An effective spares management strategy is an essential component of risk-based fleet management programs that enable utilities to maintain reliability in a cost-effective manner. There are significant costs associated with spares inventories including capital, storage, and, for some equipment, maintenance and testing. These costs and the potential benefits from spares are a function of the number of individual spares kept at hand. Keeping too few spares may prolong outages while too many spares would increase capital and operating costs. However, there are no industry standards or guidelines to help utilities optimize the number or mix of spares.

EPRI collaborated with Hydro One to apply its spares prototype strategy assessment analytics to Hydro One's transformer fleet. Hydro One provided data on transformer groups (e.g., 250 MVA 230/115 kV, 125 MVA 230/115 kV) and assumptions required for the simulation, for example, lead time to order a new spare, minimum threshold time for counting an unavailable transformer position.

The analysis results are provided from two perspectives:

- What is the probability that the system is not at full availability at any time?
- What is the probability that all positions are available for all days?

INTRODUCTION

This report describes the application of EPRI's prototype implementation of an analytics-based approach to developing optimized substation transformer spares practices for Hydro One Networks Inc.

An effective spares management strategy is an essential component of risk-based fleet management programs that enable utilities to maintain reliability in a cost-effective manner.

Background

All utilities maintain inventories of spare substation equipment to mitigate the effects of equipment failures. Without available spares, replacement times may be extended by procurement and delivery delays. In particular, substation transformers may take months to replace, potentially prolonging outages and creating significant challenges for utilities striving to maintain reliability and control capital and operating costs.

There are significant costs associated with spares inventories including capital, storage, and, for some equipment, maintenance and testing. These costs and the potential benefits from spares are a function of the number of individual spares kept. Keeping too few spares may prolong outages while too many spares would increase capital and operating costs. However, there are no industry standards or guidelines to help utilities optimize the number or mix of spares.

Approach

EPRI is developing an analytics-based approach and model to help optimize power transformer spares practices. The development of the risk based methodology for determining and evaluating spares strategies was guided by the following requirements:

- Not dependent on arbitrary assumptions
- Able to use the best available data
- Be flexible to accommodate changing needs
- Provide a system perspective
- Present probability distributions of performance metrics
- Employ risk based metrics

EPRI collaborated with Hydro One to apply the prototype implementation of its approach to Hydro One's transformer fleet. Hydro One provided data on transformer groups (e.g., 250 MVA 230/115 kV, 125 MVA 230/115 kV) and assumptions required for the simulation, for example, lead time to order a new spare, minimum threshold time for counting an unavailable transformer position.

Results

The analysis results are provided from two perspectives:

- What is the probability that the system is not at full availability at any time?
- What is the probability that all positions are available for all days?

Report Organization

This report is organized as follows:

Chapter 1: Introduction

Chapter 2: Spares Strategy Analytics and Modeling

Chapter 3: Spares Requirements Assessment Results

Chapter 4: Summary and Discussion of Results

2
SPARES STRATEGY ANALYTICS AND MODELING

Introduction

This chapter explains EPRI's approach to spares strategy analytics including proposed modeling and analytical methodologies, and presents example applications. The strategy incorporates a prototype software tool to enable users to evaluate the optimal number of spares needed to maintain a given degree of availability with a specific level of risk. The spares strategy analytics described here focuses on transformers, but it is applicable to other substation equipment as well. Additional equipment may be addressed as the analytics evolve.

The EPRI tool can be used to address the following set of decisions associated with the purchase and utilization of equipment spares:

- Demand estimation—how many spares do I need?
- Replacement planning—when do I add to the spares inventory?
- Procurement process—lead times, how many do I order, when?
- Inventory management—where do I keep them?

The strategy also considers

- Transportation from storage depot to substation site

The Big Picture

The adverse effects of transformer failures are a function of the *failure location and the time to replacement*. Thefirststepindevelopinganeffectivesparesstrategyinvolvesunderstandingthebasic elements that the strategy must address.

Evaluating an effective substation spares strategy for transformers encompasses and models the following elements:

- Substations with multiple positions for transformers
  - Attributes or characteristics associated with each substation, each transformer position, and each transformer
- Depots or repositories storing spare transformers
  - Attributes of each depot (such as types of transformers in storage)
- Time required to replace a transformer (i.e., to fill an unfilled transformer position with an operating transformer from a depot)
- Risk based on the length of time a transformer position is left unfilled

The key concept of the EPRI analytical approach is that the risks associated with the length of time a transformer position is left unfilled should be the metric for evaluating spares strategies.

To establish these risks as probabilities, in addition to the above inputs, transformer failure rates are required. Failure rates reflect the probability of failure, and can be calculated from utility historical records or based on data from the EPRI Industry-wide Transformer Database (IDB) to develop the probabilistic risk-based strategy for spares management.

This analytical methodology is intended to enable utility users to make informed decisions regarding spares that consider the risk sand, eventually, costs of different approaches.

Figure2-1isa simplified “big picture” representation of the modeling inputs. Table 2-1 shows the key attributes associated with substations, positions, and transformers.

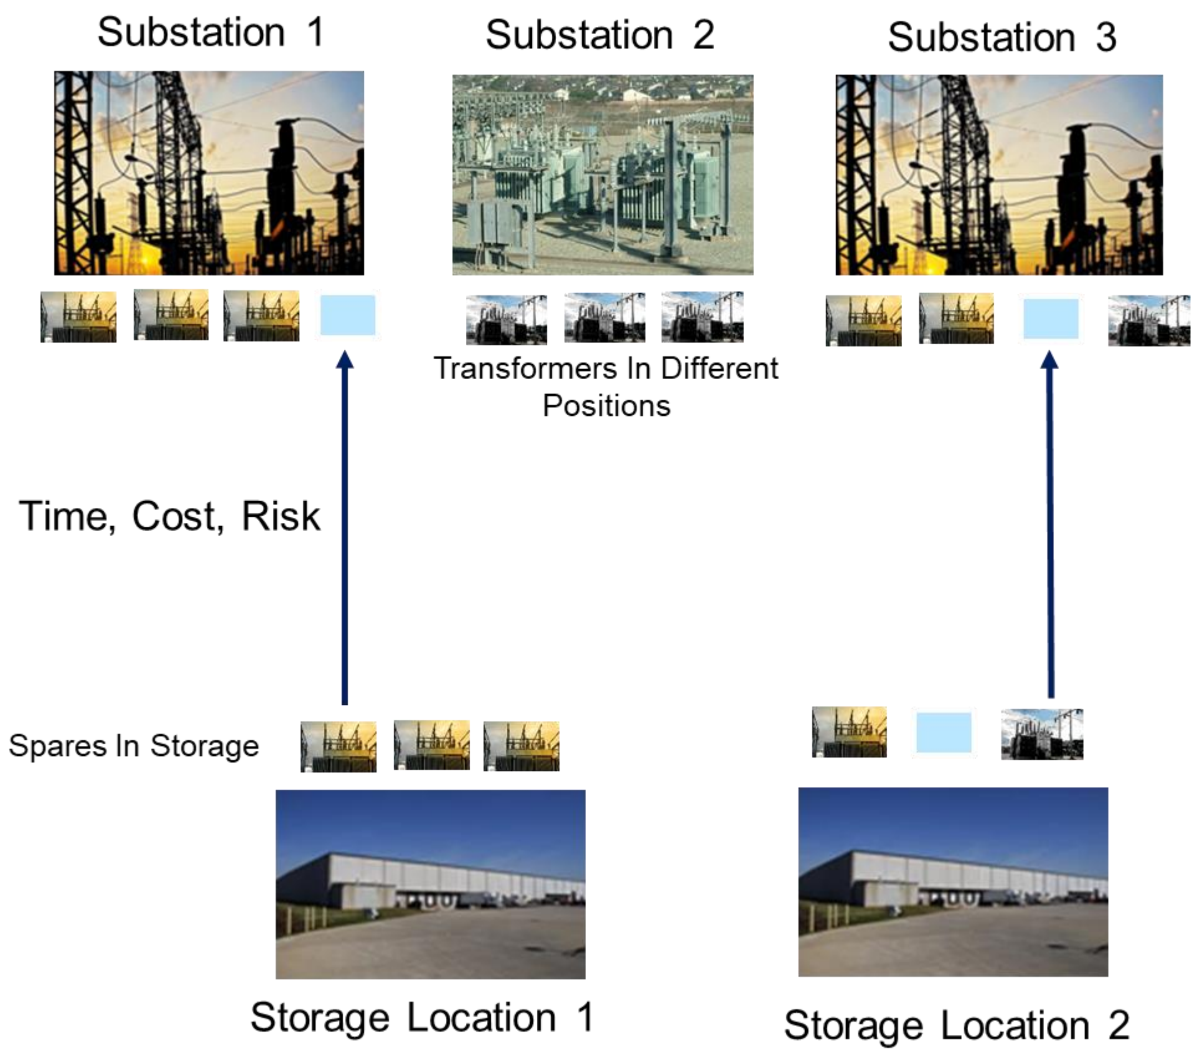

Figure 2-1
Elements of a Spares Strategy

Transformer Position

As shown in Figure 2-1, substations, transformer position, transformers, storage depots and their attributes are key modeling inputs. The most basic input is ***transformer position***, whose attributes determine the type of spare transformer that is needed and the degree of risk associated with leaving the position unfilled. It is important to understand the distinction between a transformer position and a transformer. The transformer position may be compared to a light socket whose attributes (wattage, lighting application) determine the type of bulb it can accommodate. In this analogy, a transformer may be compared to the bulb.

Nested Attributes

The model inputs form a hierarchy of nested attributes, as presented in the following table.

Table 2-1
Attributes

Station Attribute	Position Attribute	Transformer Attribute
Utility ID	Region	Serial Number
Region	Substation	Region
Design Redundancy	Utility ID	Substation
Distance from Depot 1	Voltage Class	Position
Distance from Depot 2	HV	Voltage Class
Criticality Ranking	LV1	HV
Number of Positions by transformer attribute	LV2	LV1
	Tertiary	LV2
	Auto	Tertiary
	Number of Phases	Auto (Y/N)
	LTC	Number of Phases
	NLTC	Connection Type
	Top MVA	LTC (Y/N)
	Impedance	NLTC (Y/N)
	Circuit Criticality	Top MVA
	Installation Time	Impedance
	Circuit Connection	Manufacture Date
	Physical Dimensions	Install Date
		Manufacturer
		Weight Filled
		Oil Capacity
		Availability

Spares Strategy Modeling Approach

The modeling approach uses a chronological Monte Carlo simulation utilizing non-exponential (not constant) times for equipment failure rates. Additional characteristics such as time correlation or physical constraints can be included. This approach allows for the calculation of probability distributions of the calculated indices.

A thorough review of computational techniques for statistical analysis is beyond the scope of this report. However, a brief discussion of chronological Monte Carlo simulation will establish the rational for its choice for this study.

There are three broad modeling approaches that could have been used for the EPRI spares analyses: Poisson, Markov and chronological Monte Carlo. Only the latter can account for non-exponential distributions for input parameters and provide probability distributions of the calculated simulation results.

Monte Carlo Simulation (MCS) is an established methodology for reliability evaluations. In general for such studies, two approaches to MCS may be used: non-chronological MCS (also referred to as non-sequential MCS), where system states are randomly sampled, and chronological MCS (also referred to as sequential MCS), where the time dependent, i.e. chronological, behavior of the system is simulated by sampling sequences of system states over multiple time periods created from the individual component chronological state transitions.

Chronological MCS (CMCS) sequentially simulates the states of the system in chronological order and can provide information not obtainable with non-chronological MCS or Markov models but requires parameters distributions for each component state duration. CMCS is a well-recognized technique in power system analysis, particularly for assessing generation reliability. (Ref: 1, 2, and 3) The disadvantage of CMCS is that it requires more computational time and storage.

CMCS allows for the least restrictive modeling assumptions and provides the most useful output results of the three broad approaches. Importantly, for the EPRI spares simulation studies, only CMCS simulations can provide information about the chronological aspects of the transformer fleet performance as determined by the chronological operating performance of individual transformers. For example, because age-dependent Weibull hazard rates are used, the failure rates for each transformer are determined by that transformer's age and change for each year of the study as the individual transformers age (non-exponential distributions).

Furthermore, only CMCS can account for cases where the spare waiting times depend, not only on the failure of other transformers, but also on the ordering and manufacturing delays of replacement spares or even the complete depletion of the spares stock. For example, in the EPRI simulation, replacement spares may be ordered but not available for some variable delay time beginning at any time in the simulation period or even before. Mobile units may not be available for an arbitrary time period if they are being utilized in other locations but may eventually become again available. In addition, only CMCS can accommodate arbitrary system restrictions, e.g. particular spares only suitable for specific positions due to physical limitations.

Another important distinction of the EPRI CMCS-based spares analytics is the ability to provide probability distributions of the simulation results. For example, the methodology can provide the probability density function (PDF) of the probability of the occurrence of single and multiple simultaneous unfilled positions, the PDF of the residence times in any unfilled position state or the PDF that the unfilled position state will be longer than some time period. Such

PDF's are very useful for fully assessing risk. Neither Poisson nor Markov models can provide PDF's. (4)

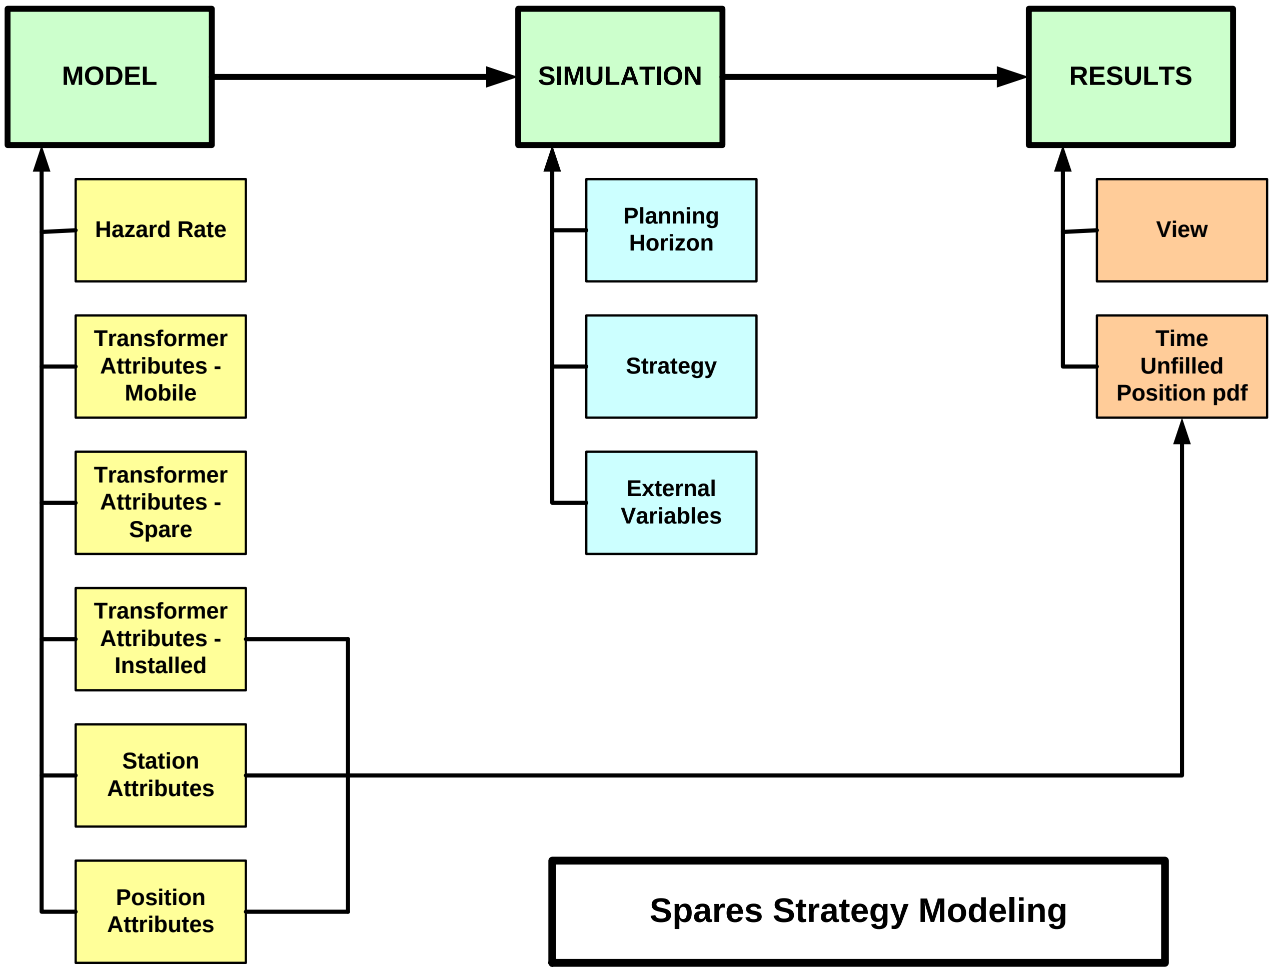

Figure 2-2
Proposed Spares Strategy Analytics Approach

Model Implementation

The spares strategy addresses:

- Stock level
- Allocation rules
- Reorder rules

External variables include:
- New spare procurement time
- New spare manufacturing time

- New spare shipping time
- Installation time

Modeling results include:
- View – chart, graph, tables
- Metrics: Unfilled position time by
  - Station
  - Specified transformer attributes
  - Criticality
  - Circuit connection
  - Combination of the above
- Probability of using nth spare
- Probability Density Function of spares to maintain some criteria

A modeling simulation flow chart is shown in Figure 2-3.

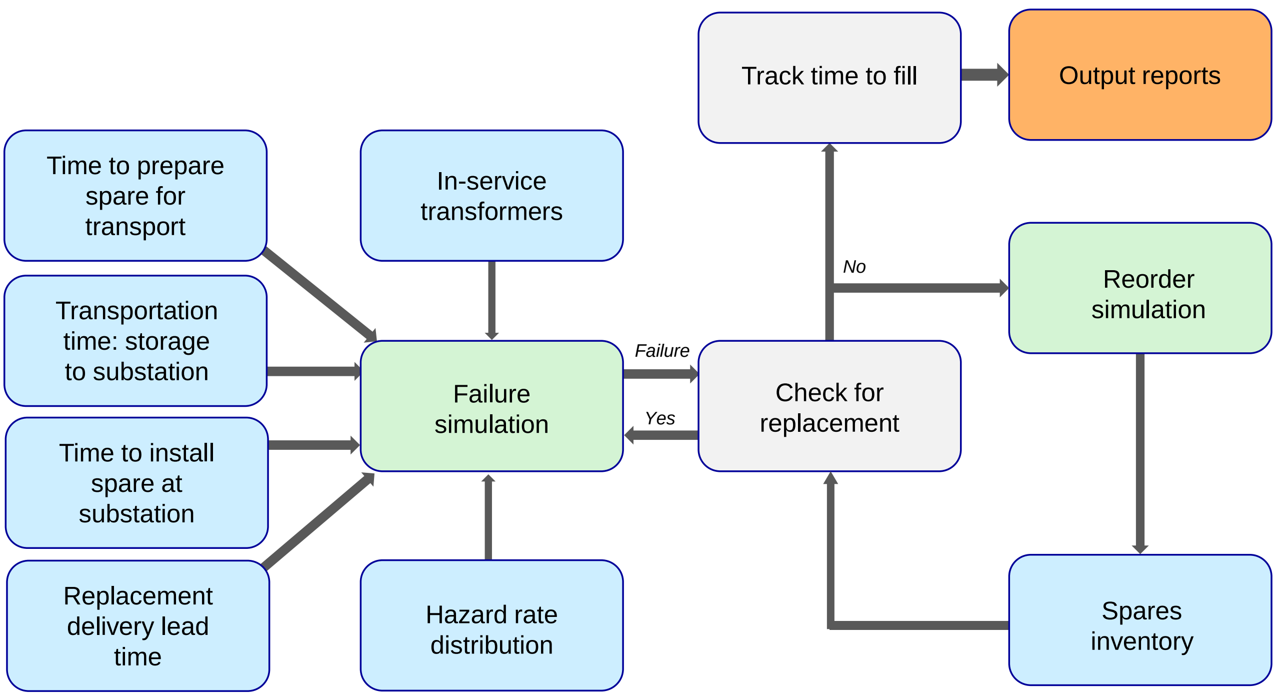

Figure 2-3
Modeling Simulation

Methodology

The methodology simulates the performance of the transformers over the planning horizon. Performance in this case refers to simply whether the transformer remains in service. The output is presented in a history table that indicates whether or not a transformer is in service for each day of the period. Each simulation develops its own history table and the final output is determined by the distribution of results from multiple simulations.

The results presented in the following chapter are composed of the distribution that results from the summation of history tables where, the number of days is equal to 1826.25 (accounting for leap year) days and a total number of positions for that particular transformer type. It is important to note that this approach has the ability to calculate the risk associated with multiple, simultaneous unfilled positions.

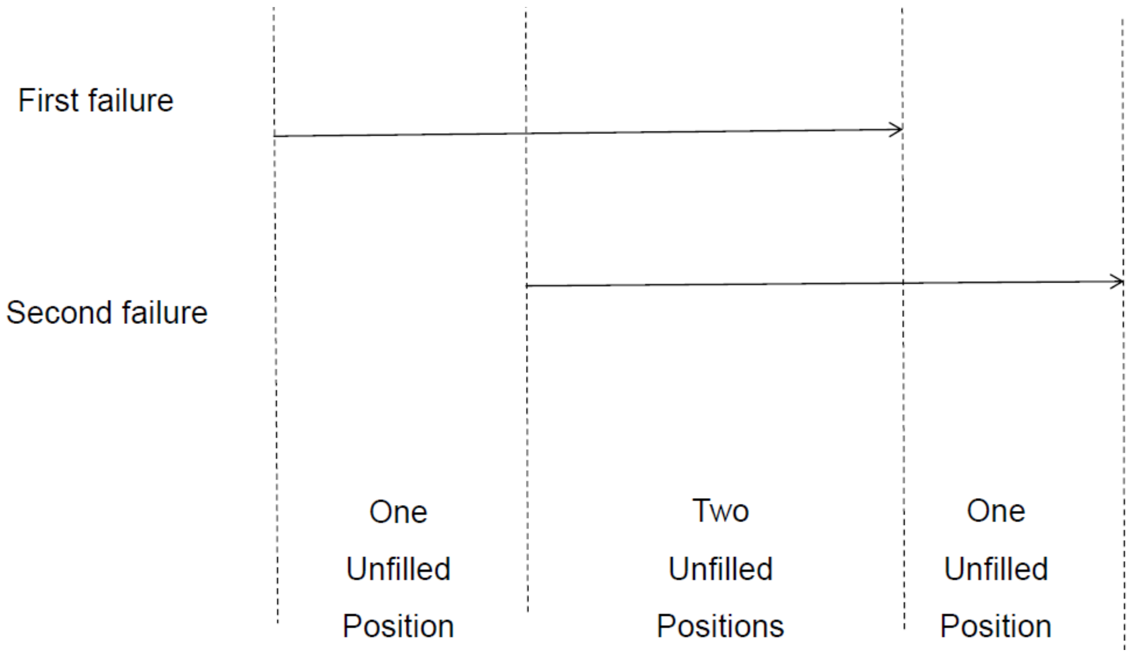

Figure 2-4
Failure Scenarios

One result is shown below for assessing system availability (all transformer positions in service = 100% availability) for different possible numbers of spares. For zero spares the system availability is 68.41% whereas it is unavailable 31.59% of time. This unavailability is composed of:

- 25.36% due to one unavailable position
- 5.39% due to two positions simultaneously unavailable
- 0.75% due to three positions simultaneously unavailable
- 0.08% due to four positions simultaneously unavailable
- 0.01% due to five positions simultaneously unavailable

For one spare the system availability is 89.84% whereas it is unavailable 10.16% of time. This unavailability is composed of:

- 8.73% due to one unavailable position
- 1.25% due to two positions simultaneously unavailable
- 0.17% due to three positions simultaneously unavailable
- 0.01% due to four positions simultaneously unavailable
- 0.00% due to five positions simultaneously unavailable

It can be observed that there is less than 0.1% change in availability in going from three to four spares.

	0	1	2	3	4	5

4 Spares	0.9977	0.0022	0.0001	0.0000	0.0000	0.0000
5 Spares	0.9977	0.0022	0.0001	0.0000	0.0000	0.0000

NUMBER OF POSITIONS UNAVAILABLE

Figure 2-6
Position Days Availability

For zero spares 99.23% of the position-days have a transformer available or for 0.77% of the time some positions are unavailable.

There is essentially no change in availability in going from two to three spares.

It is important to note that the analytical results are produced from random simulations. As a consequence, numerical values may change slightly if the exact same scenario is run another time. The differences are very small but may lead to unexpected, apparently anomalous results, such as an increase in probabilities of unfilled positions with an increase in the number of spares. These changes simply reflect the repeatability of the simulations, in effect the confidence interval around the results. They do not detract from the usefulness of the results, which readily show the number of spares where the probabilities tend to converge. These variations are a function not only of the number of simulations run but also the size of the population being studied. Hence, such variations are more likely to be evidenced in small transformer fleet analyses.

SPARES REQUIREMENT ASSESSMENT RESULTS

Overview

This chapter presents inputs and analysis by transformer groups as by provided by Hydro One. For example:

- 250 MVA 230/115 kV
- 125 MVA 230/115 kV

For each group the assumptions required for the simulation as provided by Hydro One are presented first. For example:

- Lead time to order a new spare
- Minimum Threshold time for Counting Unavailable Position

The analysis results are provided from two perspectives:

- What is the probability that the system is not at full availability at any time?
- What is the probability that all positions are available for all days?

Summary of Select Results

The following table summarizes select results for transformer groups provided by Hydro One.

Table 3-1
Summary of Select Results

Study Group	System Availability (What is the probability that the system is not at full availability at any time?)		
	2 Spares	3 Spares	4 Spares
125 MVA 230/44 kV	90.88	94.37	95.23

750 MVA 500/230 kV	91.54	93.59	93.96

The assumptions in the bulleted list below and in the following figures are necessary for running the simulations for each transformer study group. The assumptions were provided by Hydro One.

125 MVA 230/44 kV

Inputs

- 5 year simulation horizon
- One spare storage location
- Delay to install depends on distance to depot from station
- Pick from closest depot first
- Pick oldest suitable spare first
- Reorder spare upon use
- Minimum threshold time for counting unfilled position: 60 days

4

SUMMARY AND DISCUSSION OF RESULTS

The analytical results presented in the preceding chapter have been reviewed by Hydro One subject matter experts and utilized to evaluate their current spares stocking levels. One view comparing the results from the two calculations is presented in Table 4-1 below.

Study Group	System Availability (in %) (What is the probability that the system is not at full availability at any time?)					Hydro One Optimized Number of Spares (Hydro One Spares Model)	Hydro One Optimized Number of Spares (EPRI Spares Model)
	0 Spares	1 Spare	2 Spares	3 Spares	4 Spares		
125 MVA 230/44 kV	52.24	77.44	90.88	94.37	95.23	2	2
125 MVA 230/28-28 kV	51.03	78.46	89.09	91.67	92.11	2	2
83 MVA 230/28 kV	70.26	91.05	96.50	97.32	97.30	2	2

Summary of Select Results

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc.(EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.

Transformers and Circuit Breakers Expected Service Life Survey. EPRI, Palo Alto, CA: 2018.

EXECUTIVE SUMMARY

Utilities have been maintaining substation equipment reliably since the industry's inception but now many are facing increased challenges to reduce operating and maintenance costs without adversely affecting service levels or investment requirements. In this setting, utilities may benefit from knowing what programs and techniques their peers have implemented. To that end, EPRI has conducted a series of industry surveys assessing key substation equipment maintenance and replacement practices. As utilities consider modifying their maintenance or replacement programs, they can benefit from the knowledge and experience of others. Identification of best practices, as well as lessons learned from less successful trials, facilitates peer collaboration and improvements for all.

This report presents the results of two surveys designed to acquire information and insights on industry attitudes and practices related to asset management of transmission circuit breakers and transformers. Survey results may help utilities to learn how peer companies are responding to similar challenges, and may also help inform and guide research and development efforts to further improve substation asset management practices.

The information provided may be used to assess the state of the industry on these topics, determine best practices and establish areas of additional research and development need.

INTRODUCTION

This report presents the results of two surveys designed to acquire information and insights on industry attitudes and practices related to asset management of transmission circuit breakers and transformers. Survey results may help utilities to learn how peer companies are responding to similar challenges, and may also help inform and guide research and development efforts to further improve substation asset management practices.

Survey respondents are utility personnel who are members of the EPRI Substation Task Force.

Background

Utilities have been maintaining substation equipment reliably since the industry's inception but now many are facing increased challenges to reduce operating and maintenance costs without adversely affecting service levels or capital requirements. To address these challenges, many utilities are modifying existing maintenance and replacement practices and moving toward augmenting or replacing traditional methods with new approaches, such as condition and risked-based maintenance and replacement scheduling.

Utility maintenance managers and engineers need access to information about proven processes, organizational strategies, related technologies, and successful applications to help achieve high performance levels. Collaboration to share best practices and provide a basis for self-benchmarking is valuable for improving substation asset management and maintenance processes. To assist utilities in collecting the required information, EPRI has conducted a series of surveys of the current practices and experiences concerning substation equipment. This report presents the results of two surveys on high voltage circuit breaker and power transformer assessment and replacement practices.

Objectives

The main objective of the surveys was to gather and share information about how utilities are deciding which circuit breakers and transformers to replace and when.

Approach

A web-based survey tool was used to construct a set of focused questions that could provide an assessment of current industry assessment and replacement practices for transmission circuit breakers and power transformers. The survey questions are presented in Appendix A and B. Not all respondents answered all questions.

Surveys previously were conducted in 2009, 2010 and 2016[1, 2, 3]. This report presents updated responses and more detailed focus on utility practices regarding circuit breaker and transmission assessment and replacement.

Report Organization

The report is organized into the following chapters.

Chapter 1: Introduction

Chapter 2: Survey Respondent Characteristics: Circuit Breakers

Chapter 3: End of Life Concerns for Circuit Breakers

Chapter 4: Assessment and Replacement Practices for Circuit Breakers

Chapter 5: Survey Respondent Characteristics: Transformers

Chapter 6: End of Life Concerns for Transformers

Chapter 7: Assessment and Replacement Practices for Transformers

Chapter 8: Summary and Next Steps

Appendix A: Survey Questions: Circuit Breakers

Appendix B: Survey Questions: Transformers

2
SURVEY RESPONDENT CHARACTERISTICS: CIRCUIT BREAKERS

To help place the survey results in context and better interpret the responses, the characteristics of the utility participants and their respective circuit breaker fleets are presented in this chapter.

Survey respondents are members of the EPRI Substation Task Force.

Circuit Breaker Survey

Job Classification

Each circuit breaker survey respondent was classified by job description as shown in Figure 2-1.

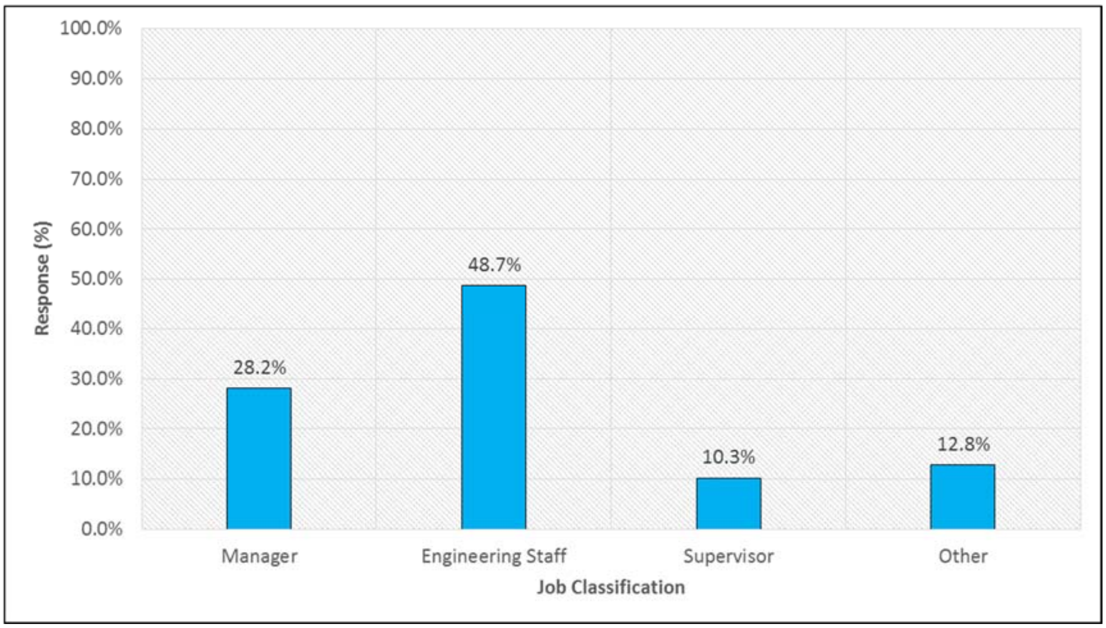

Figure 2-1
Job Classification

Organization Classification

Each respondent was classified by organization function, as presented in Figure 2-2.

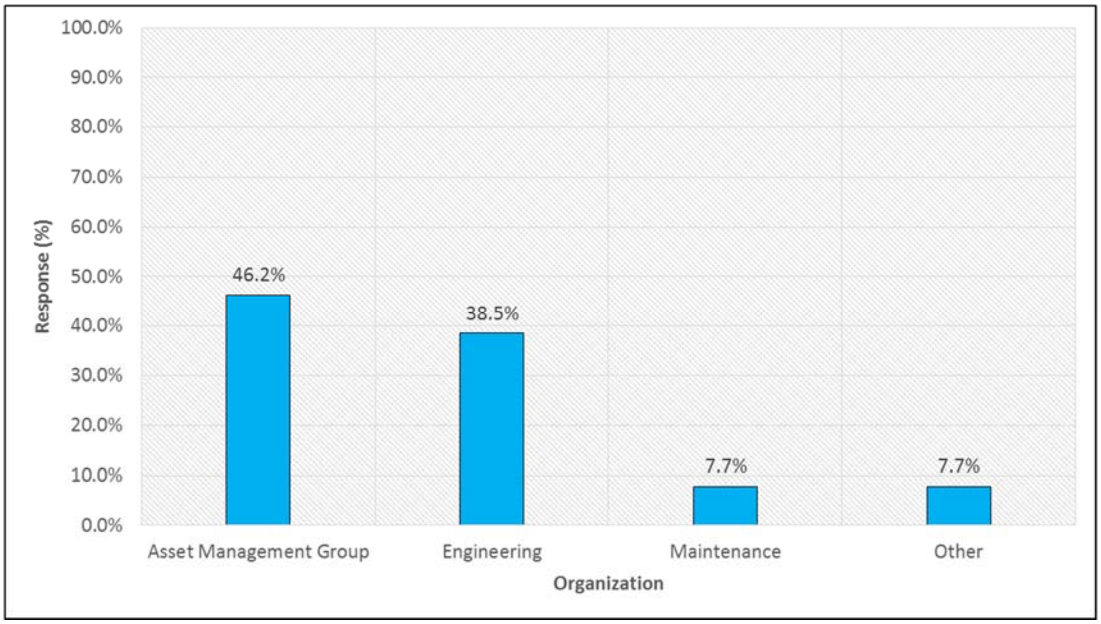

Figure 2-2
Organization Classification

Company Description

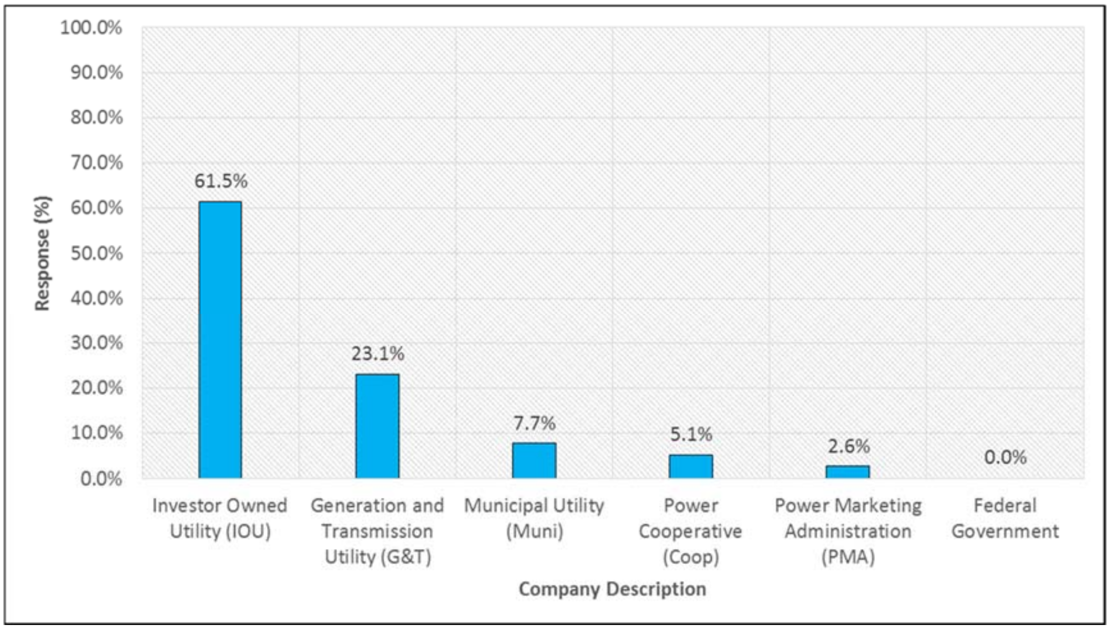

Figure 2-3
Company Description

Regulatory Structure

Respondents were asked about their company and its regulatory structure. Responses are shown in Figures 2-3 and 2-4.

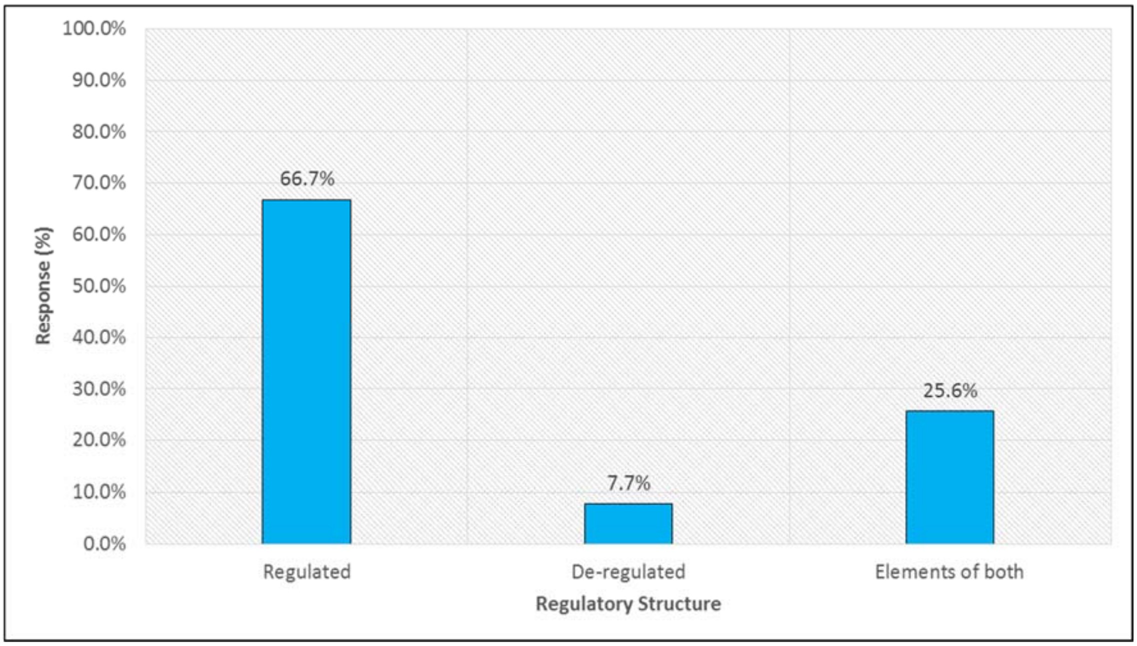

Figure 2-4
Regulatory Structure

Asked what assets their companies owned, respondents provided the information presented in Table 2-1. "None" means the respondent had none of that category. Whereas, "Part of Core Business" means the respondent considered that category to be a core business activity. Consider "Distribution" as an example. 10.3% of the respondents had no distribution assets. 71.8% considered distribution to be a core business. The balance had some distribution but did not consider it to be a core activity.

	None	Part of Core Business
Generation	20.5%	76.9%
Transmission	2.6%	94.9%
Distribution	10.3%	71.8%

Table 2-1
Assets Owned

System and Fleet Characteristics

Peak Load

Respondents were asked to define their system's peak load. Results are shown in Figure 2-5.

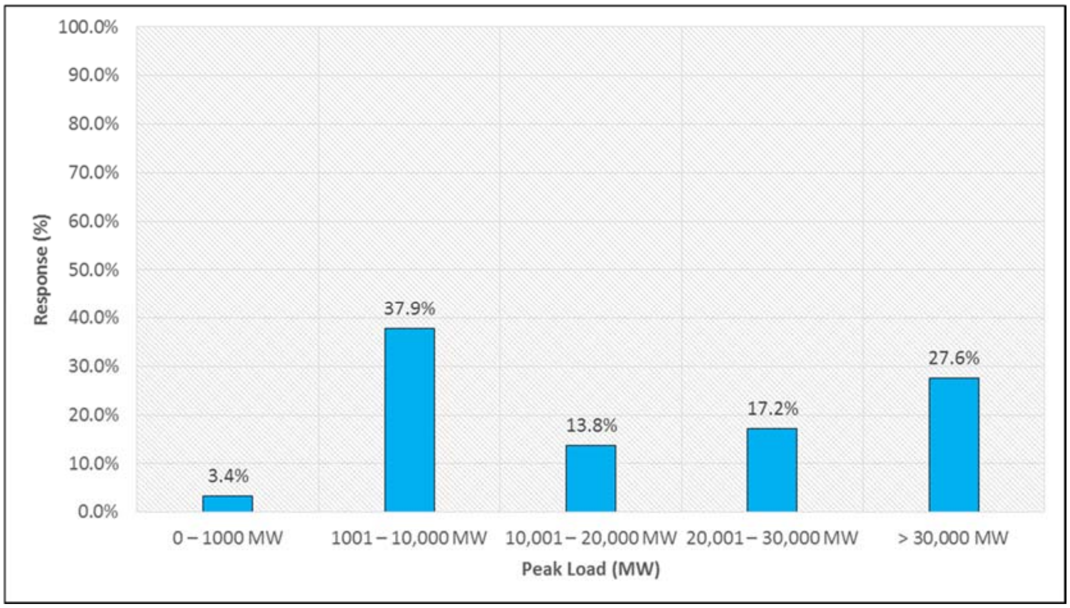

Figure 2-5

3
END OF LIFE CONCERNS FOR CIRCUIT BREAKERS

End of Life (EOL) Definitions

Utilities use different terms to define the end of life and expected service life of assets. For example, Hydro One uses the following definitions:

End of Life (EOL): The high likelihood of failure, or loss of an asset's ability to provide the intended functionality as determined through diagnostic data, wherein the failure or loss of functionality would cause unacceptable consequences. EOL can be further divided into three sub-categories:

- **Technical EOL**: The asset has failed, or condition assessment data indicates it is likely to do so, or it can no longer be expected to perform its function reliably
- **Economic EOL**: Unacceptable levels of maintenance costs are required to achieve the required performance/function.
- **Strategic EOL**: Necessary spares parts or skills set are unavailable; or the forecast loading or short circuit levels have exceeded the rating of the asset.

Expected Service life (ESL): The average time in years that an asset can be expected to operate under normal system conditions.

Use of Definitions and Utility Comments

Respondents were asked whether their company used these or similar EOL definitions. Responses are shown in Figure 3-1.

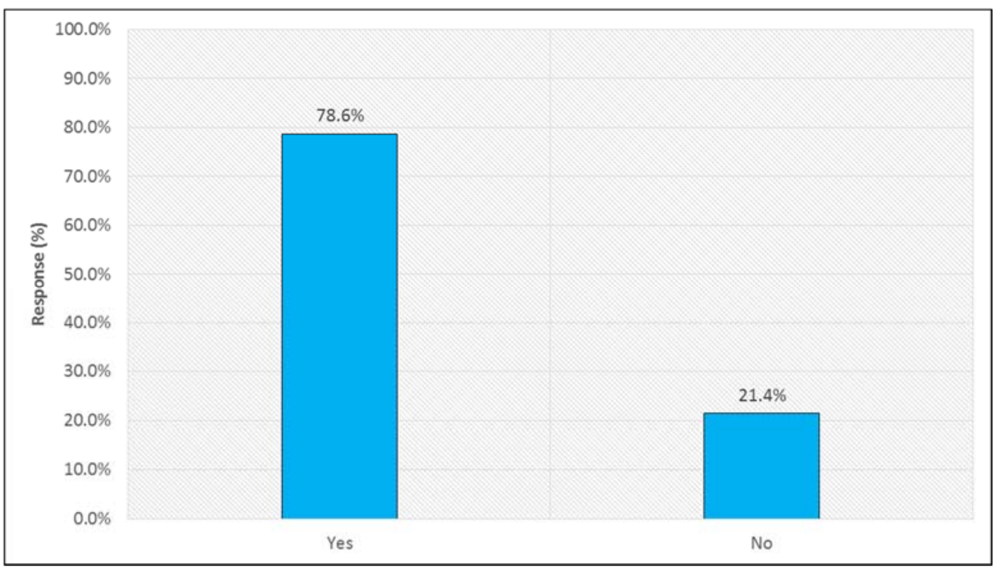

Figure 3-1
Use of Hydro One or Similar Definitions for End of Life and Expected Service Life

Respondents who answered no to this question were invited to provide comment. These are presented below.

> "There are definitions used for ESL but they lack strict guidelines aside from financial applications."
>
> "Do not use those terms specifically, but follow the same basic definitions."
>
> [Utility] does not use the exact definition, but applies the concept. In general: End of Life: The asset has failed, or condition assessment data indicates it is likely to do so, or it can no longer be expected to perform its function reliably. Parts obsolescence / High Maintenance: Necessary spares parts or skills set are unavailable; or the forecast loading or short circuit levels have exceeded the rating of the asset. Unacceptable levels of maintenance costs are required to achieve the required performance/function.
>
> "No clear definition but the philosophy is similar."
>
> "Do not distinguish different types of EOL for planning purposes."
>
> "Technical EOL only"

Ages of Concern about Leaving Breakers in Service

Oil Circuit Breakers

Respondents were asked the following question: *"For the following oil circuit breaker voltage levels, at what age would you start getting concerned about leaving the asset in service (ideally target for planned replacement in the next 5 to 10 years)?"*

Responses by voltage level are shown in Figure 3-2, Figure 3-3, Figure 3-4 and Table 3-1.

Oil Breakers: Age of Getting Very Concerned

Respondents were then asked at what ages they would start getting *very* concerned about leaving breakers in service, by interrupting media and voltage level.

Figure 3-10, Figure 3-11, Figure 3-12 and Table 3-4 show responses to the question, "For the following oil circuit breaker voltage levels, at what age would you start getting very concerned about leaving the asset in service (ideally target for planned replacement in the next 2 to 5 years)?

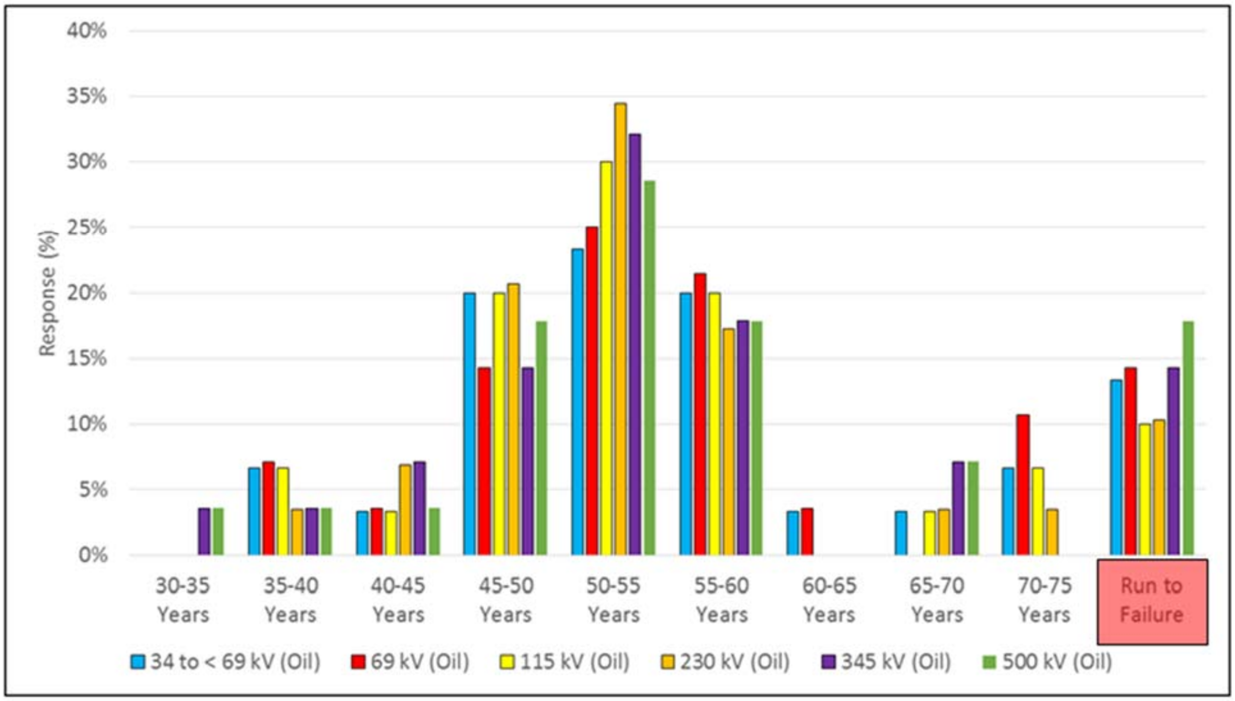

Figure 3-10

4
ASSESSMENT AND REPLACEMENT PRACTICES FOR CIRCUIT BREAKERS

Survey participants were asked a series of questions about their practices regarding assessment and replacement of breakers. Responses are presented in this chapter.

Running to Failure

Question: "*Does your company typically run a transmission circuit breaker to failure (i.e., it becomes inoperable and/or too impractical or expensive to restore to operation)?"*

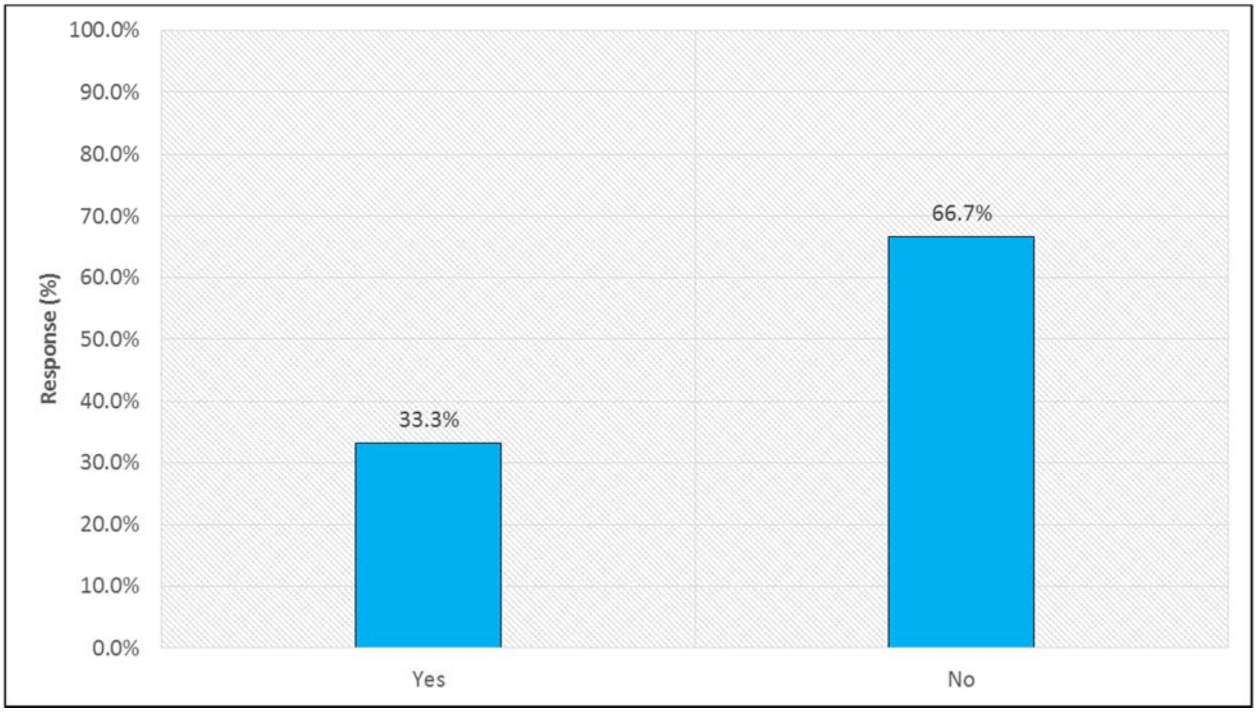

Figure 4-1
Run to Failure?

Replacement Criteria

"Please rank each of the following criteria you use to replace an asset. (Rank 1-7 with 7 being most critical.)"

Table 4-1
Ranking Replacement Criteria Averages

Criteria	Ranking Average
Safety	5.41
Condition	5.05
Reliability/Availability	4.73
Ownership Costs (Maintenance, unavailability of skills, availability of spares, etc.)	3.82
Age	3.82
Environmental Impact	3.19
Asset Health Index/Trigger	2.33

"Please comment if there are any other criteria you use to replace an asset?"

> "Overstressed interrupting rating due to increased fault current."
>
> "We don't currently have an asset health index built yet, we replace assets based on condition/age and availability of spare parts through a capital planning process. If there is a reliability or availability issue, they rise to the top. Safety and environmental are important factors when deciding to replace as well."
>
> "SME determination of when to replace."

Process or Algorithm to Assess Condition

Asked if they had a formal process or algorithm to assess circuit breaker condition, respondents provided the answers shown in Figure 4-2.

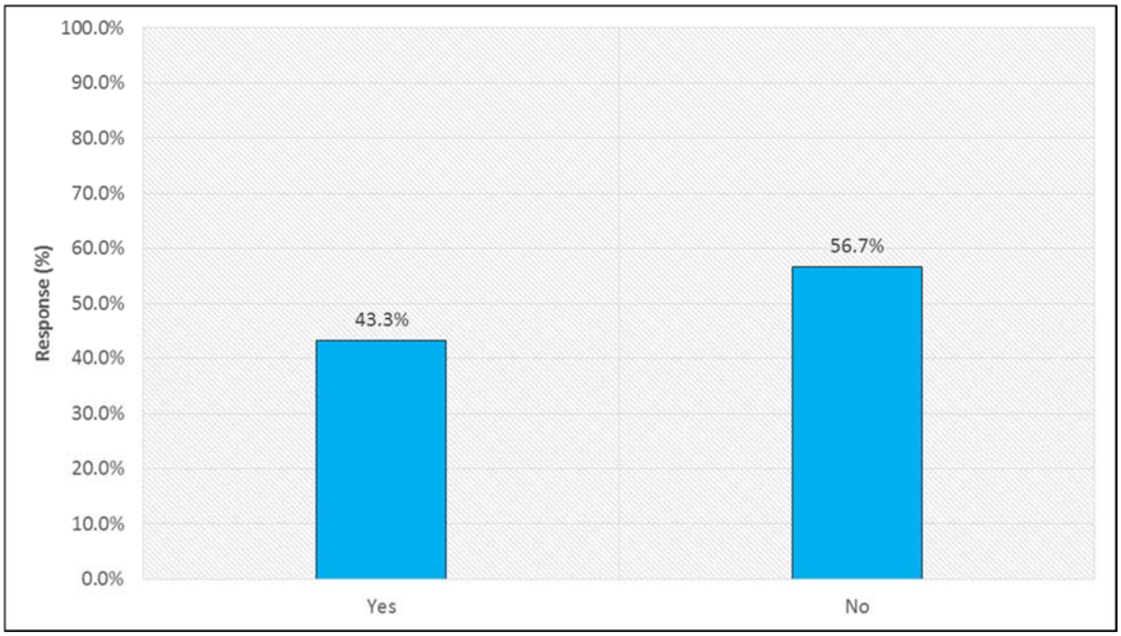

Figure 4-2
Do you have a formal process or algorithm to assess circuit breaker condition?

Respondents who answered yes then were asked to describe the process or algorithm. Their answers are shown in Figure 4-3.

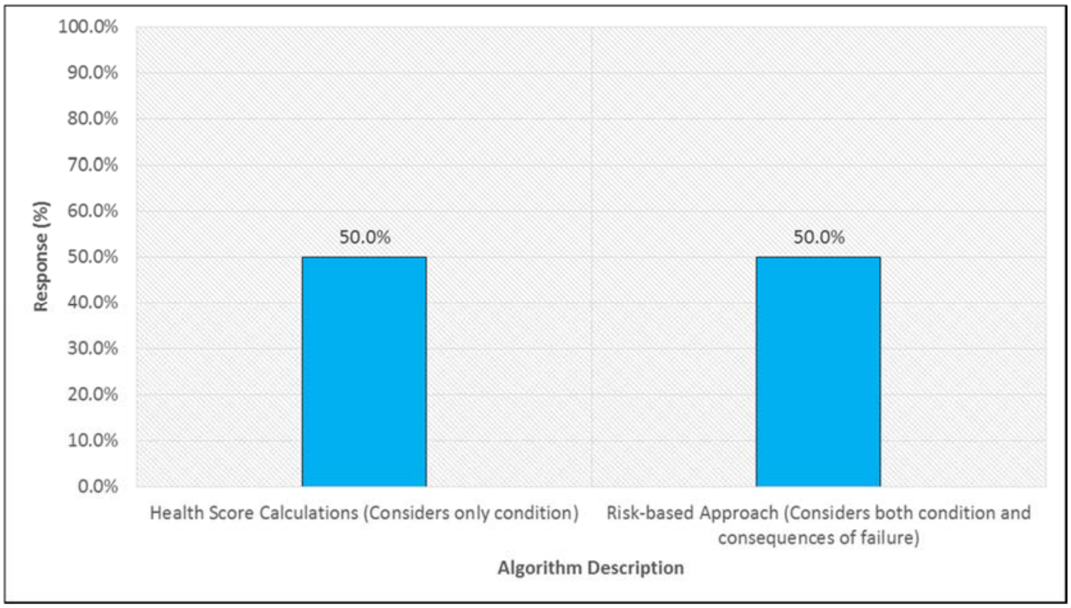

Figure 4-3
How would you best describe the formal process or algorithm to assess breaker condition?

Asked if their algorithm could trigger a replacement by itself, respondents provided answers shown in Figure 4-4.

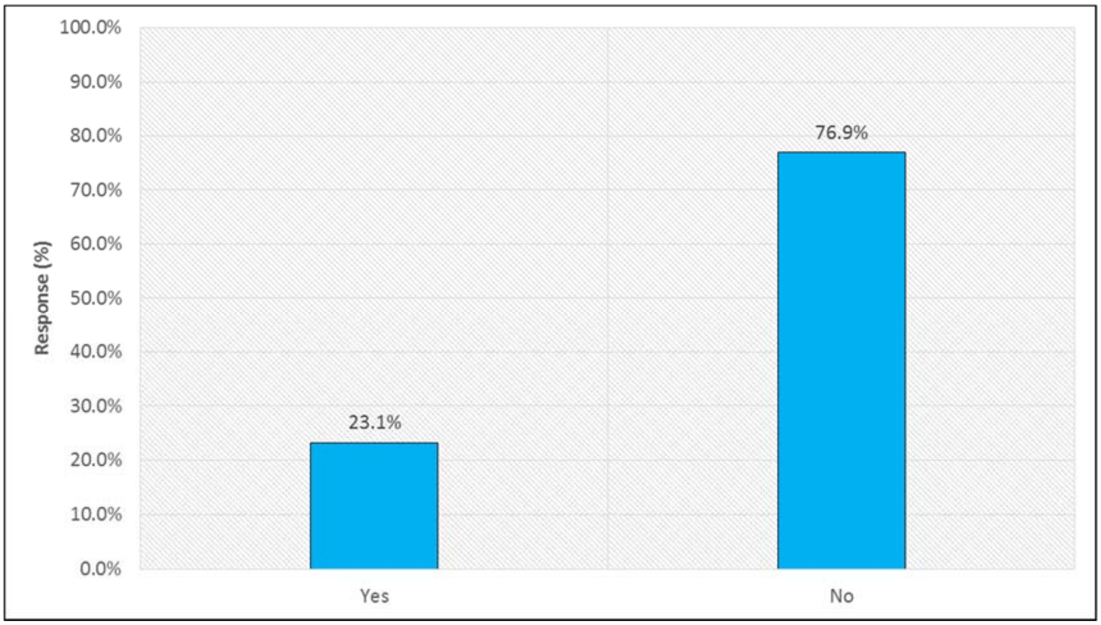

Figure 4-4
Could your algorithm trigger a replacement by itself?

Respondents were asked to provide additional comments if other factors were required, shown below.

"Decision is made using variety of factors including redundancy, spare availability, risk etc."

"The algorithm's health score output will be used in the decision to replace the CB, but there are many other factors that are taken into account before the final decision to replace the CB is made. Also, a data review of the maintenance and test data as well as a site inspection is completed on the asset(s) to confirm the algorithm's output."

> "Under development."
>
> "No. Algorithm trigger development of a mitigation plan, which may include replacement."
>
> "Other PM test conditions."
>
> "Number of operations, Historical Corrective Maintenance work performed and Fault Duty Assessment."
>
> "Use health information to develop an investment strategy."
>
> "The algorithm is taken into account when determining replacement."
>
> "Reliability & Feedback from field personnel."

Replacement by Type Regardless of Age or Condition

Respondents were asked if they replaced some circuit breakers by type or family regardless of age or condition. Figure 4-5 shows their answers.

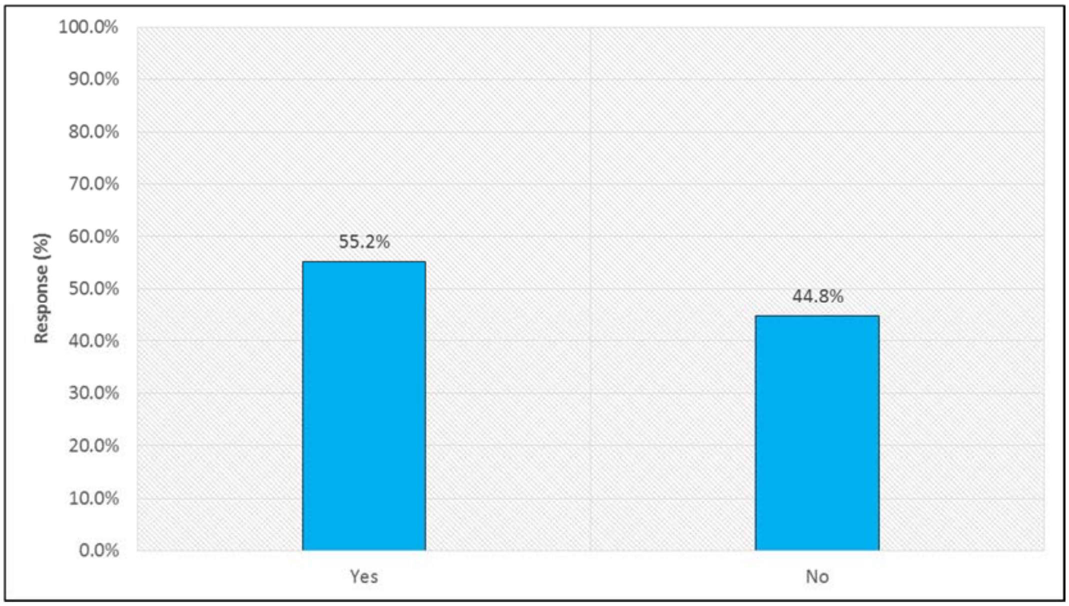

Figure 4-5
Do you replace circuit breakers by type or family regardless of age or condition (e.g., OCBs, air-blast)?

Asked to provide a list of the types of families that they had replaced regardless of age or condition, respondents answered as follows:

- Live Tank
- Interrupt rating
- Asbestos-containing ABCBs
- Distribution class OCBs
- Oil, Air Blast, Magnetic
- Westinghouse 345OSF25000, Westinghouse 345SP-40-2000, Westinghouse 362SFA40; all of which are 345-kV 1970's vintage SF6 breakers
- "SF". "SFA", "ATB", "GA", "GB", "PK", "FX", "HVB (early vintages)

Fleet Replacement Decisions

Figure 4-6 shows responses to the question, *"How do you decide when to replace a population (or fleet) of assets? (Programmatic replacement) (Select all that apply)."*

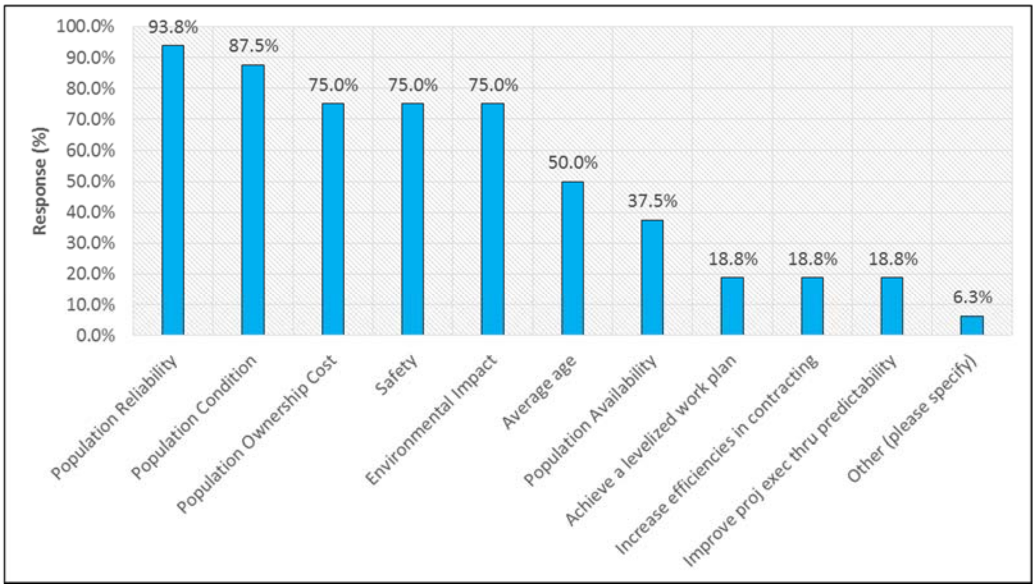

Figure 4-6
How do you decide when to replace a population (or fleet) of assets?

When asked, *Do you restrict your use of stand-alone breakers to air insulated substations?*, respondents answered as shown in Figure 4-7.

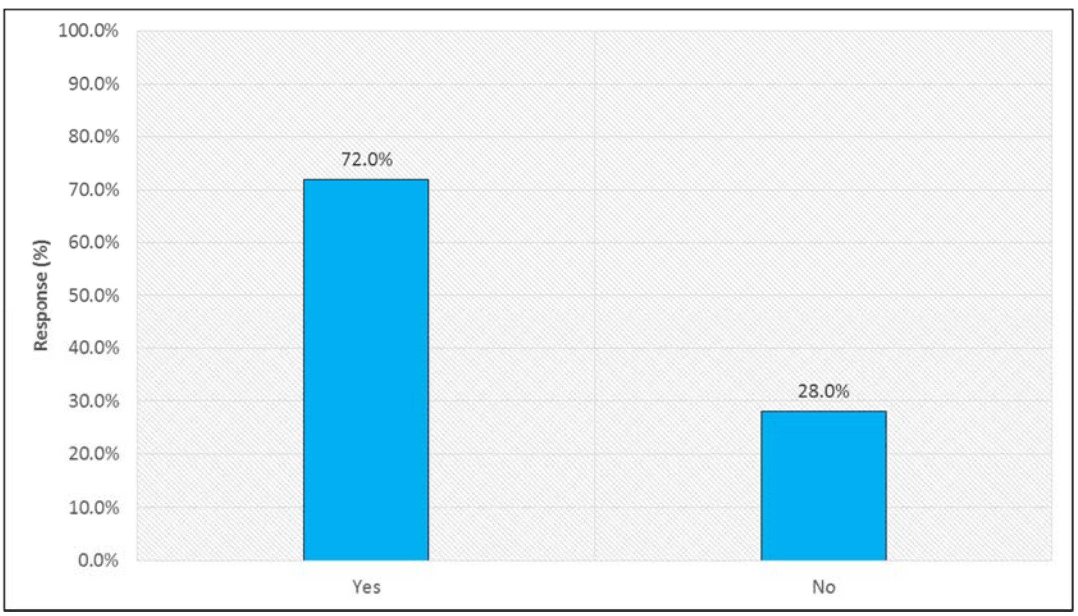

Figure 4-7
Do you restrict your use of stand-alone breakers to air insulated substations?

Other Equipment Replacement

Question: *When replacing a breaker, what other equipment is replaced? (Select all that apply)*

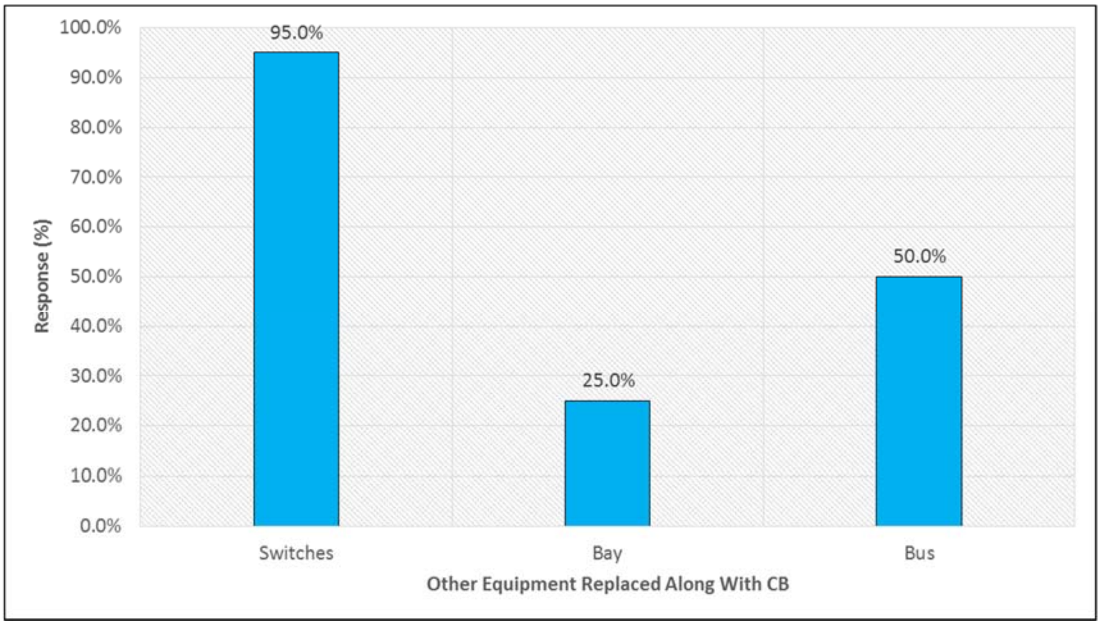

Figure 4-8
Other Equipment Replaced Along with Circuit Breaker

Drivers for Replacement Project Scope Expansion

Question: *If you expand the scope of a replacement project, what are the drivers? (Select all that apply)*

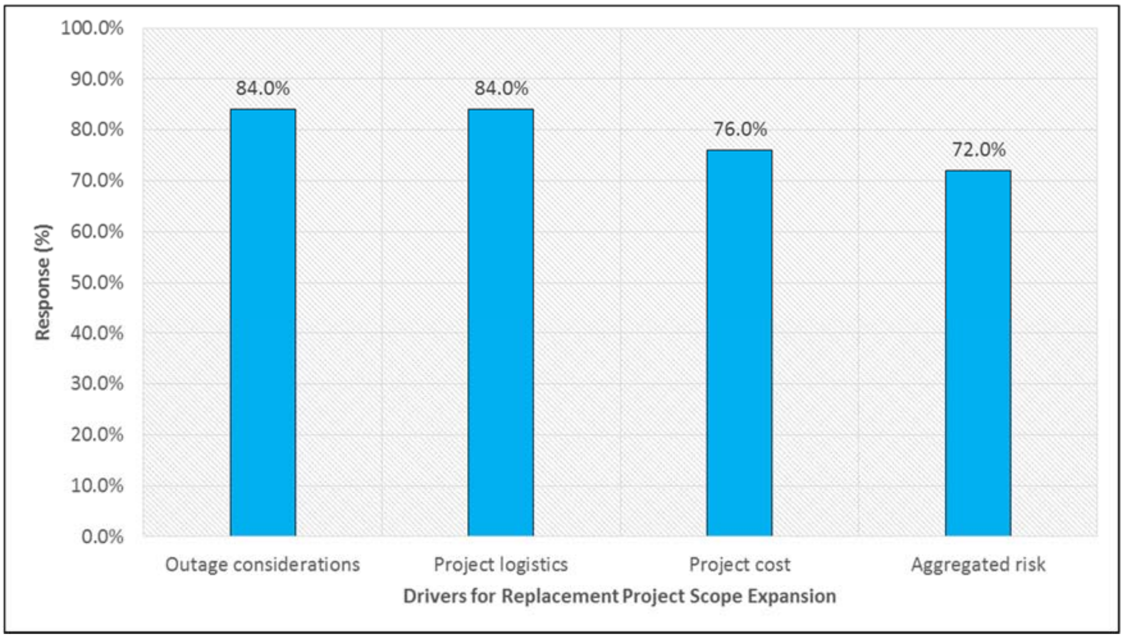

Figure 4-9
Drivers for Replacement Project Scope Expansion

5

SURVEY RESPONDENT CHARACTERISTICS: TRANSFORMERS

To help place the survey results in context and better interpret the responses, the characteristics of the utility participants and their respective transformer fleets are presented in this chapter.

Transformer Survey

Job Classification

Each transmission survey respondent was classified by job description as shown in Figure 5-1.

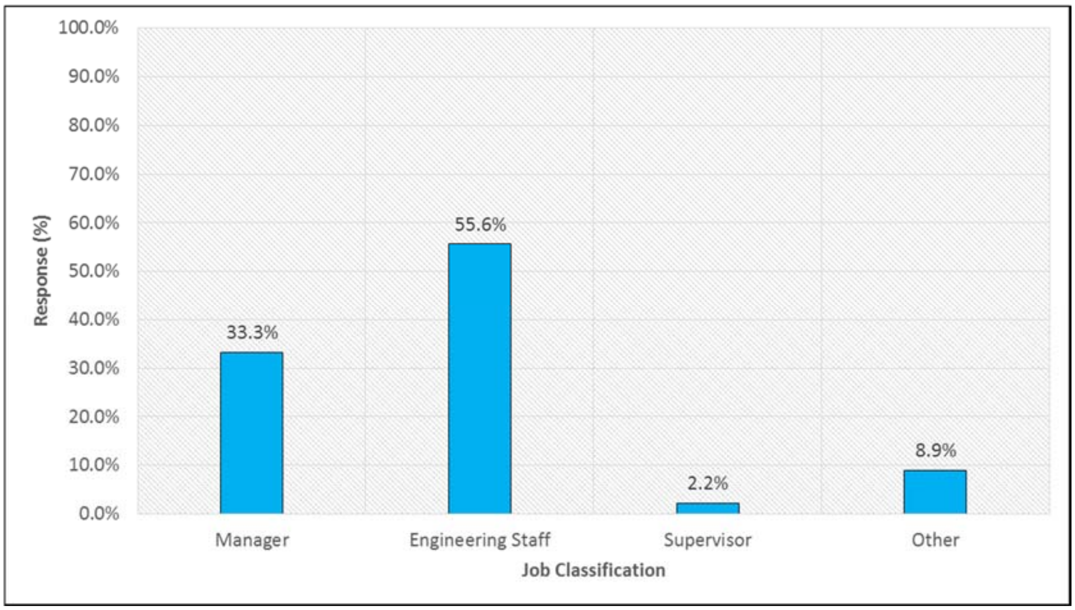

Figure 5-1
Job Classification: Transformer Survey Respondents

Organization Classification

Each respondent was classified by organization function and company description, as presented in Figures 5-2 and 5-3.

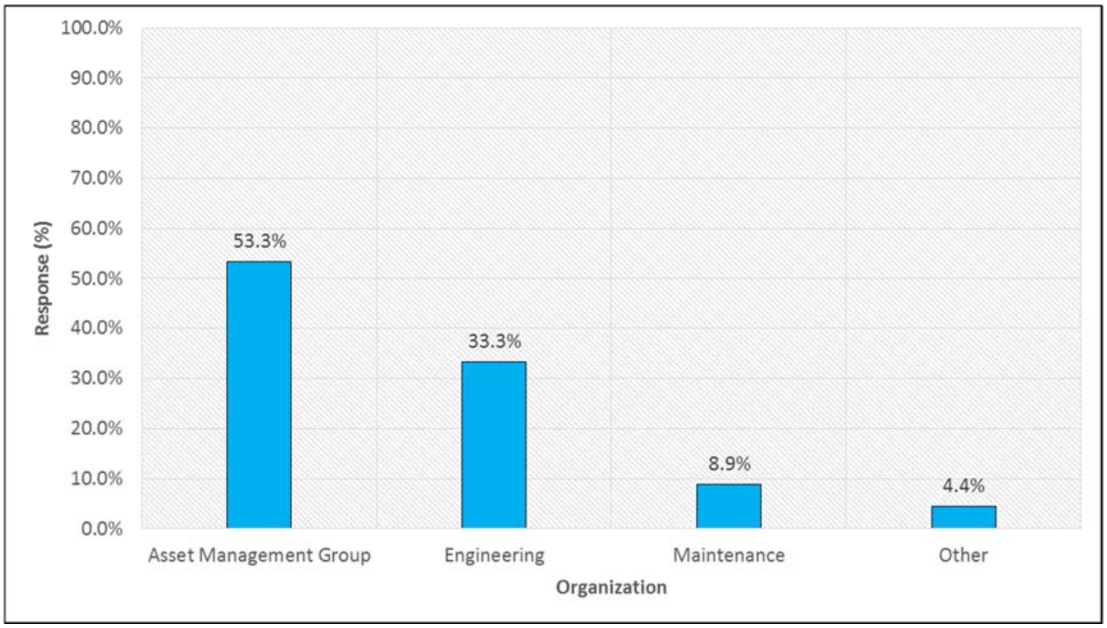

Figure 5-2
Organization Classification

Company Description

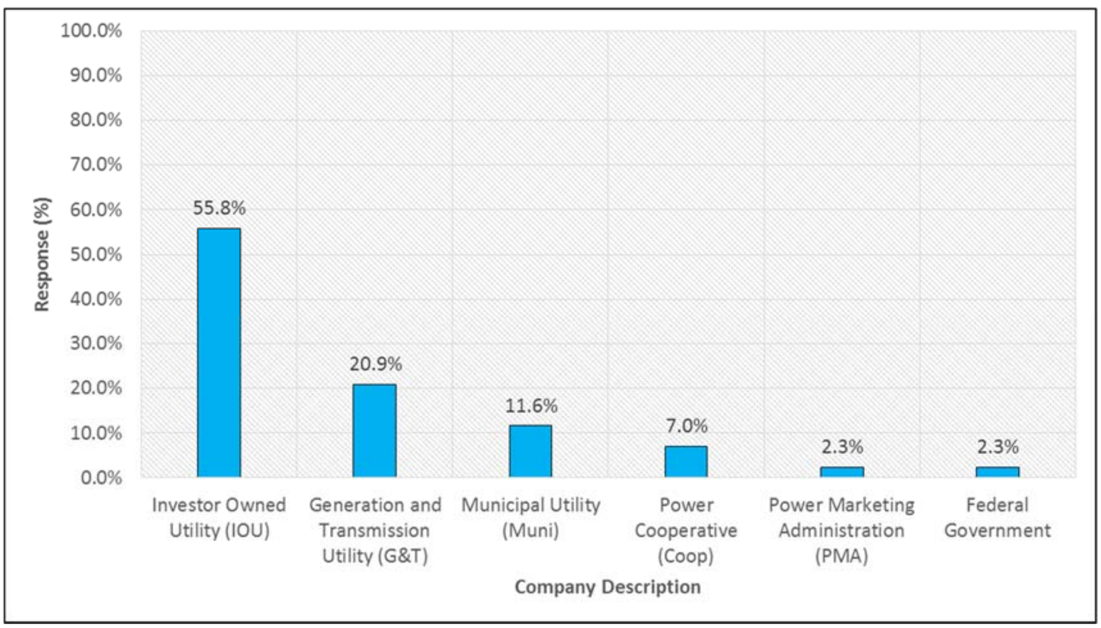

Figure 5-3
Company Description

Regulatory Structure

Respondents were asked about their company's regulatory structure. Responses are shown in Figure 5-4.

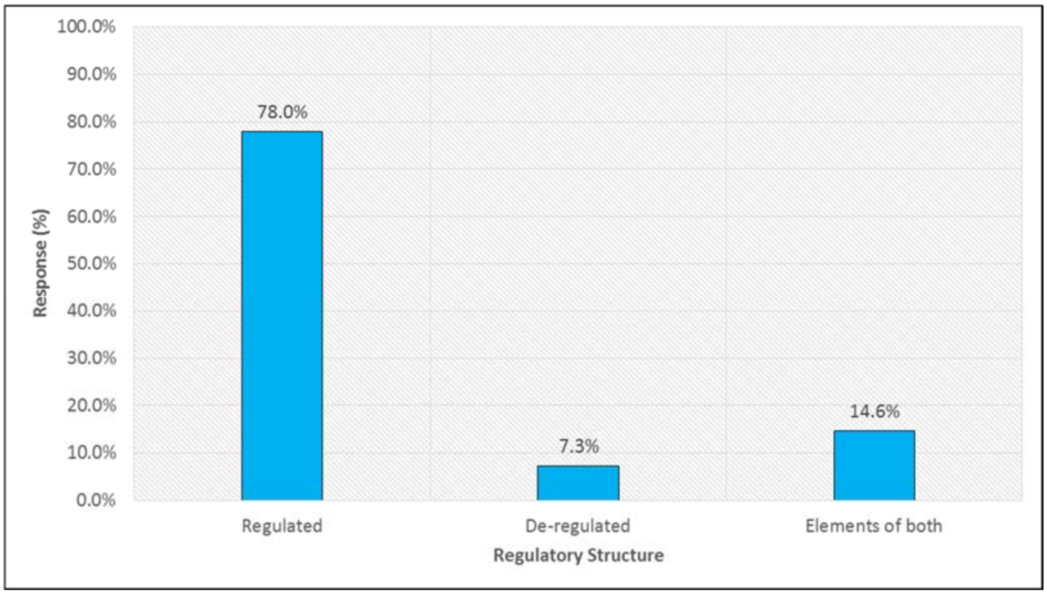

Figure 5-4
Regulatory Structure

Asked what assets their companies owned, respondents provided the information presented in Table 5-1. "None" means the respondent had none of that category. Whereas, "Part of Core Business" means the respondent considered that category to be a core business activity. Consider "Distribution" as an example. 6.7% of the respondents had no distribution assets. 71.1% considered distribution to be a core business. The balance had some distribution but did not consider it to be a core activity.

	None	Part of Core Business
Generation	26.7%	66.7%
Transmission	4.4%	88.9%
Distribution	6.7%	71.1%

Table 5-1
Assets Owned

System and Fleet Characteristics

Peak Load

Respondents were asked to define their system's peak load. Results are shown in Figure 5-5.

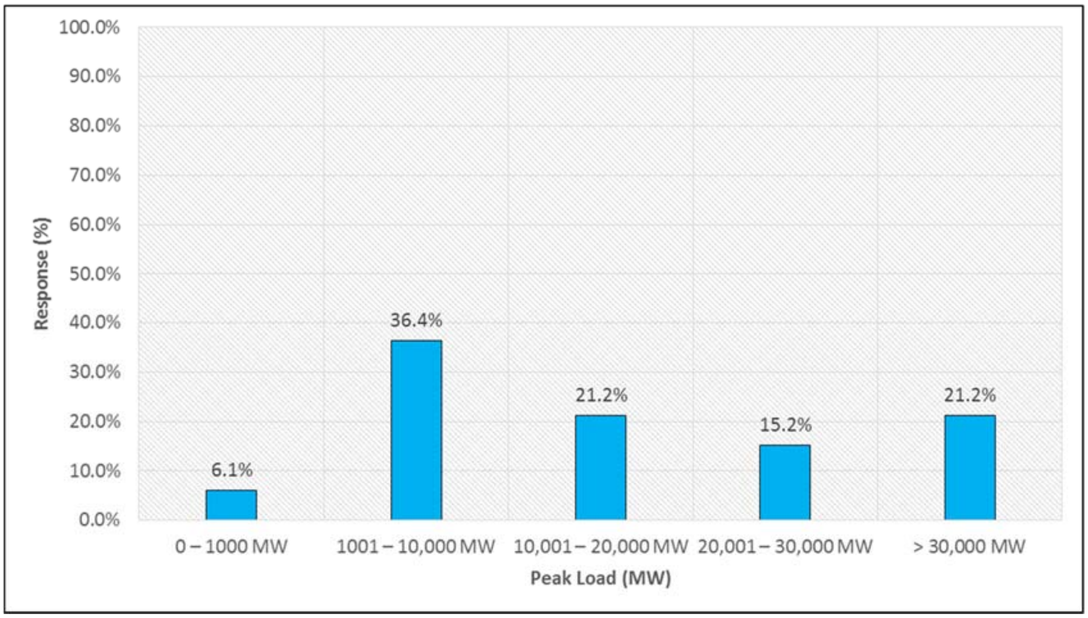

Figure 5-5
Peak Load

Number of Transformers in Service

Respondents were asked how many transmission transformers (>= 34 kV) they had in service. Figure 5-6 shows results.

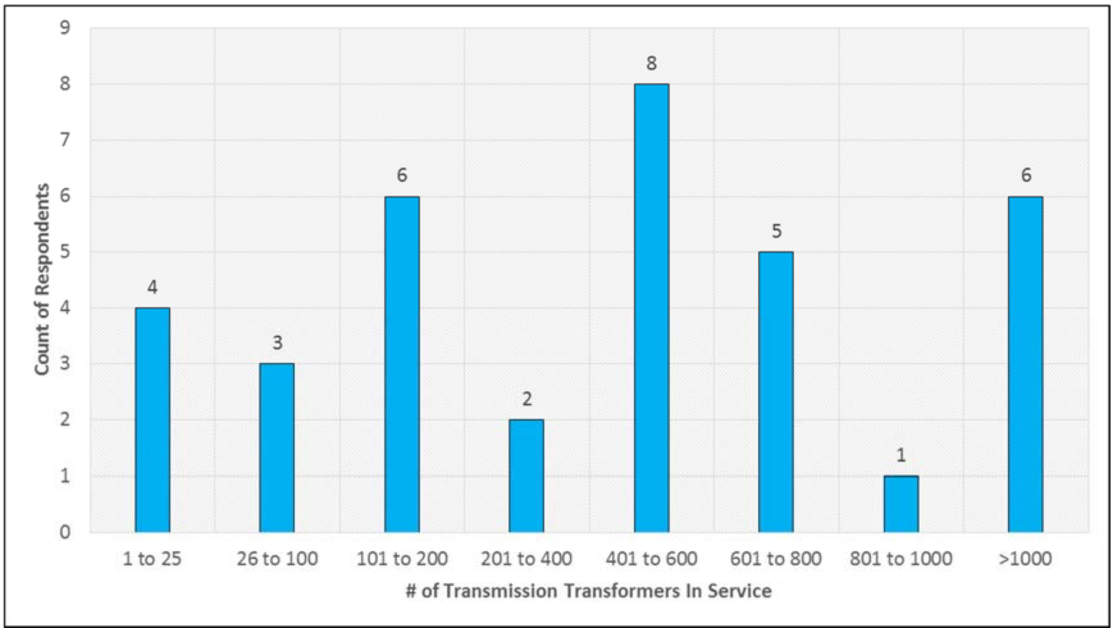

Figure 5-6
Number of Transmission Transformers in Service

Age Breakdown

What is the age breakdown of your transmission transformer fleet?

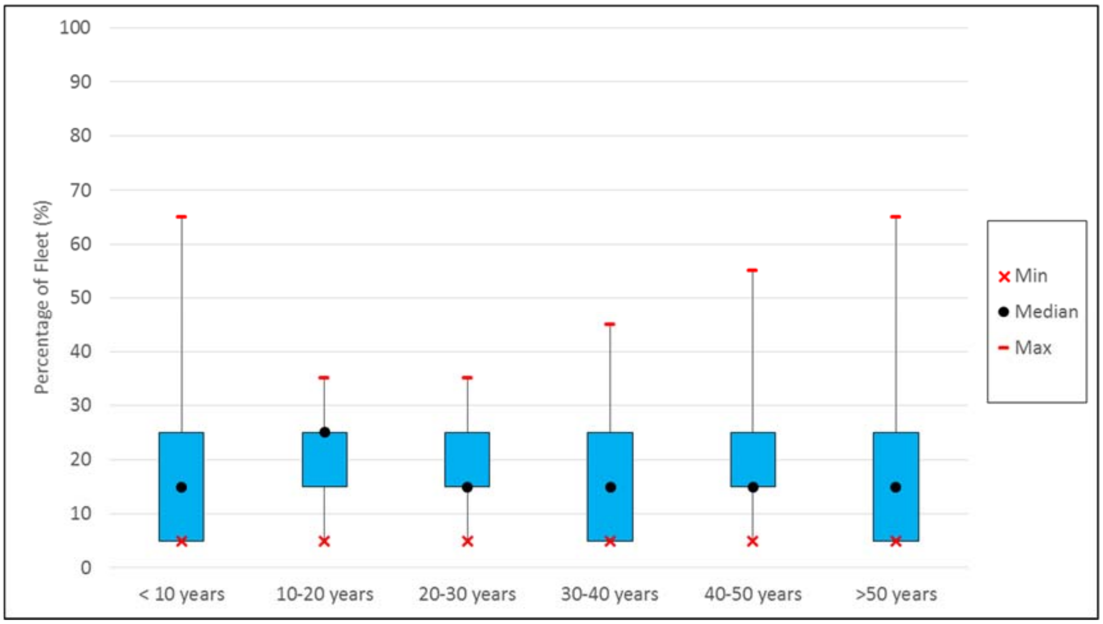

Figure 5-7
Transformer Fleet Age Breakdown

6
END OF LIFE CONCERNS FOR TRANSFORMERS

End of Life (EOL) Definitions

Utilities use different terms to define the end of life and expected service life of assets. For example, Hydro One uses the following definitions:

End of Life (EOL): The high likelihood of failure, or loss of an asset's ability to provide the intended functionality as determined through diagnostic data, wherein the failure or loss of functionality would cause unacceptable consequences. EOL can be further divided into three sub-categories:

- **Technical EOL**: The asset has failed, or condition assessment data indicates it is likely to do so, or it can no longer be expected to perform its function reliably
- **Economic EOL**: Unacceptable levels of maintenance costs are required to achieve the required performance/function.
- **Strategic EOL**: Necessary spares parts or skills set are unavailable; or the forecast loading or short circuit levels have exceeded the rating of the asset.

Expected Service life (ESL): The average time in years that an asset can be expected to operate under normal system conditions.

Use of Definitions and Utility Comments

Transformer survey respondents were asked whether their company used these or similar EOL definitions. Responses are shown in Figure 6-1.

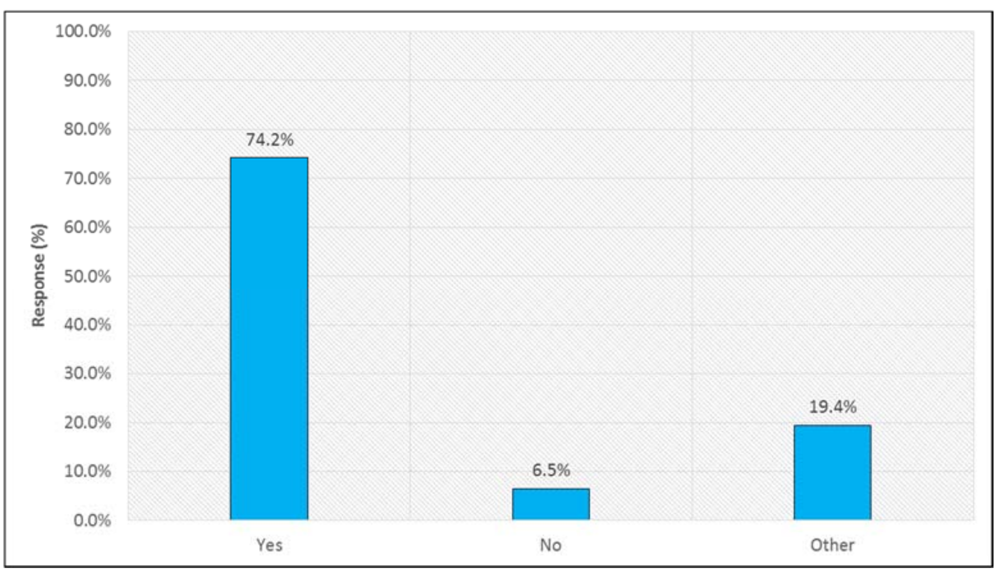

Figure 6-1
Use of Hydro One or Similar Definitions for End of Life and Expected Service Life

Comments

Respondents who answered no to this question were invited to provide comments. These are presented below.

> "Do not use these specific terms, but follow the same basic definitions."
>
> "We use these criteria, but not as formal definitions or classifications."
>
> "In general:
>
> - End of Life: The asset has failed, or condition assessment data indicates it is likely to do so, or it can no longer be expected to perform its function reliably.
> - Part Obsolescence: Necessary spares parts or skills set are unavailable; or the forecast loading or short circuit levels have exceeded the rating of the asset. Unacceptable levels of maintenance costs are required to achieve the required performance/function."
>
> "Just Technical EOL."
>
> "Use a health index that takes into account condition assessment, maintenance history, operational history and ability to repair."

Ages of Concern about Leaving Transformers in Service

Respondents were asked the question: *For transmission transformer assets, at what age would you start getting concerned about leaving the asset in service (ideally target for planned replacement in the next 5 to 10 years)?* Responses are shown in Figure 6-2 and Table 6-1.

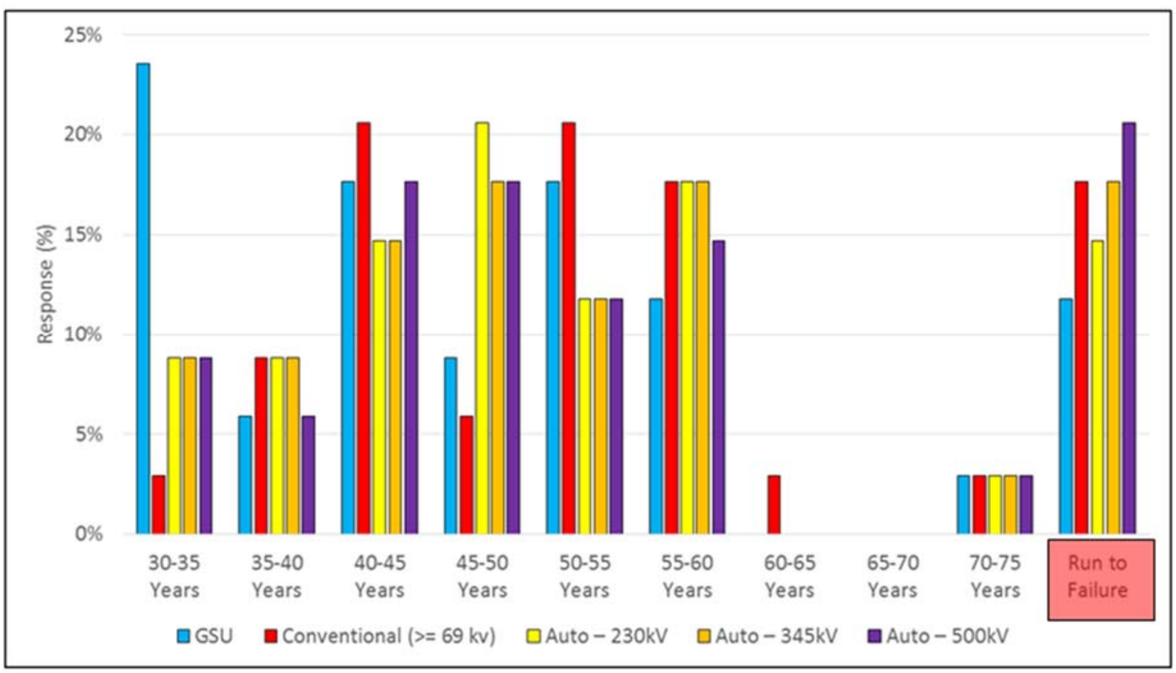

Figure 6-2
Age at Which Respondents Start Getting Concerned about Leaving Asset in Service

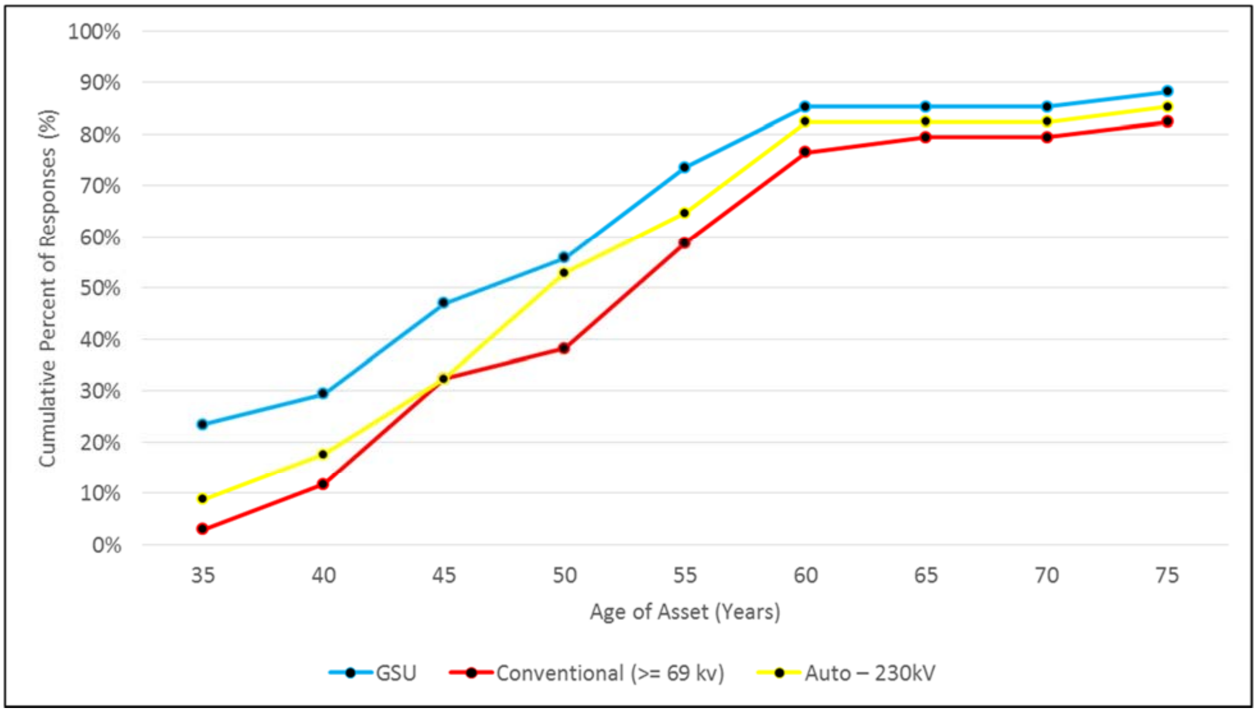

Figure 6-3
Cumulative Percentage: Age of Concern – GSU, Conventional and 230kV Auto Transformers

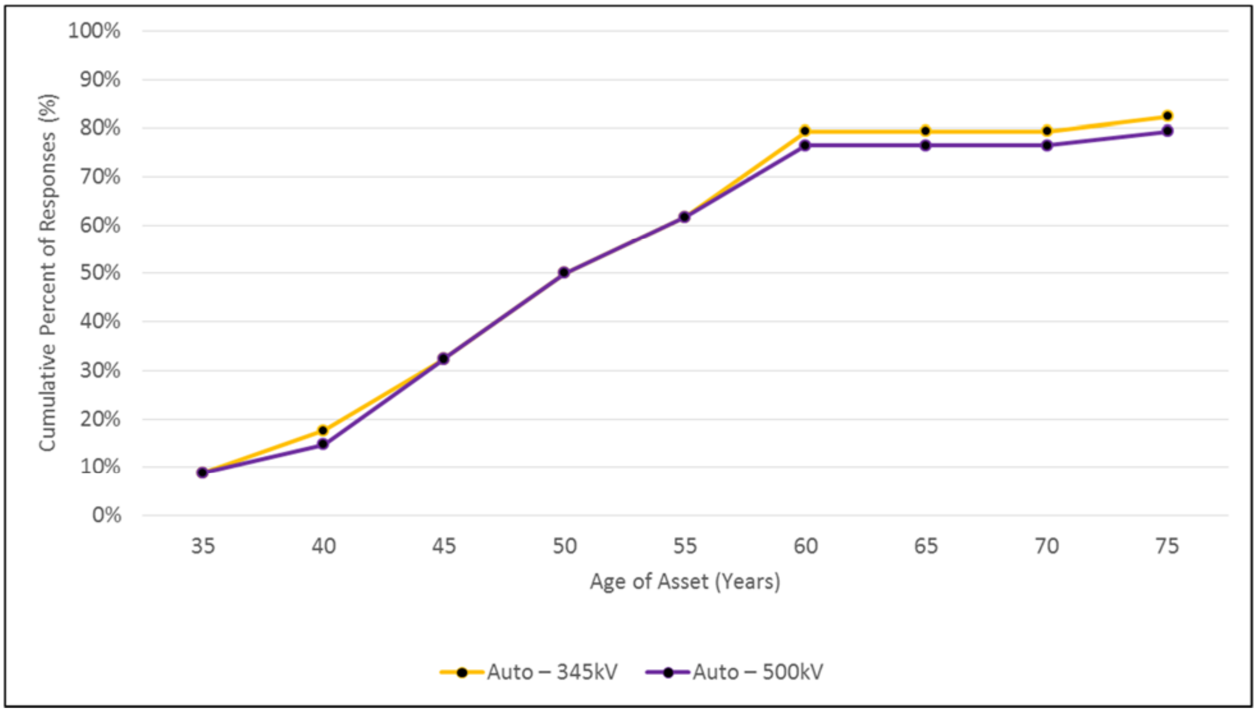

Figure 6-4
Cumulative Percentage: Age of Concern –345kV and 500kV Auto Transformers

Table 6-1
Age at Which Respondents Start Getting Concerned about Leaving Asset in Service

	30-35 Years	35-40 Years	40-45 Years	45-50 Years	50-55 Years	55-60 Years	60-65 Years	65-70 Years	70-75 Years	Run to Failure
GSU	24%	6%	18%	9%	18%	12%	0%	0%	3%	12%
Conventional (>= 69 kv)	3%	9%	21%	6%	21%	18%	3%	0%	3%	18%
Auto – 230kV	9%	9%	15%	21%	12%	18%	0%	0%	3%	15%
Auto – 345kV	9%	9%	15%	18%	12%	18%	0%	0%	3%	18%
Auto – 500kV	9%	6%	18%	18%	12%	15%	0%	0%	3%	21%

Transformer Age at Which Respondents Become Very Concerned

For transmission transformer assets, at what age would you start getting very concerned about leaving the asset in service (ideally target for planned replacement in the next 2 to 5 years)?

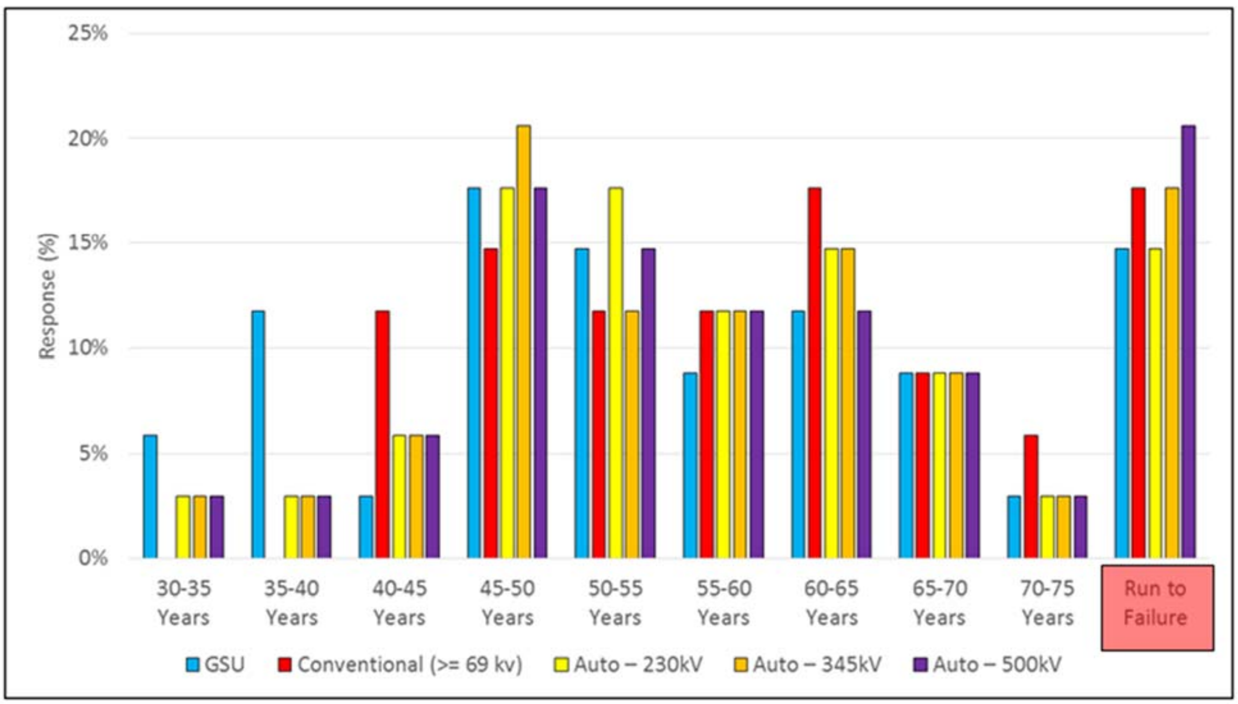

Figure 6-5
Age at Which Respondents Start Getting Very Concerned about Leaving Asset in Service

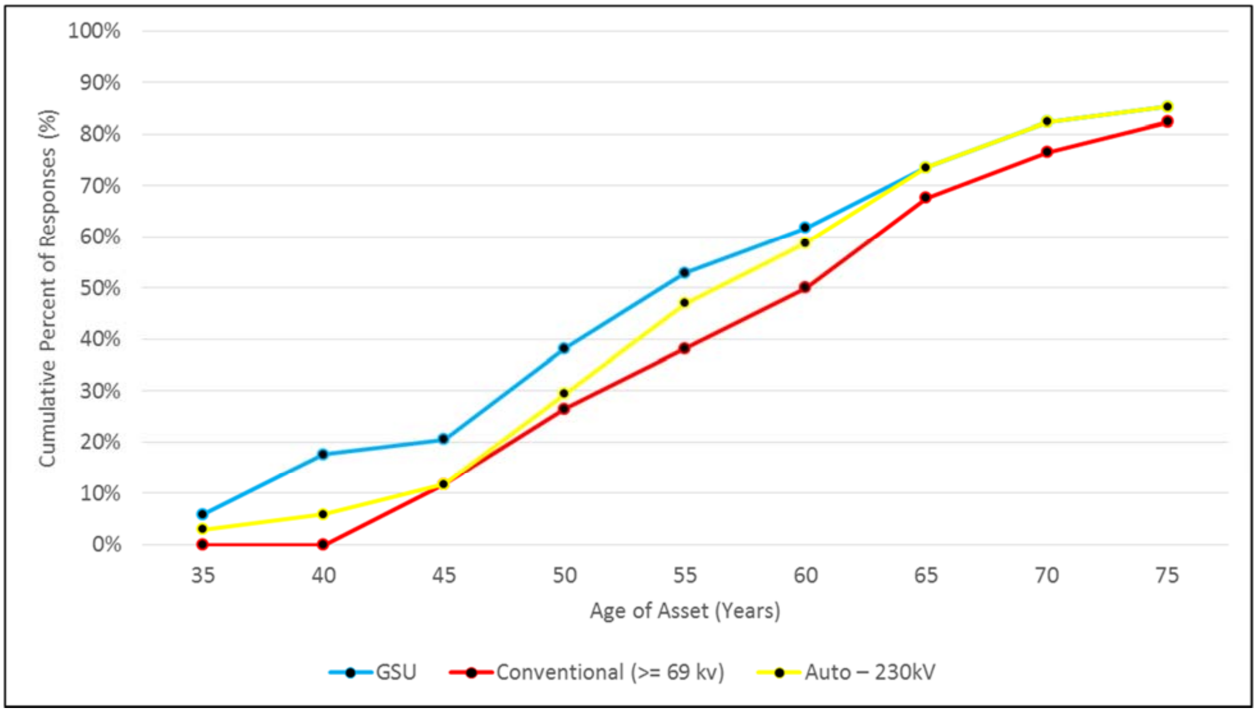

Figure 6-6
Cumulative Percentage: Age of Getting Very Concerned – GSU, Conventional, 230kV Auto Transformers

Cumulative Percentage: Age of Getting Very Concerned –345kV and 500kV Auto Transformers

Table 6-2
Age at Which Respondents Start Getting Very Concerned about Leaving Asset in Service

	30-35 Years	35-40 Years	40-45 Years	45-50 Years	50-55 Years	55-60 Years	60-65 Years	65-70 Years	70-75 Years	Run to Failure
GSU	6%	12%	3%	18%	15%	9%	12%	9%	3%	15%
Conventional (>= 69 kv)	0%	0%	12%	15%	12%	12%	18%	9%	6%	18%
Auto – 230kV	3%	3%	6%	18%	18%	12%	15%	9%	3%	15%
Auto – 345kV	3%	3%	6%	21%	12%	12%	15%	9%	3%	18%
Auto – 500kV	3%	3%	6%	18%	15%	12%	12%	9%	3%	21%

7

ASSESSMENT AND REPLACEMENT PRACTICES FOR TRANSFORMERS

Survey participants were asked a series of questions about their practices regarding assessment and replacement of transformers. Responses are presented in this chapter.

Replacement Categories

What percentage of your transmission transformers replacements fall into the following categories?

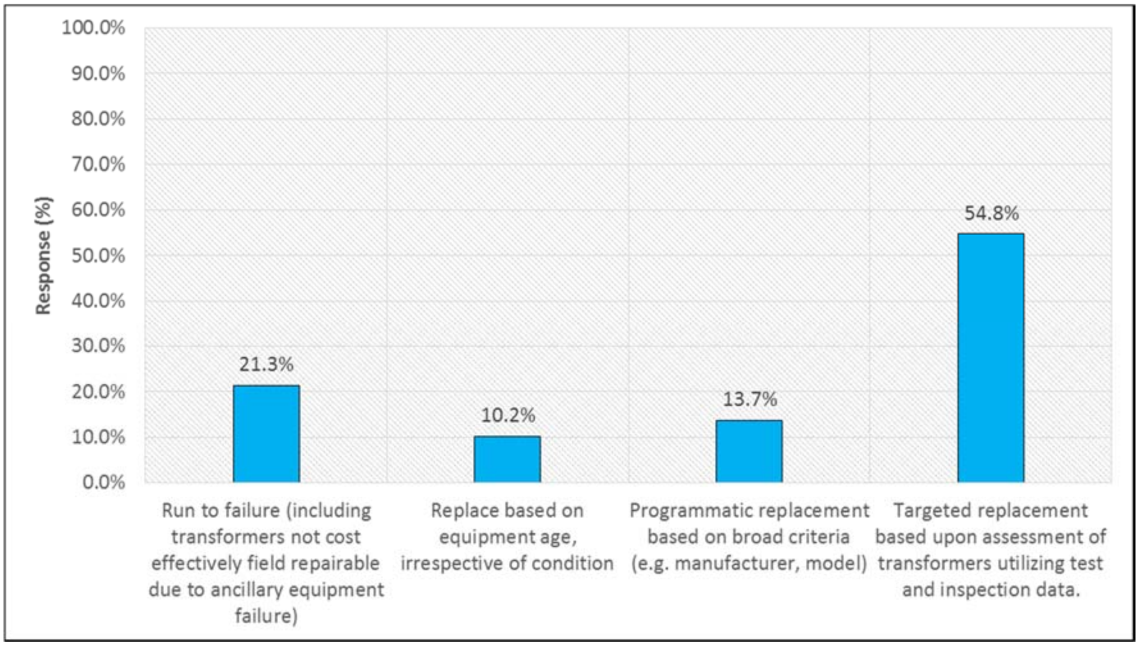

Figure 7-1
Replacement Categories

Replacement Planning and Budgeting

Question: *Do you plan/budget for a specific number of transmission transformer replacements per year?*

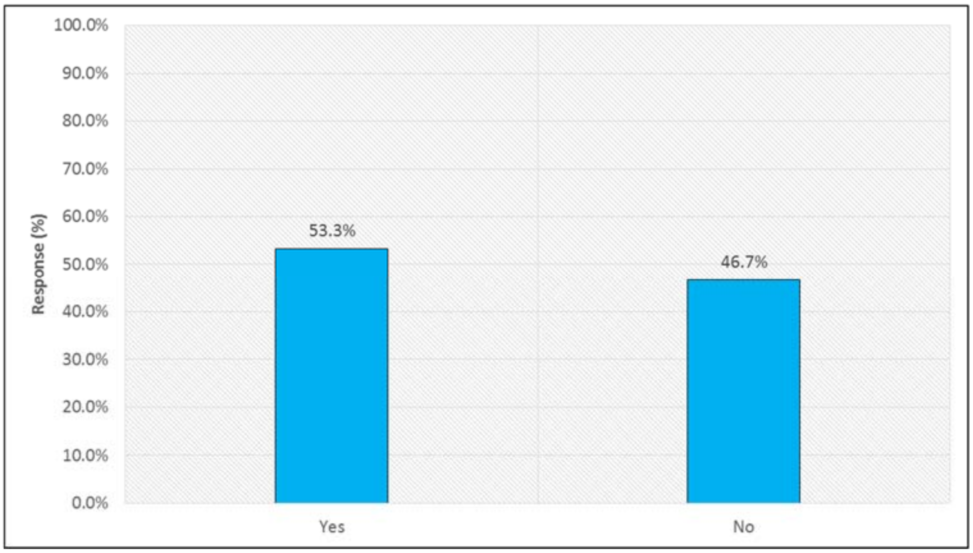

Figure 7-2
Do you plan/budget for a specific number of transmission transformer replacements per year?

Criteria for Annual Planned Replacements

Question: *What factors contribute to determine the number of planned replacements per year? (Please Rank 1-5 with 5 being most critical.)*

Table 7-1
Averages of Criteria Ranking for Determining Number of Planned Replacements per Year

Criteria	Ranking Average
Condition of individual assets	4.00
Budgetary constraints	3.18
Statistical analysis of failure rates applied to transformer population	3.00
Age distribution of transformers	2.94
Estimate based on past experience	2.50

Evaluating Replacement Rate

Question: *"How does your organization evaluate whether the future replacement rate (next 5 years) is adequate? (Select all that apply)"*

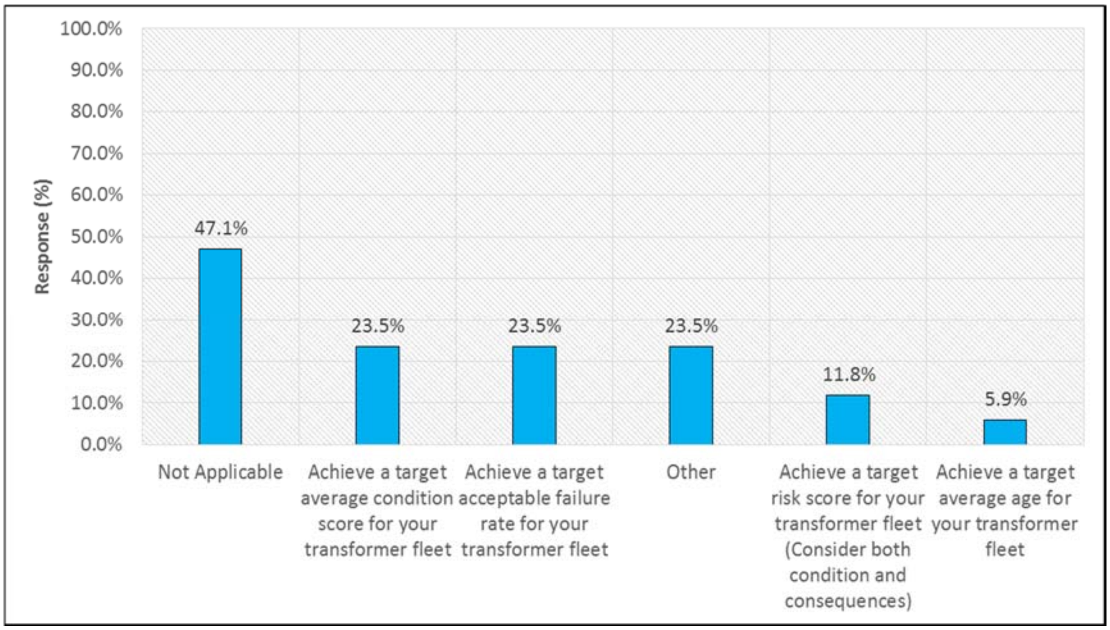

Figure 7-3
Evaluating Replacement Rate

Respondents who answered "Other" provided the following comments:

> "Moving to a targeted risk score in 2017."
>
> "Try to achieve a target average condition score for your transformer fleet. However, it's only a recommendation and does not necessarily feedback into the formal budgeting process."
>
> "We are currently developing justification to increase our proactively replaced transformers a by showing predictive indicators of failure rate and reliability."
>
> "Replacement rate is largely driven by Budgetary constraints."

Refurbishment to Extend Service Life

Question: *"Do you refurbish transformers to extend service life?"*

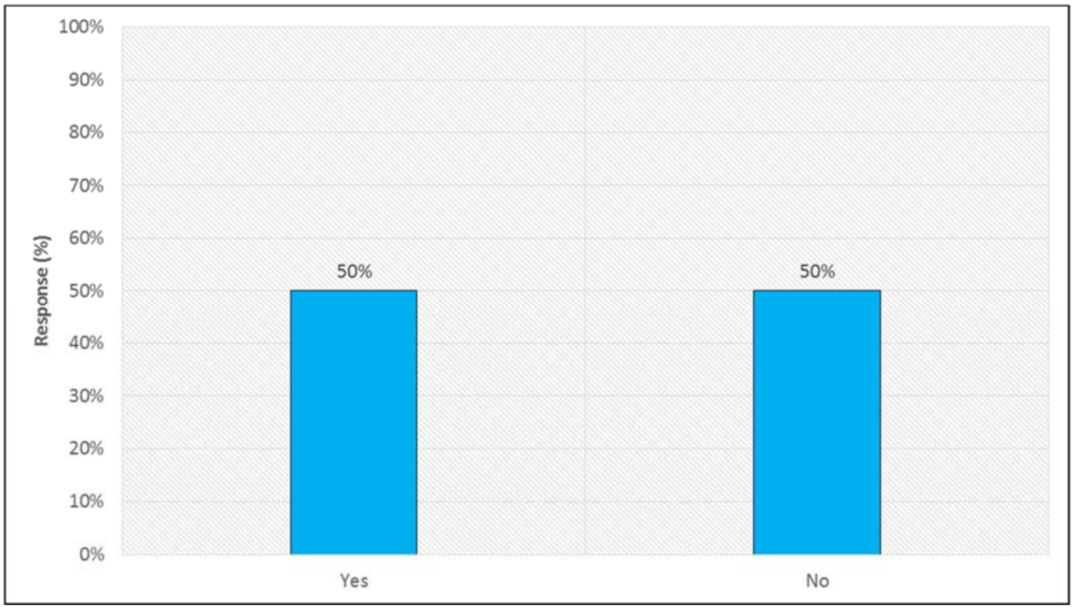

Figure 7-4
Refurbish to Extend Service Life?

Process or Algorithm to Assess Condition

Asked if they had a formal process or algorithm to assess transformer condition, respondents provided the answers shown in Figure 7-5.

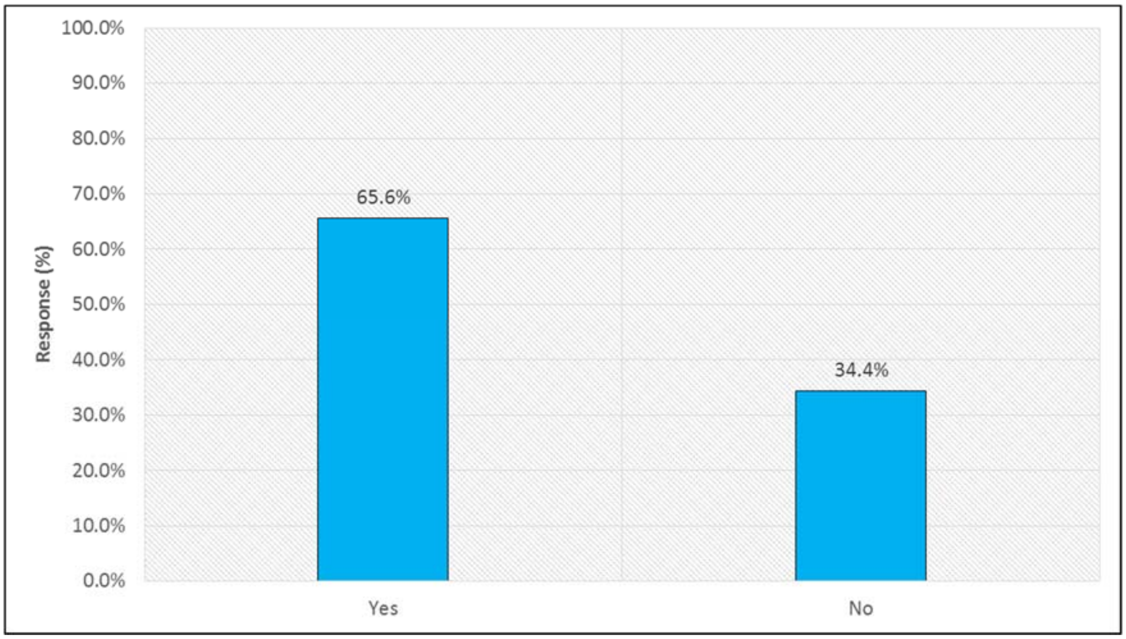

Figure 7-5
Do you have a formal process or algorithm to assess transmission transformer condition?

Respondents were asked to describe the process or algorithm. Their answers are shown in Figure7-6.

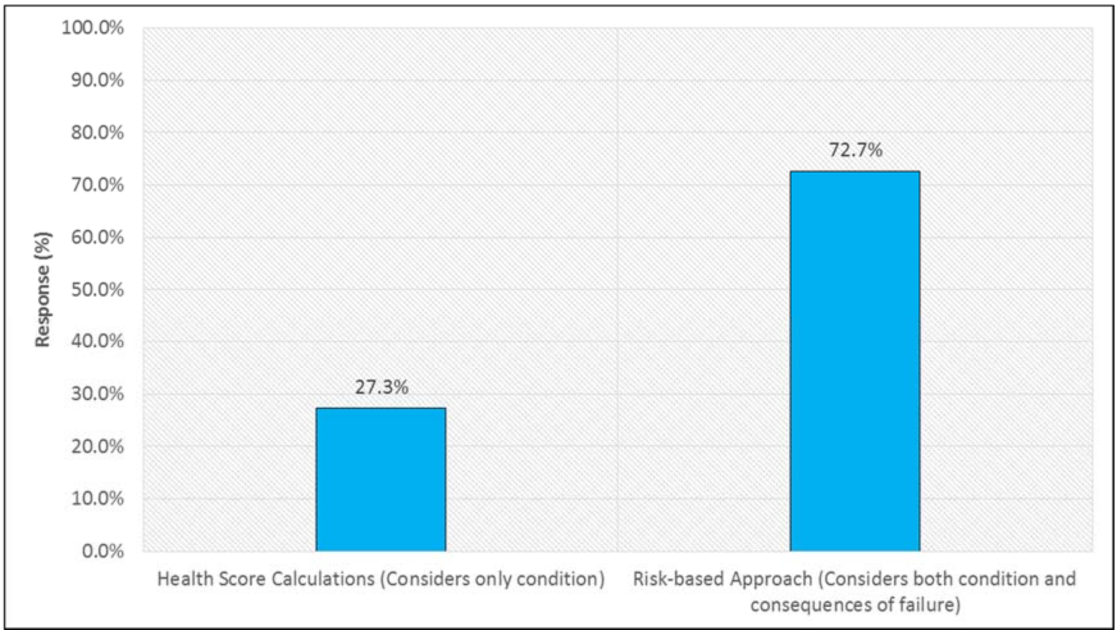

Figure 7-6
How would you best describe the formal process or algorithm?

Participants were asked to rank the input factors to this formal process or algorithm? (1-8 with 8 being most critical). Results are shown in Table 7-2.

Table 7-2
Ranking Input Averages to Formal Process or Algorithm

Criteria	Ranking Average
Condition	7.18
System Criticality	6.22
Health and Safety	5.00
Utilization	4.71
Design/Obsolesce/Maintainability	4.44
Performance (SAIDI,SAIFI,MAIFI)	4.00
Economical (Internal and/or External)	3.63
Demographics	3.55

Asked if their algorithm could trigger a replacement by itself, respondents provided answers shown in Figure 7-7.

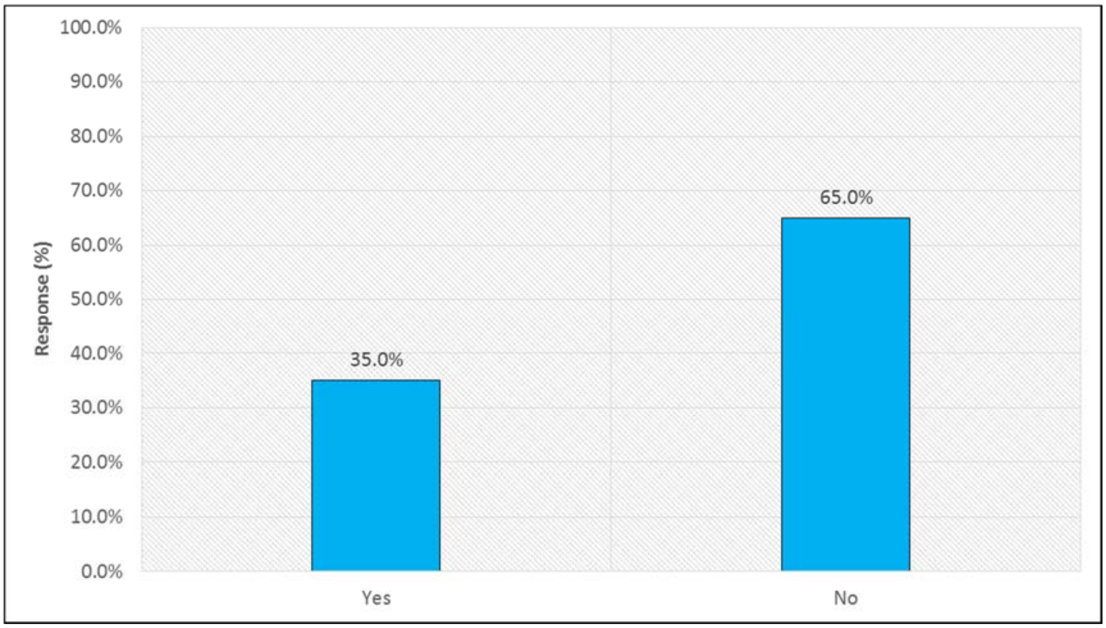

Figure 7-7
Could your algorithm trigger a replacement by itself?

Respondents answering "No" were asked a follow-up question: *What else is needed for your algorithm to trigger a replacement?* Responses follow:

> "Approval by SME."

> "Economic, criticality, redundancy factors etc."

> "Algorithm initiates an in-depth review of the asset and development of a mitigation strategy. The strategy may be other than replacement."

> "Simply another tool to make educated decisions. The final decision requires input asset management engineers."

> "Scoring reviewed and investment strategy is the developed."

> "Engineering review of all data."

> "Each of the condition factors that are inputs into the health index need to be manually assessed."

> "Evaluation by engineering and operations staff."

> "Formal process to use algorithm outputs in planning decisions with input from field personnel, equipment experts, customers and long term planning groups."

8
SUMMARY AND NEXT STEPS

Circuit Breaker Survey Summary

Respondent Characteristics

- Approximately 50% of respondents are Engineering Staff
- About 60% of member respondents' systems have a peak load equal to or greater than 10000 MW
- Around three quarters of respondents used some formal definition of End of Life

Age of Concern for Circuit Breakers

The following tables provide the approximate ages at which more than 50% of respondents would be concerned or very concerned about leaving the circuit breaker in service.

Oil Breakers

Answer Options	Concerned	Very Concerned
34 to < 69 kV (Oil)	49 Yrs	55 Yrs
69 kV (Oil)	50 Yrs	55 Yrs
115 kV (Oil)	47 Yrs	54 Yrs
230 kV (Oil)	46 Yrs	53 Yrs
345 kV (Oil)	46 Yrs	54 Yrs
500 kV (Oil)	46 Yrs	54 Yrs

Gas Breakers

Answer Options	Concerned	Very Concerned
34 to < 69 kV (Gas)	44 Yrs	53 Yrs
69 kV (Gas)	44 Yrs	53 Yrs
115 kV (Gas)	44 Yrs	53 Yrs
230 kV (Gas)	44 Yrs	52 Yrs
345 kV (Gas)	44 Yrs	52 Yrs
500 kV (Gas)	44 Yrs	52 Yrs

- 34 to 115 kV: Majority concerned 44 to 45 years. Majority <u>very</u> concerned 53 to 54 years
- 230 to 500 kV: Majority concerned 44 years. Majority <u>very</u> concerned 51 to 52 years

Vacuum Breakers

Answer Options	Concerned	Very Concerned
34 to < 69 kV (Vac)	45 Yrs	54 Yrs
69 kV (Vac)	44 Yrs	53 Yrs
115 kV (Vac)	44 Yrs	54 Yrs

Circuit Breaker Assessment and Replacement Practices

- Two-thirds of respondents do not run transmission circuit breakers to failure
- Condition and safety are the two highest ranked criteria for replacing a breaker
- Majority of utilities do not have a formal process or algorithm for assessing circuit breaker condition
- Most utilities that have a formal process or algorithm for assessing circuit breaker condition do not allow the algorithm to automatically trigger a replacement
- Majority of utilities do replace circuit breakers by type/family regardless of individual age or condition with decisions highly based on population condition, population ownership costs, population reliability, safety, and environmental impact.

Transformer Survey Summary

Respondent Characteristics

- Approximately 56% of respondents are Engineering Staff
- Almost 60% of member respondents' systems had a peak load equal to or greater than 10000 MW
- Around three-quarters of respondents used some formal definition of End of Life

Age of Concern for Transformers

The following tables provide the approximate ages at which more than 50% of respondents would be concerned or very concerned about leaving the transformer in service.

Answer Options	Concerned	Very Concerned
GSU	47 Yrs	54 Yrs
Conventional (>= 69 kv)	54 Yrs	60 Yrs
Auto – 230kV	50 Yrs	56 Yrs
Auto – 345kV	50 Yrs	57 Yrs
Auto – 500kV	50 Yrs	57 Yrs

- GSU, Conventional, Auto 230kV: Majority concerned 46 to 53 years. Majority <u>very</u> concerned 54 to 60 years
- Auto 345kV and Auto 500kV: Majority concerned 49 to 51 years. Majority <u>very</u> concerned 56 to 58 years

Transformer Assessment and Replacement Practices

- Most utilities target replacement based upon assessment of the asset using test and inspection data
- Just over 50% of utilities budget for a specified number of replacements per year with the highest weights on condition of individual asset and budgetary constraints
- Nearly half of utilities do not evaluate a 5 year replacement rate
- Half of utilities refurbish transformers to extend life
- Majority of utilities do have a formal process or algorithm for assessing transformer condition. Nearly three-fourths of utilities use a risk-based approach with condition and system criticality ranking highest for their algorithm inputs
- Most utilities that have a formal process or algorithm for assessing transformer condition do not allow the algorithm to automatically trigger a replacement

Next Steps

The results documented in this report provide additional data points in a series of EPRI utility surveys designed to acquire information and insights on industry attitudes and practices related to asset management of transmission circuit breakers and transformers. Survey results may help utilities to learn how peer companies are responding to similar challenges, and may also help inform and guide research and development efforts to further improve substation asset management practices.

A
SURVEY QUESTIONS: CIRCUIT BREAKERS

A web-based survey tool was used to construct a set of focused questions that could provide an assessment of current industry assessment and replacement practices for transmission circuit breakers and power transformers.

The circuit breaker survey questions are presented here in Appendix A. The transformer survey questions are presented in Appendix B.

Circuit Breaker Survey

About this Survey

EPRI has initiated this survey with the following goals/key objectives:

-Assess attitudes and practices related to circuit breaker replacement and asset management programs

- Understand how peer companies are responding to similar challenges

The responses that we gather through this survey will be summarized in a document in a non-attributable fashion.

In exchange for your help in completing the survey, EPRI will provide you with a summary of the results.

Should you desire to have multiple people from your company complete a copy of the survey (For example, people from different operating companies of a holding company), simply forward the link to the appropriate individuals and ask them to complete a survey.

On occasion, we ask for numbers of various populations or for specific information. While we would like the most accurate answers possible, we understand that some numbers would require some effort to collect. In these cases, best estimates would be appreciated.

I recognize that you will have to make an investment in time to gather the information required to answer the questions in this survey - thank you in advance! The more complete listing of practices we can gather, the better able we will be to produce a practices document that is truly valuable to the participants!

I am requesting your help in identifying practices in place at your company by completing this on line survey between now and May 19th, 2017.

Personal Details

1. Please enter the following contact information. Leave this blank if you prefer to remain anonymous.

Name

Company

Email Address

Phone Number

* 2. Your Job Classification

- Manager
- Engineering Staff
- Supervisor
- Other (please specify)

* 3. Your Organization

- Asset management group (if separate)
- Engineering
- Maintenance
- Other (please specify)

Company Information

* 4. Which of the following best describes your company?

- Investor Owned Utility (IOU)
- Generation and Transmission Utility (G&T)
- Municipal Utility (Muni)
- Power Cooperative (Coop)
- Power Marketing Administration (PMA)
- Federal Government

* 5. Regulatory Structure

- Regulated
- De-regulated
- Elements of both

* 6. Assets Owned

	None	Few	Secondary business	Primary business
Generation				
Transmission				
Distribution				

Survey-Part 1: System and Fleet Characteristics

7.What is your system peak load?

- ◯ 0 – 1000 MW
- ◯ 1001 – 10,000 MW
- ◯ 10,001 – 20,000 MW
- ◯ 20,001 – 30,000 MW
- ◯ > 30,000 MW

While we would like the most accurate answers possible, we understand that some numbers would require some effort to collect. In these cases, please provide best estimates for questions 8-11.

8.How many transmission circuit breakers (>= 34 kV) do you have in service that are**Live Tank SF6 Circuit Breakers**?

9. How many transmission circuit breakers (>= 34 kV) do you have in service that are**Dead Tank SF6 Circuit Breakers**?

10. How many transmission circuit breakers (>= 34 kV) do you have in service that are**Bulk Oil Circuit Breakers**?

11. How many transmission circuit breakers (>= 34 kV) do you have in service that are**Minimum Oil Circuit Breakers**?

Survey-Part 2: EOL Concerns

12. Utilities use different terms to define the end of life and expected service life of assets. For example, Hydro One uses the following definitions:

End of Life (EOL): The high likelihood of failure, or loss of an asset's ability to provide the intended functionality as determined through diagnostic data, wherein the failure or loss of functionality would cause unacceptable consequences. EOL can be further divided into three sub-categories:

- Technical EOL: The asset has failed, or condition assessment data indicates it is likely to do so, or it can no longer be expected to perform its function reliably
- Economic EOL: Unacceptable levels of maintenance costs are required to achieve the required performance/function.
- Strategic EOL: Necessary spares parts or skills set are unavailable; or the forecast loading or short circuit levels have exceeded the rating of the asset.

Expected Service life (ESL): The average time in years that an asset can be expected to operate under normal system conditions.

Does your company use these or similar definitions?

- ◯ Yes
- ◯ No (please specify)

* 13. Please indicate in the following table the age ranges at which you would **start getting concerned** about leaving the asset in service (ideally target for planned replacement in the next 5 to 10 years). Please provide comments as appropriate.

For **oil** circuit breaker voltage levels, at what age would you **start getting concerned**?

	30-35 Years	35-40 Years	40-45 Years	45-50 Years	50-55 Years	55-60 Years	60-65 Years	65-70 Years	70-75 Years	Regardless of concern, will run to failure
34 to < 69 kV	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
69 kV	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
115 kV	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
230 kV	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
345 kV	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
500 kV	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯

Comments

* 14. Please indicate in the following table the age ranges at which you would **start getting concerned** about leaving the asset in service (ideally target for planned replacement in the next 5 to 10 years). Please provide comments as appropriate.

For **gas** circuit breaker voltage levels, at what age would you **start getting concerned**?

	30-35 Years	35-40 Years	40-45 Years	45-50 Years	50-55 Years	55-60 Years	60-65 Years	65-70 Years	70-75 Years	Regardless of concern, will run to failure
34 to < 69 kV	○	○	○	○	○	○	○	○	○	○
69 kV	○	○	○	○	○	○	○	○	○	○
115 kV	○	○	○	○	○	○	○	○	○	○
230 kV	○	○	○	○	○	○	○	○	○	○
345 kV	○	○	○	○	○	○	○	○	○	○
500 kV	○	○	○	○	○	○	○	○	○	○

Comments

* 15. Please indicate in the following table the age ranges at which you would **start getting concerned** about leaving the asset in service (ideally target for planned replacement in the next 5 to 10 years). Please provide comments as appropriate.

For **vacuum** circuit breaker voltage levels, at what age would you **start getting concerned**?

	30-35 Years	35-40 Years	40-45 Years	45-50 Years	50-55 Years	55-60 Years	60-65 Years	65-70 Years	70-75 Years	Regardless of concern, will run to failure

Comments

Survey-Part 3: Assessment and Replacement Practices

19. Does your company typically run a transmission circuit breaker to failure (i.e., it becomes inoperable and/or too impractical or expensive to restore to operation)?

- ◯ Yes
- ◯ No

Survey-Part 3: Assessment and Replacement Practices

* 20. Please rank each of the following criteria you use to replace an asset. (Rank 1-7 with 1 being most critical)

[ ]	Condition	☐ N/A
[ ]	Ownership Costs (Maintenance, unavailability of skills, availability of spares, etc.)	☐ N/A
[ ]	Age	☐ N/A
[ ]	Safety	☐ N/A
[ ]	Environmental Impact	☐ N/A
[ ]	Reliability/Availability	☐ N/A
[ ]	Asset Health Index/Trigger	☐ N/A

21. Please comment if there are any other criteria you use to replace an asset?

Survey-Part 3: Assessment and Replacement Practices

22. Do you have a formal process or algorithm to assess circuit breaker condition?

- ◯ Yes
- ◯ No

Survey-Part 3: Assessment and Replacement Practices

23. How would you best describe the formal process or algorithm?

◯ Health Score Calculations (Considers only condition)

◯ Risk-based Approach (Considers both condition and consequences of failure)

24. Could your algorithm trigger a replacement by itself?

◯ Yes

◯ No (Please comment on what else would be required)

Survey-Part 3: Assessment and Replacement Practices

25. Do you replace circuit breakers by type or family regardless of age or condition (e.g., OCBs, air-blast)?

- ◯ Yes
- ◯ No

Survey-Part 3: Assessment and Replacement Practices

26. Please provide a list of the types of families that you have replaced regardless of age or condition.

27. How do you decide when to replace a population (or fleet) of assets? (Programmatic replacement) (Select all that apply)

- [ ] Population Condition
- [ ] Population Ownership Costs (Maintenance, unavailability of skills, availability of spares, etc.)
- [ ] Average age
- [ ] Safety
- [ ] Environmental Impact
- [ ] Population Reliability
- [ ] Population Availability
- [ ] Achieve a levelized work plan to increase predictability of budgets and work load forecasts
- [ ] Increase efficiencies in contracting (master contracts, bulk purchases, etc.)
- [ ] Improve project execution through predictability (i.e., meet and deliver on scope/schedule/budget annually)
- [ ] Other (please specify)

Survey-Part 3: Assessment and Replacement Practices

28. Do you restrict your use of stand-alone breakers to air insulated substations?

◯ Yes

◯ No

29. When replacing a breaker, what other equipment is replaced? (Select all that apply)

☐ Switches

☐ Bay

☐ Bus

30. If you expand the scope of a replacement project, what are the drivers? (Select all that apply)

☐ Outage considerations

☐ Project logistics

☐ Project cost

☐ Aggregated risk

While we would like the most accurate answers possible, we understand that some numbers would require some effort to collect. In these cases, please provide best estimates for the following question.

31. What is the age breakdown of your circuit breaker fleet?

	None	0 to 10 %	10 to 20 %	20 to 30 %	30 to 40 %	40 to 50 %	50 to 60 %	60 to 70 %	70 to 80 %	80 to 90 %	90 to 100 %
< 10 years	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
10-20 years	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
20-30 years	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
30-40 years	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
40-50 years	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
>50 years	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯

Thank you for participating in this survey!

Upon completion of the survey, the results will be compiled in a summary report and results will be provided to members in a webcast.

B
SURVEY QUESTIONS: TRANSFORMERS

A web-based survey tool was used to construct a set of focused questions that could provide an assessment of current industry assessment and replacement practices for transmission circuit breakers and power transformers.

The transformer survey questions are presented here in Appendix B. The circuit breaker survey questions are presented in Appendix A.

Transformer Survey

About this Survey

EPRI has initiated this survey with the following goals/key objectives:

-Assess attitudes and practices related to transformer replacement and asset management programs

- Understand how peer companies are responding to similar challenges

The responses that we gather through this survey will be summarized in a document in a non-attributable fashion.

In exchange for your help in completing the survey, EPRI will provide you with a summary of the results.

Should you desire to have multiple people from your company complete a copy of the survey (For example, people from different operating companies of a holding company), simply forward the link to the appropriate individuals and ask them to complete a survey.

On occasion, we ask for numbers of various populations or for specific information. While we would like the most accurate answers possible, we understand that some numbers would require some effort to collect. In these cases, best estimates would be appreciated.

I recognize that you will have to make an investment in time to gather the information required to answer the questions in this survey - thank you in advance! The more complete listing of practices we can gather, the better able we will be to produce a practices document that is truly valuable to the participants!

I am requesting your help in identifying practices in place at your company by completing this on line survey between now and May 19th, 2017.

Personal Details

1. Please enter the following contact information. Leave this blank if you prefer to remain anonymous.

Name

Company

Email Address

Phone Number

* 2. Your Job Classification

- Manager
- Engineering Staff
- Supervisor
- Other (please specify)

* 3. What organization do you reside in?

- Asset Management group (if separate)
- Engineering
- Maintenance
- Other (please specify)

Company Info

4. Which of the following best describes your company?

- ◯ Investor Owned Utility (IOU)
- ◯ Generation and Transmission Utility (G&T)
- ◯ Municipal Utility (Muni)
- ◯ Power Cooperative (Coop)
- ◯ Power Marketing Administration (PMA)
- ◯ Federal Government

5. Regulatory Structure

- ◯ Regulated
- ◯ De-regulated
- ◯ Elements of both

* 6. Assets Owned

	None	Few	Secondary business	Primary business
Generation	◯	◯	◯	◯
Transmission	◯	◯	◯	◯
Distribution	◯	◯	◯	◯

Survey-Part 1: System and Fleet Characteristics

7. What is your system peak load?

- 0 – 1000 MW
- 1001 – 10,000 MW
- 10,001 – 20,000 MW
- 20,001 – 30,000 MW
- > 30,000 MW

<u>A transmission transformer in this survey is being defined as >= 69 kV.</u>

8. How many transmission transformers do you have in service?

* 9. What is the age breakdown of your transmission transformer fleet?

	10 to 20 %	20 to 30 %	30 to 40 %	40 to 50 %	50 to 60 %	60 to 70 %	70 to 80 %	0 to 10 %	80 to 90 %	90 to 100 %
< 10 years										
10-20 years										
20-30 years										
30-40 years										
40-50 years										
>50 years										

Survey-Part 2: EOL Concerns

10. Utilities use different terms to define the end of life and expected service life of assets. For example, Hydro One uses the following definitions:

End of Life (EOL): The high likelihood of failure, or loss of an asset's ability to provide the intended functionality as determined through diagnostic data, wherein the failure or loss of functionality would cause unacceptable consequences. EOL can be further divided into three sub-categories:

- Technical EOL: The asset has failed, or condition assessment data indicates it is likely to do so, or it can no longer be expected to perform its function reliably
- Economic EOL: Unacceptable levels of maintenance costs are required to achieve the required performance/function.
- Strategic EOL: Necessary spares parts or skills set are unavailable; or the forecast loading or short circuit levels have exceeded the rating of the asset.

Expected Service life (ESL): The average time in years that an asset can be expected to operate under normal system conditions.

Does your company use these or similar definitions? If not, what definition(s) do you use?

- ○ Yes
- ○ No
- ○ Other (please specify)

* 11. Please indicate in the following table the age ranges at which you would **start getting concerned** about leaving the following transmission transformer assets in service (ideally target for planned replacement in the next 5 to 10 years). Please provide comments as appropriate.

	30-35 Years	35-40 Years	40-45 Years	45-50 Years	50-55 Years	55-60 Years	60-65 Years	65-70 Years	70-75 Years	Regardless of concern, will run to failure
Generator Step-up Unit (GSU)	○	○	○	○	○	○	○	○	○	○
Conventional Transformer (69 kv and Above)	○	○	○	○	○	○	○	○	○	○
Auto – 230kV	○	○	○	○	○	○	○	○	○	○

Survey-Part 3: Assessment and Replacement Practices

* 13. What percentage of your transmission transformers replacements fall into the following categories?

	None	0 to 10 %	10 to 20 %	20 to 30 %	30 to 40 %	40 to 50 %	50 to 60 %	60 to 70 %	70 to 80 %	80 to 90 %	90 to 100 %
Run to failure (including transformers not cost effectively field repairable due to ancillary equipment failure)	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
Replace based on equipment age, irrespective of condition	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
Programmatic replacement based on broad criteria (e.g. manufacturer, model)	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯
Targeted replacement based upon assessment of transformers utilizing test and inspection data.	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯	◯

14. Do you plan/budget for a specific number of transmission transformer replacements per year?

◯ Yes

◯ No

Survey-Part 3: Assessment and Replacement Practices

15. What factors contribute to determine the number of planned replacements per year? (Please Rank 1-5 with 1 being most critical)

- [ ] Age distribution of transformers ☐ N/A
- [ ] Estimate based on past experience ☐ N/A
- [ ] Statistical analysis of failure rates applied to transformer population ☐ N/A
- [ ] Condition of individual assets ☐ N/A
- [ ] Budgetary constraints ☐ N/A

16. How does your organization evaluate if the future replacement rate (next 5 years) is adequate? (How do you know if you are replacing enough, too many, or too few)

- [ ] Achieve a target average age for your transformer fleet
- [ ] Achieve a target average condition score for your transformer fleet
- [ ] Achieve a target risk score for your transformer fleet (Consider both condition and consequences)
- [ ] Achieve a target acceptable failure rate for your transformer fleet
- [ ] Not Applicable
- [ ] Other (please specify)

Survey-Part 3: Assessment and Replacement Practices

17. Do you refurbish transformers to extend service life?

- ◯ Yes
- ◯ No

18. Do you have a formal process or algorithm to assess transmission transformer condition?

- ◯ Yes
- ◯ No

Survey-Part 3: Assessment and Replacement Practices

19. How would you describe the formal process or algorithm?

☐ Health Score Calculations (Considers only condition)

☐ Risk-based Approach (Considers both condition and consequences of failure)

20. Please rank the input factors to this formal process or algorithm? (Please rank 1-8 with 1 being most critical)

Rank	Factor	N/A
	Demographics	☐ N/A
	Condition	☐ N/A
	Utilization	☐ N/A
	Performance (SAIDI,SAIFI,MAIFI)	☐ N/A
	Economical (Internal and/or External)	☐ N/A
	System Criticality	☐ N/A
	Design/Obsolesce/Maintainability	☐ N/A
	Health and Safety	☐ N/A

21. Could your algorithm trigger a replacement by itself?

○ Yes

○ No (Please comment on what else would be required)

Thank you for participating in this survey!

Upon completion of the survey, the results will be compiled in a summary report and results will be provided to members in a webcast.

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc.(EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.

SUMMARY AND RECOMMENDATIONS

Hydro One provided a great deal of historical data on its high-pressure liquid-filled (HPLF) pipe-type cable circuits and its low-pressure liquid-filled (LPLF) self-contained cable circuits. Review of that information, calculation of critical parameters such as degree of thermal aging of the insulation, and evaluation of experience of other users of these cable types, permitted making conservative estimates of the design end of service life (expected service life – ESL) for both HPLF and LPLF cables.

High-pressure Liquid-filled Cables

Circuit loading has been significantly lower than the cable ratings. As a result, the thermal aging of the cable insulation is minimum. If an extremely conservative average operating temperature of 65°C is used for determining the degree of aging, the oldest HPLF cable has used only ten years of the presently assumed 50 year life. If the cables are loaded to their full rating in future operations, they should have another 40 years of life. Although analysis of loading data indicates that this is a conservative number, we recommend that Hydro One assign an additional 20 years to the design life, to give a 70-year design life. Hydro One should repeat the analysis described in this report as the oldest circuits approach the 70-yr age.

No leaks have been reported on the cable pipes, indicating that the corrosion coating and cathodic protection system are working well and will not limit the service life of the cable system. No unusual difficulties are reported on the corrosion protection system, splices, terminations, or dielectric liquid. With proper maintenance, these components will not limit the 70-year design life as recommended.

We recommend that Hydro One establish a 70-year period for the design end of service life for its HPLF cables, and that the cable condition be reviewed five years before that time. Hydro One should continue its maintenance testing such as dissolved gas analysis, fluid moisture content, and effectiveness of corrosion protection systems for buried steel pipes and manhole pipe sections. If any test results indicate potential problems, Hydro One should investigate the cause and take corrective action.

Low-pressure Liquid-filled Cables

Loading on the LPLF circuits has also been much lower than design ratings, and the life of the cable insulation should exceed 70 years, as is the case for the HPLF cables.

However, leaks on several of the circuits and difficulties with the pressurizing system, indicate that Hydro One should consider replacing these circuits within the next ten to twenty years.

We recommend that Hydro One establish a 70-year period for the design end of service life for its LPLF cables, and that the cable condition be reviewed five years before that time. Hydro One should continue its maintenance testing such as dissolved gas analysis, fluid moisture content, and jacket integrity tests. If any test results indicate potential problems, Hydro One should investigate the cause and take corrective action. Hydro One should carefully monitor the condition of the lead sheaths and the liquid reservoirs, and should begin designing the *replacement of LPLF cables with modern generation XLPE cables and replace the LPLF cables within ten to twenty years.*

1
INTRODUCTION

Underground transmission cables have a minimum design life expectancy (expected service life – ESL) based upon cable type and installation/operating conditions. Many of the paper-insulated, laminar-dielectric cables in North America have reached this threshold and beyond. There are common concerns with respect to cable system condition and potential remaining life. Previous EPRI studies [1] identified key indicators for condition evaluation of cellulose paper-based cable insulation. The indicators utilize cable operating history and non-intrusive and/or intrusive measurements.

Hydro One has requested EPRI assistance in evaluating the expected service life of 115-kV and 230-kV paper-insulated, laminar-dielectric cables, both high-pressure fluid-filled and low-pressure fluid filled, on the Hydro One transmission system.

The total length of in-service underground transmission laminar dielectric cables installed in Hydro One is about 167 miles (270 km). The average age of the cable fleet is now over 36 years with almost one-quarter of the lines exceeding the design end of service life (ESL) of 50 years based on original design expectancy. Many of the cable circuits in service that have exceeded the 50-year ESL are considered in good condition and operated safely and reliably. A sound technical basis is needed to more accurately identify the ESLs of low-pressure and high-pressure fluid-filled cable circuits.

This report describes the analyses performed and provides results and recommendations for an expected service life for properly maintained paper-insulated cables. The report focuses on the cables themselves but includes brief discussions on major accessories. Accessories can generally be maintained and upgraded as necessary but there can be situations where the maintenance of accessories becomes sufficiently costly to justify replacement of the cable system.

Note that the analysis in this report is based upon maintenance records and other information provided.

Review of information provided by Hydro One showed that the utility has implemented very thorough maintenance practices and reporting, and this has contributed to the overall excellent condition and longevity of the cable systems.

2

BRIEF DESCRIPTION OF CABLE TYPES AND THE HYDRO ONE UNDERGROUND TRANSMISSION SYSTEM

Tabulations from Hydro One show that the underground transmission system includes 65 high-pressure liquid-filled (HPLF) cables, totaling 106 circuit-miles (171 circuit-km), and 45 low-pressure liquid-filled (LPLF) circuits, totaling 41 circuit-miles (66 circuit-km). Hydro One also has 12 cross-linked polyethylene (XLPE) cable circuits totaling 19 circuit-miles (31 circuit-km). General descriptions of HPLF and LPLF cable circuits are given below.

2.1 High-pressure Liquid-filled Cable Circuits

2.1.1 Description of Cable System

Pipe-type cable systems have the three cables (A, B, and C phase) insulated with tapes of kraft paper (or laminated paper-polypropylene in more recent installations), installed in a common steel pipe. The pipe is pressurized, usually with a dielectric liquid. The system is called a high-pressure liquid-filled (HPLF) or high-pressure fluid-filled (HPFF) cable system. This cable system was called high-pressure oil-filled (HPOF) until the 1970s when synthetic dielectric liquids began to replace the mineral oils that had been used earlier.

North America is the major user of pipe-type cables, with the earliest installation in the 1930s and significant installations at 345 kV beginning in the early 1960s. There also are installations in Ireland, Europe, and the Middle East. Japan has a few pipe-type installations.

Pipe-type cables have been the most commonly used transmission cable type in North America through the early twenty-first century for several major reasons:

- The pipe provides rugged protection against third-party damage.
- The system is reliable.
- The pipe can be installed in relatively short street openings, minimizing traffic disruption in crowded urban areas, and it can generally be installed more quickly than a concrete-encased duct bank.
- The dielectric liquid provides several options for cooling to improve the circuit rating.

The three phases making up a line are pulled together into a previously installed coated and cathodically protected steel pipe, with distances commonly 1500-3000 ft (490-980 m) between splices. Older systems typically have shorter spacings; improvements in cable installation methods have permitted longer lengths for newer systems. After the entire line is installed, including splices and terminations, and the pipe welding is completed, the line is evacuated, then filled with a dielectric liquid (or possibly nitrogen gas for lines up through 138 kV). The liquid is pressurized to a nominal 200 psig (1380 kPa) using a pressurizing plant that also has a reservoir tank to accept volume changes due to system thermal expansion and contraction, as well as pumps, controls, and alarm systems.

There have been about 3725 circuit-miles (5995 circuit-km) of HPLF cables placed in service in North America since the 1930s.

Figure 2.1 shows a HPLF cable cross-section.

Figure 2.1
Cross-section of HPLF cable

2.1.2 HPLF Cables on Hydro One System

The majority of the cables are 1250-kcmil (600 mm^2) copper-conductor cables in nominal 6-in. and 8-in (16.8-cm and 21.9-cm) pipes. Other conductor sizes are 1000 kcmil, 1500 kcmil, 1750 kcmil, 2250 kcmil, and 2500 kcmil (500, 750, 875, 1125, and 1250 mm^2). Both 115-kV and 230-kV cables are installed. Most of the cables were provided by Canada Wire and Pirelli/Prysmian, neither of which produces pipe-type cables today. In-service dates range from 1961 (56 years) to 2004 (13 years). All circuits are lightly loaded. There have been no records of fluid leaks on the HPLF pipes.

Figure 2.2 shows the age distribution, taken from spreadsheets provided by Hydro One. The majority of the circuits have been in service for 36 to 45 years.

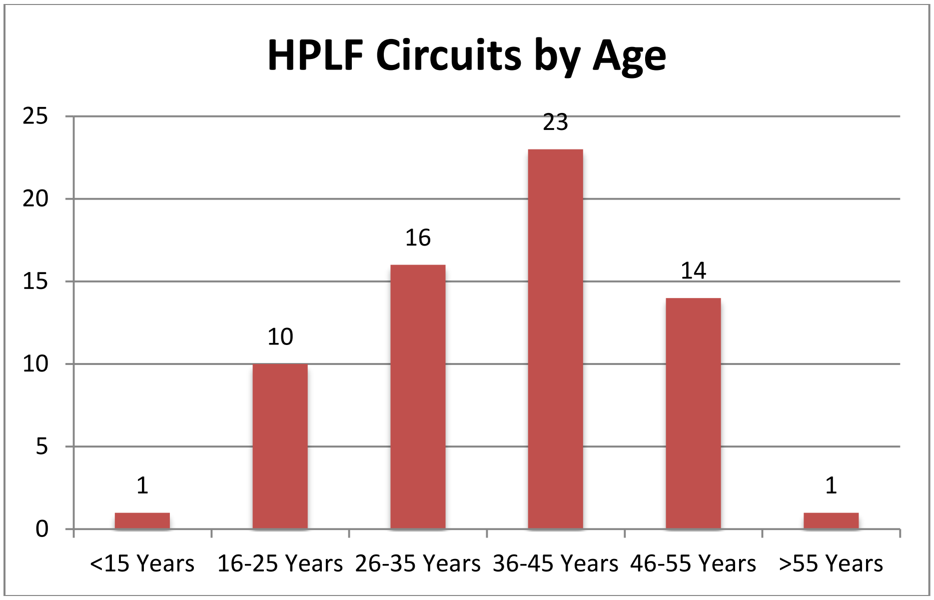

Figure 2.2
Age distribution, Hydro One HPLF circuits

The lengths of the HPLF circuits are fairly short, as shown in Figure 2.3. Most of the circuits are from one to three kilometers long.

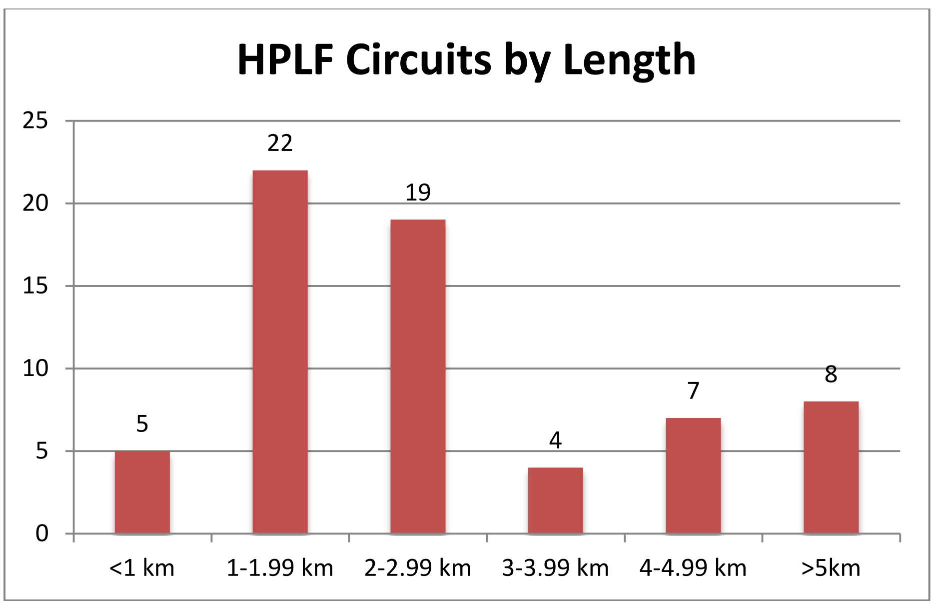

Figure 2.3
Length distribution, Hydro One HPLF circuits

2.2 Low-pressure Liquid Filled Cable Circuits

2.2.1 Description of Cable System

The first transmission cables used in North America were self-contained fluid-filled in the mid-1920s in Chicago and New York. The self-contained cable is insulated with paper (or laminated paper-polypropylene on newer lines) tapes and internally pressurized with a dielectric liquid, also named self-contained liquid-filled (SCLF) or self-contained fluid-filled (SCFF) cables in North America. This cable type was called low-pressure oil- filled (LPOF) until the 1970s when synthetic dielectric liquids began to replace the mineral oils that had been used earlier. Early cables were generally pressurized to 5-15 psig (35-105 kPa) while newer designs with aluminum or reinforced lead-alloy sheaths commonly operate at 5-75 psig (35-525 kPa). Small liquid reservoirs are placed along the route to maintain fluid pressure and accommodate fluid expansion and contraction with load changes. The presence of the dielectric liquid and reservoirs and the complexity of sheath bonding, are some of the disadvantages of the SCFF cable system.

They have been the principal cable type for EHV installations outside North America, with conductor sizes up to 6000 kcmil (3000 mm^2), carrying the highest power levels for a cable in the world. However, extruded-dielectric cables are now beginning to displace them worldwide.

The self-contained cable system consists of three individual phases, each contained within a hermetically sealed metallic sheath that is typically extruded lead-alloy or aluminum. The cables are insulated with a high-quality taped insulation. The fluid pressure necessary to prevent ionization is maintained through a hollow core in the center of the conductor. Figure 2-4 shows an SCFF cable.

There are about 1250 circuit-miles (2010 circuit-km) of LPLF cables in North America, in service since the 1920s.

Figure 2.4
Cross-section of LPLF cable

2.2.2 *LPLF Cables on the Hydro One System*

The majority of the cables are 1250-kcmil (600 mm^2) copper-conductor cables. Other conductor sizes are 1000 kcmil, 1145 kcmil, 1750 kcmil, and 2750 kcmil (500, 575, 875, and 1375 mm^2). Both 115-kV and 230-kV cables are installed. In-service dates range from 1955 (62 years) to 1992 (25 years). All circuits are lightly loaded. There have been many leaks on the LPLF cables.

Figure 2.5 shows the age distribution, taken from spreadsheets provided by Hydro One. The majority of the circuits have been in service for more than 45 years.

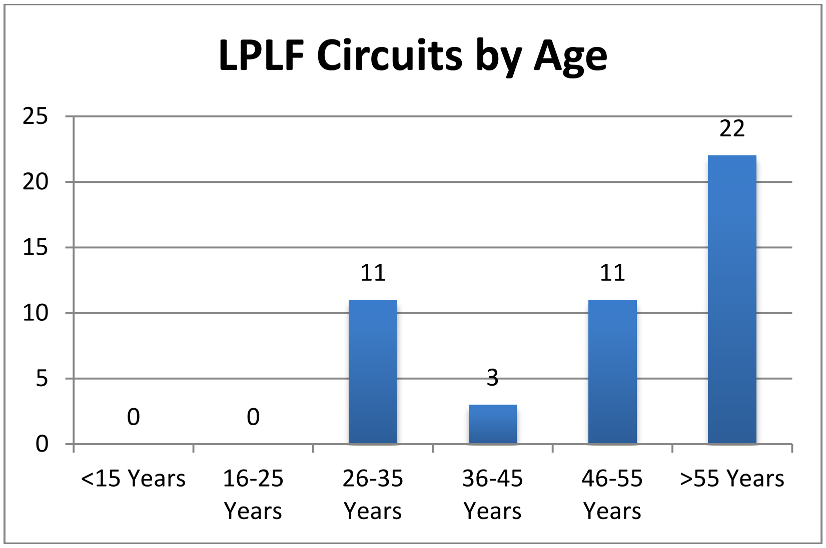

Figure 2.5
Age distribution, Hydro One LPLF circuits

Figure 2.6 shows length distribution. Most of the circuits are less than 2-km length.

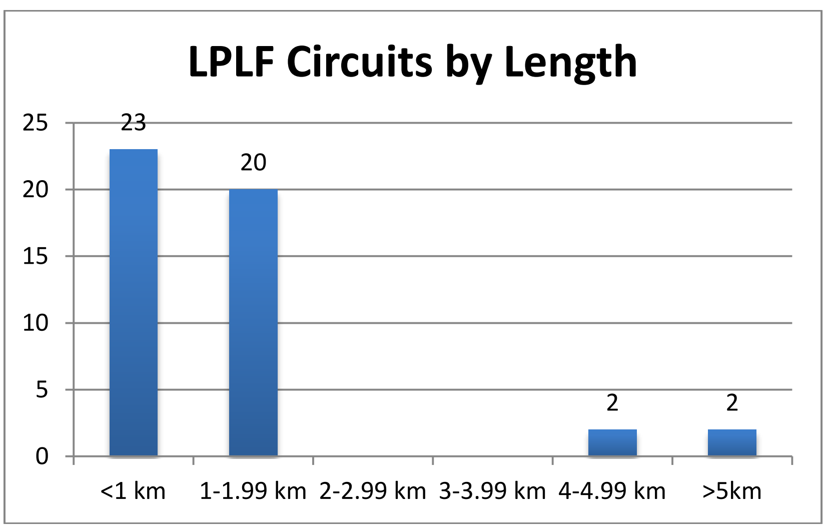

Figure 2.6
Length distribution, Hydro One LPLF circuits

3
CONSIDERATIONS FOR END-OF-LIFE OF HPLF AND LPLF CABLES

Impregnated-paper insulation can operate without incident for very long time if the following four criteria are met:

- The cables are operated within their design temperature ratings
- Required liquid pressures are maintained
- Moisture is not allowed to enter the system
- There is no mechanical damage

In addition to circuit loading history, operations of pressurizing systems, and cable and accessory mechanical constraints, the criteria mostly depend upon the integrity of the pipe for pipe-type cables, and depend upon the integrity of the sheath for self-contained fluid-filled cables. The provided Hydro One records showed limited fluid leaks as caused by pipe corrosion and jacket deteriorations, which indicated that the pipe or sheath/jacket of the Hydro One systems were well maintained. In addition, because these records are considered as isolated events on the Hydro One systems, the pipe corrosion and jacket deterioration can be treated as maintainable items and are not included in the following discussions.

The four criteria also depend upon the system operators utilizing the cable system within its design parameters and that circuit ratings take into account changes along the alignment, such as a distribution duct bank installed adjacent to the transmission cable. The general principles and comments on Hydro One cables are described in this section of the report, along with comments on industry trends for both cable types.

3.1 High-pressure Liquid-filled Cables

HPLF cables have generally had an excellent operating history. Comments on the four criteria that affect end-of-life are given below. Additional comments are given on leaks and cable availability.

3.1.1 Thermal Aging

Aging of the paper insulation as a function of operating temperature is well defined, and follows the Arrhenius aging relationship developed in the 1920s for transformer papers, and verified many times over the years for paper-insulated cables. Aging of the paper dielectric occurs following an 8-10 degree rule: for every 8 to 10 degrees increase in operating temperature, the cable aging rate is doubled. Failure is seldom measured by the electrical strength of the paper itself; it is measured by temperature-related mechanical changes to the paper. EPRI conducted an extensive program in the 1990s that performed accelerated aging tests on HPLF cables. The tests combined thermal and mechanical effects, and verified the Arrhenius aging [1]. As a simplification of the findings: the testing indicated that the aging rate doubles for every 9 Celsius degree increase in operating temperature. Therefore, a cable designed for a 50-year life at an

80°C temperature will lose two years of life if it is operated at 89°C for one year. Appendix A provides a brief summary of the thermal aging of a paper-insulated cable.

It is also true that the aging rate decreases for reductions in operating temperature. For example, a cable that would have an estimated service life of 50 years at design temperature of 80°C, would have an estimated service life of 100 years if operated at 71°C continuously, and 200 years if operated at 62°C continuously.

Although not verified by tests, the general industry feeling is that this relationship is valid over the range 60°C to 120°C.

Industry experience verifies this finding. Because of conservatism in design, provisions for future load growth, or redundancy for reliability purposes, almost all transmission cables operate well below their design temperatures, and consequently failures due to age are extremely uncommon. As further verification, there have been a few failures due to "thermal runaway" where the cables reached high temperatures due to localized conditions such as nearby trees pulling moisture from soil, resulting in high soil thermal resistivity and high cable temperatures. Those failed sections were repaired, the thermal bottleneck mitigated, and the line returned to service. Cable papers near the failure showed definite thermal aging, while papers from sections of the cable not subjected to high temperatures were still in excellent condition.

Since the rate of thermal aging is a function of cable loading, ideally an analysis would look at the average load every day of the year and calculate the degree of aging for that day (using the Arrhenius relationship described above) and sum the results for the year. This is ungainly; typically an analysis is performed for longer periods at average loading levels, e.g. first ten years of service at 50 percent of rated load, second ten years at 60 percent, etc. Since historical loading data are seldom available for older circuits, gross approximations are made. For the Hydro One study, we chose the conservative approach to say that historical loading was approximately equal to the values of loading provided by Hydro One for the three-year period January 1, 2014, to December 31, 2016.

Because of the low historical loadings on the Hydro One cables, we do not think that aging of the paper insulation will be the parameter that determines end of service life. This is discussed in detail in Chapter 4.

3.1.2 Maintaining Liquid Pressure

The electrical strength of impregnated paper insulation is maintained by pressurizing the cable system to eliminate voids and reduce ionization. HPLF cables are designed to have a nominal 200 psig (1380 kPa) pressure at the highest elevation of the circuit, and can operated for some time at pressures as low as 100 psig (690 kPa). LPLF cables operate at a much lower pressure, 15-45 psig (103-310 kPa). This is possible because the liquid is treated to remove contaminates and it is degassed.

We have no indications of pressure loss on Hydro One's HPLF and LPLF cable systems.

3.1.3 Moisture in Cable Systems

Moisture that enters the cable system is absorbed by the cable paper, creating an increase in dissipation factor. This increase results in higher electrical losses that can cause the insulation to overheat and create electrical failure.

In several cases, U.S. utilities have had to replace several manhole-to-manhole sections of HPLF cable because of water intrusion. Water pipes installed close to the cable pipes have had leaks, possibly caused by the cathodic protection system of the cable pipe. Water from the leak has jetted through the pipe coating, through the steel pipe, and into the dielectric liquid. Although cable damage can be widespread, the line can be restored to service after repairing the leak, cleaning the pipe, and replacing the cable.

Moisture can enter in other ways: moisture in the dielectric liquid (especially if it is provided in drums), improper construction operations, and loss of nitrogen atmosphere over the liquid in a pressurizing plant, etc.

We have no indications of moisture intrusion into the cable insulation for the Hydro One systems. Review of data provided by Hydro One shows very low moisture contents in all but a few isolated cases.

3.1.4 Mechanical Problems

HPLF cable circuits in the United States have had failures due to mechanical causes, identified as thermo-mechanical bending or thermo-mechanical movement. EPRI has conducted several studies of these failure mechanisms [2].

Thermo-mechanical Bending (TMB)

Thermo-mechanical bending itself is inevitable - cables subjected to load cycling move almost continually within the cable pipe due to thermal expansion and contraction with changing loads. The multiple layers of cable tapes slide on each other to accept the bending that occurs as the cables ‘snake’ within the pipe. A vast majority of the time, the cables accept many decades of this movement without incident – the cable tapes uniformly return to their original location. However, on occasion the cable tapes ratchet away from a location (typically observed to be the outside of a bend), leaving an area known as a “soft spot.” In some cases these soft spots are only in the outside layers of the cable and do not cause problems. In a few other cases, however, the soft spots progress toward the conductor to a point where electrical strength of the insulation is reduced sufficiently to cause electrical failure. This failure mechanism has been termed thermo-mechanical bending (TMB) failure. Cable construction strongly affects the tendency to form soft spots – and some constructions have been shown to be more vulnerable than others. However, field conditions (clearance within the pipe, dips and bends, degree of load changes, etc.) and possible damage during cable installation can also affect the tendency to form soft spots.

Thermo-mechanical Movement (TMM)

Thermo-mechanical movement has caused many failures, probably a greater number than TMB. TMM refers to cable movement that creates distress in the cable, typically by damaging the outer shielding which gives stress concentration and eventual failure. A typical TMM incident involves cables sliding downhill in a splice casing until the three cables wedge into the reducer at the downhill end of a joint, although this can happen in the uphill direction depending upon the cable route profile. The shielding tapes then separated, torn or badly indented, any of which lead to high electrical stresses. Other known incidents of TMM include skid wires indented into the cable at the uphill end of a sharp bend and displacement of termination stress cones by the weight of cable. Traffic-induced movement can also cause cables to migrate to one end of a splice, jamming the cables into the reducer and creating shielding tape damage.

One major U.S. utility recently replaced many HPLF cable circuits totaling more than 100 kilometers, principally because of TMB and TMM. The utility had experienced many TMB and TMM cable failures on different circuits. The utility conducted a detailed analysis of all of its HPLF cable circuits. This analysis included reviewing plan and profile drawings, evaluating historical loading, taking dissolved gas analysis samples, and X-raying all joints where movement was suspected. In many cases, the joints had migrated to one end of the casing, and wedged into the reducer. It is important to note, however, that the utility also required additional power transfer into the metropolitan area, so the utility was able to justify the installation of a larger-conductor cable with a lower loss laminated paper polypropylene cable.

External Damage

There have been many instances of cable failure due to dig-ins, but these have been random and the system can be returned to service after repairs.

3.1.5 Leaks

Pipe corrosion and resulting leaks of dielectric liquid are usually localized, for example initiated by corrosion coating damage from third-party excavation. These leaks are repaired, corrosion coating restored, and the incident does not affect life of the pipe/cable system. In a few instances corrosion has been widespread to the extent the utility has abandoned the HPLF line, and in one case the utility installed an XLPE-insulated cable (which requires no pressurization) into the pipe.

The majority of the Hydro One cable pipes are coated with coal-tar enamel and coal-tar fiberglass. Coal-tar enamel coatings (with or without fiberglass reinforcement) were extensively used in the 1940s through the 1970s on various pipe-type cable systems as well as on gas distribution and transmission systems. These coatings have performed well and have generally provided good dielectric isolation between the pipe and the soil that surrounds it.

Coal-tar coatings sometimes disbond and allow water to penetrate and contact the pipe surface. In most cases, this happens either because of poor construction practices or because the coating was poorly applied in the first place. If stray currents are present they can exacerbate the situation. Disbonded coating is worse than missing coating because while allowing moisture to reach the surface of the pipe it prevents some, if not all, cathodic protection currents from reaching these same areas, resulting in corrosion. Unfortunately there are no test methods that can find these areas, therefore they are often “discovered” only when leaks occur.

Material provided by Hydro One has not shown corrosion leaks on the HPLF cables or problems related to the corrosion coating or cathodic protection system, so end of service life should not be affected by pipe corrosion. However, for future operations and maintenance of the HPLF cable systems, evaluation of the integrity of the buried pipes can be a focus due to possible deterioration of the pipe coatings and changes of pipe installation environments. The evaluation includes ensuring effectiveness of cathodic protection and aboveground surveys to verify coating conditions.

3.1.6 Cable Availability

It should be noted that there is a concern among utilities that the sole remaining supplier of HPLF cables, The Okonite Company, in Paterson, New Jersey, USA, may discontinue producing the cables in the near future. This will have a strong negative effect on the long-term operation of HPLF cables; if Hydro One does not have sufficient spare cable, repair of a cable failure could require one or more HPLF to XLPE transition joints. The installation of transition joints is a costly, time-consuming procedure that may interrupt the fluid pressurization to sections of remaining HPLF cable.

3.2 Low-pressure Liquid-filled Cables

LPLF cables have also generally had an excellent operating history. Comments on criteria that affect end-of-life are given below, including thermal aging, lead sheaths, maintaining liquid pressure, stop joint failure, moisture in insulation, mechanical problems, leaks, sheath bonding systems, and cable availability.

3.2.1 Thermal Aging

The electrical performance of LPLF insulation has also been excellent. The Arrhenius aging relationship applies to LPLF cables just as it does to HPLF cables. The greater heat flux at the cable or duct interface with native soil, versus a HPLF cable, makes LPLF cables more vulnerable to overheating and thermal runaway, especially if special backfills are not used. The smaller mass of individual cables also causes the cables to heat more quickly during emergency loading periods.

Based upon information received from Hydro One, we do not think that aging of the paper insulation will be a concern because of the low historical loadings on the Hydro One cables. This is discussed in detail in Chapter 5.

LPLF cables do have other mechanisms that may lead to an earlier end of service life, described in the following paragraphs.

3.2.2 Lead Sheaths

Lead sheaths, and sheath wipes at joints and terminations, can crack and permit fluid leaks. This is especially true for sheaths that do not use fatigue-resistant lead and is especially true if cable joints are permitted to move in manholes.

Sheath corrosion can also create leaks, especially for early, unjacketed cables. Water can enter the LPLF cable if there are cracks in the cable sheath due to lead fatigue. Note that moisture can enter even if the cable liquid pressure is greater than the hydrostatic pressure of water because of differences in partial pressures.

At least one U.S. utility has replaced LPLF cables because of problems with leaks and with maintaining reservoirs. Programs have been conducted to develop XLPE-insulated cables that can be pulled into the LPLF ducts that are typically smaller diameter than used today [3].

U.S. utilities are concerned about the lack of skilled splicers that can make lead wipes but we understand that one or more Canadian firms, as well as those in the U.K., have the required expertise. New LPLF cables are seldom installed elsewhere in the world except for long submarine lines. XLPE-insulated cables are replacing the LPLF cables.

3.2.3 Maintaining Liquid Pressure

LPLF cables do not typically have a pressurizing plant such as those on pipe-type cables; they have liquid reservoirs installed at terminal ends and every few kilometers along the cable route. These reservoirs can create many problems if not properly maintained. Liquid in the reservoirs can sludge over time, reducing the ability of the reservoirs to supply the pressure needed to maintain dielectric strength of the insulated cable system. Alarm systems and signal wires can fail and the system can be unprotected against low pressures. Hydro One has had at least one failure due to liquid starvation, and this is an ongoing problem for U.S. utilities that still have LPLF cables in service; a major user of LPLF cables on the U.S. west coast has had many failures because of problems with liquid supply from the reservoirs and has a program to replace LPLF cables with XLPE-insulated cables, replacing one or two circuits per year.

3.2.4 Stop Joint Failure

There have been many electrical failures in the United States of LPLF stop joints (special joints required to provide hydraulic isolation between cable sections because of elevation differences or maximum section lengths that can be provided by reservoirs). The stop joints have stepped insulation and a series of concentric barriers to provide radial electrical strength in liquid-filled sections of the joint. This assembly is very sensitive to contamination from the pressurizing liquid. Contamination has caused tracking along the stepped insulation resulting in electrical failure.

Stop joints typically have insulating cones over the stepped paper insulation. These cones have failed, either due to improper installation or to pressure surges due to a fault in the insulation.

3.2.5 Moisture in the Insulation

LPLF cables are more susceptible to moisture entry than are pipe-type cables. The 15-45 psig (103-310 kPa) pressure is much lower than the pressures used in HPLF lines and the LPLF cables have many soldered connections that are subject to stress cracking---as is the cable sheath itself. In addition, the liquid is in the core of the cable, and therefore in contact with the inner layers of paper insulation that operate under the highest electrical stresses. (The outer layers of paper insulation for pipe-type cables are the ones in contact with dielectric liquid, and the outer layers have lower electrical stress than the inner layers.)

3.2.6 *Mechanical Problems*

Thermo-mechanical Movement

The greatest thermo-mechanical problem for LPLF cables is fatigue of the lead sheath due to cable expansion and contraction during temperature changes that result from load cycling. Older cables did not all have fatigue-resistant lead sheaths, and the lead wipes at the bases of terminations and the ends of joint sleeves are susceptible to cracking with mechanical stress. This does not compromise the mechanical integrity of the cable *per se*, but it does often lead to moisture intrusion.

One utility on the U.S. east coast had numerous problems with mechanical movement causing cracks in the lead wipes at the ends of splice sleeves -- giving fluid leaks and allowing moisture intrusion. They developed an epoxy encapsulation that was effective in greatly reducing, but not completely eliminating the problem. The approach to racking of the splices and cables in manholes had a large effect on the tendency for the lead wipes to crack and the effectiveness of the repair. These repairs extended the life of the LPLF cables by several decades, but they were eventually replaced.

External Damage

LPLF cables do not have the mechanical protection afforded by the steel pipe of a pipe-type cable and are therefore more susceptible to dig-in, even if the LPLF cables are in a concrete-encased duct bank.

3.2.7 *Leaks*

Leaks are a problem for many LPLF circuits; the causes are discussed earlier in this section of the report. Leak rates are typically very small, but the volume of fluid in reservoirs is also small compared to HPLF lines. If alarms are not working properly, loss of fluid could cause an electrical failure that is much more expensive and time consuming to repair than a leak. Ongoing problems with leaks and with reservoirs has been the cause of cable replacement (end of service life) on many LPLF circuits in the United States.

3.2.8 *Sheath Bonding Systems*

Most LPLF cables are single-conductor. Current flowing in the conductor causes induced currents in the sheath that de-rate the cable if the sheaths are solidly bonded and grounded at multiple locations. Therefore, most circuits divide the length of the circuit into sections using sheath insulators at splices. The individual sections are solidly grounded at one end and grounded through sheath voltage limiters at the other end, or the three sheaths may be cross-bonded. Sheath currents are generally negligible, and the sectionalizing limits induced voltages to acceptable levels.

The sheath bonding system requires maintenance to ensure the bonding leads are connected properly to avoid circulating currents that can overheat the cable, and the sheath voltage limiters must be inspected periodically. In addition, the cable oversheath (jacket) must be tested periodically to check for damage.

These maintenance requirements, in addition to the other maintenance requirements described in this section, are a consideration for the replacement programs described in Chapter 4.

3.2.9 Availability of Replacement Cable

XLPE cables are replacing paper-insulated cables worldwide, including LPLF cables. However, there are still a few LPLF cable suppliers outside of North America. There are large amounts of paper-insulated cables produced for submarine applications, so availability of LPLF cable should continue for several years. [4]

4

NORTH AMERICAN EXPERIENCE IN OPERATION/REPLACEMENT OF HPLF AND LPLF CABLES

4.1 HPLF Cable Systems

4.1.1 Cables

Replacing HPLF cables because they have reached the end of their service life is extremely uncommon, even though there are thousands of miles (km) that have exceeded their original design life. Replacement because of corrosion of the cable pipe is more common, but is still infrequent. Examples of cable replacement are given below.

A major east coast utility recently replaced more than 100 circuit-miles (more than 160 circuit-km) of 230-kV HPFF cable. There were several considerations for this major undertaking:

- The original cable had several thermo-mechanical bending failures in splices and in the cable itself, and many more "removals before failure." The utility evaluated the profile drawings of its pipe-type cable circuits and used the results, along with results of x-ray testing of splices, to prioritize cable replacement.
- There had been a few major intrusions of water into the pipe. Generally only a few manhole-to-manhole sections are replaced, but in at least one case, water intrusion was a consideration for replacement of the entire circuit.
- Additional power transfer was needed; the utility replaced 2000-kcmil (1000 mm^2) 230-kV cable with 3000-kcmil (1500 mm^2) 345-kV laminated paper-polypropylene insulation. The cable will be operated at 230 kV until 345 kV is needed.
- The entire length of pipe was inspected with a "smart pig" that evaluated wall thickness. Several corrosion spots were detected and repaired, and a few approximately 45-ft (14-m) sections of pipe were replaced because of dents or excessive corrosion.

A different east coast utility replaced high-pressure gas-filled pipe-type cable with extruded-dielectric cable on a bridge crossing where road salt caused numerous areas of severe corrosion.

A third east coast utility has areas where transition joints are used from pipe-type cable to XLPE-insulated cable because manhole-to-manhole sections of the original pipe-type cable had to be replaced.

Several major cable-using utilities were contacted to ascertain their policies regarding determining end of service life. None of the utilities had general procedures or criteria for determining ESL. In each case, the utility stated that cable replacement (equivalent to ESL) is determined on a circuit-by-circuit basis based upon the number of operating problems experienced on that circuit.

There have been a few cable section replacements because of localized overheating, e.g. due to tree roots depleting moisture from the cable backfill.

In addition, there have been a few occasions where complete circuits of HPLF cable were replaced with equivalent HPLF cable because the original cable had too many problems due to manufacturing, installation, or operation.

Note that EPRI has an active program to help utilities facilitate replacing pipe-type cable with extruded-dielectric cable, for example by evaluating reduced-insulation thickness cables to allow larger conductors to be pulled into existing steel pipes. EPRI also has a program to develop and demonstrate methods to burst existing cable pipes and pull-in new fusible PVC or steel pipes and allow larger conductors to be installed. Availability of these procedures may affect the economic decisions on determining end of service life on existing circuits.

There are replacement programs for cable system accessories as described below.

4.1.2 Terminations

The Ohio Brass Company produced two-chamber HPLF terminations through 1960 for voltages up to 161 kV. These terminations are known to be prone to leaks at gasket connections. Replacement gaskets can be obtained and installed with some success, but in many cases the terminations are replaced with modern terminations from G&W Electric or Underground Systems, Inc. An adapter plate is required; several plate designs exist and are specific to the model number of the Ohio Brass terminations.

A least one U.S. utility has an ongoing program to replace all Ohio Brass terminations on one or possibly two circuits per year, until there are no more of the original terminations in service.

4.1.3 Splices

There have been many splice failures on TMB cables over the years because of the thermo-mechanical movement or thermo-mechanical bending conditions as described in Chapter 3. If problems are suspected, utilities take fluid samples for dissolved gas analysis and also x-ray the splices through their steel casings. It is possible to determine damage, and repairs are made: the line is de-energized and tagged, fluid frozen either side of the splice, liquid drained, casings opened, cables and splices inspected and repairs made, additional supports installed to prevent future unwanted movement, the casings replaced and welded, the drained section evacuated, fluid introduced, the line pressurized and returned to service.

At least one utility has proactively opened casings to inspect the splices, and has chosen to install additional supports (spiders) on all splices on selected circuits based on their findings.

4.1.4 Pressurizing Plants

Many utilities are replacing 40-60 year old pressurizing plants with new plants, or at least new "skids" which are freestanding assemblies consisting of pumps, controls, alarms and communications equipment. This replacement can be carefully designed to fit within the footprint of the original plant equipment, and removing the original plant and installing the new skid can be done quickly. The reservoir tank is reused.

This replacement of the plant or skid is done because of leaks and high maintenance on the older plants, the older plants often have asbestos insulation on wiring and have mercury in switches, manually operated gate valves and they have outdated alarm/control units. New plants typically have reliable ball valves, and can have remote monitoring of fluid pressures; fluid levels in the reservoir tanks, etc. and can have sophisticated touchscreen controls.

4.1.5 Cathodic Protection Systems

Cathodic protection systems are required to protect the pipe from corrosion if there are problems with the corrosion coating. Antiquated systems such as resistor-rectifiers, as well as more modern rectifier systems, are being replaced with newer rectifiers, possibly with remote monitoring of rectifier voltages and currents as well as cathodic protection pipe-to-soil potentials. Anode beds commonly have a life of 20-30 years, so it is sometimes necessary to replace them with new anode beds even if the original rectifier stays in place.

In addition to regular maintenance, utilities typically have a cathodic protection study performed by a qualified firm with a NACE-certified corrosion engineer, that will evaluate all components, check pipe-to-soil potentials, determine condition of anode beds, and cathodic protection test stations, etc. That firm will recommend replacement components as needed.

4.2 LPLF Cable Systems

LPLF cables, as HPLF cables, are seldom replaced because the insulation system has reached the end of its useful life; laboratory analysis of cables more than 80 years old have showed that the fluid/paper insulation is in good condition. Lines installed in the 1920s have been replaced only recently--because of excessive leaks and excessive maintenance of the cables, splices, reservoirs, and alarm systems as well as lack of qualified personnel for making lead wipes.

Many U.S. users of LPLF cables have programs to replace those cables with extruded-dielectric cables. The earliest and most ambitious project was in Chicago in the late 1990s, undertaken because of multiple failures and high maintenance [3]. The utility worked with a cable supplier to develop cables and splices that would fit into existing ducts and existing manholes. The utility replaced 99 miles (160 km) of cables and accessories into the existing ducts, using a reduced insulation thickness.

A west coast utility has a program to replace one or perhaps two LPLF cable circuits with XLPE-insulated cables each year. The utility has experienced several stop joint failures believed to have caused by fluid starvation due to sludging of the fluid in the reservoirs and connecting tubing. The utility is also having trouble maintaining the alarm systems on the circuits.

Terminations have not been a particular problem on LPLF circuits. Straight-through splices have generally been trouble free. Stop joint splices have been sources of failure and require high maintenance for the reasons described in Section 3.2.2.

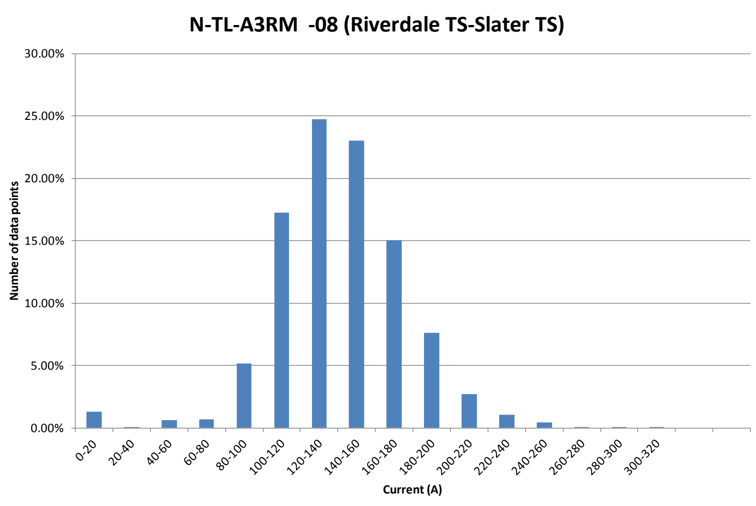
5
PROCEDURES FOR ANALYSIS OF END OF SERVICE LIFE

5.1 Thermal Aging of Impregnated Paper Insulation

Initial review of loading data provided by Hydro One indicated that the degree of thermal aging is low, even for the older cables. To verify this conclusion, we calculated the approximate degree of aging using procedures described in [1]. The procedure is summarized as follows for both HPLF and LPLF circuits:

- Obtain available information on Hydro One calculation of ratings for cables
- Obtain an indication of historical loading on the lines
- Use the Arrhenius aging relationship described in Appendix A to determine the degree of aging, identified as the number of years of cable life used versus the number of years the line has been in service. To be conservative, we assume that the loading throughout the cable lifetime has been just as high as for the last few years for which Hydro One provided data. This should be quite conservative since it the loading 40-50 years ago was probably much lower than present loading.
- Estimate the actual cable life based upon this historical loading.

Hydro One provided a summary of recent loading history. This document clearly shows that loads were almost always far below the cable rating for the three-year study period, January 1, 2014, through December 31, 2016. Durations were short in the few instances where loading exceeded the rating. Figures 5.1 and 5.2 show typical load distributions.



The continuous current rating of this cable is 690 A

Figure 5.1
Bar chart showing distribution of loading, HPLF circuit

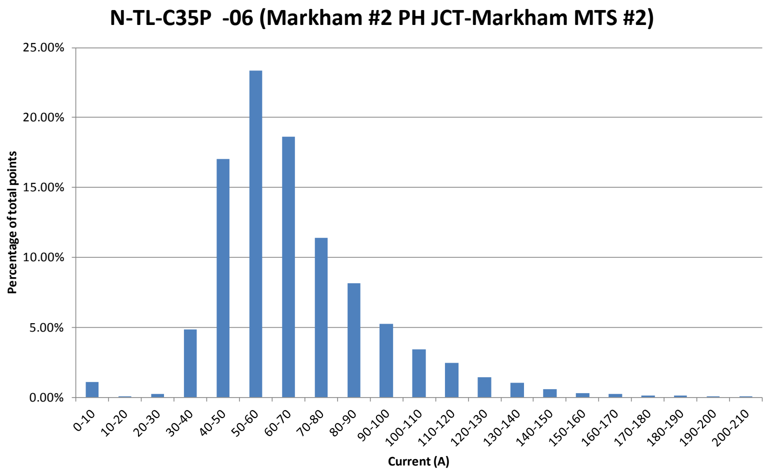


Figure 5.2
Bar chart showing distribution of loading, LPLF circuit

Hydro One provided hourly historical load data for selected circuits, and calculations were made to determine average loading, peak loading, and daily load loss factors. These calculations confirmed the very low load values given in the Hydro One graphs. Load factors and loss factors (load factor of the losses) were consistent with circuits on major transmission systems.

A summary of calculation of insulation aging for the circuit of Figure 5.1 is given below, assuming summertime conditions with an ambient earth temperature of 20 °C:

Circuit rating:	**690 A at 80°C conductor temperature**
Conservative current used for calculations:	**200 A (cable operated below that loading 90 percent of the time)**
Calculated temperature at 200 A	**25°C**
Lifetime used	**0.5 year**
Lifetime used at 65 °C conductor temperature	**10 years**

This circuit has used a negligible amount of its thermal-aging lifetime after 53 years in service. However, the 25°C temperature is below the accepted range of the Arrhenius aging relationship. Even if we assume that the cable has operated at 65 °C for the last 53 years, only ten years of thermal-aging lifetime has been used.

Conditions are similar for all of the circuits for which Hydro One provided historical loading data. We can safely state that the cable insulation is nowhere near their end of service life as regards thermal aging of the insulation. The very low percentages of rated load also result in low amounts of thermo-mechanical movement, which reduces the likelihood of thermo-mechanical bending or thermo-mechanical movement failures.

5.2 Evaluation of DGA and Other Data Relating to End of Insulation Service Life

Thermal aging should be low, as described in Section 5.1. However, there could be "hot spots" that cause localized high cable temperatures and therefore higher levels of aging. Dissolved Gas Analysis evaluates gases that are indicative of thermal aging of the paper and of the dielectric liquid. In addition, DGA provides indication of items such as electrical "spitting" because of problems with cable shielding.

Excessive moisture in the cable paper can cause heating and electrical failure. In a few occasions at U.S. utilities, several sections of cable had to be replaced because of high moisture (free water.) In one case, enough manhole-to-manhole sections had free water that the utility decided to remove the cable, swab and dry the pipe, and re-conductor the pipe. Data provided by Hydro One showed just a few liquid readings with high moisture content--not enough to affect overall performance of the circuit. It is sometimes feasible to set up an in-line liquid circulation and degassing system to remove moisture and contaminants that might be present in the dielectric liquid.

5.2.1 HPLF Systems

Repair of isolated leaks from a HPLF cable pipe may have environmental implications and be costly to locate and repair, but leaks do not determine the end of service life of a pipe-type cable unless they are too numerous to repair or are in inaccessible locations. Review of data provided by Hydro One indicates that corrosion leaks are not a problem and therefore do not affect ESL of the pipe-type cable systems.

5.2.2 LPLF Systems

Data provided by Hydro One did show a significant number of leaks from the LPLF cable circuits. As stated several times in the present report, this is not uncommon for LPLF cables and has been the major reason for replacement of this type of cable. Replacement with XLPE-insulated cables is underway on a scheduled basis at several major U.S. users of LPLF cable. Many of these circuits were installed more than 80 years ago. Until the replacements are complete, the utilities repair the leaks and occasional electrical failures that occur.

5.3 End of Service Life of Accessories

As described in Chapter 4, end of service life is seldom determined by problems with any accessories such as terminations, splices, pressurizing plants and LPLF reservoirs, cathodic protection and sheath bonding systems. Individual components can be rebuilt or replaced if failures occur or maintenance requirements become too high.

5.4 Testing to Determine Indicative Data for Cable Condition

Procedures that are used include the following:

- Perform an "ampacity audit" of the system to determine the approximate temperature history and allow calculating the degree of thermal aging. The audit consists of the following items:

- Evaluate cable rating data used during initial system design
    - Evaluate current plan and profile vs. that when the cables were installed
    - Measure soil thermal resistivity and compare with original design data
    - Evaluate loading history
    - Calculate temperatures along cable circuit, concentrating on "hot spots"
    - Using Arrhenius aging relationship to determine the number of years of aging that have occurred. This value is almost always much lower than the number of calendar years in service.
- Perform dissolved gas analysis (DGA) of the dielectric liquid. A great deal of research has been performed on aging of oil/paper insulation systems and on implications of various gases and ratios of gases on the condition of the cable. Readings at one point in time are marginally useful; readings should be repeated and trends in results evaluated. The frequency of testing is determined based upon any trends that are observed. If all values are stable, tests every five years are probably acceptable. If there is an increasing value of any of the critical dissolved gases, test frequency should be increased. If a critical value is observed, e.g., high acetylene levels, immediate action may be prudent.
- Thermo-mechanical movement (TMM) and thermo-mechanical bending (TMB) are one of the most common causes of the (infrequent) failures on paper-insulated cables. The cables move with temperature changes. In some cases this movement causes cables to jam against the reducers in splice casings, fatigue cracks in LPLF cable sheaths, or insulation tapes displaced causing "soft spots". Evaluation of plan and profile may indicate potential problem areas, and x-rays can be taken at accessible locations such as splice casings to see if damage has occurred.
- Perform field dissipation factor measurements as needed. There has been some success in measuring dissipation factor of the cable. This test measures the charging current of the cable which is a function of the geometry and the dissipation factor. An increase in dissipation factor with time is an indication of possible moisture in the paper or aging of the paper. This test only indicates average conditions for the full length of the cable.
- Ideally, a sample of cable can be removed from the circuit. If this is possible, laboratory evaluation of paper properties can provide an indication of degree of aging. EPRI conducted a major study of cable aging that gives good indications of parameters to measure [1]. It is of course a major undertaking to obtain a cable sample; this is usually done when there is a cutover or extension of a cable circuit, or if sections of cable must be replaced because of cable failure. There is no guarantee that the retrieved sample is representative of the worst condition along the circuit---which could occur some distance from the sample.
- Perform buried steel pipe corrosion surveys for pipe-type cable systems to ensure proper operations of cathodic protection systems and effectiveness of the protection to each section of the buried steel pipes, and to assess pipe coating conditions and investigate remediation methods and apply as needed.
- Perform sheath jacket integrity tests of low-pressure fluid-filled systems to assess conditions for long-term performance.

6
SUMMARY AND RECOMMENDATIONS

Hydro One provided a great deal of historical data on its high-pressure liquid-filled (HPLF) pipe-type cable circuits and its low-pressure liquid-filled (LPLF) self-contained cable circuits. Review of that information, calculation of critical parameters such as degree of thermal aging of the insulation, and evaluation of experience of other users of these cable types, permitted making conservative estimates of the design end of service life (expected service life – ESL) for both HPLF and LPLF cables.

6.1 High-pressure Liquid-filled Cables

Circuit loading has been significantly lower than the cable ratings. As a result, the thermal aging of the cable insulation is minimum. If an extremely conservative average operating temperature of 65°C is used for determining the degree of aging, the oldest HPLF cable has used only ten years of the presently assumed 50 year life. If the cables are loaded to their full rating in future operations, they should have another 40 years of life. Although analysis of loading data indicates that this is a conservative number, we recommend that Hydro One assign an additional 20 years to the design life, to give a 70-year design life. Hydro One should repeat the analysis described in this report as the oldest circuits approach the 70-yr age.

No leaks have been reported on the cable pipes, indicating that the corrosion coating and cathodic protection system are working well and will not limit the service life of the cable system. No unusual difficulties are reported on the corrosion protection system, splices, terminations, or dielectric liquid. With proper maintenance, these components will not limit the 70-year design life as recommended.

We recommend that Hydro One establish a 70-year period for the design end of service life for its HPLF cables, and that the cable condition be reviewed five years before that time. Hydro One should continue its maintenance testing such as dissolved gas analysis, fluid moisture content, and effectiveness of corrosion protection systems for buried steel pipes and manhole pipe sections. If any test results indicate potential problems, Hydro One should investigate the cause and take corrective action.

6.2 Low-pressure Liquid-filled Cables

Loading on the LPLF circuits has also been much lower than design ratings, and the life of the cable insulation should exceed 70 years, as is the case for the HPLF cables.

However, leaks on several of the circuits and difficulties with the pressurizing system, indicate that Hydro One should consider replacing these circuits within the next ten to twenty years.

We recommend that Hydro One establish a 70-year period for the design end of service life for its LPLF cables, and that the cable condition be reviewed five years before that time. Hydro One should continue its maintenance testing such as dissolved gas analysis, fluid moisture content, and jacket integrity tests. If any test results indicate potential problems, Hydro One should *investigate the cause and take corrective action. Hydro One should carefully monitor the condition of the lead sheaths and the liquid reservoirs, and should begin designing the replacement of LPLF cables with modern generation XLPE cables and replace the LPLF cables within ten to twenty years.*

A

THERMAL AGING OF PAPER CABLE INSULATION

EPRI report "Transmission Cable Life Evaluation and Management", which is Reference 1 in Section 7, has a very comprehensive analysis of cable aging, with detailed theoretical evaluation and results of a great many tests on pipe-type cables. The following sections are taken from that 474-page report.

It is a commonly held belief among cable engineers that there is little aging in HPFF cables systems that have been operated under typically conservative utility conditions which result in conductor temperatures of 40 °C to 60 °C. Moreover, the upper end of these already conservative temperatures may be experienced by a cable only in the peak-use periods such as summer air-conditioning loads. Their life expectancy may in fact be much longer than 40 years. This project has been designed to verify or disprove the critical temperature/aging relationship.

It is possible to estimate loss-of-life and remaining cable life based on operating conditions and a semi-empirical model developed as a result of this project. This model is based on an Arrhenius relationship for loss of degree of polymerization for tapes adjacent to the conductor and an empirically determined mechanical bending factor.

HPLF cables are characterized by long life. Results of this analysis indicate that the cables have a remaining life of approximately 250 years assuming that current operating conditions are continued.

The Arrhenius relationship and the so-called “inverse power law” have been applied to study aging respectively under thermal and electrical stresses, with good results. Estimate loss of life based on thermal history of cables, using EPRI statistical model (EPRI TR-111712):

$$LossOfLife = t \cdot e^{-K \cdot \frac{85 - T_C}{273 + T_C}}$$

where:

t = Time elapsed at temperature T_C, years
T_C = Conductor temperature, °C
K = Rate of property loss = 10,003/(273+85) = 27.9
(by Degree of Polymerization Degradation Model)

The equations above, and the parameters given in the table, were used to analyze the degree of aging of the Hydro One cables. A simplification is that the aging rate doubles for each 9 Celsius degree increase in operating temperatures.

EXECUTIVE SUMMARY

This report presents the findings of a recent web survey conducted by EPRI on air blast circuit breaker (ABCB) asset management practices and concerns.

High voltage ABCBs are an older technology that relies on complex mechanical and pneumatic subsystems for proper operation. ABCB technology allowed for the development of relatively compact high voltage and high current breakers and has generally performed well over decades of service. However, due to their complex design with many parts and seals, ABCBs require extensive periodic maintenance. Moreover, because ABCBs are an older technology, spare parts and mechanics experienced in their maintenance are not always readily available. For these reasons, many utilities have decided to retire all of their ABCB fleets. Other utilities are considering such actions but may be restricted by various constraints.

The survey was conducted to collect industry experience and industry plans for air blast circuit breakers with the following objectives:

- Assess industry attitudes on retaining in-service air blast circuit breakers
- Understand how peer companies are responding to ABCB operations and maintenance challenges

INTRODUCTION

This report presents the findings of a recent web survey conducted by EPRI on air blast circuit breaker (ABCB) asset management practices and concerns.

High voltage ABCBs are an older technology that relies on complex mechanical and pneumatic subsystems for proper operation. ABCB technology allowed for the development of relatively compact high voltage and high current breakers and has generally performed well over decades of service. However, due to their complex design with many parts and seals, ABCBs require extensive periodic maintenance. Moreover, because ABCBs are an older technology, spare parts and mechanics experienced in their maintenance are not always readily available. For these reasons, many utilities have decided to retire all of their ABCB fleets. Other utilities are considering such actions but may be restricted by various constraints.

The survey was conducted to collect industry experience and industry plans for air blast circuit breakers with the following objectives:

- Assess industry attitudes on retaining in-service air blast circuit breakers
- Understand how peer companies are responding to ABCB operations and maintenance challenges

The survey was sent to more than 20 transmission companies. Three companies indicated that they did not have air blast circuit breakers. Five companies responded and their responses serve as the basis for this report.

Report Organization

In addition to this Introduction, the report includes the following chapters:

Chapter 2: Air Blast Circuit Breaker Designs

Chapter 3: Air Blast Circuit Breaker Survey Findings

Chapter 4: Conclusions

2
AIR BLAST CIRCUIT BREAKER DESIGNS

Description

Some understanding of ABCB design will help to frame the asset management issues. Air blast breakers were developed in parallel with oil breakers, mainly in Europe during the1940s and 1950s, when oil was scarce. Oil was not an issue in the United States. Instead, fire was an issue to some utilities and interrupting capabilities at higher transmission voltage was a bigger issue. During the 1950s, air blast circuit breakers were installed in many parts of the world, in competition with oil designs. There are two basic design types; in this paper, they are termed the early, dead tank type and the later, permanently pressurized-head, live tank type. Most all of the remaining in-service ABCBs are this design.

The later type formed the basis of many of the international grid systems of the mid-1960s, when system voltages of ≥400 kV, up to 4000A continuous current, and 63 kA short circuit were required. Due to these ever-increasing power system voltages, the physical size limitations of oil breakers, coupled with the large quantities of insulating oil that would be required at the higher voltages, the use of oil circuit breakers became unrealistic. Development of the existing air-blast technology was necessary. Ultimately, these permanently pressurized-head design types of air-blast circuit breakers ranged in voltage class from 115 to 800 kV and in interrupting rating from 40,000 to 80,000 A. These air-blast circuit breakers have extremely rapid interrupting times, typically opening the main contacts within two cycles (33.3 ms at 60 Hz) from trip initiation.

Although various designs exist, the permanently pressurized-head, air-blast circuit breakers are also of the live tank type. On these designs, the high-pressure air is used for electrical insulation and arc-extinguishing purposes, hence the term *permanently pressurized-head*.

Interruption – Later Type (Permanently Pressurized-Head)

Permanently pressurized-head designs use dry air under pressure to quench the arc that is formed during an opening operation. This air is stored around the contacts within one of the numerous series heads that make up a pole (phase) of the circuit breaker. As the contacts separate and the current attempts to maintain its flow, an arc is formed. However, by design, the arc is directed in a designated course. With precision timing, a valve within the interrupting chamber opens, allowing some of the air contained within the breaker to exhaust to atmosphere, directly through the path of the arc. At the opening of the blast valve, the interior of the breaker rapidly becomes somewhat depressurized. This depressurization results in a blast of air that cools the arc, forcing it away from the parting contacts and out the arc chutes or arcing tubes. The arc is eliminated by being elongated and cooled beyond its ability to maintain itself. With adequate dielectric strength between the open contacts, the exhaust valve is closed, and the head is re-pressurized from the local receiver. The pressure in these types of circuit breakers is required to be maintained even when the breaker was in the open position. The distance between the open contacts and the operating rods would flash over to ground if the pressure was not present.

On all permanently pressurized-head air blast circuit breakers, the interrupter heads are modular. Normally, a particular interrupting head can be transferred from one position or breaker to another position or breaker if the current carrying capacity, interrupting capability, and accessory equipment are the same. The move could be successfully accomplished even if accessories are added, removed, or changed to meet the requirements of the new position, as long as the ratings are the same at both locations. Because of the modular design, all that is required of the manufacturer to increase the voltage of a particular type of breaker is to add the modular interrupter heads in series, within a phase, to give the breaker the desired capability. Of course, the insulation level from phase to ground must be increased as well. Therefore, the height of the interrupter support columns and drive rods must be increased. The added height is required due to the basic insulation level necessitated by the increased voltage. Interrupter support columns are hollow ceramic insulators of high mechanical (as well as electrical) strength. The interrupter operating rods pass through the opening of the center of the support column. In some cases, this contains high-pressure air; in others, the high-pressure air is within a separate tube housed within the support column. The zone between the tube and the column is kept dry by a low-pressure conditioning air system. In one manufacturer's design, the space is filled with SF_6 gas as electrical insulation. As an example of the difference in stack height, a typical 800-kV breaker reaches 41ft (12.5 m) from ground level to the top of the interrupter (and, depending on the version of the breaker, uses either four or five interrupters per phase). In contrast, a 138-kV breaker of the same type is less than 20 ft (6 m) to the top (and has only one interrupter per phase, but of the same basic type as that of the 800-kV breaker).

Interrupter Types

All modern air-blast interrupters use the axial blast principle by forcing the arc to burn on a line parallel with the axis of the contacts' travel. On some designs, the arc is initiated transversely before transferring to become axial before extinction.

The later designs of the permanently pressurized-head air-blast interrupters became extremely complex to achieve the high short-circuit interruption levels and rapid operating times. These are too complex to describe in detail, and the principle is adequately explained by consideration of the simplest forms. There are two basic axial nozzle systems: 1) a mono-blast or single-flow system, in which the air subjects the arc to one single directional blast, and 2) a duo-blast or double-flow system, in which the air blast is divided equally through two nozzles. The blast flows into the arc chamber from opposite directions and is exhausted through ports in line with the contact movement. A variant of this system is the duo-blast system in which one nozzle orifice is made smaller than the other.

The mono-blast and duo-blast systems are built into an insulating enclosure, which is supplied with compressed air. The air supply to the nozzles is controlled by a blast valve placed on the upstream side of the contacts, somewhere between the nozzles and the supply source.

The exhaust passages downstream are controlled by exhaust ports or valves. Each of these arrangements must admit compressed air to the nozzles while the exhaust passages are open and then shut off the air supply to prevent the pressure reservoirs from being exhausted.

When the interrupters are pressurized in the open position only, both the blast valves and the exhaust valves are used. The blast valves admit the air to the nozzles, and the exhaust values stop the flow and keep the interrupter pressurized. One blast valve can supply more than one interrupter at a time, and one exhaust valve can be arranged to control two adjacent exhaust passages in a twin interrupter unit.

When the interrupter chambers are permanently pressurized (that is, in closed and open positions), exhaust valves are used. The exhaust valves are used either on their own or in combination with blast valves placed across the electrodes. One exhaust valve can serve two interrupters, but in this case, separate blast valves must be provided for each interrupter.

Insofar as nozzle systems and pressurization are concerned, air-blast interrupters can be divided into nine types—that is, mono-blast, partial-duo-blast, or duo-blast, each pressurized in one of the three ways:

- During interruption only
- During interruption and in the open position
- Permanently

In circuit breakers that have both high-pressure air and SF_6 gas separated by gaskets, high-pressure air can leak into the SF_6 gas space. The high-pressure air contains far greater amounts of moisture than the SF_6 gas spaces are intended to contain. Therefore, leakage of air into these spaces can set up the potential for a catastrophic failure. In some designs, such leaks are from seals that are difficult to replace with normal maintenance. In such cases, this leaking seal can be considered a life-limiting factor because it can be expected to involve major dismantling to correct the seal; the disruption and cost might indicate that replacement is more sensible.

Further, with any air-blast circuit breaker, moist air entry into dry air chambers will degrade the insulating quality and arc−quenching capability. Wet air can cause flashovers, restrikes, or a slow deterioration of insulated parts within the circuit breaker. If slow deterioration occurs and plastics are involved, corrosive gases can be formed that will attack copper, aluminum, or silver-plated surfaces. This corrosion can include contacts, valves, seating surfaces, and all interior parts.

3

AIR BLAST CIRCUIT BREAKER SURVEY FINDINGS

EPRI developed a web-based survey to gather information about current utility thoughts regarding maintaining ABCB fleets and recent past actions regarding retiring ABCBs. All US utilities known to have or to recently have had ABCBs in service were invited to participate. The survey was sent to more than 20 transmission companies. Three companies indicated that they did not have air blast circuit breakers. Five companies responded and their responses serve as the basis for this report.

Fleet Characteristics – Installed Population

Based on the responses from the utilities surveyed, Table 3-1 and Table 3-2 show the counts for installed air blast circuit breakers by Make and Voltage and by Make and Age, respectively. The count of air blast circuit breakers currently installed is 280 in the responding utilities' fleets and consisted of GE (80), ABB (29), and Cogenel (171). Of this installed population, 99.6% are greater than 30 years of age with 74.3% being greater than 40 years of age.

Table 3-1
Count of Installed Air Blast Circuit Breakers by Make and Voltage (5 Respondents)

Make	Voltages (kV)					
	138	161	230	345	500	765
GE	12	0	66	2	0	0
ABB (Brown Boveri & Cie (BBC))	0	0	12	9	8	0
Cogenel (Delle Alsthom)	78	0	12	24	39	18
Allis-Chalmers	0	0	0	0	0	0
Merlin Gerin	0	0	0	0	0	0
Hitachi	0	0	0	0	0	0
Other	0	0	0	0	0	0

Table 3-2
Count of Installed Air Blast Circuit Breakers by Make and Age (5 Respondents)

Make	Age(Yrs)		
	< 30	30 to 40	>40
GE	0	1	79
ABB (Brown Boveri & Cie (BBC))	0	16	13
Cogenel (Delle Alsthom)	1	54	116
Allis-Chalmers	0	0	0
Merlin Gerin	0	0	0
Hitachi	0	0	0
Other	0	0	0

Fleet Characteristics – Replaced Population

Table 3-3 shows the number of air blast circuit breakers replaced in the last ten years and the principal reason for replacement of those breakers. By summing the 280 installed breakers in Table 3-1 and 556 replaced breakers in Table 3-3, the count of installed air blast circuit breakers ten years ago was 836. Over the last decade, this represents a 66.5% reduction in the number of air blast circuit breakers installed in the utility fleets with all of the utilities having performed programmatic replacements of these types of breakers. In Table 3-4, it is shown that the primary reasons for the programmatic replacements by utilities were founded upon excessive operational and maintenance costs and an unacceptable level of reliability/availability. In Table 3-5, utilities were asked to select the principal reason for not performing programmatic replacement on air blast circuit breakers. Since none of the surveyed utilities provided answers for this question, it implies that all surveyed utilities have performed programmatic replacement of air blast circuit breakers.

Table 3-3
Count of Replaced Air Blast Circuit Breakers by Make and Principal Reason for Replacement (3 Respondents)

Make	Count	Principal Reason Replaced		
		Programmatic Replacement	Individual Condition/Reliability	Insufficient Rating
GE	204	X		
ABB (Brown Boveri & Cie (BBC))	96	X		
Cogenel (Delle Alsthom)	251	X		
Hitachi

Utility Experience

For this study, utilities were asked to rate their experience with air blast circuit breakers with respect to single pressure gas breakers. The three categories for rating utility experience were reliability and maintenance practices, cost/difficulty of performing minor maintenance, and cost/difficulty of performing major maintenance. The following subsections detail the gathered responses for each utility.

Reliability and Maintenance Practices

Table 3-6 shows that 1 of the 4 utilities surveyed found that air blast circuit breakers are less reliable than single pressure gas breakers while 3 of the 4 utilities found them to be much less reliable.

Table 3-6
Reliability of Air Blast Circuit Breakers to Single Pressure Gas Breakers (4 Respondents)

Option	Utility 1	Utility 2	Utility 3	Utility 4
Much Less Reliable		X	X	X
Less Reliable	X			
Same				
More Reliable				
Much More Reliable				

Cost/Difficulty of Performing Minor Maintenance

Table 3-7 shows that 1 of the 4 utilities surveyed found that air blast circuit breakers are much more costly/difficult to perform minor maintenance than single pressure gas breakers while 3 of the 4 utilities found them to be more costly/difficult.

Table 3-7
Cost/Difficulty of Performing Minor Maintenance of Air Blast Circuit Breakers Compared to Single Pressure Gas Breakers (4 Respondents)

Option	Utility 1	Utility 2	Utility 3	Utility 4
Much More Costly/Difficult			X	
More Costly/Difficult	X	X		X
Same				
Less Costly/Difficult				
Much Less Costly/Difficult				

Cost/Difficulty of Performing Major Maintenance

Table 3-8 shows that 1 of the 4 utilities surveyed found that air blast circuit breakers are more costly/difficult to perform major maintenance than single pressure gas breakers while 3 of the 4 utilities found them to be much more costly/difficult.

Table 3-8
Cost/Difficulty of Performing Major Maintenance of Air Blast Circuit Breakers Compared to Single Pressure Gas Breakers (4 Respondents)

Option	Utility 1	Utility 2	Utility 3	Utility 4
Much More Costly/Difficult	X	X		X
More Costly/Difficult			X	
Same				
Less Costly/Difficult				
Much Less Costly/Difficult				

Current Maintenance Practices

Utilities were asked several questions on current maintenance practices of in-service air blast circuit breakers. The responses for each utility by question are shown in Table 3-9.

Only half of the utilities surveyed have dedicated crews to perform internal inspections/refurbishments on air blast circuit breakers. None of the utilities have dedicated shops to maintain/overhaul air blast circuit breakers and only one-quarter have dedicated contractors to maintain/overhaul these breakers. Also, there was a consensus that none of the utilities have a reliable source of available spare parts.

Utilities were asked if they followed vendor-recommended preventive maintenance tasks and frequencies. Only 25% of utilities followed vendor recommendations. Although vendors informed utilities' initial maintenance programs, preventive maintenance tasks and frequencies are derived through local learnings via operating experience and manufacturer-specific reliability. There was no mention from any utility about supplementary tasks, in addition to scheduled preventive maintenance and overhauls, being performed to extend the life of these breakers.

Table 3-9
Maintenance Practices for In-Service Air Blast Circuit Breakers (4 Respondents)

Question	Utility 1	Utility 2	Utility 3	Utility 4
Do you have dedicated crews to do internal inspections/refurbishments?		X	X	
Do you have dedicated shops to maintain/overhaul these breakers?				
Do you have dedicated contractors to maintain/overhaul these breakers?			X	
Do you have reliable spare parts availability?				
Do you follow vendor recommended PM tasks and frequencies?			X	
Do you have additional tasks to extend the life of these breakers in addition to scheduled PMs and breaker overhaul?				

4
CONCLUSIONS

Based on the survey results, the utility experience with air blast circuit breakers is that these types of breakers are “more” to “much more costly/difficult” on which to perform both minor and major maintenance and are “less” to “much less reliable” when compared to single pressure gas breakers. A review of planned replacements showed that the principal drivers behind programmatic replacement were operation and maintenance costs and an unacceptable level of reliability/availability

The population of air blast circuit breakers for utilities has been reduced by two-thirds over the last decade with no new air blast circuit breakers being installed. Also, nearly three-quarters of these types of breakers that are currently installed are over 40 years of age. The aging population of installed air blast circuit breakers creates difficulty and high costs in maintaining system reliability. The lack of available spare parts to properly maintain these types of breakers has become problematic for utilities due to the age of the technology.

Utilities have diminished abilities to properly maintain air blast circuit breakers. Few utilities have dedicated crews to perform internal inspections/refurbishments or dedicated shops and/or dedicated contractors to maintain/overhaul air blast circuit breakers.

The higher cost/difficulty associated with maintenance requirements when compared to newer technology, the unavailability of spare parts due to obsolescence, and the lack of dedicated crews to work on the ever-aging population of installed air blast circuit breakers may lead to longer outage times associated with both routine and emergency maintenance. This could become problematic for utilities and customers on both a cost and service-reliability perspective.

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc. (EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.

ABSTRACT

This report presents the findings of a recent web survey conducted by EPRI on oil circuit breaker (OCB) asset management practices and concerns.

High voltage OCBs are an older technology that relies on complex mechanical systems for operation and large amounts of oil for insulation. OCB technology has generally performed well over decades of service. However, due to their age and environmental concerns about oil, OCBs may be considered less desirable technology. Moreover, because OCBs are an older technology, spare parts and mechanics experienced in their maintenance are not always readily available. For these reasons, many utilities have decided to reduce the size of their OCB fleets. Other utilities are considering such actions but may be restricted by various constraints. The survey was conducted to collect industry experience and industry plans for oil circuit breakers with the following objectives:

- Assess industry attitudes on retaining in-service oil circuit breakers
- Understand how peer companies are responding to OCB operations and maintenance challenges

Chapter 2: Oil Circuit Breaker Designs

Chapter 3: Oil Circuit Breaker Survey Findings

Chapter 4: Conclusions

2
OIL CIRCUIT BREAKER DESIGNS

Description

Historically, bulk oil circuit breakers have been commonly used at voltages up to 230 kV, and on some systems, up to 345 kV. For lower ratings, up to 69 kV, oil circuit breakers often have all three phases housed in a single tank; the higher-rated units described here have three tanks, a single tank for each pole or phase.

Minimum-oil (also termed small oil volume) circuit breakers have been used at voltages up to the higher levels of transmission voltages, but because they have some application limitations, they are mainly applied to under 170 kV. They were extensively developed during the 1960s as an alternative to the bulk oil type, with its large oil volume, and the air-blast, with its need for expensive compressed air plant. They also competed with the then-new technology of the two-pressure SF6 types. Although widely used at 170 kV and below, many were found to be unreliable in service, particularly when switching capacitive currents. Those designs that are sound have given good service, and refurbishment programs exist.

Interruption Function (Bulk Oil)

As with all circuit breakers, the interrupter is a critical part of the oil circuit breaker. The most common method of interruption used in oil circuit breakers is called by several names, such as crossblast or oil blast interrupter. In these designs, the arc is drawn in front of a series of lateral vents, often called the grid assembly. The heat of the arc vaporizes the oil in the assembly, and the gases (mainly hydrogen) form a bubble that increases the pressure against the arc, finally forcing it to be blown into the grid vents. When the pressure inside the interrupter becomes sufficiently high and the length of the arc is adequately extended at current zero, the arc is extinguished.

The arc is always confined inside a bubble of gas formed from the oil, and this bubble extends and expands through the grid vents and the surrounding shell vents to the outside of the two or more interrupter assemblies in each pole (phase). The hot gases emerging from the vents are initially still ionized. It is essential to ensure, by correct grid design, that dielectric breakdowns do not occur between the outer vents of the shell system, external to the interrupter assemblies. Preventing dielectric breakdowns is particularly important for higher voltage interrupters in which multiple series grid arrangements are used. It is equally important that the shell vents in the same pole (phase) tank face away from each other. At the time the arc is being extinguished, fresh oil is drawn into the interrupter grid assembly to replace the arc-affected oil, thus cooling the arc zone and restoring the dielectric integrity of the system.

Interruption Function (*Minimum-Oil (Small Oil Volume)*)

The principle of interruption is that of an oil pump forcing clean oil into the interrupter to quench the arc. The used oil is retained within the interrupter zone, limiting the number of the short circuit clearances that are possible before oil maintenance or overhaul is required.

The arc is quenched in a similar manner to that of the bulk oil design, but in this case, the cool oil is forced into the arcing chamber by a pumping action derived from the opening movement of the contact drive shaft.

The interrupter is housed inside a porcelain enclosure as a live tank design, usually as a single vertical arrangement per pole (phase) on top of the mechanism. In some cases, the supporting insulator column is replaced by a current transformer.

3

OIL CIRCUIT BREAKER SURVEY FINDINGS

EPRI developed a web-based survey to gather information about current utility thoughts regarding maintaining OCB fleets and recent past actions regarding retiring OCBs. Several US utilities known to have or to recently have had OCBs in service were invited to participate.

Fleet Characteristics – Installed Population

Based on the responses from the utilities surveyed, Table 3-1 and Table 3-2 show the counts for installed Oil circuit breakers by Voltage and by Voltage and Age, respectively. The count of Oil circuit breakers currently installed is 11,215 in the responding utilities' fleets. Of that installed population with known ages, 92.9% are greater than 30 years of age with 84.3% being greater than 40 years of age.

>50	5040	759	287	34
Unknown	706	0	5	0

Fleet Characteristics – Replaced Population

Table 3-3 shows the number of oil circuit breakers replaced in the last ten years. The principal motivations for replacement of those breakers is shown in Table 3-4. By summing the 11,215 installed breakers in Table 3-1 and 2,410 replaced breakers in Table 3-3, the count of installed oil circuit breakers ten years ago was 13,625. Over the last decade, this represents a 17.7% reduction in the number of oil circuit breakers installed in the utility fleets with all of the utilities having performed programmatic replacements of these types of breakers. For below 138 kV, Table 3-5 shows that the drivers for programmatic replacements by utilities were unacceptable reliability/availability and insufficient ratings. For above 138 kV, Table 3-5 shows that the drivers for programmatic replacements by utilities were excessive costs, environmental, and other. In Table 3-6, utilities were asked to select the rationale for not performing programmatic replacement on oil circuit breakers. Respondents selected acceptable performance of oil circuit breakers and unavailability of capital for not performing programmatic replacement.

Utility Experience

For this study, utilities were asked to rate their experience with oil circuit breakers with respect to single pressure gas breakers. The three categories for rating utility experience were reliability and maintenance practices, cost/difficulty of performing minor maintenance, and cost/difficulty of performing major maintenance. The following subsections detail the gathered responses for each utility.

Reliability and Maintenance Practices

Table 3-7 shows that three of the five utilities surveyed found that oil circuit breakers are less reliable than single pressure gas breakers while one of the five utilities found them to have similar reliability. One out of the five utilities responded that oil circuit breakers are more reliable than single pressure gas breakers.

Table 3-7
Reliability of Oil Circuit Breakers to Single Pressure Gas Breakers (5 Respondents)

Option	Utility 1	Utility 2	Utility 3	Utility 4	Utility 5	Utility 6
Much Less Reliable						
Less Reliable	X			X		X
Same					X	
More Reliable		X				
Much More Reliable						

Cost/Difficulty of Performing Minor Maintenance

Table 3-8 shows that two of the six utilities surveyed found that oil circuit breakers are more costly/difficult to perform minor maintenance than single pressure gas breakers while three of the six utilities found them to be of similar cost/difficulty. One out of the six utilities responded that oil circuit breakers are less costly/difficulty than single pressure gas breakers.

Table 3-8
Cost/Difficulty of Performing Minor Maintenance of Oil Circuit Breakers Compared to Single Pressure Gas Breakers (6 Respondents)

Option	Utility 1	Utility 2	Utility 3	Utility 4	Utility 5	Utility 6
Much More Costly/Difficult						
More Costly/Difficult	X			X		
Same		X	X			X
Less Costly/Difficult					X	
Much Less Costly/Difficult						

Cost/Difficulty of Performing Major Maintenance

Table 3-9 shows that two of the six utilities surveyed found that oil circuit breakers are more costly/difficult to perform major maintenance than single pressure gas breakers while four of the six utilities found them to be of similar cost/difficulty.

Table 3-9
Cost/Difficulty of Performing Major Maintenance of Oil Circuit Breakers Compared to Single Pressure Gas Breakers (6 Respondents)

Option	Utility 1	Utility 2	Utility 3	Utility 4	Utility 5	Utility 6
Much More Costly/Difficult						
More Costly/Difficult			X	X		
Same	X	X			X	X
Less Costly/Difficult						
Much Less Costly/Difficult						

Current Maintenance Practices

Utilities were asked several questions on current maintenance practices of in-service oil circuit breakers. The responses for each utility by question are shown in Table 3-10. Free form comments for each of these questions can be found in Table 3-11.

Only 33.3% of the utilities surveyed have dedicated crews to perform internal inspections/refurbishments on oil circuit breakers. None of the utilities have dedicated shops to maintain/overhaul oil circuit breakers and none have dedicated contractors to maintain/overhaul these breakers. 66.6% of the utilities have a reliable source of available spare parts.

Utilities were asked if they followed vendor-recommended preventive maintenance tasks and frequencies. 50% of utilities followed vendor recommendations. Although vendors informed utilities' initial maintenance programs, preventive maintenance tasks and frequencies are derived through local learnings via operating experience and manufacturer-specific reliability. One of the six utilities mentioned they perform supplementary tasks, in addition to scheduled preventive maintenance and overhauls, at critical locations to extend the life of oil circuit breakers.

Table 3-10
Maintenance Practices for In-Service Oil Circuit Breakers (6 Respondents)

Question	Utility 1	Utility 2	Utility 3	Utility 4	Utility 5	Utility 6
Do you have dedicated crews to do internal inspections/refurbishments?	✗	✗	✗	✗	✓	✓
Do you have dedicated shops to maintain/overhaul these breakers?	✗	✗	✗	✗	✗	✗
Do you have dedicated contractors to maintain/overhaul these breakers?	✗	✗	✗	✗	✗	✗
Do you have reliable spare parts availability?	✗	✓	✓	✗	✓	✓
Do you follow vendor recommended PM tasks and frequencies?	✗	✗	✓	✓	✓	✗
Do you have additional tasks to extend the life of these breakers in addition to scheduled PMs and breaker overhaul?	✗	✗	✗	✓	✗	✗

Table 3-11
Maintenance Practices Comments for In-Service Oil Circuit Breakers (6 Respondents)

Question	Utility 1	Utility 2	Utility 3	Utility 4	Utility 5	Utility 6
Do you have dedicated crews to do internal inspections/refurbishments?						Our in-house crews are familiar with OCBs
Do you have dedicated shops to maintain/overhaul these breakers?						
Do you have dedicated contractors to maintain/overhaul these breakers?						
Do you have reliable spare parts availability?	Parts availability, especially for mechanisms, is a major factor in determining future serviceability. Some parts are beyond another rebuild cycle for some equipment.	We have found 3rd party vendors that have proven to be reliable for us.		Parts are obtained through various sources, but it's difficult to maintain these parts on hand and supplier availability is diminishing		For Most
Do you follow vendor recommended PM tasks and frequencies?	We view vendor recommendations as a guide only.	Our intervals are longer, but tasks are close to vendor specified tasks.				
Do you have additional tasks to extend the life of these breakers in addition to scheduled PMs and breaker overhaul?	Used to do Breaker Oil Analysis but found it to be of little worth.			At critical locations, some maintenance tasks are enhanced and additional tasks are added.		

4
CONCLUSIONS

Based on the survey results, the utility experience with oil circuit breakers is that these types of breakers are somewhat "more costly/difficult" on which to perform both minor and major maintenance and are somewhat "less reliable" when compared to single pressure gas breakers. A review of planned replacements showed that the principal drivers behind programmatic replacement are unacceptable reliability/availability and insufficient ratings for below 138 kV and excessive costs, environmental, and other for above 138 kV.

The population of oil circuit breakers for utilities has been reduced by approximately 18% over the last decade. Also, nearly 85% of oil circuit breakers that are currently installed are over 40 years of age. The aging population of installed oil circuit breakers may create difficulty and higher costs in maintaining system reliability.

Utilities have diminished abilities to properly maintain oil circuit breakers. None of the utility respondents have dedicated crews to perform internal inspections/refurbishments or dedicated shops and/or dedicated contractors to maintain/overhaul oil circuit breakers.

The higher cost/difficulty associated with maintenance requirements when compared to newer technology and the lack of dedicated crews to work on the ever-aging population of installed oil circuit breakers may lead to longer outage times associated with both routine and emergency maintenance. This could become problematic for utilities and customers on both a cost and service-reliability perspective.

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc. (EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.

Degradation Rates of Steel Tower Coating Systems: Atmospheric Corrosivity Model Development. EPRI, Palo Alto, CA: 2017.

ABSTRACT

Transmission structure populations are aging and many of the barrier coatings that have been applied or repaired now require additional maintenance. Wholesale application of coating systems on the entire structure population becomes cost prohibitive and methods to screen the system for maintenance items becomes critical.

This report outlines a new and novel method of screening a transmission line system for structures with a high probability of coating degradation. In addition to coating degradation the consequences of doing nothing are now made apparent by understanding the corrosion rates of the structure itself. Application of the galvanizing and steel degradation data then allows an asset management team to forecast and schedule painting or repair operations based upon present condition models.

1 BACKGROUND, OBJECTIVES AND RESEARCH APPROACH

A coating program for overhead transmission towers can be costly and difficult to justify when the utility has thousands of structures in first cycle of a coating program. It is then important to understand the environment and how the structures age within those location such that the most aggressive conditions may be targeted first. Once the circuits have been prioritized by age and environmental factors, budgets may be established and work orders assigned for coating or structural repair.

Gaps and Objectives

The objective of this project is to provide accurate information so that condition assessments may be estimated for each circuit based upon the environment. Categorizing the Ontario province by corrosivity level has been completed by measuring corrosion rates of the galvanizing and the structure through field surveys and test coupons. This results in a database that may be queried to find structures with various levels of coating integrity and corrosion damage.

Research Approach

The research approach for this project is to incorporate the structure condition assessments from four past surveys and cross reference that data with coupons that have been in atmospheric exposure for the last three years. These data sources will then allow generation of models for asset management teams to select circuits for painting operations and repairs.

2 MONITORING ATMOSPHERIC CORROSION RATES USING TEST COUPONS

Test Coupon Fabrication and Installation

Mass loss calculations may be completed using test coupons exposed to an environment for some time interval. This mass loss may then be converted into corrosion rates with a high level of confidence in accuracy.

One hundred (100) racks were fabricated for subsequent attachment to specific towers at various heights, each rack holding thirteen (13) coupons in alignment with the compass rose. The rack was designed to hold four different types of coupons which would quantify degradation in various environments (Figure 2-1).

Figure 2-1: Coupon Rack Design for Attachment to the Structure

Bare Steel Coupons

The first type of coupon is a bare steel coupon that was cut from tower members removed from service (see Figure 2-2). This coupon will provide corrosion rates of the materials used in construction of the tower for each location throughout the province. A coupon may be removed at regular intervals and weighed for gravimetric analysis and mass loss conversions to corrosion rates.

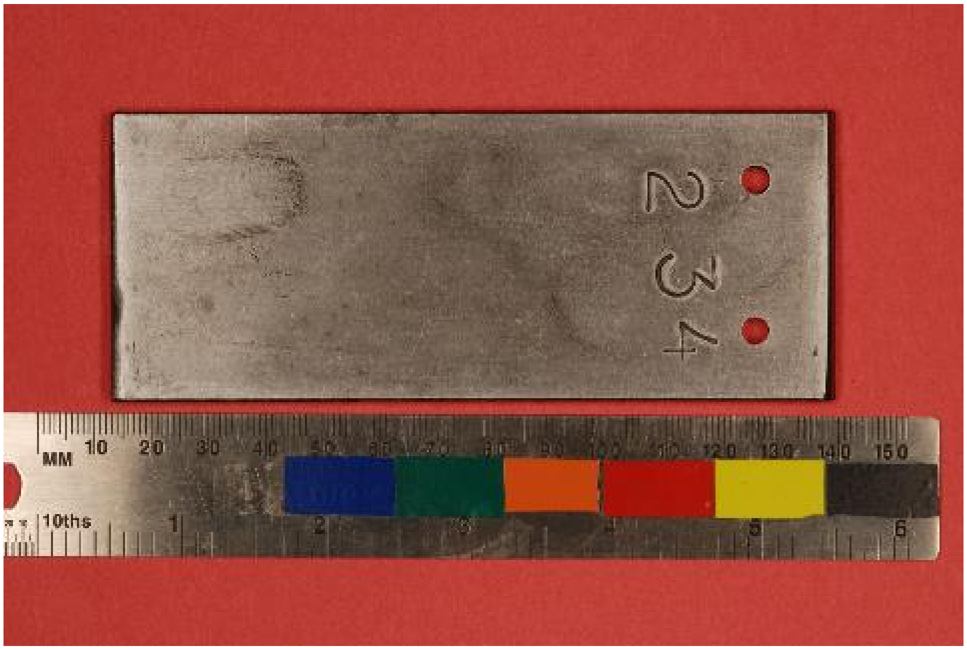

Figure 2-2: Bare Carbon Steel Coupon That Has Been Serialized, Weighed, Measured and Characterized by Color

Galvanized Coupons

The second type of coupon was also cut from tower members, blasted and hot dipped galvanized according to the ASTM A123 standard (see Figure 2-3). This coupon may also be examined at regular intervals using thickness measurements to determine galvanize (zinc) corrosion rates throughout the province.

Figure 2-3: Galvanized Test Coupon That Has Been Serialized, Weighed, Measured and Characterized by Color

Coating System Coupons

The third coupon was cut from tower members, degreased and spray painted with Galvotech (see Figure 2-4). Galvotech 2000 coating system is a high load zinc rich coating system with performance claims similar to hot dipped galvanize. The performance of this system may be summarized by attributes such as capacitance, permeability, moisture uptake, adhesion or thickness. The simplest method that may be employed to trend coating system degradation would be thickness measurements using ultrasonic or magnetic pull off gauges. This trending requires multiple inspections at specific time intervals and will support decisions on required time until recoat operations.

Figure 2-4: Coated Steel Coupon That Has Been Serialized, Weighed, Measured and Characterized by Color

Tensile Coupon

The last type of coupon is a tensile specimen that is designed to quantify the mass loss due to atmospheric exposure. This is completed by removing the specimen from the rack and pulling tension until failure while monitoring displacement and load. Unfortunately, this is a destructive test and will not allow trending but will frame the time interval required for pit formation and penetration rates for localized corrosion.

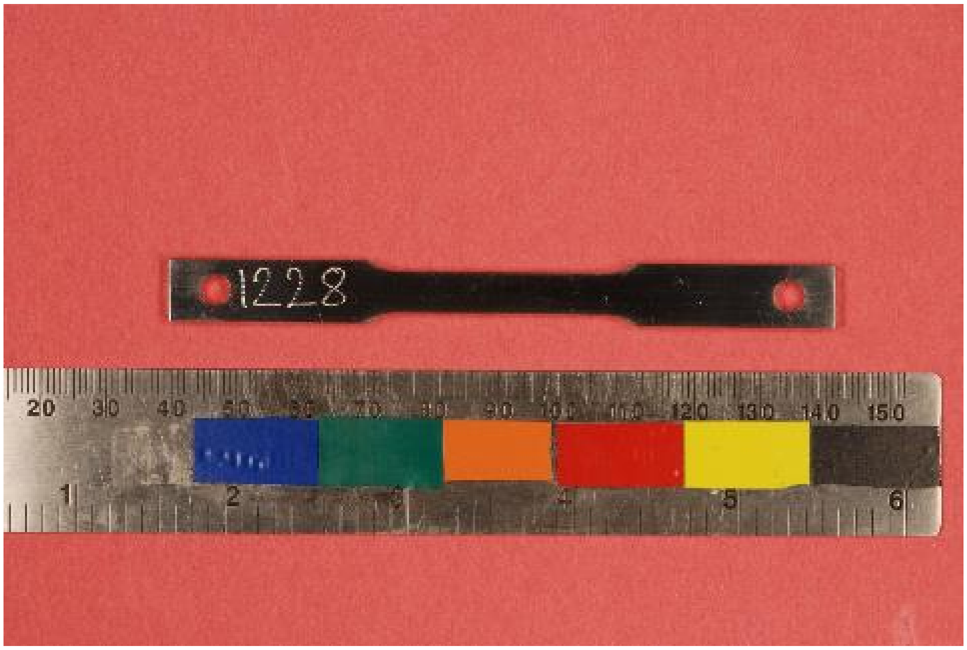

Figure 2-5: Tensile Test Steel Coupon That Has Been Serialized, Weighed, Measured and Characterized by Color

Listing of Coupon Measurements

Each coupon was characterized in the laboratory to provide a baseline condition assessment on thirteen hundred (1,300) test coupons with the following data types and equipment required.

- Surface Area
- Thickness
- Width
- Length
- Mass
- Coating System Layer Thickness
- Galvanizing Thickness
- Profile
- Photographs (with color correction using Hunter Scale)

Color Correction Baseline

The last item supporting the coupon characterization was a baseline of the color correction tabs within each coupon photograph. The Hunter Scale was selected for all color baselines using the combination of L*, a* and b*. This data may be used to understand the changes in the coupons and trend the effects of UV degradation. This could be completed within the laboratory environment using a spectrometer or by digital photography and spectral analysis. The following

Table 1 shows the baseline values of each color tab.

Table 1: Baseline Hunter Scale of the Color Correction Tabs

Reference Color	L*	a*	b*
Blue	15.040	0.107	-0.140
Green	17.720	-0.520	1.327
Orange	19.000	1.672	2.424
Red	17.970	2.127	1.138
Yellow	19.060	-1.950	5.984
Black	18.450	0.129	0.477

Coupon Rack Installation

Each coupon rack had a specific location and attachment height designated by HydroOne and all sites were above EPRI working heights so HydroOne personnel took ownership of all coupon installations (see Figure 2-6). The attachment was made using a pair of angles that were slotted to allow clamping to the horizontal member (see Figure 2-1).

Figure 2-6: Typical Coupon Rack Installation

The bare steel coupons and the tensile specimen were removed from service and returned to the EPRI Charlotte campus for characterization. The balance of coupons (Galvotech and Hot Dipped Galvanizing) will remain in service for an additional period of time.

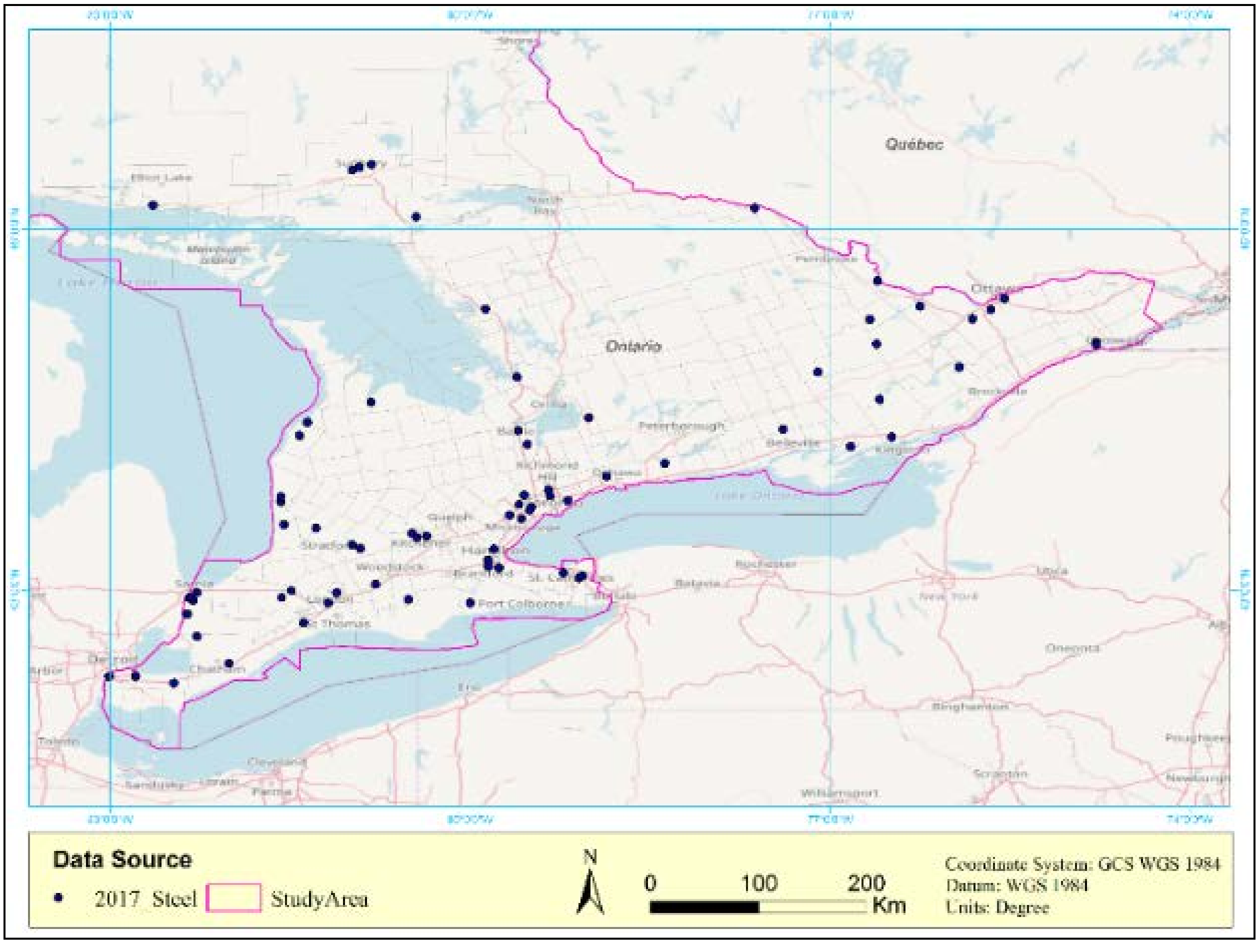

Figure 2-7 Structure Locations for Steel Coupon Data

Coupon Evaluations

Objective

The objective of this task is to measure the mass loss and thickness loss on 2 steel rectangle coupons from each coupon rack. This process will provide an average of each point on the compass rose. The tensile specimen will then be tested to determine residual strength and study the correlation with localized corrosion resulting in mass loss.

Collecting samples:

1. Unwrap the package
2. Record the following:
   a. Circuit #, Structure #, date, both rectangle #s and the tensile specimen #

Pictures:

1. Set the tensile specimen and plates, number side up on the photographic stand
2. Place the color guide next to it (see Figure 2-8)

3. On a post-it note, write clearly the circuit #, structure #, DB#s and R#
4. Take a picture
5. Flip the tensile specimen and rectangles
6. Take another picture
7. Put back the sample in the bag with the post-it note

**make a note if you see paint on the coupons*

Mass loss Measurement:

1. Make the NACE steel cleaning solution (500 ml HCL, 500 ml DI water, 3.5g hexamethyltetramine).
2. In a glass dish, pour steel cleaning solution
3. Place the steel coupon in the solution and wait approximately 3 minutes
4. Using acid resistant gloves, turn the coupon and wait 3 minutes
5. Take the coupon out of the solution, rinse it thoroughly with tap water and make sure all the rust is gone. If not, place the coupons for another 3 minutes.
6. Completely dry the coupon with paper towel or compressed air
7. Once dry, weigh the sample and record it.
8. Place the sample back into the bag
9. Repeat this procedure for the tensile specimen
10. Make thickness and width measurement in the smallest part of the tensile specimen.
11. perform tensile test on the tensile specimen (this test remains incomplete)

Figure 2-8 Image record for each coupon with color correction

Steel Coupon Analysis Results

100 coupon racks with coupons were to the environment for three (3) years and 300 coupons were returned to the EPRI campus for analysis. The rectangular coupons totaled 200 with 100 tensile specimens. 19 of the rectangular coupons were unusable due to paint applied during tower painting operations (see Figure 2-9).

Preliminary gravimetric analysis of the coupons results in the following graph of corrosion rates for steel and illustrates the structure site corrosivity classifications using the remaining 181 coupons for corrosion rate measurements (see Figure 2-10 and Table 2).

3 STRUCTURE CONDITION ASSESSMENTS – FIELD SURVEY 2017

Survey Background

One hundred transmission structures included in this survey were selected by the utility. They were chosen to cover HydroOne's territory that was not represented by the coupon racks in areas with ease of access. In preparation for the survey, accessibility to and general location of the structures were assessed in Google Earth. During this desk study period, adjustments were made to substitute some structures that were not conducive to a productive field survey (i.e. travel time, vegetation issues, etc.).

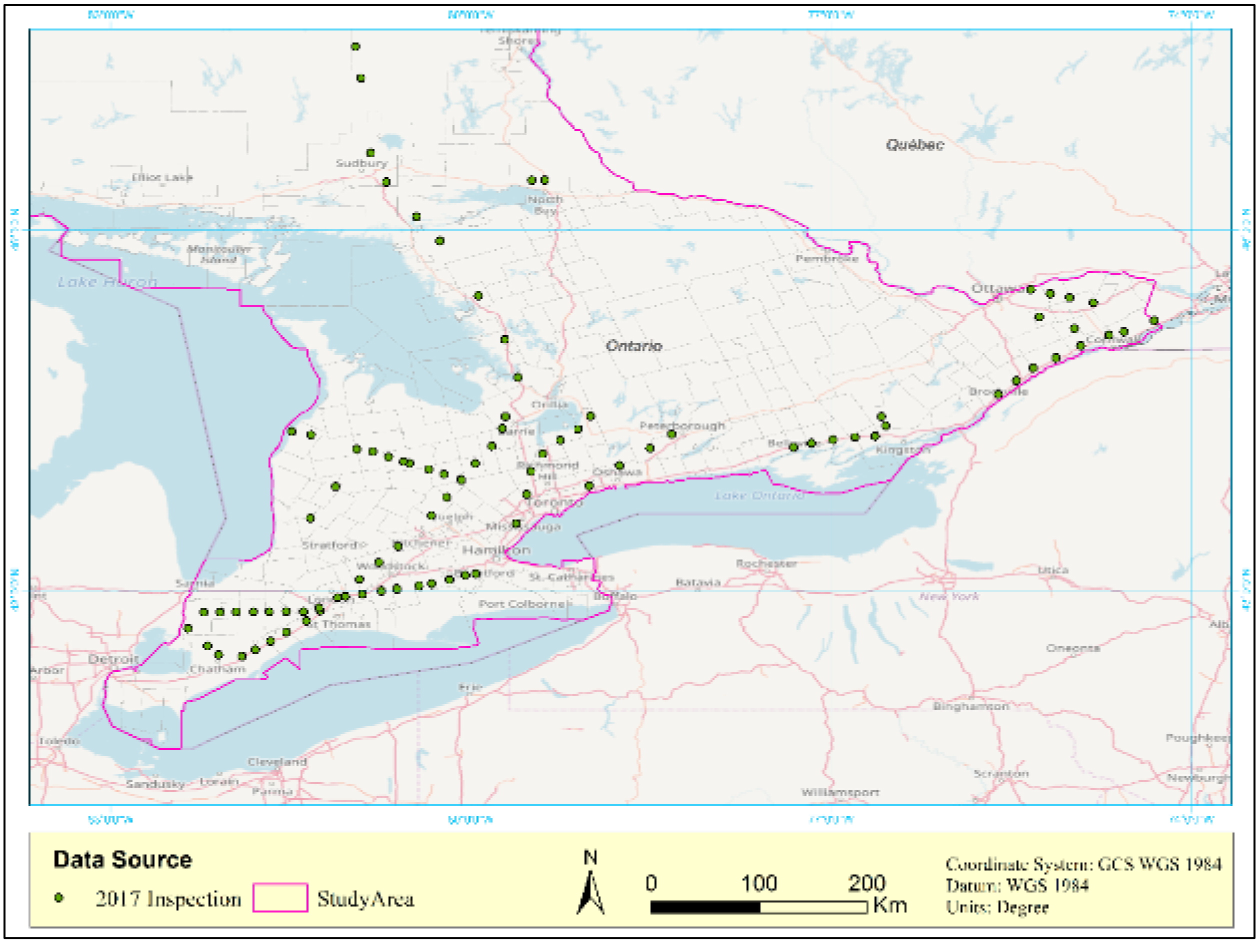

Figure 3-1 Structure Locations for 2017 Field Survey

Survey Procedure

The following field procedure was conducted at each selected HydroOne transmission structure:

1. Before beginning the survey, a safety check was conducted.
    a. It was necessary to check that all crew members were wearing appropriate PPE.

b. The structure was then observed from a safe distance to see if there were any overhead hazards, such as loose members.

c. Ground level was evaluated for safety – primarily tripping, wildlife, and vegetation hazards.

d. The structure was tested with a voltage detector to ensure it was not energized.

2. General observations were made about the location and structure itself. Observations recorded included:

   a. Structure type

   b. Foundation type

   c. Replacement members

   d. Substations/pipelines/cables

   e. Mechanical damage.

3. For each accessible structure member below six feet, the following were collected:

   a. Width and thickness of member.

   b. General observations of the member

      i. mechanical damage

      ii. presence of coating

      iii. localized corrosion.

   c. Three galvanizing or coating thicknesses, collected and averaged using a DeFelsko PosiTector.

   d. If present, the thickness of a spangle area on the member to be used as a proxy for original galvanizing thickness.

   e. If present, a rusting classification using the SSPC-VIS 2: Standard Method of Evaluating Degree of Rusting on Painted Steel Surfaces visual guide.

   f. If present, a pitting classification using ASTM G46-94(2013): Standard Guide for Examination and Evaluation of Pitting Corrosion.

Survey Analysis Results

From the original in-service dates of the structures, their galvanizing thicknesses, and their spangle thicknesses, it was possible to calculate an average corrosion rate per structure. Based on the international standard ISO 9223: Corrosion of metals and alloys – Corrosivity of atmospheres – Classification, determination, and estimation, it was possible to assign each structure to a corrosivity category: C1 – C5. Figure 1 shows the distribution of the surveyed HydroOne structures, while Table 1 is a reference guide from ISO:9223 outlining the characteristics of the classes.

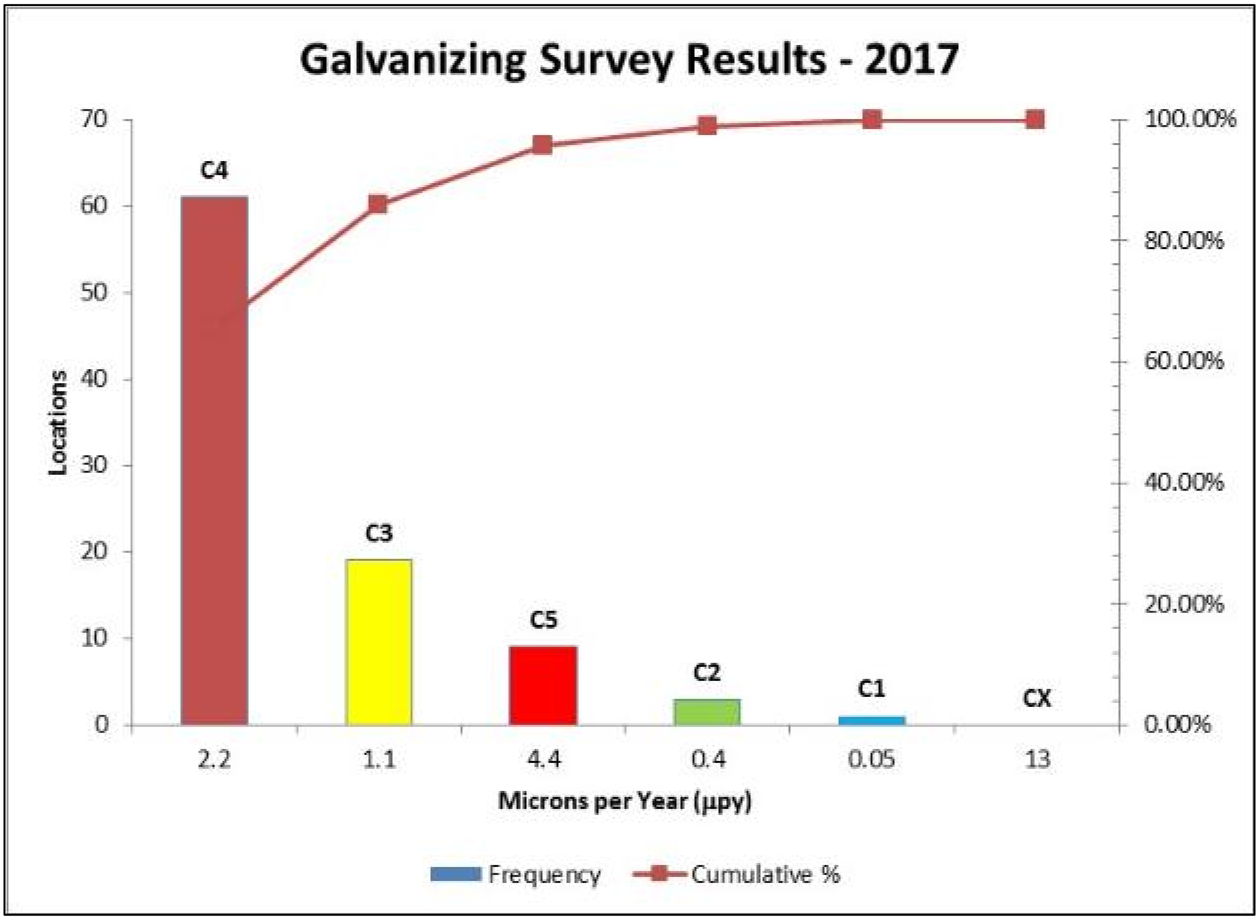

Figure 3-2: ISO 9223 Corrosion Categories for HydroOne Structure Survey (2017).

Table 3 Cumulative percentages of each corrosivity classification

Bin	*Frequency*	*Cumulative %*	*Bin*	*Frequency*	*Cumulative %*
0.05	1	1.08%	2.2	61	65.59%
0.4	3	4.30%	1.1	19	86.02%
1.1	19	24.73%	4.4	9	95.70%
2.2	61	90.32%	0.4	3	98.92%
4.4	9	100.00%	0.05	1	100.00%
13	0	100.00%	13	0	100.00%

Table 4: Description of typical atmospheric environments related to the estimation of corrosivity categories (ISO:9223:2012).

Corrosivity category[a]	Corrosivity	Typical environments — Examples[b]	
		Indoor	Outdoor
C1	Very low	Heated spaces with low relative humidity and insignificant pollution, e.g. offices, schools, museums	Dry or cold zone, atmospheric environment with very low pollution and time of wetness, e.g. certain deserts, Central Arctic/Antarctica
C2	Low	Unheated spaces with varying temperature and relative humidity. Low frequency of condensation and low pollution, e.g. storage, sport halls	Temperate zone, atmospheric environment with low pollution (SO_2 < 5 μg/m^3), e.g. rural areas, small towns Dry or cold zone, atmospheric environment with short time of wetness, e.g. deserts, subarctic areas
C3	Medium	Spaces with moderate frequency of condensation and moderate pollution from production process, e.g. food-processing plants, laundries, breweries, dairies	Temperate zone, atmospheric environment with medium pollution (SO_2: 5 μg/m^3 to 30 μg/m^3) or some effect of chlorides, e.g. urban areas, coastal areas with low deposition of chlorides Subtropical and tropical zone, atmosphere with low pollution
C4	High	Spaces with high frequency of condensation and high pollution from production process, e.g. industrial processing plants, swimming pools	Temperate zone, atmospheric environment with high pollution (SO_2: 30 μg/m^3 to 90 μg/m^3) or substantial effect of chlorides, e.g. polluted urban areas, industrial areas, coastal areas without spray of salt water or, exposure to strong effect of de-icing salts Subtropical and tropical zone, atmosphere with medium pollution
C5	Very high	Spaces with very high frequency of condensation and/or with high pollution from production process, e.g. mines, caverns for industrial purposes, unventilated sheds in subtropical and tropical zones	Temperate and subtropical zone, atmospheric environment with very high pollution (SO_2: 90 μg/m^3 to 250 μg/m^3) and/or significant effect of chlorides, e.g. industrial areas, coastal areas, sheltered positions on coastline

Overall, corrosion would vary by height and even by member – with general corrosion increasing with height and the small diagonal members being the most corroded members. However, there was no significant difference between corrosion rates on horizontal versus vertical faces (5.4% difference). When coating systems were already in place, all of the painted structures had poor paint coverage with holidays and general spalling of the coating systems – some with even entire members forgotten.

Generally, atmospheric corrosion rates were highest in the southwestern section of the province near Lake Huron and the Michigan border. There are C5 (very high) category structures in many of the surveyed circuits: B4V, B22D, D4W, L24L, L28C, M32W, P15C, P502X, W42L, X503E. However, the circuits with the highest average corrosion rates (> 2 microns/year) are included in Table 5. These circuits were not necessarily in the worst condition upon visual inspection, therefore full confidence cannot be placed in only in looking at these structures.

Table 5: Average atmospheric corrosion rates for circuits with greater than two microns lost per year.

Circuit	Avg Corrosion Rate (microns loss/year)
B22D	2.095958
B4V	2.16924
L24L	2.258941
L28C	2.189025
W42L	2.265625

Transmission lines may traverse areas of high and low corrosion rates, therefore use of this data requires an understanding of the age of the structure. If sufficient galvanizing is remaining despite the corrosivity level at that location, those structures may be monitored and trended.

4 MODEL GENERATION

Data Analysis

The data was analyzed from ninety-one (91) structures using the bare steel coupons and the galvanizing mass loss from the 2001, 2013 and 2017 field surveys totaling approximately 300 additional structures. The Ontario landmass was mapped to understand land cover (see Figure 4-1) and effects of elevation (see Figure 4-2). Additionally, the locations of generation plants were added for future Gaussian plume models to understand micro-climates (see Figure 4-3).

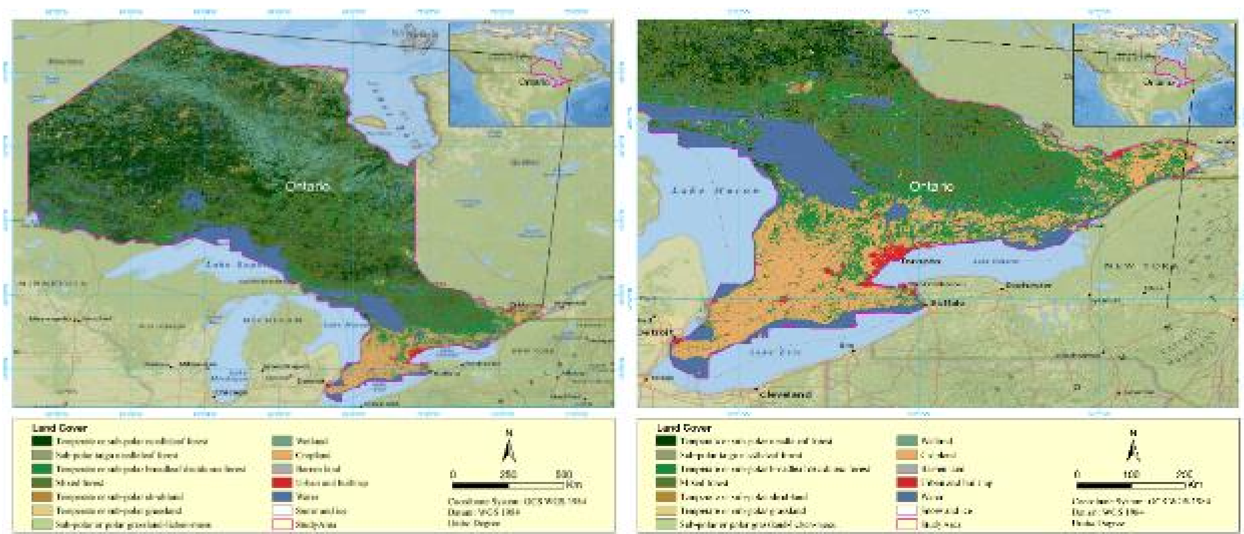

Figure 4-1 Land Cover Throughout the Ontario Province and Lower Ontario

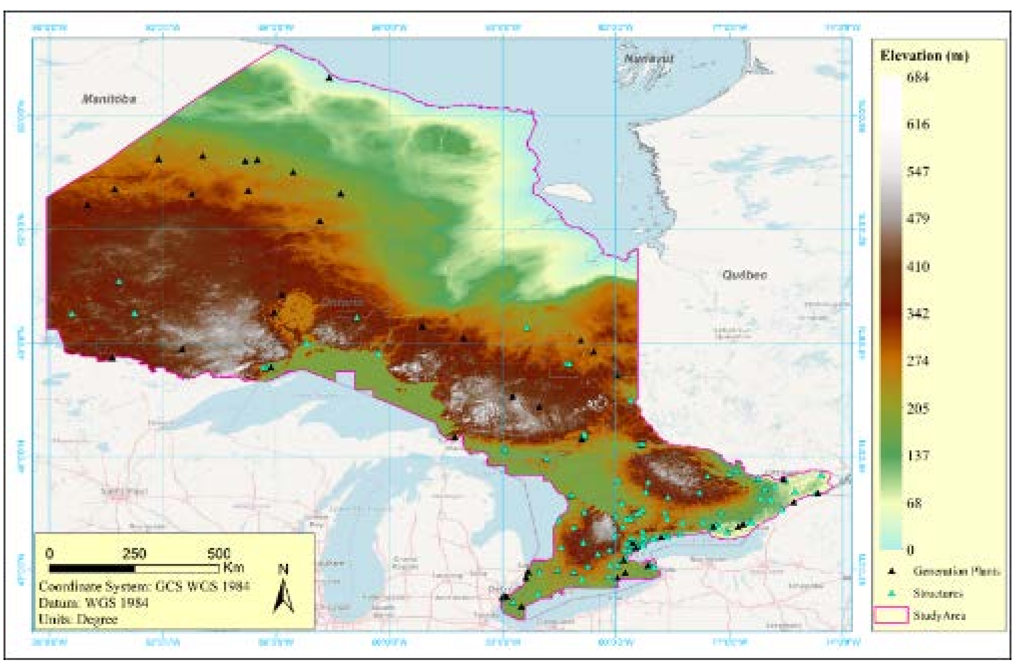

Figure 4-2 Elevation Map of Ontario

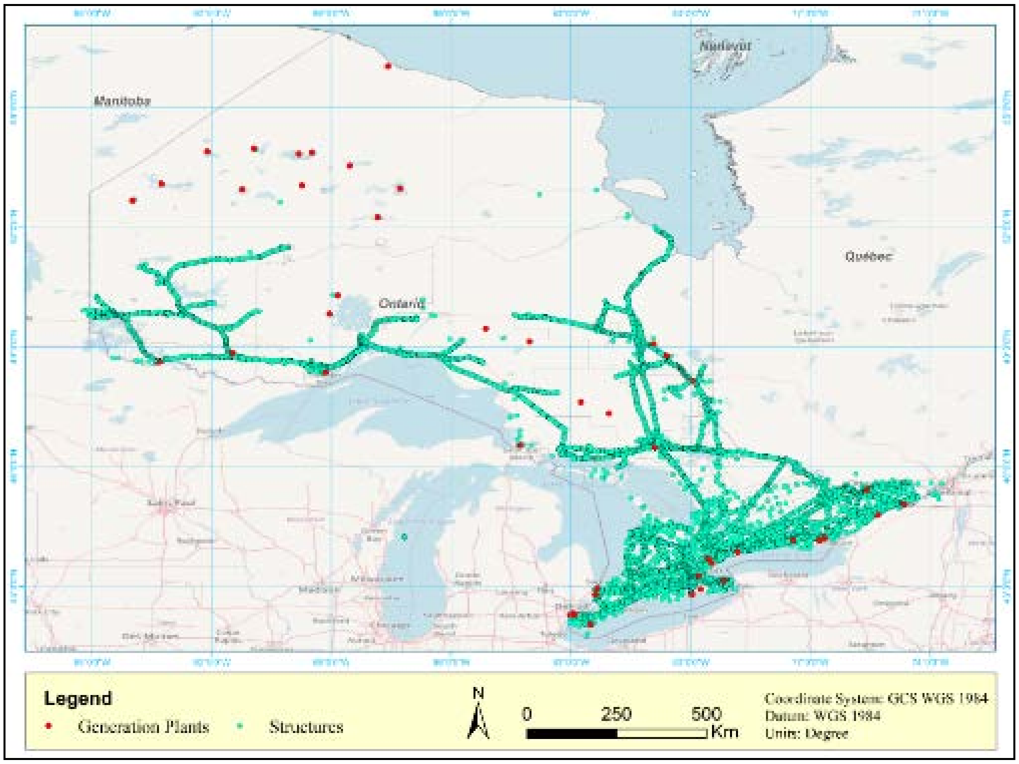

Figure 4-3 Illustrates HydroOne Structure and Generation Locations

A method for spatial interpolation was used to predict the unknown regions around structures with known corrosion rates. This was completed to understand how structures share an environment and statistically determine the effective distances that the environment may remain constant. As a result, it was decided that insufficient data was available to properly model the corrosivity levels above Sudbury.

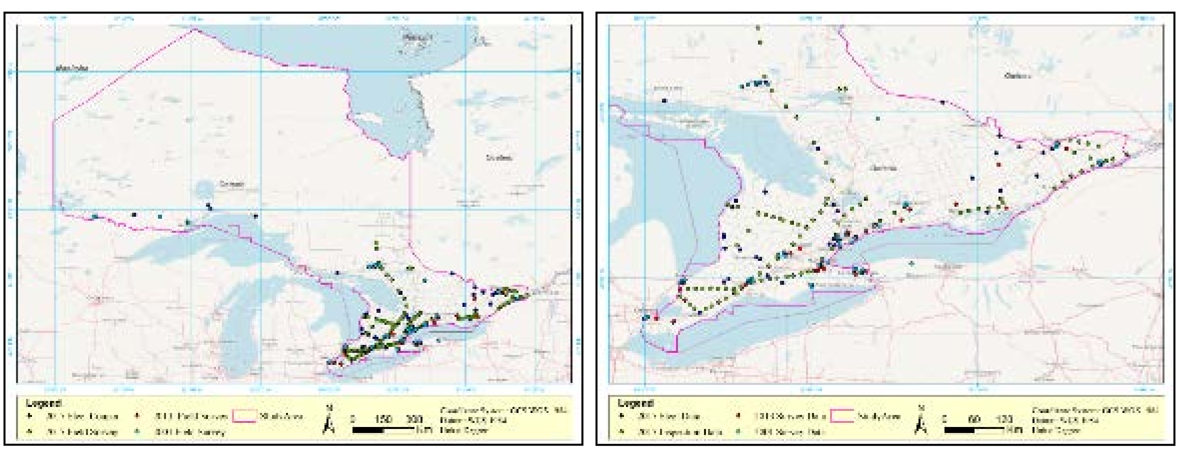

Figure 4-4 Structure Inspection Locations within Southern Ontario

Steel coupons were removed from service after three (3) years of aging in the field. Gravimetric methods were then used to measure corrosion rates based upon mass loss calculations in microns per year. Survey data for galvanizing loss was then analyzed and mapped for regional corrosivity levels.

Coupon vs Galvanizing Survey Comparisons

The 2017 steel coupons survey (see Figure 4-5) shows that a majority of the locations are categorized as “C3” (followed by a majority of “C2” and then “C4”), while the galvanized tower survey performed the same year shows that the majority of the locations are categorized as “C4” (followed by a majority of “C3” and then “C5”). These two surveys, performed the same year, show a disparity of an entire category. This “shift” of one category could be explained by the height at which the corrosion measurements were performed (see Table 6).

Table 6 Comparison of ISO 9223 Classifications for Zinc and Steel Corrosion Rates (μpy)

Metal Type	C1	C2	C3	C4	C5	CX
Galvanizing (zinc)[1]	≤ 0.05	0.05 to ≤ 0.4	0.4 to ≤ 1.1	1.1 to ≤ 2.2	2.2 to ≤ 4.4	4.4 to ≤ 13
Carbon Steel[2]	≤ 0.4	0.4 to ≤ 8.3	8.3 to ≤ 17	17 to ≤ 27	27 to ≤ 67	67 to ≤ 233

Notes:

1. *Zinc classifications are based upon 30-year corrosion rates*
2. *Carbon steel classifications are based upon 10-year corrosion rates*

In the case of the steel coupons, the coupons were placed, on average, at a height of 62 feet with some coupons placed as high as 121 feet, while the galvanized tower survey was performed at human height, resulting in corrosion rates measured at a maximum of 6 to 7 feet. Close to the ground, galvanized tower legs and other members were exposed to higher time of wetness due to vegetation, higher concentrations of chloride due to road salt, and potentially higher concentrations of nitrates due to fertilizer or pesticide broadcasting, resulting in higher corrosion rate than the steel placed higher on the tower.

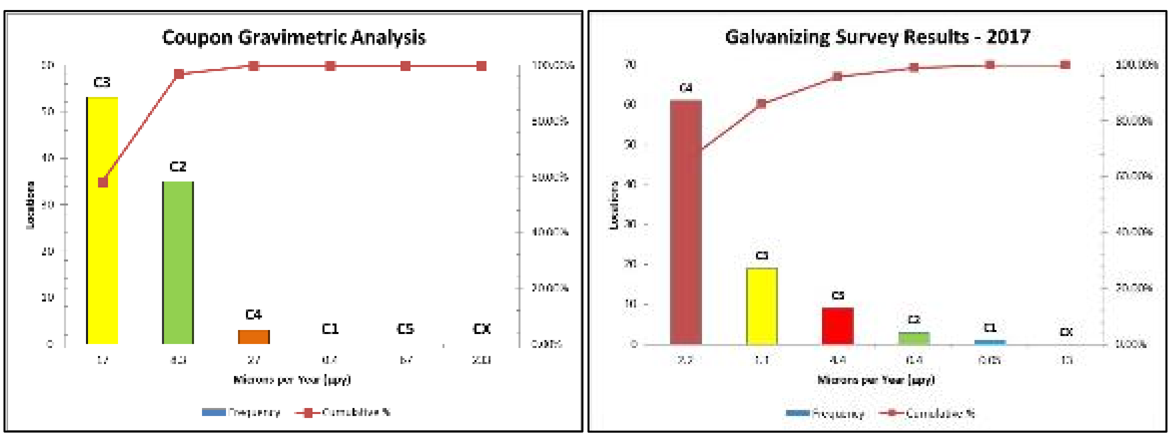

Figure 4-5 Corrosivity Distributions for Steel Categories vs Galvanizing Categories

Survey Comparisons

To understand the differences in the two data sets, the variables were defined and studied to determine if they resulted from differences in survey procedure, equipment used in the study, assumptions used in the analysis or the environment.

The first potential variable ruled out was the criteria for establishing the original galvanizing thickness for mass loss calculations. Distributions of remaining spangle were analyzed and a value of 7.6 mils (193 μ) was benchmarked for vertical member coating thickness.

The second variable ruled out was the instrumentation for the thickness measurements because the technologies were identical and within calibration.

The last variable in the study was the method of cleaning the structures. The structure surface cleaning method used in the 2001 survey used a wire brush with 25 strokes horizontally and 25 strokes vertically. The surveys in 2013 and 2017 used a twisted braided wire cup in an angle grinder for cleaning the surface.

Lab analysis on an aged galvanizing surface determined that the cleaning method had little effect on the thickness measurements (see Table 7). This is supported by the values for mean and standard deviation for each cleaning technique.

Table 7 Surface Cleaning Data Comparing Hand Tool and Power Tool Methods

		Wire brush			Angle Grinder		
		Procedure	**Galvanizing (mils)**	**Difference**	**Procedure**	**Galvanizing (mils)**	**Difference**
Base measurement	**Average**		3.62			3.7	
	St.Dev.		0.42			0.45	
1st cleaning	**Average**	25 strokes (side by side)	3.52	0.1	2 passes	**3.4**	**0.3**
	St.Dev.		0.33			**0.3**	
2nd cleaning	**Average**	25 more strokes (up and down)	**3.2**	**0.42**	12 passes	2.98	0.72
	St.Dev.		**0.23**			0.45	

These results led researchers to believe that the variance in corrosion rates with towers in close proximity may be due to Gaussian plume model effects or boundary layers due to topography but not a variance in survey methods.

Model Confidence Levels

Atmospheric models have been developed to forecast for zinc (galvanizing) and steel degradation rates based upon location within the lower Ontario province. Currently these models contain almost 383 structures with a resulting 4.19% margin of error at a 90% confidence level or 4.99% margin of error at a 95% confidence level. Use of this model then significantly lowers the probability of error in selection of structures for a painting or structural repair program.

A production rate of 1,500 structures with a per structure painting cost of $46,500 results in a yearly painting program of $69.75M with a structure selection error of $2.92M at 4.19 % error or $3.48M at 4.99% error.

5 CONCLUSIONS

Converging the galvanizing loss data from all three survey years resulted in a GIS based map that was categorized using the ISO 9223 atmospheric corrosivity levels (see Figure 5-1). Reviewing the category distributions (see Figure 4-5) it became apparent that southern Ontario has a significant number of locations falling within the C4 and C5 category for galvanizing coating loss.

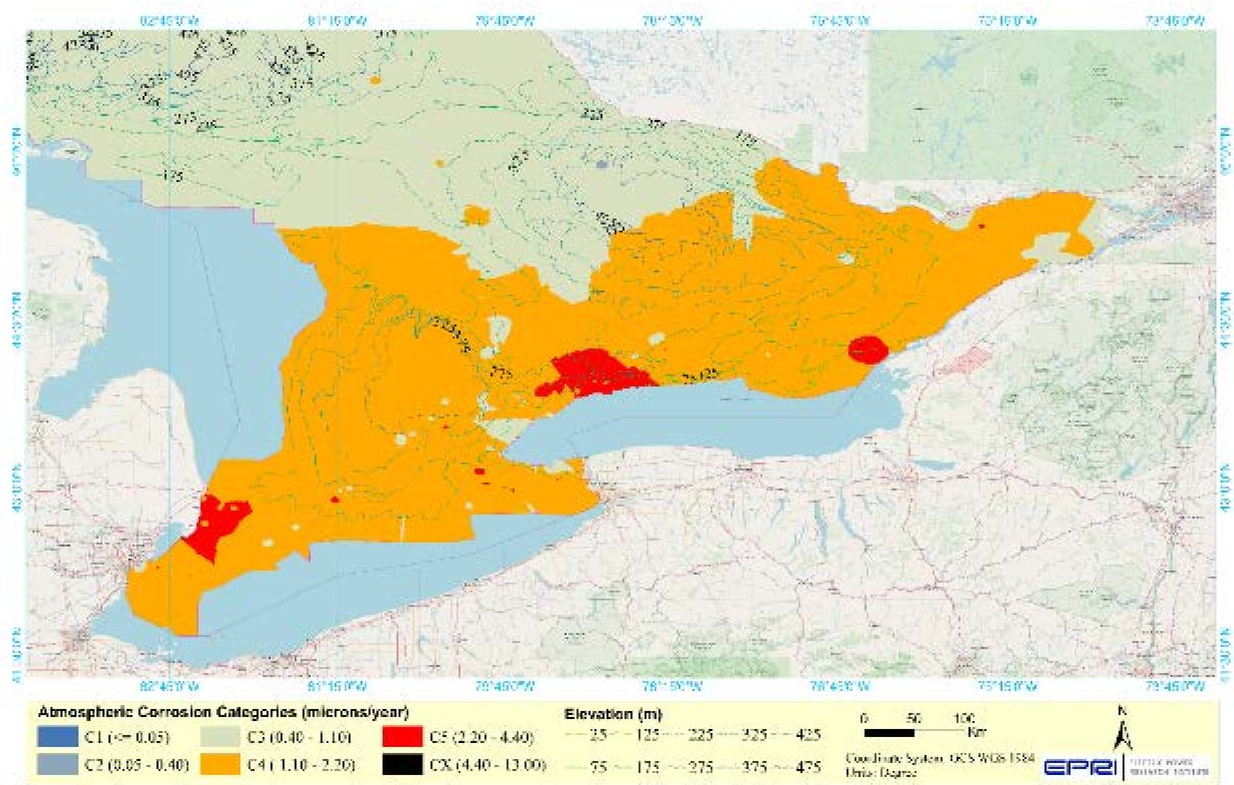

Figure 5-1 Interpolation Map for 2001, 2013 and 2017 Galvanizing Mass Loss (μpy) Surveys (C1 to CX)

Another series of maps were then developed based upon corrosion rate ranges depicting galvanize coating loss (see Figure 5-2). This was completed to allow an analyst more flexibility by defining corrosion rate ranges within each category.

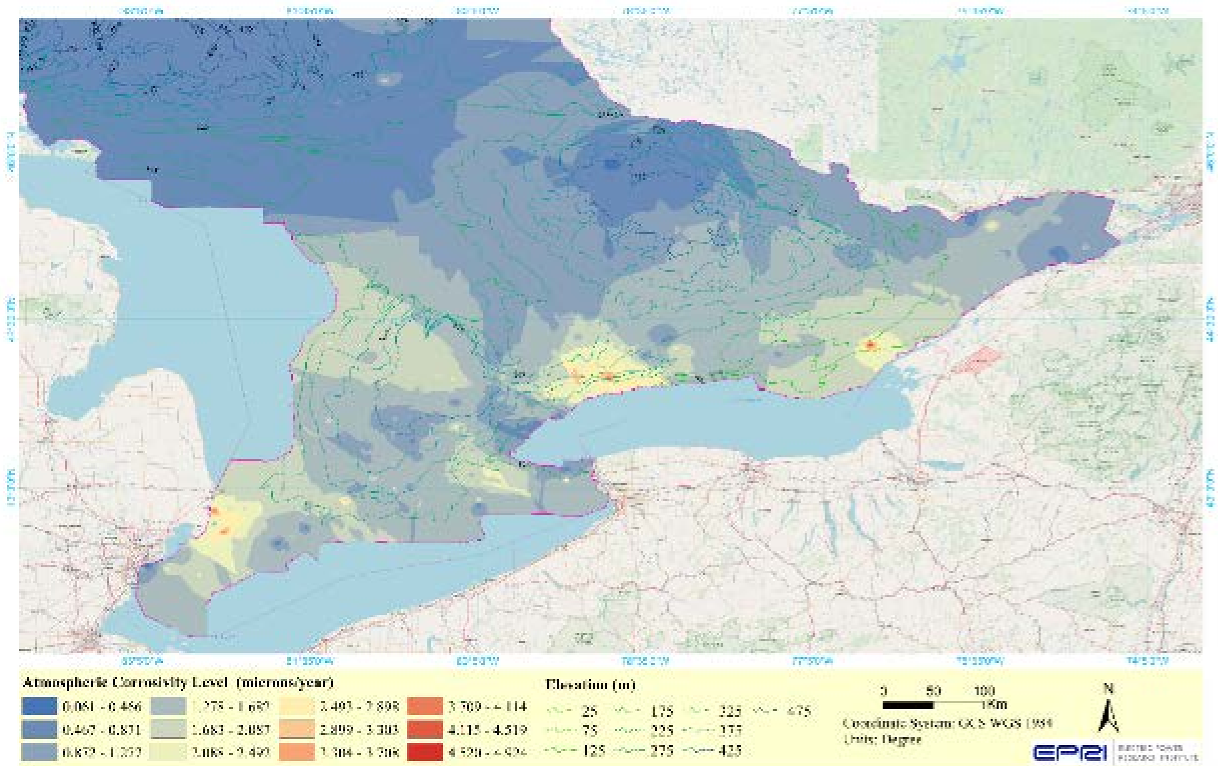

Figure 5-2 Interpolation Map for 2001, 2013 and 2017 Galvanizing Mass Loss Surveys (μpy)

Implementation of New Learning

The use of the galvanizing loss maps may allow a significant savings by targeting circuits with a large volume of structures in a very corrosive environment. With all programs it becomes important to understand levels of risk if that program is deferred and for how long. This may then be accomplished using the steel mass loss maps (see Figure 5-3 and Figure 5-4).

The consequences of delaying the coating program may be understood through the application of the steel corrosion rate map (see Figure 5-4) in an engineering case study to determine when that structure(s) is a reject. Before that calculation is valid the time to exposure must be determined using the condition assessments from the field surveys or modeled using the mass loss rates for the galvanizing.

New galvanizing thicknesses may be divided by the age of the structure to determine remaining galvanizing thickness or until the steel is exposed. Degradation rates of the steel may than be applied until that structure is considered at risk of failure. This would be modeled in a structural engineering case study to determine sectional losses and reject rates.

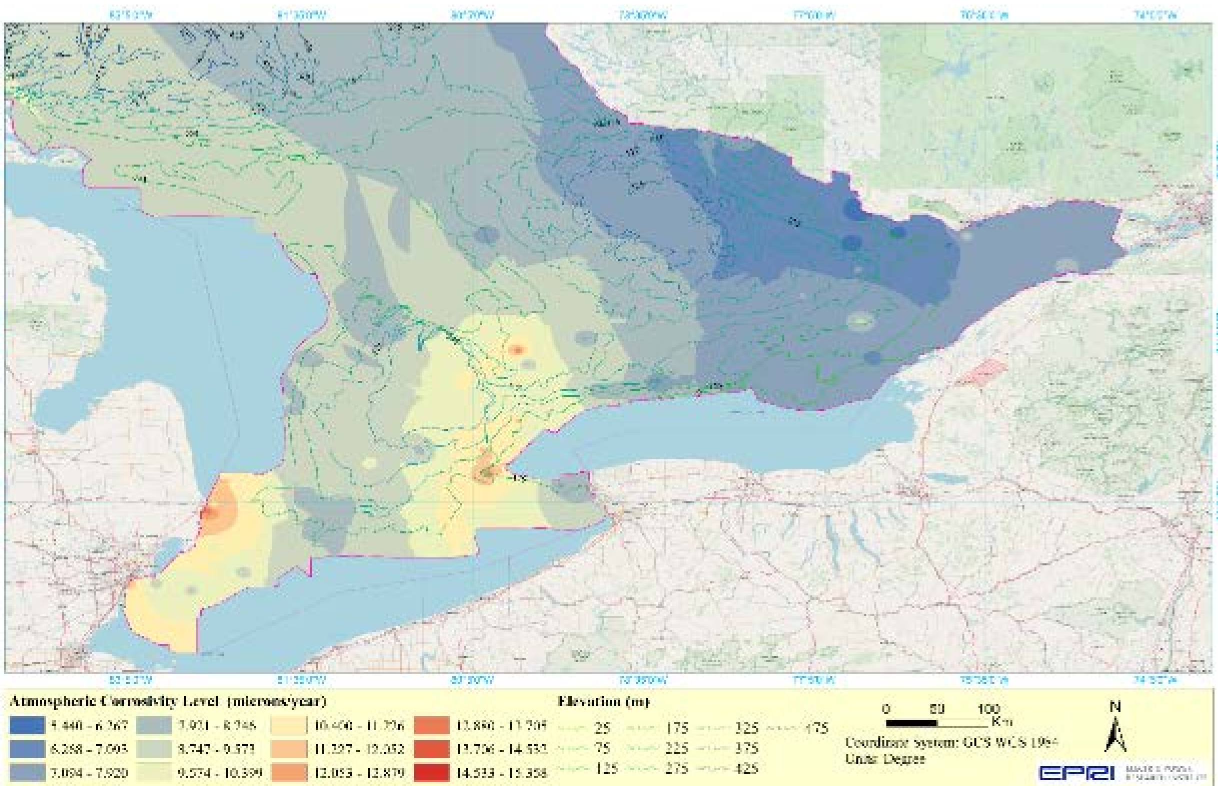

Figure 5-4 Atmospheric Corrosivity Map (μpy) for Steel Exposure

6 FUTURE RESEARCH

Additional field surveys and deployment of additional steel coupons will increase the resolution of the maps and reduce the margin of error in structure selection. A reduction in error of .8% provides a potential savings in structure selection of $560K. Areas where the resolution of the maps will benefit the most are near Sudbury and areas southeast of Sudbury.

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc. (EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.

ACKNOWLEDGMENTS

The Electric Power Research Institute (EPRI) prepared this report.

Principal Investigator
J. Kuffel

This report describes research sponsored by EPRI.

EPRI would like to acknowledge the support of the following organizations: Hydro One

This publication is a corporate document that should be cited in the literature in the following manner:

Polymer Insulator Population Assessment: [Status]. EPRI, Palo Alto, CA: 2018. [Subject].

ABSTRACT

Hydro One is concerned with the condition of their polymer transmission line insulators. At their request, EPRI performed a condition assessment of 87 polymer insulators which were removed from service for the study. The condition of the insulators was evaluated through a series of tests. Findings were made based upon the test results. Those findings were used to formulate recommendations on how Hydro One can minimize reliability and safety risks and costs associated with their transmission line polymer insulator population.

Keywords

Polymer insulator, NCI, Condition assessment

LIST OF TABLES

1
INTRODUCTION

Hydro One has a sizeable population of 230 and 115 kV polymer insulators. A significant portion of the 230 kV installed base is showing signs of deterioration. The deterioration appears due to corona activity on the insulator housing as a result of inadequately controlled electric fields. There have been several failures in the past two years. Two of these failures resulted in line drops.

Hydro One requested EPRI to perform a condition assessment of part of their polymer insulator population to in order to provide Hydro One technical data required to determine if a replacement program is warranted. The study focused on three particular insulator configurations:

- 230 kV suspension with large corona rings
- 230 kV suspension with either small (often referred to as a 'donut') or no corona rings
- 115 kV dead end.

Hydro One removed a total of 87 polymer insulators for analysis. The samples were removed from lattice and from wood pole structures.

It was recognized that locations with significant wetting or contamination would be the optimum environment from which the insulators should be removed. Based upon that, most of the insulators were removed from circuits in Southern Ontario.

2
INSULATOR SAMPLE

A total of 87 polymer insulators were removed from service and provided to EPRI for assessment. Figure 2-1 and Figure 2-2 give a breakdown of the insulators with respect to system voltage and manufacturer.

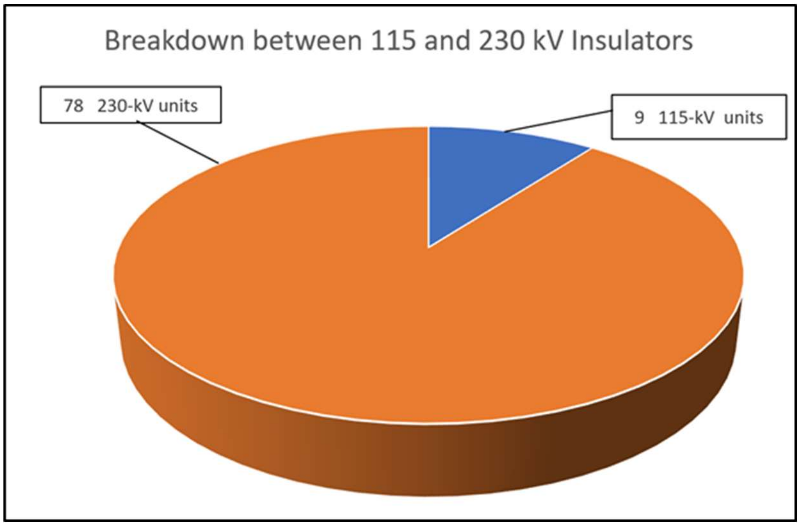

Figure 2-1
Breakdown of the insulator sample according to system voltage

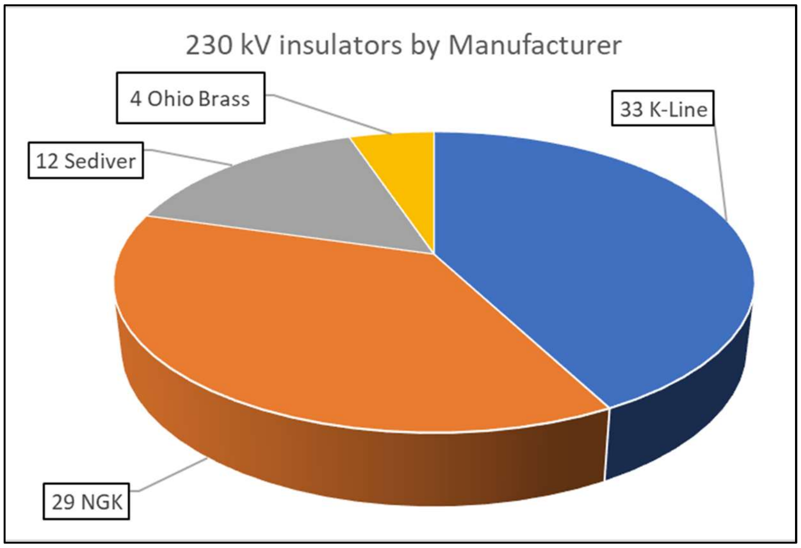

Figure 2-2
Breakdown of 230 kV insulator sample according to manufacturer

Figure 2-3 through Figure 2-5 show the mix of age included in the insulator sample. The K-Line and NGK insulators were stamped with manufacturing date information. The Sediver and OB insulators had no markings and therefore it was not possible to ascertain their age.

