recommendations and to estimate costs and timelines for the delivery of this project.

The Quantitative and qualitative analyses of risk mitigation and benefits for the proposed project are summarized as follows:

1. <u>Business Continuity Risk:</u> The number of vendor expert staff who currently supports this program has shrunk down to two individuals. One of the benefits of integrating CPR into the SAP ERP tool is that internally trained FTE will support this program, further improving business continuity and lowering cost.
2. <u>Commissioned System:</u> CPR is a stand-alone application that is not integrated as a Hydro One enterprise application. Integrating CPR into SAP further improves its business continuity benefit.
3. <u>System Documentation:</u> Currently there is a lack of visibility of stored procedures (algorithms and logics) in the CPR program. Through this project, all such embedded algorithms and stored procedures will be documented and be more visible.

4. <u>Optimization of Resources:</u> Integration with enterprise SAP self-service tools results in avoidance of the current third-party vendor support (operational, maintenance and enhancement) costs.
5. <u>Migration to an Enterprise Platform:</u> will allow for a redistribution of Performance Management resources by allowing LOB's to access data directly from SAP. Performance Management Staff to join the "Planning" organization and engage in asset management and reliability related analyses particularly those focusing on new/evolving OEB and LDC reporting requirements.

Savings from the above are expected to be achieved beginning in 2020. These savings include a potential reduction in staff necessary to support the current program, avoided vendor enhancement work, and elimination of vendor annual support fees, which are currently $500k per year, (50% of which is attributable to Hydro One Distribution).

Investment Description:

This project is to build the new reliability reporting tools used by Regulatory / Performance Management teams. The project will involve the migration of the application and data servers and install new code into a sustainable SAP-BI solution to be used for the Performance Management functionality and rules. The project will also involve the migration of historic data, and leverage available SAP and enterprise tools including self service capabilities, reporting and other tools. In contrast to the current Oracle platform, SAP is a commissioned and fully supported environment.

The recommended execution plan will take approximately 18 months to complete both the distribution and transmission reliability components by the fourth quarter of 2019.

Risk Mitigation:

<u>Business Requirements</u>

There is no expectation of major gaps given the extent of the requirements and discovery workshops, however, it is possible and likely that new reporting requirements evolve and some details will require refining as the design and build steps move ahead. All issues will be addressed using standard SAP code. The plan will include provision for these and will address both time and cost implications.

Data Quality:

Early engagement and contact with the teams contributing to identifying data entities, data gathering, data conversion and data migration has to take place to monitor their progress and alignment to the CPR Delivery plan.

Solution Complexity:

The new tools will incorporate numerous, and in some cases complex calculations to derive the performance metrics. A concern is that the build may result in components of such complexity as to make testing and error detection difficult. The project team has to engage with the Vendor to build the new tools such that testing of each and isolation of the source of issues is readily possible. The plan will include provision for this and will address both time and cost implications.

Change Management

One of the goals for this project is to provide greater access outside of the Performance Management Team to reliability related data and scores via the enterprise self-service tools. Change Management is a key player to deliver the vision, training and job aids to the LOB's wishing to access this data.

Result:

Through the delivery of the Corporate Performance Reporting project, the following performance improvements would be achieved:

1. Stability and Optimization of Resource: The number of vendor expert full time employees who support this program has decreased from four to two individuals. One of the benefits of integrating CPR into SAP tool is that internally trained employees will support this program, further improving business continuity of this program. This will also optimize resource deployment in the Performance Management department.
2. Commissioned / Supported System: The current CPR tool is a stand-alone program that is not integrated as a Hydro One enterprise application and is not supported by Corporate IT processes and Service Agreements. Integrating CPR into SAP further improves its business continuity benefit.

3. Increased Visibility: The knowledge of stored procedures (algorithms and logics) in the CPR program resides with the third party. Through this proposed project, all such embedded algorithms and stored procedures will be documented and become visible.

Outcome Summary:

Customer Focus	• Improve customer reliability by providing data directly to Lines of Business to improve their ability to determine the programs and investments that improve reliability.
Operational Effectiveness	• Reduce continuity risk to the production of corporate performance metrics. • Improved efficiency and resource deployment by focusing on evolving reporting requirements.
Public Policy Responsiveness	• The outputs from the CPR system are frequently used for regulatory agency reporting (OEB & NERC & IESO & NEB), government agency reporting (Min of Energy), customer queries, and industry associations (CEA & NATF).
Financial Performance	

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes direct LOB resource cost, Vendor cost as well as indirect costs of implementing the following application components and processes: Data Collection, Data Cleansing, Calculations, Reporting and Visualization.

The estimated cost was derived from the CPR Discovery work, in which Inergi was engaged to provide an estimate for the delivery work. At this time the estimate itself is high quality, however, it will be validated prior to submission of the business case to account for the time lapse between Discovery and Delivery phases (~ 4 years). Given the 10+ weeks of workshops to review the requirements; the gap is expected to be small and manageable.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Plan Period Total**	**Total Project Costs******

GP-08 PCMIS Modernization and Optimization

Start Date:	Q3 2019	**Priority:**	Low
In-Service Date:	Q4 2019	**Plan Period Cost ($M):**	1.6
Primary Trigger:	Cyber Security		
Secondary Trigger:	Reliability		

Investment Need:

The Protection and Control Management Information System ("PCMIS") tool is a critical platform used to support the Company's power system operations and ensure compliance with reliability and cyber security regulations. PCMIS is the single system of record for all Protection and Control ("P&C") device settings. PCMIS is utilized by Hydro One engineering, operations, and field personnel, as well as technical personnel in Local Distribution Companies across Ontario. The tool contains 'Bulk Electric System Cyber System Information' ("BESCSI"), sensitive data that must be strictly controlled and protected in accordance with Critical Infrastructure Protection regulations, as mandated by the North American Electric Reliability Corporation.

The primary function of PCMIS is to maintain device settings for the Intelligent Electronic Devices ("IED") that protect and control the grid. Over the years, PCMIS has been modified to meet various business and regulatory requirements, and has become a highly customized tool. The application and associated infrastructure are approaching end-of-life (EOL) and need to be upgraded.

PCMIS is a key Hydro One enterprise system that the company depends on to operate the Ontario electrical grid. In 2013, Accenture assessed the PCMIS platform and prepared a detailed report. The report highlighted numerous gaps in existing processes and significant deficiencies in the technology. System scalability, sustainability, and data integrity were all rated 'Poor'.

Alternative 1: Maintain the "Status Quo"

This option would have us leave the legacy system as is. However, maintaining the status quo and running an important application on unsupported infrastructure, exposes the company to the following risks:

- Inability to operate, repair, and replace critical P&C equipment;

- Failure to comply with cyber security regulatory requirements; and
- Failure to comply with reliability regulatory requirements.

Alternative 2: System Redesign and Replacement. (Recommended)

The planned changes will provide an opportunity to replace servers, operating systems, and databases with current technology to ensure operational and support longevity of the platform.

A modern PCMIS platform will be built on new infrastructure with secure, robust technology offering high availability (HA) and disaster recovery (DR). The PCMIS application will be replaced with fully supported commercial software. Functionality and integration interfaces will be optimized, consolidated with other Hydro One enterprise platforms or eliminated.

This is the preferred alternative, as this option will provide a modern robust system that will meet regulatory requirements. The company would like to address the project at the first possible opportunity, which based on available funding is expected to be in 2019.

Investment Description:

The project will maintain and further strengthen PCMIS as the single source of record for all P&C device settings. PCMIS supports users across the enterprise as well as engineering and field personnel in external utilities, providing centralized, controlled access to cyber-sensitive data. The system ensures that the configuration of critical grid protection systems is accurate and manages approval of any settings changes, supporting numerous key business processes including planning, construction, maintenance, repair, network operating and outage management. PCMIS data is used by the Distribution Management System (“DMS”) to support advanced power system application analytics.

The PCMIS platform is aging and upgrades are required to the underlying infrastructure. This investment focuses on delivering a modern technological stable solution to address gaps in existing process and deficiencies in technology as highlighted in a recent third-party assessment. Processes will be optimized. Proven, secure technology will be implemented, resulting in a system that will provide years of efficient and reliable service.

The scope of this investment is to:

Replace existing PCMIS software and infrastructure;

Develop detailed system requirements and performance criteria. Design new infrastructure with proper development, quality assurance (QA), and DR environments. Build, setup, secure, configure, and test new infrastructure and integrate with secure, encrypted communication links. Assess available commercial software and select optimal solution. Purchase, install, configure, and test new PCMIS software.

Introduce process improvements and efficiencies;

Conduct comprehensive assessment of current processes. Working with the business groups we will optimize processes and leverage opportunities for consolidation with other Hydro One enterprise systems. Rationalize and eliminate customizations where possible.

Migrate data and launch new system.

Develop, test, and execute detailed data migration plan; provide orientation and training following proven change management principles; establish effective sustainment contracts.

Risk Mitigation:

To mitigate risk associated to the implementation of a new system and the time required to provide access and train all the LDC's, the 2 new and old systems will be run in parallel for a short period of time.

To mitigate risk associated with change resistance, the project will employ a full organizational change strategy. This will include the stakeholder management at the earliest stages, performing a change impact assessment and following resistance management plans will help secure buy-in from the user community.

Result:

The anticipated outcomes of this investment include:

- a fully supported platform,
- improved system redundancy and high availability, and
- optimized operational processes.

Witness: Lincoln Frost-Hunt

Outcome Summary:

Customer Focus	• Provide secure and reliable access to the protection and control information that will allow efficient system access support and maintenance.
Operational Effectiveness	• Ensure improved system availability. • Reduce system downtime and facilitate maintenance and upgrade work. • Improve access to critical configuration information allowing Hydro One and LDC's to be more responsive to operational issues.

Costs:

Cost estimates are based on historical costs of similar projects of this type.

($ Millions)	2018	2019	2020	2021	2022	Total
Capital* and Minor Fixed Assets		1.6				1.6
Less Removals						
Gross Investment Cost		1.6				1.6
Less Capital Contributions						
Net Investment Cost		1.6				1.6

**Includes Overhead at current rates.*

GP-09 ECM Phase C

Start Date:	Q2 2017	Priority:	Low
In-Service Date:	Q4 2022	Plan Period Cost ($M):	2.1
Primary Trigger:	Public Policy Responsiveness		
Secondary Trigger:	Privacy		

Investment Need:

Enterprise Content Management ("ECM") is the technology used to capture, manage, store, preserve, and deliver content and documents related to organizational processes. ECM tools and strategies allow the management of an organization's unstructured information, wherever that information exists. Documents are centralized, searchable and retained or disposed as per requirements of regulatory bodies.

Hydro One is obligated to meet the requirements of many different regulatory bodies and programs with respect to document management. These include the North American Electric Reliability Corporation ("NERC") / Critical Infrastructure Program ("CIP"), the Ontario Energy Board, the Ontario Securities Commission ("OSC") and many others. Failure to meet these requirements will result in undue legal and regulatory risk for Hydro One.

Hydro One has commenced an Enterprise Content Management ("ECM") initiative comprised of three Phases.

- Phase A represents the classification of a majority of non-complex unstructured data. This was completed March 2015.
- Phase B (started November 25th, 2016 and is currently in progress) will develop several Proofs-Of-Concept (POC) offering options and alternatives for the implementation of records schedules (POC-1), email management (POC-2), management of physical documents (POC-3) and Records Management reporting (POC-4). Upon completion of Phase B, the proofs-of-concept will be configured for immediate implementation.
- Phase C will implement the POC across the company including records schedules, email management, management of physical documents and Records Management reporting (The purpose of this request is to seek funding to implement Phase C).

Alternative 1: Status Quo - Do Not implement Records Schedules POC

This alternative would not proceed with implementation of the Phase C Proofs of Concept and effectively defer the project indefinitely.

Maintaining the status quo is "high" risk because there are currently no records schedules (retention dates, disposition dates) activated on any Hydro One company record (emails and physical documents).

If the status quo were to be maintained, Records Schedules (retention dates, disposition/destruction dates) would not be affixed to physical documents or emails (company records). Without a "trigger" to demonstrate the requirement to retain company records or dispose of company records, Hydro One may be unwittingly storing company records that should be destroyed or inadvertently destroying company records that should be retained.

Alternative 2: Implementation of POC – 1 only

This alternative proposes the implementation of POC-1 only (records schedules POC only).

This strategy would not reduce the risk to Hydro One as the value of records schedules is in its application to company records. Records schedules need to be applied to company records as this POC cannot reduce company risk as a stand-alone product. The value of this POC is derived from its application to company records. As such, this alternative was eliminated.

Alternative 3: Full Implementation of Phase C (Recommended)

The recommended alternative is to proceed with the 3rd Phase of the ECM project - full implementation of all POCs including the implementation of records schedules, POC-1 (data retention dates, disposition activation, etc.) email management (POC-2) and physical document management (POC-3) and records management reporting and administration (POC-4) after the completion of Phase B. reporting and administration.

Investment Description:

ECM Phase C will result in the activation of records schedules including the retention, and destruction dates applied to the physical and email documents. In addition, dashboards demonstrating the growth in SharePoint usage and Open Text publishing (archiving) would allow Hydro One to monitor user adoption.

Risk Mitigation:

As ECM Phase C is the implementation of proofs-of-concepts developed in Phase B, there is a "risk" associated with the scalability of each proof-of-concept. Full implementation is the preferred alternative. However, there is risk associated with the cost to implement several solutions enterprise-wide. To mitigate this risk, the "actual" cost of implementation of POC-1 (data retention dates, disposition activation, etc.) will be reviewed and a "go-no-go" decision will be taken to determine if any or all addition POCs should be implemented.

Result:

Records Management ensures that institutional records of vital historical, fiscal, and legal value are identified and preserved and that regulatory mandated records are discarded in a timely manner according to established guidelines and identified legislation.

Benefits of Records Management include:

- More effective management, access and discovery of current records (both paper and electronic) and related enterprise content;
- Increased institutional accountability and timely access to information; and
- Greater adherence to regulatory requirements.

Outcome Summary:

Customer Focus	• Ensures the privacy, integrity of records and the security of record keeping processes.
Operational Effectiveness	
Public Policy Responsiveness	• Compliance with policy guidelines set by NERC/CIP and OEB.
Financial Performance

2

GP-10 Work Management & Mobility

Start Date:	Q1 2017	**Priority:**	High
In-Service Date:	Q4 2022	**Plan Period Cost ($M):**	10.5
Primary Trigger:	Efficiency		
Secondary Trigger:	Customer Value		

Investment Need:

The existing processes and applications used to manage work within the Provincial Lines, Stations, Forestry and some central organizations involve significant manual effort and paper processing. This creates inefficiencies, time delays and data inaccuracies.

All work and information needs to be scheduled, dispatched, executed and reported through a standard set of processes and technologies across all of these lines of business within Hydro One. For example, the existing applications used by the Provincial Lines organization to schedule, dispatch and report work lacks the functionality and integration to support the productivity gains that are possible.

The "Move to Mobile" project to implement work management and mobility improvements for the provincial lines organization is presently underway. This was described in the investment summary document IT-05 ("Field Workforce Optimization and Mobile IT"), which was provided in Exhibit D2-2-3 filed in support of Hydro One Distribution's revenue requirement application (EB-2013-0416).

Alternative 1: Status Quo

This alternative was considered and rejected as a result of the following:

- significant, achievable productivity gains would not be realized;
- would continue to rely on manual and untimely paper processes for recording work accomplishments;
- data entry would remain labour intensive, and errors and poor data quality would continue to be prevalent resulting in multiple visits to the same customer site;
- dispatchers would not be able to leverage geospatial capability related to the location of assets, crews and work in order to achieve more work in any given day; and
- the existing mobile platform would remain inconsistent with SAP's future direction.

Alternative 2: Introduce Mobility across All Lines of Business in a Single Initiative

The development and implementation of a company-wide solution incorporating all LOBs and workflows was considered. The complexity of analyzing each component of the planning, scheduling, dispatching, work execution, closeout and reporting processes for key business scenarios for all LOBs within a single initiative would require a multi-year effort and a significant level of risk. It would also introduce a very large company-wide Change Management component related to business processes and applications impacting thousands of employees. This alternative was rejected due to its size, complexity, risk and timing.

Alternative 3: Move to Mobile Implementation Projects at Individual Lines of Business (Recommended)

This alternative involves the implementation of mobile technologies and related business process changes within the Forestry, Stations and Corporate LOBs in a number of discrete, focused projects over the next few years. Each of these projects contains elements of process change, coupled with enabling technology which will result in productivity improvements being realized as the process changes are phased in across each line of business.

Building on the experience gained in the Provincial Lines Move to Mobile Project and from other utilities, particular attention will be paid to the change management strategy. The expected benefits are highly dependent on the field workers wanting to use, and continue to use the new processes and technology over time.

This alternative will result in both quantitative benefits similar to those expected from the Provincial Lines project, and qualitative benefits within Customer Care.

Investment Description:

Through a competitive procurement process in 2014, the decision to standardize using SAP's mobile capabilities was made and a systems integrator was retained to help configure and deploy the solution across the Provincial Lines organization. The systems integrator is currently designing the improved business processes to be consistent with the industry best practices they have experienced working with other clients. A commitment to achieve at least a five percent productivity gain was established, with a projected return on investment of 21.3% and projected ongoing annual savings of $12 million. This project is currently under way with an in-service date in the first quarter of 2017.

Subsequent projects for Stations, Forestry and Corporate LOBs are expected to mobilize during 2017 and 2018, using the standard business and technical solutions established during the Provincial Lines project.

This investment will streamline Hydro One work management processes and deliver an enhanced, integrated scheduling, dispatching and mobile solution for the three lines of business, achieving significant productivity benefits in each.

The projects for Provincial Lines, Stations, Forestry and the Corporate LOBs involve implementing the following:

- SAP's mobile technology for use by Hydro One's field workforce;
- new/upgraded planning & scheduling software, integrated with SAP and the SAP mobile capability;
- SAP mobile platform integration with Hydro One's geographical information system (GIS); and
- Standardized processes for work planning, scheduling, dispatch, execution and reporting, as well as for company-wide processes such as purchase requisition and invoice approvals, timesheet preparation and submission, expense management, and workplace safety inspection form preparation and submission. This includes the monitoring and reporting of the expected benefits, and if these benefits are not being fully realized, initiating remedial action to help ensure the expected benefits are realized.

Risk Mitigation:

The major risks for these projects are similar to the ones faced by the current Provincial Lines "Move to Mobile" project. For example, field workforce acceptance of the new processes and technical solution; system performance of the technical solution; the post go-live approach to supporting the changes all have risks that must be managed. Experience gained during the Provincial Lines project is a major risk mitigation element for the follow-on projects. Any combination of these risks could result in a project in-servicing delay however the same approach used in the "Move to Mobile" project will be applied in these projects. They will be led and owned by the line of business, solid project governance, similar to that being practiced in the current Provincial Lines project will be applied to these follow-on projects. The projects will also take into account the relevant lessons-learned from Provincial Lines.

Following Project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted at appropriate project milestones. The projects will be led by a field operations VP who is familiar with the culture and challenges associated with a process improvement implementation of this scale with the field work force.

Result:

These projects will provide the schedulers and field staff with real-time or near real-time work status update capability, present staff with a consolidated view of work information, provide a geographic scheduling tool on mobile devices, and enable timely, quality data capture at source.

These projects will also provide a near paperless and automated work environment which will help save paper and fuel, reduce vehicle emissions as well as save corporate operation expenses. Reducing manual steps and providing data validation at time of entry, will result in higher data quality and increased staff productivity.

In addition to a minimum five percent productivity gain for the Forestry, Stations and Corporate LOBs, there are also qualitative benefits in the areas of employee safety, customer service and employee engagement.

Outcome Summary:

Customer Focus	• Improved information reliability for customers with validation of data at source of input. • Improved service levels for customer-related processes like new-connects.
Operational Effectiveness	• Improve work processes by eliminating / automating as much of the manual & paper handling work activities as possible. • Increase efficiency by employing better scheduling and more efficient status of work accomplishment. Forestry, Stations and Corporate LOB should expect to see productivity gains of at least 5%.
Public Policy Responsiveness	
Financial Performance	• Reduce one-time costs including the mobility, planning & scheduling software.

Costs:

The following costs are based on previous experience with the first Work Management and Mobility project for the Provincial Lines organization which started in 2015 and which is planning go-live during Q1 2017.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets	4.0	4.6	0.0	1.4	0.6	10.5
Less Removals						
Gross Investment Cost	4.0	4.6	0.0	1.4	0.6	10.5
Less Capital Contributions						
Net Investment Cost	**4.0**	**4.6**	**0.0**	**1.4**	**0.6**	**10.5**

**Includes overhead at current rates.*

GP-11 Enterprise Geographical Information System

Start Date:	Q1 2017	**Priority:**	High
In-Service Date:	Q4 2022	**Plan Period Cost ($M):**	6.5
Primary Trigger:	Efficiency		
Secondary Trigger:	Customer Value		

Investment Need:

Geospatial technology is a key information technology (I/T) infrastructure component that improves the effectiveness and efficiency of a variety of business processes including design, transmission and distribution planning, outage management, work management, real estate and others. While the technology is common to both distribution and transmission functionality, the investments and costs described in this document are specific to the distribution rate filing only.

Hydro One's current GIS software has been in place for roughly 15 years. Existing investments in the Enterprise GIS Program have enabled the integration of SAP and GIS achieving a synchronized, composite asset registry, including distribution and transmission assets, comprised of SAP and Hydro One's other major asset management systems. GIS infrastructure and software need to be updated periodically to take advantage of new functions and software performance improvements, and when possible to further enhance the technology to enable additional productivity in Hydro One's lines of business. All of the major vendor software components are reaching end-of-life during the planning period, and need to be replaced or upgraded. These products are no longer vendor supported after the end of 2017. Hydro One also proposes to address gaps and redundancies in business processes to author, maintain and utilize data from the geospatial databases.

Enhanced GIS functionality is needed to better support various business operations such as load forecasting, outage management, and protection and control, all of which help drive a more reliable network. The implementation of the unregistered easement public interface, for example, will reduce customer service staff effort to respond to numerous requests for assistance and complaints.

Increase in customer satisfaction and revenue are possible as more members of the public use the new easements search system. The integration of new customer-facing web maps would reduce calls to customer care to check rate class or associated concerns.

To summarize, the planned GIS work in the 2018 to 2022 period is comprised primarily of software replacement and / or technical upgrades, as well as moving the existing vendor (ESRI) software from the 10.1 to 10.4 version. One of the software components used for field design work (ArcFM) has reached end of life after 10 years in service and will be upgraded or replaced with a better / more cost-effective vendor solution.

Alternative 1: Status Quo

This alternative was considered and rejected because if this investment is not undertaken, the currency and quality of geospatial information will suffer and impact many key business functions.

For example, one impact of this is safety related. Up-to-date geospatial information resources assist safety practices as crews have easier access to accurate and timely views of the network model. Accurate GIS records complement HONI's Work Protection Code practices.

Alternative 2: Prudent Replacement of End of Life GIS Assets (Recommended)

Upgrade or replace the GIS system components and the integration between GIS and satellite systems it supports. Invest in new technologies that improve data governance and data quality, and leverage the GIS data to provide better and more useful information to the lines of business.

This investment is intended to both sustain the software at vendor release levels that the vendor is prepared to support, and to enhance the existing functionality through a series of projects from 2017 to 2022. Each project will be justified based on return-on-investment and related corporate objectives. Some of the planned enhancements are required to support the Work Management & Mobility investments for Provincial Lines and Forestry projects.

The proposal plans on the following:

- Software version upgrades to the vendor software that will no longer be supported after the end of 2017;
- Upgrade or replace the existing field design software (ArcFM) with a more modern package that provides better functionality and system performance at a cost per tablet lower than it is today;

- Conduct a discovery period to assess the value of implementing new SAP software that more seamlessly integrates Hydro One's map layers with the corresponding asset data in SAP; and
- Rationalize, where possible, the existing custom systems.

Investment Description:

The project will maintain and further strengthen Enterprise GIS as a single system of record comprising the location and connectivity of both transmission and distribution assets. GIS is the only technology that fully supports both logical connectivity and physical location of assets. It also supports asset properties and condition which facilitate planning and outage management, supports mobile workforce management through more effective crew routing, manages real estate records and Hydro One property, and provides the underpinnings of smart grid applications.

Over the years, as various asset-related systems have evolved at Hydro One, use of the GIS as system of record for location, connectivity and phasing has not always been respected. In some cases, complex bi-directional integrations have been built due to improper data governance practices and workflows. This investment focuses on remediating the inconsistent storage of location and connectivity between systems such as the Power System Database ("PSDB") and GIS as well as issues between the Customer Information System ("CIS") and GIS for storage of service point location. Both of these issues have led to increased cost to maintain overly-complicated integrations as well as the deterioration of data quality. Finally, some additional minor data governance issues with Health, Safety and Environment GIS data will be remediated.

Risk Mitigation:

For the version upgrade projects, lessons learned from a similar GIS software upgrade project that was carried out during 2012 and 2013 will be leveraged. This project was completed on budget and close to schedule, using some of the key Hydro One and Inergi resources who will be assigned to these projects. For the replacement of the field design software (ArcFM), an RFP will be issued to select the best value for replacement. Formal project delivery methodology will be applied to ensure adequate governance. The only known risk that could be considered significant is maintaining the data synchronization between the Corporate GIS data base and the SAP Asset inventory. The Information Technology Architects will be looking towards technology enhancements with SAP to centralize both the asset and GIS data in one location to minimize costs of maintaining data synchronization across multiple databases.

Result:

The core vendor software products will be upgraded during the period of this investment and, as is typical, will provide stability and the required level of vendor support for the next four to five years.

Outcome Summary:

Customer Focus	• Improved service to customers and Ontario property owners who should have access to information about outages and unregistered easements.
Operational Effectiveness	• Improved Decision Quality - Provide immediate access to more comprehensive and integrated spatial asset and connectivity data in corporate systems, contributing to consistency and timeliness in asset planning, maintenance and outage decisions. • Improved productivity and reduced cost in both sustainment costs and labour.
Public Policy Responsiveness	
Financial Performance	

Costs:

The following costs are based on previous experience with the set of GIS software technical upgrades which occurred in 2012 and 2013.

($ Millions)	2018	2019	2020	2021	2022	Plan Period Total	Total Project Costs**
Capital* and Minor Fixed Assets	2.0	1.9	0.9	0.9	0.9	6.5	7.6
Less Removals	-	-	-	-	-	0.0	0.0
Gross Investment Cost	**2.0**	**1.9**	**0.9**	**0.9**	**0.9**	**6.5**	**7.6**
Less Capital Contributions	-	-	-	-	-	0.0	0.0
Net Investment Cost	**2.0**	**1.9**	**0.9**	**0.9**	**0.9**	**6.5**	**7.6**

**Includes overhead at current rates.*

GP-12 Business Process Consolidation

Start Date:	Q2 2020	**Priority:**	Medium
In-Service Date:	Q4 2021	**Plan Period Cost ($M):**	2.7
Primary Trigger:	Operational Effectiveness		
Secondary Trigger:	Financial Performance		

Investment Need:

The SAP Business Planning Consolidation (BPC) system is required to provide planning, budgeting, forecasting, and financial consolidation and reporting capabilities. The Investment planning maps projects & programs to specific strategic objectives. The budgeting process allocates funds to these investments. The forecasting process allows the company to track how the projects and programs are progressing.

The Business is currently using the BPC system which is a component of SAP Enterprise Performance Management portfolio and is designed to handle financial processes on a unified platform. The functional capabilities of the existing system are limited to project forecasting and legal and management consolidations.

Although Hydro One uses this application with available features, the system is not being used to its full potential due to numerous limitations. Specifically, enabled features do not support a fully integrated planning, budgeting and forecasting framework to enable continuous allocation of resources to support the business strategy and operational efficiency.

Alternative 1: Status Quo

With the status quo option, Hydro One would continue its limited use of the BPC application. This is alternative does not allow for Hydro One to take advantage of process and operational efficiencies available through the application.

Alternative 2: Expand Use of BPC by Enabling Other Features and Functionality (Recommended)

This option would go ahead with implementation of the additional features available in the BPC application. Hydro One can continue to use the BPC system for project forecasting and legal consolidation and make use of additional functional capabilities that the system can enable, which are currently not being used.

This recommended option will allow Hydro One to fully realize the benefits of the BPC system by leveraging its potential of delivering planning, budgeting, forecasting, and financial consolidation capabilities in a single application. Hydro One will be able to adjust plans and forecasts, speed up budget and closing cycles, and ensure compliance with financial reporting standards. This in turn will bring about needed process and operational efficiencies.

Investment Description:

This project will provide enhancements to the current BPC system to become a unified & single planning & consolidation tool. It will add software and analytics features to realize additional business capabilities and benefits. These sought after capabilities include:

- What-if modeling and scenario planning to assess budget suitability in real time;
- Forecast models and to quickly update and adjust forecasts as needed;
- Automated aggregations, allocations, and other manual processes to speed up planning cycles; and
- What-if scenarios to allow the business user to identify quick course corrections.

Risk Mitigation:

The following are the risks that the project plans to address and manage:

Solution Complexity

SAP BPC is a complex application and finding the right skill set to support a successful implementation can be a challenge. To mitigate this risk, Hydro One will partner with vendors that have the experience & expertise to complete the work successfully.

Resources and Competing Priorities

Hydro One has many demands on its IT infrastructure, SAP and Finance resources – All of which are integral to success of this project. To mitigate this risk, the Project Team will highlight when they expect to require these resources and services during formal Program Planning activities. This will align with priority of projects set by Hydro One's Executive Team as an outcome of the Investment Plan review and approval process.

Change Management and User Adoption

The goal of this project is to implement additional features and capabilities to improve existing processes and transactions. Change Management is a key player to deliver the vision, training and job aids to the target user community wishing to access the new features. This would need to be assessed as to applicability, timing and cost impact.

Any combination of these risks could cause the project to be delayed and this will cause any of the following: Projects will be over-budget, behind schedule or will not deliver the scope it was intended to deliver. Solid project governance will be applied, taking into account the relevant 'lessons-learned' from other similar project in order to complete the project on-time and on-budget.

Following the project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted at appropriate project milestones.

Result:

This investment will yield operational efficiencies and improved decision-making capabilities based on what-if analyses and scenario planning. It will improve accountability and planning accuracy. It will shorten cycle time, allows for financial information to be reported faster and align the company's plans with its strategic goals.

Outcome Summary:

Customer Focus	• Improve customer experience by providing timely budget and forecast data to the Business which will in turn improve the ability to manage programs and projects that affect customer-related investments.
Operational Effectiveness	• Improve decision-making capabilities and increase efficiency based on the ability to perform what-if analyses and scenario planning. • Improve accountability and planning accuracy due to shortened cycle time allowing for books to be closed faster.
Public Policy Responsiveness	• The outputs from the BPC system contribute to financial input used for regulatory agency reporting (e.g. OEB), government agency reporting (Ministry of Finance) and customer queries.
Financial Performance	• Improve financial performance and lower cost by reducing manual intervention.

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management (such as training and job aids to the target user community wishing to access the new features), Project Management and Post Deployment. It includes vendor costs as well as direct LOB resource costs, and indirect costs of implementing the solution.

The cost estimate is based on a historical cost of enabling new functionality within the Consolidation Module of BPC. Until the detailed business requirements and discovery phases are completed and vendor quotes received, a more accurate project cost estimate will not be available. If the final project costs are found to be materially different, the project will be re-evaluated given the parameters of the Hydro One review process.

Controllable costs will be minimized by reviewing the detailed cost estimate, when it becomes available, and reviewing and challenging the costs to ensure they are in line.

Hydro One will launch an open bidding competition so multiple vendors can submit their proposal and Hydro One can select based on the vendor that best meets Hydro One's evaluation criteria and budget.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets			1.5	1.2		2.7
Less Removals						
Gross Investment Cost			1.5	1.2		2.7
Less Capital Contributions						
Net Investment Cost			**1.5**	**1.2**		**2.7**

Includes Overhead at Current Rates

GP-13 HR & Pay Related Technology Investments

Start Date:	Q2 2018	**Priority:**	Medium
In-Service Date:	Multiple	**Plan Period Cost ($M):**	5.0
Primary Trigger:	Operational Effectiveness		
Secondary Trigger:	Financial Performance		

Investment Need:

The Human Resources ("HR") Division is responsible for a range of functions in support various processes and activities such as employee time reporting, board and travel recruitment, payroll, Offer Letter Creation and Processing, master data management and search, information for employees and managers as well as reporting of employee-related issues.

The current HR and Payroll functions utilize native SAP ECC system features and transactions to fulfill above mentioned functions and processes. Currently, there's significant reliance on manual, fragmented and inefficient processes and tools.

The existing HR application framework poses numerous challenges and features many inefficiencies such as: Inadequate Knowledge Database for staff, inconsistencies and confusion around the multiple templates to be used, inadequate Knowledge Base Self Service for Managers and Employees, lack of a Case Management/Ticket-Tracking System, lack of an Automated Workflow for certain processes, reliance on a multitude of workarounds and customizations that are costly to sustain as well as insufficient HR metrics and analytics.

Alternative 1: Status Quo

With the status quo option, Hydro One would continue to use the existing HR applications with their existing features.

This is not to Hydro One's advantage as there will be continued reliance on manual, fragmented and inefficient processes and tools. Also, this alternative would miss out on efficiencies and improved productivity opportunities.

Alternative 2: Implement Various System Enhancements (Recommended)

Hydro One would seek to leverage technology improvements and improve operational efficiency in the HR and Pay areas.