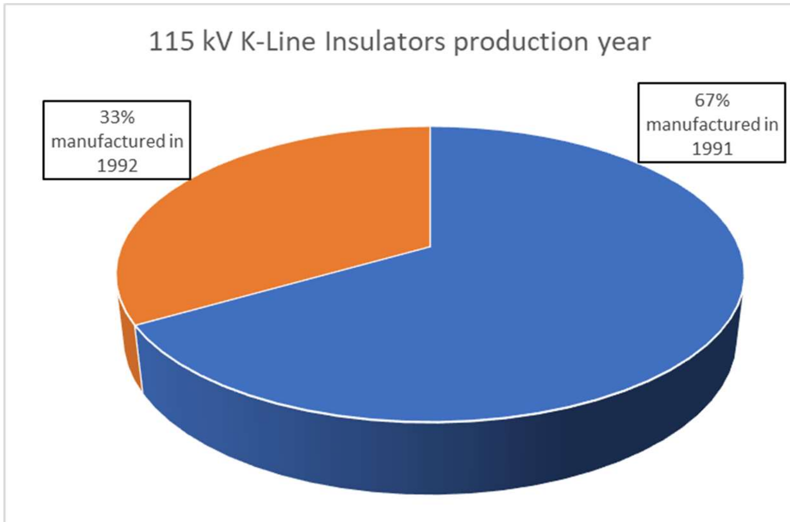

Figure 2-3
Age distribution of the 115 kV K-Line sample insulators (9 units in total)

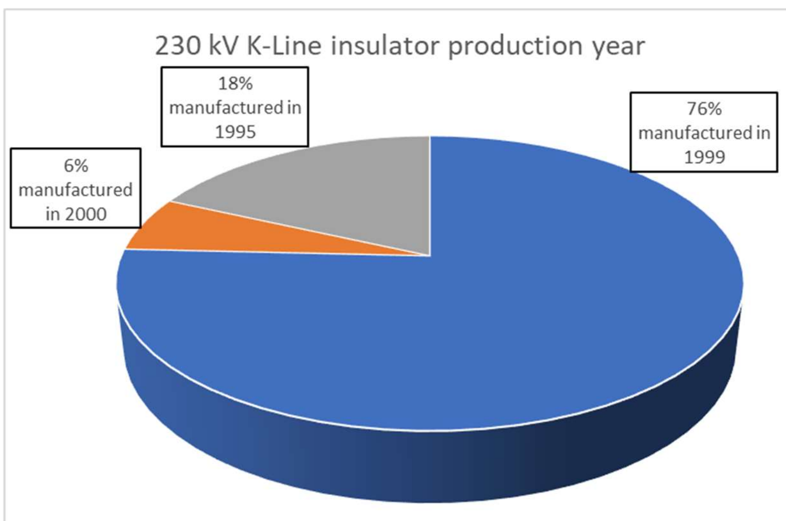

Figure 2-4
Age distribution of the 230 kV K-Line sample insulators (33 units in total)

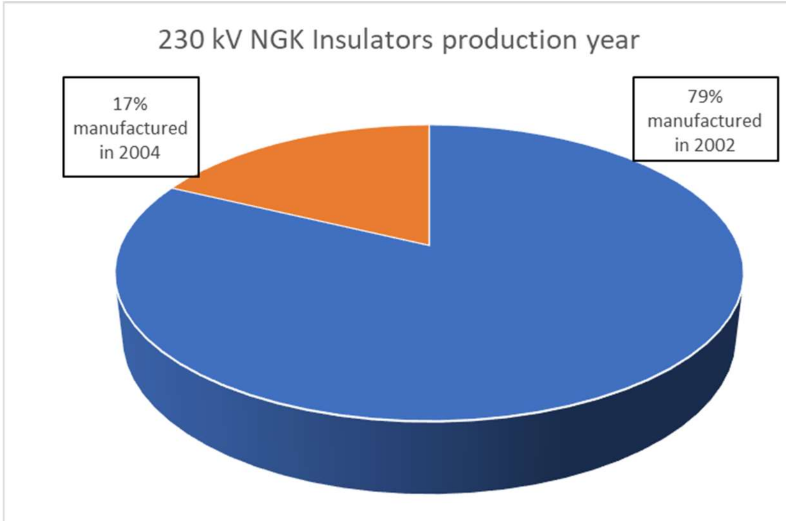

Figure 2-5
Age distribution of the 230 kV NGK sample insulators (29 units in total)

As the above figures show, the 115 kV K-Line insulators had been in service for 25 to 26 years. Eighty-two percent of the 230 kV K-Line insulators had been in service for between 17 and 18 years, while eighteen percent had been in operation for 22 years. The NGK insulators had been installed on the system for between 13 and 15 years.

Some of the removed insulators were fitted with corona rings and others were not. Figure 2-6 shows photographs of the various types of corona rings found on the sample insulators.

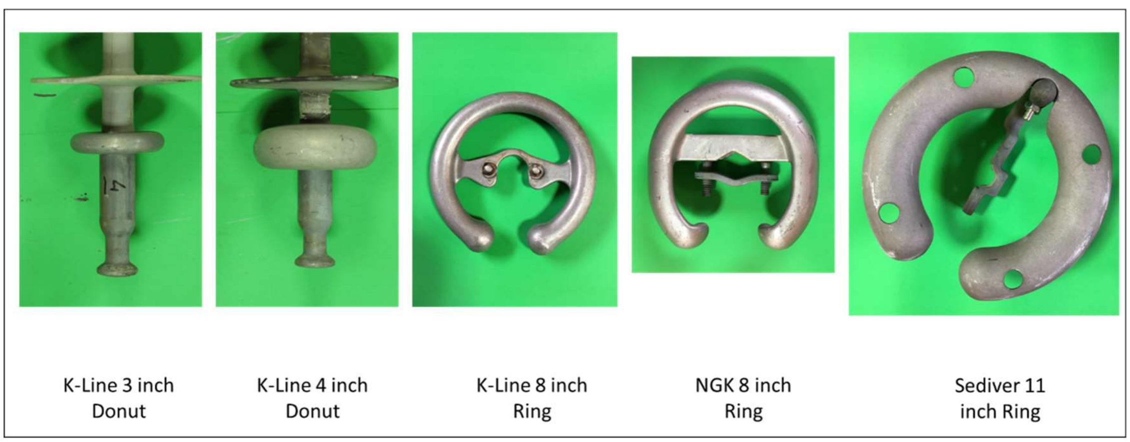

Figure 2-6
Various corona rings present on sample insulators

Details of which insulators were fitted with corona rings and the size of the ring when present are given in Table 2-1.

Table 2-1
Number of Insulators with and without corona rings

Manufacturer	Voltage rating	Total # of units	# of units without corona rings	# of units with corona rings	# of units with				
					K-Line 3 inch donut	K-Line 4 inch donut	K-Line 8 inch ring	NGK 8 inch ring	Sediver 11 inch ring
K-Line	115 kV	9	0	9	9	-	-	-	-
K-Line	230 kV	33	0	33	-	6	27	-	-
NGK	230 kV	29	6	23	-	-	-	23	-
Sediver	230 kV	12	0	12	-	-	-	-	12
Ohio Brass	230 kV	4	4	0	-	-	-	-	-

3
TEST PROGRAM

The insulator assessment included the following tasks:

Visual Inspection

- Each of the insulators was visually inspected and photographed. Any visually evident damage was noted.

Hydrophobicity Assessment

- The hydrophobicity of the polymer material making up the insulator housing was assessed for each insulator using method 3 recommended in IEC 62073, “Guidance on the measurement of wettability of insulator surfaces” [1]. The assessment was done on the shank portions of the insulator housing.

Dye Penetration Testing

- Dye penetration tests were performed on one half of the insulators. The tests were performed in accordance with clause 5.2.2 of CSA 411.4-2010.

Water Vapor Ingress Testing

- Water vapor ingress tests were performed on one half of the insulators.

Moisture Penetration Test of the End-fittings

- The integrity of the end fitting seals was checked for both end-fittings on each insulator. The tests were performed in accordance with clause 5.7.3.2 of CSA 411.4-2010.

4
TEST RESULTS

4.1 Visual Inspection

A visual inspection was performed on each of the insulators. The inspection revealed issues of concern with a number of the units. Several forms of degradation were observed. These included damage associated with flashover and the ensuing power follow current, mechanical damage to sheds such as tearing and breakage, damage to the rubber housing due to excessively high electric fields at the rubber surface, and reduction of hydrophobicity due to electrical discharges on the rubber surface. Each of these issues are addressed in the following sub-sections. Detailed explanations of the significance of each of these visually identifiable issues are provided in EPRI's Field Guide for Visual Inspection of Polymer Insulators [2].

4.1.1 Damage due to Flashover and Power Follow-On Current

Several insulators showed varying degrees of damage due to flashover and the ensuing power arcs. This type of damage is relatively independent of the insulator design and manufacturer since power arc tests are included in the relevant CSA standards to which manufacturers must qualify their products. As such, all of the insulators that had been exposed to power arcs were grouped together. Other issues such as ageing and deterioration of the rubber housings, deterioration of the seals at the triple junction between end-fittings, the fibreglass rod, and the rubber housing, and deterioration of the fibreglass rod are highly dependent upon the manufacturer. For this reason, insulators showing the latter form of deterioration are grouped according to system voltage and manufacturer.

Five of the inspected insulators showed flash marks on the corona rings and/or end fittings due to flashover and power follow current. Two of these were 115 kV units and three were 230 kV. Photographs showing the damage are given in Figure 4-1.

Figure 4-1
Localized damage due to flashover and power arc current

4.1.2 Physical Shed Damage

Eight of the 230 kV K-Line insulators were found to have damaged sheds. The damage took the form of portions of shed being missing, but the damage was limited to the sheds alone. Figure 4-2 shows examples of the observed damage. It is not clear whether this damage was sustained while the insulators were in service or whether they were damaged post removal.

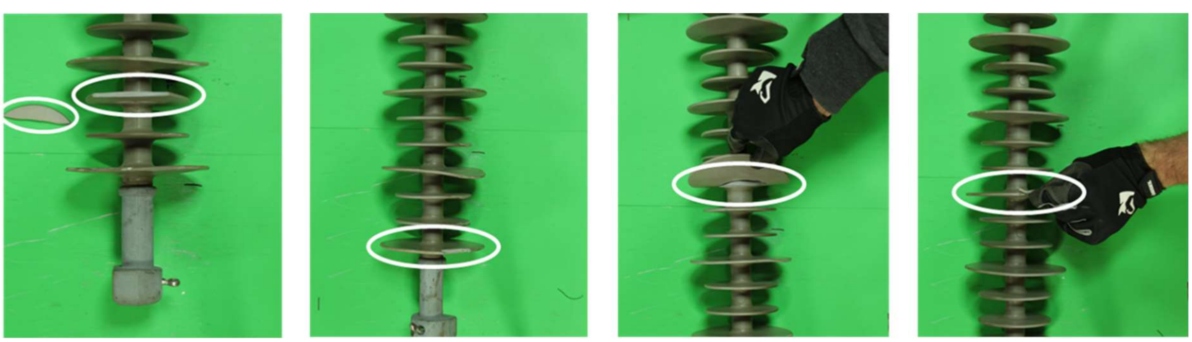

Figure 4-2
Examples of shed damage observed on 230 kV K-Line insulators

There were no instances of damage to more than one shed on any one insulator. Furthermore, there was no evidence of damage to the rubber housing on the shank of those insulators. Based upon this, the shed damage is not considered critical to the insulators' service performance or longevity. The nature of the damage suggests that, at least in some cases, the rubber may be becoming somewhat brittle. The chemical formulation of the rubber housing is proprietary to the manufacturers and as such K-Line should be contacted and asked for their input.

4.1.3 Corona Discharge Induced Damage

The most significant visual observations comprised deterioration of the rubber housing on the insulator shank near the line end, and deterioration of the end fitting seals at the triple junction. This type of damage is known to be manifested due to the presence of unacceptably high electric fields on the surface of the rubber housing at the insulator line end [3].

Extensive visible deterioration of the rubber (to varying degrees) attributable to excessive electric fields was present on all K-Line 230 kV insulators with 4-inch donut corona rings and all 230 kV NGK insulators installed without corona rings. In addition to this, a number of NGK insulators fitted with 8-inch corona rings showed visually observable rubber deterioration in the line-end areas of the housing and the triple junction seals. The 230 kV Ohio Brass insulators, all of which were installed with no corona rings also showed significant rubber and end-fitting seal damage due to excessively high electric fields on the rubber surface at the line end of the insulators. There was little evidence of damage or deterioration on any of the 230 kV Sediver insulators which were all installed with 11-inch corona rings. Inspection of the 230 kV K-Line insulators fitted with 8-inch corona rings showed no visual damage. The nine 115 kV K-Line dead-end insulators installed with 3-inch donut corona rings showed no significant visually observable deterioration of the rubber housing and seal areas other than unit 85 which had been exposed to a flashover and power follow current.

4.1.3.1 230 kV K-Line insulators with 4-inch donut corona rings

Figure 4-3 through Figure 4-5 show sample photographs of damage to the line-end rubber housing and the line-end fitting seals on the 230 kV K-Line insulators installed with the 4-inch donut corona ring, the 230 kV NGK insulators installed with no corona rings, and the 230 kV Ohio Brass insulators installed with no corona rings.

Figure 4-3 shows the spectrum of damage to the line end of 230 kV K-Line insulators installed with the 4-inch donut corona rings (Units 79 to 84).

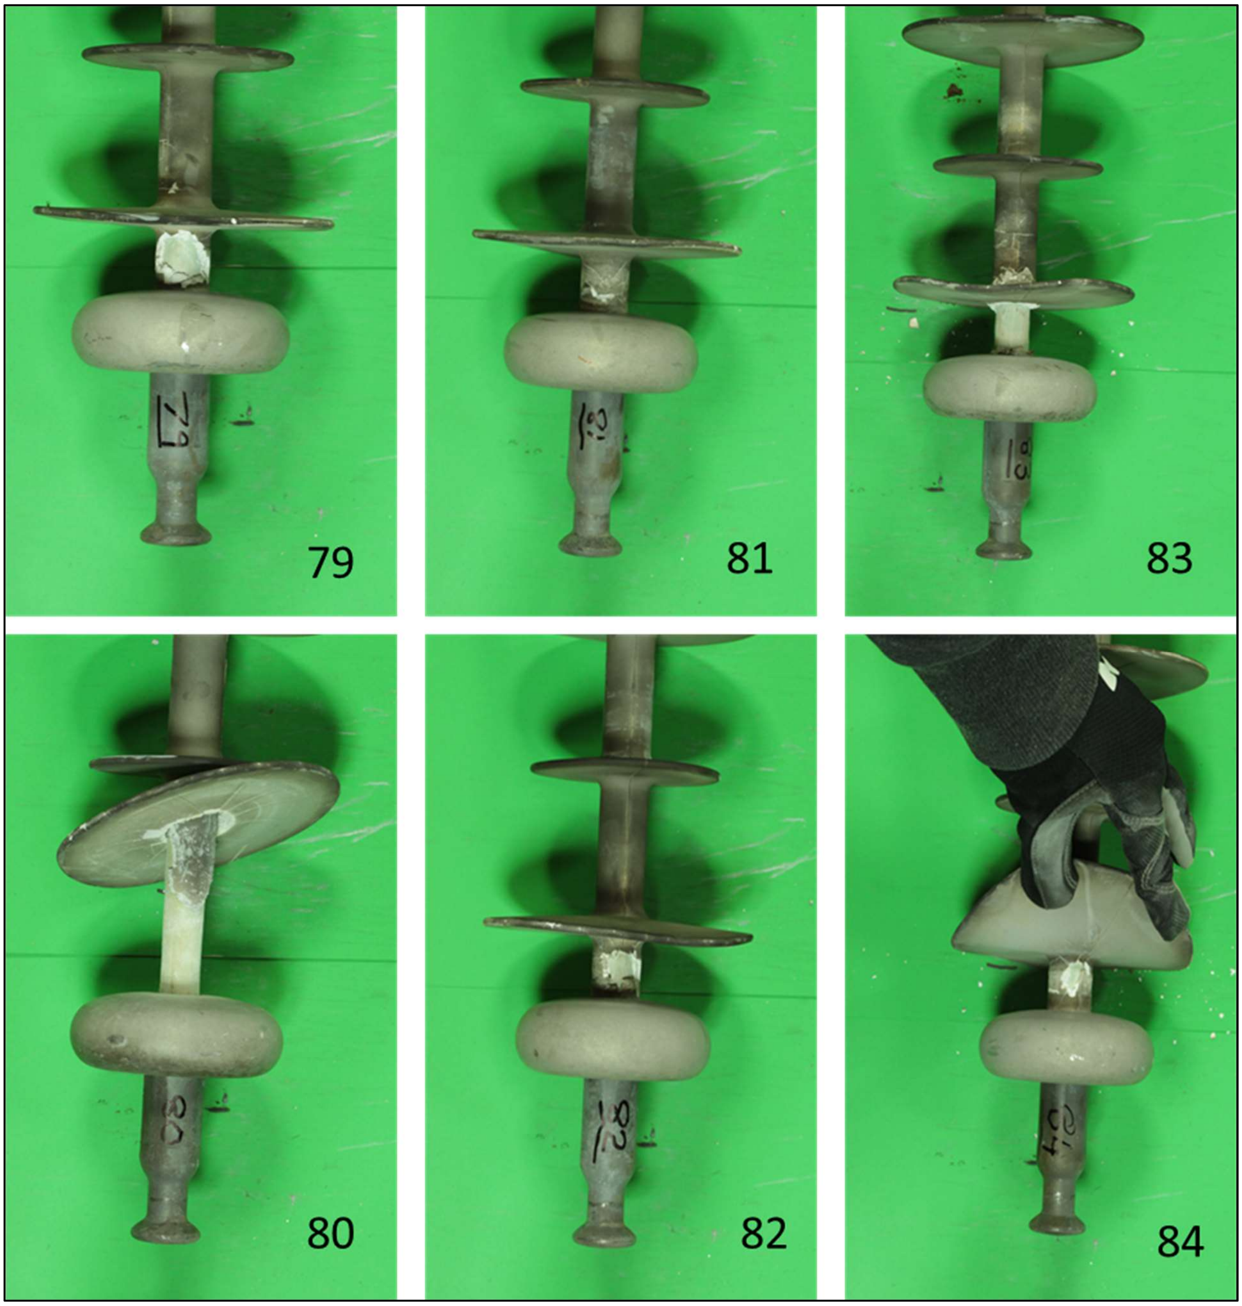

Figure 4-3
Corona damage observed on all six of the removed 230 K-Line Insulators fitted with small donut corona rings

The damage shown in Figure 4-3 spans from very serious rubber damage leading to the beginnings of rod exposure on insulator 81 to catastrophic rubber erosion, line-end shed cracking, line-end shed separation, and full rod exposure on insulator 80. Damage such as this has been undisputedly shown to result from inadequate grading of the electric field at the insulator line end. Simply put, the donut corona ring utilized on these 22-year-old insulators is too small to provide adequate electric field grading at the insulators' line end. The insulators shown in Figure 4-3 are of a design that was discontinued in the 1990s. All six of these early design insulators included in the sample showed damage sufficient to recommend their immediate removal from service. In fact, Hydro One experienced a line drop in 2016 due to the failure of this type of insulator. The details of the investigation are provided in Appendix A. The newer K-Line designs incorporate 8-inch diameter corona rings which provide far improved electric field grading.

4.1.3.2 230 kV NGK insulators with no corona rings

Figure 4-4 illustrates the varying degrees of damage to the line-end rubber housing and the secondary seal on 230 kV NGK insulators installed without any corona rings.

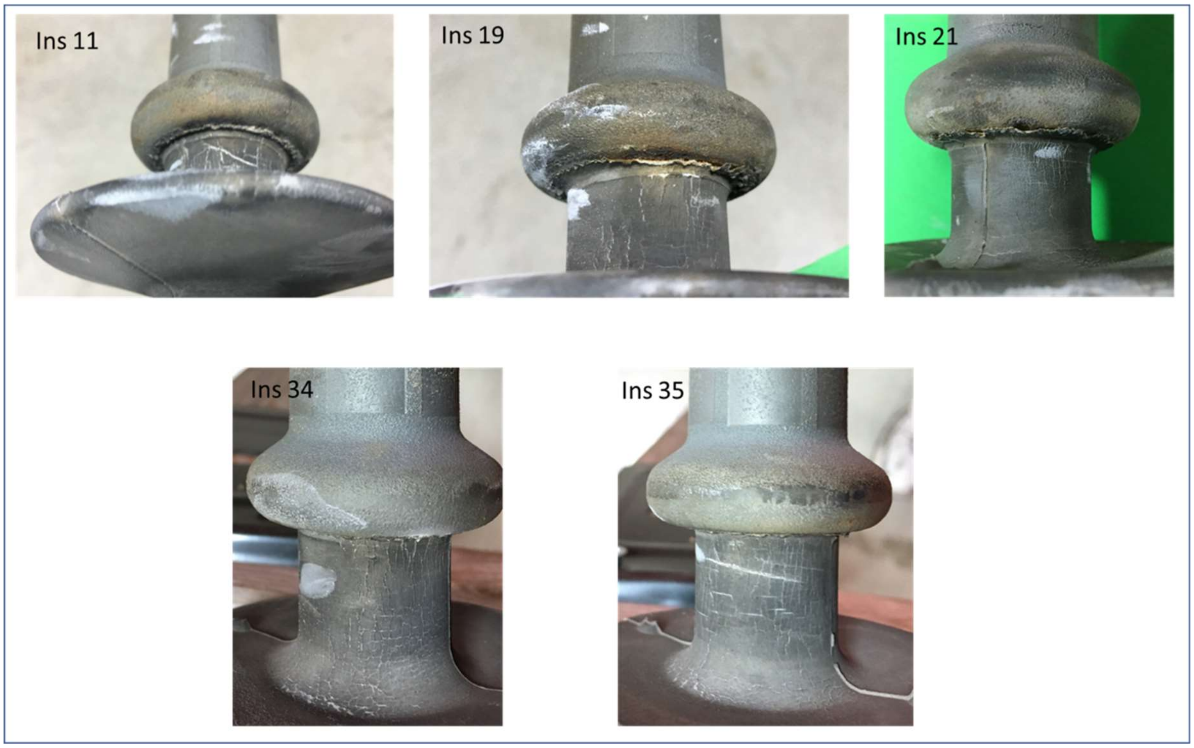

Figure 4-4
Corona damage observed on 230 NGK Insulators installed without corona rings

The cracking, erosion, and degradation of the rubber housing at the insulators' line end and the deterioration of the seal at the insulators' triple junction shown in Figure 4-4 are a direct result of the lack of adequate electric field grading. As is now commonly understood, polymer insulators installed at 230 kV voltage levels require corona rings which are designed so as to maintain an acceptably low electric field on the surface of the insulator rubber housing. The cracking observed on these units is similar to that observed on failed units analysed by EPRI from other utilities as well as a unit that failed in EPRI's 230kV accelerated aging test [4].

4.1.3.3 230 kV Ohio Brass insulators installed with no corona rings

The four Ohio Brass Hi-Lite insulators included in the sample were older units constructed using single sheds/shank units slid on to a fiberglass rod together with a silicone grease. The seals between the sheds are maintained by compression. This is often called the "top hat design" and these insulators are known to suffer from splitting of the shank as they age [2]. All four were installed without corona rings. They suffered deterioration of the rubber at the line end of the insulators and damage to the line-end fitting triple junction seal. Figure 4-5 shows the degree of damage. Note the small areas of corrosion on the end fitting. These are often the location of prolonged corona activity.

Figure 4-5
Damage to OB insulator line-end rubber and seal observed with no corona rings

The understanding of the importance of electric field grading when utilizing polymer insulators on transmission systems has become well recognized over the past 20 years and corona ring application guidelines have been provided by EPRI as well as by most of the major polymer insulator manufacturers supplying the North American market. These guidelines are summarized in an EPRI publication which provides explanations and guidance on the need for and on the design requirements of corona rings for transmission class polymer insulators [3].

4.1.3.4 230 kV NGK insulators with 8-inch corona rings

The design of the 8-inch corona ring fitted on the 230 kV NGK insulators has been shown inadequate both in the EPRI ageing chamber tests [4] and EPRI investigations into in-service failures [see Appendix B]. While the ring itself performs well, the shape of the ring's mounting bracket results in an excessively high electric field on the insulator rubber housing just above the line-end fitting. Figure 4-6 illustrates the issue.

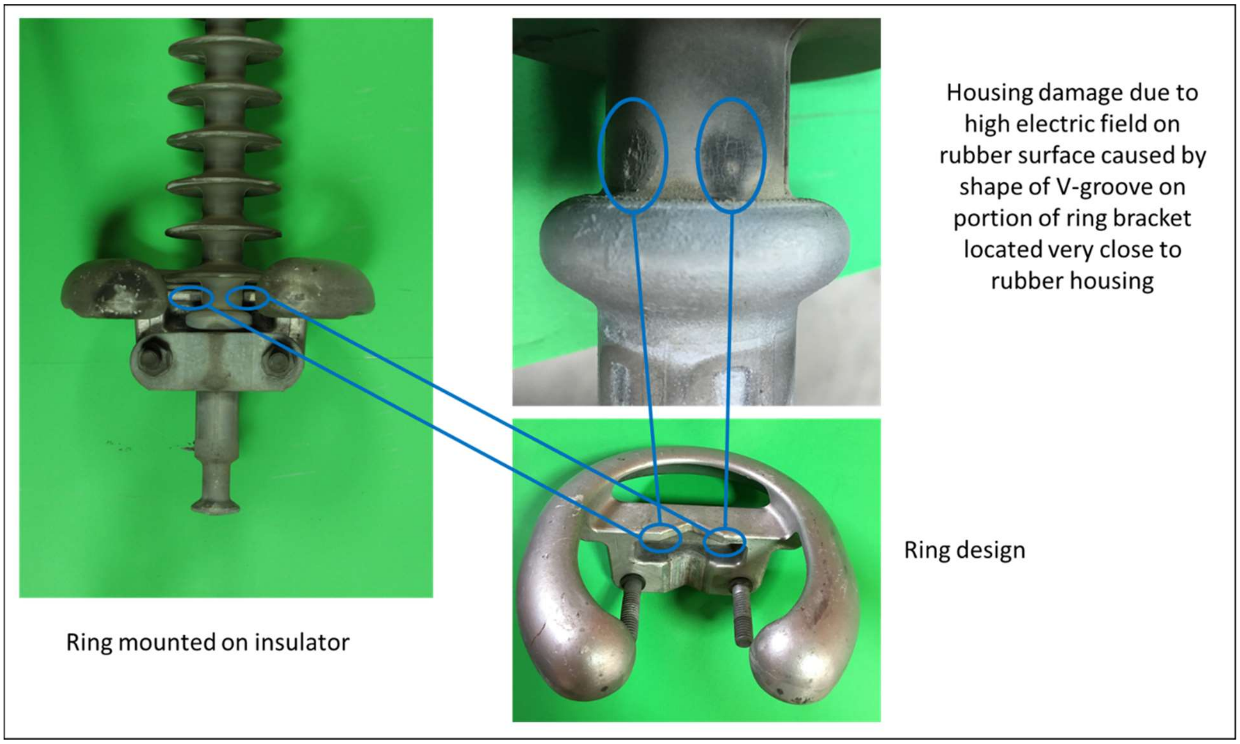

Figure 4-6
Damage to 230 kV NGK insulator due to corona ring mounting bracket

The detailed mechanism of the rubber damage due to the ring design is explained in the EPRI document given as Appendix B.

Visual inspection of the line-end housing on the 230 kV NGK insulators with the 8-inch corona rings removed from service shows a rather wide range of damage. Some insulators showed virtually no damage at all, while others showed significant rubber erosion. This same effect has been observed by EPRI on insulators removed from the field and in the EPRI aging chamber. It has been attributed to small differences in the rubber consistency and moulding process between different insulators. The range of damage observed is shown in Figure 4-7.

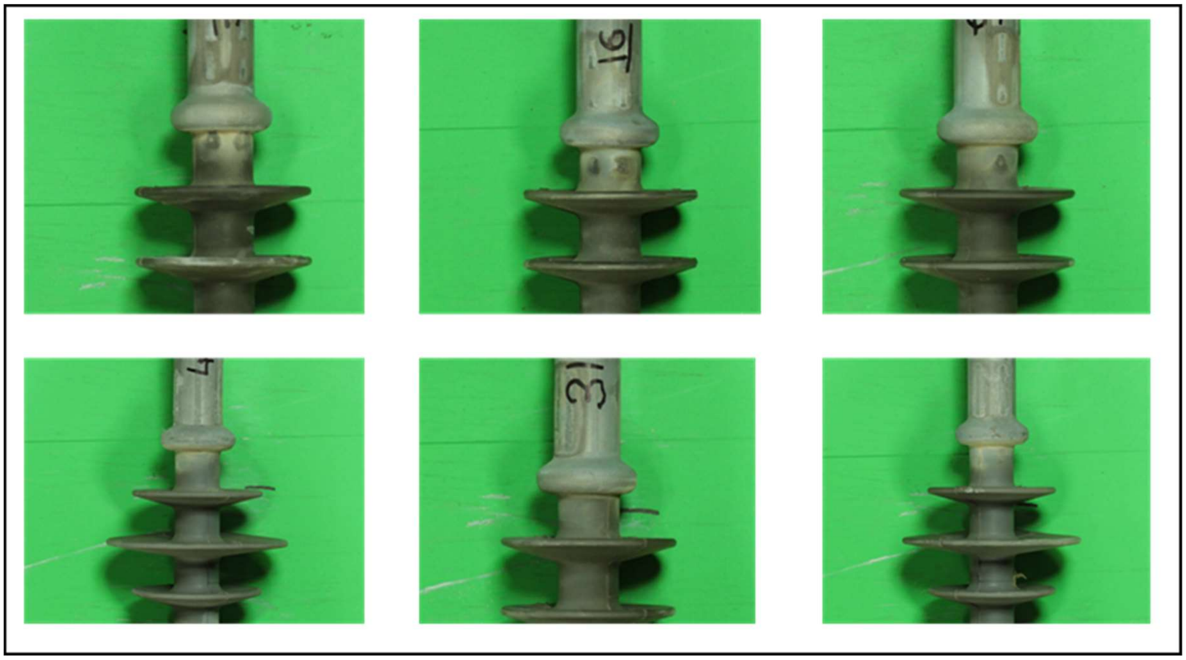

Figure 4-7
Range of damage observed on NGK insulators due to 8-inch corona ring design

As can be seen from Figure 4-7, the deterioration due to the use of the poorly designed corona ring varied across the insulator sample.

4.2 Hydrophobicity Tests

Hydrophobicity testing was performed in accordance with Method C of IEC TS62073, Guidance on the Measurement of Wettability of Insulator Surfaces [1]. The hydrophobicity of the shank on each of the sample insulators was measured in three locations: at the line end, in the middle of the insulator, and at the ground end. The hydrophobicity was quantified using the wettability classifications given in IEC TS62073. The wettability classifications for the various insulators are given in Figure 4-8 through Figure 4-12, where 1 indicates a high level of Hydrophobicity and 7 a low level.

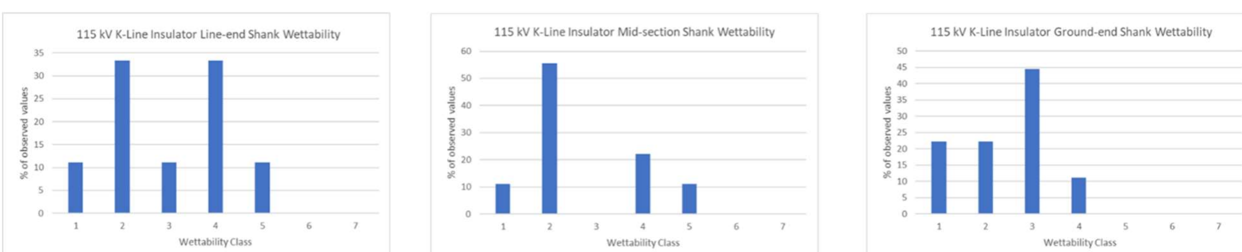

Figure 4-8
Hydrophobicity of 115 kV K-Line insulators

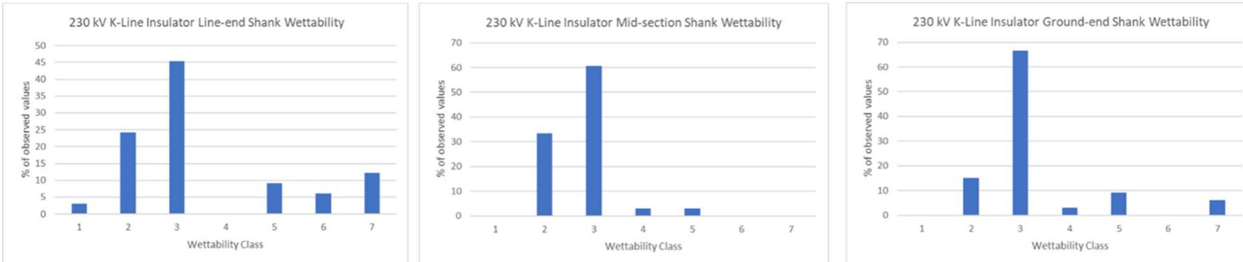

Figure 4-9
Hydrophobicity of 230 kV K-Line insulators

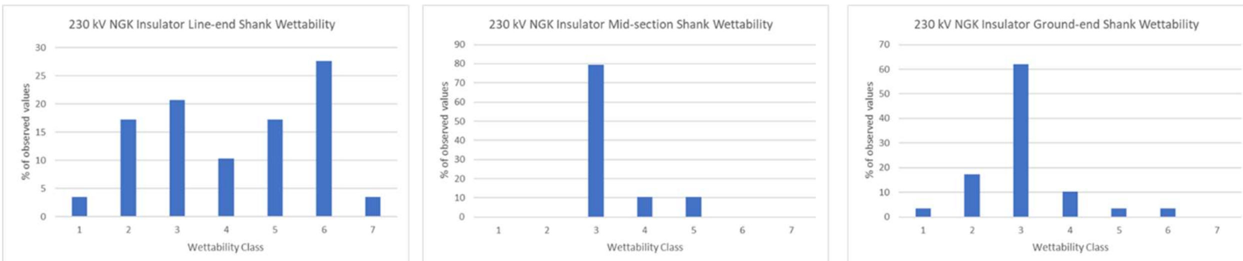

Figure 4-10
Hydrophobicity of 230 kV NGK insulators

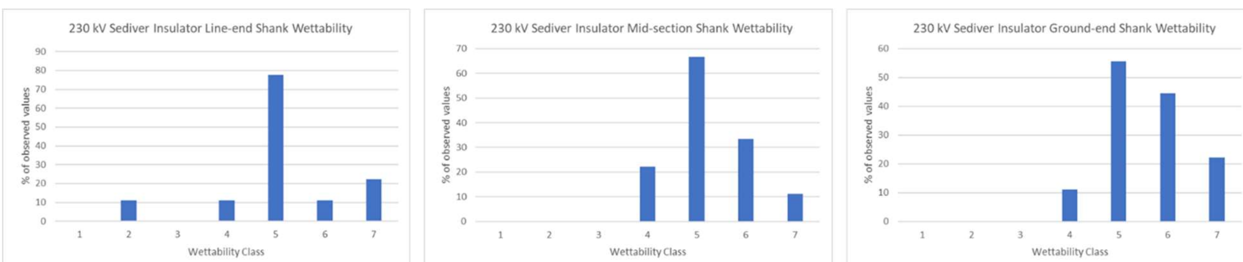

Figure 4-11
Hydrophobicity of 230 kV Sediver insulators

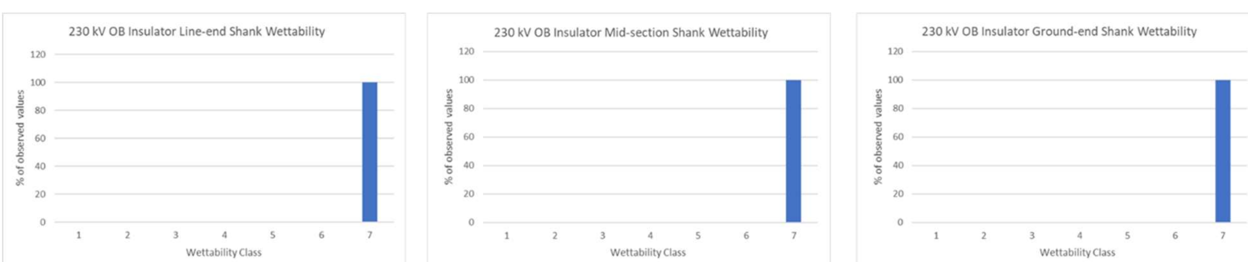

Figure 4-12
Hydrophobicity of 230 kV Ohio Brass insulators

Given their age, the silicone insulators (115 kV K-Line, 230 kV K-Line, and 230 kV NGK) have reasonable good hydrophobicity (Figure 4-8. Figure 4-9, and Figure 4-10) given their time in service. Insulators which had deteriorated rubber housings gave higher wettability readings. As expected, the non-silicone insulators showed higher levels of wettability (Figure 4-11 and Figure 4-12). The Sediver units were somewhat hydrophobic while the Ohio Brass insulators were completely hydrophilic.

4.3 Dye Penetration Test

Dye penetration testing is normally performed as a part of insulator qualification under CSA, ANSI, and IEC standards. It is intended to ensure that moisture is not able to wick vertically through the fiberglass rod or between the rubber housing and the fiberglass rod. In essence, the test checks the integrity of the fiberglass rod and the bond between the outer surface of the rod and the rubber housing. Forty-one of the sample insulators were subjected to dye penetration testing.

The dye penetration tests were performed in accordance with clause 5.4.1.2 of CSA 411.4-2010. Ten samples were cut from each tested insulator. The cuts were made at 90° to the axis of the core with a diamond-coated circular saw blade under running water. The cut surfaces were then smoothed by fine abrasive cloth and cleaned. The lengths of the samples were within the range of 10 mm ± 0.5 mm. The housing material was not removed from the samples.

The specimens were placed (fibres vertical) on a layer of steel balls of uniform diameter (1 to 2 mm) in a tray. A 1% methyl or ethyl alcohol solution of fuchsine dye was poured into the vessel, until the level of the dye was 2 to 3 mm above the balls. The specimens remained in place for a period of 15 mins. The pass requirement for the test is that there is no evidence of dye on the upper surface of the specimens after they have been in place for a period of 15 mins.

Four insulators failed to pass the test requirements. The details of the failures are given in Table 4-1.

Table 4-1
Insulators failing the dye penetration test

Insulator #	Voltage	Manufacturer	Manufacture Date	Comment
21	230 kV	NGK	2020	Samples 6 & 7 showed dye coming up through rod after 4 mins
24	230 kV	Sediver	Unknown	4 of 10 samples showed dye coming up through interface immediately
43	230 kV	K-Line	1999	1 of 10 samples showed dye coming up through the center of the rod
87	115 kV	K-Line	1992	3 of 10 samples showed dye coming up through a crack in the rod

4.4 Water Vapor Ingress Testing

Forty-four insulators were subjected to water vapor ingress testing. The test is intended to check the bonding between the fiberglass rod and the rubber housing. It is recognized that water vapor can penetrate through the silicone rubber housing of an insulator. In order to ensure that any such water vapor does not condense between the housing and the fiberglass rod, the housing is bonded to the rod. If the bond is poor or defective in some other fashion, moisture will settle at the housing-rod interface.

The test comprised conditioning the insulators for a 7-day period in a chamber with relative humidity above 90% and a temperature of 20 ºC. Following the seven-day conditioning period, the insulators were removed from the chamber and subjected to a 60 Hz withstand test. The test voltage applied across the insulators was 100 kV rms for the 115 kV insulators and 200 kV for the 230 kV insulators. The shank temperature of the insulator under test was measured at the ends and middle sections of the insulator immediately prior to applying the voltage. The voltage was then applied for a duration of 15 mins after which the insulator was de-energized and the temperature measurement repeated. In order to pass the test, the insulator had to support the applied voltage for the 15 min period without breakdown or supply overcurrent trip, and the temperature increase at any location along the insulator shank had to be less than 10 ºC during the 15 min hi-pot test. Failure to meet these requirements meant that water was present at the housing/rod interface signifying a defective housing/rod bond.

Seven of the forty-four insulators tested failed to meet the pass requirements. All seven were 230 kV K-Line insulators. The details of the insulators failing the test are given in Table 4-2.

Table 4-2
Insulators failing the water vapor ingress test

Insulator #	Voltage	Manufacturer	Manufacture Date	Visual Comment
53	230	K-Line	1999-11-25	
55	230	K-Line	1999-11-25	Power arc damage
58	230	K-Line	1999-11-25	
61	230	K-Line	1999-11-25	
78	230	K-Line	2000-03-02	
81	230	K-Line	1995-11-23	Significant Rubber Cracking at Line End. Donut corona ring.
84	230	K-Line	1995-11-23	Line End Shed Severe Cracking. Rod exposed at line end. 4 in donut ring

Examination of the data in Table 4-2 shows that of the 7 insulators which failed the test, 2 had significant rubber cracking at the line end housing, with one of these two showing exposed rod. One of the of the failed insulators had been exposed to a flashover and power arc. It is recognized that these 3 insulators had or may have had compromised sealing systems. This leaves 4 insulators (all of which had 8-inch corona rings) which failed the test with no mitigating circumstances. All 7 of the insulators identified in Table 4-2 were quarantined and will be subjected to further tests intended to identify the root cause of failure.

4.5 Moisture Penetration Test of the End-fittings

All of the insulators with the exception of those failing the water vapor ingress test were subjected to end-fitting moisture penetration tests. This test is described in clause 5.7.3.2 of CSA 411.4-2010.

The end fitting moisture penetration test was performed as follows:

- Both ends of each insulator were cut from the insulator length approximately 20 cm above the metal end fittings.
- Each insulator end was submerged to a depth of at least 50 mm above the end fitting in dye
- composed of 1 g of fuchsine in 100 g of methanol for 15 min.
- At the end of the 15 min period, each insulator end was removed from the solution and wiped dry.
- The end fittings were removed from the fibreglass rod and visually examined for evidence of dye penetration through the end-fitting seal.

Evidence of dye on the core rod or interface constituted failure of the insulator to pass the test.

All but 3 of the insulators (insulators 5, 80, and 87) passed the end-fitting moisture penetration test. Insulators 5 and 87 are 115 kV K-Line insulators which have been in service since 1991 and 1992 respectively. Insulator 80 is a 230 kV K-Line unit which utilized a 4-inch donut corona ring and showed extensive line-end rubber housing erosion and had a 4-inch length of fiberglass rod exposed from the top of the end fitting up.

The moisture penetration tests confirmed the visual observation that the secondary seal at the line-end fittings of a number of the NGK insulators installed without corona rings was compromised although experience of large quantities of NGK units removed from the field by EPRI has indicated that this not a significant issue. Figure 4-13 shows an example of this.

Figure 4-13
Dye entering the end fitting through a compromised secondary seal but not reaching the fiberglass rod

As the figure shows, the dye penetrated into the end-fitting through the secondary internal seal. The primary seal remained sound preventing the dye from reaching the fiberglass rod. This was observed on a significant number of the NGK insulators installed without corona rings but not on NGK insulators installed with the 8-inch corona rings.

5 ASSESSMENT OUTCOME

The key findings of the assessment are as follows:

Visual inspection showed that:

- The 230 kV K-Line insulators with the 4-inch donut corona ring have an extremely high likelihood of electrical and or mechanical failure due inadequate control of the electric field on the surface of the rubber housing at the line end. The rubber housing at the line end of these insulators has been severely eroded leading to exposure of the fiberglass rod. Such exposure of the rod will result in either mechanical or electrical failure with a high probability of the insulator parting and causing a conductor drop.
- The 230 kV NGK insulators installed without corona rings are showing signs of serious deterioration of the line-end rubber housing and deterioration of the secondary seal. As such, they are considered to have a high risk of failure.
- The 230 kV NGK insulators installed with 8-inch corona rings are undergoing rubber housing damage at the line end due to the poor design of the mounting portion of the ring. Currently this deterioration does not appear overly serious, but it is not known how quickly the housing deterioration will progress. In the EPRI aging chamber and at one EPRI member utility site this deterioration did result in eventual failure.
- The 230 kV Ohio Brass insulators installed without corona rings are showing rubber and seal deterioration at their line-end fittings. However, in EPRI's experience, the risk of failure can be significantly mitigated by retrofitting corona rings.
- The 230 kV Sediver insulators (all equipped with 11-inch corona rings) are not showing any significant external deterioration
- The 230 kV K-Line insulators installed with 8-inch corona rings do not show any significant signs of deterioration.
- The 115 kV K-Line dead-end insulators do not show any significant visually observable ageing even though they have been in service for 27 years,

Hydrophobicity testing showed that:

- The silicone insulators which have not been damaged due to excessive fields on the rubber surface remain hydrophobic.
- The non-silicone insulators show, as expected, a low degree of hydrophobicity.

Dye penetration testing showed that:

- Each of the insulator groups with the exception of the Ohio Brass insulators had a single insulator unable to meet the dye penetration test requirements.

Water vapor ingress testing showed that:

- Seven 230 kV K-Line insulators exhibited low resistance along their length after humidity conditioning. Of these seven, three had damage from power arcs and housing erosion which may explain their failure. The remaining four (all of which had 8-inch corona rings) will be further examined to determine the root cause of failure.

End-fitting moisture penetration tests showed that:

- All but three insulators passed the test. Of the failing three units, two have been in service for 26 and 27 years, and the third had major line-end rubber erosion and rod exposure.

6 RECOMMENDATIONS

The following recommendations are made based on the assessment outcome. They are listed in order of importance:

All 230 kV K-Line insulators fitted with 4-inch donut corona rings should be removed from service as soon as possible since they pose a proven risk of immediate failure.

All the 230 kV NGK insulators installed without corona rings should be removed from service as they are considered to be at high risk of failure.

All the 230 kV Ohio Brass insulators installed without corona rings should be removed from service.

The 230 kV NGK insulators fitted with 8-inch corona rings should be monitored for continuing degradation by removing samples periodically for inspection.

The seven 230 kV K-Line insulators which failed the water vapor ingress test should be subjected to additional testing followed by dissection to quantify the degree of concern which should be associated with their failing the water vapor ingress test. This type of issue is generally associated with poor bonding between the housing and the rod and is often a batch problem. Until the issue is understood, these insulators should not be maintained live without first checking their integrity with the EPRI developed insulator tester.

A

FAILURE INVESTIGATION OF 230 KV K-LINE INSULATOR WITH SMALL DONUT CORONA RING

Introduction

Hydro One experienced a conductor drop due to the mechanical failure of a K-Line 230 kV suspension insulator. The failure occurred in October of 2016 on tower number 382 of circuit C28C. The failed insulator and the two sister insulators from the same tower were removed and provided to EPRI for inspection. This report summarizes the findings of the insulator examination and provides recommendations based on the findings.

Insulator Examination

Three 230 kV insulators manufactured by K-Line Insulator Company were provided to EPRI for visual examination. The three insulators had been removed from tower number 382 of circuit C28C following the mechanical failure of one of the units.

A photograph of the three insulator is shown in Figure A-1.

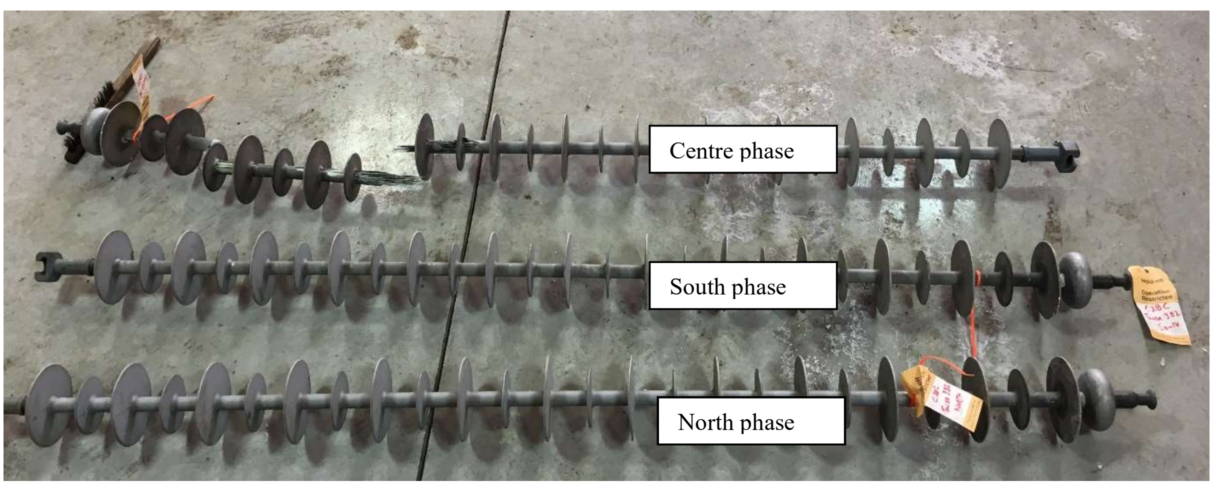

Figure A-1
Insulators provided for inspection

As shown in the photograph, the insulators were equipped with small corona rings at their line ends. The centre phase insulator which had failed mechanically in two locations along its length was severely damaged. The rubber housing was severely eroded and the exposed rod showed extensive tracking due to discharge activity along a significant portion of its length. The extent of the damage is illustrated in the photograph given in Figure A-2. Close ups of the three sections of the failed centre phase insulator are shown in Figure A-3.

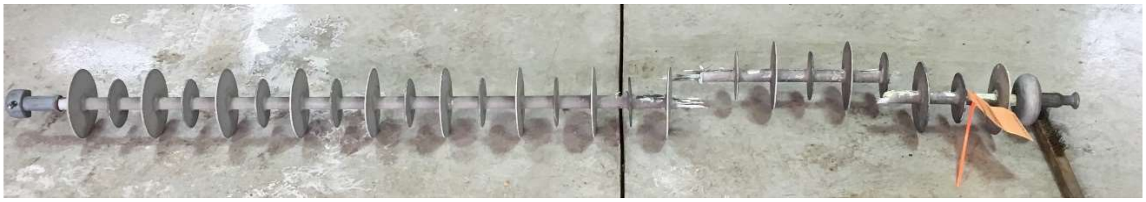

Figure A-2
Failed center phase insulator

Figure A-3
Close up views of the portions of the center phase insulator

Figure A-4 and Figure A-5 show the south and north phase insulators respectively.

Figure A-4

Figure 4: North phase insulator

Figure A-5
South phase insulator

The south and north phase insulators showed varying degrees of erosion of the rubber housing at their line ends but no visually apparent damage in any other areas. The housing erosion present on the south and north phase insulators is shown in Figure A-6 and Figure A-7 respectively.

Figure 6 shows the extent of housing erosion and rod exposure as seen by rotating the south phase insulator along its axis.

Figure A-6
Housing erosion and rod exposure present on the line-end of the south phase insulator

Figure 7 shows the extent of housing erosion as seen by rotating the south phase insulator along its axis.

Figure A-7
Housing erosion present on the line-end of the north phase insulator

Findings and Recommendations

The center phase insulator failed mechanically due to erosion of the fiberglass rod. The failure was initiated due to inadequate grading of the electric rod at the insulator's line end. Corona discharges on the surface of the rubber housing at the insulator line-end eroded the housing. This lead to exposure of the fiberglass rod and subsequent tracking and burning along the section of rod which had been exposed. In parallel with this, the fact that the rod was no longer sealed from external moisture ingress allowed moisture to penetrate the rod up through its length making the rod partially conductive through tracking. The tracking weakened the rod to the point that the insulator separated resulting in a conductor drop. The sister insulator was damaged and if left in service would have deteriorated to the point of failure through the same mechanism.

It is recommended that any of these insulators be removed from service due to the almost certain probability of catastrophic mechanical failure.

NGK Failure – Engagement with Manufacturer

- Proposal accepted by NGK:
  - NGK viewed insulator on 20th September
  - NGK provided information and images of failure
  - NGK provided aging and discharge images
  - Information was provided on Aging Test
  - NGK to provide a list of tests that they would suggest Task Force Meeting
    - Document received prior to TF meeting
  - NGK to provide a presentation at Task Force Meeting
  - NGK to view insulator again at TF meeting

EPRI

Proposed Evaluation by NGK

(1+2) EDX + SEM analysis of broken portion of FRP to detect decrease in aluminum relative to silicon

(3) GC-MS (Gas Chromatography – Mass Spectroscopy) of rubber surface samples from damaged and undamaged areas to see if there is a difference in the presence of small cyclics that indicate depolymerization by heat due to spot discharges. If water drop corona lead to loss of hydrophobicity and then sheeting out of water, it is possible that local spot discharges between water sheets damaged rubber.

(4) FT-IR analysis on the rubber at and around broken portion. FT-IR can check the existence or reduction of CH3 and ATH. It will be more effective to combine with EDX analysis for precise evaluation. It also can determine if damage to rubber was by acid attack

(5) Since the rubber at line end was damaged more on one side than the other, conceptually divide the insulation into two sides (damage portion being one side) then check ESDD to compare hydrophobicity on both sides of insulator along its length and repeat tests 3 and 4 on ground end rubber comparing sides. Maybe one side was more exposed to contamination in chamber, or one side is chemically a little different because of manufacturing process.

(6) Check degree of bonding between FRP and rubber at in region of broken portion

(7) Perform rubber strip check on insulator to determine degree of bonding between FRP & rubber.

(8) Put 2 new NGK insulators in chamber for a month. One with 4" ring and one with no ring, and closely monitor corona. At end of month inspect. It is possible the 4" ring damaged insulator in some manner and may be worse than no corona ring.

Modified insulator with 4" ring installed in aging chamber for X days, change in hydrophobicity and condition observed after test

(9) Test for ph levels on surface of insulators at line end in (8) immediately after wet cycles. Determine if acid is generated and if there are differences in amount of acid in various locations with different rings

(10) Perform 3D analysis on several ring size designs, 4", 8", 9.5" and 11" diameter rings and on different string configurations.

  - Middle phase only

EPRI

What we know

- Continuous dry corona activity degrades polymer material
- High E-field magnitudes on sheath result in non-uniform wetting discharge activity (when wet)
  - Degrades rubber
  - EPRI recommended E-fields <0.45kV/mm
- Dead-end polymer insulators have higher E-field magnitudes
  - Up to 15% higher than suspension (depends on configuration, etc.)
- Center Phase has highest E-fields due to nearby phases
- Extra Hardware such as hotlink increases E-field

EPRI

EPRI Involvement

- EPRI identified extra link as an issue while performing an aerial patrol on an unrelated project
- EPRI and SDG&E performed a corona inspection under dry conditions
  - Observed corona under dry conditions
  - No observations under wetting conditions
- E-field modeling
  - Without hotlink
  - With hotlink
  - Center phase
  - First order model

Phase 2: CP/COB Porcelain Insulator Population Assessment: Product Subtitle. EPRI, Palo Alto, CA: 2018. InsertSAPNumberHere.

ABSTRACT

Hydro One has concerns regarding the condition of in-service porcelain insulators manufactured by Canadian Ohio Brass (COB) and Canadian Porcelain (CP) installed between 1965 and 1982. These insulators are installed on 22,000 structures (33,600 Circuit structures). Approximately 10,000 of these structures (15,600 Circuit structures) are situated in locations such as road crossings, railway crossings, public spaces, etc. which Hydro One has assessed as safety critical locations. A decision has been made to replace the insulators on these critical structures over the next several years. Following completion of the critical structure string replacement, a decision on replacement of the insulators on the remaining 18,000 non-critical circuit structures will be made.

In order to assess the risk associated with the pace of replacement for both the critical and non-critical strings, and to assist in structuring the replacement program, the test program described below was carried out. The testing program comprised two phases. Phase 1 was completed in 2016. The phase 1 tests were carried out on 299 insulators removed from a combination of dead-end and suspension strings installed in safety critical locations. Phase 1 testing was intended to provide an expedient assessment of the condition of the in-service insulators in question. The results of Phase1 supported the urgent replacement of COB and CP insulators manufactured between 1965 and 1982 that are installed on critical structures where public safety is at risk. The complete findings of the phase 1 tests are presented in EPRI Report 108294, “Results and Analysis of Phase 1 Insulator Tests Performed in Support of Hydro One Insulator Replacement Program”, issued on August 19, 2016.

While Phase 1 quickly quantified the immediate magnitude of the existing problem, its limited test regimen could not generate data usable for estimating the continued rate of deterioration or remaining life of the insulator population. Phase 2 of the project focused on expanding the test program used in phase 1 by incorporating additional tests based on a CIGRE recommended procedure intended to assist utilities in determining when large populations of in-service insulators have reached their end of life and should be removed from service. The tests also included steep front puncture tests.

The Phase 2 results provided overwhelming evidence to support taking immediate action to mitigate the risk to the safety and reliability of Hydro One’s transmission system. The key recommendation made is that the population of defective COB and CP insulators installed between 1965 and 1982 be removed from service as soon as practically possible.

1
INTRODUCTION

Transmission line insulators are required to perform two basic functions. They must provide mechanical support for overhead conductors and they must provide electrical isolation between the energized conductors they support and the grounded towers to which they are attached. It is recognized throughout the industry, that both the electrical and mechanical characteristics of line insulators manufactured between the late 1960's and early 1980's by Canadian Porcelain (CP) and Canadian Ohio Brass (COB) deteriorate significantly faster than other comparable insulators due to cement expansion as described in References [1] and [2].

Porcelain line insulators are specified in terms of their combined mechanical and electrical (M&E) strengths. For example, an insulator with an M&E rating of 36 kips (1 kip = 1,000 lbs.) is designed to withstand an applied tensile load in excess of 36 kips without mechanical or electrical failure. Mechanical failure is defined as a physical breakage of the insulator while electrical failure is defined as cracking of the insulator's porcelain body in the area between the cap and the pin which results in a significant reduction of the insulator's dielectric strength. Both international and Canadian standards specify test procedures and minimum acceptable performance requirements for M&E testing of new insulators.

Hydro One has concerns regarding the condition of in-service CP and COB porcelain insulators installed between 1965 and 1982. These insulators are installed on 22,000 structures (33,600 Circuit structures). Approximately 10,000 of these structures (15,600 Circuit structures) are situated in locations such as road crossings, railway crossings, public spaces, etc. which Hydro One has assessed as safety critical locations. A decision has been made to replace the insulators on these critical structures over the next several years. Following completion of the critical structure string replacement, a decision on replacement of the insulators on the remaining 18,000 non-critical circuit structures will be made.

In order to assess the risk associated with the pace of replacement for both the critical and non-critical strings, and to assist in structuring the replacement program, the tests described in this document and in Reference 1 were performed on insulators removed from service. The full test program was made up of two phases. The results of phase 1 are presented in Reference [3].

This report details the findings of phase 2 which comprised testing of approximately 600 insulators removed from a combination of dead-end, suspension, and idler positions. The results of the phase 1 tests, performed in 2016, were intended to expediently characterize the degree of urgency with which the insulator replacement at safety critical locations should be carried out based upon a snapshot in time of the condition of the phase 1 sample of insulators. Phase two of the testing was performed in 2017. Those tests were carried out on over 600 insulators. The intent of the phase 2 tests was to supplement the phase 1 data and to attempt to provide data on the rate of deterioration of the insulator population, which can be used to infer an estimate of their remaining life. This information will be used by Hydro One to optimize the overall replacement program with respect to the risk of in-service failure.

The project utilized the Kinectrics facility in Toronto for the performance of the testing under the direction of EPRI. Analysis of the results was performed by EPRI.

2
SUMMARY OF PHASE 1 TEST PROGRAM

The goal of the Phase 1 tests was to provide a snapshot of the “as-removed” electrical and mechanical condition of the insulators. Each of the insulators removed from service were subjected to the following tests:

1. Each insulator was checked using a 10-kV Megger.
2. Each insulator was subjected to an applied ac voltage of approximately 60% of its rated flashover voltage for a period of 1 minute.
3. Each insulator was subjected to a destructive M&E (Mechanical and Electrical) test to determine its ultimate electrical and mechanical failing load.

Test 1 was used to identify units which were fully punctured and virtually short circuited internally. Test 2 was used to identify those insulators which were partially punctured and would fully puncture under an applied voltage which is lower than the unit’s external flashover voltage. Test 3 was used to generate data describing the insulators’ ultimate mechanical and electrical strength under tensile load.

The results of the phase 1 tests are summarized in Figure 2-1.

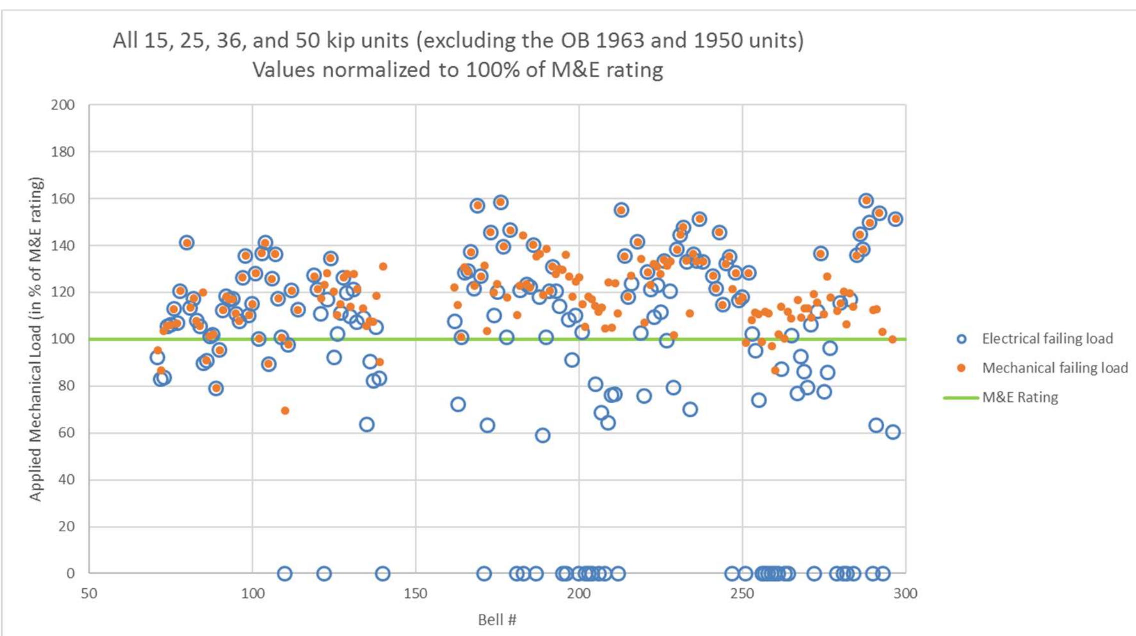

Figure 2-1
Normalized M&E test results from phase 1 testing

As can be seen from the data in Figure 2-1, a large proportion of the insulators tested (37%) failed electrically or mechanically at loads below their rated M&E strength. There was a significant number of punctured insulators (electrical failing load of zero), and the test data showed a large variation in failing loads which would not be expected for a healthy insulator population.

The condition of the Hydro One insulators was assessed through benchmarking to EPRI and public domain test data. This benchmarking data was obtained through testing of similar vintage insulators which had been in service for a comparable duration under similar field conditions. The performance of the Hydro One and the benchmarking insulators was also compared to current and historic requirements for new insulators.

The test results presented an initial snapshot of the condition of the population of defective insulators in-service on Hydro One's transmission system. Although the sample of insulators tested was not sufficient to perform a rigorous statistical analysis upon which to base recommendations, the results strongly suggested that the installed insulator population comprising CP and COB insulators manufactured between 1965 and 1982 had reached or was at least approaching the end of useful life. As such the test data supported the urgent replacement of COB and CP insulators manufactured between 1965 and 1982 that are installed on critical structures where public safety is at risk. Phase 1 included testing of 69 COB insulators manufactured in 1963. The results of those tests showed that the performance of these insulators was below expectations. Historically, Hydro One has been using a manufacturing window of between 1965 and 1982 to identify defective COB and CP insulators. These 69 COB insulators were manufactured prior to 1965 which indicates that the 1965 cut-off year may be inaccurate. Testing additional insulators from the early 1960s was recommended.

3
PHASE 2

The goal of the phase 2 testing was to generate data which can be used to qualify the current condition and continued rate of deterioration or remaining life of the insulator population. As mentioned in the introduction, following completion of the critical string replacement, the course of action to be taken with the insulators on the remaining 18,000 non-critical structures will have to be decided upon. The test results give an indication of the urgency with which suspect insulators installed in non-critical locations should be replaced based upon their as-removed condition and their anticipated end of useful life. As such, the results will provide critical input into the planning and fundamental structuring of the replacement program for the 18,000 non-critical structures.

Phase 2 Insulator Sample

The total number of insulators removed from service and made available for the project exceeded 1,500. They were removed from service in a variety of locations across Ontario. The details of these insulators are given in Table 3-1.

Table 3-1
Details of the 1500 insulators removed from service

Inventory Group	Line Voltage (kV)	Circuit	Structure	Manufacturer	Year of Manufacture	M&E rating (kips)	Number of Units	Colour
1	500	572T	25	COB	1975	50	66	White
2	500	572T	15	COB	1975	50	69	White
3	500	572T	36	COB	1977	36	69	White
4	500	572T	16	COB	1977	36	75	White
5	230		467	COB	1977	36	42	White
6	230			COB/CP	1966	25	78	Brown
7	230	Q11S	B15	COB	1979	25	42	White
8	230	Q11S	B17	COB	1979	25	42	White
9	230	C22J	10 towers	CP/COB	1952	15	540	Brown
10	230	P45, P46		COB	1963	15	84	Brown
11	115	B5C/B6C	21 towers	COB	1978	15	151	White
12	115	X2H	7 towers	COB	1972/1973	15	294	White

As shown in Table 3-1, the insulator inventory included insulators with M&E ratings of 50, 36, 25, and 15 kips. The inventory was divided into groups 1 through 10 based upon their M&E rating, the voltage rating of the circuit in which they had been installed, and their year of manufacture. Any insulators with significant portions of the shed broken off were discounted from the inventory.

From this inventory shown in Table 3-1, 591 insulators were selected for Phase 2 testing. The selection was made so as to have approximately 150 insulators of each strength category. Table 3-2 shows the details of the insulator sample selected for the phase 2 tests. As mentioned above, no insulators with significant shed breakage were chosen for testing.

Table 3-2
Details of the insulators selected for phase 2 testing

The breakdown according to M&E rating of the 591 insulators used for phase 2 testing is shown in Figure 3-1.

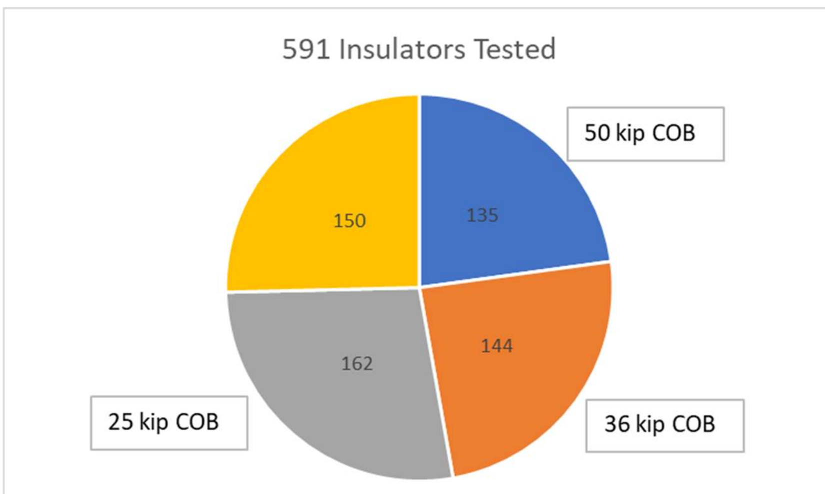

Figure 3-1
Breakdown of phase 2 insulators according to M&E rating

In addition to the insulators described in Table 3-2, 40 further insulators were chosen for limited testing. These insulators, defined in Table 3, were subjected to tests mirroring those performed in phase 1 of the test program. Phase 1 had included testing of 69 COB insulators manufactured in 1963. The results of those tests showed that the performance of these insulators was below expectations. Historically, Hydro One has been using a manufacturing window of between 1965 and 1982 to identify defective COB and CP insulators. Those 69 COB insulators were manufactured prior to 1965 which indicates that the 1965 cut-off year may be inaccurate. The insulators shown in Table 3-3 were manufactured in 1952 and 1963 and the tests were performed as a check on the accuracy of the 1965 to 1982 window historically used to define the period during which defective COB and CP insulators were manufactured.

Table 3-3
Details of additional pre-1965 insulators subjected to limited testing

Rating (kips)	# of samples to be tested	# of samples from each	
		# of samples from each inventory group	Inventory group
15	20	20	9
15	20	20	10

The results of these tests are given in Appendix A.

Phase 2 Test Program

The insulators selected for the phase 2 testing were visually inspected, photographed and catalogued. Following this process, the insulators were subjected to the phase 2 tests.

The primary phase 2 tests can be classified into two categories:

- as-found condition tests
- ageing test followed by evaluation test to infer rate of deterioration and remaining life.

The as-found condition tests were the same tests as those utilized in phase 1 of the project. Those tests included:

- Test 1: Checking each insulator using a 10-kV Megger (600 insulators)
- Test 2: Subjecting each insulator to an applied ac voltage of approximately 60% of its rated flashover voltage for a period of 1 minute (600 insulators)
- Test 3: Subjecting each insulator to a destructive M&E test (270 insulators).

Test 1 was used to identify units which were fully punctured and virtually short circuited internally. Test 2 was used to identify those insulators which are partially punctured and would fully puncture under an applied voltage which is lower than the unit's external flashover voltage. Test 3 was used to generate data describing the insulators' ultimate mechanical and electrical strength under tensile load.

The ageing test comprised:

- Test 4: Subjecting 270 insulators to thermal mechanical cycling tests

Test 4 was used as a conditioning/ageing test intended to accelerate any deterioration in the insulator performance that is related to weather cycles experienced by the remaining in-service insulators. Following this test, the conditioned/aged insulators were subjected to a destructive M&E test which followed the same procedure as Test 3. That M&E test was used to generate data describing the insulators' ultimate mechanical and electrical strength under tensile load following the ageing caused by the thermal mechanical cycling tests (Test 4). Detailed descriptions of tests 1 through 4 are provided in Appendix B.

The use of thermal mechanical cycling (Test 4) to age the insulators is based on the recommendations of a 2006 CIGRE WG B2.03 report [4]. That report outlines procedures developed for estimating the deterioration rate of in-service cap and pin insulators. Their recommended approach is to assess the rate of ageing through the performance of a combined set of M&E and Thermo-Mechanical tests. Cap and pin insulators are known to age through mechanical load and temperature cycling. Thermo-Mechanical testing of insulators comprises subjecting the insulators to a specified load (related to their M&E rated load) and cycling the temperature between two extremes for a specified duration, releasing the mechanical load, and then repeating the process for a specified number of cycles. Although the test is included in ANSI C29.2B [5], IEC 60575 “Thermal-Mechanical Performance Test and Mechanical Performance Test on String Insulator Units” [6], and CSA 411.1 “AC Suspension Insulators” [7], the test parameters vary between the standards. While there are differences between the standards, all three prescribe test conditions which are purposefully severe so as to subject brand new insulators to ageing which they may be subjected to during their expected in-service lifetime. Given that the insulators under test are both relatively old and known to be sub-standard, it was decided to apply a less severe form of thermal mechanical cycling. This approach was taken due to concern that subjecting the test insulators to the standard(s) Thermal Mechanical cycling would result in mechanical damage such as porcelain cracking (resulting in a reduction of the insulators’ electrical strength to practically zero) or physical breakage (separation of the insulator components) during the Thermal Mechanical cycling. The details of the difference in the thermal mechanical cycling parameters recommended in CSA 411.1, ANSI C29.2B, IEC 60575 and those employed during the phase 2 testing are summarized in Table 3-4.

Table 3-4
Thermal Mechanical Test Parameters

	T max	T min	Cycle Duration	# of Cycles	Applied Mechanical Load
CSA 411.1 recommendations	+50 C	-50 C	24 hrs	4	70% of M&E rating
IEC 60575 recommendations	+50 C	-50 C	24 hrs	4	65% of M&E rating
ANSI C29.2B recommendations	+40 C	-30 C	24 hrs	4	60% of M&E rating
Phase 2 test parameters	+50 C	-50 C	24 hrs	2	65% of M&E rating

As seen from Table 3-4, the Thermal Mechanical cycling parameters used in the Phase 2 tests most closely matched the IEC recommendations. T_{max}, T_{min}, cycle duration and applied mechanical load were identical to the IEC recommendations. The only deviation from the IEC procedure was a reduction in the number of cycles from the IEC recommended number of 4 to 2.

In addition to quantifying the effect of thermal mechanical cycling on the M&E strength of the sample insulators as recommended in the CIGRE report, steep front puncture tests were carried out on 60 insulators. Installed insulators are subject to steep front voltage transients generated by lightning. These transients can cause electrical breakdown of the porcelain between the cap and the pin due to the high electrical stress imposed across them. In order to evaluate the susceptibility of the as-received insulators to electrical puncture under simulated lightning voltages and to explore the effect of thermal mechanical cycling on this puncture strength, steep front puncture tests were performed before and after the thermal mechanical cycling described in the preceding paragraphs. Of the total 60 insulators subjected to steep front puncture testing, 30 were steep front puncture tested without thermal mechanical cycling and the other 30 were thermal mechanically cycled and then subjected to steep front puncture tests.

The steep front puncture tests described above are an important factor in the condition assessment because the root cause of the recent conductor drops (past few years) on Hydro One's system has been physical separation of punctured insulators when exposed to power arcs due to string flashover. If the rate of puncture is shown to increase as a consequence of thermal mechanical ageing, the finding will constitute an important input into the urgency with which the COB and CP insulators still in service on non-critical structures should be replaced.

Phase 2 Test Protocol

In preparation for testing, the insulators described in Table 3-2 were allocated to the various test regimen as show in Figure 3-2.

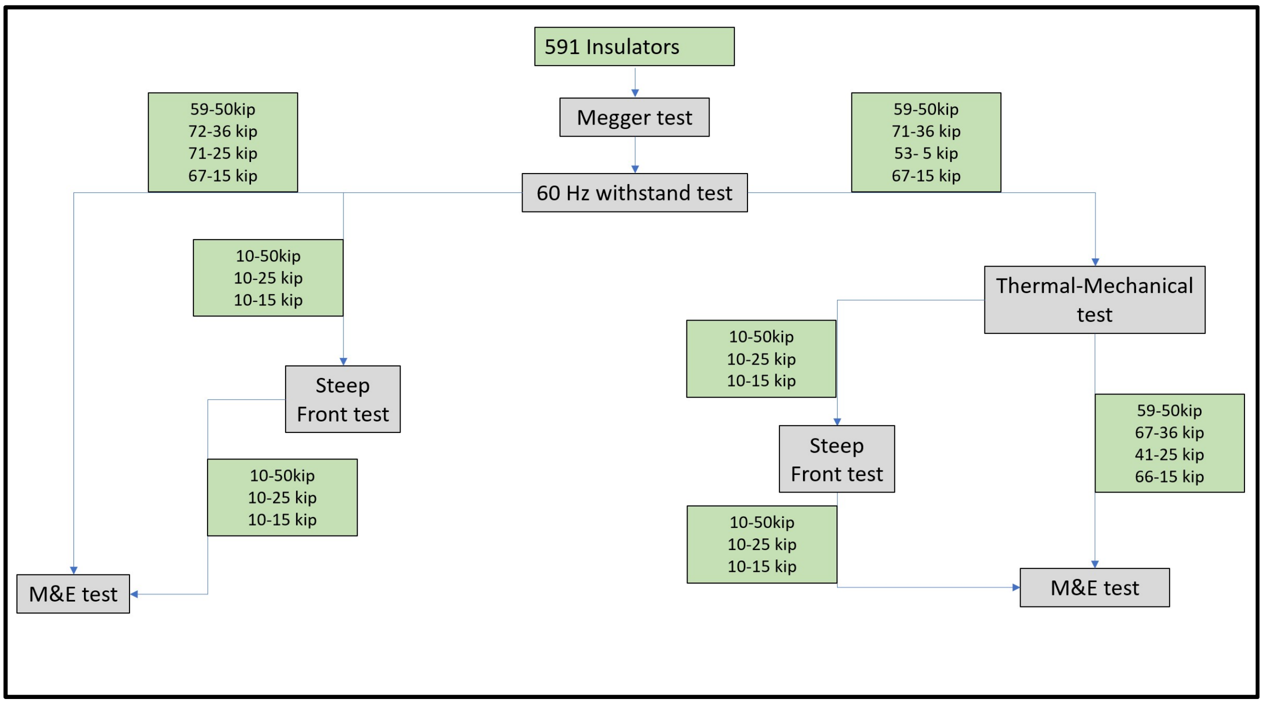

Figure 3-2
Testing protocol

Phase 2 Test Results

Megger and ac Withstand Test Results

The Megger and ac withstand tests (tests 1 and 2) were used to identify the units that were unable to support an applied voltage of 60 kV (approximately 70% of the rated withstand voltage) prior to the application of any tensile load. These insulators are referred to as punctured units because their inability to support voltage is due to a crack or puncture in the porcelain dielectric between the insulator cap and pin. Table 3-5 shows the number and percentage of units that fell into this category. As can be seen from that table, the percentage of punctured bells is low. In fact, the only punctured bells found were three 50 kip units and one 15-kip unit.

Table 3-5
Number of punctured units

Inventory Group	Line Voltage (kV)	Manufacturer	Year of Manufacture	M&E rating (kips)	# of Units	# of Units Failing Megger	# of Units Failing Hi-Pot	Number of Punctured Units	% of Punctured Units
1	500	COB	1975	50	66	2	2	2	3.0
2	500	COB	1975	50	69	1	1	1	1.4

8	230	COB	1979	25	42	0	0	0	0.0
11	115	COB	1978	15	75	0	1	1	1.3
12	115	COB	1972/1973	15	75	0	0	0	0.0

M&E Test Results Without Thermal Mechanical Pre-Conditioning

While the methodology of the M&E testing procedure is described in Appendix B, it is important to note the definition of an insulator's M&E strength. During M&E testing, the insulator is subjected to a steady continuous electrical stress and a steadily increasing mechanical tensile stress. The insulator can undergo two failing modes. It can fail electrically due to the formation of a crack in the porcelain body due to mechanical loading, or it can fail mechanically due to the applied tensile load. The M&E failing load of an individual insulator is defined as the lowest mechanical load at which either electrical failure or mechanical separation of the insulator takes place. Analysis of M&E tests typically comprises fitting a normal distribution to the measured failing load data and comparing the distribution's mean and standard deviation to the insulators' M&E rating and or the maximum anticipated design load under which the insulators operate. In a healthy insulator population, the mean measured M&E strength should exceed the rated load by a given margin related to the measured standard deviation. In the analyses carried out in this report, in addition to above defined M&E failing load, the electrical and mechanical failing loads are examined individually.

As indicated previously, approximately half the insulators were subjected to M&E testing directly after the Megger and 60 Hz withstand tests. The other half of the insulators was subjected to Thermal Mechanical Conditioning followed by M&E testing. This section covers the M&E testing of the insulators not subjected to TMC conditioning. The M&E tests performed on the insulators which had undergone TMC conditioning are presented and discussed in section 3.3.4.

Figure 3-3 through Figure 3-8 show the results of the M&E tests for the individual lots of insulators tested without Thermal Mechanical pre-conditioning.

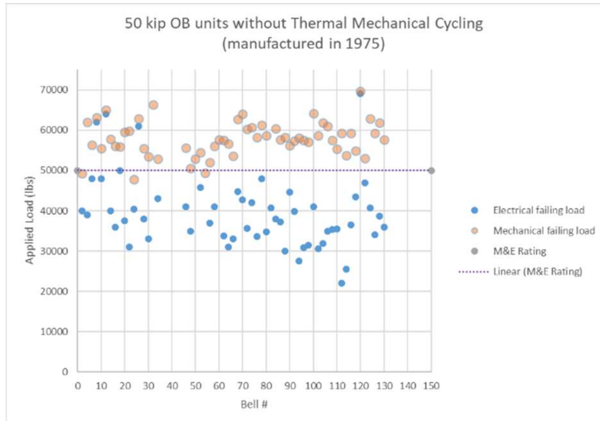

Figure 3-3
M&E test results for insulator lots 1 and 2

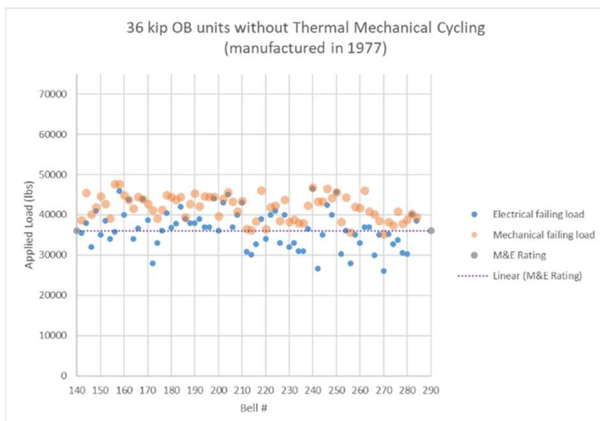

Figure 3-4
M&E test results for insulator lots 3 and 4

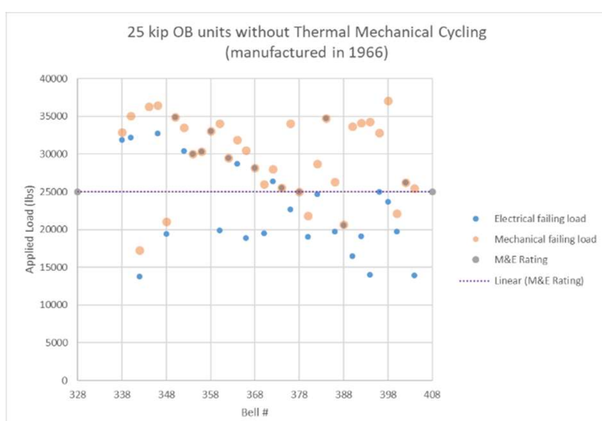

Figure 3-5
M&E test results for insulator lot 6

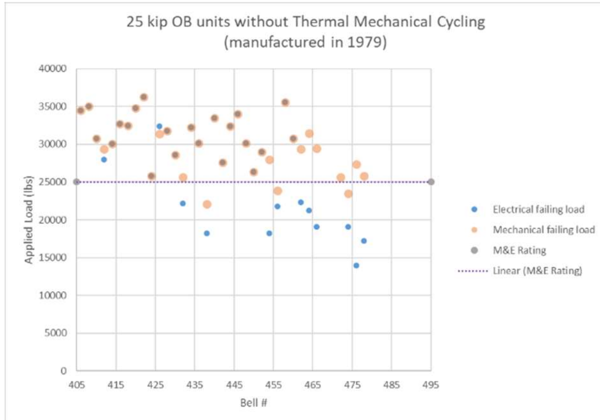

Figure 3-6
M&E test results for insulator lots 7 and 8

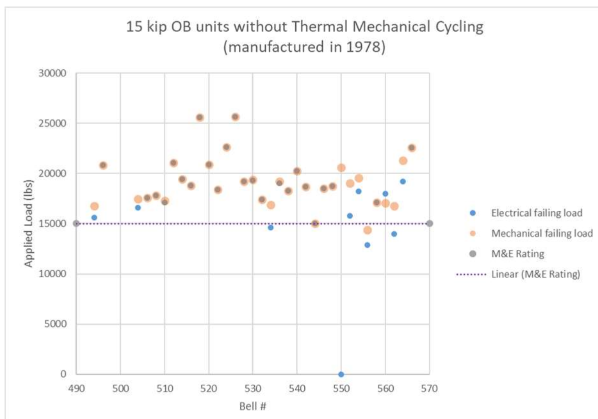

Figure 3-7
M&E test results for insulator lot 11

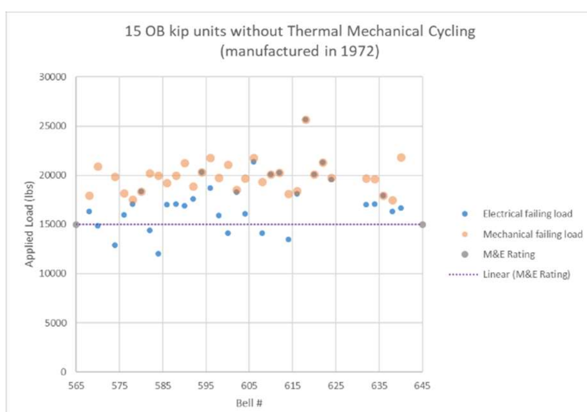

Figure 3-8
M&E test results for insulator lot 12

Examination of Figure 3-3 through Figure 3-8 yields a number of interesting observations. Looking at the graphs it is evident that for all the insulator groups tested:

- there are very few punctured insulators

- the electrical failing loads tend to be below the mechanical failing loads
- the mechanical failing loads appear be close to or above the rated failing load
- the electrical failing loads are generally below the rated failing loads
- while all of the tested insulator groups show electrical failures below the M&E rating, the number of electrical failures and the amount by which they fall short of the M&E rating appears to be greater for the higher rated units. The 50-kip insulator sample shows the highest incidence of electrical failures at loads below the rated M&E load and the greatest difference between the average electrical failing load and the M&E rated load. The number of electrical failures at below the M&E rated load and the difference between the average electrical failing load and the M&E rating both get smaller as the rating of the insulators decreases. These observations are consistent with the exception of the 25 kip units manufactured in 1966 (lot 6). This discrepancy is likely due to the fact that the lot 6 insulators have been in service for some 10 years longer than the other lots.

Table 3-6 shows the results of numerical analysis of the data behind Figure 3-3 through Figure 3-8.

Table 3-6
Percentage of insulators failing to meet their assigned M&E ratings

Data Set	M&E Rating	% failing to meet M&E rating		
-	-	Electric	Mechanical	Combined
50 kip COB units manufactured in 1975	50000	93.2	5.1	93.2
36 kip COB units manufactured in 1977	36000	47.2	2.8	47.2
25 kip COB/CP units manufactured in 1966	25000	52.9	14.7	52.9
25 kip COB units manufactured in 1979	25000	29.7	8.1	29.7
15 kip COB units manufactured in 1978	15000	11.8	2.9	11.8
15 kip COB units manufactured in 1972/3	15000	21.2	0.0	21.2

The data in Table 3-6 confirm the visual observations drawn from Figure 3-3 through Figure 3-8. All of the insulator groups fail to meet their assigned M&E rating with their M&E strength being far lower than rated value. As with the insulators tested in phase 1 of the project, this is primarily due to the extremely poor electrical strength. However, as shown in the table, the mechanical strength of these non-TMC conditioned insulators also falls short of the M&E requirement in all cases with the exception of the 15-kip COB units manufactured in 1972/3.

In comparing the Table 3-6 data to standard requirements, it should be remembered that in addition to the requirements for the calculated mean and standard deviation, most standards require that none of the tested insulators show an M&E failing load below the specified M&E

rating. Table 3-6 shows that the insulators tested fail to meet this requirement with the percentage of insulators having an overall M&E failing load below the required M&E rating varying from a maximum of 93% for the 50 kip units to a minimum of 12% for the 15 kip units manufactured in 1978.

Typical analysis of M&E testing is performed through fitting a normal distribution to the experimental M&E data. Table 3-7 shows the means and standard deviations of the normal distributions which best fit the measured electrical, the measured mechanical, and the measured overall M&E failing load data for the as-received insulators (without TMC).

Table 3-7
Best fit normal distributions of M&E data for units without TMC

Data Set	M&E rating	M&E Statistics (w/o TMC)					
		Mean Electrical Failing Load	Electrical Failing Load Sigma (%)	Mean Mechanical Failing Load	Mechanical Failing Load Sigma (%)	Mean M&E Failing Load	M&E Failing Load Sigma (%)
50 kip COB units manufactured in 1975	50000	39514	23	57850	7	39514	23
36 kip COB units manufactured in 1977	36000	36554	13	41808	8	36554	13
25 kip COB/CP units manufactured in 1966	25000	24542	26	29751	18	24542	26
25 kip COB units manufactured in 1979	25000	28690	24	30595	15	28690	24
15 kip COB units manufactured in 1978	15000	18077	24	19115	13	18077	24
15 kip COB units manufactured in 1972/3	15000	17367	16	19847	8	17367	16

The data in Table 3-7 indicates that for the 50 kip units and for the 25 kip units manufactured in 1966, the mean M&E failing load is below rating. In the case of the 50 kip units, the difference between the measured M&E rating and the rated M&E strength is 20%. For the 25 kip units manufactured in 1966 the difference is 2%. For the remaining groups of insulators, the mean M&E failing load is above the rating, however, with the large standard deviations shown in the table, it can be expected that significant numbers of installed insulators will fail electrically or mechanically under in-service loads considerably below their M&E rating.

Review of the results of the M&E testing (without TMC) shows that:

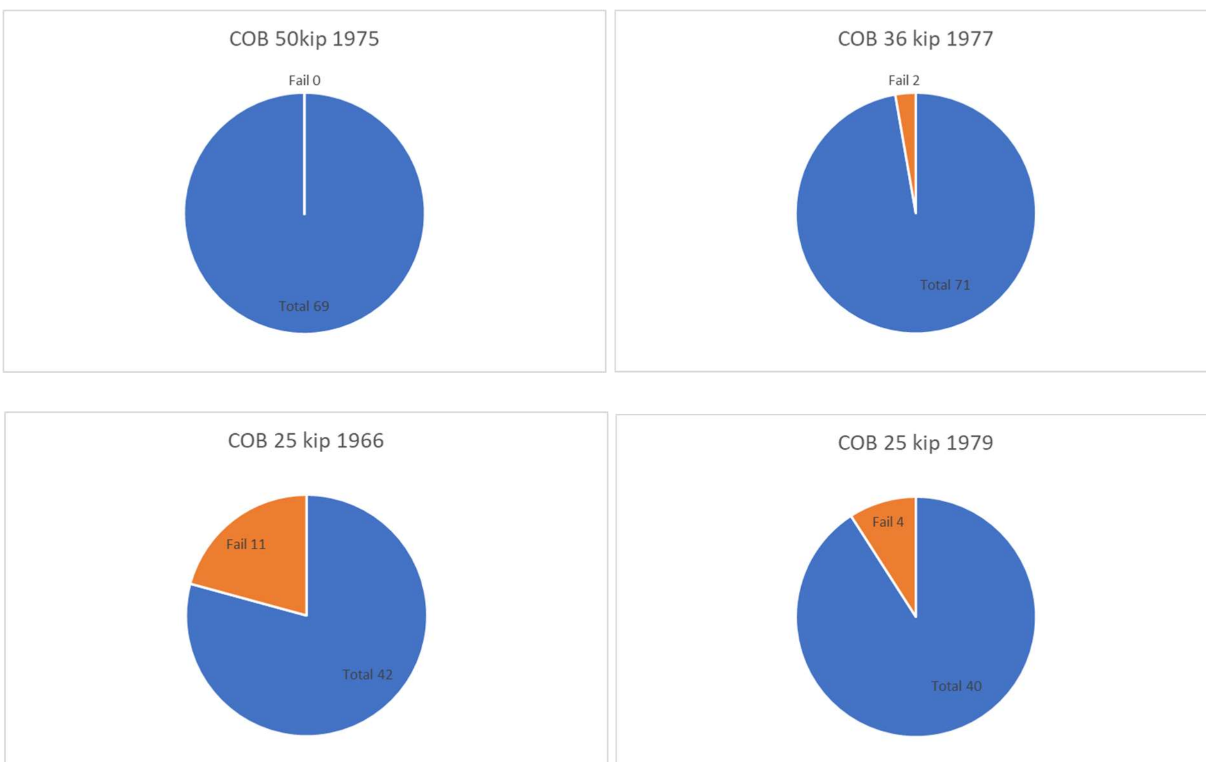
1. a large number of the tested insulators exhibited porcelain cracking (which in essence makes the insulator a punctured unit) at mechanical loads significantly below the insulators' M&E rating.
2. there is a large dispersion in the recorded M&E strengths, the recorded electrical failing loads and the recorded mechanical failing loads.

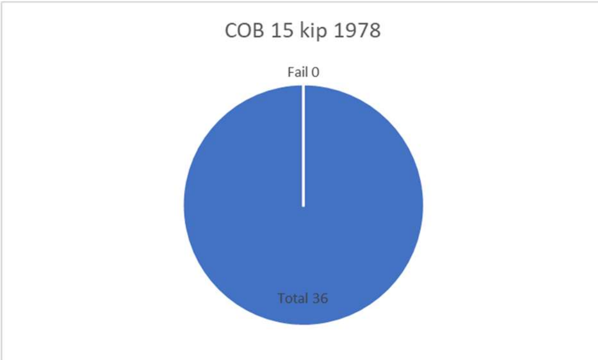
Item 1 above suggests that the number of in-service punctured units will increase as the insulators experience significant mechanical loading events. As explained in the previous section, the quality of insulators is often judged by the standard deviation of the M&E, the electrical, and the mechanical failing loads and by the margin between the recorded mean M&E strength and the M&E rating. Item 2 shows that the differences between the mean recorded M&E strengths and the M&E ratings are coupled with large standard deviations. This combination results in an increased probability of insulator failure at loads below their M&E rating. Both the above observations are atypical for a healthy insulator population.

Thermal Mechanical Cycling

Thermal Mechanical Cycling was performed on approximately half of the sample insulators. The procedure used is described in Appendix B.

A number of insulators physically separated during the TMC and a large number punctured (cracked). Figure 3-9 shows the number of insulators which physically separated. Most of these observed failures occurred during the heating cycle. In addition to the physical separation failures caused by the TMC and summarized in the figure, a number of additional insulators failed due to the recoil action which occurs when one insulator in a string undergoing TMC fails. Since these recoil failures are not directly attributable the TMC, any insulators that failed due to recoil were discounted from the analysis in Figure 3-9.





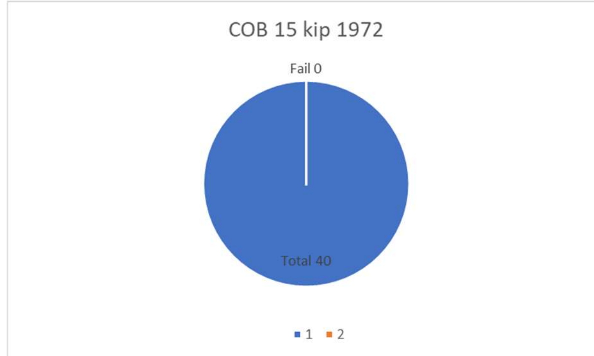


Figure 3-9
Proportion of insulators broken (physically separated) during the TMC.

The number of insulators punctured (cracked) during the TMC is summarized in Table 3-8. As the data show, the TMC induced in a disturbingly large number of punctures (cracks) in the test insulators, with the proportion of insulators punctured varying from a maximum of 90% to a minimum of 23%.

Table 3-8
Proportion of units punctured (cracked) during TMC

Group	Data Set	# of units in test lot	# of units punctured	% of units punctured
1 and 2	50 kip COB units manufactured in 1975	58	52	90
3 and 4	36 kip COB units manufactured in 1977	69	39	57
6	25 kip COB/CP units manufactured in 1966	21	13	62
7 and 8	25 kip COB units manufactured in 1979	31	7	23
11	15 kip COB units manufactured in 1978	33	9	27
12	15 kip COB units manufactured in 1972/3	34	13	38

Effect of Thermal Mechanical Cycling on M&E Strength

This section presents the results of the M&E testing performed on the insulators which had undergone TMC conditioning.

Figure 3-10 through Figure 3-15 show the results of the M&E tests for the individual lots of insulators tested with and without Thermal Mechanical pre-conditioning.

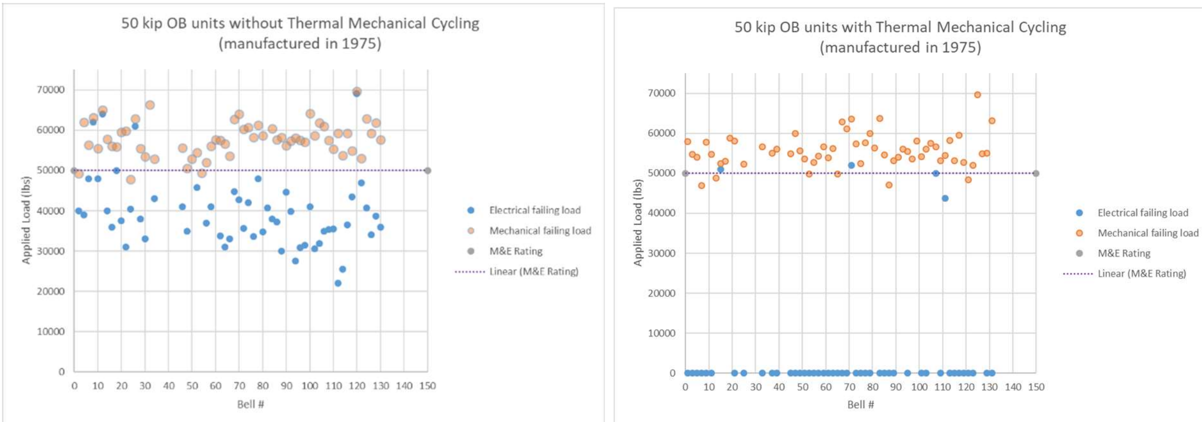

Figure 3-10
M&E test results for insulator lots 1 and 2

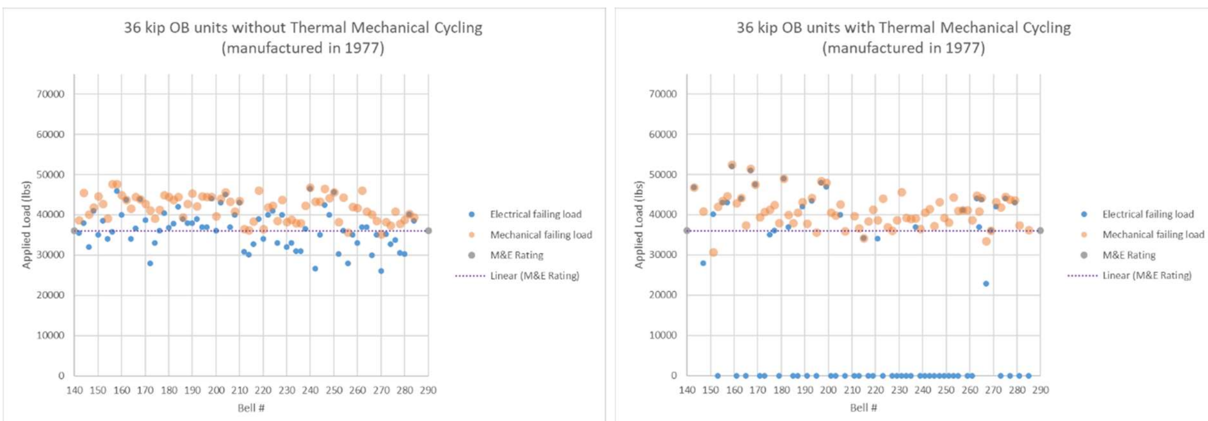

Figure 3-11
M&E test results for insulator lots 3 and 4

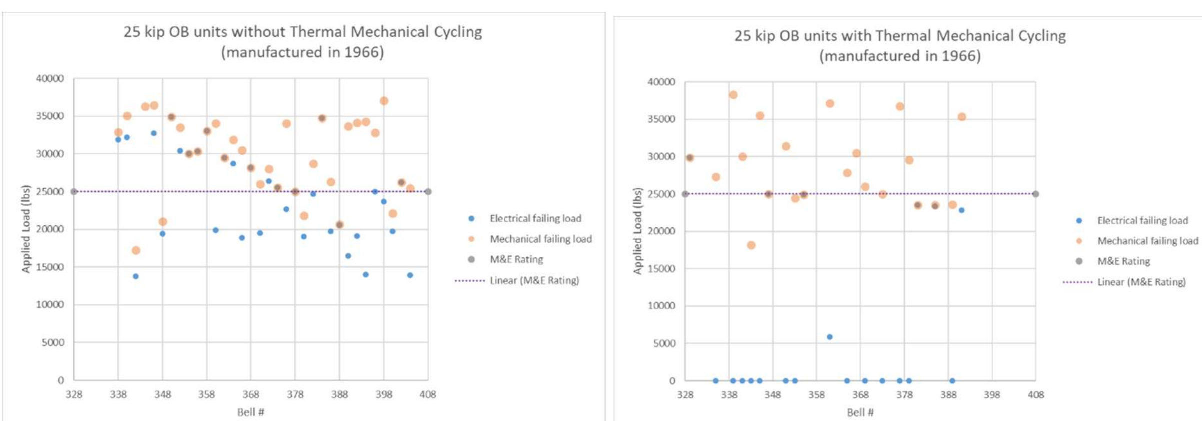

Figure 3-12
M&E test results for insulator lot 6

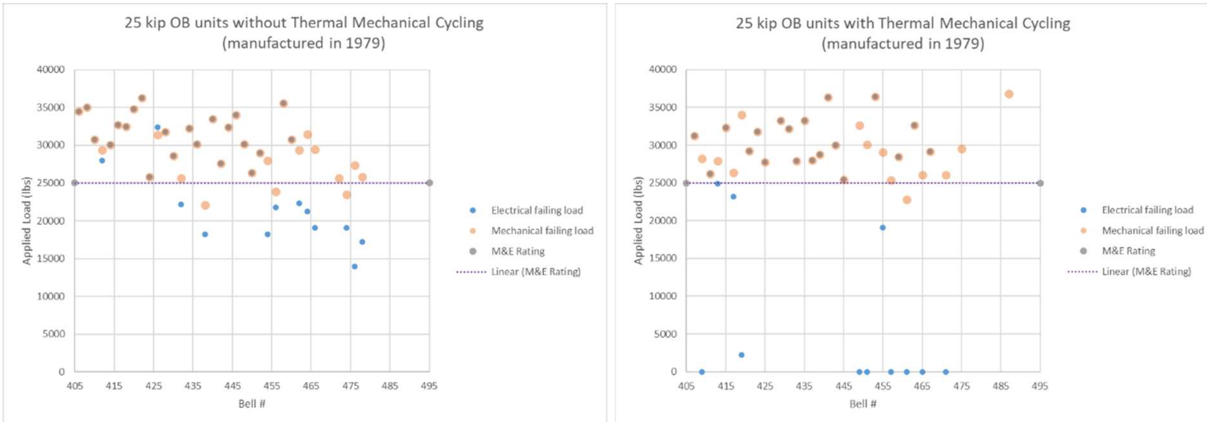

Figure 3-13
M&E test results for insulator lots 7 and 8

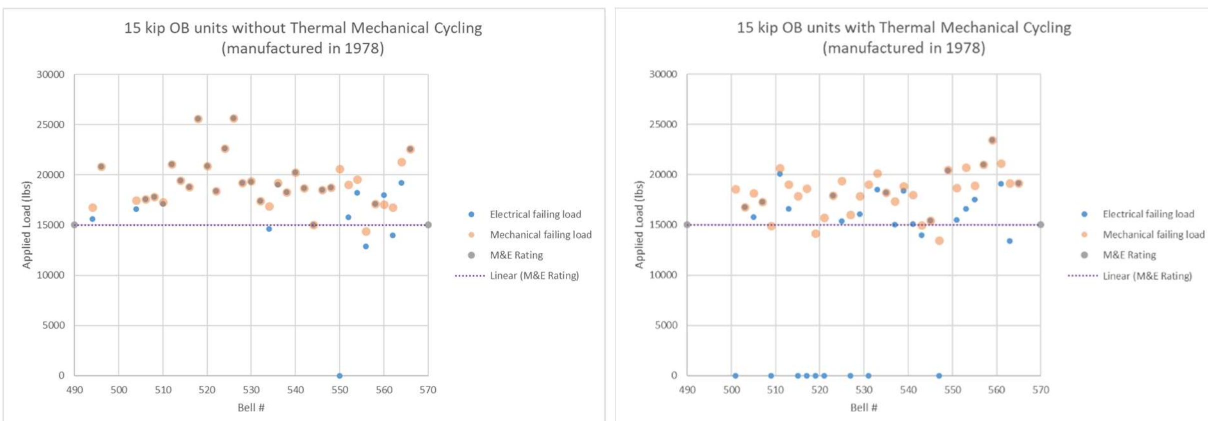

Figure 3-14
M&E test results for insulator lot 11

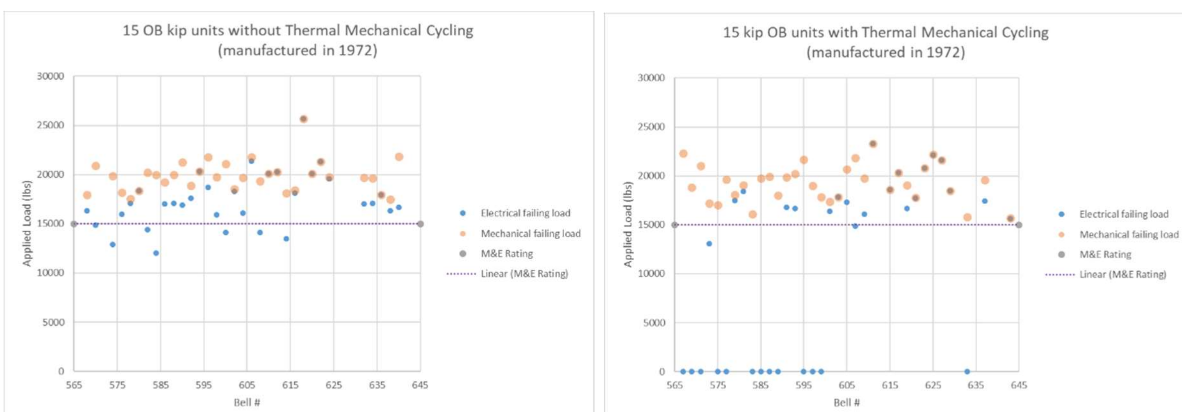

Figure 3-15
M&E test results for insulator lot 12

The left hand side of each figure gives the M&E results obtained on the insulators that had not undergone TMC conditioning (the same graphs as those shown in Figure 3-3 through Figure 3-8) while the results of the M&E tests performed on the insulators that had undergone TMC conditioning are given on the right hand sides of the figures.

Comparison of the graphs on the left hand side of each figure (representing the as-found insulators) with those on the right hand side (representing the insulators which had been subjected to TMC conditioning) reveals several obvious differences:

- the mechanical failing loads of the thermally cycled (TMC) insulators do not appear to be much lower than those of the as-found insulators
- a large number of the TMC insulators were punctured (cracked) during the thermal mechanical cycling and had virtually zero electrical strength remaining
- the proportion of insulators which punctured (cracked) during the thermal mechanical cycling appears to be greatest for the 50 kip insulators and decreases with the insulator rating.

Table 3-9 shows the results of numerical analysis of the data behind Figure 3-10 through Figure 3-15.

Table 3-9
Percentage of insulators failing to meet their assigned M&E ratings

Data Set	M&E Rating	% failing to meet M&E rating (without TMC)			% failing to meet M&E rating (with TMC)		
-	-	Electric	Mechanical	Combined	Electric	Mechanical	Combined
50 kip COB units manufactured in 1975	50000	93.2	5.1	93.2	96.6	8.6	96.6
36 kip COB units manufactured in 1977	36000	47.2	2.8	47.2	66.7	7.2	66.7
25 kip COB/CP units manufactured in 1966	25000	52.9	14.7	52.9	90.5	28.6	90.5
25 kip COB units manufactured in 1979	25000	29.7	8.1	29.7	70.8	52.3	70.8
15 kip COB units manufactured in 1978	15000	11.8	2.9	11.8	36.4	12.1	36.4
15 kip COB units manufactured in 1972/3	15000	21.2	0.0	21.2	44.1	0.0	44.1

As would be expected, the percentage of insulators failing to meet their M&E rating is larger for the insulators which were conditioned through TMC than for those not subjected to TMC.

Steep Front Testing

Steep front testing was performed on 50 kip, 25 kip, and 15 kip insulators in accordance with the test procedure detailed in Appendix B. A total of 60 of the sample insulators were tested. The tests were evenly divided between insulators that had and had not been subject to TMC. In addition to the testing of the Hydro One samples, steep front tests were performed on twenty 25 kip NGK insulators provided by EPRI. These insulators were of a similar vintage to the Hydro One insulators. The reason for testing the NGK insulators was to provide a platform for benchmarking the steep front test performance of the as-removed Hydro One 25 kip insulators. Steep front testing was not standardized until the 1980s, so the insulators tested in this work had not been subjected to steep front design tests when new. The breakdown of the steep front test samples is given in Table 3-10.

Table 3-10
Breakdown of the steep front test samples

Inventory Group	Data Set	M&E Rating	# of Units Tested	
-	-	-	Without TMC	With TMC
1	50 kip COB units manufactured in 1975	50000	5	5
2	50 kip COB units manufactured in 1975	50000	5	5
6	25 kip COB/CP units manufactured in 1966	25000	5	5
8	25 kip COB units manufactured in 1979	25000	5	5
11	15 kip COB units manufactured in 1978	15000	5	5
12	15 kip COB units manufactured in 1972/3	15000	5	5
EPRI insulators benchmarked against Hydro One units	25 kip NGK units	25000	20	-

The results of the steep front tests on the Hydro One insulators are shown in Figure 3-16 and the 25 kip NGK vs the 25-kip Hydro One benchmarking results are given in Figure 3-17. Due to the small number of samples, the results of the Hydro One insulator tests obtained for each M&E rating were grouped together. The 50 kip results reflect the aggregate results obtained with inventory groups 1 and 2, the 25 kip results combine the aggregate results obtained with inventory groups 6 and 8, and the 15 kip results combine the aggregate results obtained with inventory groups 11 and 12.

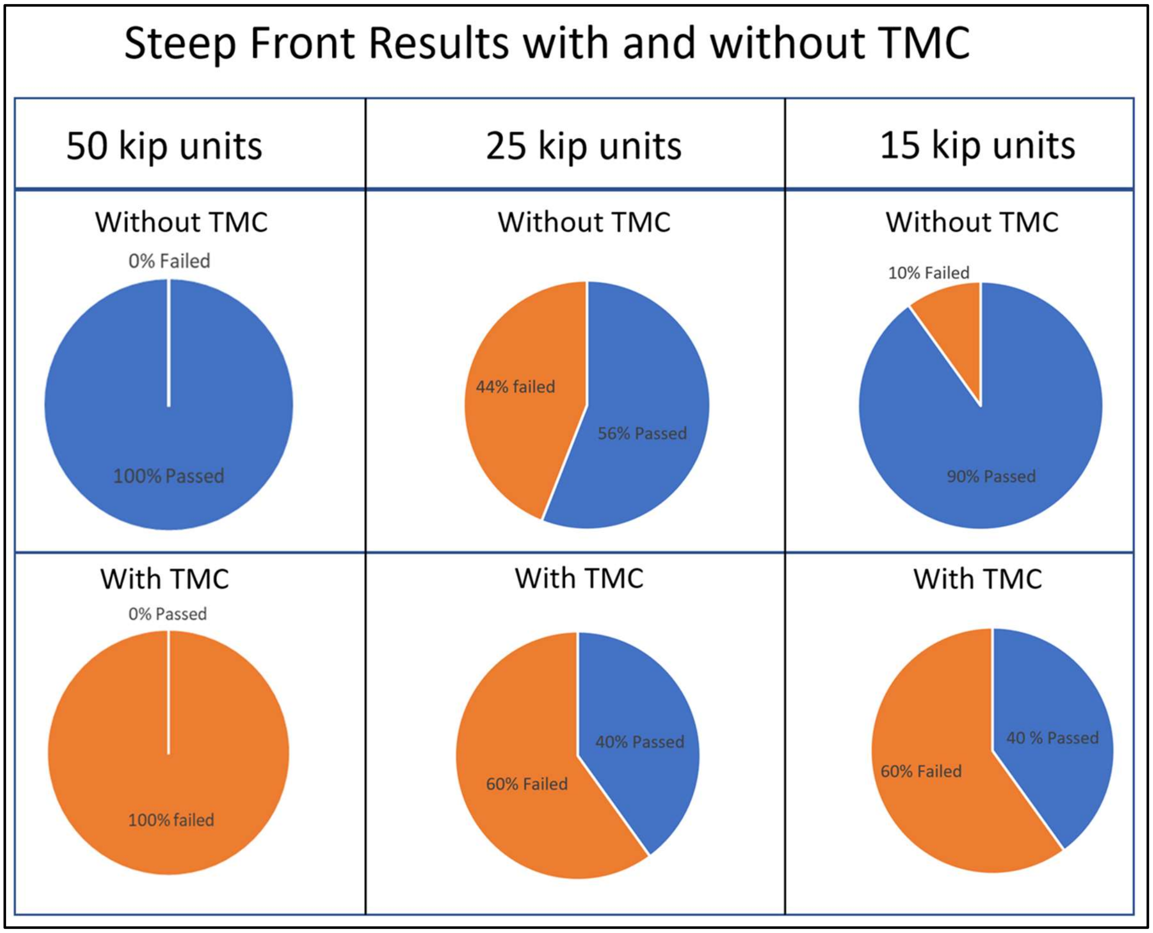

Figure 3-16
Steep front test results on Hydro One insulators with and without TMC

As can be seen from Figure 3-16, the TMC conditioning had a large influence on the percentage of Hydro One insulators passing the steep front test. The most drastic effect was observed with the 50 kip insulators which showed 100% passing without TMC and 100% failing with TMC. The 25 kip units showed 56% passing without TMC vs 40% passing with TMC, and the 90% pass rate for the 15 kip units without TMC was reduced to a 40% pass rate for insulators subjected to TMC.

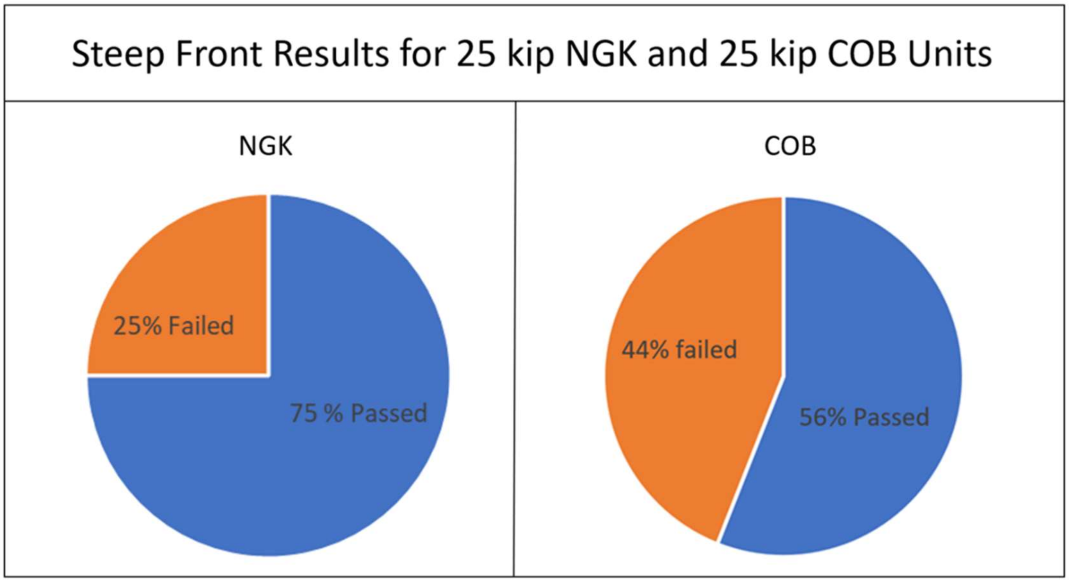

Figure 3-17
Steep front test results benchmarking Hydro One insulators against NGK units

Figure 3-17 shows that the 25-kip COB insulators (without TMC) had a steep front pass rate of 56% while the NGK benchmarking units had a pass rate of 75%. As mentioned earlier, steep front testing did not become standardized until a decade or so after these insulators were manufactured so neither design would have been exposed to this test when new. However, the 75% NGK pass rate vs the 56% COB pass rate shows that the NGK units are of a design that shows a higher resistance to steep front puncture than the Hydro One COB units.

4
COMPARISON TO STANDARDS

As mentioned at the onset of this report, M&E testing is a requirement in practically all standards prescribing the performance of insulators. The current applicable CSA standard, CSA 411.1-10: AC Suspension Insulators [7], requires that porcelain suspension insulators undergo M&E testing and that the results of the tests meet defined criteria.

CSA 411.1-10 requires that M&E tests be carried out on 10 insulators. The passing criteria for acceptance of the insulators is twofold. Firstly, the mean M&E failing load calculated for the ten insulators must equal or exceed the M&E rating plus 4 standard deviations, and secondly, each individual failing load must exceed the M&E rating. Other national standards have differing requirements but the lowest historic conformance criterion known to the authors of this report is that the mean M&E failing load calculated from the test data must exceed the rated M&E strength plus 1.2 standard deviations.

While insulators that have been in service may undergo ageing that reduces their M&E strength to below that demanded of new insulators, it is important that their M&E strength remain high enough to ensure that catastrophic insulator failures resulting in line drops do not occur. Table 4-1 shows the values of electrical, mechanical, and M&E failing loads obtained for the insulators subjected to M&E testing without TMC in light of the historic and current M&E test requirements for new insulators.

Table 4-1
Analysis of M&E data for all insulators in accordance with historic and current requirements for new insulators.

Data Set	M&E rating	M&E Statistics (w/o TMC)					
		Elect mean less 1.2 sigma	Mech mean less 1.2 sigma	M&E mean less 1.2 sigma	Elect mean less 4 sigma	Mech mean less 4 sigma	M&E mean less 4 sigma
50 kip COB units manufactured in 1975	50000	28700	52706	28700	3466	40705	3466
36 kip COB units manufactured in 1977	36000	30804	38027	30804	17389	29205	17389
25 kip COB/CP units manufactured in 1966	25000	17014	23486	17014	-551	8867	-551
25 kip COB units manufactured in 1979	25000	20336	25121	20336	843	12350	843
15 kip COB units manufactured in 1978	15000	12964	16124	12964	1033	9146	1033
15 kip COB units manufactured in 1972/3	15000	14006	17898	14006	6163	13350	6163

The data in Table 4-1 clearly demonstrate that all the groups of the as-found insulators fail to meet even the obsolete historic new insulator requirement of the mean M&E failing load being above the M&E rating plus 1.2 standard deviations. The substandard performance of the tested insulators becomes far more apparent when examined under today's requirements for new insulators which require that the mean M&E failing load exceed the M&E rating by at least 4 standard deviations. The insulator performance is so poor that the results for the group 6 insulators show that the recorded mean M&E strength less 4 standard deviations falls below 0. Such a result is clearly physically impossible and can be attributed to the combination of the extremely high 24 % standard deviation and low mean measured M&E strength.

Finally, when comparing the test data to standard requirements, it should be remembered that in addition to the requirements for the calculated mean and standard deviation, most standards require that none of the tested insulators show an M&E failing load below the specified M&E rating. Table 3-6 shows that the insulators tested (without TMC conditioning) fail to meet that requirement with the number of insulators having M&E failing loads below the specified value ranging between 93 and 12% for the six data sets.

5 APPLICATION OF THE EXPERIMENTAL FINDINGS

The state of the compromised in-service insulators can result in line drops due to two distinct mechanisms. When a string containing electrically punctured insulators undergoes a flashover due to lightning, contamination, or snow and ice bridging, there is a high likelihood that the ensuing power arc will pass through the punctured unit internally going from cap to pin [8]. This results in significant heating and pressure buildup which can cause the cap and pin to separate and the conductor to drop. The greater the number of punctured insulators in the string, the higher the probability of string flashover and string separation. Insulators which are not punctured, but have suffered a deterioration in ultimate mechanical strength do not exhibit this behavior. If a string contains mechanically compromised units, the insulators will fail if the maximum applied load exceeds the units remaining mechanical strength. The majority of conductor drops recently experienced on Hydro One's porcelain insulated transmission system fall into the former category.

In October of 2006, CIGRE WG B2.03 issued a report titled "Guide for the Assessment of Old Cap and Pin and Long-Rod Transmission Insulators Made of Porcelain or Glass: What to Check and When to Replace" [4]. The guide recommends that M&E tests be combined with Thermal Mechanical Cycling tests to assist in determining when insulator populations should be replaced. The use of TMC conditioning in our tests was based on their approach.

The CIGRE method suggests the following process:

1. Remove a sample of the suspect insulators from service.
2. Subject half of the insulators to M&E testing and calculate the mean (M1) and standard deviation ($\sigma 1$) of the measured mechanical strength.
3. Calculate the value of the mechanical load ($P1_{5\%}$) corresponding to a 5% probability of mechanical failure of the insulators based on the values of M1 and $\sigma 1$.
4. If $P1_{5\%}$ is not significantly higher than the insulators M&E rating, then subject the remaining half of the insulators to Thermal Mechanical Cycling (TMC) in accordance with IEC 60575 (see Table 3-4).
5. Perform M&E tests on the TMC insulators and calculate the mean (M2) and standard deviation ($\sigma 2$) of the measured mechanical strength and use those values to calculate the value of the mechanical load ($P2_{5\%}$) corresponding to a 5% probability of mechanical failure of the insulators based on the values of M2 and $\sigma 2$.
6. Compare the values of $P1_{5\%}$, $P2_{5\%}$ and the specified M&E rating.
7. If the value of $P2_{5\%}$ is lower than both $P1_{5\%}$ and the specified M&E strength, then the insulators should be expected to continue deteriorating and it is recommended that they be "re-tested and/or closely monitored and/or replaced". replaced have reached the end of their useful life and should be. In the case where both $P2_{5\%}$ is below $P1_{5\%}$ and both values are

lower than the specified M&E rating the insulators have reached the end of useful life and must be replaced.

The analysis concept described above is shown diagrammatically in Figure 5-1.

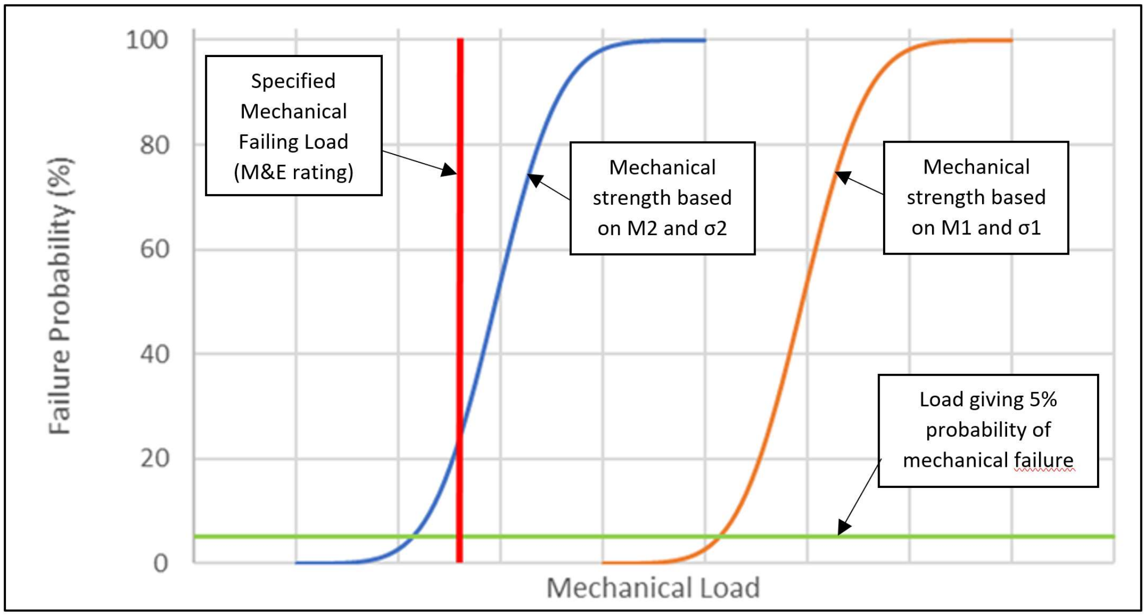

Figure 5-1
M&E and TMC analysis recommended by CIGRE

Our tests followed the above procedure with the exception that the TMC performed comprised only 2 cycles rather than the IEC recommended 4 cycles. As explained earlier, the number of cycles used in the TMC was reduced due to concern that the recommended 4 cycles would break too many of the insulators.

The IEC standard TMC procedure and the procedure that was followed in these tests are described in detail in Appendix B.

The analysis of the test results is given in Table 5-1.

Table 5-1
Results of the test analyzed in accordance with CIGRE recommendations

Inventory Group	Data Set	M&E Rating	Mechanical load corresponding to 5% failure probability without TMC ($P1_{5\%}$)	Mechanical load corresponding to 5% failure probability with TMC ($P2_{5\%}$)
		(lbs)	(lbs)	(lbs)
1 and 2	50 kip COB units manufactured in 1975	50000	49278	47305
3 and 4	36 kip COB units manufactured in 1977	36000	35506	32762
6	25 kip COB/CP units manufactured in 1966	25000	19309	17871
7 and 8	25 kip COB units manufactured in 1979	25000	21472	22896
11	15 kip COB units manufactured in 1978	15000	14131	13827
12	15 kip COB units manufactured in 1972/3	15000	16599	15464

As can be seen from the tabulated results, the mechanical load corresponding a 5% failure probability for the TMC insulators ($P2_{5\%}$) and is lower than both the mechanical load corresponding a 5% failure probability for the non TMC insulators ($P1_{5\%}$) and the specified mechanical strength (M&E rating) for all but the group 12 insulators. In addition, the data show that for the group 1, 2, 3, 4, 6, 7, 8, and 11 insulators, the mechanical load corresponding to a 5% failure probability for the non TMC insulators ($P1_{5\%}$) is below the specified M&E strength. Based on these results, it is clear that the insulators have reached the end of useful life and should be replaced. The only group of insulators not clearly requiring replacement is group 12. However, given that their performance is only marginally better than that where immediate replacement is recommended, the prudent course of action is to replace all of the insulators.

As mentioned earlier in this section, the CIGRE guidelines do not take insulator puncture into consideration. Given the fact that most of the recent line drops experienced by Hydro One have been caused by punctured insulator separation due to flashover and power follow current, further credence is given to the recommendation to replace the insulators because of:

- the propensity for the insulators to puncture (crack) during TMC
- the fact that the insulators are highly susceptible to electrical puncture under steep transient voltages due to lightning
- the finding that TMC drastically decreases the already weak ability of the insulators to withstand electrical puncture
- the fact that a significant number of insulators separated mechanically during the TMC.

6
RECOMMENDATIONS

The analysis of testing performed on the 591 insulators removed from service in 2017 provides overwhelming evidence supporting replacement to mitigate the risk to the safety and reliability of Hydro One's transmission system. The key recommendation of this work is that the identified population of COB and CP insulators be removed from service as soon as practically possible.

A
CHECK OF DEFECTIVE INSULATOR MANUFACTURING START DATE

Phase 1 of the testing identified potentially deficient performance in a sample of COB 1963 insulators, this raised the question as to whether 1965 is the correct cut-off year for defective insulator production. In order to explore this question, the as-found tests were performed on a 20 15 kip CP and COB insulators from 1952 and 20 15-kip COB insulators from 1963.

The Megger and ac withstand tests showed that there were no punctured insulators in either of the samples. The results of the M&E test are presented below in Figure A-1.

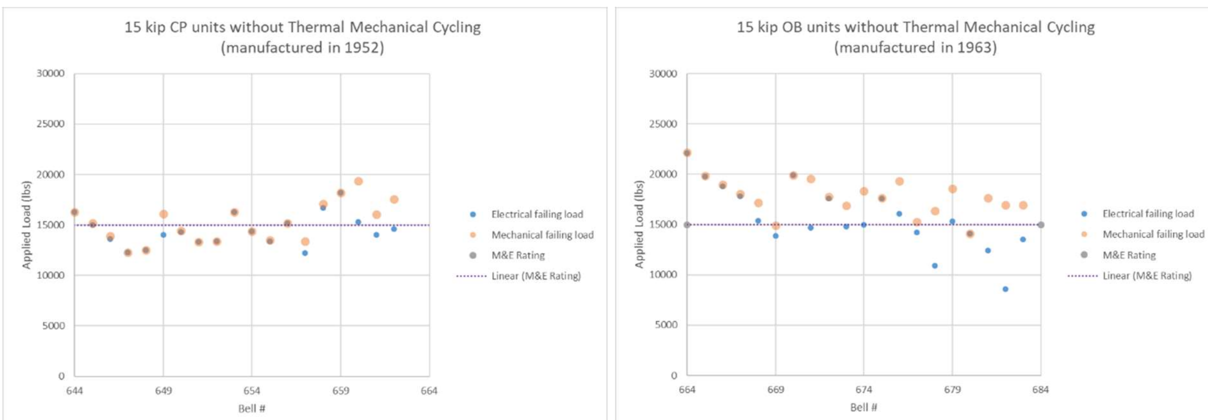

Figure A-1
Results of M&E tests on 1952 CP/COB and 1963 COB insulators

The data in Figure A-1 were analyzed as normal distributions to obtain the mean and standard deviations of the electrical strength, the mechanical strength and the M&E strength. The calculated mean and standard deviation for the two groups of insulators are shown in Table A-1.

Table A-1
M&E performance of 1952 CP/COB and 1963 COB insulators

Insulator Group	# of bells	# of bells meeting rating			M&E Statistics					
		Electric	Mech	Both	E mean (lbs)	E sigma %	M mean (lbs)	M sigma %	Comb mean (lbs)	Comb sigma %
15 kip CP units 1952	19	7	10	7	14469	11.0	15183	13.1	14469	11.0
15 kip OB units 1963	20	10	18	10	15625	20.6	17826	10.7	15625	20.6

The results shown in Table A-1 were not significantly different from those generated in the testing of the 15 kip insulators manufactured in 1978 and 1972/3. As such, the results of the tests on the 15 kip insulators manufactured in 1952 and 1963 were not sufficiently conclusive to verify the currently accepted cutoff year of 1965.

B DETAILED DESCRIPTION OF THE TEST PROTOCOLS

Megger Test

The insulator is tested using a 10 kV megger. The intent of the test is to determine the insulators resistance under a 10 kV dc voltage. The megger is connected between the cap and pin of the insulator, and insulators are tested individually with the measured resistance being recorded for each unit.

Figure B-1 shows the Megger test instrument and Figure B-2 shows insulators undergoing Megger testing.

Figure B-1
Example of a 10 kV Megger

Figure B-2
Insulators undergoing Megger test

AC Withstand Test

The ac withstand test is intended to assess the electrical condition of the insulators. The procedure comprises energizing several insulators at a time with a 60 Hz supply. The voltage is raised to approximately 70% of the insulators' power frequency flashover voltage and maintained for a period of 1 minute. If there is a breakdown in any of the units under test, the unit will be identified and assigned an internal flashover value.

Figure B-3 shows insulators undergoing the ac withstand test.

Figure B-3
Insulators undergoing ac withstand test

M&E TEST

The M&E test is performed on each of the insulators. The insulator is mounted in a tensile testing machine. The test comprises applying 60% of the insulator flashover voltage to the unit under test and gradually increasing the tensile load until failure occurs. Failure is defined as the load at which the insulator ceases to support either the mechanical load or the applied voltage. If the insulator ceases to withstand the applied voltage before mechanical failure, the load at electrical failure is recorded and the loading is increased until mechanical failure occurs. The failure mode can vary between insulators. Typical mechanical failure modes of aged insulators include pin breakage, cap breakage, pin slip-out, porcelain breakage, etc. and is recorded for each insulator. Figure B-4 shows the test setup and Figure B-5 shows several examples of different modes of failure.

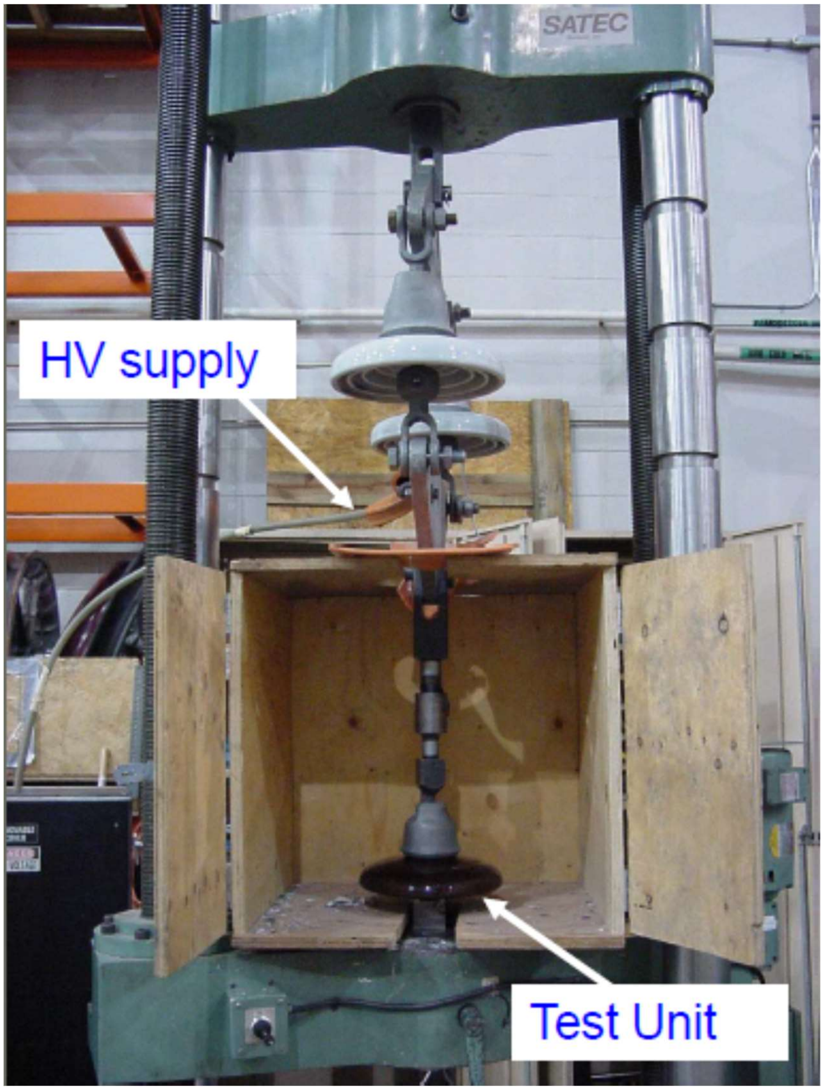

Figure B-4
M&E Test setup

B-4

Figure B-5
Typical modes of failure observed with the aged population of insulators being investigated

Thermo-Mechanical Test

The Thermal-Mechanical Load Cycle Test is designed to simulate the aggregation of everyday conditions that an insulator installed in Canada might experience during its lifetime in service. The test includes a superposition of at least three contributions to the mechanical stressing of the porcelain: the part due to the applied tension, the part due to the cement expansion, and the thermal strains.

During the Thermal-Mechanical Cycling Test described in IEC 60575, the insulators are subjected to four 24-hour cycles of ambient air cooling and heating with a simultaneously applied tensile load. Each 24-hour cycle starts with a cooling period followed by a heating period. The procedure requires that in the cooling period, a low temperature of -50 ℃ is maintained for at least a four-hour period while during the heating period a high temperature of 50 ℃ is maintained for a period of at least the same duration. During the two extreme temperature periods in each cycle, the tensile load applied to the insulators is maintained at 65% of the M&E rating of the insulators. Figure B-6 illustrates the test procedure.

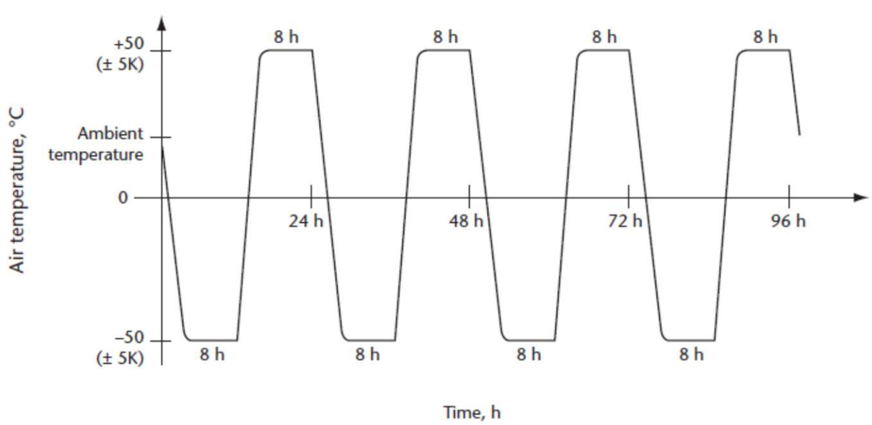

Figure B-6
Thermal-Mechanical Cycling Test Procedure

The tensile load is completely removed and reapplied at the end of each of the first three 24-hour thermal cycles. During testing, the ambient air temperature of the chamber is maintained, as required by the standard, at within 5℃ of the specified extreme temperatures in the two extreme temperature periods. At the end of the fourth thermal cycle, upon cooling the chamber to room temperature, the tensile load is removed.

The large temperature variation chosen for the test was to maximize the thermal stresses caused by the differential expansion of the steel pin, the cement and the porcelain. It is known that moisture ingress into the insulator cement is largely responsible for cement expansion.

Figure B-7 shows a set of insulators installed in the Thermal Mechanical chamber ready for testing.

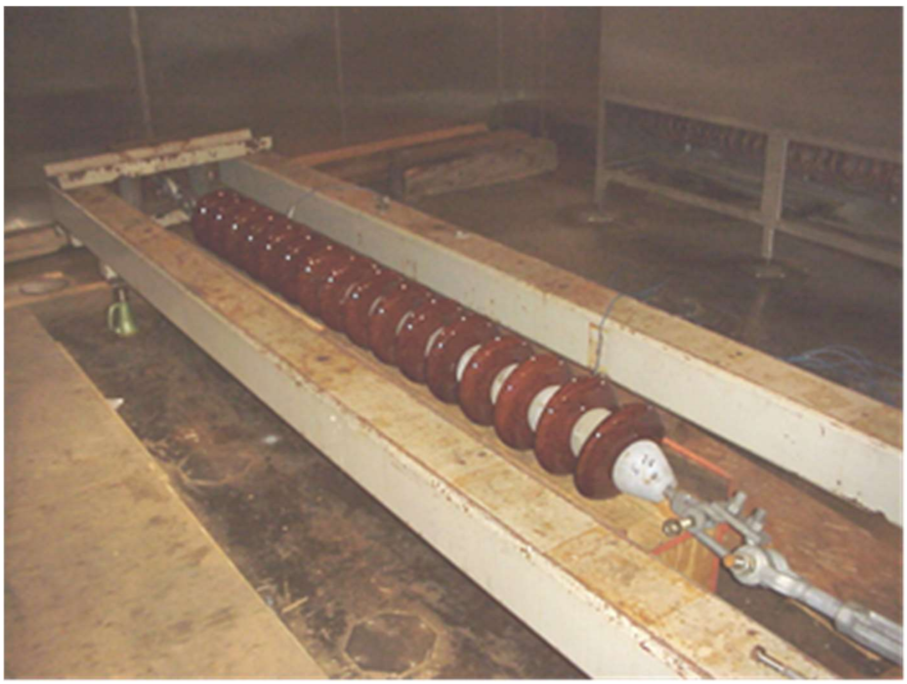

Figure B-7
Insulators installed in Thermal Mechanical test setup

Since the insulators that are to be aged through Thermal Mechanical testing have been significantly aged in-service and are known to be defective, there was concern that using the standard IEC test parameters (temperature, loading, number of cycles) as recommended for new insulators may result in mechanical failure of many of the insulators during the Thermal Mechanical test. Based upon the results of the phase 1 testing, it was elected to perform the test using the temperature, loading, and cycle duration recommended in the IEC standard (which is less severe than the CSA standard), but with the number of cycles reduced from 4 to 2.

Steep Front Puncture Test

The steep front puncture test is designed to simulate the voltage impressed on insulators as a consequence of lightning strikes. In-service line insulators are subjected to steep front overvoltages due to lightning. The rise times of these overvoltages vary from several hundred to several thousand kilovolts per microsecond. For the faster voltage surge rise times, i.e., 2,500 kV/µs, the formative time lag for external flashover of the insulator allows for a very high voltage to be reached before external flashover occurs. Although this voltage appears across the full insulator string, the non-linear voltage distribution along the string results in the development of a very high voltage stress across the first few line-end units. Repeated exposure to such high lightning generated stresses can lead to partial breakdown of the porcelain/glass dielectric, and eventual complete puncture of the dielectric within the head of the insulator.

In order to test an insulator's ability to withstand exposure to the very high lightning generated voltages which can occur in service, it is necessary to apply a very high voltage between the cap and the pin. If this is attempted in air using either power frequency or standard lightning impulse voltages, the air around the insulator always breaks down at a voltage much lower than the highest voltages seen in the field.

In the 1970's the industry expressed interest in developing a puncture test that was more representative of in-service conditions under which punctures occur. This prompted the investigation into and the development of the steep front impulse voltage puncture test. The following paragraphs explain the approach used in the development of the steep front impulse puncture test.

When a standard 1.2 x 50 us lightning impulse voltage of sufficiently high peak magnitude is applied to an insulator, a flashover through the air around the insulator will always occur. If the peak magnitude of the applied impulse is increased while the waveshape is maintained the same, the steepness of the applied voltage increases.

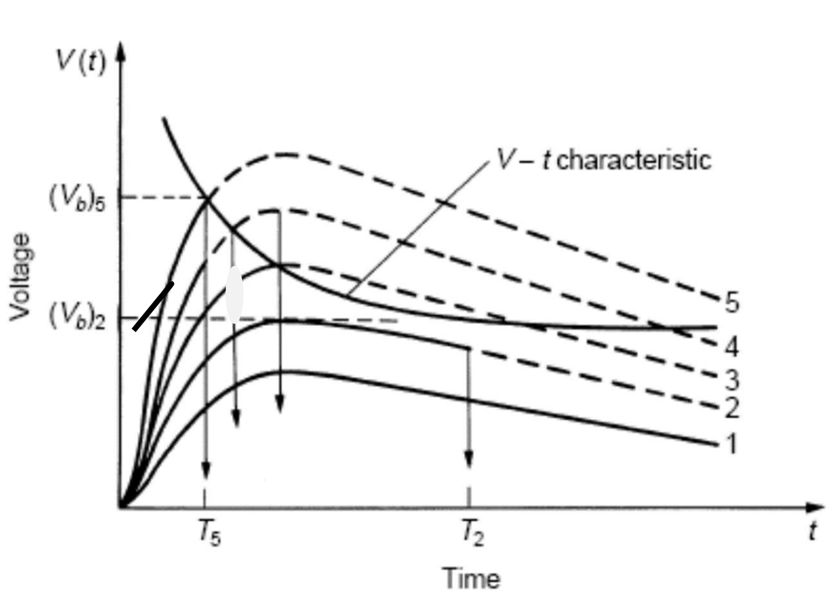

Figure B-8
Volt-time curve

Figure B-8 shows a set of 5 standard lightning impulses of constant shape but increasing peak value. Curve 1 has a peak value below the minimum breakdown voltage (Vb2) and therefore does not cause a breakdown. Curve 2 has a peak value approximately equal to the minimum breakdown voltage and therefore breakdown occurs, but takes place on the tail of the applied impulse. As the impulse magnitude is gradually increased (curves 3 through 5), the breakdown of the air occurs at progressively shorter times on the front of the impulse and at progressively higher voltages. The solid curve labeled “V-t characteristic” is the line obtained by drawing a curve through the points at which breakdown occurs under standard lightning impulses of increasing magnitude. As can be seen from the V-t curve, the voltage at which an air gap breaks down increases as the steepness of the applied voltage is increased. This phenomenon is due to the time lags associated with the development of discharges and is fully explained in the literature. This increase in the breakdown voltage of air with increasing steepness of the applied impulse is the fundamental principle upon which steep front impulse testing is based.

The primary advantage of the steep front impulse puncture test is that the voltage impressed across the solid dielectric within the insulator head is similar both in shape and magnitude to that encountered in service under lightning induced overvoltages. Figure B-9 shows the steep front test setup used for the puncture tests.

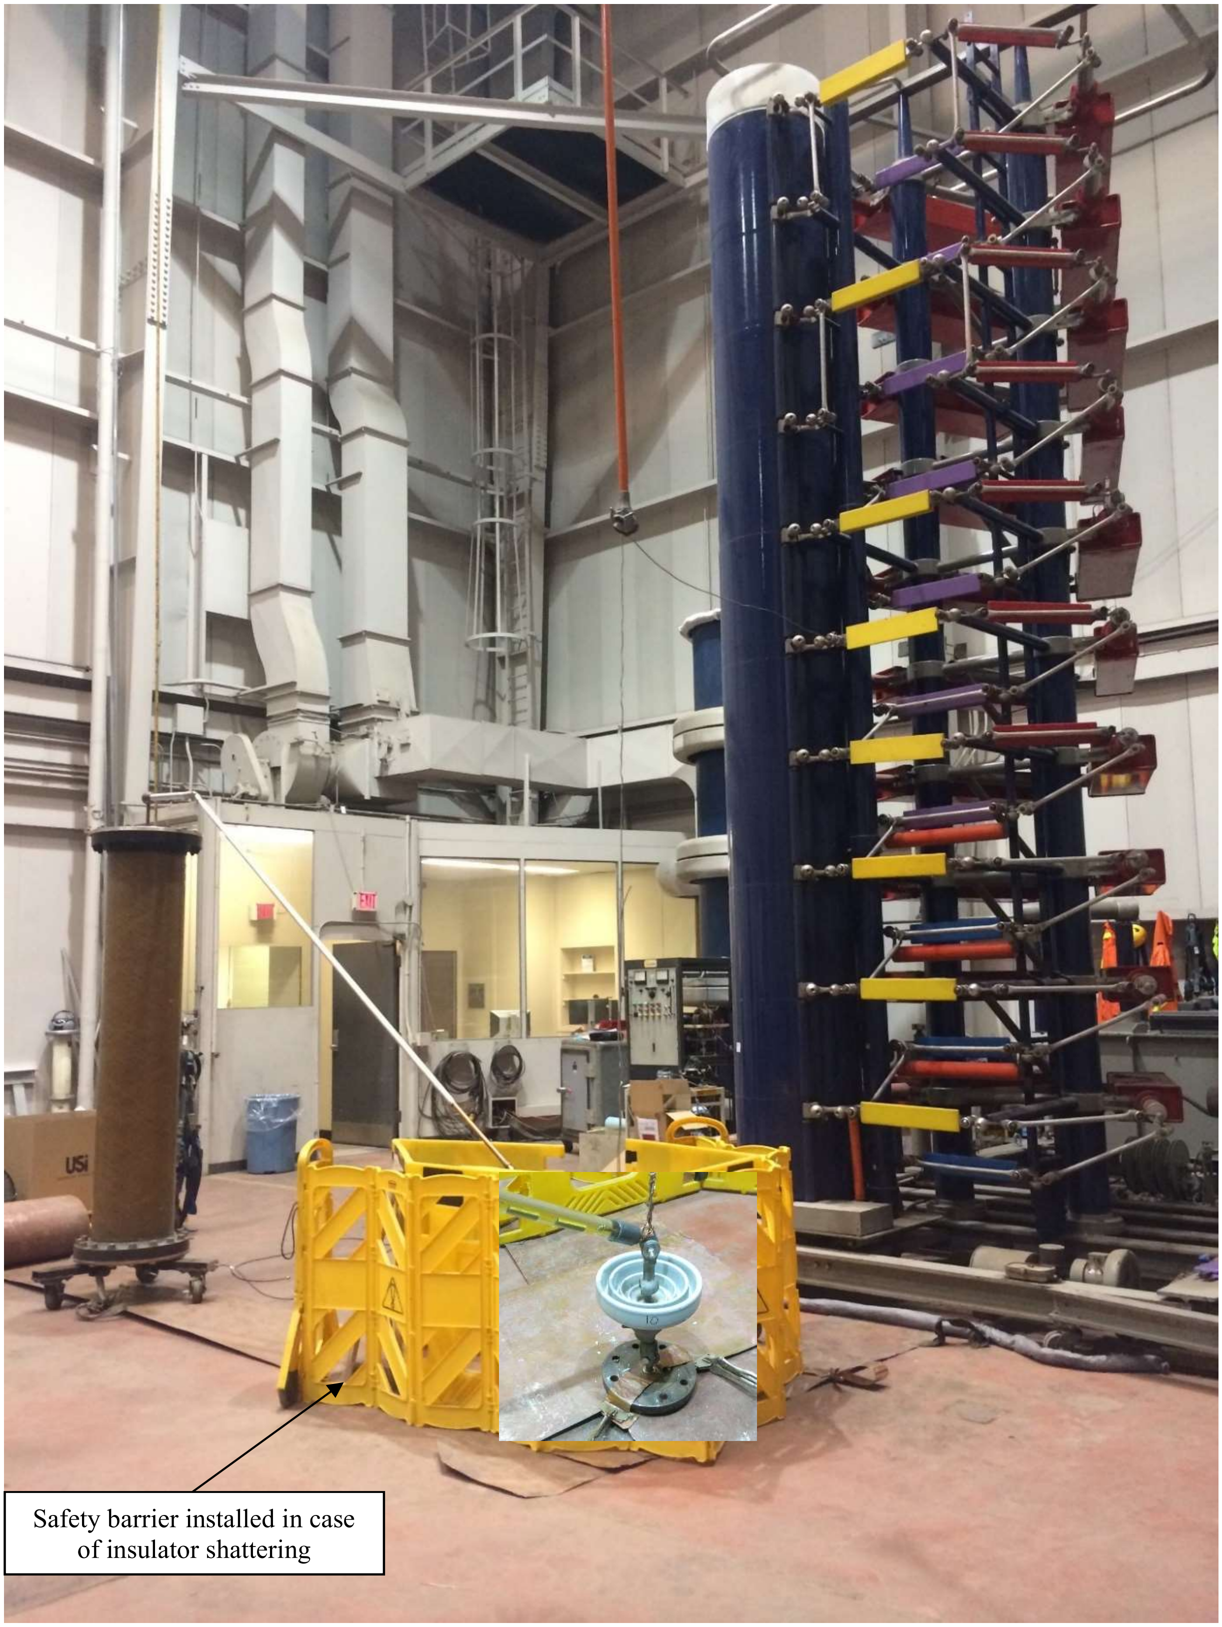

Figure B-9
Steep front test setup

The steep front puncture testing was carried out in accordance with IEC Standard 61211. Five insulators from each group were tested using a 20 impulse test sequence of

- Five positive impulses
- Five negative impulses
- Five positive impulses
- Five negative impulses

The impulse had a peak voltage of 2.8 times the CFO of the insulator. The insulator passes the test if no punctures occur.

Version 2	May 8, 2018	Final report

Executive Summary

Hydro One Networks Inc. ("HONI" or "Hydro One") retained METSCO Energy Solutions Inc. ("METSCO") to perform a third-party assessment of three elements of its transmission system asset planning process, namely the Asset Analytics (AA), Asset Risk Assessment (ARA) and Reliability Risk Model (RRM) frameworks. Each of the three capabilities plays a distinct role in the utility's transmission planning work, and along with other analytical, diagnostic and stakeholdering inputs, collectively manifest themselves in the form of Transmission System Plans (TSP) submitted to the Ontario Energy Board (OEB).

METSCO's involvement in this project entailed gathering of information and conducting document and data analysis – either through on-site interviews with HONI subject matter experts, or by way of independent review of information supplied by the utility. To structure our assessment and present our findings in both a comprehensive and a transparent manner, METSCO devised two discrete evaluation frameworks used for the AA/ARA, and the RRM frameworks respectively. We opted to rely on two separate evaluation frameworks in light of the relative degree of significance between the AA/ARA and RRM capabilities within HONI's capital planning process, and certain distinct technical attributes that warrant more focused attention.

In the case of the AA and ARA capabilities, which form the backbone of HONI's transmission system Asset Management (AM), we utilized a comprehensive three-level evaluation framework, assessing the Overall Process Integrity, Asset Class-specific Assessment Parameters, and Practical Outcomes of the Analysis. Our criteria and conclusions within each level of assessment reflect our extensive experience and expertise in the area of electricity system asset management, system planning and advanced analytics. In employing a three-level review structure, METSCO was able to consider multiple key dimensions of the AA and ARA capabilities, namely:

- Their overall robustness, completeness and sophistication;
- The suitability of technical parameters used in asset class-specific analysis;
- Whether the outputs can be expected to contribute to prudent planning.

The detailed evaluation parameters comprising each framework are outlined in the sections that follow.

Our evaluation of the RRM capability – a forecasting tool the output of which is used in customer engagement efforts to outline directional changes to reliability risk relative to expenditure levels, to demonstrate the value of proposed investments and help HONI elicit the input from customers – proceeded by way of a framework that evaluates the robustness, completeness and sophistication of system reliability forecasting.

METSCO developed this framework based on our experience of working in the issue area of reliability forecasting with utilities across North America, including development and implementation of reliability forecasting models, reliability forecasting best practices research, and third-party assessments of reliability predictive capabilities deployed by individual utilities.

In relation to the evaluation framework for the AA / ARA capabilities, the RRM evaluation framework is comparable to the top-level Overall Capability Sophistication framework, albeit using slightly modified criteria. Unlike the AA / ARA capabilities, however, METSCO did not conduct a deeper level of analysis for the RRM framework, such as the asset-class specific technical issues, or the manner in which the model's outputs inform further planning decisions. The reason for this comparatively lower granularity of review of the RRM relative to AA/ARA capabilities is the more limited degree of application of RRM results within the asset management processes. Since RRM is to show utilized within the customer engagement stage of asset planning work – an area out of scope of this report – METSCO is not in a position to opine about the merits of its practical application.

The following diagram provides a comprehensive overview of the evaluation frameworks presented in this report:

Assessment Level and Description	Asset Analytics (AA) & Asset Risk Assessment (ARA) Capabilities	Reliability Risk Model (RRM) Capability
	Criteria / Areas of Review	Criteria / Areas of Review
Level 1: **Overall Capability Sophistication** *How do HONI's capabilities rank in terms of their overall robustness, comprehensiveness and sophistication relative to common industry practices?*	Use of Risk-Based Analysis Data Utilization and Management Assessment Flexibility Ease of Comprehension Clear Sense of Gaps & Improvement Plans	Integration into the AM Process Approach Definition Forecasting Complexity Data Input Management Clear Sense of Gaps & Improvement Plans
Level 2: **Technical Parameter Robustness** *Do analytical approaches to the individual asset classes reflect the rigour expected of a utility of HONI's size and sophistication?*	Power Transformers Circuit Breakers Transmission Conductors Protection, Control & Telecom Station Ancillary Assets Underground Cables	No Further Assessments
Level 3: **Practical Application Issues** *How does HONI use the insights produced by these capabilities in practice?*	AA/ARA Application Case Studies: Projects supported by both AA & ARA Projects supported by AA but not ARA Projects Supported by ARA but not AA	No Further Assessments

METSCO Assessment Framework

Given their current methodological makeup and manner of utilization, we conclude that on balance across the categories of our assessment, the AA and ARA capabilities are comparable to advanced asset management practices found elsewhere in the industry.

Both AA and ARA capabilities are sufficiently rigorous and robust to accomplish their intended tasks, integrating within them all elements of advanced asset management capabilities, such as asset condition assessment, failure curves, and alternatives analysis, among many others. While we make a number of recommendations for further enhancements of the AA/ARA systems across the specific asset classes examined, we note that the status quo of asset-class specific evaluation parameters is predominantly in line with advanced industry practices, with certain analytical elements approaching best-in-class capabilities.

In assessing the practical application of outputs of both AA and ARA capabilities, METSCO observed case study examples supporting the complementary nature of both frameworks, including instances where the outputs of the AA framework were modified by the insights from the ARA analysis that incorporates a comparatively greater degree and variety of quantitative and qualitative information, and vice versa. In both cases, the complementary insights generated through the use of the two capabilities suggested the courses of action that were more beneficial for the utility and its ratepayers than the use of any one framework in isolation. While this is a positive finding in the context of HONI's asset management practices, it also highlights the potential pitfalls of overwhelmingly relying on automatically generated quantitative outputs alone, as we discuss in the section detailing our review of practical case studies.

With respect to the Reliability Risk Model, METSCO's finding is that the tool's analytical underpinnings and functionalities trail advanced industry system reliability practices where these are deployed in the asset management. In making this observation, we note that a number of utilities do not or have not until recently attempted to formally forecast system reliability in a comprehensive manner. This contextual observation suggests that the RRM capability constitutes a bona fide continuous improvement step. Given that the RRM tool is currently used primarily as a customer communications tool to convey indicative changes to reliability risk levels across spend scenarios, the observed gaps in its technical parameters pose no meaningful risks from the asset planning perspective. We observe that the RRM tool's outputs could add a valuable "technical implications" dimension to customer engagement efforts, so long as HONI is clear about the tool's purpose and the implications of its analysis.

Notwithstanding these findings, potential improvements to the RRM capability (or another reliability forecasting capability that HONI may choose to procure) that METSCO recommends in this report, would enhance its practical applicability and robustness, should HONI decide to integrate the tool as part of the asset management decision-making process more broadly.

I Introduction

1.1. Purpose of the Study

METSCO Energy Solutions Inc. was contracted by Hydro One Networks Inc. to perform a third-party assessment of three elements of Hydro One's transmission asset management and capital planning process, namely the Asset Analytics, Asset Risk Assessment and Reliability Risk Model capabilities.

The overarching objective of our review was to establish whether the capabilities in question are sufficiently robust and rigorous to generate objective and valuable inputs into Hydro One's transmission system asset planning, given each tool's intended purpose. The scope of the study included a review of the AA/ARA processes in the broader context of the asset management decision-making process, a review of the AA methodology and the underlying scoring criteria, along with the data inputs and areas for improvement for the following asset classes: Substation Power Transformers, Circuit Breakers, Protection Control and Telecom, Station Ancillary, Transmission Conductors and Underground Cables.

The analysis of the RRM included a review and assessment of HONI's reliability risk projection approach and underlying mathematical algorithms, and identification areas of improvement with further recommendations. Our analysis and findings are grounded in extensive subject matter interviews, independent review of the documents, data and other materials provided by Hydro One.

Of the three capabilities that METSCO reviewed, the ARA and AA elements play a significantly more prominent role in HONI's asset planning processes compared to their RRM counterpart, which to date has been used exclusively as a directional risk communication indicator across multiple expenditure scenarios, with its outputs used in customer engagement efforts. Accordingly, we dedicated the bulk of our assessment efforts to the AA and ARA capabilities, given their comparatively greater scope, nature, and impact on Hydro One's planning and budgeting decisions.

1.2. Report Structure

The introductory chapter of this report describes the purpose of the study and the report structure, with the remainder outlining the details of the framework METSCO developed to conduct the review. Chapter 2 describes the key functional characteristics and nature of all three capabilities (AA, ARA and RRM) under review. Chapter 3 contains the details of assessment work performed in relation to the Asset Analytics and Asset

Risk Assessment methodologies, including several mini-case studies that describe the manner in which these frameworks' outputs affect the utility's actual asset management decisions. Chapter 4 contains the details of assessment of the Reliability Risk Model. The final Chapter of this report contains our conclusions and recommendations with respect to potential methodological and practical enhancements related to all three examined capabilities.

1.3. METSCO's Evaluation Frameworks Applied in the Report

Each of the three capabilities METSCO examined in the context of our engagement, represents a custom solution, emanating from Hydro One's legacy technical capabilities and data availability, emerging strategic and operational needs, its response to the incremental regulatory environment changes, and other utility-specific considerations. Notwithstanding the degree of incremental customization and continuous development (altogether common in the utilities industry), in METSCO's experience, most Asset Management analytics capabilities share a fundamental set of attributes that drive their overall effectiveness, efficiency and integrity.

At the core of any capability's value proposition are the logic, rigour, and comprehensiveness of its core analytical methodology, or the manner in which the capability selects and transforms the inputs of analysis into its ultimate outputs. Equally important, however, are the operational and organizational aspects of a given AM capability, including the form and function of its integration with other utility systems and processes; the clarity / ease of its comprehension by the utility's employees; and the manner in which it approaches unique aspects of individual asset classes or system components. Finally, an AM capability's value is ultimately reflected in the degree to which its outputs enable the utility to accomplish its intended objectives in practice.

The assessment framework that METSCO devised for the purposes of this engagement reflects all of these overarching considerations across its three levels or "layers" of assessment:

- At the highest level, entitled the *Overall Capability Sophistication*, we conduct a "system-level" review of the capabilities' key methodological and operational features, in an attempt to establish whether they are appropriate for a utility of HONI's size and sophistication. This is the only level of assessment we apply to all three capabilities.

- The second level of our assessment, which we call *Technical Parameter Robustness*, reviews in greater detail the technical elements of assessments applicable to the major asset classes. This assessment stage examines whether the tools utilize the appropriate data and analytical techniques for the major asset categories they review.

- The third and final level of our assessment – the *Practical Application Issues* – entails a review of case studies illustrating the manner in which the analytical insights generated by the capabilities under review help Hydro One make asset management decisions that maximize the value of their capital expenditures.

Figure 1 provides a visual overview of the assessment framework we applied in the course of this study:

Assessment Level and Description	Asset Analytics (AA) & Asset Risk Assessment (ARA) Capabilities	Reliability Risk Model (RRM) Capability
	Criteria / Areas of Review	**Criteria / Areas of Review**
Level 1: **Overall Capability Sophistication** *How do HONI's capabilities rank in terms of their overall robustness, comprehensiveness and sophistication relative to common industry practices?*	Use of Risk-Based Analysis Data Utilization and Management Assessment Flexibility Ease of Comprehension Clear Sense of Gaps & Improvement Plans	Integration into the AM Process Approach Definition Forecasting Complexity Data Input Management Clear Sense of Gaps & Improvement Plans
Level 2: **Technical Parameter Robustness** *Do analytical approaches to the individual asset classes reflect the rigour expected of a utility of HONI's size and sophistication?*	Power Transformers Circuit Breakers Transmission Conductors Protection, Control & Telecom Station Ancillary Assets Underground Cables	No Further Assessments
Level 3: **Practical Application Issues** *How does HONI use the insights produced by these capabilities in practice?*	AA/ARA Application Case Studies: Projects supported by both AA & ARA Projects supported by AA but not ARA Projects Supported by ARA but not AA	No Further Assessments

Figure 1. METSCO Assessment Framework

Our assessment of the Reliability Risk Model does not extend beyond this first level of assessment. The rationale for this decision is primarily grounded in the limited extent to which it is integrated Hydro One's asset management processes, (notwithstanding its use in customer engagement work as a risk communications and feedback generating tool)

Moreover, given the technical complexity of the AA and ARA capabilities and their relative significance in the utility's asset management work, our decision not to proceed with Levels 2 and 3 analysis for the RRM tool is also a practical matter of prioritizing among the project's multiple objectives on the basis of their significance, in an effort to concentrate the majority of our investigative efforts in the areas expected to be most relevant to this report's ultimate audience. For clarity, it is

METSCO's professional opinion that the assessment of the RRM framework that we do undertake in this report is sufficiently rigorous to render an informed opinion on the tool's effectiveness in the context of asset management today, and provide Hydro One with practical recommendations for further potential improvements to the model, or parameters of alternative reliability forecasting solutions it may wish to explore.

METSCO's selection of specific criteria underlying each level of this assessment, along with our expectations as to what constitutes an "appropriate" level of complexity and sophistication, is informed by our extensive experience in the field of utility asset management in most Canadian provinces and territories, and multiple jurisdictions in the United States and Europe.

In the course of these past engagements, METSCO developed theoretical methodologies and practical tools for optimization of capital asset lifecycles, independently reviewed the capabilities and asset management plans of multiple utilities, conducted inter-jurisdictional best practices reviews of asset management and reliability forecasting best practices, and contributed to academic literature on the related topics. While our assessment of Hydro One's capabilities does not amount to a direct peer-to-peer comparison across specific utilities, our mode of enquiry and the subsequent conclusions reflect a diversity of these experiences, along with the expertise we acquired and refined in process.

Prior to discussing the nature of each assessment step in more detail, we note that our review did not consider the additional "upstream" procedures associated with the inputs used within AA, such as mechanics of algorithms used to calculate the condition results, nor did this evaluation consider the additional "downstream" procedures such as the hand-offs between the planning group and the execution group, where planned work is formally scheduled, resourced and executed within the system.

1.3.1. *Assessment Level One: Overall Capability Sophistication*

The first level of METSCO's assessment, applied to all of AA, ARA and RRM capabilities, entails a system-level review across the key technical, operating, and methodological dimensions that enable these tools and processes to achieve their desired objectives. The goal at this stage of analysis is to establish whether a capability exhibits the combination and quality of key features that can be reasonably expected of a similar tool for a utility of Hydro One's size and complexity. We refer to this level of assessment as the Overall Capability Sophistication review.

A complicating feature of our review at this level arises from the fact that the three capabilities subjected to our analysis are substantially different from a functional perspective. While the RRM capability amounts to a discrete tool used for a single purpose, the ARA functionality represents an overarching process that integrates multiple tools, activity systems, and types of analytical, diagnostic and consultative data. Finally, the AA capability is positioned between the two extremes in terms of complexity of its outputs and the processes that generate them.

To account for this functional variety, METSCO opted to use two separate sets of criteria – one for AA and ARA capabilities, and another for the RRM. In doing so, we were able to highlight certain issues that are specifically relevant for each set of capabilities, while ensuring that the overarching considerations (e.g. treatment of data, integration into the AM process, etc.) are incorporated into both sets of criteria.

The following Figure illustrates the criteria comprising our first level of the framework, followed by a brief description of each individual criterion:

Overall Capability Sophistication Assessment		
Capability	**AA & ARA**	**RRM**
Assessment Criteria	1. Use of Risk-Based Analysis 2. Data Utilization and Management 3. Assessment Flexibility 4. Ease of Comprehension & Downstream Application 5. Clear Sense of Gaps & Improvement Plans	1. Integration into the AM Process. 2. Approach Definition. 3. Forecasting Complexity 4. Data Input Management 5. Clear Sense of Gaps & Improvement Plans

Figure 2. Overall Capability Sophistication Assessment

<u>AA and ARA Assessment Criteria:</u>

1. Use of Risk-Based Analysis – whether and to what extent a capability utilizes the key principles of risk-based analysis, as captured by asset management standards such as ISO 5500x, where risk assessment involves consideration of both probability and impact of asset failure.

2. *Data Utilization and Management* – the degree to which an AM capability / framework is supplied with electronic data inputs from a utility's enterprise systems and databases, such that the resulting AM analytical outputs can be updated in real-time and with little to no manual intervention. Within this criterion, we also assess whether an AM tool's outputs are expressed, in whole or in part, in a numerical form (such as

an index), to facilitate their subsequent consideration on balance with outputs from other AM tools and processes in a way that facilitates objective consideration.

3. *Assessment Flexibility* – the manner in which an AM framework balances the objectives of methodological consistency and flexibility required to account for the diversity of factors influencing asset performance across the different asset classes. While flexible approaches are generally preferred to "one-size-fits-all" frameworks, a successful approach will nevertheless exhibit meaningful features of discipline and consistency across all the individual asset classes.

4. *Ease of Comprehension and Downstream Application* – the extent to which the utility's staff and other key relevant stakeholders understand the nature, implications, and the manner of presentation of its outputs. While the AM analytics landscape is becoming increasingly more sophisticated, it is nevertheless desirable that the outputs of a given tool can be meaningfully explained and presented in a simple and transparent form, to ensure that its asset planners, managers and other key staff members involved in AM planning and implementation, understand the strategic objectives, operational mechanics, and methodological limitations of a given AM functionality, to enable consistent and objective decision making downstream from the tool itself.

5. *Clear Sense of Current Gaps and Continuous Improvement Plans* – whether and to what extent the conclusion of a discrete investment project, or a broader planning cycle involving an AM capability, includes a review stage to identify any functional or methodological gaps, and assess the plans for their rectification in the future. More generally, the utility deploying AM analytics capabilities should possess an understanding of their current gaps, while recognizing that continuous improvement of its asset analytics is necessary to ensure that AM decision-making continues to evolve.

RRM Assessment Criteria:

1. *Integration into the AM process* – the extent to which a given reliability forecasting capability is integrated into the utility's overall asset management process and the tools that support it, such that the forecasted reliability outcomes are functionally incorporated into the tools and processes that determine the scope, nature and type of intervention activities across the capital and maintenance programs.

2. *Approach Definition* – the breadth and granularity of analysis underlying the forecasting methodology, including length of forecasting horizons and source data periods, the extent of and methodologies used for data exclusions, along with the manner in which outage drivers are analyzed, and system components are modelled.

3. Forecasting Complexity – sophistication of mathematical calculations supporting the forecasting model, including the degree to which it utilizes empirically derived correlations between outage modes, durations, and performance of specific asset classes and other relevant phenomena (e.g. weather/climate, human errors, foreign interference, etc.).

4. Data Input Management – efficiency of data collection procedures, and the degree to which tools and processes are in place to optimize and validate the integrity of input data used in model calculations.

5. Clear Sense of Current Gaps and Continuous Improvement Plans – consistent with the framework for the AA/ARA functionalities, this criterion assesses the degree to which the utility conducts periodic assessments of effectiveness of the forecasting tool, develops plans for its improvement, and exhibits an understanding of the tool's key gaps, along with the expectation that continuous improvement is both necessary and desirable.

1.3.2. *Assessment Level Two: Technical Parameter Robustness*

The second level of assessment in METSCO's evaluation framework concerns only the AA and ARA capabilities for reasons noted above and further substantiated in the concluding parts of the Level 1 RRM assessment. Recalling that one of the categories of our Level 1 assessment of these two capabilities is the degree of flexibility applied to analysis of various asset classes, our Level 2 assessment reviews the AA and ARA frameworks from the perspective of six major asset classes that undergo analysis by these two frameworks. These asset classes are:

- Power Transformers
- Circuit Breakers
- Protection, Control & Telecom Infrastructure
- Station Ancillary Equipment
- Overhead Transmission Conductors
- Underground Transmission Cables

Building on findings from the Level 1 assessment, Level 2 review considers the key aspects underlying the evaluation of each asset class, including (as relevant) the nature and composition of asset condition parameters, the manner of application of additional analytical and diagnostic tools, and the related strategies, policies, and implementation plans. Similar to the first level of analysis, in assessing these and other related elements of Hydro One's AM capabilities on an asset class level, we make periodic references to the state of the broader utilities industry with respect to similar issues.

METSCO notes that unlike the first level of assessment, we do not employ a single set of evaluation criteria across the six asset classes we assessed, but rather discuss the issues that we see as most pertinent in every particular case.

1.3.3. *Assessment Level Three: Practical Application Issues*

The final assessment level in our three-step framework involved the examination of practical application of the AA and ARA outputs in Hydro One's asset management and capital planning processes. Following a substantive assessment of technical and operational matters in the previous two steps of the framework, METSCO's objective in the final stage was to examine a range of practical case studies that illustrate the manner and outcomes of Hydro One's actual utilization of the AA and ARA results in the course of making real-life asset management decisions.

In practical terms, we carried out this stage of our engagement by way of interviews and collaborative record reviews with Hydro One's Subject Matter Experts (SMEs) responsible for the Stations and Lines programs. In the course of these engagements, METSCO asked Hydro One SMEs to produce examples illustrative of typical process flow within AA and ARA frameworks, as well as examples where the insights from one functionality did not align with those generated by the other. In reviewing these mini-case studies we sought to examine whether their ultimate outcomes – that is the practical decisions as to the scope, manner and timing of asset interventions – were objective and logical from the perspective of Asset Analytics, and consistent with the intended objectives of the functionalities examined.

METSCO notes that the nature of our examination within this stage (and by extension, its findings) did not constitute a detailed audit, but rather amounted to a survey of representative examples, accompanied by contextual commentary from Hydro One specialists. Given the number of projects that comprise Hydro One's capital work program each year, the scope of our survey within this Level of assessment does not give us sufficient grounds for making any broad-based conclusions about the efficiency of the utility's overall capital investment plan. However, when examined alongside our findings from the previous two levels of assessment, Level 3 insights enable METSCO to conclude whether the technical elements of the capabilities examined and opined on in earlier stages, manifest themselves in practice in a manner consistent with their intended use.

In other words, while the first two stages of our assessment entailed a static review of key process dimension and individual mechanic components, Level 3 assessment is comparable to the examination of results of a live test run, where the combination and interaction of individual components produced outcomes in a realistic setting, shaped by Hydro One's organizational dynamics at the time that these assessments took place.

The remainder of this report provides a more detailed description of the three capabilities within the scope of this assessment and relays our findings across the three levels of assessment, concluding with detailed recommendations aimed at continuous improvement of the three capabilities.

2. Scope, Nature and Function of the Asset Management Capabilities Under Assessment

Prior to proceeding with our assessment, this section provides a more detailed explanation of the Asset Analytics, Asset Risk Assessment and Reliability Risk Model capabilities. With respect to AA and ARA in particular, and as noted earlier, the AA capability represents a distinct component of the ARA process, singled out for the purposes of this assessment given its role as a quantitative analysis "engine" positioned at the outset of the broader multi-component asset need identification process that ARA represents. Yet, the AA capability is ultimately a component of the broader ARA functionality, meaning that the assessment of the latter inevitably involves the assessment of the former. As such, for the purposes of our review, we discuss the two capabilities together, specifying where our comments concern one capability or another, where relevant. This chapter concludes with the description of the Reliability Risk Model to which we apply a distinct set of evaluation criteria.

2.1. Asset Analytics and Asset Risk Assessment Capabilities Overview

HONI's AA and ARA frameworks combine to form a crucial part of the utility's asset management process. Results from AA, which include the overall composite risk score, as well as the underlying sub-index components of this composite score (e.g. condition results), provide HONI asset managers and planners with an initial means of prioritizing the assets undergoing the assessment, subject to further evaluations.

Upon the completion of the AA analysis, Hydro One proceeds to perform further steps of the ARA procedure, supplementing the comprehensive numerical index and multiple component sub-indices generated by the AA capability with additional input categories generated through other processes, such as customer preferences, regulatory constraints, etc., in order to perform a comprehensive options analysis and establish a preferred risk treatment, that is, the specific scope and nature of recommended asset interventions.

Importantly, in the course of the ARA process, Hydro One also performs a number of verification and validation steps, including site visits, and other types of needs confirmation / screening tests to ensure that the analytical insights generated thus far, are reflective of reality in the field, and sufficiently robust to be incorporated into the final prioritization assessments, passed on further down the investment planning chain.

2.1.1. *Asset Analytics Capability Characteristics*

Asset Analytics is quantitative decision-support tool which analyzes the aggregated data supplied by various enterprise platforms (ultimately organized into a centralized data warehouse) in order to produce a series of quantitative indices based upon pre-defined criteria and methodologies.

The outputs of the AA process are a Composite Risk Score and a framework of individual analytical parameter Risk Score Sub-Indices, ranging from zero (lowest risk) to 100 (highest risk). These scores are derived for each individual asset. The sub-indices represent the following assessment sub-categories:

- *Condition*: considers the data on the physical state of assets and their core components along the relevant degradation factors expected to compromise the overall condition of an asset. Condition data used in the index development is sourced from field inspections, as well as Preventative Maintenance, Defect, and Trouble Call Reports, as relevant.

    - *Demographics*: Takes into consideration the assets' physical age in relation to its projected service life value or "Expected Service Life" (ESL), along with other demographic criteria like type, batch, manufacturer, etc. Hydro One defines asset ESL as the "average time duration in years that an asset can be expected to operate under normal system conditions and is determined by considering manufacturer guidelines and Hydro One historical asset retirement data." The ESL criteria for particular asset classes were derived from the results of a 2014 Asset Failure Analysis study conducted by Foster Associates, in which asset class-specific failure curves were validated using Hydro One's own historical failure data, and Iowa curve functions [3].

- *Criticality*: Takes into consideration the impact of failure at the individual asset, asset class, and station levels respectively. Input information for the formulation of this index includes factors like total customer load, voltage rating, critical customers and interconnections related to a given asset.

- *Performance*: Considers historical performance of a given asset, including the historical outage frequency and duration, as well as results from a Laplace trend test, which provide a measure of the difference in interval time between multiple forced outages.

- *Utilization*: provides the measure of asset deterioration related to the increased rate of asset utilization. Inputs such as the summer and winter peak loads, tap changer counter readings, and unit capacity data are used to formulate the index in this category for each asset.

- *Economics*: Takes into consideration the weighted average of emergency and corrective costs required to maintain the existing asset, as compared to the benchmark cost for the specific asset type/class.

Each of the AA evaluation category sub-indices, along with the overall composite score, contain references to "risk-based" calculations, incorporating parameters related to "probability" and/or "impact" of asset failure.

In cases where not all data input points underlying the indices are available, the AA tool can still produce a normalized evaluation category score, adjusting for the missing data. Every input data parameter used in the formulation carries a flag to indicate the status of data availability. A "Normal" flag indicates that the data is available to fully support the calculation. A "Default" flag, however, means that the input data parameter is missing, and has been substituted with a standard default value defined by HONI's subject matter experts. Finally, a "Missing" flag indicates where the input data parameter is missing, and no default value is available for substitution.

To account for these flags and the data gaps they represent, the AA functionality generates a Data Completeness Score – expressed as a percentage – to indicate to the end user how many actual and default supporting factors were used in the derivation of an index score. The system also generates a confidence level (expressed as a percentage), to indicate the degree of confidence in the calculated score, given the relative significance of the individual index parameters where data is missing, or a default value is in use. Critically, the flags and data completeness / confidence scores enable Hydro One staff to exercise additional judgment when assessing the AA outputs on balance with other inputs in the subsequent stages of the ARA process.

METSCO notes that not each of the six evaluation sub-indices is used in the generation of a Composite Risk Score for all asset classes, reflecting the relevance of a particular risk sub-category to a given asset class. Moreover, in the case of Protection, Control & Telecommunications assets, the AA framework is not substantially utilized in the ARA process, for reasons discussed further in this report.

The following section describes how the AA outputs, once generated in accordance with specifications related to each asset class, undergo further assessments in the subsequent stages of the ARA process.

2.1.2. *Asset Risk Assessment (ARA) Capability Characteristics*

Asset Risk Assessment (ARA) entails a full-spectrum asset management planning process that identifies the asset candidates to be included in the scope of the investment projects, of which AA is an input component used in conjunction with other input parameters, including:

- Asset class strategy and technical assessment documents, which utilize AA results and underlying data points in their analysis;
- Customer needs and preferences related to particular asset classes;
- Legal and regulatory requirements relevant for consideration;
- System planning and coordination requirements affecting potential intervention options;
- Health & Safety, environmental, and obsolescence-related;
- Field inputs, maintenance notifications, and relevant event investigations;
- Results of detailed assessments and diagnostic testing; and
- Field visit validation of asset needs suggested by ARA analysis.

Figure 3 illustrates the entire scope of the ARA process.

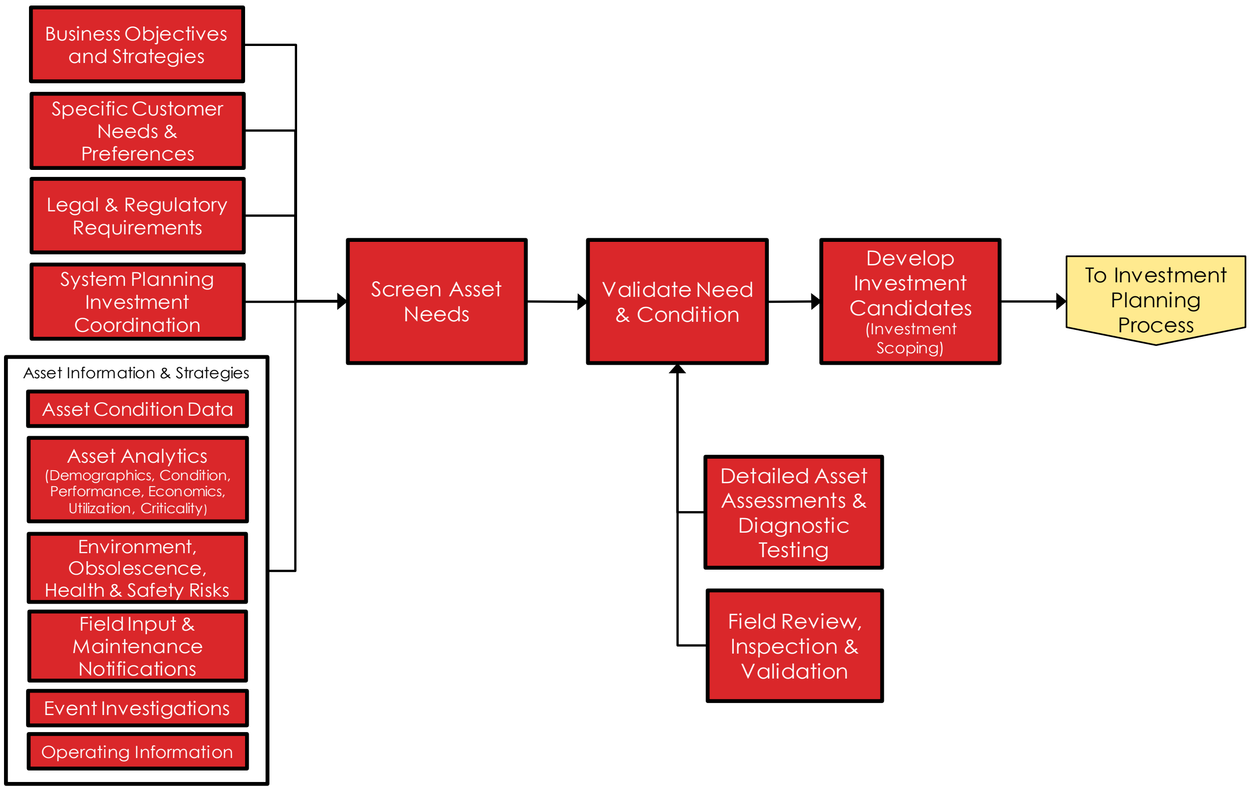

Figure 3. Asset Risk Assessment Process

Overall, the ARA functionality serves to expand upon the initial prioritization as established by AA, by allowing asset planners and managers to assess and stress-test the insights produced by the AA functionality in the context of incremental data points, and considerations that connection field data with the broader strategic, planning, and regulatory environment in which Hydro One operates.

2.1.3. *Reliability Risk Forecasting Capability Characteristics*

Reliability Risk Model is a standalone tool designed to develop system-level forecasts of changes in values of reliability risk relative to the capital investment levels underlying a particular scenario. METSCO understands that up to this point in its existence, the RRM's outputs were only used in the context of customer engagement meetings, to represent directional implications of reliability risk relative to the range of investment levels contemplated by the utility.

Given its current utilization, the tool and its outputs help contextualize Hydro One's investment considerations to customers, acting as a supporting mechanism in gathering customer feedback that is considered in the course of investment planning. With the exception of this indirect contribution into the investment planning activities, the tool and its outputs do not currently figure as input factors at any stage of the asset management process. For clarity, METSCO understands that the RRM analysis only takes place after the AM decision-making processes – including the use of AA and ARA capabilities – has been completed.

From a functional perspective, the RRM tool is grounded in failure probability curves derived in an aforementioned 2014 Asset Failure Analysis report [3], and asset demographics data of select asset classes. Using this data, the model ultimately predicts the age profile of assets over the forecasting horizon. Based on the replacement budget assumptions (i.e. the input investment scenario), the model then establishes links between investments and reliability risk.

Having described the tools within the scope of METSCO's assessment, the next chapter of this report contains our discussion of our findings with respect to the AA and the ARA functionalities.

3. Asset Analytics and Asset Risk Assessment Capabilities Evaluation

We begin the discussion of the findings of our assessment with the first system-level analysis across the following five criteria: (a) Use of Risk-Based Analysis; (b) Data Utilization and Management; (c) Assessment Flexibility; (d) Ease of Comprehension and Downstream Application; and (e) Clear Sense of Gaps & Improvement Plans.

Upon completion of the first Level of analysis, this chapter turns to the asset-class specific considerations affecting the use of AA and ARA capabilities, and finally, the results of our observations of the functional test cases showcasing the AA and ARA capabilities in action.

3.1. Level 1 Assessment: Overall Capability Sophistication

3.1.1. *Use of Risk-Based Analysis*

At the outset of this section, METSCO notes that Hydro One's process nomenclature uses the term risk extensively (including in the name of the ARA process undergoing assessment) to denote a variety of potential conditions, incidents, and contingencies that could potentially bring about adverse consequences to the utility's assets, systems and operations.[1] While we do not dispute the validity of Hydro One's use of the term "risk" and generally endorse the wide array of factors that the utility considers within its asset-related risk universe, we note that the definition of "risk" underlying this particular criterion of our assessment framework carries a particular meaning, consistent with the ISO 5500x asset management frameworks referenced in the criterion's definition.

In this context, the notion "risk" entails a single quantifiable number that combines the quantitative expressions of probability (%) and impact of an asset's failure expressed in numerical terms (e.g. outage impact that may be expressed in monetary terms) as a multiplication between the two parameters. Such an expression of risk (or risk costs) is considered to be an asset management best practice since it captures both likelihood and consequence of failure in a single numerical value – making prioritization across individual assets, asset classes, or intervention options both simpler and more transparent.

[1] We note that this is METSCO's formulation, established by way of our incremental interviews with Hydro One SMEs, rather than a definition in use at the utility.

When reviewing Hydro One's AA and ARA capabilities, we found multiple instances where failure probability and impact calculations are factored into the derivation of the AA Composite Index and its sub-components. For instance, elements of probability analysis are deployed within the calculation of the "Demographics" sub-category, which utilizes ESL criteria and failure curve calculations in deriving the sub-index score.

Similarly, parameters pertaining to probability of asset failure are present within the "Performance", "Utilization" and "Condition" evaluation category approaches. The "Criticality", "Utilization" and "Performance" categories similarly contain components that relate to the impact of Asset Failure. Of these, the "Criticality" sub-index is particularly notable from the perspective of failure impact, as it measures the relative importance of a given asset on the system in light of its electrical position relative to customers and other system components. As such, the Asset Analytics capability contains multiple elements that consider the probability and impact of asset failures, with the former largely tied to the asset condition-related criteria typically found in standalone Health Index formulations, and the latter grounded in system criticality of a particular asset, the economic considerations of proactive vs. reactive failure, etc.

While all of these risk-related factors are ultimately present in the expression of the final Composite Risk Score and individual Sub-Indices, at no point in the calculation process is risk explicitly expressed as *Failure Probability* × *Failure Impact*. Importantly, the fact that Hydro One's framework does not utilize the more commonly adopted expression of risk associated with leading technical standards, only implies than the manifestation of the relationship between the quantitative probability and impact-related elements of the Hydro One AA approach is less clear and more complex (in light of the presence of multiple other factors in the calculation of the index) than it otherwise could be. It does not, however, indicate that the model lacks quantitative considerations of probability and impact of failure into its calculations.

Accordingly, while the way the AA capability crystalizes the notion of risk are not fully aligned with the "model-derived" risk notion characterizing industry leaders, Hydro One's risk-related capabilities are nevertheless materially ahead of the more simplistic, and/or not fully quantitative asset risk definition methodologies that continue to be employed by most electric utilities in Canada and North America.

Elements of risk management and validation are also present throughout the broader ARA framework, where additional criteria related to environmental, safety, legal and other types of risks undergo assessment alongside the results of the AA capability. Ultimately, however, the comparison of AA outputs – expressed as non-dollar indices –

with the risk definitions established through other ARA inputs, is more complicated, and less intuitive than it could have been had all units were defined in numerical (preferably monetary) terms, as outcomes of Probability × Impact calculation. This representation of risk implies that the criteria comprising the assessment of asset failure Probability are clearly separated from the criteria comprising the Impact assessment if the asset failure occurs.

Accordingly, while we acknowledge the quantitative definition and application of risk principles within the AA and ARA frameworks differs from those used by other utilities, we are confident that Hydro One's current capabilities within this area place it in line with, or ahead of the majority of Canadian electric utilities. Modest incremental adjustments to the AA framework to clearly define asset probability and impact would place the utility within the best practice utilities.

Based on our findings, METSCO provides the following recommendation:

- Consider clearly separating the risk factors/criteria in AA to define probability of failure of a specific asset, and the impact of asset failure to explicitly assess a broader variety of outage consequence costs, such as utility's and socioeconomic costs, including the costs associated with the environment, safety/collateral damages, environment, customer interruption costs and financial impacts.

- In making the above recommendation, we are cognizant that many of these components are already included and evaluated as a part of the broader ARA process. As such, these potential enhancements should be considered only at the juncture where HONI may consider a more fundamental reorganization of asset management processes.

3.1.2. Data Utilization and Management

Data integration and automation of interfaces between key utility processes continue to pose challenges for many utilities in the context of asset management. This is largely the case given that many processes that generate inputs for asset management analytics occur in isolated and siloed manner, often using incompatible and/or non-electronic formats for capturing the data. Hydro One, however, is a notable exception to this common tendency given the utility's system integration advancements in the recent years.

As illustrated in Figure 4, the AA capability automatically retrieves all of its input data from a series of enterprise systems across HONI's network, centralizing it in a single data warehouse.

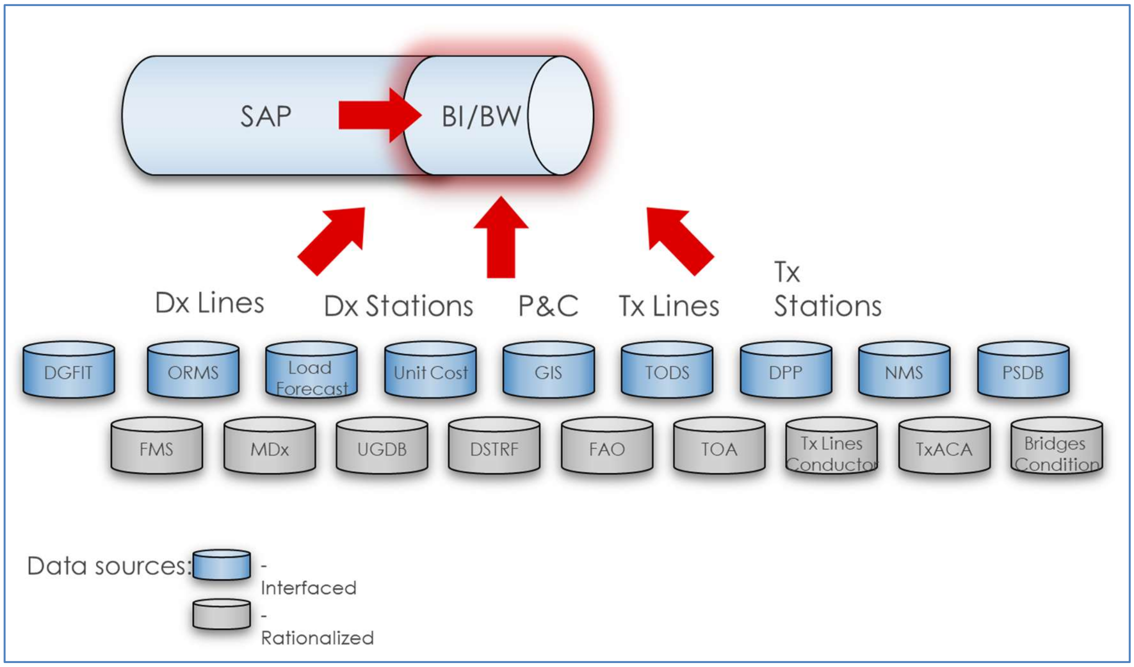

Figure 4. Data Sourcing for the Asset Analytics Capability (HONI Illustration)

The data is automatically updated on a weekly basis, as well as whenever any changes to the transmission system are reflected in the source IT systems. Importantly, once the AA analysis for a given procedure involving a group of assets is completed, its results are also automatically stored back into the SAP system. The completed results can be visualized through the utility's Space-Time Insight (STI) software, which places the assets in question in geographical context and enables disaggregation of the Composite Index into its six sub-components, as showcased in the figure below.

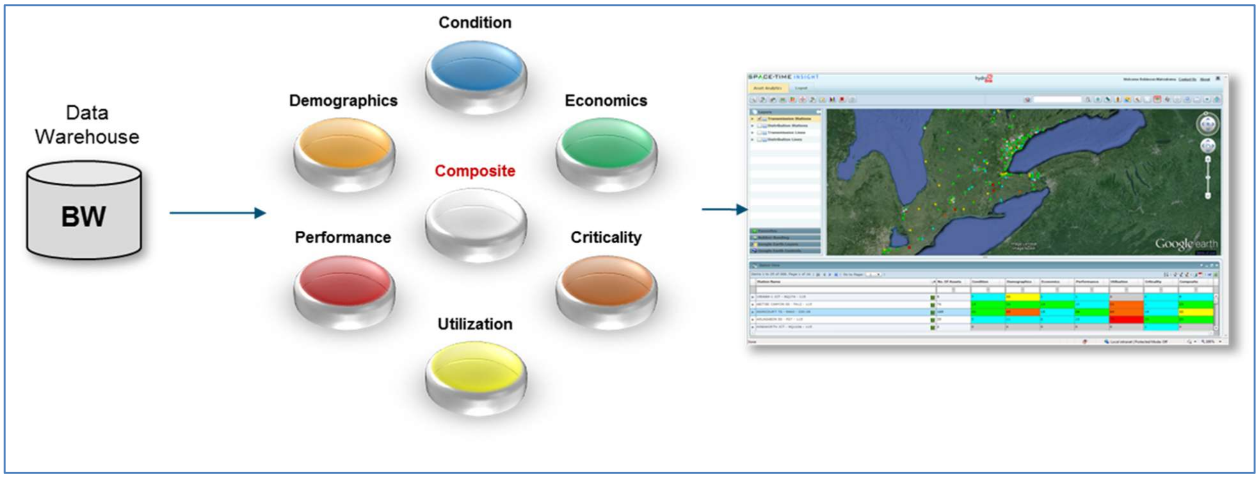

Figure 5. AA Results Storage, Retrieval and Visualization Through HONI IT Capabilities

Notwithstanding our earlier comments regarding the specific numerical form in which the AA outputs are presented, the fact that they are presented in the manner of a consistent quantitative index is in and of itself a decidedly positive feature, as this manner of presentation ensures that the subsequent consideration of outputs will be consistent across different stages of the ARA process, or different individuals conducting further assessments and diagnostics.

Equally notable is the presence and consistent utilization of the data completeness "flag" system and confidence score framework described in Section 2.1.1. Differentiating between the AA output indices where all requisite data is present, those where some inputs are filled with default settings and those where certain data is missing outright, the flag system and data confidence score framework unambiguously alert the asset management personnel conducting the ARA process of potential issues underlying a particular index calculated through the AA framework.

While we see the manner in which Hydro One alerts its staff of the instances of incomplete data as unambiguously positive, the instances of data unavailability themselves constitute a continuous improvement opportunity – for Hydro One and virtually every other utility. While our assessment's scope did not include any data accuracy verification checks, we generally see the overall scope and diversity of data inputs that Hydro One incorporates into its AA and ARA processes as a reasonable mitigation step in the instances of missing data – ensuring that the ultimate prioritization outputs are robust and reflective of a multitude of sources.

METSCO understands that Hydro One is undertaking a number of initiatives to improve the quality and completeness of its data. Although we thoroughly endorse these endeavors, we note that in pursuing them on a large scale, Hydro One should consider the opportunity costs of resources expended in the course of such projects. This consideration is particularly relevant with respect to the large populations of assets that Hydro One can reasonably expect to replace on the basis of their condition or other relevant factors in the next few years. Since all of the information related to the replacement assets would be stored in the systems, Hydro One may choose to carefully examine the value proposition of interim efforts to replenish the current records for older asset vintages.

On balance of the above-noted factors, METSCO concludes that Hydro One's data utilization and management practices are consistent with industry best practices and are substantially ahead of most Canadian utilities. This is largely because the assessment processes are quantitative data-driven, while the instances of reliance on manual data handling (which are both inefficient and carry the risks of human errors) are minor.

3.1.3. *Assessment Flexibility*

In light of the number of discrete asset classes, models, vintages and other unique or cohort-specific features related to assets that comprise a typical utility's system, any asset management /analytics methodology should embed a reasonable amount of flexibility to manage the adverse implications of any "one size fits all" approaches. As we elaborate in our description of our Second, asset-class specific Level of assessment, we found Hydro One's AA and ARA frameworks to be appropriately flexible and modular to account for relevant asset-specific considerations.

Aside from the utilization of asset-class specific condition parameters, failure curves, equipment performance thresholds, etc. inherent in the design of the AA capability, a crucial factor that facilitates flexibility of assessment is the sole existence of the ARA process that incorporates a variety of additional assessments relevant to a particular type of assets. While the overall purpose and nomenclature of the steps and stages comprising the ARA process are considered to be standard across the asset classes (see Figure 3) the form and specific content examined in the course of these assessments depends on the key performance characteristics of a particular asset class.

For instance, in the course of the ARA process for stations assets, Hydro One produces and/or updates a Station Assessment Document, which along with the AA-derived index value, considers such factors as reports of stranded load risks, capacity constraints analysis, loading stability assessment, short circuit levels, PCB-related issues of any oil-filled assets, station security concerns, and a number of others.

While it supplements Hydro One's asset management process with a degree of flexibility, ARA functionality also contains features like asset needs screening and field review validation, which provide a degree of rigour and discipline to the overall process, to ensure that the lists of asset needs produced at the end of the process are generally robust and reflective of operating reality. Combined with the data-centric nature inherent in the AA functionality, these process steps facilitate a degree of consistency and discipline that balances the considerations of flexibility.

In consideration of the above-noted factors, METSCO finds that Hydro One's AA and ARA capabilities embed an appropriate degree of assessment flexibility, balanced with overall procedural discipline that may be expected of a robust asset management framework.

3.1.4. *Ease of Comprehension and Downstream Application*

It is important not to underestimate the importance of a utility's asset management and investment planning staff possessing a clear and comprehensive understanding of the asset management capabilities' purpose, methodology, limitations, and implications of their results. In METSCO's assessment, possessing this understanding is equally important for staff operating in the areas conducting AM assessments, and their counterparts performing downstream tasks that rely on the outputs of these assessments. Absent this understanding across the relevant organizational units, the system's operation and utilization of its outputs may carry a number of risks that can compromise the accuracy of the results, compliance with process steps, or even particular courses of action suggested by the results of AM analysis.

In the course of conducting our interviews with Hydro One's asset management staff and management, METSCO found that they possessed a clear and in-depth understanding of the AM process as a whole, and the AA/ARA functionalities in particular. In most cases in METSCO's experience, only a small group of individuals within a utility may possess the specific knowledge of the AM analytics and implications of their results. In Hydro One's case, however, we found that the methodologies were clearly understood by most professional AM staff. Most importantly, the understanding of the frameworks' crucial elements appeared to be consistent between the different asset managers, planners and groups responsible for executing particular process steps or managing performance of certain asset classes.

While this finding generally positions Hydro One well for consistent and accurate application of the AA and ARA principles to its asset base, METSCO does have concerns in this area. Chief among them is the fact of the sheer complexity of the frameworks, particularly in the case of AA capability, where the assessment results are at once presented as a single index, and six component sub-indices, each reliant on unique sub-processes, assumptions and calculations, the impact of which in not readily apparent when reviewing the aggregated index results. While the AA capability enables asset managers to disaggregate the composite index into its individual components (allowing, for instance, for asset condition data to be extracted separately for a detailed assessment), we view this procedure as somewhat cumbersome to any person not deeply involved in the process.

Moreover, the methodological disaggregation of AA analysis into six discrete "pre-final" sub-indices and its subsequent incorporation into the ARA process containing other major data points, increases the conceptual complexity of the entire process, when assessed by an outside party (including METSCO staff who reviewed these processes). Considering that most of the six discrete AA risk variables / sub-indices are commonly expressed as components of a single Asset Health Index variable (a well understood industry term, which along with condition of asset components typically includes data like loading levels, demographics, etc.) Hydro One's nomenclature and the manner of derivation of its AA formula is, in our assessment, more complex in its presentation than it could be.

The potential impact of this consideration is somewhat amplified by lacking documentation practices with respect to formal explanatory literature on the scope and nature of detailed analytical steps comprising the AA and ARA functionalities. In discussing this issue with Hydro One, METSCO understands that this is in large part a product of the rapid evolution of successive asset management capabilities in recent years – the fact that the utility also indicated in its previous transmission rate application.

Although the observed difficulty of initial comprehension is not a concern for the utility's current staff that are well versed in the process mechanics, we believe that the present formulation carries a risk of being initially misinterpreted or misunderstood when explained to a new employee, a contractor, a party in a regulatory proceeding, or a peer utility in the context of best practices sharing.

On one hand, we were impressed with both the depth and consistency of the current staff's understanding of the processes, their implications and methodological limitations. On the other hand, however, it took METSCO considerable effort to fully internalize the nature of certain AA and ARA components, and reconcile them with approaches used elsewhere in the industry. Accordingly, we conclude that the downstream application of the outputs of AA and ARA processes is relatively straightforward within the context of Hydro One's current organizational structure and staffing complement. However, we find that the methodologies underlying the frameworks are moderately difficult to comprehend, which presents potential risks in the context of internal knowledge transfers, or best practices sharing.

To conclude the assessment of the Ease of Comprehension and Downstream Application, METSCO provides the recommendation that is similar in nature to the Use of Risk-Based Analysis:

- Re-visit the present formulation of the AA framework components and consider potential regrouping / renaming of assessment factors to better align it with commonly understood industry terminology (such as condition assessment/health index, or impact assessment/consequence cost), and take steps to develop more comprehensive explanatory manuals for its AA capabilities.

3.1.5. *Clear Sense of Current Gaps and Continuous Improvement Opportunities*

In our discussions with Hydro One throughout the duration of this engagement, we found the utility's staff to be cognizant of the current systems' limitations, receptive to the feedback provided by METSCO, and motivated to undertake further enhancements to its asset management capabilities. We note that the utility has clear governance protocols for identification and management of the identified gaps, which includes the aforementioned data completeness flag and confidence score frameworks, along with periodic initiatives aimed at enhancing the system's analytical robustness. For instance, METSCO understands that Hydro One is in the process of procuring professional services to enhance certain aspects of its AA algorithms, while also taking steps to address the findings of the recent successive Internal Audit reviews.

Overall, while our engagement highlighted the sense of pride in the existing analytical capabilities and the processes that support them among Hydro One's engineering and planning staff, this sentiment was invariably balanced by the realistic assessment of the systems' status quo issues, and genuine curiosity as to the practices employed elsewhere in the industry. Accordingly, we find Hydro One's understanding of current gaps inherent in their systems and plans for continuous improvement opportunities to be reflective of a utility committed to continuous improvement.

3.2. Level 2 Assessment: Technical Parameters Robustness

Having completed the first level of our assessment, this section examines the AA and ARA capabilities from the perspective of tests, diagnostics and assessment applied to individual asset classes that the capabilities evaluate. To accomplish this, METSCO examined the scope of input data and the analytical methodologies applied to derive the AA Composite Risk Index for each of the evaluated asset classes. We also reviewed the input information supporting the broader ARA procedure, along with the strategic and operational documents, developed on the basis of, and in the course of collecting the insights generated through the ARA process.

In this context, our review of asset class-specific information considered in the scope of AA and ARA assessments is structured around three issue areas (where they are relevant), namely:

- *Input Data Supporting the AA Framework*: Integrity of the inputs used to support the AA framework, by measuring the sample sizes of the data that was utilized.

- *AA Evaluation Score Criteria & Results:* Completeness of the criteria used and methodologies applied to support the evaluation category scoring results.

- *Asset Risk Assessment Components*: Assessment on the incremental inputs used in supporting the ARA procedure, including strategic and operational documents.

We supply our observations and recommendations grounded in our in-depth review and assessment within each subsection.

3.2.1. Station Power Transformers

Input Data Supporting the Power Transformer AA Framework

The Asset Analytics formulation for Station Power Transformers leverages all six evaluation categories (i.e. Demographics, Condition, Performance, Utilization, Economics, Criticality) in order to produce an overall composite risk score. Our review of data availability across all input variables supporting each evaluation category score, suggests that on average, approximately 80% of requisite data entries across evaluation categories are populated with actual data, the remainder being supplied by default scores devised by SMEs, and/or missing. Figure 6 illustrates the average data availability across the inputs for each evaluation category[2].

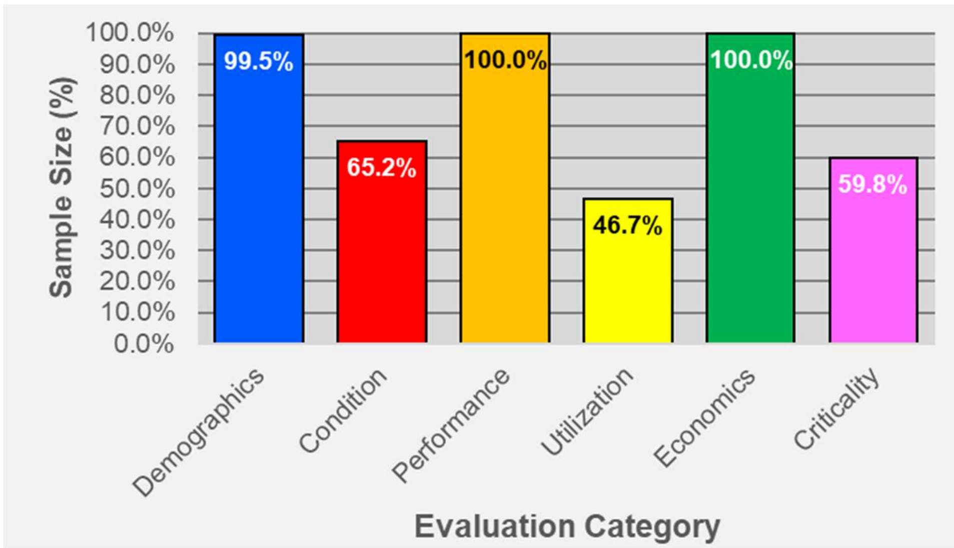

Figure 6. Station Power Transformer Average Sample Sizes for each Evaluation Category

On balance, METSCO finds that the average data availability levels across all six categories is satisfactory to make inferences and construct sub-indices for further evaluation (recall that the AA capability generates flags and scores to indicate missing or default data to notify asset managers where caution is required).

While the actual Condition data availability score of 65.2% may seem insufficient, METSCO finds it to be robust, considering the size of HONI's asset base, the span of its territory, and the manner of presentation of the condition score relative to many other utilities. Notably, and unlike most condition scores that feature in rate applications in the form of Health Indices (HI), Hydro One's condition data availability score does not include any age or utilization data (each captured in their separate demographic category), which are often included in Health Index formulas and are used (correctly) to represent discrete facets of asset health. Instead, the condition captured within HONI's Condition category is related solely to data on asset's extent of degradation, as assessed by Hydro One's field crews, and established by empirical tests like Dissolved

[2] The overall data availability score referenced above was calculated on the basis of average across all individual input values in all categories - not across the averages of each individual category

Gas Analysis (DGA). When assessed in this important context, the amount of condition-based information available for this critical asset class is substantial.

We also note that the relatively low scores across some of the six categories are a function of the number of parameters that HONI is seeking to track in the ideal circumstances and is making steps to acquire the data for. In METSCO's assessment, a lower availability score as a result of seeking to track more individual variables is more preferable that a high availability score that reflects one or two parameters only.

Notwithstanding these observations, data gaps are present, and we recommend HONI to:

- Continue to mitigate the data gaps as part of continual improvements, such that the sample sizes of evaluation categories (and overall sample size within AA) can continue to improve over time.

It should be noted, however, that all power transformer assets ultimately receive an evaluation category score as well as an overall composite risk score through the use of the data completeness procedure as discussed in Section 2.1.1.

Power Transformer AA Evaluation Score Criteria & Results

Each of the evaluation category scores for power transformers contains references to "risk-based" calculations, in which these variables refer to either the "probability" or "impact" of asset failure.

The demographics score, for instance, contains probability-related elements, as it compares the transformers existing' age to its ESL criteria, defined by the failure curve study performed by Foster Associates [3].

The Condition evaluation category score for power transformers also includes probability-related elements, taking into consideration the following criteria:

- Dissolved gas analysis (DGA) testing results;
- Furan analysis results;
- Doble testing results;
- Defect report and trouble call notifications.

The Utilization evaluation category score takes into consideration the loading and usage that the transformer has experienced, including the summer and winter peak load, 10-day limited time rating (LTR), tap changer counter reading and maximum number of operations – all of which represent an extension of condition-related components and relate to the assets' probability of failure. This score also accounts for the capacity of the transformer, where a higher risk score is assigned to a greater size of transformer, which would relate to the assets' impact of failure.

The Performance evaluation category score takes into consideration historical performance associated with the power transformer, including frequency and duration of forced outages, as well as the Laplace trend test designed to measure the difference in internal time between the forced outage occurrences. An increasing Laplace trend, coupled with decreasing interval times between outages, indicates that the condition of the power transformer is worsening. As is the case with demographics, condition and utilization, this result represents further insight into the assets' probability of failure.

The Economics category scoring accounts for the ongoing costs to manage the power transformer when a problem emerges, including emergency and corrective costs that would be associated with historical failure events. While the economic score may include the costs already taken to refurbish the transformer, typically it represents the ongoing costs of maintaining the transformer in the current fleet.

The Criticality evaluation category assigns a criticality score to the evaluated power transformer based upon the station that it is installed within, the type of power transformer as well as the individual asset voltage rating, MVA rating and single point of vulnerability.

Both the Economics and Criticality scores relate to the impact of asset failure or the impact of the asset continuing to require significant on-going spending to maintain the transformer in service.

As probability and impact components are identified within the individual evaluation scoring categories and criteria, the final output from the AA framework is representative of the overall risks applicable to the asset. However, when viewed on its own, the produced composite risk score for power transformers can be complex to understand, due to the integration of probability and impact components into a singular value. It is notable, however, that the underlying evaluation category results are modular and can be extracted as part of further analysis within the ARA procedure.

While this unnecessary score complexity is applicable to the other asset classes, the recommendation to integrate commonly employed variables for risk-based calculations is discussed in Section 3.1.4.

With respect to condition evaluation, HONI's current scoring considers the most critical testing results performed by utilities, such as DGA, Furan and Doble testing. However, METSCO recommends that HONI integrate the additional condition parameters which it already collects and applies as a part of the ARA process directly into the AA framework:

- Condition of cooling system, including radiator and fans;
- Condition of gaskets and seals;
- Condition of transformer tank;
- Foundation condition;
- Condition of connectors.

It is also notable that certain inspection parameters are considered as part of the condition scoring, but are integrated within other categories rather than individually scored and weighted. As an example, the Condition category contains a scoring parameter relating to historical defect report notifications, which can contain underlying inputs such as bushing/support insulator inspection results and infrared scanning results. As part of continual improvements, we recommend that HONI consider breaking out these parameters in order to introduce a more transparent calculation.

Overall, when examining the "highest risk" power transformers, as prioritized through the AA Composite Risk score result, we observed that the composite results reflected the underlying inputs, providing reasonable indications across the criteria. As an example, the highest-risk power transformer on the list was (a) past its ESL, (b) had a very poor condition score; and (c) had sustained a series of outage events over the past five-year period, which precipitated extensive and costly corrective and emergency repairs within that time period.

We observed similar findings for the 20 highest priority (in terms of overall risk) power transformers – the majority of which were found to be past their ESL and having encountered some form of performance issues over the past five-year period along with corrective and emergency costs.

Power Transformer ARA Analysis Components

As part of the ARA process, HONI supplements AA-generated scores with a range of additional data inputs. The combination of these factors informs the utility's power transformer strategy and technical assessment documents, which underlie its long- and short-term decision-making for a given asset class, respectively. METSCO examined these documents and discussed their content with HONI SMEs, as a means of establishing the scope and nature of additional information comprising the ARA review.

METSCO found HONI's power transformer strategy document to further supplement the AA framework results with incremental analysis conducted for each of the six evaluation categories as a part of the ARA process. Key additional parameters considered in the strategic document include:

- Demographics: Demonstrating the current and future replacement needs through assessment of units that are currently beyond their expected service life, along with their projected failure rates as derived from HONI's failure curves.

- Condition: additional assessment of operating considerations related to power transformers diagnosed to have specific condition-related issues, such as poor DGA results and oil leaks.

- Performance: Assessment of historical reliability events, including outage frequency, outage duration, frequency of asset component failures (e.g. transformer core, cooling equipment, auxiliary equipment, windings, etc.) and oil leak events (separating major and minor leaks).

- Utilization: Discussion of Summer and Winter 10-Day Limited Load capabilities across the utility's transformer fleet.

- Criticality: Discussion of critical customer types, design and voltage-related criticality impacts on these customers, along with environmental impacts.

- Economics: Discussion of economic impacts, including financial impacts to utility and socio-economic impacts to customer (e.g. customer interruption costs).

Figure 7 illustrates an example of the incremental information captured in HONI's strategy document and collected as a part of ARA - in this case with respect to transformer oil leaks across the fleet. Oil leakage information represents a significant indicator of the overall degradation and failure of a power transformer. As such, while it is not captured in the AA score, this critical information is nevertheless integrated into the decision-making process prior to concluding asset prioritization work.

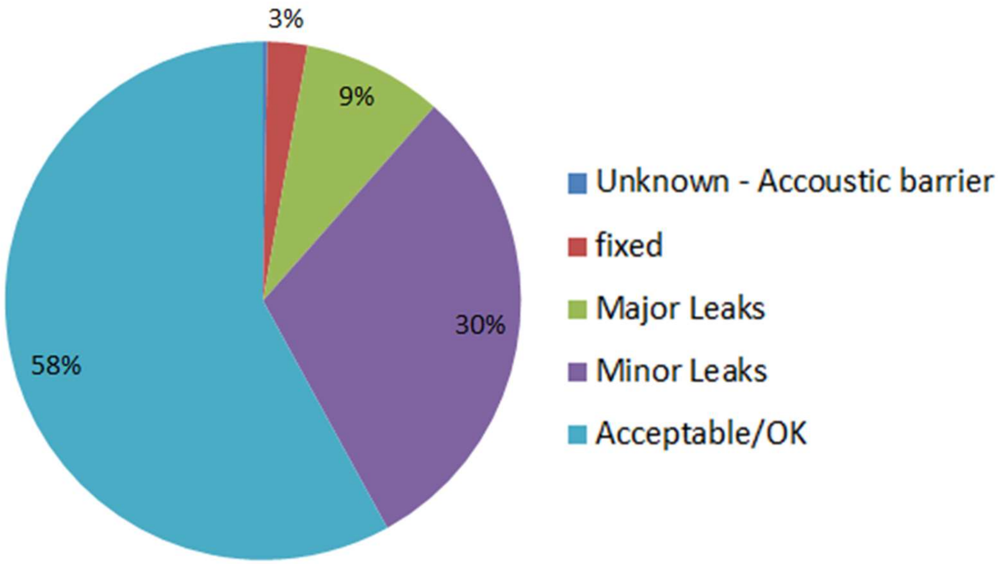

Figure 7. Hydro One Transmission Class Overview – Leak Overview [4]

The strategy documents also include additional risk factors as identified within the ARA process to further assess the need for and prudence of power transformer replacements, including obsolescence, safety and environmental impacts. Throughout this document, HONI articulates the processes applied in order to capture this input data (e.g. process for condition assessment) and also explains the consequences of no action taken (e.g. projected failure rates).

Key ARA outputs reflected in the strategy document include the master list of power transformers recommended for replacement intervention, along with strategic recommendations for how existing risks can be mitigated into the future.

In addition to strategy documents ARA assessment results also drive the development of technical assessment document produced for individual power transformers. These individual assessments provide an even greater granularity of information as to the current risks associated with individual asset, along with incremental justification of intervention. These information categories include:

- Demographics: Age of the evaluated asset when compared to its ESL as well as overall demographics across all power transformers.

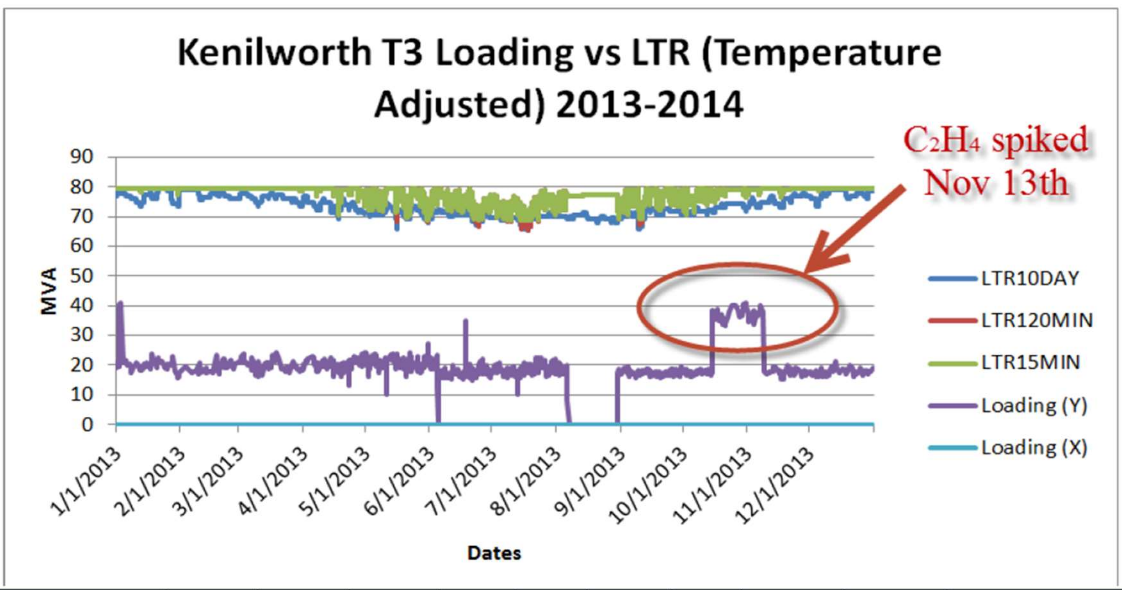
- Condition: Detailed discussion on individual testing results concerning the transformer, including findings of oil analysis (DGA), moisture analysis, oil leaks (with photos), infrared scanning results (with photos) as well as maintenance history, trouble calls and deficiency reports.

- Environment: Spill risk assessment and discussion on recent PCB testing results.

- Equipment Loading: Detailed year-by-year assessment of historical loading on power transformer versus limited time rating (LTR) limits.

- Economics: Breakdown of historical spending required to maintain the evaluated transformer, including OM&A spending.

Taken as a whole, the information noted above is used to identify serious issues that drive justification for the need and prudence of short-term intervention. An example of this is illustrated in Figure 8, where results from a yearly load profile on a particular power transformer identified a spike in loading, which was subsequently correlated to the gassing pattern as identified from the DGA analysis results.



Date	C2H2	C2H4	C2H6	CH4	CO	CO2	H2	N2	O2	Total Dissolved Gas (%)
08/29/2012	0	70	13	19	227	1870	0	67900	28700	9.84
11/13/2013	0	143	22	69	246	2130	20	70900	32100	10.51
01/31/2014	0	148	26.5	69	217	1735	30	64400	28400	9.5

Figure 8. Establishing Correlations between DGA Results and Load Profiles [2]

The technical assessment document concludes with a net present value (NPV) analysis, where different options (e.g. status quo, repair/refurbish, replacement) are compared and contrasted with each other, using the annual investment requirements as an input for each investment option in order to identify the preferred option that yields the lowest NPV result. An example of this assessment is illustrated in Figure 9.

Overall, through the technical assessment for power transformers, METSCO confirmed that HONI's decision-making does not simply rely upon the AA index results but in fact moves far beyond these scores using detailed incremental analysis of quantitative factors. As such, the ARA analysis serves to further justify the final decision to be made. Further examination of the input data supplied by AA into the strategy and assessment documents serves to validate the results of the AA framework and results, ensuring that intervention decisions consider a broad array of quantitative information.

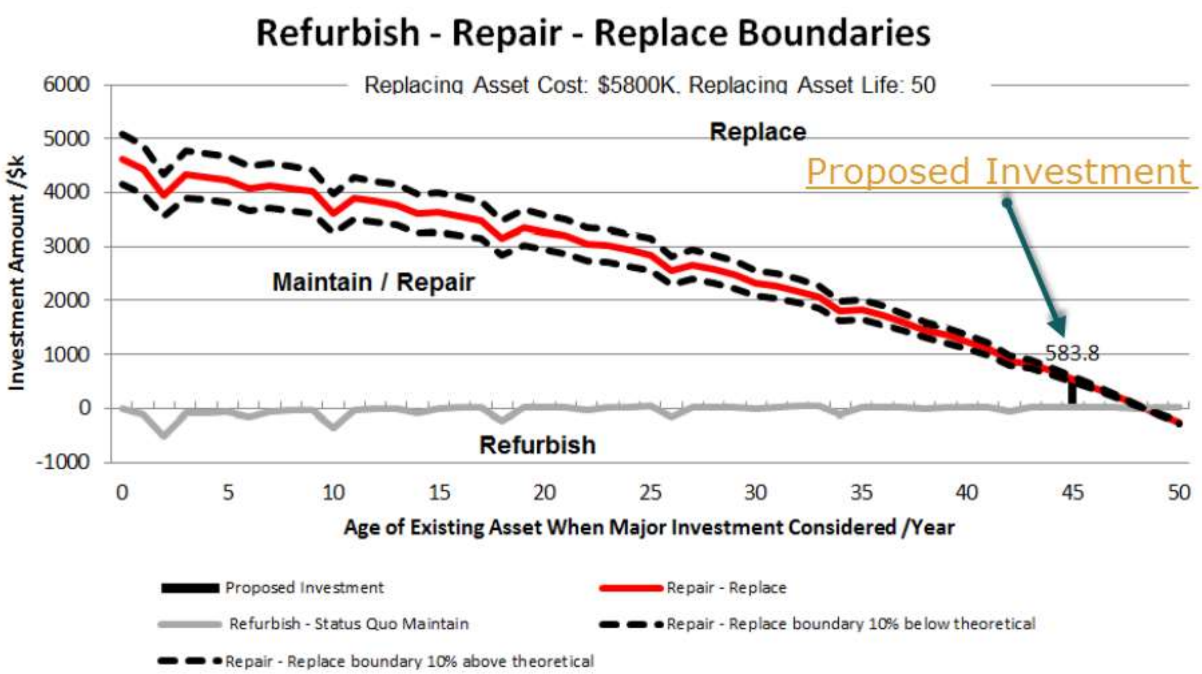


Figure 9. Net Present Value Comparison of Different Investment Options [2]

As a part of continual improvement, METSCO recommends HONI to:

- Consider integrating useful incremental asset data that exist outside of the current AA score (e.g. environmental and safety factors, along with other condition information types) directly into the condition evaluation category scoring as part of the AA framework, should HONI contemplate a substantial upgrade/reorganization of its AM processes.

- Consider integrating broader socio-economic factors into the evaluation, including costs to the customer (customer interruption costs), as well as environmental and safety-related monetary cost factors, such that the full range of economic costs (including those that go beyond those incurred by a utility or its customers).

3.2.2. *Station Circuit Breakers*

Input Data Supporting the Circuit Breaker AA Framework

Similar to Power Transformers, the Asset Analytics formulation for Station Circuit Breakers leverages all six evaluation categories (i.e. Demographics, Condition, Performance, Utilization, Economics, Criticality) in order to produce an overall composite risk score. The average data availability score across all individual input variables supporting the evaluation category scores is approximately 90%.

Figure 10 illustrates the average sample sizes across the inputs for each evaluation category[3].

[3] The overall data availability scores referenced above were calculated on the basis of an average across all individual input values in all categories – not across the averages of each individual category presented in the tables below. Individual input data availability also takes into consideration the relevance of the particular input parameter for evaluating the specified circuit breaker type.

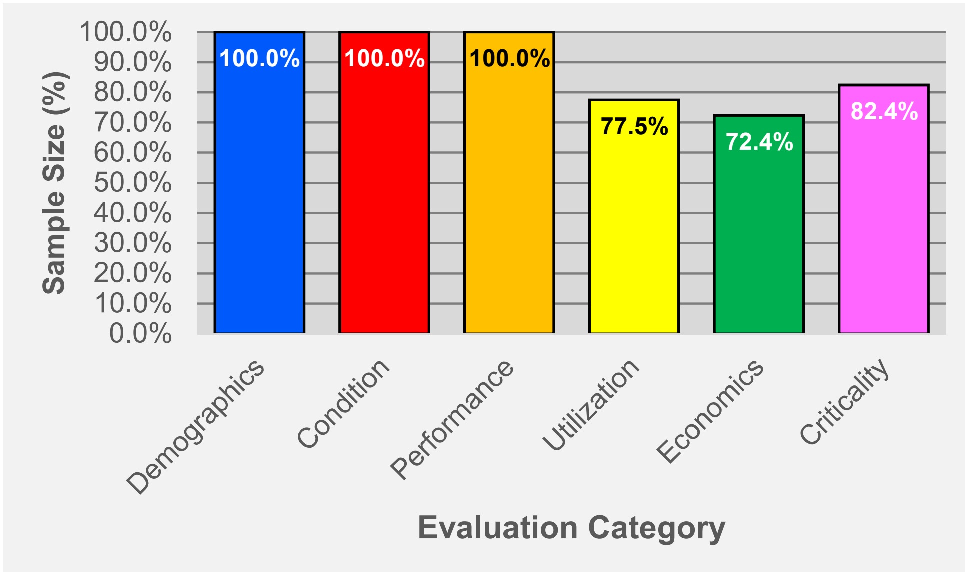

Figure 10. Station Circuit Breaker Average Sample Sizes for Each Evaluation Category

Overall, METSCO found the data availability scores for this asset class to be robust, and reasonable to make meaningful calculations across each of the categories. Moreover, METSCO notes the very high Condition, Utilization, Performance, and Criticality data availability scores.

Similar to the Station Power Transformers we recommend that HONI continues mitigating its data gaps as part of continual improvements, such that the sample sizes of evaluation categories (and overall sample size within AA) can improve over time. It should be noted, however, that all circuit breaker assets ultimately receive an evaluation category score as well as an overall composite risk score through the use of the data completeness procedure as discussed in Section 2.1.

Circuit Breaker AA Evaluation Score Criteria & Results

As is the case with power transformers, circuit breaker assets utilize the same six evaluation category scores containing references to "risk-based" calculations, in which these variables refer to either the probability or impact of asset failure. The underlying criteria for Demographics, Performance, Economics and Criticality categories are similar to the power transformers calculation as explained in Section 3.2.1, with the exception of the following incremental data points:

- Performance: Historical trouble call and defect report notifications support circuit breaker evaluation in instances where historical outage data is unavailable.

- Economics: The average work order cost is applied within this category in addition to the criteria. For air-blast circuit breakers, the average operational count of the breaker is also utilized as part of the calculation.

- Criticality: Considers the voltage rating of the breaker as well as the breaker position.

Moreover, criteria used for Utilization and Condition evaluation categories are unique to circuit breaker asset class. For Utilization, inputs that reflect the overall usage of the breaker include:

- Breaker counter readings;
- Maximum number of operations prior to reaching the end of life (EOL)[4] threshold;
- Total number of breaker operations;
- Functional location of the breaker: (whether is it a capacitor- or a reactor-positioned breaker), the interrupting rating (in kA) of the breaker at the system level, and equipment level respectively; and
- The fault adjusted operation (FAO) of the breaker (used to predict and perform breaker maintenance based upon accumulated fault duty).

The evaluation criteria within the Condition category, predictably vary with the functional type of breaker. All condition formulas for circuit breakers include:

- Annual number of defect reports and trouble calls;
- The notification benchmark, which represents the 5-year average of all annualized defects by nominal voltage;
- Number of preventative reports used for reporting findings from maintenance inspections; and
- The year when a circuit breaker has been rebuilt (if relevant).

Oil-filled circuit breakers contain additional consideration of oil top-up operations performed in a year, while SF_6-insulated breakers contain an evaluation of SF_6 top-up operations.

[4] End of Life is defined by HONI as "the likelihood of failure, or loss of an asset's ability to provide the intended functionality, wherein the failure or loss of functionality would cause unacceptable consequences." [2]

As is the case for power transformers, it is METSCO's recommendation that HONI consider integrating of more commonly used variables for risk-based calculations, such as failure probability curves coupled with the impact of failure. Specific to circuit breakers, we also recommend that HONI consider integrating additional parameters that it currently collects through maintenance and inspection activities and considers as a part of the ARA analysis directly into the AA framework. These include:

- Oil leaks, gasket and seal condition (oil-filled circuit breakers);
- Tank integrity and mechanism box condition (oil / SF_6);
- Condition of air system (air-blast circuit breakers);
- Air consumption test (air-blast circuit breakers);
- Tripping and closing resistors (air-blast circuit breakers);
- SF_6 gas analysis (SF_6-insulated circuit breakers).

It is also notable that certain inspection parameters are considered as part of the condition scoring but are integrated within other categories rather than being individually scored and weighted. As an example, the condition category contains a scoring parameter that relates to "work packages", which contains underlying inputs such as timing/travel and contact resistance tests respectively. The condition category also contains a scoring parameter relating to historical defect report notifications, which often contain underlying inputs such as bushing/support insulator inspection results and infrared scanning results. As part of continual improvements, HONI can consider breaking out these parameters in order to introduce a more transparent calculation.

When examining the "highest risk" circuit breakers as prioritized through the composite risk score result, METSCO found that the composite results agreed with the underlying inputs. As an example, the highest risk circuit breaker on the list was found to be in very poor condition and had experienced multiple trouble call /defect report notifications, sustaining corrective and emergency repair costs in the past five years.

Similar findings concern the 20 highest priority (in terms of AA risk) circuit breakers – all of which were found to possess a condition score result equivalent to a poor or very poor finding, and had encountered some form of performance-related issues (either in the form of trouble calls/defect reports or actual outages) and many of which were found to be approaching or already exceeding their ESL criteria.

Circuit Breaker ARA Components

As part of the ARA process, HONI supplements the AA-generated scores with a range of additional data inputs. The combination of these factors informs the utility's circuit breaker strategy and technical assessment documents, which underlie its long- and short-term decisions for a given asset class, respectively. METSCO examined these documents and discussed their content with HONI SMEs, as a means of establishing the scope and nature of additional information comprising the ARA review.

METSCO found HONI's circuit strategy document to further supplement the AA framework results with incremental analysis conducted for each of the six evaluation categories assessed during the ARA process. Key additional parameters include:

- Demographics: Demonstrating the current and future replacement needs through the evaluation of circuit breakers (including sub-types) that are currently beyond their expected service life.

- Condition: Discussion of the degradation issues concerning circuit breaker assets, including state of the breaker contacts, O-rings and control components.

- Performance: Assessment of historical reliability events, including forced outages by cause, and comparison of forced outage rates by breaker sub-type, as well as resulting reliability impacts on the system supply points.

- Economics: Discussion of OM&A costs for each group of breakers at each substation, along with specific spending requirements associated with breaker sub-types (e.g. ongoing spending for high-pressure air system infrastructure supporting the legacy air-blast circuit breakers to be replaced).

Figure 11 and Figure 12 illustrate examples of the types of incremental information captured from HONI's strategy document and examined as a part of ARA - in this case, the circuit breaker demographics and performance respectively. Figure 11 illustrates the quantity of breakers that are past their ESL criteria, providing an indication of the volume of breakers that may require replacements in later years. Figure 12 presents the historical reliability of different breaker types over the past 10-year period. HONI uses these results to further explore the need to prioritize the replacement of the air-blast circuit breakers over other types.

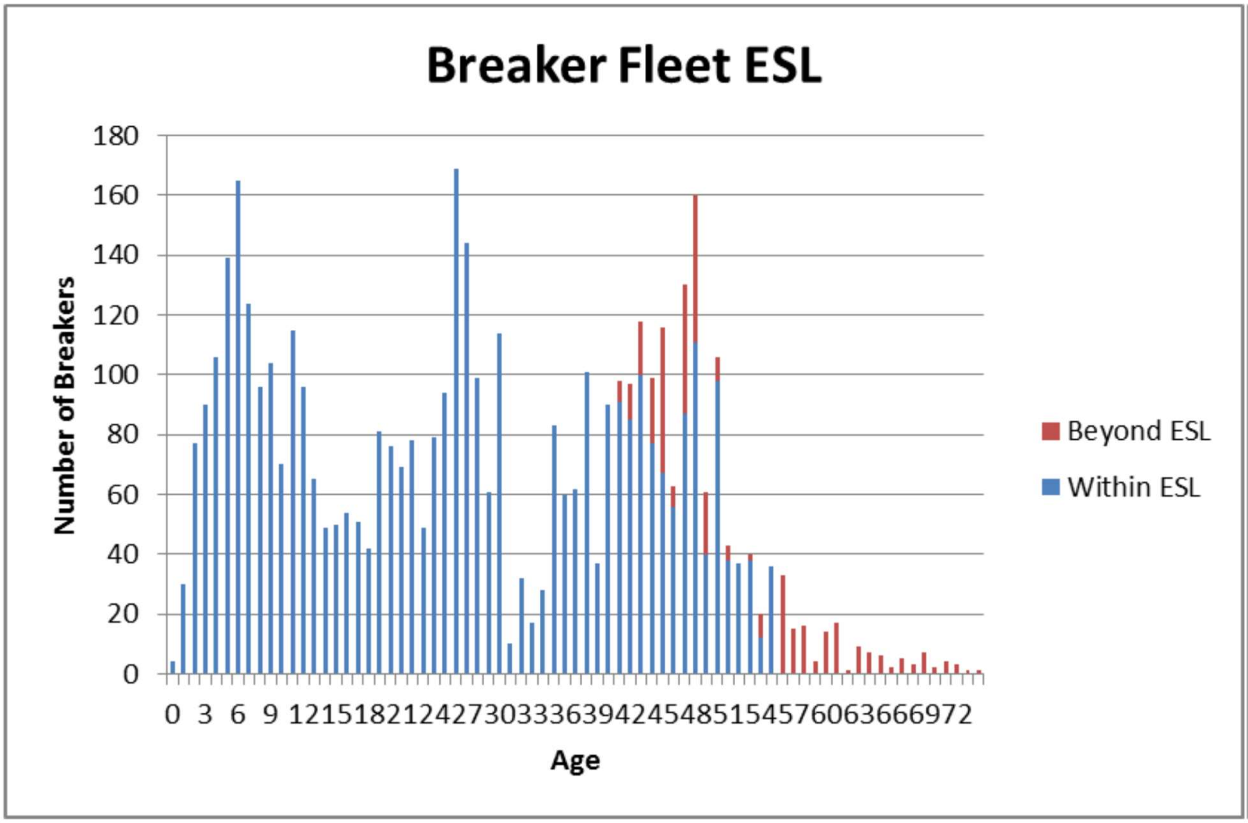

Figure 11. Station Circuit Breaker Demographics [5]

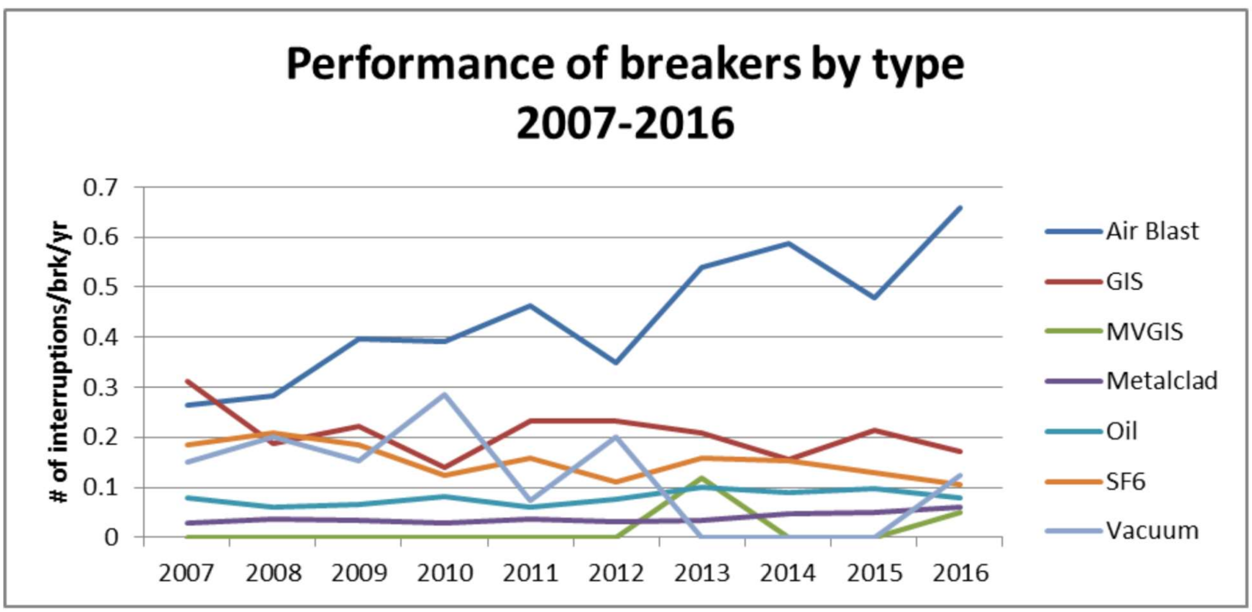

Figure 12. Performance of Circuit Breakers by Type [5]

The document also includes additional risk factors as identified within the ARA process to further justify circuit breaker replacements, including obsolescence (e.g. availability of parts) and safety (e.g. safety risks associated with failure modes for specific circuit breaker sub-types). Throughout this document, HONI articulates the processes undertaken in order to capture this input data (e.g. process for condition assessment) and also explains the consequences if no actions are taken.

Key outputs produced on the basis of the strategy document include the recommended investment and maintenance strategies, respectively.

Overall, through the assessment of circuit breaker analysis parmeter, METSCO identified that HONI's decision-making does not simply rely upon the AA results, but moves beyond these results into the detailed incremental analysis that serves to further support the final decision regarding the need for a particular intervention type. Further examination of the input data supplied into AA into the strategy documents serve to validate the AA framework and results.

As is the case with power transformers, opportunities for incremental improvements to the ARA procedure for circuit breakers would include further integration of the incremental analysis within the AA framework directly.

3.2.3. Stations Ancillary Equipment (DC Batteries & Chargers)

Input Data Supporting the Stations Ancillary AA Framework

Asset Analytics formulation for DC batteries and chargers leverages five out of the six evaluation categories that are relevant for analysis, including Demographics, Condition, Performance, Economics and Criticality, in order to produce an overall composite risk score. The average availability score across all input variables supporting the station battery evaluation categories is just over 90%, while the average availability score supporting the battery charger evaluation categories is just under 90%..

Figure 13 and Figure 14 illustrate the average sample sizes across the inputs for each evaluation category for DC battery and charger assets respectively. These results illustrate an extensive sample size of data that has been captured to support these assets[5].

[5] The overall data availability scores referenced above were calculated on the basis of an average across all individual input values in all categories - not across the averages of each individual category presented in the tables below.

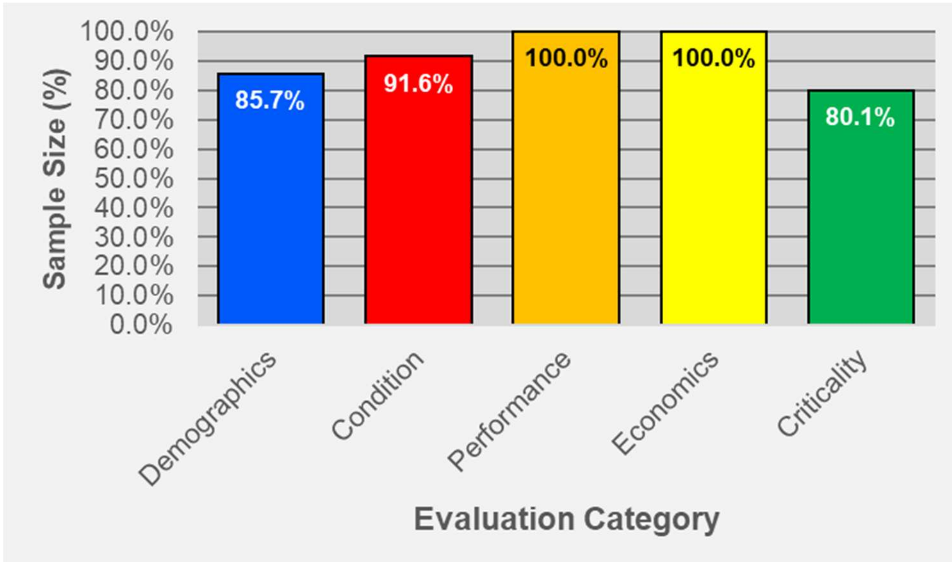

Figure 13. DC Battery Average Sample Sizes for each Evaluation Category

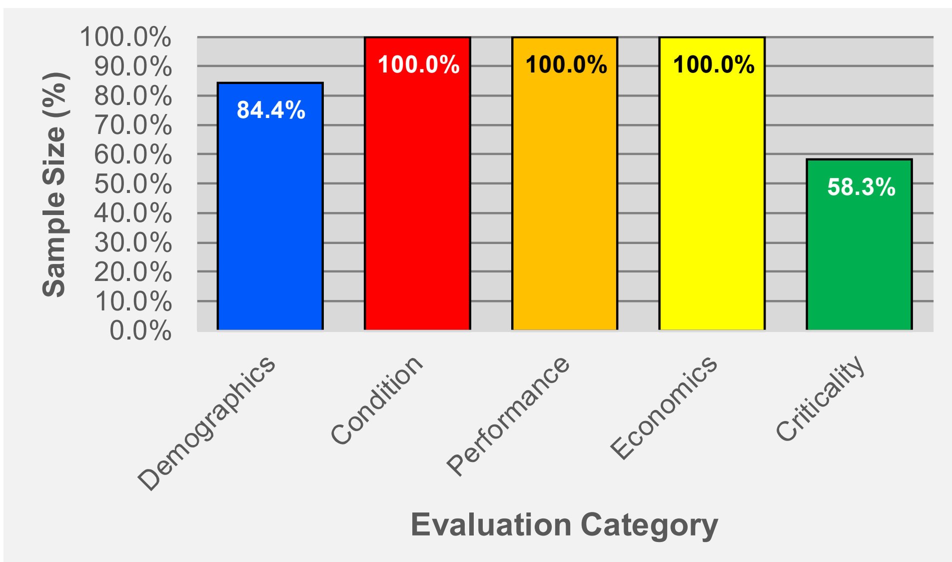

Figure 14. Charger Average Sample Sizes for each Evaluation Category

Overall, METSCO found the data availability scores for this asset class to be reasonable to make meaningful calculations across each of the categories. While the score for Criticality for chargers constitutes a relative outlier relative to other categories, we note the perfect scores for Condition and Performance, as especially relevant for this asset class.

We recommend that HONI continue mitigating the identified data gaps as part of continuous improvements, such that the sample sizes of evaluation categories (and overall sample size within AA) can continue to improve over time.

Stations Ancillary AA Evaluation Score Criteria & Results

As is the case with power transformers and circuit breakers, the evaluation category scores for stations ancillary assets contain references to "risk-based" calculations, in which these variables refer to either the probability or impact of asset failure (both being inputs of a comprehensive definition of risk as per industry best practices). The underlying criteria for Demographics, Performance, Economics and Criticality categories are similar to the power transformers calculation as explained in Section 3.2.1, with the exception of the following exceptions / incremental additions:

- Performance: Uses historical trouble call and defect report notifications (similar to circuit breakers);
- Criticality: Uses the same criteria with the exception of the single point of vulnerability.

Condition evaluation criteria used for evaluation of DC battery assets include:

- Overall physical condition (i.e. leaking, tracking, cracks, condition of seals, corrosion, etc.);
- Discharge testing results – 30 min AC (i.e. time to discharge);
- Final discharge voltage – 30 min AC and 2-hour load test;
- 2-hour Battery Load test;
- Average voltage;
- Battery float current;
- Number of cells;
- H20 added (flooded cells only);
- Specific gravity (SG) (flooded cells only).

We see the above list of DC battery degradation factors that HONI considers as being very comprehensive.

For charger assets, a single overall condition rating is currently assigned, although HONI plans to further expand this rating into individually weighted degradation factors, as we established in the course of our interviews. As is the case for power transformers and circuit breakers, it is METSCO's recommendation that HONI consider the integration of more commonly understood variables for risk-based calculations, such as failure probability curves coupled with the impact of failure.

When examining the DC battery and charger assets considered to be individual highest risk assets on the basis of AA assessment, we found that the composite results aligned with the data contained within the underlying inputs. The highest prioritized DC battery and charger assets were both found to be past their ESL criteria and had encountered a number of performance issues. Our assessment of the 20 highest-rated (in terms of AA risk) station ancillary equipment units yielded similar findings regarding consistency of the final scores and the individual factors considered in the analysis.

Stations Ancillary Equipment ARA Components

Our examination of HONI's DC battery and charger strategy document, which captures the data generated and considered as a part of the ARA process, confirmed that the utility considers a number of additional factors that supplement, enhance and help validate the quantitative insights captured in the AA analysis, including the following information grouped according to the major risk assessment factors:

- Demographics: Demonstrating the current and future replacement needs through the evaluation of station batteries and chargers that are currently beyond their expected service life.

- Condition: Discussion of degradation issues concerning the DC system assets, including material flaws within the battery container, lead contamination, plate connection weld failures, electrolyte contamination, failure of the terminal post seal, improper charging, and others.

- Criticality: Review of criticality criteria associated with the DC battery & charger assets, including ampere rating, voltage rating and station location, with the corresponding implications for the overall criticality level.

Figure 15 illustrates an example of the incremental analysis performed with respect to the criticality of the stations ancillary asset population. These results are used by HONI to further justify the prioritization approach for these assets as part of a long-term plan.

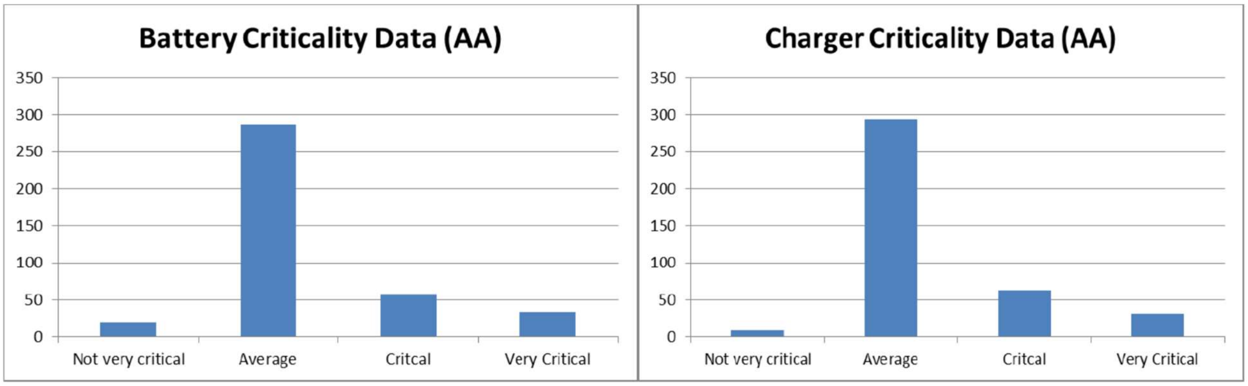

Figure 15. Overall Criticality of the Stations Ancillary Asset Fleet

The document also includes additional risk factors as identified within the ARA process to further justify stations ancillary asset replacements, including safety (e.g. the explosive nature of the "VRLA-type" batteries, which are being replaced with standardized "VLA" batteries).

For individual battery replacements, HONI performs targeted asset assessments beyond the strategy document and produces an NPV calculation. This evaluation considers various intervention options, including refurbishment, repair and replacement of the battery population. The underlying calculation methodology is similar to the NPV calculation performed for power transformers discussed above.

Key outputs produced as per the strategy document include recommended OM&A strategies, including preventative maintenance and corrective maintenance actions, along with a long-term implementation plan for the future replacement of assets.

Through the adoption of the ARA procedure, HONI's decision-making process for stations ancillary assets moves beyond the AA results, taking into consideration detailed additional factors that serve to further justify the final decision-making strategies. As with other asset classes, we see this multi-stage process to be comprehensive and reflective of a large number of diverse performance issues that cover all major categories.

Opportunities for continuous improvement include further integration of the incremental analysis occurring within the ARA framework directly into the AA analysis. As with other assets, we also recommended that the NPV analysis performed for individual station ancillary asset assessments should consider socio-economic factors in addition to financial costs, including collateral damages, environmental and customer interruption cost impacts, in an effort to consider the total economic costs associated with equipment failures.

3.2.4. Line Conductors

Input Data Supporting the Line Conductor AA Framework

The Asset Analytics formulation for Line Conductors leverages five out of the six evaluation categories relevant for Line Conductor analysis, including Demographics, Condition, Performance, Utilization and Criticality, in order to produce an overall composite risk score. The average sample size across all input variables supporting the evaluation category scores is just under 85%. Figure 16 illustrates the average sample sizes across the inputs for each evaluation category[6].

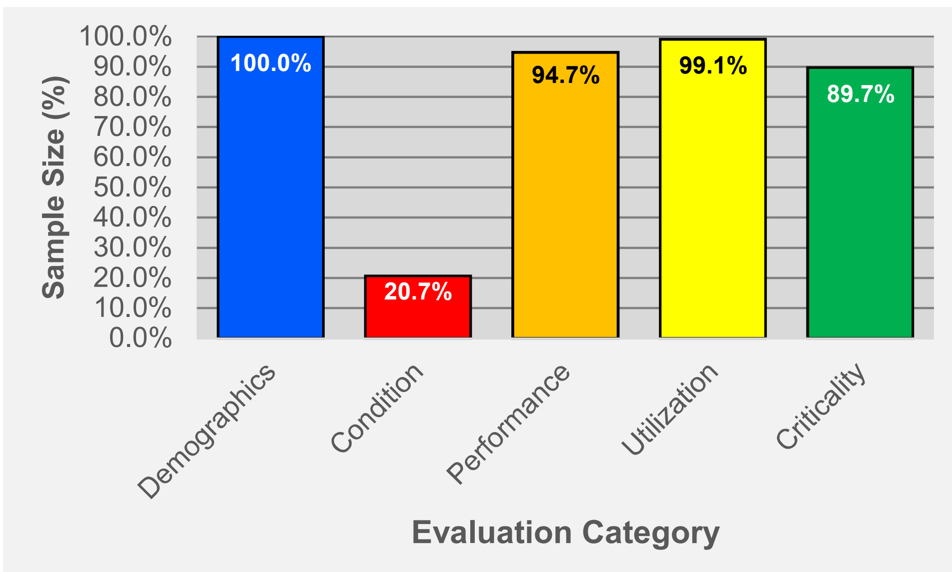

Figure 16. Line Conductor Average Sample Sizes for each Evaluation Category

Standing out from these results is the apparently low availability score for conductor Condition in particular. However, as we had learned from subsequent discussions with Hydro One, this score is largely reflective of the utility's strategy with respect to conductor condition collection, the methodology of carrying out the testing, and the manner of reflection within the underlying databases. As a matter of policy grounded in past experience, Hydro One does not collect condition data for any overhead conductors younger that 50 years, assuming that they all remain in good condition or better. Similarly, when testing cables using the new LineVue technology, or conducting laboratory tests on the basis of spliced conductors, Hydro One tests only one of the

[6] The overall data availability scores referenced above were calculated on the basis of an average across all individual input values in all categories - not across the averages of each individual category presented in the tables below. Individual input data availability also takes into consideration the relevance of the particular input parameter for evaluating the specified conductor type.

circuits on a given line and only select conductor spans. Hydro One then assumes that the condition score calculated on a given circuit and spans also applies to the adjacent circuit and spans. While the calculation algorithm makes this assumption, (which METSCO sees as reasonable), HONI data tables that METSCO examined do not clearly reflect this. Accordingly, the effective Condition data availability for overhead conductors in light of Hydro One's policies and practical testing approaches is significantly higher than what an initial review of data would indicate.

METSCO sees this prioritized approach where condition is not collected for younger vintages or adjacent circuits and spans, as a positive example of pacing and managing its data collection efforts. In other words, HONI's efforts to acquire conductor condition information within the operating and budgetary constraints are grounded in sensible managerial assumptions regarding the assets in close proximity to the ones undergoing diagnostic testing.

As with other instances of data gaps, we recommend that Hydro One continue its ongoing work to rectify the remaining gaps using the approach is already in place.

Line Conductor AA Evaluation Score Criteria & Results

Consistent with other asset classes examined, each of the evaluation category scores for line conductors contains elements that indicate probability or impact of asset failures – the two components that make up the best-practices definition of asset risk. Calculation of the demographics evaluation score is performed using the same underlying criteria as described for power transformers in Section 3.2.1, with the exception of ESL criteria that are specific to line conductor.

The Performance evaluation score takes into consideration granular historical reliability event data, including:

- quantity of total outages sustained;
- date of the most recent outage event;
- mean operating time before failures (MTBF);
- outage frequency and duration.

The Utilization evaluation score considers the summer continuous planning rating of the conductor, along with the total hours where the conductor loading was found to be in the range of 90%-110% of the rating, and the total hours where the conductor loading exceeded 110% of the rating.

The Criticality evaluation score accounts for the configuration of the line conductor, including:

- Whether the conductor provides supply to generation sources;
- If the conductor represents an interconnection;
- If the conductor is a Radial or Network asset;
- Total customer load on the conductor and;
- Customer supply, and critical customers connected to the conductor.

Finally, the Condition evaluation category score (where available) for line conductor considers the following criteria:

- Extent of rust on conductor span;
- Severity of rust on conductor span;
- Remaining zinc (%);
- Torsional ductility (expressed as number of turns)
- Tensile strength of the conductor (%)

We see HONI's condition evaluation score as fairly comprehensive - given the number of advanced tests that it performs. METSCO recommends that as HONI makes progress to supplement its condition score database related to conductors, it also consider collecting information associated with accessories including sleeves, spacers, dampers and armor rods.

When examining the individual and top 20 "highest risk" conductors as prioritized through the composite risk score result, we observed that the composite results followed logically from the values of the underlying inputs, yielding actionable insights. Importantly, those conductors where condition data was available were found to be in very poor condition. METSCO sees this as both validation of Hydro One's prioritization efforts of selecting the areas to undertake the extensive condition tests, but also a potential indication of a larger trend that we advise HONI to continuously monitor as it accumulates more new testing results.

Line Conductor ARA Components

As part of the ARA process, HONI will derive line conductor strategy documents on the basis of additional information considered in the course of the ARA process including the following:

- Demographics: assessing the current and future replacement needs through the evaluation of line conductor that are currently beyond their expected service life.

- Performance: consideration of historical reliability events, including outage frequency and duration over the past 10-year period.

- Condition: Discussion of the highest-risk assets on the basis of their condition evaluation category results.

The conductor strategy document includes assessments on obsolescent conductor spans that are reaching their ESL criteria. These particular conductors are either obsolete (e.g. use materials no longer used in conductor manufacturing or have alternatives that perform significantly better in the particular conditions), or have reached end of life on the basis of condition assessments.

Figure 17 and Figure 18 respectively illustrate an example of incremental ARA analysis captured in the line conductor strategy document. In this case, the growing backlog of conductors past ESL (as illustrated in Figure 17) over the next 10 years is compared to the proposed rate of replacement when taking into consideration available resourcing and system constraints (as illustrated in Figure 18).

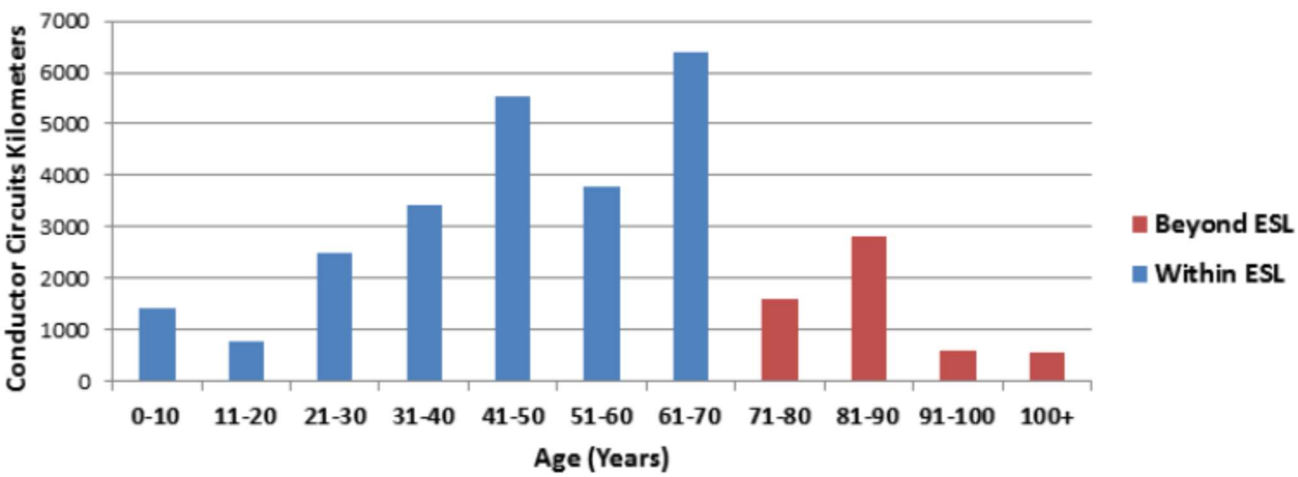

Figure 17. Conductor Demographics and Amounts past ESL Criteria

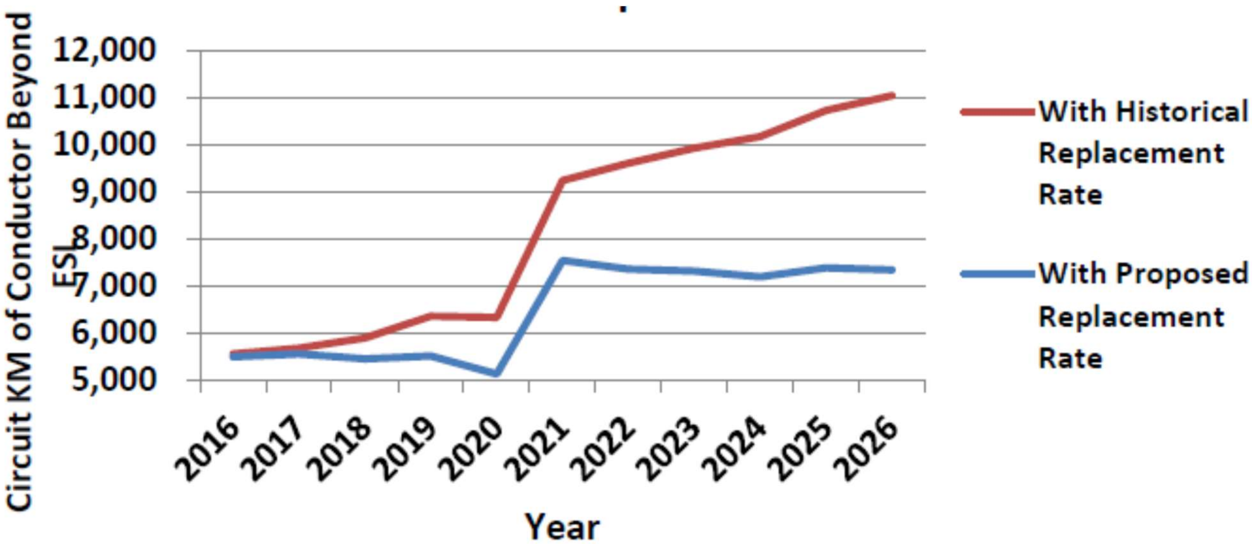

Figure 18. Comparison between Backlog and Proposed Replacement Rate

We also note that HONI continues to continually improve the underlying evaluation inputs used for the ARA procedure. An example of this is in regards to the ESL rating of line conductor, where the 70-year life span (applied in Figure 17) was recently changed to 90 years, following further research and analysis conducted by HONI experts. As part of future continual improvements, HONI will be updating their AA algorithm to account for this improvement. METSCO sees this enhancement driven by practical field insights as a notable example of capital replacement work pacing.

Importantly, in addition to the condition results as provided within AA, HONI also leverages laboratory testing in order to perform an in-depth assessment of the conductor with respect to its tensile strength, measured breaking strength and de-rated measured breaking strength. The results of this incremental analysis is utilized as part of the ARA process in order to further prioritize line conductors for intervention.

METSCO understands that HONI was recently acknowledged as one of the most progressive transmission utilities as part of an EPRI industry survey of conductor inspection practices. This conclusion was reached based upon HONI's utilization of field surveys in combination with laboratory validation technology, such as the LineVue technology and the remaining strength testing discussed above [6].

HONI's relatively recent adoption of the incremental tests comprising the ARA procedure for line conductor and the 20-year extension of the expected service life for conductors, demonstrates that asset managers are going beyond the AA results and existing assumptions, taking into consideration detailed incremental analysis and testing results in order to evaluate their final decision-making strategies and prolong the service life of its plant.

As with other asset types, while we see some merit in integrating the tests comprising the ARA more directly into the AA analysis, we recommend that such steps be considered only in the context of significant procedural reorganization of the asset management process/analytics capabilities, should they be contemplated. Absent such an initiative in the coming years, we the presence of sequential incorporation of additional criteria within the overall AM framework as sufficient, and in some ways may be seen as preferable to full integration into a single index, as the current sequencing foster a sequential multi-stage validation process. One potential context in which such integration could be justified in particular is if it is seen as a source of material administrative and/or operational efficiencies.

3.2.5. Underground Cables

Input Data Supporting the Underground Cable AA Framework

The Asset Analytics comprehensive index formulation for Underground Cable leverages five out of the six evaluation categories relevant for Underground Cable analysis, including Demographics, Condition, Performance, Utilization and Criticality, in order to produce an overall composite risk score. We calculated the average data availability across all input variables supporting the evaluation category scores to be just over 90%[7].

Figure 19 illustrates the average sample sizes across the inputs for each evaluation category.

[7] The overall data availability scores referenced above were calculated on the basis of an average across all individual input values in all categories – not across the averages of each individual category presented in the tables below. Individual input data availability also takes into consideration the relevance of the particular input parameter for evaluating the specified cable type.

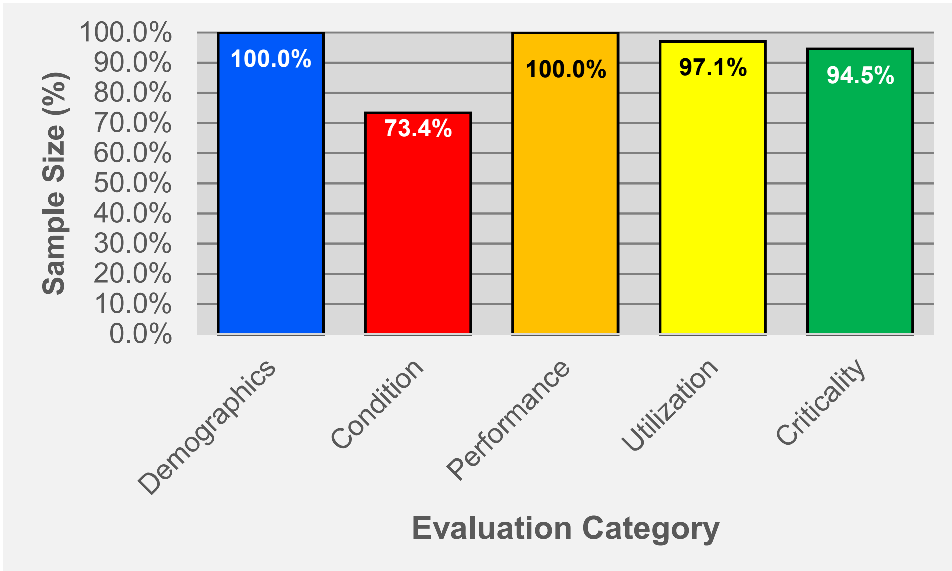

Figure 19. Underground Cable Average Sample Sizes for each Evaluation Category

In general, the results in Figure 19 illustrate a mostly complete and robust set of data being utilized for the purposes of underground cable evaluation. From these results, the condition category generates the lowest sample size. However, much of this of driven by the very low availability of a single parameter used in the condition calculation pertaining to Insulation Condition. Results for this parameter are determined from a destructive test that is only performed on paper-insulated cables under rare cases where a repair is performed. As the test is seldom performed, HONI may want to consider removing this parameter in favor of other testing results that are more commonly performed across the cable population. At present, however, METSCO endorses an approach where the condition parameter score requiring destructive testing is only collected when failures mandate destructive repairs.

In making the above observations, with respect to this and other asset classes where data gaps exist, we are cognizant of the reality that the number of potential areas where enhancements can be made substantially exceeds the financial and human resources available to complete these enhancements. Accordingly, our observations regarding the recommended enhancements reflect the expectation that HONI proceed to implement them upon a prioritization process across the process components, asset classes, etc. Expecting the balance of these gaps to be closed within a short period of time (e.g. a single five-year rate cycle) would be both unrealistic and imprudent.

Underground Cable AA Evaluation Score Criteria & Results

As is the case with line conductors, underground cable assets utilize the same five evaluation category scores containing factors related to probability and impact of asset failure. The underlying criteria for Demographics, Criticality and Utilization categories are similar to those used for line conductor calculation as explained in Section 3.2.4, using ESL rates applicable to cable demographic analysis.

Criteria used for performance and condition evaluation categories are unique to underground cable asset class. For Performance, inputs reflect historical reliability of a given cable segment, including:

- Number of historical cable faults;
- Other cable failures as recorded;
- Quantity of outages.

The evaluation criteria within the Condition category include:

- Oil testing results;
- Insulation condition;
- Accessory condition;
- Installation conditions;
- Corrosion protection condition; and
- Jacket voltage condition.

While METSCO sees HONI's current Condition evaluation criteria for transmission cables as substantially comprehensive, we recommend that Hydro One consider the thermography scanning of terminations and splices directly within the Condition scoring as part of continuous improvements (note that thermography scanning is performed and considered, but as part of the broader ARA process).

Our insights from examining the results of AA prioritization (the top segment and the 19 segments that followed in terms of the overall composite risk score) were consistent with those for other asset classes. The relative nature and magnitude of contributions from individual sub-indices and their components were indicative of a cable segment that warranted further investigation, if not outright replacement.

Underground Cable ARA Components

Consistent with other asset classes examined, HONI's ARA process provides the testing and analytical grounds for the content of the underground cable strategy documentation that drives long-term decision-making related to this asset class. Beyond the AA data, these strategy documents further supplement the results from the AA framework drawing from incremental analysis conducted for each of the evaluation categories, including:

- Demographics: replacement rate scenario comparisons as with other asset classes examined.

- Performance: comprehensive historical reliability event analysis where data is available in sufficient quantities.

- Condition: Discussion of thermography process and its results, which is currently executed in the context of the ARA work.

- Criticality: Discussion of cables of greatest criticality, including those in densely populated urban locations, servicing largest loads, and cables used to connect large load customers, such as local distribution companies (LDCs).

- Utilization: Discussion of load forecasts for large urban centers, such as the City of Toronto, along with the key results of the regional planning studies that plan to resolve these risks into the future.

Other factors considered in the course of ARA work and informing the asset strategy include obsolescence (e.g. challenges associated with obsolete LFPF and HPLF cables), safety (e.g. heightened risks associated with LFPF and XLPE joints in vaults and tunnels due to explosive failure modes) and environment (e.g. potential for oil leaks associated with LFPF and HPLF cable types).

Figure 20 and Figure 21 respectively illustrate an example of the historical reliability incremental analysis that is performed within the strategy document, in the form of cable outage frequency and duration respectively.

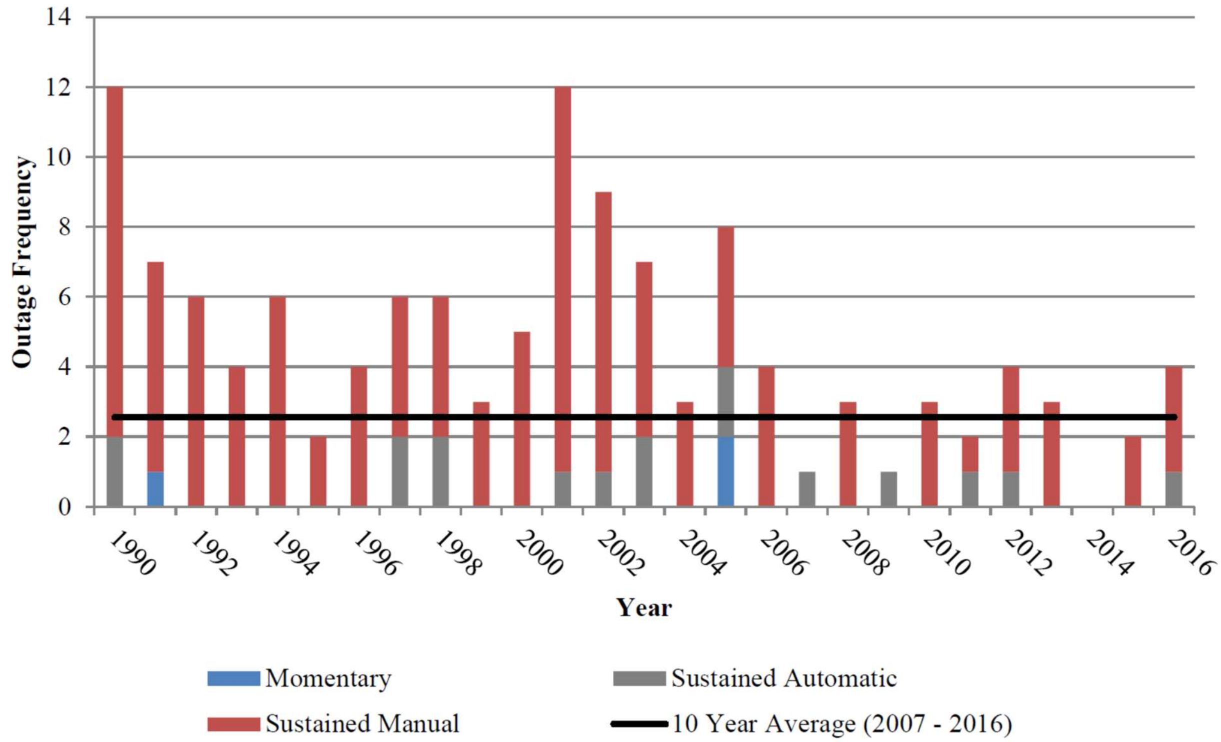

Figure 20. Underground Cable Outage Frequency

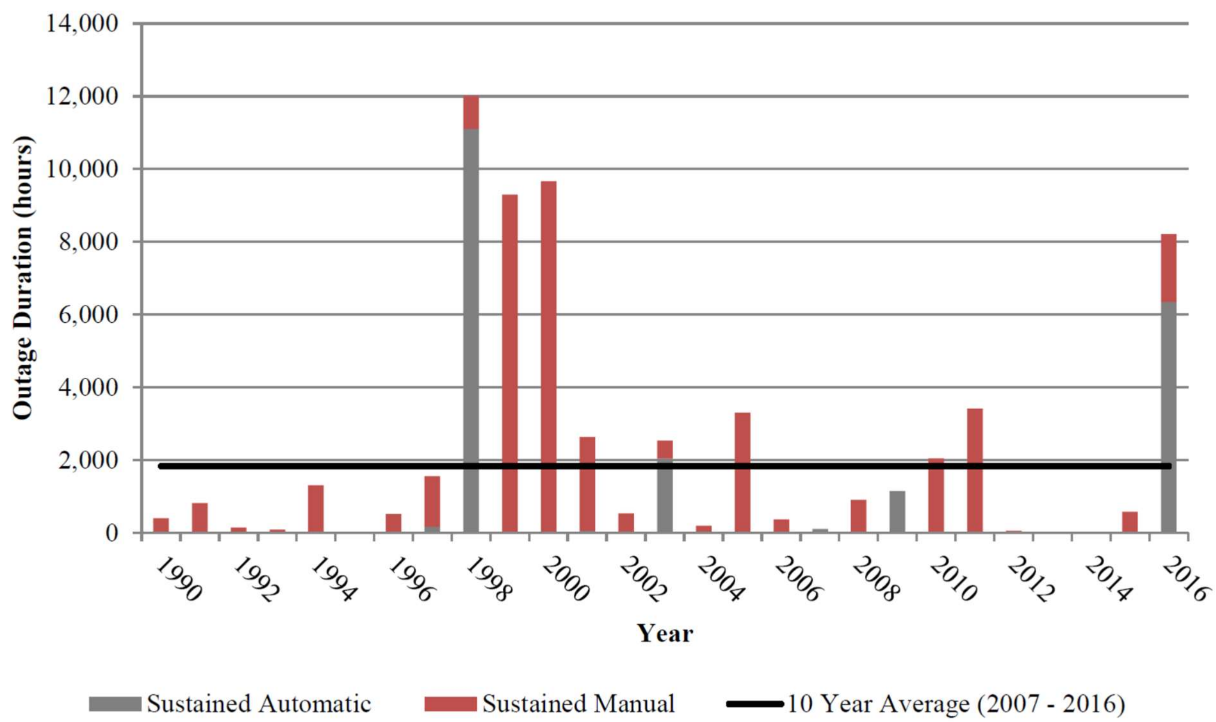

Figure 21. Underground Cable Outage Duration

Key outputs produced as per the strategy document include the long-term implementation plan associated with high-priority cables reaching their ESL based on the AA and incremental analysis results. As is the case with other assets, HONI continues to continually improve the underlying evaluation inputs used for the ARA procedure. An example of this is a recent extension of the ESL threshold for underground cable from 50 years to 70 years for HPLF and LPLF cable types. HONI has worked with third-party research entities such as the Electric Research Power Institute (EPRI) in order to define the ESL ratings for underground cables. As with our observations regarding the extension of overhead conductor ESL assumptions, we note this as a practical example of HONI's efforts to manage the pace of its capital replacements, grounded in incremental analytical insights.

As was the case with line conductor, HONI's utilization of the ARA procedure for underground cables demonstrates an approach that extends beyond the automatically generated AA results, taking into consideration incremental analysis in order to justify the final decision-making strategies, and applying balanced judgment across a number of input criteria (the insights of which can, at times, be conflicting).

3.2.6. Protection & Control (P&C) and Automation Equipment

With respect to protection & control and automation-related assets, Hydro One's asset analysis is mostly centered on technological obsolescence, as a function of interoperability, parts availability and equipment support, and regulatory requirements, among others. . Among other factors, interoperability is particularly critical for protection and communication equipment, to ensure that the assets respond appropriately and reliably during a contingency.

In METSCO's experience, Hydro One's approach to P&C and Telecom asset management is consistent with those used by other transmitters. However, we encourage Hydro One to explore incorporation of other asset management decision-making drivers into the scope of a formalized IT capability-based analytics tool, subject to feasibility and value for money analysis. As we have learned by way of SME interviews, a number of such activities do take place periodically, albeit they are largely manual in nature. These activities include:

- Internal stakeholdering to ensure alignment with other ongoing projects;
- Standards compliance monitoring to mitigate obsolescence issues;
- Examination of historical performance data (e.g. mis-operations);
- Field visits for specific data collection;

- Short-circuit analysis, relay coordination, telecom propagation and terrain radio signal penetration studies;
- Development of replacement project specification standards;
- Peer review and validation of chosen specifications.

In the manner consistent with the ARA process, Hydro One uses these insights to produce a strategy document that informs the long-term replacement approach. Figure 22 illustrates an example of such expanded analysis performed in support of strategy development. In this case, the analysis demonstrates that HONI's performance is very good with respect to mis-operations over the past three-year period.

	2013 Q2	2013 Q3	2013 Q4	2014 Q1	2014 Q2	2014 Q3	2014 Q4	2015 Q1	2015 Q2	2015 Q3	2015 Q4	2016 Q1	2016 Q2	2016 Q3	2016 Q4
HONI Cumulative Misop Rate	5.0%	8.7%	9.5%	9.4%	8.8%	7.8%	7.9%	7.8%	7.6%	7.3%	7.3%	7.4%	7.2%	7.3%	7.3%
HONI Cumulative Misop Rate (disregarding 2013 Flood)	5.0%	4.8%	6.4%	6.7%	6.5%	6.0%	6.2%	6.2%	6.2%	6.1%	6.2%	6.3%	6.2%	6.4%	6.5%

Figure 22. Historical Mis-operation Rate for HONI Infrastructure

Opportunities for continual improvements would include the further integration of the current manual planning process into existing enterprise systems, such that productivity improvements can be realized.

3.3. Level 3 Assessment: Practical Implementation Issues

As the final layer of METSCO's combined review of the AA and ARA capabilities, we sought to examine how HONI deploys them in a practical setting, on the basis of specific case studies representative of normal operating practices and using real equipment data. In doing so, we sought to ascertain whether and how the preliminary insights through the AA assessment are ultimately supported, verified, debunked and/or otherwise enhanced through the analysis comprising the broader ARA process.

From the sequencing perspective, METSCO suggested to Hydro One to conduct this analysis at the very conclusion of the interview-based and data review engagements that informed our Levels One and Two review. We did so for three reasons:

1. To ensure that specific practical examples do not interfere with our review on the process /asset class level;

2. To explore the manner in which the (largely) algorithm-driven AA calculations are assessed against the ARA insights that incorporate a greater degree of qualitative / strategic considerations; and

3. To validate our understanding of sequencing and iteration that typically occurs in the course of Hydro One's asset management procedures.

To conduct this final stage of our assessment, METSCO asked Hydro One SMEs to provide us with case studies representative of three hypothetical scenarios associated with stations and line conductor replacement (one each):

a) Investment scenarios where the preliminary AA results aligned with the results of the subsequent ARA process to select and validate an immediate short-term investment candidate;

b) Investment scenarios where the results of the broader ARA process contradicted those of the preceding AA assessment, thereby stopping the immediate consideration of an investment candidate suggested by AA; and

c) Investment scenarios where a short-term investment candidate was identified through the incremental information identified through the ARA process, but was not sufficiently supported on the basis of the AA framework alone.

We provide the descriptions of the mini-case studies supplied by Hydro One following brief recaps of the overall evaluation methodology sequencing for stations and overhead conductors, respectively. As noted earlier, we provide the examples of particular real-life projects solely for the purposes of illustrating the nature and sequencing of the associated processes – not justification of any findings relating to a given project. As such, we have substituted the specific asset identifiers with generic one (e.g. "ABC TS") to keep the focus on process, rather than particular assets.

3.3.1. Stations Evaluation

As per the ARA procedure, Hydro One station assets, (power transformers, circuit breakers and ancillary equipment) are replaced as a group – typically at a station level. By performing renewal of an entire substation and associated equipment at once, HONI seeks to realize operational savings relating to work scheduling and outage coordination, among other sources of benefits.

Results from AA analysis serve as a starting point for the evaluation. Composite risk score results are used in conjunction with the underlying individual AA sub-indices. A station assessment is subsequently performed in which a series of inputs are utilized in addition to AA in order to provide incremental decision support. These inputs are further illustrated in Figure 23.

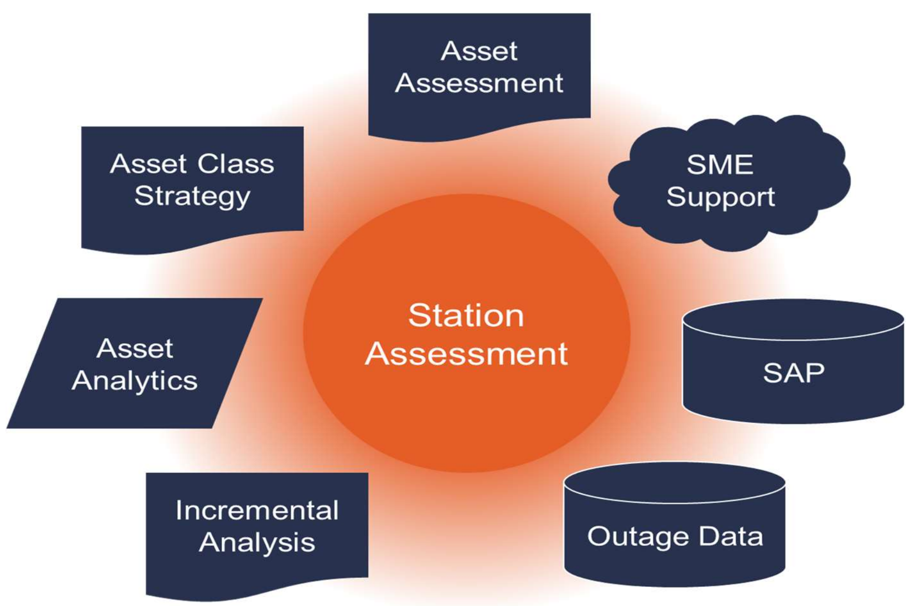

Figure 23. Station Assessment Procedure & Associated Input Data

The above figure illustrates the following process steps/concepts:

- Asset Class Strategy documentation: As discussed in sections 3.1.1-3.2.3;
- Asset Assessment documentation: As explained in sections 3.2.1-3.2.3;
- SME Support: validation of data sources (e.g. AA, outage information, etc.) including site visits;
- SAP: Central storage repository which stores all historical notification, deficiency reports and potential needs reports
- Outage Data: Historical outage frequency and duration data, as supplied within HONI's TODS data historian capability.

In addition, there are a number of incremental analysis sources that serve to provide additional insights into the ARA decision-making process. This includes the following:

- Assessment of stranded load risk;
- Assessment of delivery point performance;
- Capacity constraints analysis: Stations that are nearing capacity represent a greater risk, and changes to the configuration and overall capacity must be accounted for;
- Assessment of short circuit levels;
- Assessment of environmental risks, including PCBs;
- Assessment of physical security Issues;
- Examination of the operating diagram and overall station configuration.

Outputs from station assessment include calculated risk level assessments associated with each component of the substation, along with an overall recommendation as to whether to proceed with a short-term investment candidate, or defer the investments for re-assessment during the long-term planning process (e.g. 10 years).

The above description represents the normal process steps and components comprising the station work asset management review. METSCO understands that each of the three practical scenarios we requested from HONI underwent these analysis steps. METSCO has redacted the unique names and identifiers to focus the discussion on functional process steps, rather than project specifics.

Case 1A: Short-Term Investment Candidate Aligned to AA Results

In accordance with the first scenario, we identified a case study of "ABC TS" where the AA results identified a group of transformers at a single substation with low overall index scores, that were all nearing their ESL criteria based upon their Demographics evaluation score, with three condition scores being in Poor and Very Poor state. This is further illustrated in

Figure 24 for major assets at ABC TS.

Figure 24. Station Assessment Procedure & Associated Input Data

Further analysis revealed a number of deficiency reports and potential need issues that had emerged at the substation. These results, which are further illustrated in Figure 25 and Figure 26 respectively, illustrate a number of degradation-related issues affecting the assets installed at the substation, including corrosion, issues with the cooling system and issues concerning the power transformers including oil leaks and low oil levels .

Figure 26. Open & Outstanding Deficiency Report Notifications

A final risk analysis (ARA) concluded that there was a need to perform the work in the short term. Results from this risk analysis are further detailed in Figure 23, which include both major and minor asset investments at the station. Transformers T5 and T6 had already been included as part of another planned investment, and so additional investment was established to replace transformers T11, T12 and T13 respectively. Following a deeper investigation and field analysis, it was determined that T14 would be excluded from the investment program and revisited as part of a future initiative.

Asset / Infrastructure	Action	Reason/Rationale	Risk
T11, T12, T13 (including NGR's and surge arresters)	-replace all units including NGR's and surge arresters - fire & noise barriers likely required. To be assessed - spill containment upgrade necessary	-units are running beyond expected service life increasing the probability of failure. -condition of all units is declining with past visible oil leaks. - secondary surge arresters are old porcelain type. - NGR's required for new standard transformers. - spill containment and fire/noise barriers not up to standard.	High
T15 NGR (and HV SA)	-apply NGR as/when appropriate if not already being planned -HV SA may need to be respect due to address TOV.	- to eventually properly ground transformer to allow for eventual removal of grounding transformer at High Level.	Med
T11, T12, T13 Transformer high-side and low-side disconnects	- to be replaced	- declining condition - potential layout change to accommodate new transformers will likely require relocation of these items.	High
SS2 and high-side disconnect	-replace and put in load interrupter also	- SS2 advanced age and poor condition - potential layout change will likely require removal and relocating this equipment.	High
SS1 high-side equipment	-apply high-side fused disconnect and load interrupter	- to bring up to current standards.	High
GT1	-permanently remove when possible	-all new standard transformers have some form of secondary grounding	Med

Asset / Infrastructure	Action	Reason/Rationale	Risk
Current limiting reactors	-will require existing CLR's until three-supply High Level brickclads replaced	- potential layout change may require relocating CLRs.	Med
Potential transformers	- **AR 23630** has replaced 6 sets of delta PT's (T11X, T11Y, T12X, T13X, T13Y and T14X). These should be reused, if feasible, and relocated if necessary. - also replace T14Y and T12Y PTs.	- all units are older style oil-filled units likely containing PCBs. - potential layout change will likely require removal and relocation.	High
Insulators	- for entire station, replace all old porcelain strain insulators with glass-type. - for entire station, replace all cap&pin insulators with station post-type.	- can visually detect early failure of glass strain insulators and they maintain their mechanical strength when sheds may fail. - cap&pin insulators suffer from 'cement growth" failures.	High
Station service switchgear	- replace with standard DESN AC SS transfer scheme. Clean up and remove unused/unnecessary panels and fused disconnects, etc.	- install transfer scheme consistent with new standard and to allow loading of both SS transformers.	High
Revenue Metering	- AR 23630 has installed 8 sets of revenue metering IT's (T11-T14). These should be re-used, where feasible, and relocated if necessary.	-upgrade to current metering standards	High
SS Metering	- PCT Solutions to assess need for station service metering.	-no SS metering currently exists.	Med
Site drainage	- assess condition of drainage infrastructure and upgrade as required.	- Want to ensure drainage system is in good condition and meets standards since yard will be significantly dug up.	High
Existing structures and footings that will remain / be re-used	- For old structures and footings that will be remaining, assess condition. Perform remediation and life extension measures as required.	- to prolong the useful life of existing structure where possible.	High
Tunnel	- preference is to install standard control cable trench and remove old tunnel. However, if continued use is	- certain members appears to be decaying and remediation work would be necessary if tunnel kept.	High

Asset / Infrastructure	Action	Reason/Rationale	Risk
	necessary, then remediate to ensure structurally sound.	- tunnel may possibly interfere with spill containment or cable trenches and new drainage piping.	
Oil Building Removal	-remove old underground oil building	-no longer required. Should be cleaned up and removed. -space will be freed up.	High
Heritage Building	- assess condition of building and how much it would be to remediate or partially remediate for potential use. Assess feasibility of housing 13.8kV switchgear in the building.	- six H1 brickclad breakers/switchgear are at an advanced age and not arcproof. It is strongly recommended to replace this switchgear and preferred to relocate within Heritage building, if feasible, at ABC TS which is a H1 property.	High
Animal Mitigation	- apply all animal mitigation techniques at ABC (ie. cover up and electric fence barrier)	- lessen risk of animal contact outages	High
Fence/Security	- engage Physical Security group about ABC security needs	- Fence may need to be removed to accommodate work and new facilities. Is standard chain link fence or an opaque wall recommended?	High
32 L13W-34	-replace at Development & OGCC request with a circuit switches (Lines Sustainment will scope and fund this).	- this is a very old ABS which requires replacement.	High
High Level A1A2 and A7A8 switchgear	- Preference is to install new H1 A1A2 and A7A8 switchgear at ABC TS in heritage building, if feasible.	- these six H1 brickclad breakers / switchgear are at an advanced age and not arcproof. Old (now redundant) switchgear would remain I/S at High Level and continue to be maintained until THESL is ready replace the full lineup.	High

Figure 27. Overall Recommendations and Risk Results for ABC TS

The above example demonstrates the impact of both AA and ARA processes working together to validate and supplement the findings, resulting in the following positive intervention planning outcomes:

- Assets confirmed by the sequential AA and ARA analysis to be in a deteriorating / "risky" state were fast-tracked for intervention supported by the number of smaller issues identified through review of maintenance logs;

- The assets recommended for fast-tracking were added to the scope of already planned major work at the same station, facilitating potential operating efficiencies within the same geographical and electrical area;

- One component of the originally recommended / prioritized scope of work (T14) was actually excluded from the final scope following the field inspections where SMEs confirmed the insights of analysis, leading to deferral of capital costs.

In this case, both AA and ARA process insights combined to provide incremental economic value. An automatic algorithm-based approach identified assets indicative of serious issues in need of closer examination, while the ARA process confirmed the prioritization identified by AA, with the exception of one major asset that could be deferred for a longer period of time.

Case 2A: Lack of Alignment between AA and ARA Results

As per the second scenario, a case study was identified where the AA results identified a series of oil circuit breakers at "DEF TS" that were under heavy strain based upon their Utilization evaluation score. Majority of the breakers, as illustrated in Figure 24, were identified as having a Condition evaluation category score of just over 50, barely placing them into the Poor condition category.

Func. Location	Asset Class	Age	Condition	Demographics	Economics	Performance	Utilization	Criticality
N-TS-DEFTS-BR-JQ	Breaker: Oil_< 69 kV	43	53	56	13	60	100	29

N-TS-DEFNTS-BR-T6Q	Breaker: Oil_< 69 kV	44	53	60	14	1	100	31

Figure 28. Asset Analytics Results for TS Circuit Breakers

However, when assessing the condition and performance results of the associated transformers at this same substation as a part of the broader ARA process, HONI determined that the priority for these major station assets would be very low when compared to the breakers.

The power transformer assets were assessed to be in Very Good condition, translating into low probability of failure. Furthermore, the Performance evaluation scores for these transformers indicated that no historical events had occurred with these assets over the past 5-year period.

Following additional investigations by subject-matter experts, and when accounting for the overall operating configuration of the station and available redundancies, HONI determined that potential impact of breaker failure at this substation would be relatively low.

Therefore, despite the high probability of breaker failure, the low impact of such a failure led to the low overall risk scenario, meaning that minimal incremental investments could be performed, resulting in an acceptable risk level for the continued operation of these circuit breakers into the foreseeable future. Final recommendations were made to revisit and reevaluate the substation after a six-10 year period to re-evaluate the business case for a full or partial rebuild.

This case study demonstrates a practical example of the beneficial tension between the insights provided by the two respective functional components of Hydro One's asset management process. The more holistic evaluation enabled by the work completed at the ARA stage, led Hydro One to conclude that the risks posed by one asset class that was both aging and in poor condition, were not sufficient to move the overall risk to the point where intervention was justifiable, given the condition of other assets, the criticality of the asset and other pertinent factors available through broader analysis and diagnostics.

Importantly, this case study also demonstrates the material risk of relying on insights of a single process – even if it is quantitative and automated - given the multi-dimensional nature of potential asset scenarios, and the multitude of factors that are presently impractical to capture in the form of a single algorithm. As such, the presence of a two-stage process with multiple screens and validity checks, has prevented Hydro One from undertaking an investment that was not ultimately justified at present time.

Case 3A: Short-Term Investment Candidate Identified through ARA Process, but not from AA Framework

In the third scenario, the ARA process confirmed the need for a short-term investment candidate project to replace a group of minor assets at "GEH TS", including surge arrestors, insulators, capacitive voltage transformers and surge capacitors. Although these minor asset classes are supported within the AA framework, in this particular case the input data contained a number of incomplete areas, resulting in the AA tool not producing a score sufficiently high to flag the project as mandating prioritization.

After taking into consideration the input collected through the ARA process, including the raw demographics data, along with the consideration of legacy and obsolete technology contained in the station (along with inputs from the field and SME opinions), HONI determined that a short-term investment was necessary for this particular station.

Although in this example the fact that AA did not flag the investment as needed was a function of data availability rather than some other (less controllable) issue, it represents a realistic and commonly occurring scenario - for HONI and the vast majority of other utilities - in Ontario and beyond. While data availability is improving and will continue to do so, in the present state, the existence of two complementary capabilities/processes such as AA and ARA represents a valuable and prudent transitional solution on the path of process automation of business intelligence work.

3.3.2. *Line Conductor Evaluation*

As per the ARA procedure, line conductor segments are typically replaced as a contiguous group of assets. By replacing a group of segments together as a single investment, HONI seeks to realize operational and financial synergies.

As is the case with Stations assets, results from the AA framework serve as a starting point for evaluation of line conductor assets. In this case, condition results serve as a critical input into the decision-making process, where they are currently available. In particular, torsional ductility and tensile strength results are used as primary indicators to assess if the conductor is at end of life criteria and must be included as part of a short-term investment candidate.

In addition to the AA results, field testing results as provided by LineVue technology are also used to add incremental insights. Historical performance also plays an important role when identifying groups of line segments to replace. For instance, "line outliers" will be identified where sections of line conductor have noted performance issues. Finally, obsolescence also plays an important role where condition analysis indicates that an asset has reached its EOL. METSCO understands that the following three scenarios underwent the AA and ARA assessments as per the approach described above.

Case 1B: Short-Term Investment ARA Candidates Aligned to AA Results

In the first scenario, METSCO reviewed a case study where the AA results identified a group of line conductors on circuit "Dxyz" between "GEH Junction" and "IJK TS" that were all past their ESL thresholds, as determined from their Demographics score, and also in Poor condition as determined by their Condition scores. These results are further illustrated below:

Circuit	Composite RF	Condition RF	Demographics RF	Economics RF	Performance RF	Utilization RF	Criticality RF
	51	65	100	0	1	0	1
	38	0	100	0	1	0	1
"Dxyz"	38	0	100	0	1	0	1
	38	0	100	0	1	0	1
	38	0	100	0	1	0	1

Figure 29. Asset Analytics Results for Circuit Dxyz

It should be noted that the condition results produced for Dxyz would also be applicable to the other adjacent conductor spans and circuits. A laboratory test further validated these results and conclusions. These results are further illustrated in Figure 30.

Figure 30. Testing Results illustrating Measured Breaking Strength Deficiencies for Circuit Dxyz

This case study demonstrates how the ARA process helps to further validate and build upon the preliminary justification derived from the AA results, while allowing for a broader group of poor-performing conductor segments to be replaced at one time, creating opportunities for cost and planning efficiencies.

Lack of Alignment between AA and ARA Results

As per the second scenario, a case study identified a group of line conductor spans on "Circuit RST" between "LMN" and "IPB JCT" that were past their ESL criteria based upon their Demographics evaluation scoring results. However, the AA condition assessment was missing critical input data. As noted previously, condition results represent the most critical output from AA that is ultimately used in the decision-making procedure. Figure 31 illustrates the raw AA results including condition results on RST-115 which would also be applicable to all adjacent conductor spans.

Line Section	Composite RF	Condition RF	Demographics RF	Economics RF	Performance RF	Utilization RF	Cr

	41	0	100	0	1	0	
	31	0	100	0	1	1	
	31	0	100	0	1	1	

Figure 31. Asset Analytics Results for "Circuit RST"

In this case, however, the ultimate prioritization of the investment was driven based upon the obsolete nature and deteriorated condition of the 100-year old conductor type identified through the subsequent ARA analysis. As the conductor in question contain plant fiber cores, it cannot be spliced if a failure were to occur. Accordingly, customers would experience a far more prolonged outage event should a failure take place. For this reason, once HONI established the overall condition and presence of obsolete and deteriorated plant fiber technology, this project became a short-term investment priority, despite the preliminary AA results indicating no apparent issues (albeit as a function of missing data). These plant fiber cores are further illustrated in Figure 32.

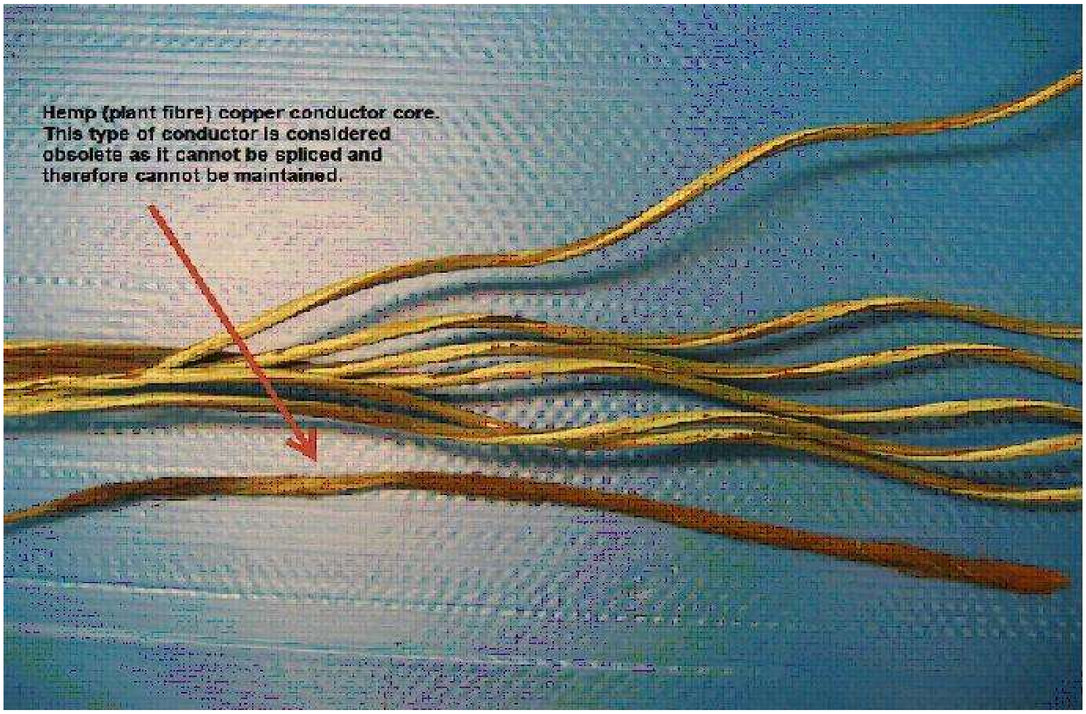

Figure 32. Example of Plant Fibre Core

This scenario therefore demonstrates how the broader ARA procedure provided incremental insights that materially affected the intervention decision due to the consideration of additional information and a discrete standards-related technical obsolescence criterion that would be highly unlikely to be factored into an automated decision support algorithm in the near future. As with the cases related to station investments, the broader ARA framework acted to override the algorithm-driven AA process to yield the combined outcome, superior to those produced by either of the two systems separately.

Case 3B: Short-Term Investment Candidate Identified through ARA Process, but not from AA Framework

As line conductors are modelled in the AA framework, the AA results will always be considered as a starting point to drive any decision-making within the broader ARA procedure. Therefore, there are no scenarios where a short-term investment is formed without any use of AA results.

4. Reliability Risk Model Capability Evaluation

This chapter contains the details of MESTCO's assessment of the Reliability Risk Model (RRM) capability. As noted earlier in this report, we limited our assessment of this tool to the "Overall Capability Sophistication" level of analysis. This is largely a function of the tool's limited application in Hydro One's asset management programs, which at once limits the information available for detailed inquiries and reduces the value of insights these inquiries may produce in the context of asset management process specifically.[8] In light of the tool's comparatively smaller "footprint" on Hydro One's current asset management landscape, METSCO believes that a single level of assessment is sufficient to draw meaningful conclusions about the RRM tool's value proposition.

METSCO employed different criteria for this assessment from those use for the Level 1 assessment of AA and ARA tools, which we see as more relevant for a reliability forecasting tool specifically. Our criteria selection is also consistent with assessments of reliability forecasting capabilities we performed for other utilities in the past. The criteria are:

- Integration and connectivity with the broader asset management procedures;
- Granularity of analysis underlying the forecasting;
- Sophistication of mathematical calculations supporting the model;
- Efficiency of data collection procedures and accuracy of input data; and
- Clear Sense of Current Gaps and Continuous Improvement Plans

4.1. Overall Capability Sophistication Assessment

4.1.1. *Integration into the Asset Management process*

Utilities may have multiple reasons to engage in forecasting of their reliability performance. Most commonly, however, motivation for doing so involves establishing a vision of the anticipated outcomes of planned or contemplated work. The forecasts, typically expressed relative to investment types or levels, may serve as inputs into project selection / investment prioritization process, customer consultation engagements, or performance measure setting activities, among others.

[8] We make this observation in full awareness that HONI utilizes the RRM tool in the customer engagement process, where its outputs enable it to convey asset reliability risk implications to customers. From our perspective, the limited nature to which HONI relies on RRM in asset management is not indicative of the tool's value in customer engagement activities.

While a given tool's forecasting strength comes from the manner its inputs are collected and analyzed (as we discuss in the criteria that follow), its overall value is also determined by the extent to which its outputs are incorporated into AM decisions that take place downstream from forecasting. A mature reliability projection approach should constitute an integrated link between capital and maintenance plans and system performance outcomes.

Where such systems are in place, their underlying reliability projection methodologies can typically be validated by comparing their past projections to actual system performance results for a given year. Where a utility identifies material variances between actual results and those forecasted by the model for the same period, the mechanics of the projection approach are adjusted by way of a standard process, in order to minimize these variances (and their impact on the AM process) going forward.

With respect to Hydro One's RRM model, we found the tool's current level of integration with Hydro One's overall asset management process to be very low. This is largely because the assessment takes place after the AA and ARA processes for a given planning cycle have been completed. Although this still enables Hydro One to consider the feedback from its customers obtained with the help of the model while formulating the nature and magnitude of the investment plan, METSCO considers this work to be outside of the scope of asset management activities, which is the focus of our inquiry.

Equally notable is the fact that RRM does not actually deliver the forecasts of reliability indices, but rather indicates the "risk" level of reliability issues associated with particular investment levels (the fact Hydro One readily acknowledges). The reliability risk derived through the model represents an aging aspect of the key asset classes, as a result of modelling the age distribution and related portion of assets that are expected to experience physical or inspection-based failure on the basis of past data.

Each of the investment level scenarios considered by the RRM includes an estimated failure rate per asset class based on the specific asset age distribution at the end of the modelling period. While the estimated failure rate for key asset classes represents the reliability risk related to the planned asset renewals, it may not be correlated with the actual reliability incidents or equipment availability to serve the load.

While the key implication of a more limited definition of reliability risk in the model is less of a concern for a tool designed to assess the changes in likelihood of certain events taking place based on the nature of actions that precede them, a more complete definition of modelled reliability indicators would provide HONI with deeper insights of the outcomes that it seeks to bring about or avoid.

METSCO recognizes that the manner in which a particular analytics tool is deployed reflects the degree of understanding and confidence that the utility that implemented it has in the model's robustness, accuracy and efficacy. Having been commissioned in 2016, we understand that the RRM model was only available for use (and by extension practical testing) in two annual planning cycles. While Hydro One does not consider the model to be a pilot project per se, the tool's limited utilization to date within an already complex and consequential asset management process is understandable from a practical standpoint.

Considering METSCO's understanding that the RRM tool represents the first instance of HONI using reliability risk modelling in the context of transmission infrastructure, its more robust integration as an explicit AM process input could be considered risky absent extensive practical stress testing.

Based on its current utilization and process positioning relative to other key asset management analytics inputs and decision points, we see Hydro One's use of its reliability risk modelling capability as comparable to less mature industry approaches. However, the sole fact of the utility possessing and using a standalone variety of reliability risk model, rather than using ad-hoc trend-based projections or other more rudimentary approaches, points to a somewhat higher maturity level and a degree of commitment to continuous improvement on the part of Hydro One.

Based on our review of Hydro One's integration of the RRM into the asset management decision making process, we make the following recommendations:

- Enhance the RRM or develop/procure an alternative system to forecast the reliability performance of the transmission system through a variety of *reliability indices*, rather than rely on the *reliability risk* modelling.

- Integrate the enhanced RRM or another forecasting system into the overall asset management process to provide asset managers with a more robust set of reliability outcome predictions based on a variety of investment scenarios under consideration.

4.1.2. *Granularity of analysis underlying the forecasting*

As with most modelling capabilities, the degree of precision of a reliability forecasting model depends on the level of detail of information that the model assesses and takes into account in producing its outputs. In the case of reliability modelling, the relevant granularity variables include:

- *Specificity of replicating the utility's electrical system configuration* – (e.g. presence of feeder- or station-specific operating parameters and performance data, vs. an aggregate reflection of key system parameters);

- *Utilization of outage cause data* – whether the model incorporates all, or only a portion of outage Cause Codes tracked (e.g. only equipment defective vs caused by tree contacts, adverse weather, foreign interference, etc) and use of Sub-Cause Codes.

- *Length of reference periods and forecasting horizons* – the amount of historical data that the model leverages in producing its forecasts, and the duration of the forward-looking forecasting window.

While higher granularity is generally desirable (to the extent that incremental detail drives incremental precision), METSCO notes that the discipline of reliability forecasting is relatively new in the utilities sector, meaning that few utilities in our experience have implemented reliability models of significant granularity. This is particularly the case with respect to the degree of specificity of system modelling. Accordingly, it is important for a reviewer to maintain reasonable expectations when assessing a particular capability.

Having reviewed Hydro One's RRM model, METSCO concludes that the level of granularity of the model's analytical capabilities is low relative to other industry examples known to us. For clarity, our assessment of the RRM is that it lacks granularity characterizing more advanced models. Our finding reflects the following considerations:

- The model's predictions apply to the overall equipment level and three specific asset classes (conductors, breakers and transformers). The model includes key asset classes and sub-categorization of the equipment into the sub-classes that enables a detailed analysis of the investment scenario impact on the projected asset failure rates. Inclusion of additional asset classes[9] (e.g. tower structures,

[9] The RRM includes the reliability issues related to the tower structures and insulators as part of the weighting mechanism to calculate the reliability risk. The model calculates the reliability risk as the weighted average equipment failure rate of three asset classes: conductors, breakers and transformers. The weight score for conductors include all the equipment issues related to lines, covering the tower structures with sub-components and insulators.

insulators, switches) may improve a precision level of the reliability risks associated with the equipment age.

- The RRM is developed to calculate the reliability risks for the equipment on the system level, lacking granular consideration on subs-system levels, such as system regions or large customer groups. In making this observation, METSCO notes that having a reliability model that would provide this level of a more localized predictive analytics would amount to the most advanced tools used by the utilities.

- The RRM model excludes failure data related to non-equipment phenomena – outage causes like weather events, adverse environment, human related errors, foreign interference, etc., are not factored into the reliability risk projection. We recognize that inclusion of other reliability cause codes into the model is a relatively large undertaking for the utility that requires a sophisticated historical analysis of all the cause codes to find the significant external and internal drivers impacting the reliability indicators.

- The model calculates reliability risk of the system relying on the asset replacement counts included in the investment scenarios. While replacing the assets on bad condition represents one of the most impactful option to mitigate the reliability risks, Hydro One may have other non-renewal projects that aim to improve the transmission system performance (e.g. adding protection devices in the system, increasing system capacity, new lines, etc.). Excluding the impact of such non-renewal projects (if they exist in in the investment plan) may skew the overall assessment of the reliability risk.

- The horizon period of the RRM extends to the next five years. Due to a longevity of the transmission assets and a complexity of the transmission related construction projects, the model may need to cover a longer horizon period to gain a better understanding of a long-term impact on the investment scenarios on the system.

In short, the RRM tool trails the industry in terms of the level of detail embedded in its inputs, outputs and governing relationships. The model also focuses only on outages related to equipment end of life, excluding the data related to other material drivers of reliability performance. Although this exclusion may be explained by the utility's desire to concentrate on the impact of equipment-related performance only, the results of such analysis bear a significant risk of painting an incomplete picture, considering, for example, the typically observed correlations between weather and defective equipment failures, (among others) that the model does not presently capture.

For reasons listed above, we conclude that the RRM model lacks granularity when compared to other industry participants that possess dedicated reliability models. However, the fact that a standalone reliability risk model has been developed, positions HONI amongst only few utilities that have this predictive capability to perform reliability risk forecasting.

Based on our review of the granularity of the RRM, we make the following recommendations for Hydro One's consideration:

- Enhance the present model or ensure that an alternative solution include additional asset classes (e.g. tower structures, insulators, switches) and sub-classes to improve the precision level of the equipment related reliability risk forecasting.

- Develop capabilities to provide reliability risk prediction on a sub-system level, such as system regions or large customer groups.

- Factor in non-equipment related outages (e.g. weather events, adverse environment, human related errors, foreign interference, etc.) to forecast the reliability risks of the transmission system as a whole.

- Assess the reliability impact of the non-renewal projects in the RRM or alternative capability. If the utility does not have any such projects in the investment plan, then the benefits of this recommendation would not outweigh the costs of developing this capability.

- Extend the forecasting horizon to at least ten years to capture a greater extent of the long-lasting renewal and non-renewal projects within the investment scenarios on the system reliability.

4.1.3. *Sophistication of mathematical calculations supporting the model*;

As with AM integration and data granularity, reliability forecasting methods and models can vary substantially in terms of complexity of calculation to model relationships between investment levels and system reliability outcomes.

At the most basic level, reliability forecasting approaches leverage trend analysis of interruption data, extending the past trends into the future with a variety of normalization techniques to smooth out volatility, or establish the bounds of reasonable performance ranges. More advanced systems utilize econometric techniques to establish mathematical relationships between asset failure instances or modes, and factors that precipitate them, such as demographic data, condition parameters, weather/climate phenomena and other types of conditions related to outages.

Models may differ significantly by predictive power of their underlying regression equations, number of modelled factors, or the type of analysis they use to define the relationships between variables (e.g. linear, logarithmic, etc.). Finally, the algorithms for the most sophisticated models will feature advanced tools of statistical analysis that capture and appropriately treat complex interactions between a multitude of factors, and account for the technical and physical factors inherent in a given system and the environment that surrounds it.

In the case of Hydro One's RRM, calculated changes in reliability risk are grounded in two factors – asset demographics and probability of physical and inspection-based failure by age across three asset classes (conductors, transformers, breakers) and sub-classes. For each investment scenario it analyses, the model starts by forecasting the demographic profile of Hydro One's asset base over the forecasting period, using these major asset types as a proxy for the system as a whole.

Having derived the forecasted demographic distribution, the model then applies statistical asset failure curves derived from Hydro One's actual field data (and supported by 2014 Asset Failure Analysis report conducted by Foster Associates), to estimate the number of assets expected to reach their end-of-life during the forecast period.

The resulting number of forecasted failure retirements is then adjusted to reflect the planned replacement volumes underlying each investment scenario. The model then calculates the total failure rate per each asset class by dividing total retirements by asset counts in each of the asset classes, and the failure rates by assigning "significance weighting" to each asset type. Significance weighting is based on the relative likelihood of a particular type of asset to contribute to the reliability issues, according to Hydro One's historical reliability data.

The resulting rate (%) represents the relative reliability risk underlying a particular investment scenario. The difference between the retirement rates associated with each scenario represents the directional difference in reliability across the potential investment scenarios – the model's ultimate output used in stakeholdering.

METSCO notes that there are several modelled assumptions that would need to be improved upon, should HONI elect to further utilize the RRM to calculate the aging equipment reliability risk. Currently, the replacement priority within each of the scenarios is based on the oldest assets to be replaced first within the asset count limits established by the each of the investment scenarios. This approach does not account for the end-of-life asset retirements that naturally occur as a result of the aging process and are modeled in the RRM by the asset failure curve and age demographics. Under these replacement algorithms, the changes in the reliability risk values may be over- or under-estimated.

In METSCO's assessment, HONI reasonably designed the significant weights to represent a contribution of each of the asset classes in the equipment reliability risk. The model uses the weights constructed from the outage database and filtered by the equipment cause code. However, the conductor weighting incorporates any issues originated in transmission lines, for example including the reliability issues caused by tower structures and its subcomponents, as well as insulators. The same approach is assumed for transformer and breaker weightings. By combining the reliability cause codes unrelated to the core asset class, the final weightings have a potential to skew the reliability risk values calculated by the model.

As the preceding description may indicate, while the RRM does employ a variation of equipment hazard rate sourced from HONI field data in deriving its projections, the ultimate output that the model relies on significant assumptions, while leaving unaddressed a number of other statistical relationships where meaningful correlations and/or causal relationships could be reasonably expected. In its present form, the model's actual forecasting output is the rate of anticipated asset retirements, while the assumed relationship between the changes in this rate and equipment outages is significantly less robust.

Utilization of hazard rates and the age distribution to forecast the reliability risks associated with the equipment can be considered as a big first step forward in deploying the reliability forecasting capabilities in the asset management decision making process. In consideration of the above-noted characteristics, METSCO rates the sophistication of the RRM model's mathematical calculation as relatively modest, when compared to dedicated reliability modelling tools employed by some utilities.

In making this conclusion, however, we note that a large number of Canadian utilities do not engage in forecasting of reliability in any organized form. This is particularly true of transmission systems, the multi-contingency nature of which makes it more challenging to construct the relationships between potential equipment failures and actual outages experienced by end customers, be they transmission- or distribution-connected. Nevertheless, we see significant opportunities for improvement in computational sophistication of HONI's model, provided the utility's management is considering expanding the manner of the model's utilization in the coming years.

Based on our review of the model algorithms deployed in the RRM, we make the following recommendations for Hydro One's consideration with respect to potential RRM enhancements or development of a new capability:

- Enhance the algorithms utilized to calculate the demographic profile for each asset class, by revisiting the priority of asset replacements and considering both reactive and inspection-determined failure modes of assets reaching their ends of lives.

- Revise asset class weights or the algorithms that calculate the reliability risk of three key asset classes per each investment scenario to incorporate more asset-specific failure considerations.

- Utilize a variety of econometric techniques to establish mathematical relationships between the non-asset and asset-related failure instances or modes, and factors that precipitate them.

4.1.4. *Efficiency of data collection procedures and accuracy of input data*

For any modelling tool, the quality of its input data and the effort involved in its collection and verification are important factors in determining that model's overall reliability. While METSCO understands that the IT systems used to report and validate Hydro One's transmission reliability statistics are advanced, robust, and undergo extensive verification on a regular basis, these systems are not directly integrated with the Reliability Risk Model. In performing its runs, it is sufficient for the model to utilize the latest demographics data available from the utility's enterprise systems, and the equipment hazard rate curves validated by the 2014 Foster and Associates report. As we discussed earlier, Hydro One's enterprise systems are well integrated, and incorporate a number of data verification steps, meaning that we are aware of no particular issues that would point at concerns with the currency of demographic data

We understand, however, that HONI manually filters its outage data to identify the cause codes and events associated with each of the equipment types in scope of the present RRM analysis. While this manual procedure is inefficient and potentially prone to entry errors, automation of this process may be relatively expensive and not worth the efforts given the narrow scope of the tool's application.

In light of the relatively modest data needs and the robustness of the enterprise systems that generate the demographic information, METSCO has no concerns regarding data accuracy or efficiency of data collection associated with the RRM capability.

4.1.5. *Clear Sense of Current Gaps and Continuous Improvement Plans*

In our discussions surrounding the RRM with Hydro One subject matter experts, we found them to be both realistic in terms of recognizing the tool's present capabilities, their limitations, and receptive to the ideas regarding potential improvement opportunities in the field of reliability forecasting.

During these discussions, Hydro One SMEs brought up the issue of methodological complexity of forecasting transmission system reliability indices, in light of the multi-contingency nature of a large portion of the utility's system, which prevents all equipment outages from manifesting themselves in the form customer interruptions. In this context, HONI staff hypothesized of forms of forecasting transmission system performance alternative to average interruption frequency and duration indices, such as system nodes, equipment availability indices, loads at risk, etc.

METSCO is of the opinion that index-based transmission reliability forecasting is feasible based on our past experience in reviewing and constructing such models. However, we see Hydro One's commentary regarding alternative paths of enhancing a given solution, as a strong indication of the company's motivation to continuously improve – but to do so in a manner that fits the company's operational environment and provides incremental value in the areas where they are most needed.

Considering the relative recency of its introduction, the RRM is yet to undergo any formal reviews or enhancements, which METSCO finds to be reasonable. However, we see the fact of Hydro One's decision to implement (albeit in a limited role) a capability that many transmitters are only beginning to contemplate, as the best practical indication of the culture of continuous improvement on the part of its Asset Management function and its management.

While the RRM trails the advanced industry practices in many respects, it provides the company with a strong foundation upon which to enhance its forecasting capability going forward.

Based on our review of the continuous improvement plans, we make the following recommendations:

- Prior to investing any incremental resources into potential refinements or alternative solutions, we encourage Hydro One's management to fully articulate a vision of the tool's ultimate place within its asset management and capital planning hierarchy, including whether such a tool is ultimately needed in light of all other capabilities.

- Once this process (which we understand to be underway) is complete, Hydro one can choose to develop a critical path and timeline towards further enhancements, if desired.

V Conclusion and Recommendations

In setting out to conduct this assessment, METSCO sought to provide a comprehensive review of Hydro One's asset analytics and reliability risk modelling capabilities across a number of dimensions. Having conducted more than 30 interviews with Hydro One SMEs, along with extensive independent review of the materials supplied by the utility, we dedicate a considerable amount of attention to the technical details related to scope and nature of inputs, data availability and validation, and practical case studies.

We also saw it as critically important to assess the higher-order managerial variables related to process coherency, reflection of best practices, and the degree of comprehensibility of the processes and their implications. These key organizational factors are often left out of the scope of purely technical assessments, leading to limited insights as to the practical utility of a given capability on a day-to-day basis. While some of these issues may not have a critical bearing on the outcome of a single assessment, their effect may compound across the investment cycles and individual processes, resulting in lost productivity, complacency with status quo, and a number of other negative consequences.

On balance of factors and practical examples considered across the three levels of assessment, it is METSCO's opinion that the AA and ARA capabilities, which represent the backbone of Hydro One's asset management analytics, are comparable to advanced asset management tools used by other utilities of similar size and sophistication. In a number of areas - such as the integration of analytics tools with the enterprise data management systems and condition assessment techniques for conductor infrastructure – we find Hydro One to be at the sector best practices level.

Importantly, when validating our Level One and Two impressions by way of a case study review in the Level Three of our framework, we saw the two parts of Hydro One's asset management capabilities working as intended – providing complementary insights that enhanced, validated, and in some cases disputed the implications of one analytical tool or process relative to those provided by its counterpart. The outcomes of this multi-stage / multi-criteria review and stress-testing were consistent with the tools' intended purpose of optimizing the value of the ultimate investments proposed. In several cases analyzed, the combination of several discrete tools and processes actually led to lowering immediate investment requirements than would otherwise be these case if only one of the two complementary capabilities was used.

Critically, our case studies also highlight the potential pitfalls of relying exclusively on the insights delivered by algorithm-driven automatically generated analytics capabilities. While automated analytics tools like AA are sufficiently rigorous and robust to deliver value to Hydro One's asset managers, the multitude of potential scenarios that manifest themselves in the context of utility planning cannot be reasonably expected to be fully captured by an algorithm at this time. Accordingly, and as illustrated by our case studies, the complementary use of the automated fully formulaic tools along with the more holistic approaches, is positioned to provide the utility with additional value – at times proactively mitigating the financial impact of suboptimal investments recommended by one tool or another.

Our conclusions are less favourable with respect to the RRM tool – which is both relatively new and currently used in a very narrow context of directional reliability risk quantification for customer engagement, rather than asset management per se. While we find that the RRM tool trails most other reliability forecasting capabilities known to us, we see it as important to contextualize this finding by stating that very few transmission utilities currently possess dedicated standalone quantitative tools, or even fully formalized processes for reliability forecasting or a related activity. As such, the fact of Hydro One's possession of such a standalone model (albeit in a fairy scoped form) represents an important step on the road to continuous improvement that sets the utility apart from many of its peers.

Throughout this report, we provide Hydro One's management with a number of recommendations about potential enhancements that it may want to consider to further refine and solidify its quantitative analytics capabilities. While all of these reflect METSCO's sector experience and proactive research endeavors, we are cognizant of the reality that Hydro One's resources available for potential implementation of any of the changes that we advocate are likely to be insufficient to implement all of them over the next five-year rate cycle, or even beyond.

Based on these considerations, our overarching recommendation is that Hydro One consider our individual suggestions as potential options for further enhancements, viewing them in the context of their opportunity costs relative to other operating and customer-oriented priorities. Selecting the areas where attaining best practices may not necessarily be a priority (especially when validated through customer engagement, value for money testing, etc.) is one of the few areas where regulated utilities have a meaningful degree of strategy-setting discretion.

Notwithstanding the above comments, the following is the list of recommendations that we recommend that Hydro One consider in its efforts of continuous improvement.

AA/ARA capabilities:

1. Consider clearly separating the risk factors/criteria in AA to (a) define probability of failure of a specific asset, and (b) incorporate the impact of asset failure to explicitly assess a broader variety of outage consequence costs, such as utility's and socioeconomic costs, including the costs associated with the environment, safety/collateral damages, environment, customer interruption costs and financial impacts. Given that many of these additional factors proposed for incorporation into AA are already considered in the subsequent ARA analysis, we qualify this recommendation by stating that HONI may wish to consider it at a juncture where a broader AM process reorganization may be contemplated.

2. Re-visit the formulation of its present AA framework and consider potential regrouping / renaming of assessment factors components to better align it with commonly understood industry terminology (such as condition assessment/health index, or impact assessment/consequence cost), and take steps to develop more comprehensive explanatory manuals for its AA capabilities.

3. Continue ongoing work to rectify data completeness gaps identified across the individual risk sub-categories for each asset class in section 3.2, aiming for the highest practicable scores within the resource availabilities, and prioritizing the categories seen as most impactful in light of the criteria weightings.

4. Consider supplementing the current condition parameters tracked for each major asset class with additional parameters tracked in the industry, as identified in the appropriate subsections of section 3.2. As with all input enhancements, evaluate the incremental value proposition of additional parameters relative to the implementation costs by way of financial value for money analysis.

5. Consider integration socio-economic factors, including costs to the customer (customer interruption costs), as well as environmental and safety-related monetary cost factors, such that the full range of economic costs (including those that go beyond those incurred by a utility or its customers) can be utilized as part of this evaluation procedure.

6. Consider supplementing the obsolescence-based intervention assessments for Protection, Control, and Telecom assets by formally incorporating the results of manual SME activities that already occur in a less formalized manner.

RRM capability:

7. Prior to investing any incremental resources into potential refinements, we encourage Hydro One's management to fully articulate a vision of the tool's ultimate place within its asset management and capital planning hierarchy, including whether such a tool is ultimately needed in light of all other capabilities.

Subject to the outcome of deliberations suggested in the above recommendation, consider further enhancements to reliability forecasting through an RRM, or an alternative solution.

8. Enhance reliability forecasting to assess reliability performance of the transmission system through a variety of reliability indices, rather than rely on the reliability risk modelling.

9. Integrate the enhanced reliability forecasting solution into the overall asset management process to provide the asset managers with a more robust set of reliability outcome predictions based on a variety of investment scenarios under consideration.

10. Include additional asset classes into the reliability forecasting approach (e.g. tower structures, insulators, switches) and sub-classes to improve the precision level of equipment related risk forecasting.

11. Develop a capability to provide reliability risk prediction on a sub-system level, such as system regions or large customer groups.

12. Expand the overall approach to reliability / reliability risk forecasting to factor in non-equipment related outages (e.g. weather events, adverse environment, human related errors, foreign interference, etc.) to forecast the reliability risks of the transmission system as a whole.

13. Assess the reliability impact of the non-renewal projects in the enhanced reliability forecasting solution. If the utility does not have any such projects in the investment plan, than the benefits of this recommendation are not expected to outweigh the costs of developing this capability.

14. Extend the reliability forecasting horizon to at least ten years to capture a greater extent of the long-lasting renewal and non-renewal projects within the investment scenarios on the system reliability.

15. Enhance the algorithms utilized to calculate the age demographic profile for each asset class, by revisiting the priority of asset replacements and considering both reactive and inspection-determined failure modes of assets reaching their ends of lives.

16. Revise asset class weights or the algorithms that calculate the reliability risk of three key asset classes per each investment scenario to incorporate more asset-specific failure considerations.

17. Utilize a variety of econometric techniques to establish mathematical relationships between the non-asset and asset-related failure instances or modes, and factors that precipitate them.

METSCO trusts that these recommendations will provide Hydro One's management with a number of strategic options to consider in the coming planning cycles.

Assessing Hydro One's Investment Planning Process
Final Report
March 13, 2018

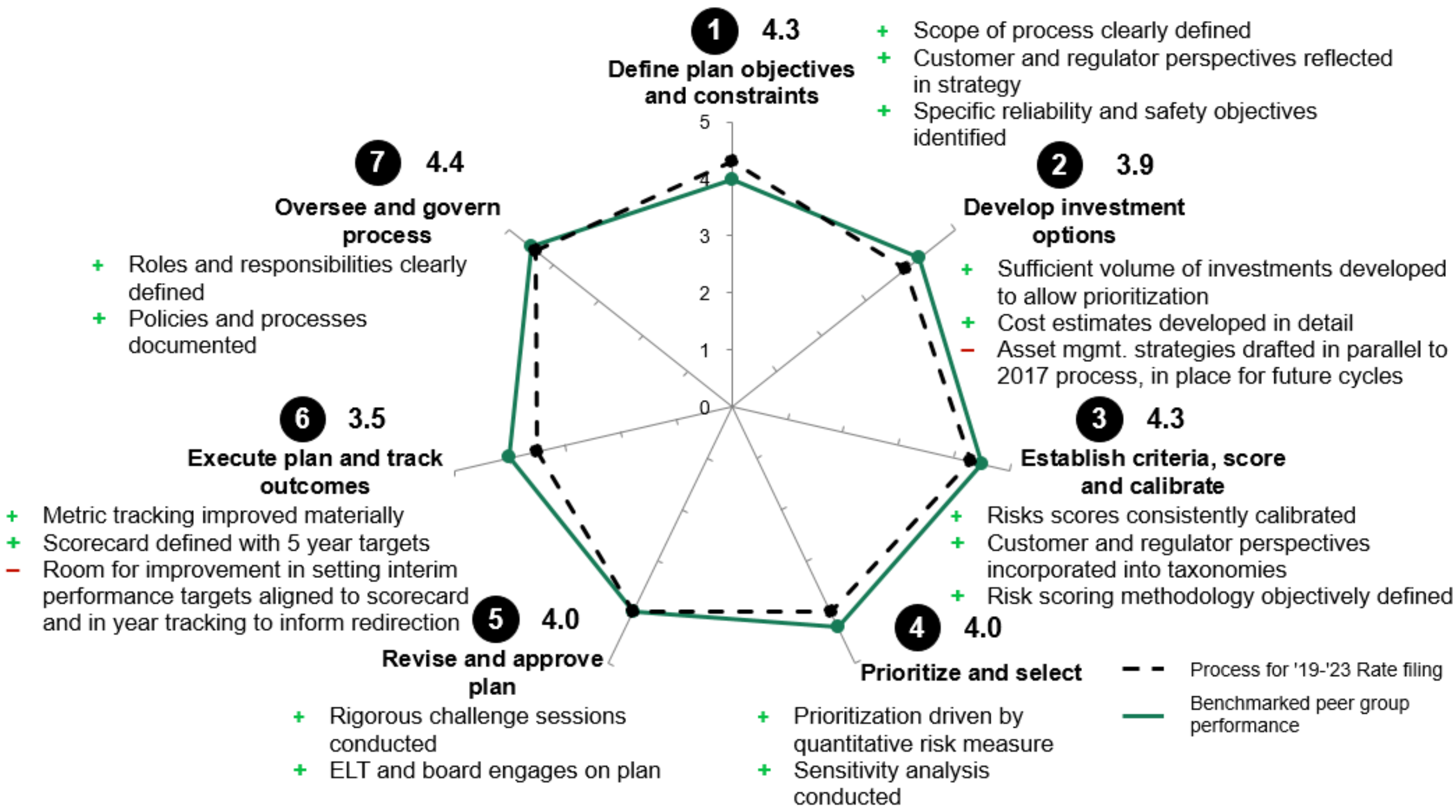
I. Executive Summary

Since its initial public offering in late 2015, Hydro One has undergone significant organizational change as it transitions towards being a more commercially oriented utility. As part of this effort, Hydro One has taken steps to address gaps in its planning process that have been identified both internally and by the Ontario Energy Board (OEB) in its previous Transmission decisions. In its last decision, the OEB ordered that Hydro One conduct a third party review of its investment planning and condition assessment processes. This report aims to address the OEB's request for a review of the investment planning process. In it, we (the Boston Consulting Group) provide our assessment of recent efforts to improve the planning process at Hydro One, and the resulting process undertaken in 2017 in support of Hydro One's 2019-2023 Transmission Rate Application (subsequently referred to as the "2017 Process" or "2017 Plan").

To conduct this assessment, we outlined a set of capabilities typically required to execute an investment planning process competently. These were drawn from two sources – ISO 55000 asset management standards and industry best practices gathered through interviews with experts and through the Boston Consulting Group's (BCG) experience working with leading utilities globally. We developed a framework encompassing the key elements of an investment planning process, and developed scoring rubrics that codified capabilities and best practices across each element of the process. We defined a spectrum of performance on each capability on a scale from 1 to 5. We assessed Hydro One's 2017 process against this framework to understand how Hydro One compares with asset management standards and peer utility performance.

Overall, Hydro One has implemented a consistent, thorough planning process that meets or exceeds expectations for a typical utility planning process in all areas. Exhibit 1 below offers a comparison of Hydro One's performance on its 2017 planning process against our selected peer set.

Exhibit 1: Summary of overall maturity assessment of Hydro One's 2017 Planning Process



In our assessment, Hydro One's planning process demonstrates key strengths in several areas:

- Inclusion of customer input in the investment plan: Hydro One's incorporation of customer input throughout its planning process exceeds what we have observed in many peer utilities, partially due to the relatively high expectations of the OEB for gathering customer input when compared to other jurisdictions. Hydro One has incorporated customer perspectives in its plan objectives, in developing individual investments, in evaluating the risk profiles of investments and in considering the outcomes that its optimized portfolio of investments ultimately delivers.

- Risk scoring: Hydro One implemented a revised risk-scoring process that introduced greater objectivity and reduced complexity when compared to its prior process.
- Identifying mandatory investments: Hydro One's revised scoring process enabled clearer distinctions of mandatory vs. discretionary investments included in the investment plan.
- Enterprise engagement: Hydro One extended the timeframe for plan review and internal stakeholder engagement, leading to more thorough engagement with draft plans at all levels of the organization.
- Productivity: Hydro One undertook an effort to improve its tracking of outcomes and metrics, including productivity and cost metrics, enabling better tracking of its efforts to improve the efficiency with which Hydro One executes its plans.
- Governance: In introducing its revised process, Hydro One had an opportunity to improve governance by codifying many of the details around investment planning. This included, but was not limited to, roles and responsibilities, process steps and timing, and education materials.

In reviewing the planning process, we identified three key areas where Hydro One is continuing to make progress towards a level consistent with peer utilities. Hydro One communicated the details of the plans that have been put in place to continue to progress on these dimensions in future planning cycles:

1. Investment Development: Hydro One has made significant progress in ensuring its investment plans, and specifically its sustainment investments, are driven by an understanding of system and asset condition, but can continue to focus on developing potential investments using a rigorous, data-driven process. Hydro One aims to conduct condition testing on all end of life assets, and has processes in place to test critical stations and lines equipment. However, for some assets where a large share of the asset base is reaching end of life (e.g. conductors, insulators), Hydro One faces a backlog in condition

testing. As a result, testing data is not available for all end of life assets, consistent with circumstances faced by many utilities with aging asset bases.

Hydro One is working to address the backlog in condition data for these assets by enlisting third party support to complete condition testing on end of life assets; in developing the 2017 plan, they relied on existing data and experienced planner judgment to develop investment candidates.

2. Asset Strategies: Hydro One conducted a significant effort to update its asset strategies in parallel to its most recent planning cycle. Having updated asset strategies will strengthen Hydro One's asset management capabilities going forward. However, the parallel effort resulted in some asset strategies not yet being in place for the onset of 2017 planning process. Teams were able to leverage legacy asset strategies as they developed the 2017 plan, and the investments included in the plan align with the finalized asset strategies. As a result, the parallel nature of the asset strategy effort had limited impact on the quality of the plan.
3. Outcomes Tracking: In 2017, Hydro One was able to translate the results of its investment plan into expected customer outcomes with greater specificity than it had in previous years, leading to 5 year targets for key scorecard metrics. As Hydro One tracks actual performance against its forecasted outcomes, there is an opportunity to refine the accuracy of its forecasting methodology for future years; this will help Hydro One more accurately predict the outcomes provided by its investment portfolio. We would also recommend Hydro One leverage the same methodology to forecast 1 year outcomes for its scorecard metrics, in addition to the 5 year forecasts already in place.

We believe that Hydro One's performance in executing its planning process is consistent with what we have observed in the selected peer set of leading utilities. While we have identified a few areas where Hydro One has demonstrated more limited maturity than leading utility peers, in our view, their performance on these dimensions has not materially impacted the quality of the plan. As Hydro One continues to focus on improving the planning process, investment plans will be expected to continue to increase in quality.

As Hydro One considers how to continue to progress towards having a best in class planning process, we would recommend they focus on the following actions:

- Investment Development:
  - Continue to clear the backlog in condition testing for critical assets, and ensure that steady state plans allow for ongoing condition data gathering as assets age.
- Asset Strategies:
  - Continue to ensure asset strategies are in place to guide investment development and updated to ensure relevancy.
- Outcomes Tracking:
  - Continue the implementation of plans to use performance data to enhance outcome forecasting capabilities.
  - Set interim annual targets for scorecard metrics to facilitate tracking towards five year goals outlined in Hydro One's regulatory scorecard.

II. Background and context for this report

The 2019-2023 Transmission rate application will be Hydro One's third major application in the three years since it became a public company. This application follows Hydro One's previous 2-year Transmission cost of service filing (EB-2016-0160), submitted in 2016 and decided by the OEB in September 2017, and its 5-year Distribution rate application (EB-2017-0049), which is currently under review by the OEB. In parallel to these filings, Hydro One has also been undergoing significant organizational change as it transitions from provincial to public ownership, which has included significant changes in personnel and processes, including revisions to the investment planning process.

In its last transmission decision, the OEB found several areas of concern with Hydro One's Transmission System Plan (TSP) and how Hydro One conducted its capital investment planning process, notably the timing of development of various inputs, the consistency of condition data collection, and the use of data to inform the levels and mix of spending in the investment plan. As a result of these concerns, the OEB required that Hydro One submit an independent, third-party review of the asset condition assessment and capital investment planning processes. Hydro One chose to respond to this request with two separate reviews: an asset condition assessment process review, conducted by a different third-party reviewer, and a capital investment planning review, which we include in this report. Our aim is to provide the OEB with an objective assessment of Hydro One's current planning process, including changes to the process since the last filing, in order to satisfy the OEB requirement and facilitate its evaluation of the TSP included in Hydro One's 2019-2023 Transmission application.

Our firm (BCG) has extensive credentials in process management, capital planning, and the utility industry that enable us to conduct this assessment. BCG is a leading global consulting firm with over 14,000 employees and 90 offices in 50 countries. More than 10% of the firm's leadership is dedicated to serving energy clients, and the energy practice is supported by a knowledge team of 35 analysts who conduct projects for clients and contribute the firm's thought leadership on energy topics. We have completed more than 2,500 energy projects in the past five years, and have worked with 15 of the 25 largest global utilities.[1] The team conducting this review consisted of senior leadership with extensive experience in utility operations, utility capital planning, and large capital project management globally and in Canada. The team also consisted of executing team members with significant experience in regulated utility operations and regulatory strategy in the US and Canada, including in Ontario. Additional detail on BCG's credentials is included in the appendix.

III. Overview of approach and process

Our approach to this review was to develop a comprehensive set of capital planning best practices, and assess Hydro One's relative performance compared to "best in class" processes and

[1] Largest utilities as defined by 2016 Platts Global Energy Corporations

industry standards. We leveraged two main sources to develop a comprehensive list of standards and best practices:

- ISO 55000 Asset Management Standards: ISO 55000 standards are industry-agnostic standards set forth by the International Standards Organization that outline required capabilities for competent asset management processes. Investment planning represents a key component of overall asset management as defined by the ISO, and thus many of the standards apply to this subset of the overall process.
- Industry Best Practices: We have observed additional best practices that define best-in-class capital planning processes and form the second component of this assessment. Reviewing industry best practices helped us identify capabilities not explicitly outlined by the ISO but required for a strong planning process.

To develop this assessment, we leveraged BCG experts' thousands of hours working in the utility industry; we supplemented our experience with information collected from interviews with experts on utility planning practices and asset management, conducted over 6 weeks while preparing this report. In Exhibit 2, we include a list of specific utilities whose planning processes we studied to develop our benchmarks and best practices (additional detail on the utilities reviewed is included in the appendix):

Exhibit 2: Utility planning processes reviewed in developing benchmarks:

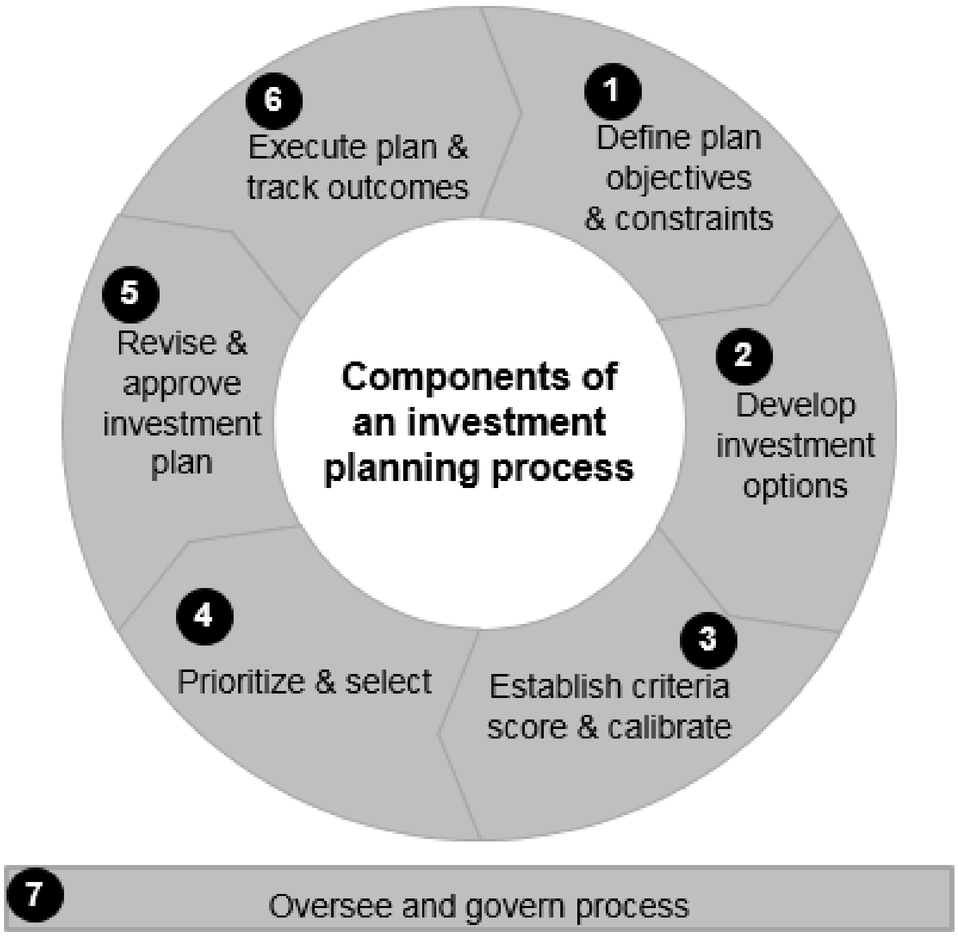
Utilities reviewed in benchmarking	
Hydro Quebec	National Grid
Berkshire Hathaway Energy	Enbridge Gas Distribution Inc.
Pacific Gas and Electric Company	BC Hydro
LS Power	Exelon
Iberdrola USA	Xcel Energy
Southern California Edison	Southern Carolina Electric and Gas
Consolidated Edison	Hanergy
Additional expertise consulted to guide assessment	
ISO-55000 implementation expert	Former Ontario Energy Board panel member

We selected a peer set that in our experience represents above average performers in utility planning, as we were seeking to understand planning processes that would help us define the characteristics of a "best in class" utility.

We recognize that the planning process for any utility is influenced by its regulatory environment and regulators' expectations, and that some elements of Hydro One's planning process are influenced by the OEB's expectations. However, we are not experts on Ontario regulation, and so have not evaluated Hydro One on any capabilities that would be explicitly required by the OEB. Rather, we have leveraged our broad-based expertise on utility capital planning across North American utilities to assess Hydro One's planning process against other utilities and against industry and jurisdiction agnostic ISO standards. In areas where parts of Hydro One's process are shaped by the OEB's requirements, we have noted the difference from peer performance, but have not assessed Hydro One's ability to meet those requirements.

We began our evaluation by developing an assessment framework. We identified 7 key elements of the planning process and defined the detailed capabilities required for a company to successfully carry out its planning process.

Exhibit 3: Components of an investment planning process



The elements are defined as follows, with the some of the key capabilities required for each element listed below and additional detail in the exhibits accompanying our evaluation:

1. Define plan objectives and constraints:
    - Incorporate corporate and operations strategy into the investment plan
    - Incorporate customer and regulatory perspectives into plan development
    - Define financial envelopes and other key constraints for the planning process

2. Develop investment options:
    - Develop candidate investments informed by condition data
    - Develop alternatives to preferred investments

3. Establish criteria, score and calibrate:
    - Identify potential risks mitigated by candidate investments

- Calibrate risks to ensure consistent application across investment types

4. Prioritize and select:
    - Use defined criteria to prioritize the universe of investments
    - Narrow the universe of investment opportunities into an initial investment plan
    - Analyze different options to arrive at a prioritized plan for review

5. Revise and approve plan:
    - Evaluate the draft plan emerging from the prioritization process
    - Pressure test proposed investments and conduct sensitivity analysis
    - Engage senior leadership to approve plan

6. Execute plan and track outcomes
    - Track execution of the plan and performance of investments using defined metrics
    - Leverage performance data to improve the planning process and future plans

7. Oversee and govern process:
    - Organize the investment planning process and dedicate resources to its execution
    - Outline roles, responsibilities, and accountability related to the planning process
    - Create appropriate documentation for policies and processes

After outlining a framework for evaluation, we developed “rubrics” that defined the characteristics of a spectrum of maturity for each capability on a scale from 1 to 5. A score of 1 on a rubric is defined as poor performance on the capability. Scores of 1 would be expected in very poorly performing organizations with weak or non-existent planning processes and governance. A score of 3 is consistent with an average or typical utility approach on a given capability. A score of 3 indicates that performance meets expectations on a given capability, and a utility scoring 3s on each step would not have any major deficiencies that would prevent it from developing an appropriate investment plan. A 5 is defined as truly excellent or innovative performance on the capability. We would expect few organizations to score 5s across all capabilities given the volume of capabilities required to execute a planning process and the complexity involved.

In evaluating Hydro One, we included an asterisk next to some scores. The capabilities scored with an asterisk fell into two categories:

- Capabilities where specific circumstances have impacted Hydro One's planning process in 2017 that are not expected to persist (e.g. process steps compressed due to the pace of recent rate filings).
- Capabilities where Hydro One has a documented plan in place to continue to improve on the capability in question, and where we would expect an upward trajectory to the score in the future.

We included the asterisk to acknowledge that Hydro One's planning process continues to evolve, while recognizing that we are primarily evaluating the plan developed in 2017 to support Hydro One's 2019-2023 Transmission rate filing.

To assess the planning process, we gathered information about Hydro One's practices through its regulatory filings, interviews and internal document reviews. We conducted multiple rounds of interviews with members of Hydro One's planning team to understand the details of the planning process and to understand how key elements described in documents were carried out in practice. We also reviewed documents shared by Hydro One that provided additional detail on how the investment planning process was conducted and how it has recently changed. We attempted, wherever possible, to obtain objective or quantitative support for assertions with significant potential for subjectivity.

Finally, we highlighted the areas where Hydro One is expected to continue to mature and provided recommendations for how Hydro One can further its progress towards best in class planning.

IV. Assessment of Hydro One's planning process for the 2019-2023 Transmission System Plan

Overall, Hydro One has significantly improved its capabilities in investment planning since its last Transmission filing. Hydro One's performance is in line with what we see from typical peer utility planning processes on all capabilities, and performs at a level consistent with what we have observed at leading utilities in a number of areas.

For those areas where Hydro One's process remains less mature than best in class peers, Hydro One has acknowledged these gaps; has plans in place to improve upon these capabilities; and shared the details of those plans as we were evaluating the process. These plans include continuing to strengthen its data coverage for key assets, ensuring asset strategies are updated, relevant and in place ahead of future planning cycles, and continuing to refine how Hydro One estimates and tracks the outcomes that the investment plan delivers.

We have summarized our assessment of Hydro One's performance relative to our selected leading peer set in Exhibit 1, referenced in the executive summary.

The detailed results of our assessment for each element of the planning process are included in the following sections 1-7, aligned to the 7 process steps in Exhibit 2.

1. Assessment of Hydro One's capabilities in defining plan objectives and constraints:

The critical first step in a planning process is to define strategic objectives and identify initial budget constraints to guide the subsequent development of the plan. This includes several activities:

- Translating corporate strategic objectives into investment planning objectives
- Ensuring customer, regulatory, and stakeholder perspectives are included in defining objectives
- Identifying financial envelope constraints based on strategic, financial and rate impact considerations

Below we outline the spectrum of maturity that we have observed across this capability. In exceptional planning processes that would score a 5, planning is guided by a comprehensive corporate strategy that is informed by customer and regulatory perspectives. The corporate strategy is translated into outcomes that a plan is expected to achieve. Capital and OM&A budgets are subsequently defined strategically, based on operational, financial, regulatory and customer considerations. Finally, capital and OM&A budgets are set to define the level of funding the company believes is necessary to meet its objectives, and the scope of the process and the budgets included are clarified to all stakeholders in the organization.

In a typical utility process, we would expect to see a high-level definition of corporate strategy and objectives that may be less specific than those defined in a truly “best in class” process. We would expect an incorporation of regulatory and customer perspectives, but perhaps not well documented or primarily focused on minimum regulatory compliance and customer satisfaction. A typical planning process includes clear definitions of budgets to guide subsequent planning, but the budgets may not incorporate benchmarking or strategic input to help substantiate spending levels.

In a poorly executed planning process, we would expect a loosely defined scope and budget that leaves high potential for “rogue” spending outside of the plan. We would also expect limited strategic input into the plan and weak alignment to regulatory and customer expectations.

We have defined the specific capabilities related to this process step and the spectrum of maturity for each in Exhibit 4 below.

1

Exhibit 4: Rubric: Define investment plan objectives and constraints

Budget definition and strategic input

Process by which a company:
- Incorporates corporate and operations strategy into investment plan
- Incorporates customer and regulatory perspectives into plan development
- Defines financial envelopes and other key constraints for planning process

Capability	Characteristics of "1"	Characteristics of "3"	Characteristics of "5"	Benchmark for "5"
Scope of investment planning process defined & articulated	• No clear scope for LOBs and types of spend included in IPP • Substantial rogue spend	• Scope understood; not fully codified • Some codification but confusion over scope; some "rogue" spend	• Scope of IPP and budgets involved widely understood	• ISO
Organizational strategy and objectives defined to guide plan	• No clear objectives or outcomes defined • No defined corporate strategy to inform investments	• Objectives and outcomes defined at high level to guide plan	• Strategy translates to quantified, outcome-driven objectives • Objectives clearly communicated ahead of IPP	• ISO
Strategy and objectives shaped by company, regulatory and customer perspectives	• Objectives reflect internal company perspectives only	• Some inclusion of customer and regulatory perspectives • Primarily focused on customer satisfaction and minimum compliance	• Robust incorporation of all key stakeholder perspectives, including desired customer outcomes, in strategy and objectives	• Industry best practice (IBP)
Budget and other constraints identified & communicated	• Corp. boundary constraints not communicated by leadership	• Timely communication of boundary conditions • Rough financial guidelines shared	• Early, clear communication of strategically-defined constraints	• IBP

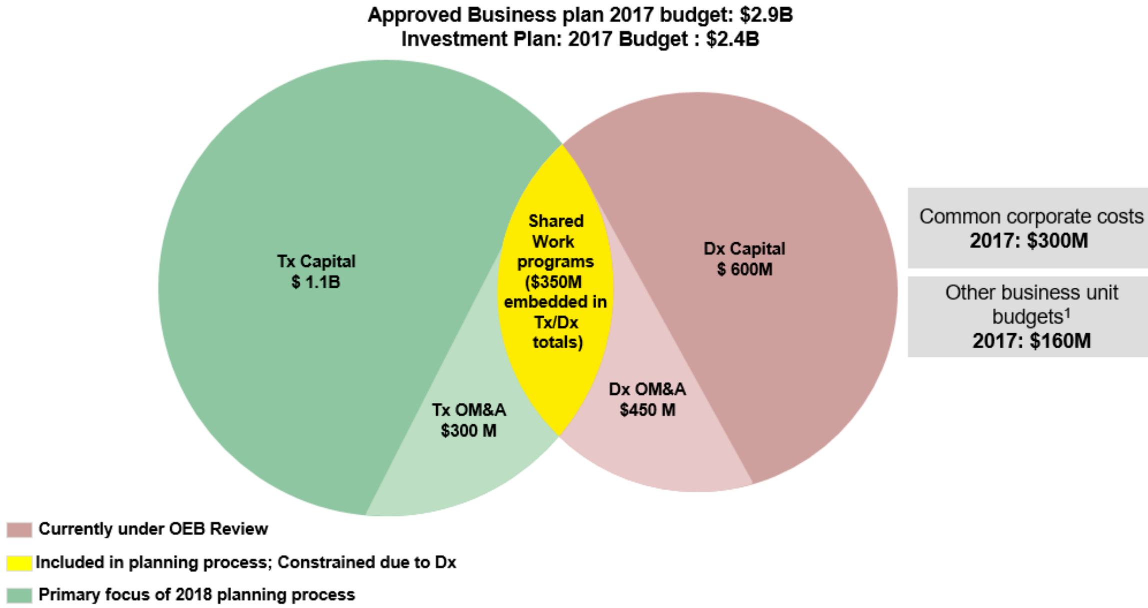
Hydro One's performance on this capability significantly exceeds what we would expect from a typical utility planning process. As a result, we scored Hydro One as a 4.3/5 on this dimension overall. In the areas where Hydro One can continue to progress towards best in class performance, Hydro One has improvement plans in place, and thus we would expect to see continued improvement in the future. Details of our assessment of Hydro One's performance on specific capabilities within this step are included in Exhibit 5.

❶ Exhibit 5: Maturity Assessment: Define investment plan objectives and constraints

Capability	1 – 3 – 5	Comments on score
Scope of investment planning process defined & articulated	4*	• Scope of process defined for operating groups and communicated • Acknowledged some minor potential for "gray areas" in common vs. work program spend • Addressing with additional education
Organizational strategy and objectives defined to guide plan	4	• Objectives defined at high level in corp. priorities • More specific objectives and outcomes communicated in corporate and operations strategy documents
Strategy and objectives shaped by company, regulatory and customer perspectives	5	• Strategy and objectives documents reflect internal company perspectives along with desired customer and regulatory outcomes • Exceed level of stakeholder input included in most utility planning objectives
Budget and other constraints identified & communicated	4*	• Budget defined in 2017 based on historical levels consistent with as-filed plan, where increases in capital were defined more strategically; filing cadence not expected to persist, enabling future budget discussions to be defined more strategically • Budget lines were widely communicated and initial budget shared with ELT and Tx filing SteerCo ahead of plan formulation

A key foundation for a planning process is defining a clear scope for the types of spending that are relevant to the plan. In 2017, Hydro One outlined clear definitions around the lines of business and types of project and program spending that are included in the investment planning process. At the same time, Hydro One notified relevant stakeholders of the timing of the process and their roles and responsibilities with respect to investment planning. One of the ways Hydro One described the scope of the 2017 process to stakeholders is included as Exhibit 6. This exhibit lays out the scope of the 2017 planning process in the context of Hydro One's overall budget, and the ongoing litigation for Hydro One's Distribution application.

Exhibit 6: Definition of Scope for 2017 Planning Process



1. Include B2M, GLP, Additional LDCs and telecom.
Source: 2017 Tx and Dx Business plans; Consolidated business plan. Totals are rounded

Hydro One also has more specific definitions for key categories of spending in the investment plan that help to clarify the scope. Hydro One has clear guidelines for program vs. project spending that are used to define differences between the two. Hydro One also has a well-defined formula for allocating overhead costs to different categories within the investment plan. Hydro One has acknowledged that there remains some room for improvement in fully articulating the scope of the plan, particularly for new types of spending that may straddle two categories, such as customer work program vs. customer common cost budgets. This gray area exists for relatively narrow categories of spending, and does not undermine performance on this capability. Hydro One plans to continue to use annual planning kick-off sessions to educate participants on the scope of the plan to mitigate the potential for gray areas to emerge.

A second key capability in defining objectives and constraints is outlining strategic objectives. Hydro One was guided by several strategy documents as it began the 2017 planning process.

Initially, Hydro One's CEO shared a list of 2017 Corporate Priorities in March 2017. This document, shared below as Exhibit 7, included high-level priorities for the year.

Exhibit 7: Hydro One 2017 Corporate Priorities

Priority	**Description**
Health and Safety	Safety is our number one priority, and as such, we will continue on our path to achieve world-class health and safety performance by creating an injury free workplace and maintaining public safety
Customer	We will put our customers first by listening and responding to their needs, advocating on their behalf, and focusing the organization on pursuing activities that have both meaning and impact
Work Programs	We will pursue continuous innovation in our work programs through building and maintaining reliable and affordable power supply as well as transmission and distribution systems
Net Income	We will maximize net earnings and increase shareholder value without compromising work program delivery through shared commitment to reduce costs and complete work more efficiently
Productivity	We will successfully implement initiatives across the organization which will improve productivity and generate significant cost savings
People	Our primary strength is the capability of our people. We will continue to build a culture of accountability and trust and are committed to delivering programs that enable greater engagement of all employees

In April 2017, Hydro One's board approved a set of strategic objectives that added additional detail to some of Hydro One's initial corporate priorities and introduced several new strategic objectives for the organization for the next five years. A summary of Hydro One's strategic objectives is included in Exhibit 8.

Exhibit 8: Strategic Objectives

Strategic pillar	Associated objectives
Optimize the core	• Achieve and maintain world-class safety performance • Maintain top tier/quartile transmission reliability performance • Achieve a step change improvement in distribution reliability • Engage in being recognized as a top employer • Be a leading employer for diversity and inclusion • Establish trusted partnerships with First Nations and Métis • Lead the consolidation of Ontario LDCs • Establish a trusted brand with strong customer loyalty • Proactively influence energy policy and regulation to appropriately incentivize modernization of the electricity system
Bring Innovation to the core	• Become known as a leading innovation company • Build and employ culture of change and innovation
Diversify via commercial business	• Lead the market in the commercial businesses we enter
Build scale through acquisition	• Pursue and close acquisitions that align with our strategy and are accretive to our earnings

Hydro One's corporate strategy added specific objectives to Hydro One's previously-defined priorities, and was subsequently translated into priorities and objectives for Hydro One's operating divisions. In May of 2017, Hydro One's Operations group, which encompasses its Transmission and Distribution operations, defined its objectives and goals for 2020. These objectives reflected the overall corporate strategy and identified targets for qualitative and quantitative outcomes, and are included in Exhibit 9. The combination of these documents provided a robust set of objectives for the organization as it developed the investment plan.

Exhibit 9: Operations 2020 goals

Vision	Metric	2016 levels	2020 Goal
Be an industry leader in **Safety & Environment** for our employees contractors, and the public	Recordable incidents per 200k hrs- Ops	1.2 (82 incidents)	**20% improvement vs. 2016** 0.95 (65 incidents)
	High MRPHs per 200k hrs- Ops	0.35 (24 incidents)	**20% improvement vs. 2016** 0.27 (19 incidents)
	Preventable MVAs per 200k hrs- Ops	1.7 (117 incidents)	**15% improvement vs. 2016** 1.4 (99 incidents)
Deliver improved **Reliability** to our customers, incorporating their input and priorities	Tx SAIDI-mc Duration (minutes)	3.9 (5 yr avg: 9.5)	**Maintain top quartile/tier performance** through continuous improvement, with a focus on the largest outage contributors today
	Tx SAIDI-mc Frequency (#interruptions)	0.25 (5 yr avg: 0.24)	
	Dx SAIDI Duration (minutes)	7.8 (5 yr avg: 7.3)	Achieve a **step change improvement** within our existing resource envelope by changing the way we plan and execute work across the province
	Dx SAIFI Frequency (#interruptions)	2.50 (5 yr avg: 2.6)	
Provide **Cost effective** service to our customers by improving our productivity	Tx Ops O&M	$7700/km[1]	**Productivity improvement in everything we do,** with resources allocated to areas that benefits our customers most
	Dx Ops O&M	$2600/km[1]	
Always be there for our **Customers** with a seamless experience in all operations interactions	Tx customer commitments mets (%)	85%[2]	**15%. Improvement vs. 2017 level** 98%
	New residential/small business customers connected on time (%)	98.6%	**Continuous improvement** 99.0%
	Scheduled appointment met on time (%)	99.5%	**Continuous improvement** 99.7%

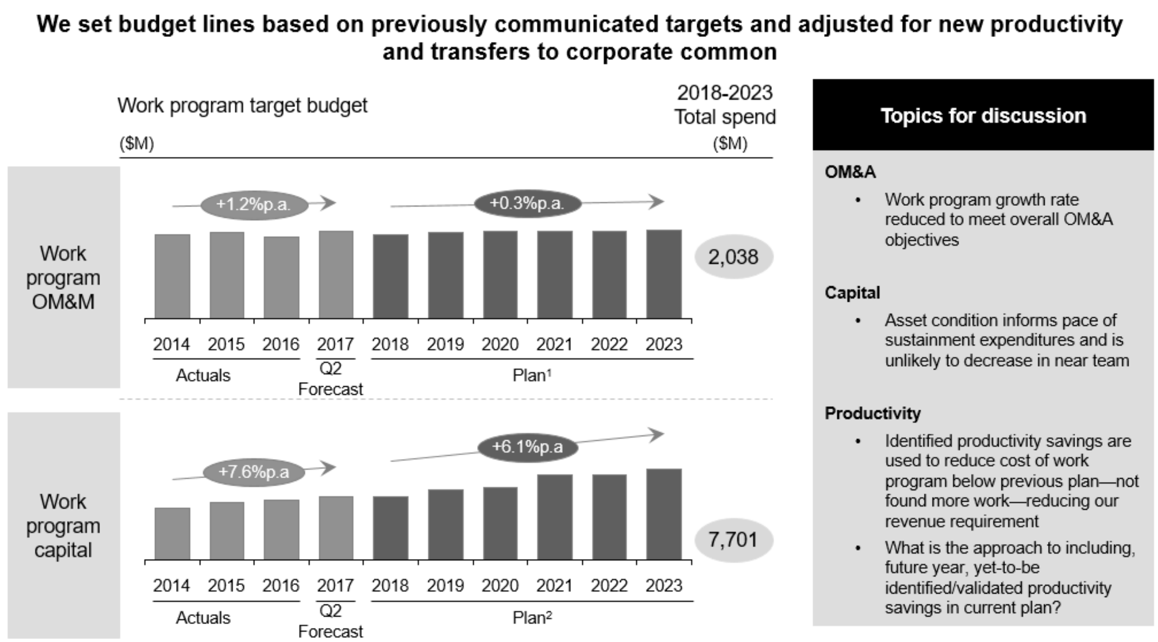
Note: (1) 2015 results: (2) Metric established in established in Q2 2017 – 85% is the 2017 goal based on estimated current performance privileged and confidential- internal use only

In some utility planning processes we have observed, strategic objectives at this stage in the process would be translated into performance goals for the planning period, measured by metrics. These metric targets would be used to guide budget development, investment option development, and subsequent prioritization. However, other utilities take a risk-based approach to planning, and then translate the risk mitigation potential of the prioritized plan into expected plan outcomes, such as reliability, safety or productivity improvement. Both approaches are valid, and each has been deployed successfully in different utilities. Hydro One's planning approach is heavily focused on risk mitigation, which helps guide how the team evaluates different investment options, ranks them in terms of priority, and assesses different marginal investment options when reviewing the plan. In this approach, performance targets are calculated based on expected results of a prioritized plan and shared as 5 year targets in Hydro One's scorecard, but are not explicitly articulated as part of the initial development of strategic inputs.

Another best practice on this dimension is to include stakeholder perspectives in defining plan objectives. This includes regulator and customer perspectives, along with other key considerations such as relevant public policies and Indigenous concerns. Given that the expectations around the consideration of stakeholder, and specifically customer perspectives, in planning in Ontario are higher than in many other jurisdictions, Hydro One's performance on this capability exceeds that of many other utilities. In other utilities we have observed, consideration of customer and regulatory perspectives is often limited to customer satisfaction and rate impact considerations in developing strategic objectives, whereas Hydro One conducted a detailed customer engagement process focused on understanding the outcomes valued by customers and providing them with scenarios to evaluate that helped inform the overall investment plan. We are not in a position to opine on whether Hydro One met the OEB's expectations for its customer engagement, but the existence of the customer engagement process puts Hydro One ahead of many utilities in its incorporation of Transmission customer perspectives into its plan. Hydro One's objectives also reflect key regulatory and public policy considerations through their reference to public safety, environmental policy, and engagement with Indigenous communities.

In addition to defining strategic objectives, another key component at the onset of a planning process involves defining relevant budget constraints for the plan. Hydro One defined and communicated an initial Transmission capital and OM&A budget at the beginning of its planning process in May of 2017. Hydro One relied on the capital levels it had previously filed with the OEB in its 2017-2018 filing and extended the trajectory of the capital plan included in that filing by 2 years to 2023. Hydro One defined its work program OM&A budget by relying on previously filed levels and adjusting for increased productivity initiatives that had been identified since its last filing. The budgets were included in initial updates to the planning teams and Hydro One's leadership; an example of content from the budget-definition discussion is included as Exhibit 10.

Exhibit 10: Summary of Budget-Setting Discussion



1. Plan over reduced by ~$6M/year transfer to corporate common and ~$1M/year in newly identified productivity savings from baseline based 2018-2022 based on previous business plan. 2023 assumed to grow at 2018-2022 CAGR 2. Plan over reduced by ~$10M/year transfer to corporate common and ~$18-25M/year in newly identified productivity savings from baseline based 2018-2022 based on previous business plan. 2023 assumed to grow at 2018-2022 CAGR

Hydro One has explained that they relied on their previously filed plan to define the capital and OM&A budgets to remain consistent with the plan under OEB review in the 2017-2018 filing until September 2017. Hydro One then revised the budget for 2019-2023 after receiving the OEB's decision. The initial five year plan was informed by Hydro One's legacy strategic objectives, its assessments of system needs and its view of the capital and OM&A levels required in order to maintain Transmission system reliability. Hydro One's 2019-2023 budget reflects many of the same objectives and continues a trajectory of capital and OM&A spending similar to its filed plan.

While relying on historical levels is not fully in line with best-in-class utility planning, where budgets are defined strategically based on financial, customer and operational concerns, we recognize that Hydro One's 2017 budget setting process was defined by uncertainty around the results of its last filing, and that these circumstances are not expected to continue in future years as Hydro One transitions to longer filing terms. In addition, we recognize that Hydro One did not rigidly adhere to its historical levels; rather there was sufficient time and flexibility in the planning period to change the budget as new information emerged.

2. Assessment of Hydro One's capabilities in developing investment plan options:

After identifying a budget and other constraints, the next step in the planning process is to develop investment options for potential inclusion in the plan. This step includes several key activities:

- Leveraging asset data to develop a set of preferred investment candidates aligned to specific asset strategies
- Using cost and benchmarking data to form estimates of project cost
- Enabling choice through the development of reasonable alternatives to the preferred investment candidates

We have observed a broad spectrum of maturity in the capabilities relevant to this step of the planning process. Best-in-class planning processes are distinguished by their development of rigorous asset strategies that guide investments, and incorporation of a data-driven methodology for investment development. While most utilities strive to have condition data that is as comprehensive as possible, many utilities we consulted face challenges with data collection given the age of their Transmission assets. As a result, few utilities reach 100% condition data collection on major assets. The best utilities, however, have fewer gaps vs. peers, which they mitigate with sound planner judgment when data is unavailable. Leaders in this capability also stand out for having thorough, accurate project cost estimates. Cost estimates, informed by internal and external benchmarking, should be more detailed for the initial 24 months of the plan. Finally, best-in-class planning processes deliver sufficient volume of investment candidates to enable rigorous prioritization.

Processes that are consistent with average performance tend to have many of the same features, but may be less comprehensive than best-in-class practices in terms of data availability or thoroughness of analysis. We would expect these processes to employ asset condition and demographic data to develop investment options through a formalized approach, but testing data may be less comprehensive, or their assessment of opportunities to aggregate work may be less quantitatively rigorous. Their project cost estimations may be detailed for only the first 12 months of the plan, or they may be informed only by internal data sources, with no external benchmarking conducted.

Poor processes are marked by simplistic or non-existent asset strategies, including a reliance on asset age as the primary data point for repair or replacement, a lack of a systematic approach to evaluating alternatives or batching work, and incomplete or low quality cost data and project estimates, even for the initial years of the plan.

We have defined the specific capabilities related to this process step and the spectrum of maturity for each in the scoring rubric for "Develop Investment Plan Options," included as Exhibit 11.

2

Exhibit 11: Rubric: Develop investment plan options (I/II)

Development of investment inputs

Process by which a company:
- Develops candidate investments informed by condition data
- Develops alternatives to preferred investments

Capability	Characteristics of "1"	Characteristics of "3"	Characteristics of "5"	Benchmark for "5"
Asset management strategies (outlining guidelines for key asset replacement/repair) defined, communicated, complied with	• No documented asset management strategies	• Asset management strategy documented, but not regularly updated/readily available for use • Asset management strategies define EOL in terms of time, not usage • Asset condition dashboards are generally populated with data collected from inspections of assets, but may be stale • Proposed investments largely aligned to strategies, with some "grey areas"	• Asset management strategy is documented, regularly updated, and easily accessible • Asset management strategies define EOL in terms of usage/condition • Asset condition dashboards are populated with real-time condition data • Clear link between AM strategy and proposed or executed investments	• IBP • ISO
Investment candidate development driven by data inputs, including condition	• Data, (e.g. condition, loading) not used in meaningful way to determine investment candidates	• Data used to identify need for some investment candidates, but process not standardized and qualitative drivers relied upon	• Standardized process in which condition data is used to identify substantially all investment candidates	• IBP
Project costs informed by unit-based data	• No unit-based measures used	• Unit-based measures calculated only for highly standardized tasks (i.e. those completed >100x/year) • Estimates based on internal data only	• Unit-based measures calculated for all repeated activities (i.e. those completed > 20x/year) • Estimates based on internal data and external benchmarking	• IBP

2

Exhibit 11: Rubric: Develop investment plan options (II/II)

Development of investment inputs

Process by which a company:
- Develops candidate investments informed by condition data
- Develops alternatives to preferred investments

Capability	Characteristics of "1"	Characteristics of "3"	Characteristics of "5"	Benchmark for "5"
Detailed estimates included for initial plan time frame	• High-level estimates included in plan for 5 years and insufficient detail for early years of spending	• Detailed estimates for initial 6-12 mos of work • High-level estimates included for remaining years of plan	• Detailed estimates for initial 18-24 mos.+ of work • High-level estimates included for remaining years of plan	• IBP
Universe of candidate investments sufficient to enable rigorous prioritization	• Incomplete universe of candidate investments • Candidate investment development influenced by premature views of prioritization/optimization results	• All candidate investments developed but unequal rigor in development guided by expected outcomes of prioritization (e.g. only develop estimates for high likelihood projects)	• All candidate investments developed, with differences in rigor based on investment size • Sum of all potential investments exceeds budget by at least 10%	• IBP
Alternatives to identified investments considered	• Investments developed as standalone candidates – no alternatives	• Alternatives (i.e., OM&A vs. capital, capital vs. capital alternatives) considered for major investment candidates	• Alternatives (i.e., OM&A vs. capital, capital vs. capital , conservation alternatives) considered for all major investment projects • Systematic approach to alternative development	• IBP
Operational benefits of batching work considered	• No consideration of how batching by location or asset type would impact overall cost or ability to complete work	• Benefits (e.g. savings, outage availability) of batching considered as part of planner evaluation, but not quantified	• Potential operational benefits of batching quantified and reflected in prioritization and selection • Only components with compelling value case (incl. economics, outage efficiency) for batching included in projects	• IBP

Hydro One's performance on this capability exceeds what we would expect from an average or typical utility planning process; we rate Hydro One at 3.9/5 overall on this capability. There are some key areas where Hydro One can continue to mature, notably continuing to develop investment options informed by data from condition testing and the asset analytics system, and ensuring relevant asset strategies are in place in time to guide future planning cycles. Details on Hydro One's performance on specific capabilities within this step are included in Exhibit 12.

2

Exhibit 12: Maturity Assessment: Develop investment plan options

Capability	Score (1 – 3 – 5)	Comments on score
Asset mgmt. strategies (outlining guidelines for key asset replacement/repair) defined, communicated, complied with	3*	• Strategies overhauled to increase rigor, but developed in parallel to IPP • Will be in place for future filings
Investment candidate development driven by data inputs, including condition	3*	• Condition data used to develop candidates • Backlog in data collection means data does not exist for all end-of-life assets, but working to address
Project costs informed by unit cost data	4	• Unit cost catalog used to inform estimates • Benchmarking for some capital programs (e.g. insulators) but not widespread
Detailed estimates included for initial plan time frame	4*	• Budgetary estimates for ~90% of plan for first year, ~80% of plan for 12-24 mos., • Efforts in place to increase estimation rigor
Universe of candidate investments sufficient to enable rigorous prioritization	5	• Sufficient volume of candidate investments to enable prioritization (Universe >10% vs. final budget) • Larger candidates developed in more detail
Alternatives to identified investments considered	4	• Viable alternatives considered for majority of investments where possible (i.e. stations) • Alternatives defined in general (i.e., repair vs. replace) and specific terms • Comparison of alternatives at times qualitative; when quant analysis is done focuses on differences in costs vs. outcomes
Operational efficiencies of batching work considered	4	• Rules outlined that govern batching decisions to introduce rigor into decisions and discourage pre-investment • Potential to add more quantitative rigor to support individual batching decisions

In the ISO 55000 asset management standards, asset strategies form a critical foundation for decision making around key utility assets. Hydro One has historically had asset management strategies in place to guide its planning process. Recently, Hydro One has undertaken an effort to strengthen its asset management strategies by updating them to reflect the latest operations strategy and most recent data, and harmonizing their format to ensure consistency across asset types.

The content of Hydro One's asset strategies is thorough and relevant to the planning process. They include information on the operational asset model (e.g., expected service life), fleet condition, historical investment levels, and capex and OM&A strategies (e.g. criteria for evaluating maintain vs. replace trade-offs). Hydro One's recent effort to update strategies represents progress towards the ISO standard and best practice of having updated, relevant, detailed asset strategies. However, not all of its updated strategies were in place to guide 2019-2023 plan as they were developed in parallel to the 2017 planning cycle. With its legacy asset strategies, Hydro One planners had access to strategy documents that helped guide the development of investment options. Given continuity in its asset strategies, the final plan largely aligned to the content of the revised asset strategies now in place.

Another key component of strong utility planning is grounding investment option development in data to ensure that the projects being developed address the most significant risks on the system. Condition and system data should also help inform the evaluation of investment alternatives before arriving at a preferred investment option.

Hydro One deploys a data-driven process for identifying potential investment projects, though detailed condition data is not yet fully available for all major assets. Hydro One collects data on age, condition (based on testing), demographics, historical maintenance costs and historical performance of assets on an ongoing basis, with information captured and shared in its asset analytics system. To assess condition, Hydro One has prioritized testing for assets reaching end of life (as defined in its asset strategies). Hydro One has acknowledged that there is a backlog in completing testing for all end of life assets due to the volume of aging transmission assets on its system. Hydro One is working to clear the backlog by enlisting additional third party resources to test certain key assets, such as conductors and insulators. We have observed that while best-in-class utility planning processes are generally informed by robust condition data that helps identify the assets requiring repair and replacement, few utilities reach 100% testing coverage on their assets given the age and geographical breadth of many transmission systems. As a result, Hydro One's performance is consistent with many typical utilities on this capability.

In developing projects, best practice is to evaluate among different types of potential options to ensure asset life cycle costs are optimized. Hydro One conducts this analysis as it is developing projects, with a focus on stations assets given the lack of maintenance or refurbishment alternatives for lines assets. Hydro One conducts a combination of qualitative and quantitative analysis to evaluate among different capital spending options and among capital and OM&A options. For transformers, NPV models are used to assess capital vs. OM&A tradeoffs, while for other types of stations assets, qualitative analysis is conducted to evaluate the risks and benefits of different capital and OM&A scenarios. Sample results of this type of analysis were provided by Hydro One, and are included below:

Exhibit 13: Sample Capital vs. OM&A Analysis for a Transformer Investment

Example 1: 500kV 750MVA Auto Transformer Repair Vs Replace.

This example demonstrates the economic assessment carried out to support a repair and delay capital replacement of a 500kV 750MVA auto transformer. This type of equipment is one of the most expensive power equipment assets within the Hydro One transmission system.

The transformer in question is a 40 year-old unit. A detailed condition assessment revealed it requires refurbishment to repair an oil leak and to mitigate a design deficiency advised by the original equipment manufacturer. These are necessary repairs to ensure safe and reliable operation of this asset. The cost for refurbishing this transformer was analyzed using the economics model described in Ex I-1-28. Details of such an analysis can be found in Ex. I-9-6, Attachment 6 - Strachan Transformer Assessment Report, Section 7- Economics.

Specific to this 500kV 750MVA auto transformer, the outcome of the economic assessment resulted in a net present value (NPV) cost of $17.2M for repair vs $18.9M for replacement. Therefore, a decision was made to proceed with repair.

Best-in-class evaluation of investment alternatives relies on quantitative analysis that enables planners to weigh risks and benefits of different options. Robust analysis focuses not only on cost but also incorporates the value of customer benefits and risks to ensure the optimal alternative is recommended for inclusion the plan. Analysis consistent with more typical utility performance on this capability focuses purely on cost to the utility to ensure the lower NPV option is selected.

Hydro One approaches investment option development by drawing on system and individual asset-level data. Planners develop potential investment projects based on an assessment of key data about assets and stations, such as system criticality, loading and outage availability. They also consider the condition of other assets at a given station where a high priority asset has been identified to develop projects, in line with Hydro One's station-centric approach. Subject matter experts focused on individual asset types (e.g. transformers, breakers, lines) help to validate projects by providing their detailed perspectives on asset condition and their understanding how aging or deteriorating assets could be addressed through different capital and OM&A alternatives. Planners incorporate this input to finalize the potential projects that will be subsequently risk scored and evaluated.

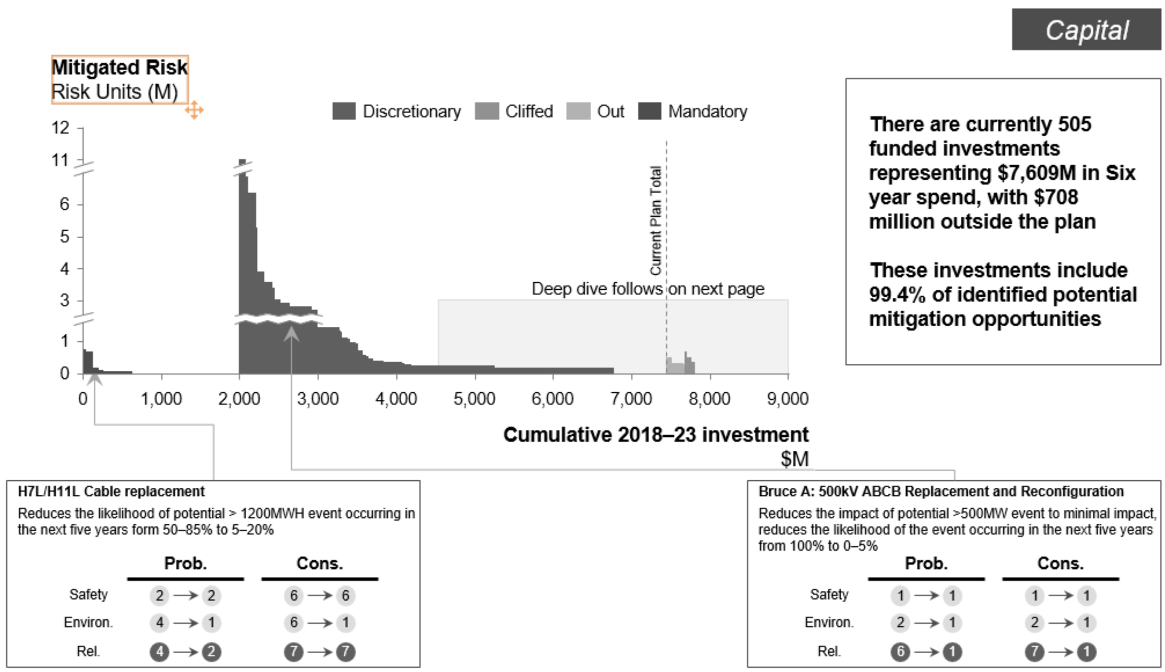
Hydro One approaches investment development by assessing system needs and analyzing asset-level data. Planners develop potential investment projects based primarily on their assessment of the condition of major power equipment (e.g. transformers, breakers), informed by data from Hydro One's asset analytics system. They also consider the condition of other assets within a given station where major equipment has been identified as needing to be replaced; this is consistent with Hydro One's integrated or station-centric planning approach. Subject matter experts focused on individual assets (e.g. transformers, breakers, lines) conduct detailed condition assessments to determine the extent of asset deterioration and conduct analysis to evaluate capital replacement or repair alternatives. This detailed input is incorporated into investment options to finalize the set of potential investments that will be subsequently risk scored and evaluated.

Hydro One's development of station projects is grounded in key guidelines that help to add rigor to its process. Hydro One planners assess whether other equipment at a station with a major asset replacement is reaching end of life within three years of planned work on the major asset. If there is, this work will be combined into a project to enable more efficient outage planning and work processes. Batching work in this way is in line with best practice for utilities given the relative difficulty of securing outages and the efficiency opportunities of dispatching crews to stations once vs. multiple times. While Hydro One's rules based approach introduces some rigor that prevents planners from "pre-investing" by requiring they consider end of life equipment only expected within 3 years of planned work, there are opportunities to further increase the level of rigor behind batching decisions by conducting quantitative analysis to ensure decisions to batch are economically efficient and support desired customer outcomes. An example of such analysis would be to compare the cost and customer impact of a batched project vs. its disaggregated parts to ensure the batching decision is correct.

Given that data input for project development comes from both subject matter experts and planners focused on developing overall projects, we would encourage continued focus on clear communication between members of the planning group, and documentation around how investments are developed to ensure investment projects are grounded in rigorous, data-driven analysis.

A key element in a rigorous planning process is ensuring that there are sufficient investments to prioritize. Less mature processes often involve developing just enough projects to fit a budget without enabling trade-offs and optimization. In best-in-class utilities, this generally means developing a universe of potential options whose value is at least 10% greater than the budget constraint. In 2017, Hydro One developed a universe of potential capital projects of $8.3 B in total spend against a final capital budget of $7.5 B, meaning the value of total investments developed exceeded the budget by more than 10%. This was in line with best practice and enabled a rigorous prioritization in subsequent steps in the process. A summary of the discussion around the size of the draft investment budget and quantity of investments falling outside the initial budget is included as Exhibit 14.

Exhibit 14: Discussion of capital budget developed for prioritization



Note: Chart is depicting 6-year spending, excludes Dx portion of common investments. Callouts are illustrative

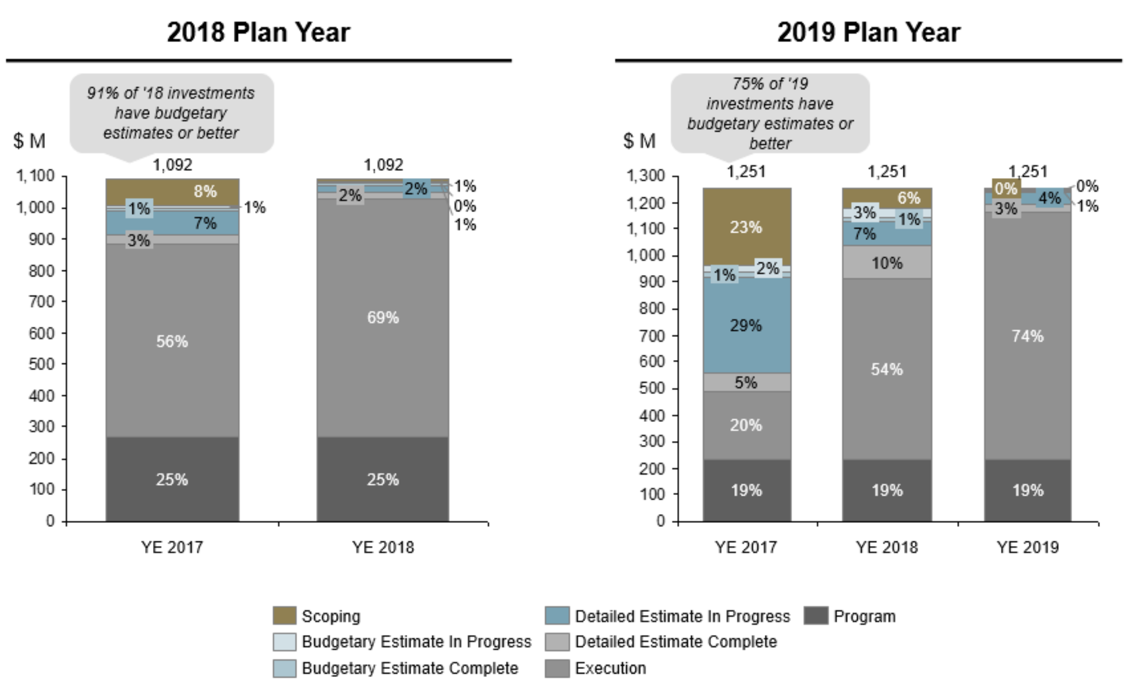
Another critical capability in developing potential investment options is evaluating estimated project costs. Hydro One's use of unit data to inform estimation and its level of estimating rigor are consistent with peer performance on these capabilities, and in some areas exceed what we expect from typical utility processes. In developing investment options, Hydro One's planners rely on a unit cost catalogue as a starting point to gauge potential costs when projects are in an initial planning phase. This catalogue is updated annually, and provides a baseline for the cost of major assets based on Hydro One's historical purchases and market conditions. Planners develop estimates with increasing levels of detail as projects are further developed, and supplement the unit cost catalogue data with actual costs as projects move closer to execution and key assets are procured.

Hydro One's internal audit (introduced into the record in Hydro One's most recent Transmission filing) identified concerns with the frequency of unit cost catalogue updates and identified gaps in ensuring the most recent catalogue was used by planners, Hydro One has worked to address these concerns through greater controls around updates to the unit cost catalogue, and increased emphasis on training. In its proposed steady state planning calendar (later included as Exhibit 27), Hydro One allocates dedicated time to updating key planning inputs, including the unit cost catalogue, before investment options are developed.

Best practice estimation for program costs relies on unit cost metrics that help ensure efficiency in executing common work programs, such as wood pole replacement or forestry. Hydro One calculates unit cost metrics as part of its productivity metric tracking on major Transmission capital and O&M programs, using the unit cost data to inform future budgeting. A best practice we have observed on program budgeting is to use internal unit cost data and external benchmarking to understand appropriate program level budgets. While Hydro One does this for some costs (e.g. Hydro One is currently conducting benchmarking for insulator replacement), there is room for additional benchmarking on other programs such as wood poles and forestry to inform productivity initiatives and ensure unit costs and overall budgets are competitive and appropriate.

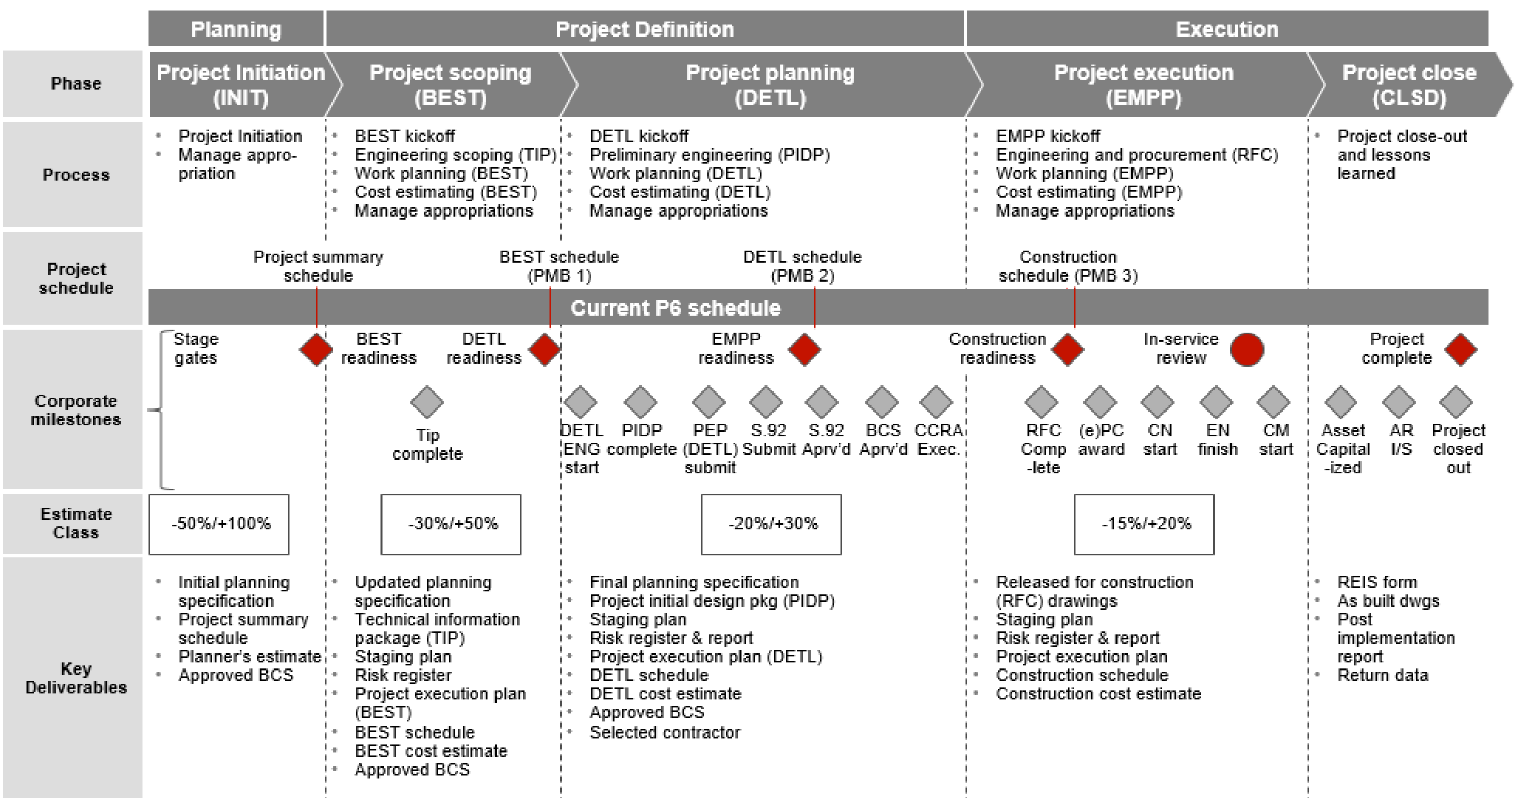
A final key capability critical to rigorous investment option development is ensuring that cost estimates that accompany potential investment options are at an appropriate level of detail. Hydro One's level of estimation detail at different stages is consistent with what we have observed as best practice. Hydro One uses detailed estimates for projects that are in execution or about to be executed and has declining levels of estimation detail as investments are farther from execution. Practically, Hydro One has a relatively high level of estimation detail for projects in the first two years of its plan, with ~80% of projects in the first two years of the plan having gone through relatively detailed estimation (budgetary or detailed estimates). Additional detail on Hydro One's level of maturity for investments in the first two years of the plan is included in the Exhibit 15.

Exhibit 15: Maturity of Hydro One capital program by year for initial two years of filing term



Hydro One has displayed relative strength on several dimensions of cost estimation, but has plans in place to continue to improve in a few key areas. For future planning cycles, Hydro One now has consistent, updated asset strategies in place to guide investment development for critical assets. Hydro One is also continuing to focus on relieving the backlog in its condition assessments for critical assets, particularly lines and insulators by enlisting third party support to conduct condition testing. Finally, Hydro One has initiatives in place to improve its estimation maturity at different project stage gates, by outlining clear expectations for the level of estimation detail and deliverables at each step in the stage gate process aligned to steps in the overall investment and business planning processes at Hydro One (detailed in Exhibit 16).

Exhibit 16: Hydro One's Transmission Capital Project Delivery Model



3. Assessment of Hydro One's capabilities in establishing criteria, scoring and calibrating investments

In this step of a planning process, potential investment options are evaluated against key criteria to enable eventual prioritization. It involves the following activities:

- Estimating the potential risk mitigation impact of investment candidates
- Calibrating risk scores to ensure consistent application across investment types

Utilities vary widely in their maturity in this step of the investment planning process. In a best-in-class process, we would expect a utility to use objective criteria to evaluate project risks and benefits. These criteria should incorporate customer and regulator concerns to ensure prioritized plans align to organizational objectives. Risk scoring should be methodological and rigorously calibrated, to increase the objectivity of the process.

In a typical investment planning process, we would still expect to clear criteria for evaluating investment options, though these criteria may be less comprehensive than in best in class utilities. Utilities performing near the middle of the peer set also had some subjectivity in the evaluation of projects and calibration of scores.

Less mature processes are characterized by their mostly subjective evaluation criteria. These processes can be ad-hoc, with no systematic evaluation criteria, and significant opportunity for gaming.

We have defined the specific capabilities related to this process step and the spectrum of maturity for each in the rubric included as Exhibit 17.

3

Exhibit 17: Rubric: Establish criteria, score and calibrate

Evaluation criteria, scoring and calibration	Process by which a company:
	• Identifies potential risks mitigated by candidate investments • Calibrates risks to ensure consistent application across investment types

Capability	Characteristics of "1"	Characteristics of "3"	Characteristics of "5"	Benchmark for "5"
Investments evaluated against risk criteria	• No methodology for evaluating risks	• Risks evaluated using standardized methodology, but scoring subjective	• Objective, quantitative risk evaluation • Risk evaluations informed by condition data	• ISO
Risk criteria incorporate customer and regulator perspectives	• Risk criteria heavily prioritize utility perspective	• Risk criteria incorporate either customer or regulator perspectives but not both	• Risk criteria incorporate both customer and regulator perspectives	• IBP
Risks calibrated consistently	• Risks evaluated by many different stakeholders, with no calibration	• Risk evaluations calibrated through discussions, with no formal methodology	• Established methodology for calibrating evaluations applied in multiple sessions	• IBP

Hydro One displays relative strength on this capability, scoring 4.3 out of 5. Additional detail on Hydro One's capabilities on this dimension is included in Exhibit 18.

In 2017, Hydro One focused on significantly improving its risk scoring capabilities, and has introduced a rigorous and transparent scoring process. Hydro One's revised risk scoring system

3

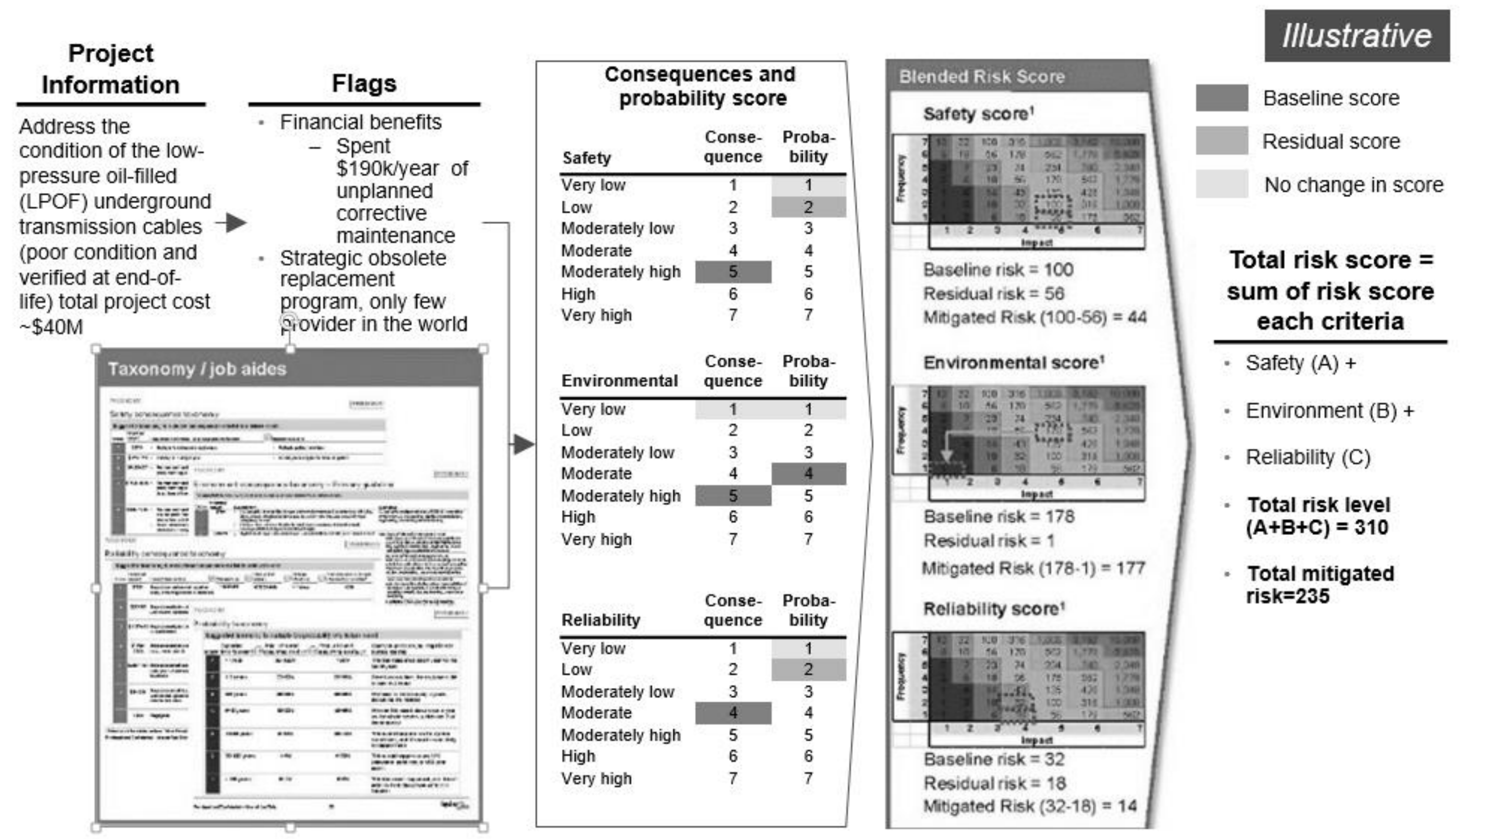
Exhibit 18: Maturity Assessment: Establish criteria, score and calibrate

Capability	1 – 3 – 5	Comments on score
Investments evaluated against risk criteria	4*	• Taxonomies were thoroughly developed and objective, but some evidence of subjectivity or inconsistency in probability and consequence calculations by planners • Opportunities to further expand use of condition data (e.g. age used for probability calculations vs. effective age) • Some identified execution concerns being addressed for future cycles with training
Risk criteria incorporate customer and regulator perspectives	5	• Evidence that customer input shaped development of taxonomies (e.g. reliability) • Flagging system allows for consideration of additional perspectives beyond risk mitigation • Customer flags incorporate customer input from ongoing engagement • Public policy flags incorporate policy considerations
Risks calibrated consistently	4*	• Multiple calibration sessions conducted with significant share of stakeholders • Self-assessment signaled potential gaps to be closed in future steady state

relies primarily on three risk taxonomies that have been developed to classify safety, environmental, and reliability risks. The taxonomies provide guidelines for planners to assess the consequence and probability of potential risks and then assess how proposed investment projects are expected to mitigate those risks. The taxonomies are fact-based, with significant analytical rigor behind the development of different levels of classification. For example, different levels of safety consequence are based on historical data of safety outcomes derived from utility industry experience. Reliability consequence information is based on realistic potential reliability outcomes, defined based on Hydro One experience and historical system data.

In evaluating investments, Hydro One planners estimate consequence and probability for two cases: a baseline case, with no investment, and a residual case, where an investment has been made and the impact of its risk reduction is estimated. Whatever risk remains is considered residual risk. The consequence and probability scores for each case are plotted on a matrix, and the difference between the two risk scores is the risk mitigation potential of the investment. These scores enable eventual prioritization of investments. The risk taxonomies are calibrated so that the risk mitigation points of each type of risk are weighted equally. Hydro One's risk evaluation approach is summarized in Exhibit 19.

Exhibit 19: Summary of Hydro One's scoring system and risk criteria



Hydro One's revised scoring system introduces new levels of additional rigor and objectivity into the risk scoring process. Best in class planning processes strive to be as objective as possible by relying heavily on quantitative data, and Hydro One has made progress toward this standard. However, we have observed that the new system still allows some room for subjectivity.

Internal documents and conversations suggest that the organization is still learning how to apply these taxonomies, and the inputs to calculating consequence and probability can remain subjective where data is not available. We have observed examples where this system was applied effectively in scoring investments; in these instances, access to condition data, hazard curves and past failure data enabled quantitative, largely objective scoring. However, this type of high-quality data does exist not for all types of assets and all types of risks, so in some cases, users applied their own judgment to assign scores.

The revised risk scoring process includes applying qualitative flags that allow consideration of other potential benefits of an investment beyond risk mitigation. Flagging allows Hydro One to make clear distinctions between mandatory investments (e.g. new connections, investments required by the regulator) and discretionary investments on the system, as well as allowing considerations like customer and productivity benefits to be included in addition to risk when assessing an investment. Hydro One introduced 4 mandatory flags, and 5 non-mandatory flags, which are described in Exhibit 20.

Exhibit 20: Types of mandatory and non-mandatory flags

Examples of mandatory flags follows

	Classification	Definition	Examples
Mandatory	Immediate/short term compliance	• Explicit obligation to a regulatory agency e.g., Ontario Energy Board (OEB) to do work within a year, with immediate risk of legal breach (Immediate) • Explicit obligation to a regulatory agency e.g., OEB with a 2–5 year risk of regulatory or legal breach (short-term)	• Upgrade systems to NERC standard (NOD)
Mandatory	Third party requests	• Explicit requests by a city, county, agency, or customer, with an 1–5 year risk of breaking the utility obligation to serve	• New ops center in Woodstock (Facilities)
Mandatory	In flight	• Under construction or 50% of total expected cost committed as of the beginning of the budget year	
Mandatory	Contractual	• Signed third party contracts for services such as IT support, call center operations, etc.	• Communication support (ISD)
Non- Mandatory	Strategic	• Codified goal by leadership team (e.g., in S-2)	• New customer portal redesign (ISD)
Non- Mandatory	Customer Engagement	• Influence of customer engagement/consultation; response to specific customer needs and preferences	
Non- Mandatory	Productivity	• Contains committed productivity savings, as tracked by corporate finance (Embedded) • Facilitates future productivity savings (Enablement)	
Non- Mandatory	Political commitments	• Explicit statement by Hydro One officer to non-agency parties such as to politicians, media or through official public statement etc.	
Non- Mandatory	Corrective or sustainment	• A risk identified by Hydro One or other utilities as a 'lesson learned' that requires near-term action • OR common sustainment pending	
Non- Mandatory	Preventative maintenance	• Opportunity to prolong asset life with planned and condition-based maintenance	
Non- Mandatory	Emergent risk	• Risk mitigation of catastrophic risk with undefined probability (outlined in common section)	

Automatically included investments should still be reviewed to identify whether scope matches the specific requirements justifying inclusion (i.e., minimum scope to meet requirement)

The use of flags helps ensure stakeholder perspectives are consistently included in evaluating investments and is a practice employed by many leading planning organizations. However, by their qualitative nature, flags introduce some subjectivity into the risk assessment process, and thus their use needs to be monitored to ensure they are not used to supersede objective risk-assessment criteria unless there is a clear justification for the investment. The calibration process helps mitigate this risk.

Hydro One's revised risk scoring method enables it to incorporate key customer and regulatory outcomes into its evaluation of projects in two ways. The first is through the definitions of consequence in the risk taxonomies, and the second is through the flagging system. Hydro One's risk taxonomies are based on key outcomes that customers and the OEB have identified as high priority. Safety consequences, can be classified in terms of harm to employees or the public. Reliability consequences can be classified in terms of unsupplied energy, load impacted and customer outage duration. Environmental consequences can be classified in terms of oil spill severity (PCB and non-PCB) and greenhouse gas emissions and the associated scale of potential impact (e.g. size of geographical area or duration of cleanup). These outcomes are reflective of customer concerns align to key regulatory and policy concerns (e.g. ensuring public safety, reducing GHG emissions). Hydro One's flags also enable it to identify investments that address key customer priorities such as improving power quality and address investments that align to strategic priorities, which include environmental and policy considerations.

As mentioned, a critical element of best in class investment planning is ensuring objectivity. The primary method Hydro One uses to ensure that taxonomies and flags are applied consistently is calibration. Hydro One conducted multiple calibration sessions that allowed for review and challenge of risk scoring for the largest proposed investments in terms of both spending and risk mitigation. The sessions allowed stakeholders to challenge how flags were applied to different investments to help reduce potential subjectivity in their application. Rigorous calibration is a hallmark of best in class planning processes, and one of the key tools used to remove subjectivity from the process in absence of perfect data. Hydro One has implemented a strong calibration process to support this goal.

While Hydro One has progressed significantly on this capability, the planning team has identified the need to continue improving the objectivity of its risk scoring, and is addressing this in future planning cycles by instituting additional training on how to apply the scoring system. This training will include showing additional case studies as examples, to ensure teams understand the risk taxonomies, the types of data used to estimate probability and consequence, and how to apply them. Hydro One has plans in place to continue to refine calibration for future cycles to ensure consistent application of risk taxonomies and flags.

4. Assessment of Hydro One's capabilities in prioritizing and selecting investments

This step encompasses the way a company develops an initial investment plan from a set of scored investment options. It involves a few key activities:

- Using defined criteria to prioritize a universe of investment candidates
- Narrowing the universe of investment candidates into an initial investment plan
- Analyzing different plan options to arrive at a recommended plan for review

A best-in-class prioritization process is based on objective criteria that allows for like comparisons, and the prioritization methodology's outcomes are well understood by stakeholders. In addition, best in class processes allow for sensitivity analysis to understand the impacts of different levels of spend and evaluate tradeoffs around a given budget.

Typical utility performance on this spectrum involves a prioritization process that is largely objective and well understood, but with some subjective assessments required due to a lack of data. Sensitivity analysis may be less rigorous than in a best in class process, or done qualitatively vs. quantitatively.

A weak utility on this spectrum would be one without a systematic prioritization process and would lack the data necessary to conduct sensitivity analysis. The outputs of its prioritization process may, as a result, be opaque and not well understood or trusted within the organization.

We have defined the specific capabilities related to this process step and the spectrum of maturity for each in Exhibit 21.

4

Exhibit 21: Rubric: Prioritize and select investments

Prioritization and selection	**Process by which a company:** • Uses defined criteria to prioritize universe of investments • Narrows the universe of investment opportunities into an initial investment plan • Analyzes different plan options to arrive at a prioritized plan for review

Capability	Characteristics of "1"	Characteristics of "3"	Characteristics of "5"	Benchmark for "5"
Investments assessed relative to each other to develop prioritized list based on decision criteria	• No clear prioritization process	• High level prioritization with some subjectivity • Some difficulty in comparing investments across types	• Full prioritization allowing for evaluation of investments on like for like basis	• IBP
Prioritization driven by risk-based methodology	• Non-risk criteria used to guide investment prioritization; risk a secondary factor	• Risk-based criteria primary driver of investment prioritization • Qualitative considerations of risk included	• Quantitative, risk-based prioritization method used	• IBP
Sensitivity analysis conducted to understand plan impact vs. cost tradeoffs	• No consideration of impact of higher/lower funding levels on risk or other outcomes	• Limited analysis around utility-focused primarily on rate impacts vs. spending levels • Limited discussion of outcomes	• Dynamic consideration of multiple levels of spending vs. rate impacts and other outcomes (e.g. risk)	• IBP
Investment selection process is understood within organization	• Process considered opaque by stakeholders within and outside of planning group • Little ability to understand or trust underlying assumptions or results	• Process understood by those directly involved with tools and assumption development, but not understood by broader stakeholder group	• Process considered transparent, with visibility into mechanics and assumptions • Results widely understood and supported	• IBP

Overall, Hydro One has improved its investment prioritization and selection process, and has introduced measures to increase transparency and objectivity into how investments are selected and traded-off. We have rated Hydro One's overall score on this dimension as 4 out of 5, exceeding the levels of performance we would expect from a typical utility planning process.

Hydro One's sub scores for investment prioritization and selection are included in Exhibit 22.

Similar to risk scoring, a key component of best-in-class prioritization processes is objectivity in evaluating investments. In Hydro One's process, investments are assessed relative to each other based on their risk mitigation potential, which has been consistently applied through its risk scoring process. In developing its plan, Hydro One first prioritizes investments that are

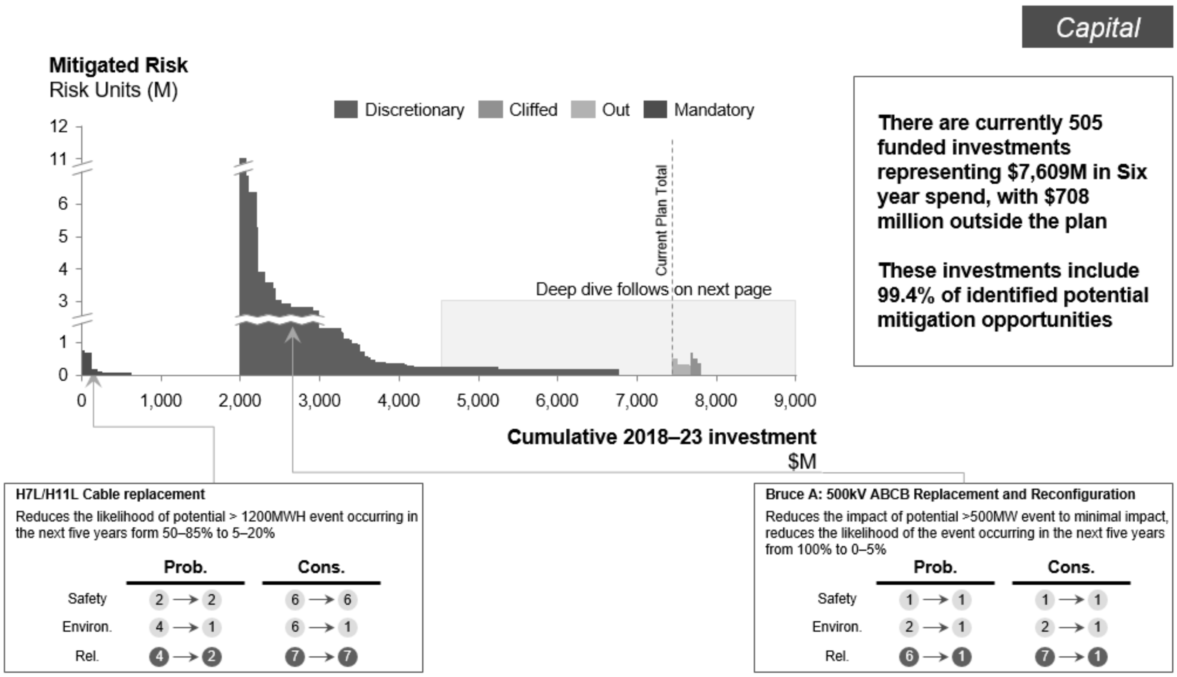
4

Exhibit 22: Maturity Assessment: Prioritize and select investments

Capability	1 3 5	Comments on score
Investments assessed relative to each other to develop prioritized list based on decision criteria	4*	• Prioritization occurs largely based on risk-scores • Segmented and prioritized for some smaller categories such as facilities, fleet, etc. • However, Power systems contained \$7.3 of \$7.8 B of spend of diverse types (e.g. reliability, innovation, telecom) – making it difficult to compare like-for-like • Efforts in place to engage in some strategic allocation for future cycles
Prioritization driven by risk-based methodology	4	• Initial prioritization driven by quantitative risk taxonomies; rank projects based on risks mitigated
Sensitivity analysis conducted to understand plan impact vs. cost tradeoffs	4*	• Understand tradeoffs made between investments at margin and from baseline to -10% scenarios using risk as outcome • Implicit consideration of rate impacts vs. explicit
Investment selection process is understood within organization	4	• Education prioritized in first year of revised process • Expect continued learning through organization as process repeated in future years

flagged as mandatory, after which it ranks investments in descending order of mitigated "risk units" that have been estimated through the application of Hydro One's taxonomies. An example of the initial output of prioritization is included as Exhibit 23.

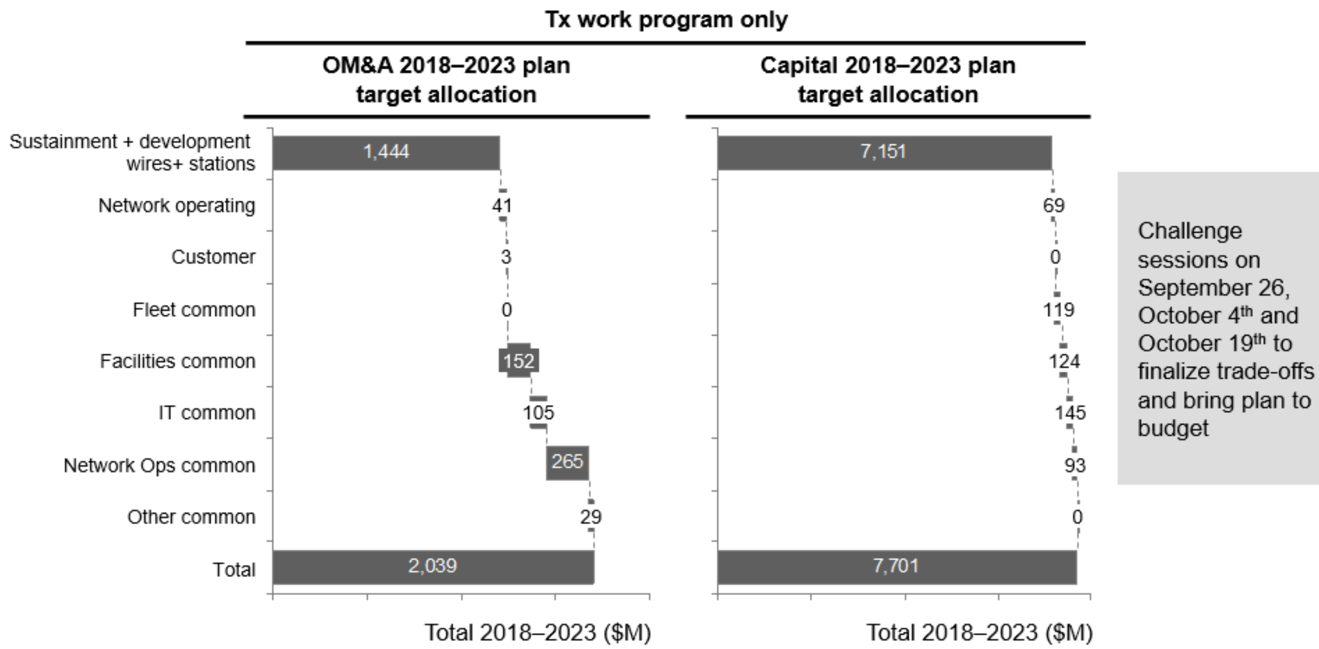
Exhibit 23: Sample output of initial prioritization based on risk



Note: Chart is depicting 6-year spending, excludes Dx portion of common investments. Callouts are illustrative

In prioritizing its draft plan, Hydro One split investments into categories to more easily compare investments (power systems, facilities, fleet, etc.). Power systems represented \$7.2B of \$7.7B in total spending prioritized in Hydro One's initial prioritization. The investments falling under power systems were diverse, including sustainment and development projects of all types (See Exhibit 24 for breakdown).

Exhibit 24: Initial breakdown of spending categories by type



Note: Allocations at group level will be updated after decision-we will maintain current budget growth assumption of 1.4% in 2023 in the interim

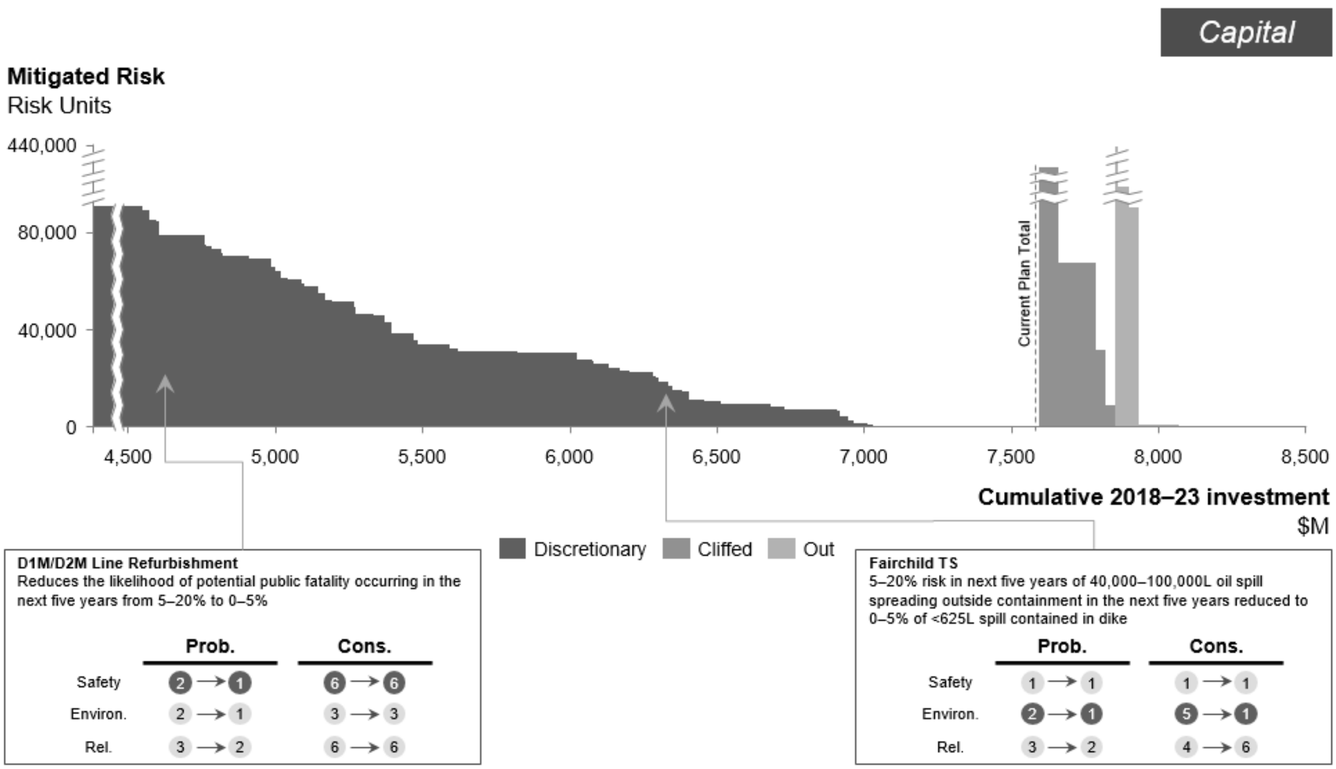
Given the large share of the power systems category, it can be difficult to compare investments "like for like" given different desired outcomes of some spending (e.g. grid modernization investments vs. reliability focused investments). While Hydro One's approach is valid and the use of standardized risk units helps mitigate this challenge, it adds some complexity to evaluating investments that Hydro One may want to consider mitigating by engaging in strategic capital allocation at the onset of future planning processes to divide the plan into smaller, discrete budgets, and then prioritizing within those budgets. This is a practice we have seen applied successfully at many leading utilities.

The qualitative flags that were used to evaluate investments in Hydro One's risk scoring process are used to identify project benefits beyond risk mitigation, and increase the consideration of some investments that may not be included in the plan on risk merits alone. The impact of discretionary flags on a project's inclusion in the plan is based on planner judgment; as a result, flagged investments can displace higher risk-mitigating investments. The role of flags introduces some subjectivity into the prioritization process, however, they also allow for consideration of non-risk benefits. The potential for subjectivity is mitigated by several factors:

- The use of clear definitions for flags so that planners understand what qualifies as a flagged investment vs. not
- The requirement for evidence to support the use of the flag
- Hydro One's rigorous calibration process that requires all flagged investments to be reviewed by the planning team to ensure comfort that the projects provide the benefits the flags describe.

Hydro One evaluated different plan scenarios to understand the impact of marginal investments on the plan and guide its ultimate prioritization. In evaluating investments at the margin, the primary metric used for spend vs. outcome trade-off was risk points vs. dollar spent (in terms of OM&A and capital – see Exhibit 25 for materials from the discussion of the risk impact of marginal investments).

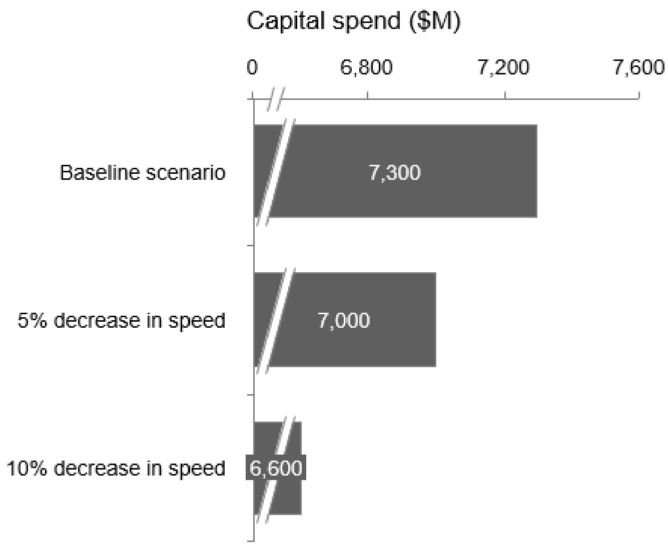
Exhibit 25: Sample from discussion of risk impact of marginal investments at challenge sessions



Note: Chart is depicting 6-year spending, excludes Dx portion of common investments. Callouts are illustrative

Hydro One reviewed three different funding levels in its initial prioritization discussion: fully funding the initial budget of $7.7 B, and two reduced scenarios that represented 5% and 10% reductions in capital and OM&A. Additional detail on these scenarios is shared in Exhibit 26.

Exhibit 26: Sample details of projects eliminated in 5% and 10% reduction scenarios



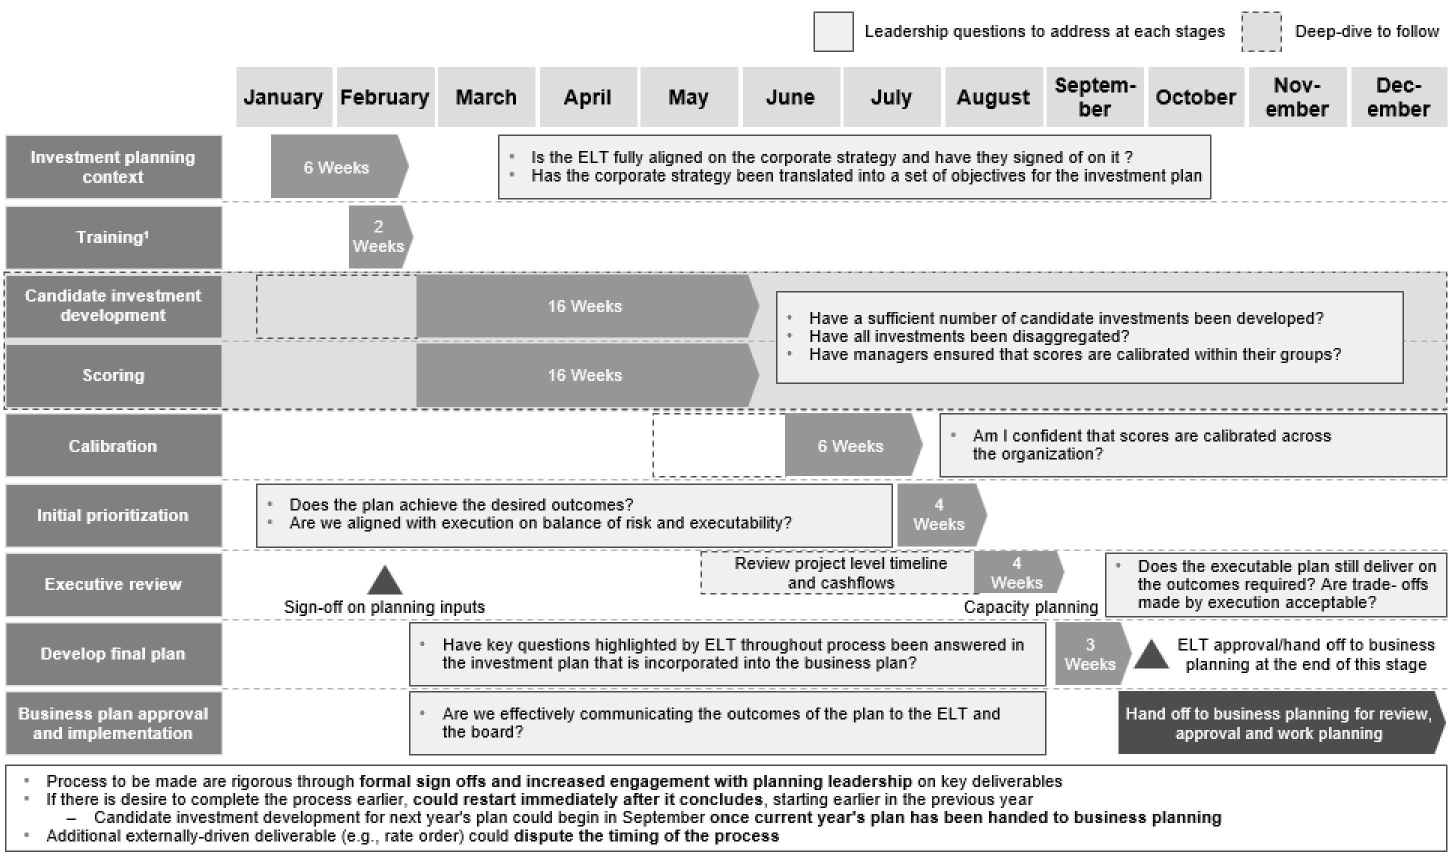
Number of projects cut	Sample project cut
• --	• --
• 9	• $1M air break switch replacement • $13M component replacement • $0.6M fire direction upgrade program
• 17	• $140M station rebuild • $50M switchyard and component replacement • $50M transmission line refurbishment

Reviewing these scenarios allowed for sensitivity analysis of each plan's risk mitigation potential. Hydro One conducted further prioritization once it received its 2017-2018 Transmission decision, leading to further capital reductions and another discussion of the tradeoffs of different levels of spending.

A final key component of a planning process is ensuring that stakeholders understand how the process works and how their investments are prioritized. In interviews, internal stakeholders have indicated that Hydro One's revised risk-based prioritization represented an improvement over prior cycles in terms of transparency and objectivity, but that there is still some room to continue education on how the process works.

Based on this and other feedback, Hydro One is taking a number of actions to continue to improve along this dimension. As part of its steady state calendar (included as Exhibit 27), Hydro One intends to continue to provide education on the risk scoring and prioritization process each year as the process begins to ensure that past participants are re-familiarized with key steps, and that new participants understand how the process works and the expectations from participants.

Exhibit 27: Hydro One's proposed steady state investment planning calendar



1. Corporate strategy defined and translated to planning objectives prior to commencement process training

To address some of the challenges in prioritizing a large sleeve of spending, Hydro One had indicated they intend to engage in more detailed strategic capital allocation during the strategy development phase of future planning cycles.

5. Assessment of Hydro One's capabilities in revise and approving plan

This step involves how a company revises its draft plan and engages senior leadership to finalize it. In involves the following activities:

- Reviewing and editing the draft plan that emerges from the prioritization process
- Pressure testing proposed investments to ensure they are justifiable and financially sound
- Engaging senior leadership to review and approve the plan

Best-in-class planning processes are characterized by the thoroughness of the revision phase. Plans are reviewed in detail by executing lines of business to ensure feasibility of execution. Plans are reviewed by team leaders, executives, and the Board, who provide timely feedback that helps shape the final plan. Reviews with senior leaders address rate impact considerations to ensure that they understand and can weigh in on the impact of the plan on customers. Quality assurance is conducted on the draft plan to minimize errors.

A typical utility planning process may involve less thoroughness in one or multiple aspects of review, but still involves multiple rounds of plan review ahead of approval. These include execution review, where the executing lines of business may only review investments in the initial years of the plan, and senior leadership reviews and quality checks.

A less mature process, in contrast, may be missing key elements. There may be limited opportunities for execution review, resulting in a plan that is difficult or impossible to execute. The executives and board may provide "rubber stamp" approval of the plan, without engaging on its details. There may be no time or process for quality assurance.

We have defined the specific capabilities related to this process step and the spectrum of maturity for each below in the rubric for this capability, shared in Exhibit 28.

5

Exhibit 28: Rubric: Revise and Approve Plan

Plan revision and approval	Process by which a company: • Evaluates the draft plan emerging from the prioritization process • Pressure tests proposed investments • Engages senior leadership to approve plan

Capability	Characteristics of "1"	Characteristics of "3"	Characteristics of "5"	Benchmark for "5"
Plan reviewed for execution feasibility	• Minimal input from executing lines of business (LOBs) into plan	• Executing teams review plan but given insufficient time or authority to make significant changes to contents	• Robust execution review of plan with opportunities to modify inclusion of investments based on feasibility to execute	• IBP
Plan reviewed for financial considerations and rate impacts	• Plan accepted as-is; limited rate impact review	• Financial and rate impact of plan reviewed; minimal opportunity to alter plan substantially if review not aligned with objectives	• Plan reviewed for financial impact and rate impact considerations; opportunity to adjust plan if misaligned • Consideration of plan impacts in context of overall customer bills	• IBP
Plan benefits beyond risk mitigation considered in review	• Plan reviewed primarily with internal focus • Limited understanding of plan benefits beyond risk	• Plan reviewed qualitatively for impact on key outcomes (e.g. reliability, safety)	• Plan reviewed quantitatively for impact on outcomes (e.g. reliability metric improvement, safety improvement)	• IBP • ISO
Sufficient management/board engagement with plan	• Management/board engages only at final approval	• Management engages prior to final approval, provides feedback capable of being incorporated into plan • Board engaged nominally on plan approval	• Management/board offers multiple rounds of guidance and have opportunity to provide meaningful feedback prior to final approval	• IBP
Quality assurance conducted on draft plans to reduce errors	• No time dedicated to QA checks and adjustments for mistakes	• Plan owners have modest dedicated time for plan review • Error checks at driver level but no audit of underlying inputs	• Plan owners have substantial time dedicated to quality assurance reviews of plan ahead of exec review and finalization • Error checks at all levels of planning input	• IBP

Hydro One exhibits several strengths on this dimension of the planning process and recent improvements have contributed to a robust review process. Scoring a 4 out of 5, Hydro One's review process puts it in line with leading utilities and close to best-in-class on many dimensions. Hydro One's sub scores on this dimension are included in Exhibit 29.

5

Exhibit 29: Maturity Assessment: Revise and Approve Plan

Capability	Score (1 – 3 – 5)	Comments on score
Plan reviewed for execution feasibility	4*	• Executing LOBs participated in all challenge sessions • Evidence of significant increase in time allocated vs. prior years (~3-4 mos of engagement vs. 2 weeks at end of plan) • Some feedback timing remained insufficient • Unfamiliarity with new process may have caused perceptions of insufficient timing; will likely improve in steady-state
Plan reviewed for financial considerations and rate impacts	4	• Proposed rate and earnings impacts of plans reviewed multiple times ahead of plan finalization
Plan reviewed for impact on customer outcomes	4	• Plan reviewed for quantitative benefits where possible (e.g. reliability) • Plan benefits primarily discussed qualitatively in review sessions
Sufficient management/board engagement with plan	4	• Two sessions conducted with ELT to review plan, supplemented with written updates between meetings • Additional ownership and review at VP level vs prior years • Board given visibility into high level plan details ahead of final review but limited time in schedule to revise plan meaningfully
Quality assurance conducted on draft plans to reduce errors	4*	• QA conducted throughout process (e.g. calibration, ahead of challenge sessions, final review) • Expected steady state process embeds more time for review vs. 2017

Hydro One's strengths stem from the time and attention dedicated to plan review throughout the organization as part of the new planning process. Hydro One has implemented a strong review process for its plans, with multiple levels of execution and leadership review through challenges sessions, and multiple discussions with the executive leadership team, culminating in final board review.

A key step in evaluating plans is ensuring sufficient time for executing teams to review draft plans and provide input on the company's ability to execute them. Hydro One's planning team began engagement with executing lines of business in late May to review key planning inputs, including cost estimates, and began execution reviews of draft plans in August; this cadence allowed for early alignment to avoid later churn on data inputs such as costs, and two months of execution review in August and September once draft plans were created.

Another critical step in plan review is executive reviews of the plan's key details and expected outcomes. Hydro One's strengthened its challenge session process in 2017 by increasing the number of sessions and expanding participation. This helped strengthen the level of executive engagement by introducing new forums for review between managers, directors, Vice Presidents and the COO ahead of reviews with the executive leadership team (ELT).

Executive leadership reviews occurred at multiple stages in the process as the plan matured. Initial reviews in July and August focused on educating leadership on the new planning process and high level plan details, such as initial guidance on the proposed rate impact of draft plans, while subsequent reviews provided more detailed summaries of the plan, including details on categories of spending and more robust rate and tariff impact discussions. These reviews also included discussions of the expected outcomes of the proposed investment plan, including qualitative and quantitative outcomes. Examples of the materials supporting these reviews is included in Exhibits 30-32.

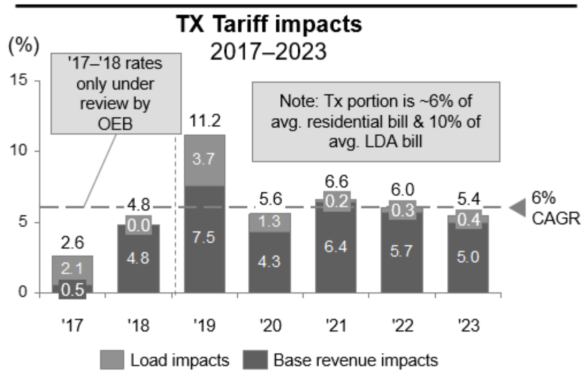
Exhibit 30: Sample of materials from ELT review of investment plan

	To meet customer needs, Hydro One will…	Highlighted Tx Investments	
Optimize the Core	Be an industry leader in **Safety & Environment** for our employees, contractors, and the public. Achieve and maintain "World Class" safety performance.	• **Journey to Zero** and Embedded Safety by Design programs • $3.9B which mitigates safety risk (e.g., $301M for targeted line insulator programs)	• $40M in condition assessments and patrols • Reducing environmental risk (e.g., $89M for PCB replacement, $22M for transformer oil leak reduction)
	Deliver improved **Reliability** to our customers, incorporating their input and priorities. Maintain top quartile/tier performance.	• $3.1B at 55 stations • $252M in Cyber Security	• $1.1B on lines to replace line segments in poor condition on 71 circuits • $61M[1] for new Control Centre
	Provide **Cost Effective** service to our customers by improving our productivity and continue to meet our budgeted commitments.	• Reduced planned spend to respond to customer and regulatory feedback	• **$431M[1] in total productivity savings** • Initiatives to extend asset life like Tower Coating ($170M)
	Always be there for our **Customers** with a seamless experience in all interactions. Seek continuous improvement in meeting our customer commitments.	• Work with customers to resolve power quality issues • $106M spend ($419M gross) for **new customer connections**	• $905M in development capital to build **new capacity to enable growth**
Bring Innovation to the Core	Pursue continuous **Innovation** in our work programs to maintain a reliable and affordable transmission system. Pursue grid modernization opportunities provided by emerging technology to enhance system visibility and automation.	• Drones, fleet electrification and advanced sensor pilots • $72M in new analytic tools	• $20M for **remote monitoring and automation** • $2.3M for new customer portal to improve customer service

1. Tx allocation

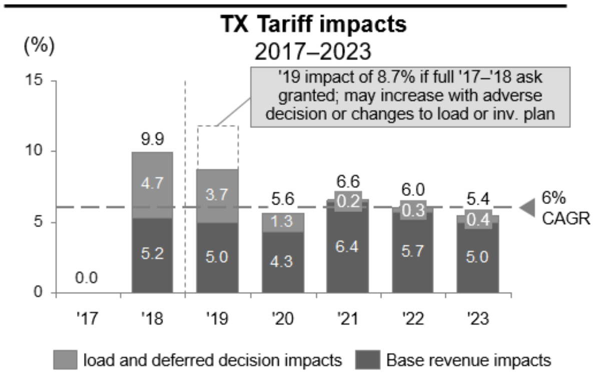
Exhibit 31: Rate impact preview from August ELT communications

Tariff impacts: July 25 ELT



- Key assumptions
  - Tx 2017 and 2018 rates approved applied for in the application
  - Includes increased revenue required and decreased load forecast

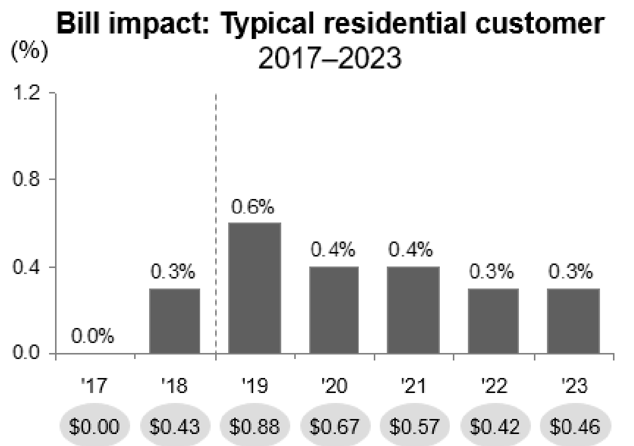
August 2017 updated

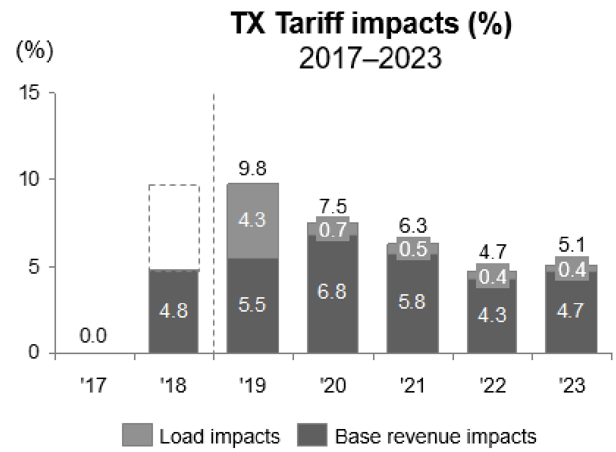


- Key changes
  - '17 revenue increase and load impact recovered in '18 as 1 year temporary increase
  - Larger than planned increase in 2018 results in a comparably smaller change in 2019

Exhibit 32: 2019 Tariff and Bill impact discussion from final ELT approval meeting

Final Investment Plan and CCC





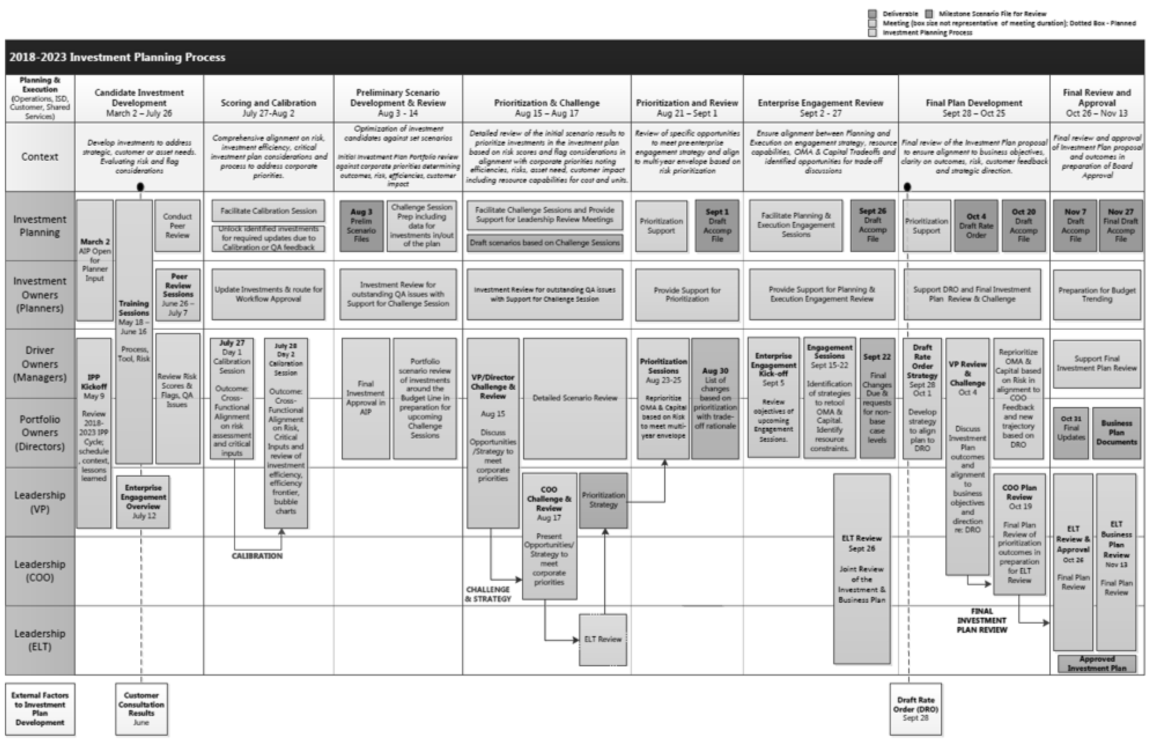
- Key changes
  - Loss of Deferred revenue in 2018 creates lower bill impact
  - Increases in load and lower prior year revenue causes larger impact in 2019, which is the first year of the next filing

- Key changes
  - Deferred decision impact removed in 2019
  - Tariff impacts increase slightly in 2019 and 2020 due to lower previous years revenue
  - Reduced rate impacts in later years

Hydro One's leadership reviews of the plan culminated in leadership approval at the end of October, incorporation of the investment plan into Hydro One's overall business plan in November, and final approval by Hydro One's board in December. Hydro One's timeline for executive review allowed substantial time for leadership to provide feedback on draft plans and for teams to incorporate it to meaningfully change the plan, in line with strong planning processes we have observed.

In addition to executive review, Hydro One's 2017 planning timeline provided sufficient time for quality assurance reviews of initial plan inputs ahead of prioritization, and reviews ahead of executive leadership reviews (see Exhibit 33). In its steady state calendar, Hydro One has allocated additional time for thorough quality assurance reviews consistent with best practice (see Exhibit 27).

Exhibit 33: Enterprise Engagement Schedule for 2017 Planning Process



Hydro One's revised process includes opportunities for quality assurance checks at multiple points in the process, including during calibration sessions, when risk scores are reviewed and sense checked, and errors can be caught before the plan is prioritized.

In the process supporting the 2019-2023 plan, Hydro One's review period was slightly more constrained, as it received its 2017-2018 Transmission decision in September 2017. The decision impacted Hydro One's draft plan, and required effort from the planning and finance teams to review the decision's impact and make changes. This occurred as Hydro One was preparing for its final executive leadership reviews of the plan, leading to compressed timelines and reduced time for review vs. expectations. These circumstances were somewhat mitigated by the opportunity for multiple prior reviews leading up to September, so many of the key components of the plan had already undergone a quality check. We expect that these circumstances would not persist in future planning cycles, given Hydro One's transition from 2 year cost of service filings to a 5 year filing timeline. As a result, we would expect Hydro One to have sufficient time for quality assurance review and executive reviews embedded in its future planning cycles.

6. Execute plan and track outcomes

The investment planning process ends with the plan transitioning into the execution phase. While plan execution encompasses a broad group of activities, the key planning components are included below:

- Tracking the execution of the plan and the performance of investments, based on metrics aligned to established goals
- Leveraging performance data to make continuous improvements to the process and future plans

A utility with a best-in-class planning process excels at both of these components. It employs a comprehensive set of quantitative metrics with which it tracks performance, including productivity. Performance against plan is given high visibility within the organization, so that leaders are aware if executed projects align to those planned in terms of impact and budget, and have the opportunity to adjust if not. Results of projects are systematically fed into future planning, so that lessons learned inform future project design, and productivity drives continuous improvement.

A typical utility planning process may be more qualitative and informal in its tracking. Its metrics may be a mix of qualitative and quantitative, with some relevant capabilities for which there are no established metrics. Execution tracking may be primarily financially-oriented and less frequent than is best practice (e.g., quarterly or more seldom). Outcomes and lessons learned may feed back into planning informally, without a clearly established process.

A poor planning process may be characterized by inconsistent or nonexistent metrics, infrequent tracking, and lack of feedback between execution and future planning.

We have detailed the spectrum of maturity for each of these capabilities in the rubric in Exhibit 34.

6

Exhibit 34: Rubric: Execute plan and track outcomes

Follow-up and tracking

Process by which a company:
- Tracks execution of plan and performance of investments using defined metrics
- Leverages performance data to make continuous improvements to process and future plans

Capability	Characteristics of "1"	Characteristics of "3"	Characteristics of "5"	Benchmark for "5"
Metrics chosen align to desired customer, operational and regulatory objectives and outcomes	• No tracking of metrics • No plan objectives or desired outcomes to which metrics can be linked • Metrics change too frequently for comparison	• Metrics mostly aligned to desired outcomes, but may lack comprehensiveness or specificity • Metrics allow for assessment of improvement over course of planning cycles • Target setting may be incomplete (e.g. short or long term only)	• Clearly defined metrics and targets (long term and short term), fully aligned to desired customer, operational and regulatory outcomes • Allow for quantitative assessment of improvement over time	• IBP
Executed investments align to finalized investment plan and evidence	• Execution diverges significantly from finalized investment plan, with limited tracking of causes or: • Plan executed highly rigidly, inhibiting response to changing circumstances to meet desired outcomes	• Capacity to fully execute finalized plan levels but potential for significant change in mix of investments; • Modest focus on outcome achievement; primary focus on spend levels	• Significant alignment between mix of investments executed and finalized plans • Sufficient flexibility in plan to respond to unexpected challenges while still achieving plan outcomes	• IBP
Execution and performance tracked in-year	• Limited execution tracking occurring in-year; low frequency of data collection	• Changes tracked; reviewed quarterly at a minimum • Required justifications for changes, focused on spending primarily	• Changes tracked, drivers of change identified and justified in consistent (e.g. monthly) forum • Discussions focus on impact on performance in addition to spending	• IBP
Execution data and outcomes tracked and used to inform future planning	• No unit cost measures tracked • No tracking of variance from estimates • No incorporation of lessons learned	• Unit cost efficiencies tracked and fed into future plans • Limited analysis of variance from estimates • Informal use of lessons learned to shape future projects	• Unit cost efficiencies tracked and fed into future plans • Analysis of variance from estimates used to improve estimation process • Systematic approach to incorporating lessons learned into future projects	• IBP

Hydro One has made significant efforts to improve its plan execution and tracking process in recent years. As a result, we find that the company has a strong process in place on several capabilities within this step, with some room for improvement in ensuring a clear feedback mechanism between performance tracking, decision making around redirection and plan adjustments, and strategic inputs for future planning cycles. Overall, we have scored Hydro One as a 3.5/5 on this capability. Additional detail on Hydro One's scores on this capability is included in Exhibit 35.

6

Exhibit 35: Maturity Assessment: Execute plan and track outcomes

Capability	Score (1 – 3 – 5)	Comments on score
Metrics chosen to align to desired outcomes	3*	• Chosen metrics comprehensive and map to key stakeholder outcomes • Scorecard expected to continue evolving as Hydro One receives regulator feedback and refines its tracking capabilities • Targets defined at 5 year level; opportunity to define targets more granularly for scorecard metrics to ensure progress towards 5 year goals and inform redirection
Executed investments align to finalized investment plan and evidence	3	• Hydro One has historically struggled to fully execute proposed capital budgets • Evidence shared demonstrates improvement in ISAs/budget; however, unclear whether mix of investments aligns to filed evidence • New redirection committee expected to help address alignment to plan
Execution tracked in-year	4*	• Actual vs plan tracked and shared in monthly reporting; initial focus on spending vs. overall performance vs. plan • New redirection committee establishes forum for in-year course correction, with senior participation on committee
Execution data and outcomes tracked and used to inform future planning	4	• Recent effort undertaken to strengthen collection of unit cost data to drive productivity • Information then used to reduce future estimates and drive productivity through budgets • Significant progress made in 2017, though not all types of investments driven by unit cost data yet

Hydro One uses metrics to track performance against key objectives and desired outcomes. Hydro One tracks performance at cascading levels through the organization (e.g. at the overall organizational level, at the operations group level, and for groups within operations), consistent with best practices we have observed.

In revising its performance measures over the past two years, Hydro One has increased its focus on unit cost metrics in an effort to increase its ability to measure productivity and use these metrics to drive continuous improvement through the business. Hydro One has added unit cost metrics for brush control and forestry and per FTE metrics for project management and construction to its scorecard to increase its focus on productivity and efficiency.

As part of its effort to improve performance tracking, Hydro One has set 5 year targets for improvement over historical average performance on each metric over the full term of the plan. The targets indicate the outcomes Hydro One's investment plan is expected to deliver. Hydro One set these targets through a combination of qualitative and quantitative analysis and is continuing to evolve its predictive analytics to improve its ability to translate planned investments' risk mitigation potential into customer outcomes. In addition to improving its predictive analytics, Hydro One can also continue to improve on this dimension by ensuring that team and division metrics align to the overall goals set by leadership on an annual basis and by setting annual goals for its published metrics to ensure performance is tracking towards the overall outcomes Hydro One is seeking to deliver with its 5 year plan.

Several of Hydro One's performance metrics focus on tracking execution progress, a critical capability in ensuring plans deliver on desired outcomes. Hydro One has demonstrated recent progress on project execution, with metrics indicating its ability to largely meet planned in service additions and planned capex in a given year. Hydro One is now focusing on its processes to monitor how executed investments track to plan, and strengthening its processes to ensure that when capital is being redirected, the drivers and impacts of changes are well understood.

Exhibit 36: Sample Hydro One Execution metrics

Measure	Measure Description

Transmission System Plan Implementation Progress	The *TSP Implementation Plan Progress* measure compares the total actual in-year sustainment, development, and operating expenditures for in-service additions to the total internal company scorecard budget expenditures for in-service additions, including any OEB carry-forward variance. This metric cannot be benchmarked against other utilities.
Capital Expenditures as % of Budget	Progress is measured as the ratio of actual total capital expenditures to the total amount of planned capital expenditures. This measure can be benchmarked against other utilities.

	2014	2015	2016
TSP Implementation Progress	99	105	100
Capital Expenditure as % of Budget	90	106	105

All utilities strive to strike a balance between executing proposed plans and remaining flexible to respond to unexpected events and changing circumstances on their system. Best in class utilities tend to have clear processes around tracking variances from plan and using data on system performance and resource availability to help make decisions to redirect capital. Hydro One has robust reporting on financial metrics tracking execution vs. plan on a monthly basis that is communicated to relevant stakeholders. In an effort to improve its understanding of the causes and potential implications of variances from the plan, Hydro One introduced a redirection committee in September 2017 to facilitate not only financial tracking of plan execution and potential changes, but also provide a forum for operations leadership to understand the root causes of variances, and review the impacts on the organization, including the impact on key outcomes such as reliability (see appendix for the terms of reference for the Redirection Committee).

Hydro One's redirection committee has participation from senior leadership of relevant lines of business, including the Vice Presidents in charge of execution and planning. The committee meets monthly and provides a forum to discuss the financial impact of changes to investment plans, including acceleration or delay of projects, and the likely impact on customer outcomes. While the committee is relatively new, its existence and the scope of its mandate provide evidence that Hydro One is moving towards best in class execution tracking with an aim towards enabling better decision-making around in-year and in-planning term adjustments.

A key function of tracking performance and plan execution is to use data to create a feedback loop to improve future plans. Hydro One has increased its focus on collecting unit cost data by tracking performance on identified productivity initiatives. This information can inform future budgeting and help ensure Hydro One's productivity goals are realized.

A final component of tracking execution information is to use lessons learned from projects and programs to improve future execution, which Hydro One does. Hydro One has instituted a formalized lessons learned process to ensure other types of information gathered from execution are incorporated into future planning. There is a strong process in place at a tactical level, where specific issues identified in project execution are reviewed and given owners for resolution. There are also new efforts in place to be more strategic in understanding trends that emerge in execution for certain types of investments and incorporating learnings into project development phase.

Hydro One is working to improve several capabilities related to plan execution and tracking, including improving its predictive analytics to more clearly tie outcomes to plans and continuing to strengthen the feedback mechanisms between plan results and future decision making through the efforts of the redirection committee and a continued focus on capturing data and lessons learned as plans are executed.

7. Oversee and govern process

Throughout each step in investment planning process, strong oversight and governance are critical to ensuring planning procedures are adhered to. Governance involves the following activities:

- Organizing the investment planning process and dedicating resources to its execution
- Outlining roles and responsibilities related to the planning process
- Documenting the policies and processes related to the investment planning process

We have observed a range of maturity levels in ensuring strong governance and oversight for planning processes. Best-in-class governance involves clearly defined and documented processes that are well understood throughout the organization. Stakeholders understand the roles and responsibilities of those involved in the process; these roles, responsibilities, and incentives support objective planning. The planning process is enabled by the dedication of sufficient internal resources. The organization conducts routine internal audits resulting in recommendations for process improvements.

Typical maturity around process governance is characterized by many of the same strengths; processes are clearly defined, resources are sufficient, and policies are well-documented. Compared to best-in-class governance, the organization's understanding of the planning team's role may be more modest, or there may be some gaps in the thoroughness of process documentation and resource allocation.

Lack of resources, unclear roles and responsibilities, and poorly defined or nonexistent documentation are all characteristics of poor governance.

We have detailed the spectrum of maturity for each of these capabilities in the rubric in Exhibit 37.

7

Exhibit 37: Rubric: Governance and oversight (I/II)

Governance and oversight

Process by which a company:
- Organizes investment planning process and dedicates resources to its execution
- Outlines roles, responsibilities, and accountability related to IPP
- Creates appropriate documentation for policies & processes

Capability	Characteristics of "1"	Characteristics of "3"	Characteristics of "5"	Benchmark for "5"
Sufficient time and resources allocated to IPP by management in business planning cycle	• Proposed planning cycle duration prevents proper execution of multiple process steps • Insufficient resources prevent proper execution of multiple process steps	• Time sufficient to produce plan but too short to conduct robust challenge and QA, or: • Planning cycle too long and results in executed plan being based on stale data and objectives • Insufficiencies in either financial or personnel resources dedicated to investment planning process • Stakeholders outside planning dedicate insufficient time to plan	• Sufficient time allocated to process within planning year to enable each step to be conducted at high quality level but not so long as to risk plan being outdated • Timeline management engagement within cycle • IPP team empowered with sufficient budget and resources to ensure high quality process • Robust engagement from all firm stakeholders to ensure quality plan	• IBP • ISO
Roles defined for designing, reporting, and executing IPP	• No clear accountability for each step in IPP	• Accountability clear, but no escalation mechanism for non-compliance	• Parties fully accountable with clear escalation authorities and consequences for poor performance	• ISO
Roles and incentives support objective process	• Process exposed to potential for "gaming" by investment owners • Insufficient reviews and challenge sessions to mitigate individual biases	• Subjectivity embedded in process at key steps • Reviews and challenge sessions exist but do not focus on identifying bias	• Investment selection process relies substantially on objective criteria and inputs • Reviews and challenge sessions specifically focus on mitigating individual biases	• IBP

7

Exhibit 37: Rubric: Governance and oversight (II/II)

Governance and oversight

Process by which a company:
- Organizes investment planning process and dedicates resources to its execution
- Outlines roles, responsibilities, and accountability related to IPP
- Creates appropriate documentation for policies & processes

Capability	Characteristics of "1"	Characteristics of "3"	Characteristics of "5"	Benchmark for "5"
Processes & policies sufficiently documented	• No formal documentation of processes & policies	• Processes & policies documented for most high-impact and frequently conducted processes, but with no clear update cadence • Documentation is available to investment planning team but is not distributed to wider organization	• Processes & policies are consistently documented, updated, and widely accessible • Evidence filed with regulator aligns with internal documentation	• ISO
Internal process audits conducted	• No internal audits conducted to assess process quality and/or adherence	• Informal self-assessments conducted periodically to assess process quality and/or adherence	• Comprehensive internal audits conducted periodically to assess both IPP process quality and adherence to processes	• ISO

Hydro One has demonstrated strong performance on this capabilities, scoring a 4.4 out of 5. Hydro One's investment planning process contains many elements of effective governance. Hydro One used the opportunity provided by making improvements in 2017 to thoroughly document the process and strengthen participants' understanding of roles and responsibilities. There is room for improvement, though, on ensuring sufficient resources are allocated to planning given how critical the planning process is to the organization, and, ultimately, its customers. Our evaluation of Hydro One's capabilities is included in Exhibit 38.

7

Exhibit 38: Maturity Assessment: Governance and oversight

Capability	Score (1 – 3 – 5)	Comments on score
Sufficient time and resources allocated to IPP by management in business planning cycle	3*	• Process is an area of significant organizational focus • Planning cycle given sufficient time in business planning calendar under steady state, but condensed in transition years • Some indication that resourcing beyond direct IPP team (e.g. planners, service providers, execs) was strained given late decision
Roles defined for designing, reporting, and executing IPP	5	• Clear definition of roles and responsibilities within planning organization
Roles and incentives support objective process	4	• Rigorous challenge process aims to eliminate bias but opportunities to strengthen objectivity of risk scoring process • Challenge process documentation quite rigorous
Processes & policies sufficiently documented	5	• Recent enhancement effort significantly strengthened process and policy documentation
Internal process audits conducted	5	• Significant internal audit resources devoted to IPP in recent years • Recommendations acted upon and results tracked

Hydro One has used the experience of revising its planning process to strengthen its documentation of process steps, and provide education to team members. Planners each have access to relevant documents that outline the process and methodology of Hydro One's risk-based prioritization, and Hydro One has enhanced education materials that it will use to outline the process for future cycles. An example of codified roles and responsibilities is included in Exhibit 39.

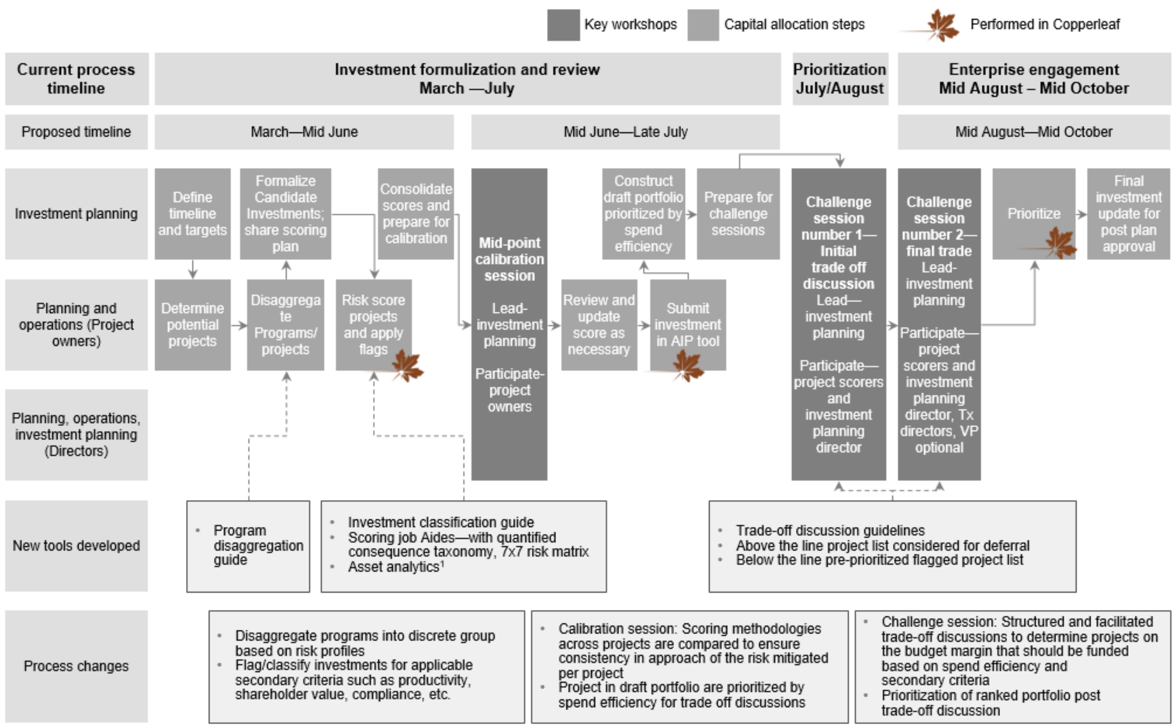
Exhibit 39: Planning Process roles and responsibilities

Group	Roles	Responsibilities
Investment management	• Manage Transmission prioritization and optimization • Facilitate scoring • Build and finalize portfolio	• Collect and quality review project lists from Driver Owners; schedule and facilitate calibration, challenge, trade-off decision, and review meetings • Assign scorers and facilitate scoring sessions • Schedule and facilitate meetings with other SMEs • Ensure each flag has the required documentation and review disaggregation/bundling decisions • Prepare and manage all material for major meetings, facilitate challenge sessions and confirm finalized portfolio
Leadership (VC, C-Suite)	• Participate in Challenge session 2 • Approve portfolio	• May attend Calibration session, Challenge session training workshop • Participate in Challenge session • Approve pre-prioritization portfolio
Portfolio Owners (Director)	• Final portfolio-level accountability for portfolio • Oversee calibration of project scores • Challenge portfolio	• Make final call on scoring of a contentious project • Attends Calibration session • Participates in Challenge session 2 alongside leadership to ensure portfolio meets strategic objectives • Approves pre-prioritization portfolio
Driver owners (Manager)	• Originate and score projects • Calibrate project scores • Challenge portfolio	• Responsible for disaggregating programs/bundling projects • Accountable for consistent and calibrated scoring within their group of investments • Participate in Calibration Session and Challenge Sessions, and shares perspective on investments to pull in/push out of portfolio
Investment Owners (Planners	• Serve as SMEs for scoring	• Submits candidate investments to generate project list for Investment Management • Gather project specifications (name, description, $ investment) to share with Investment Management Risk score project as directed by IM team (likely ~10–20 minutes per project)

While the Investment Owner will be the official scorer of his/her project, the ultimate responsibility of the final risk score assigned to a project lies with the Portfolio Owner

As part of developing this body of documents, Hydro One defined process steps and timing both for the 2017 process, that involved more detailed training and piloting of new system (Exhibit 40), and a steady state calendar that reflects how the process would unfold in a typical year going forward (Included as Exhibit 27 above).

Exhibit 40: Initial 2017 Process Map defined in May 2017



1. Hydro One tool for calculating consequence and impact risk scores for transmission station based on asset conditions

While the planning team received some feedback that 2017 schedule was compressed and therefore constrained some stakeholder resources given the changes to the plan that were introduced after the 2017-2018 Transmission decision was received, the steady state calendar is expected to provide sufficient time to execute planning process, including engage in required quality assurance and executive reviews.

Another key element of governance and oversight is the use of internal audits to review processes and ensure adherence to existing governance. Hydro One has a formal internal audit process that enables it to conduct reviews of key processes. Hydro One's internal audit process is robust and specific, including in identifying action items and tracking progress toward closure.

The legacy investment planning process was subject to an internal audit in 2015, with a follow-up audit conducted in 2017. In 2015, the audit found that asset analytics, the asset investment planning tool, and Hydro One's station centric approach were good initial foundations for the planning process, but the audit found controls ineffective ("Based on the specific areas reviewed, we conclude that controls are often ineffective and significant improvements are needed to ensure that a consistent investment planning process is used to produce a risk-based Investment Plan Proposal to address customer, asset and system needs"[2]). In a 2017 follow-up audit, the team found that Hydro One had made significant progress but introduced recommendations for how the planning team could continue to improve the planning process, which Hydro One's planning organization has begun addressing.

Hydro One is making continued efforts to ensure proper governance and oversight of the planning process. As mentioned above, Hydro One has introduced a steady state calendar that aims to address some of the key concerns around timing and resourcing that emerged in its first application of the new process in 2017. Hydro One is also implementing the recommendations from its internal audits to ensure it continues to close the gaps identified in those reviews.

V. Implications of our assessment for the upcoming transmission filing

On the whole, we assess that Hydro One's planning process will contribute to a robust Transmission System Plan. Hydro One has undertaken significant changes to its planning process that support a more rigorously developed and objective investment plan than in prior years. In particular, the general increase in rigor around scoring, calibration, and challenge sessions contributes to an improvement in plan quality. Some gaps in maturity, however, remain – specifically around the level to which investment options are informed by data, the timing of asset management strategy development, and the process to track outcomes and set interim targets to ensure plans meet Hydro One's five year goals. Of the key gaps identified, Hydro One has developed plans to continue to progress on these capabilities. In the areas where Hydro One is continuing to progress, we do not believe their current level of maturity significantly undermines the integrity of the plan being submitted.

[2] 2015 Internal Audit Documents – introduced during Hydro One's 2017-2018 Transmission application litigation

With respect to the use of data to inform investment options, Hydro One has made significant progress on by enlisting third party support to close the backlog in testing end of life assets. As a result, Hydro One is in a position similar to many utilities that have a large, aging asset base spread across a large geography – it has improved its use of data to develop investments, but 100% coverage for assets is not realistic. As a result, the judgment of experienced engineers is relied upon to help identify necessary investments.

In addition to continuing to improve the availability of data, Hydro One has continued to work to ensure comprehensive asset strategies guide its planning. Hydro One should ensure that its new asset management strategies are fully incorporated in the planning process for future cycles. When investment plans are not informed by asset management strategies, there can be a lack of consistency in the investment projects developed for submission to the plan, and the options developed may not address the most critical assets. Despite not having the revised asset management strategies fully in place ahead of planning, the team could rely on legacy documents to guide initial investment development that largely reflect Hydro One's longstanding philosophy on asset replacement and station-centric work planning. As a result, the lack of revised asset management strategies for all assets is unlikely to result in a misinformed plan and Hydro One's new strategies leave it well positioned for its next planning cycle.

Hydro One is continuing to progress towards being able to clearly link proposed plans to desired customer outcomes. In revising its risk scoring and prioritization process, Hydro One has been able to more clearly demonstrate how its investment plan mitigates risk. This enables Hydro One to make trade-offs between investments and different levels of funding based on risk as an outcome. Hydro One is continuing to evolve how it translates risk mitigation into meaningful customer outcomes. Hydro One has proposed 5 year targets for key scorecard outcomes that the investment plan is expected to help deliver, which were developed through a combination of quantitative and qualitative analysis to assess the expected results of the investment plan. This represents a strong initial effort to link plans to outcomes, though some gaps remain to being able to fully quantify the expected impact of plans. Doing so is difficult for almost any Transmission utility given the age of systems, availability of data and difficulty of predicting reliability performance on a redundant system. If Hydro One did not have a risk-based prioritization system that rates risk on dimensions linked to key outcomes (safety, reliability, and environmental risk), it would be more difficult to understand how Hydro One expects its plans to perform. However, with the combination of a rigorous risk-based prioritization and initial efforts to translate the plan into meaningful outcomes, we believe Hydro One has appropriate initial steps towards being able to predict the outcomes of its plan and deliver on its stated targets. Hydro One is continuing to progress on this effort by increasing the rigor of its predictive analytics to understand the impact investments have on key outcomes such as reliability, unsupplied energy and productivity. As a result, the relative lack of maturity on this dimension does not undermine the plan or the proposed outcomes it seeks to deliver.

VI. Conclusion and recommendations

In our assessment, Hydro One has made significant improvements in its planning process; has a process in place that is consistent with that of many utility peers; and excels in some areas of planning when compared to our leading peer set. Hydro One has strengthened the quality of its initial strategic inputs, improved its investment development and evaluation capabilities, introduced more rigorous scoring and calibration, and implemented a risk-based prioritization that improves the objectivity of its process. The resulting plan was thoroughly reviewed and will be supported by more rigorous execution monitoring and tracking than has existed in the past. While some gaps remain in ensuring assets decisions are guided by clear strategies and data, and linking plans rigorously to outcomes, none of these gaps significantly threaten the quality of the plan, and all are being addressed with specific initiatives.

As Hydro One continues to mature its planning capabilities towards a level consistent with best in class processes, they can consider continuing to focus on the following dimensions: continuing to strengthen the breadth and quality of data used to support the development of investment projects that address the most critical risks on the system; ensuring the process is guided by clear strategies that provide guidance on risk reduction and life cycle cost optimization, and strengthening long-term outcomes tracking and prediction capabilities to ensure consistent feedback between plan execution and future planning and goal-setting. Finally, Hydro One should ensure the processes and tools developed as part of the recent revisions to the process are continually reviewed and updated to ensure they continue to relevant to the organization and available to educate new participants in the process.

BCG leadership team bios

David Gee
Senior Partner and Managing director

David Gee is a Senior Partner and Managing director in the Washington, D.C. office of The Boston Consulting Group. Currently, he leads BCG's Energy and Petrochemicals practice in North America.

Prior to joining BCG, David was a Principal with McKinsey & Company where he led its U.S. refining and petrochemicals practice. He also was VP Strategic Planning for PG&E Corporation during the California Energy Crisis. Most recently, he served as President, North America for AES Corporation.
With more than 37 years' experience in the energy and chemicals industries, David's focus is on supporting a range of energy clients.

His principal areas of expertise include power generation strategy and operations; vertically integrated power and gas utilities; oil and gas exploration and production; and refining, petrochemicals, and downstream distribution.

Justin Dean
Partner and Managing director

Justin is a Partner and Managing Director working at the Boston Consulting Group. He leads the firm's Washington DC office.

Prior to joining BCG, Justin gained extensive experience in the energy sector (power generation, utilities, and sustainability) in consultant, project management and engineering capacities.

Justin is core member of BCG's energy sector practice and led a variety of projects within the power and utilities sector, including: Corporate Development / Due Diligence support, generation portfolio strategy assessment, T&D Ops improvement, and distributed generation/renewable/solar strategies. Justin also has significant transformational experience leading large Program Management Office (PMO) and Change Management efforts.

He holds a BS in mechanical engineering from the University of Virginia and an MBA from the Kellogg School of Management at Northwestern University.

Andrew Loh
Partner and Managing director

Andrew Loh is a Partner and Managing Director in the Toronto office of The Boston Consulting Group.

Andrew joined BCG in 2000 and is the Canadian Power & Gas Sector Leader and a core member of the Industrial Goods Practice where he has focused on Automation, Automotive, Engineering & Construction, and Mining & Metals. He has worked extensively on Strategy, Transformation, Corporate Development, Organizational, and Operations topics. Prior to joining BCG, Andrew worked as a research analyst at Merrill Lynch.

Andrew holds an Honors Bachelor of Commerce degree from Queen's University.

INVESTMENT REDIRECTION COMMITTEE – TERMS OF REFERENCE

1. PURPOSE

The purpose of the Investment Redirection Committee is to

- Oversee the redirection process whereby investment changes from the business plan are approved, documented, systemized and communicated to stakeholder line management to ensure that due process is followed when expenditure adjustments are made to capital, OM&A and in-service additions.

- Provide advice and direction on investment adjustments that are required to the business plan to address emerging business needs/risks or to seize opportunities related to the planning and execution of Hydro One's Investment Plan.

- Ensure integration and a common understanding across the enterprise regarding issues affecting the execution of Hydro One's business plan.

2. SCOPE

The Investment Redirection Committee shall advise regarding:

- The status of the release and execution of the Investment Plan over the business plan horizon including:
  - projects to fulfill customer and regulatory commitments or compliance to industry standards;
  - factors that are adversely affecting the timely release or execution of work; and
  - deviations from the approved Investment Plan and alternatives (including the redirection of future work releases) to address the deviations.
- The review and recommendation of adjustments to the execution of the approved Investment Plan, from Capital, OM&A and In-Service Addition perspectives, in response to prevailing industry and / or corporate circumstances[1].
- Redirection requirements and funding trade-offs which exceed the noted threshold (Appendix "A"), including those as a result of forecast updates, pending interim review of variances (IROVs) and business case summaries (BCS) with insufficient funding identified; while forecast changes will be identified retrospectively as redirection candidates, pending IROVs and BCS with insufficient funding shall be discussed, identified, and agreed to prospectively at the Redirection Committee prior to the approval.

[1] These adjustments will not change the current year's budget, which is approved annually by the Board of Directors; however approved redirection decisions will provide clear visibility to deviations from the approved budget and the resulting future year impacts.

- The management and review of capital and OM&A work programs and corporate common costs on a monthly basis; the redirection of OM&A must be balanced off with shareholder value with clear decisions to roll forward funds, redirect funds or bank funds (productivity).

Approval of redirection must be done in accordance with the EAR and adjustments must remain consistent with the funding levels, investment strategies, and performance outcomes approved by the Board of Directors.

When core committee members have insufficient EAR authority to approve redirection opportunities or the identified redirection impacts a business unit not represented on the committee (or invited as a guest), the COO shall table a redirection recommendation with the Executive Leadership Team (ELT) for approval at the Quarterly Capital Review meeting, or as required.

3. MEMBERSHIP

Membership of the Advisory Committee is outlined in Appendix "B".

IRC members may delegate an alternate person to attend the meetings.

Other staff may be invited to attend a portion of a meeting to provide briefings, updates or assistance on specific topics related to the release and execution of Hydro One's approved Investment Plan; this includes other members of the ELT (and their direct reports) who are not regularly represented at this forum to attend if/as items come up that are within their purview

4. REPORTING REQUIRMENTS

Following the review and recommendation of adjustments to the approved Investment Plan, investment level decisions will be documented and communicated, including the recommended change and rationale.

Updates on significant Investment Redirection Committee decisions, as well as recommendations related to reprioritization options that require an approval authority that exceeds that of members of the committee should be presented at the ELT's Quarterly Capital Review meeting.

5. MEETINGS and FORMAT

Meetings are scheduled once a month, typically during the fourth week of the month.

The output of the Redirection Committee Meeting shall be presented and discussed at the Operations Work Program Review and / or Monthly Operations Review, typically the second week of the subsequent month.

6. APPROVAL AND REVIEW OF TERMS OF REFERENCE

The terms of reference shall be approved by the committee.

Appendix "A"

Redirection Thresholds

Threshold	Description and Scope	Rationale
Tier 1	Individual investments with an absolute forecasted annual variance against the approved redirection budget greater than \$3M for Transmission and \$1M for Distribution for: • Capital Expenditures (net); • OM&A (net); or • In-service additions.	Aligned with the OEB filed Investment Summary Document (ISD) threshold: • Transmission = \$3M • Distribution = \$1M
Tier 2	Individual investments with an absolute forecasted annual variance against the approved redirection budget greater than \$1M within a driver with an absolute variance greater than \$3M for: • Capital Expenditures (net); • OM&A (net); or • In-service additions.	Aligned with the OEB filed Investment Summary Document (ISD) threshold: • Transmission = \$3M • Distribution = \$1M

David Gee

Partner and Managing Director,
Washington, DC

Profile summary

David was a Senior Partner in BCG's Washington, D.C. office and led its Energy Practice in North America. He was hired to build the practice. During his tenure, the practice grew over 35% a year and tripled its partnership. His personal client work focused on range of energy clients, with a primary focus on utilities. His areas of expertise include:

- Power generation strategy and operations
- Vertically integrated utilities including T&D
- Renewables and distributed energy resources
- He has also worked across all other parts of the energy value chain, e.g. oil & gas exploration and production, gas/midstream, oilfield services, refining and downstream operations, EPC
- He worked on a range of efforts including corporate and business unit strategy, operations, and transformation and organization

Prior experience and education

David has also had a long operating career at AES Corporation, PG&E Corporation, and Baker Hughes with responsibilities, which included:

- P&L for 13,000MW of generation capacity where he formulated and led a major process driven improvement program that reduced EFOR by ~50%
- Chairman of Indianapolis Power and Light, a vertically integrated utility
- Member of AES Executive Office which oversees AES' global business strategies and approves significant projects and development spending
- Served on a number of outside Boards of Directors, including C&D Technologies (NYSE), Great Point Energy (a VC backed coal gasification startup) and Greenhouse Gas Services (an AES/GE JV)

Prior to BCG David was a Principal with McKinsey and Company where he led their US Refining and Petrochemicals practice. He holds a M.S. in Finance from the Sloan School of Business at MIT and a B.S. in Chemical Engineering with highest distinction from the University of Virginia.

FORM A

Proceeding:

ACKNOWLEDGMENT OF EXPERT'S DUTY

1. My name is ....David Gee........(*name*). I live at 721 ShadyLake Lane..... (*city*), in the ....Vero Beach... (*province/state*) of ....Florida....... .

2. I have been engaged by or on behalf of ...Hydro One...... (*name of party/parties)* to provide evidence in relation to the above-noted proceeding before the Ontario Energy Board.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the Board may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

Date ....7 May 2018....

Signature

1.1 ATTACHMENT 15: BCG REPORT – IMPLEMENTATION OF RECOMMENDATIONS

In its decision in EB-2016-0160, the OEB directed Hydro One to conduct a review of its investment planning process. Hydro One engaged the Boston Consulting Group ("BCG") to conduct that analysis. The BCG report is provided at Attachment 14 of TSP Section 1.4. The study was completed on March 13, 2018. The study confirms that overall, Hydro One has implemented a consistent, thorough planning process that meets or exceeds expectations for a typical utility planning process in all areas. BCG identified three areas for Hydro One to focus on, to continue its progress towards having a best in class planning process. A description of each recommendation, as well as, a summary of Hydro One's progress regarding the implementation of these recommendations is provided below.

<u>Investment Development:</u>

- Continue to clear the backlog in condition testing for critical assets, and ensure that steady state plans allow for ongoing condition data gathering as assets age.

<u>Asset Strategies:</u>

- Continue to ensure asset strategies are in place to guide investment development and updated to ensure relevancy.

<u>Outcomes Tracking:</u>

- Continue the implementation of plans to use performance data to enhance outcome forecasting capabilities.
- Set interim annual targets for scorecard metrics to facilitate tracking towards five year goals outlined in Hydro One's regulatory scorecard.

Investment Development

Hydro One's transmission assets are replaced as condition warrants through rigorous testing. However, a backlog of asset condition testing has developed for assets such as conductors and shieldwire, where a large portion of the asset base is approaching it's Expected Service Life ("ESL").

Hydro One is working to address the backlog of condition data for these assets through the use of the Kinectrics LineVue inspection system, which traverses along a transmission line span to assess shieldwire or conductor condition. Data collected is used to estimate the remaining service life of the asset without the need for an outage or intrusive testing. The tool allows for a greater number of condition assessments per year and is more cost efficient compared to removing conductor and shieldwire samples for laboratory testing. In 2018, the LineVue system was used to assess the condition of over 2000 circuit km of conductor and 2000 circuit km of shieldwire. As a result, over 7% of Hydro One's conductor fleet and 6% of Hydro One's shieldwire fleet was assessed for condition. Hydro One will continue to complete these condition assessments annually.

To mitigate risks to customer supply and system reliability, asset condition assessment is prioritized for all assets that have surpassed their assessment criteria. Hydro One will continue to prioritize condition assessment to ensure that the assets with the highest risk are tested first. This will maximize the risk mitigated within Hydro One's proposed spending envelope.

Asset Strategies

Hydro One has detailed strategy documents for its transmission assets. These strategies formally document life cycle management for each asset. The maintenance and replacement procedures outlined in the strategy documents are incorporated in the investments proposed in Hydro One's TSP. To ensure that the asset strategy documents are kept up-to-date and accurate, the strategies are regularly reviewed. Since the Prior Proceeding, Hydro One has reviewed and revised strategy documents for the majority of Transmission Lines, Stations and Protection & Automation assets. These are among the most critical assets in Hydro One's transmission system. To further strengthen Hydro One's asset management capabilities, the development of new strategy documents for minor assets is currently underway.

Outcomes Tracking

Guided by the BCG recommendations outlined in the Investment Planning Process Review, Hydro One implemented a new process step in 2018, which included an upfront identification of corporate strategic direction, the establishment of interim targeted outcomes and more granular, strategic budget allocations based on operational, financial, regulatory and customer considerations at the beginning of the investment planning process.

Hydro One conducted a strategic budget (capital/OM&A) allocation at the beginning of the process, whereby the plan was divided into smaller, discrete budgets based on business unit, and then investments were subsequently prioritized within those budgets. The basis for this upfront allocation was the expenditure levels included in the previous plan, adjusted for efficiency gains and new strategic directions, as illustrated in Figure 1 below. This was done by business unit, resulting in nine allocations.

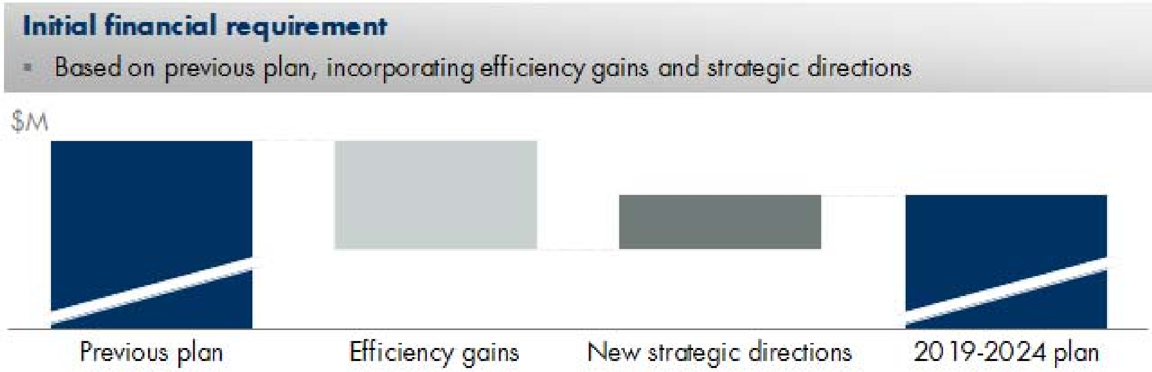

Figure 1 – Illustration of Initial Strategic Budget Allocation

The nine allocations are: Transmission Power Systems, Distribution Power Systems, System Operations, Facilities, Fleet, Information Solutions, Security, Customer Care and Health, Safety and Environment.

Along with each allocation, specific 6-year outcomes were identified. The outcomes relevant to Hydro One's Transmission Power Systems allocation are shown in Figure 2 below.

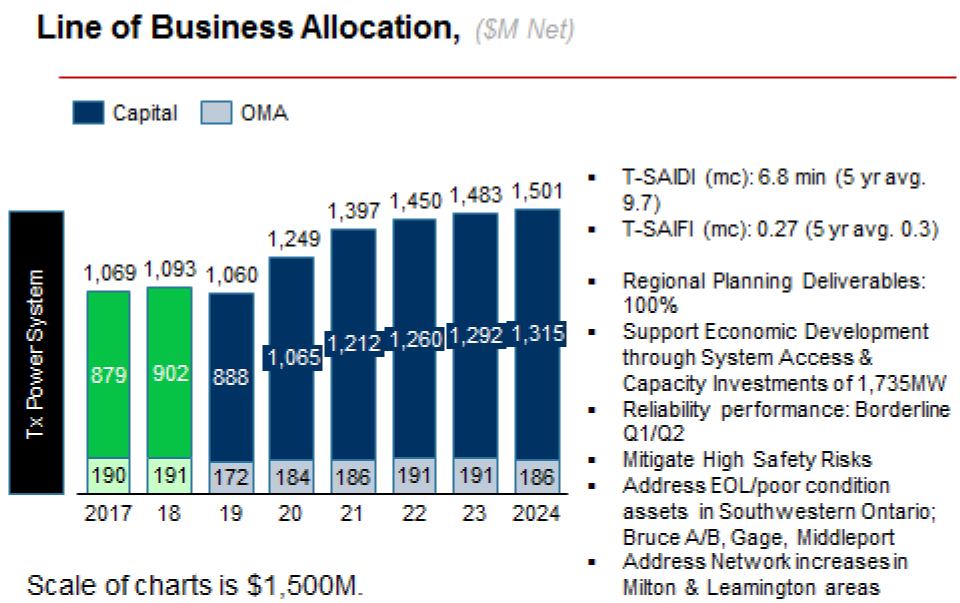

Figure 2 - Transmission Power System Outcomes

In addition to the end-of-plan outcomes, near-term, 1-year outcome metrics were identified, as outlined in Table 1 below. 1-year metrics were developed at the beginning of the Investment Planning Process and subsequently revised based on the approved plan, to form the various business unit scorecards that will be used for 2019. The establishment of interim targets supports the overall approach to long-term target setting and monitoring, ensuring that the long-term targets have updated targets annually.

Table 1 - 1-year Transmission Outcome Metrics

LOB	Initial 1-year Metrics
Transmission Power Systems	• Tx SAIDI (MC) - 8.7 minutes • Regional Infrastructure Planning Process Deliverables Met – 100%
System Operations	• Reliability of Service - 99.95% of key systems
Facilities	• Productivity Savings - $1M
Fleet	• Fleet Size – 7,200 asset count • Annual Utilization – 6.0M hours
Information Solutions	• Cost of Service - 4.5% of operating expenses • Reliability of Service – 99.53% critical system availability
Security	• Security Posture – Medium • NERC Compliance – 100%
Health, Safety and Environment	• Recordable rate - <1.0 incident per 200,000 hours

Through ongoing monitoring and analysis of the 2019 scorecard, Hydro One will be able to review the forecast to actual variance and use lessons learned to better inform future outcome forecasting.

Other Enhancement Opportunities

The BCG review noted other areas of improvement opportunity for Hydro One, including articulating the scope of the investment plan, improving consistency and objectivity of risk assessments, inclusion of execution feedback and mature cost estimates, plan execution and outcome tracking, and process timing. Hydro One has implemented the following improvements to address the various opportunities.

- **Define investment plan objectives – Scope of investment planning process defined & articulated:** Internally, Hydro One has stakeholdered and agreed to classification of expenditures between work program and corporate costs, based on the following definitions and characteristics:

Investment Plan (i.e. Work Program)	**Corporate Costs**
• All capital, consistent with SP0775 (Classification of Expenditures) is included in the investment plan • Directly related to the **sustainment, development and operation** of Hydro One's assets and systems • Typically "**direct**" costs associated with a specific cost object, such as a specific service, unit or activity (i.e. accomplishments), are included in the investment plan • Typically these costs are, to an extent, **variable** costs that vary in relation to the scope and volume of work planned.	• Provide shared **operational, strategic and/or policy support** to the organization • Typically "**indirect**" costs not associated with a specific cost object o **Administrative and general costs** / shared common services • Costs are allocated across multiple Hydro One entities (regulated and/or unregulated). • A portion of these costs may meet the criteria for capitalization through their support of the capital work program.

- **Establish criteria, score and calibrate – Risks calibrated consistently** - Hydro One undertook a new approach to bring about more consistency and remove subjectivity with investment scoring through a dedicated team which discussed and scored all of the investments collaboratively, leveraging other subject matter experts, on an as needed basis. This was done for Transmission Power Systems and Distribution Power Systems. This approach improved the consistency of risk assessments across asset disciplines, and provided an opportunity to conduct a quality assurance ("QA") review in parallel with scoring. The other business unit allocations held similar review sessions for investment calibration and QA.

- **Establish criteria, score and calibrate – Investments evaluated against risk criteria** - The Investment Planning process now involves the Execution

Organizations at the calibration stage, which is far earlier in the process than before. Participation earlier in the process provides greater visibility and puts the Executing Organizations in a better position to provide feedback and input to the Investment Plans.

- **Develop investment plan options – Detailed estimates included for initial plan timeframe** - As noted in B-02-01, a structured project stage gate process has been implemented, which requires projects to pass stage gates before moving to the next phase in the capital delivery process. Projects which pass stage gates are considered able to meet the schedule and cost outcomes presented within the estimate accuracy bands for the current level of project development.

- **Execute plan and track outcomes – Executed investments align to finalized investment plan** - The Investment Redirection Committee, as described in B-02-01, tracks the performance of the in-year work program against budget, which provides the operations leadership team an opportunity to understand month-to-month variances as well as the impacts on the annual budget and outcomes. Variances to capital expenditures, in-service additions and key accomplishment units are included in this monthly review.

- **Governance and oversight – Sufficient time and resources allocated to IPP -** Under steady state, all of the timing related issues identified in the BCG review will no longer be an issue.

List of Tables

1 Introduction

HONI periodically submits rates filings to the Ontario Energy Board. These submissions *inter alia* detail HONI's key transmission asset needs based on asset age, condition assessment, performance and other relevant factors that lead to asset replacement/refurbishment. HONI has expressed a strong need for a third party to provide independent recommendations to help support their case to the Ontario Energy Board, particularly in the area of electromechanical, solid-state and digital/numerical relays – transmission station assets that play a critical role in ensuring safe and reliable operation of the transmission system. Historically, HONI has replaced 450 relays per year on average, where population age exceeding the expected service life (ESL) is the leading factor triggering analysis as to whether the population must be maintained for a further number of years or replaced.

Table 1-1 shows the breakdown of HONI's relay systems as at close of 2018, which excludes planned replacements for 2019. Solid-state relays carry the highest priority, as the age of 91% of this population of 2nd generation relays currently exceeds ESL; this represents 55% of HONI's total relay inventory that exceeds ESL (excluding planned replacements for 2019).

Table 1-1: Breakdown of HONI's Relay Systems (as at close of 2018)

	ESL [years]	**Average Age** [years]	**Age ≤ ESL**		**Age > ESL**		**Total**	
Electro-mech.	45	38.8	2,289	63%	1,322	37%	3,611	100%
Solid-state	25	35.3	191	9%	1,835	91%	2,026	100%
Digital/numerical	20	8.7	6,663	97%	206	3%	6,869	100%
Total		**27.6**	**9,501**		**3,363**		**12,506**	

↓

Age > ESL	
1,322	39%
1,835	55%
206	6%
3,363	**100%**

Moreover, in recent work completed by Kinectrics for CEATI, an ESL range of 13 to 19 years for solid-state relays emerged based on weighted utility survey and industry review results [2]. Similarly, a range of 13 to 20 years for digital/numerical relays emerged from the CEATI work. Indeed, HONI indicates that the traditional ESL figure of 25 years for digital/numerical relays is considered by some in industry to be overstated, with 17 years being more appropriate given that these relays reach obsolescence well before hardware reliability becomes a concern. Nevertheless, HONI is also concerned about the longevity of at least one of these digital/numerical relay models in its inventory, following reliability performance issues.

The main objective in this project was to assess the expected service life (ESL) for two relay models in HONI's inventory using accelerated life testing. The information from this assessment is to be used as an input by HONI asset managers for their asset life cycle strategy.

2 Scope

For the purposes of ESL assessment, HONI selected the relay models shown in Table 2-1 and provided samples of each – according to availability – as detailed in Table 2-2 and Table 2-3. The models were selected to represent the M series of solid state relays and the UR family of digital/numerical relays manufactured by GEC and GE respectively.

Table 2-1: Selected Relay Models

Model	Function	Technology	Manufacturer	Average Service Life [years]
MCGG 22	Overcurrent relay for phase and earth faults	Solid-state	GEC Measurements	20
D60	Line distance relay	Digital/numerical	GE	15

Totals		**5**	**5**	**5**	**5**	**13**	**4**	**4**

For the MCGG 22 relays, it is clear that the sample size is eight. For the D60 relays, faulty in-service modules would be replaced with spares and so reliability targets should be applied at module level; therefore, although the nominal sample size is five, it is as low as four and as high as 13 at module level.

The scope of work set out in Kinectrics quote Q418-015-KOE-HON-REV02, was as follows:

- For each selected relay model, determine reliability target and confidence level subject to sample size
- Ascertain component types / categories and their expected failure mechanisms via component-level analysis of one unit of each selected relay model to determine range of acceleration factors, and plan an appropriate test regime
- Conduct accelerated life test – pre-qualifying test, life-test cycles (including monitoring and post-cycle tests), post-life test – on units of the selected relay models
- Results analysis and reporting

In this report, an overview of reliability concepts and testing is first provided, followed by sections describing methodology, results, conclusions and recommendations.

3 Reliability Concepts and Testing – An Overview

A modern definition of reliability may be expressed as follows [3]:

> *"Reliability is the probability of a product performing its intended function over its specified period of usage, and under specified operating conditions, in a manner that meets or exceeds customer expectations."*

The following subsections describe some of the basic concepts used in reliability engineering [4] [5] [6].

3.1 Reliability metrics

The reliability of a population of like devices at time *t* may be expressed as:

$$R(t) = \frac{N(t)}{N_0}$$

where *N(t)* is the number of surviving devices at time *t* and N_0 is the starting population. Similarly, the population fraction failing by time *t* may be expressed as:

$$F(t) = \frac{N_0 - N(t)}{N_0} = 1 - \frac{N(t)}{N_0} = 1 - R(t)$$

and this is the cumulative distribution function (cdf). The probability density function (pdf) is defined as:

$$f(t) = \frac{dF(t)}{dt}$$

which corresponds to a histogram of the population lifetimes or times-to-failure (TTF). Then the instantaneous failure rate at time *t*, or hazard rate function, may be defined as:

$$h(t) = \frac{f(t)}{1 - F(t)} = \frac{f(t)}{R(t)}$$

and is a measure of “proneness” to failure [4] as a function of population age. Its integral is the cumulative hazard function:

$$H(t) = \int_{-\infty}^{t} h(\tau) d\tau$$

which is related to *R(t)* as follows:

$$R(t) = e^{-H(t)}$$

Finally, the mean life or mean-time-to-failure (MTTF) is defined as:

$$MTTF = E(TTF) = \int_{-\infty}^{\infty} t \cdot f(t)\, dt = \int_{-\infty}^{\infty} R(t)\, dt$$

where *E(TTF)* is the expectation (or mean or average) of the distribution but does *not* mean “anticipated life.” [4]

The above brief overview of reliability metrics provides the ground-work for further discussion.

3.2 Series-system model

Considering the complexity of a solid-state or digital/numerical relay, it is expected that they will have multiple, *M*, competing failure modes. Then, for simplicity, the reliability model of the device is a series system if its life is the smallest of the *M* potential times to failure, i.e., a device fails when the first failure mode occurs. This is also known as a “weakest link system”. Furthermore, if the *M* failure modes are statistically independent, then the product rule for reliability applies such that:

$$R(t) = R_1(t)R_2(t)\dots R_M(t) = e^{-H_1(t)}e^{-H_2(t)}\dots e^{-H_M(t)} = e^{-H(t)}$$

from which the following addition rule and its derivative are derived:

$$H(t) = H_1(t) + H_2(t) + \cdots + H_M(t)$$

$$h(t) = h_1(t) + h_2(t) + \cdots + h_M(t)$$

Finally, the composite probability density function (pdf) may then be expressed as:

$$f(t) = [h_1(t) + h_2(t) + \cdots + h_M(t)]R_1(t)R_2(t)\dots R_M(t)$$

In this work it is assumed that reliability models of relays are series systems and that the *M* failure modes are statistically independent.

3.3 Bathtub curve

Consider a large population of like devices with a <u>single</u> failure mode. Then the hazard rate may be expressed as a continuous Weibull function:

$$h(t) = \frac{\beta}{\eta}\left(\frac{t}{\eta}\right)^{\beta-1}$$

where η is the characteristic life – the time by which 63.2% of the population may be expected to fail due to the single failure mode – and β is the shape parameter, as follows:

- $\beta < 1$: Decreasing failure rate (DFR) due to design, manufacturing and component defects
- $\beta = 1$: Constant failure rate (CFR) due to random causes
- $\beta > 1$: Increasing failure rate (IFR) due to wear-out of components

According to the hazard rate addition rule, a composite Weibull hazard rate function – describing the bathtub curve – may be expressed, for multiple *M* competing failure modes, as:

$$h(t) = \sum_{\substack{j=1 \\ \beta_j<1}}^{K} \frac{\beta_j}{\eta_j}\left(\frac{t}{\eta_j}\right)^{\beta_j-1} + \sum_{\substack{j=K+1 \\ \beta_j=1}}^{L} \frac{\beta_j}{\eta_j}\left(\frac{t}{\eta_j}\right)^{\beta_j-1} + \sum_{\substack{j=L+1 \\ \beta_j>1}}^{M} \frac{\beta_j}{\eta_j}\left(\frac{t}{\eta_j}\right)^{\beta_j-1}$$

where $t \geq 0$. Note that the centre summation reduces to a simple sum of constant failure rates, i.e., $\lambda = \lambda_{K+1} + \lambda_{K+2} + \ldots + \lambda_L$, because $\beta_j = 1$. An example bathtub curve is shown in Figure 3-1.

Each of the *M* failure modes acts over the entire time-scale but is dominant in its respective region so that the hazard rate is approximately constant – at 0.25% per year in this example – within the "Mid-life" failure region, as shown in Figure 3-1.

For the bathtub curve shown in Figure 3-1, the associated probability density function (pdf), i.e., *f(t)*, and cumulative distribution function (cdf), i.e., *F(t)*, are shown respectively in Figure 3-2 and Figure 3-3 on the same scale, where the cdf is simply the area under the pdf as a function of *t*.

3.4 Expected service life (ESL)

The expected service life (ESL) of a large population of like devices is the statistical expectation (or prediction) of its actual end-of-life (EOL) or age at which the population must be reviewed or may reach the end of its useful life. The EOL may be defined in various ways:

- Population age at which the hazard rate – as per the "bath-tub" curve – exceeds (and continues to exceed) a predetermined threshold, e.g., 0.5% per year (see Figure 3-1)
- Population age at which the cumulative number of failed devices exceeds a predetermined percentage of the original population, e.g., 6% (see Figure 3-3)
- Population age at which the mean-time-to-failure (MTTF) of devices – since population inception – peaks and starts to fall off

Whereas the above may be monitored as the population ages, there is value in estimating EOL well before it is reached to allow planning and budgeting for replacement or refurbishment of the population.

3.5 Accelerated life testing

Accelerated life testing (ALT) may be employed to estimate EOL, where time-to-failure for each failure mode is accelerated by subjecting a sample from the population of like devices to elevated stress compared to normal use conditions.

For simplicity and validity, a single accelerating stress is recommended [7], and temperature is the most-often used overstress for electronic devices – such as solid-state relays and digital/numerical relays – as per the Arrhenius reaction rate model:

$$AF = \frac{TTF_U}{TTF_S} = exp\left[\frac{E_a}{k}\left(\frac{1}{T_U} - \frac{1}{T_S}\right)\right]$$

where *AF* is the life acceleration factor, *TTF* is time-to-failure, *T* is temperature in K, *k* is Boltzmann's constant (8.617×10^{-5} eV/K) and E_a is the activation energy (in the range 0.3 to 1.5 eV depending on component type and failure mode). Subscripts "U" and "S" refer respectively to normal-use and stress.

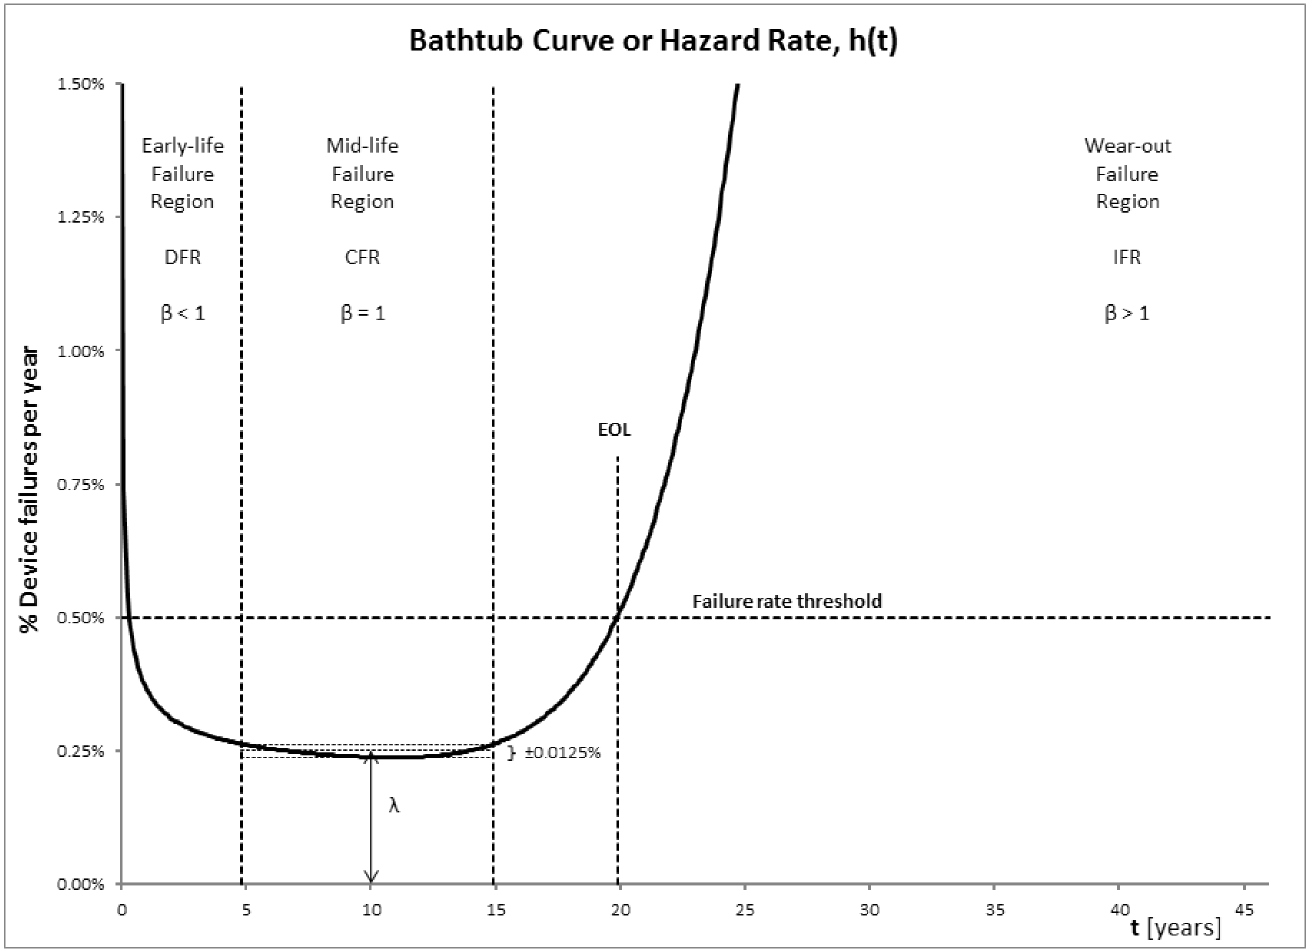

Figure 3-1: Hazard Rate "Bathtub" Curve

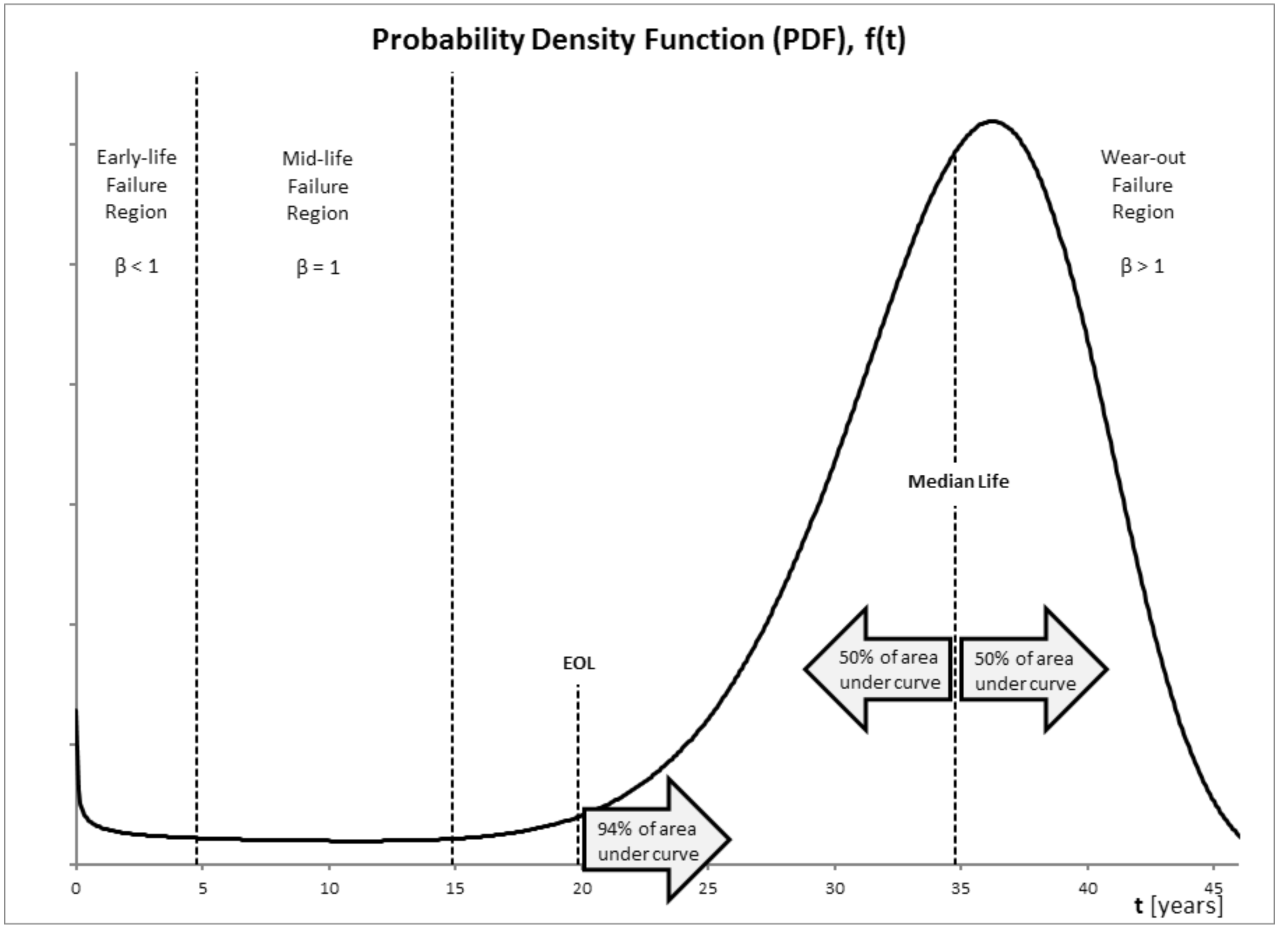

Figure 3-2: Probability Density Function (pdf)

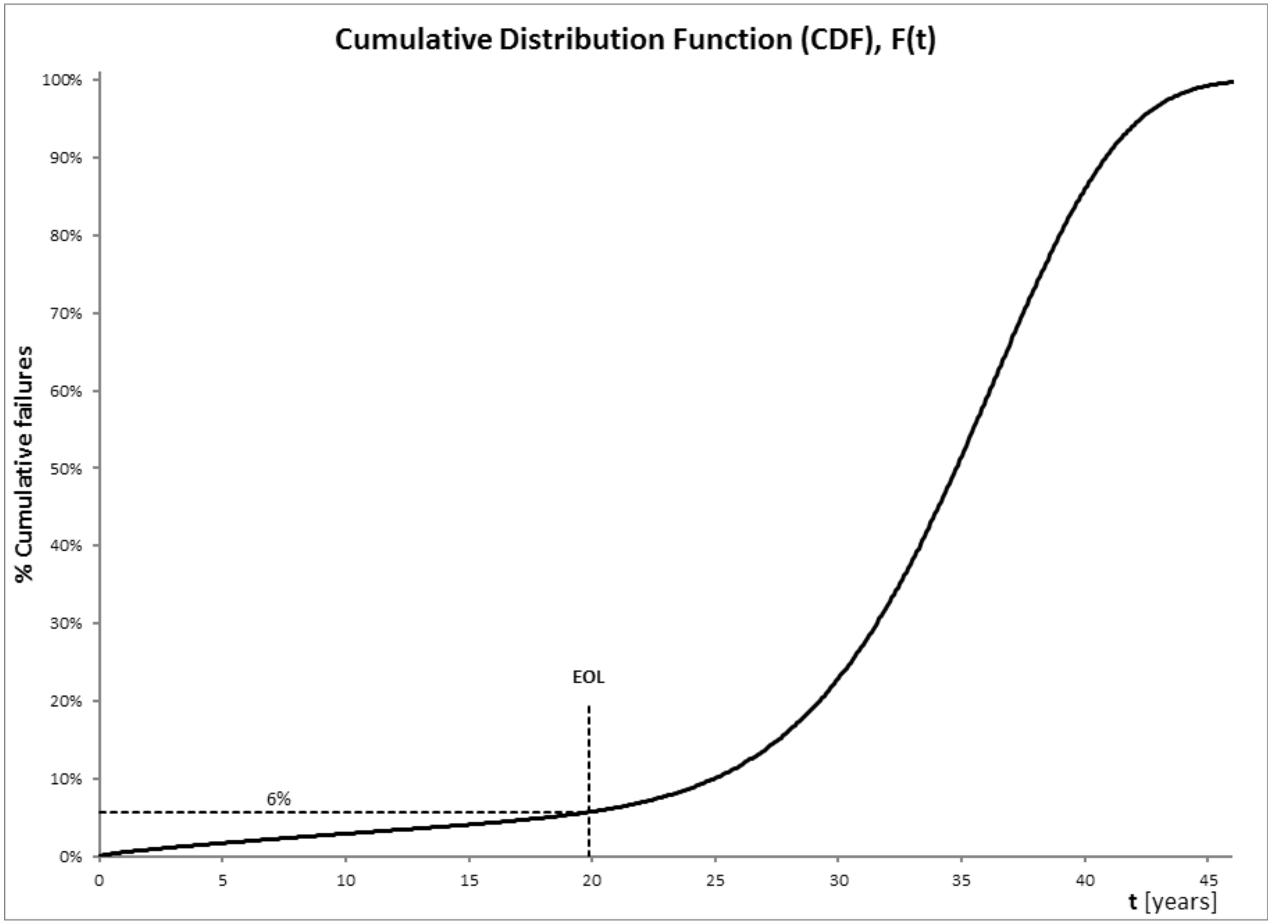

Figure 3-3: Cumulative Distribution Function (cdf)

It is important to note that each independent failure mode will have a different *AF*, as determined by E_a. In a typical accelerated life test, T_S is selected to be the maximum-allowable temperature as dictated by the component with the lowest temperature specification, e.g., 85 °C (+273), so as to prevent unrealistic component failure, and T_U is taken to be the average temperature for the population of devices, e.g., 24 °C (+273).

3.5.1 Ideal (parametric) approach

The net effect on the bathtub curve for the sample of devices is that the failure rate is amplified and the time-scale is compressed, and this must be "translated" to normal use conditions for each failure mode according to:

$$AF = \frac{\eta_U}{\eta_S}$$

under the assumption that β remains unchanged for each failure mode.

However, it is only possible to create a faithful copy of the bathtub curve for the population if:

- The sample comprises new devices
- The sample size is sufficiently large, i.e., ≥ 30 units, as per the Central Limit Theorem

The former is not a serious concern because the earlier part of the bathtub curve is not really required; the latter, however, is problematic due to the limited number of relays that can be made available for destructive testing.

3.5.2 Pragmatic (non-parametric) approach

In the non-parametric testing approach, the underlying failure distribution remains unknown. Suppose that 10 identical relays are subjected to an accelerated life test and two fail – same failure mode – by test time t_1. Then it can be stated that relay reliability under normal use conditions at time *AF* x t_1 is 8/10 or $R(AF \text{ x } t_1) = 0.8$, but this applies to the sample of relays only. Nevertheless, by using the cumulative binomial distribution that describes success/failure events, it is still possible to obtain a lower boundary on the reliability of the population of relays despite the underlying failure distribution being unknown. For instance, assuming a single-ended confidence C = 90%, the lower boundary on reliability at time *AF* x t_1 may be shown to be $R_L(AF \text{ x } t_1) = 0.55$ for the population of relays.

Now suppose that none of the 10 relays had failed by test time t_1. Then $R(AF \text{ x } t_1) = 1$ and, assuming a single-ended confidence C = 90%, the lower boundary on reliability under normal use conditions at time *AF* x t_1 may be shown to be $R_L(AF \text{ x } t_1) = 0.8$ for the population of relays. Therefore, a useful reliability metric can still be obtained for a greatly reduced sample size.

Furthermore, the lower boundary R_L may be used as a reliability target for the population of relays, such that the probability, that the reliability of the population of relays at time *AF* x t_1 is at least equal to the target reliability, is equal to the single-tailed confidence C. In reliability (probability) notation, this may be represented as follows:

$$Pr[R(AF \times t_1) \geq R_L] = C$$

The cumulative binomial distribution[1] governs the relationship between R_L, C, sample size and the number of allowable failures; this is shown in Table 3-1 for zero allowable failures – also referred to as *success testing*, which yields minimum sample sizes. As expected, minimum sample size increases with increasing R_L and/or C, and there is a trade-off between R_L and C for any given sample size.

Table 3-1: Minimum Sample Size as a Function of R_L and C

Minimum sample size (1)		Confidence level, C (2)				
		80%	85%	90%	95%	99%
Reliability target, R_L	0.7	5	6	7	9	13
	0.75	6	7	8	11	16
	0.8	7	9	10	13	21
	0.85	10	12	14	18	28
	0.9	15	18	22	28	44
	0.95	32	37	45	58	90
	0.99	160	189	229	298	458

Notes:

1) Required sample size for zero allowable failures by time t_1; larger sample sizes are required for non-zero allowable failures
2) Single-tailed confidence

The results, however, would have no bearing on EOL, unless it was known that the population age is approaching EOL. Then it is possible to assess the survival (reliability) of the population for the next *Y* years given that it has already survived *X* years, i.e., $R(Y|X)$ or:

$$Pr[R(AF \times t_1|X) \geq R_L] = C$$

[1] The F-distribution, i.e., Fisher-Snedecor distribution, gives the same results and is easier to use for success/failure calculations.

Note that this applies to each failure mode with its unique *AF*. Therefore, it is necessary to compile a bill of materials (BOM) for each relay model in order to categorise relay components – resistors types, capacitor types, semiconductors, integrated circuits, etc. – according to activation energy as per published values [8]. Then for each component category, the *AF* may be calculated to yield a t_1 milestone in the test at which it will reach its target life, i.e., $X + Y = X + AF \times t_1$. As each component category milestone is reached, the test is halted temporarily to check whether the test units are still functional. In case of component failure, if it has not met its target life according to component category, then zero allowable failures has been exceeded and the test is considered complete; otherwise, testing must continue until all component categories have reached the target life.

4 Test Preparation

4.1 Reliability target

Table 4-1 shows the chosen reliability targets with associated single-tailed confidence levels. It may be noted that the allowable number of failures, N_f, for the Digital I/O 6U modules is 2; this allows a consistent reliability target for the overall D60 relay despite the considerably larger sample size of the Digital I/O 6U modules.

Table 4-1: Reliability Target

Relay	Module	Sample Size	Reliability Target, R_L	Single-tailed Confidence, C	Allowable No. of Failures, N_f
MCGG 22	-	8	0.75	90%	0
D60	All except below	5	0.7	80%	0
	Digital I/O 6U	13	0.7	80%	2
	Digital I/O 4C MOD	4	~ 0.7	80%	0
	Digital I/O 6T	4	~ 0.7	80%	0

Moreover, given that the MCGG 22 and D60 relay populations are both within about five years of the deemed ESL of 25 and 20 years respectively, Y = 5 years was selected such that:

$$Pr[R(5|20) \geq\ 0.75] = 90\%$$

$$Pr[R(5|15) \geq\ 0.7] = 80\%$$

are the reliability targets in reliability (probability) notation for MCGG 22 and D60 relays respectively.

In other words, given the available sample of MCGG 22 relays, the goal of accelerated life testing in this project was to demonstrate that the reliability of HONI's population of MCGG 22 relays over the next five years is at least equal to a modest target of 0.75, with a probability of 90%.

Similarly, given the available sample of D60 relays, the goal of accelerated life testing in this project was to demonstrate that the reliability of HONI's population of D60 relays over the next five years is at least equal to a modest target of 0.7, with a probability of 80%.

4.2 Bill of materials

MCGG 22 relay #8 and D60 relay #5 were each disassembled to compile a bill of materials (BOM) for components affected by temperature [8], as summarised in Table 4-2.

Table 4-2: BOM Summary

Component Type	MCGG 22	D60
Resistors – metal film, wirewound, trimpot	64	891
Capacitors – ceramic, metallised polyester, tantalum, electrolytic, etc.	26	711
Semiconductors – switching, power & zener diodes, LED, transistor, FET, etc.	37	429
Integrated circuits – logic, opto-isolator, microcontroller, EEPROM, etc.	6	229
Miscellaneous – inductor, relay, transformer, LCD, etc.	6	112
Totals	**139**	**2,372**

The D60 relay is more than an order of magnitude more complex than the MCGG relay, which comprises only discrete components, whereas most of the components in the D60 are surface-mount devices (SMDs), which are more difficult to identify.

4.3 Test milestones

The operating manual for the D60 relays indicates a maximum operating temperature of 85 °C [9] but the operating manual for the MCGG 22 relays is mute on this [10]. For the latter, data sheets for components listed in the BOM were consulted and it was found that one of the integrated circuits had a maximum operating temperature of 70 °C. Therefore, the MCGG 22 and D60 relays had to be placed in separate ovens.

The average operating temperature during normal use was deemed to be 24 °C [11] and, aided by component data sheets, an activation energy, E_a, value was obtained for each of the component categories [8] in the relay models. Using the Arrhenius reaction rate equation, an acceleration factor, AF, was calculated for each component category, allowing the required heat-soak for Y = 5 years to be calculated in each case. This is shown in descending AF order in Table 4-3 and Table 4-4 for the respective relay models.

Table 4-3: Required and Rationalised Heat-soak Periods for MCGG 22

Component Category	AF @ 70 °C	Required Heat Soak for Y = 5 years		Heat-Soak		
		Per category [months]	Increment [months]	Period	Duration [months]	Cumulative Test Length [months]
Aluminium electrolytic capacitor	21.3	2.8	2.8	1	2.9	2.9
LED	20.4	2.9	0.1			
Metallised polyester capacitor	14.2	4.2	1.3	2	1.3	4.2
Zener diode, transistor, various ICs	6.6	9.1	4.9	3	5.3	9.5
Switching diode, rectifier diode	6.4	9.4	0.3			
Ceramic capacitor	6.3	9.5	0.1			
Resistors	2.9	20.7	11.2	4	11.2	20.7
Relays	2.5	24.0	3.3	5	3.3	24.0
Inductors, transformers	1.6	37.5	13.5	6	13.5	37.5

Table 4-4: Required and Rationalised Heat-soak Periods for D60

Component Category	AF @ 85 °C	Required Heat Soak for Y = 5 years		Heat-Soak		
		Per category [months]	Increment [months]	Period	Duration [months]	Cumulative Test Length [months]
Aluminium electrolytic capacitor	58.3	1.0	1.0	1	1.0	1.0
LED, LCD	46.5	1.3	0.3	2	1.2	2.2
Metallised polyester capacitor	32.4	1.9	0.6			
EEPROM, CPLD	26.8	2.2	0.3			
Opto-coupler	19.2	3.1	0.9	3	1.2	3.4
Tantalum capacitor	17.6	3.4	0.3			
Zener diode, transistor, various ICs	12.6	4.8	1.4	4	1.4	4.8
Switching diode, rectifier diode	10.6	5.7	0.9	5	1.0	5.8
Ceramic capacitor	10.3	5.8	0.1			
Resistors	4.1	14.6	8.8	6	8.8	14.6
Relays	3.2	18.8	4.2	7	4.2	18.8
Inductors, transformers, chokes	2.4	25.0	6.2	8	6.2	25.0

Clearly, in an accelerated life test, the aluminium electrolytic capacitor component category will reach *Y* = 5 years before the LED/LCD component category, and so on. For both MCGG 22 and D60 models, the required heat soak for resistors, relays, inductors, transformers and chokes is considerably longer than that for other component categories – and therefore impractical; however, the need for any subsequent heat soaking depends on whether the target reliability has been met at that point.

For testing efficiency, increments less than one month were combined with other increments, resulting in the rationalised heat-soak periods shown at right in the tables. Note that the LED/LCD component category for the D60 relays was not combined with the aluminium electrolytic capacitor component category, because it was deemed more important to detect failure of the latter within its accelerated 5-year period. Provision was made for three and five heat-soak periods respectively for the MCGG 22 and D60 models.

Prior to any heat-soaking, all relays were subjected to functional performance testing to confirm that the relays were in working order and operating within specification (refer to Appendix B and Appendix C for extracts from Omicron test set).

In order to avoid thermal shock to the relays, each heat-soak period commenced with the oven ramping up to test temperature at a rate of 20 °C/hour and ended with the oven ramping down to ambient temperature at a rate of 20 °C/hour. Different ovens were used according to availability for both relay models. Figure 4-1 and Figure 4-2 show the MCGG 22 and D60 relays installed in their respective ovens. Throughout the heat-soak periods the MCGG 22 relays and D60 relays were powered by 110 Vdc and 120 Vac respectively.

Figure 4-1: MCGG 22 Relays in Oven

Figure 4-2: D60 Relays in Oven

At the end of each heat-soak period, the relays were subjected to functional performance testing to confirm that they were in working order and operating within specification, with decision points applied as follows:

MCGG 22 relays

Decision Point:
IF number of relevant failures > N_f THEN
R(5|20) < 0.75 with 90% confidence, i.e., reliability target is <u>not</u> met for further 5 years
GOTO Final Analysis and Test Report
ELSE
GOTO Next Heat-soak Period
END IF

Note: N_f = 0 based on sample size of eight; a relevant failure is the failure of a component before it has aged a further 5 years through accelerated life testing.

D60 relays

Decision Point:
IF number of relevant failures > N_f THEN
R(5|15) < 0.7 with 80% confidence, i.e., reliability target is not met for further 5 years
GOTO Final Analysis and Test Report
ELSE
GOTO Next Heat-soak Period
END IF

Notes: N_f depends on the applicable module; a relevant failure is the failure of a component before it has aged a further 5 years through accelerated life testing.

5 MCGG 22 Test Results

The sample of eight MCGG 22 relays completed Heat-soak Period 1 (HP1) without failure, whereas a miniature relay failure (within one of the relays) occurred during HP2. However, it is understood that the type of failure – as discussed further below – is atypical and may therefore not be relevant. Nevertheless, in order to err on the side of caution, it was decided by HONI and Kinectrics to supplement the eight relays with another six relays (refer to Table 5-1), so as to allow for one relay failure, i.e., N_f = 1, for an unchanged reliability target.

Table 5-1: MCGG 22 Relays – Supplemental (6 Units)

#	S/N
9	226991A
10	226945A
11	226946A
12	226958A
13	226990A
14	226978A

Whilst the original eight relays were subjected to HP3, the six supplemental relays were subjected to HP1, HP2 and a portion of HP3. The following subsections discuss the results for the combined sample of 14 units for each heat-soak period.

5.1 Heat-soak period 1: 3.0 months (14 units)

At the end of this heat-soak period, all relays were found to be in working order and operating according to specification. Therefore, the aluminium electrolytic capacitors and LEDs in the 14 units have reached the target 25 years without failure.

5.2 Heat-soak period 2: 1.3 months (14 units)

At the end of this heat-soak period, all relays (except Relay #5) were found to be in working order and operating according to specification. For Relay #5, the “phase-fault time-delayed trip output” was found to be faulty. The relay was disassembled and subjected to component analysis, which revealed that the coil of miniature relay RL1 (refer to Figure 5-1) was open-circuited. Its drive circuitry (free-wheeling diode D9, pnp transistor TR3, bias resistor R2 and emitter diode D2) were all inspected/tested and found to be in good working order, confirming that the failure of the miniature relay was not part of a chain of failure events.

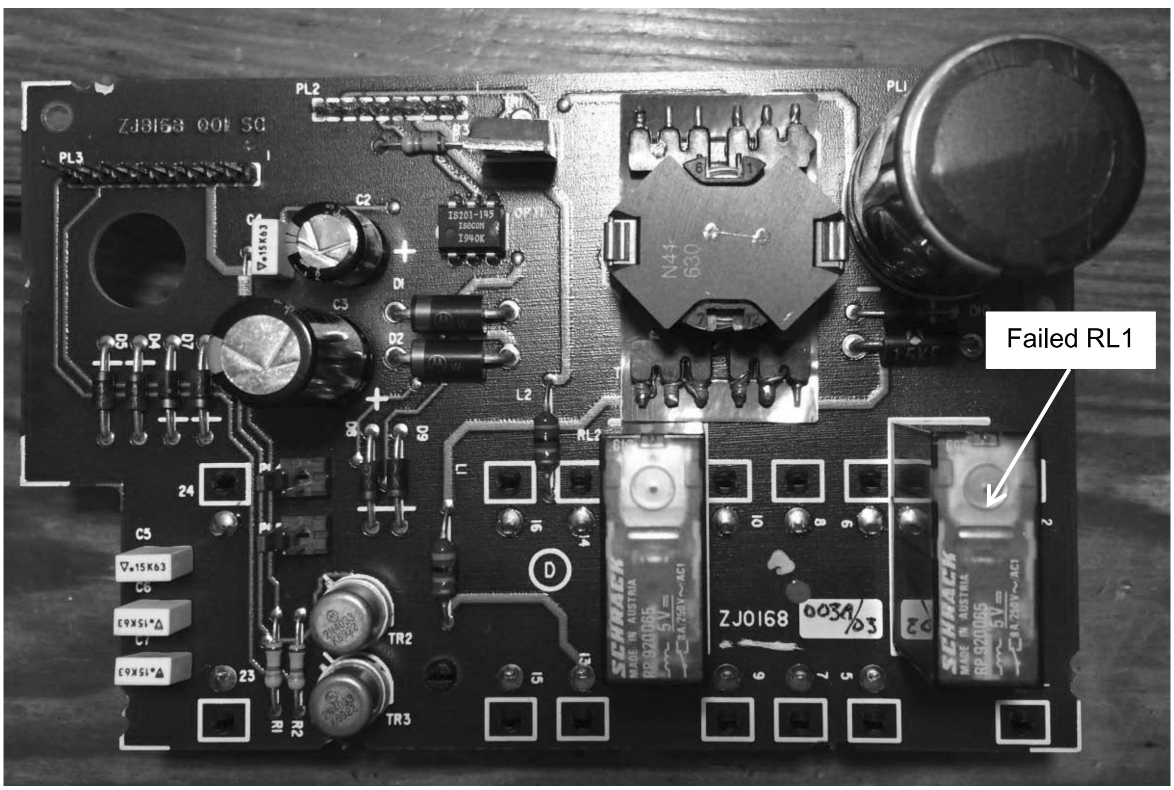

Figure 5-1: PSIO Board with Faulty Miniature Relay RL1

Miniature relay RL1 was de-soldered from the printed circuit board and carefully dissected using a cutting wheel. Via microscopic analysis, the magnet wire was found to be fractured right at the solder joint on the terminal, and it was confirmed that the coil itself was undamaged. Further analysis of the failure site, including scanning electron microscopy (SEM), would be required to ascertain the probable failure cause.

With modest *AF* = 2.5, miniature relay RL1 failed within the range[2] 20.6 to 20.9 years, which is significantly shorter than the target 25 years. However, as mentioned above, this type of failure is considered atypical and may not be relevant. Moreover, based on the sample of 14 relays, the single failure (thus far) of this type is acceptable in terms of target reliability.

Otherwise, the metallised polyester capacitors in the 14 units have reached the target 25 years without failure.

5.3 Heat-soak period 3: 5.4 months (8 units)

At the end of this heat-soak period, all relays (except Relay #3) were found to be in working order and operating according to specification. For Relay #3, some relay settings (via dip switches on the front panel) could not be achieved. The relay was opened and the continuity of each of 22 dip switches was checked in the open and closed states using a digital multimeter. In one case, the continuity value was the same whether open or closed until toggling greatly reduced the "closed" value in line with neighboring switches, and in another, toggling substantially reduced the "closed" value in line with neighbouring switches; both point to oxidation of switch contacts. The relay was retested and found to be in working order.

Otherwise, the zener diodes, transistors, various integrated circuits, switching diodes, rectifier diodes and ceramic capacitors in the eight units have reached the target 25 years without failure.

Note: By the end of HP3 for the original eight units, HP3 for the six supplemental units was only 18.5% complete. These units were also found to be in working order and operating according to specification. Therefore, pending any further accelerated life testing of the six supplemental units to complete HP3, no further consideration is required, i.e., the decision pertaining to HP3 is currently dependent on the original eight units only.

6 D60 Test Results

6.1 Heat-soak period 1: 1.0 month (5 units)

At the end of this heat-soak period, all relays were found to be in working order and operating according to specification. It was noted that darkening of the dot matrix LCD had occurred (refer to Figure 6-1); this is typical for LCDs subjected to high heat, and was therefore not considered relevant.

---

[2] 20 + 2.5 x 2.9/12 = 20.6 and 20.6 + 2.5 x 1.3/12 = 20.9

Figure 6-1: Example of Darkening of D60 LCD

Otherwise, the aluminium electrolytic capacitors have reached the target 20 years without failure.

6.2 Heat-soak period 2: 1.2 months (5 units)

At the end of this heat-soak period, all relays were found to be in working order and operating according to specification. Therefore, the LEDs, LCDs, metallised polyester capacitors, EEPROMs and CPLDs have reached the target 20 years without failure.

6.3 Heat-soak period 3: 1.2 months (5 units)

At the end of this heat-soak period, all relays were found to be in working order and operating according to specification. Therefore, the opto-couplers and tantalum capacitors have reached the target 20 years without failure.

6.4 Heat-soak period 4: 1.4 months (5 units)

At the end of this heat-soak period, all relays were found to be in working order and operating according to specification. Therefore, the zener diodes, transistors and various integrated circuits have reached the target 20 years without failure.

6.5 Heat-soak period 5: 1.0 month (5 units)

At the end of this heat-soak period, all relays were found to be in working order and operating according to specification. Therefore, the switching diodes, rectifier diodes and ceramic capacitors have reached the target 20 years without failure.

7 Analysis

7.1 MCGG 22 relays

Figure 7-1 (overleaf) shows an overview of the ALT conducted on the MCGG 22 relays, where it is evident that six out of the nine component categories, or 67%, exceeded 25 years by the end of the test. The six component categories contain 69 out of a total of 139 components, or 49.6%. For the remaining three component categories representing the remaining 70 components, many more months of heat-soaking would be required – refer to Table 4-3 – to age these to 25 years. Also shown on the chart is a single failure of a miniature relay that occurred during HP2.

Recall from Section 4.1 that the project sought to demonstrate that the reliability of HONI's population of MCGG 22 relays over the next five years is at least equal to a modest target of 0.75, with a probability of 90%. Table 7-1 shows that this was exceeded for the first six component categories.

Table 7-1: Reliability Target Decision for MCGG 22 Relays

Component Category	Sample Size	Age Reached [years]	Allowable No. of Failures	No. of Failures	Reliability Target Decision
			on or before 25 years		
Aluminium electrolytic capacitor	14	> 25	1	0	Exceeded
LED	14	> 25	1	0	Exceeded
Metallised polyester capacitor	14	> 25	1	0	Exceeded
Zener diode, transistor, various ICs	8	> 25	0	0	Exceeded
Switching diode, rectifier diode	8	> 25	0	0	Exceeded
Ceramic capacitor	8	> 25	0	0	Exceeded
Resistors	14	< 25	1	0	Inconclusive
Relays	14	< 25	1	1	Inconclusive
Inductors, transformers	14	< 25	1	0	Inconclusive

However, for resistors, relays and inductors/transformers, the reliability target decision remains inconclusive until these have also reached an effective age of 25 years. Therefore, pending further accelerated life testing, it may be stated for HONI's population of MCGG 22 relays that:

$$Pr[R(Y|20) \geq 0.75] = 90\%$$

where Y is 2.3, 2.0 and 1.3 years respectively for resistors, relays (miniature) and inductors / transformers.

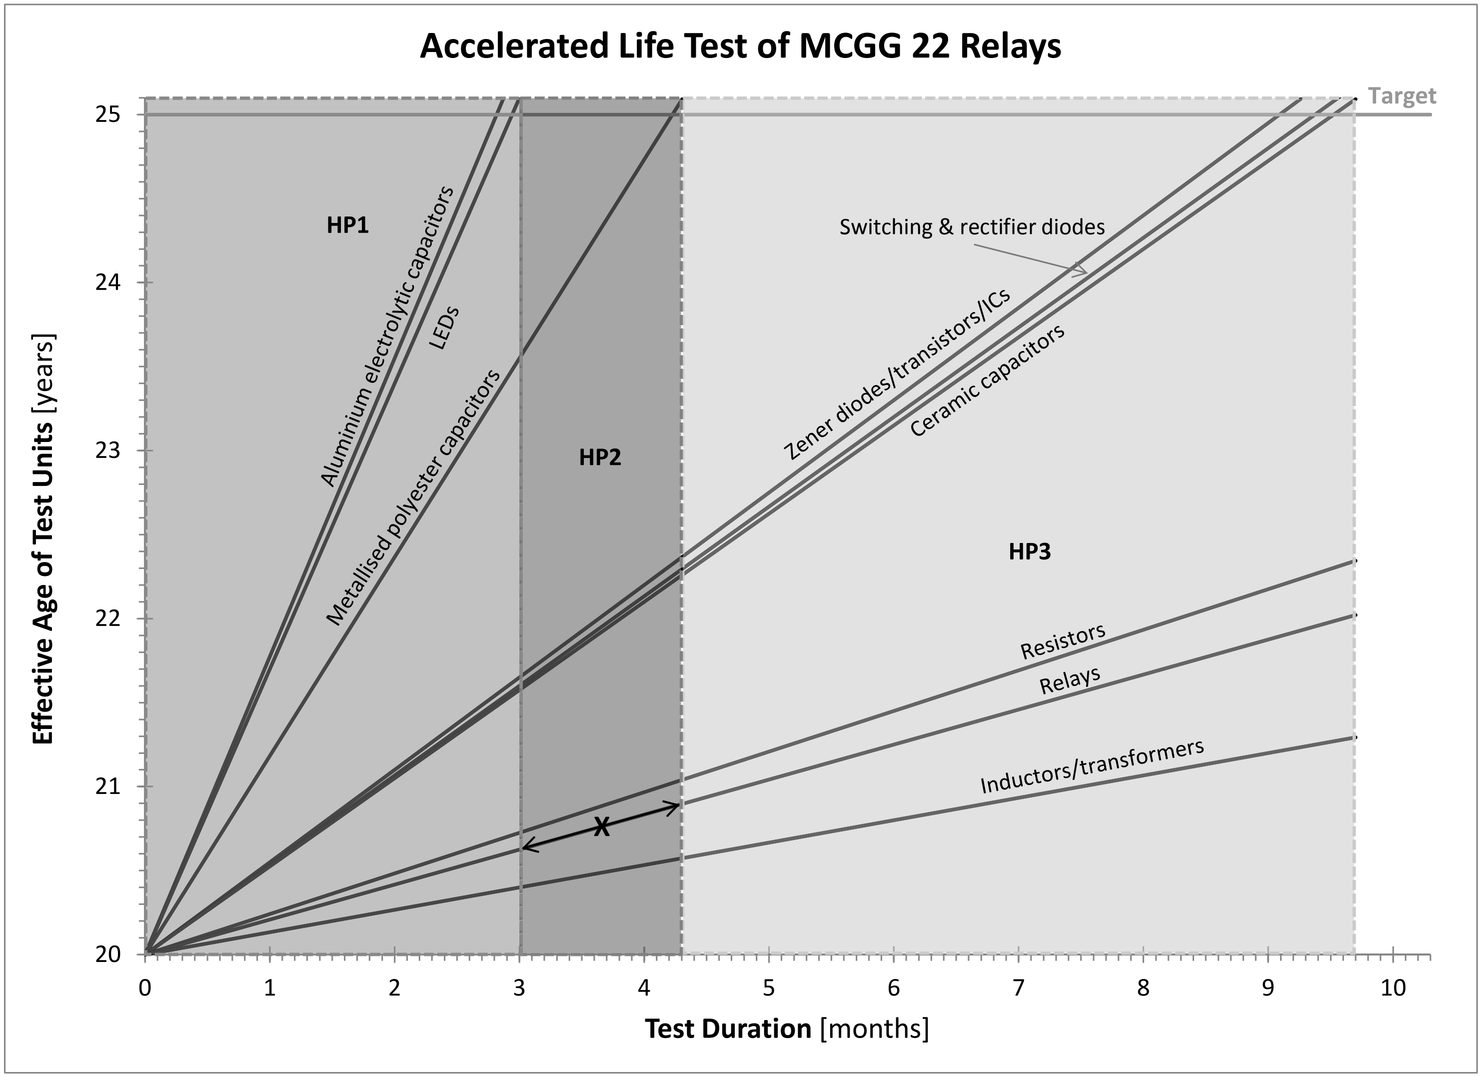

Figure 7-1: ALT Overview – MCGG 22 Relays

7.2 D60 relays

Figure 7-2 (overleaf) shows an overview of the ALT conducted on the D60 relays, where it is evident that nine out of the 12 component categories, or 75%, exceeded 20 years by the end of the test. The nine component categories contain 1,400 out of a total of 2,416 components, or 57.9%. (Note that these are average component numbers, as one of the five D60 relays had a different module configuration – refer to Table 2-3 – thereby resulting in different sample sizes at module level, as well as small differences in component category lists). For the remaining three component categories representing the remaining 1,016 components, many more months of heat-soaking would be required – refer to Table 4-4 – to age these to 25 years.

Recall from Section 4.1 that the project sought to demonstrate that the reliability of HONI's population of D60 relays over the next five years is at least equal to a modest target of 0.7, with a probability of 80%. Differentiating according to sample size, Table 7-2 to Table 7-4 each shows the applicable component category list and provides an indication of reliability target decision.

Table 7-2: Reliability Target Decision for D60 Relays – Front Panel and Standard Modules

Component Category	Sample Size	Age Reached [years]	Allowable No. of Failures	No. of Failures	Reliability Target Decision
			on or before 20 years		
Aluminium electrolytic capacitor	5	> 20	0	0	Exceeded
LED, LCD	5	> 20	0	0	Exceeded
Metallised polyester capacitor	5	> 20	0	0	Exceeded
EEPROM, CPLD	5	> 20	0	0	Exceeded
Opto-coupler	5	> 20	0	0	Exceeded
Tantalum capacitor	5	> 20	0	0	Exceeded
Zener diode, transistor, various ICs	5	> 20	0	0	Exceeded
Switching diode, rectifier diode	5	> 20	0	0	Exceeded
Ceramic capacitor	5	> 20	0	0	Exceeded
Resistors	5	< 20	0	0	Inconclusive
Relays	5	< 20	0	0	Inconclusive
Inductors, transformers, chokes	5	< 20	0	0	Inconclusive

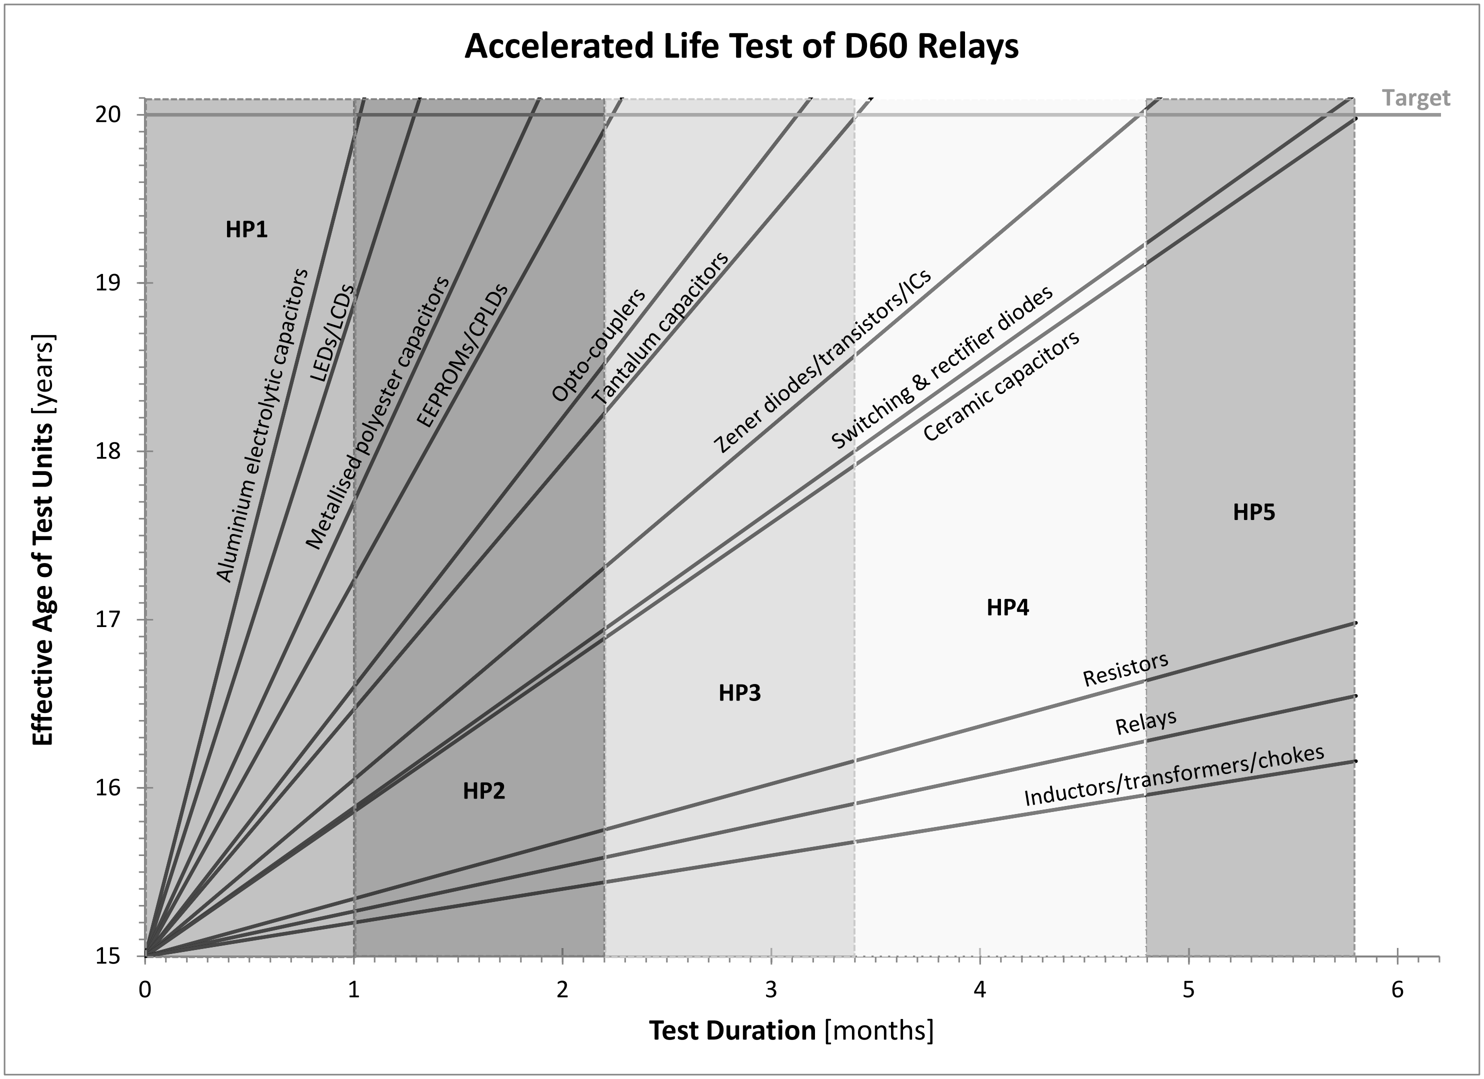

Figure 7-2: ALT Overview – D60 Relays

Table 7-3: Reliability Target Decision for Digital I/O 6U Module

Component Category	Sample Size	Age Reached [years]	Allowable No. of Failures	No. of Failures	Reliability Target Decision
			on or before 20 years		
Aluminium electrolytic capacitor	13	> 20	2	0	Exceeded
EEPROM, CPLD	13	> 20	2	0	Exceeded
Opto-coupler	13	> 20	2	0	Exceeded
Tantalum capacitor	13	> 20	2	0	Exceeded
Zener diode, transistor, various ICs	13	> 20	2	0	Exceeded
Switching diode, rectifier diode	13	> 20	2	0	Exceeded
Ceramic capacitor	13	> 20	2	0	Exceeded
Resistors	13	< 20	2	0	Inconclusive
Relays	13	< 20	2	0	Inconclusive
Inductors, transformers, chokes	13	< 20	2	0	Inconclusive

Table 7-4: Reliability Target Decision for Digital I/O 4C MOD and Digital I/O 6T Modules

Component Category	Sample Size	Age Reached [years]	Allowable No. of Failures	No. of Failures	Reliability Target Decision
			on or before 20 years		
Aluminium electrolytic capacitor	4	> 20	0	0	Exceeded
EEPROM, CPLD	4	> 20	0	0	Exceeded
Opto-coupler	4	> 20	0	0	Exceeded
Tantalum capacitor	4	> 20	0	0	Exceeded
Zener diode, transistor, various ICs	4	> 20	0	0	Exceeded
Switching diode, rectifier diode	4	> 20	0	0	Exceeded
Ceramic capacitor	4	> 20	0	0	Exceeded
Resistors	4	< 20	0	0	Inconclusive
Relays	4	< 20	0	0	Inconclusive
Inductors, transformers, chokes	4	< 20	0	0	Inconclusive

In summary:

- Front Panel and Standard modules – the reliability target was exceeded for the first nine (out of 12) component categories
- Digital I/O 6U Module – the reliability target was exceeded for the first seven (out of 10) component categories
- Digital I/O 4C MOD Module and Digital I/O 6T Module – the reliability target was exceeded for the first seven (out of 10) component categories

In all cases, for resistors, relays and inductors/transformers/chokes, the reliability target decision remains inconclusive until these have also reached an effective age of 20 years. Therefore, pending further accelerated life testing, it may be stated for HONI's population of D60 relays that:

$$Pr[R(Y|15) \geq 0.7] = 80\%$$

where *Y* is 2.0, 1.5 and 1.2 years respectively for resistors, relays and inductors / transformers / chokes.

8 Conclusions

HONI requested Kinectrics to assess the expected service life (ESL) of two of its relay populations for the purposes of asset replacement/refurbishment needs relating to its rates-filing submission to the Ontario Energy Board. The table below shows the relay models forming part of this assessment.

Model	Function	Technology	Manufacturer	**Average Service Life** [years]	**Deemed ESL** [years]
MCGG 22	Overcurrent relay for phase and earth faults	Solid-state	GEC Measurements	20	25
D60	Line distance relay	Digital/numerical	GE	15	20

Given that the average service life for both relay models is within about five years of deemed ESL and that only a small sample of relays could be provided per model, Kinectrics suggested non-parametric, elevated-temperature accelerated life testing, coupled with a modest reliability target and associated single-tailed confidence for each population of relays over the next five years.

As the acceleration factor varies according to component category, as well as stress temperature, one of each relay model was disassembled to compile a bill-of-materials (BOM) so that appropriate activation energy values could be assigned to each component category. This revealed further that separate ovens were required due to maximum operating temperature of 70 °C and 85 °C for the MCGG 22 and D60 relays respectively.

A number of heat-soak periods were designated for each relay model to allow successive component categories to reach 5 accelerated years. Between the heat-soak periods, the relays were subjected to functional performance testing to confirm that the relays were in working order and operating within specification. Then, if the number of relevant failures (of a particular component type) exceeded the maximum allowed within the 5 accelerated years for the particular component type, then the relay was considered not to have met the reliability target. Otherwise, the test remained inconclusive, requiring further heat-soak testing.

8.1 MCGG 22 relays

A sample of MCGG 22 relays was subjected to three heat-soak periods totalling 9.7 months. One relay experienced a miniature relay failure during the second heat-soak period. However, it is considered atypical and may therefore not be relevant. Moreover, the sample size allowed for the occurrence of one failure without affecting the reliability target. For HONI's population of MCGG 22 relays, the following was demonstrated:

a) For all components except resistors, relays (miniature) and inductors/transformers, the set reliability target:

$$Pr[R(5|20) \geq\ 0.75] = 90\%$$

was exceeded. In other words, it was demonstrated that in terms of all components except resistors, relays (miniature) and inductors/transformers, given an average age of 20 years, the reliability of HONI's population of MCGG 22 relays over the next five years is at least equal to 0.75, with a probability of 90%.

This may indicate that the deemed ESL is too pessimistic, i.e., that actual ESL lies somewhat beyond 25 years.

b) For resistors, relays (miniature) and inductors/transformers, the reliability target decision remains inconclusive because these components have not yet reached an effective age of 25 years. Therefore, pending further accelerated life testing, it may be stated for these components that:

$$Pr[R(Y|20) \geq\ 0.75] = 90\%$$

where *Y* is 2.3, 2.0 and 1.3 years respectively for resistors, relays (miniature) and inductors / transformers.

8.2 D60 relays

A sample of D60 relays was subjected to five heat-soak periods totalling 5.8 months. None of the relays experienced failure during the heat-soak periods. For HONI's population of D60 relays, the following was demonstrated:

a) For all components except resistors, relays (miniature) and inductors / transformers / chokes, the set reliability target:

$$Pr[R(5|15) \geq 0.7] = 80\%$$

was exceeded. In other words, it was demonstrated that in terms of all components except resistors, relays (miniature) and inductors/transformers/chokes, given an average age of 15 years, the reliability of HONI's population of D60 relays over the next five years is at least equal to 0.7, with a probability of 80%.

This may indicate that the deemed ESL is too pessimistic, i.e., that actual ESL lies somewhat beyond 20 years.

b) For resistors, relays (miniature) and inductors/transformers/chokes, the reliability target decision remains inconclusive because these components have not yet reached an effective age of 20 years. Therefore, pending further accelerated life testing, it may be stated for these components that:

$$Pr[R(Y|15) \geq 0.7] = 80\%$$

where *Y* is 2.0, 1.5 and 1.2 years respectively for resistors, relays (miniature) and inductors / transformers / chokes.

9 Recommendations

Whereas continued heat-soak testing of both MCGG 22 and D60 relays appears to be recommended for the sake of demonstrating the set reliability target pertaining to resistors, relays (miniature) and inductors/transformers/chokes, the remaining heat-soak periods are quite excessive, totalling 27.8 and 19.2 months respectively for MCGG 22 and D60 relays. Moreover, during these heat-soak periods, it is likely that numerous failures will start to occur for other component categories (with larger acceleration factors).

Otherwise, it is recommended that HONI review the deemed ESL values of 25 and 20 years respectively for the MCGG 22 and D60 relays, as they appear to be too pessimistic.

1.5 (5.2.3) PERFORMANCE MEASUREMENT FOR CONTINUOUS IMPROVEMENT

Hydro One is committed to achieving the productivity and cost efficiency goals outlined in its Business Plan, a copy of which is provided in Exhibit A, Tab 3, Schedule 1, Attachment 1. To give effect to this commitment, Hydro One has aligned its planning, execution and reporting functions around performance outcomes that are consistent with the Ontario Energy Board's ("OEB") Renewed Regulatory Framework ("RRF") outcomes. The RRF outcomes relate to Customer Focus, Operational Effectiveness, Policy Responsiveness and Financial Performance. Hydro One's performance outcomes are reflected in its Transmission Scorecard (see Figure 1), which assists Hydro One in transparently monitoring and measuring performance relative to these outcomes. The evolution of Hydro One's Transmission Scorecard is discussed below in Transmission System Plan ("TSP") Section 1.5.2.

Hydro One maintains and tracks measures across its business to align work execution in each line of business with the corporate strategic objectives, as discussed in TSP Section 2.1.2. The performance outcomes set out in the evolved Transmission Scorecard are aligned with the OEB's RRF outcomes. Hydro One's overall performance against these targets is reported to stakeholders by means of regulatory scorecards for each of the transmission and distribution businesses, as well as through Hydro One's Team Scorecard and Operational Scorecard. The incentives that are embedded in Hydro One's compensation plans support continuous improvement in Hydro One's performance measures and are designed to both increase efficiency and deliver outcomes that customers value. In addition, Hydro One has established a process to evaluate its corporate targets on an annual basis. This process aligns with the development and approval of the Business Plan.

In the sections that follow, Hydro One describes its performance measurement process, including governance, the methodologies used for each of the measures and the manner in which Hydro One has responded to specific concerns raised by the OEB in Hydro One's last transmission rate proceeding. In addition, this section provides an update on Hydro One's performance since its last transmission rate proceeding.

1.5.1 (5.2.3 A) PERFORMANCE MEASUREMENT STRUCTURE, PROCESS, AND GOVERNANCE

Hydro One is taking steps to increase the emphasis it places on performance measurement and planning. Hydro One has increased transparency in all aspects of its budgeting and performance measurement processes to ensure that cross-functional stakeholders, such as various lines of business, its Finance and Regulatory Affairs groups, the Executive Leadership Team ("ELT") and Operations Managers, are equipped with accurate and consistent information to drive business decisions and achieve performance targets.

The evolved Transmission Scorecard (see Figure 1) details Hydro One's historical performance in each area and establishes performance outcomes that Hydro One has targeted to achieve over the 2020 to 2024 plan period and the 2020 to 2022 rate period in respect of each performance measure. Hydro One is committed to achieving the performance outcomes for each measure through the execution of its 2019 to 2024 investment plan. As noted in TSP Section 2.1.2, the investment plan has been optimized to drive performance towards these outcomes, ensuring regulatory compliance, and balancing the customers' needs and preferences, the transmission asset and system needs, and rate impacts.

The evolved Transmission Scorecard is made up of performance measures that enable Hydro One to monitor, track and demonstrate performance relative to outcomes that are valued by its transmission customers.

There are a number of internal stakeholders that are directly engaged in and have responsibility for overseeing or implementing Hydro One's performance measurement and monitoring process.

Details of this process are set out in Hydro One's Performance Reporting Governance Framework, a copy of which is provided in TSP Section 1.5, Attachment 1.

1.5.2 (5.2.3 A, B, C) PERFORMANCE MEASUREMENT METHODS AND MEASURES

In its Decision and Order on Hydro One's 2017-2018 transmission rate application (the "Decision"),[1] the OEB directed Hydro One to develop and file an evolved scorecard reflecting the OEB's feedback. As discussed below, the evolved Transmission Scorecard provides continuity with Hydro One's previously filed Transmission Scorecard while also reflecting the OEB's direction. Additionally, the measures reflected in the evolved Transmission Scorecard have been influenced by internal and external sources that include Hydro One's past performance management measures, benchmarking studies, and scorecards and measures of other utilities in the public domain. The measures were also informed by the OEB's guidance in the Handbook for Utility Rate Applications[2] ("Handbook") by reflecting the following key considerations and OEB filing requirements[3]:

- A focus on strategy and results, not activities;
- The need to demonstrate continuous improvement;
- Outcomes that are demonstrated to be of value to customers; and
- Performance measures that accurately measure whether outcomes are being achieved, and that include stretch goals to demonstrate enhanced effectiveness and continuous improvement.

Hydro One has updated the targets in its evolved Transmission Scorecard to reflect continuous improvement and successful execution of the programs and projects in its Business Plan. The

[4] Satisfaction with Outage Planning Procedures survey was not performed in 2013.The return on equity achieved values for 2013 to 2015 were restated.

Overview of Hydro One's Transmission Performance Measures

Customer Focus

The measures in Table 1 were selected to demonstrate that services are provided to meet customers' expected level of service and align with the OEB's Decision.

Table 1 - Customer Focus Measures

Performance Category	Measures	Description
Service Quality	Satisfaction with Outage Planning Procedures (% Satisfied)	The Ontario Grid Control Centre ("OGCC") Customer satisfaction survey relates Customer Satisfaction with relevant business processes and transactional customer experience. The question asked is: How would you rate Hydro One's OGCC procedures on outage planning?
	Customer Delivery Point Performance, Standard outliers as % of Total Delivery Points	The percentage of customer Delivery Points ("DPs") deemed as either group or individual outliers.
Customer Satisfaction	Overall Customer Satisfaction, corporate survey (% Satisfied)	This measure reflects the overall satisfaction levels of three major transmission customer segments (Transmission End Users, Local Distribution Companies ("LDC") and Transmission-Connected Customer Generators). The survey measures customers' overall opinion of Hydro One (whether they have interacted with Hydro One recently or not). Hydro One seeks to uncover perceptions of how well it is meeting customer expectations and delivering on critical success factors. The survey is conducted online followed by computer-assisted telephone interviewing if customer prefers/is not reached.

Operational Effectiveness

The measures in Table 2 were selected to demonstrate Hydro One's commitment to continuous improvement in performance and execution. The measures also show how Hydro One delivers on system reliability and service quality objectives.

Table 2 - Operational Effectiveness Measures[5]

Performance Category	Measure	Description
Safety	Recordable Rate (#Recordable Injuries/Illnesses per 200,000 hours worked)	Work-related injuries/illnesses to that result in: restricted work, lost time, loss of consciousness, medical attention beyond first aid, death, or any other significant work-related injury or illness diagnosed by a physician or other health care professional and are confirmed by a Hydro One Occupational Health Nurse. The measure applies to Hydro One Networks Inc. employees only (not contractors).
System Reliability	T-SAIFI-S (Sustained Interruption Frequency) (Average # of times that power to a Customer is interrupted per Delivery Point)	Average Frequency of Delivery Point Sustained Interruptions is an indicator of the average number of unplanned interruptions that customers experience and is presented as number of interruptions per delivery point per year. Only includes sustained (1 minute and longer) interruptions.
	T-SAIFI-M (Momentary Interruption Frequency) (Average # of times that power to a Customer is interrupted per Delivery Point)	Average Frequency of Delivery Point Momentary Interruptions is an indicator of the average number of unplanned interruptions that customers experienced and is presented as number of interruptions per delivery point per year. Only includes momentary (less than 1 minute) interruptions.
	T-SAIDI (Duration) (Average # minutes that power to a Customer is interrupted per Delivery Point)	Average Duration of Delivery Point Interruptions is an indicator of the average minutes of unplanned interruptions that customers experienced and presented as interruption minutes per delivery point per year. Only sustained (1 minute and longer as per the Canadian Electricity Association ("CEA") industry standard) interruptions contribute to this measure.

[5] For OEB reporting and filing, capital expenditures have been remapped to the OEB categories of System Access, System Renewal, System Service, and General Plant. Internally, Hydro One uses Sustainment, Development, Operations, and Common Corporate Costs & Other Costs ("SDOC") as categories for both OM&A and capital. For internal processes, including the supporting data as well as generating and reporting on scorecards, Hydro One utilizes the SDOC categories. To maintain alignment with the existing internal processes and to provide continuity with the previous application (EB-2016-0160), the metrics have not been renamed to the OEB categories.

Performance Category	Measure	Description
	System Unavailability (% of time system equipment is unavailable)	Transmission System Unavailability captures the total duration transmission equipment is out of service due to unplanned outages.
	Unsupplied Energy (minutes)	Unsupplied Energy is an indicator of total energy not supplied to customers due to delivery point unplanned interruptions. In order to make it comparable among different sizes of utilities, the unsupplied energy is normalized by the system peak. The unit of the measure of normalized unsupplied energy is expressed in “system minutes”.
Asset & Project Management	Transmission System Plan Implementation Progress	The Transmission System Plan Implementation Progress measure compares the total actual in-year sustainment, development, and operating expenditures for in-service additions to the total internal company scorecard budget expenditures for in-service additions, including any OEB carry-forward variance.
	Capital Expenditures as % of Budget	Progress is measured as the ratio of actual total capital expenditures to the total amount of planned capital expenditures.
	Operations, Maintenance, & Administration (“OM&A”) Program Accomplishment (composite index)	The Transmission (“Tx”) OM&A Program Accomplishment (composite index) measure compares the weighted actual in-year accomplishment for significant Tx OM&A Programs against the weighted budget. There are eight programs monitored for this measure including: 1) Forestry Line Clearing; 2) Brush Control; 3) PCB Testing and Retro fill; and Station Preventive Maintenance programs which include 4) Power Equipment, 5) Ancillary Equipment, 6) Protection and Control, 7) Telecom, 8)Infrastructure.
	Capital Program Accomplishment (composite index)	The Tx Capital Program Accomplishment (composite index) measure compares the weighted actual in-year accomplishment for significant Tx Capital Programs against the weighted budget. The six programs monitored for this measure include the Steel Structure Coating Program, Tx Lines Insulator Replacement Program, Tx Wood Pole Replacement, Tower Foundation Refurbishment, Shieldwire Replacement and Purchase of Station Spare Transformers.
Cost Control	Total OM&A and Capital per Gross Book Value of In-Service Assets	Demonstrates Transmission cost effectiveness by comparing the ratio of Total Capital and OM&A to Gross Book Value of Fixed Asset costs.

Performance Category	Measure	Description
	OM&A/Gross Fixed Asset Value (%)	Demonstrates Transmission cost effectiveness by comparing the ratio of OM&A to Gross Book Value of Fixed Asset costs.
	Line Clearing Cost per kilometer ($/km)	Cost associated with line clearing activities, per kilometer completed for the year.
	Brush Control Cost per Hectare ($/Ha)	Cost associated with brush control, per hectare completed for the year.

Public Policy Responsiveness

The measures in Table 3 were selected to demonstrate Hydro One's commitment to deliver on the obligations mandated by the government and regulatory agencies.

Table 3 - Public Policy Responsiveness Measures

Performance Category	Measure	Description
Renewable Energy	% on-time completion of renewables customer impact assessments	For Transmission-connected generators, Hydro One is obligated under the Transmission System Code to complete a customer impact assessment (CIA) for renewables in 150 days.
Regional Infrastructure Planning (RIP) & Long-Term Energy Plan (LTEP) Right Sizing	Regional Infrastructure Planning Progress: % Deliverables Met	Measures progress in meeting the deliverables including meeting the Transmission System Code prescribed timelines and delivering the required products. The number of deliverables will vary in a given year. Deliverables include plans, reports and LDC status update letters.
	End-of-Life Right-Sizing Assessment Expectation	This qualitative measure gauges Hydro One's performance in meeting the expectation that no more than two (2) assessment opportunities for right-sizing end-of-life equipment are missed during the year, for all regions assessed in the year as part of the Regional Planning Process. The number of regions assessed may vary in each year.

Financial Performance

The measures in Table 4 were selected to provide financial visibility and to demonstrate that the continuous improvements in execution and cost performance highlighted in 'Operational Effectiveness' are sustainable. The measures used for the Electricity

Transmission Scorecard align with the Financial Ratio measures used in the Electricity Distributor Scorecard.

Table 4 - Financial Performance Measures

Performance Category	Measures	Description
Financial Ratios	Liquidity: Current Ratio (Current Assets/Current Liabilities)	Hydro One measures the ratio of current assets to current liabilities. Current assets are defined as cash or other assets to be converted to cash within the year and that can be used to fund daily operations and pay ongoing expenses. Current liabilities are defined as short term debts or financial obligations that become due within the year.
	Leverage: Total Debt (includes short-term and long-term debt) to Equity Ratio	The debt-to-equity ratio is a measure of Hydro One's financial leverage and serves to identify the ability to finance assets and fulfill obligations to creditors, while remaining within the OEB-mandated 60 per cent to 40 per cent debt-to-equity structure (a ratio of 1.5).
	Profitability: Regulatory Return on Equity -Deemed Return on Equity (included in rates)	Measures the OEB-approved Return on Equity that is embedded in the transmitter's base rates. Return on Equity is the rate of return that the utility is allowed to earn through its transmission rates, as approved by the OEB.
	Profitability: Regulatory Return on Equity -Achieved Regulated Return on Equity	Measures the transmitter's achieved Regulated Return on Equity earned in the preceding fiscal year. The reported return is calculated on the same basis that was used in establishing the transmitter's base rates. This shows the utility's actual Return on Equity earned each year.

Response to OEB Directions from EB-2016-0160

Customer Satisfaction

In the Decision, the OEB directed Hydro One to develop performance indicators that better reflect the satisfaction level of the ultimate end-use customer. The OEB also indicated that it does not consider the satisfaction level of a directly connected LDC to be indicative of the LDC customers' level of satisfaction, and that LDCs do not necessarily represent the interests of their customers on transmission issues nor do they suffer the same negative consequences if transmission performance levels are poor.

Hydro One measures overall transmission customer satisfaction using a corporate survey. The measure used to indicate customer satisfaction reflects the overall satisfaction levels of three major transmission customer segments:

- Transmission End-Users;
- LDCs; and
- Transmission-connected Customer Generators.

The survey measures these customers' overall opinion of Hydro One (whether they have interacted with Hydro One recently or not). It seeks to uncover perceptions of how well Hydro One is meeting customer expectations and delivering on critical success factors. Additionally, Hydro One uses a service quality measure to measure satisfaction with the outage planning procedures of the Ontario Grid Control Centre ("OGCC"). The OGCC customer satisfaction survey relates customer satisfaction to relevant business processes and transactional customer experience. This additional component provides Hydro One with direct insight into how outage planning procedures impact supply to each of the three transmission customer groups. Proper outage notifications provide transmission customers with sufficient advanced notice to allow planning, notifications, and restoration of service to Hydro One's transmission customers and, ultimately, any of their end-use customers. These are described further in TSP Section 1.3.

LDC End-User Satisfaction

Hydro One's transmission system is the upstream supplier of electricity to LDCs across the Province of Ontario. Electricity is transmitted over the Hydro One transmission system to Delivery Points ("DPs") with the LDCs. DPs are boundaries between the electricity systems of Hydro One and the LDCs. Each LDC has significant power requirements, unique needs, a diverse group of end-use customers, and most importantly, distribution systems designed to meet their requirements and needs, to service their end-use customers. There is no direct link between the Hydro One transmission system and the LDC's end-use customers.

In Hydro One's 2017 Transmission Customer Engagement Survey, Hydro One asked LDCs to identify whether or not their responses to the survey were informed by their own customer engagement activities for the purposes of their own rate applications, or by any other customer research. Of the 28 respondents, 11 answered "yes" to this question. Additionally, Hydro One's Account Executives interact with the LDCs, and engage the LDCs in discussion regarding the needs of their ultimate end-use customers.

For an LDC's end-use customers to be able to express their level of satisfaction with the upstream electricity supply provided by Hydro One, ultimate end-use customers would need to have the means or the mechanisms in place to create a positive correlation between their satisfaction and Hydro One's transmission system, while also excluding factors and variables relating to their LDC's distribution system. Similarly, for Hydro One to gauge the satisfaction of an LDC's end-use customers, it would need to be able to establish a connection beyond the DP with the LDC to create a link to the LDC's end-use customers. Furthermore, to align with the guidance in the Handbook, Hydro One would need to demonstrate continuous improvement in the satisfaction levels of the LDC's ultimate end-use customers. This would require Hydro One to not only manage its transmission system, but also to be able to exercise control and influence on the distribution systems of the LDCs that it serves, and in some cases on the distribution systems of LDCs that are embedded within those systems.

Section 2.1.4.2 in the OEB's Reporting and Record-keeping Requirements ("RRR") Filing Guide for Electricity Distributors outlines the requirements for reporting on system reliability[6]. Distributors are required to report system reliability exclusive of the impact of loss of supply, which is defined as an interruption due to problems associated with assets owned and/or operated by another party, i.e., upstream, and/or the bulk electricity

---

[6] RRR Filing Guide for Electricity Distributors' Reporting and Record Keeping Requirements (RRR), Ontario Energy Board, March 2017

supply system. In a letter[7] dated March 13, 2017, the OEB updated its RRR filing guidelines requiring distributors to also exclude the impact of Major Events when reporting on system reliability. The reasoning provided in the background section of the letter was that by adjusting for the impact of not only loss of supply, but also of Major Events, the reliability measures would be more indicative of a distributor's ability to manage interruptions caused by circumstances that are directly within the distributor's control. The principles outlined in the RRR filing guidelines recognize the limitations on the control and influence of the transmitter. The general principle demonstrated by the OEB's approach in the RRR filing guidelines is that customer satisfaction measures should gauge satisfaction in areas which can be controlled and influenced to achieve the intent of the key considerations in the Handbook.

Applying this principle to Hydro One's transmission system, there may be limited utility in Hydro One reporting on measures relating to customer satisfaction levels for customers served by distribution systems over which Hydro One exercises no influence or control. To correlate the service satisfaction levels of ultimate end-use customers of LDCs to the service performance of an upstream transmitter would require a means for LDC end-use customers to clearly distinguish between the impacts of transmitter performance and the impacts of distributor performance on the service they ultimately receive. Hydro One has not been able to implement such a measure.

Transmission System Plan Execution

In its Decision, the OEB expressed concern with Hydro One's asset management measures for "*In-Service Capital Additions as % of OEB-Approved Plan*" and "*CapEx as % of Budget*". The OEB indicated that these measures could potentially run counter to the cost control performance indicators. Notably, the OEB distinguished between the use of

[7] Reporting of Customer Interruptions Data Related to Major Events, Ontario Energy Board, March 13, 2017

the OEB-Approved Plan factor in one of the measures and its role in approving capital envelopes which provides an input to the revenue requirement and ultimately approved rates, rather than approved capital plans. The concern expressed was that the proposed asset management measures did not allow for the eventuality that execution of particular elements of the original plan could run counter to the objective of serving the best interests of Hydro One's customers. To address the OEB's concerns, Hydro One is proposing a measure, comparable to the "*Distribution System Plan Implementation Progress*" measure currently reported on Hydro One's Electricity Distributor Scorecard. The proposed measure, "*Transmission System Plan ("TSP") Implementation Progress*", tracks actual in-service additions compared to the budget, including any OEB variances.

The measure compares the total actual sustainment, development and operating expenditures for in-service additions to the total internal company scorecard budget expenditures for in-service additions, including any carry-forward variances. Hydro One is of the view that the proposed measure appropriately addresses the OEB's concerns identified above.

Asset management is at the core of Hydro One's business planning function. Hydro One has considered implementing broader Asset Management measures that are directly related to positive outcomes for its customers. For instance, performance measures related to improvements in Hydro One's asset diagnostics that enhance the accuracy of asset replacement schedules could result in direct benefits to customers. To facilitate this process, Hydro One commissioned certain studies from third party experts to validate Hydro One's approach to managing specific types of transmission assets. These studies are discussed in TSP Section 1.4. Hydro One will review and consider the key findings and recommendations of these studies for possible implementation. The development of asset-specific measures will be considered during the review.

Plan Expenditures

In the Decision, the OEB also determined that plan execution is important but should not be driven by a performance indicator solely based on ensuring the level of spending originally considered reasonable is spent. Hydro One is introducing the additional measures shown in Table 5, which are directly related to expenditures. These are expected to drive Hydro One toward having a more positive and direct impact on customer outcomes.

Table 5 - Transmission Scorecard, Asset & Project Management and Cost Control Measures

Performance Category	Measure	2014	2015	2016	2017	2018
Asset & Project Management	OM&A Program Accomplishment (composite index)	N/A	96.6	99.2	107.7	108.0
	Capital Accomplishment (composite index)	N/A	122.2	59.4	87.8	116.0

Revenue Requirement Reductions through Productivity Improvements

In the Decision, the Board directed Hydro One to establish firm short and long-term targets for productivity improvements and associated reduction in revenue requirements as a means to drive continuous improvement and improve Hydro One's internal and external benchmarking standings. A discussion of these targets can be found in TSP Section 1.6.

Public Policy Responsiveness

In the Decision, the Board did not consider the inclusion of North American Electric Reliability Corporation ("NERC") or Northeast Power Coordinating Council ("NPCC") standards to be aligned with the intent of the scorecard objectives. Hydro One has removed these measures from the evolved Transmission Scorecard.

Unit-Cost Measures of Productivity, Safety, Reliability, and Quality of Service Improvements

The OEB directed Hydro One to put more emphasis on performance measures in the scorecard so as to provide objective year-over-year unit cost measures of productivity, safety, reliability, and quality of service improvements.

Hydro One continues to focus on opportunities to become more efficient in the deployment of capital and in managing costs. The measures shown in Table 6 will be used to monitor this ability, emphasizing execution and cost performance and reflecting the outcomes of the overall business performance.

In 2018, Hydro One's transmission line clearing and brush control activities accounted for approximately 78 per cent of the overall transmission Forestry budget. The unit cost measures are calculated by dividing the annual expenditure on a given program by the number of units completed in that year. These measures are presented at a program level and have not been normalized, which may lead to some variations in the annual unit costs due to the mix of work undertaken throughout the year. For example, brush control unit costs can be affected by vegetation density. The Forestry team incorporates integrated vegetation management principles while maintaining transmission corridors on vegetation clearing cycles of 4, 6 or 8 years. Cycle lengths have been set to ensure that Right-Of-Ways ("ROW") are in good condition and maintain a sustainable level of reliability between maintenance cycles.

Table 6 - Unit-Cost Measures

Performance Category	Measure	2014	2015	2016	2017	2018
	Line Clearing Cost per kilometer Completed ($/km)	2,495	2,234	1,966	2,100	2,797
	Brush Control Cost per Hectare Completed ($/Ha)	1,624	1,566	1,542	1,356	1,539

Qualitative Measures of Public Policy Responsiveness

The OEB proposed that Hydro One should consider expanding its Public Policy Responsiveness measures to include a qualitative assessment of Hydro One's response performance related to the policy objectives embedded in the government's Smart Grid initiatives as one example of the type of measure the OEB anticipates under this element of the evolved Transmission Scorecard.

For 2017 reporting and onwards, Hydro One has introduced a measure designed to provide a qualitative assessment of the Hydro One's alignment with the policies set out in the 2017 Long-Term Energy Plan (the "LTEP").[8] Section 4 of the LTEP, "*Improving Value and Performance for Consumers*", describes the province's policies regarding the need for achieving continuous efficiencies and maintaining a culture of innovation in the energy sector. One component of achieving efficiencies is the right-sizing of end-of-life equipment. As described in the LTEP, equipment which is reaching end-of-life presents a unique opportunity to reassess needs and requirements, and to ensure that replacement equipment and facilities are right-sized to reflect present or anticipated needs and requirements. The assessment may identify opportunities to downgrade or eliminate equipment or facilities in scenarios where demand is expected to decrease; replace with similar equipment with the same or higher ratings where demand is expected to increase; and provide an opportunity to consider greater system resiliency and advanced technological solutions in areas of increased demand. The assessments are performed with the objective of achieving continuous efficiencies and improvements in the value and performance for customers.

The proposed "*End-of-Life Right-Sizing Assessment Expectation*" measure is intended to track the qualitative performance of Hydro One in making right-sizing decisions for all identified end-of-life equipment or facilities. Hydro One will assess its performance by

[8] Ontario's Long-Term Energy Plan 2017, Delivering Fairness and Choice, Government of Ontario

setting a target of a maximum of two (2) missed equipment right-sizing opportunities in annual regional planning assessments. The qualitative performance assessment is either “Met” or “Not Met” based on the quantitative maximum of two.

The proposed new measures are included in the evolved Transmission Scorecard in Figure 1.

Outcomes of Hydro One’s Overall Business

The OEB proposed that Hydro One should consider the merits of implementing measures that reflect outcomes of Hydro One’s overall business, such as gross fixed assets per unit of load service capacity, to more fully illustrate its overall cost of service provision. In addressing the gross fixed assets per unit of load serving capacity measure specifically, Hydro One has reviewed this recommendation and does not consider it to be an appropriate measure against which to assess outcomes or against which it can demonstrate continuous improvement.

Gross fixed assets include the price of assets, which generally experience upward trends due to various factors, including inflation, whereas the unit of load serving capacity is a physical measure of kW or kWh. Therefore, the ratio would have a natural tendency to increase over time, due to the effects on the numerator, even if the unit of load serving capacity remained constant. Additionally, the generation mix is likely to contain more distributed generation than large scale generation. The gross fixed assets would grow at a faster rate due to having an increased distributed generation mix over time, which would be driven by an increased demand for additional transmission lines, towers, and transformers to connect the distributed generators to the transmission system. These distributed generation connections do not benefit from the same economies of scale as connecting large scale generation. Such a measure would not be appropriate and would likely not allow for opportunities to demonstrate continuous improvement and to align with the key principles of the RRF.

Continued Development of Hydro One's Performance Management System

The OEB directed Hydro One to continue to develop its performance management system and scorecard to reflect the OEB's observations and determinations. Hydro One believes that the evolved Transmission Scorecard and the associated, updated Performance Reporting Governance Framework (TSP Section 1.5, Attachment 1) demonstrate Hydro One's commitment to continue to develop its performance management system and scorecard to reflect the OEB's observations and determinations. In doing so, Hydro One has considered the merits of implementing measures that reflect the overall business and which are expected to positively impact outcomes.

1.5.3 (5.2.3 C, D) PERFORMANCE MEASUREMENT OUTPUTS AND PERFORMANCE UPDATE

The following sections provide updates on Hydro One's performance trends since its last transmission rate proceeding, organized by the corresponding performance outcomes (i.e. Customer Focus, Operational Effectiveness, Public Policy Responsiveness and Financial Performance). As shown in Figure 1, Hydro One has provided results for 2018 and aligned the discussions in the section below to reflect those results.

Customer Focus

Customer Satisfaction: Satisfaction with Outage Planning Procedures (per cent satisfied)

Hydro One measures satisfaction with the outage planning procedures of its OGCC using a transactional survey which asks respondents to rate Hydro One's OGCC procedure on outage planning on a five-point scale. The OGCC continues to improve across several spectrums, including: customer assistance, service delivery, and outage planning procedures among its customer base.

Although, satisfaction with outage planning procedures decreased by 9 percentage points in 2018 compared to 2017, historical results are not comparable to the 2018 value. In

2018, Hydro One made changes to the survey methodology in an attempt to prompt more accurate responses from survey participants. Additionally, the survey was also published online in order to allow for greater flexibility for customers and to also provide an additional level of comfort with answering the questions online versus speaking to a representative of Hydro One. Lastly, the survey questions were also standardized across all customer types to allow for better comparison of response themes.

For these reasons, a comparison to historical results is not appropriate. Targets were set based on the new survey methodology, and over the plan period, Hydro One is targeting 88 per cent satisfaction with outage planning procedures.

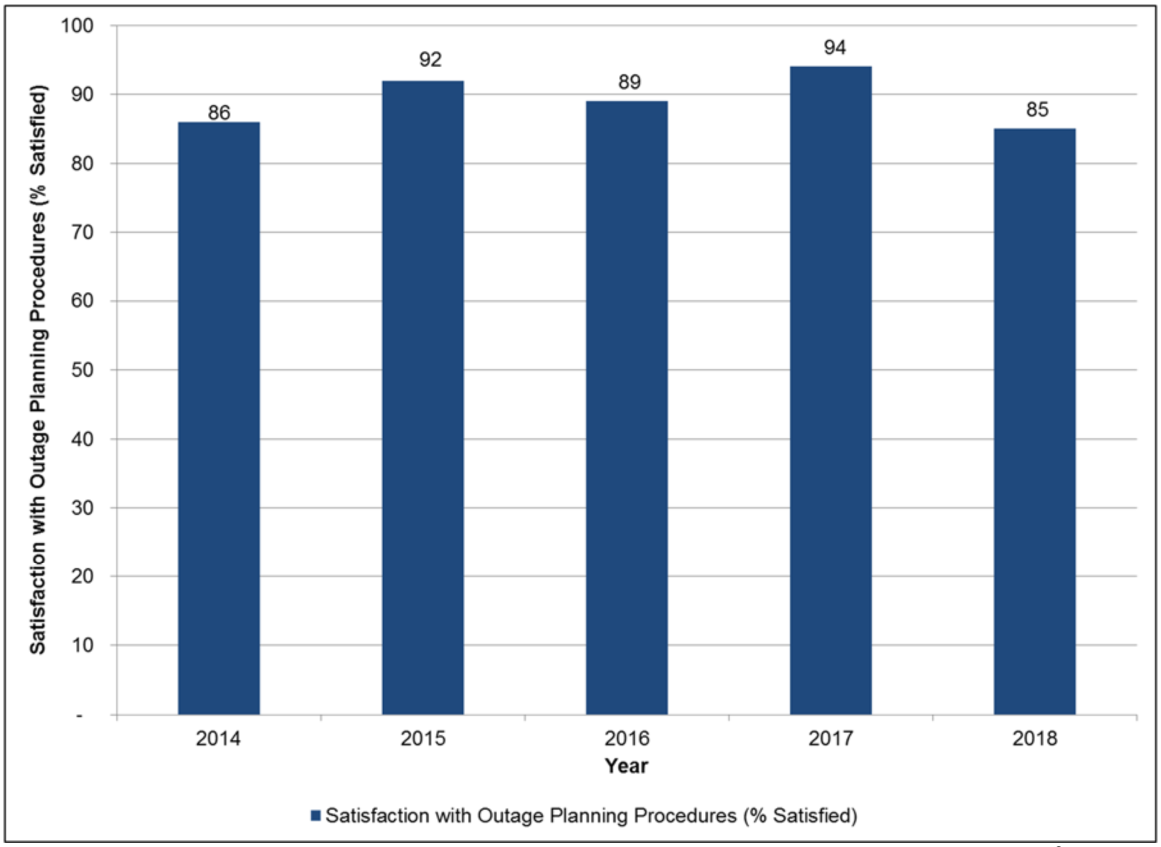

Figure 2 - Satisfaction with Outage Planning Procedures (% Satisfied)[9]

<u>*Customer Satisfaction: Overall Customer Satisfaction in Corporate Survey (% satisfied)*</u>

Hydro One conducts an annual customer satisfaction survey online, followed by computer-assisted telephone interviews based on customer preference or availability. Hydro One measures overall customer satisfaction by surveying the overall satisfaction level of its three major transmission customer segments: 1) Transmission End Users; 2) LDCs; and 3) Transmission-connected Customer Generators. The survey also measures key drivers of satisfaction among large Transmission customers by monitoring Hydro One's performance in four key service areas: 1) Price; 2) Customer Service; 3) Product Quality and Reliability; and 4) Relationship. The survey measures the opinions of

[9] Average and trend lines are not shown in Figure 2 since the survey methodology changed in 2018.

customers and seeks to uncover perceptions of how well Hydro One is meeting their expectations. Customer satisfaction levels in the areas of Customer Service, Product Quality and Reliability and Relationship have been relatively stable in recent years. However, the Price measure is at the lowest level since tracking this measure began.