Hydro One will realize benefits such as a ticket tracking system for HR issues, a knowledge database for HR staff, managers & employees, automated letter creation & processing, an automated workflow for HR forms, mobility for HR applications, additional HR reports & analytics, online access to electronic pay advice and T4s, pay optimization, board & travel route optimization.

In addition, the intended enhancements will facilitate achieving the cultural change necessary to meet key strategic objectives.

Investment Description:

This investment is required to improve efficiency / productivity in the HR & Pay Area. This will be accomplished through 2 main initiatives.

<u>HR Process Optimization (start in 2018 & complete by 2019)</u>

This investment will address the following needs:

- Lack of a Case Management/ Ticket Tracking System for HR issues. In addition to improving the response time, this system will provide better insight into the types of issues coming to the HR Support Centre, which in turn allows HR to proactively respond to issues;
- Inadequate Knowledge Database for HR staff. By implementing a knowledge base comprised of answers to questions and solutions to problems from previous HR activities, this would reduce the amount of time spent by HR Assistants searching for information and thus improve response times;
- Inadequate Knowledge Base Self Service for Managers and Employees. This would provide quicker access to accurate HR information for employees and managers and minimize the time spent searching for information. Information will be more accurate and consistent;
- Manual Offer Letter Creation and Processing. This eliminates the requirement for multiple template letters to be drafted and maintained. It also reduces the amount of time involved in maintaining content for letters;

- Lack of an Automated Workflow for all HR forms/Smart Forms. A series of Smart Forms would improve efficiency and reduce errors in completing primarily by eliminating additional data input;
- Lack of Mobile Access to HR SAP applications. Mobile applications would provide HR Consultants, Managers and employees with more convenient access to information;
- Lack of Remote Recruitment Tool. Such a tool would reduce travel time for HR Consultants, Managers and employees; and
- Limited HR Metrics and Analytics. An analytics function would allow for improved reporting and analysis on HR issues to better inform decision making with clients.

<u>HR Pay - Phase 2 (start in 2019 & complete by 2020)</u>
Hydro One's payroll and master data management is managed using its SAP ECC system. Payroll business processes need to be further aligned with industry best practices and enhanced to fully utilize the available system capability for those processes which are currently administered through manual data entry. This investment is required to improve efficiency / productivity in the Pay and Time Reporting related processes by addressing the following needs:

- On-line Access to Electronic Pay Advice and T4s This would provide all employees an opportunity to access their pay advice and T4s online;
- Mobile/Remote Access for Time Reporting. This project would develop a mobile application that utilizes the Hydro One's SAP environment. The application will allow employees to access Time Self Serve (TSS) to input time via their smart phone or tablet and increase efficiency;
- Pay Optimization. HR would streamline current pay processes to utilize standard SAP functionality by removing workarounds and customizations that are costly to sustain; and
- Board & Travel Route Automation. This would allow the automatic creation of routes based on Google Maps. Routes are used to calculate amounts owing to Trades personnel to reimburse them for travel from home locations (or city centres) to assembly points.

Risk Mitigation:

<u>Solution Complexity</u>

HR and Pay Related Technology Enhancements are expected to be complex and finding the right skill set to support a successful implementation could be a challenge. To mitigate this risk, Hydro One will partner with vendors that have the experience and expertise to complete the work successfully.

Resources and Competing Priorities

Hydro One has many demands on its IT infrastructure, SAP and HR resources; all of which are integral to success of this project. To mitigate this risk, the Project Team will highlight when they expect to require these resources and services during formal Program Planning activities. This will align with priority of projects set by Hydro One's Executive Team as an outcome of the Investment Plan review and approval process.

Change Management and User Adoption

The goal of this project is to upgrade current HR and Payroll applications. This could potentially pose both process and technology challenges to impacted staff. Change Management is a key player to deliver the vision, training and job aids to the target user community wishing to access the new features. This would need to be assessed as to applicability, timing and cost impact.

The above risks will be addressed in accordance with Corporate Projects' Project Governance framework. Following the project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted at appropriate project stage gates. In addition, the project will be led by someone from the LOB who has deep expertise within the HR Process area.

Result:

This investment will yield operational efficiencies including enabling self-serve analytics and improved decision-making capabilities.

Outcome Summary:

Customer Focus	
Operational Effectiveness	• Improve HR performance by providing better insight to the types of issues coming to the HR Support Centre and better capabilities to address those issues. • Reduce travel time for HR Consultants, Managers and employees. • Allow for improved reporting and analysis on HR issues to better inform decision making with clients and with HR initiatives. • Allow for streamlined pay process & removal of work-arounds and customizations that are otherwise costly to maintain.
Public Policy Responsiveness	
Financial Performance	• Due to integrations in the system & better access to information, this translates to improved decision making abilities which in turn can lead to better financial performance.

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes vendor costs as well as Hydro One direct and indirect costs of implementing the solution.

The cost estimate is based on historical business case estimates of a medium size, complex SAP changes. Until the detailed business requirements and discovery phases are completed and vendor quotes received, a more accurate project cost estimate will not be available.

Controllable costs will be minimized by reviewing the detailed cost estimate, when it becomes available, and reviewing and challenging the costs to ensure they are in line. Hydro One will also launch an open competition so multiple vendors can submit their proposal and Hydro One can select based on the vendor that best meets Hydro One's evaluation criteria.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets	0.5	2.9	1.6			5.0
Less Removals

Includes Overheads at Current Rates

Witness: Lincoln Frost-Hunt

GP-14 Warehouse Scanning Device Replacement

Start Date:	Q2 2018	**Priority:**	Medium
In-Service Date:	Q4 2019	**Plan Period Cost ($M):**	1.8
Primary Trigger:	Operational Effectiveness		
Secondary Trigger:	Financial Performance		

Investment Need:

In order to effectively perform material and inventory handling operations, Hydro One has been using Bar Code technology at its warehouses since 2011. A barcode is an optical, machine-readable, representation of data. Using a scanning device (typically hand-held), the bar code is scanned and this provides information about the material such as type, quantity, price. As the information is automatically acquired through the barcode, it minimizes errors and increases speed compared to key entry. This makes operations at the warehouse more efficient.

By 2019, the current system will be at its end of life. As a result, there will either be limited or no vendor support for the scanning device and system that Hydro One uses. In addition, there have been many advances in bar coding technology that would make warehouse operations more efficient but the current system cannot take advantage of these improvements.

Alternative 1: Status Quo

This alternative continues to use the current equipment past its forecast end-of-life.

Maintaining the status quo leads to the business continuity risk of relying on a system and equipment that may no longer be supported by the vendor. Status quo is therefore not a recommended option.

Alternative 2: Upgrade Bar Code Technology (Recommended)

This alternative upgrades the bar coding equipment used at Hydro One warehouses.

By upgrading the bar code technology, Hydro One will be able to leverage improvements in technology in this area. It is anticipated that the technology will provide better tracking of inventory within Hydro One's Barrie Warehouse and Central Maintenance

Shop but also at the various remote field sites including offsite storage depots and construction project sites. This will bring about higher accuracy for tracking of available inventory.

Investment Description:

This investment will upgrade the bar coding devices used at the Barrie Warehouse & Central Maintenance with up-to-date mobile applications that sit atop the approved tablet infrastructure.

Risk Mitigation:

<u>Solution Complexity</u>

Upgrading the Bar Code Technology is expected to be complex and finding the right skill set to support a successful implementation can be a challenge. To mitigate this risk, Hydro One will partner with vendors that have the experience and expertise to complete the work successfully.

<u>Resources and Competing Priorities</u>

Hydro One has many demands on its IT infrastructure, SAP and Supply Chain resources – All of which are integral to success of this project. To mitigate this risk, the Project Team will highlight when they expect to require these resources and services during formal Program Planning activities.

<u>Change Management and User Adoption</u>

The goal of this project is to upgrade or replace its current warehouse scanning device with a more current version. This could potentially pose both process and technology challenges to impacted staff particularly at the Barrie Warehouse, Central Maintenance as well as several other remote locations as they learn to use the technology.

Change Management is a key player to deliver the vision, training and job aids to the target user community wishing to access the new features. This would need to be assessed as to applicability, timing and cost impact.

The above risks will be addressed in accordance with Corporate Projects' Project Governance framework. Following the project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted at appropriate project stage gates.

In addition, the project will be led by someone from the LOB who has deep expertise within the Supply Chain and Warehouse area.

The timing took into consideration that the last time the bar code technology was implemented at Hydro One was in 2011. Typical software lifespan is 5 – 7 years. By 2019, it would already be time for Hydro One to upgrade to a more current version or replace its current warehouse scanning device with a new technology or solution.

Result:

This investment will yield operational efficiencies. By proceeding with this investment, Hydro One will be able to monitor its inventory with better accuracy and speed, leading to greater efficiency.

Outcome Summary:

Customer Focus	• Improve customer experience by providing efficient material availability to the Business which will in turn improve the ability to deliver timely programs and projects that affect customer-related investments.
Operational Effectiveness	• Provide accurate inventory count within warehouses and in remote field depots and construction sites.
Public Policy Responsiveness	
Financial Performance	

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes direct LOB resource cost, vendor cost as well as indirect costs of implementing the solution.

The cost estimate is based on historical estimate of when Hydro One last implemented bar coding technology. When the discovery phase is complete and vendor quotes received, a more accurate project cost estimate will be available.

Controllable costs will be minimized by reviewing the detailed cost estimate, when it becomes available, and reviewing and challenging the costs to ensure they are in line. Hydro One will also launch an open competition so multiple vendors can submit their proposal and Hydro One can select based on the vendor that best meets Hydro One's evaluation criteria and budget.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets	0.7	1.1				1.8
Less Removals						
Gross Investment Cost	0.7	1.1				1.8
Less Capital Contributions						
Net Investment Cost	**0.7**	**1.1**				**1.8**

Includes Overheads at current rates.

GP-15 SAP Treasury Implementation

Start Date:	Q2 2019	**Priority:**	Medium
In-Service Date:	Q4 2020	**Plan Period Cost ($M):**	2.7
Primary Trigger:	Operational Effectiveness		
Secondary Trigger:	Financial Performance		

Investment Need:

Treasury Management includes management of enterprise's debt, cash and short-term investments, currency and derivatives exposures, with the ultimate goal of managing the Company's liquidity and mitigating its operational, financial and reputational risk. Common Treasury functions include cash flow forecasting, investment recording and settlements as well as financial reporting. Treasury functions support all lines of business at Hydro One.

Currently, the business operates on a Sungard Integrity v.8.2 platform while most of Hydro One's finance functions operate on the SAP platform. Vendor support for the current Treasury system (Sungard Integrity) ended in December 2016. The company needs to upgrade to Integrity v.8.5 by April 2017 in order to retain vendor support.

There are certain intercompany transactions generated by Treasury in Sungard Integrity that impact the general ledger in SAP. This interaction of data requires technical interfaces between the two different systems, increasing complexity and reducing processing time efficiency.

Alternative 1: Status Quo

This alternative would continue to use Sungard's Integrity application.

Integration between Integrity and SAP will continue to be via batch process rather than real-time. With real-time processing, data is processed immediately when it is received. As a result, data is more up-to-date and potentially more accurate as data can be accessed and corrected immediately by the user. Batch processing, on the other hand, takes time to process. If there are errors, these are typically not caught immediately.

Alternative 2: Implement SAP Treasury & Risk Management (Recommended)

This alternative proposes to replace Sungard Integrity with the implementation of a new SAP Treasury and Risk Management (TRM) module. The estimated cost for licensing is $1 million with an associated maintenance of $220,000 per year (22% of the license cost). Implementation costs were based (business case estimate) on a medium sized complex new SAP module.

The Licensing, implementation, and first year maintenance costs are considered to be a capital cost. Maintenance costs from year 2 onwards would be considered an OM&A cost.

This investment improves business performance through:

- Using standard SAP automated processes for cash and liquidity management, risk analysis and transaction management. Access to real time accounts receivable and accounts payable payment data in SAP will help improve cash flow forecasting and working capital management;
- Simplifying integration and movement of data with existing SAP core financial modules;
- Real time availability of data permits mitigation of issues and errors throughout the month rather than only at the end of the month. This will help Corporate Accounting meet aggressive deadlines;
- Reducing manual work by sending wire and EFT payments directly from SAP to the banks;
- Eliminating manual process in valuation of derivatives and managing exposures by direct feed of valuation data to SAP for financial reporting; and
- Timely update of bank transactions data in SAP for bank account reconciliations to identify any unusual transactions.

Investment Description:

The implementation of SAP Treasury & Risk Management includes the SAP modules: Cash and Liquidity Management; In House Banking; Bank Communication Management; Treasury and Risk; Hedge Management.

Risk Mitigation:

The following are the risks that the project plans to address and manage:

Solution Complexity

The implementation of the SAP Treasury and Risk Management module is expected to be complex and finding the right skill set support successful implementation can be a challenge. To mitigate this risk, Hydro One will partner with vendors that have the experience and expertise to complete the work successfully.

Resources and Competing Priorities

Hydro One has many demands on its IT infrastructure, SAP and Finance resources – All of which are integral to success of this project. To mitigate this risk, the Project Team will highlight when they expect to require these resources and services during formal Program Planning activities. This will align with priority of projects set by Hydro One's Executive Team as an outcome of the Investment Plan review and approval process.

Change Management and User Adoption

The goal of this project is to replace its existing treasury system with SAP. This could potentially pose both process and technology challenges to impacted staff. Change Management is a key player to deliver the vision, training and job aids to the target user community wishing to access the new features. This would need to be assessed as to applicability, timing and cost impact.

The above risks will be addressed in accordance with Corporate Projects' Project Governance framework. Following the project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted at appropriate project stage gates.

Result:

This investment will yield operational efficiencies and improved decision-making capabilities. The SAP Treasury and Risk Management module will provide the Treasury department with a functionally complete set of solutions to support Hydro One's business. Being an SAP integrated solution will promote the harmonization of the system landscape and application rationalization. In addition, integrations between Treasury and other SAP modules will move away from batch processing towards real-time processing, which improves productivity, processing efficiencies and decision-making abilities.

Outcome Summary:

Customer Focus	
Operational Effectiveness	• Simplify the application landscape and integrate more tightly with the existing core SAP solutions. • Increase efficiency through reduced interface requirements, real-time data availability and the leveraging of recent technology upgrades in the SAP stack.
Public Policy Responsiveness	
Financial Performance	• Reduce reliance on IT support by migrating to a common enterprise platform that allows direct access data. • Improve financial management of Hydro One's debt, cash, short term investments, currency and derivatives.

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes vendor costs, as well as Hydro One's direct and indirect costs of implementing the solution.

The cost estimate is based on historical business case estimates of a medium size, complex new SAP module. When discovery phases are complete and vendor quotes received, a more accurate project cost estimate will be available.

Controllable costs will be minimized by reviewing the detailed cost estimate, when it becomes available, and reviewing and challenging the costs to ensure they are appropriate. Hydro One will also launch an open competition so multiple vendors can submit their proposal and Hydro One can select based on the vendor that best meets Hydro One's evaluation criteria.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets	-	1.5	1.2	-	-	2.7
Less Removals	-	-	-	-	-	-
Gross Investment Cost	-	1.5	1.2	-	-	2.7
Less Capital Contributions	-	-	-	-	-	-
Net Investment Cost	-	**1.5**	**1.2**	-	-	**2.7**

Includes overheads at current rates.

GP-16 Customer Self-Service Technology

Start Date:	Q2 2019	**Priority:**	High
In-Service Date:	Multiple	**Plan Period Cost ($M):**	12.9
Primary Trigger:	Customer Focus		
Secondary Trigger:	Operational Effectiveness		

Investment Need:

Self-serve technology has now become common in our society - from banks which offer ATM machines to grocery stores where a customer can scan purchases and make payments without going through a cashier. For the customer, this is convenient and often saves time. For the company, this fosters increased productivity and cost savings. Offering these service capabilities is rapidly becoming a demand from customers and a necessity of doing business.

Hydro One can provide similar convenience to its customers. Customers can view their bill, understand their usage, find out what conservation tools are available to them, submit a meter reading when communication is unreliable, report outages, pay bills and many other activities; all online. This improves customer satisfaction and engagement. These offerings may also represent a time-saver compared to having to call the call centre. From the Company's perspective, by empowering customers with self-serve technology, this improves productivity through a reduction of the volume of calls into the call centre. This can then be factored into future outsourcing arrangements.

Mobile access is a key channel going forward. In 2016, 40% of customers accessed Hydro One's website on their mobile device. This number is expected to grow over the coming years as new technology is introduced.

Hydro One does offer certain online services to its customers currently. These include:

- HydroOne.com - Hydro One's corporate website provides customers with safety education, energy conservation tools, a breakdown of their bill, payment options, conditions of service, etc.; and
- Mobile App - Hydro One's current mobile app provide information on power outages, including number of customers and affected estimated restoration time.

These offerings are high value. However, customers are saying that they want more of these services. For instance, the ability to send meter readings by uploading a photo of the meter read, the ability to report power outages through a mobile phone and the ability to pay bills through mobile application.

The customer facing infrastructure used by the current online system is aging. If Hydro One were to offer enhanced online services, the current infrastructure would be inadequate to ensure that customers accessed the material in a timely and efficient manner. High system latency and insufficient bandwidth would negatively offset the benefits of offering the new features and could even cause customer satisfaction to be negatively impacted.

Alternative 1: Status Quo

This alternative would stay with the current suite of online tools and not introduce new self-serve capabilities.

If the status quo alternative is selected, although this would not have any impact in terms of reliability of the distribution of electricity, Hydro One would likely experience deterioration in customer satisfaction. Without enhancing the usability of these self-service tools, Hydro One will not realize benefits associated with greater use of self-service channels. Aging infrastructure and software which are no longer under vendor support would pose an unacceptable risk to Hydro One.

Alternative 2: Upgrade Existing Self-Service Technology (Recommended)

This alternative would implement new self-serve technologies in the Customer Service area.

This alternative is recommended since this will improve customer service and maximize the ability of the company to establish a digital channel. This alternative will allow Hydro One to easily increase capacity of the solution as additional customers leverage web based, self-service solutions across multiple devices. In terms of the impact to the customer rate, the cost to implement this investment will be partially offset by operational savings gained by implementing this technology.

Investment Description:

This investment is required to upgrade customer self-service technology to enhance the customer experience and upgrade the underlying technology since it has reached the end of its useful life.

This investment will cover rolling out various mobile application enhancements in 2019 and 2020. These include providing customers the ability to send meter readings by uploading a photo of their meter reading.

This investment will also provide funding for website upgrades and enhancements in 2022. Hydro One is currently upgrading & enhancing its website in 2017 to provide a better digital customer experience. This new website that will be rolled out in 2017 will be mobile-friendly, will provide customers ability to access an interactive bill, will provide interactive tool to assist with energy conservation, will make it easier for customers to submit and track service requests. However, as technology evolves and as customers' needs grow and change, by 2022, this website will already be out-dated and will require another round of upgrades.

Risk Mitigation:

This is a complex project requiring multiple vendors in order to deliver a robust, secure, and cost effective technology platform. As such, a market scan will be conducted to determine best-in-class technology. With respect to customer privacy and security, market leading security technology will be sought to ensure customer data is well protected.

The timing of this investment is based on the useful life of the existing technology and the need to ensure the self-service tools remain relevant and up-to-date.

Result:

This investment will allow customers to interact with Hydro One via their channel of choice and better manage their electricity usage, thereby increasing satisfaction.

The solution will enable customers to conveniently access information, services, and transactions online, in an easy-to-use and intuitive manner, using both mobile and conventional desktop access.

The new technology will increase adoption of self-service channels by providing customers with additional self-service options, thereby reducing call centre interactions. A mobile first design approach will also ensure that our customers can access the website using the technology of their choice.

The new mobile application will allow customers to report outages and will potentially include other functions, including meter reading, payment options, and billing history to provide another avenue for customers to interact with Hydro One.

Outcome Summary:

Customer Focus	• Improve customer engagement by providing a mechanism for customers to conveniently interact with the company. • Provide customers a streamlined online and mobile experience.
Operational Effectiveness	• Increase in productivity since call centre agents can focus on helping customers with issues that can't be addressed via self-serve technology. • Reduce risk of operating on an aging infrastructure and software which are no longer under vendor support.
Public Policy Responsiveness	• Promote government policy on energy conservation by providing consumers easy access to information and interactive portals.
Financial Performance	• Minimize costs by reducing calls to the call centre.

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes direct LOB resource cost, vendor cost, as well as indirect costs of implementing the solution.

This project has a high degree of complexity; it includes redefining the customer experience, a new technology platform, and multiple vendors that require coordination. Given this project is customer facing, thorough testing is required to ensure that the customer experience is positive and security is maintained. The cost estimate is based on implementing similar complex applications in the customer domain. Final costs will be determined once detailed business requirements are finalized after a competitive Request for Proposal (RFP) is initiated and a vendor is selected.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets		2.3	1.4	2.3	6.9	12.9

Gross Investment Cost		**2.3**	**1.4**	**2.3**	**6.9**	**12.9**
Less Capital Contributions						
Net Investment Cost		**2.3**	**1.4**	**2.3**	**6.9**	**12.9**

Includes overheads at current rates.

GP-17 S4 HANA for Finance

Start Date:	Q2 2020	**Priority:**	Medium
In-Service Date:	Q4 2022	**Plan Period Cost ($M):**	6.4
Primary Trigger:	Operational Effectiveness		
Secondary Trigger:	Financial Performance		

Investment Need:

IT Need
SAP has announced that they will stop improving the current enterprise BI platforms immediately and vendor support for the current platform altogether will end in 2025. SAP will shift development to their new SAP S/4 HANA platform. All business functions performed on the current platform will ultimately have to migrate to the new platform.

Business Need – Finance
Multiple systems are required to produce the monthly financial statements at Hydro One. They include SAP BI, SAP ECC, SAP BPC and MS Excel. This drives delay and complexity into the month end processes.

The company faces higher requirements for financial reporting and has a need for improved month end, quarterly and year-end financial reporting procedures and processes.

SAP has, over the past 3 decades, created a platform that can be configured to perform any one business function in multiple ways. While "best practice" has always been built into every SAP transaction, user interpretation of what data needs to input has led to inconsistent transaction processing and erroneous or missing data. SAP has re-architected the Enterprise Resource Planning ("ERP") system, consolidated into ERP the financial functions that currently reside on the BI system, streamlined the financial consolidation processes and simplified the reporting functions. Business Planning has been moved from BW (business warehouse) and incorporated directly into the SAP ERP platform. This means that the impact of planning changes can be immediately reviewed.

More recently, further improvements have taken place in the continued simplification of processes that removes the need for data replication. This provides end users with faster access to data to generate real time reporting and ultimately reduce the time to close the books by 10 – 20% according to SAP estimates. Additionally, new systems provide the ability to facilitate predictive forecasts and dynamic simulations using real time data to provide greater reasonability to the numbers. Embedded predictive algorithms and simulation capabilities enable management to better monitor and forecast business needs.

Alternative 1: Status Quo

This alternative would continue to use the current BI and ECC platforms in conjunction with other applications to produce statements and reporting.

IT

The current SAP platform will reach end of life status, by 2025 at which time SAP will cease providing any support for the current platform.

Business

Continue to plan and manage and report financials in less than optimal manner.

Alternative 2: Replace SAP with an alternative software system

This alternative would replace the current SAP BI platform with competing ERP software and/or adopt a multi-vendor approach by replacing the various business functions with Commercial off-the-shelf ("COTS") applications.

Not justifiable due to the investment Hydro One has made in SAP.

Alternative 3: Migrate to the S/4 HANA platform (Recommended)

IT Benefit

Migrating to S/4 HANA will ensure continued vendor support to reduce IT costs and ensure ongoing, timely performance.

Business Benefit General

Hydro One has significant investment and experience in implementing and maintaining SAP. Over the past 10 years, Hydro One has consolidated over 130 applications, and the functions they performed, into SAP leading to IT and business process savings.

S/4 HANA is proven to offer superior query performance, faster load times thus increasing performance in the numerous business areas that use the ECC platform.

S/4 HANA has a streamlined user interface which has been built upon the same design concept that most mobile applications use which is to present the user with exactly the data they require and limit input options. On the S4 HANA platform business functions or processes have been simplified resulting in less time required to perform the associated processes and improved data quality. The database structures have been greatly simplified. SAP has done away with the sub ledger/ledger construct thus increasing performance.

Business Benefit Finance

Over and above the general business benefits finance functions such as business planning, consolidation and disclosure, financial accounting and financial reporting have been consolidated on the S4. This will reduce the time required perform many of the finance processes.

Investment Description:

Planned investments include HANA which is SAP's new database technology; S4 which is SAP's new application software, SAP's new software configuration guides. This investment will also include, but is not limited to: integration with other enterprise systems; and data migration of financial data from the existing ECC to the new S4. With S4 Finance the business planning and consolidation (BPC) functions that used to be performed on SAP BW have been incorporated into S4 Finance. Data will have to be migrated to S4 from ECC and BPC. When complete all Finance functions can be performed in S4. The S4 version of BPC offers improved plan and forecast capabilities.

This investment will not be impacted by other investments such as SAP Treasury, Business Planning and Consolidation and others. However, it should be noted that anything added to SAP through some other investment will ultimately have to be migrated into SAP and implementation collisions must be managed.

Risk Mitigation:

Following the project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted at appropriate project milestones. The following are the risks that the project plans to address and manage:

Solution Complexity

The SAP HANA delivery is expected to be a complex implementation and finding the right skill set support successful implementation can be a challenge. To mitigate this risk, Hydro One will partner with vendors that have the experience & expertise to complete the work successfully.

Configuration guides will remove significant amounts of implementation inconsistency normally introduced by 3rd party implementers.

Resources and Competing Priorities

Hydro One has many demands on its IT infrastructure, SAP, and Enterprise Architecture resources. All of these resources are integral to success of the project. To mitigate this risk, the Project Team will highlight when they expect to require these resources and services during formal Program Planning activities. This will align with priority of projects set by Hydro One's Executive Team as an outcome of the Investment Plan review and approval process.

Any combination of these risks could result in a project in-servicing delay. To minimize the risk, solid project governance will be applied taking into account the relevant lessons-learned from other similar projects.

Result:

This investment will yield operational efficiencies, improved decision-making through real time reporting, process simplification, better data driven by standard and consistently performed transactions, better user adoption due to a simpler and modern interface.

Outcome Summary:

Customer Focus	• Leverage out-of-the-box, customer functions that represent the full spectrum of utility customer interactions.
Operational Effectiveness	• Increase operational effectiveness through simplified user interfaces, superior performance and more consistent processes. • Drive opportunities for cost savings through leaner processes and in-platform planning and reporting
Public Policy Responsiveness	• Improve capability to meet statutory reporting capabilities.
Financial Performance	• Reduce the inconsistencies in month end reporting through simpler user interfaces and consistent process execution.

Costs:

The underlying premise is that S/4 HANA will help us fine tune what we have today, not reinvent it. This will extend the investment in the current SAP ERP that was implemented in phases between 2008 and 2013. The cost estimate for this investment assumes the use of the standardised configuration and that the project will be based on migrating data from our existing ERP platform to the new S/4 HANA platform, without the need for lengthy business requirements gathering and interpretation. This is what commonly results in very expensive SAP implementations.

Hydro One will also launch an open competition so multiple vendors can submit their proposals and Hydro One can select based on the vendor that best meets Hydro One's evaluation criteria and budget.

GP-18 Integrated System Operating Centre

Start Date:	Q1 2015	**Priority:**	High
In-Service Date:	Q3 2020	**Plan Period Cost ($M):**	56.4
Primary Trigger:	Asset Driven – Failure Risk & Capacity		
Secondary Trigger:	Regulatory		

Investment Need:

The Network Operating Divisions ("NOD") Backup Control Centre ("BUCC") facility was placed in-service in 1956, and is the means that regulatory, business and operational requirements are sustained for monitoring and control operations to North American Electricity Reliability Corporation ("NERC") standards, Distribution and Transmission System Code ("DSC") requirements and Hydro One standards respectively. The BUCC facility consists of the building, computer tools and systems that support Operations in the event of a partial or total loss of the primary Ontario Grid Control Centre.

A risk of future extended outages, inability to execute necessary upgrades /replacements and increase capacity to required computer systems and tools, could result in significant disruption to business continuity and Hydro One's ability to meet customer's service level expectations. The facility is currently at capacity in computing space, HVAC, power and due to the age of the structure, among other factors, remedial efforts are either not viable alternatives, cannot be mitigated or are cost prohibitive to execute. In addition, a prolonged activation would impede supporting Operations; i.e., Outage Planning, Operations studies and support due to a lack of back office support space. Current Operations support groups that are fundamental in daily Operations, are unable to occupy the BUCC during any event, and would require current staff at the Richview facility to be relocated, procurement and set up of required computer equipment and would take vital time to implement.

Alternative 1: Status Quo/ Use Offsite Leased Space

Hydro One Network Operating maintains the existing Control Room, and Security Operations maintain existing facilities. A new offsite leased Data Centre facility (to mirror capacity of OGCC data centre based on 20 year lease and initial setup costs) could be provisioned and additional office space would be required and furnished for prolonged activations. This alternative includes additional leased space for the Backup Integrated Telecommunications Management Centre's ("BUITMC") control room and compute needs.

The total cost of this option is estimated to be $78M, of which, the distribution portion will be 50.07%.

This alternative has been rejected as the current BUCC for Network Operating and the Backup ITMC do not meet operational requirements.

- The current facility imposes a high level of risk to both regulatory compliance and, Hydro One's reputation and customers, if any failures are experienced.
- This alternative fails to provide for the Security Operations Centre's ("SOC") need for an adequate primary control centre.
- Even with extensive investment in the existing facilities, this option does not adequately remediate all risk factors (e.g., basement flooding, power capacity constraints, electrical hazards due to proximity to TS).
- This alternative cannot accommodate current or projected growth, requiring further investment in leased facilities in the future.
- This alternative would require the relocation of the existing compute space and critical support infrastructure, currently housed at the BUCC, to a new leased BUITMC.
- This alternative cannot mitigate all known risks due to site conditions, size and location. In the event of a prolonged activation, some existing staff of the Richview facility would be asked to leave to make space for operating activities, and even if this arrangement can be made, there is not sufficient onsite parking, work space, or basic facility infrastructure for the overflow of staff.

Further information relating to the rejection of Alternative 1 is found on pages 22-24 of this Investment Summary Document.

Alternative 2: Build NOD Backup Control Centre and Data Centre exclusively.

This alternative was reviewed in light of the 2013 Toronto rainstorm and ensuing flooding that occurred in the GTA. This event required the ITMC to activate the BUITMC located in Kitchener Ontario. During this event, it was made apparent that a failure in the ITMC function or delays in Backup activation, created an inability to remediate, troubleshoot telecommunication outages, and had a significant impact on Network Operating's ability to monitor and control. Loss of communications had severe impacts on the Control Room's ability to monitor and control field assets and clearly showed that a new NOD Backup Control Centre and Data Centre would not remediate all risks currently identified. This alternative proved that a more robust BUITMC is required.

Due to the importance of the ITMC, the identified need for a new BUITMC and the economies that would be foregone with this alternative, this alternative was removed from further consideration. The estimate for this alternative is $104.8M, of which, the distribution portion will be 50.07%.

Alternative 3: Build Backup Control Centre's for Hydro One Networks and ITMC including shared critical infrastructure, back office support areas and an integrated Data Centre.

This alternative includes Control Rooms, an integrated Data Centre and shared back office support areas for prolonged activation and is considered the minimum requirement to address known operational risks that currently exist. This alternative also includes the purchase of the preferred site. This alternative is estimated at a cost of $124.7M, of which, the distribution portion will be 50.07%.

While this alternative meets Network Operating and the Integrated Telecommunications Management Centre's minimum requirements, it has been rejected as it fails to maximize investment utilization through synergistic lines of business occupancy as well as shared use of critical infrastructure. The incremental cost of the SOC inclusion is $ 6.5M. This also fails to take advantage of operation synergies for operational response to security threats, both physical and cyber.

Alternative 4: Acquire an existing facility that could be retrofitted / utilized to accommodate NOD Backup Control Centre, BUITMC and an integrated Date Centre.

A market assessment was completed that reviewed potential sites against identified requirements for size, location, travel times, power infrastructure, telecommunications and occupancy. This also included an internal assessment of Hydro One owned sites. At the completion of the assessment, it was determined that no suitable site was available in the market or within Hydro One's owned locations. As a result, this alternative was excluded from further consideration.

Retrofitting an existing facility was also considered. In order to suit the environments and critical support infrastructure required for Data Centre reliability, real time 24x7 Control Rooms, Security considerations including dual power supply and telecommunications expansions, extensive investment would be required. At the time of the assessment, no suitable site / facility was available and as such it was removed from further consideration. In addition, the total cost to retrofit was anticipated to be equal to or greater than greenfield construction and as such was removed from further consideration.

Alternative 5: Build ISOC with incremental capacity for a Primary NOD Control Centre, SOC Primary Centre, and BUITMC including an Integrated Data Centre, Shared critical support infrastructure and back office support space.

This option involves building the ISOC as described in alternative 6 and making the necessary arrangements to utilize the ISOC as the Primary Operating Control Centre from Day 1. The OGCC, which is the existing primary operating control centre, will then be converted to be the backup centre.

The additional cost for the building, site and the uplift / upgrades to current mission critical Operating systems and IT architecture to initiate the ISOC as a primary NOD Control Centre, from inception, was determined to be high when weighed against the initial benefits; therefore, this option was rejected. The total cost of this option is estimated to be $141.9M, of which, the distribution portion will be 50.07%.

A strategy to enable a "Dual Control" operational strategy was pursued in an effort to leverage current upgrade investments for their useful life. This alternative does not facilitate the Dual-Control strategy and, without costly upgrades, there will not allow the transition to occur in a more organic nature, representing less cost impacts and less disruption to the Operating functions and staff.

Alternative 6: (Recommended) Initiate Build of the Integrated System Operations Centre (ISOC).

This alternative provides for:

1. a Network Operating Control Centre;
2. a Backup Control Centre for the Integrated Telecommunications Management Centre; and
3. primary facilities for Security Operations.

This Alternative also includes the provision for a shared integrated Data Centre, all critical support infrastructures at the preferred site. This alternative will maximize Operational flexibility for Hydro One Networks and associated lines of business while eliminating the need to duplicate investments in multiple sites, and costly critical support infrastructure (emergency generators, uninterrupted power supplies, telecommunications etc.). The total distribution share of this option is estimated to be $64.6M, and the specific amount for this plan period would be $56.4M.

The ISOC strategy will enable a "Dual Primary" scenario where both Centres can be live as compared to the current live/passive (standby) model. Functionality required to facilitate this strategy is not expected until 2022 and will be implemented within current/future lifecycle schedules for the primary applications (i.e. ORMS, DMS, NMS etc.). This effectively negates the need to prematurely replace, re-architect and implement newer systems prior to their lifecycle expiration while providing the benefits and future flexibility of Primary Control ability.

Further details about the project are included in Appendix A.

A detailed option comparison is included in Appendix B.

Investment Description:

The Integrated System Operations Centre will house multiple lines of business through the provision of dedicated Control Centres: an integrated Data Centre and shared back office areas. This facility will be a hardened facility employing emergency preparedness criterion, industry best practices that meets physical and cyber security standards. This strategy provides flexibility for Hydro One Networks to enable future dual control through a systematic and cost effective approach with planned lifecycle upgrades. These facilities are essential in maintaining adequate redundancy for Operation of the Bulk Electric System, management of the Distribution network and associated customer responsiveness (i.e., outage and storm management). In addition, this will ensure Telecom Communication Network management and adherence to mandated North American Electricity Reliability Corporation (NERC) requirements for Emergency Operating Procedure 008-1 "Loss of Control Centre Functionality". It ensures achievement of reliability and availability targets commensurate with the criticality of these facilities. The ISOC will provide in house security operations, mitigating reliance on third party services and provides needed compute capacity for Security Event Monitoring (SEM).

The ISOC design provides the following:

<u>Facility:</u>

- Provide NOD with a new backup control centre including a control room, back office space and a shared data centre, employing the following strategies; provides the operating flexibility that allows Network Operating to duplicate the current OGCC functionality mitigating the current heightened risk profile with the current BUCC.

- Provides additional training synergies through the use of simulation technologies, allowing use of the facility while not required for backup activation (dual purpose).
- Enables future dual control potential, increasing the readiness and customer response times for any future event that may impact the Ontario Grid Control Centre and NODs ability to manage, monitor, control and dispatch on the distribution system.
- Ensures security requirements, both physical and cyber, including a hardened facility to guard against physical and environmental threats (i.e., tornadoes).
- Provides the ITMC with a new backup operations control centre including a control room, back office and integrated computing facilities mitigating the current risks at the BUITMC and the risks a failure of ITMC Operations poses on Network Operating.
- Provide the Security Event Management centre with needed integrated computing facilities.
- Provide Security Operations with a headquarter location including a control centre, office space, investigative rooms, emergency operations centre (room) and integrated computing facilities.
- Shared and redundant critical support infrastructure.

The total distribution portion cost of the construction build, including contingency and escalation, is estimated to be $43.3M.

Site:

Provides a 16.4 acre site in Orillia Ontario at a cost of $3.0M, and 50.07% of this is the total distribution portion cost. The site was selected based on an extensive Market Assessment in Q1 of 2015. The Orillia site met essential criteria, and included material advantages and associated cost savings in terms of; location, current site development activities completed, forgoing of water detention requirements, improved commute and activation times, and significant municipal development charge savings realized through the Industrial Development Charge Moratorium offered by the City of Orillia.

Architecture and IT design:

The detailed design is expected to be completed by the middle of 2017. The distribution portion of the total engineering and IT consultant costs, for the detailed design, is estimated at $7.7M.

Connectivity and Telecommunication:

Connectivity and SONET at the new ISOC facility allows the ISOC data center to communicate with the OGCC and the rest of the Hydro One telecommunication network. The distribution portion cost to establish this communication connectivity and SONET is estimated to be at $6.8M.

Network Infrastructure:

Lastly, an additional $5 million (distribution portion only) has been budgeted for IT infrastructure. This covers the cost associated with connecting each individual workstation console to the ISOC data hall.

Compliance

In order for Hydro One Network Operating to be compliant, there are many requirements, Regulatory Standards and internal Hydro One Standards that must be satisfied. In addition, industry best practices are respected to build on reliability and availability of critical system. The ISOC investment must adhere to; but not limited to the following:

1. North American Energy Reliability Corporation (NERC) –EOP-008 "Loss of Control Centre Functionality" necessitating backup activation to be equal to or less than two hours.
    a. In a related Federal Energy Regulatory Commission (FERC) order (Docket No. RD11-4-000 at 14) FERC signalled its concern that the two hour activation requirement is too long and that "it is imperative that full backup functionality occur as soon as possible after the loss of primary control functionality". FERC also noted that "…it may revisit this transition timeframe". This signalled that the new BUCC facility must take into consideration that activation timelines could be reduced in the future.
    b. NERC and FERC also require the Backup to be "capable of operating for a prolonged period and providing functionality sufficient to maintain compliance with all reliability standards that depend on primary control functionality."
2. Restoration Participant Attachment as required by the IESO administered 'Market Rules' for the Ontario Power System Restoration Plan (OPSRP).
    a. The BUCC is listed as one of the key facilities which comprise Hydro One's contribution to the Ontario Basic Minimum Power System.

3. Required as per EOP-005-2 NPCC-D8 (NPCC Directory 8) and IESO Market Rules & Manuals (Market Rules Chapter 5 – Power System Reliability, Market Manual 7: System Operations, Part 7.8: Ontario Power System Restoration Plan.
4. NERC Critical Infrastructure Protection (CIP) Requirements – ensuring assets are protected logically (electronic security perimeter) and physically (physical security perimeter).
5. Communications: NERC & IESO Market Rules:
   - NERC-COM-001-2;
   - Chapter 2, Appendix 2.2, Section 1.1.4- Technical Requirements: Voice Communication, Monitoring and Control, Workstations and Re-Classification of Facilities;
   - Chapter 2, Appendix 2.2, Section 1.2.3 – Transmitter Submission to the Energy Management System;
   - Chapter 5, Section 12.1.1 – Voice Communications Methods;
   - Chapter 5, Section 12.1.6 & Section 12.2.12 – Alternatives During Loss of Communications;
   - Chapter 5, Section 12.2.3 – Required Voice Communication Facilities;
   - Chapter 5, Section 12.2.4 – Voice Communication Reliability;
   - Chapter 5, Section 12.2.11 - Voice Communication Monitoring and Testing; and
   - Chapter 5, Section 12.3.2 - Required Data Communication Facilities.

Additional Design Criteria

In addition to the above requirements, the following Industry Best Practices have been incorporated into the ISOC design:

- Designed for Dual Hot Centre's with Increased Security
  - Provides additional functionality that improves operational proficiency;
  - Improved system security and redundancy; and
  - Meets minimum provincial anti-terrorism standards (i.e., blast protection).
- Multifunctional Facility / Business Continuity
  - Increased building utilization (multipurpose, real time, simulation and future Dual Control);
  - Operational flexibility and scalability (modular expansion); and
  - Emergency Preparedness criteria – facility separation for common mode failure.
- High Availability / Reliability 99.95%
  - Employing an Uptime Institute guiding principles for a Tier III facility; and
  - Provides for redundancy in computing, communications, cooling and power.

- Emergency Preparedness risk considerations were factored into site selection and facility design, mitigating the current risk the BUCC is exposed to (i.e., not in a flight path, transformer station, etc.).

Risk Mitigation:

- Construction commencement is contingent on the required OEB approvals and if not planned accordingly, could pose project schedule risk. This has been mitigated through a schedule adjustment that will initiate commencement in alignment with OEB schedules.
- Municipal Approvals impose risk to the project schedule however during the current detailed design stage, the municipality has been consulted throughout the process mitigating the risk of future change requests or delay for approvals.
- Site development and environmental risk due to discovery of adverse subsoil conditions. This risk has been mitigated through several borehole assessments of subgrade soil conditions to determine: (a) foreign objects; (b) soil contaminants; and (c) suitability of soil cohesion for adequate foundation strength and no notable issues have been discovered.
- Construction risk due to change requests, lack of performance of proponent and increased costs have been mitigated through plans for Hydro One's and the external designer monitoring on site activities throughout construction ensuring issues are discovered and addressed early and that required contract quality is delivered to schedule.
- Alignment of dependent sub-projects has been identified as a potential risk as a delay in delivery of communication path connectivity to the control network would delay future in-service and commissioning activities. This risk is mitigated through early commencement of this activity to ensure adequate lead times.
- Factors affecting implementation timing and priority are those identified in the Investment need section which speak to the increased reliability risk for backup Operations. These factors have been reviewed and the priority has been set to "high" given the high cost for remedial efforts and the impacts on Operations and Hydro One customers if further failures are experienced.

Result:

The integrated strategy behind the ISOC facility maximizes investment utilization as well as value generated by eliminating the need for additional sites and facilities that would otherwise be required. By building one centralized site to house all stakeholders, economies of scale synergies will be realized. These come in the form of negating the need for multiple designs, development, sites, facilities (buildings), critical support infrastructure, future maintenance maximizing capital investment, limiting overall rate impacts.

All proposed tenants require critical support infrastructure to meet an availability target commensurate with the criticality of the systems and functions they support (99.95%). The requirements are prescribed by Hydro One internal reliability standards and guided by industry best practices (Uptime Institute Availability "Tier" levels). Critical support infrastructure and IT investment to achieve this objective represent significant investment. With the current ISOC strategy, critical support infrastructure is shared and represents incremental cost to achieve rather than replicating with several installations that would be required to support several sites across Ontario.

- Enhanced monitoring, control and coordinated Customer response (Operating, ITMC, Security and Emergency Preparedness);
- Examples include;
    - Coordinated response for all system vulnerabilities i.e. system events, telecommunication events, cyber events or physical threats through integrated communication within the ISOC facility.
    - Enables future dual active sites, removing activation timelines of backup Operations.
- Share enhanced building protection design and security (physical facility hardening to protect against severe weather or man made threats);
- Share redundant backup generator power supply and other emergency supplies;
- Enhanced site location for improved activation response, elimination of NOD's interim BUCC, adherence to emergency preparedness criteria, dual purpose use for training (negating need for additional training facilities) and other business operations; and
- Enhanced security with centralized operations, improved monitoring and analysis trending for proactive response, and situational awareness for coordinated resolution. An Emergency Operations Centre for Business Continuity and Emergency Preparedness will also be provisioned as part of the Security Operations Centre.

Outcome Summary:

Customer Focus	• Improve the reliability and availability of emergency activation, response and restoration in the event any failure is experienced in the Primary Control Centres. • Reduced rate impacts from a single integrated solution as compared to multiple standalone investments. • Retiring of the current interim NOD BUCC and removal of the risk of costly remedial efforts in the event further failures are experienced.
Operational Effectiveness	• Mitigates the critical risks (infrastructure failures, capacity constraints, location and activation timelines etc.) that exist at the Network Operating Backup Control Centre and the Backup Integrated Telecommunication Management Centre. • Monitoring and control reliability will be sustained under all system contingency scenarios improving Hydro One's compliance risk, customer responsiveness and Operational agility.
Public Policy Responsiveness	• Accommodate all regulatory requirements for physical protection, cyber security and activation timelines responsiveness. (See Appendix A and Compliance section of this document for further details).
Financial Performance	• Reduce the cost impact to Hydro One customers through the realization of economies of scale, mitigating the need to provide multiple sites, buildings and shared critical support infrastructure. • Negate the need to maintain an Interim NOD BUCC and reduce the risk of costly mitigation in the event additional failures are experienced at the main BUCC.

Costs:

Key considerations affecting the final cost of the project consist of the following:

- Availability and Reliability Standards including the need for redundancy in system and building architecture to maintain the existing target of 99.95%. The largest cost element revolves around the Data Center and critical support infrastructure, and the "Tier" or "Redundancy" level can weigh heavily on the investment required. Given the criticality of the Control Centre functions, with leading industry advice, a Tier III level was recommended and designed. This category includes the investment required in the SONET control telecommunications network required to connect the BUCC to field assets for monitoring and control.

- Security Requirements impose additional cost considerations ensuring the facility can withstand both natural and human events i.e. Tornado's, blast protections. Included in this consideration are prescribed regulatory requirements for six sided secure perimeters, cyber security (IT architecture), site access and monitoring of critical assets.
- Costs have been managed through an extensive and thorough assessment with various third party industry experts, internal subject matter experts as it relates to industry best practices, cost saving initiatives (i.e., free cooling), alternative option assessment for independent project elements (site selection, industry comparators), integration of solutions for various business units, functions and needs across Hydro One at a single site. An independent cost consultant has provided costing of the current stage of detail designs.

APPENDIX A – DETAILED PROJECT DESCRIPTION

This investment, formerly known as the Backup Control Centre – New Facility Development, has expanded to include other operational synergistic lines of business that require facilities to perform similar functions (operating, monitoring, control and response functions) that are critical to support Network Operating and to secure Hydro One's assets. An integrated solution was sought to ensure costs are minimized, maximizing the effective utilization of critical infrastructure, office space and the site with the intent to maximize capital investments and reducing customer rate impacts. Below is a description of the Security Operations (SOC), Security Event Monitoring (SEM) and the Integrated Telecommunications Management Centre (ITMC) identified investment need.

The Backup Integrated Telecommunications Management Centre (BUITMC), in-serviced in 1950, requires extensive setup during activation and cannot accommodate back office support staff and regulatory security requirements for access control for critical computing equipment. The current HVAC is not adequate for net new occupancy or equipment and lacks the necessary facilities should a prolonged activation be required. ITMC is a critical element in ensuring that the Network Operations telecommunications network is available and in providing first level support in the event of any communications failure. In the event the ITMC cannot meet its service objectives, and Hydro One experiences an issue with telecommunications paths, Network Operating will be unable to monitor or control the respective field assets. ITMC requires a new Backup Control Centre to alleviate the risk at the current location.

Security Event Monitoring (SEM) is accountable to provide cyber surveillance monitoring services and requires Data Centre capacity, (not a physical tenant) to support primary and backup operations. SEM monitors Network Operating's Compute Network to ensure threats are detected, assessed and remediated so that critical cyber assets are not negatively impacted. Loss of visibility, control or erroneous operations of equipment due to a cyber-vulnerability, poses a serious threat to Hydro One's Operating functions. The risk of cyber related events has increased rapidly due to the relative increase in the amount of IT critical cyber assets employed in Hydro One Networks.

A Security Operations Centre (SOC) and an Emergency Operating Centre are required to provide a primary site for operations, monitoring and coordinated response for physical security threats and are imperative for business continuity. Currently, Security Operations are dispersed across the province and is reliant on third party services. In the event the current vendor cannot meet service obligations, Hydro One will be unable to monitor its critical sites. An integrated security presence at the ISOC will ensure physical threats can be detected, assessed and appropriate response dispatched. If a physical threat goes undetected, catastrophic impacts can result, in the event critical assets are damaged, which has potential to result in sever impacts to the Transmission and Distribution system networks. In addition, a lack of detection has potential to expose Hydro One to safety and environment risk for staff and the general public.

The current ISOC investment has evolved through a significant collaborative effort with Hydro One Network Operating, ITMC, SEM, Security Operations, industry participants and external subject matter experts. Initiation of this investment was predicated on current asset driven deficiencies / requirements (documented safety hazards, capability constraints, Reliability/Performance Impacts and risks, failures, condition, age, obsolescence, and regulatory and/or Hydro One standards (as described above).

Below is a detailed description of the ISOC investment planning process and execution strategy, which has been developed with the aim to a) fully understand requirements and needs across Hydro One; b) gather leading industry best practices, lessons learned; c) develop detailed programmed space and sizing requirement and asses against industry benchmarks; d) project costing from leading industry experts; e) ensures cost controls and oversight.

Planning Needs Assessment: Phase One

Requests for Proposals (RFP) were issued to conduct a Market scan and a Planning Needs assessment. This provided a detailed assessment of sites available in the market that met a set of specific "essential location requirements" and to provide expertise into the conceptualization and documentation of business needs and requirements of Hydro One Networks, ITMC, SEM and Security operations. The main focus was balancing needs and costs against reliability requirements, industry best practices (including Industry participant's feedback (New York ISO, New England ISO)) and lastly with lessons learned from the current Primary Ontario Grid Control Centre (OGCC). In addition, business requirements were translated into programmed space requirements based on Hydro One's experience and at the advice of industry experts. A basis of design was developed, capturing the stated requirements and a cost estimate was provided by an external estimator (for building and support infrastructure) and internal Hydro One engineering groups (for Telecommunications and Dual Power and Power System IT).The final basis of design and cost estimate were utilized to initiate the subsequent Detailed Design Phase.

The sizing of the ISOC is predicated on duplicating the OGCC current functions for Backup Control, including parallel use for training simulation and controller / dispatcher training.

The training facilities at the OGCC are currently at capacity. This effectively reduced the size of the ISOC facility by negating the need to program space for training simulation and instead uses technology to use real-time operating space while not active (in backup mode). In the event the OGCC is rendered inoperable or uninhabitable, the new ISOC facility will be able to continue all day to day functions indefinitely with a limited transition period, expected to be one hour or less.

Security Operations sizing was predicated on defined needs of operators, support staff, an investigation room and an Emergency Operations Centre (which will utilize a shared conference rooms when required).

ITMCs Backup Control Centre duplicated the current Primary Centre exclusively, including Control Room space, Data Centre requirements and provisions a back office support compliment to ensure adequate facilities are available for prolonged activation redundancy and assurance of Operations.

SEMs compute needs were documented, forecasted and the incremental capacity was added to the Data Centre white tile space.

Future growth has been accommodated and captured in the detail design however not all space will be built in the initial ISOC build. Data Centre growth has been included up to and including 2035 due to the sensitivity of the equipment and the risk future construction would pose; however the support infrastructure will be purchased on an as needed basis. Future facility expansion will be enabled for future consideration by way of footings and ensuring construction can be achieved without impacting operations (designing connection points etc.) Future extension of the facility, when required will be included in future OEB rate cases.

Detailed Design: Phase Two

At the completion of the Planning Needs Assessment Phase, a Detailed Design phase commenced with the objective to provide all required documentation, designs and costing to tender the end state solution for construction. During this phase, all drawings, facility programing (space definition), IT architecture etc. will be completed, including site procurement (~$3M), Proof of Concept for IT architecture and a final estimation. This information will be packaged and ready for submission for RFP for the construction phase. It is expected to be completed in 2017.

Pending completion of the Detailed Engineering Design and receipt of required approvals, Hydro one will leverage its internal Supply Chain, an Open Market Construction Tender process in two phases.

Phase One: Request for Pre-Qualification ('RFPQ")

Hydro One will seek to pre-qualify a select number of vendors in an open market process, who demonstrate "required competencies" (e.g., proven large project construction experience, defined safety/environmental programs, change control process controls, demonstrated ability to deliver large construction projects on time and to budget, etc.) related to the construction of the ISOC and acceptance of HONI required market-based Terms and Conditions.

Phase Two: Request for Proposal ("RFP")

Hydro One will release to only the pre-qualified vendors a detailed RFP with a complete set of construction documents. Pre-qualified vendors will be required to review the construction documents, offer input with respect to area's which could result in increased costs if not addressed before construction and provide a "fixed" price proposal to a defined scope of work and schedule, linked to a delivery penalty.

Construction Phase: Phase Three

The successful proponent will commence construction and is planned for Q4 2017.

Post Construction award: Hydro One's external designer will monitor on site activities throughout the construction to ensure any issues are addressed early and that required contract quality is delivered. HONI and designates will participate in interactive Bi-weekly onsite construction process meetings to gauge progress to requirements and address concerns which may impact the process.

The ISOC investment has been identified and assessed as a high priority and was subsequently prioritized and planned due to risk and considerations described below.

Site location risks that will continue to be present as there are no viable remedial alternative to the following risks:

- The current site location, and required travel time, requires maintaining an interim backup facility to perform limited functions in the event the OGCC is rendered inoperable and staff have to transition to the BUCC. The ISOC will eliminate this requirement;

- Structure is landlocked, and no expansion potential exists as the facility is surrounded by a Transformer Station;
- Current emergency preparedness risks will remain:
  - In a flight paths (Pearson International Airport);
  - Between two major highways (Hwy 427 & Hwy 401) in the event of hazardous spills;
  - Gas pipe lines located underneath property;
  - Adjacent to transformer station (electrical, fire and asset failure hazard). In 2011, T7 and T8 transformers at Richview both failed catastrophically, resulting in loss of the station and a major fire. This removed the BUCC from use for an extended period of time;
  - Congested area in the event of wide spread emergencies i.e. Civil unrest, blackout, natural disaster, and commute;
  - Adjacent to public storage facilities.
- Facility risks that could render the Hydro One Networks Control Centre or critical equipment unavailable for an extended period of time, eliminating redundancy of critical monitoring and control of the Distribution system include:
  - Flooding in basement, roof and cable entrances, where computer rooms, power rooms, telecom rooms, switchgear, and SONET communications are currently located;
  - Failures of critical support infrastructure including; the fire panel, HVAC, emergency backup power (generator);
  - Inability for expansion and a high cost for retrofit / maintenance activities;
  - Relocation of the equipment located in the basement of the facility is not viable given the space required on the main floor (Computer rooms, telecommunication gear (SONET), Uninterrupted Power Supply units, switchgear etc.;
  - Competing demands for physical space, power, cooling from multiple tenants; and
  - Electric power system is undersized (Station Service).
- ITMC's current BUITMC has documented the following risk and constraints;
  - Located in a shared space with an inability to expand;
  - Requires extensive setup during activation as the facility cannot accommodate a permanent active installation;
  - Cannot accommodate current back office support requirements;
  - Cannot meet security requirements for access control for critical computing equipment;
  - The current HVAC is not adequate for net new occupancy or equipment;

- Lacks the necessary facilities should a prolonged activation be required; and
- ITMC is a critical element in ensuring that the Network Operations telecommunications network is available and in providing first level support in the event of any communications failure.

Hydro One’s Security Operations are currently reliant on an external facility that is owned and operated by a third-party creating corporate and regulatory risks given that Hydro One lacks a contingency site that is capable of monitoring the physical security of its sites and assets. Should the facility or 3rd party services no longer be available to Hydro One due to factors outside of Hydro One’s control, Hydro One will not be in a position to monitor the real-time security (including door alarms, motion sensors etc.) of its critical sites, creating both a security and public and employee safety risk. Such an occurrence would also lead to a regulatory non-compliance violation with NERC Standards and possible sanctions, financial penalties and risk to corporate reputation.

APPENDIX B – DETAILED ALTERNATIVE COMPARISON

Detailed Alternative Comparison

Alternative	Description	Cost ($)	Size (Sq.Ft)	Site (Acres)	Cost / Sq.Ft	OM&A**	Benefits / Risks
Alternative One: Status Quo	Maintain existing facilities. (BUCC remediation activities, lease new data hall space and for BUITMC Requirements).	$78M*	18,921	N/A	N/A	N/A	No provision for SOC. BUCC existing location, space, and site constraint risk remains. Significant difficulties for prolonged activation. Includes a leased space for BUITMC, leased Data Centre space for NOD and remedial work to retrofit office space to better accommodate prolonged activation.
Alternative Two	Build NOD BUCC and Data Centre.	$104.8M*	95,420	10+	$1,098	$3.72M	Site, SONET, Dual Power and critical support infrastructure included.
Alternative Three	Build ISOC as BUCC, BUITMC with back office and Data Centre.	$124.7M*	99,716	16.41	$1,251	$4.0M	This includes the preferred site and all critical support infrastructures including but not limited to: SONET, Dual Power, redundant generation, UPS, cooling, shared office and common space. This excludes SOC from inclusion.

Alternative	Description	Cost ($)	Size (Sq.Ft)	Site (Acres)	Cost / Sq.Ft	OM&A**	Benefits / Risks
Alternative Four	Acquire an existing facility for BUCC and BUITMC and integrated Data Centre	Not available. Building specific market scan by Andrew Thompson and Associates (ATA) indicated no suitable site for consideration at time of assessment. Hydro One owned sites were reviewed internally; however also found that no suitable site or facility existed.					
Alternative Five	Build Primary NOD Control Centre, primary SOC, and BUITMC.	$141.9M*	146,200	16.41	$971	$4.47M	This option assumes that the existing OGCC staff would be moved to the new ISOC and the current OGCC used a Backup. Additional compute / system investment required which is not included in total cost.
Alternative Six	Initiate Build of ISOC with future dual operating capabilities.	$130.0M*	126,200	16.41	$1,030	$4.47M	Provides a NOD BUCC, BUITMC, and Primary SOC including shared integrated Data Centre, and back office support. Current lifecycles for critical applications respected, alleviating addition IT requirements to enable Primary operability. Dual Primary enabled for future implementation.
Ontario Grid Control Centre (data for comparison purposes)		$144.9M	68,000	9.25	$2,131	N/A	Presented in 2016 dollars (originally $118M investment in 2003) Provided for comparison.

*The Distribution portion of this total is 50.07% of the total cost.

**The OM&A cost estimates are the full total cost, and these have not been adjusted to show the distribution portion only.

Data Centre Construction vs. Leased Data Centre

In addition to the above alternatives, a comparison between the option of construction versus a comparable colocation or leased data centre option was conducted by engineering firm Morrison Hershfield, to ensure the most cost effective means of providing needed Data Centre space. This is the largest cost consideration in the overall project total. This assessment was based on a 15 year term based on market prices in the Toronto area. The Toronto area was utilized for this study as it provided a much larger pool of lease options with the required reliability / Tier level standards. The results are shown below which indicated that the co-location/lease option ($122.1M), based on the current design criteria, far exceed the cost of the build option ($73.2M) ($30M in Capital + Incremental annual OMA at $2.5M escalated at 2% per year for 15 years, $43.2M).

	IT/POWER MRC*	**Annual Cost of Rent**
Year 1	$ 341,144.00	$ 4,093,728.00
Year 2	$ 372,529.25	$ 4,470,350.98
Year 3	$ 406,801.94	$ 4,881,623.27
Year 4	$ 444,227.72	$ 5,330,732.61
Year 5	$ 529,725.56	$ 6,356,706.73
Year 6	$ 529,725.56	$ 6,356,706.73
Year 7	$ 578,460.31	$ 6,941,523.75
Year 8	$ 631,678.66	$ 7,580,143.93
Year 9	$ 689,793.10	$ 8,277,517.17
Year 10	$ 753,254.06	$ 9,039,048.75
Year 11	$ 822,553.44	$ 9,870,641.24
Year 12	$ 898,228.35	$ 10,778,740.23
Year 13	$ 980,865.36	$ 11,770,384.33
Year 14	$ 1,071,104.97	$ 12,853,259.69
Year 15	$ 1,169,646.63	$ 14,035,759.58
	Total 15 Year Spend	$122,101,320.25
*MRC = Monthly Recurring Charges include IT load rent, estimated power charges and PUE of 1.6		

Other factors that affected this consideration are; a) no co-location facility provides NERC certified space which would require additional upfront capital cost in year one, b) many facilities have policies that dictate access, upgrade, expansion and security for the facility without renter input which exposed Hydro Ones critical equipment to further risks.

ISOC Breakdown	**Est. Cost**	**Ft2**	**$ / ft^2**	**Report Findings of Morrison Hershfield on Build Comparisons**
Building Shell Cost	$23M	120,534	$250	Includes shell and basic Mechanical Electrical Power services. This is considered at the bottom of the range of $250/ft2 -$1000/ft2 for hardened facilities of this type, which equals the cost per square foot for SaskPower's most recent facility design. Variance consisted of EF3 Tornado rate vs. EF4 for SaskPower with less office space and did not have Control Room space. Average generic office space range from $150 - 250/sq. ft. dependent on finish and furnishings.
Data Centre Cost	$30M	11,990*	$2502	SaskPower's estimates cost per sq. ft. for data centre space was $3,000 / sq. ft. and it is MH's conclusion that $2502 is within range of similar facilities. A similar telecom project in 2015 with a similar Tier level as HONI was $2575/sq.f.t.
ISOC Total	$130M**	127,703	$1018	This includes Building Shell, Outdoor Yard and Data Centre.

- **Included support galleries (cooling, power distribution).*
- ***Note: The Distribution portion of this total is 50.07% of the total cost.*

<u>Comparisons to Similar Facilities at Other Utilities</u>

Lastly, NOD reviewed a number of utilities investments in facilities and data centre development projects to ascertain the reasonableness of the ISOC scope as compared to the rest of the industry. Below is a table summarizing these findings; which show the ISOC is in line with the cost per square foot for comparable projects.

Industry Comparators	**Description/Name**	**Cost ($M)**	**Size (Sq. ft.)**	**Year Built**	**Adj. Cost to 2016 $ (CPI)**	**Cost (2016 $) / Sq. ft.**
New York Independent System Operator	NYISO Control Center	$59.4M	64,000	2014	$60.82M	$950
American Electric Power	Transmission Operations center	$57.2M	83,500	2007	$65.92M	$789
ISO-New England	Windsor Backup Control Centre	$50.7M	70,000	2014	$51.91M	$742
Pacific Gas & Electric	Distribution Control Center	$52.0M	37,674	2015	$52.57M	$1,395
	Distribution Control Center	$37.05M	24,000	2014	$37.97M	$1,582
	Distribution Control Center	$46.8M	50,000	2016	$46.8M	$936
First Energy	FirstEnergy Tx Control Centre	$58.5M	70,000	2013	$61.16M	$874
BC Transmission Corporation	System Control Modernization Project	$133M	113,022	2008	$148.07M	$1,310
	System Control Centre (building ONLY)	$40M	64,584	2008	$44.53M	$689
	Backup Control Centre (building ONLY)	$30M	48,438	2008	$33.4M	$690
Average Cost :				-	$60.3M	$996
Distribution Portion of ISOC.		$64.4M	63,851.5	2016	$64.4M	$1,009
Proposed ISOC Cost Comparison		$130M	127,703	2016	$130M	$1018

Converted from USD to CDN at an exchange of 1 USD to 1.3CDN

Note: The ISOC is comprised of Distribution, Transmission, ITMC and SOC.

Site Assessment

As the table below shows, sites south of Barrie were higher cost and the sites North of Barrie were considerably less expensive. Orillia, given its relative location compared to the Primary Centre, was optimal given the City size, access, lodging, development and emergency services, including the OPP headquarters. Communities further away were ranked lower due to distance, access to emergency services, development and lodging, winter driving hazards and relative site suitability among other factors.

Ranking	Community	# of Sites	Ave. Cost / Acre
1	City of Orillia	4	$114,935 - $181,200
2	Town of Bradford	3	$346,636
3	Town of Collingwood	3	$135,469
4	Town of Midland	6	$90,000
4	Town of Penetanguishene	3	$87,500
5	Town of Alliston (New Tecumseth)	3	$273,900
6	Town of Newmarket	2	$850,000
7	Town of Orangeville	1	$215,000
8	East Gwilliambury	6	$400,000
9	Angus	1	$80,000
10	Innisfill	0	$ -
11	Schomberg (King Township)	1	$475,000
12	Wasaga	0	$ -

Note: An assessment of internal Hydro One TS sites was reviewed against available acreage and emergency preparedness criteria and was determine that there was no existing Hydro One site that could accommodate the proposed facility. This represented a departure for previous assumptions with impacts of land purchase and support infrastructure that must be extended to the preferred site.

GP-19 Operating - Common Information Technology Infrastructure

Start Date:	Q1 2017	**Priority:**	High
In-Service Date:	Q4 2022	**Plan Period Cost ($M):**	11.0
Primary Trigger:	Asset Driven		
Secondary Trigger:	Reliability/Performance		

Investment Need:

The Common IT ("Information Technology") infrastructure is the shared IT backbone of Network Operating's critical enterprise systems. It is technically more efficient and maintains a lower total cost of ownership as compared to multiple discrete instances to support specific systems. This translates into less sustainment and total system component purchases. Common IT infrastructure is further defined into sub categories, which include:

- Data storage (devices that retain, retrieve and archive digital computer data "information");
- Compute servers (processors that fetch, decode, execute and write data in response to system processes and application inquiries);
- Computer consoles (microcomputers used by Operating Dispatchers, Operators and Managers to interface with applications);
- Information Technology networks (a series of communication paths interconnecting IT devices); and
- Operating Systems/Applications/Software (i.e., VMware, a virtualization of servers/desktops), Citrix (presentation software), Windows Server and Desktop OS.

Each sub category includes hundreds of individual assets, both hardware and software products. IT products have lifecycles for a number of reasons, for example market performance, and technology innovation and development, drive change in products or the product matures and is replaced by functionally richer technology. As new technologies are developed, support and the ability to purchase spares or replacements equivalent to in-serviced assets is more costly and difficult to achieve. Regardless of the reason for change, supporting products beyond their lifecycle poses increased risk to Operations.