In 2018, overall customer satisfaction increased to the highest point in the past six years at 90 per cent, which represents a 2 percentage point increase compared to 2017. The increase in overall satisfaction can be largely attributed to LDCs and End-User customers. Both showed continuity of improvement that started previous year, with satisfaction ratings climbing to their highest points since tracking began. Generator customers continued to show consistent satisfaction with Hydro One, with satisfaction ratings rising steadily over the past few survey waves. Both scorecard metrics show improvement over the previous year. LDC customer ratings of Hydro One are at their highest over time, with a significant increase in satisfaction with Hydro One keeping commitments and making decisions promptly. Consistent with 2017, Generators continued to identify product and planning issues (outage planning, infrastructure upgrades) as key areas for Hydro One to address in order to increase satisfaction

Hydro One is committed to improving satisfaction levels for these customer segments. Considerable focus will be placed on a renewed commitment to customer advocacy and becoming a company that is easy to do business with. This includes a review of Hydro One's processes and practices to ensure Hydro One keeps commitments and is responsive to the needs of these customers. Improving customer service for our large customers will be driven by ensuring Hydro One is easy to do business with.

Insights from the 2017 surveys reveal the following areas where customers are seeking improvements:

- providing more assistance with investigating power quality events;
- reducing timelines for connection estimates;

- reducing connection costs;
- improving communications and transparency; and
- becoming easier to do business with.

Hydro One's average performance over the past five years (2014-18) was 84 per cent and the overall customer satisfaction trend is improving (see Figure 3).

Over the plan period, Hydro One aims to improve against its five-year average, and is targeting 90 per cent overall customer satisfaction.

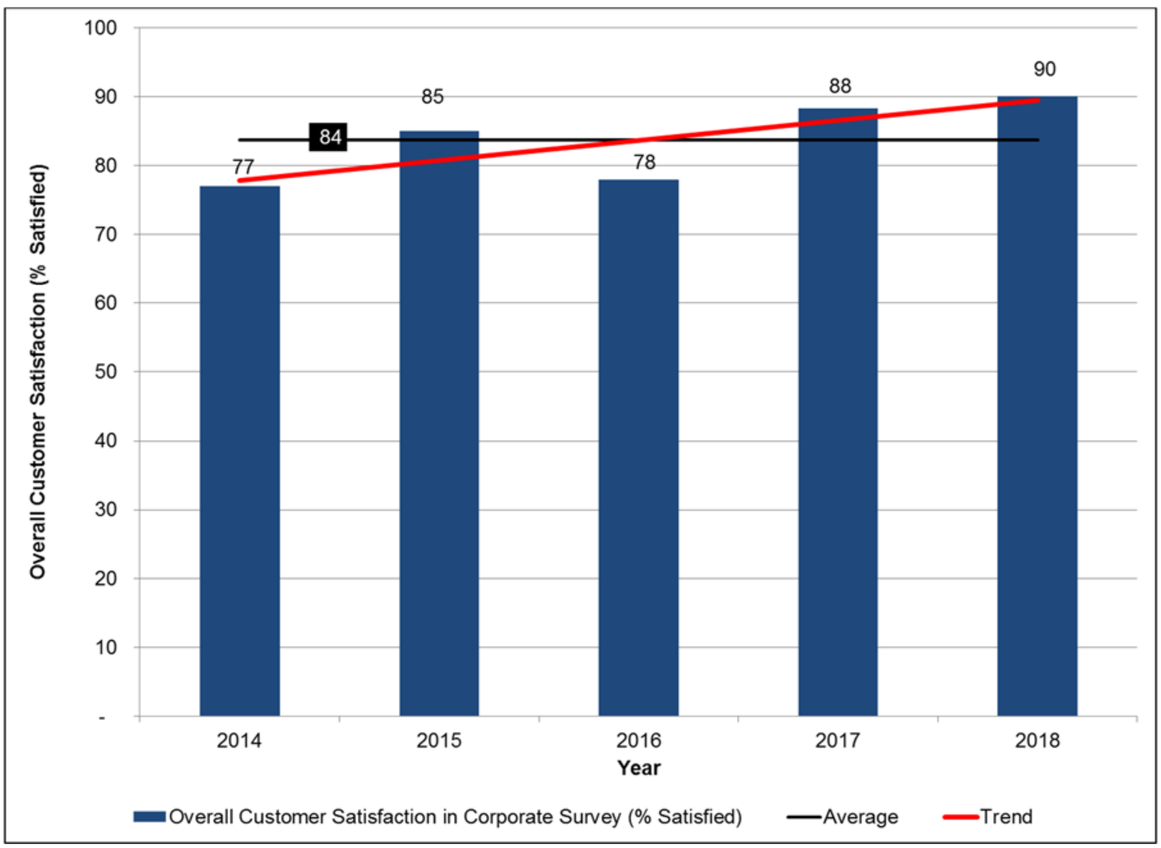

Figure 3 - Overall Customer Satisfaction, Corporate Survey (% satisfied)

Service Quality: Customer Delivery Point Performance, Standard Outliers as per cent of Total Delivery Points

Hydro One tracks customer DP performance as the percentage of group or individual outliers compared to the total number of DPs on the transmission system.

The percentage of standard outliers in 2018 increased by 0.6 percentage points compared to 2017, mainly due to more Weather, Equipment, and Foreign caused interruption (the 2018 Ottawa tornado event is excluded).

Hydro One's average performance over the past five years (2014-18) was 11.1 per cent and the performance trend is indicating a reduction in the number of delivery point outliers (see Figure 4).

Over the plan period, Hydro One aims to improve against its five-year average, targeting 10.8 per cent for its customer DP performance[10].

[10] In setting the targets for the rate period and the plan period for this measure, Hydro One examines its performance over the past ten years and makes a conservative performance forecast. For this reason, the targets are higher in future years relative to recent performance. However, the targets for 2022 and 2024 are both better than the historical five-year average.

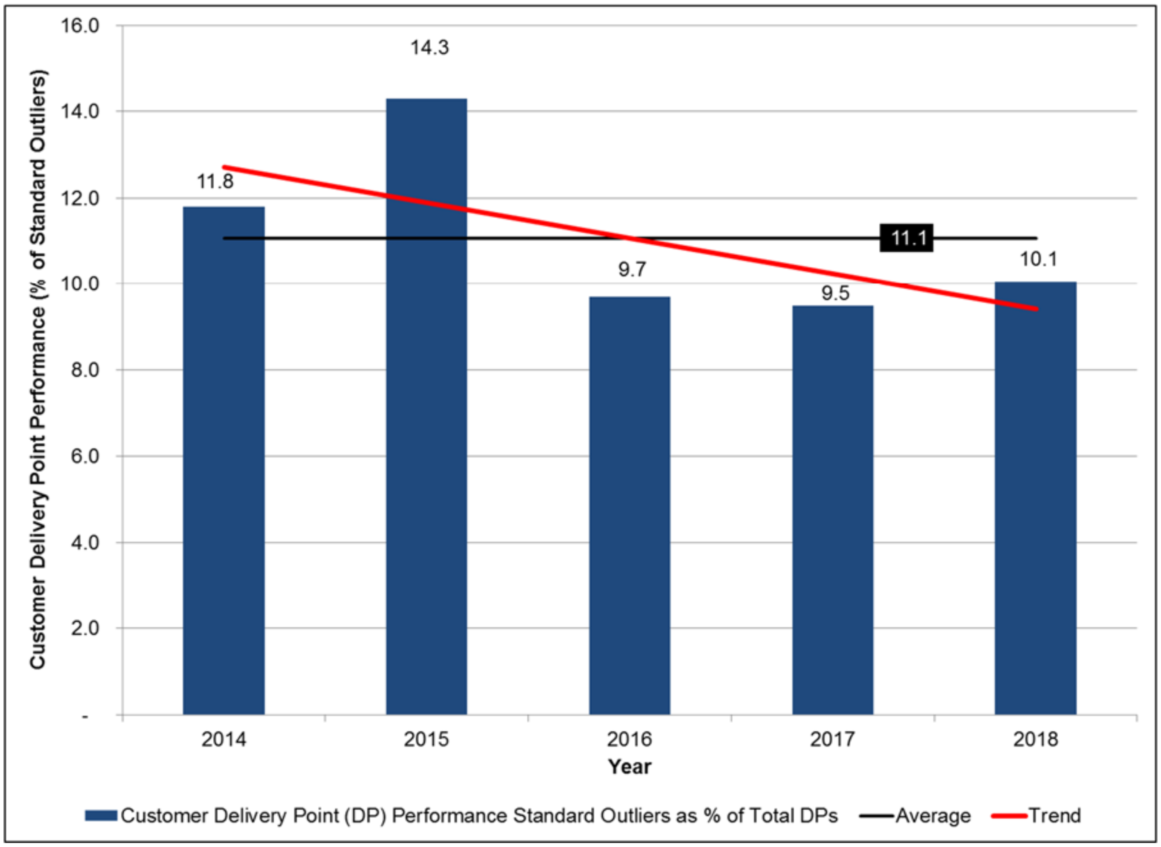

Figure 4 - Customer Delivery Point (DP) Performance, Standard Outliers as % of Total Delivery Points

Operational Effectiveness

Safety: Recordable Incident Rate (# of Recordable Injuries/Illnesses per 200,000 Hours Worked)

Hydro One tracks the number of work-related injuries or illnesses per 200,000 hours worked (recordable rate), which result in: 1) restricted work; 2) medical attention beyond first aid; 3) death or; 4) any other significant work-related injury or illness diagnosed by a physician or other healthcare professional and confirmed by a Hydro One Occupational Health Nurse. This measure only applies to employees of Hydro One and excludes contractors and the general public.

For 2018, Hydro One’s recordable rate was 1.1 incidents per 200,000 hours worked, representing a decrease of 0.1 incidents compared to 2017. Continued focus on improvements through the Journey to Zero initiatives, ensuring the Health, Safety and Environment Management System is effective through regular leadership reviews and audits; ongoing training and development; regular safety meetings; workplace safety observations and employee communications; and proactive engagement with employees and their representatives will assist Hydro One in achieving world-class safety performance.

Specific new initiatives for 2019 include a focus on improving Hydro One’s safety leadership skills to facilitate meaningful and effective safety conversations with employees, improving our skills development process for employees and apprentices and building on Human Success by identifying situations to minimize the likelihood of errors that my result in workplace injuries.

Hydro One's average performance over the past five years (2014-18) was 1.4 incidents per 200,000 hours worked, and Hydro One’s performance trend indicates a continued reduction in the recordable rate (see Figure 5).

Over the plan period, Hydro One aims to continue to improve against its historical average and is planning to reduce the recordable rate to less than one incident per 200,000 hours worked.

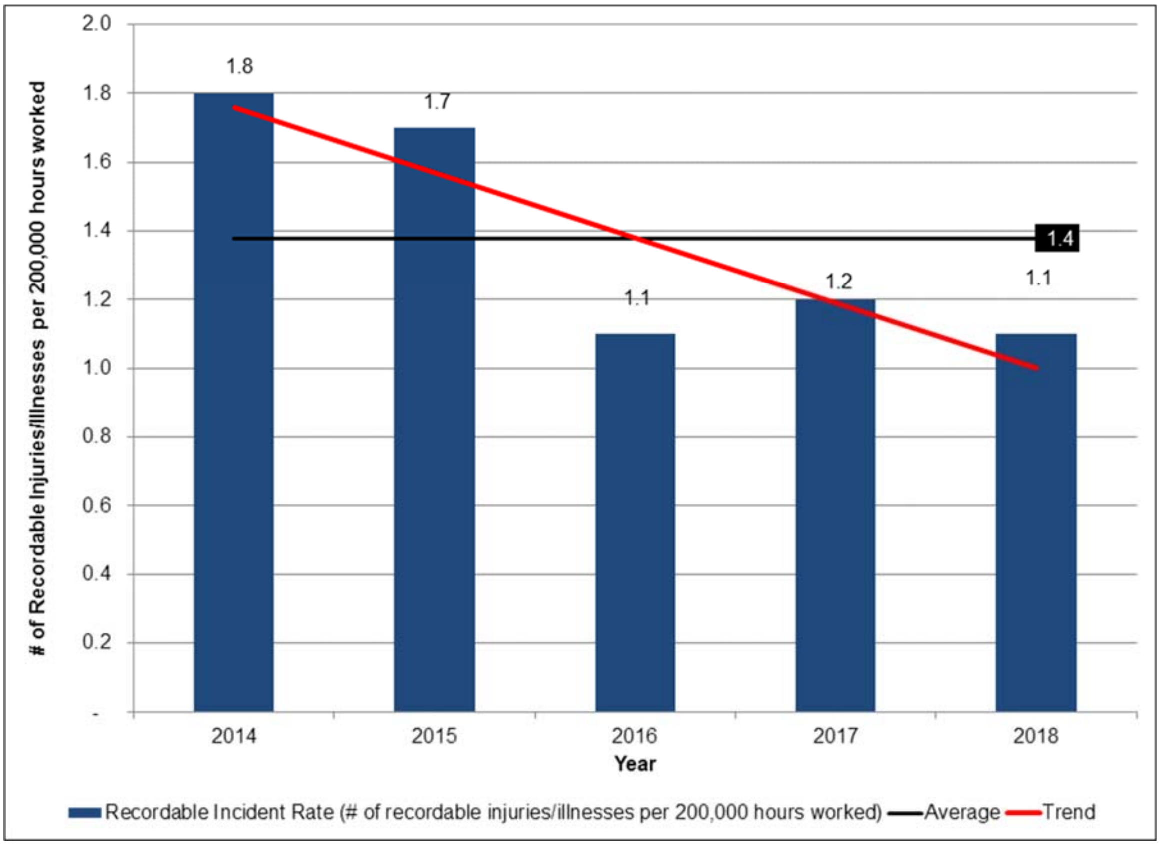

Figure 5 - Recordable Incident Rate

<u>*System Reliability: T-SAIFI-S, T-SAIFI-M, T-SAIDI, System Unavailability and Unsupplied Energy*</u>

Hydro One tracks and measures the reliability of its electricity transmission system using five distinct measures, defined as:

1. Transmission System Average Interruption Frequency Index – Sustained Interruption (“T-SAIFI-S”);
2. Transmission System Average Interruption Frequency Index – Momentary Interruption (“T-SAIFI-M”);
3. Transmission System Average Interruption Duration Index (“T-SAIDI”);
4. System Unavailability; and
5. Unsupplied Energy.

Hydro One removes extraordinary events from its reliability metrics that have had an “excessive” impact on the transmission system and that, in Hydro One’s assessment, strongly skew the historical trend of the measure. This exclusion threshold has been determined using a statistical method (log-standard deviation (β)) resulting in a threshold of 10,000 MW*min being used to exclude major unsupplied energy events from reliability metrics. Hydro One will apply this exclusion threshold to performance tracking and target setting starting in 2019. The historical reliability metrics below have been presented using the previous reliability metric approach and the one described above. Trends and averages relate to the previous reliability metric approach.

T-SAIFI-S is the average frequency of DP sustained interruptions – those greater than one minute in duration – and is used as an indicator of the average number of unplanned sustained interruptions that customers experienced per DP in the year.

The average number of sustained interruptions per delivery point in 2018 was 0.83, an increase in the index value of 0.18 or about 27 per cent compared to 2017, primarily due to more weather and equipment caused interruptions.

Hydro One’s average performance over the past five years (2014-18) was 0.63, and the performance is trending up, indicating an increase in the average number of sustained interruptions per delivery point (see Figure 6).

Over the plan period, Hydro One aims to improve against its historical average, targeting 0.50 for T-SAIFI-S.

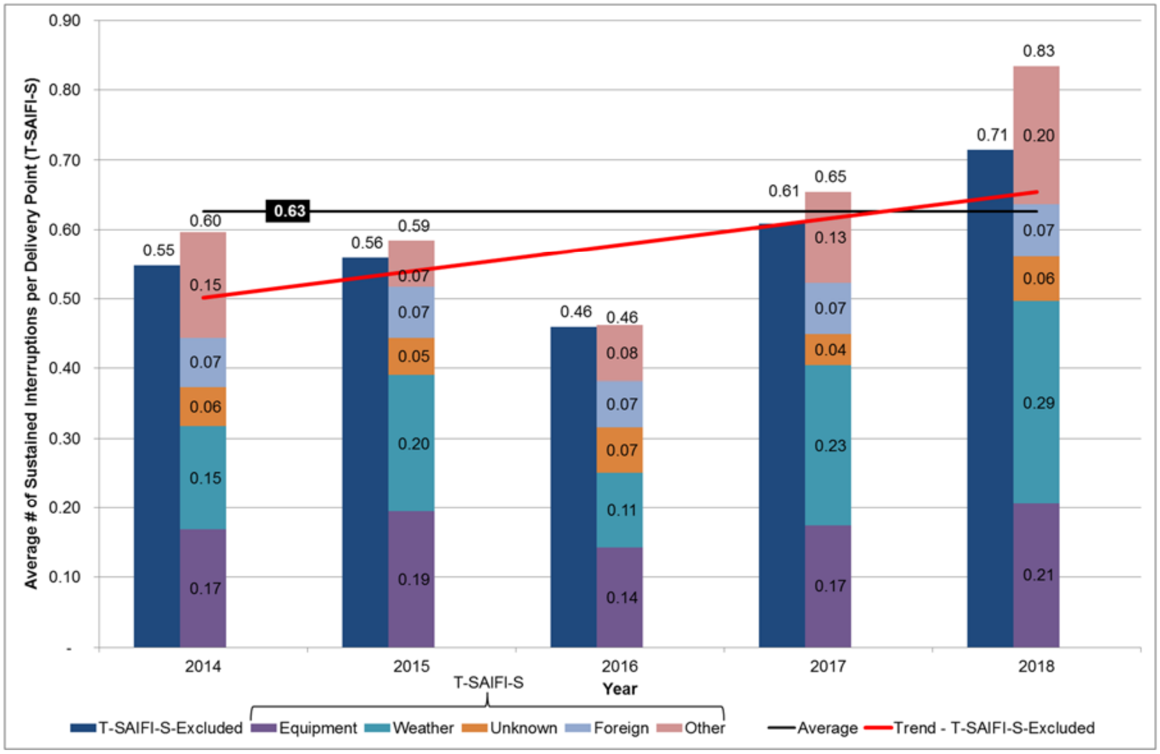

Figure 6 - Transmission System Average Interruption Frequency Index – Sustained Interruption

T-SAIFI-M is the average frequency of DP momentary interruptions – those less than one minute in duration – and is used as an indicator of the average number of unplanned momentary interruptions that customers experience per DP in the year.

The average number of momentary interruptions per DP in 2018 was 0.50, an increase in the index value of 0.03 or about 6 per cent compared to 2017, primarily due to more weather caused interruptions.

Hydro One's average performance over the past five years (2014-18) was 0.46 interruptions per DP, and the performance trend is relatively flat (see Figure 7).

Over the plan period, Hydro One aims to improve against its historical average, targeting 0.45 for T-SAIFI-M.

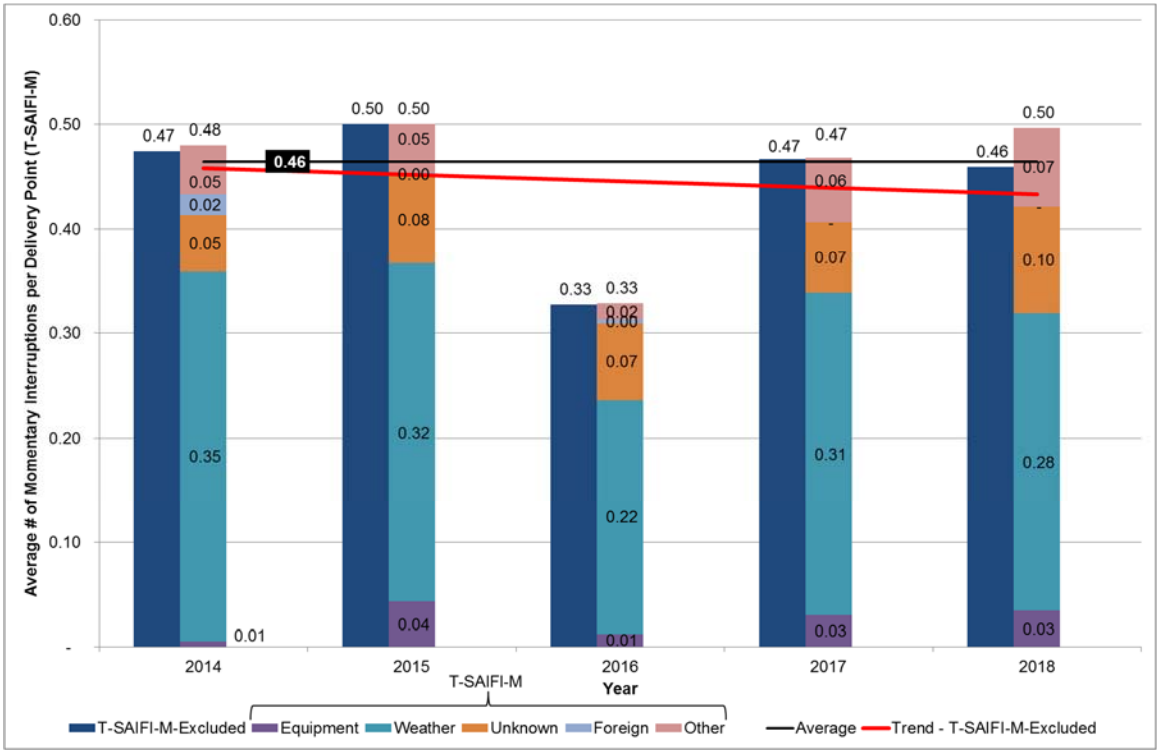

Figure 7 - Transmission System Average Interruption Frequency Index – Momentary Interruption

T-SAIDI is the average duration of sustained DP interruptions – those greater than one minute in duration – and is used as an indicator of the average minutes of unplanned interruptions that customers experience per DP in the year.

The average duration of sustained interruptions per DP in 2018 was 69.9 minutes, an increase of 27.1 minutes or about 63 per cent compared to 2017. The result in 2018 was driven by a large freezing rain event on April 14th, an extreme wind storm in southern Ontario on May 4, 2018, outages impacting eastern Toronto as a result of events in proximity to Hearn SS and Gerrard TS on Jan 8, 2018 and Feb 10, 2018 and the Finch TS T2 failure on July 27-28, 2018.

Hydro One's average performance over the past five years (2014-18) was 54.9 minutes (see Figure 8) and the performance is trending up, indicating an increase in the average minutes of interruptions per delivery point. T-SAIDI performance can vary significantly from year to year due to following reasons:

- limited number of DPs;
- a small number of events which can contribute most of the index;
- major events which had occurred and will happen randomly; and
- radially supplied DP performance, which can vary significantly due to lack of alternative source.

Based on the uncertainty in the performance on this measure year-over-year, the future targets are set based on multiple year averages.

Over the plan period, Hydro One aims to improve against its five-year average, targeting 32.0 minutes for T-SAIDI.

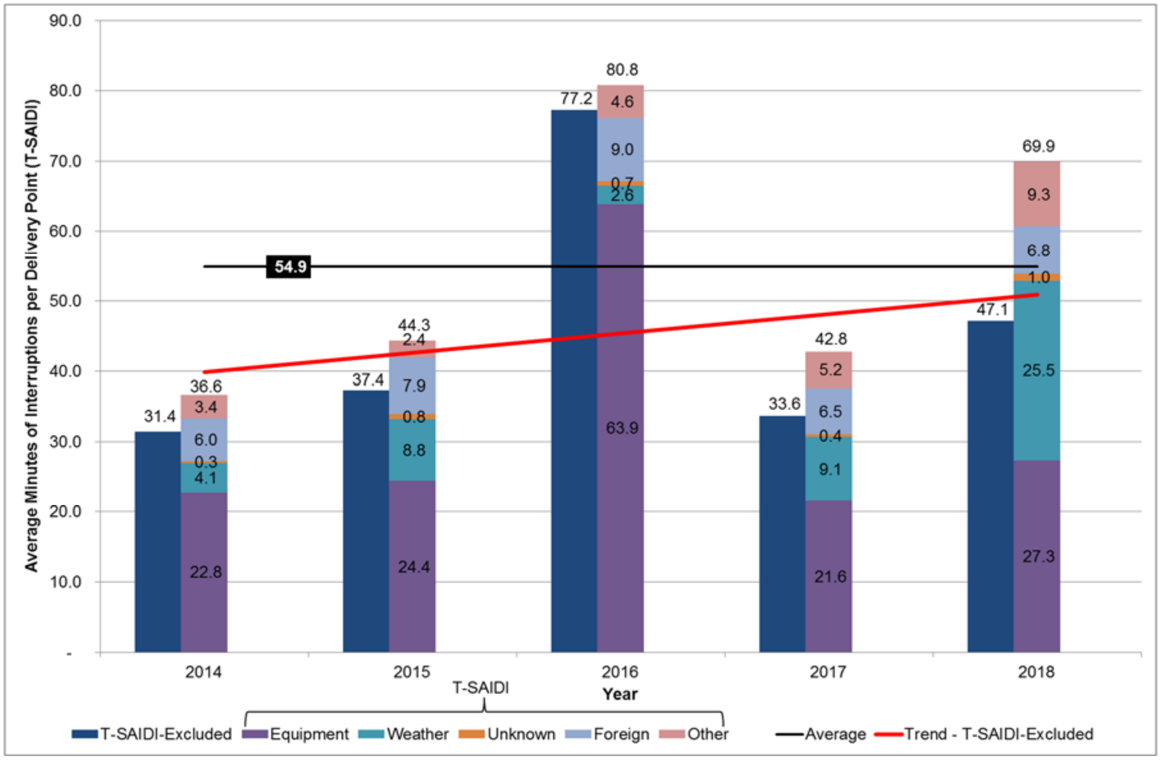

Figure 8 - Transmission System Average Interruption Duration Index (minutes)

System unavailability examines the unavailability of transmission lines and major transmission station equipment, due to direct automatic or forced manual outages caused by factors such as defective equipment, adverse weather, adverse environment, foreign interference and human element. This measure does not consider the subordinate outages of healthy transmission equipment removed from service as a result of an outage caused by other equipment. The information derived from monitoring this measure is trended over time and helps influence business decisions that affect the reliability of transmission equipment. This measure is specifically defined to enable comparison with all-Canada averages from all transmission utilities which participate in the Equipment Reliability Information System program of the Transmission Consultative Committee on Outage Statistics at the Canadian Electricity Association.

System unavailability for 2018 was 0.83 per cent, and 0.15 percentage points higher compared to 2017. Increases in lines unavailability in 2018 were driven to a large extent by tornado damage on a circuit and the need to repair two separate faulted cable circuits. Increases in the unavailability of stations equipment in 2018 were driven to a large extent by the unavailability of high voltage capacitors due to issues with the capacitor itself or the capacitor breaker.

Hydro One's average performance over the past five years (2014-18) was 0.67 per cent system unavailability and the performance trend indicates an increase in system unavailability over the past five years (see Figure 9).

Over the plan period, Hydro One aims to improve against its five-year average, targeting 0.44 per cent for system unavailability.

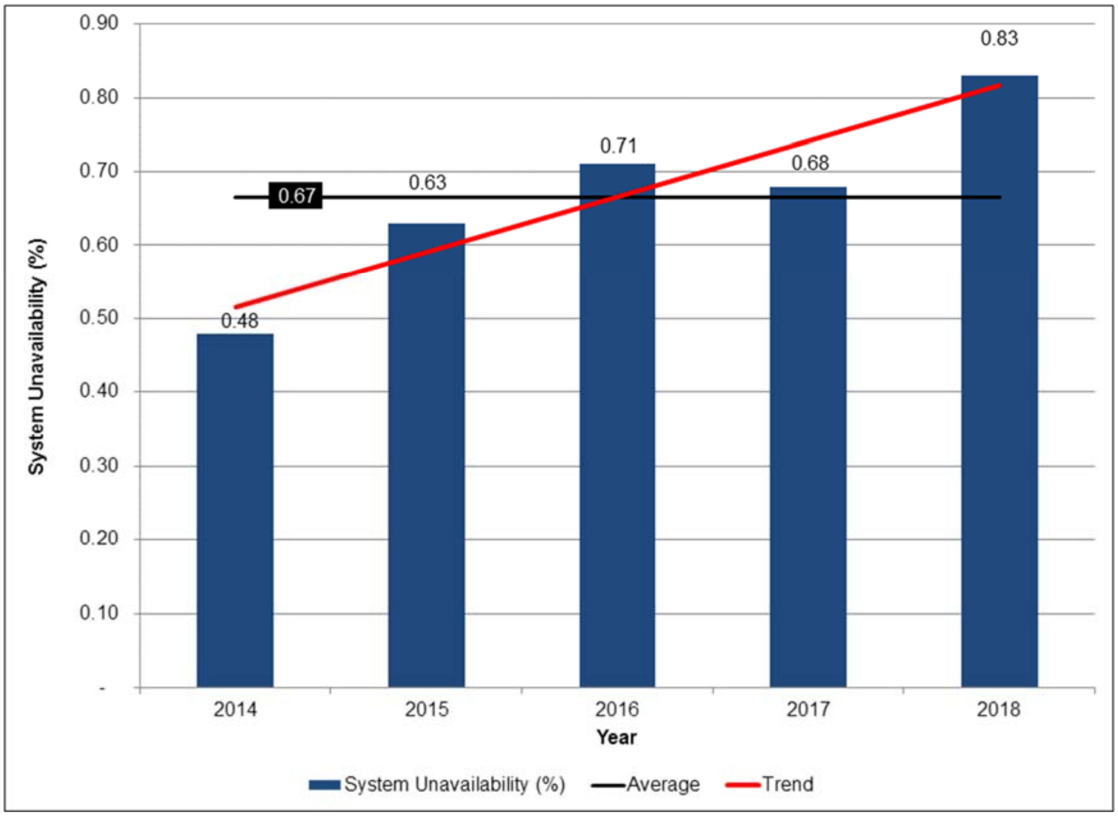

Figure 9 - System Unavailability (in %)

Unsupplied Energy is the total energy not supplied to customers during the year, measured in system minutes, due to unplanned interruptions to all delivery points. This measure is normalized against the system peak to make the performance comparable to that of other utilities.

Unsupplied Energy for 2018 was 19.5 system minutes, higher by approximately 6 minutes or about 48 per cent compared to 2017 primarily due to more weather-caused interruptions such as a large freezing rain event on April 14th and large wind event on May 4th.

Hydro One's average performance over the past five years (2014-18) was 13.6 system minutes of unsupplied energy, and the performance trend is showing a deterioration or an increase in unsupplied energy over the past five years mostly attributable to 2018 (see Figure 10).

Over the plan period, Hydro One aims to improve against its five-year average, targeting 8.8 system minutes for unsupplied energy.

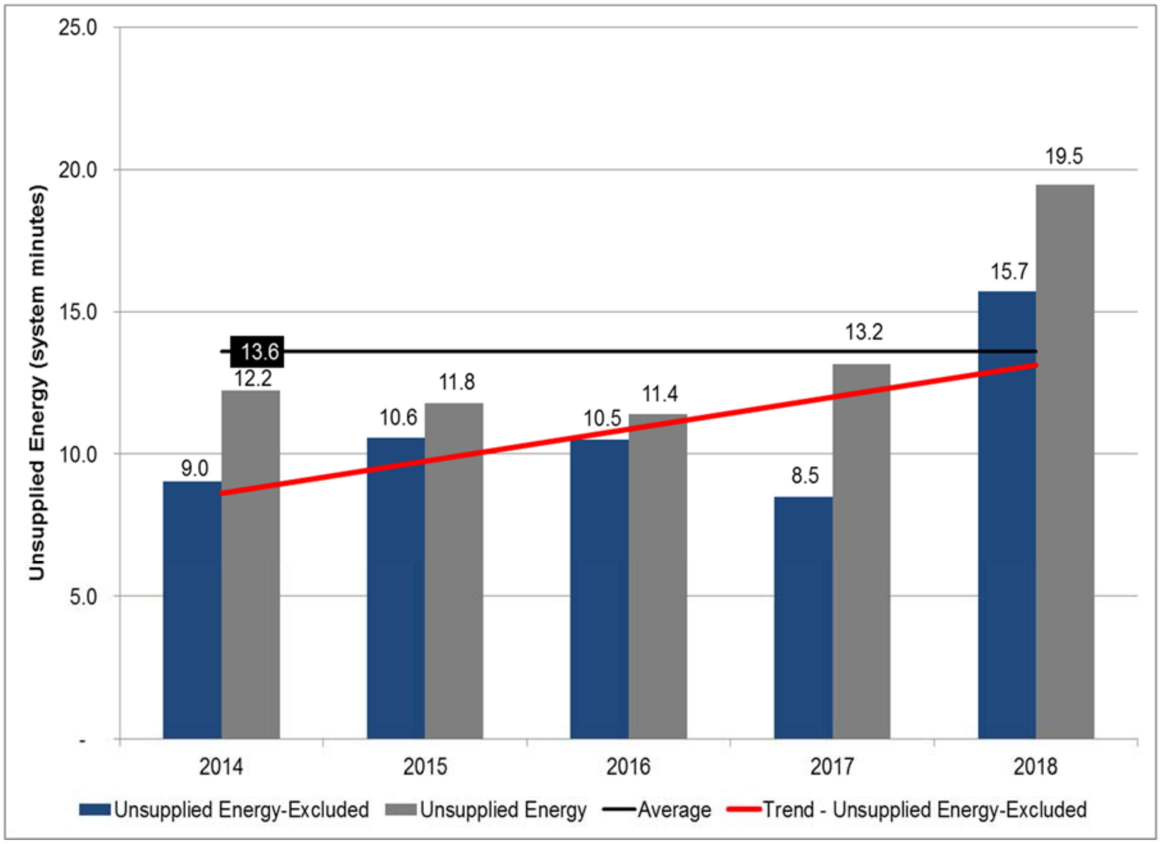

Figure 10 - Unsupplied Energy (System Minutes)

T-SAIFI-S, T-SAIFI-M, T-SAIDI, System Unavailability and Unsupplied Energy, Additional Discussion

While equipment unavailability doesn't necessarily lead to interruptions due to redundancy on Hydro One's transmission system, it is a leading indicator of future reliability erosion. Equipment reliability risk similarly is an indicator of the potential for future reliability issues. Reliability risk provides a comparable illustration of the potential for reliability issues over time. Reliability risk assessment is a proactive measure to mitigate risks before reliability performance starts to deteriorate and negatively impact customers.

To improve reliability and meet the targets over the test year period, Hydro One commissioned a number of third party expert studies to validate Hydro One's approach to managing specific types of transmission assets (see TSP Section 1.4). Hydro One has included specific projects in the Business Plan to replace equipment due to asset condition and performance. Investments to replace some of these assets are described in Investment Summary Documents, including but not limited to:

- Air Blast Breaker Replacement Project – SR-01;
- Line Replacements – SR-19, SR-20;
- Transformer Replacements – SR-03, SR-05; and
- Protection Replacements – SR-07, SR-10.

Asset & Project Management: Transmission System Plan Implementation Progress

In-service capital additions are tracked and reported in a manner consistent with the regulatory requirements of the transmission business, and reported as a percentage value relative to the transmission plan. For 2018, the TSP implementation achieved 99 per cent of the planned in-service capital expenditures, including the OEB carry-forward variance.

Hydro One's average performance over the past five years (2014-18) was 99 per cent of the TSP, and the company's past performance trend is flat (see Figure 11).
Over the plan period, Hydro One aims to improve against its five-year average, and complete 100 per cent of the TSP.

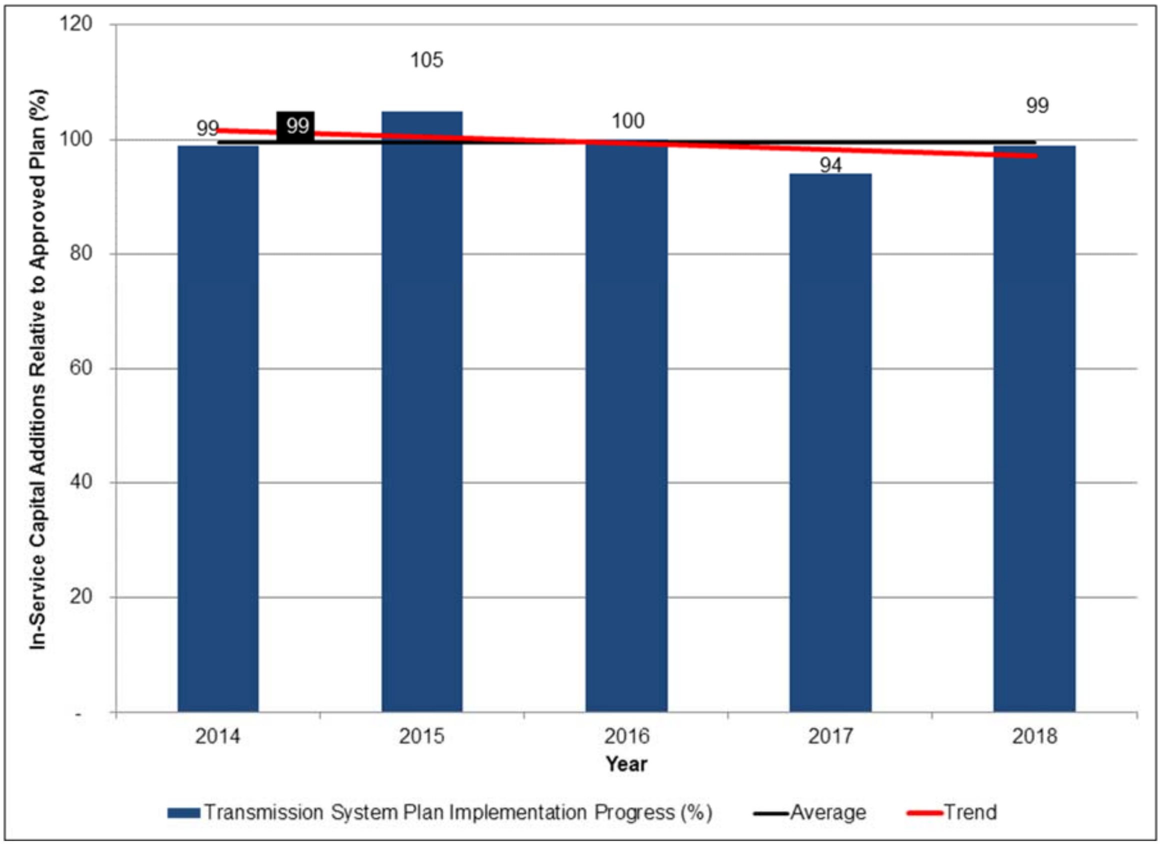

Figure 11 – Transmission System Plan Implementation Progress (in %)

Asset & Project Management: Capital Expenditures as per cent of Budget

Hydro One measures the progress of its capital expenditures towards the approved plan as the ratio of actual total capital expenditures to the total amount of planed capital expenditures.

For 2018, the company's capital expenditures were 97% of budget and lower by 3 percentage points compared to 2017. The result in 2018 was mainly due to delays of work to 2019 on various projects including the underground cable circuit investment from Leaside to Main transmission station and deferred projects to future years including the Integrated System Operations Centre.

Hydro One's average performance over the past five years (2014-18) was on budget (100%), and Hydro One's past performance indicates an upward trend in the percentage of capital expenditures relative to the approved budget (see Figure 12). This is mainly due to timing of capital expenditures on large Inter Area Network Transfer Capability projects.

Over the plan period, Hydro One aims to improve against its five-year average, and meet 100 per cent of the approved plan.

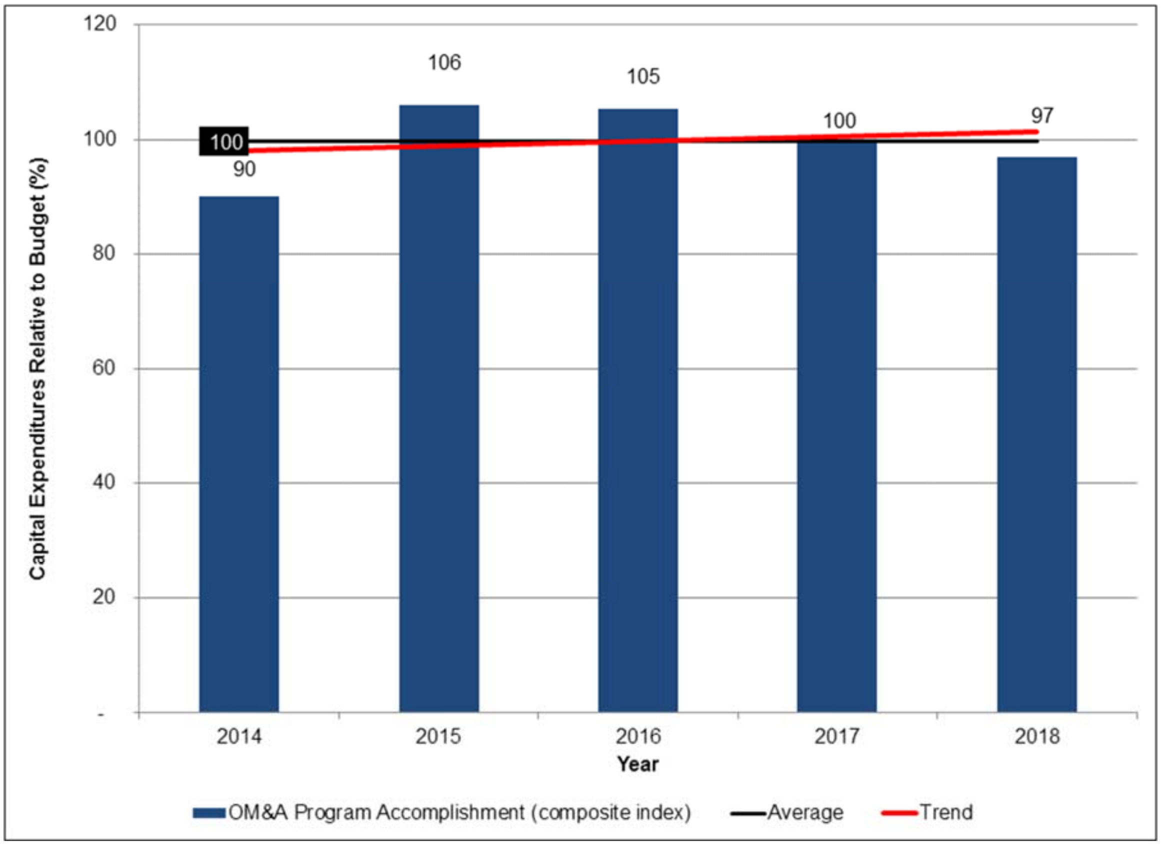

Figure 12 – Capital Expenditures as % of Budget

Asset & Project Management: OM&A Program Accomplishment (Composite Index)

For 2018, Hydro One's OM&A Program Accomplishment composite index value was 108.0, compared to 107.7 in 2017. The increase over the last two years is mainly due to an improvement in the accomplishment of power equipment preventive maintenance, and an increase in the volume of testing and retro-filling of PCB-contaminated equipment.

Hydro One's average index value over the past four years (2015-18) was 102.9, and Hydro One's past performance indicates an upward trend (see Figure 13). This is mainly due to improved preventative maintenance planning processes.

Over the plan period, Hydro One is targeting a composite index value of 100.

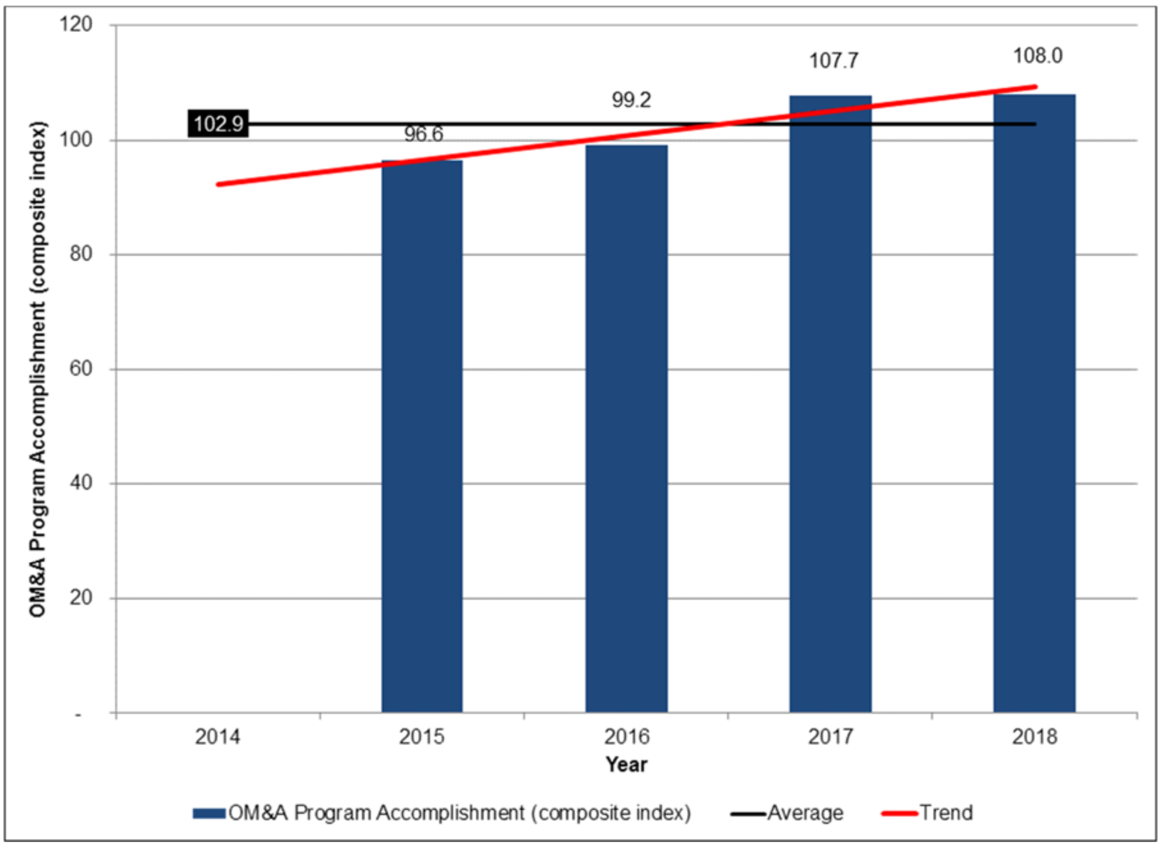

Figure 13 - OM&A Program Accomplishment (Composite Index)

Asset & Project Management: Capital Program Accomplishment (Composite Index)

For 2018, Hydro One's Capital Program Accomplishment composite index value was 116.0, compared to 87.8 in 2017, an improvement resulting from full completion of the planned steel structure re-coating and insulator replacements, improved rate of completion of the shield wire replacements and higher purchased number of spare transformers compared to budget, partially offset by lower than planned completion of wood pole replacements.

Hydro One's average index value over the past four years (2015-18) was 96.4, and Hydro One's past performance indicates a slight upward trend (see Figure 14).

Hydro One plans to stabilize its five-year average, targeting an index value of 100 over the plan period.

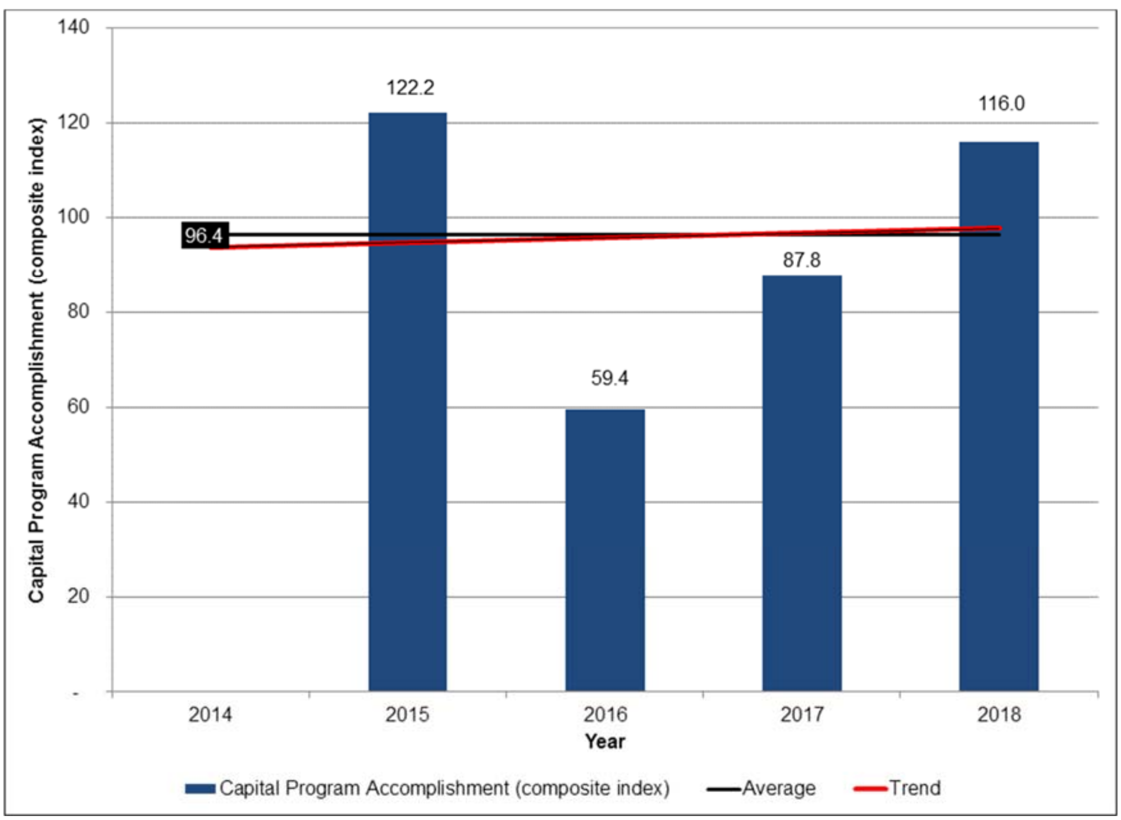

Figure 14 - Capital Program Accomplishment (Composite Index)

Cost Control

Hydro One measures cost control using four OM&A and capital measures:

1. Total OM&A and Capital Expenditures ("CapEx") as a percentage of Gross Fixed Asset Value;
2. OM&A as a percentage of Gross Fixed Asset Value;
3. Line Clearing Cost per kilometer; and
4. Brush Control Cost per kilometer.

Total OM&A and capital expenditure relative to the gross fixed asset value in 2018 was 7.7 per cent, or 0.2 percentage points lower compared to 2017, due to a higher growth in gross fixed asset value compared to OM&A and capital expenditure. Several large capital projects were placed in-service in 2018 such as the Clarington transmission station, Horning transmission station, NRC transmission station and St. Isidore transmission station.

Hydro One's average performance over the past five years (2014-18) was 8.3 per cent, and performance is moderately upward, mainly due to required reinvestment and maintenance in gross fixed assets (see Figure 15).

Over the plan period, Hydro One aims to improve on results compared to its historical average, targeting 7.0 per cent.

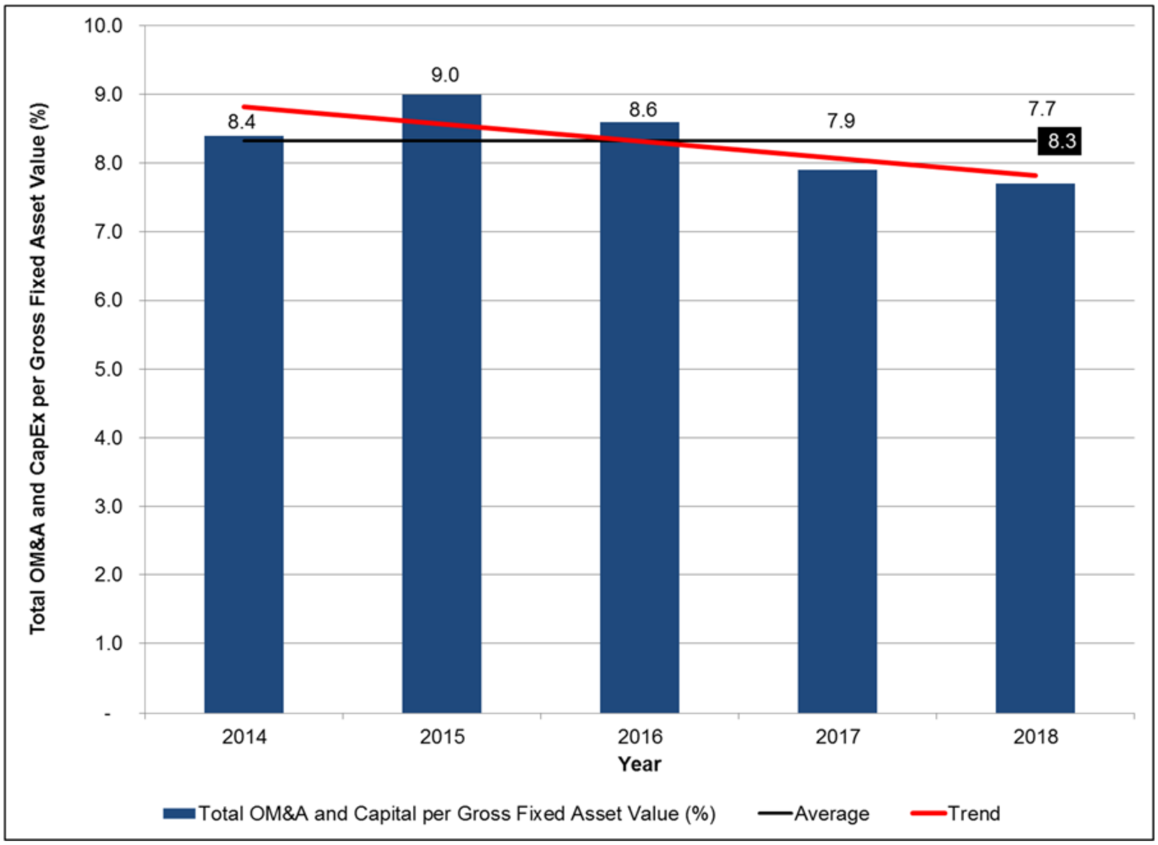

Figure 15 - Total OM&A and Capital per Gross Fixed Asset Value (as %)

OM&A expenditure per gross fixed asset value in 2018 was unchanged from 2017 at 2.3 per cent. The lower OM&A expenditure ratio compared to past years was mainly due to a reduction to the provision for payments in lieu of property taxes following a favourable reassessment of the regulations and estimates related to the liabilities lower property taxes, insurance proceeds received for equipment failures at the Fairchild and Campbell transmission stations and lower corporate support costs.

Hydro One's average performance over the past five years (2014-18) was 2.5 per cent. The OM&A ratio is trending downwards, due to decreased levels of operating and maintenance expenditures (see Figure 16).

Over the plan period, Hydro One aims to improve on results compared to its historical average, and is targeting 1.5 per cent for the OM&A ratio.

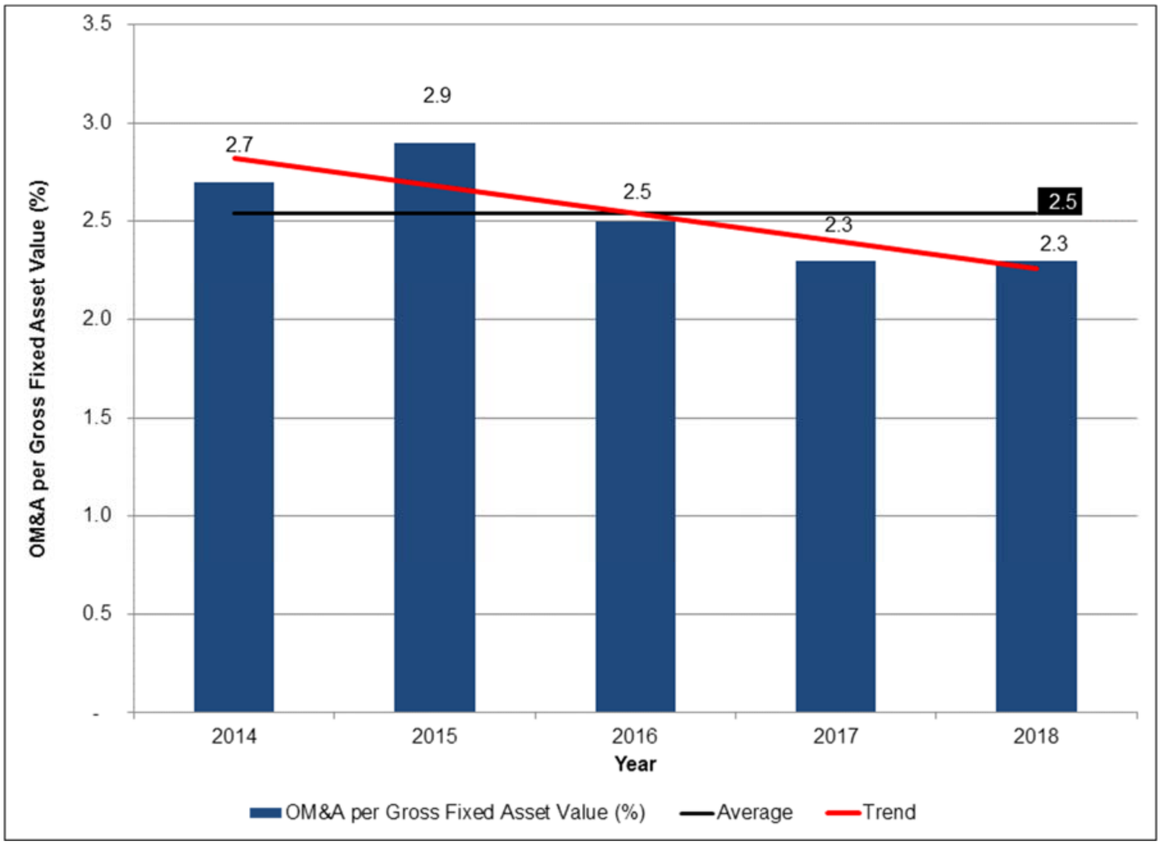

Figure 16 - OM&A per Gross Fixed Asset Value (as %)

Hydro One measures the cost of the line clearing program per kilometre cleared annually. In recent years, Hydro One's vegetation management activities have migrated to operating near their optimal levels in the years 2014-2018, using a six-year cycle in the South, Central, and East regions and an eight-year cycle in North. During these years (2014-2018) the main objective of the program was to get ahead on the backlog created during the period 2008-2013. The focus has also been on gaining greater control of the corridors by bringing tree edges back to the original design specifications. This has directly improved transmission system reliability by decreasing tree encroachments and reducing future maintenance costs. Additionally, Hydro One is experiencing a spike in the volume of work in urban corridors in areas including but not limited to the Greater Toronto Area, Ottawa, Burlington, and Waterloo, where previously, vegetation was not adequately addressed due to community pressure to preserve the trees. Zero tolerance enforcement for non-compliance to NERC FAC-003 Standard regarding minimum clearances for vegetation growth, has led Hydro One to revise its urban vegetation management planning and execution strategy.

For 2018, Hydro One's cost per kilometer of line cleared was $2,797, an increase of $697 or about 33 per cent compared to 2017, primarily due to the factors discussed below (see Figure 17).

Hydro One's average line clearing cost over the past five years (2014-18) was $2,318 per kilometer, and the average annual number of kilometers cleared over the same period was 3,200 kilometers (including the over-accomplishment years 2014 and 2015). Hydro One's past performance indicates an increasing trend in the cost per kilometer, mainly attributable to the increase in work required to bring back corridors to design width across the province and increased work requirements to maintain urban corridors based on the Transmission industry and NERC standards. Additionally, there was a NERC violation in the GTA area that caused an outage on a 230kV BES line. Because of that, field resources took extra caution on all the corridors planned for 2018 to make sure they get as much clearance as possible to the design width standards.

Over the plan period, Hydro One aims to improve against its five-year average, targeting $2,100 per kilometer of line cleared, and expects to clear 3,000 kilometers of line on average annually.

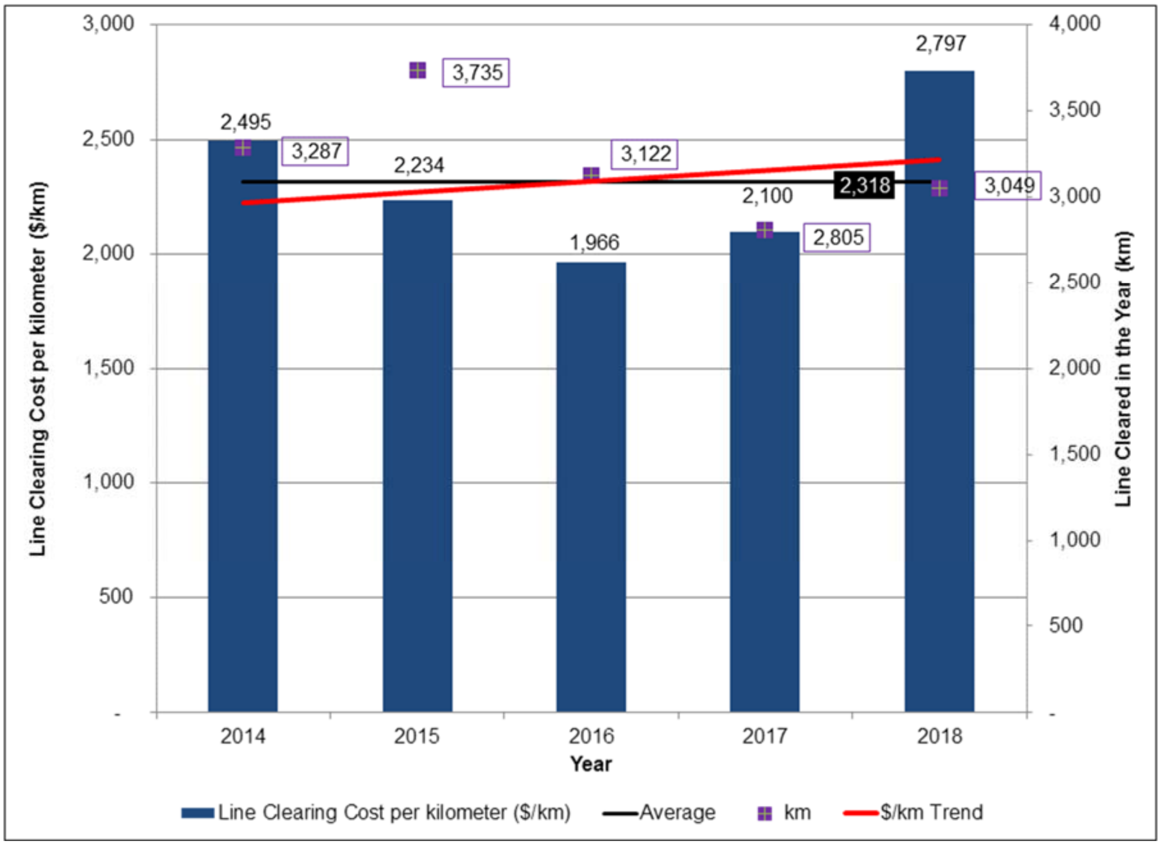

Figure 17 - Line Clearing Cost per kilometer and Number of kilometers Cleared Annually

Hydro One measures the cost of its brush control per hectare completed in the year. For 2018, Hydro One's brush control cost was $1,539 per hectare, completing 12,850 hectares, compared to $1,356 per hectare in 2017 when it completed 12,040 hectares. Similar to the line clearing program, brush control programs are also being managed near optimal levels, using the same cycles as line clearing, by minimizing program deferrals.

Hydro One's average brush control cost over the past five years (2014-18) was $1,525 per hectare, and the average annual number of hectares completed over the same period was 12,203 hectares. Hydro One's performance trend indicates a modest decrease in the cost per hectare, mainly attributable to increased use of herbicide and mechanical means to control ROW areas (see Figure 18). Hydro One continues to invest in vegetation management on all of the transmission corridors to maintain adherence to design standards and decrease backlog conditions.

Over the plan period, Hydro One is targeting $1,608 per hectare completed (including cost escalations due to inflation) and expects to complete 12,500 hectares on average annually.

Unit costs for line clearing for the rate period (2020 to 2022) are forecasted to be higher than the five-year average, but generally lower during the plan period (2020 to 2024). Unit costs for brush control over both the rate period and the plan period are forecasted to be higher than the five-year average. Hydro One's focus has been on gaining greater control of its corridors by bringing tree edges back to the original design specifications, making progress on backlogs, and ensuring its activities operate near their optimal cycle. This work is expected to continue through the plan period and is the primary driver for the forecast costs.

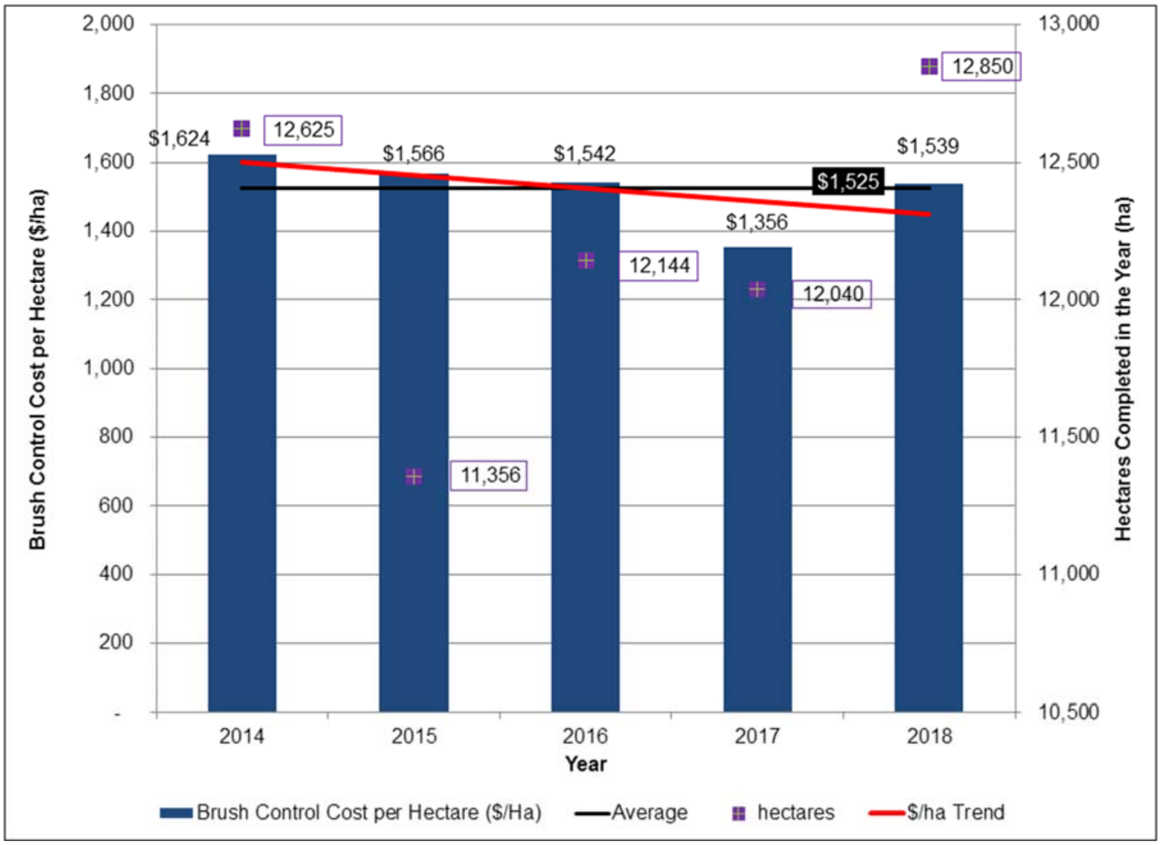

Figure 18 - Brush Control Cost per Hectare and Hectares Completed Annually

Public Policy Responsiveness

__Renewable Energy: On-Time Completion of Renewables Customer Impact Assessments (as per cent)__

For transmission-connected generators, Hydro One completes customer impact assessments and measures its performance in the successful completion of these assessments against a period of 150 days. In 2018, for the fifth consecutive year, Hydro One completed 100 per cent of the customer impact assessments within the allotted time (see Figure 19). Hydro One attributes its consistent performance mainly due to its well defined internal processes and closely coordinating and managing these activities with the Independent Electricity System Operator ("IESO").

Over the plan period, Hydro One aims to maintain its historical performance average, and is targeting 100 per cent on-time completion of renewables customer impact assessments.

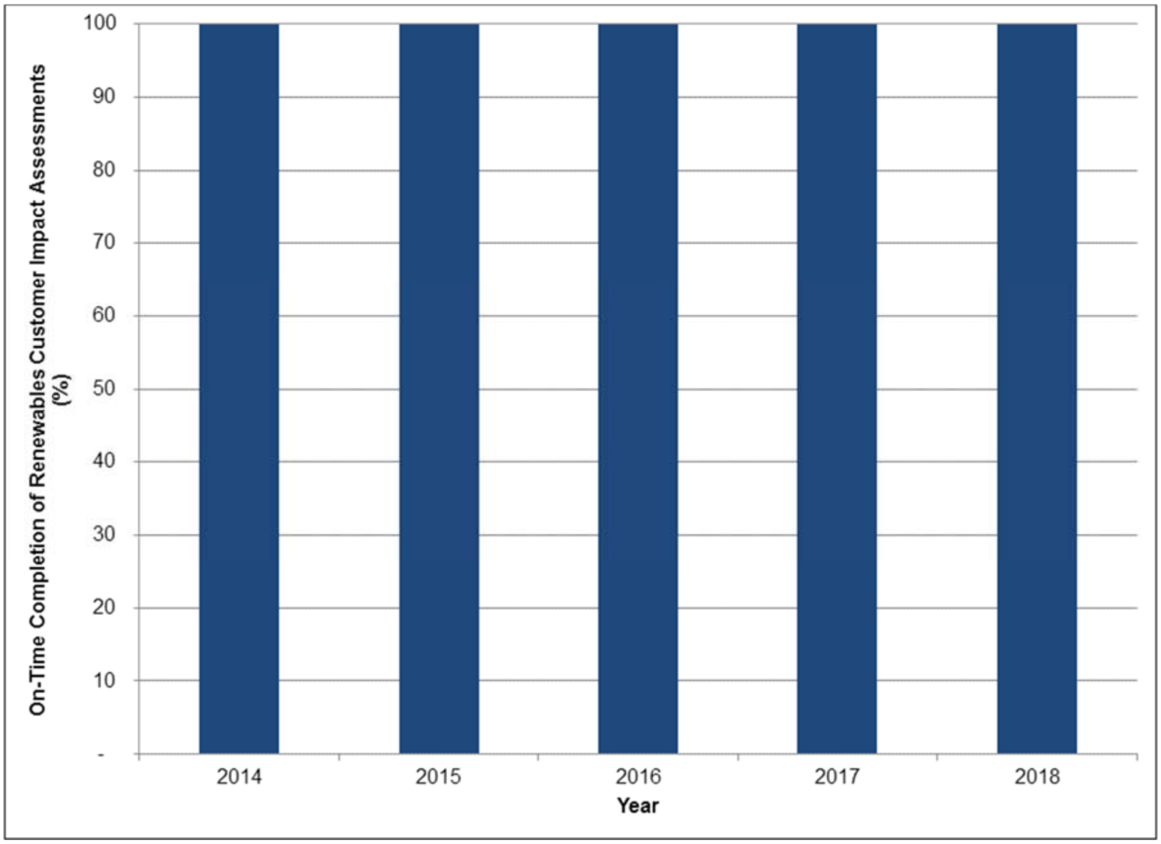

Figure 19 - On-Time Completion or Renewables Customer Impact Assessment (as %)

Regional Infrastructure: Regional Infrastructure Planning Progress (per cent of Deliverables Met)

To drive performance relative to the Public Policy Responsiveness outcome, Hydro One measures the performance of its Regional Infrastructure Planning process. The Regional Infrastructure Planning process was established by the OEB in the third quarter of 2013.

Hydro One measures the percentage of deliverables completed within the prescribed timelines in the Transmission System Code, which includes certain deliverables such as plans, Regional Planning reports, and LDC Planning Status letters for their rate applications. These reports are published on the Hydro One website.

In 2018, for the fifth consecutive year, Hydro One met 100 per cent of its regional infrastructure planning deliverable obligations, within the allotted time (see Figure 20). Hydro One also files an Annual Status Report with the OEB on November 1 of each year. Hydro One attributes its consistent performance mainly due to its well defined process and closely coordinating and managing these activities with the LDCs and IESO, to meet the mandatory obligations.

Over the plan period, Hydro One aims to maintain its historical performance average, and is targeting 100 per cent.

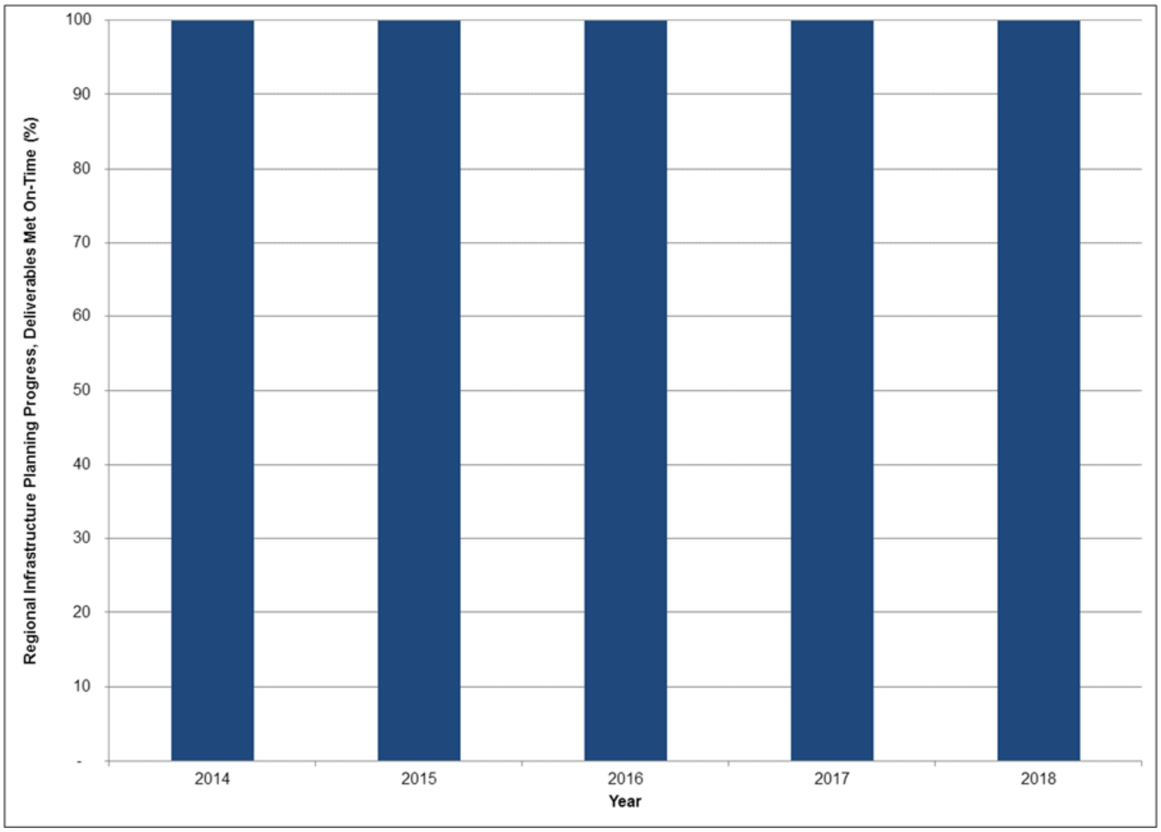

Figure 20 - Regional Infrastructure Planning Progress (% of Deliverables Met)

Long-Term Energy Plan ("LTEP"): End-of-Life Right-Sizing Assessment Expectations Met

This is a new measure introduced in response to the Decision, which qualitatively measures and tracks Hydro One's public policy responsiveness. For further details on this measure, see TSP Section 1.5.2.

In 2018, Hydro One met 100% of its End-of-Life Right Sizing Assessment Expectations.

Over the plan period, Hydro One is targeting to continue a "Met" result in all years.

Financial Ratios

Liquidity: Current Ratio

For 2018, Hydro One reported a current ratio for the transmission segment of 0.18, representing a minimal decrease from 2017 and about a 35 per cent decrease compared to 2016. The 2018 result indicates that for every one dollar of current liabilities, Hydro One had $0.12 in current assets. Current assets are defined as cash or cash equivalents to be converted to cash within the year and which can be used to fund daily operations and pay ongoing expenses. Current liabilities are defined as debt or other financial obligations that become due within the year.

Hydro One's average current ratio over the past five years (2014-18) was 0.25, and is trending downwards, reflecting a decrease in the amount of cash or cash equivalents (see Figure 21). The trend is largely attributable to the high current ratios in 2014 which was mainly due to a positive balance in the inter-company demand facility. Subsequently, the current ratio decreased to 0.13 in 2015 and subsequent years. Due to the nature of this measure, Hydro One has not provided a forecast outlining future financial performance expectations.

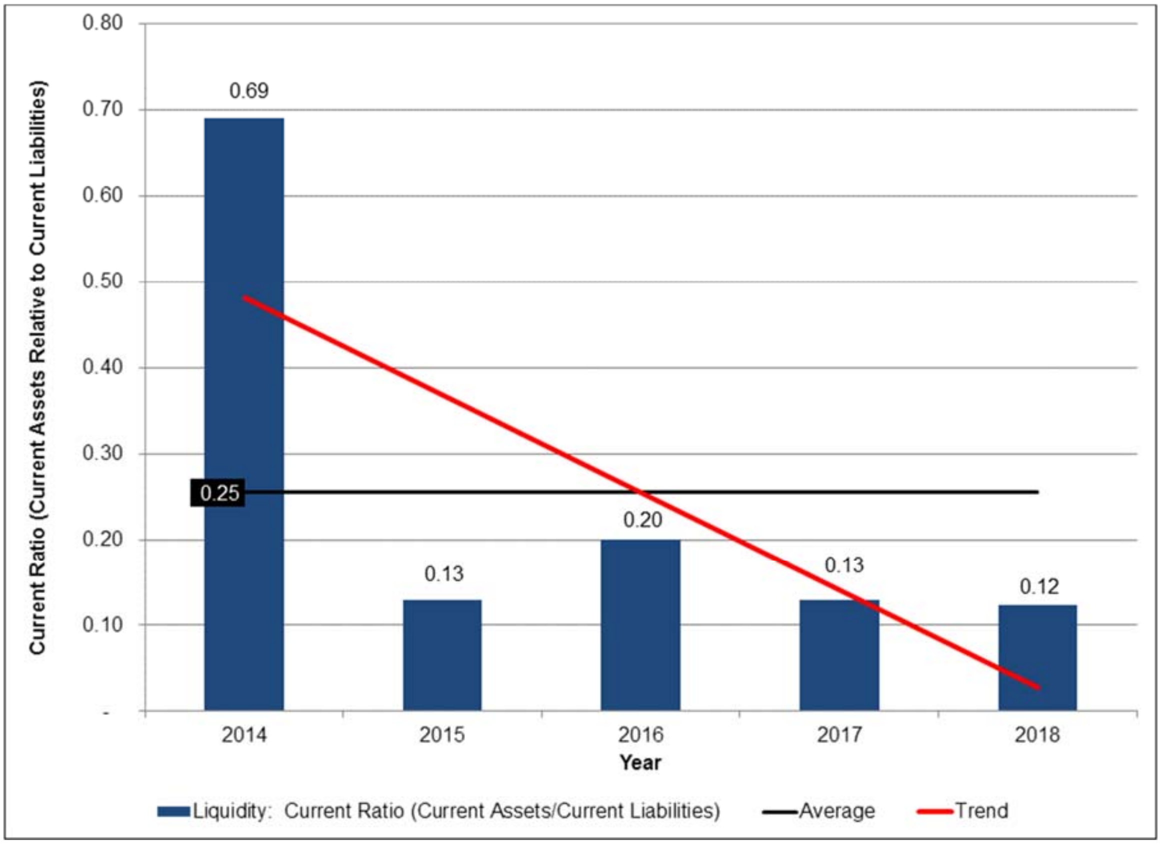

Figure 21 - Liquidity: Current Ratio

<u>Leverage: Total Debt to Equity Ratio</u>

Hydro One's total debt to equity ratio as measured for its transmission segment was 1.53 in 2018, representing an increase of about 4 per cent compared to 2017. The debt to equity ratio is a measure of Hydro One's financial leverage and serves to identify the ability to finance assets and fulfill creditor obligations. The OEB-deemed capital structure is 60 per cent to 40 per cent debt to equity (a ratio of 1.50).

Hydro One's average debt to equity ratio over the past five years (2014-18) was 1.40, and is trending upwards in order to match the OEB-deemed ratio of 1.50 (see Figure 22). The average debt to equity ratio was previously less than the deemed structure of 1.50 largely due to a low dividend payout for the business, as directed by its prior sole shareholder, the Province of Ontario. After Hydro One's Initial Public Offering in 2015, its debt to equity ratio was adjusted to conform more closely to the OEB-deemed capital structure, and company management has stated publicly that it intends to maintain this ratio at or around that level.

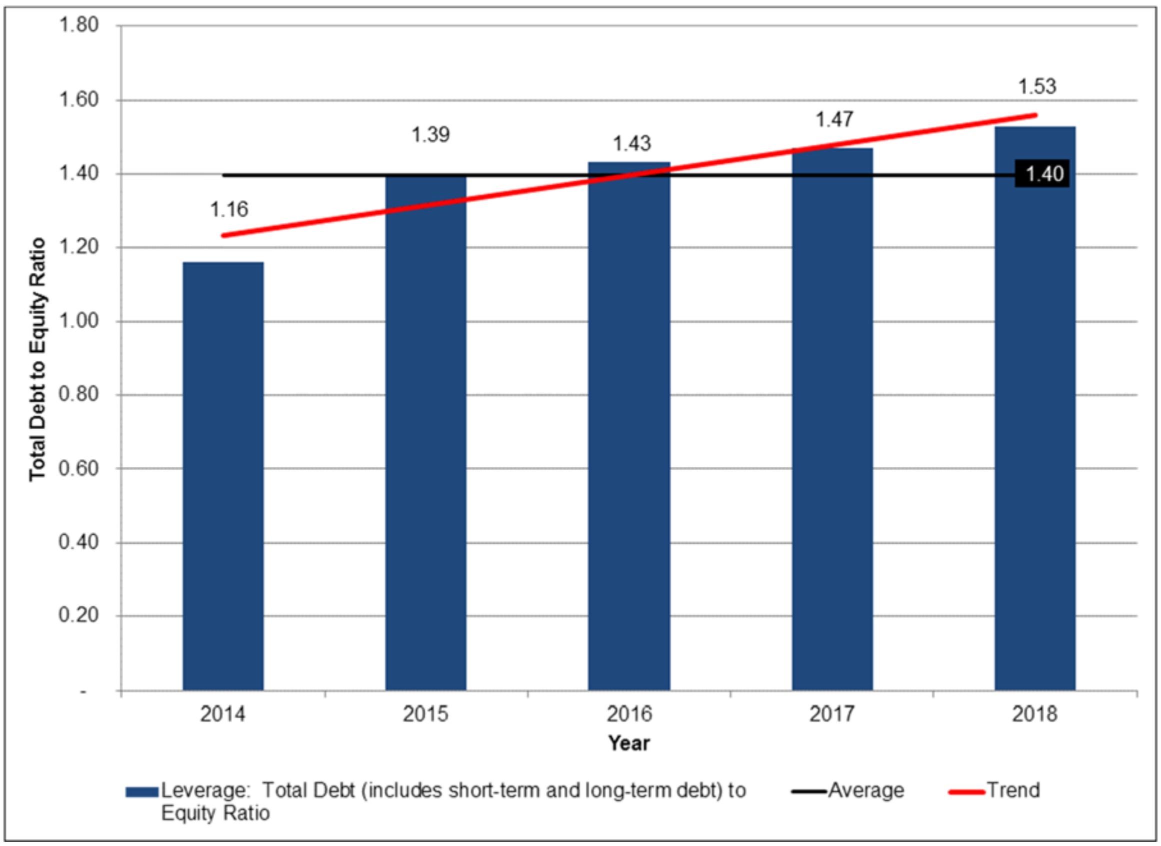

Figure 22 - Leverage: Total Debt to Equity Ratio

__Profitability – Achieved Regulatory Return on Equity__

Hydro One's 2018 achieved regulatory return on equity ("ROE") was 9.63 per cent for its transmission segment, against an OEB-deemed ROE of 8.98 per cent.

Hydro One’s average achieved regulatory return on equity over the past five years (2014-18) was 10.55 per cent and is trending down (see Figure 23).

Due to the nature of this measure, Hydro One has not provided a forecast outlining future financial performance expectations, except that the company strives to achieve the OEB deemed return.

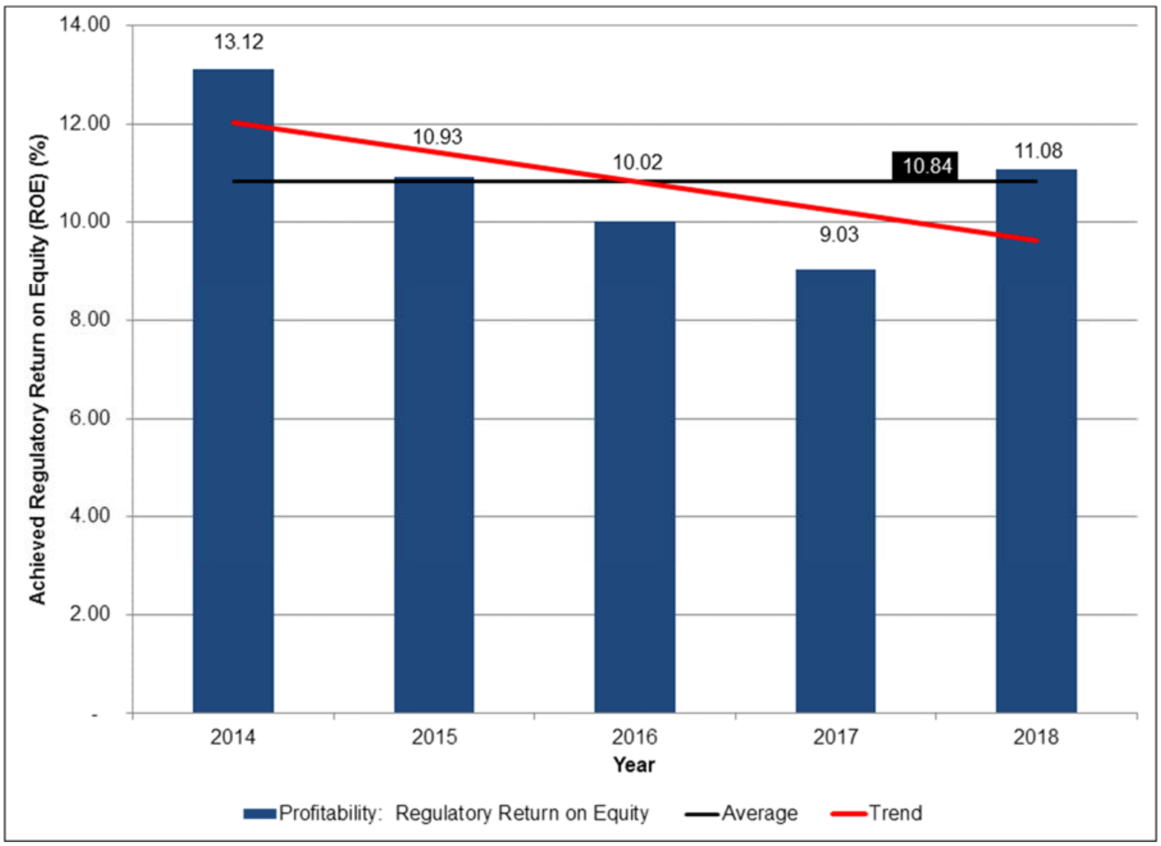

Figure 23 - Achieved Regulatory Return on Equity (ROE)

Summary

The evolved Transmission Scorecard and measures presented herein reflect Hydro One’s response to the Decision and provide continuity with Hydro One’s previously filed Transmission Scorecard. As directed in the Decision, and as evidenced through the evolved Transmission Scorecard and supporting Performance Reporting Governance Framework (TSP Section 1.5, Attachment 1), Hydro One has continued to develop its performance management system and scorecard to reflect the OEB's observations and determinations. In doing so, Hydro One has considered the merits of implementing measures that reflect the overall business and which are expected to positively impact outcomes. In the sections above, Hydro One summarized the methods and approaches it used to select measures for the evolved Transmission Scorecard, and what it believes are the expected merits and outcomes. Additionally, these measures were influenced by internal and external sources that include Hydro One's past performance management measures, benchmarking studies, scorecards, and measures of other utilities in the public domain to align with the key considerations presented in the Handbook. Hydro One's targeted performance outcomes, as reflected in the evolved Transmission Scorecard, will assist Hydro One in transparently monitoring and measuring its performance relative to these outcomes.

Performance Reporting Governance Framework

Distribution & Transmission

January 2019

Contents

Performance Measurement Governance

The Ontario Energy Board ("OEB" or the "Board") assesses Hydro One's transmission and distribution rate applications using a performance and outcomes-based approach, as established in the Board's Renewed Regulatory Framework (RRF). The RRF outlines four performance outcomes (customer focus, operational effectiveness, public policy responsiveness, and financial performance) which articulate the OEB's goals to align the interests of customers and utilities. The outcomes are supported by key principles in the RRF which include the expectation for continuous improvement, robust integrated planning and asset management which paces and prioritizes investments, strong incentives to enhance utility performance, ongoing monitoring of performance against targets, and customer engagement to ensure utility plans are informed by customer expectations.

In rate applications, a utility is expected to integrate its business challenges and customer preferences to create a compelling business plan that directly links the proposals and investments from the rate application to the four performance outcomes. In reviewing utility rate applications, the Board will analyze a utility's past performance on the outcomes, placing greater emphasis on future performance to ensure the key principles of the RRF are considered.

Performance scorecards are used to capture the four outcomes and the key principles of the RRF and are one of the mechanisms used by the Board in assessing the alignment of a utility's rate application to the RRF and the alignment of the interests of the utility to those of its customers.

This document describes how Hydro One tracks and reports its performance outcomes on its scorecards to align with the performance and outcomes-based approach of the Board in assessing utility rate applications and the key principles of the RRF.

In governing this process, Regulatory Affairs receives information and support from Hydro One's various operational lines of business and the Finance group, as further described below. The VP Planning has ultimate accountability for the Performance Reporting Governance Framework, working with various stakeholders to deliver on the requirements of the framework.

Performance Principles & Measures

The OEB requires Hydro One to report on its performance using a variety of measures contained in scorecards that are either developed or required by the OEB. For distribution rate applications, Hydro One uses the following scorecards: (i) the OEB's *Electricity Distributor Scorecard* (at Appendix A); and (ii) Hydro One's *Distribution OEB Scorecard* (at Appendix B). The Electricity Distributor Scorecard is produced by the OEB using the annual Reporting and Record-keeping Requirements (RRR) filings of Hydro One, Distribution. The Distribution OEB Scorecard was proposed by Hydro One in its 2018 to 2022 Distribution Rate Application (EB-2017-0049) to fulfill the requirements set forth in the Handbook for Utility Rate Applications[1], to propose measures in addition to those in the Electricity Distributor Scorecard. For transmission rate applications, Hydro One uses the following scorecard: (iii) Hydro One's

[1] Handbook for Utility Rate Applications, October 13, 2016, Ontario Energy Board

evolved Transmission Scorecard (at Appendix C). Together, the three scorecards are referred to as the "regulatory scorecards". At the overall corporate level, Hydro One uses (iv) the Team Scorecard and for Operations (v) the Operations Scorecard. The interactions between the various scorecards are shown below in Figure 1.

The regulatory scorecards are organized around the four RRF outcomes, and each outcome informs subsequent "performance categories" which are evaluated, for the most part, using quantitative measures that are tracked over a time and compared to targets that are specific to either the industry, Hydro One, or both. The regulatory scorecards are included at Appendices A through C and include the complete list of measures utilized to track and report performance improvements.

Planning for Performance Outcomes

To meet the targets in the regulatory scorecards, Hydro One incorporates the RRF principles and associated measures into its planning, execution, and reporting functions. RRF principles are integrated into Hydro One's corporate objectives and business plan and specific measures from each of the three regulatory scorecards are included in two of Hydro One's internal scorecards – the Team Scorecard and the Operational Scorecard. The Team Scorecard is included at Appendix D and the Operational Scorecard is included at Appendix E.

Figure 1 below shows how the RRF principles are incorporated into the performance reporting process for the regulatory scorecards and Hydro One's Team Scorecard and Operational Scorecard.

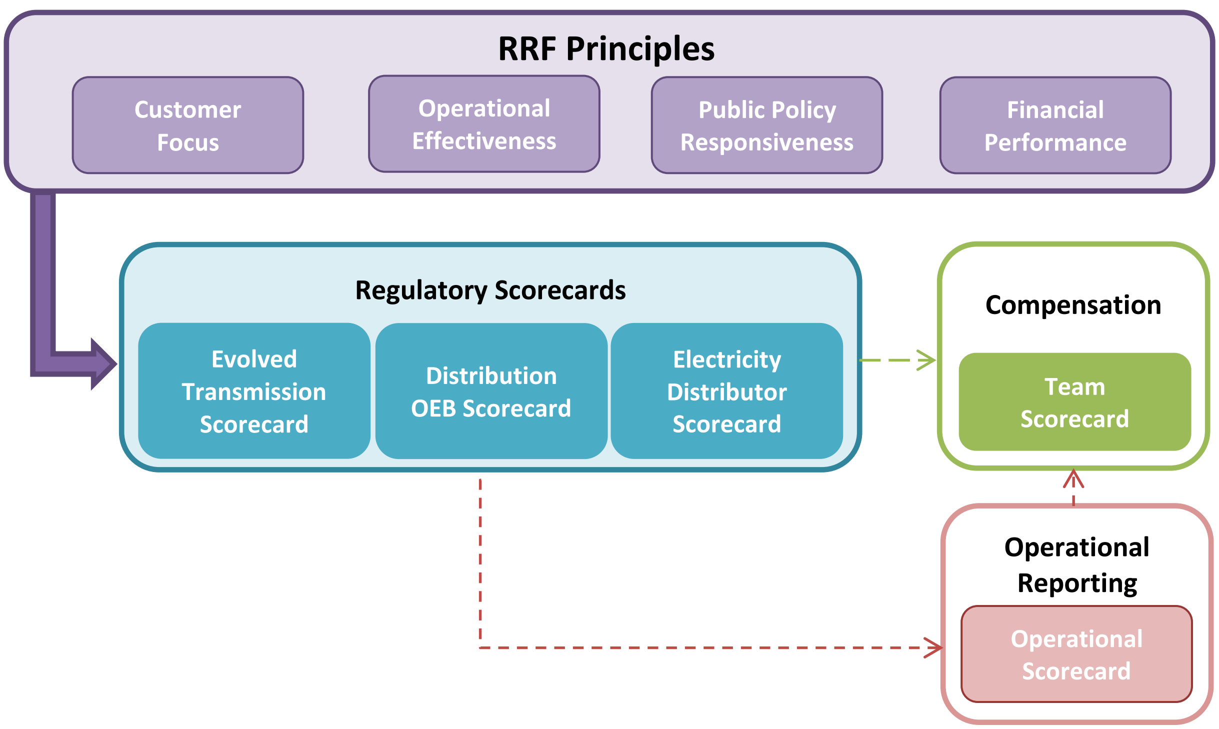

Figure 1 - Performance Reporting Scorecards & Interactions

Governance for Reporting & Development of Measures and Targets

Hydro One's governance framework is designed to support the key principles of the RRF of improvement, robust integrated planning and asset management, strong incentive to enhance performance, ongoing monitoring of performance against targets, and customer engagement to inform rate applications. The framework focuses on two primary activities of (i) performance reporting and (ii) measure and target development, which are supported by the governance matrices in Table 1 and

Table 2 respectively.

The primary stakeholders supporting the governance framework are:

- VP, Planning
- Line of Business Vice President (LoB VP)
- Line of Business (LoB)
- Finance
- Regulatory Affairs

The governance matrices define the roles and activities of each stakeholder using a responsible, accountable, consulted, and informed (RACI) framework, defined as:

- **Responsible** – for implementing or completing the identified activity or task. Responsibility can be shared amongst multiple stakeholders, with various degrees of responsibility;
- **Accountable** – for making decisions and taking actions on the activity or task. This stakeholder has ultimate decision-making authority and therefore, accountability cannot be shared;
- **Consulted** – with or communicated to prior to any final decisions being made or actions being taken. These stakeholders are typically subject matter experts and two-way communication is required;
- **Informed** – after decisions have been made or actions taken. These stakeholders may be required to act as a result of a decision being made or action being taken, however communication is typically one-way.

Table 1 - Governance Matrix for Performance Reporting

Activity	LoB	LoB VP	Finance	Regulatory Affairs	VP, Planning.
Provide executive sponsorship for performance measurement reporting, including by coordinating processes sponsored by LoB VPs	I	-	-	-	A
Sponsor performance reporting within the respective LoB	C	R	-	I	-
Execute performance targets and calculate results	R	A	I	I	I
Collect LoB performance results and produce regulatory scorecards for VP Planning/Executive Leadership Team (ELT) reporting	C	-	C	R/A	I
Integrate regulatory scorecard performance results into ELT reporting materials and report same to ELT	C	I	-	C	R/A
Update Team Scorecard on a regular basis for reporting	R	C/I	A	-	I
Monitor results and review Team Scorecard to ensure accuracy and alignment with approved methodology	C/I	C/I	R/A	-	I

Activity	LoB	LoB VP	Finance	Regulatory Affairs	VP, Planning
Advise LoBs on regulatory requirements associated with the development of performance measures	I	C	C	R/A	C
Develop performance measures	R	A	C	C/I	C/I
Develop targets for the planning period	R	A	I	C/I	C/I
Review performance measures and targets to ensure alignment with OEB RRF, OEB Decisions, and regulatory requirements	C/I	C	C	R/A	C
Ensure each measure and target is defined, documented, measureable, reviewed, and approved by the LoB VP	R	I	I	R	A
Confirm measures and targets are included in the Business Plan	C	R	C	I	AI

R – Responsible; A – Accountable; C – Consulted; I – Informed

To support ongoing monitoring of performance against targets, scorecards are reported to the OEB, Hydro One's Executive Leadership Team, and Operations Managers as outlined in Table 3 below.

Table 3 - Scorecard Reporting Cadence & Deliverables

	Ontario Energy Board	Executive Leadership Team[2]	Operations Managers
Evolved Transmission Scorecard	As Required	Quarterly	Not Provided
Distribution OEB Scorecard	As Required	Quarterly	Not Provided
Electricity Distributor Scorecard	Annual, RRR	Quarterly	Not Provided
Team Scorecard	Upon Request	Monthly	Monthly
Operational Scorecard	Not Provided	Not Provided	Monthly

The Performance Reporting Governance Framework was designed and implemented by Hydro One to align with the Board's performance and outcomes-based approach to utility rate applications and in support of the key principles of the RRF to manage a network that is efficient, reliable, sustainable, and provides value for customers.

[2] For quarterly reporting, measures which are reported by external third-parties (e.g. PEG or ESA) or which cannot be reported in interim periods during the year (e.g. annual customer satisfaction) are omitted.

Appendix A - Electricity Distributor Scorecard – Example

Performance Outcomes	Performance Categories	Measures		2013	2014	2015	2016	2017	Trend	Target	
										Industry	Distributor
Customer Focus Services are provided in a manner that responds to identified customer preferences.	Service Quality	New Residential/Small Business Services Connected on Time		97.40%	97.40%	97.50%	98.60%	98.06%	↑	90.00%

1.6 (5.2.3) PERFORMANCE MEASUREMENT FOR CONTINUOUS IMPROVEMENT: PRODUCTIVITY

To further its commitment to delivering outcomes that are valued by its customers, Hydro One has developed a comprehensive and rigorous process for identifying, developing, implementing, monitoring and measuring productivity initiatives that will reduce costs while maintaining or improving service quality and work outputs. Hydro One's commitment to achieving incremental and continuous productivity improvements is central to the planning and execution of work programs across the company. Within this framework, quantifiable productivity improvements are included in the Business Plan and corporate scorecards with clear accountabilities for delivering the anticipated savings. Using this approach, as described below, Hydro One has identified savings opportunities in Capital and OM&A totalling approximately $704M over the 2020-2024 TSP period.

This section describes Hydro One's productivity framework and its clearly defined process for achieving demonstrable productivity improvements, followed by a summary of the specific productivity savings that are accounted for and built into its proposed OM&A and capital expenditure plan.

1.6.1 PRODUCTIVITY FRAMEWORK

Hydro One's productivity framework is comprised of internal governance around the classification of productivity savings and the process for identifying and obtaining internal approval for productivity initiatives, which must meet certain criteria for acceptance, along with the corresponding accountabilities for approving initiatives, achieving savings, tracking and reporting on productivity performance, and integrating planned savings into business planning.

1.6.1.1 (5.2.3 A) PRODUCTIVITY GOVERNANCE

Hydro One's Finance group has designed a process (described below in sections 1.6.1.2 and 1.6.1.3) to support continuous improvement in the company's efforts to identify, implement, measure and report on productivity across all lines of business. The process is managed and maintained by the Finance group, which oversees the effective, consistent and disciplined implementation of this process so as to ensure that productivity changes are accurately measured and reported on Hydro One's scorecards, and that anticipated productivity improvements are consistently identified in the company's Business Plan. In addition to the oversight and management roles played by Finance, staff from each of the affected lines of business play an integral role in the Hydro One's productivity process and framework. Reporting of productivity results are provided on a monthly basis to senior executives within each line of business, as well as to the CEO.

To ensure continuity in the planning process, rate filing applications, and tracking methodology, Hydro One's productivity initiatives are considered using 2015 as the baseline year for evaluating savings of legacy initiatives. Most legacy initiatives were identified as part of Hydro One's 'Good to Great' initiative. Newly identified incremental initiatives use the last approved plan period as the baseline year. When describing the productivity savings that are incorporated into Hydro One's capital expenditure plan, only the productivity savings anticipated over the TSP plan period are referenced.

1.6.1.2 (5.2.3 A) TIERED PRODUCTIVITY REPORTING

Hydro One introduced a tiered reporting structure so as to clearly differentiate between productivity improvements that will result in actual cost savings ("Tier 1 Productivity") and those that will enable Hydro One to complete more work for the same cost ("Tier 2 Productivity"). Only those savings that contribute to overall direct cost reductions in the Business Plan relative to their baseline, i.e. Tier 1 Productivity savings, are reported against productivity targets in Hydro One's corporate scorecards. However, all savings are monitored and tracked. For greater certainty, Hydro One defines the tiers as follows:

> "Tier 1 Productivity" means net savings with a direct correlation to a budget and/or spending forecast reduction (i.e. 'hard savings'), which are monitored, tracked and reported on corporate scorecards.

> "Tier 2 Productivity" means all unit based savings, other than Tier 1 Productivity savings, which are derived from calculation methodologies approved by Finance and result in Hydro One getting incremental work completed or increased output for the same dollars input (i.e. 'more work'), which are not reported on corporate scorecards but which are otherwise monitored and tracked.

1.6.1.3 (5.2.3 A) METHODOLOGY AND REVIEW PROCESS

Hydro One's productivity process was executed in parallel with, and as an input to, its business planning process. Through the productivity process and framework, each of Hydro One's lines of business[1] was asked to identify productivity initiatives that would have the potential to result in savings. In consultation with the Finance group, the lines of

[1] Hydro One's lines of business with productivity commitments are Fleet Services, Supply Chain, Station Services, Network Operating, Distribution Lines, Forestry Services, Information Technology, Corporate Groups, Planning, Customer Service, and Engineering**.**

business were required to demonstrate that each proposed productivity initiative would be capable of achieving demonstrable unit based savings, that each initiative had a corresponding auditable measurement methodology, and that each initiative was considered in the development of the Business Plan and associated investments. Finance worked with initiative owners to validate planning assumptions and spending reductions to ensure that the expected savings were appropriately embedded in the Business Plan wherever possible, and that expected savings would be passed on to ratepayers. The embedded savings resulted in actual plan reductions which would otherwise not have been attainable.

In the early stages of the process, each of the lines of business submitted their proposed productivity initiatives to Hydro One's Finance group for review. Finance reviewed each submission for completeness and to ensure that the measurement methodology was unit based and auditable. If Finance approved the initiative and confirmed that it would have the effect of reducing a department or program budget, then the initiative was deemed to qualify for tracking and reporting against the company's Tier 1 Productivity target up to the forecast amount of the spending reduction, with further savings to be tracked as Tier 2 Productivity savings. Collectively, the approved and validated initiatives included in the Business Plan comprise Hydro One's productivity plan.

Productivity achievements are reported on a monthly basis. As noted above, all productivity initiatives must be approved by Finance before any actual savings can be reported against savings targets or on corporate scorecards. This approval process ensures that each productivity initiative is carefully tracked using a detailed and robust calculation methodology so as to ensure savings are verifiable and auditable.

For purposes of reporting, Finance reviews all productivity initiatives to ensure they are:

- Consistently and thoroughly documented (including detailed description/logic, identified systems/dependencies, clear calculation methodology/data source and reasonable exclusions/adjustments);
- Auditable (with an applicable baseline for reporting);
- In-line with Hydro One's definitions and classifications of productivity (i.e. Tier 1/Tier 2); and
- Reviewed and approved by a VP or delegate.

Similar processes are followed and approvals required for any new productivity initiatives or forecast changes to existing productivity initiatives that are identified by lines of business.

The lines of business are accountable for achieving the productivity savings through their approved initiatives, as well as for regularly providing budget and forecast trends and actuals on a monthly basis, which are verified by Finance for reporting purposes. Finance maintains and tracks performance for all initiatives and manages the governance documents relating to the productivity process and framework.

Reported productivity savings are tracked and monitored by Hydro One on a continuous basis to ensure business outcomes are achieved. All planned Tier 1 Productivity savings in the 2020-2024 TSP period have been validated as being considered in the creation of the Business Plan. These expected savings are discussed in section 1.6.2.2 below.

1.6.2 (5.2.3 D) PRODUCTIVITY SAVINGS IN THE PLAN

The following describes the OEB's directions to Hydro One from its last transmission rates proceeding, followed by an overview of the specific productivity savings that have been included in Hydro One's plans.

1.6.2.1 OEB DIRECTION FOR PRODUCTIVITY IMPROVEMENTS IN EB-2016-0160

In the OEB's Decision in EB-2016-0160, it directed Hydro One to establish firm short-term and long-term targets for productivity improvements and associated reduction in revenue requirement as a means to drive continuous improvement and improve the company's internal and external benchmarking standings. Hydro One has identified savings opportunities in Capital and OM&A totalling approximately $704M over the 2020-2024 TSP period. These savings have been embedded into the Business Plan and this TSP. The savings targets are measured and tracked continuously, and reported on a monthly basis to Hydro One's Executive Leadership Team to ensure that Hydro One is meeting its planned deliverables at a lower unit cost without a reduction in planned work volumes. Developing initiatives and processes that drive Hydro One to continuously become more productive and more efficient over time are cornerstones of Hydro One's plan.

1.6.2.2 OVERVIEW OF PRODUCTIVITY SAVINGS

The savings driven by Hydro One's internally approved productivity initiatives have been included in the detailed OM&A and Capital expenditure plans. A summary of Hydro One's forecast productivity savings for the 2020-2024 TSP period is provided in Table 1.

Table 1 - Productivity Savings Forecast Summary ($Millions)

$mm	2020	2021	2022	2023	2024	Total
Operations	47	52	53	53	54	259

OM&A Total	**$22**	**$25**	**$23**	**$23**	**$22**	**$114**
Total Defined	**$87**	**$99**	**$97**	**$93**	**$92**	**$468**
Progressive Operations (Undefined Capital)	11	27	49	68	81	237
Grand Total	**$98**	**$126**	**$146**	**$161**	**$173**	**$704**
Progressive Productivity						
Progressive Operations (Defined Capital)	6	12	12	10	10	49
Progressive Operations (Undefined Capital)	11	27	49	68	81	237
Progressive Productivity Placeholder	17	39	61	78	91	286

As noted in the table above, Hydro One has identified savings opportunities totalling approximately $704M over the 2020-2024 TSP period. This reflects Tier 1 Productivity savings only. There are $353M in capital productivity savings, $114M in OM&A productivity savings and $237M in undefined capital savings. This latter category of savings falls within “Progressive Productivity”. Progressive Productivity is a further reduction in cost that Hydro One has included in the final Transmission Business Plan in response to concerns that were raised in the OEB’s decision in the Prior Proceeding regarding the level of investment. It represents a commitment from Hydro One to find further efficiencies over the planning period when executing the necessary planned investments in its transmission system without reducing work volumes. Progressive Productivity savings total $286 million over the planning period and are included in the Transmission Business Plan in the form of:

1. $49 million in Progressive Operations (Defined Capital) savings associated with initiatives that have been identified but which have not yet been proven and verified through the productivity governance framework; and
2. $237 million in Progressive Operations (Undefined Capital) savings which are included as placeholder in the Business Plan to be allocated to any future initiatives that have not yet been identified.

Approximately $590M of the identified savings opportunities are related to Operations (Operations OM&A, Operations Capital, Progressive Operations (Defined Capital) and Progressive Operations (Undefined Capital), approximately $44M in savings are IT-related (OM&A and Capital) and $70M in savings are related to Corporate Initiatives (OM&A and Capital).

Underlying the savings in Hydro One’s productivity plan are specific productivity initiatives that have been identified, reviewed, approved and made subject to tracking and reporting requirements in accordance with the productivity framework and process described in Section 1.6.1, above. The savings arising from each of these initiatives are real reductions from department or program budgets. Additional Tier 2 Productivity savings may be achieved in connection with these and other initiatives, but such additional savings cannot be forecasted and are not accounted for in the planned savings.

By embedding all of the forecast productivity savings - from specific productivity initiatives and progressive productivity (discussed below under progressive productivity section) - into Hydro One’s Business Plan, Hydro One bears the risk of not delivering its planned productivity improvements. This creates a strong incentive for Hydro One to follow through on its productivity commitments.

Operations

In Table 1 above, $590M of savings (Capital, OM&A and Progressive) are related to Operations. These savings are comprised of:

- $304M of savings that have been identified through specific underlying Operations productivity initiatives (OM&A and Capital) including Procurement, Fleet Services, Station Maintenance and Network Operating.
- $286M of savings that will be achieved through the application of Progressive Productivity over the 2020-2024 TSP period on the transmission work program. Progressive productivity initiatives have not been planned at a specific project or program level but have been applied to the business plan as a negative 'Progressive Productivity Placeholder' in the capital work program. Hydro One will continue to define and validate initiatives until all of the undefined progressive savings targets ($237M) are allocated to specific work programs and projects as discrete initiatives. Upon validating the defined initiative, the Progressive Productivity Placeholder will be eliminated and the affected cost driver will be reduced.

Together, these savings demonstrate Hydro One's commitment to identifying and implementing efficiencies and minimizing operations expenses before passing such costs on to customers. Operations savings will be realized by committing to the implementation of productivity initiatives that leverage new technology and processes, and in some cases drive significant change to the way that Hydro One plans and completes work. The basis for Hydro One's identified savings in each of these areas is discussed below.

Procurement

Hydro One's Supply Chain division has made several changes to its sourcing processes to increase productivity and reduce expenses. Of the expected $590M in total Operations savings (OM&A and Capital including progressive productivity), Hydro One forecasts that $190M in savings over the 2020-2024 TSP period will result from procurement enhancements. Enhancements such as, but not limited to the following, are enabling these significant procurement savings:

- **Bundling/Volume Discounts –** Hydro One will undertake a comprehensive review of its sourcing categorization by grouping materials/services supplied by like-suppliers to maximize savings and take better advantage of volume discount opportunities by addressing multiple sub-categories at once. Through this approach, Hydro One will seek to bundle multiple contracts with a single supplier and negotiate volume discounts across multiple categories and contracts.
- **Feedback Rounds –** Hydro One will seek to maximize competitive pressure by implementing multiple feedback rounds on rates so as to provide an opportunity for potential vendors to improve their proposals.
- **'Lean' RFPs –** Hydro One will emphasize leaner, "bidder-friendly" scope and value in RFP formats with fewer and less onerous requirements.
- **Standardization of Specifications –** Hydro One will standardize requirements to allow for direct, like-for-like comparisons across bidders. It will also employ industry-standard specifications where appropriate, rather than Hydro One specifications, to reduce unnecessary costs.
- **Streamlined Evaluation –** Hydro One will seek to compress timelines and streamline evaluation processes to meet business needs and accelerate the realization of negotiated savings.
- **Cost Transparency –** Hydro One will enhance its understanding of bidder pricing elements to improve its ability to challenge and negotiate more competitive pricing.

Fleet Services

Hydro One forecasts, and has embedded in the Business Plan, over $56M in fleet savings over the 2020-2024 TSP period as a result of the implementation and use of telematics. Telematics integrates telecommunications systems, including global positioning systems

(GPS) and informatics systems that provide vehicle locations and live vehicle operation and performance data. The telematics project was successfully rolled out to all fleet vehicles and equipment at the end of 2016 and provides analytics that will allow Hydro One to realize productivity efficiencies for the 2020-2024 TSP period. In 2017, Fleet Services started to leverage telematics data to define baseline metrics with respect to equipment utilization, non-productive idling and fuel efficiency. The accumulated data has enabled Fleet Services to accelerate the rationalization of the fleet and reduce the need to purchase additional equipment without compromising service quality to operating divisions.

Stations Services and Network Operating Groups

Hydro One forecasts, and has embedded in the Business Plan, over $37M in savings over the 2020-2024 TSP period as a result of the implementation of various initiatives for the Station Services and Network Operating groups, including:

- Overtime Reduction Strategies - Hydro One is focusing on reducing overtime spending by tightening controls and implementing more stringent approval methods. High priority corrective maintenance can account for a large portion of overtime spend.
- Improved Scheduling - Maintenance plans are being reviewed in a more stringent manner between lines of business to ensure that the right work is being released for the right equipment to be completed in the most optimal conditions and on a more consistent basis. Improved technology and software has also resulted in cost savings relating to scheduling staff.
- Ongoing Wrench Time Studies - A detailed analysis of specific work tasks performed on the same equipment across all zones is being performed to determine the best and worst cost ratios and establish a median standard for internal benchmarking. The identified best practices used by the most efficient crews will be implemented across all zones to increase overall efficiency.

Progressive Productivity

Progressive Productivity is a further reduction in cost that was applied to Hydro One's final transmission investment plan as a 'Progressive Productivity Placeholder' in response to the concerns that were raised by the OEB regarding the pacing of investments in Hydro One's 2017/2018 Transmission Rate Decision (EB-2016-0160).

During the planning process, after the Decision in EB-2016-0160 was received, project planners worked with management to reduce the total capital plan and associated rate impacts. While reviewing the system requirements and planned work, it was ultimately determined that rather than reducing specific programs and projects further, Hydro One would commit to finding additional efficiencies during the 5 year plan which would allow the completion of the necessary work while also benefiting customers with reduced rate impacts. With the exact source of these efficiencies unknown, the savings were estimated on the overall work program; committing the company to delivering the same work program volume for 1%-3% less on a year over year basis. These savings will be sought in common project-specific areas such as:

- better utilization of tools;
- improved processes to reduce labour waste/churn;
- optimization of commissioning work; and
- additional project initiatives designed to meet the productivity commitments that will be identified as projects progress through their estimation and execution life cycle.

The identification and inclusion of these savings in this application represent a significant incremental commitment from Hydro One to find further efficiencies over the planning period when executing the necessary planned investments without reducing work volumes. Hydro One has given the benefit of these savings to ratepayers up front and has taken on the execution risk to deliver its planned work program within a reduced funding envelope. As initiatives are defined, they will be reviewed in line with Hydro One's productivity governance framework and, if approved, the savings will be tracked and credited as an achievement by the project against the savings target.

Information Technology

Overall, Information Technology savings over the plan period is primarily driven by the renegotiation of the outsourced Inergi agreement. The new agreement results in rationalized IT spending and considerable contractor rate reductions. IT savings totalling over $44M (OM&A and Capital) over the 2020-2024 TSP period have been embedded into the transmission business plan.

Corporate Costs

In conjunction with enhancing value for customers and all stakeholders of the Company, a thorough review of corporate based costs was completed during the latter portion of 2018 which resulted in identified and embedded savings of approximately $70 million (OM&A and Capital) over the 2020-2024 TSP period. The reductions were achieved primarily through a reduction in vacancies and limiting consulting and contracts to critical functions, with an overall focus on building internal capabilities.

1.7 (2.4) LONG-TERM ENERGY PLAN

The Minister of Energy is required by Section 25.29 of the *Electricity Act, 1998* to periodically issue a Long-Term Energy Plan ("LTEP") to set out the Government of Ontario's goals and objectives regarding energy plans. The goals and objectives described in the LTEP address the issues of cost effectiveness and reliability of the province's transmission system, as well as distribution systems, and thereby have a direct impact on Hydro One's transmission capital plans.

The following Sections provide: (a) an overview of the evolution of the long-term energy plan and its context; (b) a summary of the relevant aspects of the 2017 LTEP; and (c) a discussion of the impact of the 2017 LTEP on Hydro One's transmission capital plans.

1.7.1 THE LONG-TERM ENERGY PLAN EVOLUTION

The LTEP has evolved over the last nine years since it was introduced. The initial 2010 plan, entitled "Ontario's Long-Term Energy Plan, Building Our Clean Energy Future"[1], focused on a number of key areas:

- Supply (including retirement of coal fired generation and the development of renewable generation);
- Demand management and energy conservation;
- Development of priority transmission facilities (including five transmission projects to facilitate reliability and renewable energy growth);
- First Nations engagement; and
- Electricity prices.

[1] https://www.ontario.ca/document/2010-long-term-energy-plan

In 2013, the second LTEP was released by the Ministry of Energy entitled 'Ontario's Long Term Energy Plan, Achieving Balance'[2]. This 2013 LTEP continued to build on the principles laid out in the 2010 LTEP and was designed to balance the following five principles: cost-effectiveness, reliability, clean energy, community engagement, and an emphasis on conservation and demand management before building new generation. Special attention was also given to transmission development in the Northwest and joint project development with First Nations.

In 2016, the Government of Ontario modified the *Electricity Act, 1998* to formalize the LTEP process. These legislative changes include a requirement for consultation with local communities, stakeholders and other ministries, along with engagement with First Nation and Métis communities. The legislative changes also required a technical report to be developed by the Independent Electricity System Operator ("IESO") on the adequacy and reliability of electricity resources with respect to anticipated electricity supply, capacity, storage, reliability, and demand.

In addition to these legislative changes, Ontario's energy use has changed substantially in the last decade. Ontario homes, businesses and industries are becoming more efficient, while at the same time new technology and renewable energy sources are being explored. To guide Ontario in adapting to these changes, a third LTEP was issued on October 26, 2017 by the Minister of Energy, entitled "Delivering Fairness and Choice"[3].

[2] https://www.ontario.ca/document/2013-long-term-energy-plan
[3] https://www.ontario.ca/document/2017-long-term-energy-plan

1.7.2 OVERVIEW OF THE 2017 LTEP

The 2017 LTEP purports to set the course for Ontario's energy supply over the coming years by building on the work of the past years. It maintains the key priorities established in previous plans and includes a number of new initiatives to further these objectives.

The 2017 LTEP's primary goals are to keep electricity prices affordable, cut costs where possible, facilitate market renewal, limit new supply procurements, support renewable generation, support supply to remote First Nations communities, put conservation first, and stimulate innovation. The main features that affect the electricity sector are as follows:

- **Affordability:** Electricity prices for large customers are expected to be in line with inflation over the forecast period. The costs of existing investments will be spread over a longer period of time.

- **Flexible Energy Supply:** Movement away from long term electricity contracts to a more market based competitive approach where the most cost effective resources would be utilized to provide supply under the IESO's market renewal process.

- **Innovation:** Work on incorporating innovation across the entire energy supply chain through initiatives to: provide customers more choice in their electricity price plans, enhance the net metering framework to allow customers to incorporate clean renewable generation, facilitate grid modernization including distributed energy resources and electric vehicle grid integration, reduce barriers to energy storage, evaluate use of electricity to create hydrogen, and collaborate with the federal government, universities, and industry to support the nuclear sector.

- **Value and Performance to Customers:** Renew consumer-focus by improving efficiency and reliability, making utilities more accountable to their customers, promoting cost reductions, and improving and streamlining regulatory process and reliability standards. The focus will also be on developing a process for competitive procurement for transmission and promoting the right sizing of transmission and distribution assets at end-of-life.

- **Energy Conservation and Efficiency:** Reaffirm the provincial government's commitment to conservation and a clean electricity system which includes renewable generation that supports the Climate Change Action Plan[4]. Also, promoting opportunities to access renewable generation and energy storage technologies by expanding net-metering options.

- **Support First Nation Capacity and Leadership:** Prioritize the connection of remote First Nation communities to the grid and provide support for the four First Nation communities for which transmission connection is not economically feasible. Also explore options to integrate small scale renewable energy projects, net metering or other solutions to address local or regional energy needs.

- **Support Regional Solutions and Infrastructure:** Continue to implement conservation policies in regional and local energy planning processes; looking at ways to improve the existing regional planning process and reduce barriers to the use of conservation, demand response or other distributed energy resources.

The Minister of Energy directed the OEB[5] and the IESO[6] to develop implementation plans by January 31, 2018 to meet these LTEP goals.

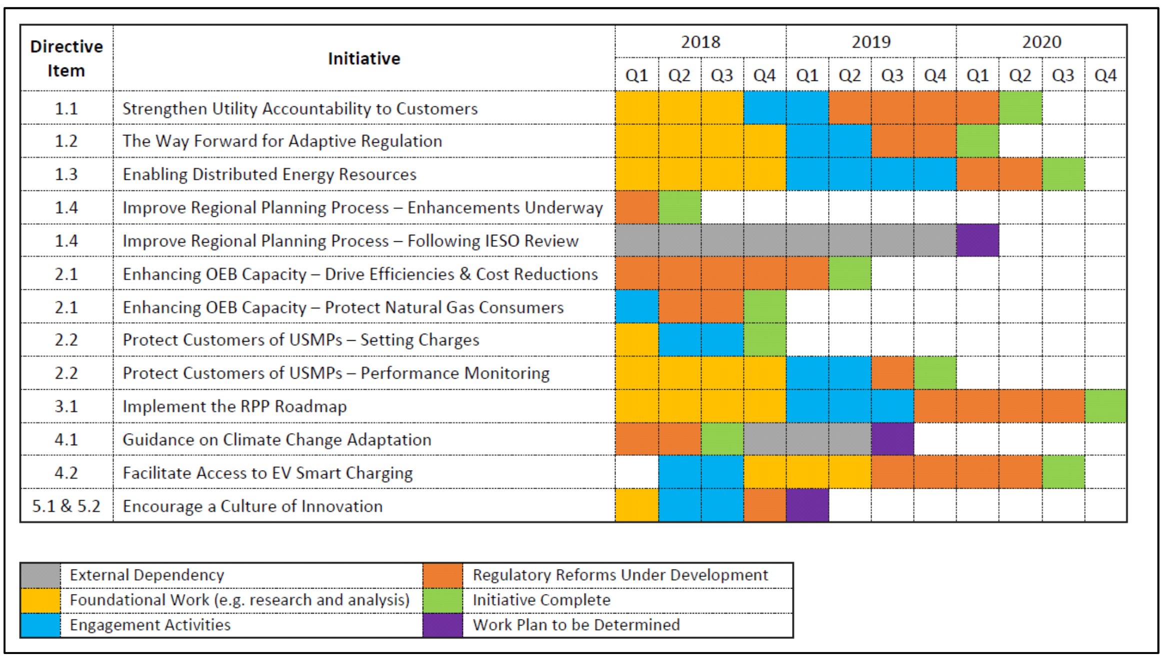
---

[4] https://www.ontario.ca/page/climate-change-action-plan
[5] https://www.oeb.ca/sites/default/files/Directive_to_OEB_LTEP_Implementation_Plan_20171026.pdf
[6] http://www.ieso.ca/corporate-ieso/ministerial-directives *(Directive dated: October 26, 2017)*

On February 15, 2018 the Minister of Energy approved both the OEB's Implementation Plan[7] and the IESO's Implementation Plan[8] that set forth their action plans to meet the LTEP goals.

The OEB implementation plan initiatives and their timings are given in Figure 1 below. Most of the initiatives will primarily impact the distribution system. The impact on the transmission system will be due to potential change in load forecasting on the distribution system as a result of these initiatives. Initiative 1.4 is aimed at enhancing and improving the Regional Planning Process and is expected to improve the determination of the need and timing for new facilities.

Figure 1: OEB Implementation Plans



Extract from page 40 of the OEB Implementation Plan

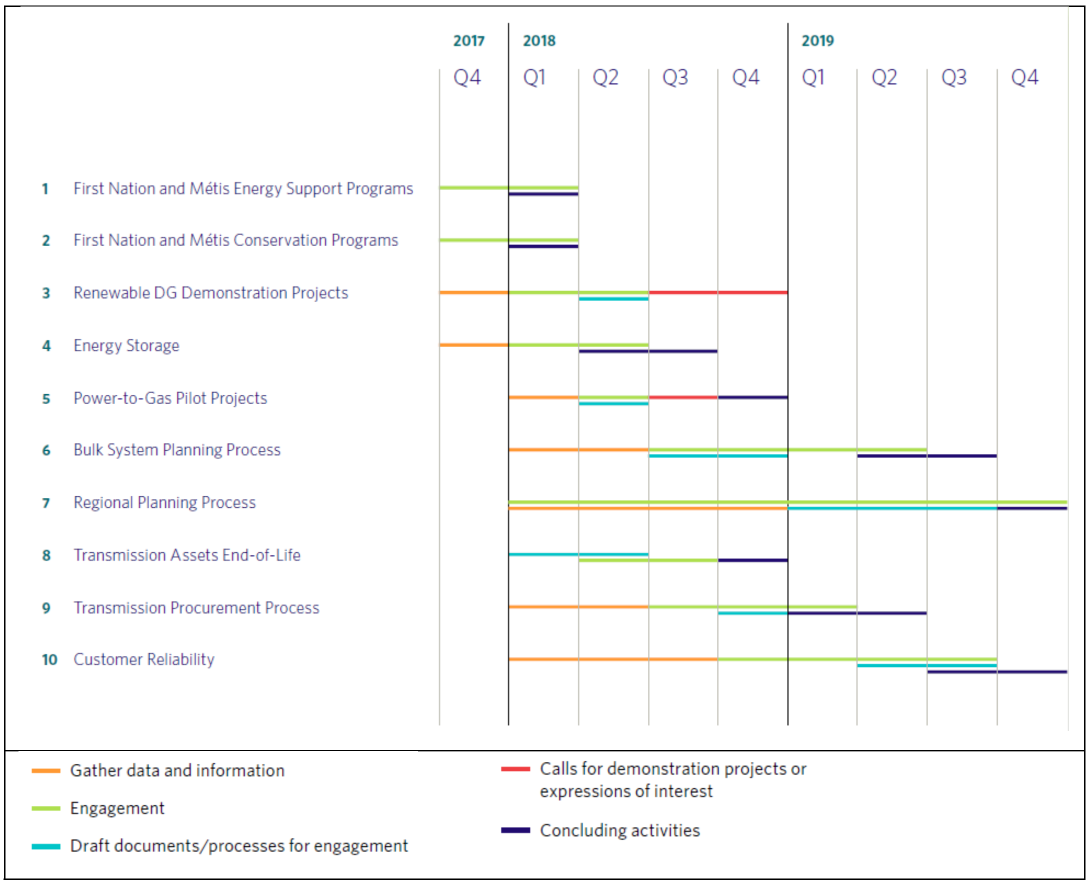
[8] http://www.ieso.ca/-/media/Files/IESO/Document-Library/ltep/IESO-ltep-implementation-plan.pdf

The IESO implementation plan initiatives and their timings are given in Figure 2 below. Initiatives 6 to 10 impact transmission. Of these, Initiatives 6, 7 and 8 are aimed at improving the planning processes for determining the need and timing of the facilities; Initiative 9 will consider the development of competitive transmission; and Initiative 10 covers a review of the existing Ontario transmission reliability criteria.

Figure 2: IESO Implementation Plan



Extract from page 26 of the IESO Implementation Plan "Putting Ontario's Long-Term Energy Plan into Action"

1.7.3 IMPACT OF THE 2017 LTEP ON THE TRANSMISSION CAPITAL PLAN

The 2017 LTEP indicates that the IESO's forecasts for electricity demand[9] remain relatively flat until 2035 and, therefore, no major expansion of the provincial transmission system is required beyond those projects that are already planned or under development.

The transmission system initiatives referred to in the LTEP that form part of Hydro One's 2020 to 2024 capital plans, are summarized in Table 1 below. One of these transmission system initiatives (Project 6) was completed in 2018; however the project has been included in the table for completeness.

Table 1: 2017 LTEP Major Transmission Projects

No	Project Description	Need and Details	In-Service Date
1	Northwest Bulk Transmission Line	Support growth and maintain a reliable supply to areas west of Atikokan. Further details are presented in TSP Section 3.3.8 ISD SS-08.	(Phase 1) mid-2030s*
2	East – West Tie Transmission Line	Improve supply reliability to meet demand and changes in supply mix in Northwest Ontario. Further details are presented in TSP Section 3.3.8 ISD SS-04.	2022
3	Greater Toronto Area West Bulk Reinforcement	Improve supply capability in the western section of the Greater Toronto Area. Further details are presented in TSP Section 3.3.8 ISD SS-07.	2025
4	Hawthorne to Merivale	Optimize use of the interties with Quebec and increase capability to serve load in western Ottawa. Further details are presented in TSP Section 3.3.8 ISD SS-06.	2022
5	Lake Erie Connector	Facilitate interconnection between Ontario and markets in US. Further details are presented in TSP Section 3.3.8 ISD SS-03.	2022
6	Clarington Transformer Station	Construction of the Clarington TS to meet the needs of the growing eastern GTA and prepare for the eventual retirement of Pickering Nuclear Generating Station. Further details were presented in EB-2016-0160, Exhibit B1, Tab 3, Schedule 11, ISD D01.	2018

** As noted in ISD SS-08, Hydro One's transmission capital plan only includes the development work for this project at this time. The in-service date is based on the IESO's assessment that additional capacity is needed by the mid-2030s, but could potentially arise in the early 2020's under the high load growth scenario.*

[9] http://www.ieso.ca/sector-participants/planning-and-forecasting/ontario-planning-outlook *(Sept. 1, 2016)*

Projects 1, 3, 4 and 6 are being led by Hydro One, and Hydro One will be owning the facilities and carrying out the associated investments. Projects 2 and 5 are being led by parties other than Hydro One and many of the related facilities will be owned by those parties. Hydro One investments for these projects cover work required to enable these customer facilities to interface with Hydro One's transmission system. These investments are required to fulfil Hydro One's obligation in accordance with its Transmission License.

In addition to the major transmission projects listed above, the 2017 LTEP also identifies a number of regional planning projects that form part of Hydro One's 2020 to 2024 capital plans and which are summarized in Table 2 below. Two of these regional planning projects (Projects 2 and 6) mentioned in the 2017 LTEP are currently under construction and Hydro One expects the work to be completed by 2019. Furthermore, Projects 4 and 7 were completed and placed in service in 2018. However, these four projects have been included in the table for completeness.

Table 2: 2017 LTEP Regional Planning Projects

<table>
<tr><th>No</th><th>Region</th><th>Project Description</th><th>Need and Details</th><th>In-Service Date</th></tr>
<tr><td>1</td><td>North of Dryden*</td><td>New 230 kV transmission line from the Dryden/Ignace area to Pickle Lake.</td><td>Connect remote First Nation communities currently served by diesel generators. Further details are presented in TSP Section 3.3.8 ISD SS-02.</td><td>2020</td></tr>

<tr><td>3</td><td>New transformer station and transmission line in South Nepean.</td><td>Meet growing electricity needs from new developments. Further details are provided in TSP Section 3.3.8 ISD SS-11.</td><td>2021</td></tr>
</table>

No	Region	Project Description	Need and Details	In-Service Date
4	Central Toronto	Investment in Runnymede transformer station.	Ensure new customers can be connected to the grid. Further details were presented in EB-2016-0160 Exhibit B1, Tab 3, Schedule 11, ISD D19.	2018
5		Investment in Horner transformer station.	Ensure new customers can be connected to the grid. Further details are presented in TSP Section 3.3.8 ISD SA-02.	2020
6		Investment in Copeland transformer station.	Ensure new customers can be connected to the grid. Further details were presented in EB-2014-0140 Exhibit D2, Tab 2, Schedule 3, ISD D10.	2019
7	Windsor -Essex	New transmission line and transformer station near Leamington.	Address growth and improve restoration timelines. Further details were presented in EB-2016-0160 Exhibit B1, Tab 3, Schedule 11, ISD D14.	2018
8		Refurbish the Kingsville transformer station.	Address growth and improve restoration timelines. Further details are presented in TSP Section 3.3.8 as part of ISD SR-05.	2022
9		Refurbish the Keith transformer station.	Address growth and improve restoration timelines. Further details are presented in TSP Section 3.3.8 as part of ISD SR-03.	2023
10	York Region	New transformer station in the City of Markham.	Address capacity and reliability in the York Region.	2026

** The 2017 LTEP also identified, in the North of Dryden region, a project to upgrade the existing transmission lines from Dryden to Red Lake, however Project 1 will result in reinforcing the Pickle Lake area thereby eliminating the need for the Dryden to Red Lake reinforcement.*

While the investments associated with Projects 2 to 5, and 7 to 9 are being led by Hydro One, the investments associated with Projects 1, 6, and 10 (as well as the new transformer station of Project 3) are in support of projects being led by parties other than Hydro One and many of the related facilities will be owned by those parties. However, as described above in the context of the major transmission initiatives, Hydro One needs to undertake certain investments to fulfil its obligation to enable those customer facilities to interface with Hydro One’s transmission system in accordance with its Transmission License.

The LTEP also discusses certain future transmission corridor requirements, which align with the IESO's Integrated Regional Resource Plan for the Greater Toronto Area. In particular, the northwest GTA has a long term need for a new transmission corridor to supply increased forecast demand in portions of Halton Region, Peel Region and York Region. Hydro One will be working with the IESO to further define plans for future development of the corridor.

Furthermore, the implementation plans put forward by the OEB and IESO to deliver on initiatives set out in the 2017 LTEP will potentially have an impact on the current planning processes (both bulk and regional) as well as the OEB's codes and requirements. Hydro One intends to be an active participant in the consultation and/or engagement sessions related to these activities and will continue to manage the transmission system in accordance with these processes, codes and requirements as required by Hydro One's Transmission License.

1.8 TRANSMISSION LINE LOSSES

In Hydro One's 2017-2018 Transmission Rate Application (EB-2016-0160), there was considerable discussion on how Hydro One deals with transmission line losses. The Board in its Decision and Order in that proceeding requested Hydro One to report on the following initiatives as part of its next rate application:

> *'Hydro One should work jointly with the IESO to explore cost effective opportunities for line loss reduction.*
>
> *Hydro One should also explore, as part of its investment decision process, opportunities for economically reducing line losses.'*

This Section describes the issues related to line losses on the transmission system and the steps taken by Hydro One in response to direction from the Board.

1.8.1 LINE LOSSES ON THE TRANSMISSION SYSTEM

Line losses occur in the transmission system as power flows from the generation source to the load. The amount of losses is dependent on the specific type of transmission line conductor, other transmission assets (i.e., transformers), the amount of power flowing in the line, and the length of the line. The line conductor and its length determine the resistance ("R") of the line and the power flow determines the current ("I") in the line. Transmission line losses are represented by the following equation:

$$\textbf{Transmission Line Losses} = 3 \times I^2 \times R$$

Where the '3' represents the number of phase conductors in the transmission line circuit.

Once the line has been built, the line resistance is fixed. However, current flow depends on many factors including network voltage and configuration, the amount of customer load and its location in regards to generation source location and output, time of day, weather conditions, etc. The load and generation is continuously changing and balancing these two elements across the system results in current flowing through the network. This effect has become even more pronounced with the introduction of renewable generation; where the output of the wind and solar generation plants varies constantly with the weather conditions. As a result, current flow and line losses on the transmission system vary from minute to minute.

Hydro One’s ability to manage line losses is limited to its role as a Transmission Owner (asset owner) in planning, selection, maintenance and operation of its transmission equipment, subject to the inherent limitations of that equipment.

There is typically little ability to cost effectively reduce line losses in line upgrade work where the existing conductor section is being replaced. The size of the conductor that can be considered is limited by the capability of the original tower structures and generally only conductors of the same size or one to two sizes larger can be accommodated. Changing to larger size conductors results in lowering line losses; however selecting a larger conductor size beyond the tower structure design capability, triggers major tower reinforcement work and is therefore not cost effective. Hydro One is increasingly using Aluminum Conductor Steel Reinforced Trapezoidal Wire (“ACSR/TW”) conductor in these situations. The ACSR/TW conductor has the same diameter as the conductor being replaced, but has more aluminum content and a 10 to 20% lower resistance. The net effect is to reduce the losses on that line by the corresponding amount.

Network reinforcements offer more opportunities for loss reduction. Building a new line in parallel with an existing line reduces the losses by 50% and building a third line in parallel with two lines reduces the losses by 33% assuming loading levels remain constant. Losses however, will increase with time as the load demand increases. Also, building these additional lines to reduce line losses is not economically justifiable unless the lines are required for providing capacity or increasing reliability.

Voltage upgrades also offer opportunities for loss reduction. Increasing the system nominal voltage (i.e. from 115kV to 230kV) can reduce line losses; as the current reduces by half in the 230kV system. However, similar to network reinforcement, a system voltage upgrade involves rebuilding transmission lines and station facilities and is not economically justifiable on its own merits, unless the lines are required for providing additional capacity or increasing reliability.

1.8.2 COLLABORATION WITH THE IESO

Managing the transmission system and reducing the associated transmission losses, is a split responsibility between Hydro One and the Independent Electricity System Operator (“IESO”). Loss mitigation measures are considered at all levels in the utility industry, from planning and the selection of the equipment to day-to-day system operations.

Hydro One and the IESO work collaboratively on transmission planning in two principal ways. Firstly, the IESO, in consultation with Hydro One, regularly performs bulk transmission planning to facilitate meeting supply mix and/or load growth. Secondly, Hydro One, as a lead transmitter, engages with the IESO (and the applicable local distributors) in regional planning activities to identify and recommend solutions to regional supply needs, as discussed further in TSP Section 1.2. For both bulk transmission planning and regional planning, while the recommended projects are primarily aimed at addressing specific reliability and system capacity needs, the recommended solutions also reduce line losses. Some of these projects are further discussed below in Section 1.8.5.

As a transmitter, Hydro One is responsible for the design, selection, and installation of equipment to address the needs that have been established through the transmission planning processes noted above. When designing solutions to address these transmission asset needs, Hydro One considers industry best practices such as: use of lower loss conductors and transformers, conductor bundling, insulator hardware systems to improve corona losses, and insulator assemblies and structure configurations to improve insulation losses. Some of these are further discussed below in Section 1.8.4.

As a system operator, the IESO directs the operation of the transmission system including maintaining voltage schedules, and generation dispatch to meet the load demand. Historically, the system has been operated to higher voltages, up to safe equipment limits, so there is little opportunity to further reduce losses. Losses are also a factor considered in the IESO's overall optimization of the generation dispatch. However, generation is selected so as to result in the lowest overall costs and not necessarily the lowest losses.

1.8.3 INDUSTRY PRACTICES

To explore effective opportunities for transmission line loss reduction, Hydro One requested the Electrical Power Research Institute ("EPRI") to review transmission line loss mitigation practices from other utilities and compare Hydro One practices with work done in other jurisdictions. EPRI is an independent, non-profit organization that conducts research, development and demonstration projects for the benefit of the public in the United States and internationally. EPRI's report can be found as Attachment 1 to this Exhibit and the results of EPRI's review are discussed here.

EPRI's review highlights that transmission line losses can be mitigated by transmitters through both planning and design practices. However, losses are not the utilities' primary driver for developing new transmission projects, rather losses are taken into consideration and mitigated where practical during the development of solutions to meet the primary need. The primary drivers for new transmission projects identified are:

- Security of supply;
- New connections;
- Generation integration;
- Economic;
- Market access;
- Loop flows; and
- Refurbishment.

Based on EPRI's utility survey, the methods being considered by other utilities to mitigate transmission line losses include:

- Raising Nominal Voltage;
- Optimization of Voltage Profile;
- Use Lower Loss Conductors;
- Re-direct Power Flows;
- Bundle Conductor Optimization;
- Improve Corona Losses;
- Shieldwire Segmentation;
- Improve Insulation Losses; and
- Installation of Low-Loss Transformers.

Overall, EPRI noted that Hydro One design practices are materially consistent with industry best practices for loss mitigation. The main conclusions of the EPRI report are as follows:

1. Transmission losses are not avoidable.

2. Losses can be mitigated to a limited extent with appropriate application of design.

3. Transmission losses and their mitigation are not a focal point of transmitters, their independent system operators, or their regulatory bodies. At best, a few entities include the impact on losses that various design options may have in the selection of their project solutions.

4. Transmission grids seldom operate at near-capacity levels. The generation – transmission grid – load network system is designed for reliability and economic electric delivery with contingencies for the loss of one or many elements.

5. Transmission projects are initiated based on system need to ensure adequacy and reliability of supply or provide supply to customers. No utility is pursuing loss mitigation projects solely based on the potential mitigated loss savings over the life cycle of the asset.

1.8.4 HYDRO ONE'S CURRENT PRACTICES AND STRATEGY

In Ontario, transmission line losses are not the primary driver for transmission investments because the transmission capital costs of implementing loss mitigation outweigh the loss reduction benefits over the life of the asset. However, line loss mitigation factors are considered in the planning process.

Planning for Reliability

Ontario's transmission planning criteria is focused on capacity in order to satisfy reliability requirements. The IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC") requires Hydro One to maintain sufficient transmission capacity in the design of the transmission system so that supply to customers is not interrupted when outages for planned work are required or when unplanned outages occur. For example, many of Hydro One's transformer stations have two independent sources of supply: two transformers supplied by two transmission circuits. At such stations, when a circuit and transformer are out of service, the remaining circuit and transformer are required to be capable of supplying the entire load of the station under forecast peak demand conditions. Therefore most transmission circuits and transformers are, on average, lightly loaded compared to their full capacity and losses in any individual circuit or transformer are small.

Voltage Considerations

The standard maximum operating voltage limits on Hydro One's transmission system are 550kV, 250kV and 127kV based on equipment limits. The transmission system is operated at or near these maximum voltages and therefore there is limited opportunity to reduce losses by further optimizing the transmission system voltage profile.

Increasing the system nominal voltage (i.e. from 115kV to 230kV) can reduce line losses. However, projects to change the nominal voltage are driven by reliability and adequacy needs. This is due to high costs as these projects require rebuilding the line(s) and replacing the station equipment. The projects identified below in Section 1.8.5 demonstrate the reduced losses due to system voltage upgrades.

Conductor Selection

When new investments are proposed and the selection of new equipment is evaluated, options to reduce line losses are taken into account. Using larger conductors results in lower line losses, however, the incremental capital costs for the larger conductor, supporting towers and other hardware that are needed to support the larger conductor must be weighed against the resultant reduction in line losses. The economic benefit of the line loss reductions is substantially less than the costs needed to make the infrastructure changes.

In an effort to promote continuous improvement, Hydro One investigates new conductor technology to mitigate line losses. For example, Hydro One tested Aluminum Conductor

Composite Core (“ACCC”) conductor as it has lower resistance than standard Aluminum Conductor Steel Reinforced (“ACSR”) conductors and is used by some utilities. However, this conductor had poor performance under ice loading conditions and is therefore, given the local climate, not suitable for use in Ontario. Currently, as previously stated, Hydro One employs ACSR/TW conductor which is a newer conductor technology with a lower resistance than standard ACSR of the same size.

Hydro One also uses bundled conductors where it is prudent to do so to increase the thermal capacity of a transmission line and/or mitigate corona. Bundling conductors also reduces the resistance of a transmission line and therefore also reduces losses. For example, Hydro One uses four conductor bundles for its 500kV system; and is using two conductor bundles on the 230kV system for the high capacity interconnection to Quebec, as well as for the 230kV conductor upgrade project from Merivale TS to Hawthorne TS (TSP Section 3.3.8, ISD SS-06).

Transformer Selection

In addition to selecting the type of conductor, losses are also factored into the tendering of new transformers. As noted in EB-2016-0160, Hydro One includes “both the cost of core and full load losses into the tender specifications to manufactures for their design and bid. Hydro One selects the best overall equipment considering needs, performance and costs, including losses.”[1] Hydro One’s practice in this regard has been consistent over the years.

A summary of Hydro One’s current practices for each of the loss mitigation strategies and methods considered by other utilities, as described in EPRI’s report, are presented in Table 1 below. The EPRI report concluded that Hydro One’s design practices are aligned with industry best practices for loss mitigation.

[1] EB-2016-0160, Transcript Volume 5, page 39

Table 1: Summary of Hydro One's Loss Mitigation Practices

Methods	Hydro One’s Practices
Raising Nominal Voltage	Due to expense, increasing the system nominal voltage is driven by reliability and adequacy needs. Hydro One will continue to evaluate opportunities to convert 115kV systems to 230kV operation for cost effectiveness and reduction of losses.
Optimization of Voltage Profile	Hydro One’s transmission system is already operated at voltages that are at or near equipment limits and therefore there is limited opportunity to reduce losses by further optimizing the transmission system voltage profile.
Use Lower Loss Conductors	Hydro One currently uses lower loss conductor (i.e., compact ACSR/TW conductors) for capacity needs. Hydro One will also continue to consider the use of larger conductors with a corresponding lower resistance, where cost effective.
Re-direct Power Flows	Power flows at any given time are dependent on the connected load and generation. Losses are a factor considered in the overall optimization of the generation dispatch by the IESO.
Bundle Conductor Optimization	Hydro One currently uses bundled conductors for 500kV and some 230kV lines.
Improve Corona Losses	Hydro One implements insulator hardware systems that have been designed to eliminate corona. Conductor sizes are also selected to avoid corona.
Shieldwire Segmentation	Hydro One does not use shieldwire segmentation due to high tower ground potential rise.
Improve Insulation Losses	Hydro One considers losses during insulation coordination design of insulator assemblies and structure configurations.
Installation of Low-Loss Transformers	Hydro One’s purchase specifications already include cost of losses. Hydro One assesses the vendor transformer quotations and designs based on best overall economic benefit including losses.

1.8.5 HYDRO ONE'S PROPOSED CAPITAL PLANS THAT WILL HAVE A LINE LOSS REDUCTION BENEFIT

Hydro One has incorporated line loss reduction benefits into Hydro One's proposed capital plan as demonstrated in Table 2. These development capital projects have been identified through the planning processes, and although loss reduction is one of the benefits, it was not the primary driver for any of these projects. All of these projects are outcomes of regional planning studies and are primarily driven by need to support load growth, with the exception of the "Merivale TS to Hawthorne TS: 230kV Conductor Upgrade" project which is needed to optimize the use of the existing interconnection between Ontario and Quebec, in addition to supporting future growth.

Table 2: Capital Investments that have Incorporated Loss Mitigation Methods

ISD #	Investment Name	Reduction in Peak Losses*	Loss Mitigation Method Incorporated
SS-06	Merivale TS to Hawthorne TS: 230kV Conductor Upgrade	1.4 MW	Increasing the conductor size on existing circuits reduces resistance which in turn reduces losses.
SS-09	Barrie Area Transmission Upgrade	0.6 MW	Converting the supply to Barrie to a higher voltage (from 115kV to 230kV) reduces current flow which in turn reduces losses.
SS-11	South Nepean Transmission Reinforcement	0.7 MW	Converting an existing single circuit supply to a double circuit at higher voltage reduces current flow which in turn reduces losses.
SS-12	Aylmer-Tillsonburg Area Transmission Reinforcement	1.5 MW	Reconfiguring the network and building a short section of line to provide dual supply to the area creates a parallel path for current which in turn reduces losses.
SS-14	Southwest GTA Transmission Reinforcement	0.8 MW	Converting an existing idle line to a higher voltage (from 115kV to 230kV) creates a parallel path for current which in turn reduces losses.

** This represents the loss reduction in the peak hour. At other times the loss reduction will be smaller.*

1.8.6 FUTURE

Hydro One will continue to consider the reduction of line losses for all projects and will work collaboratively with the IESO to identify and investigate other opportunities to reduce line losses as part of the regional planning process. Hydro One will also continue to participate in industry affiliations to keep abreast of the developments in loss reduction and other new technological opportunities.

This report describes research sponsored by EPRI.

This publication is a corporate document that should be cited in the literature in the following manner:

Hydro One Transmission Losses. EPRI, Palo Alto, CA: 2018. 3002012721.

ABSTRACT

Hydro One requested EPRI's assistance in preparing a best-practices review of the electric transmission industry concerning how transmission line and transformer losses are being addressed across the industry, and also a review of Hydro One's own efforts at mitigation of transmission losses.

To meet the request, this report presents an overview of what causes losses within the transmission grid, how different mitigation techniques are applied to reduce losses, how the industry is addressing loss mitigation in its planning and capital improvement programs, and obstacles preventing direct loss mitigation efforts. The report also describes Hydro One's accomplishments in mitigation losses on its system and discusses the results of a sensitivity study of 11 Hydro One transmission assets, addressing the magnitude of losses incurred over a year and the impact potential mitigation efforts would have on the level of losses.

The investigation of industry best practices and Hydro One's efforts at mitigating transmission losses showed these key points:

1. Transmission losses and their mitigation are not a focal point of transmission service providers, their independent system operators, or their regulatory bodies. At best, a few entities include the impact on losses that various design options may have in the selection of their project solutions.
2. Transmission Projects are initiated based on system need to ensure adequacy and reliability of supply. No utility is pursuing loss mitigation projects solely based on the potential mitigated loss savings over the life cycle of the asset.
3. The industry's best practices address transmission losses during the design and purchase of assets, such as: reducing losses with proper conductor selection and transformer design.
4. Hydro One design practices are materially consistent with industry best practices for loss mitigation.

Transmission Line

EXECUTIVE SUMMARY

Electric utilities are facing continuing growth in demand for reliable, high-quality, low-cost electricity to meet everyday demands and expanding applications of electricity. To meet these demands, utilities are employing a mixture of increased system efficiencies, conservation efforts, controlled capital expenditure, and a diverse injection of distributed generation, mostly renewable.

Following the Ontario Energy Board's decision in Hydro One transmission rate application, Hydro One (with support from the IESO) requested EPRI to carry out a comprehensive assessment of current best practices in the industry relative to the mitigation of losses in transmission line and station equipment.

The study investigated the current best practices relative to how transmitters, independent system operators, and regulatory bodies are addressing the loss mitigation concern. The research explored how transmission losses occur, the chief sources of losses, the methods employed by utilities to mitigate losses through reducing equipment resistance and upgrading voltage levels, and the incorporation of loss mitigation from a system planning perspective. While driving for a goal of more efficient delivery of electricity, the electric utility industry does not pursue rebuilding and upgrading existing facilities solely for loss mitigation. The lifetime benefits of the mitigated losses do not offset the financial cost of performing the necessary transmission line modifications. In addition, the majority of transmission assets operate at levels 30-40% of their capacity, only operating near capacity a few hours a year if at all. The low load factor means transmission lines generally do not create significant losses and loss mitigation has an even smaller impact.

The study was also intended to better understand Hydro One's own transmission loss mitigation efforts in the context of these industry best practices. The project reviewed Hydro One's accomplishments in loss mitigation to date. A sensitivity analyses was also performed using characteristic data from nine transmission lines and two transformers in the Hydro One system. To assess the potential loss mitigation levels, an assessment was conducted on the level of losses that occurred in 2016 based on available element loading patterns and equipment characteristics for the subject transmission assets and a set of more efficient transmission conductors and transformers that are available.

The investigation in best practices and review of Hydro One's current practices showed these key points:

- Transmission losses and their mitigation are not a focal point of transmitters, independent system operators, or their regulatory bodies. At best, a few entities include the impact on losses that various design options may have in the selection of their project solutions.
- Transmission Projects are initiated based on system need to ensure adequacy and reliability of supply or provide supply to customers. No utility is pursuing loss mitigation projects solely based on the potential mitigated loss savings over the life cycle of the asset.
- The industry's best practices address transmission losses during the design and purchase of assets, such as: reducing losses with proper conductor selection and transformer design.
- Hydro One design practices are materially consistent with industry best practices for loss mitigation.

INTRODUCTION

Objective

Electric utilities are facing continuing growth in demand for reliable, high-quality, low-cost electricity to meet everyday demands and expanding applications of electricity. To meet these demands, utilities are employing a mixture of increased system efficiencies, conservation efforts, controlled capital expenditure, and a diverse injection of distributed generation, mostly renewable.

Following the Ontario Energy Board's decision in the Hydro One transmission rate application, Hydro One (with support from the IESO) requested EPRI to carry out a comprehensive assessment of current best practices in the industry relative to the mitigation of losses in transmission line and station equipment. The study investigated the current best practices relative to how transmitters, independent system operators, and regulatory bodies are addressing the loss mitigation concern.

The study also assessed how Hydro One is applying the identified best practices in loss management and provided examples of loss mitigation efforts.

Background

Efficiencies are required to address the differences between demand-driven project requirements and the available capital investment in infrastructure that utilities can commit. Efficiency is also critical due to changes in load and the unpredictability of the availability of renewable generation. To address these challenges, utilities are pushing their aging infrastructure to provide a longer service life, and to carry increased loading to meet the demand.

An important aspect of this interaction is the fact that the electric utility infrastructure is aging. Although the book life from an economic standpoint of a utility asset is typically 40 years, its service life in most cases can be exceeded with appropriate maintenance. Utility assets typically are removed or replaced only for failure, end of life, or inadequate capacity. For example, a conductor may be in-service for many decades; and is removed only when increased capacity requirements lead to a reconductoring of the line, or as a result of weathering, the conductor deteriorates and needs to be replaced. Hydro One has been proactive in asset management of existing facilities, identifying infrastructure and equipment that has reached or is reaching its end of life, and is taking steps to repair, or maintain as appropriate, equipment to extend its life.

With time, system topology grows and changes with various load, transmission capacity and generation injection changes. Existing facilities are very seldom removed completely. Rather, the assets are modified or upgraded as needed. One aspect that remains constant with each specific asset is its characteristics relative to current-carrying capability and its associated resistance. Transmission losses are intrinsically related to the resistive properties of the equipment, which cannot be altered. Therefore these parameters may mean the equipment or asset is not as efficient as newer designs and applications of technologies that have been applied in newer-technology equipment.

This report will address the characteristics of losses in current technology applied on transmission systems and what newer-technology has to offer in loss mitigation. The report also addresses what the best practices are being applied across the electric utility industry related to loss mitigation and how Hydro One is applying loss mitigation efforts in managing their transmission system.

2
LOSSES WITHIN THE TRANSMISSION SYSTEM

The section provides a brief overview of how transmission losses occur in an electric utility system and the impact of these losses on electricity delivery.

Sources of Losses

Losses on the transmission system can be attributed to the system configuration/topology as well as the equipment characteristics.

System Configuration/Topology

The size, configuration and topology of the transmission system have a large impact on the amount of losses that can be incurred. As the following section on Equipment Characteristics will disclose, each type of equipment has loss characteristics. Some are fixed per piece of equipment, e.g., the losses associated with a transformer; while other characteristics are attributed to size, e.g., length of a transmission line and kilometers of conductor in operation or voltage class of equipment which influences losses.

Hydro One's transmission system is very large, with substantial distances between generation sources and load demand centers. The transmission system is also an aging asset with lines and equipment that are older technologies that are less efficient than newer technology equipment. Older transmission lines that traverse many kilometers typically used smaller conductors which were adequate based on loading at that time. These lines contribute a large portion of the losses incurred as loading levels have increased. As the transmission system changes to meet reliability and load demand, the topology changes with newer assets added as greenfield installations or as upgrades and replacements of existing assets to meet capacity requirements.

Evolving Industry

The electricity industry is experiencing a new paradigm relative to providing a network to provide cost-efficient and reliable energy to its consumers. At one time, utilities operated in a monopolistic environment and did their planning and design, construction, and operation to meet their specific customer needs. With deregulation, open access allows any company with the wherewithal to build generation. Initially, these new generation forays were by utility or ex-utility interests using typically identifiable sites at the juncture of fuel and water sources and high-voltage transmission lines. That was the first wave, and the transmission grid had to expand to provide adequate transmission capacity to move power from these new nodes to an unconfined array of load nodes.

The next wave of generation encompassed larger-scale renewables. Initially, these facilities, too, were at logical large-scale sites, often remote due to size, which required transmission expansion. Now the size and site-ability of renewable generation mean that it can be placed anywhere. This flexibility creates new constraints and contingency scenarios on both the distribution and transmission grids in their areas.

Transmitters have been required to maintain open access to any requester, and to expand, upgrade, or rebuild many of its assets to meet the new and/or modified load and generation. The most difficult aspect of this expanding market is that it is less than predictable when it comes to reliability. Renewable generators are predominantly fueled by wind and solar and therefore depend on favorable environmental conditions to generate power. However, the transmission system is required to provide capacity whether these renewables are on line or not on line. Thus the transmission system must be designed for both of these two operating scenarios which often require a diametrically different transmission system. Power will flow in one pattern with congestion constraints when renewables are on and a different pattern when they are not.

Daily market drivers (load demand, generation bid pricing, equipment outages, system congestion) make the electric industry a dynamic environment where assets from generation through transmission, and substation are required to perform differently on an hourly basis. For example, the load, which may have been supported by a few large scale generation sources in the past, may now be supported by multiple small scale generation sources throughout the network or a combination of both the large and small-scale generation. The transmission system will need to support each of these delivery path scenarios reliably. The transmission system has become a dynamic topology, physically and operationally.

Equipment Characteristics

Transmission equipment experiences losses while transmitting power. This is a normal and accepted phenomenon in the electrical industry. The amount of losses is governed predominantly by two parameters, which have passive and dynamic aspects.

Passively, the losses are determined, first, by the resistance of the current-carrying component—e.g. the higher the resistance of a conductor, and the longer the length of the conductor, the greater the thermal losses, and, second, by the associated equipment construction—e.g., the core construction of a transformer. These parameters are fixed once the asset is manufactured and installed.

Dynamically, the losses are proportional to the amount of power flowing through the asset, squared. With an ever-expanding demand for capacity, the current level generally increases and the losses increase.

Transmission Lines

Conductors, whether elevated in open air or buried in underground facilities, have a known resistance, which creates heat when the current flows through them. The only alternatives to reduce losses are to use a different conductor with lower resistance or to reduce the current flowing through the equipment.

Any elements within the transmission path that carry current are sources of losses due to joule heating.

Joule heating losses are proportional to the square of the current load. The joule heating causes two operating issues—namely, conductor elongation and increased resistance. The conductor elongation is a driving influence on transmission line design dictating span lengths and structure heights. The elevated resistance accentuates the joule heating with power flow, increasing losses.

On a much smaller scale, losses are attributed to corona discharge around hardware and to conductor and field effects induced on parallel metallic objects, such as pipelines, other electric circuits, railroads, etc. Fortunately, current design practices have reduced these contributions to minimal levels.

Corona consumes energy, creating a line loss, as it ionizes air around energized parts of insulator assemblies and along the conductor. Corona only occurs at high voltage levels, increasing in severity as voltage rises above 230 kV. The voltage causes a gradient around all energized parts. Generally, the shape of the components is smooth enough that the voltage gradient is fairly smooth and low. However, if the surface is rough and has some protuberances, the voltage gradient is distorted, causing high gradient transitions. If the gradients are large enough, the energy causes ionization of the air and corona. The phenomenon requires a high base voltage (i.e., EHV level) and a protuberance (e.g., water droplet ready to drop from the surface, a metal nick sticking out, or bird droppings).

Station Equipment

Equipment, such as transformers, breakers, and switches, have internal current carrying components that are like conductors fixed in their resistive characteristics. Transformers have an additional component of losses associated with the core construction of the transformer and induced currents through them. Newer designs and core materials have provided increased efficiencies that reduce the transformer losses, but their application requires replacement of the existing assets.

Station equipment, breakers, switches, bus conductors and metering equipment all create a small contribution to system losses. Mitigation of losses in stations is limited since the majority of the equipment is sized for withstanding fault levels of current which dictate the design and sizing of components.

Overall, transformers drive station losses and are the focal area for loss mitigation.

Transformer losses have both voltage-related and power-flow-related losses. Voltage-related losses are associated with transformer construction and core materials. Eddy currents develop within the core that contributes to the losses. They are induced by the voltage level and occur anytime the transformer is energized.

Power flowing through the transformer coils experiences losses from the joule heating due to conductor resistance. The level of these losses is proportional to the square of the current flowing through the transformer.

Losses are also incurred from the auxiliary devices on transformers that assist in cooling the unit. Pumps for passing the mineral oil through radiators and fans blowing air across the radiators are used on some units to cool the units. These losses become proportional to the transformer load; the more load transferred through the transformer, the hotter the unit becomes.

Impact of Losses

Losses represent energy, or units of electricity that must be created in the process of generating electricity to replace energy lost. Replacing lost energy has several impacts on the electric system.

Each unit of energy lost must be generated, requiring additional fuel sources. Additional generation capacity may be needed if the cumulative losses cause demand greater than the installed capacity. Additional generation may also cause additional pollutants and environmental impacts depending on type of generation source.

Similarly for transmission lines, additional capacity may be required on certain lines to meet demand at load points. Meeting this demand may require new lines, upgrades, or some other measures to ensure a reliable transmission system.

EPRI performed a study for the New York State Energy Research and Development Authority to assess the level of electric losses across the electric production, delivery and use spectrum. Cumulatively, transmission losses average 1.5 to 5.8%.[1]

An important factor in reviewing the impact of losses on transmission lines is the actual loading that most lines experience under normal operation compared to the actual load-carrying capability of the line. If losses are estimated on capacity, they give a false representation of the actual system losses. This point will be expanded upon in the discussion in the Sensitivity Study in Section 5.

[1] *Assessment of Transmission and Distribution Losses in New York*, EPRI, Palo Alto, CA: 2012. PID071178 (NYSERDA 15464).

3 LOSS MITIGATION METHODS

This section reviews constraints to loss mitigation, several general principles related to loss mitigation, the results of utility surveys on loss mitigation efforts, and methods of mitigating losses through reducing equipment resistance, upgrading of voltage level, and power flow control.

Loss Mitigation

Loss mitigation reduces overall demand on the transmission system by requiring less power from generation. However, due to the geographic nature of the power system, a reduction in losses doesn't necessarily lead to fewer transmission and/or distribution facilities. These facilities are still required to serve customers across the utility's service territory.

One of the major constraints to pursuing loss mitigation is the need to justify the benefits of the loss reduction versus the capital expenditure to execute the mitigation. Unfortunately, in most cases, the benefits do not offset the cost of mitigating losses, even when considering the life cycle economics. Initiating and funding projects for the sole purpose of mitigating transmission losses are not typical throughout the industry. Rather the economic benefits realized from different aspects of a project that mitigate losses are part of the life cycle cost analysis of a project that may sway approval of a project or make one project a better choice over another solution. In reality, today loss reduction is driven by available opportunities, not direct need.

Key Principles Related to Loss Mitigation

Through EPRI's research, a framework around improving transmission efficiencies (including transmission losses) and a methodology for measuring the potential benefits has been developed. The key principles related to transmission efficiency that have been identified are:

- **Efficiency is more than simply reducing losses**: A more economically efficient transmission system that fully utilizes existing assets and incorporates renewable energy sources and storage technologies may actually have higher losses.
- **Efficiency initiatives should not reduce reliability**: Transmitters (e.g., Hydro One) and system operators (e.g., IESO) must focus their efforts first on reliability to meet customer and regulatory expectations. In a simple example, removing a transformer that is not carrying much load may reduce some of the core losses but introduce risks to reliability if another transformer is lost.
- **Efficient transmission will require new and upgraded systems:** The expansion of the grid to meet the challenge of adding renewables and storage capabilities to meet load growth and to replace retiring infrastructure will offer significant opportunities to improve the efficiency of the transmission system. However, the application of better equipment and new technologies and the replacement of less efficient retiring equipment are part of a long-term process that will take many years.
- **Efficiency must be considered in business cases**: Transmission system expansion and refurbishment must incorporate efficiency considerations in the development of projects.

- **A regulatory framework with incentives is needed to encourage transmission loss reduction**: For loss reduction to be a prioritized criterion requires regulatory change to incentivize it. Currently the life cycle benefits of loss mitigation are not large enough to make direct loss mitigation projects justifiable.

These findings have been documented in several reports including:

Transmission Efficiency Technology Assessment: Phase 1. EPRI, Palo Alto, CA: 2008 1010692.

Transmission Efficiency Initiative: Key Findings, Plan for Demonstration Projects, and Next Steps to Increase Transmission Efficiency. EPRI, Palo Alto, CA: 2009. 1017894.

Transmission System Efficiency Technology and Methodology Assessment, EPRI, Palo Alto, CA: 2010. 1020143.

Transmission System Efficiency and Utilization Improvement: Summary of R&D Activity and Demonstration Projects. EPRI, Palo Alto, CA: 2012. 1024345.

Utility Practices on Loss Mitigation

This section lists some of the results of the studies and important factors that other utilities are considering to reduce transmission losses.

New York State Study

Losses can be mitigated in several ways. EPRI performed a study with the New York State Energy Research Development Authority[2] reviewing the issue of line losses in support of NYSERDA's larger investigation into Electricity Efficiency improvements across the state. The New York investigation is much broader than transmission line losses and focused on other efficiency initiatives; but EPRI was asked to participate to provide visibility to the transmission loss impact.

Each utility provided some insight into their current loss calculation methodology and mitigation actions. In general, losses were not tracked or directly measured throughout the industry. Transmission losses were obtained based on a high-level view—measured sales versus generation input.

The utilities also noted the ways they are looking at mitigating losses. Of the eight utilities participating in the project, the following methods were being applied:

- Reconductoring projects (seven utilities)

---

[2] *Assessment of Transmission and Distribution Losses in New York.* EPRI, Palo Alto, CA: 2012. PID071178 (NYSERDA 15464).

- Application of capacitors and shunt devices for reactive power control (five utilities)
- System operating methods for voltage control (two utilities)
- Replacing substation transformers (two utilities)
- Voltage upgrade of circuits (two utilities)

EPRI Utility Survey

Through a utility survey, EPRI researched energy efficiency activities with utilities related to transmission line losses.[3] Table 3-1 provides a summary of the loss mitigation efforts being considered and applied by the 25 EPRI survey respondents, including investor owned, public power, cooperatives, transmission providers, and federal utilities. The respondents covered voltages from 115 to 765 kV. Note that, while many options are being considered, few methods are being actively applied, and few utilities are actively pursuing the efficiency efforts.

Table 3-1
Transmission Loss Mitigation Areas of Interest

Methods Under Consideration	Under Consideration (%)	Actively Applying (%)
Raising Nominal Voltage	33	4
Optimization of Voltage Profile	22	0
Use Lower Loss Conductors	56	0
Re-direct Power Flows	44	8
Bundle Conductor Optimization	11	0
Improve Corona Losses	11	0
Shieldwire Segmentation	22	0
Improve Insulation Losses	11	0
Installation of Low-Loss Transformers	56	8
Convert to DC, Bipole or Tripole	0	0
Switch off Equipment Not in Use	0	0

The survey asked whether the utilities were conducting loss studies. Of the 25 participants, 29% responded that they had done loss studies on lines and some transformers. However, only 14% reported that they had used measured data for their investigation.

When asked by EPRI why the loss studies were performed, 36% reported they needed the data for a rate or regulatory filing. Billing of transmission services accounted for 36% of the reasons. Again the application of actual data in loss quantification was only in 28% of the cases.

[3] *Transmission Efficiency Technology Assessment: Phase 1*, EPRI, Palo Alto, CA: 2008. 1010692.

The survey further asked whether the loss considerations were at peak loading. Of the 56% percent that responded, 70% said they made their analysis at peak loss levels using computer simulations, SCADA data was used 25% and 5% were based on transmission studies.

The EPRI study summarized that loss mitigation within the transmission system can be addressed in three general concepts: equipment characteristics, voltage level, and power flow control. In many cases, aspects of these three concerns interplay and contribute collectively to losses and their mitigation. For example, the resistance of the conductors and the amount of current flowing through the conductor define the losses. The greater the current flow, the higher the losses. Coincidentally, the losses are the result of resistance heating; the heat rise causes the conductor resistance to increase, coupling to further cause losses. Voltage and current levels can mitigate congestion—increased power can be accomplished with higher voltage and less current or by maintaining voltage and increasing current. Since losses increase by the square of current flow, I^2R, voltage increases and lower currents improve losses

Equipment Resistance

Joule resistance heating is the greatest contributor to transmission equipment losses. The majority of transmission lines are constructed using electrical grade EC 1350 aluminum strands for current-carrying capacity. Various constructions are available using aluminum alloys, steel, or composite materials for providing additional mechanical strength to the conductor. Figure 3-1 shows cross sections of a traditional steel core ACSR conductor and an ACCC composite core conductor. Typically, a core stranding provides the mechanical strength and supports the aluminum strands. The number of strands and their diameters build up a cross-sectional area that is sized to provide the desired current-carrying capacity. The strand resistance causes joule heating when electrons flow through the conductor, creating a temperature rise. The temperature rise has two effects on the conductor: first, it causes thermal elongation in the strands, which cause the line conductor to expand and sag more. Second, the increased heat causes the resistance to slightly increase, causing additional thermal losses.

Figure 3-1
Comparison ACSR and ACCC

On any given operating day, the ambient conditions of temperature, wind, and solar radiation affect the thermal stability of the conductor catenary system. As current flows, heat is created from the resistance heating. In addition, under daylight conditions, solar heating can occur. The ambient temperature serves as the base thermal setting. The hotter the ambient, the higher the conductor temperature; conversely, cool days and night reduce the thermal content. Wind blowing across the conductor also cools the conductor. Under power flow, a quasi-steady-state condition develops, where the heat being introduced by resistance and solar heating is balanced by the ambient temperature and wind effects. The transmission line is designed such that the conductor temperature remains below a certain operating temperature with the design power flow. Structure type, heights, and strengths are determined by the conductor selected and the terrain and environmental loadings that will govern design for safety and reliability concerns. Larger conductors provide lower resistance and losses but require taller and stronger structures to perform as required. Thus, a life cycle cost evaluation must be performed of the initial capital expenditures, maintenance costs, cost to deliver power (including losses), and service life.

Figure 3-2 illustrates the cost development of a transmission project, including capital costs and the cost of electrical losses on the transmission line. The Present Worth of Future Requirements for Revenue (PWRR) is the present worth sum of the cost to build a line (increasing cost with increase in diameter) plus the present worth of the future savings attributed to line losses (lower cost of losses with increase in conductor diameter). A range of conductors provide an optimum life cycle cost.

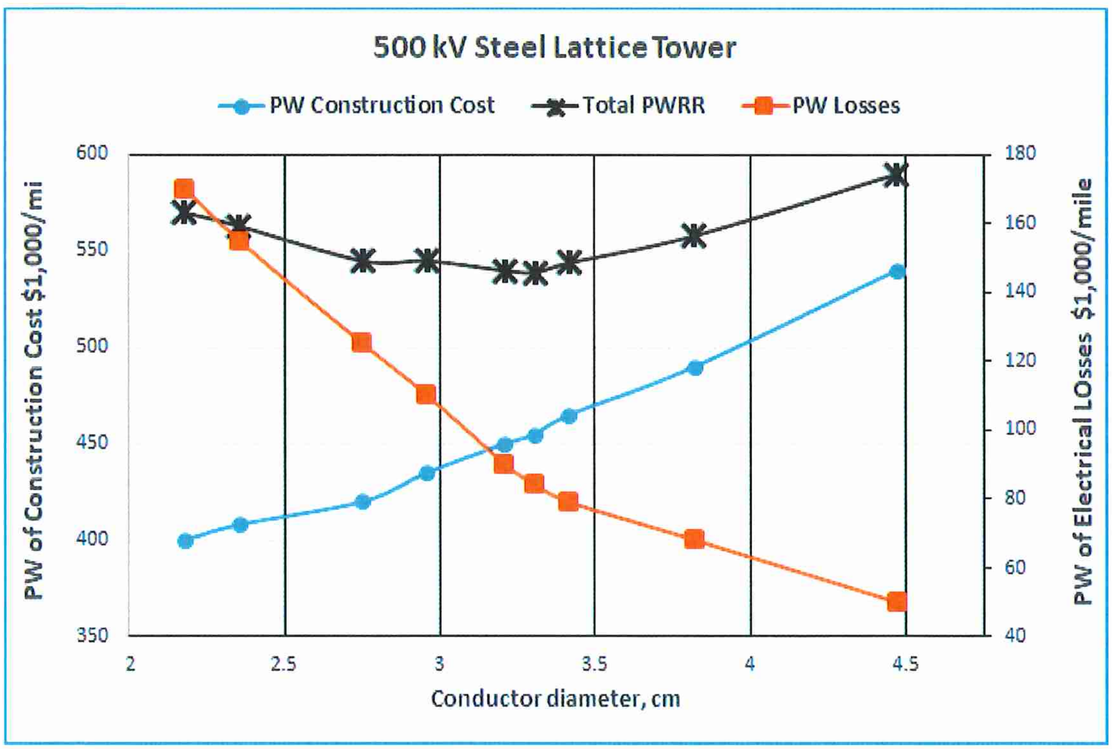

Figure 3-2
Lifetime Cost as a function of conductor diameter

With the different types of conductors available, and various sizes and strandings, an optimization study can be performed to select a conductor that will provide the capacity desired, while maintaining code clearances, optimizing life cycle costs, and mitigating line losses. One of the caveats of conductor selection is that a different conductor could be the best fit for each project. This is not a practical solution, however, for transmission providers to design a transmission line for each unique situation. The costs of maintaining and building unique designs are too high. Rather, utilities typically develop classes of capacity designs that optimize the design and life cycle costs for a manageable number of designs to meet transmission needs. This is particularly true for new construction.

When looking at increasing capacity on existing lines, an economic study is required to select a solution that has supportable life cycle costs. Some projects can be solved with re-conductoring the line on existing structures, with or without modest modifications. Advancements in conductor designs using composite materials for the mechanical support have made this solution viable in many cases. However, some upgrades require significant additional capacity that requires line reconstruction. These solutions revert back to the optimized solutions based on new construction design packages. Note: one of the issues with many of the composite core conductors is their inability to provide conductor sag within acceptable clearance limits.

Voltage Level

Power is equivalent to the Voltage times the Current (VI). So, for an equivalent level of power transmission, the lower the voltage, the higher the current level must be. Increased current means increased line losses. Operating lines at higher voltages reduces losses.

In day-to-day operations, voltage levels fluctuate on lines by a manageable few percent. These changes are not sufficient or intended to mitigate losses. Slightly larger voltage changes are accomplished with Load Tap Change (LTC) transformers, intended for voltage control and reliability concerns. Again, LTCs are not loss mitigation measures, but are a technology to maintain voltage levels at the ends of long transmission lines and power quality.

Transmission grids are developed around specific voltage classes of construction to appropriate bulk power levels. For example, common transmission voltages at a utility may include 69, 138, 230, and 500 kV. Other combinations could be 138, 230 and 345 kV or various combinations of 69, 115, 138, 230, 345, 500, and 765 kV. Changing a voltage class typically calls for a change to a higher level that requires significant system changes. For example, insulator assemblies need to change out to higher class voltages requiring more space, new structure geometry, and probably a complete rebuild. The voltage upgrade becomes a complete rebuild. Voltage upgrades also affect customer equipment and facilities, requiring added expense at their stations, which must be borne by the customer.

EPRI has performed studies and developed a guideline for voltage upgrades that require minimal structure modifications, *Feasibility of Increasing Transmission Line Capacity by Voltage Upgrade.* EPRI, Palo Alto, CA: 2007, 1013984.

EPRI and AEP performed a study investigating the benefits of an overlay EHV system. This example is greater in scale than evaluating the benefit of upgrading the voltage class of a single line, but it exemplifies that grid efficiency can be significantly enhanced when a "large" EHV overlay is used to improve the overall performance of a grid's region. *Evaluation of Efficiency and Utilization Benefits from Extra High Voltage Transmission Overlay.* EPRI, Palo Alto, CA: 2011, 1024617.

Power Flow Control

Since current-driven losses are the most significant driver for line losses, controlling the amount of current that flows through a given line section could reduce losses. Power sources provide electricity which follows the path of least resistance to the points of load.

Another important factor in power flow control and grid operations is that the grid topology changes constantly. It changes from continuous completion of transmission, load, and generation projects. As load changes by the connection of new load points and demand at existing points, the grid itself is inherently dynamic in responding to that load, changing the power flow levels and paths constantly. Interconnection of generation changes due to traditional generation connections, distributed generation, and the burgeoning smart grid impacts constantly changes the flow patterns across the grid. Topology changes daily due to the outages taken to complete emergency as well as planned maintenance on equipment throughout the grid.

Methods used by utilities to "direct" flow include:

- Phase shifters can be used to direct flow over a transmission path.
- Direct Current technology is another way to gain some control over the flow of current. The cost of DC station equipment makes this option viable only for long distance, bulk power transfer over 450 km without intermediate stations.
- Another option is using Flexible Alternating Current Transmission Systems, FACTS. FACTS equipment allows control of the impedance of a line and can direct power down some paths rather than others. FACTS is also typically applied to bulk power transfer lines over longer distance to control reliability characteristics and enhance efficiency.

The power flow control systems require installation of sophisticated equipment at key locations. The solutions noted are not applicable to local issues, but are typically applied for issues that arise for long-haul bulk power transfer cases.

Summary on Loss Mitigation Methods

Loss mitigation can be achieved through application of a variety of technologies including application of equipment that create fewer losses at the same power flow, controlling power flow through lines to prevent high losses attributed to less efficient assets, and upgrading assets to a higher voltage class. Unfortunately, these changes cannot easily be applied to existing assets; they require upgrading, reconductoring or construction of new transmission assets.

Surveys of have shown that the preferred options under consideration are:

- Use of Lower Loss Conductors
- Installation of Low-Loss Transformers
- Raising Nominal Voltage
- Optimizing Voltage Level
- Re-direct Power Flow

One other key aspect is that Reliability is the driving force in transmission system development, maintenance and operations. Efficiency is an aspect of consideration but does not drive or initiate projects.

4
SYSTEM PLANNING PERSPECTIVE

This section summarizes the best industry practices for incorporating loss mitigation in system planning efforts. It reviews different kinds of system planning efforts, including customer connection projects, reliability projects, and economic relief projects. The section also looks at the process of project selection and development, the findings of a CIGRE survey on drivers for transmission investment, how refurbishment and end-of-life drives transmission projects, and a US Department of Energy analysis of opportunities for energy efficiency.

Transmission lines are justified and planned based on capacity requirements. Capacity requirements are attributable to a snapshot in time with a certain transmission grid topology, generation mix, and forecast load built in a nodal model of the grid. Numerous scenarios are configured and run against the transmission grid to test the reliability level of operation and to identify cost constraints due to congestion patterns. The results of those runs identify deficiencies in the grid—i.e., elements in the grid that are inadequate in capacity and become reliability or congestion constraints during scenario solutions. When a threshold of concern established by the responsible operating manager is reached, added transmission assets may be required. Many of the transmission elements are only governed by a few or a singular contingency scenario. Under those conditions, that transmission asset's full capacity may be required. Under all other conditions, that element may be loaded at a significantly lower level. One of the critical aspects of transmission operations, planning, and design is that capacity is required for reliability first, and for congestion cost possibly second. Lightly-loaded lines are the grid's insurance against the contingency.

Responsibility Roles

The responsibility for managing the transmission facilities, and the losses that are realized, is a split responsibility. Mitigation of losses, or the process that leads to mitigation, occurs in all aspects of the utility industry, from the selection of the equipment to the day-to-day decisions on operations. The transmitter such as Hydro One, is responsible for managing transmission assets (e.g., lines, transformers, etc.); and bulk system planning as well as generation dispatch and flow control are the responsibility of the grid system operator, such as the Independent Electricity System Operator (IESO) in the case of Ontario.

Planning for grid enhancements is a shared responsibility between the System Operator (the IESO in Ontario) and the associated Transmitters (such as Hydro One in Ontario).

In Ontario, the provincial Minister of Energy has the authority to set policy objectives for transmission and distribution planning. The Ontario Energy Board established the province's regional planning process framework, which it advances through codes and license conditions.

In Ontario, bulk system planning is carried out by the IESO to ensure sufficient resources are available to meet Ontario's electricity needs, and that the transmission system is capable of delivering electricity to consumers in a reliable and cost effective manner. When designing solutions to address transmission needs, the IESO works collaboratively with stakeholders, including Hydro One, Distributors, and Direct Customers.

At a regional level, planning in Ontario is coordinated between the IESO, Transmitters and Distributers, following the Process for Regional Infrastructure Planning formalized by the OEB in 2013[4]. The process identifies regional transmission and distribution needs and develops plans which recommend solutions for addressing those needs.

Types of Projects

Transmission projects typically fall in the following main categories. These projects, however, have decision points where the outcome will impact transmission losses. The influence that these decisions play in transmission projects will be reviewed as we progress through the following sections.

Customer Connection Projects

Transmitters are required to provide service to load points and access to the grid for generation interconnections. These projects establish the need. Like all projects, they are planned and assessed to provide the best connection at an optimal cost. All of these projects have direct connection components (e.g., the transmission connection from the grid to the point of interconnection [POI]). Other aspects of the project may be associated with reinforcing the grid in the area of the interconnection point (e.g., upgrading existing lines or adding lines to ensure the system meets all reliability criteria once the load or generation is connected).

Reliability Projects

Reliability needs are recognized through planning assessments or through the normal system operations performance of the grid. The IESO and most utility systems are operated on an N-1 or N-2 contingency basis. This means that the grid will remain within all reliability constraints when either one or two elements are lost, no assets are overloaded, and voltages are within acceptable limits.

Planning assessments will indicate if the grid will develop unacceptable voltages or thermal overloads with forecasted load growth. This behavior is recognized, and planning starts to evaluate different options to resolve the issue.

Economic Relief Projects

Economic relief projects are largely associated with congestion relief. Congestion constraints that cause less economical dispatch of generation can have significant financial impacts on customers and market participants.

Project Development and Selection

As the projects are identified to meet one of these three areas, different solution scenarios are proposed and evaluated. Since transmission grids are interactive dynamic systems, the issues and solutions are typically broader in impact than a direct one-on-one solution to issue. Rather issues affect regions, and solutions affect the characteristics of the grid over a broad region. Therefore many solutions have interrelated impacts on other grid operation characteristics. These impacts can be beyond the borders of a single transmission owner or even more owners.

CIGRÉ Findings

CIGRÉ conducted several surveys of its members to assess various drivers for transmission investment. While not a direct survey for loss mitigation efforts, the results of the reports address the prioritization accorded by utilities to address various demands for capital investment for new construction and refurbishing existing assets; energy efficiency and mitigation of losses were among the drivers. The surveys included the following:

> *Life Cycle Assessment (LCA) of Overhead Lines TB265.* CIGRÉ WG B2.15. 2004.
>
> *Refurbishment Strategies Based on Life Cycle Cost and Technical Constraints TB448.* CIGRÉ WG B5.08. 2011.
>
> *Market Price Signals and Regulatory Frameworks for Coordination of Transmission Investments TB692.* CIGRÉ WG C5.18. 2017.
>
> *Review of Drivers for Transmission Investment Decisions TB701.* CIGRÉ WG C1.15. 2017.

The survey participants represented a broad range of committees and study groups constitutes within the utility industry, covering planning, design, operations, and regulatory and financial concerns.

The first survey concerning drivers for transmission investment, *TB701*, 24 respondents were received. 75% were TSOs from state ownership companies; however, of the six non-state respondents, four were TSO respondents from North America, Italy, Spain, and Great Britain.

Three significant drivers were stated for investment: security of supply, connections for demand and generation, and economically driven projects, in that order. Two main drivers were identified for refurbishments: end of useful life (50%) and upgrade of assets (35%).

Table 4-1 provides a summary of how the respondents attributed the various driving factors impacting their project identification and development. It is evident the development of projects and their selection for funding are driven by Long Term Integrated Strategic Basis. Reducing transmission losses is not a singular driving factor, but is embedded as part of the solutions' process for all categories.

Table 4-1
Summary of Percentage of Projects Impacted by External Factors[5]

Project Category	Environmental & Societal			Technical			Strategic / General Approach		
	Site or Route Access / Space	Local opposition / Concerns	Statutory / Planning Processes	Novel / Unconventional Transmission Tech.	Equipment / Tech. Obsolescence	Financial	Minimum Incremental Approach	Long Term Integrated Strategic Basis	Renewable Energy Related – State Policy
Security of Supply	46%	59%	56%	15%	8%	12%	7%	76%	20%
New Connection	50%	68%	58%	18%	5%	14%	7%	65%	40%
Generation Integration	35%	72%	62%	21%	4%	10%	7%	58%	55%
Economic	31%	47%	63%	22%	8%	15%	8%	80%	19%
Market Access	37%	37%	59%	41%	4%	15%	7%	81%	41%
Loop Flows	44%	50%	72%	8%	8%	0%	3%	81%	28%
Refurbishment	36%	57%	64%	21%	50%	7%	14%	36%	14%

Similarly CIGRÉ document, *TB692*[6], focuses on the changing environment that transmission systems must respond to today's unregulated industry. The diversity and granularity of generation sources entering the industry put a different light on the traditional electric delivery system. A new paradigm has arisen where the wires industry will serve as insurance to those depending on distributed generation as their primary source of energy, yet insist that the traditional wires business is ready and willing to provide the energy when the customer needs it with total transparency of the shift. The demand capacity required to support nominal load and the "insured load" must be provided by the wires delivery system. Continuing to support this demand on the transmission system is critical for the future and requires greater coordination during operations and efficiency from planning through operations. Conversely, systems will become less efficient as segments only serve as insurance for contingency loads or customer-choice load (fallback load). Caution must be exercised to avoid creating stranded investments that operate with minimal loading if any.

Furthermore, CIGRE's document, TB448[7], undertaken by CIGRE's Protection and Automation Study Committee addressed the refurbishment and end of life drivers. While the work was largely focused on station equipment used for protection systems, their strategies and application

[6] *Market Price Signals and Regulatory Frameworks for Coordination of Transmission Investments – TB692, CIGRÉ WG C5.18. 2017.*

[7] *Refurbishing Strategies Based on Life Cycle Cost and Technical Constraints – TB448*, CIGRÉ WG B5.08, 2011.

of life-cost analysis are fully applicable to the development of projects to address concerns with aging or degraded assets and when best to replace them.

Many utilities are facing end-of-life issues with many of their transmission assets. Infrastructure assets reach end-of-life levels due to age, environmental degradation, or obsolescence (e.g., parts are no longer available to repair and maintain older vintage equipment). The question of when to refurbish or replace equipment is a major consideration in planning budgets. The risk of failure or misoperation presents substantial liabilities to the utility and the public. Several sub-drivers in this arena affect the need and justification to replace an existing asset, including:

- Upgrades and expansions of facilities to accommodate load growth
- Obsolescence of equipment, including lack of spare parts, non-maintainable equipment, and inefficiency of operations
- Reliability and availability
- Excessive maintenance costs

The life-cost analysis is especially important in this evaluation because direct justification in a cost-benefit analysis seldom supports a decision to proceed. Rather incorporating all factors of risk, liability, maintenance, and efficiencies to be gained is required to fully justify proceeding to action. Loss mitigation costs and projected benefits are other facets that should be incorporated into these life-cycle studies.

US Department of Energy Policy and Systems Analysis

The U.S. Department of Energy (DOE) in the United States conducted a study into the opportunities for energy efficiencies in transmission and distribution systems[8]. The study's summary identified the advantages, drawbacks, key uncertainties, road blocks to application, and range of loss reduction for the same initiatives that we have identified throughout this report. The key drawbacks identified support the position that major policy changes and investment to the grid are required to reduce losses (e.g., reconductoring lines, replacing transformers, adding reactive power compensation, and FACTS equipment).

The constraint to accomplishing improvements is realizing a positive benefit-to-cost ratio for initiating the project on its incremental benefit. Once again, the long-term strategies incorporating loss mitigation strategies in the expansion, maintenance and refurbishment of the transmission grid are the best means to realize additional energy efficiencies.

Best Practices Summary

As part of this study, contact was made with several Independent System Operators (ISOs), including PJM, CAISO, SPP, ERCOT, MISO, NYISO, and ISO-New England. In addition, the project team also reviewed the ISOs' Planning Criteria and Guidelines, which are available on their websites. Transmission line losses, including station equipment, are not a substantive part

---

[8] *Opportunities for Energy Efficiency Improvements in the U.S. Electricity Transmission and Distribution System*. Oak Ridge National Laboratory, Oak Ridge, TN: 2015.

of any documents. The same is applicable to the Planning Guides and Criteria used by the transmitters within these areas of grid operations.

A few guidelines indicate that loss mitigation benefits attributed to different project solutions may be included in the assessment of the best solution to propose for approval by the ISO and subsequently funded by the transmitter.

Loss mitigation is not used as justification for any project development or required for project evaluations.

Planning Summary on Loss Mitigation

The review of best practices applied across the industry, including international concerns, supports several clear points about the issues associated with incorporating loss mitigation efforts on transmission grids:

- Transmission grids seldom operate at near-capacity levels. The generation – transmission grid – load nodal system is designed for reliability and economic electric delivery with contingencies for the loss of one or many elements.
- The advent and expansion of distributed generation of many forms and sizes affect the transmission grid in ways that we are just beginning to experience and respond to.
- Loss mitigation projects are not self-supporting in that the projected loss savings do not exceed the cost of performing a mitigation project. As such projects with their primary objective being mitigation of transmission losses can seldom be justified based on lifetime savings alone.
- Loss mitigation costs and benefits should be considered in all project development and solution total cost analyses, such that the most cost-efficient solution is pursued that meets all reliability and safety criteria.

5
HYDRO ONE'S LOSS MITIGATION EFFORTS

This section discusses Hydro One's accomplishment in loss mitigation and the potential for additional future loss mitigation. It identifies accomplishments in line losses and station losses; reviews the utility's efforts at operating voltage adjustment; provides a listing of opportunities for Hydro One to mitigate losses; and presents the results of a sensitivity study of Hydro One data, which revealed the potential for future loss mitigation.

Hydro One Accomplishments

Network Characteristics/System Configuration/Network reinforcement

The IESO market rules define the voltage range for each voltage class. The Hydro One transmission network is operated at the upper end of the voltage range; the 230-kV system operates between 240 kV and 250 kV, and the 115-kV system between 121 kV and 127 kV. This helps to reduce losses.

For new projects, consideration is given to converting 115-kV areas to 230-kV supply. Two area supply projects in the Hydro One five year plan to meet capacity needs in the Barrie and Ottawa West areas involve conversion to 230kV supply. While the main reason for the both conversions is the inadequacy and cost of maintaining the existing 115kV supply, both projects also help reduce system losses. The Barrie area project converts an end-of-life 115-kV line and station to 230-kV facilities. The Ottawa West area project converts an existing 115-kV line to a 230-kV line to supply new load.

System reinforcement by building a new line or reconfiguring the system also helps reduce losses. The Southwest GTA Reinforcement project, provides for reinforcement of the existing supply by building a new double circuit 230kV line as the existing lines would be overloaded. The Aylmer-Tillsonburg Project provides for system reinforcement by reconfiguring the network and building a short section of line to provide dual supply to Tillsonburg TS. Capacitor banks will also be installed at Tillsonburg TS. Both projects reduce flows on the existing lines and help reduce losses.

Table 5-1 shows the loss mitigation projected through these three projects.

Table 5-1
Impact of Network Upgrades

Project	Reduction in Peak Losses (MW)	Estimated Annual Energy Savings (MWh)
Barrie Area Transmission Upgrade	0.6	2,238
South Nepean Transmission Reinforcement (Ottawa West)	0.7	1,202
Aylmer Tillsonburg Transmission Reinforcement	1.5	3,778
Southwest GTA Transmission Reinforcement	0.8	2,942

Lines and Station Equipment

Corona Losses

Hydro One has addressed the corona issue throughout its transmission design standards. Conductor diameter selection for high-voltage lines is made with corona mitigation as a parameter. In addition, all hardware assemblies are designed to mitigate corona by providing smooth edges and surfaces of hardware and incorporating appropriate corona and gradient rings to manage the electric field strength around the hardware assemblies.

Conductor Losses

Hydro One implicitly considers the impact of losses in all of its conductor selection for new projects and upgrades of existing lines.

For new projects, conductors are usually selected to satisfy the capacity requirements in the planning criteria based on forecast demand growth. Normally this approach results in the selection of a large conductor that has low losses. For line reconductoring projects, the conductor selection is limited by the existing tower structures. Hydro One has used ACSR TW (Aluminum Conductor Steel Reinforced Trapezoidal Wire) conductor on many projects. This conductor has lower resistance for the same diameter as the ACSR conductor and has lower losses.

Table 5-2 shows the loss mitigation projected through two of the upcoming projects involving line reconductoring.

Table 5-2 Impact of Reconductoring Adjustments

Project	Reduction in Peak Losses (MW)	Estimated Annual Energy Savings (MWh)
Manby TS to Wiltshire TS Conductor Upgrade	0.9	3,615
M30A/M31A Conductor Upgrade	1.4	3,167

Transformer Losses

Hydro One addresses transformer losses in several ways. First, during procurement, each transformer's design and performance are evaluated per requirements and criteria in the purchase specification. HO requires the transformers to be designed to minimize losses at load and while unloaded. Second, overall transformer losses are reduced as transformers of older and less efficient designs at existing stations are replaced with newer more efficient designs due to end-of-life or load growth considerations. This is a gradual and long-term strategy given the economic impact and timing of the replacements.

Samples of the loss mitigation estimates for two transformers that were replaced on the Hydro One system are shown later in the Sensitivity Study and Appendix A.

Summary of Current Practice and Opportunities

As the study has shown, the majority of loss mitigation tasks must be resolved during the development of different project solutions to the mandated generation and load interconnections, regulatory, and reliability projects. Reduction in transmission losses is considered at the planning level as one of many priorities that the IESO and Hydro One must balance. Economic impact assessments of losses are conducted when such losses could reasonably be consequential to the selection of a least cost plan.

Energy efficiency projects do not justify their funding solely based on improving the socio-economic-environmental issues that efficiency can derive. However, Hydro One already addresses many of the identified means to mitigate losses in their current practices listed in Table 5-3. Hydro One practice is summarized in Table 5-3below.

Table 5-3 Summary of Hydro One Practices

Methods Under Consideration	HO Current Practice
Raising Nominal Voltage	Due to expense, voltage upgrades are driven more by reliability and adequacy concerns. Will continue to evaluate conversion of 115kV systems to 230kV operation for cost effectiveness and reduction of losses.
Optimization of Voltage Profile	System is already operating close to equipment limits.
Use Lower Loss Conductors	Currently use ACSR or compact ACSR TW conductors for capacity needs. Consider use of larger size conductors which have lower resistance, where cost effective, in the future. Hydro One does not use ACCC conductors because of poor performance under ice loading conditions.
Re-direct Power Flows	Power flow at any given time is dependent on the connected load and generation. Losses are a factor considered in the overall optimization of the generation dispatch by the IESO.
Bundle Conductor Optimization	Use bundled conductors for 500 kV
Improve Corona Losses	Insulator Hardware systems have been designed to eliminate corona. Conductor sizes also selected to avoid corona.

Shieldwire Segmentation	Not used due to high tower ground potential rise.
Improve Insulation Losses	Considered during insulation coordination design of insulator assemblies and structure configurations.
Installation of Low Loss Transformers	Purchase specifications include cost of losses and vendor transformer designs and quotations are assessed based on lowest lifetime costs including the cost of losses.
Convert to DC, Bipole or Tripole	Currently there are no HVDC systems in the province.
Switch off Equipment Not in Use	Not used due to safety and reliability concerns. Uncertainty as to the availability of equipment when it is required to be back in-service.

Sensitivity Study

Hydro One provided loading information and conductor and transformer characteristics for nine transmission lines and two load transformers to allow the performance of a sensitivity analysis to see how much loss mitigation could potentially be achieved on a sample of Hydro One assets. The sensitivity study is further described in Appendix A.

The power flow data was provided in the format of the hourly average line flow or transformer loading for the assets for every hour in 2016. One of the significant aspects of the loading data is the fact that the assets were loaded much less than their full thermal capacity. Table 5-4 shows that only three of the lines are loaded over 30% above average. .

Table 5-4 Sample Line Descriptions and Annual Load Factor

Line #	Voltage (kV)	Section Length (km)	Conductor Size	Conductor Material	Conductor Stranding	Conductors Per Bundle	Average Loadflow
1	230	7.3	1780.0 (kcmil)	ACSR	59/19	1	38%
2	500	208.7	585.0 (kcmil)	ACSR	26/7	4	19%
3	115	6.9	605.0 (kcmil)	ACSR	54/7	1	39%
4	115	40.0	336.4 (kcmil)	ACSR	26/7	1	23%
5	230	12.1	1192.5 (kcmil)	ACSR	54/19	1	13%
6	230	12.0	1192.5 (kcmil)	ACSR	54/19	1	31%
7	230	168.3	795.0 (kcmil)	ACSR	26/7	1	11%
8	230	116.8	795.0 (kcmil)	ACSR	26/7	1	24%
9	230	30.4	795.0 (kcmil)	ACSR	26/7	1	14%

This is not an indication that Hydro One is underutilizing its assets. Rather it is proof that the way transmission grids are operated per NERC requirements of meeting N-1 contingency criteria means many assets are lightly loaded, supporting the heavier loaded assets for occasions when they fail or are take on outage for maintenance. In addition, economic dispatch of generation to meet loads on the system governs line loading.

In the case of the two transformers, Table 5-5, you see that they are more heavily loaded, but again, on average, only 60%.

Table 5-5 Sample Transformer Descriptions and Annual Load Factor

Asset	Voltages (kV)	Average Loadflow
50 MVA	121/28	60%
75 MVA	244/44	60%

Using the provided power flows, calculations of the estimated losses were made for every hour using the asset characteristics (e.g., resistance-impedance) for the existing conductor or transformer and the more efficient lower resistance conductor or transformer.

Hourly plots throughout the year were made to visualize the potential loss mitigation. The first frame in Figure 5-1 is for Line 1 and is similar to most of the line plots. The second frame in Figure 5-1 is for the 500 kV line, where loading levels averaged just under 20% for 2016. In both cases there is a marginal difference between the losses calculated for the in-service conductor versus the more efficient conductor for the loading profiles of Hydro One.

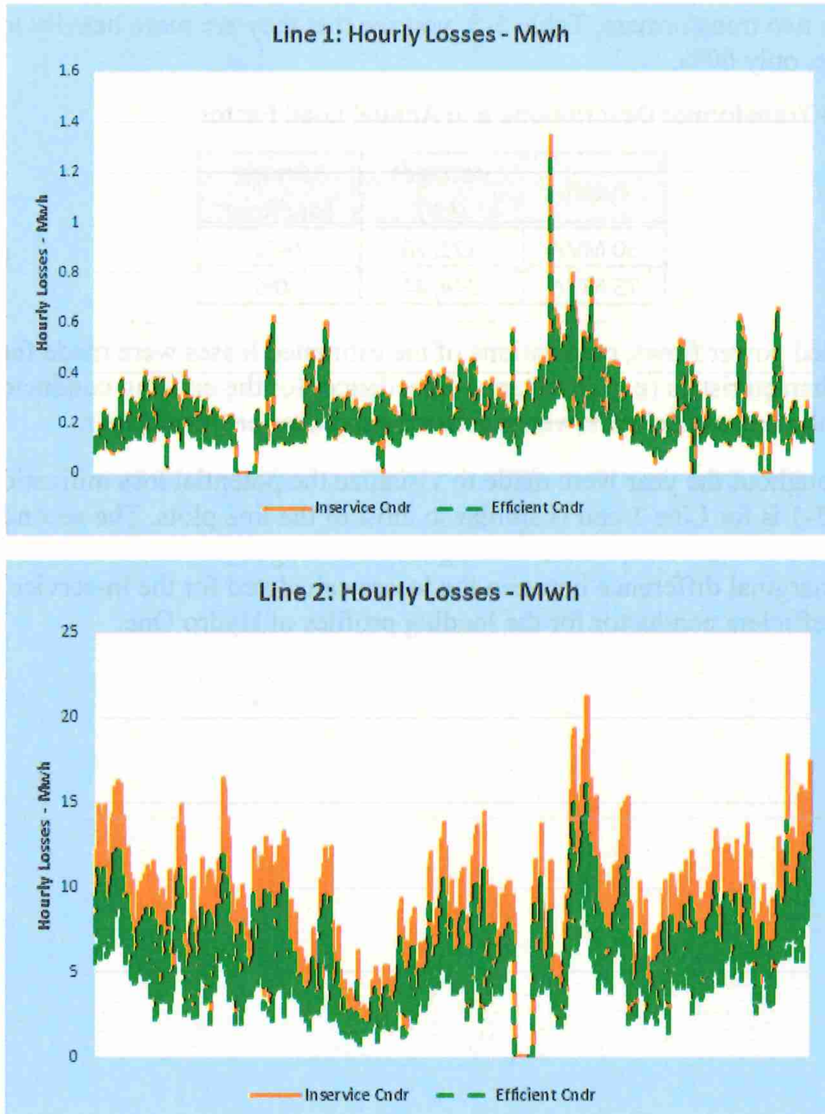

Figure 5-1
Sample Plots for Transmission Lines

Hourly plots throughout the year were also made to visualize the potential loss mitigation for the two transformers. The results are shown in Figure 5-2. The constant No-load losses are shown in each frame for the in-service unit and a potentially more efficient design transformer of the same size. The hourly tracking data represents total losses (i.e., No-load plus the losses from power flow).

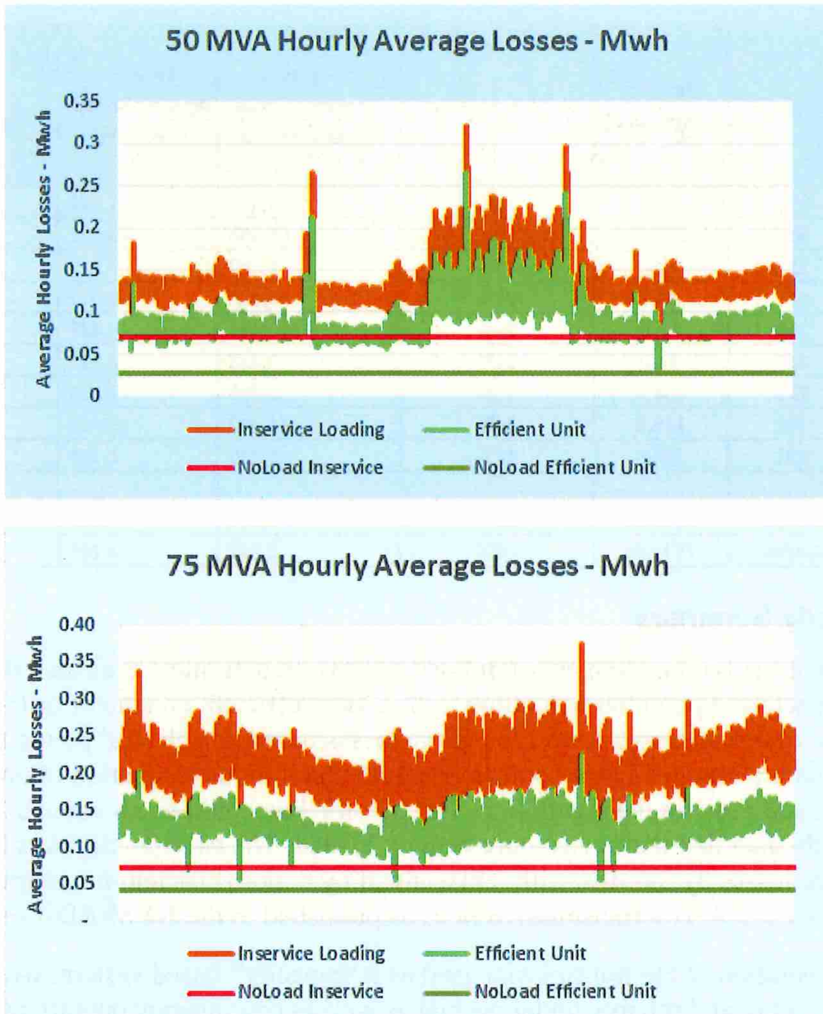

Figure 5-2
Sample Loss Plots for Transformers

Newer transformers offer more benefits as they are more efficient with lower losses than older units. However, replacement costs are high and transformer replacement is not undertaken for loss mitigation alone.

Table 5-6 summarizes the results of the loss mitigation comparison. For the transmission lines, the potential benefits of reconductoring existing lines are limited. The loss mitigation percentage is not significant, and it would not offset the costs to install the replacement conductor. This example validates why line loss mitigation projects are not self-justifying themselves.

Newer transformers offer more benefits as they are more efficient with lower losses than older units. However, replacement costs are high and transformer replacement is not undertaken for loss mitigation alone.

Table 5-6
Loss Mitigation Potential

Asset	Voltage (kV)	Section Length (km)	Average Loadflow	In-service Approx Annual Losses (Mwh)	Efficient Approx Annual Losses (Mwh)	% Loss Reduction
1	230	7.3	38%	1,987	1,922	3%
2	500	208.7	19%	63,185	48,772	23%
3	115	6.9	39%	1,567	1,510	4%
4	115	40.0	23%	3,000	2,617	13%
5	230	12.1	13%	451	428	5%
6	230	12.0	31%	2,438	2,311	5%
7	230	168.3	11%	3,785	3,589	5%
8	230	116.8	24%	14,442	13,752	5%
9	230	30.4	14%	1,225	1,161	5%
50 MVA	121/28	50 MVA	60%	1,230	815	34%
75 MVA	244/44	75 MVA	60%	1,887	1,134	40%

Sensitivity Study Summary

The sensitivity analysis on nine transmission lines and two transformers indicated the following potential loss impacts and potential reductions with a more efficient conductor or transformer design. The lines' effective losses were 11% of the losses based on full load power flow. Reconductoring with a more efficient conductor would result in loss reduction of only 3-5% for seven of the lines and 13% on the eighth line. The 500-kV line could reach about a 23% reduction due to the fact that the line is more heavily loaded. The two transformers have the potential to reduce losses by 34-40% with replacement by a more efficient transformer. Losses in general amount to 1.5-5.8% on transmission lines as published in the NYSERDA report[9].

The design and operation of the transmission grid as a "capacity"-based system, with adequate capacity to serve safely and reliably under normal as well as contingency operations due to loss of one or more elements, cause many transmission assets to operate normally in ranges of 30-50% of their full rated capacity. The cushion of capacity is needed to meet reliability criteria when system models indicate the capacity is needed for contingencies. The fact that assets operate at lower load factors also greatly reduces the impact of potential losses due to full capacity levels.

---

[9] *Assessment of Transmission and Distribution Losses in New York*, EPRI, Palo Alto, CA: 2012. PID071178 (NYSERDA 15464).

6 CONCLUSIONS

Hydro One requested EPRI's support in preparing a comprehensive assessment of current best practices in the industry relative to the mitigation of transmission losses for line and station equipment. This report addresses how losses are realized during the operation of the transmission grid and various mitigation techniques that can be applied to reduce losses. More importantly, the study investigated the current industry best practices relative to how transmission system providers, independent system operators, and regulatory bodies are addressing the loss mitigation concern.

Conclusions

The investigation in best practices showed these key points:

1. Transmission losses are not avoidable.
2. Losses can be mitigated to a limited extent with appropriate application of design.
3. Transmission losses and their mitigation are not a focal point of transmitters, their independent system operators, or their regulatory bodies. At best, a few entities include the impact on losses that various design options may have in the selection of their project solutions.
4. Transmission grids seldom operate at near-capacity levels. The generation – transmission grid – load network system is designed for reliability and economic electric delivery with contingencies for the loss of one or many elements.
5. Transmission Projects are initiated based on system need to ensure adequacy and reliability of supply or provide supply to customers. No utility is pursuing loss mitigation projects solely based on the potential mitigated loss savings over the life cycle of the asset.

Hydro One design practices are materially consistent with industry best practices for loss mitigation.

A
APPENDIX A

Loss Calculations for Sample Hydro One Data

Hydro One supplied loading data for nine transmission lines and two transformers. With the data provided, the project team could calculate estimates of the losses incurred throughout the year and make a comparison to an alternative conductor or transformer design that is more efficient from a losses perspective. A range of line lengths, voltage classes and conductor sizes was provided as shown in Table A-1. Of particular note is the average power flows for the lines. All lines are loaded at 40% or lower capacity typical of transmission networks.

Table A-1
Sample Transmission Line Descriptions

Line #	Voltage (kV)	Section Length (km)	Conductor Size	Conductor Material	Conductor Stranding	Conductors Per Bundle	Average Loadflow
1	230	7.3	1780.0 (kcmil)	ACSR	59/19	1	38%
2	500	208.7	585.0 (kcmil)	ACSR	26/7	4	19%
3	115	6.9	605.0 (kcmil)	ACSR	54/7	1	39%
4	115	40.0	336.4 (kcmil)	ACSR	26/7	1	23%
5	230	12.1	1192.5 (kcmil)	ACSR	54/19	1	13%
6	230	12.0	1192.5 (kcmil)	ACSR	54/19	1	31%
7	230	168.3	795.0 (kcmil)	ACSR	26/7	1	11%
8	230	116.8	795.0 (kcmil)	ACSR	26/7	1	24%
9	230	30.4	795.0 (kcmil)	ACSR	26/7	1	14%

The in-service conductors are ACSR (Aluminum Conductor Steel Reinforced), which have a steel core strand. The steel stranding increases the conductor's resistance and thus losses. The ACCC (Aluminum Conductor Composite Core) has a composite core rather than a steel core and has trapezoidal-shaped aluminum strands that allow for a greater area of aluminum for the same overall conductor diameter; both characteristics provide lower losses... Figure A-1shows a side-by-side cross-section view of the ACSR (left) and ACCC (right). The aluminum strands are the same electrical grade aluminum. The cores are different: galvanized steel versus a carbon-composite matrix core.

Figure A-1
Cross Sections: ACSR and ACCC

The following sets of charts for each line, Figure A-2 to Figure A-10, identify the power flow in a histogram showing loading level frequency on the vertical axis. Note that, all of the loadings are skewed to lower load factors, in quantity and level.

The second frame shows the hourly loading as a load factor, % of line capacity, during the course of the year. Finally, each line has a plot of the line losses calculated for the in-service conductor and an appropriate more efficient alternative, ACCC conductor. Note how seldom, the load factors peak and how short the peak loadings are throughout the year.

Table A-2 contains a comparison of the line losses for the in-service conductor and a more efficient alternative.

Similar data was provided for two transformers on the Hydro One system for analysis—a 50 MVA and a 75 MVA transformer. Hourly average loading was provided, as well as the No-load and Loaded losses measured at manufacture by the vendor (Figure A-11 and Figure A-12).

The 50-MVA unit shows a slightly skewed lower loading histogram, while the 75-MVA unit shows a near normal distribution. Both units averaged a 60% load factor for the year.

The third plot in the two sets provides a plot of the losses estimated for each unit using the hourly average loading values. For a transformer, there are No-load losses associated with just energizing the unit and the eddy current hysteresis in the coils. That value remains constant while the unit is energized. In this case, the in-service units had 71- and 72-kW losses for the 50- and 75-MVA units, respectively. When the units carry load, they incur additional joule heating losses, and those losses follow the loading pattern. In plot three of the two sets, the loss curves, other than the No-load, contain the sum of the Load-loss and No-load losses.

In comparison, Hydro One supplied transformer characteristics for replacement transformers that would be purchased according to their new specifications that require improved efficiency by the transformer vendors. The No-load loss levels are considerably lower, 27 and 43 kW for the 50- and 75-MVA units, respectively.

Figure A-12
75 MVA Transformer Loading and Loss Comparison

Loss Calculation Comparison

Based on the analysis and comparison for the transmission lines and transformers, the comparative losses and reductions are shown in Table A-2. Only two of the transmission lines showed significant savings from using a more efficient conductor to reduce losses. The other seven lines ranged from a 3 to 5% reduction. The analysis of the two transformers showed that more efficient transformer designs available on the market today efficiently reduce losses by 30-40%.

Table A-2

Loss Comparison Results

Asset	Voltage (kV)	Section Length (km)	Average Loadflow	In-service Approx Annual Losses (Mwh)	Efficient Approx Annual Losses (Mwh)	% Loss Reduction
1	230	7.3	38%	1,987	1,922	3%
2	500	208.7	19%	63,185	48,772	23%
3	115	6.9	39%	1,567	1,510	4%
4	115	40.0	23%	3,000	2,617	13%
5	230	12.1	13%	451	428	5%
6	230	12.0	31%	2,438	2,311	5%
7	230	168.3	11%	3,785	3,589	5%
8	230	116.8	24%	14,442	13,752	5%
9	230	30.4	14%	1,225	1,161	5%
50 MVA	121/28	50 MVA	60%	1,230	815	34%
75 MVA	244/44	75 MVA	60%	1,887	1,134	40%

The line losses estimated from the loading information provided by Hydro One are a very small portion of the losses if estimated based on the rating of the transmission element. This is especially true in the case of the line losses.

Export Control Restrictions

Access to and use of EPRI Intellectual Property is granted with the specific understanding and requirement that responsibility for ensuring full compliance with all applicable U.S. and foreign export laws and regulations is being undertaken by you and your company. This includes an obligation to ensure that any individual receiving access hereunder who is not a U.S. citizen or permanent U.S. resident is permitted access under applicable U.S. and foreign export laws and regulations. In the event you are uncertain whether you or your company may lawfully obtain access to this EPRI Intellectual Property, you acknowledge that it is your obligation to consult with your company's legal counsel to determine whether this access is lawful. Although EPRI may make available on a case-by-case basis an informal assessment of the applicable U.S. export classification for specific EPRI Intellectual Property, you and your company acknowledge that this assessment is solely for informational purposes and not for reliance purposes. You and your company acknowledge that it is still the obligation of you and your company to make your own assessment of the applicable U.S. export classification and ensure compliance accordingly. You and your company understand and acknowledge your obligations to make a prompt report to EPRI and the appropriate authorities regarding any access to or use of EPRI Intellectual Property hereunder that may be in violation of applicable U.S. or foreign export laws or regulations.

The Electric Power Research Institute, Inc. (EPRI, www.epri.com) conducts research and development relating to the generation, delivery and use of electricity for the benefit of the public. An independent, nonprofit organization, EPRI brings together its scientists and engineers as well as experts from academia and industry to help address challenges in electricity, including reliability, efficiency, affordability, health, safety and the environment. EPRI members represent 90% of the electric utility revenue in the United States with international participation in 35 countries. EPRI's principal offices and laboratories are located in Palo Alto, Calif.; Charlotte, N.C.; Knoxville, Tenn.; and Lenox, Mass.

2.0 (5.3.1 A) ASSET MANAGEMENT PROCESS

Hydro One's asset management goal is to identify and prioritize capital investments and asset maintenance throughout the life cycle of its assets. To achieve this goal, Hydro One undertakes a strategic and methodical asset management process, drawing upon the company's extensive expertise and experience in a variety of disciplines (including management, financial, economic, engineering, and operations) to monitor its transmission system assets, identify and define needs, and determine the optimal timing for investment and maintenance activities. In doing so, Hydro One strives to ensure that it delivers, and can continue to deliver over the long-term, a level of transmission service that is responsive to identified customer needs and preferences, as well as operational needs, while also mitigating rate impacts and risks in support of the company's strategic objectives.

Section 2 of the TSP focuses on the process Hydro One uses to manage its transmission assets. The overall process includes two main components: (i) the Asset Needs Assessment, during which Hydro One undertakes extensive and detailed technical reviews of its assets to identify a portfolio of investment candidates; and (ii) the Investment Planning process, during which the investment candidates are scored, prioritized, reviewed and developed into a capital investment plan in alignment with intended outcomes based on corporate objectives, asset needs, regulatory requirements, investment risks, customer preferences, and other identified constraints.

For greater clarity, the Asset Needs Assessment (including the resulting candidate investment portfolio) can be thought of as a major input into the Investment Planning process. As such, under Section 2.1, Asset Needs Assessment is presented not as a separate stand-alone process, but as one of the crucial inputs that inform the full strategic planning context underlying the Investment Planning process.

Section 2 of the TSP consists of the following sections:

Section 2.1 - Investment Planning Process

For the planning of capital investments, Hydro One utilizes a comprehensive Investment Planning process for the identification and prioritization of capital investments. As noted above, the Investment Planning process is informed and underpinned by the relevant planning context, which necessarily includes the results of Hydro One's Asset Needs Assessment, as well as other factors such as customer preferences, economic assumptions, load forecast, and system needs. Section 2.1 provides a detailed discussion of the planning process.

Section 2.2 – Asset Component Information

Hydro One's transmission system consists of a number of key components that must all work effectively in order to deliver reliable service. Section 2.2 provides details on each of the key asset components, including their purpose, condition and outlook.

Section 2.3 – Asset Life Cycle Optimization

Hydro One develops and implements asset strategies for various components of the transmission system based on their characteristics and associated business requirements. Section 2.3 describes the asset strategy for key components and outlines the specific maintenance and replacement strategies for each asset type with a view to optimizing the total lifecycle cost of the asset.

2.1 (5.3.1, 5.4.2) INVESTMENT PLANNING PROCESS

2.1.1 (5.3.1) INTRODUCTION

Asset Management is the combination of management, financial, economic, engineering, and other practices applied to physical assets, with the objective of providing a level of service that is consistent with customer needs and preferences, consistent with asset needs and responsive to rate impacts. Hydro One's asset management goal is to monitor system assets and determine the optimal timing of asset maintenance and capital investments throughout the asset life cycle. This is done to manage risks and to support the achievement of Hydro One's business objectives and outcomes, while managing total cost and customer rate impacts.

Hydro One uses a comprehensive and robust Investment Planning process to identify, prioritize and optimize investments to manage costs, asset/system operational risks, customer needs and preferences, customer rate impacts, and achieve the company's business objectives and outcomes.

Hydro One has recently revised and implemented an improved eight-step risk-based investment planning process to identify, prioritize and optimize investments set out in Hydro One's Transmission System Plan ("TSP").

Hydro One continues to make improvements to its risk-based Investment Planning process by incorporating feedback received, implementing leading industry practices and responding to concerns raised during the prior rate proceedings. The improved investment planning process is designed to provide a consistent understanding of risks to enable Hydro One to cost effectively deliver the highest value investments and service for its customers. This process allows candidate investments to be consistently assessed and prioritized based on the level of risk mitigated and the cost and value delivered toward achieving business objectives.

The overall Investment Planning process is set out below in Figure 1**.**

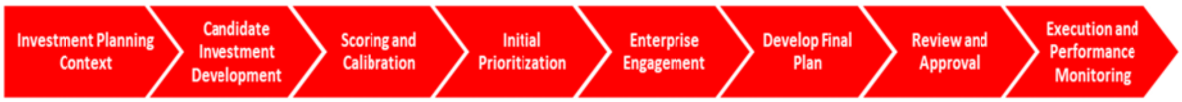

Figure 1 – Improved Eight-Step Investment Planning Process

Key improvements to Hydro One's investment planning process include the use of:

- Revised risk assessment framework to provide consistent risk assessment of safety, reliability and environmental risks;
- Clear definitions of risk impacts to enable consistent assessments across investments and calibration sessions to calibrate and align risk assessment practices; and
- Challenge sessions to engage stakeholders across the organization to review the investments and discuss potential trade-offs.

Hydro One management at all levels, including the Executive Leadership Team ("ELT"), are involved in the investment planning process to develop an investment plan that achieves the overall corporate strategy, efficiently mitigates risks, and delivers value to customers.

The Investment Planning process generates an annual budget for Operations, Maintenance and Administration ("OM&A") and capital work programs, and a six-year planning forecast that allows Hydro One to meet the OEB's filing requirements. The 2020-2024 Investment Plan presented in this TSP is a product of the improved investment planning process.

The sections below detail each step of Hydro One's improved Investment Planning process and provide the rationale and benefits of the specific process improvements that have been implemented.

2.1.2 (5.3.1) INVESTMENT PLANNING CONTEXT

Figure 2 - Investment Planning Context

As shown above in Figure 2, Hydro One's Investment Plan is primarily guided by: (i) the company's strategic vision and objectives; (ii) planning economic assumptions (e.g., economic assumptions, load forecast, etc.); (iii) customer engagement feedback; and (iv) asset/system needs, customer needs and preferences.

2.1.2.1 (5.3.1 A) STRATEGIC CONTEXT

Hydro One used its strategic priorities and objectives to develop its TSP. These priorities and objectives are presented in Figure 3 below.

Strategic Priorities

- **Employees**
  - Maintain a safe and inclusive workplace for all employees
  - Foster a high level of employee engagement throughout Hydro One through a new engagement approach focused on developing company –wide action plans ("Time for Action")
- **Customer Experience**
  - Deliver industry-leading customer service, in response to identified customer preferences
  - Foster innovation in the business to adapt to changing customer requirements and market opportunities
  - Advance reconciliation and work proactively to build relationships with Indigenous peoples and communities based on understanding, respect and mutual trust
- **Operational Effectiveness**
  - Invest in grid infrastructure and grid modernization to deliver a high level of reliability and quality to our customers
  - Focus on continuous improvement in productivity and operating efficiency to maintain lowest possible costs
- **Government and Regulatory Relationships**
  - Maintain and build constructive, transparent relationships with governments and regulatory entities in all jurisdictions where we operate
  - Deliver on obligations mandated by government through legislation and regulatory requirements
- **Financial Strength**
  - Maintain a strong balance sheet to support continuing investment in our business
  - Invest in assets to better serve customers

SAFETY COMES FIRST | STAND FOR PEOPLE | EMPOWERED TO ACT | OPTIMISM CHARGES US | WIN AS ONE

Figure 3 – Hydro One's Strategic Priorities and Objectives

As part of its Renewed Regulatory Framework ("RRF"), the OEB introduced the following four outcomes:

- **Customer Focus** – services are provided in a manner that responds to identified needs and customer preferences;
- **Operational Effectiveness** – continuous improvement in productivity and cost performance is achieved; and transmitters deliver on system reliability and quality objectives;
- **Public Policy Responsiveness** – transmitters deliver on obligations mandated by government (e.g., in legislation and in regulatory requirements imposed further to Ministerial directives to the Board); and

- **Financial Performance –** Financial viability is maintained; and savings from operational effectiveness are sustainable.

In managing its transmission assets that are critical to customers and Ontario's economy, Hydro One is committed to meet the RRF outcomes and has integrated them into its improved Investment Planning process. Figure 4 below demonstrates the close alignment of Hydro One's business objectives to the RRF outcomes.

Customer Focus	**Customer Satisfaction**	• Improve current levels of customer satisfaction
	Customer Focus	• Engage with our customers consistently and proactively • Ensure our investment plan reflects our customers' needs and desired outcomes
Operational Effectiveness	**Cost Control**	• Actively control and lower costs through OM&A and capital efficiencies
	Safety	• Drive towards achieving an injury-free workplace
	Employee Engagement	• Achieve and maintain employee engagement
	System Reliability	• Provide top quartile reliability relative to transmission peers
Public Policy Responsiveness	**Public Policy Responsiveness**	• Ensure compliance with all codes, standards and regulations • Partner in the economic success of Ontario
	Environment	• Sustainably manage our environmental footprint
Financial Performance	**Financial Performance**	• Achieve the ROE allowed by the OEB

Figure 4 - Hydro One's Business Objectives

Guided by Hydro One's strategic priorities and objectives Hydro One evaluates its assets and other needs to inform and guide the development of its investment candidates. For example, the RRF outcomes corresponding to the relevant transmission objectives are measured by a set of risk-based taxonomies and qualitative flags which form the criteria against which candidate investments are evaluated, risk mitigation is quantified, and trade-offs between investments are made in the prioritization and optimization of the investment plan. These are further described below.

Consistent with the recommendations included in the Investment Planning process benchmarking report, provided in Attachment 14 of Section 1.4 of the TSP, Hydro One implements a strategic allocation process at the onset of its planning cycle. This process step divides the plan into smaller, discrete allocations, which provides the framework for subsequent investment prioritization and optimization. Through this process, Hydro One's corporate strategy and objectives are translated into key outcomes, and the level of funding required to achieve those objectives is defined. Specific business unit capital and

OM&A allocations are subsequently defined strategically based on customer, operational, public policy and financial outcomes and funding level necessary to meet its objectives.

The basis for this upfront allocation is the expenditure level included in the prior year's plan, adjusted for efficiency gains and new strategic directions as presented in Figure 5 below. The overall investment envelope and year-over-year pacing of investments is also informed by the feedback received through the customer engagement process.

Figure 5 - Upfront Allocation Setting Framework

As noted in TSP Section 1.3, through the customer engagement survey, respondents were provided with descriptions of four illustrative investment scenarios (Scenarios A, B, C, D), and provided a line of data points that started at zero and extended beyond the four of the illustrative investment scenarios. Customers were asked to select any point along that continuum that reflected what they believed to be the best and most appropriate balance between rate impacts and outcomes. Scenario C, which maintains the level of investment proposed in the previous application, improves long-term reliability performance and offers level future rate increases, was strongly favored over the other three scenarios. Customer preference for long-term reliability performance with level future rate increases is reflected in the initial funding envelope, which was subsequently divided into smaller, more discrete allocations.

This new process step enabled Hydro One to directly link the investment planning process with the corporate strategy and provided an opportunity to incorporate executive level inputs early in the process. It also provided clarity and direction to the planning process stakeholders with regards to investment allocations and targeted outcomes. This process step was initiated in early 2018 and finalized prior to the calibration session.

In parallel with the allocation setting process, Hydro One held a formal risk assessment workshop to identify risks in achieving its business objectives, including asset management and maintenance, extreme natural events and climate change, resource adequacy performance and the changing resource mix. Based on the initially identified list of risks, Hydro One developed candidate investments to address these risks. Throughout the planning process, Hydro One monitored and tracked the funding status of these investments.

2.1.2.2 (5.3.1 B) PLANNING ASSUMPTIONS

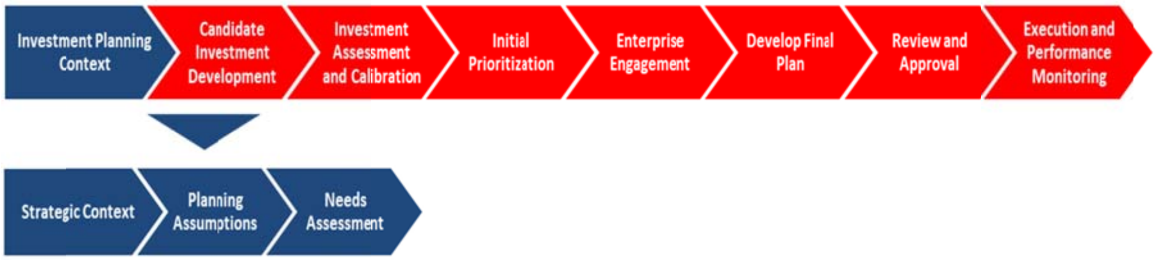

Figure 6 – Investment Planning Context – Planning Assumptions

To facilitate the preparation of its Investment Plan, Hydro One compiled an economic outlook forecasting customer load and key economic statistics as shown in Figure 6 above.

A (5.3.1 B) LOAD FORECAST

Hydro One uses various methods, such as econometric models, end-use models, and customer forecast surveys to produce the load forecasts that are required for its transmission business and that inform investment needs. A detailed description of Hydro One's forecasting methodology, models and their elements is included in Exhibit E, Tab 3, Schedule 1.

The system forecast for the period 2020 to 2022 has been prepared in accordance with the OEB-approved forecasting methodology, which is summarized in Table 1 below.

Table 1– Forecast of Transmission Charge Determinants (12-month average peak in MW)

Year	Network	Change (%)	Line Connection	Change (%)	Transformation Connection	Change (%)
2020	19,604	0.0	19,071	0.0	16,252	0.0
2021	19,469	-0.7	18,941	-0.7	16,142	-0.7
2022	19,322	-0.8	18,800	-0.7	16,021	-0.7

The decrease in load over the test period is primarily attributable to conservation and demand management activities and economic conditions. At the same time, pockets of load growth are expected across Hydro One’s transmission service territory due to urban and industrial/mining developments. Further details on the areas experiencing local load growth are provided in the various Regional Planning reports attached to TSP Section 1.2.

B (5.3.1 B) ECONOMIC ASSUMPTIONS

Consumer Price Index

Hydro One, as an Ontario based transmitter, has relied on the Ontario Consumer Price Index (“CPI”) for its assumptions about inflation. The CPI provides a broad measure of the cost of living. CPI reflects the change in retail price of a representative shopping basket of about 600 goods and services from an average household’s expenditure: food, housing, transportation, furniture, clothing, and recreation.

Table 2 – Ontario CPI (%)*

	Historical Years					**Bridge Year**	**Forecast Period**				
	2014	**2015**	**2016**	**2017**	**2018**	**2019**	**2020**	**2021**	**2022**	**2023**	**2024**
CPI-Ontario	2.3	1.2	1.8	1.7	2.4	1.8	2.0	1.9	2.0	2.0	2.0

** Source: IHS Global Insight's November 2018 forecast.*

Exchange Rates (CDN:USD)

The exchange rate figures and forecasts for 2019 to 2022 are based on the November 2018 edition of the Global Insight Forecast. These exchange rates, as presented in Table 3 below, are used to forecast other variables such as fleet vehicle related costs, which are typically obtained in US dollars.

Table 3 – Exchange Rate *

USD:CAD	Historical Years					Bridge Year	Forecast Period				
	2014	2015	2016	2017	2018	2019	2020	2021	2022	2023	2024
Exchange Rate	0.905	0.783	0.755	0.771	0.775	0.782	0.793	0.797	0.799	0.800	0.803

** Source: IHS Global Insight's November 2018 forecast.*

2.1.2.3 (5.3.1 B) NEEDS ASSESSMENT

Figure 7 - Investment Planning Context – Needs Assessment

As shown in Figure 7 above, Hydro One performs a needs assessment to identify the drivers in the development of candidate investments and collect the data necessary to enable the assessment of risks and subsequent calibration process. The needs assessment identifies (i) asset needs, (ii) customer needs and preferences, (iii) system needs (including regional planning considerations), and (iv) other external influences. The needs assessment also identifies potential hazards, vulnerabilities, threats or other risk sources that could present risks to achieving Hydro One's business objectives.

A ASSET NEEDS ASSESSMENT

A detailed and systematic assessment of asset-specific investment needs is an essential prerequisite of, and critical input into, the Investment Planning process that underpins this TSP. The output of the Asset Needs Assessment is a portfolio of investment candidates which reflects the asset-related needs and risks (particularly on the basis of asset condition) to be further evaluated against the relevant planning context. The investment candidates are further scored and prioritized through Hydro One's Investment Planning process (as described in TSP Section 2.1.4 below) to achieve the optimal balance of risk and benefits.

Hydro One performs a continuous asset risk assessment ("ARA") process to determine individual asset needs which rely on asset condition data, engineering analysis and other information including the input of experienced planning professionals. The ARA is primarily concerned with the major equipment groups (e.g. transformers, conductors, breakers, and protection and control systems) that directly affect system reliability.

One of the inputs into the ARA is a quantitative asset analytics system, which combines information from various Hydro One databases to provide an initial common understanding of asset health. This process drives efficiency and effective planning decisions by ensuring a consistent view of asset information for all planners. As part of the preliminary risk assessment, asset analytics enables the review and consolidation of a variety of information from enterprise reporting systems, such as condition information driven by deficiency and preventive maintenance reports, demographic information including make, model, and type, criticality to the transmission system, performance data based on equipment outages, utilization information, and economics. While not a determinative driver in the ARA process, asset analytics is one useful tool that aids Hydro One planners in identifying asset risks for further screening and confirmation. Hydro One's planners also take into account additional factors such as load forecasts, equipment ratings, operating restrictions, security incidents, environmental risks and requirements, compliance obligations, equipment defects, obsolescence, and health and safety considerations to ensure capital expenditures target the most appropriate mix of assets. As part of the ARA process, transmission assets are evaluated on the following six risk factors:

- **Condition** - Risk related to the increased probability of failure that assets experience when their condition degrades over time. Asset condition is defined using different criteria, depending on the asset. For example, the condition of a transmission station transformer is measured by visual inspections and analysis of the oil within the transformer. The condition of a wood pole is measured by a visual inspection, a sounding test, and if required, a boring test. While methods to evaluate condition vary from asset type to asset type, the condition of all assets of a given type is evaluated consistently. Assets of a given type that have a relatively high condition risk are candidates for refurbishment or replacement.
- **Demographics** - Risk related to the increased probability of failure exhibited by assets of a particular make, manufacturer, and/or vintage. Typically, the probability of asset failure increases with age. Thus, the asset demographic risk increases as an asset ages. Assets with relatively high demographic risk are candidates for refurbishment or replacement.
- **Criticality** - Represents the impact that the failure of a specific asset would have on the transmission system. Primarily, it is used to show relative importance of an asset compared to other assets of the same type. Assets whose failure would result in an interruption to a larger amount of load would have an asset criticality that is higher than assets whose failure would have a smaller impact on the system load. Asset criticality is used to prioritize the refurbishment or replacement of assets whose condition, demographic, performance, utilization or economic risk has already resulted in the asset being considered a candidate for refurbishment or replacement.
- **Performance** - Risk that reflects the historical performance of an asset, derived from the frequency and duration of outages. Past performance can be a good indicator of expected future performance. Therefore, assets with a relatively high-performance risk can be considered candidates for refurbishment or replacement.
- **Utilization** - Risk that reflects the increased rate of deterioration exhibited by an asset that is highly utilized. The relative deterioration of some assets is highly

dependent on the loading placed upon them or the number of operations they experience. For example, transformers that are heavily loaded relative to their nameplate rating deteriorate more quickly than those that are lightly loaded. Similarly, circuit breakers utilized for capacitor and reactor switching which are subject to significant operations experience accelerated mechanical and electrical wear-out of the breaker. Therefore, the asset utilization risk for transformers and circuit breakers attempts to consider their relative deterioration based on available loading and operational history, respectively.

- **Economics** - Risk based on the economic evaluation of the ongoing costs associated with the operation of an asset. Depending on the asset type, this evaluation may be as simple as determining the replacement cost of the asset, or as complex as comparing the present value of ongoing maintenance to that of complete refurbishment or replacement. While an economic evaluation can identify assets that are candidates for replacement, more typically, the evaluation assists in selecting the best form of remediation for assets already deemed to be candidates for refurbishment or replacement.

It is important to recognize that although asset analytics aids in the identification of asset needs as an initial step, it is not the sole input or driver of the ARA. Hydro One planners take into account a range of other considerations and data sources, as informed by sound engineering oversight and experience-based decision making, in the initial determination of asset needs, which are then ultimately verified against asset condition assessments.

Throughout the assessment of individual asset needs, Hydro One's planners carry out a process of grouping identified needs into logical, functional and geographic groups. For example, a customer need for increased capacity and an asset need to replace transmission station equipment, such as a transformer or switchgear, might be grouped together if the same transmission station is involved. Through this process, diverse individual needs are brought together to form potential projects or programs that may be brought forward as candidate investments. These groupings of potential candidate investments are then scoped and defined based on an identified asset needs, customer feedback and other inputs. Once grouped, Hydro One undertakes a further validation process to confirm that the need for the project or program remains, has not evolved and will not be addressed by any other means.

Hydro One planners conduct on-site assessments with field personnel to validate and confirm asset condition and related information identified through enterprise reporting systems and asset analytics. For instance, planners speak with personnel who manage and maintain the equipment on a daily basis and solicit first-hand insight regarding deficiencies or potential upgrades which may be required. For high-value assets, such as transformers, subject matter experts perform a thorough assessment of asset condition and consider and advise on issues such as equipment obsolescence, manufacturer support, and “repair vs. replace” evaluations. All transformer replacements are reviewed by subject matter experts who prepare Transformer Assessment Reports that are used to justify investment decisions. The detailed asset assessment and field review, inspection and validation are invaluable tools for ensuring that the identified needs actually reflect the condition of assets in the field and relevant operating information including the concerns of field personnel, which could not otherwise be verified through asset analytics alone.

The outputs of the ARA process are potential candidate investments that are put forth for further consideration during the Investment Planning process that have been evaluated and justified on the six risk factors described above. For detailed information on asset condition, demographics and performance for Hydro One’s four major asset categories please refer to TSP Section 2.2.

ARAs establish the necessary fact base to later assess the probability and consequence of safety, reliability and environmental risks at the scoring stage of the Investment Planning process. Risks relating to asset condition, demographics, performance and utilization directly inform the probability score, and risks relating to asset criticality directly inform the consequence score. As discussed in TSP Section 2.1.4 below, the probability and consequence scores are then converted into risk scores which inform the initial prioritization and optimization.

Asset Management of Stations vs. Lines

While the above described process generally applies across transmission asset types, it is important to note that Hydro One tailors the specific approach according to the characteristics of each major transmission asset class – stations and lines.

For station assets, Hydro One has established a seven to ten-year assessment cycle that enables all necessary renewal work to be performed at each of the 294 transmission stations during the cycle. This assessment process is carried out by experienced planning professionals where information is aggregated from customers, enterprise reporting systems, field personnel, and asset specific subject matter experts to develop a comprehensive assessment report of current asset condition. This ensures that asset needs at all stations are reviewed on a recurring basis, which may or may not result in the need for an investment as per the ARA process described above. This is a planning level assessment which is used to inform the development of candidate investments that are an input to the Investment Planning process and complements the planned inspections, maintenance and testing performed on the assets as discussed in TSP Section 2.3. Rather than making numerous return visits to the same stations to repair or replace different types of assets, requiring multiple outages, Hydro One has adopted an integrated approach whereby assets requiring replacement at a station are bundled together (based on key station assets) and executed at once. The candidate investments identified through the Asset Management process include station-specific integrated investments that have been developed in accordance with the established assessment cycle.

Hydro One’s approach to asset management for its transmission line assets is shaped by the nature of the specific line assets and their typical service lives. For example, the expected service life for overhead transmission conductors is 90 years, though the conductor may reach end of life before or after that time depending on the specific environmental circumstances. When a conductor fails or has been determined to have reached end of life based on its condition, as confirmed by testing, replacement is the only solution. When the conductor needs replacement, this creates a rare opportunity in the asset lifecycle for Hydro One to implement a full line refurbishment of the relevant segment in order to bring the associated assets (i.e., poles, parts of steel structures, foundations and the conductors) to a condition that is as close to new as possible. Other transmission line components (e.g., wood poles, shield wire, aviation lighting and U-bolts) do not last this long and as such are subject to separate, recurring asset replacement programs. Regardless of the type of transmission line asset, Hydro One will not replace assets unless their condition warrants the replacement.

B CUSTOMER NEEDS

Hydro One believes that understanding its customers, and their needs, is critical to its business. Hydro One engages with customers proactively and regularly through various mechanisms. Customer needs can be categorized as either (i) initial connection needs, or (ii) needs of connected customers. Initial connection needs are generally identified either by a direct customer connection request through the Hydro One customer connection process or by need assessments and customer consultations as part of the Regional Planning process. Once connected, customer needs are identified by continuous monitoring of the power system and engagement with transmission customers.

C CUSTOMER ENGAGEMENT

Hydro One’s senior management team has renewed the company’s focus on customer relationships. As described in TSP Section 1.3, in addition to regular customer engagement, Hydro One commissioned Innovative Research Group (“Innovative”) to conduct a customer engagement survey (the "Customer Survey") with 156 transmission customers in May and June 2017. The results of this survey have been used as an input to this TSP.

Through its customer engagement efforts, Hydro One learned the following:

- Safety, reliability, and environment are among the top prioritized outcomes;
- Customers' reliability requirements differ. While some process-oriented industrial customers may prefer reducing the frequency of outages over duration, non-industrial customers may prefer multiple shorter duration outages;
- All customer segments prefer the even pacing of investments over time to achieve a gradual and uniform impact on rates; and
- When presented with several investment scenarios, the majority of customers preferred investment levels in line with the investment plan that was before the OEB in the prior transmission proceeding by at least a three to one margin. It is seen as reflective of the current approach which has served the system well, and a less risky option.

In developing the improved taxonomies **(**as explained in TSP Section 2.1.4 below), Hydro One considered specific customer feedback and added outage frequency to the probability framework to incorporate specific feedback from customers. Over 80% of customers surveyed identified safety, reliability, or environmental considerations as high priority items (seven or higher on a scale of ten). The details of how Hydro One incorporated customers' feedback into its investment plan are included in TSP Sections 2.1.4 and 3.2.1.3.

D SYSTEM NEEDS

System needs cover work necessary to ensure that the transmission system is maintained and operated to provide an adequate and reliable supply to customers. They are driven by the requirement to meet current and forecast load demand resulting from the connection of new load customers and generation facilities. System needs include:

- Provision of adequate transmission capacity to reliably deliver electricity to the local areas connected to Hydro One's transmission system;
- Provision of inter-area network transfer capability to enable electricity delivery from areas with sources of supply to load centers across the system;
- Provision of necessary protection and control modifications to Hydro One's transmission stations to address the impacts of distribution connected generation;
- Implementing the necessary mitigation measures to minimize high-impact risk (e.g., installing special protection systems to protect equipment from overload conditions; uprating of station short circuit capacity) and to ensure the safe, secure and reliable operation of Hydro One's transmission system in accordance with the IESO's Market Rules, OEB's Transmission System Code, and other mandatory industry standards such as those established by the North American Electric Reliability Corporation ("NERC") and Northeast Power Coordinating Council ("NPCC"); and
- Provision of power quality data collection capabilities and pilot cost effective mitigation measures to address specific issues faced by Hydro One customers.

Under the electricity industry structure in Ontario, the need for new transmission system facilities or system enhancements may be identified by Hydro One Transmission, the IESO, the Government of Ontario (e.g. through the Long Term Energy Plan referenced in TSP Section 1.7), or customers. These needs are identified and assessed by Hydro One Transmission in conjunction with customers, the IESO and LDCs under the regional planning process as outlined in TSP Section 1.2 or by the IESO as part of the planning for the bulk electric system.

E EXTERNAL AND OTHER INFLUENCES

Hydro One also uses information on industry best practices, trends and benchmarking to compare its operations and performance to other utilities within the industry. Technical studies performed on the transmission system with the support of the Electric Power Research Institute or other industry partners provide further insight into the state of the asset base and support the decisions regarding which assets are candidates for investment. A description of the benchmarking studies and the resulting recommendations are included in TSP Section 1.4.

2.1.3 (5.3.1 B) CANDIDATE INVESTMENT DEVELOPMENT

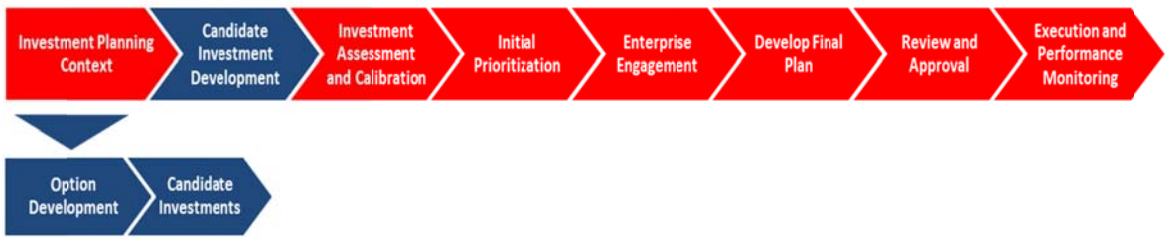

Figure 8 - Candidate Investment Development

Based on the asset needs identified through the ARA process (as discussed in TSP Section 2.1.2.3), Hydro One planners develop a set of candidate investments that are likely to address the relevant asset needs and risks as shown in Figure 8 above. These candidate investments are then evaluated for inclusion in the Investment Plan.

While the candidate investments arising from the ARA process primarily pertain to System Renewal investments, there are other types of investment candidates that are not necessarily asset condition triggered, and these are discussed in the following section.

2.1.3.1 OPTION DEVELOPMENT

To become a candidate for consideration, a proposed investment must demonstrate a need, reflect appropriate planning assumptions, and be supported by unbiased information to enable credible evaluation.

2.1.3.2 INVESTMENT CATEGORIES

Proposed investments are classified into one of the four OEB investment categories: System Renewal, System Access, System Service, and General Plant.

A SYSTEM RENEWAL

System Renewal investments aim to extend the expected service life of transmission assets through replacement and/or refurbishment, thereby minimizing life cycle costs and maintaining reliability performance.

Identifying and selecting System Renewal investments involves several steps. The first step is to consolidate the asset needs in the ARA by major asset type. The next step is to identify options to mitigate risk for assets that are deemed to have a significant increased risk of failure. In doing so, Hydro One relies upon multiple factors used to evaluate failure risk, including condition, criticality, performance, and demographics as described in TSP Section 2.1.2. Hydro One then performs a detailed review of the asset needs to determine if there are opportunities for an integrated approach for stations or lines investment. Where practical, Hydro One examines alternative levels of investment and their corresponding level of risk to which it might be exposed. Finally, the preferred option to mitigate the risk is selected through the "Scoring and calibration" step described in TSP Section 2.1.4.

B SYSTEM ACCESS

System Access investments are non-discretionary investments driven by mandated service obligations to connect customers in accordance with Hydro One's Transmission Licence. They include provision of new customer connections or modification of existing customer connections. System Access investments fall into the following three categories: load customer connections, generator customer connections, and third-party transmission.

Load Customer Connections

Load Connection investments are initiated based on customers' requirements for capacity and reliability improvements or identified by the regional planning process as documented in TSP Section 1.2. The investments cover provision of new or modified transformation connection facilities, including new feeder positions at existing transformer stations, or construction of new connection lines and stations.

In accordance with the Transmission System Code, a customer has discretion as to whether a new load connection will be provided by the customer or by Hydro One. If requested, Hydro One is required under the Transmission System Code and its Transmission License to provide new line connection and/or transformation connection facilities.

For investments identified as part of the regional planning process, the need and timing are outlined in the Regional Infrastructure Plan report prepared by Hydro One in conjunction with all regional LDCs and the IESO.

The costs of the load connection investment are the responsibility of the benefiting customer(s) and the costs are fully recovered from these customers via incremental connection revenues and/or capital contribution as per a Connection Cost Recovery Agreement ("CCRA"), the calculation of which is based on Hydro One's Connection Procedures.

Generator Customer Connections

Generation connection investments are based solely on customer requests. In most cases, the generation investments have been triggered as a result of provincial government policy under which the IESO has initiated procurement of renewable, clean and/or high efficiency energy. The needs are typically addressed by radial connection facilities. However, in some cases, other modifications (such as enhancements to protection systems, voltage or reactive power support, and/or breaker and station upgrades to address increased short circuit levels) may be required to Hydro One's local area connection or network facilities in order to reliably integrate new generation into the system. In accordance with Section 6.3.4 of the Transmission System Code, modifications to connection facilities associated with generation connection are fully recovered from the generators via capital contribution as per a Connection Cost Recovery Agreement ("CCRA"), the calculation of which is based on Hydro One's Connection Procedures. Any incurred investment in network facilities is recoverable as specified in Section 6.3.5 of the Transmission System Code.

Third-Party Transmission

In certain circumstances, Hydro One is mandated to complete investments due to the actions of third parties such as governmental bodies and transit organizations. These investments are usually fully-funded by the third party. In rare cases, they may fall under a provincial statute that allows for cost sharing. They are included in the plan as a cost placeholder calculated on the basis of historical data.

C SYSTEM SERVICE

System Service investments address the need for modifications to the transmission system to ensure it continues to meet operational objectives while also addressing anticipated future customer electricity requirements through:

- increasing the inter-area transfer capability between generation areas and load centres within Ontario and/or with neighbouring utilities;
- addressing anticipated future load requirements in local areas where existing transmission facilities have reached capacity; or
- satisfying system operational objectives (e.g., local area supply adequacy; acceptable voltages; operation of equipment within the ratings; system stability; and/or operating flexibility).

System Service investments typically affect many customers over a significant period of time.

System Service investments are identified and developed as part of regional planning and/or the IESO bulk planning studies. The scope of System Service investments can range from installation of special protection systems or capacitor banks to maximize the use of existing facilities (in order to defer the need for a major investment) to major transmission expansion projects. Major transmission expansion projects may include construction of new transmission lines into the area, and/or new or additional 500/230kV or 230/115kV autotransformer capacity. These major projects typically require long lead-times, particularly if there are statutory or regulatory approval requirements under the *Environmental Assessment Act* or Section 92 of the *Ontario Energy Board Act (1998)*.

Line loss mitigation investments fall under this category. In the EB-2016-0160 Decision, the OEB found that Hydro One should work jointly with the IESO to explore cost effective opportunities for line loss reduction. In response, Hydro One has worked with the IESO and initiated an independent third party review by EPRI of Hydro One’s current practice along with the industry best practices. At the conclusion of its analysis, EPRI confirmed that Hydro One’s current design practices are consistent with these best practices for loss mitigation. Further details are provided in TSP Section 1.8.

D GENERAL PLANT

General Plant investments are comprised of modifications or replacements to assets that are not directly or specifically part of the transmission system. These may include investments related to Hydro One’s transport and work equipment fleet, facilities, and information technology. The process to identify and select investments in each of these areas is discussed below.

Transport and Work Equipment Fleet

Transport and work equipment investments ensure that crews have the ability and the vehicles required to access and perform the work required. Investments are primarily replacements of existing equipment. Hydro One identifies and selects the investments on the basis of need, which is driven by the following key factors:

- work program requirements;
- staffing requirements;
- industry standards (manufacturer's recommendations) for life cycle expectancy; and
- operating cost drivers.

Based on this information, a preferred alternative is recommended in line with Hydro One's expected business plan and work programs.

Facilities

Facility investments are necessary to provide appropriate and adequate accommodations for core work programs and changing requirements of the various lines of business. The investments are identified and selected based on need which is driven by the following key factors:

- aging facilities that are confirmed to be at or near their end of life;
- compliance with legal requirements, such as the *Accessibility for Ontarians with Disabilities Act*;
- expanding work programs;
- evolving work practices;
- improved health and safety;
- improved security;
- sustainable development; and
- work efficiency and productivity.

Based on the information gathered, Hydro One undertakes a comparative evaluation of alternatives, which may include the lease or purchase of existing or green-field developments against status quo condition. A preferred alternative is recommended based on the objective to pursue the most cost-effective strategy that addresses operational requirements and manages risk.

Information Technology

Information Technology ("IT") investments are identified and selected based on the need to address:

- potential end of life IT systems and the optimal point in time to initiate their upgrade or replacement;
- changing business needs;
- existing or new business processes; and
- mandatory regulatory or compliance changes to systems as and when required, (e.g., security, policy changes).

2.1.3.3 CANDIDATE INVESTMENTS

The final step before determining the portfolio of candidate investments is to further screen and validate the needs that triggered the identified investments:

1. Grouping the identified needs into logical, functional, and geographic groups. For example, a customer need for increased capacity and an asset need to replace transmission station equipment, such as a transformer or switchgear, could be grouped together if the same physical assets are involved.
2. Scoping investments appropriately based on asset need and customer feedback. Condition remains the primary driver for all asset replacement decisions. At the same time, Hydro One planners engage with customers (e.g., LDCs, transmission connected industrial customers) to solicit feedback regarding the planned station work, including any operational or performance concerns and whether the identified investment can feasibly address the identified needs and preferences. For instance, in respect of each planned transformer replacement, Hydro One interfaces with

customers, including the relevant LDCs to identify the need for building in capacity flexibility for purposes of accommodating future load growth.

3. Validating that the investment need still exists, that the need has not evolved, and that the need will not be addressed by other means. For instance, a planned new station may eliminate the need to replace and reconfigure an end-of-life station asset and could also provide the additional capacity required by customer.

Once it has been determined that a proposed investment meets a relevant need, planners prepare a high-level scope and preliminary estimate of cost and pacing so it can be considered for inclusion in the Investment Plan.

2.1.4 (5.3.1 B) INVESTMENT ASSESSMENT AND CALIBRATION

Figure 9 – Investment Assessment and Calibration

The “Investment Assessment and Calibration” step refers to the process by which Hydro One assesses the potential investment options it has identified as shown in Figure 12 above. It involves the following activities:

- Assessing the risk mitigation impact of investment candidates developed in the previous step of the planning process;
- Assessing the impact of investment candidates on desired outcomes; and
- Calibrating risk assessments to enable consistent assessments across investments.

Hydro One continuously improves its risk assessment process.[1] Since the last transmission rate application, Hydro One has introduced a more rigorous and transparent process that includes the use of:

- Revised risk assessment framework to provide consistent risk assessment of safety, reliability and environmental risks;
- Clear definitions of risk impacts to enable consistent assessments across investments and calibration sessions to calibrate and align risk assessment practices; and

[1] See Appendix 1 for a summary of improvements made to Hydro One’s Investment Planning process.

- Challenge sessions to engage stakeholders across the organization to review the investments and discuss potential trade-offs.

The improved risk assessment process relies primarily on three risk taxonomies that have been developed to classify safety, reliability and environmental risks. The taxonomies provide guidelines for planners to assess the consequence and probability of existing operational risks and the residual risks remaining based on how investment projects are expected to mitigate those risks. The taxonomies are fact-based, with significant analytical rigor behind the development of different levels of classification. For example, different levels of safety consequence are based on historical data of safety outcomes derived from utility industry experience. Reliability consequence information is based on realistic customer outcomes for escalating levels of consequence based on Hydro One's experience.

Hydro One's improved risk assessment method enables it to incorporate key customer and regulatory outcomes into its evaluation of projects in two ways. The first is through the definitions of consequence in the risk taxonomies, and the second is through the flagging system (described in more detail below). Hydro One's risk taxonomies are based on key outcomes (safety, reliability, and environment)[2] that customers and the OEB have identified as high priority. These outcomes are reflective of top customer priorities identified through Hydro One's customer engagement, detailed in TSP Section 1.3, and align with key regulatory and policy concerns (e.g., reducing GHG emissions, ensuring public safety). Through multi-level, executive reviews, Hydro One continuously monitors the alignment of investment drivers with identified customer needs and preferences.

---

[2] Reliability consequences can be classified in terms of unsupplied energy, load impacted and minutes of interruption duration. Environmental consequences can be classified in terms of overall impact to the environment, oil spill severity and greenhouse gas emissions. Safety consequences can be classified in terms of harm to employees or the public.

The improved risk assessment process is conducted in the following six steps.

1. **Understand the primary purpose of the candidate investment:** Identify the primary objective of the investment and the risks addressed (safety, reliability or environmental).
2. **Define worst reasonable direct impact ("WRDI"):** Identify the worst reasonable direct outcome of not making the investment and, if available, the additional costs associated with such an event occurring.
3. **Determine the consequence of the baseline risk:** Establish the consequence of the WRDI in the event the investment is not completed, using the updated risk-based framework.
4. **Determine the probability of the baseline event:** If no investment occurs, evaluate the consequence and probability of the WRDI occurring using the risk-based framework.
5. **Determine the residual consequence and probability:** Determine the consequence and probability of the WRDI occurring even if the investment is made.
6. **Calculate the final mitigated risk score:** Determine the final mitigated risk score based on the difference in baseline and residual risk score for each of the three risk areas (safety, reliability, and environment).

The WRDI is determined by examining what a reasonably undesirable outcome might be as a direct result of not making the investment (e.g., failure event that is the most reasonable, additional cost/risk of repair during emergency compared to regular operation). Determination of a "reasonable" outcome is based on an assessment of expectation based on: (i) historical events, (ii) unique characteristics of the proposed investment, and (iii) confidence in the outcome occurring. Determination of what a "direct" outcome is based on an assessment of whether the event/damage is an immediate result of the failure itself, or it is a secondary/coincidental result.

2.1.4.1 INVESTMENT ASSESSMENT

As described above, Hydro One assesses each proposed investment on the consequence and probability of the safety, reliability and environmental risks that they are designed to mitigate. The three risk taxonomies measure the probability and impact of specific risks and are comparable across investment types and sources of risk. These taxonomies were developed in an iterative and collaborative process based on: (i) historical data from Hydro One and other utilities, (ii) economic impact studies (e.g. insurance tables), (iii) management insights, and (iv) customer feedback (e.g., outage frequency was added to the probability framework to incorporate specific feedback from customers).

Each risk taxonomy has seven consequence levels upon which each investment is assessed. The seven consequence levels are based on the financial impact of the WRDI and are quantified to the same scale for each of the three risk taxonomies. Each risk taxonomy features clear definitions and consistent assessment, which permits a proper comparison between candidate investments. The assessments are calibrated across taxonomies. For example, a score “6” in the reliability consequence taxonomy is comparable to a score “6” in safety and environmental taxonomies. For safety, the impact on both the workforce (employees and contractors) and the public may be considered and the higher assessment is used. For reliability, four metrics are considered (number and significance of customers, load loss, unsupplied energy, and outage duration), which capture the impact to Hydro One’s customers from interruptions. Figures 10 to 12 below illustrate the three risk taxonomies.

Taxonomy to evaluate consequences related to one failure event

Score	Impact on workforce : employee and contractor[1]	OR	Impact on public
7	▪ Multiple fatalities of employees		▪ Multiple public fatalities
6	▪ Fatality to 1 employee		▪ Fatality to a single member of public
5	▪ Permanent health consequence that precludes injured party from regular day-to-day activity (e.g., paralysis)		▪ Permanent health consequence that precludes or hinders injured party from regular day-to-day activity
4	▪ Permanent health consequence that hinders the injured party from regular day-to-day activity / doing their job (e.g., loss of hand)		▪ Permanent health consequence that does not prevent injured party from most regular day to day activity ▪ Injury to member of public requiring extended medical treatment with more than 8 weeks recovery time
3	▪ Permanent health consequence that does not prevent injured party from most regular day to day activity, e.g. doing their job (loss of finger) ▪ Injury requiring medical treatment resulting in 8+ weeks absence or temporary modified work for the employee		▪ Injury or illness to member of public requiring medical treatment with less than 8 weeks recovery time ▪ No permanent health consequences
2	▪ Injury requiring medical treatment resulting in less than 8 week absence and no modified work for the employee ▪ No permanent health consequences		▪ Minor injury to member of public requiring First Aid with quick and complete recovery in less than 1 week; No permanent health consequences
1	▪ Minor injury requiring First Aid resulting in less than a week absence and no modified work for the employee ▪ Quick and complete recovery without permanent health consequences		▪ No impact on public

Figure 10 – Safety Consequence Framework

Taxonomy to evaluate consequences related to one failure event

Score	Impact on customers	OR	Load impacted	OR	Unsupplied energy	OR	Outage Duration
7	Impacts an entire metropolitan area, including multiple customers **and** 2+ priority customers		>500 MW		>1 200 MWh		> 7 days
6	(Impacts on at least 3 customers **and** one priority customer) **or** Impact on 2+ priority customers		200-500 MW		500 -1 200 MWh		1-7 days
5	Impacts on at least 3 customers **or** including multiple critical locations **or** one priority customer		75-200 MW		200 – 500 MWh		10-24 hours
4	Impacts on at least 2 customers **or** including a single critical location		25-75 MW		25 – 200 MWh		1-10 hours
3	Impacts one customer resulting in a small area outage with no disruption of service to critical locations (e.g., water plan)		<25MW		<25 MWh		<1 hour
2	No power interruption		None		None		None
1	No power interruption and no supply through redundancy		None		None		None

Figure 11 – Reliability Consequence Framework

Taxonomy to evaluate consequences related to one failure event

Score	Description[1]	Examples[2]
7	• **Catastrophic / irreversible changes to the environment** such as entire loss of habitat, plant, and/or animal populations/ species at risk in the impacted area; will never completely recover • Chronic threat to human health; National media coverage, viral social media coverage/criminal charges/ major fines/charges	Catastrophic/negligent release of PCB oil to sensitive environmental area requiring significant remediation, engineering, and/or long-term monitoring
6	• **Significant change to the environment** – substantial loss of habit, plant and/or animal populations / species at risk in the impacted area; requires multiple years to recover completely; Chronic risk to human health; • Widespread provincial media coverage; significant fines/charges/order to comply	Very large off-site soil and/or groundwater contamination due to historical practices; significant release of PCB oil to a sensitive environmental area requiring significant remediation, engineering and/or long-term planning; catastrophic SF6 release
5	• **Notable change to environment** – visible loss of habitat, plant and/or animal populations / species at risk in impacted area; requires 1-2 years to recover completely • Definite acute risk to human health • Provincial media coverage; fines/order to comply	Large off-site soil and/or groundwater contamination due historical practices; notable PCB oil to sensitive environmental area requiring significant remediation, engineering and/or long term planning; some SF6 release
4	• **Measurable change to environment** – moderate loss of plant and/or animal populations/species at risk in impacted area; damage to environmentally sensitive sites/special interest sites; requires months/year to recover completely • Potential for acute risk to human health • Widespread local media coverage; limited fines/order to comply	Moderate on/off-site soil and/or groundwater contamination due to historical practices; measurable PCB oil, mineral oil, hydraulic oil or other hazardous liquid spill to an environmentally sensitive area requiring moderate remediation, engineering, and/or long-term planning
3	• **Limited change to environment** – limited loss of habitat, plant and/or animal populations/species at risk; requires weeks/months to completely recover • Potential for limited risk to human health • Local media coverage; inspection/ comment from regulator/order to comply but no charges/fines	PCB regulatory infraction/fine; minor on/off-site contamination from historical practices; large spill/fire of PCB oil, mineral oil, hydraulic oil or other hazardous liquid requiring remediation, engineering, and/or long-term monitoring
2	• **Limited change to environment/ requires day(s) to recover completely** • No plant and/or animal species impacted • No acute risk to human health • No media coverage; minor regulatory fine or order	Large spill/fire of PCB oil or mineral oil requiring cleanup; other large volume liquid spills requiring cleanup (i.e., hydraulic oil, coolant); SAR infraction/fine; invasive species infraction/fine
1	• **Limited change to environment/ recovers immediately after remedial action** • No media coverage; no regulatory fine or order	Typical pole-top/ padmount transformer spill of PCB oil or mineral oil requiring cleanup; other liquid spills requiring clean up (i.e., hydraulic oil, coolant) Minor liquid spills (mineral oil, hydraulc coil, coolant); minor environmental incidents (e.g., wood pole treatment seepage)

Figure 12 – Environmental Consequence Framework

The probability scoring (set out below in Figure 13 below) is an assessment of the likelihood of a failure event happening in a given year or any associated period of time based on the WRDI defined for the associated consequence. This framework has been informed by customer feedback. For example, the 4 or more failures per year under score "7" was incorporated based on customer feedback that frequent outages were highly disruptive to their operations. Hydro One assesses its investments on each framework according to the metric with the maximum score.

Taxonomy to evaluate the probability of a failure event

Score	Frequency	Expected time to event	Prob. of event occurring in the next yr.	Prob. of event occurring in the next 5 yr.	Example phrases you might hear during scoring
7	4+ per year	<3 months	100%	100%	This has happened 10 times every year for the last 5 years
6	1-4 times per year	3-12 months	100%	100%	Based on run time, the equipment life is over for 2 years, it will fail in the next year
5	1 every 1-3 years	1-3 years	33-100%	85-100%	We have to trench every 2 years, disturbing the habitat
4	1 every 3-10 years	3-10 years	10-33%	40-85%	We see this event about once a year on the whole system, which has 8 of these assets
3	1 every 10-25 years	10-25 years	4-10%	20-40%	This event happens on the system sometimes, and it's much more likely to happen here
2	1 every 25-100 years	25-100 years	1-4%	5-20%	This would happen on an APD (abnormal peak day), a 1/90 year event
1	Less than 1 every 100 years	>100 years	0-1%	0-5%	This has never happened, would be unexpected and an outlier

Figure 13 – Probability Framework

The significance and value enhancements made to the risk assessment process emphasize fact-based and quantitative decision-making to the extent possible relying on historical data and experience for the purpose of making and justifying a particular assessment decision.

2.1.4.2 FLAGGING

As part of its improved assessment process, Hydro One has introduced a new "flagging" process to account for special considerations and ensure stakeholder perspectives are consistently included in the evaluation of investments. Investment considerations that cannot be quantified using the risk framework described above are captured by using qualitative flags to allow consideration of potential benefits of an investment beyond risk mitigation. To incorporate key customer and regulatory outcomes into its evaluation of projects, Hydro One's flags enable it to identify investments that address key customer priorities such as improving power quality, and investments that align to strategic priorities and objectives.

Flags are classified as either "mandatory" or "non-mandatory". The flags were developed based on expert knowledge and Hydro One's corporate priorities. They were further customized to align with the RRF outcomes. The flagging process is intended to reduce the number of proposed investments that are considered mandatory and foster a more effective discussion of what should be completed. The net result of this process is more efficient investment prioritization and optimization, which eventually leads to lowered costs for customers.

Flagging is guided by specific and defined categories which are common and consistent across proposed investments. As risk scoring cannot always capture all relevant considerations, flags are applied to investments when such other considerations ought to be material drivers of the funding decision.

The following flags have been established to provide clear guidance and a more rigorous definition of what constitutes a *mandatory* investment:

- **Immediate / Short-term Compliance** – Explicit obligation to a regulatory agency (e.g. OEB requires work to be done *within a year* with *immediate risk* of legal breach, or there is a *two to five-year risk* of regulatory or legal breach);
- **Third party requests** – Explicit connection request by a city, county, agency, or customer, with a *one to five-year risk* of breaking the utility obligation to serve;
- **Contractual –** Signed, fixed-sum contracts with third parties for services such as IT support, facility support, etc.; and
- **In-Flight –** Project already under construction.

The following flags are used for *non-mandatory* investments and represent factors that are important to Hydro One and its customers:

- **Customer Engagement** – Influence of customer engagement/consultation; response to specific customer needs and preferences;
- **Productivity** – Contains committed productivity savings, as tracked by the company, or facilitates future productivity savings;
- **Corrective Maintenance/Demand Replacements** – A risk identified by Hydro One or other utilities that requires near-term action (e.g. break/fix);
- **Preventive Maintenance/System Renewal** – Opportunity to prolong asset life with planned and condition-based maintenance;
- **Strategic** – Codified goal by leadership team or explicit request by senior leadership; and
- **Political Commitments –** Explicit statement by Hydro One officer to non-agency parties such as politicians, media or through official public statement, etc.

2.1.4.3 CALIBRATION

Once candidate investments have been scored and flagged, the scores are reviewed in facilitated discussions among investment owners in calibration sessions. Hydro One has implemented improved enterprise-wide calibration sessions to ensure that scoring is comparable across different types of investments. Facilitated calibration sessions bring scorers and management from across the organization together to compare approaches, assumptions and quality of data used in scoring investments. The sessions ensure that all stakeholders have applied the scoring process consistently. After the session, investment owners have an opportunity to revise their scores consistent with feedback received at the session.

2.1.4.4 RISK SCORES

The results of the risk assessment are translated into risk scores, which are used to generate an initial prioritization and optimization of investments, which provides consistency across the organization. The conversion is completed using a risk matrix, as presented in Figure 14 below, and total risk mitigated is calculated by summing the risk score for each taxonomy (i.e. safety, reliability and environmental). To more effectively differentiate between the risk levels of investments with similar consequence and probability scores, Hydro One uses a logarithmic scale to assign risk scoring points.

Risk score (risk unit)

Consequence								
	7	900	4,200	12,000	36,000	100,000	400,000	1,000,000
	6	430	1,900	5,000	17,000	50,000	200,000	500,000
	5	170	800	2,100	7,000	20,000	80,000	200,000
	4	60	280	800	2,400	7,000	28,000	70,000
	3	20	80	230	700	2,200	8,000	20,000
	2	4	20	50	150	460	1,700	4,200
	1	1	3	10	30	90	350	800
		1	2	3	4	5	6	7
		Probability						

Figure 14: Risk Matrix

Based on the risk scores and cost estimates associated with each investment, candidate investments (broken into mandatory versus discretionary groups) are ranked according to risk mitigation achieved per dollar.

2.1.5 (5.3.1 B) PRIORITIZATION AND OPTIMIZATION

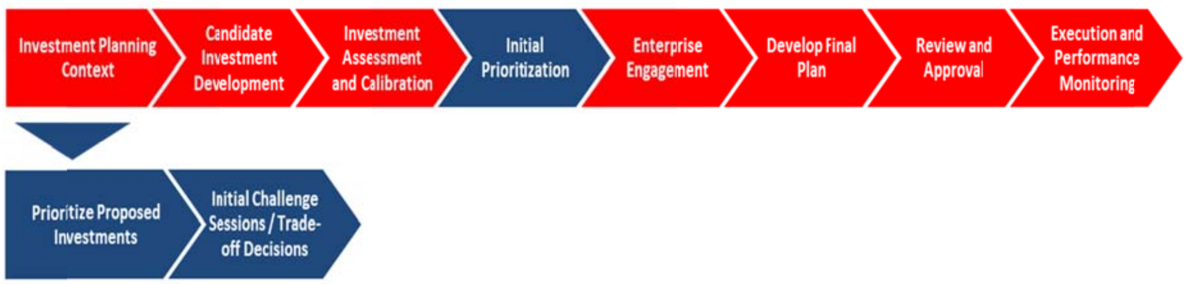

Figure 15 –Prioritization and Optimization

Prioritization and optimization has been enhanced through standardized risk scoring and the introduction of challenge sessions as presented in Figure 15 above.

2.1.5.1 CHALLENGE SESSIONS

Challenge sessions are facilitated discussions among a broad set of stakeholders (investment planning, transmission, regulatory, finance, etc.). Challenge sessions are held to (i) review an integrated portfolio, (ii) evaluate and confirm non-risk parameters (e.g. strategic, productivity investments), (iii) assess and debate investments on the margin of the funding decision, and (iv) make trade-off decisions based on facts.

Challenge sessions are designed to provide a fact-based and structured approach, aimed at defining the funded investments portfolio, with the focus on ensuring that the most valuable work to customers is included in the plan. The discussions allow for the merits of an investment to be considered from both risk and non-risk perspectives. Challenge sessions are attended by various levels and types of stakeholders, which provide for execution feasibility and strategic alignment considerations. Discussions are guided by the draft investment plan, as well as new analytic tools that enable a more holistic view of the plan's effectiveness through different lenses (e.g., comparing risk efficiency and absolute risk).

Initial challenge sessions are held to identify investments that should be funded considering factors related to risk mitigation, productivity and other non-risk parameters (i.e., qualitative flags). The output is a funded investment portfolio, which is subsequently reviewed by portfolio owners and members of the executing lines of business. Additional/final challenge sessions are then held to confirm final trade-offs.

Trade-off Decisions

As part of the challenge sessions, trade-off decisions assess which investments should be promoted or demoted based on the following levers:

- **Risk:** Is Hydro One comfortable with the remaining risk? Are there unfunded investments which mitigate large risks?
- **Flags (non-risk parameters):** Which investments need to be funded for non-risk merits?
- The consideration of both risk efficiency and risk mitigated per dollar supports the making of prudent and data-driven trade-off decisions. The final output from a challenge session typically includes:
    - prioritized plan within investment budget and associated narrative (i.e. overall theme, rationale for changes made and final portfolio); and
    - list of investments discussed during challenge session.

2.1.6 (5.3.1 B) ENTERPRISE ENGAGEMENT

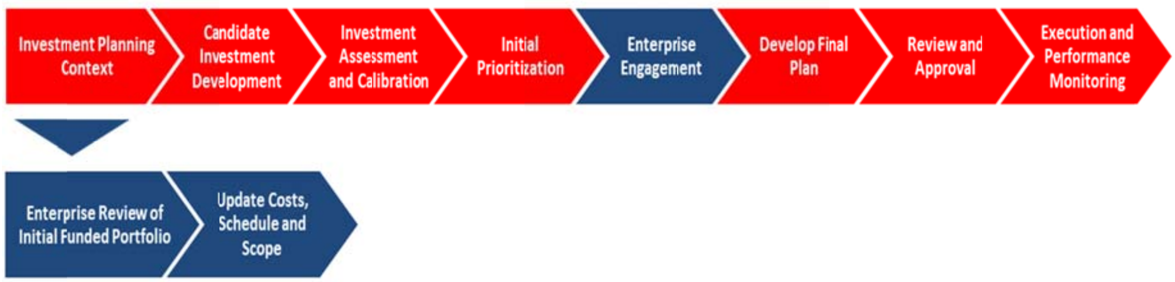

Figure 16 – Enterprise Engagement

Hydro One has improved the enterprise engagement process to ensure that the investment plan is properly reviewed and updated, where needed, by the executing lines of business. The goal is to create a realistic and up-to-date version of the investment plan to be considered at the final challenge session. Figure 16 above demonstrates the enterprise engagement process. This process incorporates operational and execution considerations such as resourcing, material availability and outage feasibility. Candidate investments are updated with the latest cost estimates, schedule, and investment scope. Enterprise review also identifies interim milestones for investment definition stages that will set the organization up for success by providing the ability to monitor the associated milestones and identify potential challenges earlier in the process. Any investments deemed infeasible, and therefore incapable of delivering the risk mitigation or other non-risk value expected, are replaced with the next best alternative. Based on discussions during enterprise engagement sessions, adjustments may be made to reflect emerging execution or asset management risks. The result of the enterprise review is a revised investment plan which is subject to a review at a final challenge session.

2.1.7 (5.3.1 B) DEVELOP FINAL PLAN

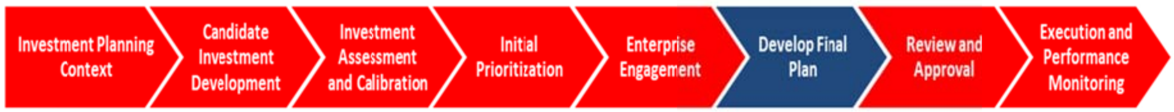

Figure 17 – Develop Final Plan

As presented in Figure 17 above, the investment plan that will ultimately be presented to ELT and the Board of Directors for approval is finalized at this stage through a final challenge session that incorporates the following:

- **Feedback from enterprise engagement review**- reprioritizing proposed investments based on what is feasible from an execution perspective.
- **Updated costs, schedule and scope**- reprioritizing based on finalized costs, permitting completion of more/less proposed investments that are on the margin.

The final challenge session output includes a prioritized investment plan and associated outcomes compared against strategic, customer, and risk considerations.

2.1.8 (5.3.1 B) REVIEW AND APPROVAL

Figure 18 – Review and Approval

Once developed, the investment plan is submitted first to the ELT and then to the Board of Directors for review and comment. The ELT and the Board of Directors review and assess the investment plan to ensure it delivers the best set of outcomes for Hydro One and its customers. In general, feedback from the ELT and Board of Directors is incorporated by returning to the initial prioritization step and repeating relevant steps in the process in consideration of the feedback received. In this Application, Hydro One is putting forward a final, approved Investment Plan, which has been approved by the ELT and Board of Directors and which incorporates their feedback..

2.1.9 (5.3.1 B) EXECUTION AND PERFORMANCE MONITORING

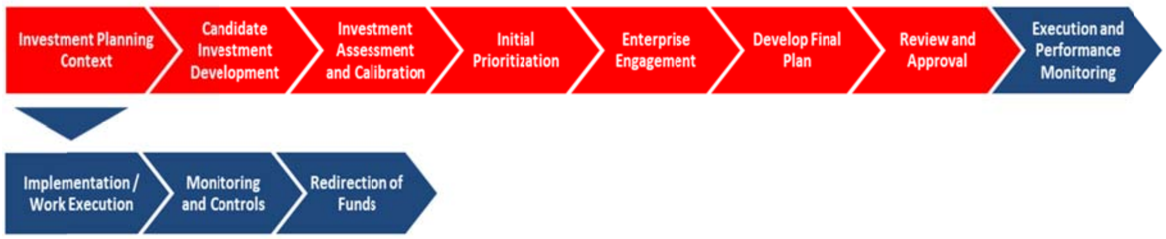

Figure 19 – Execution and Performance Monitoring

Hydro One closely monitors the execution of its investment plan to ensure it is effectively delivered. Once the Board of Directors approves the plan, the execution team takes ownership for delivery as presented in Figure 19 above. The plan is reviewed throughout the execution phase as new information on asset condition and risks become available. If needed, resources can be redeployed through the redirection process.

2.1.9.1 INDIVIDUAL INVESTMENT APPROVAL

Individual investments will be further reviewed and approved through the business case process, consistent with the provisions of the corporate expenditure authority register. Once approval is granted, the individual investments move to the implementation and work execution phase.

2.1.9.2 MONITORING & CONTROL

Hydro One monitors year-to-date expenditures and accomplishments, as well as projected year-end expenditures, on a monthly basis. Variances from the plan are identified and managed through a variance and redirection process. The approval of the variance proposal is in accordance with the limits set out in the expenditure authority register based on the cost and criticality of the investment.

2.1.9.3 REDIRECTION OF FUNDS

As changes to investments or other circumstances occur during the year, Hydro One reprioritizes during execution as new information may change one or more projects' expected value, timing, cost, customer needs, etc. In 2017, Hydro One formalized a Redirection Committee to appropriately redirect funds or authorize additional spending as necessary. Such redirection or allocation allows prudent and timely adjustments to be made to the work originally identified in the investment plan.

Hydro One's Redirection Committee: (i) oversees the redirection process where investment changes are approved, documented, systemized and communicated to the relevant stakeholders; (ii) provides advice and direction on investment adjustments to address emerging business needs or risks; and (iii) ensures an enterprise-wide understanding regarding issues affecting the execution of Hydro One's investment plan.

The Redirection Committee meets once a month. Following the review and recommendation of plan adjustments, investment level decisions are documented and communicated to appropriate stakeholders, including the recommended change and rationale. Updates regarding significant Redirection Committee decisions, as well as recommendations related to reprioritization options that require an approval authority that exceeds that of members of the committee are communicated to the ELT.

2.1.9.4 PERFORMANCE REPORTING

The final stage of the planning process is monitoring performance of the approved Investment Plan by tracking actual outcomes, measuring performance, and benchmarking. Hydro One continuously compares actual investment costs and accomplishments to the proposed investment plan. In this Application, Hydro One is proposing to include a set of key performance measures in its scorecard to track the company's performance. Hydro One also benchmarks its performance against other utilities on the basis of specific accomplishments and costs for each investment as indicators. Details of Hydro One’s benchmarking activities that informed this Application can be found in Section 1.4 of this TSP.

APPENDIX 1

OVERVIEW OF ENHANCEMENTS TO HYDRO ONE'S INVESTMENT PLANNING PROCESS ("IPP")

Table 1. Enhancements to IPP Based on OEB Feedback

	OEB Comments	Actions Taken	TSP Section Reference
1	Incorporate customer feedback into the plan in a meaningful way	• Earlier, more comprehensive customer engagement • New risk and probability frameworks informed by customer engagement feedback	Sections 1.3 and 2.1.4
2	Need a comprehensive asset condition process that informs the prioritization and explains the gap	• Risk scores are tied back to asset risk assessments and available condition assessments • Updated inventory of assets and condition assessment strategy with identified opportunities • Third-party assessments and data initiatives are underway	Section 1.4 and Attachment 13 Section 2.1.2.3 See also Section 3.2.5
3	Appropriate pacing of capital expenditures that achieves a proper balance of need and rate impact	• Enhanced enterprise-level pacing through improved planning and prioritization and optimization • Improved risk prioritization and optimization ensures that investments mitigating most risk per dollar are completed before those with smaller impact	Sections 2.1.4 and 2.1.5

	OEB Comments	Actions Taken	TSP Section Reference
4	More focus required on ability to execute the proposed capital program in a timely fashion	• Extensive review and improvement of the Capital Delivery process over the past 12-18 months to ensure processes reflect best practices and ensure safe and cost effective delivery of the capital work program • Creation of a Redirection Committee to appropriately redirect funds and resources as necessary to allow prudent and timely adjustments to be made to the work program • Enhanced upfront engineering and planning deliverables • Increased governance throughout investment lifecycle, to timely and prudently identify when redirection of funds and resources are required • Improved estimating and scheduling tools and processes	Capital Work Execution Strategy (Exhibit B, Tab 2, Schedule 1) Section 2.1.9
5	There is room for further improvement in optimization and prioritization within the process	• Clear, comparable new frameworks drive investment scoring and prioritization and optimization • Risk scores used to carry out assessment from holistic perspective (i.e. absolute risk vs. risk efficiency) and to maximize risk mitigated per dollar	Sections 2.1.4 and 2.1.5
6	Plan did not change over seven months of review	• Multiple challenge sessions are now held to provide a fact-based and structured approach to define the investment portfolio, with a focus on ensuring that the most valuable work to customers is included in the plan.	Sections 2.1.5 and 2.1.7
7	Previous plan was submitted for rate filing before Hydro One Board of Directors approval	• Sequencing issues addressed for this filing	Section 2.1.9

	OEB Comments	Actions Taken	TSP Section Reference
8	Capital and OM&A programs had not historically been delivered to OEB-approved level	• Enhanced upfront engineering and planning deliverables • Increased governance throughout investment lifecycle • Improved estimating and scheduling tools and processes	Section 2.1.9 Execution and Performance Monitoring Capital Work Execution Strategy (Exhibit B, Tab 2, Schedule 1) OM&A Work Execution Strategy (Exhibit F, Tab 1, Schedule 7)

1

2 **Table 2. Enhancements to IPP Based on Internal Audit Findings**

	Recommendation	Actions Taken/Planned
1	Annually perform a formal risk assessment to ensure that business risks facing the planning organization are identified and mitigating actions are developed and tracked.	Planning has worked with the Corporate Risk Department Group to conduct a risk workshop to identify risks in achieving the planning business objectives. The requirement to conduct risk assessments on the Investment Plan will be added to the overall Investment Planning deliverables each year. Any recommendations/action items resulting from the risk assessment will be tracked to completion.

	Recommendation	**Actions Taken/Planned**
2	Develop, review and approve sufficiently detailed policies, standards, procedures and guidelines to ensure a consistent risk-based approach to planning and decision making. This would require a review of the existing governance documents and ARIS process models for their accuracy and validity. Management has informed us that a Policy Review project is currently underway to consolidate policy and directive documents	Completed review of processes, procedures, standards and guidelines to determine their need, effectiveness, currency and to ensure they are aligned with and support the relevant operational policies. Established a review cycle for these documents; and incorporated into the Operational Policy Program the need of a Communication and Implementation Plan for all new and reviewed policies. Appropriate governance documents (e.g. policy, process, procedure, standard or guideline) will be established taking the existing Investment Planning training material into account.
3	Clarify the timing and level of input to be sought by the planners from the service providers as they develop their plans. Define and communicate the required level of engagement with the service provider when investment plans are being developed to ensure that plans are based on asset needs	It was determined that planners would discuss their investments (e.g. risks, costs) with the relevant service providers early on in the planning process so as to enable the early identification and resolution of issues. Subsequent review sessions between Planning and the service providers are scheduled to be held following the optimization process.
4	Implement a formalized Quality Assurance process and related performance measures to assess the effectiveness of the "end-to-end" planning process.	Quality expectations and associated metrics for the end-to-end process have been established by Planning, together with steps to improve quality assurance for everyday planning activities (e.g. through data validation, site assessment reports and checklists, manager/director review, and improved enterprise engagement), as well as plans to incorporate associated training through the IPP training module. Work is underway to incorporate key performance indicators for the IPP into 2018 scorecards for impacted directors.
5	Formalize and track all process and tool related training being given to planners in their Learning Management System. Establish refresher training requirements whenever there are significant changes in process and tools.	Training for end-to-end investment planning has been developed and rolled out to planners. Attendance is being tracked on a local basis.

	Recommendation	**Actions Taken/Planned**
6	Document and communicate lessons learned after each planning cycle and use them for continuous improvement of the planning process.	Survey results and action plan associated with opportunities for improvement have been completed and shared across the organization.
7	Request an audit of Asset Analytics (“AA”) data sources and algorithms to confirm that quality data and appropriate calculation methods are used for calculating the six Asset Risk Indexes for individual assets as well as asset groups.	Efforts to improve AA algorithm is currently underway, including SAP data audit on asset and maintenance data. Workshops between Planning and the lines of business have been set up to consider existing AA algorithms. A tender has been issued seeking input from potential vendors related to their expertise and high-level estimated cost to improve AA. Plans relating to AA data, including associated milestones and recommendations, will be tracked in the Divisional Scoreboard.
8	Consider expanding the scope of the AA tool to include up-to-date power system historical data such as load flows, connectivity, voltages, statuses, etc.	A tool enhancement roadmap has been prepared and submitted to Management, which will review and determine the necessary enhancements taking into account cost/benefit associated with decisions to keep, defer or discard items.
9	Continue to develop sufficiently detailed Asset Strategy Documents for all asset groups and ensure that all future asset needs are assessed against these documented strategies.	Asset strategy development is a continuous improvement process to address asset needs and respond to emerging issues. Hydro One has reviewed and revised strategy documents for the majority of Transmission Lines, Stations and Protection & Automation assets. These are among the most critical assets in Hydro One’s transmission system. To further strengthen Hydro One’s asset management capabilities, the development of new strategy documents for minor assets is currently underway.
10	Increase the number of investments that are optimizable by requiring more robust definitions of project alternatives.	Through more rigorous documentation and communications around relevant program governance requirements, the proportion of optimizable investments with multiple alternatives has increased from 24% in 2014 to 30% in 2016 and to 67% in 2018. This is inclusive of both Transmission and Distribution investments.

	Recommendation	Actions Taken/Planned
11	Simplify the risk assessment matrix and provide suitable training and guideline to planners to perform an effective risk assessment. Specific focus should be on using quantitative data from AA and other systems to determine/support appropriate probability and consequence on the established risk matrix.	Specific risk training was developed for the 2017-22 planning cycle using the established corporate risk universe matrix. A mapping has been developed to consistently apply AA risk score to the AIP risk matrix.
12	Review and confirm the Unit Price Catalogue ("UPC") with the service providers prior to the start of each planning cycle to ensure that the most current unit prices are being used to determine the funding level for the program work.	The IPP has included a deadline for the service provider to provide a draft UPC and a deadline for the Planners to review and accept the UPC.
13	Make the AIP tool available year around to allow the planners to input and update their plans and risk assessments throughout the year.	Based on consultation with vendor, year round availability was deemed to be too costly and cumbersome to implement (i.e., it is Hydro One's understanding that it is not typical for utilities to adopt this capability). However, more time is made available for planners to input and update their plans throughout the year.
14	Increase the enterprise engagement period to allow a detailed line by line review of unreleased work in the IPP by the project and program managers who will be executing the plan.	The Enterprise Engagement period was extended (from 4 days to 4 weeks) starting with the 2016-2020 IPP cycle. Planning and the execution lines of business were encouraged to discuss preliminary plans, costs and risks associated with investments during the input period.
15	Implement a formal change log to document all recommended changes. This should also include appropriate review, approval and incorporation of changes with appropriate communication back to the requestor of the changes.	Change log was implemented starting with the 2016-2022 IPP cycle.

	Recommendation	**Actions Taken/Planned**
16	Determine and document which types of changes to the individual plans require the IPP to be run through the optimization process again to ensure that the resulting plan remains optimal.	Optimization condition guideline was developed and incorporated into the investment optimization manager procedural document starting with the 2016-2020 IPP cycle. The guidelines document the conditions to be met in order to optimize or re-optimize the investment plan, establishes best practices to handle post-optimization changes, and establishes expectations in terms of documentation.
17	Clarify the approval requirement and progress monitoring for "projam" (i.e. station-centric) investments. Review the project and program approval process with specific focus on shortening the approval timeline.	All projam investments have been converted to projects to follow more robust processes already in place for project initial approvals and variances.

2.2 (5.3.2) ASSET COMPONENT INFORMATION

This section presents the characteristics, condition and outlook for Hydro One's transmission assets which are covered by its asset management process, as well as its common assets such as Fleet, Facilities and Information Technology. The asset lifecycle optimization policies and practices for these assets are found in TSP Section 2.3.

Hydro One uses the Expected Service Life ("ESL") of assets as a general guideline to inform investment decisions. The ESL is defined as the average time duration in years that an asset can be expected to operate under normal system conditions and is determined by considering manufacturer guidelines and Hydro One's historical asset retirement data. Assets operating beyond ESL generally have a higher likelihood of failing or being in poor condition.

The term End of Life ("EOL") is also used and is defined as the likelihood of failure, or loss of an asset's ability to provide the intended functionality, wherein the failure or loss of functionality would cause unacceptable consequences. Therefore, while assets may be operating beyond ESL they may not be at EOL. At the same time, as the primary driver of replacement decisions, asset condition will be verified prior to the work being undertaken.

Figure 1 shows the forecasted cumulative number of assets that will exceed their ESL from 2019 through to 2029 in the absence of any planned or unplanned replacements. There is significant demographic pressure on some asset classes as their ESL will increase by 1.7 to 2.9 times absent replacement. This rapid shift poses inherent operating and resourcing risks that must be planned for and mitigated through proactive and strategically paced investments in order to prevent pressure on OM&A and capital costs and to maintain customers' expected level of service.

	2019	2020	2021	2022	2023	2024	2025	2026	2027	2028	2029
Breakers	604	713	778	915	955	1,088	1,198	1,259	1,439	1,568	1,766
Transformers	192	230	239	251	276	280	288	296	304	315	332
Conductor	1,650	1,683	2,416	2,980	3,115	3,653	3,828	3,914	4,221	4,493	4,516
Protections	3,703	4,036	4,220	4,529	4,795	5,184	5,406	5,814	6,236	6,639	6,952

Figure 1 - Number of Assets beyond ESL per Year Summary

Hydro One tracks asset utilization for certain assets and asset classes. However, utilization is not the ultimate driving factor in asset replacement decisions.[1] Utilization is defined by major asset class using available and applicable asset characteristics. In the case of transformers, utilization is defined by historical loading as a ratio of the nameplate capacity rating. Utilization for breakers is defined as a combination of the total count of operations, breaker nameplate fault rating relative to available system fault

[1] There have been instances where Hydro One replaced assets with higher rated equipment to satisfy system performance standards pursuant to the IESO Market Rules and/or Transmission System Code (Appendix 2). For example, to enable the connection of distribution generation facilities, a number of equipment replacements were made around 2009 so as to increase short circuit capacity and thermal ratings of stations and lines.

current and fault adjusted operations (i.e. cumulative current interrupted). For information regarding utilization and asset replacement decisions, see TSP Section 2.3.