If extended support agreements are made available, the costs are typically a minimum of two to three times that of current supported market products, which drives consumption to the latest offering. Furthermore, product replacement parts become scarce and inflated in price and run the risk of non-compatibility with other more current devices. These factors and others make the employment of products beyond their lifecycles untenable. As each device is interdependent and the future replacement technology attributes are almost always unknown, pacing and prioritizing is an ongoing effort. Vendors often announce lifecycle support conclusion dates with minimal notice. The continuous process of assessing device compatibility at its lifecycle conclusion requires careful architectural consideration to ensure system reliability and performance standards are constantly being met.

This investment is comprised of multiple asset groupings, and is required to maintain the viability of the common IT infrastructure for Operating's computer applications such as the Outage Response Management System, Network Outage Management System, Network Management System, and Distribution Management System. (Discrete application infrastructure is not included in this investment). These applications are leveraged by both Distribution and Transmission. However this investment represents the Distribution portion exclusively.

Alternative 1: Status Quo:

This alternative is to maintain status quo: do nothing and continue to use the existing IT infrastructure. As each device represents an important interconnected component of the common infrastructure, not proceeding with these lifecycle replacements could result in the following:

- Hydro One's diminished capacity to serve and respond to customers;
- Regulatory non-compliance with the potential for heavy fines;
- Potential loss of one or more mission critical applications;
- Significant increase in Operating maintenance costs;
- Loss of the original equipment manufacturer/vendor support;
- Increased probability of system failures;
- Inability to recover from system failures;
- Increased vulnerability of cyber terrorist attacks;
- Potential to strand future application upgrades and enhancements; and
- Risk of costly remedial efforts in the event of a failure.

Alternative 2: Maintain Supported IT Infrastructure (Recommended*)*:

Lifecycle management based on industry best practices and vendor support schedules ensures the viable operation of Operating IT infrastructure assets, including the enablement and continued reliability of critical application systems. The dynamic architectural model requires Operating to plan and replace devices with the appropriate current technology and is recommended as the only viable option. This option offers the following benefits:

- Continued compliance with availability and reliability standards;
- Current market product maintenance and support costs;
- Original Equipment Manufacturer ("OEM")/vendor provided updates and software patches;
- OEM/vendor available replacement parts at current market prices;
- System compatible infrastructure devices; and
- Improved ability to recover from random failures.

Through systematic replacement of common IT infrastructure Hydro One Networks can sustain business functions by ensuring the tools and systems used to support Operations are functioning as designed, are fully supported, and ensure any failure can be readily remediated. This provides the assurance to Hydro One customers that IT failures will be minimized and if a failure is experienced it will be returned to service in a timely fashion. This approach maintains Hydro One's commitment to customer satisfaction by ensuring responsiveness through system availability.

Investment Description:

These IT infrastructure investments include the following asset sub categories and are located at both the Ontario Grid Control Centre ("OGCC") and the Back-up Control Centre ("BUCC"). Servers, PCs and disc drive counts are always fluctuating depending on the current state of lifecycle management projects. Lifecycles of the various components are dynamic, and can at times be interdependent, influencing other components. The hardware is generally problem-free, however lifecycle management means keeping it in a supportable state as dictated by the vendor. Disc drives do fail but are replaced under service agreements. All devices would be current to the year they were "lifecycled" and there isn't a single "project" that replaces everything at once in a single year therefore the age distribution will always vary. Lifecycle planning forecasts in each category has leveraged historical trends, however careful consideration regarding the lifecycle replacement and transferability of the infrastructure will be provided as Operating relocates the BUCC into the Integrated System Operations Center beyond 2020 including:

- Data Storage (i.e., storage area network devices "SAN"; achieve data storage backups);
- Compute Servers (i.e., secure file transfer devices; monitoring systems; server operating systems);
- Computer Consoles (i.e., Windows operating systems; peripheral devices);
- IT Networks (i.e., remote access devices; satellite time clocks); and
- Operating Systems/Applications/Software (i.e., VMware, a virtualization of servers/desktops), Citrix (presentation software), Windows Server and Desktop OS. Oracle and SQL database applications.

A failure of a single component has the potential to cause cascading impacts including; a failure of a critical application and the business function it supports, removal of system redundancy, or worst case, render the OGCC and/or computer systems unavailable. The resulting impact on work execution and customers could be as follows:

- Cancellation or delay of outages requiring planned field work causing customer or Hydro One work to be delayed, requiring rescheduling, reprioritization and rework;
- Unresponsive distribution outage management and lack of communication with customers and staff posing work delays, safety risks and inability to respond to emergency events (i.e. if failure occurs during Storm event); and
- Backup activation which limits full business function and hinders critical response.

Risk Mitigation:

Replacing end of life infrastructure assets is recommended as "best practice" in order to maintain Network Operating's current supported, compatible and redundant IT infrastructure and equipment. The ongoing dynamic processes to cost effectively assess, prioritize and stage each product in its respective category must remain in focus by Hydro One's Power System IT architecture team and supporting management and staff at all times in order to achieve success now and in the future. The driving focus behind these processes is to maintain current reliability and service levels with the continued support of mission critical applications and their function is to serve Hydro One's customers in the most cost effective manner possible.

Result:

These investments will provide cost conscious ongoing product support and dynamic lifecycle management for all common Operating IT infrastructure assets.

Outcome Summary:

Customer Focus	• Provides continued support to key customer applications such as the Outage Management System supporting emergency storm response, communication, and outage coordination. • Minimizes customer risk and associated impacts of outages of the system.
Operational Effectiveness	• Provides Operating IT infrastructure the required facilities to holistically support mission critical Operations applications, systems and their functions. • Decreases risk of reduced performance, or an inability to meet service levels in the event of a failure.
Public Policy Responsiveness	• Ensures mission critical Operations applications and systems are supported with the current, compatible and supported IT infrastructure to maintain reliability and availability targets and meet regulatory requirements with regards to cyber security, reliability (redundancy), etc.
Financial Performance	• Provides cost effective management of IT lifecycles with current and supported common “shared” IT infrastructure. • Reduce OM&A and negate the need for costly extended support. • Improved asset performance, and greater ability to recover from a failure. A single failure can impose significant costs from the disruption to business function, increased labour cost for emergency break fix needs and other remedial efforts.

Costs:

This group of investments is estimated based on historical cost, subject matter and industry experts input, assessments and will be adjusted for the project scope, local condition and market pricing at the time of the investment.

Controllable cost have been minimized through the continued use and shared costs of common platforms, maximizing space, storage, and networking; maintaining current versions / latest technologies to maintain or reduce OM&A costs; and bundling of work to minimize outages or impacts to Network Operating.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

GP-20 Network Outage Management System (NOMS) Refresh

Start Date:	Q1 2016	Priority:	High
In-Service Date:	Q2 2018	Plan Period Cost ($M):	1.1
Primary Trigger:	Business Operations Efficiency		
Secondary Trigger:	Reliability -Regulatory		

Investment Need:

The Network Operating Divisions ("NOD") Network Outage Management System ("NOMS") is Hydro One's primary outage planning tool. The associated hardware and software is specific to NOMS and does not include any shared storage in the Common Information Technology infrastructure. As required by the Ontario Energy Board ("OEB") Distribution System Code ("DSC") and Hydro One's Conditions of Service, NOMS provides essential coordination and scheduling of planned outages through integration with enterprise systems and the internal lines of business for reduced customer impact, optimized outage performance and improved communication amongst stakeholders (i.e., Local Distribution Companies, Large Distribution and Transmission customers, Hydro One work groups).

NOMS is an essential tool for planning, scheduling, assessing and executing distribution equipment outages. The viability of the tool is being reviewed and investigated for potential options including the implementation of a version upgrade or a total replacement of NOMS. Factors being considered are availability, sustainment cost, system growth, the availability of new technologies, and compatibility with other critical Operations systems and applications, such as the Equinox Control Room Operations Window ("CROW"), Utility Work Protection Code, Electronic Log, and SAP applications. The system must be supported by the vendor or Original Equipment Manufacturer (OEM) as the risk of system downtime directly affects distribution operations and Hydro One customers.

The investment in a new NOMS tool must also satisfy regulatory requirements such as the OEB DSC Section 4, Operations; specifically Section 4.4.7 which requires a utility to provide as much advance notice as possible for the duration and frequency of a planned outage. This outage tool must also ensure compliance with Hydro One's Conditions of Service policy, Section H, Outage Notifications Process with customers.

The current version of NOMS was placed in service in 2010 after an application software upgrade to version 2.0 (NOMS V2). The software upgrade did not include a hardware upgrade at that time. The NOMS system consists of application servers, primary database servers, reporting database servers and a backup disaster recovery database server. An investment is now needed to upgrade the NOMS application and hardware to address four inadequacies of the current system that pose operational risks to Hydro One:

- Vendor support has expired and extended support is no longer available on servers running Oracle's 10g software;
- Application and Database servers have reached end of life; and
- The Windows 2003 Operating System used for the NOMS application server is no longer supported and update patches are no longer available.

The results of these operational risks of running an unsupported application will only increase Hydro One's inability to recover outage planning systems in the event of a system failure. The impacts to Hydro One's business in the event of these failures would be loss of outage planning and coordination abilities, higher maintenance costs, failure to efficiently communicate outage planning efforts with stakeholders, and decreased safety for Hydro One employees.

Alternative 1: Status Quo:

The Status Quo alternative would maintain the existing NOMS unsupported software and end of life hardware. This alternative has been rejected for the following reasons:

- Continuing operations with end of life system hardware will increase the likelihood of a NOMS failure;
- Continuing operations on end of life hardware without vendor support will hinder Operations ability to recover systems in the event of a failure;
- Maintaining end of life hardware results in increased maintenance costs and workarounds; and
- The risk of increased frequency and duration of customer outages and reduced distribution system performance.

The risk and impact in the event of a failure of NOMS will be significant given the primary function of NOMS is to plan and coordinate all Hydro One work execution activities. This will have a significant effect on the operation of the Hydro One distribution system and its customers.

Alternative 2: Upgrade NOMS *(*Recommended*)*

This alternative would upgrade both hardware and software for the current NOMS application and address the unsupported software and the operational risks currently faced by Hydro One.

A new application, upgraded servers and operating systems will provide Hydro One with improved outage planning capabilities as part of the version upgrade and the ability to recover systems in the event of a failure that would otherwise not be possible with the Status Quo option. A reliable outage planning tool is a requirement of the OEB's Distribution System Code and Hydro One's Conditions of Service. It is prudent that a full NOMS upgrade is performed to maintain Hydro One's outage and work planning capabilities and to ensure the distribution system reliability and availability.

Investment Description:

Planned investments include a hardware refresh, operating system upgrade and the integration with other enterprise systems such as the Electronic Log, Utility Work Protection Code, SAP and the Outage Grouping and Assessment System Tool. These are either a part of the version upgrade or existing stand-alone systems that when integrated will enhance the flow and assimilation of information that will enhance the outage planning and reporting processes.

Risk Mitigation:

IT Infrastructure investments are complex and dependent on multiple technology factors including: application software, server capacity, physical constraints (i.e., cooling capacities), hardware compatibility and vendor support terms. Given these complexities, a development phase is being conducted as a part of the full NOMS upgrade to more effectively determine project costs and manage the risks and requirements associated with the project implementation. Additionally, an assessment of the enterprise systems; Electronic Log, Utility Work Protection Code, SAP, and the Outage Grouping tool will be performed to ensure value creation when merging the systems with NOMS.

Result:

This investment will result in the following accomplishments:

1. Increased stability of the NOMS system with upgraded hardware and software that has vendor support;
2. Reduced risk of a NOMS system failure;
3. Ensured regulatory compliance with the OEB Distribution System Code, IESO Market Rules and adherence to Hydro One's Conditions of Service;
4. Assessment and integration of internal and enterprise systems; and
5. Improved operational efficiencies and outage performance gained through the integration of enterprise systems and new technologies.

Outcome Summary:

Customer Focus	• Mitigate Customer impacts by providing as much advance notice as possible for the duration and frequency of a planned outage.
Operational Effectiveness	• Ensure reliability and availability of NOMS to ensure scheduling, coordinating and planning of Hydro One Distribution and Transmission System Outages. • Ensure operational efficiencies and process changes are fully leveraged by improving current workflow, coordination, grouping and execution of outage planning activities.
Public Policy Responsiveness	• Deliver outage management service obligations related to OEB Distribution System Code, Section 4, Operations, and IESO Market Rules part 7.3 Outage Management. • Maintain compliance with Hydro One's Conditions of Service.
Financial Performance	• Reduce extended support and maintenance costs associated with maintaining the system to mitigate failures.

Costs:

Costs are being controlled via an initial development phase, which will finalize scope, system architecture, and an execution strategy prior to full execution of this investment. In addition, several vendor products will be reviewed and assessed to determine which are the most cost effective and provide the most value. Lastly, through a full capital replacement, testing and commissioning activities will be completed simultaneously. This will negate the need for independent system component testing and allow the more efficient use of resources.

GP-21 Data Centre Remediation

Start Date:	Q4 2016	Priority:	Demand
In-Service Date:	Q3 2020	Plan Period Cost ($M):	4.6
Primary Trigger:	Asset Driven – End of Life – Capacity		
Secondary Trigger:	Reliability -Regulatory		

Investment Need:

Hydro One maintains substantial Information Technology ("IT") infrastructure to operate, manage and control the Bulk Electric System ("BES") and Provincial Distribution Networks. These systems must operate in compliance with various regulatory bodies including North American Electric Reliability Corporation, Independent Electricity System Operator's market rules and Hydro One standards.

The Ontario Grid Control Centre (OGCC) Data Centre facilities can no longer accommodate the immediate and short term capacity requirements, given that the existing facility is beyond its space, power distribution and cooling thresholds.

The OGCC IT infrastructure is critical to the reliable operations of the Bulk Electric System and ensuring that NERC requirements are addressed in a timely and focus manner. The Power System IT (PSIT) department which (a part of the Hydro One Information Solutions Division (ISD)) focuses exclusively on the tools and IT equipment that are used by the OGCC to monitor and control the Bulk Electric System. An analysis by PSIT has determined that in order to maintain the following 24/7 Operating applications and systems over the next four years: Distribution Management System ("DMS"); Outage Response Management System ("ORMS"); Network Outage Management System ("NOMS"); Control Room Information System ("CRIS"); and Information Technology Service Management ("ITSM"), additional Data Centre capacity will be required.

These systems are used exclusively by Operating to monitor and control the distribution and transmission system asset in a 24/7 environment. They are physically separated from any other H1 network or domain. However, due to the aforementioned space, cooling and power distribution constraints at the OGCC and the BUCC, and given that ISOC (ISD –GP-18) will not be in service until 2020, PSIT has determined that remediation of the OGCC Data Centre is the most strategic option for the following reasons:

- A number of the major infrastructure at the OGCC is either approaching or has reach its end of life and will have to be replaced. These will include PDU, CRAC units and the Cooling tower;
- Remediation of the OGCC Data Centre addresses the current capacity constraints as it relates to space, power distribution and cooling; and
- Ensures that the OGCC Data Centre which will become the Backup Data Centre once ISOC is built is fully operational and can provide redundancy to meet the required NERC standards and maintain operational best practices.

Alternative 1: Status Quo

This option assumes Hydro One maintains the current over capacity state specific to the Ontario Grid Control Centre's computer room facilities and continues utilization beyond asset useful life. This is not considered a prudent approach due to the criticality of the systems that reside within the Data Centre and could result in the following:

- Increased risk from use of equipment and system components beyond end of life;
- Hydro One's diminished capacity to serve and respond to customers;
- Potential loss of one or more mission critical applications;
- Increased probability of system failures;
- Inability to recover quickly from system failures; and
- Risk of costly remedial efforts in the event of a failure.

Alternative 2: Remediate the OGCC Data Center *(Recommended)*

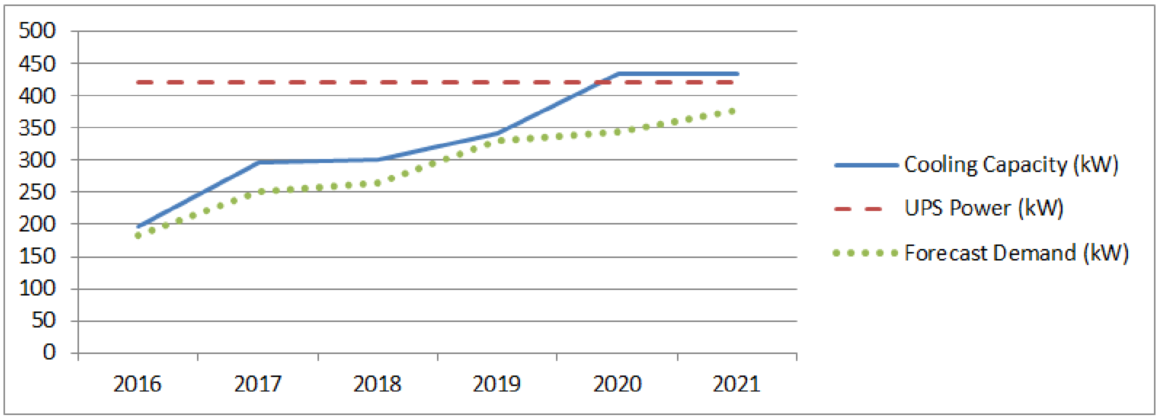
This alternative will remediate both computer rooms (A and B) located in the OGCC Data Centre in order to maintain system lifecycles and provide required capacity for system lifecycle management of critical operating systems and applications. This alternative remediates constraints and deficiencies to mitigate the increasing risk that the Data Centre environment and support infrastructure are posing on reliability of the system that reside within it. This will be accomplished by the following updates and changes such as:

- End of life replacements including increased capacity;
- Rack consolidation and defined infrastructure standardization;
- Decommission end-of-life powered IT infrastructure;
- Controlled air flow to enhance cooling efficiencies;

- Balance critical system loads over two Uninterrupted Power Supplies (UPSs) for redundancy; and
- Enhance Data Center protection, security monitoring and fire suppression.

The Data Centre's UPS power is reflected in the "dash line" at the top of the graph below. To utilize the 420kW of UPS power the project's activities will increase the cooling capacity (step function) from 197kW "solid line" and ultimately provide the Data Centre net capacity of 420kW. The "dotted line" represents the accommodated forecast demand over the project duration.

OGCC Data Centre – Cooling, Power and Demand (Computer Rooms A & B)



The remediation of the OGCC Data Centre to provide the needed facility capacities will support Operations functions over the next five years. This provides the assurance to Hydro One customers that Operations IT facilities are resilient with the capacity to facilitate mission critical applications and systems. This approach maintains Hydro One's commitment to customer responsiveness.

Investment Description:

This investment will provide an additional 223kW in Data Centre capacity through increased cooling and the redistribution of the available power based on the optimal physical space redesign of the computer rooms. This represents an increase from the Data Centre's current capacity of 197kW and provides the required Information Technology infrastructure into the foreseeable future.

This investment will ensure business continuity by maintaining the appropriate IT infrastructure to operate, manage and control the BES and Provincial Distribution

Networks. This is achieved via "mission critical" power system application lifecycle sustainment, maintaining continued vendor support, and without undue risk or threat of failure. This provides the assurance to Hydro One customers that IT failures will be minimized and if a failure is experienced, it will be returned to service in a timely fashion. As failures affect critical applications and tools, any failure can result in the OGCC being rendered unavailable for an extended period of time. A recent UPS failure and resulting equipment fire has shown that failures of support infrastructure have impacts on downstream elements. This investment approach maintains Hydro One's commitment to customer responsiveness by ensuring IT availability to maintain Network Operating key Operating and Dispatch functions. Below are the key activities of this investment:

- Reduce Data Center Load Risks:
  - Free Data Center floor space from rack consolidation activities and build new hosting standardization;
  - Reduce IT Infrastructure load to Power and Cooling by building new Pre-Prod and Prod environments at the Co-Location facility (ORMS, ITSM, NOMS, DMS); and
  - Decommission End of life powered IT infrastructure.
- Cooling:
  - Short term - Fix and control data center air flow to enhance cooling efficiencies;
  - Remediation of under floor cabling which is restricting airflow (utilized as the main plenum). This will include relocating cabling above the racks and improvements to the perforated tile system;
  - Define infrastructure standardization;
  - Expand cooling system infrastructure by using standalone (independent) cooling units with redundancy; and
  - Reduce the bottleneck demand on one type of cooling system inside Data Center.
- Power:
  - Build modern core power distribution;
  - Increase remote power distribution high-availability and flexibility at the rack level; and
  - Balance critical system loads over two Uninterrupted Power Supply (UPSs).
- Management and Remote Monitoring:
  - Implement remote management system and automated processes;
  - Enable proper monitoring system and automated reporting; and
  - Enhance data centre protection and security monitoring.
- Improved Fire Suppression and Monitoring:

- o Build level one first protection system (Gas system);
  - Gas protection systems can extinguish quickly, minimize damages lowering repair costs and providing a speedy recovery time.

Risk Mitigation:

Increasing the available capacity of OGCC Data Centre facilities to facilitate applications and system lifecycles is recommended as "best practice". The driving focus behind these facilities is to maintain current reliability and service levels and their function to serve Hydro One customers in the most cost effective means possible.

Ongoing work at the primary production Data Centre has potential to cause an unplanned system outage. This is mitigated by thorough failover automation and practices to the redundant production system located at the Back-Up Control Centre. In addition, co-location facilities will be leveraged to provide further redundancy and staging space.

In order to provide required interim capacity to enable this investment, a Co-location Data Centre facility will be leased during the remediation of the Ontario Grid Control Centre's onsite Data Centre. This ensures the work at the existing Data Centre can be accommodated in off-peak cooling seasons (the winter months) without outages or a significant reduction in the redundancy requirements, and ensures that both current and planned system lifecycle upgrades are not stranded.

Result:

This investment will provide a cost conscious approach and ongoing IT infrastructure resiliency supporting dynamic lifecycle management for IT assets located at the OGCC Data Centre. More specifically it will achieve the following results:

- Maximized cooling efficiency in both Data Centre rooms:
  - o Reduced load on chilled water cooling system;
  - o New cooling units to support Data Centre demand and enhance redundancy; and
  - o Eliminate the need to rent a mobile chiller unit during the summer months.
- Modern power distribution with enhanced monitoring and remote management system;
- Replacement of End Of Life (EOL) hardware infrastructure resulting in lower operating costs;

- Gain valuable data centre space for current planned investments and future growth; and
- Enhanced fire detection and suppression.

Outcome Summary:

Customer Focus	• Maintain Network Operating Customer service level agreements and meet reliability expectations. • Support customers by maintaining ability to provide storm or emergent response activities, communication outage coordination, dispatching functions, etc.
Operational Effectiveness	• Provide greater output capacity through optimization of support infrastructure and ensure adaptability to respond to business, regulatory or technological change. • Maximize available space, allow full utilization of existing assets and allow for future consolidation and standardization among IT racks, cabling, etc.
Public Policy Responsiveness	• Ensure that the primary Data Centre can maintain availability and reliability targets to a 99.95% target and maintain overall viability of the OGCC. • Maintains regulatory compliance to NERC, IESO Market Manual (Reliability of System Operations) and OEB Distribution & Transmission System codes.
Financial Performance	• Avoid costly new build or long-term rentals of a new facility for capacity offsite. This effectively negates further investment in net new equipment.

Costs:

The project will meet reliability / redundancy requirements by procuring interim short term co-location capacity to allow for Data Centre elements to be taken out of service while maintaining redundancy in critical applications. This will include a staged approach to ensure limited downtime / outages during execution.

A third party industry expert has reviewed the current requirements and has provisioned a detailed plan and cost estimate leveraging industry best practices, and market pricing with an aim to minimize ongoing maintenance (through Data Centre standardization and optimal configuration design).

GP-22 OGCC Office Remediation

Start Date:	Q2 2020	Priority:	Medium
In-Service Date:	Q4 2022	Plan Period Cost ($M):	1.6
Primary Trigger:	Business Operations - Efficiency		
Secondary Trigger:	Health, Safety & Productivity		

Investment Need:

The Ontario Grid Control Centre ("OGCC") is Hydro One's primary facility that operates and controls the Distribution System. The facility is the headquarters for Network Operations and Hydro One's primary Control Room, and the Distribution Outage Management Centre among other supporting functions, essential in operations, monitoring and control of the Distribution System. The OGCC building has been in-service and operational, 24 hours a day, seven days a week, and 365 days a year since inception in 2003. Since this time, there has been minimal investment to maintain it as a productive office environment beyond normal break-fix remediation.

The OGCC building now accommodates more people and technology than was originally forecasted. The interior office space requires renovation to replace end of life fixtures, furnishings, floor coverings, walls, and other items. A thorough review of the security features (windows, doors, mantraps) is required to ensure efficient entry and egress, while respecting regulatory requirements including monitoring. The office furnishings including cubicles, cabinets and tables were in "used condition" when installed at the OGCC in 2003. The furnishings are end of life and will be over 20 years old when this investment is implemented in 2020. Life cycle assessments recommend that the useful life for carpeting and wall paint is roughly ten years for an office environment. The disrepair of floor coverings has created a safety concern for employees. As the OGCC houses the main control room with 24/7/365 operations, it must be brought up to current safety standards.

Alternative 1: Status Quo

This option assumes Hydro One maintains the current conditions at the Ontario Grid Control Centre. This approach poses risks to Hydro One employees and Hydro One's public image. This alternative has been rejected for the following reasons:

- Safety concerns including floor coverings are lifting and creating hazards;

- Amenities such as fixtures, carpeting, furnishings and wall paint are all well beyond their useful life and are showing signs of disrepair; and
- The diminishing office condition can affect employee engagement over time.

Alternative 2: Remediate OGCC Office *(Recommended)*

The recommended alternative for the OGCC Office Centre remediation is to proceed with the investment as a refurbishment of the current facility in line with the construction of the ISOC. The existing fixtures, carpeting, cubicles and paint have diminished below acceptable standards since it was established in 2003 and will be refreshed. Control Room consoles will be replaced and or retrofitted to include sit /stand functionality to improve ergonomics for staff and to reduce the risk for potential musculoskeletal injuries which will reduce lost time. A remediation of the facility is the least costly option and operationally disruptive due to the magnitude of the current investment in the OGCC and the business functions it supports. This option also allows scheduling flexibility to align with the construction of the new ISOC facility. This recommended investment will address the concerns of degrading working conditions and safety at the OGCC while delivering the most cost effective approach.

Investment Description:

This investment will involve Control Room renovations and office area/hallways refresh of the OGCC. Expenditures include replacing carpeting, repainting areas, enhancing lighting, upgrading conference rooms, and replacing furnishing to meet Hydro One Corporate standards, Ontario Building codes and Health and Safety objectives. This investment will review and implement security upgrades to replace the “PODS” (mantraps with dual authentication) in the front lobby as well as enhance security in the reception area to maintain six sided security in compliance with NERC standards.

Risk Mitigation:

Safety is the number one mandate at Hydro One and should be considered in this investment. As fixtures and carpeting age and deteriorate at the OGCC, lifted flooring has posed an increasing safety risk to the employees working in the facility. A remediation of the office facility will avert this safety risk and aligns with Objective OS3 of the Ontario Building Code which aims to minimize the probability that a person is exposed to an unacceptable risk of injury due to hazards caused by tripping.

A remediation to the OGCC facility is warranted. To mitigate the risk of cost escalation, the remediation is scheduled to occur in 2020 and 2021 to capitalize on the available space at the new Integrated System Operations Centre ("ISOC") facility allowing the temporary relocation of staff during construction. The ISOC is the closest and most cost effective site for the temporary relocation of Control Room employees. This will also eliminate the cost of a leased/rented third party office. Remedial efforts are currently hampered by the impacts that would result on the real-time operations environment. Alignment with the ISOC will ensure remediation efforts are not restricted by health and safety concerns (i.e. off gassing) and facilitates the completion of remediation work during regular hours for the support office areas, avoiding overtime costs. This investment timing offers the most strategic and cost effective approach to remediating the OGCC and will minimize the cost burden to rate payers. The current BUCC is limited by space and cannot support both the Control Room and the supporting offices currently working out of the OGCC and therefore is not an option.

Remediation will focus on furnishings that offer the best durability for economic value so that the expected life of the office remediation can be maximized. This will include leveraging office cubicles that maximize occupancy thresholds in the building. A proactive approach is more cost effective than a break fix strategy by mitigating costs for overtime, emergency material orders and a disruption to daily events in a real-time work environment.

Result:

Completion of the necessary improvements to OGCC office and control room space to gain efficiencies and mitigate the health and safety hazards associated with a deteriorating workplace infrastructure. The timing of the investment will provide a cost effective solution for providing an effective work location during the office remediation and a more productive work environment on completion.

Outcome Summary:

Customer Focus	• Ensure fulfillment of Hydro One's mandate to its customers by maintaining a healthy/safe working 24/7/365 working environment.
Operational Efficiency	• Ensure that aging infrastructure is replaced in a timely manner to minimize disruption to operations resulting from the unavailability of the equipment or facility.
Public Policy Responsiveness	• Align with objectives set out in the Ontario Building Code that aim to minimize preventable safety risks inside and outside of Ontario buildings. • Address Occupational Health and Safety considerations to ensure staff are provided with the appropriate tools to prevent injury (i.e., Musculoskeletal risk requiring ergonomic requirements for 24/7 shift environment). • Maintain NERC requirements for six sided physical security perimeter for access control to the Ontario Grid Control Centre.
Financial Performance	• Reduction of OM&A costs for break fix / remedial efforts (at project completion).

Costs:

This investment is being timed to coincide with the construction of the ISOC project to minimize cost impacts for staff relocation to a third party site, or labour premiums and enhanced work efforts to isolate areas during construction.

GP-23 Integrated Voice Communications and Telephony Refresh

Start Date:	Q1 2021	**Priority:**	Demand
In-Service Date:	Q4 2022	**Plan Period Cost ($M):**	6.5
Primary Trigger:	Business Operations Efficiency		
Secondary Trigger:	Regulatory		

Investment Need:

The Integrated Voice Communications and Telephony System ("IVCT") is a mission critical system that provides voice communication management between the control centre, the IESO, Hydro One field staff, connected customers, and emergency services. The IVCT system provides integrated access and intelligent call routing via multiple communication methods incorporating multiple technologies to adequately manage the hundreds of control room calls each day. The IVCT system runs on various software, operating system, and hardware with vendor support, software patching and service lifecycles. Based on the current vendor support schedules and hardware lifecycles the IVCT system will require replacement in 2021 to maintain support and reliability of the system and the ability to recover in the event that a failure is experienced. The IVCT system allows Hydro One to meet various compliance regulations (Distribution System Code, NERC, Market Rules) that require redundant voice communications, and emergency communications that ensure constant communications paths.

The loss of voice communication between the Control Room (the primary users of the IVCT system), Hydro One customers and field staff, will result in the cancellation of planned outages and work activities until communication has been re-established. Without effective communication, there is a heightened risk to worker and customer safety (cannot dispatch emergency services or field staff), and a lack of situational awareness of local activities or external system events. This can have dire impacts on the Distribution System.

Alternative 1: Status Quo

This alternative maintains the existing IVCT system at end of life. This will expose Hydro One to reliability and sustainment risk as the current IVCT system will no longer be supported by the vendor. In addition, the ability to recover from a system failure will be negatively impacted and the maintenance cost for extended repairs or replacement components (old technology at this time) will be higher and more difficult to procure.

Witness: Colin Penny

The IVCT system is mission critical, as it handles all calls coming into and out of the Ontario Grid Control Centre (“OGCC”) and Back Up Control Centre (“BUCC”) control rooms. This includes communication with field staff, customers, and the IESO among others. A failure of the system would eliminate control room communication efforts, therefore impeding the operational effectiveness of the OGCC.

Alternative 2: “Off the Shelf” IP Phone

This alternative proposes the current system be replaced with generic IP phones utilized by back office staff, after the existing IVCT system reaches end of life. The generic IP phones do not have the same call handling functionalities or rolodex of frequent calls capabilities requiring additional tools and processes to ensure that control room staff efficiency is maintained and not subject to additional effort to complete the same tasks. These processes, which must be recreated for this Alternative, are more error prone and can impact employee and customer safety. Furthermore, the generic IP phones do not have any call recording capabilities to meet NERC compliance requirements. Lastly, the IVCT system includes the OGCC Interactive Voice Response (“IVR”) system which is used to direct incoming calls to the appropriate OGCC department and sort calls into queue(s) for processing. To ensure normal work flow can continue, integration with the IVR system is needed. Due to the aforementioned issues and concerns, and the inability to provide needed functionality, and integration with key elements, such as IVR, this alternative has been rejected from further consideration.

Alternative 3: IVCT System Refresh Project (Recommended)

It is recommended that Hydro One proceeds with the IVCT system replacement to ensure system reliability and sustainability. This alternative provisions the necessary replacement of the IVCT system in 2021, with a “like for like” system, taking advantage of productivity enhancements, and leveraging newer technologies when the existing IVCT system has reached end of life. This will maintain operational effectiveness and reliability of the control room by maintaining the communication channels utilized daily. This will also mitigate risk of control room downtime, work execution, planned outage cancellations, and the resulting impacts on Hydro One customers that these incidents cause. Control room staff utilizes the IVCT system when coordinating storm restoration, planned system maintenance outages, fulfilling IESO notification obligations, managing helicopter services, and, most importantly, emergency response assistance for field staff and Hydro One customers.

Investment Description:

Network Operating Division operates two Grid Control Centres. The IVCT system is used on a 24/7 basis at both control centres (OGCC & BUCC) and the Operating Planning department. The IVCT system is mission critical and provides effective voice communication management from both control centres with the IESO, interconnected utilities, Hydro One customers, emergency services and field staff. Due to the critical nature of the IVCT system, and the impact of a failure on Hydro One's work execution, customer outages, responsiveness, and inability to effectively dispatch for emergencies, this system is planned to be replaced based on recommended lifecycle schedules. The failure of the IVCT system would severely impair Hydro One's ability to monitor and mitigate system events.