The risk rating of individual assets is based on the probability of failure determined through qualitative and quantitative assessment. Quantitative assessment considers the results of diagnostic testing as well as the corrective history of the asset which may indicate a higher probability of failure. Qualitative assessment is based on engineering analysis and judgment to assign a relative risk level. Examples of qualitative considerations include technical obsolescence (i.e., lack of manufacturer support), potential health and safety concerns, the nature and detail of trouble calls and deficiency reports, visual inspection and maintenance records, and operating conditions or system configurations that may cause undue stress on assets. The risk ratings of major transmission stations and lines assets have been summarized in Table 1 below. Hydro One plans to address assets with a high, or very high, risk condition before they affect reliability and the level of service expected by customers.

Table 1 - Major Asset Condition Summary

Asset Type	Very Low Risk*	Low Risk	Fair Risk	High Risk	Very High Risk*	To be Assessed
Transformers	336	163	95	99	23	-
Circuit Breakers	2035	1475	804	293	167	-
Protection Systems	4,800	3,846	497	2,387	976	-
Conductors (km)	16,050		3,316	3,680		6,061
Wood Poles	-	17,640	0	5,460	-	18,900
Underground Cables (km)	-	179	77	8	-	0

** These categories are not used for all assets.*

To address the reliability of the transmission system, Hydro One considers many asset-related factors including the condition, ESL, utilization and overall performance of the asset. The cumulative contribution of each major asset to delivery point interruptions over the past decade is illustrated in Figure 2 below. Since 2008, lines, protection and control equipment, transformers, and breakers have been the predominant sources of equipment-related delivery point interruptions, highlighting the significant impact they have on system reliability.

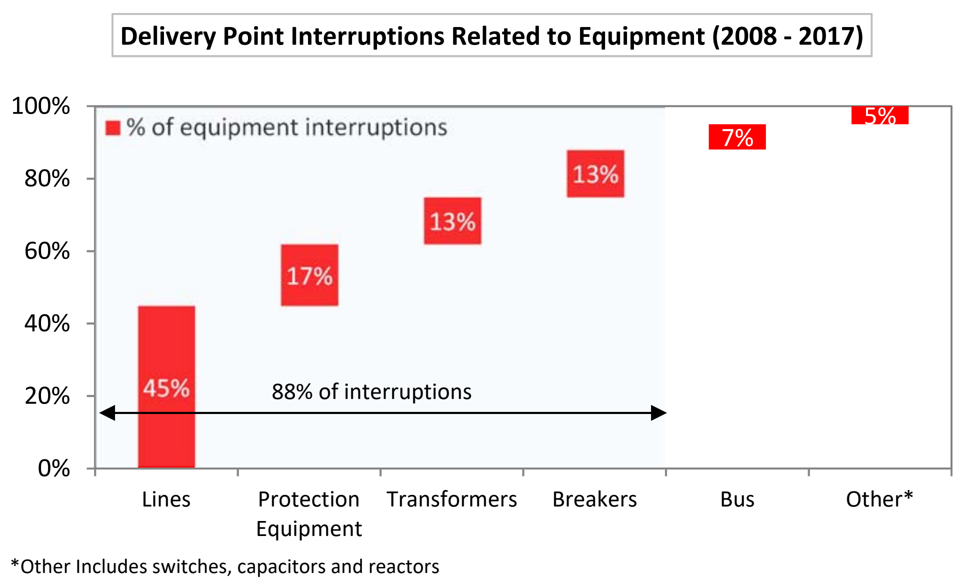

Figure 2 - Delivery Point Interruptions Related to Equipment (2008 through 2017)

Asset component information for stations (including transformers and breakers) and lines is provided below in TSP Sections 2.2.1 and 2.2.2 respectively. TSP Section 2.2.3 discusses general plant assets.

2.2.1 (5.3.2 B, C, D) ASSET COMPONENT INFORMATION – TRANSMISSION STATIONS

This section discusses the main assets that are found in transmission stations, including transformers, breakers, protection schemes, control and monitoring equipment, power system telecom equipment, switches, capacitor banks, instrument transformers, ancillary equipment and civil structures.

2.2.1.1 TRANSFORMERS

Asset Description / Purpose

Transformers are extensively used in electric power systems to convert power from one voltage level to another. Hydro One operates the following types of transmission class power transformers from 115kV to 500kV primary voltages levels, as summarized in Table 2 below:

Table 2 - Transformer Fleet Description

	Transformer Type	Description
	**Step-down**	Step-down transformers convert transmission voltages (50 kV or higher) to distribution voltages (less than 50 kV)
	**Autotransformer**	Autotransformers are a special type of power transformer, used to cost effectively transform voltages and currents between transmission system voltage levels (higher than 100kV)
	**Phase Shifter**	Phase shifting transformers are employed in selected locations to optimize power flows across international tie-lines.
	**Regulator**	Regulator transformers provide voltage regulation through the use of an internal tap changer.
	**Reactor**	Shunt reactors are a single winding device that absorbs reactive power from the system as a way of controlling voltage and increasing the energy efficiency of the system.

Asset Condition / Demographics

Demographics

As of December 2018, Hydro One had 716 transmission class transformers in service, as outlined in Table 3 below. Currently, 24.7% of Hydro One's transformer population is beyond ESL. ESL varies based on transformer type as outlined in Table 3. The average

age of the transformer fleet is 30 years. Assuming no replacement, Hydro One anticipates that 280 units (39% of the transformer population) will exceed their ESL by 2024, and 332 units (46% of the population) will exceed their ESL by 2029.

Table 3 - Summary of Transformer Demographics

Type of Transformer	Voltage	Quantity	Average Age (Years)	ESL (Years)	Currently Beyond ESL	Beyond ESL *2024	Beyond ESL *2029
Step-down	500 kV	1	7	40	0	0	0
	230 kV - 2 winding	172	32.88	50	37	72	87
	230 kV - 3 winding	126	26.04	40	24	38	53
	115 kV - 3 winding	112	31.53	40	53	57	63
	115 kV - 2 winding	161	29.63	60	29	53	58
Auto	500 kV	42	25.46	40	12	14	14
	345 kV	4	41.25	50	0	2	2
	230 kV	89	37.38	50	18	39	50
Phase Shifter	230 kV	4	30.25	40	1	2	2
Regulator	230 kV	2	31.5	40	1	1	1
Reactor	500 kV	3	39.33	40	2	2	2
Total		**716****	**30.8**	**-**	**177**	**280**	**332**

Data current as of 31 December 2018
** As of December 31 of that year assuming no failures or replacements*
***Three Single phase banks in one operating designation only count as one transformer*

<u>Condition</u>

Transformer condition is a leading predictive indicator of equipment reliability. Condition is determined by industry standard diagnostic testing which includes routine transformer oil testing and other maintenance examinations. Transformer insulation generally degrades as a function of time and this degradation is irreversible, ultimately requiring asset replacement. According to Hydro One's assessment of the transformer fleet's condition, 17% of transformers are rated high or very high risk based on oil testing results up to 2018, as illustrated in Figure 3 below.

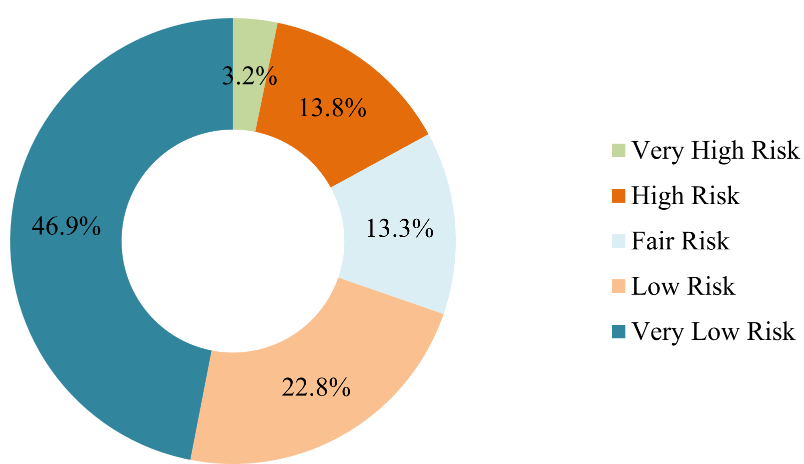

Figure 3 – Transformer Fleet Condition Assessment

Further, 40% of the transformer fleet has been confirmed via visual inspections to have oil leaks, with 10% being classified as major leakers, as illustrated in Figure 4 below. Based on Hydro One's experience, new leaks will appear in approximately 1% of the fleet per year, most commonly as a result of gasket deterioration over time. Transformer leaks not only create environmental concerns, but also lead to reliability issues (e.g. in-service transformers may be forced out due to low oil levels). Active leaks also provide a path of moisture ingress into the transformer's internal winding, which can cause Class 1 transformer failures. Finally, severe oil leaks and frequent oil top ups also compromise the accuracy of condition assessments because these activities dilute the oil and may result in a false improved oil test result.

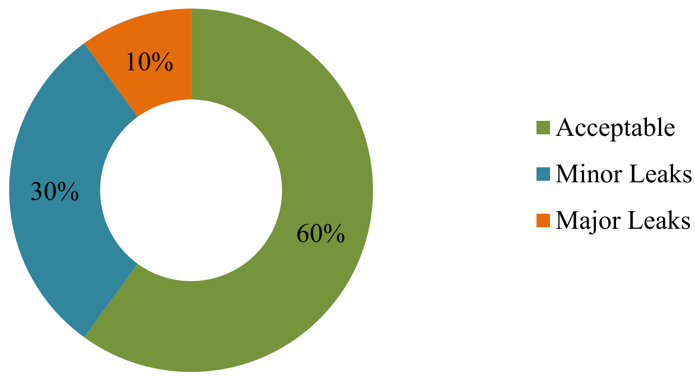

Figure 4 – Transformer Leak Assessment Overview

Federal Polychlorinated biphenyl ("PCB") regulations require all PCB contaminated equipment to be removed from service by 2025. Details regarding applicable PCB requirements are provided as part of the discussion regarding breakers in the Asset Condition / Demographics section below (the same regulatory requirements apply to breakers and transformers). As of December 2018, 43% of Hydro One's transformer oil-filled bushings that are manufactured pre-1985 require work related to PCB testing verification or replacements. Hydro One has an ongoing program to sample equipment with unknown PCB content. By the end of 2018, it is estimated that 6,267 pieces of transmission equipment still require sampling, the majority of which are transformer or breaker bushings.

Performance

Transformer equipment performance is measured by assessing the duration and frequency of forced outages related to the transformer. A "forced outage" is the automatic or forced manual removal of a transformer caused directly by it or its auxiliary equipment.

Transformer forced outages have been a major cause of equipment unavailability over the past 10 years, representing 13% of these equipment-caused events as shown in the Introduction of this section.

As shown in Figure 5 below, the forced outage duration resulting from transformer forced outages in recent years is generally consistent with the average for the past decade. The increase in duration from 2015 to 2017 (compared to 2013 and 2014) is driven by a combination of factors, primarily transformer failures which required replacements. Examples of major contributors in 2015 include failures of Trafalgar TS T15 (500-230kV autotransformer), Bridgman TS T6 (115-13.8kV step-down transformer), and Lorne Park TS T1 (230-28-28kV step-down transformer). The contribution of transformer failures to forced outage durations persisted through 2016, where the failure of the Red-Phase of Essa TS T3 (500-230kV autotransformer) was the major contributor to outage duration. The failure of Campbell TS T2 (230-13.8k-13.8V step-down transformer) in 2017 was one of the contributors to the outage duration in that year.

The effect of fleet-level condition deterioration (as illustrated in Figure 3) contributed to the increase in forced outage duration observed from 2015-2017. The most frequently observed issues were associated with unsatisfactory testing results, tap changer malfunctions and auxiliary equipment failures (where transformer replacement was not required). Lastly, oil leaks, along with instrument transformer defects (e.g., affecting current and voltage transformers)[2] continued to play a significant role as contributors to outage duration.

[2] Failure of instrument transformers can result in the removal of the transformer from service. This is because the OGCC would lose visibility to voltage and current through a transformer due to the loss of a voltage/current reference.

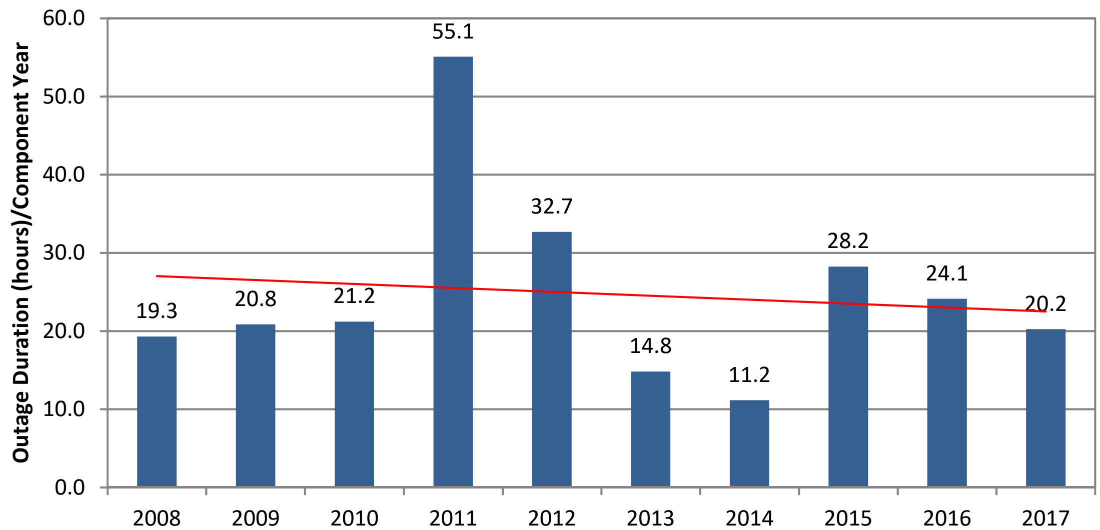

Figure 5 - Forced Outage Duration of Transformers

Overall, the forced outage frequency of transformers has improved over the past 10 years as shown in Figure 6 below. Nevertheless, historical reliability performance is a lagging indicator of transformer condition and is not necessarily predictive of asset need. In fact, as explained above, fleet-level deterioration can be reasonably expected to negatively impact asset performance (and thus contribute to increased equipment outages) over time in the absence of proactive investments to address the issue.

It is important to understand that a forced outage will not always result in an interruption to customers. In other words, forced outage statistics speak to equipment availability, and not necessarily to the actual level of reliability experienced by customers. Therefore, improvements observed in outage frequency statistics do not eliminate the underlying need to address actual asset condition, which is ultimately the underpinning driver for asset replacement decisions. In this regard, every transformer in the replacement plan will be verified to be in such a condition that is no longer suitable to provide long term service reliably.[3]

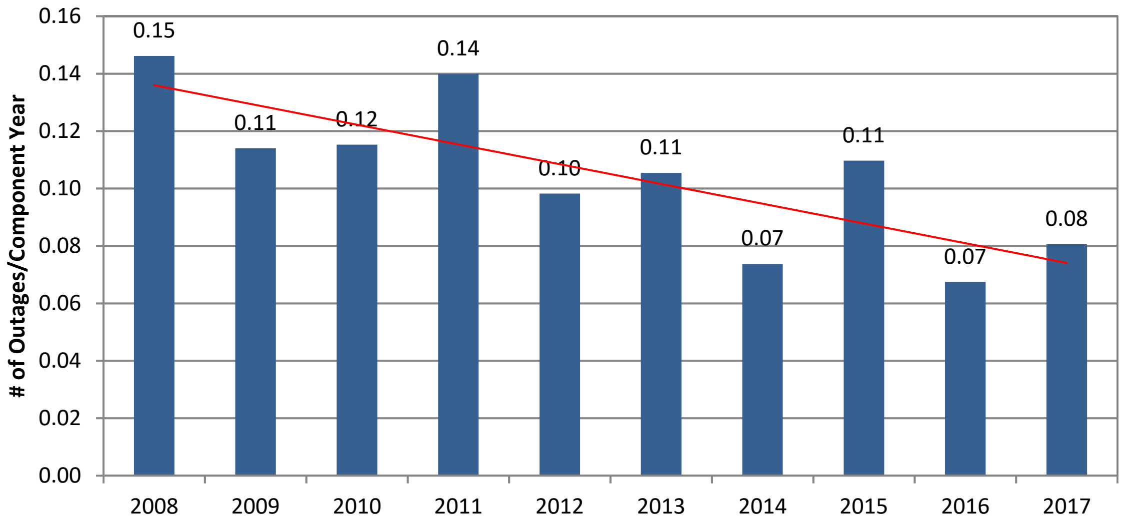

Figure 6 - Forced Outage Frequency of Transformers

Over the last 10 years, Hydro One has experienced an average of four Class 1 transformer failures annually. Class 1 failures are unpredictable and irreparable, and can lead to catastrophic consequences. For example, a major failure of Richview T7 and T8 in 2011 resulted in both transformers being engulfed in fire, producing smoke that severely impaired traffic on Highway 401 during rush hour. Table 4 below summarizes the number of Class 1 failures by voltage class.

When comparing the 2008-2012 period to the 2013-2017 period, the failure rate of 500kV transformers has doubled from 1.41% during 2008 to 2012 to 2.44% during 2013 to 2017. The failure rates of 115kV and 230kV transformers have remained relatively

[3] See discussion in Section 1.4 regarding EPRI's verification of Hydro One's asset condition assessment.

stable over the same 10-year period. More frequent 500kV failures may be attributed to design and manufacturing deficiency, higher operating voltage and loading requirements.

Table 4 - Annual Class 1 Transformer Failure Rates over the Past 10 Years (2008-2017) in Percentage of Transformer Population

Year	115kV	230kV	500kV	5 Year Average Annual Failure Rate, All Voltage classes
2008-2012	0.40%	0.37%	1.41%	0.44%
2013-2017	0.56%	0.41%	2.44%	0.59%
10 Year Average Annual Failure Rate	0.48%	0.39%	1.92%	0.51%

Future Outlook / Need

Hydro One's plan for its transformer fleet over the next five years has been influenced by fleet demographics, observed conditions, anticipated conditions, and performance factors as well as environmental and safety concerns. The plan aims to sustain the transformer fleet via maintenance and replacements. Based on Hydro One's transformer demographic profile described in Section 2.2.1.1, it is anticipated that an increasing number of units will age beyond their ESL within the next five years. Transformer ESL is known to have a direct correlation to anticipated insulation condition.[4] Operating a large percentage of the fleet beyond their ESL increases the risk to system reliability as there is an increased probability of failure as the transformers age. The increasing proportion of transformers in a high and very high-risk condition can be expected to continue if no investments are made to mitigate this risk.

[4] This correlation can be measured via the detection of furan – a by-product of insulation paper degradation – in transformer oil samples as an indicator of insulation strength and condition.

Consequently, Hydro One plans to manage this anticipated risk by replacing approximately 25 transformers annually from 2020 to 2023, which would allow Hydro One to maintain the ratio of transformers that are within, rather than beyond their ESL, with condition being the primary driver for replacement. After 2023 and once the transformer demographic forecast shown in Figure 7 is achieved, the replacement rate is expected to decline. Through the proposed replacement rate, Hydro One would be able to maintain the number of units that are beyond ESL by the end of 2029 to approximately the same level as 2019.

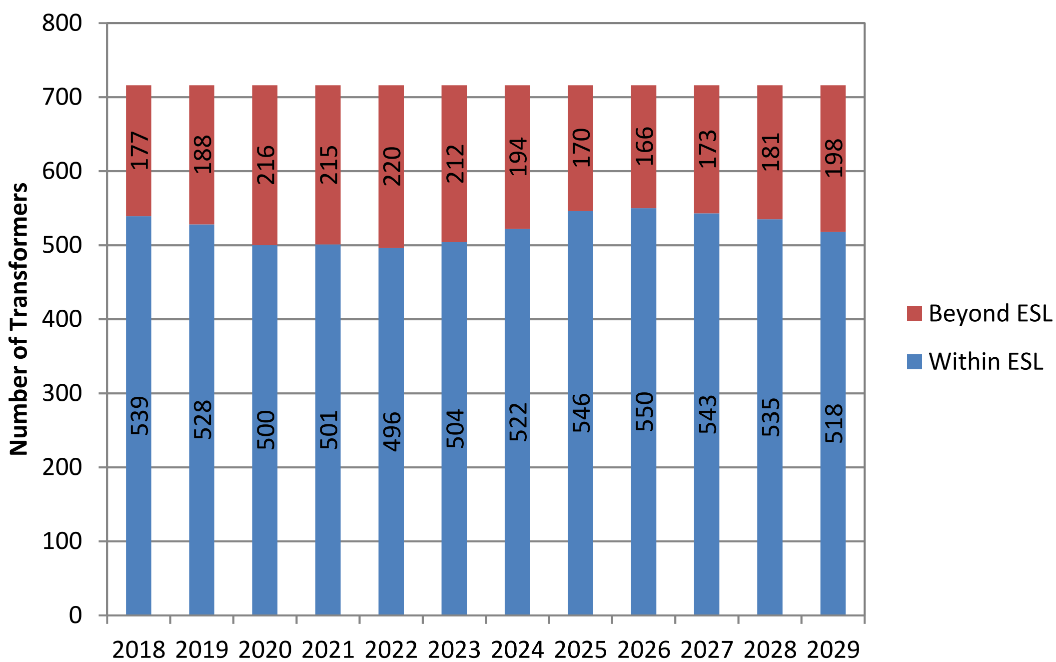

Figure 7 – Transformer Demographic Forecast – With Replacement

Hydro One's 500 kV transformer fleet has recorded a higher failure rate compared to transformers of other system voltages, particularly in the last five years. In the next ten years, approximately twenty 500kV autotransformers are planned for replacement. To support the in service fleet, Hydro One has a sparing strategy is in place to mitigate the impact of unplanned failures across all transformer types. Validation of the Hydro One transformer spare strategy and model is discussed in Section 1.4.

2.2.1.2 CIRCUIT BREAKERS

Asset Description / Purpose

A circuit breaker is a mechanical switching device that is capable of carrying and interrupting electrical current under normal and abnormal conditions. During abnormal conditions, circuit breakers are capable of operating rapidly to interrupt high current thereby minimizing its effect on the rest of the power system.

Circuit breakers use a variety of interrupting mediums that have evolved over time. Hydro One's circuit breaker fleet has been summarized in Table 5 below according to the interrupting medium used, along with the production and environmental status.

Table 5 – Breaker Fleet Description

	Breaker Type	Interrupting Medium	Production Status	Safety and Environmental Concerns
	Oil Circuit Breakers ("OCB")	Oil	Legacy, Out of Production	Oil spill, PCB* content
	Air Blast Circuit Breaker ("ABCB")	Air	Legacy, Out of Production	Noise
	Sulfur Hexafluoride ("SF6") Breaker	SF6	Commercially available	SF6 is a greenhouse gas

	Gas Insulated Switchgear (“GIS”)	SF6, Vacuum**	Commercially available	SF6 is a greenhouse gas
	Metalclad Switchgear	SF6, Vacuum, Air, Air Magnetic	Commercially available	Arc flash hazard
	Vacuum Breaker	Vacuum	Commercially available	None

** Polychlorinated Biphenyls (“PCB”)*
*** MVGIS uses vacuum interrupters as interrupting medium and SF6 acts as insulating medium*

Asset Condition / Demographics

Demographics

Hydro One has 4,774 High Voltage (“HV”) and Medium Voltage (“MV”) breakers. The breaker fleet includes 549 breakers that are currently beyond their ESL. Projections for 2024 and 2029 (assuming no replacements or failures) are summarized in Table 6 below. A large number of oil, air blast and metalclad breakers have reached their ESL with an increasing number of breakers forecasted to reach ESL within the next decade. As breakers approach their ESL, vendors typically communicate their transition to limited support or complete obsolescence of aged product lines. It is important to proactively manage and mitigate this impending wave of assets approaching ESL in order to avoid difficulties in obtaining spare parts to sustain breakers that vendors no longer support.

Table 6 - Summary of the ESL of Hydro One's Breakers*

Type of Breaker	HV 115-500kV	MV 44-12.5kV	Total	Avg. Age	ESL (Years)	Currently Beyond ESL	Beyond ESL **2024	Beyond ESL **2029	% of Fleet Currently Beyond ESL (2018)
Oil Breaker	377	1,242	1,600	42.2	55	151	499	773	9.40%
Air Blast Breakers	133	24	157	46.5	40	129	157	157	82.20%
SF6 Breakers	783	1,074	1,857	14.2	40	10	17	142	0.50%
GIS Breakers	276	88	364	23.9	40	108	147	161	29.70%
Metalclad Breakers	0	767	767	27.8	40	151	268	341	20%
Vacuum Breakers	0	29	29	15.4	40	-	-	3	0.00%
Total	**1,569**	**3,224**	**4,774**	**27.6**		**549**	**1088**	**1766**	**11.50%**

* data current as of Dec 30, 2018
** as of December 31 of that year assuming no failures or replacements

Condition

Breaker condition is monitored through information gathered during preventive inspection and maintenance activities. Breaker failures can severely impact system stability, other connected equipment and employee and public safety. Consequently, it is important to ensure that the current carrying components are in good shape, the mechanical and control systems are operating within specification and that the insulating medium has not been compromised.

As breakers age their O-rings and gaskets slowly degrade, thereby causing leaks, which will result in a lower pressure and a path for moisture ingress. Over time, this condition can result in lower dielectric strength in the breaker and potential for internal flashover, which could lead to an explosive failure of the breaker. Where feasible based on parts availability, cost and projected future reliability, breakers with leaks are repaired as part of ongoing maintenance activities.

As of December 2018, the breaker fleet's condition shows that 9% are rated at a high or very high risk, as illustrated in Figure 8 below.

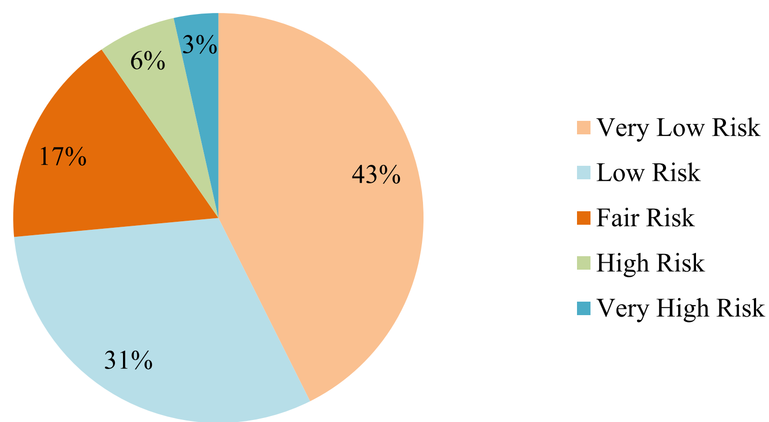

Figure 8 - Overall Breaker Fleet Condition

Performance

Circuit breaker performance is measured by assessing the number of forced outages. A "forced outage" is the automatic or forced manual removal of high voltage breakers caused directly by the breaker itself or terminal equipment directly adjacent to the breaker. Typical breaker failure modes have included control component issues, air leaks, gas leaks, operating mechanism issues, moisture content problems and auxiliary equipment malfunctions.

The number and duration of forced outages due to circuit breakers have increased over the past decade with a flattening trend in the last five years, as illustrated in Figure 9 and Figure 10 below. This overall increase is primarily attributed to the number of ABCB-related forced outages.

The significant increase in the 2013 forced outage frequency was predominantly due to the increase in ABCB air system control component failures. The CGE AT breaker population experienced the greatest number of air system component failures. In some cases, such failures led to breaker fail protection operations that forced the tripping/opening of adjacent breakers. This can cause interruptions to circuits and busses, which could give rise to customer outages. These performance issues have also resulted in multiple instances where generators were forced offline.

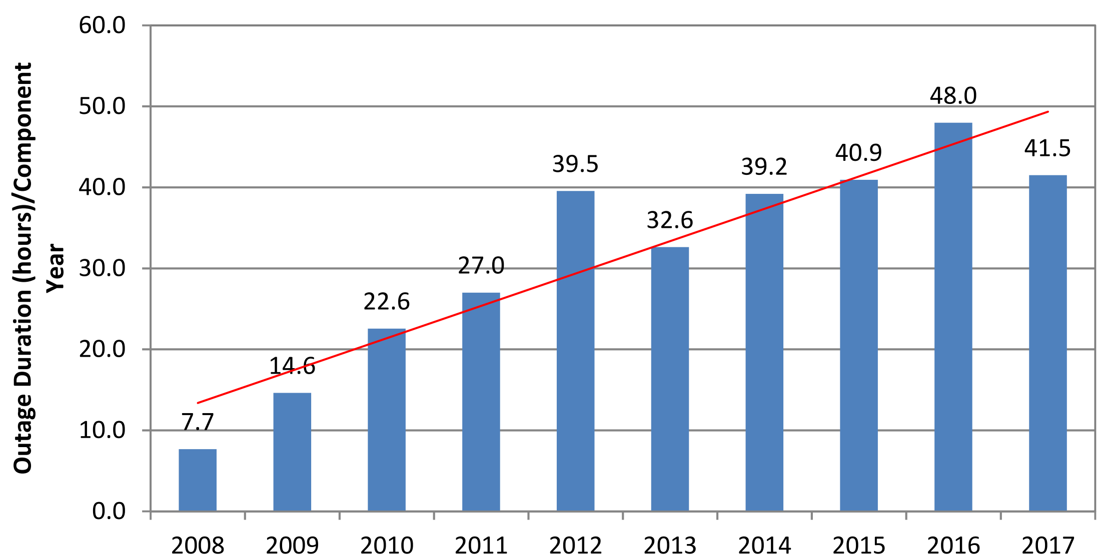

Figure 9 - Circuit Breaker Forced Outage Duration

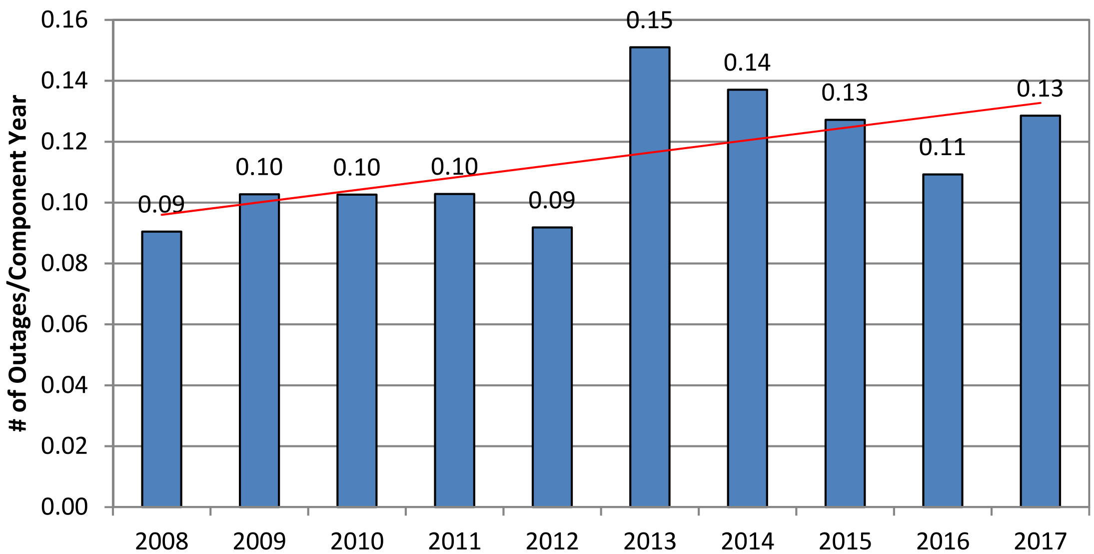

Figure 10 - Circuit Breaker Forced Outage Frequency

Forced outage frequency by breaker type in Figure 11 below illustrates the doubling of ABCB related outages over the last 10 years. This increasing trend is due to known air system issues caused by deteriorated O-rings, valves and problems with control components.

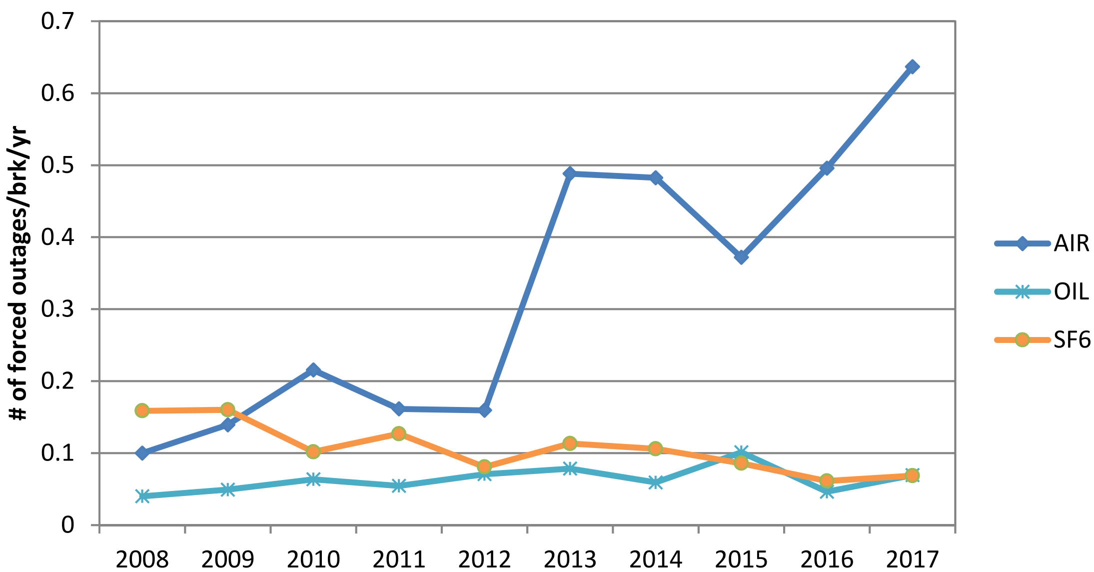

Figure 11 - Summary of Forced Outages by Breaker Type

Vendor Support

Some of the Hydro One fleet of breakers (approximately 2% of the overall fleet) are no longer supported by vendors and aftermarket parts are no longer available or are costly to acquire or fabricate. This is a significant risk factor to the ABCB fleet, some first generation SF6/GIS circuit breakers and certain types of oil circuit breakers. Where parts are difficult to procure, specific units are replaced so the decommissioned devices can serve as strategic spares for the remaining in-service fleet.

Air Leaks

Severe air leaks are a significant concern for the ABCB fleet as large groupings of breakers are supplied by a common airline. In the winter months issues arise with air pressure and safety valves as they freeze in the open position. This leads to the loss of air and subsequently, the loss of breaker control. This can result in the removal or isolation of multiple adjacent breakers and high voltage circuits, thereby causing large load interruptions and generation bottling.

Polychlorinated Biphenyls (“PCB”)

Hydro One plans to sample all oil filled equipment in its Transmission Stations (“TS”) manufactured prior to 1985 by the end of 2020 and remove or retro-fill the PCB oil filled equipment to less than 45 parts per million (“ppm”) by year end 2024. This timeline allows for a one year buffer for any outstanding issues to be identified and addressed in order to meet the federally mandated completion deadline of year end 2025.[5]

Based on a review of the error margin associated with the applicable analytical methods, Hydro One established a limit of 45 ppm, which provides 95% confidence that the

[5] As per Canadian Environmental Protection Act, 1999 – PCB Regulations SOR/2008-273.

federally mandated limit of 50 ppm will be met upon regulatory verification. These requirements impact breaker oil filled bushings and the oil in the main breaker tank. It is estimated that approximately 528 breakers require PCB mitigation, which entails replacing or retro-filling the bushing (i.e., putting in new PCB free oil to bring the PCB ppm value lower). To date, Hydro One has sampled 779 breakers, with another 168 breakers projected to contain high PCB content once sampled. This projection is based on the rate at which Hydro One has been finding high PCB concentrations in the equipment sampled to date.

SF6 – Greenhouse Gas

Sulfur Hexafluoride ("SF6") is a common and effective dielectric medium used in a large portion of the breaker fleet. Hydro One continues to monitor and track its SF6 emissions. Hydro One primarily has issues with leaks on its SP model type population of breakers (211 in total). There is a known leak point on the bushing flange for which there is a repair procedure, but there is a subset of the population (about 5% identified so far) for which these repairs do not prove to be effective, thereby requiring replacement.

Future Outlook / Need

Hydro One's plan for the breaker fleet over the next five years has been influenced by the demographic, condition, performance, vendor support, air leak, PCB factors described above and health and safety concerns. The plan aims to employ maintenance and replacements in order to maintain fleet performance.

In order to limit the number of breakers beyond ESL, Hydro One plans to replace on average 128 breakers annually from 2020 to 2024. The approach is to target specific breaker populations to deal with system risks, and steadily pace investments driven by obsolescence caused by reduced vendor support for aged product lines. Early vintage GIS has begun to approach the point where vendors are declaring obsolescence, but maintenance is still a viable option in the short term to deal with reliability and SF6 issues. Integrated GIS replacements are expected to commence outside of the current five year planning period. Replacement of breakers is prioritized and paced through the ARA and investment planning process which places an emphasis on executing projects that will mitigate the most risk. A summary of the replacements have been described below:

Table 7 - Summary of Breaker Replacements

Type of Breaker	# for Annual Replacement*	Reason for Replacement
Oil Breaker	49	• obsolescence, no vendor support • non-compliance with current system operating ratings • PCB regulatory compliance
Air Blast Breakers	21	• significant negative impact on outage frequency • deteriorating condition and performance • obsolescence, reduced or no vendor support • elimination of high maintenance costs
SF6 Breakers	12	• no vendor support • SF6 emissions
GIS Breakers	1	• reliability concerns • obsolescence • SF6 emissions
Metalclad	41	• arc flash hazards • obsolescence, reduced or no vendor support
Vacuum	2	• obsolescence, reduced or no vendor support
Total	**128**	

**Annual average replacement planned for the next five years*

2.2.1.3 PROTECTION SCHEMES

Asset Description / Purpose

Hydro One's protection systems are comprised of instrument transformers, relays, sensors and communication devices. The protection system is a critical element of the transmission system that detects abnormal system conditions. Upon detecting an abnormal condition, the protection systems immediately cause the necessary station equipment to operate to isolate faulted components. If not isolated in time, a faulted element could cause a cascading effect resulting in a major system disruption involving service interruptions, equipment damage and employee and public safety issues.

Protection system components also capture detailed records for post event analysis. This information assists in determining the root cause of power system events and facilitates the mitigation or elimination of the issue. The three vintages of protection systems found at Hydro One are summarized in Table 8 below.

Table 8 - Protection Fleet Description

	Protection Type	Description
	Electromechanical Systems	Electromechanical systems utilize the principles of electromagnetic induction to convert electrical energy to mechanical movement in order to detect faults.
	Solid State Systems	Solid State systems rely on integrated circuit technology to detect fault conditions.
	Microprocessor Systems	Microprocessor based protection systems, also known as Intelligent Electronic Devices ("IED") are the newest technology. These relays utilize microprocessors to offer multiple protection functions and additional features. These features enable post-fault technical analyses not available in legacy technologies.

Asset Conditions / Demographics

Hydro One currently has 12,506 protection systems in-service. Approximately 27% of the protection system population is operating beyond its ESL. Furthermore, over 90% of the solid-state fleet is already operating beyond ESL, as outlined in Table 9 below. Such devices are subject to an elevated risk of failure, while also having very limited or no support from vendors in terms of replacement units, spare parts, and engineering and firmware support. As such, reactive repairs may involve extended durations as re-engineering and construction work will be required to install new devices based on different technology. These risks could lead to protracted outages for customers.

Table 9 – Summary of the ESL of Hydro One's Protection Systems by Technology*

Protection Type	Quantity	Avg Age (Years)	ESL (Years)	% Beyond ESL (if no protections are replaced) **					
				2018		2024		2029	
				Qty.	% of Type	Qty.	% of Type	Qty.	% of Type
Solid State	2,026	35.3	25	1,835	91%	1906	94%	1941	96%
Electro-mechanical	3611	38.8	45	1,322	37%	2,038	56%	2,279	63%
Microprocessor	6,869	8.7	20	206	3%	1,240	18%	2,732	40%
TOTAL	**12,506**	**27.6**		**3,363**	**27%**	**5,184**	**41%**	**6952**	**56%**

* data current as of Dec 31, 2018
** as of December 31 of that year assuming no failures or replacements

Hydro One is currently analyzing the ESL for microprocessor relays as internal and industry experience suggests that the 20-year figure may not apply to many vintages and models in this category. The historic ESL for these types of relays was based mainly on original manufacturers' statements of product support, ESL of device components and the average lifespans for similar devices adopted by peer utilities.

Witness: Donna Jablonsky, Lincoln Frost-Hunt, Rob Berardi

Hydro One uses the ESL of relays as a trigger to further investigate the health or condition of a relay and the risk of its potential failure with respect to reliability and safety. Kinectrics performed an assessment on behalf of Hydro One regarding the ESL of specific relays, including solid-state and microprocessor relays and found the ESL was in-line with utility practice but could be increased for the two assessed model types. Refer to TSP Section 1.4 for further information.

Condition

Programmable Auxiliary Logic Controller ("PALC") relays are a type of solid state protection system. They have shown an increase in recorded defects and trouble calls over the years due to deteriorating components within the relay. As a result, and due to the inability to obtain replacement units, PALC relays are considered high risk assets. Hydro One has been actively replacing PALC relays since 2014 and to date, approximately 250 PALC relays have been replaced. This has driven down the number of annual defects as shown in Figure 12 below. Hydro One still has approximately 300 PALC relays in operation and plans to replace them over the following five years.

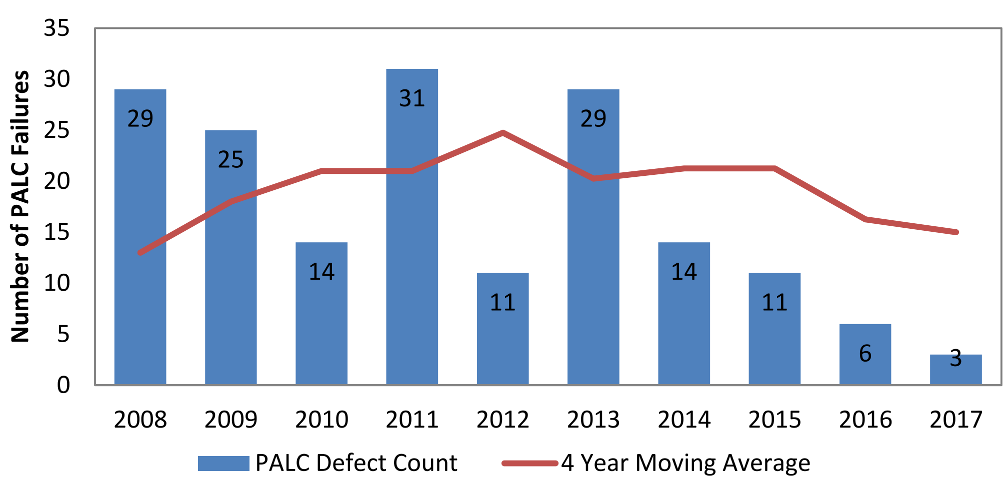

Figure 12 - Number of PALC Relay Defects

Performance

Protection system misoperations are the single most important indicator of the protection system's overall performance. Hydro One tracks the performance of the protection system by analyzing every protection system operation to determine if it operated as expected. A subset of this data that relates to devices that form part of Hydro One's Bulk Electric System ("BES") (approximately 40% of all Hydro One assets) is reported to the North American Electric Reliability Corporation ("NERC") and Northeast Power Coordinating Council ("NPCC") as part of the company's compliance obligations. Based on NERC data, Hydro One is able to track its protection system performance compared to other utilities in North America. As shown in Figure 13, Hydro One's BES protection system misoperation rate is generally at or below the level experienced by other utilities in North America.

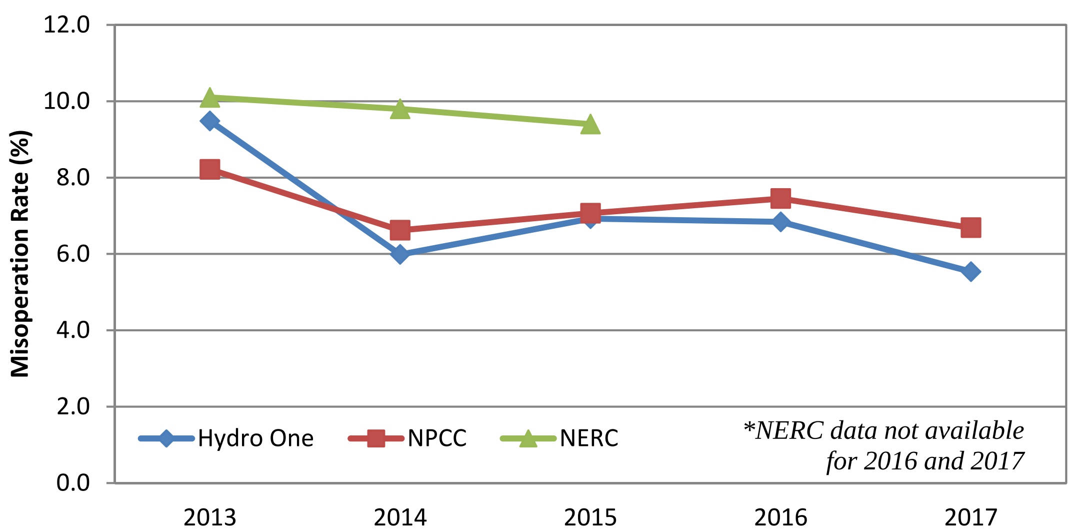

Figure 13 – Misoperation Rate (%)[6,7]

---

[6] http://www.nerc.com/pa/RAPA/ri/Pages/ProtectionSystemMisoperations.aspx

Misoperations can be categorized into two types: hardware failure and incorrect settings. Between 2008 and 2017, on average, 6.6% of station protection misoperations and 11.1% of line protection misoperations were caused by human error (incorrect settings) while the rest can be attributed to hardware failures.

Future Outlook / Need

Hydro One's replacement strategy for protection systems is focused on replacing systems that have a high likelihood of causing delivery point interruption and impacting the reliability of BES.

Because it is not easy to monitor the condition of all protection systems, ESL and other factors are used as a trigger to identify high risk assets which undergo further condition assessment to identify replacement candidates. Other factors driving protection system replacements are summarized below:

- Safety – Protection system failure to operate can potentially expose workers and the public to the risk of electrocution, which can result in significant injuries or fatalities. Proactive replacements are required to mitigate this risk.
- Regulatory Compliance – Hydro One's protection system must comply with all applicable NERC and NPCC standards. Protection system upgrades are often needed in order to comply with new or updated standard requirements.
- Historical Performance – An increase in the rate of failures over the historical period can indicate fleet deterioration.
- System Reliability Risk – The impact of protection on power system reliability depends on its location in the power system, the criticality of the protected element, protective function and redundancy. Power system reliability risk due to

[7] NPCC figures include misoperation data from ON, QC as well as US states of Maine, New England etc. NERC data combines data from all of North America

potential protection failure or misoperation is being factored in the replacement decision process.

- Functional Requirements – The requirements for protection system functionality may change due to power system changes (e.g., system stability requirements) or changes to other components of the integrated protection and automation system, which may lead to incompatibility of the existing protection hardware with the associated devices.
- Technology Obsolescence – Many protection system components are no longer available, limiting the availability of spare parts and support; which can adversely impact outage planning and overall system reliability. This is a significant factor for electromechanical and solid state systems as they are no longer supported by relay vendors which are focusing their efforts on microprocessor based relays.
- Innovation – New microprocessor based protection systems have advanced monitoring and diagnostic capabilities which can provide insight into station equipment performance and early detection of problems, potentially avoiding equipment damage.

2.2.1.4 AUTOMATION

Asset Description / Purpose

Automation assets are complex electronic systems that enable the monitoring and control of power system assets and facilities at all times to achieve the safe, reliable and efficient operation of the Ontario transmission grid. They also enable timely responses to emerging problems, real-time condition assessments, restoration activities, and work planning.

Automation systems provide several critical capabilities such as:

- Local and remote real-time monitoring, control and troubleshooting facilities for Hydro One field staff, control center staff and the IESO in accordance with Market Rules;
- Critical transmission station automation and integration functions to support the operations of all power system equipment;
- Collection, processing, and archival of non-operational data for post-event analysis and to support the asset management decision-making processes;
- Enabling cyber security functionalities such as system event monitoring, authentication, authorization, logging and accounting;
- Supporting the fulfillment of regulatory obligations; and,
- Interfaces with external utilities, generation, and customers.

Hydro One's automation assets consist of legacy and modern technological vintages, as described below.

Legacy Automation Equipment

Legacy automation components primarily consist of Remote Terminal Units ("RTU"). This equipment is based on the concept of physical wiring and the digital conversion of electrical signals delivered by wires, generally for a single function/application. These systems utilize slow communication connections and employ a variety of protocols.

Modern Automation Equipment

Modern automation equipment is network enabled to utilize high-speed communications and has a smaller physical form-factor, exponentially increased computational capabilities, and greater ability for integration with the Network Management System ("NMS") as compared to its legacy counterparts. Information is conveyed through standard protocols which shift previous manual labour work related to hard wiring, towards skilled programming capability.

Asset Conditions / Demographics

There are over 18,000 components and devices in service to support automation functionalities of Hydro One's Power System Monitoring & Control ("PSMC"). Forty six percent (46%) of the automation system population is of the modern vintage type, while 54% is of the legacy vintage type. The ESL for automation systems, outlined in Table 10 below, is classified according to their vintage and is based on generally accepted industry practices and Hydro One's experience.

Table 10 - Automation System Expected Service Life

Automation Vintage	***Expected Service Life***
Legacy (copper-based)	20 years
Modern (IP-based)	15 years

Condition

Automation system condition is an important indicator of equipment reliability. Internal components degrade as a function of time, which can alter the performance of the automation equipment.

Hydro One has been tracking the reliability of automation equipment (i.e., on the basis of relevant defect reports, trouble calls, and potential need identifications) with the objective of determining future work programs. Based on those statistics, presented in Table 11 below, legacy systems have experienced defects four times more often than modern control systems within the past decade. Moreover, 54% of automation equipment is of the legacy vintage, and makes up 79% of the total defect occurrences. This is expected to trend upward as the fleet continues to age.

Table 11 - Summary of Defect Reports (2008-2018)

Year	LEGACY			MODERN			
	RTU	**PSR**	**Transducer**	**LMC/LCC**	**Gateway**	**Router**	**Switches**
2008	325	23	19	11	18	4	2
2009	550	68	21	27	25	5	0
2010	635	42	36	19	18	10	1
2011	674	69	29	52	12	4	2
2012	555	39	20	43	34	20	9
2013	577	48	14	71	30	17	10
2014	431	39	29	67	38	19	19
2015	384	39	31	78	56	16	18
2016	478	44	16	195	63	24	20
2017	912	8	3	208	63	31	43
2018	465	14	6	136	98	21	82
Total	**5986**	**433**	**224**	**907**	**455**	**171**	**206**

Future Outlook / Need

Hydro One's plan for its automation assets is focused on the following key objectives:

1. Evaluation of modern industry offerings and migration towards cost-effective alternatives. The legacy technology and design has been in service for over thirty years. Risks and costs are mounting as more of these systems reach or exceed their ESL. As Hydro One modernizes its automation fleet though the deployment of station Local Area Networks ("LAN"), there is no longer a need for expensive legacy RTU installations. Modern solutions have a small form factor, are a fraction of the cost, and are IP-based with flexible scalability to match the company's needs.
2. Optimization of existing designs to reduce capital and OM&A expenditures. Hydro One will be evaluating changes in controls design architecture to maximize device functionalities. Many existing deployments were designed with legacy technologies that provided certain capacities or redundancies to meet reliability requirements. As some legacy technologies are discontinued and replaced with modern industry offerings, reliability targets and mandated requirements will be met with reduced or no redundancy required.

In comparison to protection, the automation world has seen significant advancements over the past decade. Hydro One is undertaking these opportunities to further modernize and bring improvements to operational efficiency, reduce operational risks, and cost containment. Examples of such initiatives include: (i) removal of EOL Local Controller Computers and implementation of the same functionality into Station Gateways; (ii) deployment of direct Supervisory Control and Data Acquisition ("SCADA") to allow stations to communicate directly with the Ontario Grid Control Centre ("OGCC") so as to phase out hub sites; and (iii) substitution of multiple Local Maintenance Computers at a station with a single transient cyber asset which complies with the NERC Critical Infrastructure Protection ("CIP") standards.

2.2.1.5 POWER SYSTEM TELECOM

Asset Description / Purpose

Power System Telecom includes communication systems, infrastructure, and leased facilities that enable essential protection, control, monitoring and operation of the transmission system in Ontario.

Power system telecom services ("PSTS") are used for the following applications:

- Station-to-station telecommunications used by protection systems;
- Telecommunications between the control center, hub site and transmission stations for remote monitoring and control of equipment; and
- Communications with customer owned protection and control equipment.

Power System Telecom assets are categorized as part of the following systems or asset types:

- Synchronous Optical NETworking ("SONET") transport network;
- Fibre optic cable infrastructure;

- Power Line Carrier ("PLC") systems;
- Teleprotection terminal devices;
- High Voltage Protection ("HVP") systems;
- Microwave radio systems; and
- Provincial Mobile Radio System ("PMRS").

In addition to the above telecom assets, Hydro One also:

- Utilizes carrier-based leased services to provide PSTS. These include communication channels over copper pairs as well as Virtual Private Networking ("VPN") services from telecommunication providers;
- Engages Hydro One Telecom, an affiliate of Hydro One, for operational services for the communication network that include coordinated network management, vendor management, alarm based monitoring and system analysis services;
- Leases approximately 1,700 km of fibre acquired under Indefeasible Right of Use ("IRU"); and,
- Leases sites and/or space from third parties for the provincial mobile radio system.

SONET Transport Network

Hydro One's communication network is based on SONET technology and is primarily utilized by protection systems and SCADA systems. Additionally, it is used for communicating non-operational data, business data, voice and security information, and is used as backhaul for the provincial mobile radio system. The network topology is such that stations are connected in the form of a ring to provide redundant communication links that can stretch up to hundreds of kilometres long across the province.

The SONET network utilizes multiplexer equipment composed of two vintages; the first generation initially deployed between 1998 and 2007 and the second generation from

2004 onwards. In addition to the multiplexer equipment, the SONET network includes microwave links, optical amplifiers and 48Vdc power supplies. There are certain segments of the network that are made up of microwave links as opposed to fibre connected paths. These obsolete microwave links have created a capacity/bandwidth limitation on a typical ring topology.

Fibre Optic Cable Infrastructure

Hydro One utilizes fibre optic cable infrastructure including Hydro One owned/operated aerial fibre optic cables and fibre strands acquired through IRU. Aerial fibre optic cable is primarily comprised of (i) Optical Ground Wire ("OPGW") technology with strands of fibre embedded inside the shieldwire mounted on top of high-voltage transmission structures and (ii) All-Dielectric Self-Supporting ("ADSS") fibre cable that is attached to towers or poles typically below the phase conductors.

Power Line Carrier Systems

Power Line Carrier ("PLC") systems are used by Hydro One to provide an alternative means of dependable communications between stations. These systems use high-voltage power lines as the communication medium. The primary components include radios, line traps, matching units and coupling capacitors.

Teleprotection Terminal Devices

As part of the standalone or integrated teleprotection systems, teleprotection terminal devices provide an interface between the protective relay and the communication network, SONET or carrier-based leased services. Based on the communication medium used, these devices are classified as:

- T1 access multiplexers that provide digital teleprotection over the SONET network; and,

- Tone devices that cater to teleprotection applications over leased facilities.

High Voltage Protection ("HVP") Systems

Hydro One leases telephone communication circuits from third party telecommunication service providers which may be subjected to a very high voltage rise when a fault occurs on the power system, thus potentially exposing personnel and equipment to hazardous high voltages. For this reason, special HVP is required for all of Hydro One's leased telecom.

The primary component of the HVP system is the High-Voltage Interface ("HVI") equipment that provides the required electrical isolation and safe limits of any difference in potential. Hydro One's inventory of HVI equipment includes neutralizing transformers, isolating transformers and optical isolators.

Microwave Radio Systems

Hydro One's licensed microwave radio systems support the SONET network and last mile point-to-point telecom applications. The microwave radio systems are supported by infrastructure that includes marked radio communication towers to satisfy aviation safety requirements, microwave buildings, and backup power supplies. Hydro One's communication towers are also utilized by the provincial mobile radio system and for third party attachments.

Provincial Mobile Radio System

Hydro One owns and operates a private radio system that is used for two-way voice communication between control centers and field crews during restoration efforts, emergency operations and day-to-day construction and maintenance work. The mobile radio provides coverage that exceeds the cellular coverage in remote areas, and is often the only means of communication in these areas. The system includes radio base stations and radios equipped in Hydro One's fleet.

Asset Conditions / Demographics

Hydro One currently owns 4,229 microprocessor based communication devices, 1,203 ancillary communication equipment, 145 radio communication towers, 143 mobile radio base stations and approximately 2,178 km of fibre optic cable that, combined with 1,700 km of third-party fibre acquired through IRU, make up the communication systems and infrastructure used to provide PSTS.

Hydro One takes into account asset age, manufacturer recommendations and historical asset retirement in order to determine ESL and to plan asset replacements. Field deficiency reports, trouble calls and failure incidents provide an indication of the overall condition of the power system telecom assets. The ESL for most microprocessor based equipment is 15-20 years. Table 12 shows typical ESL in years for each type of power system telecom asset.

Table 12 – Summary of Telecom Asset Type

Telecom System/Asset Class	Asset Type	Quantity	Expected Service Life (Years)	Currently Beyond ESL*	Beyond ESL 2024	Beyond ESL 2029
SONET Communication Network	Multiplexers	263	15	86	197	247
	Digital Radios	35	15	35	35	35
	Optical Amplifiers	32	15	29	31	32
	48 VDC Batteries	281	10-20[1]	23	49	141
	48 VDC Chargers	281	20	87	129	165
	OPGW	2,017 km	40	0	0	0
	ADSS	161 km	15	161	161	161
Power Line Carrier Systems	PLC Radios	431	20	228	305	392
Teleprotection Terminal Devices	T1 Multiplexers & Tone Devices	3165	20	1025	1880	2655
Microwave Radio Systems	T1 Radios/ Sub-T1	303	15	17	39	170

Telecom System/Asset Class	Asset Type	Quantity	Expected Service Life (Years)	Currently Beyond ESL*	Beyond ESL 2024	Beyond ESL 2029
Radio Communication Towers	Hydro One Owned	145	80	Unknown		
	Leased space	71	N/A	N/A		
High-Voltage Protection System	Neutralizing/Isolation Transformers/ Opto-Isolators	641	30-50	325	Unknown	
Provincial Mobile Radio System	Radio Base Stations Equipment	143	20	143	143	143

Note: "Unknown" denotes assets for which there is insufficient data.
[*] Data as of December, 2018
[1] Varies based on equipment make and/or model

SONET Transport Network

The first vintage of multiplexer equipment is approaching its ESL and is facing technological obsolescence as vendors withdraw support and, as such, spare parts become increasingly harder to find. The majority of SONET equipment failures are associated with the first vintage of multiplexer equipment (Vintage A MUX) as shown in Figure 14. These failures have resulted in multiple power system telecom services being rendered unavailable until repairs were carried out.

Loss of communications channels can result in the removal of power system equipment from service and/or power flow constraints on the transmission system (as protection systems dependent on communications cannot protect the equipment and the OGCC loses visibility of the status of the equipment). In turn, this can have a negative impact on the reliability of the transmission system, and potentially expose customers to a less reliable configuration due to the loss of redundancy.

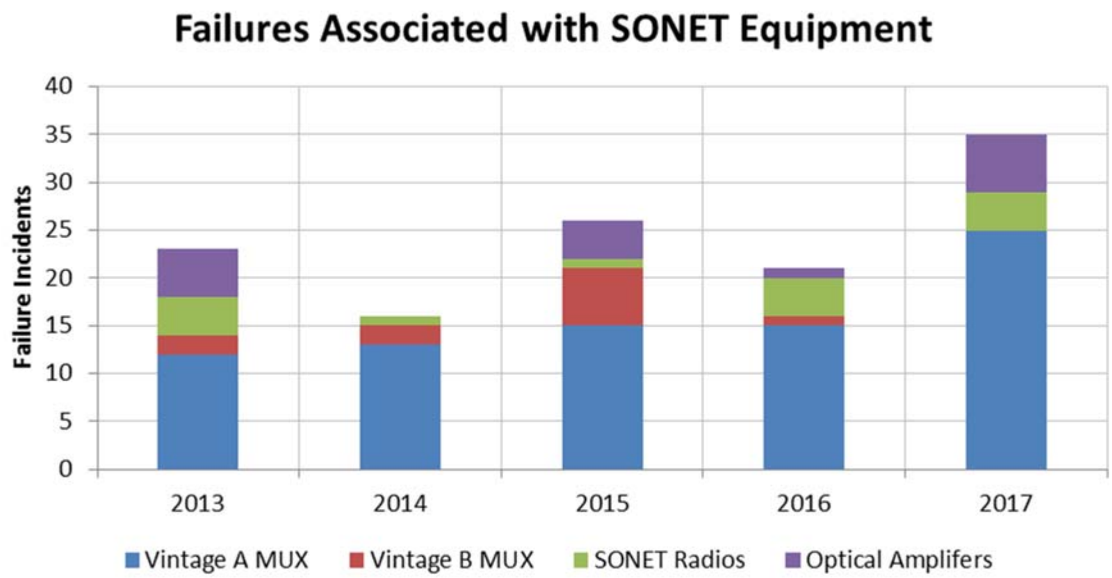

Figure 14 – Failure Incidents for SONET Equipment

Hydro One is experiencing degraded performance by many of the SONET digital microwave radio systems. Due to the age and performance of these systems, and the significant reliability risk they pose, more frequent preventive maintenance is currently being carried out until they can be replaced.

Batteries are a critical component for the normal operation of the SONET's power supply and degrade significantly once they exceed their ESL. Hydro One plans to minimize the number of batteries that exceed ESL and is monitoring the condition of those that remain. There are, however, certain types of 48Vdc charger units in the Hydro One fleet that are prematurely failing due to internal component failures and thus require replacement. Hydro One is targeting these known problematic units along with those that exceed ESL for replacement.

Fibre Optic Cable Infrastructure

The ESL of fibre optic cable is based on the type of cable. The manufacturers' recommended ESL for OPGW is 40 years and 25 years for ADSS. Historical performance shows that the mechanical aspects of fibre cable have prematurely reduced the cable's life span. In the case of ADSS cables, premature failures have caused its ESL to be lowered to 15 years.

In terms of reliability, leased fibre routes perform significantly worse than Hydro One-owned OPGW sections as they tend to be installed on public road allowances, on wood poles, or along railway tracks which makes them more prone to frequent and sometimes prolonged outages due to road accidents or train derailments. The worst performing SONET ring in the Hydro One network is Ring 7 (located north of Essa in North/North Eastern Ontario) which was built using 100% third party provided fibres. Figure 15 shows the historical occurrences of fibre breaks for each SONET ring.

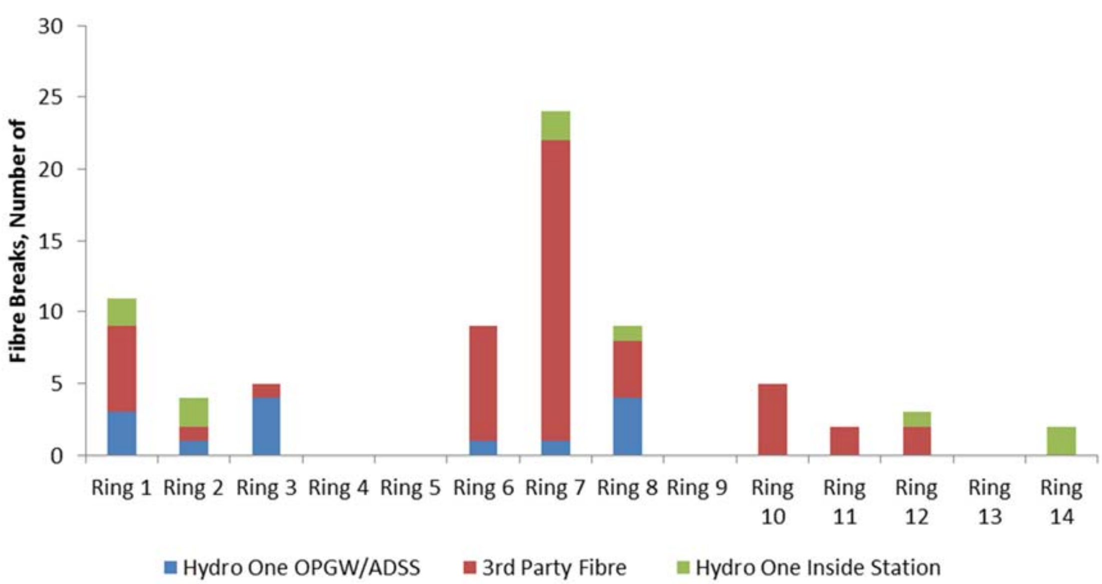

Figure 15 - Fibre Breaks by SONET Ring (2009-2017)

Power Line Carrier Systems

PLC radios have an ESL of 20 years as these are considered microprocessor based devices. Outdoor equipment such as line-traps, tuners and coupling capacitors have an ESL of 40 years, similar to that of other station yard equipment such as power instrument transformers or HV/LV switches.

Approximately 60% of the PLC radios exceed their ESL, are no longer supported by the manufacturer and are considered technologically obsolete. As shown in Figure 16 below, these vintages of radios have been contributing to the majority of the defects that Hydro One has experienced on its PLC systems.

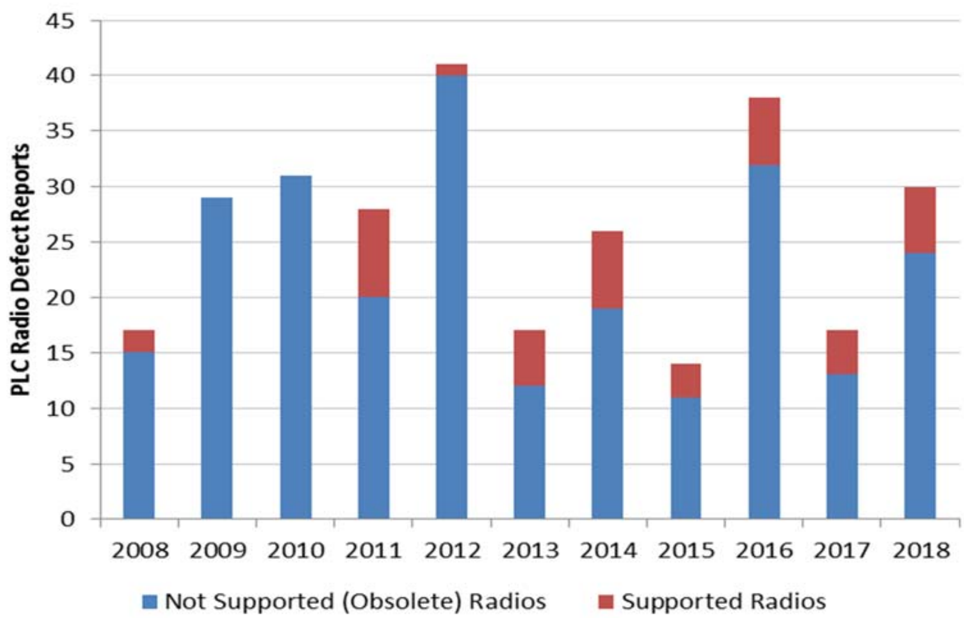

Figure 16: PLC Radio Deficiencies

Failure of the outdoor passive PLC equipment is significantly less compared to the indoor PLC radios. Since 2010 there have been only 17 failures or defects associated with outdoor PLC equipment compared to 15 defects of PLC radios on an annual basis.

Teleprotection Terminal Devices

Based on the industry-accepted ESL for microprocessor based devices, the ESL of these communication devices is estimated to be 20 years. The majority of T1 access multiplexers were deployed as part of the analog microwave replacement program that occurred from 1998 to 2007. These devices will reach ESL over the next five years. Inventory reports show that 28% of tone devices are obsolete and exceed their ESL.

Performance of both of these types of teleprotection devices has been good. This is one of the reasons why the ESL for the T1 MUX has been extended from 15 years to 20 years.

High Voltage Interface Equipment

Neutralizing transformers ("NT") have been deployed in Hydro One's system since the 1950s. These make up 48% of the HVI equipment that have reached ESL (between 30-50 years, as per Table 12). Other HVI equipment (i.e., optical isolators, isolation transformers) is fairly new. ESL considerations for NTs include degraded insulation, underrated NTs and the overall physical condition of the NT. Some NTs which are oil-filled are also subject to Environment Canada's PCB regulations (SOR/2008-273) however Hydro One has sampled these units and found no PCB content in them.

Microwave Radio Systems

Hydro One's fleet of microwave systems is fairly young. Microwave systems consist of two equipment types based on technology, newer sub-T1 digital microwave systems and T1 digital microwave systems. The majority of sub-T1 digital microwave systems were installed in the last five to six years to provide communication to and from distributed generation customers. None of the sub-T1 microwave systems exceed their ESL. Some T1 microwave systems, however, are experiencing performance as well as maintenance issues where parts are difficult to source because of equipment obsolescence. Of the T1 type microwave systems, 35% of them exceed ESL and are considered obsolete.

Hydro One considers the ESL for radio communication towers to be the same as that for transmission steel structures. Thus, an average ESL of 80 years is used for steel structures assuming they have not yet been re-coated. About 75% of the towers are more than 40 years of age, but none are beyond 80 years. Unlike steel structures, communication tower failures such as a complete tower collapse or a broken (or bent) tower member are very rare.

Provincial Mobile Radio System

The provincial mobile radio system includes 143 base stations and approximately 2,000 radios that connect the OGCC and Richview Backup Control Centre to fixed interim control centres, radio-equipped fleet vehicles and hand-held portable devices spread across Ontario.

The radio technology deployed for the exiting PMRS is technologically obsolete. The equipment is no longer manufactured or supported, and is considered beyond ESL. Hydro One's strategic spares will only last another five years. Maintenance of the PMRS equipment is contracted to an external company for both base stations as well as fleet trucks.

Future Outlook / Need

Telecom technologies typically have a 15-20 year ESL. Many of Hydro One's systems are now approaching their ESL and are facing technological obsolescence. In such cases, the risk of failure increases, and when vendor support ceases, operational sparing becomes challenging.

Hydro One continues to address the sustainment needs of power system telecom assets that exceed their ESL. Technological obsolescence remains the primary focus for the majority of replacement needs. As a result, new technologies are being sought where existing ones are obsolete and no longer meet Hydro One's business requirements. Hydro One is currently:

- Finding a new technology solution to replace the obsolete SONET network as the majority of first generation equipment will exceed ESL in the next three to four years;
- Sustaining and phasing out obsolete and poor performing power system telecom assets that have reached their ESL. This includes ADSS type fibre cables, obsolete PLC systems, teleprotection terminal devices, HVI equipment and microwave radio systems;
- Pursuing a next generation solution for the replacement of PMRS in order to ensure continuity of voice communication services;
- Refining maintenance programs, policies and practices to ensure that they meet the life-cycle optimization as well as reliability requirements as dictated by NERC and NPCC;
- Extending third party IRU contracts where Hydro One ownership of fibre is not economical; and
- Continuing to lease carrier-based services from telecommunication providers to provide PSTS where Hydro One-owned communication facilities are not economical.

In the past, ESL replacements were driven by sustainment capital programs that were based on an asset-centric approach. Going forward, integrated station projects, shield wire replacement projects, and line refurbishment programs will drive Telecom's key asset replacements to meet power system telecom sustainment and development needs. In this way, power system telecom assets can be bundled with other work at a particular station so as to achieve execution efficiencies.

Replacement of SONET Network

Given the obsolescence of both the technology and network equipment on which SONET is built, Hydro One has developed a migration plan towards a modern solution. Implementation in the short and mid-term will begin with the replacement of SONET terminal equipment on Rings 1-9 taking into account other telecom sustainment needs and direction of the strategic expansion of the network.

IP-Based Communications for Teleprotection Applications

Legacy leased analog and digital circuits offered by carriers which are based on carrier time-division multiplexing infrastructure are no longer supported. Moreover, telecom carriers no longer guarantee performance for analog leased circuits due to obsolescence and have indicated that some of these circuits will not be available in the near future.

New IP-based technologies are being investigated by many utilities and regulatory bodies (e.g. NPCC, CIGRE) to migrate existing telecom services to newer IP-based ones. Guidelines and migration paths are being developed. However, it is left up to the individual utility to assess their readiness and establish a migration path which best suits their situation. Hydro One is developing a migration plan to move away from legacy carrier-based leased services. Hydro One also actively monitors industry developments relating to the feasibility assessment and testing of new IP-based technologies.

Expansion of Fibre Optic Cable Infrastructure

The use of fibre optic cable as a communication medium has become a viable alternative for providing reliable high-speed communication between Hydro One stations. There is a foreseen need to expand the footprint of fibre cable infrastructure in order to:

- Meet the growing need of connecting new stations;
- Displace obsolete technologies such as microwave and PLC; and

- Reduce ongoing OM&A costs by moving away from leased services in favour of Hydro One owned facilities.

In the short-term, Hydro One's primary focus is to displace microwave links, leased facilities and third party IRU fibre with OPGW primarily, where economically feasible. Hydro One will also systematically phase out poor performing ADSS cables from its asset base. In the long-term, Hydro One will expand and/or sustain the fibre footprint with 80-100km of new OPGW installed annually.

New Mobile Radio System

The infrastructure sustainment needs of the PMRS are being addressed in the short-term and will continue for the next five to six years with the majority of the work around base station shelters and communication towers. The planned mobile radio replacement project will:

- Examine available technologies such as radio over IP, trunked radio system and integrated solutions to the existing hand-held and in-vehicle units used by field staff;
- Study the technical and economic feasibility of each of the viable technologies, proof of concept, and include a look at future operating costs; and
- Review required infrastructure development to ensure necessary coverage is provided prior to new system deployment.

2.2.1.6 OTHER STATION COMPONENTS

Asset Description / Purpose

Hydro One transmission stations contain a number of other components that are essential to system operation. These components can be broken into three subsections:

- Other Power Equipment;
- Ancillary Equipment; and

- Civil Infrastructure.

Other Power Equipment

Other power equipment assets include HV/MV disconnect switches, capacitor banks, HV/MV instrument transformers, insulators etc.

Table 13 - Summary of Other Power Equipment

Asset	Description
HV/MV Disconnect Switches	High voltage ("HV") and medium voltage ("MV") disconnect switches are used to visually and electrically isolate sections of the transmission system for maintenance, safety, and other operational requirements.
HV/MV Capacitor Banks	Capacitor Banks provide voltage support to maintain power transmission efficiency. These are static devices that provide capacitive compensation into the power system. They are switched in and out of the system based on operating needs.
HV/MV Instrument Transformers	Instrument transformers convert high voltages and currents into proportionately lower values that are used for measurement by protection and control devices. There are three types of instrument transformers: voltage (potential) transformers ("PTs"), capacitive voltage transformers ("CVT") and current transformers ("CTs").

Ancillary Equipment

Ancillary Equipment enable protection and control (P&C) equipment and power equipment to operate as expected. AC/DC station service ("SS") equipment, DC batteries/chargers and high pressure air systems are considered ancillary equipment.

Table 14 - Summary of Ancillary Equipment

Asset	Description
AC/DC station service equipment	AC/DC SS equipment consists of many types of sub-equipment such as AC Station service transformers, AC/DC breakers, AC/DC switches and AC/DC transfer schemes. SS equipment provide DC power to circuit breakers and protection and control equipment as well as

	auxiliary equipment such as fans, pumps, heating, lighting, etc.
DC Batteries and Chargers	All transmission stations have at least one Station DC system to ensure a source of power is available for power equipment operation under all system conditions. Batteries and chargers provide secure DC power within the station. The chargers convert AC into DC to supply the station DC load and charge the batteries. The charged batteries can provide a minimum standard of 8 hours of energy to maintain system operation.
High Pressure Air System	Centralized High-Pressure Air systems ("HPA") are installed at all locations that have ABCB. The system consists of a centralized HPA compressor/dryer plant, an air storage facility, extensive piping and valve arrangements and controls. These systems are being phased out as the ABCBs are phased out as described in TSP Section 2.2.1.2.

Civil Infrastructure

Civil infrastructure consists of the physical structures such as station structures, fences and gates, spill containment, buildings, etc. within the transmission station perimeter.

Table 15 - Summary of Civil Infrastructure

Asset	Description
Station Structures	Station structures are used in stations for mounting electrical equipment such as switches, fuses, breakers, station service transformers, bus, and Intelligent Electronic Devices ("IED"s). Some station structures are wooden, though most are made of steel. The earliest station structures were built in the 1920's.
Fences and Gates	Fences and walls are used to separate live station equipment from the public to maintain public safety. Gates are used as an entry point for Hydro One vehicles, equipment and staff. Most station fences are chain link, though some are wooden.
Spill Containment Systems	Spill containment systems are present in stations that pose a possible detrimental effect to the environment if a spill were to occur (e.g. near river, pond). These spill containment systems collect transformer oil in the event of a transformer tank rupture.
Security and Fire Protection	The Security and Fire Protection asset class includes systems that protect transmission station facilities from fire, break-ins and vandalism. The security systems include additional measures ranging from conventional door control security systems to video surveillance facilities. The fire protection systems are primarily of two types: those associated with buildings and those associated with equipment.

Asset	Description
Station Site and Yard	Station site and yard are site elements including station drainage and geotechnical systems, vegetation/weed management inside the station, gravel, garbage, etc.

Asset Conditions / Demographics

Hydro One determines the overall condition of Other Station Components by considering all of the significant factors and relevant degradation processes associated with each individual asset group. Table 16 summarizes the number of Other Station Components that are present in Hydro One's transmission stations.

Table 16 – Number of Other Station Components

Asset Type	Quantity
Other Power Equipment	
HV/MV disconnect Switch	14,331
HV/MV Instrument Transformer	8,130
HV/MV Capacitor Banks	370
Ancillary Equipment	
DC Batteries & Chargers	1,425
High Pressure Air System	482
AC/DC Station Service Eq.	1,060
Civil and Infrastructure	
Building	823
Infrastructure	251
Fences and Gates	391
Spill Containment	420
Fire and Security system	43
Site and Yard	637

Data current as of 31 December 2018

Other Power Equipment

- HV/MV Disconnect Switches

The disconnect switch demographic has been presented in Figure 17. Approximately 46% of the HV and MV switches are over 40 years old, with an ESL ranging between 40 to 50 years. Replacements are recommended once the equipment reaches ESL and Hydro One has completed condition assessments by analyzing data from maintenance records to inform the need for replacement. Currently, 25% of the switch fleet is responsible for the majority of recorded defect reports. Out of the 25%, approximately half are beyond their ESL. Hydro One monitors the condition of these assets via preventive maintenance plans, visual inspections and thermo vision. The results from monitoring help identify the problems to be repaired or replaced in a timely manner. Switches require regular maintenance and corrective actions to keep the fleet in operating condition.

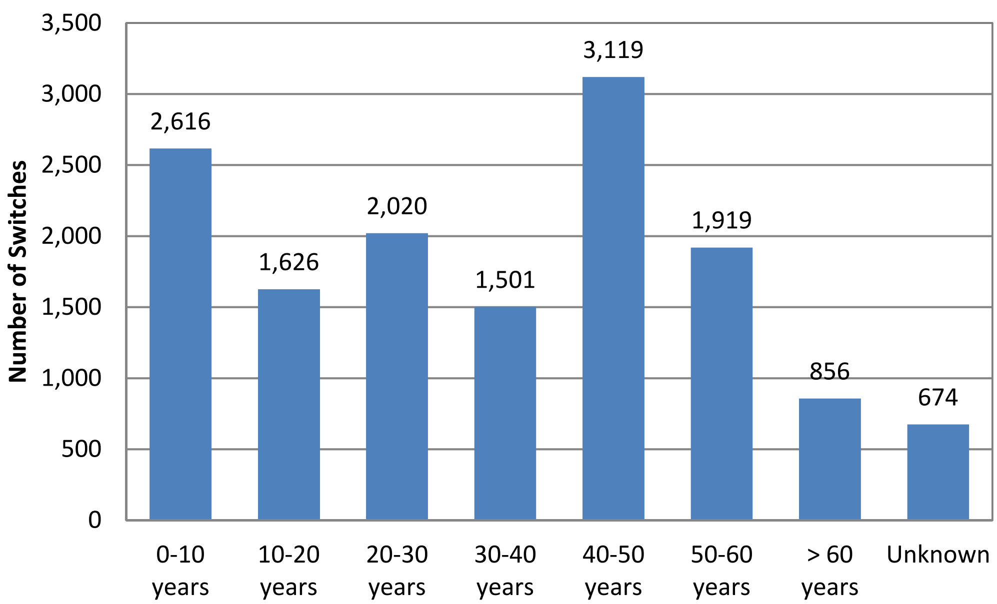

Figure 17 - Demographics for HV and MV Disconnect Switches

- HV/MV Capacitor Banks

Hydro One manages approximately 370 capacitor banks. Approximately 75% of the capacitors were installed within the last 20 years. Capacitors are closely monitored for signs of deterioration and Hydro One focuses on replacing these capacitors in a timely and efficient manner.

- HV/MV Instrument Transformers

Hydro One manages more than 8,000 free-standing instrument transformers out of which approximately 5,000 are High Voltage Instrument Transformers ("HVIT") and 3,000 are Medium Voltage Instrument Transformers ("MVIT"). The fleet of HVITs and MVITs are used for various purposes, including to measure voltage and current or to meter usage. Instrument transformers that are beyond their ESL and use oil as an insulating medium are assessed for replacement in order to avoid oil leak and increasing maintenance costs. Through regular maintenance, Hydro One is able to identify and address the issues affecting these assets, such as leaks, gassing, wrong turn ratios, etc.

Ancillary Equipment

- AC/DC Station Service

Hydro One manages more than 1,000 AC/DC SS equipment devices. ESL varies in AC/DC SS as it is comprised of various components such as AC switches, transfer schemes, AC breakers but on average 40 years is considered the appropriate ESL at Hydro One. Through regular inspections, the company is able to identify defects to be either replaced or repaired.

- DC Batteries and Chargers

Hydro One currently manages 385 battery banks and 387 chargers supplying protection and control and other station ancillary DC services. About 12% of station batteries have exceeded their ESL which is 20 years and 15% of chargers have exceeded their ESL which is 30 years. Hydro One maintains, monitors, and proactively replaces this equipment to maintain redundancy as coincident battery failures can have severe consequences on power system safety and reliability.

- High Pressure Air System

Hydro One currently manages HPA systems at 10 transmission stations, including 61 compressors, 53 dryers, 300 air receivers, and other related HPA ancillary systems. These assets generally experience minor leaks from the compressor, dryers or air lines. Leaks or failures in the HPA system can result in the removal of high voltage ABCBs from service until repairs can be completed. ABCBs are primarily installed at bulk transmission stations, and are critical in supporting bulk power flows within Ontario and through international tie lines. Through the replacement of the ABCB fleet, the associated HPA system will be removed as it will no longer be needed.

Civil Infrastructure

Civil Infrastructure assets are comprised of station drainage systems, yard surface /subsurface, access roads, structural footings, foundations, perimeter fencing, fire detection/protection, yard lighting and cable trenches. These systems provide infrastructure and support services to station equipment and station environmental systems. Asset condition is determined by monthly visual inspections and resulting deficiencies are a measure of the overall condition.

Foundations, footings, spill containment and asphalt roads can heave and crack due to freeze/thaw cycling. Drainage systems are made of clay piping and can deteriorate and/or collapse as they age. Station fences and gates are damaged or otherwise compromised by thieves seeking to gain access to yards to steal copper grounds. Theft creates additional safety hazards and potential power quality issues.

Future Outlook / Need

Any HVIT and MVIT containing PCB contaminated oil will be replaced prior to 2025 to meet compliance with federal regulatory requirements. In addition to these replacements, it is expected that a further 800 free-standing CTs will be removed in conjunction with the ABCB replacements as most of the CTs on newer breakers are installed around the breaker bushing.

The battery replacement program will target Valve Regulated Lead Acid (“VRLA”) batteries as Hydro One has experienced the coincident failure of two VRLA batteries. The loss of two VRLA batteries can result in inoperative protection and control equipment that creates a safety and reliability risk for the power system and employees. Cost effectiveness is another factor considered in the decision to replace or repair DC battery systems.

The timing of HPA system decommissioning is driven by ABCB replacements. By 2025, all HPA systems are expected to be removed from the system. The HPA systems will continue to be maintained due to their critical function of supporting the ABCB fleet where it is cost effective.

2.2.2 (5.3.2 B, C, D) ASSET COMPONENT INFORMATION – TRANSMISSION LINES

Transmission lines are used to transmit electric power, via network and radial circuits, to either direct transmission customers or to transformation points for distribution to retail customers. Transmission line major components include overhead conductors, underground cables, structures, foundations, insulators, and shieldwires.

2.2.2.1 OVERHEAD CONDUCTORS

Asset Description / Purpose

The conductor of an overhead transmission line is the asset responsible for transporting electricity between system nodes. Over 99% of Hydro One's transmission system is comprised of overhead power lines as opposed to underground cables. The conductor is the single largest and most vulnerable component of the transmission line system. Close to 98% of Hydro One's overhead conductor fleet utilises aluminum conductor steel reinforced ("ACSR") conductor types; with copper, aluminum and aluminum conductor steel supported ("ACSS") types making up the balance.

Asset Condition / Demographics

Demographics

Following a recent analytical study conducted the Electric Power Research Institute ("EPRI") Hydro One has changed ESL for its ACSR conductor type from 70 years to 90 years. Further details on this study are available in Section 1.4. The actual life span of each conductor can vary between 50 and 120 years because numerous uncontrollable variables affect conductor deterioration, including manufacturing material quality, location, orientation, local atmospheric pollution levels, weather cycles and stringing tension. Presently, Hydro One's conductor fleet has an average age of 55 years.

Currently, about 5% of the overhead conductor fleet has reached or exceeded its ESL of 90 years. Table 17 below summarizes the demographic profile of the overhead conductor fleet. Without any further replacements, the percentage of conductors exceeding ESL will increase to about 13% by 2024.

Table 17 - Overhead Conductor Demographics

Conductor Type	Circuit km in Service	Average Age (Years)	ESL (Years)	Beyond ESL	Beyond ESL 2024	Beyond ESL 2029
ACSR	28,437	54	90	876	3,125	3,988
Copper	512	97	70	512	512	512
Aluminum	21	89	100	0	15	15
ACSS	137	26	N/A*	0	0	0
Total	**29,107**	**55**		**1,389**	**3,653**	**4,516**

** Relatively new conductor type to Hydro One, limited installation, ESL to be established*

Condition

Hydro One operates a condition assessment program that identifies conductors that are beyond 50 years as candidates for assessment to determine the condition through testing. Based on Hydro One's operating experience, conductors below 50 years of age are considered low risk and have a small likelihood of being in a deteriorated condition.

By the end of 2024, about 13% or 3,653 circuit km of the conductor fleet will reach or exceed its ESL. Condition assessment results indicate that about 13% or 3,680 circuit km of the conductor fleet is known to be in high risk conditions, as shown in Figure 18 below. This includes ACSR conductors verified to be in poor condition through testing, and copper conductors, many of which suffer from damage caused by lightning strikes, mechanical strength loss and can no longer be repaired due to obsolete repair components.

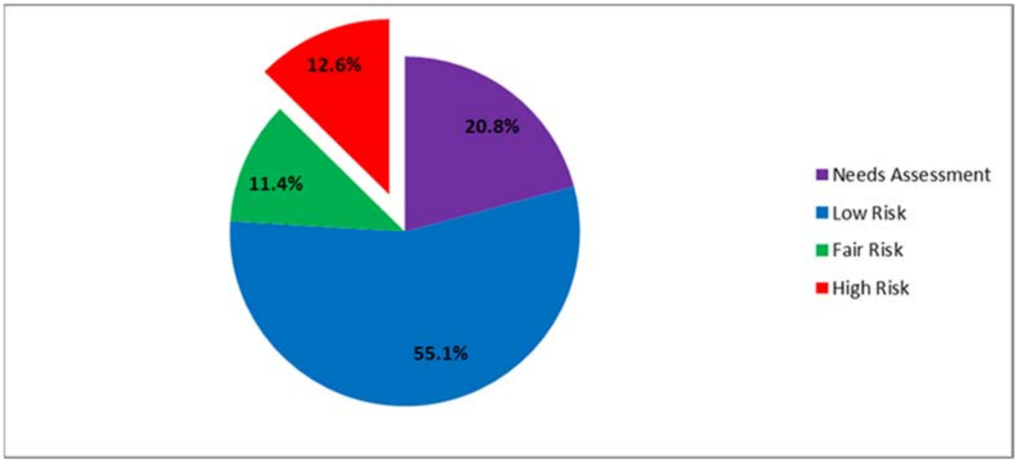

Figure 18 - Distribution of Overhead Conductor Condition

Performance

Failure of an overhead conductor can have severe consequences both in terms of reliability and safety. The number of forced outages due to conductor failures has improved over the past ten years while the outage duration has been relatively stable over the same period with the exception of abnormalities in 2009 and 2015, as outlined in Figure 19 and Figure 20. In 2009, circuits B10H/B20H required an extended forced outage to accommodate an emergency conductor replacement.[8] In 2015, an extended forced outage was required to replace twelve misaligned conductor sleeves along circuit A6R.

Hydro One has made some progress in addressing the condition assessment backlog for conductors. Relative to the EB-2016-0160 filing, the percentage of conductors requiring assessment has decreased from 31% to 21%. While many of the circuits assessed were found to be in low risk condition, the proportion of high risk conductors increased from 9% to 13% as confirmed by testing. As more conductors deteriorate and fall into the high-risk category, the risk of failure is also expected to increase, which is likely to

[8] B10H/B20H circuits are self-damping conductors that required replacement due to mechanical failures (rather than due to age-related deterioration).

translate into more frequent conductor-related outages and/or prolonged outage durations (i.e., where the line is a radial supply). While age is not the determining factor for conductor replacement decisions, it is nevertheless a useful proxy in relation to asset condition and associated risk of failure, which are confirmed through actual assessment and testing. Given the drastic increase in conductors reaching or exceeding their ESL from now to 2024 (see Table 17 above), coupled with testing results to date showing an increase in the proportion of high risk conductors, Hydro One has to proactively replace conductors in a well-planned and paced manner so as to ensure the ongoing safe and reliable operations of Ontario's BES. As illustrated in Figure 19 and Figure 20, there have been significant spikes in outage frequency and duration in certain years, which impact the overall trend line and simply cannot be predicted with any degree of accuracy. In light of the above considerations, despite the overall downward trend of forced outage frequency and duration relating to overhead conductors, it would not be prudent to wait until noticeable reliability degradations materialize before undertaking the required investments.

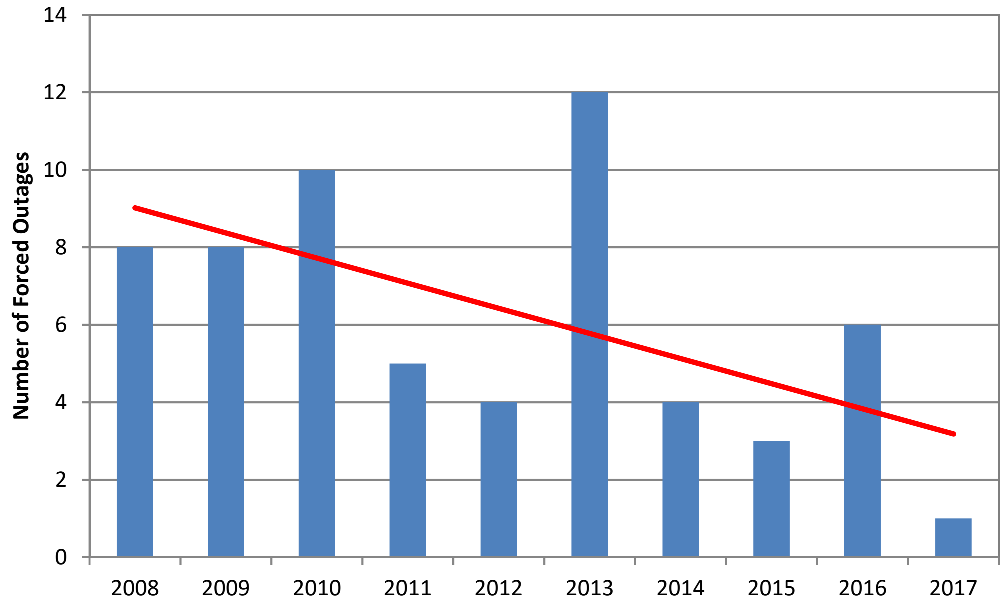

Figure 19 - Overhead Conductor Forced Outage Frequency

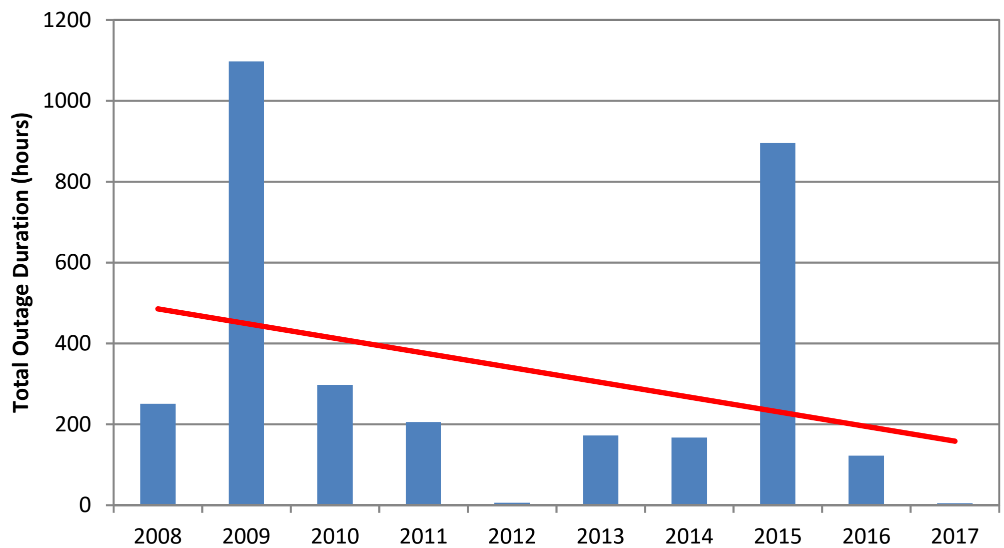

Figure 20 - Overhead Conductor Forced Outage Duration

Future Outlook / Need

The number of conductors beyond ESL is increasing, despite a planned increased level of replacements when compared to historical levels. If this issue is not addressed in a proactive and timely manner, system and customer reliability and safety will be placed at risk. Consequently, an increase in planned replacements is required to maintain acceptable fleet condition and performance and to avoid a drastic spike in investments that would otherwise be required in the future as a result of deferred replacements. However, not all conductors beyond ESL require replacement, as many conductors beyond ESL have been found to be in good or fair condition. Hydro One has increased the condition assessment program in order to accurately assess the conductor fleet that has yet to be reviewed (21% of the fleet) and thereby effectively identify conductors requiring replacement.

Hydro One is currently evaluating the C-corr technology developed by EPRI. This device is a non-contact tool that can be operated from the ground and can be used to assess the condition of conductors with steel cores by analyzing the discolouration signatures between the aluminum layers. C-corr technology can potentially reduce the cost of conductor condition assessment if proven to be accurate. Hydro One will re-evaluate implementation of this technology as test results become available to prove its reliability and cost-benefit values.

2.2.2.2 UNDERGROUND CABLES

Asset Description / Purpose

Underground transmission line cable systems are typically used to link portions of the overhead network or connect substations. They are mainly used in urban areas where it is either impossible or extremely difficult to build overhead transmission lines due to urban density, legal, environmental or safety issues.

Cable systems consist of the main cable and ancillary equipment (i.e. accessories) used to support cable operation. Cables are classified into the following three types; (i) Low-Pressure Liquid-Filled ("LPLF"); (ii) High-Pressure Liquid-Filled ("HPLF"); and (iii) Extruded Cross-linked Polyethylene ("XLPE"). LPLF and HPLF cables use oil as a dielectric (insulation) medium while XLPE cables utilize oil-free solid-dielectric insulation.

Asset Condition / Demographics

Demographics

There are approximately 264 circuit km of in-service underground transmission line cables in the system rated at either 115 kV or 230 kV. The majority of Hydro One's underground transmission system (88%) is comprised of oil-filled cables (i.e. LPLF and HPLF), with the remainder (12%) being XLPE. All new underground cable installations and replacements generally use XLPE, which is currently the most widely used cable technology and eliminates negative environmental impacts associated with oil leaks.

Hydro One's underground cable fleet has an average age of 37 years with an ESL of 70 years for LPLF and HPLF cables and 50 years for XLPE cables.[9] A demographics summary of the cable population is shown in Table 18. This data is as of 2018 year-end and does not include planned replacement for 2019 and beyond.

[9] Hydro One has previously used an ESL of 50 years for LPLF and HPLF cables. The ESL has been increased to 70 based on an EPRI study, which is discussed in Section 1.4.

Table 18: Underground Cable Demographics

Cable Type	Circuit kms in Service	Average Age (Years)	ESL (Years)	Beyond ESL	Beyond ESL 2024	Beyond ESL 2029
LPLF	60	52	70	0	2	15
HPLF	173	38	70	0	2	2
XLPE	31	6	50	0	0	0
Total	**264**	**37**	**-**	**0**	**4**	**17**

Condition

Cable condition assessment is based on a variety of quantitative test factors applicable to the cable type. Condition assessment is described in more detail in Section 2.3.2.2. Routine preventive maintenance and more intrusive diagnostic tests have shown that many underground cables are in good operating condition and, as such, have a low risk profile. Overall, Hydro One's underground cable population is in good condition. The majority of cables identified as high-risk have been planned for replacement by 2025. Figure 21 illustrates the breakdown of cable assets by assigned risk ratings.

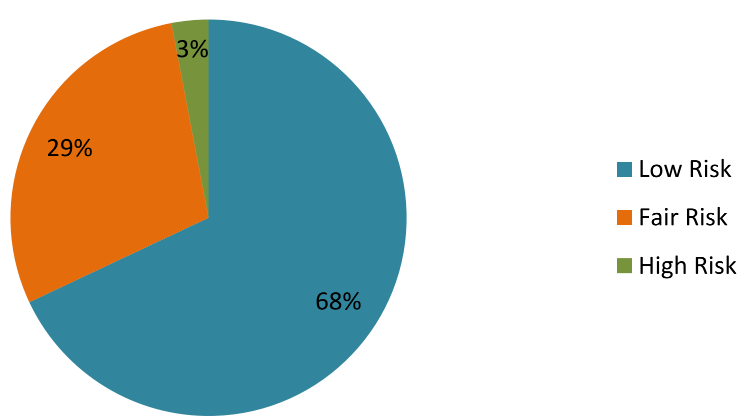

Figure 21 - Cable Asset Condition Summary

Performance

Cable outages are infrequent and normally do not result in delivery point interruptions. Most delivery points are connected to two circuits for redundancy and have a network configuration. However, an outage resulting from an underground cable failure can be lengthy in duration, with an average repair time of approximately 42 days. The frequency and duration of underground cable caused circuit outages from 2008 through 2017 is summarized in Figure 22 and Figure 23 below. Due to the relatively small number of outages, it is not possible to infer a statistically significant performance trend.

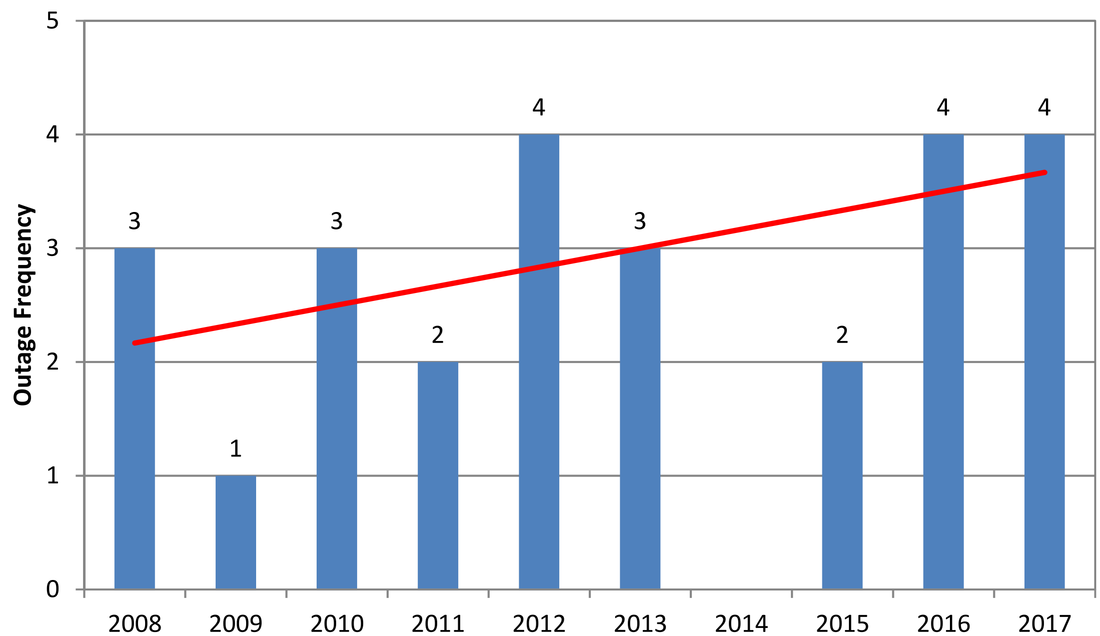

Figure 22 - Cable Outage Frequency

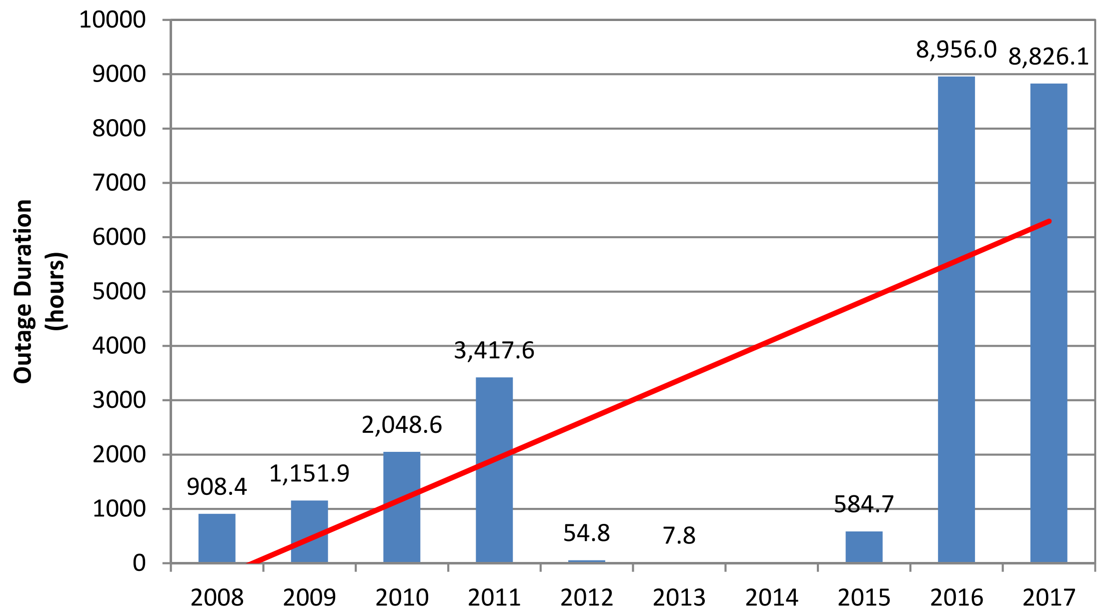

Figure 23 - Cable Outage Duration

While the number of outages in 2016 and 2017 are not unusually high, the high outage durations in those years were caused by a joint failure on circuit H11L that allowed moisture to permeate the paper insulation, leading to cable failure. The repair time was significant due to the material lead time and excavation required.

Future Outlook / Need

The majority of Hydro One's cable assets are in good condition. This is due to rigorous maintenance programs and operation practices (i.e. operating cables below their maximum thermal rating and insulating 115 kV cables to 230 kV (post-1970)). However, if historical maintenance levels are not continued, outage frequency and duration are expected to increase in the long-term.

There is an industry shift away from the use of LPLF and HPLF to XLPE cable systems. As such, manufacturers have been reducing production and support for oil-filled cables.

To mitigate this obsolescence risk, Hydro One manages a spare inventory of LPLF and HPLF cables and ancillary equipment. There is also a significant environmental risk in the event of a HPLF or LPLF cable breach. Breaches are not only caused by failed or degraded components but also by dig-ins from unauthorized excavation, which can result in the discharge of large volumes of oil into the surrounding environment.

Hydro One plans to integrate distributed temperature sensing ("DTS") systems where needed and feasible. Cable operating ampacity can change over time due to external factors leading to cable overheating and damage thereby reducing its useful life. These systems enable real-time temperature monitoring and thermal optimization to manage ampacity and extend cable ESL.

For new construction and replacement, XLPE cables are used to eliminate environmental and obsolescence risks. LPLF and HPLF cables may be considered for special applications such as repairs and the relocation of short circuit lengths.

2.2.2.3 STRUCTURES & FOUNDATIONS

Asset Description / Purpose

Steel Structures

Steel structures elevate transmission lines above the ground, providing clearance from ground objects and separation between the circuit conductors and other line components. These structures have various designs, sizes and configurations and support transmission circuits from 115 kV to 500 kV.

Wood Pole Structures

Wood poles serve the same purpose as steel structures.The majority of the wood pole structure population is located in Northern Ontario, typically in remote locations with difficult access. Similar to steel structures, wood pole structures have various designs, sizes and configurations and support transmission circuits from 115 kV to 230 kV.

Foundations

Foundations support and anchor transmission structures to the ground and enable the structures to withstand the weight of the structure itself, attached components and weather related external forces such as wind and ice. There are three dominant foundation types in Hydro One's transmission system: cast-in concrete footings, steel grillage footings, and steel anchors.

Asset Condition / Demographics

Demographics – Steel Structures

Hydro One has approximately 52,000 steel structures including 1,950 steel poles supporting 115kV to 500kV transmission lines. The demographics of the steel structure population are outlined in Table 19 below. Current steel structures have an average age of 58 years and an ESL of 80 years if they are not re-coated.

Table 19 - Steel Structure Demographics

	Quantity	Average Age	ESL (Years)	Beyond ESL currently	Beyond ESL 2024	Beyond ESL 2029
Steel Towers in Light Corrosion Zones	37,300	59	80	6,605	8,005	9,510
Steel Towers In Heavy Corrosion Zones	13,000	59	80	3,000	3,550	4,150
Steel Poles	1,950	33	80	85	95	150
Total	**52,250**	**58**	**80**	**9,690**	**11,650**	**13,810**

As explained in the following section, Hydro One's current strategy is to focus on structures in very high corrosion zones (i.e. C5[10] zones). The demographics of these structures are shown in Figure 24.

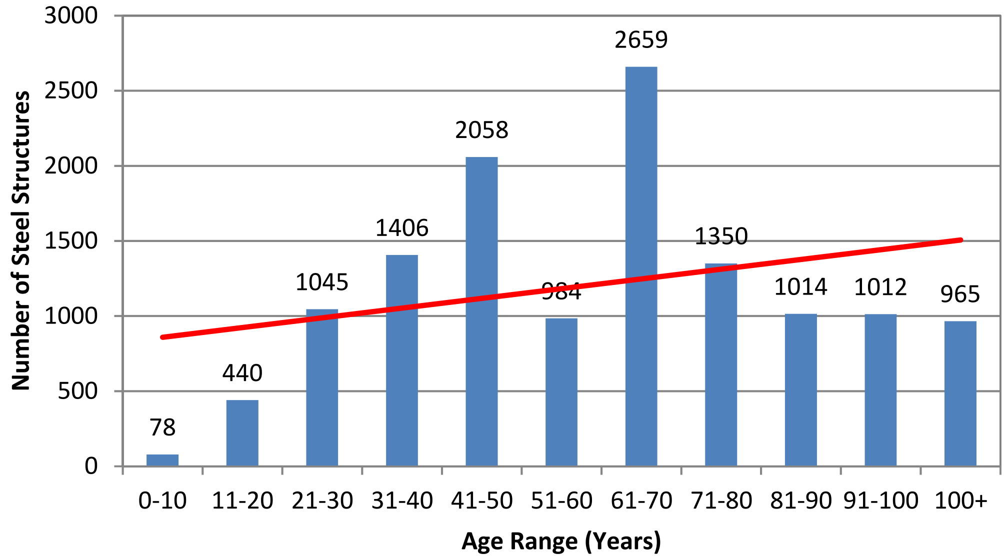

Figure 24 - Demographics of Steel Structure Fleet in Very High Corrosion Zones

Condition – Steel Structures

The service life of a steel structure primarily depends on the condition of its Hot Dip Galvanizing ("HDG") coating. Once this protective zinc layer is lost, the structure's carbon steel is exposed and the corrosion rate could increase by a factor of 8 to 10. This will result in the loss of structural strength, ultimately requiring replacement.

There are approximately 13,000 steel towers located in very high corrosion zones with 7,500 of them currently meeting tower coating criteria.

[10] Based on the ISO 9223, typical atmospheric environments are categorized from C1 through to C5, with C1 exhibiting very low in corrosivity, and C5 exhibiting very high corrosivity.

Based on the current assessment, 6% of Hydro One's steel structures have been re-coated, 8% require major refurbishment or replacement, and 14% require coating that will be addressed in the steel structure coating program. Seventy-two percent (72%) of the structures are currently in good condition and are not expected to require any maintenance in the near future. This assessment is continuously reviewed and updated as more structures are assessed and inspected. Based on the current business plan, condition assessments will be performed on approximately 1,500 towers annually in heavy corrosion zones.

Performance – Steel Structures

Forced outages for steel structures represent the number of times an outage is caused by a steel structure failure such as complete tower collapse, or a broken (or bent) tower member. It excludes forced outages caused by catastrophic damage (i.e. caused by transmission lines being struck by tornado, aircraft, truck, etc.).

The number of forced outages due to steel structure failures has shown a slight downward trend over the past ten years (see Figure 25), while outage duration has been relatively stable except for 2011 (see Figure 26). In 2011, there were multiple tower collapses on two different tower lines due to high wind. 2016 also saw a severe weather event, which caused the collapse of several towers and consequently a significant outage.

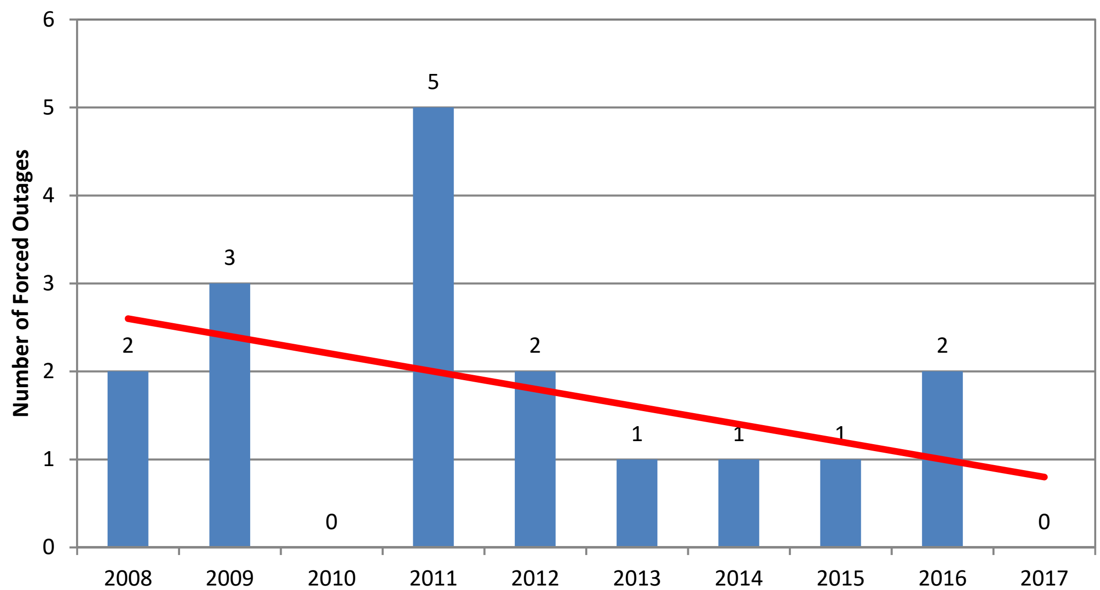

Figure 25 - Forced Outages Frequency due to Steel Structure Failures

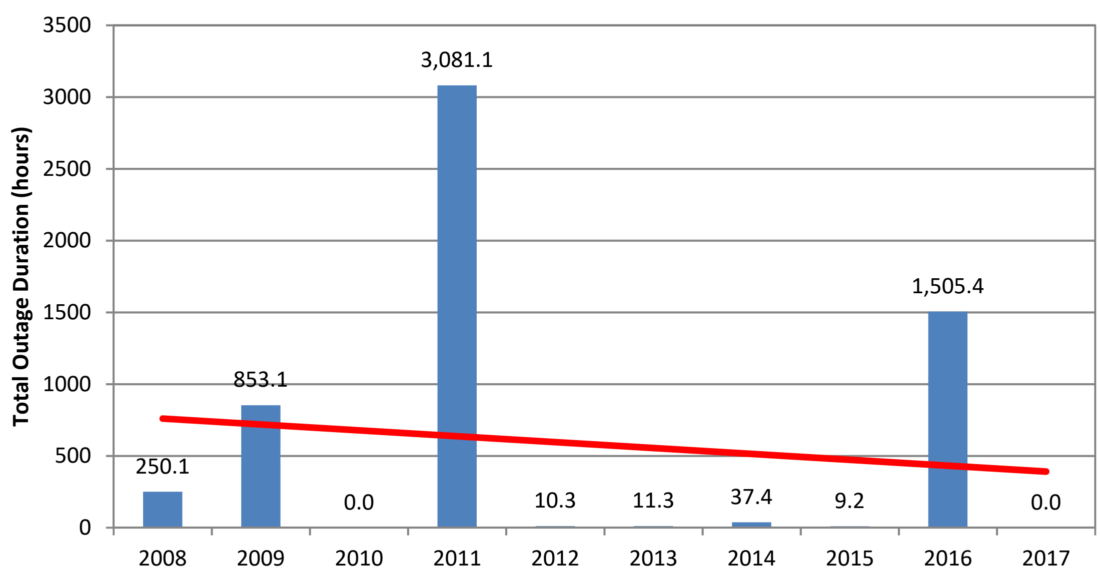

Figure 26 - Forced Outage Duration due to Steel Structure Failures

Demographics – Wood Pole Structures

Hydro One has approximately 42,000 wood pole structures in its transmission system. The average age of the wood pole fleet is 41 years and 34% of the wood poles are beyond their ESL of 50 years. The demographics of the wood pole population are outlined in Table 20.

Table 20 - Wood Pole Structure Demographics

Wood Structure	Quantity	Average Age	ESL (Years)	Beyond ESL currently	Beyond ESL 2024	Beyond ESL 2029
Total	42,000	41	50	14,400	15,100	17,940

Condition – Wood Pole Structures

Wood structures deteriorate over time. The rate of deterioration depends on many factors including location, weather, type of wood, treatment, insects and wildlife. As a result, uniform deterioration does not occur and the condition of wood structures varies, even in the same location. Due to the nature of the design, the wood cross-arm tends to be the weak link and is typically the primary cause of failure.

Based on wood pole assessments, 13% of Hydro One’s wood pole population requires replacement, as illustrated in Figure 27. These poor condition poles typically exhibit woodpecker damage, mechanical damage or insect damage. Approximately 45% of the wood pole population needs to be assessed to determine its condition, while about 42% of the population is either in good condition or not eligible for assessment (i.e. younger than 25 years).

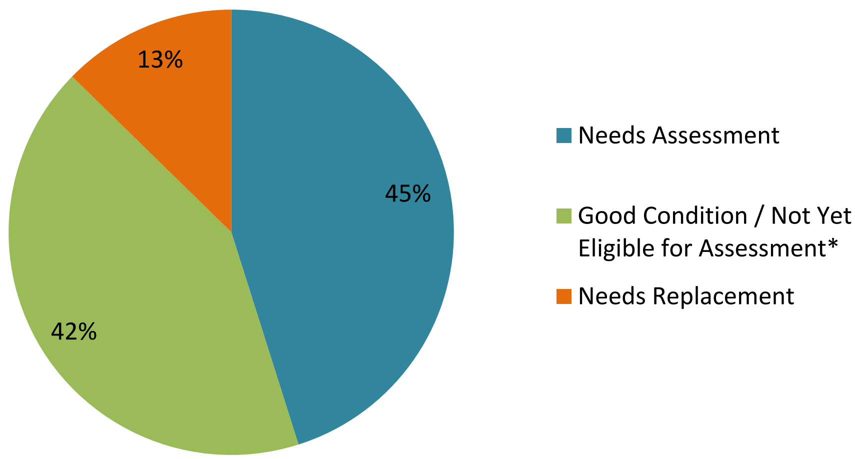

Figure 27 - Wood Pole Fleet Condition Status

Performance – Wood Pole Structures

The majority of transmission wood pole structures are located in Northern Ontario and many of these structures support radial circuits. As a result, a wood pole or cross-arm failure can often directly result in a customer outage. Many of these northern wood pole circuits feed major industrial customers. Without an adequate supply of power, these customers may be forced to shut down until power is restored. Such an event can add significant cost to a customer's operations.

As shown in Figure 28, the number of forced outages due to wood pole structure failures has increased over the past ten years. Wood pole failure is the result of a combination of factors, such as pole condition, weather condition, physical loading, and the local environment. Wood poles are a natural product that despite treatment, have some quality inconsistencies in each pole, which can result in an unpredictable failure under certain conditions.

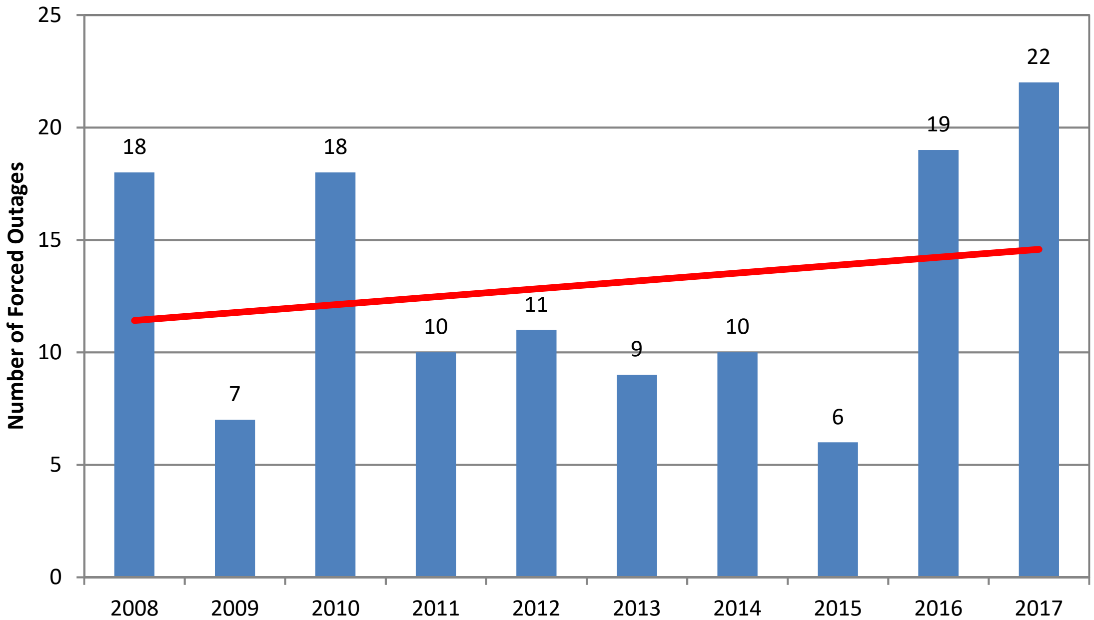

Figure 28: Forced Outage Frequency Due to Wood Pole Failures

As shown in Figure 29 the forced outage duration due to wood pole failures has generally improved over the past ten years. The relatively high outage incidences and durations in 2016 and 2017 may point to the start of an upward trend (although a few more years of data would be needed to be certain). Hydro One will continue to monitor the condition of its wood pole feet and implement the necessary steps to mitigate any emerging trend.

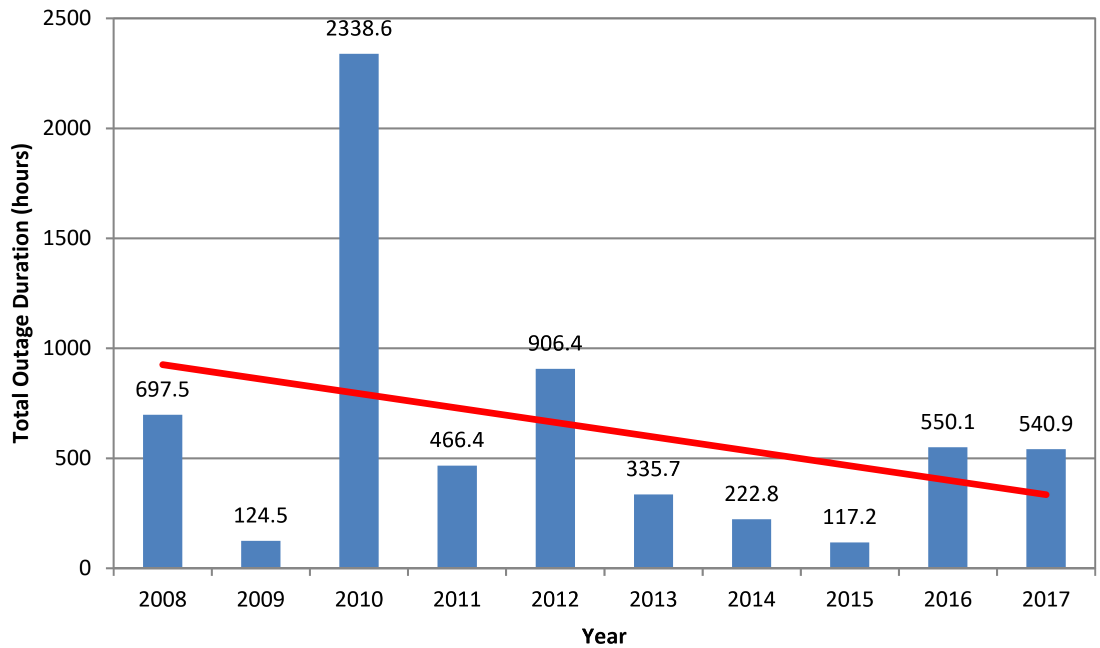

Figure 29: Forced Outage Duration due to Wood Pole Failures

<u>Demographics – Foundations</u>

Hydro One's transmission system contains approximately 52,000 steel structures with foundations made of either concrete or steel. Approximately 32,000 foundations are steel grillage and the other 20,000 foundations are cast in concrete (auger or pad and pier). The reason for the change was the construction efficiency and asset durability of concrete auger type foundations plus more restrictive environmental protection regulations. All grillage foundations are or will be 50 years or older during the course of the next five years and will need to be assessed through the Assess, Clean and Coat program. Table 21 shows the demographics of all foundations:

Table 21 - Foundation Demographics

Foundation Type	Quantity	Average Age (Years)	ESL (Years)	Beyond ESL	Beyond ESL 2024	Beyond ESL 2029
Cast-in Concrete Footings	20,000	33	100+	0	0	0
Steel Grillage Footings	32,000	74	80	10,235	12,185	14,360
Steel Anchors	3,500	46	80	0	0	0
Total	**55,500**	**57**	**-**	**10, 235**	**12,185**	**14,360**

Conditions – Foundations

The Transmission Lines Foundation Assess, Clean, Coat and Repair Programs consist of two components. The first component, Assess, Clean and Coat, is intended to assess the condition of transmission tower foundations. Each tower is assessed and is either coated immediately or scheduled for future repairs. The status of foundation condition assessments is shown in Figure 30. The decision to coat or repair depends on the severity of corrosion (metal loss) that is found and the complexity of potential repairs (some minor repairs can be executed under this activity). The second component of the program, Foundation Repair, is designed to complete more complex repairs and/or the replacement of foundations identified during previous assessment activities.

If a line is scheduled to be refurbished, then activities forming part of the Assess, Clean, Coat and Repair activities will occur as a part of the refurbishment projects. Based on inspection results, where severe corrosion has caused significant strength reduction, the foundation will be identified as a candidate for repair or replacement. Hydro One is currently focusing on grillage footings and anchors due to their age and configuration which sustain a higher incidence of corrosion. Concrete footings are younger and are not displaying signs of corrosion. The current plan is to assess/clean/coat approximately 800 grillage foundations in 2020 and 1600 foundations per year from 2021-2024.

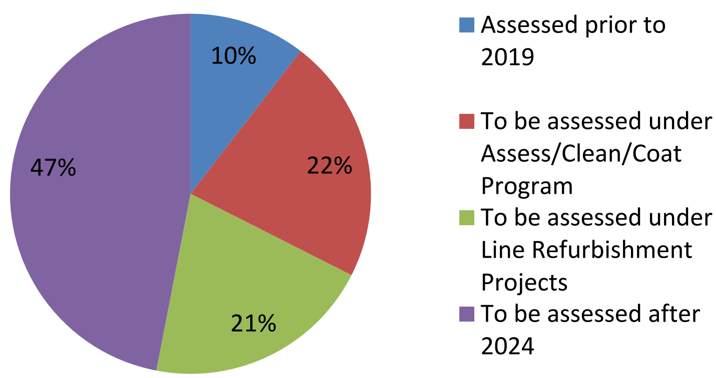

Figure 30 - Steel Grillage Foundation Condition Assessment Status

Future Outlook / Need

Steel Structures

With the current condition of the steel structures and the demographics of the fleet, it is expected that increased capital investments will be required to maintain the integrity of the steel structure fleet in order to avoid future failures and outages.

Wood Pole Structures

Hydro One will continue to replace wood poles that have failed condition assessments. Although failures in this population can occur at any time, the likelihood increases during severe weather events.

Hydro One has started using composite pole technology to replace wood poles. Composite pole technology has the potential to reduce long-term maintenance costs. Currently, 25% of the poles replaced in any given year are with composite material, which nonetheless only accounts for less than 1% of the pole structure fleet. The gradual installation of composite poles will allow for the evaluation of this technology in Hydro One's system.

Foundations

There are very few cases where concrete foundation deteriorations have occurred in Hydro One's system. As a result, current Hydro One programs related to foundations focus on steel grillages and steel anchors installed before 1970. These steel footings are at least 50 years old and recent inspection results have shown a higher incidence of degradation.

2.2.2.4 INSULATORS

Asset Description / Purpose

Transmission line insulators are an integral component of the transmission system. Transmission line insulators are required to perform two basic functions. They must provide mechanical support for overhead conductors and they must provide electrical isolation between the energized conductors they support and the grounded towers to which they are attached. A typical transmission line insulator is shown in Figure 31 below. A summary of insulator classifications can be found in Table 22 below.

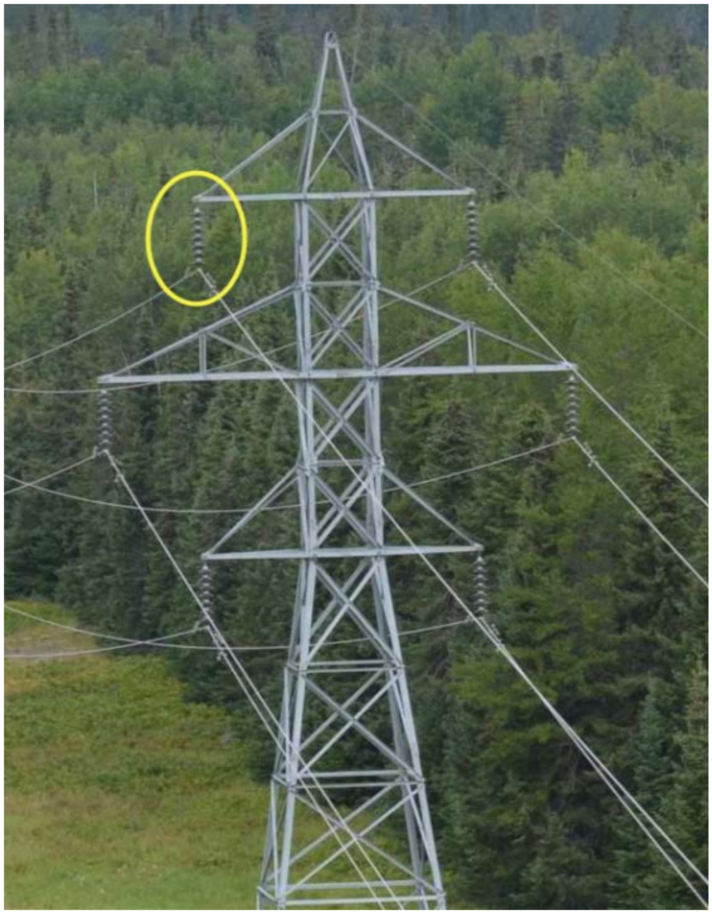

Figure 31 Transmission Line Insulator

Table 22 – Insulator Material Classifications

Type		Vintage	Voltage (kV)	Description
Porcelain		1910+	115, 230, 500	Porcelain insulators are the oldest and most common insulator type used by Hydro One. They are projected to last for the life of the line; however, isolated failures do occur and there are known issues affecting specific vintages.
Glass		Mid-1980s+	115, 230, 500	Hydro One began installing glass insulators in the mid-1980s as an alternative to defective porcelain. They are projected to last for the life of the line; however, isolated failures do occur.
Polymer		Mid-1980s+	115, 230	Polymer insulators were developed as an alternative to porcelain and glass. Their material properties entail the following benefits: • Lighter-weight (making them easier to install); • Vandalism resistance (less susceptible to mechanical damage); and, • Better contamination performance (less likely to flashover in contaminated environments).

Asset Condition / Demographics

Demographics

There are approximately 437,000 insulator strings in Hydro One's overhead transmission network. The percentage of insulators by material type is shown in Figure 32.

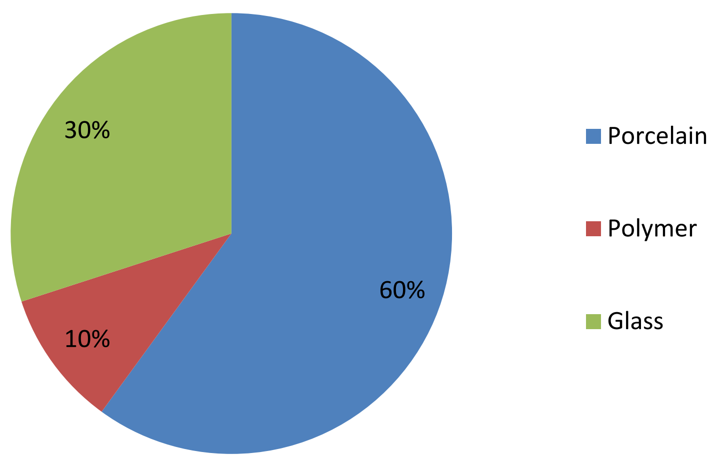

Figure 32 – Percentage of Insulators by Material

Demographics are not a driving factor for the replacement of porcelain or glass insulators since insulators are generally expected to last for the life of the transmission line and significant condition degradation is not expected to occur over time. Replacement is normally done as part of other work programs (e.g. line refurbishment). Program specific insulator replacement work targets strings that have prematurely reached their EOL due to one-off failures (e.g. broken shells), manufacturing defects, improper functionality or poor design.

Hydro One uses polymer insulators on the 115 kV and 230 kV transmission system. Polymer insulators have an ESL of 30 years and, due to their material properties, degrade with age. First-generation polymers installed in the mid-1980s are approaching the end of their ESL and will need to be evaluated for replacement. First-generation polymers are more problematic when compared to more recent generations. When older polymer insulators were designed and manufactured, the long-term effects of electric fields were not well understood which caused unexpected polymer degradation. Newer generations use modified designs and refined manufacturing techniques.

Condition

Quality porcelain and glass insulators have low failure rates and are not expected to reach EOL before the conductor. However, porcelain insulators manufactured by Canadian Ohio Brass ("COB") and Canadian Porcelain ("CP") between 1965 and 1982 suffer from a phenomenon known as cement expansion or cement growth. The purpose of the cement is to bond the pin to the porcelain. Cement expansion creates radial cracks in the cement and porcelain shell resulting in two possible failure modes:

- Mechanical Failure: where the pin separates from the porcelain causing a conductor drop; and/or,
- Electrical Failure: where the cracked porcelain reduces insulating properties.

The cement growth phenomenon is illustrated in Figure 33. Cracks in the cement and porcelain shell are not readily visible or easily detectable. Insulators suffering from cement expansion are expected to fail prematurely and unpredictably since failure is influenced by mechanical load and environmental conditions.

Figure 33 - Porcelain Insulator Unit Affected by Cement Expansion

To address concerns associated with defective porcelain insulators, Hydro One retained a third-party expert, EPRI to perform laboratory testing on COB and CP porcelain insulators in order to assess their condition. The purpose of the study was to assist Hydro One in determining the pacing of porcelain insulator replacement.

Phase one of the EPRI study was completed in 2016 and included testing of 299 insulators removed from a combination of dead-end and suspension strings installed in publicly accessible (critical) locations. Phase one testing was intended to provide an expedient assessment of the condition of the in-service insulators in question. The results of the Phase one study supported the urgent replacement of COB and CP insulators manufactured between 1965 and 1982 that are installed in publicly accessible (critical) structures where public safety is at risk.

A large proportion of the insulators tested (37%) during the Phase one study failed electrically or mechanically at loads below their rated mechanical and electrical strength. There was a significant number of punctured insulators (electrical failing load of zero), and the test data showed a large variation in failing loads which would not be expected for a healthy insulator population. The condition of these Hydro One insulators was assessed through benchmarking by EPRI and public domain test data. This benchmarking data was obtained through testing of similar vintage insulators which had been in service for a comparable duration under similar field conditions. The performance of Hydro One's and the benchmarking insulators was also compared to current and historic requirements for new insulators. The test results presented an initial snapshot of the condition of the population of defective insulators in-service on Hydro One's transmission system. Although the sample of insulators tested was not sufficient to perform a rigorous statistical analysis upon which to base recommendations, the results strongly suggested that the installed insulator population comprising CP and COB insulators manufactured between 1965 and 1982 had reached or was at least approaching the end of useful life.

Phase two of the testing was performed in 2017. Those tests were carried out on 591 insulators. The intent of the Phase two tests was to supplement the Phase one data and to provide data on the rate of deterioration of the insulator population. The results of the analysis showed that:

- a large number of the tested insulators exhibited porcelain cracking after mechanical and electrical testing;
- the propensity for the insulators to puncture (crack) during thermal mechanical cycling ("TMC");
- the insulators are highly susceptible to electrical puncture under steep transient voltages (e.g. lightning);
- TMC drastically decreases the already weak ability of the insulators to withstand electrical puncture; and
- a significant number of insulators separated mechanically during TMC.

These results suggest that the number of in-service punctured units will increase as the insulators experience significant mechanical loading events. When a string containing electrically punctured insulators undergoes a flashover due to lightning, contamination, or snow and ice bridging, there is a high likelihood that the ensuing power arc will pass through the punctured unit internally travelling from cap to pin. This results in significant heating and pressure buildup which can cause the cap and pin to separate and the conductor to drop. The greater the number of punctured insulators in the string, the higher the probability of string flashover and string separation. Insulators which are not punctured but have suffered deterioration in mechanical strength do not exhibit this behavior. If a string contains mechanically compromised units, the insulators will fail if the maximum applied load exceeds the units' remaining mechanical strength. The majority of conductor drops recently experienced on Hydro One's porcelain insulated transmission system fall into the former category.

The Phase one and two analyses provided overwhelming evidence supporting replacement of defective porcelain insulators to mitigate the risk to the safety and reliability of Hydro One's transmission system. The key recommendation provided by EPRI is that the identified population of COB and CP insulators be removed from service as soon as practically possible.

The porcelain insulators manufactured by CP and COB are used province-wide in Hydro One's transmission system. There are approximately 34,000 circuit structures with defective porcelain insulators and roughly 15,000 have been identified as being on structures in publicly accessible (critical) locations. Publicly accessible (critical) structures include those located near roads, waterways, urban areas, golf courses, educational and health care facilities. To date approximately 8900 publicly accessible COB and/or CP insulators have been replaced. A breakdown of the defective population in relation to the total insulator population as of 2018 can be seen in Figure 34 below.

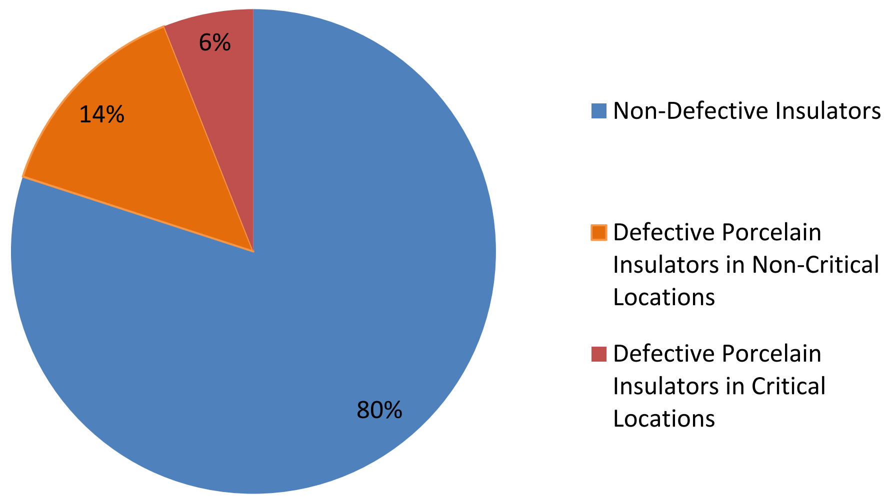

Figure 34 - Defective Porcelain Insulator Population

Hydro One has experienced porcelain insulators failures due to cement expansion. For example, in March 2015, an insulator on circuit V76R mechanically failed causing the conductor to fall to the ground in a commercial parking lot in Etobicoke. Similarly, in January 2017, an insulator on circuit HL3 mechanically failed causing the conductor to fall over a roadway in Hamilton. Photos of these failures are provided in Figure 35 through Figure 38 below.

Figure 35 - V76R Insulator Failure

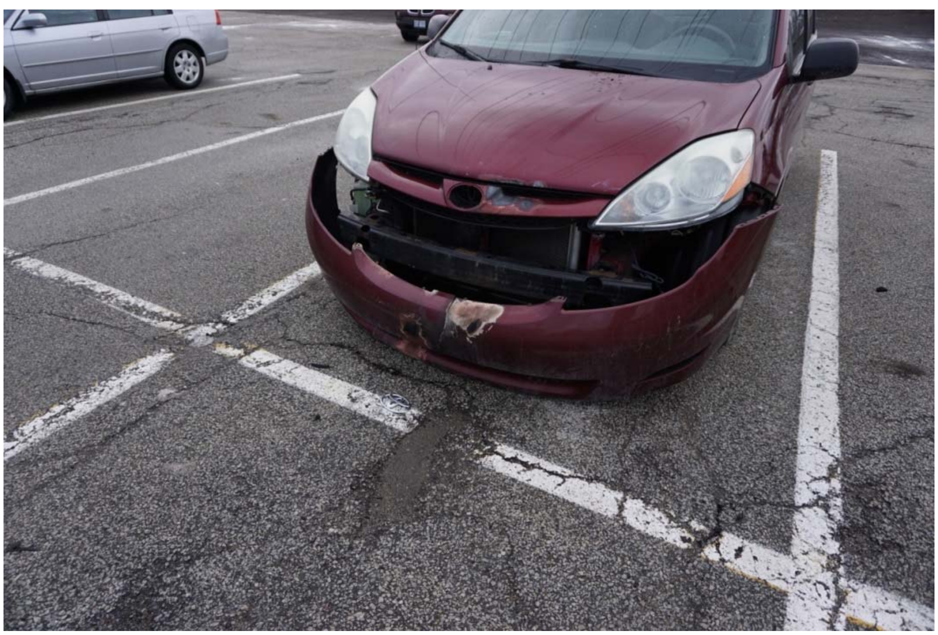

Figure 36 - V76R Insulator Failure

Figure 37 - V76R Insulator Failure

Figure 38 - HL3 Insulator Failure

Since portions of Hydro One's polymer insulator population are approaching their ESL, Hydro One retained EPRI to perform a detailed condition assessment of polymer insulators to assist Hydro One in determining the need and pacing of polymer insulator replacement. The condition assessment study focused on 87 polymer insulators from various manufacturers with the service life ranging from 13 to 26 years. The following three insulator configurations form the scope of the EPRI study:

- 230 kV suspension with large corona rings;
- 230 kV suspension with either small (known as a "donut") or no corona rings; and
- 115 kV dead end.

Based on its assessment of 87 insulators, EPRI found that the condition of polymer insulators currently in-service in Hydro One's transmission system varies based on voltage, manufacturer and use of corona rings. The results of this study have shown that Hydro One should plan to remove specific 230 kV insulators from service as soon as possible due to immediate or high risk of failure. Other types of 230 kV insulators should continue to be assessed periodically for signs and degree of degradation. EPRI further recommends that linemen should check the integrity of these insulators prior to performing any live maintenance procedures due to potential safety issues. Considering the study results, Hydro One will prioritize the removal of specific polymer insulators in its current replacement program.

The need to address the polymer insulator issue is underscored by two failures which occurred in October and November 2016. Both failures were a result of a 230 kV polymer suspension insulators on C28C failing mechanically resulting in a conductor drop, as shown in the photos in Figure 39 through Figure 41. The dropped conductor did not contact the ground but was held in the structure window.

Figure 39 – Failed Polymer Insulator

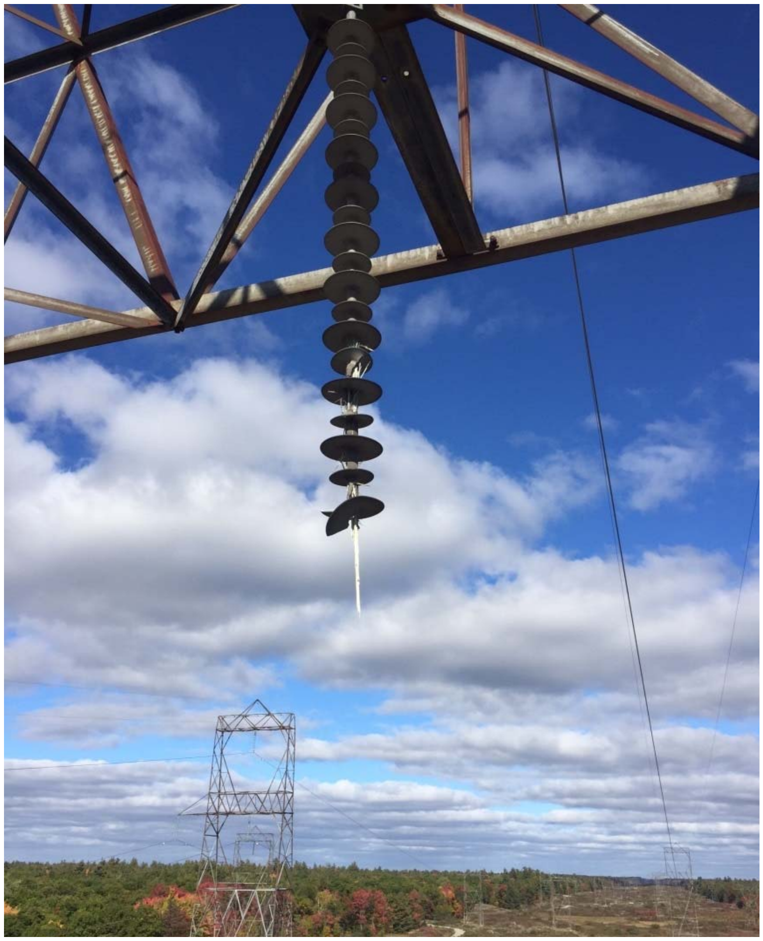

Figure 40 – Failed Polymer Insulator

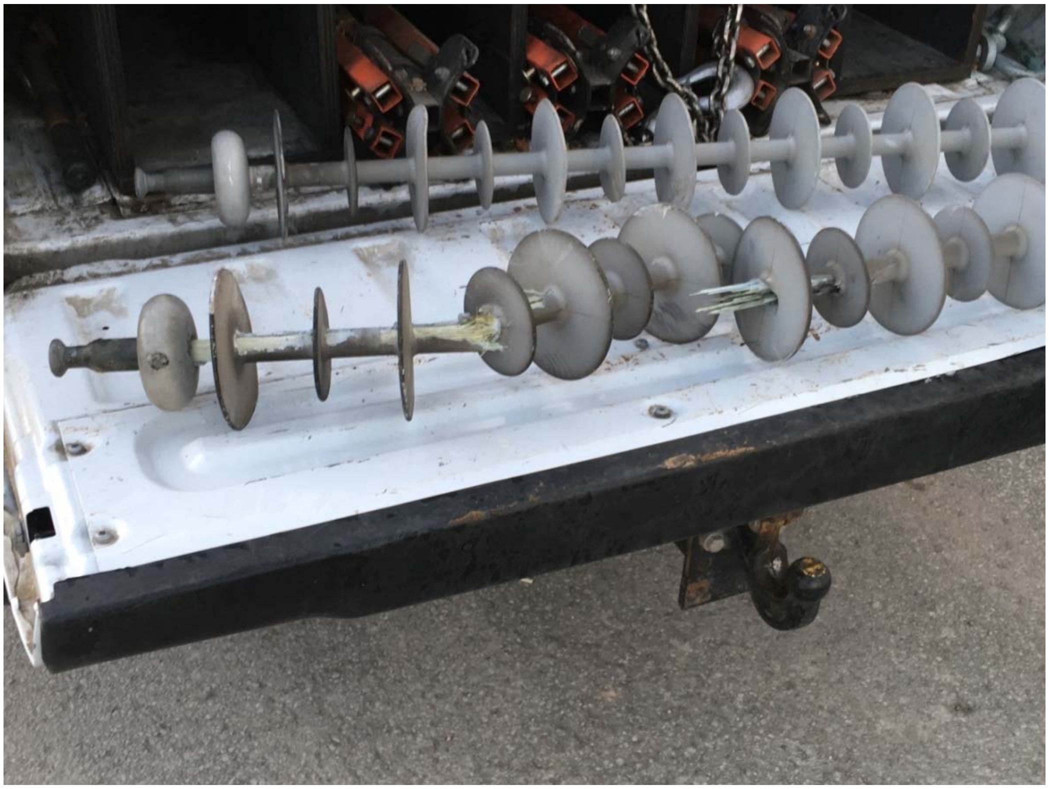

Figure 41 – Failed Polymer Insulator

Performance

Figure 42 and Figure 43 illustrate the frequency and duration of insulator-caused circuit outages between 2008 and 2017, which have remained relatively stable. However, the number of failures is expected to rise due to the degradation of the known defective COB and CP porcelain insulators. Figure 44 illustrates the number of COB and CP failures over the past 10 years, which shows a significant upward trend.

Failed insulators normally result in a sustained forced outage because of the permanent electrical fault they create. Repair time can be significant, averaging 37 hours per outage, depending on the location and severity of the failure. The majority of the recent failures have been due to defective porcelain or polymer insulators.

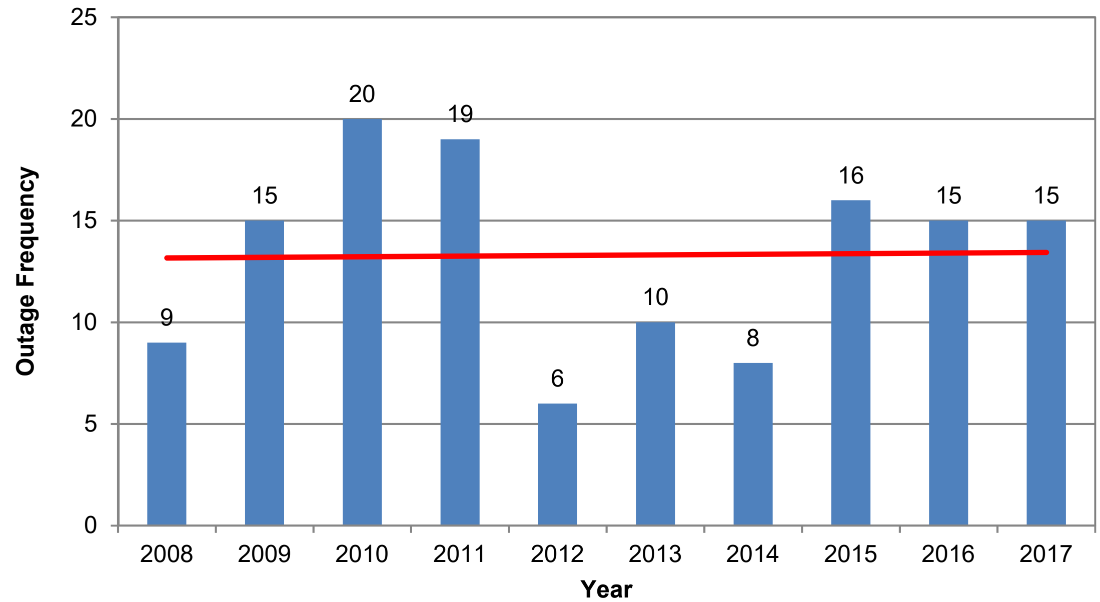

Figure 42 - Insulator Outage Frequency

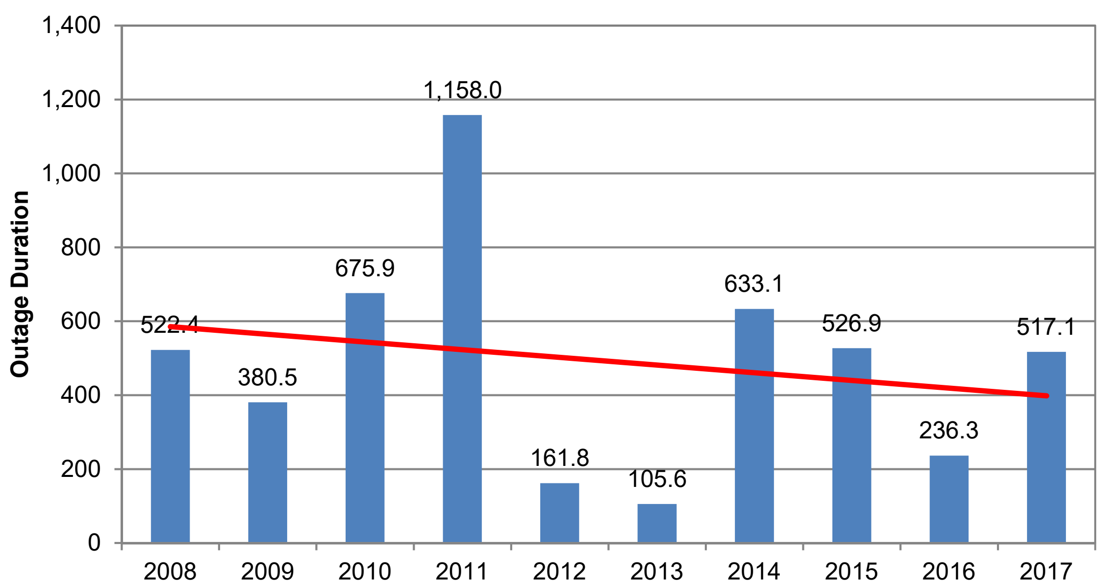

Figure 43 - Insulator Outage Duration

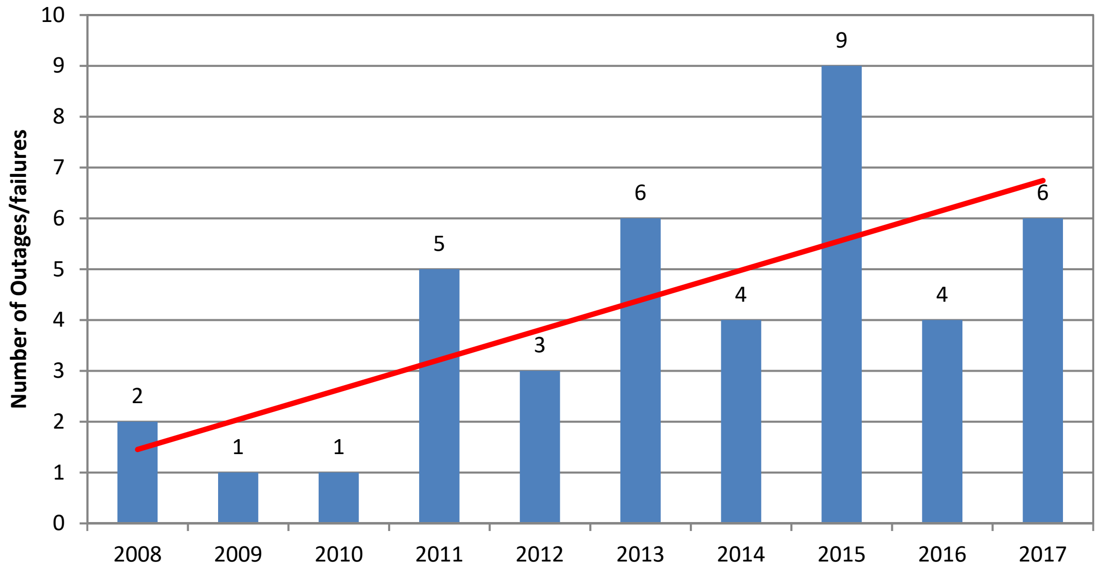

Figure 44- Frequency of COB/CP Insulator Failures

Safety

Many insulators are used on structures in public areas or in areas that can be easily accessed by the public. In the event of a mechanical failure and conductor drop, these locations pose a high risk to the public, and therefore need to be prioritized as part of a proactive plan.

Future Outlook / Need

Porcelain Insulator Replacement

The testing results discussed in Section 2.2.2.4 provide overwhelming evidence supporting replacement of defective porcelain insulators to mitigate the risk to the safety and reliability of Hydro One's transmission system. The key recommendation provided by EPRI is to remove the identified population of COB and CP insulators from service as soon as practically possible. As a result, Hydro One has targeted for replacement defective porcelain insulators that pose a substantial public safety risk, as further discussed in Section 2.3.2.4 of this TSP and ISD SR-25.

Polymer Insulator Replacement

Polymer insulators in 230 kV dead-end configurations are known to fail due to their exposure to high electric-field gradients that cause silicone degradation. The degradation exposes the fibreglass rod to moisture which causes rapid deterioration leading to failure. These insulators are also being targeted for replacement.

Hydro One is using the information provided by EPRI, discussed in Section 2.2.2.4, to optimize the overall replacement program with respect to the risk of in-service failure.

2.2.2.5 RIGHTS OF WAY

Asset Description / Purpose

The strip of land that is occupied by a transmission line is referred to as a right-of-way ("ROW") or a corridor. Hydro One's in-service ROWs cover an area of approximately 82,500 hectares and consist of 115, 230, 345 and 500 kV circuits. To ensure system reliability and access, Hydro One is responsible for maintaining clearance distances between the energized equipment and the vegetation located on and adjacent to all of these ROWs.

Asset Condition / Demographics

Demographics

Hydro One's service territory is divided into three operational Forestry Zones: North, South and East. These zones have been defined based on similarities in weather patterns and vegetation growth conditions and are used to maximize operational efficiencies.

Hydro One maintains its ROWs on vegetation clearing cycles of 4, 6 or 8 years. Fast growth areas are placed on a shorter cycle. Cycle lengths have been set to ensure that

ROWs are in good condition and maintain a sustainable level of reliability between maintenance cycles. A summary of Hydro One's ROW route hectares by zone and maintenance cycle is shown in Figure 45.

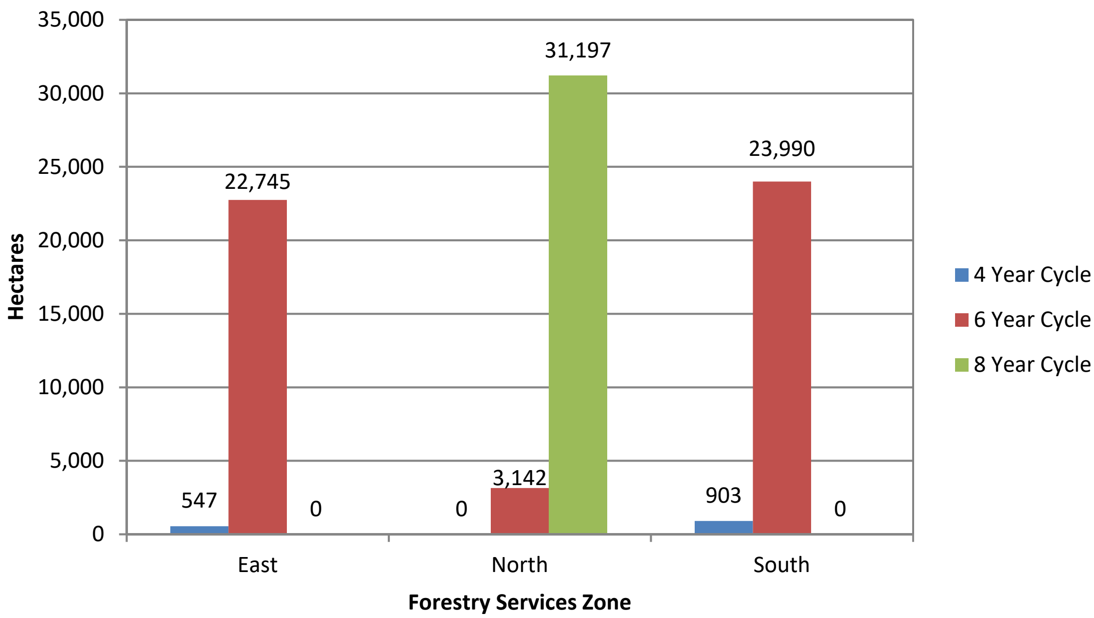

Figure 45 - Hectares by Maintenance Cycle Length and Zone

Condition

If left unmanaged, vegetation on or adjacent to a ROW presents the risk of growing or falling into energized conductors and preventing access to Hydro One's transmission lines. Figure 46 illustrates the breakdown of ROWs in poor, fair, and good condition. Approximately 9% (i.e. 7,400 hectares) of Hydro One's ROWs are beyond their target clearing cycle and are therefore considered to be in poor condition.

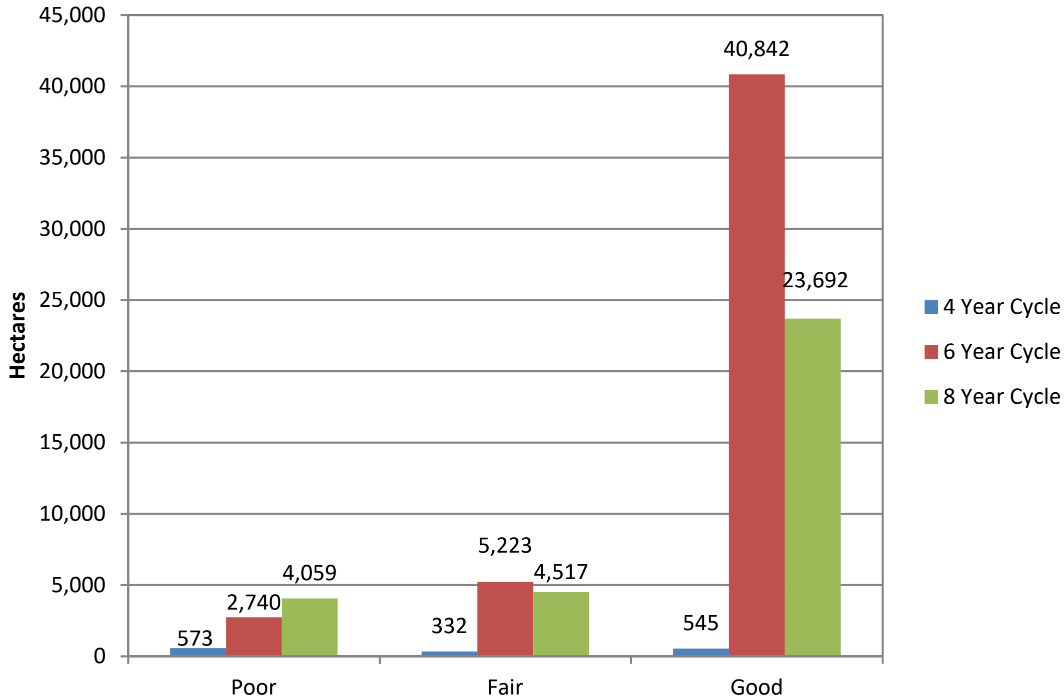

Figure 46 – Condition of Hydro One ROW

Performance

Asset performance for vegetation management is measured by the number of annual vegetation caused outages. The majority of Hydro One's vegetation related outages have been due to trees falling on 115 kV conductors from outside of the ROW due to extreme weather conditions such as heavy winds, snow and/or ice storms.

Hydro One's transmission lines are subject to NERC standard FAC-003, *Transmission Vegetation Management Reliability Standard*, which currently requires Hydro One to report all vegetation related outages on 230, 345 and 500 kV circuits within Hydro One's control (i.e. natural disasters and human activity such as logging are excluded). Vegetation caused outages affecting Hydro One's 115 kV system are not currently NERC reportable. Figure 47 provides a summary of all vegetation caused forced outages on

Hydro One's network presenting both the NERC reportable and non-reportable outages.[11] The duration of these outages is displayed in Figure 48.

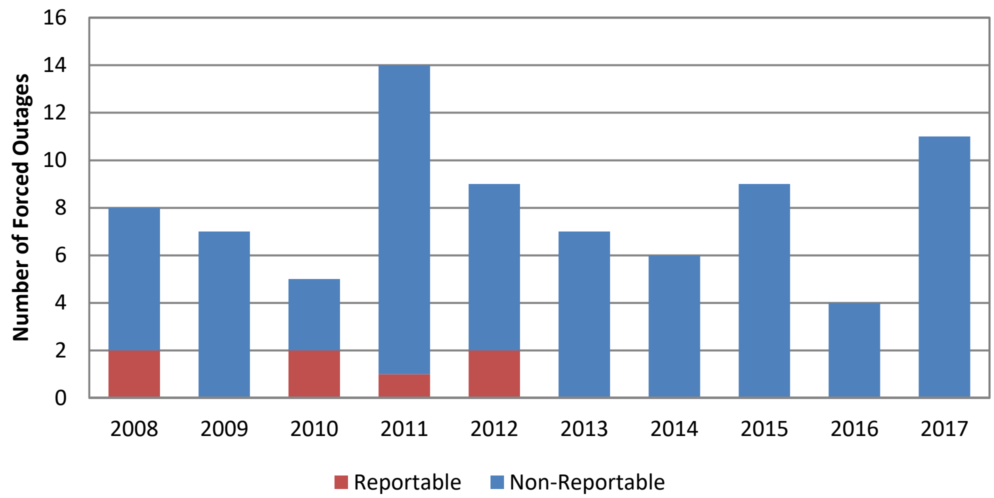

Figure 47 - Hydro One's Vegetation Related Outage Frequency

[11] NERC reportable outages have primarily decreased due to changes in NERC's definition of which outages are reportable. For example, there have been less NERC reportable outages in recent years because momentary and human caused outages are now excluded.

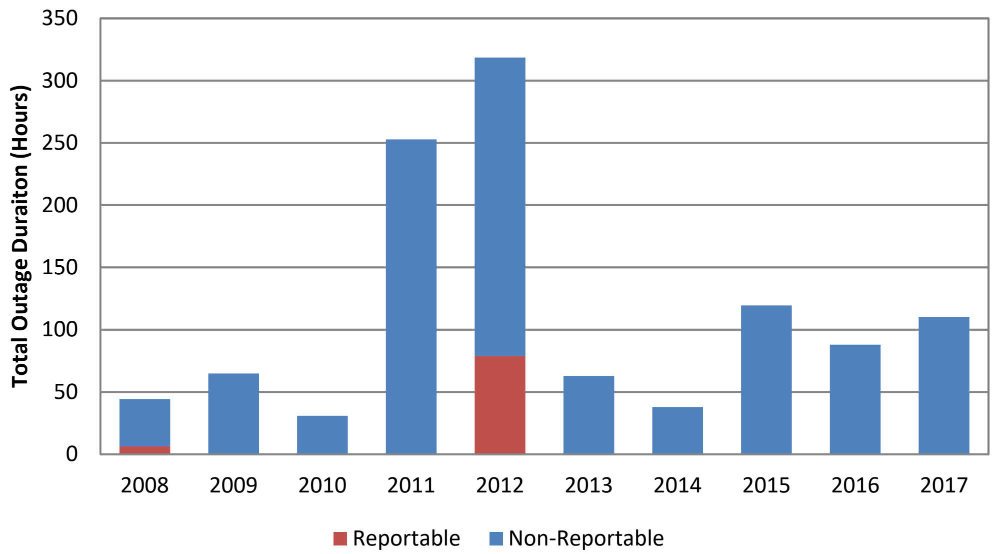

Figure 48 - Duration of Vegetation Related Outages on Hydro One Circuits

Future Outlook / Need

As maintenance cycles extend past targeted cycles, vegetation growth continues to increase along Hydro One's transmission corridors. Consequently, approximately 7,400 ha of ROW are considered to be in poor condition. Hydro One plans to prioritize vegetation maintenance on NERC FAC-003 regulated and critical ROWs in order to manage this backlog. To further optimize the program, new technological opportunities, such as Light Detection and Ranging ("LiDAR"), are being considered to help identify any potential vegetation encroachments upon Hydro One's transmission lines. As discussed in Section 2.3.2.5.3, LiDAR is a remote sensing technology that is used by utilities to obtain accurate geospatial images and measurements of circuits and the vegetation surrounding them.

2.2.2.6 SHIELDWIRE

Asset Description / Purpose

Shieldwire is used to provide lightning protection and grounding continuity to transmission lines. There are approximately 34,600 km of shieldwire strung along Hydro One's overhead transmission lines. Hydro One's network consists of the following five types of shieldwire: (i) Galvanized Steel, (ii) Alumoweld, (iii) Optical Ground Wire ("OPGW"), (iv) Aluminum Conductor Steel Reinforced ("ACSR") and (v) Copperweld. Alumoweld and OPGW are the most recent types of shieldwire and are currently used to replace EOL shieldwire. Further details regarding each type of shieldwire are provided in Table 23.

Table 23 – Summary of Shieldwire by Type

Shieldwire Type	Vintage	Description
Galvanized Steel	Installed until approx. 1990	Galvanized Steel is the most common type of shieldwire currently installed on the Hydro One network. However, galvanized steel shieldwire is no longer being used for new installations by Hydro One as the protective zinc coating tends to deteriorate over time and result in a loss of metal, a reduction in mechanical strength, and eventual failure of the shieldwire.
Aluminum cladded steel, also known as Alumoweld	Installed for approximately 40 years	Alumoweld is the most recent type of shieldwire installed on Hydro One's network and is being used to replace shieldwire that has reached EOL. Alumoweld shieldwire consists of a thick aluminum cladding used to protect against corrosion and a steel, conductive core.
Optical Ground Wire ("OPGW")	Installed for approximately 30 years	In locations where a fibre optic communication channel is required for telecommunication purposes, Hydro One installs OPGW, which consists of Alumoweld shieldwire with a core containing fibre optic strands.

Shieldwire Type	Vintage	Description
Aluminum Conductor Steel Reinforced ("ACSR")	Installed as required	ACSR conductors are installed as shieldwire on a limited basis and are used when estimated fault current levels are too high for conventional galvanized steel or Alumoweld wires.
Copper cladded steel, also known as Copperweld	Installed between 1930 and 1960	Copperweld is an older type of shieldwire that was installed in limited numbers across the Hydro One network. This shieldwire is not capable of adequately sustaining lightning strikes and is therefore targeted for replacement.

Asset Condition / Demographics

Demographics

The average age of Hydro One's shieldwire fleet is approximately 37 years. Approximately 61% of Hydro One's shieldwire fleet is galvanized steel and 30% is Alumoweld. The demographic details of Hydro One's shieldwire fleet as of year-end 2018 are displayed in Table 24. Due to historic construction and demographic patterns, Hydro One is now entering a period where many shieldwire sections are approaching ESL.

Table 24 - Summary of Shieldwire Demographics

Shieldwire Type	In- Service Length (km)	Average Age	ESL (Years)	Currently Beyond ESL (km)	Beyond ESL 2024 (km)	Beyond ESL 2029 (km)
Galvanized Steel	21,142	53	50	10,005	15,300	16,769
Alumoweld	10,682	27	60	0	0	0
OPGW	2,017	21	40	0	0	0
ACSR	599	45	90	0	4	14
Copperweld	204	63	N/A*	204	204	204
Total	**34,644**	**37**	**-**	**10,209**	**15,508**	**16,987**

**ESL is not applicable to Copperweld as it is end of life regardless of age*

Condition

Hydro One does not replace shieldwire based upon age. A detailed condition assessment is used to determine when shieldwire has reached EOL.

Shieldwire that has been verified by condition assessment to have reached EOL is considered to be high risk and is scheduled for replacement. Fair risk shieldwire assets have condition test results that indicate minor deterioration but have not yet reached EOL. These shieldwires are scheduled for re-assessment at a later date. The timeframe for re-assessment varies depending on the level of deterioration indicated by the test results. Shieldwire classified as low risk has either been assessed to be in good condition or has not yet reached the age at which shieldwire condition assessment begins. Of the total shieldwire fleet, 24% has reached the condition assessment age threshold, which varies depending on shieldwire materials, as further discussed in Section 2.3.2.6, and will be assessed in the future under Hydro One's shieldwire condition assessment program. The condition of Hydro One's shieldwire fleet is summarized in Figure 49.

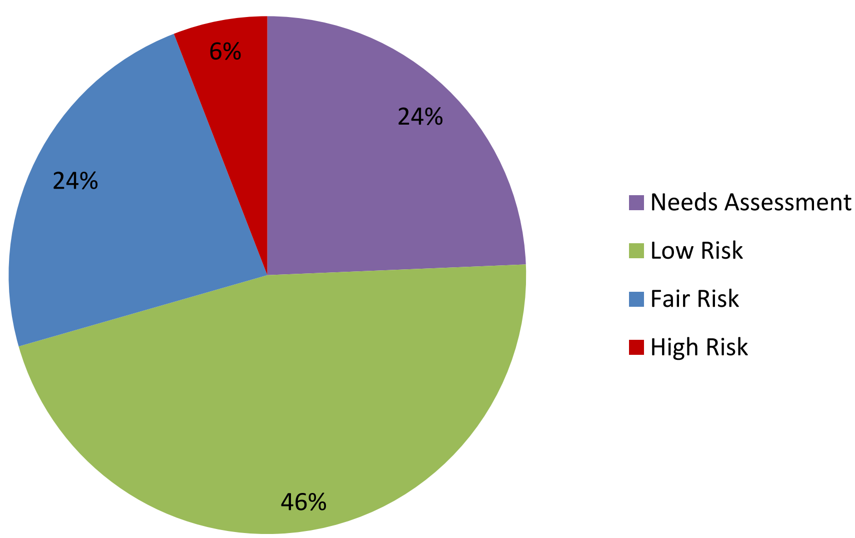

Figure 49 - Condition Risk of Shieldwire Assets

Performance

Asset performance for shieldwire is measured by the number of shieldwire caused outages that occur each year. The majority of Hydro One's shieldwire caused outages occur during extreme weather conditions such as heavy winds, snow, and/or ice storms. Figure 50 and Figure 51 provide a summary of all shieldwire caused forced outages.

The frequency of shieldwire caused forced outages has remained fairly stable over the recent years, while outage duration increased significantly in 2016 due to inclement weather that prevented shieldwire repairs. Circuit outages are common when shieldwire failure occurs, as the broken shieldwire typically makes contact with the conductors before falling to the ground. In addition, broken and hanging shieldwire can expose members of the public or Hydro One employees to a safety risk.

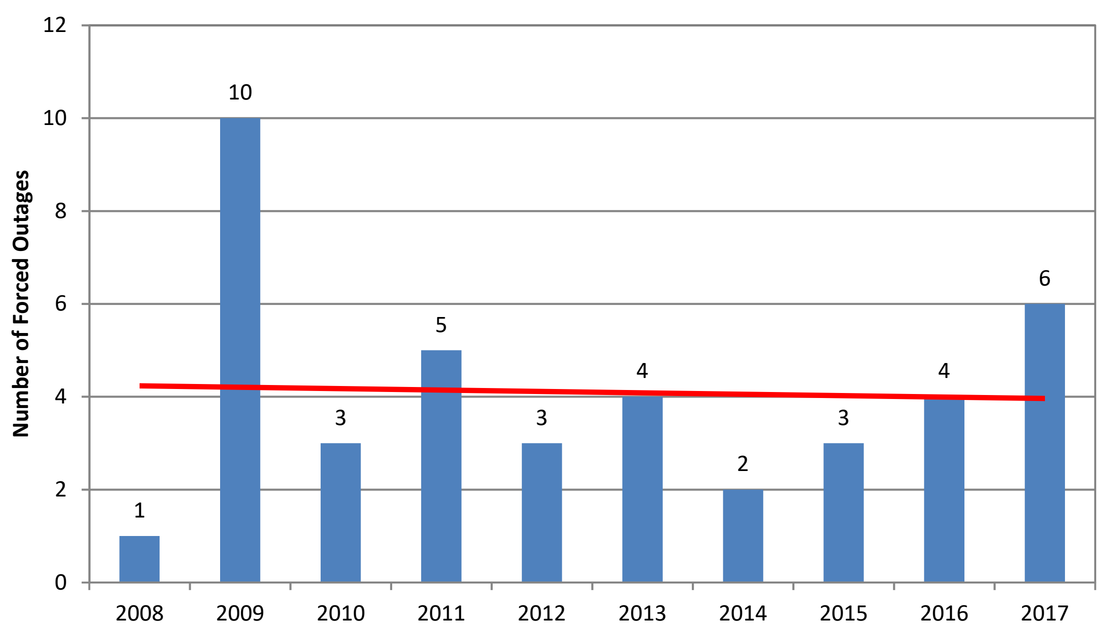

Figure 50 - Frequency of Shieldwire Related Outages

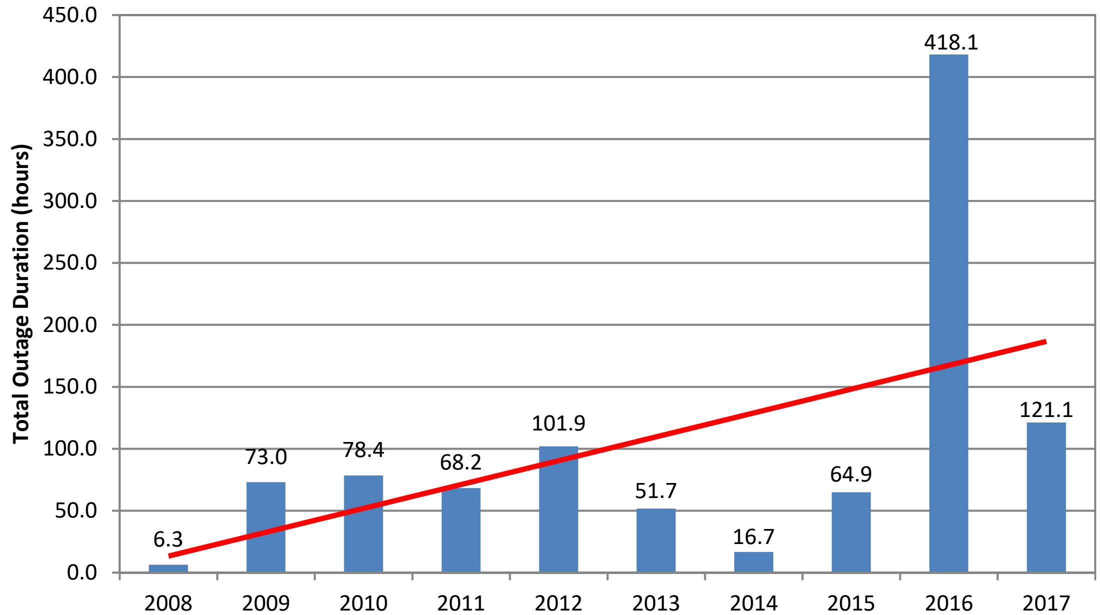

Figure 51 - Duration of Shieldwire Related Outages

Future Outlook / Need

To prevent shieldwire-related outages and reduce the risk to public safety, Hydro One is focusing on replacing all shieldwire that has been confirmed through condition assessment to have reached their EOL. Going forward all shieldwire that requires replacement will be replaced with Alumoweld or OPGW shieldwire, with the exception of any line sections requiring ACSR to withstand higher fault currents.

Currently, 24% of Hydro One's shieldwire fleet has reached the age threshold for condition assessment. These assessments are required to plan, schedule and execute replacements of EOL shieldwire.

2.2.2.7 OTHER LINES ASSETS

Asset Description / Purpose

Other transmission line assets include U-bolts, switches, aviation lights, and numerous other hardware components such as dampers and ground wires.

U-bolt Hardware

U-bolt hardware is the physical link between a transmission structure and insulator (refer to Figure 52). The majority of suspension circuit structures contain U-bolt hardware.

Figure 52 - U-bolt on a suspension structure

Lines Switches

Transmission line switches are primarily used to sectionalize lines and isolate customers during planned and unplanned outages. Transmission line switches can be generalized into the two types: In-Line Disconnect switches and Mid-Span-Openers ("MSO").

Aviation Obstruction Lights

Hydro One has approximately 100 transmission line structures that are equipped with aviation obstruction lighting to warn pilots of potential objects within the flight path. These systems must comply with Transport Canada's aviation regulation "Standard 621 –

Obstruction Marking and Lighting." Structures equipped with aviation obstruction lights are located near airports or river crossings.

Figure 53 - Aviation Obstruction Lighting

Asset Condition / Demographics

U-bolt Hardware

U-bolt hardware under suspension configuration deteriorates over time due to the swinging movement of the attached insulators and conductors. The swinging causes friction and wear on the U-bolt hardware or tower eye. Over time the cross-sectional area of the U-bolt and/or the tower eye wears out as shown in Figure 54. Eventually the hardware will no longer have the mechanical strength to support the suspended insulator and conductor, leading to a catastrophic failure.

Figure 54 - A Worn U-bolt

There are various external factors, such as wind, weather and circuit configuration, that can impact the rate of deterioration of U-bolt hardware. The age of U-bolt hardware alone does not reflect its physical condition. U-bolt hardware are visually assessed by either detailed helicopter inspection or climbing inspection to determine its physical condition.

U-bolt replacement is primarily driven by EOL condition, when the wear on the U-bolt cross sectional area has reached over 50%. The ESL of U-bolt hardware is set at 65 years.

Line Switches

Time-based preventive maintenance is performed on Hydro One line switches. During maintenance, switch functionality is verified and associated defects are reported for corrective repair or future replacement is planned.

Aviation Obstruction Lights

All of the aviation obstruction lighting systems installed on Hydro One Transmission structures underwent replacements between 2003 and 2012. All of the installed systems were manufactured by the company OTL. Over the service life of the aviation lighting systems, significant investments were made to repair or replace defective components. These defects primarily include: repeated integrated circuit cards failure, xenon flash tube capacitors failure, malfunctioning control boxes, and incorrect remote monitoring alarms. In 2016, OTL went out of business, thereby affecting technical support and spare parts availability. As such, Hydro One approved a new vendor to supply material for new replacement systems. Installation of this new system started in 2016. As the lighting systems are replaced, useable parts are salvaged as spares for remaining in-service systems.

Future Outlook / Need

U-bolt hardware

To maintain system reliability and reduce the risk to public safety, Hydro One will continue to utilize detailed helicopter inspection and climbing inspection to assess U-bolt condition of circuits that has reached the age threshold for condition assessment.

EOL U-bolts cannot be repaired and are therefore targeted for replacement. A U-bolt is considered hardware associated with the structure/insulator. Therefore, component replacement programs such as wood pole replacement, insulator replacement or line refurbishment projects will typically include replacement of U-bolt hardware on the circuit structure. For example, during insulator replacement, the associated U-bolt hardware will be replaced at the same time for execution efficiency. EOL U-bolts that are not addressed through component replacement programs will be replaced through the planned corrective program.

Lines switches

Switches that are inoperable, obsolete or at EOL are targeted for replacement. The intent is to proactively replace switches prior to failure, minimizing customer and system impact in the event that the switch is required.

Aviation Obstruction Lights

LED aviation obstruction lighting systems are to be installed on both transmission structures and telecom microwave towers. The aviation light locations identified for replacement are prioritized based on the type of lighting system (determined by tower height) and identified defects. The existing plan is to replace all aviation light systems manufactured by OTL by the end of 2023.

Emergency Replacement

Each year, a number of transmission line components fail or are identified to be in imminent danger of failure, due to adverse weather, component deterioration, vandalism, or accidents. Replacement or repair of these line components is carried out under a demand emergency program to minimize reliability and safety risk. The type of emergency work covered includes replacement of failed or defective transmission line components such as wood structures, cross-arms, towers, insulators, conductor, shieldwire and hardware.

2.2.3 (5.3.2 B, C, D) ASSET COMPONENT INFORMATION – OTHER ASSETS

Other assets of the Hydro One transmission system include real estate and facilities, transport and work equipment and information technology. These assets support all lines of business and are vital to the operation and maintenance of the transmission system.

2.2.3.1 REAL ESTATE AND FACILITIES

Asset Description / Purpose

Hydro One Facilities and Real Estate assets include sites and buildings accommodating administrative and service functions to support business operations. Administrative and service functions include: Administrative Centres, Operations Centres, Maintenance/Work Centres, Warehouses, Maintenance Garages, Helicopter Hangars, Material Yards and limited others ("Facilities"). Capital investment is periodically required to provide appropriate and adequate accommodations for core work programs, changing requirements of the various lines of business and/or the operation and security of network equipment.

In addition, Facilities and Real Estate maintains buildings and related site infrastructure that exclusively houses transmission network equipment ("Network Buildings"). The objective is to provide for the ongoing operation and security of the network equipment.

Asset Condition / Demographics

Hydro One Facilities and Real Estate manages 323 transmission sites which contain approximately 994 buildings, comprising both Facilities and Network Buildings. All of these transmission Facilities are owned by Hydro One. In addition, there are 132

Facilities independent of transmission sites containing 397 buildings, where 288 buildings are Hydro One owned on 89 sites and 109 buildings are leased on 43 sites.
The assessment of Facilities and Network Buildings is an ongoing process. The focus to date has been on field assessments of roof and HVAC systems, which are considered critical to operations. These field assessments are used to establish condition profiles to prioritize and plan work.

Facilities are comprised of multiple buildings and are distributed to align with the configuration and demands of the network and customers as well as the diverse operational requirements of the various lines of business. Largely historically based, network additions, end of life conditions, performance and market conditions dictate periodic readjustment.

The average age of the Facilities and Network Buildings across the province is approximately 50 years old supporting the need to closely manage and maintain them through planned condition assessment.

Approximately one third of the Facilities supporting the transmission work program are located within transmission sites. These facilities are often configured in a co-occupancy arrangement with network equipment as originally planned or through repurposing of space (e.g. conversion of control rooms).

Given that most Network Buildings are over 50 years old, their configuration, design and layout are dated and they do not necessarily meet present day standards. Building condition assessments of all Facilities are ongoing. To date, assessments have been completed for approximately 70% of the Facilities. Condition assessments account for a range of factors, including environmental issues such as mould or water treatment upgrades, adequacy for work program and space demands, and security and safety concerns for employees and first responders. These assessments have identified that approximately 25% of the buildings are in very poor and poor condition. Without capital investment, it is estimated that more than half of the Facilities will be assessed as being in very poor and poor condition by 2024.

Future Outlook / Need

Facilities requirements are based on operational needs at each site while ensuring health and safety standards are maintained. Older and re-purposed buildings/sites are assessed on a case by case basis and are commonly found to be undersized, ill configured and underperforming to meet current operational requirements in addition to not meeting current building occupancy standards and regulations. These conditions contribute to inefficiencies to business operations and elevated health and safety risks in conjunction with increasing maintenance and repair costs associated with aging assets.

The need to refresh these aging assets considers various alternatives, that include replacement or renovation, but with the overarching objective of consolidating Facilities to reduce cost.

To address the estimated deterioration of Hydro One's Facilities and Network Buildings, approximately $15 million per year in capital investment is required to keep the majority of these structures in good and fair condition while carefully maintaining the ones in poor condition.

2.2.3.2 TRANSPORT & WORK EQUIPMENT

Hydro One Fleet Management Services provides centralized and turnkey services that include equipment acquisition, maintenance, administration, vehicle replacement and final disposition of Hydro One's Transport and Work Equipment ("TWE").

Fleet vehicles support various lines of business ("LOB"), including Distribution Lines, Stations, Forestry, and Construction Services. Fleet vehicles must be adequately maintained to ensure public safety, employee safety, compliance with laws and regulations (including CSA 225, the *Highway Traffic Act* and the Commercial Vehicle Operator's Registration regulations).

Asset Description / Purpose

Hydro One Fleet Management Services controls and manages vehicles and other fleet equipment to support distribution and transmission work programs and staffing requirements. Fleet assets are categorized into 56 classes and 5 large equipment categories as shown in Table 25 below:

Table 25 - Summary of Fleet Vehicles

Large Categories	Equipment Type	LOB Requirement
Light duty	**Cars/SUVs**	Used by all LOBs for employees who drive more than 23,000 km.
	Vans/Pickups	Used by all LOBs to transport tools and crews to work locations and to tow small trailers
Heavy duty Radial Boom Derrick 	**Service Trucks**	Used primarily by Distribution Lines, Forestry, Stations, Construction and Fleet Maintenance to support and service off-road units and work locations
	Highway Tractors	Used primarily by Distribution Lines, Forestry and Construction to tow large equipment and Off-Road units.
	Cranes	Used primarily by Distribution Lines, and Construction for lifting poles and other material.
	Bucket Trucks	Used primarily by Distribution Lines and Forestry to work at heights to complete line maintenance and tree trimming.
	Radial Boom Derricks ("RBD")	Used by Distribution Lines to dig holes and to set poles at road side and for heavy towing.

Off-Road 	**Off Roads**	Used by Distribution Lines, Forestry and Construction to perform the following activities: build roads and right-of-ways, clearing brush, build/maintain lines and act as personnel/material carriers.
Miscellaneous Chipper  Tensioner 	**Boats**	Used primarily by Distribution Lines and Forestry work programs and strategically located around the province to minimize hauling the boats from waterway to waterway to access our isolated customers.
	Trailers	Used by all LOBs and includes boat trailers, office trailers, open-deck trailers, cargo trailers, pole trailers for various business requirements.
	Chippers	Used by Forestry in conjunction with the bucket trucks required for environmental cleanup.
	Manlifts	Used by Stations working within a non-energized environment and by Fleet for working on elevated equipment/aerial devices.
	Forklifts	Used by all LOBs and are required for loading/unloading material at various work sites.
	Tensioners	Used by Distribution Lines and Construction for stringing projects.
Helicopters 	**Helicopter**	Used by Distribution Lines, Forestry and Construction to inspect transmission lines, conduct line maintenance and to transport workers and materials to remote locations.

Asset Condition / Demographics

Hydro One has approximately 7,000 vehicles and other fleet equipment. Table 26 shows the breakdown of the Fleet asset demographics and their current condition. Fleet Management Services and the LOB complete annual asset reviews. Assets are identified for replacement based on their ESL and mileage which are recommended by the manufacturers as a guideline to initially identify vehicles for replacement. Specialized technicians will assess the condition of the asset to determine if the asset can be retained for an additional period of time or if it needs to be replaced.

Table 26 - Average Age and ESL of TWE[1]

Equipment Type	Quantity of TWE Fleet (%)	Average Age (Years)	Average Mileage (kms)	ESL (Years)	ESL (kms)
Light	37.8%	4	108,000	6	180,000
Heavy	19.5%	7	127,000	8-14	300,000-400,000
Off-Road	6.6%	8	N/A	individual asset assessment	
Miscellaneous	36.1%	8	N/A	individual asset assessment	
Helicopters	0.1%	15	N/A	individual asset assessment	

[1] Data from December 31, 2018

<u>Condition</u>

Hydro One specialized technicians monitor and asses the condition of the transport and work equipment during inspections and routine maintenance. Adequate maintenance and service intervals help to reduce degradation of the equipment and maximize the life of the asset. The condition of the assets, along with the age and kilometres driven/hours used, determine the need for replacement and any risks that need to be mitigated.

Future Outlook / Need

Fleet requirements for asset replacement are primarily based on industry standards or manufacturers' recommendations for life cycle expectancy. This includes age and kilometres driven as well as the overall condition of the asset. The objective is optimal operating cost management, maximum LOB productivity and reduced environmental impacts by minimizing downtime and travel time and by leveraging technology with continuous improvement opportunities.

Fleet Electrification

In an effort to reduce Hydro One's carbon footprint, Fleet Management Services is analyzing the benefits of electric vehicles that would be suitable for the Company's needs in relation to the Hydro One service area geography, weather conditions and work execution requirements. In this regard, Hydro One has tested and purchased a new Chevrolet Bolt EV and Chevrolet Volt EV in 2018 for long term evaluation and will be introducing a new Altec JEMS 55-ft bucket truck and a Altec JEMS 48-ft bucket truck into the Fleet equipped with a fully Electric Power Take Off (PTO).

Fleet Management Services is continuing to work with the Corporate Strategy Team on new Fleet Electrification opportunities as the industry evolves (Hybrid/PHEV/EV). A cost benefit analysis is being completed to determine feasibility of implementation of this technology into Hydro One's Fleet.

2.2.3.3 INFORMATION TECHNOLOGY

Asset Description / Purpose

Information Technology ("IT") refers to computer systems (hardware, software and applications), enterprise data storage and processing systems, and voice communication systems that support grid and administrative operations. The reliability of these systems is critical as they must always be available to customers and to the employees delivering Hydro One's business services.

Hydro One currently manages approximately $150 million in IT assets and uses approximately 800 business software applications. IT assets include:

- Enterprise Resource Planning ("ERP") systems that provide the tools to seamlessly manage administration across multiple lines of business.
- Work Management Systems that enable timely connection of customers and effective operations through scheduled plant maintenance or storm restoration activities.
- Minor Fixed Assets ("MFA") that include desktops, laptops, printers, plotters, rugged tablets and mobile devices which are used to provide the information and capability of Hydro One's enterprise systems to employees.
- Telecommunication infrastructure that includes hardware equipment and software for Hydro One's network and telecommunication needs.

Asset Condition / Demographics

Demographics

The replacement of aging hardware is based on technical obsolescence and the nature of the applications running on the hardware. IT MFA is broken down into the categories shown in Table 27 below with corresponding quantities and projections.

Table 27 - IT Minor Fixed Assets

Description	Quantity	Average Age (Years)	End of Support (Years)	Number of Units Currently beyond End of Support
Enterprise Servers	489	4.0	5	431
Desktop Computers	1727	3.4	4	1407
Laptop Computers	5829	2.8	4	1161
Tablets	1408	2.5	5	326
Printers and Plotters	1165	5.5	5	652
Volume of Enterprise Data Storage (TB)	2418	2.6	5	0

Investment in MFA Enterprise Servers and Storage is required to respond to and manage annual growth in demand for additional IT processing and storage capacity and to address servers approaching End of Support.

As detailed in Table 27, approximately 37.5%[12] of Hydro One's IT MFA is currently at End of Support. The condition and required replacement of these assets is described below.

Condition

Hydro One manages the condition of its IT hardware by managing assets through a lifecycle management program. The primary factor that drives the program is the vendor warranty period. All assets are managed under a standard warranty and vendor support period of three to five years to ensure hardware currency and supportability. Once the asset age exceeds the vendor support period of three to five years, the asset is deemed to have reached End of Support. It is at this point in time that the asset is either placed under extended maintenance with the vendor or flagged for replacement.

The replacement timeline and approach is consistent with industry standards, as outlined by leading technology analytics organizations, including Gartner[13]. Warranty periods and hardware obsolescence reports are actively managed and reviewed to drive the refresh of assets nearing End of Support, thereby ensuring the reliability and performance of IT assets.

---

[12] Excludes Volume of Enterprise Data Storage as the unit of measure is terabytes ("TB").
[13] Leslie Fiering, *PC Hardware Replacement Strategies: Planning Considerations* (Gartner, 2012).

Performance

When an application is placed into service, it is assigned a Support Level ("SL") designation. The SL contains a set of characteristics and performance expectations that determine the standards to which each application will subsequently be maintained to achieve a desired system availability. In 2017 actual availability exceeded expected levels as shown in Table 28 below.

Table 28 - Uptime Expectations by IT Support Level

Support Level	Expected System Availability	Minimum System Availability	2017Actual System Availability	Hours of Operation
SL-1	99.91%	99.53%	99.99%	7x24x365
SL-2	97.30%	95.25%	100.0%	7x24x365
SL-3	99.55%*	97.15%*	100.0%	Mon. - Fri. x Business Hours x 6:00 – 18:00

** Higher than SL-2 as Hours of Operation are Business Hours only. No single outage of a SL-1 or SL-2 Application shall exceed thirty cumulative minutes during any measurement window.*

In addition to vendor warranty and support, business requirements, employee productivity, and system health and performance are contributing factors when determining the need and rate of the replacement of IT assets, the latter of which is managed through software management and monitoring tools. It is the consideration of these factors that drive the lifecycle management of our IT assets.

Future Outlook / Need

Hydro One will continue to target a 99.5% uptime of key systems and associated data (SL-1) for customer service programs and work management programs linked to Hydro One Customer satisfaction goals/KPIs which are discussed further in TSP Section 1.5.

IT infrastructure needs will continue to be assessed to support and improve the cyber security posture of the company's assets based on the mandatory NERC version 5 and 6 standards. Where feasible, new technologies such as cloud computing solutions that eliminate server investments, will be adopted to lower IT costs.

Investment in MFA will continue as they reach the End of Support period to address warranty considerations, maintain hardware reliability and to meet business performance needs.

2.3 (5.3.3) ASSET LIFECYCLE OPTIMIZATION POLICIES AND PRACTICES

Introduction

Lifecycle costs of transmission assets are the total costs of an asset throughout its useful life. The total costs are determined by using a corporate financial evaluation model that identifies the most cost-effective lifecycle management approach. This approach maximizes benefits to Hydro One and its customers during the asset service life, while balancing asset performance (including physical condition) and risks to Hydro One's business objectives.[1]

Based on this identified lifecycle management approach, Hydro One's lifecycle optimization policy describes various processes, procedures, and decision-making points relating to the management of transmission assets (e.g. planning, procurement, maintenance). Hydro One strives to ensure that all relevant processes and procedures are aligned with its optimization policy so that transmission assets are managed using a consistent approach.

Asset-specific strategies for transmission assets are based on the lifecycle approach. These strategies are meant to represent the operationalization of the asset lifecycle policy. Lifecycle strategies for assets such as stations equipment and lines include the following, but are not limited to:

- replacement approach and criteria (based on demand or planned replacement, conditions, technical obsolescence, environmental and other factors);
- approach to optimize repair/refurbishment versus replacement;
- maintenance criteria (e.g. preventive, corrective, time-based, condition-based, predictive; regulatory);

[1] See Section 2.1.2.1 of the TSP

- tools and training requirements;
- operational criteria and constraints that can impact asset life;
- spare parts requirements (entire units or specific components); and
- consideration for standardization of assets to optimize lifecycle costs and improve productivity.

Asset-specific strategies are reviewed periodically with the subject matter experts and updated on an ongoing basis, as needed. The lifecycle management strategy for each asset class must be considered from an overall power system perspective and cannot be considered in isolation. The strategy includes an evaluation of the failure modes, causes of individual component failures, consequences of asset failure, impacts on system performance and other corporate strategic objectives, such as environment, health and safety.

Asset information, which includes condition information, is periodically reviewed by subject matter experts to ensure quality and accuracy of the data, which in turn is used for the refinement and further development of the asset-specific strategies. As part of such review, subject matter experts may determine that some assets may require replacement due to new or increased demands on the system (such as higher load growth or increased generation connections) introduced partway through the lifecycle of the asset. For example, if a customer requests a larger capacity transformer due to their forecasted load growth, Hydro One will accommodate the request and the customer will be required to pay a capital contribution. In accordance with Section 6.3 of the Transmission System Code, the capital contribution will cover the difference in costs between the standard transformer that Hydro One would plan to install when the existing transformer reached its end of life, and the larger capacity transformer required to satisfy the customer request for incremental capacity. Asset utilization may be another factor used to evaluate asset replacement. For transformers, asset utilization takes into account the peak loading of the transformer compared to the transformer's capacity. There are circumstances where a transformer can be operated above its designed ratings or beyond its limited time rating for a period of time. If these situations result in operating constraints, the unit may be considered as a candidate for replacement.

Hydro One will also review the asset's historical loading and may decide to address the system's need with a like-for-like replacement or to install a new standard asset.

Typically, Hydro One replaces assets on a like-for-like basis. With respect to transformers, as an example, Hydro One considers the following factors before the decision to replace is made:

- any customer requests;
- the option of utilizing a different type and size of transformer to standardize the fleet which would reduce the number of operating spares required, while considering the implication of losses; and
- reconfiguring the station from a non-standard four transformer layout to a two-transformer layout to reduce asset count and footprint and increase operational efficiency.

Asset-specific strategies have been summarized in Table 1 below with references to the relevant sections in this Exhibit that outline their application.

Table 1 - Asset Strategy Summary

Section	Component	Asset Strategy
2.3.1.1	Transformers	Hydro One proactively inspects and monitors the transformer fleet to manage maintenance, monitor deterioration, remediate deficiencies and assess condition to determine the need for asset refurbishment or replacement on an individual basis. Asset assessment is based on risks inferred from demographics, condition, environmental settings, utilization, costs comparison between repair and replacement, and other lifecycle considerations.
2.3.1.2	Breakers	Hydro One performs routine maintenance and replaces breakers that are obsolete, pose safety risks, operate at or above their nameplate rating, exhibit unacceptable level of reliability performance, or have a poor environmental footprint in order to proactively address and prevent failure modes that could lead to outages.
2.3.1.3	Protection	Hydro One strives to maintain system reliability by ensuring the correct protective operation is initiated to isolate a faulted asset from the system. Hydro One performs preventive and corrective maintenance to ensure acceptable performance, maintain compliance, monitor deterioration and remediate deficiencies whenever technically and economically feasible.
2.3.1.4	Automation	Hydro One strives to ensure reliable functionality between its Control Centre and transmission assets by managing legacy obsolescence through timely replacement. As legacy automation equipment is replaced, it increases the standardization of asset and reduces corrective maintenance costs.
2.3.1.5	Power System Telecom	To ensure robust and reliable telecommunications for the protection, control and operation of the transmission system, Hydro One maintains and replaces power system telecom assets that pose a risk to reliability, safety or the environment.

Section	Component	Asset Strategy
2.3.1.6	Other Station Assets	Hydro One proactively manages assets through inspections and routine maintenance and monitors the fleet's condition to ensure compliance with regulatory bodies such as NERC, NPCC and the Ministry of Environment, Conservation and Parks. Repair vs. replacement assessments are done on an individual basis and are based on the risks that might arise from a demographic, condition, environmental, utilization, economic, and customer perspective. Such assessment balances the asset needs and risks as well as costs of the overall fleet.
2.3.2.1	Overhead Conductor	Hydro One manages the conductor population in a manner that maintains reliability and limits safety risk to acceptable levels. When a conductor, based on its condition as confirmed by testing, has been determined to have reached end of life, replacement is the only solution.
2.3.2.2	Underground Cables	Hydro One performs rigorous condition assessment and maintenance to maximize cable service life and replacing cables at end of life (EOL) where maintenance (repair) is no longer practical.
2.3.2.3	Steel Structures	Hydro One manages the fleet through a combination of planned structure replacements, component refurbishments and tower coating in order to maintain the reliability of the system and decrease the lifecycle costs.
2.3.2.3	Wood Pole Structures	Hydro One proactively replaces wood poles that are in poor condition, so as to reduce failures that impact customer reliability and safety, and to minimize emergency response activities. Hydro One uses a condition-based asset management strategy to sustain its wood pole fleet. Hydro One uses age of the wood pole as a criterion to identify the candidates for further assessment.
2.3.2.4	Insulators	Hydro One's primary focus is on the replacement of defective porcelain insulators that pose a high-risk to public safety, and end of life polymer insulators.
2.3.2.5	Rights of Way ("ROW")	Hydro One performs vegetation management on a cyclical basis. This asset strategy ensures all ROWs are regularly cleared to respect the applicable design width and to only contain compatible vegetation

Section	Component	Asset Strategy
2.3.2.6	Shieldwire	The asset strategy for shieldwire is to maintain system reliability and public and employee safety by replacing all shieldwire assessed to be at the end of useful service life.
2.3.2.7	Other Line Components	The asset strategy for other line components is to perform preventive maintenance and condition assessments along overhead transmission lines to identify defective equipment and components prior to failure. Hydro One executes corrective and demand maintenance to repair defective components, including end-of-life U-bolt and other hardware components. This strategy minimizes impact to customers, system reliability and public safety.
2.3.3.1	Facilities and Real Estate	Hydro One maintains facilities that are required for its operations by conducting planned maintenance of key facility systems and infrastructure. Hydro One undertakes regular inspections to identify any issues and undertake corrective maintenance where required. Hydro One conducts annual assessments to confirm facility requirements and, as necessary, complete renovations, additions, or replacements for new requirements and/or end of life condition.
2.3.3.2	Transport and Work Equipment (Fleet)	Hydro One strives to provide reliable equipment to employees so as to ensure the delivery of safe and economical services. Fleet Management Services and the Transmission and Stations line of business (“LOB”) complete a yearly review of all fleet and equipment that have met replacement factors against future work programs and staff needs.

Section	Component	Asset Strategy
2.3.3.3	Information Technology	Hydro One's strategy is to adhere to the IT industry standard practice. It includes managing hardware assets through a life cycle program ensuring vendor support is available and decreasing the likelihood of failure. Investment decisions are based on software life cycles, vendor schedules, reliability requirements, customer requirements, and experience with similar equipment. Hydro One replaces or upgrades applications where required to ensure continued vendor support and compatibility with the current IT environment. The primary goal is to minimize business interruptions. Investment decisions are based on return on investments calculations which reflect savings and constraints of software life cycles, vendor schedules and, reliability requirements.

2.3.1 (5.3.3 A, B) ASSET LIFECYCLE OPTIMIZATION POLICIES AND PRACTICES – TRANSMISSION STATIONS

This section discusses the lifecycle optimization policies and practices for assets that are found in transmission stations, which includes transformers, breakers, protection schemes, control and monitoring equipment, power system telecom equipment, switches, capacitor banks, instrument transformers, ancillary equipment and civil structures.

2.3.1.1 TRANSFORMERS

Hydro One performs both Preventive Maintenance and Corrective Maintenance activities to proactively verify condition, monitor deterioration, and remediate deficiencies of its transformer fleet when it is technically feasible and economical.

Asset Strategy

Hydro One's asset strategy is to proactively inspect and monitor the transformer fleet. This allows the Company to manage maintenance needs and assess the transformer's condition as a factor to determine the need for asset refurbishment. Assessments to repair or replace transformers are done on an individual basis. The assessment is based on risks identified from condition, performance, utilization, demographics, criticality and environmental factors as well as cost comparison between refurbishment and replacement, and any other lifecycle considerations. Units in poor condition, with known manufacturing defects/obsolescence, or with anticipated higher repair costs, are prioritized for replacement.

Transformers that do not meet criteria for replacement within the next five years, particularly those that have reported severe oil leaks, or those with proven PCB concerns, will be prioritized for refurbishment. Hydro One's annual oil leak refurbishment rate averages about 1% to 1.5% of its transformer fleet. The refurbishment rate is subject to pacing of capital investment and the rate of leak development considerations.

Testing & Maintenance Practices

Preventive Maintenance

Preventive Maintenance consists of time-based activities that are in the manufacturer's manual, industry technical reports and Hydro One's operating experience. Asset condition information collected during maintenance enables further analysis for assessing corrective work requirements and adjusting future maintenance needs. Based on the condition information collected, Hydro One implements condition-based preventive maintenance strategies in parallel with its time-based maintenance to mitigate known risks that can be reasonably expected to materialize in the future. For example, tap changer internal inspections are primarily initiated from counter readings, which are collected from Hydro One's time-based station inspection. Hydro One believes that the changes to maintenance work from transitioning to increased online monitoring activities will be beneficial in the future, once Hydro One completes its full assessment.

Hydro One performs the following Preventive Maintenance activities with respect to transformers:

Table 2 - Transformer Testing and Maintenance Summary

Maintenance	Frequency	Description
Visual Testing	Bi-annual	Visual and audible deficiency inspection.
Oil Testing	6 months - Annual	Analysis of dissolved gas ("DGA") and oil quality to evaluate transformer condition.
Diagnostic Level 1	4 years	Function testing of transformer sub-components to verify correct operation.
Diagnostic Level 2	8 years	Replacement of the Gas Accumulation Relay and associated cable.
Power Factor Test (Doble Test)	8 years	Assessment of the transformer and the insulating condition of its bushings.
Selective Intrusive (SI) Inspection	4-8 years	Condition inspection of all internal components, contacts and mechanisms.
Oil Filter Change	2 years	Replacement of the under-load tap changer filter.

In addition to routine preventive maintenance, Hydro One also performs special diagnostic tests as required for troubleshooting purposes. These tests include:

- Transformer Turn Ratio Test - This test confirms that the transformer has the correct ratio of primary turns to secondary turns. This test can help to identify tap changer performance concerns, shorted turns, open windings, incorrect winding connections and other faults inside the transformer.
- Transformer Winding Resistance Test - This test measures the resistance of the winding to verify that connections are correct. This test is commonly used to identify tap changer performance concerns and detect any poor or open connections.

Corrective Maintenance

Hydro One performs Corrective Maintenance to remediate defects reported during routine inspection and testing. Hydro One remediates defects on a timely basis provided that the remediation is feasible, will preserve the life of the asset, and provides assurance that the asset will continue to economically meet existing operating requirements. If remediation or repair is not feasible, Hydro One will assess the need for demand replacement.

Hydro One has the following three kinds of commonly performed corrective maintenance activities:

- Oil Leak Repair

Natural gasket deterioration over time will cause oil to leak from the transformer. Oil leaks create environmental concerns (leading to potentially costly remediation and repairs) and can negatively impact reliability. Oil leak reduction requires case by case scoping to target leaking areas. Typical work scopes include oil handling, gasket replacement, gas relay piping upgrade, pump overhauls and radiator valve re-packing.

- Tap Changer Troubleshooting

A tap changer is a mechanical device that is an integral part of modern power transformer to provide voltage regulation in response to loading changes throughout the day. Tap changers can experience a wide range of mechanical and operational problems including tap changer being out-of-step, tap changer lockout, mechanical fatigue on motor drive parts, and deficiencies with current carrying parts. These deficiencies will impair the normal voltage regulation functionality that the tap changer provides. Maintenance and inspection intervals are determined by manufacturer's recommendations, and equipment specific performance determined by time in-service and operation count. Tap changer repair work may include anything from cleaning the control relay contact to removal and overhaul of the entire assembly.

- Cooling Failure Troubleshooting

Transformers rely on cooling fans and pumps to provide necessary cooling in order to achieve a higher loading limit, up to its full nameplate MVA rated cooled operation. A non-functional cooling system will force the transformer to operate at reduced loading capacity. Subject to the load transfer capability and loading profile of individual stations, operating a transformer at reduced capacity risks the station's ability to meet customer load demand. Typical remediation includes contact cleaning, replacing individual fans or even complete banks of fans.

Outlook Implementation

Hydro One continues to enhance its practice for maintenance and monitoring of transformer assets to ensure that the best industry practices are employed. Over the next 10 years, Hydro One plans to adopt the following measures to enhance its maintenance and monitoring activities for transformer assets:

Greater Use of Online Monitoring Systems:

Traditional transformer maintenance involves sampling transformer insulating oil on a periodic basis, usually from 6 months to 1 year intervals. Online Dissolved Gas Analysis ("DGA") monitoring devices can withdraw and analyse oil samples several times per day and provide real-time warnings to prevent transformer failure. Such devices are installed close to the main transformer units and are capable of withdrawing and analyzing oil samples from the main tank via installed piping at regular interval. Some include internal temperature monitors on transformers that provide real time loading feedback as well as utilization history. Due to cost and reliability concerns, Hydro One has only used online DGA devices on mission-critical units, which require special monitoring due to suspected defects, or units with very high replacement costs. Over the past decade, the accuracy, reliability and capability of these monitoring devices have improved and their cost has come down. Hydro One has a dedicated program to install and upgrade online DGA devices on larger power transformers and critical units, while online partial discharge monitors that detect abnormal electrical discharges are also being evaluated and considered.

Condition Based Maintenance Approach

Traditional preventive maintenance practices are largely time based. This includes the collection of condition and utilization data. As more data becomes available through online monitoring devices, Hydro One can adjust its maintenance plans to focus the required condition-triggered maintenance, while alleviating the need of time-based maintenance. Some tap changers are also equipped with fibre-optic monitors which can supervise the safe switching of the tap changer and provide leading condition indicators for any further inspections and maintenance.

Oil Leak Repair Sealant

Traditional transformer oil leak repairs are invasive, costly and lengthy. Hydro One has been evaluating and implementing the use of a sealant that can be injected between gaskets as an oil leak repair alternative, in cases where it is feasible and cost effective compared to traditional oil leak repair approaches. This method of repair can help avoid costly and time-consuming procedures related to oil processing during transformer repair.

2.3.1.2 CIRCUIT BREAKERS

Breaker testing is conducted to ensure the proper mechanical operation and electrical integrity of Hydro One's breaker fleet, in order to mitigate the possibility of a breaker's failure to interrupt fault current when called upon.

Asset Strategy

Hydro One performs routine maintenance and replaces breakers that are obsolete, pose safety risks, operate at or above their nameplate rating, exhibit unacceptable level of reliability performance, or have a poor environmental footprint (e.g., leaking Sulphur Hexafluoride ("SF6") or containing PCB levels in excess of regulatory criteria). Maintenance tasks facilitate the collection of diagnostic information on breakers to assess their health and need for overhaul or replacement. In addition, maintenance packages include tasks to proactively address and prevent failure modes that could lead to outages.

Testing & Maintenance Practices

Hydro One's maintenance practices are informed by manufacturers' maintenance manuals, industry technical reports and the Company's maintenance experience. The following maintenance packages are generally applied to circuit breakers:

Table 3 - Breaker Testing & Maintenance Summary

Maintenance	Frequency	Description
Visual Inspection	Bi-annual	Visual and audible inspection of external and ancillary components
Diagnostic Testing	6-7 years	Function testing to assess the breaker performance
Selective Intrusive (SI) Inspection	12-14 years,	Internal inspection, cleaning and replacement of worn components

Maintenance	Frequency	Description
Oil Analysis	1-3 years	Analysis of oil samples to assess the condition of an oil breaker's internal components
Power Factor Test	12-14 years	Condition assessment of live tank and oil breaker insulating components
Moisture Content Test	Bi-annual	Assess and manage moisture content within air blast breakers and some SF6 breakers.
Maintenance Level 1	3 years	Assess the performance and condition of pneumatic systems and comply with the Technical Standards & Safety Authority's requirements

Replacing breakers that are based on obsolete technology eliminates maintenance activities that are no longer required for modern breakers. Examples include the elimination of air blast breakers and the replacement of pneumatic mechanisms with simpler mechanisms.

Where spare parts are difficult to obtain or are no longer commercially available, sustainment of associated breaker fleets will be achieved by harvesting subcomponents from decommissioned units until the remaining fleet can be replaced. Where breakers exhibit unacceptable performance that cannot be resolved with a reasonable level of maintenance, these breakers will be targeted for replacement.

Bushings from oil circuit breakers need to undergo oil retro-fill or replacement in order to satisfy federal PCB regulatory requirements[2] by 2025 for equipment containing concentrations of PCB greater than 50 parts per million ("ppm"). All transmission station oil-filled equipment manufactured prior to 1985 must be sampled by the end of 2020, so that the PCB contained in such equipment can be removed or retro-filled to less than 45 ppm[3] by the end of 2024. The aforementioned timeline has been adopted by Hydro One

[2] Canadian Environmental Protection Act, 1999 - PCB Regulations SOR/2008-273.
[3] The 45 ppm criteria was established by Hydro One to account for any uncertainties in measurement and to ensure the federal criteria of 50 ppm is met with a high confidence level

to allow for a one-year buffer period, during which any issues that might arise can be rectified before the Environment Canada deadline of December 31, 2025.

Outlook Implementation

Hydro One's plan prioritizes breaker replacements based on obsolescence, vendor support availability, poor performance, environmental footprint, system criticality and safety risk.

To assess the changes in short circuit levels due to system upgrades and new or modified customer connection facilities, Hydro One performs project-specific short circuit studies to evaluate the increase in short circuit levels and identifies any required breaker upgrades as part of the Independent Electricity System Operator ("IESO") Connection Assessment and Approval ("CAA") process. Where short circuit level is exceeded, breakers need to be upgraded to higher short circuit rating, since operating beyond the nameplate rating can cause the breaker to fail.

SF6 is a colourless gas and conventional leak detection methods require the power equipment to be taken out of service, followed by the use of soap or bags placed over the suspected leak to look for bubbling from the leak, which can take many hours or days. Hydro One is exploring technologies to resolve SF6 leaks, such as the use of SF6 cameras to detect leaks prior to taking breakers out of service. This may lead to reduced outage times and improved work planning.

Alternatives to O-ring replacements are being explored in order to reduce outage times, repair costs and minimize poor performance until the asset can be retired. Deteriorated O-rings can cause leaks of the insulating medium and possible ingress of moisture, leading to a degradation of dielectric properties. If determined to be feasible, alternatives to O-ring replacement, such as sealant injection, may allow for shorter repairs that are less labour intensive in nature.

First trip testers are being explored as a diagnostic tool to detect intermittent mechanical issues without removing breakers from service. The device can assist in diagnosing if breaker operating time is beyond applicable limits due to issues with the trip/close coil or main mechanism. It can also help detect the condition of the DC supply and the existence of any sticky or faulty circuit breaker auxiliary contacts.

A non-operational data network is being established to collect and store data that is not required for day to day operations, such as diagnostic information. By facilitating the collection of such maintenance data, the operational data network would support more informed condition-based maintenance decisions. For more details on this investment, refer to ISD GP-05 - *Transmission Non-Operational Data Management System*.

Hydro One is exploring the use of online monitoring on circuit breakers using dedicated electronic devices to collect breaker performance information automatically and more frequently. These monitors would reduce the need for manual condition assessments and support greater use of condition-based maintenance rather than time-based maintenance.

2.3.1.3 PROTECTION

Protective relays and associated systems are critical in sensing and responding to abnormal system conditions. These devices protect local supply as well as supply within Ontario's Bulk Electric System ("BES") and mitigate the potential impact of abnormal conditions to the rest of the interconnected grid.

Asset Strategy

Hydro One's strategy for protection relays and protection schemes is to maintain system reliability by ensuring the correct protective operation is initiated to isolate a faulted asset from the system. To this end, Hydro One performs both preventive and corrective maintenance to ensure acceptable performance, monitors deterioration and remediates deficiencies whenever technically and economically feasible. The type and frequency of maintenance often depend on the type of protection system, the type of power system asset being protected, and the criticality of that asset. A number of North American Electric Reliability ("NERC") and Northeast Power Coordinating Council ("NPCC") standards govern the protection system maintenance program, including:

- PRC-004 *Protection System Misoperation Identification and Correction* – Purpose of this standard is to identify and correct the causes of protection system misoperations for BES elements.
- PRC-005 *Transmission and Generation Protection System Maintenance and Testing* - Purpose of this standard is to document and implement programs for the maintenance of all protection systems affecting the reliability of the BES so that they are kept in proper working order.
- PRC-012 *Remedial Action Schemes* - Purpose of this standard is to ensure that Remedial Action Schemes do not introduce unintentional or unacceptable reliability risks to the BES.
- NPCC Regional Reliability Reference Directory # 4 – *System Protection Criteria* – This document provides the design criteria for bulk power system protection within the service territories of NPCC member organizations.
- NPCC Regional Reliability Reference Directory # 7 - *Special Protection Systems* - This document provides the basic criteria for Special Protection Systems to ensure the reliable operations of the bulk power system.
- NPCC Regional Reliability Reference Directory # 8 - *System Restoration* - This document sets out the requirements for performing bulk power system restoration.

One of the greatest sustainment challenges for protection systems is the short vendor support time. Reduced duration of vendor support has significant adverse impact in terms of asset lifecycle management. For example:

- In 2013, one of the leading relay suppliers issued end of life notices for its Intelligent Electronic Devices ("IED"), also known as microprocessor based relays, with firmware which were up to 15 years old at that time. This only allowed Hydro One 6 months to procure any spare units that might have been available.

- Certain cyber-security related firmware features lost vendor support when the age of the firmware reached or just exceeded 10 years. To ensure compliance with cyber security standards, Hydro One had to replace the firmware before it reached Expected Service Life ("ESL").
- Lack of parts due to short support windows renders defects irreparable and forces the replacement decisions to be made before the end of the 20 year ESL.

The duration of vendor support continues to trend lower, which is largely driven by their own parts sourcing issues, faster technology changes as well as functional advances that manufacturers make for competitiveness. This problem is further complicated with ongoing changes to network connection standards that limit like-for-like replacements. A consequence of this problem is that some large North American utilities are already considering a shorter ESL for IEDs with typical values ranging from 15 to 20 years. Some utilities have gone further to announce the expected adoption of even shorter lifecycles.

Hydro One has decided to manage this issue rather than simply accept the downward trend. In this regard, as part of the procurement process, Hydro One is working with suppliers to gain extended support for their products so as to ensure the viability of its strategy to maintain ESL at 20 years. Given that the asset age versus ESL ratio is one input into the replacement decision, every year of ESL gained represents a better probability for the reduction or deferral of planned capital investments.

With respect to protection replacements, Hydro One's strategy is to target protections with a high likelihood of failure. Since the condition of this class of asset cannot easily be monitored, other factors are used as triggers for replacement decision, including:

increased failure rates related to specific models or families of devices, limited or non-existent manufacturer support (i.e. in terms of the provision of spare parts and repair services), and the inability to comply with current reliability standards.

Testing & Maintenance Practices

Preventive Maintenance

Preventive Maintenance involves time based routine testing or re-verification of protection systems. Protection systems spend most of their service life in a dormant state, yet must be relied upon to perform flawlessly during a fault or other abnormal system condition. Routine testing is the only means to maintain a high degree of certainty that the system will operate correctly when called upon.

The testing frequency of protection systems that are part of the BES is governed by applicable mandatory NERC standards.[4] For the remainder of its protection systems, Hydro One follows internal policies in accordance with good utility practice. Where a new microprocessor-based relay is installed, its self-monitoring capabilities allow the maintenance interval to be extended, which is also reflected in NERC standards.

In the past, Hydro One employed similar maintenance planning criteria for all protection systems, regardless of whether their maintenance was required by the applicable NERC standards. Additionally, Hydro One has adopted more aggressive maintenance frequencies than what NERC prescribes. This was done to mitigate the risk of non-compliance by providing some buffer to account for cases where regulatory maintenance cannot be performed on time due to operational and other reasons. Historically, the maintenance plans were aligned with maintenance cycles under an initiative where maintenance was performed on defined groups of equipment with the intent to mitigate

---

[4] See: PRC-005- Transmission and Generation Protection System Maintenance and Testing and PRC-012 Remedial Action Schemes

customer outage impact. The alignment of protection maintenance was reviewed to achieve more cost-effective delivery of the maintenance program. Table 4 below summarizes the preventive maintenance schedules for protection systems.

Table 4 - Preventive Maintenance Intervals

	Regulatory Maintenance (Required by NERC or NPCC)[5]			**Timed Maintenance[6]**	
	Hydro One Maintenance Cycle (Years)		**Maximum Allowed Cycle by NERC**	**Non-Regulatory Maintenance**	
	Historical	**From 2019**		**Historical**	**From 2019**
Microprocessor Relays (non-feeder)	8	10	12	8	12
Electromechanical and solid state (non-feeder)	4	5	6	8	12
Microprocessor Relays (feeder) [7]	N/A	N/A	N/A	8	12
Electromechanical and solid state (feeder)	N/A	N/A	N/A	8	8
Breaker Trip Coil Tests (BTCT)[8]	4	4	6	N/A	N/A
Zone Test Tripping (ZTT)	4	8	12	8	8
ST3 - NPCC Directory #8[8]	5	5	5	N/A	N/A
Property Visual Inspection (PVI)[9]	N/A	N/A	N/A	3 or 8	3 or 8
Special Protection Transfer Tripping (SPTT)[8]	4	4	6	N/A	N/A

[5] Regulatory maintenance is performed on a subset of Hydro One protection system assets (approximately 40%) that are part of the BES system
[6] Timed maintenance covers maintenance of protections assets not included in BES system
[7] Maintenance of Hydro One's feeder protections is not required by NERC standards
[8] Tests performed on BES assets only
[9] No regulatory requirements for visual inspections to be performed. Interval of 3 or 8 years is selected based on the history of silver migration issues at a specific station.

Corrective Maintenance

Given the unplanned nature of failures or defects, there is variability as to the number and severity of corrective maintenance activities performed every year and these can be further split into the following two distinct groups: Emergency and Planned. Emergency corrective maintenance cannot be planned and involves remedying issues that occur during normal, everyday operations. Planned corrective maintenance proactively addresses known issues with certain makes and models of protection relays/systems, discovered from analysis of events, which may have an impact on other installations depending on the issue.

Support Processes and Systems

Hydro One maintains a set of support processes and systems for protection equipment. The support systems are in place to manage change control of the settings and configuration of protection and control systems, keep records of events, as well as manage the inventory and the re-seal schedule for revenue meters. Additionally, any protection operation requires field staff to validate and gather event records required for Natural Occurring Event Analysis (NOEA) investigations, which are mandated by NERC standard PRC-006 to determine whether the protection system performed as designed. When corrective maintenance involves a problem that exists in other locations, a program is created to remedy the deficiencies in all identified locations.

Outlook Implementation

In the past, electromechanical devices on Hydro One’s transmission network typically operate between 40-60 years before needing replacement. The ESL of modern microprocessor protection relays has been estimated at 20 years and an increase in failures is expected after that time. Systemic failures across whole platforms of protection relays have triggered a substantial increase in corrective maintenance and, in many cases, the need for large scale component replacements.

Given the demographics of Hydro One's protection system fleet and the condition trends and risks associated with equipment failures, a continued focus on replacement efforts is required to maintain system reliability performance. Modern protections include self-monitoring features which alert control room staff when they fail. The control room can then take appropriate action and dispatch crews to perform repairs. Old style relays, such as electromechanical relays, do not contain these features. Their malfunction can only be detected during routine maintenance or when they fail to perform as designed during system events. Because of this difference, NERC standard PRC-005 allows for an increased period between required testing of modern relays. For example, the PRC-005 maintenance cycle for electromechanical relays (no self-monitoring features) is 6 years; whereas modern microprocessor relays can be maintained once every 12 years, resulting in decreased Operations, Maintenance & Administration ("OM&A") costs associated with preventive maintenance.

Further, there might be other efficiencies to be gained through greater integration and application of new functionalities (i.e., functionalities that were previously built in but not utilized due to a lack of certain required enabling systems). Multiple initiatives, such as Remote Fault Data Collection, IEC 61850 Pilot and Distance to Fault Analysis, have already been rolled out to seize the opportunities that newer technologies are providing. Once fully implemented, these initiatives will allow Hydro One to utilize features already built into the relays to increase the ability to react to system events and/or reduce OM&A costs. For example, for every protection system operation, Hydro One dispatches field staff to download fault data and pass it to engineers for analysis. By being able to remotely access fault data from the IEDs, engineers will be able to obtain this data, thus reducing the cost associated with field staff dispatch.

2.3.1.4 AUTOMATION

Automation assets are highly complex electronic systems which integrate substation and switchyard devices. These systems enable the monitoring and control of power system assets and facilities at all times to achieve safe, reliable and efficient operation of the Ontario transmission grid. They also enable timely responses to emerging problems, real-time condition assessments, expedited restoration activities, and work planning.

Asset Strategy

The asset strategy for automation systems is to ensure reliable functionality of Hydro One's Control Centre such as monitoring and control, and the ability to remotely control and react to adverse power system situations. To ensure reliable functionality, Hydro One plans to manage legacy equipment obsolescence through timely replacement. The primary goal of replacements is to increase standardization across the modern automation system fleet. Moving away from different legacy variations will allow activities to be streamlined from a work management and lifecycle management perspective. Modern automation devices have far more powerful computational capabilities, allowing the consolidation of functionalities that were previously provided by multiple devices.

Through its automation strategy, Hydro One will evaluate changes in design architecture to maximize device functionalities and improve efficiency. Optimization is required as some legacy technologies are discontinued and reliability targets can be met with reduced redundancies or no redundancy in some cases.

As part of its automation asset lifecycle strategy, Hydro One, through the procurement process, will be working with automation product vendors in a similar manner as with protection IED vendors with the goal to avert a further shortening of product support windows.

Testing & Maintenance Practices

Legacy automation equipment requires preventive maintenance, such as replacement of subcomponents, to ensure operational availability. Maintenance is scheduled on a 7-year cycle for subcomponent replacement. In contrast, modern automation equipment requires significantly less maintenance and has embedded self-monitoring capabilities to provide performance alerts.

Corrective maintenance work for automation assets is reactive in nature and involves prioritizing and remedying issues that occur during everyday operations.

Outlook Implementation

With respect to its automation portfolio, Hydro One will focus on resolving known problems associated with the following equipment - RTUs, PSRs, LMCs, and LCCs, as further described below in this section. For example, direct Supervisory Control and Data Acquisition ("SCADA") will be implemented as a way to optimize the SCADA architecture. A new Transmission Non-operational Data Management System will provide a platform to realize efficiencies and cost savings related to maintenance.

Legacy automation systems primarily rely on a remote terminal unit ("RTU"), which is the core of the system. This equipment is based on the concept of physical wiring and digital conversion of electrical signals delivered by wires for SCADA purposes. The RTU equipment is expensive and labour intensive to install, modify and maintain. The equipment is generally built for a single function/application and does not offer much flexibility. From a communications perspective, these legacy systems utilize slow, serial, point-to-point connections and employ a variety of protocols. Failures of RTUs are considered very high risk as they can result in a complete loss of station functionality. Hydro One's goal is to move away from centralized RTU design as the costs are high and it does not offer a path towards substation modernization. RTU life is now being extended as much as possible while new, cost-effective solutions are being researched and developed. The goal is to land on modern I/O solutions with a small form factor, lower cost, and IP-based flexible scalability to match Hydro One's needs. Multiple technologies and standards are being examined as potential means to achieve this productivity and functionality improvement.

Legacy automation equipment contributes to about 80% of total defect costs and is likely to exhibit higher failure rates as the fleet ages and deteriorates, thereby increasing maintenance costs. Data shows that legacy systems are four times more likely than modern control systems to experience defects. Internal components degrade over time, which can adversely impact the performance of the automation equipment. This is primarily a concern with legacy systems along with the lack of vendor support and limited ability to provide replacement components. Hydro One plans to prioritize problematic high-risk installations (i.e., on the basis of statistics relating to failure/defect rates), which should be addressed before planned replacement.

Programmable Synchrocheck Relays (“PSR”) have been in-service for over 30 years. These relays were developed by Ontario Hydro’s research division, have an extremely high failure rate, require specialized expertise and tools to configure and are only single sourced due to their proprietary nature. Modern solutions will be used to replace these devices.

The Local Maintenance Computers (“LMC”) and Local Control Computers (“LCC”) exhibit high maintenance costs and require frequent software patching and updates. Hydro One plans to phase out these computers and replace them with modern solutions. Hydro One expects to minimize life cycle costs and address generic operating system vulnerabilities related to these computers.

Hydro One’s current SCADA network consists of approximately 40 hub sites that are used to facilitate communication of remote stations with control centres. They are no longer necessary as the communication protocols have been consolidated and the ability to communicate directly between a station and control centre now exists. Hydro One will be converting to the Direct SCADA architecture with the intent of removing the hub sites. Implementing Direct SCADA will provide improved reliability, performance, operational visibility and productivity as well as reduced costs and compliance obligations relating to NERC CIP standards since their functionality will be removed.

Hydro One is embarking on an initiative to implement a Transmission Non-Operational Data Management System to decrease costs by reducing maintenance, improve system availability, improve efficiency and automate dispatching of field resources. The system will enable the automatic collection of non-operational data (e.g., not used for day to day operations, but can relate to asset condition) at the substations to be processed in real-time and captured through a centralized enterprise system for further reporting and analytics. A key expected benefit of the system is the support of condition-based maintenance activities. More information can be found in the ISD GP-05 - *Transmission Non-Operational Data Management System*.

As part of its Condition-based Maintenance ("CBM") roadmap, which aims to maximize the number of stations subject to automatically managed CBM, Hydro One aims to implement a Computerized Maintenance Management System ("CMMS") with automated dispatch functionality that would automatically create maintenance work orders and communicate to field crews immediately upon detection of trouble conditions. This is a mature implementation of CBM which is expected to be implemented in future enhancement phases after the deployment of the Transmission Non-Operational Data Management System.

2.3.1.5 POWER SYSTEM TELECOM

Power System Telecom includes communication systems, infrastructure, and leased facilities that enable essential protection, control, monitoring, and operation of the transmission system in Ontario. Hydro One performs both preventive maintenance and corrective maintenance activities to proactively verify functionality, performance, monitor deterioration, and remediate deficiencies of all of Power System Telecom assets and systems to ensure their normal operational status. Hydro One also carries out strategic sparing as part of this essential asset maintenance.

Asset Strategy

Hydro One's asset strategy for Power System Telecom is to provide robust and reliable telecommunications for the protection, control and operation of the transmission system by maintaining and replacing assets that pose safety, reliability or environmental risks.

As part of its Power System Telecom asset lifecycle strategy, Hydro One will be working with vendors in a similar manner as with protection IED vendors, with the goal to avoid further shortened product support windows. Hydro One is also supporting wider industry initiatives in this domain.

Testing & Maintenance Practices

Hydro One's testing and maintenance practices for Power System Telecom assets include time-based preventive maintenance, emergency corrective maintenance and strategic sparing.

Time-based Preventive Maintenance

Hydro One maintains and field tests all communication system devices to verify that they are functional and meeting performance criteria. These are maintained under Hydro One's established Protection System Maintenance Program ("PSMP") which is based on NERC PRC-005, *Protection System, Automatic Reclosing and Sudden Pressure Relaying Maintenance*. In addition, 48Vdc backup power supplies at certain sites (those identified by the IESO that are critical for restoration of Ontario's transmission system) are maintained as per NPCC Directory 8, *System Restoration*, requirements. More specifically, Telecom Preventive Maintenance involves the following maintenance activities:

1. **Routine Maintenance / Re-verification**. Routine maintenance is performed, among others, on the Synchronous Optical NETworking ("SONET") equipment, teleprotection terminal devices, PLC radios, and microwave radios. Maintenance includes visual inspections, air filter replacements (if applicable), verification of performance parameters and checks on alarm monitoring modules;
2. **Signal Adequacy Tests**. Signal adequacy testing performed on the PLC systems where the communication channels are unmonitored and don't have alarms.
3. **Radio Communication Tower Visual/Structural Inspection**. Communication towers are inspected visually for structural integrity and functioning of aviation obstruction lighting;
4. **Telecom Battery / Charger Maintenance**. Maintenance of 48Vdc batteries and chargers includes visual inspections, diagnostic test level 1 (equipment integrity check), diagnostic level 2 (AC interruption test) and battery load test;
5. **Auxiliary telecommunication equipment inspections**. Inspections of High-Voltage Interface ("HVI") equipment to verify their integrity (condition including rusting, leaking, equipment connections) and that they do not pose a risk to reliability and safety. Overhead metallic cables are inspected for wear and tear as well as any safety hazards; and
6. **OPGW / ADSS maintenance and inspections**. Aerial inspections of All-Dielectric Self-Supporting ("ADSS") cables which includes visual inspections for signs of excessive wear and other abnormal conditions of the cable as well as associated suspension assemblies.

Timing intervals for telecom maintenance are dependent on the technology of the communications scheme and/or equipment, and whether the telecom equipment directly interfaces with protection schemes that form part of the BES. For BES protection schemes, the maintenance of telecom devices is non-discretionary, and is based on the NERC PRC-005 standard, and requires annual compliance reporting. Maintenance on non-BES elements is performed on longer time intervals in line with industry best practices.

As Hydro One performs time-based preventive maintenance work, it tracks progress on a monthly basis and keeps maintenance records in a central repository. NERC and NPCC regulatory maintenance activities are reported on an internal monthly compliance scorecard. Unmonitored communication systems are tested for signal adequacy every four months and maintained/re-verified every six years while self-monitoring devices with remote alarming capabilities are maintained on a ten year interval. These maintenance intervals are stringent in order to mitigate the risk of non-compliance by providing some buffer to account for cases where regulatory maintenance cannot be achieved on time due to operational limitations.

Corrective Maintenance

Hydro One performs corrective maintenance to remedy defects identified during preventive maintenance and failure events. Corrective maintenance activities include fibre break repairs, telecom equipment repairs and diagnostic activities. Corrective work is prioritized based on the urgency of restoring the affected equipment. Maintenance of the provincial mobile radio system ("PMRS") equipment is contracted to a third party.

Strategic Sparing

Strategic sparing ensures that there are adequate operational spares available for all power system telecom assets, so that all categories of equipment can be maintained and repaired.

Strategic sparing also ensures that all materials and test equipment are available to meet the requirements of Hydro One's Fibre Cable Emergency Response and Restoration Plan. The following activities are included in power system telecom sparing programs:

- Procurement of operational spares for all power system telecom equipment;

- Ensuring fibre cable emergency response capability; and
- Providing maintenance support to field staff.

In addition to keeping track of failure rates and determining maximum and minimum stock levels, Hydro One also proactively monitors the equipment that have been discontinued and no longer supported by manufactures. Similar to other utilities, Hydro One is presented with “last buy opportunities” for strategic sparing of certain equipment in order to support the current installed base.

Outlook Implementation

Going forward, Hydro One will sustain assets to maintain reliability and meet communication system performance requirements. This will be achieved by systematically phasing out poor performing equipment from the asset base and working with suppliers to extended product support to reduce equipment obsolescence.

Hydro One is migrating its existing power system telecom services to new technologies. SONET and Provincial Mobile Radio System (“PMRS”) replacements will be sought with foresight to new application requirements such as non-operational data, remote condition-based monitoring and synchrophasor technology. ADSS cable and microwave system replacements will lead to less failures and performance issues leading to a more robust and reliable power system communication network. This will allow Hydro One to seek efficiencies by utilizing existing power system telecom infrastructure while maintaining reliability and OM&A costs associated with power system telecom services.

2.3.1.6 OTHER STATION COMPONENTS

Hydro One Transmission has numerous other station components categorized as other power equipment, other ancillary equipment, civil infrastructure and environmental management; which must be maintained to support the continued functionality of all major station assets.

Asset Strategy

With respect to this asset class, Hydro One's strategy is to proactively manage the asset fleet through inspections and routine maintenance to monitor condition and ensure compliance with applicable regulatory standards (including requirements of NERC/NPCC and Ministry of Environment, Conservation and Parks). Repair versus replacement assessments are done case-by-case based on the risk from a demographic, condition, environmental, utilization, economic, and customer perspective, as balanced against asset needs, asset reliability, safety risk and costs for the overall fleet. Additionally, decisions include the use of financial models to estimate the most economical option for the asset.

Testing & Maintenance Practices

Hydro One performs visual inspections, thermographic surveys and periodic testing of power and ancillary assets.

Other Power Equipment

Other power equipment mainly consists of HV/MV switches, capacitor banks and HV/MV Instrument transformers. Maintenance includes visual inspection for signs of external degradation such as chipped or cracked sub-components, thermographic testing, signs of corrosion and detection of other visual/audible issues (leaks, etc.). Where necessary, Hydro One schedules component replacement.

Ancillary Equipment

- AC/DC Station Service

On AC/DC station service equipment such as transfer schemes, switches and breakers, significant damage, deterioration, or loss of functionality identified through inspection or alarms are addressed through the appropriate remedial action. Consideration for more significant intervention, i.e. refurbishment or replacement of systems, would normally occur if a report indicated serious degradation. Inspections of AC station service breakers include manual operation tests, inspection of all internal components, insulation condition, contacts and rack-in mechanisms (where applicable).

- DC Batteries and Chargers

Hydro One maintains DC batteries and chargers by verifying functional and performance criteria according to regulatory standards governed by NERC PRC-005-02 and NPCC Directory 4 & 8 regulations. Diagnostics testing is performed every 12 months and battery load testing is performed every 3 to 5 years. As prescribed by applicable standards, maintenance activities include visual inspections and recording of critical battery and charger values. Other scheduled maintenance includes inspection of battery plate condition, conductance measurements, capacity and continuity testing of the DC system and battery load tests. Online battery monitors are being evaluated as an alternative to frequent testing activities.

- High Pressure Air System

Inspections include dryer and compressor condition checks, leak detection, verifying subcomponent operation, measuring dryer moisture content, and assessing and recording indicator, level and run time values. Other scheduled maintenance includes function testing, overhauling and component replacement where necessary. In compliance with Technical Standards and Safety Authority (“TSSA”) regulations, the pressure relief valve is tested every three to five years.

Civil Infrastructure

Visual inspections are performed to assess the condition and functionality of an array of assets including: below grade cable penetrations, station roadways, perimeter fencing/gates, structure footings/foundations, railway spur lines, site storm drainage, yard stone and cable trenches/trays. Also included is testing of building fire alarm systems and deluge systems where applicable; in compliance with the Fire Code and Ontario Building Code.

Environmental Management

Visual inspections are performed to assess the condition and functionality of spill control systems which include spill containment pits, passive/mechanical oil water separators, managing individual station environmental compliance approvals and any effluent testing/monitoring required in being compliant with the Ministry of Environment, Conservation and Parks.

Outlook Implementation

The outlook for other power equipment, ancillary equipment, environmental management and civil infrastructure varies due to differences in their respective functionality and modes of failure.

Other Power Equipment

Hydro One expects to see increased costs as ancillary systems are assessed to ensure compatibility with new station assets and regulatory compliance that require more frequent and stringent maintenance to be performed. Inspection work in advance of integrated replacement plans will identify when certain ancillary systems will not deliver safety and reliability benefits required for the new station asset arrangements and upgraded equipment.

Increased use of Drones for Outdoor Station Inspection

Drones are being used for both normal visual inspection and thermo-visual inspection. This is expected to allow for enhanced inspections of certain outdoor assets like switches and other equipment, which would help prevent outages that may increase customer interruption risks.

Battery Monitors

Batteries are a maintenance intensive item that may see improved reliability, safety and maintenance cost benefits from enhanced monitoring systems. Enhanced battery monitoring of conventional lead acid batteries will be installed and assessed for providing maintenance, safety and reliability benefits. This will also adhere to applicable compliance requirements.

The battery replacement program will focus on Valve Regulated Lead Acid ("VRLA") batteries due to the safety concerns they pose and the additional work protection required when working on these batteries.

High Pressure Air Systems-Reduced Population

Hydro One will continue to maintain high pressure air systems while air blast circuit breakers (ABCBs) remain in-service at stations. As the ABCBs are replaced with other technologies, maintenance costs are expected to decrease for high pressure air systems.

Environmental Management and Civil Infrastructure

Hydro one will continue to perform visual inspections and preventive maintenance to assess condition and functionality of assets in order to be safe, reliable and compliant.

2.3.2 (5.3.3 A, B) ASSET LIFECYCLE OPTIMIZATION POLICIES AND PRACTICES – TRANSMISSION LINES

2.3.2.1 OVERHEAD CONDUCTOR

Asset Strategy

Overhead transmission conductors are designed to transmit electrical power safely, reliably and efficiently between nodes in an electrical system. Hydro One's strategy for this asset class is to manage the conductor population in a manner that maintains reliability and limits safety risk to acceptable levels.

Currently, Hydro One has 3,680 circuit km of overhead conductors that are known to be in high risk condition. This represents approximately 13% of the total overhead conductor population. Due to the increased risks these deteriorated assets pose, Hydro One has planned the replacement of approximately 2,127 circuit km of overhead conductors over the next five years.

When prioritizing replacement candidates, Hydro One considers condition assessment results, performance data, asset demographics and consequence of failure to the system and customer reliability. When test results conclude that a conductor has reached end of life ("EOL"), a line refurbishment project is initiated and incorporates the refurbishment of all deteriorated major components within the relevant line section, including structures, shieldwire, and insulators. Components that are in good condition are not refurbished or replaced. Based on the conductor condition assessment results over the next five years, Hydro One will re-evaluate and adjust the replacement rates.

Bundling conductor replacement with other components is a cost effective approach used when replacing conductors. The cost of deployment and mobilization of crews to perform line work represents a significant cost, and as such, when multiple tasks are performed in an area in a coordinated fashion significant economies of scope can be established.

Testing & Maintenance Practices

Deterioration of overhead conductors cannot be reversed. Therefore, these assets are tested and, where required, replaced in order to sustain the overhead transmission line system. Based on Hydro One's experience, testing practices have focused on assessing conductors that are greater than 50 years of age to identify segments that are high risk.

Hydro One is an industry leader in assessing the condition of transmission line assets, particularly aluminum conductor steel reinforced ("ACSR") conductors. Since the late 1980s, Hydro One has been using a conductor sample removal method combined with laboratory testing to assess the condition of conductors. As a result of making replacement decisions based on condition assessment, many good condition conductors that have aged beyond ESL are kept in service to safely and successfully operate beyond their ESL; and conversely, condition-based replacements also allow prematurely deteriorated conductors to be identified and addressed before they fail.

Recently, Hydro One started using the Kinectrics LineVue tool, which travels along energized and non-energized conductor span to measure the remaining cross-sectional area of the steel core wires in ACSR conductors. The tool allows for a greater number of condition assessments per year and is more cost efficient compared to removing conductor samples for laboratory testing.

Outlook Implementation

As discussed above, Hydro One has 3,680 circuit km of overhead conductors that have deteriorated and have been rated as high risk. For the next 5 years, Hydro One plans to prioritize the replacement of 2,127 circuit km of overhead conductors. The remaining 1,553 circuit km, along with any additional circuits that are identified as replacement candidates through planned condition assessment over the next five years, will be targeted for replacement in 2025 and beyond.

Hydro One is also evaluating EPRI's "C-corr" solution that can assess the condition of steel cores. This device is a non-contact tool that can be operated from the ground and does not require crew to physically ascend the tower structure. It is anticipated that C-corr will allow for more scans to be performed thereby reducing condition assessment costs for conductors. Given Hydro One's recent adoption of LineVue, C-corr would be adopted if it proves to be feasible and provides additional benefits for Hydro One in practice.

2.3.2.2 UNDERGROUND CABLES

Asset Strategy

Hydro One's cable strategy is to maximize service life, while maintaining current risk levels, to minimize capital replacement expenditures. This involves performing rigorous condition assessment, prioritizing maintenance and replacing cables at end of life where maintenance (repair) is no longer practical.

Testing & Maintenance Practices

Hydro One's maintenance programs are implemented to identify and repair deteriorated components as well as monitor cable health to provide insight into remaining life. Cable maintenance reduces the risk of cable equipment failure, which can seriously impact service and reliability. Deteriorated components are identified and monitored through a rigorous preventive maintenance (condition assessment) program. Routine preventive maintenance and more intrusive diagnostic tests have shown that many underground cables are in good operating condition. Refer to Figure 21 in TSP Section 2.2.2.2.

Preventive Maintenance

Preventive maintenance reduces the likelihood of premature cable degradation and failure, delivery point interruptions and oil leaks. Preventive maintenance activities are aimed at assessing cable condition and ensuring system reliability. Activities include: condition assessment patrols and routine testing/diagnostics of cables and ancillary equipment. Condition patrols and routine testing are done cyclically. The optimal frequency is based on industry best practices, historical experience and known asset deterioration rates. However, maintenance activities and their frequency are adjusted based on condition and reliability. Routine tasks include: vault inspections, oil tests and analysis, jacket tests, etc. Condition and test data collected by this program is used to determine the optimal timeframe for capital replacement.

Corrective Maintenance

Corrective maintenance activities are undertaken to investigate and repair cable and ancillary equipment deficiencies with the intent of returning the asset to its normal operable state. Deficiencies are typically noted during preventive maintenance condition assessments or trouble call responses. Demand corrective maintenance addresses repairs requiring immediate attention (i.e. emergencies) while planned corrective maintenance addresses less critical deficiencies not requiring immediate repair. Corrective maintenance activities include excavating and repairing cable components, and locating, repairing and the environmental remediation (clean-up) of oil leaks, etc.

In addition, supplemental non-routine tests are done on a demand basis to verify repairs and obtain detailed condition data if routine testing results show abnormalities. These non-routine tests are typically more intrusive (sometimes destructive), costly and require specialized equipment and external service providers. Where appropriate, this data can be used to increase the confidence in cable condition information, facilitating the selection and prioritization of replacement candidates.

Locates

Upon request, Hydro One is required by provincial legislation[10] to provide locate services for its underground infrastructure. The locate program covers the cost of field stakeouts and site representation of Hydro One's underground transmission system. This investment reduces the probability of underground transmission cable damage caused by dig-ins and the associated public safety risk.

Outlook Implementation

The fundamental objective of Hydro One's cable sustainment strategy is to maximize service life in order to minimize capital replacement expenditures. This is primarily done through preventive and corrective maintenance programs. Hydro One will continue to perform rigorous preventive maintenance and critical planned and demand repairs. Non-critical planned corrective maintenance and supplemental non-routine tests to obtain detailed condition data will be prioritized and/or deferred. While this deferral may result in an increased number of demand failure repairs, this risk will be mitigated through the prioritization of planned repairs. Furthermore, Hydro One will continue to replace end of life cables and ancillary equipment that can no longer be practically maintained. For example, widespread jacket deterioration and sheath corrosion (resulting in end of life conditions) are the driving factors for Low-Pressure Liquid-Filled ("LPLF") cable replacement.

2.3.2.3 STRUCTURES & FOUNDATIONS

Asset Strategy

Steel Structures

Hydro One's strategy for steel structures is to manage the fleet through a combination of planned structure replacements, component refurbishments and tower coating in order to maintain the reliability of the system and decrease life cycle costs. Structure

[10] Ontario Underground Infrastructure Notification System Act, 2012, S.O. 2012, c. 4

replacements and component refurbishments are usually part of bundled line refurbishment work.

Wood Poles

Hydro One's strategy for wood poles is to proactively replace wood poles in poor condition in order to reduce failures that impact customer reliability and to minimize emergency response activities. Hydro One uses a condition-based asset management strategy to sustain its fleet. Age is used as a criterion for determining assessment candidates only.

Foundations

Hydro One's strategy for transmission structure foundations is mainly focussed on repairing or replacing steel grillage footings and steel anchors, which are directly buried into the ground.

Testing & Maintenance Practices

Steel Structures

The condition of towers is determined through patrols, inspections, and detailed corrosion assessments. Towers are visually rated based on field guides[11] that have been developed in accordance with the National Association of Corrosion Engineers ("NACE"). Based on patrol results, a detailed engineering corrosion assessment is undertaken for severe cases to measure metal loss and assess bolts and fittings. The assessment also determines whether tower refurbishment and/or coating are necessary. Typically, 10% steel loss is usually the threshold that triggers refurbishment/replacement consideration.

[11] Field guides are tools that crews can use to decide how to rate the condition of a tower. The guides provide pictures and descriptions associated with certain rust levels and help to standardize the ratings between different crew members performing the assessment.

Hydro One's tower coating program aims to maintain steel tower structures at their design capacity by re-application of the coating approximately every 35 to 75 years. Tower coating is targeted for high corrosion zones, as classified under ISO 9223, where environmental factors give rise to high corrosivity.

If towers are not re-coated prior to an acceptable extent of strength loss (i.e., typically, before reaching 10% thickness loss), the opportunity is missed and the towers will ultimately have to be replaced or heavily refurbished at a significantly higher cost. Based on Hydro One's assessment and experience, tower coating has been one of the most economic and efficient methods of prolonging the service life of steel structures.

In light corrosion zones steel structures will likely be protected and maintained in good condition for a minimum of 115 years without requiring any additional coating. There are 39,250 steel structures (37,300 steel towers and 1,950 steel poles) in light corrosion zones but none of them are older than 115 years so there is no immediate tower coating planned within these zones.

Wood Poles

Wood poles are tested through the overhead line condition assessment program based on circuit age, known deficiencies, past failures and field recommendations. Aerial patrols are used to inspect the condition of the top of the pole, the cross arms and the associated hardware, while ground patrols and wood pole testing are used to assess the rest of the pole.

Wood pole inspections and tests results are assessed in accordance with Hydro One guidelines that set out the procedure and criteria for identifying end of life assets that warrant replacement. Performance data, asset demographics and the impact of failure to system and customer reliability are all considered when making replacement decisions for the yearly wood pole replacement program. This program aims to address wood poles confirmed to be at end of life.

Foundations

Tower foundations are assessed through the Transmission Lines Foundation and Anchor Assess, Clean and Coat Program (as discussed in Section 2.2.2.3) and line refurbishment projects. Based on the severity of corrosion, they are either cleaned and coated to re-establish the layer of protection or scheduled for future repairs/replacements. The Foundation Repair Program is used to complete repairs or replacements of foundations identified through the previous program.

Outlook Implementation

Steel Structures

The steel tower coating program has mainly been driven by economic considerations rather than risk mitigation. Based on the most recent analysis, the Net Present Value ("NPV") calculations show significant savings from tower coating versus tower replacement. Over the planning period, savings are estimated at $162M compared to single isolated tower replacements, or $101M compared to single tower replacements that are part of a multiple tower replacement project (i.e. replacing multiple towers is more efficient resulting in comparatively lower savings from tower coating). Based on reliability, safety, and environmental trade-offs, the current pacing of tower coating is approximately 500 towers per year. These towers are selected from structures that are already experiencing corrosion and metal loss.

At this rate, Hydro One expects to eliminate the tower coating backlog within 15-20 years, instead of the previously planned five years. While overall safety and reliability are not expected to be compromised under the revised pacing, the continuing aging of towers means that more work may be required in terms of surface preparation and/or structure member replacements before coating can be undertaken.

Hydro One currently uses live line work methods for tower coating on 230 kV circuits, which significantly reduces line outages. In some cases, compromised structure members will need to be replaced prior to tower coating, and depending on the deterioration, a complete tower replacement may be necessary.

Hydro One will continue using Rust Anode for the majority of the tower coating program. In the past three years, Hydro One has investigated and validated the use of Rust Anode as a recoating product, which has proven to be superior compared to the traditional Keeler Long paint. It requires less surface preparation work, dries quicker, and is a more robust treatment. The test results also showed that Rust Anode permits a higher number of towers to be coated with limited resources and outage windows. However, recent observations have shown that when a tower has corroded to a certain degree, even though it is still functionally sound, re-coating may not be economically and operationally feasible without intensive surface preparation. Hydro One and EPRI are re-evaluating current coating criteria to identify the optimal coating time and method to improve the performance and durability of Rust Anode coating.

Hydro One will continue working with EPRI to refine corrosion zones in Ontario by collecting and analyzing more data and increasing the resolution of the corrosion map. This will help Hydro One to improve its tower coating program.

Wood Poles

Hydro One plans to maintain current replacement levels in order to eliminate EOL structures over the next 10 years. This plan includes addressing the backlog of EOL structures, and newly identified EOL poles. This is expected to maintain the outage frequency and duration performance. Delaying these replacements increases the risk of failures, which could affect reliability and shift expenditures to the more costly demand emergency replacement program. Hydro One will continue to refine its data collection process related to the structure replacement and line refurbishment programs, thereby permitting an accurate depiction of the network inventory in order to improve decision making.

Solutions such as radar and laser technologies (involving helicopters and drones with HD cameras) continue to be explored in order to more efficiently detect wood poles and cross arms that are nearing EOL. Hydro One will consider utilizing steel and composite poles when replacing EOL wood pole structures because they have a greater life expectancy and lower life cycle costs.

Foundations

Hydro One will prioritize all grillage foundations of 500kV towers, and of 230kV / 115kV towers built before 1940, as they reach/approach EOL. At the current proposed pacing, the target is to complete the assess/clean/coat work for all grillage foundations by 2035. Poor condition grillage foundations can potentially contribute to tower collapse and significantly increase restoration costs.

Hydro One will develop a more specific maintenance strategy for concrete foundations, with input from EPRI and CEATI. In the meantime, concrete foundations identified yearly through foot or helicopter patrols will be scheduled for repair or replacement as required.

2.3.2.4 INSULATORS

Asset Strategy

Hydro One's insulator strategy is focussed on mitigating public safety risk by targeting defective porcelain insulators and end of life polymer insulators for replacement. Hydro One retained a third party expert, the Electric Power Research Institute ("EPRI"), to assess the condition of defective COB and CP porcelain insulators to assist Hydro One in determining the pacing of porcelain insulator replacement. The key recommendation made by EPRI is that the population of defective COB and CP insulators installed between 1965 and 1982 be removed from service as soon as practically possible. Defective porcelain insulators in publicly accessible (critical) areas are targeted for replacement by 2022, with the remaining defective insulators planned for replacement by 2027.

Testing & Maintenance Practices

Insulators cannot be maintained or repaired to extend the service life. They are assessed by using various methods and replaced when condition warrants the replacement. Condition assessment methods include visual inspections from the air or ground and are bundled with line and structure inspections and patrols; infrared thermography (thermo-vision) used to detect electrical insulation deficiencies; and electrical testing (polymer insulators only) using a live-working non-ceramic insulator testing tool to detect internal conductive defects.

Outlook Implementation

Insulators posing a higher public safety risk (i.e. insulators in critical locations) are to be replaced by 2022 at a rate of approximately 3,700 circuit structures per year. Insulators in non-publicly accessible areas will be replaced at an approximate rate of 3,450 circuit structures per year over a five year period beginning in 2022. Details on these programs can be found in TSP Sections 1.4, TSP 2.2.2.4 and ISD SR-25- *Transmission Line Insulator Replacement*. Replacement rates also take into account the urgency of the investment and practical pacing considerations (i.e. resource availability).

The replacement program includes polymer and other insulators however, these types of insulators constitute a small portion of the work program. The issues associated with polymer insulators are discussed in TSP Sections 1.4, TSP 2.2.2.4 and ISD SR-25 - *Transmission Line Insulator Replacement*.

2.3.2.5 RIGHTS OF WAY

Asset Strategy

Hydro One's Transmission Vegetation Management Program will be managed on a cyclical basis to ensure that all transmission right-of-ways ("ROW") are regularly cleared to Hydro One's Transmission Vegetation Management Standard. To meet this standard, Hydro One's ROWs are cleared to their designed width and all non-compatible vegetation on or adjacent to the ROW is removed.

Testing & Maintenance Practices

Hydro One's cyclical vegetation management program is primarily completed on a 6-year cycle in the East and Southern zones and on an 8-year cycle in the North. Some corridors in Eastern and Southern Ontario are maintained on a 4-year cycle due to faster vegetation growth rates. Maintenance is completed in Northern Ontario on a longer cycle due to the colder temperatures and slower vegetation growth rates.

Maintenance of Hydro One's ROW corridors consists of seven programs designed to identify and mitigate potential vegetation encroachments on energized overhead conductors. The seven programs are:

1. **Brush Control**: includes manual cutting, herbicide application and/or mechanical clearing to manage vegetation growth on the right-of-way to ensure adequate clearances and access to Hydro One's overhead circuits.
2. **Line Clearing**: consists of trimming tree branches and removing any unhealthy or danger trees on the edge of or adjacent to the right-of-way that have the potential to exceed Hydro One's clearances to the overhead transmission lines. Split, hanging, uprooted, dead and diseased trees are referred to as danger trees.
3. **Condition Patrol**: is mid-cycle working inspections which identify and mitigate any vegetation which requires maintenance prior to the next scheduled line clearing or brush control activity. ROW condition is also recorded and used to prioritize future maintenance activities.

4. **Property Owner Notifications**: Prior to the execution of ROW vegetation maintenance, Hydro One contacts all required adjacent property owners to communicate maintenance plans, obtain approval for access onto private property and acquire permission for the use of any herbicides to be applied during maintenance. Hydro One also actively engages all other external stakeholders, such as government agencies, municipal officials and special interest groups as required.
5. **Annual Vegetation Patrol**: in accordance with NERC standard FAC-003, Hydro One is required to annually inspect all of its circuits operating at a voltage of 230 kV or greater. Consequently, visual inspections by helicopter or ground are performed on all NERC applicable circuits not receiving Line Clearing or Condition Patrol maintenance in the current calendar year.
6. **Demand Maintenance**: addresses vegetation management issues that cannot wait until the next scheduled line clearing or brush control activity.
7. **Grounds Maintenance**: includes grass cutting, snow removal, garbage clean-up, and repair of access barriers and fences on Hydro One's urban ROWs, and is required to comply with local by-laws.

Outlook Implementation

Hydro One aims to operate an efficient vegetation management program while completing the regularly scheduled cyclical maintenance schedule. Postponement of vegetation management work increases reliability risks and results in a vegetation backlog that is harder and more costly to clear in the future.

Light Detection and Ranging ("LiDAR") is a remote sensing technology that is used by utilities to obtain accurate geospatial images and measurements of circuits and the vegetation surrounding them. Hydro One is exploring the use of LiDAR technology to obtain accurate measurements of circuits and the surrounding vegetation. Potential benefits and concerns associated with the technology and the value it offers the work program are currently being reviewed.

2.3.2.6 SHIELDWIRE

Asset Strategy

Hydro One's shieldwire asset strategy is to maintain system reliability and public and employee safety by actively replacing all shieldwire assessed to be at end of life. Hydro One uses a condition-based asset management strategy to assess and prioritize the replacement of its shieldwire fleet. Age is used as a criterion for determining assessment candidates only.

Testing & Maintenance Practices

Shieldwire cannot be maintained or repaired to extend life. Rather, Hydro One's shieldwire population is monitored through the condition assessment program and is replaced as condition warrants. Line sections of shieldwire are targeted for condition assessment after reaching an established age threshold, which varies between 25 and 50 years depending on the type, as illustrated in Table 5.

Table 5 - Shieldwire Condition Assessment Ages

Shieldwire Type	Age for Condition Assessment
Galvanized Steel	25 years
Alumoweld	40 years
ACSR	50 years
Copperweld	Not Required All Copperweld shieldwire is at EOL
Optical Ground Wire ("OPGW")	Condition assessment process for OPGW is currently being developed.

Traditionally, shieldwire condition assessment was conducted through laboratory testing of samples. Now, Hydro One primarily uses the Kinectrics LineVue inspection system to traverse along a span and assess the shieldwire condition. Data collected is used to estimate the remaining service life of the shieldwire without the need for an outage or intrusive testing.

Outlook Implementation

To maintain system reliability, Hydro One aims to ensure that all EOL shieldwire assets, identified through condition assessment, are scheduled for replacement in a timely manner.

EPRI has developed a non-contact device that is capable of identifying rusted shieldwire. While testing is still required to verify condition results obtained from this tool, it may potentially enhance future shieldwire condition assessment capabilities. Hydro One will evaluate the feasibility and practical benefits of this technology pending further testing results.

2.3.2.7 OTHER LINES COMPONENTS

Asset Strategy

The asset strategy for other lines components (e.g. U-bolts, downgrounds, bondwire, structure signs) is to perform preventive maintenance and condition assessments along overhead transmission lines to identify defective equipment and components prior to failure. Corrective and demand maintenance are executed to repair defective components, including EOL U-bolt and other hardware components and to minimize any customer impact, system reliability and public safety risk.

Testing & Maintenance Practices

Preventive Maintenance and Asset Assessment

The overhead lines maintenance program encompasses cyclical and non-cyclical based maintenance activities. Cyclical based maintenance activities include helicopter patrol, foot patrol, thermovision patrol, switch maintenance and insulator washing. Non-cyclical based activities include detailed helicopter inspection (“DHI”), climbing inspections and other asset assessment activities described in the corresponding sections for conductor, shieldwire, structures and insulator.

Cyclical Based Maintenance Activities

Helicopter and foot patrols are used to assess the condition of transmission line components. Helicopter patrols involve a high-speed patrol to identify major defects whereas foot patrols are a ground based patrol for circuits in no-fly regions. The optimal patrol cycle is either five or ten years for circuits that can be aerially inspected, or two years for circuits in no-fly regions.

Thermovision patrol identifies defective transmission line components by detecting their heat signature using infrared cameras. Switch maintenance inspects and maintains switch components, as well as verifies switch functionality on a ten year cycle. Insulator washing is performed on transmission structures located near urban highway and road crossings where salt contamination is a concern.

Non-cyclical Based Maintenance Activities

DHI involves a low-speed aerial-based patrol to assess the condition of tower structure hardware, including U-bolts and other smaller components such as dampers and clamps. Generally, DHI is performed on circuits older than 50 years and where U-bolt hardware has not been replaced in the past 50 years. Circuits that contain U-bolt hardware at 25% wear or more are to be re-assessed within 5 years from the time of the previous condition assessment. Circuits containing U-bolt hardware at less than 25% wear are to be re-assessed within 10 years from the time of the previous condition assessment.

Climbing inspections are performed on selected structures located in no-fly regions that cannot be inspected by helicopter. Typically, structures with higher public safety risk are selected. The general criteria to perform climbing inspection on a circuit section are similar to DHI.

Demand Maintenance

Demand maintenance is needed to respond to emergencies and to restore power when necessary. This program includes activities such as unplanned data collection, emergency component repair and trouble call response. This program also addresses problems identified during line patrols that need a near term response to prevent a potential outage or to address a serious safety issue.

Planned Corrective Maintenance and Projects

The planned corrective maintenance and projects includes minor corrective work and technical support, to resolve reliability and safety problems with transmission line assets. The planned corrective maintenance activities and projects are developed using the data collected during patrols and asset assessment activities, as well as information about equipment reliability performance.

Planned corrective maintenance addresses multiple line components including defective ground wire connections, missing or broken safety signs and nomenclature signs, U-bolt hardware that support the insulator strings and conductors; replacement of dampers that limit vibration of conductor.

Outlook Implementation

To minimize any customer impact, system reliability and public safety risk, Hydro One will continue to perform cyclical inspections to identify defects on the overhead line system as well as to perform asset condition assessment to identify EOL assets. EOL U-bolts identified through DHI or climbing inspection will be replaced through the planned corrective program or through other major component replacement programs. Out of approximately 123,500 circuit structures within the Hydro One transmission network, approximately 2,800 circuit structures have been identified with U-bolts in EOL condition and will require replacement. Defects with imminent reliability or safety risk will be addressed through the demand maintenance program.

2.3.3 (5.3.3 A, B) ASSET LIFECYCLE OPTIMIZATION POLICIES AND PRACTICES – OTHER ASSETS

This section discusses the lifecycle optimization maintenance and replacement strategies for real estate and facilities, Transport and Work Equipment ("TWE") and Information Technology ("IT").

2.3.3.1 FACILITIES AND REAL ESTATE

An effective facilities management program is contingent upon identifying and prioritizing business and operational requirements. These requirements can range from minor capital repair or upgrade of existing facilities through to the establishment of a new work centre to address operational, business or regulatory requirements.

Asset Strategy

The asset strategy for Facilities and Real Estate is to maintain facilities that serve operational requirements in accordance with a lifecycle approach by conducting planned maintenance of key facility systems and infrastructure and undertake inspections at an appropriate frequency to identify and trigger corrective maintenance.

Facilities and Real Estate also conducts annual operational assessments with various lines of business to confirm facility requirements and, as necessary, complete renovations, additions or replacements for new requirements and/or end of life condition.

Testing & Maintenance Practices

Hydro One's facilities maintenance program is supported by visual inspections and Building Condition Assessments ("BCA") at planned frequencies. Execution of facility maintenance and inspections is outsourced to Brookfield Global Integrated Solutions ("BGIS") in accordance with Hydro One standards as well as industry specific standards relating to facility management. These standards involve operational and corporate-defined requirements, regulatory requirements and general commercial standards employed by the facilities industry.

Visual Inspections

Visual inspections are conducted at all facilities (with frequencies ranging from monthly to annual) to optimize performance. Each facility and its major sub-systems (e.g., HVAC, lighting, fire extinguishers, spill kits, eye wash stations, first aid kits and fences) are visually inspected on a monthly basis. Bi-monthly visual inspections are completed on the building envelope and site. Annual inspections address fire systems, building auxiliary systems, sewage system, and foundation and floor pads. Hydro One may carry out additional inspections as appropriate after events such as storms, earthquakes, fire, vandalism, or other relevant incidents.

Building Condition Assessments

BCAs are performed every five years to provide Hydro One with comprehensive insight on a facility’s condition. BCAs provide the life cycle analysis of each facility, forecasts expected performance and establishes the required short term, medium and long term investments for on-going operational requirements.

Project priority is based on timely and cost effective investments that serve system reliability, operational requirements, regulatory and corporate compliance, health and safety objectives. These priorities are established on the basis of asset condition assessments, frequency of trouble/corrective calls, business and operational risks (i.e. flooding, roof damage, etc.), and expanding/changing work programs or practices.

In line with the asset strategy, the results from the visual inspections and BCAs either trigger corrective maintenance, capital expenditure for renewal or replacement or are documented and re-evaluated in future planning with the lines of business (i.e. through annual operational assessments).

The level of corrective maintenance at each site depends on a combination of factors, including whether the site is owned or leased, the remaining estimated life of the asset, and future operational requirements. There is an exception with respect to Hydro One's leased facilities, where the burden of capital repairs and/or replacements resides with the lessor, other than those specific to Hydro One's operations, such as tenant improvements.

The operational assessment process entails conducting ongoing operational assessments with each line of business to ensure facilities are fully aligned with operational requirements and to identify and reaffirm planned investments. An annual planning meeting is conducted with each line of business to review their specific portfolio to identify facility requirements to current, planned or operational trends/strategies. As part of this review an opportunity/risk analysis is conducted to assist in the prioritization of facility requirements among the various lines of business.

In addition to the annual meeting, broader stakeholder meetings are conducted on a semi-annual basis with all lines of business. This provides each group with operational status updates of the various facility projects and initiatives in progress to confirm alignment with operational requirements. These stakeholder meetings may lead to the identification of operational synergies, such as co-location opportunities, so that different lines of business can leverage common infrastructure and facility elements. Periodic meetings are also conducted as needed to review newly identified corporate initiatives, which may impact the operational and facility requirements of the lines of business.

Outlook Implementation

Once the facility requirements are determined, Hydro One Facilities, in conjunction with BGIS, develops a capital investment plan to meet those operational requirements. Hydro One Facilities then analyzes the priorities and proposes a candidate investment. All of the accommodation needs, BCA data and infrastructure information are entered into a capital planning tracker where it undergoes various managerial reviews. In accordance with

Hydro One's arrangement with BGIS, continuous reviews are conducted pursuant to the scope of regular and periodic equipment inspections and building assessments, so as to improve the quality of BCA data with the objective of identifying equipment for repair or replacement prior to failure.

Hydro One Facilities aggregates the pool of candidate facility projects into a consolidated capital plan which undergoes a priority optimization in light of current, planned or operational trends and strategies. Feedback from internal stakeholders and management is then considered to further optimize the facility capital plan. The core responsibility of Hydro One Facilities is to preserve, maintain, and to maximize the useful life of capital investments. Facilities works with Hydro One lines of business to provide the requisite infrastructure that would allow employees to safely and effectively perform their job duties.

2.3.3.2 TRANSPORT AND WORK EQUIPMENT

Hydro One Fleet Management Services provides centralized and turnkey services that include equipment acquisitions, maintenance, administration, vehicle replacement and final disposition of Hydro One's Transport and Work Equipment ("TWE"), supporting the Transmission and Distribution workforce.

The main accountabilities of Fleet Management Services are to, among other things:

- Provide safe and reliable work equipment;
- Provide personnel transportation;
- Maintain cost effective equipment rates; and
- Adhere to engineering specifications and designs.

Asset Strategy

Fleet Management Services manages a fleet replacement capital investment program based on manufacturer recommended guidelines for end-of-life replacements. The TWE capital plan directly benefits Hydro One's customers by enabling lower overall work program costs. The availability of up to date and reliable TWE for work crews, when and where they need it, helps to reduce downtime and increase productivity while reducing maintenance costs associated with aging equipment.

Fleet Management Services and all Hydro One lines of business (including Distribution Lines, Forestry Operations, Transmission Lines, Stations Construction and Stations Services) complete a yearly review of all the equipment (including Fleet Maintenance Pool units that have met the manufacturer replacement guideline) against future work programs and staffing requirements. Telematics utilization data, which includes global positioning system ("GPS") data and a vehicle operation and performance data informatics system, is also considered in this review as an on-going initiative, to continually assess and right-size the fleet complement where possible.

In performing its asset management duties, Fleet Management Services considers a number of factors, including: equipment capital forecast; equipment productivity, functionality, and future requirements; equipment standards, equipment age, mechanical condition, kilometres traveled and cost per kilometre, downtime, and repair time; safety/risk; work programs; evaluating staff and equipment complement; tendered procurement process; fleet's original capital value and net book value; historical and future utilization; and strategic procurement when considering the replacement of an asset.

Helicopters are replaced on a case by case basis depending on utilization, condition of the aircraft and the cost of refurbishment. The strategy for the replacement of helicopters is designed to mitigate the risks of equipment failure, emergency response, work program repair time and costs as well as environmental impacts.

Testing & Maintenance Practices

Inspection and Maintenance Program

Fleet Management Services has developed a balanced maintenance model to efficiently service and repair equipment and minimize downtime. Work crews can arrange to have local mechanics provide service at their work sites or the asset can be towed to a centralized facility. There are 45 provincial maintenance hubs, shown in 1 below, that are strategically positioned throughout the province to provide a high quality service which minimizes response and travel time.

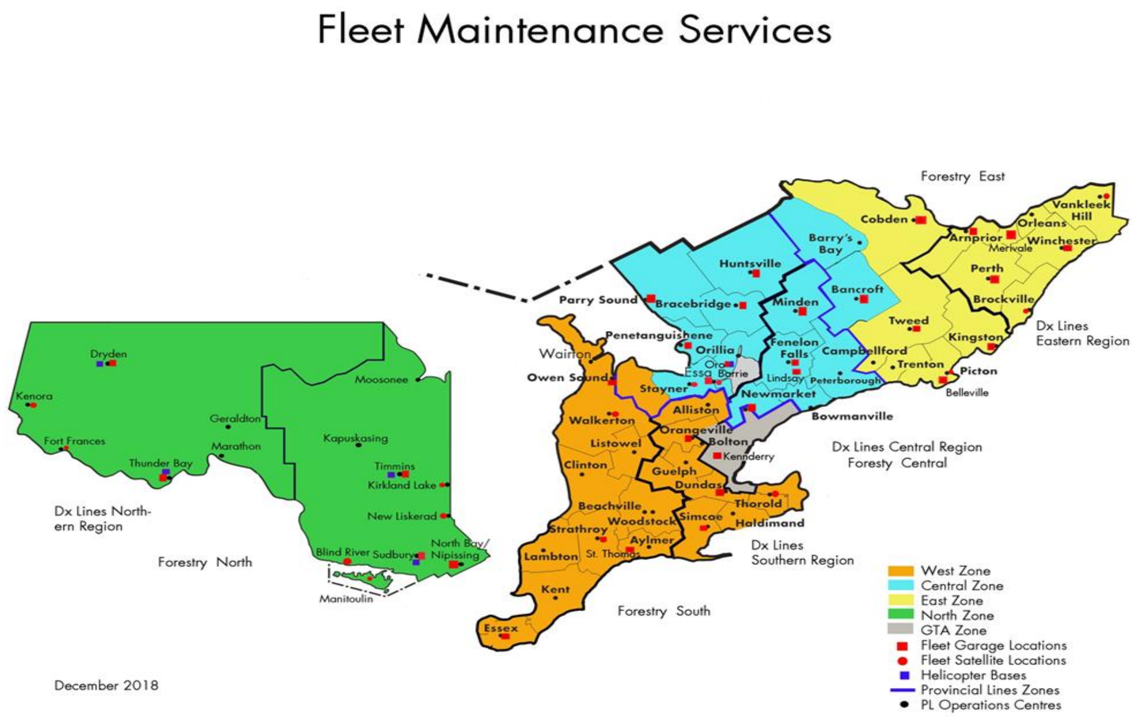

Figure 1 - Map of Fleet Garages and Helicopter Hangers

Fleet Management Services employs specialized heavy duty mechanics that inspect and repair heavy, off-road and miscellaneous equipment. Hydro One's skilled technicians and their service trucks provide timely on-site field support for various nomadic work programs, such as vegetation control, new construction and off-road tower maintenance.

The Hydro One garages are Motor Vehicle Inspection Stations licensed by the Ministry of Transportation.

For all light duty vehicles, Hydro One outsources all inspections, services and repairs. This approach allows Hydro One technicians to focus on the inspection and repairs of the specialized hydraulic equipment. All external vendors receive pre-approval from authorized personnel in Fleet Management Services prior to the commencement of any work.

For helicopters, Fleet Management Services has a team of experienced pilots and air maintenance engineers based in five strategic locations across the province to support the Hydro One lines of business, as shown in Figure 1 above. All pilots and air maintenance engineers hold Transport Canada licenses and receive annual training and testing to maintain a high level of proficiency.

Table 6 below summarizes the Fleet Maintenance Service Interval Guidelines for transport and work equipment.

Table 6 - Fleet Maintenance Service Interval Guidelines (Transport and Work Equipment)

Equipment Type	Lube, Oil, Filter			Dry Services	Type of work
	km	Engine Hours	Months	Months	
Light	8,000	-	6	N/A	• Service • Annual Inspection
Light - dual wheels	8,000	-	6	3	• Service • Annual Inspection • Attachment Inspection

Equipment Type	Lube, Oil, Filter			Dry Services	Type of work
	km	Engine Hours	Months	Months	
Heavy - Service Trucks, Compact Bucket trucks	8,000	200	6	3	• Service • Annual Inspection • Attachment Inspection
Heavy – RBD and Bucket Trucks	20,000	250-500	12	3	• Service • Annual Inspection • Attachment Inspection
Miscellaneous	-	250	12	3-6	• Service • Annual Inspection • Attachment Inspection

The Helicopter Service Intervals Guidelines include inspection and maintenance for the airframe, hydraulic servos, main gearbox, tail gearbox, engine, engine modules and fuel controls after a certain amount of flight hours. Complete refurbishment of the hydraulic servos, main gearbox, tail gearbox engine modules and fuel controls are also completed based on the flight hours or age of the unit.

Telematics

Fleet Management Services has implemented a fleet Telematics system in more than 4,700 of its fleet vehicles. Through its integrated telecommunications, GPS and informatics systems leveraging satellite and cellular data, Telematics provides the location of vehicles as well as live vehicle operation and performance data. Telematics also serves as a Driver Behaviour Modification System by educating and informing drivers of any speeding habits, harsh driving events and idling statistics. With on-going coaching and training, Hydro One has realized a reduction in speeding incidents of more than 80% and a reduction in harsh driving (sharp acceleration and harsh braking) incidents by more than 65% since the implementation of Telematics in 2016**.**

More specifically, the Telematics system provides the following benefits:

- Improves operator safety, fuel efficiency, and greenhouse gas reductions through increased awareness of driving habits (e.g. through reports regarding speeding, sharp acceleration, and harsh braking);
- Provides Fleet Management Services with important equipment data, including idling and utilization statistics, allowing for more informed decisions on the requirement of the assets and how they are being used;
- Improves Fleet Management Services' response time and security with the visibility of live vehicle locations as well as more efficient crew deployment during storm restorations;
- Improved Power Take Off fuel tax credit supporting documentation; and
- Improved visibility to the Engine Control Module for tracking of vehicle condition (where available).

Outlook Implementation

The TWE Replacement Program balances a five-year business planning cycle for capital investment requirements while maintaining a safe, reliable and cost effective fleet. It is imperative to evaluate and forecast spending requirements to minimize fluctuating spending patterns and to stabilize long term capital investment. A reduction in capital spending in a given year is likely to result in increased operating costs, which could ultimately result in increased equipment rates directly impacting the costs of the Transmission work programs.

Adoption of Technology for A More Cost Effective Fleet Complement

With the use of the Telematics technology, Fleet Management Services will continue to collect and leverage vehicle performance and utilization data, which will enable the continuous review of the fleet to ensure the optimal number of vehicles for future corporate work programs and staffing requirements.

2.3.3.3 INFORMATION TECHNOLOGY

Asset Strategy

The asset strategy for IT hardware is to adhere to the IT industry's standard practices to manage assets through a life cycle program and to ensure availability of vendor support. Investment decisions are made based on software life cycles, vendor schedules, reliability requirements, customer requirements, and experience with similar equipment.

In addition, the Asset Strategy for IT applications aims to perform replacements or upgrades as required, including to ensure compatibility with the current IT environment and minimize business interruptions. .

Testing & Maintenance Practices

Hydro One's practice is to replace IT Minor Fixed Assets (e.g., desktops, laptops, printers, plotters, rugged tablets, mobile devices) on cycles that range from every three to five years. The renewal timeline is consistent with industry best practices as outlined by leading technology analytics organizations. Hydro One strongly values and takes industry insight into consideration for its own IT strategies and practices.

Another factor governing replacement timelines is hardware maintenance costs which typically increase after the three to five-year expected life cycle period, thus making it a more appropriate time for hardware refresh. However, the refresh cycle has been adjusted to accommodate business requirements and may be necessitated by application upgrade projects performed on broadly used applications, such as Microsoft Windows, which have increased hardware requirements. Hydro One has implemented its current refresh cycles in order to minimize the overall life cycle costs of the assets. Refreshing equipment maintains or reduces maintenance costs as the cost of extending a warranty late in an asset's life is more costly than buying a warranty at the time of purchase. The ongoing maintenance and sustainment of Hydro One IT applications and the supporting infrastructure is outsourced to Inergi LP.

Lifecycle Optimization Policies and Practices

The following general architectural principles apply to all Hydro One IT applications:

- Applications will be commercial-off-the-shelf ("COTS") and maintained in a vendor-supported version lifecycle to ensure continued functionality and maximum longevity;
- Custom applications are migrated to COTS solutions wherever possible to minimize development, integration and maintenance costs;
- Where possible, application rationalization is applied to reduce the number of applications supported and lower support costs; and
- Middleware will be used to facilitate application interconnectivity. Hydro One has invested in implementing middleware or Service Oriented Architecture to enable data integration within and between applications to ensure continued interoperability.

There are a number of important and coincident factors that must be considered when determining whether an application should be upgraded/replaced. These include:

- age (lifecycle) of the existing application;
- complexity, cost and duration of the upgrade process;
- potential impact to the business (e.g. tolerance for downtime);
- risk, dependencies and potential impacts to other upstream or downstream applications;
- maintaining vendor supportability;
- providing enhanced business functionality/capability required by Hydro One; and
- integration with other applications.

Applications are replaced when they become inadequate for current functional needs; where the platform is no longer supported by the vendor; to address legislative changes or market driven initiatives; or to significantly modify the application to better support an evolving business capability. IT development projects enable the replacement and/or upgrade of end-of-life applications and may also include investments in new applications to meet changing business and customer requirements.

In determining when equipment requires replacement, Hydro One Assesses equipment's functionality, operating, and warranty maintenance costs. Spending varies depending upon hardware life cycles and business requirements for increased processing capacity. Lifecycles vary primarily depending on the demand for additional functionality from the applications being hosted or the expected failure rate provided by the vendor.

The strategic decisions to conduct system upgrades are largely based on industry standard Systems Development Life Cycle ("SDLC") methodologies. An SDLC is composed of a number of clearly defined and distinct work phases which are used to plan for, design, build, test, and deliver information systems. An SDLC aims to produce high-quality systems that meet or exceed customer expectations, based on customer requirements, by delivering systems which move through each phase, according to scheduled time frames and cost estimates.

Outlook - Implementation

Business planning is performed on an annual basis with business stakeholders to assess whether investments in business processes and IT technology are required. Projects are generally one of two types:

Investments in new functionality to meet business objectives

These investments include new or upgraded applications designed to improve functionality, customer support and efficiency. The projects may support other business objectives. Examples of these projects include:

- HR and Payroll Related Technology Investments (ISD GP-08 - *Corporate Services Transformation - HR / Payroll*);
- Transmission Customer Portal Enhancement; and
- Asset Analytics (re-platform and Flexible Asset Analytics).

Investments to replace or upgrade end-of-support applications

These investments address hardware/software deficiencies to support efficiency and performance. An example of this type of project is the S/4 HANA for Finance and Enterprise Asset Management (ISD GP-09 - *Corporate Services Transformation - Finance*) and Enterprise Geographical Information System.

3.0 (5.4.1 A, B) CAPITAL EXPENDITURE PLANNING OVERVIEW

Hydro One completes an annual detailed investment planning process to establish a plan that appropriately reflects customer needs and preferences, system and asset needs, and rate impacts. The planning process that ultimately leads to the investment levels set out in this TSP forms part of Hydro One's overall asset management process, which is aimed at identifying and scoping the optimal timing of capital investments and asset maintenance throughout the life cycle of assets. Hydro One's 2020-2024 capital expenditure plan is an ouput of its asset management framework, including outputs stemming from the investment planning process (as detailed in Section 2.1 of this TSP). In particular, the following considerations are key to the derivation, refinement and finalization of the capital expenditure plan:

- assessment of potential investment candidates through a systematic approach of scoring and calibration;
- enterprise engagement to ensure feasibility of funded portfolio with respect to operational and execution considerations; and
- pacing of work at an enterprise-level to appropriately reflect risk-based prioritization and optimization as well as productivity expectations.

Given that the specific activities associated with the aforementioned considerations are detailed in Section 2.1 of this TSP, the discussion below is intended to highlight the key features and enhancements relating to these activities that directly impact and underpin the 2020-2024 capital expenditure plan.

Over the past year, Hydro One has improved its investment planning process to provide a standardized, consistent and fact-based approach to cost-effectively maximize value for customers. The enhanced process includes the introduction of clear and consistent frameworks and scoring across candidate investments to build a capital expenditures plan that is reflective of asset needs, customer needs and preferences, and system needs.

These improvements are also intended to address feedback from a number of sources, including customer input and the Ontario Energy Board's (OEB) concerns from the EB-2016-0160 proceeding. Additionally, Hydro One has enhanced its approach to prioritization and optimization by introducing a series of challenge sessions to more effectively calibrate the priority assignments of candidate investments, address pacing concerns and properly define an investment portfolio based on risk and non-risk merits. These enhancements are further discussed below in relation to the key components of the capital expenditure planning process.

3.0.1 (5.4.1 A, B) INVESTMENT ASSESSMENT AND CALIBRATION

"Investment Assessment and Calibration" refers to Hydro One's process for assessing potential projects identified in the course of investment planning, including by evaluating the risk mitigation impact of investment candidates, assessing the expected impact on desired outcomes, and calibrating risk assessments to enable consistent decision making across the entire portfolio (see Section 2.1.5 of the TSP). A key enhancement to this process has been the introduction of multiple challenge sessions involving relevant lines of business, as a fact-based and holistic approach to considering project merits (both risk and non-risk based) and making trade-off decisions. This approach increases the rigour around the examination of proposed investments (particularly those that are on the margin) by a broad group of professionals and allows greater scrutiny of the investments that drive the overall budget. In addition, the following new features or enhancements were also implemented:

- **Flagging** – The introduction of new "flags" to represent special considerations or investment drivers (compliance, net prevent value, strategic, etc.) that are important to fact-based project scoring, and to ensure supporting documentation is provided.
- **Consistent frameworks –** The implementation of a seven-level framework (known as scoring "taxonomies") for consequence and probability analysis based

on quantified impacts across all risk dimensions (including by using an exponential scale that allows the two ends of scale to be more effectively differentiated).

- **Standardized scoring -** Scoring is based on three quantifiable risk criteria – safety, reliability, and environment. Consequence scores are based on worst reasonable direct impact as opposed to worst credible impact.
- **Calibration -** Ensures flags and scores are "calibrated" (i.e. to enable consistent assessments across investments) before, during and/or after scoring.

The revised process for scoring and calibrating potential investments was in part influenced by customer survey feedback. For instance, surveyed customers ranked safety, reliability, and environmental considerations as high priority risks[1], which are used as the three quantifiable criteria for standardized scoring. New flags for investments relating to customer service and productivity outcomes were also introduced to better evaluate and align investments relative to customer priorities.

Figure 1 below outlines the scoring results of four example investments included in the plan: Bruce A TS & Bruce B SS air blast circuit breaker ("ABCB") replacements, John TS station reinvestment and High Voltage ("HV") Underground ("UG") cable replacements. For more detailed information on each investment, please refer to SR-01 - *Air Blast Circuit Breaker Replacement Projects*; SR-08 - *John Transformer Station Reinvestment*; and SR-27 - *C5E/C7E Underground Cable Replacement*.

[1] On a priority scale of 1 to 10 (with 10 being the highest priority), over 80% of customers surveyed identified safety, reliability, or environmental considerations as a 7 or higher.

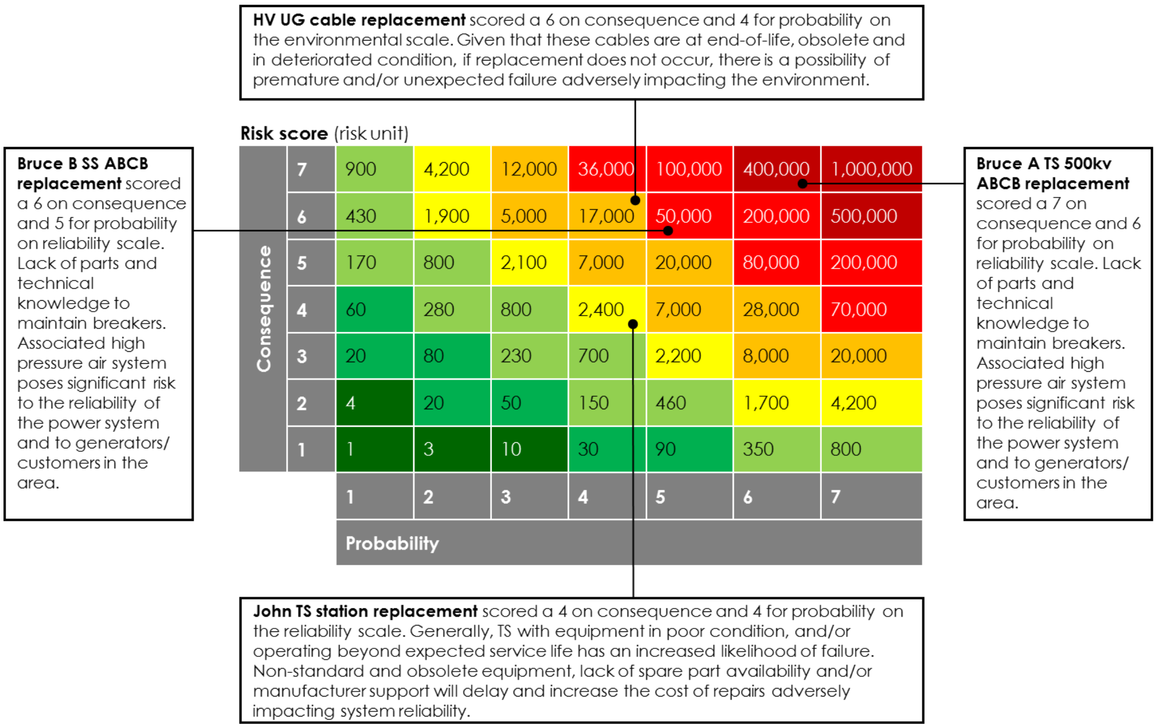

Figure 1 – Candidate Investment Scoring Examples

3.0.2 ENTERPRISE ENGAGEMENT

A lengthened "enterprise engagement" step was designed to (i) address the concerns raised in the EB-2016-0160 proceeding regarding Hydro One's ability to execute its proposed capital programs, and (ii) place more emphasis on collaboration between different levels and divisions of the organization. Engagement with the enterprise team and the incorporation of their input into the preparation of the final plan ensure that the funded portfolio will be feasible from an operational and execution perspective, which in turn mitigates potential risks in future investment delivery. For example, enterprise engagement led to the deferral of an investment at Havelock TS by two years in order to address emerging asset needs at Port Hope TS (see ISD SR-05).

3.0.3 (5.4.1 B) PACING

The effective pacing of the overall investment portfolio over the TSP period is crucial to establishing the final capital expenditure plan. Hydro One views enterprise-level pacing as a function of three elements: (i) overall spend, (ii) prioritization and optimization, and (iii) productivity. OEB staff previously submitted that the proper pacing of capital investments does not mean ignoring or minimizing an identified need but spreading out required investments to balance system needs and avoid sudden cost or rate impacts. Hydro One has addressed these concerns through the following actions:

- Overall spend: Hydro One's proposed budget envelope was set at a level below what was tested with customers, as evidenced in Sections 1.3 and 3.2 of this TSP. Hydro One agreed with customer feedback that this approach offered the appropriate balance between ratepayer costs and risk mitigation.
- Productivity: Through increased productivity, Hydro One has committed to deliver the same work program at a lower cost. New productivity initiatives continue to be identified but represent a commitment to continuous improvement across the organization.
- Prioritization and Optimization: Based on risk-based prioritization and optimization through the enhanced planning process, candidate investments that are expected to most effectively mitigate the highest risk for the least cost should be performed first. For example, this is demonstrated through the prioritization and optimization of capital station sustainment work at Port Hope TS (ISD SR-05) to address emerging asset needs over a candidate investment at Havelock TS.