This investment will replace or upgrade the application software, and associated hardware (dedicated servers) at the OGCC and BUCC (which is ultimately planned to be relocated to the Integrated System Operating Centre ("ISOC")).

This investment is scheduled based on historical IT life cycles for previous instalments of the IVCT system with consideration of software, operating system, and server hardware lifecycles. An asset condition assessment review may be made closer to the investment start date to determine how best to proceed.

Risk Mitigation:

To reduce project execution risk, a pilot IVCT system will be designed and tested prior to full deployment, including parallel system use prior to final cutover. Furthermore, an experienced system integrator vendor, with expertise in deploying similar IVCT systems, will be retained to oversee the project.

Productivity enhancements and new technologies, such as automated voice-to-text capabilities, will be individually evaluated through a cost-benefit analysis closer to the project start date to ensure value for the required investment. Timing of this activity is required prior to commencement, as technologies and improved functionality today may differ significantly in 2020/2021.

Result:

This investment will ensure reliability of the IVCT system and promote productivity in the control room while meeting all regulatory requirements. The IVCT is set with user friendly touchscreen interface, quick dial functionalities, and a customized Rolodex contact database to help controllers do their job more accurately, more efficiently, and faster. The IVCT helps Hydro One operations meets its obligations under the OEB Distribution System Code, IESO Market Rules, and NERC (see Public Policy Responsiveness section below for full details).

Outcome Summary:

Customer Focus	• Support customer reliability by maintaining low call handling time and fast storm restoration response. • Keep customers informed of outage status using Autodialer functions and therefore improving customer satisfaction.
Operational Effectiveness	• Allows Hydro One control room staff to more efficiently co-ordinate storm restoration, protection maintenance work, system events with field staff, other LDC, and end use customers. • Ensure effective response and minimizing outage times.
Public Policy Responsiveness	• Allow Hydro One to meet obligations under OEB Distribution System Code (Section 4) regarding operations requirements. • Allow Hydro One to meet obligations under IESO Market Rules (Part 7.3) regarding outage management procedures. • Allow Hydro One to meet event reporting and investigation obligations as specified in NERC standard EOP-004, and COM.
Financial Performance	• Effective communications ensure the quickest dispatch for faster restoration times which translates into less hours spent by field crews during unscheduled events, reducing field costs.

Costs:

This is a reoccurring investment and the budget cost has been determined based on estimates by the Power System Information Technology ("PSIT") division utilizing historical IVCT investments. Based on lessons learnt from previous IVCT projects, this proposed budget takes into consideration all relevant costs (including license fees, changes to interest/overhead charges) which may not be initially obvious. The ongoing sustainment upkeep cost of the new IVCT system will have to be submitted by prospective vendors as part of their solution proposal. The OM&A cost for the current IVCT system is approximately $1 million annually. Hydro One will strive for the new IVCT system to have OM&A cost equivalent to the current system or less. Final costs of the project are influenced by the change in technologies and costs associated with the infrastructure supporting it, including market pricing at that time. Technological uncertainties and obsolescence are always a challenge for capital projects that are expected to start four to five years later. Hydro One is continuously monitoring technological developments and industry best practices to ensure the most cost effective solution.

GP-24 Station Security Upgrades

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Q4 2022	**Plan Period Cost ($M):**	5.7
Primary Trigger:	Security		
Secondary Trigger:	Safety		

Investment Need:

Grounding systems are used in stations to safely dissipate fault currents into the ground in the event of equipment failure and to safely dissipate neutral currents into the ground to protect Hydro One employees and the public. Copper in station and fence grounding systems, ground connections and neutral connections for electrical equipment are often targeted for theft in Hydro One distribution stations. The removal of ground and neutral copper connections compromises the electrical integrity of the grounding system. This can pose safety hazards to Hydro One employees and the general public, which can result in physical injury, including death.

Thieves have gained access into stations by cutting through chain-link fence fabric or breaking lock mechanisms. This investment addresses break, enter and theft at stations through the installation of improved security measures to reduce such occurrences. These upgraded security measures will improve health and safety, benefiting Hydro One employees and the general public.

The Distribution Station Security Upgrades investment addresses the need to implement increased security methods to mitigate break, enter and theft occurrences within distribution stations.

Alternative 1: “No Funding Alternative”

If no funding is provided to allow for security upgrades in distribution stations, then stations will continue to have break-in occurrences, and copper and neutral grounds will continue to be stolen. Hydro One maintenance staff will continue to replace the stolen grounds under corrective maintenance programs, and thieves will continue to return to the same stations to steal the ground and neutral conductors once they are replaced, jeopardizing the health and safety of those involved.

Urban stations are inspected by maintenance staff monthly and rural stations are inspected every 6 months. If station fences are cut, locks are broken and/or grounds are stolen, the public could be exposed to these dangerous conditions until the next station inspection.

Alternative 2: Install Security Upgrades *(Recommended)*

The preferred alternative is to install security upgrades including more robust perimeter protection and alternatives to copper in distribution stations to deter break and enter occurrences, and prevent thieves from stealing copper grounds and neutral conductors in specific areas. Installation of security upgrades will mitigate the exposure of the public to compromised grounding systems, as well as compromised station perimeters.

Investment Description:

The scope of work for this investment involves the installation of upgraded security measures at distribution stations to mitigate break and enter occurrences, and prevent thieves from stealing copper grounds and neutral conductors. Over the past five years, there has been 120 break, enter and/or theft occurrences at Hydro One distribution stations. During this period, the total number of occurrences has been reduced by 50% through minor security upgrades which are addressing fence perimeter grounding. However, break and enter occurrences have been increasing each year. Yearly candidates for distribution station security upgrades under this investment will include those which have had multiple break, enter and/or theft occurrences in recent years. The proposed funding level will allow for three stations to receive major security upgrades each year over the planning period. The major security upgrades will mitigate break and enter occurrences in addition to addressing perimeter grounding. Stations which are candidates for station refurbishment projects will also be considered for major security upgrades.

Risk Mitigation:

The risk associated with completion of the security upgrades projects includes the lead time required to procure the security upgrade materials, which Hydro One does not typically purchase. Completion of the projects within the planned years could be at risk if long lead time materials are not procured in a timely matter. The risk is mitigated by the procurement of long lead time materials in the year before the project is planned for completion, to allow the construction to be completed in the planned year.

Result:

Station security upgrades will result in the following:

- Break, enter and copper theft occurrences at stations which have received multiple occurrences in recent years will be mitigated;
- The electrical integrity of station and fence grounding systems in distribution stations will be preserved, allowing for the safe dissipation of fault currents and neutral currents into the ground;
- Exposure of the public to compromised station perimeters and grounding systems will be mitigated; and
- The safety of Hydro One employees and the general public will be improved.

Outcome Summary:

Customer Focus	• Improve integrity of station perimeters and grounding systems to maintain public safety.
Operational Effectiveness	• Maintain safe operation of distribution stations by addressing stations with multiple break, enter and theft occurrences. • Introduction of innovative ways of upgrading security measures to reduce theft.
Public Policy Responsiveness	• Comply with the Distribution System Code requirement to ensure that appropriate follow up and corrective action is taken regarding problems identified during station inspections.
Financial Performance	• Reduce high cost of material theft; primarily copper.

Costs:

Factors affecting the cost of each project can include the type, manufacturer and magnitude of the material to be installed. Vendors with the most cost effective and practical material will be selected.

GP-25 Leamington TS Capital Contribution

Start Date:	Q2 2016	**Priority:**	High
In-Service Date:	Q2 2018	**Plan Period Cost ($M):**	2.2
Primary Trigger:	System Capital Investment Support		
Secondary Trigger:	Load Growth		

Investment Need:

To increase transformation capacity to accommodate the forecast customer load growth and to improve reliability in the Windsor-Essex region, as documented in the Windsor-Essex Regional Infrastructure Plan as well as in Exhibit B1, Tab 3, Schedule 11, ISD# D-14 of Hydro One's 2017-2018 cost of service transmission application (EB-2016-0160). Not proceeding with this investment would result in further degradation of load supply reliability in the region.

Alternatives:

Alternative 3 was approved by the Ontario Energy Board under s.92 application for the transmission investment (EB-2013-0421).

Alternative 1: Do Nothing

This alternative is not recommended because Hydro One Distribution would not be able to meet the supply needs for normal load growth and the additional capacity requirements for large distribution load customers and distributed generation customers.

Alternative 2: Build a New Transformer Station near Woodslee Junction and Upgrade the 115 kV Connection Line Supplying Kingsville TS

One alternative is to strengthen the existing 115 kV system and replace the assets reaching their end of expected service life. The existing 115 kV transmission system would be strengthened by building a new transformer station near Woodslee junction and upgrading the 115 kV connection line between the new TS and Kingsville TS. The three transformers at end of expected service life at Kingsville TS would be replaced like-for-like. In addition, two new feeders would be built to address the load growth in Leamington. This alternative is not recommended because the total project cost would be approximately $97 million, which is significantly higher than the recommended alternative.

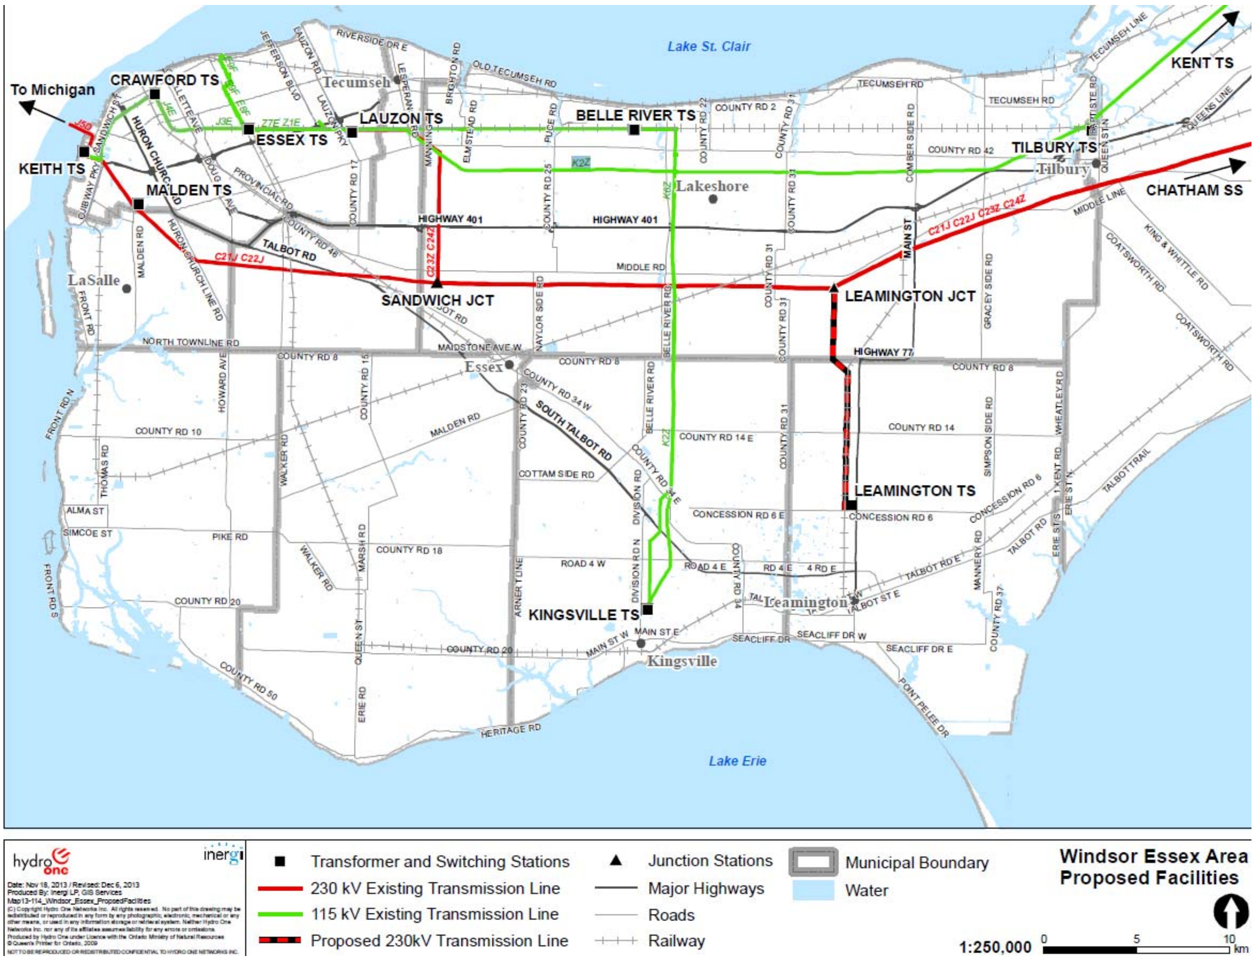
Alternative 3: Supply to Essex County Transmission Reinforcement ("SECTR") project *(Recommended)*

The preferred alternative is to build a new 230 kV – 27.6 kV DESN station at Leamington TS. This alternative offers significant reliability, efficiency and operational improvements. It enables the decommissioning of two of the transformers at Kingsville TS that are reaching the end of their expected service life, and replacement of a third which has also reached its service life. It also addresses the concerns with limited thermal capacity and short circuit levels. Furthermore, distribution feeder lengths supplying the Leamington area would be reduced from 15-20 kilometres to 5-10 kilometres, providing improved supply reliability, supply voltage and reduced line losses. This alternative meets all the identified transmission system needs as well as providing additional capacities for both load growth and distributed generation. The total project cost would be approximately $72 million with a Hydro One Distribution capital contribution of $21 million. It is expected that a portion of the contribution will be recovered from the embedded local distribution companies and large distribution load customers in the Kingsville-Leamington area, subject to OEB approval under the Regional Planning and Cost Allocation proceeding (EB-2016-0003).

Not proceeding with this investment would result in multiple, costly projects to address the transmission and distribution issues within the area. This investment provides the most cost effective solution for meeting the needs in the Kingsville-Leamington area and the surrounding Windsor-Essex area.

Investment Description:

The map below depicts the existing and proposed electricity transmission systems in the area:



The preferred solution includes construction of a new transmission station, Leamington TS and approximately 13 kilometres of new 230 kV double-circuit line. The installation of a new 230 kV – 27.6 kV DESN at Leamington improves reliability, provides capacity to accommodate the load growth within the Kingsville-Leamington area, and provides restoration capability for the Windsor-Essex area. With the new DESN in the area, Kingsville TS capacity can be reduced. Only one of the three transformers at the end of their expected service life will be replaced and the other two transformers will be decommissioned.

Hydro One Transmission will build the new Leamington TS and the new 230 kV double-circuit line and they have already commenced work on the project. Hydro One Distribution will pay capital contributions to Hydro One Transmission. A portion of these contributions is anticipated to be recovered from the embedded local distribution companies and large distribution load customers in the Kingsville-Leamington area. The capital contribution amounts provided in the "Costs" section below are preliminary and will be determined and finalized in accordance with the Transmission System Code.

Risk Mitigation:

This project is subject to the outcome of the Regional Planning and Cost Allocation Review proceeding (EB-2016-0003) which is currently before the OEB. The cost table below is based on the latest estimate of project cost, and assume the OEB approves the Hydro One proposed methodology described in its application for leave to construct a new transmission line and facilities in the Windsor-Essex Region (EB-2013-0421). Revised project costs or approval of a different cost allocation methodology may affect these numbers.

Hydro One Distribution has been in direct contact with affected LDCs and Hydro One Transmission on the SECTR project since the Windsor Essex Regional planning initiative began in 2014. Furthermore, Hydro One Distribution met with the impacted LDCs in March 2016 to review the distribution work in the SECTR project and the overall transmission project status.

Result:

- Increase transformation capacity to meet future load requirements for the Kingsville-Leamington area as per section 3.3.1 of the Distribution System Code;
- Improve operational effectiveness by increasing reliability of supply for customers in the Kingsville-Leamington area and the surrounding Windsor-Essex area; and
- Savings financially through reduction in costs and resources by addressing multiple issues simultaneously.

Outcome Summary:

Customer Focus	• Increase capacity to allow connection of large distribution customers and promote economic development in the area. • Allow more distributed generation customers to connect to the system.
Operational Effectiveness	• Leamington TS will provide 230kV service in the area and shorten feeder lengths which increase efficiency and reliability of the system.
Public Policy Responsiveness	• Meet the requirements of the Distribution System Code and distribution license to respond to embedded LDCs and large customer requests for increased capacity and to accommodate load growth.
Financial Performance	• Cost savings are realized by addressing multiple issues simultaneously in one project.

Costs:

The estimated cost of the contribution to the project is based on detailed estimates prepared by Hydro One Transmission, which have been determined using a cost allocation methodology submitted to the OEB for approval in proceeding EB-2016-0003. In the current planning period, the capital contribution to Hydro One Transmission is approximately $21 million. Of this amount, the LDC's and large customers' share is approximately $14 million, and Hydro One Distribution's share is approximately $6.7 million.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Plan Period Total**	**Total Project Costs****

GP-26 Hanmer TS Capital Contribution

Start Date:	Q2 2017	**Priority:**	Medium
In-Service Date:	Q1 2019	**Plan Period Cost ($M):**	3.7
Primary Trigger:	System Capital Investment Support		
Secondary Trigger:	Failure Risk		

Investment Need:

To address end-of-life assets, load growth and reliability in the East Sudbury area. The corresponding transmission investment was described in Exhibit B1, Tab 3, Schedule 11 of Hydro One's 2018-2018 transmission cost-of-service application (investment summary document #D18).

There are a range of needs to be addressed in the northeast Sudbury region including:

- The Valley East community within the City of Greater Sudbury has experienced steady load growth and is expected to continue growing at 2% per year. Martindale TS M6 is presently approaching its planned loading limit;
- Martindale TS M6 feeder is in poor condition and has demonstrated very poor reliability. There are also accessibility issues as portions of the M6 feeder are off-road through a mining reserve;
- Hydro One Transmission has concluded that the T2 and T3 transformers at Coniston TS are reaching end of life, and in need of replacement. The transformers are 76 and 67 years old, respectively. Coniston TS currently feeds a 22 kV network, which is an obsolete sub-transmission voltage that does not exist anywhere else in the province. The 22 kV network is an electrical island which cannot be supplied from any other source. When an outage occurs, the load cannot be easily restored due to lack of a back-up supply. All new 22 kV load connections in the past 20 years have been equipped with dual-voltage transformers for eventual operation at 44 kV; and
- Clarabelle TS M7 and Coniston TS M1 have exhibited poor reliability for feeders supplying an urban area with a large number of commercial and industrial customers.

The transmission needs at Coniston TS and Martindale TS presented an opportunity for Hydro One Distribution to work with the transmitter, Hydro One Transmission, and review the transmission connection facilities in order to determine the most appropriate and cost-effective options for meeting needs in the area.

Alternative 1: Do Nothing

This alternative is not acceptable because it will not resolve the issues in the area. In addition to being one of the worst performing feeders in the province, sections of the Martindale TS M6 feeder are in poor locations and difficult to access. Coniston TS operates at 22 kV, an obsolete voltage level, and the two transformers are reaching end of life. Furthermore, Clarabelle TS M7 and Coniston TS M1 have poor reliability for feeders supplying an urban area with a large number of commercial and industrial customers.

Alternative 2: Replace Assets Reaching End of Life on a Like for Like Basis

One alternative is to retain the existing system configuration and replace assets reaching end of life. The transformers at Coniston TS could be replaced with new 22kV units. A new feeder could be built and double circuited with the M6 to address any future overloading on the Martindale TS M6. The Martindale TS M7 would be rebuilt double circuiting with Martindale TS M6 and Clarabelle TS M7. While this would be a less expensive replacement alternative, it would not be cost effective because retaining a 22 kV voltage requires continued use of non-standard equipment leading to higher costs and limited suppliers. The shortage of supply of non-standard equipment often leads to prolonged outages. Not standardizing the voltage will eventually lead to deteriorated reliability and reduced operational efficiency in the area.

Alternative 3: New Assets at Hanmer TS *(Recommended)*

The preferred alternative is for Hydro One Transmission to build two new 230/44 kV step-down transformers and associated switchgear at Hanmer TS to supply the Valley East load currently connected to longer feeders out of Martindale TS and Clarabelle TS. Coniston TS would be decommissioned, by converting its load to 44 kV and connecting it to Martindale TS M6 feeder.

Alternative 3 costs approximately ten percent more than Alternative 2, but offers more benefits, specifically, significant reliability, efficiency and operational improvements. Alternative 3 allows for elimination of the non-standard 22 kV operating voltage in Coniston, and provides new connection capacity right in the Valley East load center making it much better positioned for future growth in this area as well as the rest of the north-east Sudbury area. Alternative 3 reduces the length of 44 kV feeders supplying the Valley East area from 20-25 km in length to less than 2 km. Therefore, Alternative 3 is more cost effective.

Under Alternative 3, feeder lengths supplying the Hanmer area would be reduced from 12-14 km to about two kilometres, which would reduce line exposure to faults and improve reliability. Line losses would be reduced by 40%. This alternative also allows for the elimination of the non-standard 22 kV operating voltage at Coniston TS and provides new connection capacity to accommodate forecast load growth in the area and new generation.

This investment provides the most cost effective solution for meeting the needs in northeast Sudbury. The two new 230/44 kV step-down transformers and associated switchgear at Hanmer TS provide an alternate solution to simply replacing assets in the area. Not proceeding with this investment would result in multiple, costly projects to address the transmission and distribution issues within the area.

Investment Description:

To meet growing customer load in Valley East and address assets reaching end of life at Coniston TS, Hydro One will redirect load from Coniston TS to Martindale TS. It will then redirect Valley East load from Martindale TS and Clarabelle TS to Hanmer TS. This will involve:

1. Hydro One Transmission constructing two new 50/83 MVA step-down transformers and associated switchgear at Hanmer TS to supply Valley East load;
2. Hydro One Distribution conversion of the northeast Sudbury area supply to 44 kV; and
3. Hydro One Transmission decommissioning the existing Coniston TS.

The map below depicts the existing and proposed electricity transmission and distribution systems in the area:

The preferred solution is for Hydro One Transmission to construct two new 230/44 kV step-down transformers and associated switchgear at Hanmer TS, which is an existing 500kV – 230kV station connected to the Bulk Electricity System. This new installation at Hanmer TS would replace end-of-life station assets, improve reliability, and provide capacity to accommodate the load growth within the City of Greater Sudbury. This would provide Martindale TS with the capacity to service the Coniston area for both load and generation (for example allowing an increase in existing hydraulic generation), removing the requirement to replace the assets reaching their end of life at Coniston TS.

The existing Clarabelle TS M7 and Martindale TS M7 feeders and the Valley East Branch of the Martindale TS M6 feeder would be transferred to Hanmer TS. The placement of the two new 230/44 kV step-down transformers and associated switchgear at Hanmer TS would remove the requirement to rebuild the Martindale TS M6 and M7 feeders on-road. Hanmer TS would also provide new connection capacity in the Valley East load centre to better accommodate future load growth in the northeast Sudbury area. This solution would also eliminate Coniston TS by extending Martindale TS M6 and converting the load to 44kV.

The capital contribution amount from Hydro One Distribution to Hydro One Transmission is considered preliminary and will be determined and finalized in accordance with the Transmission System Code once the Capital Cost Recovery Agreement is signed and the project is placed in service.

Risk Mitigation:

The main risks to completion of this work are lack of labour resources for design and construction. These risks will be mitigated by ensuring appropriate planning lead times are followed for project scheduling and by considering constructability issues early in the project definition stage.

Result:

- Increased transformation capacity to meet future load requirements;
- Improved reliability of Martindale TS M6 feeder; and
- Improved operating efficiency by eliminating obsolete 22kV operating voltage from Coniston TS and the Hydro One system.

Outcome Summary:

Customer Focus	• Accommodate customer load growth and improve reliability in the Greater Sudbury area.
Operational Effectiveness	• Improve operating efficiency by eliminating obsolete 22kV voltage from Coniston TS.
Public Policy Responsiveness	• Comply with license requirements to respond to load growth needs.

Costs:

The estimated cost of the contribution to the project is based on planner's estimates prepared by Hydro One Transmission.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Plan Period Total**	**Total Project Costs****

GP-27 Enfield TS Capital Contribution

Start Date:	Q2 2017	**Priority:**	High
In-Service Date:	Q2 2019	**Plan Period Cost ($M):**	3.0
Primary Trigger:	System Capital Investment Support		
Secondary Trigger:	Load Growth		

Investment Need:

To increase transformation capacity to accommodate the forecast customer load growth and to improve supply reliability in the Oshawa – Clarington area, as documented in the GTA East Regional Infrastructure Plan and Hydro One's 2017-2018 transmission cost-of-service application Exhibit B1, Tab 3, and Schedule 1, investment summary document #D21. Not proceeding with this investment would result in inadequate supply capacity in the area.

Alternative 1: Do Nothing

This alternative is not recommended because Wilson TS is currently overloaded and is expected to exceed its capacity by a significant amount due to load growth and increased generation in the Durham region.

Alternative 2: Upgrade Wilson TS

This alternative requires upgrade of Wilson TS to provide additional supply capacity in the area. This alternative addresses the Hydro One Distribution short-term capacity needs in the area. However, based on the load forecast, it will result in shortfall of supply capacity in another ten years. Also, this alternative would potentially result in high costs due to development of new distribution feeders in developed and congested surroundings.

Alternative 3: Contribute to Build New Enfield TS (Recommended Alternative)

The recommended solution is to contribute to a new transmission station at Enfield TS to provide the capacity required to accommodate long-term growth. The feeders out of Enfield TS will also diversify the feeder routes and increase load transfer flexibility for improved outage response times and increased reliability in the region.

Investment Description:

The proposed plan is to build a new 230/44 kV 170 MVA transformer station at Enfield TS with 44 kV feeders shared between Hydro One Distribution and Oshawa PUC to serve the increasing needs in the Region of Durham and City of Oshawa. The Enfield TS will have provision for two future additional 44 kV feeders. The overloading at Wilson TS will be addressed by transferring some load to the two new Hydro One Distribution feeders at Enfield TS. The new feeders will also improve reliability in the region by diversifying feeder routes. Additional load transfer options between Wilson TS and Enfield TS will reduce the number and duration of outages.

Hydro One Distribution and Oshawa PUC will be required to pay their portion of the capital contribution to Hydro One Transmission. The capital contribution amounts provided under the "Costs" section of this document are considered preliminary and will be determined and finalized in accordance with the Transmission System Code.

Risk Mitigation:

At this point of time, the contribution cost to Enfield TS is based on planner's level estimate. The total contribution cost will be determined once the cost estimate for the Enfield TS is available, and actuals will be determined after the completion of Enfield TS project work.

Result:

- Increased transformation capacity to meet future load growth requirements; and
- Improved supply reliability by increasing redundancy of transmission supply.

Outcome Summary:

Customer Focus	• Increased reliability of supply to existing customers in the Durham area. • Accommodate connection of future customers.
Operational Effectiveness	• Improved supply reliability by increasing redundancy of transmission supply and by diversifying feeder routing to allow for better load transfer capability.
Public Policy Responsiveness	• Meet the requirements of the DSC and Distribution Licence to provide increased capacity to meet load growth.
Financial Performance	

Costs:

The estimated cost of the contribution to the project is based on budgetary cost estimates prepared by Hydro One Transmission.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Plan Period Total**	**Total Project Costs****
Capital* and Minor Fixed Assets	2.0	1.0	-	-	-	3.0	5.0
Less Removals	-	-	-	-	-	0.0	0.0
Gross Investment Cost	**2.0**	**1.0**	-	-	-	**3.0**	**5.0**
Less Capital Contributions	-	-	-	-	-	0.0	0.0
Net Investment Cost	**2.0**	**1.0**	-	-	-	**3.0**	**5.0**

**Includes overhead at current rates. ** Total Project includes amounts spent prior to 2018. This cost estimate has been modified since the last Hydro One distribution rate application (EB-2013-0416) based on updated estimates provided by Hydro One Transmission.*

GP-28 Call Centre Technology

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Program	**Plan Period Cost ($M):**	17.5
Primary Trigger:	Customer Focus		
Secondary Trigger:	Operational Effectiveness		

Investment Need:

Hydro One has two call centres. One is located in Markham, Ontario and the other is located in London, Ontario. Billing and service inquiries are handled from 7:30 am to 8:00 pm, Monday to Friday in the call centres. Hydro One also offers a 24 hour emergency hotline to report power outages, fallen trees or other emergency issues.

To handle these calls, the call centre relies on technology to operate effectively. Key systems that the call centre relies upon include the Interactive Voice Response ("IVR") System, the Computer Telephony System and SAP CRM / iCare System. IVR is an automated telephony system that interacts with callers, gathers information through voice prompts and routes calls to the appropriate recipient. The Computer Telephony Integration ("CTI") allows interactions on a telephone and a computer to be integrated or coordinated.

Hydro One uses SAP Customer Relationship Management for its customer information system integrated with an interface called iCare. When a customer calls the call centre, the screen that pops up with customer information is iCare gathering information from the underlying SAP CRM system. Through SAP CRM / iCare, the call centre agent is able to access wide amounts of data and handle most all customer inquiries (manage account information, provide billing information, maintain budget billing, payment and collections, etc.) in a fast and efficient manner.

Hydro One's CTI & IVR systems were last replaced in 2004 and there were subsequent enhancements to the IVR system since then. The CTI & IVR technology allows Hydro One's customer information system ("CIS") to interact with the telephone system used by the call centre as well as other forms of communication (email, text messaging, web messaging, fax, etc.). There have been advances in technology in this space since the previous implementation such as better analytics and speech recognition. Words spoken by the caller are used to determine what command to execute or which agents to route the calls to. This allows for a better customer experience since this will result in less likelihood that the call will have to be transferred from one agent to another, thereby reducing the time the customer has to be on the call. Newer systems also offer more effective monitoring of agent, department and call centre performance.

The CTI & IVR system that Hydro One uses is past the recommended service life of 5 – 7 years. The current IVR is at risk of not being supported by vendors from a break fix perspective. Extended maintenance contracts only address existing defects but will not develop or release new code for legacy versions of software. The extended maintenance contract for the CTI&IVR systems will not cover any new code development for any issues experienced during normal operations. This introduces a high risk around recovery time when system outages are experienced, thus in turn impacting not only the customers who have billing or service related inquiries, but also those who are calling to report emergencies.

The SAP CRM system went live in 2013. Technology changes at a fast pace. This investment is required to implement system enhancements from the vendor to keep current and ensure continued functionality for customers. The enhancements are discussed in the various alternatives below.

Alternative 1: Status Quo

This alternative would continue to operate with the current CTI/IVR system and refrain from investing in the newest SAP upgrades.

The existing system was last replaced in 2004. If the status quo alternative was selected, Hydro One would continue to rely on existing systems that are past their recommended useful life. Not retaining systems in vendor supportable levels prevents Hydro One from enforcing Service Level Agreements (SLA) with our outsourced partner in the event of an outage or issue. As the vendor would not be able to release new code for legacy software, Hydro One would be unable to have our outsourced service partner maintain key system uptime SLA's. If the system is unavailable, our customers will potentially be unable to reach the call centre, which directly impacts customer satisfaction.

Status quo would also mean there no enhancements to SAP CRM / iCare. Enhancements are new functionality or improvements to existing functionality that SAP develops. These are rolled out in terms of patches (minor enhancements) or upgrades (significant changes to the software). Enhancements improve customer’s experience. In addition, for SAP to support the application, Hydro One needs to be at a certain software level.

Witness: Colin Penny

Alternative 2: Upgrade the Telephony Technology Suite (Recommended)

This alternative would replace the aging CTI and IVR technologies and enhance the existing SAP CRM / iCare System.

This investment is recommended since it will replace end of life technology in the call centre and improve customer interaction on various platforms. The enhancements in SAP CRM / iCare will provide improved service to customers who call our call centre and ensure that the software continues to be supported by SAP. Improvements to the overall customer experience are discussed in the Result and Outcome sections below.

Investment Description:

This includes both hardware and the software replacements, including a possible switch to a cloud-based solution or a hybrid consisting of on-premise and off-premise hardware/software. This investment will also introduce new call routing and call monitoring capabilities for Hydro One's commercial and industrial customers.

This investment also covers the funding required to implement enhancements to Hydro One's SAP CRM / iCare system.

Risk Mitigation:

This is a complex project requiring multiple vendors in order to deliver a robust, secure, and cost effective technology platform. As such, a market scan will be conducted to determine best-in-class technology. Hydro One will also engage with customers to solicit input and ensure their needs are met in terms of new features and functionality. With respect to customer privacy and security, market leading security technology will be sought to ensure customer data is well protected. Thorough testing will be performed to minimize system defects which can impact customers significantly – from ability to reach the call centre, get calls routed to the proper agent and system enhancements that otherwise would improve the ability to serve our customers.

Result:

The primary driver for this investment is to ensure reliability of Hydro One's technology within the call centre. Since these systems are past their recommended useful life, they are more prone to system failure.

Upgrading this technology will improve customer service with modern speech recognition and text-to-speech technologies, more intuitive graphical user interfaces, improved performance, integration of relevant caller information into a unified dashboard, more efficient call routing, more effective monitoring of call centre agents, and more effective monitoring of call centre performance.

Implementing enhancements will also result in improvements in how we serve our customers. Based on feedback received during Hydro One's Customer Consultation, commercial and industrial customers were dissatisfied with the level of customer service. The end result of these investments will be improved customer communication and satisfaction.