3.1 (5.4.2, 5.4.3.1) CAPITAL EXPENDITURE SUMMARY

The capital expenditure plan set out in this Transmission System Plan ("TSP") is $1.2 billion for 2020. The plan increases to $1.4 billion in 2022 and plateaus from 2022 to 2024. This proposal represents approximately $6.6 billion in total capital expenditure over the five year TSP period and includes approximately $0.7 billion of capital productivity savings and improvements through information technology, procurement, and other process efficiencies[1]. The proposed plan balances: (i) asset-related needs of the transmission system arising from age, condition and environmental and regulatory compliance requirements; (ii) customer needs and preferences relating to reliability; (iii) regional infrastructure and broader system needs to address system constraints, enable new load growth, and facilitate access and new connections to the transmission system; and (iv) impact on customer rates.

Table 1 below summarizes the 2020-2024 capital expenditure plan which is detailed in this section of the TSP. Actual and forecast expenditures, by category, from 2015 to 2024 are presented in Figure 1 below and detailed in TSP Section 3.3. Note that the test period for this Application is 2020 to 2022.

[1] These amounts include approximately $0.3 billion in Progressive Productivity savings as shown in the Progressive Productivity Placeholder line of Figure 1 and detailed in TSP Section 1.6.

Table 1 - Forecast Period Capital Expenditure Summary

OEB Category	Forecast (Planned $M)				
	2020	**2021**	**2022**	**2023**	**2024**
System Access	24.8	11.3	11.7	12.7	4.1
System Renewal	865.2	1,103.1	1,172.8	1,177.4	1,193.8
System Service	204.1	148.2	151.8	174.3	204.2
General Plant	115.4	94.4	94.7	83.6	58.9
Progressive Productivity Placeholder	(17.0)	(39.0)	(61.0)	(78.0)	(91.0)
Directive Adjustment[2]	(0.3)	(0.3)	(0.4)	(0.4)	(0.4)
Total	**1,192.2**	**1,317.7**	**1,369.6**	**1,369.6**	**1,369.6**
System OM&A[3, 4]	**375.8**	*	*	**N/A**	**N/A**

[2] The Directive Adjustment reflects the impact of the directive issued by Ontario's Management Board of Cabinet on February 21, 2019 and the associated compensation framework they approved on March 7, 2019. Refer to Exhibit F, Tab 4, Schedule 1 for further details.
[3] System OM&A includes Operations, Maintenance and Administration expenses. System OM&A for 2021 to 2022 is determined based on the escalation factor identified in Exhibit A, Tab 4, Schedule 1
[4] Includes the Directive Adjustment described in Exhibit F, Tab 1, Schedule 1.

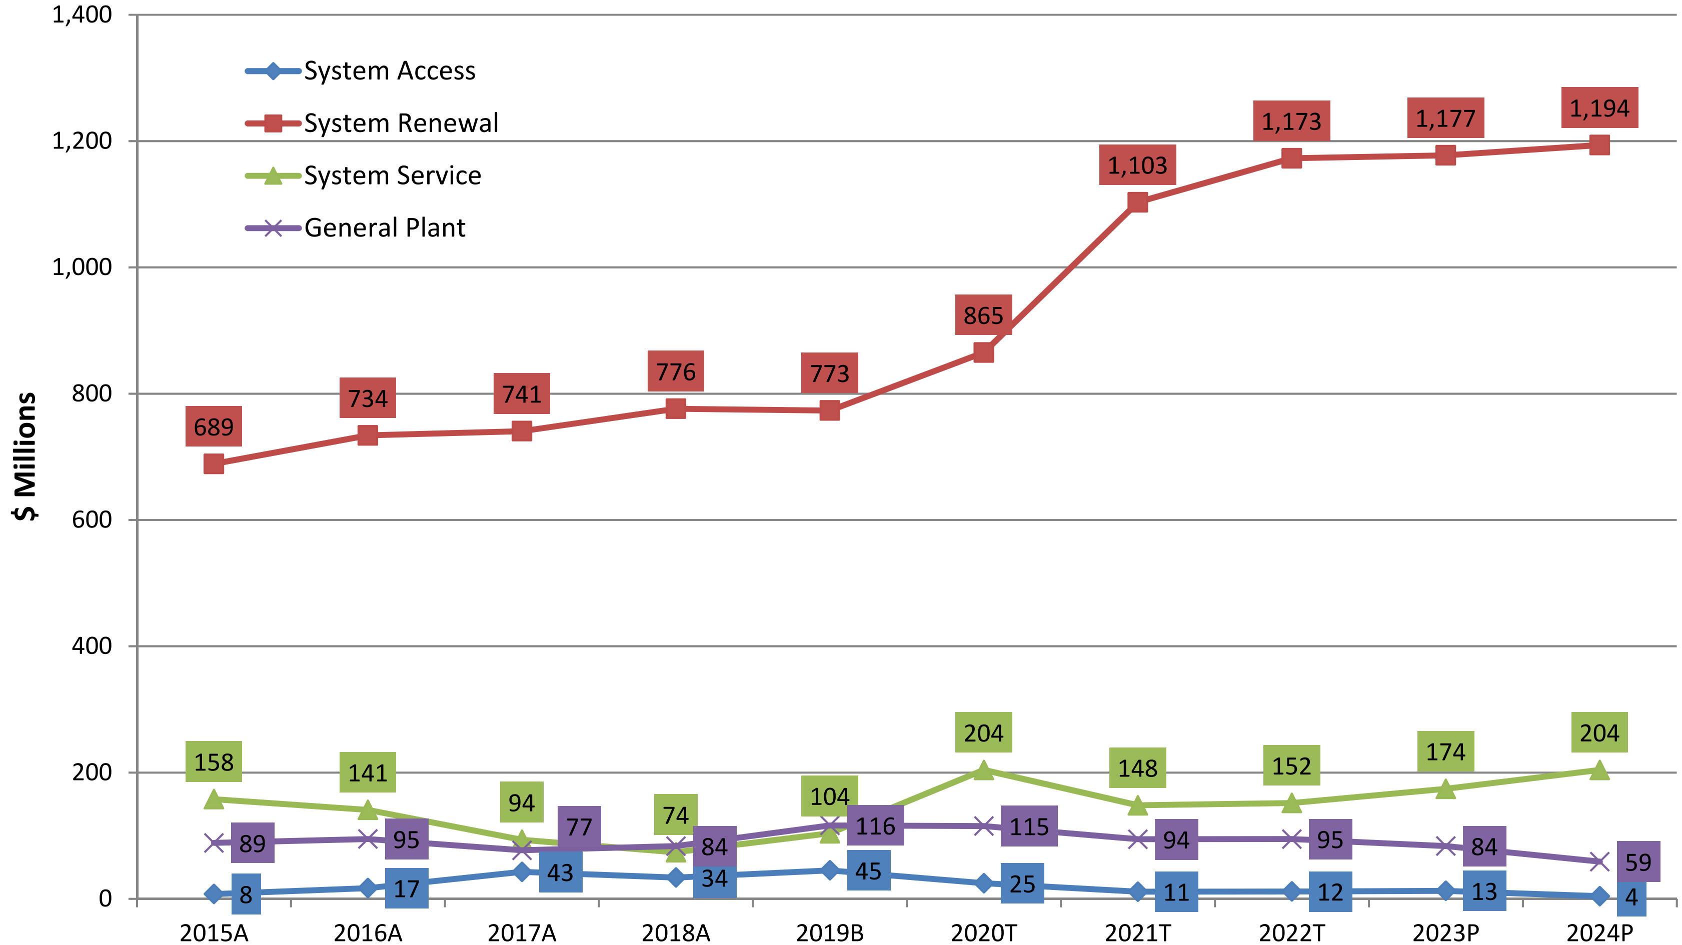

Figure 1 - Actual / Forecast Capital Expenditures 2015 - 2024 by Category

(A=Actual, B=Bridge Forecast, T=Test Forecast, P=Plan)

Hydro One seeks to achieve the following key outcomes through the capital expenditure plan set out in this TSP:

- improved five-year average of delivery point performance, power quality improvements, and increased customer satisfaction with outage coordination through integrated investment planning (Customer Focus);
- an injury-free workplace, lower long-term costs to maintain transmission system infrastructure, and restoring top quartile reliability by mitigating risk arising from asset deterioration and targeting improvements in reliability metrics (i.e., T-SAIDI/SAIFI, System Unavailability) (Operational Effectiveness);
- continued compliance with regulatory requirements, including applicable environmental statutes and regulations, reliability standards, Regional Infrastructure Planning deliverables, and policies regarding the connection of renewable generation (Public Policy Responsiveness); and
- manageable and stable rate impacts over the course of the planning period by undertaking investments to optimize asset value and mitigate future capital investment (Financial Performance).

Hydro One is sensitive to the impacts of the investment plan on its customers. Section 3.2 of the TSP discusses, among other things, how the capital expenditure plan was impacted by and is responsive to customer needs and preferences. Hydro One's approach to investment and targeted outcomes is aligned with the principles in the RRF:

- the TSP reflects customer needs and preferences;
- the company has identified opportunities to extend the useful life of assets and mitigate future higher capital spending requirements for asset replacements;
- the company is actively driving cost reduction and improved productivity and efficiency to offset rate impacts of the proposed investment plan;
- the company has worked with the IESO, transmitters, distributors and other key stakeholders to ensure regional infrastructure needs are addressed in an integrated manner; and

- the company implemented an improved performance management system to provide greater accountability for delivering outcomes to Hydro One's customers.

Hydro One's capital expenditure plan was developed using Hydro One's ongoing process of assessing the condition of critical assets and enhanced investment planning process, which are both detailed in Section 2.1 of the TSP. The proposed capital expenditure plan (including associated outcomes) for each investment category of System Renewal, System Access, System Service, and General Plant is detailed in the following sections.

3.1.1 SYSTEM RENEWAL

System Renewal investments cover the refurbishment or replacement of stations and lines facilities, accounting for about $5.5 billion, or 83% of the net capital expenditures over the five-year TSP period. These investments are required to address assets and systems at the end of their service life (as described in TSP Section 2.2) due to failure, failure risk, substandard performance, high performance risk or functional obsolescence. They allow Hydro One to ensure safety, mitigate reliability risk and maintain compliance with regulatory, environmental and reliability standards. Where feasible, asset life is extended through maintenance programs in order to avoid larger capital replacement costs.

A key finding of Hydro One's asset condition assessment was that a significant portion of transmission system assets have deteriorated to the point where they pose material risks to business objectives for safety, reliability, minimizing environmental impacts and meeting customer needs. This is illustrated in Figure 2 below for major stations and lines assets that are expected to reach the end of their expected service life ("ESL") over the next five years. The significant increase in end-of-life assets is largely due to the historical timing of system expansion and build-up of assets following World War II that are now due for renewal.

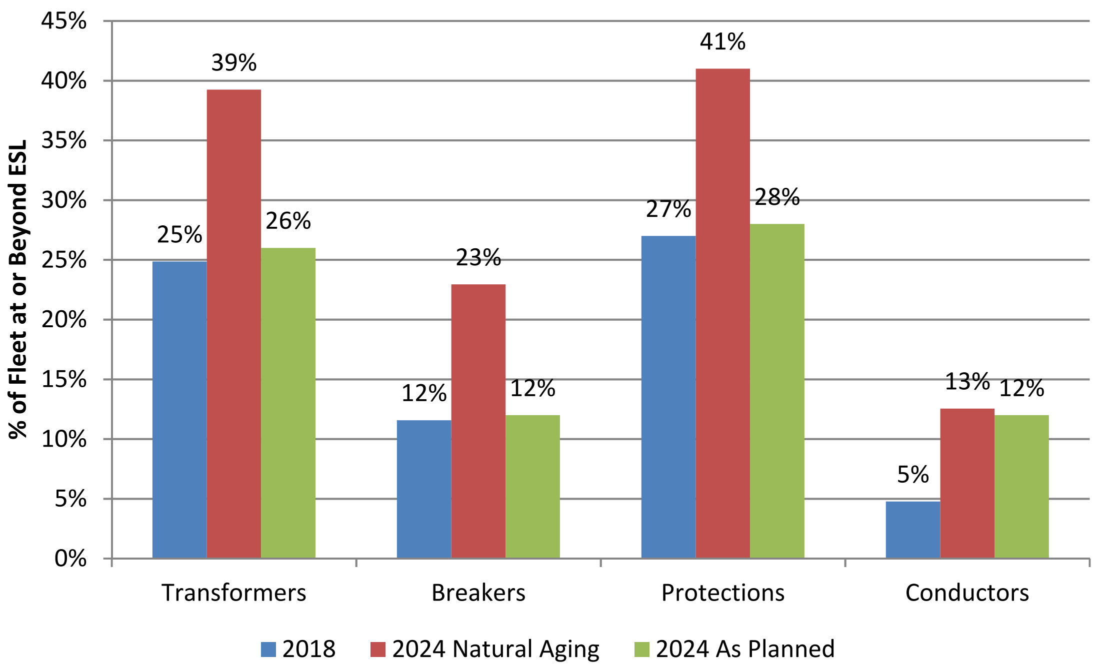

Figure 2 - Assets Operating at or Beyond Expected Service Life

Without the proposed renewal investment, the following percentages of major stations and lines assets are expected to reach the end of ESL by 2024: 41% of protections assets, 39% of transformers, 23% of breakers, and 13% of lines (conductors) assets.

The material System Renewal investments for the TSP period are listed in Table 2 below and are primarily driven by asset condition and performance considerations. Further details on the individual investments are provided in the attachments to Section 3.3.

Table 2 - Major System Renewal Investments

ISD	Investment Title
	Transmission Stations
SR-01	Air Blast Circuit Breaker Replacement Projects
SR-02	Station Reinvestment Projects
SR-03	Bulk Station Transformer Replacement Projects
SR-04	Bulk Station Switchgear and Ancillary Equipment Replacement Projects

SR-05	Load Station Transformer Replacement Projects
SR-06	Load Station Switchgear and Ancillary Equipment Replacement Projects
SR-07	Protection and Automation Replacement Project
SR-08	John Transformer Station Reinvestment
SR-09	Transmission Station Demand and Spares and Targeted Assets
SR-10	Transformer Protection Replacement
SR-11	Legacy SONET System Replacement
SR-12	Telecom Performance Improvements
SR-13	ADSS Fibre Optic Cable Replacements
SR-14	Mobile Radio System Replacement
SR-15	Telecom Fibre IRU Agreement Renewals
SR-28	OPGW Infrastructure Projects
Transmission Lines and Cables	
SR-19	Transmission Line Refurbishment - End of Life ACSR, Copper Conductors & Structures
SR-20	Transmission Line Refurbishment - ACSR Conductor Near End of Life
SR-21	Wood Pole Structure Replacements
SR-22	Steel Structure Coating Program
SR-23	Tower Foundation Assess/Clean/Coat Program
SR-24	Transmission Line Shieldwire Replacement
SR-25	Transmission Line Insulator Replacement
SR-26	Transmission Line Emergency Restoration
SR-27	C5E/C7E Underground Cable Replacement
Cyber Security	
SR-16	NERC CIP-014 Physical Security Implementation
SR-17	NERC CIP Transient Cyber Asset Project
SR-18	PSIT Cyber Equipment Replacement
SR-29	Physical Security ISL Application Replacement

The $5.5 billion in total System Renewal investments include (i) $3.5 billion for stations, which are required to refurbish or replace existing assets located within transmission stations; and (ii) $2.0 billion for lines, which are required to refurbish or replace existing assets associated with overhead and underground transmission lines. The forecast of System Renewal expenditures was determined through the investment planning process (see TSP Section 2.1), based on system needs and condition assessments (see TSP Section 2.2), and with regard to asset life cycle optimization policies (TSP Section 2.3). For the TSP period, individual projects have been bundled into integrated, larger scale station or line projects in order to address all asset needs at a specific site or circuit within a single investment. This integrated approach enables efficient project delivery by optimizing project planning and execution, which minimizes outage requirements and customer impacts.

System Renewal investments aim to address the following stations and lines impacts:

- Prevent a reduction to station reliability as a result of increased asset failures or malfunctions, which could cascade into wider-spread system outages;
- Prevent non-compliance with applicable statutes and regulations, including in relation to equipment oil and noise levels, as well as PCB content restrictions;
- Prevent non-compliance with Northeast Power Coordinating Council's ("NPCC") and North American Electricity Reliability Corporation's ("NERC") reliability standards for protection and control systems;
- Prevent power outages along lines assets due to conductor, structural, insulator and other component failures; and
- Reduce risks to public safety by remediating or replacing poor condition assets situated in and near public areas.

System Renewal investments for stations and lines assets are separately discussed below.

3.1.1.1 Stations Renewal

The TSP includes stations renewal investments of $3.5 billion (53% of the total planning period forecast) to address transformers, circuit breakers, and protection, control and telecom equipment that are deteriorated as determined by condition assessments. Replacement is paced to maintain (though not lower) the proportion of assets beyond ESL over the planning period. Without the proposed investment, the proportion of assets beyond ESL will increase significantly, as set out in Figure 2. As also shown in Figure 2, assuming the planned level of renewal is carried out over the TSP period:

- the population of transformers beyond ESL will increase slightly from 25% to 26% (instead of deteriorating to 39% without the investment),
- the population of breakers beyond ESL will remain steady at 12% (instead of deteriorating to 23% without the investment), and
- the population of protections assets beyond ESL will increase slightly from 27% to 28% (instead of deteriorating to 41% without the investment).

Key stations renewal investments for the TSP period include:

- Replacement of 108 (15%) high risk and deteriorated condition transformers at 44 transmission stations, while eliminating 17 (2%) non-standard or redundant transformers;
- Replacement of 95 (72%) obsolete and poor performing air-blast circuit breakers ("ABCBs") and associated high-pressure air systems located at 8 bulk transmission stations that are key for the reliable operation of the transmission system;
- Replacement of 2,403 (20%) obsolete, non-standard and poor performing protection devices at 72 transmission stations;
- Implementation of cyber security and physical security measures pursuant to regulatory requirements at 26 stations and one control centre; and
- Meeting environmental compliance requirements including the elimination of assets containing PCBs.

Investment in load supply, or customer connected stations is the largest investment in the System Renewal category with $1.6 billion over the five-year plan, which is driven by asset condition and prioritized based on safety, reliability, and environmental impact (see ISD SR-02, SR-05, SR-06, SR-07, and SR-08). Together, the completion of these investments will result in the replacement of 79 transformers, 405 breakers, and 1,341 protection systems over 2020-2024. Additionally, 11 non-standard or redundant transformers and 21 breakers will be eliminated from the system as a result of station reconfiguration to enhance operational effectiveness and meet customer needs and preferences.

Investment in bulk transmission stations will total $578 million over the five-year plan. Similar to load supply stations, bulk station investments are driven by asset condition and prioritized based on safety, reliability and environmental impact. They focus on broader transmission network reliability issues and will be executed in an integrated manner (e.g., see ISD SR-03 and SR-04). These investments will result in the replacement of 19 transformers, 37 breakers, and 290 protection systems over the five-year plan.

Hydro One will invest $158 million over the five-year plan in transformer protections, telecommunication infrastructure and fibre-optic infrastructure to maintain current levels of system reliability (see ISD SR-10, SR-11, SR-12, SR-13, and SR-15). Further, to support field personnel, $19 million will be invested to refresh the provincial mobile radio system (ISD SR-14).

With respect to physical and cyber security infrastructure, Hydro One will invest $82 million over the five-year plan (see ISD SR-16, SR-17 and SR-18) to ensure regulatory compliance and the physical and electronic security of critical system assets.

Lastly, Hydro One will invest $194 million over the five-year plan to purchase spare transformers, support the emergency replacement of failed transformers and other station equipment (see ISD SR-09).

In developing the TSP, Hydro One planned the pace of renewal work so that certain critical work could be completed in the next five years to ensure that transmission assets remain in service and are not subject to increased outage constraints (i.e., resulting from increased failures or additional maintenance requirements) that would make the work more difficult to complete. Hydro One considered both its own ability to execute capital work efficiently and the ability to secure planned outage time to minimize impacts on customers and other stakeholders in Ontario.

Renewal drivers relating to transformers, breakers and protection equipment are more specifically explained below.

3.1.1.1.1 Transformers

Transformers are critical components used in electric power systems to convert power from one voltage level to another to facilitate supply to local distribution companies and industrial customers. Transformer forced outages have been a major cause of customer delivery point interruptions over the past 10 years, representing 13% of equipment-caused events on Hydro One's transmission system. Through asset condition assessment, 17% of Hydro One's transformer fleet are rated high or very high risk based on oil testing results. Currently, 25% of Hydro One's transformer population is beyond its ESL. Assuming no replacements are undertaken, Hydro One anticipates that 280 units (39% of the transformer population) will exceed their ESL by 2024, and 332 units (46% of the population) will exceed their ESL by 2029.

Hydro One plans to manage this risk by replacing an average of 22 transformers annually from 2020 to 2024 selected based on condition. With this replacement rate, Hydro One would be able to maintain the number of units that are beyond ESL to approximately the same level as of 2018, through to the end of 2029.

3.1.1.1.2 Circuit Breakers

A circuit breaker is a mechanical switching device that is capable of carrying and interrupting electrical current under normal and abnormal conditions. During abnormal conditions, breakers operate rapidly to interrupt high currents and minimize impact on the rest of the power system. Hydro One's circuit breaker fleet includes 549 units that are currently beyond their ESL. Breakers have been a significant contributor to customer delivery point interruptions over the past 10 years, representing 13% of these equipment-caused events. Projections for the number of breakers operating beyond ESL by 2024 and 2029, in the absence of replacements or failures, are 1,088 and 1,766, respectively. Condition assessment of the current breaker fleet shows that 9% are rated at a high or very high risk. Furthermore, the entire population of high voltage ABCBs (133 in total) is rated at a high or very high risk when considering factors such as condition diagnostics, performance, criticality, obsolescence and economics.

The frequency and duration of forced outages due to circuit breakers have increased over the past ten years. The frequency increase is primarily attributed to the number of forced outages involving ABCBs, which are the poorest performing breakers in the fleet (see TSP Section 2.2) and are located in critical stations. ABCBs are about ten times more expensive to maintain and four times less reliable compared to SF6 circuit breakers. In addition, approximately 2% of the Hydro One fleet of breakers is no longer supported by vendors, and aftermarket parts are no longer available or are costly to acquire or fabricate. In response to these risks, Hydro One will invest $594 million over the five-year TSP period to replace 95 ABCBs and remove their associated high-pressure air systems (see ISD-SR-01).

3.1.1.1.3 Protection Systems

Protection systems are a critical element of the transmission system. They detect abnormal system conditions and immediately trigger the operation of relevant station equipment (e.g., breakers) to isolate faulted components. Hydro One currently has 12,506 protection systems in-service, approximately 27% of which are operating beyond their ESL. These assets have been a significant contributor to customer delivery point interruptions over the past 10 years, representing 17% of equipment-caused events. Furthermore, over 90% of Hydro One’s solid-state protection fleet is already operating beyond ESL.

Hydro One's replacement strategy for protection systems focuses on assets that have a high likelihood of causing delivery point interruptions and impacting the bulk electric system. Due to the challenges associated with monitoring the condition of all protection systems, other factors like ESL are used to identify high risk assets, which then undergo further condition assessment to identify replacement candidates. Hydro One will replace an average of 480 protection systems per year in the 2020-2024 period, which will largely maintain the current proportion of assets beyond ESL over the planning period (from 27% as of 2018 to 28% by 2024).

3.1.1.2 Lines Renewal

The TSP includes an increased emphasis on lines renewal investments at a cost of $2.0 billion (30% of the total planning period forecast) to refurbish and replace end of life transmission lines, insulators, and wood poles and to continue the steel tower coating program (albeit at a slower pace consistent with the OEB's direction in EB-2016-0160).

Given that a significant portion of Hydro One's transmission lines were built in the 1950s, they will reach the end of their ESL of 90 years in the next two decades. Detailed condition assessments are being conducted for lines exceeding 50 years of age to inform line refurbishment program development. The planned circuit-kilometres of conductor to be replaced in the TSP have been confirmed to be at end of life through condition assessment. While the planned rate of refurbishment does not keep up with the aging lines demographics, risk is being managed by prioritizing line refurbishment investments based on detailed asset condition assessments, which account for the fact that the deterioration rate of transmission line assets depends on location, environmental and system conditions.

Key lines renewal investments for the TSP period include:

- Replacement of 2,127 circuit-km (7%) of end-of-life conductors;

- Replacement of defective insulators on 10,850 (8.5%) primarily critical circuit structures;
- Replacement of 4,000 (9.5%) end-of-life wood poles; and
- Coating of 2,260 (4.3%) steel structures to extend their useful life.

Transmission line sections are comprehensively refurbished when major line components are verified through condition assessment to be deteriorated. Hydro One will invest $425 million to address end of life aluminum core steel-reinforced (“ACSR”) and copper conductor and structures (see ISD SR-19), and $493 million for near end of life ACSR conductor (ISD SR-20). These investments aim to replace a total of 2,127 km, including about 224 km of copper conductor, which is the oldest conductor type in the system and is obsolete since Hydro One can no longer mend certain broken copper conductors. Hydro One will also refurbish steel structures with associated conductors and other lines assets where it has determined that it is economical to replace the entire structure as part of the line refurbishment.

Where Hydro One has determined that complete line refurbishment is not appropriate, it instead pursues overhead line component replacements to address specific asset needs. The wood pole replacement program (see ISD SR-21) is the second largest lines asset investment that will entail $265 million over the five-year plan.

The steel structure coating program, which enables the asset life extension of steel structures, will see $101 million invested over the five-year plan to target 500 structures per year (see ISD SR-22). In addition, Hydro One will invest $104 million from 2020 to 2024 for the refurbishment of steel structure foundations (see ISD SR-23).

Hydro One will invest $64 million over the five-year plan to assess and replace shieldwire that does not meet current design requirements (ISD SR-24). This will address shieldwire that is at risk of mechanical failure (including falling to the ground).

Defective porcelain insulators manufactured by Canadian Ohio Brass ("COB") and Canadian Porcelain ("CP") are identified as high risk and have been targeted for replacement. Hydro One will invest $341 million over the TSP period. In each of 2020 and 2021, it will target 3,700 circuit structures that have defective insulators and that are situated in publicly accessible areas. Beginning in 2022, Hydro One will target 3,450 such circuit structures per year that are not situated in publicly accessible areas (ISD SR-25). This investment is key to preventing insulator failures, which can result in outages and energized conductors falling to the ground (thereby posing significant safety hazards and reliability concerns).

Hydro One will invest $50 million over the five-year plan to support power restoration following transmission line component failures and to replace or repair line components that are likely to fail as identified through line patrols or asset assessment (see ISD SR-26). Given the demand and reactionary nature of this program, the level of investment is in line with historic levels.

Lastly, Hydro One will invest $124 million over the five-year plan to replace 7.2 km of high voltage underground cable due to poor cable performance, condition, and component obsolescence (see ISD SR-27).

Renewal drivers relating to overhead conductors and line insulators are more specifically discussed below.

3.1.1.2.1 Overhead Line Conductors

The conductor of an overhead transmission line transports electricity between system nodes. As such, overhead conductors are the single largest and most vulnerable component of the transmission line system. Lines have been a major contributor to customer delivery point interruptions over the past 10 years, representing 45% of these equipment-caused events. Specifically, given the lack of redundancy, single circuit supplies, which include radial connections, are more likely to result in a customer interruption due to a component failure or weather event. Currently, about 5% of the overhead conductors have reached or exceeded their ESL of 90 years. Without the proposed level of investment, the percentage of conductors exceeding ESL would increase to 13% by 2024.

Hydro One operates a condition assessment program that focuses on conductors beyond 50 years of age. Condition assessment results indicate that 13% of the conductor fleet is at high risk. Despite a planned increased level of replacements when compared to historical levels, the number of conductors beyond the ESL of 90 years is still increasing. An overhead conductor failure can have severe reliability and safety consequences. If this issue is not addressed in a proactive and timely manner, system and customer reliability as well as safety will be placed at risk. Consequently, an increase in planned replacements – even though it will not completely stop or reverse the trend in line demographics – is required to maintain acceptable fleet condition and performance and to avoid a sudden spike in future investments that would otherwise be required as a result of deferred replacements.

3.1.1.2.2 Line Insulators

Line insulators are an integral component of the transmission system. They mechanically support and electrically insulate the conductor from the pole or tower structure, and provide sufficient dielectric strength to prevent short circuits to ground. There are approximately 437,000 insulator strings in Hydro One's overhead transmission network.

As noted above, porcelain insulators manufactured by COB and CP between 1965 and 1982 are known to be defective and susceptible to mechanical and electrical failure. There are approximately 34,000 circuit structures with defective porcelain insulators, including about 15,000 that have been identified as being on structures in critical locations (i.e., near roads, water railways, urban areas, golf courses, educational and health care facilities). Failed insulators typically result in a sustained forced outage because of the resulting permanent electrical fault. Repair time can be prolonged, averaging 36 hours per outage, depending on the location and severity of the failure. To date, Hydro One has replaced approximately 8,900 publically accessible COB and/or CP insulators.

3.1.2 SYSTEM ACCESS

System Access investments are required to provide new load and generation customer connections, and address transmission asset modifications to accommodate third party requests. These investments account for about $345 million of Hydro One's gross capital expenditures for the TSP period. However, the majority of these investments are recoverable from customers in accordance with the Transmission System Code. Therefore, the net capital impact is approximately $65 million or less than 1% of the total net capital expenditures over the five-year plan.

The load and generation connection investments are customer driven, based on requests for connection capacity, as well as reliability needs identified through the regional planning process (as described in Section 1.2) or in connection with IESO generation contracts. Transmission asset modification investments are driven by third party requests to facilitate or permit secondary land use. The magnitude and volume of work in this investment category can vary significantly year over year based on customer requirements. The material System Access investments within the five-year plan are shown in Table 3 below. A complete listing and further details regarding individual material investments are provided in Section 3.3.

Table 3 - System Access Material Investments

ISD	Investment Title
SA-01	Connect New IAMGOLD Mine
SA-02	Horner TS: Build a Second 230/27.6 kV Station *
SA-03	Halton TS: Build a Second 230/27.6kV Station*
SA-04	Connect Metrolinx Traction Substations
SA-05	Future Transmission Load Connection Plans
SA-06	Protection and Control Modifications for Distributed Generation
SA-07	Secondary Land Use Transmission Asset Modification Projects – Recoverable from Customers

(*) Represents investment that was identified in the Regional Planning Process

All of the System Access investments forecast over the planning period are based on investment needs identified through a specific load or generator customer and/or third party request as mentioned above. These investments are non-discretionary, since Hydro One is required to provide transmission access when requested pursuant to the terms of its Transmitter License and the Transmission System Code.

Hydro One plans to undertake approximately $206 million of work to connect load customers over the planning period. A significant portion of this work is recoverable from customers; therefore, the net capital impact of this work is about $58 million over the planning period. This investment in load customer connection work is required to: build new or expand existing transformer stations to increase capacity and meet load growth (see ISD SA-02 and SA-03), and provide connection to customer owned stations (see ISD SA-01) including the connection to six traction power stations for the Metrolinx rail electrification project (see ISD SA-04).

Hydro One also plans to undertake approximately $35 million of work related to generation customer connections over the TSP period. The majority of the projects in this category are below the materiality threshold and associated costs are recoverable from relevant customers. The net capital impact of this work is less than $2 million over the planning period. Generator customer connection work is required to: connect generation customers at the transmission level and execute transmission system upgrades to enable such connections (see ISD SA-06).

Lastly, Hydro One plans to undertake approximately $103 million of work related to secondary land use transmission asset modifications over the TSP period. The size and complexity of these projects vary from year to year; the costs of majority of the projects in this category are recoverable from third parties. The net capital impact of this work is approximately $4 million over the planning period which covers the re-establishment of property rights and corridor safety enhancements. These investments include the relocation, removal, or reinforcement of transmission assets to facilitate third-party projects (e.g., roadwork, transit systems, and other major infrastructure or development work) that may encroach upon or impact Hydro One assets and rights-of-ways (see ISD SA-07).

3.1.3 SYSTEM SERVICE

System Service investments are required to: maintain inter-area network transfer capability, ensure local area supply adequacy, mitigate system risks related to safety, security and reliability, and address customer power quality concerns. These investments account for about $955 million of gross capital expenditures over the five-year plan. However, some of these investments are recoverable from customers in accordance with the Transmission System Code. The net capital impact is approximately $883 million or about 13% of the total net capital expenditures over the 2020-2024 period.

These investments are non-discretionary with the majority having been identified as a result of regional planning processes, IESO bulk planning studies, or the 2017 Long-Term Energy Plan.

The material System Service investments outlined in this TSP are listed in Table 4. A complete listing and further details on individual material investments are provided in Section 3.3.

Table 4 - System Service Material Investments

ISD	Investment Title
SS-01	Lennox TS: Install 500kV Shunt Reactors
SS-02	Wataynikaneyap Line to Pickle Lake Connection **
SS-03	Nanticoke TS: Connect HVDC Lake Erie Circuits**
SS-04	East-West Tie Connection**
SS-05	St. Lawrence: Phase Shifter Upgrade
SS-06	Merivale TS to Hawthorne TS: 230kV Conductor Upgrade**
SS-07	Milton SS: Station Expansion and Connect 230kV Circuits**
SS-08	Northwest Bulk Transmission Line**
SS-09	Barrie Area Transmission Upgrade*
SS-10	Kapuskasing Area Transmission Reinforcement
SS-11	South Nepean Transmission Reinforcement*
SS-12	Aylmer-Tillsonburg Area Transmission Reinforcement*
SS-13	Leamington Area Transmission Reinforcement*
SS-14	Southwest GTA Transmission Reinforcement*

(*)Represents investment that was identified in the Regional Planning Process
(**) Represents investment identified in the 2017 Long-Term Energy Plan

Hydro One plans to invest approximately $481 million on inter-area capacity investments; with a net capital impact of $446 million over the planning period. These investments will provide: new or upgraded transmission facilities to increase the transfer capability between generation areas and load centres within Ontario and with neighbouring utilities (see ISD SS-02 to SS-04, and, SS-06 to SS-08), and provide bulk system reactive control (see ISD SS-01 and SS-05).

Hydro One also plans to invest about $435 million in local area supply; with a net capital impact of $398 million over the planning period. These investments will provide new or upgraded facilities to ensure area supply adequacy, and meet load forecast requirements in areas where existing transmission facility loading levels reach or exceed capacity (see ISD SS-09 to SS-15).

Lastly, Hydro One plans to invest approximately $39 million in risk mitigation, reliability performance enhancement, and addressing customer power quality issues. The majority of the projects in this category are below the material threshold except for customer power quality (see ISD SS-16). These investments will ensure compliance with mandatory standards and demonstrate Hydro One's responsiveness to customer concerns.

3.1.4 GENERAL PLANT

General Plant assets are not part of the electricity transmission system but are nonetheless required to support the safe, efficient and effective performance of the utility's core business and operational functions. The TSP includes $447 million in General Plant investments (7% of net capital expenditures over the five-year plan), which are required to support business and operations activities relating to buildings, tools, equipment, rolling stock, and information technology hardware and software.

General Plant investments tend to be relatively smaller in size and are grouped as shown in Table 5. Further details are provided in Section 3.3 of this TSP.

Table 5 - General Plant Categories

ISD	Investment Category
GP-01	Integrated System Operations Centre - New Facility Development
GP-02	Grid Control Network Sustainment
GP-03	Network Management System Capital Sustainment
GP-04	Integrated Voice Communications and Telephony System Refresh
GP-05	Transmission Non-Operational Data Management System
GP-06	Operating Common IT Infrastructure
GP-07	Hardware/Software Refresh and Maintenance
GP-08	Corporate Services Transformation - HR / Payroll
GP-09	Corporate Services Transformation - Finance
GP-10	Facility Accommodation & Improvements Service Centres & Admin
GP-11	Transmission Facilities & Site Improvements
GP-12	Transport & Work Equipment

Major investments in the General Plant category are highlighted below.

<u>Operating Infrastructure and Control Facilities</u>

Hydro One proposes to invest $189 million in operating infrastructure and control facilities. This includes an investment of $45 million[5] over 2020-2021 to build the new Integrated System Operating Centre (“ISOC”) to ensure the continued safe and reliable operations of the transmission system (see ISD GP-01). The ISOC will provide a reliable primary operation and telecommunication management centre as well as a security operation centre which will ensure compliance with NERC reliability standards.

Hydro One will also invest $23 million in the development of a non-operational data management system (see ISD GP-05) to establish the necessary framework to enable automation and modernization of the transmission system, leading to more effective and better informed decision making as well as enhanced post-fault analysis. In addition, $34 million is allocated for the replacement of end of service life elements of the grid control

[5] The ISOC will be used by both Hydro One Transmission and Hydro One Distribution. $45 million is allocated to Hydro One Transmission. See ISD GP-18 of Exhibit B1-1-1 in Hydro One Distribution’s 2018-2022 application (EB-2017-0049) for the amount allocated to Hydro One Distribution. Details on Common Asset Allocation are described in Exhibit C, Tab 3, Schedule 1.

network (see ISD GP-02) to maintain system operability. The Network Management System ("NMS") will be upgraded between 2021 and 2023 at a projected cost of $38 million, which will maintain the reliable operation of the bulk electric system (see ISD GP-03). The Integrated Voice Communications and Telephony System ("IVCT") will be refreshed to enable the efficient management of daily call volumes and communication between the Ontario Grid Control Centre, Backup Control Centre and IESO as per regulatory requirements at a planned cost of $6 million[6] over the planning period (see ISD GP-04).

Transport, Work and Service ("TWE") Equipment

The TSP includes $76 million for TWE equipment including $66 million for fleet and $10 million for service equipment.

Hydro One will invest $66 million[7] between 2020 and 2024 to keep its 7,000 fleet vehicle units operating safely and to support its work programs (see ISD GP-12). Vehicles at end of life will be replaced to minimize day-to-day maintenance and operational costs, maximize productivity (i.e, minimizing downtime), protect public and employee safety, and meet compliance obligations (e.g., under the *Highway Traffic Act*).

Information Technology ("IT")

The General Plant category includes an investment of $91 million on IT assets, including:

- $14 million[8] in hardware and software refresh and maintenance programs (see ISD GP-07) to ensure the continued operation of the IT application infrastructure and upgrade existing systems;

---

[6] Amount allocated to Hydro One Transmission. Refer to EB-2017-0049, ISD GP-23 for Distribution allocation.
[7] Amount allocated to Hydro One Transmission. Refer to EB-2017-0049, ISD GP-01 for allocation to Distribution.
[8] Amount allocated to Hydro One Transmission. Refer to EB-2017-0049, ISD GP-05 for allocation to Distribution.

- $12 million[9] in critical IT infrastructure (see ISD GP-06) to address equipment needs generated by the growth in demand for IT services, capacity limitations and the replacement of end-of-life equipment;
- $21 million[10] in planned financial and work management system transformation (see ISD GP-09) and $7 million[11] in planned human resources ("HR") and payroll transformation (see ISD GP-08) aimed at optimizing talent management, time and payroll management and HR performance; and
- other smaller investments below the $3 million materiality threshold, such as refreshing enterprise analytics, GIS modernization, enterprise content and document management and reporting systems, IT security programs to ensure ongoing sustainment of newly commissioned security tools, policies, practices, standards and regulatory requirements.

Facilities

Hydro One will invest $90 million in facility accommodation and transmission site facility capital repairs and improvements (ISD GP-10[12], ISD GP-11). This includes additions to and renovation of existing facilities and the acquisition of new facilities to address existing and/or new accommodation requirements; replacement of major building system/components, including roof structures; windows and cladding; HVAC systems, electrical, lighting and control systems, and other fundamental structural elements; and site-related replacements and additions, including drainage, asphalt, and fencing.

Material General Plant investments are described in detail in Section 3.3.

---

[9] Amount allocated to Hydro One Transmission. Refer to EB-2017-0049, ISD GP-19 for allocation to Distribution.
[10] Amount allocated to Hydro One Transmission. Refer to EB-2017-0049, ISD GP-17 for allocation to Distribution.
[11] Amount allocated to Hydro One Transmission. Refer to EB-2017-0049, ISD GP-13 for allocation to Distribution.
[12] This ISD represents the Transmission allocation. See EB-2017-0049, ISD GP-02 for Distribution allocation.

3.2 CAPITAL PLANNING DRIVERS AND CONSIDERATIONS

Section 3.1 provided a summary of Hydro One's capital expenditure plan for the four major investment categories (System Renewal, System Access, System Service, and General Plant). While that section outlined the capital expenditure plan largely from the lens of system and asset needs as well as certain key investment drivers (i.e., reliability, safety, customer requirements and compliance obligations), it is important to recognize the role and significance of a myriad of other drivers and considerations that shaped, informed, and impacted the development of this TSP, in accordance with the principles and requirements of OEB's Renewed Regulatory Framework ("RRF"). Section 3.2 discusses these other drivers and considerations and their impact on Hydro One's TSP, including:

- Customer needs and preferences as identified through customer engagement;
- Customer connection and regulatory and public policy requirements (i.e., regional planning processes, and the Long Term Energy Plan ("LTEP"));
- Benchmarking analyses;
- Performance measurement;
- Productivity Savings; and
- Timing and pacing that appropriately account for customer rate impacts and execution considerations.

3.2.1 (5.4 B, 5.4.1 A, 5.2.1 B)HOW THE PLAN REFLECTS CUSTOMER ENGAGEMENT

Hydro One's objective is to engage with customers consistently and proactively. The company's full spectrum of customer engagement initiatives, as described in TSP Section 1.3, is designed to: (i) increase the company's understanding of customer needs and preferences; (ii) enhance Hydro One's ability to provide services that meet these needs; (iii) achieve outcomes that are valued by customers; and (iv) attain an improvement in overall customer satisfaction with service received from Hydro One.

In May 2017, Hydro One engaged with its customers through a formal Customer Engagement Survey to learn about the outcomes that customers care about, as well as the level of spending and mix of investments that customers would like to see included in the plan. Through this engagement, customers rated seven outcomes on a scale of importance. Based on the information collected during this engagement process (as described in TSP Section 1.3), the following customer needs and preferences were identified:

- Customer priorities are as follows: safety, reliability and outage restoration, followed by power quality, customer service, productivity and environmental stewardship.
- All business customer segments, particularly LDCs, prefer that investments be spread out over time, along with stable rate increases. This preference is due primarily to perceived affordability for ratepayers and the ability to plan ahead.
- Reducing the frequency of power interruptions is more important than reducing the duration. Most important is reducing the number of day-to-day interruptions.

Hydro One's TSP is customer focused and designed to meet customer needs and preferences and result in outcomes that customers value. This plan reflects the results of the customer engagement process while balancing system/asset needs, risk mitigation and cost by:

- Optimizing the life of existing assets while mitigating the risk to safety and to current service levels posed by asset deterioration;
- Improving system and customer reliability;
- Addressing customer needs and preferences through new customer connections, and regional development to enable growth and system renewal to meet current requirements;
- Coordinating system renewal investments and maintenance with generator customers during planned outages to minimize disruption to operations;
- Responding to customer power quality concerns by proactively monitoring power quality across the province and working with customers to resolve specific issues; and
- Incorporating increased cost reductions, efficiency and productivity improvements to offset the customer rate impacts of the proposed investment plan.

In addition to its Customer Engagement Survey, Hydro One has several ongoing activities that it uses to engage with its customers. These are described below.

3.2.1.1 Oversight Committees and Working Groups

In addition to formal customer engagement research, Hydro One has established a number of specific oversight committees and working groups with its customers, as described in TSP Section 1.3. These committees and working groups provide avenues for feedback for customers in areas where there has been a high level of customer interest, where careful and ongoing coordination with other entities is particularly valuable, and/or where there is a need for coordinated health and safety oversight.

3.2.1.1.1 Sarnia Area Reliability Oversight Committee

In light of the sensitivity of industrial and generation-connected customers to voltage and power quality issues in the Sarnia area, the Sarnia Area Reliability Oversight Committee meets to identify reliability issues in the Sarnia area and review proposed annual work plans and investments. This forum enables collaborative discussion on proposed work programs that would affect customers in the area, including discussion on proposed investment at *Sarnia Scott TS* (ISD SR-03) and *St. Andrews TS* (ISD SR-02) to ensure the switchyard reliability and configuration meet customer needs. A recent investment at Wanstead TS, completed in 2018, has resulted in the station being supplied from the 230 kV network instead of the previous 115 kV connection point in light of concerns expressed over reliability of the current supply to Wanstead TS.

3.2.1.1.2 LDC Working Group and Toronto-Hydro Oversight Committee

With several investments planned for the Toronto Hydro-Electric System Ltd. ("THESL") service area, including station reinvestment at Runnymede TS, and Fairbank TS (ISD SR-02) and John TS (ISD SR-08), transformer replacements at Bathurst TS, Bridgman TS, Charles TS, Duplex TS, Fairchild TS, Main TS, and Strachan TS (ISD SR-05), and switchgear replacement at Finch TS, Leaside TS, and Rexdale TS, and additional capacity at Horner TS (ISD SA-02), the oversight committee provides a venue to consult and collaborate with THESL to ensure customer needs and preferences inform planning and investment decisions. This includes incorporating feedback on switchyard configuration, equipment ratings, feeder egress, and outage coordination.

3.2.1.1.3 Switchyard Oversight Committees

Significant investment is planned for the replacement of air blast circuit breakers ("ABCBs") at major Hydro One facilities connected to Bruce Power and Ontario Power Generation nuclear generation facilities. To this end, coordination and collaboration are paramount to the successful execution of these projects. These committees ensure that specific generator requirements (e.g., equipment ratings and synchronizing capability) are captured within the proposed investment plan. The ABCB replacement projects at Bruce A TS, Bruce B TS, and Cherrywood TS are detailed in ISD SR-01.

3.2.1.1.4 Metrolinx Working Group

This working group provides a forum for considering issues in a coordinated manner in connection with the large scale and broad scope of transportation infrastructure work that Metrolinx is undertaking in Ontario. Through this forum, the working group reviews and addresses, in an efficient and coordinated manner, customer escalations arising from the Metrolinx work program work. This includes the ongoing work to connect the Metrolinx Traction Substations (ISD SA-04) as part the GO Transit electrification project.

3.2.1.1.5 Hydro Ottawa Oversight Committee

This working group provides a forum to identify and resolve any issues and to ensure safe and efficient operations between Hydro One and Hydro Ottawa. Meetings also allow the parties to coordinate efforts relating to capital projects and other matters.

3.2.1.2 Focused Planning Meetings with Customers

Customer engagement is a common theme throughout Hydro One's investment planning process described in TSP Section 2.1. In addition to the above, customer engagement is a key consideration in the development of the investments contained within this TSP. Hydro One's planning staff engages with customers regularly and through a variety of mechanisms, in a manner that is most effective for the relevant customer. This includes regularly scheduled meetings or conference calls (e.g., on a monthly or quarterly basis, or on a per project basis) as asset or system needs are identified during initial planning phases. These ongoing conversations with customers ensure their needs and preferences inform the investment plan, whether for new or existing connections.

System Access investments presented within this TSP reflect customer needs for new load or generation connections and are driven based on customer requests for connection capacity and reliability improvements or needs identified as part of the regional planning process, described in TSP Section 1.2, or in connection with Independent Electricity System Operator ("IESO") generation contracts.

System Service investments presented within this TSP reflect system and customer needs to maintain network transfer capability and system reliability and also address customer power quality concerns. These needs are identified through direct customer engagement or through the Regional Planning processes discussed in TSP Section 1.2. Investments to maintain network transfer capability, system reliability and power quality concerns are included as part of this TSP.

System Renewal investments presented within this TSP incorporate customer needs and preferences as established through the Asset Risk Assessment (“ARA”) process detailed in TSP Section 2.1.2.3. Planners engage connected customers during the preparation of the scope of work to solicit input and feedback on the proposed plans to ensure needs and preferences are addressed in a collaborative manner.

These continuous communications and engagement activities enable Hydro One to ensure customer needs and preferences inform investment planning decisions and strengthen customer relationships on an ongoing basis.

3.2.1.3 Investment Planning Informed by Customer Engagement

As described in TSP Section 2.1, as part of Hydro One’s investment planning process, Hydro One planning functions assess the risks of not proceeding with investments based on the applicable investment prioritization and optimization framework. This framework reflects Hydro One’s priorities, the principles of the RRF and outcomes valued by customers, which have been identified through customer engagement processes. This alignment ensures Hydro One’s investment planning decisions are positioned to deliver outcomes that are valued by customers.

In addition to a broad alignment of investment planning decisions criteria with customer values, Hydro One identifies and tracks other, more qualitative customer needs and preferences that are incorporated into its investment plans, such as outage/asset renewal coordination, proactive communication, power quality, and performance improvements, as captured through the customer engagement flag.

As discussed in Section 1.3, throughout the planning process, the ongoing alignment of investment drivers with identified needs and preferences was monitored. From the candidate investment development stage through to TSP finalization, the funding status of customer flagged investments was monitored, discussed and considered.

A number of investments were identified and proposed over the five-year planning horizon to respond to specific customer needs and preferences. Examples of these investments are highlighted by theme in Table 1 below; further details on material capital investments are provided in Section 3.3 and discussion on OM&A programs is provided in Exhibit F.

Table 1 – Investments Informed by Customer Feedback

ISD	Description	Customer Engagement Considerations
Customer Coordination of Asset Renewal		
SR-02	Carlton TS	Customer (Alectra) was consulted on final station configuration to meet customer needs
SR-02	Gage TS	Reconfiguration of switchyard based on customer needs and decreased industrial loading
SR-02	Glendale TS	Customer (Alectra) was consulted on final station configuration to meet customer needs
SR-02	Kenilworth TS	Customer (Alectra) was consulted on final station configuration to meet customer needs
SR-05	Strachan TS	Request for larger capacity transformer by Toronto Hydro.
N/A[1]	St. Thomas TS	Coordination with Aylmer Tillsonburg Area Transmission Reinforcement Project (SS-14) to address voltage drop and customer reliability.
SR-07	Frontenac TS	Coordination with Utilities Kingston to address asset needs and feeder protections

[1] Investment is below $3 million materiality threshold.

ISD	Description	Customer Engagement Considerations
Customer Coordination/Communication		
N/A[2]	ROW Notification Program	The notification program is required to inform all adjacent property owners of upcoming ROW maintenance. Customers are accustomed to receiving notifications prior to maintenance and without the program, may have strong objections to the vegetation changes. Negative media attention would likely result.
N/A[1]	Tx Portal Enhancement	Enhancement to Transmission Customer Portal
Customer Outage Coordination		
N/A[2]	Circuit Breaker Maintenance and Refurbishment	OPG Darlington has provided their overhaul schedule for their generating units, with the expectation that Hydro One will complete the refurbishment of the breakers within the timing of the unit overhaul, in order to minimize requirements for outages for performing this type of maintenance in the future.
SR-01	Bruce B SS	Replacement of Air Blast Circuit Breakers (ABCBs) will be aligned with Bruce Power refurbishment project.
SR-01	Cherrywood TS	Replacement of Air Blast Circuit Breakers (ABCBs) will be aligned with OPG to coordinate with Pickering GS shutdown plan.
SR-01	Beck 1 SS	Replacement of Air Blast Circuit Breakers (ABCBs) will to be aligned with OPG canal refurbishment project.
SR-01	Bruce A TS	Replacement of Air Blast Circuit Breakers (ABCBs) will be aligned with Bruce Power refurbishment project
SR-03	Sarnia Scott TS	Asset replacements will be coordinated with petroleum sector customers to minimize outages to customer supply points.
Performance Improvement		
N/A[2]	Nuisance Wildlife Control	Numerous customers request animal mitigation performance numbers and updates on investments (i.e. Domtar, Alectra, Toronto Hydro)
N/A[2]	Nuisance Wildlife Control (Civil)	Numerous customers request animal mitigation performance numbers and updates on investments (i.e. Domtar, Alectra, Toronto Hydro)
SR-02	Kent TS	Entegrus Powerlines have expressed issues with delivery point performance due to physically split transitional bus.
SR-19	K1/K2 Refurbishment	Improve reliability performance of circuits supplying outlier delivery points.
SR-20	A4L Refurbishment	Improve reliability performance of circuits supplying outlier delivery points.

[2] See Exhibit F for discussion of OM&A programs.

ISD	Description	Customer Engagement Considerations
N/A[1]	Circuit Switchers for Outlier Improvement	Based on recent customer survey, most consider reliability to be extremely important. This investment is proposed to improve the reliability of some of the worst performing delivery points (outliers)
Power Quality		
N/A[1]	Customer Power Quality (Tx) – OM&A	The planned Customer PQ program expenditure will address the expected demand of customer enrollments in the PQ meter integration initiative program and the expected increase in third party audit activities. Hydro One will continue to monitor the effectiveness of this program and adjust future program funding accordingly.
SS-16	Customer Power Quality (Tx) - Capital	Installation of cap-switchers at transmission stations based on the severity of transient over voltages and the complaints received from industrial customers. For example: the installation of a cap-switcher at Napanee TS to address a complaint received from a large customer supplied from that transmission station.

While the topic of capacity expansions was also raised by select respondents, connection facility investments are typically at least partially customer funded and have generally been excluded from this aspect of the investment planning framework, as they are captured as third-party requests.

3.2.2 (5.4.1 B, 5.4.1 D) HOW THE PLAN REFLECTS REGIONAL PLANNING

Many of the System Access, System Service and System Renewal investments mentioned above in Section 3.2.1 have been identified as a result of Regional Planning processes.

The investments identified through the Regional Planning process account for about $1.8 billion of gross capital expenditures over the five-year plan. However, some of these investment costs are recoverable from customers in accordance with the Transmission System Code. Therefore, the net capital impact is approximately $1.7 billion or about 25% of the total net capital expenditures over the five-year plan.

Detailed information on the Regional Planning process and region by region outcomes, including the list of projects contributed, can be found in Section 1.2. The material TSP investments identified through Regional Planning are listed in Table 2 below. Further details on these individual material investments are provided in Section 3.3.

Table 2 - Material Investments Identified in Regional Planning

ISD	Investment Title
System Access	
SA-02	Horner TS: Build a Second 230/27.6kV Station
SA-03	Halton TS: Build a Second 230/27.6kV Station
System Service	
SS-02	Watay Line to Pickle Lake Connection
SS-07	Milton SS: Station Expansion and Connect 230kV Circuits
SS-09	Barrie Area Transmission Upgrade
SS-11	South Nepean Transmission Reinforcement
SS-12	Aylmer-Tillsonburg Area Transmission Reinforcement
SS-13	Leamington Area Transmission Reinforcement
SS-14	Southwest GTA Transmission Reinforcement
System Renewal	
SR-02	Arnprior TS: Station Reinvestment
SR-02	Elgin TS: Station Reinvestment
SR-02	Fairbank TS: Station Reinvestment
SR-02	Gage TS: Station Reinvestment
SR-02	Kenilworth TS: Station Reinvestment
SR-02	Runnymede TS: Station Reinvestment
SR-02	Sheppard TS: Station Reinvestment
SR-02	Slater TS: Station Reinvestment
SR-02	St. Andrews TS: Station Reinvestment
SR-02	Wonderland TS: Station Reinvestment
SR-03	Beach TS: Transformer Replacement
SR-03	Detweiler TS: Transformer Replacement
SR-03	Keith TS: Transformer Replacement
SR-03	Manby TS: Transformer Replacement
SR-03	Sarnia Scott TS: Transformer Replacement
SR-05	Bermondsey TS: Transformer Replacement
SR-05	Birmingham TS: Transformer Replacement
SR-05	Bridgman TS: Transformer Replacement
SR-05	Cedar TS: Transformer Replacement
SR-05	Charles TS: Transformer Replacement
SR-05	Duplex TS: Transformer Replacement
SR-05	Fairchild TS: Transformer Replacement

ISD	Investment Title
SR-05	Hanlon TS: Transformer Replacement
SR-05	Hawthorne TS: Transformer Replacement
SR-05	King Edward TS T3 and PCT Replacement
SR-05	Kingsville TS: Transformer Replacement
SR-05	Lauzon TS: Transformer Replacement
SR-05	Leslie TS: Transformer Replacement
SR-05	Longueil TS: Transformer Replacement
SR-05	Main TS: Transformer Replacement
SR-05	Minden TS: Transformer Replacement
SR-05	Newton TS: Transformer Replacement
SR-05	Orangeville TS: Transformer Replacement
SR-05	Parry Sound TS: Transformer Replacement
SR-05	Preston TS: Transformer Replacement
SR-05	Strachan TS: Transformer Replacement

SR-06	Burlington TS: MV Switchard Refurbishment
SR-06	Dundas TS: MV Switchyard Refurbishment
SR-06	Lake TS: MV Switchyard Refurbishment
SR-06	Norfolk TS: Switchyard Refurbishment
SR-08	John Transformer Station Reinvestment Project
SR-19	B3/B4 | Horning Mountain JCT-Glanford JCT: Line Refurbishment
SR-19	H1L/H3L/H6LC/H8LC | Bloor Street x Leaside: Line Refurbishment
SR-27	C5E/C7E: HV Underground Cable Replacement

3.2.3 (2.4 TRANSMISSION) HOW THE PLAN REFLECTS LTEP

As highlighted in the 2017 LTEP, there will be no need for any further major expansion of the transmission system beyond the projects already planned or under development, based on the demand forecast and the years of investment in Ontario to renew the electricity system.

The planned or under-development transmission investments identified in the LTEP are required to facilitate supply to First Nations, facilitate new or optimize existing interconnection capabilities, prepare for the retirement of the Pickering Nuclear Generating Station, and accommodate long term load growth.

These LTEP investments are reflected under the System Service category (see TSP Section 3.1) and account for $420 million or about 5% of the total capital expenditures over the five-year plan.

The LTEP major transmission investments are listed in Table 3 below. Further details on these individual investments are provided in Section 3.3 of the TSP, with the exception of Clarington Transformer Station which was placed in-service in 2018.

Table 3 - LTEP Major Transmission Projects

ISD	Project Description
SS-02	Wataynikaneyap Power Line to Pickle Lake Connection
SS-03	Nanticoke TS: Connect HVDC Lake Erie Circuits
SS-04	East-West Tie Connection
SS-06	Merivale TS to Hawthorne TS: 230kV Conductor Upgrade
SS-07	Milton SS: Station Expansion and Connect 230kV Circuits
SS-08	Northwest Bulk Transmission Line
*	Clarington Transformer Station

(*) This project was completed in 2018. For details on this project, refer to proceeding EB-2016-0160, Exhibit B1, Tab 3, Schedule 11, ISD D01.

In addition to the major transmission projects listed above, the LTEP identifies a number of Regional Planning projects that form part of Hydro One's five-year plan, as previously noted in Section 1.7.

3.2.4 (5.4.1 A, 5.4.1 B) HOW THE PLAN REFLECTS BENCHMARKING

As described in Section 1.4.1.1, Hydro One engaged various third party experts to perform a series of studies on major asset types and their treatment, so as to assess whether Hydro One is following industry best practices in the areas of condition assessments, asset management and capital expenditure pacing. The studies confirm Hydro One's use of industry best practices and affirm the pacing of capital expenditures.

3.2.4.1 Operating Spare Transformers Requirement Assessment

This study found that the results of Hydro One's Markov model analysis (used to determine the appropriate number of spare transformers), aligns with the independent and alternative analysis from the third-party expert, Electric Power Research Institute ("EPRI"). Hydro One continues to take steps to achieve and maintain the required quantity of operating spare transformers to ensure reliability and improve cost efficiency.

3.2.4.2 Derivation of Transformer Hazard Functions

This study confirmed that Hydro One's pacing approach to the replacement of transformers is appropriate. This pacing of transformer replacement has been reflected in the following ISDs: SR-02 (Station Reinvestment Projects), SR-03 (Bulk Station Transformer Replacement Projects), SR-05 (Load Station Transformer Replacement Projects), and SR-08 (John Transformer Station Reinvestment).

3.2.4.3 Derivation of Circuit Breaker Hazard Function

This study was performed by EPRI and describes EPRI's efforts to (i) model and develop circuit breaker removal rates from historical replacement records and (ii) apply them to forecast the number of circuit breakers expected to require replacement based on past practices. EPRI has developed a methodology using advanced statistical techniques for analyzing circuit breaker historical removals and applied it to the Hydro One's circuit breaker fleet. Using Hydro One's circuit breaker retirement data, EPRI modeled Hydro One's circuit breaker removals and has forecast probable future removal rates. The study confirmed that Hydro One is replacing younger circuit breakers at a rate expected from the statistical model. However, older circuit breakers are being replaced at a quicker rate than expected. The reason for faster paced replacement is due to replacement criteria that are not included in the EPRI report as explained below.

Hydro One plans to address 638 breakers over the planning period. This includes the removal of 49 breakers as a result of station decommissioning and reconfiguration as well as the additional installation of 15 breakers resulting from customer requests to increase operational flexibility in the Toronto area. As per the EPRI analysis, there is a 90% probability that Hydro One will need to replace 491 breakers or fewer. However, Hydro One's volume of replacement over the plan period is higher primarily due to obsolescence concerns, safety concerns (e.g. insufficient arc resistance), PCB mitigation, and integrated investments which are not reflected in the EPRI analysis.

The EPRI analysis is derived from asset retirement data from 1981 to 2017. The analysis does not reflect the necessary replacement of 95 ABCBs over the planning period due to worsening reliability, as Hydro One has operated its fleet longer than industry peers. Similarly, the historical mid-life refurbishment of oil breakers from 1950 to 2007 has enabled Hydro One to operate approximately 300 currently in-service breakers for a longer period prior to retirement. Based on how the calculations were performed, this skews the predicted replacement rate. PCB mitigation also contributes to the increased rate of replacement in order to meet federally legislated deadlines. Out of the 247 oil circuit breakers identified for replacement over the planning period, 69 (28%) have measured above the acceptable level of 45 ppm for PCBs. Due to increased obsolescence concerns and the lack of, or reduction of, vendor support with respect to oil, metalclad, and vacuum breakers, the capital plan paces breaker replacements to mitigate reliability impact. Where breakers that are not end of life are removed from service because it is part of an integrated investment (e.g., due to the replacement and relocation of a switchyard), these breakers are placed into spares to support the remaining fleet. Oil circuit breakers can be salvaged for parts to support the remaining fleet, while complete SF6 breakers are placed into the spare equipment pool to support demand replacements.

This pacing of circuit breaker replacement has been reflected in the following ISDs: SR-02 *Station Reinvestment Projects*, SR-04 *Bulk Station Switchgear and Ancillary Equipment Replacement Projects*, SR-06 *Load Station Switchgear and Ancillary Equipment Replacement Projects*, and SR-08 *John Transformer Station Reinvestment*.

3.2.4.4 ESL Survey of Transformers

This EPRI survey confirmed Hydro One's current asset management practices relating to transformers and the definition of Expected Service Life ("ESL") are aligned with industry best practices.

Depending on the type of transformer, Hydro One uses an ESL between 40-60 years, in line with industry peers. Hydro One uses asset condition as a primary driver for replacement, and all transformers undergo condition assessment to confirm the need for replacement. Replacement decisions take into consideration multiple factors, including an analytics algorithm as part of the assessment tool kit, which is common throughout industry. Hydro One has a formal process for assessing condition where the ultimate decision for replacement is made by a subject matter expert, which is in line with industry best practices.

3.2.4.5 ESL Survey of Circuit Breakers

This EPRI survey confirmed that Hydro One's asset management practices relating to circuit breakers are in line with best industry practices.

Hydro One uses 40 years as the ESL for circuit breakers and 50 years for oil circuit breakers in line with industry peers. In alignment with the majority of utilities in the industry, Hydro One proactively pursues replacements based on condition and reliability concerns. Hydro One does not operate equipment to failure. Hydro One has a formal process for assessing condition with the ultimate decision for replacement being made by a subject matter expert – which is in line with industry best practices. Recommendation for replacement takes into consideration multiple factors where an analytics algorithm is part of the assessment tool kit. Hydro One targets families of breakers for replacement if family-wide performance or condition issues are experienced (e.g., Siemens SP breakers).

3.2.4.6 Review of Utilities' Management of Air Blast Circuit Breakers

The data EPRI collected from this survey has demonstrated that Hydro One's approach to managing ABCBs is consistent with the industry. More specifically, the survey found that the both minor and major maintenance of ABCBs are "more" to "much more costly/difficult" to perform, and "less" to "much less reliable" when compared to single pressure gas breakers. Principal drivers behind programmatic replacement were operation and maintenance costs and an unacceptable level of reliability/availability. The population of ABCBs utilized by the utilities has been reduced by two-thirds over the last decade, with no new ABCBs currently being installed. The lack of available spare parts to properly maintain these types of breakers has become problematic for utilities due to the age of the technology and obsolescence. Hydro One currently has 133 ABCBs in its system. Over the next five years, Hydro One plans to remove 95 ABCBs from service and replace them with SF6 equivalents. For more details pertaining to this project, refer to SR-01 *Air Blast Circuit Breaker Replacement Projects*.

3.2.4.7 Review of Utilities' Management of Oil Circuit Breakers

The data EPRI collected from this survey has demonstrated that Hydro One's approach to managing Oil Circuit Breakers ("OCB") is consistent with the industry. More specifically, the survey found that the OCBs are somewhat "more costly/difficult" for purposes of performing both minor and major maintenance. OCBs are somewhat "less reliable" when compared to single pressure gas breakers. Principal drivers behind programmatic replacement are: unacceptable reliability/availability and insufficient ratings for below 138 kV; and excessive costs, environmental, and other for above 138 kV. The population of OCBs utilized by the utilities has been reduced by 18% over the last decade and nearly 85% of OCBs that are currently installed are over 40 years old. Utilities have diminished abilities to properly maintain oil circuit breakers as no utilities have dedicated crews to perform internal inspections/refurbishments or dedicated shops/contractors to maintain and overhaul oil circuit breakers. The higher cost and difficulty associated with maintenance requirements when compared to newer technology and the lack of dedicated crews to work on the ever-aging population of installed OCBs may lead to longer outage times associated with both routine and emergency maintenance. Hydro One currently has 1,600 OCBs in its system. Over the next five years, Hydro One plans to replace 247 OCBs with SF6 equivalents. OCB replacements are included as part of the following ISDs:

- SR-01 - *Air Blast Circuit Breaker Replacement Projects*
- SR-02 - *Station Reinvestment Projects*
- SR-03 - *Bulk Station Transformer Replacement Projects*
- SR-04 - *Bulk Station Switchgear and Ancillary Equipment Replacement Project*
- SR-05 - *Load Station Transformer Replacement Projects*
- SR-06 - *Load Station Switchgear and Ancillary Equipment Replacement Projects.*

For more details pertaining to these investments, refer to the ISDs noted above.

3.2.4.8 ESL Assessment of Specific Relays

This Kinectrics study was carried out to determine the risk associated with operating solid state and microprocessor relays beyond ESL and inform Hydro One of replacement pacing. The study was based on the samples of the currently in-service solid state and microprocessor-based relay population. These samples of relays were subject to accelerated aging tests. The report identified that the ESL range used by Hydro One is in-line with utility practice of 13 to 19 years for solid-state relays and a range of 13 to 20 years for microprocessor relays. The study results recommended Hydro One to increase the ESL for solid-state and microprocessor relays but did not provide a recommended ESL level.

While the study results confirm that Hydro One's ESL and treatment of these relays is appropriate and aligned with industry best practices. Hydro One will review its current practices and decision making process as well as continue to track and monitor the performance of its relays, based on the report's recommendations, to maximize the utilization of the relay fleet while managing its associated risk. For the time being, Hydro One will maintain the current ESL for all solid state and microprocessor-based relays systems as 25 years and 20 years, respectively as described in Section 2.2.

Specific integrated investments that include the replacement of protection system over the next five years are further described in ISDs SR-01, SR-02, SR-03, SR-04, SR-05, SR-06, SR-07, and SR-08.

3.2.4.9 Degradation Rates of Steel Tower Coating Systems

The EPRI study supports Hydro One's current investment plan by validating the existing approach and assumptions. Using the findings of the study, Hydro One continues to focus on coating steel structures in C4 and C5 corrosion zones whose age has reached 35-75 years of age.

3.2.4.10 Derivation of Overhead Conductor Hazard Function

The purpose of this EPRI study is to provide valuable insights into fleet mean life expectancy from analysis of historical condition assessment and replacement data pertaining to overhead conductors. In particular, this study presents EPRI's analysis to develop a conductor hazard curve and its ESL which can be used to project expected replacement needs for planning purposes.

As a result of the study, Hydro One has changed its conductor ESL from 70 to 90 years. The EPRI report forecasts that 3,920 circuit km of the ACSR conductor fleet will be at End-Of-Life ("EOL") or near EOL condition by 2024.[3] This forecast of ACSR conductor condition aligns with the fact that by the end of 2024, about 13% or 3,653 circuit km of the overall conductor fleet will reach or exceed their ESL without further replacements.

[3] TSP Section 1.4 Attachment 4 - Derivation of Overhead Conductor Hazard Function, section 5-3, p 93.

Hydro One only uses ESL for long term planning purposes and the planned conductor replacements are based on detailed condition assessments, Hydro One does not plan to increase its conductor replacement plan for the next 5 years based on EPRI's new ESL for conductors. Hydro One intends to replace 2,127 circuit km of conductor over 2020-2024 to address a prioritized subset of the existing ~3,680 kms of high risk conductors (13% of the fleet). The proposed plan will help with the pacing of the high risk conductor replacements over the longer planning horizon (i.e., the next 10 or 20 years) and also allow Hydro One to better manage the required capital expenditures associated with conductor replacement projects going forward.

Hydro One will continue to determine its conductor replacement needs through condition assessments and use ESL to only project replacement requirements for planning purposes. More details on overhead conductors that have reached or will reach their ESL during the test period are described in SR-19 and SR-20.

3.2.4.11 ESL Assessment of Specific Underground Transmission Cables

EPRI has determined the suitable ESL for low-pressure and high-pressure liquid-filled cables ("LPLF" and "HPLF", respectively) to be 70 years, as compared to the 50 years ESL previously used by Hydro One. Based on the newly established ESL, Hydro One is not projecting additional replacement projects beyond what is in the current investment plan. Hydro One forecasts that only 1.5% of the cable population will be beyond ESL by the end of 2024. As such, Hydro One will continue to monitor cable condition and repair or replace cables, as needed, to ensure a safe and reliable system operation. This study supports Hydro One's current condition-based replacement methodology.

3.2.4.12 Polymer Insulator Population Assessment

The focus of this study is to perform a detailed assessment of a sample of polymer insulators and to provide insights into overall population condition to inform Hydro One's replacement needs. Based on its assessment of 87 insulators, EPRI found that the condition of polymer insulators currently in-service in Hydro One's transmission system varies based on voltage, manufacturer and use of corona rings. Depending on the configuration, EPRI recommended an immediate removal, paced removal or continued monitoring. Hydro One is developing a program to identify locations requiring replacement and monitoring that will leverage current assessment programs. Hydro One will develop a replacement plan to address polymer insulators that are known to be in poor condition and will be structured to allow for appropriate investment prioritization and pacing. The current *Transmission Line Insulator Replacement* program (ISD SR-25) will prioritize the replacement of polymer insulators in deteriorated condition in and high risk porcelain insulators.

3.2.4.13 Phase 2: CP/COB Porcelain Insulator Population Assessment

This is Phase 2 of the 1965 to 1982 vintage Canadian Ohio Brass ("COB") and Canadian Porcelain ("CP") insulator population condition assessment study. Phase 1 was completed in 2016 and was intended to ascertain the urgency for taking action to ensure safety at publicly accessible locations. Phase 2 involved the removal of 591 insulators from service and detailed laboratory testing (compared to Phase 1) to further assess their long-term condition and assist Hydro One in prioritizing and pacing future replacements of these assets. The analysis of testing performed on these insulators provides overwhelming evidence supporting replacement to mitigate the risk to the safety and reliability of Hydro One's transmission system. The key recommendation of this study is that the identified population of COB and CP insulators be removed from service as soon as practically possible. This study reinforces the urgency to increase pacing of CP/COB insulators replacement in non-critical locations. For more details on pacing and urgency to replace CP/COB insulators, refer to SR-25.

3.2.4.14 Asset Condition Assessment Process Review

In response to the findings in the OEB decision regarding Hydro One's 2017/2018 transmission application, Hydro One engaged Metsco to perform an Asset Condition

Assessment Process Review. The study reviewed Hydro One's Asset Risk Assessment ("ARA"), Asset Analytics ("AA") and decision-making process, the six criteria, methodology, and data inputs utilized to calculate asset scores, and identified areas for improvement and other recommendations.

Metsco's overall conclusion was that across the categories of the assessment, both the ARA and AA are adequately aligned to other asset management frameworks found in the industry and are sufficiently rigorous and robust to accomplish their intended tasks from the analytical perspective.

In light of the recommendations in the report, Hydro One will continue to collect relevant condition data and improve data governance to further enhance the asset management and decision-making processes. The recommendations from this review will inform Hydro One's efforts to continuously improve and enhance its asset management processes used for managing critical transmission infrastructure. As part of its commitment to continuous improvement, Hydro One has implemented enhancements to its Asset Analytics investment planning decision support tool in 2018. The enhancements updated the existing algorithms and weighting calculations to improve the quality of the asset risk model to better inform decision making.

3.2.4.15 Investment Planning Process Review

Hydro One engaged Boston Consulting Group ("BCG") to prepare this report in response to the OEB's request for Hydro One to review its investment planning process. This study confirms that, overall, Hydro One has implemented a consistent and thorough planning process that meets or exceeds expectations for an above average utility planning process, in all areas. This information supports Hydro One's submission that the investment planning process is robust and previous issues identified have been addressed.

In light of the recommendations of the report, Hydro One will continue to collect relevant condition data, update strategies, and implement forecasting outcome measures. Hydro One's progress regarding the implementation of these recommendations is provided in Attachment 15 to Section 1.4 of the TSP.

3.2.5 (5.4.1 B) HOW THE PLAN REFLECTS PERFORMANCE MEASUREMENT

As described in more detail in TSP Section 1.5, Hydro One is committed to achieving the productivity and cost efficiency goals outlined in its Business Plan. To give effect to this commitment, Hydro One has aligned its planning, execution and reporting functions around performance outcomes that are consistent with the OEB's RRF outcomes. The RRF outcomes relate to Customer Focus, Operational Effectiveness, Policy Responsiveness and Financial Performance. Hydro One's performance outcomes are reflected in its Transmission Scorecard (found in TSP Section 1.5, Figure 1), which assists Hydro One in transparently monitoring and measuring its performance relative to these outcomes. The evolution of Hydro One's Transmission Scorecard is discussed in TSP Section 1.5.2.

Key initiatives with respect to planning and execution have been undertaken to improve cost efficiencies and operating effectiveness. Hydro One is committed to achieving the incremental and continuous productivity and cost efficiency improvements included in its Business Plan. As described in TSP Section 1.6, both specific productivity initiatives and a Progressive Productivity Placeholder have been embedded within the Business Plan, reducing the revenue requirement, with corresponding cost control metrics reflecting improved levels of performance.

The evolved Transmission Scorecard establishes performance outcomes that Hydro One has targeted to achieve over the 2020 to 2022 test period and reflects Hydro One's commitment to achieve the performance outcomes for each measure through the execution of its 2020 to 2024 investment plan. The investment plan has been optimized so as to drive performance towards these outcomes, which reflect the need to ensure regulatory compliance and to appropriately balance the identified needs and preferences of Hydro One's transmission customers with Hydro One's transmission asset and system needs, while being mindful of the resulting transmission rate impacts.

In the context of the performance outcomes set out in the evolved Transmission Scorecard, the performance categories and measures corresponding to the outcomes of customer focus, operational effectiveness, and public policy responsiveness are particularly relevant to the TSP.

With respect to customer focus, Hydro One's commitment to service quality is reflected in its outage planning and coordination activities with customers. Customer preferences and priorities are to have safe, reliable transmission of energy with minimal outages. The transition to integrated investments was a core aspect of achieving this outcome. The integrated approach to investments provides not only efficiencies during the planning and design phases, but also greater efficiencies during construction and commissioning, leading to more effective outage coordination with customers. With an increased target of 90% Satisfaction with Outage Planning Procedures, the integrated investments for stations and lines highlighted in ISDs SR-01 to SR-08, and SR-19 to SR-20 will assist Hydro One in achieving this outcome.

Hydro One's objective is to engage with customers consistently and proactively. The Company's full spectrum of customer engagement initiatives is designed to: (i) increase the Company's understanding of customer needs and preferences; (ii) enhance Hydro One's ability to provide services that meet these needs; (iii) produce outcomes that are valued by customers; and (iv) result in an improvement in overall customer satisfaction with the services received from Hydro One. With an average of 84% overall customer satisfaction over 2014 to 2018, Hydro One has set an overall customer satisfaction target of 90 per cent over 2020 to 2024, which reflect an improvement over the long-run average through an ongoing focus on meeting expectations and delivering on critical success factors.

Safety, reliability and outage restoration are customers' top prioritized outcomes. Hydro One is committed to continuous improvement in operational effectiveness, and this TSP will deliver improved safety and system reliability outcomes. In addition, Hydro One plans to invest $17 million to mitigate the power quality impact of shunt capacitor bank switching on customers with sensitive equipment as highlighted in ISD SS-16. Hydro One's average frequency of sustained delivering point interruptions (T-SAIFI-S) performance over the past five years was 0.63 per delivery point, and the performance trend is indicating an increase in the average number of sustained interruptions per delivery point. Over the TSP period, Hydro One plans to improve against its historical average, targeting 0.52 interruptions per delivery point by 2022 and 0.5 interruptions per delivery point by 2024. Hydro One's Customer Delivery Point Performance Standard Outliers have historically been an average of 11.6% from 2013 to 2017, and over the term of this TSP, is targeting 10.8% by 2024.

Safety is a core value of the company, and Hydro One continues to pursue improvements in its safety record and achieve world class safety performance, as is reflected in the improved targets. The revised risk assessment process enables safety risks to be highlighted and mitigated through investments. Over the plan horizon, $3.5 billion of the proposed work program will aid in mitigating safety risks.

Continuous improvement in the execution of the plan includes dedicated efforts to improve Hydro One's project definition and execution capabilities to improve cost, risk and schedule management. In addition, the execution teams have an increased role during the Investment Planning Process to ensure the proposed plan is achievable. Employing the TSP Implementation Progress metric and Capital Program Accomplishment Index, Hydro One intends to deliver, monitor and pace work to accomplish the TSP in the plan period.

3.2.6 (5.4.1 B) HOW THE PLAN REFLECTS PRODUCTIVITY

To further its commitment to delivering outcomes that are valued by its customers, Hydro One has developed a comprehensive and rigorous process for identifying, developing, implementing, monitoring and measuring productivity initiatives that will reduce costs while maintaining or improving service quality and work outputs. Hydro One's commitment to achieving incremental and continuous productivity improvements is central to the planning and execution of work programs across the company. Within this framework, quantifiable productivity improvements are included in the Business Plan and corporate scorecards with clear accountabilities for delivering the anticipated savings. Using this approach, Hydro One has identified savings opportunities in capital and OM&A totalling approximately $704M over the plan period (2020-2024).

Hydro One has undertaken a number of productivity initiatives to reduce costs while maintaining or improving service quality and work outputs. The 2020-2024 TSP includes an incremental increase in productivity benefits over the previous plan. Hydro One has implemented a robust governance structure around productivity reporting to ensure productivity savings are accurately reflected on corporate scorecards and that there is continuity of savings in the Business Plan. The largest value initiatives included are related to:

- More effective procurement programs and fleet rationalization;
- Reductions in administrative expenditures enabled by software enhancements and improved process execution; and
- Rationalization of Information Technology spending

Out of total productivity savings of $704 million over the 2020-2024 period, $590 million is forecast to stem from the capital work program. Included within these savings is a progressive productivity factor on the transmission work program of 1% to 3% annually. This progressive productivity factor accounts for $286 million of the planned capital operations savings, as further discussed in TSP Section 1.6. This is a further reduction in cost that was applied to Hydro One's final transmission investment plan and represents a commitment from the company to find further efficiencies over the planning period to manage rate impacts when executing the necessary planned investments without reducing work volumes.

A detailed review of Hydro One's productivity initiatives as related to the TSP is set out in TSP Section 1.6.

3.2.7 (5.4.1 B) TIMING AND PACING

In determining the timing and pacing of its investments, Hydro One considered both its own ability to execute capital work efficiently and the ability to secure planned outage time to minimize impacts on customers and other stakeholders in Ontario. Given the condition and age of Hydro One's stations and lines, the deferral of work to future years will escalate the proportion of assets operating beyond their ESL and exacerbate the reliability impacts related to condition. A greater proportion of assets operating beyond ESL and in a condition requiring action results in increased future work requirements with existing planning, design, field and construction resources and work constraints related to outages. While replacements are condition driven, with condition assessments performed to verify whether an asset is a candidate for replacement, a correlation exists between operating the asset beyond ESL and the likelihood of that asset being in a deteriorated condition. Within a transmission system that has assets of high criticality, outage duration and frequency impact transmission customers both operationally and economically. This underlies the customer preference regarding reliability and outage management outlined above and in Section 1.3 of this TSP. If the demographic and condition pressures of assets operating at or beyond ESL are left unmanaged, Hydro One expects to face greater constraints to resources and outage scheduling in the future. As a result, Hydro One has planned the pace of renewal work so that certain critical work to reduce risks on the system could be completed in the planning period and investment levels are established in line with customer preferences.

3.3 CAPITAL EXPENDITURE DETAILS

3.3.1 (5.4.2, 5.4.3.1) CAPITAL EXPENDITURE TRENDS

Over the planning period, Hydro One plans to spend approximately $6.6 billion in capital representing an annual growth of 3.6% over five years to maintain transmission reliability performance, to address customer needs and preferences, and to mitigate asset and operational risks by accomplishing the planned capital work. The overall trend of the capital expenditures as it compared to the historical years is as follows:

- System Access – Capital expenditures over the test years are forecast to decrease compared to recent historical levels as a number of projects – Supply to Essex County Transmission Reinforcement, Enfield TS, and Runnymede TS, as well as the connection of Seaton MTS and Copeland MTS – are either complete or expected to be complete by end 2019.
- System Renewal – Capital expenditures increase compared to historical levels in order to address the demographic pressures through condition-based replacement of stations and lines assets.
- System Service – Capital expenditures return to historical levels after three years of lower spending as previous projects were completed and new ones are initiated over the test years.
- General Plant – Capital expenditures are in line with historical spending to support the operation and maintenance of the transmission system, with an increase in 2019 largely attributed to the construction of the new operations centre.

Hydro One's historical capital spending relative to planned amounts is shown in Table 1. Table 2 shows the forecast capital spending for the bridge year (2019) and TSP planning period.

Table 1 - Historical Capital Expenditure Summary

For explanatory notes on Plan vs. Actual Variance Trends by Category, please see Section 3.3.3.

For explanatory notes on System OM&A, please see Exhibit F.

[2] The Directive adjustment reflects the impact of the directive issued by Ontario's Management Board of Cabinet on February 21, 2019 and the associated framework they approved on March 7, 2019. Refer to Exhibit F, Tab 4, Schedule 1 for further details.

[3] Includes the Directive adjustment. Refer to Exhibit F, Tab 1, Schedule 1 for further details.

3.3.2 (5.4.2, 5.4.3.1) FORECAST TRENDS VS. HISTORICAL BUDGETS BY CATEGORY

System Renewal

System Renewal spending will increase above historical levels starting in 2019. Significant investment is required for the replacement and removal of air blast circuit breakers from the transmission network (ISD SR-01) at Bruce A and Bruce B transmission stations and increased load supply station reinvestment projects (ISD SR-02) including expenditures at the downtown Toronto station, John TS (ISD SR-08). Significant investment is also required over the plan to replace deteriorated and end-of-life transformers at load supply stations (ISD SR-05) as supported by the condition and performance considerations discussed in Section 2.2 of this TSP. The increased spending is needed to address an aging infrastructure, characterized by a large number of assets in poor condition and the strategic removal of air blast circuit breakers at critical stations. System Renewal investments will increase 5.5% over the course of this TSP, with investment in both stations and line refurbishment seeing a 5.7%, and 5.5% increase over the plan, respectively. The objective over the planning period is to return to top quartile reliability performance and this level of spending is designed to accomplish this objective.

System Access

System Access spending over 2020 to 2024 is expected to be be lower compared to historical levels as a number of major load connection projects (Supply to Essex County Transmission Reinforcement, Enfield TS, Runnymede TS, Seaton MTS and Copeland MTS) have been completed or expect to be completed by 2019. Generator connection projects have also been reduced as the IESO generation procurement nears completion.
The main investments over the forecast period include the connection of IAMGOLD and Metrolinx Traction Substations (ISD SA-01, SA-04), and expansion of Horner TS and Halton TS (ISD SA-02, SA-03).

System Service

System Service spending over the 2020 to 2024 period is expected to return to historical 2015 to 2016 actual levels after three years of lower spending in 2017, 2018, and 2019. System Service projects in these three years were not of the same magnitude as the major transmission projects identified in the previous rate applications such as the Midtown Transmission Reinforcement Plan, Guelph Area Transmission Project and the Clarington Project have either been completed or are in the final completion stage.

Spending level increases in 2020 with expenditures on major transmission projects such as: the Lennox TS Shunt Reactors (ISD SS-01), the Wataynikaneyap Line to Pickle Lake Connection (ISD SS-02), the East-West Tie Expansion (ISD SS-04), and the Barrie Area Transmission Upgrade (ISD SS-09) projects. In the 2022 to 2024 period, spending continues as work starts on the Leamington Area Transmission Reinforcement (ISD SS-13) and the Milton SS (ISD SS-07) projects. The East-West Tie Expansion, the Wataynikaneyap Line to Pickle Lake Connection, and the Milton SS projects are identified in the 2017 Long-Term Energy Plan.

General Plant

General Plant spending in 2018 remained in line with historical levels however spending is projected to increase through 2019 and 2020 before decreasing and returning to historical levels in 2021. The increases in 2019 and 2020 are attributed to increased spending in grid operating and control facilities associated with the new Integrated System Operating Centre (ISD GP-01). Spending in 2021 to 2022 declines to historical levels, while spending through 2023 and 2024 declines below historical levels as a result of the completion of investments associated with operating infrastructure that are required to sustain the grid control network (ISD GP-02), the network management system (ISD GP-03), and corporate services transformations (ISD GP-08). Investment in real estate and information technology remains in line with historical levels through 2024.

Investment in transport and work equipment (ISD GP-12) decreases from historical levels due to equipment right-sizing and telematics initiatives which took place in 2017, as described in Section 3.3.3. These initiatives have reduced Hydro One's fleet complement by 10%, resulting in reduced replacement levels in 2017 which persist through to 2024.

3.3.3 (5.4.2, 5.4.3.1) PLAN VS. ACTUAL VARIANCE TRENDS BY CATEGORY

System Access

Over 2015 to 2016, System Access investments were approximately $12 million, and $15 million below planned spending levels, respectively. These variances are attributable primarily to delays in the starting of the Seaton MTS and the Supply to Essex County Transmission Reinforcement projects. The spending for 2017 and 2018 was $9 million and $9 million above planned expenditure due to spending on the Supply to Essex County Transmission Reinforcement and Enfield TS projects.

System Renewal

In each year from 2015 to 2017, System Renewal projects were $115 million, $194 million, $7 million above planned spending, respectively. In 2018, System Renewal projects were $4 million below planned spending.

In 2015, integrated investments at several stations resulted in a net increase of $119 million to address significantly deteriorated and poor condition station assets including investments at Beach TS, Allanburg TS, Buchanan TS, Gerrard TS, and Hinchinbrooke TS. Additional increased costs associated with the timing of the Bruce A 230 kV ABCB replacement project (SR-01) and increased spending on emergency replacements and spare transformer purchases contributed to the variance. Transmission line refurbishments contributed an additional $21 million to the overage to address asset needs on circuits C25H, CxJ and CxZ, Q11S/Q12S, and D2L, but in total was offset by a $25 million reduction in planned spending on underground cable refurbishment due to delays resulting from project complexity and adjusted execution timelines for H2JK and a number of investments.

In 2016, investment in transmission stations saw an overall increase of $147 million to address deteriorated, poor condition assets in addition to projects from previous years that were under construction and had significant portions carry over into 2016 including work at Allanburg TS, Gerrard TS, and Beck 2 TS. Transmission line refurbishments contributed $62 million to the overage due to increased wood pole replacement needs based on poor condition and increased expenditures to replace defective CP/COB insulators to mitigate pu1blic safety risk. However, underground cable refurbishments resulted in a $15 million reduction in planned spending due to the complexity of the required environmental assessments and public consultation.

For 2017 and 2018, System Renewal projects were generally in line with planned spending. The primary driver of decreased capital spending below plan in 2018 was a result of the increased number of catastrophic transformer failures, namely those at Finch TS, Minden TS, and Nanticoke TS that required replacement along with associated restoration efforts to replace damaged and failed equipment, offsetting planned replacement work. Forecast expenditures for 2019 are in line with 2018 levels, maintaining the overall investment levels within the envelope afforded in Hydro One's 2019 transmission revenue cap adjustment application (EB-2018-0130).

System Service

From 2015 to 2016, System Service investments were approximately $32 million, and $39 million below planned spending annually. These variances are due primarily to cancellation of the Preston TS reinforcement project, deferral of the Cherrywood TS capacitor bank project, delay in the Midtown Transmission reinforcement project and the lower expenditures on the Guelph Area Reinforcement project and the Clarington TS project.

For 2017 and 2018, System Service spending was generally in line with total planned spending over that period.

General Plant

General Plant investments were $28 million below planned spending in 2015, $20 million below planned spending in 2016, and $9 million below in 2017.

In 2015, $23 million of the variance was the result of the continued transition to integrated investment planning which encapsulated operating infrastructure needs, and the delayed availability of new technology to meet operating requirements. $6 million was attributed to lower than planned costs associated with renovations and project delays in real estate and facilities investments. The decrease in spending was partially offset by an increase of $2 million in transport and work equipment due to the implementation of the approved telematics technology.

In 2016, reduced operating infrastructure spending contributed $20 million to the variance as a result of the review of the investment strategy due to technology advancements and functionality integration with existing infrastructure. In addition, $4 million of the variance was due to schedule and cost variance of the Integrated System Operating Centre ("ISOC") Project (ISD GP-01). Plans for a new Backup Control Centre ("BUCC") to replace the end of life BUCC were included and approved by the OEB as part of proceedings EB-2013-0416 and EB-2014-0140. The project had a planned in-service date of December 2018. In 2015, Hydro One decided to pursue a revised scope of the BUCC investment and instead, pursue the ISOC, which would increase the scope to include an Integrated Telecommunications Management Centre, Security Operations, an

Integrated Data Centre, and general back office space. The variance is a result of the change in scope and revised project schedule. Real estate and facilities investments under spending contributed an additional $11 million to the variance. However, the spending below plan was partially offset by a $13 million increase in Information Technology spending in 2016 driven by improvements to Hydro One's integrated financial planning and work management systems.

Spending in 2017 was approximately $9 million lower than planned expenditures primarily due to renovations and project delays in real estate and facilities investments ($2 million), lower spending on the ISOC ($2 million) largely due to savings realized during the detailed design phase and lower spending in Information Technology ($2 million).

Spending in 2018 is $36 million below planned expenditures, with a reduction of $25 million in grid operating and control facilities largely due to the ISOC. Hydro One realized there was a shorter construction window than previously estimated and the start date for the ISOC was deferred. Hydro One had reductions of $8 million in operating infrastructure due to redirection of investments, $14 million in facilities and real estate due to a mix of delays in commencement of several projects, as well as, lower than planned expenditures on others, and $7 million in transport and work and service equipment as a result of productivity gains due to right-sizing and deferral of expenditures due to fleet asset optimization and specification review.

These reductions are partially offset by an increase of $6 million in transmission site facilities to accelerate replacement of roofs at critical building on transmission station sites and $13 million in information technology ("IT") primarily driven by advancing spend related to Hardware/Software refresh and maintenance (ISD GP-07), minor fixed asset programs and an increase in common IT investments to make improvements to SAP and work management tools.

3.3.4 (5.4.2, 5.4.3.1) IMPACT OF CAPITAL INVESTMENT ON OPERATIONS, MAINTENANCE AND ADMINISTRATION SPENDING

Hydro One has a number of capital investments that reduce OM&A spending. Several examples of capital initiatives that reduce OM&A costs are listed below.

Hydro One is investing in the replacement of air blast circuit breakers, which are not only the poorest performing breakers on the system, but also contribute approximately $3 million in OM&A spending to maintain the associated high-pressure systems (ISD SR-01). Replacement of these breakers will enable the removal of the high-pressure air systems and the associated spending. On average, it is approximately 10 times more expensive to maintain an air blast circuit breaker and the ancillary components than the equivalent SF6 breaker.

Investment in the sustainment and replacement of obsolete and end of life station assets will result in downward pressure on OM&A spending. The replacement of poor condition oil circuit breakers will eliminate the need for oil sampling, and on high voltage oil circuit breakers - power factor/dissipation testing, also known as “Doble” tests. For transformers, Hydro One utilizes vacuum tap changers in place of oil filled units for replacement units, eliminating the need for future internal preventative maintenance. Replacement units are also deployed with low oil alarms and monitors, which eliminate manual oil level inspections.

Station reinvestment projects (see ISD SR-02) can reduce the number of transformers or breakers due to changes in the operating configuration of a station. Over the 2020 to 2024 planning period, 17 transformers, and 49 breakers have been identified for removal as a result of reconfiguration. The removal of these assets from the system eliminates all future preventative and corrective maintenance costs. Further detailed discussion on OM&A is included in the application throughout Exhibit F.

3.3.5 (5.4.2, 5.4.3.1) FORECAST AND HISTORICAL ASSET REPLACEMENT RATES

Hydro One's planned replacement rates are derived through the processes described in TSP Section 2.1, based on the assessment of the assets and system needs and asset lifecycle optimization (see TSP Sections 2.2 and 2.3). The historical and forecast rate of replacement for transmission stations and lines assets are noted in Tables 3 and 4 below.

The replacement rates shown below are the culmination of Hydro One's asset management and investment planning processes. In the context of System Renewal, for example, these processes have resulted in striking a balance between the asset needs (arising from age, condition, environmental and regulatory compliance), customer needs and preferences, and bill impact. Given the demographic pressures and impending wave of assets that will be at the end of their expected service life ("ESL") within the TSP period, Hydro One identified the following trends for each of the asset groups:

- Transformers – the proposed rate of replacement is largely in line with historical rates, and will ultimately maintain the percentage of the transformer fleet that operates at or beyond ESL
- Breakers – the proposed rate of replacement maintains the percentage of the breaker fleet that is operating beyond ESL at 12%.
- Protections – the proposed rate of replacement maintains protection systems that operate beyond their ESL at the current 27%.
- Conductor – the proposed rate of replacement mitigates the risk by managing the current 5% of conductor fleet that operates beyond ESL. Otherwise, the percentage of the conductor fleet operating beyond their ESL would have been 13% in the next five years which would create a high risk to manage.
- Wood Pole – the proposed rate of replacement maintains system reliability with a customer focus, as majority of wood poles are located in northern Ontario and

supply industrial customers on radial (single supply) feeds. Hydro One will maintain the rate of replacement to mitigate safety and reliability risk.

- Steel Structure – poor condition steel structures that are eligible for coating will be coated proactively at a pace aligning with the OEB's Decision and Order in proceeding EB-2016-0160.
- Insulator – the proposed rate of replacement focuses on public safety, by addressing insulators in critical locations first (road crossings etc.) followed by non-publicly accessible areas.

3.3.6 (5.4.3.2) MATERIAL INVESTMENTS

In accordance with Section 2.1.1 of Chapter 2 of the OEB's *Filing Requirements for Electricity Transmission Applications*, Hydro One's materiality threshold is $3 million. The following section describes investments included in this application that are greater than Hydro One's materiality threshold in any one year. It also identifies material investments that require leave to construct in accordance with Section 92 of the OEB Act as well as investments undertaken as a result of directives from the Ministry of Energy, Northern Development and Mines and investments that have been declared as a priority by the Governor in Council.

3.3.6.1 (5.4.3.2) LIST OF MATERIAL CAPITAL INVESTMENTS

The tables below provide a listing of Hydro One's Investment Summary Documents ("ISD"). Note that each ISD includes a priority.

- "**High" Priority** projects represent those that pose the greatest risk to the Hydro One system if not completed. Failure to complete these projects is expected to have significant impacts on the risk profile of the system in the short term. This includes demand-based work to address emergency replacements. This priority of projects also includes those required to ensure compliance with regulatory or legal obligations and customer agreements.
- "**Medium" Priority** projects represent those that pose a risk to the Hydro One system over the planning period if not completed. Failure to complete these projects is expected to have moderate impact on the risk profile of the system over the planning period. If reductions are required and sufficient savings are not available from the Low priority group, the Medium items would be reviewed as well for possible decreases in spending.
- **"Low" Priority** is for those projects ranking among the lowest group in the risk prioritization and optimization methodology. These projects are important to Hydro One but should a reduction in spending be necessary, Hydro One would

look at these projects first for reprioritization. Failure to complete Low Priority projects is not expected to have significant detrimental effects on the system in the near term.

Table 5 - System Access - Material Capital Investments Proposed

3.3.8 (5.4.3.2) ATTACHMENTS: INVESTMENT SUMMARY DOCUMENTS

GP-01 Integrated System Operating Centre – New Facility Development

Start Date:	Q1 2015	**Priority:**	High
In-Service Date:	Q1 2021	**3-Year Test Period Cost ($M):**	45.2
Trigger(s): Immediate/Short-Term Compliance, Strategic, System Renewal, Reliability, Productivity Enablement, Cost Avoidance			
Outcomes: Improved reliability and availability of emergency activation, response and restoration, mitigation of existing critical risks, sustained monitoring and control reliability, maintenance of regulatory compliance			

A. OVERVIEW

This investment describes the construction and in-servicing of an Integrated System Operating Centre ("ISOC") and enabling the ISOC to serve as the primary operating control centre. The project, which began in 2015, provides for:

- A System Operating Division Control Centre;
- A Backup Integrated Telecommunications Management Centre;
- Primary facilities for Security Operations; and
- A shared integrated data centre and all critical support infrastructures at the preferred Orillia site.

This investment will maximize operational effectiveness, flexibility and scalability for Hydro One and associated lines of business while eliminating the need to duplicate investments at multiple sites and costly critical support infrastructure (e.g. emergency generators, uninterruptible power supplies, telecommunications, etc.).

The Ontario Grid Control Centre ("OGCC") is the current primary operating control centre and also functions as a data centre. The OGCC was built in 2003 and is currently at limited space capacity and in need of remediation to address heating and infrastructure concerns. In the event that the OGCC or its computer systems are rendered unavailable, an alternate facility is required to provide service continuity and maintain compliance with mandatory regulatory requirements.

Infrastructure problems, capacity constraints, and other site issues (e.g. flood risk) are impacting the viability of the existing Back-Up Control Centre ("BUCC") to provide service continuity and to maintain compliance with mandatory regulatory requirements.

The ISOC will serve as Hydro One's primary operating Control Centre. When the ISOC is fully in-service, the OGCC (which is the current primary operating control centre) will be re-designated as the backup centre and the existing BUCC will be decommissioned.

The investment in the ISOC, along with the re-designation of the OGCC and the decommissioning of the BUCC will allow Hydro One to address the deficiencies discussed above. This will ensure that the Company will have the necessary infrastructure in place to provide service continuity, maintain compliance with mandatory regulatory requirements, and will allow the Company to continue to effectively monitor, operate, control the transmission system, and continue to meet customer expectations.

The outcomes of the investment also include improved activation of emergency systems and protocols, response and restoration of power in the event of system faults, mitigation of existing critical risks at the control centres, sustained monitoring and control reliability, and maintenance of regulatory compliance. The projected transmission-allocated[1] costs of the project are estimated to be $45.2 million over the 2020-2024 planning period.

[1] Hydro One has used the approved Black & Veatch Common Asset Allocation methodology outlined in Exhibit F, Tab 2, Schedule 6 of the Application in order to allocate the costs between Transmission and Distribution.

B. NEED AND OUTCOME

Investment Need

Hydro One maintains primary and back up control centres to comply with regulatory requirements and to ensure business continuity remains at a service level that meets customer expectations at all times. These centres are governed by North American Electricity Reliability Corporation ("NERC") standards, the Transmission System Code ("TSC"), Hydro One standards, and other standards identified in the Investment Description section which follows. In particular, the NERC Emergency Operating Procedure standard EOP-008-02, "Loss of Control Centre Functionality", states that the transition period between the loss of primary control center functionality and the time to fully implement the backup functionality is less than or equal to two hours.

Hydro One's current primary control centre, the OGCC, has known deficiencies that include but are not limited to:

- A Heating, Ventilation, and Air-Conditioning ("HVAC") system which cannot handle summer heat loads and is normally complemented by a leased HVAC system;
- Data centre capacity constraints that are impacting business requirements and resulted in third-party lease costs for an off-site data centre;
- A sewage line under the control room which represents a challenge as repairs can only be done if the control room is shifted away from the OGCC for an extended time. This is continuously monitored closely and a repair plan remains a work in progress; and
- The existing facility is at capacity and lacks flexibility and scalability for any future system upgrades.

The inability to affect upgrades/replacements, increase capacity to computer systems and tools and makes necessary repairs to infrastructure, can result in significant disruption in Hydro One's ability to manage the Bulk Electric System ("BES").

The BUCC facility has been in service since 1956. The expectation is that it will not be a viable facility by 2021, due to infrastructure failures, capacity constraints, and inherent site issues that include the risk of flooding. For instance, the 2013 flood event in the Greater Toronto Area resulted in wide spread outage in the region, leading to an estimated unsupplied energy of 1,406,218 MW-minutes and $6.5 million in repair costs. The flood damaged computer room equipment and power supplies, rendering the BUCC unavailable for an extended period of time. The damaged systems that had to be replaced included but were not limited to: servers, server chassis, server racks, uninterrupted power supplies, routers, switches, cabling, and associated cable trays.

The BUCC also does not have the back office space capacity to support operations groups such as outage planning and operations studies and support that are fundamental to the daily operations of Hydro One's transmission network. A prolonged event would require the relocation of headquartered staff to make space for staff relocating from the OGCC, along with the procurement and set up of additional necessary computer equipment that would take time to implement. These challenges would impede the ability to maintain system integrity and reliability.

Furthermore, the BUCC is located adjacent to a major transformer station, exposing the facility to emergency preparedness risk including electrical hazards, environmental hazards such as fire, oil spills and other asset failure hazards (for example, transformer fires have previously rendered the BUCC unavailable). Increasing traffic congestion around the site, situated between two major highways, also compromises the ability to meet the two hour activation timeline mandated under NERC EOP-008-2. Other hazards include the centre's proximity to public storage facilities, gas pipelines, and its location directly below the flight path of a major international airport, increase the risk that the BUCC would become unavailable/inoperable.

In Hydro One's previous OEB rate filing applications, this ISOC investment was planned for a dual primary control and monitoring configuration, but to realize better operating synergies, it was decided that a single primary configuration will deliver more benefits. The updated plan involves making the ISOC Hydro One's primary control centre once it is fully in-service so that the deficiencies at the OGCC will be remedied without impact on real-time operations. The OGCC will then be re-designated as the backup centre. The existing BUCC will then be decommissioned. Incremental costs associated with this updated plan will only be from employee relocation considerations. This amount is forecast to be between $1 million to $3 million. The relocation cost will be budgeted as a one-time OM&A charge, and it is not included in this Investment Summary Document costing.

If the investment is not made on the proposed timeline, there will be an increased risk of future extended outages which will impact Hydro One's ability to effectively monitor, operate and control the transmission system, maintain regulatory compliance, and meet customer expectations

This proposed investment will provide for a new Integrated Telecommunications Management Centre ("ITMC") control room, replacing the existing Backup ITMC ("BUITMC") which will then be decommissioned. Hydro One Telecom, a subsidiary of Hydro One Networks Inc., operates and maintains mission-critical telecommunications services on a 24x7 basis. Hydro One relies on these telecommunications services to monitor and control the BES. The 2013 flood event made the primary ITMC unavailable. Telecommunication services were restored from the BUITMC that is currently located in a shared space at a remote transformer station that cannot accommodate a permanent active installation. This limitation in configuration resulted in delays during the 2013 Flood restoration efforts. The proposed investment is required to address this risk.

The ISOC would also incorporate a centrally located Security Operations Centre ("SOC"), which would provide physical security monitoring services. Hydro One Security Operations is currently reliant on an external third-party for primary and backup physical security monitoring services. Recent NERC trends indicate increasingly stringent security requirements are inevitable. Third-party security costs have been increasing as Hydro One requires additional monitoring and services due to increasing NERC regulatory requirements as it pertains to physical security monitoring of high impact facilities. Hydro One will improve its financial performance if some services are provided internally and third-party costs are reduced or eliminated. The establishment of a centrally located SOC to host all security management systems and servers would greatly reduce the risk of non-compliance with the NERC Critical Infrastructure Protection ("CIP") standard since NERC audit, assessment and compliance would then be conducted internally with a clear framework of ownership and accountability.

Investment Description

This investment involves the construction of a facility for the ISOC, enabling the ISOC to serve as the primary operating control centre. The ISOC will house multiple lines of business through the provision of dedicated control centres, an integrated data centre, and shared back office areas. This facility will be a hardened facility, built to withstand an EF3 tornado, and will reflect emergency preparedness criteria, industry best practices, and physical and cyber security standards. The facility is essential in maintaining the required redundancy in operations centres to ensure the reliability of the BES and associated customer responsiveness (i.e. outage and storm management).

Customers on the transmission system include large industrial companies and Local Distribution Companies, which identified the reliability of the BES as a top priority in the 2017 Transmission Customer Engagement survey. In addition, the ISOC will enable a coordinated approach to all real-time operating functions and continued adherence to NERC EOP-008-2, TSC requirements, and Hydro One standards. Conditions at the BUCC are deteriorating and there is a risk that these NERC requirements will not be met in the near future. The ISOC will allow for the provision of in-house security operations, thereby lessening reliance on costly third party services.

The ISOC design includes the following elements:

Facility:

- Provides the System Operating Division ("SOD") with a new control centre including a control room, back office space and a data centre;
- Provides the operating flexibility that allows Hydro One to accommodate industry modernization and future improvements;
- Mitigates the emergency preparedness risk and risk profile associated with the current BUCC as previously discussed;
- Ensures security requirements, both physical and cyber, including a hardened facility to guard against physical and environmental threats (i.e. tornadoes);
- Provides the ITMC with a new backup operations control centre including a control room, back office and integrated data centre mitigating the current risks at the BUITMC and the risks associated with a failure at the ITMC;
- Provide Security Operations with a headquarter location including a control centre, office space, investigative rooms, emergency operations centre (room) and integrated data centre; and
- Shared and redundant critical support infrastructure.

Site:

Provides a 16.57 acres site in Orillia, Ontario at an overall cost of $3.0 million, of which 49.93% is allocated to Hydro One transmission. The site was selected based on an extensive market assessment conducted in 2015 and was purchased in 2016 as part of Phase 2 of the project. The Orillia site met essential criteria, and included material advantages and associated cost savings in terms of location, current site development activities completed, existing water drainage/retention capability, improved commute and activation times, and significant municipal development charge savings realized through the Industrial Development Charge Moratorium offered by the City of Orillia.

Architecture and IT design:

The detailed design was completed in Q2 of 2017. The transmission portion of the total engineering and IT consultant costs, for the detailed design, was budgeted for $4.1 million.

Connectivity and Telecommunication:

Connectivity at the new ISOC facility allows for communication with OGCC utilizing the Hydro One telecommunication network. The transmission portion cost to establish this communication connectivity is estimated to be $6.7 million.

Network Infrastructure:

An additional $5.3 million (transmission portion only) has been budgeted for Information Technology ("IT") infrastructure. This covers the cost associated with connecting each individual workstation console to the ISOC data centre.

Compliance

Hydro One is required to follow a number of compliance requirements, public policy standards and internal standards relating to reliable system operations. In addition, industry best practices have been incorporated to safeguard reliability and availability of critical systems. The requirements that the ISOC must adhere to include the following:

1. NERC EOP-008-2 necessitating backup activation to be equal to or less than two hours.

a) In a related Federal Energy Regulatory Commission ("FERC") order[2], FERC signalled its concern that the two hour activation requirement is too long and that "it is imperative that full backup functionality occur as soon as possible after the loss of primary control functionality". FERC also noted that "…it may revisit this transition timeframe". This signalled that the new ISOC must take into consideration that activation timelines could be reduced in the future.

b) NERC and FERC also require the backup to be "capable of operating for a prolonged period and providing functionality sufficient to maintain compliance with all reliability standards that depend on primary control functionality." (NERC EOP-008-2, R3)

2. Restoration Participant Attachment as required by the Independent Electricity System Operator ("IESO") administered 'Market Rules' for the Ontario Power System Restoration Plan ("OPSRP"): the BUCC is listed as one of the key facilities which comprise Hydro One's contribution to the Ontario Basic Minimum Power System. Restoration participants are obligated, within the design and safe operation of their facilities, to help restore the grid after a partial or complete system blackout.
3. NPCC-D8 (NPCC Directory 8), "System Restoration" defines the Basic Minimum Power System Requirements, and outlines the redundancy requirements for computer systems, power supplies, and generators at these key facilities.
4. NERC EOP-005-2, "System Restoration from Blackstart Resources" is an obligation for transmission operators/owners to have plans, facilities, and personnel in place to enable system restoration following a disturbance,
5. NERC Critical Infrastructure Protection ("CIP") Requirements – ensuring assets are protected logically (electronic security perimeter) and physically (physical security perimeter).
6. Communications: NERC & IESO Market Rules:

[2] Docket No. RD11-4-000 at 14.

- NERC-COM-001-2 - Telecommunications
- Chapter 2, Appendix 2.2, Section 1.1.4- Technical Requirements: Voice Communication, Monitoring and Control, Workstations and Re-Classification of Facilities;
- Chapter 2, Appendix 2.2, Section 1.2.3 – Transmitter Submission to the Energy Management System;
- Chapter 5, Section 12.1.1 – Voice Communications Methods;
- Chapter 5, Section 12.1.6 & Section 12.2.12 – Alternatives During Loss of Communications;
- Chapter 5, Section 12.2.3 – Required Voice Communication Facilities;
- Chapter 5, Section 12.2.4 – Voice Communication Reliability;
- Chapter 5, Section 12.2.11 - Voice Communication Monitoring and Testing; and
- Chapter 5, Section 12.3.2 - Required Data Communication Facilities.

Additional Design Criteria

In addition to the above requirements, the following industry best practices have been incorporated into the ISOC design:

- Designed for increased security protection;
    - Improved system security and redundancy; and
    - Provides adequate setback and building wall enforcement to protect against small explosives; and
- Multifunctional Facility / Business Continuity
    - Increased building utilization (multipurpose, real time, and simulation);
    - Operational flexibility and scalability (modular expansion); and
    - Emergency Preparedness criteria – facility separation for common mode failure.
- High Availability / Reliability

- Employing the Uptime Institute guiding principles for a Tier III facility[3]; and
- Provides for redundancy in computing, communications, cooling and power.

- Emergency preparedness risk considerations were factored into site selection and facility design, mitigating the current risk the BUCC is exposed to (i.e. not in a transformer station, flight path, etc.).

Outcomes

The integrated strategy behind the ISOC facility reduces third-party costs, optimizing financial performance by also eliminating the need for additional sites and facilities that would otherwise be required. By building one centralized site to house all stakeholders, the following synergies will be realized: negating the need for multiple designs, development, sites, facilities (buildings), critical support infrastructure, future maintenance maximizing capital investment, limiting overall rate impacts.

All proposed tenants, including various lines of business departments such as the System Operating Division, Hydro One Telecom, Security Operations, and Power System IT, among others, require costly critical support infrastructure and IT investment to meet an availability target (99.95% uptime) commensurate with the criticality of the systems and functions they support. These requirements are prescribed by Hydro One internal reliability standards PP-66400-002-R1 and guided by industry best practices (Uptime Institute Availability - *Tier levels*, as outlined in Internal Power System Monitoring and Control Reliability Requirements PP-66400-002-R1 sections 4.1.2 and 4.1.8). With the current ISOC strategy, the critical support infrastructure is shared by the tenants and represents an incremental cost to achieve it rather than replicating the installations that would be required to support several sites across Ontario.

---

[3] A Tier III data centre facility requires no shutdowns for equipment replacement and maintenance by including redundant power and cooling equipment and redundant delivery paths into the design. Uninterruptable Power Supplies, Computer Room Air Conditioning units, and standby generators are some of the components providing increased margin of safety to protect against disruptions.

The ISOC provides for:

- Enhanced monitoring, control and coordinated customer response (SOD, ITMC, Security and Emergency Preparedness) for all system vulnerabilities (i.e. system events, telecommunication events, cyber events or physical threats through integrated communication within the ISOC facility).
- Shared enhanced building protection design and security (physical facility hardening to protect against severe weather or man made threats);
- Shared redundant backup generator power supply and other emergency supplies;
- Enhanced site location for improved activation response, adherence to emergency preparedness criteria, and other business operations;
- Enhanced centralized security operations, improved monitoring and analysis trending for proactive response, and situational awareness for coordinated resolution; and
- An Emergency Operations Centre for Business Continuity and Emergency Preparedness will also be provisioned as part of the SOC

The following table summarizes the anticipated benefits as a result of this project:

Customer Focus	• Improve the reliability and availability of emergency activation, response and restoration if system fault events are experienced. • Reduce rate impacts from a single integrated solution as compared to multiple standalone investments. • Retiring of the current SOD BUCC arrangements and removal of the risk of costly remedial efforts in the event further failures are experienced.
Operational Effectiveness	• Mitigates the critical risks (infrastructure failures, capacity constraints, location and activation timelines etc.) that exist at the SOD OGCC and BUCC and the BUITMC. • Monitoring and control reliability will be sustained under all system contingency scenarios reducing compliance risk and improving customer responsiveness and operational capability.
Public Policy Responsiveness	• Satisfy regulatory requirements for physical protection, cyber security and activation timelines responsiveness. (See *Appendix A* and *Compliance* sections of this document for further details).

Financial Performance	• Allow the deficiencies at the OGCC to be addressed in a planned manner that facilitates better cost control. • Reduce the risk of costly mitigation in the event additional failures are experienced at the main BUCC (2013 flood event resulted in $6.5 million in repair work).

C. EXPENDITURE PLAN

Key considerations affecting the final cost of the project consist of the following:

- Availability and reliability standards include the need for redundancy in system and building architecture to maintain the existing Hydro One target of 99.95% availability. To achieve a higher reliability, additional facility redundancy support will be implemented at the ISOC such as the Uninterruptable Power Supply, multiple utility power supply, and multiple lines of communication. The largest cost element revolves around the data centre and critical support infrastructure, and the *Tier* or *redundancy* level can weigh heavily on the required investment. Given the criticality of the control centre functions, with leading industry advice, a Tier III+ level was recommended and designed. The industry standard for this type of critical facility is actually Tier IV, which some other utilities have chosen to build to. Due to the high cost associated with building a Tier IV facility, and after a meeting with various Hydro One internal stakeholders and IT experts, it was decided that a Tier III+ design would suffice for Hydro One's purposes. This category includes investment in the telecommunications network required to connect the new ISOC to the OGCC and field assets for monitoring and control.
- Security requirements impose additional cost considerations ensuring the facility can withstand both natural and human events (i.e. tornado, adequate setback from security perimeter). Included in this consideration are prescribed regulatory requirements for six sided secure perimeters, cyber security, site access and monitoring of critical assets. The six sided secure perimeters is a requirement from NERC with respect to any space that is designated as a Physical Security Perimeter (“PSP”) area. This standard requires that the four walls, ceiling, and flooring surrounding the area must

be protected, monitored and secured to avoid trespassing and other security concerns. For example, if the door allowing for access to the PSP area is held open for an extended period of time, it is required that an alarm is sounded and the incident is tracked accordingly.

Costs have been managed through an extensive and thorough assessment with various third party industry experts, internal subject matter experts relating to industry best practices, and cost saving initiatives (such as the *free-cooling*[4] design), alternative option assessment for independent project elements (site selection, industry comparators) and integration of solutions for various business units, functions and needs across Hydro One at a single site.

An independent cost consultant has provided a Class A +/- 5% cost estimate on the construction of the facility. Hydro One requested an update to the cost estimate in late 2018 to understand changing economic conditions. Skilled trade labour rate escalations, new foreign tariff structures, and competition for local construction resources resulted in an increase to the cost estimate. The updated cost estimate was then used to evaluate vendor bids through the RFP process.

The ISOC project started in 2015 and will continue until anticipated in-service in 2021. Prior year spending (Table 1) indicates the total costs incurred prior to the test period.

[4] Free cooling design is a way to optimize overall cooling/energy cost in the data centre.

Table 1 – Total Project Costs

($ Millions)	Prior Years	2020	2021	2022	2023	2024	Forecast 2025+	Total

D. ALTERNATIVES

Alternative 1: Status Quo/ Use Offsite Leased Space

Hydro One SOD maintains the existing control room, and Security Operations maintain existing security arrangements. A new offsite leased data centre facility (to mirror capacity of the OGCC data centre based on a 20-year lease and initial setup costs) could be provisioned and additional office space would be required and furnished for prolonged activations. This alternative includes additional leased space for the BUITMC control room and compute needs. The total cost of this option is estimated to be $83.1 million, of which the transmission portion would account for 49.93%.

This alternative has been rejected as the current SOD BUCC and the BUITMC do not meet operational requirements:

- The current facility imposes a high level of risk to both regulatory compliance and, Hydro One's reputation and customers, if any failures are experienced;
- This alternative fails to provide for the SOC need for an adequate primary control centre, and fails to address the third party risks of Security Monitoring;

- Even with extensive investment in the existing facilities, this option does not adequately remediate all operational effectiveness risk factors (e.g., electrical hazards due to proximity to TS, traffic congestion adversely impacting activation, basement flooding, and power capacity constraints);
- This alternative cannot accommodate current or projected growth, requiring future investments;
- This alternative would require the relocation of the existing compute space and critical support infrastructure, currently housed at the BUCC, to a new leased space to be shared with the BUITMC; and
- This alternative cannot mitigate all known risks due to site conditions, size and location. In the event of a prolonged activation, some existing staff of the BUCC facility must leave to make space for operating activities, and even if this arrangement can be made, there is insufficient onsite parking, workspace, and basic facility infrastructure for the overflow of staff.

Alternative 2: *Build a modified version of ISOC on the preferred Orillia Site*

There are multiple build configurations which were considered as alternatives to the recommended investment:

1. Removing the Telecom Control Centre (reduction of $22.2M), and/or
2. Removing the Security Operation Centre(reduction of $11.5M),

Depending on which scenario(s) are selected, the estimate for these alternatives ranges from $126.1M to $148.3M, which the transmission portion would have been 49.93%. . These alternatives were rejected as analysis showed that the recommended ISOC alternative provided the best long term value and efficiency of risk mitigation for Hydro One and its customers.

Due to the importance of the ITMC, the identified need for a new BUITMC and the financial performance that would be foregone, this removal of the BUITMC was rejected.

The exclusion of the SOC was rejected, because it fails to maximize financial performance through synergistic lines of business occupancy and maximize use of shared critical infrastructure. Bringing SOC services to the ISOC will reduce security monitoring service OM&A cost by approximately $0.6M on an annual basis. This SOC exclusion also fails to leverage operational effectiveness synergies for operational response to security threats, both physical and cyber. By co-locating physical security monitoring (i.e. SOC) with the other lines of business, opportunities for collaboration on physical risk mitigation will be optimized. The risk of third party contractors for physical security monitoring will be eliminated.

Alternative 3: Acquire an existing facility that could be retrofitted / utilized to accommodate SOD Control Centre, BUITMC and an integrated Data Centre

A market assessment was completed that reviewed potential sites against identified requirements for size, location, travel times, power infrastructure, telecommunications and occupancy. This also included an internal assessment of Hydro One owned sites. At the completion of the assessment, it was determined that no suitable site was available in the market or within Hydro One owned locations. As a result, this alternative was excluded from further consideration.

Retrofitting an existing facility was also considered in connection with this alternative. In order to provide the environment and critical support infrastructure required for data centre reliability, continuous (24x7) control rooms, and security considerations (including dual power supply and telecommunications expansions), extensive investment would be required. At the time of the assessment, no suitable site/facility was available and as such this option was removed from further consideration.

Alternative 4: Initiate Build of the Integrated System Operations Centre (“ISOC”) (*Recommended*)

This alternative provides for:

- A SOD Control Centre;
- A BUITMC;
- Primary facilities for Security Operations; and
- A shared integrated data centre and all critical support infrastructures at the preferred site.

This alternative will maximize operational effectiveness, flexibility and scalability for Hydro One and associated lines of business while eliminating the need to duplicate investments in multiple sites, and costly critical support infrastructure (emergency generators, uninterrupted power supplies, telecommunications, etc.). This alternative is estimated at a cost of $159.8 million, of which, the transmission portion would be 49.93%.

This option involves building the ISOC to serve as the primary operating Control Centre. When the ISOC is fully in-service, the OGCC, which is the existing primary operating control centre, will be re-designated as the backup centre and the current BUCC will then be decommissioned.

Further details about the project are included in Appendix A.

A detailed option comparison is included in Appendix B.

E. EXECUTION RISK AND MITIGATION

- Construction commencement is contingent on the required OEB approvals and if not planned accordingly, could pose project schedule risk. This has been mitigated through a schedule adjustment that will initiate commencement once the OEB has provided a decision on both Transmission and Distribution portions of the investments.
- Municipal approvals pose risk to the project schedule. During the current detailed design phase the municipality has been consulted throughout the process, thereby mitigating the risk of future change requests or delay for approvals. Building permits are needed for construction. This ensures compliance with zoning requirements, health, fire, structural safety standards and other building standards.
- Site development and environmental risk may result from the discovery of adverse subsoil conditions. This risk has been mitigated through several borehole assessments of subgrade soil conditions to determine: (a) foreign objects; (b) soil contaminants; and (c) suitability of soil cohesion for adequate foundation strength and no notable issues have been discovered.
- Construction risk results from change requests, proponent's lack of performance and increased costs. These risks have been mitigated through plans for Hydro One and the external designer to monitor construction site activities throughout construction. This will ensure issues are discovered in a timely manner and addressed as soon as possible and that required contract quality is delivered.
- Alignment of dependent sub-projects has been identified as a potential risk. A delay in delivery of communication path connectivity to the control network would delay future *in-service* date and commissioning activities. This risk is mitigated through early commencement of this activity to ensure adequate lead times.
- Factors affecting priority are those identified in the *Investment Need* section that describes the increased reliability risk. These factors have been reviewed and reprioritized as *high* given the cost for remedial efforts such as those resulting from the 2013 flood in Toronto and the impacts on operations and Hydro One customers.

APPENDIX A – DETAILED PROJECT DESCRIPTION

This investment, formerly known as the Backup Control Centre – New Facility Development, has expanded to include other operational synergistic lines of business that require facilities to perform similar functions (operating, monitoring, control and response functions) that are critical to support SOD and to secure Hydro One's assets. An integrated solution was sought to ensure costs are minimized, maximizing the effective utilization of critical infrastructure, office space and the site and reducing customer rate impacts. Below is a description of the SOC and the ITMC identified investment need.

The BUITMC facility, in-service since 1950, requires extensive setup during activation and cannot accommodate back office support staff and regulatory security requirements for access control for critical computing equipment due to physical space limitations. The current HVAC is not adequate for net new occupancy or equipment and lacks the necessary facilities should a prolonged activation be required. The ITMC is a mission-critical element in ensuring that telecommunications network is available and in providing first level support in the event of any communications failure. Without the telecommunication connectivity from the OGCC to the stations, the OGCC is unable to monitor and control the BES. In the event the ITMC cannot meet its service objectives, and Hydro One experiences an issue with telecommunications paths, SOD will be unable to monitor or control the respective field assets. The ITMC requires a new Backup Control Centre to alleviate the risk at the current location.

A SOC and an Emergency Operating Centre are required to provide a primary site for operations, monitoring and coordinated response for physical security threats and are imperative for business continuity. Currently, Security Operations are dispersed across the province and are reliant on third party services. In the event the current vendor cannot meet service obligations, an eventuality that has occurred historically, Hydro One will be unable to monitor its critical sites. An integrated security presence at the ISOC will ensure physical threats can be detected, assessed and appropriate response dispatched. If a physical threat goes undetected, catastrophic impacts may result if critical assets are damaged. This has the potential to result in severe impacts to the Transmission and Distribution system networks across the province. In addition, a lack of detection has potential to expose Hydro One to public and employee safety and environment risk.

The current ISOC investment has evolved through a significant collaborative effort with Hydro One SOD, ITMC, Security Operations, industry participants and external subject matter experts. Initiation of this investment was predicated on current asset driven deficiencies/requirements (i.e. documented safety hazards, capability constraints, reliability/performance impacts and risks, failures, condition, age, obsolescence, and regulatory and/or Hydro One standards as described above).

Below is a detailed description of the ISOC investment planning process and execution strategy, which has been developed with the aim to a) fully understand requirements and needs across Hydro One, b) gather leading industry best practices and lessons learned, c) develop detailed programmed space and sizing requirement and assess against industry benchmarks, d) seek project costing from leading industry experts, and e) ensure cost controls and oversight.

Planning Needs Assessment: Phase One

Requests for Proposals (“RFP”) were issued to conduct a market scan and a planning needs assessment. This provided a detailed assessment of sites available in the market that met a set of specific “essential location requirements” and to provide expertise into the conceptualization and documentation of business needs and requirements of SOD, ITMC, and SOC. The main focus was balancing needs and costs against reliability requirements, industry best practices (including feedback from New York Independent System Operator and New England Independent System Operator) and lastly with lessons learned from the Ontario Grid Control Centre (OGCC) build. In addition, business requirements were translated into programmed space requirements based on Hydro One's experience and at the advice of industry experts. A basis of design was developed, capturing the stated requirements and a cost estimate was provided by an external estimator (for building and support infrastructure) and internal Hydro One engineering groups (for Telecommunications and Dual Power and Power System IT). The final basis of design and cost estimate was utilized to initiate the subsequent detailed design phase.

The sizing of the ISOC is predicated on duplicating the OGCC current functions. The new ISOC facility will be able to continue all day to day functions indefinitely.

Security Operations sizing was predicated on defined needs of operators, support staff, an investigation room and an Emergency Operations Centre (which will utilize a shared conference room when required).

The ITMC Backup Control Centre duplicated the current primary centre exclusively, including control room space, data centre requirements and provisions a back office support compliment to ensure adequate facilities are available for prolonged activation redundancy and assurance of operations.

Detailed Design and RFP: Phase Two

At the completion of the planning needs assessment phase, a detailed design phase commenced with the objective to provide all required documentation, designs and costing to tender the end state solution for construction. During this phase, all drawings, facility programing (space definition), IT architecture etc. were completed, including site procurement (~$3 million) and a final estimation. This information was packaged and ready for submission for RFP for the construction phase. RFPQ was completed in December 2017. The official RFP documents were issued to the shortlisted vendors in 2018.

Hydro One sought to pre-qualify a select number of vendors, in a competitive open market process, who demonstrated "required competencies" (e.g., proven large project construction experience, defined safety/environmental programs, change control process controls, demonstrated ability to deliver large construction projects on time and to budget, etc.) required for the construction of the ISOC. Pre-qualified vendors were required to offer input with respect to areas which could result in increased costs if not addressed before construction and provide a *Guaranteed Maximum Price* proposal to a defined scope of work and schedule, linked to a delivery penalty.

Construction Phase: Phase Three

The current plan is for the successful proponent to commence construction in Q2 2019.

Post Construction award: Hydro One's engineering consultants will monitor on site activities throughout the construction to identify issues early in the stage and solve them as soon as possible, and ensure quality is delivered according to the standards. Hydro One will participate in interactive bi-weekly onsite construction process meetings to gauge progress to requirements and address any potential concerns.

Other Risk Considerations:

The ISOC investment has been identified as a high priority as the historical failure issues at the OGCC/BUCC demonstrate the demand for the ISOC, which will become a critical facility in managing the BES. The project was subsequently prioritized and planned due to risk and considerations described below.

Current BUCC site location risks that will not be remedied include the following:

- Travel time to the current BUCC site location necessitates an interim backup facility to perform limited functions in the event the OGCC or its computer systems are rendered inoperable to comply with the NERC-mandated activation time of two hours. The ISOC will eliminate this risk;

- BUCC structure is landlocked with no expansion potential as the facility is surrounded by a transformer station;
- Current emergency preparedness risks will remain, which will be mitigated by decommissioning the BUCC, and replacing it with the OGCC:
- Adjacent to a major transformer station which exposes the BUCC to the following emergency preparedness risk: electrical hazards, environmental hazards such as fire, oil spills and other asset failure hazards.
- In a congested area in the event of wide spread emergencies i.e. civil unrest, blackout, natural disaster, terrorism at Pearson International Airport, which would negatively affect the mandated two-hour activation timeline.
- Between two major highways (Hwy 427 & Hwy 401)
    - The BUCC is adjacent or close to multiple highways (Hwy 401, Hwy 409 and Hwy 27) so any spills or major motor vehicle accidents could lead to an evacuation.
- Adjacent to public storage facilities.
    - Risk of terrorism and other disturbances as there is insufficient setback with neighbouring businesses.
    - The nature of high profile neighbouring businesses poses additional risk to Hydro One's ability to access and maintain a prolonged activation without further disruption (e.g. 1980s bombing of nearby industrial company).
- Gas pipelines located underneath property.
    - A pipeline failure leading to an explosion or a leak resulting in an evacuation is an example of very high consequence event, but carries a low probability.
- In a flight path (Pearson International Airport).
    - There are over 1,100 daily flights in and out of Pearson International Airport.
    - Given the proximity to the runway, an airplane crash during take-off or landing is an example of a very high consequence event, which could render the BUCC inoperable, but carries a low probability.

- Facility risks that could render the BUCC or critical equipment unavailable for an extended period of time, eliminating redundancy of critical monitoring and control of the transmission system include:
  - Basement flooding where computer rooms, power rooms, telecom rooms, switchgear, and SONET communications are currently located;
  - Failures of critical support infrastructure including; the fire panel, HVAC, emergency backup power (generator);
  - Inability for expansion and a high cost for retrofit / maintenance activities;
  - Relocation to the main floor of the equipment located in the basement of the facility is not a viable option given the space required for Computer rooms, telecommunication gear (SONET), Uninterrupted Power Supply units, switchgear etc.;
  - Competing demands for physical space, power, cooling from multiple tenants; and
  - Electrical station service is undersized.
- ITMC's current backup centre, the BUITMC has the following documented risks and constraints;
  - Located in a shared space with an inability to expand;
  - Requires extensive setup during activation as the facility cannot accommodate a permanent active installation;
  - Cannot accommodate current back office support requirements;
  - Cannot meet security requirements for access control for critical computing equipment;
  - The current HVAC is not adequate for net new occupancy or equipment;
  - Lacks the necessary facilities should a prolonged activation be required; and
  - ITMC is a mission-critical element in ensuring that the System Operations telecommunications network is available and in providing first level support in the event of any communications failure.

Hydro One's Security Operations are currently reliant on an external facility that is owned and operated by a third-party creating corporate and regulatory risks under NERC CIP standards, given that Hydro One lacks a contingency site that is capable of monitoring the physical security of its sites and assets. Should the facility or third party services no longer be available to Hydro One due to factors outside of Hydro One's control, Hydro One will not be in a position to monitor the real-time security (including door alarms, motion sensors etc.) of its critical sites, creating both a security and public and employee safety risk. Such an occurrence would also lead to a regulatory non-compliance violation with NERC Standards and possible sanctions, financial penalties and risk to corporate reputation.

APPENDIX B – DETAILED ALTERNATIVE COMPARISON

Detailed Alternative Comparison

Alternative	Description	Cost ($)	Size (ft^2)	Site (Acres)	Cost / ft^2	OM&A**	Comments/Additional Considerations
Alternative One: Status Quo	Maintain existing facilities. (BUCC remediation activities, lease new data hall space, lease for BUITMC).	$83.1M*	18,921	N/A	N/A	N/A	No provision for SOC. Existing BUCC location, space, and site constraint risks remain. Significant difficulties for prolonged activation. Includes a leased space for BUITMC, leased Data Centre space for SOD and remedial work to retrofit office space to better accommodate prolonged activation.
Alternative Two	Build SOD BUCC and Data Centre.	$126.1M* - $148.3M*	95,420 - 99,716	16.41	$1,322 - $1,487	$2.4M yearly and one-time charges of $3.6M	Site, SONET, Dual Power and critical support infrastructure included. This includes the preferred site and all critical support infrastructures including but not limited to: telecommunication, Dual Power, redundant generation, UPS, cooling, shared office and common space
Alternative Three	Acquire an existing facility for BUCC and BUITMC and integrated Data Centre	Not available. Building specific market scan by Andrew Thompson and Associates (ATA) indicated no suitable site for consideration at time of assessment. Hydro One owned sites were reviewed internally; however also found that no suitable site or facility existed that meet the business requirements.					

Alternative	Description	Cost ($)	Size (ft^2)	Site (Acres)	Cost / ft^2	OM&A**	Comments/Additional Considerations
Alternative Four	Initiate Build of ISOC.	$159.8M*	126,200	16.41	$1,266	$3.4M yearly and one-time charges of $7.6M	Provides a SOD primary control centre, BUITMC, and primary SOC including shared integrated data centre, and back office support staff area. Current lifecycles for critical applications respected, alleviating addition IT requirements to enable primary operability. This option assumes that direct SOD operating staff would be moved to the new ISOC and the current OGCC used a Backup.
Ontario Grid Control Centre (data for comparison purposes)		$154.4M	68,000	9.25	$2,271	$1.5M yearly	Presented in 2018 dollars (originally $118M investment in 2003). Provided for comparison.

*The Transmission portion of this total is 49.93% of the total cost.

**The OM&A cost estimates are the full total cost and these have not been adjusted to show the transmission portion only.

Data Centre Construction vs. Leased Data Centre

In addition to the alternatives discussed above, Hydro One retained an engineering firm, Morrison Hershfield to conduct a comparison between the option of construction versus a comparable co-location or leased data centre option. This ensured that the most cost effective means of providing needed Data Centre space is to build/acquire a new facility. The data centre space is the largest cost consideration in the overall project total. The Morrison Hershfield assessment was based on a 15 year term at market prices in the Greater Toronto Area ("GTA"). The GTA was utilized for this study as it provided a much larger pool of lease options with the required reliability / Tier level standards. The results of the 2016 study shown below indicate that the co-location/lease option ($122.1 million), based on the current design criteria, far exceed the cost of the build option ($73.2 million) ($30 million in Capital + Incremental annual OMA at $2.5 million escalated at 2% per year for 15 years, $43.2 million).

	IT/POWER MRC*	**Annual Cost of Rent**
Year 1	$ 341,144.00	$ 4,093,728.00
Year 2	$ 372,529.25	$ 4,470,350.98
Year 3	$ 406,801.94	$ 4,881,623.27
Year 4	$ 444,227.72	$ 5,330,732.61
Year 5	$ 529,725.56	$ 6,356,706.73
Year 6	$ 529,725.56	$ 6,356,706.73
Year 7	$ 578,460.31	$ 6,941,523.75
Year 8	$ 631,678.66	$ 7,580,143.93
Year 9	$ 689,793.10	$ 8,277,517.17
Year 10	$ 753,254.06	$ 9,039,048.75
Year 11	$ 822,553.44	$ 9,870,641.24
Year 12	$ 898,228.35	$ 10,778,740.23
Year 13	$ 980,865.36	$ 11,770,384.33
Year 14	$ 1,071,104.97	$ 12,853,259.69
Year 15	$ 1,169,646.63	$ 14,035,759.58
	Total 15 Year Spend	$122,636,866.99

**MRC = Monthly Recurring Charges include IT load rent, estimated power charges and PUE of 1.6.*

***Pricing in this table and this section are 2016 dollars.*

Other factors that affected this consideration are: a) no co-location facility provides NERC certified space which would require additional upfront capital cost in the first year, and b) many facilities have policies that dictate access, upgrade, expansion and security for the facility without renter input which exposes Hydro One's critical equipment to further risks.

Comparisons to Similar Facilities at Other Utilities

In a separate study, Hydro One asked Morrison Hershfield to compare the ISOC build cost with other critical utility builds that they are familiar with and the findings are presented in the table below. SaskPower was used as the reference utility for the comparison per below.

ISOC Breakdown	**Est. Cost**	**ft^2**	**Report Findings of Morrison Hershfield ("MH") on Build Comparisons**
Building Shell Cost	$30M	120,534	Includes shell and basic Mechanical Electrical Power services. This is considered at the bottom of the range of $250/ft^2 -$1000/ft^2 for hardened facilities of this type, which equals the cost per square foot for SaskPower's most recent facility design. Variance consisted of EF3 Tornado rate vs. EF4 for SaskPower with less office space and did not have Control Room space. Average generic office space range from $150 -250/ft^2. dependent on finish and furnishings.
Data Centre Cost	$30M	11,990*	SaskPower's estimates cost per ft^2 for data centre space was $3,000/ft^2. and it is MH's conclusion that $2,502 is within range of similar facilities. A similar telecom project in 2015 with a similar Tier level as the ISOC was $2575/ft^2.
ISOC Total	$159.8M**	126,200	This includes Building Shell, Outdoor Yard and Data Centre.

**Included support galleries (cooling, power distribution).*

***Note: The Transmission portion of this total is 49.93% of the total cost.*

Lastly, Hydro One reviewed a number of utilities investments in facilities and data centre development projects to ascertain the reasonableness of the ISOC scope as compared to the rest of the industry. Below is a table summarizing these findings; which show the ISOC is in line with the cost per square foot for comparable projects.

Industry Comparators	Description/Name	Cost ($M)	Size (ft^2)	Year Built	Adj. Cost to 2018 $ (CPI)	Cost (2018 $) / ft^2
New York Independent System Operator	NYISO Control Center	$59.4M	64,000	2014	$64.22M	$1,003
American Electric Power	Transmission Operations center	$57.2M	83,500	2007	$71.46M	$856
ISO-New England	Windsor Backup Control Centre	$50.7M	70,000	2014	$54.81M	$783
Pacific Gas & Electric	Distribution Control Center	$52.0M	37,674	2015	$56.27M	$1,494
	Distribution Control Center	$37.05M	24,000	2014	$40.05M	$1,669
	Distribution Control Center	$46.8M	50,000	2016	$49.95M	$999
First Energy	FirstEnergy Tx Control Centre	$58.5M	70,000	2013	$64.24M	$918
BC Transmission Corporation	System Control Modernization Project	$133M	113,022	2008	$159.34M	$1,410
	System Control Centre (building ONLY)	$40M	64,584	2008	$47.92M	$742
	Backup Control Centre (building ONLY)	$30M	48,438	2008	$35.94M	$742
Average Cost :				-	-	$1,141
Transmission Portion of ISOC.		$79.8M	63,851.5	2021	$79.8M	$1,250
Proposed ISOC Cost Comparison		$159.8M	126,200	2021	$159.8M	$1,266

Converted from USD to CDN at an exchange of 1 USD to 1.3CDN

Note: The ISOC is comprised of Distribution, Transmission, ITMC and SOC.

Site Assessment

As per the table below, the average cost per acre for the sites South of Barrie are higher than the costs per acre for the sites North of Barrie. In light of the foregoing, the City of Orillia was chosen as a primary location for the ISOC, given its relative location compared to the OGCC, the City size, access, lodging, development and emergency services, including the OPP headquarters. Communities further away were ranked lower due to distance, access to emergency services, development and lodging, winter driving hazards and relative site suitability among other factors.

Ranking	Community	# of Sites	Ave. Cost / Acre
1	City of Orillia	4	$114,935 - $181,200
2	Town of Bradford	3	$346,636
3	Town of Collingwood	3	$135,469
4	Town of Midland	6	$90,000
4	Town of Penetanguishene	3	$87,500
5	Town of Alliston (New Tecumseth)	3	$273,900
6	Town of Newmarket	2	$850,000
7	Town of Orangeville	1	$215,000
8	East Gwillimbury	6	$400,000
9	Angus	1	$80,000
10	Innisfill	0	$ -
11	Schomberg (King Township)	1	$475,000
12	Wasaga	0	$ -

Note: An assessment of internal Hydro One TS sites was reviewed against available acreage and emergency preparedness criteria and was determine that there was no existing Hydro One site that could accommodate the proposed facility. This represented a departure for previous assumptions with impacts of land purchase and support infrastructure that must be extended to the preferred site.

GP-02 Grid Control Network Sustainment

Start Date:	Q1 2020	**Priority:**	High
In-Service Date:	Program	**3 Year Test Period Cost ($M):**	20.5
Trigger(s): Strategic, Cost Avoidance, System Renewal			
Outcomes: Cost Savings, Regulatory Compliance, Replacement of End of Vendor Support Hardware			

A. OVERVIEW

The Grid Control Network is a computer network which allows Hydro One controllers located at the Ontario Grid Control Center ("OGCC") in Barrie ON to continuously monitor and control the Hydro One grid. Information from the Grid Control Network is also passed on to and utilized by external parties, such as other utility control centers, customers, and the IESO.

This program involves the replacement of both end of vendor support and components which are approaching end of vendor support of the Grid Control Network. It also migrates the Grid Control Network to a new and simplified network topology. The new network topology removes hub sites as well as Local Control Computers ("LCC") and Local Maintenance Computers ("LMC").

Hub sites were necessary in the past to act as a regional consolidation point for Supervisory Control And Data Acquisition ("SCADA") information from Hydro One stations. Over the last 20 years the need for hub sites has diminished due to two reasons:

1. The majority of Hydro One stations now have local protocol conversion, a necessary step to transmitting SCADA information to Hydro One's OGCC. When hub sites were first deployed they performed protocol conversion for the Hydro One stations connected to it because the equipment at Hydro One stations was unable to perform this protocol conversion.

2. Telecom circuits have migrated from older point to point connections to modern IP based routable circuits. These newer circuits do not have the same geographic limitations.

LCCs and LMCs are separate Windows based computers used in Hydro One stations. The LCC function is to provide local control of the primary power equipment within the station. The LMC function is to interface with protection and control equipment within the station in order to assist field staff with commissioning and troubleshooting activities. The new network topology migrates the function of the LCC into the station gateway. The function of the LMC has been replaced by the Transient Cyber Asset ("TCA") – a secure USB based operating system issued to field staff, used in conjunction with their corporate laptops. The removal of the LCC and LMC from Hydro One stations is preferred because:

1. It removes the need to update the Microsoft Windows operating system at Hydro One stations.
2. It reduces the amount of equipment which needs to be commissioned and maintained at Hydro One stations.

Gateways are a critical component within the Grid Control Network because they perform the necessary protocol conversion describe above as well as act as a concentration point for SCADA information. The majority of Hydro One's gateways will lose vendor support on June 30, 2022. Other existing hardware – Remote Terminal Units ("RTU") have already lost vendor support, and are targeted for replacement. RTUs are important in the Grid Control Network because they interface with the primary yard equipment at a station to execute control operations initiated by the OGCC. Proactive phased replacement of this hardware is necessary due to the critical importance of the Grid Control Network to the daily operation of Hydro One's transmission system. Unreliability of the Grid Control Network due to a lack of vendor support would pose operational risks.

The migration of the Grid Control Network topology to a new, simplified topology would allow Hydro One to eliminate hub sites (which as explained below, are no longer necessary and add unnecessary processing delays) thereby ensuring Hydro One satisfies the IESO Market Rules[1] that require high performance telemetry measurements have data measurement/equipment status change available at the IESO communications interface in less than two seconds.

This program will impact approximately 40 hub sites and 300 stations. One existing hub site will remain at Manby TS in order to accommodate the requirements associated with certain minor Hydro One transmission assets, as well as its transmission connected customers.

B. NEED AND OUTCOME

Investment Need

The Grid Control Network provides monitoring capabilities and remote control of the assets at Hydro One stations to the OGCC and Backup Control Center ("BUCC"). It is critical to Hydro One's real time operation of its transmission grid and is necessary to ensure safe, reliable and efficient power delivery.

This investment is required to: (i) replace elements of the Grid Control Network that are at or approaching end of vendor support, including: RTUs, LCCs, LMCs and gateways, and (ii) facilitate the migration of the Grid Control Network to a new network topology.

(i) <u>Replace Grid Control Network elements</u>

As described above, gateway hardware within the Grid Control Network will lose vendor support on June 30, 2022. It is impossible to predict when the existing gateways will fail.

[1] IESO Market Rules, Chapter 4, Appendix 4.21 – IESO Monitoring Requirements: Transmitter Performance Standards.

If the gateways are left to run until failure, a large portion of the gateways at existing Hydro One hub sites may fail at the same time, raising the cost to replace many gateways concurrently.

Furthermore, Hydro One also has an installed base of legacy RTUs which are well beyond end of vendor support and in need of replacement. Proactive phased replacement of this hardware is necessary due to the criticality of the Grid Control Network to the daily operation of the transmission system. Unreliable performance of the Grid Control Network would pose operational risks and challenges for the OGCC.

At the station level, the Grid Control Network allows centralized control of primary yard equipment (such as a circuit breaker, or disconnect switch) from an LCC. More specifically, the LCC is a Microsoft Windows based computer which allows local field staff to monitor and control station assets from centralized locations within the station. The Microsoft Windows operating system software for existing LCCs, which requires regular updates, will lose vendor support by January 14, 2020. This program will replace the LCC with a Human Machine Interfaces ("HMI"). HMI's are software feature enhancements that will be purchased for the new station gateways. The HMI will replace the functionality previously provided by the LCC, thus eliminating the need for the LCC. The proposed HMI within the station gateways are superior to the LCC as they do not have the same end of support issues associated with Windows based computers and will instead have the same lifespan as the station gateway hardware.

LMCs are Windows based computers installed in Hydro One stations which help facilitate commissioning and maintenance activities by field staff. As described above, the LMC function has been migrated to the TCA, and they have become redundant. LMCs face the same software lifecycle problems as LCCs. This work will decommission LMCs in Hydro One's stations.

(ii) Migrate to New Topology

From a network perspective, this program will also implement a new and simplified topology for the Grid Control Network, which eliminates all but one existing hub site at Manby TS. The hub sites were put in place when the OGCC was originally built almost two decades ago. Their function is to perform protocol conversion and provide a consolidation point when connecting telecom (Bell S4T4) circuits to Hydro One stations. Over time, Hydro One stations have been equipped with their own protocol conversion and the telecom circuits at stations have transitioned to be IP-based, therefore eliminating the need for information to be relayed through a hub site before reaching the OGCC. Figure 1 provides a diagram of the existing network topology, and the simplified topology to be implemented is illustrated in Figure 2 below.

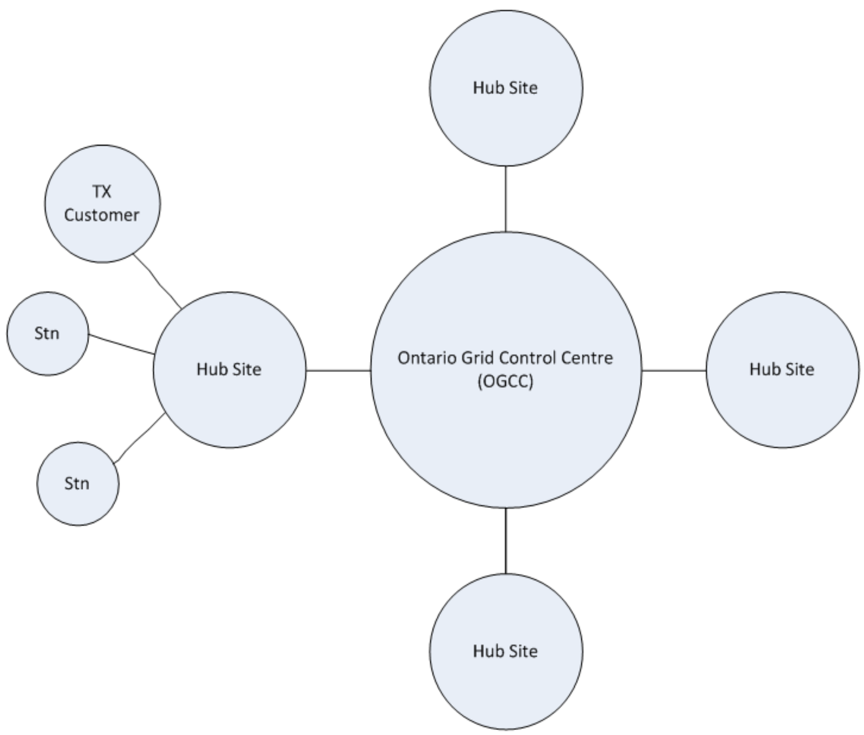

Figure 1 – Existing Network Topology

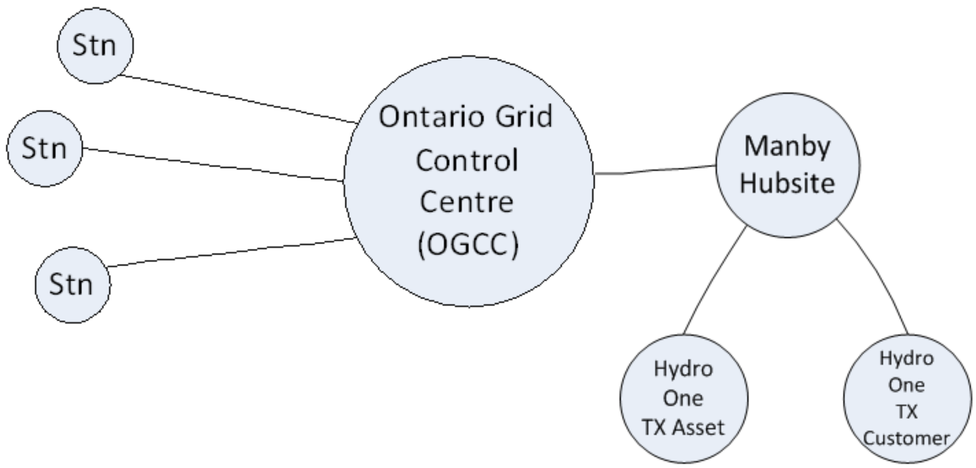

Figure 2 – Simplified "New Proposed" Network Topology

This new and simplified configuration is desirable and necessary because it would allow Hydro One to meet the IESO Market Rules requiring high performance telemetry measurements have data measurement/equipment status change available at the IESO communications interface in less than two seconds. Each additional level of hardware inherently introduces a processing delay. Therefore, by removing the hub site, the processing time of the relevant equipment is reduced, increasing the speed of the high performance telemetry measurements on the whole. Connections to the Manby TS hub site will not have this requirement, because they will be classified by the IESO market rules as medium performance telemetry measurements. The Manby TS hub site will remain solely for the purpose of (i) processing SCADA information from Hydro One transmission assets which currently do not warrant having their own local protocol conversion; and (ii) processing and consolidating SCADA information from Hydro One's transmission connected customers. Additionally, the new network topology is simpler, reducing the potential points of equipment failure and increasing the reliability of the Grid Control Network.

Investment Description

As explained above, this investment entails the replacement of equipment in Hydro One's Grid Control Network that are at or approaching end of vendor support, and the migration of the Grid Control Network to a new architecture. At each station there are four major components of work to be carried out as part of this investment:

(1) Upgrading the station gateway with HMI;
(2) Implementation of new Grid Control Network topology;
(3) Removal of LCCs and LMCs;
(4) Replacement of legacy RTU (if applicable).

All components of this work are related, and Hydro One will utilize a "bundling" approach (i.e. perform all components of the work concurrently at a station) in order to reduce costs and shorten timelines. An additional aspect of this program work will be to reroute some Hydro One transmission assets to the Manby TS hub site. These transmission assets which are currently connected to existing Hydro One hub sites are unable to perform their own protocol conversion. This is necessary to ensure that hub sites in our existing network topology can be removed from service, thus realizing the new Grid Control Network topology.

There are approximately 300 Hydro One stations to be addressed through this program work. Every year a list of stations will be addressed based on their criticality to the Grid Control Network. The cost of doing this work at each station will vary depending on its size and complexity of the local network. Program funding levels are expected to be higher in 2020, due to the additional expense of work performed at larger, higher priority stations. Implementing the required changes at these stations will be more costly given there will be more equipment to replace, remove, and test. In general, larger stations that are subject to NERC Critical Infrastructure Protection ("CIP") requirements are given higher priority. Program funding levels remain steady past 2022 to focus on replacing the remaining legacy RTUs. Due to the volume of work, it is not possible to complete all four work components by the end of 2022 at all of Hydro One's stations. Legacy RTU replacement, although important, is less important than the remaining three work components.

Hydro One's objective is to ensure the Grid Control Network equipment is replaced and fully migrated to the new network topology by the end of 2022 (with the exception of the legacy RTUs). This work cannot be deferred largely for three reasons:

1. If the network continues to operate with end-of-support hardware and an issue arises, there will be no support available. The overall reliability of the Grid Control Network would be impacted, which is of critical concern since it is relied upon by the OGCC to operate the transmission system.
2. Hydro One has a large installed base of RTUs in the Grid Control Network that are no longer supported by vendors. Due to their age, these RTUs have a high risk of failure. If repair is not possible with available spare parts, a RTU replacement will have to be engineered as a reactionary project, resulting in a lengthy equipment restoration time.
3. The new network topology will ensure Hydro One is compliant with IESO market rules.

Outcomes

There are a number of significant benefits to performing this work:

1. *Addressing end of life station computers (LCCs and LMCs):*
   LCCs and LMCs currently use either Windows XP or Windows 7. Windows XP is no longer supported by Microsoft. Windows 7 will lose all support on January 14, 2020. LCCs provide the important function of local control of primary yard equipment. They will be replaced by station gateway HMIs. The HMI will allow the continued local control of station primary yard equipment. LMCs support field staff in commissioning and maintenance activities. Their function has been

replaced by the TCA. The elimination of LCCs and LMCs will mitigate Hydro One's reliance on Windows based software at its stations.

2. *Addressing end of life gateways:*

   Gateways are a critical part of the Hydro One Grid Control Network. Vendor support for the gateways installed at the majority of the stations ends June 30, 2022. Gateway replacement will ensure reliability of the Grid Control Network, as well as facilitate the removal of the LCC at Hydro One stations.

3. *Addressing end of support RTUs:*

   RTUs are a critical part of the Hydro One Grid Control network. Hydro One has an install base of approximately 32 older RTUs which are well beyond vendor support. This investment will systematically replace these RTUs with units that are aligned with Hydro One's current design standard. Retired RTUs will be kept as spares until the entire install base is upgraded.

4. *IESO Monitoring requirements:*

   The IESO Market Rules require high performance telemetry measurements have data measurement/equipment status change available at the IESO communications interface in less than two seconds. The new network topology will ensure that this requirement is met by eliminating the processing delay currently introduced through the existing hub sites.

The following table presents anticipated benefits of the investment in accordance with the Ontario Energy Board's ("OEB") Renewed Regulatory Framework ("RRF"):

Customer Focus	• By migrating to the new topology the total amount of equipment in the network is reduced, thereby reducing the possible points of failure, resulting in the network becoming more reliable. This will improve Hydro One's ability to safely and effectively operate its transmission system. As a result, customers will experience fewer and shorter service interruptions.
Operational Effectiveness	• Migration to the new Grid Control Network topology allows Hydro One to meet IESO monitoring requirements. • When a hub site has its gateway files reconfigured the information collected from all of its remote stations becomes unavailable. As stations are migrated off the hub sites such that information is relayed directly to the OGCC, loss of availability will only be experienced by the station being worked on. This will improve system performance by reducing the number of stations impacted by routine station work.

C. EXPENDITURE PLAN

Through this investment, a certain number of stations will be addressed each year in a phased manner, so as to complete the required work at approximately 300 stations by the end of 2022. The estimated costs shown below have been determined on a per unit basis, with reference to the volume of equipment at each station. The per unit cost was estimated based on historical costs of the same work performed at previous stations.

Larger stations that are more critical to the Bulk Electrical System have been prioritized. The target date to complete the migration to the new network architecture is the end of 2022. Funding levels remain steady in 2023 as the focus of the program shifts resources on legacy RTU replacement.

Table 1 - Total Investment Cost

($ Millions)[1]	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total

[1] Due to the in-year nature of program investments, only 2020-2024 expenditures are shown
[2] Includes Overhead at current rates.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred option:

Alternative 1: Status Quo

Alternative 1 is to maintain existing Grid Control Network equipment until the work described by this investment can be bundled as part of other integrated station work. The current integrated station investment practice at Hydro One is to evaluate the need to perform work at each station on a seven year cycle. Under this option, end of vendor support equipment would not be replaced in a timely manner. Operating equipment without vendor support reduces the reliability of the Grid Control Network, which is critical to the daily operation of the transmission grid. Additionally, replacement parts for failed end of vendor support components will become harder to obtain over time. For these reasons, the status quo alternative is not recommended.

Alternative 2: Replacement of Grid Control Network elements without Vendor Support

Alternative 2 is to only replace the elements of the Grid Control Network that are no longer supported by vendors, without addressing the migration of the Grid Control Network to its new network topology. This alternative is not recommended, as it will impede Hydro One's ability to meet the IESO Market Rules for high performance telemetry. Additionally, Hydro One will not benefit from the increased reliability that could be achieved by the reconfiguration of the Grid Control Network, and will not realize the cost efficiencies associated with executing both components of this investment at the same time.

<u>Alternative 3: Replacement of Grid Control Network elements without Vendor Support and migration of the Grid Control Network to its new network topology (*Recommended*)</u>

The recommended alternative is to replace the elements of the Grid Control Network that are at or approaching end of vendor support and migrate the Grid Control Network to its new network topology. The existing station gateways will be replaced with versions that incorporate HMIs, and LCCs and LMCs will be removed. By the end of 2022, all eligible Hydro One stations will be migrated to the new network architecture. From that point forward, the program will focus on legacy RTU replacement.

This alternative minimizes Hydro One's operational risk by proactively replacing equipment in the Grid Control Network prior to expiry of vendor support for both hardware and software and replacing end of vendor support RTUs. This alternative would allow Hydro One to meet the IESO Market Rules for high performance telemetry data. It is cost and time effective to perform both aspects of the investment at the same time because the equipment, engineering and commissioning work are closely related.

E. EXECUTION RISK AND MITIGATION

The major risk associated with the execution of this program is the ability to obtain the project outages necessary for field commissioning. Cancellations may arise due to higher priority projects or unforeseen system contingencies. The strategy for risk mitigation will be to apply for project outages as soon as possible.

GP-03 Network Management System Capital Sustainment

Start Date: Q1 2021		**Priority:**	High
In-Service Date: Q3 2023		**3 Year Test Period Cost ($M):**	30.2
Trigger(s): Immediate/Short-Term Compliance, Preventative Maintenance /System Renewal, Reliability			
Outcomes: Regulatory Compliance, Maintenance of Performance and Reliability			

A. OVERVIEW

The Network Management System ("NMS") is a critical operating tool used to control switching operations and alarm monitoring at Hydro One's control centres; the Ontario Grid Control Centre ("OGCC") and the Back Up Control Centre ("BUCC"). The current NMS application software, server hardware and operating system are forecasted to be out of the vendor support window by 2023. All NMS end of vendor support components require an upgrade before reaching the end of vendor support. This upgrade is necessary to maintain required levels of NMS performance, reliability, availability and regulatory compliance. The projected costs of the project are estimated to be $38.3 million over the 2020-2024 planning period.

B. NEED AND OUTCOME

Investment Need

This investment provides for an upgrade of the NMS, a critical operating tool used for the monitoring and control of the Hydro One transmission system. The NMS system includes the application software and associated licenses, hardware and infrastructure, operating system, databases, and front end processors. The NMS application is used to monitor the status (e.g. open, closed, loading) and condition (e.g. alarm annunciation) of the transmission system and its assets, and to control and operate the assets to change system configuration or restore supply to customers after a contingency from the OGCC and/or the BUCC. This includes the execution of maintenance outage requests by field staff, customers, and the Independent Electricity System Operator ("IESO"). The reliable operation of the Ontario Bulk Electric System ("BES") is dependent on the consistent high availability and reliable performance of the NMS.

Without this investment, the continued high availability, high performance, and security of the NMS would not be assured. Alarms may not annunciate if the NMS system is impeded operationally or rendered unavailable. Failure to clear a fault or isolate a faulted element from the system in a timely manner, could result in a wide spread interruption in the BES due to the cascading effect of protection systems. One example of the potential impact of a delayed response is the 2003 Northeast Blackout, ultimately attributed to control room operation and tool issues.

Upgrades to the NMS are required prior to reaching end of vendor support for the software, hardware components, and operating system to ensure that Hydro One will receive the appropriate level of vendor support including software patches to maintain compliance to North American Electricity Reliability Corporation ("NERC") Cyber Security. The current application software, Alstom Energy Management System ("EMS") version 2.6, server hardware and existing operating system will all be out of the vendor support window in 2023.

Implementation of the NMS upgrade is also triggered to maintain compliance with regulatory standards. These standards are described below:

<u>NERC Reliability Standards</u>

NERC TOP-001-4 R10 and R13, govern the standards for monitoring and frequency of real-time assessments of the transmission system.

<u>IESO Hydro One Operating Agreement</u>

Operational Responsibilities under Part 2 of the IESO Hydro One Operating Agreement, including responsibilities under Section 4.2 govern: the availability and capability of equipment; the connection and disconnection of equipment to the IESO-controlled grid; and actions or recommendations regarding control voltage, loading, and configuration of facilities.

<u>OEB Transmission System Code</u>

OEB Transmission System Code Section 5.4 sets out a transmitter's performance requirements under emergency operations conditions.

NMS alarm monitoring capabilities facilitates situational awareness of changing conditions that may affect operation of the BES. NMS remote operation and control of assets minimize the impacts of an emergency situation. Upgrade of the NMS is required to continue these capabilities.

Investment Description

This investment will upgrade the NMS software and provide additional upgrades to the server operating system, database software and all end of vendor support monitoring and control computers, network and storage hardware. This investment will provide capacity for emerging transmission system requirements, create the opportunity to leverage a new baseline functionality and ensure that the NMS remains a fully vendor supported system.

This project investment has significant customer impacts as it allows for Hydro One control room staff to monitor customer connection status, coordinate customer outage requests, and restore or investigate events impacting customers. The NMS upgrade will also allow Hydro One control room staff to efficiently coordinate system operations and explore improved operating availability.

This investment will maintain required levels of NMS performance, reliability, availability and regulatory compliance by upgrading all NMS end of vendor support components; (i) power system, operating system, database software, and (ii) NMS specific infrastructure hardware for continued sustainability. The project has been scheduled based on information technology lifecycles with consideration of software, operating system, and server hardware lifecycles.

Outcomes

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Allows for Hydro One control room staff to monitor customer connection status, coordinate customer outage requests, and restore/investigate events impacting customers.
Operational Effectiveness	• Allows for Hydro One control room staff to efficiently coordinate system operations. • Enable improved operating availability by allowing Hydro One to have two active control centres.
Public Policy Responsiveness	Allows Hydro One to meet the obligations of: • OEB Transmission System Code (Section 5); • Operational Responsibilities as outlined under Part 2 of the IESO Hydro One Operating Agreement, including responsibilities under Section 4; and • NERC standards, NERC TOP-001-4 R10 and R13
Financial Performance	• Avoid expensive extended support costs for end of vendor support NMS application.

C. EXPENDITURE PLAN

This is a recurring investment. The budgeted cost is based on historical NMS investments and is in line with Hydro One's 2015 NMS upgrade, which cost $38M. The final costs will be determined nearer to the investment date, at which point the products offered and the associated costs will be available. To increase cost estimation accuracy and to reduce project execution risks, the development phase will provide the following deliverables:

- vendor statement of work cost estimates; and
- architecture for the main upgrade environments for more accurate hardware cost estimates.

Final costs of the project will be influenced by any change in available technologies, costs associated with infrastructure support and the market price at time of purchase. Technological uncertainties can be a challenge when forecasting for future capital projects. Hydro One is continuously monitoring technological developments and industry best practices to ensure the most cost effective solution.

The investment schedule was derived by understanding that the existing NMS system will be end of life in 2023 and working backwards on a 3 year implementation schedule.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	0.0	0.0	7.8	22.4	8.2	0.0	0.0	38.3
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.0**	**0.0**	**7.8**	**22.4**	**8.2**	**0.0**	**0.0**	**38.3**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**0.0**	**7.8**	**22.4**	**8.2**	**0.0**	**0.0**	**38.3**

[1] *Includes Overhead at current rates.*

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking:

<u>Alternative 1: Status Quo</u>

This alternative maintains the existing NMS application beyond the end of vendor support. Hydro One rejected this alternative because it would expose the company to reliability and sustainment risk as the current NMS will no longer be supported by the vendor beyond 2023. The lack of vendor support would negatively impact the ability to recover from a system failure. Maintenance costs for extended repairs or replacement components would be higher and more difficult to procure as the technology becomes obsolete. NMS failure would hinder control room monitoring and control capabilities, impeding the operational effectiveness of the OGCC and rendering Hydro One non-compliant with NERC requirements.

The NMS is an essential tool that helps Hydro One meets a number of NERC requirements as a transmission owner/operator. Failure of this system would risk non-compliance with NERC requirements, such as NERC TOP-001-4 R10 and R13. Therefore, this alternative is not recommended.

Alternative 2: New Software Application

This alternative proposes the current system be replaced with a new application from an alternative vendor when the existing NMS application reaches end of vendor support. This alternative has been rejected as Hydro One has many customizations to optimize use of the Alstom EMS suite and therefore cannot switch to another vendor product without significant risk and cost. Integration with other mission critical systems, such as the Control Room Information System, and many years of development of OGCC staff expertise and work processes would be jeopardized. As such, this alternative is not recommended.

Alternative 3: Upgrade NMS Software and pace ancillary upgrades

This alternative proposes upgrading the NMS Software but delaying or pacing upgrades of the accompanying server operating system, database software, and related hardware.
This approach is not advisable because it would require additional testing, labour costs, and outages on the NMS system. The risk on the existing production level system would also be elevated. While Hydro One does maintain redundancy on the NMS system, the redundancy is a requirement of NERC and even the redundant system is subject to availability scrutiny and auditing. There is not enough capacity in the current hardware setup to allow for the rollout of a new NMS application.

Alternative 4: NMS Capital Sustainment Project (*Recommended*)

It is recommended that Hydro One proceed with the NMS replacement to ensure continued system reliability and sustainability. Under this alternative, when the existing NMS has reached end of life in 2023, the NMS will be replaced with the updated version, with expected benefits including functional enhancements and improved technological capabilities. This alternative maintains operational effectiveness and the continued reliability of the daily operating, monitoring and control functions of Hydro One's transmission business. Unlike alternatives 1 and 2, the proposed investment mitigates the risk of control room downtime, interruption of work execution and planned outages that can negatively impact Hydro One customers.

E. EXECUTION RISK AND MITIGATION

To reduce project execution risk, proof of concept NMS console(s) will be designed and tested prior to full deployment, including use of the proof of concept NMS console in parallel with the current system prior to the final transition to the upgraded system. This approach provides for more testing opportunities and allows for non-conformances to be corrected prior to deployment into service. Furthermore, leveraging the lessons learned from the previous NMS upgrade project, completed in 2015, product maturity risk will be minimized by avoiding the installation of a product that is not yet in a production release status. Instead, Hydro One will wait for another utility to first implement the new product and review the project success with that utility to learn from their implementation experience. As a member of the North America Transmission Forum, Hydro One attends meetings and conferences where these experiences are shared.

GP-04 Integrated Voice Communications and Telephony System Refresh

Start Date:	Q1 2021	**Priority:**	High
In-Service Date:	Q4 2023	**3 Year Test Period Cost ($M):**	5.1
Trigger(s): Immediate / Short-Term Compliance			
Outcomes: Minimized Customer Interruption, Prompt Restoration to Normal Operating Conditions, Efficient Communications, Maintenance of Regulatory Compliance			

A. OVERVIEW

The Integrated Voice Communications and Telephony System ("IVCT") Refresh investment is to upgrade the IVCT system software prior to end of vendor support. This is a critical system to the Hydro One transmission network that provides voice communication managements between control centers, field staff, customers, the Independent Electricity System Operator ("IESO") and emergency services. The existing system is custom designed to meet the needs of Hydro One. The software is anticipated to be out of vendor support by 2023. Without vendor support, risks include interrupted voice communications that could delay response times in an emergency or outage restoration. As safety and restoration response times are highly valued and regulated, these drivers trigger the need for this investment. The proposed investment would replace application software and associated phone system hardware at the control centres. The projected costs of the project are estimated to be $6.3 million over the 2020-2024 planning period.

B. NEED AND OUTCOME

Investment Need

This investment replaces the IVCT, which is a critical system that provides voice communication management between the Ontario Grid Control Centre ("OGCC"), Backup Control Centre ("BUCC"), and the IESO, Hydro One field staff, connected customers and emergency services. The IVCT system provides integrated access and intelligent call routing via multiple communication platforms (i.e. mobile satellite phone, Iridium satellite phone, mobile radio) that efficiently manage thousands of daily control room calls.

The IVCT system ensures continued public policy responsiveness by allowing Hydro One to comply with various regulations. These include North American Electric Reliability Corporation ("NERC") communication standards (COM-001-3) and multiple IESO Market Rules that require redundant voice communications, and emergency communications that ensure constant communications paths, as outlined in the Outcome Summary table below.

The end of vendor support for this software is a key date, and the IVCT software will require upgrading prior to becoming unsupported. Although there is currently no announced end-of-support for components of the IVCT, based on forecasted vendor support schedules and hardware lifecycles, the IVCT system will likely require replacement by 2023.

The IVCT is based on commodity hardware provided by CISCO. This includes network-related devices and general purpose computing devices (servers). Typically, these systems have a lifespan of five years, but Hydro One has been successful in extending the life of similar assets in other areas such as the Network Management System, to about seven to eight years by strategic sparing of components, however the software in the system must remain vendor-supported. As new technologies are developed, support for older versions and the ability to purchase spare or replacement hardware becomes more difficult and costly. Also, supporting software products beyond their lifecycle poses increased risk to operations.

The IVCT is a core communication tool for the control room. On average, 2,582 calls are processed through the IVCT per day. Backup emergency communication systems are insufficient to perform regular management of planned activities. A loss of voice communication between the OGCC staff and field staff, the IESO, and Hydro One customers, could result in a negative impact on: wide-spread reliability; finance for Hydro One and its customers; restoration of power after a contingency or planned outage; public and employee safety and the execution of planned outages and work activities; and effective operation of the BES in Ontario.

The IVCT is custom designed to meet Hydro One's Governance and Compliance requirements ("NERC CIPv5") and to be auditable to NERC CIPv5 mandates. These and other unique and custom designed elements include the following:

- The IVCT provides a backup system that is completely separate in terms of physical location, hardware and software across all levels;
- The IVCT has as an operational uptime of 99.99% per year;
- The IVCT is capable of planned or unplanned operational failover between primary and secondary systems at each site;
- PSTN Interface: Public Switched Telephone Network ("PSTN") represents the primary means by which Hydro One field staff, customers and organizations such as the IESO contact Hydro One. Time sensitive, safety sensitive, and mission critical communications require that the PSTN interface be reliable, appropriately sized, and capable of delivering the connectivity required to perform the OGCC mandate;
- Incoming Call Management: The IVCT is responsible for answering and directing all inbound communications to the OGCC, BUCC, or other locations as required. In this role, it assures that callers reach the correct grid operating function in a timely and efficient manner via IVR, and allows System Operating Division ("SOD") staff to prioritize and manage their workload based on the information input by callers;
- Media Voice Prompts: The IVCT System provides navigation instructions for incoming callers through system media prompts;

- Emergency Calls - Inbound: Callers are able to identify their call as an emergency that is placed as priority to be immediately processed by OGCC Dispatchers and Controllers;
- Call Recording: The IVCT is responsible for recording all voice communications traffic, including telephone and radio communications;
- Contact Management ("Rolodex"): The IVCT Rolodex provides users with a rapid interface for making calls via a touch screen interface, and plays an essential role in improving operator efficiency due to the large number of contacts that are required to interact with daily;
- Control Room Site Maps: Provides a visual representation of control room layout, with IVCT consoles, as well as sector queues, displayed as clickable targets for softphone features such as calling and call-forwarding;
- Site In-Out Logging: Site In-Out Logging is a Hydro One policy that tracks the arrival, onsite, and departure status of visitors to stations and restricted areas in situations where they are onsite but do not require interaction with Control Room staff. Upon arrival at a station, visitors are able to register their entry via the toll free IVR system, obtain confirmation that they have logged in at the correct station, and leave a call back number. Similarly, on departure from a station, visitors again call the toll free number, and via the IVR log out of a site;
- Reporting: The IVCT provides a facility for the creation of reports based on activity and audit logging; and
- Outbound Autodialer: The IVCT Autodialer performs five different types of callouts: Planned Maintenance Outages, Planned Outage Cancellation, Verification of Fixes, Informational, and Estimated Time of Resolution. However, the IVCT also allows custom callouts and ad hoc campaign workflows. The Autodialer has the ability to accept and process voice prompts from the customer and update Hydro One systems based on those voice prompts.

These custom elements illustrate the need to maintain the existing IVCT system. If replaced with a generic system, in order to serve the same purpose, external processes would be required to recreate these functionalities and a means to integrate the IVR system would need to be designed, requiring substantial investments of time and money. These factors and others make IVCT utilization beyond vendor-supported lifecycles untenable.

EB-2017-0049, ISD GP-23 describes the distribution portion of this investment.

Investment Description

Hydro One currently has two control centres: the OGCC and the BUCC. The IVCT is a critical system that provides voice communication management between the OGCC and BUCC, the IESO, Hydro One field staff, connected customers and emergency services. The IVCT system provides integrated access and intelligent call routing via multiple communication platforms and is used on a continuous (24/7) basis at both sites as well as within the Operating Planning department.

A failure of the IVCT system will impact work execution, customer outages, responsiveness, and the ability to effectively dispatch for emergencies. Due to the critical nature of the IVCT system and the impact of a failure on daily operations, this system is planned to be replaced based on forecasted vendor lifecycle schedules. Furthermore, failure of the IVCT system would severely curtail the ability to monitor and mitigate system events, leading to negative impacts on customer satisfaction and operational effectiveness.

This investment will upgrade the application software, and associated phone system hardware at the OGCC and BUCC which will be relocated to the Integrated System Operating Centre ("ISOC") when it is completed in 2021. This investment is scheduled in consideration of the vendor's forecasted software and server hardware lifecycles.

Outcomes

This investment will ensure reliability of the IVCT system, which enables efficiency in daily control room operations, minimizes customer interruption, and supports prompt restoration of power equipment, while meeting regulatory requirements. The current features of the IVCT system include a user-friendly touchscreen interface, quick dial functionalities, and a customized rolodex contact database, which will be preserved. Additional features to help controllers do their job more efficiently will be available with the new system, such as automated voice-to-text capability. The IVCT will allow Hydro One to continue to meet its obligations under the IESO Market Rules and NERC.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• This investment helps to ensure a timely and efficient response to failures, unplanned outages, or imminent risks to the transmission system to minimize customer interruption and prompt restoration to normal operating conditions. Customer engagement has indicated that most transmissions customers value prompt restoration as "extremely important". • Supports system reliability by maintaining a communication medium between control room and customers. • A low call-handling time minimizes the impact of business interruptions and enhances customer experience.
Operational Effectiveness	• Supports system reliability by maintaining a communication medium between the control room and field staff. • Allows OGCC and BUCC staff to more efficiently coordinate maintenance work, and system events with LDCs, generators and customers on the transmission system.

Public Policy Responsiveness	• Allows Hydro One to meet Market Rules, including, but not limited to:
	    o Chapter 2, Appendix 2.2, Section 1.1.4
	    o Chapter 2, Appendix 2.2, Section 1.2.3
	    o Chapter 5, Section 12.1.1
	    o Chapter 5, Section 12.1.6 & Section 12.2.12
	    o Chapter 5, Section 12.2.3
	    o Chapter 5, Section 12.2.4
	    o Chapter 5, Section 12.2.11
	    o Chapter 5, Section 12.3.2
	• Allows Hydro One to meet NERC-COM-001-3.
	• Allows Hydro One to meet NERC CIPv5
	• Allows Hydro One to meet Transmission System Code, section 10.1.

Financial Performance	• Promotes efficient communications to minimize restoration times during planned and unscheduled events.

C. EXPENDITURE PLAN

Costs have been determined based on estimates utilizing historical IVCT investments. Based on lessons learned from previous IVCT projects, this proposed budget takes into consideration all relevant costs (i.e. license fees, interest/overhead, and other miscellaneous charges). The best available predictor of the technology costs are past costs and performance. It is not possible to predict, with much certainty, what products will be available and at what cost, this early in the planning horizon. Utilization of a more refined estimate method to determine cost will result in estimates that will no longer be relevant for a project with a start date of 2021.

The OM&A cost for the current IVCT system is approximately $0.7M annually. Hydro One will strive to reduce these costs with the new IVCT system.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total

[1] *Includes Overhead at current rates.*

D. ALTERNATIVES

<u>Alternative 1: Status Quo</u>

This alternative maintains the existing IVCT system beyond end of vendor support for the software and hardware. Hydro One has been successful in extending the life of similar assets in other areas by strategic sparing of components, as long as the software in the system remains vendor-supported. Even if the hardware has become obsolete, as long as the software remains supported, the equipment can continue to be used with minimal risk, as software fixes can be obtained from the vendor, and hardware can be replaced by drawing down spares. There is the potential to negotiate extended support arrangements (at additional OM&A cost) with the vendor for some of the IVCT software, but the software associated with the hardware is typically tied to the end of vendor support of the hardware itself. Hence the need to upgrade by this time a**s** this will expose Hydro One to reliability risk as the current IVCT system will no longer be supported by the vendor. In addition, the ability to recover from a system failure will be negatively impacted and extended repairs or replacement components will pose higher maintenance costs and be more difficult to procure.

A failure of the IVCT system will interrupt control room communication efforts, impede the operational effectiveness of the OGCC or the BUCC and could render Hydro One non-compliant with various NERC and Market Rules requirements. Therefore, this alternative has been rejected.

<u>Alternative 2: Replacement with an Off-the-Shelf Generic Phone System</u>

This alternative proposes that the current system be replaced with generic phones after the existing IVCT system reaches end-of-life. A generic phone system does not have the required functionality for control room operations such as a "rolodex of frequent calls", call recording capabilities to meet NERC compliance requirements, and an Interactive Voice Response ("IVR") system to direct and prioritize incoming calls. For the same functionality, external processes must be recreated for this alternative and a means to integrate the IVR system must be designed.

Due to the aforementioned issues and concerns, and the inability of this alternative to provide the needed functionality and integration with key elements, such as IVR, this alternative has been rejected.

Alternative 3: IVCT System Refresh (*Recommended*)

It is recommended that Hydro One proceed with a similar IVCT system replacement to ensure continued system reliability and sustainability. This alternative plans for the IVCT system replacement starting in 2021, leveraging newer technologies when the existing IVCT system has reached end-of-life. Hydro One is not currently aware of an announced end-of-support for any component in IVCT. End-of-support announcements are not always made sufficiently in advance to support a five-year planning cycle. Past experience must therefore inform the anticipation of this investment need. To meet the forecasted end-of-life and in-service target in 2023, the project must start in 2021. This will maintain the operational effectiveness and reliability of the OGCC and BUCC by maintaining these critical communication channels. This will also mitigate the risk of control room downtime, work execution delays, planned outage cancellations and the resulting negative impacts on Hydro One customers that these incidents cause.

E. EXECUTION RISK AND MITIGATION

Prior to the full deployment of the new IVCT system and to reduce project execution risk, a pilot IVCT system will be designed, installed and tested in parallel with the existing system. An experienced system integrator, with expertise in deploying similar IVCT systems, will be retained to oversee the project.

Functional enhancements and new technologies, such as automated voice-to-text capability, will be individually evaluated through a cost-benefit analysis closer to the project start date to ensure that value to customers can be demonstrated. Timing of this review is required prior to project commencement, as technologies and improved functionality today may have evolved significantly by 2021.

GP-05 Transmission Non-Operational Data Management System

Start Date:	Q2 2020	**Priority:**	High
In-Service Date:	Q4 2024	**3 Year Test Period Cost ($M):**	15.9
Trigger(s): Immediate/Short-Term Compliance, Productivity, Strategic, Corrective Maintenance, Preventative Maintenance			
Outcomes: Automatic collection and real-time processing and archiving of Non-Operational data, Condition-Based Maintenance			

A. OVERVIEW

The Transmission Non-Operational Data Management System project will leverage the capabilities of existing technology by connecting existing monitoring devices to a centralized and integrated data management system. Data will be collected centrally and used for monitoring, reporting and analysis. The project consists of hardware and engineering development at the substation level to ensure interfacing of all substation devices and components and the collection and processing of non-operational data. Software and hardware integration at the Central/Enterprise level will also be required to ensure processing and archiving of all substation non-operational data, and to connect, interface and exchange data with external programs which will facilitate analytics, reporting and visualization. A pilot project has been developed and is underway which will assess the most effective implementation of the project moving forward. Based on this pilot project, a data acquisition and management system ("the system") will be chosen or developed.

This project provides the necessary framework to enable the automation and use of enhanced technology to realize costs reductions related to maintenance activities and dispatching field personnel, perform condition-based maintenance, and provide access to detailed and accurate information to be used in analysis and modeling. The system also provides an essential foundation to pursue future initiatives and provide system controllers with additional operational awareness, allowing for proactive control actions to avoid equipment failure and minimize customer impacts. The Non-Operational Data

Management System will build on and enhance Asset Analytics ("AA") accuracy and dependability by including previously unavailable monitoring device data in the asset risk modeling.

B. NEED AND OUTCOME

Investment Need

In an effort to reduce OM&A costs, Hydro One is embarking on an initiative to implement a Transmission Non-Operational Data Management System. Non-operational data is defined as data, in a variety of formats, generated during the operation of the transmission and distribution grid that is not continually utilized by the Ontario Grid Control Centre ("OGCC") for real-time operating processes. While this data is not required for the real-time operations of the Hydro One transmission system, the collection of this data will provide the platform to empower various lines of business to pursue efficiencies and streamline business processes, such as moving from time based maintenance to maintenance based on condition which will result in OM&A savings as well as increase in reliability by minimizing the possibility of catastrophic asset failure. This data can also be utilized to support or supplement real-time operating processes and decisions.

Figure 1 depicts a conceptual diagram of the envisioned Transmission Non-Operational Data Management System.

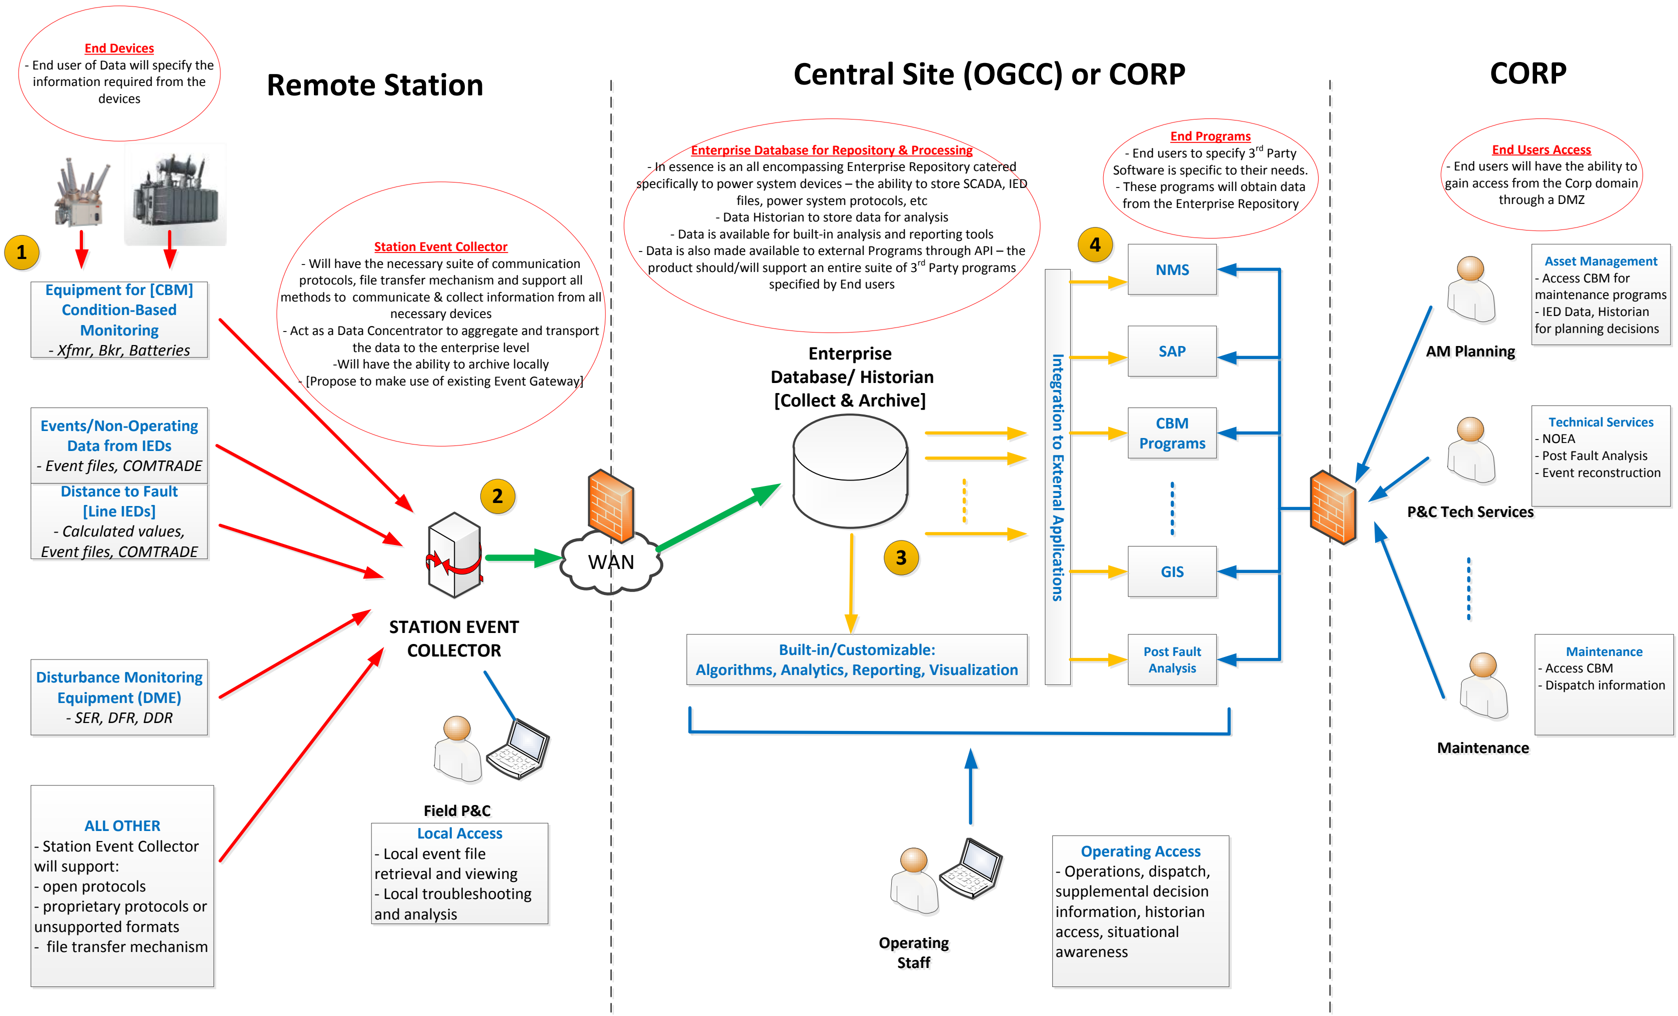

Figure 1 - Transmission Non-Operational Data Management System

There are essentially four sub-components which collectively make up the system:

1. Remote Station Collection: The Remote Station Collection are end devices that act as data sources for the Station Event Collector.
2. Station Event Collector: The Station Event Collector is a data concentrator for non-operational data coming from various end devices. It will be required to support the necessary suite of communication protocols, file transfer mechanisms and support all methods to communicate and collect information. As a data concentrator, it will be required to aggregate and transport the data to the Database/Historian at the Enterprise level.
3. Enterprise Database/Historian: The Enterprise Database/Historian will collect and archive all non-operational data from the various "enabled" substations. It will have the ability to create customized dashboards, perform analytics, generate reports, annunciations, trending, and will include alerting capabilities via methods such as alarms and emails.
4. Interface: The interface will allow the data from the Database/Historian to connect with external applications to enable users across the corporation to effectively access and utilize the data.

This initiative provides the necessary framework to enable automation and use of enhanced technology to realize cost reductions related to maintenance activities and personnel dispatch. The system also provides an essential foundation to pursue future initiatives.

The assets to be monitored will include, but are not limited to: transformers, breakers, capacitors, reactors, batteries, Intelligent Electronic Devices ("IEDs") such as protection relays, buildings, cables and lines. Examples of data that will be collected and aggregated in the system include:

- For Breakers: I^2T (a measure of energy dissipation), duty cycles, number of operations, and other measures of mechanical health;

- For Transformers: Gas measurements, bushing conditions, partial-discharge measurements, temperatures and tap-changer movements;
- For Lines: Distance to fault calculations; and
- For Disturbance monitoring: Sequence of Events, digital fault and waveforms and dynamic response measurements.

The availability of this additional information will make Hydro One processes more efficient and effective and will aid in: real-time operating decisions, life cycle management decisions for power system assets, and post fault analysis and event reconstruction efforts.

The deployment of the Transmission Non-Operational Data Management System will allow Hydro One to realize the following benefits:

<u>Condition-Based Maintenance ("CBM"):</u> Currently, Hydro One's maintenance activities for station assets are completed at pre-determined time intervals or are performed reactively. In contrast, a CBM approach monitors the current condition of the assets to gauge when maintenance activities are necessary. Information collected through the monitoring process, such as indications of deteriorating performance, are used to determine the frequency and specific type of maintenance activities that are required. This strategy optimizes station maintenance resources and activities. Cost savings are expected to be realized in the form of reduced maintenance activities, less frequent dispatching of staff for manual data sampling and retrieval, and fewer unplanned activities.

The predictive approach, incorporating non-operational data and analysis, will allow assets to be operated beyond their estimated service life if the data being collected supports continued use. This will result in an increased useful life of assets and optimized performance outputs.

Automated Non-Operational Data Collection from Substation Devices: Currently, the protection IEDs serve only two purposes: power system protection and reporting of real-time operating information. However, these devices have the capability to provide additional non-operational data through sensing and calculating functions. Programming the IEDs to collect this information and having the ability to access data remotely such as: Distance to Fault data and system logs for post-fault analysis would provide savings by eliminating manual processes and the need to dispatch personnel and would improve employee safety by reducing road time.

For example: Distance to Fault data can be used to dispatch line crews to the approximate fault location with a higher degree of accuracy. This will provide savings by reducing resource intensive inspections and patrols, performed via airborne helicopter fly-by inspection or ground based visual line inspection. Similarly, when a disturbance on the power system occurs, system data needs to be collected for proper fault analysis, a process which currently requires the dispatch of field personnel for manual data collection. Automating this collection method would enable savings by eliminating the need to dispatch personnel and improve employee safety by reducing travel to stations some of which are quite remote.

Averting Catastrophic Failure: A non-operational data management system, as proposed, is expected to deliver financial and labour efficiencies stemming from averting serious power system failures, which would have resulted in environmental impacts and extended customer outages. For example: several utilities (i.e. Alectra, PG&E and AEP) have been able to avert major transformer failures with the use of non-operation data. The transformer monitoring provided a warning that the transformer was about to fail. The utilities were able to preemptively remove the transformer from service prior to failure, resulting in cost savings in damages and mitigating outage impact to customers.

In another example, the oil of a 75/125 MVA 230 kV-27.6 kV transformer was monitored for gassing vs. load and oil temperature. The monitoring provided an indication of increased transformer gassing, which is a signal of potential impending failure. The utility was able to preemptively react and repair a manufacturing defect in the transformer at a cost of $100,000, averting up to $2 million in damages if the unit had failed catastrophically or with serious internal damage to the windings or core.

AEP also provided three examples in just two years (between 2014 and 2016) in which transformer failure was averted due to operating action taken after analyzing non-operational data. In each case, measurements indicated issues with the transformer and the transformer was taken out of service while manual testing was performed to confirm the indications. When the results were confirmed further testing was conducted to assess whether the unit could be repaired or replaced. In each case, the online measurement indications provided sufficient warning to take the transformer out of service prior to failure, avoiding significant costs and damage in each event.

A significant portion of the cost for this investment could be offset by the avoidance of a single major disaster such as a transformer explosion. The cost of the replacement transformer itself may be up to $1 million, while costs of environmental clean-up, reputational damage, labour required to remove the destroyed transformer and install the new transformer, associated extended outages and possible damage to the station surroundings would also be significant. The total expected cost associated with a single transformer explosion could easily amount to several million dollars.

Regulatory Compliance:

A Non-Operational Data Management System will support compliance with NERC PRC-005-6 *Protection System, Automatic Reclosing, and Sudden Pressure Relay Maintenance* in relation to station battery maintenance through the use of battery monitors to allow for reduced visual time based maintenance as battery monitoring would be real-time.

Hydro One uses two types of station batteries: Vented Lead-Acid ("VLA") and Valve-Regulated Lead-Acid ("VLRA"). All batteries associated with components of a protection system DC supply that are Vented Lead-Acid Batteries or Valve-Regulated Lead-Acid Batteries require time-based maintenance programs within certain specified maximum maintenance intervals according to Table 1-4(a) and Table 1-4(b), of NERC PRC-005-6.

However, the specified time-based maintenance activities for NERC compliance can be completely eliminated if adequate remote monitoring of this data (non-operational in nature) is in place. Certain monitoring functions may be used in lieu of periodic maintenance, as specified in Table 1-4(f) of NERC PRC-005-6. Monitoring functions that may eliminate the need for periodic maintenance include monitoring and alarming of the battery charger voltage to detect charger overvoltage and failure, electrolyte level monitoring and alarming, unintentional dc ground monitoring and alarming, and monitoring and alarming of battery string continuity, among others. By requiring a specified set of non-operational data to be monitored and alerts to be provided based on specific criteria, this standard allows for the elimination of station battery maintenance. Effective implementation of the Non-Operational Data Management System to provide monitoring and alerts based on these criteria will eliminate the need for field personnel to provide regular on-site inspections, will result in a more comprehensive understanding of battery condition, and will provide a more efficient means of NERC compliance. Cost analysis performed for battery maintenance (specific for NERC PRC-005-6 compliance) determined that installing online monitors on NERC impacted sites will generate an estimated cost savings of $760,500 per year.

<u>Foundation for Future Initiatives</u>: The Non-Operational Data Management System will also provide an essential foundation for future initiatives. Once developed, this infrastructure will allow for additional metrics and models to be implemented to assist in better decision-making by using a predictive approach for maintenance planning resulting

in improved levels of asset performance. For example, when the system is first implemented, distance to fault data will be assessed based on calculated IED values applicable only to permanent faults for radial lines. In the future, additional models could be implemented in order to calculate multi-ended lines, transient faults, correlations with weather / lightning data, and other scenarios. Another example is the opportunity to augment and enhance the capability of AA, currently used by planners for assessment of asset condition. The use of non-operational data can be used to model asset condition with increased accuracy.

This project is assigned a high level priority since it will result in OM&A savings and efficiencies related to labour and processes. The movement towards a CBM approach is in line with the regulator's expectation of managing and replacing assets based on actual condition rather than age.

Investment Description

The investment scope includes the development and implementation of several components, which are expected to be executed in parallel. Hardware and engineering development will be required at the substation level to ensure interfacing of all substation devices and components and the collection and processing of non-operational data.

The Database/Historian component will reside at the Central/Enterprise level where all data is aggregated, rather than at the Operations level where typical power system work occurs. This will permit the data to be accessed across the corporation, but will also require certain steps to be taken at the Central/Enterprise level.

- Software and hardware integration at the Central/Enterprise level will be required to ensure processing and archiving of all substation non-operational data. Installation of addition software/hardware is anticipated.
- Software and hardware integration at the Central/Enterprise level to connect, interface and exchange data with external programs which will facilitate analytics,

reporting and visualization. This will enable several Lines of Business ("LOB") to make practical use of the collected data to realize efficiencies and make better decisions for the maintenance and management of transmission system assets. Installation of addition software/hardware is anticipated.

The implementation plan will involve a staged approach. Criteria will be established to prioritize which processes would benefit most from the automatic collection and analysis of non-operational data. In prioritizing and pacing the implementation of this system, the following factors will be considered:

- Stations in which station battery maintenance is performed for NERC PRC-005-6 compliance will be prioritized, as implementation of this project will completely eliminate the need for maintenance on these systems.
- Stations will also be prioritized where:
    - DME equipment is already in place;
    - many equipment sensors are already installed; and/or
    - there is high spending on power system equipment maintenance.
- The overall plan will be to implement the system at as many stations as possible.

The decision for recommending the proposed alternative is based on the delivery of cost savings for process and personnel efficiencies as well as allowing Hydro One to realize a CBM approach to maintain and manage power system assets. Currently, approximately $900,000 is spent yearly on dispatching field personnel to retrieve non-operational data. The goal is to reduce this expense as much as possible. The ultimate savings due to implementation will depend on what issues will arise, at what frequency, and at which stations.

Outcomes

The following table presents anticipated benefits of the investment in accordance with the Ontario Energy Board's ("OEB") Renewed Regulatory Framework ("RRF"):

Customer Focus	• Improvements to reliability are expected as other utilities which have implemented a similar Non-Operational Data Management System have prevented catastrophic failure of power system equipment such as transformers, thereby avoiding potential lengthy outages.
Operational Effectiveness	• Access to non-operational data will offer additional insight into power system assets condition, which will facilitate a more proactive approach to CBM resulting in improved reliability and a reduction in the cost of maintenance and asset failures. This will also result in improvements in SAIDI and reduction in OM&A as remote access to station data will eliminate the need to dispatch personnel during line fault events.
Financial Performance	• Cost savings are expected to be realized by shifting from time-based maintenance to condition-based maintenance, as well as through the efficiencies of minimizing or eliminating manual processes.

C. EXPENDITURE PLAN

The estimated costs have been assessed on a preliminary basis and will be revised according to the final assessed need. The ultimate cost of the project will depend on several factors:

- An evaluation of whether existing corporate systems meet the functional requirements or if a new system is required to be implemented. Accordingly, there may be additional upfront costs to facilitate new hardware, software, and licensing.
- Each substation currently has different levels and vintages of devices. The total project costs will be impacted by the extent of data integration required at each station and the requirement of installation of any additional remote sensing devices.
- Additional software packages may need to be purchased if evaluation deems it more cost effective than developing in-house algorithms. Potential costs associated with the purchase of software packages or the labour efforts required to develop in-house algorithms will be assessed if and when a need for new software is assessed.

Since the Non-Operational Data Management System will provide the foundation for future initiatives, there may be additional feature enhancements, modifications, or rectification required as future initiatives are implemented. The primary focus of this project is to build the foundation for the system and integrate as many substations as possible into the system. Future initiatives will be funded at a later time or through additional funding.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total

[1] *Includes overhead at current rates.*

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking:

<u>Alternative 1: Status Quo</u>

Alternative 1 is to continue with time-based maintenance schedules and manual collection of substation non-operational data. This alternative has been ruled out, as this solution is less efficient and more expensive in the long run than the alternatives.

<u>Alternative 2: Improve Existing Systems</u>

Alternative 2 is to make improvements to existing non-operational systems which are segregated in nature. The current system was developed without anticipating the potential to develop CBM or system integration. Automation of some of the non-operational systems is possible but the remainder will still require either manual intervention or personnel dispatch to retrieve data due to limitations of the existing technology. This alternative has been ruled out, since the existing systems do not have the archival, analytic or integration capabilities for systems which would properly facilitate the CBM approach and enable remote access of data collected at the stations.

Alternative 3: Full Implementation of Non-Operational Data Management System (Recommended)

This alternative includes the full implementation and development of a Non-Operational Data Management System. The implementation and development program will include Remote Station Collection, Station Event Collector, Enterprise Database/Historian and a component of integrating the system.

This alternative allows Hydro One to realize a full CBM approach to maintaining and managing transmission system assets and allows remote access of data collected from devices at the station. This alternative has been recommended since it will deliver cost savings stemming from process and labour efficiency gains and it aligns with RRF outcomes as demonstrated in the outcome summary above.

E. EXECUTION RISK AND MITIGATION

A potential risk affecting the delivery and completion time of this project is the difficulty in integrating several different data systems into one common data management system, due to interoperability challenges. Hydro One will mitigate the integration risks by limiting the initial roll out to a pilot site(s) and applying the lessons learned through that process to the broader roll out that follows. A pilot project has been developed which will determine the implementation path going forward. From 2020 onward, the final project will be implemented and rolled out.

GP-06 Operating Common Information Technology Infrastructure

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Q4 2024	**3 Year Test Period Cost ($M):**	6.4
Trigger(s): Immediate/Short-Term Compliance			
Outcomes: Continued support for key customer applications, maintained IT facilities supporting critical grid operations, maintained compliance with regulatory requirements, cost effective management of IT lifecycles, and improved asset performance			

A. OVERVIEW

This investment involves the systematic replacement of common Information Technology ("IT") infrastructure for the Hydro One critical network operating systems used to facilitate business operations. Hydro One adheres to an IT industry standard practice of managing its assets through a lifecycle program in order to ensure vendor support continues to be available and the likelihood of failure is minimized. This investment is driven by the need to maintain current reliability and service levels with the continued support of mission critical applications in order to serve Hydro One customers in the most cost effective manner possible while maintaining compliance. While a number of factors may drive product replacement, product lifecycles and available support agreements established by vendors are the major determining factors for product replacement. The investment will result in continued support for key customer applications, maintenance of the required IT facilities to support critical grid operations, maintained compliance with regulatory requirements with regards to cyber security and reliability, cost effective management of IT lifecycles, and improved asset performance. The projected costs of the project are estimated to be $12.0 million over the 2020-2024 planning period.

B. NEED AND OUTCOME

Investment Need

This investment will sustain the IT common infrastructure which is the shared platform for the Hydro One critical network operating Enterprise Information Systems ("EIS"). EIS is the combined hardware and software IT system(s) used to facilitate business operations. The use of a shared IT platform used by multiple systems is technically more efficient and maintains a lower total cost of ownership as compared to multiple discrete instances to support specific systems. This translates into less sustainment and total system component purchases.

However, failure of any individual component has the potential to cause cascading system impacts including the failure of critical applications and the business functions they support, removal of system redundancy, and the possible unavailability of the Ontario Grid Control Centre ("OGCC") and/or computer systems. Resulting impacts on customers and work execution may include:

- Cancellation or delay of outages involving planned field work, causing customer inconvenience, and work delays, rescheduling, reprioritization and rework;
- Unresponsive outage management, lack of communication with customers and staff, safety risks, and an inability to respond to emergency events; and
- Backup activation which limits full business function and hinders critical response.

The common IT infrastructure consists of many subcategories of both hardware and software. The lifecycles for different IT product are influenced by a number of factors, including North American Electric Reliability Corporation ("NERC") security patch standard compliance, market performance of current products as evaluated against competitive products, technology innovation and development and the drive to replace existing products as they mature and are supplanted by newer and functionally superior technologies. As new technologies are developed, support and the ability to purchase spares or replacements for previous versions become more costly and difficult to source. Extended support agreements may be available for certain products at the end of their vendor support window, but historically, the extended support costs are significantly more expensive than standard market products. Product replacement parts also become scarce and inflated in price outside the vendor support window and there is an increased risk of non-compatibility with more current devices. Furthermore, supporting products beyond their vendor assessed lifecycle poses increased risk to operations. Loss of vendor support means potential security vulnerabilities are not addressed creating non-compliance, the potential for reduced availability of parts, and increased complexity when the system requires upgrading.

These factors and others make utilization of products beyond their lifecycles untenable. Each device is interdependent and future replacement technology attributes are almost always unknown, pacing and prioritizing is a continuous effort. The process of assessing device compatibility at the end of its lifecycle requires careful architectural consideration to ensure that system reliability and performance standards are consistently being met.

Investment Description

This investment is comprised of multiple asset groupings, and is required to maintain the viability of the common IT infrastructure for Hydro One network operating computer applications. These include the Network Outage Management System, Network Management System, Outage Response Management System, and Distribution Management System. These applications are leveraged by both Transmission and Distribution at both the OGCC and the Back-up Control Centre (“BUCC”). However this investment represents the Transmission portion exclusively. Hydro One has used the approved Black & Veatch Common Asset Allocation methodology in order to allocate the costs between Transmission and Distribution.

The common IT infrastructure consists of both hardware and software and is further defined into subcategories, which include:

- Data storage (devices that retain, retrieve and archive digital computer data);
- Computer servers (processors that fetch, decode, execute and write data in response to system processes and inquiries);
- Computer consoles (used by control room staff to interface with applications);
- IT networks (a series of communication paths interconnecting devices); and,
- Operating Systems/Applications/Software (i.e. VMware, a virtualization of servers/desktops), Citrix (presentation software), Windows Server and Desktop operating system.

Each of the above subcategories can include hundreds of individual hardware and software products and/or assets. The lifecycle of the various components are dynamic, and can at times be interdependent, influencing other components. The hardware is generally problem-free, however lifecycle management means keeping it in a supportable state as dictated by the vendor.

Hardware lifecycle is an ongoing evaluation for all current and future IT investments. All devices are current to the year they were "*lifecycled*" (when they were last replaced or updated) and there is no single project that replaces everything at the same time in any given year. Therefore, the equipment age distribution will always vary. Lifecycle planning forecasts in each category have leveraged historical trends, however, careful consideration regarding the lifecycle replacement and transferability of the infrastructure will be determined as Hydro One moves to the Integrated System Operations Centre ("ISOC") (described in ISD GP-01) beyond 2021. Considerations of the relocation of assets to the proposed ISOC facility may influence decisions on the timing and implementation of certain asset renewals, including data storage, compute servers, computer consoles, IT networks and operating systems/applications/software.

Outcomes

These investments will provide cost conscious ongoing product support and dynamic lifecycle management for all common IT infrastructure assets.

The following table summarizes the anticipated benefits as a result of this project:

Customer Focus	• Provides continued support to key customer applications such as the Network Outage Management System and the Network Management System, which support emergency storm response, communication, and outage coordination. • Minimizes customer risk and associated impacts of system outages.
Operational Effectiveness	• Provides the required IT facilities to holistically support mission critical grid operations, applications, systems, and their functions. • Decreases risk of reduced performance, or an inability to meet service levels in the event of a failure.
Public Policy Responsiveness	• Ensures mission critical grid operations, applications, and systems are supported with the current, compatible and supported IT infrastructure to maintain reliability and availability targets and meet regulatory requirements with regards to cyber security and reliability.
Financial Performance	• Provides cost effective management of IT lifecycles with current and supported common IT infrastructure. • Reduces OM&A expenditures and negates the need for costly extended support. • Improves asset performance, and the ability to recover from a failure. Grid failure can impose significant costs from the disruption to business function operational, increased labour cost for emergency break fix needs and other remedial efforts. These systems are used by Operating to monitor and control the Bulk Electric System and to manage planned and unplanned outage work in a proactive way.

C. EXPENDITURE PLAN

This group of investments is estimated based on historical costs, subject matter and industry expert input, and ongoing assessment. The cost estimate will be adjusted for the project scope, local condition and market pricing at the time of the investment.

Controllable costs have been minimized through the continued use and shared costs of common platforms, maximizing space, storage, and networking; maintaining current versions/latest technologies to maintain or reduce OM&A costs; and bundling of work to minimize outages or impacts to grid operations. Competing technologies are evaluated based on cost analysis and overall, the common IT platform requires less maintenance effort and a lower cost of acquisition as compared to multiple discrete components.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	1.7	0.8	2.0	3.7	3.3	2.2	0.0	13.7
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

[1]*Includes Overhead at current rates.*

D. ALTERNATIVES

Alternative 1: Status Quo

This alternative is to maintain status quo: do nothing and continue to use the existing IT infrastructure. As each device represents an important interconnected component of the common IT infrastructure, not proceeding with these lifecycle replacements could result in the following:

- A diminished capacity to serve and to meet customers' expectations;
- Regulatory non-compliance with potential financial penalties;
- Possible loss of one or more mission critical applications;
- Significant increase in system maintenance costs;
- Loss of the original equipment manufacturer/vendor support;
- Increased likelihood of system failures, and an inability to recover from these;
- Increased system security vulnerability to cyber-attacks;
- Potential to strand future application upgrades and enhancements; and
- Risk of higher cost of remedial efforts in the event of a failure.

Alternative 2: Maintain Supported IT Infrastructure (Recommended)

Lifecycle infrastructure management, based on industry best practices and vendor support schedules, ensures the continued viable operation of common IT infrastructure assets. There are a number of factors that drive hardware refresh – vendor supportability being a primary driver. Hydro One adheres to an IT industry standard practice of managing its assets through a lifecycle program ensuring vendor support is available and decreasing the likelihood of failure. There are other important considerations as well, including hardware age, the general availability of supported replacement parts, reliability requirements, and experience with similar initiatives/projects. However, lifecycles and available support agreements are the major determining factor for product replacement and are determined by the individual vendors. The dynamic architectural model requires Hydro One to plan and replace devices with the appropriate current technology and involves consistent assessment of available technologies and their versatility and compatibility with current and future needs. It is recommended as the only viable option. This option offers the following benefits:

- Continued availability and compliance with reliability standards;
- Current market product maintenance and vendor support;
- Original Equipment Manufacturer ("OEM")/vendor provided updates and software patches;

- OEM/vendor available replacement parts; and
- Improved ability to recover from random failures.

Through systematic replacement of common IT infrastructure, Hydro One can sustain business functions by ensuring that tools and systems used to support grid operations are functioning as designed and are fully vendor supported. This provides the assurance to Hydro One customers that IT failures are minimized and systems are returned to service in a timely fashion. This approach maintains Hydro One's commitment to customer satisfaction by ensuring responsiveness through system availability.

E. EXECUTION RISK AND MITIGATION

Replacing *end-of-life* infrastructure assets is recommended as best practices in order to maintain Hydro One's currently supported, compatible, and redundant IT infrastructure and equipment. The ongoing dynamic processes to cost effectively assess, prioritize, and stage each product in its respective category must remain in focus by the Hydro One Power System IT architecture team at all times in order to achieve success in each individual project. The driving focus behind these processes is to maintain current reliability and service levels with the continued support of mission critical applications whose function is to serve Hydro One customers in the most cost effective manner possible while maintaining compliance.

GP-07 Hardware/Software Refresh and Maintenance

Start Date:	Q1 2020	**Priority:**	High
In-Service Date:	Program	**3 Year Test Period Cost ($M):**	6.0
Trigger(s): Productivity			
Outcomes: Operational effectiveness, reliability of enterprise & customer applications, reduced risk of failure			

A. OVERVIEW

This investment plan involves the replacement of aging hardware and the upgrade and patching of existing enterprise applications. The planned investments relate to the implementation of Enterprise Resource Planning ("ERP") applications and related tools including SAP, further Information Technology security access control and monitoring capabilities, middleware and databases, productivity tools, and server upgrades to keep the data center infrastructure vendor supported and to make improvements to the disaster recovery platforms. These investments are required in order to ensure continued operational effectiveness, maintain the reliability of critical customer applications and build contingency so as to ensure that critical systems are available and can survive a system failure. The proactive investment approach reduces the risk of prolonged system outages and reduces the costs of unplanned investments to resolve failures. The projected costs of the project are estimated to be $13.7 million over the 2020-2024 planning period.

B. NEED AND OUTCOMES

Investment Need

Hydro One makes significant investments in enterprise technology to ensure the reliability and availability of business critical systems. This investment plan achieves this through the replacement of aging hardware and the upgrade and patching of enterprise applications. Most notably, Hydro One has made significant investments in SAP, Microsoft and a Geographic Information System ("GIS"). These enterprise systems enable meter data aggregation, some billing, and settlement activities. The enterprise systems also provide the backbone of business operations within finance, human resources, supply chain management as well as asset and work management for the field staff. Asset Management is responsible for defining the investment plan for Hydro One's distribution and transmission networks, and the management of these investments. Work management is responsible for the execution of projects and programs. The reliability of these systems is critical to keeping Hydro One's business running effectively. The investment plan maintains the Enterprise systems at service levels aligned with business criticality as defined in Exhibit B, Tab 1, Schedule 1 (TSP), Section 2.3.3.3.

In addition to ensuring operational effectiveness, the investment plan ensures critical customer applications and supporting systems are reliable and available to customers. Key systems and the data generated will always be available (99.5%) to customers and employees involved with the delivery of our customer service programs and work management programs linked to Hydro One customer satisfaction goals Key Performance Indicators ("KPI"s). For example, Customer Satisfaction is a KPI on the Hydro One Corporate Scorecard. Hydro One therefore strives to ensure the customer supporting systems such as Microsoft CRM, Customer Information Services, and Itron are reliable and available. Microsoft CRM enables the management of customer information, projects and customer communications; Customer Information Systems enables the effective execution of customer settlements; Itron enables the aggregation of meter data in support of customer billing. Further, SAP Work Management Systems enable timely connection of customers and demand related activities.

Assets included in these systems are mainly application software and the associated hardware (servers and storage). The primary enterprise application is SAP. SAP is a vital component in supporting a variety of customer services such as settlements and some billing functions. SAP is the source of truth for the data and is the information system that drives all of these customer actions.

Investments are required to build contingency so as to ensure that critical systems are available and can survive a system failure (result of a manufacturer bug, security patch, etc.) of any single supporting technology component. Investments in supporting technology components include telecom, Information Technology ("IT") hardware and software. Leveraging these investments with effective vendor maintenance means that the assets can be fixed and/or replaced expeditiously in the event of failure. To that end, Hydro One adheres to an IT industry standard practice of managing its assets through a lifecycle program ensuring vendor support is available and decreasing the likelihood of failure. Funding decisions are made based on software lifecycles, vendor schedules, reliability requirements, and experience with similar initiatives/projects.

Investment Description

In 2020 to 2024, the planned investments relate to the implementation of ERP applications and related tools including SAP, further IT security access control and monitoring capabilities, middleware and databases, productivity tools, and server upgrades to keep the data center infrastructure vendor supported and to make improvements to the disaster recovery platforms. New applications are driven by business needs and technology requirements. Existing applications that are approaching end of vendor support are upgraded to current versions and the supporting hardware is either refreshed or maintenance is extended. Investment related to hardware and server upgrades is variable by project and the complexity of the architecture. Where possible, Hydro One upgrades and refreshes hardware concurrently.

Refreshes for applications that are currently in sustainment are funded from this investment. The only exception is if the refresh is going to drive new functionality that can be tied to a business case. In that case, the investments will be treated separately and not included in the cost estimates. The cost estimates for this program are based on "like for like" refreshes of applications already in sustainment. The refresh activity is part of maintenance and supportability of that application asset. Any new functionality required by the business requires a business case that would drive the additional release of funds.

Lastly, a system being refreshed in order to accommodate its inclusion into the Disaster Recovery Program (“DRP”) would also be funded by this investment.

Assets are replaced as they approach end of life. At the time of replacement, investments are sized in order to support future demand and growth as well as ensuring the architecture is redundant and thus remains available to users in the event of a disaster (for example, investment is required to ensure critical systems have disaster recovery capabilities), thereby building contingency into the new asset investment.

Outcomes

This proactive investment approach reduces the risk of prolonged system outages and reduces the costs of unplanned investments for problem resolution. This investment in IT system reliability enables general employee productivity as it will allow internal users to have access to the tools they require to work and minimize downtime. The investment also enables customer satisfaction through increased availability of enterprise wide applications and, outage management systems.

The following table summarizes the anticipated benefits as a result of this project:

Customer Focus	• Ensure IT Hardware / Software is supported and reliable to prevent information gaps for customers. • Performance and Stability of IT Hardware / Software directly impact ability to service customers in a timely manner (i.e.: Outages, Billing Inquiry, Program Enrollment, etc.)
Operational Effectiveness	• Maintain the reliability of IT Hardware/Software to allow applications / systems to function as designed and provide Hydro One employees with the information they require to perform their daily work.
Public Policy Responsiveness	• Maintain efficacy of the IT systems that interact with market participants and support the IESO in its market oversight mandate.
Financial Performance	• Overall costs are minimized, by reducing the potential for costly outages and unplanned refreshes or upgrades.

C. EXPENDITURE PLAN

Estimates are driven by historical costs, which are determined by the inherent lifecycle of the devices. In order to calculate the cost estimations, Hydro One reviews the past actual spend over a 3-5 year period. As assets “cycle” at the same rate and are managed under an asset lifecycle program, future investment needs can be projected based on historical investments. The forecasted spending in 2020-2023 is lower than historical levels as some of the future spending was advanced to 2018-2019. In 2024 the spending is forecasted to return to sustainable levels in line with historical spending.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years[1]	2020	2021	2022	2023	2024	Forecast 2025+[1]	Total
Capital[2] and Minor Fixed Assets	-	2.0	2.0	1.9	1.9	5.8	-	13.7
Less Removals	-	0.0	0.0	0.0	0.0	0.0	-	0.0
Gross Investment Cost	**-**	**2.0**	**2.0**	**1.9**	**1.9**	**5.8**	**-**	**13.7**
Less Capital Contributions	-	0.0	0.0	0.0	0.0	0.0	-	0.0
Net Investment Cost	**-**	**2.0**	**2.0**	**1.9**	**1.9**	**5.8**	**-**	**13.7**

[1] Due to the in-year nature of program investments, only 2020-2024 expenditures are shown
[2] Includes Overhead at current rates.

D. ALTERNATIVES

Alternative 1: Delay Refresh

This alternative would defer replacement of assets due for refresh and maintain the status quo. This alternative was rejected as it would create additional issues caused by increasing failure rates of the systems.

Extending the timeline of the current life-cycle asset refresh strategy and delaying replacement of assets takes Hydro One out of line with industry practice and significantly increases risk to the business in the following areas:

- Increases in employee dissatisfaction and decreased productivity due to frequent and/or prolonged service outages;
- Degraded regulatory relationship from disruptions to market operations of IT systems that interact with market participants;
- Decrease in customer satisfaction due to failure of enterprise wide applications such as SAP, ihub/Tivoli, Microsoft Exchange, mobile applications, customer billing, relationship management, and call centre systems; and

- Productivity declines due to the high unit cost of supporting and servicing applications without vendor support.

Alternative 2: Refresh Per Plan (Recommended)

This proposed alternative would replace servers within life cycle guidelines. A number of factors drive the refresh of an application. This investment covers the capital costs, including Professional Services, to build new Web/Database/Application and Infrastructure servers along with all relevant data migration, Operating System, hardening, and decommissioning activities. There are a number of factors that drive hardware refresh – vendor supportability being a primary driver. There are other important considerations as well, including hardware age, and the general availability of supported replacement parts. Additional application functionality or performance considerations will also drive a refresh. Assets will be replaced in line with vendor support timelines, or**,** if there are new business requirements that require new functionality and/or increased performance of an asset, Hydro One will evaluate a refresh or replacement of an asset.

Server hardware is refreshed every 3-7 years based on hardware type. Hardware refresh is required to support enterprise applications from a performance/capacity and overall availability perspective to meet both customer and business expectations. Hardware refreshing per scheduled plan allows for sustainment costs to be favourably negotiated due to technology improvements being implemented as part of new deployments.

From an application perspective, today's business demands performance levels that are only offered by the latest server hardware and network technologies. From a technology perspective, the entire IT market continues to virtualize and optimize key areas that are common across all data-centres – virtualizing server compute, storage and network. Through the virtualization of our IT assets, IT becomes more responsive and agile to evolving business needs. As such, replacing old hardware with new technologies enables us to reduce our physical asset footprint and move to an increasingly virtual environment. This not only decreases our cost of maintenance but also increases our ability to service the business. Refreshing the current aging hardware allows for greater scalability and higher server densities, since it is possible to run additional virtual servers with a smaller hardware footprint.

E. EXECUTION RISK AND MITIGATION

No unique concerns are foreseen with completing the Hardware/Software refresh program beyond generic project risks, such as schedule delays, business disruption, and system outages. Any project risk is mitigated through stakeholders and modification of scope to reach desired business outcome. Through project governance, risks are proactively communicated, evaluated, and managed by project/program leadership and/or a steering committee, when applicable.

Any risks around resourcing, with respect to specific skillset requirements, will be addressed with systems integrators prior to awarding the project. The award will ensure proper expertise is maintained during the life of the project and is well documented as part of the execution scope.

GP-08 Corporate Services Transformation – HR/Payroll

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Q2 2021	**3 Year Test Period Cost ($M):**	6.5
Trigger(s): Strategic, Productivity			
Outcomes: Increased operational effectiveness, superior performance, consistent processes, cost savings			

A. OVERVIEW

This investment involves the implementation of a new Human Resources ("HR") and Payroll solution developed with SAP SuccessFactors as the main enabling technology platform. HR and Payroll are currently experiencing a number of operational challenges and have identified a number of improvement opportunities in the operations. Delivery of HR and Payroll services currently rely on the use of manual and MS Excel-based processes built around a relatively customized SAP system and near end-of-life or legacy systems. The proposed new solution offers improvement in HR and Payroll-related processes and will reduce the need for outsourcing to third parties. The projected costs of the project are estimated to be $6.5 million over the 2020-2024 planning period.

B. NEED AND OUTCOME

Investment Need

The HR and Payroll organizations are seeking enhancements to their operating models to better serve staff as well as stakeholders. Improvements are being sought to address the following areas: (a) changing workforce demographics and expectations; (b) the company's increasing use of a more flexible workforce (e.g. through hiring halls); (c) elimination of process and system-related inefficiencies (due to a significant degree of customization on the current system and manual & paper-based processes); and (d) the ability to process payroll, travel and board transactions efficiently and accurately. Meanwhile, SAP is re-architecting its solutions and support structure, with on-premise ERP-ECC applications no longer supported after 2025. SAP's HR module and functionalities will be transitioned from the ECC-based HR System to cloud-based SuccessFactors applications.

HR and Payroll are currently experiencing a number of operational challenges and have identified a number of improvement opportunities. The 2017 HR Effectiveness Survey conducted by HR in relation to HR services identified further process and operational improvements that can be enabled by a robust and modern technology platform. Examples of the improvement opportunities include: (a) payroll processing cost savings; (b) reduction in manual processes with respect to master data maintenance, error corrections and timesheet entries; and (c) automation in the areas of scheduling, employee ID creation and authentication management.

Delivery of HR and Payroll services currently rely on the use of manual and MS Excel-based processes built around a relatively customized on-premise SAP system and near end-of-life or legacy systems (e.g. PeopleSoft, Lotus Notes). Substantial portions of these functions are currently outsourced to a third party (Inergi) and Hydro One is in the process of renegotiating such agreement in view of the expiry of the existing outsourcing agreement in 2019.

While the switch to the new solution will not necessarily eliminate the need for third party outsourcing, the new platform and solution offers improvement in HR and Payroll-related processes – many of which are currently being provided by Inergi. As such, it would provide Hydro One with strategic leverage and negotiating power with Inergi should it decide to renew the contract or with other third party outsourcing service providers such as ADP or Ceridian should the company elect to change the service provider.

Investment Description

This investment involves the transformation of HR and Payroll processes with SAP SuccessFactors as the main enabling technology platform. Implementation of the project will be broken down into logical work streams aimed at achieving the following objectives and business outcomes: (a) Optimizing Talent Management and HR Performance; and (b) Time and Payroll Optimization and HR Modernization.

The technology architecture and solution will serve as the key enabler to the business transformation and will include key SAP SuccessFactors modules on HR as well as Time & Attendance applications. Overall, the scope will include:

- Implementation of new HR and Payroll business processes and technologies required to build capabilities and flexibilities across the in-scope functions; the in-scope functions include all core HR functions currently handled through the existing on-premise SAP HR system such as recruitment, organizational management, employee master data management, time & attendance and payroll processing.
- Formulation and implementation of new HR and Payroll operating models that will leverage the HR, Time & Attendance and Payroll Processing technology solution as the basis for improving the delivery of the HR and Payroll services in an integrated manner; and
- A technology architecture and solution that is aligned with Hydro One's IT Strategy and enterprise standards and leverages the investments made in other technology solutions such as the mobile platform.

Outcomes

The following table summarizes the anticipated benefits as a result of the project:

Operational Effectiveness	• Optimize standardized SAP processes, increase operational effectiveness through simplified user interfaces, superior performance and more consistent processes such as: o Enterprise-wide – provides leverage for outsourcing negotiations with the third party and provides a platform to support new Corporate cultural values through better in-sights-driven analytics; o Time and Attendance-related – moving to positive pay (without planned time) improves accuracy of employee pay, reducing unknown overpayments; o Manager and Employee Productivity – simplifies time entry and approval process and reduces administration burden, increasing employee productivity, and accelerates on-boarding time to make new employees productive, earlier; and o Data-related – enables more detailed data capture and reduces the risk of over payment by improving processes and strengthening controls.
Financial Performance	• Drive opportunities for cost savings and productivity gains such as: o Payroll Processing Cost Savings – Reduction in overpayments and improvements in process efficiencies with process automation and standardization; o Process Standardization Cost Savings – Improvements in process efficiencies with process standardization for HR and Payroll; o Process Automation Cost Savings – Improvements in process efficiencies with process automation for HR and Payroll; o Hydro One Full Time Equivalent Cost Savings – Reduction in cost for minor enhancements and support; and o Application Landscape Rationalization and Maintenance Cost Savings – Application elimination and reduction in costs to complete minor enhancements and support.

C. EXPENDITURE PLAN

The estimated project implementation cost includes the costs for the System Integrator, Inergi (as they are currently managing and supporting the existing system) ,and SAP (for Software Licenses and QA services) as well as Hydro One costs (for Project Management, Change Management, and Security). These costs were an output of the Discovery and Assessment work done by PwC in collaboration with HR, Payroll and IT. In addition there will be recurring software licensing & maintenance costs, but these are covered by IT's sustainment OM&A budget and are not within the scope of this investment.

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	1.7	5.0	1.5	0.0	0.0	0.0	0.0	8.2
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**1.7**	**5.0**	**1.5**	**0.0**	**0.0**	**0.0**	**0.0**	**8.2**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**1.7**	**5.0**	**1.5**	**0.0**	**0.0**	**0.0**	**0.0**	**8.2**

[1] Includes Overhead at current rates.

D. ALTERNATIVES

Alternative 1: Status Quo

This alternative contemplates no changes being made to the current HR and Payroll operating models. This alternative was rejected as it does not address the operational challenges currently faced by these departments. Maintenance of the status quo also means that the realization of associated benefits of the improvements identified will not be achieved.

Alternative 2: Cloud-based Solutions

Alternative cloud-based solutions (such as Workday, Oracle Fusion etc.) were considered. However, Hydro One has already made a substantial investment in SAP and the cloud-based SAP SuccessFactors platform. Additional investment in any of these alternative solutions will result in much higher systems integration costs and other costs as the existing SAP HR technology infrastructure would need to be replaced in its entirety. Therefore, this alternative was rejected.

Alternative 3: Transformation of HR and Payroll models (Recommended)

The recommended alternative is to pursue HR and Payroll transformation with SAP SuccessFactors as the main enabling technology platform. This will ensure that the solutions will be consistent with the company's IT Strategy of transitioning from a highly customized solution towards standard SAP processes and functionalities, leveraging industry best practices and providing a more cost effective solution. To facilitate execution, the implementation will be broken down into logical work streams aimed at achieving the following objectives and business outcomes: (a) Optimizing Talent Management and HR Performance; and (b) Time and Payroll Optimization and HR Modernization.

E. EXECUTION RISK AND MITIGATION

Following Project Approval by the Executive Leadership and the Project Governance bodies, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted on a quarterly basis thereafter. This is a line of business project that will be led and owned by the appropriate lines of business, supported by proven SAP and IT solution project execution methodologies and standards.

Key factors (medium-level risks) associated with the project include:

a) Possible underestimation of the degree of organizational change a transformational initiative of this type actually entails. *Mitigation*: A comprehensive Organizational Change Management ("OCM") strategy will be developed and implemented from the outset of the project. The strategy will include: (a) ensuring the OCM is involved in the project at an early stage in the process; (b) undertaking a comprehensive stakeholder assessment; (c) critical assessment of the impact of the new process and systems to the current functions and organization involved; (d) a comprehensive training strategy and plan; and (e) a proactive and effective communication plan.

b) Outcomes of Labour Relations' re-negotiation of collective agreements Society of Engineering Professionals (2019). Procedures and solutions within the scope of this project will touch on processes driven by existing collective agreements. As such, significant changes to the agreements may pose constraints with respect to the implementation of the target solutions (particularly with respect to time & attendance, payroll, travel and lodging), which could put the achievement of the anticipated project benefits at risk. *Mitigation*: Union representatives and other relevant stakeholders will be engaged from the outset of the project.

c) Decision on Payroll Operating Model prior to Inergi contract renewal in 2019. *Mitigation*: Hydro One's Payroll team and key stakeholders will be engaged throughout the project. As the Payroll Operating Model and contract with Inergi are reviewed, the impact(s) of these on the HR Operating Model and the activities within the project work streams will be monitored on an ongoing basis.

GP-09 Corporate Services Transformation – Finance

Start Date:	Q1 2018	**Priority:**	Medium
In-Service Date:	Multiple	**3 Year Test Period Cost ($M):**	9.0
Trigger(s): Strategic, Productivity			
Outcome: Operational efficiencies, process simplification, improved data and decision-making, reduced inconsistencies in reporting			

A. OVERVIEW

The company requires an upgrade to its Finance function to provide greater capability and flexibility to respond to increasing demand for accurate and timely reporting, ensure data integrity, provide better planning and analytics, and efficiently/effectively service its internal and external stakeholders. To achieve this, Finance needs to include processes for transaction processing, planning, reporting and analysis that optimize standard SAP processes, leverage industry best practices and take advantage of capabilities provided by new technologies. These improvements will enhance overall end-user experience, drive productivity gains and realize sustainable cost savings. The projected costs of the project are estimated to be $20.5 million over the 2020-2024 planning period.

B. NEED AND OUTCOMES

Investment Need

This investment is required in order to migrate to the new S/4HANA platform being developed by SAP prior to losing support on the existing applications in 2025.

Hydro One currently uses multiple systems to enable Finance perform its functions and provide service to its stakeholders. Such systems include SAP Business Intelligence (“BI”), SAP Enterprise Resource Planning Central Component (“ERP-ECC”), SAP Business Planning and Consolidation (“BPC”) and MS Excel. Over the past 10 years, Hydro One has consolidated over 130 applications, and the functions they performed, into SAP, which resulted in Information Technology (“IT”) and business process savings, such as reduced manual effort with respect to transaction processing, report generation and data reconciliation. However, there are still process inefficiencies, data integrity issues, long reporting cycle times and complexities and high cost in managing and supporting such systems.

To support the business, Hydro One's Information & Solutions Division ("ISD") needs to have: (a) strategic options on IT architecture and support model; (b) capability to develop and deploy new advanced planning and analytics with reduced effort and shorter timelines; (c) advanced capabilities for managing and analyzing big data sets and applying advanced algorithms and robotic trends.

SAP has, over the past three decades, created a platform that can be configured to perform any one business function in multiple ways. While "best practice" has always been built into every SAP transaction, user interpretation of what data needs to be inputted has led to inconsistent transaction processing and erroneous or missing data. In addition, SAP is currently re-architecting its solutions and support structure and shifting its product development efforts towards their new S/4HANA platform. This new platform promises to deliver core ERP-ECC capabilities in one place with one underlying data store, thus providing their customers with a centralized and streamlined system, with greater computing power, flexibility and data integrity. As a result, SAP has announced that their on-premise ERP-ECC applications will no longer be supported after 2025. There are some alternatives that Hydro One can consider. However, if Hydro One continues to be on SAP, all business functions using SAP will ultimately have to migrate to the new S/4HANA platform prior to 2025.

Investment Description

Finance as well as the upstream and downstream functions currently relies on the relatively customized on-premise SAP ERP systems as well as a significant number of manual and MS Excel-based workaround processes. A substantial portion of these functions are also currently outsourced to a third party (Inergi) and Hydro One is in the process of renegotiating such agreement in view of the expiry of the existing outsourcing agreement in 2019**.** The switch to S/4HANA per se will not eliminate the need for Inergi. However, the new platform and solution offers more power, analytics capability, streamlined processes, reduced manual effort, among other things; a lot of which is currently being provided by Inergi. As such, it would provide Hydro One with strategic leverage and negotiating power.

The Finance transformation project, as enabled by the new S/4HANA platform, will include:

- Re-engineering (as required) of relevant business processes to build target capabilities and flexibilities across the in-scope functions, move towards standard SAP processes, and leverage industry best practices. This will result in more efficient processes, reduced manual effort, shorter cycle-time, enhanced data integrity and greater reporting and analytics capability;
- A new Finance Operating Model that will leverage S/4HANA functionalities, enhanced computing power and better end-user interface; and
- A technology architecture that is aligned with Hydro One's IT Strategy and enterprise standards and leverages the investments made in other technology solutions (such as the mobile platform). As Hydro One relies significantly on SAP, the IT strategy is to be aligned with the SAP roadmap and standards, including mobility solutions.

S/4HANA is a real-time ERP suite that can form the digital core of the business. The promise of S/4HANA includes:

- Simplified functionality, with the elimination of redundantly-mapped business requirements which make promoting innovation difficult and cause data integrity issues and manual workaround processes;

- Simplified data structure eliminating data redundancy and providing end-users with faster access to data to generate real time reporting, ultimately reducing the time to close the books by 10 – 20% according to SAP estimates;
- An in-memory platform that provides better system performance. Additionally, new systems provide the ability to facilitate predictive forecasts and dynamic simulations using real time data to provide greater reasonability to the numbers. Embedded predictive algorithms and simulation capabilities enable management to better and proactively monitor and forecast business needs; and
- An intuitive, role-based user interface (SAP Fiori) structured on advanced design principles and simplified system landscape.

While the initial focus during the earlier years of the planning horizon will be the relevant finance modules and functionalities, the later part of the planning period will look into the upstream and downstream modules (e.g. those related to customer, enterprise asset management, supply chain, etc.) required to optimize full integration and realization of overall business benefits.

Outcomes

This investment will yield operational efficiencies, improved decision-making through real time reporting, process simplification and better data driven by standard and consistently performed transactions and better user adoption due to a simpler and more modern interface.

The following table summarizes the anticipated benefits as a result of the project:

Operational Effectiveness	• Increase operational effectiveness through simplified user interfaces, superior performance and more consistent processes. • Drive opportunities for cost savings through leaner processes and in-platform planning and reporting.
Public Policy Responsiveness	• Improve capability to meet statutory reporting requirements.
Financial Performance	• Reduce the inconsistencies in month end reporting through simpler user interfaces and consistent process execution.

C. EXPENDITURE PLAN

The underlying premise is that S/4HANA will help Hydro One fine-tune the current system investments, not reinvent them. This will extend the investment in the current SAP ERP that was implemented in phases between 2008 and 2013.

Hydro One will also initiate an open competitive bid process for the implementation stage of the investment so multiple vendors will be able to submit their proposals. There will be a need for a System Integrator. In addition, specific vendors for specific requirements will be required. Inergi will also be involved as they are currently managing and supporting the existing system. SAP of course will provide the Software Licenses and QA services as required. There could also be hardware requirements depending on the final strategy. Hydro One will select the most qualified vendor that best meets Hydro One’s evaluation criteria and budget.

The strategy is to have a phased implementation. Core Finance functionalities will be the focus for the initial year, followed by Logistics and Enterprise Asset Management modules. The last module to be implemented will be the Customer-related module. This approach enables Hydro One to implement the core functionalities as soon as possible, while at the same time making the most of recent investments - particularly on Move-to-Mobile and Customer-related modules

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	1.0	1.0	3.0	5.0	6.5	5.0	0.0	21.5
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**1.0**	**1.0**	**3.0**	**5.0**	**6.5**	**5.0**	**0.0**	**21.5**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**1.0**	**1.0**	**3.0**	**5.0**	**6.5**	**5.0**	**0.0**	**21.5**

[1] *Includes Overhead at current rates.*

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking:

Alternative 1: Status Quo

This alternative would require Finance to continue to use/rely on the current BI and ECC platforms in conjunction with other applications to produce financial statements and conduct reporting. This platform will reach end-of-life status by 2025 and will put the company at risk due to loss of vendor support, which would then require Hydro One to invest heavily on resolving any future issues or implementing fixes on its own. In addition, Finance will continue to perform its functions at a sub-optimal level and give up the opportunity to generate cost savings and productivity gains.

Alternative 2: Replace SAP with an alternative software system

This alternative would replace the current SAP BI platform with competing Enterprise Resource Planning ("ERP") software and/or adopt a multi-vendor approach by replacing the various business functions with Commercial Off-The-Shelf ("COTS") applications.

However, there could be differences in functionalities to those offered by SAP. This alternative is not justifiable due to the investment Hydro One has currently made in SAP technology, that would be lost if a replacement platform was adopted. In addition, moving to a new non-SAP platform would entail changes to processes and significant training/change management requirements. Therefore replacing the existing systems with COTS applications would not be justifiable.

Alternative 3: Finance Transformation enabled by S/4HANA (Recommended)

The recommended alternative is to pursue Finance Transformation, with S/4HANA platform as the technology enabler. This will ensure that the solution will be consistent with the company's IT strategy, and contribute to the objective of moving towards standard SAP processes rather than reliance on extensive customization. The investment will also leverage industry best practices and aim for the most cost effective solutions. In addition, it will assure continued vendor support over the long-term to keep IT costs in check and ensure ongoing timely performance.

S/4HANA has a streamlined user interface which has been built upon the same design concept that most mobile applications use which is to present the user with exactly the data they require and limit input options. Training will be required for use of the new interface, and all components of the solution as well as corresponding process changes. However, the interface is much more user-friendly than the existing solution. On the S/4HANA, platform business functions or processes have been simplified resulting in less time required to perform the associated processes and with improved data quality.

A major architectural shift in S/4HANA Finance is the use of what they refer to as the Universal Journal, which would serve as a single source of truth with respect to financial elements of a transaction. Currently, each module or sub-ledger has its own master data elements, which poses a lot of reconciliation challenges between modules. The database structures have been greatly simplified. SAP has done away with the sub ledger/ledger design thus increasing performance. As part of the implementation, baseline performance metrics will be determined against which performance of the new solution will be measured.

E. EXECUTION RISK AND MITIGATION

Following the project approval by the Executive Leadership as recommended by the Project Governance structure, the Corporate Risk group will be engaged to conduct a formal risk workshop. Follow up workshops will be conducted at appropriate project milestones. The following are the risks that the project plans to address and manage:

Solution Complexity

The S/4HANA delivery is expected to be a complex implementation and finding the right skill set to support successful implementation can be a challenge. To mitigate this risk, Hydro One will partner with vendors that have the experience & expertise to complete the work successfully.

Resources and Competing Priorities

Hydro One has many demands on its IT infrastructure, SAP, and Enterprise Architecture resources. All of these resources are integral to success of the project. To mitigate this risk, the eventual Implementation Project Team will highlight when they expect to require these resources and services during formal Program Planning activities. This will align with priority of projects set by Hydro One's Executive Team as an outcome of the Investment Plan review and approval process.

Any combination of these risks could result in a project in-servicing delay. To minimize the risk, solid project governance will be applied taking into account the relevant lessons-learned from other similar projects.

Change Management

As this initiative is transformational, there will be significant change which will impact both Finance (and potentially other Lines of Business), Investment Summary Documents and Inergi. To mitigate the risk, Hydro One Change Management Organization will be engaged throughout and a robust change program will be part of the scope of the project.

GP-10 Facility Accommodation & Improvements Service Centres & Admin

Start Date:	Q1 2020	**Priority:**	Medium
In-Service Date:	Program	**3 Year Test Period Cost ($M):**	21.2
Trigger(s):	Safety, Reliability, Immediate/Short Term Compliance, Strategic, Corrective Maintenance, System Renewal.		
Outcomes:	Lower maintenance costs, improved operational performance, regulatory compliance, enhanced health & safety, reduced risk of component failure, improved life cycle management, adaptability		

A. OVERVIEW

This investment entails improvements or additions to existing field facilities and/or the construction of new facilities as needed. The impacted field facilities include administration centres, operation centres, warehouses, heliports/helicopter hangers, fleet garages, as well as the head office and other Hydro One office spaces. Without the necessary capital repairs, upgrades and replacements, facility conditions will deteriorate to the point where Hydro One's operational efficiency and personnel safety become impaired. Through this program, Hydro One expects to achieve the following: lower maintenance costs, improved operational performance, regulatory compliance, enhanced health and safety, reduced risk of asset failure resulting in business disruptions, and adaptability to accommodate known or anticipated changes to the business. The projected costs of the project are estimated to be $41.9 million over the 2020-2024 plan period.

B. NEED AND OUTCOME

Investment Need

The field facilities that need to be addressed through this investment include administration centres, operation centres, warehouses, heliports/helicopter hangers, fleet garages, and all sites that are not transmission stations (including the head office and other Hydro One offices). This capital work program is designed to addresses field facilities with respect to required improvements, building additions and new facilities, as based on Hydro One's operational requirements and overall building and site condition.

This program ensures that essential and supportive improvements are made to field facilities to minimize building and site related risks, including in terms of health and safety and equipment protection, meeting operational requirements, and promoting efficiencies in facility maintenance and operations over the long-term.

Capital investment in field facilities is periodically required in order to continue to provide appropriate and adequate accommodations for core work programs and changing requirements of the various lines of business. This investment need is driven by the following key factors:

- Deteriorating facilities that require increased maintenance for components in poor condition, to the point where it is more cost effective to replace the component;
- Compliance with current regulatory requirements, such as the *Accessibility for Ontarians with Disabilities Act* and the *Ontario Building Code*;
- Expanding work programs;
- New accommodation needs;
- Evolving work practices;
- Improved health and safety by providing adequate and appropriate space for employees and equipment;
- Improved security; and
- Work efficiency and productivity.

More than 40 per cent of Hydro One’s field facilities are estimated to be more than 40 years old. These facilities are largely undersized, inadequately configured and underperforming relative to current operational requirements, resulting in increased operating costs for maintenance and repair and areas of inefficiencies in facility and business operations.

This program focuses on facility work in the areas of improvements, additions or new facilities. Work will be prioritized and executed on a project basis. Expenditures are limited to the extent required to support business operations in delivering work programs, in alignment with network requirements arising from operational plans and strategies, supporting customer needs, corporate and government policy and regulatory compliance.

Without the necessary capital repairs, upgrades and replacements, facility conditions will deteriorate to the point where operational efficiency and personnel safety become impaired, which will adversely impact Hydro One's ability to carry out its core business and serve customers in an effective manner.

Investment Description

The key program work activities include:

- Addition and/or renovation of existing facilities and the acquisition or development of new facilities to address existing and/or new accommodation requirements;
- Replacement of major building system/components, including roof structures; windows and cladding; Heating, Ventilating and Air Conditioning ("HVAC") systems; electrical, lighting and control systems; and other crucial/fundamental structural elements and building systems that are at end of life based on regular building condition assessments, and monthly inspections of various components; and
- Site-related replacements and additions, including drainage; asphalt, fencing; and septic/well (servicing).

Table 1 shows the expected annual volumes of work, based on project type, anticipated over the 2019-2023 period with New Facilities and Major Renovations accounting for the bulk (approximately 40%) of the program costs.

Table 1 – Net Investments by Category for 2020-2024 in ($ millions)

	2020	2021	2022	2023	2024
New Facilities and Major Renovations	2.7	0.1	3.3	11.4	2.8
Site Improvements (asphalt; drainage; servicing; fencing; security)	1.9	1.1	1.5	0.1	0.1
Building Envelope (roof; windows/doors; cladding)	2.1	2.4	1.5	3.4	-
Mechanical & Electrical (HVAC; lighting; generators)	0.4	0.4	0.6	0.3	0.5
Minor Building Renovations and Furniture	1.1	0.9	1.3	1.0	0.9
Total Net Investments:	8.1	4.9	8.2	16.4	4.3

May not add due to rounding.

Outcomes

Benefits associated with this investment are expected to be realized through a number of areas, such as lower maintenance costs, improved operational performance, regulatory compliance, enhanced health and safety, reduced risk of component failure resulting in business disruptions, improved life cycle performance and adaptability to address known or anticipated changes in business requirements.

This investment will enable Hydro One to achieve the following:

- Meet the current operating requirements of the various lines of business;
- Align commitments (e.g. facility leases) and investments with known and emerging operating requirements and corporate business decisions;
- Effective facilities maintenance through timely replacement of major building systems/components; and
- Enhanced health and safety of employees.

The following table summarizes the anticipated benefits as a result of this project:

Customer Focus	• Improve the ability of the lines of business to address customer needs through facilities that are commensurate with operational requirements.
Operational Effectiveness	• Maintain and improve operational effectiveness of the lines of business through timely and strategic facilities investments.
Public Policy Responsiveness	• Compliance with government policy and regulatory/licensing directives (e.g. Accessibility for Ontarians with Disabilities Act).
Financial Performance	• Cost effectiveness realized through regular condition assessment and timely intervention prior to asset failure. • Cost efficiency realized through facilities investments that align with current and emerging operating requirements and business decisions.

C. EXPENDITURE PLAN

The development of facilities and resulting final cost of a project are influenced by various factors beyond the typical realm of design, such as market, regulatory and site/building conditions/factors. Regulatory and site conditions are somewhat predictable through assessment, which is initiated at the outset of a market. In contrast, the market is highly influential on the final cost depending on availability of suitable sites, market opportunity and competing demand. These market factors could have a significant negative or positive impact on the cost of the project. Therefore, early planning, examination of alternatives and implementation serve to optimise opportunities and neutralise market forces.

The cost for the development and/or renovation of field facilities is controlled where applicable through template design, consistency of application, and the adoption of consistent commercial building standards and practices. Specifically, Hydro One recognises that its operational needs for facilities is relatively the same across the province and seeks maintain a consistent approach and leverage proven design that is cost predictable in construction and maintenance. More so, these facilities are to be developed to prevailing industry building standards for the planned use to ensure an appropriated level of investment, facility performance and maintenance cost.

The program costs outlined below are forecast to be needed to fund required improvements of existing field facilities and the development of new accommodation solutions through renovation, expansion and the acquisition or development of new field facilities as required by the company's work programs. Projects can be multi-year, and in certain instances will depend on the successful identification and acquisition of development sites and in all instances contingent on obtaining the requisite regulatory (including municipal planning) approvals.

Table 2 - Total Investment Cost

($ Millions)[1]	**Prev. Years**	**2020**	**2021**	**2022**	**2023**	**2024**	**Forecast 2025+**	**Total**
Capital[2] and Minor Fixed Assets	0.0	8.5	5.3	8.6	16.8	4.4	0.0	43.6
Less Removals	0.0	0.4	0.4	0.4	0.4	0.1	0.0	1.7
Gross Investment Cost	**0.0**	**8.1**	**4.9**	**8.2**	**16.4**	**4.3**	**0.0**	**41.9**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**8.1**	**4.9**	**8.2**	**16.4**	**4.3**	**0.0**	**41.9**

[1] Due to the in-year nature of program investments, only 2020-2024 expenditures are shown
[2] Includes Overhead at current rates.
[3] The annual investment cost fluctuations are due the cost of new facilities that are only periodically initiated in support of the transmission program.

D. ALTERNATIVES

Alternative 1: Status Quo

This alternative is to effectively defer future investment to a minimum in an attempt to continue to operate within the current, out-dated field facilities.

This alternative is not sustainable. Without the necessary capital repairs, upgrades and replacements, facility conditions will deteriorate to the point where operational efficiency and personnel safety become impaired. Any incidents arising from such risks would hamper Hydro One's ability to operate its business and serve customers. For example, a roof failure at an office building will result serious safety concerns as well as displaced staff, which will result in the need for alternate office space, increased costs, and inefficiencies. This alternative would require additional operating expenses for maintenance repairs, including for HVAC systems and roofing systems. Due to the unacceptable risks and cost consequences stemming from this alternative, it is not recommended.

<u>Alternative 2: Update Field Facilities (Recommended)</u>

This alternative would bring field facilities to an acceptable state of repair and make strategic additions or replacements according to a cost-benefits analysis. The cost-benefits analysis is undertaken during the development of the business case for the project, and incorporates relevant considerations such as trends in maintenance costs and the frequency of trouble calls in relation to the particular equipment and components.

The spending requested herein is an estimate of the work to be performed over the planning period. The management of field facilities entails an on-going comparative evaluation of alternatives, including the expansion and/or renovation of existing facilities, the lease or purchase of suitable facilities and greenfield developments against maintenance of the status quo condition. The specific work to be executed from year to year will be scoped and finalized based on the specific circumstances of each project. The objective is to pursue the most cost effective strategy that addresses operational requirements and mitigates risks. Operational considerations are for both existing and future requirements. Consideration of future requirements incorporates potential changes to the business. Each project will be subject to analysis and approval based on its benefits prior to implementation.

An overarching consideration is to maximize the value of existing field facilities through ongoing operations, maintenance and sustainment investments in line with operational requirements. Where facility and/or operational condition and requirements warrant an examination of facility alternatives, the objective is to derive the greatest net assessable benefit to the company.

E. EXECUTION RISK AND MITIGATION

Cost certainty for new operating centres is established through the use of a scalable template design and experience from recently completed projects. Developments are completed in accordance with applicable commercial standards and practices.

Development of new facilities will in many instances depend on the availability of suitable sites and ability to obtain municipal approvals, which can be managed through advance planning and acquisition. Development interests are cultivated by leveraging coordination with applicable municipal officials and departments, and effectively utilizing the services of the real estate and development community. In this regard, advance planning and engaging the right parties can allow risk to be mitigated by obtaining the requisite approvals ahead of time and proactively managing the often lengthy regulatory timelines involved in the development of sites and.

GP-11 Transmission Facilities & Site Improvements

Start Date:	Q1 2019	**Priority:**	Medium
In-Service Date:	Program	**3 Year Test Period Cost ($M):**	28.5
Trigger(s): Preventive Maintenance/System Renewal, Corrective Maintenance, Strategic, Productivity, Immediate/Short-term Compliance, Safety			
Outcomes: Maintain and/or improve system reliability, maintain and improve operational effectiveness, compliance with government policy and regulatory requirements, cost effectiveness realized through regular condition assessment and timely investments			

A. OVERVIEW

This investment pertains to the improvement and replacement of Transmission Station ("TS") Facilities, which includes building assets and facilities' infrastructure. This investment mitigates system reliability and safety risks associated with deteriorating and/or failing building assets, site infrastructure, and environmental risks associated with non-compliance; for items such as septic systems and release of halocarbons into the environment from aging Heating Ventilation and Air Conditioning ("HVAC") systems. The planned investment involves replacement of essential building assets and site improvements including but not limited to the building envelope, roofs, HVAC systems; required for sensitive transmission system protection and control equipment, building auxiliary systems, cranes, and elevators at Hydro One TSs. The investment will also help optimize capital expenditure through timely and cost-effective maintenance of operating requirements, and compliance with government policy and regulatory requirements. The projected costs of the project are estimated to be $48.1 million over the 2020-2024 plan period.

B. NEED AND OUTCOME

Investment Need

Aging TS facilities across the province require funding to provide for necessary improvements, asset additions, and refurbishments. This funding requirement is also driven by evolving work programs and a dynamic regulatory environment.

On-going building condition assessments provide insight into the overall condition of key facilities assets at TS's in addition to monthly building inspections and annual roof inspections. Furthermore, regular maintenance is carried out on key Facility assets at regular intervals to help maintain their life cycle until replacement. Based on analysis from the condition assessments and other inspections, a capital investment profile has been developed which determines projected end of life for certain building attributes. Without continued investment, the TS Facilities will deteriorate, resulting in increased operating and maintenance costs and potentially compromise the operational integrity and reliability of the electrical equipment, negatively impact work efficiency and effectiveness, and increase the likelihood of health and safety incidents.

The main drivers for this investment continue to be:

- End of life replacement of building assets components;
- Equipment and overall infrastructure that have exhausted their operational life and/or are technologically obsolete, resulting in higher maintenance costs due to scarcity of replacement parts and technical operating knowledge in maintaining and servicing such equipment;
- Higher failure rates due to mechanical/structural issues;
- Stringent regulatory requirements (e.g. building code, fire code, etc.); and
- Maintaining health, safety, and environmental standards by mitigating associated risks associated (for example, investment in well water facilities such as cisterns and septic cisterns for stations that are not on municipal services).

The planned investment entails site improvements and replacement of essential building assets that are now exhibiting diminishing returns when their maintenance costs surpass their serviceable life expectancy and replacement costs. The assets contained in this investment portfolio support the core business in Transmission and Distribution and directly and indirectly impact system reliability, regulatory compliance, and business operations. Direct impact to system reliability would entail projects like roof replacements for relay buildings and other critical buildings that provide support to the network. Indirect impact would be timely replacement of an HVAC system that maintains a serviceable temperature range for the critical equipment contained in the building. HVAC failure in this case would result in equipment failure which would then have a negative impact on supply reliability. In instances where the building asset investments are more incremental, indirect benefits will be realized through improved reliability and reduced maintenance. Changes in the business have also created the need for renovations and/or expansion of existing facilities to accommodate the need for increased staff at specific transmission stations.

This investment mitigates the following corporate risks:

- Reliability: This work program mitigates any system reliability risk associated with failed building assets and site infrastructure necessary to sustain regular operations at TS facilities. Failing to address building asset components such as leaking roofs, lack of cooling for relay rooms, and other end-of-life assets beyond service maintenance life can pose as a moderate reliability risk. While a failed roof or failed HVAC can force an entire station from service, there are systems in place to prevent roof failures, including bi-annual roof inspections to assess condition, which triggers remediation or replacement based on condition assessment. The risk of failure is mitigated through scheduled inspections, maintenance and corrective repairs.
- Regulatory: The Ministry of the Environment, Conservation and Parks and other regulatory bodies stipulate requirements for items such as septic systems and

release of halocarbons into the environment from aged HVAC systems that have reached end of life, as well as a requirement to remove light ballasts containing polychlorinated biphenyls ("PCB") by 2025. In the absence of funding, the regulatory risks associated with these items will be increased and result in potential fines for non-compliance and higher remediation costs for measures taken under emergency situations. The risk is mitigated through regular inspections and maintenance which help reduce risk of end of life failures, and facilitates addressing asset performance in a timely systematic manner.

- Safety: Safety risks posed by aging buildings are mitigated by maintaining the assets through regular inspection, timely replacement before failure, and incorporating safety by design where possible. This approach will minimize likelihood of any equipment failures and accidents and ensure operations remain uninterrupted.
- Customer and Shareholder Service/Value: Incidents resulting from failed assets/components erode customer confidence and relations, service level targets, and affects shareholder value through unplanned costs and reduced revenue.

Investment Description

The facilities department currently manages infrastructure at approximately 331 TSs, which also include facilities serving the accommodation needs of various lines of businesses, in support of the transmission program.

The key investment activities at TS facilities pertain to:

- The replacement of major building system/components, including roof structures; windows and cladding; heating, HVAC systems; electrical, lighting and control systems; and other crucial/fundamental structural elements and building systems that are at the point of failure.
- Site replacements and additions, including drainage; and septic/well (servicing); and water treatment upgrades to improve quality and reliability of water supply,

including conversions to municipal supply that will only occur when financially prudent and when municipal services are extended to the property;

- The addition and/or renovation of existing facilities and the acquisition or development of new facilities to address existing and/or new accommodation requirements;
- Buildings additions and major facility renovations; and
- Dealing with environmental issues that may arise such as mold.

Life cycle optimization practices pertaining to this program are mainly related to analyzing current condition assessment data, past performance, and field input along with detailed building condition assessment that provides insight into remaining life of the asset. Building condition assessments are performed on a five year cycle, while roof inspections are performed annually, and building inspections performed monthly.

Condition/point of failure is assessed based on condition ratings derived from building condition assessments and regular maintenance inspections and based on experience for similar asset components. Site replacements will occur only when condition assessments confirm that the asset is at end of life. Building upgrades that are not associated with a condition assessment include interior modifications such as changes to accommodate disabled employees, or modifications to create work space for additional staff as a result of organizational changes.

Table 1 below shows the number of projects performed on a historic and anticipated basis over the planning period. These projects address replacement of near end-of-life TS facility infrastructure that constitutes the bulk of the program spending. The program has been ongoing since 2015.

Table 1 - Historical and Anticipated Building and Site Improvements

Project	2015	2016	2017	2018	2019	2020-2022
Building Envelope-Roofs	15	9	13	66	15	15
Building Systems - HVAC	6	13	12	10	12	12
Yard Works & Building Structures,	9	6	15	10	15	15

Based on historic spend and conditions, forecasted investment levels are expected to remain relatively stable, reflecting the anticipated costs in the costs table at the end of this document.

There were 66 roof projects in 2018. This increase was a result of a corporate drive to reduce number of roof related outages at TSs. Due to additional funding available, 44 additional critical roofs that accelerated from 2019-2021 in 2018.

Outcomes

Proper maintenance of existing TS facilities results in:

- maintaining system reliability,
- Ensuring operational requirements are addressed in a timely and cost effective manner,
- Maintaining adherence to corporate policies and regulatory requirements.
- Compliance with regulatory requirements and corporate policies;
- Cost effective maintenance of existing TS facilities through timely replacement of major building systems/components prior to failure; and
- Enhanced health & safety of employees operating within TS facilities.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Support of system performance and reliability and the ability of the lines of business to address customer needs through facilities that are commensurate with operational requirements.
Operational Effectiveness	• Maintenance and improvement of operational effectiveness of the lines of business through timely and strategic facilities investments that are aligned with operational requirements.
Financial Performance	• Cost savings realized through the broad consideration of facilities alternatives. • Cost effectiveness realized through regular condition assessment and timely investment prior to failure. • Cost efficiency realized through facilities investments that align with current and emerging operating requirements.

C. EXPENDITURE PLAN

On a yearly basis, the program elements and historical average costs are approximately:

Roofs - Replacements and Capital Repairs (Coating)	~$4M
HVAC	~$2M
Site Works - Septic, drainage, paving	~$2M
Accommodation/Upgrades (including PCB removals)	~$4M

These historical estimates call for a funding envelope of a minimum of $12 to $13 million per year. However, the investment plan currently calls for an average award of $9.5 million per year during the 2020-2022 test period. These cost reductions are possible, but come at a significant cost. The opportunity to achieve the required reduction can be derived from various scenarios:

- Core program elements may be implemented only at point of failure, deferring the funding for the capital sustainment program into future years. This approach has been used historically.
- Given the high risk to operational equipment posed by roof failures, funding continues to be applied to roof replacements, but reductions have been implemented with respect to the coating program (~$1.5 million annually), which

serves to extend the life of the roofs by 10+ years before replacement. The benefit of eliminating the coating program is only a short term gain that will result in higher annual maintenance costs and ultimately increase the number of annual roof replacements, thereby exceeding the cost of the coating program if used as a preventative measure.

- HVAC is generally only undertaken at point of failure. HVAC expenditures are typically small and uneven, which does not allow for the ability to achieve reductions with any certainty.

Facilities staff have a subjective element that allows for adjustment to the timing and magnitude of the work which can achieve incremental cost reductions. However, the magnitude of these adjustments is not material and may result in higher costs impacting future capital or maintenance costs.

To control the actual costs of the implemented projects, majority of contracts are awarded on a fixed price basis.

Table 2 below shows the total planned investment costs from 2020-2022.

Table 2 - Total Investment Cost

($ Millions)[1]	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[2] and Minor Fixed Assets	0.0	10.3	10.3	10.4	10.5	10.7	0.0	52.3
Less Removals	0.0	0.8	0.8	0.8	0.8	0.9	0.0	4.2
Gross Investment Cost	**0.0**	**9.4**	**9.5**	**9.6**	**9.7**	**9.9**	**0.0**	**48.1**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**9.4**	**9.5**	**9.6**	**9.7**	**9.9**	**0.0**	**48.1**

[1] Due to the in-year nature of program investments, only 2020-2024 expenditures are shown

[2] Includes Overhead at current rates.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking:

Alternative 1: Status Quo- Run to Failure

This alternative is a "run to failure approach" for building assets and site infrastructure at TS facilities. This alternative represents continued operation with the current state of equipment and infrastructure at these facilities, only carrying out capital expenditure reactively after the occurrence of a failure of equipment, assets, or key site infrastructure.

This alternative was rejected as it undermines system reliability, would be a disruption to business operations, and would result in non-compliance with regulatory requirements and corporate policies. A run to failure approach ultimately increases the likelihood of unplanned system outages and emergency situations that will have a negative impact on system performance, operational efficiencies and costs, health and safety, and customer and shareholder service/value. Typically these buildings house critical assets, and would have direct reliability and customer impacts if the roof were to fail or the cooling system that supports critical infrastructure were to fail. Non-compliance with respect to regulatory requirements could also result in orders to comply issued by the Ministry of Labour or other building code violations.

Alternative 2: TS Facilities and Site Improvements (Recommended) - Maximize Life Cycle & Replacement Before Failure

This alternative maintains aging infrastructure by replacing building assets that are not easily serviceable and have exhausted their operational/performance life by carrying out timely and cost effective site improvements at TS facilities. The spending requested herein is an estimate of the work to be performed over the planning period necessary to keep these assets from reaching failure and causing service disruptions and creating potential health and safety risks. Cost estimates are based off of costs from previous similar projects and estimates from building engineers carrying out the building condition assessments. The objective is to pursue the most cost effective strategy that addresses operational requirements and manages risk. Each substantial investment will be subject to analysis and approval based on its cost/operational benefit prior to implementation.

The prime consideration throughout is to maximize the value of existing TS facilities through ongoing operations, maintenance and sustainment investments in line with operational requirements.

E. EXECUTION RISK AND MITIGATION

A potential risk with this type of infrastructure investment is the prospect of going over budget during implementation. To mitigate this risk, contracts are generally negotiated for fixed pricing which also include a competitive bid process to procure the most suitable vendor, when applicable.

Additional potential risks include unavailability of outages that are sometimes required to perform certain types of work such as roof replacement inside a TS. To mitigate this risk, outage requests will be submitted well in advance of the project dates and the required facilities outages will be scheduled in combination with outages required for power assets.

Execution risk is also mitigated through due diligence process by means of detailed upfront job scoping and asset condition assessments that help develop a comprehensive and accurate scope of work.

GP-12 Transport & Work Equipment

Start Date:	Q1 2020	**Priority:**	Medium
In-Service Date:	Program	**3 Year Test Period Cost ($M):**	39.7
Trigger(s): Productivity Enablement and Cost Avoidance			
Outcomes: Optimize fleet service levels, maximize equipment efficiencies, reduce required repairs and minimize equipment downtime, maintain regulatory compliance			

A. OVERVIEW

The Transport & Work Equipment ("TWE" or "Fleet") program involves the replacement of end-of-life fleet vehicles and helicopters. The program is driven by the need to replace these vehicles based on a thorough review of age, mileage and overall condition, and by the requirement to support Hydro One work programs and staffing requirements (including transmission and distribution capital and Operations, Maintenance & Administration ("OM&A") sustainment, development and operations work programs). This program will result in optimized fleet service levels to mitigate potential delays in response time to unplanned customer incidents, such as trouble calls and storm response and optimal levels of availability of fleet vehicles and other specialized equipment to reduce human effort and minimize risk of personal injury in the field. This program will also benefit employees by ensuring that employees have the right equipment to do their job, thereby increasing employee engagement levels, minimizing risk of injury and increasing work satisfaction. This investment will allow for maximum equipment efficiencies and ensure compliance with all codes, standards and regulations to sustainably manage our environmental footprint. The projected costs of the program are estimated to be $ 66.3 million over the 2020-2024 plan period.

B. NEED AND OUTCOME

Investment Need

The investment to replace end-of-life fleet vehicles and helicopters is required to maintain a healthy and optimal fleet to ensure public and employee safety and compliance with laws and regulations, which include CSA 225, the Highway Traffic Act and the Commercial Vehicle Operator's Registration regulations. TWE plays a wide-reaching and integral role in the day-to-day operations, safety and success of Hydro One's business. Availability of TWE has a direct impact on work program delivery.

Hydro One controls and manages approximately 7,000 fleet vehicles which support the Distribution and Transmission business, including Distribution Lines, Stations, Forestry and Construction Services. Fleet vehicles must be maintained at an optimum level to ensure public and employee safety and compliance with laws and Ministry regulations. These regulatory requirements include, but are not limited to, CSA 225, the Highway Traffic Act and the Commercial Vehicle Operator's Registration regulations. A well-maintained fleet lowers day-to-day operating costs, maximizes line-of-business productivity by minimizing downtime and travel time. Optimal investment levels allow for maximum equipment efficiencies and minimize Hydro One's environmental impact, as newer vehicles emit fewer greenhouse gas emissions due to more efficient vehicle mechanics and enhanced technology.

TWE expenditures for 2020 through 2022 are primarily required to accomplish the following:

- Replace end of life TWE based on a thorough review of age, km and overall condition;
- Support the Hydro One work programs and staffing requirements (including transmission and distribution capital and OM&A sustainment, development and operations work programs); and
- Replace end-of-life helicopters.

The identification of vehicles for replacement are based on industry standards (manufacturer's recommendations) for life cycle expectancy, the remaining net book capital value, operating cost drivers and overall condition assessment of the vehicle.

Light vehicles are replaced after the earlier of six years or 180,000 km. Heavy vehicles have several replacement guidelines depending on the type of equipment: service trucks are replaced after six years or 300,000 km, and single axle work equipment is replaced after eight to ten years or 400,000 km. Tandem axle work equipment is replaced after twelve to fourteen years or 400,000 km. Off-Road and Miscellaneous equipment is replaced on a case by case basis focusing on a condition assessment of the equipment performed by our licensed technicians and ongoing line of business need.

Helicopters are replaced on a case by case basis focusing on a condition assessment of the aircraft performed by the Air Maintenance Engineers, as well as a review of the cost of refurbishment versus the cost of replacement.

Investment Description

The TWE Replacement Program involves capital investment to replace existing TWE that has reached its determined end of life.

Fleet asset capital replacement requirements are based on:

1. Industry standards (manufacturer's recommendations) for life cycle expectancy;
2. Operating cost drivers which are linked to the Business Plan and Work Programs.

Key contributors to the 2020-2022 capital replacement programs include:

- The replacement of core transport and work equipment (about 6% annually, based on replacement criteria described above); and
- Replacement of end-of-life helicopters.

The proposed breakdown of Transmission-allocated spending over the test period is summarized in Table 1 below. Fleet Services performs an on-going assessment of equipment needs and the costs indicated per equipment type may be subject to change based on replacement priorities and available funding.

Table 1 - Forecast of Acquisitions for 2020 to 2022 (Tx Allocation) ($ millions)

Equipment Type	2020 Cost	2021 Cost	2022 Cost
Light	3.3	4.1	2.8
Heavy	4.1	3.2	5.1
Off-Road	1.5	1.5	1.4
Miscellaneous	0.6	0.7	0.2
Service Equipment	1.0	1.0	1.0
Helicopter	2.7	2.7	2.8
Total [1]	**13.2**	**13.2**	**13.3**

Light– cars, SUVs, pickups, vans
Heavy– service trucks, highway tractors, radial boom derricks (RDB), bucket trucks
Off Roads – rubber tire, tracked equipment
Miscellaneous – boats, chippers, tensioners, manlifts, forklifts
Service Equipment – snowmobiles, ATVs, managed Fleet Services.
[1]Total investment costs are based on average unit costs and relate to approximately 400 units annually

Outcomes

The TWE Replacement Program promotes an orderly system of purchasing and funding a standardized fleet replacement program and provides for projected TWE requirements based on work program and staffing forecasts. The TWE Replacement Program incorporates an annual analysis of five-year business planning cycles for capital investment requirements while maintaining a safe and efficient fleet. Evaluation of current spending and forecasted spending requirements will minimize fluctuations in spending and stabilize long term capital investment. The TWE Replacement Program is based on the Line of Business' work program prioritization and future projections and is evaluated against the business plan on an annual basis.

The objective is to maintain a stable fleet replacement program and minimize capital investment fluctuations year-over-year. A reduction in capital expenditures on TWE in a given year can potentially result in increased operating costs, ultimately resulting in increased equipment rates directly impacting the work program costs.

This investment will:

- Ensure compliance with all safety standards, as well as Ministry of Transportation ("MTO") and regulatory requirements;
- Reduce required repairs and minimize equipment downtime; and
- Optimize fleet complement and maximize productivity efficiencies and utilization.

The following table summarizes the anticipated benefits as a result of the program:

Customer Focus	• Optimize Fleet Service levels to mitigate potential delays in response time to unplanned customer incidents, such as trouble calls and storm response.
Operational Effectiveness	• Fleet vehicles and other specialized equipment at optimal levels of availability reduce human effort and minimize risk of personal injury. • Optimal investment levels allow employees to have the right equipment to do their job, increase employee engagement levels, minimize risk of injury and increase work satisfaction.
Public Policy Responsiveness	• Optimal investment levels allow for maximum equipment efficiencies and minimize Hydro One's environmental impact. • Ensure compliance with all codes, standards and regulations to sustainably manage our environmental footprint. • Vehicles will be maintained at an optimum level to ensure public and employee safety and to meet Ministry regulations.

Financial Performance	• Ensure savings from operational effectiveness are sustainable. • Control maintenance costs (external repair, parts and internal labour), potential rental costs and maintain equipment rates at optimal levels.

C. EXPENDITURE PLAN

Costs in the table below are the costs of the TWE Replacement Program, and are based on the Hydro One current work program, direction and strategy. The TWE Replacement program will be adjusted as required with the changing needs of the business. The costs indicated below are average unit costs as provided by the awarded manufacturer's approved contract with Hydro One (which includes escalation for future years).

Table 2 - Total Investment Cost

($ Millions)[1]	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[2] and Minor Fixed Assets	0.0	13.2	13.2	13.3	13.3	13.3	0.0	66.3
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.0**	**13.2**	**13.2**	**13.3**	**13.3**	**13.3**	**0.0**	**66.3**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**13.2**	**13.2**	**13.3**	**13.3**	**13.3**	**0.0**	**66.3**

[1] Due to the in-year nature of program investments, only 2020-2024 expenditures are shown
[2] Includes Overhead at current rates.

D. ALTERNATIVES

The primary alternative to the proposed investment plan is to maintain the current TWE at its existing level. This alternative centres on a reduction in capital spending on TWE in favour of increased use of rental equipment, if available, and extended retention of existing equipment to satisfy work program and staffing requirements. Hydro One employs specialized equipment specifically outfitted to Hydro One safety specifications.

Short term rentals would be utilized where available for light duty vehicles only, as heavy duty vehicles are not readily available for rent. Historical rental usage has demonstrated that due to the challenges inherent in the nature of the work, i.e. remote and difficult to access locations and challenging weather, any savings attributable to the use of rentals are quickly offset by incremental maintenance and repairs incurred by the harsher wear and tear on the rental vehicles in this type of industry. Hydro One is responsible for the cost of the incremental maintenance and repairs on the rental vehicles. As a result of retaining existing equipment, increased maintenance and repair costs will be incurred on the retained vehicles, as older vehicles tend to have more breakdowns and require more maintenance, which will ultimately result in increased vehicle downtime and decreased equipment availability.

E. EXECUTION RISK AND MITIGATION

The TWE Replacement Program is dependent on the manufacturer’s delivery and production schedule. Manufacturing delays may result in delayed delivery of the asset in the budget year, which would result in retention of existing equipment until the new acquisition is delivered.

SA-01 Connect New IAMGOLD Mine

Start Date:	Q3 2019	**Priority:**	High
In-Service Date:	Q3 2020	**3 Year Test Period Gross Cost ($M):**	24.9
Trigger(s): Customer Request			
Outcome: Connect industrial customer to the transmission system.			

A. NEED AND OUTCOME

Investment Need

This investment is required to facilitate the request from Iamgold Corporation (“Iamgold”) to provide supply to their Cote Gold Mine near Timmins, Ontario. Iamgold is an established mining company that is planning to start a brand new “Cote” mine with expected load of approximately 70MW to be located about 40 km from Shining Tree Junction. Shining Tree Junction is an existing transmission junction 115 km south of Timmins that serves as the interconnection point between the customers’ line to Hydro One’s transmission system.

Hydro One is obligated to make connections when requested by customers in accordance with its Transmission License and the Transmission System Code. Not proceeding with this investment would result in the customer’s project receiving inadequate supply. This project has been assigned a High Priority in order to meet this customer obligation.

Investment Description

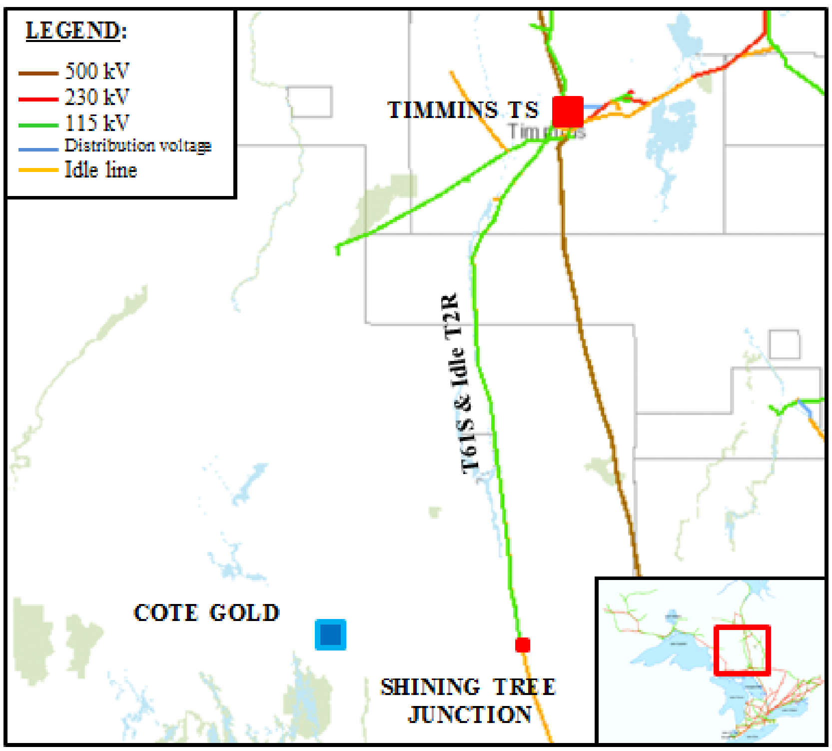
The proposed project involves providing a 115kV supply to the Iamgold Cote Gold mine from Timmins TS; including the:

- Addition of switching facilities and line termination to connect an existing idle 115kV circuit (T2R) to Timmins TS;
- Reinforcement of a 115 km section of the idle 115kV circuit (T2R) between Timmins and Shining Tree Junction;

- Installation of switching facilities at Shining Tree Junction; and
- Incorporation of the customer facility into the existing Northeast Load Rejection scheme.

Note: In conjunction with this project, Hydro One is also proposing a project to refurbish the existing 115kV transmission circuit (T61S); which shares common steel towers with the 115kV circuit (T2R) along the 115 km route from Timmins to Shining Tree Junction. This additional project for the existing 115kV transmission circuit (T61S) is described in ISD SR-20.

A map showing the project location is provided below.



The System Impact Assessment and Customer Impact Assessment were completed in 2018, and both confirm that the project will not adversely affect the reliability of the IESO-controlled grid or service to other transmission connected customers.

Witness: Robert Reinmuller

Iamgold received approval from the Board in Q4 2018 with respect to its "Leave to Construct" application (EB-2018-0191) under Section 92 of the *Ontario Energy Board Act* to allow the construction of the customer line from Hydro One's Shining Tree Junction to the Cote Mine.

Hydro One has also applied for "Leave to Construct" approval (EB-2018-0257) for the reinforcement of 115kV circuit (T2R) under Section 92 of the *Ontario Energy Board Act* and initiated the Class Environmental Assessment under the *Environmental Assessment Act* in Q3 2018. A summary of the need, project description, risks, and costs have been presented in the Section 92 application. All land matters will be addressed in the Section 92 application. Hydro One is currently awaiting the Board's decision in this matter.

Commencement of the project is subject to signing of the Connection Cost Recovery Agreement ("CCRA") with the customer.

Outcomes

This investment will provide the required transmission facilities to supply power to the new Cote Gold mine, which has a projected load of 70MW.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Satisfy customer request for connection.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License to provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recoverable through capital contributions from the customer. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the CCRA. The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	10.5	24.9	0.0	0.0	0.0	0.0	0.0	35.4
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**10.5**	**24.9**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**35.4**
Less Capital Contributions	10.0	15.0	0.0	0.0	0.0	0.0	0.0	25.0
Net Investment Cost	**0.5**	**9.9**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**10.4**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

No alternative was considered, as this investment is in response to a specific customer request.

D. EXECUTION RISK AND MITIGATION

The risks with respect to execution of this investment as planned would be as a result of potential delays in securing the Section 92 and environmental assessment approvals. These risks are mitigated by initiating the Section 92 application process and environmental assessment process in a timely manner. There is also a risk that the customer requirements may change, resulting in a delay or cancellation of the need for this project. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer decides to cancel the project.

SA-02 Horner TS: Build a Second 230/27.6kV Station

Start Date:	Q4 2018	**Priority:**	High
In-Service Date:	Q4 2020	**3 Year Test Period Gross Cost ($M):**	29.9
Trigger(s): Customer Request			
Outcome: Increase transformation capacity in Southwest Toronto.			

A. NEED AND OUTCOME

Investment Need

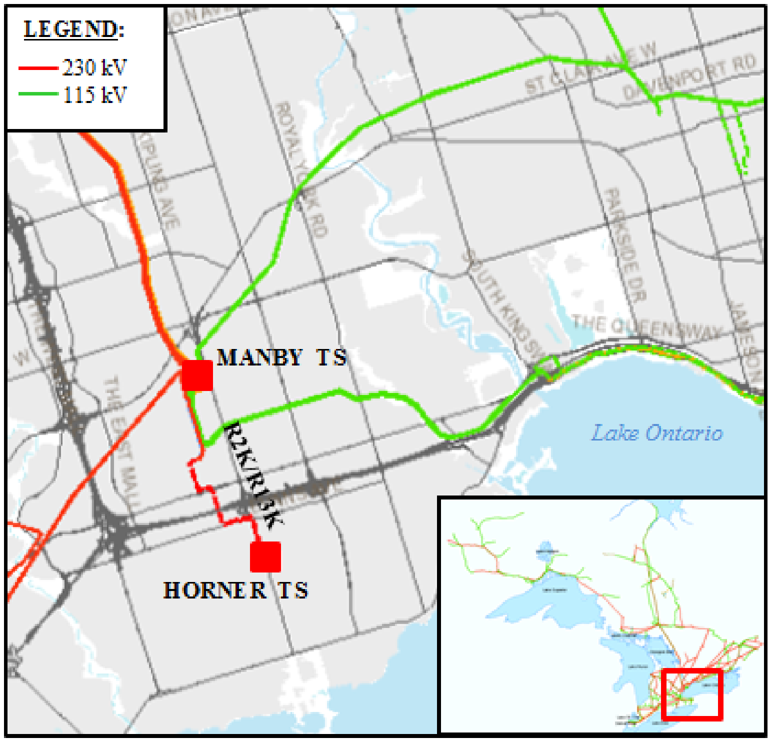
The Southwest Toronto area is supplied by two 230/27.6kV transformer stations, Manby TS and Horner TS. Based on current load forecast, the loading at these two stations is expected to exceed their combined capacity of 400MW by summer 2021. This investment is required to facilitate the request from Toronto Hydro to increase the transformation capacity to accommodate this forecast customer load growth in the Southwest Toronto area; as documented in the Metro Toronto Regional Infrastructure Plan (Exhibit B, Tab 1, Schedule 1, TSP Section 1.2, Attachment 8).

Hydro One is obligated to provide expanded facilities when requested by customers in accordance with its Transmission License and the Transmission System Code. Not proceeding with this investment would result in inadequate transformation capacity to supply customer demand in the area. This project is assigned a High Priority in order to meet this customer obligation.

Investment Description

The proposed project involves the construction of a new 230/27.6kV Dual Element Spot Network ("DESN") station with two 75/125MVA transformers along with a new 27.6kV switchyard at the existing Horner TS site. The new transformer station will be supplied by the existing 230kV transmission circuits (R2K/R13K) which run between Manby TS and Richview TS. This work will increase the existing capacity at Horner TS by 170MVA.

A map showing the project location is provided below.



The System Impact Assessment for the project was completed in 2016 and confirms that the project will not adversely affect the reliability of the IESO-controlled grid. The Customer Impact Assessment process is underway and completion is anticipated in Q1 2019. The assessment also confirms that there is no adverse impact of the new facilities on other transmission connected customers.

Commencement of the project is subject to signing of the Connection Cost Recovery Agreement ("CCRA") with the customer.

Outcomes

This investment will provide the required increase in transformation capacity to supply load growth in the Southwest Toronto area.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Satisfy customer request for additional capacity.
Operational Effectiveness	• Increase capacity, and improve operational flexibility, with the addition of a second DESN.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License to provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be fully recoverable through incremental revenue from the appropriate rate pool and capital contribution from the customer. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the CCRA. The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2022	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	21.0	29.9	0.0	0.0	0.0	0.0	0.0	50.9
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**21.0**	**29.9**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**50.9**
Less Capital Contributions	18.8	25.8	0.0	0.0	0.0	0.0	0.0	44.6
Net Investment Cost	**2.2**	**4.1**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**6.3**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

Two alternatives were considered for providing additional capacity in the Southwest Toronto area.

- Alternative 1: Build a new transformer station at a new site in Southwest Toronto. Acquiring a new site and building new 230kV lines to supply the new station would be required.

- Alternative 2 (Recommended): Build a second transformer station at the existing Horner TS. The existing footprint of Horner TS has sufficient space to build the new facilities and there is sufficient capacity on the existing 230kV lines at the station to supply the new transformer station.

Both Alternative 1 and 2 provide the needed capacity for the area; however, Alternative 1 would incur additional costs involved in acquiring a new site and time to obtain the necessary approvals. Therefore, Alternative 2 is the recommended alterative as it maximizes the use of existing facilities, can be executed in a timely manner and has a lower cost. This alternative is also in accordance with the recommendations of the Metro Toronto Regional Infrastructure Plan, which recommended building the second DESN at the Horner TS site.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: outage availability that is required for the work to be executed and timely customer approval of the CCRA. These risks will be mitigated by working with the customer on setting a schedule that aligns with outage availability. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer decides to cancel the project.

SA-03 Halton TS: Build a Second 230/27.6kV Station

Start Date:	Q2 2020	**Priority:**	High
In-Service Date:	Q2 2022	**3 Year Test Period Gross Cost ($M):**	31.7
Trigger(s): Customer Request			
Outcome: Increase transformation capacity to supply the GTA West area.			

A. NEED AND OUTCOME

Investment Need

Halton TS is a 230/27.6kV transformer station supplying Halton Hills Hydro and Milton Hydro load in the Halton Region. Based on the current demand forecast, the station load is expected to exceed its capacity of 186MW by summer 2022. This investment is required to facilitate the request from Milton Hydro to increase the transformation capacity to accommodate this forecasted customer load growth in the Town of Milton, as documented in the GTA West Regional Infrastructure Plan (Exhibit B, Tab 1, Schedule 1, TSP Section 1.2, Attachment 6).

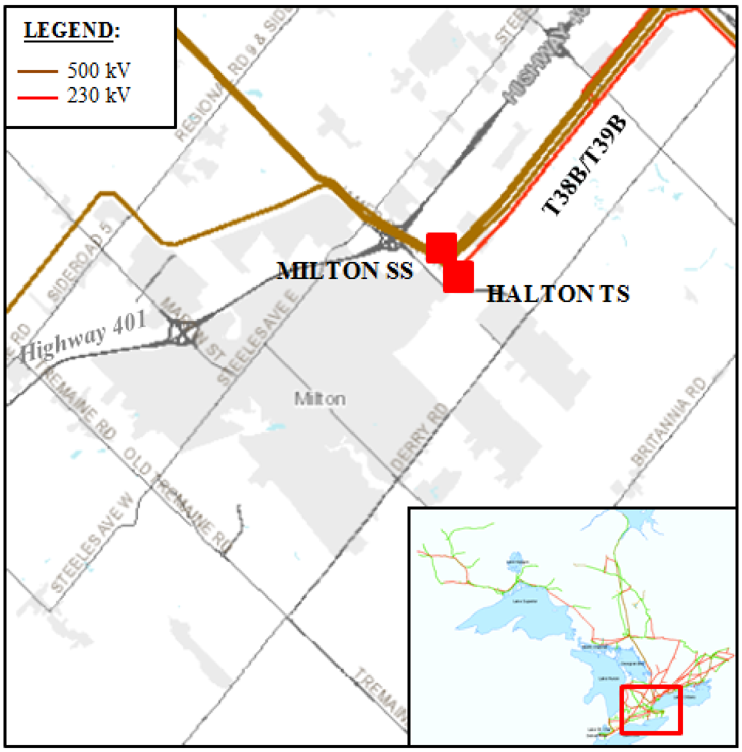
Hydro One is obligated to provide expanded facilities when requested by customers in accordance with its Transmission License and the Transmission System Code. Not proceeding with this investment would result in inadequate transformation capacity to supply customer demand in the Town of Milton. This project has been assigned a High Priority in order to meet this customer obligation.

Investment Description

The proposed project involves the construction of a new 230/27.6kV Dual Element Spot Network (“DESN”) station with two 75/125MVA transformers along with a new 27.6kV switchyard at the existing Halton TS site. The new transformer station will be supplied by the existing 230kV transmission circuits (T38B/T39B) which also supply the existing Halton TS. This work will increase the existing capacity at Halton TS by 170MVA.

The proposed project is intended to provide relief for only the Milton Hydro load; as any increase in Halton Hills Hydro load will be met by the new Halton Hills Hydro MTS planned for in-service in Q1 2019.

A map showing the project location is provided below.



The System Impact Assessment and Customer Impact Assessment will be completed for the project by Q4 2019 to confirm that the project will not adversely affect the reliability of the IESO-controlled grid or service to other transmission connected customers.

Commencement of the project is subject to signing of the Connection Cost Recovery Agreement ("CCRA") with the customer.

Outcomes

This investment will provide the required transformation capability to meet Milton Hydro's forecast customer load growth.

Witness: Robert Reinmuller

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Satisfy customer request for additional capacity.
Operational Effectiveness	• Increase capacity, and improve operational flexibility, with the addition of a second DESN.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License to provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recoverable through incremental revenue from the appropriate rate pool and capital contribution from the customers. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the CCRA. The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	0.8	8.0	17.7	6.0	0.0	0.0	0.0	32.5
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.8**	**8.0**	**17.7**	**6.0**	**0.0**	**0.0**	**0.0**	**32.5**
Less Capital Contributions	0.4	6.0	14.0	6.0	0.0	0.0	0.0	26.4
Net Investment Cost	**0.4**	**2.0**	**3.7**	**0.0**	**0.0**	**0.0**	**0.0**	**6.1**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

Two alternatives were considered for providing additional capacity for Milton Hydro loads.

- Alternative 1: Transfer loads to adjacent area stations. However, the adjacent area stations either have no capacity or were located far away from the Milton Hydro load center and were ruled out due to a lack of technical feasibility. Therefore, this alternative was not considered further.

- Alternative 2 (Recommended): Build a second transformer station at Halton TS. The existing footprint of Halton TS has sufficient space to build the new facilities and there is sufficient capacity on the existing 230kV lines at the station to supply the new transformer station.

Alternative 2 is the recommended alternative as it is the lowest cost and practical alternative to provide the needed capacity. This recommended alternative is in accordance with the recommended plan in the GTA West Regional Infrastructure Plan by providing additional capacity to support the area's growth.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: outage availability that is required for the work to be executed and timely customer approval of the CCRA. These risks will be mitigated by working with the customer on setting a schedule that aligns with outage availability. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer decides to cancel the project.

SA-04 Connect Metrolinx Traction Substations

Start Date:	Q2 2019	**Priority:**	High
In-Service Date:	Q1 2023	**3 Year Test Period Gross Cost ($M):**	21.4
Trigger(s): Customer Request			
Outcome: Connect six Metrolinx traction power substations to the transmission system.			

A. NEED AND OUTCOME

Investment Need

This investment is required to facilitate the request from Metrolinx to provide connection to six traction power substations that are required as part of the GO Transit electrification project.

Hydro One is obligated to make connections when requested by customers in accordance with its Transmission License and the Transmission System Code. Not proceeding with this investment would result in Metrolinx's inability to proceed with their electrification project. This project has been assigned a High Priority in order to meet this customer obligation.

Investment Description

Metrolinx is electrifying the GO Train rail network across the Greater Toronto and Hamilton Area as part of a multi-year project. The electrification requires the construction of traction power substations ("TPSS") to provide power along the rail corridors. Each of the Metrolinx TPSS are planned to be located adjacent to Hydro One's existing transmission circuits and will require a dual 230kV supply. The TPSS loads, with planned supply circuits, and Metrolinx's expected in-service dates are outlined in the following table.

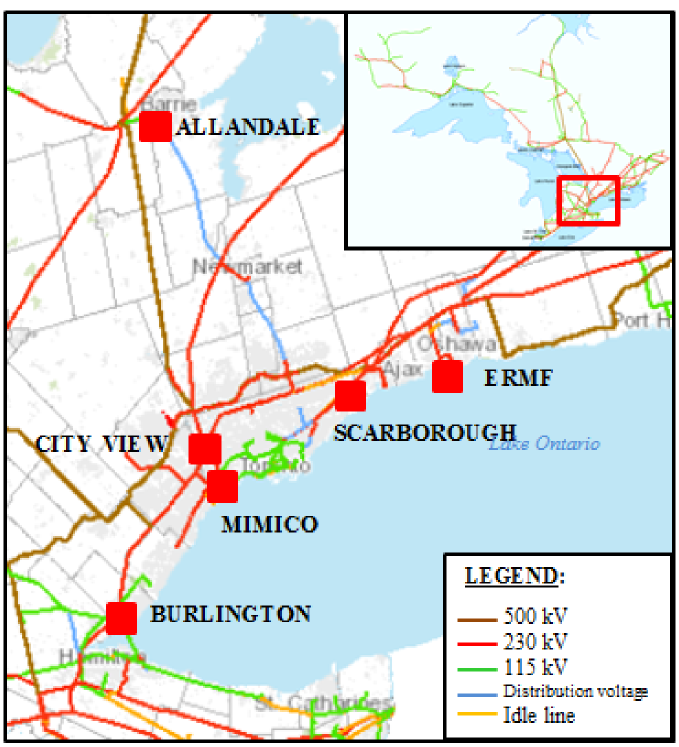
Table 1: TPSS Loads, Supply and Planned In-Service Dates

No.	Traction Power Station	MW Load	Supplied from 230kV Transmission Circuits	Required in-service date
1	Mimico	26	K21C / K23C	Q4 2021
2	Cityview	28	V73R / V77R	Q4 2021
3	Burlington	12	B40C / B41C	Q1 2022
4	Allandale	10	E28 / E29	Q1 2022
5	Scarborough	41	C2L / C14L	Q1 2023
6	East Rail Maintenance Facility	22	T24C / T26C	Q1 2023

Hydro One has set up six separate projects to cover each of the six connection requirements to these TPSS. The proposed projects involve the following:

- Construction of a dual 230kV line tap from the transmission circuits to the Metrolinx TPSS; and
- Modification of the protection and control facilities for the transmission circuits to incorporate and integrate the TPSS.

A map showing the six Metrolinx TPSS locations is provided below.



The System Impact Assessments and Customer Impact Assessments were completed for all six of the Metrolinx TPSS connection projects over the 2017 and 2018 period. The assessments confirmed that the projects will not adversely affect the reliability of the IESO-controlled grid or service to other transmission connected customers.

The project start for each of the TPSS connection projects is subject to signing of their respective Connection Cost Recovery Agreements ("CCRA") with the customer.

Outcomes

This investment will facilitate electrification of the GO Transit rail network by providing the required electric supply to Metrolinx TPSS.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Satisfy customer requests for connection.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License and Transmission System Code to provide customers with non-discriminatory access. • Support Provincial GO Regional Express Rail Initiative.[1]

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be fully recoverable through incremental revenue from the appropriate rate pool and capital contribution from the customer. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the CCRA. The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

No alternative was considered, as this investment is in response to a specific customer request. Each connection was reviewed to provide the lowest cost connection possible.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: outage availability that is required for the work to be executed. These risks will be mitigated by working with the customer on setting a schedule that aligns with outage availability. There is also a risk that the customer requirements may change resulting in a delay or cancellation of the need for this project. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer decides to cancel the project.

SA-05 Future Transmission Load Connection Plans

Start Date:	Program	**Priority:**	High
In-Service Date:	Program	**3 Year Test Period Gross Cost ($M):**	29.8
Trigger(s): Customer Request			
Outcome: Respond to future requests to connect transmission customers.			

A. NEED AND OUTCOME

Investment Need

This investment is required to enable Hydro One to accommodate future requests from load customers to connect to Hydro One's transmission system for which the need and scope have yet to be determined. This investment anticipates load customer requests that are currently unknown, but are expected to arise, during the test period.

Hydro One is obligated to make connections when requested by customers in accordance with its Transmission License and the Transmission System Code. This investment has been assigned a High Priority to ensure customer future needs are addressed in a timely manner.

Investment Description

This investment has been set up to cover future load connection projects anticipated in the test period; for which the need and scope have not yet been identified at this time. Each project would be initiated based on the customers' requirements for capacity and/or reliability improvements. A project may also be initiated by regional planning needs or to address end-of-life facilities.

Load customer connections are typically addressed by providing new or modified transformation and/or line connection facilities. Each investment would be specific to the customer needs. Based on past customer requests, the requested investments may require Hydro One to construct one or more of the following:

- New feeder positions at existing transformer stations;
- New or modified transformation facilities at existing transformer stations;
- New connection lines; and/or
- New transformer stations.

Commencement of each project will be subject to signing of the Connection Cost Recovery Agreement ("CCRA") with the customer and obtaining all necessary regulatory and environmental approvals, as applicable.

Outcomes

This investment will address specific customer requests for connection or transformation capacity to supply the customers' forecasted load growth.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Satisfy customer requests for additional capacity.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License to provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, have been forecasted based on typical costs incurred by load connections over the past five year period. The project costs will be fully recoverable through incremental revenue from the appropriate rate pool and capital contribution from the customer(s), determined on a project-by-project basis in accordance with the Transmission System Code. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the CCRA. The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

The projects' actual in-service costs would be included in the rate base when the projects go into service, subject to Board approval. For any projects that require “Leave to Construct” approval under Section 92 of the *Ontario Energy Board Act*, prudency of the expenditures will be tested during the Section 92 process.

Table 1 - Total Investment Cost

($ Millions)	2020	2021	2022	2023	2024	Total[1]
Capital[2] and Minor Fixed Assets	0.0	5.0	24.9	24.9	0.0	54.7
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0

[1] *Due to the in-year nature of program investments, only 2020 to 2024 expenditures are shown.*
[2] *Includes Overhead at current rates.*

C. ALTERNATIVES

This investment will be in response to a specific customer(s) request received in the future; alternatives (if any) will be reviewed with the customer(s) as part of the connection assessment process.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: outage availability that is required for the work to be executed and timely customer approval of the CCRA. These risks will be mitigated by working with the customer on setting a schedule that aligns with outage availability. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer decides to cancel the project.

SA-06 Protection and Control Modifications for Distributed Generation

Start Date:	Program	**Priority:**	High
In-Service Date:	Program	**3 Year Period Gross Cost ($M):**	9.6
Trigger(s): Customer Request, Reliability			
Outcome: Allow connection of distributed generation.			

A. NEED AND OUTCOME

Investment Need

This investment is needed to perform the necessary protection and control upgrades on the transmission system to preserve its loading and protection capability in order to accommodate the distributed generation connections on Hydro One's distribution system. Distributed generation are generators that connect to the distribution system and these connections may require modifications to the transmission protection system in order to maintain a safe and reliable operation of the transmission system.

Hydro One is obligated to make connections when requested by customers in accordance with its Transmission License and the Transmission System Code. Not proceeding with this investment would result in new distributed generation resources not being able to connect. This program is assigned a High Priority in order to meet mandated obligations to customers.

Investment Description

There are a variety of generation procurement programs organized by the IESO to encourage new distributed generation connections, such as: the Large Renewable Program, the Combined Heat and Power Standard Offer Program, and the Energy Storage Procurement Program. Hydro One Distribution continues to receive requests from distributors and individual generation customers to connect distributed generation. In order to accommodate the connection of generation to the distribution system, Hydro

One's transmission system requires protection and control systems modifications and/or additions in the transmission stations to ensure proper protection of transmission assets, reliability of supply to the distribution systems, and a safe interconnection for the distributed generators.

The proposed program involves, but is not limited to, the following protection and control modifications and/or additions:

- Feeder Protection Replacement to preserve the protection capability of the feeders and provide directioning in order to prevent false tripping;
- Bus Protection Modification to prevent mis-operation;
- Line Back-up Protection Installation to protect transmission assets from distributed generators' fault current contribution;
- Transfer Trip Signalling Installation to prevent distributed generation islanding and to coordinate with reclosing and restoration;
- Station Telecom Facilities Installation to enable transfer trip signaling; and
- Station Telemetry Expansion to provide feeder telemetry and additional equipment alarms.

Commencement of each project is subject to signing of the Connection Cost Recovery Agreement ("CCRA") with the customer(s).

Outcomes

This investment will provide the required connection of distributed generation throughout Ontario without compromising system reliability, by maintaining proper protection and loading capability of the transmission assets.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Satisfy customer requests for connection of distributed generation to Hydro One's distribution system.
Operational Effectiveness	• Preserve the loading and protection capability of the transmission system while incorporating renewable generation.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License to provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The program costs, as presented in the table below, will be fully recoverable through capital contribution from the customers. The gross costs have been forecast based on current generation customer requests, and anticipated future requests resulting from the IESO's generation procurement programs. The program costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the CCRA. The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

Table 1 - Total Investment Cost

($ Millions)	2020	2021	2022	2023	2024	Total[1]
Capital[2] and Minor Fixed Assets	3.8	3.1	2.7	2.8	2.8	15.2
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**3.8**	**3.1**	**2.7**	**2.8**	**2.8**	**15.2**
Less Capital Contributions	3.8	3.1	2.7	2.8	2.8	15.2
Net Investment Cost	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**

[1] *Due to the in-year nature of program investments, only 2020 to 2024 expenditures are shown.*
[2] *Includes Overhead at current rates.*

C. ALTERNATIVES

No alternative was considered, as failure to implement the protection and control modifications and/or additions would result in the inability to respond to connection requests. Required modifications will be determined on a project-by-project basis.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: outage availability that is required for the work to be executed and timely customer approval of the CCRA. These risks are mitigated by working with customers on setting a schedule that aligns with outage availability. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer(s) decide to cancel the project.

SA-07 Secondary Land Use

Start Date:	Program	**Priority:**	High
In-Service Date:	Program	**3 Year Test Period Cost ($M):**	2.9
Trigger(s):	Third Party Request		
Outcomes:	Relocation and/or modification of Hydro One's transmission facilities to accommodate third party requests.		

A. NEED AND OUTCOME

Investment Need

This investment is required to facilitate requests from third parties for the relocation, removal, or reinforcement of transmission assets in response to project proposals, such as: roadwork, transit systems, and other major infrastructure or development work that may encroach upon or impact Hydro One assets and rights-of-ways.

The Province of Ontario has established a Provincial Secondary Land Use Program that allows for the use of corridors, while recognizing the primary use of the lands is for electricity infrastructure. This investment has been assigned a High Priority given Hydro One's obligations and the requirements to this broad group of stakeholders, including: municipalities, third-party developers, pipeline companies, Metrolinx and the Ministry of Transportation Ontario ("MTO").

Investment Description

The proposed program involves accommodating third party requests to utilize Hydro One's transmission corridors for secondary land-use purposes. Hydro One may require additional or modified land rights to accommodate the request. In these cases, the proponents will acquire the additional land rights on Hydro One's behalf.

The material projects planned over the plan period, including the estimated costs and details relating to each identified project, are outlined in Table 1 below. The most common investment drivers are: municipal and regional transit planning, highway expansions and development projects adjacent to or crossing Hydro One's right of way.

Table 1 - List of Material Projects

No	Project Name	Description	Total Gross ($M)
1	**Burlington Beach Line Relocation** *Customer: Region of Halton*	The Region of Halton ("*Region*") and the City of Burlington are preparing a Community Plan. The Region has expressed an interest in transforming a portion of Burlington Beach into a waterfront park consistent with the vision for the area outlined in its official plan. This development would encroach on Hydro One's existing structures supporting circuits serving the western Greater Toronto and Hamilton Area and Golden Horseshoe. The Region has inquired about the feasibility of relocating or modifying the affected circuits. If the project proceeds, the structures on the Burlington TS by Beach Road Junction right-of-way would be modified.	**22.0**
2	**Manvers - Lafarge Aggregate Pit** *Customer: Lafarge*	Four of Hydro One's 230kV transmission circuits (H24C, H26C, C28C, and M29C) cross through Lafarge's aggregate pit located in the Clarington and Kawartha Lakes region. These transmission lines extend across the operating pit—a distance of about 14 circuit km. Over the years, aggregate excavation has left several of these circuit towers islanded atop 100 feet high pedestals of land. Lafarge has expressed interest in excavating the material beneath these towers. To accommodate this proposal, Hydro One must relocate these structures.	**12.3**
3	**Metrolinx – Don Yard Relocation** *Customer: Metrolinx*	Metrolinx has announced improvements to the Union Station Go rail corridor that includes an upgrade and expansion of the Don Yard facility. To accommodate Metrolinx's planned development, Hydro One must relocate the 115kV transmission circuits (H9EJ/H10EJ) and the 115kV underground cable (H2JK).	**15.0**

No	Project Name	Description	Total Gross ($M)
4	**Metrolinx - Caledonia GO Station Modification** *Customer: Metrolinx*	Metrolinx has identified improvements to its Barrie GO rail corridor (near Eglinton Avenue West and Croham Road in Toronto) that includes the expansion to the rail corridor from one track to three tracks, and the addition of a new GO station with two pedestrian platforms. To accommodate Metrolinx's planned development, Hydro One must relocate or bury the 115kV double-circuit line (K1W/K3W) that is located within the rail corridor.	**15.3**
5	**Metrolinx – Electrification** *Customer: Metrolinx*	Metrolinx has proposed the installation of new overhead catenary systems ("OCS") along all rail corridors owned, operated or serviced by Metrolinx. The OCS conflicts with existing Hydro One assets at multiple locations along the rail corridor. To accommodate Metrolinx's planned development, Hydro One must address these OCS conflicts which will require mitigation prior to the end of 2020.	**16.7**
6	**Ottawa LRT** *Customer: City of Ottawa*	The City of Ottawa is implementing a light rail transit system. One proposed alignment presents the following two potential conflicts with Hydro One's transmission assets: • <u>Trim Road</u>: Grade separation of Trim and Ottawa Road 174 intersections, including: two bridge structures, access and egress ramps, conflict with existing 115kV transmission line (H9A). • <u>Lincoln Fields</u>: The proposed LRT alignment conflicts with underground cables (F10MV and C7BM). To accommodate this proposal, Hydro One will require modification of the 115kV transmission line (H9A) to allow for appropriate clearances to the structures; and relocation of the 115kV underground cables (F10MV and C7BM).	**17.6**
7	**Thunder Bay - Hwy 11/17-Pearl Lake** *Customer: MTO*	The MTO has identified plans to realign and widen a 14.4km section of Highway 11/17 in the Municipality of Shuniah (near Thunder Bay). MTO's proposal will impact Hydro One's 115kV transmission circuits (A7L/R1LB and A6P). To accommodate this proposal, Hydro One must modify and/or relocate several transmission structures on the affected lines.	**12.4**

Note: The Total Gross includes the total cost of the project, including any costs prior to the test years, if applicable.

Outcome

These investments will allow Hydro One to fulfill its obligations in accommodating the development work of customers and other third parties, while also ensuring public safety is maintained with respect to the siting and operations of affected Hydro One transmission assets.

The following table summarizes the anticipated outcomes of the investment:

Customer Focus	• Satisfy the proposed project-related requirements of customers and third parties.
Operational Effectiveness	• Maintain sufficient clearances to Hydro One transmission assets to ensure public safety.
Public Policy Responsiveness	• Support provincial secondary land use policies through the relocation and/or modification of transmission facilities to accommodate compatible uses.

B. EXPENDITURE PLAN

This investment is non-discretionary. The program costs, as presented in the table below, will be mainly recoverable through capital contributions from the customers. The size and complexity of these projects vary from year to year; the forecast is based on preliminary estimates for the projects which are in various stages of development.

Table 2 - Total Investment Cost

($ Millions)	**2020**	**2021**	**2022**	**2023**	**2024**	**Total[1]**
Capital* and Minor Fixed Assets	55.1	15.0	13.9	15.6	3.9	103.4
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**55.1**	**15.0**	**13.9**	**15.6**	**3.9**	**103.4**
Less Capital Contributions	54.2	13.7	13.1	14.8	3.1	98.9
Net Investment Cost	**0.9**	**1.3**	**0.8**	**0.8**	**0.8**	**4.4**

[1] *Due to the in-year nature of program investments, only 2020 to 2024 expenditures are shown*
[2] *Includes Overhead at current rates.*

C. ALTERNATIVES

Hydro One works with third parties that propose secondary land uses and assesses whether the proposals are technically compatible with the safe and reliable operation of Hydro One's transmission infrastructure. Some proposals are deemed to be incompatible and do not proceed. For those proposals that are compatible and consistent with Provincial Secondary Land Use principles, no alternative was considered, as this investment is in response to specific customer and third party requests. However, each investment is scoped, planned and executed to provide the lowest cost relocation or modification possible, given the nature of existing infrastructure.

D. EXECUTION RISK AND MITIGATION

Certain normal project execution risks may affect the timely completion of each project, such as: the outage availability that is required for the work to be executed, delays in securing regulatory approvals, and timely customer approval of the Connection Cost Recovery Agreement ("CCRA"). These risks are mitigated by working with customers on setting a schedule that aligns with availability. These investments are also demand-driven and susceptible to delays, cancellations and scope changes driven by external factors that are beyond Hydro One's control. Ongoing coordination and engagement, as well as structured capital cost recovery agreements mitigate the risk of investment uncertainty in the event of scope changes or cancellation. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer decides to cancel the project.

SR-01 Air Blast Circuit Breaker Replacement Projects

Start Date:	Q4 2013	**Priority:**	High
In-Service Date:	Q4 2027	**3 Year Test Period Cost ($M):**	366.2
Triggers: Strategic, System Renewal, Customer Engagement			
Outcome: Increase reliability and performance to large customers and generators; improve reliability to the BES, stage approach to minimize customer outages, reduce maintenance cost associated with End of Life ("EOL") equipment and air systems, reduce constrained power flow through the station; replace EOL PCT equipment; reduce costs of unplanned outages due to ABCB failures and leaking air systems.			

A. OVERVIEW

Air Blast Circuit Breaker Replacement Project (the "Project") involves the replacement of Air Blast Circuit Breakers ("ABCBs") and their auxiliary station equipment that are at a high risk of failure due to deteriorated condition and asset obsolescence. The principal drivers of the Project are unacceptable reliability performance, high operation and maintenance costs and unavailability of spare parts and technical support due to obsolescence. The majority of installed ABCBs have surpassed their EOL and the entire population of ABCBs will exceed their expected service life by the end 2023 if proactive replacements are not undertaken. Currently, the obsolescence of ABCBs, which were originally installed in the 1970s, already pose significant challenges in terms of the high operating costs required to maintain system reliability. The lack of available spare parts due to the obsolescence of the technology further constrains Hydro One's ability to maintain these assets and implicitly the resulting system reliability at the appropriate level. Almost half of Hydro One's ABCBs population is installed at critical stations that are delivery points to hydraulic, gas and nuclear plant operators and interties. Any forced outages at the critical stations due to ABCB failures would adversely impact these sensitive customers, who have expressed the view that a high level of reliability is paramount to their operations. To address customer concerns, high risk to reliability performance of deteriorated ABCB assets, and associated escalating maintenance costs, Hydro One evaluated several alternatives, as described below, and concluded that the targeted replacement of ABCBs, whose condition have been rated as a high or very high risk, is a prudent and preferred alternative. The projected cost of the Project is estimated to be $366.2 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

ABCBs were developed in the 1950's to solve the technical limitations that oil circuit breakers could not overcome. ABCBs rely on complex mechanical and pneumatic subsystems for proper operation. Between 1950 and 1982, the former Ontario Hydro (predecessor of Hydro One) installed 278 High Voltage ("HV") (i.e., 115 kV and above) and 10 Medium Voltage ("MV") (i.e. 44 kV and below) ABCBs. Since the time of installation, 148 HV and 5 MV ABCBs have been replaced as a result of various control components issues such as air leaks, operating mechanism issues, moisture content problems and auxiliary equipment malfunctions. Hydro One's typical practice is to repair the breakers where issues (e.g. air leaks) have been identified. However, Hydro One's fleet of ABCBs is no longer supported by vendors and as such, it is extremely difficult to obtain technical support and spare parts which are either no longer available or are costly to acquire or fabricate. For example, ABCBs require high pressure air systems that consist of compressors, holding tanks and extensive piping. These systems cause Hydro One to incur $3 million in annual maintenance costs.

The high pressure air system is highly susceptible to air leaks that cause outages. Severe air leaks are a significant concern for the ABCB fleet as large groupings of breakers are supplied by a common airline. Maintaining high pressure air systems increases the Operations, Maintenance & Administration ("OM&A") cost by approximately $15 thousand per air blast breaker. In the winter months, issues with air pressure and safety valves freezing in the open position lead to the loss of air and the loss of breaker control. This can result in the removal or isolation of multiple adjacent breakers and high voltage circuits, thereby causing large load interruptions and generation bottling. For example, in winter 2017, after experiencing pressure loss on the air system due to low temperatures, multiple HV breakers were forced out of service at Cherrywood TS in the 230kV switchyard, thereby constraining generation capacity and power flow throughput.

The average age of the ABCBs population installed on Hydro One's transmission system is 46.5 years, surpassing the manufacturer's specified service life of 40 years. As part of the asset condition assessment, Hydro One rated the entire population of ABCBs at a high or very high risk. This assessment is based on the factors such as internal condition diagnostics, performance, criticality, obsolescence and economics. Hydro One performs internal condition diagnostics (Level 1 and Level 2 diagnostic testing) where it gains condition data on the breakers via micro-ohm measurement and timing tests. In accordance with Hydro One performance records, ABCBs are the highest risk breaker population in Hydro One's transmission system. Circuit breaker performance is measured by assessing the number of forced outages due to some inherent failure of the breaker itself. A "forced outage" is the automatic or forced manual removal of high voltage breakers caused directly by the breaker itself or terminal equipment directly adjacent to the breaker. Typical ABCB failure modes have included control components issues, air leaks, operating mechanism issues, moisture content problems and auxiliary equipment malfunctions. The number of forced outages due to ABCB failure has significantly increased over the past ten years as shown in Figure 1 below. This increasing trend is due to known air system issues caused by deteriorated O-rings (as described above), valves and problems with control components.

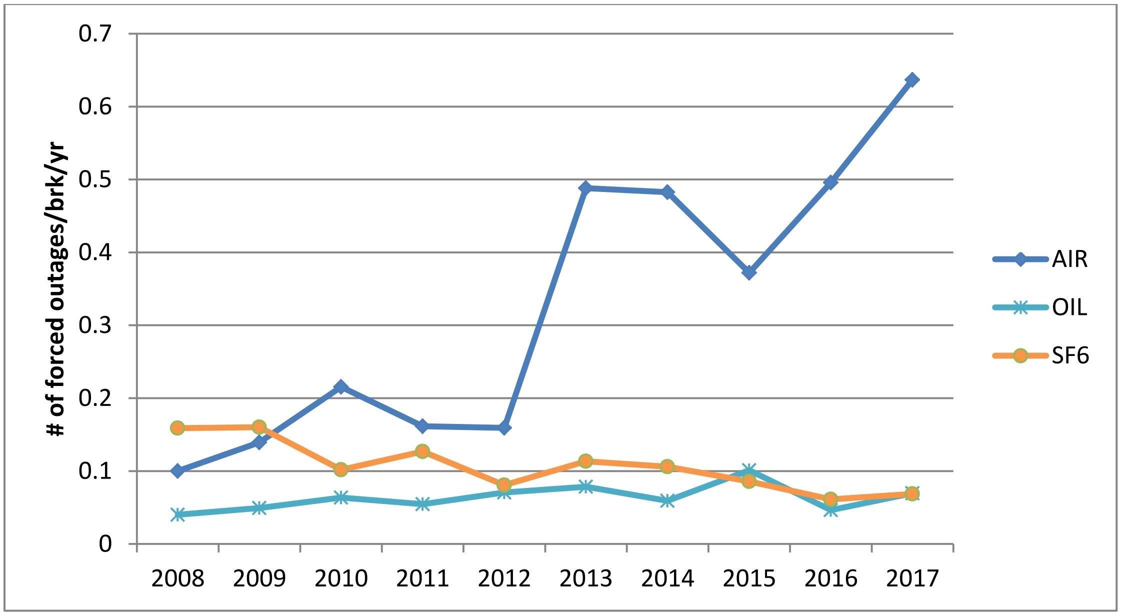

Figure 1 - Circuit Breaker Forced Outage Duration by Breaker Type

As of December 31, 2018, 47% of the remaining ABCBs are installed at critical transmission stations as presented in Table 1 below.

Table 1 - Generators connected through Hydro One stations with ABCBs

Hydro One Station	Connected Generator(s)	Generator Capacity (MW)
Bruce A TS	Bruce A GS	3,116
Bruce B SS	Bruce B GS	3,268
Cherrywood TS	Pickering GS	3,100
Lennox TS	Lennox GS	2,100
Sir Adam Beck I SS	Sir Adam Beck I GS	450
Sir Adam Beck II TS	Sir Adam Beck II GS Sir Adam Beck Pump GS	1,499 174
Total:		**13,707**

These critical transmission stations support major nuclear and hydraulic generation plants as well as connect international power flow to the states of New York and Michigan.

Forced outages at these critical stations, attributed to ABCBs, have a significant impact on customers. In the case of nuclear generating plants, the outages have caused supply interruptions to the station service transformers or in other cases, the outages have caused the loss of production. For example, in 2016, Sir Adam Beck II had a loss of 6 ABCBs which resulted in 100 MW of reduced generation, impacting the imports and exports of power to the New York Power Authority (NYPA) and the customer, Ontario Power Generation (OPG) had to redirect the river water flow to avoid flooding parts of downtown Niagara Falls.

Further, the major bulk transmission stations are subject to special considerations in accordance with Section 5.7 of the IESO's Ontario Power System Restoration Plan ("OPSRP"). The OPSRP is the required operating procedure for the IESO and the restoration participants, such as Hydro One, to restore the power system and mitigate the emergency in the event of a partial or complete blackout. The majority of the bulk stations listed in OPSRP are still operating through ABCBs. As such, Hydro One is required, pursuant to section 5.7.3 of the OPSRP, to pre-determine the air system's ability to support multiple breaker operations, adopt operating procedures to monitor for problems and to mitigate any identified shortfalls in capability. Extensive OM&A cost is needed to maintain current deteriorated high pressure air systems in these stations. (e.g., use of a diesel generator).

The higher cost and difficulty associated with maintenance requirements when compared to newer technology, the unavailability of spare parts due to obsolescence, and the lack of technical support to work on the deteriorating population of installed ABCBs lead to longer outage times associated with both routine and emergency maintenance. This is problematic for Hydro One and its customers from both a cost and service-reliability perspective. In order to address all of these issues, Hydro One is required to proceed with this Project and, as such has assigned it a high priority.

Investment Description

The Project involves a series of individual projects at various transformer stations. Each ABCB replacement project will vary in size and scope and will include some or all of the following: the replacement of ABCBs, removal of the high pressure air system, upgrade AC and DC systems, protection, upgrades to control and telecom systems, upgrades to high risk station ancillary equipment, site or property upgrades, customer triggered upgrades as well as upgrades driven by safety concerns, environmental compliance and operational issues. Cumulatively, the Project targets the replacement of 132 ABCBs and their auxiliary station equipment at ten transformer stations (95 during the planning period), as further detailed in Appendix “A” below.

The level of investment has been determined based on the assessment of ABCBs condition and in consideration of customer preferences, safety concerns, compliance requirements and Hydro One’s ABCBs strategy. An Asset Management Strategy to effectively manage numerous risks associated with this aging breaker population recommends the replacement of ABCBs within the bulk electric system before or at the age of 50 years old due to, among others, performance and reliability issues as well as the maintenance costs. Due to the significant impact that ABCBs have on the provincial transmission system and international tie-line connections, Hydro One actively engages with the IESO to review the scope and timing of the proposed replacement projects.

Outcome

As a result of the Project, Hydro One will improve system reliability by reducing the frequency and duration of outages caused by failed ABCBs. The Project will result in reduced operational risks associated with the operation of end-of-life equipment. Hydro One will reduce it operating costs associated with ABCBs and reduce maintenance costs associated with high pressure air systems. The Project will also assist Hydro One in ensuring compliance with the North American Electric Reliability Corporation (“NERC”) and the Northeast Power Coordinating Council (“NPCC”) requirements.

The following table presents anticipated benefits as a result of the Project in accordance with the Ontario Energy Board's ("OEB") Renewed Regulatory Framework ("RRF"):

Outcome Summary:

Customer Focus	• Improve system reliability by reducing the frequency and duration of the outages due to high risk, obsolete and EOL equipment, which are particularly vulnerable to failures during extreme cold weather • Staged approach to minimize customer outages
Operational Effectiveness	• Reduce operational risks associated with the operation of EOL equipment • Improve reliability to the bulk electric system • Reduce constrained power flow through the station which results in less redundancy
Public Policy Responsiveness	• Replace EOL PCT equipment to comply with NERC and NPCC requirements for redundant and physical separation
Financial Performance	• Reduce operating and maintenance costs associated with EOL equipment and air systems • Realize cost savings by addressing multiple deteriorating components within the station as part of the same project

C. EXPENDITURE PLAN

As discussed above, the Project involves the replacement of ABCBs and their auxiliary station equipment that are at a high risk of failure due to deteriorated condition and asset obsolescence. Hydro One planned the Project in a way that strives for completion as effectively and efficiently as possible to minimize the cost of performing this sustainment task. As part of this optimization, Hydro One will not only replace the ABCBs, but will address replacement of all other deteriorated assets, upgrade Protection, Control and Telecom equipment to the latest industry standards and improve reliability and operability of system within each investment.

Table 2 below summarizes historical and projected spending on the aggregate project level. The "Previous Years" costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 test year. Likewise, the costs noted in "Forecast 2025+" are project costs forecast beyond 2024.

Table 2 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total

Lennox TS	5.9	4.6	5.8	2.0	0.0	18.3	88.1	2023
Bruce B SS 500kV	12.9	16.6	20.1	18.4	10.5	78.5	85.5	2024

Bruce A TS 500kV	3.7	21.0	21.9	38.0	38.6	123.2	147.3	2025
Essa TS	0.5	6.6	20.3	13.9	14.2	55.5	71.4	2025
Beck #1 SS 115kV	3.3	2.9	3.5	3.5	3.0	16.2	30.7	2026
Cherrywood TS 230kV/500kV	0.4	10.4	13.2	26.6	29.5	80.1	135.2	2027
Net Investment Cost	**105.9**	**126.9**	**133.4**	**129.2**	**98.7**	**594.0**	**1127.4**	

The factors influencing the cost of the Project include:

- The circuit breaker voltage level and the number of ABCB replacements – the higher the voltage levels the higher the cost of equipment needed. Higher voltage levels require additional space requirements due to increased electrical clearances, more structures and etc.
- The station design and configuration - foundation/structural replacements, in-situ or Greenfield replacement. Safety by design based on latest Hydro One standards (i.e. new clearance requirements, Arc Flash requirements and etc.)
- NERC and/or NPCC requirements require physical separation and redundancy
- Outage availability, and reduced contingency concerns customers. Outage availability is more difficult to achieve at nuclear facilities due to stricter contingency planning (N-2 contingency).
- By-pass construction where needed to minimize customer impacts. In many situations, to avoid constraining generation and power flow, additional by passes are required; these are costly to install and are typically removed at the end of the project (i.e. between $3 million and $5 million)

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: Reactive Component Replacement is a "Do Nothing" alternative and is based on reactive response as the failures occur, and replacing ABCB sub-components as and where needed. Hydro One rejected the "Do Nothing" alternative for the following reasons:

- Reactive management of ABCBs at critical transformer stations would decrease reliability of the 500kV, 230kV, and 115kV transmission networks and international tie-line connections by increasing outage durations to facilitate emergency repairs. Increased frequency and duration of outages could impact connected customers, increase OM&A cost due unplanned corrective work, and the air system must be maintained until all ABCBs are replaced.
- This result would be contrary to the clear preferences of the relevant customers.
- Reactive replacement would be limited to addressing failed sub-components and would not address other deteriorated sub-components with a similar risk of failing. Reactive repairs would result in increasing OM&A costs as the frequency of outages increase as presented in the Transmission System Plan ("TSP") Exhibit 2.2.1.2.
- Should a major failure occur, like-for-like replacement of the entire breaker would not be possible in many cases due to the unavailability of spare units. Replacement with a modern SF6 circuit breaker, requiring additional time for design, construction, and commissioning, would prolong the outage thereby impacting system reliability and customer satisfaction if done on a reactive basis.

Alternative 2: Switchyard Rebuild is based on rebuilding the entire ABCB switchyard in a new location (Greenfield) using modern SF6 breakers instead of replacing only assets in need of replacement by installing them in new locations within station property (Brownfield). This alternative has been rejected as Greenfield construction will be more costly due to the expansion of the existing station property, real estate acquisition (if required) and potential reconfiguration of the existing switchyard connections. While the construction of a new switchyard in a Greenfield location will minimize outage constraint and availability, these benefits do not offset the additional costs. For example, at Beck 2, Hydro One performed a comparison between Brownfield and the percent difference for Greenfield came out to 70% more.

Due to the significant cost difference Hydro One's typical direction is to carry out an in-situ replacement unless in-situ replacement is not feasible.

Alternative 3: Planned In-Situ Replacements is the preferred undertaking. This alternative is based on replacing ABCBs and auxiliary systems within the same station footprint using modern SF6 breakers. SF6 is the predominant insulating medium in the industry; possessing the highest dielectric strength of any known gas, excellent arc extinguishing and quenching capabilities, thermal stablity, and superior heat transfer properties. This alternative has been selected as the preferred alternative for the following reasons:

1. In-situ replacement resolves all of the challenges facing the ABCB fleet described above by increasing system reliability in the most cost effective manner. It aligns with the needs of Hydro One's customers and Hydro One's ABCB strategy to resolve current ABCB performance challenges.
2. The preferred alternative, unlike the "Do Nothing" alternative, proactively addresses and paces replacements without jeopardizing system reliability and customer supply points. Unlike Alternative 2, the preferred alternative results in a more cost effective solution since most real-estate and station reconfiguration challenges are avoided.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of bulk station transformer replacement projects are: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges and/or regulatory approvals. A thorough risk assessment workshop is performed during the initial project planning phase where all known risks are identified and a mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize the loss of supply to the customer. The plan may include switching a customer to an alternative supply, the construction of a temporary by-pass circuit or supplying portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages. As another example, to allow for early identification of real estate issues, Hydro One involves real estate from project inception. The aim is to identify issues such as missing or inadequate land rights, so that Hydro One can try to resolve them prior to execution of the project.

1 **APPENDIX A – DETAILED TOTAL PROJECT PLAN**

2

Station Name	Scope	Number of Remaining Air Blast Circuit Breakers to be Replaced	In Service Year
Richview TS	In-situ replacement of twenty four 230 kV ABCBs and associated switches as well as Protection & Control ("P&C") system upgrades and associated EOL assets replacements.	5	2020
Bruce A TS	Bay by bay replacement of sixteen 230 kV ABCBs and associated switches as well as P&C system upgrades and other EOL assets replacements.	7	2020
Beck #2 TS	In-situ replacement of twenty 230 kV ABCBs and associated switches, as well as P&C system upgrades and other EOL asset replacements. Eighteen breakers remain to be replaced	18	2022
Middleport TS	Replacement of twenty-one 230 kV ABCBs, their associated switches, two auto-transformers, two under-rated 500 kV SF6 breakers, P&C system upgrades and other EOL asset replacements	21	2023
Nanticoke TS	In-situ replacement of eight 500kV ABCBs and associated switches with possible bus reconfiguration, as well as P&C system upgrades and other EOL assets replacements.	8	2023
Cherrywood TS	Replacement of twelve 230 kV ABCBs and associated switches, 230 kV and 500 kV switchyard AC system upgrade, 230 kV switchyard DC system upgrades, P&C system upgrades and other EOL asset replacements	12	2023
Lennox TS	In-situ replacement of six 500 kV and eight 230 kV ABCBs and associated switches as well as P&C system upgrades and other EOL asset replacements.	14	2023
Bruce B SS	Replacement of ten 500 kV ABCBs, P&C system upgrades and other EOL asset replacements.	10	2024
Bruce A TS 500kV	Replacement of nine 500 kV ABCBs and associated switches, P&C system upgrades and other EOL asset replacements.	9	2025

Station Name	Scope	Number of Remaining Air Blast Circuit Breakers to be Replaced	In Service Year
Essa TS	Replacement of six 500 kV ABCBs and associated switches, P&C system upgrades and other EOL asset replacements. Potential to merge Development project to connect 230 kV line to Essa and eliminate an auto-transformer.	6	2025
Beck #1 SS	Replacement of two 115 kV ABCBs, rebuilding of the existing main bus on the 9th floor of the power house, the addition of a new ring bus on the 4th floor to facilitate future maintenance and operation, line connection upgrades to facilitate two new generation connections, P&C system upgrades and other EOL asset replacements	2	2026
Cherrywood TS 230kV/500kV	Replacement of fourteen 230 KV breakers, six 500 KV ABCBs and associated switches and elimination of two 230 kV breakers (due to Pickering GS shutdown), 500 kV switchyard DC system upgrade, P&C system upgrade and other EOL asset replacements	20	2027

SR-02 Station Reinvestment Projects

Start Date:	Q2 2015	**Priority:**	Medium
In-Service Date:	Q4 2025	**3-year Test Period Cost ($M):**	352.9
Trigger(s):	Strategic, System Renewal		
Outcomes:	Maintain reliability performance of bulk electricity system power flows through the replacement of end of life equipment. Maintain reliable power delivery at load supply stations. Improve the operational effectiveness of bulk and load supply stations through reconfiguration and standardization of new equipment and design		

A. OVERVIEW

Station Reinvestment Projects (individually, the "Project") involves complete refurbishment of critical station assets at a single transmission station. Each Project includes a consolidated replacement of multiple station assets that are at the end of their life and whose condition has been rated as high risk or very high risk in accordance with the asset condition assessment. The scope of the Project is primarily on the key station assets, such as transformers, breakers, switchgear and protection and control systems. It may also include other station assets, such as instrument transformers, disconnect switches and other ancillary equipment, where needed. The Project covers bulk transmission stations and load supply transmission stations.

As described in Transmission System Plan ("TSP") Section 2.1, prior to 2014, Hydro One's approach to station asset management was asset-specific. Separate programs were used to consider, plan for and implement replacements for particular asset types (i.e. transformers, breakers and switches) across the province. In 2014, Hydro One transitioned to an integrated approach to station asset management where possible. This change was largely driven by outage analysis and the recognition, based on asset demographics, that a large volume of renewal work would need to be performed in the coming years. Rather than making numerous return visits to the same stations to repair or replace different types of assets, requiring multiple outages, the integrated approach enables work that is required at a particular station to be bundled together and executed at once. Integration of station work and the timing for this work is oriented around key station assets (i.e. transformers, breakers, switches and protection and control equipment).

This station-focused approach addresses infrastructure that is aging and a high risk to system operation. Hydro One has established a recurring 7-10 year assessment cycle that enables all necessary renewal work to be performed at each of the 293 transmission stations during the cycle. By developing and implementing work packages for each station, this approach enables Hydro One to efficiently use outages and to minimize the total number of outages required to complete necessary renewal work. The candidate investments identified through the Asset Management process include station-specific packages of work that have been developed in accordance with the established assessment cycle.

Using the integrated approach, Hydro One plans to refurbish 21 transmission stations over the test period. Hydro One has evaluated various alternatives for the Project, as described below, and concluded that replacing multiple assets using an integrated approach at a single transmission station is the most cost effective and efficient undertaking. The projected sum of costs for the Projects is estimated to be $352.9 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need:

The Projects focus on the replacement of multiple station assets that facilitate power flows across the bulk electric system and transform power from a high transmission voltage to a lower transmission voltage. A Project is undertaken when multiple assets within the station may compromise the reliability of supply and result in higher failure rates due to their operation in deteriorated condition and beyond their expected service lives. Failures at a bulk station could constrain generation and interrupt supply to load centres. Failures at a load station typically result in outages for local distribution companies, constraining embedded generation resources and leaving customers without power, sometimes for prolonged periods of time.

The Projects address replacement needs identified during the asset assessment process. As discussed in TSP Section 2.1.2, Hydro One has a comprehensive asset management process that involves the ongoing monitoring and assessment of transmission asset needs. The assessment is based on risks identified from asset demographics, condition, environmental factors, utilization, costs comparison between refurbishment and replacement, and other lifecycle considerations. The goal of each asset assessment is to ensure that assets are not in deteriorated condition and to minimize any safety, reliability and/or environmental risks. All assets at a given station are assessed at the same time. Focus is given to transformers, breakers, and protection and control systems – as these are the most critical assets in the system and, in the event of their failure, can result in a direct outage to customer supply, compromise the integrity of the bulk system and/or constrain generation from key generation facilities in the Niagara, Bruce, and Pickering areas.

Upon identification of all the assets requiring replacement within the station, a decision is made whether an integrated approach or a specific asset replacement is preferred. If the assessment identifies multiple key station assets (i.e. transformers, breakers, and protection and control equipment) the condition of which warrants a replacement now or within the next three years, Hydro One then pursues an integrated approach. This approach focuses on a particular station where multiple key station assets require replacement, as driven by their condition, and may be accompanied by some level of electrical re-configuration to address operating concerns and customer preferences or to standardize the installed equipment. In the case where there are relatively few assets identified for replacement (e.g., one of the key station asset and accompanying ancillary equipment or a small subset of other minor station assets), then this station is identified as a candidate for a particular asset-focused replacement project (e.g. transformer replacement project or breaker replacement project). Ultimately all stations are assessed using the same asset risk assessment process. Depending on the final outcome of the assessment, (i.e. what assets are in high risk and in need of replacement) it dictates what grouping the project would fall into.

The next step is to consider if electrical reconfiguration of the station will result in any operational efficiencies through a reduction of major assets identified for replacement. These assets may include transformers, circuit breakers and the associated connection elements such as disconnect switches and main bus elements. For example, the existing configuration at Gage TS has been reviewed in light of changes in the load profile and as such, four end-of-life transformers will be replaced with two units. The new configuration will be a standard two transformer configuration resulting in operational efficiencies due to the application of standard procedures and a reduced complement of assets for maintenance. A similar reconfiguration is also being planned at Elgin TS and other stations, resulting in a total reduction of 17 power transformers over the planning period.

Assets requiring replacement due to condition-based assessments are then further evaluated based on the forecasted load growth in the area. If load is projected to increase, then the bundling of assets identified for replacement may be prudent to minimize future outage risk. Execution of the investment is likely to be accelerated to minimize the risk of unexpected failure at the forecasted loading. If load is projected to decrease, the bundled investment may result in reconfiguration that involves equipment decommissioning.

Hydro One actively works with the customers to capture their needs and preferences and implement the necessary changes to Hydro One designs, where feasible, to meet those needs. In cases where the need for asset replacement or upgrades is established due to customer requests, a bundled investment strategy would be recommended if it is likely to lower the costs to the customer and the rate pool. The relevant customer is consulted with respect to the pacing of the bundled investment so as to minimize any outages and direct costs to customers while maintaining the reliability of supply.

These factors are considered in conjunction every alternative listed below to determine the preferred alternative. The final decision to bundle asset replacements into a single integrated investment is established on a case-by-case basis. Details such as the in-service date and timing of the bundled investment are determined to minimize costs and maintain reliability of supply.

The above discussion describes the process Hydro One undertakes to determine whether to pursue an integrated approach to bundle the replacement of multiple key assets at a particular bulk station or load supply station. For each major station asset category, the specific asset-related drivers and needs for replacing particular key station assets are described in the following investment summary documents:

- For transformer replacement need and drivers, refer to SR-3 and SR-5;
- For switchgear need and drivers, refer to SR-4 and SR-6; and
- For protection and automation system need and drivers, refer to SR-7.

Investment Description

The Projects address the consolidated replacement of several assets that are end-of-life and are in deteriorated condition at a single transmission station. The Projects target stations with a significant population of station equipment that are identified as candidates for replacement and possible reconfiguration as a result of identified asset replacement needs.

As described in more details in TSP Section 2.1.2, Hydro One performs an asset risk assessment and, if as a result of this assessment, Hydro One identifies a significant number of major assets for replacement, then this station is subsequently identified as a candidate for a complete station refurbishment. Through the Investment Planning process described in TSP Section 2.1, all candidate investments undergo the risk based prioritization to determine whether they are included in the Investment Plan. The Projects target 21 bulk stations and load supply stations. Hydro One will replace 41 transformers, 286 breakers, and 780 protection systems. Hydro One will also address other minor station assets (e.g. ancillary equipment) where condition warrants replacement as well as any potential site and property issues, customer issues, safety and/or environmental concerns. A more detailed list of assets planned for replacement is presented in Appendix "A".

The Projects include functional reconfiguration to ensure alignment with applicable industry and regulatory standards. Functional reconfiguration is the reconnection of power system elements (e.g. breakers, transformers) within a transmission station into a new electrical configuration. This can either better facilitate a customer connection, a connection to the bulk power system or help eliminate operational restrictions or limitations which can aid in the transfer or restoration of power during a faulted condition where an element is removed from service. Functional configuration, where possible, allows Hydro One to replace two smaller rated transformers with a single standardized transformer that delivers the same capacity. This helps Hydro One maintain a standardized catalogue of power equipment to minimize the various types of spare equipment required. As a part of this investment, Hydro One will remove 17 transformers and 49 breakers from service through functional reconfiguration over the planning period.

Outcome

As a result of this investment, Hydro One will eliminate operational concerns through reconfiguration; reduce operational risks associated with the operation of end of life equipment; ensure compliance with Ministry of Environment, Conservation and Parks ("MOECP"), North American Electric Reliability Corporation ("NERC") and Northeast

Power Coordinating Council ("NPCC") requirements; maintain long-term bulk system reliability; maintain long-term reliability of the load supply stations; reduce constraints on generation resources.

The following table presents anticipated benefits in accordance with the Ontario Energy Board's ("OEB") Renewed Regulatory Framework ("RRF"):

Outcome Summary:

Customer Focus	• Maintain reliability performance of bulk electricity system through the replacement of end of life equipment that is in poor condition • Maintain reliable power delivery at load supply stations.
Operational Effectiveness	• Improve the operational effectiveness of bulk and load supply stations through reconfiguration and standardization of new equipment and design
Public Policy Responsiveness	• Ensure compliance with applicable regulatory and environmental requirements
Financial Performance	• Realize cost savings by addressing multiple deteriorated assets within a station as part of the same project.

C. EXPENDITURE PLAN

As discussed above, this investment is needed to replace various bulk power and load supply station assets that have reached their expected service life ("ESL") and are in deteriorated condition, which may lead to unexpected failures. Hydro One planned this investment to achieve completion as effectively and efficiently as possible.

Table 1 summarizes historical and projected spending on the aggregate project level. Since this investment consists of a multiple Projects, as presented in Appendix "A", Table 1 below consolidates all the costs for individual projects and presents the total investment cost. The "Previous Years" costs are the direct costs for Projects incurred prior to 2020. Likewise, the costs noted in "Forecast 2025+" are project costs forecasted beyond 2024.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	296.4	113.5	129.9	125.2	90.6	55.6	14.7	825.9
Less Removals	8.7	6.4	4.5	4.6	2.7	1.7	0.4	28.9
Gross Investment Cost	**287.8**	**107.0**	**125.4**	**120.6**	**87.9**	**53.9**	**14.3**	**796.9**

Wawa TS	0.2	0.8	3.4	11.0	10.3	25.7	28.7	2025
Net Investment Cost	**106.9**	**125.4**	**120.6**	**87.9**	**53.9**	**494.7**	**796.4**	

Furthermore, the following factors also affect the capital expenditures required for this investment:

- The number of transformers, breakers, protection systems, and ancillary equipment being replaced
    - Higher voltage transformers and breakers and ancillary equipment are more costly from a material perspective as is the overall installed cost due to required clearances for high voltage equipment.
- Applicability of MOECP, NERC and/or NPCC requirements

  - Where stations are subject to NERC/NPCC requirements or environmental work (i.e. spill containment and/or oil water separators are required) increased costs may be incurred to facilitate the work required to meet the requirements.
- The complexity of project staging and outages required to facilitate work
  - The more complex the project, the more inter-connections, and the more outages required will increase the cost of the project.
- Whether the Project is a Greenfield replacement or *in-situ* replacement requiring complex contingency planning
  - Generally, if space permits, either within the existing station fence or nearby, a Greenfield solution may be less costly as it can be constructed with minimal interference to daily operations.
  - *In situ* replacement is generally more difficult, from both engineering design and construction perspectives as other equipment will need to be removed from service to facilitate construction and ensure safety and appropriate clearances. This increases the time required for construction and can impact customers as they will be supplied from only a single supply during these times.
- The location of the station, whether in an isolated rural area or congested urban area
  - Generally working in a congested urban station will increase costs and lengthen the overall construction time of the project with respect to clearances in order to work safely.

D. ALTERNATIVES

Hydro One considered the following alternatives before arriving at this investment decision.

Alternative 1: Reactive Component Replacement involves waiting for deteriorated condition transformers, breakers, or ancillary equipment to fail and replace components on a reactive basis. This alternative is more costly not only for Hydro One but also for impacted customers. Hydro One has rejected this alternative for the following reasons.

- Assets in deteriorated condition will continue to deteriorate and decline, thereby increasing the likelihood of unexpected failures. These failures might be prolonged and might result in extended equipment and customer outages which will subsequently lower the System Average Interruption Duration Index ("SAIDI") and Transmission System Average Interruption Frequency Index ("SAIFI") performance.
- An increased likelihood of unexpected failures would lead to increased environmental risk due to the possibility of a release into the environment during a failure event.
- An increased likelihood of unexpected failures would lead to increased safety risk due to the possibility of a failure event being catastrophic in nature.
- Since these replacements would likely be executed on an emergency basis, it would result in constant reprioritization of planned work and inefficient redeployment of resources.
- This alternative limits the ability to account for future requirements and has a high risk of re-work and future additional costs.
- This strategy is likely to increase operating and maintenance costs, decrease equipment performance and may impact the safety of personnel on site.

Alternative 2: Planned Replacement of Components (Unbundled) involves replacing individual station components in high risk and deteriorated condition on a sequential basis as each component reaches its end of useful service life. This alternative is viable only when single components at a transmission station are deteriorated. Unlike reactive replacements, planned replacements have the advantage of minimizing system and equipment outages through coordinated outage plans. However, this alternative is not efficient when multiple components at a transmission station are in deteriorated condition or operational concerns exist with respect to these components. Since a component-based planned replacement strategy would only replace assets as they come to end of life, Hydro One would not realize any efficiency during execution of the design, construction, and commissioning stages of the work that a station-centric, bundled replacement strategy offers. Furthermore, this alternative does not offer any opportunities to reconfigure the physical or electrical layout of the station in order to minimize future maintenance requirements or to eliminate any existing operational concerns.

Alternative 3: Station Refurbishment – Bundled Replacement of Components is the preferred investment option. It addresses the needs identified at the transmission station to maintain reliability for Hydro One's bulk transmission system in the most cost effective and efficient manner. Hydro One can refurbish entire stations that have a significant population of assets in high risk condition, before failures occur. Furthermore, for transmission stations that have a significant population of deteriorated, high risk condition assets and where operational concerns could be mitigated or eliminated through reconfiguration, station refurbishment is the best alternative as it enables a holistic assessment of asset and operational needs which are consolidated into a single integrated investment. Bundling the replacement of transmission station components also reduces the number and duration of planned outages affecting customers connected to the station. For example, if a circuit breaker disconnect switch is replaced together with the circuit breaker outages efficiencies are realized since the grouped equipment that requires an outage is similar for the switch as it is for the breaker. Had the replacements been sequential the outages for the replacements would have to be duplicated, as would the resource requirements to complete the work.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of bulk station transformer replacement projects are: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges, or regulatory approvals. A thorough risk assessment workshop is performed during the initial project planning phase where all known risks are identified and a mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan that aims to eliminate or minimize the loss of supply to the customer. The plan might include the construction of a temporary by-passing circuit or supply of portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages. As another example, to allow for early identification of real estate issues, Hydro One involves real estate from project inception. The aim is to identify issues such as missing or inadequate land rights, so that Hydro One can try to resolve them prior to execution of the project.

APPENDIX A – DETAILED TOTAL PROJECT PLAN

Station Name	Scope and Impacts	Transformers		Breakers		Prot.	In Service Year
		Repl.	Rem.	Repl.	Rem.		
Elgin TS	This investment will result in the complete rebuild and reconfiguration of Elgin TS with new equipment built to current standards. The station refurbishment will address four (4) high risk rated power transformers with the installation of two (2) new transformers, forty-six (46) low risk low voltage breakers with the installation of new Medium Voltage Gas Insulated switchgear (MVGIS) and non-standard spill containment with the installation of current MOECP compliant spill containment facilities. The reduction in assets as a result of reconfiguration along with installation of current Hydro One standard equipment will reduce near term maintenance commitments. Customer consultations have taken place with Alectra Utilities and coordination of distribution supply egress modification is planned to facilitate minimal customer impact.	2	2	46	0	90	2020
Sheppard TS	This investment involves the complete rebuild of the existing Sheppard TS T3/T4 switchyard which includes two power transformers, 27.6kV switchyard, protection and control equipment, and supporting infrastructure in a greenfield location beside the existing T3/T4 switchyard. The T3 and T4 transformers, both constructed in 1962, show signs of insulation degradation, as determined through dissolved gas analysis; have significant oil leaks; and contain high levels of polychlorinated biphenyls (PCBs) within the high voltage bushings. As well, the existing T3/T4 switchyard structure contains “back-to-back” switching resulting in clearance concerns. Many of the associated protection and control systems are either obsolete or in poor condition. Not proceeding with this investment will lead to increased risk of declining long-term supply reliability to Toronto Hydro in the Toronto Area.	2	0	12	0	36	2020
Pine Portage SS	The investment will result in the rebuild of the Pine Portage SS station including 115kV oil circuit breakers, 115kV disconnect switches, protection and control systems, and other associated auxiliary components that are at end of life due to poor condition, obsolescence, declining performance and high maintenance costs. The protection and control systems and associated auxiliary systems will be relocated to the switchyard of the station as they are currently located in OPG facilities as part of the demerger process. Implications of not completing this work include significant risk of further equipment deterioration and declining reliability to the customers in the Thunder Bay area, as well as a negative impact on transmission capacity, reliability and operability of the station.	0	0	5	0	15	2020

Station Name	Scope and Impacts	Transformers		Breakers		Prot.	In Service Year
		Repl.	Rem.	Repl.	Rem.		
Hanmer TS	This investment involves replacement of 500kV reactors and associated spill containment systems, 230kV circuit breakers; 500kV free standing current transformers, 500kV & 230kV disconnect switches, protection and control systems, and other associated auxiliary components in order to maintain the reliability of supply to the customers in the Sudbury area. It will decrease the risk of further equipment deterioration and maintain transmission reliability between Northern and Southern Ontario.	0	0	11	0	35	2020
Gage TS	This investment will result in a complete rebuild of the station and replacement of end of life equipment including 115kV to 13.8kV transformers and low voltage circuit breakers in a new configuration. The new equipment will maintain the reliability of supply to Alectra Utilities and to embedded customers such as Arcelor Mittal Dofasco, US Steel, Max Aicher North America and several other retail customers by reducing the risk of equipment failure.	2	2	10	1	65	2021
Kenilworth TS	Assets including power transformers and low voltage breakers in addition to associated protection and control facilities are in degraded condition as verified through visual inspection and diagnostic testing. Oil analysis of the power transformers show advanced signs of insulation degradation, indicating a high probability of failure in the near future. The station refurbishment will replace a power transformer, low voltage metalclad facilities comprised of a number of breakers with current Hydro One standard metalclad equipment along with associated PCT facilities in addition to installation of current MOECP compliant spill containment facilities and drainage requirements. The reduction in assets along with installation of current Hydro One standard equipment will reduce near term maintenance commitments along with improving personnel safety by deploying current Hydro One standard equipment that eliminates the present need for additional safety measures to be taken when performing maintenance activities on the low voltage switchgear identified for replacement. In addition, replacing these assets will maintain reliability of supply to Alectra Utilities and embedded major industrial customer ArcelorMittal Dofasco.	1	2	16	11	48	2021

Station Name	Scope and Impacts	Transformers		Breakers		Prot.	In Service Year
		Repl.	Rem.	Repl.	Rem.		
Runnymede TS	The majority of assets in the Runnymede T3/T4 switchyard, including two power transformers and the 27.6kV switchyard, are at end of life due to deteriorating condition. The T3 and T4 power transformers show signs of insulation degradation as determined through dissolved gas analysis; show evidence of oil leaks within the acoustic housing; and each have a subset of bushings with high levels of polychlorinated biphenyls (PCBs). The existing 27.6kV switchyard is a legacy structure that requires expanded outage zones to complete maintenance activities. Rebuilding the Runnymede T3/T4 switchyard will renew asset conditions and continue to ensure long term supply reliability and performance to Toronto Hydro customers.	2	0	13	0	0	2021
Belleville TS	The transformer T2 is at end of life and degraded condition. The station work will include replacing T2 and existing station service transformers and associated protection and control equipment.. Replacement will maintain reliability of supply to Veridian Utility customers and decrease the risk of equipment failure.	1	0	1	0	1	2021
Martindale TS	This investment will address end of life asset replacements in the 230kV and 115kV including 230kV to 115kV transformers, 230kV circuit breakers, 115kV and 230kV disconnect switches, protection and control systems, and other associated auxiliary components. Implications of not completing this work include a significant risk of further equipment deterioration and declining transmission system reliability in the Sudbury Area.	2	0	7	0	88	2021
Carlton TS	The existing metalclad switchgear, low voltage oil circuit breakers supplying non-industrial customer load along with all site PCT facilities are in a degraded condition as verified through visual inspection and diagnostic testing. In addition, due to reduced customer loading, it has been deemed prudent at this time to reconfigure the station by removing power transformers and associated switchyard comprised of a number of low voltage breakers from service. The reduction in assets along with installation of current Hydro One standard equipment will reduce near term maintenance commitments. Customer consultations have taken place with Alectra Utilities and coordination of distribution supply egress modification is planned to facilitate minimal customer impact.	0	2	19	8	68	2022
Port Colborne TS	This investment will result in replacement of transformers T61/T62, low voltage switchyard and associated P&C devices. Spill containment facilities will also be addressed through this investment. The assets are at the end of their useful life and replacing them will maintain reliability of supply to Canadian Niagara Power Inc.	2	0	8	0	18	2022

Station Name	Scope and Impacts	Transformers		Breakers		Prot.	In Service Year
		Repl.	Rem.	Repl.	Rem.		
Slater TS	The transformers at Slater TS are at end of life and degraded condition (i.e. leaking oil). The station work will consist of Replacing , T2, and T3, the AC station service system and reconfigure the station DC supply, remove auto ground switch and upgrade associated protection and control equipment. Replacement will maintain reliability of supply to downstream customers and decrease risk of equipment failure.	2	0	0	0	0	2022
Wonderland TS	This investment will address end of life asset replacements including one 230kV to 27.6kV transformer, low voltage circuit breakers, associated protection and control systems, and other associated auxiliary components. The new equipment will maintain the reliability of supply to London Hydro and Hydro One distribution customers by reducing the risk of equipment and delivery point failure.	1	0	13	0	26	2023
Lambton TS	This investment will address end of life asset replacements including 230kV to 27.6kV transformers, 27.6kV circuit breakers, associated disconnect switches, protection and control systems, and other associated auxiliary components in order to maintain the reliability of supply to customers. This investment will be coordinated with OPG to maintain the reliability of supply in the area.	2	0	9	0	24	2023
Glendale TS	This investment will address end of life assets resulting in replacement of transformer T1, reconfiguration and replacement of all low voltage switching facilities along with all site P&C.	1	2	18	3	75	2023
Fairbank TS	The majority of assets at Fairbank TS including four power transformers and both 27.6kV switchyards are at the end of life due to deteriorated condition and obsolescence. Refurbishing the Fairbank TS switchyards will ensure long term supply reliability and performance to Toronto Hydro Customers. This station is rated as one of the worst stations for delivery point interruptions.	4	0	24	0	44	2023
Arnprior TS	A station assessment has identified that station equipment including transformers and associated protection and control equipment are at end of life and are in degraded condition. The station refurbishment work will replace T1/T2, have new PCT building, replace MV switchyard, and reconfigure the AC station service. Replacing these assets will maintain reliability of supply to Hydro Ottawa and decrease the risk of equipment failure.	2	0	5	0	25	2023
Hanover TS	This investment will address end of life asset replacements which includes one 115kV to 44kV transformer, low voltage circuit breakers, associated protection and control systems, and other associated auxiliary components. Replacement of this equipment will result in a reduced risk of equipment failure thereby maintaining the reliability of supply to embedded customers such as Westario Power, Wellington North Power and other distribution retail customers.	1	0	10	0	38	2024

Station Name	Scope and Impacts	Transformers		Breakers		Prot.	In Service Year
		Repl.	Rem.	Repl.	Rem.		
Kent TS	This investment will result the replacement of end of life equipment including two 230kV to 27.6kV transformers and seventeen low voltage circuit breakers, associated protection and control and ancillary equipment. The new equipment will maintain the reliability of supply to Entegrus Powerlines Inc. and several embedded retail customers by reducing the risk of equipment and delivery point failure.	2	0	15	2	26	2025
St. Andrews TS	This investment will address end of life asset replacements including two 115kV to 27.6kV transformer, low voltage circuit breakers, associated protection and control systems, and other associated auxiliary components. The new equipment will maintain the reliability of supply to Blue Water Power and embedded customers (Imperial Oil) by reducing the risk of equipment and delivery point failure.	2	0	13	0	35	2025
Wawa TS	This investment will address end of life asset replacements in the 230kV and 115kV switchyards which are negatively impacting transmission system reliability due to their poor condition and poor performance. End of life assets include 230kV to 115kV transformers, 230kV circuit breakers, 115kV circuit breakers, 115kV and 230kV disconnect switches, protection and control systems, and other associated auxiliary components.	2	0	7	0	23	2025

SR-03 Bulk Station Transformer Replacement Projects

Start Date:	Q1 2016	**Priority:**	Medium
In-Service Date:	Q4 2027	**3 Year Test Period Cost ($M):**	157.5
Trigger(s):	Strategic, System Renewal		
Outcomes:	Ensure compliance, system reliability, customer satisfaction, operational efficiencies and reduce maintenance costs		

A. OVERVIEW

Bulk Station Transformer Replacement Projects (the "Project") are primarily a series of individual transformer replacement projects that involves the replacement of bulk station power transformers (autotransformers, phase shifters, regulators) that are at or beyond the end of their life. The Project might also involve the replacement of other equipment such as select breakers, protection and control systems and other ancillary equipment, where needed. Prior to replacement, Hydro One will perform an asset risk assessment to ensure that these additional assets are also at the end of their life and that their condition or other factors warrant the replacement.

The bulk transmission system is the "backbone" of the Ontario electricity system. Large bulk transformers are critical at ensuring the reliable performance of the bulk electricity system. These transformers facilitate the transfer of large power flows between the 500kV, 230kV, and 115kV systems and between interties with other jurisdictions. As a licensed transmitter operating transmission facilities greater than 100 kV, Hydro One is obligated to comply with the planning, operating and reliability criteria and standards mandated by NERC and NPCC. Furthermore, Hydro One transmission customers include large electricity generators, large industrial end-users and the majority of Ontario's LDCs. In light of the foregoing, it is apparent that there is a heightened need to ensure that these critical assets of the bulk electricity system are in good condition for safe, secure and reliable operation.

The Project pacing has been influenced by bulk transformer fleet demographics, observed condition, anticipated condition, and performance factors as well as environmental and safety concerns, as described below. Based on Hydro One's overall transformer demographic profile, it is forecasted that an increasing number of units will age beyond expected service life ("ESL") within the next five years. Operating a large percentage of the fleet beyond ESL increases system reliability risk as this equipment tends to have a higher probability of failure. Consequently, Hydro One plans to manage this anticipated risk by undertaking the Project.

Hydro One has evaluated various alternatives for the Project, as described below, and concluded that replacing deteriorated bulk station transformers is the most cost effective and efficient undertaking. The projected costs of the Project are estimated to be $157.5 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

As discussed in TSP Section 2.2.1, Hydro One has a thorough and ongoing asset management process that involves monitoring and reviewing transmission assets and assessing their condition. Hydro One's transformer asset strategy is to proactively inspect and monitor the transformer fleet. This allows Hydro One to manage maintenance needs and assess the transformer's condition as a factor to determine the need for asset refurbishment or replacement. Assessments to repair or replace transformers are done on an individual basis. The assessment is based on risks identified from demographics, condition, environmental factors, utilization, costs comparison between refurbishment and replacement, and other lifecycle considerations. Units that are considered high risk, or with known manufacturer defects/obsolesce, or with anticipated higher repair costs are prioritized for replacement.

Hydro One's transmission system includes 293 stations. Hydro One has established a recurring 7-10 year assessment cycle that enables all necessary renewal work to be performed at each of the 293 transmission stations during the cycle. The goal of each asset assessment is to ensure that the assets are not deteriorated, there are no risks that may compromise the reliability of the system, and they do not pose any safety and/or environmental risk. All assets at a given station are assessed at the same time with a particular focus to transformers, breakers, and protection & control systems – as these are the most critical assets in the system and have a direct impact on a customer. If the assessment identifies multiple station assets (i.e. transformers, breakers and protection and control equipment) whose condition warrants a replacement, Hydro One then pursues an integrated approach. The asset replacements are bundled into an integrated station-centric investment project with the main components being identified as the driver for the project. This integrated approach is further described in SR-02. In the case where only transformers are identified as the main asset for replacement along with a small subset of other minor station assets, the station is identified as a candidate for a transformer-focused replacement project.

As of December 2018, Hydro One has 140 bulk station transformers in service. Currently, 24.7% of the Hydro One bulk station transformer population is beyond ESL. Hydro One defines ESL as the average age in years that an asset can be expected to operate under normal system conditions. The average age of the bulk station transformer fleet is 32 years. Assuming no replacements, Hydro One anticipates that 39% of the bulk station transformer population will exceed their ESL by 2024, and 46% of the population will exceed their ESL by 2029.

Transformer condition is a leading predictive indicator of equipment reliability and usually the main driver for replacement. Condition is determined by industry standard diagnostic testing which includes routine transformer oil testing and other maintenance examinations. Transformer insulation generally degrades as a function of time and other operational factors (i.e. loading levels) and this degradation is irreversible, ultimately requiring asset replacement. Furthermore, transformer ESL has a direct correlation to anticipated insulation condition. Within the industry, there is a correlation between the highly flammable and volatile chemical compound - furan and the degree of polymerization of insulation paper. The degree of polymerization of the paper is an indicator of insulation strength and condition. Furan is a chemical that can be detected via oil samples. Furan is a by-product of paper degradation as it ages and decomposes. Operating a large percentage of the fleet beyond ESL increases system reliability risk as this equipment tends to have a higher probability of failure. Assessment of the bulk station transformer fleet's condition based on oil analysis results shows that approximately 14% are rated high or very high risk, as illustrated in Figure 1.

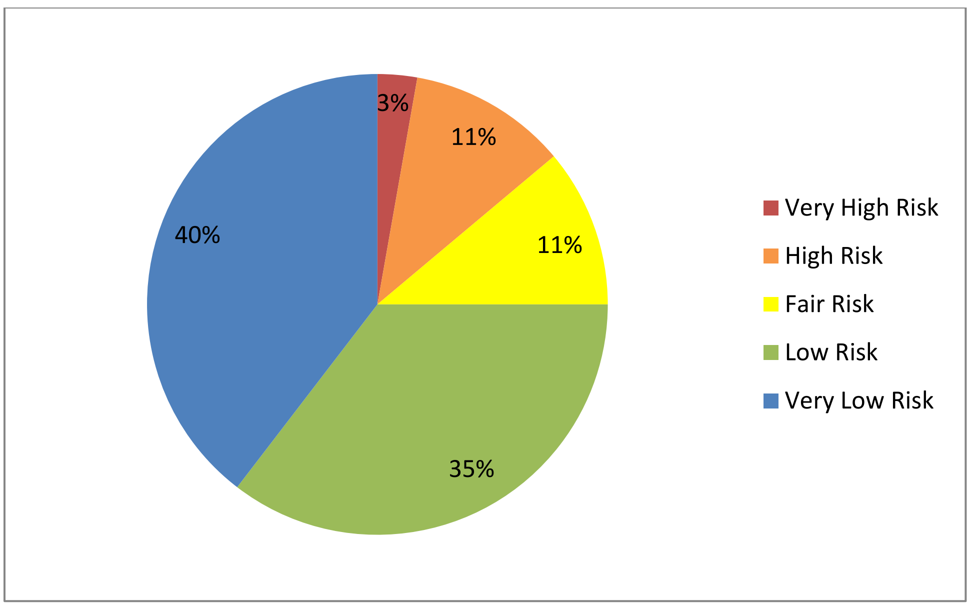

Figure 1 - Condition Summary of Bulk Station Transformer Fleet

Transformer equipment performance is measured by assessing the duration and frequency of forced outages related to the transformer. A "forced outage" is the automatic or forced manual removal of a transformer caused directly by it or its auxiliary equipment. Transformer forced outages have been a major cause of equipment unavailability over the past 10 years, representing 13% of these equipment-caused events. Over the last 10 years, Hydro One has experienced an average of 4 Class 1 failure annually. Class 1 failures are unpredictable and irreparable, and can lead to catastrophic consequences. Table 1 below summarizes the number of Class 1 failures by voltage class.

Table 1 - Transformer Annual Class 1 Failure Rates over the Past 10 Years (2008-2017) in Percentage of Transformer Population

Year	115kV	230kV	500kV	5 Year Average Annual Failure Rate, All Voltage classes
2008-2012	0.40%	0.37%	1.41%	0.44%
2013-2017	0.56%	0.41%	2.44%	0.59%
10 Year Average Annual Failure Rate	0.48%	0.39%	1.92%	0.51%

Regarding oil leaks, approximately 36% of the bulk transformer fleet has confirmed oil leaks via visual inspections, with 8.5% classified as major leakers. Based on Hydro One's experience, new leaks will appear in approximately 1% of the fleet's population per year, most commonly as a result of gasket deterioration over time. Transformer leaks not only create environmental concerns, but also generate reliability issues, as in-service transformers may be forced out due to low oil levels. Active leaks also provide a path of moisture ingress into the transformer's internal winding. Finally, severe oil leaks and frequent oil top ups also compromise the accuracy of condition assessments because they dilute the oil and may result in a false improved oil test result.

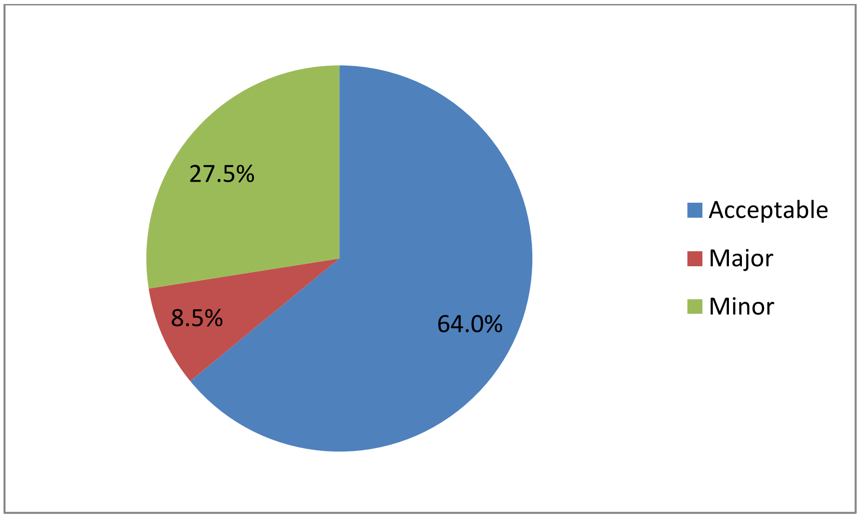

Figure 2 – Bulk Station Transformer Leak Assessment

Furthermore, the PCB Regulations, which came into effect in 2008, and for which amendments came into force on January 1, 2015, implemented deadlines on equipment already in use and in storage, in order to accelerate the elimination of PCBs from the Canadian environment. The PCB Regulations require all oil-filled equipment to contain PCB levels of less than 50 parts per million (ppm) by December 31, 2025. The PCB Regulations impact transformer oil filled bushings. From a fleet wide perspective, as of December 2018, up to 43% of Hydro One's transformer oil-filled bushings may require work related to PCB testing verification or replacements. When high PCB levels are present in a transformer approaching end of life, it may be more economical to slightly advance replacement than to make repairs to resolve high PCB levels on a unit near end of life.

With regards to failure risk, bulk transformer failure could partially or entirely constrain generation resources and would lessen the reliability of bulk power flows to load centres. For select transmission interties between Ontario and other jurisdictions that utilize phase shifters and regulating transformers, failures would result in decreased available import/export capacity. As well, reduced bulk transformation capacity could result in bottlenecks that affect the wholesale power market and power flows between regions. If left unattended, the Hydro One bulk station transformer fleet will continue to degrade and the fleet demographic with transformers that are in a high or very high risk state will continue to increase, thereby resulting in more frequent and unexpected failures.

Investment Description

The Project is classified primarily as a transformer replacement project. The Project involves a series of individual projects that target a like-for-like replacement of deteriorated bulk power transformers at several bulk transformer stations. The Project also addresses replacements of select breakers, protection and control systems, switches, batteries, chargers, instrument transformers and may additionally address site or property issues, customer issues, safety concerns, environmental compliance, and operational issues.

Hydro One's plan for the transformer fleet replacement over the next five years has been influenced by fleet demographics, observed condition, anticipated condition, and performance factors as well as environmental and safety concerns, as described above. Cumulatively, the Project targets the replacement of 33 transformers, 52 breakers, and 216 protection systems at 12 stations, as further detailed in Appendix "A" below.

Outcome

As a result of the Project, Hydro One will reduce operational risks (e.g. bottled generation, reduced transfer capability, restricted power flows) associated with the operation of end-of-life equipment; ensure compliance with government and industry regulations; maintain long-term bulk power flow reliability throughout the power system; maintain long-term reliability of import/export capacity on select transmission interties; and mitigate the risk of constraining generation resources.

The following table presents anticipated benefits as a result of the Project in accordance with the OEB's RRF:

Outcome Summary:

Customer Focus	• Maintain reliability performance of bulk electricity system power flows through the replacement of end-of-life units.
Operational Effectiveness	• Maintain operational flexibility of the bulk electricity system through the replacement of end-of-life units.
Public Policy Responsiveness	• Comply with applicable regulatory and environmental requirements
Financial Performance	• Realize cost savings by addressing multiple deteriorated assets within the station as part of the same project.

C. EXPENDITURE PLAN

As discussed above, the Project is needed to replace bulk power transformers as well as other bulk station assets that may compromise the reliability of supply due to the assets being deteriorated and at end of life, which may lead to unexpected failures. Hydro One has planned the Project in a way that strives to complete it as effectively and efficiently as possible so as to minimize the cost.

Table 2 summarizes historical and projected spending on the aggregate project level. Since the Project consists of multiple projects, as presented in Appendix "A", Table 2 below consolidates all the costs for individual projects and presents the total Project costs. The "Previous Years" costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 Test year. Likewise, the costs noted in "Forecast 2025+" are project costs forecast beyond 2024.

Table 2 - Total Investment Cost

($ Millions)	**Prev. Years**	**2020**	**2021**	**2022**	**2023**	**2024**	**Forecast 2025+**	**Total**
Capital[1] and Minor Fixed Assets	13.4	34.5	53.8	75.4	140.7	131.7	65.8	515.3

Net Investment Cost	**12.8**	**33.2**	**52.0**	**73.1**	**136.5**	**127.8**	**63.8**	**499.2**

[1] *Includes overhead at current rates.*

Table 3 below presents projected costs on an individual project basis. It also provides a total costs for each individual project along with the proposed in-service date.

Table 3 - Detailed Total Project Costs

Project	Net Investment Costs ($ Millions)					20-24 Total ($M)	Project Total ($M)	In Service Date
	2020	2021	2022	2023	2024			
Detweiler TS	9.1	4.8	0.0	0.0	0.0	13.9	22.2	2021
Keith TS	12.2	11.4	8.7	8.7	0.0	41.0	42.6	2023
Seaforth TS	7.4	17.4	6.3	7.9	0.0	39.0	40.1	2023
Sarnia Scott TS	0.6	2.9	9.3	9.0	2.2	23.9	24.3	2024
Otto Holden TS	1.8	7.5	15.5	12.3	2.8	40.0	40.5	2024
Fort Frances TS	0.5	2.8	9.0	8.7	2.2	23.1	23.5	2024
Buchanan TS	0.4	0.6	3.2	10.6	10.1	24.9	27.5	2025
Middleport TS	0.0	0.4	0.8	5.3	16.4	22.9	29.0	2025
Manby TS	0.2	0.6	3.0	22.7	27.8	54.2	62.3	2025
Algoma TS	0.5	0.9	5.9	16.2	14.5	38.1	41.8	2025
Porcupine TS	0.5	1.2	9.3	25.0	21.8	57.9	63.3	2025
Beach TS	0.0	1.3	1.3	5.2	16.1	23.9	58.7	2027
Net Investment Cost	**33.2**	**52.0**	**73.1**	**136.5**	**127.8**	**422.5**	**499.2**	

Furthermore, the following factors also affect the capital expenditures required for the Project:

- Applicability of government and industry regulations:
    - When a transformer is replaced, there are requirements from the Ministry of the Environment, Conservation and Parks (MOECP) for spill containment and oil/water separators to mitigate the risk to the environment if oil is spilled.
    - As well, PCB compliance regulations established by Environment Canada drive the cost analysis of whether to retro-fill (refill) oil equipment or replace the PCB affected equipment. The OM&A cost to retro-fill the main tank on a power transformer is not deemed prudent for units approaching or beyond their ESL given the increased likelihood of failure. The preference is to proceed with a capital replacement due to the reduced rate impact, greater reliability and long-term benefits.

- Complexity of project staging and outages required to facilitate work:
    - Increases the cost of the planning portion of the project.
    - Increases overall duration of project (interest and overhead costs increases).

- Whether like-for-like replacements are installed in a new location or installed in-situ requires complex contingency planning:
    - New location will require additional facilities to be installed to connect the equipment rather than re-using existing facilities (i.e. bus work and supporting structures/foundations), increases cost.
    - Contingency planning can increase cost by requiring backup transformer installations, temporary supplies, etc.

- Site conditions and challenges:
    - Urban areas have many constraints such as outage planning, construction staging and contingency planning which could add to the project's duration and complexity and result in higher costs (e.g. working in space-constrained stations; work within neighborhoods where streets are congested and working hours may be constrained due to noise requirements; unique design and construction challenges; outage constraints as service still needs to be maintained amidst the required work).
    - Remote rural areas will increase costs due to difficulty of working on difficult terrain, difficulty accessing the station with heavy equipment, delivery of large equipment, etc.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: Reactive Component Replacement involves waiting for deteriorated condition transformers, breakers, or ancillary equipment to fail and replace components on a reactive basis. This alternative is more costly not only for Hydro One but also for impacted customers. Hydro One has rejected this alternative for the following reasons:

- Assets in deteriorated condition will continue to deteriorate and decline, thereby increasing the likelihood of unexpected failures. These failures might be prolonged and might result in extended equipment and customer outages which will subsequently lower SAIDI and SAIFI performance.
- An increased likelihood of unexpected failures would lead to increased environmental risk due to the possibility of a release into the environment during a failure event.
- An increased likelihood of unexpected failures would lead to increased safety risk due to the possibility of a failure event being catastrophic in nature.
- Since these replacements would likely be executed on an emergency basis, it would constantly result in the reprioritization of planned work and inefficient redeployment of resources.
- This alternative limits the ability to account for future requirements and has a high risk of re-work and future costs.
- This strategy is likely to increase OM&A costs, decrease equipment performance and might impact the safety of personnel on site.

Alternative 2: Station Refurbishment involves the refurbishment of the entire station where significant populations of assets are in a high risk condition, before failure occurs. This alternative is only a viable solution where other station assets, such as transformers and switching facilities, are in a deteriorated, high risk condition. This alternative has been considered for the Project and has been rejected as there is insufficient justification to proceed with a complete station refurbishment. Hydro One does not replace transmission assets unless asset condition or other factors warrant replacement. Where the majority of assets are EOL, this alternative may then be considered, but then the project would fall under the SR-02.

Alternative 3: Like-for-Like Planned Replacement is a preferred undertaking. It involves proactively replacing individual station components in a single integrated investment, with transformers being the primary project driver and additional station assets such as switchgear and ancillary equipment being included that have a deteriorated, high risk condition. This alternative is recommended as it addresses the needs identified at the station to maintain the reliability of Hydro One's transmission system in the most cost effective manner, consistent with the findings of the customer engagement process. This alternative focuses on the replacement of select equipment in a like-for-like manner, unless otherwise requested to meet broader system needs.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of bulk station transformer replacement projects are: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges, or regulatory approvals. A thorough risk assessment workshop is performed during the initial project planning phase where all known risks are identified and a mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize the risk of supply loss to the customer. The plan might include the installation of a temporary transformer or supply of portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages. Another example is the involvement of real estate from the project inception. It allows for the early identification of real estate issues, such as missing or inadequate land rights. Once the issue is identified, Hydro One tries to resolve it prior to execution of the project.

1 **APPENDIX A – DETAILED TOTAL PROJECT PLAN**

Station Name	Scope and Impacts	Transformer Repl.	Breakers Repl.	Prot. Repl.	In Service Year
Detweiler TS	T2 and T4 are to be replaced as they have significant leaks and are at end of life. In 2011 and 2014 a total of 5870 litres of oil were required in emergency corrective top-ups for T2 amounting to over 3.5% of total oil volume. In 2011 and 2013 a total of 1900 litres of oil were required in emergency corrective top-ups for T4. This investment will maintain the reliability of supply to the Kitchener-Waterloo area.	2	0	11	2021
Keith TS	In addition to being at end of life and obsolete, T11 and T12 autotransformers do not have a self-cooled rating and represent a high risk of failure in case of loss of AC station service. The T11 and T12 units are to be replaced and upgraded from 125 MVA to 250 MVA in order to maintain the reliability of supply in the Windsor area and of the international tie-lie connection to the United States via Michigan. This project will also address the end of life step-down transformer, T1 that supplies Enwin Utilities.	3	1	17	2023
Seaforth TS	T1 and T2 DESN transformers are to be replaced to maintain reliability of supply to Erie Thames Power Lines, Festival Hydro, Dublin DS and embedded generation customers such as St.Columban 2 Wind farm, Brussels DS and Hurondale DS. The T5 and T6 autotransformer's off load tap changers are inoperable and obsolete. In order to maintain the reliability of supply and voltage regulation to customers and generators in the area, the IESO has recommended advancing the replacement of T5 and T6. This investment will maintain the reliability of supply in western Ontario between London, Kitchener-Waterloo and the Bruce generation complex.	4	2	25	2023

Station Name	Scope and Impacts	Transformer Repl.	Breakers Repl.	Prot. Repl.	In Service Year
Sarnia Scott TS	This investment will address end of life asset replacements in the 230kV and 115kV switchyards which are negatively impacting transmission system reliability due to their poor condition. End of life assets include one 230kV to 115kV transformer, five 115kV circuit breaker, 115kV and 230kV disconnect switches, protection and control systems, and other associated auxiliary components. This investment is expected to maintain the reliability of supply in the Windsor area.	1	5	23	2024
Otto Holden TS	This investment is driven by the need to replace a number of assets that are near end of life at Otto Holden TS. The main assets driving this investment are transformers T3, T4 (six single-phase units) and 115kV oil circuit breakers DT3L5 and DT4L4. Where possible, other asset replacements are also incorporated such as component upgrades to meet present day Hydro One standards. This investment will maintain the reliability of supply between North Bay and Petawawa.	6	2	13	2024
Fort Frances TS	The main assets driving this investment are the T4 step-down transformer, AC/DC SS transfer schemes, three 230kV oil circuit breakers and EOL protections. This investment will maintain reliability of supply to customers in northwestern Ontario in the Fort Frances area, and maintain the reliability and integrity of power flow through the international transmission connection with the state of Minnesota, United States.	1	3	46	2024
Buchanan TS	Replacement of end of life autotransformers T3, T4 and their associated protections and disconnected switches as well as upgrade the end of life DC station service transfer scheme. This investment will maintain reliability of the bulk system in the London area. However, transformer T4 has recently failed and is being replaced under the demand capital failure replacement program in 2019.	2	0	10	2025

Station Name	Scope and Impacts	Transformer Repl.	Breakers Repl.	Prot. Repl.	In Service Year
Middleport TS	Replacement of end of life autotransformer T6 and associated protections, disconnected switches and surge arrestors.	1	0	6	2025
Manby TS	As per the preliminary condition assessment, this investment will result in replacement of the end-of-life, Polychlorinated Biphenyl (PCB) contaminated T7, T9, and T12 230kV 250MVA autotransformers and T13 230kV 93MVA transformer as well as other deteriorated, end-of-life assets including circuit breakers, protection equipment and other ancillary assets. This investment will result in improved overall station reliability and eliminate operational risks associated with operating end-of-life equipment, eliminate PCB contaminated equipment in the station in order to comply with environmental regulations and will maintain reliability of supply to Toronto Hydro customers in downtown and west Toronto.	4	12	28	2025
Algoma TS	This investment is driven by the need to replace a number of assets that are near end of life at Algoma TS. The main assets driving this investment are transformers T5 and T6, five 115kV oil circuit breakers AL1, AL4, HL2, HL4, and L1L2 and AC and DC transfer schemes. Four of the five 115kV oil circuit breakers identified for replacement have confirmed high levels of PCBs in their bushings and need to be replaced by 2025. This investment will maintain the reliability of supply between northern and southern Ontario.	2	5	0	2025
Porcupine TS	This investment is driven by the need to replace a number of assets that are near end of life at Porcupine TS. The main assets driving this investment are transformers T3, T4 and T8 as well as station service transformers. This investment will maintain the reliability of supply in the Timmins area.	3	0	29	2025

Station Name	Scope and Impacts	Transformer Repl.	Breakers Repl.	Prot. Repl.	In Service Year
Beach TS	This investment is driven by the need to replace a number of assets that are near end of life at Beach TS. Preliminary assessments indicate step down transformers T5, T6 and auto transformers T7, T8 along with non-arc proof metalclad switchgear and associated protection and control equipment are at end of life and require replacement to ensure supply reliability to Alectra Utilities and overall bulk system operation are maintained.	4	22	8	2027

SR-04 Bulk Station Switchgear and Ancillary Equipment Replacement Projects

Start Date:	Q2 2017	**Priority:**	Medium
In-Service Date:	Q2 2027	**3 Year Test Period Cost ($M):**	90.0
Trigger(s):	Strategic, System Renewal		
Outcomes:	Ensure compliance, system reliability, customer satisfaction, operational efficiencies and reduce maintenance costs		

A. OVERVIEW

Bulk Station Switchgear and Ancillary Equipment Replacement Projects (the "Projects") are primarily switchgear replacement projects that involve the replacement of bulk transmission station circuit breakers, which includes circuit breakers rated greater than 100 kV and can be oil, air-blast, Gas Insulated Switchgear ("GIS") or Sulfur Hexafluoride ("SF6") type, that are at the end of their life and whose risk has been rated as high or very high in accordance with the asset risk assessment. The Projects might also involve the replacement of ancillary equipment (e.g. AC and DC station service equipment, disconnect switches, instrument transformers, etc.) where needed. Prior to replacement, Hydro One will perform the asset risk assessment to ensure that these assets are also at the end of their life and their condition or other factors warrant the replacement.

The bulk transmission system is the "backbone" of Ontario electricity system. Bulk power flows through the 500kV, 230kV, and 115kV transmission systems. A circuit breaker is a mechanical switching device that is capable of carrying and interrupting electrical current under normal and abnormal conditions. During abnormal conditions, circuit breakers are capable of operating rapidly to interrupt high current thereby minimizing its effect on the rest of the system. As a licensed transmitter operating transmission facilities greater than 100 kV, Hydro One is legally obligated to comply with the planning, operating and reliability criteria and standards adopted by North American Electric Reliability Corporation ("NERC") and Northeast Power Coordinating

Council ("NPCC"). Furthermore, Hydro One transmission customers include large electricity generators, large industrial end-users and the majority of Ontario's Local Distribution Companies ("LDC"). In light of the foregoing, it is apparent that there is a heightened need to ensure that this critical asset of the bulk electricity system is in a good condition and perform reliably.

The Projects pacing has been influenced by the assessment of equipment condition and in consideration of operational effectiveness, customer preferences, and safety concerns. Based on Hydro One's bulk station breaker demographic profile, it is forecasted an increasing number of units will age beyond expected service life ("ESL") within the next five years. Operating a large percentage of the fleet beyond ESL increases system reliability risk as this equipment tends to have a higher probability of failure. Consequently, Hydro One plans to manage this anticipated risk by undertaking the Projects.

Hydro One has evaluated various alternatives for the Projects, as described below, and concluded that replacing the deteriorated bulk station breakers is the most cost effective and efficient undertaking. The projected costs of the Projects are estimated to be $90.0 million over the 2020-2022 test period.

B. NEEDS AND OUTCOME

Investment Need

As discussed in TSP Section 2.2.1, Hydro One has a thorough and ongoing asset management process that involves monitoring and reviewing transmission assets and assessing their risk. Hydro One's asset strategy is to proactively inspect and monitor the breaker fleet. This allows Hydro One to manage maintenance needs and assess the breaker's associated risk to determine the need for asset replacement. Assessments to repair or replace breakers are done on an individual basis. The assessment is based on risks identified from demographics, condition, environmental factors, utilization, performance, obsolescence, costs comparison between refurbishment and replacement, and other lifecycle considerations.

Hydro One's transmission system includes 293 stations. Hydro One has established a recurring 7-10 year assessment cycle that enables all necessary renewal work to be performed at each of the 293 transmission stations during the cycle. The goal of each asset assessment is to ensure that the assets are not deteriorated, there are no risks that may compromise the reliability of the system, and they do not pose any safety or and/or environmental risk. All assets at a given station are assessed at the same time with a particular focus to transformers, breakers, and protection & control systems – as these are the most critical assets in the system and have a direct impact on a customer. If the assessment identifies multiple key station assets (i.e. transformers, breakers and protection and control equipment) whose risk warrants a replacement, Hydro One then pursues an integrated approach. The asset replacements are bundled into a single integrated station-centric investment project with the main components being identified as the driver for the project. This integrated approach is further described in SR-02**.** In the case where only the breakers are identified as the main asset for replacement along with a small subset of other minor station assets, the station is identified as a candidate for a breaker-focused replacement project.

Hydro One has 1,569 bulk station breakers in service. Currently, 16% of Hydro One bulk station breaker population is beyond their ESL. Hydro One defines ESL as the average age in years that an asset can be expected to operate under normal system conditions. Assuming no replacement, Hydro One anticipates that 381 units (24% of the bulk station breaker population) will exceed their ESL by 2024, and 493 units (31% of the population) will exceed their ESL by 2029.

Asset condition is one of several drivers for breaker replacement. Breaker condition is monitored through information gathered during preventative inspection and maintenance activities. Hydro One performs routine maintenance and replaces breakers that are obsolete, pose safety risks, operate at or above their nameplate rating, have unacceptable performance and a poor environmental footprint. Poor performance is judged based upon the likelihood of the equipment contributing to load interrupted or unsupplied energy to the customer. Poor environmental footprint is judged based on Polychlorinated Biphenyl (“PCB”) levels in excess of legislated requirements. The following issues are examples that have been observed by Hydro One as part of its breaker risk assessment that warrants the replacement of the breakers that are the subject of the Projects:

- As breakers age, their O-rings and gaskets slowly degrade, thereby causing leaks. The leaks will result in a lower pressure and a path for moisture ingress. This condition over time can result in lower dielectric strength in the breaker and potential for internal flashover which could result in an explosive failure of the breaker.
- Some of the Hydro One fleet of breakers are no longer supported by vendors and aftermarket parts are no longer available or are costly to acquire or fabricate. This is a significant risk factor to some first generation SF6 circuit breakers and certain types of oil circuit breakers. Strategic sparing of breakers is done through replacements where parts are difficult to procure such that removal can help sustain the remaining in-service fleet.

The assessment of the bulk station breaker fleet, as of December 2018, shows that there are 11% of the bulk station breakers that are rated at a high or very high risk, as illustrated in Figure 1.

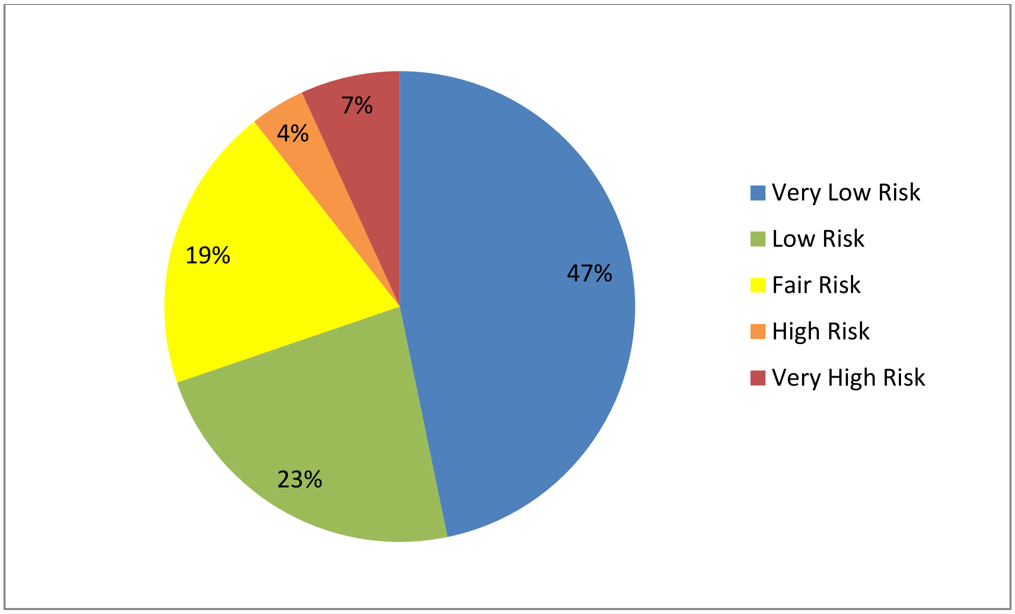

Figure 1 - Summary of Risk for Bulk Station Circuit Breakers

Operating a large percentage of the fleet beyond ESL increases system reliability risk as this equipment tends to have a higher probability of failure. When unexpected failure occurs, it could partially or entirely constrain generation resources and would negatively impact the reliable bulk power flows to load centres. For select transmission interties between Ontario and other jurisdictions, unexpected failures would result in decreased available import/export capacity. Failures can be catastrophic or it can be just the asset failing to do what it is intended to do (e.g. breakers can fail to operate/open when needed or they can have insulation failure and short out during operation, causing irreparable damage). Furthermore, what complicates the situation is that when a certain type of breaker approaches the end of its ESL, vendors often communicate their transition to a limited support and complete obsolescence of aged product lines. As such, it is important to stay on top of this wave of assets approaching ESL in order to avoid situations where it may become difficult to obtain parts to sustain breakers that vendors no longer support.

Breaker equipment performance is measured by assessing the duration and frequency of forced outages related to the transformer. A "forced outage" is the automatic or forced manual removal of a breaker caused directly by it or its auxiliary equipment.

Furthermore, the PCB Regulations, which came into effect in 2008, and for which amendments came into force on January 1, 2015, implemented deadlines on equipment already in use and in storage, in order to accelerate the elimination of PCBs from the Canadian environment. The PCB Regulations require all oil-filled equipment to contain PCBs less than 50 parts per million (ppm) by December 31, 2025.These requirements impact breaker oil filled bushings and the oil in the main breaker tank. It is estimated that approximately 528 breakers require PCB mitigation, which entails replacing or retro-filling the bushing (i.e., putting in new PCB free oil to bring the PCB ppm value lower). To date, Hydro One has sampled 779 breakers, with another 168 breakers being projected to contain high PCB content once sampled. This projection is based on the rate at which Hydro One has been finding high PCB concentrations in the equipment sampled to date. Using a repair vs. replace analysis, circuit breaker failures that are repairable may be considered for replacement under this program since if there is confirmed PCB content greater than the 45ppm Hydro One set limit, additional costs for the PCB mitigation will also be taken into consideration in addition to the required corrective repairs as a result of the failure.

Breaker failure could partially or entirely constrain generation resources and would lessen the reliability of bulk power flows to load centres. For transmission interties between Ontario and other jurisdictions, failures would result in decreased available import/export capacity. If left unattended, Hydro One bulk station breaker fleet will continue to degrade and the fleet demographic with breakers that are in poor or very poor condition will continue to increase, thereby resulting in more frequent and unexpected failures. Figure 2 below shows the forecast of Hydro One bulk breaker fleet with breakers reaching their ESL.

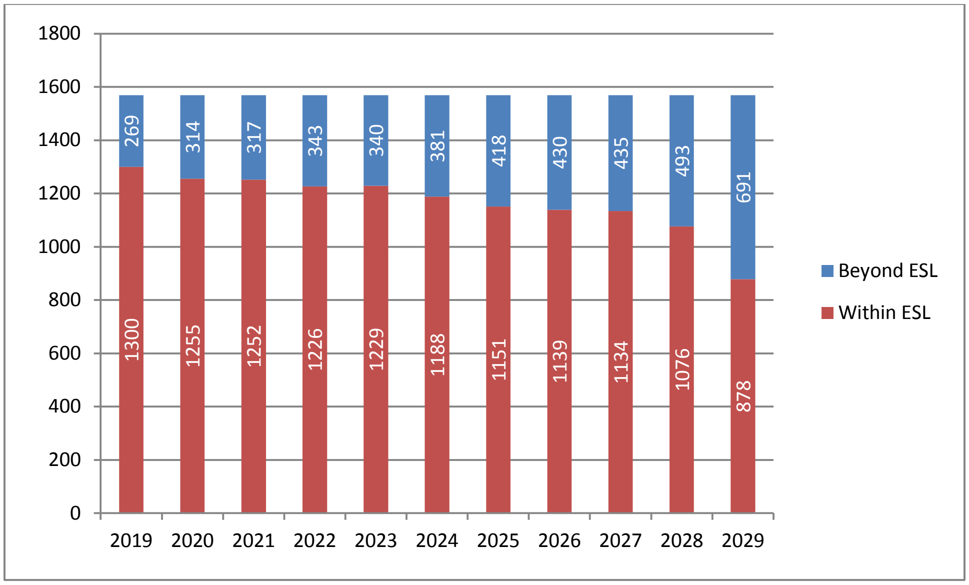

Figure 2 - Bulk Station Class Circuit Breaker Demographic Forecast – without replacement

Breaker failures can severely impact system stability, other connected equipment and employee and public safety. Consequently, it is important to ensure that the current carrying components are in good shape, the mechanical and control systems are operating within specification and that the insulating medium has not been compromised.

Investment Description

The Projects are classified as primarily breaker replacement driven. This investment will result in the replacement of switchgear and ancillary equipment at bulk transmission stations that are in a deteriorated, high risk condition where the likelihood of a failure is high. The Projects involve a series of individual projects which vary in scope and in size. The Projects target a like-for-like replacement of deteriorated bulk power breakers at various bulk transformer stations. It also addresses the replacements of select ancillary equipment such as switches, batteries, chargers as well as may additionally address site or property issues, customer issues, safety concerns, environmental compliance, and operational issues whose condition might also warrant the replacement.

Hydro One's plan for the breaker fleet replacement over the next five years has been influenced by fleet demographics, observed condition, anticipated condition, and performance factors as well as environmental concerns, as described above. Cumulatively, the Projects target the replacement of 64 breakers over the five year period at 11 stations. Further details pertaining to the Project are provided in Appendix "A" below.

Outcome

As a result of the Project, Hydro One will reduce operational risks (e.g. bottled generation, reduced transfer capability, restricted power flows) associated with the operation of end-of-life equipment; ensure compliance with NERC and NPCC requirements as well as PCB Regulations; maintain long-term bulk power flow reliability throughout the power system; maintain long-term reliability of import/export capacity on select transmission interties; and mitigate the risk of constraining generation resources.

The following table presents anticipated benefits as a result of the Project in accordance with the Ontario Energy Board's Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Maintain reliable performance of the bulk electricity system power flows through the replacement of end of life ("EOL") equipment.
Operational Effectiveness	• Improve the operational effectiveness of bulk stations through standardization of new equipment.
Public Policy Responsiveness	• Comply with applicable regulatory and environmental requirements.
Financial Performance	• Realize cost savings by addressing multiple deteriorated assets within the station as part of the same project.

C. EXPENDITURE PLAN

As discussed above, the Project is needed to replace the bulk power breakers and ancillary equipment failure of which may compromise the reliability of supply due to the assets being deteriorated and at end of life. Hydro One planned the Project in a way that strives to complete it as effectively and efficiently as possible so to minimize the cost of performing this sustainment task.

Table 1 summarizes historical and projected spending on the aggregate project level. Since the Project consists of a multiple projects, as presented in Appendix "A", Table 1 below consolidates all the costs for individual projects and presents the total Project costs. The "Previous Years" costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 test year. Likewise, the costs noted in "Forecast 2025+" are project costs forecast beyond 2024.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	4.5	18.0	33.4	42.6	35.7	50.8	26.4	211.4
Less Removals	0.1	0.5	1.0	1.2	1.1	1.5	0.8	6.2

Mississagi TS	0.0	0.4	0.5	2.2	9.3	12.3	15.9	2025
Lakehead TS	0.0	0.1	0.5	9.5	8.3	18.4	31.0	2027
Net Investment Cost	**17.5**	**32.4**	**40.2**	**34.6**	**49.3**	**173.9**	**204.0**	

Furthermore, the following factors also affect the capital expenditures required for the Project:

- Applicability of Ministry of the Environment, Conservation, and Parks, NERC and/or NPCC requirements;
    - PCB compliance regulations established by Environment Canada drive the cost analysis of whether to retro-fill (refill) oil equipment or replace the PCB affected equipment. The Operations, Maintenance and Administration cost to retro-fill the main tank or bushings on a circuit breaker is not deemed prudent for units approaching or beyond their ESL given the increased likelihood of failure. The preference is to proceed with a capital replacement due to the reduced rate impact and future benefit and reliability a new unit would provide.

- Complexity of project staging and outages required to facilitate work:
    - Increases the cost of planning the project
    - Increases overall duration of project (interest and overhead costs increases).

- Whether like-for-like replacements are installed in a new location or installed in-situ which may require complex contingency planning:
    - New location will require additional facilities to be installed to connect the equipment rather than re-using existing facilities (i.e. bus work and supporting structures/foundations), increases cost
    - Contingency planning can increase cost by requiring bypass installations, temporary supplies and etc.

- Site conditions and challenges:
    - Urban areas will have constraints with outage planning, construction staging and contingency planning which could add to project duration and complexity and result in higher costs (e.g. working in space-constrained stations; work

within neighborhoods where streets are congested and working hours may be constrained due to noise requirements; unique design and construction challenges; outage constraints as service still needs to be maintained amidst the required work)

Remote rural areas will increase costs due to difficulty of working on difficult terrain, difficulty accessing the station with heavy equipment, and delivery of large equipment.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: Reactive Component Replacement involves waiting for deteriorated breakers or ancillary equipment to fail and replace components on a reactive basis. Hydro One has rejected this alternative for the following reasons:

- Assets in deteriorated condition will continue to deteriorate and decline, thereby increasing the likelihood of unexpected failures. These failures might be prolonged and might result in extended equipment and customer outages which will subsequently lower System Average Interruption Duration Index and System Average Interruption Frequency Index performance.
- An increased likelihood of unexpected failures would lead to increased environmental risk due to the possibility of a release into the environment during a failure event.
- An increased likelihood of unexpected failures would lead to increased safety risk due to the possibility of a failure event being catastrophic in nature.
- There is expectation that there will be more catastrophic failures and systemic failures which based on past experience, cost more to replace compared to planned replacements due to the amount of damage, number of equipment affected and duration of outages related to these events.

- The maintenance frequency would likely increase and result in increased maintenance costs. As assets age beyond their ESL, repairs become more costly as the assets are no longer supported by vendors and aftermarket parts are no longer available or are costly to acquire or fabricate.
- Replacing reactively would lead to assets being replaced in an uncoordinated fashion. This would lead to assets only being replaced on an in-situ basis and reduce the ability to prudently address other station infrastructure. Uncoordinated fashion here is referring to planning the work in a holistic approach.
  - Many of the assets at a station are interconnected and replacing a single asset can either limit Hydro One in the design options for this replacement or cause the need for rework in the future, for example, coordinating protection replacements with breaker replacements
  - When multiple assets are reaching EOL, there is opportunity to make changes to the electric configuration to make improvements to the reliability and performance of the bulk electricity system. Uncoordinated fashion can also pertain to the mobilization of construction forces, the staging of work to minimize impact to customers (outage frequency and duration).

Alternative 2: Station Refurbishment involves the refurbishment of the entire station where significant populations of assets are in a high risk condition, before failure occurs. This alternative is only a viable solution where the other key station assets, such as transformers and switching facilities are in a deteriorated, high risk condition. This alternative has been considered for the Project and has been rejected as there is insufficient justification to proceed with a complete station refurbishment. Hydro One does not replace the transmission assets unless the asset condition warrants the replacement. Where majority of assets are EOL, this alternative may then be considered, but then the project would fall under the SR-02.

Alternative 3: Like-for-Like Planned Replacement is a preferred undertaking. It involves proactively replacing individual station components in a single integrated investment, with switchgear and ancillary equipment that are in a deteriorated, high risk condition. This alternative is recommended as it addresses the needs identified at the station to maintain the reliability of Hydro One's transmission system in the most cost effective manner, consistent with the findings of the customer engagement process. This alternative focuses on the replacement of select equipment in a like-for-like manner, unless otherwise requested to meet broader system needs.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of bulk station breaker replacement projects are: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges, or regulatory approvals. A thorough risk assessment workshop is performed during the initial project planning phase where all known risks are identified and mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize to a minimum the loss of supply to the customer. The plan might include the construction of a temporary by-passing circuit or supply of portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages. Another example is the involvement of real estate from the project inception. It allows for the early identification of real estate issues, such as missing or inadequate land rights. Once the issue is identified, Hydro One tries to resolve it prior to execution of the project.

APPENDIX A – DETAILED PROJECT PLAN

Station Name	Scope and Impact	Breakers Repl.	Prot. Repl.	In Service Year
Trafalgar TS	Replacement of end of life of protections as well as select surge arresters, air-gas bushings, DC station service equipment, instrument transformers, and minor ancillary assets. These replacements will decrease the risk of equipment failure and contribute to maintaining bulk power supply reliability to the Greater Toronto Area.	-	44	2022
Claireville TS	Replacement of end of life protections, as well as select surge arresters, air-gas bushings, DC station service equipment, AC station service equipment, instrument transformers, and minor ancillary assets. These replacements will decrease the risk of equipment failure and contribute to maintaining bulk power supply reliability to the Greater Toronto Area.	6	28	2022
Rabbit Lake SS	Replacement of end of life breakers and protections to maintain reliability in the Kenora area.	5	23	2022
Milton SS	Replace end of life protections as well as select surge arresters, air-gas bushings, DC station service equipment, AC station service equipment, instrument transformers, and other minor ancillary assets. These replacements will decrease the risk of equipment failure and contribute to maintaining bulk power supply reliability to the Greater Toronto Area.	-	9	2023

Station Name	Scope and Impact	Breakers Repl.	Prot. Repl.	In Service Year
Marathon TS	Replacement of end of life breakers, protections, station service and instrument transformers. This investment will maintain reliability of the bulk system connection between the northern and southern Ontario.	7	8	2023
Mackenzie TS	Replacement of end of life breakers, protections, station service and instrument transformers. This investment will maintain bulk system reliability in northwestern Ontario.	6	43	2024
Merivale TS	Replacement of four 115 kV oil circuit breakers, eight 115 kV switches and the AC/ DC system as well as upgrading protection and control systems. This will maintain reliability in delivering bulk power to eastern Ontario in the Ottawa area.	4	55	2025
St. Lawrence TS	The main assets driving this investment are five 115kV oil circuit breakers (KL2,PL1, PL2, T2K and T2L1) and two 230kV oil circuit breakers (AL34 and HL34) and their associated disconnect switches are being replaced. The assets are at the end of life and replacing them will maintain reliability of bulk power delivery from New York Power Authority (NYPA) to Ontario’s high voltage networks. Implications of not completing this work include a significant risk of further equipment deterioration and declining transmission system reliability.	7	7	2025
Kenora TS	Replacement of end of life breakers, protections, station service and instrument transformers. This investment will maintain reliability in the Kenora area.	5	24	2025

Station Name	Scope and Impact	Breakers Repl.	Prot. Repl.	In Service Year
Mississagi TS	Replacement of end of life breakers, protections, station service and instrument transformers. This investment will maintain reliability of the bulk system connection between the northern and southern Ontario.	7	30	2025
Lakehead TS	Replacement of end of life breakers, protections, station service and instrument transformers. This investment will maintain bulk system reliability in the Thunder Bay area.	17	53	2027

SR-05 Load Station Transformer Replacement Projects

Start Date:	Q1 2015	**Priority:**	Medium
In-Service Date:	Q1 2026	**3 Year Test Period Cost ($M):**	352.4
Trigger(s):	System Renewal		
Outcomes:	Ensure compliance, system reliability, customer satisfaction, operational efficiencies and reduce maintenance costs		

A. OVERVIEW

Load Supply Station Transformer Replacement Projects (the “Projects”) are primarily a series of individual transformer replacement projects that involves the replacement of load supply station transformers (e.g. step-down transformers) that are at or beyond the end of their life. The Project might also involve the replacement of select breakers, protection and control systems and other ancillary equipment, where needed. Prior to replacement, Hydro One will perform an asset risk assessment to ensure that these additional assets are also at the end of their life and that their condition or other factors warrant the replacement.

Load supply stations, via the step-down power transformers, transfer power from higher voltages to lower voltages to facilitate the distribution of power via the downstream distribution network. The main Hydro One customers at the load supply stations are LDCs and large industrial customers. The LDCs that are served by Hydro One’s transmission system serve most of Ontario’s residential, commercial, institutional and small industrial end-users. The end-user facilities that are indirectly affected by the reliability and performance of Hydro One’s transmission system include such critical infrastructure as telecommunications systems, water and wastewater treatment facilities, hospitals and other health care facilities, airports and transportation systems, schools and universities, financial services systems, etc. In essence, Hydro One’s load supply stations and step-down power transformers provide the electrical energy necessary to power the provincial economy and meet society’s daily needs. In light of the foregoing, it is apparent that there is a heightened need to ensure prudent and proactive replacement of step-down power transformers as warranted by condition assessments and other factors.

The Project pacing has been influenced by load supply transformer fleet demographics, observed condition, anticipated condition, and performance factors as well as environmental and safety concerns, as described below. Based on Hydro One's overall transformer demographic profile, it is forecasted that an increasing number of units will age beyond Expected Service Life ("ESL") within the next five years. Operating a large percentage of the fleet beyond ESL increases supply reliability risk as this equipment tends to have a higher probability of failure. Consequently, Hydro One plans to manage this anticipated risk by undertaking the Project.

Hydro One has evaluated various alternatives for the Project, as described below, and concluded that replacing deteriorated load supply station transformers is the most cost effective and efficient undertaking. The projected costs of the Projects are estimated to be $352.4 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

As discussed in TSP Section 2.1.2, Hydro One has a thorough and ongoing asset management process that involves monitoring and reviewing transmission assets and assessing needs. Hydro One's transformer asset strategy is to proactively inspect and monitor the transformer fleet. This allows Hydro One to manage maintenance needs and assess the transformer's condition as a factor to determine the need for asset refurbishment or replacement. Assessments to repair or replace transformers are done on an individual basis. The assessment is based on risks identified from demographics, condition, environmental factors, utilization, costs comparison between refurbishment and replacement, and other lifecycle considerations. Units that are considered high risk, or with known manufacturer defects/obsolesce, or with anticipated higher repair costs are prioritized for replacement.

Hydro One's transmission system includes 293 stations. Hydro One has established a recurring 7-10 year assessment cycle that enables all necessary renewal work to be performed at each of the 293 transmission stations during the cycle. The goal of each asset assessment is to ensure that the assets are not deteriorated, there are no risks that may compromise the reliability of the system, and they do not pose any safety or and/or environmental risk. All assets at a given station are assessed at the same time with a particular focus to transformers, breakers, and protection and control systems – as these are the most critical assets in the system and have a direct impact on a customer. If the assessment identifies multiple station assets (i.e. transformers, breakers and protection and control equipment) whose condition warrants a replacement, Hydro One then pursues an integrated approach. The asset replacements are bundled into a single integrated station-centric investment project with the main components being identified as the driver for the project. This integrated approach is further described in SR-02**.** In the case where only transformers are identified as the main asset for replacement along with a small subset of other minor station assets, the station is identified as a candidate for a transformer-focused replacement project.

As of December 2018, Hydro One has 576 load supply station step-down transformers in service. Currently, 24.4% of the Hydro One load supply station step-down transformer population is beyond ESL. Hydro One defines ESL as the average age in years that an asset can be expected to operate under normal system conditions. The average age of the load supply station transformer fleet is 29 years. Assuming no replacements, Hydro One anticipates that 37.9% of the load supply station transformer population will exceed their ESL by 2024, and 48.6% of the population will exceed their ESL by 2029.

Transformer condition is a leading predictive indicator of equipment reliability and usually the main driver for replacement. Condition is determined by industry standard diagnostic testing which includes routine transformer oil testing and other maintenance examinations. Transformer insulation generally degrades as a function of time and other operational factors (i.e. loading levels) and this degradation is irreversible, ultimately requiring asset replacement. Furthermore, transformer ESL has a direct correlation to anticipated insulation condition. Within the industry, there is correlation between the highly flammable and volatile chemical compound - furan and the degree of polymerization of insulation paper. The degree of polymerization of the paper is an indicator of insulation strength and condition. Furan is a chemical that can be detected via oil samples. Furan is a by-product of paper degradation as it ages and decomposes. Operating a large percentage of the fleet beyond ESL increases system reliability risk as this equipment tends to have a higher probability of failure. Assessment of the load supply station transformer fleet’s condition based on oil analysis results shows that approximately 18% are rated high or very high risk, as illustrated in Figure 1.

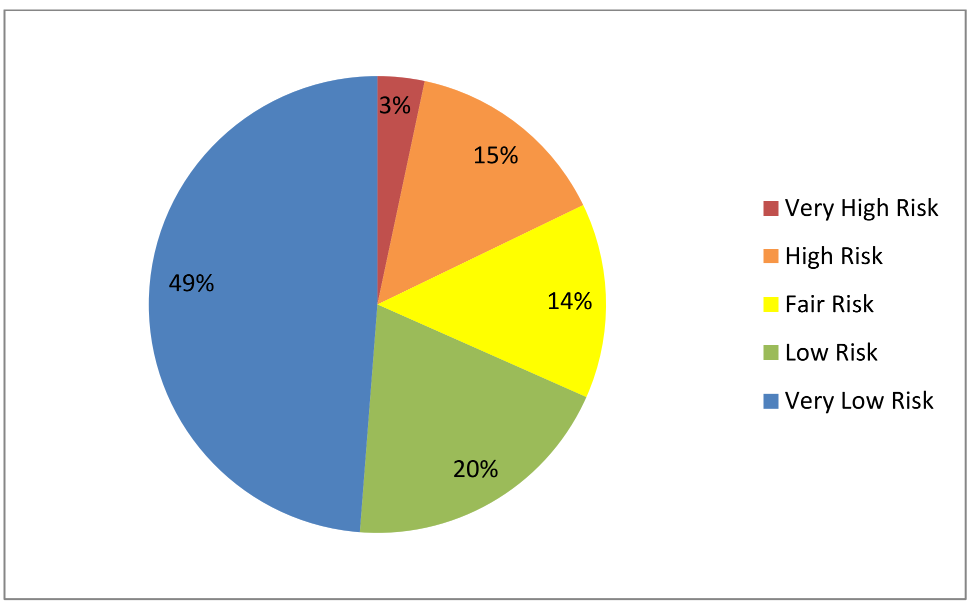

Figure 1 - Condition Summary of Load Supply Station Transformer Fleet

Transformer equipment performance is measured by assessing the duration and frequency of forced outages related to the transformer. A "forced outage" is the automatic or forced manual removal of a transformer caused directly by it or its auxiliary equipment. From a fleet wide perspective, transformer forced outages have been a major cause of customer delivery point interruptions over the past 10 years, representing 13% of these equipment-caused events. Fleet wide, over the last 10 years, Hydro One has experienced an average annual Class 1 failure rate of 0.51%. Class 1 failures are unpredictable, catastrophic and irreparable. An example is the 2011 Richview T7 and T8 failures, where both transformers were engulfed in fire. The smoke that it produced severely impaired traffic on Highway 401 during rush hour. Table 1 below summarizes the number of Class 1 failures by voltage class.

Table 1 - Transformer Annual Class 1 Failure Rates over the Past 10 Years (2008-2017) in Percentage of Transformer Population

Year	115kV	230kV	500kV	5 Year Average Annual Failure Rate, All Voltage classes
2008-2012	0.40%	0.37%	1.41%	0.44%
2013-2017	0.56%	0.41%	2.44%	0.59%
10 Year Average Annual Failure Rate	0.48%	0.39%	1.92%	0.51%

Regarding oil leaks, approximately 42% of the load supply transformer fleet has confirmed oil leaks via visual inspections, with 11% classified as major leakers as summarized in Figure 2 below. Based on Hydro One's experience, new leaks will appear in approximately 1% of the fleet's population per year, most commonly as a result of gasket deterioration over time. Transformer leaks not only create environmental concerns, but also generate reliability issues, as in-service transformers may be forced out due to low oil levels. Active leaks also provide a path of moisture ingress into the transformer's internal winding. Finally, severe oil leaks and frequent oil top ups also compromise the accuracy of condition assessments because they dilute the oil and may result in a false improved oil test result.

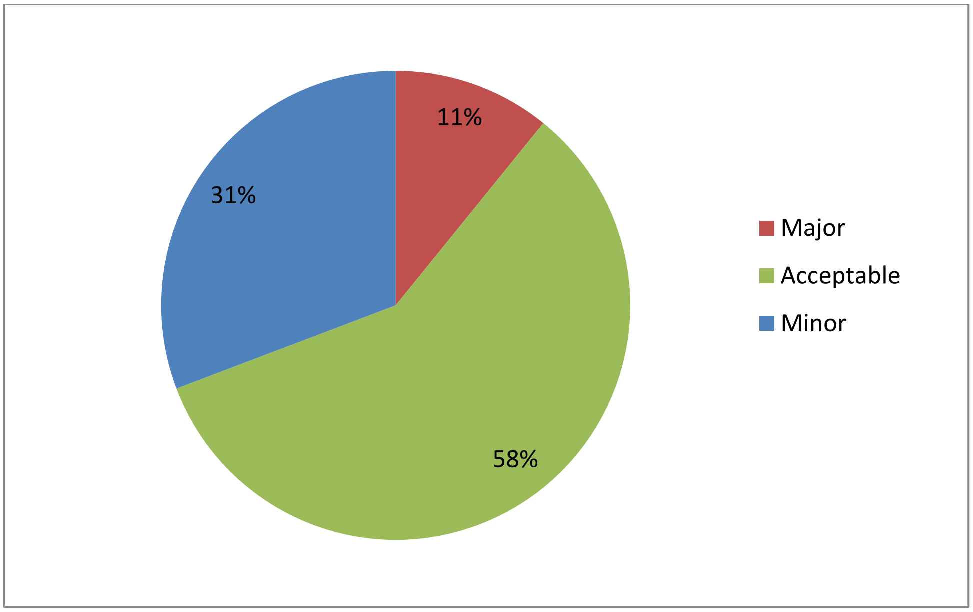

Figure 2 - Load Station Transformer Leak Assessment

Furthermore, the Polychlorinated Biphenyl (“PCB”) Regulations, which came into effect in 2008, and for which amendments came into force on January 1, 2015, implemented deadlines on equipment already in use and in storage, in order to accelerate the elimination of PCBs from the Canadian environment. The PCB Regulations require all oil-filled equipment to contain PCB levels of less than 50 parts per million (“ppm”) by December 31, 2025. The PCB Regulations impact transformer oil filled bushings. From a fleet wide perspective, as of December 2018, up to 43% of Hydro One’s transformer oil-filled bushings may require work related to PCB testing verification or replacements. When high PCB levels are present in a transformer approaching end of life (“EOL”), it may be more economical to slightly advance replacement than to make repairs to resolve high PCB levels on a unit near EOL.

With regards to failure risk, under normal operating conditions, failure of one step-down power transformer at a load supply station will usually not result in load interruptions due to the redundant nature of the load supply station’s configuration. However, the load supply station would be put into a more vulnerable state for potentially 2-4 months until a replacement step-down power transformer could be installed to restore redundancy (i.e. backup). As a result, there would be an elevated risk to supply reliability while in this vulnerable state of lost redundancy (i.e. lost backup). Furthermore, at many load supply stations, a significant proportion of load may be ‘stranded’, or unable to be easily supplied from another station, if necessary. Consequently, loss of a step-down transformer combined with stranded load at a station would further heighten vulnerability and reliability risk. During this state of vulnerability, if the remaining companion step-down transformer were to be removed from service due to other power system issues, such as a high voltage line outage, momentary to lengthy load interruptions would result depending on the issue. If the remaining companion step-down transformer itself were to fail during this state of vulnerability, it is possible that stranded load could remain unsupplied for an extended time until another feasible emergency measure is implemented. Generally, if left unattended, the Hydro One load supply station step-down transformer fleet will continue to degrade and the fleet demographic with transformers that are in a high or very high risk state will continue to increase, thereby resulting in more frequent and unexpected failures.

Investment Description

The Project is classified primarily as a transformer replacement project. The Project involves a series of individual projects that target a like-for-like replacement of deteriorated load supply power transformers at various load supply transformer stations. The Project also addresses replacements of select breakers, protection and control systems, switches, batteries, chargers, instrument transformers and may additionally address site or property issues, customer issues, safety concerns, environmental compliance, and operational issues.

Hydro One's plan for the transformer fleet replacement over the next five years has been influenced by fleet demographics, observed condition, anticipated condition, and performance factors as well as environmental and safety concerns, as described above. Cumulatively, the Project targets the replacement of 74 transformers, 143 breakers, and 591 protection systems over the five year period at 40 stations, as further detailed in Appendix "A" below.

Outcome

As a result of the Project, Hydro One will reduce operational risks (e.g. local area supply risk, momentary/extended load interruption risk) associated with the operation of end-of-life equipment; ensure compliance with government and industry regulations; maintain long-term supply reliability to downstream customers; and mitigate the risk of local area outages.

The following table presents anticipated benefits as a result of the Project in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Maintain long-term supply reliability to downstream customers through the replacement of end-of-life equipment.
Operational Effectiveness	• Maintain operational flexibility of the load supply electricity system through the replacement of end-of-life equipment.
Public Policy Responsiveness	• Comply with applicable regulatory and environmental requirements
Financial Performance	• Realize cost savings by addressing multiple deteriorated assets within the station as part of the same project.

C. EXPENDITURE PLAN

As discussed above, the Project is needed to replace load supply power transformers as well as other load supply station assets that may compromise the reliability of supply due to the assets being deteriorated and at EOL, which may lead to unexpected failures.

Hydro One has planned the Project in a way that strives to complete it as effectively and efficiently as possible so as to minimize the cost.

Table 2 summarizes historical and projected spending on the aggregate project level. Since the Project consists of multiple projects, as presented in Appendix "A", Table 2 below consolidates all the costs for individual projects and presents the total Project costs. The "Previous Years" costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 test year. Likewise, the costs noted in "Forecast 2025+" are project costs forecast beyond 2024.

Table 2 - Total Investment Cost

($ Millions)	**Prev. Years**	**2020**	**2021**	**2022**	**2023**	**2024**	**Forecast 2025+**	**Total**
Capital[1] and Minor Fixed Assets	91.1	94.0	136.4	133.4	184.0	206.2	67.0	912.0

Furthermore, the following factors also affect the capital expenditures required for the Project:

- Applicability of government and industry regulations:
  - When a transformer is replaced, there are requirements from the Ministry of the Environment, Conservation and Parks ("MOECP") for spill containment and oil/water separators to mitigate the risk to the environment if oil is spilled.
  - PCB compliance regulations established by Environment Canada drive the cost analysis of whether to retro-fill (refill) oil equipment or replace the PCB affected equipment. The Operations, Maintenance and Administration ("OM&A") cost to retro-fill the main tank on a power transformer is not deemed prudent for units approaching or beyond their ESL given the increased likelihood of failure. The preference is to proceed with a capital replacement due to the reduced rate impact and future benefit and reliability a new unit would provide.

- Complexity of project staging and outages required to facilitate work:
  - Increase planning costs portion of the project.

    - Increases overall duration of project (interest and overhead costs increases).

- Whether like-for-like replacements are installed in a new location or installed in-situ requires complex contingency planning:
    - New location will require additional facilities to be installed to connect the equipment rather than re-using existing facilities (i.e. bus work and supporting structures/foundations), increases cost.
    - Contingency planning can increase cost by requiring backup transformer installations, temporary supplies, etc.

- Site conditions and challenges:
    - Urban areas have many constraints such as outage planning, construction staging and contingency planning which could add to project duration and complexity and result in higher costs (e.g. working in space-constrained stations; work within neighborhoods where streets are congested and working hours may be constrained due to noise requirements; unique design and construction challenges; outage constraints as service still needs to be maintained amidst the required work).
    - Remote rural areas will increase costs due to difficulty of working on difficult terrain, difficulty accessing the station with heavy equipment, delivery of large equipment, etc.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: Reactive Component Replacement involves waiting for deteriorated condition transformers, breakers, or ancillary equipment to fail and replace components on a reactive basis. This alternative is more costly not only for Hydro One but also for impacted customers. Hydro One has rejected this alternative for the following reasons:

- Assets in deteriorated condition will continue to deteriorate and decline, thereby increasing the likelihood of unexpected failures. These failures might be prolonged and might result in extended equipment and customer outages which will subsequently lower System Average Interruption Duration Index and System Average Interruption Frequency Index performance.
- An increased likelihood of unexpected failures would lead to increased environmental risk due to the possibility of a release into the environment during a failure event.
- An increased likelihood of unexpected failures would lead to increased safety risk due to the possibility of a failure event being catastrophic in nature.
- Since these replacements would likely be executed on an emergency basis, it would constantly result in the reprioritization of planned work and inefficient redeployment of resources.
- This alternative limits the ability to account for future requirements and has a high risk of re-work and future costs.
- This strategy is likely to increase OM&A costs, decrease equipment performance and might impact the safety of personnel on site.

Alternative 2: Station Refurbishment involves the refurbishment of the entire station where significant populations of assets are in a high risk condition, before failure occurs. This alternative is only a viable solution where the other key station assets, such as transformers and switching facilities are in a deteriorated, high risk condition. This alternative has been considered for the Project and has been rejected as there is insufficient justification to proceed with a complete station refurbishment. Hydro One does not replace the transmission assets unless the asset condition or other factors warrants the replacement. Where the majority of assets are EOL, this alternative may then be considered, but then the project would fall under the SR-2.

Alternative 3: Like-for-Like Planned Replacement is a preferred undertaking. It involves proactively replacing individual station components in a single integrated investment, with transformers being the primary project driver and additional station assets such as switchgear and ancillary equipment being included that have a deteriorated, high risk condition. This alternative is recommended as it addresses the needs identified at the station to maintain the reliability of Hydro One's transmission system in the most cost effective manner, consistent with the findings of the customer engagement process. This alternative focuses on the replacement of select equipment in a like-for-like manner, unless otherwise requested to meet broader system needs.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of load supply station transformer replacement projects are: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges, or regulatory approvals. A thorough risk assessment workshop is performed during the initial project planning phase where all known risks are identified and a mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize the risk of supply loss to the customer. The plan might include the installation of a temporary transformer or supply of portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages. Another example is the involvement of real estate from the project inception. It allows for the early identification of real estate issues, such as missing or inadequate land rights. Once the issue is identified, Hydro One tries to resolve it prior to execution of the project.

1 **APPENDIX A – DETAILED PROJECT PLAN**

Station Name	Scope and Impact	Transformers Replaced	Breakers Replaced	Protections Replaced	In Service Year
Hawthorne TS	This investment will replace two end-of-life power transformers, three 500kV circuit breakers, and associated protections, controls and telecom facilities. These facilities now require replacement to prevent further equipment condition deterioration and to address the increased risks of equipment failures. The station transforms 230kV into 44 kV and supplies approximately 70MW to Hydro Ottawa Limited, and failure of these assets would adversely affect Hydro Ottawa customers and supply capability to the Ottawa area.	2	3	4	2020
Strachan TS	This investment will replace the deteriorated, EOL T12 transformer and other end-of-life station assets and infrastructure including switches, surge arrestors, site drainage, protection equipment and potential transformers. Failure of these assets would adversely impact the reliability of supply to Toronto Hydro customers. In addition, at the request of Toronto Hydro to meet future supply demand, the T12 transformer will be replaced with a larger standard Hydro One unit. The T12 power transformer has confirmed PCB contamination in its high voltage bushings. This investment will replace end-of-life equipment, meet the customer's request for increased capacity and maintain the reliability of supply.	1	0	12	2020
Stanley TS	The following equipment at Stanley TS is obsolete, at EOL and in degraded condition requiring replacement; transformer T2, medium voltage switching facilities and associated protection and control equipment. Replacing the equipment identified will maintain supply reliability to Niagara Peninsula Energy Inc. and decrease risk of equipment failure.	1	8	41	2021
Minden TS	Replace T1 and T2 transformers at Minden TS which is somewhat remotely located with challenging ground conditions. T1 and T2 are identified for replacement due to leak points on older units and signs of insulation degradation. In addition, the 44kV switchyard will be rebuilt including the associated protection & control equipment. The 44kV switchyard is a legacy structure that requires expanded outage zones to complete maintenance or reconstruction activities. The AC station service equipment and eleven end-of-life 230kV disconnects will also be replaced. These replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to Hydro One Distribution customers in the Minden area.	2	0	8	2021

Station Name	Scope and Impact	Transformers Replaced	Breakers Replaced	Protections Replaced	In Service Year
Main TS	Replace T3 & T4 transformers at Main TS which is a space-constrained urban station located in Toronto. T3 was identified for end-of-life replacement due to leaks, overheating and a rising dissolved gas trend indicating internal degradation. T4, which is beyond expected service life, is currently planned for replacement due to a customer request for increased station capacity. In addition, ancillary equipment such as switches and minor instrument transformers are also identified for replacement. These replacements will decrease the risk of equipment failure, increase station capacity as per a customer request, and contribute to maintaining supply reliability to downtown Toronto Hydro customers.	2	0	0	2021
King Edward TS	King Edward TS is a major load centre for the Ottawa area serving ~80MW of customer load with projected load growth to ~100MW. Hydro Ottawa has requested transformer T3 be upgraded to 100MVA. By 2021, T3 will be replaced along with EOL protections and batteries in order to maintain the reliability of supply to Hydro Ottawa Limited. Not proceeding with this work could increase the risk of equipment failure resulting in higher delivery point interruptions.	1	8	21	2021
Hanlon TS	T1 and T2 supply Guelph Hydro with approximately 22 MW and are to be replaced in order to maintain equipment reliability and long term reliability of supply. These units are in a degraded condition and are at EOL. All the associated obsolete protection and control facilities are also to be replaced. EOL AC and DC station services are also to be addressed in this investment to ensure reliable performance for station equipment.	2	0	27	2022
Wingham TS	This investment is driven by the need to replace a number of assets that are near EOL at Wingham TS. The main assets driving this investment are power transformers T1 and T2, and 15 equipment protections. This investment will maintain the reliability of supply to Hydro One Distribution customers in the Wingham area.	2	0	15	2022
Kingsville TS	This investment will replace transformers T1, and T3 with a new 83 MVA 115/28kv transformers as transformers T1, T2 and T4 are at EOL. T2 and T4 were replaced in 2018 due to their failing condition leading to a more immediate need for replacement. In addition, six oil circuit breakers in the 27.6kV switchyard will be replaced as well as other minor components such as insulators, AC and DC station service equipment and protection & control equipment. These replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to customers in the Kingsville area.	2	6	25	2022

Station Name	Scope and Impact	Transformers Replaced	Breakers Replaced	Protections Replaced	In Service Year
Thorold TS	The following equipment at Thorold TS is at EOL, in degraded condition and requires replacement: transformer T1, non-arc proof metalclad medium voltage switchgear, and all associated protection and control equipment. Replacing the equipment identified will maintain supply reliability in the Thorold area, decrease the risk of equipment failure and address safety risk posed by medium voltage switchgear.	1	12	33	2022
Stratford TS	This investment will replace the end of life transformer T1 at Stratford TS. The transformer is will be operating past ESL in 2020 and has major oil leaks requiring significant effort to repair. The driver for this replacement is the need for leak reduction work and other preventative maintenance activities.	1	0	0	2023
Cedar TS	This investment will replace the end of life transformer T7 and T8 at Cedar TS. Both units are operating beyond their expected service life and oil tests have shown that they are in poor condition. Replacing these units will maintain supply reliability to load customers in the Guelph area.	2	0	0	2023
Crowland TS	Transformers T5 and T6 have been identified for replacement due to various factors including condition, performance and expected service life. The replacement of T5 and T6 transformers will ensure reliability of supply to customer Welland Hydro.	2	0	4	2023
Murray TS	Based on preliminary assessment, the following equipment at Murray TS has been identified as EOL, obsolete and requiring replacement; transformer T14, Y1Y2 non-arc proof medium voltage metalclad switching facilities, associated protection and control equipment. Replacing the equipment identified above in a single integrated investment will maintain supply reliability to Niagara Peninsula Energy Inc., and Hydro One Distribution customers along with decrease risk of equipment failure.	1	9	68	2023

Station Name	Scope and Impact	Transformers Replaced	Breakers Replaced	Protections Replaced	In Service Year
Orangeville TS	Replace EOL, non-standard T1 and T2 transformers at Orangeville TS due to significant leaks on these older units and their declining condition leading to reliability and environmental concerns. In addition, replace Orangeville T3 & T4 units, which are relatively advanced in age, to facilitate the optimal replacement all four transformers (T1, T2, T3, & T4) with standard transformers while maintaining existing capacity. This replacement strategy delivers reliability, spares/inventory, and financial advantages by avoiding the purchase of custom transformers and avoiding the need to purchase a dedicated custom spare transformer. In addition, select switchgear, instrument transformers, and protection & control equipment have been identified for replacement. This replacement plan will decrease the risk of equipment failure and contribute to maintaining supply reliability to Orangeville Hydro and Hydro One Distribution customers in the Orangeville area.	4	2	12	2023
Bridgman TS	Replace T11, T12, T13, and T14 transformers at Bridgman TS which is a space-constrained urban station located in Toronto. These transformers were identified for replacement due to oil leaks and internal insulation degradation. Spill containment for all four units is not up to current standards and presents an environmental risk. In addition, other end-of-life ancillary equipment such as switches, insulators, instrument transformers and other minor assets & infrastructure are also identified for replacement. These replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to midtown Toronto Hydro customers.	4	0	0	2023
Parry Sound TS	This investment is driven by the need to replace assets that are near EOL at Parry Sound TS. The main assets driving this investment are power transformer T1 and T2, equipment protections and DC station service. Other asset replacements and upgrades have been incorporated into this investment. This investment will maintain the reliability of supply to Hydro One Distribution customers in the Parry Sound area.	2	0	0	2023
Moose Lake TS	This investment is driven by the need to replace a number of assets that are near EOL at Moose Lake TS. The main assets driving this investment are power transformers T2 and T3, two medium voltage circuit breakers and 31 equipment protections. This investment will maintain the reliability of supply to Atikokan Hydro Inc.	2	2	27	2023

Station Name	Scope and Impact	Transformers Replaced	Breakers Replaced	Protections Replaced	In Service Year
Lauzon TS	Based on field testing the T6 and T8 autotransformers are verified to be deteriorating and are to be replaced to maintain the long term reliability of supply to Hydro One Distribution and EnWin Utilities in the Tecumseh and Windsor areas. Two low voltage circuit breakers are in a degraded condition and an additional breaker has high levels of PCBs. These breakers are to be replaced to maintain equipment reliability, minimize unplanned outages and to comply with regulatory requirements. Two additional high voltage breakers are in a degraded condition and also exhibiting high levels of PCBs. These will also be replaced to maintain the reliability of supply. Additionally, all associated and obsolete protection and control systems are to be replaced to minimize the risk of unplanned equipment outages.	2	5	36	2024
Port Hope TS	Based on field reports, transformers T3 and T4 are in degraded condition, are leaking oil and have tap-changer issues. This investment consists of replacing existing units in order to prevent equipment failure and maintain reliability to Hydro One Distribution customers.	2	0	0	2024
Longueil TS	The transformers at Longueil TS are at EOL and in degraded condition. This investment will replace the following; T3 and T4 transformers, and associated protection and control equipment. This investment will maintain reliability of supply to Hydro One Distribution customers and decrease risk of equipment failure	2	0	0	2024
Clarke TS	T3 and T4 supply London Hydro with approximately 60 MW and are to be replaced in order to maintain equipment and long term reliability of supply. These units are in a degraded condition and at EOL. Three low voltages circuit breakers are also in a degraded condition and are to be replaced to minimize the risk of customer interruptions. All the associated obsolete protection and control facilities are also to be replaced together with the identified equipment.	2	0	0	2025
Preston TS	Preston TS is a major load centre for Cambridge area serving ~90MW of customer load. Preston TS transformers T3 and T4 are operating beyond ESL and are in poor condition. The station has 6 Programmable Auxiliary Logic Controller (“PALC”) relays that have been identified with a high failure rate in the HONI system. By 2025, the solid-state relays would have been in-service for ~35 years. It also contains first vintage of microprocessor relays due for replacement. Not proceeding with this work could increase the risk of equipment failure resulting in higher delivery point interruptions. The replacement of these EOL protections is required to maintain the reliability of supply to Energy+ Inc.	2	0	31	2025

Station Name	Scope and Impact	Transformers Replaced	Breakers Replaced	Protections Replaced	In Service Year
Birmingham TS	This investment will address the following EOL equipment; transformer T1, non-arc proof metalclad medium voltage switchgear comprising of six buses and nineteen breakers, poor performing line and ground switches, associated protection and control, AC and DC station service, and two station service transformers. Replacing the equipment identified will maintain supply reliability to Alectra Utilities and an embedded customer Air Liquide. In addition, replacing the equipment identified will decrease the risk of equipment failure and address the safety risk posed by existing medium voltage switchgear.	1	21	28	2025
Newton TS	Based on demographic, condition, environmental hazards, equipment loading and economic data, transformers T1 and T2 are to be replaced under this investment to ensure supply reliability to Alectra Utilities is maintained.	2	0	4	2025
Palermo TS	The following equipment at Palermo TS is obsolete, at EOL, and in degraded condition requiring replacement; transformers T3 and T4, medium voltage oil circuit breakers, and ancillary equipment including the station service transformer and transfer scheme. Replacing the equipment identified above in a single integrated investment will maintain supply reliability to Burlington Hydro, Oakville Hydro and Hydro One Distribution customers, and decrease risk of equipment failure.	2	11	0	2025
Gage TS	Transformers T8 and T9 have been identified for replacement based on preliminary assessment data. The replacement of T8 and T9 transformers will ensure reliability of supply to customer Alectra Utilities.	2	0	8	2025
Bermondsey TS	This investment will result in the replacement of the EOL T3 and T4 Transformers and other EOL station assets and infrastructure including low voltage circuit breakers. Failure of these assets would adversely impact the reliability of supply to Toronto Hydro customers. This investment will result in improved overall station reliability and eliminating operational risks associated with operating EOL equipment, and will preserve reliability to the load customers in the GTA.	2	7	0	2025

Station Name	Scope and Impact	Transformers Replaced	Breakers Replaced	Protections Replaced	In Service Year
Leslie TS	Preliminary assessments have identified T1 230-28-14kV step-down transformer at Leslie TS for replacement with a standard unit. The transformer has two secondary windings supplying 27.6kV and 13.8KV. Toronto Hydro has stated that they plan on decommissioning the 13.8KV bus at this station within the next five years and T1 should only be replaced after this occurs. In addition, a select number of circuit breakers and a significant number of protections require replacement to address end-of-life condition and obsolescence. Coordination with Toronto Hydro is required for this project as they are the owner of the majority of feeder breakers and feeder protections at this station. These replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to local area Toronto Hydro and Alectra Utilities customers.	1	8	48	2025
Wilson TS	Preliminary assessments have identified T1, and T2 for replacement at Wilson TS, an urban station located in Oshawa, due to declining condition. In addition, select switchgear and a significant number of protections require replacement to address EOL condition and obsolescence. These replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to local area Oshawa PUC and Hydro One Distribution customers.	2	13	40	2025
Charles TS	Preliminary assessments have identified T3 and T4 for replacement at Charles TS, a space-constrained urban station located in downtown Toronto, due to declining condition. As well, Toronto Hydro may request that T3 and T4 transformers be replaced with larger units to accommodate future loading and operating considerations. In addition four low voltage circuit breakers and a significant number of protections require replacement to address EOL condition and obsolescence. These replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to Toronto Hydro customers.	2	4	31	2025
Duplex TS	This investment will result in the replacement of the end-of-life T1, T2, T3 and T4 step-down transformers that have been displaying condition issues and other EOL station assets and infrastructure including spill containments, disconnect switches and protection equipment. Failure of these assets would adversely impact the reliability of supply to Toronto Hydro ("THESL") customers in the City of Toronto. In addition, THESL may request these transformers to be replaced with larger standard units in order to meet future supply demand. This investment will replace EOL equipment, eliminate PCB contaminated equipment in the station in order to comply with environmental regulations and will preserve reliability to customers in the GTA.	4	0	12	2025

Station Name	Scope and Impact	Transformers Replaced	Breakers Replaced	Protections Replaced	In Service Year
Woodbridge TS	This investment will result in replacement of the deteriorated, end-of-life T5 transformer that has been displaying condition issues. In addition, other station assets and infrastructures including spill containments, surge arresters and neutralizing transformers require replacement to address end-of-life condition and obsolescence. This investment will decrease the risk of equipment failure and contribute to maintaining supply reliability to Alectra Utilities and Hydro One Distribution customers in the north GTA.	1	0	0	2025
Bathurst TS	This investment will result in the replacement of the end-of-life T3 step-down transformer that has been displaying condition issues. In addition, a select number of circuit breakers and other station components such as surge arresters require replacement to address end-of-life condition and obsolescence. Failure of these assets would adversely impact the reliability of supply to Toronto Hydro customers in the City of Toronto. Coordination with Toronto Hydro is required for this project as they are the owner of feeder breakers and feeder protections at this station. This investment will decrease the risk of equipment failure and contribute to maintaining supply reliability to Toronto Hydro customers.	1	7	0	2025
Strachan TS	This investment will replace the EOL T13 & T14 transformers and associated end-of-life station assets and infrastructure including surge arrestors, and protection equipment. Failure of these assets would adversely impact the reliability of supply to Toronto Hydro customers.	2	0	8	2025
Wallace TS	The following equipment at Wallace TS is at EOL, in degraded condition and requires replacement; T3 and T4 power transformers, oil circuit breakers, and associated protection and control equipment. Replacing them will maintain reliability of supply to Hydro One Distribution customers in eastern Ontario and decrease the risk of equipment failure.	2	3	1	2025
Bilberry Creek TS	This investment is driven by the need to replace T1 and T2 transformers which they are at their EOL. Associated Surge arresters and protections also will be replaced under this investment.	2	0	3	2025
Russell TS	This investment is driven by the need to replace T2 transformer which it is at EOL. Associated Surge arrester and protections also will be replaced under this investment.	1	6	0	2025

Station Name	Scope and Impact	Transformers Replaced	Breakers Replaced	Protections Replaced	In Service Year
Elliot Lake TS	This investment is driven by the need to replace a number of assets that are near EOL at Elliot Lake TS. The main assets driving this investment are power transformers T1 and T2, a medium voltage circuit breaker and associated protections. The option to eliminate one of the three transformers will be evaluated during the estimating stage of the investment. This investment will maintain the reliability of supply to Hydro One Distribution customers in the Elliot Lake area.	2	2	10	2025
Fairchild TS	A preliminary assessment has identified the T1 transformer at Fairchild TS for eventual replacement as unit condition is beginning to decline. In addition, a select number of circuit breakers and a significant number of protections require replacement as they are at end-of-life or obsolete. Coordination with Toronto Hydro is required for this project as they are the owner of the majority of feeder breakers and feeder protections at this station. These replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to local area Toronto Hydro and Alectra Utilities customers.	1	6	34	2026

SR-06 Load Station Switchgear and Ancillary Equipment Replacement Projects

Start Date:	Q3 2017	**Priority:**	Medium
In-Service Date:	Q2 2026	**3 Year Test Period Cost ($M):**	97.5
Trigger(s):	System Renewal		
Outcomes:	Ensure compliance, system reliability, customer satisfaction, operational efficiencies and reduce maintenance costs		

A. OVERVIEW

Load Supply Station Switchgear and Ancillary Equipment Replacement Projects (the "Projects") are primarily switchgear replacement projects that involve the replacement of load supply station circuit breakers, which include circuit breakers operating between a nominal voltage of 12 kV and 44 kV and can be oil, vacuum, metalclad, Gas Insulated Switchgear ("GIS") or Sulfur Hexafluoride ("SF6") type, that are at the end of their life and whose condition has been rated as high or very high risk in accordance with the asset risk assessment. The Project might also involve the replacement of ancillary equipment (e.g. AC and DC station service equipment, disconnect switches, instrument transformers, etc.) where needed. Prior to replacement, Hydro One will perform the asset risk assessment to ensure that these assets are also at the end of their life and their condition and other factors warrant the replacement.

Load supply stations step down power flow from higher voltages to lower voltages to facilitate the distribution of power via the downstream distribution network. The main Hydro One customers at the load supply stations are LDCs and large industrial customers. The LDCs that are served by Hydro One's transmission system serve most of Ontario's residential, commercial, institutional and small industrial end-users. The end-user facilities that are indirectly affected by the reliability and performance of Hydro One's transmission system include such critical infrastructure as telecommunications systems, water and wastewater treatment facilities, hospitals and other health care facilities, airports and transportation systems, schools and universities, and financial services systems. In light of the foregoing, it is apparent that there is a heightened need to ensure that this critical asset of load supply stations is in good condition and performs reliably.

The Project pacing has been influenced by the assessment of equipment condition and in consideration of operational effectiveness, customer preferences, and safety concerns. Based on Hydro One's load supply station breaker demographic profile, it is forecasted an increasing number of units will age beyond expected service life ("ESL") within the next five years. Operating a large percentage of the fleet beyond ESL increases system reliability risk as this equipment tends to have a higher probability of failure. Consequently, Hydro One plans to manage this anticipated risk by undertaking the Project.

Hydro One has evaluated various alternatives for the Project, as described below, and concluded that replacing the deteriorated load supply station breakers is the most cost effective and efficient undertaking. The projected costs of the Project are estimated to be $97.5 million over the 2020-2022 test period.

B. NEEDS AND OUTCOME

Investment Need

Hydro One's asset strategy is to proactively inspect and monitor the breaker fleet. This allows Hydro One to manage maintenance needs and assess the breaker's associated risk to determine the need for asset replacement. Assessments to repair or replace breakers are done on an individual basis. The assessment is based on risks identified from demographics, condition, environmental factors, utilization, performance, obsolescence, costs comparison between refurbishment and replacement, and other lifecycle considerations.

Hydro One's transmission system includes 293 stations. Hydro One has established a recurring 7-10 year assessment cycle that enables all necessary renewal work to be performed at each of the 293 transmission stations during the cycle. The goal of each asset assessment is to ensure that the assets are not deteriorated, there are no risks that may compromise the reliability of the system, and they do not pose any safety or and/or environmental risk. All assets at a given station are assessed at the same time with a particular focus to transformers, breakers, and protection & control systems – as these are the most critical assets in the system and have a direct impact on a customer. If the assessment identifies multiple key station assets (i.e. transformers, breakers, protection and control equipment) whose risk warrants a replacement, Hydro One then pursues an integrated approach. The asset replacements are bundled into a single integrated station-centric investment project with the main components being identified as the driver for the project. This integrated approach is further described in SR-02**.** In the case where only the breakers are identified as the main asset for replacement along with a small subset of other minor station assets, the station is identified as a candidate for a breaker-focused replacement project.

As of December 2018, Hydro One has 3,205 load supply station breakers in service. Currently, 9% of Hydro One load supply station breaker population is beyond their ESL. Hydro One defines ESL as the average age in years that an asset can be expected to operate under normal system conditions. Assuming no replacement, Hydro One anticipates that 568 units (18% of the load supply station breaker population) will exceed their ESL by 2024, and 994 units (31% of the population) will exceed their ESL by 2029.

Asset condition is one of several drivers for breaker replacement. Breaker condition is monitored through information gathered during preventative inspection and maintenance activities. Hydro One performs routine maintenance and replaces breakers that are obsolete, pose safety risks, operate at or above their nameplate rating, have unacceptable performance and have a poor environmental footprint. Poor performance is judged based upon the likelihood of the equipment contributing to load interrupted or unsupplied energy to the customer. Poor environmental footprint is judged based on Polychlorinated Biphenyl ("PCB") levels in excess of legislated requirements. The following issues are examples that have been observed by Hydro One as part of its breaker risk assessment that warrants the replacement of the breakers that are the subject of the Project:

- As breakers age their O-rings and gaskets slowly degrade, thereby causing leaks. The leaks will result in a lower pressure and a path for moisture ingress. This condition over time can result in lower dielectric strength in the breaker and potential for internal flashover which could result in an explosive failure of the breaker.
- Some of the Hydro One fleet of breakers are no longer supported by vendors and aftermarket parts are no longer available or are costly to acquire or fabricate. This is a significant risk factor to some first generation SF6 circuit breakers and certain types of oil circuit breakers. Strategic sparing of breakers is done through replacements where parts are difficult to procure such that removal can help sustain the remaining in service fleet.

The assessment of the load supply station breaker fleet, as of December 2018, shows that 10% of the load supply station breakers are rated at a high or very high risk, as illustrated in Figure 1.

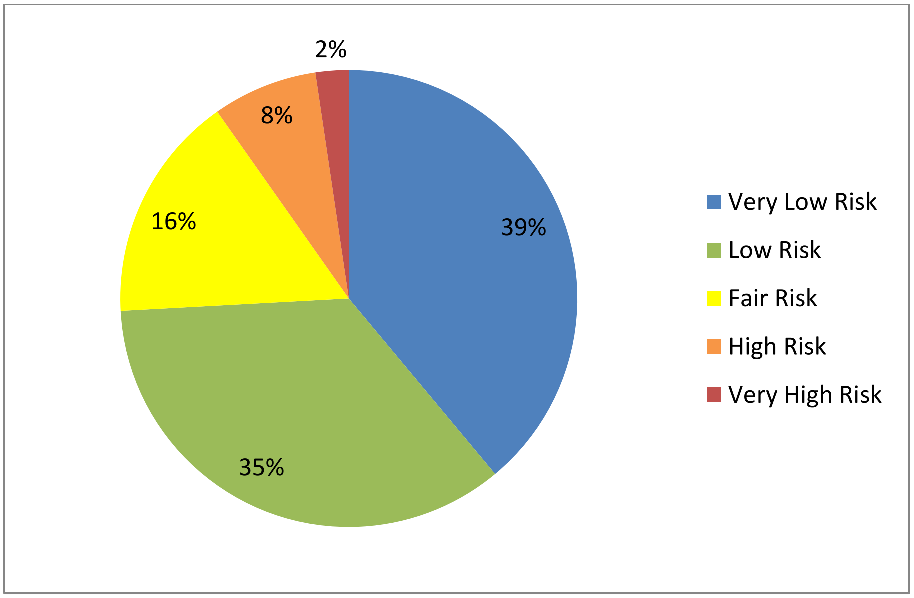

Figure 1 - Summary of Risk Assessment for Load Supply Station Circuit Breakers

Operating a large percentage of the fleet beyond ESL increases system reliability risk as this equipment tends to have a higher probability of failure. When unexpected failure occurs, it could partially or entirely interrupt power flow to load customers as well as constrain embedded generation on the distribution network connected to the load supply station. For the majority of load supply stations, load is considered "stranded" (load that cannot be transferred to an alternate supply without some sort of emergency bypass work, for example, the connection of a mobile substation unit.). Unexpected failures at these stations would result in interruptions to customer delivery points with significant durations. Failures can be catastrophic or the asset could be failing to do what it is intended to do (e.g. breakers can fail to operate/open when needed, i.e. as it is intended to, or they can have insulation failure leading to internal arcing during operation, causing irreparable damage, i.e. catastrophic failure). Furthermore, what complicates the situation is when a certain type of breaker approaches the end of its ESL, vendors often communicate their transition to a limited support and complete obsolescence of aged product lines. As such, it is important to stay on top of this wave of assets approaching

ESL in order to avoid situations where it may become difficult to obtain parts to sustain breakers that vendors no longer support.

Breaker equipment performance is measured by assessing the duration and frequency of forced outages related to the breaker. A “forced outage” is the automatic or forced manual removal of a breaker caused directly by it or its auxiliary equipment.

Furthermore, the PCB Regulations, which came into effect in 2008, and for which amendments came into force on January 1, 2015, implemented deadlines on equipment already in use and in storage, in order to accelerate the elimination of PCBs from the Canadian environment. The PCB Regulations require all oil-filled equipment to contain PCBs less than 50 parts per million (ppm) by December 31, 2025. These requirements impact breaker oil filled bushings and the oil in the main breaker tank. It is estimated that approximately 528 breakers require PCB mitigation, which entails replacing or retro-filling the bushing (i.e., putting in new PCB free oil to bring the PCB ppm value lower). To date, Hydro One has sampled 779 breakers, with another 168 breakers being projected to contain high PCB content once sampled. This projection is based on the rate at which Hydro One has been finding high PCB concentrations in the equipment sampled to date. Using a repair vs. replace analysis, circuit breaker failures that are repairable may be considered for replacement under this program since if there is confirmed PCB content greater than the 45ppm Hydro One set limit, additional costs for the PCB mitigation will also be taken into consideration in addition to the required corrective repairs as a result of the failure.

Breaker failure could partially or entirely constrain generation resources and would lessen the reliability of supply to load customers. If left unattended, Hydro One load supply station breaker fleet will continue to degrade and the fleet demographic with breakers that are in poor or very poor condition will continue to increase, thereby resulting in more frequent and unexpected failures.

Figure 2 below shows the forecast of Hydro One load supply breaker fleet with breakers reaching their ESL.

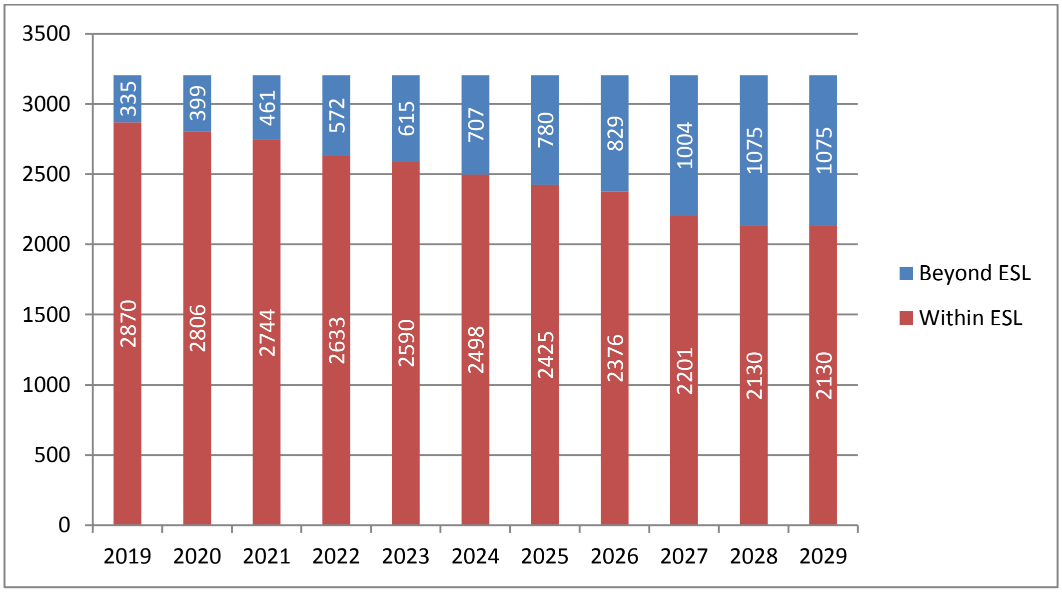

Figure 2: Load Supply Station Class Circuit Breaker Demographic Forecast – without replacement

Breaker failures can severely impact system stability, other connected equipment and employee and public safety. Consequently, it is important to ensure that the current carrying components are in good shape, the mechanical and control systems are operating within specification and that the insulating medium has not been compromised.

Investment Description

The Project is classified as primarily a breaker replacement project. This investment will result in the replacement of switchgear and ancillary equipment at load supply stations that are in a deteriorated, high risk condition where the likelihood of a failure is high. The Project involves a series of individual projects which vary in scope and in size. The Project targets a like-for-like replacement of deteriorated load supply station breakers at various load supply stations. It also addresses the replacements of select ancillary equipment such as switches, batteries, chargers as well as may additionally address site or property issues, customer issues, safety concerns, environmental compliance, and operational issues whose condition might also warrant the replacement.

Hydro One's plan for the breaker fleet replacement over the next five years has been influenced by fleet demographics, observed condition, anticipated condition, and performance factors as well as environmental concerns, as described above. Cumulatively, the Project targets the replacement of 223 breakers over the five year period at 20 stations. Further details pertaining to the Project are provided in Appendix "A" below.

Outcome

As a result of the Project, Hydro One will reduce operational risks (e.g. bottled generation, reduced transfer capability, restricted power flows) associated with the operation of EOL equipment; ensure compliance with North American Electric Reliability Corporation ("NERC") and Northeast Power Coordinating Council ("NPCC") requirements as well as PCB Regulations; maintain long-term reliability of import/export capacity on select transmission interties; and mitigate the risk of constraining generation resources.

The following table presents anticipated benefits as a result of the Project in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Maintain reliable performance of load supply to customers through the replacement of EOL equipment.
Operational Effectiveness	• Improve the operational effectiveness of load supply stations through standardization of new equipment.
Public Policy Responsiveness	• Comply with applicable regulatory and environmental requirements.
Financial Performance	• Realize cost savings by addressing multiple deteriorated assets within the station as part of the same project.

C. EXPENDITURE PLAN

As discussed above, the Project is needed to replace the load supply station breakers and ancillary equipment failure of which may compromise the reliability of supply due to the assets being deteriorated and at EOL. Hydro One planned the Project in a way that strives to complete it as effectively and efficiently as possible so to minimize the cost of performing this sustainment task.

Table 1 summarizes historical and projected spending on the aggregate project level. Since the Project consists of a multiple projects, as presented in Appendix “A”, Table 1 below consolidates all the costs for individual projects and presents the total Project costs. The “Previous Years” costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 test year. Likewise, the costs noted in “Forecast 2025+” are project costs forecast beyond 2024.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	33.0	19.5	32.9	48.9	60.2	79.4	33.8	307.6
Less Removals	0.8	0.2	2.1	1.5	1.8	2.4	1.0	9.9

Port Arthur TS #1	0.1	0.5	1.4	9.6	9.5	21.1	23.6	2025
Muskoka TS	0.0	0.3	0.6	1.4	3.5	5.7	7.0	2025
Pleasant TS	0.0	0.1	0.5	0.9	5.8	7.3	16.8	2026
Net Investment Cost	**19.2**	**30.8**	**47.5**	**58.4**	**77.0**	**232.9**	**297.7**	

Furthermore, the following factors also affect the capital expenditures required for the Project:

- Applicability of Ministry of the Environment, Conservation, and Parks, NERC and/or NPCC requirements;
    - PCB compliance regulations established by Environment Canada drive the cost analysis of whether to retro-fill (refill) oil equipment or replace the PCB affected equipment. The Operations, Maintenance and Administration cost to retro-fill the main tank on a circuit breaker is not deemed prudent for units approaching or beyond their ESL given the increased likelihood of failure.

The preference is to proceed with a capital replacement due to the reduced rate impact and future benefit and reliability a new unit would provide.

- Complexity of project staging and outages required to facilitate work:
  - Increase planning costs portion of the project
  - Increases overall duration of project (interest and overhead costs increases).

- Whether like-for-like replacements are installed in a new location or installed in-situ which may require complex contingency planning:
  - New location will require additional facilities to be installed to connect the equipment rather than re-using existing facilities (i.e. bus work and supporting structures/foundations), increases cost
  - Contingency planning can increase cost by requiring bypass installations, temporary supplies and etc.

- Site conditions and challenges:
  - Urban areas will have constraints with outage planning, construction staging and contingency planning which could add to project duration and complexity and result in higher costs (e.g. working in space-constrained stations; work within neighborhoods where streets are congested and working hours may be constrained due to noise requirements; unique design and construction challenges; outage constraints as service still needs to be maintained amidst the required work)

Remote rural areas will increase costs due to difficulty of working on difficult terrain, difficulty accessing the station with heavy equipment, delivery of large equipment and etc.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: Reactive Component Replacement involves waiting for deteriorated breakers or ancillary equipment to fail and replace components on a reactive basis. Hydro One has rejected this alternative for the following reasons:

- Assets in deteriorated condition will continue to deteriorate and decline, thereby increasing the likelihood of unexpected failures. These failures might be prolonged and might result in extended equipment and customer outages which will subsequently lower System Average Interruption Duration Index and System Average Interruption Frequency Index performance.
- An increased likelihood of unexpected failures would lead to increased environmental risk due to the possibility of a release into the environment during a failure event.
- An increased likelihood of unexpected failures would lead to increased safety risk due to the possibility of a failure event being catastrophic in nature.
- There is expectation that there will be more catastrophic failures and systemic failures which based on past experience, cost more to replace compared to planned replacements due to the amount of damage, number of equipment affected and duration of outages related to these events.
- The maintenance frequency would likely increase and result in increased maintenance costs. As assets age beyond their ESL, repairs become more costly as the assets are no longer supported by vendors and aftermarket parts are no longer available or are costly to acquire or fabricate.
- Replacing reactively would lead to assets being replaced in an uncoordinated fashion. This would lead to assets only being replaced on an in-situ basis and

reduce the ability to prudently address other station infrastructure. Uncoordinated fashion here is referring to planning the work in a holistic approach.

- Many of the assets at a station are interconnected and replacing a single asset can either limit Hydro One in the design options for this replacement or cause the need for rework in the future, for example, coordinating protection replacements with breaker replacements
- When multiple assets are reaching EOL, there is opportunity to make changes to the electric configuration to make improvements to the reliability and performance of the bulk electricity system. Uncoordinated fashion can also pertain to the mobilization of construction forces, the staging of work to minimize impact to customers (outage frequency and duration).

Alternative 2: Station Refurbishment involves the refurbishment of the entire station where significant populations of assets are in a high risk condition, before failure occurs. This alternative is only a viable solution where the other key station assets, such as transformers and switching facilities are in a deteriorated, high risk condition. This alternative has been considered for the Project and has been rejected as there is insufficient justification to proceed with a complete station refurbishment. Hydro One does not replace the transmission assets unless the asset condition warrants the replacement. Where majority of assets are EOL, this alternative may then be considered, but then the project would fall under the SR-02.

Alternative 3: Like-for-Like Planned Replacement is a preferred undertaking. It involves proactively replacing individual station components in a single integrated investment, with switchgear and ancillary equipment that are in a deteriorated, high risk condition. This alternative is recommended as it addresses the needs identified at the station to maintain the reliability of Hydro One's transmission system in the most cost effective manner, consistent with the findings of the customer engagement process. This alternative focuses on the replacement of select equipment in a like-for-like manner, unless otherwise requested to meet broader system needs.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of load supply station breaker replacement projects are: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges, or regulatory approvals. A thorough risk assessment workshop is performed during the initial project planning phase where all known risks are identified and mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize to a minimum the loss of supply to the customer. The plan might include the construction of a temporary by-passing circuit or supply of portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages. Another example is the involvement of real estate from the project inception. It allows for the early identification of real estate issues, such as missing or inadequate land rights. Once the issue is identified, Hydro One tries to resolve it prior to execution of the project.

1 **APPENDIX A – DETAILED PROJECT PLAN**

Station Name	**Scope and Impact**	**Breakers Repl.**	**Prot. Repl.**	**In Service Year**
Leaside TS 27.6kV	Replace 27.6kV switchgear, switchyard and associated protection & control equipment at Leaside TS which is a space-constrained urban station located in mid-town Toronto. In addition, replace the main AC station service equipment, upgrade the station perimeter security system, and upgrade sections of the station drainage system. These replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to midtown Toronto Hydro customers.	14	20	2020
SACE Breakers – Woodroffe TS / Russell TS	This investment will replace select SACE type metalclad breakers used for capacitor bank switching. These breakers have been a concern for several years. The interrupter contacts have been found to be excessively worn causing the metalclad breaker to fail explosively, resulting in significant damage. This problem is compounded by the difficulty in checking the contacts and the excessive number of switching operations. There are four remaining breakers to be replaced; two at Woodroffe TS and two at Russell TS. The capacitor protections for three of these units are end of life and their replacement has been integrated into this investment	4	3	2021
Finch TS	This investment includes the replacement of the majority of protection and control equipment and a significant subset of breakers at Finch TS that are at EOL due declining condition and obsolescence. In addition other minor EOL assets and infrastructure will be replaced. These replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to Toronto Hydro customers.	14	49	2023
Rexdale TS	Rexdale TS is a step-down transformer station located in in the western area of Toronto, Ontario. The Rexdale 27.6kV switchyard consists of four bus-connected capacitor banks and twelve M-class feeders that supply the surrounding area. The primary transmission-connected customer served by the station feeders is Toronto Hydro. This investment includes the replacement of existing 27.6kV metalclad switchgear assets with indoor Medium Voltage Gas-Insulated Switchgear (MVGIS) equipment as well as a significant number of protections due to their end-of-life condition and obsolescence. The existing breaker type is not suited for capacitive switching and failures have been experienced in the past. The existing breakers are also obsolete and retro-fit options are not available for this 27.6kV voltage class; therefore, the reliability of the station would be enhanced with the removal and replacement of these obsolete circuit breakers. Also, with the installation of modern protective relays maintenance intervals will be extended therefore resulting in a reduction in maintenance costs. New protective relays are equipped with self-monitoring capabilities which allows for remote oversight of the relay health. This investment will decrease the risk of equipment failure and contribute to maintaining supply reliability to Toronto Hydro customers.	22	37	2023

Station Name	Scope and Impact	Breakers Repl.	Prot. Repl.	In Service Year
Bridgman TS	This investment replaces Hydro One’s switchgear that is part of Toronto Hydro’s end-of-life High Level A1/A2 switchgear lineup. These replacements will be done in coordination with Toronto Hydro’s High Level A1/A2 switchgear replacement project. Due to potential space and feeder egress limitations at Toronto Hydro’s High Level MTS facility, there is the possibility that refurbishment of the large heritage building at Bridgman TS may be required to provide space for the installation of the new A1/A2 switchgear lineup. These end-of-life switchgear replacements will decrease the risk of equipment failure and contribute to maintaining supply reliability to midtown Toronto Hydro customers.	6	0	2023
Kirkland Lake TS	The main assets driving this investment are 115kV PTs, 44kV circuit breakers and protections that have reached EOL. This investment will maintain the reliability of supply to Hydro One Distribution customers in the Kirkland Lake area.	5	9	2023
Campbell TS	Campbell TS is a major load centre for the Guelph area serving ~150MW of customer load with future load growth to ~160MW. Campbell TS has three 13.8kV metalclad lineup, of which, metalclad #2 is in poor condition and also has growing concerns for obsolescence. In addition, the station has 17 Programmable Auxiliary Logic Controller (“PALC”) relays that have been identified with having a high failure rate in the HONI system. It also contains first vintage of microprocessor relays due for replacement. Remaining electro-mechanical relays would have been in-service for over 50 years by 2022. Not proceeding with this work could increase the risk of equipment failure resulting in higher delivery point interruptions. The replacement of this EOL equipment is required to maintain the reliability of supply to Guelph Hydro Electric Systems.	12	32	2024
Norfolk TS	The following equipment at Norfolk TS is at EOL, obsolete and requires replacement; medium voltage oil circuit breakers, associated protection and control, AC station service transfer scheme, and two station service transformers. Replacing the equipment identified above in a single integrated investment will maintain supply reliability to Hydro One Distribution customers in the Simcoe area and decrease the risk of equipment failure.	13	27	2024
Bunting TS	Preliminary assessments indicate that the following equipment has reached EOL and will require replacement; partially arc proof metalclad medium voltage switchgear, associated protection and control including station battery, and the AC distribution scheme. Replacing this equipment in a single integrated investment will maintain supply reliability to Alectra Utilities in St. Catharines and decrease the risk of equipment failure.	17	33	2024
Owen Sound TS	The main assets driving this investment are 44kV circuit breakers and protections that have reached end of life. This investment will maintain reliability of supply to Hydro One Distribution customers in the Owen Sound area.	12	14	2025

Station Name	Scope and Impact	Breakers Repl.	Prot. Repl.	In Service Year
Dundas TS	The non-standard BY switchyard at Dundas TS is a legacy Hydro One structure that presents breaker and insulator replacement challenges due to space limitations that impact worker safety. The average service life of the low voltage breakers are approximately 50 years and the replacement of the BY switchyard is required to ensure reliability of supply to Alectra Utilities can be maintained. This investment will also result in the replacement of end of life protection and control equipment and station service transformer SS1.	13	10	2025
Lake TS	This investment is driven by the need to replace non-arc-proof metalclad switchgear that presents health and safety risks to employees and obsolescence issues pertaining to replacement of breakers in the event of failure. This investment will result in the replacement of the J1J2 and Q1Q2 metalclad switchgear and station service transformers SS1 and SS2.	17	0	2025
Burlington TS	The non-standard BY switchyard at Burlington TS is a legacy Hydro One structure that presents breaker and insulator replacement challenges due to space limitations that impact worker safety. The average service life of the low voltage breakers are approximately 55 years and the replacement of the BY switchyard is required to ensure that the reliability of supply to Burlington Hydro can be maintained. This investment will also result in the replacement of end of life protection and control equipment, station service transformer SS15 and capacitor bank SC4.	9	34	2025
Mohawk TS	This investment is driven by the need to replace non-arc-proof metalclad switchgear that presents health and safety risks to employees and along with obsolescence issues pertaining to replacement of breakers in the event of failure. This investment will result in the replacement of the B1B2 metalclad switchgear and associated protection and control equipment.	9	9	2025
Vansickle TS	This investment is driven by the need to replace non-arc-proof metalclad switchgear that presents health and safety risks to employees and along with obsolescence issues pertaining to replacement of breakers in the event of failure. This investment will result in the replacement of the BY metalclad switchgear and associated protection and control equipment.	9	13	2025
Cherrywood TS	Replace 44kV outdoor switchyard breakers, disconnect switches and associated protection & control equipment at Cherrywood DESN yard which they are at their EOL. The main assets driving this investment are 44kV oil circuit breakers. This investment will maintain reliability of supply to Toronto Hydro (Cavanagh MTS).	13	20	2025
Port Arthur TS #1	The main assets driving this investment is the 25kV DESN yard which poses significant health and safety risks to Hydro One personnel due to inadequate electrical clearances. This investment will maintain the reliability of supply to Thunder Bay Hydro and Hydro One Distribution customers in the Thunder Bay area.	17	67	2025

Station Name	Scope and Impact	Breakers Repl.	Prot. Repl.	In Service Year
Muksoka TS	This investment is driven by the need to replace a number of assets that are near EOL at Muskoka TS. The main assets driving this investment are 44kV oil circuit breakers. This investment will maintain reliability of supply to Hydro One Distribution customers in the Muskoka area.	8	0	2025
Pleasant TS	Pleasant TS is a transformer station located in the GTA (Brampton, Ontario) which primarily supplies Alectra Utilities. This investment includes the replacement of EOL oil-filled circuit breakers as well as a significant number of protections which require replacement due to condition and obsolescence. With the installation of modern protective relays, maintenance intervals will be extended reducing maintenance costs.	9	26	2026

SR-07 Protection and Automation Replacement Project

Start Date:	Q4 2016	**Priority:**	Medium
In-Service Date:	Q2 2026	**3-year Test Period Cost ($M):**	28.0
Trigger(s):	Strategic, System Renewal		
Outcomes:	Ensure compliance, system reliability, customer satisfaction, operational efficiencies and reduce maintenance costs		

A. OVERVIEW

The Protection and Automation Replacement Project (the "Project") is primarily a project that involves the replacement of protection and automation systems that have reached their End of Life ("EOL"). The Project might also involve the replacement of auxiliary equipment (e.g. instrument transformers, disconnect switches, AC and DC systems etc.) where needed. Prior to replacement, Hydro One will visually inspect and where applicable test the condition to ensure that these assets are, also, at the end of their life and their condition warrants the replacement. The Project targets the replacement of protection and automation systems at bulk transmission stations and load supply transmission stations.

The bulk transmission system provides the "backbone" of Ontario's electricity system. Bulk power flows through the 500kV, 230kV, and 115kV transmission systems. The protection system is a critical element of the transmission system that detects abnormal system conditions. Upon detecting an abnormal condition, the protection systems immediately trigger the necessary station equipment to operate to isolate faulted components. Automation assets are highly complex electronic systems and devices which integrate substation and switchyard devices. These systems enable the monitoring and control of power system assets and facilities at all times to achieve safe, reliable and efficient operation of the Ontario transmission grid. As a licensed transmitter operating transmission facilities greater than 100 kV, Hydro One is legally obligated to comply with the planning, operating and reliability criteria and standards adopted by North

American Electric Reliability Corporation ("NERC") and Northeast Power Coordinating Council ("NPCC"). Hydro One transmission customers include large electricity generators, large industrial end-users and the majority of Ontario's Local Distribution Companies ("LDCs"), all of whom are directly affected by the reliability and performance of Hydro One's transmission system.

Load supply stations step down power from higher voltages to lower voltages to facilitate the distribution of power via the downstream distribution network. The main Hydro One customers at the load supply stations are LDCs including Hydro One distribution system. The LDCs and Hydro One distribution system that are served by Hydro One's transmission system serve most of Ontario's residential, commercial, institutional and small industrial end-users. The end-user facilities that are indirectly affected by the reliability and performance of Hydro One's transmission system include such critical infrastructure such as telecommunications systems, water and wastewater treatment facilities, hospitals and other health care facilities, airports and transportation systems, schools and universities, financial services systems, etc.

In light of the foregoing, it is apparent that the protection and automation systems are critical assets of the transmission system and there is a heightened need to ensure that these systems are in a good condition and perform reliably.

The Project pacing has been influenced by the assessment of equipment condition where Hydro One assessed the likelihood of the protection and automation systems to cause a delivery point interruption or a major reliability risk, thereby, impacting the bulk electric system. Because it is not easy to monitor the condition of all protection and automation systems, expected service life ("ESL") is being used as flag for assessment while other factors, such as safety, regulatory compliance, grid reliability, technology obsolescence and innovation, have been used to identify high risk assets that form part of the Project.

Hydro One has evaluated various alternatives for the Project, as described below, and concluded that replacing those protection and automation systems that are at EOL is the most cost effective and efficient undertaking. The projected costs of the Project are estimated to be $28.0 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

As discussed in TSP Section 2.2.1.3 and 2.2.1.4, Hydro One has a thorough and ongoing asset management process that involves monitoring and reviewing transmission assets and assessing their condition. Hydro One’s protection and automation asset strategy is to proactively inspect and monitor the protection and automation systems, track their failure rate, misoperations and manufacturers’ support. This allows Hydro One to manage maintenance needs and assess the protection and automation systems’ condition as a factor to determine the need for asset replacement. Assessments to repair or replace protection and automation systems are done on an individual basis. The assessment is based on risks identified from demographics, condition, safety, technology obsolescence, innovation, utilization, and costs comparison between refurbishment and replacement. Units in poor condition, known manufacturer defects/obsolesce, or anticipated higher repair costs are prioritized for replacement.

Hydro One’s transmission system includes 293 stations. Hydro One has established a recurring seven- to ten-year assessment cycle that enables all necessary renewal work to be performed at each of the 293 transmission stations during the cycle. The goal of each asset assessment is to ensure that the assets are not deteriorated, there are no risks that may compromise the reliability of the system, and they do not pose any safety or and/or environmental risks. All assets at a given station are assessed at the same time with a particular focus to transformers, breakers, and protection and automation systems – as these are the most critical assets in the system and have a direct impact on a customer. If the assessment identifies multiple key station assets (i.e. transformers, breakers, and protection and automation equipment) whose condition warrants a replacement, Hydro One then pursues an integrated approach. The asset replacements are bundled into a single integrated station-centric investment project with the main components being identified as the drivers for the project. This integrated approach is further described in Investment Summary Document SR-02. In the case where only one asset, e.g. protection system or automation system identified as the main asset for replacement along with some auxiliary equipment, the station is identified as a candidate for a protection and automation systems replacement project.

Protection Systems

Hydro One's protection systems are comprised of instrument transformers, relays, sensors and communication devices. The protection system is a critical element of the transmission system that detects abnormal system conditions. Upon detecting an abnormal condition, the protection systems immediately operate the necessary station equipment to isolate faulted components. A faulted element could cause a cascading effect and result in a major system disruption involving service interruptions, equipment damage and employee and public safety issues.

Protection system equipment is activated only when there is a fault or other power system problem. A fault or system disturbance can result in equipment damage, personnel exposure to hazards, wide area disturbances and prolonged customer outages. Protection system misoperations provide an overall indication of the protection system's health. It is the most important indication of the protection system performance. Hydro One tracks the performance of the protection system by analyzing every protection system operation to determine if it operated as expected. Protection system components also capture detailed records for post event analysis. This information assists in determining the root cause of power system events and facilitates in the mitigation or elimination of the issue.

Hydro One currently has 12,506 protection systems in-service. Approximately 27% of the protection system population is operating beyond its ESL. Hydro One defines ESL as the average age in years that an asset can be expected to operate under normal system conditions. Assuming no replacement, Hydro One anticipates that 5,184 units (41% of the protection system population) will exceed their ESL by 2024, and 6,952 units (56% of the population) will exceed their ESL by 2029. Table 1 below presents a summary of the ESL of Hydro One's protection systems broken by technology type. Once the protection system reaches its ESL, the risk of failure is significantly elevated**.** There is no way to predict time of failure with certainty as most of the systems and their components do not show signs of wear and fatigue. They usually operate until they suffer an abrupt failure.

Table 1 - Summary of the ESL of Hydro One's Protection Systems by Technology

Protection Type	**Quantity**	**Avg Age (Years)**	**ESL (Years)**	**% Beyond ESL (if no protections are replaced)***					
				2018		**2024**		**2029**	
				Count	**% of Type**	**Count**	**% of Type**	**Count**	**% of Type**
Solid State	2,026	35.3	25	1,835	91%	1906	94%	1941	96%
Electro-mechanical	3611	38.8	45	1,322	37%	2,038	56%	2,279	63%
Microprocessor	6,869	8.7	20	206	3%	1,240	18%	2,732	40%
TOTAL	**12,506**	**27.6**		**3,363**	**27%**	**5,184**	**41%**	**6952**	**56%**

** Data as of Dec 2018 and does not include protections planned to be replaced in 2019*

On average, 94% of station protection and 89% of line protection misoperations are related to hardware failures associated with protection systems.

Programmable Auxiliary Logic Controller ("PALC") relays are a type of solid state protection system. They have shown an increase in recorded defects and trouble calls over the years due to deteriorating components within the relay. As a result, and due to the inability to obtain replacement units, PALC relays are considered high risk assets. As such, Hydro One has been actively replacing PALC relays since 2014 and, to date, it has replaced approximately 250 PALC relays. Figure 1 demonstrates that once the deteriorated equipment is taken out of service, the number of annual defects and subsequent outages is reduced. Currently, Hydro One has approximately 300 PALC relays in operation and plans to replace them over the next five years.

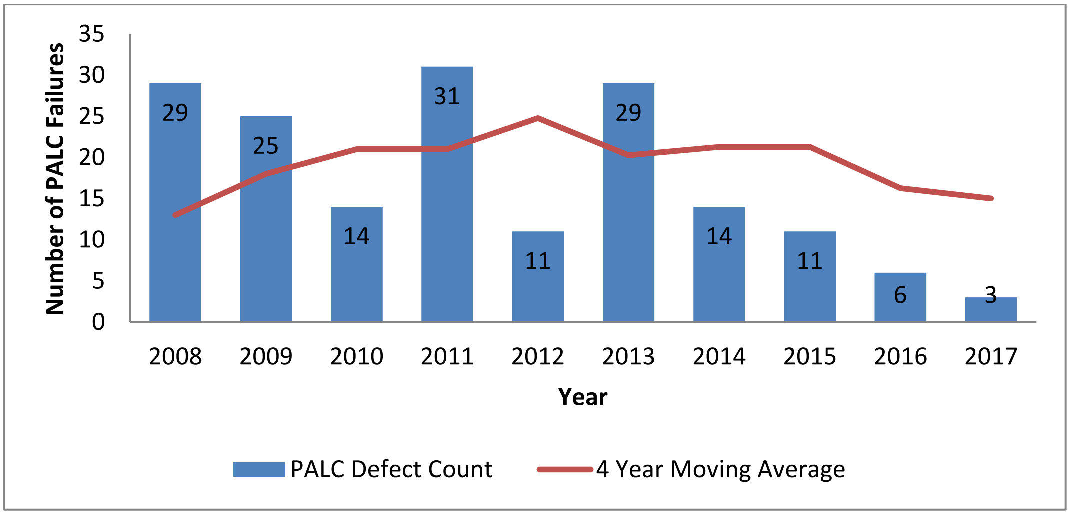

Figure 1 - Number of PALC Relay Defects

Furthermore, vendor support is critical. For example, as could be seen in Table 1 above, over 90% of the solid-state fleet of protection system is operating beyond their ESL. Because this equipment is obsolete, Hydro One has little or no support from its vendors when it comes to service, replacement units or provision of spare parts. When a device operates beyond its ESL, the risk of failures is elevated. It even further elevates when there is no vendor support, including supply of spare parts and/or firmware and engineering support. This might impact restoration time of the outage, caused by faulty, obsolete protection system, as the repair time will be longer. The repair might include the installation of a new device based on different technology which will require further reengineering and construction work.

As a licensed transmitter operating transmission facilities greater than 100 kV, Hydro One is legally obligated to comply with the planning, operating and reliability criteria and standards adopted by NERC and NPCC. With respect to protection systems, Hydro One is required to comply with *NPCC Regional Reliability Reference Directory # 4 - Bulk Power System Protection Criteria* (the “Directory”). The Directory sets out the minimum protection system design criteria and review process for protection systems for the Bulk Power System. It requires entities such as Hydro One to include level of redundancy in the design. As part of the compliance verification, for any construction work in a station that is part of Bulk Power System, Hydro One is required to prepare and deliver Facility Presentation to NPCC’s Task Force for System Protection (TFSP). By reviewing Facility Presentation package, TFSP reviews and approves the project scope and its design concept. Currently, most of Hydro One bulk stations comply with most of the requirements of the Directory. However, in older stations which were built before the requirements came into effect, there are often areas that require investments in order to fully comply with this standard. Even though the older installations are “grandfathered” against the Directory requirements, when upgrade work is planned for certain equipment in the station, the requirement is that other related systems are upgraded progressively to bring station into full compliance over time. An example for this is: when a transformer replacement is done, the expectation is for the project to result in the related equipment meeting the standard e.g. control cables, relays, DC auxiliary supply. This may trigger installation of new cable trenches and replacement of cables, and go as far as including the replacement of the related protection relays in the project scope. Among other objectives described in this section, the Project is targeting these investments to ensure that the protection systems are compliant with the Directory.

<u>Automation Systems</u>

Automation assets are highly complex electronic systems that enable the monitoring and control of power system assets and facilities at all times to achieve safe, reliable and efficient operation of the Ontario transmission grid. They also enable timely responses to emerging problems, real-time condition assessments, expedited restoration activities, and work planning.

Automation systems provide several critical capabilities such as:

- Local and remote real-time monitoring, control and troubleshooting facilities for Hydro One field staff, control center staff and the Independent Electricity System Operator ("IESO") in accordance with Market Rules;
- Critical transmission station automation and integration functions to support the operations of all power system equipment;
- Collection, processing, and archival of non-operational data for post-event analysis and to support the asset management decision-making processes;
- Enabling cyber security functionalities such as system event monitoring, authentication, authorization, logging and accounting;
- Supporting the fulfillment of regulatory obligations; and,
- Interfaces with external utilities, generation, and customers.

Hydro One automation system assets consist of legacy and modern technological vintages. Legacy automation components primarily consist of Remote Terminal Units ("RTU"). This equipment is based on the concept of physical wiring and the digital conversion of electrical signals delivered by wires, generally for a single function/application. These systems utilize slow communication connections and employ a variety of protocols. Modern automation equipment is network enabled to utilize high-speed communications and has a smaller physical form-factor, exponentially increased computational capabilities, and greater ability for integration with the Network Management System ("NMS") as compared to its legacy counterparts. Information is conveyed through standard protocols which shift previous manual labour work related to hard wiring, towards skilled programming capability.

There are over 18,000 components and devices in service to support automation functionalities of Hydro One's Power System Monitoring & Control ("PSMC"). 46% of the automation system population is of the modern vintage type, while 54% is of the legacy vintage type. The ESL for automation systems, outlined in Table 2 below, is classified according to their vintage and is based on generally accepted industry practices and Hydro One experience.

Table 2 - Automation System Expected Service Life

Automation Vintage	Expected Service Life
Legacy (copper-based)	20 years
Modern (IP-based)	15 years

Automation system condition is an important indicator of equipment reliability. Internal components degrade as a function of time, which can alter the performance of the automation equipment. The potential risks to system and customer reliability as a result of this long term demographic pressure needs to be managed through consistent capital replacement programs. Legacy automation systems experience defects four times more often than modern control systems within the same timeframe. Furthermore, 54% of automation equipment is of the legacy vintage and makes up about 79% of the total defect occurrences and associated maintenance costs. This is expected to trend upward as the legacy equipment reaches its expected service life. Table 3 presents the number of defect reports for modern and legacy automation equipment over the last 11 years.

Table 3 - Summary of Defect Reports Broken Down by Year

Year	LEGACY			MODERN			
	RTU	**PSR**	**Transducer**	**LMC/LCC**	**Gateway**	**Router**	**Switches**
2008	325	23	19	11	18	4	2
2009	550	68	21	27	25	5	0
2010	635	42	36	19	18	10	1
2011	674	69	29	52	12	4	2
2012	555	39	20	43	34	20	9
2013	577	48	14	71	30	17	10

2016	478	44	16	195	63	24	20
2017	912	8	3	208	63	31	43
2018	465	14	6	136	98	21	82
Total	**5986**	**433**	**224**	**907**	**455**	**171**	**206**

Hydro One has been tracking the reliability of automation equipment with the objective of determining future work programs. The following are the key objectives that Hydro One focuses to determine the level of investment needed for its automation system fleet.

- Evaluation of modern industry offerings and migration towards cost-effective alternatives. The legacy technology and design has been in service for over thirty years. Risks and costs are mounting as more of these systems reach or exceed ESL. As Hydro One modernizes its automation fleet though the deployment of station Local Area Networks ("LAN"), there is no longer a need for expensive legacy RTU installations. Modern solutions have a small form factor, are a fraction of the cost, and are IP-based with flexible scalability to match our needs. Hydro One is pursuing options to modernize the system by working with vendors and other utilities through EPRI and NATF to establish and implement modern solutions with the intent to replace legacy systems.
- Optimization of existing designs to reduce capital and Operations Maintenance and Administration ("OM&A") expenditures. Hydro One evaluates changes in controls design architecture to maximize device functionalities. Many existing deployments were designed with legacy technologies that provided certain

capacities or redundancies to meet reliability requirements. As some legacy technologies are discontinued and replaced with modern industry offerings, reliability targets and mandated requirements will be met with reduced or no redundancy required.

In comparison to protection, the automation world has seen significant advancements over the past decade. Hydro One is undertaking these opportunities to further modernize and bring improvements to operational efficiency, a reduction in operational risks, reliability, and cost containment. The following are examples of modernization being implemented as part of the Project:

i. Removal of end of life Local Controller Computers and implementation of the same functionality into Station Gateways;
ii. Deployment of direct Supervisory Control and Data Acquisition to allow stations to communicate directly with the OGCC so as to phase out hub sites; and
iii. Substitution of multiple Local Maintenance Computers at a station with a single transient cyber asset which complies with the NERC Critical Infrastructure Program standards.

Investment Description

The Project is classified as primarily protection and automation systems replacement project. The Project is targeting protection and automation systems that have reached their EOL. These systems do not offer the functionalities of modern relays, such as monitoring and diagnostic capabilities, and have a high likelihood of failure. Protection system failure can result in unexpectedly removing power system elements from service or failing to operate when required to isolate faulted equipment which directly impacts power flow through the bulk electricity system. Hydro One is also targeting for replacement; populations of equipment which are showing increasing failure, rates have limited manufacturer support or can no longer reliably perform their intended function due to equipment technological advances.

Through the investment planning process documented in TSP Section 2.1, needs assessments are conducted on station assets to identify and coordinate candidate investments. These investments will replace protection systems and auxiliary equipment in high risk condition where the likelihood of failure is high and, in doing so, standardize them and bring them into compliance with applicable requirements. The investment level has been determined based on the assessment of asset condition and performance. In addition, this investment provided further consideration of customer preferences, safety concerns, and compliance requirements.

The Project involves a series of individual projects. Each bulk station and load supply station protection and automation replacement project will vary in size and scope. The investment will address: associated protection, control and telecom systems, ancillary station equipment in deteriorated condition, site or property issues, customer issues, safety concerns, environmental compliance, and operational issues whose condition might also warrant the replacement. Further details pertaining to the Project as well as individual investment for bulk station and load supply stations can be found in Appendix "A".

Outcome

As a result of the Project, Hydro One will reduce operational risks (e.g. bottled generation, reduced transfer capability, restricted power flows) associated with the operation of EOL and deteriorated equipment; ensure compliance with NERC and NPCC requirements; enhance protection and automation functionality where technological advances can help reduce outage duration (fault location algorithms) and prevent protection misoperations (e.g. second harmonic restraint); maintain long-term bulk power flow reliability throughout the power system and mitigate the risk of constraining generation resources.

The following table presents anticipated benefits as a result of the Project in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Maintain reliability performance of bulk electricity system power flows through the replacement of EOL protection systems.
Operational Effectiveness	• Improve operational flexibility of the bulk electricity system through the implementation of modern protection and automation systems, enabling enhanced telemetry, control, and operational capabilities
Public Policy Responsiveness	• Comply with applicable regulatory requirements
Financial Performance	• Realize cost savings by addressing multiple degrading components within the station as part of the same project.

C. EXPENDITURE PLAN

As discussed above, the Project is needed to replace the protection and automation systems at bulk power stations and load supply stations which may compromise the reliability of supply due to the high risk assets that have reached their EOL. Hydro One planned the Project in a way that strives to complete it as effectively and efficiently as possible so to minimize the cost of performing this sustainment task.

Table 4 summarizes historical and projected spending on the aggregate project level. Since the Project consists of a multiple projects, as presented in Appendix "A", Table 4 below consolidates all the costs for individual projects and presents the total Project costs. The "Previous Years" costs are the direct project costs for projects noted above that have incurred costs prior to 2020. Likewise, the costs noted in "Forecast 2025+" are project costs forecast beyond 2024.

Table 4 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	2.5	7.0	8.8	13.1	12.6	22.3	15.5	81.8
Less Removals	0.1	0.2	0.3	0.4	0.4	0.7	0.5	2.4
Gross Investment Cost	**2.4**	**6.7**	**8.6**	**12.7**	**12.2**	**21.7**	**15.0**	**79.3**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**2.4**	**6.7**	**8.6**	**12.7**	**12.2**	**21.7**	**15.0**	**79.3**

[1] *Includes overhead at current rates.*

Table 5 presents projected costs on an individual project basis. It also provides a total costs for each individual project along with the proposed in-service date.

Table 5 - Detailed Project Costs

Project	Net Investment Costs ($ Millions)					20-24 Total ($M)	Project Total ($M)	In Service Date
	2020	2021	2022	2023	2024			
Tillsonburg TS	3.8	2.4	0.2	0.0	0.0	6.3	7.0	2021
Frontenac TS	2.0	3.0	0.8	0.0	0.0	5.7	7.3	2022
Hunta SS	0.5	1.4	4.3	1.6	0.0	7.7	8.0	2023
Halton TS	0.5	0.8	5.5	2.6	0.2	9.6	9.6	2024
Minden TS	0.0	0.2	0.5	0.8	3.6	5.1	6.5	2025
Erindale TS	0.0	0.7	0.9	5.6	6.8	13.9	15.9	2025
Bramalea TS	0.0	0.2	0.6	1.6	11.0	13.4	25.0	2026
Net Investment Cost	**6.7**	**8.6**	**12.7**	**12.2**	**21.7**	**61.9**	**79.3**	

The following factors also affect the capital expenditures required for the Project.

- Applicability of NERC and/or NPCC requirements

  - Replacement of protection and automation systems must comply with applicable NERC/NPCC which has significant increase on costs. When protection/control equipment is replaced, if applicable in to the given elements in the station, the systems must be designed to meet the application NERC and/or NPCC requirements (for example redundancy or protection systems, AC and DC supply, physical and diverse separation of equipment).
- Need for additional civil infrastructure such as cable trenching, and/or ducts
  - This could include physical separation of A & B communication paths which have significant increase on costs. This requirement is mandated by the applicable NPCC design criteria.
- Available space within the control building o relay room to facilitate upgrades
  - New location will require additional facilities to be installed to connect the equipment rather than re-using existing facilities (i.e. relay room rack space), increases cost. The lack of space could or additional cabling in cable pans could trigger a new relay building.
- Complexity of stages and outages required to facilitate work
  - Increases planning costs portion of the project, and
  - Increases overall duration of project (interest and overhead costs increases)

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: Reactive Component Replacement involves waiting for deteriorated and end-of-service life protection and automation systems to fail and replace components on a reactive basis. This alternative is more costly not only for Hydro One but also for impacted customers. Hydro One has rejected this alternative for the following reasons.

- Assets in deteriorated condition will continue to deteriorate and decline, thereby increasing the likelihood of unexpected failures. These failures might be prolonged and might result in extended equipment and customer outages which will subsequently lower System Average Interruption Duration Index ("SAIDI") and System Average Interruption Frequency Index ("SAIFI") performance.

- An increased likelihood of unexpected failures would lead to increased environmental risk due to the possibility of a release into the environment during a failure event.
- An increased likelihood of unexpected failures would lead to increased safety risk due to the possibility of a failure event being catastrophic in nature.
- Since these replacements would likely be executed on an emergency basis, it would constantly result in the reprioritization of planned work and inefficient redeployment of resources.
- This alternative limits the ability to account for future requirements and has a high risk of re-work and future costs.
- This strategy is likely to increase operating and maintenance costs, decrease equipment performance and might impact the safety of personnel on site.

Alternative 2: Planned Component Replacement is the preferred investment option. It involves proactive replacement of end of life protection systems and associated ancillary equipment that are in a high risk condition, before failures occur. Hydro One's replacement strategy for protection systems is focused on replacing systems that have a high likelihood of causing delivery point interruption and impacting the reliability of bulk electricity system. Because it is not easy to monitor the condition of all protection systems, ESL and other factors are used as a trigger to identify high risk assets which undergo further condition assessment to identify replacement candidates. Other factors driving protection system replacements are summarized below.

- Safety – Protection system failure to operate can potentially expose workers and the public to the risk of electrocution which ultimately can result in significant injuries or even death. Proactive replacements are required to mitigate this risk.

- Regulatory Compliance – Hydro One's protection system must comply with all applicable NERC and NPCC standards. Protection system upgrades are often needed in order to comply with new or updated standard requirements.
- Functional Requirements - the requirements for protection system functionality may change due to power system changes (e.g, system stability requirements) or changes to other components of integrated protection and automation system which lead to incompatibility of the existing protection hardware with the associated devices.
- Technology Obsolescence – Many protection system components are no longer available, limiting the availability of spare parts and support; which can adversely impact outage planning and overall system reliability. This is a significant factor for electromechanical and solid state systems as they are no longer supported by relay vendors which are focusing their efforts on microprocessor based relays.
- Innovation – New microprocessor based protection systems have advanced monitoring and diagnostic capabilities which can provide insight into station equipment performance and early detection of problems, potentially avoiding equipment damage. This alternative is recommended as it addresses the needs identified at the transmission station to maintain reliability for Hydro One's bulk transmission system in the most cost effective manner.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of bulk station breaker replacement projects are: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges, or regulatory approvals. A thorough risk assessment workshop is performed during the initial project planning phase where all known risks are identified and mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize the probability of loss of supply to the customer. The plan might include switching a customer to an alternative supply, the construction of a temporary by-passing circuit or supply of portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages. While protection and automation replacement projects are rarely real estate dependent, in some cases there is a need to involve real estate from the project inception. This allows for the early identification of real estate issues, such as missing or inadequate land rights. Once the issue is identified, Hydro One tries to resolve it prior to execution of the project.

1

APPENDIX A – DETAILED PROJECT PLAN

Station Name	Scope and Impacts	Number of Protections	In Service Year
Tillsonburg TS	The majority of the protection and control equipment at Tillsonburg TS are end of life due to obsolescence and pose a high risk to reliability. This investment will address these EOL protections and control and maintain supply reliability to the Tillsonburg area.	30	2021
Frontenac TS	Frontenac TS – DESN is a major load centre for the Kingston Area serving ~100MW of customer load. It contains Electro-mechanical relays that would have been in-service for over 45 years by 2022. It also contains first vintage of microprocessor relays due for replacement. Due to space limitation within the existing building, A new PCT building (PCT-box design) will be installed along with the new protections. Not proceeding with this work could increase the risk of equipment failure resulting in higher delivery point interruptions. The replacement of these EOL protections is required to maintain the reliability of supply Kingston Hydro.	51	2022
Hunta SS	This investment will address EOL protections that are negatively impacting the reliability of the transmission system. This investment will maintain reliability in the 115kV transmission network and supply to customers north of Timmins.	13	2023
Halton TS	Halton TS is a step-down transformer station that supplies Milton Hydro and Halton Hills Hydro customers via twelve 27.6kV feeders. This investment will replace end-of-life PALC relays that have been identified with high rates of failure. By installing modern protective relays, maintenance intervals will be extended and maintenance costs will be reduced. Station reliability will be enhanced with the removal and replacement of these obsolete devices.	31	2024
Minden TS	This investment will primarily address end-of-life protection, control, and telecommunication equipment. Furthermore, the main DC station service transfer scheme is end-of-life; its condition and performance is declining and there are obsolescence and vendor support risks. This investment will maintain the reliability of the bulk electric system.	20	2025
Erindale TS	This investment will address end-of-life PALC relays that have been identified with high rates of failure. It will also address AC & DC station service systems, and six circuit breakers that have declining condition and performance.	31	2025

SR-08 John Transformer Station Reinvestment

Start Date:	Q3 2018	**Priority:**	High
In-Service Date:	Q4 2024	**3-year Test Period Cost ($M):**	44.0
Trigger(s):	System Renewal, Reliability		
Outcomes	Improve reliability, maintain safe and reliable transmission system, ensure compliance with regulatory requirements, realize cost savings		

A. OVERVIEW

The John Transformer Station Reinvestment (the "Project") involves the refurbishment of John Transformer Station ("TS") due to the end of life assets, supply limitations, short circuit levels that limit transfer capability as well as clearance issues that pose a safety concern for maintenance personnel and limit the work that can be completed.

John TS is the most heavily loaded transformer station in the Central Toronto 115kV network and is critical to the supply of power to downtown Toronto. The station was built in the 1950s with facilities added in the 1960s and 1970s. Many components in the station have reached or are approaching their expected service life.

Hydro One has reviewed various alternatives for the John TS reinvestment, as described below and concluded that a staged reinvestment and replacement of the station facilities is the most cost effective option. The projected cost of the Project is estimated to be $44.0 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

John TS, located in downtown Toronto is a major source of supply to the City's core and comprises the following facilities:

- A 115kV switchyard consisting of ten 115kV breakers. The 115kV switchyard contains eight breakers that are oil type and are about 42 years old.
- Two 45/75 MVA, 115/13.8kV kV Transformers T1/T4. The transformers are 50 years and 48 years old respectively.
- Two 45/75 MVA, 115/13.8kV kV Transformers T2//T3. The transformers are 42 and 33 years old respectively.
- Two 75/125 MVA, 115/13.8kV kV Transformers T5/T6. The transformers are 42 and 41 years old respectively.
- An outdoor 13.8kV switchyard that interconnects transformers T1/T2/T3 and T4 to the Toronto Hydro low voltage metalclad switchgear. The 13.8kV outdoor switchyard is about 50 years old with obsolete equipment.
- 13.8kV low voltage metalclad switchgear. This switchgear is mostly owned by Toronto Hydro with the exception of transformer secondary and bus tie breakers that are owned by Hydro One. This switchgear ranges in age from 33- 50 years old.

As mentioned above most of the equipment is between 40-50 years old. The oil breakers in the 115kV switchyard have limited manufacturer support and parts availability. The switchyard insulators are almost entirely cap and pin type that are prone to failure with age. There is a need to reinvest in the switchyard and replace the aging and deteriorated assets.

Four of the transformers have been identified for replacement due to their condition. Two transformers T1 and T4 are being monitored for rapid degradation and need to be replaced on a priority basis.

The 13.8kV low voltage outdoor switchyard is very congested with limited electrical clearances and non-standard design. The existing clearances at the station pose a safety concern for maintenance personnel and limit the work that can be completed. Many of the buses, switches, cables, insulators and duplex reactors are end of life or obsolete and need to be replaced or removed as they are limiting capacity and are in poor condition.

Lastly, transformer secondary breakers that are part of the Toronto Hydro non-arc proof switchgear need to be separated from the Toronto Hydro line-up and replaced by Hydro One. These breakers have been identified as posing health and safety concerns and require additional precautions in order to perform maintenance. Such precautions include large outage zones for maintenance work which are difficult to achieve. Hydro One work will be coordinated with Toronto Hydro switchgear replacement plans to ensure that supply to area customers is maintained while the refurbishment work is under way.

Toronto Hydro is currently in the process of building a new load supply station, Copeland MTS. One of the objectives of this station was to have the ability to supply a portion of John TS's load in order to enable outages at John TS to facilitate maintenance or capital work. Once Toronto Hydro's Copeland MTS is completed, Hydro One will have the ability to transfer partial load from John TS and this will allow for a staged replacement of assets within the station to meet current and future needs. This investment is dependent upon Toronto Hydro maintaining its current schedule for in-servicing Copeland MTS.

Investment Description

The Project involves a staged replacement of assets of John TS on the existing property. This will include replacement of the existing transformers, removal of the 13.8kV outdoor low voltage switchyard and installation of transformer secondary 13.8kV low voltage breakers in the first stage. The first stage will also include replacement of the associated transformer protections and the AC and DC station service equipment.

Toronto Hydro have advised that their new replacement metalclad switchgear will be rated at 72MVA compared to the 48MVA rating of the present switchgear to meet future requirements and have requested that the existing 45/75MVA transformers be replaced with larger size 60/100MVA units.

The second stage will consist of replacement of the 115kV breakers, the upgrade of the 115kV switchyard and replacement of existing switchyard protections

Outcome

The Project will result in the following:

- Improve the long-term reliability of supply to downtown Toronto and increase the security of a critical station;
- Reduce operational risks associated with end-of-life equipment; and
- Ensure compliance with MOECP requirements.

The following table presents anticipated benefits as a result of the Project in accordance with the OEB's Renewed Regulatory Framework:

Customer Focus	• Improve reliability to customers by minimizing outages due to poor performing, obsolete and end-of-life equipment
Operational Effectiveness	• Maintain a safe and reliable transmission system by addressing end-of-life, obsolete equipment, and incorporating safety by design in an integrated manner.
Public Policy Responsiveness	• Ensure compliance with Ministry of Environment and Climate Change requirements by upgrading site drainage, spill containment, and noise abatement.
Financial Performance	• Realize cost savings by replacing multiple end of service life components within the station in a staged manner.

C. EXPENDITURE PLAN

Table 1 below presents forecasted costs for the Project. The project costs were developed using a Hydro One planner's estimate. The "Previous Years" costs are the direct project costs incurred prior to the 2020 test year. Likewise, the costs noted in "Forecast 2025+" are project costs forecast beyond 2024.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	0.4	3.6	18.4	26.3	24.7	21.5	16.1	111.1
Less Removals	0.1	0.1	0.6	0.7	0.6	0.6	0.5	3.2
Gross Investment Cost	**0.3**	**3.5**	**17.9**	**25.6**	**24.0**	**20.9**	**15.6**	**107.8**
Less Capital Contributions	0.0	0.0	0.0	3.0	3.0	0.0	0.0	6.1
Net Investment Cost	**0.3**	**3.5**	**17.9**	**22.6**	**21.0**	**20.9**	**15.6**	**101.8**

[1] *Includes Overhead at current rates.*

The expenditures in 2021, 2022 and 2023 are associated with replacement of the transformers T2, T3, T5 and T6 and the replacement of the 13.8kV and 115kV switchyard. The following factors might further affect the costs of the Project:

- Final station design and configuration due to the complexity of the station's configuration and coordination required with Toronto Hydro; and
- The complexity of project staging and outages required to facilitate work.

D. ALTERNATIVES

Three alternatives were considered for the refurbishment of John TS as follows:

Alternative 1: In-situ Replacement of All Station Equipment involves the replacement of assets at the existing station site. This option would plan for a like-for-like replacement of the station asset except for the 115kV switchyard where consideration is being given to using GIS equipment to replace the existing switchyard

Alternative 2: Station Relocation involves a complete rebuild and relocation of John TS to another property in downtown Toronto. This alternative was rejected as impractical because of the difficulty in finding an appropriate site for the new station. Even if a new site were to be available, it would be extremely difficult and costly to relocate the 115kV high voltage underground lines and the 13.8kV underground distribution feeders to the new site.

Alternative 3: Staged Partial or Entire Station Rebuild By Expanding to the Adjacent Property. A third option considers utilizing an existing adjacent parking lot to facilitate the refurbishment of John TS. This alternative while feasible and simplifying the construction, expands the John TS footprint and would be significantly more expensive than an in-situ replacement. It was therefore not considered further.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of the Project are: the availability of Copeland MTS to supply portions of John TS during construction, the availability of outages, resource constraints, construction execution difficulties, customer coordination, equipment procurement challenges, or regulatory approvals. A thorough risk assessment is performed during project planning where all known risks and mitigating actions are identified. For example, to address outage constraints, Hydro One develops an outage coordination plan. This operation plan aims to eliminate or minimize the loss of supply to the customer. The plan might include the construction of a temporary by-pass circuit or connecting portable generation to maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages.

SR-09 Transmission Station Demand, Spares and Targeted Assets

Start Date:	Q1 2020	**Priority:**	High
In-Service Date:	Ongoing Program	**3 Year Test Period Cost ($M):**	117.6
Trigger(s):	Compliance, Strategic, Customer Satisfaction, Corrective Maintenance, Reliability and Environment		
Outcomes:	Compliance with ORTAC and TSC; improve customer satisfaction by carrying out replacements in a timely manner to minimize unplanned customer interruptions; maintain transmission system reliability, safety, and/or power quality; reduce safety risks associated with failing equipment		

A. OVERVIEW

Transmission Station Demand and Spares (the “Program”) is a reactive program that is primarily designed to prevent, immediately respond to, or minimize the effects of an emergency situation. The Program involves the procurement of spare transmission station equipment such as transformer operating spares, circuit breakers, instrument transformer, disconnect switches, insulators, power cables, surge arrestors, capacitor banks, reactors, protection, and control and telecom equipment. The Program covers the resources required for emergency replacement of transformers or other minor station equipment that have failed or shown signs of deterioration while in-service and near term deteriorated asset replacements that do not align with station centric projects. It also includes the necessary design, construction and commissioning resources to replace failed station equipment in a timely manner.

Failed or deficient station equipment may cause an impact on the transmission system that varies from being minor to significant. It might pose safety or environmental risks as well as impose generation and/or power flow constraints, affecting regional load flow limits and customer operations. As a licensed transmitter, Hydro One is legally obligated to comply with the planning, operating and reliability criteria and standards administered by the IESO and the Transmission System Code (the “TSC”). The Program ensures that Hydro One continues to comply with its legal obligations while mitigating safety, system reliability and environmental risks that an unforeseen failure might cause.

B. NEED AND OUTCOME

Investment Need

Hydro One operates one of the largest transmission systems in North America. As a critical asset for Ontario, Hydro One's transmission system extends to most of the province, and encompasses diverse geographic and climactic condition. It comprises the Bulk Electric System ("BES"), which is subject to the reliability standards established by the North American Electric Reliability Corporation ("NERC") that ensure the integrity of the interconnected North American BES. Transmission stations are a key category of infrastructure that is critical to the function of Hydro One's transmission system. The major components of transmission stations include power transformers, circuit breakers, disconnect switches, bus work, insulators, power cables, surge arrestors, capacitor banks, reactors, station service, grounding systems, protection and telecom systems, site infrastructure and buildings.

If a transmission station asset fails or is in imminent danger of failure, it is critical for Hydro One to have the ability to perform emergency replacements of that asset as soon as possible, so as to ensure the integrity and reliability of the transmission system. When a transmission station asset fails, the impact varies depending on the location of the component and level of redundancy (if any) built into the station's electrical configuration. In a best case scenario, transfer capability could be reduced even though the customer will not see any interruption. But in the worst case, where there is stranded load without any transfer capability, customers can be interrupted until the component is replaced (or manually bypassed if possible). Other types of failures of transmissions station assets might pose safety or environmental risks.

The Program ensures that Hydro One maintains an adequate inventory of spares for its transmission station assets in order to facilitate the expedient replacement of a failed or deficient component at a transmission station. These assets might include transformers, power equipment, ancillary equipment, protection, control and telecom equipment and other minor equipment.

The reliability framework for Ontario's electricity transmission system is based on the reliability standards established by NERC, which have been adopted and are enforced in Ontario by the IESO. The IESO has established load restoration criteria for high voltage supply to a transmission customer. In accordance with the Section 7.2 of the IESO's *Ontario Resource and Transmission Assessment Criteria* ("ORTAC"), Hydro One is required to restore an affected load within the following restoration times:

- All load must be restored within approximately 8 hours.
- When the amount of load interrupted is greater than 150MW, the amount of load in excess of 150MW must be restored within approximately 4 hours.
- When the amount of load interrupted is greater than 250MW, the amount of load in excess of 250MW must be restored within 30 minutes.

Furthermore, the OEB's *Transmission System Code* ("TSC") sets out, among other things, the minimum requirements that a transmitter must meet in maintaining its transmission system. In accordance with Section 5.4 of the TSC, Hydro One is required to take immediate actions during an emergency or to prevent or minimize the effects of an emergency, ensure public safety or safeguard life, property or the environment, as well as to protect the stability, reliability, or integrity of Hydro One's transmission facilities. As a licensed transmitter, Hydro One is legally obligated to comply with the planning, operating and reliability criteria and standards imposed by the IESO and the TSC.

In light of the foregoing, to maintain system reliability and prevent load interruption to customers, Hydro One needs to maintain a stock of a spare transmission station equipment (e.g. transformers, circuit breakers, instrument transformer, disconnect switches, insulators, power cables, surge arrestors, capacitor banks, reactors, protection, control and telecom equipment) and the sustained ability to respond immediately to an emergency situation or to prevent or minimize the effects of an emergency.

Investment Description

The Program includes the procurement of spare transmission station equipment such as transformer operating spares, circuit breakers, instrument transformer, disconnect switches, insulators, power cables, surge arrestors, capacitor banks, reactors, protection, control and telecom equipment. The Program also covers the resources required for emergency replacement of transformers or other minor station equipment that have failed while in-service. This includes the necessary design, construction and commissioning resources to replace failed station equipment in a timely manner to ensure compliance with standards imposed by the IESO and the TSC.

According to historical data (see Table 1 below), Hydro One has experienced an annual average of 4 transformer failures or a 0.51% annual failure rate, which is aligned with the industry average as indicated by data from EPRI's Industry Wide Transformer Database for 1995 to 2015.

Table 1 - Transformer Annual Class 1 Failure Rate over Past 10 Years

Year	115kV	230kV	500kV	5 Year Average Annual Failure Rate, All Voltage classes
2008-2012	0.40%	0.37%	1.41%	0.44%
2013-2017	0.56%	0.41%	2.44%	0.59%
10 Year Average Annual Failure Rate	0.48%	0.39%	1.92%	0.51%

As Hydro One's transformer fleet ages, the probability of failure increases requiring resources and funding to be available to respond to these failures.

The bulk of the Program comprises of the spare transformer inventory. Hydro One uses the Markov Model to determine the appropriate number of spare transformers required to ensure continuity of electricity supply to customers, safety and reliability. The Markov Model takes into consideration the probability of failure, carrying costs and procurement lead time to determine the most cost effective number of spares to be kept in inventory. Hydro One retained a third party expert, EPRI, to undertake a study to verify that Hydro One's spare transformer requirements are appropriate and consistent with industry best practices. EPRI developed analytics tools to optimize the power transformer spares practice, which was compared with Hydro One's own Markov modeling. The study,[1] determined that Hydro One's operating spare transformer analysis using the Markov Model is sound. Hydro One continues to take steps to achieve and maintain the required quantity of operating spare transformers to ensure reliability and improve cost efficiency.

The Program is also comprised of activities related to replacing near term deteriorated asset that have yet to fail but warrant replacement in a timely manner. These targeted replacements are planned where there is no integrated station replacement project to address the replacement. This program mainly focuses on smaller equipment i.e. switches, instrument transformers, batteries, station service ancillary etc.

Outcome

The Program aims to maintain reliable supply to customers by replacing failed station equipment in a timely manner and mitigating safety and environmental risks. It will allow Hydro One to replace failed station equipment as promptly as possible to restore the system to normal operating conditions, which will ensure compliance with Hydro One's regulatory obligations.

The following table presents anticipated benefits as a result of the Program in accordance with the OEB's Renewed Regulatory Framework:

Customer Focus	• Improve customer satisfaction by minimizing interruptions and providing timely power restoration to customers. • Reduce risk and severity of customer supply interruptions due to lack of operating spares.
Operational Effectiveness	• Maintain transmission system reliability and safety. • Reduce safety risks associated with failing equipment.

[1] See TSP 1.4 Attachment 5 "Operating Spare Transformers Requirement Assessment".

Public Policy Responsiveness	• Ensure Hydro One meets its compliance obligations with respect to power system restoration and reactive response.

C. EXPENDITURE PLAN

Table 2 below presents forecasted costs for the Program, which are established based on based on comparable historical costs and projected future needs.

Table 2 - Total Investment Cost

($ Millions)[1]	**Prev. Years**	**2020**	**2021**	**2022**	**2023**	**2024**	**Forecast 2025+**	**Total**
Capital[2] and Minor Fixed Assets	0.0	45.4	37.5	38.1	38.8	39.5	0.0	199.2
Less Removals	0.0	1.2	1.1	1.1	1.1	1.2	0.0	5.6
Gross Investment Cost	**0.0**	**44.2**	**36.4**	**37.0**	**37.7**	**38.3**	**0.0**	**193.6**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**44.2**	**36.4**	**37.0**	**37.7**	**38.3**	**0.0**	**193.6**

[1] Due to the in-year nature of program investments, only 2020-2024 expenditures are shown
[2] Includes Overhead at current rates.

Factors driving the costs of this Program are:

- The scope of the replacement work required to address the failure;
- The type, rating and quantity of the assets requiring replacement;
- The historical annual quantity of transformer failures and demand transformer replacements that require spare deployment; and
- The type of transformer requiring spare deployment, as the costs of the operating spare transformers can vary based on transformer specifications such as voltage and capacity.

Controllable costs are being managed and minimized through the standardization of station designs and equipment ratings that result in the reduction of spare inventory for replacement parts, and through the establishment of unit price contracts with vendors.

D. ALTERNATIVES

The Program is non-discretionary and, as such, no alternatives have been considered. Failure to respond to an emergency or to prevent or minimize the effects of an emergency in a timely manner may result in non-compliance with the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC") and/or the TSC. It might also negatively impact customer operations and customer service. For example, the lead time to procure a new transformer can be a year or more which would introduce lengthy replacement timelines and negatively impact system reliability.

E. EXECUTION RISK AND MITIGATION

The risks of potential customer supply interruptions and longer outages caused by a failed transformer must be mitigated by timely response, which will be unplanned and reactive by definition. There are risks to executing such unplanned work including the availability of resources and long lead times for the purchase of new transformers. The risk of resources being unavailable is mitigated by having a process to enable the effective prioritization of resources to support immediate and emergent work as required.

SR-10 Transformer Protection Replacement

Start Date:	Q4 2015	**Priority:**	Medium
In-Service Date:	Q4 2020	**3 Year Test Period Cost ($M):**	3.8
Triggers:	Strategic, Preventative Maintenance/ System Renewal, Reliability, Immediate / Short-Term Compliance		
Outcomes:	Reduced risk or regulatory non-compliance, lower OM&A cost and increased system reliability		

A. OVERVIEW

Transformer Protection Replacement due to Second Harmonic Misoperations (the "Project") involves the replacement of old electromechanical protection systems with modern, microprocessor based relays. The Project was developed to mitigate transformer protection misoperations due to low second harmonic content. The main drivers of the Project is to ensure Hydro One continues to be compliant with the reliability standards established by North American Reliability Corporation ("NERC") and to ensure that Hydro One continues to operate its transmission system in a reliable and efficient manner. Hydro One has evaluated various alternatives for the Project, as described below, and concluded that proactive replacement of identified transformer protection relays with new microprocessor-based protection systems is the most cost effective and efficient undertaking. The projected costs of the Project are estimated to be $3.8 million over the test period.

B. NEED AND OUTCOME

Investment Need

Every transformer, when being energized, initially draws a large amount of current, called inrush current. The inrush current is up to fifteen times larger than the normal current that transformers typically experience. As such, the transformer protection system would normally interpret the inrush current as abnormal, and will result in the transformer being automatically removed from service by protection operation. The inrush currents are rich in harmonics, particular second harmonic. The increased presence of the second harmonic is detected by the relay and identifies that a transformer is being energized for the first time. Once the second harmonic is identified, a relay's tripping function is intentionally blocked for a short period of time to allow transformer current to settle to its steady-state value.

New style transformers which employ low loss core designs as well as some of the older transformers under certain system and design conditions are known to produce insufficient amount of second harmonic current. When an insufficient amount of second harmonic is produced, a protection relay is unable to detect that a transformer is being energized and causes a protection relay to operate incorrectly. This results in misoperations of a protection system. When transformer protections misoperate, Hydro One has to dispatch two crews to the site. One crew inspects the transformer and performs tests (e.g. dissolved gas analysis) to make sure that the fault is not caused by some real, transformer related issue. Another crew collects the necessary data from relays and sends it to engineering staff to analyse the operation and determine what actually caused the relay to operate.

As a licensed transmitter operating transmission facilities of the Bulk Energy System ("BES"), Hydro One is legally obligated to comply with the planning, operating and reliability criteria and standards adopted by NERC and Northeast Power Coordinating Council ("NPCC"). NERC Standard PRC-004-3 — *Protection System Misoperation Identification and Correction* (the "PRC-004") establishes the process for monitoring protection system events for BES elements, as well as identifying and correcting the causes of any misoperations caused by protection systems. The PRC-004 standard requires entities, such as Hydro One, to investigate BES system events involving protection operations in order to determine if they were correct operations or misoperations, and report misoperations to NERC. Once a misoperation is confirmed, Hydro One is required to establish and complete a corrective plan within a prescribed period of time that mitigates the identified sources of misoperation.

When a protection system misoperates due to second harmonic issue, Hydro One has to designate the transformer as unavailable until all tests are completed and it is verified that a transformer is safe to go back online. This might negatively impact Hydro One customers as the misoperation decreases system reliability. Hydro One transmission system is designed with a certain level of redundancy. If a backup transformer or other related equipment (protections, breakers etc.) fails, there is a high probability of customer power outages occurring or Hydro One may have to start shedding load (i.e. disconnecting customers) in order to balance the load demand vs. supply capacity and prevent further cascading outages.

Investment Description

The Project was developed to mitigate transformer misoperations due to low second harmonic content and to ensure Hydro One is in compliance with the PRC-004. The Project involves replacing old electromechanical protection systems with modern, microprocessor based relays.

Over the last 15 years, Hydro One has recorded more than 100 transformer protection misoperations related to the low second harmonic in the transformer inrush current. In accordance with the PRC-004, Hydro One developed a solution to mitigate these misoperations. The solution requires the use of protective functions which are available in modern microprocessor based relays, also known as Intelligent Electronic Devices ("IED"). The solution uses a feature known as "second harmonic cross blocking" which is an algorithm that allows the relay to detect energization based on how it detects the second harmonic. This feature is only found in modern microprocessor based relays. Using historical misoperation data as well as the transformer asset registry, Hydro One identified a list of candidate protection systems that utilize old electromechanical relays to be replaced. Hydro One conducted further analysis to identify the station reinvestment projects. As described elsewhere in the evidence, Hydro One utilizes integrated approach to replace major assets of a transformer station (e.g. transformer, breakers, protection and automation systems) where condition of these assets warrants replacement. As such, where it was possible, Hydro One bundled the replacement of the old electromechanical protection system with modern, microprocessor based relays into station reinvestment projects.

The Project targets transformer stations that are not part of a station reinvestment project, however, and contain older vintage relays that need to be replaced to ensure NERC compliance and system reliability. Hydro One plans to replace 15-20 old electromechanical protection systems with modern, microprocessor based relays per year, totalling 80 protection relays since the start of this project in 2016. This pacing prioritizes the sites that experience the largest number of misoperations while mitigating the demand on engineering and construction resources.

Outcome

The Project has been in execution since 2016 and has proved to be successful, to date. It has reduced the number of misoperations significantly. In 2013 there were 7 misoperations, 4 in 2014, 5 in 2015, and only 2 in 2016 and 2017.

Once the Project is fully executed, the risk of protection misoperations due to low second harmonic content will be significantly lowered. This will result in:

- Ensuring compliance with applicable the PRC-004 standard;
- Reduced Operations, Maintenance and Administration ("OM&A") expenditures due to fewer misoperations and related investigations; and
- Increased operational flexibility, as transformer protection misoperations will be reduced, maintaining equipment availability and system reliability;

The following table presents anticipated benefits as a result of the Project in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary

Customer Focus	• Improve system reliability
Operational Effectiveness	• Improve the ability to respond to system events by increasing availability of critical power systems components
Public Policy Responsiveness	• Ensure compliance with the PRC-004 standard
Financial Performance	• Reduction in OM&A expenditures resulting from reduced dispatches of field staff for protection misoperation as well as reduced need for analysis and tracking of misoperations.

C. EXPENDITURE PLAN

Table 1 below presents forecasted costs of the Project. Costs for the Project are based on budgetary estimates prepared by Hydro One using historical costs of projects of similar scope. These factors determine the complexity of the installation and the amount of alteration required for each station to the new protection system. Controllable costs have been minimized through the standardization of transformer protection design. The "Previous Years" costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 test year. Likewise, the costs noted in "Forecast 2025+" are project costs forecast beyond 2024.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	11.9	3.8	0.0	0.0	0.0	0.0	0.0	15.7
Less Removals	0.1	0.0	0.0	0.0	0.0	0.0	0.0	0.1
Gross Investment Cost	**11.8**	**3.8**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**15.6**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**11.8**	**3.8**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**15.6**

[1] *Includes Overhead at current rates.*

D. ALTERNATIVE

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: Reactive Maintenance of the Asset involves waiting until the identified protections are replaced by a sustainment capital project as they become candidates for replacement when reaching their Expected Service Life ("ESL"). This alternative was considered and rejected due to the negative impact on potential NERC non-compliance issues and the reliability of Hydro One's system since the relays involved in this project are not planned for replacement as part of integrated station investments within the 2020 to 2024 planning period. Allowing these relays to remain in service would result in prolonged risk of protection misoperation, negatively impacting customer reliability.

Alternative 2: Proactively Replace Affected Protection Relays is a preferred undertaking. It involves proactively replacing identified transformer protection relays with new microprocessor-based protection systems. This alternative utilizes a verified solution and employs microprocessor-based relays which are the current Hydro One standard. This alternative allows Hydro One to significantly reduce potential service interruptions, reduce OM&A expenditures associated with misoperation tracking and analysis, and eliminate risk of non-compliance with NERC standard PRC-004.

E. EXECUTION RISK AND MITIGATION

The Project risks and their mitigation measures are outlined below:

- Equipment Outage Availability – In order to replace protection relay, one of the redundant protection channels must be taken out of service. Often, network operations require that the power system component being protected is taken out of service. There is a risk that, due to operating conditions, Hydro One is not able to obtain outages to perform the work. In order to mitigate this risk, project management stuff was instructed to give enough lead time to outage planners.

- Engineering Resources – There is always a risk that highly specialized engineering and construction personnel needed to execute this type of work are not available at the time of execution. This will be mitigated by coordinating with internal service providers well as well as exploring possibilities to outsource the work to third party provides.

Witness: Donna Jablonsky

SR-11 Legacy SONET System Replacement

Start Date:	Q2 2017	**Priority:**	High
In-Service Date:	Q4 2024	**3 Year Test Period Cost ($M):**	57.7
Trigger(s):	System Renewal		
Outcomes:	Maintain reliability of the transmission system operation and maintenance		

A. OVERVIEW

Legacy SONET Systems Replacement (the "Project") involves the replacement of Hydro One's Synchronous Optical Network ("SONET") system with a new packet-based technology. The SONET system is based on SONET technology which is primarily utilized by Protection and Supervisory Control and Data Acquisition ("SCADA") systems. The SONET system, along with the physical infrastructure (fibre or microwave-based) that establishes communication links, are the cornerstones of Protection and Automation systems which support grid reliability as well as protection of costly station and line assets. Additionally, SONET is used for communicating non-operational data, business data, voice and security information, and is used as backhaul communication for the provincial mobile radio system.

SONET system, which primarily includes multiplexer equipment at transmission stations, is approaching its end of life ("EOL").The determination of approaching EOL in this case is made by the facts listed below:

- Large segments of the system are exceeding expected service life ("ESL"), and
- High risk for grid reliability,
- Technological obsolescence as vendors withdraw support (end of vendor support), and;
- Long lead times for planning and execution of asset replacements due to large installed base.

Witness: Donna Jablonsky

When end of vendor support ("EVS") is reached, spare parts become increasingly harder to find which leads to repairs and maintenance becoming increasingly costly, systems are at risk of longer outages and reliability is degraded. Hydro One's first generation of SONET system (the "Legacy System") equipment has reached its ESL as well as its EVS. It is no longer being developed by vendors.

Other factors influencing the EOL decision are:

- This system is critical for operation of the grid as its failure would have high reliability impact.
- Accelerated rate of failures in the future could require replacement volume that would be impossible to execute due to a very large installed base.

The failures caused by SONET equipment have resulted in multiple power system telecom services being rendered unavailable until repairs were carried out. Loss of communications channels can result in real-time control actions to be taken in order to either constrain power flow on transmission system and/or to remove power system elements from service such as breakers, lines, transformers etc. In turn, this can result in negative impact to the reliability of the transmission system, and potentially expose customers to a less reliable configuration due to the loss of redundancy. To address the reliability issues associated with the obsolescence of the technology and network equipment on which SONET is built, Hydro One has developed the Project, which aims towards replacing the Legacy System with a modern solution. Hydro One has evaluated various alternatives for the Project, as described below, and concluded that proactive replacement of the Legacy System with new packet-based technology is the most cost effective and efficient undertaking. The projected costs of the Project are estimated to be $57.7 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

The SONET communication network is primarily utilized for mission critical protection and SCADA applications. Mission critical protection means communications that are essential for the safe and reliable operation of the transmission system. These are protection trip signals that are initiated by protection systems to isolate high voltage equipment during a fault condition to prevent further or widespread outages. This can include the tripping of circuit breakers at multiple stations by sending a signal from one station to another through the SONET network in order to isolate a fault on a transmission line. Operation of the transmission system requires equipment telemetry and status information being continuously communicated to the Ontario Grid Control Centre ("OGCC") through the SONET network.

Protection trip signals, also known as teleprotection signals, along with other data traffic, are multiplexed, using time-division multiplexing ("TDM"), to higher bandwidth signals by SONET add-drop multiplexers on the network providing reliable and robust communication between Hydro One facilities. The SONET network multiplexer equipment is composed of two vintages; the first generation initially deployed between 1998 and 2007 and the second generation from 2004 on-wards. In addition to the multiplexer equipment, other key components that make up the SONET network include microwave links, optical amplifiers and 48Vdc backup power supplies. The network topology is such that communication rings are created connecting the stations to provide redundant communication links that can stretch up to hundreds of kilometres across the province. There are certain segments of network that are made up of microwave links as opposed to fibre connected paths. Although they were economical at the time of SONET deployment, over time they have created a capacity and bandwidth limitation on a typical ring topology while higher capability equipment from the vendor is not available as they have obsoleted the equipment.

To assess asset condition and determine its EOL, Hydro One takes into account asset age vs. ESL, rate of failures, reliability risk, vendor support, manufacturer recommendations and historical asset retirement. In addition, field deficiency reports, trouble calls and failure incidents provide an indication of the overall condition of the power system telecom assets and play a role in the determination of the EOL.

As one of the reference data, the ESL for most microprocessor based equipment is 15-20 years. Table 1 below shows typical ESL in years for the SONET communication Network.

Table 1 - Summary of SONET Equipment

Telecom System/Asset Class	Asset Type	Quantity	Expected Service Life (Years)	Currently Beyond ESL*	Beyond ESL 2024	Beyond ESL 2029
SONET Communication Network	Multiplexers	263	15	86	197	247
	Digital Radios	35	15	35	35	35
	Optical Amplifiers	32	15	29	31	31
	48 VDC Batteries	281	10-20[1]	23	49	141
	48 VDC Chargers	281	20	87	129	165

** Data as of December, 2018*
[1] Varies based on equipment make and/or model

The first vintage of multiplexer equipment has reached its ESL and is facing technological obsolescence as vendors withdraw support and, as such, spare parts become increasingly harder to find. The majority of SONET equipment failures are associated with the first vintage of multiplexer equipment (Vintage A MUX) as shown in Figure 1 below. These failures have resulted in multiple power system telecom services being rendered unavailable until repairs were carried out. Loss of communications channels can result in the removal of power system equipment from service and/or power flow constraint on the transmission system. Protection systems dependent on communications cannot ensure the equipment is adequately protected and the OGCC will lose visibility of the status of the equipment and system power flows. In turn, this will result in a negative impact to system reliability and expose Hydro One and its customers to the loss of redundancy which can lead to equipment being forcibly removed from service.

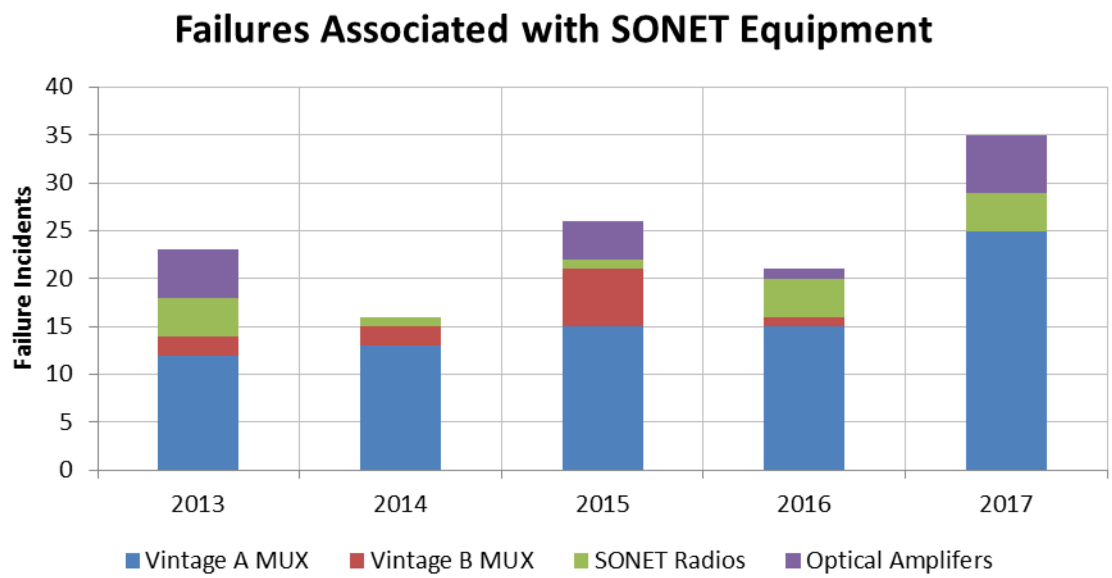

Figure 1 - Failure Incidents for SONET Equipment

Investment Description

Given the obsolescence of both the technology and network equipment on which SONET is built, Hydro One has developed the Project to replace the Legacy System with a modern solution. Implementation in the short and mid-term will begin with the replacement of legacy SONET equipment on Rings 1-9 taking into account other telecom sustainment needs and direction of the strategic expansion of the network. More specifically, the Project will replace the first vintage of SONET multiplexers that have been in service for close to 20 years with a new packet-based technology solution at 73 stations. The Project’s scope includes the necessary work to evaluate available technologies in the market, lab evaluations for proof of concept and field trials at select Hydro One transmission station(s) in order to validate the solution to be deployed. Once the new technology platform that satisfies the technical requirements is determined by the end of 2019, an overall implementation and staging plan will be developed, followed by multiyear systematic replacements. The technology evaluation will allow Hydro One to

be in an informed position to implement a viable technology in an orderly manner, and to mitigate operational impacts to the transmission system.
Based on the volume and complexities of the changeover, it is anticipated that it will take until 2024 to migrate communication services to the new platform for all nine rings of the communication network. As the network undergoes this changeover there will be a period of overlap when both the existing and the new platform will need to be operated and maintained.

Hydro One has completed the technical evaluation of available technologies, selected potential technologies, and conducted lab testing to demonstrate proof of concept as part of the development phase of the Project. Currently, field trials at being conducted at Claireville TS to further validate the technologies to be selected for deployment.

Outcome

The Project will result in Hydro One’s ability to support safe and reliable operation of the transmission system by migrating power system telecom services from Hydro One’s legacy SONET system to a new technology platform. In addition to its utilization for protection and SCADA systems, the new technology will also enable the cost-effective deployment of applications that require modern IP connectivity and eliminate the performance failures currently attributed to the older multiplexer equipment.

The following table presents anticipated benefits as a result of the Project in accordance with the OEB’s Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Maintain telecommunication reliability of the protection and SCADA systems thereby maintaining the quality of service to customers.
Operational Effectiveness	• Maintain reliability of the transmission system by ensuring the communication network used for protection, control and monitoring of the grid is reliable.
Public Policy Responsiveness	• Hydro One is obligated to build and maintain a redundant communication/protection system to ensure that Hydro One meets the transmission system performance standard of NERC TPL-001. If the cable begins to break down, it must be fixed.

C. EXPENDITURE PLAN

Table 2 below presents forecasted costs for the Project. Planned costs are currently based on previous SONET implementations. The “Previous Years” costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 test year. These costs include the development phase cases that cover evaluation, testing and proof of concept. The test period costs include the implementation costs which involve engineering, procurement and construction. Costs noted in “Forecast 2025+” are project costs forecast beyond 2024. Final costs of the project will be based on the selected technical solution that will be determined at the conclusion of the development phase. Detailed estimates will also be prepared following the conclusion of the development phase.

Table 2 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	5.4	4.3	27.1	28.7	29.3	29.3	0.0	124.2
Less Removals	0.1	0.2	1.1	1.1	1.2	1.2	0.0	4.8
Gross Investment Cost	**5.4**	**4.1**	**26.0**	**27.6**	**28.1**	**28.1**	**0.0**	**119.3**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0

[1] *Includes overhead at current rates.*

D. ALTERNATIVES

Alternative 1: Reactive Replacement of Failed SONET Equipment involves replacing the legacy SONET equipment as it fails. This alternative has been rejected as reactive replacements result in unplanned equipment outages that negatively impact communication system performance and customer satisfaction. Repair times can be longer due to material sourcing delays and resource availability. Because SONET equipment is facing obsolescence, Hydro One's inventory of some spare parts is diminishing, further reducing the viability of a reactive replacement approach.

Alternative 2: Planned SONET Replacement is a preferred undertaking. This alternative will replace the legacy SONET system with new packet-based technology. It allows Hydro One to maintain the reliability of the transmission system. Replacements will be coordinated, thereby, scheduling and reducing outage impacts which will in turn alleviate the impact on communication system performance and Hydro One's customers. Complete replacement will also enhance the capability of the communication network resulting in utilization of communication infrastructure for future communication applications.

E. EXECUTION RISK AND MITIGATION

The main risk to the Project is finding a solution that satisfies Hydro One's functional and economical requirements. The developmental phase of the Project will find a technology that will fulfill these requirements by the end of 2019 before pursuing implementation.

SR-12 Telecom Performance Improvements

Start Date:	Q1 2021	**Priority:**	Medium
In-Service Date:	Q4 2023	**3 Year Test Period Cost ($M):**	6.5
Trigger(s):	Strategic, System Renewal		
Outcomes:	Maintain reliability of the communication network, maintain customer satisfaction, more reliable SONET network which will be supported by robust and reliable fibre cable infrastructure		

A. OVERVIEW

Telecom Performance Improvements project (the "Project") involves the replacement of obsolete digital microwave links with optical ground wire ("OPGW") on Ring 6 of the Synchronous Optical Network ("SONET") system.

Hydro One's SONET system is supported by physical infrastructure that establishes the communication medium that links transmission stations and control centers. A vast majority of these links utilize Hydro One owned or leased fibre-cable infrastructure, however, certain links are microwave based. While the Legacy SONET System Replacement project (SR-11) involves the replacement of end multiplexer equipment with a new technology, this Project establishes more robust and reliable fibre-based communication links within the above mentioned Ring.

The associated equipment of these microwave links is at its End of Life ("EOL") or, in some segments, soon approaching EOL due to the fact that assets:

- Have reached its Expected Service Life ("ESL"),
- Are technologically obsolete, and
- Have experienced higher rate of failures of SONET system's digital microwave radios which resulted in multiple power system telecom services being rendered unavailable until repairs were carried out.

The above facts make the reliability risk high. Loss of power system telecom services which include communications channels for protection systems can result in the removal of power system elements from service and/or power flow constraints on the transmission system (as protection systems dependent on communications cannot protect the equipment and the OGCC loses visibility of the status of the equipment). In turn, this can result in a negative impact to the reliability of the transmission grid and potentially expose Hydro One and customers to forced outages or a less reliable grid configuration due to the loss of redundancy. In addition to the high reliability risk, these microwave links are bandwidth bottleneck for the SONET network, limiting the full utilization of capacity of the SONET Rings.

In light of the foregoing, the Project is needed to improve the network performance in order to maintain the communication network's reliability. Hydro One has evaluated various alternatives for the Project, as described below, and concluded that proactive replacement of the obsolete ESL equipment is the most cost effective and efficient undertaking. The projected costs of the Project are estimated to be $6.5 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

Hydro One's communication network is based on SONET technology and is primarily utilized by protection systems, and SCADA monitoring systems. Additionally, it is used for communicating non-operational data, business data, voice and security information, and is used as backup for the provincial mobile radio system. The system includes multiplexers, optical amplifiers, digital microwaves and 48Vdc backup power supply (battery and charger systems). The network topology is such that stations are connected in the form of a ring to provide redundant communication links that can stretch up to hundreds of kilometers long across the province.

Hydro One's SONET network has a number of digital microwave links that were originally deployed where either fibre-based infrastructure was not economically feasible to install or third party leased fibre was not available. The associated digital microwave equipment is at EOL having reached its ESL and being technologically obsolete. Hydro One takes into account asset age, installed base, strategic spares, rate of failures, compliance, functionality, vendor support, manufacturer recommendations and historical asset retirement in order to determine EOL and to plan asset replacements. Field deficiency reports, trouble calls and failure incidents provide an indication of the overall condition of the power system telecom assets. The ESL for most of the digital microwave equipment is 15 years.

These failures have resulted in multiple power system telecom services being rendered unavailable until repairs were carried out. Loss of power system telecom services which include communications channels for protection systems can result in the removal of power system equipment from service and/or power flow constraint on the transmission system (as protection systems dependent on communications cannot protect the equipment and the Ontario Grid Control Centre ("OGCC") loses visibility of the status of the equipment).

Investment Description

As described above, the Project is needed to improve the network performance in order to maintain the communication network's reliability. The Project is paced such that the last major microwave links will be removed by 2023.

Digital microwave systems have been part of SONET Rings 4, 6 and 8 which provide a microwave radio path between stations as opposed to fibre cable links. Most of the microwave equipment is on SONET Ring 6 and 8. Replacement of microwave links on Ring 8 with OPGW is already underway leaving Ring 6 with major links to be removed on the SONET system by 2019. The investment is paced in such a way that following the replacement of microwave equipment on Ring 8 with more reliable and robust fibre-based links, work on Ring 6 will begin. Investment for the replacement of the last microwave link in Ring 4 is also in Hydro One's Business Plan that is targeted for completion by 2023. Table 1 below identifies the work that will be completed under this project.

Table 1 - Telecom Performance Improvement Projects

Circuits	Project Description	Project In-Service Year
B22D	Replacement of the remaining obsolete digital microwave radios on Ring 6 with the installation of OPGW on B22D	2022

Outcome

The Project will result in robust and reliable fibre-optic based communication infrastructure that will maintain transmission system reliability. Additionally, telecommunication service outages will be reduced and fewer inspections and repairs of microwave link equipment will be required.

The following table presents anticipated benefits as a result of the Project in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Maintain telecommunication reliability and the quality of service provided to customers.
Operational Effectiveness	• Maintain reliability of the transmission system by maintaining the reliability of the communication network.
Financial Performance	• Avoid maintenance costs associated with obsolete asset.

C. EXPENDITURE PLAN

Table 2 summarizes historical and projected spending on the aggregate project level. Planned costs are currently based on estimates from previous projects. Final costs will be based on detailed estimates prior to project execution. The "Previous Years" costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 test year.

Table 2 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	0.0	0.0	1.0	5.8	3.8	0.0	0.0	10.5
Less Removals	0.0	0.0	0.0	0.2	0.2	0.0	0.0	0.4
Gross Investment Cost	**0.0**	**0.0**	**0.9**	**5.5**	**3.7**	**0.0**	**0.0**	**10.1**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**0.0**	**0.9**	**5.5**	**3.7**	**0.0**	**0.0**	**10.1**

[1] *Includes overhead at current rates.*

D. ALTERNATIVES

Alternative 1: Reactive Repair of SONET Equipment involves repairing microwave links as they fail. This alternative has been rejected as Hydro One will be unable to maintain the required performance of the communication networks supporting protection and control systems that are reliant on the microwave links. This approach would lead to an unacceptable level of risk to system reliability.

Microwave equipment is obsolete and vendor support is diminishing. This results in longer repair times during which the equipment is out of service and there is loss of redundancy in that SONET ring. This is undesirable level of equipment performance as it degraded the reliability of the protection systems in the area.

Alternative 2: Planned Replacement of Microwave Links is a preferred undertaking. This alternative will replace SONET microwave links with OPGW as it provides robust and reliable communication links for Ring 6. It also allows for the replacement to be coordinated thereby scheduling and reducing outage impacts which will alleviate the impact on telecommunication system performance and Hydro One's customers.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of the Project are: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges, or regulatory approvals. A thorough risk assessment workshop is performed during the initial project planning phase where all known risks are identified and mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize to a minimum the loss of supply to the customer. The plan might include switching a customer to an alternative supply, the construction of a temporary by-passing circuit or supply of portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages. Another example is the involvement of real estate from the project inception. It allows for the early identification of real estate issues, such as missing or inadequate land rights. Once the issue is identified, Hydro One tries to resolve it prior to execution of the project.

SR-13 ADSS Fibre Optic Cable Replacements

Start Date:	Q3 2018	**Priority:**	High
In-Service Date:	Q4 2022	**3-year Test Period Cost ($M):**	15.1
Trigger(s) : System Renewal			
Outcomes: Maintain reliability, improved safety			

A. OVERVIEW

Hydro One utilizes fibre optic cable infrastructure including Hydro One owned/operated aerial fibre optic cables as well as fibre strands acquired through indefeasible right of use ("IRU") from telecom providers. An IRU is a permanent contractual agreement that cannot be undone, between the owners of a communications system and a customer of that system. Hydro One's aerial fibre optic cables include both Optical Ground Wire ("OPGW") and All-Dielectric Self-Supporting ("ADSS") types. Hydro One has been phasing out ADSS fibre optic cables from its asset base due to high risks to reliability and safety. The remaining sections of ADSS fibre cable have deteriorated significantly over the recent years. Excessive premature wear and tear has compromised the asset and hence Hydro One's ability to operate the transmission system reliably. In order to maintain the reliability of the transmission system, there is a need to replace remaining sections of Hydro One owned ADSS fibre optic cable.

B. NEED AND OUTCOME

Investment Need

This investment is needed to mitigate the reliability and safety risk posed by deteriorating ADSS fibre optic cables.

Hydro One's communication network is based on Synchronous Optical Network ("SONET") technology and is primarily utilized by protection systems, and SCADA monitoring systems, as well as for communicating non-operational data, business data, voice and security information, and is used as backhaul communication for the provincial mobile radio system. The network topology is such that communications among stations are connected in the form of a ring to provide redundant communication links that can stretch up to hundreds of kilometers across the province.

The SONET rings provide robust and reliable communication between transmission stations because of the reliable fibre optic cable infrastructure and network configuration that essentially provides redundancy paths for communications. Hydro One Networks utilizes approximately 3,900 kilometers of fibre optic cable infrastructure including Hydro One owned/operated aerial fibre optic cables as well as fibre strands acquired through IRU. Aerial fibre optic cable is primarily comprised of (i) OPGW technology with strands of fibre embedded inside of the shieldwire mounted on top of high-voltage transmission structures and (ii) ADSS fibre otpic cable that is attached to towers or poles typically below the phase conductors, with a small share being attached to low-voltage wood poles located along roadways and/or railways.

Hydro One’s fibre optic cable infrastructure includes approximately 160 km of ADSS type fibre cable. The ADSS cable along the Q25BM and Q29HM right of way (“ROW”) is an essential segment of the Ring 3 that spans from Hamilton, Niagara and the Southwest connecting many Bulk Electric System as well as load supply transmission stations, while the ADSS cable along circuits D6V and E9V connects Detweiler TS, Orangeville TS and Essa TS. Historical performances have shown that the mechanical aspects of the fibre cable have prematurely reduced the cable’s life span. Specifically, excessive vibrations have led to compromising the integrity of the cable itself as well as connection hardware. Inspections reveal damaged cables, missing or broken hardware assemblies on a yearly basis.

Figure 1 – ADSS Fibre Optic Cable Damage in 2017

The Expected Service Life (ESL) of fibre optic cable is based on the type of cable. The manufacturers' recommended ESL for OPGW is 40 years and 25 years for ADSS. Historical performance shows that the mechanical aspects of the fibre cable can prematurely reduce the cable's life span. In the case of ADSS cables, unusual mechanical stresses have resulted in high rate of premature failures before its ESL expired. ESL is now lowered to 15 years and it is used to trigger the asset condition assessment in the replacement decision making process.

Due to the high risks to reliability and safety posed by this degradation, Hydro One has been phasing out ADSS fibre cables from its asset base. The remaining sections of ADSS fibre cable have deteriorated significantly over the recent years. Excessive premature wear and tear has compromised the asset and hence placed at risk Hydro One's ability to operate the transmission system reliably. Annual helicopter patrols for inspections along the Q25BM/Q29HM and D6V/E9V ROW have shown a declining trend in the overall condition of the ADSS cable with damages to the cable jacket, fibre strands, as well as hardware assemblies.

Failures of ADSS cable would lead to loss of power system telecom services and loss of redundancy of protection systems leading to degraded reliability of communications for the transmission stations served by the cable. Degraded reliability is not desirable for transmission system operations and maintenance by the Independent Electricity System Operator ("IESO") and the Ontario Grid Control Centre ("OGCC") because it places the system at risk of forced outages due to second contingency resulting in complete loss of communication to multiple stations. Failure of one cable places the system in a high risk scenario should another failure occur on the ring, which in turn would lead to multiple power outages as a result of complete loss of communication. Failures of ADSS cable is also a safety risk as the cable can break and fall to the ground that can cause injury.

Keeping the existing configuration in place represents a major reliability risk. In order to maintain the reliability of the transmission system, there is a need to replace the remaining sections of ADSS cable with better performing OPGW.

Investment Description

This investment addresses the replacement of remaining deteriorated ADSS cable with optical ground wire, designed to current standards. The ADSS cable to be replaced by this project includes 60 km of ADSS cable along the Q25BM/Q29HM right of way as well as replacement of 98 km of deteriorated ADSS on circuits D6V and E9V between Detweiler TS, Orangeville TS and Essa TS. The remaining 5 km ADSS population will be included, where technically and financially feasible, as part of the Shieldwire Replacement Program. Asset condition information for power system telecom is discussed in TSP Section 2.2.1.5.

Keeping the existing configuration in place represents a major reliability risk to certain sections of the Hydro One SONET network. In order to maintain the reliability of the transmission system, remaining sections of ADSS cable will be replaced with better performing OPGW. Although both OPGW and ADSS have their own benefits and drawbacks, OPGW is the preferable replacement for the following reasons:

- Better suited for high voltage environments due to robust construction
- Less susceptible to vandalism
- Higher ESL

Outcomes

The following table presents anticipated benefits as a result of the Project in accordance with the OEB's Renewed Regulatory Framework:

Customer Focus	• Maintenance of system reliability and reduced risk of outages and safety concerns
Operational Effectiveness	• Maintain reliability of the transmission system through maintaining a reliable communication network by replacing poor performing and degraded ADSS cable.
Public Policy Responsiveness	• Hydro One is obligated to build and maintain a redundant communication/protection system to ensure that Hydro One meets transmission system performance standard of NERC TPL-001. If the cable begins to break down, it must be fixed.
Financial Performance	• Avoid Operations, Maintenance & Administration ("OM&A") costs associated with ADSS repairs required upon failures.

C. EXPENDITURE PLAN

Table 1 below presents forecasted costs of the Projects. The planned costs are based on estimated unit costs. Final costs will be based on detailed estimations performed prior to project execution. Controllable costs will be effectively managed during the execution of this project.

Previous year costs are associated with developing a detailed execution plan and estimated costs for the Q25BM/Q29HM portion of the work. Future year costs are for work execution costs with the bulk of engineering and procurement work to occur in 2020 and 2021, as well as the start of construction. The investment is paced to allow for timely cost estimation followed by complete execution of the replacement work. The majority of the construction work will be carried out in 2020, 2021 and 2022. Previous year costs are associated with developing a detailed execution plan and estimated costs for the D6V/E9V portion of the work followed by work execution costs until 2022.

Planned costs are based on the following sequence of work with work execution and construction spanning over multiple years:

- Estimation, preliminary planning/engineering
- Details design/execution planning/work execution/construction
- Wrap up/project closure activities

Table 1 - Total Project Costs

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	1.6	7.5	7.5	1.0	0.0	0.0	0.0	17.6
Less Removals	0.1	0.5	0.4	0.0	0.0	0.0	0.0	1.0
Gross Investment Cost	**1.5**	**7.0**	**7.1**	**1.0**	**0.0**	**0.0**	**0.0**	**16.6**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**1.5**	**7.0**	**7.1**	**1.0**	**0.0**	**0.0**	**0.0**	**16.6**

[1] Includes overhead at current rates.

D. ALTERNATIVES

Alternative 1: Reactive Treatment of ADSS Fibre Cable. Hydro One can repair or replace sections of fibre communication cable reactively upon failures. This alternative is rejected due to criticality of the fibre communication cable to the operation of the transmission system, the reliability risk associated with cable failure and undesirable OM&A costs of repairs.

Undesirable OM&A costs are costs associated with more than usual maintenance of an asset. Because of all the issues highlighted above, every year repairs are identified that need to be carried out on ADSS. Compared to OPGW, inspections are done but major repairs are not identified every year. In order to carry out this 'discovery' maintenance, crews have to first assess the extent of the damaged and come up with a plan to fix, mobilize, seek outages, parts, repair kits, etc. which comes out of our planned maintenance budget. Since the nature of the repair work is different than conventional PCT equipment failure, costs range from $20,000 to $100,000 per repair.

Alternative 2: Planned Replacement of ADSS Fibre Cable. This is the preferred alternative. Hydro One can replace approximately 60 km of ADSS cable along the Q25BM/Q29HM right of way, as well as 98 km of deteriorated ADSS cable on circuits D6V and E9V between Detweiler TS, Orangeville TS and Essa TS. This alternative will maintain the integrity of communication channels used for protection systems of the high voltage transmission system in turn, maintaining system reliability and avoid OM&A costs associated with ADSS repairs.

E. EXECUTION RISK AND MITIGATION

There is a risk to complete the project as planned due to potential delay in required circuit outages to carry out replacement work. Hydro One will manage and stage the project to ensure that outages are available in time. Availability of resources and other competing projects requiring similar resources is a risk to project priority and timely completion. Hydro One will develop a detailed project and resource plan in order to ensure resources are available.

SR-14 Mobile Radio System Replacement

Start Date:	Q1 2019	**Priority:**	Medium
In-Service Date:	Q4 2023	**3-year Test Period Cost ($M):**	15.2
Trigger(s): System Renewal			
Outcomes: New radio system**,** Increased reliability of communications during power outages and restoration efforts, Shorter outage duration as a result of effective communication between control centres and field staff			

A. OVERVIEW

This investment involves the procurement of a solution to replace the existing provincial mobile radio system. The existing radio technology that Hydro One uses for its private mobile radio system is obsolete and requires replacement when the strategic spares are exhausted in 2023. The planned mobile radio replacement project addresses the concerns regarding the end of life of the existing technology, the commercial unavailability of radio equipment in the 49 MHz frequency band and the condition of the deployed equipment by implementing a new technology solution to continue providing communications between control centres and field staff when maintaining and restoring transmission system assets.

B. NEED AND OUTCOME

Investment Need

Hydro One owns and operates a private radio system that is used for two-way voice communication between control centers and field crews. This system is used by forestry and lines crew during restoration efforts, emergency operations as well as day-to-day construction and maintenance work. The mobile radio provides coverage that exceeds the cellular coverage in remote areas and is often the only means of communications in these areas.

The existing radio technology Hydro One uses for its private mobile radio system is obsolete having reached end of vendor support ("EVS"). Equipment for the system is no longer manufactured, and Hydro One's strategic spares will only last up to five years from 2018. When the strategic spares have been exhausted in 2023, Hydro One will be unable to restore radio communications upon failure of equipment. This would render voice communication unavailable for field staff and control centers, especially in parts of the province where there is no cellular coverage. As a result, Hydro One will be unable to maintain transmission system equipment and/or restore power in remote areas in a safe and timely manner resulting in longer than expected outages. The potential reliability impact resulting from the EVS leads to the system being classified as having reached its end of life ("EOL").

The concerns of equipment at end of life, the commercial unavailability of radio equipment in the 49 MHz frequency band and condition of the deployed equipment necessitate an overhaul of the current provincial radio system. In light of the foregoing, a new technology solution is needed to continue providing communications between control centres and field staff when maintaining and restoring transmission system assets.

Investment Description

This investment will procure a solution to replace the existing provincial mobile radio system. The planned mobile radio replacement project will:

- Examine available technologies such as satellite based-communication, radio over IP, trunked radio system, and integrated solutions to the existing hand-held and in vehicles units used by field staff;
- Study the technical and economic feasibility of each of the viable technologies, select technology for small scale deployment as a proof of concept, with due consideration for future operating costs; and

- Carry out assessment to determine the required infrastructure that would be needed to ensure the necessary coverage is provided prior to new system's deployment.

The investment is paced to allow the new system to be fully tested prior to deployment. Multi-year deployment will also smooth the transition to the new system while utilizing the existing system to its full extent. It is expected that the new system will be fully implemented by 2023.

Outcomes

By replacing the existing provincial mobile radio system, Hydro One will continue to provide voice communication between control centers and field crews maintaining efficiency and safety during restoration efforts, emergencies as well as routine work. This in turn will allow Hydro One to keep power outage durations to a minimum to the benefit of customers.

The following table presents anticipated benefits in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Maintain the ability to restore transmission equipment in remote areas in a timely manner to minimize impacts on the system and customers
Operational Effectiveness	• Maintain equipment outage durations and power restoration times.
Financial Performance	• Work efficiency will result is lower Operations, Maintenance, and Administration ("OM&A") costs associated with power restoration and emergency operations.

C. EXPENDITURE PLAN

Table 1 below presents forecasted costs of the Project. Planned costs are based on past system deployment costs. Final costs will be based on the technology solution selected to replace the existing system. Hydro One will follow its established estimating process and project management practices to minimize controllable costs.

The previous years' costs (2019) are for the development phase of the project where a new technology will be evaluated, tested and estimated to determine system deployment costs. Planned costs in 2020 and beyond are costs related to province-wide deployment of the new solution. The project is planned for completion in 2023, and lower costs will be expected that year as the project wraps up.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	0.7	3.0	6.5	6.4	4.2	0.0	0.0	20.6
Less Removals	0.0	0.1	0.3	0.3	0.2	0.0	0.0	0.8
Gross Investment Cost	**0.6**	**2.9**	**6.2**	**6.1**	**4.0**	**0.0**	**0.0**	**19.8**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.6**	**2.9**	**6.2**	**6.1**	**4.0**	**0.0**	**0.0**	**19.8**

[1] *Includes overhead at current rates.*

D. ALTERNATIVES

Alternative 1: Maintaining the Existing System. Hydro One can maintain the existing provincial mobile radio system. This alternative is rejected as Hydro One would be unable to restore failed radio equipment in fleet trucks and base station beyond 2023. This would render voice communication unavailable for field staff and control centers. As a result, Hydro One would be unable to maintain transmission system equipment and/or restore power in remote areas in a safe and timely manner resulting in longer than expected outages.

Alternative 2: Replace Legacy Mobile Radio System. This is the preferred alternative. Hydro One can replace the existing legacy provincial mobile radio system with a new system. This alternative involves procuring a fully integrated solution that meets the communication needs of the control centre dispatch and field crews using commercially available and supported technology. This approach allows Hydro One to continue to provide voice communications between field staff and control centers during restoration efforts, emergency operations as well as day-to-day construction and maintenance work.

E. EXECUTION RISK AND MITIGATION

The risk to the implementation of this investment is finding a technologically and economically feasible solution. For example, a new system at higher frequency may require proportionally larger infrastructure, resulting in higher costs than estimated. Hydro One will execute a developmental phase of the project to explore the available technologies that meet technical and business requirements before pursuing implementation.

SR-15 Telecom Fibre IRU Agreement Renewals

Start Date:	Q1 2021	**Priority:**	High
In-Service Date:	Ongoing Program	**3 Year Test Period Cost ($M):**	11.3
Trigger(s): Contractual, System Renewal			
Outcomes: Maintained reliability of communications systems			

A. OVERVIEW

This investment involves the renewal of leases of fibre acquired through Indefeasible Right of Use ("IRU") agreements for use in Hydro One's telecommunication network. Indefeasible right of use is a permanent contractual agreement that cannot be undone, between the owners of a communications system and a customer of that system. The agreements for the leased fibre used in Hydro One networks will begin to expire in 2021. These agreements require renewal upon expiration in order to continue to provide telecommunication for reliable network operation.

B. NEED AND OUTCOME

Investment Need

Hydro One's Synchronous Optical Network ("SONET") used for station to station and control centre telecommunication utilizes approximately 1,700 km of fibre acquired through IRU agreements. These agreements were negotiated for initial terms of 20-25 years that are due for renewal starting 2021. The last scheduled renewal is planned to occur in 2026. In order to continue to provide telecommunications for the reliable operation of the transmission system, there is a need to renew these agreements that provide for the necessary fibre infrastructure underpinning power system protection, control and monitoring applications.

In certain locations, Hydro One is leveraging the existing shieldwire replacement program to install new Optical Ground Wire ("OPGW") in place of the shieldwire. In locations where shieldwire replacement is necessary and a fibre optic communication channel is required for telecommunication purposes, Hydro One will install OPGW, which consists of overhead shieldwire with a core containing fibre optic strands. Where the new OPGW will make the leased IRU fibres redundant, leases for that section of cable will not be renewed. Leveraging the shieldwire replacement program allows Hydro One to provide more reliable communication and avoid renewal costs. IRU fibre cables are generally located along roads and railroads on wood poles, while OPGW is installed on top of high voltage transmission structures, making them less prone to outages caused by accidents. When considering whether a specific site is suitable for this approach, the following considerations will be assessed:

- Whether the shieldwire replacement program is scheduled to occur within a reasonable timeframe (5-7 years).
- Whether there are communication system reliability issues associated with existing leased fibre.

Investment Description

The need to renew leased fibre in each geographical area will be assessed, and renewals will be pursued where justified in order to continue to provide telecommunication for reliable network operation. Where the shieldwire replacement program will install OPGW in the near future, the lease will not be renewed.

Hydro One leases certain strands in the IRU fibre cables, which are owned and maintained by others. Leased IRU fibres are owned by Hydro One Telecom, a subsidiary of Hydro One, as well as Bell, Eastlink and Cogeco, among others. Where the fibre is owned by parties other than Hydro One Telecom, Hydro One Telecom will lease the fibre and in turn lease the fibre to Hydro One under service-level agreements.

The pacing of the investment is based on when the initial term ends for each section of the fibre. Contracts will expire between 2021 and 2026, triggering a concurrent renewal requirement. Therefore, the need for renewals will be assessed according to this timeline.

Outcomes

This investment will allow Hydro One to provide telecommunication for transmission system operations by providing the required fibre infrastructure in the most economical manner.

The following table summarizes the anticipated benefits as a result of the project in accordance with the OEB's Renewed Regulatory Framework:

Customer Focus	• Reduce risk to the operation of the transmission system by ensuring leased fibres are secured under contract.
Operational Effectiveness	• Maintain reliability of the transmission system by providing fibre cable for telecommunication used for protection, control and monitoring of the grid.
Financial Performance	• Minimize controllable costs through the use of Hydro One Telecom in the negotiation of IRU agreements.

C. EXPENDITURE PLAN

Planned costs are based on initial term one-time lump sum payments. The scheduling of the expenditure plan is based on the expiration dates of the initial term for each of the IRU fibre segments. Contracts for certain segments start expiring in 2021, triggering a need for renewals in that year while the last of the segments initial term expires in 2026.

As in the past, Hydro One will engage Hydro One Telecom to negotiate extensions and prices under existing Hydro One – Hydro One Telecom service-level agreements.

Table 1 - Total Investment Cost

($ Millions)[1]	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[2] and Minor Fixed Assets	0.0	0.0	2.8	8.5	2.6	1.5	0.0	15.4
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.0**	**0.0**	**2.8**	**8.5**	**2.6**	**1.5**	**0.0**	**15.4**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**0.0**	**2.8**	**8.5**	**2.6**	**1.5**	**0.0**	**15.4**

[1] Due to the in-year nature of program investments, only 2020-2024 expenditures are shown
[2] Includes Overhead at current rates.

D. ALTERNATIVES

Alternative 1: Construct Fibre Cable Infrastructure. Construct required fibre cable infrastructure to support the Hydro One SONET network requirements. This alternative is rejected as construction of Hydro One owned fibre cable infrastructure is not economically feasible to completely displace all IRU fibre.

Alternative 2: Renew Subset of Fibre IRU Agreements. This is the preferred alternative. Renew a subset of IRU contracts where it is not economically feasible to build Hydro One owned fibre cable infrastructure. This alternative will allow Hydro One to maintain the reliability of the transmission system by continuing to provide telecommunications infrastructure for protection, control and monitoring of transmission system assets. Where prudent and feasible, fibre optic cable infrastructure will be constructed by Hydro One that would eliminate the need of renewals for certain IRU contracts.

E. EXECUTION RISK AND MITIGATION

Completion risks involve paying elevated renewal prices if negotiations are delayed until the end of the lease period, and potential high risk to the operation of the transmission system if extensions are not sought prior to the expiration of the lease. Renewal costs will need to be negotiated with third parties in a timely manner to ensure that there is no interruption in communications. If delayed until the end of the lease period, Hydro One will face increased pressure to secure these fibres under contract. These risks will be mitigated by adopting a pro-active approach to the assessment and renewal of leased fibre segments, and leveraging Hydro One Telecom to seek these IRU renewals.

SR-16 NERC CIP-014 Physical Security Implementation

Start Date:	Q1 2020	**Priority:**	High
In-Service Date:	Program	**3 Year Test Period Cost ($M):**	54.0
Trigger(s):	Compliance, Strategic, Customer Satisfaction, Corrective Maintenance, Reliability and Environment		
Outcomes	Compliance with NERC CIP-014; ensure security of crucial transmission facilities		

A. OVERVIEW

Hydro One's transmission system is a critical asset for the Province; it comprises the Bulk Electric System ("BES"), which requires compliance with reliability standards established by the North American Electric Reliability Corporation ("NERC") to ensure the integrity of the interconnected North American BES. NERC Critical Infrastructure Protection - 014 ("CIP") standard requires entities, such as Hydro One, to identify and protect transmission stations and transmission substations (and their associated primary control centers) that if rendered inoperable or damaged as a result of a physical attack could result in widespread instability, uncontrolled separation or cascading effects to the BES. The CIP-014 Physical Security Implementation project (the "Project") involves specific physical security improvements to Hydro One transmission stations and control centres that are subject to CIP-014 compliance. Hydro One identified 26 stations and 1 control centre that meet criteria of CIP-014 and as such are subject to NERC CIP-014 requirements. The Project ensures that Hydro One continues to be compliant with the regulatory requirement thereby, ensuring that the critical transmissions assets are safe and secured.

B. NEED AND OUTCOME

Investment Need:

Hydro One operates one of the largest transmission systems in North America. Hydro One's transmission system extends to most of the Province and operates in diverse geographic and climactic conditions. Hydro One's transmission system is a critical asset for the Province, among others, it comprises the BES, which requires compliance with reliability standards established by the NERC to ensure the integrity of the interconnected North American BES. The reliability framework for Ontario's electricity transmission system is based on the reliability standards established by NERC, which have been adopted and are enforced in Ontario by the Independent Electricity System Operator ("IESO").

The *Electricity Act, 1998* ("Electricity Act") grants the IESO jurisdiction to maintain the reliability of the IESO-controlled grid and the statutory power to create market rules establishing and enforcing standards and criteria relating to the reliability of the electricity service or the IESO-controlled grid. The Government of Ontario has also directed the IESO to coordinate standards development activities with, among others, the NERC by assigning it the statutory object to participate in the development by any standards authority of criteria and standards relating to the reliability of the integrated power system. NERC is identified in the *Electricity Act* as standards authorities that approve standards and criteria relating to the reliable operation of the integrated power system. In addition to other reliability requirements in the market rules and market manuals, the market rules incorporate NERC reliability standards and criteria by reference. Subject to the IESO's applicability determination, these standards and criteria form part of the law in Ontario. The market rules assign to the IESO various functions, powers and authorities to supervise, administer and enforce the market rules. The market rules also provided the IESO with the general power to undertake such monitoring as it considers necessary to determine whether market participants, such Hydro One, are complying with the market rules. This power necessarily extends to those provisions mandating reliability standards compliance in Ontario.

With an increased focus on physical security, NERC has developed physical security reliability standards to ensure the critical infrastructure of the utilities is kept secured and safe. In 2014, NERC released the CIP-014 standard that provides guidance to utilities in addressing the protection of key physical assets. The stated purpose of the standard and its requirements is to identify and protect transmission stations and transmission substations (and their associated primary control centers) that if rendered inoperable or damaged as a result of a physical attack could result in widespread instability, uncontrolled separation or cascading effects to the BES.

In accordance with CIP-014, Hydro One is required to perform an initial threat risk assessment of its transmission stations and transmission substations (existing and planned to be in service within 24 months) that meet the criteria specified in CIP-014. The risk assessments consist of a transmission analysis designed to identify the transmission station(s) and transmission substation(s) that if rendered inoperable or damaged could result in widespread instability, uncontrolled separation, or cascading within an Interconnection. Furthermore, CIP-014 also requires Hydro One to have an unaffiliated third party verify the results of the risk assessment that has been performed.

Investment Description

Hydro One has identified 26 stations and 1 control centre that meet criteria of CIP-014 and as such are subject to NERC CIP-014 requirements. Hydro One performed a threat risk assessments of these stations and the control center in April 2016. A Threat Risk Assessment (TRA) is a detailed risk assessment process performed by Hydro One security specialists who evaluate, among other things, Hydro One transmission stations for security gaps. In accordance with the CIP-014 requirements, the results of the risk assesments are then verified by an independent third party. Hydro One's TRA was reviewed and verified by Ontario Provincial Police.

The Project will implement physical security measures, based on the recommendations of the TRA, on these critical stations. Providing adequate physical security to Hydro One critical stations will ensure operational effectiveness, as well grid resiliency and reliability to Hydro One customers.

Specific physical security improvements will vary by station to ensure NERC compliance and may include:

- Physical barriers such as upgraded fences, gates, and jersey vehicle barriers which will act as the outermost layer of security.
- Surveillance cameras with thermal night vision and motion detection used to deter unwanted entry will provide incident verification and historical analysis.
- Security lighting provides visual-assessment during darkness and acts as a deterrent.
- Physical Access Control System such as electronic door controls, magnetic card readers and access cards will trigger alerts in response to detected unauthorized access.
- Extending the height of the conduit protecting the fiber inside an optical ground wire cable that provides the supervisory, teleprotection, corporate and power system IT communication will reduce the possibility of tampering or malicious damage.

Outcome

The Project will ensure that Hydro One is compliant with the regulatory requirements of NERC CIP-014, while ensuring adequate physical protection to Hydro One critical transmission assets. Furthermore, the Project will sustains at the least the same level of system reliability and resiliency by minimizing physical threats and vulnerabilities that might occur as a result of a physical attack and cause instability and impact customers.

The following table presents the anticipated benefits as a result of the Project in accordance with the Ontario Energy Board's Renewed Regulatory Framework:

Customer Focus	• Maintain system reliability and supply to customers by ensuring secure operation of critical transmission facilities.
Operational Effectiveness	• Maintain operational effectiveness, as well grid resiliency and reliability.
Public Policy Responsiveness	• Comply with NERC CIP-014 regulatory requirements.

C. EXPENDITURE PLAN

Specific physical security improvements will vary by station to ensure NERC compliance and are evaluated on site-by-site basis and will affect the total project cost.

Table 1 below presents forecasted costs for the Project. Costs for the Project are based on historic costs and future needs.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years[1]	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[2] and Minor Fixed Assets	-	18.0	18.0	18.0	0.0	0.0	-	54.0
Less Removals	-	0.0	0.0	0.0	0.0	0.0	-	0.0
Gross Investment Cost	**-**	**18.0**	**18.0**	**18.0**	**0.0**	**0.0**	**-**	**54.0**
Less Capital Contributions	-	0.0	0.0	0.0	0.0	0.0	-	0.0
Net Investment Cost	**-**	**18.0**	**18.0**	**18.0**	**0.0**	**0.0**	**-**	**54.0**

[1] Due to the in-year nature of program investments, only 2020-2024 expenditures are shown
[2] Includes Overhead at current rates.

D. ALTERNATIVES

The Project is non-discretionary and, as such, no other alternatives have been considered. A failure to perform the proposed security measures will result in non-compliance with NERC CIP-014 requirements and might expose Hydro One 26 stations and 1 control centre to physical attacks and other security threats.

E. EXECUTION RISK AND MITIGATION

The risk to this project includes scheduling of resources to complete all the necessary work. This risk is mitigated through coordinated planning and scheduling of TRAs.

SR-17 NERC CIP Transient Cyber Asset Project

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	December 2020	**3 Year Test Period Cost ($M):**	3.5M
Trigger(s):	Compliance, Reliability, Customer Satisfaction		
Outcomes:	Compliance with NERC Reliability Standards; ensure reliability and security of Bulk Electric System		

A. OVERVIEW

The Bulk Electric System ("BES") and related assets comprising Hydro One's transmission facilities are subject to compliance with applicable reliability standards, which are established by the North American Electric Reliability Corporation ("NERC") to ensure the integrity of the interconnected North American BES and enforced in Ontario by the Independent Electricity System Operator ("IESO"). To ensure Hydro One's compliance with NERC Critical Infrastructure Protection ("CIP") standards CIP-010 (*Cyber Security – Configuration Change Management and Vulnerability Assessments)* and CIP-003 (*Cyber Security – Security Management Controls*), the NERC CIP Transient Cyber Asset Project (the "Project") is intended to design and implement Hydro One's long-term transient cyber asset ("TCA") and removable media solution for medium impact BES sites (under CIP-010) and low impact BES sites (under CIP-003).

TCAs are those devices that interface with or run applications that support BES cyber systems and that are capable of transmitting executable code to BES cyber assets or systems. They range from specially-designed devices for maintaining BES equipment to an end-user platform such as a laptop, desktop or tablet. Removable media include compact disks, floppy disks, USB flash drives, external hard drives, and other memory cards or drives that contain nonvolatile memory. In contrast to devices that are network-connected on a more permanent basis, the use (or misuse) of TCAs and removable medium presents particular challenges in terms of security management and control. For instance, it is difficult to ensure that intermittently-connected mobile devices (e.g. laptops) remain appropriately updated and patched, thus making them susceptible to malwares that may in turn introduce cyber threats onto the Hydro One network. Similarly, the improper use of removable media such as CDs and USB flash drives (if undetected) not only risks the transmission of malware onto the network, but can also lead to the unauthorized exfiltration of highly sensitive BES system information off of the network. Through this Project, Hydro One will address the long-term secure management and control of TCA and removable media that are directly connected to its BES cyber systems for 30 consecutive calendar days or less at a time, in compliance with NERC CIP requirements, and in support of the ongoing reliability and security of Ontario's BES.

B. NEED AND OUTCOME

Investment Need

Hydro One operates one of the largest transmission systems in North America. Hydro One's transmission system extends to most of the Province of Ontario, serving a large number of customers and encompassing immense geographic areas. As a critical asset for the Province, the BES that comprises Hydro One's transmission facilities is subject to a rigorous set of regulatory and technical criteria, including the NERC-established and IESO-enforced reliability standards. As part of such standards, applicable CIP requirements impose various compliance obligations on Hydro One with respect to critical infrastructure protection and cyber security, including the mitigation of potentially serious threats stemming from the misuse and/or inadequate control of TCAs and removable media.

While most BES cyber assets and systems are isolated and protected from external public or untrusted networks, TCAs and removable medium represent a potential "back door" for cyber threats and intrusions. As indicated above, their inherent portable and mobile nature, combined with intermittent network-connectivity, poses serious challenges with respect to security updates and patching as well as ongoing tracking and control. At the same time, TCAs and removable media are indispensable to BES operations, given they are often the only way to transport files to/from secure areas or cyber assets for purposes of maintaining, monitoring or troubleshooting critical systems. As such, NERC CIP standards specifically require BES facility owners and operators to evaluate and mitigate the risks associated with such devices in relation to BES sites and cyber systems.[1]

Since CIP-010 came into effect in relation to Hydro One's medium impact BES sites in 2017, the utility has designed and implemented a temporary method to achieve compliance, which involves and relies on the use of a portable USB solution by field personnel to ensure the secure connection to BES cyber systems. In addition, pursuant to NERC CIP-003, similar compliance obligations will begin to apply to Hydro One's low impact BES sites by the end of 2019. Consequently, Hydro One has also been introducing the aforementioned USB-based method at low impact BES sites, so that interim compliance for both medium and low impact sites can be met according to applicable timelines while this Project is being undertaken to arrive at a sustainable solution.

While an important short-term tool for meeting NERC requirements and protecting the BES' cyber security, the USB method is not intended for or capable of serving Hydro One's compliance and operational needs on an ongoing basis. Rather, it is a bridge to a sustainable and long-term compliance solution, as proposed through this Project.

As described below, the proposed long term solution will enable the secure connection (both direct and indirect) of TCAs and removable media to all BES substation power

[1] While NERC CIP-010 applies to both high and medium impact sites, Hydro One's high impact sites are already considered compliant, and therefore only its medium impact sites need to be brought into compliance with CIP-010. Further, CIP-003 applies to low impact sites, which are also covered by this investment, as detailed herein.

assets and systems, by providing the necessary security measures such as logging and monitoring of access, in satisfaction of applicable NERC CIP requirements.

Investment Description

Through this Project, a Privileged Access Management ("PAM") solution will be developed and deployed to Hydro One's medium and low impact BES sites[2]. Specifically, field personnel requiring access to BES cyber systems to perform maintenance and sustainment activities will physically and securely connect to a PAM server at the applicable site. As its name suggests, this solution will administer user privilege or access based on the appropriate approval and authorization being in place as part of a systematic access and change management framework. Key benefits of PAM include two-factor authentication, protected passwords, and a robust audit trail of system access and user actions.

Upon completion of the Project by the end of 2020, access to Hydro One's medium and low BES impact cyber assets as well as associated Protected Cyber Assets ("PCA")[3] will be accessed entirely through the PAM application, therefore eliminating the risks and threats stemming from the intermittent connections of TCAs and removable media. Prior to users being able to access BES, Electronic Security Perimeter ("ESP")[4] or PCA, PAM will require users to undergo strong, multi-factor authentication[5], in adherence of the continuous 'least privileged" concept (i.e., granting a user only those access rights that are must-haves for a given job function), enforcing robust policy over who can access

[2] As of March 2018, Hydro One has 42 stations that are categorized as medium impact BES sites, and 57 as low impact BES sites.
[3] Protected Cyber Assets, or PCAs, refer to cyber assets connected using a routable protocol within or on an Electronic Security Perimeter ("ESP") that is not part of the highest impact BES cyber system within the same ESP. The impact rating of PCAs is equal to that of the highest rated BES cyber system in the same ESP.
[4] An Electronic Security Perimeter, or ESP, refers to the logical border surrounding a network to which BES cyber systems are connected using a routable protocol.
[5] Multi-factor authentication is an authentication method in which a computer user is granted access only after successfully presenting two or more pieces of evidence to an authentication mechanism.

privileged accounts, and restricting privileged users' authorized activities to only those required for their jobs as identified through Request for Change ("RFC") tickets. No direct connections to BES cyber assets will be permitted unless in the event of a CIP "exceptional circumstance".[6] In addition, the proposed solution will eliminate the use of static passwords, and provide for the monitoring and logging of access through a detailed audit trail of privileged log-in sessions and activities. The PAM solution will meets all applicable NERC requirements with respect to TCA management and authorization, malicious code mitigation, and software vulnerability mitigation.

Outcome

When completed, the Project will eliminate the concept of and risks associated with transient devices, since devices that connect to Hydro One's BES cyber systems through a PAM server will no longer be considered TCAs, and any vulnerabilities or malicious code potentially existing on such devices will pose no direct threat to the relevant BES cyber assets. The detailed records to be generated by PAM for all user sessions, including activity /security logs will support real-time event correlation and alerts, as well as ongoing review and audits.

The following table presents anticipated benefits as a result of the Program in accordance with the OEB Renewed Regulatory Framework:

Customer Focus	• Maintain system reliability for customers by ensuring the secure and uninterrupted operation of BES transmission facilities.
Operational Effectiveness	• Maintain operational effectiveness, reliability and resiliency against potential cyber threats by mitigating the risks

[6] A CIP exception circumstance refers to a situation that involves, or threatens to involve, one or more of the following types of conditions that impact safety or BES reliability: a risk of injury or death; a natural disaster; civil unrest; an imminent or existing hardware, software, or equipment failure; a cyber security incident requiring emergency assistance; a response by emergency services; the enactment of a mutual assistance agreement; or an impediment of large scale workforce availability.

	associated with TCAs and removable media that require connection to BES cyber assets.
Public Policy Responsiveness	• Comply with requirements under NERC CIP-010 and CIP-003 with respect to the management and control of TCAs and removable media in relation to medium and low impact BES sites.

C. EXPENDITURE PLAN

Table 1 below presents forecasted costs for the Project. Costs are based on historic costs of similar projects.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2024	Total
Capital[1] and Minor Fixed Assets	3.5	3.5	0.0	0.0	0.0	0.0	0.0	7.0
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**3.5**	**3.5**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**7.0**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**3.5**	**3.5**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**7.0**

[1] Includes Overhead at current rates.

D. ALTERNATIVES

The Project is non-discretionary given its mandatory compliance driver and associated timing pursuant to applicable NERC CIP standards. As such, the only relevant alternatives analysis pertained to the optimal technical solution for ensuring and sustaining compliance.

Alternative 1. Continuing with Short-Term USB Solution

As indicated above, Hydro One began adopting a short-term USB solution in 2017 to meet the immediate NERC compliance obligations for all medium impact BES sites, as well as in anticipation of NERC requirements that will begin to apply to low impact BES sites by the end of 2019. While this USB solution meets the minimum requirement for compliance logging, it relies on manual processes. More specifically, field protection and control personnel log into a portal to download such access logs on a monthly basis. In addition, the USB solution is not capable of capturing complete configuration changes, or integrating with Hydro One's Security Event Management system to support real-time event correlations and alerts for remote or onsite access. Since the USB devices do not have network connectivity, to implement any updates and patches relating to the operating system, application, or anti-virtus signatures, the USBs need to be reimaged and shipped to the appropriate Field Protection and Control technicians, which can take three to four months to complete. Further, the effectivenss of the USB solution is heavily dependent upon field resources' adherence to applicable process and procedures.

Alternative 2. Proposed PAM Solution *(Recommended)*

In parallel with the roll out of the short-term USB solution, the Project is recommended and required in order to ensure and sustain long-term NERC compliance and cyber asset security. The above-mentioned weaknesses and inefficiencies associated with the short-term solution will all be addressed by the proposed PAM solution, which will support two-factor authentication, protected passwords, and a robust and automated audit trail of system access and user actions.

E. EXECUTION RISK AND MITIGATION

The risk to this Project includes scheduling of resources to complete all the necessary work. This risk is mitigated through coordinated planning and scheduling. Estimates for the majority of the applicable sites will be completed in Q1 2019, with the implementation plan slated for execution over 2019 and 2020.

SR-18 PSIT Cyber Equipment Replacement

Start Date:	Q1 2018	**Priority:**	High
In-Service Date:	Multiple In-Service Dates	**3 Year Test Period Cost ($M):**	13.7
Trigger(s):	Compliance, Strategic, Reliability, Public Policy Responsiveness		
Outcomes:	Compliance with NERC requirements; ensure cyber security of transmission system operation		

A. OVERVIEW

Power System Information Technology ("PSIT") Cyber Equipment Replacement (the "Project") involves the replacement of End of Life ("EOL") cyber security equipment. This equipment protects the network used at the Ontario Grid Control Center to control the operation of transmission system in Ontario. Business and operational demands for managing and maintaining a reliable transmission system increasingly rely on cyber assets supporting critical reliability functions and processes to communicate with each other, across functions and organizations, for services and data, resulting in increased risks to these cyber assets. As an operator of a Bulk Electric System ("BES"), Hydro One is required to comply with the reliability standards established by the North American Electric Reliability Corporation ("NERC") to ensure the integrity of the interconnected North American BES. NERC Critical Infrastructure Protection ("CIP") Reliability Standards provide a comprehensive set of requirements to protect the BES from malicious cyber-attacks. Responsible entities, such as Hydro One must have minimum security management controls in place to protect critical cyber assets. As such, completing the Project is integral to Hydro One to address evolving cyber threats to ensure ongoing regulatory compliance, reliability and operational effectiveness of the systems controlling the Ontario transmission network and North American BES.

Witness: Lincoln Frost-Hunt

B. NEED AND OUTCOME

Investment Need

Hydro One operates one of the largest transmission systems in North America. Hydro One's transmission system extends to most of the province and operates in diverse geographic and climactic conditions. Hydro One's transmission system is a critical asset for the province, among others, it comprises the BES, which requires compliance with reliability standards established by the NERC to ensure the integrity of the interconnected North American BES. The reliability framework for Ontario's electricity transmission system is based on the reliability standards established by NERC, which have been adopted and are enforced in Ontario by the Independent Electricity System Operator.

The NERC CIP standard provides a cyber-security framework for the identification and protection of critical cyber assets (i.e. devices that use a routable protocol or are dial-up accessible) that control or affect the reliability of North America's bulk power systems. The CIP Cyber Security Standards are mandatory and enforceable across all regulated entities, such as Hydro One. The following CIP Cyber Security Standards applicable to this investment are:

- **CIP-005-1 – Cyber Security – Electronic Security Perimeters:** Requires the identification and protection of an electronic security perimeter and access points. The electronic security perimeter is to encompass the critical cyber assets identified pursuant to the methodology required by CIP-002-1.
- **CIP-007-1 – Cyber Security – Systems Security Management:** Requires a responsible entity to define methods, processes, and procedures for securing the systems identified as critical cyber assets, as well as the non-critical cyber assets within an electronic security perimeter.
- **CIP-008-1 – Cyber Security – Incident Reporting and Response Planning:** Requires a responsible entity to identify, classify, respond to, and report cyber security incidents related to critical cyber assets.

- **CIP-009-1 – Cyber Security – Recovery Plans for Critical Cyber Assets:** Requires the establishment of recovery plans for critical cyber assets using established business continuity and disaster recovery techniques and practices.

The investment is needed to address the EOL cyber security equipment for the PSIT used at Hydro One Control Centers. This technology includes Intrusion Detection/Prevention equipment, Authentication, Authorization, and Accounting technology, Electronic Security Perimeter equipment (firewalls), log collection and retention technology, and cyber vulnerability assessment technology. The Cyber EOL investments, like this Investment, are used to keep technology deployed for security of the grid control infrastructure within support windows of the various technology vendors. Cyber equipment only has a lifespan of 5 years. With fast-paced innovation that responds to an emerging and increasingly aggressive threat landscape, security impacts an asset's life expectancy. Keeping the cyber equipment current is essential to addressing emerging vulnerabilities and maximizing the protection of Hydro One systems and data.

The grid cyber security technology is integrated with the systems that allow operators to remotely control power system equipment on the transmission system. There are two risks associated with failure of this equipment. The main risk of the failure can affect the ability of Hydro One controllers to effect control of transmission system equipment. For example, a firewall failure would not allow the control systems at the control centres to communicate to field equipment. This could prevent a critical control action from being executed when required, and loss of visibility of key power system operating parameters. Another risk is associated with NERC compliance obligations. For example, failure of the logging system could result in loss of historical system logs. NERC CIP standards require that logs for such systems are kept for a minimum of 90 days.

Investment Description

As already stated, the Investment involves the replacement of EOL cyber security equipment for PSIT. This investment is a Project to refresh the cyber security equipment that helps protect, detect, and respond to cyber security threats such as firewalls, authentication managers and identity access management, network visibility and traffic monitoring technology, advanced threat detection and file integrity monitoring, and vulnerability management. Projected life cycle planning is based on a rolling 5-year.

Outcome

The Project will result in regulatory compliance with applicable NERC CIP standards, while ensuring grid reliability and resiliency against cyber security threats to Hydro One's Control Centers which are operating the transmission network.

The following table presents anticipated benefits as a result of the Investment in accordance with the Ontario Energy Board's Renewed Regulatory Framework:

Operational Effectiveness	• Maintain the applications and systems controlling the grid to ensure safe, reliable operation of the transmission network.
Public Policy Responsiveness	• Comply with mandatory NERC-CIP requirements.

C. EXPENDITURE PLAN

The Project scoping is currently under development to determine size and scope which will affect the total Project cost. Table 1 below presents forecasted costs for the Project. These costs are based on historical information and anticipated future needs.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	6.7	1.0	5.0	7.7	7.0	3.4	-	30.9
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	-	0.0
Gross Investment Cost	**6.7**	**1.0**	**5.0**	**7.7**	**7.0**	**3.4**	-	**30.9**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	-	0.0
Net Investment Cost	**6.7**	**1.0**	**5.0**	**7.7**	**7.0**	**3.4**	-	**30.9**

[1] *Includes Overhead at current rates.*

D. ALTERNATIVES

The Project is non-discretionary and no alternatives have been considered. Failure to address obsolete, unsupported systems will put Hydro One in a position where it will not be able to meet regulatory obligations or provide adequate cyber security protection which would result in non-compliance. In addition, this would result in jeopardizing system reliability by leaving it exposed to cyber security risks. As a result of replacing EOL Cyber Security equipment, the Project will meet regulatory compliance obligations and ensure operational effectiveness of the systems used in the control of the Ontario transmission network.

E. EXECUTION RISK AND MITIGATION

There are no significant risks identified to the completion of this investment.

SR-19 Transmission Line Refurbishment - End of Life ACSR, Copper Conductors & Structures

Start Date:	Q4 2015	**Priority:**	High
In-Service Date:	Q4 2025	**3 Year Test Period Cost ($M):**	298.4
Trigger(s):	Strategic, System Renewal		
Outcomes:	Improve system reliability, minimize customer outages, reduce maintenance costs associated with the EOL assets, realize cost savings and efficiencies as a result of bundling needed work within this investment		

A. OVERVIEW

This set of Transmission Line Refurbishment Projects involve the replacement of all End-Of-Life ("EOL") components along all or part of a line section. These projects are driven by the need to replace major transmission line components, verified to be at EOL by condition assessment, including Aluminum Conductor Steel Reinforced ("ACSR") conductor, obsolete copper conductor, or deteriorated structures in high risk condition.

These assets pose safety and system reliability risks should they fail. In addition, copper conductors are the oldest type of overhead conductors in the Hydro One transmission system and are now obsolete. Hydro One is no longer able to mend some broken copper conductors due to this obsolescence. These Line Refurbishment Projects aim to remove and replace these deteriorated EOL conductors, or refurbish high risk structures to sustain safe and reliable delivery of electricity. Hydro One has evaluated various alternatives for these Projects, as described below, and concluded that replacing the EOL deteriorated ACSR, obsolete copper conductors, or refurbishing deteriorated structures is the most cost effective and efficient undertaking for sustaining these assets. The projected cost of these Projects is estimated to be $298.4 million over the 2020-2022 test period.

B NEED AND OUTCOME

Investment Need

Long transmission circuits are required to deliver power across Hydro One's vast territory. These transmission assets are exposed to environmental stresses, including severe weather and temperature variations that degrade equipment over time.

Hydro One has approximately 29,000 circuit kilometres of high-voltage transmission conductors. Over 99% of Hydro One's transmission system is comprised of overhead power lines. The conductor of an overhead transmission line is the single largest and most vulnerable component. Close to 98% of Hydro One's overhead conductor fleet utilizes ACSR conductors, with copper, aluminum, and aluminum conductor steel supported ("ACSS") types making up the balance.

Hydro One defines Expected Service Life ("ESL") as the average age in years that an asset can be expected to operate under normal system conditions. Hydro One also defines End of Life ("EOL") as the state of having a high likelihood of failure, or loss of an asset's ability to provide the intended functionality. EOL state is established only through testing, where an asset is empirically verified to have deteriorated to a point where its ability to perform is compromised. A conductor in a deteriorated condition translates to a loss of mechanical strength or ductility, resulting in the conductor possessing a greater likelihood of breaking and dropping. EOL is always determined by condition assessment.