Outcome Summary:

Customer Focus	• Ensure a reliable system is available for customers. • Improve customer service with modern speech recognition and text-to-speech technologies, thereby improving how call centre agents interact with customers.
Operational Effectiveness	• Improve performance and provide more efficient call routing inside the call centre. • Integrate relevant caller information into a unified dashboard.
Public Policy Responsiveness	• Ensure that emergency services continue to be available to customers on a 7/24 basis.
Financial Performance	• Provide better call centre analytics to improve performance and lower cost.

Costs:

The final cost of the project covers deliverables and supports activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes direct LOB resource cost, Vendor cost as well as indirect costs of implementing the solution.

This project has a high degree of complexity; it includes a new technology platform and multiple vendors that require coordination. Given this project is customer facing, thorough testing is required to ensure that the customer experience is positive and security is maintained. The cost estimate is based on implementing similar complex applications in the customer domain. Final costs will be determined once detailed business requirements and discovery phases are finalized and a competitive Request for Proposal (RFP) is initiated and a vendor is selected.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital and Minor Fixed Assets	7.5		7.2	2.9		17.5
Less Removals						
Gross Investment Cost	**7.5**		**7.2**	**2.9**		**17.5**
Less Capital Contributions						
Net Investment Cost	**7.5**		**7.2**	**2.9**		**17.5**

GP-29 Customer Service Billing Investments

Start Date:	Q4 2021	**Priority:**	Medium
In-Service Date:	Multiple	**Plan Period Cost ($M):**	10.4
Primary Trigger:	Customer Focus		
Secondary Trigger:	Operational Effectiveness		

Investment Need:

Hydro One's paper bill is the most common communications vehicle with customers. About 14 million invoices are mailed annually to customers.

Hydro One's 2016 survey results indicated that only 62% of customers find their bill easy to understand. The design of the current bill has been identified by customers as a weakness and an area of opportunity (via customer satisfaction surveys and the Distribution Customer Engagement results the Ontario Ombudsman, and Hydro One's Ombudsman). As a result, Hydro One is introducing a redesigned bill in 2017. Additional capital funding will be required in 2022 to introduce further enhancements to ensure customers remain satisfied and understand their bill.

In addition to the need for producing bills that customers find easier to understand, there's also a need to improve billing for non-energy services. Hydro One provides specialized work for non-energy services to external parties. These include:

1. IESO Charges;
2. Retailer Settlements;
3. Secondary land use;
4. Land corridor leases;
5. Training for other municipalities and utilities;
6. Damage claims;
7. Trouble calls / Storm damage;
8. New service connections;
9. Service Upgrades;
10. Forestry Clearing;
11. Distributed Generation & MicroFit set up;
12. Long term load transfer;
13. Key Account Management connected customers (i.e. Ontario Power Generation);
14. Joint use pole rentals; and

15. Stations Modifications.

A review of the non-energy billing process identified inconsistencies in how the various non-energy services are handled. There is also inconsistency on the customer service policies between energy related billing versus non-energy related billing. The processes, tools and technology for non-energy billing are inefficient.

Alternative 1: Status Quo

Hydro One could elect not to embark on another bill redesign project in 2022 and not to integrate its non-energy billing practice in 2021. This alternative was considered and rejected because Hydro One is committed to improving its' relationship with its customers.

Alternative 2: Redesign Customer Bills and Improve Non-Energy Billing (Recommended)

This alternative is recommended since this will enhance customer service. The bill redesign project will improve customer understanding of their bill and more effectively promote and market new programs and services. The Non-Energy Billing investment will ensure consistency with energy billing customer service policies and will improve customer satisfaction.

Investment Description:

This investment is required to fund the following initiatives:

1. Bill Redesign – The Hydro One bill will be redesigned in 2022 to make it easier for customers to understand. The redesigned bill will also encourage energy conservation by providing customers information on how they can manage their usage better to take advantage of off-peak rates; and
2. Non Energy Billing Enhancements – Hydro One generates bills for the following non-energy services: damage claims, new service connections, service upgrades, forestry clearing, Distributed Generation and MicroFit set up, joint use pole rentals, secondary land use, land corridor leases, etc. This investment is required to enhance the entire end-to-end process, including invoicing, collections, and customer service.

Risk Mitigation:

The following are the risks that the project plans to address and manage:

Solution Complexity

This is a complex project requiring multiple vendors in order to deliver a robust, secure, and cost effective technology platform. As such, a market scan will be conducted to determine best-in-class technology. Hydro One will also engage with customers to solicit input and ensure their needs are met in terms of new features and functionality. With respect to customer privacy and security, market leading security technology will be sought to ensure customer data is well protected.

Resources and Competing Priorities

Hydro One has many demands on its IT infrastructure, SAP and Customer Service resources – all of which are integral to success of this project. To mitigate this risk, the Project Team will highlight when they expect to require these resources and services during formal Program Planning activities. This will align with priority of projects set by Hydro One's Executive Team as an outcome of the Investment Plan review and approval process.

Risk of Customers Not Trusting Their Bills

For the Bill Redesign Project, one risk of implementing this project is the customers may again not trust the billing system if there are any issues during implementation. The Bill Redesign Project will not change how the bill is calculated. It will only change how the bill is presented. Energy billing redesign will continue to comply with prescribed provincial regulation. Yet any defects during implementation may cause customers to believe that their bill is not being calculated properly. This risk will be minimized through thorough testing and by hiring consultants who have expertise in bill print functionality.

The above risks will be addressed in accordance with Corporate Projects' Project Governance framework. Following the project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. In addition, follow up workshops will be conducted at appropriate project stage gates.

Result:

Redesigning the Hydro One bill will make it easier for customers to understand the bill. As a result, it is expected to lower calls to the call centre and improve customer satisfaction. It will also encourage energy conservation as the bill will break down consumption based on on-peak and off-peak usage.

The Non-Energy Billing investment is expected to improve the entire end-to-end process, including invoicing, collections, and customer service. For example, these customers do not have access to electronic bills or self-service capabilities. New tools, processes, and technology will improve customer satisfaction.

Outcome Summary:

Customer Focus	• Improve customer experience and satisfaction through bills that are easier to understand.
Operational Effectiveness	• Reduce calls to the call centre through reduction of billing related questions and reducing call centre costs overall. • Ensure consistency between energy billing customer service policies and non-energy billing.
Public Policy Responsiveness	• Encourage energy conservation as bills will better display usage consumption into on-peak & off-peak hours.
Financial Performance	

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes vendor costs as well as Hydro One direct and indirect costs of implementing the solution.

This project has a high degree of complexity; it includes redefining the customer experience, a new technology platform, and multiple vendors that require coordination. Given this project is customer facing, thorough testing is required to ensure that the customer experience is positive and security is maintained. The cost estimate is based on implementing similar complex applications in the customer domain. Final costs will be determined once detailed business requirements are finalized and a competitive Request for Proposal (RFP) is initiated and a vendor is selected.

($ Millions)	2018	2019	2020	2021	2022	Plan Period Total	Total Project Costs**

GP-30 Customer Service Regulatory Related

Start Date:	Q1 2018	**Priority:**	Demand
In-Service Date:	Multiple	**Plan Period Cost ($M):**	14.0
Primary Trigger:	Public Policy Responsiveness		
Secondary Trigger:	Customer Focus		

Investment Need:

This investment would implement the Demand to Interval change which is required by the Ontario Energy Board. It would also implement the Dynamic Pricing Pilot which is a pilot program offered by the government to encourage energy conversation.

Alternatives:

This investment would implement the Demand to Interval change which is OEB required. This is a non-discretionary investment. It would also implement the Dynamic Pricing Pilot which is a pilot program offered by the government to encourage energy conversation. Finally, it will implement the new rate design for Commercial & Industrial customers. This new rate is not OEB required. Hydro One will seek OEB's approval, via current process for changing rates, for this new rate design which is intended to encourage energy conservation among Commercial & Industrial customers.

Not performing the mandated changes, such as 'Demand to Interval Meter' that is non-discretionary, means Hydro One will not be compliant with regulatory changes.

For the Dynamic Pricing investment, while not specifically required by regulatory code at this time, Hydro One proposes to implement the pilot program offered by the government to encourage energy conservation. This will assist the government in its efforts to address the issue of high electricity cost in Ontario.

Investment Description:

This investment will implement the following regulatory and government changes and introduce pricing options for customers:

1. Demand to Interval Migration - Funding is required to implement system changes to support the Distribution System Code amendments that came into force on August

21, 2014. Section 5.1.3 requires a distributor to install an interval meter on any installation that is forecast to have a monthly average peak demand during a calendar year of over 50 kW and pay the hourly Ontario energy price from the IESO-administered real-time energy market based on their actual usage by August 21, 2020.

2. Dynamic Energy Pricing - On July 18, 2016, the Ontario Energy Board (OEB) issued its Regulated Price Plan Roadmap: Guideline for Pilot Projects on RPP Pricing. Hydro One submitted an application to develop and implement price and non-price pilots, including the continuation of Hydro One's existing pilot which allows customers to have different variations of Time of Use rates. Dynamic Energy Pricing encourages customers to reduce electricity usage and shift usage away from peak hours. Some participants also receive enabling technologies such as Wi-Fi thermostats and in-home displays to assess the associated incremental savings. On September 23, 2015, the OEB agreed that there is value in extending Hydro One's existing pilot until April 30, 2017. Capital funding is required to extend the pilot beyond April 2017.

3. New Rate Design for Commercial and Industrial Customers - Hydro One plans to develop an innovative rate design for commercial and industrial customers that incents customers and influences their behavior. This is not OEB required but is included in this Investment Summary Document as this will require approval from the OEB before the new rate is changed.

Risk Mitigation:

This is a complex project requiring multiple vendors in order to deliver a robust, secure, and cost effective platform. As such, a market scan will be conducted to determine best-in-class programs. Hydro One will also engage with customers to solicit input and ensure their needs are met.

The timing of this investment is based on the need to comply with upcoming regulatory changes and introduce programs to assist customers with their electricity costs and affordability issues.

Result:

This investment will ensure Hydro One complies with regulatory and government changes. This investment will also provide customers with new pricing options, thereby reducing affordability issues for customers.

Outcome Summary:

Customer Focus	• Make electricity more affordable and improve customer satisfaction through the new pricing model. • Reduce electricity cost by encouraging usage in off-peak hours. • Improve customer satisfaction by providing enabling technologies such as Wi-Fi thermostats and in-home displays to assess the associated incremental savings.
Operational Effectiveness	
Public Policy Responsiveness	• Encourage energy conservation by incenting customers to reduce electricity usage and shift usage away from peak hours. • Comply with regulatory requirements and government policy changes.
Financial Performance	

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes vendor costs, as well costs Hydro One's direct and indirect costs of implementing the solution.

This project has a high degree of complexity; it includes redefining the customer experience, a new technology platform, and multiple vendors that require coordination. Given this project is customer facing, thorough testing is required to ensure that the customer experience is positive and security is maintained. The cost estimate is based on implementing similar complex applications in the customer domain. Final costs will be determined once detailed business requirements are finalized and a competitive Request for Proposal (RFP) is initiated and a vendor is selected.

GP-31 Collection Enhancements

Start Date:	Q1 2022	**Priority:**	Medium
In-Service Date:	Multiple	**Plan Period Cost ($M):**	6.1
Primary Trigger:	Financial Performance		
Secondary Trigger:	Customer Focus		

Investment Need:

Overdue accounts present a financial risk to Hydro One. There is a need to improve the collections process and associated technological options for mitigating the financial risks.

The cost of electricity in Ontario has been steadily increasing. This has resulted in a number of customers having difficulty in paying their bills on-time. The Allowance for Doubtful Accounts has increased from 3.8% of its gross accounts receivable (as of December 2013) to 7.3% of its gross accounts receivable (as of December 2015). The portion of net accounts receivables that were aged more than 60 days went from 4% in 2013 to 6% in 2015.

When customers are in arrears, they are contacted by HONI through the Collections “Dunning” process. Dunning is the process of methodically communicating with customers to ensure the collection of accounts receivable. Communications progress from gentle reminders to pointed letters and phone calls to location visits as accounts become in more serious arrears.

One method of enabling customer control of their electricity consumptions, while in arrears condition, and minimizing Hydro One Network’s financial risk, is through the use of pre-paid meters. Pre-paid meters are a type of energy meter that requires users to pay for energy before using it. This is done via a smartcard, token or key that can be "topped up" at a corner shop, via a smartphone application or online. For customers who are high collection risk, the financial risk will be minimized by rolling out this type of meter. With a pre-paid meter, electricity is paid up-front. Once the pre-paid amount is used up, power is cut-off until the customer is able to load the meter with more credits.

Alternative 1: Status Quo – No enhancements to Collections Process & Technology. No implementation of pre-paid metering.

With the status quo scenario, Hydro One will not be implementing technology & process changes that are geared towards improving collections such as redesigning the collections process and implementing pre-paid meters.

If Hydro One does not proceed with this project, Hydro One's current increased level of uncollected accounts receivables will continue. This is not preferred since Hydro One's financial performance can be improved if the Company can improve its ability to collect money from its customers. This also does not provide the customer with new technology tools to manage their electricity consumption and reduce their outstanding overdue amounts while in arrears.

Alternative 2: Implement Process & Technology Enhancements for Collections. Roll Out Pre-Paid Meters (Recommended)

With this alternative, Hydro One will implement technology & process changes to encourage customers to promptly pay their bills. Hydro One will be able to implement pre-paid metering which is an effective way to collect payment from its customers. For the rest of the customers who are not high collection risks, the redesigned Dunning process will encourage customers to be prompt in paying their bills. This is the recommended approach as this is expected to increase collections and payment and therefore improve Hydro One's financial performance.

Risk Mitigation:

This is a complex project requiring multiple vendors in order to deliver a robust, secure, and cost effective technology platform. As such, a market scan will be conducted to determine best-in-class functionality and technology. Hydro One will partner with vendors that have the experience and expertise to complete the work successfully. With respect to customer privacy and security, market leading security technology will be sought to ensure customer data is well protected.

Another risk is potentially the negative customer reaction to the pre-paid meter technology. This risk will be mitigated through proper customer stakeholdering and customer engagement.

The timing of this investment is based on the need to introduce new functionality and technology to encourage collections and payment. Although there is no legislative requirement that is driving this change, delaying this investment any further will result in delayed achievement of benefit which impacts financial performance.

This project has a high degree of complexity; it includes a new technology platform and multiple vendors that require coordination. Given this project is customer facing, thorough testing is required to ensure that the customer experience is positive and security is maintained. The cost estimate is based on implementing similar complex applications in the customer domain. Final costs will be determined once detailed business requirements and discovery phases are finalized and a competitive Request for Proposal (RFP) is initiated and a vendor is selected.

Result:

Collection enhancements will increase likelihood of payment and reduce uncollectable accounts receivables moving forward. Other Canadian and American utilities have successfully implemented this technology and are yielding financial benefits from the deployment.

Outcome Summary:

Customer Focus	• Help customers manage their electricity usage. Active and timely actions to address customers in arrears will help customers stay current with their invoices and will improve payment.
Operational Effectiveness	• Increase operational effectiveness by not having to send field staff to disconnect or reconnect meters for customers who are on pre-paid meter. Meters will automatically shut off once the credit has been consumed on the meter and activate once credit has been loaded.
Public Policy Responsiveness	
Financial Performance	• Encourage customers to be prompt in paying their bills. • Reduce risk of non-payment from high risk customers by through implementing pre-paid meters.

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes direct LOB resource cost, Vendor cost as well as indirect costs of implementing the solution.

The project is expected to take 2 years to implement. The remaining expenditures relating to this project will be spent in 2023 and are estimated to be $3.0M.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**
Capital* and Minor Fixed Assets					6.1	6.1
Less Removals						
Gross Investment Cost					**6.1**	**6.1**
Less Capital Contributions						
Net Investment Cost					**6.1**	**6.1**

**Includes Overhead at current rates.*

GP-32 Customer Data and Analytics

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Multiple	**Plan Period Cost ($M):**	9.9
Primary Trigger:	Customer Focus		
Secondary Trigger:	Operational Effectiveness		

Investment Need:

Customers have told Hydro One that they are concerned about the high cost of electricity. Customers have the right to know and understand what makes up the fees they are being charged.

One way to support customers is through high bill alert functionality. Customers can sign up for e-mail or text messages to alert them if their consumption is trending to exceed a certain threshold that they also are able to set. With high bill alerts, customers may be able to adjust their energy usage and potentially avoid an unusually high bill.

An enhanced web portal provides interactive access to energy-usage information and personalized energy savings recommendations based on usage patterns. By having information available to customers on the website, this reduces the need for customers to call the call centre and the additional effort that comes along with that call.

Equipping Hydro One's Customer Service Agents with tools and systems that provides a comprehensive view of customer information improves the agent's ability to provide good service to customers and get them what they need in a single call. It can be quite frustrating for customers if they call and the Agent they speak with has limited information about the customer's usage and what they can do to reduce their energy bill.

Alternative 1: Status Quo

If the status quo alternative was selected, Hydro One would not be providing customers with the tools they require to effectively manage their electricity account. As such, Hydro One would likely experience deterioration in customer satisfaction, as measured by Hydro One's reputational and transactional surveys.

Alternative 2: Implement Customer Tools and Analytics (Recommended)

This alternative is recommended since it aligns with feedback received from customers via the Distribution Customer Engagement and provides customers with the service they want.

Investment Description:

This investment is required to upgrade the following technology which will enhance customer analytics. The majority of the $9.9 million is allocated to High Bill Alerts.

1. High Bill Alerts - Hydro One will proactively deliver high bill alerts to customers if their bill in a particular billing period is trending higher than a predefined threshold. Customers will also receive guidance on how they can adjust their energy use before the end of the billing period. The alerts are triggered based on the customer's smart meter data combined with historical usage and weather patterns.
2. Enhanced Web Portal for Commercial and Industrial Customers - Hydro One will implement an enhanced web portal for commercial and industrial customers that provides interactive access to energy-usage information and personalized energy savings recommendations based on usage patterns.
3. Customer Analytics and Insights – This investment will allow Hydro One to have a comprehensive view of customer information and will provide analytics and insights, which will allow Hydro One to better understand customer needs and energy patterns.

Risk Mitigation:

The following are the risks that the project plans to address and manage:

<u>Solution Complexity</u>

This investment involves implementation of 3 complex projects. Each project will require multiple vendors to deliver a robust, secure, and cost effective technology platform. As such, a market scan will be conducted to determine best-in-class technology. Hydro One will also engage with customers to solicit input and ensure their needs are met in terms of new features and functionality. With respect to customer privacy and security, market leading security technology will be sought to ensure customer data is well protected.

Resources and Competing Priorities

Hydro One has many demands on its IT infrastructure, SAP and Customer Service resources – all of which are integral to success of this project. To mitigate this risk, the Project Team will highlight when they expect to require these resources and services during formal Program Planning activities. This will align with priority of projects set by Hydro One's Executive Team as an outcome of the Investment Plan review and approval process.

The above risks will be addressed in accordance with Corporate Projects' Project Governance framework. Following the project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted at appropriate project stage gates.

The timing of this investment is based on the need to introduce these customer facing tools to residential, commercial, and industrial customers based on feedback from the Distribution Customer Consultation.

Result:

Overall, this investment caters to diverse customers' needs, thereby improving customer education and customer satisfaction.

High Bill Alerts are expected to reduce average handle times within the call centre for high bill calls and first call resolution will improve. Hydro One expects these initiatives to measurably strengthen Hydro One's relationship with its customers and drive greater credibility and trust.

The Enhanced Web Portal for Commercial and Industrial Customers will deliver energy consumption analysis, building specific insights and savings tips that are personalized for each and every customer – driving awareness, engagement, and action throughout a progressive customer journey. Hydro One seeks to become a trusted advisor by helping customers understand their energy usage.

Outcome Summary:

Customer Focus	• Improve customer service and increase customer satisfaction by providing customers with tools to help manage their energy usage. • Serve customers better by providing Customer Service Agents with tools and resources to enhance call centre operations.
Operational Effectiveness	• Improve efficiency at the call centre by providing Customer Service Agents access to tools and information to better serve customers and reducing average call handling time.
Public Policy Responsiveness	• Encourage energy conservation management by providing consumers the resources to help manage their energy usage.
Financial Performance	• Improve financial performance through more efficient call centre operations and reduction of cost to operate the call centre due to anticipated drop in call volume.

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes vendor costs as well as direct and indirect Hydro One costs for implementing the solution.

This project has a high degree of complexity; it includes redefining the customer experience, a new technology platform, and multiple vendors that require coordination. Given this project is customer facing, thorough testing is required to ensure that the customer experience is positive and security is maintained. The cost estimate is based on implementing similar complex applications in the customer domain. Final costs will be determined once detailed business requirements are finalized and a competitive Request for Proposal (RFP) is initiated and a vendor is selected.

($ Millions)	2018	2019	2020	2021	2022	Plan Period Total	Total Project Costs**
Capital* and Minor Fixed Assets	1.8	-	2.6	5.5	-	9.9	11.7
Less Removals	-	-	-	-	-	0.0	0.0
Gross Investment Cost	**1.8**	-	**2.6**	**5.5**	-	**9.9**	**11.7**
Less Capital Contributions	-	-	-	-	-	0.0	0.0
Net Investment Cost	**1.8**	-	**2.6**	**5.5**	-	**9.9**	**11.7**

**Includes overhead at current rates.*
*** Total Project includes amounts spent prior to 2018.*

GP-33 Customer Service Complaint Management Tool

Start Date:	Q4 2017	**Priority:**	Medium
In-Service Date:	Q4 2019	**Plan Period Cost ($M):**	3.3
Primary Trigger:	Customer Focus		
Secondary Trigger:	Operational Effectiveness		

Investment Need:

Hydro One receives approximately 3,000 complaints from customers on an annual basis. Complaints vary in nature but the majority are associated with billing. Customers who log complaints are already experiencing a certain level of frustration. Failing to act promptly and effectively to address the customer's complaint can understandably cause significant additional aggravation.

Currently, complaints are handled on a MS Access database that is not integrated to SAP. As a result, complete and robust customer information is often not available to the staff member handling the complaint and sub-optimal service may result. These databases are not robust enough to contain automatic workflows and related tools to help better serve the customer. Workflows help customer service staff by routing the complaint to the appropriate group(s) that is in the best position to address the customer's complaint. Other customer centric workflows include reminders designed to alert staff if they are lagging on tasks that impact the resolution of a customer's complaint. There are no analytics available to do trending of the root causes of customer's complaints so that the company can handle these issues pro-actively and in turn, reduce the number of complaints going forward.

Alternative 1: Status Quo

If the status quo alternative were selected, Hydro One would continue to use spreadsheets and databases to log customer complaints. This option is not ideal since these spreadsheets and databases are not integrated within Hydro One's SAP system and customer information may not be readily available to assist in addressing the customer's complaint.

Alternative 2: Implement a Dedicated Complaint Management System (Recommended)

This alternative is recommended since the Complaint Management System will be integrated with our SAP Customer Relationship Management. SAP offers a complaint management bundle that enable users to create and store customer complaints about products or services directly in SAP Customer Relationship Management (CRM). Although the decision on whether this will be the tool that will be used has not been determined, this will be the most logical choice given SAP is Hydro One enterprise system. The Complaint Management System will contain workflows to improve productivity. It will document sources, trends, and assist with root cause analyses. As such, it will be utilized to develop a culture of continuous improvement.

Investment Description:
This investment is required to implement an integrated complaint management tool that tracks customer complaints from initiation to resolution. The tool will record and respond to customer complaints and will be fully integrated into Hydro One's SAP Customer Information System (CIS).

Risk Mitigation:

The following are the risks that the project plans to address and manage:

<u>Solution Complexity</u>

The implementation of the Complaint Management System which is integrated into SAP system is expected to be complex. Finding the right skill set to support a successful implementation can be a challenge. To mitigate this risk, Hydro One will partner with vendors that have the experience and expertise to complete the work successfully.

<u>Resources and Competing Priorities</u>

Hydro One has many demands on its IT infrastructure, SAP and Customer Service resources – All of which are integral to success of this project. To mitigate this risk, the Project Team will highlight when they expect to require these resources and services during formal Program Planning activities. This will align with priority of projects set by Hydro One's Executive Team as an outcome of the Investment Plan review and approval process.

Change Management and User Adoption

The goal of this project is to implement a complaint management system that is integrated into SAP. This could potentially pose both process and technology challenges to impacted staff. Change Management is a key player to deliver the vision, training and job aids to the target user community wishing to access the new features. This would need to be assessed as to applicability, timing and cost impact.

The above risks will be addressed in accordance with Corporate Projects' Project Governance framework. Following the project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted at appropriate project stage gates.

This is a complex project requiring multiple lines-of-business across the company to deliver a robust, secure, and cost effective technology platform. A project governance team will be established and corporate risk workshops will be conducted.

Result:

Customer complaints will be logged in the new Complaint Management Tool. The solution will enable employees to conveniently access the customer's complaint (including previous complaints), account information, and status update. The call center agent will be able to respond to the customer with the latest information on the status of the customers' complaint. This investment will allow Hydro One to manage customer complaints effectively, which in turn improves customer service.

Outcome Summary:

Customer Focus	• Improve customer satisfaction through more efficient and faster handling of customer complaints.
Operational Effectiveness	• Achieve operational efficiencies by identifying trends and root-causes of complaints. • Handle complaints more effectively via built-in task notifications.
Public Policy Responsiveness	
Financial Performance	• Reduce calls to the call centre and the associated effort.

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes vendor costs as well as direct and indirect Hydro One costs.

The cost estimate is based on historical business case estimates of a medium size, complex new SAP module. Until the detailed business requirements and discovery phases are completed and vendor quotes received, a more accurate project cost estimate will not be available.

Controllable costs will be minimized by reviewing the detailed cost estimate, when it becomes available, and reviewing & challenging the costs to ensure they are in line. Hydro One will also launch an open competition so multiple vendors can submit their proposal and Hydro One can select based on the vendor that best meets Hydro One's evaluation criteria.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Plan Period Total**	**Total Project Costs******

Net Investment Cost	**3.0**	**0.3**	**-**	**-**	**-**	**3.3**	**4.1**

**Includes overhead at current rates.*
*** Total Project includes amounts spent prior to 2018.*

GP-34 Smart Meter Network Investments

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Multiple	**Plan Period Cost ($M):**	14.7
Primary Trigger:	Customer Focus		
Secondary Trigger:	Operational Effectiveness		

Investment Need:

Hydro One was one of the first LDCs to implement a smart meter network in the province of Ontario. The smart meter project started in 2006 and ended in 2014. This project delivered the advanced meter infrastructure (AMI) in the field and installed approximately 1.2 million smart meters across its customer premises. The CIS billing project started in 2011 and ended in 2014. Its purpose was to replace the legacy billing CSS system in production at that time that was 20 years old and long past its end of life. Both projects were complex and difficult to implement because there was no ubiquitous end to end solution available on the market at the time. The systems had to be "stitched" together using in-house custom development to integrate the smart meter systems, the IESO Meter Data Management and Repository (MDM/R) and the billing systems to create the meter to bill processes that met regulatory requirements set by the Ontario Energy Board.

The Advanced Meter Infrastructure consisted of the Trilliant head end system, collectors and smart meters. The smart meters installation was completed by the 2010 OEB target date. The smart meter communication network was initially completed by 2013 but Hydro One experienced issues in that the network was not providing consistent communications due to factors such as topology, seasonal effects and availability of reliable cellular network services in its rural and remote territory. These constraints required the development of custom applications to handle the exception in the communications network. The smart meter project was concluded in December 2014 once it was determined that there was adequate consistency in the smart meter communications to meet OEB billing accuracy of greater than 98% accuracy.

The 20 year old CSS billing system was replaced with an SAP / Itron IEE solution. The Customer Information System (CIS) project was started in 2011 and implemented in 2013. The synchronization of the CIS with the smart meter network required further customization in order to integrate it with the smart meter systems. The remediation phase of the CIS project concluded in 2014 once it was determined that billing accuracy of greater than 98% could be maintained.

During the smart meter project lifecycle, Hydro One hired consultants to design and implement a number of applications to resolve issues that arose during the integration of the MDM/R. While integrating the Smart Meter network with the SAP CIS billing system additional customized solutions were required to report, track and resolve exceptions. This practice was necessary to create the smart meter to bill processes which was considered new territory for advanced meter infrastructure billing. Today Hydro One continues to operate those customized systems. However, there is both a cost and risks to maintaining this practice because the customized applications are not supported by vendors and they are reaching end of life. Hydro One must rely on very specialized knowledge from a few consultants to maintain these applications that are limited in their scalability and performance. Also costly modifications are required when adding new meter equipment.

Alternative 1: Status Quo

If the status quo alternative was selected, Hydro One would continue to rely on existing technology. This alternative is not recommended since the systems are past their recommended useful life and they are costly to maintain. As such, there is a higher risk of system failure. If the systems were to fail then our customers would receive estimated bills until such time the systems were restored. Furthermore, custom solutions developed internally are no longer consistent with the Company's IT strategy.

Alternative 2: Replace EOL Smart Meter Network tools with new Technology (Recommended)

This alternative is recommended since it will replace end of life technology and reduce the risk of system failure and impact to our 98% billing accuracy performance indicator.

Investment Description:

This investment is required to replace the following tools that support the Smart Meter network. Note that some of the tool replacements or upgrades will be grouped under one or multiple projects depending on the current and future level of integration. Each project will be assessed base on individual business cases that will define the specific costs, return on investments and timeline to implement.

A. Customer Migration Tool - Required to support mass migration of customers from two-tier RPP to Time of Use billing. Hydro One continues to have a number of customers for which a smart meter solution was not available at the time of conversion. This tool will be required to manage the migration of these customers to smart meters.

B. Customer Meter Order Management Tool - Tracks new smart meter installations.

C. Collector Design and Deployment Tool - Coordinates the activities and handoffs for design and deployment of the smart meter network equipment, including regional collectors and repeaters.

D. Customer Service Order Network Tool - Provides reporting for all service orders (planned and unplanned).

E. Index Read Tracking Tool (IRTT) – This tool is the core of the daily meter reading delivery process and serves to provide meter triage, meter reliability metrics, network performance metrics, manual estimation generator, missing read tickets and demand meter reading support.

F. Itron Enterprise Edition Meter Data Management Tool - This tool is an enterprise-wide data management solution that stores interval and register data for residential, commercial, and industrial customers. This tool will have reached end of life and will require an upgrade from the vendor.

G. Network Infrastructure performance reporting – These reports provide the Company's Advanced Meter Infrastructure support team with statistics as to the health of the network.

Risk Mitigation:

This is a complex investment that will require a phased projects approach with multiple vendors in order to deliver a robust, secure, and cost effective technology platform to replace or upgrade the tools listed above. As such, a market scan will be conducted as part of the discovery phase and business case development to determine best-in-class technology and cost to implement.

Result:

The key result is reduction in risk of using meter related customized applications that are not vendor supported. In addition, this is expected to bring efficiencies in the meter-to-bill process through improved reporting & analytics.

Outcome Summary:

Customer Focus	• Improve customer satisfaction as a result of issues being identified quickly and resolved within a timely manner. • Reduce risk to customers in using meter related applications that are no longer supported by the vendor. • Improve operational performance for maintaining billing accuracy.
Operational Effectiveness	• The new technology will result in improved performance.
Public Policy Responsiveness	• Comply with the OEB requirement of 98% billing accuracy.
Financial Performance	

Costs:

This project has a high degree of complexity; it includes a new technology platform and multiple lines of business that require coordination. Given this project is customer facing, thorough testing is required to ensure no impact to the billing process. The cost estimate is based on implementing similar complex applications in the customer domain. Final costs will be determined once detailed business requirements and discovery phases are finalized.

($ Millions)	**2018**	**2019**	**2020**	**2021**	**2022**	**Total**

GP-35 Asset Analytics Risk Factor

Start Date:	Q1 2020	**Priority:**	Medium
In-Service Date:	Q4 2020	**Plan Period Cost ($M):**	2.0
Primary Trigger:	Reliability Enhancement		
Secondary Trigger:	Efficiency Improvements		

Investment Need:

Asset Analytics (AA) is a major investment planning decision support toolset. It is an SAP-powered application which represents an enterprise asset risk factor program that consistently measures and models Transmission and Distribution asset risks. The Business has been using the AA program since 2013.

The existing AA program collects asset related information from SAP and other non-SAP interfaces. The data received is used to calculate “Controls” such as Supporting Factors which in turn contribute to the calculation of Risk Factor scores that are used to assess the assets. These controls assist planners identify assets whose status indicates that replacement and/or repair is warranted.

Asset Managers leverage AA output information to make decisions regarding power delivery reliability and supply continuity. Consequently they initiate plans for future capital investments and work programs to improve delivery reliability, customer satisfaction and shareholder value.

Since existing calculations have remained unchanged since the initial deployment of AA, it has been identified by the Asset Managers that current Controls require remediation and extension to improve the quality of the asset risk model, and the granularity for decision making. Specifically required Risk Factor upgrades cover:

a. Adding two new Risk Factors, (Obsolescence and Health, Safety and Environment); and
b. Modifying current Risk Factors with improved data feeds, calculations and reporting.

Alternative 1: Maintaining the Status Quo

- With status quo option, Hydro One can continue to use the AA program with its existing features. This is not to Hydro One's advantage since some of the controls of the existing system require remediation and extension in order to be able to fully realize intended business value and operational efficiencies.

Alternative 2 (Recommended): Implement AA Risk Factor Upgrades

In addition to leveraging the capabilities of the existing AA program, this alternative will lead to realizing the needed business values and operational efficiencies including:

a. Adding two new Risk Factors: The Health, Safety and Environment Risk Factor will contribute to further improving decision data and reducing exposure to employee, public and environmental safety, negative regulatory and media attention. The new Obsolescence Risk Factor will also improve the investment decision data by providing a view to the investment planner of the asset's ongoing sustainability, improving the quality of the investment; and
b. Modifying current Risk Factors: This will contribute to improving the quality of the asset risk model as well as the granularity for decision making.

Investment Description:

This investment is to upgrade the Asset Analytics Risk Factors which are used by Investment Planners to support asset maintenance programs and future capital investments planning. The high level scope of the project is expected to be as follows:

a) Add two new Risk Factors. These include:
    - Health, Safety & Environment (HS&E) will incorporate key initiatives around health or environment concerns, such as PCB levels in the insulating oil. Legislation has been enacted that PCB needs to be within certain levels to limit exposure of individuals to the health risk and this investment will support that initiative.
    - Obsolescence will assist with planning the asset useful service life including identification of corrective measure related to equipment defects and availability of spare parts.

b) Modify current Risk Factors with improved calculations and reporting. These include:

- Adding additional Supporting Factors_to algorithms or data feeds to improve the granularity and sensitivity of the Risk Factor scores leading to improved prioritization of assets for work and replacements.
- Adjusting the weighting of Supporting Factors in the algorithms to improve Risk Factor score sensitivity. If an algorithm was not correctly_designed and implemented the first time, correcting it improves the confidence in the Risk Factor scores.

c) Train end users on the operation of the changes in AA.

The recommended execution plan will take approximately 12 months to complete by the fourth quarter of 2020.

Risk Mitigation:

The following are the risks that the project plans to address and manage:

Solution Complexity

The Asset Analytics (AA) Tool a complex application and finding the right skill set support successful implementation can be a challenge. To mitigate this risk, Hydro One will partner with vendors that have the experience and expertise to complete the work successfully.

Resources and Competing Priorities

Hydro One has many demands on its IT infrastructure, SAP and Asset Management – all of which are integral to success of this project. To mitigate this risk, the Project Team will highlight when they expect to require these resources and services during formal Program Planning activities. This will align with priority of projects set by Hydro One's Executive Team as an outcome of the Investment Plan review and approval process.

Change Management and User Adoption

The goal of this project is to implement additional features and capabilities to improve existing processes and transactions. Change Management is a key player to deliver the vision, training and job aids to the target user community wishing to access the new features. This would need to be assessed as to applicability, timing and cost impact.

The above risks will be addressed in accordance with Corporate Projects' Project Governance framework. Following the project approval, the Corporate Risk group will be engaged to conduct a formal risk workshop. In addition, follow up workshops will be conducted at appropriate project stage gates.

Result:

The delivery of the AA Risk Factor Upgrade project will lead to refining the existing risk factor calculations and will help improve quality of investment planning supporting data and in turn the decision quality and results.

The addition of the new Health Safety & Environmental Risk Factor will further improve this decision data and reduce risks to employee, public and environmental safety, and in turn investor confidence and negative regulatory and media attention.

The new Obsolescence Risk Factor will also improve the investment decision data by providing a view to the investment planner of the asset's ongoing sustainability, improving the quality of the investment.

Outcome Summary:

Customer Focus	• Improve customer reliability by providing asset risk data directly to Lines of Business to improve their ability to determine the programs and investments that improve reliability.
Operational Effectiveness	• Upgrades to the AA Risk Factors will ultimately help improve electrical power delivery reliability, supply continuity, data quality, system efficiency and asset investment decision making.
Public Policy Responsiveness	• The outputs from the AA system feed into several information and reports frequently used for regulatory agency reporting (OEB, NERC, IESO, and NEB), government agency reporting (Min of Energy) and customer queries.
Financial Performance	

Costs:

The final cost of the project covers deliverables and support activities such as Design, Infrastructure, Building, Testing, Training, Deployment, Change Management, Project Management and Post Deployment. It includes direct LOB resource cost, vendor cost as well as indirect costs of implementing the solution.

The cost estimate is based on the historical business case estimates of previous AA implementations. Detailed business requirements will be completed during the design phase of the project in order to determine final project costs. If the final project costs are found to be materially different, the project will be re-evaluated given the parameters of the Hydro One investment review and approval processes.

Controllable costs will be minimized by reviewing the detailed cost estimate, when it becomes available, and reviewing and challenging the costs to ensure they are in line.

Hydro One will launch an open bidding competition so multiple vendors can submit their proposal and Hydro One can select based on the vendor that best meets Hydro One's evaluation criteria and budget.

ACQUIRED UTILITIES

1. INTRODUCTION

Hydro One, since its last rebasing of rates for 2015-2017, has acquired three local distribution companies – Haldimand County Hydro Inc. ("HCHI"), Norfolk Power Distribution Inc. ("NPDI"), and Woodstock Hydro Services Inc. ("WHSI") (collectively the "Acquired Utilities"). Operationally, all three of the Acquired Utilities have been integrated into normal Hydro One operations. The investment planning for these areas follows the process described in Section 2.1 of the DSP. The Asset registry information and the Asset Strategies employed to monitor and maintain the Acquired Utilities' assets are included in Sections 2.2 and 2.3 of the DSP.

For rate making purposes the Acquired Utilities have been kept separate from Hydro One. The financial information presented in the DSP and the Application excludes the financial information for the Acquired Utilities until January 1, 2021. The purpose of this Exhibit is to present information related to the investment planning process that is unique to the Acquired Utilities until January 1, 2021. This information is provided for each Acquired Utility in the following three areas:

Regional Planning

The Service Areas covered by the LDCs were included in the Regional Planning exercise and the outcomes are included in Section 2 of this Appendix.

Asset Management

The Acquired Utilities are already integrated operationally and from an Asset Registry perspective. Section 3 of this Appendix provides the summary information about each entity and the current respective asset base for each of the Acquired Utilities.

Capital Expenditures

As described in Exhibit A, Tab 7, Schedule 1, the Rate Bases of the Acquired Utilities will be financially integrated into Hydro One for rate making purposes as of January 1, 2021. Details on the capital expenditures for the Acquired Utilities on a historic and forecast basis are provided in Section 4 of this Appendix.

2. REGIONAL PLANNING

2.1.1 HALDIMAND COUNTY HYDRO

The area of the former Haldimand County Hydro was part of the Niagara Sub-region in Group 3. HCHI was a participant in the latest round of regional planning. Details of the Regional plan are included in Section 1.2 of the DSP and the Needs Assessment Report for the region is included in Section 1.2.5 – Attachment #24.

No significant actions were determined for Haldimand County Hydro as a result of the Regional Planning activities.

2.1.2 NORFOLK POWER

The area of the former Norfolk Power was part of the Burlington to Nanticoke Sub-region in Group 1. NPDI was not a formal participant in the latest round of regional planning as the company was integrated prior to the last round. Hydro One represented NPDI customers at the meetings. Details of the regional plan for this area are included in Section 1.2 of the DSP and the Local Planning Report for the region is included in Section 1.2.5 – Attachment #5.

Recommendation #7 found that there was a need for Reactive support in the Norfolk Area. However, it was also found that the coincident load at Norfolk TS and Bloomsburg TS can be managed by load transfer and kept below the area supply limit of 87 MW. The study team recommended that Hydro One Distribution can manage the overload in the Norfolk area by performing load transfers to neighbouring stations. As a result, no material capital spending was identified as a result of the Regional Planning exercise for NPDI customers.

2.1.3 WOODSTOCK HYDRO

The area of the former Woodstock Hydro was part of the London Sub-region in Group 2. WHSI was a participant in the latest round of regional planning. Details of the Regional plan are included in Section 1.2 of the DSP and the Needs Assessment Report for the region is included in Section 1.2.5 – Attachment #17.

No significant actions were determined for WHSI as a result of the Regional Planning activities.

3. ASSET MANAGEMENT OF ACQUIRED UTILITIES

3.1 INVESTMENT PLANNING PROCESS

Hydro One's planning process includes determining appropriate investment for the Acquired Utilities. For investments over the planning period, the process will follow that outlined in detail for Hydro One in Section 2.1 of the DSP.

3.2 OVERVIEW OF ASSETS MANAGED

3.2.1 HALDIMAND COUNTY HYDRO INC.

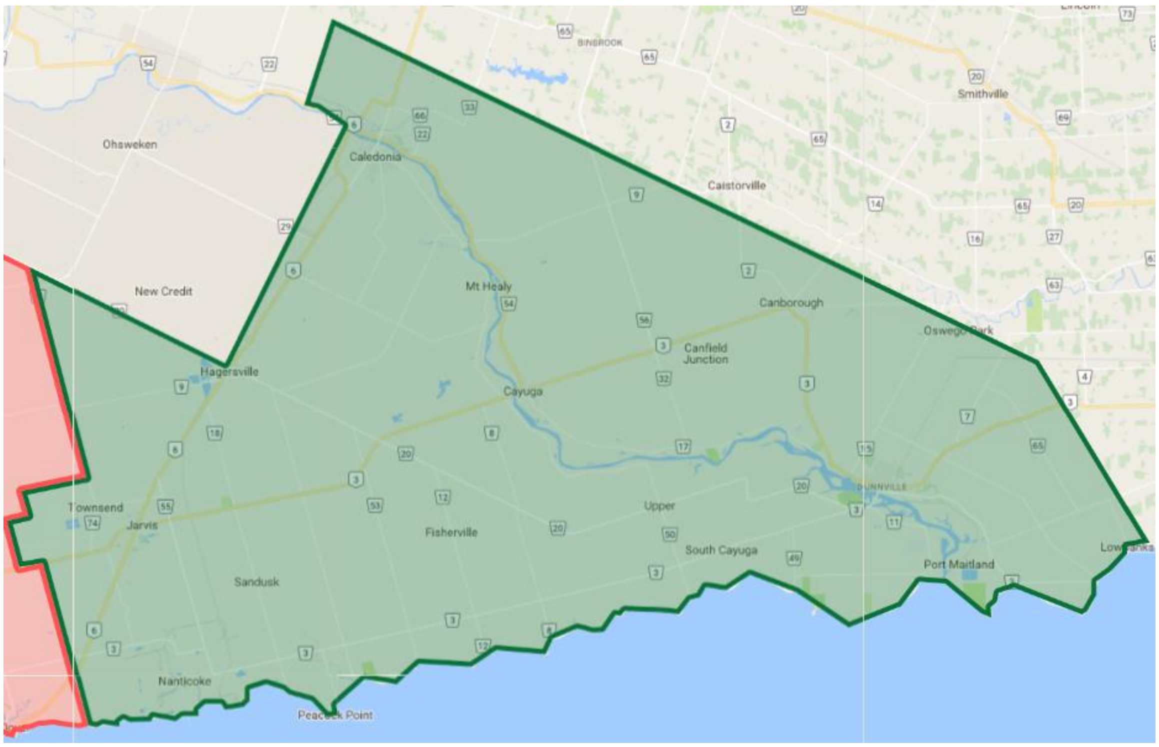

Figure 2 - Map of the Former Service Territory of Haldimand County Hydro Inc.

The former HCHI service territory is 1,252 square kilometres. The area is over 97% rural with a few urban pockets in towns such as Caledonia, Nanticoke and several others.

Prior to integration, HCHI served 21,407 customers – 18,899 residential and 2,508 commercial/industrial. The economic base is mainly made up of agricultural and manufacturing enterprises.

The predominantly rural make-up of the territory leads to a relatively low 12.4 customers per circuit km. Most customers are serviced by overhead assets. Underground lines comprise 6% of total circuit kilometres.

Assets integrated into Hydro One from HCHI include over 1,733 circuit kilometres of feeders, 27,931 poles, 7,259 transformers, and 5 sub-stations. The net book value of fixed assets, including Property, Plant, and Equipment, at the end of 2016 is approximately $53.3 million. Table 1 provides historical continuity of total fixed assets.

Table 1 - HCHI Historical Fixed Assets

3.2.2 NORFOLK POWER DISTRIBUTION INC

NPDI is a non-contiguous rural service territory of 693 square kilometres. The area is 79% rural with a few urban pockets including Simcoe and Port Dover. The territory also includes the satellite towns of Delhi and Port Rowan.

Prior to integration, NPDI served 19,559 customers – 17,393 residential and 2,166 commercial/industrial.

The former NPDI territory is predominantly rural with a customer per circuit kilometre measure of 24.7. Most customers are serviced by overhead assets, with underground lines comprising 16% of the total.

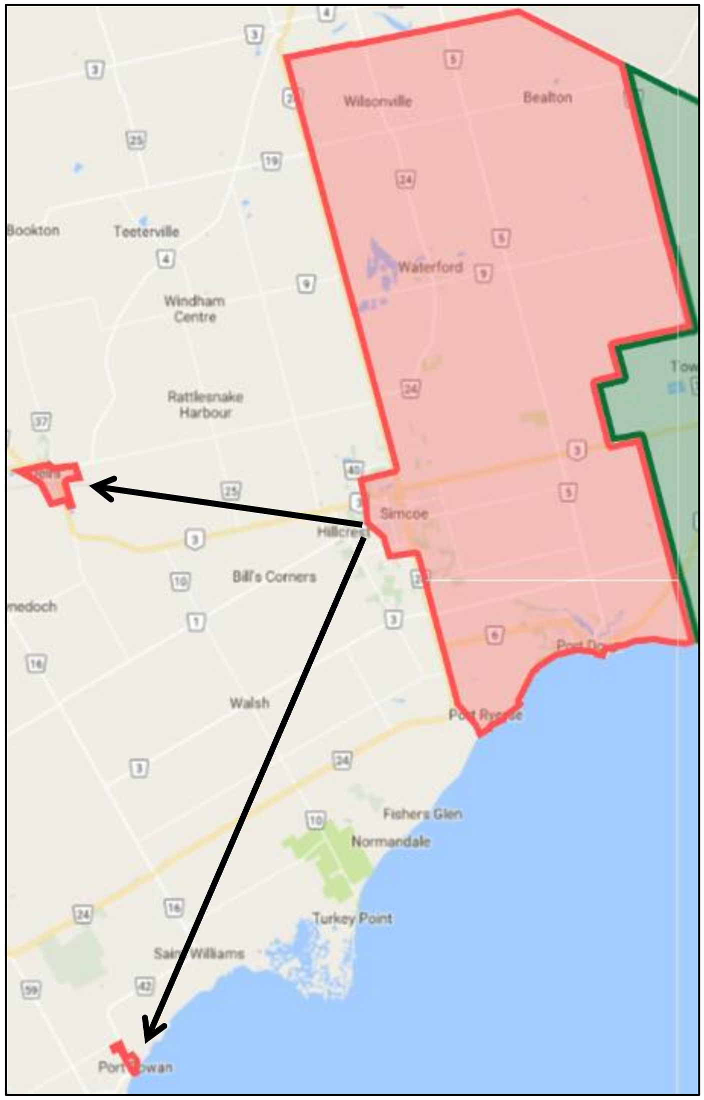

Figure 3 - Map of the Former Service Territory of Norfolk Power Distribution Inc.

Assets integrated into Hydro One from NPDI include 793 circuit kilometres of feeders, 11,020 poles, 4,469 transformers, and 9 sub-stations. The net book value of fixed assets, including Property, Plant and Equipment at the end of 2016 is approximately $54.7 million. Table 3 provides historical continuity of total fixed assets.

Table 3 - NPDI Historical Fixed Assets

Year End Fixed Assets	2012 Plan	2012 Actual	2013 Actual	2014 Actual	2015 Actual
Utility Plant (Year End)					
Gross Plant at Cost	84.7	83.6	86.9	56.6	56.2
Less: Accumulated Depreciation	(30.8)	(29.7)	(32.1)	(0.8)	(2.8)
Net Fixed Assets	**53.9**	**53.9**	**54.8**	**55.7**	**53.4**

NPDI's forecast rate base for the years 2016-2020 is shown in Table 4.

Working Capital		3.6	3.7	3.9	4.1	4.3
Rate Base		**58.9**	**60.0**	**60.8**	**61.6**	**63.0**

3.2.3 WOODSTOCK HYDRO SERVICES INC.

WHSI is a contiguous, purely urban service territory serving a relatively small geographic area (under 30 square kilometres) comprising the majority of the City of Woodstock.

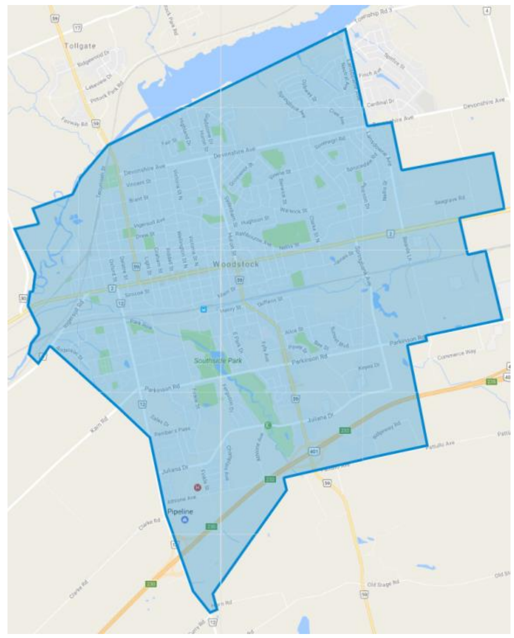

Figure 4 - Map of the Former Service Territory of Woodstock Hydro Services Inc.

Prior to integration, WHSI served 15,966 customers – 14,507 residential and 1,459 commercial/industrial. The economic base is driven by manufacturing including automobile assembly with a large Toyota Plant located on the east side of the city.

WHSI is a pure urban area with a customer per circuit kilometre measure of 62.6 and underground lines comprise 44% of the total.

Assets integrated into Hydro One from WHSI include 255 circuit kilometres of feeders, 4,200 poles, 1,618 transformers, and 7 sub-stations. The net book value of Property, Plant and Equipment at the end of 2016 is approximately $27.2 million. Table 5 provides historical continuity of total fixed assets.

Table 5 - WHSI Historical Fixed Assets

Net Plant	**27.2**	**28.3**	**29.6**	**30.3**	**31.2**	**32.3**
Average Net Plant		27.8	28.9	29.9	30.7	31.7
Working Capital		4.1	4.3	4.6	4.8	5.0
Rate Base		**31.9**	**33.3**	**34.5**	**35.5**	**36.8**

3.2.4 TOTAL RATE BASE

Table 7 presents the total gross plant, accumulated depreciation, net plant, working capital and rate base for the three acquired utilities. The December 31st 2020 ending balance of gross plant and accumulated depreciation of the Acquired Utilities have been added to the opening balance of Hydro One's gross fixed assets and accumulated depreciation effective January 1, 2021. This results in an increase in net fixed assets for Hydro One of $150.9 million. This amount has been included in the Hydro One's total rate base starting in 2021 as presented in Exhibit D1, Schedule 1, Tab 1. The total impact of adding the acquired utilities to Hydro One's rate base is the average net plant for 2021 of $153.5 million plus the associated working capital of $14.9 million.

Table 7 - Total Rate Base All Acquired Utilities

Total Rate Base	**2016**	**2017**	**2018**	**2019**	**2020**	**2021**
Utility Plant (Year End)						
Gross Plant at Cost	143.7	151.9	159.7	167.4	175.6	184.9
Less: Accumulated Depreciation	(8.5)	(12.4)	(16.4)	(20.5)	(24.6)	(28.9)
Net Plant	**135.2**	**139.5**	**143.3**	**147.0**	**150.9**	**156.0**
Average Net Plant		137.4	141.4	145.1	148.9	153.5

Rate Base		**149.7**	**154.2**	**158.6**	**163.1**	**168.3**

4. CAPITAL EXPENDITURE SUMMARY

4.1 TOTAL – ALL ACQUIRED UTILITIES

Table 8 - Total Spending - All Acquired Utilities

	Historical (previous actual)				Forecast		
	2014 Actual	2015 Actual	2016 Actual	2017 Bridge	2018 Test	2019 Test	2020 Test
CATEGORY	$M	$M	$M	$M	$M	$M	$M
System Access				2.1	2.1	2.1	2.1
System Renewal				4.9	4.5	4.6	4.9
System Service				1.2	1.2	1.1	1.2
General Plant				0.0	0.0	0.0	0.0
Total	13.2	11.1	8.6	8.2	7.8	7.8	8.1
System OM&A*	18.8	17.8	12.5	10.2	10.3	10.6	10.5

Capital spending for the acquired utilities on a total basis is relatively steady over the planning period, varying from $7.8 million in 2018 to $8.1 million in 2020. Approximately 60% of forecast spending is in System Renewal.

The variance in spending over the years of the planning period is almost exclusively in the System Renewal category, varying from a low of $4.5 million in 2018 to a high of $4.9 million in 2020.

Historical data on a combined basis is available since 2014. Spending over the planning period represents a decline from 2015 levels but slightly above 2016.

Specific variance explanations within projects and programs are contained in the material for each individual acquired utility included below.

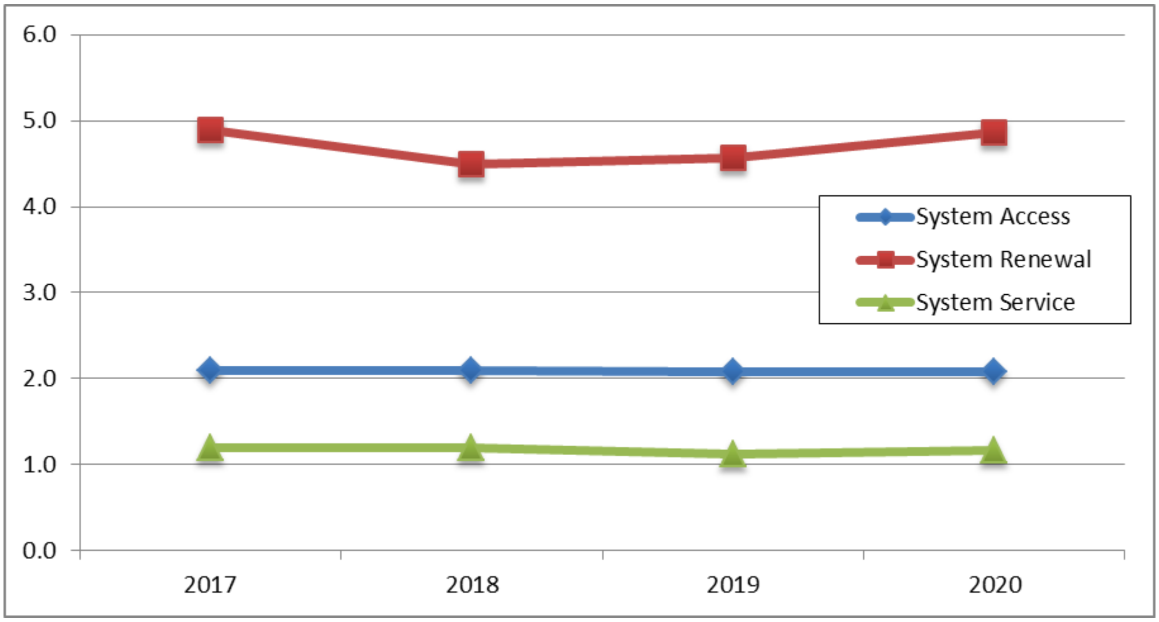

Figure 5 - Total Forecast Capital Spending by Category

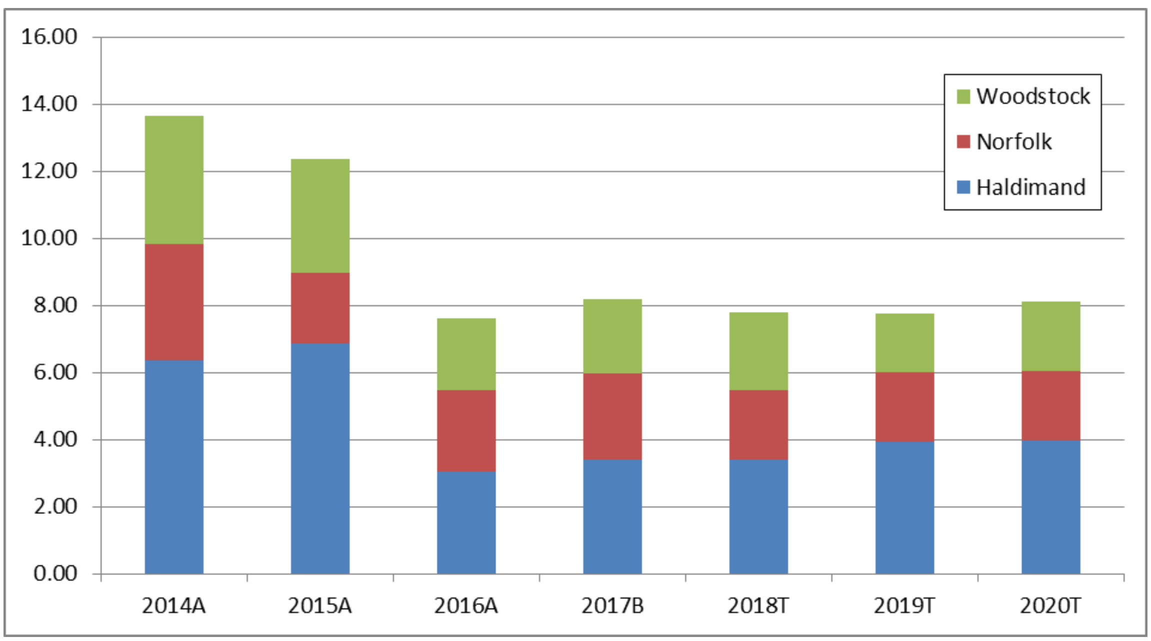

Figure 6 - Total Capital Spending by Acquired Utility

4.1.1 HALDIMAND COUNTY HYDRO INC.

Table 9 - Total Spending - HCHI

CATEGORY	Historical (previous plan and actual)						Forecast (planned)		
	2014			2015	2016	2017	2018	2019	2020
	Plan	Actual	Var	Actual	Actual	Bridge	Test	Test	Test
	$M		%	$M	$M	$M	$M	$M	$M
System Access						0.9	0.9	0.9	0.9
System Renewal						1.7	1.7	2.3	2.4
System Service						0.8	0.8	0.7	0.7
General Plant						0.0	0.0	0.0	0.0
Total	6.4	6.3	-1.2%	6.9	4.6	3.4	3.4	3.9	4.0
System OM&A*	8.2	7.5	-8.5%	6.0	6.0	5.1	5.1	5.2	5.3

** System OM&A values include all Operations, Maintenance and Administration expenses.*

Forecast vs. Historical Variance

HCHI last rebased in 2014 (EB-2013-0134). Spending against 2014 approved amounts was generally consistent through 2014 and 2015. Spending was reduced in 2016 and 2017. The primary reduction in 2016 occurred due to the deferral of the following significant projects: (i) elimination of Jarvis DS Phase 1; (ii) underground (non-duct) Cable Replacements in Townsend; and (iii) Grand River Crossing in Caledonia.

Spending is expected to be steady throughout the planning period. A modest increase is expected in 2019 and 2020 based primarily on a $150k increase in the Transformer replacement program and a $400k increase in the Underground cable replacement program.

Witness Lyla Garzouzi

4.1.2 NORFOLK POWER DISTRIBUTION INC.

Table 10 - Total Spending – NPDI

	Historical (previous plan and actual)								Forecast (planned)

System OM&A*	5.7	6.4	12.5%	6.0	7.2	5.9	2.7	3.1	3.1	3.2	3.2

** System OM&A values include all Operations, Maintenance and Administration expenses.*

Forecast vs. Historical Variance

NPDI last rebased in 2012 (EB-2011-0272). Capital spending was slightly above approved amount in 2012. In 2013 and 2014 spending was reduced due to: (i) a $200k reduction in Transformer inventory; (ii) a $200k reduction in spending on Demand Meter inventory; and (iii) a $200k reduction in spending on Computer and SCADA equipment. For fiscal 2015 to 2017, capital spending came in lower due primarily to a reduction in pole ($300k) and transformer ($200k) replacements along with a deferral of a number of conversion projects that, in total, contributed an additional reduction of $300k. Spending is expected to be steady through 2018 to 2022 at $2.1 million per year.

4.1.3 WOODSTOCK HYDRO SERVICES INC.

Table 11 - Total Spending - WHSI

	Historical (previous plan and actual)									Forecast (planned)		
	2011			2012	2013	2014	2015	2016	2017	2018	2019	2020

System OM&A*	4.0	3.8	-5.7%	4.0	4.3	4.1	4.2	3.8	2.1	2.1	2.3	2.1

** System OM&A values include all Operations, Maintenance and Administration expenses.*

Forecast vs. Historical Variance

Woodstock last rebased in 2011 (EB-2010-0145). Capital spending in 2011 was higher than approved primarily due to the Commerce Way Transmission Station Contribution of $2.5 million. Spending was reduced in 2015 through 2017 with the reduction in expenditures for underground conduit, overhead transformers, and general plant, including transportation equipment and software.

Spending throughout the application period is expected to be generally in line with 2017 levels. A decrease in 2019 is forecast based on a temporary $250k reduction in Large Sustainment Initiatives for 2019. There is also a $100k reduction in the Recloser upgrade program and a $150k reduction in the Station Component program in 2019. The increase in 2020 is largely driven by a $150k increase in Small Sustainment Initiatives.

Attention: Mr. Oded Hubert, P. Eng. MBA
Vice President, Regulatory Affairs

Dear Sir

Re: Hydro One Networks Inc. Distribution System Plan for their 2018 – 2022 OEB Rate filing

As part of the filing requirements set out by the Ontario Energy Board (OEB) for Distributor's, Hydro One Networks Inc. has prepared the attached Distribution System Plan (DSP). Hydro One Networks Inc. prepared the data and furnished the information contained in the plan.

The Plan was prepared in accordance with Good Asset Management Practice, Industry Best Practices and the current Chapter 5 Filing Requirements. AESI critiqued this plan, made recommendations and suggestions, all of which were reviewed by Hydro One Networks Inc.

AESI confirms that the attached DSP satisfies the OEB filing requirements; addressing the goals and achieving the purpose of the OEB *Chapter 5 Consolidated Distribution System Plan Filing Requirements* dated March 28, 2013.

Please find attached AESI's Final Report which provides further details regarding AESI's review of Hydro One Networks Inc.'s Distribution System Plan.

Sincerely,

N. Sandford.

Neil Sandford P. Eng.
Senior Vice President
AESI Acumen Engineered Solutions International Inc.

Introduction

As part of the filing requirements set out by the Ontario Energy Board (OEB) for Distributor's, Hydro One Networks Inc. prepared its Distribution System Plan (DSP) addressing the goals and achieving the purpose of the OEB *Chapter 5 Consolidated Distribution System Plan Filing Requirements* dated March 28, 2013.

Hydro One Networks Inc. prepared the data and furnished the information contained in the plan. AESI critiqued the plan, made recommendations and suggestions, all of which were reviewed by Hydro One Networks Inc.

Please find below further details regarding AESI's review of Hydro One Networks Inc.'s Distribution System Plan.

Findings and Recommendations

AESI found this DSP demonstrated Hydro One's commitment to the Renewed Regulatory Framework for Electricity Distributors in that it includes a performance based approach that is based on outcomes that provide value for customers.

AESI was impressed with the reliability and robustness of the Asset Management Process. Key strategic messages have been included throughout the DSP. Hydro One has also illustrated an appropriate alignment between the proposed investment levels, customer engagement results and asset need.

AESI was pleased to see that the investment planning process applied in the DSP was iterative. Hydro One created several different asset investment plans with different customer outcomes and rate impacts and chose the plan that best balanced its business objectives with preferred customer outcomes, especially as it focuses on a more competitive business model.

AESI felt that Hydro One showed a good effort at following the Chapter 5 Table of Contents, although the document does not totally line up and Hydro One did not accept all of AESI's suggestions for format. This is Hydro One's first complete, comprehensive DSP and the utility agrees that it will be even more comprehensive in the next filing.

Hydro One received the IESO letter of comment regarding Hydro One Network Inc.'s Distribution System Plan (DSP) on March 9, 2017. Hydro One explained the reasons for the small differences in numbers between the DSP and the IESO numbers. The differences were due to different reference points, Hydro One's reference point was August 31st, 2016 whereas the IESO's was January 31st, 2017 as well as the different interpretation regarding what is included in the MicroFit projects. With this explanation, AESI is satisfied that Hydro One has met IESO's requirements.

AESI did recognize a few specific areas within the DSP that did not follow the prescribed Chapter 5 outline. For example, Section 1.3, Customer Engagement. AESI found its positioning appropriate considering the importance of its customer engagement within its business objectives and planning process. AESI also considered the placement of Sections 1.5 Productivity and Continuous Improvement and Section 1.6 Benchmarking appropriate as this highlights the importance of these topics with Hydro One's increased commercial focus.

Hydro One also made the decision to discuss "How the Plan reflects Regional Planning, Customer Needs and Benchmarking" in its first chapter, with a summary in the later section as prescribed in Chapter 5. This reflects Hydro One's desire to illustrate the complete picture of those activities in one section. AESI is in agreement with this approach.

AESI did identify areas of opportunity to better demonstrate alignment with the OEB requirements.

- In the section 1.4.2 (5.2.3b) - Performance Trends (Table 13 – SAIDI by Outage Cause) Hydro One only reported on 8 causes rather than the 10 prescribed by the OEB. Hydro One explained to AESI that this is due to software application limitations. Hydro One recognizes this difference in reporting and is working on correcting its outage cause data.
- AESI had several questions about Hydro One's use of the term "cost savings". Hydro One explained its interpretation of cost saving; the change in nature of costs within a specific timeframe - the "input/output" cost savings. Hydro One explained that; the "input/output" types of savings are included in the Productivity section. Other references to "cost savings" may include avoided costs, efficiency costs, or process innovation costs which may not directly affect productivity.
- AESI provided Hydro One with suggestions regarding other reporting metrics such as; job estimate to actual. Hydro One acknowledged that this was a meaningful metric and stated that it would be considered in the future.
- AESI suggested that in addition to the raw numbers for SAIDI, SAIFI and CAIDI that Hydro One also compute each to the attributable cause codes. Hydro One appreciated the suggestion and subsequently included that information in the DSP.