Hydro One uses an ESL of 90 years for overhead transmission conductors, although the life span of each conductor can vary between 50 and 120 years, as numerous uncontrollable variables affect conductor deterioration, including manufacturing material quality, location, orientation, local atmospheric pollution levels, weather cycles and stringing tension. Currently, about 5% of the overhead conductor fleet has reached or exceeded their ESL of 90 years.

Table 1 below summarizes the demographic profile of the overhead conductor fleet. Without any further replacements, the percentage of conductors exceeding ESL will increase to 13% by end of 2024.

Table 1 - Overhead Conductor Demographics

Conductor Type	Circuit km in Service	Average Age (Years)	ESL (Years)	Beyond ESL	Beyond ESL 2024	Beyond ESL 2029
ACSR	28,437	54	90	876	3,125	3,988
Copper	512	97	70	512	512	512
Aluminum	21	89	100	0	15	15
ACSS	137	26	N/A*	0	0	0
Total	**29,107**	**55**		**1,389**	**3,653**	**4,516**

** Relatively new conductor type to Hydro One, limited installation, ESL to be established*

Hydro One operates a condition assessment program to determine the condition of conductors that are beyond 50 years of age. Presently, condition assessment results indicate that about 3,680 km, or 13% of the conductor fleet is known to be at high risk as outlined in Figure 1. This includes lines with ACSR conductors and structures verified to be in high risk condition through testing, and copper conductors, many of which suffer from damage caused by lightning strikes, mechanical strength loss and can no longer be repaired due to obsolete repair components.

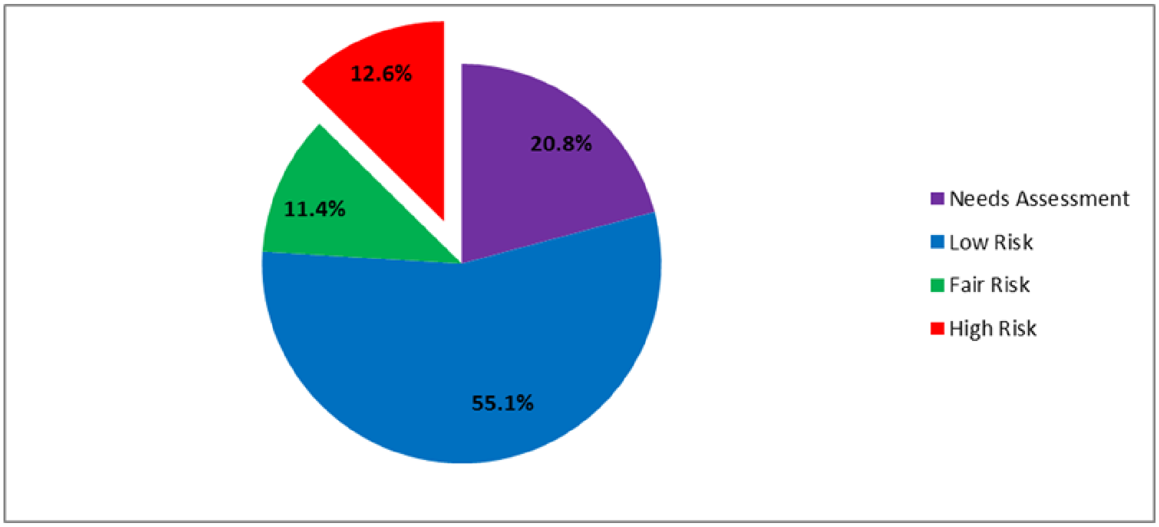

Figure 1 - Distribution of Overhead Conductor Condition

ACSR conductors consist of aluminum strands that surround galvanized steel strands, referred to as the core. Once the galvanized coating of the core wears off, for example as a result of weather or strand movement, the exposed steel strands corrode quickly, resulting in a loss of tensile strength or ductility. Deterioration of tensile strength results in a failure to hold required loads, while deterioration in ductility, makes the conductor brittle, making the suspended conductor which is moved by wind forces susceptible to cracking and breaking, as shown in Figure 2.

Figure 2 - Broken ACSR Conductor

Less than 2% of Hydro One conductor fleet is Copper conductor. Copper conductors are the oldest conductor type Hydro One has in its Network. Although copper conductors are not as susceptible to deterioration from corrosion when compared to ACSR conductors, this type of conductor has been exposed to the elements for a much longer time and many suffer from damage caused by lightning strikes. Figure 3 illustrates a dissected Hydro One copper conductor revealing a plant fibre core. This conductor type cannot be spliced and therefore its failure would result in the need to replace an entire dead-end to dead-end span, needing extensive resources and financing to perform on an unplanned emergency basis.

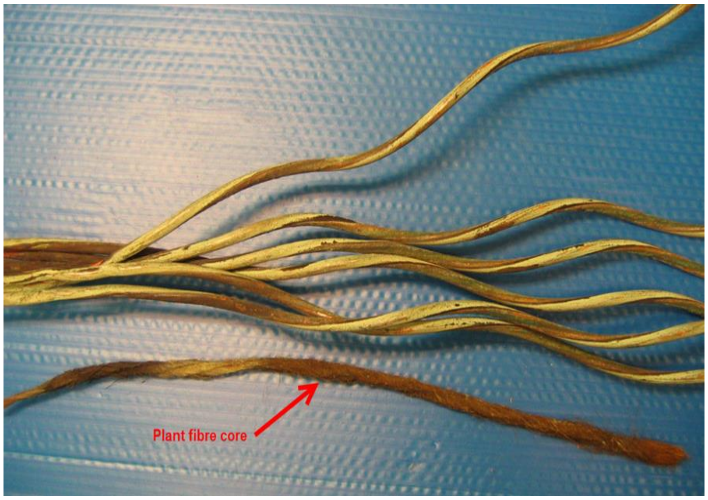

Figure 3 - Dissected copper conductor

The breaking of a conductor will lead to the overhead suspended conductor dropping, potentially along with its hardware as shown in Figure 4 below. A broken and dropped conductor will result in an outage to the circuit and endangers all in proximity of its fall. A typical transmission line spans 300 m at a rough height of 30 meters. At about 1.6 kg/m, a falling conductor span is equivalent to a 480 kg metallic mass falling from 30 m above. Potential damage as a result of this fall is demonstrated in Figure 5 below. In some cases a broken conductor can remain energized, which presents an added danger of electrocution and fire hazard to its surroundings.

Figure 4 - Fallen span of conductor

Figure 5 - Damage from a fallen conductor

Figure 5 shows a fallen conductor as a result of an insulator failure. Although the cause of this conductor dropping was not the breakage of the actual conductor, the result would be the same.

Line refurbishment projects are triggered by a confirmed need to replace the conductor or in a minority of cases, extensive structure deterioration, along a line section. This confirmation comes empirically through testing which confirms a deteriorated condition of the conductor or structure. Work plans to perform the replacement of EOL conductors or refurbishment of structures also consider the replacement or refurbishment of all other line components. As such, a conductor replacement project frequently includes the refurbishment of all major components within that line section, based on an assessment of the line's structures, shieldwire, insulators and hardware.

During the development of a line refurbishment project, the line section targeted for conductor replacement is surveyed, at which point other assets that are at EOL or near EOL are identified and also targeted for replacement. Components in good condition are not refurbished or replaced. Bundling conductor replacement with the replacement or refurbishment of other components is cost effective.

Presently, the Hydro One overhead transmission system has 3,680 km of conductor known to be in high risk condition, as verified empirically through condition assessment. Of this set of identified high risk conductors, 859 km, or 23% of the known high risk population have been planned and packaged into refurbishment projects that address conductors confirmed to be in EOL condition during the planning period. Confirmed EOL lines, as opposed to confirmed Near EOL lines, have deteriorated further, and therefore present the greatest risk of failure.

Investment Description

Table 2, Table 3, Table 4, and Table 5 present the set of material projects that aim to completely refurbish the listed sections of the circuits. Hydro One has confirmed, through condition assessment that these line sections have deteriorated to the extent that their conductor or structure has reached EOL and, as such, require replacement or refurbishment.

The project list below also includes a “placeholder” line item that allocates funding for packaging an additional 456 km, or 12% of verified high risk conductors in addition to the planned and packaged 859 km of EOL projects. This is intended to reserve funding for conductors that are confirmed to be at EOL but are still undergoing the planning process. As an example, some of these projects are under review by Hydro One System Development group to verify whether a sustainment based project is the most appropriate approach to address the short and long term system requirements. The projected cost for forecast projects are based on a historical average cost for line refurbishment projects which is being used for planning purposes prior to formal project estimation.

Each project will entail an assessment of all assets along the line section and the replacement or refurbishment of all components that are deemed at or near EOL. These components might include shieldwire, insulators or hardware, to comprehensively renew the line as a whole. In addition, all structures and foundations will be refurbished as required.

Bundling conductor replacement with the replacement/refurbishment of other components is cost effective. Bundled work does not mean replacing assets that are in good condition. The development of a line refurbishment project, through budgetary and detailed estimation stages, which collectively average 18 months, is used to identify which other assets have also limited service life and can benefit from replacement, while work crews are already deployed to replace the conductor.

Outcome

The following table presents anticipated benefits as a result of the aforementioned Projects in accordance with the OEB's Renewed Regulatory Framework:

Customer Focus	• Replacement of EOL conductors decreases the likelihood of their failure. Decreased likelihood of conductor failure results in a decreased likelihood of an outage to the customer.
Operational Effectiveness	• Operating a circuit with EOL conductors subjects that circuit to an increased likelihood of failure, which directly threatens reliable operation of the system. Line refurbishment will alleviate this threat.
Public Policy Responsiveness	• Decreased likelihood of failure reduces the likelihood of a conductor dropping and potentially causing injury to public or employees, damaging property or damaging local environment (fire caused by dropped energized conductor)
Financial Performance	• Realize cost savings by bundling conductor replacement with associated deteriorated line components as part of the same project.

C. EXPENDITURE PLAN

As discussed above, Line Refurbishment Projects are needed to replace/refurbish the EOL ACSR conductors, obsolete copper conductors and line sections with deteriorated structures, in order to mitigate the risk to safety and reliability that would result from their failure. Hydro One planned these projects in a way that strives to complete it as effectively and efficiently as possible to minimize the cost of performing this sustainment need.

Table 6 summarizes historical and projected spending on the aggregate. The “Previous Years” costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 test year. Likewise, the costs noted in “Forecast 2025+” are project costs forecast beyond 2024.

Table 6 - Total Investment Cost

Witness: Donna Jablonsky

As shown in Figure 1, demographics for Hydro One overhead conductors demographics that have reached and exceeded EOL is increasing, thereby necessitating the replacement of those deteriorated EOL conductors. Line refurbishment investments are increasing over the test year period as compared to historical years which reflects the increase in circuit kilometres that are being replaced.

The following factors also influence the costs of Line Refurbishment Projects:

- The circuit voltage level, site accessibility, structure type (wood pole vs. steel structure);
- The length of conductor being replaced;
- Whether replacement of deteriorated shieldwire, insulators, or additional hardware is required; and
- Any structure or foundation work required.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: The “Do Nothing” - Reactive Replacement involves waiting for deteriorated conductors to fail before replacing them on a reactive basis. This alternative has been rejected since a failed conductor will immediately lead to a circuit outage requiring emergency restoration. Replacement of conductors on an emergency basis will require constant reprioritization of planned work and lead to inefficient deployment of resources. Reactive conductor replacements would also prolong circuit outages and may therefore extend equipment and customer outages.

Alternative 2: Replacements based on Risk Mitigation Assessments is a preferred undertaking. It involves proactively replacing/refurbishing EOL ACSR conductors, obsolete copper conductors and deteriorated structures based on risk mitigation assessments. The risk mitigation assessment allows Hydro One to replace High Risk assets in a way that mitigates safety and reliability risks while balancing the asset needs, resource availability and the cost impact to customers. This alternative has been selected as a preferred undertaking as it reduces the number of customer outages and allows taking advantage of planned customer outages to perform the necessary conductor replacements. Furthermore, with a planned outage, a customer can be temporarily connected to an alternative supply in order to avoid any unforeseen interruptions as a result of the outage. It further allows Hydro One to bundle all the necessary work in a particular geographic area in order to maximize the productivity of a deployed work crew. This is especially relevant in remote areas, where access is extremely difficult.

E. EXECUTION RISK AND MITIGATION

Risks to these projects include: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges or regulatory approvals. A thorough risk assessment workshop is performed during the project planning phase where all known risks are identified and mitigation plan is developed. For example, to address outage constraints, Hydro One develops an outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize to a minimum the loss of supply to the customer. The plan might include switching a customer to an alternative supply, the construction of a temporary by-passing circuit or supply of portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer’s planned maintenance driven outages. Another example is the involvement of real estate from the project inception. It allows for the early identification of real estate issues, such as missing or inadequate land rights. Once the issue is identified, Hydro One tries to resolve it prior to execution of the project.

SR-20 Transmission Line Refurbishment - Near End of Life ACSR Conductor

Start Date:	Q4 2016	**Priority:**	Medium
In-Service Date:	Q4 2026	**3 Year Test Period Cost ($M):**	237.3
Trigger(s): Strategic, System Renewal			
Outcomes: Improve system reliability, minimize customer outages, reduce maintenance costs associated with the High Risk assets, realize cost savings and efficiencies as a result of bundling needed work within this investment			

A. OVERVIEW

Near End-of-Life Transmission Line Refurbishment Projects (the "Projects") involves the proactive replacement of the Aluminum Conductor Steel Reinforced ("ACSR") conductors that are confirmed, through condition assessments, to be in a deteriorated condition and approaching End-Of-Life ("EOL"). The near EOL conductors are assets whose condition is expected to be in a state requiring removal from service in the near future. Over the test period, there is large population of overhead ACSR conductor that will reach or exceed their Expected Service Life ("ESL") and therefore the probability of their failure is increasing as a result of their aggregate increase in deteriorated condition. This conclusion is supported through mathematical modelling completed by a third party expert, Electric Power Research Institute ("EPRI").

EPRI developed a conductor hazard curve and applied it to forecast the amount in kilometres of ACSR overhead transmission conductor expected to be in high risk condition (i.e. EOL or near EOL). The EPRI report forecasts that 3,920 circuit km of the ACSR conductor fleet will be at EOL or near EOL condition by 2024.[1] This forecast of ACSR conductor condition aligns with the fact that by the end of 2024, about 13% or 3,653 circuit km of the overall conductor fleet will reach or exceed their ESL without further replacements.

[1] TSP Section 1.4 Attachment 4 - Derivation of Overhead Conductor Hazard Function, section 5-3, p 93.

Hydro One plans to replace 812 of circuit kilometres of near EOL ACSR conductor in order to manage the safety and system reliability risks associated with the forecasted increasing volume of conductors in High Risk condition. Hydro One has evaluated various alternatives for the Project, as described below, and concluded that replacing near EOL ACSR conductors is the most prudent and cost effective undertaking. The estimated cost of these near EOL Line Refurbishments projects total an estimated $237.3 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

Hydro One is striving to maintain the reliability of its transmission network while controlling maintenance, repair and replacement costs. Aging equipment, more stringent operating requirements, financial constraints and retiring expertise have made the management of transmission line assets increasingly challenging. To address these challenges, Hydro One is reviewing its maintenance and replacement practices to ensure that they are underpinned by sound evidence. This includes the use of condition and risked-based maintenance and replacement scheduling using advanced analytics-based techniques. Understanding the condition and remaining life of conductors help Hydro One to make better decisions about conductor maintenance, repair, and replacement.

As part of this asset management effort, Hydro One asked EPRI to investigate Hydro One overhead transmission line conductor demographic and condition data and to determine what insights could be obtained to support asset management decisions. EPRI has developed a methodology using advanced statistical techniques for analyzing conductor historical replacements and assessments and applied it to the Hydro One overhead ACSR transmission conductor fleet. Hydro One provided in-service, removed-from-service and condition assessment data for its overhead ACSR transmission conductor fleet. Using this data, EPRI developed a mathematical model relating ACSR conductor age to the probability that an ACSR conductor would be in high risk condition. The model, along with demographic information about the present fleet, was used to forecast the amount in kilometres of ACSR conductors expected to be in high risk condition (i.e. EOL and near EOL) over the next five, ten and twenty-year periods.

The Hydro One transmission system has approximately 29,000 circuit kilometers of high-voltage transmission conductors with close to 98% being ACSR type of conductors. Hydro One defines ESL as the average age in years that an asset can be expected to operate under normal system conditions. Hydro One also defines EOL as the state of having a high likelihood of failure, or loss of an asset's ability to provide the intended functionality.

Based on the analysis and modeling performed by EPRI, ACSR conductors reach ESL at about the age of 90 years. As EPRI stated in its report, unless there is some dramatic change in the stressors leading to degradation (e.g. loading), it is reasonable to expect future performance to continue to fit this age-related model. Comparing this age-dependent hazard curve model with the ages of the in-service conductor lengths can provide an estimate of the conductor lengths that would be in high risk condition (based on historical criteria) in future years.

Table 1 below provides EPRI cumulative estimates of ACSR circuit-km expected to be in high risk condition (i.e. EOL and near EOL) within the next five, ten and twenty-year periods.

Table 1 - Mean Values for the 5, 10, and 20 year projection (from 2018)[2]

Life Event Modeled	Input Data	Projection Means (and 95% Confidence Bands) in km		
		5 Years (2023)	**10 Years (2028)**	**20 Years (2028)**
Reaching EOL Or near EOL condition	Condition assessment data	3,273 (2,552, 4,123)	6,467 (5,182, 7,867)	12,366 (10,468, 14,134)

Table 1 contains information from the projection model. It shows that the amount of circuit kilometers of conductors expected to be in high risk condition over the next twenty years is about 42% of the fleet. As such, it is prudent for Hydro One to proactively engage in conductor replacement, so to ensure that the collective High Risk conductor assets are managed in a timely manner that maintains system reliability and limits the safety risks. Failure to address the issue proactively would result in unmanageable risk and Hydro One will be in a position where it would not be feasible, even impossible, to manage the set of cumulative assets deteriorated to EOL condition.

Investment Description

As described above, EPRI developed a ACSR conductor hazard curve and applied it to forecast the amount in kilometers of ACSR overhead transmission conductor expected to be in high risk condition (i.e. EOL and near EOL). As part of the Project, Hydro One intends to replace approximately 812 circuit km, or 22% of the known high risk population of conductor in order to manage the safety and system reliability risks associated with confirmed near EOL conductors over the next five years.

The individual near EOL line refurbishment projects are presented in Table 2 below. Each project will entail an assessment of all assets along the line section and the replacement/refurbishment of all components that are deemed at or near EOL. These

[2] TSP Section 1.4 Attachment 4 - Derivation of Overhead Conductor Hazard Function, section 5-4, p 94.

components might include shieldwire, insulators and hardware, to comprehensively renew the line as a whole. In addition, all structures and foundations will be assessed and refurbished or replaced as required.

These projects will address this prioritized set of 812 circuit km of existing confirmed near EOL conductors. Line refurbishment prioritization will help with the pacing of the high risk conductor replacements over the longer periods (i.e. over the next 10 or 20 years) and also will allow to better manage the required capital expenditures associated with conductor replacement projects.

Outcome Summary

The following table presents anticipated benefits as a result of the aforementioned Projects in accordance with the OEB's Renewed Regulatory Framework:

Customer Focus	• Replacement of Near EOL conductors manages the population of High Risk condition conductors, which ultimately mitigates the risk of their failure. Decreased likelihood of conductor failure results in a decreased likelihood of an outage to the customer.
Operational Effectiveness	• Operating a circuit with near EOL conductors subjects that circuit to an increased likelihood of failure, which threatens reliable operation of the system. Line refurbishment will alleviate this threat.
Public Policy Responsiveness	• Decreased likelihood of failure reduces the likelihood of a conductor dropping and potentially causing injury to public or employees, damaging property or damaging local environment (fire caused by dropped energized conductor)
Financial Performance	• Realize cost savings by bundling conductor replacement with associated deteriorated line components as part of the same project.

C. EXPENDITURE PLAN

As discussed above, Line Refurbishment projects are needed to replace condition verified near EOL ACSR transmission overhead conductors over the next five years to manage the increasing population of conductors in High Risk condition. Hydro One planned these projects in a way that strives to complete it as effectively and efficiently as possible so to minimize the cost of performing this sustainment need.

Since the Project consists of a multiple projects, as presented in Table 2 above, Table 3 below consolidates all the costs for individual material projects and presents the total cost for this set of Projects. The "Previous Years" costs are the direct project costs for projects noted above that have incurred costs prior to the 2020 test year. Likewise, the costs noted in "Forecast 2025+" are project costs forecast beyond 2024. Table 3 summarizes historical and projected spending on the aggregate.

Table 3 - Total Investment Cost

($ Millions)	**Prev. Years**	**2020**	**2021**	**2022**	**2023**	**2024**	**Forecast 2025+**	**Total**

Witness: Donna Jablonsky

As shown in Table 1 Hydro One overhead conductors are forecasted to be in High Risk condition is increasing. Line refurbishment investments are therefore increasing over the test year period as compared to historical years to manage this.

The following factors influence the costs of Line Refurbishment Projects:

- The circuit voltage level, site accessibility, structure type (wood pole vs. steel structure)
- The length of conductor being replaced;
- Whether replacement of deteriorated shieldwire, insulators, or additional hardware is required;
- Any structure or foundation work required.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: the "Do Nothing" alternative involves waiting for identified near EOL ACSR conductors to deteriorate EOL. This alternative has been rejected since it does not address the main purpose of this investment, to address the issue of a large volume of conductors approaching their EOL, thereby necessitating their proactive replacement. Furthermore, the time at which a conductor deteriorates to become EOL from near EOL is not predictable, and without continuous monitoring cannot be identified. Continuous testing to identify the point at which the condition of conductors reaches EOL would require additional funding and resources.

Alternative 2: Proactive Replacements of near EOL Conductors is the preferred undertaking as it will provide Hydro One with the ability to manage the large population of conductors in High Risk condition over the test period.

E. EXECUTION RISK AND MITIGATION

Risks to these projects include: outage constraints, resource constraints, construction execution challenges, customer coordination, real estate requirements, procurement challenges or regulatory approvals. A thorough risk assessment workshop is performed during the project planning phase where all known risks are identified and mitigation plan is developed. For example, to address outage constraints, Hydro One develops an outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize to a minimum the loss of supply to the customer. The plan might include switching a customer to an alternative supply, the construction of a temporary by-passing circuit or supply of portable generation that will maintain supply to the customer. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages. Another example is the involvement of real estate from the project inception. It allows for the early identification of real estate issues, such as missing or inadequate land rights. Once the issue is identified, Hydro One tries to resolve it prior to execution of the project.

SR-21 Wood Pole Structure Replacements

Start Date:	Q1 2020	**Priority:**	High
In-Service Date:	Ongoing Program	**3 Year Test Period Cost ($M):**	156.1
Trigger(s):	System Renewal, Safety, Reliability, Environment		
Outcomes	Maintains system reliability by preventing wood pole failures; prevents poles from collapsing and potentially causing public injuries or fatalities; reduce emergency restoration frequency and costs through proactive replacement		

A. OVERVIEW

Wood Pole Structure Replacement Program (the "Program") involves the replacement of the wood poles that have failed condition assessment. Typically, a wood pole fails a condition assessment due to being rotten and being at the end of its service life. Although failures in this population can occur at any time, the likelihood increases during severe weather events. Therefore, the objective is to clear the existing backlog of high-risk structures by 2024. Furthermore, as a result of the Program, Hydro One will be able to maintain system reliability, and reduce safety risk to its employees and the public associated with failing structures. The Program targets the replacement of approximately 800 wood poles each year, totalling 4000 wood poles over the five year planning period. Hydro One has evaluated various alternatives for the Program, as described below and concluded that the most cost effective and efficient undertaking is to proactively replace end of service life wood poles. The projected costs of the Program are estimated to be $156.1 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

Wood poles elevate transmission lines above the ground, providing clearance from ground objects and separation between the circuit conductors and other line components. These structures have various designs, sizes and configurations and support transmission circuits from 115 kV to 230 kV. The majority of the wood pole structure population is located in Northern Ontario, typically in remote locations with difficult access.

Hydro One Transmission currently owns and manages approximately 42,000 wood pole structures spanning about 7,000 kilometers. As presented in Table 1 below, the average age of the wood pole fleet is currently 41 years and 34% of the wood poles are beyond their expected service life of 50 years.

Table 1 - Wood Pole Structure Demographics

Wood Structure	Quantity	Average Age	ESL (Years)	Beyond ESL currently	Beyond ESL 2024	Beyond ESL 2029
Total	42,000	41	50	14,400	15,100	17,940

Wood structures deteriorate over time. The rate of deterioration depends on many factors including location, weather, type of wood, treatment, insects and wildlife. As a result, uniform deterioration does not occur and the condition of wood structures varies, even in the same location. Due to the nature of the design, the wood cross-arm tends to be the weak link and is typically the primary cause of failure.

Wood poles are deemed to be End of Life when the surface condition degrades and the poles are no longer climbable; there is significant surface and pole top rot; or where wood pecker holes have weakened the strength of the pole. Poles that are drilled and have 2.5 inches or less of solid circumferential wood remaining from internal rot will be replaced as they have fallen below their required design strength. All wood poles and components are to be replaced when their condition has deteriorated to a point where there is a significant risk of failure under adverse weather conditions. Based on wood pole assessments, 13% of Hydro One's wood pole population requires replacement, as outlined in Figure 1 below. These poor condition poles typically exhibit woodpecker damage, mechanical damage or insect damage. Approximately 45% of the wood pole population needs to be assessed to determine its condition, while about 42% of the population is either in good condition or not eligible for assessment (these poles are under 25 years old and therefore they do not currently meet the criteria for assessment).

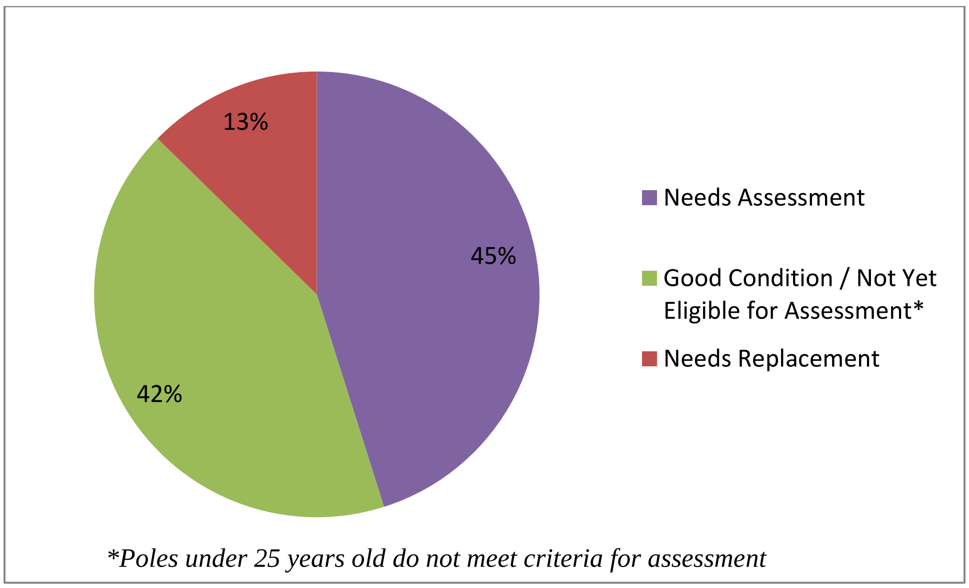

Figure 1 - Wood Pole Fleet Condition Status

The majority of transmission wood pole structures are located in Northern Ontario and many of these structures support radial circuits. As a result, a wood pole or cross-arm failure can often directly result in a customer outage. Many of these northern wood pole circuits feed major industrial customers, who may be forced to shut down until power is restored. Such an event can add significant cost to a customer's operations. Moreover, these Northern circuits supply electricity to local distribution companies in Indigenous communities, which would be adversely affected by any supply interruption.

Figure 2 illustrates a failure of a wood pole. Figure 3 illustrates rotten pole tops that could fail imminently.

Figure 2 - Downed wood pole on circuit M1T

Figure 3 - Rotten pole tops on M1T that could fail imminently

The number of forced outages due to wood pole structure failures has increased over the past ten years, as illustrated in Figure 4. Wood pole failure is the result of a combination of multiple factors such as pole condition, weather condition, physical loading on the pole, and the environment of pole location. Wood poles are a natural product that despite treatment, have some quality inconsistencies in each pole, which can result in an unpredictable failure under certain conditions.

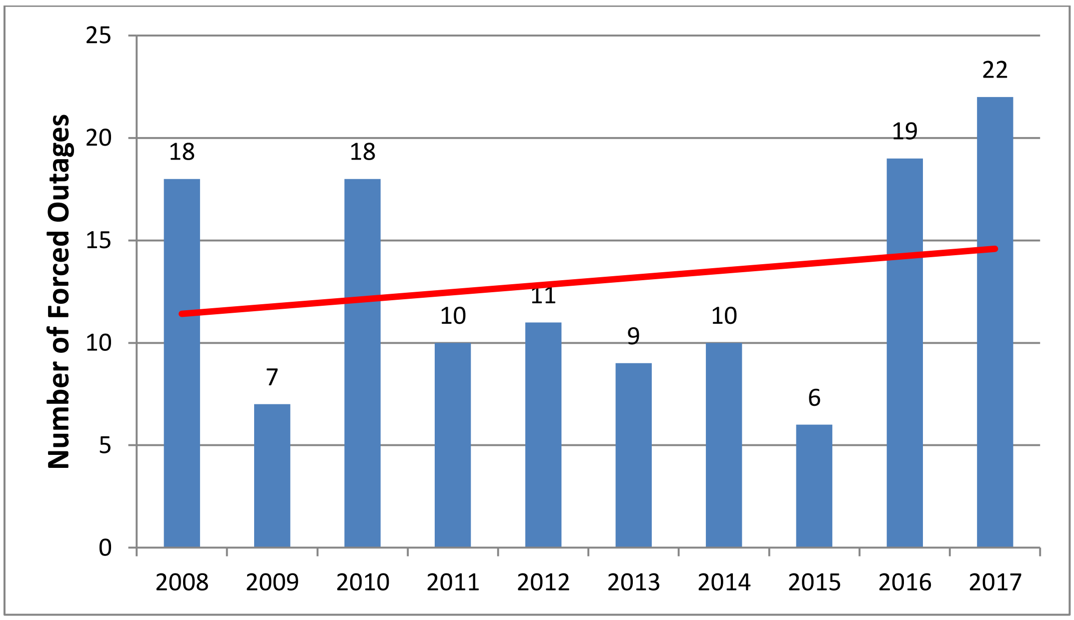

Figure 4 - Forced Outage Frequency Due to Wood Pole Failures

The forced outage duration due to wood pole failures, shown in Figure 5, demonstrates a general improvement over the past ten years. The relatively high outage incidences and durations in 2016 and 2017 may point to the start of an upward trend (although a few more years of data would be needed to be certain).

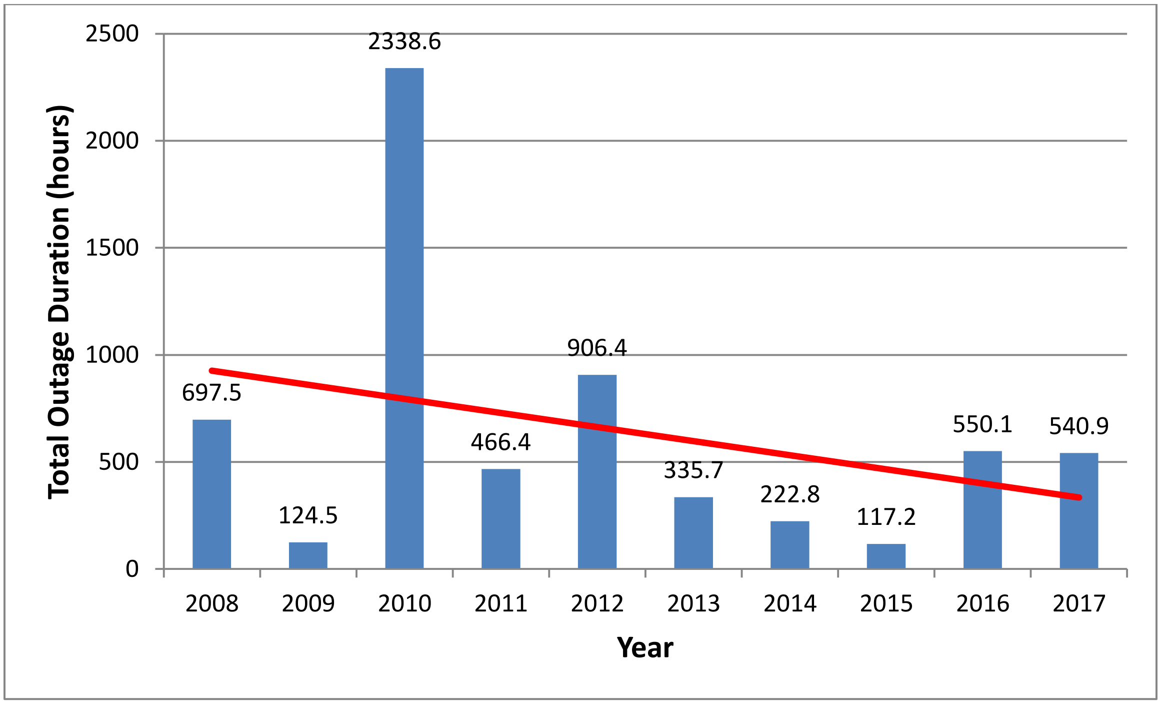

Figure 5 - Forced Outage Duration due to Wood Pole Failures

Investment Description

Hydro One will continue to replace wood poles that have failed condition assessments and any remaining Gulfport structures. Although failures in this population can occur at any time, the likelihood increases during severe weather events. Therefore, the objective is to clear the existing backlog of end of service life structures by 2024.

Replacement candidates are selected based on condition assessments. Wood pole structure condition is collected from visual inspections of the various components that make up the structure, including the cross-arms. Visual inspections include both a detailed helicopter inspection to assess the upper area of wood structures and a ground line inspection to assess the lower part of wood structures. In addition to the visual inspections, other diagnostic testing that focuses on internal rot and wood pecker holes is used to assess condition. Representative samples of wood poles are drilled once they meet a certain age criteria to determine the presence of internal rot.

The wood pole structures scheduled for replacement in the five years will be replaced with new wood pole or composite structures. The Program targets the replacement of approximately 800 wood poles each year, totalling 4,000 wood poles over the five planning years 2020-2024. This represents an average annual replacement rate of 2%. This rate of replacement has been able to keep pace with end of life wood poles identified through inspections as well as address other known wood pole deficiencies on the transmission system.

Outcome

As a result of the Program, Hydro One will maintain system reliability, and reduce safety risk to employees and the public associated with failing structures. Through customer engagement process, Hydro One has heard from its customers that they need Hydro One to pay more attention to addressing situations today that can provide greater reliability and lower costs in the future. The Program is an exemplary investment to address all of the aforementioned concerns.

The following table presents anticipated benefits as a result of the Program in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary

Customer Focus	• Reduce public safety risk associated with wood pole failures • Maintain customer reliability by replacing end-of-life wood poles
Operational Effectiveness	• Maintain system reliability by replacing end-of-life wood poles • Proactive wood pole replacement will reduce emergency restoration frequency

C. EXPENDITURE PLAN

Table 2 below presents forecasted costs for the Program. Costs for the Program are based on an average unit cost estimate calculated utilizing historical replacement costs.

Table 2 - Total Investment Cost

($ Millions) [1]	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital and Minor Fixed Assets[2]	0.0	55.4	56.6	57.6	58.8	60.0	0.0	288.4
Less Removals	0.0	4.4	4.5	4.6	4.7	4.8	0.0	23.1
Gross Investment Cost	**0.0**	**51.0**	**52.0**	**53.0**	**54.1**	**55.2**	**0.0**	**265.3**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**51.0**	**52.0**	**53.0**	**54.1**	**55.2**	**0.0**	**265.3**

[1] *Due to the in-year nature of program investments, only 2020-2024 expenditures are shown*
[2] *Includes Overhead at current rates.*

The following factors affect the capital expenditures required for the Program:

- Structure type – The cost varies depending on whether it is single pole, two-pole or three-pole structure. The larger the structure, the more expensive it is to replace. Likewise, a dead-end structure will be more difficult and costly to replace.
- Pole size – There are various pole heights depending on the voltage level and ground clearance requirements, and larger poles may require heavier equipment to replace.
- Location of the pole (whether it is easily accessible or in a remote area) – Accessibility is very important, as having to clear brush and build roads adds significant costs.

- Environmental restrictions (whether it's a sensitive area to access) – crossing an environmentally sensitive area requires time and money to be spent on permits.
- Work bundling – it is cheaper to replace poles that are in the same area if some costs can be shared between them.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: The "Do Nothing" - Reactive Pole Replacement involves waiting for the wood poles that are at end-of-life to fail and replace the failed wood poles on a reactive basis. This alternative has been rejected since the reactive management of transmission lines wood poles would lead to increased asset failures resulting in elevated safety and reliability risks. In addition, as wood poles deteriorate and reach end-of-life, emergency restorations and trouble calls would increase. This has a direct and significant impact on customers, who may be faced with long outages due to the radial nature of many wood pole lines.

Alternative 2: Planned Pole Replacement at the Optimal Level is based on replacing end-of-life wood poles at a rate that addresses confirmed end-of-life assets, resulting in elimination of backlog of end-of-life wood poles. This alternative would lead to long term cost savings by improving the operation efficiency and reducing reactive replacements. The wood poles would be managed optimally, where defects and end-of-life wood poles are addressed in a timely and proactive manner. This alternative is rejected as it is not deemed prudent to pursue based on the risk mitigated for the funding required

Alternative 3: Pole replacement Based on Risk Mitigation Assessments is the preferred undertaking. Plan to replace end-of-life wood poles based on risk mitigation assessments. This alternative will address end-of-life wood poles to mitigate the safety and reliability risks that balance wood poles needs, resource availability, and cost impact to customers. This alternative is selected, as it will maintain the safety and reliability of the transmission system.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of the Program include access to the assets depending on the season, and equipment outage availability. These risks are mitigated through extensive planning, scheduling and outage coordination across lines of business and stakeholders. Furthermore, a thorough risk assessment workshop is performed during the initial Program planning phase where all known risks are identified and mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize to a minimum the loss of supply to the customer (i.e. switching a customer to an alternative supply). Outage planning also aims to synchronize Hydro One supply outages with the customer’s planned maintenance driven outages.

SR-22 Steel Structure Coating Program

Start Date:	Q1 2020	**Priority:**	Medium
In-Service Date:	Program	**3-year Test Period Cost ($M):**	55.5
Trigger(s):	Cost Avoidance, Preventative Maintenance / System Renewal, Safety, Reliability		
Outcomes:	Extends the life of steel structures by coating them and thus preventing costly future capital investments into complex repairs or structure replacements;		

A. OVERVIEW

Steel Structure Coating Program (the "Program") involves coating transmission line steel structures that are corroding. Coating the steel structure with zinc-based product will provide on-going protection to the underlying carbon steel and preserve the steel structure. Given the condition and the risks associated with steel structure failures, the Program is required to avoid tower failure, negative impacts to reliability and increased costs for tower replacements. Avoiding significant costs in the future through tower coating is the objective of the Program. Doing so will provide economic benefit and value to ratepayers because a relatively small investment now will result in large savings to customers in the future. The tower coating program is an exemplary investment that considers repair versus replace options. In this case, repairing the asset by coating, which extends asset life, is clearly the preferred option that results in a significant present value positive investment. Hydro One has evaluated various alternatives for the Program, as described below, and concluded that the coating of 2260 (260 in 2020 and 500 in 2021-2024) corroded steel towers balances the safety and reliability risks with the economic benefits. The projected costs of the Program are estimated to be $55.5 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

Steel structures elevate transmission lines above the ground, providing clearance from ground objects and separation between the circuit conductors and other line components. These structures have various designs, sizes and configurations and support transmission circuits from 115 kV to 500 kV.

Steel structures are manufactured from carbon steel and protected by hot dip galvanizing (“HDG”), a zinc based product to protect the steel from corrosion. Based on the studies conducted by corrosion experts, such as Electric Power Research Institute (“EPRI”), the service life of steel structures is primarily dependent on the condition of its HDG, as once a structure has lost its galvanizing protection the carbon steel is exposed to the environment, and the corrosion rate of the structure accelerates by a factor of eight to ten. If steel corrosion is not addressed prior to corrosion setting in, the steel structure will begin to lose structural strength and the only option would be partial or complete replacement of the tower. When the structural strength diminishes below design strength, the integrity and capacity of the structure is compromised and a failure may occur under certain weather loading conditions. Figure 1 illustrates the steel transmission towers from Sarnia region that are 72 years old which exhibit heavy pitting corrosion and require complete replacement.

Figure 1 - Steel Structures in the Sarnia area exhibiting heavy pitting corrosion

Recoating the structure with zinc-based product will provide on-going protection to the underlying carbon steel and preserve the steel structure. It will extend the steel tower service life by restoring the protective layer of galvanized coating, thereby avoiding the more costly option of replacement.

Hydro One retained EPRI to conduct an engineering study to define corrosion zones and corrosion rates in the province of Ontario and assess impact of corrosion to Hydro One's transmission towers. The study includes condition assessment of steel towers located in various corrosion zones. In conducting its study, EPRI utilized the international standard, ISO 9223:2012, *Corrosion of metals and alloys - Corrosivity of atmospheres – Classification.* The ISO 9223:2012 establishes a classification system for the corrosivity of atmospheric environments. Using the ISO 9223:2012, EPRI completed its study and established that the province of Ontario is divided into four corrosion zones ranging from C2 to C5. Each of these corrosion zones has a range of corrosion rates which can be used to estimate the service life of HDG steel based on its location. C2 and C3 zones are defined as light corrosion zones and the towers will be protected and maintained in good condition for minimum of 115 years without requiring any coating. Based on Hydro One asset records, there are approximately 39,000 steel structures in these light corrosion zones and 2,200 of them are older than 100 years. However, none of them are older than 115 years and there is no immediate tower coating needs for structures within these zones.

C4 & C5 zones are defined as heavy corrosion zones which have high and very high corrosion rates, respectively, for zinc and carbon steel. Figure 2 illustrates corrosion zones in Ontario. Based on EPRI study, the towers will, on average, lose their protective zinc 45 years after installation in C5 zones. Furthermore, they would lose 10% of their metal in the following 30 years. At this stage, structures are no longer able to withstand the original design loads and either a major refurbishment or complete tower replacement would be required. Applying these results to Hydro One’s steel tower population, the EPRI study indicated that a significant portion of towers located in very high corrosion zones are in need of coating to arrest further deterioration and prevent eventual replacements. Appendix “A” attached is a reference guide from ISO 9223:2012 that provides a description of typical atmospheric environments related to the estimation of corrosivity categories (C1 to C5).

C1 and CX zones are not applicable to Hydro One assets in Ontario, as they refer to very light corrosiveness (i.e. arctic environments) or very heavy corrosiveness (i.e. marine coastal environments) respectively.

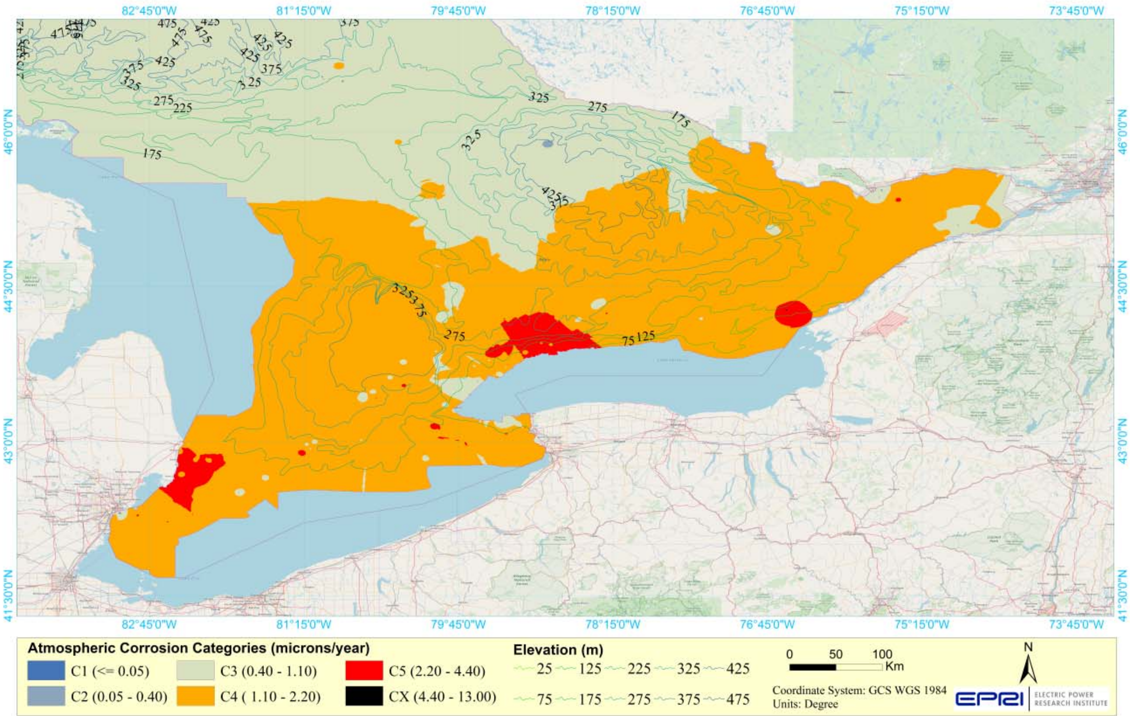

Figure 2 - Corrosion zones in Ontario, courtesy of EPRI, 2017

Table 1 shows the demographics of the steel structure population. Hydro One has 52,250 steel structures that have an average age of 58 and an expected service life ("ESL") of 80 years. There are approximately 13,000 steel towers that are located in very high (C5) corrosion zones such as Windsor, Sarnia, Hamilton, Kingston and GTA.

Based on the current assessment, 6% of Hydro One's steel structures have been recoated, 8% require major refurbishment or replacement, and 14% require coating that will be addressed as part of the steel structure coating program. 72% of the structures are currently in good condition and are not expected to require any maintenance in the near future. This assessment is continuously reviewed and updated as more structures are assessed and inspected.

Table 1 - Steel Structure Demographics

	Quantity	Average Age	ESL (Years)	Beyond ESL currently	Beyond ESL 2024	Beyond ESL 2029
Steel Towers in Light Corrosion Zones	37,300	59	80	6,605	8,005	9,510
Steel Towers In Heavy Corrosion Zones	13,000	59	80	3,000	3,550	4,150
Steel Poles	1,950	33	80	85	95	150
Total	**52,250**	**58**	**80**	**9,690**	**11,650**	**13,810**

A transmission steel tower is deemed to have reached its end of life ("EOL") when it has experienced 10% metal loss, rendering it incapable to withstand design loads. A new tower comes with a layer of protective zinc applied over bare steel via hot-dip galvanizing process. This layer varies in thickness. The American Society of Testing and Materials ("ASTM") specifies a minimum thickness of 100 microns for tower steel. It is common for a fabricator to deliver steel with an average zinc thickness of 150 microns. The most common steel member thickness for 115 and 230 kV towers is 8mm i.e. 8000 microns. In very high (C5) corrosion areas, the average annual zinc corrosion rate is 3.3 microns and bare steel is 27.5 microns, as described by EPRI.

- Most common steel member thickness = 8mm.
- EOL Criteria = 10% loss of steel thickness, 800 microns
- Opportunity to coat = in the time interval between when the zinc layer is nearly depleted and before EOL.

New steel members come with 150 microns zinc layer. At the average annual zinc corrosion rate of 3.3 microns, it takes 45 years (150/3.3=45) to deplete the zinc layer. Once the zinc layer is depleted, the exposed bare steel corroding at an average annual rate of 27.5 microns will take 29 years (800/27.5=29) to lose 800 microns of thickness. Thus, a tower in C5 very high corrosion area will, on average, reach EOL in 74 years (45+29). Therefore, the window of opportunity to economically extend life of towers located in high corrosion areas via coating is when a tower reaches around 45 years and before 75 years. As the towers exceed 75 years, various level of refurbishment effort will be required to restore strength before coating can be applied. Eventually, costly refurbishment or tower replacement becomes the only feasible option.

Investment Description

The Program is a preventive maintenance investment or asset life extension program where costs are incurred today to avoid far greater costs in the future. As discussed above, Hydro One Transmission currently owns and manages 52,250 steel structures.

As part of the Program, Hydro One targets steel towers that are located in very high (C5) corrosion zones. As described previously, towers in these zones lose their protective zinc after an average of 45 years, and 10% of their metal in the following 30 years. At this stage, structures are no longer able to withstand the original design loads and either a major refurbishment or complete tower replacement would be required. Currently, there are approximately 13,000 steel towers located within very high corrosion zones. Of 13,000 steel towers, 7,500 towers have met coating criteria and are within the window of opportunity for coating. 55 percent of the 7,500 towers (4,125) are currently experiencing corrosion and metal loss. As these towers approach 75 years old, the ability to extend their service life by coating diminishes.

Hydro One intends to complete coating of an average of 452 steel towers per year between 2020 and 2024. This is a total of 2,260 towers, which are selected from the 4,125 structures that are already experiencing corrosion and metal loss.

The steel tower coating program has mainly been driven by economic considerations rather than risk mitigation. Based on the most recent analysis, the net present value

("NPV") calculations show significant savings from tower coating versus tower replacement. Over the 5-year planning period (2020-2024), savings are estimated at $162 million compared to single isolated tower replacements, or $101 million compared to single tower replacements that are part of a multiple tower replacement project (i.e. replacing multiple towers is more efficient resulting in comparatively lower savings from tower coating). Avoiding investment today exacerbates the quantum of investment in the future and drives higher future rates, which is contrary to the public interest.

Outcome:

As a result of the Program, Hydro One will maintain reliability, address employee and public safety concerns and minimize future costs. Coating steel structures before they lose their zinc protective layer prolongs their life and prevents higher capital expenditures in the future. The integrity of steel structures is critical to the reliability of the system and to public safety. If a tower corrodes enough, it could fail, causing damage to property, injury to people present in the proximity or potentially even death. Furthermore, through customer engagement process, Hydro One has heard from its customers that they need Hydro One to pay more attention to addressing situations today that can provide greater reliability and lower costs in the future. The Program is an exemplary investment to address all of the aforementioned concerns.

The following table presents anticipated benefits as a result of the Program in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• This investment will maintain the long term reliability of the system by optimizing investment costs today and provide improved reliability and lower costs in the future.
Financial Performance	• Defer capital replacement costs by coating transmission line steel structures to preserve structural strength and extend service life.

C. EXPENDITURE PLAN

Table 2 presents forecasted costs for the Program. Costs for the Program are based on an average unit cost estimate calculated utilizing historical costs.

Table 2 - Total Investment Costs

($ Millions) [1]	**Prev. Years**	**2020**	**2021**	**2022**	**2023**	**2024**	**Forecast 2025+**	**Total**
Capital and Minor Fixed Assets[2]	-	11.4	21.8	22.3	22.7	23.2	-	101.3
Less Removals	-	0.0	0.0	0.0	0.0	0.0	-	0.0
Gross Investment Cost	**-**	**11.4**	**21.8**	**22.3**	**22.7**	**23.2**	**-**	**101.3**
Less Capital Contributions	-	0.0	0.0	0.0	0.0	0.0	-	0.0
Net Investment Cost	**-**	**11.4**	**21.8**	**22.3**	**22.7**	**23.2**	**-**	**101.3**

[1] *Due to the in-year nature of program investments, only 2020-2024 expenditures are shown*
[2] *Includes Overhead at current rates.*

The following factors affect the capital expenditures required for the Program:

- Structure type/size – Depending on the voltage of the line, the structures will be different sizes. As the voltage increases, so does the size of the structure. Structure type also impacts the cost, as dead-end towers are bigger than suspension and will cost more to coat;
- Location of the structure (whether it is easily accessible or in a remote area) – Accessibility is very important, as having to clear brush and build roads adds significant costs;

- Environmental restrictions (whether it is a sensitive area to access) – crossing an environmentally sensitive area requires time and money to be spent on permits;
- Work bundling – it is cheaper to coat towers that are in the same area if some costs can be shared between them; and
- Live-line work (whether work can be performed live-line) – conducting coating without an outage is a major benefit to work scheduling and can optimize resource deployment

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: The "Do Nothing" - Reactive Replacement of Failed Structures involves reactive responding and replacing failed steel structures that are at EOL. This alternative has been rejected because reactive management of transmission lines structures would lead to increased asset failures, resulting in elevated safety and reliability risks. Further, as steel structures deteriorate and reach EOL, the cost to perform demand emergency repairs would cause a high financial impact on the company and its ratepayers.

Alternative 2: Coating at the Optimal Level is based on coating steel structures at a rate that is coordinated with the optimal period in the structures' life cycle at which coating is most beneficial. This plan would eliminate the backlog of eligible steel structures, and reduce future reactive replacement/repair costs. This alternative is not deemed prudent to pursue based on Hydro One's decision to prioritize investments that mitigate the most safety and reliability risk over investments predominantly driven by economic benefits.

Alternative 3: Coating at Currently Planned Pacing is the preferred undertaking because it aligns with the EB-2016-0160 Decision. Under these budget constraints, Hydro One strived to balance safety and reliability risks with economic benefits. Poor condition steel structures that are eligible for coating will be coated proactively, in order to maintain long term reliability and provide maximum value to ratepayers.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of the Program include access to the assets depending on the season, availability of qualified resources, and line outage availability. These risks are mitigated through extensive planning, scheduling and outage coordination across lines of business and stakeholders. Furthermore, a thorough risk assessment workshop is performed during the initial Program planning phase where all known risks are identified and mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize the loss of supply to the customer (i.e. switching a customer to an alternative supply). Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages.

APPENDIX "A"

Description of typical atmospheric environments related to the estimation of corrosivity categories (ISO:9223:2012)

Corrosivity category[a]	Corrosivity	Typical environments — Examples[b]	
		Indoor	Outdoor
C1	Very low	Heated spaces with low relative humidity and insignificant pollution, e.g. offices, schools, museums	Dry or cold zone, atmospheric environment with very low pollution and time of wetness, e.g. certain deserts, Central Arctic/Antarctica
C2	Low	Unheated spaces with varying temperature and relative humidity. Low frequency of condensation and low pollution, e.g. storage, sport halls	Temperate zone, atmospheric environment with low pollution (SO_2 < 5 µg/m^3), e.g. rural areas, small towns Dry or cold zone, atmospheric environment with short time of wetness, e.g. deserts, subarctic areas
C3	Medium	Spaces with moderate frequency of condensation and moderate pollution from production process, e.g. food-processing plants, laundries, breweries, dairies	Temperate zone, atmospheric environment with medium pollution (SO_2: 5 µg/m^3 to 30 µg/m^3) or some effect of chlorides, e.g. urban areas, coastal areas with low deposition of chlorides Subtropical and tropical zone, atmosphere with low pollution
C4	High	Spaces with high frequency of condensation and high pollution from production process, e.g. industrial processing plants, swimming pools	Temperate zone, atmospheric environment with high pollution (SO_2: 30 µg/m^3 to 90 µg/m^3) or substantial effect of chlorides, e.g. polluted urban areas, industrial areas, coastal areas without spray of salt water or, exposure to strong effect of de-icing salts Subtropical and tropical zone, atmosphere with medium pollution
C5	Very high	Spaces with very high frequency of condensation and/or with high pollution from production process, e.g. mines, caverns for industrial purposes, unventilated sheds in subtropical and tropical zones	Temperate and subtropical zone, atmospheric environment with very high pollution (SO_2: 90 µg/m^3 to 250 µg/m^3) and/or significant effect of chlorides, e.g. industrial areas, coastal areas, sheltered positions on coastline

SR-23 Tower Foundation Assess/Clean/Coat Program

Start Date:	Q1 2020	**Priority:**	Medium
In-Service Date:	Program	**3 Year Test Period Cost ($M):**	57.0
Trigger(s):	Cost Avoidance, Preventative Maintenance / System Renewal, Safety, Reliability		
Outcomes:	Extends the life of foundations by re-coating them and thus preventing costly future capital investments into complex repairs or tower replacements; maintains system reliability by preventing foundation and tower failures; prevents towers from collapsing and potentially causing public injuries or fatalities		

A. OVERVIEW

Tower Foundations Assess/Clean/Coat Program (the "Program") involves coating and/or repairing steel structure tower foundations that have deteriorated to the point of increasing their risk of failure (which could include structure collapse), and impacting public safety and system reliability. The Program focuses on steel grillage footings and anchors, which due to their age and material sustain a higher incidence of corrosion. The need of the Program is asset condition driven. The scope of the Program includes those steel grillage footings where coating or minor repairs can be applied to extend the foundation's service life. However, where severe corrosion has caused significant strength reduction, the steel foundation will be identified as a candidate for major repair or replacement.

The proposed plan will assess, clean, and coat 820 grillage foundations in 2020 and 1600 foundations per year from 2021-2024. Hydro One has evaluated various alternatives for the Program, as described below, and concluded that the assessing, cleaning and coating of 7220 tower foundations and anchors is the most cost effective and efficient undertaking. The projected costs of the Program are estimated to be $57.0 million over the 2020-2022 test period.

B. NEED AND OUTCOME

Investment Need

Foundations support and anchor transmission structures to the ground and enable the structures to withstand the weight of the structure itself, attached components and weather related external forces such as wind and ice. There are three dominant foundation types in Hydro One's transmission system: cast-in concrete footings, steel grillage footings, and steel anchors. Hydro One is currently focusing on grillage footings and anchors, which due to their age and material sustain a higher incidence of corrosion. Concrete footings are younger and are not displaying signs of corrosion.

From the early 1900s into the 1960s, most lattice steel structures were constructed with a grillage (buried steel) foundation. There are approximately 32,000 grillage footings and approximately 3,500 guyed structures which rely on the integrity of the steel grillage and anchors for support. Steel tower grillage foundations and anchors are fabricated with a zinc-based galvanized coating which protects the underlying steel against corrosion. Coating life can vary considerably depending on the surrounding environment. Once the galvanizing has been depleted, the underlying bare steel begins to corrode; typically much faster than with the galvanized coating. The accelerated corrosion results in metal loss which reduces the mechanical strength of the grillage foundation.

All steel grillage foundations that are in Hydro One fleet are or will be 50 years or older during the course of the next five years and, as such, will need to be assessed through the Program. When a steel grillage footing foundation reaches 50 years old, it becomes prone to degradation. Currently, 32% of steel grillage footing population is beyond its End of Service Life ("ESL"). Hydro One defines ESL as the average age in years that an asset can be expected to operate under normal system conditions. The average ESL of the steel grillage footing fleet is 80 years. Assuming no repair and/or replacement, Hydro One anticipates that approximately 12,185 units (38% of the steel grillage footing population) will exceed their ESL by 2024 and 14,360 units (45% of the population) will exceed their ESL by 2029.

The need is determined based on foundation type and consequence of asset failure. Based on condition assessment, where severe corrosion has caused significant strength reduction, the foundation will be identified as a candidate for major repair or replacement. The failure of foundation could directly result in structure failures which could cause a lengthy system operation interruption and a possible employee or public safety concern. Furthermore, damaged foundations could result in very costly repairs or even necessitate the replacement of the entire tower.

Figure 1, Figure 2, and Figure 3 illustrate damaged grillage footings. The towers eventually had to be replaced due to the damage.

Figure 1 - Towers sitting in water causes the foundations to corrode, leading to towers leaning (circuit D2L, near North Bay, ON)

Figure 2 - Buckled legs and tower leaning (circuit M80B, Minden, ON)

Figure 3 - Leg and diagonals are corroded through, necessitating costly repairs (circuit D2L)

Investment Description

The Program is intended to inspect, assess, clean and coat the steel grillage footings buried underground, to restore any depleted coating protection and extend the foundations' service life. The Program also includes minor repairs on damaged footings and identification of footings that need major repair or replacement.

The refurbishment candidates are selected based on condition assessments. If no metal loss is visible at the time of assessment, the footings and/or anchors are re-coated to restore the corrosion protection and extend the life of the components. If metal loss is visible at the time of assessment, the affected components are scheduled for refurbishment.

The Program is focused on assessing, restoring, and refurbishing the grillage foundations to extend the life of the steel that is at or below the ground line. This is achieved through two planned activities:

1. Assess/Clean/Coat – This activity assesses the condition of a tower's foundation and either immediately coats it or schedules future repairs. The decision to coat or repair depends on the severity of the corrosion that is found and the complexity of potential repairs.
2. Foundation Refurbishment – This activity completes more complex repairs and/or replaces the foundations identified during previous assessment activities.

The proposed plan will assess, clean, and coat 820 grillage foundations in 2020 and 1600 foundations per year from 2021-2024. As per Hydro One strategy for steel structure and foundation, this program is to prioritize the foundations based on line voltage, type of structures and geographic location of the lines. For example, the current plan is focusing on 500 kV guyed towers located in Northern region where most of towers are located in wetland or muskeg area. These towers were built in 1960s and there is a high volume of tower foundation failures.

Outcome

The Program will maintain system reliability and mitigate public safety concerns by addressing 7,220 grillage foundations over the five year plan and extending the life of steel structure foundations.

The following table presents anticipated benefits as a result of the Program in accordance with the OEB's Renewed Regulatory Framework:

Customer Focus	• Reduce public safety risk associated with steel tower failures • Maintain customer reliability by replacing end-of-life tower foundations
Operational Effectiveness	• Maintain system reliability by replacing end-of-life steel tower foundations • Proactive foundation replacement will reduce emergency restoration frequency

C. EXPENDITURE PLAN

Table 1 below presents forecasted costs for the Program. Costs for the Program are based on an average unit cost estimate calculated utilizing historical replacement costs.

Table 1 - Total Investment Cost

($ Millions) [1]	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[2] and Minor Fixed Assets	0.0	11.8	22.3	22.8	23.3	23.7	0.0	104.0
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.0**	**11.8**	**22.3**	**22.8**	**23.3**	**23.7**	**0.0**	**104.0**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**11.8**	**22.3**	**22.8**	**23.3**	**23.7**	**0.0**	**104.0**

[1] *Due to the in-year nature of program investments, only 2020-2024 expenditures are shown*
[2] *Includes Overhead at current rates.*

The following are some factors that affect the cost of foundation assess/clean/coat and refurbishment:

- Structure type/size – repairing the foundation on a single leg of a 500 kV tower is much more costly than a four-leg tower. Depending on the voltage of the line, the structures will be different sizes. As the voltage increases, so does the size of the structure and its foundations;
- Location of the structure: whether it is easily accessible or in a remote/swampy area – accessibility is very important, as having to clear brush and build roads adds significant costs and some work can only be performed under frozen ground conditions;
- Environmental restrictions: whether it is a sensitive area to access – crossing an environmentally sensitive area requires time and money to be spent on permits;

- Work bundling – it is cheaper to work on towers that are in the same area if some costs can be shared between them; and
- The extent of the damage - the damage will determine what kind of equipment is required to perform the repairs.

D. ALTERNATIVES

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: Reactive Foundation Replacement involves a reactive responding and replacing failed tower foundations and anchors that are end-of-life. This alternative has been rejected for the following reasons:

- Reactive management of tower foundations and anchors would lead to increased asset failures, resulting in elevated safety and reliability risks;
- As tower foundations and anchors deteriorate and reach end-of-life, emergency restoration and trouble call volumes would be unmanageable;
- Due to the complicated procedure to replace a tower foundation, multiple lengthy power outages will be required, which will significantly interrupt the power supply to customers and reduce system operation reliability;
- Cost of replacing a tower foundation could be as much as 20-30 times that of clean and coating the foundation, as more labour and heavy equipment is required.

Alternative 2: Planned Foundation Coating/Repair at the Optimal Level is based on assessing, cleaning and coating steel structure foundations at a rate that is coordinated with the optimal period in the foundation's life cycle at which coating and repair is most beneficial. This alternative would eliminate the backlog of eligible steel structures foundations and reduce long term planned or reactive replacement/repair costs. This alternative is preferred for the following reasons:

1. Poor condition steel structure foundations that are eligible for coating will be coated proactively
2. Risks to transmission system safety and reliability can be mitigated by balancing asset needs, resource availability, and cost impacts.

E. EXECUTION RISK AND MITIGATION

The risks to the completion of this investment include access to the assets depending on the season, availability of qualified resources and equipment outage availability. These risks are mitigated through extensive planning, scheduling and outage coordination across lines of business and stakeholders. Furthermore, a thorough risk assessment workshop is performed during the initial Program planning phase where all known risks are identified and mitigation plan is developed. For example, to address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize the loss of supply to the customer (i.e. switching a customer to an alternative supply). Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages.

SR-24 Transmission Line Shieldwire Replacement

Start Date:	Q1 2020	**Priority:**	High
In-Service Date:	Program	**3 Year Test Period Cost ($M):**	37.8
Triggers: Reliability and Safety			
Outcomes: Minimize public safety risk associated with shieldwire failures; maintain system and customer reliability by replacing EOL shieldwire; proactive shieldwire replacement will help to reduce emergency restoration frequency as well as associated costs.			

A. OVERVIEW

The Transmission Line Shieldwire Replacement Program (the "Program") is required to replace End-of-Life[1] ("EOL") galvanized steel, Aluminum Conductor Steel Reinforced ("ACSR") and Copperweld shieldwire installed on Hydro One's transmission system. Due to demographic patterns and the resulting quantity of EOL shieldwire currently installed on the Hydro One system, 290 km of shieldwire is required to be replaced annually over the test period. At this rate, all shieldwire currently identified as being EOL and all critical sections of shieldwire identified during the five-year period as having reached EOL will be replaced by the end of the five-year period. If EOL shieldwire is not replaced, it is likely to break and make contact with the conductor, resulting in a circuit outage and potential customer interruption. Additionally, the broken shieldwire represents a significant safety risk as it may fall and swing to the ground. By replacing EOL shieldwire prior to failure, these reliability and safety risks are mitigated. Hydro One has evaluated various alternatives to the Program, as described below, and concluded that replacing EOL shieldwire is the most cost-effective and efficient undertaking. The projected costs of the Program are estimated to be $37.8 million over the 2020-2022 test period.

[1] EOL is defined as the likelihood of failure, or loss of an asset's ability to provide the intended functionality, wherein the failure or loss of functionality would cause unacceptable consequences.

B. NEED AND OUTCOME

Investment Need

There is approximately 34,600 km of shieldwire strung above Hydro One's overhead transmission lines. Shieldwire is used to provide lightning protection and grounding continuity for the transmission line. An example of transmission line shieldwire is presented in Figure 1.

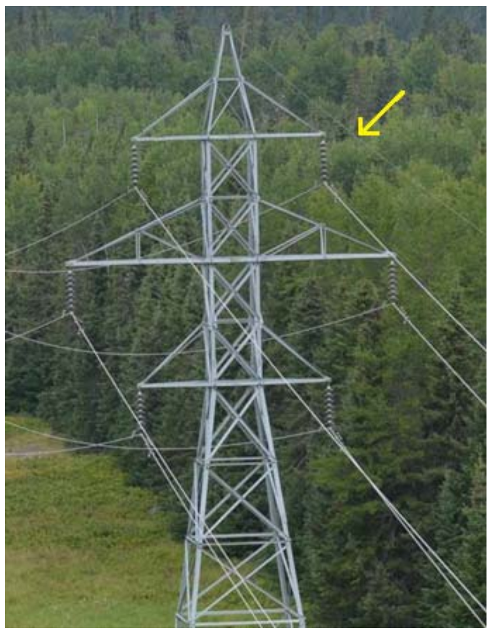

Figure 1 - Transmission Line Shieldwire

Hydro One's network has five types of shieldwire; Galvanized Steel, Alumoweld, Optical Ground Wire ("OPGW"), Aluminum Conductor Steel Reinforced and Copperweld. The breakdown of shieldwire by type currently installed on the Hydro One network is displayed in

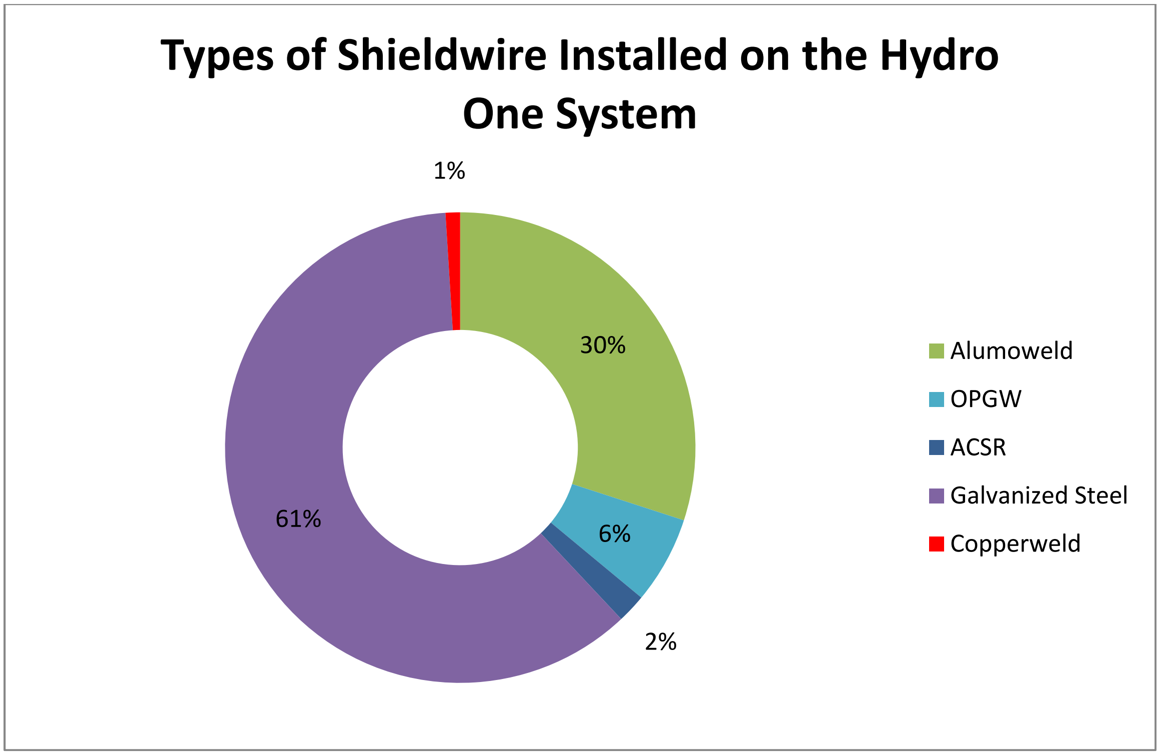

Figure 2: Shieldwire by Type

Galvanized steel is the most common type of shieldwire currently installed on the Hydro One transmission network. Galvanized steel shieldwire is no longer installed by Hydro One because its protective zinc coating tends to deteriorate over time, thereby reducing its mechanical strength and leading to eventual failure. Aluminum cladded steel, also known as Alumoweld, is the most recent type of shieldwire installed on Hydro One's network and is being used to replace shieldwire that has reached EOL. In locations where a fibre optic communication channel is required for telecommunication purposes, Hydro One installs OPGW, which consists of Alumoweld shieldwire with a core containing fibre optic strands. ACSR conductors are also installed as shieldwire in limited cases where estimated fault current levels are too high for conventional galvanized steel or Alumoweld wires. Copper cladded steel, also known as Copperweld, is the final type of shieldwire at Hydro One and was previously installed in limited numbers across the network. Copperweld is not capable of adequately sustaining lightning strikes and is therefore targeted for replacement.

Witness: Donna Jablonsky

Shieldwire cannot be maintained or repaired to extend its service life. Rather, Hydro One's shieldwire population is monitored through the condition assessment program and is only replaced once condition warrants. As of 2016, Hydro One began utilizing a non-destructive testing device that is able to assess shieldwire condition without requiring a circuit outage. With the cost and difficulties associated with obtaining an outage eliminated, Hydro One is now able to more easily assess shieldwire condition.

Hydro One does not replace shieldwire based upon age since a multitude of factors, including geographic location, weather and atmospheric contamination contribute to shieldwire lifespan. A detailed condition assessment is used to determine when shieldwire has reached EOL. Line sections of shieldwire are targeted for condition assessment after reaching an established age threshold, which varies based on the shieldwire type. Once selected for condition assessment, the remaining tensile strength and corrosion levels on the shieldwire are examined to determine the remaining service life. If the condition assessment results indicate that the shieldwire has not yet reached EOL, it is scheduled for re-assessment at a later date; otherwise, it is scheduled for replacement under the Program.

If the EOL shieldwire is not replaced, it is at high risk of breaking. As broken shieldwire falls, it often makes contact with the conductors below it, causing a circuit outage and decreased reliability to customers. Broken shieldwire that falls in an urban area will also pose a high public safety risk. Broken shieldwire may hit a pedestrian, employee, vehicle or public property as it falls or blows in the wind, and has the potential to cause severe injury and property damage. Examples of shieldwire failure experienced at Hydro One can be found in Figure 3 to Figure 5 below.

To maintain system reliability and public safety, EOL shieldwire must be replaced under the Program. Due to the safety and reliability concerns associated with shieldwire replacement, completion of this program is considered a high priority.

Witness: Donna Jablonsky

Figure 3: 2016 Shieldwire Failure on K2Z

Figure 4: 2016 Shieldwire Failure on D10H

Figure 5: 2017 Shieldwire Failure on S22A

Investment Description

Hydro One's Shieldwire Replacement Program actively replaces galvanized steel, ACSR and Copperweld shieldwire that has reached EOL. Alumoweld and OPGW are the most recent shieldwire installations on Hydro One's network and have not yet reached EOL. The Program includes all design, procurement, field verification, installation and commissioning required to replace the EOL shieldwire with new Alumoweld or OPGW, including the necessary dampers and associated attachment hardware.

Due to historical construction and demographic patterns, Hydro One is now entering into a period where the shieldwire on many overhead transmission line sections has reached EOL. In order to effectively manage these circuits and prevent shieldwire related outages, this Program targets the replacement of 290 km of shieldwire per year from 2020 to 2024. This represents an average replacement rate of about 0.8% over each year. At this replacement rate, all backlogged shieldwire previously identified as having reached EOL and all critical sections of shieldwire identified during the five year period as having reached EOL will be replaced by the end of the five year period.

Outcome

Hydro One aims to achieve the following outcomes as a result of the Program:

- Maintain system and customer reliability by replacing EOL shieldwire and mitigating outages caused by failing shieldwire
- Reduce the likelihood of employee and public safety incidents related to falling shieldwire. The likelihood of such injuries occurring can be reduced if EOL shieldwire is replaced.
- Replace 0.8% of Hydro One’s shieldwire fleet each year over the 2020 to 2024 period. At this replacement rate, all sections of shieldwire that are currently at EOL and all critical sections of shieldwire identified during the five year period as having reached EOL will be replaced by the end of the five year period.

The following table presents anticipated benefits as a result of the Program in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Reduce public safety risk associated with shieldwire failures • Maintain customer reliability by replacing EOL shieldwire
Operational Effectiveness	• Maintain system reliability by replacing EOL shieldwire • Proactive shieldwire replacement will reduce emergency restoration frequency

C. EXPENDITURE PLAN

As discussed above, the Shieldwire Replacement Program is required to mitigate the safety and reliability risks associated with EOL shieldwire. Hydro One will strive to complete the Program in an effective and efficient way to minimize the cost of performing this sustainment task. The Program begins in January and ends in December of each of the test years.

Table 1 presents forecasted costs for the Program. Costs for the Program are based on an average unit cost estimate calculated utilizing historical replacement costs. Year over year costs fluctuate due to the added inflation. The replacement costs are influenced by structure type and accessibility. To replace all backlogged shieldwire previously identified as having reached EOL and all critical sections of shieldwire expected to reach EOL during the five year period, 290 km of shieldwire is required to be replaced annually through the Shieldwire Replacement Program for the next five years.

Table 1: Total Investment Cost

($ Millions) [1]	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[2] and Minor Fixed Assets	0.0	13.4	13.7	13.9	14.2	14.5	0.0	69.8
Less Removals	0.0	1.1	1.1	1.1	1.1	1.2	0.0	5.6
Gross Investment Cost	**0.0**	**12.3**	**12.6**	**12.8**	**13.1**	**13.4**	**0.0**	**64.2**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**12.3**	**12.6**	**12.8**	**13.1**	**13.4**	**0.0**	**64.2**

[1] Due to the in-year nature of program investments, only 2020-2024 expenditures are shown
[2] Includes Overhead at current rates.

D. ALTERNATIVES:

Hydro One considered the following alternatives before selecting the preferred undertaking.

Alternative 1: Reactive Replacement of Failed Shieldwire involves replacing the EOL shieldwire once a failure occurs. This alternative has been rejected because reactive management of shieldwire would lead to an increased number of asset failures and elevated safety and reliability risks. Replacement of shieldwire on an emergency basis will require constant reprioritization of planned work and lead to inefficient redeployment of resources. Reactive shieldwire replacements would also prolong circuit outages and may therefore extend equipment and customer outages.

Alternative 2: Proactive Replacement of Critical EOL Shieldwire and Backlog is the preferred undertaking. By the end of the five year period, this alternative will replace all backlogged shieldwire previously identified as having reached EOL as well as critical sections of shieldwire identified during the five year period as having reached EOL. Shieldwire replacement will be prioritized based upon circuit criticality. Risk mitigation assessments will be conducted to balance shieldwire replacement needs with resource availability and the cost impact to customers. The risk mitigation assessment allows Hydro One to replace EOL shieldwire in a way that mitigates safety and reliability risks while balancing the asset needs, resource availability and the cost impact to customers.

Alternative 3: Proactive Replacement of All EOL Shieldwire involves planning for the replacement of all backlogged shieldwire previously confirmed to be EOL and all shieldwire that is expected to reach EOL during the five year period. Condition assessment conducted during the five year period will reveal additional sections of shieldwire that have reached EOL and require replacement. This alternative will ensure that these sections of shieldwire are replaced within the five year period, regardless of criticality. In addition to both the critical and non-critical sections of recently identified EOL shieldwire, all backlog shieldwire previously identified as having reached EOL will also be replaced. This alternative will address all confirmed EOL assets and result in the elimination of the backlog of EOL shieldwire. However, this alternative is rejected as it is not deemed prudent to pursue based on the risk mitigated for the funding required.

E. EXECUTION RISK AND MITIGATION

Implementation risks to the Program include outage restrictions and material lead time. These risks are mitigated through proactive planning and coordination well in advance of the program’s execution to ensure outage and material availability. For example, because required shieldwire lengths and sizes can vary greatly, Hydro One only stores small sections of shieldwire for emergency repair. All material required for planned replacements is ordered specifically for each project. Shieldwire and accessories can take between 6-12 months to order and receive, and will delay the planned replacement if not obtained in time. To reduce the likelihood of this delay occurring, refurbishments are planned and material is ordered approximately one year in advance.

SR-25 Transmission Line Insulator Replacement

Start Date:	Q1 2019	**Priority**	High
In-Service Date:	Ongoing Program	**3Year Test Period Cost ($M):**	204.2
Trigger(s):	Strategic, Public Safety, System Reliability		
Outcomes:	Eliminate risk to public safety by replacing defective porcelain insulators; maintain customer and system reliability		

A. OVERVIEW

Transmission Lines Insulator Replacement Program (the "Program") involves primarily the replacement of defective porcelain insulators manufactured by Canadian Ohio Brass (COB) and Canadian Porcelain (CP) between 1965 and 1982. These defective insulators are used province-wide in Hydro One's transmission system. The defect associated with porcelain insulators results in two failure modes: (i) mechanical failure, which cause the conductor to fall on the ground; and (ii) electrical failure which triggers a forced outage, sometimes for a prolonged period of time. These types of failures pose significant safety and system reliability concerns. Hydro One retained a third-party expert, the Electric Power Research Institute ("EPRI"), to assess the condition of defective COB and CP porcelain insulators to assist Hydro One in determining the pacing of porcelain insulator replacement. EPRI completed laboratory testing which provided overwhelming evidence to support taking immediate action to mitigate the risk to the safety and reliability of Hydro One's transmission system. The key recommendation made by EPRI is that the population of defective COB and CP insulators installed between 1965 and 1982 be removed from service as soon as practically possible.

This Program will also address the replacement of deteriorated polymer insulators. Polymer insulators in 230 kV dead-end configurations are known to fail due to their exposure to high electric-field gradients that cause silicone degradation. The degradation exposes the fiberglass rod to moisture which causes rapid deterioration leading to failure. Hydro One retained EPRI to perform a detailed condition assessment of polymer insulators to assist Hydro One in determining the need and pacing of polymer insulator replacement. EPRI completed laboratory testing and provided technical data showing that condition varies based on voltage, manufacturer and use of corona rings. The results of this study indicate that Hydro One should plan to remove certain 230 kV insulators which show extensive degradation from service as soon as possible due to immediate or high risk of failure. Other types of 230 kV insulators should continue to be assessed periodically for signs and degree of degradation. EPRI further recommends that field staff should check the integrity of these insulators prior to performing any live maintenance procedures due to potential safety issues. As part of the Program, Hydro One will be replacing the deteriorated polymer insulators on an “as-needed” basis. Prior to replacing the polymer insulators, Hydro One will perform an asset condition assessment to ensure that the condition of a polymer insulator warrants a replacement.

Program pacing is mainly influenced by the number of defective porcelain insulators located in publicly accessible (critical) locations. Publicly accessible (critical) locations include structures located near roads, water railways, urban areas, golf courses, educational and health care facilities. Hydro One plans to replace defective porcelain insulators posing a higher public safety risk (i.e. insulators in critical locations) by 2022 at a rate of approximately 3,700 circuit structures per year. Insulators in non-publically accessible areas will be replaced at an approximate rate of 3,450 circuit structures per year over a five-year period. The projected costs of the Program are estimated to be $204.2 million over the 2020-2022 test period and the replacement quantities include both porcelain and polymer insulator replacement.

B. NEED AND OUTCOME

Investment Need

Transmission line insulators are an integral component of the transmission system. Transmission line insulators are required to perform two basic functions. They must provide mechanical support for overhead conductors and they must provide electrical isolation between the energized conductors they support and the grounded towers to which they are attached. A typical transmission line insulator is shown in in Figure 1 below.

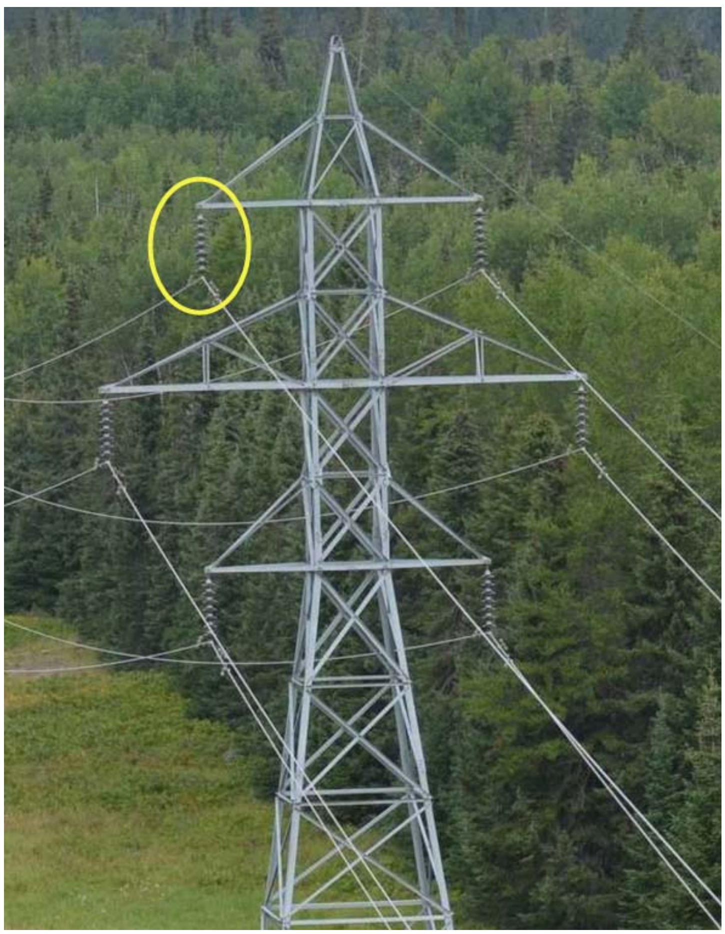

Figure 1 - Transmission Line Insulator

There are approximately 437,000 insulator strings in Hydro One's overhead transmission network. As described in TSP Section 2.2.2.4, Hydro One has three types of transmission line insulators in its fleet: porcelain, glass and polymer. The percentages of insulators by material type are shown in Figure 2. The scope of the Program includes defective porcelain insulators and deteriorated polymer insulators.

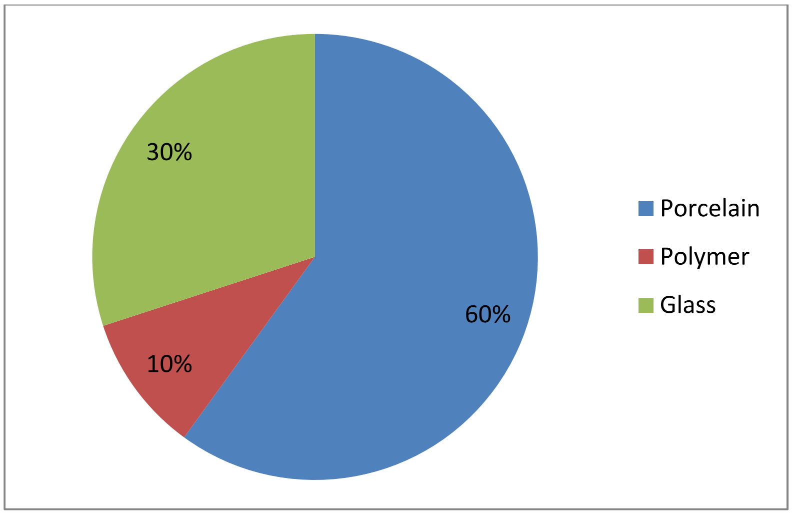

Figure 2 - Percentage of Insulators by Material

<u>Defective Porcelain Insulators</u>

Age demographics are not a driving factor for the replacement of porcelain or glass insulators since these types of insulators generally expected to outlast the life of the transmission line. However, porcelain insulators manufactured by Canadian Ohio Brass and Canadian Porcelain between 1965 and 1982 suffer from a phenomenon known as cement expansion or cement growth, as shown in Figure 3 below. It is recognized throughout the industry, that both the electrical and mechanical characteristics of line insulators manufactured between the mid-1960s and early 1980s by COB and CP deteriorate faster than other comparable insulators due to cement expansion.

Figure 3 - Porcelain Insulator Unit Affected by Cement Expansion

Porcelain transmission line insulators are specified in terms of their combined mechanical and electrical (“M&E”) strengths. For example, an insulator with an M&E rating of 36 kips (1 kip = 1,000 lbf.) is designed to withstand an applied tensile load in excess of 36 kips without mechanical or electrical failure. With respect to cement expansion, mechanical failure is defined as a physical breakage of the insulator while electrical failure is defined as cracking of the insulator’s porcelain body or cement in the area between the cap and the pin which results in a significant reduction of the insulator’s dielectric strength.

Cement expansion creates radial cracks in the cement and porcelain shell resulting in two possible failure modes:

- **Mechanical failure –** as described above, it is a physical breakage of the insulator which may result in a conductor falling to the ground. The mechanical failure poses an extremely significant risk to public and employee safety. For example, in March 2015, an insulator on circuit V76R mechanically failed causing the conductor to fall to the ground in a commercial parking lot in Etobicoke. Photos of this incident are shown in Figure 4 and Figure 5 below. Similarly, in January 2017, an insulator on circuit HL3 mechanically failed causing the conductor to fall over a roadway in Hamilton. A photo of this incident is shown in Figure 6 below.

- **Electrical failure –** cracks in the porcelain reduce the insulating properties of the material. This failure typically results in customer outages that might be prolonged due to repair time.

Figure 4 - V76R Insulator Failure

Figure 5 - V76R Insulator Failure

Figure 6 - HL3 Insulator Failure

The porcelain insulators manufactured by COB and CP are used province-wide in Hydro One’s transmission system. There are approximately 34,000 circuit structures with defective porcelain insulators and roughly 15,000 have been identified as being on structures in publicly-accessible (critical) locations. Publicly-accessible (critical) structures include those located near roads, water railways, urban areas, golf courses, educational and health care facilities. To date approximately 8,900 publicly- accessible COB and CP insulators have been replaced. A breakdown of the defective population in relation to the total insulator population can be seen in Figure 7.

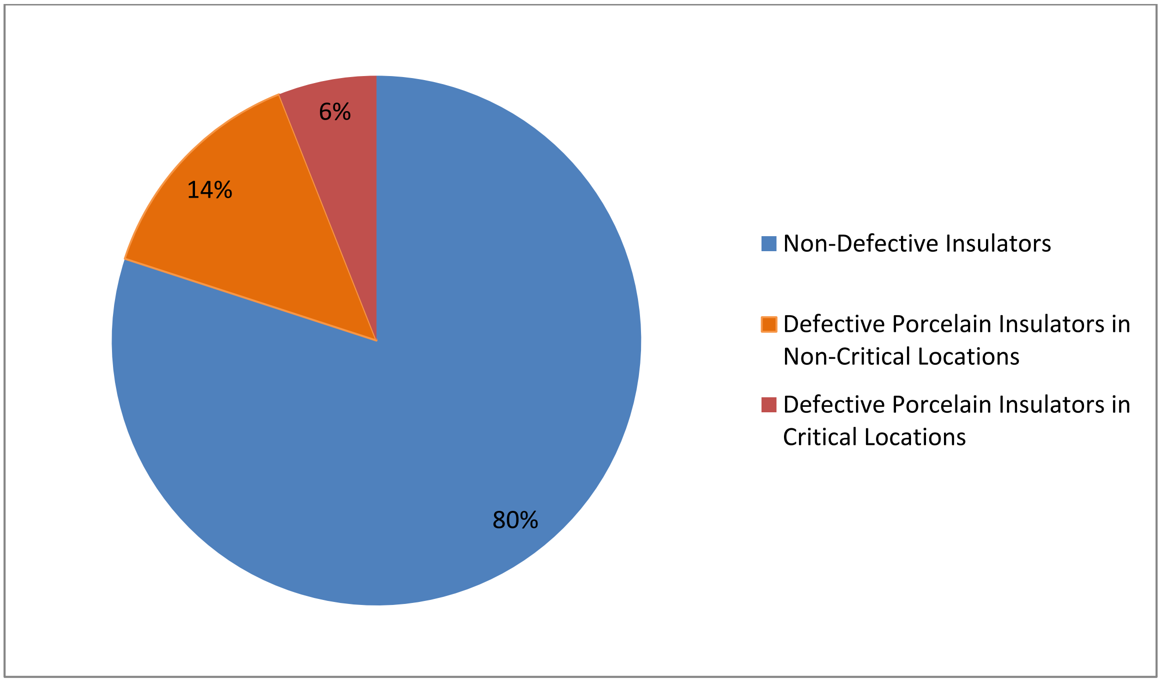

Figure 7 - Defective Porcelain Insulator Population

Figure 8 illustrates the number of COB and CP failures over the past ten years, showing an increasing trend. The number of failures is expected to rise due to the degradation of the known defective COB and CP porcelain insulators, potentially impacting public safety, system performance and customer reliability. Failed insulators normally result in a sustained forced outage due to the permanent electrical fault they create. Repair time can be significant, averaging 37 hours, depending on the location and severity of the failure.

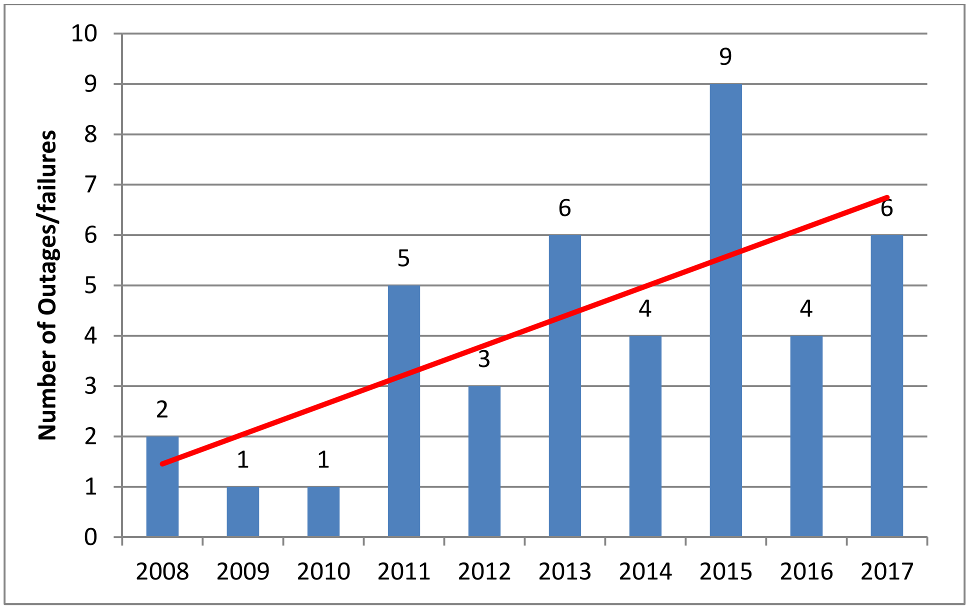

Figure 8 - Frequency of COB/CP Insulator Failures

To address concerns associated with defective porcelain insulators, Hydro One retained a third party expert, EPRI. EPRI performed laboratory testing on COB and CP porcelain insulators in order to assess the condition of defective COB and CP porcelain insulators to assist Hydro One in determining the pacing of porcelain insulator replacement. The testing program comprised of two phases. Based on the Phase one COB and CP testing results, Hydro One significantly increased the insulator replacement rate, compared to pre-2016 levels, and prioritized the replacement of insulators in publically accessible (critical) locations.

Phase one was completed in 2016 and included testing of 299 insulators removed from a combination of dead-end and suspension strings installed in publicly-accessible (critical) locations. Phase one testing was intended to provide an expedient assessment of the condition of the in-service insulators in question. The results of phase one supported the urgent replacement of COB and CP insulators manufactured between 1965 and 1982 that are installed in publicly-accessible (critical) structures where public safety is at risk.

A large proportion of the insulators tested (37%) during phase one failed electrically or mechanically at loads below their rated M&E strength. There was a significant number of punctured insulators and the test data showed a large variation in failing loads which would not be expected for a healthy insulator population. The condition of the Hydro One insulators was assessed through benchmarking against EPRI and public domain test data. This benchmarking data was obtained through testing of similar vintage insulators which had been in service for a comparable duration under similar field conditions. The performance of the Hydro One and the benchmarking insulators was also compared to current and historical requirements for new insulators. The test results presented an initial snapshot of the condition of the population of defective insulators in-service on Hydro One's transmission system. Although the sample of insulators tested was not sufficient to perform a rigorous statistical analysis upon which to base recommendations, the results strongly suggested that the installed insulator population comprising CP and COB insulators manufactured between 1965 and 1982 had reached or was at least approaching the end of useful life.

Phase two of the testing was performed in 2017. Those tests were carried out on 591 insulators. The intent of the phase two tests was to supplement the phase one data and to provide data on the rate of deterioration of the insulator population. The results of analysis showed that:

- a large number of the tested insulators exhibited porcelain cracking after M&E testing
- the propensity for the insulators to puncture (crack) during Thermal Mechanical Cycling (TMC);
- the fact that the insulators are highly susceptible to electrical puncture under steep transient voltages (e.g. lightning);
- the finding that TMC drastically decreases the already weak ability of the insulators to withstand electrical puncture; and
- a significant number of insulators separated mechanically during TMC.

These results suggest that the number of in-service punctured units will increase as the insulators experience significant mechanical loading events. When a string containing electrically punctured insulators undergoes a flashover due to lightning, contamination, or snow and ice bridging, there is a high likelihood that the ensuing power arc will pass through the punctured unit internally travelling from cap to pin, causing significant heating and pressure buildup which can cause the cap and pin to separate and the conductor to drop. The greater the number of punctured insulators found in the string, the higher the probability of string flashover and string separation. Insulators which are not punctured, but have suffered deterioration in mechanical strength do not exhibit this behavior. If a string contains mechanically compromised units, the insulators will fail if the maximum applied load exceeds the units remaining mechanical strength. The majority of conductor drops recently experienced on Hydro One’s porcelain insulated transmission system fall into the former category.

The phase one and two analyses provided overwhelming evidence supporting replacement of defective porcelain insulators to mitigate the risk to the safety and reliability of Hydro One’s transmission system. The key recommendation provided by EPRI is that the identified population of COB and CP insulators be removed from service as soon as practically possible.

Deteriorated Polymer Insulators

Hydro One uses polymer insulators on the 115 kV and 230 kV transmission system. Polymer insulators have an Expected Service Life[1] (“ESL”) of 30 years and, due to their material properties, degrade with age. First-generation polymers installed in the mid-1980s will reach their ESL during the test period and need to be evaluated for

[1] Hydro One defines ESL as the average age in years that an asset can be expected to operate under normal system conditions.

replacement. First-generation polymers are more problematic when compared to most recent generations. When older polymer insulators were designed and manufactured, the long term effects of electric fields were not well understood which caused unexpected polymer degradation. Newer generation polymer insulators use modified designs and refined manufacturing techniques.

Furthermore, 230 kV polymer insulators are showing signs of deterioration. The deterioration appears due to corona activity on the insulator housing as a result of inadequately controlled electric fields. The degradation exposes the fiberglass rod to moisture which causes rapid deterioration leading to failure. The need to address the polymer insulator issue is underscored by two failures which occurred in October and November 2016. Both failures were a result of 230 kV polymer suspension insulators on C28C failing mechanically resulting in a conductor drop, as shown in the photos in Figure 9 and Figure 10. The dropped conductor did not contact the ground but was held in the structure window.

Figure 9 - Failed Polymer Insulator

Figure 10 - Failed Polymer Insulator

Since portions of Hydro One’s polymer insulator population are approaching their ESL, Hydro One retained EPRI to perform a detailed condition assessment of polymer insulators to assist Hydro One in determining the need and pacing of polymer insulator replacement. The condition assessment study focused on 87 polymer insulators from various manufactures with the service life range from 13 to 26 years. The following three insulator configurations form the scope of the study:

- 230 kV suspension with large corona rings;
- 230 kV suspension with either small (known as a “donut”) or no corona rings; and
- 115 kV dead end.

The condition of the insulators was evaluated through a series of tests which included:

- Visual Inspection;
- Hydrophobicity Assessment;

- Dye Penetration Testing;
- Water Vapor Ingress Testing; and
- Moisture Penetration Test of the End-fittings.

The following are the key findings of EPRI condition assessment analysis:

Visual inspection showed that:

- The 230 kV K-Line insulators with the 4-inch donut corona ring have an extremely high likelihood of electrical and/or mechanical failure due inadequate control of the electric field on the surface of the rubber housing at the line-end. The rubber housing at the line-end of these insulators has been severely eroded leading to exposure of the fiberglass rod. Such exposure of the rod will result in either mechanical or electrical failure with a high probability of the insulator parting and causing a conductor drop. Smaller (4-inch) corona rings were used on earlier generations of polymer insulators. When older polymer insulators were designed and manufactured, the long-term effects of electric fields were not well understood and it was standard practice to use small or no corona rings which caused unexpected polymer degradation. Newer generation polymer insulators use modified designs and refined manufacturing techniques.
- The 230 kV NGK insulators installed without corona rings are showing signs of serious deterioration of the line-end rubber housing and deterioration of the secondary seal. As such, they are considered to have a high risk of failure.
- The 230 kV NGK insulators installed with 8-inch corona rings are experiencing rubber housing damage at the line-end. Currently this deterioration does not appear overly serious, but it is not known how quickly the housing deterioration will progress. In the EPRI aging chamber and at one EPRI member utility site this deterioration did result in eventual failure.

Dye penetration testing showed that:

- Each of the insulator groups with the exception of the Ohio Brass insulators had a single insulator unable to meet the dye penetration test requirements.

Water vapor ingress testing showed that:

- Seven 230 kV K-Line insulators exhibited low resistance along their length after humidity conditioning. Of these seven, three had damage from power arcs and housing erosion which may explain their failure. The remaining four (all of which had 8-inch corona rings) will be further examined to determine the root cause of failure.

End-fitting moisture penetration tests showed that:

- All but three insulators passed the test. Of the failing three units, two have been in service for 26 and 27 years, and the third had major line-end rubber erosion and rod exposure.

At the conclusion of its condition assessment analysis, EPRI provided Hydro One with its recommendations. Key EPRI recommendations are as follows:

- All 230 kV K-Line insulators fitted with 4-inch donut corona rings should be removed from service as soon as possible since they pose a proven risk of immediate failure.
- All the 230 kV NGK insulators installed without corona rings should be removed from service as they are considered to be at high risk of failure.
- All the 230 kV Ohio Brass insulators installed without corona rings should be removed from service.
- The seven 230 kV K-Line insulators which failed the water vapor ingress test should be subjected to additional testing followed by dissection to quantify the degree of concern which should be associated with their failing the water vapor ingress test. This type of issue is generally associated with poor bonding between

the housing and the rod and is often a batch problem. Until the issue is understood, these insulators should not be maintained live without first checking their integrity with the EPRI-developed insulator tester.

Hydro One is using this information to optimize the overall replacement program with respect to the risk of in-service failure. Hydro One will be using the results and recommendations of the EPRI study to develop a polymer insulator replacement strategy. Hydro One will leverage current condition assessment and patrol programs to locate polymer insulators that were identified by EPRI and target them for replacement.

Investment Description

Transmission line insulators cannot be maintained or repaired to extend their service life; therefore, defective porcelain insulators and end-of-life polymer insulators are targeted for replacement as part of the Program. The defective porcelain insulators will be replaced with either glass type or porcelain type insulators. Replacements of defective porcelain insulators will be prioritized based on locations posing a higher public safety risk. The deteriorated polymer insulators will be replaced with either glass, polymer, or porcelain type insulators. Due to their longer ESL porcelain and glass are the preferred insulator types and are used wherever practical. However, polymer insulators will be considered when their material properties prove beneficial (i.e. in areas with high contamination).

Hydro One has approximately 34,000 circuit structures with defective porcelain insulators and roughly 15,000 have been identified as being on structures in publicly-accessible (critical) locations. Publicly-accessible (critical) structures include those located near roads, water railways, urban areas, golf courses, educational and health care facilities. As such, defective porcelain insulators posing a higher public safety risk (i.e. insulators in critical locations) are to be replaced by 2022 at a rate of approximately 3,700 circuit structures per year. Insulators in non-publicly- accessible areas will be replaced at an approximate rate of 3,450 circuit structures per year over a five-year period beginning in 2022.

Outcome

As a result of the Program, Hydro One will reduce public safety risk associated with insulator failures resulting in conductor drops and maintain system reliability by removing electrically and/or mechanically compromised insulators that may cause forced outages.

The following table presents anticipated benefits as a result of the Program in accordance with the OEB Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Eliminate public safety risk associated with defective porcelain insulators • Maintain system and customer reliability by replacing defective and/or end-of-life insulators
Operational Effectiveness	• Maintain system and customer reliability by replacing defective and/or end-of-life insulators

C. EXPENDITURE PLAN

As discussed above, the Program is primarily needed to replace the defective COB and CP porcelain insulators that pose significant public safety and system reliability risks. Hydro One will strive to complete the Program in an effective and efficient way to minimize the cost of performing this sustainment task. The Program starts in January and ends in December of each of the test years.

Table 1 below presents forecasted costs for the Program. Costs for the Program are based on an average unit cost estimate calculated utilizing historical replacement costs. The replacement costs are influenced by the voltage level, structure type and accessibility.

Table 1 - Total Investment Cost

($ Millions)[1]	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total

[2] *Includes Overhead at current rates.*

D. ALTERNATIVES:

Hydro One considered the following alternatives before selecting the preferred undertaking:

Alternative 1: The "Do Nothing" - Reactive Replacement of Failed Insulators involves reactive replacement insulators as they fail. This alternative has been rejected due to the unacceptable public safety risk that may arise when a failure results in a conductor drop in a public area. Due to the continued degradation of these defective insulators the number of failures is expected to rise, negatively affecting safety, reliability and customer satisfaction. Furthermore, a systemic investment approach is needed to pace replacements to minimize the impact to customers and reliability.

Alternative 2: Planned Insulator Replacement is a recommended undertaking. This alternative involves planned replacement of defective porcelain and end-of-life polymer insulators prior to failure. This alternative is recommended as it will reduce the risk to public safety. In addition, it will enable investment pacing and outage planning to mitigate customer and reliability impacts.

E. EXECUTION RISK AND MITIGATION

Risks that can impact the completion of the insulator replacement program include: outage constraints, resource constraints, construction execution challenges, customer coordination, and procurement challenges. To address outage constraints, Hydro One develops a planned outage coordination plan. This plan is the operation plan with the goal to eliminate or minimize the loss of supply to the customer. The plan might include switching a customer to an alternative supply. Outage planning also aims to synchronize Hydro One supply outages with the customer's planned maintenance driven outages.

SR-26 Transmission Line Emergency Restoration

Start Date:	Q1 2020	**Priority:**	High
In-Service Date:	Ongoing Program	**3Year Test Period Cost ($M):**	29.4
Trigger(s):	Corrective Maintenance, Safety, Reliability		
Outcomes:	Align with obligations with TSC; make safe and minimize public/employee safety risk, improve customer satisfaction by carrying out replacement in a timely manner to minimize unplanned customer interruptions; maintain transmission system reliability,		

A. OVERVIEW

Transmission Lines Emergency Replacement program is reactive in nature, mainly to provide an immediate response to an emergency situation or to prevent or minimize the effects of an emergency situation. This investment program funds the emergency replacements of transmission line components that have failed or identified to be in imminent danger of failure. A failed or deficient transmission line component may cause an impact on the transmission system that varies from being minor to significant. It poses safety risk as well as power delivery risk which might affect regional load flow limits and customer operations. As a licensed transmitter, Hydro One is legally obligated to comply with the planning, operating and reliability criteria and standards imposed by the Transmission System Code (“TSC”). This investment program ensures that Hydro One continues to comply with its commitment and legal obligations to mitigate safety, system reliability and environmental risks that an unforeseen failure might cause.

B. NEED AND OUTCOME

Investment Need

Hydro One’s transmission system extends to most of the province and operates in diverse geographic and climatic conditions. Hydro One operates transmission lines primarily at 500 kV, 230 kV and 115 kV, with minor lengths operating at 345 kV. These lines are used to transmit electric power to connected commercial and industrial customers, as well as to Local Distribution Companies (“LDC”) who in turn distribute the power to their end-use customers.

The majority of Hydro One's transmission system is composed of overhead lines, with a small portion being underground cables.

The major components of the overhead transmission lines system include conductors, steel and wood pole structures, foundations, insulators, shieldwire, switches and line hardware. Transmission line components may fail or be at risk of imminent danger of failure due to weather events, component deterioration, design deficiencies, vandalism, or accidents caused by public activity. Almost all of the transmission lines system is in public domain. The primary focus of this investment is to make safe of any emergent situation to ensure public and employee safety.

This investment is designed to maintain reliability and minimize power delivery impact. If any of the major transmission line components fail or are in imminent danger of failure, Hydro One must replace the asset as soon as possible in order to ensure public and employee safety and the integrity and reliability of the transmission system. When a transmission line component fails, the impact varies depending on where the component is and the redundancy level of the electrical configuration. In some cases, failed transmission line components may fall onto public areas such as road crossings and public or private properties, which could jeopardize public or employee safety, impacting power delivery and resulting in customer interruptions.

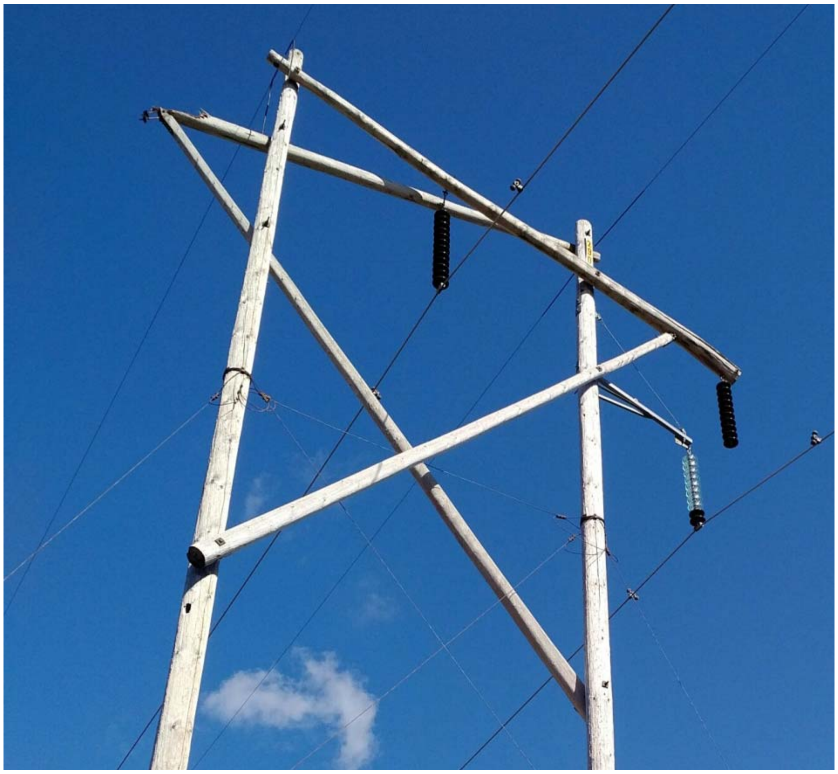
The OEB's TSC states a transmitter is required to take immediate action during an emergency or in order to prevent or minimize the effects of an emergency, to ensure public safety and to safeguard life, property and the environment as well as to protect the stability, reliability, and integrity of Hydro One's transmission facilities. As a licensed transmitter, Hydro One is legally obligated to comply with the planning, operating and reliability criteria and standards imposed by the TSC.

Investment Description

An emergency is defined as a structure or component that has failed or is at risk of imminent failure, where the failure could result in a serious public or employee safety hazard, circuit interruption and system reliability impact.

This investment is to fund the emergency replacements of failed or defective transmission line components, such as wood structures, cross-arms, towers, insulators, conductor, shieldwire and hardware. The reasons for transmission line components failure include, but are not limited to: normal weather conditions (i.e. lightning), severe weather events (i.e. tornado), deterioration, design deficiencies, vandalism, accidents caused by public activity, etc. In addition to structures and/or components that have failed as shown in the figures below, Hydro One must also respond to structures and components at risk of imminent failure that are identified through condition patrols. An example would be a wooden cross-arm or structure that has been damaged by lightning and poses a risk of failure. Such repairs are also considered an emergency.

Figure 1 - 2016 L20D (Kipling GS x Harmon Jct) steel structure failure due to windstorm



1 **Figure 2 – 2017 W71D (Lower Notch Jct x Widdifield SS) wood pole failure**

2 **Figure 3 – 2017 K2Z (Gosfield Wind CGS x Kingsville TS) wood arm at imminent danger**
3 **of failure**

Figure 4 – 2018 K2Z (Haycroft DS x Belle River Jct) Steel structure failure

Outcome

This program aims to:

- Mitigate safety risks by replacing failed overhead line components or components that are at risk of imminent failure.
- Maintain reliability of the transmission system by ensuring a timely response to replace failed overhead line components or components that are at risk of imminent failure.
- Satisfy Hydro One's commitments and obligations under the TSC

The following table presents anticipated benefits as a result of the investment program in accordance with the OEB's Renewed Regulatory Framework:

Customer Focus	• Improve customer satisfaction by minimizing interruptions and providing timely power restoration to customers
Operational Effectiveness	• Minimize public/safety risk and system reliability impact by repairing and/or replacing assets that failed or are at risk of imminent failure. • Comply with TSC obligations by providing safe and reliable electricity to Ontario electric consumers.

C. EXPENDITURE PLAN

Table 1 below presents forecasted planned expenditures for this investment program. The planned expenditures are based on historical spending. Historically the actual expenditure of this program is in line with the planned expenditure. For program work, cash flows are only shown for the five year period. Program work is started and completed in-year.

Table 1 - Total Investment Cost

($ Millions)[1]	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[2] and Minor Fixed Assets	0.0	10.4	10.7	10.9	11.1	11.3	0.0	54.3
Less Removals	0.0	0.8	0.9	0.9	0.9	0.9	0.0	4.3
Gross Investment Cost	**0.0**	**9.6**	**9.8**	**10.0**	**10.2**	**10.4**	**0.0**	**50.0**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**9.6**	**9.8**	**10.0**	**10.2**	**10.4**	**0.0**	**50.0**

[1] *Due to the in-year nature of program investments, only 2020-2024 expenditures are shown*
[2] *Includes Overhead at current rates.*

The average investment cost for this program over the five-year period is in line with the average five-year historical spending. Factors affecting this investment's costs are:

- The scope of the replacement work required to address the failure; and
- The type and quantity of the assets requiring replacement.

D. ALTERNATIVES

This investment program is non-discretionary and, as such, no alternatives have been considered. Failure to respond to an emergency or to prevent or minimize the effects of an emergency in a timely manner may jeopardize public and/or employee safety and violate the TSC. It might have a negatively impact on customer service.

E. EXECUTION RISK AND MITIGATION

The work that is part of this investment program is unplanned in nature and the risks of public/employee safety and potential customer supply interruptions are mitigated by timely response. However, there are risks to executing such unplanned work including the availability of resources and long lead times for the purchase of new transmission lines components.

SR-27 C5E/C7E Underground Cable Replacement

Start Date:	Q4 2016	**Priority:**	Medium
In-Service Date:	Q4 2024	**3 Year Test Period Cost ($M):**	62.8
Trigger(s):	Reliability, Environment		
Outcomes:	Maintains system and customer reliability by preventing cable failures associated with end of life equipment; eliminate the risk of obsolescence and supportability by replacing infrastructure with reduced production and manufacturer support; and eliminate environmental risk associated with oil leaks by replacing oil-filled cable.		

A. OVERVIEW

This high voltage underground cable project (the "Project") involves the replacement of oil-filled underground transmission cables on circuit C5E and C7E between Esplanade TS and Terauley TS. These underground cables provide a critical supply to Toronto's downtown core, particularly, hospitals, the University of Toronto, Toronto City Hall, financial district and tourist/entertainment areas. Based on a detailed asset condition assessment, these cables are in deteriorated condition and have reached their end of life. There is also a significant environmental risk associated with oil-filled cables. Cable breaches can be caused by failed or degraded components as well as by dig-ins from unauthorized excavation. The breach can result in the discharge of large volumes of oil into the surrounding environment which may cause significant environmental issues. Furthermore, there is an industry shift away from the use of oil-filled to cross-linked polyethylene ("XLPE") cable systems. This means that manufacturers have been reducing production and support for oil-filled cables. A limited number of manufacturers may lead to long delivery times and price increases. Due to their deteriorated and end of life condition, location and component obsolescence, these underground cables require immediate replacement. Hydro One has evaluated various alternatives for the Project, as described below, and concluded that replacing the deteriorated oil-filled underground transmission cables with the XLPE type cables is the most cost effective and efficient undertaking. The projected costs of the Project are estimated to be $62.8 million over the 2020-2022 Test period.

B. NEED AND OUTCOME

Investment Need

C5E and C7E from Esplanade TS to Terauley TS (7.2 circuit km) are 115 kV paper insulated low-pressure oil-filled underground transmission cables that provide a critical supply to Toronto’s downtown core and are partially routed along Lake Ontario. These circuits were put into service in 1959 and are in poor condition. Through a detailed condition assessment, Hydro One has determined that these underground circuits are at the end of life, and require immediate replacement. End of life means that an asset has a significant risk of failure, or loss of the ability to provide the intended functionality.

The cable jackets have been tested and were found to be in deteriorated condition necessitating the need for cable replacement. Deteriorated jackets can adversely affect cable performance by allowing circulating currents to flow leading to overheating damaging insulation, accelerated corrosion and oil leaks. Analysis of the paper insulation was performed and the results were indicative of thermal aging/degradation beyond what is normally seen in comparable Hydro One cables, by approximately 25%. Thermally degraded paper insulation can lead to cable failure during faults, resulting in prolonged circuit outages and negative environmental impact due a release of oil. Additionally, the oil pressure system has been the source of many nuisance oil leaks and is obsolete with few spare part suppliers. Due to their deteriorated condition, the risk of cable failure and oil leaks that may result in loss of supply and an adverse environmental impact will increase with time.

Interruption or failure of C5E and C7E can negatively impact power supply to Toronto Hospitals along University Ave., the University of Toronto, Toronto City Hall, financial district and tourist/entertainment areas. Further, approximately 2.6 circuit km of cable is directly buried under Queens Quay along the Lake Ontario. If a leak occurs along Queens Quay, it would likely be confined to the surrounding soil. However, if the leak is significant enough to contaminate ground and/or surface (Lake Ontario) water, the remediation will be very challenging and costly, requiring booms, wells, etc.

Investment Description

The Project will replace 7.2 circuit km of 115 kV low-pressure oil-fill underground cables that are at end of life with XLPE type cable. The replacement will encompass both C5E and C7E circuits from Esplanade to Terauley TS. The new underground cables may follow an alternate route allowing the existing circuits to remain in-service until the load can be transferred.

Outcome

As a result of the Project, Hydro One will maintain reliability and minimize future costs through the replacement of the end of life oil-filled cables on circuits C5E and C7E with modern XLPE cable. This will eliminate the risks to reliability associated with operating end of life assets, and eliminate the environmental and obsolescence risk associated with operating oil-filled cables. The removal of legacy oil-filled cables will also eliminate the preventative maintenance and repair costs associated with this legacy infrastructure.

The following table presents anticipated benefits as a result of the Project in accordance with the OEB's Renewed Regulatory Framework:

Outcome Summary:

Customer Focus	• Maintain system and customer reliability in downtown Toronto by replacing degraded end-of-life cable systems
Operational Effectiveness	• Maintain operational flexibility with supply to downtown Toronto
Public Policy Responsiveness	• Reduce risk of environmental contamination due to possible oil leaks

C. EXPENDITURE PLAN

Table 1 below presents forecasted costs for the Project. Costs for the Project are based on a budgetary estimate and will be significantly influenced by the final cable route. Costs up to 2022 are associated with the environmental assessment which includes public consultation and preliminary engineering and design. Costs in 2022-2024 are associated with the execution of the Project, which includes detailed design, construction and execution.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	4.5	2.1	30.0	31.0	32.3	29.3	0.0	129.3
Less Removals	0.0	0.0	0.1	0.2	0.2	0.1	0.0	0.6
Gross Investment Cost	**4.5**	**2.1**	**29.8**	**30.9**	**32.2**	**29.2**	**0.0**	**128.7**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**4.5**	**2.1**	**29.8**	**30.9**	**32.2**	**29.2**	**0.0**	**128.7**

[1] *Includes Overhead at current rates.*

D. ALTERNATIVES

Alternative 1: Reactive Replacement of Underground Cables is the "Do Nothing" alternative which means Hydro One will continue to operate and maintain the existing C5E and C7E cables and replace them upon failure. This alternative has been considered and has been rejected as failure of these cables will result in prolonged circuit outages, potential customer interruptions, loss of redundant supply negatively affecting operational flexibility, and potentially oil leaks requiring environmental remediation.

Alternative 2: Planned Replacement of Underground Cables is a preferred undertaking. This alternative involves planned replacement of 7.2 circuit km of deteriorated end-of-life 115 kV low-pressure oil-filled underground transmission cable with oil-free XLPE cable between Esplanade and Terauley TS. Due to their deteriorated condition and the increased risk of cable failure and oil leaks, planned replacement will mitigate the risk to reliability, loss of supply and adverse environmental impact.

E. EXECUTION RISK AND MITIGATION

The primary risk to the Project completion will be the final cable route. Multiple potential routes are being evaluated and include open-cut and tunneling options. Open-cut construction is significantly more impactful to the public (i.e. traffic, business, etc.), will likely face public opposition and may not be feasible due to underground congestion, whereas the tunnel option is less impactful to the public but may be more costly. The final route will be selected during detailed estimation and will be influenced by a technical feasibility study, environmental assessment, public consultations and economics. An execution risk assessment workshop will be completed as part of the detailed estimating for this project to identify and mitigate potential project risks.

SR-28 Fibre Optic Infrastructure Development Projects

Start Date:	Q1 2021	**Priority:**	Medium
In-Service Date:	Q4 2025	**3 Year Test Period Cost ($M):**	14.9
Trigger(s):	System Renewal, Strategic		
Outcomes:	Maintain Reliability		

A. OVERVIEW

Hydro One utilizes fibre optic cable infrastructure including Hydro One owned and operated aerial fibre optic cables, as well as fibre strands acquired through indefeasible right of use (“IRU”) agreements from third-party telecom providers. The latter fibre infrastructures will be referred to in this document as “third-party” fibre(s). An IRU is an exclusive and irrevocable right of use granted by the owner of a communications system to a customer or user of that system. Instances of past failures of third-party fibres have compromised Hydro One's ability to reliably operate the transmission system. Historical failure incidents from 2009-2017 on Hydro One SONET network show that third-party fibres are three to four times more likely to fail than Hydro One’s own Optical Ground Wire (“OPGW”) fibres.

In order to maintain the reliability of the transmission system, Hydro One’s current asset management strategy is to (i) identify opportunities and gradually replace the use of third-party fibres that are subject to higher failure risk with the use of Hydro One’s OPGW fibres to the extent possible; and (ii) increase the existing OPGW footprint in order to extend fibre coverage to Hydro One facilities that currently experience less reliable leased services from telecom service providers (“Telco”) To this end, Hydro One has proactively leveraged and installation of OPGW as part of transmission line shieldwire replacements and line refurbishment projects where economically feasible. Because these projects are driven by EOL replacements, the OPGW installation may not provide complete end-to-end fibre connectivity. This project is designed to complement the aforementioned initiative and build remaining OPGW infrastructure such that an end-to-end fibre-based telecom path can be constructed.

B. NEED AND OUTCOME

Investment Need

This investment is needed to address the reliability risks posed by failing, leased third party fibre as well as leased circuits provided by Telcos.

Based on the Synchronous Optical Network ("SONET") technology, Hydro One's communication network is primarily utilized by protection systems and SCADA monitoring systems, as well as for communicating non-operational data, business data, voice, and security information. It is also used for backhaul communication for the provincial mobile radio system. The current network topology connecting stations is in the form of a ring to provide redundant communication links that can stretch up to hundreds of kilometers long across the province.

These SONET rings provide robust and reliable communication between transmission stations because of the reliable fibre optic cable infrastructure and network configuration that provide redundancy paths for communications. Hydro One utilizes approximately 3,800 kilometers of fibre optic cable infrastructure including Hydro One owned and operated aerial fibre optic cables as well as fibre strands acquired through IRUs. Aerial fibre optic cable is primarily comprised of (i) OPGW technology with strands of fibre embedded inside of the shieldwire mounted on top of high-voltage transmission structures and (ii) All-Dielectric Self-Supporting ("ADSS") fibre cable that is attached to towers or poles typically below the phase conductors, with a small share being attached to low-voltage wood poles located along roadways and/or railways.

Hydro One also utilizes a large number of leased metallic copper-based circuits from Telcos for communication-aided protection schemes at many transmission stations. Due to the current age and obsolescence of these communication circuits they have become failure-prone and hence not desirable for transmission protection, control and monitoring applications. Furthermore, Telcos intend to upgrade these legacy copper-based systems to fully digital and fibre-based facilities.

As part of Hydro One's proposed investment for Fibre Optic Infrastructure Development, the following four projects are identified for the planning period, as further described in the next section:

- Ottawa Ring 9 Fibre Infrastructure Development
- Martindale TS by Widdifield SS OPGW link
- Martindale TS by Algoma TS OPGW link
- Claireville TS by Beaverton TS OPGW link

Investment Description

The projects described herein aim to maintain or restore reliability of Hydro One's existing power system telecom network by placing replacing the use of third-party fibres and Telco metallic cable facilities with the use of highly-reliable OPGW fibre.

Through the Ottawa Ring 9 fibre infrastructure project, Hydro One plans to place 130 km of new OPGW fibre to connect Merivale TS to South March TS, Chats Falls SS, Arnprior TS, Barret Chute TS, and Stewartville TS. This project will allow the legacy Telco metallic circuits that provided communications for protection and SCADA systems to be replaced with modern, fibre-based Hydro One-owned telecom facilities. The expected benefits will be improvement of communications reliability for protection and SCADA applications, avoiding the need for upgrades to Telco entrances at these stations, lower OM&A leased circuit costs and avoiding upgrades to Power Line Carrier ("PLC") systems in Eastern Ontario as they approach end-of-life.

Taking advantage of synergies by leveraging the transmission line shieldwire replacement program, Hydro One will be installing 80 km of OPGW between Martindale

TS and Widdifield TS. The Martindale TS by Widdifield SS OPGW link project covers installation of the remaining 56 km of OPGW on line H24S East of Martindale TS, towards Widdifield TS. Once the 80 km and 56 km paths are both completed, the end-to-end fibre path from Martindale to Widdifield (between Sudbury and North Bay) will allow the replacement of failure-prone third party IRU fibre on Ring 7 with Hydro One-owned highly reliable fibre facilities.

The Martindale TS by Algoma TS OPGW link project aims to provide complete the end-to-end fibre infrastructure between the two stations that already has certain sections with OPGW installed under the shieldwire replacement program. The existing power system telecom link from Martindale by Algoma is on a third-party fibre provider installed on wood pole in the area. Historically, this link has experienced one of the highest rates of failures on Hydro One’s power system telecom network. This project will build the remaining sections of OPGW (approximately 95 km) on line S2B in this area to fill in the gaps and complete an end-to-end fibre path in order to restore the communication reliability on SONET Ring 7.

Claireville TS by Beaverton TS OPGW link project aims to install approximately 105 km of OPGW fibres on lines H82V/H83V and B88H/B89H from Claireville TS to Brown Hill TS and on lines M80B/M81B from Brownhill TS to Beaverton TS. The communication for these 230kV Bulk Power System lines has experienced reliability degradation due to the high failure rates of Telco legacy metallic circuits. The project is intended to restore the reliability of existing power system telecom services by installing Hydro One owned fibre facilities to replace Telco legacy metallic-based communication circuits.

A summary of expenditures for the four projects described above is provided in Table 1:

Table 1 - Project Summary ($ millions)

Circuits	Project Description	2020-2024 Net Expenditures	Project In-Service Year
M32S, C3S, M31A, W6CS, W3B	Ottawa Ring 9 Fibre Infrastructure Development	8.6	2021
H24S	Martindale TS by Widdifield SS OPGW link	5.1	2022
S2B	Martindale TS by Algoma TS OPGW link	7.4	2025
H82V/H83V, B88H/B89H, M80B, M81B	Claireville TS by Beaverton TS OPGW link	9.7	2025

Outcome

The following table presents the anticipated benefits of the Program in accordance with the OEB RRFE framework:

Customer Focus	• Maintain system reliability and reduce risk of outages that affect customers.
Operational Effectiveness	• Maintain reliability of the transmission system through ensuring a reliable communication network by replacing poor performing and degraded third party fibre cables with Hydro One-owned OPGW cable to the extent possible.
Public Policy Responsiveness	• Hydro One is obligated to build and maintain a reliable and redundant communication/protection system (including to address the reliability issues associated with third-party fibre cables) to ensure compliance with applicable performance standards under NERC TPL-001.
Financial Performance	• Mitigate OM&A costs associated with the relative high failure rates of third-party fibre cables.

C. EXPENDITURE PLAN

Table 2 below presents the forecasted costs of this investment. These costs are based on estimated unit costs, which are derived from similar historical projects.

"Previous years" costs are associated with development of a detailed execution plan for the Ottawa Ring 9 Fibre Infrastructure Development. The costs for that project in the subsequent years are work execution costs, with the bulk of engineering, procurement and construction work to occur in 2020 and 2021.

Year 2020 costs are associated with the development of a detailed execution plan for the Martindale TS by Widdifield SS OPGW link project. The bulk of the engineering and construction work for this project will occur in 2021 with project completion expected in 2022.

Project year 2021 costs are associated with the development of a detailed execution plan for Martindale TS by Algoma TS OPGW link project. The bulk of the engineering and construction work for this project will occur in 2022 and 2023, taking advantage of lines construction crews that will already be in the area for other planned work.

Claireville TS by Beaverton TS OPGW link project will start in 2022. 2022 costs are associated with the development of a detailed execution plan and budget for this project.

The bulk of the engineering, procurement and construction work for this project will occur in 2023 and 2024, with project completion expected in 2025.

Table 2 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	1.2	5.5	7.8	2.3	6.5	10.1	4.7	38.1
Less Removals	0.0	0.2	0.3	0.1	0.3	0.4	0.2	1.5
Gross Investment Cost	**1.2**	**5.3**	**7.5**	**2.2**	**6.2**	**9.7**	**4.5**	**36.5**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**1.2**	**5.3**	**7.5**	**2.2**	**6.2**	**9.7**	**4.5**	**36.5**

[1] *Includes overhead at current rates.*

D. ALTERNATIVES

Alternative 1: Status Quo "Do Nothing" Option

This alternative is not recommended as the reliability degradation of Hydro One's power system telecom network will directly impact the operation of the transmission system. Hydro One cannot continue to rely on third-party fibre facilities and legacy Telco metallic facilities for its long-term power system telecom needs, due to the high failure rates associated with these facilities. Such failures result in loss of redundancy and loss of communication of protection systems, adversely impacting the reliability of the transmission system and delivery of service to customers.

Alternative 2: "Fibre Optic Infrastructure Development Projects"

This alternative is preferred as it will maintain or restore robust and reliable communications through Hydro One's power system telecom network. The installation of new OPGW fibres to replace the use of Telco metallic cables that currently serve various protection and SCADA facilities. It will also allow Hydro One to avoid the need to upgrade to Telco entrances and existing standalone communication systems.

Additional OPGW investments in areas to the East and West of Martindale TS will allow Hydro One to complete certain end-to-end fibre optic paths by filling in the gaps between the OPGW fibres that are already being installed as part of Hydro One's shieldwire replacement project. This will enable Hydro One to remove certain highly unreliable third-party fibres in these areas and replace them with Hydro One-owned facilities, thus avoiding the costs that are otherwise required for leasing or renewing the use of third-party fibre facilities.

E. EXECUTION RISK AND MITIGATION

Execution risks include potential delays in required circuit outages to carry out replacement work. Hydro One will manage and stage the projects under this investment to ensure that outages are available in time. The availability of resources and other competing projects requiring similar resources are also a risk to project completion. Hydro One will develop a detailed project and resource plan in order to ensure resources are available.

SR-29 Physical Security ISL Application Replacement

Start Date:	Q1 2018	**Priority: High**	
In-Service Date:	Q2 2021	**3 Year Test Period Cost ($M):**	6.1
Trigger(s): NERC compliance, reliability			
Outcomes:	**NERC Compliance**		

A. OVERVIEW

This investment entails the implementation of a new integrated physical security access control and video monitoring application, which is required to mitigate potential vulnerability and compatibility issues, and maintain compliance with the North American Electric Reliability Corporation's ("NERC") requirements for Critical Infrastructure Protection ("CIP" (CIP-006: Physical Security of Bulk Electric System ("BES") Cyber Systems).

B. NEED AND OUTCOME

Investment Need

Hydro One's current physical security monitoring system is comprised of two, non-integrated, components; Intercon Security Ltd. ("ISL") access control and IndigoVision video monitoring. The former is based on a legacy application (ISL10000) that manages and controls physical access and monitoring at 135 facilities; whereas IndigoVision is used to manage camera and recorded video surveillance at 107 facilities.

The ISL access control system is end of life, resulting in limitations in terms of compatibility with newer access control devices (such as card readers) for physical access monitoring. The ISL application and the supporting hardware are no longer being manufactured and will only be supported on a best effort by Johnson Controls until December 2020.

The current IndigoVision software and approximately 80 per cent of the associated surveillance hardware used by Hydro One will no longer be vendor-supported after December 2019.

Investment Description

The ISL and IndigoVision systems are a foundational component of Hydro One's NERC CIP security program at high impact control centers and medium and low impact[1] transmission stations (approximately 75 to 80 stations). The–NERC CIP-006 standard requires full time access control and monitoring of each Physical Security Perimeter ("PSP")[2]. Johnson Controls currently maintains a small inventory of replacement parts. Therefore, a failure of ISL or IndigoVision equipment or supporting software will require Hydro One Networks to secure full time (24x7) security personnel coverage until a solution can be implemented. Once the inventory of replacement parts is depleted, spare parts required to service and maintain the ISL and IndigoVision systems would need to come from removed hardware, as facilities migrated to the new system (as described below) over the next three years until all stations are converted.

In conjunction with Supply Chain, Hydro One Security Operations developed a scope of work for a competitive tendering physical security systems assessment and recommendations.

The Genetec Security Centre solution was selected as it was the best fit for Hydro One's current and future system architecture, complies with NERC CIP requirements, and it is used across the Canadian electric industry and by other large corporations.

[1] High, Medium, and Low impact as defined in NERC CIP-002.
[2] The PSP is the physical border surrounding locations in which BES Cyber Assets, BES Cyber Systems, or Electronic Access Control or Monitoring Systems reside, and for which access is controlled.

The proposed investment will include the following activities:

- Install new central physical security monitoring system application at the Ontario Grid Control Centre ("OGCC") (primary) and at the Back Up Control Centre ("BUCC") (backup).
- Replace existing site access controllers with Genetec controllers at 135 existing Hydro One sites (high/medium/low impact and service centers) and upgrade the older card readers at approximately 70 of the 135 sites to ensure compatibility with the new physical security monitoring system.
- Replace the current unsupported IndigoVision video hardware (network video recorders and cameras) at 135 sites.
- Install a new Virtual Private Network ("VPN") to provide full control of user access to the Video Surveillance Telecom System security network.
- Create a physical security operations library database of systems, devices and capabilities (including features and functionality) for future competitive bidding process.
- Update site drawings.
- Integrate the current Hydro One employee Identity Management on-boarding / off-boarding processes to ensure timely revocation in compliance with CIP-006.
- Decommission the current physical security access control and video system, and archive relevant data in compliance with CIP-006.
- Replace the current Kantech access control systems at Hydro One Sault Ste. Marie's (HOSSM) 6 facilities[3].

[3] HOSSM as a subsidiary of Hydro One Inc. and is currently being monitored internally by HOSSM. Replacement of the existing access control systems at HOSSM creates a single, integrated system to monitor, support, and maintain.

Outcome

The key outcomes and benefits that are expected to result from this investment are as follows:

- The Genetec system provides integrated access control and video monitoring, therefore Hydro One will not be required to upgrade the IndigoVision software which is estimated to cost $0.7 million. This will replace the IndigoVision software.
- Provides an integrated platform interface for all of Hydro One's security operations components (e.g. access card, CCTV/cameras, intercom, key-lock, gate control) using current physical security encrypted protocols).
- Ensures Hydro One maintains compliance with NERC CIP-006, including being able to control and monitor each Physical Access Point[4] ("PAP") into for unauthorized access and issue an alert in response to detected unauthorized access within 15 minutes of detection as required under NERC CIP-006.
- Mitigate legal, financial, reputational and compliance risks as the current legacy system becomes obsolete and no is longer adequately protected from security vulnerabilities and device failures.
- New installed hardware will be under warranty (access control hardware for two years and video recording hardware for three years), ~~,~~ thus reducing Operations, Maintenance & Administration ("OM&A") cost exposure for any replacements related to device failures in the near term.
- Genetec's non-propriety system will provide Hydro One with additional flexibility and options with respect to third-party monitoring solutions, including the ability to conduct a competitive bidding process in June 2021 when the current contract with Johnson Controls expires.

[4] A Physical Access Point ("PAP") is any opening that can be used to physically gain unauthorized access into a PSP.

The following table presents anticipated benefits as a result of the project in accordance with the OEB RRF framework:

Public Policy Responsiveness	• Ensure Hydro One's compliance with NERC CIP-006. • Reliability

C. EXPENDITURE PLAN

The solution had to meet the system and feature functionality requirements as well as NERC compliance reporting. Genetec Security Centre is the best fit for Hydro One's current system architecture and future needs. Genetec Security Centre offers pass-card access control that is an open platform and non-proprietary which facilitates independence from a single vendor for support as well as the ability to integrate easily with many other physical security technologies (e.g., cameras, radar systems etc.). The system offers a truly unified platform single interface for all the Hydro One Security Operations (pass-card, CCTV, intercom, key-lock, gate control). The installation of the new video system can be accomplished at the same time as the access control system representing an estimated $0.5M in labor savings. The roll out schedule will take into consideration implementing stations within a geographical area and work in conjunction with CIP-014 Physical Security Project to minimize resource effort.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Forecast 2025+	Total
Capital[1] and Minor Fixed Assets	12.8	5.0	1.1	0.0	0.0	0.0	0.0	18.9
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**12.8**	**5.0**	**1.1**	**0.0**	**0.0**	**0.0**	**0.0**	**18.9**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**12.8**	**5.0**	**1.1**	**0.0**	**0.0**	**0.0**	**0.0**	**18.9**

[1] *Includes overhead at current rates.*

D. ALTERNATIVES

This is a non-discretionary investment that is required to ensure ongoing compliance with NERC requirements. Doing nothing is not recommended as the current physical security monitoring system is at end of life of vendor support and requires an upgrade to maintain compliance with NERC CIP-006

Hydro One evaluated two systems; the Genetec System met Hydro One requirements, while the other system did not offer Hydro One the same capabilities.

E. EXECUTION RISK AND MITIGATION

No significant risks identified. The risk to this project includes scheduling of resources to complete all the necessary work. This risk is mitigated through coordinated planning and scheduling.

SS-01 Lennox TS: Install 500kV Shunt Reactors

Start Date:	Q3 2018	**Priority:**	High
In-Service Date:	Q4 2020	**3 Year Test Period Gross Cost ($M):**	32.3
Trigger(s): Third Party Request, Operating Reliability			
Outcomes: Maintain acceptable voltages on the transmission system.			

A. NEED AND OUTCOME

Investment Need

This investment is in response to the IESO's request to Hydro One dated March 8, 2017 (see Appendix "A" below) to undertake the installation of two line-connected shunt reactors (each rated at 125MVAR at 500kV) on two of the 500kV circuits from Lennox TS to Bowmanville SS.

The IESO has observed low transfers across the transmission path from Bowmanville SS to Hawthorne TS, under light load conditions, that frequently result in high voltages. In order to maintain voltages within acceptable limits, the IESO has been temporarily removing one of the 500kV Lennox TS to Bowmanville SS circuits from service to reduce voltages.

The IESO expects that this situation will be further exacerbated following the retirement of Pickering NGS, requiring more than one of the 500kV Lennox TS to Bowmanville SS circuits to be taken out of service unless additional reactive control devices are installed. In response to this issue the IESO has identified the need to install shunt reactors at Lennox TS. These facilities will permit the IESO to manage the voltages on the transmission system within acceptable limits.

Not proceeding with this investment would result in inadequate voltage control that would negatively impact system reliability. This project is assigned a High Priority in order to remain compliant with the IESO's voltage criteria.

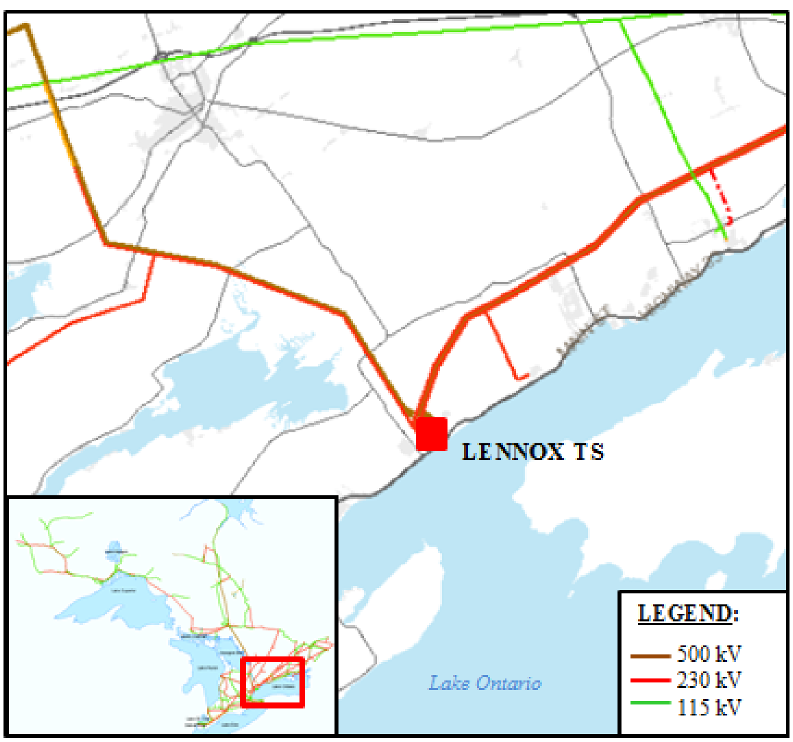
Investment Description

In response to the request from the IESO to provide additional reactive power absorption capability, the proposed project involves the:

- Installation of two 500kV line-connected reactors (each rated at 125MVAR at 500kV) at Lennox TS and connect each reactor to one of the 500kV Lennox TS to Bowmanville SS circuits;
- Installation of two 500kV breakers to connect reactors to the 500kV circuits; and
- Modification of the protection and control facilities at Bowmanville SS and Lennox TS to incorporate the new reactors.

The IESO indicated that the system enhancements that form part of this investment are required as soon as possible. Hydro One has placed a High Priority on this investment to address this requirement.

A map showing the project location is provided below.



Outcomes

This investment will result in maintaining acceptable voltages in order to ensure system reliability.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Improve reliability of the bulk transmission system.
Operational Effectiveness	• Maintain acceptable voltage limits to eliminate the risk associated with switching 500kV circuits for voltage control.
Public Policy Responsiveness	• Maintain voltage between the maximum and minimum range specified by the IESO Market Rules.

B. EXPENDITURE PLAN

The project costs, presented in the table below, will be recovered from the network rate pool as these 500kV facilities are network assets and thus no capital contribution is required from customers.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	16.2	32.3	0.0	0.0	0.0	0.0	0.0	48.5
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**16.2**	**32.3**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**48.5**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**16.2**	**32.3**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**48.5**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

Hydro One worked with the IESO to consider a number of options to address the high voltage concerns described above. The three alternatives below describe the technically feasible options that have been assessed by Hydro One and the IESO.

- Alternative 1: Install four line shunt reactors at Lennox TS; with a reactor connected to each one of the 500kV Lennox TS to Bowmanville SS circuits.

- Alternative 2: Install two shunt reactors at Lennox TS; where each reactor is connected to one of the 500kV buses at Lennox TS.

- Alternative 3 (Recommended): Install two line shunt reactors at Lennox TS; with a reactor connected to only two of the 500kV Lennox TS to Bowmanville SS circuits.

Alternatives 1 to 3 would provide the additional reactive power absorption capability required; however Alternative 3 met the required need at the lowest cost. As such, Alternative 3 was selected as the recommended alternative.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: outage availability that is required for the work to be executed. These risks will be mitigated by setting a schedule that aligns with the outage availability.

March 8, 2017

Mr. Bing Young
Director, Transmission System Development
Hydro One Networks
483 Bay Street,
Toronto, Ontario M5G 2P5

Dear Bing,

Re: Installation of 500 kV Reactors at Lennox TS

The purpose of this letter is to request that Hydro One Networks undertake the installation of two line-connected shunt reactors (each rated at 125 Mvar at 500 kV) on two of the 500 kV circuits from Lennox TS to Bowmanville SS.

Having these facilities will permit the IESO to better manage the high voltage events which are occurring increasingly frequently on the transmission network in eastern Ontario and the Greater Toronto Area (GTA). Ever since this high voltage concern was first observed a few years ago, staff at Hydro One Networks and the IESO have worked together to develop this recommended solution, which is described in more detail below.

Background

Over the past several years, high voltages were observed on the transmission system in eastern Ontario and the GTA, which were caused by low transfer levels across the 500 kV transmission system from Bowmanville SS to Hawthorne TS. This 500 kV transmission system consists of four 500 kV circuits from Bowmanville SS to Lennox TS and two 500 kV circuits from Lennox TS to Hawthorne TS, which can produce a significant level of capacitive injection into the 500 kV system when it is lightly loaded and raise voltages unless adequately compensated.

The resources normally available to provide reactive power compensation and control voltages in eastern Ontario and the GTA include shunt reactors connected to the tertiary winding of the autotransformers at Lennox TS and Hawthorne TS, and the generators at the two nuclear stations – Pickering NGS and Darlington NGS. However, especially when some of these facilities are not available, such as during planned or forced outages, these resources are not always sufficient to maintain voltages below acceptable limits. As a result, the IESO is often required to temporarily remove Bowmanville to Lennox 500 kV circuits from service to reduce voltages. For example, in 2016 a Bowmanville to Lennox 500 kV circuit was taken out of service for voltage control for ~ 200 days.

Following the planned retirement of all of the generating units at Pickering NGS between 2022 and 2024, there will be fewer reactive absorption facilities available to manage voltages, which would worsen the problem. Studies showed that after the retirement of the Pickering units, high voltage concerns would occur when the transfers across the Bowmanville by Lennox 500 kV circuits are below 700 MW eastwards and 500 MW westwards. These flow levels are expected to occur ~300 days per year after Pickering retires. Without additional reactive compensation or voltage control devices, to manage these high voltage events it is expected that more than one 500 kV circuit would need to be removed from service.

Ontario's 500 kV network is the backbone of the transmission system. It was designed with a level of redundancy that allows the system to withstand and quickly recover from contingencies on the power system. Switching out 500 kV circuits to manage voltages reduces this redundancy and could, therefore, delay the restoration of the power system to a secure operating state following a disturbance. This is because it would take time to reconnect the circuit following the disturbance and switching equipment could fail when attempting to reconnect the circuit.

Another challenge with relying on switching out 500 kV circuits for voltage control is that it may not always be possible to switch out the Bowmanville to Lennox 500 kV circuits. Those 500 kV circuits terminate at the Bowmanville 500 kV bus, where the Darlington nuclear units are also connected and there may be situations where switching in the Bowmanville station is restricted.

Therefore, new reactive power compensation and/or voltage control facilities are needed in the area.

Working with Hydro One, a number of options were considered for addressing the high voltage concerns described above. The table below shows the technically feasible options that were assessed.

Option	Description	Cost
1	Install four line shunt reactors at Lennox TS	$92M
2	Install two line shunt reactors at Lennox TS	$66M
3	Install two shunt reactors on the Lennox 500 kV bus	$76M

A number of other options were considered, such as connecting reactors to the tertiary windings of the Cherrywood TS and Parkway TS autotransformers, however they were ruled out because they did not address the concern.

Required System Enhancements

Based on technical analysis performed by the IESO, and budgetary cost estimates received from Hydro One on November 30th, 2016, the recommended option is:

- Install two 500 kV line-connected reactors (each rated at 125 Mvar at 500 kV) at Lennox TS and connect each reactor to one of the circuits of each of the Bowmanville × Lennox 500 kV lines.
- To maintain the present Flow-into-Ottawa (FIO) operating limit, it may be necessary to include the two 500 kV line-connected reactors in an existing Remedial Action Scheme (most probably the Lennox Reactor Switching Scheme). The details would be determined through the Connection Assessment and Approval (CAA) process.

The IESO requests that Hydro One undertake the installation of these facilities. Since there is a need today, these system enhancements are required as soon as possible. Our understanding is that these facilities will be in-service by Q4 2020 at a cost of ~ $66 million.

We look forward to working with Hydro One in the related Connection Assessment and Approval (CAA) process for this work and provide any assistance in the approvals processes associated with these facilities.

Yours truly,

R. F. Chow

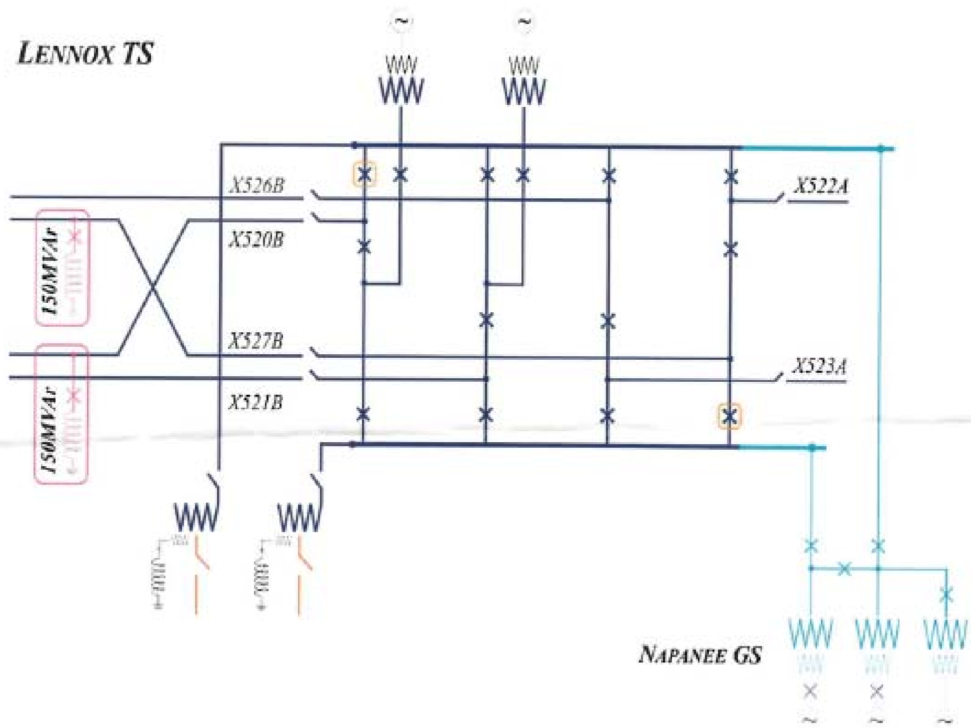
Single Line Diagram of Required Facilities



SS-02 Wataynikaneyap Power LP Line to Pickle Lake Connection

Start Date:	Q2 2019	**Priority:**	High
In-Service Date:	Q4 2020	**3 Year Test Period Gross Cost ($M):**	26.4
Trigger(s): Third Party Request, Political Commitment			
Outcomes: Connect the Wataynikaneyap Power's new line to the transmission system by installing a new switching station at Pickle Lake and a junction at Dinorwic.			

A. NEED AND OUTCOME

Investment Need

This investment is to facilitate the connection of the Wataynikaneyap Power LP ("WPLP") Line to the Hydro One's transmission system at Dinorwic and Pickle Lake.

In both the 2013 and 2017 Long-Term Energy Plan ("LTEP"), the provincial government identified that connecting remote North-Western First Nation communities is a priority for the Government of Ontario. The government also confirmed that a new line to Pickle Lake would, among other things, provide increased capacity to connect remote communities north of Pickle Lake and, for that reason, that line is a key priority for Ontario.

On July 20, 2016, the Lieutenant Governor in Council made an order declaring that the construction of electricity transmission lines to Pickle Lake and extending north from Red Lake and Pickle Lake required to connect sixteen named remote First Nation communities (Remote Communities) to the provincial electricity grid are needed as priority projects. In its Order in Council, the Lieutenant Governor in Council required WPLP to undertake the development of the line to Pickle Lake and the Remotes Connection Project.

In light of the foregoing and pursuant to its Transmission License, Hydro One is required to make this connection. This investment has been assigned a High Priority as the WPLP Line to Pickle Lake and the Remotes Connection Project has been designated as priority project.

In addition to providing capacity for connection of remote communities and new mining developments, the project also improves the reliability for the customers connected to the 115kV circuit (E1C), including Musselwhite Mine and distribution customers, as well as increases the supply capacity for the North of Dryden, by creating a second supply point at Pickle Lake.

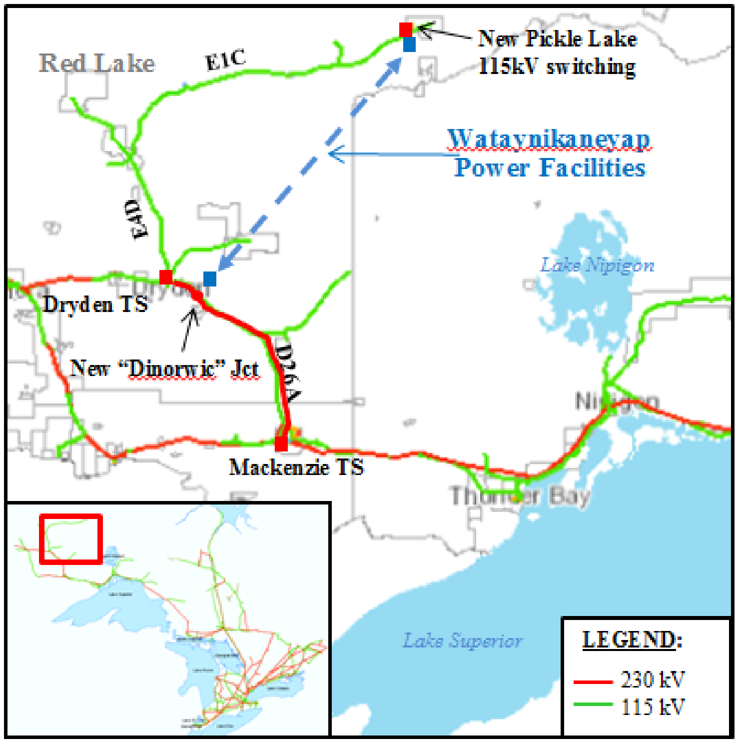
Investment Description

The proposed project to connect the WPLP's new 230kV line and 230/115kV transformer station to Hydro One facilities involves:

- Connection of the WPLP's 230kV Dinorwic switching station to Hydro One's existing 230kV circuit (D26A). This connection will require the construction of a new 230kV "Dinorwic Junction" with two motorized switches; and
- Connection of the WPLP's 230/115kV transformer station to Hydro One's existing 115kV circuit (E1C) at Pickle Lake. This connection will require the construction of a new 115kV switching station (in proximity to the WPLP transformer station) as well as protection and control modifications to incorporate the new line.

WPLP have applied for "Leave to Construct" approval for the WPLP transmission facilities (EB-2018-0190) under Section 92 of the *Ontario Energy Board Act*. The application contains a description of Hydro One's new facilities to connect the WPLP facilities to the grid.

A map showing the project location is provided below.



Outcomes

This investment will provide the required connection of the WPLP facilities to the Hydro One transmission system thereby facilitating supply of electric power to remote First Nations communities.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Ensure adequate supply capacity for the existing and new customers. • Improve reliability for the existing customers.
Operational Effectiveness	• Improve outage management for the existing radial connections.
Public Policy Responsiveness	• Comply with the Government policy of providing electric supply connection to remote First Nations communities. • Comply with Hydro One's obligation under its Transmission License to connect neighboring transmitters and provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, presented in the table below, will be recovered from the network rate pool as these facilities are network assets and thus no capital contribution is required from customers.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	3.4	24.9	1.5	0.0	0.0	0.0	0.0	29.8
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**3.4**	**24.9**	**1.5**	**0.0**	**0.0**	**0.0**	**0.0**	**29.8**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**3.4**	**24.9**	**1.5**	**0.0**	**0.0**	**0.0**	**0.0**	**29.8**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

No alternative was considered, as this investment is in response to WPLP's plans for connection of their facilities at Pickle Lake and Dinorwic.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: the outage availability that is required for the work to be completed. Also, delays in WPLP obtaining "Leave to Construct" approval under Section 92 of the *Ontario Energy Board Act* or Environmental Assessment approvals might impact this project completion. These risks will be mitigated by working with WPLP on coordinating the project schedule.

SS-03 Nanticoke TS: Connect HVDC Lake Erie Circuits

Start Date:	Q2 2020	**Priority:**	High
In-Service Date:	Q2 2022	**3 Year Test Period Gross Cost ($M):**	17.0
Trigger(s): Third Party Request			
Outcomes: Connect ITC's HVDC line to the Ontario transmission system.			

A. NEED AND OUTCOME

Investment Need

This investment is required to facilitate the request from Lake Erie Connector LLC ("ITC") to connect a 1000MW High Voltage Direct Current ("HVDC") line between Ontario and Pennsylvania; with a connection to Hydro One's transmission system at Nanticoke TS.

Hydro One is required to make connections when requested by customers. Not proceeding with this investment would be a violation of the Transmission System Code and Hydro One's Transmission License. This project is assigned a High Priority in order to meet this customer obligation.

Investment Description

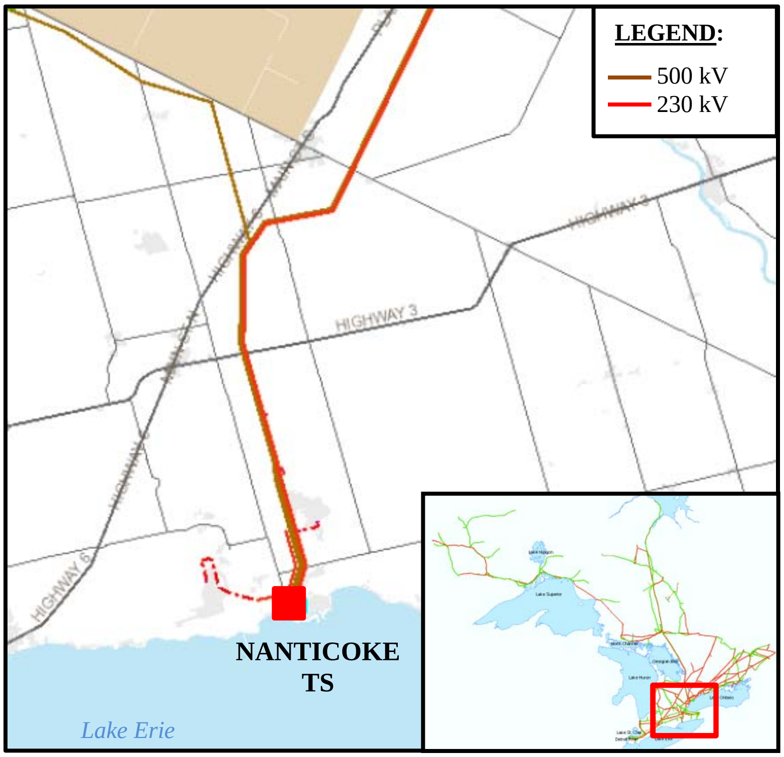
The ITC is constructing a 117 km long, underwater 1000MW HVDC cable line between converter stations in Nanticoke, Ontario and Erie, Pennsylvania, USA. Short AC lines will connect the converter stations to the Ontario and Pennsylvania transmission systems.

The proposed project involves connecting ITC's 500kV line at Nanticoke TS. This requires the expansion of the Nanticoke TS 500kV switchyard to accommodate the connection, including:

- Extension of the 500kV main busses;
- Addition of a new 500kV diameter with two new 500kV breakers;
- Protection and control modifications to incorporate the new line; and

- Relocation of one 500kV transmission tower.

A map showing the project location is provided below.



The System Impact Assessment and Customer Impact Assessment have been completed for this project. These assessments confirm that the incorporation of the project will not negatively impact the reliability of the IESO-controlled grid nor will it degrade the electricity service of the customers.

The ITC has obtained necessary approvals for a cross border interconnection project. The National Energy Board ("NEB") issued a Certificate of Public Convenience Necessity for the project on June 26, 2017. The US Department of Energy granted a Presidential Permit for the project on January 12, 2017.

Commencement of the project will be subject to the signing of the Capital Cost Recovery Agreement ("CCRA") with the customer.

Witness: Robert Reinmuller

Outcomes

This investment will provide the required connection of the ITC HVDC line to the Ontario transmission system**.**

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Satisfy ITC's request for connection.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License and Transmission System Code to connect neighboring transmitters and provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, are fully recoverable through capital contributions from ITC. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the CCRA. The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

Table 1: Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	0.5	3.0	10.0	4.0	0.0	0.0	0.0	17.5
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.5**	**3.0**	**10.0**	**4.0**	**0.0**	**0.0**	**0.0**	**17.5**
Less Capital Contributions	0.5	3.0	10.0	4.0	0.0	0.0	0.0	17.5
Net Investment Cost	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**	**0.0**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

No alternative was considered, as this investment is in response to a specific request from ITC.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: the outage availability that is required for the work to be executed. These risks will be mitigated by setting a schedule that aligns with the outage availability. There is also a risk that the customer requirements may change resulting in a delay or cancellation of the need for this project. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer decides to cancel the project.

SS-04 East-West Tie Connection

Start Date:	Q2 2018	**Priority:**	High
In-Service Date:	Q2 2022	**3 Year Test Period Gross Cost ($M):**	107.7
Trigger(s): Third Party Request, Political Commitment			
Outcomes: Connect the new East-West Tie Line to the transmission system by expanding and reconfiguring Wawa TS, Marathon TS and Lakehead TS.			

A. NEED AND OUTCOME

Investment Need

The East-West Tie ("EWT"), identified as a priority project in the 2013 Long-Term Energy Plan ("LTEP") and reaffirmed in the 2017 LTEP, is a cornerstone of the government's policy to support expansion of transmission infrastructure in North-Western Ontario. The EWT project consists of building a new 450 km long 230kV double circuit transmission line between Wawa and Thunder Bay in Northern Ontario and is the IESO recommended alternative to maintain a reliable and cost-effective supply of electricity to North-Western Ontario for the long term.

Under the authority of Section 96.1 (1) of the *Ontario Energy Board Act*, the Lieutenant Governor in Council made an order declaring that the construction of the EWT transmission line is needed as a priority project.

In 2013, the Ontario Energy Board designated Upper Canada Transmission Inc., now operating as NextBridge Infrastructure ("NextBridge"), to carry out the development of the new EWT transmission line. On January 30, 2019 the Ontario Minister of Energy issued an Order in Council and Directive to the Ontario Energy Board, mandating that the new EWT transmission line will be constructed by NextBridge. Hydro One as the neighbouring transmitter is required to connect the new lines to the existing transmission system.

This investment, in addition to connecting the new transmission line, includes expansion and reconfiguration of the three stations, Wawa TS, Marathon TS and Lakehead TS as required by the IESO's System Impact Assessment. This investment has been assigned a High Priority in accordance with the EWT transmission line being designated as priority project.

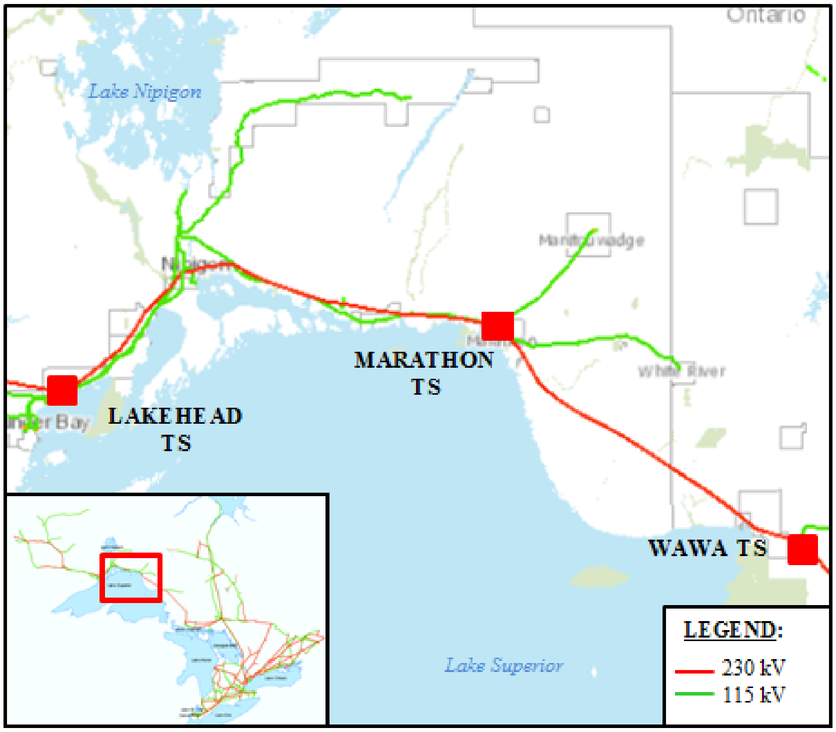
Investment Description

The proposed project constitutes Stage 1 of the EWT station work, and involves the reconfiguration and modification of the existing stations to incorporate the new 230kV EWT transmission line and provide 450MW East-West power transfer capability while respecting the reliability standards of North American Electric Reliability Corporation ("NERC") and the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC"). Stage 1 of the project requires the following:

- Installation of necessary switching facilities to connect the new East-West Tie 230kV circuits at Wawa TS, Marathon TS, and Lakehead TS, including 12 breakers and associated switches, protection and control, etc.;
- Re-termination of the existing 230kV circuits (W21M, W22M and W23K at Wawa TS; and W21M, M23L at Marathon TS), including 5 breakers, associated switches, protection and control, etc.;
- Addition of two new 230kV shunt reactors at Marathon TS and a 230kV shunt reactor and 230kV shunt capacitor bank at Lakehead TS, including 9 breakers, associated switches, protection and control, etc.; and
- Expansion of the existing Northwest Special Protection Scheme to reject load, switch reactors and capacitors, and cross-trip 115kV lines in response to 230kV contingencies.

Stage 2 of the project, which is not included in this investment, consists of the installation of a static-var compensator at Marathon TS and upgrade of the 115kV circuits (A5A and T1M) to increase the East-West transfer capability to 650MW, when the need arises.

A map showing the project location is provided below.



The System Impact Assessment and Customer Impact Assessment were completed in 2016 and 2017 respectively; both confirm that the project will not adversely affect the reliability of the IESO-controlled grid or service to other transmission connected customers.

Hydro One applied for "Leave to Construct" approval for the Stage 1 of the EWT station work (EB-2017-0194), under Section 92 of the *Ontario Energy Board Act*. A summary of the need, project description, risk, and costs have been presented in the Section 92 application. In its Decision and Order, dated December 20, 2018, the Ontario Energy Board approved Hydro One's application for the station work, subject to granting "Leave to Construct" approval for the new transmission line between Wawa and Thunder Bay. The Board also granted Hydro One approval of the land purchase agreements and temporary land use or access agreements under Section 97 of the Act.

Outcomes

This investment will provide a reliable and cost-effective supply of electricity in North-Western Ontario, increase operational flexibility, reduce congestion payments and remove a barrier to resource development in the region.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Improve reliability while increasing the transfer capability.
Operational Effectiveness	• Provide operational flexibility by providing adequate reactive support to operate the system within voltage limits.
Public Policy Responsiveness	• Comply with the government policy and direction for providing sufficient capacity for demand growth in North-Western Ontario.

B. EXPENDITURE PLAN

This project is non-discretionary. The project costs, as presented in the table below, will be recovered from the network rate pool as these 230kV facilities are network assets and thus no capital contribution is required from customers.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	47.7	46.6	39.8	23.2	0.0	0.0	0.0	157.3
Less Removals	0.4	0.3	1.0	0.6	0.0	0.0	0.0	2.3
Gross Investment Cost	**47.3**	**46.3**	**38.8**	**22.6**	**0.0**	**0.0**	**0.0**	**155.0**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**47.3**	**46.3**	**38.8**	**22.6**	**0.0**	**0.0**	**0.0**	**155.0**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

Hydro One in consultation with the IESO, considered two alternatives to provide connection of the EWT transmission line to Hydro One's transmission system. Each of these alternatives consists of two stages, as recommended by the IESO, to address the 450MW near-term and 650MW future requirement for East-West transfer capability. In both alternatives the second stage will be completed when the need arises for 650MW transfer capability.

- Alternative 1: In Stage 1 the two new 230kV EWT circuits are connected together to form one super-circuit (or twinned circuit) and the two existing 230kV EWT circuits are connected together to create a second super-circuit. This was expected to reduce the station work in Stage 1 by allowing the use of existing line terminations. In Stage 2, the two twinned circuits are separated into four circuits and the stations reconfigured to individually terminate the four circuits at the stations. A static-var compensator is also added at Marathon TS.

- Alternative 2 (Recommended): In Stage 1, the three terminal stations are reconfigured to connect the two new 230kV EWT circuits individually at each of the stations. In Stage 2, a static-var compensator is added at Marathon TS.

Both Alternative 1 and 2 would meet the required transfer capability; however Alternative 2 has lower total cost compared to Alternative 1 and poses less risk with respect to technical challenges such as: outages; configurations; capabilities of existing breakers, protections; and connection of existing direct-connected customer. Therefore Alternative 2 is the recommended alternative.

D. EXECUTION RISK AND MITIGATION

The risks to the completion of this investment as planned would be as a result of potential delays in securing regulatory approvals and outage availability. These risks are mitigated by developing project construction schedule that aligns with the outage availability.

SS-05 St. Lawrence TS: Replace Phase Shifters PS33 and PS34

Start Date:	Q4 2018	**Priority:**	High
In-Service Date:	Q4 2022	**3 Year Test Period Gross Cost ($M):**	36.0
Trigger(s):	Operating Reliability, Equipment Failure		
Outcomes:	Maintain interconnection capability at the Ontario – New York intertie at St. Lawrence TS.		

A. NEED AND OUTCOME

Investment Need

This investment is required to replace the phase shifters (PS33, PSR34) at St. Lawrence TS. These phase shifters are part of the Ontario-New York 230kV interconnection circuits (L33P/L34P) at St. Lawrence TS. Phase shifters provide an important and preferred means of achieving active power flow control in a transmission system, including enforcing power flow and rebalancing line loading. In this case, phase shifters (PS33, PSR34) are used to control flow on the Ontario-New York interconnection lines, maximize east-west transfers in Ontario and help reduce overall losses.

The phase shifter (PS33) failed in April 2018 due to an arcing fault in its internal winding and is no longer serviceable. With the failure of this phase shifter, only phase shifter (PSR34) is left in-service and intertie transfer capability has been reduced from 400MW to 200MW, impacting both Ontario and New York. The remaining phase shifter (PSR34) has exceeded its expected service life of 40 years and is also planned to be replaced to avoid the risk of another unexpected phase shifter failure at the intertie.

Following the phase shifter (PS33) failure event, the New York Independent System Operator (“NYISO”), the New York Power Authority (“NYPA”), the Ontario Independent Electricity System Operator (“IESO”) and Hydro One discussed the future of the Ontario-New York 230kV interconnection at St. Lawrence TS. All parties agreed that the existing interconnection is still needed and that both phase shifters are required to maintain interconnection capability.

Not proceeding with this investment would result in a reduction of the interconnection capacity and the reliability of the Ontario – New York intertie at St. Lawrence TS.

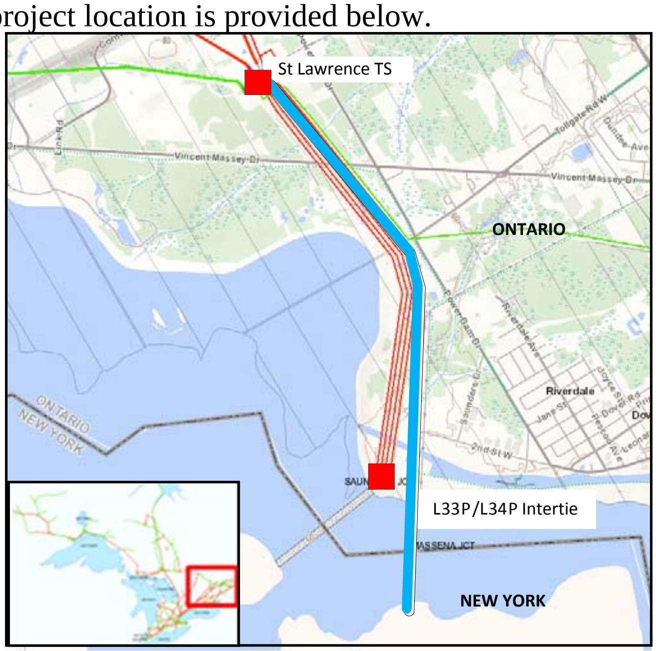
Investment Description

In response to the unavailability of phase shifter (PS33) and to maintain interconnection capability on the Ontario-New York intertie at St. Lawrence TS, Hydro One plans to:

- Replace phase shifter (PS33) and its associated voltage regulator transformer (R33). The new unit will be rated similar to the existing unit but will combine the phase shifter and voltage regulator transformer functions into one unit; and
- Replace the existing phase shifter (PSR34), which is a combined phase shifter and regulating transformer; as well as two 230kV breakers and disconnect switches. The new unit will be rated similar to the existing unit.

To ensure that the capability of the Ontario – New York interconnection is restored as soon as possible Hydro One has placed a High Priority on this investment. The replacement of phase shifter (PS33) is to be completed by 2021 and phase shifter (PSR34) by 2022.

A map showing the project location is provided below.



Outcomes

This investment will maintain interconnection capability between Ontario and New York.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Restore reliability of the bulk transmission system.
Operational Effectiveness	• Eliminate operating constraints resulting from operating with one phase shifter only.
Public Policy Responsiveness	• Maintain interconnection capability between Ontario and New York.

B. EXPENDITURE PLAN

The project costs, as presented in the table below, will be shared equally between Hydro One and NYPA. Hydro One's share of the project costs will be recovered from the network rate pool as these phase shifters are network assets.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	0.5	9.0	18.0	9.0	0.0	0.0	0.0	36.5
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.5**	**9.0**	**18.0**	**9.0**	**0.0**	**0.0**	**0.0**	**36.5**
Less Capital Contributions	0.0	4.5	9.0	4.5	0.0	0.0	0.0	18.0
Net Investment Cost	**0.5**	**4.5**	**9.0**	**4.5**	**0.0**	**0.0**	**0.0**	**18.5**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

There is no cost effective alternative to replacing the phase shifters (PS33 and PSR34) at St. Lawrence TS for restoring the interconnection capacity between Ontario and New York. Replacement of the two phase shifters is the preferred and recommended option.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: the procurement of the specialized and complex phase shifter equipment and outage availability that is required for the work to be executed. These risks will be mitigated by setting a schedule that aligns with equipment and outage availability.

SS-06 Merivale TS to Hawthorne TS: 230kV Conductor Upgrade

Start Date:	Q2 2020	**Priority:**	High
In-Service Date:	Q4 2022	**3 Year Test Period Gross Cost ($M):**	23.4
Trigger(s): Third Party Request, Political Commitment			
Outcomes: Increase transfer capacity.			

A. NEED AND OUTCOME

Investment Need

This investment is required to increase the loading capability of the 230kV double circuit line (M30A/M31A) between Hawthorne TS and Merivale TS to serve growth in western Ottawa and optimize the use of Ontario's interties with Quebec; as identified in the 2017 Long-Term Energy Plan ("LTEP").

The IESO's 2017 Ontario-Quebec Interconnection Capability technical review has indicated that the two 230kV circuits between Hawthorne TS and Merivale TS are currently a limiting factor in Ontario's capability to import electricity from Quebec. These circuits must be upgraded to allow increased import capability in order to optimize the connection with the Quebec transmission system. The 2017 LTEP has also identified a need to proceed with this project in order to serve anticipated growth in western Ottawa.

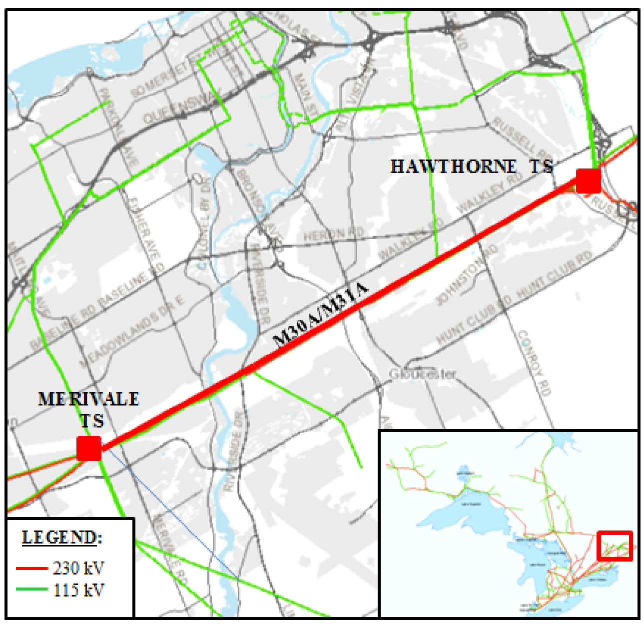
Not proceeding with this investment would result in not complying with provincial policy direction as laid out in the 2017 LTEP. This project is assigned a High Priority in order to meet this obligation.

Investment Description

Hawthorne TS and Merivale TS are the two main supply stations for the Ottawa area. The flow on the 230kV circuits (M30A and M31A) connecting Hawthorne TS to Merivale TS is largely dependent on the loads in western Ottawa and on the imports from Hydro Quebec into Hawthorne TS.

The IESO has identified that the conductors comprising the two 230kV circuits between Hawthorne TS and Merivale TS would require upgrading to accommodate the full capacity of the 1250MW Ontario-Quebec Intertie. This proposed project involves replacing the existing conductor with a two conductor bundle thereby allowing the circuit rating to be increased from 650MW to about 1080MW.

A map showing the project location is provided below.



The System Impact Assessment has been completed for this project which confirms that the incorporation of these facilities will not adversely impact the reliability of the IESO-controlled grid. The Customer Impact Assessment will be completed in Q2 2019; however, based on the System Impact Assessment results, the project is not expected to affect electricity service to transmission customers in the Ottawa area.

Hydro One will apply for “Leave to Construct” approval under Section 92 of the *Ontario Energy Board Act* once direction from IESO to proceed is provided. A summary of the need, project description, risk, and costs have been presented herein; with specific details to be provided in the Section 92 application. There are no land matters as the existing right of way will be utilized.

Outcomes

This investment will increase loading capability of the 230kV circuits between Hawthorne TS and Merivale TS to satisfy the requirements of forecasted loads in western Ottawa and optimize the electricity imports from Quebec.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Ensure adequate supply capacity for western Ottawa loads.
Operational Effectiveness	• Increase operating flexibility of the transmission system by providing increase in transfer capacity.
Public Policy Responsiveness	• Comply with IESO request to increase transfer capability. • Align with the direction in the 2017 Long-Term Energy Plan.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recovered from the network rate pool as these 230kV circuits are network assets and thus no capital contribution is required from customers.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	0.7	5.0	10.0	8.4	0.0	0.0	0.0	24.1
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.7**	**5.0**	**10.0**	**8.4**	**0.0**	**0.0**	**0.0**	**24.1**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.7**	**5.0**	**10.0**	**8.4**	**0.0**	**0.0**	**0.0**	**24.1**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

Two alternatives were considered for providing the additional loading capability.

- Alternative 1: Build a new 12 km 230kV double-circuit transmission line between Hawthorne TS and Merivale TS. The right of way for the existing 230kV transmission line does not have sufficient space for additional circuits; requiring acquisition of a new right of way.

- Alternative 2 (Recommended): Re-conductor the existing 12 km 230kV double-circuit transmission line (M30A/M31A) with higher capacity conductor. The existing tower structures are adequate to support the new conductor and would not require replacement.

Both Alternative 1 and 2 would address the need; however Alternative 1 was not considered further due to the higher costs, community impact, and complexity of securing a new right of way. Alternative 2 is the recommended alternative.

D. EXECUTION RISK AND MITIGATION

The risks with respect to the execution of this investment as planned would be as a result of potential delays in securing the Section 92 approval. These risks will be mitigated by initiating the Section 92 application process in a timely manner after receiving the IESO direction to proceed with the project.

Normal project risks may also affect the timely completion of the project such as the outage availability that is required for the work to be executed. As the affected circuits are critical for supplying Ottawa, it may be challenging to schedule outages to complete the required work. These risks will be mitigated by setting a schedule that aligns with outage availability.

SS-07 Milton SS: Station Expansion and Connect 230kV Circuits

Start Date:	Q4 2022	**Priority:**	Medium
In-Service Date:	Q2 2025	**3 Year Test Period Gross Cost ($M):**	5.0
Trigger(s): System Adequacy			
Outcome: Provide adequate supply to West GTA region and improve system reliability.			

A. NEED AND OUTCOME

Investment Need

The IESO bulk system studies described in the 2015 North-West GTA Integrated Regional Resource Plan[1] had indicated that the bulk transmission facilities in West GTA; specifically the 500/230kV autotransformers at Trafalgar TS and the Trafalgar to Richview 230kV transmission circuits (R14T, R17T, R19T and R21T) would require relief as early as 2020. The two primary factors driving the need for relief were: (a) load growth in the GTA, specifically in the West GTA; and (b) increased inter-area flows due to the scheduled refurbishment of nuclear units at Bruce NGS and Darlington NGS along with the planned retirement of Pickering NGS.

The North-West GTA Integrated Regional Resource Plan had also identified that loads connected to the Burlington TS to Trafalgar 230kV circuits (T38B/T39B) are at risk of not meeting the restoration criteria as defined in the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC").

In order to address these needs, the IESO had recommended adding 500/230kV transformation facilities at Milton SS and reconfiguring the 230kV transmission facilities in North-West GTA.

[1] *http://www.ieso.ca/-/media/Files/IESO/Document-Library/regional-planning/Northwest-Greater-Toronto/2015-Northwest-GTA-IRRP-Report.pdf*

As described in the 2017 Long-Term Energy Plan; growth in demand, the eventual retirement of the Pickering NGS and new renewable generation all impact the bulk transmission system in West GTA. The IESO is studying the need and timing of these transmission reinforcements. Based on the lower load growth forecast and the deferral of the Pickering NGS retirement to 2024, the need for the Milton SS expansion and reconfiguration of 230kV transmission facilities have been deferred to 2025.

Not proceeding with this investment would limit transfer capability and would result in inadequate capacity to supply the West GTA loads.

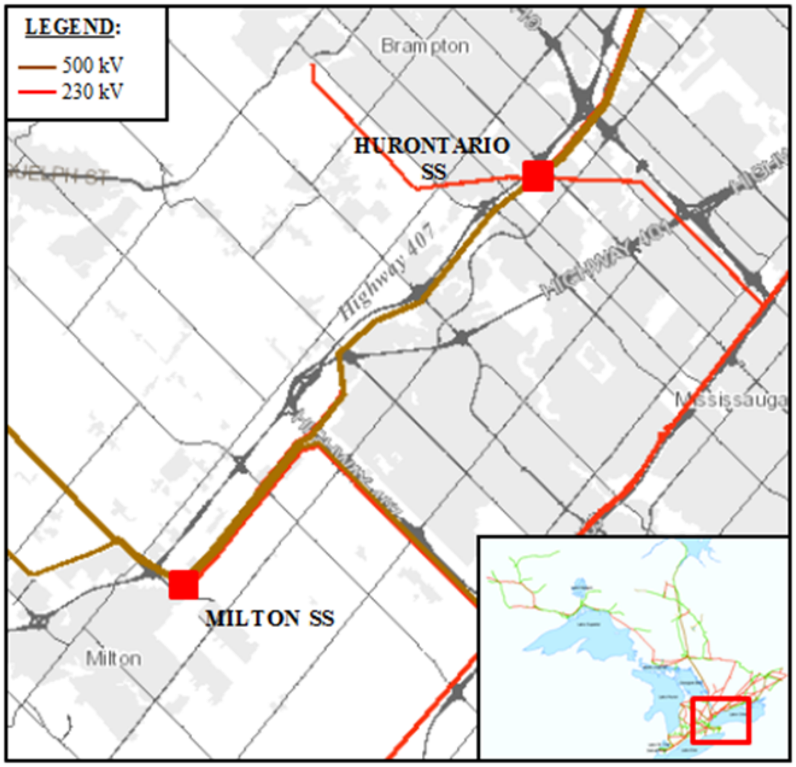
Investment Description

The proposed project involves the:

- Installation of two 500/230kV, 750MVA autotransformers and associated switching facilities at Milton SS;
- Construction of a new 230kV switchyard at Milton SS;
- Construction of an approximately 12.5 km 230kV double circuit line to connect the new Milton SS to Hurontario SS using the existing right of way; and
- Modification of Hurontario SS to incorporate the new 230kV circuits.

The new facilities will provide relief for the loading on autotransformers at Trafalgar TS and the 230kV circuits between Richview TS and Trafalgar TS. The reconfiguration will also allow the 230kV circuits (T38B/T39B) loading to continue to comply with the IESO's ORTAC as loads increase.

A map showing the project location is provided below.



Once the IESO confirms the need and timing for the project Hydro One will apply for a "Leave to Construct" approval under Section 92 of the *Ontario Energy Board Act*, and a Class Environmental Assessment approval under the *Environmental Assessment Act*. A summary of the need, project description, risk, and costs have been presented herein; with specific details to be provided in the Section 92 application. All land matters will be addressed in the Section 92 application.

The project is not expected to adversely affect the reliability of the IESO-controlled grid or service to other transmission connected customers. The System Impact Assessment and Customer Impact Assessment will be completed to confirm the above prior to the submission of the Section 92 application.

Outcomes

This investment will provide adequate supply to West GTA region and improve system reliability.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Ensure adequate capacity to supply the West GTA loads.
Operational Effectiveness	• Improve operational flexibility with the addition of 230kV transformation at Milton SS.
Public Policy Responsiveness	• Align with the direction in the 2017 Long-Term Energy Plan.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recovered from the network rate pool as these 500kV and 230kV facilities are network assets and thus no capital contribution is required from customers.

Table 1: Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	0.0	0.0	2.0	3.0	69.4	119.1	45.0	238.5
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.0**	**0.0**	**2.0**	**3.0**	**69.4**	**119.1**	**45.0**	**238.5**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**0.0**	**2.0**	**3.0**	**69.4**	**119.1**	**45.0**	**238.5**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

Two transmission alternatives were considered by the IESO to address the needs in the West GTA region. These alternatives are:

- Alternative 1 (Recommended): Install two new autotransformers, construct a new 230kV switchyard at Milton SS, and construct approximately 12.5 km of double circuit 230kV line between Milton SS and Hurontario SS.

- Alternative 2: Install two new autotransformers, expand the 230kV switchyard at Trafalgar TS, and construct approximately 8 km of double circuit 230kV line between Meadowvale TS and Hurontario SS.

The IESO concluded based on preliminary studies that Alternative 1 is the preferred option as it is the least cost alternative and provides greater operating flexibility.

E. EXECUTION RISK AND MITIGATION

The risks with respect to execution of this investment as planned would be as a result of potential delays in securing the Section 92 and environmental assessment approvals. These risks will be mitigated by initiating the Section 92 application process and environmental assessment process in a timely manner.

SS-08 Northwest Bulk Transmission Line

Start Date:	Q1 2019	**Priority:**	High
In-Service Date:	Q4 2022*	**3 Year Test Period Gross Cost ($M):**	29.8
Trigger(s): Third Party Request, Political Commitment			
Outcomes: Undertake the development work required for submission of approval requests for the building of a 230kV double circuit line between Thunder Bay and Atikokan and a single-circuit line between Atikokan and Dryden.			

** As described below, this date represents the completion of the required development work to the point of approval submission only.*

A. NEED AND OUTCOME

Investment Need

This investment is required in response to the IESO's request to Hydro One dated October 24, 2018 (see Appendix "A" below) to undertake development work for the Northwest Bulk Transmission Line ("NWBTL") Project, which is a priority project identified in the 2013 and 2017 Long-Term Energy Plans ("LTEP"). The purpose of this project is to augment the transmission capacity and maintain the reliability of electricity supply to the area of northwestern Ontario located west of Thunder Bay and support forecast electricity demand growth.

The 2017 LTEP recommended that the project proceed in three phases:

- <u>Phase One</u>: a line from Thunder Bay to Atikokan by 2024.
- <u>Phase Two</u>: a line from Atikokan to Dryden by 2034 (or earlier depending on the demand forecast).
- <u>Phase Three</u>: a line from Dryden to the Manitoba border, if needed, after 2035 (or earlier if recommended by the IESO).

An Order in Council issued December 11, 2013 directed the Ontario Energy Board to amend Hydro One's Transmission Licence, requiring Hydro One to develop and seek approvals for the NWBTL in accordance with the scope and timing recommended by the IESO.

The IESO has recently reviewed the NWBTL in relation to updated area load forecast, and outlined the recommended scope and timing of the project in its October 24, 2018 letter to Hydro One. In that letter, the IESO indicated that while additional transmission capacity in the area may not be needed until the mid-2030s, a capacity need could potentially arise under the high load growth scenario in the early 2020s. The IESO will continue to monitor the development and load growth in the area and advise when the new line would be required.

Given the risks associated with load forecast uncertainty, and to shorten the project lead time if the need for additional capacity arises pursuant to the high growth scenario, the IESO recommends that Hydro One commence project development work as soon as possible on Phase One and Phase Two of the NWBTL as follows:

- Phase One: a new double circuit 230kV line from Lakehead TS to Mackenzie TS.
- Phase Two: a new single circuit 230kV line from Mackenzie TS to Dryden TS.

In addition, the IESO has also asked Hydro One to separate the necessary sections of the existing 230kV circuits (F25A, D26A) that originate from Mackenzie TS to ensure that the circuits do not share a common structure over a distance exceeding one mile.

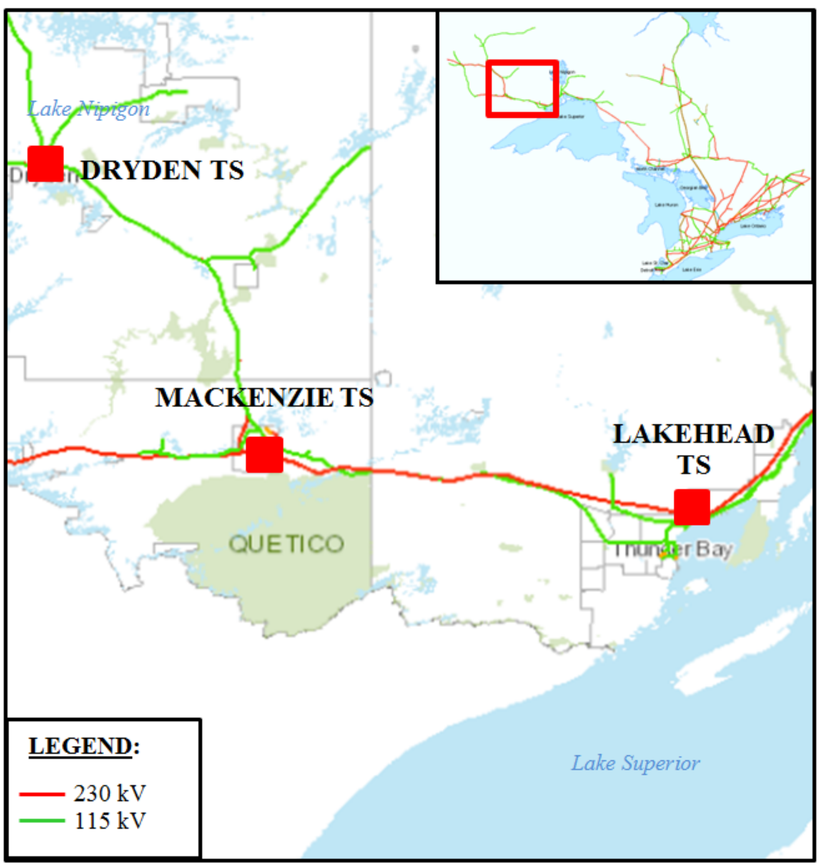
Not proceeding with this investment risks potential delay in providing additional transmission capacity when required. This project has been assigned a High Priority given the identification of the NWBTL as a priority project in the 2017 LTEP, and the most recent IESO determination that Hydro One should begin development work as soon as possible.

Investment Description

This investment will allow Hydro One to undertake the development work for Phase One and Phase Two of the NWBTL as described above. The scope of this development work includes:

- Initiating preliminary design/engineering;
- Preparing cost estimates;
- Carrying out public engagement/consultation;
- Undertaking routing and siting studies; and
- Environmental assessment.

A map showing the general location of the proposed NWBTL project is provided below.



Outcomes

Pursuant to the IESO's request, this investment will allow Hydro One to undertake the development work for the installation of Phase One and Phase Two of the NWBTL, which will increase transfer capability in the area west of Thunder Bay and provide sufficient capacity for the forecasted growing demand.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Ensure timely capacity increase to meet future customer loads.
Operational Effectiveness	• Maintain reliability while increasing the transfer capability in the area.
Public Policy Responsiveness	• Comply with the IESO request to initiate the development work for Phase 1 and Phase 2 of the NWBTL to provide sufficient capacity for demand growth in Northwest Ontario, including connection of remote communities. • Align with the direction in the 2017 Long-Term Energy Plan.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, are only for development work, including preliminary design/engineering, cost estimation, public engagement/consultation, routing and siting, and environmental assessment, for Phase One and Phase Two of the NWBTL. Some of the expenditure may extend beyond 2022, to facilitate interactions with regulators during Environmental Assessment review periods and ongoing consultation with Indigenous Communities and stakeholders. These project costs will be recovered from the network rate pool as these 230kV facilities are network assets and thus no capital contribution is required from customers.

Table 1: Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total[2]
Capital[1] and Minor Fixed Assets	5.2	8.0	12.9	8.9	0.0	0.0	0.0	35.0
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**5.2**	**8.0**	**12.9**	**8.9**	**0.0**	**0.0**	**0.0**	**35.0**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**5.2**	**8.0**	**12.9**	**8.9**	**0.0**	**0.0**	**0.0**	**35.0**

[1] Includes Overhead at current rates.
[2] As described above, this would bring development work to the point required for submission of approval requests only.

C. ALTERNATIVES

No alternative was considered by Hydro One, as this investment is in response to a specific directive.

D. EXECUTION RISK AND MITIGATION

This investment covers only the development work, including environmental assessment, for the NWBTL. Normal project risks associated with extensive public consultation apply, as well as potential delays for obtaining the final environmental assessment approvals.

APPENDIX "A" – Letter from the IESO to Hydro One

ieso
Connecting Today.
Powering Tomorrow.

Independent Electricity System Operator
1600-120 Adelaide Street West
Toronto, ON M5H 1T1
t 416.967.7474
www.ieso.ca

October 24, 2018

Mr. Robert Reinmuller
Director, Transmission Planning
Hydro One Inc.
483 Bay Street, 13th Floor, North Tower
Toronto, Ontario M5G 2P5

Dear Robert,

Update on the Need and Scope for the Northwest Bulk Transmission Line

The Independent Electricity System Operator (the "IESO") recently updated its electrical load forecast and completed an assessment of the need for additional capacity to supply the West of Thunder Bay and North of Dryden areas (together, the "Region"), shown in Figure 1. The purpose of this letter is to describe the supply needs for the Region and the IESO's recommended next steps for meeting those needs.

Figure 1 – The Region

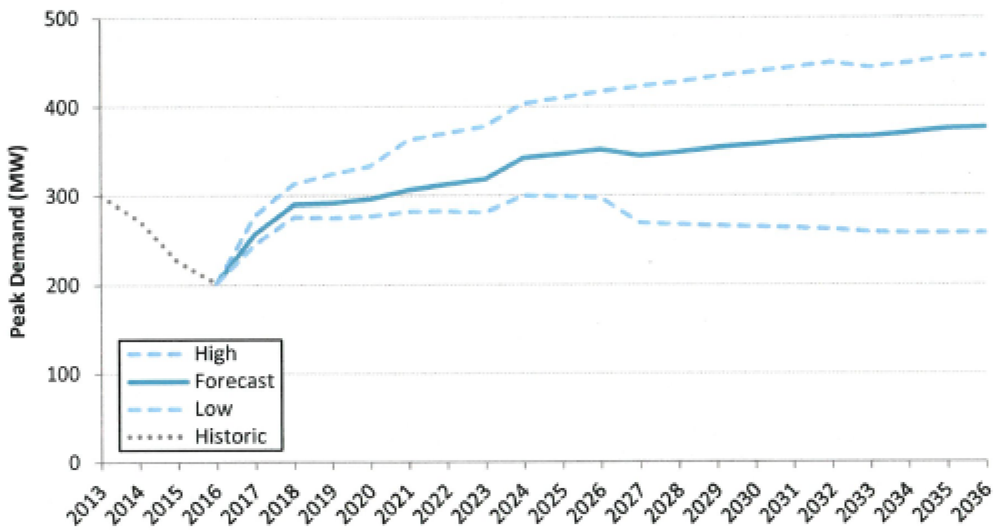
Supply Needs in the Region

Figure 2 below shows an updated electrical load forecast for the Region. The updated forecast considers new loads from potential mining developments, the connection of remote communities and the removal of loads from the cancelled Energy East pipeline conversion project.

Based on the forecast the Region is adequately supplied today; however, a need for additional capacity will arise in the mid-2030s.

The IESO's updated electrical load forecast also includes high and low growth scenarios to capture the uncertainty around industrial developments. Under the high growth scenario, which considers development of the Ring of Fire with electricity supplied by the Ontario transmission system, a capacity need could potentially arise in the early 2020s.

Figure 2 - Electrical Load Forecast – the Region



Addressing the Need

The Northwest Bulk Transmission Line Project (the "Project") was identified as a priority project in the 2017 Long-Term Energy Plan (the "LTEP") and can address the capacity needs described above. The LTEP divides the Project into three phases:

Phase 1 – a line from Thunder Bay to Atikokan;

Phase 2 – a line from Atikokan to Dryden; and

Phase 3 – a line from Dryden to the Manitoba border.

An Order in Council issued December 11, 2013 directed the Ontario Energy Board to amend the Hydro One Networks Inc. Electricity Transmission License to require Hydro One to develop and seek approvals for the Project in accordance with the scope and timing recommended by the IESO. The IESO's recommended scope and timing is outlined in the following paragraphs.

Scope and Timing

Since the capacity need is not likely to materialize until the mid-2030s, a commitment for additional supply to the Region is not required at this time. However, the IESO recognizes the risks associated with load forecast uncertainty and the potential for large industrial projects to add significant load to the Region utilizing the remaining capacity margin sooner than anticipated.

Therefore, to shorten the Project lead time if the need for additional capacity materializes earlier than expected, the IESO recommends that Hydro One begin development work on Phase 1 and Phase 2 of the Project as soon as possible. The scope of development work is to include preliminary design/engineering, cost estimation, public engagement/consultation, routing and siting, and Environmental Assessment. At this time the IESO is not committing to a timeline for the construction of the line. The IESO will continue to monitor developments in the Region to determine when construction of the transmission line should begin.

To supply the Region under the high growth scenario, the Project must meet the following specifications:

a) Consist of a new double circuit 230 kV line between Lakehead TS and Mackenzie TS (Phase 1) with a thermal capacity that is equal to or greater than the existing double-circuit 230 kV transmission between Lakehead TS and Mackenzie TS. This would achieve the required westbound transfer of at least 350 MW into Mackenzie TS and Moose Lake TS.

b) Consist of a new single circuit 230 kV line from Mackenzie TS to Dryden TS (Phase 2) with a thermal capacity that is equal to or greater than the existing single-circuit 230 kV transmission line between Mackenzie TS and Dryden TS. This would achieve the required westbound transfer of at least 350 MW from MacKenzie and Moose Lake.

c) Separate the necessary sections of F25A and D26A to ensure the circuits do not share a common structure over a distance that exceeds one mile.

Hydro One should consider various routing options as appropriate. Since requirements for switching and reactive facilities would depend on the configuration and line options, they are not specified at this time.

The 2014 letter from the Ontario Power Authority (the "OPA") to Hydro One indicated that the Project must be capable of 550 MW transfer west from the Thunder Bay area. At the time the letter was written, the OPA's electrical load forecast was significantly higher and included potential mining developments and the Energy East pipeline conversion project. If in the future additional transfer capability beyond 350 MW is needed, the solution would be to install dynamic reactive facilities in addition to the transmission lines indicated above.

The IESO will provide support to Hydro One as required, including discussion of possible routing alternatives. As well, the IESO will continue to monitor developments in the Region and confirm the best course of action to address supply needs, and will keep Hydro One apprised of this work.

Sincerely,

Ahmed Maria
Director - Transmission Planning
Independent Electricity System Operator

SS-09 Barrie Area Transmission Upgrade

Start Date:	Q2 2019	**Priority:**	High
In-Service Date:	Q2 2022	**3 Year Test Period Gross Cost ($M):**	74.8
Trigger(s): Supply Reliability, End-of-Life			
Outcomes: Increase supply reliability and ensure adequate capacity for the Barrie area.			

A. NEED AND OUTCOME

Investment Need

This investment is required to address the capacity needs in the Barrie/Innisfil sub-region and the poor condition of the aging assets at Barrie TS and Essa TS; as documented in the South Georgian Bay/Muskoka Region Infrastructure Plan (Exhibit B, Tab 1, Schedule 1, TSP Section 1.2, Attachment 13).

Barrie TS is located in the Barrie/Innisfil sub-region and is the main supply for the City of Barrie. Barrie TS is a 115/44kV transformer station with a capacity of 115MVA and is supplied from 115kV circuits (E3B/E4B) from Essa TS. Barrie TS and the 115kV circuits (E3B/E4B) are supplied from the 230/115kV autotransformers and the 115kV switchyard at Essa TS. Both Barrie TS and Essa TS facilities are nearing end-of-life.

The Barrie area is experiencing significant load growth and the loading on Barrie TS currently exceeds its normal supply capacity. The 115kV circuits (E3B/E4B) are forecast to exceed the circuit capability by 2022.

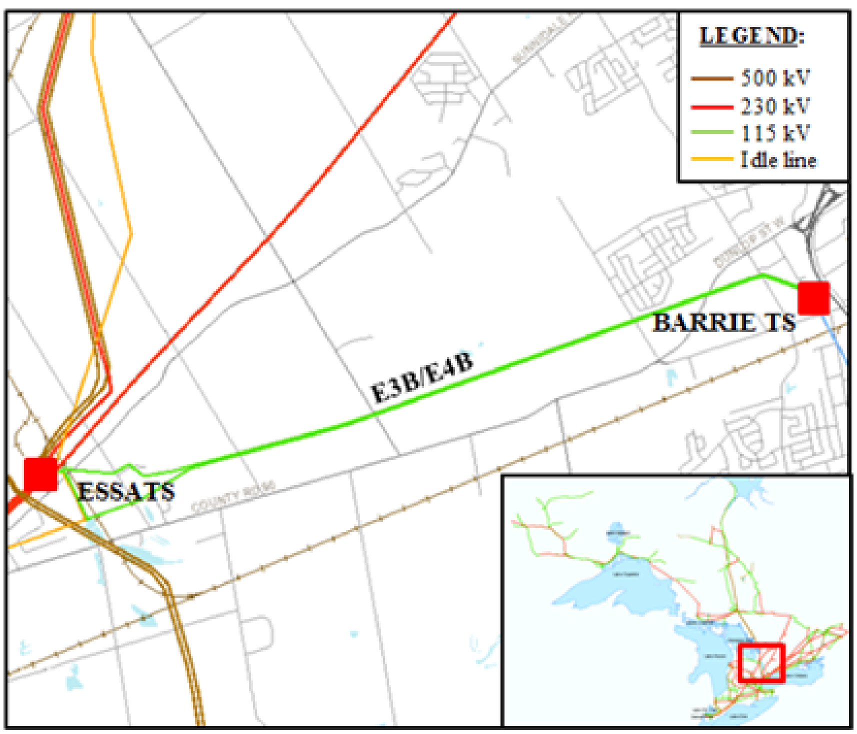
Not proceeding with this investment would result in the inability to supply forecast customer load demand, and an increased risk of load interruptions affecting supply reliability to customers. This project has been assigned a High Priority in order to provide capacity and maintain supply reliability to area customers.

Investment Description

The proposed project involves rebuilding Barrie TS as a 230kV supplied transformer station to address both the capacity and aging infrastructure related needs. The project requires the following:

- Replacement of the existing 115/44kV transformers with new 230/44kV transformers with a capacity of 170MVA;
- Construction of a new 44kV low voltage switchyard with eight 44kV feeders;
- Replacement of the existing 115kV Essa TS to Barrie TS single circuit lines (E3B/E4B) with a new 230kV double circuit line;
- Decommissioning and removal of the 230/115kV autotransformers and the 115kV switchyard at Essa TS; and
- Construction of a new 230kV diameter to provide two new switching positions for the new 230kV circuits that will supply Barrie TS.

A map showing the project location is provided below.



The System Impact Assessment and Customer Impact Assessment have been completed for this project. These assessments confirm that the incorporation of these facilities will not negatively impact the reliability of the IESO-controlled grid nor will it degrade the electricity service of the customers.

Hydro One has also completed the Class Environmental Assessment for this project in March 2018 as required under the *Environmental Assessment Act*.

Hydro One will apply for a "Leave to Construct" approval under Section 92 of the *Ontario Energy Board Act* in Q2 2019. A summary of the need, project description, risk, and costs have been presented herein; with specific details to be provided in the Section 92 application. All land matters will be addressed in the Section 92 application.

Outcomes

This investment will address the end-of-life assets and provide capacity to meet current and forecast needs for the Barrie/Innisfil area.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Ensure adequate capacity to meet future load growth.
Operational Effectiveness	• Reduce line losses by increasing voltage from 115kV to 230kV.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recoverable from the network and connection rate pools for the respective new 230kV and 44kV facilities. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the Connection Cost Recovery Agreement ("CCRA"). The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

Table 1 - Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	8.4	38.1	28.2	8.5	0.0	0.0	0.0	83.2
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**8.4**	**38.1**	**28.2**	**8.5**	**0.0**	**0.0**	**0.0**	**83.2**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**8.4**	**38.1**	**28.2**	**8.5**	**0.0**	**0.0**	**0.0**	**83.2**

[1] *Includes Overhead at current rates.*

C. ALTERNATIVES

Two alternatives were considered to address the transformation capacity and end-of-life needs Barrie/Innisfil sub-region.

- Alternative 1: Continue to supply Barrie TS at 115kV. This would require like-for-like replacement of the existing equipment at Essa TS and Barrie TS to address the aging facilities, rebuilding the existing 115kV circuits (E3B/E4B) and constructing a second 115/44kV transformer station in order to meet the capacity needs.

- Alternative 2 (Recommended): Convert Barrie TS to 230kV supply. This would require replacing the existing 115kV facilities at Barrie TS and the existing 115kV circuits (E3B/E4B) with new 230kV facilities. The Essa TS 230/115kV facilities will be removed and a new 230kV diameter added to supply the two new 230kV circuits.

Alternative 1 (like-for-like option) provides for a limited capacity increase that cannot meet the future forecast requirements. Alternative 2 ensures adequate capacity to meet future load growth and has the least cost; therefore it is the recommended alternative.

D. EXECUTION RISK AND MITIGATION

The risks with respect to execution of this investment as planned would be as a result of potential delays in securing the Section 92 approval. These risks will be mitigated by initiating the Section 92 application process in a timely manner. There is also a risk that the area customer requirements may change resulting in a delay or cancellation of the need for this project. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer decides to cancel the project.

SS-10 Kapuskasing Area Transmission Reinforcement

Start Date:	Q1 2019	**Priority:**	High
In-Service Date:	Q4 2020	**3 Year Test Period Gross Cost ($M):**	10.4
Trigger(s): Third Party Request			
Outcome: Increase thermal rating and provide reactive control at Kapuskasing TS.			

A. NEED AND OUTCOME

Investment Need

This investment is to facilitate the IESO's request to Hydro One dated April 13, 2016 (see Appendix "A" below) to increase power transfer capability on the 115kV single circuit transmission line (H9K) and to provide reactive support to supply the Kapuskasing area loads following the contract expiry of Kapuskasing CGS and Calstock CGS.

The IESO bulk system study has identified that with the Kapuskasing CGS and Calstock CGS unavailable, there is a need to reinforce a section of the 115kV circuit (H9K) and to provide additional reactive support facilities at Kapuskasing TS to support the area loads.

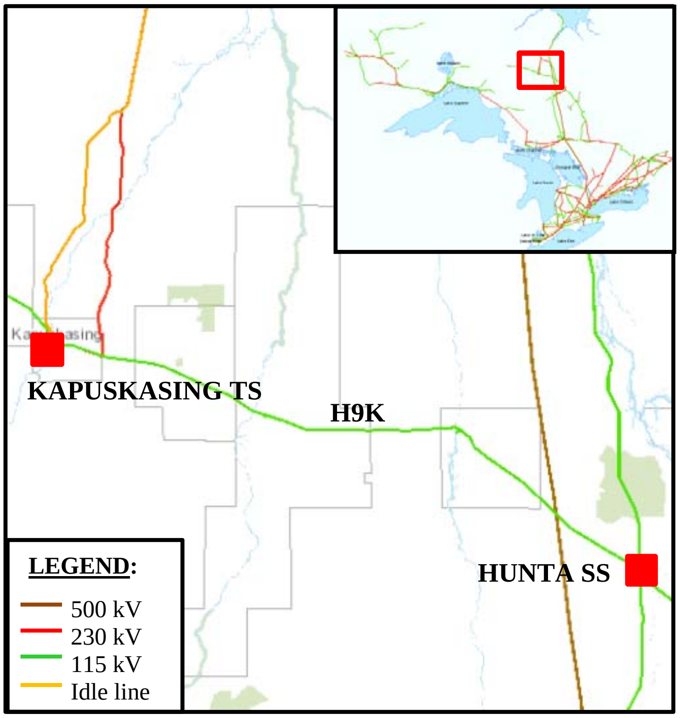
Not proceeding with investment would result in inadequate transfer capability and reactive support in the Kapuskasing area. This project is assigned a High Priority in order to maintain reliability and adequate voltage support in the area.

Investment Description

The proposed project, to reinforce supply to the Kapuskasing area, involves:

- Increasing the thermal rating of a section of the 115kV circuit (H9K) from Carmichael Falls Junction to Spruce Falls to 370A; and
- Installation of an 115kV, 10MVAR capacitor bank and 115kV, 10MVAR reactor at Kapuskasing TS to provide the reactive power control.

A map showing the project location is provided below.



The System Impact Assessment and Customer Impact Assessment have been completed for this project. These assessments confirm that the incorporation of these facilities will not negatively impact the reliability of the IESO-controlled grid nor will it degrade the electricity service of the customers.

Hydro One completed the Class Environmental Assessment for the project in November 2017 as required under the *Environmental Assessment Act*. Hydro One has also received "Leave to Construct" approval for the project from the Board on August 23, 2018 under Section 92 of the *Ontario Energy Board Act*. A summary of the need, project description, risk, and costs have been presented in the Section 92 application (EB-2018-0098). All land matters have been addressed in the Section 92 application.

Outcomes

This investment will maintain the reliability of supply, increase power transfer capability, and provide reactive support needed for the Kapuskasing area.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Ensure adequate supply to Kapuskasing area loads by increasing power transfer limits.
Operational Effectiveness	• Maintain reliability of supply to the Kapuskasing area.
Public Policy Responsiveness	• Comply with IESO request to increase transfer capability.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recovered from the network rate pool as these facilities are required to support the network, and thus no capital contribution is required from customers.

Table 1: Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	20.6	6.7	3.8	0.0	0.0	0.0	0.0	31.0
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**20.6**	**6.7**	**3.8**	**0.0**	**0.0**	**0.0**	**0.0**	**31.0**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**20.6**	**6.7**	**3.8**	**0.0**	**0.0**	**0.0**	**0.0**	**31.0**

[1] Includes Overhead at current rates.

C. ALTERNATIVES

No alternative was considered, as this investment is in response to a specific request from the IESO.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: the outage availability that is required for the work to be executed. These risks will be mitigated by setting a schedule that aligns with the outage availability.

April 13, 2016

Mr. Bing Young
Director, System Development
Hydro One Networks Inc.
483 Bay Street
Toronto, Ontario M5G 2C9

Dear: Bing

Re: Bulk System Reinforcement for the Kapuskasing Area

Background

On September 1, 2015, the IESO published the NUG ("Non-Utility Generator") Framework Assessment report ("NUG Report") to the Minister of Energy. This report identified that following the contract expiry of Kapuskasing Customer Generating Station ("CGS") and Calstock CGS, local reliability standards may not be met without further reinforcement. The NUG Report also indicated that the North/East of Sudbury regional planning study would begin immediately.

Since September 2015, the IESO has been working jointly with Hydro One to assess the local issues identified in the NUG Report. This included initiating the North/East of Sudbury Regional Planning process on September 24, 2015. Based on the fact that there were existing challenges in operating the bulk transmission system in the area, the IESO and Hydro One agreed that a bulk system study should be run in parallel with the formalized Regional Planning Process. This enabled the bulk system study to be expedited to ensure timely solutions are in place given the potential lead time for transmission based solutions.

The scope of the bulk system study for the Kapuskasing area investigated the adequacy and operability of the system supplying the area, as it currently exists, and following the contract expiry of generation facilities Kapuskasing CGS and Calstock CGS.

In accordance with the formalized Regional Planning Process, the Hydro-One led Needs Assessment process was conducted in parallel and assessed needs driven by customer growth. The Needs Assessment process concluded that the bulk system planning process and local planning process are most appropriate to address all the potential needs for the North/East of Sudbury region, and that there is no need for further review of this issue in the formal Regional Planning process.

Summary of Needs from the Bulk System Study

The Ontario Resource and Transmission Assessment Criteria ("ORTAC"), applicable operating limits, and market rules were used to assess the performance of the system. The ORTAC specifies maximum continuous voltage limits of 250 kV and 127 kV for nominal 230 kV and 115 kV system facilities, respectively. There are also some individual stations that have different operating limits than specified by ORTAC. The joint IESO-Hydro One team has identified that maximum voltage limits specified by ORTAC and some specific operating limits would be exceeded for the existing system during outages and system restoration. Respecting voltage limits is of critical importance for the safe and reliable operation of the power system. Therefore there is a need to install facilities to control voltages to within acceptable limits irrespective of the contract status of Kapuskasing CGS and Calstock CGS.

Should it not be possible to rely on the firm capacity of Kapuskasing CGS and Calstock CGS in the future, load customers would be supplied from additional power transfers into the Kapuskasing area through the provincial transmission system. In order to enable these greater transmission flows, there is a need to reinforce a section of circuit H9K and to provide additional voltage support in the area.

The study also found that during periods of high output from hydroelectric generation in the area, records indicate that circuit H9K has been binding and has resulted in congestion. Analysis indicates that this situation is expected to continue in the future. Therefore, reinforcement of circuit H9K is also expected to provide the added benefit of reducing congestion.

Requirement for Transmission Facilities

Based on technical and economic analysis performed by the IESO, and planning-level cost estimates received from Hydro One on February 24, 2016, the facilities outlined below are the least cost options for providing required levels of reliability, voltage performance, efficiency and operational flexibility, and must be placed in-service prior to June 2020.

1. Install a Programmable Synchrocheck Relay at Kapuskasing TS to enable breaker L21L38 to make the parallel between circuits K38S and L21S. This work is required to address existing energization needs.

2. Install a 10 Mvar (at 120 kV) reactor at the Kapuskasing 115 kV bus. To maintain required voltage levels during contingencies, this reactor must be capable of being disconnected from the 115 kV system by a cross-tripping scheme triggered by the loss of circuit L21S. This work is required to address existing energization needs, and outage conditions.

3. Increase the capability of circuit H9K between Carmichael and Spruce Falls (30 km) to provide a continuous summer rating of at least 310 A, and up to 370 A. This work is required to cover the risk of not being able to rely on the firm capacity of Kapuskasing CGS and Calstock CGS, and is also justified based on reducing congestion.

4. Install one 10 Mvar (at 120 kV) capacitor bank at the Kapuskasing 115 kV bus. This capacitor must be capable of being disconnected from the 115 kV system by a cross-

tripping scheme triggered by the loss of Spruce Falls transformer T7. This work is required to cover the risk of not being able to rely on the firm capacity of Kapuskasing CGS and Calstock CGS. If feasible, this work should include space provisions for the installation of a second future 10 Mvar capacitor bank at Kapuskasing 115 kV bus.

Please inform us of the planned in-service dates and the ultimate disposition of work, based on your scoping and project development work. We look forward to working with Hydro One in the related Connection Assessment and Approval (CAA) process for this work when your plans are finalized.

The IESO would be pleased to provide Hydro One with any required assistance in approvals processes associated with these facilities.

Yours truly,

Joe Toneguzzo

SS-11 South Nepean Transmission Reinforcement

Start Date:	Q3 2019	**Priority:**	High
In-Service Date:	Q2 2021	**3 Year Test Period Gross Cost ($M):**	38.0
Trigger(s): Customer Request			
Outcomes: Connect the South Nepean customer owned station.			

A. NEED AND OUTCOME

Investment Need

This investment is required to provide increased transmission capacity in the South Nepean area and connection to Hydro Ottawa's new transformer station. The South Nepean area is currently supplied by two Hydro Ottawa stations, Richmond MTS and Fallowfield MTS and one Hydro One distribution station Manotick DS. The stations are fed by a single 115kV circuit (S7M) which emanates from Merivale TS. The South Nepean area is expected to exceed available station capacity by 2019 and to exceed the line capacity of the 115kV circuit (S7M) by 2027. The need has been documented in both the Greater Ottawa Region Integrated Regional Resource Plan[1] and the Regional Infrastructure Plan (Exhibit B, Tab 1, Schedule 1, TSP Section 1.2, Attachment 3).

Hydro One is obligated to make connections when requested by customers. Not proceeding with this investment would be a violation of the Transmission System Code and Hydro One's Transmission License. This project is assigned a High Priority in order to meet this customer obligation.

Investment Description

The proposed project involves the:

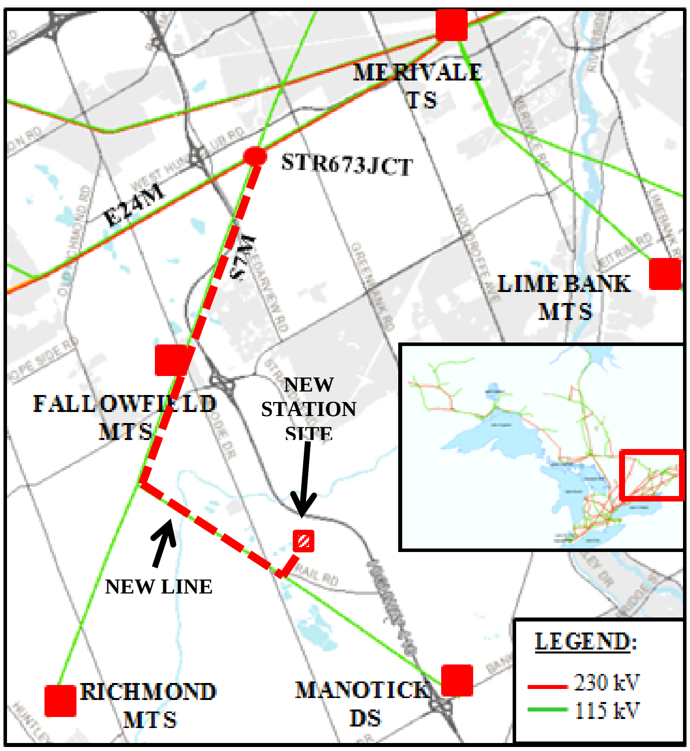
- Rebuilding of approximately 12 km of the existing 115kV single circuit line (S7M) with a new 230kV double circuit transmission line – from tower structure

[1] *http://www.ieso.ca/-/media/Files/IESO/Document-Library/regional-planning/Greater-Ottawa/2015-Ottawa-IRRP-Report.pdf*

#673 (noted as STR673JCT in the map below) to Hydro Ottawa's new station in South Nepean;

- Connection of one of the new 230kV circuits to the existing 230kV circuit (E34M) to supply Hydro Ottawa's new station;
- Connection of the other circuit of the new line to the 115kV circuit (S7M) to supply Fallowfield MTS, Richmond MTS, Manotick DS, and Hydro Ottawa's new station; and
- Modification of protection and control facilities associated with the existing circuits (E34M and S7M).

A map showing the project location is provided below.



Hydro One has initiated a Class Environmental Assessment for this project as required under the *Environmental Assessment Act*, and approvals are expected to be obtained by Q2 2019.

Witness: Robert Reinmuller

Hydro One will apply for a "Leave to Construct" approval under Section 92 of the *Ontario Energy Board Act* in Q2 2019. A summary of the need, project description, risk, and costs have been presented herein; with specific details to be provided in the Section 92 application. All land matters will be addressed in the Section 92 application.

Hydro One studies show that the project will not adversely affect the reliability of the IESO-controlled grid or service to other transmission connected customers. The System Impact Assessment and Customer Impact Assessment have been initiated. Both assessments will be completed by Q2 2019 to confirm the above prior to the submission of the Section 92 application.

Outcomes

This investment will provide the required increase in transmission capacity to supply load growth in South Nepean area.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Satisfy customer request for additional capacity.
Operational Effectiveness	• Improve operational flexibility and mitigate line losses by reconfiguring to a 230kV system.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License to provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recoverable through incremental revenue from the appropriate rate pool and capital contribution from the customers. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the Connection Cost Recovery Agreement ("CCRA"). The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

Table 1: Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total*
Capital[1] and Minor Fixed Assets	2.3	27.5	10.5	0.0	0.0	0.0	0.0	40.3
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**2.3**	**27.5**	**10.5**	**0.0**	**0.0**	**0.0**	**0.0**	**40.3**
Less Capital Contributions	2.3	26.5	10.0	0.0	0.0	0.0	0.0	38.8
Net Investment Cost	**0.0**	**1.0**	**0.5**	**0.0**	**0.0**	**0.0**	**0.0**	**1.5**

[1] Includes Overhead at current rates.
**These project costs are based on preliminary planner estimates; the detailed cost estimates will be presented in the Section 92 application.*

C. ALTERNATIVES

Two alternatives were considered to address the transmission capacity need. This is in line with the IESO's direction (refer to Appendix "A" below) and reaffirmation of the regional planning recommendations that a 230kV connection to meet the need had system benefits.

- Alternative 1: Rebuild approximately 9 km of existing 115kV single circuit (L2M) as a 230kV double circuit transmission line from Merivale TS to Limebank MTS and build a new 6 to 8 km single circuit 230kV line from Limebank TS to provide connection to the new Hydro Ottawa station.

- Alternative 2 (Recommended): Rebuild approximately 12 km of existing 115kV single circuit (S7M) as a 230kV double circuit transmission line to provide connection to Hydro Ottawa's new station using the existing 115kV circuit (S7M) corridor.

Both Alternative 1 and 2 would address the need; however Alternative 1 was not considered further due to the cost, community impact, and complexity of securing a new right of way. Alternative 2 is the recommended alternative as it utilizes the existing 115kV circuit (S7M) corridor and is the lowest cost alternative.

D. EXECUTION RISK AND MITIGATION

The risks with respect to execution of this investment as planned would be as a result of potential delays in securing the Section 92 and environmental assessment approvals. These risks will be mitigated by initiating the Section 92 application process and environmental assessment process in a timely manner soon after customer's consent to proceed with the project. There is also a risk that the customer requirements may change resulting in a delay or cancellation of the need for this project. The CCRA will allow Hydro One to recover the actual costs incurred even if the customer decides to cancel the project.

APPENDIX "A" – Letter from the IESO to Hydro One

ieso
Independent Electricity System Operator

1600 - 120 Adelaide Street West

April 25, 2016

Lance Jefferies
Chief Electricity Distribution Officer
Hydro Ottawa Limited

Bing Young
Director, System Planning
Hydro One Networks Inc.

Dear Mr. Jefferies and Mr. Young,

Re: Initiating a Transmission Project for Supplying the Growing Electricity Demand in the South Nepean Area of Ottawa

The purpose of this letter is to:

- Recommend that an integrated solution, which comprises conservation and additional transmission and distribution ("wires") facilities, be pursued at this time to meet the growing electricity demand in the South Nepean area of Ottawa ; and
- Request Hydro Ottawa and Hydro One to initiate work associated with the development of a new transmission station and connection line in the South Nepean area for an in-service date of 2021.

As you are aware, a regional planning Working Group for the Ottawa area, consisting of the Independent Electricity System Operator (IESO), Hydro One and Hydro Ottawa, has been active since 2011. In 2013, the planning process was restructured to conform to the timeline and requirements of the Ontario Energy Board (OEB) formalized Regional Planning Process. In April 2015 the IESO released an Integrated Regional Resource Plan (IRRP) for the Ottawa area, documenting a 20 year plan developed by the Working Group. That plan provided forecasts of electricity demand growth in the region, identified short, medium and long-term needs, presented possible solutions, and recommended near-term actions. In December 2015 Hydro One completed a Regional Infrastructure Plan (RIP) as a subsequent step of the regional planning process.

The IRRP identified two issues affecting the western portion of the City of Ottawa which required additional planning focus. First, the more immediate need to supply demand growth in the southwest corner of the City (referred to as the South Nepean area), and second, the longer-term need to reinforce the 115 kV supply capability in the broader West Ottawa area, which includes the supply to downtown Ottawa. These areas are shown in Figure 1 below.

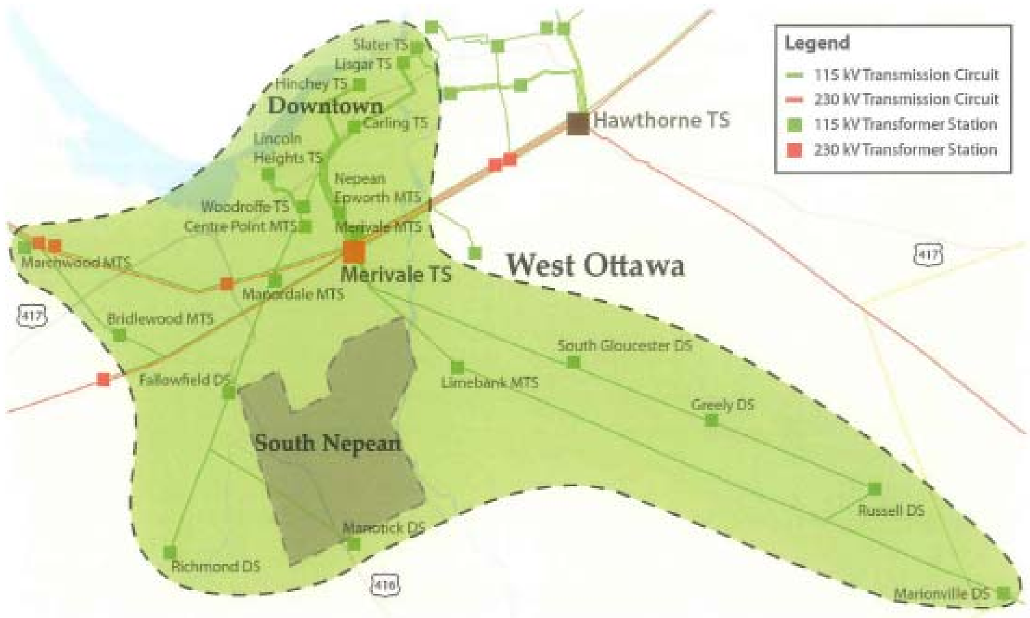

Figure 1. The South Nepean and West Ottawa areas.

While this letter is mainly focused on addressing the South Nepean issue, the proposed solution will contribute to relieving the broader West Ottawa supply issue.

Electricity Demand Growth in the South Nepean Community

For electricity planning purposes, the South Nepean service area is shown on the map in Figure 2, below. It is bounded by Fallowfield Road to the north, the Rideau River to the east, Bankfield Road to the south and Moodie Drive to the west. Hydro Ottawa, the local distribution company which serves customers in this part of the City, is forecasting robust electricity demand growth for this area. This forecast is consistent with the City of Ottawa's development plans for the area, including plans for the development of the Nepean Town Centre, the Strandherd Business Park, and residential developments that are associated with the Barrhaven South Community Design Plan, the Barrhaven South Urban expansion and Longfields Community Plan.

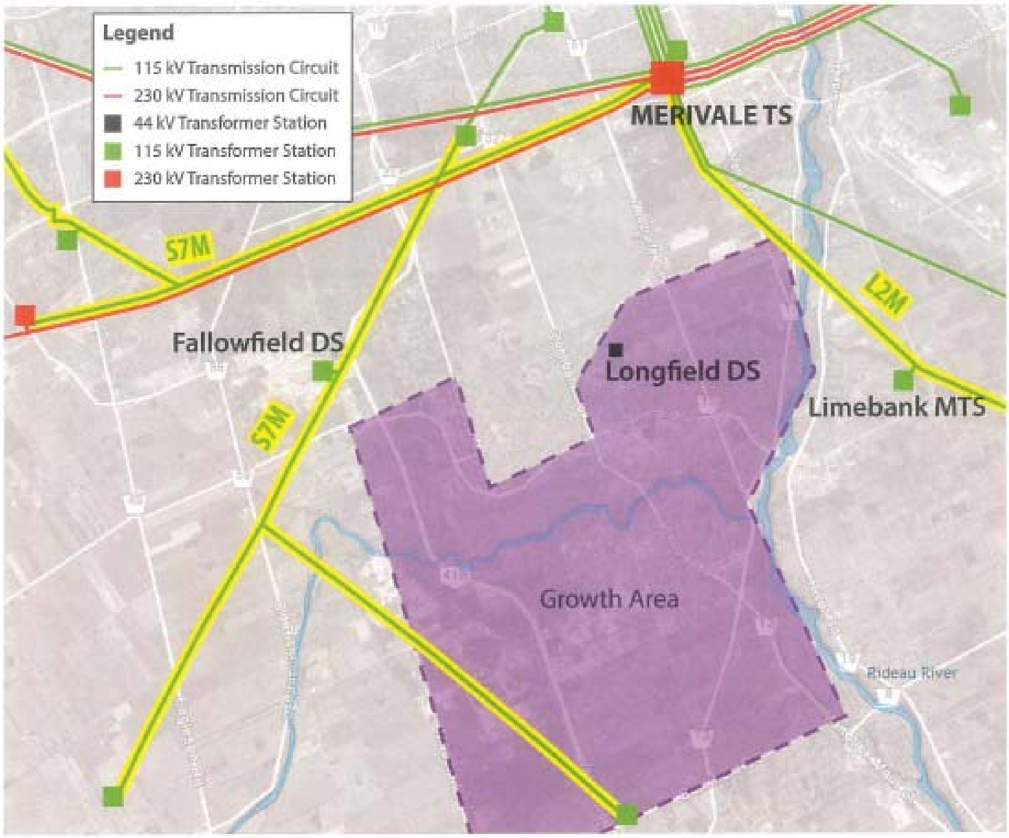

Figure 2. Electricity Supply to the South Nepean area.

The electricity demand in the South Nepean area peaked at 59 MW in the summer of 2015. Much of that demand was supplied from the provincial grid through the Merivale "hub" station in west Ottawa and delivered to the South Nepean area by two 115 kV transmission lines (S7M and L2M), and three step-down stations (Longfield DS, Limebank MTS and Fallowfield DS). These facilities are shown in Figure 2. In addition to the grid supply, there is some distributed generation connected to the three step-down stations, totaling about 7 MW, contributing to the area's supply.

The 115 kV network in the South Nepean area was originally developed to supply a relatively small number of customers in a rural area. Regional development has since given rise to significant demand growth on this legacy system as the area is being transformed into denser residential communities and commercial areas. With the forecasted growth, Hydro Ottawa anticipates the peak demand in the area to reach 88 MW by 2020 and 134 MW by 2032, an increase of about 78 MW, more than doubling today's level. This growth will place increased stress on the existing transmission and distribution infrastructure – the 115 kV line, step-down stations and distribution feeders. Over time these system elements will exceed their respective capacities.

Adequacy of Existing Supply to South Nepean

The Province's conservation initiatives are helping to manage future demand growth across the City of Ottawa. The forecast used for this planning study assumes that roughly 25% of growth in the South Nepean area will be met by increased efficiency, time of use savings, and conservation programs. Peak demand impacts associated with the aggressive conservation targets established in the 2013 LTEP were assumed before identifying the residual planning forecast, which is shown in Figure 3, below.

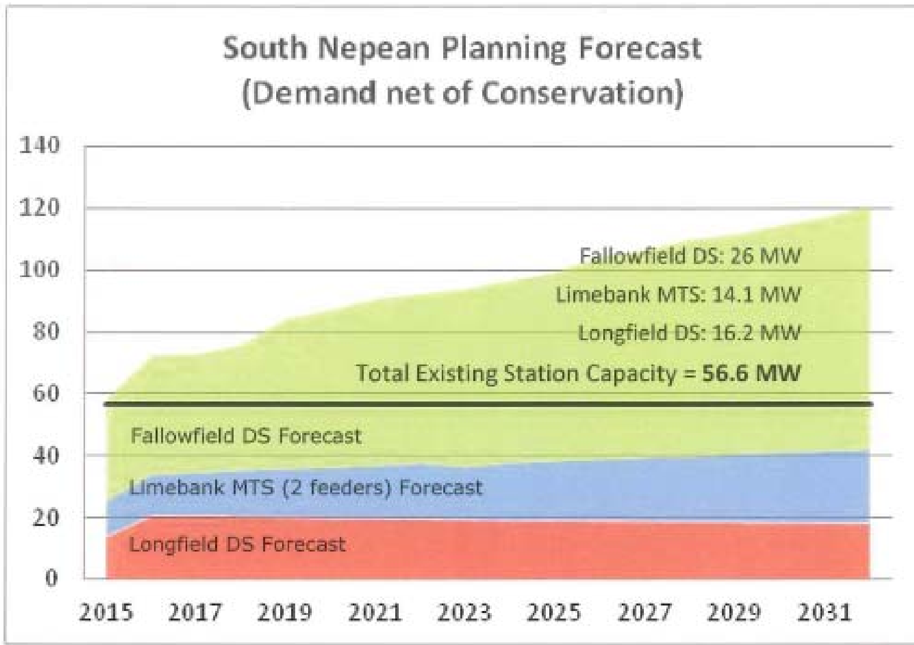

Figure 3. South Nepean Planning Forecast.

Figure 3 also shows that each of the three stations supplying South Nepean is reaching, or has already exceeded its planning capacity. Total supply capacity for South Nepean based on Hydro Ottawa's planning criteria is approximately 57 MW. This capacity is based on a combination of the ratings for the three stations, as well as the thermal ratings of individual feeders. The capability to transfer load at the distribution feeder level post contingency permits Hydro Ottawa to maintain reliable supply beyond the planning threshold, however this is not a permanent solution. Therefore, there is an imminent need to supply new connections in this growing corner of the City.

In addition to the station and feeder capacities being exceeded, the 115 kV single circuit transmission line, S7M, which provides the primary supply to this area and its surroundings, is also approaching its limit. The forecast demand on this circuit will reach its capacity of 108 MW in 2026. Therefore, solutions to relieving the station and feeder capacity constraints will also need to consider the line loading.

Solution Options Considered

Additional conservation, local generation, and transmission and distribution expansion were considered as means of increasing supply capacity in South Nepean. Given the near-term timing of the need for additional supply, in order for a solution to be feasible it must provide firm capacity in about five years, and be able to meet the total capacity need of over 60 MW by the end of the forecast period.

In order to rely entirely on conservation initiatives to provide additional capacity, more than four times the currently targeted level would need to be achieved. In terms of local generation, the magnitude of generation which would need to be connected to the distribution system in order to offset the need for additional station capacity is significantly higher than the historical uptake in the area. In addition, a distribution station like Fallowfield DS is not capable of absorbing a large amount of generation due to equipment rating limitations such as short circuit and thermal limits. New transmission connected generation in the area would not address the station limitation.

Based on the timeline and magnitude of the need for additional supply capacity in South Nepean, it is clear that it will not be feasible to address the need through additional conservation and local generation. Therefore, a new supply station and connection line are recommended for the South Nepean area.

Integrating Regional Transmission Considerations

As shown in Figure 1, South Nepean overlaps with the West Ottawa area, which is the 115 kV system supplied mainly by the Merivale hub station. A longer-term need to reinforce the 115 kV supply capability in West Ottawa was identified during the Ottawa area IRRP and in the RIP. The Merivale hub station has the capability of supplying roughly 645 MW and the 2015 peak demand in West Ottawa was 586 MW. The forecasted demand growth across West Ottawa, including the growth in South Nepean, will begin to exceed the Merivale hub capability as early as 2019. As a result of the overlap, if the new station in South Nepean is connected to the 230 kV system via a new 230 kV connection line into the area, it will take some pressure off the Merivale hub by moving demand growth off the West Ottawa 115kV system. The RIP report also reviewed potential wires solutions and indicated a preference for a 230 kV supply option if a wires solution were selected.

Community Engagement

In June of 2015 the IESO initiated the community engagement process by forming a Local Advisory Committee ("LAC") for the Greater Ottawa region consisting of eight volunteers from the community. Three meetings have been held thus far to discuss the issues which have been identified in the South Nepean and West Ottawa areas, and comments and advice have been received from the committee. Committee members generally agreed that there is a need to secure additional supply for the South Nepean area. While some LAC members support the recommended transmission solution, others feel that conservation and generation alternatives should be considered further. After consideration of the LAC's advice, transmission system expansion is nonetheless recommended, based on the magnitude and timing of the need for additional supply capacity, as well as the characteristics of the legacy system in the area. However, a broader range of solutions may be feasible to address other planning issues where there is a longer timeline and broader scope.

Summary of Recommended Integrated Plan

The IESO, on behalf of the Working Group, recommends that an integrated solution, which comprises conservation and additional transmission and distribution ("wires") facilities be pursued at this time to meet the growing electricity demand in the South Nepean area. This recommendation also contributes to a longer-term plan to address the broader needs across the West Ottawa area.

Hydro Ottawa and Hydro One are requested to initiate work associated with the development of a new transmission station and connection line in the South Nepean area for an in-service date of 2021.

The Working Group looks forward to engaging with local communities, LAC members, and the broader public while continuing to develop a long-term integrated plan for the Greater Ottawa region.

Kind regards,

Michael Lyle
Vice President, Planning, Law and Aboriginal Relations
Independent Electricity System Operator

SS-12 Aylmer-Tillsonburg Area Transmission Reinforcement

Start Date:	Q2 2020	**Priority:**	High
In-Service Date:	Q2 2022	**3 Year Test Period Gross Cost ($M):**	29.3
Trigger(s): Supply Reliability, Compliance			
Outcomes: Improve supply reliability to the Aylmer-Tillsonburg area.			

A. NEED AND OUTCOME

Investment Need

This investment is required to improve voltage performance and supply reliability issues in the Aylmer-Tillsonburg area. Aylmer TS and Tillsonburg TS are normally supplied by a 60 km single 115kV circuit (W8T) which emanates from Buchanan TS. The combined station summer peak load is forecast to increase from 106MW in 2016 to about 122MW by 2023.

Regional planning studies have identified a number of issues for the supply to the area:

- The HV and LV voltages at Tillsonburg TS do not meet the IESO's Ontario Resource and Transmission Assessment Criteria ("ORTAC"), under peak load conditions;
- The thermal ratings of a 1.5 km section of 115kV circuit (W8T) are exceeded; and
- The frequency of delivery point interruption at Tillsonburg TS falls below the minimum Customer Delivery Point performance standard.

These needs are described and documented in the London Area Regional Infrastructure Plan (Exhibit B, Tab 1, Schedule 1, TSP Section 1.2, Attachment 11). Upon the completion of the London Area Regional Infrastructure Plan, it was concluded that the transmission reinforcement will be required in order to provide voltage support and improve customer delivery performance.

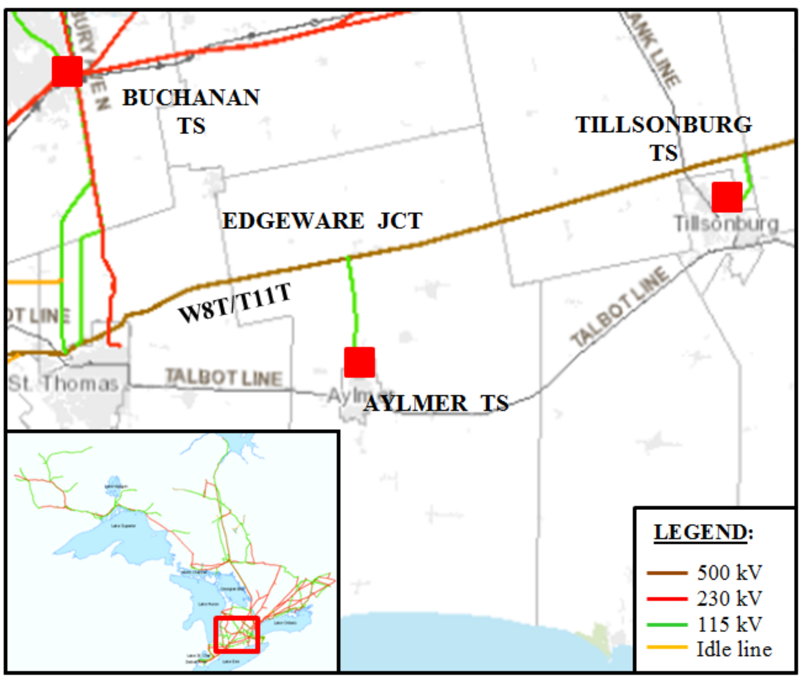
Not proceeding with this investment would result in inadequate supply capacity and reliability in the Aylmer-Tillsonburg area. This project is assigned a High Priority to improve supply to customers.

Investment Description

As per the need described above, the proposed project involves the:

- Installation of two capacitor banks on the 27.6kV bus at Tillsonburg TS to provide reactive power support; and
- Construction of 3.5 km of new 115kV single circuit transmission line from Cranberry Junction to Tillsonburg TS.

A map showing the project location is provided below.



Hydro One will apply for a “Leave to Construct” approval under Section 92 of the *Ontario Energy Board Act* in Q4 2019. A summary of the need, project description, risk, and costs have been presented herein; with specific details to be provided in the Section 92 application. All land matters will be addressed in the Section 92 application.

Hydro One will initiate a Class Environmental Assessment, as required under the *Environmental Assessment Act*, for this project in Q2 2019 with approvals planned to be obtained by Q4 2019.

Hydro One studies show that the project will not adversely affect the reliability of the IESO-controlled grid or service to other transmission connected customers. The System Impact Assessment and Customer Impact Assessment will be completed in 2019 to confirm the above prior to the submission of the Section 92 application.

Outcomes

This investment will address the supply capability issue and reduce risk of interruption to customers in the Aylmer-Tillsonburg area.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Improve supply reliability in the Aylmer-Tillsonburg area.
Operational Effectiveness	• Improve operational flexibility with provision of dual supply to Tillsonburg TS.
Public Policy Responsiveness	• Comply with the IESO's Ontario Resource and Transmission Assessment Criteria.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recovered from the appropriate rate pool(s) and/or capital contribution from the customers. Hydro One will be responsible for the cost of installation of low-voltage capacitors and will also partially fund the 115kV line extension to improve delivery point performance as per Hydro One's Customer Delivery Point Performance ("CDPP") Standard[1]. The remaining project cost will be recoverable through incremental revenue from the appropriate rate pool and/or capital contribution from the customers. The project costs and capital contribution amount are considered preliminary as they are only

[1] *The CDPP Standard is provided in Attachment 1 of Exhibit D, Tab 2, Schedule 1.*

finalized after the project is placed in-service, subject to the terms of the CDPP Standard and Capital Cost Recovery Agreement. The final capital contributions will be determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

Table 1: Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	1.0	10.0	13.1	6.1	0.0	0.0	0.0	30.2
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**1.0**	**10.0**	**13.1**	**6.1**	**0.0**	**0.0**	**0.0**	**30.2**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**1.0**	**10.0**	**13.1**	**6.1**	**0.0**	**0.0**	**0.0**	**30.2**

[1] Includes Overhead at current rates.

C. ALTERNATIVES

Hydro One has considered two alternatives to address the voltage, thermal and customer delivery point performance needs of the sub-region. These alternatives are as follows:

- Alternative 1: Maintain a single supply to Tillsonburg TS; reconfigure existing 115kV circuits in the area by connecting W8T and T11T in parallel.

- Alternative 2: Provide a second 115kV supply by extending the existing 115kV circuit (T11T) by approximately 4 km from Cranberry Junction to Tillsonburg TS.

Both alternatives include the installation of reactive power support at Tillsonburg TS.

While Alternative 1 and 2 can both improve voltage performance and address thermal overload of the 115kV system in the local area, Alternative 1 may worsen the customer delivery point performance to Tillsonburg TS as exposure to interruption is increased due to longer length of line. The preferred option will be selected in consultation with the London Area regional planning stakeholders in Q1 2019. Cost and timeline presented above reflect that of Alternative 2.

D. EXECUTION RISK AND MITIGATION

The risks with respect to execution of this investment as planned would be as a result of potential delays in securing the Section 92 and environmental assessment approvals. These risks will be mitigated by initiating the Section 92 application process and environmental assessment process in a timely manner soon after customer's consent to proceed with the project.

SS-13 Leamington Area Transmission Reinforcement

Start Date: Q1 2019	**Priority:** High
In-Service Date: Q2 2024	**3 Year Test Period Gross Cost ($M):** 73.8
Trigger(s): Customer Request	
Outcomes: Increase load supply capability and enable customer load connection in the Leamington area.	

A. NEED AND OUTCOME

Investment Need

This investment is required to reinforce the transmission system in the Windsor – Essex region and to increase load supply capability in the Leamington area. The existing bulk transmission in the Windsor – Essex region consists of 230kV circuits (C21J, C22J, C23Z and C24Z). These circuits pass through the Leamington Junction where 230kV circuits (C21J and C22J) are tapped off to supply Leamington TS and the planned transmission-connected customer stations. Hydro One Distribution has indicated a substantial increase in requests for load connection in the Leamington – Kingsville area driven by expansion in the greenhouse sector and the existing transmission system cannot support this additional load demand. This need for transmission reinforcement has been highlighted by the IESO in the Scoping Assessment[1] as part of its development of the 2019 Windsor-Essex Integrated Regional Resource Plan.

Hydro One is obligated under its Transmission License to accommodate connections when requested by customers. Not proceeding with this investment would directly and adversely impact Hydro One's ongoing capability to reliably supply customers need in this area. This investment is assigned a High Priority given the requirement to meet customer needs in a timely manner.

[1] http://www.ieso.ca/-/media/Files/IESO/Document-Library/regional-planning/Windsor-Essex/2018-Windsor-Essex-Scoping-Assessment-Outcome-Report.pdf

Investment Description

The proposed project involves building a new 230kV switching station at Leamington Junction, and a new 230kV double circuit line between the new station and Chatham SS to reinforce the area load supply capability. A Dual Element Spot Network ("DESN") station will also be built at Leamington Junction to supply new customer load. Hydro One proposes to execute the project in two stages. Stage 1 will address the station work to facilitate customer connection and Stage 2 will address the line work, as follows:

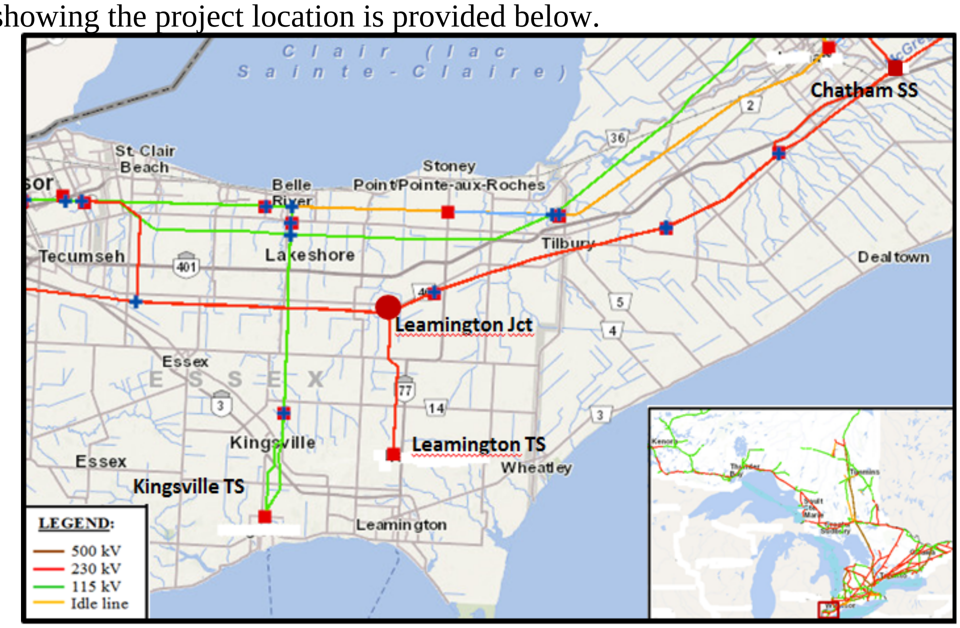
<u>Stage 1</u>: Station work (Target In-Service for Q4 2022)

- Build a new 230kV switching station at Leamington Junction and sectionalize the existing 230kV circuits (C21J, C22J, C23Z and C24Z). Connect this new switching station to the existing tap to Leamington TS; and
- Build a new 75/125MVA, 230/27.6kV DESN station with twelve feeders at Leamington Junction.

<u>Stage 2</u>: Line Work (Target In-Service for Q2 2024)

- Build a new 230kV transmission line, approximately 50 km long, from Chatham SS to the new switching station at Leamington Junction; and
- Modify Chatham SS to connect the new line into the 230kV switchyard.

A map showing the project location is provided below.



Hydro One will initiate a Class Environmental Assessment process, as required under the *Environmental Assessment Act*, for this project in Q1 2019 and approvals are expected to be obtained by Q1 2020.

Hydro One will apply for a "Leave to Construct" approval under Section 92 of the *Ontario Energy Board Act* in Q1 2020. A summary of the need, project description, risk, and costs have been presented herein; with specific details to be provided in the Section 92 application. All land matters will be addressed in the Section 92 application.

Hydro One studies show that the project will not adversely affect the reliability of the IESO-controlled grid or service to other transmission connected customers. The System Impact Assessment and Customer Impact Assessment will be undertaken to confirm the above prior to the submission of the Section 92 application.

Outcomes

This investment will reinforce the transmission system in the Windsor – Essex region to increase load supply capability for the Leamington area.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Satisfy customer request for additional capacity.
Operational Effectiveness	• Enhance reliability of supply in the Leamington area.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License to provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recovered from the appropriate rate pool and capital contribution from customers. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the Connection Cost Recovery Agreement. The capital contributions are determined as per Hydro One's

Transmission Customer Contribution Policy in accordance with the Transmission System Code.

Table 1: Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total

[1] Includes Overhead at current rates.

C. ALTERNATIVES

Hydro One considered two alternatives to provide the required additional capacity for the area:

- Alternative 1: Upgrade the four existing 230kV circuits between Chatham SS and Leamington Junction with a higher capacity conductor and build a new switching station and DESN station at Leamington Junction.

- Alternative 2 (Recommended): Build a new 230kV double circuit line between Chatham SS and Leamington Junction and build a new new switching station and DESN station at Leamington Junction.

Alternative 1 would not provide an adequate supply capacity for the longer term. It has lower supply reliability and construction will be very challenging because of the difficulty in obtaining outages. By-pass circuits will be required to ensure that existing loads can continue to be supplied while the circuits are being uprated. Alternative 2 requires building a double circuit line on a new right of way. It provides higher capacity and maintains reliability during the construction phase. Alternative 2 is therefore the preferred alternative and recommended by the IESO and Hydro One.

D. EXECUTION RISK AND MITIGATION

The risks with respect to the execution of this investment as planned would include, potential delays in securing the Section 92 and environmental assessment approvals. These risks will be mitigated by initiating the Section 92 application process and environmental assessment process in a timely manner.

SS-14 Southwest GTA Transmission Reinforcement

Start Date:	Q2 2020	**Priority:**	High
In-Service Date:	Q2 2024	**3 Year Test Period Gross Cost ($M):**	25.0
Trigger(s): Supply Reliability			
Outcomes: Increase supply reliability and support future load growth for the customers in the Southwest GTA area.			

A. NEED AND OUTCOME

Investment Need

This investment is required to increase the transfer capability between Richview TS and Manby TS to support the continued load growth in the South-West GTA area, as identified in the Metro Toronto Area Regional Infrastructure Plan (Exhibit B, Tab 1, Schedule 1, TSP Section 1.2, Attachment 8).

The 230kV transmission corridor between Richview TS and Manby TS is the main supply path for the western half of the City of Toronto. It also supplies the load in the southern Mississauga and Oakville areas via Manby TS. The corridor has two 230kV double-circuit lines (R1K/R2K and R13K/R15K) and one idle 115kV double-circuit line. The Metro Toronto Area Regional Infrastructure Plan had identified the need for reinforcing the transmission system on the South-West GTA transmission corridor by rebuilding the existing idle 115kV transmission line as a new 230kV double circuit line and connecting it to Manby TS and Richview TS.

Investment Description

The proposed project involves reinforcing the transmission system on South-West GTA transmission corridor. Hydro One proposes to execute the project in two stages. Stage 1 will address the line work and Stage 2 will address the station work in order to coordinate with future breaker replacement work at Manby TS, as follows:

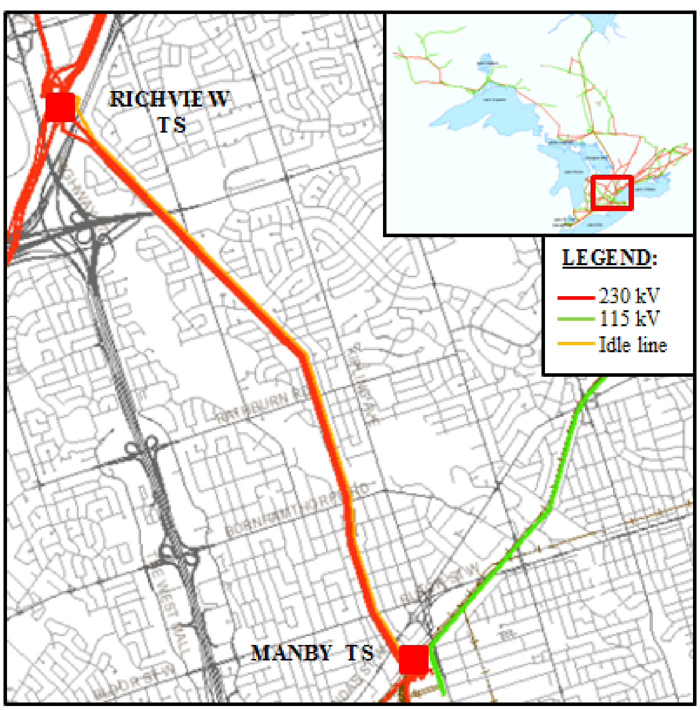
<u>Stage 1</u>: Line Work (Target In-Service for Q4 2022)

- Rebuild the existing 6.5 km idle 115kV double-circuit line as a 230kV double-circuit line;
- Connect the new 230kV conductors in parallel with existing 230kV circuits (R2K and R15K) at Richview TS and Manby TS; and
- Modify the protection and control settings at Richview TS and Manby to incorporate the new line.

<u>Stage 2</u>: Station Work (Target In-Service for Q2 2024)

- Remove the parallel connections made in Stage 1 and terminate the two new circuits into Manby TS 230kV switchyard;
- Connect new circuits at the Richview TS end to two of the existing 230kV transmission circuits from Claireville TS to Richview TS; and
- Add and/or modify protection and control equipment at Richview TS, Claireville TS and Manby TS to incorporate the two new circuits.

A map showing the project location is provided below.



Hydro One initiated a Class Environmental Assessment process, as required under the *Environmental Assessment Act*, for this project in Q4 2018 and approvals are expected to be obtained by Q3 2019.

Hydro One will apply for a "Leave to Construct" approval under Section 92 of the *Ontario Energy Board Act* in Q3 2019. A summary of the need, project description, risk, and costs have been presented herein; with specific details to be provided in the Section 92 application.

Hydro One studies show that the project will not adversely affect the reliability of the IESO-controlled grid or service to other transmission connected customers. The System Impact Assessment and Customer Impact Assessment will be undertaken to confirm the above prior to the submission of the Section 92 application.

Outcomes

This investment will provide the required increase in supply reliability for the customers in Toronto and southern Mississauga/ Oakville areas and support future load growth.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Ensure adequate supply capacity to support future load growth.
Operational Effectiveness	• Increase supply reliability in the Southwest GTA area.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, will be recovered from the network rate pool as these 230kV facilities are network assets and no capital contribution is required from customers.

Table 1: Total Investment Cost

($ Millions)	Prev. Years	2020	2021	2022	2023	2024	Future Years	Total
Capital[1] and Minor Fixed Assets	2.9	10.3	7.8	6.9	3.9	2.0	0.0	33.8
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**2.9**	**10.3**	**7.8**	**6.9**	**3.9**	**2.0**	**0.0**	**33.8**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**2.9**	**10.3**	**7.8**	**6.9**	**3.9**	**2.0**	**0.0**	**33.8**

[1] Includes Overhead at current rates.

C. ALTERNATIVES

Three alternatives were considered to provide additional capacity:

- Alternative 1: Upgrade the four existing 230kV circuits between Richview TS and Manby TS with higher capacity conductor.

- Alternative 2 (Recommended): Rebuild the existing idle 115kV transmission line on the Richview to Manby transmission corridor as a 230kV double circuit transmission line and connect at Manby TS and Richview TS.

- Alternative 3: Extend the existing 230kV transmission line between Cooksville TS and Oakville TS to Trafalgar TS.

Alternative 1 provides lower supply reliability and construction will be very challenging because of the difficulty in obtaining outages. Alternative 3 requires building a line on a new right of way resulting in a higher cost. Alternative 2 is the lowest cost alternative, and maintains reliability during the construction phase. Alternative 2 is therefore the recommended alternative. This is in line with the recommended plan in the Metro Toronto Area Regional Infrastructure Plan.

D. EXECUTION RISK AND MITIGATION

The risks with respect to execution of this investment as planned would be as a result of potential delays in securing the Section 92 and environmental assessment approvals. These risks will be mitigated by initiating the Section 92 application process and environmental assessment process in a timely manner.

SS-15 Future Transmission Regional Plans

Start Date:	Program	**Priority:**	High
In-Service Date:	Program	**3 Year Test Period Gross Cost ($M):**	10.5
Trigger(s): Customer or Third Party Request			
Outcome: Respond to future regional plan projects.			

A. NEED AND OUTCOME

Investment Need

This investment is required to enable Hydro One to accommodate future transmission regional plan projects that may be triggered during the second cycle of the regional planning process, as documented in Exhibit B, Tab 1, Schedule 1, TSP Section 1.2, for which the need and scope have yet to be determined.

Regional plans are initiated based on customer needs for load supply capability and reliability. Hydro One is obligated to meet these needs when requested by customers. Not proceeding with this investment would be a violation of Hydro One's Transmission License. This investment is assigned a High Priority to ensure customer future needs are addressed in a timely manner.

Investment Description

This investment has been set up to cover future local area supply projects anticipated in the test period. These projects need and scope have not yet been identified at this time. Local area supply projects are identified during regional planning and address issues with supply facilities that connect and deliver power to a group of load stations in an area or region. Each project would be initiated based on a need identified within a Regional Infrastructure Plan.

The scope of these projects may include: new or modified transformation connection facilities, or construction of new connection lines and/or stations, and installation of breakers and/or circuit switchers. Each project would be specific to the local area and entail Hydro One to construct one or more of the above listed facilities.

Each project start is subject to obtaining all necessary regulatory and environmental approvals. The System Impact Assessment and Customer Impact Assessment will also be carried out for each project to ensure that there are no adverse impacts to the system or other transmission connected customers.

Outcomes

This investment will address specific needs for various local areas as identified in the second cycle of the regional planning process.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Ensure adequate supply capacity for the local area.
Public Policy Responsiveness	• Comply with Hydro One's obligation under its Transmission License to provide customers with non-discriminatory access.

B. EXPENDITURE PLAN

This investment is non-discretionary. The project costs, as presented in the table below, have been forecasted based on typical costs incurred by local supply projects over the past five year period. The project costs will be recovered from the appropriate rate pool and capital contribution from customer(s), determined on a project-by-project basis in accordance with the Transmission System Code. The project costs and capital contribution amounts are considered preliminary as they are only finalized once the project is placed in-service subject to the terms of the Connection Cost Recovery Agreement. The capital contributions are determined as per Hydro One's Transmission Customer Contribution Policy in accordance with the Transmission System Code.

The projects' actual in-service costs would be included in the rate base when the projects go into service subject to Board approval. For any projects that require "Leave to Construct" approvals, under Section 92 of the *Ontario Energy Board* Act, prudency of the expenditures will be tested during the Section 92 process.

Table 1: Total Investment Cost

($ Millions)	2020	2021	2022	2023	2024	Total[1]
Capital[2] and Minor Fixed Assets	0.0	0.0	10.5	19.6	0.0	30.1
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**0.0**	**0.0**	**10.5**	**19.6**	**0.0**	**30.1**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**0.0**	**0.0**	**10.5**	**19.6**	**0.0**	**30.1**

[1] Due to the in-year nature of program investments, only 2020 to 2024 expenditures are shown.
[2] Includes Overhead at current rates.

C. ALTERNATIVES

This investment will be in response to a specific need identified during the regional planning process; alternatives (if any) will be reviewed as part of this planning process.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of the project, such as: the outage availability that is required for the work to be executed. These risks will be mitigated by setting a schedule that aligns with outage availability.

SS-16 Customer Power Quality Program

Start Date:	Program	**Priority:**	High
In-Service Date:	Program	**3 Year Test Period Gross Cost ($M):**	10.1
Trigger(s): Customer Engagement			
Outcomes: Improve customer power quality.			

A. NEED AND OUTCOME

Investment Need

This investment is required to mitigate the power quality impact of shunt capacitor bank switching on customers with sensitive equipment.

Shunt capacitor banks are employed on Hydro One’s transmission system for power factor correction and voltage support. Capacitor bank switching results in voltage transients and can adversely impact nearby industrial and commercial customers as variable speed drives and other sensitive customer loads are tripped. With the continued implementation of new technologies and equipment at the customer's end it is anticipated that there will be increased sensitivity to these transients by customers.

Voltage transients can be mitigated by installing a new device – the “Cap-Switcher” – to switch the capacitor bank. The device reduces the switching voltage transients and thereby significantly improves the power quality to connected customers. The significant reduction of power quality events was confirmed at recent installations.

Not proceeding with this investment would result in adverse impact on customers’ operations and satisfaction. This project is assigned a High Priority to ensure responsiveness to customer needs.

Investment Description

This proposed program involves the installation of cap-switchers at a number of Hydro One stations. The stations are selected based on the severity of the transient overvoltages experienced when switching the existing capacitor bank, as well as on the basis of feedback from customers.

The proposed plan is based on installing approximately 20 cap-switchers over a five year period. Eighteen capacitor banks at ten transformer stations (Cherrywood TS, Thornton TS, Wilson TS, St. Andrew TS, Erindale TS, Woodstock TS, Beaverton TS, Smith Falls TS, Manby TS, and Waubaushene TS) have been identified so far as requiring installation of these devices to reduce capacitor switching transients. Further studies are under way to identify the remaining cap-switcher installations locations.

Outcomes

This investment will mitigate the adverse effects of capacitor switching and improve the power quality for customers affected by switching transients.

The following table summarizes the anticipated benefits as a result of the project:

Customer Focus	• Improve customers' supply by reducing the risk of tripping sensitive loads.
Operational Effectiveness	• Reduce switching transients on the system to facilitate switching operations of capacitor banks without disrupting customer loads.

B. EXPENDITURE PLAN

The project costs, as presented in the table below, will be recovered from the network rate pool as these Cap-Switchers are network assets and thus no capital contribution is required from customers.

Table 1: Total Investment Cost

($ Millions)	2020	2021	2022	2023	2024	Total[1]
Capital[2] and Minor Fixed Assets	3.3	3.4	3.4	3.4	3.5	17.0
Less Removals	0.0	0.0	0.0	0.0	0.0	0.0
Gross Investment Cost	**3.3**	**3.4**	**3.4**	**3.4**	**3.5**	**17.0**
Less Capital Contributions	0.0	0.0	0.0	0.0	0.0	0.0
Net Investment Cost	**3.3**	**3.4**	**3.4**	**3.4**	**3.5**	**17.0**

[1] Due to the in-year nature of program investments, only 2020 to 2024 expenditures are shown.
[2] Includes Overhead at current rates.

C. ALTERNATIVES

No alternative was considered. This investment is in response to specific power quality concerns that have been identified by customers and for which Hydro One has committed to addressing the concerns.

D. EXECUTION RISK AND MITIGATION

No major execution risk is expected. However, there is potential for normal project risks that may affect the timely completion of this project, such as: the outage availability that is required for the work to be executed. These risks will be mitigated by setting a schedule that aligns with outage availability.

Notes on year over year Plan vs. Actual variances for Total Expenditures

TSP Section 3.3

Notes on Plan vs. Actual variance trends for individual expenditure categories

TSP Section 3.3

CAPITAL WORK EXECUTION STRATEGY

1. INTRODUCTION

Hydro One has the ability to successfully execute large capital work plans and reduce the variability of its capital and in-service additions. Because of the implementation of new or improved initiatives and capital delivery processes, Hydro One will continue to improve on its past performance. These initiatives and processes include:

a) Hydro One project managers oversee project delivery early in the process, beginning at the Project Scoping phase. This reduces the number of project changes made in the Execution phase and provides a consistent and accountable vision of the project throughout its lifecycle;
b) Hydro One re-configured its Primavera 6 scheduling tool to develop standardized project schedule reports and standardized cost and performance comparisons on an aggregate basis;
c) Hydro One adopted the American Association of Cost Engineers ("AACE") estimating framework, which is an industry established cost estimating classification system which allows the company to standardize its approach to estimating and project planning;
d) Hydro One has implemented a new risk definition and management program;
e) Hydro One has improved its change management process to more accurately track costs and forecast and communicate variances in resourcing and cash flow; and
f) Hydro One has introduced a number of new reporting and governance frameworks that provide greater transparency into and accountability for the capital delivery program.

Hydro One's work planning and execution activities focus on the company's business objectives including safety, quality, efficiency, and meeting customer commitments. As a result, Hydro One takes an efficient, adaptable approach to its capital work program, which gives it flexibility to accommodate new circumstances that may arise over the course of a multi-year project such as outage constraints, external approvals, material delivery, site conditions, evolving customer needs, changing priorities, and emergent investments. Hydro One is committing to executing its proposed capital work program using the process and framework set out herein.

2. IMPROVEMENTS OVER TIME

Hydro One has demonstrated its ability to improve on the execution of its work program while reducing the variability of its capital and in-service additions. Table 1 below shows the five-year variance between approved and actual capital and in-service additions between 2014 and 2018. Over the past five years, the company placed $4,556.4 million in-service with an overall variance of 3.5% and modest variances in 2018 when Hydro One placed $1,160.4 million in-service demonstrating its ability to meet its target at a portfolio level. Indeed, the company's recent performance reflects the initial effects of the improvements described in the introduction and further described in section 5 below.

Table 1: Capital and In-Service Additions Performance ($ millions)

	Capital Expenditures		**In-service Additions**	
	Actual	**Approved**	**Actual**	**Approved**
2014	844.7	899.2	914.5	863.3
2015	943.0	899.4	699.1	821.3
2016	986.7	866.3	910.2	673.3
OEB-Approved Cumulative ISA Total for 2014-2016[1]	2,774.4	2,664.9	2,523.8	2,357.9
2017	953.9	950.0	872.2	867.7
2018	**967.3**	**1,000.0**	**1,160.4**	**1,178.4**
Total (2014 to 2018)	**4,695.4**	**4,614.9**	**4,556.4**	**4,404.0**
5-Year Variance	**1.7%**		**3.5%**	

Throughout 2017 and 2018, Hydro One achieved $2,032.6 million of in-service additions which is within 1% of the OEB-approved plan total for those years, demonstrating its ability to achieve results very close to target at a portfolio level.

3. RESOURCES TO EXECUTE

To execute the capital portfolio over the test period, from 2020 to 2022, Hydro One has a range of resources available to it. Hydro One has internal resources, manages a direct-hire casual building trades workforce and is able to supplement these resources through contracts with qualified service providers. Hydro One contracts a variety of services to

[1] In 2016, Hydro One placed $910.2 million in-service to achieve the OEB- approved cumulative 2014 to 2016 in-service additions of $2,357.9 million. The 2016 actuals are in-line with the 2016 "Bridge Projected" in EB-2016-0160, Exhibit D1, Tab 1, Schedule 2, Table 1 with a variance of $1.5 million dollars. The Bridge Projected for 2016 was $911.7 million.

help deliver its capital work program including: third party Engineer, Procure, Construct ("EPC") services for select projects; specialty construction skills that are not retained within Hydro One (i.e. tunnelling, high voltage cable installation); and specialty equipment rentals with operators (e.g. cranes, day lighting / vacuum trucks). In January 2017, as part of the strategic vision to build partnerships in the construction industry, Hydro One identified qualified service providers for line refurbishments, buildings, substations and high voltage cable work. Hydro One uses a competitive Request For Proposal ("RFP") process to select from the qualified service providers for particular work.

4. CAPITAL DELIVERY PROCESS

Hydro One's capital delivery process is illustrated in Figure 2 below and is comprised of three key stages: (i) Planning; (ii) Project Definition, which includes Project Scoping and Project Planning; and (iii) Execution, which includes Project Execution and Project Close. Each project has a "Primavera 6" or "P6" schedule that is refined throughout the process comprised of scope, schedule and cost elements and must pass through certain stage gates before proceeding to the next phase. Cost and schedule accuracy improves throughout the process, which is further described below.

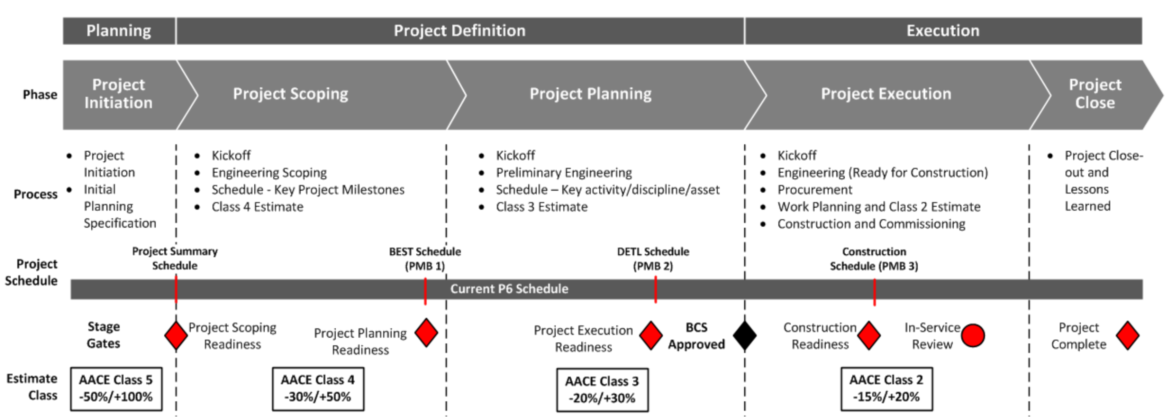

Figure 2: Transmission Capital Project Delivery Model

In early 2017, Hydro One made improvements to its capital delivery process, primarily in the Project Definition phase. These are described in section 5 below. These initiatives will result in greater efficiencies in execution when projects reach the Execution phase.

4.1 THE PLANNING PHASE

The Planning phase coincides with Hydro One's Investment Planning process as described in the TSP Section 2.1. During the Planning phase, Hydro One identifies project needs, develops a high-level project scope and prioritizes investments using its risk-based methodology. Lines of business are included in the planning process to ensure the investment plan is realistic and achievable, to clarify assumptions and to identify interim milestones for the subsequent Project Definition phase so the company can monitor its progress and identify challenges earlier in the process. As a result of this work, a high-level project summary schedule and cost forecast are identified using a unit price catalogue and/or comparator projects. The cost forecast is within the range of an AACE Class 5 estimate (minus 50% to plus 100%).

4.2 PROJECT DEFINITION PHASE

Project Definition consists of two phases: Project Scoping and Project Planning as further described below. This phase is led by project managers who lead a cross-functional team of Hydro One professionals with functional accountabilities including engineering, project controls, real estate, environmental approvals and compliance, construction services, system operations, and maintenance workgroups, as well as lines of business representing customers, communities (including First Nations and Métis communities) and external agencies.

In each of the Project Scoping and Project Planning phases, the scope of work and project execution plan may be further refined including: the work plan, the integrated project schedule and cost estimates (including risk registers and basis of estimate). As more work is completed, estimates improve and potential variability decreases.

4.2.1 PROJECT SCOPING

The objective of Project Scoping is to finalize the scope of work. Alternative designs may be identified and evaluated during this phase to assist in this process.

The project manager conducts a site meeting with the project team to review the constructability, operability, maintainability, safety and environmental impacts of the project. This gives Hydro One an opportunity to identify any outage requirements or incremental scope such as components that may need to be made compliant with applicable standards. Hydro One also identifies long-lead materials requiring procurement or environmental assessment requirements to be completed during the subsequent Project Planning phase. Anticipated execution risks and potential outage issues arising from customer constraints or geographic concerns may also be incorporated into the project plan in this phase. At the end of this phase, a preliminary project execution plan is completed which contains an estimate based on unit cost and a schedule which identifies relevant milestones selected from a pre-determined list. The project must also pass through the Project Planning Readiness stage gate before proceeding to the next phase.

An AACE Class 4 estimate with an accuracy range of minus 30% to plus 50% is prepared using unit cost-based estimates and available site specific information. The maturity level of the project definition deliverables is in the order of 15% complete.

4.2.2 PROJECT PLANNING

In Project Planning, Hydro One prepares a project execution plan that captures the scope, schedule and cost requirements and identifies risks that have the potential to change the project scope, schedule or cost. During this phase Hydro One may conduct preliminary community engagements. The project execution plan includes the following items, as referenced in the capital delivery process diagram at Figure 2:

- Schedule: a more comprehensive schedule is prepared at this point identifying key activities by discipline and asset (for instance timeframe to construct foundations, breakers, transformers, etc.);
- Risk workshop: to quantitatively analyze risk and develop project contingencies, a risk workshop is conducted for all projects over $10 million to identify the potential likelihood and consequence of project risks materializing, which informs the project contingency;
- Outage plan: a preliminary outage staging plan is prepared to identify work being executed each year, elements that may have to be taken out of service, system constraints, and contingency plans or bypasses if an outage is not an option; and
- Engineering package: At the conclusion of this phase, all major material and engineering studies and surveys are complete and basic layout drawings including the phasing of work are determined.

This package is reviewed by the project delivery team as part of the Project Execution Readiness stage gate.

Between the Project Planning and Execution, the final plan is reviewed and approved by senior management. Upon approval, it is largely expected that the project will be executed per scope, cost and timeline set out in the project plan, within the estimate accuracy range (as described in the paragraph below).

An AACE Class 3 estimate with an accuracy range of minus 20% to plus 30% is prepared using information provided in the engineering deliverables and project execution plan. The maturity level of deliverables in the project definition phase is in the order of 25% complete for stations projects and up to 75% complete for lines projects.

4.3 EXECUTION PHASE

In the Execution Phase, work moves through the Project Execution and Project Close sub-phases. Project Execution contains three steps: (i) detailed engineering and procurement; (ii) construction; and (iii) commissioning, as set out in Figure 2 above and described below.

4.3.1 PROJECT EXECUTION - DETAILED ENGINEERING AND PROCUREMENT

In this phase, detailed design packages are developed and issued for construction, environmental approvals are obtained and major equipment is procured. Once most of the production engineering work is complete, a significant component of variability is removed from the project and it is reasonable to expect that the cost, planned accomplishments, and schedule milestones will be met within the specified tolerance, barring extraordinary circumstances.

4.3.2 PROJECT EXECUTION - CONSTRUCTION

Starting in 2018, Hydro One will take the opportunity to review its ready for construction civil engineering packages, update its plan and verify it costs before moving into construction where errors and changes are expensive and could cause delays.

In Project Execution, the project is built to the required technical standards and detailed engineering specifications. The project manager is responsible for coordination of all contributing workgroups to deliver the work plan on time and in a manner that is safe and cost effective. The project manager monitors the work plan through regular communication with construction; manages change order requests if required; ensures the timely delivery of material, equipment and drawings; and provides monthly cost, schedule and work accomplishment (scope) updates on the project for the purposes of month-end reporting as described below in section 5.3 under Portfolio Management. Detailed job planning and daily onsite planning meetings are used as key communication tools during the process from site preparation and civil/electrical work to major equipment installation and site remediation activities to ensure the safe execution of planned work.

4.3.3 PROJECT EXECUTION - COMMISSIONING

When construction is complete, the project is handed to the Station Services and Operating divisions for formal site acceptance testing and commissioning before the asset is transferred to the Ontario Grid Control Centre. This step ensures quality, safety, efficiency and readiness of the new assets.

4.3.4 PROJECT CLOSURE

The project closure process was introduced as a new stage gate in 2018 to ensure that all post in-service project closure activities were completed within agreed upon timelines. This will ensure that the newly built or refurbished assets are transitioned into operations in a timely manner and that all records, drawings and systems are updated to reflect the assets as-built.

A site meeting is held for capital projects with a budget of $5 million or greater to review project objectives, ensure they have been met and to discuss ‘lessons learned’. The project closure process engages key individuals who participated in the capital work program life cycle to ensure knowledge transfer for future projects and to reinforce a culture of continuous improvement.

5. PRODUCTIVITY AND EFFICIENCY IMPROVEMENTS – PROJECT DEFINITION

Hydro One has recently undertaken a number of initiatives to increase the effectiveness and efficiency of its capital work program delivery. These initiatives are described in the following sections.

5.1 PROJECT MANAGEMENT

In April 2017, Hydro One aligned project management accountabilities under one team. Project Delivery Managers (“PM”) were identified as being accountable for a project at the beginning of the Project Scoping phase rather than previously at the Project Execution phase. This reduced the handoffs in the project lifecycle and provided a consistent approach to execution planning thereby giving the PMs the authority to design the project execution plan from the beginning, with the input of all supporting lines of business, rather than after the budget and schedule is defined. This will lead to earlier recognition of potential project issues and risks and increase the likelihood of delivering projects on scope, schedule and cost with acceptable levels of change.

5.2 PROJECT CONTROLS

Hydro One's Project Controls office has made improvements to its processes and tool suite for the following: (i) estimating; (ii) scheduling; (iii) project change management; and (iv) risk management.

Estimating: In 2017, Hydro One adopted the AACE Classification Scheme which is an industry-established estimating classification scheme intended to appropriately communicate and set expectations for estimate accuracy by project phase based upon the maturity of underlying deliverables associated with planning/engineering/construction work that has been completed. Hydro One is working on a quality assurance process using the AACE methodology to ensure the inputs and outputs of each phase are consistent. Hydro One is also in the process of capturing a performance measurement baseline estimate and schedule at the end of each phase to be compared to actual results to ensure that the mapping is accurate. This baseline will also improve the lessons learned process as it will provide a consistent time and value to compare back to.

Scheduling: In 2017, Hydro One rebuilt and refreshed its Primavera P6 scheduling tool introducing standardized project schedule reports to improve the communication of schedule information at each phase of the capital delivery plan. A new standard work breakdown structure has been applied consistently together with a defined set of business rules and standard templates for all new investments transitioning to the Execution phase. This will ensure that the work is scheduled the same way, and at the same level of detail, that it is estimated and executed at. A standard set of project milestones have been developed that will allow standard portfolio and project views of projects to proactively see issues, enable resource planning and scheduling, as well as quickly monitor portfolio/project performance. Hydro One will now use P6 to capture schedule information during the Project Definition phases, define the appropriate level of detail required at each phase in the delivery model and conduct internal benchmarking across similar projects.

Change Management Process: Enhancement of cost control and change management processes is an ongoing initiative. Hydro One has improved its change management process to allow project teams to more accurately track costs, forecast and communicate variances in resourcing and cash flow both during a project and at project close. Improvements include a new simplified and standardized work breakdown structure on all new investments starting in Q4 2017. A new cost controller role was created to build out SAP for cost control and reporting utilizing the new work breakdown structure. The project manager is now supported by cost controllers and cost reports are generated with the new work breakdown structure to assist with project forecasting and reporting variances.

Risk Definition and Management Program: Hydro One implemented a new robust risk definition and management program for projects with a gross total estimated cost of more than $10 million. This risk program reviews scopes, execution plans and schedules to identify potential likelihood and consequence of project risks materializing, which is used to quantitatively analyze risk and develop project contingency using a predictive modeling and optimization tool. Project risk mitigation plans are also developed at this stage. Each project is subject to a risk review meeting to develop the project-specific risk registry. The risk review meeting includes Hydro One representatives from across the organization to provide full representation of different corporate mandates. Early, integrated review and mitigation planning allows greater control of project variances by anticipating issues and planning for the responses (actions and funds) as opposed to reacting and not having planned for the cost and/or schedule impacts. For smaller projects, a risk registry is created. However, a formal workshop and predictive modeling is not required.

5.3 TRACKING AND REPORTING

As part of its capital delivery process, Hydro One has established the mechanisms below to enable appropriate tracking and reporting of project progress.

Reporting on Project and Program Status: Hydro One reviews its project and program status on a monthly basis. Projects in the Project Definition phase that are planned for construction in the next one to three years are reviewed from a readiness perspective. Projects that have significant capital or in-service additions in the year are reviewed from an execution perspective. Hydro One uses a combination of standard reporting requirements, key performance indicators, change management approval processes, both at the project and portfolio level to provide assurance that projects are being well managed. This allows Hydro One to respond to a changing landscape as projects naturally encounter changes, such as outage constraints, delays in external approvals, material delivery delays, site conditions, customer needs, priorities and emergent investments.

Contingency Reviews: As discussed in Attachment 1 of Exhibit A, Tab 2, Schedule 4, Hydro One regularly reviews the amount of contingency held within each portfolio along with future year capex and in-service addition assumptions. The review considers the project and the associated risk to determine appropriate contingency amount to hold in the portfolio.

Portfolio Management: Project managers provide a multi-year forecast for all work in Execution and starting in 2018, they are providing a multi-year forecast for work that is in Project Planning where an estimate has been completed. Hydro One reviews its capital budget and ISAs on a two-year rolling basis and for projects in the execution stage, Hydro One reviews ISAs on a multi-year basis. This allows the company greater flexibility to plan and reschedule projects within a two-year rolling window. Project managers forecast multi-year in-service additions and report partial in-servicing to optimize portfolio management resulting in minimized interest costs for assets under construction. This allows Hydro One to foresee and track the impact of in-year changes on future years.

Redirection: Redirection refers to a process where there are changes in the investments forming part of Hydro One's business plan. In January of 2018, Hydro One introduced a Redirection Committee at the executive level to oversee the redirection process whereby changes to investments relative to those in the business plan are approved, documented, and communicated to stakeholder line management. This standardizes the process for expenditure adjustments to capital, Operations, Maintenance & Administration ("OM&A"), and in-service additions. The Committee provides direction on required investment adjustments to the business plan to address emerging business needs/risks or to seize opportunities related to the planning and execution of Hydro One's investment plan to ensure that Hydro One meets the commitments set out in its investment plan. The committee reviews adjustments to the current year and any future year impacts will be documented and incorporated into the annual investment planning process.

Stage Gate Approvals: Projects must pass stage gates before moving to the next phase in the capital delivery process. The stage gate review process provides senior management with visibility into current project performance, risks and issues allowing for proactive adjustments in project delivery and/or project budgets if required. Projects which pass stage gates are considered able to meet the schedule and cost outcomes presented within the estimate accuracy bands for the current level of project development.

6. PRODUCTIVITY AND EFFICIENCY IMPROVEMENTS – PROJECT EXECUTION

The benefits of introducing upstream efficiencies in the Project Definition phase as well as the evolution of the company's delivery model strategy will result in tangible downstream improvements. Field workforce productivity will benefit from improved project planning, engineered drawing timeliness, material delivery certainty and outage and staging plan optimisation. Throughout 2019 the focus will turn to efficiency initiatives relating to downstream work practices and capturing the benefit of improved project planning. As discussed in TSP Section 1.6, the company has a placeholder of $704 million in productivity savings over the plan period (2020-2024) in its Capital and OM&A programs. This includes a placeholder of $117 million in progressive productivity savings to be realized over the 2020-2022 test period as discussed in detail in TSP section 1.6. Hydro One anticipates that the improvements and efficiencies described in this exhibit will contribute to identifying and defining further progressive productivity savings. Specific initiatives will be identified throughout the test period and may include better utilization of tools, improved processes and design to reduce labour and materials, and the optimization of commissioning work.

7. SAFETY INITIATIVES

Hydro One continually launches safety-related improvement initiatives, in-line with the value the corporate culture places on safety. As shown in Figure 4, these initiatives have resulted in a steady decrease to the recordable injury frequency per 200,000 hours worked by the groups primarily accountable for the execution of the capital work program, Stations Construction and Transmissions Lines, at the same time that the overall work program has grown substantially. The most severe incidents are classified as high Maximum Reasonable Potential for Harm (high MRPH) and have also shown an improving trend over recent years.

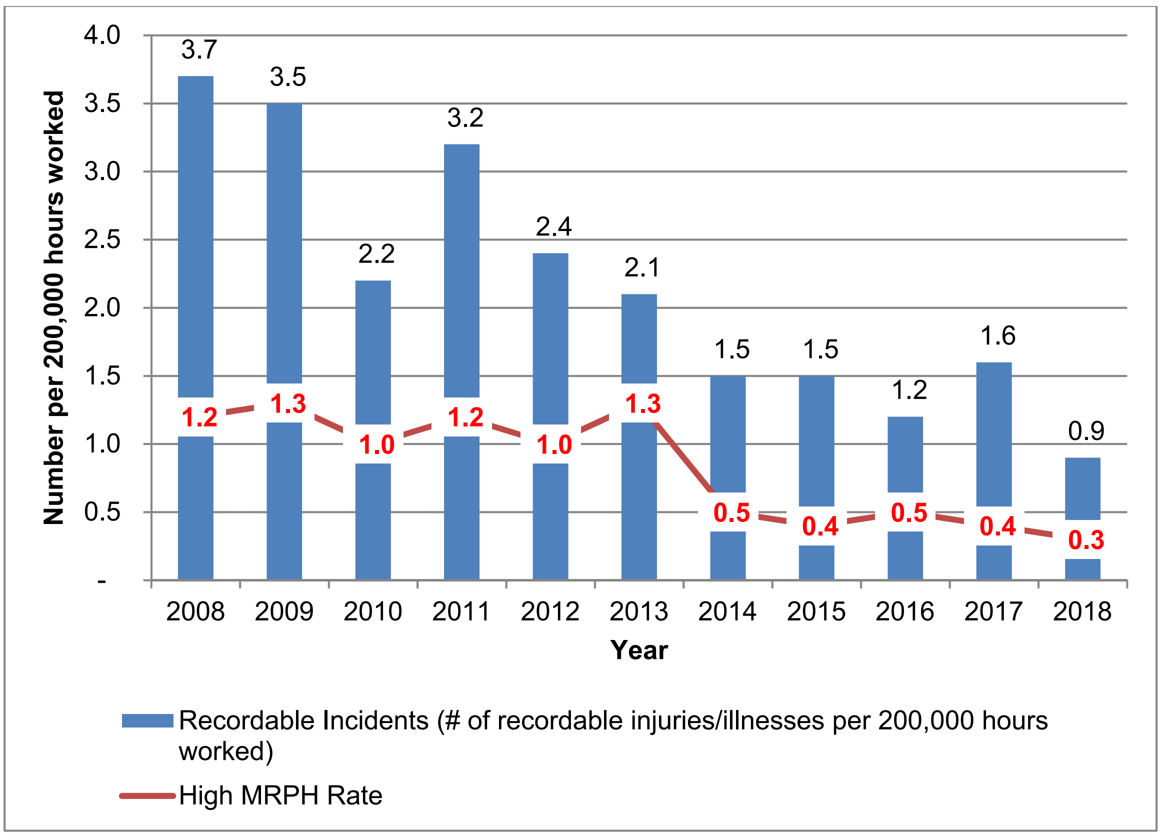

Figure 4: Recordable Injury Frequency per 200,000 Hours Worked (Capital Work Execution, Tx Construction Services & Tx Maintenance)

Hydro One continues to focus on the implementation of its annual Health, Safety and Environment (HSE) initiatives and programs to improve its health and safety culture including the Journey to Zero, Leadership Commitments and the engagement of employees.

The overall safety theme in 2019 is "Safety Culture Brand Campaign" which emphasizes human performance and distractions as the largest contributing cause for most incidents with the goal of improving risk-based decision making. Every year Hydro One conducts safety risk assessments to identify the risks that are most probable and have the highest impact with a view to developing initiatives to address them. The safety campaign was developed by Hydro One with support from a third-party expert and will launch a new Safety Brand in the first quarter, along with training and communications for five Human Success principles that each Hydro One employee will receive. As well Hydro One will focus on the development of leadership by providing training for all managers in communication skills for the positive delivery of safety messages in the field. Throughout the year in monthly Safety Communication Packages themed topics will focus on high risk practices, while providing tools and guidance to eliminate and bring awareness to our highest risk activities. In 2019, the focus will be on the following areas: People Development, Leadership Skills, Human Success Principles and the reduction of lacerations.

Hydro One will continue to conduct safety roll-outs to the field crews in both the first and third quarters of 2019. The safety roll-outs allow senior management to reinforce the company's commitment to safety and ensure that corporate targets and goals are communicated consistently. The safety roll-outs focus on driver safety, including Hydro One Safety Rules governing driving, vehicle collision avoidance practices and techniques; job planning; and recent incidents to provide lessons learned using real and relatable examples.

There is an increased focus to have visible leadership in the field; an increased manager presence during work place observations as well as actively seeking opportunities for coaching/mentoring. Managers and above are expected to participate in the workplace safety observations and in-cab assessments of their staff supervisors and increase site visits to provide additional feedback to staff on their work practices from a safety perspective.

Hydro One has made improvements to the job planning function with the overall goal of improving engagement at the working level. Weekly safety bulletins are distributed and shared with staff at the Monday morning tailboard sessions. This ensures that the discussions include relevant and fresh topics to share with staff. Once per month the topic includes driver safety tips. Daily onsite planning meetings are expected at the start of the day and after breaks to refocus field staff on critical hazards and reinforce safe and effective work practices. The use of open-ended questions is encouraged to generate good discussion and to ensure that everyone is heard. Crews participate in warm-up/stretch sessions during the course of the day as needed to reduce the occurrence of musculoskeletal injuries.

8. SUMMARY

Hydro One has demonstrated that it can execute a very large work program while maintaining the needed flexibility to accommodate required adjustments in its capital work plan due to changing priorities, project challenges and emergent investments. The improvement initiatives discussed in this exhibit have been carefully selected to ensure that the company can conduct an increasing work program in a cost-effective, safe and reliable manner. The transmission capital work execution strategy will result in greater effectiveness throughout the stage-gate process and increased accuracy in forecasting work and timelines. A continued focus on the business objectives of the transmission system plan including safety, quality, efficiency, and meeting customer commitments will ensure Hydro One's success in accomplishing its capital work program.