AESI provided Hydro One with numerous other points of clarification and suggestions. Hydro One stated that it appreciated AESI's points and suggestions. Hydro One provided AESI with comments on all of the points. In some cases Hydro One did not heed the comments but explained its rationale and appreciated that they would be of assistance in more thoroughly preparing for interrogatories during the hearing process.

AESI confirms that the attached DSP satisfies the OEB filing requirements; addressing the goals and achieving the purpose of the OEB *Chapter 5 Consolidated Distribution System Plan Filing Requirements* dated March 28, 2013 and appreciates Hydro One's commitment to further refining its DSP in future filings.

AESI

Ruth Greey, M.Sc.

Professional Summary

Ruth Greey has over 30 years' of in-depth management, interpersonal and leadership experience in the energy industry. She has extensive expertise in many aspects of the energy sector regulatory environment, including environment, LDC rate approvals, energy infrastructure approvals, CDM, customer relations, new energy technologies and First nation relations.

Relevant Project Experience

Regulatory

- Work with numerous Local Distribution Companies in developing their Distribution System Plans and 5 year custom incentive regulation rate applications.
- Liaise with the OEB and the Consumers Council of Canada (CCC) to ensure customer interests are considered and addressed through regulation and public review. Specific projects include:
  - developed and reviewed the process to address the remaining Long Term Load Transfers for all electric utilities in Ontario
  - developed and reviewed the process to address Cost Allocation of Transmission facilities (on-going)
  - participated in all stages of the OEB regulatory approval process related to rate applications for Oshawa PUC, Kingston Hydro, Hydro Ottawa, Toronto Hydro, PowerStream, Enersource Hydro Mississauga and Horizon Utilities
- Prepare and deliver written reports and oral communications to external stakeholders and provincial shareholder to facilitate positive working relationships
- Develop and deliver witness training including working with external facilitator and lawyers
- Lead the development, submission and approval of regulatory filings associated with rate applications for Hydro One's Transmission, Distribution and Remotes businesses
- Work with the OEB to develop new effective generic proceedings for Long Term Load Transfers (LTLTs), Smart Meters, CDM, Incentive Regulation, Minimum Filing Requirements, Development Costs for Transmission Projects and other generic issues.
- Lead all aspects of preparation and execution for Ontario Energy Board Oral hearings
- Manage cooperative, effective relationships with OEB, Hydro staff, Intervenors and other advocacy groups for Hydro One

Advocate

- Lead the development, nurturing and management of the relationships with provincial and municipal government Ministries to ensure the implementation of key corporate priorities and to advocate

Areas of Expertise

- Interpersonal, Communications and Facilitation Skills
- Ontario Regulatory Requirements
- Transmission and Distribution
- Environment

Education

- Ryerson University, Continuing Education, January 2015 - present
- Master of Science, University of Guelph, 1982
- Bachelor of Science (Honours), Queen's University, 1979

Professional Associations

- Canadian Environmental Management Committee
- National Round Table on Environment and Economy
- Steering Committee – Edison Electric Institute
- Steering and Executive Committee – Utility Health

legislative changes to advance Hydro One's interests

- Lead external agency teams and industry associations to influence the direction of the electrical industry priorities and strategies
- Lead the liaison between the provincial government and Hydro One regarding regulatory applications
- Represent Hydro One on inter-agency working groups to ensure the successful implementation of the corporate objectives
- Establish credible and timely communications with the provincial government shareholder and other government Ministries

Environment

- Lead a Team with the Ministry of Environment and Hydro One major industrial customers to amend the Class Environmental Assessment for Transmission Facilities. This involved initiating, planning, setting objectives and targets, leading multi-stakeholder teams, implementing strategies, negotiating, presenting to the public and interest groups. This necessitated strong communication and negotiating skills as well as excellent people management skills.
- Lead a Team for the Ontario Energy Board to amend Hydro One's Transmission System Code. This position necessitated excellent negotiating skills, good internal team leadership skills such as coaching, communicating and translating concepts and knowledge regarding regulatory policies into practice with staff, stakeholders and the public.
- Lead other corporate programs involving setting environmental policy and then implementing and communicating the appropriate programs for the Provincial government, external stakeholders and customers.
- Developed and Lead CEA's Flagship National environmental program. In directing this Program, Ruth advised Utility Executives regarding managing their environmental and related issues at a national level. She worked with federal government agencies to influence proposed federal regulations, and provided advice on Sustainability Reporting across the country. Ruth facilitated a Public Advisory Panel made up of international environmental experts. She facilitated the administration of the program including; preparing an Annual Report; managing the Program Steering Committee, reporting to the CEA Board of Directors and leading an independent verification process.
- Lead federal, provincial and municipal government consultation to influence regulations on PCBs, EMF and other electricity issues

EMF Issue Management

- Corporate Spokesperson for the Electric and Magnetic Fields issue including releasing Ontario Hydro health study results to employees and the public, as well as presenting the results worldwide
- Through coordination, influence, motivation and collaboration with all stakeholders in Ontario interested in EMF, Ruth changed the focus and direction of EMF issue management in Ontario.
- Provided leadership and support to Senior Management regarding issues management techniques. Developed and facilitated the implementation of corporate public and environment programs and policies working with employee and Union representatives
- Chaired several provincial, national and international communication and corporate planning committees. Chaired an international symposium on EMF in Denmark attended by delegates from 45 countries.

AESI

Ruth Greey, M.Sc.

Customer Care

- Manage all contact handling activities for residential customers through an outsourced service provider (for customer billing, meter reading, collections programs), as well as an escalated complaint centre
- Manage the outsourced contract to ensure all service level agreements are met and that the contract demonstrates continuous improvement
- Manage the relationship between customer care, corporate communication, conservation management programs and the customer focused field activities
- Ensure effective business readiness and sustainment in support of our new Customer Information System that was implemented in May 2013
- Provide negotiating expertise and skills, to develop service agreements, statements of work, contractual service and pricing methods, negotiation or pricing approaches, governance or approval needs for Hydro One's outsourced Customer Call Centre, Billing and Collections Department, and special Customer related projects such as Customer Outage strategies
- Manage the contractual interface and overall relationship management with Inergi for outsourced Customer Care services

AESI

Ted Wojcinski, P.Eng., C.I.M., SMIEEE

Professional Summary

Ted Wojcinski has more than 34 years of engineering, operations and management expertise and a proven track record in the electricity distribution utility industry. Ted has worked his way up through the ranks from system engineering to planning, operations, regulatory, environmental and management. His comprehensive experience provides a broad perspective that allows him to bring a full-circle approach to projects enhancing the derived value. His experience is complimented with consistent involvement and research on regulatory obligations and Smart Grid Applications—keeping him up-to-date on requirements, technology and industry trends.

Relevant Project Experience

Regulatory

- Development of consolidated Distribution System Plans and supporting documents, processes, etc. for Newmarket-Tay Power Distribution Ltd. and Milton Hydro Distribution Inc.(2014 – 2015)
- Reviewed Asset Management practices of Peterborough Distribution Inc. to identify practice gaps and recommended actions to address the gaps and guide the preparation of their Distribution System Plan (2014)
- Provided utility expertise in crafting capital related project justifications for PowerStream's IRM submission to the Ontario Energy Board in 2013.
- Providing assistance to Horizon Utilities Corp.in the implementation of its Smart Grid plans (2013)
- Monitoring developments in the Ontario government's Green Energy Act as it pertained to the utility industry to assess its impact on connecting distributed generation
- As a member of the Rate Base and Capital Panel team, successfully defending PowerStream's Green Energy Plan and 2013 $114M capital submission, a 45% increase in spending over 2012 levels, to the Ontario Energy Board (OEB)
- Spearheading a gap analysis study to determine PowerStream's current level of achievement under the PAS-55 Asset Management Standard to comply with future regulatory guidelines
- As a member of PowerStream's Smart Grid Task Force, providing engineering expertise in the development of PowerStream's Smart Grid Strategic Plan in response to provincial government and regulatory guidelines
- Providing engineering and operations expertise to the OEB as a member of the OEB Performance Based Rates and Service Quality consultation working groups

System Planning

- Developing PowerStream's first ever comprehensive Distribution System Planning Report that has since evolved into PowerStream's 5 Year Capital Plan

Areas of Expertise

- System Planning
- Regulatory and environmental
- Utility Operations and Management
- Smart Grid applications

Education

- Masters Certificate in Electricity Sector Leadership (MCESL), York University Schulich School of Business, 2012
- Certified in Management (CIM), Canadian Institute of Management, 1988
- Bachelor of Applied Science in Electrical Engineering, University of Toronto, 1980

Professional Associations

- Senior Member, IEEE
- Professional Engineers of Ontario
- Ontario Society of Professional Engineers

- Providing management and engineering expertise in development of PowerStream's Asset Condition Assessment program through the development and incorporation of asset health models for critical equipment infrastructure to strengthen regulatory rates submissions
- Developing and executing Engineering Planning's 5 year Capital Plans that encompassed asset condition assessment and replacement programs and most recently, successfully managing $20M in 2012 Capital expenditures
- Initiating the York Region Supply Study with the OPA that included external stakeholder groups such as Hydro One, Independent Electricity System Operator (IESO) and other Local Distribution Companies (LDC) and providing distribution engineering expertise in the development of near, medium and long term plan options
- Providing engineering expertise as PowerStream's representative to the 2005 Northern York Region supply study including consultation with ratepayer group representatives

Utility Management

- As a member of the Senior Leadership Team provided the overall strategic direction and management of the Engineering Planning department for the second largest electricity distributor in Ontario
- Presenting engineering related updates and recommendations to PowerStream's Executive Leadership Team, board of directors and municipal politicians on distribution issues
- Providing management and engineering expertise to the review of distribution Inspection and Maintenance practices at PowerStream
- Chairing PowerStream's Reliability Committee to drive the organization's performance towards a 5-9s reliability standard
- As Corporate lead and Committee Chair, developing and coordinating PowerStream's 2010 and 2013 strike contingency planning efforts
- Instituting PowerStream's first annual Environmental Sustainability Report and generating recommendations for PowerStream's 2008 Environmental Program, the first of which was the adoption of PowerStream's Environmental Policy Statement and creation of an Environmental Section
- Creating PowerStream's Environmental Section and developing the associated corporate policies/procedures on environmental sustainment including the identification of Environmental Aspects and Impacts and identification of Environmental Requirements
- Successfully managing a multi-disciplinary team of in-house and contract resources to develop and deliver PowerStream's Conservation and Demand Management programs, including the design, construction and commissioning of Wind and Solar demonstration facilities at PowerStream's Head office, a Gold LEED building

Station Design and Sustainment

- As a member of the Senior Leadership Team provided the overall strategic direction and management of the Station Design and Sustainment department
- Providing oversight of station projects that encompassed the Class Environmental Assessment (EA) approval, design, construction and commissioning of Markham Transformer Station #4, a $20M project
- Conducting a comprehensive organizational assessment of the Stations capabilities and developing action plans to facilitate the effective functioning between engineering and operations Directed and managed all operational functional areas such as system control, lines and station maintenance

Engineering

- Prepared report for PowerStream Inc. that presented various options, for PowerStream's consideration, to effectively "harden" the distribution system against ice storms and severe weather in general (2014)
- Performed a review of the supply options to the Kenora Paper Mill site and adjacent areas for Kenora Hydro to align with regulatory requirements (regional planning, Distribution System Code) and "good utility planning" practices that impact on how new electrical infrastructure is planned. Respective electrical supply and cost allocation obligations of Kenora Hydro and the site developer(s) were identified and recommendations were provided to Kenora Hydro's executive management to guide their infrastructure planning (2013)
- Cultivating PowerStream's Stations department into a high performance team to deliver best in class Distribution Generation assessment and connection services under the Ontario Power Authority (OPA) Feed-In-Tariff (FIT) program
- Underground Engineering Supervisor (Toronto Hydro, 1988 – 1991)
- Network Engineering Supervisor, (Toronto Hydro, 1987 – 1988)
- Low Voltage Services Supervisor (Toronto Hydro, 1985 – 1987)
- Project Engineer (Toronto Hydro, 1980 – 1985)

AESI

Neil J. Sandford, P. Eng.

Professional Summary

- Neil Sandford has over 38 years of experience in the electricity distribution industry, including 17 years as a senior engineering and operations manager with an Ontario distribution utility. As Senior Vice President he provides leadership for and participates in a number of managerial and technical distribution projects for electric utility clients in Canada and the United States. He serves on the Board of Directors of an Ontario distribution utility and acts as the General Manager for the GridSmartCity Cooperative (13 Ontario Local Distribution Companies). He was chair of the Electrical Safety Authority's Utility Advisory Council for 10 years since its establishment, in 2004. He is also past chair of the Electricity Distributors Association Commercial Members Steering Committee.

Relevant Project Experience

Management and Planning

- Utility management and Regulation
- Asset Management and Distribution System Plans
- Green Energy Act Plans
- Consulting
- Administration
- Planning, safety and regulatory requirements
- Established/investigated new business ventures for fibre optic/telecommunications, meter services, co-generation plant opportunities,

Engineering and Operations

- System Performance Reports
- Electrical Safety Authority, Ont. Reg. 22/04 Consulting, Training and managing ESA Annual Audits
- Underground distribution, distribution automation and energy management

Electrical Design

- Specializing in land development and underground electrical distribution systems,
- Sub-station design and system planning,
- Electrical power projects within oil refinery operations
- Power cable contracts and construction

Areas of Expertise

- Utility Management: Strategic Planning, Performance Management, Labour Negotiations
- Electrical Distribution: Engineering, Operations, Planning, Safety
- Electric Industry and Utility Restructuring
- Project Management
- Asset Management
- Risk Management

Education

- Electrical & Electronic Engineering, Portsmouth and Plymouth Polytechnics, U.K.
- Executive Program, University of Western Ontario, 1994

Professional Associations

- PEO - Professional Engineers of Ontario
- Electricity Distributors Association (EDA)

WORK EXECUTION STRATEGY (CAPITAL/OM&A)

1. INTRODUCTION

The purpose of Hydro One's Work Execution Strategy is ensure that Hydro One effectively and efficiently completes its annual distribution work program, while focusing on the Company's business objectives including safety, reliability, innovation, protecting the environment, employee engagement, shareholder value and meeting customer commitments. Hydro One has demonstrated its ability to successfully execute a large work program while maintaining the necessary flexibility to address emergent work and changing priorities. By actively identifying ways to be more efficient and cost-effective, Hydro One can accommodate an increasing working program, provide customers with value for money, and produce distribution system outcomes that reflect customer preferences.

Hydro One's work planning and execution activities are designed to increase efficiency and innovation and contribute to a culture of continuous improvement. The implementation of Move to Mobile technology will improve productivity through geographic bundling and scheduling of work, enhance overall reporting and facilitate access to the latest maps, standards and designs. Move to Moble will also create a safer workplace for Hydro One employees because supervisors will be able to spend more time coaching field staff.

2. FACTORS IMPACTING FUTURE WORK PROGRAMS

The Hydro One Distribution work program has continued to increase and sustained growth is forecast over the next five years. Utility acquisitions, productivity and efficiency initiatives, Move to Mobile, regulation compliance, distribution asset condition and workforce demographics will all have an effect on work programs and projects in the coming years. This Exhibt will discuss these factors and their overall impacts on work programs and projects.

2.1 PRODUCTIVITY AND EFFICIENCY INITIATIVES

Hydro One has undertaken several productivity initiatives which will improve process efficiencies and result in cost savings in the execution of its work programs. Details regarding these initiatives, along with the estimated savings are provided in section 1.5 of the Distribution System Plan (Exhibit B1, Tab 1, Schedule 1).

2.2 INCREASING WORK VOLUMES

Hydro One Distribution's overall OM&A and Capital work programs are increasing:

- to satisfy the PCB testing and replacement requirements by 2025 set by Environment Canada regulations;
- to address the significant number of smart meters that require replacement in the next five years;
- to continue to address select areas of overgrown regions under the vegetation management program to manage costs and improve reliability;
- to manage the wood pole population through replacement of end of life wood poles and poles showing signs of premature decay;
- to address aging distribution station transformers and other distribution assets through replacement or refurbishment programs;
- to integrate and manage new customers as a result of LDC acquisitions;

- for the submarine cable maintenance programs to meet challenges as a result of receding water levels in the Great Lakes and to replace deteriorated cable as a result of age; and
- to ensure compliance with Ontario Regulation 22/04. This regulation has established a standard for electrical distribution safety requirements for all licensed electricity distributors in Ontario as well as national technical standards for infrastructure design and construction (including utility plant) with an audit-based compliance system. This has resulted in increased hours and costs to work on existing plant in order to ensure adjacent existing structures meet this regulation.

The wood pole replacement and vegetation maintenance programs are two major areas affected by increased work volumes. However, Hydro One continues to refine its strategies to adapt and become more efficient in work execution.

Wood Pole Replacement: Hydro One owns approximately 1.6 million distribution poles across the province of Ontario. The Company's end of life pole replacement program is the largest funded capital work program within Provincial Lines, with an average of about 14,000 poles to be replaced each year over the next five years. With each pole replaced, system reliability directly improves as poles at risk of failure are replaced with new poles. To become more efficient and cost effective in executing the program, Hydro One strategically selects poles to be replaced based on priority and identified criteria and aligns targeted work with Forestry's annual trimming cycle. By doing so, the costs are significantly reduced as a forestry crew has already cleared the line and an unplanned return trip for forestry is not required. In addition, Hydro One has leveraged local knowledge to bundle poles that are nearing end of life or showing premature signs of decay on the same feeder. Utilizing dedicated project crews that focus on pole replacement has proven to be an efficient and cost-effective strategy, but is dependent on the Company's annual work program and emergent needs. An increased focus on reporting to improve program visibility has been instrumental in monitoring program costs. The implementation of productivity and efficiency initiatives such as Move to Mobile and Perform will further improve scheduling of resources, reduce administrative efforts and enhance reporting, resulting in additional unit cost savings.

Vegetation Management: Hydro One's vegetation management program is required to manage electrical contact risk created from incompatible vegetation growth. There are approximately 7 million trees along the Company's rights-of-way. Trees are the primary cause of distribution outages; vegetation maintenance work programs are therefore crucial as accumulated vegetation will eventually lead to costly unplanned maintenance and frequent, lengthy, and capital-intensive storm restoration efforts. Leveraging integrated vegetation management practices and various optimization opportunities within the Forestry work program is the key focus of the vegetation maintenance plan over the next five years to improve system reliability and reduce program costs.

In addition to the annual Forestry work program, there are several initiatives that are being undertaken to synergize work execution and increase the use of technology. Hydro One's long-term direction is to use a staged approach to re-establishing assets on an appropriate cycle. Long-term strategies that are being considered include increasing focus on high priority and high density urban feeders and maintaining them on an on-going cyclic basis, as well as identifying strategic program kilometers to be completed annually. This strategy includes rural and single-phase sections of the system scheduled for maintenance based on reliability, condition, outage history and age criteria. Managing rights-of-way on a shorter and stricter cycle is part of the strategic vision for Hydro One's vegetation management program. Achievement of a more regular cycle lowers maintenance costs and provides a preventative treatment to mitigate tree-related outages. In addition, environmental and social impacts of operations will be reduced by limiting the quantity of vegetation removed and employee and public safety risks that overgrown power lines can pose will be minimized.

2.3 AGING DISTRIBUTION SYSTEM

Hydro One Distribution manages 1,005 distributing and regulating station facilities which are used for the delivery of power, voltage transformation and switching. An increased capital re-investment program is being undertaken to address the changes in load profile and deteriorating asset condition of the distribution stations fleet. Integrated station refurbishment and replacement programs are required to address the overall condition of the station assets and facilities. Failure to complete this work may result in decreased distribution system performance, negative effects on reliability, and impact the Company’s ability to maintain customer commitments. To prevent these issues from arising, distribution station refurbishment investments are released under an annual program framework. This increases visibility and allows Hydro One to prioritize stations identified for refurbishment to maximize accomplishment each year and minimize schedule delays and inefficiencies.

To align with transmission and distribution capital investments and better deploy resources, the station refurbishment program was transferred from the Stations and Operating Division to Construction Services in 2015. Hydro One is currently implementing productivity and efficiency initiatives to improve the capital estimating process and minimize issues and inefficiencies in the execution phase. A greater emphasis on cross-functional governance and reporting will also drive contiuous review of project scope, costs and timeframes and allow the Company to communicate and mitigate any risks with key stakeholders involved.

2.4 MATERIAL AND EQUIPMENT AVAILABILITY

The materials, equipment and fleet incorporated into the distribution work program account for approximately 25% of the total cost of the work. By actively monitoring equipment enhancement opportunities, Hydro One will improve work execution efficiencies. Increased demand for specialized materials continues to be a challenge as a result of rapid growth in work programs throughout North American utilities and the changing nature of the distribution business to enable distributed generation and Smart Grid technology. Mobile Unit Substation ("MUS") availability has been a challenge as Hydro One has a limited number of units that continue to be in high demand. MUSs are used to perform many maintenance activities, address system failures and support outages. As a result, effective management of fleet and equipment plays a significant role in Hydro One Distribution's ability to complete its annual work program. This becomes even more critical during peak customer demand periods to ensure customers do not experience delays.

2.5 WORK EXECUTION CAPACITY CHALLENGES

Hydro One has an integrated workforce for its transmission and distribution businesses. This allows Hydro One to take advantage of economies of scale and efficiencies that would not be realized through separate transmission and distribution operations. In order to successfully complete the work program, internal and external resources are utilized. Hydro One and other Electrical Utilities have recently been faced with a shortage of skilled trades, making it difficult to secure resources. To mitigate this shortfall, a greater volume of work will need to be outsourced. Where work is very integrated with existing facilities, it is always managed by Hydro One staff with support from outsourced specialists when required. All categories of external resources and services are becoming more difficult to contract as the North American demand increasingly exceeds available supply. Further details on how these issues are being addressed are discussed in the Staffing Strategy below.

3. IMPLEMENTATION OF WORK EXECUTION STRATEGY FOR 2017-2022 WORK PROGRAM

Hydro One Distribution has taken a number of actions to increase the volume of work the Company can complete in future years. Hydro One Distribution utilizes a fully integrated work planning method that optimizes the use of internal and external resources, manages costs and material availability, minimizes system outages and is mindful of customer needs.

3.1 INCREASED WORK BUNDLING AND OUTAGE OPTIMIZATION

Many of Hydro One's distribution projects and work programs require parts of the system to be electrically isolated while work is being performed. Obtaining the required planned outages becomes increasingly difficult as the distribution system grows larger and more complex with the addition of distributed generation and Smart Grid components, LDC acquisitions and supplied load increases. As a result, additional outages may be required to complete the annual work program and ensure system reliability is maintained. To accomplish this, Hydro One bundles work at common locations to become more efficient. Completing more bundled work enables Sustainment work and Development work to be planned and executed in an integrated manner under a common work plan.

Planned outages are also susceptible to being cancelled. Cancellation can be attributed to storm activity, customer demands and system constraints. When planned outages are cancelled, crews have to be demobilized and the work and required outages are rescheduled for a future date. This can result in increased project costs and limit work accomplishment. To minimize any inefficiency in outage coordination efforts due to these unforeseen issues, Hydro One has made a number of improvements to internal processes and communication with regard to outage planning and bundling of work. Some examples include meetings to review work plans and required outages for large projects to improve coordination between controlling authorities and formally establishing lead times for outage approvals to minimize risk of outage delays. This enables the Company to reduce the number of system outages required, utilize resources more efficiently, increase the total volume of work that can be executed and positively impact customer satisfaction.

Hydro One has also implemented a long-term balancing of preventive maintenance programs for switches, distribution transformers and instrument transformers. Work programs have been aligned into integrated and optimized maintenance frequencies and plan dates to minimize outages. For example, switch maintenance on a given feeder circuit is planned for the same year, with a single outage requirement. Optimized outages and bundled work directly reduces switching time requirements, crew windshield time and the number of required mobilization and demobilization activities for field staff.

3.2 WORK PROGRAM RELEASES

Quality upfront planning is essential for service groups to effectively and efficiently execute work. Hydro One continues to refine this practice to accommodate an increasing work program. In 2016, Provincial Lines separated planning and scheduling from execution of work to drive consistency and efficiencies throughout the province. Asset Management continues to improve the project definitions and timelines by which work is released. When work is released it means that the work and funding are ready for field execution. Earlier releases allow:

- the service groups to more efficiently plan, schedule and execute work;
- sufficient time to order materials with long lead times;
- coordination with other capital or maintenance work;
- the development of new commissioning and maintenance procedures and associated documents; and
- for work to be scheduled when site conditions are optimal. For example, crews take advantage of frozen conditions when access may be an issue.

Moving from annual work releases to multi-year releases for programs enables long term contractual vendor relationships and work to be bundled and scheduled more effectively. Multi-year programs also enable resources to be scheduled beyond the current year so that specific materials, equipment, and resources can be allocated over the entire duration of the program.

3.3 WORK PRIORITIZATION

To become more efficient in work prioritization, Hydro One has developed processes to improve investment prioritization and the assessment of asset risk. The investment prioritization process outlined in Section 2.1.5.1 of the Distribution System Plan (DSP) (Exhibit B1, Tab 1, Schedule 1), is a multi-criteria analysis which quantifies business risks so that objective decisions can be made respecting priorities in order to align cost effectiveness, asset and business needs and customer expectations. The asset risk assessment process outlined in Section 2.1.4.2 of the DSP, is Hydro One Distribution's new methodology for identifying current asset needs and creating a line of sight to future needs. This new methodology enables a holistic view of asset risk that improves decision making through the systematic evaluation of risk associated with distribution assets.

3.4 STRATEGIC SOURCING

Collaborative planning and strategic sourcing are fundamental components of the work execution strategy. Hydro One has an increased focus on streamlining sourcing events in order to drive increased value for the company. These initiatives ensure contracts are in place and long lead-time materials are being effectively managed to mitigate any potential impacts on Hydro One program execution due to delays in availability of materials. Strategic sourcing, which includes "bulk purchasing", is a significant contributor to Hydro One's cost savings initiatives and the Company's ability to complete the work programs.

Strategic sourcing also ensures materials arrive when scheduled so that work can be executed efficiently. Hydro One has implemented an increased focus on supplier performance management that will address any issues with delayed material delivery. Delayed delivery of material can have far reaching impact on many crews, outages and customers. Spend analysis, strategic and tactical sourcing, and developing a sourcing strategy to maximize value through negotiations, vendor management, and continuous improvements, will all play a key role in ensuring the Company's work execution needs are being met.

3.5 LOGISTICS SUPPORT

An important element of the Work Execution Strategy is optimizing the material stocked in the Company's warehouse. Hydro One has embarked on a Logistics approach to support the need for project and program timelines. The strategy provisions core materials from stock rather than waiting to purchase these materials after projects have received final approval. The materials lead times are therefore reduced. Materials are staged from a central warehouse and deployed as soon as they are needed on the work site. The result is that materials delays associated with vendor lead times have been largely eliminated.

3.6 IMPROVED DESIGNS

An increased use of standardized and modular designs are being used to streamline the design process, allowing faster, more consistent, and lower cost work execution. This reduces the demands on specialist engineering resources, improves installation and maintenance efficiency, drives lower costs, optimizes inventory management of standardized materials, and maximizes opportunities for strategic sourcing savings. Standardized designs are already in use for distribution lines and stations. New designs currently under development include standardized generation connection designs. In addition, Engineering designs are being advanced in the project schedule to allow for field design review. This ensures that constructability and maintainability concerns are addressed, promoting safe work execution and minimizing re-design effort.

Hydro One has implemented “virtual designs” using technology to limit travel time of staff in order to complete distribution designs (e.g. railway, water and pipeline crossing designs). The result is a decrease in time required to complete designs and extended availability of resources, therefore increasing the number of designs the Company can complete.

3.7 STAFFING STRATEGY

Hydro One utilizes a work-based approach to staffing, whereby the Company sources staff according to work programs rather than plans the work around the number of internal resources available. To address the fluctuating and seasonal nature of work programs, the Company maintains as much flexibility as possible by utilizing a variety of labour resources, including regular, temporary, hiring hall and contract staff.

3.7.1 OUTSOURCING

Hydro One has a highly flexible Construction workforce that is able to meet the demands of the work program. Although Hydro One's construction workforce is scalable, there is a practical limit to its size defined by the volume of work that can be safely and efficiently planned and managed by internal staff. The work contracted out, typically greenfield and brownfield projects, as well as some major refurbishment projects, is completed using a combination of internal resources, engineering subcontracts, construction contracts or arrangements contracted on a fixed-price basis. Through a combination of regular staff, casual trades, and overtime, skill sets and cost are optimized.

Hydro One utilizes contractors for staff augmentation purposes when it is recognized that some specific skill sets required on a non-regular basis are not available internally. This is necessary to ensure the efficient execution of the work program and address the ongoing variation in requirements for specific skills. Due to the shortage of skilled trades required to complete the Company's growing work program, Hydro One is focusing more on its outsourcing strategy through the use of Request for Proposal ("RFP"). By stipulating the Company's business requirements and necessary skill set, Hydro One maintains control of the scope of work while driving price transparency and efficiency amongst proponents. The success of the Company's cable locate outsourcing initiative has demonstrated the benefits of outsourcing by reducing costs and optimizing the use of internal resources. The significant increase to Hydro One's meter change projects is an example of an area the Company has identified as key outsourcing initiatives in the coming years.

3.7.2 RESOURCES AND ENHANCED EXPERTISE

A key component of the work execution strategy is the optimal deployment of internal resources to maximize work program execution. This includes utilizing Hydro One's robust apprenticeship program with the guidance of experienced tradespersons to learn the required skills as well as integrating experienced acquisition staff into the Company.

This fast tracking of skills development allows projects to be efficiently delivered while ensuring qualified resource succession. To mitigate the shortage of skilled trades, Hydro One maintains relationships with the Ministry of Colleges and Universities and the Ontario College of Trades to influence curriculum, stimulate interest and share resources. These relationships are critical to ensuring Hydro One can execute its work program in future years.

Hydro One's staffing strategy also addresses issues such as staff attrition, enhanced internal training programs, educational partnerships and opportunities, and increased utilization of casual workers and temporary employees. More information regarding Hydro One's staffing strategy is available in Exhibit C1, Tab 2, Schedule 1.

3.8 IMPROVED WORK METHODS

Productivity and cost efficiencies are being recognized in the field through improved work methods. The implementation of Move to Mobile will enable bundling of work geographically and real-time asset validation. Work will be easier to plan, schedule and dispatch, which reduces the administrative workload of field staff. As a result, Hydro One will better utilize its resources and become more efficient in completing its work program. Geographic Information System ("GIS") is an integrated component of business initiatives such as Move to Mobile, cable locate outsourcing and the implemention of smart grid technology to modernize the distribution system. This helps drive the Company in a direction that utilizes technology to streamline workflows, improve asset data, mapping and employee safety. GIS technology also plays a key role in improving daily maintenance of the system to help address reliability concerns and assist in planning capital improvements to the electrical system.

Utilization of equipment enhancements such as the Pole Setter for Provincial Lines and the Feller-Buncher for Forestry has improved work execution efficiencies. The Feller-Buncher is a fleet vehicle that significantly increases the efficiency of the Forestry division by cutting trees and stacking them in clusters. This machine reduces the total labour time required per tree by 80%. The Feller-Buncher is also used to widen and reclaim heavily backlogged and overgrown corridors.

Hydro One's Forestry Management System application is a reporting tool for Forestry programs and is approaching end of life. Hydro One is currently developing a business case to leverage the Move to Mobile core functionalities with added business capabilities to gain program, scheduling, resourcing and fleet efficiencies. These efficiencies will lead to cost-savings and improve overall system reliability as it relates to tree-related outages. Hydro One is also looking to incorporate next generation technologies including Light Detection and Ranging ("LiDAR") to integrate into the program mix. LiDAR is a surveying technology that measures distance by illuminating a target with a laser light. LiDAR technology has been increasingly adopted within the utility industry to patrol transmission lines to assess the vegetation growth and the need for pruning. Hydro One is currently validating the results of this technology through field visits to determine if the Company's requirements identified in the pilot project were met and the technology could be integrated into future vegetation maintenance plans.

Another area of work showing efficiency gains is in storm and outage restoration. The integration of smart meter data with the Outage Response Management System (“ORMS”) to confirm outage locations has greatly reduced interruption time. Prior to this capability, Hydro One relied on customers to call in when there was an interruption or power quality issue and the lines staff would patrol the area to locate the site of the cause. With the GIS enabled, the field staff are able to access GPS coordinates for most of the Company’s distribution assets. This aids greatly in directing staff with limited knowledge of a geographical area to the outage location. Once the cause of the outage has been rectified, the “pinging” of the smart meter again can confirm the restoration of power to all affected customers.

4. SUMMARY

There are many factors changing the volume, characteristics and priorities of Hydro One Distribution’s work program. The Company has developed a comprehensive strategy that embraces these factors while maximizing its work execution capacity. The strategy remains focused on Hydro One’s overall business objectives: safety, reliability, innovation, protecting the environment, employee engagement, shareholder value and meeting customer commitments. Continuing to identify efficient and cost-effective ways to execute work will not only enable Hydro One to complete its expanding work program but will play a critical role in the Company’s long term success.
